Abstract

The single crystal X-ray structure of the compound $[(Me_3P\text{-}Au\text{-}Selenourea)_2^{2+}\ 2Cl^-]$ has been determined. The $[Me_3P\text{-}Au\text{-}(selenourea)]$ units are dimerized and adopt a binuclear structure characterized by a metal–metal interaction (Au–Au:3.0386(5) Å) and a torsion angle of 69.71(2)°. Hydrogen bonding takes place between the selenourea ligands and the chloride ions. The principal components of the ^{77}Se, ^{31}P and ^{13}C shielding tensors were determined from solid-state NMR data.

1. Introduction

There has been a considerable recent interest in the study of gold(I) phosphine complexes of the type R_3PAuL, because of the successful use of auranofin for the treatment of rheumatoid arthritis [1,2]. In addition, auranofin and a number of gold(I) complexes of Ph_3P have been reported to have anticancer activity [3,4]. We have been investigating the coordination chemistry of >C=S and >C=Se ligands with d^{10} metal ions in an attempt to examine their mode of binding and to study their physical properties. In this regard, we have recently reported the characterization of several R_3PAuTu complexes (Tu, thiourea) [5]. Numerous studies have shown, that heavy metal toxicity is lower in the case of selenium based gold drugs and understanding the structure of such complexes will help in the characterization of their biochemical mechanism [6]. In this context and since the crystallographic data related to Au–selenourea complexes are relatively scarce [7], we have undertaken the X-ray structure determination, as well as the solid state NMR characterization of the title compound $[(Me_3P\text{-}Au\text{-}SeU)_2^{2+}\ 2Cl^-]$ (where SeU = selenourea). We report herein its X-ray crystal structure and the results of the ^{77}Se, ^{31}P and ^{13}C solid state NMR investigations.

2. Experimental

Selenourea (Seu) MeOD, Me_2S and all solvents were obtained from Fluka-Aldrich Chemical Co., Germany. $HAuCl_4 \cdot 3H_2O$ and trimethylphosphine were obtained from Strem Chemical Co., USA.

2.1. Synthesis of the complex

The title compound was prepared as reported earlier [8]. Single crystals suitable for X-ray diffraction analysis were grown from an acetonitrile solution.

2.2. X-ray data collection and structure determination

A colorless octahedral crystal of the complex $[(Me_3P\text{-}Au\text{-}SeU)_2^{2+}\ 2Cl^-]$ was mounted on a glass fiber.

Diffraction data were recorded at 24 °C, on a Bruker-Axs Smart Apex system equipped with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). The data were collected using SMART [9]. The data integration was performed using SAINT [10]. An empirical absorption correction was carried out using SADABS [11]. The structure was solved with direct methods and refined by full matrix least square methods based on F^2, using the structure determination and graphics package SHELXTL [12], based on SHELX 97 [13]. Hydrogen atoms were included at calculated positions using a riding model. For the NH_2 groups, sp^2 hybridization was assumed for the nitrogen atoms. Crystallographic data are given in Table 1. Selected bond lengths and angles are given in Table 2. The ORTEP atomic labelling scheme is given in Fig. 1.

2.3. Solid state NMR

Natural abundance ^{13}C solid state NMR spectra were obtained on a JEOL LAMBDA 500 spectrometer operating at 125.65 MHz (11.74 T), at an ambient temperature of 25 °C. Samples were packed into 6 mm zirconium oxide rotors. Cross polarization and high power decoupling were employed. A pulse delay of 7.0 s and a contact time of 5.0 ms were used in the CPMAS experiments. The magic angle spinning rates were from 2000 to 5000 Hz. Carbon chemical shifts were referenced to TMS by setting the high frequency isotropic peak of solid adamantane to 38.56 ppm. Solid state cross-polarization magic-angle spinning (CP/MAS) $^{31}P\{^1H\}$ NMR spectra were obtained at ambient temperature on the same spectrometer, operating at a frequency of 202.35 MHz. A contact time of 3 ms was used with a proton pulse width of 6 μs, with a recycle delay of 10 s. Approximately 500 FID's were collected and transformed with a line broadening of 50 Hz. Chemical shifts were referenced using an external sample of solid PPh_3

($\delta = -8.40$ ppm from 85% H_3PO_4). The CPMAS ^{77}Se spectrum of [$(Me_3P\text{-}Au\text{-}SeU)_2^{2+}$ $2Cl^-$] was obtained on the same instrument operating at a frequency of 95.35 MHz. A contact time of 5 ms with proton pulse width of 6.0 μs and a recycle delay of 12 s were used. The sample was spun at 3 and 5 kHz at the magic angle, to determine the isotropic peak. Approximately 5000 scans were employed. ^{77}Se chemical shifts are referenced using an external ammonium selenate sample by setting its isotropic peak to 1040.2 ppm [14], relative to liquid Me_2Se at 23 °C. The CPMAS spectra (selenone carbons, ^{31}P and ^{77}Se) containing spinning side-band manifolds were analyzed using a program based on Maricq and Waugh [15] and developed by Durham University, U K using an iterative method.

3. Results and discussion

3.1. X-ray structure of [$(Me_3P\text{-}Au\text{-}SeU)_2^{2+}$ $2Cl^-$]

The crystal structure of the compound is depicted in Fig. 1. Selected bond distances and bond angles are given in Table 2. The compound crystallizes in a tetragonal unit cell and a non-centrosymmetric space group $P\bar{4}2_1c$. The asymmetric unit contains one [Me_3P-Au-SeU] moiety that dimerizes and adopts a binuclear structure characterized by a metal–metal interaction (Au–Au:3.0386(5) Å). The metal–metal weak bond distance is within the range found in other binuclear species [16–19]. The dimer is located on a twofold axis, hence generating symmetrical [Me_3P-Au-SeU] units with a torsion angle of 69.71(2)°, calculated as the dihedral angle between the (Au1′, Au1, P1, Se1) and (Au1, Au1′, P1′, Se1′) least square mean planes. The coordination at the gold atom deviates from the perfect linearity (P1–Au1–Se1:175.06(4)°) and the Au–P bond distance (2.2648(16) Å) is within the range found in related compounds [7] while the Au1–Se1 bond length (2.4360(6) Å) is significantly longer than the one observed in the mononuclear triphenylphosphine complex (2.412(2) Å) [7]. The Au–P–C and the C–P–C bond angles range from 112.8(3)° to 114.6(3)° and 102.9(4)° to 106.2(4)°, respectively. The absence of a bridging ligand imposing such a metal–metal interaction [7,20], the bending of the P–Au–Se unit and the lengthening of the Au–Se bond suggest the occurrence of a significant dimerization through a metal–metal interaction as found in other complexes [17]. In this case, the dimerization is not hindered by the steric effect of the ligand. However, such a steric hindrance takes place significantly in the monomeric triphenyl phosphine gold complex [7], preventing the gold atoms from coming into bonding range in the absence of a bridging ligand. The two Cl^- ions of the asymmetric unit, lying on two C2 axes, respectively, have nonbonding contacts with the two nitrogen atoms of the selenourea ligands. The N Cl^- distances are in the range of 3.306–3.333 Å, suggesting hydrogen bonding.

3.2. MAS NMR studies

The room temperature ^{77}Se CPMAS spectrum of the complex is shown in Fig. 2. The spectrum shows a set of spinning side-bands arising from the large shielding anisotropy. The selenium is considered as an isolated nucleus, the interaction with ^{13}C at natural abundance is below the detection limit. With a line broadening of 50 Hz, we were unable to resolve the two bond P–Se coupling ($^2J_{P\text{–}Se}$). Hence we could not perform spinning side-band analysis to obtain tensor parameters corresponding to the two spin states of phosphorus, which would yield the sum and difference of the shielding tensor and dipolar tensor. We assume that ^{77}Se chemical shift anisotropy is substantially greater, than the dipolar coupling constant over the P–Se distance of 4.7 Å. Moreover at the rotor speed of 4.5 kHz, we were, most probably, spinning out the dipolar coupling. The fact that we were able to get a good fit for the ^{77}Se spinning side-band manifold intensities with the calculated intensities justifies the above assumption.

The principal components of the ^{77}Se, ^{31}P and ^{13}C (selenone carbon) chemical shift tensors σ_{ii} were calculated from spinning side-band intensities employing an iterative computer program. Nuclear magnetic shielding tensors of selenourea and the complex [$(Me_3P\text{-}Au\text{-}SeU)_2^{2+}$ $2Cl^-$] are shown in Table 3, along with the span, which is the breadth of the chemical shift tensor and the skew, which describes the shape of the powder pattern [21]. The ^{13}C and ^{31}P chemical shift tensors are believed to have an error of ± 1 ppm and that of ^{77}Se is ± 4 ppm. It is known [22], that span reflects the distortion of molecular structure from ideal tetrahedral, while the skew parameter reflects the asymmetry of the electron density distribution about the atom.

It is seen that the ^{77}Se isotropic shift moves 25 ppm downfield whereas ^{13}C isotropic shift moves 4.4 ppm upfield upon complexation. However, when tensor components are considered, a large downfield shift of 98 ppm

[b] δ_{iso} is obtained from the isotropic peak of an MAS sample.
[c] Span $\Omega = \sigma_{33} - \sigma_{11}$.
[d] Skew $\kappa = 3(\sigma_i - \sigma_{22})/\Omega$.
[e] From [1], δ_{iso} is the weighted average position of the 5 different crystallographic sites.

is observed for the ^{77}Se shielding tensor σ_{11}, while 16 ppm upfield shift and 12 ppm downfield shift were observed for the shielding tensors σ_{22} and σ_{33}, respectively on complexation of selenourea. The greater paramagnetic contribution, due to possible π bonding between Se and Au, is leading to lesser shielding along the Se–Au axis. Hence the molecular axis containing the Au–Se bond can be associated with the principal value of σ_{11} of the ^{77}Se chemical shift tensor. The symmetry around Se in the SeU ligand decreases upon complexation and this is borne out by the decrease in the skew parameter.

Studies on the chemical shift tensors of carbonyl carbons have shown [23], that the principal axes of the tensor σ_{33} is perpendicular to the carbonyl sp^2 plane and the principal axes associated with σ_{22} and σ_{11} components are ca. 10° and 80° off the C═O bond, respectively. For the selenone carbon, we observe a very small change in the σ_{11} component, whereas both σ_{22} and σ_{33} components are deshielded by ca. 7 ppm upon complexation. So it is plausible, that there exists a parallel between chemical shift tensor directions and molecular geometry in selenone compounds and the carbonyl system. The ^{31}P shielding tensor span, Ω, is rather small in comparison to that in four coordinate systems [24]. The skew value of 0.72 shows the ^{31}P chemical shift tensor has a near tetrahedral shape.

4. Supplementary material

Crystallographic data, tables of atomic coordinates, thermal parameters, bond lengths and bond angles have been deposited with the Cambridge Crystallographic Data Centre, CCDC, with the deposition No. 205930. Abstract

The coordinating properties of the title ligand, 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone (HMPz3Hex), synthesized and characterized (elemental analysis, MS, IR, ^1H and ^{13}C NMR and X-ray crystallography) for the first time, are reported by solid-state isolation of cobalt(III) complexes, $[Co(MPz3Hex)_2]X \cdot nH_2O$ ($X = Cl$, Br, NO_3, ClO_4 or BF_4; $n = 1$ to 2). The reported complex species have been spectroscopically characterized with X-ray structural identification of $[Co(MPz3Hex)_2]Br \cdot H_2O$. IR and NMR data ($^1H$ and ^{13}C) for the free ligand and its Co^{III} complexes confirm that the ligand, HMPz3Hex, behaves as a uninegative anion with NNS tridentate function via the pyrazolyl *tert*-nitrogen, azomethine nitrogen and thiol sulfur. Electronic spectral data recommend a distorted octahedral environment for the six-coordinate Co^{III} species. X-ray crystallography of $[Co(MPz3Hex)_2]Br \cdot H_2O$ ($C2/c$, monoclinic), has shown unambiguously that the crystallographic asymmetric unit consists of a $[Co(MPz3Hex)_2]^+$ cation and one Br^- anion with one H_2O molecule as solvent of crystallization. The two NNS ligands coordinate orthogonally to the central Co^{III} ion with *mer*-configuration. A critical scrutiny of the X-ray data of free HMPz3Hex ($Pna2_1$, orthorhombic) and $[Co(MPz3Hex)_2]Br \cdot H_2O$ indicates that an unusual rotation about the azomethine (C=N) double bond occurs during complexation with Co^{III}. A plausible reaction mechanism for the same has been proposed. Sulfur is involved in a C(7)–H(7)···S(1) intramolecular contact restricting the conformation of the ligand both in free and its complexed form.

1. Introduction

The well-documented biological activities of heterocyclic N(4)-substituted thiosemicarbazones have prompted further investigation on the coordination chemistry of such ligands during the past several years [1–3], with the recommendation that structural variation of the N(4)-substituent on the thiosemicarbazone (tsc)

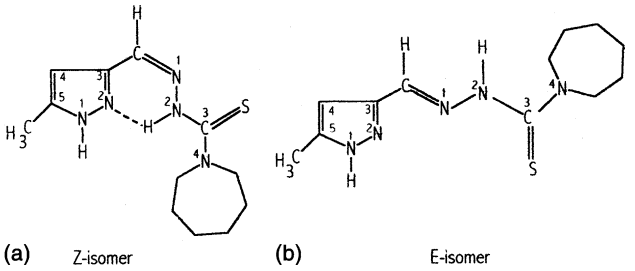

Fig. 1. Methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone (HMPz3Hex).

moiety as well as modification of the heterocyclic ring might bring out significant enhancement of the biological properties of such new metal ion complexes, often with novel structural information. As a part of our comprehensive efforts [4–12] towards synthesis and structural characterization of new materials containing bio-relevant pyrazolyl thiosemicarbazones, the present paper reports the synthesis, spectroscopic and structural properties of new cobalt(III) complexes with 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone (HMPz3Hex) (Fig. 1) with X-ray crystallographic identification of the free ligand, HMPz3Hex, and a representative Co(III) species $[Co(MPz3Hex)_2]Br \cdot H_2O$.

2. Experimental

2.1. Preparation of 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone

All chemicals of AR grade were used without further purification. The title ligand, HMPz3Hex, was synthesized for the first time in our laboratory by a similar, but appropriately modified method [4], followed by final *trans*amination [15,16] of *S*-methyl dithiocarbazate of 5-methyl-3-formyl pyrazole (HMPzSMe) (2.14 g, 10 mmol) with hexamethyleneimine (Fluka) (0.99 g, 10 mmol) in EtOH (30 cm^3) at water bath temperature. The white crystalline product was filtered off and dried over fused $CaCl_2$. The compound (Yield: 2.0 g, 75%) melts at 204 °C (from EtOH) (Found: C, 54.4; H, 7.2; N, 26.3%. Calc. for $C_{12}H_{19}N_5S$: C, 54.3; H, 7.2; N, 26.4%). EIMS: m/z 265 (M^+, 65%).

2.2. Preparation of cobalt(III) complexes: $[Co(MPz3Hex)_2]X \cdot nH_2O$ ($X = Cl$, Br, NO_3, ClO_4 or BF_4; $n = 1$ to 2)

To the title ligand (0.530 g; 2 mmol) dissolved in 1:1 EtOH–MeOH (40 cm^3), an EtOH (20 cm^3) solution of the corresponding hydrated cobalt(II) salt (1 mmol) was added dropwise under hot condition (ca. 40–50 °C). The resulting wine red mixture (pH ≅ 4.0) was boiled under reflux over a water bath for 1.5 h. The coloured solution, upon slow evaporation at RT (~30 °C), yielded a nearly brown crystalline cobalt(III) complex in each case. The complex was filtered off, washed with 1:1 MeOH–EtOH and dried over fused $CaCl_2$ at room temperature. Yield: 60–70%.

2.2.1. Preparation of $[Co(MPz3Hex)_2]Br \cdot H_2O$

The same procedure, as outlined above, was adopted for the preparation and isolation of reddish brown crystals of the desired the cobalt(III) complex (yield: 0.48 g, 70%) using the $CoBr_2 \cdot 6H_2O$ (0.327 g, 1 mmol); X-ray quality crystals of this complex were successfully grown from EtOH–MeOH mixture (1:1) on slow evaporation at room temperature (~303 K).

2.3. Physical measurements

Elemental analyses (C, H and N) using a Perkin–Elmer CHNS/O analyzer 2400 and magnetic measurements in the polycrystalline state in a PAR 155 sample vibrating magnetometer were carried out at the Indian Association for the Cultivation of Science (IACS), Kolkata. The cobalt contents of the complexes were determined gravimetrically as anhydrous $CoSO_4$, except for the perchlorate complex, where the metal was determined as $CoHg(SCN)_4$ after decomposing the complex with a conc. HNO_3–H_2SO_4 mixture. Molar conductances of complexes were measured in methanol with a Systronic Model 304 digital conductivity meter. IR spectra (4000–200 cm^{-1}) were recorded in a JASCO FT-IR model 420 with KBr pellets at the University of Burdwan, Burdwan. The electronic spectra in methanol (ca. 298 K) and the diffuse reflectance spectra were recorded in a Hitachi U-3501 spectrophotometer. ^1H and ^{13}C NMR spectra were recorded in d^6-DMSO with a Bruker AM 300L (300 MH_z) superconducting FT-NMR. The mass spectrum (EIMS) of the ligand was recorded with a Jeol JMS-D 300 spectrometer at the Indian Institute of Chemical Biology (IICB), Kolkata.

2.4. Structure determination

The crystal data, X-ray diffraction data collection and refinement information, for the free ligand, HMPz3Hex, and its cobalt(III) complex, $[Co(MPz3Hex)_2]Br \cdot H_2O$, are summarized in Table 1. Both the structures were solved using the program SHELXS [17]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms, either located from difference electron density maps or fixed geometrically, were included in the structure factor calculations. Full-matrix least-squares refinement of the structures were carried out using the program SHELXL [18–20].

3. Results and discussion

3.1. Characterization of 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone

The title ligand, HMPz3Hex, has been characterized by elemental analyses (C, H and N), NMR (^{1}H and ^{13}C – discussed along with those of the Co(III) complexes) and mass spectrum. The mass fragmentation data (M^+; $m/z = 265$) are compatible with the proposed molecular formula, $C_{12}H_{19}N_5S$. The proposed structure of the ligand has also been authenticated by X-ray crystallography (discussed later).

3.2. Characterization of the cobalt(III) complexes

All the cobalt(III) complexes gave satisfactory C, H, N and Co analyses (Table 2) conforming to the general composition, $[Co(MPz3Hex)_2]X \cdot nH_2O$ (X = Cl, Br, NO_3, ClO_4 or BF_4); the complexes are all diamagnetic as expected. The molar conductance values ($\Lambda_M = 80.3$ to 85.1 $\Omega^{-1}\,cm^2\,mol^{-1}$) in MeOH (303 K) identify the species as 1:1 electrolytes.

Table 2
Colours, conductivity and analytical data for cobalt(III) complexes

3.3. Spectroscopy

Assignments of selected characteristic IR bands (4000–200 cm^{-1}) for the free ligand (HMPz3Hex) and its cobalt(III) complexes, compiled in Table 3, indicate the bonding sites of the primary ligand molecule when complexed with the cobalt(III) ion. A negative shift of the band assigned to ν(CH=N) of the free ligand (1563 cm^{-1}) to a lower value (1500–1508 cm^{-1}) in its complexes, is consistent with coordination of the azomethine nitrogen to the central cobalt(III) ion; the bands at 445–473 cm^{-1} in the complexes are then assignable to ν(Co–N) [4,8,13,14,21]. A second band at 1480 cm^{-1} assignable to ν(C=N) of the pyrazole ring is shifted positively with a split band (1550–1574 cm^{-1}) in each of the complexes; this is because while coordinating to the cobalt(III) ion, the ligand molecule undergoes deprotonation, generating a double bond between N(2) and C(3) of its tsc moiety (Fig. 1). Moreover, the bands at 1003 and 634 cm^{-1} for ν(N–N) and in-plane deformation, respectively, of the pyrazole ring, are shifted to higher wave numbers on complexation; the positive shifts indicate the participation of the pyrazolyl ring nitrogen (tertiary) in complexation [4,8,13,14,21]. An intense band at 869 cm^{-1} assigned to ν(C=S) of the free ligand is found to have been shifted to a lower frequency region by ca. $\Delta\nu > 69$ cm^{-1} indicating that thiol sulfur participates as a coordinating site [4,8,13,14,21]. Moreover, the appearance of new bands at the 342–352 and 273–288 cm^{-1} regions in the spectra of the complexes substantiates the proposed bonding sites of the thiol sulfur and pyrazolyl ring nitrogen (tertiary), respectively.

The diffuse reflectance spectra of all the reported cobalt(III) complexes are very similar, exhibiting four bands in the 11 710–11 876, 14 881–15 773, 20 408–21 322 and 23 753–24 272 cm^{-1} regions which may be assigned as $^1A_{1g} \rightarrow {}^3T_{1g}$, $^1A_{1g} \rightarrow {}^3T_{2g}$, $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ transitions, respectively, in an octahedral symmetry [8], although CT bands in the 19 800–24 500 cm^{-1} range seem to have been mixed with the d–d transition bands; the observed lower energy bands are not split to a large extent. The electronic spectra of the MeOH solutions of the complexes exhibit two intense-bands in the region 37 104–41 154 cm^{-1} ($\log\varepsilon = 4.18-4.47$) and 30 796–30 818 cm^{-1} ($\log\varepsilon = 4.46 - 4.49$) attributable to intraligand CT bands ($\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$, respectively). The spectra also exhibit a shoulder at 25 000–25 978 cm^{-1} ($\log\varepsilon = 3.56 - 4.07$) which may be due to $S \rightarrow Co^{III}$ charge transfer (LMCT) bands. The absence of bands corresponding to $d \rightarrow d$ transitions may be due to the masking of $d \rightarrow d$ bands by strong CT bands [4,5].

The ^{1}H NMR (in d^6-DMSO) spectral data (Table 4) reveal that the free ligand molecule in solution exists in isomeric forms [1,22–27], i.e., *Z*- and *E*-forms (Fig. 1). The *Z*:*E* ratio in DMSO is ca. 2:1; whereas, in the solid state the molecule exists only in the *Z*-form, being stabilized with intramolecular hydrogen bonding (Fig. 1(a)). In solution the higher value of the ^{1}H chemical shift (δ_H 10.67) corresponding to the iminyl hydrogen (^{2}NH) indicates the presence of an intramolecular hydrogen bond stabilizing the *Z*-form. The predominance of the *Z*-isomer is possibly due to the bulky group on the N(4)-position of the substituted tsc moiety. A slightly higher value of the ^{13}C chemical shift corresponding to one of the two neighbouring carbons of nitrogen in the hexamethyleneiminyl moiety can be thought to be due to intramolecular C–H···S contacts [^{13}C NMR: C7, δ 52.6; C12, δ 51.4]. In solution the transformation from *Z*- to *E*-form is believed to occur via the reaction mechanism (Fig. 3) proposed showing the rotation about the azomethine double bond owing to its fluxional nature which is, perhaps, due to the electron withdrawing nature of the azomethine carbon (sp^2-hybridised and directly attached to the aromatic pyrazole ring, as well as the azomethine double bond being in conjugation with the aromatic double bond). The higher value of the ^{13}C chemical shift (Table 4) assigned to the azomethine carbon (δ_c 146.4) indicates its electron deficient nature which favours the reaction mechanism from step I to II (Fig. 3) involving the loss of the azomethine double bond character momentarily and then rotation about the C–^{1}N bond takes place followed by proton transfer from azomethine carbon to imine nitrogen (^{2}N) giving rise to the *trans*-isomer (*E*-form) in solution. An earlier communication from this laboratory [11] reported an unusual finding that the azomethine hydrogen of a similar type of ligand had been replaced by an ethoxy group while complexed with

copper(II). This fact provides a good support for the electron attracting nature of the azomethine carbon. The ^{1}H NMR data of the complexes, when compared with those of the free ligand, point to the following: (i) the ^{1}H shift corresponding to the imine ^{2}NH of the moiety tsc at δ 10.67 (7.34) disappears after complexation, indicating that the ligand molecule undergoes deprotonation followed by coordination to the metal ion through the thiolato sulfur atom; (ii) maximum downfield shift occurs with the methine proton (azomethine C*H*) appearing at δ 8.28–8.38 in the complexes, corresponding to δ 7.99 (8.10) in the free ligand, as expected due to coordination of the azomethine nitrogen to the central cobalt(III) ion; and (iii) the shifting of the ^{4}CH (the pyrazole ring) from δ 6.32 (6.22) (free ligand) to δ 6.39–6.47 in the case of the complexes indicating the coordination site of the pyrazolyl nitrogen (tertiary, ^{2}N). Comparison of the ^{13}C NMR spectra of the uncomplexed ligand with those of its cobalt(III) complexes reveals that the thioamide carbon [^{3}C(S)] shifts slightly downfield from δ_c 177.8 (free ligand) to ca. δ_c 178.6 (in the complexes) showing a coordination through the thiolato sulfur. The significant downfield shift occurs with the azomethine carbon appearing at ca. δ_c 151.3 in the complexes corresponding to δ_c 146.4 in the free ligand as expected due to coordination of the azomethine nitrogen to the metal ion and also the maximum downfield shifting of the ^{3}C ring (pyrazole) carbon from δ_c 132.2 (free ligand) to ca. δ_c 142.3 in the complexes is quite reasonable with the proposition that the neighbouring ^{2}N (pyrazole) coordinates strongly with the central atom; moreover, downfield shifts of the ^{5}C ring carbon and its methyl carbon (pyrazole) support the proposed pyrazolyl *tert*-nitrogen (^{2}N) as a coordination site.

Both the ^{1}H and ^{13}C NMR spectra thus provide excellent support for the bonding characteristics of the primary ligand (HMPz3Hex) in forming complexes with the cobalt(III) ion through the pyrazolyl ring nitrogen (tertiary), azomethine nitrogen and the thiolato sulfur atom [4,5,8,13,14,22–27].

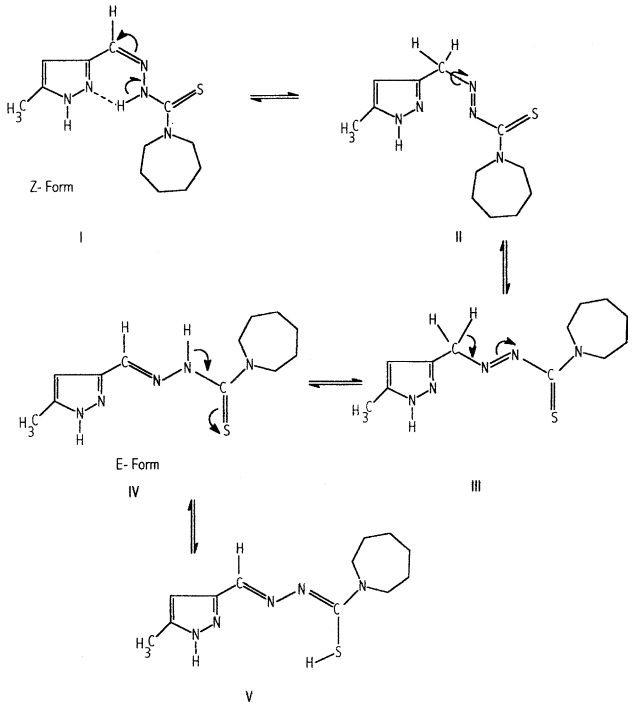

Fig. 3. Reaction mechanism showing the rotation about the azomethine double bond owing to the fluxional nature of the bond.

3.4. Structural determinations of HMPz3Hex and $[Co(MPz3Hex)_2]Br \cdot H_2O$

Figs. 2 and 4 are ORTEP [28] diagrams of the free ligand and the complex $[Co(MPz3Hex)_2]Br \cdot H_2O$, respectively, together with the atom numbering schemes. The crystallographic asymmetric unit in the complex comprises of a $[Co(MPz3Hex)_2]^+$ cation, a Br^- anion and a molecule of water of crystallization. Some selected bond distances, nonbonded contacts, bond angles and torsion angles in the two examined structures are compiled in Table 5.

Two molecules (A and B) of the tridentate ligand [5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone] coordinate to the Co(III) ion to form four five-membered chelate rings [Co–N(1A)–C(4A)–C(5A)–N(3A), Co–N(1B)–C(4B)–C(5B)–N(3B), Co–N(3A)–N(4A)–C(6A)–S(1A) and Co–N(3B)–N(4B)–C(6B)–S(1B)]. The two azomethine nitrogen atoms [N(3A) and N(3B)] are *trans* to each other while the pyrazolyl ring nitrogen atoms [N(1A) and N(1B)] and the thiolato sulfurs [S(1A) and S(1B)] are in the *cis* positions.

The C(6)–S(1) double bond distance of 1.681(3) Å in the free ligand is comparable to those found in other similar heterocyclic N(4)-substituted thiosemicarbazones [29,30]. This bond lengthens to 1.741(5) and 1.746(5) Å in ligands A and B, respectively, in the complex, indicating a conversion to single bonds; this has been observed for other Co(III) complexes with similar thiosemicarbazone ligands with NNS donor sites [8,31]. A concurrent shortening of the N(4)–C(6) bonds, from 1.363(4)Å in the free ligand to 1.324(6) Å [ligand A] and 1.319(6) Å [ligand B] in the complex, shows that deprotonation of the imine nitrogen [N(4)] results in a conversion from thione to thiol sulfur. Deprotonation of the imine nitrogen is further corroborated by the closing of the N(3)–N(4)–C(6) angle by about 9° in the complex. Whereas, in nickel(II) and copper(II) complexes of similar ligands, where the imine nitrogen is not deprot-

onated, the corresponding endocyclic bond angles are wider: 119.0(3)° in octahedral $[Ni(HMPzNBu_2)_2](ClO_4)_2$ [7], and 117.2(2)° in square pyramidal $[Cu(HMPz4BM)(NO_3)_2]$ [10]. The relevant C–S bond distances is 1.699(4) Å, with the N–C bond distance being 1.355(5) Å in the nickel(II) complex [7]. The corresponding distances in the copper(II) complex are 1.724(3) and 1.354(3) Å [10]. In the present complex, the release of the iminyl hydrogen in the ligand during complexation is, perhaps, facilitated by the harder acid character of the cobalt(III) ion compared to the nickel (II) and the copper(II) ions.

In the complex, the cobalt(III) ion has a distorted octahedral coordination with each of the two tridentate ligands, A and B, coordinating to the metal ion through the pyrazolyl nitrogen, N(1), the azomethine nitrogen, N(3), and the thiol sulfur, S(1). The geometrical requirements of coordination result in a significant closing of the C(4)–C(5)–N(3) and N(1)–C(4)–C(5) angles by about 15° and 10°, respectively, as indicated in Table 5. The tridentate ring systems [Co–S(1)–C(6)–N(4)–N(3)–C(5)–C(4)–C(3)–C(2)–N(2)–N(1)] of the chromophores in the complex are practically planar; the maximum deviation from planarity is +0.110(5) Å for C(6A) in ligand A and −0.212(4) Å for C(2B) in ligand B. The coordinating ligands A and B are nearly orthogonal to each other while bonding to Co(III) resulting in a meridonial structure with a dihedral angle of 86.78(5)°

between them. The three individual rings, in both the ligands, namely, the pyrazole and the two five-membered chelate rings, are individually almost planar with small dihedral angles between them; the maximum dihedral angle is observed between the chelate ring Co–S(1)–C(6)–N(4)–N(3) and the pyrazole ring N(1)–C(4)–C(3)–C(2)–N(2) in both the ligands, being 3.77(12)° in ligand A and 9.53(14)° in ligand B.

The most interesting feature of the complex formation is an unusual rotation about the azomethine C=N double bond to form the Co–N(1)–C(4)–C(5)–N(3) chelate ring This is indicated by the torsion angles C(4)–C(5)–N(3)–N(4), which are 3.3(5)° in the free ligand, and 175.5(4)° (ligand A) and −177.1(4)° (ligand B) in the complex (identified by an asterisk in Table 5). The expected rotation about either the N(3)–N(4) bond or the N(4)–N(6) bond does not take place during complexation as indicated by the torsional angles C(5)–N(3)–N(4)–C(6) and N(3)–N(4)–C(6)–N(5), respectively, which remain practically the same in the ligand, both in its free and complexed forms (Table 5). The unexpected rotation about the azomethine double bond, C(5)–N(3), during complexation can be explained by the reaction mechanism proposed in Fig. 3. The feasibility of this mechanism is due to the electron attracting character of the azomethine carbon, C(6). The electron attracting nature of this carbon atom has already been documented in a complex of a similar ligand with a copper(II) ion [11].

The transient conversion of the C=N double bond to a single bond allows the rotation of the thiosemicarbazone moiety about this bond so that the sulfur atom, S, is in a *cis* position with respect to the pyrazolyl nitrogen (tertiary), N(1), in order to cater to the requirement of complexation. The C(5)–N(3) bond distance, which is 1.278(4) Å in the free ligand, resumes its double bond character in the complex with bond distances of 1.278(6) Å in ligand A and 1.281(6) Å in ligand B.

Figs. 5 and 6 show the hydrogen bonds and C–H···X contacts in the free ligand and its Co(III) complex; the geometrical details are listed in Table 6. As has been observed in other similar structures [7,10], S(1) is involved in a C(7)–H(7)···S(1) intramolecular contact which practically restricts the conformation of the ligand about the C(6)–N(5) bond, both in its free and complexed forms. The torsion angle about the C(6)–N(5) bonds varies between −3.8(5)° and 14.4(7)° (Table 5). The *Z*-isomeric conformation of the free ligand is stabilised by an intramolecular N(4)–H(4)···N(1) hydrogen bond. This finding is exactly in agreement with the cases of similar thiosemicarbazone type ligands, with one exception, namely, 2-acetylpyridine 3-hexamethyleneiminyl thiosemicarbazone which is crystallographically different and has been reported earlier [29,30]. The crystal structure of the free ligand is further stabilised by the formation of a pair of bifurcated hydrogen bonds; the pyrazolyl secondary nitrogen, N(2), contributes a hydrogen atom which is shared by the azomethine nitrogen, N(3), and the thione sulfur, S(1), of a glide related moiety. In the complex, the pyrazolyl secondary nitrogen, N(2A), of one of the ligands forms a N(2A)–H(2A)···Br hydrogen bond with a bromine ion. The corresponding nitrogen from the other ligand forms a N(2B)–H(2B)···O(1W) hydrogen bond with the water

Symmetry equivalents: (i) $-1/2+x$, $1/2-y$, z; (ii) $1/2-x$, $-1/2+y$, $1+1/2-z$ and (iii) x, $-y$, $1/2+z$.

of crystallization; the water molecule, in its turn, is the donor in an O(1W)–H(11W)···N(2B) hydrogen bond with the same nitrogen. This leads to a situation where a pair of atoms, N(2B) and O(1W), are doubly hydrogen bonded to each other with both atoms playing the roles of donor as well as acceptor. The second hydrogen atom, H(12W), from the water molecule participates in an O(1W)–H(12W)···Br hydrogen bond. In addition, the bromide ion is the acceptor in a C(5A)–H(5AA)···Br contact with an azomethine carbon atom, C(5A).

4. Conclusion

The present study shows that the bio-relevant pyrazolyl thiosemicarbazone, NNS tridentate ligand, HMPz3Hex (Fig. 1), undergoes deprotonation during complexation with cobalt(III) and forms a *bis*-ligated complex, with the two ligands coordinating with the central metal ion orthogonally in the distorted octahedral environment, while azomethine nitrogens are in *trans* and sulfur atoms are in *cis*-positions (*mer*-configuration). Comparison of the X-ray crystallographic data of both the free ligand and its cobalt(III) complex brings out an interesting feature of the complex formation that the thiosemicarbazone moiety (tsc) of the ligand undergoes unexpected rotation about the azomethine double bond joining tsc and pyrazole moieties together, by the driving force for complexation with cobalt(III).

5. Supplementary material

Crystallographic data for the structures reported here have been deposited with the Cambridge

Crystallographic Data Centre, CCDC numbered 201868 and 201869. Copies of these information may be obtained free of charge from The Director, CCDC Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Abstract

Six ferrocene-containing enaminones $[C_5H_5FeC_5H_4C(O)CH=C–(NHAr)R]$ (**HL^1**, $R=CH_3$, $Ar=C_6H_5$; **HL^2**, $R=CH_3$, $Ar=2\text{-}CH_3C_6H_4$; **HL^3**, $R=CH_3$, $Ar=2,6\text{-}(CH_3)_2C_6H_3$; **HL^4**, $R=C_6H_5$, $Ar=C_6H_5$; **HL^5**, $R=C_6H_5$, $Ar=2\text{-}CH_3C_6H_4$; **HL^6**, $R=C_6H_5$, $Ar=2,6\text{-}(CH_3)_2C_6H_3$) and their copper(II) complexes (**I**, $L_2^1Cu{\cdot}2H_2O$; **II**, L_2^2Cu; **III**, L_2^3Cu; **IV**, $L_2^4Cu{\cdot}2H_2O$; **V**, $L_2^5Cu{\cdot}2H_2O$) have been synthesized and characterized by elemental analyses, ^{1}HNMR, IR and UV spectroscopies. Their structures have been determined by the X-ray crystallography of enaminone **HL^6** and complex **I**.

1. Introduction

In the last few decades enaminones and enaminecarbaldehydes have been widely investigated because of their applications in the synthesis of heterocyclic compounds [1] and plentiful reaction chemistry [2] and coordination chemistry [3]. Therefore, enaminones of the type $[R'C(O)CHC(NHAr)R]$ constitute an important class. Recently non-metallocene complexes of Group IV metals have attracted much interest as possible alternatives for olefin polymerization catalysts using N_4-macrocycles, porphrins, tripodal amides, mixed cyclopentadienyl-amides and Schiff bases as spectator ligands [5–7]. Because the anions $[R'C(O)CHC(NAr)R]^-$ generated from the above enaminones offer potential isoelectronic alternatives to the cyclopentadienyl-based anion and can be used as good chelating ligands for copper complexes that exhibit catalytic activity [3,8], organometallic enaminones of the new type $[C_5H_5FeC_5H_4C(O)CH=C(NHAr)R]$ have been studied. To our knowledge, so far no article on organometallic enaminones has appeared, and herein we report the syntheses and structures of the ferrocenyl enaminones and their copper complexes.

2. Experimental

2.1. Reagents and general procedures

All chemicals used were of reagent grade. Toluene and THF were distilled from Na/benzophenone under dinitrogen atmosphere. Absolute ethanol for sodium ethoxide was distilled from Na/diethyl phthalate. DMF, ethyl acetate and ethyl benzoate were redistilled before use. Other commerial chemicals were used without further purification. Acetylferrocene was synthesized from ferrocene according to the literature method [9]. Progress of the reactions was monitored by TLC. ^{1}H NMR spectra were determined with a Bruker Avance 500 spectrometer using TMS as external standard in $CDCl_3$. IR spectra were recorded on a Perkin–Elmer 402 as KBr disks in the range of 400–4000 cm^{-1}. UV spectra were measured with a Shimadzu UV-240 spectrometer using a solution in DMF. Analyses for C, H and N were performed on an Elementa Vario EL III instrument.

Melting points were measured on a Yanagimoto apparatus and were uncorrected.

2.2. Syntheses of enaminones

2.2.1. Syntheses of β-diketones *1* and *2*

Modified literature syntheses were used [10,11]. A solution of sodium ethoxide (8.85 g, 130 mmol), acetylferrocene (16.42 g, 72 mmol) and ethyl acetate (11.45 g, 130 mmol) in 60 ml of THF was refluxed under nitrogen for 2 h. The yellow solid was filtered, washed with THF and acidified with aqueous acetic acid to give the β-diketone **1** (16.14 g, 83%) as a red solid. M.p. 97 °C (lit: 97–97.5 °C) [10]. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 261 (1.02), 308 (1.12).

The similar reaction of sodium ethoxide (4.08 g, 60 mmol), acetylferrocene (7.98 g, 35 mmol) and ethyl benzoate (5.56 g, 37 mmol) in 60 ml of THF for 2 h after the above-mentioned workup and extraction with CH_2Cl_2 (three times, each 20 ml) gave the combined organic layer. The mixture was dried with anhydrous $CaCl_2$ and then the solvent of the filtrate was removed to give a purple–red oil, which was separated with the eluant (CH_2Cl_2: petroleum ether, 2:1) by vacuum liquid chromatography (VLC). A main band was collected to afford the β-diketone **2** (5.81 g, 50%) as a purple–red solid. M.p. 106 °C (lit: 106–107 °C) [11]. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 268 (0.85), 332 (0.64), 360 (0.65).

2.2.2. Syntheses of enaminones

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)CH_3]$ (Ar = C_6H_5, **HL[1]**). Aniline (1.86 g, 20 mmol) was added to a solution of β-diketone **1** $[C_5H_5FeC_5H_4C(O)CH_2C(O)\ CH_3]$ (2.7 g, 10 mmol) and a catalytic trace amount of p-TsOH (≈10 mg) in 20 ml of toluene, and then the mixture was refluxed with a Dean-Stark apparatus to remove water for 2 h. The solvent was evaporated under vacuum, and the residue was recrystallized from petroleum ether (60–90 °C) to afford 2.76 g (80%) of **HL[1]** as a red crystalline solid. M.p. 120–121 °C. *Anal.* Found: C, 69.60; H, 5.52; N, 3.72. Calc. for $C_{20}H_{19}NFeO$: C, 69.58; H, 5.55; N, 4.06%. IR (KBr disk): ν(NH) 3084 (s), ν(C=O) and ν(C=C) 1582 (vs, br) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 259 (8.7), 275 (1.5) (B-band); 328 (1.9) (K-band). ^1H NMR ($CDCl_3$): δ 2.15 (s, 3H, CH_3), 4.24 (s, 5H, C_5H_5), 4.58 (s, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.83 (s, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.54 (s, 1H, CH), 7.10–7.37 (m, 5H, C_6H_5), 12.64 (s, 1H, NH).

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)CH_3]$ (Ar = 2-$CH_3C_6H_4$, **HL[2]**). The similar reaction of 2-methylaniline (2.14 g, 20 mmol) and β-diketone **1** (10 mmol) afforded 2.83 g (80%) of **HL[2]** as a red crystalline solid. M.p. 96–97 °C. *Anal.* Found: C, 70.24; H, 5.70; N, 3.85. Calc. for $C_{21}H_{21}FeNO$: C, 70.21; H, 5.89; N, 3.90%. IR (KBr disk): ν(NH) 3080 (s), ν(C=O) 1601 (vs), ν(C=C) 1554 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 274 (0.9) (B-band), 333 (1.2) (K-band). ^1H NMR ($CDCl_3$): δ 1.99 (s, 3H, CH_3), 2.33 (s, 3H, CH_3), 4.21 (s, 5H, C_5H_5), 4.41 (s, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.79 (s, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.54 (s, 1H, CH), 7.12–7.27 (m, 4H, C_6H_4), 12.44 (s, 1H, NH).

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)CH_3]$ (Ar = 2,6-$(CH_3)_2C_6H_3$, **HL[3]**). The similar reaction of 2,6-dimethylaniline (2.42 g, 20 mmol) and β-diketone **1** (10 mmol) afforded 2.99 g (80%) of **HL[3]** as a red crystalline solid. M.p. 114–116 °C. *Anal.* Found: C, 70.81; H, 6.04; N, 3.27. Calc. for $C_{22}H_{23}FeNO$: C, 70.79; H, 6.21; N, 3.75%. IR (KBr disk): ν(NH) 3079 (w), ν(C=O) 1603 (vs), ν(C=C) 1553 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 265 (1.51) (B-band), 330 (1.36) (K-band). ^1H NMR ($CDCl_3$): δ 1.73 (s, 3H, CH_3), 2.26 (s, 6H, $2CH_3$ of benzene ring), 4.21 (s, 5H, C_5H_5), 4.41 (s, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.82 (s, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.57 (s, 1H, CH), 7.10–7.15 (m, 3H, C_6H_3), 12.03 (s, 1H, NH).

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)C_6H_5]$ (Ar = C_6H_5, **HL[4]**). The similar reaction of aniline (0.93g, 10 mmol) and β-diketone **2** $[C_5H_5FeC_5H_4C(O)CH_2C(O)\ C_6H_5]$ (1.66 g, 5 mmol) afforded 1.71 g (84%) of **HL[4]** as a deep red crystalline solid. M.p. 118–120 °C. *Anal.* Found: C, 73.29; H, 5.00; N, 3.02. Calc. for $C_{25}H_{21}$ FeNO: C, 73.72; H, 5.20; N, 3.44%. IR (KBr disk): ν(NH) 3087 (s), ν(C=O) 1589 (vs), ν(C=C) 1567 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 369 (1.06) (K-band). ^1H NMR ($CDCl_3$): δ 4.25 (s, 5H, C_5H_5), 4.57 (s, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.87 (s, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.77 (s, 1H, CH), 6.75–7.13 (3m, 5H, NC_6H_5), 7.27–7.44 (m, 5H, C_6H_5), 12.43 (s, 1H, NH).

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)C_6H_5]$ (Ar = 2-$CH_3C_6H_4$, **HL[5]**). The similar reaction of 2-methylaniline (1.07 g, 10 mmol) and β-diketone **2** (5 mmol) afforded 1.71 g (81%) of **HL[5]** as a light red crystalline solid. M.p. 138–140 °C. *Anal.* Found: C, 73.98; H, 5.22; N, 2.88. Calc. for $C_{26}H_{23}FeNO$: C, 74.12; H, 5.50; N, 3.32%. IR (KBr disk): ν(NH) 3082 (s), ν(C=O) 1591 (vs), ν(C=C) 1567 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 274 (1.32) (B-band), 369 (1.03) (K-band). ^1H NMR ($CDCl_3$): δ 2.48 (s, 3H, CH_3), 4.27 (s, 5H, C_5H_5), 4.50 (s, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.90 (s, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.70 (s, 1H, CH), 6.40–7.50 (4m, 9H, (C_6H_4, C_6H_5)), 12.26 (s, 1H, NH).

$[C_5H_5FeC_5H_4C(O)CH=C(NHAr)C_6H_5]$ (Ar = 2,6-$(CH_3)_2C_6H_3$, **HL[6]**). The similar reaction of 2,6-dimethylaniline (1.21 g, 10 mmol) and β-diketone **2** (5 mmol) was refluxed for four days. After removal of the solvent, the deep-red oil obtained was chromatographed on a silica gel column with $CH_2Cl_2$and petroleum ether (3:1). The second band was collected and further recrystallized from petroleum ether (60–90 °C) afforded 1.31 g (46%) of **HL[6]** as a deep red crystalline solid. M.p. 153–154 °C. *Anal.* Found: C, 74.89; H, 5.67; N, 2.79. Calc. for $C_{27}H_{25}FeNO$: C, 74.49; H, 5.79; N, 3.22%. IR (KBr

disk): ν(NH) 3080 (w), ν(C = O) 1586 (vs), ν(C = C) 1567 (vs) cm^{-1}. 2.3. Syntheses of copper complexes

A solution of 1 mmol of the appropriate ligand (except enaminone **HL^6**) in absolute ethanol (10 ml) was added dropwise to a stirred solution of 0.5 mmol of hydrated copper acetate in the same solvent (10 ml). The mixture was stirred for 24 h at room temperature and then filtered to afford the crude product. The resulting solid was recrystallized from CH_2Cl_2 and petroleum ether to give the corresponding complex.

Complex **I** as a black solid, yield: 0.335 g (85%). M.p. 201–202 °C (dry sample). *Anal.* Found: C, 60.82; H, 4.71; N, 3.14. Calc. for $C_{40}H_{40}N_2O_4Fe_2Cu$: C, 60.97; H, 5.12; N, 3.55%. IR (KBr disk): ν(OH) 3436 (m, br), ν(C = O) 1562 (s), ν(C = C) 1513 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 275 (2.5), 358 (3.4) (K-band), 450 (0.49) (CT-band).

Complex **II** as a black red solid, yield: 0.312 g (80%). M.p. 209.5–210.5 °C. *Anal.* Found: C, 64.75; H, 5.21; N, 3.33. Calc. for $C_{42}H_{40}N_2O_2Fe_2Cu$: C, 64.67; H, 5.17; N, 3.59%. IR (KBr disk): ν(C = O) 1561 (s), ν(C = C) 1512 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 275 (2.9), 355 (4.3) (K-band), 447 (0.50) (CT-band).

Complex **III** as a purple red solid, yield: 0.331 g (82%). M.p. 213–214.5 °C. *Anal.* Found: C, 65.30; H, 5.16; N, 3.04. Calc. for $C_{44}H_{44}N_2O_2Fe_2Cu$: C, 65.40; H, 5.49; N, 3.47%. IR (KBr disk): ν(C = O) 1557 (s), ν(C = C) 1513 (vs) cm^{-1}. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 278 (2.4), 351 (3.2) (K-band), 447 (0.37) (CT-band).

Complex **IV** as a black solid, yield: 0.379 g (83%). M.p. 203.5–205 °C (dry sample). *Anal.* Found: C, 65.51; H, 4.47; N, 3.14. Calc. for $C_{50}H_{44}N_2O_4Fe_2Cu$: C, 65.84; H, 4.86; N, 3.07%. UV (nm, in DMF): $\lambda_{max}(\varepsilon \times 10^4)$ 378 (2.67) (K-band).

2.4. Crystal structure determinations

Single crystals of enaminone **HL^6** for X-ray analysis were obtained by slow evaporation of its solution in CH_2Cl_2 and petroleum ether at room temperature. Single crystals of complex **I** for structure determination were obtained by further recrystallization from CH_2Cl_2 and ethanol. X-ray data of both compounds were measured on an Enraf–Nonius CAD4 diffractometer using graphite-monochromated Mo K_α radiation ($\lambda = 0.71073$ Å) at 293 K. The structures were solved by direct methods and refined by full-matrix least-squares methods based on F^2 with anisotropic thermal parameters for all non-hydrogen atoms [12]. A summary of the data collection and structure refinement parameters is given in Table 1. Selected bond distances (Å) and angles (°) are listed in Tables 2 (enaminone **HL^6**) and 3 (complex **I**).

3. Results and discussion

3.1. Syntheses of enaminones and their complexes

Syntheses of enaminones and their complexes are represented in Schemes 1 and 2. Reaction of the β-diketone **1** or **2** [$C_5H_5FeC_5H_4C(O)CH_2C(O)R$] (R = CH_3, C_6H_5) and an excess of an appropriate aniline [H_2NAr] (Ar = Ph, 2-$CH_3C_6H_4$, 2,6-$(CH_3)_2C_6H_3$) in the presence of a catalytic trace amount of *p*-toluenesulfonic acid in refluxing toluene via removal of water using a Dean–Stark apparatus affords the corresponding enaminones in satisfactory yields. For enaminones **HL^4**, **HL^5** and **HL^6**, in view of the electronic and steric effects of the phenyl and ferrocenyl groups, it may be expected that the anilines attack the carbonyl with the Ph substituent. This conclusion is further supported by X-ray diffraction analysis on the enaminone **HL^6** (see below). Also because of steric hindrance from the N-phenyl and C-phenyl groups, reaction of the β-diketone **2** with 2,6-dimethylaniline is incomplete and accordingly enaminone **HL^6** is obtained only in moderate yield. Except **HL^6**, each enaminone can react with the copper(II) ion forming the corresponding neutral complex with the release of HOAc. TLC analyses of all the complexes show that each exists as a single isomer. However, because of the steric hindrance of **HL^6**, all attempts to synthesize the corresponding complex $\mathbf{L^6_2}Cu{\cdot}xH_2O$ were unsuccessful and the starting materials were recovered.

Analytical data of all the new complexes listed in Section 2 suggest that they may be formulated as $\mathbf{L^1_2}Cu{\cdot}2H_2O$, $\mathbf{L^2_2}Cu$, $\mathbf{L^3_2}Cu$, $\mathbf{L^4_2}Cu{\cdot}2H_2O$ and $\mathbf{L^5_2}Cu{\cdot}2H_2O$, respectively.

3.2. ^1H NMR spectra of enaminones

The ^1H NMR spectral data of the enaminones are presented in Section 2. The spectra of the free ligands display two singlets at δ 4.41–4.58 and 4.79–4.90 ppm, with the integration corresponding to 2H attributed to the H^3/H^4 and H^2/H^5 protons of the substituted cyclopentadienyl ring. Another singlet signal with the integration corresponding to 5H at δ 4.21–4.27 ppm is due

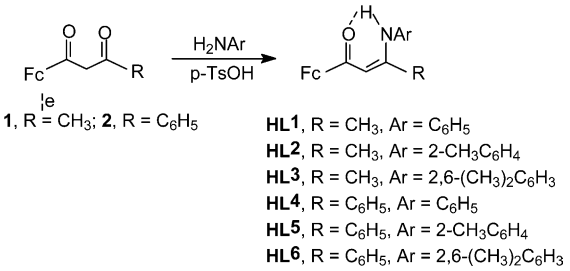
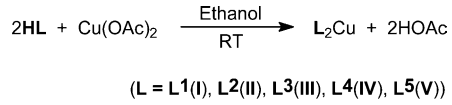
to the unsubstituted cyclopentadienyl ring protons. For enaminones **HL¹**, **HL²** and **HL³**, the methyl protons of the C(O)CHC(NHAr)CH_3 moiety show a singlet corresponding to 3H at δ 1.73–2.15 ppm. The methyl protons of the NHAr moiety also show a singlet corresponding to 3H and 6H for **HL²** and **HL⁵** and for **HL³** and **HL⁶** at δ 2.21–2.48 ppm, respectively. For each ligand, the vinylic proton as a singlet appears at δ 5.54–5.70 ppm, and the relative integrated intensity ratio of this peak to other peaks shows that there is only one H atom bonded to the α-C atom in the C(O)C$_\alpha$HC(NHAr)R moiety. The aromatic protons of the ligands exhibit multiplets corresponding to 5H, 4H and 3H for **HL¹**, **HL²** and **HL³** and 10H, 9H and 8H for **HL⁴**, **HL⁵** and **HL⁶** at δ 6.40–7.44 ppm, respectively. The spectra of all ligands display a singlet signal at δ 12.03–12.64 ppm, which is assigned to the enamino NH and disappears in the presence of D_2O. The downfield position of this signal may mainly arise from the intramolecular hydrogen bonding as shown in Scheme 1. Obviously, the above evidence is in agreement with the proposed structure of the ligands and also supported by the crystal structure of enaminone **HL⁶** [2a,3c].



Scheme 1. Syntheses of enaminones.



Scheme 2. Syntheses of complexes.

3.3. Crystal structure

3.3.1. Crystal structure of HL⁶

As mentioned above, enaminones with the general formula [R′C(O)CHC(NHAr)R] may have the following four isomers: *cis*-s-*cis*, *cis*-s-*trans*, *trans*-s-*cis* and *trans*-s-*trans* in which *cis* and *trans* refer to two possible geometric arrangements for the carbon–carbon double bond and s-*cis* and s-*trans* to both isomerisms about the carbon–carbon single bond between the carbon–carbon and carbon–oxygen double bonds [2a]. Owing to very few X-ray diffraction studies, so far the structure of enaminones [R′C(O)CHC(NHAr)R] has resulted in inconsistencies and remains uncertain [2b,4]. Therefore, a single crystal X-ray analysis on **HL⁶** was carried out to determine the structure of the new enaminones. The molecular structure of **HL⁶** together with the atomic numbering is shown in Fig. 1. As seen from Fig. 1, **HL⁶** in the solid state belongs to the *cis*-s-*cis* isomer. All atoms in the skeleton O=C–C=C–N can be regarded as sp^2 hybridized. As shown by the comparison of the C=O, C–C, C=C and C–N distances (Table 2) with the corresponding pure double or single bond distances C(sp^2)=O ≈1.20, C(sp^2)–C(sp^2) ≈ 1.48, C(sp^2)=C(sp^2) ≈ 1.33 and C(sp^2)–N (sp^2) ≈ 1.44 Å, **HL⁶** exhibits partial delocalization of the O=C–C=C–N system. That the H···O distance of 1.971 Å is significantly shorter than the sum of the van der walls radii (2.60 Å) indicates the existence of intramolecular hydrogen bonding; this is also in accordance with spectroscopic data. The plane of the skeleton and the plane of the substituted cyclopentadienyl ring only form a dihedral angle of 13.6°, whereas the skeleton with the N-benzene ring and C-benzene ring makes two angles of 74.4 and 116.9° to avoid the steric repulsions. Therefore, in the solid state, neither the N-benzene ring nor the C-benzene ring is involved in the conjugation of the skeleton, whereas the substituted cyclopentadienyl ring may in part conjugate with the enaminonic system [3c,4a].

3.3.2. Crystal structure of complex *I*

In view of *cis* or *trans* isomerism of donor atoms and planar or tetrahedral coordination geometry of the central metal ion, as well as anti or syn arrangement of the ferrocenyl groups with respect to the plane with the central metal ion and donor atoms, four-coordinate copper(II) complexes may possess eight stereoisomers: planar-*cis*-anti, planar-*cis*-syn, planar-*trans*-anti, planar-*trans*-syn, tetrahedral-*cis*-anti, tetrahedral-*cis*-syn, tetrahedral-*trans*-anti and tetrahedral-*trans*-syn [13,14]. Therefore, to further establish their structures and to provide more structural evidence for the new complexes, the crystal structure of complex **I** was determined. The molecular structure of the new copper complex **I** together with the atomic numbering is shown in Fig. 2. The metal atom displays a tetrahedral coordination geometry surrounded by two nitrogen atoms and two oxygen atoms of two deprotonated ligands (L^-), so complex **I** exists only in the tetrahedral-*trans*-syn form, which is further supported by the above-described TLC. More interestingly, against usual expectation, both

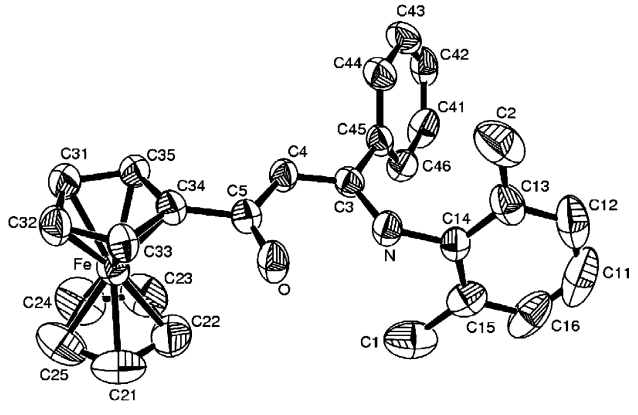


Fig. 1. Molecular structure of enaminone **HL⁶** together with the atomic numbering. Hydrogen atoms are omitted for clarity.

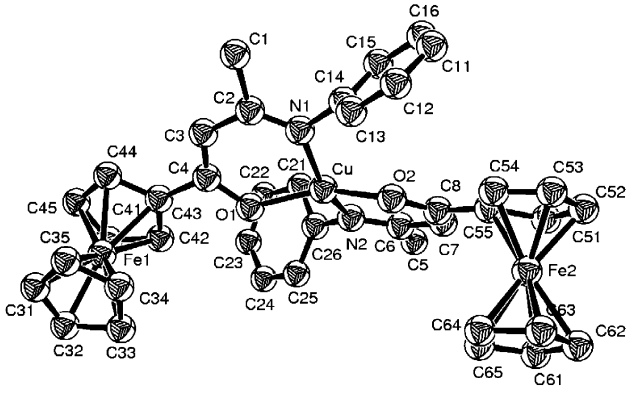

Fig. 2. Molecular structure of complex **I** together with the atomic numbering. Hydrogen atoms and water molecules are omitted for clarity.

ferrocenyl groups in complex **I** are syn to each other. In view of the Fe···Fe distance of 10.502 Å, it may be concluded that one ferrocenyl group in complex **I** does not interact sterically with the other and therefore the syn isomer can be isolated, whereas the corresponding anti-isomer cannot be found. As expected, both six-membered chelate rings are planar. Angles O(1)–Cu–N(1) and O(2)–Cu–N(2), which are 92.1(5) and 94.1(5)°, are slightly larger than the corresponding values observed in related structures [15,16]. Values of angles O(1)–Cu–O(2) and N(1)–Cu–N(2) are 154.1(5) and 155.5(5)°, therefore indicating that the coordination geometry about the copper ion is tetrahedral as mentioned above. The bonds between the copper atom and the donor sites of the deprotonated ligand are within the range of values normally found for these bonds [15,16]. Interestingly, the Cu–O distances (Cu–O(1) = 1.92(1); Cu–O(2) = 1.89(1) Å) are significantly different from each other whereas the Cu–N distances (Cu–N(1) = 1.95(1); Cu–N(2) = 1.99(1) Å) are similar. The structural features of two $\mathbf{L}^-$ ions (Table 3) are as follows. One exhibits N(1)–C(2), C(2)–C(3), C(3)–C(4) and O(1)–C(4) bond distances of 1.28(2), 1.42(2), 1.35(2) and 1.31(2) Å, and the other shows N(2)–C(6), C(6)–C(7), C(7)–C(8) and O(2)–C(8) bond distances of 1.31(2), 1.42(2), 1.36(2) and 1.31(2) Å whereas the corresponding bond distances of **HL⁶** are 1.349(5), 1.367(5), 1.408(5) and 1.250(4) Å. These suggest that the O=C–C=C–N system of the complex has more delocalization than that of the corresponding ligand [16]. It should be pointed out that the water molecules in complex **I** are non-coordinate and disordered.

3.4. IR spectra

The important IR data of the enaminones and the complexes are given in Section 2. The band at ≈3080 cm^{-1} in the spectrum of each ligand is due to *v*(NH) and does not occur in that of the corresponding complex. This suggests that the enaminones are bonded to copper ions in the monoanionic form. Moreover, the strong bands assignable to stretching vibrations of the skeleton C=O and C=C groups, which are observed at 1585–1603 and 1552–1567 cm^{-1} in the ligands, are all red-shifted to the region 1550–1580 and 1510–1513 cm^{-1} in the complexes [3c,7a]. This is because the complexes possess resonance forms as shown in Fig. 3, which lead to a decrease in double bond character of the C=O and C=C groups [17]. As expected, the spectra of complexes **I**, **IV** and **V** display a broad and weak band at ≈3430 cm^{-1} due to the presence of *v*(OH) of lattice water molecules. Further, this has been confirmed by another band appearing at about 600 cm^{-1} [18,19]. Also this is consistent with the above-described X-ray crystal structure determination and elemental analyses data.

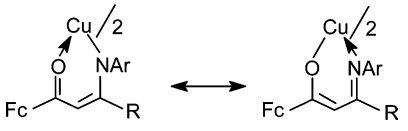

Fig. 3. Resonance forms of copper complexes.

3.5. UV spectra

The UV spectral data of the enaminones and the complexes are listed in Section 2. In the UV spectra, complexes **I**, **II** and **III** show three maxima at ≈275, 350 and 450 nm while for complexes **IV** and **V** each exhibits one maxima at ≈378 nm. The shortest wavelength absorption which is due to the B-band of cyclopentadienyl or benzene rings, displays a red shift compared with the corresponding ligand [20]. Unlike other ligands, only **HL¹** exhibits the respective B-band for the cyclopentadienyl ring and benzene ring. On the other hand, the longer wavelength band in the region 350–379 nm may be attributed to the $(\pi \rightarrow \pi^*)$ transition (viz. K-band) while the corresponding absorption in each ligand is observed in the region 328–369 nm. Therefore, compared with those absorptions of the corresponding ligands, the K-bands of all the complexes also show red shifts. Because deprotonated ligands bonded to the central metal ions strengthen the conjugative effect of the skeleton as shown in Fig. 3, red shifts of K-bands in the complexes are observed, whereas slightly decreased bonding of the cyclopentadienyl groups of the complexes results in a bathochromic shift of the B-band of the cyclopentadienyl group, which is also supported by the X-ray crystallography of enaminone **HL⁶** and complex **I** [20,21]. Furthermore, unlike the corresponding ligands, complexes **I**, **II** and **III** exhibit an intense absorption band in the region 450–447 nm which may be assignable to a ligand-to-metal charge transfer transition [22]. However for complexes **IV** and **V** no charge transfer transitions are observed. Finally, because weak d–d transtions in ferrocene-containing complexes are obscured by much more intense UV transitions from a different nature, the ligand field absorptions in these complexes cannot be resolved.

4. Conclusion

Reaction of the ferrocene-containing β-diketone $[C_5H_5FeC_5H_4C(O)CH_2C(O)R]$ (**1**, R = CH_3; **2**, R = C_6H_5) and the corresponding aniline $[H_2NAr]$ (Ar = Ph, 2-$CH_3C_6H_4$, 2,6-$(CH_3)_2C_6H_3$) in the presence of a catalytic amount of *p*-toluenesulfonic acid yields a series of *cis*-s-*cis* enaminones $[C_5H_5FeC_5H_4C(O)CH=C(NH Ar)R]$ (**HL¹**–**HL⁶**). Reaction of enaminones **HL¹**–**HL⁵** and copper acetate affords tetrahedral-*trans*-syn complexes **I**–**V** in which each of the enaminones coordinates to the copper ion as a monoanionic bidentate ligand via

carbonyl oxygen and enamine nitrogen atoms after deprotonation.

5. Supplementary material

Full crystallographic data (CCDC No. 200938 for enaminone **HL**[6] and CCDC No. 207417 for complex **I**) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; Email:deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Three types of copper(II) complexes, $[Cu(HL)Cl \cdot H_2O] \cdot xH_2O$, $[\{Cu(HL)Cl\}_2]$ and $[\{Cu(L)\}_2]$, derived from *N*-Salicylidene-*n*-alkanoylhydrazines (H_2L) have been synthesized and characterized by elemental analyses, infrared spectra and field desorption mass spectra as well as variable temperature magnetic susceptibility measurements. The X-ray molecular structure of bis[monochloro(μ-*N*-salicylidene myristoylhydrazine)ONO′(−1)]dicopper(II) showed that this complex is a centrosymmetric dimer in which each copper(II) is in a distorted square pyramidal environment and coordinated in the equatorial plane to the ONO mononegative tridentate acylhydrazone ligand. The fourth coordination site is occupied by the symmetry related phenoxy oxygen of the other monomeric unit. The chloride ion occupies the fifth axial coordination site. Magnetic susceptibility measurements at different temperatures (5–298 K) showed that the hydrated chloro complexes $[Cu(HL)Cl \cdot H_2O] \cdot xH_2O$ are monomeric and no spin–spin interaction was detected, while the anhydrous chloro complexes $[\{Cu(HL)Cl\}_2]$ are dimeric and exhibit strong antiferromagnetic coupling with $-2J$ values the range 466–477 cm^{-1}. The neutral complexes $[\{Cu(L)\}_2]$ also show antiferromagetic behaviour with $-2J$ varying from 170 to 243 cm^{-1}.

1. Introduction

N-salicylideneacylhydrazines show a wide spectrum of biological activities [1–6]. The cytotoxicity of these acylhydrazones and their transition metal(II) complexes against T-cell leukaemia and human colon adenocarcinoma cell lines were recently evaluated [5,6]. As *N*-salicylideneacylhydrazines can act towards transition and non-transition metal ions either as neutral, mono- or dinegative ONO tridentate ligands [5,7–12], their biological activities appear to be associated with their ability to bind essential metal ions in vivo [1–6]. QSAR analysis revealed that the cytotoxicity of *n*-alkanoylhydrazones and their copper(II) complexes are dominated by the transport factor as measured by log the octanol/water partition coefficient (*P*) [5], while for the aroylhydrazone series, both electronic factors, as measured by the Hammett sigma parameter (σ), and transport factors (log *P*) play a key role in the observed cytotoxicity [6].

Moreover, the biological activities of metal(II), especially copper(II), complexes were found more significantly active than the metal free ligands [1–6].

In this paper, we report the synthesis and characterization of some novel lipophilic copper(II) complexes derived from *N*-salicylidene-*n*-alkanoylhydrazines. The X-ray crystal and molecular structure of bis [monochloro-(*N*-salicylidenemyristoyl-hydrazine)ONO(−1)] dicopper(II) has been determined and the magnetic properties of the different types of the prepared copper(II) complexes will be discussed.

2. Results and discussion

2.1. Synthesis

Condensation of *n*-alkanoylhydrazines with salicylaldehyde in methanol afforded the corresponding *N*-salicylidene-*n*-alkanoylhydrazines, (H_2L), (**1**, $n = 0$, 4, 5, 6, 12 and 16). The reaction of **1a**–**1d** (Scheme 1) with copper(II) chloride gave the green monomeric chloro complexes $[Cu(HL)Cl \cdot H_2O] \cdot xH_2O$ (**2a**–**2d**) (Scheme 2), while with **1e**−**1f** the anhydrous brown dimeric chloro complexes (**3e**–**3f**) (Scheme 3) were isolated. Similar to other ONO tridentate *N*-salicylideneacylhydrazines, the reaction of **1a**–**1f** with copper(II) acetate in methanol, using a 1:1 molar ratio, gave the neutral dimeric copper(II) complexes $[\{Cu(L)\}_2]$, where L refers to the hydrazone dianion [2,5–7,13]. The elemental analyses of the prepared copper(II) complexes are listed in Table 1.

2.2. Mass spectra

The electron impact (EI) mass spectra of **1a**–**1f** display the corresponding molecular ion peak together with other fragments originated from both *N*-salicylidene and *n*-alkanoylhydrazine residues. The field desorption (FD) mass spectra of both hydrated and anhydrous chloro complexes, Table 2, show peaks corresponding to $[L]^+$, $[\{Cu(L)\}]^+$, $[\{Cu(L)Cl\}_2 - Cl]^+$ and $[\{Cu(L)\}_2]^+$. The relative abundances of these ions, Table 2, suggest the higher stability of the dimeric species $[\{Cu(L)\}_2]^+$ relative to the corresponding monomeric species $[\{Cu(L)\}^+]$ in the gas phase. On the other hand, the field desorption

(FD) mass spectra of neutral complexes $[\{Cu(L)\}_2]$ ($n = 4$, 5, 6, 12 and 16), Table 2, show only the molecular ion peak at $m/z = 590$, 618, 646, 815 and 927 corresponding to the dimeric species $[\{Cu(L)\}_2]^+$.

2.3. Infrared spectra

The infrared spectra of the metal free ligands (**1a**–**1f**), are more or less similar and show a series of bands at ca. 3200, 1670, 1620, 1540 and 1280 cm^{-1} due to ν(N–H), amide I [ν(C=O)], ν(C=N), amide II [δ(NH)] and amide III [ν(C–N)] bands, respectively [14]. The recorded spectra reveal the predominance of the ketoamide tautomer in the solid state. The infrared spectra of both hydrated monomeric (**2a**–**2d**) and anhydrous dimeric chloro complexes (**3a** and **3b**) show bands at ca. 3220, 1625, 1600, 1550 and 1330 cm^{-1} due to ν(N–H), amide I [ν(C=O)], ν(C=N), amide II (δ(N–H) and amide III [ν(C–N)] bands, respectively. Both amide I [ν(C=O)] and ν(C=N) are shifted to lower frequencies, while the amide III band appears at higher frequencies relative to those of the corresponding metal free ligands. The recorded spectra indicate that the *n*-alkanoylhydrazone in these complexes behaves as a mononegative ONO tridentate ligand. The spectra of the neutral dimeric complexes $[\{Cu(L)\}_2]$, on the other hand, lack absorptions due to ν(N–H), amide I [ν(C=O)] and amide II [δ(N–H)] bands, but show intense bands at ca. 1615 cm^{-1} due to an asymmetric vibration of the conjugated C=N–N=C residue [5,7,15]. The recorded spectra suggest the deprotonation of both phenolic and enolimide

Symmetry transformation used to generate equivalent atoms: # $(-x, -y, -z+1)$.

the atom numbering scheme are shown in Fig. 1, and some selected bond distances and angles are listed in Table 4. This complex is a centrosymmetric dimer in which each copper(II) is coordinated in the equatorial plane to the *N*-salicylidene *n*-alkanoylhydrazine through the deprotonated phenolic oxygen (O1), imine nitrogen (N1) and ketoamide oxygen (O2). The fourth coordination site is occupied by the symmetry related phenoxy oxygen of the other monomeric unit, while the chloride ion is in the axial coordination site. The coordination polyhedron around each copper(II) is best described as (4 + 1) distorted square pyramidal. This is in agreement with the value of the tetragonality parameter $\tau = [(\beta - \alpha)/60] = 0.14$ where α and β are N1–Cu–O1# (155.81°) and O1–Cu–O2 (164.50°) angles, respectively [16,17]. In this dimer, the two chloride ions are in *trans* positions with respect to each other and are perpendicular to the Cu_2O_2 plane with angles O1–Cu–Cl and O2–Cu–Cl of 100.57° and 93.35°, respectively. The Cu· · · ·Cu separation (3.0398 (8) Å) in the Cu_2O_2 moiety is similar to other related dimeric copper(II) complexes with mononegative ONO tridentate acylhydrazones [5,9,10,18]. The Cu1–O1–Cu1# bridging angle (100.84°) compares favourably with that reported for [{Cu(HStbu)Cl}$_2$] (100.9°) (HStbu refers to the *N*-salicylidene-*t*-butanoylhydrazine mononegative anion) [5], but higher than that of [{Cu(HSbzh)Cl}$_2$] (99.1°) (HSbzh) refers to the *N*-salicylidenebenzoylhydrazine mononegative anion) [18]. The two chloride ions in each dimer form short contacts with two other symmetrically related dimers. Thus the dimeric units are linked together via two N2H···Cl1 hydrogen bonds forming a supramolecular structure which consist of a chain of double chains of hydrogen bonds as shown in Fig. 2.

2.5. Magnetic studies

The room temperature magnetic moments of the hydrated chloro copper(II) complexes (**2a**–**2d**) (1.85–1.92 μ_B), Table 5, are within the range expected for magnetically diluted mononuclear copper(II) complexes [19]. The variation of χ_M over the temperature range [5–298 K] reveals no substantial deviation from Curie–Weiss behaviour. The θ values recorded for these complexes, Table 5, are within the range (−2.8 to −4.0 K), indicating very weak antiferromagnetic magnetic intermolecular interaction. The magnetic data, Table 5, suggest that these hydrated chloro complexes exist, in solid state, as discrete monomers, in agreement with the previously reported X-ray molecular structure of **2a** (**2**, $n = 0$) [10]. In this complex, the central copper(II) is in a distorted square pyramidal environment. The monoanionic tridentate hydrazone ligand is coordinated to the Cu(II) in the equatorial plane while the fourth coordination site is occupied by a water molecule. The fifth axial coordination site is occupied by the chloride ion [10]. A similar structure

4f	1.53	181	2.06	−19.6	1.71

can be adopted for the other hydrated chloro complexes.

The anhydrous chloro complexes **3a** and **3b** (**3**, $n = 12$ and 16) show room temperature magnetic moments (1.20 and 1.22 μ_B) much lower than expected for spin only values [19]. The variation of χ_M and μ_{eff} recorded for **3a** (**3**, $n = 16$) with temperature, Fig. 3, suggest strong antiferromagnetic interaction between the copper(II) centers in the dimeric structure shown in Fig. 1. Similar behaviour was also observed for **3b** (**3**, $n = 12$). The recorded variable temperature magnetic susceptibility data were fitted to the modified Bleaney–Bowers equation [20]:

$$\chi_M = (1-\rho)\frac{2N_L\mu_B^2 g^2 \exp(2J/kT)}{k(T-\theta)(1+3\exp(2J/kT))} + \rho\frac{2N_L\mu_B^2 g^2}{4kT} + 2N_\alpha, \quad (1)$$

where N_α is the temperatue independent paramagnetism (60×10^{-6} cm^3 mol^{-1} per Cu(II)), ρ is the mole fraction of monomeric impurity and θ is a correction term for interdimer interaction [21,22]. Other terms have their usual meaning. The best fit values of $2J$, g, ρ and are listed in Table 5.

The $-2J$ values measured for **3a** (477 cm^{-1}) and **3b** (466 cm^{-1}) are more or less similar, implying similar

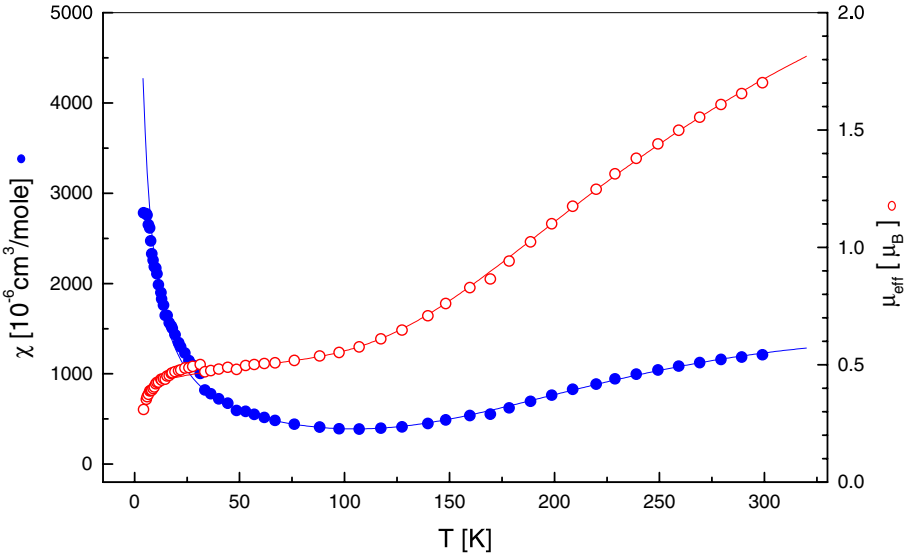

Fig. 3. Magnetic susceptibilities χ_M (•) and magnetic moments (○) vs. temperature for **3a** (**3**, $n = 12$). Solid lines represent the best least square fit to Eq. (1) with $2J = -477$, $g = 2.31$ and $\rho = 1.90\%$.

structures. However, these $-2J$ values, Table 5, are higher than that reported for other similar dichloro dicopper(II) complexes with *N*-salicylidenearoylhydrazines (406–452 cm^{-1}) [13,18].

The X-ray structures of **3a** (Fig. 1), [{Cu(HSbh)Cl}$_2$] [18] and [{Cu(HStbu)Cl}$_2$] [5] revealed that these five coordinate dichloro dicopper(II) complexes belong to a coplanar (distorted square pyramidal) rather than parallel planar (distorted trigonal bipyramidal) type [23]. In this type the extent of antiferromagnetic interaction, as measured by singlet–triplet separation ($-2J$), increases on increasing either Cu–O–Cu bridge angles or Cu···Cu separation, but shows a pronounced decrease as the dihedral angle between the Cu_2O_2 plane and that of the remaining ligand increases [24]. In both **3a** and [{Cu(HSbh)Cl}$_2$], this dihedral angle is more or less similar with an average value of 25.8°. Accordingly the higher $-2J$ value recorded for **3a** (477 cm^{-1}) relative to that of [{Cu(HSbh)Cl}$_2$] (452 cm^{-1}) [13,18] can be related to the increase in both Cu–O–Cu angle (100.84°) and Cu···Cu separation (3.0398 Å) of **3a** as compared with the Cu–O–Cu angle (99.10) and Cu···Cu separation (3.0290 Å) of [{Cu(HSbh)Cl}$_2$].

At room temperature (298 K), the neutral copper(II) complexes [{Cu(L)}$_2$] show low lying magnetic moments (1.53–1.60 μ_B), and the magnetic susceptibility measurements within the temperature range 4.2–298 K recorded for these neutral complexes indicate antiferromagnetic exchange coupling between two copper(II) centers. The variation of χ_M and μ_{eff} as a function of T recorded for the neutral copper(II) complex derived from *N*-salicylidenestearoylhydrazine is shown in Fig. 4. The magnetic susceptibility curve shows a broad maximum around 120 K then rapidly decreases to a minimum at 50 K as the temperature is lowered. This type of temperature dependence is expected for antiferromagnetic coupled copper(II) binuclear complexes. The further increase in χ_M as the temperature is lowered is due to the presence of paramagnetic mononuclear impurity.

The variable temperature magnetic susceptibility data collected for neutral copper(II) complexes [{Cu(L)}$_2$] were fitted in the Bleaney–Bowers equation (Eq. (1)) and the best fit magnetic parameters (g, $2J$, θ and ρ) are included in Table 5. Similar to other copper(II) complexes with dinegative *N*-salicylideneacylhydrazines [13,25] and other dinegative ONO tridentate Schiff bases [24], the antiferromagnetic behaviour of these copper(II) complexes confirm their dimeric nature. Dimerization of copper(II) complexes with dinegative tridentate *N*-salicylideneacylhydrazones usually occurs via the phenoxy oxygen as shown in structure **4** (Scheme 4) [13,25]. However, Leukov et al. [26,27] showed that dimerization may also occur via oxazine oxygens (Scheme 5) (**5**). The calculated exchange parameter ($-2J$) of the phenoxy bridged isomer lies in the range $230 < -2J < 520$ cm^{-1} while $25 < -2J < 125$ cm^{-1} was reported for an oxazine oxygen bridged isomer [27]. The $-2J$ values recorded in the present work for [{Cu(L)}$_2$] complexes, Table 5, varies from 170 to 243 cm^{-1}. This range is lower than that expected for other neutral dicopper(II) complexes with dinegative ONO tridentate ligands where dimerization occurs via phenoxy oxygens [13,24,25] but is still higher than the range proposed by Leukov et al. for oxazine bridged isomers. Thus, the results of the present magnetic measurements cannot provide non-equivocal evidence for the structure of these neutral copper(II)

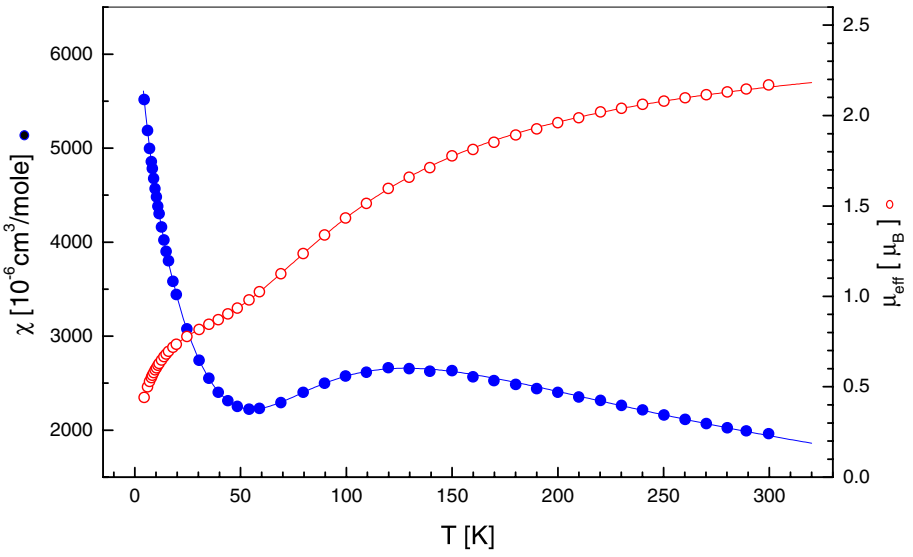

Fig. 4. Magnetic susceptibilities χ_M (•) and magnetic moments (○) vs. temperature for **4f** (**4**, $n = 16$). Solid lines represent the best least square fit to Eq. (1) with $2J = -181$, $g = 2.06$, $\theta = -19.6$ and $\rho = 1.71\%$.

complexes. Meanwhile, the X-ray molecular structures reported for all dimeric copper(II) complexes with *N*-salicylideneacylhydrazines with different degrees of deprotonation indicate dimerization through the phenoxy oxygen [5,9–12,18]. To the best of our knowledge there is no X-ray structure reported for an oxazine oxygen bridged complex. This may favour structure (**4**) for the dimeric neutral copper(II) [{Cu(L)}$_2$] complexes where dimerization occurs via phenoxy oxygens (**4**) rather than oxazine oxygens (**5**). The lower $-2J$ values recorded for **4a**–**4f**, Table 5, relative to the dicopper(II) complexes derived from other *N*-salicylideneacylhydrazines [13,18,25] may be related to an increase in the dihedral angle between the Cu_2O_2 plane and that of the remaining ligand resulted, most probably, from the hydrophobic interactions between the *n*-alkyl chains within the crystal lattice. The actual structure of this type of dicopper(II) complex, however, must remain in doubt until a complete X-ray molecular structure is available.

3. Experimental

3.1. Preparation of n-alkanoylhydrazines and N-salicylidene-n-alkanoylhydrazines (*1a*–*1f*)

N-alkanoylhydrazines were prepared, as previously described [5,28], by the hydrazinolysis of fatty acid methyl esters in methanol. The corresponding *N*-salicylidene-*n*-alkanoylhydrazines (**1a**–**1f**) were prepared by the condensation of salicylaldehyde with *n*-alkanoylhydrazine in methanol [5,28], (**1a**, m.p. = 200–202 °C; **1b**, m.p. = 123–124 °C; **1c**, m.p. = 110°C; **1d**, m.p. = 103–104 °C; **1e**, m.p. = 106–108 °C; **1f**, m.p. = 114 °C).

3.2. Preparation of dimeric neutral copper(II) complexes [{Cu(L)}$_2$] (*2b*–*2f*)

A solution of *N*-salicylidene-*n*-alkanoylhydrazine (**1b**–**1f**) (5.0 mmol) in dry methanol (40 cm^3) was added

to a solution of copper(II) acetate monohydrate (5.1 mmol) in dry methanol. The reaction mixture was heated under reflux with constant stirring for ca. 15 min. On cooling the formed green complex was filtered, washed with hot methanol and then dried in vacuo.

3.3. Preparation of monomeric hydrated monochloro copper(II) complexes $[Cu(HL)Cl \cdot H_2O] \cdot xH_2O$ (**3b**–**3d**)

To a solution of $CuCl_2 \cdot 2H_2O$ (5.0 mmol) in dry methanol (20 cm^3), a solution of *N*-salicylidene-*n*-alkanoylhydrazine (5.0 mmol) in dry methanol (30 cm^3) was added dropwise with constant stirring. The reaction mixture was stirred at room temperature for 1 h and the formed complex was filtered, washed successively with dry methanol and ether then dried in air.

3.4. Preparation of anhydrous dimeric monochloro copper(II) complexes $[\{Cu(HL)Cl\}_2]$ (**3a** and **3b**)

A solution of *N*-salicylidene-*n*-alkanoylhydrazine (**1e** or **1f**) (5.0 mmol) in absolute ethanol (50 cm^3) was added dropwise to a solution of $CuCl_2 \cdot 2H_2O$ (5.0 mmol) in absolute ethanol (20 cm^3). The reaction mixture was then heated under reflux for 10 min. On cooling, the crystalline anhydrous chloro copper(II) complex (**3a** or **3b**) which separated out was filtered, washed with dry diethylether then dried in vacuum.

3.5. Physical measurements

Infrared spectra were recorded on a Perkin–Elmer 1430 Data system and/or a Perkin–Elmer (FT-IR spectrophotometer) PARAGON 1000 PC infrared spectrophotometer. Calibration of frequency reading was made with polystyrene film. Solid samples were examined as KBr discs. Electron impact and field desorption mass spectra on Finnigan Mat 212 (70 eV) instrument. Magnetic susceptibilities of powdered dried samples were recorded on a Faraday-type magnetometer using a sensitive computer controlled D-200 Cahn RG microbalance in the temperature range 4.2–298 K. The magnetic field applied was ~1.5 T. Details of the apparatus have been described elsewhere [29]. Experimental susceptibility data were corrected for the underlying diamagnetism using Pascal's constants [20].

3.6. X-ray crystal and molecular structure

X-ray diffraction measurements were carried out on an Oxford diffraction Xcalibur (TM) single crystal X-ray diffractometer with a Sapphire CCD detector. The structure of **3a** was solved by a direct method using SHELXS 97 [30] and refined by a full-matrix least squares method on all F^2 data using SHELXL 97 [31] programs.

4. Supplementary material

Atomic coordinates, equivalent isotropic displacement parameters, hydrogen coordinates, isotropic displacement parameters, anisotropic displacement parameters and a complete list of bond distances and bond angles of **3a** have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC 211370. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The di- and mono-zinc(II) complexes of diporphyrins (D) were synthesized, in which two porphyrin halves were covalently linked through a variable length hydrocarbon spacer ($-CH_2)_n-$, where $n = 2$–4, D2–D4, respectively) attached via the *ortho* oxygen atom of the *meso*-phenyl ring. Three *p*-tolyl substituents were attached to other *meso* positions of both porphyrins. The zinc(II) complexes were studied by 1-D and 2-D COSY and NOESY ^{1}H NMR spectroscopy. The stability constants of dizincdiporphyrins with azaaromatic ligands: pyridine (py), pyrazine (pyr), and 4,4′-bipyridyl (bipy) were determined by spectrophotometric titration. The discriminating factor for stability of dinuclear complexes with diazaaromatic ligands was the length of the diporphyrin spacer. The formation constant for ZnTTP with pyr and bipy were very close to that for py, whereas they were about 1.3 orders of magnitude larger for **D2Zn$_2$**-pyr, **D3Zn$_2$**-bipy, and **D4Zn$_2$**-bipy complexes which was attributed to the formation of nitrogen base bridged species. The monozincdiporphyrin complexes were demonstrated to be a convenient starting material for synthesis of heterodimetallodiporphyrins. The Zn(II)/Cu(II)diporphyrin complex was synthesized and characterized by EPR spectroscopy.

Keywords: Diporphyrins; Zinc(II) complexes; Nitrogen base ligation; Stability constants

1. Introduction

Diporphyrins are suitable ligands that are able to coordinate two metal ions. This feature renders them good candidates for synthesis of dinuclear complexes, which can be applied as bifunctional catalysts, especially in the case when two different catalytic metal ions are incorporated. The diporphyrins linked with rigid spacers attached to *meso* positions were studied in detail [1–7]. The most explored were those with *ortho*-, *meta*- or *para*-phenylene [1,2] and pillard diporphyrins, in which biphenylene, anthracene, xanthene and 1,10-phenanthroline were attached to *meso* positions of the porphyrin subunits [3–7]. Some heterodimetallodiporphyrins containing for example Mn(III)/Cu(II) and Al(III)/Co(II) metal ion pairs were characterized structurally [3,7]. Synthesis of heterodimetallodiporphyrins requires the insertion of the metal ion under stoichiometric control. In this paper, we have described the synthetic route for obtaining the di- and monozinc complexes of the diporphyrins with flexible spacers. Two porphyrin halves are linked via *meso* positions at which phenyl substituents are connected by variable length hydrocarbons attached to the *ortho* oxygen. The monozincdiporphyrins are useful starting materials for synthesis of heterodimetallodiporphyrins, which was exemplified by the mixed-metal Zn(II)/Cu(II)diporphyrin complex, characterized by EPR spectroscopy.

2. Experimental

2.1. Syntheses

2.1.1. General syntheses

The 5-(*ortho*-hydroxyphenyl)-10,15,20-tris(*p*-tolyl)-porphyrin (**H$_2$TTP-*o*-OH**) and diporphyrins with variable-length hydrocarbon spacers **S** attached to the peripheral oxygen of two porphyrin macrocycles:

doi:10.1016/j.poly.2003.09.021

(H_2TTP-*o*-OCH_2)$_2$(CH_2)$_n$: **D2H$_4$** ($n = 0$, **S** = 2), **D3H$_4$** ($n = 1$, **S** = 3) and **D4H$_4$** ($n = 2$, **S** = 4) were synthesized as described previously [8–12]. The 5,10,15,20-tetra(*p*-tolyl)porphyrin (**TTPH$_2$**) was obtained as a side-product and its zinc(II) complex (**TTPZn**) was used for comparative purposes.

*2.1.2. Mono- and bis-zinc(II)diporphyrin complexes (DSH$_2$Zn, DSZn$_2$, **S** = 2, 3 and 4)*

The insertion of the zinc(II) ion into diporhyrins **DSH$_4$** was performed on the 30–75 μmol scale (50–100 mg of diporphyrins were used) by stepwise addition of ca. 0.1 M zinc(II) chloride in methanol into a refluxing solution of **DSH$_4$** in chloroform containing potassium carbonate (about 1 g). The progress of reaction was monitored by TLC on silicagel using 65/35 v/v% dichloromethane/hexane eluent The chromatographic mobility decreased in order: **DSH$_4$** > **DSZnH$_2$** > **DSZn$_2$** in every case. The insertion procedure was continued until the near disappearance of starting **DSH$_4$** was noticed. Separation of **DSZnH$_2$** and **DSZn$_2$** was achieved by column chromatography on silicagel using dichloromethane/hexane eluent; traces of **DSH$_4$** were eluted with 30% CH_2Cl_2, while fractions eluted with 35% and 45% CH_2Cl_2 contained almost pure of **DSZnH$_2$** and **DSZn$_2$**, respectively. The second fractions were re-chromatographed using the same conditions in order to obtain high-purity **DSZnH$_2$**. Total yields of the products of insertion were close to 100% (45% and 50% for **DSZnH$_2$** and **DSZn$_2$**, respectively). The free ligands **DSH$_4$** were recoverable by the demetallation procedure based on the extraction of a chloroform solution of **DSZnH$_2$** and/or **DSZn$_2$** with 2 M HCl 1:1 H_2O: CH_3OH within 1 h with about 20% loss of diporhyrin, which in those conditions gave starting ***o*-HOTTPH$_2$** and other products, which were easy to separate from **DSH$_4$** due to their chromatographic immobility under standard conditions. The complexes have been identified on the basis of their ^{1}H NMR spectra. Resonances were assigned using standard ^{1}H COSY and NOSEY experiments. The numbering scheme of the ligands is presented in Fig. 1.

2.1.3. Synthesis of D2ZnCu

To the solution of **D2ZnH$_2$** (35 mg, 2.4×10^{-2} mmol) in chloroform (50 cm^3) containing 1 g K_2CO_3 under reflux, 1.8-fold molar excess of $CuCl_2$ was added dropwise as a 0.058 M methanolic solution. The color of the mixture changed from pink-purple to orange-red. The products of reaction were separated chromatographically on silicagel. The first compound eluted with 35% CH_2Cl_2/hexane (v/v) was $D2Cu_2$ (15 mg, 1.0×10^{-2} mmol, 42%), identified by comparison with an authentic sample of the complex obtained in a separate synthesis, while **D2ZnCu** was eluted with CH_2Cl_2 (yield 18 mg, 1.2×10^{-2} mmol, 50%).

D2ZnCu was demetallated by stirring of a chloroform solution (20 cm^3) of the complex with 2 M HCl H_2O/CH_3OH (20 cm^3) for 2 h, followed by chromatographic separation of **D2H$_4$**, which was identified easily by its ^{1}H NMR spectrum.

^{1}H NMR ($CDCl_3$, 298 K); chemical shift (ppm) (intensity, multiplicity, assignment, coupling constant): −2.76 (2H, s, NH), 2.66 (12H, s, 2x(p-CH_3(1)) + 2x(p-CH_3(1′))), 2.69 (6H, s, CH_3 (p-CH_3(2)) + CH_3(p-CH_3(2′))), 3.29 and 3.31 (2H and 2H,s and s, CH_2(1) + CH_2(1′)), 5.86–6.06 (4H, m, p-H + m_6-H + p'-H + $m_{6'}$-H, $J(p\text{-}m_5) = 8.0$ Hz, $J(p\text{-}m_6) = 8.0$ Hz, $J(p'\text{-}m_5) = 8.0$ Hz, $J(p'\text{-}m_{6'}) = 8.0$ Hz), 6.26–6.51 (4H, m, m_5-H + $m_{5'}$-H), 7.40–7.60 (12H, m, m_1-m_4-H, o_5-H, and $o_{5'}$-H), 7.98–8.13 (12H, m, o_1- o_4-H), 8.37 and 8.69 (2H and 2H, d and d, AB spectrum, 2(8)-H, 3(7)-H, $J(2,3) =$ 4.7 Hz), 8.59 and 8.82 (2H and 2H, d and d, AB spectrum, 2′(8′)-H, 3′(7′)-H, $J(2',3') = 4.7$ Hz), 8.83 (4H, s, 12,13,17,18-H), 8.92 (4H, s, 12′,13′,17′,18′-H).

RF = 0.50.

UV–Vis: 420 (3.6×10^5, Soret band), 516 (7.5×10^3), 549 (1.5×10^4), 589 (4.0×10^3), 646 (1.4×10^3).

2.2.10. D2ZnCu

MS (ESI): m/e: (**1**$^+$) 1496 (40%); (**1**-Zn + 3H) 1434 (100%).

2.3. Spectrophotometric titration of $DSZn_2$ with nitrogen bases

Formation constants of PZnL (where P is the porphyrin subunit in **DSZn$_2$** or TTP, and L = pyridine (py), pyrazine (pyr) or 4,4′-bipyridyl (bipy)) have been obtained by spectrophotometric titration of **DSZn$_2$** (concentration 3.00×10^{-5} mol/dm^3) with L (concentration varied in the 3.00×10^{-5}–0.1 mol/dm^3 range) with the assumption that no other species are present in the equilibrium except those defined by reaction scheme

$$\mathrm{PZn} + \mathrm{L} \Longleftrightarrow \mathrm{PZnL}$$

Stability constants were calculated from the general formula

$$K = \frac{(\varepsilon_1 C_{\mathrm{Zn}} - A)(\varepsilon_1 - \varepsilon_2)}{(A - \varepsilon_2 C_{\mathrm{Zn}})[C_{\mathrm{L}}^0(\varepsilon_1 - \varepsilon_2) - \varepsilon_1 C_{\mathrm{Zn}} - A]},$$

derived from initial equations:

$$C_1 + C_2 = C_{\mathrm{Zn}},$$

$$C_{\mathrm{L}}^0 = C_{\mathrm{L}} + C_2,$$

$$K = \frac{C_2}{C_1 C_{\mathrm{L}}},$$

$$A = \varepsilon_1 C_1 + \varepsilon_1 C_2,$$

where C_1 and C_2 are concentrations of PZn starting complex and PZnL adduct, respectively, C_{L}^0 is total concentration of L, C_{L} is concentration of free L, ε_1 and ε_1 are extinction coefficients of PZn and PZnL, respectively, A is the value of absorbance at the monitoring wavelength, and K is the formation constant. The monitoring wavelength corresponding to Q-bands was chosen for every case.

2.4. Methods and instruments

^{1}H NMR spectra were obtained with a Bruker AMX300 spectrometer operating in the quadrature mode at 300 MHz. The residual peaks of deuterated solvents were used as internal standards. ^{1}H COSY and NOESY spectra were obtained using standard pulse sequences as described before [10]. UV–Vis spectra were recorded on Beckman DU 640 instrument. EPR spectra were obtained with a Bruker ESP300E at X band for frozen solutions (77 K) in CH_2Cl_2/toluene 1/3 v/v. The mass spectrum was obtained on a Finnigan MAT TSQ 700 spectrometer by the ESI method at 4.5 kV ionization potential and 250 °C capillary temperature in chloroform.

3. Results and discussion

3.1. ^{1}H NMR studies of DSH_4, $DSZn_2$ and $DSZnH_2$

It has been demonstrated previously that the ring current effect imposed by a porphyrin macrocycle caused an upfield shift of the adjacent second porphyrin in diporhyrins [10,12]. It is especially pronounced in the case of a peripheral *meso*-phenyl substituent to which the spacer is attached (Table 1). A simple comparison of the chemical shifts of m_6-H, p-H, m_5-H and o_5-H in the diporphyrins studied here with those for the mono-porphyrin reference compound (Table 1) shows that: (i) the upfield shift decreases in order $m_6 > p > m_5 > o_5$ for **S** = 3 and 4, and $p > m_6 > m_5 > o_5$ for **S** = 2, (ii) the upfield shift of m_6-H decreases with increasing spacer length, i.e., in order of **S**; $2 \cong 3 > 4$, (iii) the same relationship holds for **DSZn$_2$** complexes as well as for **DSZnH$_2$** and (iv) introducing one zinc(II) ion into the porphyrin subunit induces considerable differentiation of the chemical shifts of the two porphyrin subunits, which can be exemplified by Δ (where Δ is the chemical shift difference between the corresponding resonances of linking 5-phenyl and pyrrole β-H protons in PH_2 and PZn porphyrin halves (see Fig. 2)). In the case of **D3ZnH$_2$** and **D4ZnH$_2$** Δ decreases in the order:

D3ZnH$_2$: $m_6(0.36) > p(0.35) > m_5 = \beta_{2,3}$ $(0.23) > o_5(0.21) > \beta_{12,13}(0.18)$.

D4ZnH$_2$: $p(0.52) > m_6(0.39) > m_5(0.28) > \beta_{2,3}(0.13) o_5$ $(0.10) > \beta_{12,13}(0.09)$.

The largest values of Δ for **D4ZnH$_2$** indicate that the ring current effect is most pronounced in this case. On the other hand the Δ values for **D2ZnH$_2$** are very small

Table 1
Relevant ^{1}H NMR data of **DSH$_4$**, **DSZnH$_2$** and **DSZn$_2$**

Entry	Compound	Chemical shift (ppm) (chemical shift difference related to reference[a])

9	**D4ZnH$_2$**	5.79 (−1.53)	6.44 (−1.32)	6.64 (−0.73)	7.68 (−0.36)
		6.18 (−1.14)	6.96 (−0.80)	7.02 (−0.35)	7.78 (−0.26)

[a] The chemical shifts were related to reference compound of C_{2v} effective symmetry; 5-(*ortho*-(3-bromopropoxy)phenyl)-10,15,20-tris(*para*-methylphenyl)porphyrin (entry 1, **TTP-*o*-PrBr**).

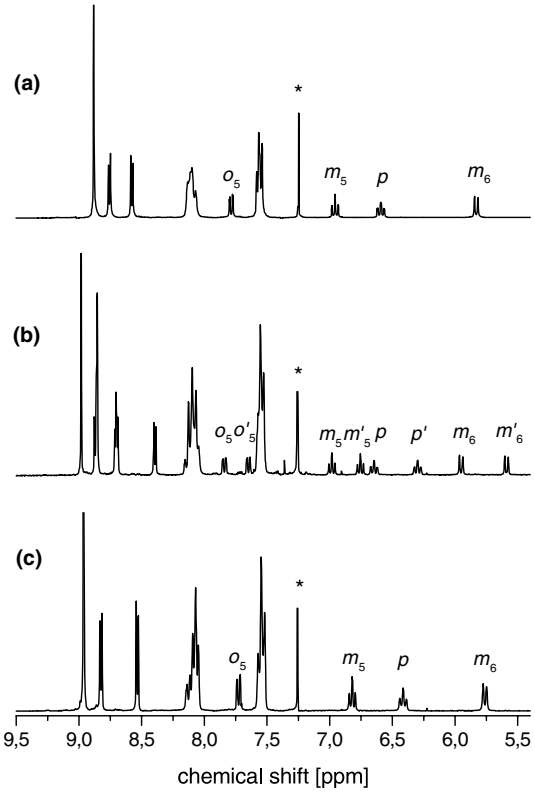

Fig. 2. Relevant fragments of the ^{1}H NMR spectra of **D3H$_4$** (a); **D3ZnH$_2$** (b) and **D3Zn$_2$** (c). The residual $CHCl_3$ resonance is labelled with an asterisk. The resonances labelled with $\prime$ at trace B were tentatively attributed to the PZn part of **D3ZnH$_2$**.

and the corresponding resonances of 5-*meso*-phenyl substituents almost overlap. These features suggest that in all **DSZnH$_2$** the two porphyrin subunits are in face-to-face conformation, however, in the case of $\mathbf{S} = 2$ the average conformation is slightly different from those for $\mathbf{S} = 3$ and 4.

3.2. Coordination of nitrogen aromatic ligands into dizincdiporphyrins

Coordination of pyridine-type bases into PZn causes red shift of the Soret band and a 14 nm red shift of the Q-band centered at about 550–560 nm. The titration of PZn indicated well-resolved isosbestic points for all studied systems at the concentration of L up to 10^{-2} M (Fig. 3). Above that concentration of L a further red shift (1–2 nm) of the Q-band could be detected, typical for formation of PML_2 (P – porphyrin or phthalocyanine) [13] with a very small change of extinction at the analytical wavelength. In order to avoid overlapping equilibrium related to the formation of bis-ligand $PZnL_2$ complexes only the points for base concentration below 10^{-3} M were used for the calculation of formation constants. The values of ε_1 and ε_2 were taken from

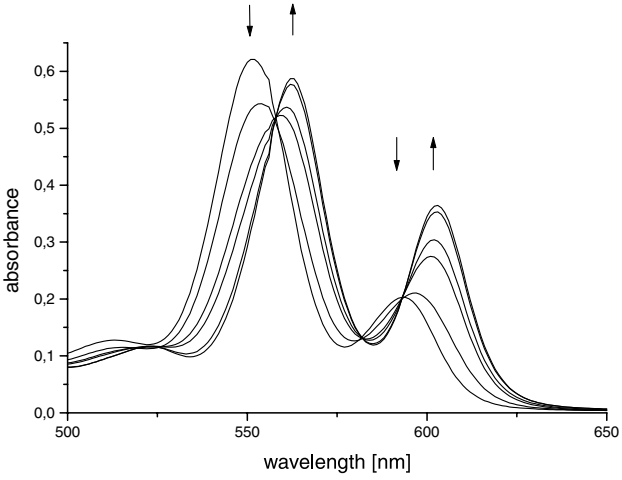

Fig. 3. The Q-band regions of UV–Vis spectra of the solutions containing **D4Zn$_2$** ($c = 2.2 \times 10^{-5}$ mol dm^{-3}) and pyr in CH_2Cl_2. Vertical arrows indicate absorbance changes upon addition of pyr, whose concentrations are (from top to bottom at 550 nm): 0; 3.0×10^{-5}; 6.0×10^{-5}; 2.5×10^{-4}; 5.0×10^{-3} and 0.10 mol $\times$ dm^{-3}.

Table 2
Formation constants of PZnL complexes (where L = py, pyr and bipy) determined by spectrophotometric titration of PZn in methylene dichloride at 298 K

Entry	Starting complex	log K (K – formation constant in mol/dm^3) (EM (mol dm^{-3}))		
		py	pyr	bipy
1	**TTPZn**	3.61 (3.68)[a]	3.90	3.20
2	**D2Zn$_2$**	3.35	4.61 (0.00065)	3.22
3	**D3Zn$_2$**	3.63	4.90 (0.0012)	4.63 (0.017)
4	**D4Zn$_2$**	3.65	3.83	5.19 (0.062)

[a] Determined in benzene solution [14].

experimental data at an analytical wavelength chosen at the maximum of two Q-bands of PZnL. The calculated data on K are collected in Table 2. The formation constants of PZnL, where L = py are in every case close to that of TTPZnL. Pyrazine and bipyridyl form in some cases considerably stronger complexes, which was attributed to an entropic factor due to the bridging mode of coordination of the ligands. Thus, the best fit between size of heteroaromatic base and length of spacer was obtained for bipy and **D4Zn$_2$**, while for pyr the best fit was in the case of **D3Zn$_2$** and **D2Zn$_2$**. The complementarity between host (dizincdiporphyrin) and bidentate ligand (here pyr or bipy) can be rationalized using the concept of effective molarity [15] expressed as

$$\mathrm{EM} = K/K_i^2,$$

where K_i is the microscopic equilibrium constant for binding of monodentate ligand into metal ion.

This approach was successfully applied for quantification of oligopyridyl ligands to butadiyne-linked porphyrin dimers, trimers and tetramers [16]. The best host–guest complementarity was found in the case of a relatively rigid cyclic diporphyrin with bipy, resulting in EM as large as 76 mol dm^{-3}, while in the case of the corresponding linear diporphyrin the EM was merely 0.5 mol dm^{-3}.

Here the EMs were calculated using experimental K_i obtained as the formation constant for binding bidentate ligand into TTPZn (entry 1 in Table 2). The values of EM are listed in Table 2. Obtained EM are much lower in comparison with those found for well-fitted host–guest pairs based on rigid cyclic oligoporphyrins [16], which seems reasonable considering the flexibility of the diporhyrins studied here. Nevertheless, the best complementarity within the **D4Zn$_2$**/bipy and **D3Zn$_2$**/pyr pairs is clearly seen.

3.3. Synthetic route to heterodimetallodiporphyrin D2ZnCu

The insertion of Cu(II) ion into **D2ZnH$_2$** was accompanied by partial replacement of Zn(II) with Cu(II) resulting in the formation of two species: **D2ZnCu** and **D2Cu$_2$**. The complexes were identified by their EPR spectra (Fig. 4). The **D2Cu$_2$** complex was obtained in an independent synthesis by insertion of Cu(II) into **D2H$_4$**. The mixed-metal **D2ZnCu** was identified by MS measurement. Moreover, the complexes were demetallated and the identity of **D2H$_4$** was verified by its ^{1}H NMR spectrum. The EPR spectrum of **D2Cu$_2$** is composed of broad lines, probably due to weak interaction between the two copper(II) centers and does not show superhyperfine coupling with nitrogen donors [17]. The characteristic feature of **D2ZnCu** is the presence of 18 lines of superhyperfine structure related to two distinct $g_\perp$, typical for monomeric copperporphyrins [17].

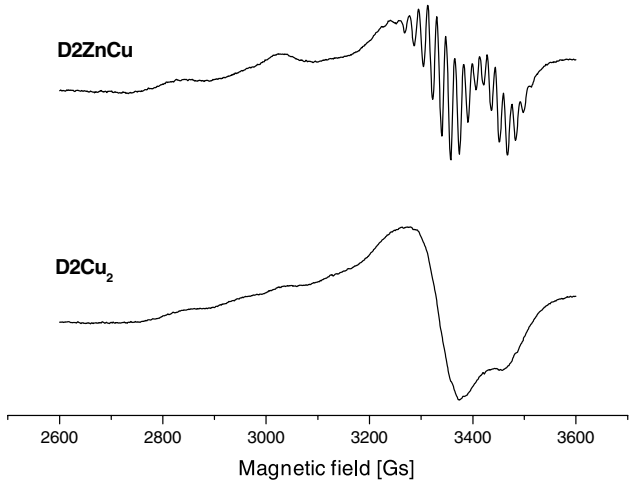

Fig. 4. EPR spectra of **D2ZnCu** and **D2Cu$_2$** in CH_2Cl_2/toluene glass in 77 K.

4. Conclusion

We have presented the successful method of synthesis and separation of mono-zinc diporphyrin complexes, which are useful starting materials for the synthesis of heterodimetallodiporphyrins. Heterometallodiporphyrins with flexible spacers of tunable length and geometry may be used as catalysts in many reactions, depending on the metal ions incorporated. The most promising is the application of diiron(II)diporphyrins in activation of dioxygen and oxygen atom

transfer from diferryldiporphyrins into dienes. Especially interesting seems to study the influence of different metal ions in Fe(II)/M(II)diporphyrin complexes on the chemoselectivity of such catalytic reaction.

Received 6 May 2003; accepted 3 September 2003

Abstract

An interesting series of four novel mixed ligand Co(III) complexes of 2-hydroxyacetophenone 4-phenyl semicarbazone (H_2L), heterocyclic base, B [1,10-phenanthroline (phen), piperidine (pip) and pyrrolidine (pyrr)] and azide/thiocyanate (X) with a general formula [$CoLB_xX$] (where $x = 1$ for phen and 2 for pip and pyrr) were prepared. They were characterized by a variety of physicochemical techniques. All the four complexes are diamagnetic indicating that the cobalt is in a d^6 strong field. The tridentate character of the semicarbazone in all cases is inferred from IR spectra. The structure of the compound $CoLphenN_3$ is solved by single crystal X-ray diffraction. It shows that the compound crystallizes in the orthorhombic system, [space group is *P 21 21 21*, $a = 10.6590(8)$ Å, $b = 11.9150(16)$ Å, $c = 19.1650(4)$ Å, $Z = 4$]. The coordination geometry around the cobalt is distorted octahedral with tridentate L^{2-}, bidentate phenanthroline and unidentate azido anion. The azido nitrogens and phenanthroline hydrogens form intermolecular hydrogen bonds to give a sandwich type of packing to the molecule.

1. Introduction

In the quest of exploring the chelating behavior of some ONS and NNS donor thiosemicarbazones in several metal complexes, we could acquire more information about their nature of coordination and related structural, spectral and biological properties [1–5]. Recently, we have reported the spectral and structural studies of Co(III) complexes containing N(4)-substituted thiosemicarbazones [6]. Thiosemicarbazones and their metal complexes have been the subject of extensive investigations because of their potential pharmacological properties and a wide variation in their modes of bonding and stereochemistry whereas their semicarbazone analogs received much less attention. However, semicarbazones are reported to possess versatile structural features [7] and very good antifungal and antibacterial properties [8,9]. Spectral studies of some complexes of furfuraldehyde semicarbazone were recently reported [10]. So we considered it worthwhile to extend our studies to semicarbazones, which are structurally similar to thiosemicarbazones, except that they have an oxygen atom in place of sulfur. Herein we report the synthesis and spectral studies of a new ligand 2-hydroxyacetophenone N(4)-phenyl semicarbazone (Scheme 1) and its four Co(III) complexes containing heterocyclic bases, 1,10-phenanthroline, piperidine and pyrrolidine. The crystal structure of the compound $CoLphenN_3$ (**1**) is also reported.

2. Experimental

2.1. Materials

1,10-Phenanthroline, pyrrolidine and piperidine were purchased from Merck and used as received. 4-Phenyl semicarbazide (Fluka), 2-hydroxyacetophenone (CDH)

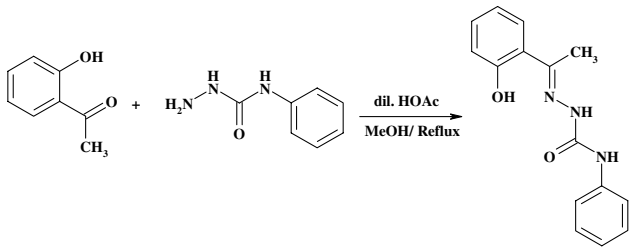

Scheme 1.

and cobalt acetate (BDH) were used without further purification. All solvents obtained commercially were distilled before use.

2.2. Syntheses of compounds

2.2.1. Synthesis of ligand H_2L

The ligand was prepared from a methanolic solution of 4-phenyl semicarbazide and 2-hydroxyacetophenone in acidic medium. 4-Phenyl semicarbazide (0.151 g; 1 mmol) dissolved in hot methanol (50 ml) was added to a solution of 2-hydroxyacetophenone (0.136 g, 1 mmol) in the same solvent. Two drops of concentrated acetic acid was added to the reaction mixture to change the pH. Then the reaction mixture was refluxed for 3 h on a water bath and cooled to room temperature. The product formed was filtered off and washed with methanol to obtain an off-white crystalline compound. M.p. 188–189 °C. Yield 70%. *Anal.* Calc. for $C_{15}H_{15}N_3O_2$: C, 66.90; H, 5.61; N 15.60. Found: C, 66.70; H, 5.57; N, 15.6%. ^{1}H NMR, DMSO-d_6, 500 Hz: $\delta = 12.79$ (s, br, 1H, OH); $\delta = 7.52$ (d, $J = 8$ Hz, 1H, H-3); $\delta = 6.89$ (d, $J = 7.9$ Hz, 1H, H-4); $\delta = 7.25$ (t, $J = 7.3$ Hz, 1H, H-5); $\delta = 6.87$ (d, $J = 7.6$ Hz, 1H, H-6); $\delta = 2.23$ (s, 3H, methyl); $\delta = 9.87$ (s, 1H, N(3)H); $\delta = 8.89$ (s, 1H, N(4)H); $\delta = 7.57$ (d, $J = 7.3$ Hz, 2H, H-11 and H15); $\delta = 7.32$ (t, $J = 7.7$ Hz, 2H, H12 and H14); $\delta = 7.01$ (t, $J = 7.3$ Hz, 1H, H13). ^{13}C NMR, DMSO-d_6, 125 Hz: $\delta = 152.79$ C9; 151.20 C7; 13.90 C8; 158.80 C1; 121.09 C2; 128.70 C3; 119.37 C4; 131.12 C5; 117.86 C6; 140.05 C10; 110.37 C11 and C15; 129.73 C12 and C14; 123.12 C13.

2.2.2. Syntheses of complexes

The complexes $[CoLB_xX]$ were prepared by the following general method. A hot methanolic solution (30 ml) of $Co(CH_3COO)_2 \cdot 5H_2O$ (0.458 g, 2 mmol) was added to a mixture of H_2L (0.598 g, 2 mmol) and appropriate heterocyclic base (2 mmol phen and 4 mmol pip and pyrr) in the same solvent. The resulting green solution was stirred for 10 min. To this 2 mmol NaN_3/KCNS was added and refluxed for 20 min. Then microcrystalline powders of the complexes were separated out which were filtered and washed with methanol, water and diethyl ether. They were then dried over P_4O_{10} in vacuo. *Anal.* Calc. for $[CoLphenN_3]$: C, 58.59; H, 4.58; N, 18.85; Co, 9.91. Found: C, 58.11; H, 4.04; N 19.02; Co, 9.63%. *Anal.* Calc. for [CoLphenNCS]: C, 59.57; H, 3.75; N, 14.89; Co, 10.44. Found: C, 55.92; H, 6.62; N, 20.21; Co, 11.16%. *Anal.* Calc. for $[CoLpyrr_2N_3]$: C, 54.12; H, 6.12; N, 21.95; Co, 11.54. Found: C, 54.89; H, 6.02; N 21.83; Co, 11.8%.

2.3. Physical methods

Molar conductance measurements of the complexes were carried out in DMF solvent at 28 ± 2 °C on a Centuary CC-601 digital conductivity meter with a dip type cell and platinum electrode. Approximately 10^{-3} M solutions were used. The magnetic susceptibility measurements were made using a simple Gouy balance at room temperature using mercury tetrathiocyanatocobaltate(II), $Hg[Co(NCS)_4]$ as calibrant. Microanalysis of carbon, hydrogen and nitrogen content of the ligand and the metal complexes was carried out using a Heraeus Elemental Analyzer at CDRI, Lucknow, India. Electronic spectra were recorded on a Shimadzu UV-160A spectrophotometer. IR spectra were recorded as KBr pellets on a Perkin–Elmer model 1620 FT IR spectrophotometer. Metal estimation was done by the AAS method on a Varian spectrometer AA-10/20. NMR spectra were obtained in a Bruker DRX 500 instrument

2.4. X-ray crystallography

A dark brown orthorhombic crystal of $CoLphenN_3$ (**1**) having approximate dimensions $0.35 \times 0.3 \times 0.05$ mm was sealed in a glass capillary, and intensity data were measured at room temperature (293 K) on a Nonius MACH3 diffractometer equipped with graphite-monochromated Mo Kα ($\lambda = 0.7093$ Å) radiation. The crystallographic data along with details of structure solution refinements are given in Table 1. The intensity data were collected by the ω-scan mode within $2.01° < \theta < 24.93°$ for *hkl* ($0 \leqslant h \leqslant 12$, $0 \leqslant k \leqslant 14$, $0 \leqslant l \leqslant 22$) in the monoclinic system. The trial structure was obtained by direct methods using SHELXS 97 [11] and refined by full-matrix least-squares on F^2 (SHELXL 97) [12]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All the hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

3. Results and discussions

The principal ligand H_2L was synthesized by the direct condensation of 2-hydroxyacetophenone with 4-phenyl semicarbazide. The elemental analysis is in good accordance with the proposed structure. 2-Hydroxyacetophenone N(4)-phenyl semicarbazone can exist either as the keto or enol form or an equilibrium mixture of the two since it has an amide –NH–C(=O) function. However, the IR and NMR spectra of H_2L indicate that in solid state it remains in the keto form. The IR spectra of complexes, however, does not show any intense absorption band at 1696 cm^{-1} due to the carbonyl stretching of the semicarbazone moiety. This shows that in solution, it converts to the enol form and coordinates to the metal in the enolate form.

Four new complexes are readily formed by the reaction of the ligand and heterocyclic base with cobaltous acetate followed by a metathetical displacement of the acetate anion by azide or thiocyanate anions. It is found that cobalt(II) is getting oxidized to cobalt(III) in all the complexes.

The elemental analysis corresponds to a general formula $[CoLB_xX]$ for all complexes. The principal ligand H_2L undergoes double deprotonation to form L^{2-} and acts as a tridentate ligand thus occupying three positions of an octahedral geometry. In the case of [CoLphenX], phenanthroline acts as a bidentate ligand and occupies the fourth and fifth positions. The azido or thiocyanato group occupies the sixth position. In the case of the complexes with piperidine and pyrrolidine, two molecules of heterocyclic base complete the fifth and sixth position of the six coordinate geometry. Room temperature magnetic susceptibility measurements of the complexes reveal that all compounds are diamagnetic indicating the oxidation of cobalt(II) to cobalt(III). All complexes are found to be non-conducting in DMF solution.

3.1. NMR spectrum of H_2L

The ^1H and ^{13}C NMR spectra of H_2L were recorded in DMSO-d_6 as solvent. The tentative structure of the compound H_2L and the ^1H NMR spectral assignments are given in Fig. 1. In the ^1H NMR spectrum, the signal for N(2)H is observed at $\delta = 9.87$ which is consistent with hydrogen bonding to the oxygen of DMSO-d_6 [13,14]. The N(4)H is observed as a singlet at $\delta = 8.89$. The OH proton is observed at $\delta = 12.79$. These values are in agreement with salicylaldehyde and 2-hydroxyacetophenone thiosemicarbazones [2,6]. Upon addition of D_2O the intensities of these signals significantly decrease, confirming the assignments. A singlet at $\delta = 2.23$ is attributed to the methyl protons which are chemically and magnetically equivalent. Aromatic protons of both rings appear within the range 6–8 ppm with coupling constants around 7 Hz.

The assignments made from ^{13}C NMR spectrum of the ligand are shown in Fig. 2.

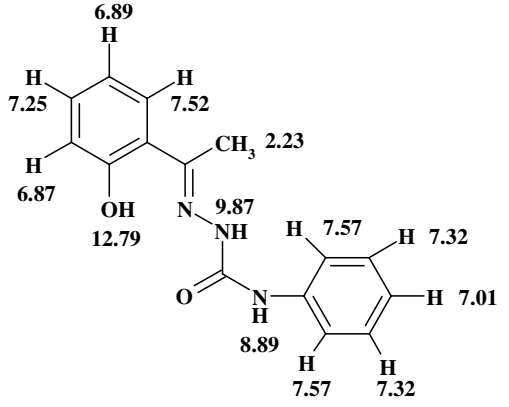

Fig. 1. ^1H NMR spectral assignments of the compound H_2L.

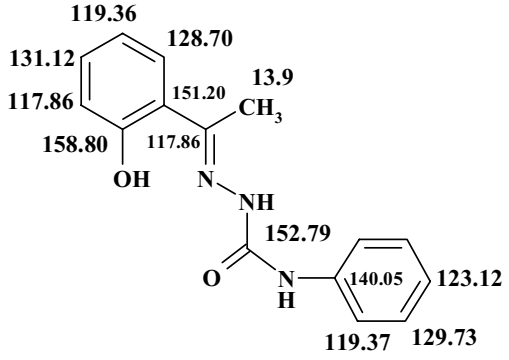

Fig. 2. ^{13}C NMR spectral assignment of the compound H_2L.

3.2. X-ray diffraction studies

Dark brown X-ray quality single crystals of compound **1** $CoLphenN_3$ were grown by slow evaporation of the compound from DMF solution. The molecular structure of compound **1** along with atomic labelling is given in Fig. 3, and selected bond lengths and bond angles are summarized in Table 2. The cobalt atom is six coordinate and has a distorted octahedral geometry. The three donor atoms of the semicarbazone, *viz* phenolato oxygen, azomethine nitrogen, enolate oxygen, constitute a meridional arrangement around the cobalt atom, along with the phenanthroline nitrogens and terminal azido group. The Co–O(1) and Co–O(2) bond lengths are 1.866(4) and 1.914(3) Å and the Co–N bond lengths are 1.856(4) Å (azomethine) and 1.961(4) Å (phen). The fifth and sixth positions of the distorted octahedral geometry are occupied by the second nitrogen of 1,10-phenanthroline, N(4) and the unidentate azide ion N(1). The bond length Co–N(4) is found to be 1.968(5) Å (slightly larger value) and Co–N(1) is 1.926(4) Å. These bond length values agree with that of a bipyridyl analog of a cobalt complex of a thiosemicarbazone compound reported elsewhere [6]. The shorter $Co–N_{azomethine}$ bond length indicates that the azomethine nitrogen coordinates more strongly than the phenanthroline nitrogen. The difference in bond lengths can be attributed to the difference in the extent of π-back bonding between the phenanthroline and semicarbazone moiety. However the comparatively larger bond distance of Co–N(5) supports the lack of significant out-of-plane π-bonding. The azido group has practically a linear configuration with a N(1)–N(2)–N(3) bond angle of 174.7(6)° and bond length N(1)–N(2) 1.214(6) Å slightly longer than N(2)–N(3) 1.147(7) Å.

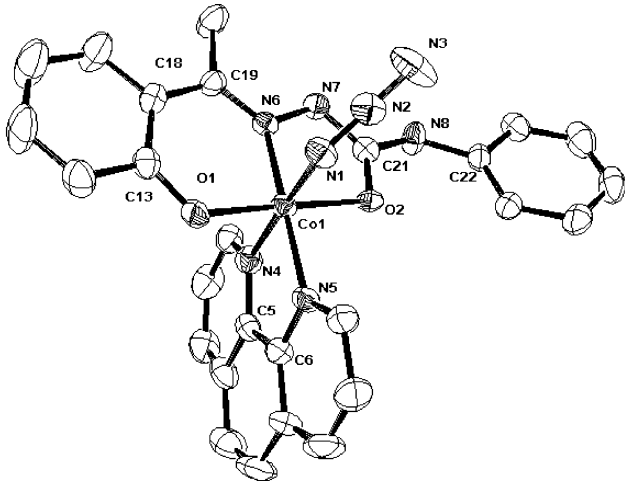

Fig. 3. ORTEP diagram for compound **1**, displacement ellipsoids are drawn at the 54% probability level and hydrogen atoms are removed for clarity.

Table 2
Bond lengths and angles of compound **1**

Bond lengths	
Co(1)–N(6)	1.856(4)

O(2)–Co(1)–N(1)	92.14(18)
N(6)–Co(1)–N(5)	175.37(19)
O(1)–Co(1)–N(5)	86.50(16)
O(2)–Co(1)–N(5)	92.57(16)
N(1)–Co(1)–N(5)	94.0(2)
N(6)–Co(1)–N(4)	93.04(19)
O(1)–Co(1)–N(4)	89.10(18)
O(2)–Co(1)–N(4)	88.83(17)
N(1)–Co(1)–N(4)	177.0(2)
N(5)–Co(1)–N(4)	83.08(19)
C(13)–O(1)–Co(1)	124.1(3)
C(21)–O(2)–Co(1)	107.5(3)
N(2)–N(1)–Co(1)	118.2(4)
N(3)–N(2)–N(1)	174.7(6)
C(1)–N(4)–Co(1)	129.0(4)
C(5)–N(4)–Co(1)	112.1(4)
C(10)–N(5)–C(6)	118.0(5)
C(10)–N(5)–Co(1)	129.4(4)
C(6)–N(5)–Co(1)	112.5(4)
C(19)–N(6)–N(7)	117.9(4)
C(19)–N(6)–Co(1)	129.1(4)
N(7)–N(6)–Co(1)	112.9(3)

But the Co–N(1)–N(2) bond angle is 118.2(4)° showing bent coordination and the Co–N(1) bond length is 1.926(4) Å. The bond angles N(1)–Co–N(4) 177.0(2)° and N(5)–Co–N(4) 83.08(19)° indicate distortion from octahedral geometry.

It is found that hydrogen bonding, π–π stacking and C–H–π interactions affect the molecular packing [16–18] (Table 3). The phenanthroline proton H(1) forms an intramolecular hydrogen bond with N(6) of the same molecule, [C(1)H···N(6) 2.48 Å], while H(10) forms an intermolecular hydrogen bond with the N(7) nitrogen of the neighboring molecular unit [C(10)H··· N(7) 2.50 Å]. A hydrogen bond from H(9) links one molecule to the azido nitrogen N(3) of the neighboring molecule [C(9)H···N(3) 2.50 Å]. The intramolecular hydrogen bond influences the geometry of the molecule. However, the two intermolecular hydrogen bonds lead to a "sandwich" type of packing, resulting in centrosymmetric architecture (Fig. 4). This arrangement gives a

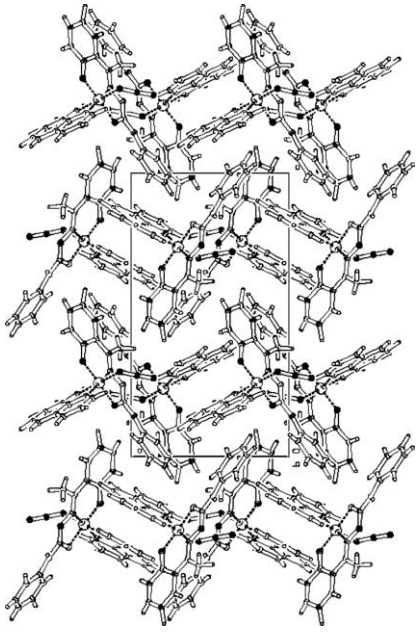

Fig. 4. Packing diagram for compound **1** viewed along a axis.

polar nature to the region between the semicarbazone planes. The non-polar phenanthroline groups of two neighboring sandwich units assemble via a π–π stacking interaction. The aromatic rings of two neighboring sandwich units are arranged in an off-set fashion in which the Cg(1) ring interacts with the Cg(2) ring of the neighboring unit and is separated by an average face-to-face distance of 3.8583 Å. The packing is further assisted by the π–π interactions between the Cg(3) ring of phen and the Cg(5) ring of the semicarbazone of the neighboring group at a Cg–Cg distance of 3.7875 Å. The network of hydrogen bonds and π–π stacking interactions leads to a two-dimensional arrangement of molecular units in a periodic fashion in the unit cell lattice. The 2-D chains are assembled into a 3-D network *via* CH–π interactions.

3.3. Electronic and IR spectra

Electronic spectral data of the ligand and its complexes are presented in Table 4. The semicarbazone and its complexes show bands in the range 46 300–30 000 cm^{-1} due to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions. Charge transfer bands were observed in the range 32 000–23 000 cm^{-1} which is rather too broad and is explained as the combination of $O \rightarrow Co$, and $N \rightarrow Co$ LMCT transitions. For low spin Co(III) complexes, there are two spin allowed transitions at relatively low energy, $^1A_{1g} \rightarrow {}^1T_{1g}$, $^1A_{1g} \rightarrow {}^1T_{2g}$. We have assigned them to be the bands at ~20 370 [$^1A_{1g} \rightarrow {}^1T_{1g}$] and 25 900 cm^{-1} [$^1A_{1g} \rightarrow {}^1T_{2g}$]. There are additional spin-forbidden transitions $^1A_{1g} \rightarrow {}^3T_{1g}$ and $^1A_{1g} \rightarrow {}^3T_{2g}$ at higher energies and these are usually complicated by overlap of interligand and charge transfer transitions. $^1A_{1g} \rightarrow {}^3T_{2g}$ is the most difficult to assign because this weak spin-forbidden band is always at the onset of other high-energy intense bands [19,20].

The observed spectra fitted to the corresponding Tanabe–Sugano diagram enabled us to obtain D_q values for the complexes. In addition we have evaluated the electronic repulsion parameter B. The value of B is found to be less than that of free ion B' (1100 cm^{-1}). This is attributed to the nephalauxetic effect. The ne-

$CoLpyrr_2N_3$ (**4**)	1592 s	2096 s, 2029 s	525 m	3300 b, 1157 m	752 w	1057 w, 893 w

phalauxetic ratio β is also calculated and is found to be less than unity. D_q values are in good agreement with low spin Co(III) complexes.

The significant bands observed in the IR spectra of H_2L and its complexes are presented in Table 5. The IR spectra of the complexes do not exhibit a broad absorption band at 3420 cm^{-1}, which is due to the O–H stretching modes of phenolic oxygen, indicating deprotonation during coordination. Weak bands in the region 720–755 cm^{-1} indicate the presence of a Co–O bond, resulting from coordination of the phenolic oxygen [9,15]. Besides, the shifting of the band due to the Ar–O group to lower frequencies indicates the weakening of the Ar–O bond due to coordination. A band around 1696 cm^{-1} attributable to the ν(C=O) stretching in the ligand spectrum is absent in the spectra of all complexes which indicates the coordination in the enolate form. A sharp band at 1621 cm^{-1} in the spectrum of H_2L is shifted to lower frequencies by 30–40 cm^{-1} in the spectra of the complexes which indicates coordination via the azomethine nitrogen. This band is broad and intense compared to that of the ligand and can be attributed to overlapping of the bands of the newly formed N=C bond stretching. The spectra of the complexes exhibit a systematic shift in the position of bands in the region 1600–1350 cm^{-1} due to ν(C=C) and ν(C=N) vibrational modes and their mixing patterns are different from those present in the ligand spectrum. Coordination of the bases is indicated by the presence of weak bands in the 410–485 cm^{-1} region. The presence of the terminal azido group in the coordination sphere is evident from a strong and sharp absorption peak at ~2050 cm^{-1}. The slight lowering in values is assumed to be the result of its coordination with Co(III) [21,22]. There are bands at 2105 and 696 cm^{-1} in the spectra of compound **2** due to the N-coordinated thiocyanato group.

4. Supplementary data

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data center, CCDC 204600 for compound $CoLphenN_3$. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2, IEZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Seven lathanide cryptates $[LnL](NO)_3 \cdot nH_2O$ ($n = 1$–3; Ln = La, Ce, Pr, Sm, Eu, Gd, Tb) were synthesized by the reactions of lanthanide nitrates with free ligand L (L was derived from the (2 + 3) condensation of 2,6-diformyl-pyridine (*dfp*) with tris-(2-aminoethyl) amine (*tren*)) and characterized by physical methods. ES-MS spectra show that except for La(III) cryptate, the other six are all stable in solution. The crystal structure of the Eu(III) cryptate showed a tricapped prismatic coordination geometry.

Keywords: Lanthanide; Cryptate; Crystal structure; ES-MS

1. Introduction

There has been a great deal of interest in design and synthesis of lanthanide complexes [1–5] due to their unique properties and many valuable applications [6], such as fluorescent probes in biological systems [7], magnetic resonance imaging and as contrast agents in clinical NMR images [8] as well as chemical logics in molecular information processing [9]. Cryptand ligands containing appropriate binding sites of suitable size and shape have been designed to form lanthanide cryptates [10,11]. The europium(III) cryptates are of particular interest in view of their novel photophysical properties [12], and several reports on their syntheses and properties have appeared [13,14]; for example, the luminescence properties of solutions of Eu(III) cryptates with 2,2-bipyridine and pyridine N-oxide units have been studied in detail [15–18]. A cryptand L synthesized by condensation of 2,6-diformyl-pyridine (*dfp*) with tris-(2-aminoethyl) amine (*tren*) has been reported [19], but its lanthanide cryptates and their crystal structure reported to date are few. Generally, the lanthanide cryptates are obtained by template synthesis involving alkali, alkali-earth [20] or lanthanide ions [21] as templating agents. We failed to obtain the lanthanide cryptates of ligand L by the template method. On the other hand, we obtained seven lanthanide cryptates $[LnL](NO)_3 \cdot nH_2O$ (Ln = La, Ce, Pr, Sm, Eu, Gd, Tb) (Scheme 1) by directly reacting the free ligand L with the corresponding lanthanide nitrates. The crystal structure of the Eu(III) cryptate displays a tricapped prismatic coordination geometry which is different from the structure of the sodium cryptate with the same ligand [22] and those of other lanthanide cryptates [20]. The ES-MS spectra of the seven cryptates show that, except for La (III) cryptate, all complex cations are stable in the solution.

2. Experimental

2.1. Materials

All starting chemicals were of reagent grade. Hydrated lanthanide nitrate was prepared by dissolving Ln_2O_3 (99.99%) in an excess amount of nitric acid. Tris(2-aminoethyl)amine [23] and 2,6-diformyl-pyridine [24] were prepared by literature methods. Cryptand L was prepared by the condensation of *dfp* with *tren* as described in the literature [19]. Their physical constants and spectroscopic data are in agreement with previously reported values.

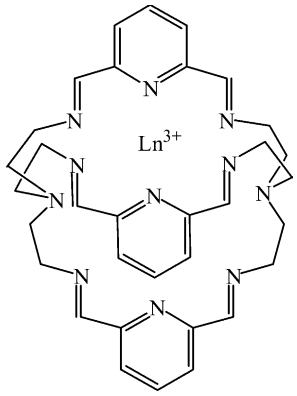

Scheme 1. The chemical formulas of the complex cations, Ln = Eu (III), La (III), Ce (III), Pr (III), Sm (III), Gd (III), Tb(III).

2.2. Preparation of the compounds

[EuL](NO₃)₃·H₂O (1): $Eu(NO_3)_3 \cdot 6H_2O$ (0.054 g, 0.12 mmol) in 20 ml MeCN was added to a boiling solution of L (0.059 g 0.1 mmol) in 150 ml MeCN. After refluxing for 12 h, the orange product was filtered out and washed with MeCN and Et_2O, and then dried. Red solid 0.078 g were obtained. Yield: 82%. (*Anal.* Calc. for $C_{33}H_{41}N_{14}O_{10}Eu$ (M_w 945.74): C, 41.91; H, 4.37; N, 20.73. Found: C, 41.63; H, 4.75; N, 21.11%.) IR (cm^{-1}): 1641 (s, ν(C=N)); 1383 (s, $\nu(NO_3^-)$), UV–Vis (λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}), H_2O): 215 (1 00 200), 246 (40 800), 317 (20 700), 330 (17 000). Λ_M(H_2O, 293 K): 412 S cm^2 mol^{-1}. Red block-like crystals suitable for X-ray diffraction were obtained by diffusion of Et_2O into MeOH/DMF solution over 1 week.

The cryptates $[LaL](NO_3)_3 \cdot 2H_2O$ (**2**), $[CeL](NO_3)_3 \cdot 2H_2O$ (**3**), $[PrL](NO_3)_3 \cdot 3H_2O$ (**4**), $[SmL](NO_3)_3 \cdot 2H_2O$ (**5**), $[GdL](NO_3)_3 \cdot 2H_2O$ (**6**), $[TbL](NO_3)_3 \cdot 2H_2O$ (**7**) were prepared by a similar procedure as for **1**, except that the corresponding lanthanide(III) nitrates were used instead of $Eu(NO)_3 \cdot 6H_2O$.

[LaL](NO₃)₃·2H₂O (2): Yellow tiny crystals. Yield: 75%. (*Anal.* Calc. for $C_{33}H_{43}N_{14}O_{11}La$ (M_w 951.91): C, 41.69; H, 4.56; N, 20.63. Found: C, 41.25; H, 4.18; N, 20.66%.), IR (cm^{-1}): 1641 (s, ν(C=N)); 1384 (s, $\nu(NO_3^-)$), UV–Vis (λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}), H_2O): 208 (68 700), 246 (20 430), 316 (10 200), 330 (8300). Λ_M(H_2O, 293 K): 409 S cm^2 mol^{-1}.

[CeL](NO₃)₃·2H₂O (3): Orange solid. Yield: 75%. (*Anal.* Calc. for $C_{33}H_{43}N_{14}O_{11}Ce$ (M_w 970.71) C, 41.64; H, 4.55; N, 20.60. Found: C, 41.85; H, 4.89; N, 20.35%.), IR (cm^{-1}): 1640 (s, ν(C=N)); 1383 (s, $\nu(NO_3^-)$), UV–Vis (λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}), H_2O): 207 (97 600), 249 (25 400), 316 (12 200), 329 (9700). [TbL](NO₃)₃·2H₂O (7): Orange solid. Yield: 74%. (*Anal.* Calc. for $C_{33}H_{43}N_{14}O_{11}Tb$ (M_w 970.72) C, 40.84; H, 4.46; N, 20.20. Found: C, 41.40; H, 4.43; N, 20.67%.) IR (cm^{-1}): 1638 (s, ν(C=N)); 1384 (s, $\nu(NO_3^-)$), UV–Vis (λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}), H_2O): 205 (94 500), 246 (22 500), 317 (15 600), 330 (9500). Λ_M(H_2O, 293 K): 441 S cm^2 mol^{-1}.

2.3. Physical measurements

Elemental analysis of C, H, N were performed on a Perkin–Elmer 240c analytical instrument. The molar electrical conductivities in aqueous solution containing 10^{-4} mol l^{-1} complexes were measured at 25 ± 0.1 °C using a BSD-A conductometer (Jangsu, China). Electronic spectra were recorded on a UV-3100 spectrophotometer. IR spectra were measured using KBr discs with a vector 22 FI-IR spectrophotometer. Electrospray mass spectrum (ES-MS) was determined on a Finnigan LCQ ES-MS mass spectrograph using methanol as the mobile phrase with a sample concentration of about 1.0 mmol dm^{-3}. The diluted solution was electrosprayed at a flow rate of 5×10^{-6} dm^3 min^{-1} with a needle voltage of +4.5 kV. The temperature of the heated capillary in the interface was 200 °C and a fuse silica sprayer was used.

2.4. Crystal structure determination

Diffraction intensity data were collected on a SMART-CCD area-detector diffractometer at 293 K using graphite monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å). Data reduction and cell refinement were performed by SMART and SAINT programs [25]. The structure was solved by direct methods (Bruker SHELXTL) and refined on F^2 by full-matrix least-squares (Bruker SHELXTL) using all unique data [26]. The non-H atoms in the structure were treated as anisotropic. Hydrogen atoms were located geometrically and refined in the riding mode.

3. Results and discussion

3.1. Synthesis and characterization

We have tried to synthesize lanthanide cryptates by the condensation of *dfp* with *tren* in the presence of Ln^{3+} or alkali-earth metal ions as templates by previous methods, but pure products could not be obtained. An effective method has been developed by reacting free ligand with the lanthanide nitrate. However, by the same procedure, we could not get pure products of the cryptates of the heavier lanthanides, which may be due to mismatch of their ionic size with the cavity of the ligand.

The conductivities of all the seven lanthanide cryptates are in the range of 399–412 S cm^2 mol^{-1}, typical for a 1:3 electrolyte [27] and consistent with the chemical formulas from elemental analysis. The IR spectra of all cryptates show the characteristic vibrations of the C=N bond (1634–1642 cm^{-1}) and nitrate ions (~1384 cm^{-1}). The vibration frequency of the observed C=N bond shifts to longer wavelength by 5–13 cm^{-1}in contrast to that of the free ligand (1647 cm^{-1}) [19]. The intense absorptions in the electronic spectra of the cryptates at 200–240 and 310–330 nm are designated to the π–π^* transitions of the pyridyls and C=N groups, respectively.

3.2. Electrospray mass spectra

ES-MS data are listed in Table 1. There, except for **2**, the ES-MS spectra of all cryptates show common features, and the spectra are composed of two to three simple peaks. The dominant peaks are assigned to the formation of $[ML]^{3+}$ (M = Eu, Ce, Pr, Sm, Gd, Tb) and the other peak clusters are due to $[ML]^{3+}$ that captures one to two nitrate anions forming $[ML(NO_3)]^{2+}$ or $[ML(NO_3)_2]^{+}$. The simplicity of the spectra can be attributed to the thermodynamic and kinetic stability of the cryptates. For example, Fig. 1(a) shows the positive-ion ES mass spectrum of **1** $[EuL](NO_3)_3 \cdot H_2O$. The base peak at $m/z = 247.5$ corresponds to $[EuL]^{3+}$. The peaks at $m/z = 402.1$ can be assigned to the species $[EuL(NO_3)]^{2+}$. The isotopic distribution of the peak at $m/z = 247.5$ is shown in Fig. 1(a). From the numbers

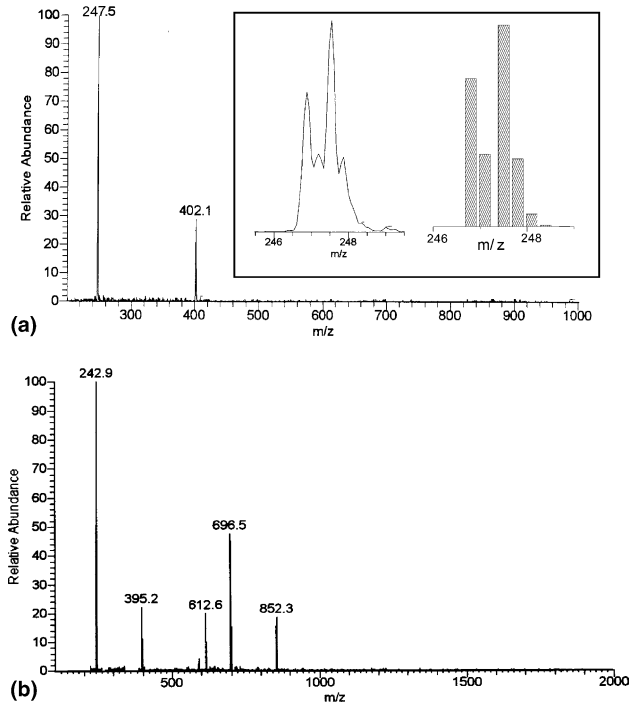

Fig. 1. The ES-MS spectra of cryptates **1** and **2** in MeOH solution: (a) cryptate **1** (inset: the isotopic distribution of the peak at $m/z = 247.5$; left: experimental pattern; right: calculated pattern); (b) cryptate **2**.

Table 1
ES-MS spectroscopic data for the cryptates **1**–**7**

No.	Cryptate	Peak (m/z)	Relative abundance (%)	Assignment
1	$[EuL](NO_3)_3 \cdot H_2O$	247.5	100	$[EuL]^{3+}$
		402.1	29	$[EuL(NO_3)]^{2+}$
2	$[LaL](NO_3)_3 \cdot 2H_2O$	242.9	100	$[LaL]^{3+}$
		395.2	23	$[LaL(NO_3)]^{2+}$
		612.6	20	$[NaL]^{+}$
		696.5	47	$[Na_2L(NO_3)]^{+}$
		852.3	19	$[LaL(NO_3)_2]^{+}$
3	$[CeL](NO_3)_3 \cdot 2H_2O$	243.2	100	$[CeL]^{3+}$
		395.7	11	$[CeL(NO_3)]^{2+}$
4	$[PrL](NO_3)_3 \cdot 3H_2O$	243.7	100	$[PrL]^{3+}$
		396.3	18	$[PrL(NO_3)]^{2+}$
		854.3	10	$[PrL(NO_3)_2]^{+}$
5	$[SmL](NO_3)_3 \cdot 2H_2O$	247.3	100	$[SmL]^{3+}$
		402.7	22	$[SmL(NO_3)]^{2+}$
6	$[GdL](NO_3)_3 \cdot 2H_2O$	249.1	100	$[GdL]^{3+}$
		403.8	19	$[GdL(NO_3)]^{2+}$
7	$[TbL](NO_3)_3 \cdot 2H_2O$	249.5	100	$[TbL]^{3+}$
		405.7	29	$[TbL(NO_3)]^{2+}$

and isotopic abundances of the atoms in $[EuL]^{3+}$, a revised program is used to calculated the pattern which is in good agreement with the experimental one (Fig. 1(a) inset). For the six cryptates, no peak of free ligand or ligand fragments is observed, showing that the cryptates and the ligand are rather stable in solution. For **2**, the ES-MS spectra (Fig. 1(b)) are more complicated. Besides the species of $[LaL]^{3+}$ and $[LaL(NO_3)]^{2+}$, two peaks at $m/z = 612.5$ and at $m/z = 696.5$ are designed to $[NaL]^{+}$ and $[Na_2L(NO_3)]^{+}$, respectively, implying that the cryptand can bind the Na^{+} ion to form an inclusion complex. The Na^{+} is present in a trace amount. The dissociation of the La^{+} ion implies that the cryptate is less stable than the other six. Because of its larger radius, La^{3+} in the ligand cage is not so stable as Eu^{3+} so that the binding of the ligand to La^{3+} is weaker than those of other lanthanide ions.

3.3. Crystal structure of the cryptate

The crystal data of **1** are listed in Table 2. Selected bond distances and bond angles are listed in Table 3. In the complex **1** (Fig. 2(a)), the central cation Eu1 is lo-

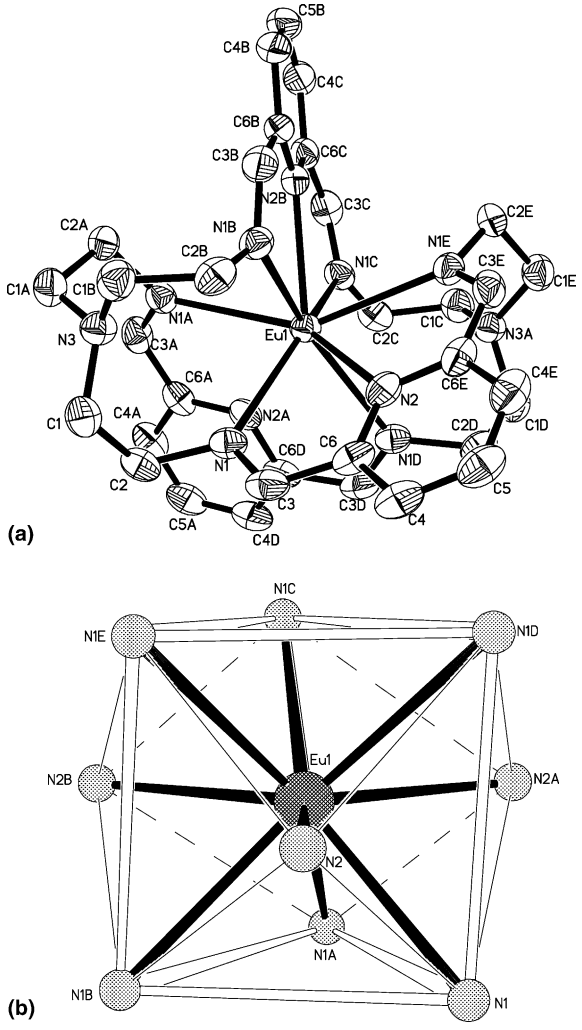

Fig. 2. (a) A perspective view of the $[EuL]^{3+}$cation; (b) the structure of the coordination polyhedron. Symmetry transformation used to generate equivalent atoms: (i) $1-y, 1+x-y, z$ (N1A, N2A); (ii) $-x+y, 1-x, z$ (N1B, N2B); (iii) $-1/3+y, 1/3+x, 5/6-z$ (N1C, N3A); (iv) $2/3+x-y, 4/3-y, 5/6-z$ (N1D); (v) $2/3-x, 1/3-x+y, 5/6-z$ (N1E).

cated in the center of the macrocycle and coordinated by three pyridyl nitrogen atoms (N2, N2A and N2B) and six imino nitrogens (N1, N1A, N1B, N1C, N1D, N1E) to form a tricapped prism (Fig. 2(b)). The complex cation has a threefold axis through Eu1 and the two bridgehead nitrogen atoms (N3, N3A). The average bond length between Eu1 and nitrogen atoms of the pyridine groups is 2.559 Å, being slightly shorter than those for the imino groups (2.598 Å). The average length of Eu1–N (bridgehead) is 3.768 Å. No interaction between Eu1 and N(bridgehead) is observed. The coordination polyhedron of **1** can be described approximately as a tricapped prism. The upper and basal planes of the prism, which are approximately parallel, are composed of the imino nitrogen atoms (N1, N1A, N1B and N1C, N1D, N1E, respectively). The distance between the two planes is 3.446 Å. The distance between Eu1 and the upper plane is 1.723 Å. The three pyridyl nitrogen atoms are located at the capping positions. Eu1 is located in the symmetrical center of the prism. The distances of Eu1 to each least squares prism plane is approximately 0.964 Å. The tricapped prism structure is different from the unsymmetrical structure of sodium cryptate with the same ligand [22] and those of phenol-based lanthanide cryptates [13,20,21], in which the central ions are located at one side of the macrocycles. The present Eu(III) cryptate is located at the inversion center of the cavity of the macrocycle in order to satisfy the requirement of a higher coordination number of the lanthanide ion. To our knowledge, this is the first crystal structure of a lanthanide cryptate derived from 2,6-pyridyl-dicarboxaldehyde.

Neutral coordination frameworks with host–guest properties constructed by dicopper(II) units and 4,7-phenanthroline

Hui Huang, Shu-Yan Yu *, Hong-Bo Liu, Mei Shi

State Key Laboratory of Polymer Physics and Chemistry, and Joint Laboratory Polymer Science and Materials, Center for Molecular Science, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, PR China

Received 22 April 2003; accepted 5 September 2003

Abstract

Reaction of $[Cu_2(O_2CR)_4]$ [R = Me(**1**), Ph(**2**)] with 4,7-phenanthroline produced neutral coordination frameworks $\{[Cu_2(O_2CR)_4](C_{12}N_2H_8)\}_n$ showing inclusion behavior toward solvent molecules; through variation of the equatorial ligands of the dimetal units, the channels size and host–guest properties of the coordination polymers can be controlled.

Keywords: Copper; 4,7-Phenanthroline; Coordination framework; Host–guest properties; Polymers; Extended structures

1. Introduction

Crystal engineering of coordination polymers is of considerable interest in the area of materials chemistry [1]. The coordination-driven assembly of these polymers has shown high promise in various potential applications, such as molecular recognition, catalysis, gas storage and molecular magnetization [2,3]. However, most of the assembled structures are complicated and restricted by the choice of counter cations or anions, which can occupy part of the space within the framework [4]. To avoid such drawback, attention has been paid to construct neutral coordination frameworks with dimetal units [5]. Notably, constructing channels with various size and shapes in this type of polymers can be finely tuned by a suitable choice of both equatorial and axial ligands on the dimetal units. While much study is focused on changing the axial ligands, such as 4,4-bipyridine [3d], less attention has been paid to altering the equatorial ligands. The latter approach has many advantages: (1) as the equatorial ligands can be selective in the synthesis of dimetal units, it is very easy to design the size and the shapes of the channels; (2) it is a very efficient way to extend the size of the channels because the distance between adjacent layers can be increased by using lucky equatorial ligands. Herein, we report the preparation, crystal structures and properties of a novel coordination framework constructed with the neutral dimetal units $[Cu_2(O_2CR)_4]$ (R = Me, Ph) and the rigid aromatic ligand 4,7-phenanthroline (L) [6]. Furthermore, this ligand has been successfully employed in self-assembly of molecular crowns in our laboratory [7].

2. Experimental

4,7-Phenanthroline and $Cu(CH_3COO)_2$ were obtained commercially. $Cu(C_6H_5COO)_2$ was prepared according to a published method [8]. Other materials were of the highest available purity and used without further treatment.

2.1. Synthesis

2.1.1. $\{[Cu_2(O_2CCH_3)_4](C_{12}N_2H_8)\}_n$ (**1**)

A buffer layer of *p*-xylene (5 ml) was carefully layered over a solution of 4,7-phenanthroline (14.4 mg, 0.080

doi:10.1016/j.poly.2003.09.014

mmol) in *p*-xylene (10 ml), and a layer of $Cu(O_2CCH_3)_2 \cdot H_2O$ (16.0 mg, 0.08 mmol) in methanol (10 ml) was carefully placed on top of the buffer layer. Green, cube-like crystals were harvested after several days in ca. 60% yield based on $Cu(O_2CCH_3)_2 \cdot H_2O$. *Anal.* Calc. for $C_{20}H_{20}Cu_2N_2O_8$: C, 44.20, H, 3.71, N, 5.14. Found: C, 44.11, H, 3.62, N, 5.17%.

2.1.2. $\{[Cu_2(O_2CC_6H_5)_4](C_{12}N_2H_8)(C_8H_{10})\}_n$ (2)

As above, a buffer of *p*-xylene (5 ml) was carefully layered over a solution of 4,7-phenanthroline (14.4 mg, 0.080 mmol) in *p*-xylene (10 ml), and a layer of $Cu(O_2CC_6H_5)_2$ (36.9 mg, 0.080 mmol) in methanol (10 ml) was carefully placed on top of the buffer layer. Green, cube-like crystals were harvested after several days in ca. 65% yield based on $Cu(O_2CC_6H_5)_2$. *Anal.* Calc. for $C_{24}H_{19}CuNO_4$: C, 59.92, H, 4.78, N, 3.49. Found: C, 59.88, H, 4.71, N, 3.52%.

2.2. X-ray single-crystal analysis

Intensity data were collected on a Rigaku R-AXIS RAPID IP area detector diffractometer with graphite monochromated Mo Kα radiation (50 kV, 300 mA). Crystal parameters and refinement results for both compounds are summarized in Table 1. Empirical absorption corrections were employed. The structure was solved by SHELXTL [9]. The final refinement was done by full-matrix least squares based on F^2 with anisotropic thermal parameters for all non-hydrogen atoms, and the hydrogen atoms were generated geometrically.

3. Results and discussion

Fig. 1(a) shows the structural unit of **1.** In the centrosymmetric dicopper units, each Cu (II) ion has four oxygens of different carboxylate groups in the equatorial positions, and an infinite chain along the [−1, 1, −1] axis is formed by linking consecutive dimetal units with bridging 4,7-phenanthroline ligands. Fig. 2(a) shows that along the chain each $Cu_2(OOCCH_3)_4$ paddle wheel is rotated by ca. 45° with respect to its nearest neighbor.

The molecular packing of complex **1** is shown in Fig. 3(a). Normally, the arrangement of paddle wheels belonging to neighboring layers give rise to a channel system, and the size of the void is $\approx 8.0(5) \times 5.57(6)$ Å, which can accommodate some solvent molecules as guests [10]. However, the channels in the framework of **1** are void. Owing to the alternate rotation of the paddle wheels, the actual size of the channel is even smaller. Thus, the size of the channel is not large enough to accommodate solvent molecules as guests.

For controlling the actual size of the channel in the framework to absorb some guests, we substituted R = Me with R = Ph in order to enlarge the distance between two adjacent layers. The X-ray structure of **2** (Fig. 1(b)) shows that this structure also contains centrosymmetric dinuclear Cu units with the paddle-wheel cage unit. The bridging 4,7-phenanthroline ligand coordinates two neighbor dimetal units to form an extended structure along the *c*-axis. Along the chain, the conformations of successive $[Cu_2(O_2CPh)_4]$ units are alike, as distinct from the conformation of the chain in **1**.

Fig. 3(b) shows the molecular packing of **2**. The *p*-xylene molecules are trapped in the channels formed by the paddle wheels between adjacent layers. The size of the void is $\approx 14.22(6) \times 5.57(5)$ Å, which is sufficiently large to include the solvent molecules as guests.

However, not only *p*-xylene molecules but also methanol molecules exist in the mixture during preparation. It is very notable that the neutral coordination framework of **2** can selectively absorb *p*-xylene molecules as guests, which may involve favorable edge to face C–H interactions. The distance between the center of the *p*-xylene molecule and the center of the just adjacent

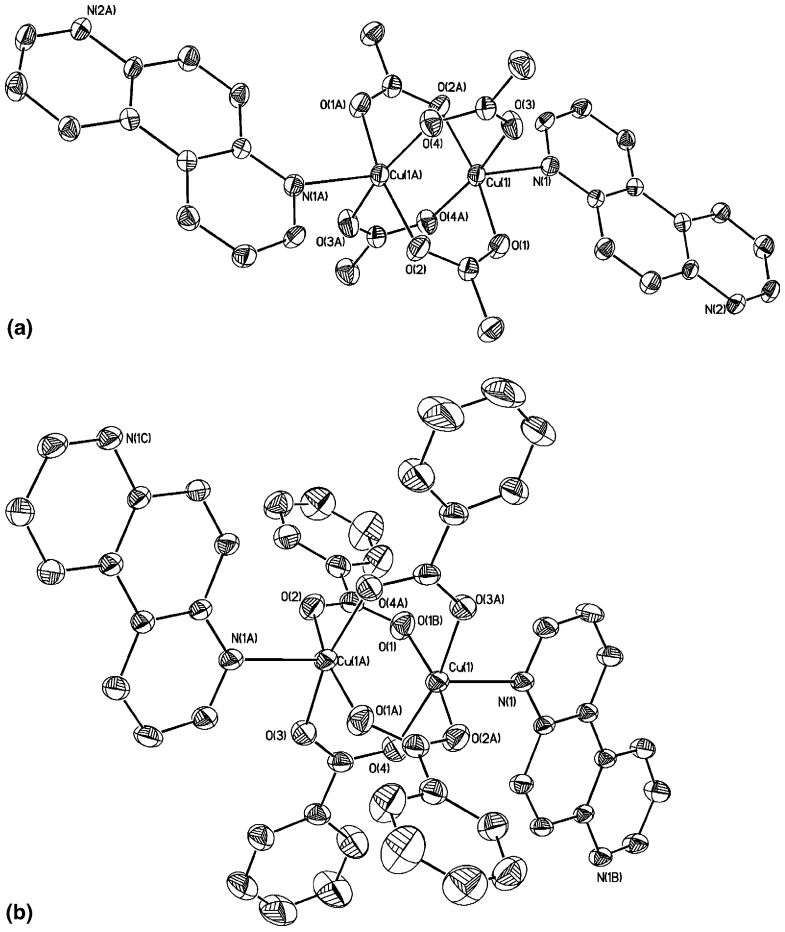

Fig. 1. (a) The structural unit of **1**. (b) The structural unit of **2**.

phenylene ring to which the *p*-xylene molecule is about perpendicular is 5.026 Å. It suggests a strong edge-to-face interaction (the standard distance of T-shaped orientation is 4.99 Å and the energy of that that interaction is −2.3 kcal mol^{-1}) [11].

In conclusion, we have succeeded in controlling the size of the pore and the host–guest properties in a neutral coordination framework by changing the substituents in a $[Cu_2(O_2CR)_4]$ unit. Further investigation will be extended to other multiple-bonded dimetal units [6] (e.g. Mo_2^{4+}, Rh_2^{4+}, Ru_2^{4+}, etc.) with larger substituted aromatic R groups so as to constitute larger channels for the accommodation of various organic guests.

A silica immobilized cobalt complex: absorption of dioxygen and the redox ability in aqueous solution

Jian Gao, Ralph A. Zingaro *, Ming Z. Gao

Department of Chemistry, Texas A&M University, College Station, TX 77842-3012, USA

Received 3 March 2003; accepted 8 September 2003

Abstract

A new dioxygen carrier supported on a solid matrix has been synthesized through the tethering of a dinuclear chelating ligand to the surface of mesoporous silica. The material thus prepared is extremely efficient for the selective absorption of dioxygen from gaseous mixtures. In aqueous solution, this material displays good catalytic ability for the disproportionation of H_2O_2.

Keywords: Immobilization; Silica support; Cobalt(II) complexes; H_2O_2

1. Introduction

During the past two decades, a number of dinuclear metal complexes have been reported to serve as dioxygen carriers for the chemical separation of dioxygen from other gases [1]. A dicobalt complex having polyamine moieties has been found to rank among the best of the chemical dioxygen carriers [2]. However, in aqueous solution, all dioxygen–dicobalt(II) complexes undergo degradation to form inert Co_2(III) complexes [3]. This observation has been attributed to the formation of H_2O_2 with concurrent reduction of dissolved oxygen during the redox processes. On the other hand, solid oxygen selective absorbents play a very important role in gas separation [4], gas sensor [5] and as reactants towards O_2-contaminated reducing gases in a catalytic reactor [6]. Furthermore, recyclable dinuclear complexes are of use in the industrial disposal of H_2O_2 [7]. Therefore, the design and synthesis of supported inorganic–organic materials [8–10] are applicable in this area. This is attributed to the active Si–OH sites on silica surface, which can covalently bind to organic functional groups. In this report, a generic approach to the design and synthesis of heterogenized dicobalt–hexacyclen complexes is described. The O_2 absorption ability and catalytic properties of the material are also described.

2. Experimental

2.1. Material and equipment

Mesoporous silica was synthesized according to methods described in the literature [11]. Prior to the binding procedure, it was washed with 1 N HNO_3, and thoroughly rinsed with water and then dried at 473 K in vacuo (24 h). Other materials were purchased from the Aldrich Chemical Company and were of analytical grade.

Metal analyses were performed using EDTA titration: Co(II) ions on the solid support were separated by adding $HClO_4$ (0.1 M aqueous solution). After removing the solid from the system, the resulting solution and washings were neutralized by adding NaOH (0.1 M aqueous solution) and the metal ion concentration was determined by titration. The electronic spectrum of the hexacyclen dicobalt(II) complex (in methanol) was measured using a Shimadzu UV-365 spectrophotometer. The diffusion reflection spectrum (DRS) of the solid catalyst was measured with SiO_2 serving as a reference. The temperature programmed desorption (TPD) product were detected with a quadrupole mass spectrometer, model LZL-203.

2.2. Preparation of bromopropyl-trimethoxysilane (BPTS) modified silica support

2.0 g of silica was treated with 2.0 mmol of BPTS in 10 ml of dry MeCN in the presence of 0.5 ml Et_3N. After the reaction had proceeded for a period of 2 h, the solid material was removed by filtration and washed with 30 ml of MeCN (10 ml × 3). This material was extracted with MeCN using a Soxhlet apparatus to remove unreacted species and was then dried in vacuo for 1 h. *Anal*. Calc. for 1 mmol (BPTS)/g SiO_2: C, 3.13; Br, 6.95. Found: C, 1.51; H, 1.06; N,<0.5; Br, 3.35%.

2.3. Preparation of hexacyclen functionalized silica

The solid material obtained in the above step was suspended in 10 ml of MeCN, and to this 2.0 mmol of *N*-bisdien in 10 ml MeCN was added dropwise in the presence of 2.5 mmol Et_3N. The mixture was allowed to react for 8 h at 60 °C and then the solid was filtered off, washed three times with MeCN and dried in vacuo at 60 °C for 2 h. *Anal.* Calc. for 1 mmol (hexacyclen)/g SiO_2: C, 13.57; N, 6.33. Found: C, 7.62; H, 2.13; N, 3.17%; Br, <0.1%.

2.4. Preparation of immobilized dicobalt(II) complexes

To the hexacyclen functionalized material in 10 ml of MeCN, 2.0 mmol of hexacyclen in 10 ml of MeCN was added dropwise in the presence of 2.5 mmol Et_3N. The mixture was allowed to react for 8 h at 60 °C and then 4.0 mmol of $Co(II)(ClO_4)_2$ in 5 ml of MeOH was added. After the reaction had proceeded for 0.5 h, the color of the solid material changed to deep purple, indicating that Co(II) was immobilized on the surface. *Anal*. Calc. for 1 mmol hexacyclen–Co(II) complex/g SiO_2: Co, 6.39. Found: Co, 2.30%.

2.5. Measurement of the O_2 volume in absorption

The O_2 absorption by the solid material in dry and aqueous solution was measured by determining the volume of gaseous dioxygen absorbed from a mixture of N_2 and O_2 (50%). To a 50 ml three-neck flask was added 200 mg of the solid. A modified procedure and apparatus, which were described previously [12], was employed.

2.6. TPD-MS (mass spectral) experiments

In the TPD-MS experiments, 850 mg of solid material were loaded on a quartz micro-reactor and the two sides were packed with asbestos fiber. Before the adsorption of O_2, the solid sample was treated by heating to 373 K under vacuum (1.0×10^{-4} Pa) for 2 h. The absorption was measured at 298 K by the injection of a gaseous mixture of O_2, N_2 and CO_2 (0.5 mmol, respectively). Following a 2 h period of absorption, the excess of O_2 was removed by evacuation to 1.0×10^{-4} Pa. The catalyst was ramped at a linear heating rate of 8 K/min. The desorbed gases were analyzed using a quadrupole mass spectrometer at $m/e = 32$ (for O_2), 28 (N_2) and 44 (CO_2), respectively.

2.7. Study of catalase-like activity

The disproportionation reaction was carried out in air at 20 °C in a 50 ml reactor containing a stirring bar. To 14.85 ml H_2O was added a sample of the supported complex (0.005 mmol, 25.0 mg solid sample) and the flask was sealed with a rubber septum. Hydrogen peroxide (1.33 mmol, 0.150 ml) was injected through the septum with a syringe. The reactor was connected to a graduated gas burette filled with water and dioxygen evolution was measured at 1 min time intervals by volumometry. The initial rates observed were expressed as mol Ms^{-1} by taking the volume of the solution (15 ml) into account and were calculated from the maximum slope of curve describing evolution of O_2 versus time.

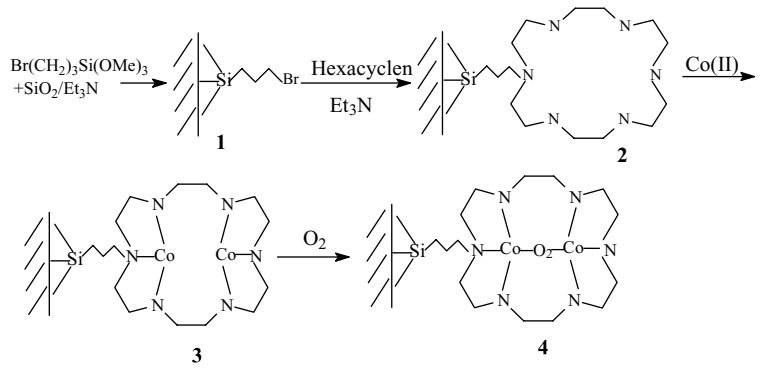
3. Results and discussion

3.1. Synthesis of the immobilized solid material

The surface reaction is described in Scheme 1. The degree of loading of grafted macrocycles was calculated from elemental analyses. The amount of support was chosen so as to give a theoretical loading of 1.0 mmol hexacyclen/g. However, the true loading was about 24.6% (mmol/gSiO_2). The graft of Co(II) ions onto the surface was conducted by simply charging the modified silica with a stoichiometric amount of $Co(II)(ClO_4)_2 \cdot 6H_2O$ in MeCN under argon. After refluxing for 6 h, the solid acquired a purple color (**3**). The Co(II) content in the final material was determined by titration, and the formation of the supported dinuclear complexes was clearly indicated. The comparison of the DRS of the supported complex **4** with that of the corresponding untethered dicobalt–hexacyclen–O_2 adducts [13] revealed a similar absorption maximum at 380 nm (Fig. 1), further indicating that the supported dicobalt complex material had been formed.

3.2. Selective absorption of O_2 on the dry solid and from aqueous solution

In the initial experiment, the solid supported dicobalt complex was studied as an oxygen carrier. The absorption of O_2 was determined by the method described in Section 2. As shown in Fig. 2, after the absorption and evacuation procedures were repeated more than ten



Scheme 1.

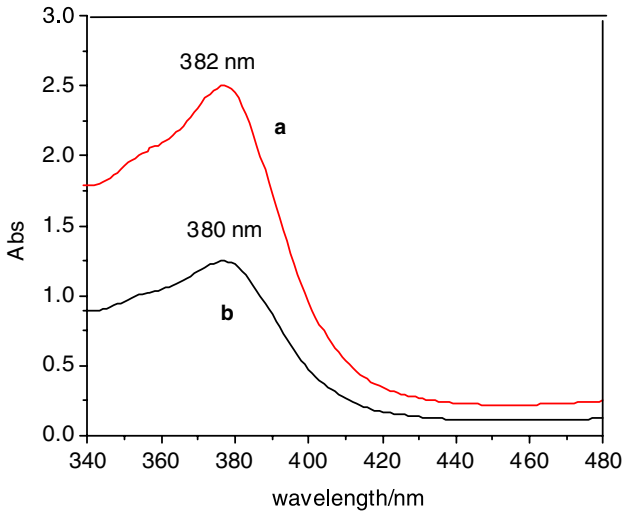


Fig. 1. DRS spectra (a) of the solid sample and the solution absorption spectra (b) of the complex precursor.

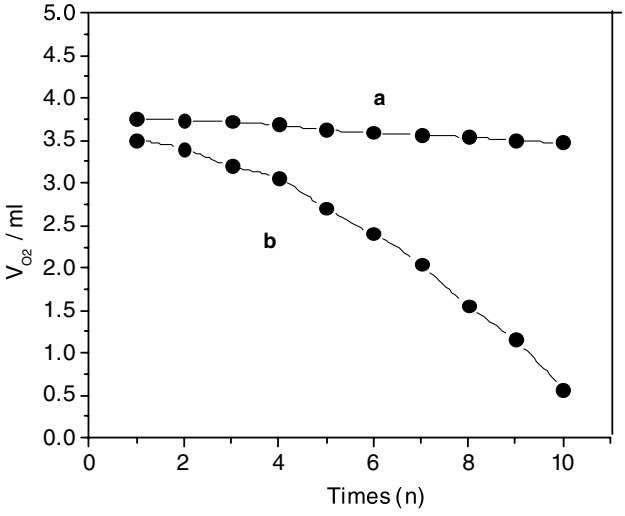

Fig. 2. Variation of the absorption ability (ml of O_2 at 25 °C) of the solid sample in dry (a) and aqueous (b) conditions with the recycling times.

times, no obvious loss of absorption volume, V_{O2}, was noted. This observation suggests the occurrence of a reversible oxygenation process. The reversibility results from variation in the pressure of O_2 and the temperature of the system during evacuation. However, when this experiment was conducted in the presence of H_2O (by introducing 5 ml H_2O to the above system), at pH 8.0, the color of the sample changed from the initial purple Co(II) color to a brownish-red indicating the formation of Co(III). The brownish-red colored species results from the formation of cobalt–polyamine–dioxygen complex [3,13]. After several repetitions, the solid material becomes inert towards the absorption and release of O_2.

3.3. Selective absorption of O_2 from a gaseous mixture

A temperature programmed desorption mass spectrum was employed to observe the selective absorption of O_2 from a gaseous mixture by the solid material. As is shown in Fig. 3, with an increase in temperature, one peak at ca. 368 K was observed for $m/e = 32$. The result

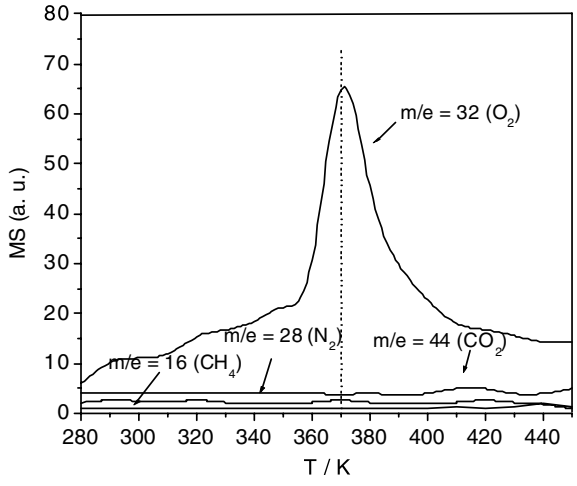

Fig. 3. TPD-MS profiles of the solid sample monitored at $m/e = 32$, 28 and 44, respectively.

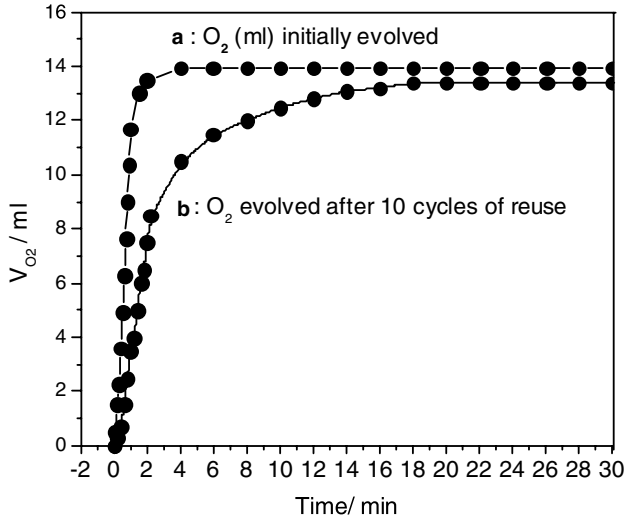

Fig. 4. The H_2O_2 dismutation curve of the immobilized dicobalt(II) complex in aqueous solution.

indicated that O_2 molecules are physico-chemically absorbed on the silica surface by binding to the coordination unsaturated Co(II) ions. Mass profiles monitored at 16, 28 and 44 reveal that this material does not absorb CH_4, N_2 or CO_2.

3.4. Catalytic activity in disproportionation of H_2O_2

The catalytic activity of this material was tested by measuring the dioxygen evolution with a Co(II) complex (supported):H_2O_2 ratio of 1:500. This condition was found to be optimal in a controlled reaction process. The amount of residual hydrogen peroxide (measured by iodometric titration) was compared with the amounts of dioxygen formed (as calculated from volumometry) and was found to satisfy the stoichiometry implied by equation: $2H_2O_2 \rightarrow 2H_2O + O_2$. The time course of oxygen evolution for the catalysis is shown in Fig. 4. The evolution profile suggests the involvement of a quick catalytic process occurring at the initial stage followed by a very short term of a slow catalytic process. The fast catalytic rate calculated graphically was 0.132 $M(O_2)$/min. The dioxygen evolution ceased after 10 min. At this stage the evolved dioxygen correspond to 100% decomposition of hydrogen peroxide. When more H_2O_2 was added, the disproportionation reaction rate resumed, indicating the supported dicobalt complex still functioned as an active catalyst.

4. Concluding remarks

A new dicobalt complex bound to a solid silica matrix functions as an effective and selective oxygen absorbent and is capable of recycling O_2 more than 10 times without loss of activity. This type of immobilization provides the possibility for the prevention of degradation of the active centers. This is an intrinsic problem encountered by oxygen carriers in water solution. This result indicates that this material can be of practical value in the separation of O_2 from gaseous mixtures. In water solution, this material displays effective catalytic activity towards the disproportionation of H_2O_2. This effectiveness is due to the redox reaction from Co(II) to Co(III) which occurs in aqueous solution. It was proposed that any residual hydrogen peroxide formed during industrial processes can be decomposed prior to disposal through the application of immobilized transtion metal complexes.

Abstract

The reaction of 2-PySK with [Pt(dppf)Cl_2] [dppf = 1,1′-bis(diphenylphosfinoferrocene and 2-PyS = 2-mercaptopyridine] produced Pt(dppf)(2-SPy)$_2$ (**1**) and its subsequent reaction with $SnBu_2(BF_4)_2$ or $SnBu_3(BF_4)$ yielded [{Pt(dppf)(2-SPy)}{BF_4}] (**2**). Compounds **1** and **2** were fully characterised by multinuclear NMR [^{1}H, ^{13}C{^{1}H}, ^{31}P{^{1}H} and ^{195}Pt{^{1}H}] and ^{57}Fe Mössbauer spectroscopies. In addition the structure of **2** was determined by X-ray crystallographic studies, which can be summarised as follows: monoclinic $P2_1/c$, $a = 9.9291(9)$ Å, $b = 22.270(4)$ Å, $c = 16.919(2)$ Å, $\gamma = 103.6(9)°$, $V = 3636.2(8)$ Å^3 and $Z = 4$. Finally, a thermal decomposition study was carried out with **2** in three different atmosphere: oxygen, nitrogen or hydrogen. The residues were characterised by X-ray powder diffraction (XRD), X-ray electron probe microanalysis (EPMA), scanning electron microscopy (SEM) and ^{57}Fe Mössbauer spectroscopy. The results have shown the formation of a disordered $Pt_{1-x}Fe_x$ based alloy when the pyrolysis process was performed in H_2, simultaneously with small amount of Fe(II) and Fe(III) phosphides. Furthermore, in oxygen and nitrogen the thermal decomposition of **2** produced metallic agglomerates of Pt dispersed in a combination of Fe(II) and Fe(III) phosphates in O_2, and an intricate mixture of sulphides and phosphides in N_2.

1. Introduction

The compound [Fe(η^5-$C_5H_4PPh_2$)$_2$], dppf, still plays an important role in organometallic chemistry [1]. The coordination versatility of this metalloligand is highly remarkable. Actually, the various coordinating modes of dppf just reflect its ability to change conformation in order to match the steric demands of the surrounding molecular environment. However, in most examples it is η^2 bonded to metal centres. So far more than 250 structures determined by X-ray crystallography, containing the dppf fragment, have been deposited at CCDC (version 5.24 of April 2003).

The considerable research attention granted to dppf relates to: (i) the various coordination modes towards metallic anions [2], (ii) the catalytic activity of the complexes [3] and (iii) the chemotherapeutic potential for cancer treatment of some derivatives [4].

Our research interest towards dppf concerns the preparation of well characterised Pt(II) [5], Ru(II), and its Sn(II)-containing heterometallic derivatives in order to obtain oxides and Fe/Pt/Sn or Fe/Ru/Sn containing alloys. For that, thermal decomposition of single source organometallic precursors has received special attention from us in the last two years [6]. Heterometallic

doi:10.1016/j.poly.2003.09.017

derivatives of dppf seems to be attractive since it possesses different metallic species close enough to interact and produce synergetic effects which can result in interesting properties. Therefore, this work reports the thermal decomposition of [{Pt(dppf)(SPy)}{BF_4}] (**2**) carried out in oxygen, nitrogen and hydrogen. The residues were studied by X-ray powder diffraction (XRD), scanning electron microscopy (SEM), X-ray electron probe microanalysis (EPMA) and ^{57}Fe Mössbauer spectroscopy.

2. Experimental

2.1. Synthesis and characterisation of metal complexes

The synthetic work was conducted in an atmosphere of dry N_2. All solvents were treated by the appropriate method in order to remove moisture and oxygen, prior to use. All chemicals unless stated were obtained from Aldrich or Strem Co. NMR spectra were recorded in $CDCl_3$, at 400 MHz, ^{1}H, 100.62 MHz; ^{13}C{^{1}H}, 50.29 MHz; ^{31}P{^{1}H}, 161.92 MHz; ^{195}Pt{^{1}H}, 86.00 MHz using a Bruker DPX-400 spectrometer equipped with an 89 mm wide-bore magnet. ^{13}C and ^{1}H shifts are reported relative to $SiMe_4$, ^{31}P to H_3PO_4 and ^{195}Pt to K_2PtCl_4. Carbon and hydrogen elemental analyses were performed on a Perkin–Elmer PE-2400 CHN-analyses using tin sample-tubes. The X-ray diffraction data were collected using a Enraf Nonius FR590 with SMART CCD area detector and graphite–graphite-monochromated Mo Kα.

2.2. Synthesis of Pt(dppf)(2-SPy)$_2$ (1)

To a Schlenk-flask containing a suspension of 0.88 g (5.90 mmol) of 2-PySK and 20 ml of thf, was slowly added a thf solution of [Pt(dppf)Cl_2], 2.42 g (2.95 mmol in 15 ml). Within 4 h of stirring the thf was removed in vacuum and CH_2Cl_2 (30 ml) was added in order to extract the product, originating an orange solution and KCl which was separated by filtration. A yellow solid was obtained after removing the solvent and re-crystallisation in CH_2Cl_2/toluene (1:1, 30 ml). Yield based in [Pt(dppf)Cl_2]: 70% (2.00 g, 2.07 mmol). Mp 180(d) °C. ^{1}H NMR δ 6.2–7.5(m) (Py and Ph), 4.4(s) and 4.2(s) (Cp); ^{13}C{^{1}H} NMR δ 168, 147, 137, 125, 115 (Py), δ 134–127 (Ph and Cp); ^{31}P{^{1}H} δ 16.87 ^1J(^{31}P–^{195}Pt) = 3139 Hz; ^{195}Pt{^{1}H} δ −4684 ^1J(^{31}P–^{195}Pt) = 3195 Hz. Elemental analysis for $C_{44}H_{38}FeP_2PtN_2S_2$, found (calc): C, 57.41(58.35); H, 3.99(4.01); N, 2.99(3.09)%.

2.3. Synthesis of [{Fe(η^5-$C_5H_4PPh_2$)$_2$Pt(SPy)}{BF_4}] (2)

To a solution of $AgBF_4$, 42 mg (0.22 mmol) in thf (20 ml), was added 70 mg (0.22 mmol) of $SnBu_3Cl$ in thf. The clear solution remained stirring for 30 mim in dark. The AgCl formed was filtered off by cannula and the solution transferred to another Schlenk-flask containing 210 mg (0.22 mmol) of Pt(dppf)(2-SPy)$_2$ in thf (20 ml). After 15 h of stirring the solvent was removed and the residue was washed with *n*-hexane, extracting $SnBu_3$-SPy. The resultant golden-yellow solid was re-crystallised in toluene (30 ml) affording X-ray quality crystals. Yield 69% (144 mg, 0.150 mmol). Mp 215(d) °C. ^{1}H NMR δ 7.9–6.6 (m) (Py and Ph), 4.9(s) and 4.4(s) (Cp); ^{13}C{^{1}H} NMR δ 166, 145, 136, 125, 119 (Py), δ 134–128 (Ph and Cp); ^{31}P{^{1}H} δ 17.27 ^1J(^{31}P–^{195}Pt) = 3162 Hz and δ 11.56 ^1J(^{31}P–^{195}Pt) = 3609 Hz; ^{195}Pt{^{1}H} δ −3500. Elemental analysis for $C_{39}H_{32}BF_4FeP_2PtS$, found(calc): C, 49.78(49.49); H, 2.81(2.78); N, 1.39(1.38)%. The same product was obtained using $SnBu_2Cl_2$ (50 mg, 0.16 mmol).

2.4. X-ray structure determination of 2

The structure was solved by direct methods with SIR-92 [7] and the refinements were carried out using SHELXL 97 [8], minimising on the weighted *R* factor *wR*2. Further details are given in Table 1. All non-H atoms are anisotropic. The ORTEP drawing shows the non-H atoms as 50% thermal vibration ellipsoids. The crystals were obtained by slow evaporation of a toluene solution of **2**. The BF_4^- group showed to be very disordered.

2.5. Thermal analysis of **2**

In order to determine the range of temperature of degradation of **2**, thermogravimetric analysis (TG) with simultaneous differential thermal analysis (DTA) experiments were performed in a TA Instruments SDT 2960 with a heating rate of 5 °C/min until 900 °C in oxygen.

2.6. Pyrolysis of **2**, chemical, structural and morphological characterisation of the residue

Thermal decomposition of **2** was carried out in a tube furnace in N_2, O_2 and H_2, using a heating rate of 5 °C/min until a final temperature of 900 °C employing a gas flux of 100 ml/min. The decomposed products were characterised by XRD, SEM, ^{57}Fe Mössbauer spectroscopy and EPMA.

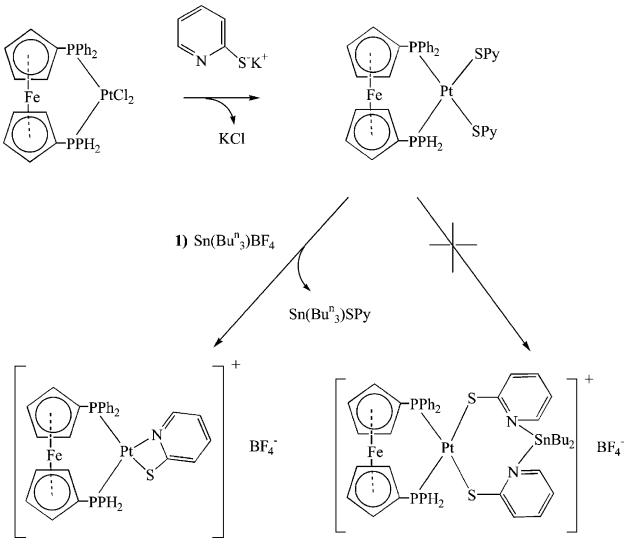
X-ray powder diffraction was executed in a Rigaku Geigerflex using a Cu Kα radiation ($\lambda = 1.54178$ Å). A scan rate of 4°/min in the 2θ range from 4° to 100° was used. In those samples containing platinum its main diffraction line at 39.76° (1 1 1) was used as internal standard for angle calibration.

The scanning electron micrographs was recorded in a JEOL JSM-840A equipment and the electron probe X-ray microanalysis were carried out in a JXA 89000 RL wavelength dispersive/energy dispersive combined microanalyser. For the SEM images and X-ray microanalysis the samples were recovered with a thin film of gold and carbon, respectively, deposited by sputtering.

^{57}Fe Mössbauer measurements were obtained in order to identify the Fe oxidation states and number of different sites in the decomposed materials by using a conventional apparatus with ^{57}Co as source of γ-radiation, kept at room temperature.

3. Results and discussion

Organometallic compounds are good candidates for single source precursors for thermal decomposition because they decompose at low temperature, producing metallic oxides, metallic particles or inorganic salts. Following our interest in this research area, we have attempted to prepare a Pt/Fe/Sn derivative, as described in Scheme 1, to be employed as an source for the trimetallic containing materials. Firstly, the reaction of [Pt(dppf)Cl_2] with 2-PySK produced the bimetallic derivative [Pt(dppf)$(SPy)_2$] (**1**) (see Scheme 1) that was used as a S and N electron donor ligand towards another metal centre. Organotin(IV) Lewis acid were chosen due to the great Sn–N affinity observed in other complexes [9]. However, instead of a simple coordination reaction, it was observed an exchange of 2-PyS$^-$ ligand between Pt(II) and Sn(IV) atoms.



Scheme 1. Pathway of the preparation of compound **1**.

Similar interchange was also detected when the reaction of [$SnPh_3SPy$] with [Pt$(PPh_3)_2Cl_2$] was performed in order to obtain a bimetallic complex where Pt(II) was coordinated through the S donor centre. However, two separated compounds $SnPh_3Cl$ and [Pt$(PPh_3)_2(SPy)_2$] [10] were isolated and identified.

Compounds **1** and **2** are air and moisture stable golden-yellow products, readily soluble in CH_2Cl_2 and toluene, and they showed satisfactory results of elemental analysis. NMR spectroscopic measurements were carried out using a $CHCl_3/CDCl_3$ solutions. For both compounds the ^{13}C and ^{1}H NMR spectra exhibited the expected resonances for Cp, Ph and Py groups. Compound **1** displayed a single signal at δ 16.9 [$^1J(^{31}P–^{195}Pt) = 3139$ Hz] in the ^{31}P NMR spectrum, and a peak at δ −4684 [$^1J(^{31}P–^{195}Pt) = 3195$ Hz] in the ^{195}Pt NMR spectrum. It possesses a smaller $^{31}P–^{195}Pt$ coupling constant, 3195Hz compared to the starting material [Pt(dppf)Cl_2], 3768 Hz. The latter is a consequence of the better π-acceptor character of S compared to Cl which causes a decrease in the Pt–P bond strength.

The ^{31}P NMR spectrum of **2** revealed two signals at δ 17.3 [$^1J(^{31}P–^{195}Pt) = 3162$ Hz] and 11.6 [$^1J(^{31}P–^{195}Pt) = 3609$ Hz]. Moreover, it was detected a coupling constant between the two non-equivalent phosphorus at 17 Hz. The first set of chemical shifts and coupling constants are similar to the signals displayed by **1**. Therefore, it might be assigned to the P atom *trans* to S of the –SPy moiety and the remaining signal can be attributed the other P atom *trans* to N. A broad resonance centred at δ −3500 was detected in the ^{195}Pt NMR spectrum, resulting from a complicated coupling pattern of ^{195}Pt with the non-equivalent ^{31}P nuclei.

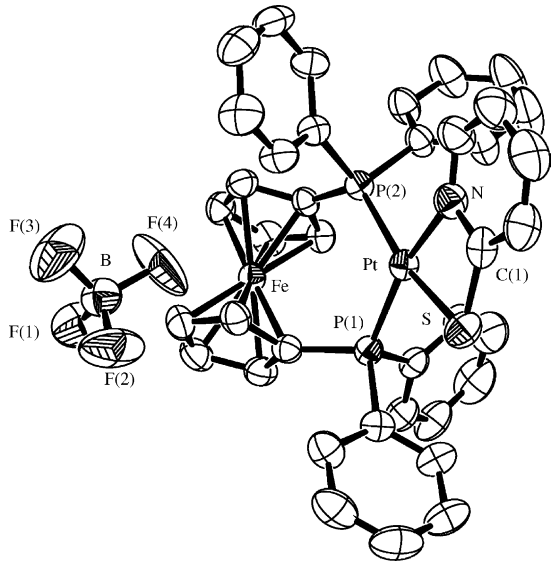


Fig. 1. Molecular structure of **2** determined by X-ray crystallography.

Table 2
Selected bond lengths (Å) and angles (°) for **2**

Bond lengths	
Pt–N	2.1160(4)
Pt–P(1)	2.2521(11)
Pt–P(2)	2.2910(11)
S–C(1)	1.7470(5)
Pt–S	2.3635(12)
Bond angles	
N–Pt–P(1)	164.07(14)
P(1)–Pt–P(2)	99.09(5)
P(1)–Pt–S	95.09(6)
S–C(1)–N	110.00(3)
N–Pt–P(2)	96.82(14)
N–Pt–S	69.00(14)
P(2)–Pt–S	165.81(6)

A single-crystal X-ray experiment confirmed the structure of **2** to be composed of $Pt(dppf)(SPy)^+$ cations and BF_4^- anions, with no direct contact between the two fragments, Fig. 1. The Pt(II) atom lies in the centre of a distorted square where it is bonded to both S {Pt–S, 2.3641(15) Å} and N {Pt– N, 2.113(5) Å} of the pyridyl group. These bond length and angles {N– Pt–S 69.00(14)°, P(1)–Pt–P(2) 99.09(5)°, S–C(1)–N 110.00(3)°} are very close to the ones observed for $[\{Pt(PPh_3)_2(SPy)\}\{PF_6\}]$ [11] (Table 2).

The coordination position of the fluorine atoms in the BF_4^- group was very disordered, similarly to other reported results [11].

3.1. Thermal analysis

Compound **2** displayed a highly exothermic decomposition process in a pseudo single step, which started at 300 °C and finished at 800 °C. The initial loss of weight at 60 °C was subtracted from the curve in order to disregard the loss of solvent. In this step the complex loses 54.2% of the weight. After 400 °C, the material continues to decompose losing at the end, 800 °C, 47% of mass, leaving a final residue containing 7.2% of the initial amount, which suggests that an appreciable amount of material was lost to the gas phase.

3.2. X-ray electron probe microanalysis

The chemical composition of the residues was determined by EPMA in different regions of the samples in order to evaluate their level of homogeneity. The presence of carbon peaks in all residues is a consequence of the deposit of graphite at the sample's surface.

Two different regions were identified in the residues obtained in oxygen: a bright one, formed by agglomerates of metallic platinum (approximately 10 μm in size) dispersed in an amorphous media, dark region, constituted basically of P, Fe and O, Fig. 2. No sulphur was identified in this sample. A similar situation was revealed for the residue obtained in N_2, Fig. 3(b), however, the particles of platinum are much smaller than the previous one. Moreover, in this case it was noticed only a trace of oxygen, and the major components were Fe, P and S. The residue from decomposition of **2** in H_2 has not shown oxygen or sulphur, but only Pt, P and Fe, Fig. 3(c). The nature of the species formed could only be tentatively identified with the support of XRD and ^{57}Fe Mössbauer spectroscopies.

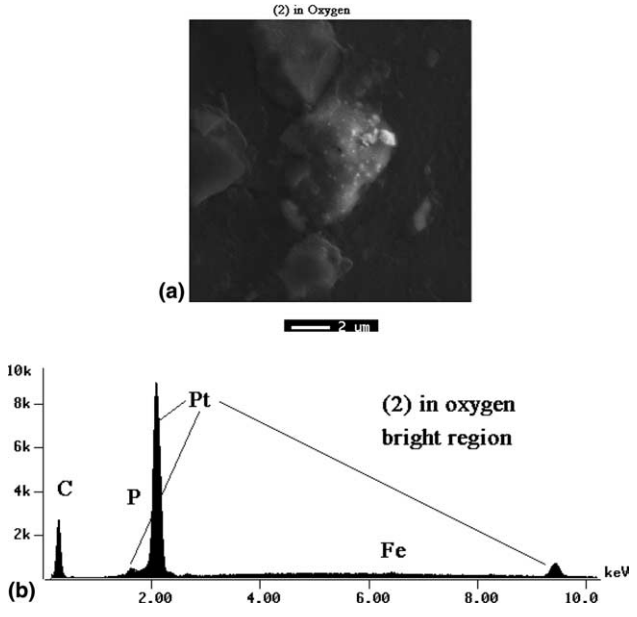

Fig. 2. The image and the dispersive energy X-ray microanalysis (EPMA) of **2** decomposed in O_2.

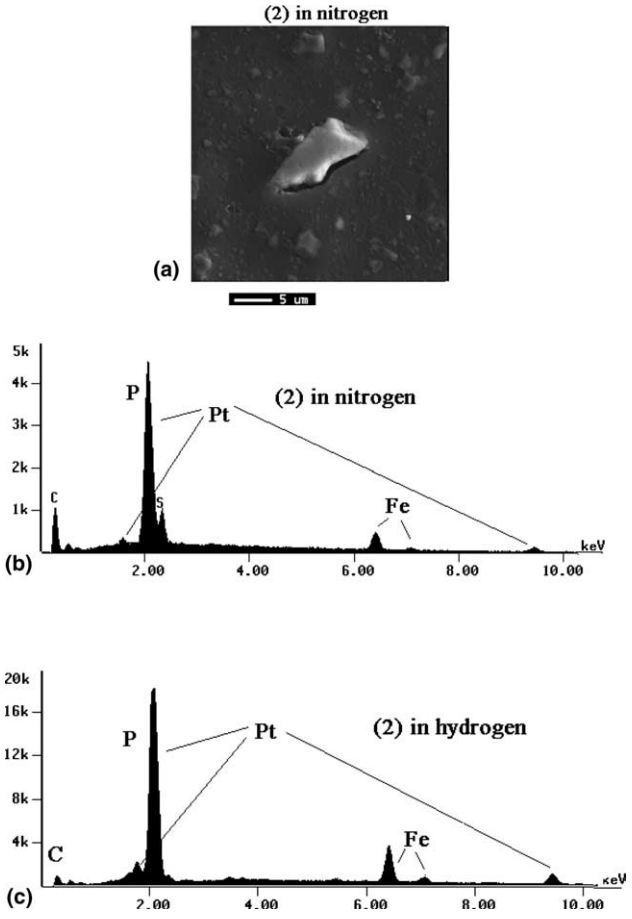

Fig. 3. (a) The image and the EPMA of **2** decomposed in N_2 (b) and H_2 (c).

3.3. X-ray powder diffraction

X-ray diffraction measurements were executed in order to identify the pyrolysis residues of **2**, Fig. 4. The diffractogram of the decomposed material in oxygen, Fig. 4(a) revealed lines at $2\theta = 39°$, 46°, 67° and 81°; corresponding, as indicated by the Miller index to the diffraction planes (1 1 1), (2 0 0), (2 2 0) and (3 1 1) to metallic platinum (Cubic, $Fm3m$, $a = 3.923$ Å) {04-0802} [12]. The high intensity of the Pt diffraction lines suggests the production of large and well formed particles of platinum as observed in the electron backscaterred image. The other diffraction lines can be clearly attributed to the formation of $FePO_4$ and $Fe_3(PO_4)_2$ [13] and it is in accordance to the EPMA and ^{57}Fe Mössbauer spectroscopic results.

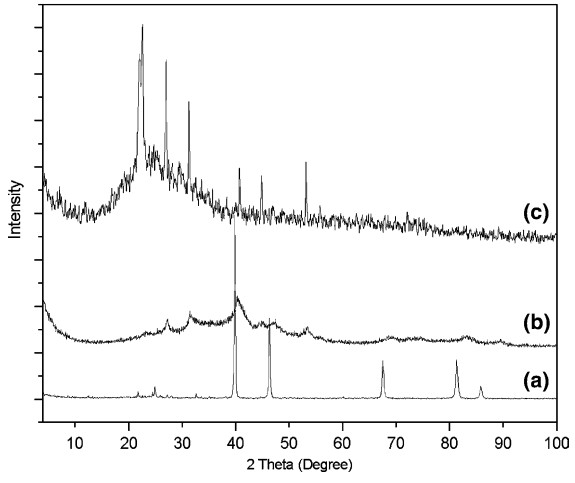

Fig. 4. XRD pattern of **2** decomposed in O_2 (a), N_2 (b) and H_2 (c).

Much more broader Pt diffraction lines (1 1 1), (2 0 0), (2 2 0) and (3 1 1) were revealed for the residue prepared in N_2, in consequence of the lower crystallinity of the decomposed material. The much less intense lines at approximately $2\theta = 28°$, 47° and 56° might be attributed to the cubic FeS [14a] {pyrite form – 06-0710} and those at $2\theta = 32°$ and 53° which are also observed in the diffractogram of the sample decomposed in H_2, can be associated to the orthorhombic FeP_4 [14b] {34-0996i}, Fig. 4(b). On the basis of the EPMA analysis there is no oxygen in the sample which frustrate the presence of phosphate anions. Therefore, it is reasonable to assume that Fe(II) and Fe(III) are in the form of sulphide and phosphide. The diffraction pattern of the product obtained in H_2 has shown lines, at $2\theta = 25°$, 31°, 32° and 53°, corresponding to orthorhombic FeP_4, as before, and the diffractions at $2\theta = 41°$ and 46°, may be associated to the planes (1 0 0) and (2 0 0) of the Pt–Fe alloy (cubic – 29-0718). The intense line at $2\theta = 24°$ is probably related to the alloy as well since other similar materials with different stoichiometry present diffraction lines at angles smaller than 30° [12].

3.4. ^{57}Fe Mössbauer experiments

The room temperature ^{57}Fe Mössbauer spectroscopy experiments supported the identification of iron compounds and its oxidation state, Fig. 5 and Table 3.

For the starting material, **2**, it was observed the presence of Fe(II) to which the parameters $\delta = 0.40(2)$ mm s^{-1} and $\Delta = 2.25(3)$ mm s^{-1} relates very well with the classical values reported for ferrocene, [$FeCp_2$], $\delta = 0.44(2)$ mm s^{-1} and $\Delta = 2.38(3)$ mm s^{-1} and the dppf $\delta = 0.42(2)$ mm s^{-1} and $\Delta = 2.30(3)$ mm s^{-1} [15], Fig. 5(a). The ^{57}Fe Mössbauer spectrum of the residue prepared in O_2, Fig. 5(b) displayed two signals with the corresponding parameters, $\delta = 0.30(2)$ mm s^{-1}, $\Delta = 0.44(3)$ mm s^{-1} and $\delta = 0.37(2)$ mm s^{-1}, $\Delta = 0.98(3)$ mm s^{-1} assigned to the presence of Fe(III), 63%, and Fe(II), 37%, respectively, that are in the form of phosphates [13]. Two sites of Fe(II), $\delta = 0.25(2)$ mm s^{-1}, $\Delta = 1.49(3)$ mm s^{-1} (14%) and $\delta = 0.37(2)$ mm s^{-1}, $\Delta = 0.80(3)$ mm s^{-1} (43%) and one site of Fe(III) $\delta = 0.29(2)$ mm s^{-1}, $\Delta = 0.23(3)$ mm s^{-1} (43%) were

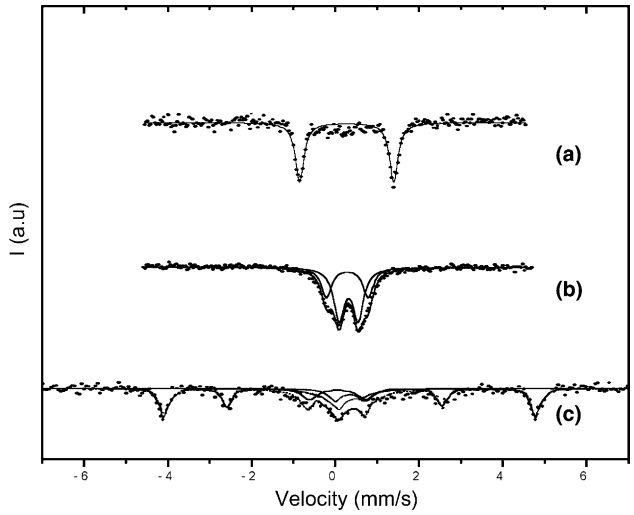

Fig. 5. ^{57}Fe Mössbauer spectra of **2** and the corresponding residues obtained in O_2 (a), N_2 (b), and H_2(c).

found in the material obtained in N_2, Fig. 5(c). The iron species are associated to the sulphide and phosphide, as attested by the other results. Finally, the sample obtained in H_2 presents signals related to Fe(II), $\delta = 0.36(2)$ mm s^{-1}, $\Delta = 0.83(3)$ mm s^{-1} (12%), and Fe(III) with $\delta = 0.26(2)$ mm s^{-1}, $\Delta = 0.12(3)$ mm s^{-1} (11%). These cations are in the form of orthorhombic phosphide FeP_4 as the XRD pointed out. The more remarkable is the sextet with $\delta = 0.26(2)$ mm s^{-1}, $\Delta = 0.19(3)$ mm s^{-1} and a hyperfine field (B_{hf}) = 27 T (77%), which indicates some form of metallic iron, Fig. 5(e). It was attributed to a disordered $Pt_{1-x}Fe_x$ phase on the basis of the ^{57}Fe Mössbauer parameters of

Table 3
^{57}Fe Mössbauer parameters for the complex **2** and the residue of decomposition of **2** under O_2 (a), N_2 (b) and H_2 (d)

Sample	Fe oxidation state	IS (mm s^{-1})	QS (mm s^{-1})	Area (%)
2	Fe(II)	0.40	2.25	100
O_2	Fe(III)	0.30	0.44	63
	Fe(II)	0.37	0.98	37
N_2	Fe(III)	0.30	0.44	43
	Fe(II)	0.25	1.49	14
	Fe(II)	0.37	0.80	43
H_2	Fe	0.26	0.19	77
	Fe(III)	0.26	0.12	11
	Fe(II)	0.36	0.83	12

The experimental errors associated to IS and QS are 0.02, 0.03, respectively.

other Fe/Pt alloys [16] and the data of metallic iron $\delta = 0.29(2)$ mm s^{-1}, $\Delta = 0.14(3)$ mm s^{-1} and $B_{hf} = 28$ T. The experiments of ^{57}Fe Mössbauer have shown the formation of different sites of iron which can not be directly attributed to any particular compound without the help of other techniques. However, it is clear that a very different iron phase is formed in the sample decomposed in H_2, that is very similar to the pattern exhibited for iron containing alloys. No further evidence was found for the formation of iron carbides, carbonates or oxides, at least as major products.

3.5. Scanning electron microscopy

The SEM images, Fig. 6, were obtained for each residue in order to investigate the level of homogeneity

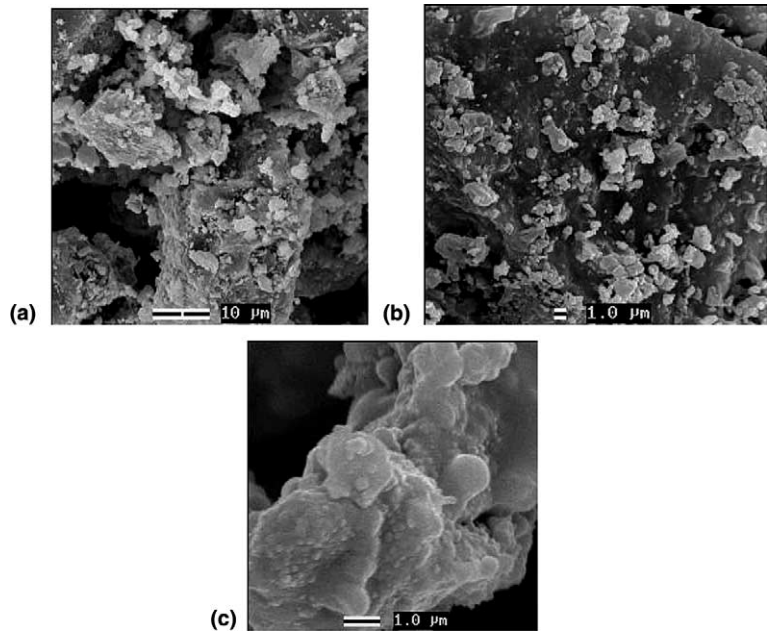

Fig. 6. Electron scanning micrographs of **2** decomposed in O_2 (a), N_2 (b) and H_2 (c).

and the presence of metallic agglomerates. No considerable difference is observed for the decomposed material in O_2, Fig. 6(a), or N_2, Fig. 6(b). It is obvious since the grains correspond to the presence of metallic platinum. The major difference consists in the nature of the dark and amorphous material that in the first case consists of a mixture of Fe(II) and Fe(III) phosphates and in the second product it is associated to a complex combination of Fe(II) and Fe(III) phosphides or sulphides. Also, the size of the particles obtained in oxygen vary from 40 to 70 μm whist in nitrogen it is much smaller. In the case of **2** decomposed in H_2 a more compact and homogenous material was obtained and seems to be formed by very big grains (100–200 μm).

4. Conclusions

In this work the synthesis and structural characterisation of [{Pt(dppf)(SPy)}{BF_4}] (**2**) was described. The thermal behaviour of **2** was studied by simultaneous TG/DTA measurements. The preparation of products of decomposition of **2** in O_2, N_2 and H_2 was investigated and the obtained residue was fully characterised by XRD, SEM, EPMA and ^{57}Fe Mössbauer spectroscopy. The results have attested the formation of a disordered $Pt_{1-x}Fe_x$ alloy when the pyrolysis process was performed in H_2. However, the procedure also produced Fe(II) and Fe(III) containing materials, as contaminants. The degradation product of **2** in O_2 and N_2 consisted of metallic platinum and again Fe(II) and Fe(III) species.

5. Supplementary data

Crystallographic data for the structural analysis of compound **1** have been deposited at the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1 EZ, UK, and are available free of charge from the Director on request quoting the deposition number CCDC 192715 (fax: 44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Reactivity behavior of (hydroxy)diorganotin(IV)methanesulfonates with ionic nucleophiles – synthesis and structural characterization of novel diorganostannate salts, $[R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2 2Bu_4N$

Abstract

The reaction of $R_2Sn(OH)OSO_2Me$ [R = *n*-Pr (**1a**), or *n*-Bu (**1b**)] with one equivalent of Bu_4NNO_3 in CH_2Cl_2 proceeds via nucleophilic addition of NO_3^- ion to the Lewis acidic tin center and results in the formation of novel diorganostannates, $[R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2 2Bu_4N$ [R = *n*-Pr (**2a**), *n*-Bu(**2b**)]. The molecular structure of **2b** comprises of hydroxy-bridged dimer with monodentate methanesulfonate and nitrate groups bonded to each tin atom. Analogous reactions of the tin precursor, **1b** with strong nucleophiles such as Bu_4NX ($X = F^-$, OAc^-) and RLi (R = *n*-Bu, Me) favor ionic metathesis pathway involving $Sn–OSO_2Me$ bond cleavage. This approach provides a simple and facile synthetic route for triorganotin oxides, $(R_2R'Sn)_2O$ ($R = R' = n$-Bu, $R = n$-Bu, $R' =$ Me).

1. Introduction

The property of diorganotin (IV) compounds, R_2SnX_2 (X = halogen) to act as Lewis acids has been frequently utilized to synthesize a large number of trihalodiorganostannates, $[R_2SnX_3]^-$ [1] as well as tetrahalodiorganostannates, $[R_2SnX_4]^{2-}$ [2]. Recently, Tudela et al. [3] have reported solvent dependence on the formation of these class of compounds. It has been shown that the reaction of Me_2SnBr_2 with Et_4NBr in $CHCl_3$/hexane mixture yields $[Me_2SnBr_4](Et_4N)_2$ while $[Me_2SnBr_3](Et_4N)$ is exclusively formed in water. Extensive studies have been reported on selective anion binding capability of "tailormade" organotin hosts with high nuclearity tin centers as Lewis acids [4]. This has led to the isolation of wide structural diversity of diorganostannate derivatives. In contrast, anionic tin derivatives bearing functional ligands other than halogen on the tin atom are much less known. The identity of 'ate' complexes, $[Bu_2SnI_2H]Li$ and $[Bu_2SnIHBr]MgBr$ generated in situ has been gleaned by ^{119}Sn NMR spectroscopy and their utility in regio/stereoselective reduction of various enals and aliphatic alkynes has been reported [5]. The diorganostannates bearing carboxylate ligands such as, $[R_2Sn(O_2C)_2C_5H_3N{\cdot}X]Et_4N$ ($X = Cl^-$, F^-) [6] and $[Me_2Sn(OAc)_3]Me_4N$ [7] have also been structurally characterized and examined for their antitumor activity.

In recent years, we have been interested in the development of new synthetic strategies for functional organotin derivatives and reported on the preparation

and structural characterization of (hydroxy)diorganotin (IV)methanesulfonates, $R_2Sn(OH)OSO_2Me$ (R = *n*-Pr, *n*-Bu, etc.) [8]. The reaction chemistry of these bifunctional tin compounds has attracted our attention. It has been demonstrated that the selective dehydration reaction involving Sn–OH group with carboxylic acids results in the isolation of diorganotin carboxylates [9], which are not accessible by classical route. Another interesting aspect concerns the reactivity of these tin precursors towards the ionic nucleophiles. In the present work, preliminary investigations on this aspect have been undertaken. While the reaction of **1a** or **1b** with Bu_4NNO_3 results in the isolation of novel diorganostannate derivatives, **2a** or **2b**, the use of strong nucleophiles such as Bu_4NX ($X = F^-$, OAc^-) and RLi (R = *n*-Bu, Me) favor ionic metathesis reaction involving $Sn–OSO_2Me$ bond cleavage. The results obtained from these studies are reported herein.

2. Results and discussion

The synthesis of $[R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2\,2Bu_4N$ [R = *n*-Pr (**2a**), *n*-Bu (**2b**)] is accessible from the reaction of (hydroxy)diorganotin methanesulfonates (**1a** or **1b**) with one equivalent of tetra-*n*-butylammonium nitrate (Eq. (1)). These compounds are moderately sensitive to moisture and are soluble in common organic solvents such as chloroform, dichloromethane, methanol, acetonitrile, etc.

$$2R_2Sn(OH)OSO_2Me + 2Bu_4NNO_3 \xrightarrow{RT/8\text{–}10\ h} [R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2 2Bu_4N$$
$$R = n\text{-Pr}\ (\mathbf{2a}),\ n\text{-Bu}\ (\mathbf{2b}) \qquad (1)$$

The single crystals of **2b** suitable for X-ray structure were obtained upon cooling solution of the compound in dichloromethane at 4 °C for several days. The compound crystallizes with two independent molecules in the unit cell of which only one is shown in Fig. 1. The relevant crystal data are given in Table 1, while selected bond distances and angles are given in Table 2. The anion in each molecule adopts a centrosymmetric hydroxy-bridged dimeric structure with highly distorted octahedral geometry around each tin atom. The SnO_4 coordination sphere formed by two bridging OH, a monodentate methanesulfonate and a nitrate group is planer (360° ± 1). Principle differences between the two molecules in the unit cell appear in the Sn–O (methanesulfonate and nitrate) bond distances and O–Sn–O/C–Sn–C angles. A comparison of these metrical parameters with those of the precursor [Sn–O (methanesulfonate) = 2.410(4) Å] [8] reveals significant elongation of Sn–O (methanesulfonate) bond distance in the stannate [Sn(1A)–O(2A) = 2.451(6)/Sn(1B)–O(2B) = 2.552(7) Å] and suggests appreciable ionic character. The angle C(5A)–Sn(1A)–C(1A) = 159.6(3)°/C(5B)–Sn(1B)–C(1B) = 153.3(4)° is much larger than observed in the tin precursor **1b** [C–Sn–C = 151.4(3)°]. Secondary interactions such as intramolecular hydrogen bonding [O(3A)···H–O(1A) = 2.694 Å, O(3B)···H–O(1B) = 2.780 Å] as well as intermolecular C–H···O

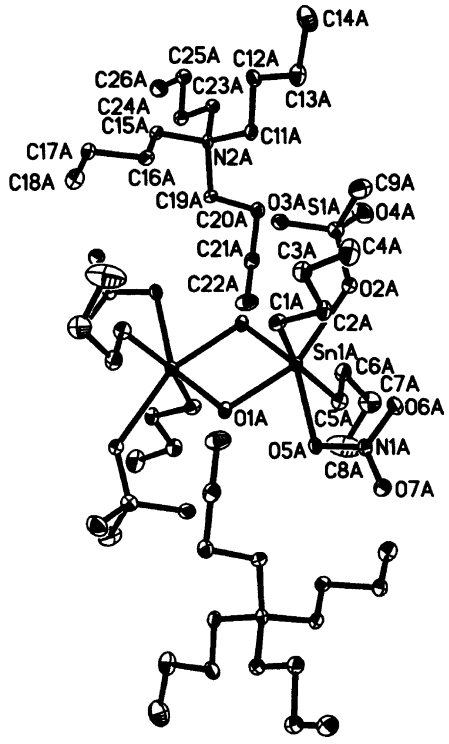

Fig. 1. ORTEP view of one independent molecule of **2b**, showing 30% probability ellipsoids. Hydrogen atoms have been omitted for clarity.

interaction [C(11B)–H(11D)···O(7A) = 2.506 Å, C(15A)–H(15B)···O(7B) = 2.458 Å] have also been observed. Similar interactions have been previously reported in organotin carboxylates derived from ferrocenyl carboxylic acid [10].

The IR spectra (KBr) of **2a** and **2b** reveal two bands at 1485–1490 and 1384–1388 cm^{-1} due to $\nu_a NO_2$ and $\nu_s NO_2$, respectively, and suggest unidentate coordination mode of the nitrate group [11]. The strong absorptions due to νSO_3 mode appear at 1205–1210 and 1050–1060 cm^{-1}. The absence of additional splitting of these bands may be attributed to the monodentate character of methanesulfonate group [12]. ^1H NMR spectrum of each compound identifies Pr_2Sn/Bu_2Sn, Bu_4N and SMe groups in 1:1:1 integrated ratio and conforms to the structural composition. ^{119}Sn NMR spectra in $CDCl_3$ show four distinct signals spanning a broad chemical shift range and appear at δ −155, −159, −191, −234 (for **2a**) and −157, −159, −194, −234 (for **2b**). The ^{119}Sn NMR chemical shift values and spectral intensity of the signals between δ −155 and −195 show a close resemblance to those of parent tin precursors, **1a** and **1b**, while the appearance of a new upfield signal at δ −234 may be ascribed to the stannates (**2a** and **2b**). These results coupled with the lack of $^2J(^{119}Sn–O–^{117}Sn)$ coupling may suggest a fast equilibrium in solution between the precursor tin compound and the product. Such phenomena have been reported in a few studies related to the formation of stannate derivatives [13]. No change in the δ ^{119}Sn NMR values was observed upon addition of another equivalent amount of Bu_4NNO_3 to **1a** or **1b** suggesting that the tin precursor binds only one NO_3^- ion.

Nucleophilicity of the anionic reagents has been found to substantially alter the reaction chemistry of the tin precursors. This is evident by studying the reactions of **1b** with Bu_4NX (F, OAc) or RLi (*n*-Bu, Me). These reactions invariably proceed via an ionic metatheses pathway involving the cleavage of Sn–OSO_2Me bond. The products obtained in these reactions are shown as:

$$2Bu_2Sn(OH)OSO_2Me + 2Bu_4NX \rightarrow [Bu_2Sn(X)]_2O + 2Bu_4NOSO_2Me + H_2O \quad (X = F, OAc) \quad (2)$$

$$2Bu_2Sn(OH)OSO_2Me + 2RLi \rightarrow (Bu_2RSn)_2O + 2LiOSO_2Me + H_2O \quad (R = n\text{-}Bu, Me) \quad (3)$$

The identity of these products has been confirmed by comparison of IR, ^1H, and ^{119}Sn NMR spectral data with those of the known compounds previously reported in literature [14].

A final comment concerns the formation of the stannates, **2a** and **2b.** Complexation of the NO_3^- ion to the tin center of **1a** or **1b** can be rationalized by considering coordinative dissociation of bridging bidentate methanesulfonate in the tin precursors [8]. It appears that the nucleophilicity of NO_3^- and $MeSO_3^-$ ions being comparable [15] inhibits the ionic metathesis pathway. Nevertheless, the use of organometallic reagents such as RLi may also be of significant synthetic utility in the formation of mixed triorganotin oxides. This aspect is presently being investigated in our laboratory.

3. Experimental

All reactions were conducted in an inert atmosphere of nitrogen. Solvents were dried using standard techniques (dichloromethane and *n*-hexane over P_2O_5, diethyl ether over sodium benzophenone). Glassware was dried in an oven at 110–120 °C and further flame dried under vacuum prior to use. The precursors, (hydroxy)di-*n*-propyl/di-*n*-butyltin(IV)methanesulfonates [8] and di-*n*-propyltin oxide [16] were prepared using literature methods, while the reagents such as Bu_4NX (X = NO_3, F, OAc) and RLi (R = Bu, Me) were obtained commercially (Aldrich). ^1H, ^{13}C and ^{119}Sn NMR spectra

were recorded on Bruker DPX-300 at 300, 75.46 and 111.88 MHz, respectively. ^{1}H and ^{13}C chemical shifts are quoted with respect to the residual protons of the solvent, while ^{119}Sn NMR data are given using tetramethyltin as internal standard. The IR spectra were recorded on Nicolet protégé 460 E.S.P. spectrophotometer using KBr optics. Elemental analysis (C, H and N) was performed on a Perkin–Elmer model 2400CHN elemental analyzer. Tin was estimated gravimetrically [17].

3.1. Reactions of (hydroxy)diorganotin methanesulfonate with tetrabutylammonium nitrate

To a stirred suspension of (hydroxy)di-*n*-propyltin(IV)methanesulfonate (0.69 g, 2.16 mmol) or (hydroxy)di-*n*-butyltin(IV)methanesulfonate (0.75 g, 2.16 mmol) in dichloromethane (~50 ml) was added a solution of Bu_4NNO_3 (0.65 g, 2.16 mmol) in the same solvent. The clear reaction mixture was stirred for 12–15 h. at room temperature. The resulting solution was concentrated under vacuum and *n*-hexane was added. A white solid, thus obtained in each case was filtered and dried in vacuum.

3.1.1. [n-Pr$_2$Sn(μ-OH)(OSO$_2$Me)(ONO$_2$)]$_2$2Bu$_4$N (**2a**)

Yield: (85%), m.p. 80–83 °C. ^{1}H NMR ($CDCl_3$): δ 3.33 (t, 8H, NCH_2), 2.77 (s, 3H, SMe), 1.78 (m, 16H, $Sn(CH_2)_2 + NCH_2CH_2$), 1.50 (m, 8H, $N(CH_2)_2CH_2$), 1.01 (t, 18H, $Sn(CH_2)_2CH_3 + N(CH_2)_3CH_3$). $^{13}C\{^{1}H\}$ NMR ($CDCl_3$): 58.3 (NCH_2), 39.2 (SMe), 29.2 ($SnCH_2$), 18.1 ($SnCH_2CH_2$), 12.2 ($Sn(CH_2)_2CH_3 + N(CH_2)_3CH_3$), 23.5 ($NCH_2CH_2$), 19.3 $N(CH_2)_2CH_2$. ^{119}Sn NMR ($CDCl_3$): δ −155, −159, −191, −234. IR (KBr, cm^{-1}): 3420 (νOH), 1487, 1386 (νNO_2), 1209, 1054 (νSO_3), 784 (SME). *Anal.* Calc. for $C_{23}H_{54}N_2O_7SSn$: C, 44.37; H, 8.68; N, 4.50; Sn, 19.29. Found: C, 44.10; H, 8.75; N, 4.61; Sn, 19.91%.

3.1.2. [n-Bu$_2$Sn(μ-OH)(OSO$_2$Me)(ONO$_2$)]$_2$2Bu$_4$N (**2b**)

Yield: (90%), m.p. 72–75 °C. ^{1}H NMR ($CDCl_3$): δ 3.33 (t, 8H, NCH_2), 2.77 (s, 3H, SMe), 1.65 (m, 16H, $Sn(CH_2)_2 + NCH_2CH_2$), 1.45 (m, 12H, $N(CH_2)_2CH_2 + Sn(CH_2)_2CH_2$), 1.03 (t, 12H, $N(CH_2)_3CH_3$), 0.93 (t, 6H, $Sn(CH_2)_3CH_3$). $^{13}C\{^{1}H\}$ NMR ($CDCl_3$): δ 58.3 (NCH_2), 39.2 (SMe), 26.5 ($SnCH_2$), 23.5 ($SnCH_2CH_2 + NCH_2CH_2$), 18.1 ($Sn(CH_2)_2CH_2$), 12.2 ($Sn(CH_2)_2CH_3 + N(CH_2)_3CH_3$, 23.5 ($NCH_2CH_2$), 19.3 ($Sn(CH_2)_2CH_2 + N(CH_2)_2CH_2$), 13.2 ($Sn(CH_2)_3CH_3 + N(CH_2)_3CH_3$). ^{119}Sn NMR ($CDCl_3$): δ −157, −159, −194, −234. IR (KBr, cm^{-1}): 3400 (νOH), 1487, 1384 (νNO_2), 1210, 1058 (νSO_3), 784 (SME). *Anal.* Calc. for $C_{25}H_{58}N_2O_7SSn$: C, 46.15; H, 8.92; N, 4.30; Sn, 18.46. Found: C, 46.91; H, 8.33; N, 4.21; Sn, 18.01%.

3.2. Reactions of (hydroxy)di-n-butyltin methanesulfonate with Bu$_4$NX (X = F$^-$, OAc$^-$)

To a stirred suspension of (hydroxy)di-*n*-butyltin methanesulfonate, **1b** (0.62 g, 1.79 mmol) in dichloromethane was added Bu_4NF (1.79 ml (1.0 M/THF), 1.79 mmol). The resulting clear solution was stirred for 8–10 h at room temperature. Thereafter the reaction mixture was concentrated under vacuum and diethyl ether was added to precipitate a white solid identified as tetra-*n*-butyl ammonium methanesulfonate, Bu_4NOSO_2Me. Solvent was evaporated from the ether solution to afford $[Bu_2Sn(F)]_2O$ as a white solid. The reaction of **1b** (0.62 g, 1.79 mmol) with Bu_4NOAc (0.53 g, 1.79 mmol) was performed by following a similar procedure as above. *n*-Hexane was added to precipitate the salt Bu_4NOSO_2Me which was filtered and dried under vacuum. The compound $[Bu_2Sn(OAc)]_2O$ was isolated from the concentrated hexane solution as a white solid.

3.2.1. Bu$_4$NOSO$_2$Me

Yield: (45%), ^{1}H NMR ($CDCl_3$): δ 3.31 (t, 8H, NCH_2), 2.75 (s, 3H, SMe), 1.66 (m, 8H, NCH_2CH_2), 1.44 (m, 8H, $N(CH_2)_2CH_2$) 1.01 (t, 12H, CH_3). IR (KBr, cm^{-1}): 2960, 2932 (νCH), 1240, 1193, 1058 (νSO_3), 784 (SME). *Anal.* Calc. for $C_{17}H_{39}NO_3S$: C, 60.53; H, 11.57; N, 4.15; Found: C, 61.01; H, 11.43; N, 4.21%.

3.2.2. [Bu$_2$Sn(F)]$_2$O

Yield: (41%), m.p. 137–140 °C (Lit. 140 °C). ^{1}H NMR ($CDCl_3$): δ 0.92 (t, 6H, CH_3), 1.20 (m, 8H, $(CH_2)_2CH_3$), 1.54 (m, 4H, $SnCH_2$). ^{119}Sn NMR ($CDCl_3$): δ −160. IR (KBr, cm^{-1}): 2959, 2928, 2857 (νCH), 660 (νSn–O–Sn). *Anal.* Calc. for $C_{16}H_{36}OF_2Sn_2$: C, 36.78; H, 6.89. Found: C, 36.60; H, 6.75%.

3.2.3. [Bu$_2$Sn(OAc)]$_2$O

Yield: (51%), m.p. 52–53 °C (Lit. 54 °C). ^{1}H NMR ($CDCl_3$): δ 1.89 (s, 3H, OAc), 0.86 (t, 6H, CH_3), 1.30 (m, 8H, $(CH_2)_2CH_3$), 1.57 (m, 4H, $SnCH_2$). ^{119}Sn NMR ($CDCl_3$): δ −215, −226. IR (KBr, cm^{-1}): 2961, 2926, 2870 (νCH), 1636, 1559 ($\nu_a CO_2$), 1372 ($\nu_s CO_2$), 639 (νSn–O–Sn). *Anal.* Calc. for $C_{20}H_{42}O_5Sn_2$: C, 39.86; H, 6.97. Found: C, 39.60; H, 6.74%.

3.3. Reactions of (hydroxy)di-n-butyltin methanesulfonate (**1b**) with RLi (R = n-Bu, Ph)

To a stirred solution of **1b** (0.75 g, 2.16 mmol) in diethyl ether (~75 ml) was added *n*-BuLi (3.45 ml, 1.6 M/hexane, 2.16 mmol) or MeLi (2.16 ml, 1.0 M/THF, 2.16 mmol) at 25 °C. The reaction mixture was stirred for 12 h and subsequently hydrolyzed by 25 ml of water. The organic layer was extracted in each case and kept on anhydrous sodium sulfate. Evaporation of solvent ether

gave $(Bu_3Sn)_2O$ or $(Bu_2Me)_2SnO$ as colorless viscous liquids.

3.3.1. $(Bu_3Sn)_2O$

Yield: (55%): b.p. 205–210 °C/10 mm (Lit. 210–214 °C/10 mm). ^{1}H NMR ($CDCl_3$): δ 0.90 (t, 6H, CH_3), 1.37 (m, 8H, $(CH_2)_2CH_3$), 1.65 (m, 4H, $SnCH_2$). ^{119}Sn NMR ($CDCl_3$): δ 85.6. IR (KBr, cm^{-1}): 2961, 2926, 2870 (νCH), 689 (νSn–O–Sn). *Anal.* Calc. for $C_{24}H_{54}OSn_2$: C, 48.16; H, 9.03. Found: C, 47.95; H, 9.21%.

3.3.2. $(Bu_2MeSn)_2O$

Yield: (50%): b.p. 180–185 °C/10 mm. ^{1}H NMR ($CDCl_3$): δ 0.91 (t, 6H, CH_3), 1.40 (m, 8H, $(CH_2)_2CH_3$), 1.71 (m, 4H, $SnCH_2$), 1.85 (s, 3H, $SnCH_3$). ^{119}Sn NMR ($CDCl_3$): δ 95.0. IR (KBr, cm^{-1}): 2963, 2927, 289 (CH), 680 (νSn–O–Sn). *Anal.* Calc. for $C_{18}H_{42}OSn_2$: C, 42.02; H, 8.17. Found: C, 42.11; H, 8.10%.

3.4. X-ray crystallography

A colorless, block shaped crystal was mounted along with the largest dimension and data were collected on a Bruker SMART APEX diffractometer equipped with a molybdenum sealed tube and a highly oriented graphite monochromator. There were no systematic absences in the data, therefore space group $P\bar{1}$ was assumed and later confirmed by successful refinement of the structure. The structure was solved by direct methods using SHELXTL-PC [18,19]. All non-hydrogen atoms were refined anisotropically by the full matrix least-square method. The function was minimized to $\sum w(\|F_o\| - \|F_c\|)^2$. Hydrogen atoms were included in the ideal position with fixed isotropic U values equal to 1.2 times that of the atom they are attached to. A weighting scheme of the form $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ with $a = 0.1185$ and $b = 0.00$ was used. (P is defined as $\max(F_o^2, 0) + 2F_c^2/3$.) An extinction correction was also applied. The refinement converged to the R indices given in Table 1. All calculations were done on an IBM compatible PC using Windows-NT operating system.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 204117 for compound **2b**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EC, UK (Fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Effect of free and chelating phosphine coordination environments on the NiS_2P_2 chromophore: synthesis, NMR and other spectral studies. Crystal and molecular structures of (*N*,*N*-dipropyldithiocarbamato)di(triphenylphosphine)nickel(II) perchlorate and (*N*,*N*-dipropyldithiocarbamato)1,2-bis((diphenylphosphino)ethane)nickel(II) tetraphenylborate

Abstract

Planar $[Ni(dnpdtc)(PPh_3)_2]$ $ClO_4 \cdot PPh_3$ (**1**) and $[Ni(dnpdtc)(dppe)]BPh_4 \cdot H_2O$ (**2**) (dnpdtc = *N*,*N*-dipropyldithiocarbamate, dppe = 1,2-bis(diphenylphosphino)ethane) complexes were prepared and characterized by elemental analysis, electronic, IR and NMR spectra and their structures were determined by single crystal X-ray crystallography. Both the complexes were diamagnetic. IR spectra of the two compounds show isobidentate coordination of the dithiocarbamate moiety. The important stretching mode characteristic of the thioureide bond occurs at 1536 and 1526 cm^{-1} for **1** and **2**, respectively. The BVS data support the highly covalent nature of the Ni–S interaction. NMR spectra of the complexes show very large (~20 ppm) ^{31}P chemical shifts in both compounds. The most important $N^{13}CS_2$ chemical shifts appear at 199.17 and 201.88 ppm for **1** and **2**, respectively. Structural implications are very large for **2** compared to **1** when free phosphines are replaced by chelating dppe with the P–Ni–P angle shrinking to approximately 12°.

1. Introduction

Divalent nickel complexes of dithiocarbamates with different substituents contain planar diamagnetic MS_4 chromophores. Ni(II)dithiocarbamates are borderline acceptors and they prefer to react with soft Lewis bases such as phosphines and hard bases such as nitrogenous ligands [1,2]. The symbiotically induced softness and the electronic effects of the substitutents on the dithiocarbamate ligands were found to be important in deciding the reactivity [3,4]. On reaction with phosphines, they form complexes with a NiS_2P_2 chromophore which are again planar and diamagnetic in nature [5–7]. Synthetic and structural studies on $[Ni(dtc)Cl(PPh_3)]$ and $[Ni(dtc)(PPh_3)_2]ClO_4$ complexes, where dtc = $S_2CN(C_2H_5)_2$, $S_2CNH(C_2H_4OH)$, $S_2CN(C_2H_4OH)_2$, $S_2CN(C_4H_8O)$, $S_2CN(C_5H_{10})$ have been reported from our laboratory [8]. The effect of alkyl substitutents in the metal dithiocarbamates have been investigated earlier [9]. In order to understand the influence of free and chelating phosphines on the NiS_2P_2 chromophore and on the thioureide C–N bond, in this paper, we report the synthesis, spectral and structural characterization of two new complexes, $[Ni(dnpdtc)(PPh_3)_2]ClO_4 \cdot PPh_3$ (**1**), and $[Ni(dnpdtc)(dppe)]BPh_4$ (**2**) where, dnpdtc = *N*,*N*-dipropyldithiocarbamate.

2. Experimental

All the reagents and solvents employed were commercially available analytical grade materials and were used as supplied, without further purification. IR spectra were recorded on an ABB Bomem MB 104 spectrophotometer (range 4000–400 cm^{-1}) as KBr pellets. The UV–vis spectra were recorded in CH_2Cl_2 on a U-2001 spectrophotometer. NMR spectra were recorded on a Bruker AMX 400 spectrometer at room temperature, using $CDCl_3$ as solvent.

2.1. Preparation of complexes

2.1.1. Bis(triphenylphosphine)(N,N-dipropyldithiocarbamato)nickel(II) perchlorate

*2.1.1.1. [Ni(dnpdtc)(PPh$_3$)$_2$]ClO$_4$ (**1**).* A mixture of $Ni(dnpdtc)_2$ (210 mg, 0.5 mmo1), PPh_3(520 mg, 2 mmol), $NiCl_2 \cdot 6H_2O$ (120 mg, 0.5 mmol) and NH_4ClO_4 (115 mg, 1 mmol) was refluxed for about 2 h in methanol–dichloromethane solvent mixture (50:50, 50 cm^3), and was then concentrated to ca. 25 cm^3. The purple-red solution obtained was filtered and was left for evaporation. The fine single crystals suitable for X-ray structural analysis were obtained by repeated recrystallization from the same solvent mixture (yield 60%, 520 mg, dec. 178 °C). *Anal.* Calc. for $C_{61}H_{59}ClNNiO_4P_3S_2$: C, 65.34; H, 5.30; N, 1.25. Found: C, 65.12; H, 5.14; N, 1.17%.

2.1.2. 1,2-Bis((diphenylphosphino)ethane)(N,N-dipropyldithiocarbamato)nickel(II) tetraphenylborate

*2.1.2.1. [Ni(dnpdtc)(dppe)]BPh$_4$ · H$_2$O (**2**).* A mixture of $Ni(dnpdtc)_2$ (420 mg, 1 mmol), dppe (790 mg, 2 mmol), $NiCl_2 \cdot 6H_2O$ (240 mg, 1 mmol) and $NaBPh_4$ (680 mg, 2 mmol) was refluxed for about 3 h in methanol–dichloromethane solvent mixture (50:50, 50 cm^3). The solution was then concentrated to ca. 25 cm^3. The purple-red solution obtained was filtered and was kept for evaporation. After 2 days a purple-red coloured solid separated out and was recrystallized from methanol–dichloromethane mixture. Single crystals suitable for X-ray structural analysis were obtained by repeated recrystallization from the same solvent mixture (yield 65%, 1.2 g, dec. 182 °C). *Anal.* Calc. for $C_{57}H_{58}BNNiOP_2S_2$: C, 70.67; H, 6.03; N, 1.44. Found: C, 70.12; H, 5.97; N, 1.32%.

2.2. X-ray crystallography

Details of the crystal data, data collection and refinement parameters for **1** and **2** are summarized in Table 1. Intensity data were collected at ambient temperature (295 K) on Philips PW 100 (for **1**) and SMART

AXS (for **2**) diffractometers using graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). Lorentz and polarization corrections were applied. The structures were solved by direct methods using SHELXS-97 [10] and were refined by SHELXL-97 [11]. All the non-hydrogen atoms were refined anisotropically and all the hydrogen atoms were refined isotropically. Selected bond lengths and bond angles are given in Table 2.

3. Results and discussion

3.1. IR spectral studies

The IR spectrum of **1** shows the thioureide ν_{C-N} band at 1536 cm^{-1} and that of compound **2** at 1526 cm^{-1}. The mesomeric shift of electrons from the dithiocarbamate moiety towards the metal centre increases the contribution of the polar thioureide form in both the cases. This is reflected in the shift in ν_{C-N} values to higher wave numbers compared with that observed in the parent complex at 1508 cm^{-1}. The ν_{C-S} band appears at 1091 cm^{-1} for **1** and 999 cm^{-1} for **2** without any splitting, supporting the bidentate coordination of the dithiocarbamate moiety [12].

3.2. NMR spectral studies

NMR spectra were recorded at room temperature using TMS as an internal reference. For all the compounds $CDCl_3$ was used as solvent. The ^{13}C NMR spectra were recorded in the proton decoupled mode. The ^{1}H, ^{13}C and ^{31}P NMR chemical shift values are given in Table 3 with splitting patterns.

Table 3
NMR spectral data (chemical shift values in ppm)

Compound	NMR	PPh_x	BPh_4	CH_3	β-CH_2	α-CH_2	–PCH_2CH_2P–	$S_2^{13}CN$
1	^{1}H	7.20–7.60(m)		0.81(t)	1.61(m)	3.50(t)		
	^{13}C	128–137		11.06	20.70	51.13		199.17
	^{31}P	31.0						
2	^{1}H	7.10–7.60(m)	6.7–6.9	0.88(t)	1.62(m)	3.49(t)	1.91(t)	
	^{13}C	121–136	163–165	11.12	20.71	51.27	25.80	201.88
	^{31}P						60.80	

Where $x = 3$ for compound **1** and 2 for compound **2**.

3.2.1. ^{1}H NMR

For compound **1**, the methyl group protons resonate at 0.81 ppm as a triplet. The methylene protons were observed at 1.61 and 3.50 ppm. Of these two signals, the triplet at 3.50 ppm was assigned to α-CH_2 protons and the multiplet at 1.61 ppm was assigned to β-CH_2 protons. A multiplet in the region of 7.20–7.60 ppm was due to aromatic protons. For compound **2**, apart from the propyl group signals (the splitting pattern was the same as observed for compound **1**), a triplet in the upfield region of 1.91 ppm was assigned to methylene protons present in the chelating phosphine. In the downfield region, two sets of signals were obtained for aromatic protons of PPh_3 and BPh_4.

3.2.2. ^{13}C NMR

The chemical shifts of thioureide carbon (N–$^{13}CS_2$) were observed at 199.17 and 201.88 ppm for complexes **1** and **2**, respectively. The slight upfield shift from the normal chemical shift values of $Ni(dtc)_2$ complexes (206–210 ppm) [13] is supported by the higher ν_{C-N} values observed for complexes **1** and **2** in the present study. This was due to the mesomeric shift of electron density from the dithiocarbamate moiety towards the metal centre. This supports the bidentate coordination of the dithiocarbamate and the strong back bonding in both the compounds. For compound **2**, the low intensity signals in the region of 163–165 ppm were due to BPh_4 aromatic carbons.

3.2.3. ^{31}P NMR

^{31}P NMR for compound **1** shows a signal at 31 ppm and is assigned to coordinated phosphorus. The free PPh_3 phosphorus resonates at the more upfield region of −5.8 ppm. For compound **2**, the signal at 60.8 ppm is assigned to the phosphorus of the chelating phosphine [14]. The very high deshielding for the coordinated phosphorus in both the cases compared with the free phosphines indicates the drift of electron density from the phosphorus towards the metal centre. The shift is phenomenal with the free dppe chemical shift being observed at 40 ppm [15].

3.3. BVS calculations

For the two complexes, BVS values were calculated by two procedures [16,17]. The values are 3.0646 (B/OK), 2.9338 (OK/B); 3.2629 (B/OK), 3.1602 (OK/B) for the two complexes **1** and **2**, respectively. In both the complexes, the values are higher than the expected formal oxidation state of +2. The higher value observed in the present set of compounds supports the fact that the Ni–S, Ni–P bonds are more covalent and the back bonding effects are very highly pronounced [18].

3.4. Structural analysis

The ORTEP diagram of **1** is shown in Fig. 1. Two units of $[Ni(dnpdtc)(PPh_3)_2]ClO_4 \cdot PPh_3$ are present in the unit cell. It is interesting to note that a free triphenylphosphine molecule is also present along with the complex in the unit cell. The NiS_2P_2 chromophore is not of perfect square planar geometry because of the small bite angle associated with the dithiocarbamate moiety [78.61(4)°]. The Ni–P distances [2.1919(10) and 2.2253(10) Å] show asymmetry, as reported earlier for similar compounds [8]. The planarity of the molecule is in keeping with the observed diamagnetism of the complex. The asymmetry in the Ni–P distances and the observed large P–Ni–P bond angle is due to the bulkiness of the PPh_3 group. The C–S bond lengths are 1.722(3) and 1.727(4) Å, which are shorter than the single bond length of 1.81 Å and higher than the C=S distance of 1.69 Å. The observed intermediate value between the single and double bond distances indicates a partial double bond character. The short thioureide C–N distance, 1.304(3) Å, indicates that the π electron density is delocalized over the S_2CN moiety and that this bond has a strong double bond character. This is also confirmed by the fact that the two S–C–N angles are much greater than that of the S–C–S (108.60(14)°) angle.

There is a shortening of the Ni–P distances for the *N*,*N*-dipropyl analogue [2.1919(10) and 2.2253(10) Å] compared to its *N*,*N*-diisopropyl analogue [2.215(2) and 2.224(3) Å] [19]. Also, the S–Ni–S angle decreases in the *N*,*N*-diisopropyl compound [77.7(1) Å] compared to that in the *N*,*N*-dipropyldithiocarbamate analogue [78.61(4) Å] indicating a reduced steric requirement of the isopropyl compound. In $[Ni(dnpdtc)(PPh_3)_2]ClO_4$

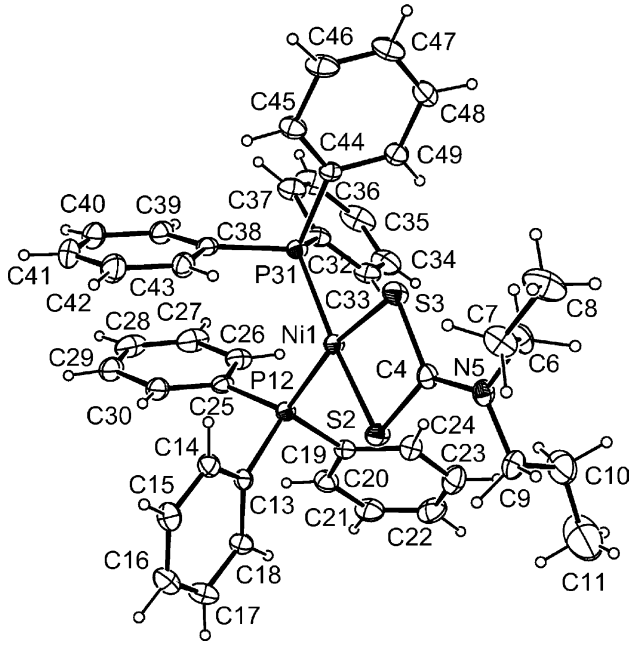

Fig. 1. ORTEP diagram for compound **1** (PPh_3 is omitted for clarity).

(**1**) the thioureide C–N distance is 1.304(3) Å and in $[Ni(dipdtc)(PPh_3)_2]ClO_4$ it is 1.321(11) Å, the observed reduction of the thioureide distance in **1** shows the effective π back bonding of the phosphines in **1**. The Cl–O distances vary from 1.340 to 1.421 Å and the O–Cl–O angles vary from 107.8° to 112.5° in **1** indicating the distortion from tetrahedral geometry. The phenyl rings show normal bond parameters. The P–C bond distances are also normal with an average value of 1.8286 Å. The C–P–C angles deviate appreciably from the ideal tetrahedral angle of 109.5° and the resultant crowding of the phenyl rings causes the P–C–C angles to be asymmetric.

$[Ni(dnpdtc)(dppe)]BPh_4$ (**2**) is monomeric with two molecules per unit cell. The ORTEP diagram of the molecule is shown in Fig. 2. The molecule is approximately planar, in keeping with the observed diamagnetism. The Ni–S [2.1931(8) and 2.2108(9) Å] and C–S [1.718(3) and 1.715(3) Å] bonds are symmetric, showing that the negative charge on the dithiocarbamate ligand is equally distributed all over the two donor atoms as found in **1**. One molecule of water is found in the unit cell. The short thioureide C–N distance of 1.314(4) Å indicates that the electron density is delocalized over the S_2CN moiety and this bond has partial double bond character. The bond lengths and bond angles of $[Ni(dipdtc)(dppe)]^+$ reported from our laboratory [19] show a similarity in thioureide C–N distance [(1.314(4) Å] in **2**, and 1.316(8) Å in $[Ni(dipdtc)(dppe)]^+$). The *N*,*N*-dipropyl complexes (**1**) and (**2**) exhibit a relatively larger steric influence compared to the diisopropyl analogue. In **2**, the P–Ni–P angle is 86.50(3)° which is smaller than that in the diisopropyl analogue: 87.3(1)°.

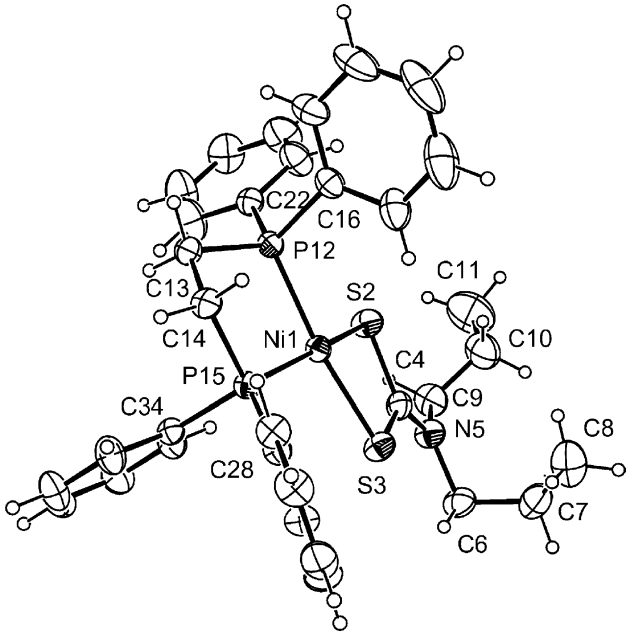

Fig. 2. ORTEP diagram for compound **2** (BPh_4 and H_2O are omitted for clarity).

Comparison of **1** and **2** shows that S–Ni–S bite angles [78.61(4)° versus 79.49(3)°] and the Ni–S–C angles [85.625° versus 84.995°] are very similar. On the other hand, a significant difference is observed in the P–Ni–P angles that are subtended by dppe, a bidentate ligand, being about 12° smaller than that found in **1**, where the PPh_3 groups exert higher steric hindrance. Thus, the P–Ni–P angles show a large change and are influenced by the bulkiness of the nature of the phosphines. The thioureide C–N bond is **1** is shorter than the bond in **2**. The significant shortening is a clear manifestation of mesomeric shift of electron density towards nickel through the thioureide C–N bond in **1** compared to **2**. Though the Ni–P bonds in **2** are relatively shorter than those in **1**, the back bonding effects are felt more pronounced in **1** and hence the corresponding thioureide bond shows a shortening of its length. As a result of the reduced P–Ni–P chelated angle in **2**, the S–Ni–S angle increases by 0.49° compared to **1**. Hence, both electronic and steric influences of dppe over PPh_3 are exemplified by compound **2** with respect to the compound **1**.

4. Supplementary data

Received 16 July 2003; accepted 10 September 2003

Abstract

The preparation and crystal structures of four Mn^{II} carboxylate complexes containing 2-pyridinealdoxime, (py)CHNOH, are reported. The 1:1 reaction between $Mn(O_2CPh)_2 \cdot 2H_2O$ and (py)CHNOH in MeCN, followed by evaporation of the resulting solution, redissolution of the residue in $CHCl_3$ and precipitation with Et_2O leads to isolation of $[Mn_4(O_2CPh)_6\{(py)CO_2\}_2\{(py)CHNOH\}_2] \cdot 0.6CHCl_3$ (**1** · 0.6$CHCl_3$). The most interesting synthetic feature is the in situ formation of the picolinate(−1) ligand, $(py)CO_2^-$. The centrosymmetric tetranuclear cluster consists of an exactly planar zig-zag array of Mn^{II} ions and is held together by four *syn*, *syn* $\eta^1{:}\eta^2{:}\mu_2$ and two $\eta^1{:}\eta^2{:}\mu_3$ $PhCO_2^-$ groups, two $\eta^1{:}\eta^2{:}\mu_2$ $(py)CO_2^-$ ligands and two *N*,*N*′-bidentate chelating (py)CHNOH molecules. The 1:4:7 $[Mn_3^{II,III,III}O(O_2CPh)_6(pyr)_2(H_2O)]$/$Me_3SiCl$/(py)CHNOH reaction mixture in MeCN (pyr = pyridine) yields the 1D coordination polymer $[Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}]_n$ (**2**), in which the partial (py)CHNOH → $(py)CO_2^-$ transformation has again occurred. In each chain the Mn^{II} ions are bridged by *syn*, *anti* carboxylate groups of the $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ $(py)CO_2^-$ ligands, while the monodentate $PhCO_2^-$ group and the *N*,*N*′-bidentate chelating (py)CHNOH molecule complete the octahedral coordination at each metal ion. The 1:3 reaction between $Mn(O_2CMe)_2 \cdot 4H_2O$ and (py)CHNOH in EtOH leads to the isolation of the dinuclear complex $[Mn_2(O_2CMe)_2\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ (**3**); crystallography reveals again the partial (py)CHNOH → $(py)CO_2^-$ transformation. The dinuclear molecule is located at a centre of symmetry; the Mn^{II} ions are bridged by two oxygen atoms from the two symmetry-related $\eta^1{:}\eta^1{:}\mu_2$ $(py)CO_2^-$ ligands, whose nitrogen atoms are ligated to different metal ions. Each Mn^{II} ion is further coordinated by a monodentate $MeCO_2^-$ group and a *N*,*N*′-bidentate chelating (py)CHNOH molecule. Reaction of $Mn(hfac)_2 \cdot 3H_2O$ (hfacH = hexafluoroacetylacetone) with 1 equivalent of (py)CHNOH in CH_2Cl_2 yields complex $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$ (**4**); the $CF_3CO_2^-$ ligand is one of the decomposition products of the $hfac^-$ ligand. The Mn^{II} ion in **4** is coordinated by two monodentate $CF_3CO_2^-$ groups and two *N*,*N*′-bidentate chelating (py)CHNOH ligands in a *cis–cis–trans* fashion. The four complexes have been characterised by IR spectroscopy; characteristic bands are discussed in terms of the known structures and the coordination modes of the ligands. Variable-temperature magnetic susceptibility and EPR studies indicate weak antiferromagnetic exchange interactions in **1**.

1. Introduction

Manganese carboxylate chemistry is of great current interest from several viewpoints, including bioinorganic chemistry and molecular magnetism. In the former area,

☆ This work is dedicated to the memory of our young inorganic chemistry colleague Spyridoula Kasselouri.

small Mn carboxylate clusters are found at the active sites of a variety of metallobiomolecules [1]; for example, the water oxidising complex (WOC) of photosystem II contains a tetranuclear Mn carboxylate cluster whose structure and mechanism of function have not yet been fully elucidated [2]. Thus, synthetic Mn_4 molecular clusters have been sought as models of the WOC [3–5]. Most of these have many structural/physical/spectroscopic properties similar to those of the WOC, but no synthetic species currently seems to reproduce the properties (especially the functional ones) of the catalytic active site in all ways. In the molecular magnetism arena, it has been discovered that some Mn carboxylates clusters can function as single-domain nanomagnets at very low temperatures [6–9]. These complexes have been called single-molecule magnets (SMMs) to reflect the fact that their magnetic properties are due to a combination of two intramolecular properties (and not to intermolecular exchange interactions and long-range ordering), namely a high-spin ground state and a large magnetoanisotropy, the latter reflected in a large and negative value of the zero-field splitting parameter, D [6,7]. Several groups, including our group [10–12], are actively developing methods to high-nuclearity, high-spin Mn molecular species that might be new SMMs.

There is currently a renewed interest in the coordination chemistry of oximes [13,14]. These efforts are driven by a number of considerations, including the solution of pure chemical problems [15–19], the desire to provide useful bioinorganic models (oximes may be considered to be reasonable models for the biologically important imidazole donor group of the amino acid histidine) [20], the development of new oxygen activation catalysts [21], the application of metal/oxime systems as simple and efficient catalysts for the hydrolysis of organonitriles [22], the mechanistic study of corrosion inhibition by Acorga P5000 (a modern corrosion inhibitor) on iron surfaces [23] and the employment of oximate ligands in the synthesis of homometallic [10–12,24] and heterometallic [25] clusters with interesting magnetic properties. For example, the pure chemical interest in the coordination chemistry of oximes arises from the ability of the oximate(−1) group (–C=N–O$^-$) to stabilise higher oxidation states of metals, e.g. Ni^{III} or Ni^{IV} [26,27], and the fact that the activation of oximes by transition metal centres towards further reactions seems to be an emergent area of modern synthetic chemistry [13,14]. In contrast to the great number of studies concerning metal complexes of simple oximes and salicylaldoxime [12,15–19,23–25], very little is known about complexes of pyridyloximes [28], although this class of compounds could offer unique features in terms of structural and physical properties.

We have recently embarked on a programme aiming at the amalgamation of the above two areas, namely the use of pyridyloxime ligands in manganese carboxylate cluster chemistry, in order to explore the influence of the ligands on the cluster identity; the main objectives are the access to new structural types of clusters with interesting magnetic properties and the study of Mn-mediated reactions of the oxime group. Reaction schemes involving di-2-pyridyl ketone oxime, $(py)_2CNOH$ (Fig. 1), and various Mn carboxylate sources in the presence of X^- led [11] to the new family of valence-trapped, mixed-valent complexes $[Mn_2^{II}Mn_2^{III}(O_2CR)_2X_2\{(py)_2CNO\}_2\{(py)_2CO_2\}_2]$(X = Cl,Br;$(py)_2CO_2^{2-}$ = the *gem*-diolate(−2) form of di-2-pyridyl ketone); it has been of great interest that an appreciable quantity of the oxime ligand undergoes transformation to yield the coordinated dianion of the *gem*-diol form of di-2-pyridyl ketone. The mechanism of this transformation probably involves reaction(s) of the electrophilically activated coordinated oxime group [11]. The use of phenyl 2-pyridyl ketone oxime, (ph)(py)CNOH (Fig. 1), in Mn carboxylate chemistry has yielded [10] the novel clusters $[Mn_4^{II}Mn_4^{III}O_2(OH)_2(O_2CR)_{10}\{(ph)(py)CNO\}_4]$; the core of these complexes has a unique topology consisting of two linked $\{Mn_2^{II}Mn_2^{III}(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ units. The above prior results with 2-pyridyloximes encouraged us to proceed to the use of 2-pyridinealdoxime ((py)CHNOH, Fig. 1) to Mn carboxylate chemistry, and we have thus been exploring the reactions of (py)CHNOH with suitable Mn starting materials. The results of this investigation are reported here. It is worth mentioning that (py)CHNOH has been used only sparingly in Mn chemistry to date. The only known compounds comprise two heterometallic complexes and one homometallic coordination polymer. The chain $[Mn_2^{III}(saltmen)_2Ni\{(py)CHNO\}_2(pyr)_2]_n(ClO_4)_{2n}$ (saltmen^{2-} = *N*,*N*′-(1,1,2,2-tetramethylethylene) bis(salicylideneiminate)) shows evidence for single-chain magnet behaviour; the 2-pyridinealdoximate(−1) ligand in this 1D complex bridges two adjacent Mn^{III} and Ni^{II} ions [29]. The dinuclear complex $[LCr^{III}\{(py)CHNO\}_3Mn^{II}](ClO_4)_2$, where L is 1,4,7-trimethyl-1,4,7-triazacyclononane, is composed of two pseudooctahedral

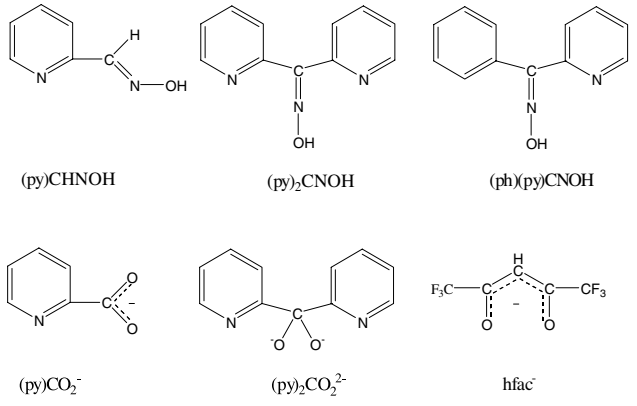

Fig. 1. Some of the ligands discussed in the text; note that (py) $_2CO_2^{2-}$ does not exist as a free species but exists only in its metal complexes.

polyhedra which are joined by three oximato (=N–O$^-$) groups [30]. Complex $[Mn(SO_4)\{(py)CHN\,OH\}(H_2O)]_n$ is a double-chain polymer in which the Mn^{II} ions are bridged by μ_3-SO_4^{2-} ligands [31].

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. $Mn(O_2CPh)_2 \cdot 2H_2O$ [32] and $[Mn_3O(O_2CPh)_6(pyr)_2(H_2O)]$ [33] were prepared as described elsewhere.

Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyser. IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT spectrometer with samples prepared as KBr pellets. Magnetic susceptibility measurements were carried out for a polycrystalline sample of complex **1** (vide infra) in the range 2–300 K using a SQUID susceptometer; the applied magnetic field was 0.1 T. Diamagnetic corrections were applied to the observed paramagnetic susceptibilities using Pascal's constants. Solid-state EPR spectra in the 77–300 K temperature range were recorded on a Bruker ES200 spectrometer at X-band frequency.

2.2. Compound preparation

2.2.1. $[Mn_4(O_2CPh)_6\{(py)CO_2\}_2\{(py)CHNOH\}_2] \cdot 0.6CHCl_3$ (**1** $\cdot$ 0.6$CHCl_3$)

A colourless solution of $Mn(O_2CPh)_2 \cdot 2H_2O$ (0.33 g, 1.0 mmol) in MeCN (20 ml) was treated with solid (py)CHNOH (0.12 g, 1.0 mmol). The solid soon dissolved. The resulting yellow solution was evaporated under reduced pressure, and the residue redissolved in $CHCl_3$ (20 ml) to give an orange solution. This was layered with Et_2O (40 ml). After several days, large yellow prisms were formed; they were collected by filtration, washed with Et_2O and dried in air. Yield: 72% (based on total Mn). The dried sample analysed as solvent-free. *Anal*. Calc. for $C_{66}H_{50}N_6O_{18}Mn_4$: C, 55.2; H, 3.5; N, 5.9. Found: C, 55.4; H, 3.4; N, 6.0%. Selected IR data (KBr pellet, cm^{-1}): 3446mb, 3020w, 2926w, 1602s, 1555sh, 1544s, 1476w, 1404s, 1068w, 1024m, 776w, 720s, 674m.

2.2.2. $[Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}]_n$ (**2**)

To a stirred deep brown solution of $[Mn_3O(O_2CPh)_6(pyr)_2(H_2O)]$ (0.34 g, 0.3 mmol) in MeCN (30 ml) was added Me_3SiCl (0.16 ml, 1.2 mmol) dropwise to give a solution of essentially the same colour. No immediate precipitate was observed, but slow formation of a dark brown solid began soon after. When precipitation was judged complete (2–3 h), the powder was removed by filtration. The filtrate was treated with (py)CHNOH (0.24 g, 2.0 mmol) under reflux. The dark brown–green solution slowly faded to orange over the course of 1 h. The homogeneous orange solution was layered with Et_2O (60 ml). Slow mixing yielded orange crystals of X-ray quality, which were collected by filtration, washed with Et_2O and dried in air. Yield: 43% (based on total Mn). *Anal.* Calc. for $C_{19}H_{15}N_3O_5Mn$: C, 54.3; H, 3.6; N, 10.0. Found: C, 54,1; H, 3.7; N, 10.2%. Selected IR data (KBr pellet, cm^{-1}): 3442mb, 3064w, 1610m, 1588s, 1564m, 1474w, 1394s, 1332w, 1148w, 1092w, 1054m, 1012w, 918m, 892w, 830w, 782w, 766m, 714m, 674m, 490m.

2.2.3. $[Mn_2(O_2CMe)_2\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ (**3**)

Solid (py)CHNOH (0.09 g, 0.7 mmol) was added to a stirred, colourless solution of $Mn(O_2CMe)_2 \cdot 4H_2O$ (0.06 g, 0.25 mmol) in EtOH (20 ml). The resulting yellow solution was allowed to stand undisturbed at 5 °C for several days. Well-formed, X-ray quality yellow crystals appeared, which were collected by filtration, washed with Et_2O and dried in vacuo over silica gel. Yields as high as 75% were obtained. *Anal.* Calc. for $C_{28}H_{26}N_6O_{10}Mn_2$: C, 46.9; H, 3.7; N, 11.7%. Found: C, 46.5; H 3.7; N, 11.5%. Selected IR data (KBr pellet, cm^{-1}): 3442mb, 1602m, 1548sb, 1478m, 1416s, 1330m, 1308w, 1258w, 1048s, 1010w, 924w, 888w, 782m, 678sh, 668m, 656s, 638w, 618w, 522w, 488w.

2.2.4. $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$ (**4**)

To a pale yellow slurry of $Mn(hfac)_2 \cdot 3H_2O$ (0.47 g, 1.0 mmol) in CH_2Cl_2 (20 ml) was added dropwise a colourless solution of (py)CHNOH (0.12 g, 1.0 mmol) in the same solvent (10 ml). The reaction mixture colour changed slightly from pale yellow to darker yellow. This was stirred for about 10 min, a small quantity of undissolved material removed by filtration and the filtrate layered with *n*-hexane (60 ml). Slow mixing yielded yellow crystals (some of them were of X-ray quality), which were collected by filtration, washed with Et_2O and dried in air. The yield was typically 40%. *Anal.* Calc. for $C_{16}H_{12}N_4O_6F_6Mn$: C, 36.6; H, 2.3; N, 10.7. Found: C, 36.9; H, 2.4; N, 10.5%. Selected IR data (KBr pellet, cm^{-1}): 3428mb, 1668s, 1602m, 1508m, 1448m, 1328m, 1310m, 1206s, 1144s, 1038s, 890m, 840m, 780m, 678w, 640w.

2.3. X-ray crystallographic studies

Crystals of complexes **2**, **3** and **4** were mounted in air, while a crystal of complex **1** $\cdot$ 0.6$CHCl_3$ was mounted in a capillary filled with drops of mother liquid. Diffraction measurements for **1** $\cdot$ 0.6$CHCl_3$, **3** and **4** were made on a Crystal Logic Dual goniometer diffractometer using graphite-monochromated Mo radiation. Data for

complex **2** were collected on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using Ni-filtered Cu radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the ranges $11° < 2\theta < 23°$ (**1** · 0.6$CHCl_3$, **3** and **4**) and $22° < 2\theta < 54°$ (**2**). In all cases, three standard reflections, monitored every 97 reflections, showed less than 3% fluctuation and no decay. Lorentz, polarisation and Ψ-scan absorption (except for **3**) corrections were applied using CRYSTAL LOGIC software.

The structures were solved by direct methods using SHELXS-86 [34] and refined by full-matrix least squares techniques on F^2 with SHELXL-93 [35]. For **2**, **3** and **4**, all hydrogen atoms – except those on the methyl carbon (C(14)) in **3** which were introduced at calculated positions as riding on their bonded atom – were clearly visible in subsequent Fourier maps and refined isotropically. For **1** · 0.6$CHCl_3$, all hydrogen atoms – except HO(11) which was located by difference maps and refined isotropically – were placed in ideal, calculated positions riding on their respective carbon atoms. All non-hydrogen atoms were refined using anisotropic thermal parameters, except those of the solvate $CHCl_3$ molecule in **1** · 0.6$CHCl_3$ which were refined isotropically with occupation factors fixed at 10.3; the fluorine atoms of the $–CF_3$ groups in **4** were found disordered and refined anisotropically over two positions with occupation factors summing one.

3. Results and discussion

3.1. Syntheses

The reaction that we initially investigated was that between $Mn(O_2CPh)_2 \cdot 2H_2O$ and (py)CHNOH. Treatment of a solution of $Mn(O_2CPh)_2 \cdot 2H_2O$ with one equivalent of (py)CHNOH in MeCN, followed by evaporation of the resulting solution, redissolution of the residue in $CHCl_3$ and layering the solution with Et_2O allowed yellow crystals of the product to be obtained in a form suitable for crystallography. The product was identified as the interesting new tetranuclear cluster $[Mn_4(O_2CPh)_6\{(py)CO_2\}_2\{(py)CHNOH\}_2] \cdot 0.6CHCl_3$

($\mathbf{1}\cdot 0.6CHCl_3$). The most remarkable feature of this reaction is the in situ formation of the picolinate(−1) ligand, $(py)CO_2^-$ (Fig. 2). The following experimental points should be mentioned at this point: (a) the 1:1 reaction between $Mn(O_2CPh)_2\cdot 2H_2O$ and (py)CHNOH in MeOH under strictly anaerobic conditions affords a solid, whose analytical data correspond to the formula $Mn(O_2CPh)_2\{(py)CHNOH\}_2$ and IR spectrum confirms the absence of $(py)CO_2^-$. (b) No colour change, indicative of oxidation of Mn^{II} to Mn^{III}, was observed during the preparation/crystallisation of **1**. (c) The partial $(py)CHNOH \rightarrow (py)CO_2^-$ transformation noticed in **1** was also observed in the reactions of other Mn carboxylate sources with (py)CHNOH (vide infra), and (d) analogous reactions of Co^{II} or Ni^{II} carboxylates and the oxime did not give any evidence [36] for the formation of picolinate(−1). The above experimental facts do not provide us with a clear mechanistic view. Without any mechanistic implication, we suggest that the formation of **1** is triggered by hydrolysis of an amount of (py)CHNOH to the corresponding aldehyde, 2-pyridinealdehyde ((py)CHO), followed by oxidation of the latter to picolinic acid, (py)COOH, which is deprotonated by the excess of $PhCO_2^-$s present in the reaction mixture. This simplified transformation scheme is shown in Fig. 2. The difference between regular and metal-mediated conditions lead us to the belief that the transformation is Mn^{II}-assisted and probably involves the reaction of electrophilically activated coordinated oxime group [14,37].

It has been demonstrated that direct hydrolysis of oximes to carbonyl compounds proceeds slowly in low yields and is subject to side reactions [13,14]. Attanasi et al. [37] have proposed a facile method for this conversion based on copper(II)-assisted hydrolysis, which is not reductive or oxidative in nature but involves the reaction of the electrophilically activated, coordinated oxime group with water. In general, the conversion of oximes into the parent carbonyl compounds requires reductive or oxidative cleavages, strongly basic or acidic media [13,14]. Oximes can be converted to the corresponding aldehydes or ketones by treatment with, among other reagents, microwave irradiation on clay (Clayan), on wet sodium periodate impregnated silica gel or in the presence of $BiCl_3$, $CuCl_2$ in MeCN, aqueous $NaHSO_3$, $KMnO_4$-aqueous MeCN, Amberlyst 15 and acetone, alkaline H_2O_2 and with $Me_3NH^+CrO_3Cl^-$ [38].

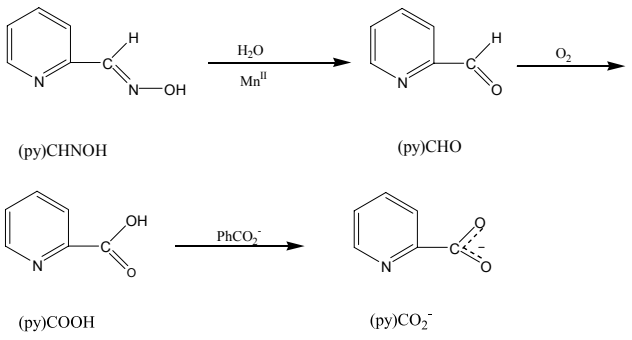

Fig. 2. A simplified view for the partial transformation of 2-pyridinealdoxime to picolinate(−1) during the preparation of complexes **1**–**3**.

Oxidation of aldehydes to carboxylic acids is one of the most common oxidation reactions in organic chemistry [38] and has been carried out with many oxidising agents, the most popular of which is MnO_4^- in acidic, basic or neutral solution. Aldehydes are also oxidised to carboxylic acids by atmospheric oxygen, but the actual direct oxidation product is the peroxy acid RCO_3H ($(py)CO_3H$ in our case), which with another molecule of aldehyde disproportionates to give two molecules of acid ((py)COOH in our case).

Since single-crystal X-ray crystallography (vide infra) revealed the existence of the interesting tetranuclear cluster **1** and the $(py)CHNOH \rightarrow (py)CO_2^-$ transformation, we sought to prepare the acetate analogue of **1**. Our main goals were to determine whether this would be isostructural with the benzoate species and (if they are isostructural) to access any influence of the alkyl vs. aryl difference on magnetochemical properties. A completely analogous reaction scheme with that used for **1** was initially employed, i.e., the 1:1 $Mn(O_2CMe)_2\cdot 4H_2O$/(py)CHNOH mixture in MeCN. This yielded a solid with poor crystallinity. 1:1 reactions of (py)CHNOH with $Mn(O_2CMe)_2\cdot 4H_2O$ in other solvents, including alcohols, have also been carried out, but attempts to crystallographically characterise the products have all been unsuccessful to date. The isolation of the dinuclear product $[Mn_2(O_2CMe)_2\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ (**3**) came about from the employment of excess of (py)CHNOH, i.e., Mn^{II}: (py)CHNOH = 1:2.5–3.0, in EtOH. X-ray crystallography revealed again the partial $(py)CHNOH \rightarrow (py)CO_2^-$ transformation! Since the two systems that lead to **1** and **3** are clearly not analogous, the difference in stoichiometry is not surprising; the $(py)CHNOH + (py)CO_2^-$:Mn^{II} ratio in the formula of **3** is 2:1 (whereas it is 1:1 in **1**), and we attribute this to the excess of (py)CHNOH used in the synthesis of the acetate complex.

With the identity of **3** established, its benzoate version was sought. Note that since only a dinuclear species was being sought, excess of oxime was added. Several 1:2 and 1:3 $Mn(O_2CPh)_2\cdot 2H_2O$/(py)CHNOH reaction mixtures were studied using various conditions, but almost all led to a mixture of **1** and a yet unidentified product. Since the RCO_2^-:Mn^{II} ratio in **1** is higher than that in **3** (1.5:1 vs. 1:1), methods to reduce the benzoate concentration were examined. Use of $MnCl_2\cdot 4H_2O$, $Mn(NO_3)_2\cdot 6H_2O$ or $Mn(ClO_4)_2\cdot 6H_2O$ as starting materials, followed by addition of one equivalent of NaO_2CPh, complicated the reaction mixtures. The carboxylate-abstraction reagent Me_3SiCl [39,40] was our

next choice; this reagent forms the silyl ester as shown in Eq. (1). Treatment of $Mn(O_2CPh)_2 \cdot 2H_2O$ with 2–3 equivalents of

$$Me_3SiCl + RCO_2^- \rightarrow RCO_2SiMe_3 + Cl^- \quad (1)$$

Me_3SiCl and 2–2.5 equivalents of (py)CHNOH in alcohols or MeCN gave orange powders whose analytical data were consistent with the formulation $Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}$. The rather low solubility and platelike crystallinity of the material precluded a crystallographic investigation. Somewhat to our surprise, the preparation and crystallisation of this orange compound were achieved by the reaction of the mixed-valence compound $[Mn_3^{II,III,III}O(O_2CPh)_6\ (pyr)_2(H_2O)]$ [33] with 4 equivalents of Me_3SiCl and ~7 equivalents of (py)CHNOH (Mn:oxime ≈1:2, in fact the actual Mn:oxime ratio is lower, e.g. 1:3, because a small quantity of a dark brown, Mn-containing solid was removed prior to the addition of the oxime) in MeCN. The advantage of the present procedure is its slow crystallisation of product upon layering with Et_2O and the well-formed nature of the resulting crystals that have proven excellent diffractors of X-rays. The product was crystallographically identified as the coordination polymer $[Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}]_n$ (**2**) rather than the expected dinuclear species $[Mn_2(O_2CPh)_2\ \{(py)CO_2\}_2\{(py)CHNOH\}_2]$; note that the partial (py) CH NOH → $(py)CO_2^-$ transformation again occurred. The fading of the reaction solution after the addition of the oxime and the Mn^{II} nature of **2** both require reduction of Mn^{III} to have occurred; the source of the reducing equivalent is probably solvent, solvent impurities or excess ligand, facilitated by the strongly oxidising nature of Mn^{III} [32].

Complex $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$ (**4**) was not prepared from the reaction of a trifluoroacetate-based Mn starting material and (py)CHNOH. However, we have incorporated this compound in the present work because it does contain a carboxylate ligand! Treatment of $Mn(hfac)_2 \cdot 3H_2O$ (hfac = hexafluoroacetylacetonate) with one equivalent of (py)CHNOH in CH_2Cl_2, followed by stirring of the slurry, leads to a yellow solution that can be layered with *n*-hexane to give **4** in 40% yield. Single-crystal X-ray diffraction unambiguously established that this complex contains monodentate $CF_3CO_2^-$ ligands. The origin of the trifluoroacetate ligands is intriguing, and the $hfac^- \rightarrow CF_3CO_2^-$ transformation has been confirmed in at least two cases [41,42]. The $CF_3CO_2^-$ ligand should be one of the decomposition products of the $hfac^-$ ligand (Eq. (2)). β-Diketones have been known to undergo the retro-Claisen condensation reaction to produce a ketone and a carboxylate when strong bases are present. The (py)CHNOH ligand could function as the base to promote the decomposition of the hfacH molecule [41].

$$CF_3COCH_2COCH_3 \xrightarrow{H_2O/base} CF_3CO_2^- + CH_3COCF_3 \quad (2)$$

It has been previously suggested that hfacH reacts with H_2O to form initially a "dihydrate", i.e. $hfacH \cdot 2H_2O$ [43]; however, later rigorous studies by Christou's group demonstrated [44,45] that this reaction is far from simple. These latter researchers have demonstrated that hfacH reacts with H_2O to yield the tetraol $F_3CC(OH)_2CH_2C(OH)_2CF_3$, which can act as ligand in transition metal chemistry at various degrees of deprotonation. Ultimately, the pH of the reaction solution seems to have a profound effect on the nature of the product and how the $hfac^-$ ligand is cleaved [42].

3.2. Description of structures

Selected interatomic distances and angles for complexes **1** · 0.6$CHCl_3$, **2**, **3** and **4** are listed in Tables 2–5, respectively.

Complex **1** · 0.6$CHCl_3$ crystallises in monoclinic space group $P2_1/n$. Its structure consists of the tetranuclear $[Mn_4(O_2CPh)_6\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ species (Fig. 3) and lattice $CHCl_3$ molecules; the latter will not be further discussed. The tetranuclear molecule lies on a crystallographic inversion centre, resulting in an exactly planar zig-zag array of Mn^{II} atoms. The bridging system comprises four *syn*,*syn* $\eta^1:\eta^1:\mu_2$ $PhCO_2^-$ groups, two $\eta^1:\eta^2:\mu_3$ $PhCO_2^-$ groups (those containing atoms O(41), O(42) and O(41′), O(42′)) and two $\eta^1:\eta^1:\mu_2$ picolinate(−1) ligands. Each outer metal ion (Mn(1), Mn(1′)) is chelated by a single (py)CHNOH molecule bound in a *N*,*N*′-bidentate fashion and forming a five-membered ring. Atoms Mn(1) and Mn(2) are bridged by one $\eta^1:\eta^1:\mu_2$ $PhCO_2^-$ group, the "triatomic" part of one $\eta^1:\eta^2:\mu_3$ $PhCO_2^-$ group and one $\eta^1:\eta^2:\mu_2$ $(py)CO_2^-$ ligand, while two oxygen atoms (O(42), O(42′)) from the $\eta^1:\eta^2:\mu_3$ $PhCO_2^-$ ligand and its symmetry partner doubly bridge atoms Mn(2) and Mn(2′). The Mn(1)···Mn(2′) pair is bridged by one $\eta^1:\eta^1:\mu_2$ $PhCO_2^-$ group and the "triatomic" part of the same μ_3 benzoate that bridges Mn(1) and Mn(2). The central Mn(2)O(42)Mn(2′)O(42′) core is strictly planar due to the presence of the inversion centre in the middle of the core, with an Mn(2)–O(42)–Mn(2′) angle of 103.1(1)° and a Mn(2)···Mn(2′) separation of 3.460(2) Å. This separation is shorter than the Mn(1)···Mn(2) (3.557(2) Å) and Mn(1)···Mn(2′) (4.522(2) Å) separations presumably due to the greater number (two) of monoatomic bridges.

The Mn^{II} atoms are octahedrally coordinated, their chromophores being *cis*-$Mn(1)N_2O_4$ and $Mn(2)NO_5$. Both polyhedra are distorted; the main distortions arise from the chelating rings with the narrow N(11)–Mn(1)–N(12) (69.8(2)°) and O(1)–Mn(2)–N(1) (74.1(1)°) bond

angles. The Mn–N and Mn–O bond lengths agree well with values expected for high-spin Mn^{II} [30,31,46–50]. The bridging Mn–$O_{picolinate}$ distances are symmetric (2.224(3), 2.233(3) Å), whereas the analogous Mn–$O_{benzoate}$ distances are asymmetric (2.140(3), 2.278(3) Å). The two bridging oxygens are essentially planar ($\Sigma^{o}O(1)=357.5°$, $\Sigma^{o}O(42)=355.7°$). An intramolecular hydrogen bond is present in **1**$\cdot 0.6CHCl_3$ with the oxime oxygen, O(11), as donor and the uncoordinated picolinate oxygen, O(2), as acceptor; its dimensions are O(11)···O(2) 2.564 Å, HO(11)···O(2) 1.382 Å and O(11)–HO(11)···O(2) 162.9°.

There is a rather small family of tetranuclear manganese(II) clusters [51–62], which mainly adopt the cubane, planar rhomboidal, zig-zag, adamantane-like and pair-of-dimer topologies. Complex **1** joins a small family of manganese(II) picolinate complexes [47–50] and it is only the second such complex comprising the $(py)CO_2^-$ ligand in the rare $\eta^1{:}\eta^2{:}\mu_2$ coordination mode, the first example being the 2D coordination polymer $[Mn(N_3)\{(py)CO_2\}(H_2O)]_n$ [47].

Views of the structure of complex **2** are shown in Figs. 4 and 5. The compound contains zig-zag chains of repeating $[Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}]$ units.

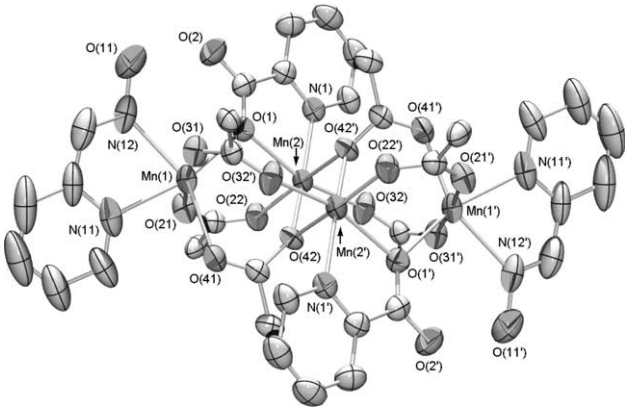

Fig. 3. An ORTEP plot at the 30% probability level of complex $\mathbf{1}\cdot 0.6CHCl_3$. Primed and unprimed atoms are related by the crystallographic inversion centre. Only the *ipso* carbon atoms of the phenyl groups of the benzoate ligands are shown.

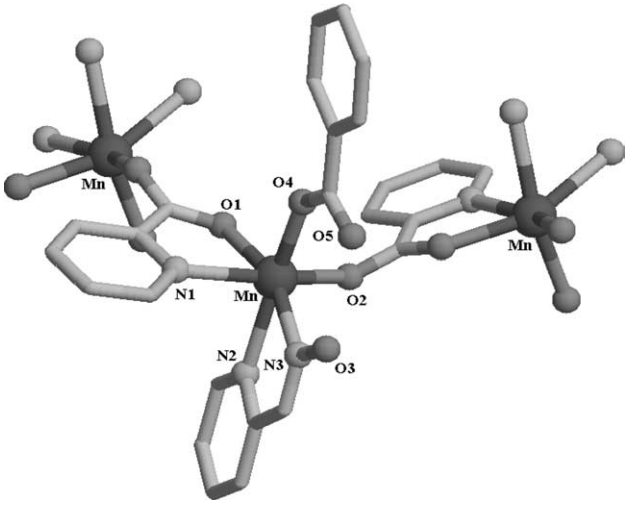

Fig. 4. A very small section of the polymeric chain of complex **2** emphasising the coordination sphere of the Mn^{II} atom.

The polymeric chain extends along the *c* axis of the *Pcab* space group. In each chain the Mn^{II} atoms are bridged by *syn*, *anti* carboxylato groups of the $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ picolinate(−1) ligands. The Mn^{II} atom is octahedrally coordinated to one oxygen atom (O(4)) from the monodentate $PhCO_2^-$ group, two nitrogen atoms (N(2),

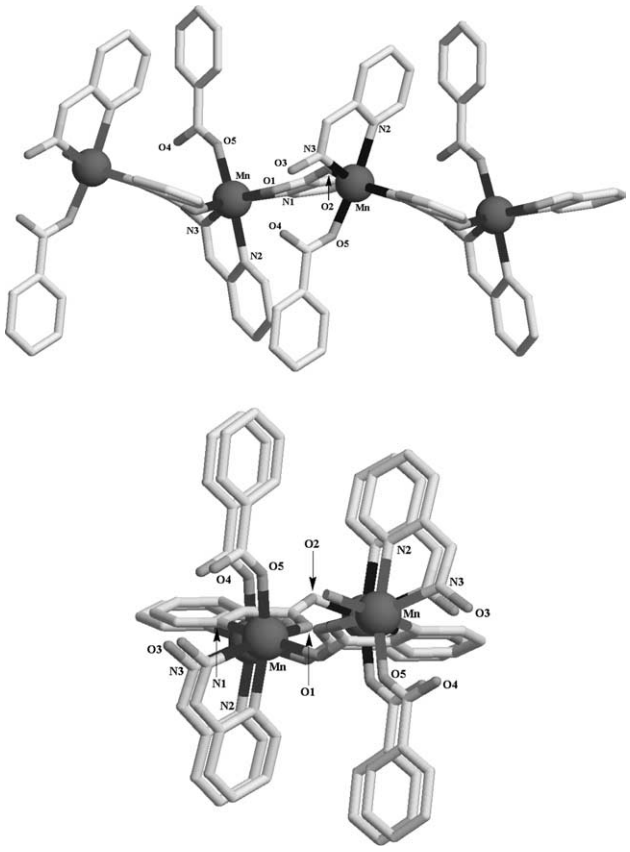

Fig. 5. Views of complex **2** along *b* axis (up) and *c* axis (down).

N(3)) from the chelating neutral 2-pyridinealdoxime molecule, one nitrogen and one oxygen (N(1), O(1)) from a picolinate(−1) ligand and to one oxygen atom (O(2)) from a neighbouring picolinate(−1) ligand; thus, the chromophore is *fac*-MnN_3O_3. The Mn–O and Mn–N bond lengths are in the narrow 2.092(3)–2.168(2) and 2.301(3)–2.324(3) Å ranges, respectively. Inspection of the bond angles listed in Table 3 shows that the octahedral coordination sphere of Mn is distorted. The intrachain Mn···Mn distance is 5.855(1) Å, slightly outside the typical range (5.2–5.8 Å) reported for singly *syn*, *anti* carboxylate-bridged Mn^{II} atoms [63]. A strong intrachain hydrogen bond is present in **2** with the oxime oxygen, O(3), as donor and the uncoordinated benzoate oxygen, O(5), as acceptor; its dimensions are O(3)···O(5) 2.489 Å, HO(3)···O(5) 1.440 Å, O(3)–HO(3)···O(5) 175.9°.

Complex **2** joins a small family of structurally characterised, neutral, 1D coordination polymers containing six-coordinate Mn^{II} sites; representative examples are described in [64–68]. It is also the first example in manganese(II) picolinate chemistry in which the $(py)CO_2^-$ ion adopts the $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ coordination mode, i.e., chelating one Mn^{II} atom through its nitrogen and one carboxylate oxygen, and bridging an adjacent Mn^{II} atom through its second carboxylate oxygen.

An ORTEP plot of complex **3** is shown in Fig. 6. Its structure consists of a dinuclear $[Mn_2(O_2CMe)_2\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ molecule located at a centre of symmetry. The two Mn^{II} atoms are bridged by two oxygen atoms (O(2), O(2′)) from the two symmetry-related $\eta^1{:}\eta^2{:}\mu_2$ $(py)CO_2^-$ ligands, the nitrogen atoms of which are ligated to Mn and Mn′. Each Mn^{II} atom is further coordinated by a monodentate acetate ion and a *N*,*N*′-chelating (py)CHNOH ligand, completing a distorted octahedral coordination at each metal. The central MnO(2)Mn′O(2′) core is strictly planar due to the presence of the inversion centre in the middle of the core. As for $\mathbf{1}\cdot 0.6CHCl_3$, the bridging $Mn–O_{picolinate}$ distances are symmetric (2.204(4), 2.210(4) Å). The Mn···Mn′ distance of 3.633(2) Å is somewhat longer than the analogous Mn(2)···Mn(2′) distance in $\mathbf{1}\cdot 0.6CHCl_3$ (Fig. 3) reflecting the different nature of the monoatomic bridge (picolinate versus benzoate); in accord with this the corresponding Mn–O–Mn angle in **3** (110.8(2)°) is larger than that in $\mathbf{1}\cdot 0.6CHCl_3$ (103.1(1)°). The Mn–N and Mn–O bond lengths are normal [30,31,46–50]. The bridging oxygen is perfectly planar ($\Sigma^{o}O(2) = 360°$).

An intramolecular hydrogen bond is present in **3** with the oxime oxygen, O(1), as donor and the "free", i.e., uncoordinated, acetate oxygen, O(5), as acceptor; its dimensions are O(1)···O(5) 2.479 Å, HO(1)···O(5) 1.602 Å and O(1)–HO(1)···O(5) 153.3°.

The structure of complex **4** consists of well-separated $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$ molecules (Fig. 7). The Mn^{II} atom is coordinated by two monodentate trifluoroacetates and two *N*,*N*′-bidentate chelating (py)CHNOH molecules. The six-coordinate molecule is the

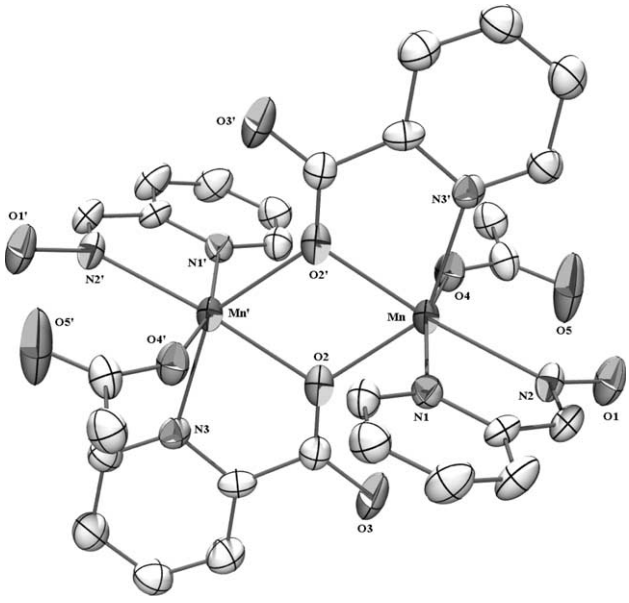

Fig. 6. An ORTEP plot at the 30% probability level of complex **3**. Primed and unprimed atoms are related by the crystallographic inversion centre. The carbon atoms are not labelled for clarity.

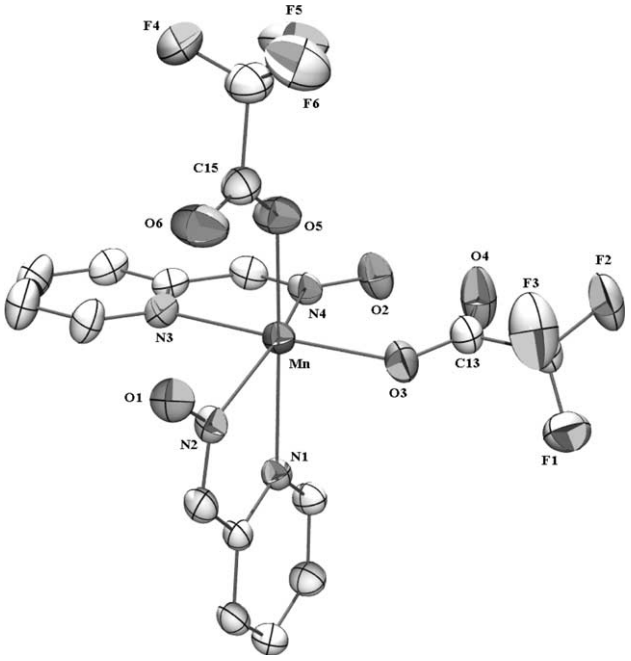

Fig. 7. ORTEP representation of the molecule of complex **4** at the 30% probability level. The plot has derived considering the positions of the F atoms with the larger occupation, i.e., 70% for F(1), F(2), F(3) and 60% for F(4), F(5), F(6).

cis–cis–trans isomer considering the positions of the oxygen, pyridyl nitrogen and oxime nitrogen atoms, respectively. The molecule has no imposed symmetry, although it approximates closely to C_2 symmetry, the C_2 axis bisecting the O(3)–Mn–O(5) angle. The four Mn–N bond lengths are almost identical (2.286(3)–2.289(2) Å). Angular distortions from octahedral geometry are primarily a consequence of the chelating oxime ligands and their restricted bite angles. There are two intramolecular hydrogen bonds with the uncoordinated oxime oxygens as donors and the "free" carboxylate oxygens as acceptors. Their dimensions are: O(1)···O(6) 2.582 Å, HO(1)···O(6) 1.612 Å, O(1)–OH(1)···O(6) 145.7° and O(2)···O(4) 2.571 Å, HO(2)···O(4) 1.697 Å, O(2)–HO(2)···O(4) 177.3°.

Complex **4** represents a new addition to the very small family of Mn^{II} complexes possessing monodentate $CF_3CO_2^-$ ligands [69,70]. Complex $[Mn(O_2CCF_3)_2(bpy)_2]$ [70] comes closest to reproduce the structural features of **4**; it has chelating 2,2′-bipyridine molecules instead of (py)CHNOH molecules.

3.3. Characteristic IR bands

A common, characteristic feature in the IR spectra of **1**–**4** is the appearance of a medium broad band at 3446–3428 cm^{-1} assignable [71] to ν(OH) of the (py)CHNOH ligand. The broadness and relatively low frequency of this band are both indicative of hydrogen bonding. Several bands appear in the 1670–1350 cm^{-1} range. Contributions from RCO_2^- (R = Me, Ph, CF_3) and/or picolinate $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ would be expected in this region, but overlap with the stretching vibrations of the aromatic rings renders assignments difficult. It seems that the frequencies of the $\nu_s(CO_2)$ bands of $PhCO_2^-/MeCO_2^-$ and $(py)CO_2^-$ coincide in the spectra of **1** (1404 cm^{-1}), **2** (1394 cm^{-1}) and **3** (1416 cm^{-1}). The bands at 1544, 1564 and 1548 cm^{-1} in **1**, **2** and **3**, respectively, are assigned to the $\nu_{as}(CO_2)_{PhCO_2^-/MeCO_2^-}$ vibration [72,73]. The difference Δ ($\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$) for **1** is 140 cm^{-1}, less than that for NaO_2CPh (184 cm^{-1}), as expected for the bridging modes of benzoate ligation [72]. The value of this parameter is 170 cm^{-1} for **2** and 132 cm^{-1} for **3**, less than the corresponding value for NaO_2CPh (184 cm^{-1}) and NaO_2CMe (164 cm^{-1}), respectively. These low Δ values might be interpreted as indicating bidentate (bridging or chelating) benzoate/acetate groups [72]; however, the crystal structures of both complexes reveal the presence of monodentate carboxylate groups. This disagreement with the spectroscopic criterion of Deacon and Phillips [72] is presumably due to the uncoordinated carboxylate oxygen's involvement (O(5) in Figs. 4 and 6) in hydrogen-bonding linkages [72,74] with the oxime group.

In the IR spectrum of NaO_2CF_3, the $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ bands appear at 1680 and 1457 cm^{-1}, respectively, i.e., $\Delta = 223$ cm^{-1} [72], while the corresponding bands for KO_2CCF_3 are at 1678 and 1437 cm^{-1} ($\Delta = 241$ cm^{-1}) [72]. In the spectrum of **4**, the bands at 1668 and 1448 cm^{-1} are assigned to $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$; the Δ value (220 cm^{-1}) is not as large as expected ($\Delta > 260$ cm^{-1}) for monodentate trifluoroacetate ligands [72]. This is again due to the fact that the carboxylate oxygens (O(4), O(6) in Fig. 7) not coordinated to Mn^{II} are hydrogen bonded to the oxime groups, giving what can be regarded as a "pseudo-bridging" arrangement [72]. In addition, the $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ frequencies of **4** are sufficiently close to those of the alkali metal trifluoroacetates to raise the possibility of anion ($CF_3CO_2^-/Br^-$) exchange [72].

3.4. Magnetic properties and EPR spectra of *1*

Solid state variable-temperature (2–300 K) magnetic susceptibility (χ_M) studies were performed on a polycrystalline sample of compound **1** in a 0.1 T field. The data are plotted as $\chi_M T$ and χ_M versus T in Fig. 8. The χ_M versus T curve shows a maximum at approximately 5 K, indicative of weak antiferromagnetic coupling [60]. The room-temperature $\chi_M T$ value is 16.1 cm^3 mol^{-1} K, somewhat lower than the expected value of $\chi_M T = 17.5$ cm^3 mol^{-1} K for four $S = 5/2$ uncoupled spins with $g = 2$. The $\chi_M T$ product decreases steadily with decreasing temperature and tends to zero at very low

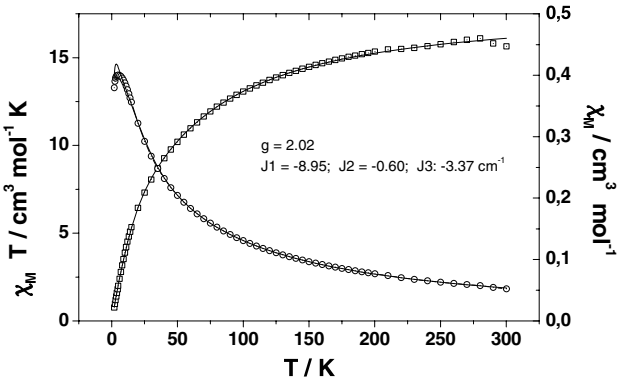

Fig. 8. Plots of $\chi_M T$ and χ_M vs. T for the tetranuclear complex **1**.

temperatures, indicating an overall antiferromagnetic behaviour. Since the spins carriers are all d^5 Mn^{II} ions, and therefore orbital singlet (S) ions, only the isotropic part of the exchange interaction was considered and the contribution of the zero-field splitting was neglected [60].

For a molecule such as **1** a total of five exchange parameters J_{ij} are required to cover each possible pairwise exchange interaction between Mn^{II} ions i and j; a sixth parameter $J_{11'}$ (the numbering scheme is the same as that shown in Fig. 3) is assumed to be zero, given the large distance and superexchange pathway involved ($Mn(1)\cdots Mn(1') = 7.364(3)$ Å). However, due to symmetry, a total of three exchange parameters are enough to cover each possible pairwise interaction. The magnetic model that was used is shown graphically in Fig. 9. Inspection of the molecular structure of **1** reveals that the three exchange pathways can be described as follows: The first one, J_1, refers to the interaction between Mn(1) and Mn(2) (and their symmetry equivalents) mediated by one monoatomic picolinate O-bridge, one *syn*, *syn* bidentate bridging $PhCO_2^-$ group and the "triatomic" part of one $\eta^1{:}\eta^2{:}\mu_3$ $PhCO_2^-$ group. The second one, J_2, refers to the interaction between Mn(1) and Mn(2′) (and their symmetry equivalents) mediated by one *syn, syn* bidentate bridging $PhCO_2^-$ group and the "triatomic" part of the same μ_3 $PhCO_2^-$ that bridges Mn(1) and Mn(2). The third exchange pathway, represented by J_3, refers to the $Mn(2)\cdots Mn(2')$ interaction mediated by two monoatomic benzoate O-bridges. Best-fit parameters, obtained by means of the full-matrix diagonalisation program CLUMAG [75] and applying the Hamiltonian given in Eq. (3) (where S_1, S_2, S_3 and S_4 correspond to Mn(1), Mn(2), Mn(2′) and Mn(1′), respectively),

$$H = -J_1(S_1S_2 + S_3S_4) - J_2(S_1S_3 + S_2S_4) - J_3(S_2S_3) \quad (3)$$

are $J_1 = -8.95$ cm^{-1}, $J_2 = -0.60$ cm^{-1}, $J_3 = -3.37$ cm^{-1} and $g = 2.02$ ($R = 5.1 \times 10^{-5}$).

The g parameter presents a value very close to 2.0, in accord with the presence of Mn^{II} ions which do not exhibit spin-orbit coupling [67]. The obtained J values are in agreement with qualitative magnetostructural correlations found in Mn^{II} complexes. J values reported in the literature with *only* carboxylate groups as bridging ligands are always small and negative, between approximately −0.2 and −5 cm^{-1} [67,76,77], indicating weak antiferromagnetic coupling. The J_2 value is well within the reported range. The carboxylate group involving O(41) and O(42) can be considered as poorly efficient to transmit the superexchange interaction between Mn(1) and Mn(2′) due to the quasi orthogonal arrangement, evidenced by the Mn(1)–O(41)–O(42)–Mn(2′) dihedral angle of 88.0°; this may explain the very low J_2 value, since only one *syn*, *syn* carboxylate bridge is operative (the group involving O(31) and O(32′)). DFT calculations on Mn–$(OR)_2$–Mn systems indicate a strong dependence of the antiferromagnetic coupling as function of the Mn–O–Mn bond angle below 98° and weak, but increasing, antiferromagnetic response for Mn–O–Mn bond angles in the 98°–110° range [78]. Thus, on the basis of the Mn(2)–O(42)–Mn(2′) angle of 103.1(1)°, the weak antiferromagnetic coupling J_3 (−3.37 cm^{-1}) is understandable. The fact that the J_1 value is outside the reported range (−0.2 to −5 cm^{-1}) may be due to the different carboxylate bridges involved (picolinate and benzoate).

The X-band EPR spectrum of a polycrystalline sample of **1** (Fig. 10) consists of an isotropic featureless signal centred at $g = 2$ (linewidth 390 G), and one weak half-field signal centred at $g = \sim 4$. The spectrum remains unchanged in the 77–300 K range. Such a spectrum is typical for magnetically interacting Mn^{II} ions in the solid state [61].

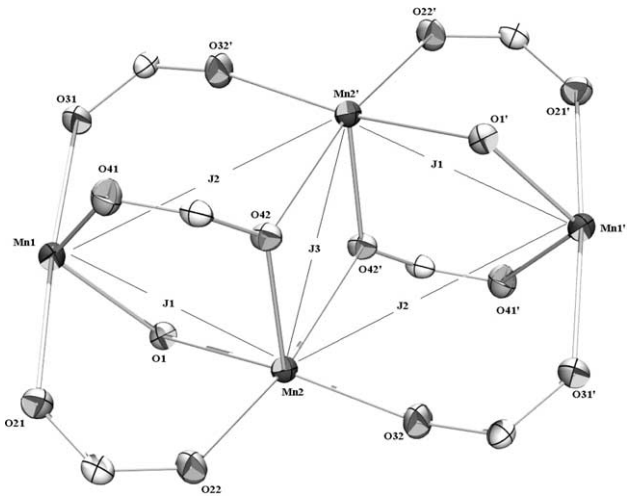

Fig. 9. Assignment of J values to $Mn\cdots Mn$ interactions for the magnetic model used for **1**. The numbering scheme used for the Mn^{II} ions is the same with that used in Fig. 3. Atoms O(1) and O(1′) are the μ_2 picolinate(−1) oxygens, while all the rest oxygen atoms belong to benzoate ligands.

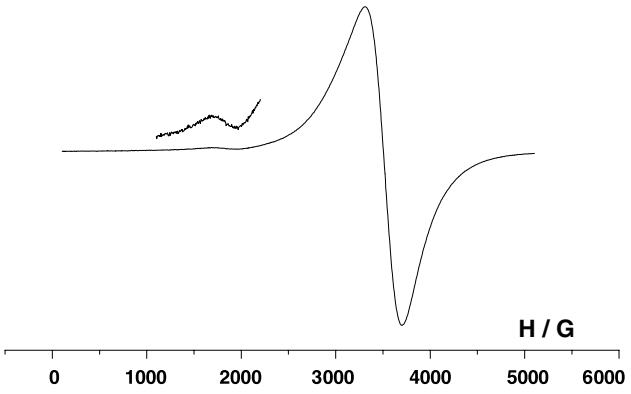

Fig. 10. Room temperature X-band EPR spectrum of a powdered sample of complex **1**.

4. Conclusions

The initial use of the pyridylaldoxime ligand (py)CHNOH in Mn^{II} carboxylate chemistry has provided accessto three new Mn^{II} complexes with interesting structures and properties: one dinuclear (**3**), one tetranuclear (**1**) and one polymeric (**2**). In all three cases, a Mn^{II}-assisted partial (py)CHNOH $\rightarrow$ (py)CO_2^- transformation has been observed. In view of this transformation, we strongly believe that the activation of 2-pyridyloximes by 3d-metals centres towards further reactions will become a fruitful area of research. The formation of the trifluoroacetate ligands and their incorporation in complex **4** are also interesting and warrant further study and expansion to other 3d-metals and β-diketonates. Since (py)CHNOH has been previously shown by others to be capable of acting as a anionic, i.e. (py)$CHNO^-$, bridging ligand, our current activity is directed towards the isolation of Mn (at various oxidation levels) carboxylate clusters containing (py)$CHNO^-$; parallel studies with Fe^{III}, Co^{II}, Ni^{II} and Cu^{II} carboxylates are also in progress. Results at the time of writing reveal that the nature of (py)$CHNO^-$ makes it a versatile ligand for a variety of objectives/advantages, including μ_2 and μ_3 behaviour, high-nuclearity cluster formation, linking of clusters into polymeric arrays, 3d–4f mixed-metal chemistry and ferromagnetic exchange interactions.

5. Supplementary material

Crystallographic data in CIF format have been deposited at the Cambridge Crystallographic Data Centre with CCDC Nos. 214660 (**1** · 0.6$CHCl_3$), 214661 (**2**), 214662 (**3**) and 214663 (**4**). Synthesis and hypodentate Cu(II) complexes of new tripodal tetraamine ligands incorporating a long pendant arm

Natasha J. Lundin, Ian G. Hamilton, Allan G. Blackman *

Department of Chemistry, University of Otago, P.O. Box 56, Dunedin, New Zealand

Received 16 July 2003; accepted 13 September 2003

This paper is dedicated to Professor George Christou on the happy occasion of his 50th birthday

Abstract

The synthesis and characterisation of the new aliphatic tripodal amine ligands apba (*N*-(5-aminopentyl)-*N,N*-bis(2-aminoethyl)amine) and ahba (*N*-(6-aminohexyl)-*N,N*-bis(2-aminoethyl)amine) are reported. The tetrahydrochloride salts of these ligands, as well as that of the previously reported ligand abba (*N*-(4-aminobutyl)-*N,N*-bis(2-aminoethyl)amine), react with $CuCO_3 \cdot Cu(OH)_2$ to give complexes in which the tripodal ligand coordinates to the Cu(II) ion in a hypodentate fashion, with the longest arm of the tripodal ligand remaining protonated and unbound in all cases. The crystal structure of $[Cu(abbaH)Cl_2]Cl \cdot 2H_2O \cdot CH_3OH$ reveals a five-coordinate Cu(II) ion in a slightly distorted square pyramidal geometry.

Keywords: Hypodentate; Tripodal amine ligand; Cu(II) complexes; Crystal structure; Five-coordinate

1. Introduction

The stereochemical features peculiar to tripodal tetradentate amine ligands have led to their use in a wide variety of inorganic systems. Six-coordinate octahedral complexes containing such ligands invariably display *cis* geometries, and the inequivalence of the remaining two coordination sites in such complexes has been utilised in numerous studies aimed at monitoring the stereochemical outcome of ligand substitution reactions in Co(III) complexes containing these ligands [1–4]. The steric constraints imposed by such ligands often result in trigonal bipyramidal geometries for five-coordinate systems [5–7], while the rare examples of four-coordinate complexes containing tripodal ligands display distorted tetrahedral geometries [8,9], owing to the inability of these ligands to accommodate a square planar geometry. Of the fully aliphatic tripodal tetradentate amine ligands, the C_{3v} symmetric ligands tren (tris(2-aminoethyl)amine) and trpn (tris(3-aminopropyl)amine), in which all three arms are the same length, have been known for many years [10,11], and it is only in relatively recent times that ligands of lower symmetry have been prepared and their complexes studied (Fig. 1). These ligands generally bind to a single transition metal ion using all four nitrogen donor atoms, although examples of hypodentate coordination [12], in which the ligand binds using less than its full complement of donor atoms, have been reported [13–18]. A number of the ligands outlined in Fig. 1 contain 4-aminobutyl or 5-aminopentyl arms [19–22] and can potentially form seven- or eight-membered chelate rings on binding to a metal ion, but their coordination chemistry has not been investigated to date. In this paper we report the synthesis of the new tripodal ligands apba (*N*-(5-aminopentyl)-*N,N*-bis(2-aminoethyl)amine) and ahba (*N*-(6-aminohexyl)-*N,N*-bis(2-aminoethyl)amine), as well as an alternative synthesis of abba (*N*-(4-aminobutyl)-*N,N*-bis(2-aminoethyl)amine). Although capable of forming complexes containing large chelate rings, these ligands display hypodentate coordination in Cu(II) complexes, with the longest arm remaining protonated and unbound in all cases. These findings are confirmed by a

crystal structure of the complex $[Cu(abbaH)Cl_2]Cl \cdot CH_3OH \cdot 2H_2O$.

2. Experimental

2.1. General

All chemicals used were LR grade or better. ^{13}C and ^{1}H NMR spectra were obtained in D_2O solution on a Varian Inova 300 MHz spectrometer at 25 °C. Chemical shifts are reported relative to NaTSP (^{1}H, 0.00 ppm) or dioxane (^{13}C, 67.8 ppm) as internal references. Elemental analyses were performed by the Campbell Microanalytical Laboratory, University of Otago. Electrospray mass spectra were recorded on a Shimadzu LCMS-QP800α spectrometer.

Diphthaloyldiethylenetriamine was prepared as described [19]. *N*-(4-bromobutyl)phthalimide and *N*-(6-bromohexyl)phthalimide were prepared by adaptation of the method used for the synthesis of *N*-(2-bromoethyl)phthalimide [23] (recrystallisation from cyclohexane and ethanol, respectively), while *N*-(5-bromopentyl) phthalimide was prepared according to a literature method [24].

2.2. Ligand syntheses: general procedure

An equimolar mixture of diphthaloyldiethylenetriamine and the appropriate bromoalkylphthalimide was heated at ~190 °C for 30 min with constant stirring. Following cooling, the glassy brown solid was ground to a powder and heated under reflux in 8 M HCl overnight. The solution was cooled and the precipitated phthalic acid removed by filtration. The filtrate was reduced to a yellow oil (rotary evaporator), which was diluted to 1 L with water and loaded onto a Dowex 50W-X2 (H^+ form) column. This was washed with 1 M HCl and the product was removed on elution with 3 M HCl. Removal of the solvent (rotary evaporator) gave the crude product which was recrystallised from hot ethanol (a small amount of ether was added to the cooled solution to induce crystallisation if necessary) to give the pure ligand tetrahydrochloride as a white powder.

2.2.1. *N-(4-aminobutyl)-N,N-bis(2-aminoethyl)amine tetrahydrochloride (abba·4HCl)*

Diphthaloyldiethylenetriamine (31.0 g, 85.3 mmol), *N*-(4-bromobutyl)phthalimide (24.6 g, 87.2 mmol), 8 M HCl (600 mL). Yield: 11.0 g (40.3%). Found: C, 29.6; H, 8.3; N, 16.9; Cl, 43.9. Calc. for $C_8H_{26}N_4Cl_4$: C, 30.0; H,

8.2; N, 17.5; Cl, 44.3%. ^{1}H NMR (D_2O), δ_H: 1.8 (m, 4H), 3.08 (t, $J = 6$ Hz, 2H), 3.36 (t, $J = 6$ Hz, 2H), 3.56 (m, 8H) ppm. ^{13}C NMR (D_2O), δ_C: 21.8, 25.0, 35.1, 40.1, 50.9, 54.5 ppm. MS (ESI): m/z 175 (MH^+).

2.2.2. *N-(5-aminopentyl)-N,N-bis(2-aminoethyl)amine tetrahydrochloride (apba · 4HCl)*

Diphthaloyldiethylenetriamine (23.1 g, 63.6 mmol), *N*-(5-bromopentyl)phthalimide (19.2 g, 64.8 mmol), 8 M HCl (190 mL). Yield: 8.02 g (37.7%). Found: C, 32.2; H, 8.4; N, 16.4; Cl, 42.0. Calc. for $C_9H_{28}N_4Cl_4$: C, 32.3; H, 8.4; N, 16.8; Cl, 42.4%. ^{1}H NMR(D_2O), δ_H: 1.51 (m, 2H), 1.78 (m, 2H), 1.87 (m, 2H), 3.06 (t, $J = 7.5$ Hz, 2H), 3.39 (t, $J = 8.7$ Hz, 2H), 3.56 (m, 4H), 3.66 (m, 4H) ppm. ^{13}C NMR (D_2O), δ_C: 23.3, 23.4, 26.9, 34.3, 39.8, 50.2, 54.4 ppm. MS (ESI): m/z 189 (MH^+).

2.2.3. *N-(6-aminohexyl)-N,N-bis(2-aminoethyl)amine tetrahydrochloride (ahba · 4HCl)*

Diphthaloyldiethylenetriamine (4.57 g, 12.6 mmol), *N*-(6-bromohexyl)phthalimide (3.99 g, 12.9 mmol) 8 M HCl (100 mL). Yield: 1.14 g (26.0%). Found: C, 34.7; H, 9.1; N, 15.9; Cl, 40.7. Calc. for $C_{10}H_{30}N_4Cl_4$: C, 34.5; H, 8.7; N, 16.1; Cl, 40.7%. ^{1}H NMR (D_2O), δ_H: 1.47 (m, 4H), 1.72 (m, 2H), 1.83 (m, 2H), 3.03 (t, $J = 7.8$ Hz, 2H), 3.35 (t, $J = 8.4$ Hz, 2H), 3.57 (m, 4H), 3.64 (m, 4H) ppm. ^{13}C NMR (D_2O), δ_C: 23.5, 25.78, 25.81, 27.1, 34.3, 39.9, 50.1, 54.6 ppm. MS (ESI): m/z 203 (MH^+).

2.3. Complex syntheses

Caution! Although we have experienced no difficulties with the perchlorate complexes described below, the usual care afforded all perchlorate species should be taken in their preparation and handling.

2.3.1. *[Cu(abbaH)Cl$_2$]Cl · 2H$_2$O · CH$_3$OH*

A suspension of abba · 4HCl (0.50 g, 1.6 mmol) and $CuCO_3 \cdot Cu(OH)_2$ (0.17 g, 0.77 mmol) in acetonitrile (50 mL) was heated under reflux for 2 h. The solution was allowed to cool, and the resulting green powder was removed by filtration. The powder was dissolved in the minimum volume of methanol and slow diethyl ether diffusion over three days gave bright blue needles suitable for X-ray diffraction. These crystals lose solvent readily and the analytical data thus refer to the desolvated material $[Cu(abbaH)Cl_2]Cl \cdot 2H_2O$ (0.21 g, 36%). Found: C, 24.7; H, 7.0; N, 14.2; Cl, 28.2. Calc. for $C_8H_{27}N_4Cl_3CuO_2$: C, 25.2; H, 7.1; N, 14.7; Cl, 27.9%.

2.3.2. *[Cu(apbaH)Cl(ClO$_4$)]ClO$_4$*

A suspension of apba · 4HCl (0.50 g, 1.5 mmol) and $CuCO_3 \cdot Cu(OH)_2$ (0.17 g, 0.77 mmol) in MeOH (20 mL) was heated under reflux for 2 h to give a deep green solution which was then hot filtered. Addition of $LiClO_4$ to the filtrate gave rapid formation of blue microcrystals. Following cooling in the freezer, the product was filtered off, washed with diethyl ether and dried in a vacuum desiccator. (0.29 g, 40%). Found: C, 22.2; H, 5.3; N, 11.2; Cl, 22.3. Calc. for $C_9H_{25}N_4Cl_3CuO_8$: C, 22.2; H, 5.2; N, 11.5; Cl, 21.8%.

2.3.3. *[Cu(ahbaH)Cl(ClO$_4$)]ClO$_4$*

A suspension of ahba · 4HCl (0.50 g, 1.4 mmol) and $CuCO_3 \cdot Cu(OH)_2$ (0.15 g, 0.68 mmol) in MeOH (20 mL) was heated under reflux for 2 h to give a deep green solution which was then hot filtered. Addition of $LiClO_4$ to the filtrate and storage in the freezer gave the product as blue microcrystals, which were then washed with diethyl ether and dried in a vacuum desiccator (0.27 g, 40%). Found: C, 24.1; H, 5.7; N, 11.0; Cl, 21.7. Calc. for $C_{10}H_{27}N_4Cl_3CuO_8$: C, 24.0; H, 5.4; N, 11.2; Cl, 21.2%.

2.4. X-ray crystallography

Data for $[Cu(abbaH)Cl_2]Cl \cdot 2H_2O \cdot CH_3OH$ were collected at −115 °C on a Siemens SMART system using graphite monochromated Mo Kα radiation with exposures over 0.3°. Data were corrected for Lorentz and polarisation effects using SAINT [25]. The structure was solved by direct methods using SIR-97 [26] running within the WinGX package [27], with the resulting Fourier map revealing the location of all non-hydrogen atoms. Weighted full matrix refinement on F^2 was carried out using SHELXL-97 [28] with all non-hydrogen atoms being refined anisotropically. Hydrogen atoms were included in calculated positions and were refined as riding atoms with individual (or group, if appropriate) isotropic displacement parameters. O3 was found to be disordered over two sites, with approximately 60:40 occupancy. Disorder of O2 was also evidenced by large thermal parameters, but this was not investigated further. Details of the crystal, data collection and structure refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis of the tripodal ligands

The tetrahydrochloride salts of the ligands abba, apba and ahba were prepared in moderate yields in an analogous fashion to similar tripodal tetraamine ligands, by the solventless reaction of a melt of the appropriate bromoalkylphthalimide with diphthaloyldiethylenetriamine, followed by deprotection in refluxing HCl (Scheme 1) [19,20,29–31]. In our hands, this appears to be an easier method of preparing tripodal ligands than the alternative procedure involving synthesis of the appropriate trinitrile and subsequent reduction with $LiAlH_4$/H_2SO_4 [32,33]. Purification of the crude ligands was

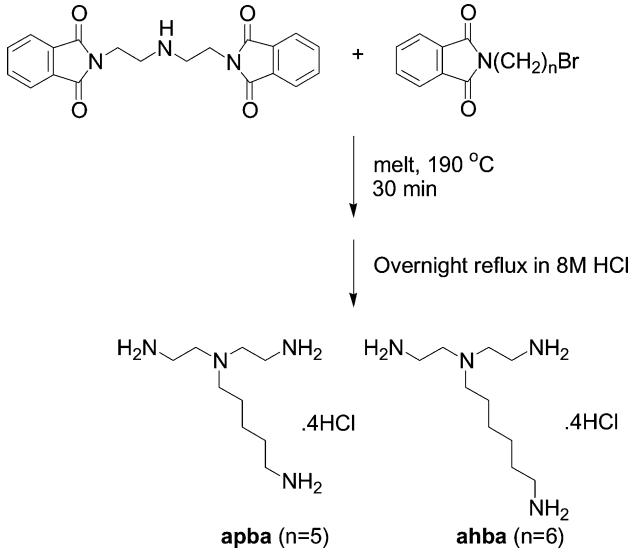

Scheme 1. The synthetic method used to prepare apba · 4HCl and ahba · 4HCl.

achieved by chromatography on Dowex 50W-X2 cation exchange resin (elution with 3M HCl) and the tetrahydrochloride salts of the pure ligands were obtained as white powders on recrystallisation from ethanol. Elemental analysis, mass spectral and ^1H and ^{13}C NMR data were consistent with the structures given in Fig. 1.

3.2. Synthesis of metal complexes

The tetrahydrochloride salts of abba, apba and ahba react with half a mole equivalent of $CuCO_3 \cdot Cu(OH)_2$ in either acetonitrile (abba) or methanol (apba, ahba), to give dissolution of the metal salts and production of bright green solutions. A green abba complex precipitated from the acetonitrile solution on cooling and the blue complex $[Cu(abbaH)Cl_2]Cl \cdot 2H_2O \cdot CH_3OH$ was isolated following recrystallisation from methanol. The green solutions obtained from the reaction of both apba and ahba in methanol slowly turned blue on cooling, and addition of $LiClO_4$ to these solutions gave the complexes $[Cu(apbaH)Cl(ClO_4)]ClO_4$ and $[Cu(ahbaH)Cl(ClO_4)]ClO_4$, respectively. Microanalytical data for all complexes were consistent with the presence of three counterions (Cl^- or ClO_4^-), strongly suggesting that the tripodal ligands were coordinating in a hypodentate fashion with a protonated pendant arm remaining uncoordinated to the metal ion. This was confirmed by the X-ray structure of $[Cu(abbaH)Cl_2]Cl \cdot CH_3OH \cdot 2H_2O$.

3.3. Crystal structure of $[Cu(abbaH)Cl_2]Cl \cdot CH_3OH \cdot 2H_2O$

Crystallographic data for $[Cu(abbaH)Cl_2]Cl \cdot CH_3OH \cdot 2H_2O$ are given in Table 1, bond lengths and

angles are given in Table 2, and Fig. 2 shows an ORTEP [34] diagram of the $[Cu(abbaH)Cl_2]^+$ cation. The structure consists of a five-coordinate Cu(II) ion coordinated to two chloride ligands and three nitrogen atoms of the abba ligand in a slightly distorted square pyramidal geometry ($\tau = 0.03$) [35], with the three nitrogen atoms and one chloride ion occupying the basal plane. The remaining *N* atom of the abba ligand is protonated, as evidenced by the presence of three chloride ions in the structure, and remains uncoordinated to the metal ion. The copper ion lies approximately 0.32 Å above the basal plane defined by the atoms N1, Cl2, N2 and N3. The axial Cu1–Cl3 bond (2.541(2) Å) is significantly longer than the Cu1–Cl2 bond (2.3221(14) Å), as has been found in a number of other five-coordinate Cu(II) complexes [36]. The Cu1–N1–C2–C1–N3 chelate ring adopts a symmetric skew λ conformation while the Cu1–N3–C3–C4–N2 chelate ring exists in an asymmetric envelope δ conformation [37]. The dangling aminobutyl chain displays an *anti* conformation about all C–C and C–N bonds, and the protonated terminal nitrogen atom is involved in hydrogen-bonding to both Cl3 and Cl4 of a neighbouring molecule (N4···Cl3 = 3.209(5) Å, N4···Cl4 = 3.106(6) Å) and the oxygen atom of the methanol of crystallisation (N4···O1 = 2.827(7) Å). N1 and N2 also participate in hydrogen-bonding interactions with chloride counterions.

3.4. Discussion

The stability of five- and six-membered chelate rings in coordination complexes is usually explained in terms of the chelate effect, in which a positive entropy term renders chelation thermodynamically favourable [38]. However, the process of chelation becomes less entropically favourable for systems in which chelate rings containing more than six atoms can be formed, and such rings are also inherently strained. In agreement with this, a search of the Cambridge Structural Database [39] revealed 9891 metal complexes containing the chelated $-N(CH_2)_2N-$ fragment and 2762 containing the chelated $-N(CH_2)_3N-$ fragment, but only 140, 59 and 6 containing the chelated $-N(CH_2)_4N-$, $-N(CH_2)_5N-$ and $-N(CH_2)_6N-$ fragments, respectively. In the majority of these latter complexes, the large chelate rings are incorporated in macrocyclic or cryptand ligands, and this preorganisation undoubtedly aids chelation. The moderate steric constraints afforded by the tripodal ligands abba, apba and ahba are apparently not sufficient to

enforce chelation of the longest pendant arm of these ligands, and they thus coordinate to Cu(II) in a hypodentate fashion. However, it is interesting to note in this respect that when abba is incorporated into a Schiff-base macrocycle, all four N atoms coordinate to Cu(II) in the resulting complex [20].

X-ray quality crystals of $[Cu(apbaH)Cl(ClO_4)]ClO_4$ and $[Cu(ahbaH)Cl(ClO_4)]ClO_4$ could not be obtained and thus the exact geometries of these complexes remain uncertain. However, the presence of three counterions, as shown by elemental analysis, strongly suggests both complexes to be hypodentate, with either a five-coordinate (coordinated chloride and perchlorate) or four-coordinate (coordinated chloride) Cu(II) ion and a non-coordinated protonated aminoalkyl arm.

The presence of non-coordinated nitrogen atoms in the hypodentate complexes described herein affords several synthetic opportunities, as these complexes can potentially be used as building blocks for the synthesis of polymetallic species. The non-coordinated nitrogen atom can bind to another metal ion following deprotonation, or it can be used to prepare novel Schiff-base ligands through condensation with an appropriate carbonyl functionality. We are currently investigating these possibilities.

4. Supplementary material

Crystallographic data for $[Cu(abbaH)Cl_2]Cl \cdot CH_3OH \cdot 2H_2O$ (CCDC 214721) have been deposited with the Cambridge Crystallographic Data Centre. A copy of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-3360333; e-mail: deposit@ccdc.cam.ac.uk; www: http://www.ccdc.cam.ac.uk).

Received 26 June 2003; accepted 16 September 2003

Abstract

Reactions of $[Sn(CH_2CH_2CN)_4]$ and $[Sn_2(CH_2CH_2CN)_6]$ with $[Rh_2Cl_2(CO)_4]$ give pentanuclear complex $[Sn\{CH_2CH_2CNRhCl(CO)_2\}_4]\cdot CH_2Cl_2$ (**1**) and hexanuclear compound $[Sn_2\{CH_2CH_2CNRhCl(CO)_2\}_4(CH_2CH_2CN)_2]\cdot CHCl_3$ (**2**). In acetone solution complex **2** slowly decomposes giving $[Rh_6(CO)_{16}]$ (**3**). X-ray structures of the compounds have been determined. In complexes **1** and **2** in the solid state square planar entities $[NRhCl(CO)_2]$ relatively strongly interact giving one-dimensional and two-dimensional compounds. In complex **2** the ditin moiety possesses an unexpected eclipsed conformation.

Keywords: Organotin complexes; Organorhodium complexes; Organorhodiumtin complexes; One-dimensional compounds; Two-dimensional compounds; Rhodium carbonyl complexes

1. Introduction

Metal complexes containing bridging ligands often form polynuclear one- and two-dimensional polymeric compounds. They have recently been intensely investigated because of their interesting structure and physicochemical properties [1–4]. Investigation of organotin(IV) compounds in turn results from application of $[SnR_nX_{4-n}]$ in organic syntheses, for preparation of SnO_2 films and coatings on glass, in catalysis [5–7], as biocidal [5,6] and antitumor agents [8–12], etc. Functionalized alkyl and aryl complexes of tin(IV) have been much less investigated than the unsubstituted organometallic tin compounds. Organotin compounds containing 2-cyanoethyl ligands are interesting because they can be easily prepared electrochemically from a tin cathode and acrylonitrile [11,13,14] and may be used for preparation of amino, amido and carboxylic derivatives. The mononuclear compound $[Sn(CH_2CH_2CN)_4]$ is potentially a tetradentate lignd and the binuclear compound of tin(III), $[Sn_2(CH_2CH_2CN)_6]$, a hexadentate ligand coordinating via CN groups. In this paper, we describe the syntheses, structures and properties of pentanuclear one-dimensional complex $[Sn\{CH_2CH_2CNRhCl(CO)_2\}_4]\cdot CH_2Cl_2$ (**1**) and hexanuclear $[Sn_2\{CH_2CH_2CNRhCl(CO)_2\}_4(CH_2CH_2CN)_2]\cdot CHCl_3$ (**2**), a two-dimensional rhodium–tin compound which in solutions slowly decomposes giving $[Rh_6(CO)_{16}]$ (**3**).

2. Results and discussion

Reaction of $[Sn(CH_2CH_2CN)_4]$ and $[Sn_2(CH_2CH_2CN)_6]$ with $[Rh_2Cl_2(CO)_4]$ in carbon monoxide atmosphere in polar solvents give compounds with $[RhCl(CO)_2]$ moieties coordinated with the N atoms of the tin compounds. The complexes $[Sn\{CH_2CH_2CNRhCl(CO)_2\}_4]\cdot CH_2Cl_2$ (**1**) and $[Sn_2\{CH_2CH_2CNRhCl(CO)_2\}_4(CH_2CH_2CN)_2]\cdot CHCl_3$ (**2**), were obtained in dichloromethane and chloroform, respectively. It was not possible to obtain complexes containing a lower or higher number of rhodium entities. In reactions at molar ratios of tin(IV) or ditin(III) complex to dirhodium(I) compound in the range 1:1–1:3, always complexes **1** and

doi:10.1016/j.poly.2003.09.033

2 are formed. They are stable in the solid state under CO atmosphere at room temperature, however, in air **1** decomposes over several days and **2** in one day. They are soluble in organic polar solvents, e.g., dichloromethane, chloroform, acetone, acetonitrile. The solutions in carbon monoxide atmosphere are stable for several days. However, in solutions under inert atmosphere or in air compound **2** decomposes with deposition of dark brown compounds. Decomposition of compound **1** is slower. Complex **2** in acetone solution after several days at room temperature is reduced giving black crystals as the main product and an unidentified brown compound. The black compound was identified as the known hexanuclear cluster $[Rh_6(CO)_{16}]$ (**3**) [15,16]. The molecular structures of complexes **1**, **2** and **3** are shown in Figs. 1–3 and details of X-ray data collected are summarized in Table 1. Tables 2–4 contain selected bond lengths and angles for compounds **1**–**3** and in Table 5 hydrogen bonds parameters for complex **2** are given.

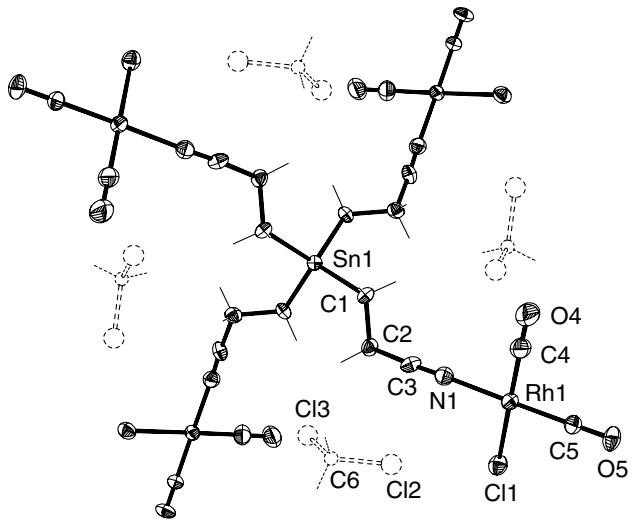

Fig. 1. ORTEP representation of **1** showing solvate molecules.

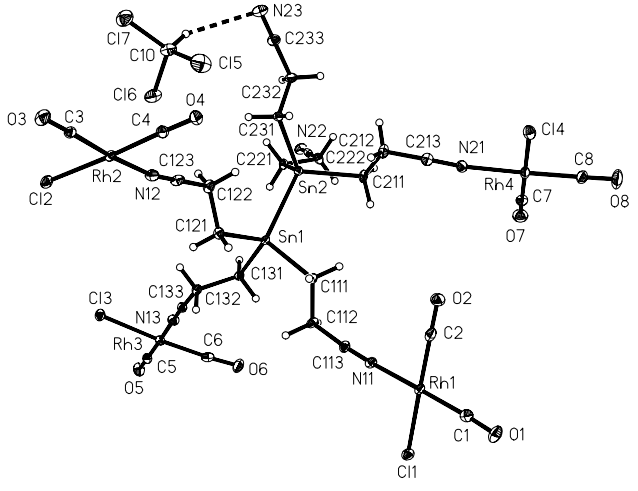

Fig. 2. ORTEP representation of complex **2**.

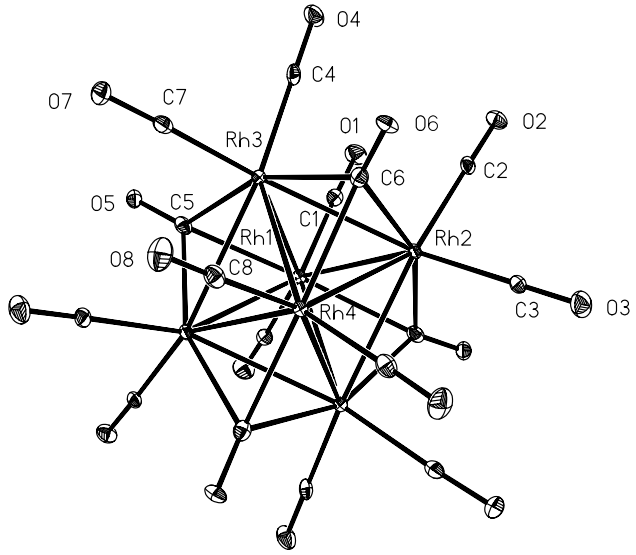

Fig. 3. ORTEP diagram showing the atom labelling scheme for the complex $[Rh_6(CO)_{16}]$ (**3**).

Compound **1** consists of discrete units $[Sn\{C_2H_4CNRhCl(CO)_2\}_4]$ of $\bar{4}$ tetrahedral symmetry with $RhCl(CO)_2$ entities coordinated through N atoms of the bridging 2-cyanoethyl ligands (Fig. 1). The Rh atoms have square-planar coordination. Compound **1** is a one-dimensional polymer linked along the [0 0 1] direction via Rh–Rh bonds (Fig. 4). The Rh–Rh distances are equal 3.134(2) Å. They are considerably shorter than those in $[Rh_2Cl_2(CO)_4]$ (3.31 Å) [7]. The neighboring square-planar $NRhCl(CO)_2$ entities are parallel with a staggered conformation. The N–Rh–Rh–N torsion angle is equal to 68.4(6)°. The disordered CH_2Cl_2 molecules (the respective occupancy parameter is equal to 0.25) occupy channels between linear chain polymers along the fourfold axes (Figs. 4 and 5). Complex **1** can also crystallize from other solvents giving analogous compounds with solvent molecules of crystallization in the channels.

The structure of **2** consists of a binuclear tin(III) unit with both tin(III) central atoms residing in a distorted tetrahedral coordination (Fig. 2). Three rhodium(I) atoms are coordinated with three 2-cyanoethyl ligands connected with the Sn(1) atom and one rhodium atom with the CH_2CH_2CN ligand bound with Sn(2). The Sn(1)–Sn(2) distance (2.7500(6) Å) is slightly shorter than that in $[Sn_2(CH_2CH_2CN)_6]$ [11]. The C–Sn and C–N distances as well as C–Sn–C and C–Sn–Sn angles are almost the same for complex **2** and for $[Sn_2(CH_2CH_2CN)_6]$. The following average distances were determined: Sn–C 2.176(7) Å, CH_2–CH_2 1.528(9) Å, CH_2–CN 1.464(9) Å, C–N 1.142(8) Å, Rh–N 2.063(5) Å, Rh–Cl 2.3423(17) Å and Rh–C 1.852(8) Å. It is interesting that the conformation of the tin moieties is

eclipsed. The C–Sn–Sn–C torsion angles are very small: C(121)–Sn(1)–Sn(2)–C(231) 4.8(2)°, C(111)–Sn(1)–Sn(2)–C(211) 7.5(2)° and C(131)–Sn(1)–Sn(2)–C(221) 8.6(2)°. The eclipsed conformation was also found for $[Sn_2(CH_2CH_2CN)_6]$. However, all known alkyl ditin(III) $[Sn_2R_6]$ compounds have staggered conformation [5,6,17]. The calculation of the structure of $[Sn_2(CH_2CH_2CN)_6]$ using PM3, MP2 and DFT B3LYP methods indicated that the eclipsed conformation is more stable in comparison with the staggered one [11]. Thus the stabilization of the eclipsed conformation of this complex results from electronic reasons and steric effects do not play a decisive role. Compound **2** is a

two-dimensional polymer containing $[Sn_2\{CH_2CH_2CNRhCl(CO)_2\}_4(CH_2CH_2CN)_2]$ units linked via three Rh–Rh bonds with three other monomers (Fig. 6). They

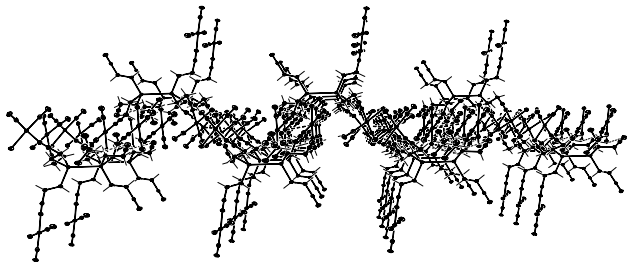

Fig. 6. View of a polymeric layer of **2** along the [0 0 1] direction.

form a puckered polymeric layer perpendicular to the [110] direction. All Rh–Rh junctions are centrosymmetric. It results in parallel and eclipsed orientations of the Rh square coordination entities. The Rh–Rh distances are different: Rh1–Rh1$(3 - x, 1 - y, 2 - z)$ 3.277(1) Å, Rh2–Rh2$(3 - x, 1 - y, 1 - z)$ 3.203(1) Å and Rh4–Rh4 $(2 - x, -y, 2 - z)$ 3.679(1) Å. The crystal structure of compound **2** is also stabilized by hydrogen bonds formed between the CH group of chloroform and the N(23) atom of a 2-cyanoethyl ligand (3.381(10) Å) and between α-CH_2 groups and the N(22i) atom (3.220(8) Å). The interaction between metal atoms of square planar complexes is characteristic for coordination compounds with d^8 electronic configuration [7]. This type of interaction can lead to the formation of column-like conductors and semiconductors. In the case of complexes **1** and **2** owing to this interaction one-dimensional and two dimensional compounds are formed. Formation of one-dimensional carbonyl rhodium(I) compounds containing Rh–Rh infinite bonds was found in complexes $[RhX(CO)_2(NCR)]$ [18], $[RhX(CO)_2(H_2NR)]$ [19] and $[Rh(CO)_2(N–N)][RhX_2(CO)_2]$ (N–N = 2,2′-bipyridine and 1,10-phenanthroline and their derivatives) [20].

The structure of complex **3** has been determined by Corey et al. [15] and recently by Farrah et al. [16]. The structure of **3** consists of discrete hexanuclear octahedral clusters (Fig. 3, Table 4). The average Rh–Rh distances and C–O bonds for terminal carbonyl ligands are slightly shorter and Rh–C bonds slightly longer than those reported by Corey et al. [15]. The following average distances were found: Rh–Rh = 2.7618(7) Å, for the terminally bonded carbonyls, Rh–C = 1.916(6) Å, C–O = 1.130(6) Å, and for bridging μ_3-CO ligands, Rh–C = 2.194(5) Å, C–O = 1.154(6) Å. The compound prepared by Farrah et al. [16] crystallized in the $P2_1/c$ space group and Rh–Rh average bond length in this crystal is slightly shorter (2.75(1) Å). Preparation of complexes of hexakis(2-cyanoethyl)ditin containing hexanuclear clusters coordinated with C–N groups was unsuccessful. Decomposition of complex **2** always leads to the cluster **3**. Reactions of the tin complex $[Sn_2(CH_2CH_2CN)_6]$ with compound **3** in acetone and acetonitrile were also unsuccessful. This most likely results from the relatively strong Rh–CO bond and less stable Rh–NC bond.

In solutions the Rh–Rh interactions are split and complexes **1** and **2** in solutions dissociate to the pentanuclear and hexanuclear compounds: [Sn{CH_2CH_2CN $RhCl(CO)_2$}$_4$] and [Sn_2\{$CH_2CH_2CNRhCl(CO)_2$\}$_4$(CH_2 CH_2CN)$_2$]. Triplets of Sn*CH*$_2$ and *CH*$_2$CN methylene protons with resolved $^{119/117}$Sn satellites for complex **1** are observed at 1.53 ppm ($^3J(^1H–^1H) = 8.2$ Hz, $^2J(^{119/117}Sn–^1H) = 52.0$ Hz) and 2.99 ppm ($^3J(^{119/117}Sn–^1H) = 49.6$ Hz) and for complex **2** at 1.68 ppm ($^3J(^1H–^1H) = 8.2$ Hz, $^2J(^1H–^{119/117}Sn) = 43.0$ Hz) and 2.97 ppm ($^3J(^1H–^{119/117}Sn) = 50.0$ Hz). The chemical shifts of α- and β-methylene groups for complexes **1** and **2** are ca. 0.06 and 0.13 ppm larger than for [Sn(CH_2CH_2CN)$_4$] and [Sn_2(CH_2CH_2CN)$_6$] [11]. The $^2J(^{119}Sn–^1H)$ coupling constants in tin(IV), SnR_2X_2 and SnR_3X, compounds depend on C–Sn–C angles [21–23]. The low values of $^2J(^{119/117}Sn–^1H)$ indicate that in polar solvents in compounds **1** and **2** tin atoms have tetrahedral coordination. Coordination of four rhodium(I) moieties with NC groups changes the dynamic properties of the 2-cyanoethyl ligands in complex **2**, as evidenced by ^{1}H NMR spectra in $(CD_3)_2CO$ and CD_2Cl_2 at lower temperatures. In deuterated acetone at room temperature both Sn*CH*$_2$ and *CH*$_2$CN signals are resolved, but at 273 K the *CH*$_2$CN signal becomes broader, at 253 K it loses resolution and at 233 K both signals are not resolved. The spectrum of [Sn_2(CH_2CH_2CN)$_6$] in $(CD_3)_2CO$ is resolved in this range of temperatures [11]. Very similar changes in the spectra were found in solution of complex **2** in CD_2Cl_2 in the same range of temperatures.

3. Experimental

3.1. Physical measurements and materials

Infrared spectra (KBr pellets) were recorded on a Bruker IFS 113v, ^{1}H NMR spectra were taken on a Bruker AMX 300. The amounts of tin and rhodium were determined using ICP-AES method on a ARL 3410.

The reagents, acrylonitrile (Aldrich), tin (POCH, Poland) and sodium hydroxide (POCH) were used as received. Complexes [Sn(CH_2CH_2CN)$_4$] [13,14] and [Sn_2(CH_2CH_2CN)$_6$] [11] were prepared according to the literature procedures from a sacrificial tin cathode in inert atmosphere and [$Rh_2Cl_2(CO)_4$] [24] in carbon monoxide atmosphere.

3.2. Preparation of [Sn{$CH_2CH_2CNRhCl(CO)_2$}$_4$]·CH_2Cl_2 (1)

A mixture of [Sn(CH_2CH_2CN)$_4$] (0.0336 g, 0.1 mmol) and [$Rh_2Cl_2(CO)_4$] (0.0778 g, 0.2 mmol) was dissolved in dichloromethane (5 cm^3) under CO atmosphere at room temperature and left for two days. The orange crystalline product [Sn{$CH_2CH_2CNRhCl(CO)_2$}$_4$]·CH_2Cl_2 (**1**) was filtered off and washed with cold dichloromethane and dried in vacuo. Yield: 0.066 g, 55%. *Anal.* Calcd. for: $C_{21}H_{18}Cl_6N_4O_8Rh_4Sn$: C, 21.06; H, 1.52; N, 4.68; Cl, 17.76. Found: C, 20.87; H, 1.44; N, 4.52; Cl, 17.58%. 3.4. X-ray crystallographic measurements

Crystals of **1** and **2** used for X-ray structure determination were obtained in reactions of [Sn(CH_2CH_2 CN)$_4$] and [Sn_2(CH_2CH_2CN)$_6$] with [$Rh_2Cl_2(CO)_4$] at room temperature in dichloromethane and chloroform, respectively. All measurements were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystal was positioned at 65 mm from the CCD camera. 612 frames

were measured at 0.75° intervals with a counting time of 12 s. Accurate cell parameters were determined and refined by a least-squares fit of the 3300 strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. zoo (formerly Kuma Diffraction Wrocław, Poland) programs. The structure was solved by direct methods (program SHELXS-97 [25]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 [26] programs. Non-hydrogen atoms were refined with anisotropic thermal parameters; hydrogen atoms were included from the geometry of molecules and were fixed.

4. Supplementary data

Crystallographic data for the structures reported in this paper (excluding structure factors) have been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition Nos. 192924 (**1**), 192923 (**2**) and 192922 (**3**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Prolonged storage of solutions in the $Al(OPr^i)_3$–$Ta(OPr^i)_5$–^{i}PrOH system containing additional ^{n}PrOH leads to crystallization with minor yields of a new aluminium oxopropoxide, $Al_{11}O_6(OPr^n)_{10}(OPr^i)_{10}(OR)(ROH)_2$ ($R = Pr^i$, Pr^n) (**1**). Interaction of $Al(OPr^i)_3$ with $Mg(acac)_2$ (in a 1:1 ratio) in toluene on refluxing leads to formation of $Al_5Mg_4O_3(OH)_3(OPr^i)_8(acac)_6 \cdot 0.5PhMe$ (**2**) in minor yields. Both molecules contain two pentanuclear cores $[M_5(\mu_4\text{-}O)(\mu_3\text{-}O)(\mu\text{-}OX)_6(Y)_4]$ ($X = H$, Pr^n, $Y = OPr^i$, acac/2) and differ only in the manner in which they are attached to each other, i.e. via the central $[Al(\mu_3\text{-}O)_2(\mu\text{-}O)_2(OR)]$ unit in **1**, and via a common [Al–(μ_3-O)] edge and an additional (μ-OH)-group in **2**. The core structures in the molecules of aluminium and iron oxoalkoxides are discussed.

1. Introduction

The interest revealed recently to the homo- and heterometallic oxoalkoxides is due to their specific role as direct precursors of oxide materials in Sol–Gel Technology and also to the fundamental interest to new possible types of oligomeric "cluster" aggregates [1].

Aluminum isopropoxide belongs to the best studied and most commonly applied derivatives of this metal. The data on its oxoderivatives has been, however, quite limited. There have only been reports on the crystalline oxoalkoxochloride, $Al_4(\mu_4\text{-}O)(OPr^i)_5[H(OPr^i)_2]Cl_4$, (earlier described as "$AlCl(OPr^i)_2$" [2]), and a complex of aluminum oxoisopropoxide with ammonia, $[Al_{10}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_4(\mu\text{-}OPr^i)_6(OPr^i)_{12}(NH_3)_8]$ [3]. At the same time, at present a considerable number of oxoalkoxide derivatives of other alcohols have been reported including, for example, decameric oxoethoxide, $[Al_{10}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}OEt)_{14}(OEt)_8]$, formed on decomposition of the polymeric $Al(OEt)_3$ ("crystalline aluminium ethoxide") [4] and also a series of oxo-isobutoxides and trifluoroethoxides such as $[Al_4(\mu_4\text{-}O)(\mu\text{-}OR)_5(OR)_5(ROH)]$ ($R = Bu^i$ [5,6], CH_2CF_3 [6,7]), $[Al_5(\mu_5\text{-}O)(\mu\text{-}OBu^i)_8(OBu^i)_5]$, $[Al_8(\mu_4\text{-}O)_2(\mu\text{-}OH)_2(\mu\text{-}OBu^i)_{10}(OBu^i)_8]$, reported recently by Bradley and co-workers [6] as the products of controlled partial hydrolysis or thermolysis. A number of other tetra- and pentanuclear complexes, where a part of the alkoxide ligands has been replaced by different OR-groups, have also been reported. Among the heteroleptic

oxoalkoxides it is important to mention also the recently reported pentanuclear alkoxide hydride $[H_5Al_5(\mu_5\text{-}O)(\mu\text{-}OBu^i)_8]$ [8].

2. Experimental

All the operations were carried out in dry argon or nitrogen atmosphere using a vacuum line or a glove box. The alcohols were dried by distillation over the corresponding aluminium alkoxides and the hydrocarbons by distillation over metallic sodium or $LiAlH_4$. Crystalline samples of $Al(OPr^i)_3$ were obtained by the action of alcohol on liquid freshly distilled isopropoxide. Its m.p. was 140 °C [9]. $Mg(acac)_2$ was obtained by the action of Mg metal on excess of acetylacetone and purified by recrystallization from toluene. IR spectra of nujol mulls were registered with a Perkin–Elmer FT-IR spectrometer 1720 X. ^1H NMR spectra were recorded for the $CDCl_3$ solutions on a Bruker 400 MHz spectrometer at 30 °C. Mass-spectra were recorded using a JEOL JMS-SX/SX-102A mass-spectrometer applying electron beam ionization ($U = 70$ eV) with direct probe introduction.

2.1. Synthesis and isolation of *1* and *2*

A crop of single crystals of $Al_{11}O_6(OPr^n)_{10}(OPr^i)_{10}(OR)(ROH)_2$ ($R = Pr^i$, Pr^n) (**1**) was formed after prolonged storage of a solution containing 0.75 g (3.65 mmol) $Al(OPr^i)_3$ and 2.6 g (5.5 mmol) $Ta(OPr^i)_5$ in 15 ml ^{i}PrOH after addition of 8 ml ^{n}PrOH and subsequent storage at ~0 °C. The low yield of this product precluded its further characterization. Elemental analysis for **1**: found: C, 45.9; H 9.1; Al, 17.2. Calc. for $C_{69}H_{163}Al_{11}O_{29}$: C, 47.2; H, 9.3; Al, 16.9%.

A crop of single crystals of $Al_5Mg_4(\mu_4\text{-}O)_2(\mu_3\text{-}O)(\mu\text{-}OH)_3(\mu\text{-}OPr^i)_8(\mu,\eta^2\text{-acac})_4(\eta^2\text{-acac})_2 \cdot 0.5PhMe$ (**2**) was obtained in the following experiment: $Al(OPr^i)_3$ (0.24 g, 1.2 mmol) and $Mg(acac)_2$ (0.26 g, 1.2 mmol) were dissolved in 3 ml of toluene and subjected to reflux for about 1 h. The solution was diluted with an additional 1.5 ml toluene and left for crystallization at −30 °C overnight. The needle-shaped crystals formed (about 0.1 g) were shown to be the initial $Mg(acac)_2$. They were separated by decantation and the mother liquor was concentrated to about one fourth of the initial volume and left at room temperature for one month. A number of large (up to 1.5 mm) rod-shaped single crystals of **2** were formed and isolated by removal of solvent by syringe and dried in vacuo. Found: C, 46.1; H, 7.0%. Calculated for $Al_5Mg_4O_3(OH)_3(OC_3H_7)_8(O_2C_5H_7)_6(C_7H_8)_{0.5}$: C, 47.2; H, 7.2. 2.2. Crystallography

For the details of the data collection and treatment see Table 2. The structures were solved by standard direct methods. The majority of the non-hydrogen atoms were located directly from the initial solutions and completed using difference Fourier syntheses. All non-hydrogen atoms (except for the propoxide groups based on C(4), C(5), C(9) and C(10) in **1**, which were subjected to rotational disorder that could not be successfully resolved, and the highly disordered toluene molecule in **2**, where only isotropic refinement was possible) were refined first in isotropic and then in anisotropic approximation. The positions of the hydrogen atoms connected to the carbon atoms were calculated geometrically and included into the final cycles of refinement in riding isotropic approximation with the temperature factors $U = 1.2$ Uiso of the corresponding C atom for the CH and $U = 1.5$ Uiso for the CH_3 groups. The hydrogen atom of the solvating alcohol molecule could not be located in a reliable way in the difference Fourier syntheses and was supposed to be attached to the oxygen atom O(10), demonstrating relatively longer distances to the corresponding Al atoms. The hydrogen atoms of the hydroxide groups in **2** were located in difference Fourier syntheses and included into the final solution in isotropic approximation. In the determination of the structure of **2** the automatic solution contained only one type of metal atom, but systematically longer metal–oxygen distances for four of them permitted to suppose that magnesium atoms occupied these positions. The introducing of Mg into them resulted in a very strong decrease in *R*-factors, supporting the chosen model. An additional confirmation for this choice is provided by the sum of the formal charges in the structure, corresponding to the presence of five trivalent and four divalent metal atoms and by the evidently analogous placement of the four Mg atoms in the molecule (symmetric in observation, while not supported by the formal crystallographic symmetry elements). All calculations were performed on a personal computer using the SHELXTL-NT program package [10].

3. Results and discussion

Formation of oxogroups in the structures of compounds **1** and **2** occurs apparently via decomposition of the bimetallic complexes – isopropoxides of aluminium and tantalum in the first case and alkoxoacetylacetonates of aluminium and magnesium in the second. It is well known that the bimetallic alkoxides are much easier decomposable via, for example, ether elimination, than the homometallic derivatives [1]. In the $Al(OPr^i)_3$–$Ta(OPr^i)_5$–^{i}PrOH system a drastic increase in solubility of the components has been observed in the composition range from 1:1 to 1:2. The individuality of the liquid heterometallic complexes of these compositions has been confirmed by the mass-spectrometric studies [11]. Crystallization of **1** occurred only on addition to the solution the alcohol with normal chain structure – ^{n}PrOH. The duration of this process permits to suppose that uncontrolled hydrolysis might be involved in this case, the oxoalkoxide **1** being the least soluble compound in this multi-component system.

It has earlier been found out that the interaction of $Al(OPr^i)_3$ with $Mg(acac)_2$ in 2:1 ratio in toluene in the presence of 2 additional equivalents of Hacac leads to almost quantitative formation of $Mg(\mu\text{-}OPr^i)_4[Al(acac)_2]_2$ [12]. In the present work, the same reaction was carried out in 1:1 ratio in the absence of additional acetylacetone. Cooling down of the solution initially subjected to reflux led to crystallization of approximately half of the initial $Mg(acac)_2$, and changed the ratio of the components to 1:2. Long-term storage of the mother liquor led to formation of a small crop of single crystals of $Al_5Mg_4O_3(OH)_3(OPr^i)_8(acac)_6 \cdot 0.5PhMe$ (**2**). It can be supposed that the formation of **2** (according to its stoichiometry) might be due to decomposition of bimetallic alkoxo-acetylacetonate complexes formed in solution. The presence of hydroxide groups in its molecule cannot be taken as an ultimate proof of involvement of uncontrolled hydrolysis in this case, as, for example, a hydroxide complex $Al_8O_2(OH)_2(OBu^i)_{18}$ has been obtained by Abrachams et al. [6] under anhydrous conditions on distillation of an aseotrop of toluene and alcohol from $Al_4O(OBu^i)_{10}$(^{i}BuOH). The positive effect of bases on such decomposition processes as, for example, ether elimination is well known resulting in often

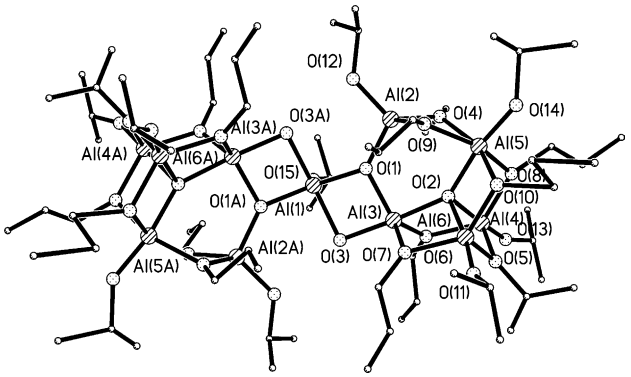

Fig. 1. Molecular structure of $Al_{11}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}O)_2(\mu\text{-}OPr^n)_{10}(\mu\text{-}OPr^i)_2(\mu\text{-}ROH)_2(OPr^i)_8(OR)$ (**1**).

rather deep transformation of the bimetallic species formed [13].

The molecule of $Al_{11}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}O)_2(\mu\text{-}OPr^n)_{10}(\mu\text{-}OPr^i)_2(\mu\text{-}ROH)_2(OPr^i)_8(OR)$, R = Pr^i, Pr^n (**1**) (Fig. 1, Table 3) contains two pentanuclear cores $[Al_5(\mu_4\text{-}O)(\mu_3\text{-}O)(\mu\text{-}O)(\mu\text{-}OR)_6(OR)_4]$, connected to each other via a central $[Al(\mu_3\text{-}O)_2(\mu\text{-}O)_2(OR)]$ group. In the latter the Al(1) atom has trigonal bipyramidal coordination, where the μ–O(3) and μ–O(3A) atoms occupy the axial positions. The bonds around the μ_3-O(1) oxogroups are arranged in one plane (the sum of bond angles being 359.7). The aluminium atoms in the pentanuclear cores display tetrahedral, Al(2), trigonal bipyramidal, Al(3, 4, 6), and octahedral, Al(5), coordination. Four metal atoms – all except Al(3), connected to the central group via two oxo-bridges, – each bear one terminal OR-group. Metal atoms in the core are coordinating one μ_4-O(2), six μ-OR-groups and one bridging alcohol molecule –O(10). It is very important to note that 10 of the 12 bridging OR-groups have normal structure hydrocarbon groups. This fact explains supposedly the absence of information in the literature on aluminium oxoalkoxides containing only OPr^i-groups. [1] The alcohol molecule RO(10)H could be identified by comparably longer Al–O distances (see Table 3).

The same kind of pentanuclear cores have been observed earlier in the structure of the decanuclear oxoethoxide, $[Al_{10}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}OEt)_{14}(OEt)_8]$ [4]. The difference between the structures of 10- and 11-nuclear complexes consists only in that in the first one the cores are connected via two μ_3-O-groups (forming a four-member ring $[Al_2O_2]$), and in the second – via an additional fragment containing one more (the 11th) aluminium atom (in the central $[Al(\mu_3\text{-}O)_2(\mu\text{-}O)_2(OR)]$ group).

The molecule of $Al_5Mg_4(\mu_4\text{-}O)_2(\mu_3\text{-}O)(\mu\text{-}OH)_3(\mu\text{-}OPr^i)_8(\mu, \eta^2\text{-acac})_4(\eta^2\text{-acac})_2 \cdot 0.5PhMe$ (**2**) (Fig. 2,

[1] Partial substitution for *n*-chain structure alkoxide groups has been reported earlier to permit isolation of such crystalline derivatives as $Ti_3O(OPr^i)_9(OMe)$ [14] and $Ti_{11}O_{13}(OPr^i)_{13}(OEt)_5$ [15].

Table 4) also contains five-nuclear cores, in which two aluminium atoms, connected to the μ_4-O, are replaced by Mg ones. It is to be noted that one of them – Mg (7) or Mg (8) conserves the trigonal bipyramidal coordination of the corresponding Al atoms, while the second one turns out to be octahedrally coordinated [Mg (6) or Mg(9)]. Both Mg atoms and one Al atom [(4) or Al(5)] coordinate one acac-group each. One of the latter contains only monodentate oxygen atoms [η^2-coordinated to Mg(6) or Mg(9)], while the two other contain one μ_2-O atom each. In addition, one of the μ-OR groups in the core is replaced by a μ-O group [O(7) or (12)s]. The major structural difference of **2** in comparison with the above mentioned aluminium alkoxides lies in the fact that the two cores in it are connected via a common edge Al(3)-[μ_3-O(8)] (containing the Al atom not connected to μ_4-O) and an additional μ-OH bridge. The sum of bonding angles at O(8) is 360°. The metal–oxygen

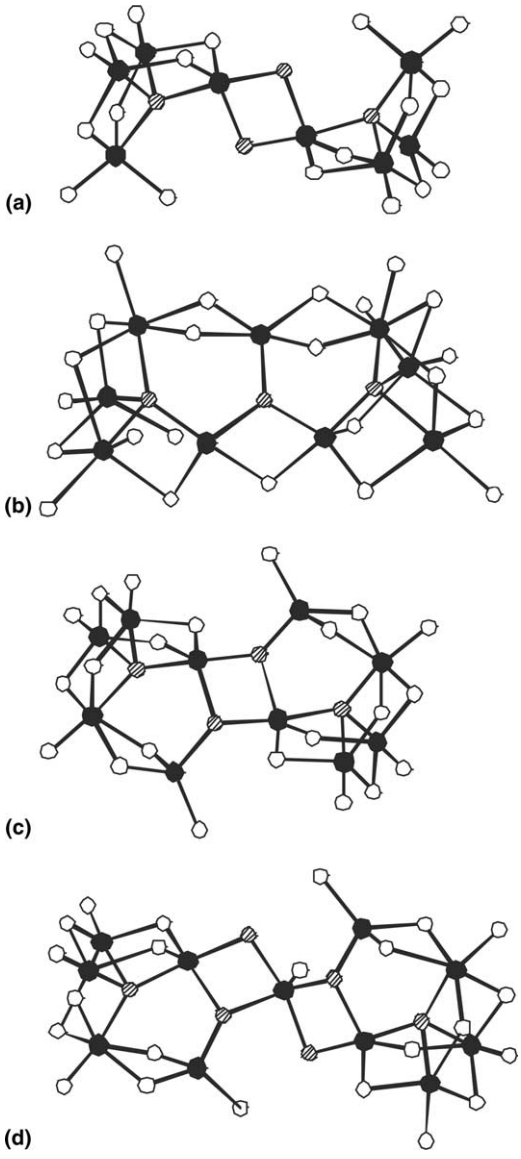

Fig. 3. Comparison of the metal–oxygen cores in the molecules of eight- (a), nine- (b), 10- (c) and 11-nuclear (d) oxoalkoxides – $[Al_4(\mu_4\text{-}O)(\mu\text{-}OH)(\mu\text{-}OBu^i)_5(OBu^i)_4]_2$ [6] $Al_5Mg_4O_3(OH)_3(OPr^i)_8(acac)_6 \cdot 0.5PhMe$, $[Al_{10}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}OEt)_{14}(OEt)_8]$ [4], $Al_{11}O_6(OPr^n)_{10}(OPr^i)_{10}(OR)(ROH)_2$ ($R = Pr^i$, Pr^n).

skeleton of the pentanuclear cores in **2** does not differ from those in the 10- and 11-nuclear complexes and the structure as a whole turns out to be analogous to that of the recently reported nine-nuclear iron oxoethoxide $Fe_9(\mu_4\text{-}O)_2(\mu_3\text{-}O)(\mu\text{-}OEt)_{15}(OEt)_6 \cdot EtOH$ [16].

The Al–OR bond lengths in the molecule of **1** increase regularly with the increase in the coordination number of the metal atom (Table 1) and differ only negligibly from those found in the molecules of decaaluminium oxoethoxide or tetranuclear $Al_4(\mu_4\text{-}O)(OR)_{10}$ (R), $R = Bu^i$, CF_3CH_2 [5,6]. At the same time in the molecule of **2** (and its structural analog $Fe_9O_3(OEt)_{21} \cdot EtOH$ [16]) one can hardly find the same kind of correlation due, supposedly to considerable steric tension in this highly condensed structure.

Combinations of two structural fragments close to the described pentanuclear cores is observed also in other molecules. Thus, for example, the structure of $[Al_8(\mu_4\text{-}O)_2(\mu\text{-}OH)_2(\mu\text{-}OBu^i)_{10}(OBu^i)_8]$ [6] can be considered as a derivatization of the decanuclear analog of the oxoethoxide, where the fifth aluminium atom, not connected to μ_4-O, is missing (Fig. 3(a)). The two molecular structures described in this work permit the completion of the structural series of aluminium oxoalkoxides – from octamer to undecamer (Fig. 3).

4. Supplementary material

Supplementary data are available from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 205865 and 205866 for compounds **1** and **2**, respectively.

Novel mercury(II) complexes of 1,3-dithiole-2-thiones containing the 2-pyridyl moiety: syntheses, X-ray crystal structures and solution behavior

Hye Jin Nam, Ha-Jin Lee, Dong-Youn Noh *

Department of Chemistry, Seoul Women's University, Seoul 139-774, Republic of Korea

Received 7 July 2003; accepted 19 September 2003

Abstract

The mercury(II) complexes of 5-pyridin-2-yl-5,6-dihydro-[1,3]dithiolo[4,5-*b*][1,4]dithiin-2-thione (2PyEDT-DTT: **1**), [Hg(2PyEDT-DTT)X_2] (X = Cl (**2a**), Br (**2b**) and I (**2c**)) were obtained from the reaction of HgX_2 and 2PyEDT-DTT. These complexes adopt a dimeric arrangement of [Hg(2PyEDT-DTT)X_2]$_2$ through intermolecular Hg···N and Hg···S interactions. According to the FT-IR/UV–Vis/NMR spectroscopy data, these intermolecular interactions are cleaved in media containing trace H_2O. [Hg(2PyDT-DTT)$_2$] (**3**; 2PyDT-DTT: 5-(1-pyridin-2-yl-vinylsulfanyl)-2-thioxo-[1,3]dithiole-4-thiolate) was isolated from the filtrate of **2**. The Hg(II) ion is located in a center of symmetry and adopts a distorted octahedral geometry with four sulfur atoms (two from the thiolate groups and two from the sulfide groups) and two nitrogen atoms from the pyridyl group. The time-dependent solution UV–Vis and ^{1}H NMR measurements showed the transformation of 2PyDT-DTT to 2PyEDT-DTT caused by trace H_2O in organic solvents.

1. Introduction

The coordination chemistry of mercury(II) with N-, O- and S-donors has been extensively studied so far as its versatile coordination modes [1] and biological applications [2] are concerned. The mercury(II) ion has a large polarizability and, therefore, shows a specific affinity to S-donor ligands such as dithiocarbamate [2g], alkylthiolate [3], thione [4] and thioether [5]. Moreover, mixed N-/S-donor systems such as heterocyclic thiones [6] exhibit various coordination modes to the mercury(II) ion. Given their capacity to act as an S-donor, 1,3-dithiol-2-thione derivatives have been used to make complexes of Hg(II), Ag(I) and Cu(I) ions [7]. In these complexes, the sulfur atoms in the sulfide and thione moieties participate as S-donors. Mercury(II) compounds, such as mercury acetate, have also been routinely used in the modification of the thione moiety in 1,3-dithiol-2-thiones to create the corresponding thioketone, which is frequently used in the phosphite-based coupling reaction for tetrathiafulvalene (TTF) derivatives [8].

In our previous papers, we reported on the various coordination modes of the mercury(II) ion with S-donors: i.e. the bi-mercury complex of three- and four-coordination with 1,2-dithiolate ligand [9a], an unusual three-coordinated mercury(II)–thiolate complex [9b] and a dimeric [Hg(μ-Cl)Cl(dPhEDT-DTT)]$_2$ (dPhEDT-DTT: 2,3-dihydro-2,3-diphenyl-1,3-dithiolo[4,5-e][1,4] dithiin-6-thione) complex with a tetrahedral (μ-Cl)$_2$ $HgClS_{thione}$ core [9c]. Here, we report on the synthetic and structural investigation of mercury(II) complexes with the mixed N-/S-donor ligands, 2PyEDT-DTT (5-pyridin-2-yl-5,6-dihydro-[1,3]dithiolo[4,5-*b*][1,4] dithiine-2-thione) and 2PyDT-DTT (5-(1-pyridin-2-yl-vinylsulfanyl)-2-thioxo-[1,3]dithiole-4-thiolate) performed by X-ray crystal structure analysis and FT-IR spectroscopy. The transformation of 2PyDT-DTT from/to 2PyEDT-DTT in a solution state was investigated by means of time-dependent UV/Vis and ^{1}H NMR spectroscopies.

2. Experimental

2.1. Materials

All chemicals and solvents used in the syntheses were of reagent grade and used without further purification. The solvents used for the spectroscopic measurements were purified according to the literature method [10].

2.2. Measurements

The melting point was measured using an LA9100 electrothermal digital melting point apparatus. Elemental analyses were performed at the Korea Basic Science Institute (KBSI), Seoul. Infrared spectra were recorded on a MIDAC Prospect FT-IR spectrophotometer using the KBr pellet and/or Nujol mull methods. Electronic spectra were obtained on an HP 8452 diode array spectrophotometer and a Shimadzu Double-Beam UV-2100 spectrophotometer for the liquid and solid-state measurements, respectively. ^{1}H NMR spectra were recorded on a 300 MHz Bruker AC-250 spectrometer in $CDCl_3$ and DMSO-d_6.

2.3. Syntheses

2.3.1. 2PyEDT-DTT (**1**)

To a suspension of oligo(1,3-dithiole-2,4,5-trithione) (0.59 g, 3.0 mmol) [11,12] in benzene (50 ml) was added 2-vinylpyridine (0.32 ml, 3.0 mmol). After refluxing for 1 h at 80 °C, the hot solution was filtered and decolorized with activated charcoal (3.0 g). The brown solution was purified by column chromatography on silica gel with chloroform as the eluent. The yellow product was washed with EtOH and dried in a high vacuum. Yield 48%; mp 109–110 °C (decomp); FABMS (*m*/*z*) 302 ($M^+ + 1$); ^{1}H NMR ($CDCl_3$, ppm) δ 3.60(1H, dd), 3.85(1H, dd), 4.86(1H, dd), 7.30(1H, m), 7.45(1H, d), 7.76(1H, dt), 8.62(1H, d); ^{13}C NMR ($CDCl_3$, ppm) δ 34.763, 49.139, 122.738, 123.340, 123.512, 123.958, 137.268, 150.032, 156.532, 208.159; IR (KBr, cm^{-1}) 1581m, 1566m (py C=N), 1485m, 1467ms, 1430m (py C=C), 1055vs (C=S), 786m, 751ms, 608m (py C–H); λ_{max}(CH_3CN, nm): 214(st), 268(m), 406(m).

2.3.2. Hg(2PyEDT-DTT)X_2 (**2**)

To a 20 ml CH_2Cl_2 solution of **1** (0.15 g, 0.50 mmol) was added HgX_2 (0.50 mmol, 0.14 g for X = Cl; 0.18 g for X = Br; 0.23 g for X = I) dissolved in CH_3CN with stirring at room temperature. The red crystals formed from the mixture after standing for two days were filtered and washed with MeOH, and then dried *in vacuo*.

*Hg(2PyEDT-DTT)Cl_2 (**2a**)*. Yield 69%; mp 140–141 °C (decomp); *Anal*. Calc. for $C_{10}H_7NS_5Cl_2Hg$: C 20.95, H 1.23, N 2.44, S 27.91; Found: C 20.82, H 1.34, N 2.21, S 27.39%; IR (Nujol, cm^{-1}) 1583m, 1568m (py C=N), 1463s, 1455s, 1432m (py C=C), 1027s (C=S), 784m, 745ms, 610w (py C–H).

2.4. X-ray crystal structure determinations

The X-ray crystal data were collected on an Enraf–Nonius CAD-4 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K. The structures were solved by the direct method (compound **1**) or the heavy-atom method (compounds **2** and **3**) with SHELXS 86 [13] and refined by full-matrix least-squares analysis on F^2 with SHELXS-93 [14]. Atomic scattering factors for all non-hydrogen atoms were supplied by the SHELXS-86 system [13]. The crystallographic data collection and refinement details are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

2PyEDT-DTT (**1**) was synthesized by employing the [2 + 4] cycloaddition reaction of oligomeric 1,3-dithiole-2,4,5-trithione and 2-vinylpyridine under the modified reaction condition (Scheme 1), and obtained in a higher yield (48%) than the reported one (20%) [15]. The 2-pyridyl compound thus prepared was fully characterized by spectroscopic methods and X-ray crystal structure analysis (Fig. 1). The preparation of its Hg(II) complexes **2** was achieved at room temperature (RT) with a 1:1 molar ratio of HgX_2 (X = Cl, Br and I) and **1** in a mixed solvent of acetonitrile and methylene chloride. After the filtrates of **2** were left to stand for an extended period of time, **3** was unexpectedly obtained, regardless of the halide ion being used (Scheme 1). This was confirmed by elemental analysis and X-ray structure analysis as will be discussed below. The total yield of **3** was about 3–6%, while that of **2** was 69–74% at RT, irrespective of the amount of HgX_2 used. However, the yields of **2** and **3** were strongly dependent upon the reaction temperature: When the reaction was performed at 60 °C, the yield of **3** (synthesized from $HgCl_2$) increased to 21%, while that of **2a** went down to 5%, indicating that **2a** is a major product at RT, but a minor product at 60 °C. On the other hand, the yields of **3** (synthesized from $HgBr_2$ and HgI_2) were almost unchanged (5%) even at 60 °C, with those of **2b** and **2c** being 3% and 32%, respectively. This indicates that **2c** is a major

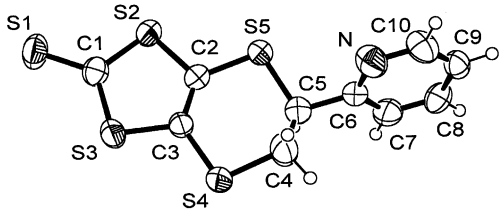

Fig. 1. Molecular structure of 2PyEDT-DTT (**1**) with the atomic numbering scheme.

product both at RT and at 60 °C. This observation can be understood based on the principle of *hard and soft acid and base* [16]: Hg(II) and the chloride ion are the most unfavorable couple among the three halide complexes, so that the elimination of HCl would be expected to be the most favorable process and would therefore give **3** as a major product at 60 °C instead of **2a**. However, in the case of HgI_2, the I_2HgSN core in **2c** is the most favorable soft acid–soft base combination, so that **2c** is still the major product even at the more elevated reaction temperature. It is noticeable, however, that the total recovery of **2** and **3** was decreased at 60 °C. The same trend was found when a mixed solvent consisting of methanol and acetone was used both at RT and at 60 °C.

Based on these observations, it can be conjectured that the formation of complexes **2** and **3** occurs via two intermediate states, [**A**] and [**B**], as shown in Scheme 1. The involvement of intermediate [**A**] can be proposed based on the assumption that the pyridyl group is a stronger Lewis base than the sulfur atoms in the thione and sulfide moieties. When the intermediate [**A**] is dimerized by adopting a sulfur atom in a thione moiety as the fourth coordination of the mercury(II) ion, it forms the dimeric complex **2**. On the other hand, when the fourth coordination of the mercury(II) ion is found in a sulfide moiety of the same molecule, it proceeds to another transition state [**B**]. In this state, the hydrogen atom in between the coordinating sulfur and nitrogen atoms becomes more acidic due to the electron donation of $S \rightarrow Hg(II)$ and $N \rightarrow Hg(II)$. Consequently, the cleavage of the C–S bond induced by the deprotonation of the acidic proton results in the ring-opening of the 1,3-dithiin moiety, which is accompanied by the formation of a C=C bond.

3.2. X-ray structure analysis of *2b* and *2c*

The crystal data and structure refinement parameters of **2b** and **2c** are shown in Table 1 and the selected bond lengths and angles are listed in Table 2. The X-ray crystal structures obtained from the diamond-shaped

single crystals are demonstrated in Figs. 2 and 3. From the structural analysis results, it was revealed that **2b** is isostructural with **2c** and that they form a head-to-tail type dimeric arrangement with the general formula $[Hg(\mathbf{1})X_2]_2$ (X = Br, I). The mercury(II) ions in these complexes are tetrahedrally coordinated by two bromides (or iodides), one sulfur atom from a thione moiety and one nitrogen atom from the neighboring pyridyl group. Such a coordination mode results in a structural deformation of the coordinated **1**. That is, the C(1)═S(1) bond length (1.680(8) Å for **2b** and 1.672(12) Å for **2c**) is longer than that of the free ligand (**1**) (1.633(6) Å). Furthermore, the difference between the two angles around the C(1) atom (S(1)–C(1)–S(2) and S(1)–C(1)–S(3)) of 7.1° (**2b**) and 9.3° (**2c**) is comparable to the situation of the corresponding angles of free ligand (**1**) which are almost identical (123.7(4)° and 124.0(4)°). This is due to the coordination of S(1) to Hg(II). The Hg···S(1) bond lengths of **2b** (2.670(3) Å) and **2c** (2.711(4) Å) are somewhat longer than the sum of the covalent radii of S and Hg (2.50 Å), but shorter than the sum of the van der Waals radii (3.53 Å) [1b]. The Hg···N# bond lengths of **2b** (2.510(7) Å) and **2c** (2.590(12) Å) are in between the sum of the covalent radii (2.23 Å) and the van der Waals radii (3.28 Å) [1b] of N and Hg. These facts indicate that the intermolecular Hg···S(1) and Hg···N# interactions are relatively significant. In terms of the coordination mode, however, it is worthwhile to consider that $[Hg_2(EDT\text{-}DTT)_2Cl_4]_n$ (EDT-DTT: 4,5-ethylenedithio-1,3-dithiole-2-thione: $C_5H_4S_5$) possesses a one-dimensional polymeric structure with a penta-coordinated Hg(II) ion [7b]. The sulfur atom in the 1,4-dithiin ring of the EDT-DTT ligand coordinates to Hg(II), and this kind of coordination mode is also observed in the corresponding Ag(I) and Cu(I) complexes [7]. However, this coordination mode is not observed in the case of **2b** and **2c**. Instead, a N atom in a pyridine moiety coordinates to Hg(II). The sulfur atom from a thione moiety coordinates to Hg(II) and the Hg···S distance in both **2b** and **2c** is much longer than that in $[Hg_2(EDT\text{-}DTT)_2Cl_4]_n$ (2.454(2) Å). These observations strongly suggest that the intermolecular Hg···S(1) and Hg···N# interactions in **2b** and **2c** could be cleaved in the solution state as will be discussed below.

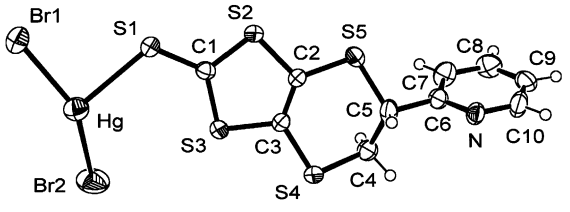

Fig. 2. Molecular structure of Hg(2PyEDT-DTT)Br_2 (**2b**) with the atomic numbering scheme. Complex **2c** is isostructural with **2b**.

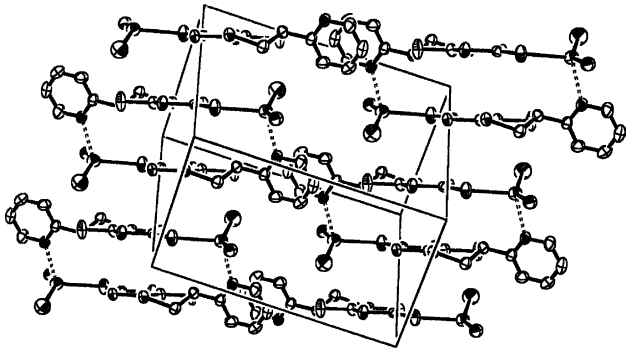

Fig. 3. Crystal structure of Hg(2PyEDT-DTT)Br_2 (**2b**) showing the dimeric arrangement with intermolecular Hg···N interaction (dashed lines). Hydrogen atoms are omitted for clarity.

3.3. X-ray structure analysis of 3

The crystal data and structural refinements for **3** are given in Table 1 and the selected bond lengths and angles are listed in Table 3. As shown in the ORTEP drawing (Fig. 4), the Hg(II) ion is situated in the inversion center with a distorted octahedral geometry, directly linked to two thiolates, two sulfides and two nitrogen atoms from the pyridyl moiety. This complex has a short Hg–S(4) bond of 2.3743(17) Å, whose distance is in between those of the three-coordinated Hg(II)–thiolate complexes such as mononuclear $Hg(SC_6H_5)_3$ (2.448(3) Å) [17] and $[Hg(S\text{-}2,4,6\text{-}Pr^i_3C_6H_2)_3]^{1-}$ (2.442(4) Å) [2e], and those of the two-coordinated ones such as $[Hg(S\text{-}2,4,6\text{-}Pr^i_3C_6H_2)_2]$ (2.322(6) Å) [2e]. Moreover, the Hg···S(5) distance (3.0195(17) Å) is apparently shorter than the Hg···S(sulfide) distance (3.271(2) Å) of $[Hg_2(EDT\text{-}DTT)_2Cl_4]_n$ [7b] and the van der Waals distance (3.53 Å) [1b]. The intramolecular Hg···N distance (2.794 Å) of **3**, however, is much longer than the reported Hg···$N_{pyridyl}$ distances (2.560(3)–2.595(4) Å) [18] and the covalent distance (2.23 Å) [1b]. Moreover, the S(5)–Hg–N angle (64.53(5)°) deviates significantly from 90°, whereas the S(4)–Hg–N angle (88.46(5)°) is quite close to 90°. Based on these findings, it can be supposed that this structure would not be stable in the solution state, even though it exhibits a stable molecular structure in the solid state.

3.4. Infrared spectroscopy

The influence of H_2O on **2** was investigated by FT-IR, and the FT-IR spectra of **2a** in different matrices and with different H_2O contents are demonstrated in Fig. 5. The FT-IR spectrum of **2a** measured in Nujol (Fig. 5(a)) is different from that of the free ligand **1** (Fig. 5(L)) in two main regions: the C═S absorption band of the free ligand **1** (1055 cm^{-1}) shifted to 1023–1027 cm^{-1} (**2**), and the change in the ring stretching vibrations of the pyridyl

Symmetry transformation used to generate equivalent atoms: # $-x+1, -y+1, -z+1$.

group (1400–1600 cm^{-1}). These are surely due to changes in the intermolecular Hg···S and Hg···N interactions, as confirmed in the X-ray structure analysis. The H_2O content in the KBr pellet of **2a** was controlled semi-quantitatively and identified in its FT-IR spectra by the intensity change of the scissoring mode of H_2O observed at around 1620 cm^{-1} (denoted by # in Fig. 5). As the H_2O content increases from (b) to (d) in Fig. 5, the intensity of the free C=S vibration peak at 1055 cm^{-1} (denoted by $*$ in Fig. 5) also increases, whereas that of the coordinated C=S vibration peak at 1027 cm^{-1} (denoted by + in Fig. 5) decreases. Finally, in the spectrum of (d), the peaks are identical to that of ligand (L) except for the broad H_2O peak. The same trend is observed in the ring stretching vibrations of the pyridyl group in the 1400–1600 cm^{-1} range: the ring stretching peaks of the pyridyl group at 1584, 1568, 1468, 1452, 1433 cm^{-1} (Fig. 5(b)) are changed to those of the free ligand at 1583, 1566, 1486, 1469, 1431 cm^{-1} (Fig. 5(d)). From these observations, it can be surmised that due to the trace amount of H_2O in the KBr pellet, the intermolecular Hg···S and Hg···N interactions in **2** are cleaved and that **2** is possibly decomposed into its components, HgX_2 and **1**. These intermolecular interactions, however, have been revealed to be unaffected by increasing temperature up to 50 °C. In the case of complex **3**, the strong peak at 1058

[b] Complexes **2b** and **2c** give the same results as those of **2a**.

cm^{-1} was identified as a C=S vibrational peak of the 2PyDT-DTT ligand, which is free from intermolecular interaction with Hg(II). Additionally, a newly formed vinylidene peak was observed at 917 cm^{-1}.

3.5. Electronic absorption spectroscopy

The electronic transition spectra of **2** and **3** were measured in several liquid and solid media, in which the characteristic $n \rightarrow \pi^*$ transitions of the C=S moiety in **2a** and **3** are listed and compared with those of **1** in Table 4. The $n \rightarrow \pi^*$ transition of **2a** was observed at 406 nm in acetonitrile, which is surprisingly identical with that of the free ligand (**1**). On the other hand, the corresponding transition for solid **2a** (453 nm) measured in a $BaSO_4$ matrix was observed at a higher wavelength than that of solid **1** (430 nm). This blue-shift surely indicates the coordination of the sulfur atom in the C=S moiety to the Hg(II) ion in the solid state. In the solution state, however, the intermolecular Hg···S and Hg···N interactions would be cleaved as soon as the complex is dissolved in the organic solvent. Considering these observations in the light of the IR results, the trace amount of water in the solvents might play an important role in the cleavage of the intermolecular interactions. More interesting results were found for **3**. The $n \rightarrow \pi^*$ transitions were observed near 397 nm for both the solid and liquid forms of **3**, possibly because there were no intramolecular interactions in the C=S moiety. Within four days in a solution state, however, the original $n \rightarrow \pi^*$ transition of **3** exhibited a blue-shift, which resulted in their final values being the same as those of **1**. It is suggested that the 2PyDT-DTT ligand in **3**, formed by deprotonation as proposed in Scheme 1, gradually returned to its original form **1** in the solution state. This transformation can be regarded as being promoted by trace water present in the solvent. More systematic evidence of this transformation was obtained in the time-dependent ^1H NMR study.

3.6. ^1H NMR spectroscopy

The ^1H NMR spectrum of **1** exhibits a total of seven peaks, four of which can be attributed to the protons in the 2-pyridyl group (Fig. 6(e)) and three to those in the ethylene group. As expected from the electronic spectroscopy, the ^1H NMR spectra of **2** measured in $CDCl_3$ and DMSO-d_6 were completely identical to those of the free ligand (**1**), indicating the rapid cleavage of the intermolecular Hg···S and Hg···N interactions in the solvents (see Table 5). Complex **3** showed two sets of ^1H NMR peaks; one set from the free ligand (**1**) and the other from **3**. With the possibility that **3** may contain

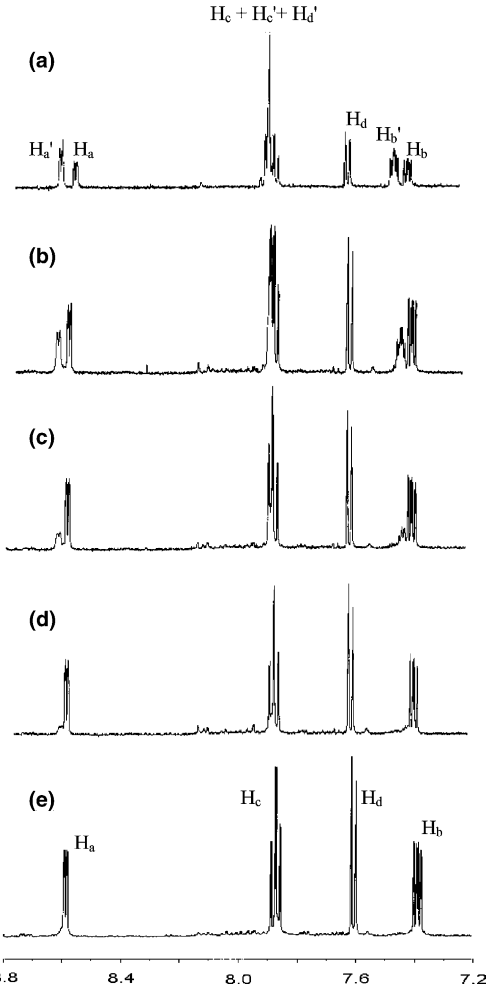

Fig. 6. Time-dependent ^1H NMR spectra of (**3**) in DMSO-d_6 measured after (a) 0 days, (b) 1 day, (c) 4 days and (d) 14 days, compared with (**1**) (e) (see Scheme 1 for the assignments of the different protons).

Table 5
^{1}H NMR spectral data of the complexes measured in DMSO-d_6 (in ppm)[a]

Complex	H_a	H_b	H_c	H_d	H_e	H_f	H_g	$H_{a'}$	$H_{b'}$	$H_{c'}$	$H_{d'}$	$H_{f'}$	$H_{g'}$
PyEDT-DTT (**1**)	8.58	7.38	7.86	7.59	5.13	3.88	3.80						
Hg(2PyEDT-DTT)X_2 (**2**)	8.58	7.39	7.87	7.60	5.13	3.88	3.80						
Hg(2PyDT-DTT)$_2$ (**3**)[b]	8.58	7.39	7.87	7.61	5.14	3.87	3.81	8.62	7.46	7.92	7.87	6.31	5.66

[a] Measured at 303 K. See Scheme 1 for the hydrogen labelling.
[b] Measured just after the sample was dissolved in DMSO-d_6.

some proportion of **1** having already been excluded by the FT-IR, UV–Vis and X-ray structure analyses, as well as by the elemental analysis, it is likely that complex **3** reaches the equilibrium state (Eq. (1)) rapidly after it is dissolved in NMR solvents. Therefore, between 7.2 and 8.8 ppm where the pyridyl protons are observed, two sets of NMR peaks corresponding to the free ligand and **3** were observed, as shown in Fig. 6(a). The initial molar ratio of **1** to **3** is calculated as being 0.7, based upon the intensity ratio of H_a/H'_a and H_b/H'_b.

$$\mathrm{Hg(II)} + 2\mathbf{1} \Longleftrightarrow \mathbf{3} + 2\mathrm{H}^+ \quad (1)$$

This equilibrium slowly moved backward and, finally, the peaks of **3** ($H_{a'}$–$H_{d'}$ in Fig. 6) completely shifted to those of **1** (H_a–H_d in Fig. 6) after 14 days. The two peaks corresponding to $=CH_2$ in the vinylidene group of **3** ($\delta = 6.31$ and 5.66 ppm) also gradually diminished, while those corresponding to $–CH_2–$ and –CH– in the ethylene group ($\delta = 3.87$, 3.81 and 5.14 ppm) intensified.

4. Conclusion

We synthesized the dimeric mercury(II) complexes ([Hg(2PyEDT-DTT)X_2]$_2$ where X = Cl, Br and I) through the reaction of mercury halides and pyridine-containing 1,3-dithiol-2-thione (2PyEDT-DTT). In these complexes, the tetrahedrally-coordinated mercury(II) ion forms intermolecular Hg···S and Hg···N interactions with S- and N-donors. It was revealed by FT-IR investigation that these interactions are easily destroyed by trace H_2O resulting in the Hg(II) ion and the free ligand (2PyEDT-DTT). As a product of the mercuration of 2PyEDT-DTT, the Hg(2PyDT-DTT)$_2$ complex was isolated, wherein the mercury(II) ion is octahedrally coordinated to form the N_2HgS_4 core. This complex is reversibly transformed to 2PyEDT-DTT and Hg(II) in solvents as evidenced by the time-dependent UV–Vis and ^{1}H NMR measurements.

5. Supplementary data

Supplementary data for the structural analyses are available from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 212796–212799 for the complexes **1**, **2b**, **2c** and **3**, respectively.

Rotational barriers in dialkylaminochlorophosphines: methyl-substituted piperidinochlorophenylphosphines

Jason Anagnostis, Mark M. Turnbull *

Carlson School of Chemistry and Biochemistry, Clark University, 950 Main St., Worcester, MA 01610, USA

Received 19 July 2003; accepted 22 September 2003

Abstract

Barriers to rotation about the P–N bond in a series of substituted piperidinochlorophenylphosphines were measured. The barriers for piperidine, 2-methylpiperidine and *cis*-2,6-dimethylpiperidine are the same within experimental error. The thermal condensation of the corresponding bis(piperidino)phosphine oxides with $Mo(CO)_6$ show that only the *cis*-2,6-dimethyl compound produces significant quantities of the $[R_2NPO]_4[Mo(CO)_4]_2$ complex. These observations are explained in terms of the steric requirements of the various amines and aminophosphines via cone angle measurements. Condensation of the mixed phosphine oxide, $(^iPr_2N)(Et_2N)PHO$, with $Mo(CO)_6$ produces $[Et_2NPO]_4[Mo(CO)_4]_2$.

Keywords: Rotational barriers; Polyphosphoxane; Cage complexes; Cone angles

1. Introduction

Since the initial discovery by Wong et al. [1] of the condensation reaction between bis(di-isopropylamino)phosphine oxide and molybdenum hexacarbonyl to produce the polycyclic Cage complex $(CO)_4Mo[^iPr_2NPO]_4Mo(CO)_4$ (**1**) (Fig. 1, $R = {}^iPr$), a number of related complexes of the general formula $L_aM[R_2NPO]_nM'L'_b$ have been prepared (M, M′ = Cr, Mo, W, Fe, Ni, Pd, Pt, Cu, Ag, none; L′ = CO, Cl, Br, I; R_2N = various secondary amino groups; $n = 3$–6) [2–6]. The complexes can be prepared by four pathways: direct synthesis by reaction of two diphosphine-substituted metal complexes [2], substitution of one metal for another in a Cage [4], reaction of a metal complex with a cyclotriphosphoxane [3,5], and direct thermal condensation of a bis(dialkylamino)phosphine oxide with $M(CO)_6$ (M = Cr, Mo, W) [2,3,5].

The latter route to these Cage complexes exhibited an apparent steric dependence as the reaction was successful only when large secondary amino groups, such as diisopropyl and dicyclohexyl, were employed. With less hindered amino substituents such as dimethyl-, diethyl-, and dibenzylamino, no Cage complexes could be isolated and only traces were observed spectroscopically [2]. The proposed mechanism for the thermal condensation involves initial coordination to the metal center by the diaminophosphine oxide (in its phosphinous acid tautomeric form, $\mathbf{I_1}$) followed by elimination of one molecule of dialkylamine to generate the coordinated phosphinidene oxide ($\mathbf{I_2}$). Condensation of the P=O functions and addition of a second metal atom leads to the observed products [2] (see Scheme 1).

The key step appears to be the elimination of the dialkylamine to produce the coordinated phosphinidene oxide ($\mathbf{I_2}$) and the observed requirement for bulky amines suggests that the step is driven by the relief of steric strain in intermediate $\mathbf{I_1}$.

We previously examined the steric requirements of the various alkyl substituents by variable temperature NMR experiments to determine the barrier to rotation about the P–N bond on the related dialkylaminochlorophenylphosphines [7]. We had reasoned that, within a homologous family of compounds, the electronic contributions to the barrier would remain constant and any differences observed would result from the steric bulk of

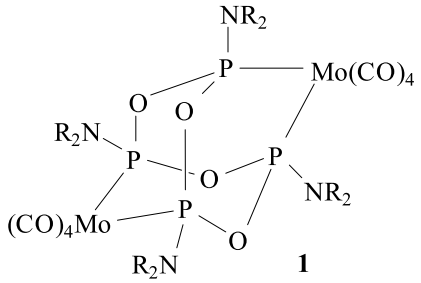

Fig. 1. The structure of the Cage complexes **1**.

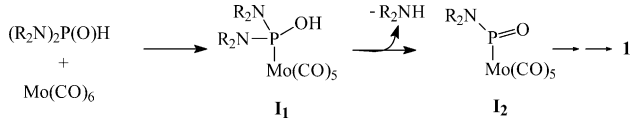

Scheme 1. Proposed mechanism for the synthesis of **1**.

the alkyl substituents. The barriers for the dialkylamino groups studied, Me_2N–, Et_2N–, Bz_2N–, $^iPr_2N$– and C-hex_2N–, fell into two distinct classes. Those with primary alkyl groups had rotational barriers of 11.6 ± 0.1 kcal/mol, while those with secondary alkyl groups had barriers of 13.4 ± 0.2 kcal/mol. Only those amino groups exhibiting the higher barrier were observed to produce Cage complexes by thermal condensation, suggesting that the steric bulk requirement in the diaminophosphine oxides for the formation of **1** was correct. However, we wished to test whether this correlation of barrier to P–N bond rotation in the dialkylaminochlorophenylphosphines would have predictive value for the success of the Cage-forming thermal condensations. Thus, we undertook the present study where we determined the barrier to rotation about the P–N bond in the series $(R_2N)PhPCl$ [R_2N = piperidine (pip), (±)-2-methylpiperidine (Mepip), *cis*-2,6-dimethylpiperidine (Me_2pip), 2,2,6,6-tetramethylpiperidine (Me_4pip)] and examined the reaction of the corresponding phosphine oxides, $(R_2N)_2P(O)H$, with $Mo(CO)_6$.

2. Experimental

All reactions were carried out under argon using Schlenk technique. CH_2Cl_2 was distilled from CaH_2, toluene from Na metal, and Et_2O and THF from Na/benzophenone ketyl. Amines were distilled just prior to use from KOH. PCl_3 and $PhPCl_2$ were purchased from Aldrich and used as received. IR spectra were recorded on a PE-1600 or PE Paragon 500 spectrophotometer. NMR spectra are reported at r.t. (unless otherwise noted) and were recorded on a Bruker AC-200 spectrometer. ^1H and ^{13}C NMR spectra were referenced to the solvent while ^{31}P NMR spectra were referenced to external Ph_3P (broadband proton decoupled unless otherwise noted). All values are given in ppm [s, singlet; d, doublet; t, triplet and br, broad]. Diisopropylaminophenylchlorophosphine (**2e**) was prepared as previously described [7]. Elemental analyses were performed at the Instrumentation Center, University of New Hampshire. Computer simulations of NMR spectra were performed on a VAX system using the KUBO program [8].

2.1. Cone angle measurements

Cone angle measurements on phosphines were carried out using CPK models according to the procedure of Tolman [9], and measurements on amines were carried out according to the procedure of Seligson and Trogler [10]. In both cases, the individual half-angles were measured and the value of the cone angle calculated as

$$\Theta = 2/3 \sum_i \theta_i. \quad (1)$$

Measurements on trigonal amines are reported as fan angles [11]. In these cases, only two measurements θ_i were possible since there were only two substituents on the N-atom in addition to the metal. Θ was calculated in the same fashion. In all cases, the sleekest conformation (that conformation resulting in the smallest value of Θ) was used.

2.2. Chlorophenylpiperidinophosphine (*2a*)

Dichlorophenylphosphine (0.905 g, 5 mmol) was dissolved in 20 ml of CH_2Cl_2 and cooled to −78 °C. Piperidine (0.861 g, 10 mmol) was added dropwise with stirring. The reaction mixture was allowed to warm to r.t. and stirred for an additional 3 h. The resulting white suspension was diluted with Et_2O (6 ml) and filtered. The filtrate was evaporated to dryness under reduced pressure to give a pale yellow oil, 1.07 g (93%). *Anal.* Calc. for $C_{11}H_{15}NPCl$: C, 58.03; H, 6.64; N, 6.15. Found: C, 57.18; H, 6.02; N, 5.85%. *Note*. Repeated attempts failed to give better results, presumably due to the ease of hydrolysis of the compound. ^{31}P NMR (d_6-acetone): δ 140.1 (s). ^{13}C NMR (d_6-acetone): δ 140.1 (d, $J = 28$ Hz), 131.2 (d, $J = 16$ Hz), 130.6 (s), 129.4 (s), 50.4 (br s), 27.2 (s), 24.5 (s). ^1H NMR ($CDCl_3$): δ 7.7 (m, 2H, *o*-Ph) 7.4 (m, 3H, *m-p*-Ph) 3.0 (br, 4H, NCH_2) 1.5 (br s, 6H, $NCH_2CH_2CH_2$). IR(neat): 3040w, 2900s br, 1040s, 745s, 690s cm^{-1}. *Note*. IR spectra for the chlorophenylpiperidinophosphines are all quite similar with minor changes in the alkyl CH stretching region and the appearance of a band at 1375 cm^{-1} for the methyl-substituted compounds.

The remaining dialkylaminophenylchlorophosphines were prepared in similar fashion on scales of 5–11 mmol. Yield and NMR data are reported below.

*2.2.1. Chloro(2-methylpiperidino)phenylphosphine (**2b**) mixed diastereomers*

Yield: 1.1 g (70%). *Anal.* Calc. for $C_{12}H_{17}NPCl$: C, 59.63; H, 7.09; N, 5.79. Found: C, 59.93; H, 7.20; N, 5.54%. ^{31}P NMR (d_6-acetone): δ 136.9 (s, major), 136.3 (s, minor). ^{13}C NMR (d_6-acetone): δ 140.2 (d, $J = 29$ Hz, major), 140.1 (d, $J = 26$ Hz, minor), 131.9 (br s, minor), 129.5 (br s, major), 129.1 (s), 127.9 (s); Major diasteromer: 55.2 (d, $J = 12.3$ Hz), 46.5 (s), 33.6 (s), 27.0 (d, $J = 4.0$ Hz), 21.4 (s), 19.3 (d, $J = 4.2$ Hz); minor diastereomer: 54.7 (d, $J = 7.1$ Hz), 44.4 (s), 32.5 (d, $J = 9.0$ Hz), 26.8 (s), 19.8 (s), 17.7 (d, $J = 7.0$ Hz). ^1H NMR (d_6-acetone): δ 7.7 (m, 2H, *o*-Ph) 7.4 (m, 3H, *m-p*-Ph) 3.7/3.4 (br, 1H, NCH) 3.1/2.9 (br, 2H, NCH_2) 1.9–1.2 (br m, 9H).

*2.2.2. Chloro(cis-2,6-dimethylpiperidino)phenylphosphine (**2c**)*

Yield: 1.9 g (83%). *Anal.* Calc. for $C_{13}H_{19}NPCl$: C, 61.06; H, 7.49; N, 5.47. Found: C, 60.78; H, 7.41; N, 5.72%. ^{31}P NMR (d_6-acetone): δ 141.4 (s). ^{13}C NMR (d_6-acetone): δ 140.0 (d, $J = 27$ Hz), 130.5 (d, $J = 20$ Hz), 129.3 (s), 128.1 (s) 53.4 (br s), 52.8 (d, $J = 18$ Hz), 31.1 (d, $J = 8.1$ Hz), 30.8 (s), 22.6 (d, $J = 8.6$ Hz), 18.1 (s), 13.2 (s). ^1H NMR ($CDCl_3$): δ 7.75 (m, 2H, *o*-Ph) 7.4 (m, 3H, *m-p*-Ph) 3.7 (br, 2H, NC*H*) 1.8–1.2 (br m, 6H, $NCH_2CH_2CH_2$) 1.3 (d, $J = 9.0$ Hz, 3H, CH_3) 1.1 (d, $J = 7.1$ Hz, 3H, CH_3).

*2.2.3. Chloro(2,2,6,6-tetramethylpiperidino)phenylphosphine (**2d**)*

Yield: 1.01 g (64%). *Anal.* Calc. for $C_{51}H_{23}NPCl$: C, 63.49; H, 8.17; N, 4.93. Found: C, 63.40; H, 8.26; N, 4.78%. ^{31}P NMR (d_6-acetone): δ 126.8 (s). ^{13}C NMR (d_6-acetone): δ 139.9 (d, $J = 29$ Hz), 130.1 (d, $J = 23$ Hz) 129.2 (s) 129.0 (s) 62.8 (d, $J = 10.6$ Hz), 59.6 (d, $J = 30$ Hz), 42.2 (s), 40.3 (s), 37.3 (d, $J = 33$ Hz), 33.8 (s), 31.1 (s), 30.9 (s), 17.3 (s). ^1H NMR ($CDCl_3$): δ 7.6 (m, 2H, *o*-Ph) 7.2 (m, 3H, *m-p*-Ph) 1.6, 1.45, 1.3, 0.9 (br singlets, 18H, piperidine protons).

*2.3. Bis(piperidino)phosphine oxide (**3a**)*

PCl_3 (1.80 g, 13 mmol) was dissolved in 30 ml of CH_2Cl_2 and cooled to −78 °C. With stirring, piperidine (6.69 g, 78 mmol) was added dropwise. The reaction mixture was then allowed to warm to r.t. and stirred an additional 5 h. Et_2O (40 ml) was added and the resulting slurry was filtered. The filtrate was evaporated to dryness under reduced pressure and the resulting gum was redissolved in 50 ml of CH_2Cl_2. With stirring, 15 ml of 5% aqueous $NaHCO_3$ was added slowly, followed by an additional 50 ml of H_2O. The layers were separated and the organic layer dried over anhydrous $MgSO_4$. The mixture was filtered and the solvent removed from the filtrate under reduced pressure to give an off-white waxy solid, 1.06 g (37%). *Anal.* Calc. for $C_{10}H_{21}N_2OP$: C, 55.54; H, 9.79; N, 12.95. Found: C, 55.91; H, 9.61; N, 12.68%. IR(neat): 2950–2850s, 2340m, 1230s cm^{-1}. ^{31}P NMR ($CDCl_3$): δ 18.0 (s). ^{13}C NMR ($CDCl_3$): δ 46.0 (d, $J = 16$ Hz), 25.5 (d, 5.5 Hz), 24.1 (s). ^1H NMR ($CDCl_3$): δ 6.6 (d, $J = 573$ Hz, 1H, PH), 3.05 (br, 4H, NCH_2), 1.4 (br, 6H, $NCH_2CH_2CH_2$).

*2.4. Bis(2-methylpiperidino)phosphine oxide (**3b**) (mixed diastereomers)*

The diastereomeric mixture **3b** was prepared in a manner analogous to **3a** on a 22-mmol scale. Yield: 3.35 g (59%). *Anal.* Calc. for $C_{12}H_{25}N_2OP$: C, 58.99; H, 10.31; N, 11.47. Found: C, 55.91; H, 9.61; N, 12.68%. IR(neat): 2950–2850s, 2335m, 1235s cm^{-1}. ^{31}P NMR (d_6-acetone): δ 16.2 (s), 15.5 (s), 14.7 (s). ^1H NMR ($CDCl_3$): 6.7 (d, 3 peaks, $J = 570$ Hz, PH), 4.0–2.6 (br, m) 1.8–1.1 (br, m) 1.2 (d, $J = 6.9$ Hz, CH_3).

*2.5. Bis(2,6-dimethylpiperidino)phosphine oxide (**3c**)*

Compound **3c** was prepared in a manner analogous to **3a** on a 34-mmol scale, except that a solution of 2,6-dimethylpiperidine (40 ml, 30% by volume) in H_2O was used in the hydrolysis step in place of aqueous $NaHCO_3$. Yield: 3.63 g (40%). IR(neat): 2950–2850s, 2345m, 1240s cm^{-1}. ^{31}P NMR (d_6-acetone): δ 20.2 (s). ^{13}C NMR ($CDCl_3$): δ 44.7 (d, $J = 14$ Hz), 44.3 (d, $J = 5.1$ Hz), 30.5 (s), 22.6 (s), 14.1 (s). ^1H NMR ($CDCl_3$): δ 6.6 (d, $J = 656$ Hz, PH), 3.7 (m, NCH_2) 1.6 (m, $NCH_2CH_2CH_2$), 1.30 (d, $J = 7$ Hz, CH_3), 1.29 (d, $J = 7$ Hz, CH_3). *Note*. This compound has been reported previously [5], but spectroscopic data were not given.

*2.6. Diethylaminodiisopropylaminophosphine oxide (**3f**)*

PCl_3 (7.34 g, 53 mmol) was dissolved in 150 ml of CH_2Cl_2 and cooled to −78 °C. Diisopropyl amine (10.83 g, 107 mmol) was added dropwise with stirring. The reaction mixture was allowed to warm to r.t. and stirred an additional 3 h. The resulting white slurry was filtered and the filtrate evaporated to dryness under reduced pressure. The residue was redissolved in 100 ml of CH_2Cl_2, cooled to −78 °C and diethylamine (4.52 g, 60 mmol) was added dropwise. The solution was again allowed to warm to r.t., stirred an additional 3 h and the resulting suspension filtered. The filtrate was evaporated to dryness under reduced pressure and the residue dissolved in 50 ml of THF. With stirring, H_2O (0.29 g, 16 mmol) was added along with solid $NaHCO_3$ (1.43 g, 16 mmol). After stirring for 2 h, the resulting suspension was filtered and dried over $MgSO_4$. The mixture was filtered and the solvent removed from the filtrate under reduced pressure to give a clear, viscous oil, 1.38 g

(11.2%). *Anal.* Calc. for $C_{10}H_{25}N_2OP$: C, 54.52; H, 11.43; N, 12.71. Found: C, 54.32; H, 11.21; N, 12.46%. IR(neat): 2980–2830s, 2330m, 1235s cm^{-1}. ^{31}P NMR ($CDCl_3$): δ 12.3. ^{13}C NMR ($CDCl_3$): δ 44.1 (d, $J = 3.9$ Hz), 37.3 (d, $J = 5.7$ Hz), 23.2 (s), 22.7 (s), 13.7 (s). ^1H NMR ($CDCl_3$): δ 6.9 (d, $J = 561$ Hz), 3.4 (observed d of quin, $J_d = 14$ Hz, $J_{quin} = 6.4$ Hz), 3.0 (observed hex, $J = 6.5$ Hz), 1.2 (d, $J = 6.0$ Hz), 1.15 (d, $J = 6.5$ Hz), 1.1 (t, $J = 7.0$ Hz).

2.7. Reaction of phosphine oxides with $Mo(CO)_6$

The various phosphine oxides (**3a**–**c**,**f**, 5–6 mmol scale) were combined with $Mo(CO)_6$ (0.5 equivalents) in toluene (20 ml) and heated to reflux. Heating was continued for up to 48 h, or until no sign of starting material remained, and aliquots were removed every 4–8 h to monitor the reaction progress by ^{31}P NMR and IR. Reaction with **3a** did not show any signs of Cage formation. Reaction with **3b** showed traces of the desired Cage complex **3b** [^{31}P NMR (toluene/d_6-acetone): δ 151.2(s)] among a complex pattern of signals, but attempts to isolate the material from the reaction mixture were unsuccessful. Products were purified by chromatography on silica gel followed by recrystallization from acetone as described previously [2].

2.7.1. $(CO)_4Mo[(2,6\text{-dimethylpiperidino})PO]_4Mo(CO)_4$ (**1c**)

Yield: 0.49 g (35%). ^{31}P NMR (d_6-acetone): δ 150.4. NMR data agree with those reported previously [5].

2.7.2. $(CO)_4Mo[(diethylamino)PO]_4Mo(CO)_4$ (**1f**)

Yield: 0.46 g (36%). *Anal.* Calc. for $C_{24}H_{40}N_4O_{12}P_4Mo_2$: C, 32.30; H, 4.52; N, 6.28. Found: C, 32.61; H, 4.68; N, 6.12%. IR(KBr): 2970–2880m, 2025s, 1930vs br cm^{-1}. ^{31}P NMR (d_6-acetone): δ 150.6. ^{13}C NMR (d_6-acetone): δ 40.0(s), 15.4 (s). ^1H NMR (d_6-acetone): δ 3.4 (quar, $J = 6.8$ Hz), 1.1 (t, $J = 6.8$ Hz).

3. Results

3.1. Dialkylaminochlorophenylphosphines

3.1.1. Synthesis and characterization

The compounds (R_2N)PhPCl **2a**–**e** were prepared by reaction of $PhPCl_2$ with two equivalents of the appropriate amine in 60–90% yield (Scheme 2).

$$PhPCl_2 + 2\ R_2NH \longrightarrow \underset{\mathbf{2}}{(R_2N)PhPCl}$$

(R_2N = **a**, pip; **b**, 2-Mepip; **c**, 2,6-Me_2pip; **d**, 2,2,6,6-Me_4pip; **e**, $^iPr_2N$)

Scheme 2. Synthesis of the aminochlorophenylphosphines.

The compounds were characterized by IR, NMR and combustion analysis. The $^{31}P\{^1H\}$ NMR spectra showed the expected singlets in the 125–140 ppm range except for **2b** where two singlets were observed (4.5:1 ratio) for the two diastereomers resulting from the chiral centers at P and the tertiary carbon. The ^1H NMR spectra for all compounds were complex as a result of a combination of restricted rotation about the P–N bond and the similar values of coupling constants for $^3J_{H-H}$ and $^3J_{P-H}$. The observed spectra were in agreement with the proposed structures, but complete correlation and assignment was not attempted since the ^{13}C NMR spectra were to be used for determination of the P–N rotational barrier.

The ^{13}C NMR spectrum of **2a** showed the expected resonances for the phenyl substituent with the ipso and ortho carbons appearing as doublets due to coupling to the phosphorus atom. The chemical shifts and coupling constants of the phenyl carbons did not change significantly in the series **2a**–**e**. Three signals were seen for the piperidine ring and assigned as the 2(6)-, 3(5)- and 4-carbons in accordance with the method of Eliel [12] (see Fig. 2(a) for numbering scheme). The chemical shifts of these carbons were then used along with Eliel's parameters for axial and equatorial methyl substituents on piperidine rings to assist in assigning the spectra of the remaining aminochlorophenylphosphines.

Assignment of the room temperature spectrum of **2d** was made based on calculated values using Eliel's parameters [12] and the observed chemical shifts from **2a**, Fraser and Grindley's [13] study of *N*-nitroso methylpiperidines and the use of the INEPT pulse sequence for distinguishing methyl and methine carbons from methylene carbons. Fraser and Grindley observed that carbons *syn* to an exocyclic substituent on the piperidine nitrogen were shifted upfield relative to their *anti* counterparts. Aminophosphines have been previously shown, by both experimental observation and molecular modeling studies, to have planar nitrogen atoms and to exist predominantly in conformations where the lone pair on the phosphorus is orthogonal to the nitrogen lone pair [14] (see Fig. 2(b)). The presence of the two geminal pairs of methyl substituents facilitated the assignment by ensuring that there was one each axial and equatorial methyl group on C2 and C6. Thus, the doublets at 62.8 and 59.6 ppm were assigned as C6 (*anti*) and C2 (*syn*), respectively, in agreement with both their

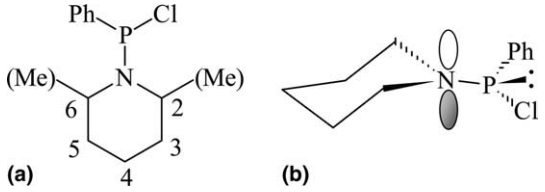

Fig. 2. Structure and geometry of the piperidinochlorophenylphosphine.

predicted chemical shifts and the magnitudes of their $^2J_{PNC}$ coupling constants (see Variable Temperature NMR Studies, below). The signals at 37.3 and 30.9 ppm were similarly assigned to C3 and C5, respectively, and that at 17.3 to C4 as a result of the strong shielding by the two γ-axial methyl substituents. The methyl groups were observed at 42.3 and 40.3 (equatorial) and 33.8 and 31.1 (axial) ppm.

Subsequent assignment of the room temperature ^{13}C NMR spectrum of **2c** was straightforward. Unlike **2d**, where the room temperature spectrum represented the low-temperature limit, in **2c** the room temperature spectrum was nearer to the high temperature limit (although with some unresolved P–N–C coupling). The *cis*-dimethyl substituents were assumed to be in the axial position based upon Fraser and Grindley's [13] observations in the nitrosopiperidine compounds, the work of Tavares and co-workers [14a] on piperidine amides, and the observed conformation of the 2,6-Me_2pip rings in the crystal structures of the chromium and molybdenum complexes of Wong and co-workers [5]. In addition, the chemical shifts were calculated for both the diaxial and diequatorial conformations, and the predicted values for the diaxial conformation agreed much better with the observed values. The diastereotopic methine carbons were assigned to a broad signal at 53.4 and a broad doublet at 52.8 ppm ($J = 18$ Hz). The C-3 and C-5 carbons were observed at 31.1 and 30.0 ppm and C-4 was shifted strongly upfield to 13 ppm by the two axial methyl groups (22.6 and 22.1 ppm).

The ^{13}C NMR spectrum of **2b**, the 2-Mepip compound, was more complicated due to the presence of two diastereomers, each of which has two distinct conformations with the phosphorus and nitrogen lone pairs orthogonal (see Fig. 3). In addition, the different rotomers were anticipated to have unequal populations. Structures **2b**-1 and **2b**-2 represent the two rotomers of one diastereomer while **2b**-3 and **2b**-4 represent the rotomers of the second diastereomer. We presumed that rotomers **2b**-1 and **2b**-3 would be the higher population forms for their respective diastereomers due to the reduced steric interactions between the methyl substituents and the phenyl and chloro groups on the phosphorus.

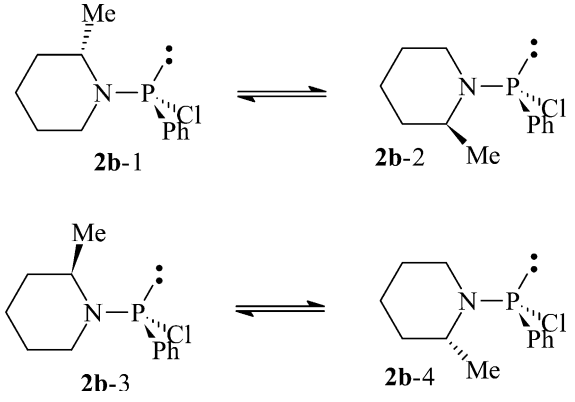

Fig. 3. Rotomers and diastereomers of **2b**.

Signals for all six carbons in each diastereomer were observed at room temperature with sufficiently different intensities to assign them to major and minor products (relative intensities ranging from 4:1 to 5:1). The resonances for the major isomer were assigned as: 54.7 (C-2) 46.5 (C-6) 33.6 (C-3) 27.0 (C-5) 21.4 (C-4) and 19.3 (Me) (coupling constants and resonances for the minor isomer are given in the experimental). Assignments for the major and minor isomers agreed well with the nitroso compound of Fraser and Gridley [13] and calculated values [12].

3.2. Variable temperature ^{13}C NMR and P–N rotational barriers

^{13}C NMR spectra were obtained for **2a**–**e** from 326 to 190 K or until the spectrum ceased to change (for **2d** and **2e**) in 5–12 °C intervals (smaller near the coalescence temperature). The carbon atoms α to the piperidine nitrogen were chosen for simulation based upon previous work demonstrating the correlation between conformation about the P–N bond and the $^2J_{PNC}$ coupling constant [15]. At the low temperature limit, aminophosphines adopt a conformation where the phosphorus and nitrogen lone pairs are orthogonal, resulting in a structure where one α-C is *syn*-periplanar to the phosphorus lone pair and one α-C is *anti*-periplaner to it. The *syn*-C exhibits a $^2J_{PNC}$ of +23 to 45 Hz while the *anti*-C exhibits a $^2J_{PNC}$ of −5 to −15 Hz. The opposite signs of the coupling constants are clearly demonstrated by the average coupling constants in the high temperature spectra which typically fall in the 10–20 Hz range. Poor solubility for **2c** at low temperature in d_6-acetone prevented obtaining the low temperature limiting spectrum, however, the full range of spectra were obtained in $CDCl_3$. Data were collected on **2e** in both d_6-acetone and $CDCl_3$ to determine the effect of the solvent on the observed barrier to rotation about the P–N bond. High temperature limiting spectra for **2d** and **2e** were not obtained below the boiling point of the solvent. Individual spectra were analyzed and exchange pairs for simulation were assigned as previously described in accordance with the known difference in sign and magnitude of the $^2J_{PNC}$ coupling constants [7,14]. The chemical shifts and coupling constants for the low- and high-temperature limiting spectra of the α-carbons used in the simulations are given in Table 1.

Spectra were simulated using the KUBO program of Saunders [8] and agreement between simulated and experimental spectra was determined by eye. At very low (<30 Hz) and very high (>20 000 Hz) frequencies, changes of up to 20% in the rotational frequency produced negligible change in the simulated spectra and

Table 1
Low- and high-temperature limiting ^{13}C NMR data for **2a**,**c**,**d**,**e**[a] Chemical shifts (ppm) and ($^2J_{PNC}$ coupling constants) [Hz]

Compound	Solvent	Low temperature	High temperature
2a	d_6-acetone	52.5 (32), 47.5 (−10.0)	50.5 (11.5)
2c	$CDCl_3$	55.1 (+43.9), 49.2 (−12.2)	53.4 (16.1)
		54.6 (+44.0), 48.7 (−14.0)	52.8 (15.3)
2d	d_6-acetone	62.8 (−10.6), 59.6 (+30.0)	[b]
2e	$CDCl_3$	52.0 (−12.0), 45.1 (+22.8)	[b]

[b] Not observed below the boiling point of the solvent.

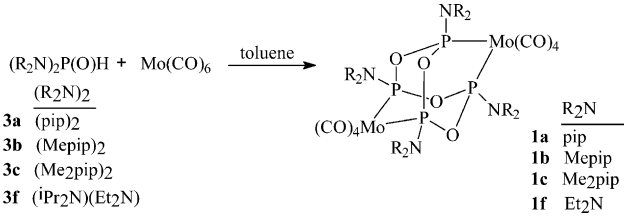
data outside that range was not used in determining the rotational barriers. In addition, nonlinearity was observed at very low and high rotational rates, but this leads to compensating errors in $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ so that the values of $\Delta G^{\ddagger}$ obtained are still reliable [16]. We estimate the error in the rotational rate of individual spectra to be within 5%. Standard Eyring plots of $1/T$ versus $\ln k/T$ for each series of spectra gave $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ from which $\Delta G^{\ddagger}$ (298 K) was calculated. The activation barriers were also calculated based on the coalescence temperatures and low temperature limiting frequency separation of the exchanging resonances [17]. All data are given in Table 2.

The values for the P–N rotational barrier derived from the coalescence temperature are in agreement with those derived from the Eyring plots when the difference in temperature is taken into account. Attempts to simulate the variable temperature spectra of **2b** were unsuccessful due to the low percentage of the minor conformers (**2b**-2 and **2b**-4) and overlap of the signals from the two diastereomers, especially as those signals broadened at temperatures above the low temperature limit. Large changes in rotational rate throughout the temperature range made minimal changes in the simulated spectrum leading to unacceptably high error. The reported coalescence temperature is that of maximum width for the overlapped signals for both the primary α-carbon and the secondary α-carbon. Comparison of the values for the rotational barrier of the diisopropylamino compound, **2e**, in acetone and $CDCl_3$ showed no difference within experimental error and the data collected in $CDCl_3$ agree with the report of Burdon et al. [18], therefore allowing us to compare the barrier for **2c** (measured in $CDCl_3$) with the other Me_n piperidine compounds.

3.3. Reaction of bis(dialkylamino)phosphine oxides with $Mo(CO)_6$

The phosphine oxides **3a**–**c**,**f** were prepared by standard techniques. Attempts to prepare **3d** (using Me_4pipH) were unsuccessful. We were unable to produce the needed bis(Me_4pip)$_2$PCl precursor; only (Me_4pip)PCl_2 was isolated even using a 10-fold excess of Me_4pipH and prolonged reaction times, presumably due to steric congestion. The phosphine oxides were then combined with $Mo(CO)_6$ in refluxing toluene (see Scheme 3) and the reactions monitored for the formation of the corresponding Cage complexes via their characteristic ^{31}P NMR (∼150 ppm) and IR (2010-2020 cm^{-1}) signatures.

No trace of **1a** was detected in the reaction of **3a** even after 48 h. Reaction of **3b** produced traces of a com-



Scheme 3. Synthesis of the Cage complexes **1**.

Table 2
Activation parameters and P–N rotational barrier estimates for **2a**–**e**

Compound (solvent)	Coalescence temperature (K)	$\Delta G_c^{\ddagger}$ (kcal/mol)	$\Delta H^{\ddagger}$ (kcal/mol)	$\Delta S^{\ddagger}$ (cal/mol K)	$\Delta G^{\ddagger}$ (298 K) (kcal/mol)	r^2
2a (acetone)	255	11.6	8.19	−12.9	12.03	0.9986
2b (acetone)	261	11.7			[a]	
2c ($CDCl_3$)	249	11.3	8.91	−10.2	11.95	0.9931

pound presumed to be **1b** as part of a complex mixture (based on the ^{31}P NMR spectrum of the reaction mixture which showed a resonance at δ 151.2 ppm), although we were unsuccessful in isolating the material. However, reaction of **3c** yielded the corresponding Cage **1c** in fair yield after purification. Reaction of the mixed compound **3f**, containing one diisopropylamino and one diethylamino substituent, gave uniformly the diethylamino-substituted compound **1f**, also in fair yield. No sign of the diisopropyl group was observed in either the ^{1}H or ^{13}C NMR spectra after purification and only one singlet was observed in the ^{31}P NMR in the 150 ppm region ($\delta = 150.6$ ppm).

3.4. Cone angle measurements

The cone angles [9] of the various amines and bis(dialkylamino)phosphines (see Table 3) were measured according to the method of Seligson and Trogler [10] who first applied the technique to amines. An M–N bond length of 2.2 Å and an M–P bond length of 2.28 Å were used in the measurements for consistency with published data. There is some disagreement over the appropriate technique for measuring cone angles in relation to the appropriate conformation for the molecule. The predominant method involves placing the molecule in its sleekest conformation [9] and this model has been used, although there is frequently evidence to indicate that the molecules do not typically occur in those conformations, such as the known gearing of the isopropyl groups in some diisopropyl-aminophosphines [18]. Measurements of PH_3, PMe_3, NH_3 and NMe_3 were used to calibrate the models and agreed with published data [9,10] within ±3°. Fan angles [11] were also measured for the amines where the H-atom has been removed and the N-atom was in a trigonal planar geometry (R_2N–M). Measurements were reproducible within ±3° and averages are reported.

Table 3
Cone and fan angles for amines and bis(dialkylamino)phosphinous acids (°)

Compound	Tet-amine[a]	Trig-amine[b]	Phosphine[a]
Piperidine	119	93	124

4. Discussion

Hindered rotation about the P–N bond in a variety of aminophosphines and aminophosphine oxides has been observed by NMR techniques for more than three decades [19]. More recently, the use of a wide variety of alkyl and aryl substituents on the nitrogen atom has confirmed the principle that within a particular class of phosphorus compounds, the barrier is principally dependent upon the steric congestion around the P-atom [20]. Based on our previous results [7], we were surprised to find that the P–N rotational barriers in compounds **2a**–**c** are the same (within experimental error). The unsubstituted-, monomethyl- and dimethylpiperidine compounds **2a**–**c** all have a barrier to P–N rotation that is in agreement with the values previously observed for $Ph(R_2N)PCl$ compounds [7] where R was a primary alkyl substituent [$\Delta G^{\ddagger}$ (298 K) = 11.6 ± 0.1 kcal/mol] in spite of the fact that **2b** has one secondary alkyl substituent and **2c** has two secondary alkyl substituents. Compound **2d** has two tertiary alkyl substituents and, as expected, exhibits a barrier significantly higher than previously observed for compounds with two secondary substituents [$\Delta G^{\ddagger}$ (298 K) = 13.4 ± 0.2 kcal/mol] [7]. Due to the lack of high temperature data, we suggest that the value of $\Delta G^{\ddagger}$ given in Table 2 for **2d** represents a lower limit.

Cone angle measurements (Table 3) indicated that the various amines should have significantly different steric requirements, and therefore, we would expect different rotational barriers for the corresponding aminochlorophenylphosphines. However, the variability of cone angle in a variety of ligands, as observed in crystal structures, has been demonstrated clearly by Müller and Mingos [21] in their work on determining cone angles based on the crystallographic data. In their measurements of cone angles via geometric calculation, they found that although the mean values agreed with those determined by Tolman's method [9], there was great variability from one structure to the next as a result of the actual ligand conformation in the molecule and the standard deviations of the average values were significant (typically 5°). For example, they found that the average observed cone angle for PEt_3 was 137.3(5.0)° compared to the Tolman cone angle of 132° ± 2°, but the range of observed angles was 126.6°–159.4°. Most interesting was Müller and Mingos' observation that the cone angles observed in X-ray structures for the "very bulky" P(c-Hex)$_3$ ligand [ave = 160.1(5.1)°; range = 146.2°–171.7°] were actually significantly less than that proposed by Tolman [9]. Similar observations have been made by Smith and Coville [22] for phosphite ligands.

Examination of the crystal structures of **1** (R_2N = *cis*-2,6-dimethylpiperidine) and its related metal complexes all show the methyl substituents to be in the *cis*-diaxial conformation. Although surprising at first, this is in

agreement with the assignments of the ^{13}C NMR chemical shifts for the piperidine ring carbons for both the 2-methyl- and 2,6-dimethylpiperidine compounds, suggesting that it is the axial conformation that predominates in solution as well. In addition, it is observed that the nitrogen atoms are generally planar, or nearly so, in crystal structures of aminophosphines [23] unless restricted by incorporation of the nitrogen atom into a ring, or by interactions with neighboring groups. We remeasured the steric volume for the various amines replacing the tetrahedral nitrogen atoms with trigonal nitrogen atoms. These measurements are based on the fan angle measurements of Bagnall and Li [11] who determined steric requirements for a variety of ligands, not just those with pseudo-tetrahedral geometry. With the piperidine nitrogen in a trigonal hybridization, methyl substituents in the axial position on the α-carbons *do not occupy any additional volume relative to the cone swept out by rotation about the N–M bond!* The same is not true for substituents in the equatorial position. With this realization, it is clear that the rotational barrier study is in agreement with the steric requirements of the sp^2 hybridized nitrogen in the piperidinophosphines.

Cone angle measurements were also made on the phosphinous acids with the various amine substituents. In all cases, trigonal nitrogen atoms were used and, in the case of substituted piperidines, the methyl groups were placed in the axial position. In these molecules, there is an increase in cone angle with increasing substitution on the piperidine ring due to interactions between the substituents, even with axial substituents. There are three possible diastereomers of the bis(2-methylpiperidino) compound, **3b**, and all three were observed by ^{31}P NMR. The cone angles for the three diastereomers are quite different, with the chiral isomer showing the largest value.

Based solely on the results of the rotational barrier study, we did not expect any of the phosphine oxides **3a**–**c** to produce measurable quantities of the associated Cage complexes, **1**, upon reaction with $Mo(CO)_6$. However, previous experiments had also suggested that the presence of secondary alkyl substituents on the amine nitrogen was sufficient for the success of the thermal condensation and, in fact, traces of product from the reaction with $(Et_2N)_2P(O)H$ had been observed via ^{31}P NMR [2,5]. In addition, the cone angle measurements on the phosphinous acids indicated that the P–N rotational barriers, as determined in the aminochlorophenylphosphines, were not a good measure of the steric requirements of the phosphinous acids.

Reaction with **3c** does produce Cage **1c** in fair yield, but the yield is lower than observed with either $(^{i}Pr_2N)_2P(O)H$ or $(c\text{-}Hex_2N)_2P(O)H$ [2]. This suggests that while secondary alkyl substituents on the nitrogen may be sufficient to promote the condensation, the yield is still dependent on the relief of steric strain in some intermediate (presumably $\mathbf{I_1}$, Scheme 1). The reduced steric congestion in the Me_2pip compound, **3c**, compared to the other secondary amines, raises the activation barrier to the formation of the coordinated phosphinidene oxide ($\mathbf{I_2}$) and hence reduces the yield. This difference is, perhaps, not surprising in light of the known difference in steric requirements of piperidine itself relative to open chain analogues as has been observed by ^1H NMR shifts in cobaloxime complexes [24]. The observation of traces of the Mepip complex **1b** in the ^{31}P NMR of the reaction mixture with **3b**, but no Cage product in the reaction of the pip compound **3a**, also supports this hypothesis. It is possible that only the most sterically crowded diastereomer of **3b** produces Cage under these reaction conditions.

Finally, the success of the reaction with **3c** in spite of its low rotational barrier prompted our attempt to prepare the diethylamino-substituted Cage complex **1f** using the mixed aminophosphine oxide, **3f**. We believed that the diisopropyl amino substituent would provide sufficient crowding to promote the conversion of $\mathbf{I_1}$ to $\mathbf{I_2}$, the step in the mechanism which we have proposed to be rate limiting [2,5]. Moreover, we reasoned that if the reaction was indeed driven by the relief of steric strain, loss of the diisopropylamino group should be greatly preferred over loss of the diethylamino group. The isolation of **1f** in yields comparable to those observed in the synthesis of **1c** justified these predictions.

5. Conclusions

It is clear that the barrier to rotation about the P–N bond in dialkylaminochlorophenylphosphines is not a useful predictor of the results of the thermal condensation of bis(dialkylamino)phosphine oxides with $Mo(CO)_6$. Cone angle measurements show that the steric bulk of the amine is strongly dependent upon the geometry at the nitrogen atom. The interaction between the two amino substituents in the bis(dialkylamino)phosphine oxides is significant and therefore comparison to monoamino complexes is not reliable. However, the successful synthesis of the diethylamino-substituted Cage compound **1f** from the mixed bis(dialkylamino)phosphine oxide provides a new route to the synthesis of Cage complexes with less bulky substituents. Previous work on these Cage complexes has shown that they have highly selective and unique reactivity with oxidizing agents [25]. The structure and stability of the products of these reactions appeared to be strongly dependent on the steric environment around the metal centers. Thus, the ability to synthesize Cage complexes with smaller dialkylamino substituents will provide a means to further study the mechanism of these reactions and to probe the use of the complexes as templates for organic synthesis. In addition, work on the preparation of Cage complexes with smaller amino

substituents via the use of Me_4pip in mixed phosphine oxides similar to **3f** is in progress.

Abstract

Efficient and convenient methods for the preparation of thienyl-substituted 2,2′:6′,2″-terpyridines are reported. The formation and characterization of Fe(II), Ru(II), Os(II) and Co(II) complexes containing the isomeric ligands 4′-(2-thienyl)-2,2′:6′,2″-terpyridine (**1**) and 4′-(3-thienyl)-2,2′:6′,2″-terpyridine (**3**) are described. The crystal structure of **3** is reported. During studies of possible routes to ligands **1** and **3**, the reactions of thiophene-2-carbaldehyde or thiophene-3-carbaldehyde with 2-acetylpyridine under basic conditions led to 3-(2-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol or 3-(3-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol, respectively. These compounds have been fully characterized and their crystal structures have been determined.

1. Introduction

2,2′:6′,2″-Terpyridines (tpy = 2,2′:6′,2″-terpyridine) are versatile building blocks in metallosupramolecular chemistry. A wide range of functional groups can be introduced as substituents and used to control self-assembly processes and/or the properties of the complexes which result upon coordination to metal centres [1–5]. We have shown that ruthenium(II) complexes containing 4′-(2-thienyl)-2,2′:6′,2″-terpyridine (**1**) or 2,5-bis(2,2′:6′,2″-terpyridin-4′-yl)thiophene (**2**) possess unusually long-lived ^{3}MLCT states which facilitate efficient energy transfer between metal centres [6,7]. In other studies, we have utilized complexes of **1** in studies of ligand exchange processes leading to the establishment of dynamic combinatorial libraries [8]. In this paper, we report efficient and convenient methods for the preparation of thienyl-substituted 2,2′:6′,2″-terpyridines using a one-pot method. We also report new aspects of the coordination chemistry of ligand **1** and its positional isomer 4′-(3-thienyl)-2,2′:6′,2″-terpyridine (**3**). This ligand is of interest in having a pendant sulfur-containing substituent which can be used to attach complexes to gold surfaces, and may be used as an assembly motif for the construction of a variety of novel architectures [9–11].

2. Experimental

2.1. General

Infrared spectra were recorded on Mattson Genesis or Shimadzu FTIR 8300 Fourier-transform spectrophotometers with samples in compressed KBr discs or as solids using a Golden Gate ATR. ^{1}H and ^{13}C NMR spectra were recorded on Bruker AM 250, AC 300, AV 300, AM 400, DRX 500 or AV 600 spectrometers; the proton numbering for the ligands is shown in the structure diagrams.

UV/VIS measurements were recorded using Perkin–Elmer Lambda 19 or Shimadzu UV 3101PC spectrophotometers in acetonitrile at a concentration of $\sim 10^{-4}$ mol dm^{-3}. Luminescence spectra were recorded on Shimadzu RF 5301PC or Perkin–Elmer LS50B spectrofluorophotometers. FAB and EI mass spectra were recorded on Kratos MS 50, 890, 902, Profile or VG 70-250 or Prospec instruments. Time-of-flight (MALDI) spectra were recorded using a PerSeptive Biosystems Voyager-RP Biospectrometry Workstation using dihydroxybenzoic acid as matrix with C_{60} as the internal reference. Electrospray mass spectra (ES MS) were recorded using a Finnigan Mat LCT or LCQ mass spectrometer. Electrochemical measurements were performed with Autolab PGSTAT 20 or 30 systems using platinum or glassy-carbon working and auxiliary electrodes with an Ag/AgCl electrode as reference or a silver wire as pseudo-reference using purified acetonitrile as solvent and 0.1 M [^{n}Bu$_4$N][BF$_4$] as supporting electrolyte. Potentials are quoted versus the ferrocene/ferrocenium couple (Fc/Fc$^+$ = 0.0 V), and all potentials were referenced to internal ferrocene added at the end of each experiment.

2.2. Preparation of 4′-(2-thienyl)-2,2′:6′,2″-terpyridine (1)

2-Acetylpyridine (0.271 ml, 6.3 mmol) was added dropwise to a solution of KO^{t}Bu (1.06 g, 9.5 mmol) in dry THF (40 ml) and the mixture stirred at room temperature for 30 min to give a creamy yellow suspension, after which thiophene-2-carbaldehyde (0.277 ml, 3.1 mmol) in dry THF was added. The solution turned red and was stirred for 20 h at room temperature, after which time a solution of NH_4OAc (5.0 g) in 2:1 EtOH/AcOH (60 ml) was added and the reaction mixture heated to reflux for 5 h. The reaction mixture was then cooled to room temperature, poured onto ice (50 g) and treated with water (100 ml) to give a pale yellow precipitate that was collected by filtration and dried to give **1**. The filtrate was extracted with $CHCl_3$; removal of the organic solvent gave a brown oil that was purified by column chromatography (4% Et_2NH, toluene, Al_2O_3) to give a small additional amount of **1** (total yield 0.612 g, 62%), m.p. 185 °C; ^{1}H NMR ($CDCl_3$) δ 8.73 (dd, $J = 2.0$, 4.9 Hz, 2H, H^6), 8.70 (s, 2H, H$^{3'}$), 8.64 (d, $J = 7.8$ Hz, 2H, H^3), 7.87 (dd, $J = 7.8$, 8.0 Hz, 2H, H^4), 7.78 (dd, $J = 1.2$, 3.6 Hz, 1H, H^{3S}), 7.44 (dd, $J = 1.2$, 5.1 Hz, 1H, H^{5S}), 7.35 (ddd, $J = 1.0$, 2.0, 7.8 Hz, 2H, H^5), 7.16 (dd, $J = 3.6$, 5.1 Hz, 1H, H^{4S}); ^{13}C NMR ($CDCl_3$) δ 156.1, 156.0, 149.1, 143.4, 141.9, 136.8, 128.2, 127.1, 125.8, 123.9, 121.3, 117.1; *m/z* 315 (M), 38 (M + Na) (MALDI-TOF), 315.0829 calc. for $C_{19}H_{13}N_3S$, 315.0830 (HRMS-EI); $\bar{\nu}_{max}$/cm^{-1} 1600 s, 1572 s, 1565 s, 1549 s, 1520 m, 1466 s, 1445 m, 1413 s, 1358 m, 1269 m, 1071 w, 1039 m, 990 w, 893 w, 879 w, 834 w, 782 s, 742 m, 732 m, 671 m, 658 w, 623 m, 568 m; λ_{max}/nm ($CHCl_3$) 231 (ε/M^{-1} cm^{-1} 19.1×10^3), 253 (22.4×10^3), 284 (34.9×10^3).

2.3. Preparation of 4′-(3-thienyl)-2,2′:6′,2″-terpyridine (3)

2.3.1. Method 1

A solution of 2-acetylpyridine (2.00 ml, 0.018 mol), 3-thiophenecarbaldehyde (1.00 g, 0.009 mol) and NaOH (3.00 g, 0.051 mol) in H_2O (50 ml) and EtOH (350 ml) was stirred for 24 h after which the solvent was removed in vacuo, and the residue dissolved in CH_2Cl_2 (300 ml). The CH_2Cl_2 solution was washed with water (3×250 ml), dried ($MgSO_4$) and the solvent removed to give an orange oil which was used in the cyclization step without further purification.

This oil was dissolved in a solution of NH_4OAc (7.00 g, 0.091 mol) in EtOH (150 ml) and the mixture heated to reflux for 12 h, after which the solvent was removed in vacuo, and the residue purified by column chromatography (4% Et_2NH, toluene, Al_2O_3). The first yellow fraction was collected and recrystallized from toluene to give cubic yellow crystals of **3** (yield 0.25 g, 10 %), m.p. 233–233.5 °C.

2.3.2. Method 2

The method was as for compound **1** but using thiophene-3-carbaldehyde (0.277 ml, 3.1 mmol) and omitting the final extraction of the filtrate (yield 522 mg, 52%). (Found: C, 72.13; H, 4.33; N, 13.15. $C_{19}H_{13}N_3S$ requires C, 72.36; H, 4.15; N, 13.32%); ^{1}H NMR ($CDCl_3$) δ 8.73 (dd, 2H, $J = 4.9$, 2.0 Hz, H^6), 8.70 (s, 2H, H$^{3'}$), 8.66 (dd, 2H, $J = 8.0$, 1.0 Hz, H^3), 7.94 (dd, 1H, $J = 2.9$, 1.5 Hz, H^{2S}) 7.88 (dt, 2H, $J = 8.0$, 7.8, 2.0 Hz, H^4), 7.71 (dd, 1H, $J = 4.9$, 1.5 Hz, H^{4S}), 7.46 (dd, 1H, $J = 4.9$, 2.9 Hz, H^{5S}), 7.35 (ddd, 2H, $J = 7.8$, 4.9, 1.0 Hz, H^5); ^{13}C NMR ($CDCl_3$) δ 156.1, 155.9, 148.9, 144.7, 138.9, 137.0, 126.6, 126.3, 123.9, 123.7, 121.4, 118.2; *m/z* 315 (M) (MALDI-TOF);. $\bar{\nu}_{max}$/cm^{-1} 1600 s, 1572 s, 1565 s, 1549 s, 1520 m, 1466 s, 1445 m, 1413 s, 1358 m, 1269 m, 1071 w, 1039 m, 990 w, 893 w, 879 w, 834 w, 782 s, 742 m, 732 m, 671 m, 658 w, 623 m, 568 m; λ_{max}/nm ($CHCl_3$) 227 (ε/M^{-1} cm^{-1} 50.7×10^3), 253 (66.6×10^3), 278 (81.8×10^3).

2.4. Preparation of 1,5-bis(2-pyridyl)-3-(2-thienyl)penta-1,5-dione (4) and 3-(2-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol (5)

A solution of 2-acetylpyridine (3.8 ml, 34 mmol) in EtOH (150 ml) was stirred with thiophene-2-carbaldehyde (0.8 ml, 8.56 mmol) and aqueous NaOH (25 ml, 2 M) for 24 h. The solvent was then reduced to half its original volume and equal volume of water was added, precipitating an orange gum and a white solid. The solid

was separated by filtration and the gum was redissolved in CH_3OH and more water added. This was continued until all of the gum had solidified. The solid consisted of two compounds which were separated by chromatography (15% Et_2NH, hexanes, silica gel) and identified as the dione **4** (0.71 g, 25%) and the condensation product **5** (1.17 g, 30%).

Compound **4**: m.p. > 215 °C (dec.); ^{1}H NMR ($CDCl_3$) δ 8.60 (dm, 2H, H^{6py}), 7.93 (dm, 2H, H^{3py}), 7.72 (ddd, 2H, H^{4py}), 7.38 (ddd, 2H, ddd, H^{5py}), 7.03 (d, H, $H^{5thienyl}$), 6.94 (d, H, $H^{3thienyl}$), 6.82 (dd, H, dd, $H^{4thienyl}$), 4.51 (quin, H, $J = 7.2$, H^{CH}), 3.7 (m, 4H, H^{CH2}); *m/z* 336 (M) (EIMS); $\bar{\nu}_{max}/cm^{-1}$ 3098 m, 3067 w, 3011 w, 2952 w, 2879 m, 1692 s, 1582 m, 1566 m, 1467 w, 1434 m, 1409 m, 1353 s, 1280 s, 1246 s, 1208 m, 1145 m, 1129 w, 1092 w, 1058 w, 1042 m, 995 s, 969 m, 853 m, 781 s, 743 m, 723 s, 701 m, 610 m, 597 m, 533 m.

Compound **5**: m.p. 183–184 °C; ^{1}H NMR ($CDCl_3$, see text for comments on assignments of aromatic protons) δ 8.53 (dm, 1H, H^6), 8.45 (dm, 1H, $H^{6'}$), 8.27 (dm, 1H, $H^{6''}$), 7.77 (d, 1H, H^3), 7.69 (ddd, 1H, H^4), 7.57 (d, 1H, $H^{3''}$), 7.51–7.49 (m, 2H, $H^{3',4'}$), 7.41 (ddd, 1H, $H^{4''}$), 7.20 (m, 1H, $H^{5'}$), 7.15 (ddd, 1H, H^5), 6.89–6.83 (m, 3H, $H^{5'', 5S, 3S}$), 6.61 (dd, 2H, $H^{4S,OH}$), 6.24 (s, 1H, H^{OH}), 5.38 (d, 1H, H^a), 4.44 (ddd, 1H, H^b), 3.10 (d, 1H, H^e), 2.73 (dd, 1H, H^d), 2.26 (dt, 1H, H^c), 2.01 (dm, 1H, H^f); *m/z* 459 (M) (MALDI-TOF); $\bar{\nu}_{max}/cm^{-1}$ 3052 w, 2915 w, 1687 s, 1588 s, 1570 m, 1469 m, 1434 s, 1414 m, 1397 m, 1378 m, 1349 m, 1320 m, 1302 m, 1272 m, 1243 w, 1216 m, 1136 m, 1085 m, 1045 w, 993 m, 967 w, 880 w, 850 w, 774 s, 745 m, 689 s, 618 w, 545 w, 521 w.

3-(3-Thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl) cyclohexane-1,5-diol (**7**). The method of preparation was as above using thiophene-3-carbaldehyde (0.8 ml, 8.56 mmol) to give **7** (1.17 g, 30%) m.p. 214–215 °C; ^{1}H NMR ($CDCl_3$, see text for comments on assignments of aromatic protons) δ 8.53 (d, 1H, H^6), 8.49 (d, 1H, $H^{6'}$), 8.26 (d, 1H, $H^{6''}$), 7.70 (d, 1H, H^3), 7.68 (ddd, 1H, H^4), 7.58 (d, 1H, $H^{3''}$), 7.50 (ddd, 1H, $H^{4'}$), 7.47 (d, 1H, $H^{3'}$), 7.41 (ddd, 1H, $H^{4''}$), 7.20 (m, 1H, $H^{5'}$), 7.13 (m, 1H, H^5), 7.03 (overlapping dd, 2H, $H^{2S,4S}$), 6.93 (dd, $J = 4.9$, 2.9 Hz, 1H, H^{5S}), 6.87 (m, 1H, $H^{5''}$), 6.53 (br s, H, H^{OH}), 6.23 (s, H, H^{OH}), 5.42 (d, 1H, H^a), 4.24 (ddd, 1H, H^b), 3.06 (d, 1H, H^e), 2.67 (dd, 1H, H^d), 2.14 (dt, 1H, H^c), 2.01 (dm, 1H, H^f); *m/z* 459 (M) (MALDI-TOF); $\bar{\nu}/cm^{-1}$ 3385 w, 3094 w, 3052 w, 2913 w, 1689 s, 1588 s, 1570 m, 1469 m, 1434 s, 1415 m, 1396 m, 1355 m, 1322 m, 1302 m, 1273 m, 1243 w, 1216 m, 1141 w, 1122 m, 1084 m, 1050 w, 993 m, 673 w, 774 s, 746 m, 656 m, 618 w, 540 w.

2.5. Preparation of $[Co(\mathbf{3})_2][PF_6]_2$

A solution of **3** (31.2 mg, 0.099 mmol) and $[Co(H_2O)_6][BF_4]_2$ (15 mg, 0.048 mmol) in CH_3CN/CH_3OH (1:1, 50 ml) was stirred for 10 min. at room temperature to give a pink-red solution. Aqueous NH_4PF_6 was added to precipitate **2** as a brown solid (47 mg, 100%). *m/z* (ESMS) 344 $\{M - 2PF_6\}^{2+}$; $\bar{\nu}_{max}/cm^{-1}$ 1616 m, 1554 w, 1527 w, 1469 w, 1434 m, 1346 m, 1259 w, 1218 w, 1161 w, 1049 w, 1045 w, 821 s [PF_6], 783 s, 744 m, 729 m, 682 m, 655 m, 617 m, 551 s; λ_{max}/nm (MeCN): 285 (ε/M^{-1} cm^{-1} 52 000), 314 (38 000), 364sh (7320), 516 (2150); ^{1}H NMR (CD_3CN) δ 93.5 (4H, tpy), 55.3 (4H, tpy), 44.4 (4H, tpy), 32.6 (4H, tpy), 14.7 (2H, thienyl), 13.1 (2H, thienyl), 9.47 (2H, thienyl), 9.22 (4H, tpy) (see text for assignments).

2.6. Preparation of $[Fe(\mathbf{1})_2][PF_6]_2$

A solution of ligand **1** (15.0 mg, 0.048 mmol) and $[Fe(H_2O)_6][BF_4]_2$ (8.0 mg, 0.023 mmol) in CH_3CN/CH_3OH (1:1, 20 ml) was stirred for 10 min at room temperature to give a purple solution. Aqueous NH_4PF_6 was added to precipitate $[Fe(\mathbf{1})_2][PF_6]_2$ as a purple solid (yield 22.5 mg, 100%). *m/z* (MALDI-TOF MS) 687 $\{M - 2PF_6\}^+$; *m/z* (MALDI-TOF MS) (calc.) 686 (687, $[M - 2PF_6]^+$); $\bar{\nu}_{max}$ (neat solid, cm^{-1}) 1613 m, 1468 w, 1432 m, 1400 w, 1245 w, 841 s, 788 m, 753 w, 723 w, 557 m; λ_{max}/nm (MeCN): 283 (ε/M^{-1} cm^{-1} 43 300), 327 (49 300), 456 (23 000); δ_H (CD_3CN) 9.10 (s, 4H, $H^{3'}$), 8.62 (d, 4H, H^3), 8.30 (dd, 2H, H^{3S}), 7.90 (overlapping ddd, 4H, H^4; dd, 2H, H^{5S}), 7.47 (dd, 2H, H^{4S}), 7.21 (d, 4H, H^6) 7.08 (dd, 4H, H^5).

2.7. Preparation of $[Fe(\mathbf{3})_2][PF_6]_2$

$(NH_4)_2Fe(SO_4)_2$ (13.5 mg, 0.034 mmol) was added to a solution of ligand **3** (30.8 mg, 0.097 mmol) in MeCN/MeOH (1:1; 20 ml). The solution was stirred at room temperature for 10 min, and the product was precipitated as a dark purple solid by adding aqueous NH_4PF_6. Yield (33 mg, 99 %). *m/z* (FAB MS) 831 $\{M - PF_6\}^+$, 343 $\{M - 2PF_6\}^{2+}$; $\bar{\nu}_{max}$ (neat solid, cm^{-1}) 1616 m, 1542 w, 1527 w, 1469 w, 1434 m, 1396 w, 1373 w, 1245 w, 1211 w, 825 s (PF_6), 783 s, 756 m, 729 m, 655 m, 617 m, 555 s (PF_6); λ_{max}/nm (MeCN): 569 (ε/M^{-1} cm^{-1} 26 000), 368sh (8400), 322 (57 800), 286 (71 400); ^{1}H NMR (CD_3CN) δ 9.20 (s, 4H, $H^{3'}$), 8.64 (d, $J = 8.03$ Hz, 4H, H^3), 8.60 (dd, $J = 3.01$, 1.33 Hz, 2H, H^{2S}), 8.16 (dd, $J = 5.01$, 1.33 Hz, 2H, H^{4S}), 7.94 (dt, $J = 1.33$, 7.36 Hz, 4H, H^4), 7.89 (d, $J = 3.01$, 2H, H^{5S}), 7.22 (d, $J = 5.68$ Hz, 4H, H^6), 7.10 (dt, $J = 1.33$, 5.68 Hz, 4H, H^5).

2.8. Preparation of $[Ru(\mathbf{3})_2][PF_6]_2$

Ligand **3** (308.5 mg, 0.979 mmol) and $RuCl_3.3H_2O$ (128.3 mg, 0.489 mmol) were suspended in ethane-1, 2-diol (10 ml). After adding four drops of *N*-ethylmorpholine, the reaction mixture was heated in a microwave oven (600 W) for 4 min. A red solution

resulted. The product was precipitated by addition of aqueous NH_4PF_6, collected on Celite and removed by dissolution in MeCN. The solvent was removed in vacuo and the product purified by column chromatography (SiO_2 eluting with MeCN/saturated aqueous KNO_3/H_2O, 20:1:3). The red solid product was isolated in 35% (176.5 mg) yield. *m/z* (MALDI-TOF MS) 1044 $\{M + Na\}^+$, 732 $\{M - 2PF_6\}^+$; $\bar{\nu}_{max}$ (neat solid, cm^{-1}) 1612 w, 1542 w, 1523 w, 1465 w, 1434 m, 1391 m, 1326 m, 1242 w, 1211 w, 1029 w, 879 m, 829 s (PF_6), 779 s, 752 m, 729 m, 651 m, 621 m, 555 m (PF_6), 516s; λ_{max}/nm (MeCN): 493 sh, 310, 285; emission (MeCN, 298 K, nm) $\lambda_{490} = 675$, 700; ^{1}H NMR (CD_3CN) δ 9.03 (s, 4H, $H^{3'}$), 8.67 (d, 4H, H^3), 8.48 (dd, 2H, H^{2S}), 8.08 (dd, 2H, H^{4S}), 7.97 (dt, 4H, H^4), 7.85 (d, 2H, H^{5S}), 7.45 (d, 4H, H^6), 7.20 (dt, 4H, H^5).

2.9. Preparation of [Os(3)$_2$][PF$_6$]$_2$

Ligand **3** (30.0 mg, 0.095 mmol) and K_2OsCl_6 (14.1 mg, 0.045 mmol) were suspended in ethane-1,2-diol (10 ml). After adding eight drops of *N*-ethylmorpholine, the reaction mixture was heated in a microwave oven (600 W) for 4 min, giving a dark brown solution. The product was precipitated by adding aqueous NH_4PF_6, collected on Celite and removed by dissolution in MeCN. The solvent was removed in vacuo and the product purified by column chromatography (SiO_2 eluting with MeCN/saturated aqueous KNO_3/H_2O, 14:2:1). The brown solid product was isolated in 43% (21.3 mg) yield. *m/z* (MALDI-TOF MS) 820 $\{M - 2PF_6\}^+$; $\bar{\nu}_{max}$ (neat solid, cm^{-1}) 1616 w, 1477 w, 1434 m, 1367 s, 1338 s, 1161 w, 1095 w, 1029 w, 918 w, 883 w, 825 s (PF_6), 786 m, 756 m, 725 w, 651 w, 621 w, 559 m (PF_6); λ_{max}/nm (MeCN): 671, 493, 315, 286; emission (MeCN, 298 K, nm) $\lambda_{490} = 742$; ^{1}H NMR (CD_3CN) δ 9.06 (s, 4H, $H^{3'}$), 8.66 (d, 4H, H^3), 8.40 (dd, 2H, H^{2S}), 8.05 (dd, 2H, H^{4S}), 7.83 (dt, 4H, H^4), 7.80 (d, 2H, H^{5S}), 7.32 (d, 4H, H^6), 7.12 (dt, 4H, H^5).

2.10. Preparation of [Ru(tpy)(3)][PF$_6$]$_2$

[Ru(tpy)Cl_3] (24 mg, 0.054 mmol) and ligand **3** (15 mg, 0.048 mmol) were added to ethane-1,2-diol (25 ml). After adding four drops of *N*-ethylmorpholine, the reaction mixture was heated in a microwave oven (600 W) for 4 min after which time, the mixture was cooled. The product was precipitated by adding aqueous NH_4PF_6, and purified by column chromatography (SiO_2 eluting with MeCN/saturated aqueous KNO_3/H_2O, 14:2:1). The one major fraction was collected and the volume of the solution was reduced to about half in vacuo, and aqueous NH_4PF_6 was added to precipitate the product which was filtered and collected on Celite. The residue was dissolved in MeCN; distilled H_2O was added carefully until a precipitate was obtained. This precipitate was again filtered and collected on Celite and was dried overnight under high vacuum. The product was isolated as an orange-red solid (40 mg, 89%). *m/z* (MALDI-TOF MS) 650 $\{M - 2PF_6\}^+$, 417 $\{M - tpy - 2PF_6\}^+$; $\bar{\nu}_{max}$ (KBr, cm^{-1}) 1614 m, 1466 w, 1449 m, 1435 m, 1388 m, 1368 w, 1287 w, 1244 w, 1031 w, 840 s (PF_6), 784 m, 767 m, 558 m (PF_6); λ_{max}/nm (MeCN): 484 (ε/M^{-1} cm^{-1} 44 900), 308 (67 600), 284 (44 900); ^{1}H NMR (CD_3CN) δ 9.00 (s, 2H, $H^{3'}$(**6**)), 8.74 (s, 2H, $H^{3'}$(tpy)), 8.64 (d, 2H, H^3(**6**)), 8.49 (d, 2H, H^3(tpy)), 8.45 (dd, 1H, H^{2S}), 8.41 (dd, 1H, $H^{4'}$(tpy)), 8.04 (dd, 1H, H^{4S}), 7.93 (ddd, 4H, H^4(**6** + tpy)), 7.82 (dd, 1H, H^{5S}), 7.43 (d, 2H, H^6(**6**)), 7.33 (d, 2H, H^6(tpy)), 7.16 (dd, 4H, H^5(**6** + tpy)). Electrochemical data: see text.

2.11. Preparation of [Os(tpy)(3)][PF$_6$]$_2$

[Os(tpy)Cl_3] (20 mg, 0.022 mmol) and ligand **3** (6 mg, 0.019 mmol) were added to ethane-1,2-diol (25 ml). Four drops of *N*-ethylmorpholine were added, the reaction mixture was heated in a microwave oven (600 W, 4 min), and then cooled. The product was precipitated with aqueous NH_4PF_6, and purified by column chromatography (SiO_2, MeCN/saturated aqueous KNO_3/H_2O, 14:2:1). The one major fraction was collected, and the solution was reduced in volume. The product was precipitated with aqueous NH_4PF_6, filtered and collected on Celite. The residue was dissolved in MeCN and distilled H_2O was added to produce a precipitate which was filtered, collected on Celite and dried overnight under high vacuum. The product was isolated as a brown solid (17 mg, 87%). *m/z* (MALDI-TOF MS) 739 $\{M - 2PF_6\}^+$; λ_{max}/nm (MeCN): 661 (ε/M^{-1} cm^{-1} 1400), 484 (5600), 312 (20 100), 274 (12 400); ^{1}H NMR (CD_3CN) δ 9.02 (s, 2H, $H^{3'}$(**6**)), 8.75 (d, 2H, H^3(tpy)), 8.64 (d, 2H, H^3(**6**)), 8.47 (s, 2H, $H^{3'}$(tpy)), 8.36 (dd, 1H, H^{2S}), 7.92 (dd, 1H, $H^{4'}$(tpy)), 8.01 (dd, 1H, H^{4S}), 7.83 (dd, 1H, H^{5S}), 7.78 (ddd, 4H, H^4(**6** + tpy)), 7.29 (d, 2H, H^6(**6**)), 7.21 (d, 2H, H^6(tpy)), 7.09 (dd, 4H, H^5(**6** + tpy)). Electrochemical data: see text.

2.12. Crystal structure determinations

Data were collected on a CAD4 diffractometer. The structures were solved and refined by direct methods using standard techniques as indicated in Table 1 using the programmes SIR 92 [12] and CRYSTALS [13]; a Chebychev polynomial weighting scheme was used [14]. Diagrams and supplementary material were prepared using the above programmes together with ORTEP-3 for Windows [15] and PLATON [16,17]. In **5**, the pyridyl rings exhibited a rotational disorder that was modelled by partial occupancies (0.72:0.28 and 0.53:0.47) of N and C atoms about the interannular bond. In the case of **7**, the thienyl ring was disordered, with two rotamers differing in the orientation being present; this disorder

was modelled with partial occupancies of 1:1 for all ring atoms.

3. Results and discussion

3.1. Ligand synthesis

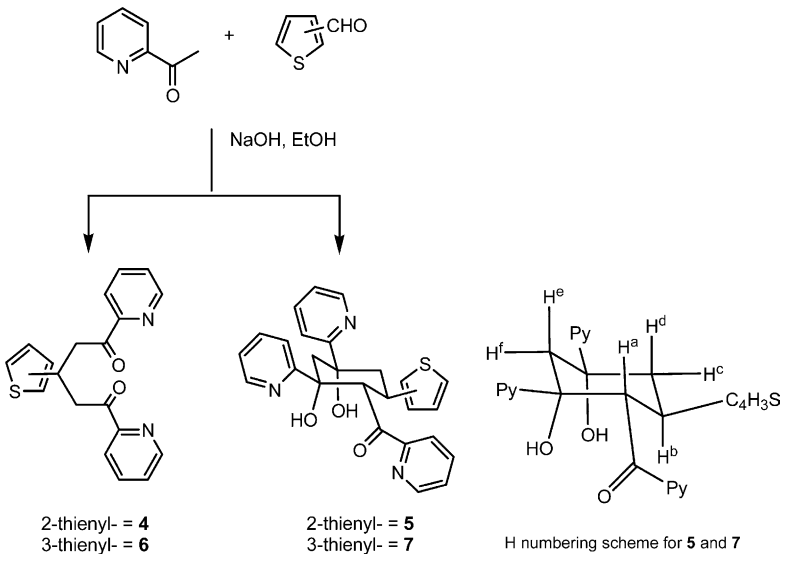
We have previously described the synthesis of the 2-thienyl-functionalized ligand **1**, which was obtained in 40% yield from a one-pot reaction of 2-acetylpyridine and thiophene-2-carbaldehyde in the presence of ammonium acetate [7]. Although the yield in this reaction was low, in our hands attempts to prepare **1** by Kröhnke [18] methodology using the enone 1-(2-pyridyl)-1-oxoprop-2-enylthiophene (readily prepared in good yield from 2-acetylpyridine and thiophene-2-carbaldehyde) were unsuccessful or very low-yielding although an unspecified ''modified'' Kröhnke approach has been reported [19]. In the course of attempts to optimize the yield of **1** and to develop general methods for other 4′-aryl-2,2′:6′,2″-terpyridines, we have investigated a number of other approaches.

3.2. The 1,5-dicarbonyl route and the solid-state structures of 5 and 7

One of the approaches that we have shown to be successful for the synthesis of 4′-phenyl-2,2′:6′,2′-terpyridine is the preparation of 4-phenyl-1,5-di(2-pyridyl)pentane-1,5-dione from the reaction of benzaldehyde with an excess of 2-acetylpyridine followed by oxidative cyclization with ammonium acetate under aerobic conditions [20]. We have, however, shown that in the case of other aromatic aldehydes, the 1,5-dicarbonyl compound is the minor product compared to other cyclic condensation products.

The reaction of thiophene-2-carbaldehyde with an excess of 2-acetylpyridine in basic (aqueous ethanolic NaOH) conditions resulted in the formation of a mixture of two compounds, identified as the desired 1,5-dicarbonyl 1,5-bis(2-pyridyl)-3-(2-thienyl)penta-1,5-dione (**4**) and the 3:1 cyclic condensation product 3-(2-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol (**5**) (Scheme 1). The isolated yield of **4** was only 25% and the reaction sequence offered no advantage in terms of yield or convenience over the previously described one-pot method. A similar reaction with thiophene-3-carbaldehyde gave small amounts of the 1,5-dicarbonyl compound **6** and the 3:1 cyclohexane derivative 3-(3-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol (**7**) as the major product (Scheme 1). All of these compounds were fully characterized by spectroscopic and mass spectrometric methods (see Section 2).

The new compounds **5** and **7** are worthy of some additional discussion and both have been further characterized by crystal structure determinations. We have previously published details of the assignment of the ^{1}H NMR spectrum of a derivative related to **5** and **7**, but with the thienyl substituent replaced by a 4-^{t}BuC$_6$H$_4$ group [21]. The ^{1}H NMR spectra of ligands **5** and **7** exhibit resonances assigned to the two sets of geminal protons H$^{c/d}$ and H$^{e/f}$ (see Scheme 1) with a characteristic coupling constant ($^2J = 14$–15 Hz). In addition, two hydroxy resonances are observed for **7**, one broadened through exchange with the solvent, and the other sharp as a result of hydrogen-bonding with the



Scheme 1.

adjacent carbonyl group. In the case of **5**, integration shows that the more broadened OH signal lies under the thienyl H^4 peak. The aromatic signals were assigned by COSY NMR spectroscopy which allowed differentiation between the signals belonging to different pyridine rings (distinguished in the experimental section by use of prime marks), but did not permit their absolute assignment.

Slow evaporation of methanolic solutions of **5** and **7** afforded colourless, cubic crystals of X-ray quality. The solid-state X-ray determinations of the two compounds were very similar and confirmed the structures. The structure of compound **5** is shown in Fig. 1. The only constitutional difference between **5** and **7** lies in the position of substitution of the thienyl ring. In both compounds all of the aromatic substituents are in the favoured equatorial positions, resulting in a (1*RS*, 2*SR*, 2*RS*, 5*RS*) configuration. All bond lengths and angles lie in the normal ranges. The O···O and OH···O distances between the two hydroxy-groups are 2.732(3) and 1.87(3) Å for **5**, and 2.729(3) and 1.89(2) Å for **7**, respectively, which support the ^{1}H NMR spectroscopic data in suggesting that these groups are hydrogen-bonded. Both enantiomers of the chiral compounds **5** and **7** are present in the unit cell. Rotational disorder of the thienyl ring of **7** leads to 53% and 47% occupancy of two rotamers, distinguished by the location of the sulfur atom with respect to adjacent substituents, although compound **5** shows no such disorder.

Attempts to prepare **1** or **3** from **5** or **7**, respectively, by reaction with ammonium acetate were unsuccessful.

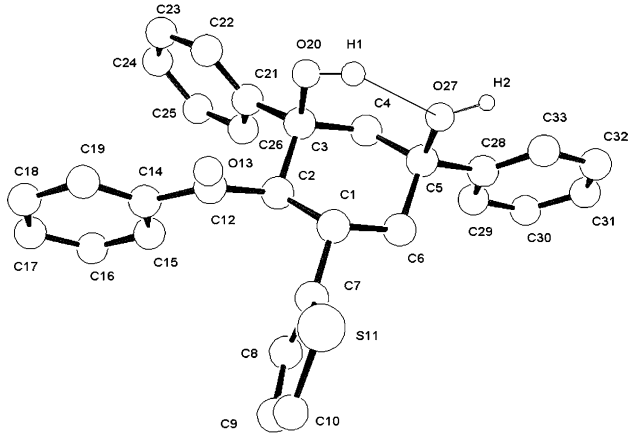


Fig. 1. Solid-state structure of **5** showing the numbering scheme adopted. Hydrogen atoms involved in hydrogen bonding are included in the diagram; all other H atoms are omitted for clarity. Selected bond distances: S(11)–C(7) = 1.696(2), S(11)–C(10) = 1.679(3), O(13)–C(12) = 1.209(3), O(20)–C(3) = 1.429(3), O(27)–C(5) = 1.434(4), O(20)–H(1) = 0.95(3), O(27)–H(2) = 0.96(3) Å.

3.3. Modified one-pot synthesis of *1* and *3* and the solid-state structure of *3*

We finally adopted a modification of the one-pot synthetic method originally described by Calzaferri [22] in which 2-acetylpyridine is converted to the enolate by reaction with potassium tert-butoxide, followed by reaction with half an equivalent of the aromatic aldehyde. Subsequently, the reaction mixture is treated with ammonium acetate in ethanolic acetic acid. Using this method, compounds **1** and **3** were obtained in 62% and 52% yield from thiophene-2-carbaldehyde and thiophene-3-carbaldehyde, respectively. Extraction and column chromatographic purification gave the desired ligands analytically pure.

Compound **3** shows a parent ion in its mass spectrum and the ^{1}H NMR spectrum is fully in accord with the

structure proposed. The solid state structure of **3** is presented in Fig. 2. The thiophene rings exhibited a rotational disorder and only one rotamer is shown in the Figure. The tpy-domain adopts the expected transoid conformation of the pyridine rings. In the solid state, the pyridine rings are almost coplanar, with a torsion angle of only 4.5° between the terminal and central rings. The average deviation of the disordered thienyl ring from the plane of the central group is only 6.0°. The C–C and C–N bond lengths in the pyridine rings lie within expected ranges as do the average C–C and C–S distances within the disordered thienyl ring. In the lattice, the molecules form a herring-bone pattern with classical π-stacking interactions between terminal pyridine rings of adjacent ligands.

3.4. Complexes of 1 and 3 with Co(II), Fe(II), Ru(II) and Os(II)

We have previously published details of the complexes $[Co(\mathbf{1})_2][PF_6]_2$ [8], $[Ru(\mathbf{1})_2][PF_6]_2$, $[Os(\mathbf{1})_2][PF_6]_2$, $[Ru(tpy)(\mathbf{1})][PF_6]_2$ and $[Os(tpy)(\mathbf{1})][PF_6]_2$ [7]. Here, we add to this series by reporting the preparation and characterization of $[Fe(\mathbf{1})_2][PF_6]_2$, and of the 4′-(3-thienyl)-2,2′:6′,2′-terpyridine-containing complexes $[Co(\mathbf{3})_2][PF_6]_2$, $[Fe(\mathbf{3})_2][PF_6]_2$, $[Ru(\mathbf{3})_2][PF_6]_2$, $[Os(\mathbf{3})_2][PF_6]_2$, $[Ru(tpy)(\mathbf{3})][PF_6]_2$ and $[Os(tpy)(\mathbf{3})][PF_6]_2$. Each complex containing ligand **3** is an isomer of the corresponding complex containing ligand **1**, differing only in the position of the sulfur atom in the thienyl ring. One of our interests in thienyl-derivatized bis(tpy) metal complexes is their adsorption properties on surfaces. With the sulfur donor in the 3- rather than 2-position, the complex is better suited sterically for interaction through S-donation to the surface.

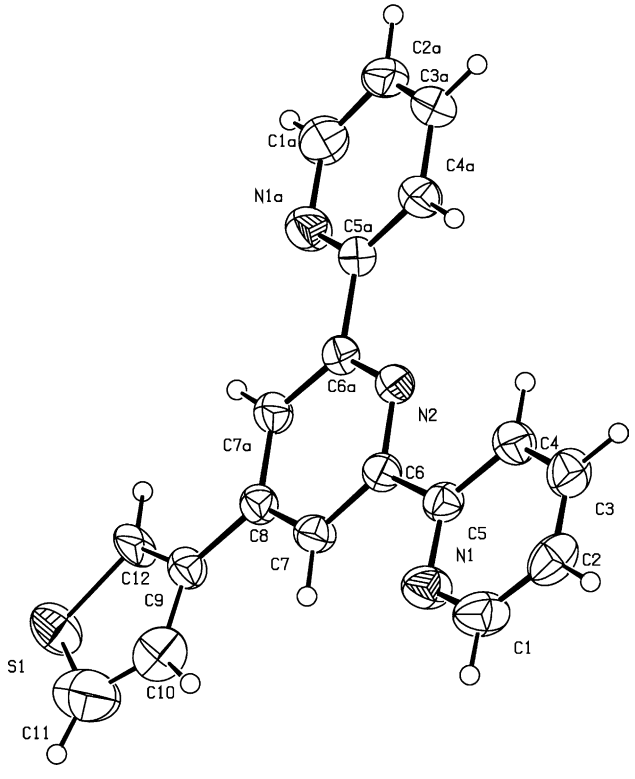

Fig. 2. Solid state structure of **3** showing the atom numbering scheme adopted. Only one conformation of the disordered thiophene ring is shown. Selected bond distances: S(1)–C(11) = 1.686(11), S(1)–C(12) = 1.664(4), N(1)–C(1) = 1.338(3), N(1)–C(5) = 1.335(2), N(2)–C(6) = 1.338(1) Å.

The diamagnetic complex $[Fe(\mathbf{1})_2]^{2+}$ was prepared in quantitative yield as the $[PF_6]^-$ salt from iron(II) tetrafluoroborate and ligand **1**, followed by precipitation with $[NH_4][PF_6]$. The highest mass peak in the MALDI-TOF mass spectrum was at *m/z* 687 corresponding to the $[M - 2PF_6]^+$; the isotopic pattern of the envelope matched that calculated. The ^1H NMR spectrum of $[Fe(\mathbf{1})_2]^{2+}$ is consistent with a symmetrical complex. On going from $[Fe(\mathbf{1})_2]^{2+}$ to $[Fe(\mathbf{3})_2]^{2+}$, there are negligible changes in the ^1H NMR spectrum for signals assigned to the tpy protons. The thiophene region in the ^1H NMR spectrum of $[Fe(\mathbf{1})_2]^{2+}$ is characterized by signals at δ 8.30, 7.90 and 7.47 assigned on the basis of the coupling constants and chemical shifts to H^{3S}, H^{5S} and H^{4S}, respectively. The signal for H^{5S} is unaffected on going from $[Fe(\mathbf{1})_2]^{2+}$ to $[Fe(\mathbf{3})_2]^{2+}$, but the signal for H^{4S} shifts from δ 7.47 to 8.16 in response to the change in position of the ring S atom. The doublet of doublets at δ 8.30 assigned to H^{3S} in $[Fe(\mathbf{1})_2]^{2+}$ is replaced by a doublet of doublets at δ 8.60 assigned to H^{2S} in $[Fe(\mathbf{3})_2]^{2+}$. The highest mass peak at *m/z* 831 in the FAB mass spectrum of $[Fe(\mathbf{3})_2][PF_6]_2$ is consistent with $[M - PF_6]^+$.

The homoleptic complexes $[Ru(\mathbf{3})_2]^{2+}$ and $[Os(\mathbf{3})_2]^{2+}$ were prepared by the reaction of $RuCl_3 \cdot 3H_2O$ or $K_2[OsCl_6]$ with **3** in ethane-1,2-diol under microwave conditions in the presence of *N*-ethylmorpholine as reducing agent. These strategies are similar to those previously reported for the syntheses of $[Ru(\mathbf{1})_2]^{2+}$ and $[Os(\mathbf{1})_2]^{2+}$ [7]. Both complexes were isolated as the $[PF_6]^-$ salts. As for the Fe(II) complex, the ^1H NMR spectra of $[Ru(\mathbf{3})_2]^{2+}$ and $[Os(\mathbf{3})_2]^{2+}$ are consistent with symmetrical species. Fig. 3 illustrates the effect that coordination of ligand **3** to each group 8 metal(II) centre has on the chemical shifts of the protons in the tpy part of the ligand; values of $(\delta_{free\ ligand} - \delta_{complex})$ are plotted for each proton. Proton H^6 is affected the most and shifts to significantly lower frequency as ligand **3** forms $[M(\mathbf{3})_2]^{2+}$, the magnitude of the change following the sequence Fe > Os > Ru. These shift correlations are a good qualitative measure of the change in coordination environment of the ligand upon coordination to the metal ion. The upfield shift of H^6 is due to the proton lying above the shielding region of a pyridine ring of the other tpy ligand. Fig. 3 shows that the δ value of tpy protons H^3 and H^4 are scarcely influenced by coordination. The signal assigned to H^5 shifts slightly to lower

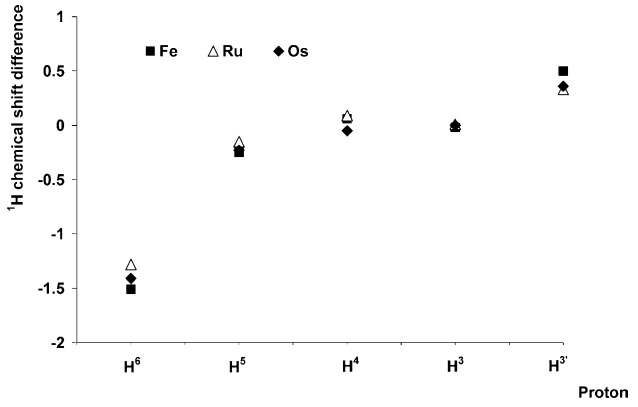

Fig. 3. Changes in the ^{1}H NMR chemical shifts ($\delta_{\text{free ligand}(CDCl_3)} - \delta_{\text{complex}(CD_3CN)}$) for the tpy proton signals on going from free ligand **3** to $[Fe(\mathbf{3})_2]^{2+}$, $[Ru(\mathbf{3})_2]^{2+}$ and $[Os(\mathbf{3})_2]^{2+}$.

frequency, while that for H$^{3'}$ (the only proton in the central ring of the tpy part of the ligand) shifts to higher frequency with the magnitude of the change following the order Fe > Os > Ru.

The paramagnetic complex $[Co(\mathbf{3})_2]^{2+}$ was prepared in quantitative yield by the reaction of $[Co(H_2O)_6][BF_4]_2$ with ligand **3** followed by anion exchange to yield $[Co(\mathbf{3})_2][PF_6]_2$. The highest mass peak in the electrospray mass spectrum came at $m/z = 344$ and the isotope pattern was consistent with the formulation $[M - 2PF_6]^{2+}$. In the ^{1}H NMR spectrum (Fig. 4), all signals were paramagnetically shifted and, although broadened, were well-resolved with the exception of the lowest frequency signal at δ 93.5. The Co(II) ion (d^7) may be high or low-spin, and in complexes derived from $[Co(tpy)_2]^{2+}$, the proton chemical shift range for the tpy protons is characteristic of the spin state [8,23]. In $[Co(\mathbf{3})_2]^{2+}$, the ^{1}H NMR spectrum showed signals over the range δ 9.22–93.5, indicative of low-spin Co(II). The signals at δ 93.5, 55.3, 44.4 and 32.6 in the ^{1}H NMR spectrum of $[Co(\mathbf{3})_2]^{2+}$ are at similar shifts to those assigned by COSY [24] to protons H^6, H^3, H$^{3'}$ and H^5 in $[Co(tpy)_2]^{2+}$ (δ 99.8, 57.2, 48.2, 34.5 for the $[PF_6]^-$ salt in CD_3CN), and we therefore assign these signals to the corresponding protons in $[Co(\mathbf{3})_2]^{2+}$. In $[Co(tpy)_2]^{2+}$, a signal at δ 8.91 has been assigned by COSY [24] to proton H^4. In the spectrum of $[Co(\mathbf{3})_2]^{2+}$, two broadened peaks appear at δ 9.47 and 9.22 with relative integrals 1:2. The signal at δ 9.22 is assigned to tpy H^4. The signals in the spectrum at δ 14.7, 13.1 and 9.4 with relative integrals 1:1:1 are assigned to the three thienyl protons but it has not been possible to unambiguously assign the peaks to individual protons. The presence of the paramagnetic Co(II) centre causes significant shifting of the signals for all protons in coordinated ligand **3** compared to their shifts in the diamagnetic Fe(II), Ru(II) and Os(II) analogues.

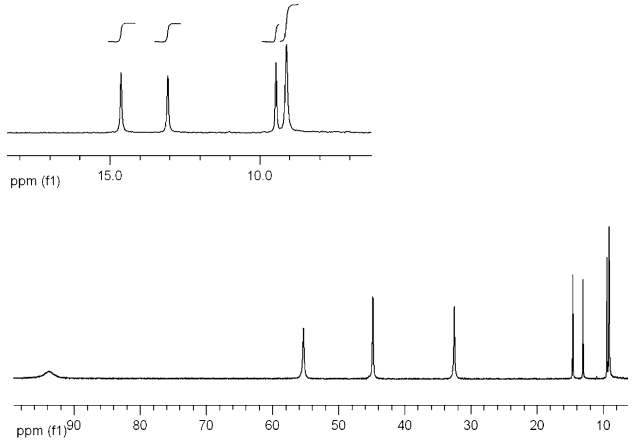

Fig. 4. The 250 MHz ^{1}H NMR spectrum of $[Co(\mathbf{3})_2][PF_6]_2$ (CD_3CN, room temperature). The expansion shows the region of the thienyl protons and the tpy H^4 proton.

The mixed-ligand complexes $[Ru(tpy)(\mathbf{3})]^{2+}$ and $[Os(tpy)(\mathbf{3})]^{2+}$ were prepared by reactions of $[M(tpy)Cl_3]^{3+}$ (M = Ru or Os) with ligand **3** under reducing conditions (*N*-ethylmorpholine). The complexes were isolated in good yields as the hexafluorophosphate salts. In the MALDI-TOF mass spectra of $[Ru(tpy)(\mathbf{3})][PF_6]_2$ and $[Os(tpy)(\mathbf{3})][PF_6]_2$, the highest mass peaks at $m/z = 650$ and 739, respectively, corresponded to $\{M - 2PF_6\}^+$ and showed the correct isotopic distribution for this formulation. The ^{1}H NMR spectrum of $[Ru(tpy)(\mathbf{3})]^{2+}$ is a superimposition of the corresponding spectra for $[Ru(tpy)_2]^{2+}$ and $[Ru(\mathbf{3})_2]^{2+}$ and the spectrum could be assigned accordingly. Similarly, the signals in the ^{1}H NMR spectrum of $[Os(tpy)(\mathbf{3})]^{2+}$ could be assigned by comparison with the spectra for $[Os(tpy)_2]^{2+}$ and $[Os(\mathbf{3})_2]^{2+}$. In both heteroleptic complexes, therefore, the ligands have little or no influence on one another.

Electrochemical data for CH_3CN solutions of $[Ru(tpy)(\mathbf{3})][PF_6]_2$ and $[Os(tpy)(\mathbf{3})][PF_6]_2$ were recorded (versus Fc/Fc^+). For each of the ruthenium and osmium complexes, a fully reversible metal-centred redox wave occurs at +0.88 and +0.52 V, respectively, and is assigned to the M^{3+}/M^{2+} process. The ease of oxidation is therefore, as expected, Os(II) > Ru(II). The metal redox processes are shifted to less positive potentials compared to the corresponding $[M(tpy)_2]^{2+}$ complexes [25,26], indicating that the thienyl group is electron-donating. Quasi-reversible ligand-based electrochemical processes are observed for $[Ru(tpy)(\mathbf{3})]^{2+}$ at −1.52 and −1.82 V, and for $[Os(tpy)(\mathbf{3})]^{2+}$ at −1.65, −1.87 and −2.25 V.

4. Conclusion

We have developed an efficient method for the preparation of 4′-(2-thienyl)-2,2′:6′,2″-terpyridine and 4′-(3-thienyl)-2,2′:6′,2″-terpyridine; the latter was structurally characterized. During the synthesis development, the cyclic condensation products 3-(2-thienyl)-1,5-bis

(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol (**5**) and 3-(3-thienyl)-1,5-bis(2-pyridyl)-2-(2-pyridylcarbonyl)cyclohexane-1,5-diol (**7**) were isolated and structurally characterized. The formation and characterization of paramagnetic Co(II) and diamagnetic Fe(II), Ru(II) and Os(II) complexes containing 4′-(2-thienyl)- and 4′-(3-thienyl)-2,2′:6′,2′-terpyridine ligands have been described.

5. Supplementary material

Full crystallographic details have been deposited in CIF format with the Cambridge Crystallographic Data Centre. Copies of the data can be obtained free of charge on request from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336408, email: deposit@ccdc.cam.ac.uk or www at http://www.ccdc.cam.ac.uk.) quoting the deposition numbers CCDC 210433 (**3**), 210434 (**5**) and 210435 (**7**).

Abstract

An extended MM3 model has been used to identify all low energy configurations for U(IV) complexes with catecholate and aquo ligands. Both stochastic and systematic conformational analyses of $[U(cat)_n(OH_2)_{8-2n}]^{4-2n}$ complexes, $n = 1$–4, establish that 20 of the 67 possible stereochemistries are minima on the MM3 potential surface. The stable stereochemistries are reported for each stoichiometry and, where possible, the results are compared with experimental data and with the predictions from prior repulsion energy calculations.

1. Introduction

Research on computer-aided molecular design has led to the development of HostDesigner, the first computer software specifically created for the discovery of host molecules for metal ions [1]. The use of this software requires the definition of geometries that represent optimal arrangements of one or more binding sites about the metal ion of interest. One design strategy consists of placing two or more bidentate ligands on the metal and then using the software to identify molecular fragments that are suitable for bridging between the bidentate components. In this case the geometry of the initial metal complex must be defined. It is desirable to use all low energy configurations of the metal complex as input geometries to ensure that potentially viable architectures are not overlooked in the building process. Identification of these configurations can be problematic.

Consider the case where the coordination sphere will be filled with some combination of bidentate ligands and water. If the bidentate ligands are identical and symmetric (in other words, the two binding sites are equivalent) then there are only a limited number of possible configurations at low coordination numbers. For example, in an octahedral system with a coordination number of six there are two ways to place two bidentate ligands and only one way to place three bidentate ligands [2]. The situation becomes much more complex at higher coordination numbers where there may be several polyhedra and each polyhedron may exhibit multiple stereoisomers, and nonequivalent coordination sites.

This issue was brought to our attention when we considered the strategy of designing ligands for 8-coordinate U(IV) by connecting two or more catecholate groups that had been pre-positioned on the metal ion. Prior studies suggest that there are three polyhedra that should be considered for eight-coordinate U(IV) complexes: the square antiprism (SAP), the dodecahedron (DOD), and the bicapped trigonal prism (BTP) [3–9]. An enumeration of all possible ways to place one to four symmetrical bidentate ligands onto these three polyhedra, assuming vacant vertices are occupied by an identical type of unidentate ligand and excluding the optical

isomers, reveals that there are 130 distinct stereoisomers [11]! Which of these many possibilities actually represent stable configurations for U(IV) catecholate and aquo complexes?

This question may be addressed with force field calculations. Early analyses of eight-coordinate stereochemistries for [M(unidentate)$_8$] complexes were performed with a simple model in which the total repulsion energy in the inner coordination sphere was computed by applying $1/r^n$ potential functions between all pairs of points on the surface of a sphere [3,4a]. Such calculations have been extended to complexes containing bidentate ligands by keeping the distance between the pairs of atoms in the same chelate ring constant and used to analyze the stereochemistries of [M(bidentate)$_2$(unidentate)$_4$] and [M(bidentate)$_4$] complexes; providing one basis for the assignment of likely stereoisomers for these stoichiometries [4b–4e].

Molecular mechanics models, which mimic some of the features of the repulsion energy models, also can be used to evaluate the structures of high-coordinate metal complexes and to identify their stable stereochemistries [12]. Herein, we report the use of an extended MM3 model to perform conformational analyses of all stoichiometries for 8-coordinate U(IV) complexes with aquo and catecholate ligands. All stable stereochemistries are reported for each stoichiometry and, where possible, the results are compared with experimental data and with the predictions from prior repulsion energy calculations.

2. Methods

Molecular mechanics calculations were carried out using the MM3 program, [1] which has been modified to support "points-on-a-sphere" metal atom types [13]. The default parameter set was modified to allow treatment of the U(IV)-catecholate interactions and U(IV)-aquo interactions. With one exception, the U–O$_{cat}$ bond stretch, the parameters used for the U(IV)-catecholate interactions were taken directly from a prior study of Fe(III)-catecholate complexes [14]. The aquo ligand, which was modeled as a neutrally charged oxygen atom, also required the assignment of only U–O$_{aquo}$ bond stretch parameters. Extrapolating from Badger's rules [15], we estimate that U–O stretching force constants, k_r, should fall in the range of 1.0–1.5 mdyn/Å^2 over the range of 2.25–2.35 Å. After assigning the U–O$_{cat}$ interaction the upper limit of $k_r = 1.5$ mdyn/Å^2, an ideal length, $r_0 = 2.29$ Å, was assigned by adjusting r_0 to obtain the best fit to the U–O distances in the [U(cat)$_4$]$^{4-}$ crystal structure [16]. After assigning the U–O$_{aquo}$ interaction the lower limit of $k_r = 1.0$ mdyn/Å^2, an ideal length, $r_0 = 2.33$ Å, was assigned by interpolating a probable U–O distance from known [Ln(OH$_2$)$_8$]$^{3+}$ structures (see Section 3.2), and then adjusting r_0 to yield this U–O distance in a calculated square antiprism [U(OH$_2$)$_8$]$^{4+}$ model complex.

Extensive conformational searches on [U(OH$_2$)$_8$]$^{4+}$, [U(cat)(OH$_2$)$_6$]$^{2+}$, [U(cat)$_2$(OH$_2$)$_4$], [U(cat)$_3$(OH$_2$)$_2$]$^{2-}$, and [U(cat)$_4$]$^{4-}$ were carried out using Saunders' stochastic search algorithm as implemented in MM3 [17]. In each cycle of this algorithm, each atom is randomly displaced by up to a maximum distance of 2.0 Å, the resulting structure is energy minimized, and, if the optimized structure is unique, it is stored. Each conformer search was stopped after 10,000 cycles, after which no new conformers were being generated. Energy minimizations were done with the block diagonal Newton–Raphson method followed by the full-matrix Newton–Raphson method using a convergence criterion of RMS force of 0.0001 kcal mol^{-1} Å^{-1}. The absence of negative eigenvalues in the Hessian matrix was used to confirm that the calculated geometries were minima on the MM3 potential surface.

Given the random nature of the conformational analyses, it is possible that some minima might be overlooked. To exclude this possibility, we systematically built all possible SAP and DOD stereoisomers using the graphical user interface, Molden [18], and performed MM3 optimizations from these starting coordinates. During the building process, catecholate ligands were placed onto the edges of SAP and DOD polyhedra obtained from [U(OH$_2$)$_8$]$^{4+}$ calculations such that the U–O–C–C dihedral angles were either 0 or 180°.

An extended MM3 parameter file and Cartesian coordinates for the optimized structures are available as supplemental data.

3. Results and discussion

3.1. Idealized polyhedra

Three ideal polyhedra for 8-coordinate complexes – SAP, DOD, and BTP – are illustrated in Fig. 1. The SAP structure has D_{4d} symmetry. All eight vertices are identical. The 16 edges divide equally between two types, *s* along the square faces and *l* along the lateral edges [3]. The DOD structure has D_{2d} symmetry. It is composed of a pair of interpenetrating tetrahedra, one elongated tetrahedron giving rise to four *A* vertices and one flattened tetrahedron giving rise to four *B* vertices. The 18 edges are distributed among four classes: *a* (2 edges), *b* (4 edges), *m* (4 edges) and *g* (8 edges) [3]. The BTP has

[1] MM3 (96). The program may be obtained from Tripos Associates, 1699 S. Hanley Road, St. Louis, MO 63144 for commercial users, and it may be obtained from the Quantum Chemistry Program Exchange, Mr. Richard Counts, QCPE, Indiana University, Bloomington, IN 47405, for noncommercial users.

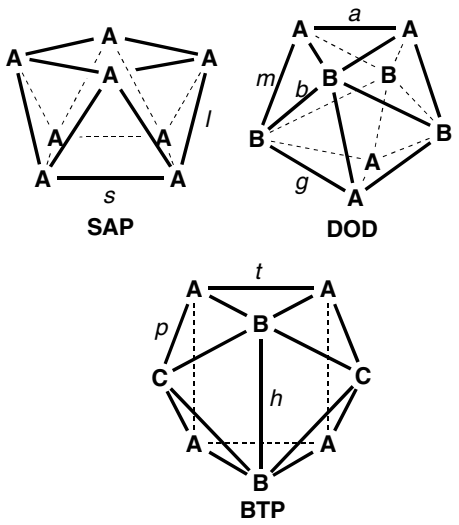

Fig. 1. Ideal polyhedra for coordination number eight. The square antiprism (SAP) and dodecahedron (DOD) are given with edge and vertex notations following the Hoard and Silverton convention [3]. The bicapped trigonal prism (BTP) is given with edge notation following the Porai-Koshits and Aslanov convention [7].

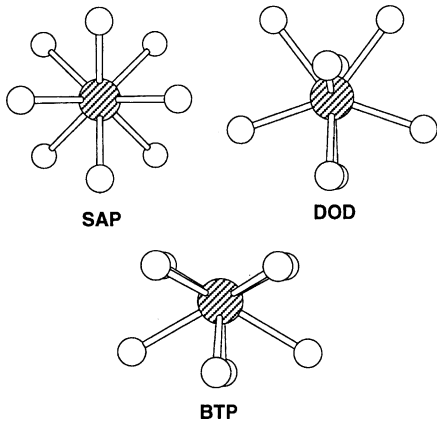

Fig. 2. Geometries for $[U(OH_2)_8]^{4+}$ obtained with the MM3 model. U–O distances, the edge lengths, and the angles formed between the U–O vectors and a symmetry axis: SAP form, U–O_A = 2.36 Å, s = 2.82 Å, l = 2.95 Å, θ = 57.7° (S_8 axis); DOD form, U–O_A = 2.37 Å, U–O_B = 2.36 Å, m = 2.77, g = 2.88 Å, a = 2.85 Å, b = 3.50 Å, Å, θ_A = 37.0°, θ_B = 71.5° (S_4 axis); BTP form, U–O_A = U–O_B = 2.36 Å, U–O_C = 2.39 Å, t = 2.87 Å, p = 2.71 Å, h = 3.37, θ_A = 69.4°, θ_B = 45.5°, θ_C = 60.0° (C_2 axis).

C_{2v} symmetry. It is composed of a trigonal prism that is capped on two of the rectangular faces giving rise to four A vertices, two B vertices and two C vertices. The 17 edges are distributed among three classes: t (6 edges), p (8 edges), and h (3 edges) [7,8].

3.2. Octaaquo complex – $[U(OH_2)_8]^{4+}$

Oxygen atoms were used to represent the aquo ligands in the U(IV) complexes. This approach, which has been used successfully in prior studies [13a,19], maintains the inner coordination sphere, but eliminates the potential for multiple minima associated with different hydrogen atom orientations. The van der Waals interactions between these charge–neutral oxygen atoms, which are equivalent to those used in the MM3 force field to model alcohol and ether oxygen atoms in organic compounds, provides a reasonable approximation of the forces present within the inner coordination sphere.

The random conformational search of the $[U(OH_2)_8]^{4+}$ complex yields a single minimum energy structure. Of the three ideal polyhedra shown in Fig. 1, only the SAP form is stable. The DOD form is located as a transition state when the initial coordinates are given in strict D_{2d} symmetry. The BTP structure is not a stationary point on the MM3 potential surface, but can be obtained by imposing D_{3h} symmetry on the trigonal prism portion of the structure during optimization. On removal of the symmetry constraints, the BTP structure optimizes to the SAP form. The relative energies for these three structures, shown in Fig. 2, are 0 kcal/mol (SAP), 0.30 kcal/mol (DOD), and 2.83 kcal/mol (BTP).

The MM3 results are consistent with those obtained from prior repulsion energy calculations for eight points on a sphere. In the earliest calculations, which focused on the SAP and DOD polyhedra, the geometries were optimized within the limitations of symmetry constraints [3,4a]. Although absolute energy differences were not reported, these calculations suggested that the SAP and DOD forms were very close in energy. Subsequently, repulsion energy calculations were used to generate a potential surface revealing that the DOD form is actually a transition state between two possible SAP forms [4e]. The BTP form has not been discussed in the repulsion energy calculation studies. It has been noted, however, that the BTP form is unlikely to represent a sterically stable polyhedron and that it should distort toward the SAP geometry if symmetry restrictions are removed [9].

No structures have been reported that contain an octaaquo U(IV) complex. However, there are 10 crystal structures that contain octaaquo ions for the smaller lanthanide metal ions, from Gd(III) to Lu(III) [20–28]. The Shannon ionic radii (CN = 8) for these metal ions range from 1.05 to 0.98 Å, bracketing the corresponding value of 1.00 Å for U(IV) [29]. A plot of the average M–O distance versus Shannon ionic radius (CN = 8) was linear (M–O distance = 1.463 + 0.897 × ionic radius, r = 0.979). Interpolation gives the U(IV)–O_{aquo} distance of 2.36 Å that served as a basis for assigning the MM3 stretching parameters.

Half of the lanthanide complexes exhibit the SAP geometry and the other half exhibit the DOD geometry. The higher energy BTP geometry is not observed. Comparison of the geometric parameters calculated for U(IV) with those observed in the lanthanide complexes,

U(IV) this work	DOD	1.000	2.37	2.36	37.0	71.5

Table 1, establishes that the simple model used here well reproduces the shapes of these polyhedra. Although the model used in this study, as well as repulsion energy models [4e], do not predict that the DOD polyhedron to be a local minimum, they do predict a small difference in energy between the SAP and DOD forms. This small energy difference could allow other factors such as intra- and inter-molecular hydrogen bonding to stabilize the DOD form in the crystal lattice. In addition, although the lanthanide-aquo ligand interaction is more ionic than covalent in character, directional bonding at the metal center, not included in the MM3 model, could also play a role in stabilizing the DOD stereochemistry [10].

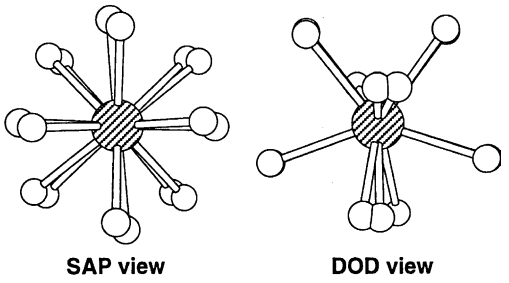

Fig. 3. Superposition of the SAP and DOD stereochemistries from Fig. 2 illustrates the similarity in these two geometries. In the SAP view, the SAP structure is oriented with the square planes parallel to the plane of the page. In the DOD view, the DOD structure is oriented with four oxygen atoms in the plane of the page and four oxygen atoms in the vertical plane perpendicular to the page.

3.3. General comments on catecholate complexes

Examination of the Cambridge Structural Database [30] reveals that catecholate ligand exhibits an average bite of 2.61 ± 0.06 Å when coordinated to a metal ion in tris- and tetrakis–catecholate complexes. Comparison of this value with the edge lengths calculated for the three $[U(OH_2)_8]^{4+}$ polyhedra (with U–O distances ranging from 2.36 to 2.39 Å) shows that the catecholate bite is too small to span even the shortest edges in these polyhedra, which are 2.82 Å in the SAP, 2.77 Å in the DOD, and 2.71 Å in the BTP. It follows that the structures calculated for catecholate complexes will contain polyhedra that are distorted, to some extent, from the polyhedra shown in Fig. 2.

This raises the problem of how to identify which stereochemistry is present. The three $[U(OH_2)_8]^{4+}$ polyhedra shown in Fig. 2 are actually not that different in shape. For example, when the idealized SAP and DOD forms are superimposed in Fig. 3, it is clear that even a perfect SAP geometry can appear to be a distorted DOD from a certain perspective, and vice versa. Even worse, if a molecule has an inner sphere geometry intermediate between these two forms, it is exceedingly difficult, to classify the polyhedron accurately by visual inspection alone. In the superposition shown in Fig. 3, the average distance between corresponding pairs of oxygen atoms is 0.38 Å and the movement required to convert the SAP to the DOD form is $\leqslant 10°$ for any U–O vector. Superposition of the SAP and BTP forms or DOD and BTP forms yield similar results.

One approach for distinguishing between the SAP, BTP, and DOD forms involves calculating the dihedral angles between the normal vectors of selected adjacent triangular faces [7,8,31]. Application of this method is not straightforward. One must correctly identify all edges in the polyhedron. As noted above, the three polyhedra in question actually have different numbers of edges and which pairs of ligands constitute an edge must be determined. In addition, before the assignment can be made, it is necessary to correctly select which edges are shape-determining for the structure. There may be more than one way to choose them, resulting in the possibility of ambiguous assignments [9].

An alternate approach involves attempting to superimpose the inner sphere atoms of an observed polyhedron onto to those of an ideal polyhedron [32]. Once the optimal superposition has been achieved by least squares fitting, the deviation, taken as the root-mean-squared distance (rmsd) between corresponding atom pairs, provides a single criterion that measures how well the observed polyhedron conforms to the ideal polyhedron.

During this process, all possible pairings of atoms from the two sets are considered and the best superposition is retained. When there are several possible ideal polyhedra, the one that yields the best superposition with the observed structure is the polyhedron that most closely resembles the observed structure.

The superposition method was used to assign the polyhedra of the calculated catecholate complexes by comparing their inner sphere geometry to the ideal polyhedra calculated for $[U(OH_2)_8]^{4+}$ (Fig. 2). Prior to performing these superpositions, all U–O distances were normalized to 1.0 Å [9]. Thus, this method of determining similarity to an ideal polyhedron is based on the degree of correspondence between the U–O vectors in the distorted polyhedron and those in the ideal polyhedron. This is equivalent to analyzing only the O–U–O angles while excluding variation in U–O distances.

Conformational analyses of $[U(cat)(OH_2)_6]^{2+}$, $[U(cat)_2(OH_2)_4]$, $[U(cat)_3(OH_2)_2]^{2-}$, and $[U(cat)_4]^{4-}$ identified 20 stable structures. The stereochemistries of these structures were assigned by first identifying which ideal polyhedron gave the best fit to the inner sphere and then noting which edges were spanned by the catecholate ligands. The inner sphere geometry in the majority of these structures most closely resembles the SAP polyhedron. The DOD polyhedron gave the best fit in

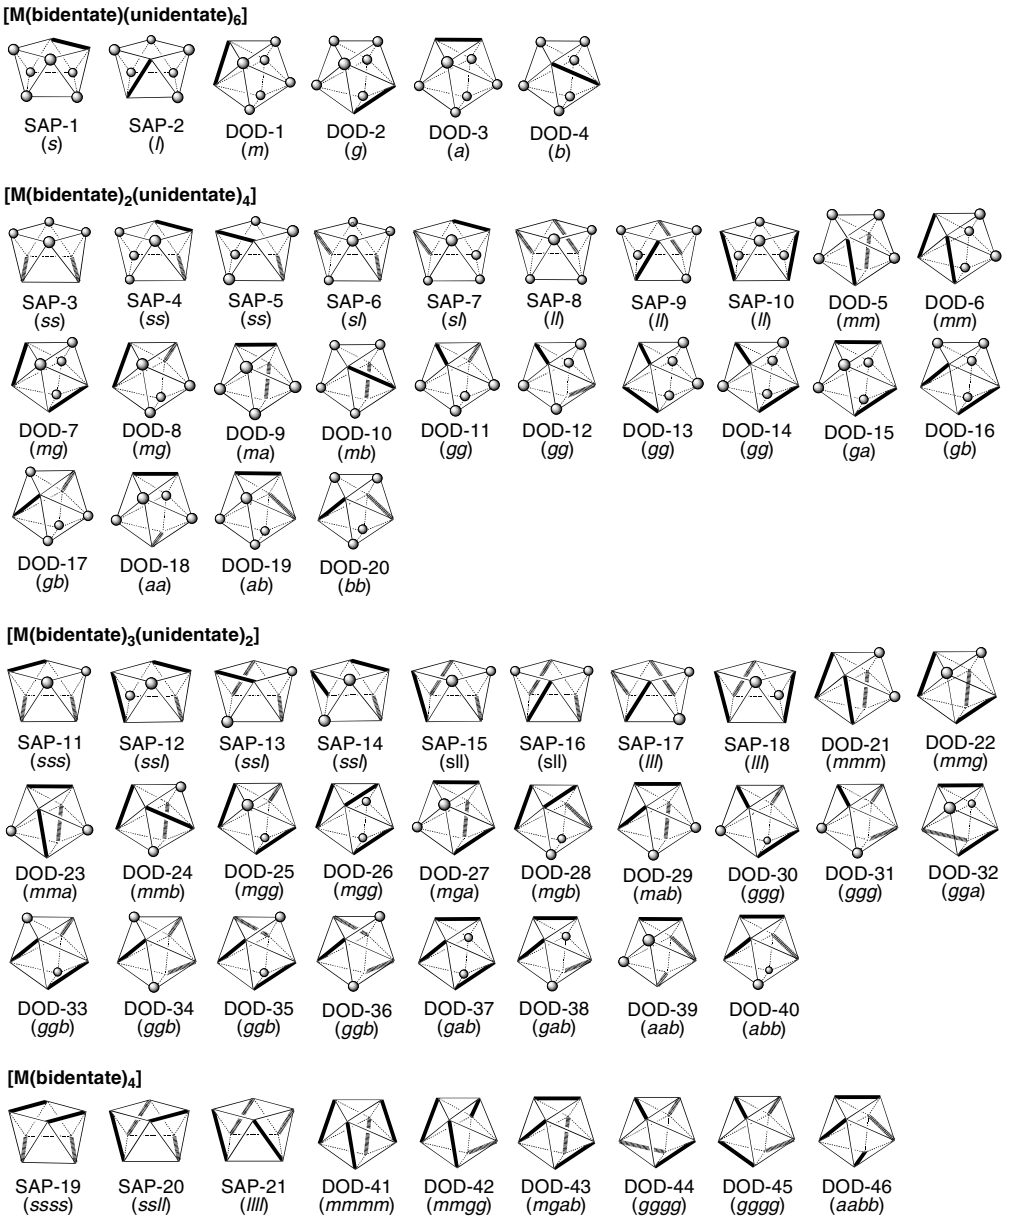

Fig. 4. Views of the 67 distinct stereochemistries, excluding optical isomers, that can be formed by placing identical unidentate ligands and identical symmetric bidentate ligands onto SAP and DOD polyhedra. The edges spanned by the bidentate ligands, given beneath each ID, are indicated by bold lines. The central M is omitted for clarity.

only a couple of instances, while the BTP polyhedron never gave the best fit. This result confirms that the BTP does not represent a sterically favorable arrangement of ligands about the metal ion.

Excluding optical isomers, there are 67 possible stereochemistries for SAP and DOD polyhedra [11]. These are illustrated in Fig. 4. Only 20 of these stereochemistries were located by the conformational analyses. To exclude the possibility that some stereochemistries might have been missed, we systematically constructed all possible SAP and DOD stereoisomers on a graphical user interface and used these structures as starting points for MM3 optimizations. This systematic analysis gave identical results to those obtained from the random conformational searches. No additional structures were obtained for any stoichiometry. In all cases, the alternative starting configurations either collapsed to those already located in the random searches or yielded structures that were transition states.

The results of the stereochemical analyses of the catecholate complexes are summarized in Table 2. Three-dimensional views of each structure are presented in Figs. 5–8. Further details for each stoichiometry are provided below.

3.4. The mono catecholate stoichiometry, $[U(cat)(OH_2)_6]^{2+}$

This stoichiometry has two possible SAP forms and four possible DOD forms (Fig. 4). The MM3 analysis yields only the two SAP stereochemistries shown in Fig. 5. The SAP-1 stereochemistry, in which the catecholate ligand spans the shorter *s* edge of a square face, is 0.52 kcal/mol more stable than the SAP-2 stereochemistry, in which the catecholate ligand spans the longer *l* edge of a triangular face. This result is consistent with the concept that a more stable complex is obtained when the bite of a bidentate ligand most closely matches the edge length of the polyhedron. None of the DOD forms are minima on the MM3 potential surface. However, the analysis of the $[U(OH_2)_8]^{4+}$ case suggests that distortion to DOD forms could be accomplished without substantial energetic penalty.

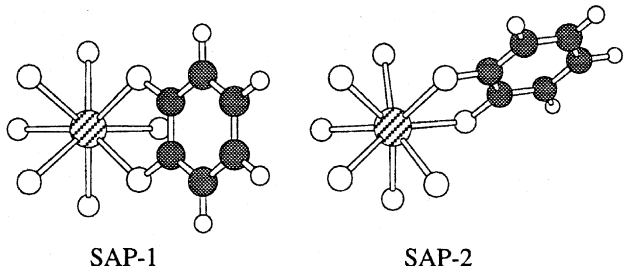

Fig. 5. MM3 geometries for the two stable stereochemistries of $[U(cat)(OH_2)_6]^{2+}$.

No crystal structures have been reported [30] for any complex with the stoichiometry $[M(cat)(OH_2)_6]$. In addition, prior stereochemical analyses for any [M(bidentate)(unidentate)$_6$] complex have not been reported.

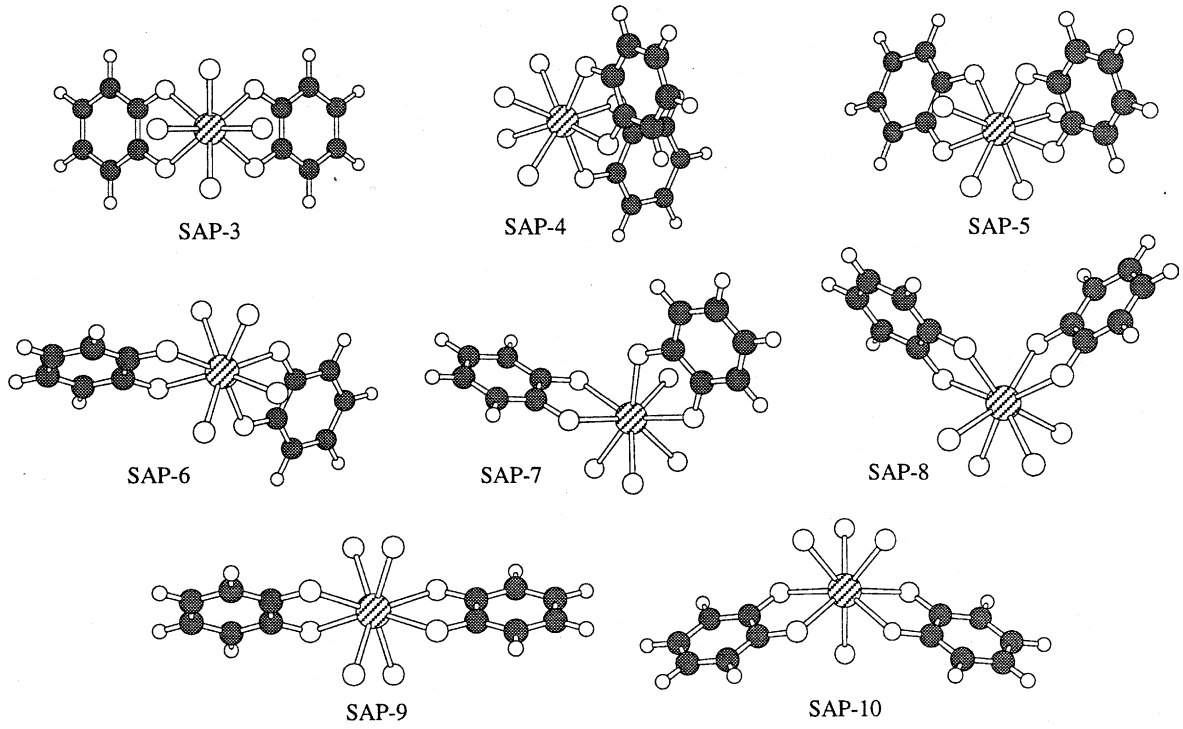

Fig. 6. MM3 geometries for the eight stable stereochemistries of $[U(cat)_2(OH_2)_4]$.

3.5. The bis catecholate stoichiometry, $[U(cat)_2(OH_2)_4]$

This stoichiometry has eight possible SAP forms and 16 possible DOD forms (Fig. 4). As with the $[U(OH_2)_8]^{4+}$ and $[U(cat)(OH_2)_6]^{2+}$ complexes, the MM3 analysis yields local minima that have polyhedra that are most similar to the SAP form. All eight possible SAP stereochemistries, shown in Fig. 6, are obtained. The relative energies span a range of 1.5 kcal/mol. The relative stabilities, which follow the order *ss* < *sl* < *ll*, again confirm the energetic preference for the catecholate ligand to occupy the shorter *s* edges of the SAP polyhedron.

No crystal structures have been reported [30] for any complex with the stoichiometry $[M(cat)_2(OH_2)_4]$. However, the results can be compared with prior stereochemical analyses of the $[M(bidentate)_2(unidentate)_4]$ stoichiometry [4b,4e]. Repulsion energy calculations were used to examine seven possible stereoisomers corresponding to SAP-3, SAP-4, SAP-5, SAP-8, SAP-9, SAP-10, and DOD-9. Plots of the repulsion energy for these forms as a function of the bite/M–L distance shows that at a value of 1.12, corresponding to the U(IV)-catecholate complexes, the stability of these forms is SAP-3 ~ SAP-4 < SAP-5 < DOD-9 ~ SAP-9 < SAP-10 < SAP-8, very similar to the ordering obtained here (see Table 2). Both models predict the forms with three *ss* edges are lower in energy than the forms with three *ll* edges. The DOD-9 form is a transition state on MM3 potential surface. When the geometry optimization is started from the DOD-9 stereochemistry, an SAP-7 form is obtained. The DOD-9 transition state is 0.52 kcal/mol higher in energy than the SAP-7 form.

3.6. The tris catecholate stoichiometry, $[U(cat)_3(OH_2)_2]^{2-}$

This stoichiometry has eight possible SAP forms and 20 possible DOD forms (Fig. 4). MM3 analysis yields a total of eight local minima (7 SAP and 1 DOD), shown in Fig. 7. Although these tris-catecholate structures are on average showing higher degrees of distortion from the ideal polyhedra than the structures presented above, the superposition method identifies seven of the structures to be closer to the SAP form and one of the structures to be closer to the DOD form. This is the first case where the inner sphere geometry, which in this case can be viewed as either a distorted DOD-22 or a distorted SAP-14, more closely resembles the DOD form (see Δ values in Table 2). The relative energies span a range of 2.34 kcal/mol. The relative stability order with respect to chelated edge lengths is *sss* < *ssl* ~ *mmg* (*ssl*) < *ssl* < *sll* < *lll* < *sll* < *lll*, again showing a clear preference for the chelate rings to span the shorter edge lengths.

No structures have been reported [30] for any complex with the stoichiometry $[M(cat)_3(OH_2)_2]$. In addition, prior stereochemical analyses of any $[M(bidentate)_3(unidentate)_2]$ complex have not been reported.

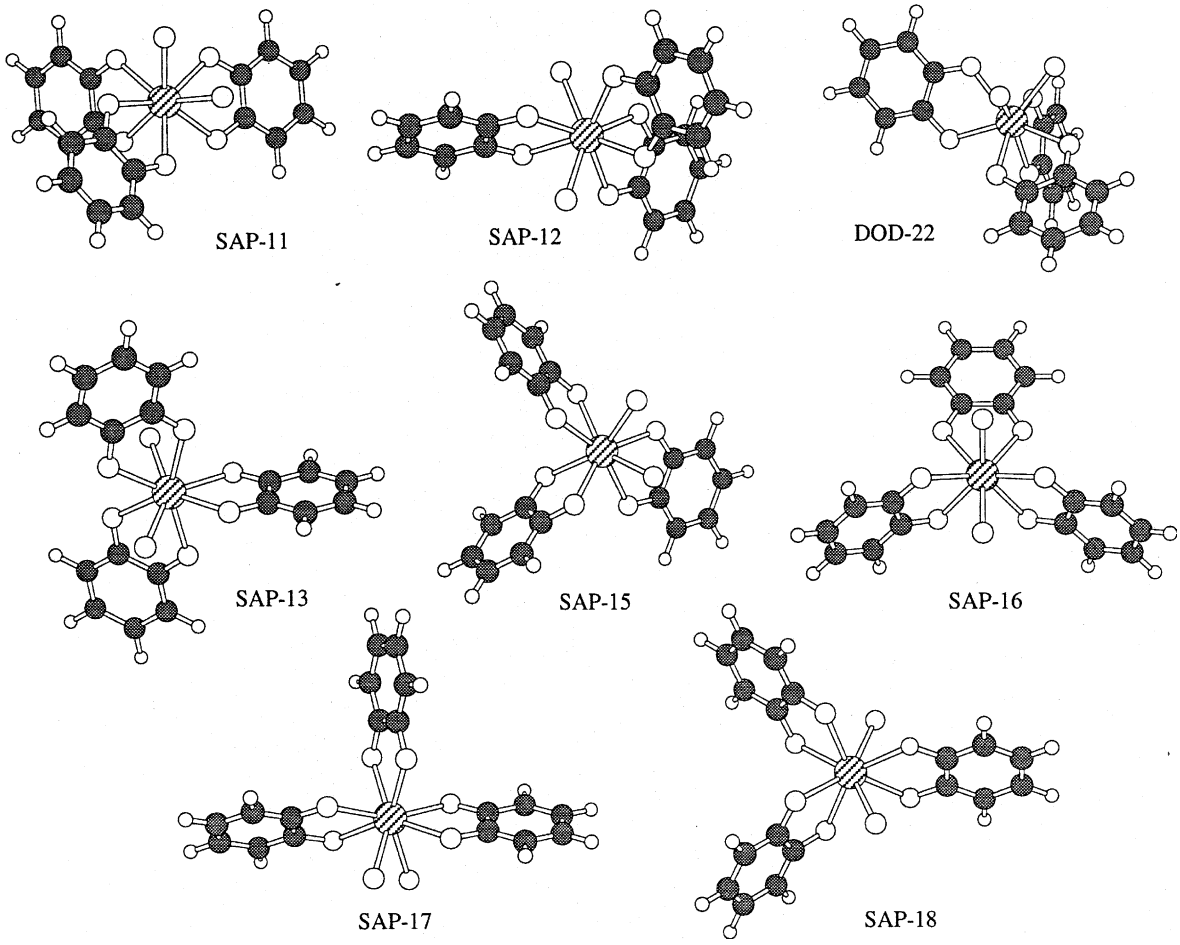

Fig. 7. MM3 geometries for the eight stable stereochemistries of $[U(cat)_3(OH_2)_2]^{2-}$.

3.7. The tetrakis catecholate stoichiometry, $[U(cat)_4]^{4-}$

This stoichiometry has three possible SAP forms and six possible DOD forms (Fig. 4). MM3 analysis yields only two local minima, shown in Fig. 8. The most stable form is a distorted DOD with D_2 symmetry in which the ligands span *m* edges. The nature of the distortion is illustrated in Fig. 9. Each of the catecholates is slightly twisted around an axis passing through the center of the catecholate ligand and the metal ion. This distortion is quantified by the dihedral angle, Φ, defined by the $m-a-m$ edges (see Fig. 1). An ideal D_{2d} DOD would have a value of $\Phi = 0°$. The calculated D_2 form has $\Phi = 18.7°$. As shown in Fig. 9, the ideal D_{2d} form is a transition state on the MM3 potential surface lying between two D_2 enantiomers. The potential surface is very flat in this region, the D_{2d} form is only 0.03 kcal/mol above the two D_2 minima.

The other stable structure is 2.69 kcal/mol higher in energy than the D_2 DOD form. It is a distorted SAP geometry with D_4 symmetry in which the ligands span *l* edges. This form can be viewed as a four-bladed propeller analogous to the three-bladed propeller that occurs in [M(bidentate)$_3$] complexes [4e].

The MM3 analysis predicts that DOD-41 should be the predominant stereochemistry for the $[U(cat)_4]^{4-}$ complex. This prediction is confirmed by crystal structures for a series of tetrakis catecholate complexes with Hf(IV), Ce(IV), Gd(III), U(IV), and Th(IV), all of which exhibit the DOD-41 form [16,33]. The chelate bite to M–O bond length ratio is similar in these structures, ranging from 1.10 to 1.17, with a value of 1.12 for U(IV). The experimental U–O_A and U–O_B distances are 2.39 and 2.36 Å. For comparison, the MM3 model yields values of 2.38 and 2.37 Å, respectively, qualitatively reproducing the elongation of the U–O_A distances. The experimental bite, 2.65 Å, is well reproduced by the model, 2.66 Å. The X-ray structure also exhibits the twist distortion predicted by the model. However, with a value of $\Phi = 5.5°$, it lies closer to the ideal D_{2d} polyhedron than to the calculated D_2 structure. In this case, there are four $[Na(OH_2)_4]^+$ counter-cations about each $[U(cat)_4]^{4-}$ complex. Each sodium ion sits above a *g* edge and is coordinated to an oxygen atom from each of

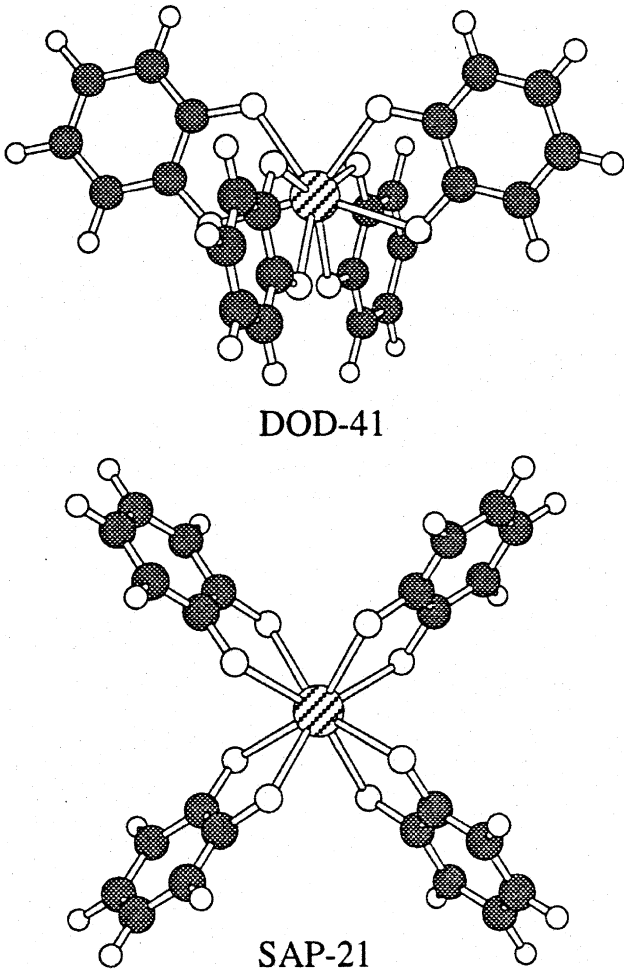

Fig. 8. MM3 geometries for the two stable stereochemistries of $[U(cat)_4]^{4-}$.

the two catecholates sharing that edge (see Fig. 10). Given the flat nature of the potential surface, the variation in Φ could easily result from these environmental effects.

The results reported here are also completely consistent with prior analyses of the stereochemistry for [M(bidentate)$_4$] complexes. Repulsion energy calculations have been used to generate potential surfaces for the [M(bidentate)$_4$] complex at different bite/M–L ratios

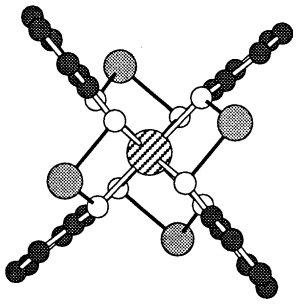

Fig. 10. A view of the $[U(cat)_4]^{4-}$ complex in the crystal structure [16] showing the location of the four sodium cations.

[4c,4d,4e]. When the ratio is 1.0, the D_{2d} DOD (DOD-41, *mmmm*) is the only stable form. As the ratio increases to 1.1, two D_2 DOD minima appear on either side of a D_{2d} DOD saddle point (see Fig. 9). On further increase of the ratio to 1.2, the D_2 DOD forms have become distorted D_2 SAP forms (SAP-19, *ssss*) and additional minima, corresponding to the optical isomers of D_4 SAP (SAP-21, *llll*), have appeared. Our analysis of the $[U(cat)_4]^{4-}$ complex, with a bite/M–L ratio of 1.12, yields results that are intermediate between the reported results for ratios of 1.1 and 1.2.

4. Summary and conclusions

An extended MM3 model was used to identify all low energy configurations for U(IV) complexes with catecholate and aquo ligands. Both stochastic and systematic conformational analyses of $[U(cat)_n(OH_2)_{8-2n}]^{4-2n}$ complexes, $n = 1$–4, establish that 20 of the 67 possible stereochemistries are minima on the MM3 potential surface. In the majority of these structures, the inner coordination sphere most resembles an SAP polyhedron. With one to three catecholates, the most stable structures are those in which the catecholates span the shorter *s* edge of the square face. With four catecholates, the most stable structure is a DOD form in which the catecholates span the *m* edges. Where comparisons are possible, we have shown that the extended MM3 model gives structures and relative energies that are consistent with available

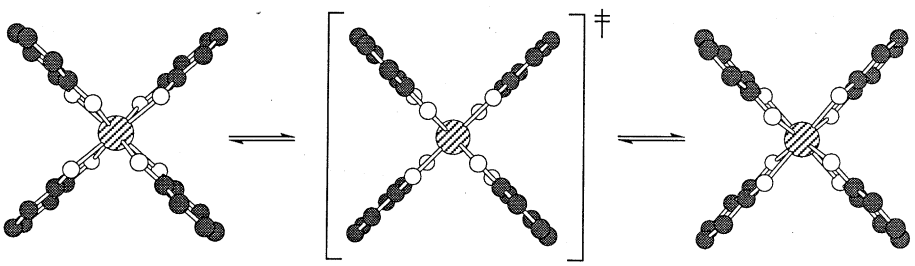

Fig. 9. Two D_2 DOD structures, the lowest energy forms for $[U(cat)_4]^{4-}$, interconvert via a D_{2d} transition state that is only 0.03 kcal/mol higher in energy.

experimental data. In addition, the MM3 model yields results that are consistent with prior repulsion energy calculations. This study has shown that conformational analysis with a simple force field model is an efficient way to identify the optimal arrangements for a set of ligands about a metal ion, thereby providing a basis for rational design of effective host structures. Work is now in progress to use the results from this study as a design basis for U(IV) hosts composed of catecholate binding sites.

5. Supplementary data

Cartesian coordinates for each structure and the MM3 parameter files are available.

Abstract

Oxidative cyclization of 1,2-phenylenediamine, 2-aminophenol, and 2-aminothiophenol with pyridine carboxaldehydes affords the corresponding benzimidazole, benzoxazole, and benzothiazole pyridyl ligands. Addition of these compounds (L_P) to $[PtCl_2(coe)]_2$ (coe = *cis*-cyclooctene) or K_2PtCl_4 gives didentate *cis*-$PtCl_2(L_P)$ or monodentate *cis*-$PtCl_2(L_P)_2$ in moderate to high yields. Crystals of *cis*-dichloro(2-pyrid-2-ylbenzothiazole)platinum(II) (**1c**) as the CH_2Cl_2 solvate were triclinic, space group $P\bar{1}$, $a = 7.8715(6)$ Å, $b = 9.9873(7)$ Å, $c = 10.5883(8)$ Å, $\alpha = 104.149(1)°$, $\beta = 103.754(1)°$, $\gamma = 96.864(1)°$, $Z = 2$. *cis*-dichlorodi(2-pyrid-3-ylbenzoxazole)platinum(II) (**2b**) crystallized with a molecule of THF and H_2O and were monoclinic, space group $C2/c$, $a = 18.698(10)$ Å, $b = 16.325(10)$ Å, $c = 8.853(6)$ Å, $\beta = 90.149(17)°$, $Z = 4$.

1. Introduction

Cisplatin, *cis*-$[PtCl_2(NH_3)_2]$, is one of the most effective chemotherapeutic agents currently used for the treatment of ovarian, bladder, and testicular cancer [1–3]. The drug has to be administered intravenously, however, and has dose-limiting side effects such as severe renal toxicity, neurotoxicity, and emesis, arising, in part, from the low solubility of cisplatin in water. These problems, along with the observation that cancer cells treated with cisplatin acquire resistance to the drug, have provided an impetus for research focused on the development of a more effective platinum drug that can be administered orally and with reduced side effects. Cisplatin acts by making intra- and interstrand cross-links with DNA, resulting in a halt of replication and leading to programmed cell death. Structural analogues of cisplatin, however, react with DNA the same way as the parent drug and therefore cause similar biological effects [1]. Indeed, to be considered for clinical evaluation, a new platinum drug should have activity different from that of cisplatin and eliminate multi-factorial drug resistance. Therefore, it is unlikely that future platinum drug candidates will adhere to the classical structure-activity relationships for cisplatin analogues. Toward this objective, we have begun to prepare platinum complexes containing biologically active carrier groups [4,5]. In this study we report the synthesis and characterization of platinum complexes containing pyridyl benzimidazole derivatives.

2. Experimental

2.1. General

Reagents and solvents were purchased from Aldrich Chemicals and used as received. Platinum salts were obtained from Precious Metals Online Ltd. The melting points were determined using a Mel-Temp apparatus and they are uncorrected. The infrared spectra were obtained using a Mattson Genesis FT-IR spectrometer in nujol and are reported in cm^{-1}. NMR spectra were

doi:10.1016/j.poly.2003.09.020

recorded with a Jeol JNM-GSX270 FT NMR (^{1}H 270 MHz) spectrometer. Chemical shifts (δ) are reported in ppm relative to internal TMS and coupling constants (J) in Hz. Multiplicities are reported as singlet (s), doublet (d), triplet (t), multiplet (m), broad (br), and overlapping (ov). Elemental analyses were performed by Chemisar Laboratories Inc. (Guelph, ON) and Desert Analytics (Tucson, AZ). $[PtCl_2(coe)]_2$ was prepared by an established method [6,7].

2.2. Syntheses

2.2.1. Preparation of cis-dichloro(2-pyrid-2-ylbenzimidazole)platinum(II) (**1a**)

2-Pyrid-2-ylbenzimidazole (55 mg, 0.28 mmol) in 10 ml of CH_2Cl_2 was added dropwise to a stirred solution of $[PtCl_2(coe)]_2$ (105 mg, 0.14 mmol) in 10 ml of CH_2Cl_2. The reaction was allowed to proceed for 3 h, at which point a yellow precipitate formed and was collected by suction filtration. Yield: 59 mg, 46%. Mp 238 °C (decomposition). *Anal.* Calc. for $C_{12}H_9N_3Cl_2Pt$: C, 31.24; H, 1.97; N, 9.11. Found: C, 31.57; H, 1.82; N, 8.98%. ^{1}H NMR (dmso-d_6): δ 9.47 (d, $J = 5$ Hz, 1H), 8.78 (d, $J = 8$ Hz, 1H), 8.44 (m, 1H), 8.33 (m, 1H), 7.79 (d, $J = 8$ Hz, 2H), 7.52–7.40 (ov m, 2H). IR (nujol): 3165, 3110, 2922, 2856, 1614, 1462, 1377, 1308, 1265, 1236, 1151, 1063, 823, 750, 739, 654.

2.2.2. Preparation of cis-dichloro(2-pyrid-2-ylbenzoxazole)platinum(II) (**1b**)

2-Pyrid-2-ylbenzoxazole (55 mg, 0.28 mmol) in 10 ml of CH_2Cl_2 was added dropwise to a stirred solution of $[PtCl_2(coe)]_2$ (105 mg, 0.14 mmol) in 10 ml of CH_2Cl_2. Within 1 h a red precipitate had formed that was collected by suction filtration. Yield: 101 mg, 78%. Mp 210 °C (decomposition). *Anal.* Calc. for $C_{12}H_8N_2Cl_2OPt \cdot 0.5CH_2Cl_2$: C, 29.74; H, 1.80; N, 5.55. Found: C, 29.67; H, 1.80; N, 6.26%. ^{1}H NMR (dmso-d_6): δ 9.46 (d, $J = 5$ Hz, 1H), 8.69 (d, $J = 8$ Hz, 1H), 8.48 (t, $J = 8$ Hz, 1H), 8.36 (d, $J = 8$ Hz, 1H), 8.10 (d, $J = 8$ Hz, 1H), 7.97 (t, $J = 5$ Hz, 1H), 7.72–7.64 (ov m, 2H). IR (nujol): 2914, 2858, 1549, 1462, 1377, 1306, 1273, 1147, 972, 897, 816, 781, 746, 681, 609.

2.2.3. Preparation of cis-dichloro(2-pyrid-2-ylbenzothiazole)platinum(II) (**1c**)

2-Pyrid-2-ylbenzothiazole (30 mg, 0.14 mmol) in 10 ml of CH_2Cl_2 was added dropwise to a stirred solution of $[PtCl_2(coe)]_2$ (50 mg, 0.07 mmol) in 10 ml of CH_2Cl_2. After 1 h, the mixture was stored at 5 °C overnight and the resultant orange precipitate was collected by suction filtration and dried under vacuum. Yield: 49 mg, 73%. Mp 244 °C (decomposition). *Anal.* Calc. for $C_{12}H_8N_2Cl_2PtS \cdot CH_2Cl_2$: C, 27.72; H, 1.79; N, 4.97. Found: C, 28.08; H, 1.48; N, 5.14%. ^{1}H NMR (dmso-d_6): δ 9.68 (d, $J = 8$ Hz, 1H), 9.52 (d, $J = 5$ Hz, 1H), 8.55 (d, $J = 8$ Hz, 1H), 8.45–8.41 (ov m, 2H), 7.89 (t, $J = 8$ Hz, 1H), 7.77–7.68 (ov m, 2H). IR (nujol): 2922, 2868, 1714, 1606, 1462, 1377, 1309, 1261, 1157, 1076, 970, 760, 723.

2.2.4. Preparation of cis-dichlorodi(2-pyrid-3-ylbenzimidazole)platinum(II) (**2a**)

2-Pyrid-3-ylbenzimidazole (102 mg, 0.52 mmol) in 10 ml of ethanol was added dropwise to a stirred solution of potassium tetrachloroplatinate (II) (109 mg, 0.26 mmol) in 10 ml of water. The mixture was heated gently at 40 °C for 1 h. The yellow precipitate was collected and washed with wet ethanol (2×3 ml). Yield: 122 mg, 71%. Mp 240 °C (decomposition). *Anal.* Calc. for $C_{24}H_{18}N_6Cl_2Pt \cdot 2H_2O$: C, 41.62; H, 3.20; N, 12.13. Found: C, 41.77; H, 2.61; N, 11.84%. ^{1}H NMR (dmso-d_6): δ 9.68 (s, 2H), 8.90 (m, 2H), 8.68 (m, 2H), 7.68 (m, 6H), 7.29 (m, 4H). IR (nujol): 3150, 2916, 2858, 2725, 2671, 1712, 1608, 1462, 1377, 1315, 1281, 1228, 1153, 1072, 970, 820, 739, 723, 692.

2.2.5. Preparation of cis-dichlorodi(2-pyrid-3-ylbenzoxazole)platinum(II) (**2b**)

2-Pyrid-3-ylbenzoxazole (102 mg, 0.52 mmol) in 10 ml of ethanol was added dropwise to a stirred 10 ml water solution of potassium tetrachloroplatinate (II) (109 mg, 0.26 mmol). After 1 h of heating gently at 40 °C, a beige precipitate was collected by suction filtration and washed with wet ethanol (2×3 ml). Yield: 124 mg, 72%. Mp 170 °C (decomposition). *Anal.* Calc. for $C_{24}H_{16}N_4Cl_2O_2Pt$: C, 43.78; H, 2.45; N, 8.51. Found: C, 43.67; H, 2.26; N, 8.32%. ^{1}H NMR (dmso-d_6): δ 9.70 (s, 2H), 9.02 (d, $J = 5$ Hz, 2H), 8.72 (d, $J = 8$ Hz, 2H), 7.89 (t, $J = 8$ Hz, 4H), 7.69 (t, $J = 8$ Hz, 2H), 7.55–7.45 (ov m, 4H). 2.2.6. Preparation of cis-dichlorodi(2-pyrid-3-ylbenzothiazole)platinum(II) (**2c**)

Potassium tetrachloroplatinate (II) (55 mg, 0.13 mmol) was dissolved in 10 ml of water and a 10 ml ethanol solution of 2-pyrid-3-ylbenzothiazole (59 mg, 0.28 mmol) was added dropwise. The reaction was stirred and heated gently at 40 °C for 1 h. The precipitate was collected by suction filtration and washed with wet ethanol (2×3 ml) to afford a yellow solid. Yield: 83 mg, 91%. Mp 290 °C (decomposition). *Anal.* Calc. for $C_{24}H_{16}N_4Cl_2PtS_2$: C, 41.74; H, 2.34; N, 8.11. Found: C, 41.68; H, 2.24; N, 7.75%. ^{1}H NMR (dmso-d_6): δ 9.66 (s, 2H), 8.98 (m, 2H), 8.66 (m, 2H), 8.27–8.19 (ov m, 4H), 7.67–7.45 (ov m, 6H). IR (nujol): 2918, 2856, 1714, 1614, 1462, 1377, 1311, 1167, 976, 835, 764, 723, 557.

2.3. X-ray data

Crystals of **1c** and **2b** were grown from saturated CH_2Cl_2 and wet THF solutions, respectively, at 5 °C. Single crystals were coated with Paratone-N oil, mounted using a glass fibre and frozen in the cold stream of the goniometer. A hemisphere of data were collected on a Bruker AXS P4/SMART 1000 diffractometer using ω and ϕ scans with a scan width of 0.3° and 30 s (**1c**) and 40 s (**2b**) exposure times. The detector distance was 6 cm. The data were reduced [8] and corrected for absorption [9]. The structure was solved by direct methods and refined by full-matrix least squares on F^2 [10]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located in Fourier difference maps and refined isotropically.

3. Results and discussion

3.1. Ligands

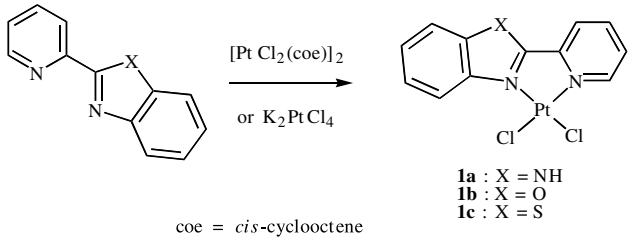
2-Arylbenzimidazoles, -oxazoles, and -thiazoles are a remarkably important class of biologically active compounds [11–16]. For instance, a recent study has shown that 2-(4-aminophenyl)-benzothiazole displays unusual anticancer activity originally discovered in a regimen designed for screening tyrosine kinase inhibitors [11]. More potent analogues have since been prepared and their biological profiles are unlike that of any known anticancer agent [12]. Analysis of the structure activity relationships identified the benzothiazole unit as being essential for potent activity. Likewise, potent fungicides derived from benzimidazole have recently been reported [13].

Our interest in generating platinum complexes with biologically active carrier ligands therefore prompted us to make complexes containing arylbenzimidazole, and related benzoxazole and benzothiazole groups. In this study we have focused on making monodentate and bidentate pyridine derivatives which are readily prepared by the oxidative cyclization of the appropriate Schiff bases [17–19].

3.2. Platinum complexes

Addition of 2-thiophen-2-ylbenzimidazole derivatives (L_T) to organic soluble $[PtCl_2(coe)]_2$ (coe = *cis*-cyclooctene, [6,7]) resulted in complexes of the type *trans*-$PtCl_2(coe)L_T$, where the benzimidazole ligand coordinates to the metal in an η^1-fashion *via* the imine moiety. No interaction of the thiophene unit with the metal centre was observed in these cases [20]. However, addition of analogous 2-pyridin-2-ylbenzimidazole derivatives (L_P) to $[PtCl_2(coe)]_2$ gave didentate complexes of the type *cis*-$PtCl_2(L_P)$ (**1a–c**) in moderate yields (46–78%), where coordination occurs, as expected, through the pyridine and imine nitrogens (Scheme 1) [19].

Complexes **1a–c** have been characterized using a number of physical methods, including ^{1}H NMR spectroscopy. A significant downfield shift is observed for the sp^2 hydrogen alpha to the nitrogen of the pyridine ring, upon coordination of the ligand to the metal. For



Scheme 1.

instance, the doublet at δ 8.73 ppm for the 2-pyrid-2-ylbenzimidazole ligand in dmso-d_6 shifts to 9.47 ppm in complex **1a**. Similar trends are also observed in **1b** and **1c**. The low solubility of these complexes in common organic solvents precluded the acquisition of ^{13}C NMR data.

Binding of benzimidazole derivatives to a number of other metals has been reported previously [19,21–25], where coordination of the ligand occurs predominantly through the imine nitrogen. For complex **1a** the FT-IR spectrum shows a distinct N–H stretch at 3165 cm^{-1} compared to that for the free ligand, which appears as a broad band at 3056 cm^{-1}. The low frequency and broadness of the absorption band for the free ligand has been attributed to a considerable amount of hydrogen bonding between the NH group and the pyridine nitrogen of a neighbouring molecule in the solid state [21]. Related palladium complexes containing pyridine imidazolines [26] have been used as catalysts in the copolymerization of CO/4-*tert*-butylstyrene and lanthanide complexes with substituted bis(benzimidazolyl)pyridines have been investigated for their luminescent properties [27].

Although we were unable to obtain single crystals of **1a**, we have characterized complex **1c** by an X-ray diffraction study to confirm the N,N-chelation mode (Fig. 1). Crystallographic data are given in Table 1 and

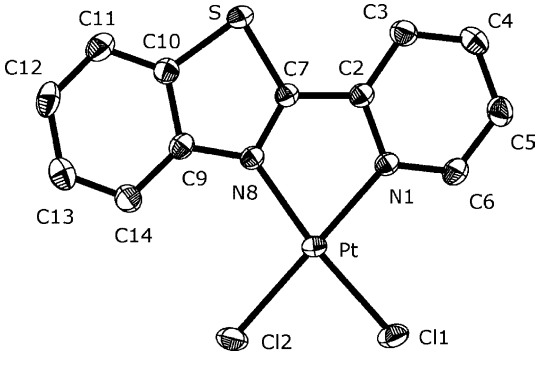


Fig. 1. The structure of **1c** showing the atomic labeling scheme and 30% probability displacement ellipsoids with hydrogen atoms omitted for clarity.

wR_2[b] (all data)	0.0435	0.1080

[a] $R_1 = \sum||F_o| - |F_c||/\sum|F_o|$.
[b] $wR_2 = \left(\sum[w(F_o^2 - F_c^2)^2]/\sum[wF_o^4]\right)^{1/2}$, where $w = 1/[\sigma^2(F_o^2) + (0.0219 * P)^2 + (0.4739 * P)]$ (**1c**) and $w = 1/[\sigma^2(F_o^2) + (0.0746 * P)^2]$ (**2b**), where $P = (\max(F_o^2, 0) + 2 * F_c^2)/3$.

selected bond distances and angles shown in Table 2. As expected, coordination of the ligand occurs through the two nitrogen atoms. The platinum pyridyl benzothiazole fragment is planar with the nitrogen–platinum bonds of 2.019(2) (pyridine) and 2.041(2) (imine) being similar to those reported in other iminopyridine platinum systems [28,29]. Slightly longer Pt–N bond distances are observed in related five coordinate Pt(II) [30,31] and Pt(IV) complexes [32]. The C(7)–N(8) distance is 1.309(4) and in the range of accepted carbon–nitrogen double bonds found in benzothiazoles [19,33,34].

We also decided to prepare complexes of the type *cis*-$PtCl_2(L_P)_2$ with 2-pyridin-3-yl- and 2-pyridin-4-ylbenzimidazole derivatives (Scheme 2). Reactions were carried out with K_2PtCl_4 to ensure stereospecific formation of the *cis* isomer [35]. Once again, a downfield shift is observed in the ^1H NMR spectra for the sp^2 hydrogens alpha to the nitrogen of the pyridine ring upon coordination of the pyridine to the metal. For example, a singlet is observed at δ 9.68 ppm for complex **2a** compared to that of free 2-pyrid-3-ylbenzimidazole (9.34

ppm). Similar trends were observed for the other compounds (**2b,c** and **3a–c**). The N–H stretch was observed in the FT-IR spectrum at 3150 cm^{-1} for both complexes **2a** and **3a**.

An X-ray diffraction study on **2b** was carried out to confirm the formation of a *cis* geometry. The molecular structure is shown in Fig. 2, where the ligands are bound to the metal via the pyridine nitrogen with a typical distance of 2.033(5). Bond distances and angles within the benzoxazole ring are consistent with those reported previously [36,37]. The two planar benzoxazole groups are 77.3° to one another, presumably to relieve steric crowding within these bulky molecules.

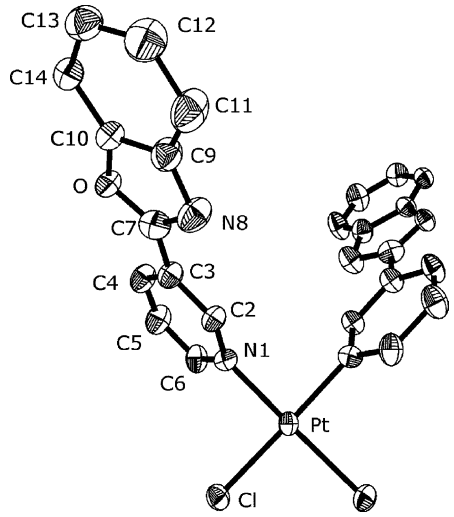

Fig. 2. The structure of **2b** showing the atomic labeling scheme and 30% probability displacement ellipsoids with hydrogen atoms omitted for clarity.

4. Conclusions

We have prepared and characterized *cis* dichloroplatinum complexes containing biologically relevant 2-pyridylbenzimidazole, oxazole, and thiazole derivatives. Chelating didentate complexes are formed with 2-pyrid-2-ylbenzimidazole compounds where coordination to the metal occurs via the pyridine and ring imine nitrogens. Future work in this area will investigate the cytotoxicities of these complexes against cisplatin-sensitive and cisplatin-resistant cells, the results of which will be published in due course.

Abstract

A new dithiocarbazate ligand, *S*-2-picolyldithiocarbazate (S2PDTC) was synthesized using 2-picolylchloride hydrochloride. Tridentate Schiff bases were prepared by condensation of *S*-2-picolyldithiocarbazate (S2PDTC) with pyridine-2-carboxaldehyde (NNS′), 2-acetylpyrrole (NNS″) and 2-acetylthiophene (NSS), while a bidentate Schiff base (NS) was prepared by condensing the S2PDTC with 2-acetylfuran. Complexes of S2PDTC and its Schiff bases with Ni(II) salts were synthesized and characterized by elemental analyses and various physico-chemical techniques. A square-planar structure has been proposed for the diamagnetic $[Ni(S2PDTC)_2]$ and $[Ni(NNS'')\cdot Cl]$ complexes while $[Ni(NS)\cdot Cl]$ complex was dimeric. Complexes of $[Ni(NNS')_2]$ and $[Ni(NSS)_2]$ were paramagnetic with octahedral stereochemistry. S2PDTC showed activity against bacteria and fungi (inhibitory zones above 15 mm). The NS and NSS Schiff bases showed activity toward a number of the bacteria assayed, while the NS and NSS Schiff bases, and the $[Ni(NNS'')\cdot Cl]$ and $[Ni(NS)\cdot Cl]$ complexes were found to be active only against *C. lypolytica* (2075). S2PDTC proved moderately active against HT-29 and weakly active toward CEM-SS with CD_{50} values of 9.5 and 24.0 μg cm^{-3}, respectively, while among its Schiff bases reported herein, only the NNS′ Schiff base showed strong activity toward CEM-SS (Human cell T-lymphoblastic leukemia) and HT-29 (Human colon adenocarcinoma cells) with CD_{50} values of 2.3 μg cm^{-3}. All of the Ni(II) complexes were inactive against CEM-SS cancer cells.

Keywords: *S*-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride); Bidentate NS Schiff base; Tridentate NNS and NSS Schiff bases; Ni(II) complexes; Dithiocarbazate derivative

1. Introduction

Dithiocarbazate, NH_2NHCS_2, and its substituted derivatives have been synthesized and investigated over the past few decades [1–28]. Interest remains high in these compounds and the Schiff bases derived from them through condensation with various aldehydes and ketones because of the intriguing observation that they sometimes show different biological properties, although they may differ only slightly in their molecular structures [1–11,15–22]. Transition metal complexes of these ligands are widely studied because of their potential for therapeutic use [2–4,6–20]. They also find applications in health and skin care products and in paint manufacturing [29]. Publications to date have mainly focused on

S-benzyldithiocarbazate (SBDTC) and *S*-methyldithiocarbazate (SMDTC). Although *S*-benzoyldithiocarbazate (SBODTC) has been synthesized [27], little work has been reported using this ligand. Herein we introduce a new dithiocarbazate derivative, S2PDTC, containing a picolyl group, some of its Schiff bases and their nickel(II) complexes. Isomeric dithiocarbazate derivatives prepared from the 3- and 4-pyridylmethyl halides have also been successfully isolated in our laboratory and will be discussed in later communications. It is anticipated that these compounds will open up many interesting avenues for further research.

2. Experimental

All chemicals were of reagent grade and unless otherwise mentioned, were used as received. The solvents were purified using conventional methods.

2.1. Physical measurements

Carbon, hydrogen, nitrogen and sulfur analyses were carried out using a LECO CHNS-932 instrument. The IR spectra were recorded as KBr pellets, in the 4000–400 cm^{-1} region, on a Perkin–Elmer 1750X FTIR spectrometer. Metal determinations were carried out using a Perkin–Elmer Plasma 1000 Emission Spectrometer. ^1H NMR spectra were recorded on a Jeol JNM 400 MHz NMR spectrometer. The molar conductance of 10^{-3} M solutions of the metal complexes in DMSO were measured at 30 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinised electrode. The UV–Vis spectra were run on a Shimadzu UV-2501 PC spectrophotometer (900–200 nm). Melting points (m.p.) were determined using an Electrothermal digital melting point apparatus. Magnetic susceptibilities were carried out using a Sherwood Auto MSB balance at 298 K. All susceptibilities were corrected for the diamagnetic contribution using Pascal's constants.

2.2. Preparation of S-2-picolyldithiocarbazate (S2PDTC)

The previously reported methods for preparation of substituted dithiocarbazate [12,13] were modified by reaction with 2-picolylchloride hydrochloride.

Potassium hydroxide (11.4 g, 0.2 mol) was dissolved completely in 90% ethanol (70 ml) and the mixture was cooled in ice. To the cold solution, hydrazine hydrate (10 g, 0.2 mol) was added slowly with stirring. Carbon disulfide (15.2 g, 0.2 mol) in ethanol (25 ml) was then added dropwise with vigorous stirring for about 1 h. The temperature of the reaction mixture was kept below 263 K during the addition. During this time two layers formed. The resulting yellow oil (lower layer) was separated using a separatory funnel, dissolved in 40% ethanol (40 ml) and cooled in ice. 2-Picolylchloride hydrochloride (32.8 g, 0.2 mol) was completely dissolved in 100 ml of 80% ethanol and added slowly to the above solution with vigorous mechanical stirring. The resulting light green product was separated by filtration, washed with water and dried. The crude product was recrystallized from absolute ethanol. Yield, 75.1%; melting point, 124 °C.

2.3. General method for preparation of the Schiff bases

The previously reported method for preparation of Schiff bases [12,13] was used to prepare S2PDTC derivatives with pyridine-2-carboxaldehyde, 2-acetylpyrrole, 2-acetylfuran and 2-acetylthiophene.

S2PDTC (4.69 g, 0.02 mol) dissolved in hot absolute ethanol (30–40 ml) was added to the solution of an equimolar amount of carbonyl compound in hot absolute ethanol (20 ml). The mixture was heated for 10 min and then cooled to 0 °C in an ice-bath. The products were filtered, washed with absolute ethanol, recrystallized from absolute ethanol and then dried over silica gel. The yields and melting points are given for each of the Schiff bases in Table 1.

2.4. General method for preparation of metal complexes

The previously reported methods for preparation of metal complexes [12,13] were employed using nickel(II) acetate tetrahydrate or nickel (II) chloride hexahydrate with the prepared ligands. For each preparation 0.1 mol of metal salt was dissolved in absolute ethanol (40 ml) and to the solution was added Schiff base (0.2 mol) in 40 ml of absolute ethanol. The mixture was heated while being stirred. Each precipitate was filtered, washed with ice-cold ethanol and dried over silica gel. The yields and melting points for these metal complexes are given in Table 1.

2.5. X-ray structure determination

The selected crystal of *S*-2-picolyl-β-*N*-(2-acetylpyrrole)dithiocarbazate was mounted on a Bruker SMART 1000 CCD diffractometer. Reflection data were measured at 25 °C using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation with a detector distance of 4 cm and a swing angle of −35 °C. The data collected were reduced using the program SAINT [30] and an empirical absorption correction was carried out using SADABS [31]. The structure was solved using direct methods and refined using the full-matrix least-square method on F^2_{obs} using the SHELTXL [32] software package. All non-H atoms were anisotropically refined. The hydrogen atom at N4 was located in the difference Fourier map and was refined isotropically, whereas the other H atoms were geographically fixed and treated as riding atoms with C–

Table 1
Analytical data for the ligands, Schiff bases and their complexes

Compound	Colour	Melting point (°C)	Found (calculated)					Yield
			C	H	N	S	M	(%)

Note. NNS′ = S2PDTC + pyridine-2-carboxaldehyde; NNS″ = S2PDTC + 2-acetylpyrrole; NS = S2PDTC + 2-acetylfuran; NSS = S2PDTC + 2-acetylthiophene.

H distances = 0.93–0.97 Å, and N–H = 0.86 Å while $U_{iso}(H) = 1.2U_{eq}(C)$ or $1.5U_{eq}(C)$ and $1.2U_{eq}(N)$. The molecular graphics were created using SHELTXL. Crystal data and details on data collection and refinement are summarized in Table 4.

2.6. Bioactivity

2.6.1. Culture of cells and cytotoxic assay

Two types of cell line were used, CEM-SS (Human T-lymphoblastic leukemia) cells and HT-29 (Human colon andenocarcinoma) cells. The CEM-SS cell line was obtained from the National Cancer Institute, USA while the HT-29 cell line was obtained from ATCC (American Type Culture Collection). The cells were cultured in RPMI-1640 (Sigma) medium supplemented with 10% fetal calf serum. Cytotoxicity was determined using the MTT (3-[4,5-dimethylthiozol-2-yl]-2,5-diphenyltetrazolium bromide) assay following Mosmann's report [33]. Cytotoxicity was expressed as CD_{50}, i.e., the concentration that reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin and tamoxifen were used as cytotoxic standards.

2.6.2. Qualitative antimicrobial assay

Eight pathogenic microbials were used to test the biological potential of the compounds: (i) Methicillin resistant *staphylococcus* (MRSA), (ii) *Bacillus subtilis* wild type (B29), (iii) *B. subtilis* mutant defective DNA repair (B28), (iv) *Pseudomonas aeruginosa* (60 690), (v) *Candida albicans* (C.A.), (vi) *Aspergillus ochraceous* (398), (vii) *Saccharomyces cerevisiae* (20341) and (viii) *Candida lypolytica* (2075). The sources of microbes and culture maintenance were as previously described [33]. The antimicrobial activity of the extracts was qualitatively determined by a modified disc diffusion method as previously reported [34]. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs. Commercially available streptomycin was used for antibacterial control while nystatin was used as antifungal control.

2.6.3. Quantitative antimicrobial assay

Compounds that showed positive antimicrobial activity with the disc diffusion assay were subjected to the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [35]. The lowest concentration which completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg cm^{-3}). Streptomycin and nystatin (Sigma) were used as positive controls for the bacteria and fungi, respectively.

3. Results and discussion

As noted above, many studies have been reported on Schiff bases of *S*-methyl- and *S*-benzyl dithiocarbazate and their metal complexes. The successful preparation of a series of *S*-picolyldithiocarbazate derivatives may help in the understanding of the bioactivity of this class

of compounds. We have recently reported the structure of *S*-2-picolyldithiocarbazate [36]. Unlike other dithiocarbazate compounds such as *S*-methyldithiocarbazate [37] and *S*-benzyldithiocarbazate [38], it exists in ionic form with a zwitterionic $^{-}SCNNH_3^{+}$ group and a protonated N on the picolyl ring with Cl^{-} as counter ion [36]. Retention of the protonated character of the picolyl ring has been observed previously [39] and its presence has not seemed to interfere in reaction [40]. It is not surprising that similar behavior is observed in these reactions. Condensation of S2PDTC with pyridine-2-carboxaldehyde, 2-acetylpyrrole, 2-acetylfuran and 2-acetylthiophene produced the expected Schiff bases NNS′ (**2**), NNS″ (**3**), NS (**4**) and NSS (**5**) in high yields. The melting points, elemental analyses and percentage yields are given in Table 1. In the solid phase, all of the Schiff bases exist only in thione (Fig. 1a) tautomeric form as evidenced by their IR spectra (Table 2). However, in solution, they may be expected to exist as an equilibrium mixture of both the thione (Fig. 1a) and thiolo (Fig. 1b) tautomeric forms [34]. None of the solids exhibit ν(S–H) at ca. 2700 cm^{-1}, but strong bands, which can be assigned to the ν(N–H) of the free ligands, are observed at 3241 cm^{-1} and 3064–3093 cm^{-1} in the IR spectra of **1** and its Schiff bases. These bands disappear in the IR spectra of the metal complexes suggesting that the proton attached to the α-nitrogen atom is lost upon complexation. In solution then, tautomerization occurred and through the loss of thiolo proton,

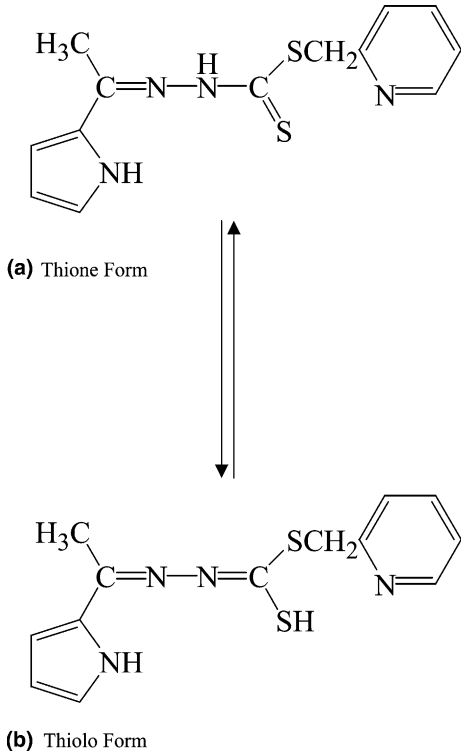

Fig. 1. Tautomeric forms of NNS″ Schiff base.

Schiff bases **2**, **3** and **5** behaved as uninegatively charged tridentate ligands while **1** and **4** behaved as uninegatively charged bidentate ligands. Strong bands at 1041 cm^{-1} and between 1032 and 1054 cm^{-1} for **1** and the Schiff bases, respectively, are assigned to the ν(C=S) mode. This band also disappears in the metal complexes supporting the contention that enethiolization, and consequent deprotonation, gives the thiolate in situ. The **2**, **3**, **4**, and **5** Schiff bases display strong bands at 1470, 1542, 1516 and 1532 cm^{-1}, respectively, which can assigned as the C=N stretching frequency of the aliphatic free ligands [41]. These bands are shifted to lower frequencies in the IR spectra of their complexes. This lowering of the ν(C=N) on complexation may be attributed to a lowering the C=N bond order as a result of the M–N bond formation. The lowering of the frequency of the ν(N–N) band in all the complexes is additional evidence for involvement of azomethine nitrogen in the coordination. The splitting of the ν(CSS) band of the ligands at between 994 and 1010 cm^{-1} in the spectra of the Ni(II) complexes evidences unidentate coordination of aliphatic sulfur [42]. In complex **9**, there was no significant displacement of the frequency of the ring breathing and ν(C–O–C) vibration at 1204 cm^{-1} [43] and there was also no absorption observed at 440–460 cm^{-1} that can be assigned to metal–oxygen bond stretching. It is thus apparent that the furan ring is not coordinated to the metal. In contrast there was significant displacement of the frequency of the pyridine, pyrrole and thiophene ring absorptions in complexes **7**, **9** and **10**, respectively, indicating that the pyridyl-nitrogen, pyrrole-nitrogen and thiophene-sulfur were coordinated to their central metal ion.

The ^{1}H NMR spectra of **1**, **2**, **3**, **4** and **5** in DMSO do show a peak at ca. δ 4.00 ppm attributable to the S–H proton [44], confirming that the thiolo tautomer is present in solution. A signal at ca. δ 8.0–8.5 ppm is attributed to the N–H group on the aliphatic nitrogen atom, and resonance peaks associated with the aromatic groups are observed in the range δ 6.5–7.3 ppm.

The brown complex **6**, resulting from reaction of nickel(II) acetate tetrahydrate with S2PDTC is a non-electrolyte in DMSO (Table 3). Complexes **7** and **10** are also non-electrolytes in DMSO. The non-electrolytic nature of the complexes indicates that these ligands are coordinated to the metal ions as uninegatively charged species. However, complexes **8** and **9** exhibit molar conductances corresponding to 1:1 electrolytes in DMSO [34]. Presumably these complexes undergo solvation releasing Cl^{-} ions as has been previously reported under similar conditions [13].

The magnetic susceptibility data are shown in Table 3. The brown complex **6** was found to be a diamagnetic species consistent with a square-planar stereochemistry. This data provides strong evidence of coordination through the thiolo sulphur, since thiolo

[a] log ε (cm^{-1} mol^{-1} L) are given in parentheses.

but not thioethers, cause spin pairing in nickel(II) complexes [2]. The electronic spectra of the complexes recorded in DMSO are summarized in Table 3. An absorption band at approximately 330 nm for complex **6** is attributed to the $n \rightarrow \pi^*$ intra ligand transitions while the band at approximately 400 nm can be assigned to $S \rightarrow Ni(II)$ charge transfer. The appearance of this LMCT band in Ni(II) complexes is also strong evidence that the Ni(II) ion is coordinated to sulfur through the thiolo sulfur atom. The complexes **7** and **10** were dark brown and were found to be paramagnetic at room temperature with magnetic moments of ca. 2.8 and 3.0 BM, respectively, indicating that they are high-spin, six-coordinate complexes. The Schiff bases in complexes **7** and **10** are therefore proposed to be uninegatively charged tridentate ligands. Because the NNS and NSS donors are characteristically planar [45], a meridional disposition of the ligand donor atoms in a distorted octahedral environment is most likely. In all cases, there is no evidence that the picolyl nitrogen is coordinated to the metal ion. Unfortunately, we have not yet been able to grow crystals of the metal complexes suitable for single crystal X-ray analysis.

3.1. X-ray crystal structure

The ORTEP diagram of the *S*-2-picolyl-β-*N*-(2-acetylpyrrole)dithiocarbazate molecule with atomic numbering scheme is shown in Fig. 2. The methyl-pyridine, N1/C4/C3/C2/C1/C5/C6, and (pyrrole-2-yl)ethylamide, N4/C12/C11/C10/C9/C8/C13/N3, groups are at *trans* and *cis* positions with respect to the terminal thione S2 atom about the C7–S1 and C7–N2 bonds, respectively. The bond lengths and angles are in normal ranges typical of dithiocarbazate compounds [37,38,46]. However, the slight shortening of N2–N3 (1.382 (5) Å) and N2–C7 (1.308 (6) Å) bond lengths compared to N1–N2 and N2–C5 of 1.372 (4) and 1.360 (5) Å, respectively, in *S*-methyl-β-*N*-(methylacetyl)methylenedithiocarbazate [46] is due to the conjugation effect in the N4/C12/C11/C10/C9/C8/N3 fragment. The discrete molecule is not planar but with inclination between the methyl-pyridine, N1/C4/C3/C2/C1/C5/C6, group and S2/C7/N2/N3/C8/C9 fragments of 73.43(19)°. Methyl-pyridine, N1/C4/C3/

C2/C1/C5/C6, methyl-pyrrole, N4/C12/C11/C10/C9/C8 and S2/C7/N2/N3/C8/C9 fragments are planar (Table 5).

3.2. Biological activities

3.2.1. Cytotoxic activities

Compounds **3**–**10** were found to be inactive against all cell lines tested (Table 4). Compound **1** was shown to be moderately active against HT-29 with CD_{50} value of 9.5 μg cm^{-3}. This is in contrast to *S*-benzyldithiocarbazate (SBDTC) [28] which was inactive. However, compound **1** showed very weak activity against CEM-SS (CD_{50} value of 24.0 μg cm^{-3}), whereas SBDTC has been shown to be very active with CD_{50} value of 2.6 μg cm^{-3} [28]. Compound **2** was found to be very active against T-lymphoblastic leukemic cells (CEM-SS) and colon adenocarcinoma cells (HT-29) with CD_{50} value of 2.3 μg cm^{-3} for both. That compound **2** is very active towards this cancer cells line compared to compound **1**, is perhaps, due to the presence of two pyridyl nitrogen groups. Complexation with Ni(II) decreases the cytotoxicity (Table 6). The differing activities are currently being investigated in terms of the mechanism of action of these compounds at the cellular level.

3.2.2. Antimicrobial activities

Compounds **2**, **3**, **6**, **7** and **10** were found to be inactive against all bacteria and fungi tested. Whereas the

[a] MIC (μg ml^{-3}) = minimum inhibitory concentration, i.e., the lowest concentration to completely inhibit microbial growth.

parent compound **1** showed activity against all the bacteria and fungi assayed (inhibitory zones above 15 mm). Qualitative antimicrobial analyses showed that this compound **1** was more active than SBDTC towards all the bacteria and fungi assayed [28] except for *C. lypolytica* (2075) (Table 7). Compounds **4** and **5** showed activity toward some of the bacteria. Meanwhile, compounds **4**, **5**, **8** and **9** were found to be active against the fungus, *C. lypolytica* (2075). Against bacteria, the MIC values (= 1562.5–12 500 μg cm^{-3}) for compounds **1**, **4**, **5**, **8** and **9** indicate that they are less active than the standard drug, streptomycin, However, the MIC values for compounds **1**, **4** and **5** against fungi were comparable to the drug standard, nystatin (Table 8).

4. Conclusion

The compounds **1** and **4** are uninegatively charged bidentate ligands, whereas **2**, **3** and **5** are uninegatively charged tridentate ligands like their *S*-benzyl analogs [2]. IR spectral analyses have shown that the Schiff bases are in the thione form when in solid state [2]. However, in solution, there occurs an equilibrium between the thione and thiolo isomer forms. The magnetic susceptibility measurements indicate that complexes **7** and **10** are high spin octahedral complexes [2], while complexes **6** and **8** are square-planar in structure. Complex **9** is proposed to be dimeric. The cytotoxic activities have been shown to follow the order S2PDTC < SMDTC < SBDTC for CEM-SS. However, SBDTC was inactive against HT-29 while the SMDTC was shown to be more active than S2PDTC (Table 6). The lower activities of S2PDTC are possibly due to the presence of pyridyl nitrogen group but the actual mechanism of interaction at the cellular level requires further investigation. It was found that SMDTC showed higher activity than SBDTC and S2PDTC for all fungi tested. Comparison studies with *S*-3-picolyldithiocarbazate (S3PDTC) and *S*-4-picolyldithiocarbazate (S4PDTC) are in progress.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 186636. Received 22 July 2003; accepted 29 September 2003

Abstract

Four lanthanide(III) complexes $\{[Ce(L^1)_{1.5}(NO_3)_3](CH_2Cl_2)_{0.25}(H_2O)_{0.25}\}_\infty$ **1**, $[Ln(L^2)_{1.5}(NO_3)_3]_\infty$ (Ln = Ce, **2**; Gd, **3**), and $[Yb(L^2)(CH_3OH)(NO_3)_3]_\infty$ **4** have been synthesized using 1,2-bis(4-pyridyl)ethane-N,N'-dioxide (L^1) and *trans*-1,2-bis(4-pyridyl)ethene-N,N'-dioxide (L^2). Bridged by the flexible L^1 ligand to form binuclear Ce_2O_2 units, compound **1** shows a three-dimensional network with triangular and distorted square channels. The isomorphous pair **2** and **3** composed of rigid L^2 linkers and Ln_2O_2 units (Ln = Ce, Gd) exhibit a layered structure of (4,4) topology. In compound **4**, the mononuclear Yb(III) ions are bridged by L^2 ligands to generate a sinuous chain.

Keywords: Lanthanide nitrate; N,N'-dioxide; Self-assembly; Coordination polymer

1. Introduction

The use of transition metal centers and multidentate ligands for directing the assembly of complex structures has developed into one of the most widely used strategies for organizing molecular building blocks into supramolecular arrays in the last decade [1]. An important goal in constructing coordination polymers is to design functional molecular materials, which have potential application as catalytic, conductive, luminescent, magnetic, spin-transition, non-linear optical, and/or nanoporous materials [1–3]. In this context, the most utilized linear spacer for linking the transition metal centers is 4,4′-bipyridine [4]. More recently, other building blocks containing nitrogen donors such as pyrazine [5], 1,2-bis(4-pyridyl)-ethane [6], *trans*-1,2-bis(4-pyridyl)-ethene [7], 1,4-bis(4-pyridyl)benzene [8] and 2,4,6-tri(4-pyridyl)-1,3,5-triazine [9] have been employed in self-assembly reactions with various labile metal moieties. However, few coordination polymers based on bifunctional neutral ligands containing oxygen donors have been explored until recently [10]. 4,4′-Bipyridine-N,N'-dioxide was first employed as a bridging ligand in the construction of coordination networks [11], and a widely applicable strategy using poly(*N*-oxide) ligands as spacer linkers for assembling networks based on f-block metals has been developed [12]. More recently, 1,2-bis(4-pyridyl) ethane-N,N'-dioxide (L^1) and *trans*-1,2-bis(4-pyridyl)ethene-N,N'-dioxide (L^2) have been synthesized in our laboratory (Scheme 1) and used to generate a series of lanthanide(III) coordination polymers: $\{[Ln(L^1)_3]\cdot(ClO_4)_3\cdot(H_2O)\}_\infty$ (Ln = Er, Yb), which comprises two interpenetrating α-polonium nets; $\{[Ln(NO_3)_3(L^1)_{1.5}]\cdot H_2O\}_\infty$ (Ln = Er, Yb), which exhibits a mat-like pattern of three interwoven (6,3) nets; $\{[La(NO_3)_3(L^1)(CH_3OH)]\cdot CH_3OH\cdot CH_2Cl_2\}_\infty$, which is built of an offset stacking of distorted square grids; and $\{[Er(L^2)_{0.5}(H_2O)_3(C_2O_4)](ClO_4)\cdot L^2\cdot 6H_2O\cdot(dioxane)_{0.5}\}_\infty$, which is composed of (6,3) nets [13]. We have extended our investigation and report here three other kinds of lanthanide(III) coordination complexes

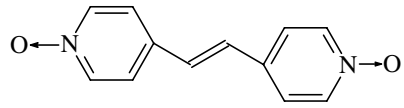
1,2-bis(4-pyridyl)ethane-*N,N'*-dioxide (L^1)



trans-1,2-bis(4-pyridyl)ethene-*N,N'*-dioxide (L^2)

Scheme 1.

constructed with these two ligands, which display new kinds of framework structures, namely $\{[Ce(L^1)_{1.5}(NO_3)_3](CH_2Cl_2)_{0.25}(H_2O)_{0.25}\}_\infty$ **1**, $[Ln(L^2)_{1.5}(NO_3)_3]\}_\infty$ (Ln = Ce, **2**; Gd, **3**) and $[Yb(L^2)(CH_3OH)(NO_3)_3]\}_\infty$, **4**.

2. Experimental

2.1. Materials

The bipyridyl-dioxide ligands 1,2-bis(4-pyridyl)ethane-N,N'-dioxide (L^1) and *trans*-1,2-bis(4-pyridyl)ethene-N,N'-dioxide (L^2) were synthesized as described previously [13]. The lanthanide(III) nitrates were obtained commercially (Aldrich) and used without further purification.

2.2. Synthesis of $\{[Ce(L^1)_{1.5}(NO_3)_3](CH_2Cl_2)_{0.25}(H_2O)_{0.25}\}_\infty$ (*1*)

A solution of L^1 (anhydrous, 50 mg, 0.2 mmol) in MeOH (8 ml) was carefully layered over CH_2Cl_2 (5 ml) in a test tube with solid $Ce(NO_3)_3 \cdot 6H_2O$ (65 mg, 0.15 mmol) placed at the bottom. Several days later, light yellow needle-like crystals gradually appeared on the walls at the bottom of the test tube. Yield ca. 35% (based on L^1). *Anal.* Calc. for $C_{36.5}H_{38}Ce_2ClN_{12}O_{24.5}$: C, 32.42; H, 2.83; N, 12.43. Found: C, 31.94; H, 3.03; N, 12.13%. IR (KBr, cm^{-1}): 3385brs, 3106s, 1656w, 1501m, 1383s, 1339s, 1234s, 1044w, 863m, 789w, 494w.

2.3. Synthesis of $[Ce(L^2)_{1.5}(NO_3)_3]_\infty$ (*2*)

Orange crystals of **2** were obtained by a similar procedure to **1** using L^2 in place of L^1. Yield ca. 40%. *Anal.* Calc. for $C_{18}H_{15}N_6O_{12}Ce$: C, 33.39; H, 2.34; N, 12.98. Found: C, 32.83; H, 2.52; N, 12.56%. IR (KBr, cm^{-1}): 3113w, 1629w, 1486s, 1456s, 1387m, 1315s, 1242s, 1038w, 970w, 863m, 802m, 561w, 500m.

2.6. X-ray crystallography

Selected single crystals of **1**–**4** sealed inside Lindemann glass capillaries were used for data collection on a Bruker SMART 1000 CCD diffractometer with graphite monochromated Mo Kα radiation ($\gamma = 0.71073$ Å) at 293 K. An empirical absorption correction was applied using the SADABS program [14]. The structures were solved by direct methods and refined by full-matrix least squares based on F^2 using the SHELXTL program package [15]. The crystallographic data for complexes **1**–**4** are summarized in Table 1.

3. Results and discussion

Pale yellow crystals of **1** were synthesized by slow reaction of $Ce(NO_3)_3$ and L^1 in a MeOH–CH_2Cl_2–H_2O medium. Crystalline compounds **2**, **3** and **4** were prepared in a similar way with $Ln(NO_3) \cdot 6H_2O$ (Ln = Ce and Gd) or $Yb(NO_3)_3 \cdot 5H_2O$ and L^2. Single crystal X-ray analyses confirmed that these materials have polymeric structures. Selected bond lengths and angles are given in Table 2.

In compound **1**, the asymmetric unit contains a Ce(III) ion, three nitrate ions, three independent halves of L^1 ligands that occupy special positions of symmetry

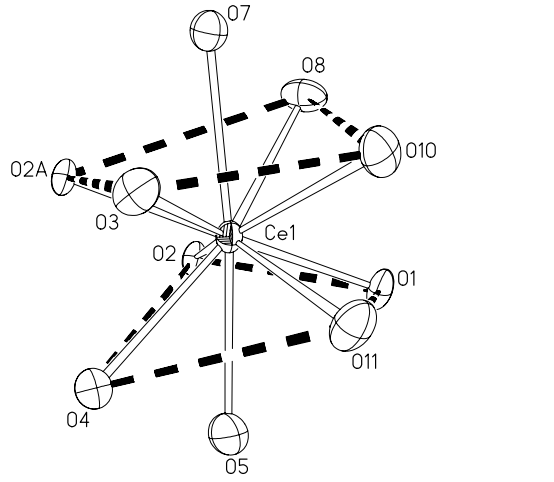

Fig. 1. Bicapped square-antiprismatic coordination environment of the Ce(III) ion in compound **1**.

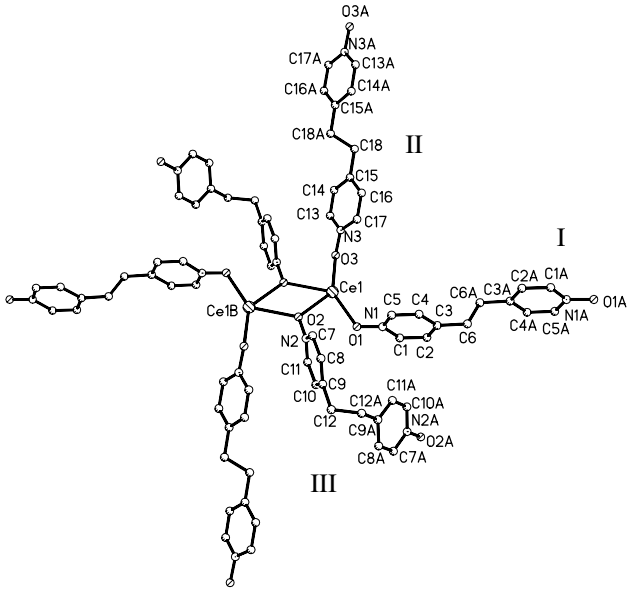

Fig. 2. The centrosymmetric Ce_2O_2 binuclear unit of compound **1**. The nitrate ions, water molecule, CH_2Cl_2 molecule and hydrogen atoms are omitted for clarity.

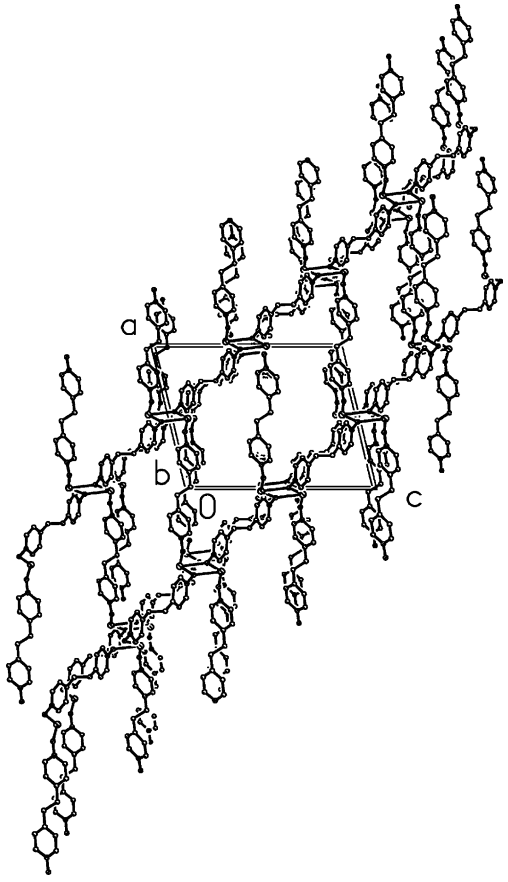

Fig. 3. Three-dimensional framework self-assembled by L^1 ligands of Type II (site symmetry $\bar{1}$) and Type III (site symmetry 2) with large distorted rectangular channels, viewed along the *b* direction.

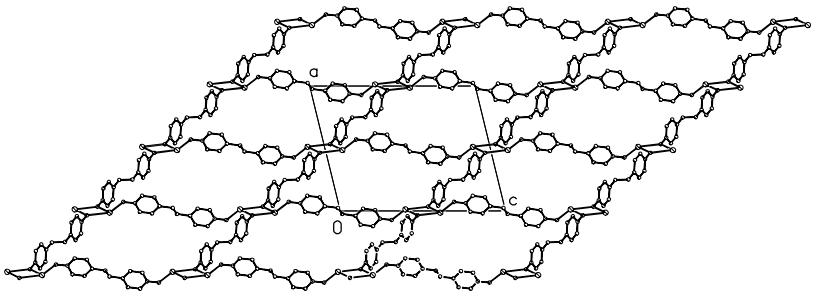

Fig. 4. Layer structure connected by L^1 ligands of Type I (site symmetry $\bar{1}$) and Type III (site symmetry 2), viewed along the *b* direction.

$\bar{1}$ or 2, and lattice water and dichloromethane molecules with only quarter site occupancy. The Ce(III) ions is located inside a bicapped square antiprism [Ce–O, 2.426(3)–2.690(3) Å], being surrounded by three chelating bidentate nitrate and four *N*-oxide groups (Fig. 1). The square antiprism is formed by O1, O2, O3 and O2A from *N*-oxide groups and O4, O8, O10 and O11 from nitrate ions, whereas the caps are formed by O5 and O7 from nitrate ions. Among the three distinguishable L^1 ligands, two located in $\bar{1}$ sites (labeled Type I and II in Fig. 2) act as an end-to-end linkers, whereas the third having site symmetry 2 (labeled Type III in Fig. 2) functions as a μ_4 linker with each *N*-oxide group bridging a pair of Ce(III) ions, leading to a centrosymmetric binuclear Ce_2O_2 subunit with a Ce···Ce distance of 4.42 Å. The dihedral angle of the two pyridine rings of the latter ligand is 57.3° and the torsion angle C9–C12–C12A–C9A is −70.2° (A: $-x+3/2, y, -z+1/2$). The centrosymmetric Ce_2O_2 moieties are bridged by the L^1 ligands of Type II and Type III to generate a three-dimensional network with large distorted rectangular channels (Fig. 3). In addition, the L^1 ligands of Type I

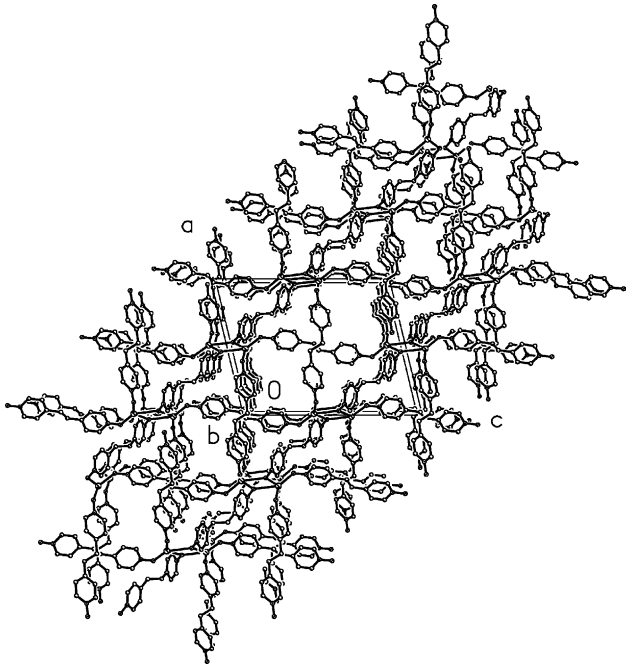

Fig. 5. Three-dimension network of **1** viewed along the *b* direction. This is a combination of the two networks shown in Figs. 3 and 4.

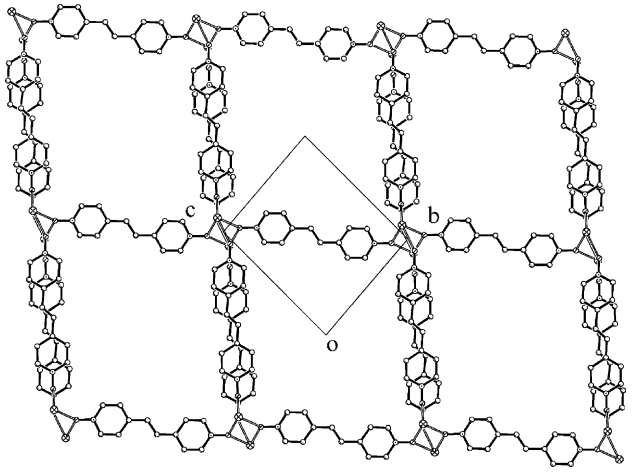

Fig. 7. Two-dimensional framework with large distorted square grids (ca. 12×13.9 Å) in compound **2**.

together with Type III also generate Ce_2O_2 moieties that are connected to form a layer structure normal to *b* axis (Fig. 4). The latter further consolidates the former three-dimensional network into a more complex structure and divides each large distorted rectangular channels into one distorted square and two triangular channels (Fig. 5). The disordered water molecule and CH_2Cl_2 are both located at special positions of site symmetry $\bar{1}$, occupying the larger distorted square channels of the three-dimensional network. In contrast, with the same L^1 ligand, the heavier lanthanide nitrates $Er(NO_3)_3$ and $Yb(NO_3)_3$ give complexes displaying an interpenetrating weave pattern of 3 two-dimensional (6,3) nets [13] that is different from the three-dimensional framework of **1**.

In compound **2**, the asymmetric unit contains a Ce(III) ion, three nitrate ions and one and a half L^2 ligands. The Ce(III) ion is coordinated by four *N*-oxide groups from different rigid L^2 ligands and three chelating bidentate nitrate groups, forming the same bicapped square-antiprismatic CeO_{10} coordination geometry as in **1** [Ce–O 2.370(4)–2.672(4) Å]. In this compound, the oxygen atoms O1, O3 and O2A from *N*-oxide and O5, O7, O8, O10 and O11 from nitrate ions construct the square antiprism, which are capped by O3B and O4 from *N*-oxide and nitrate groups, respectively (A: $x-1, y+1, z+1$; B: $-x+1, -y, -z$). Of the two independent L^2 ligands, one acts as an end-to-end linker, whereas the other occupying a $\bar{1}$ site functions in a μ_4

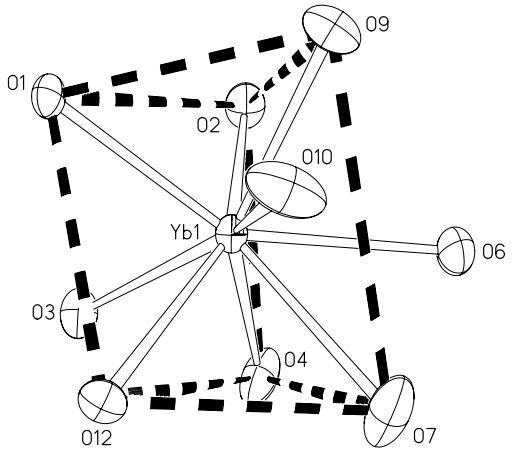

Fig. 8. Tricapped trigonal-prismatic coordination environment of the Yb(III) ion in compound **4**.

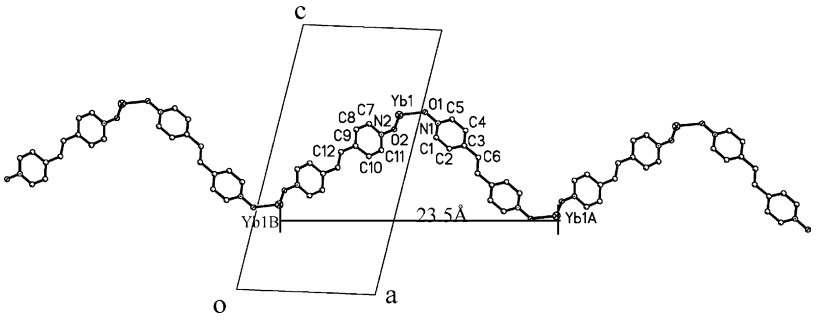

Fig. 9. The wavelike polymeric chain of compound **4**. The nitrate ions, MeOH molecules and hydrogen atoms are omitted for clarity. Symmetry transformations: A $(-x-1, -y+2, -z)$ and B $(-x+1, -y+3, -z)$.

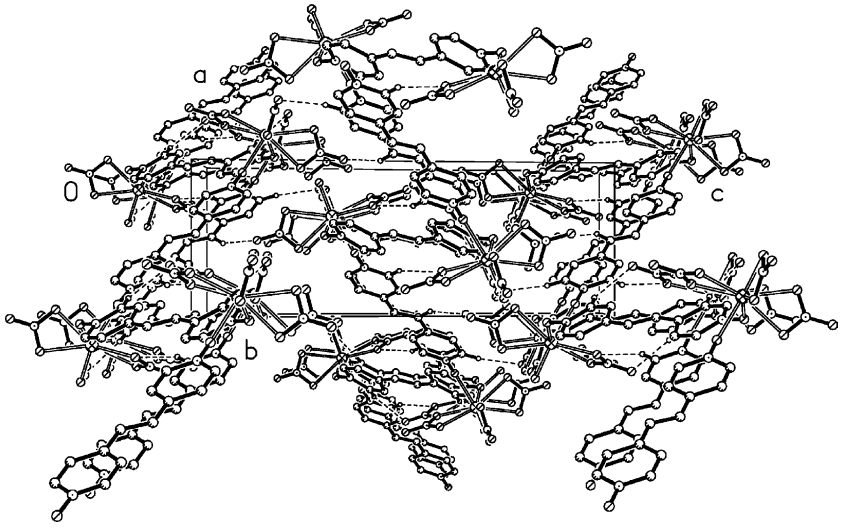

Fig. 10. Hydrogen bonded three-dimensional framework in **4**. The MeOH molecules and hydrogen atoms that have no contribution to the hydrogen bonding are omitted for clarity.

mode with each *N*-oxide group bridging a pair of Ce(III) ions, forming a centrosymmetric Ce_2O_2 binuclear unit with Ce···Ce distance 4.531 Å (Fig. 6). The end-to-end L^2 ligands link the binuclear centers along the [0 1 1] direction, generating an infinite double chain. And these double chains are further cross-linked by the μ_4 L^2 ligands, which bridge the binuclear centers to form an infinite single chain along the [0 1 $\bar{1}$] direction, leading to a layered structure with large distorted square grids (ca. 12×13.9 Å) (Fig. 7). The double chains overlap through π–π interactions between the adjacent pyridyl rings of neighboring L^2 ligands belonging to different chains with the center-to-center distance 3.61 Å and dihedral angel 6.3°. If each Ce_2O_2 unit can be considered as a 4-connected node, this layered structure has the topology of a (4,4) net. Though there are large square grids in this two-dimensional coordination network, the cavities are not filled by solvate molecules.

Compound **3** is isomorphous to compound **2**, with Gd(III) ions replacing Ce(III) ions.

In compound **4**, the asymmetric unit contains a Yb(III) ion, three nitrate ions, two half L^2 ligands and a methanol molecule. The MeOH molecule, three chelating bidentate nitrate ions and two *N*-oxide groups coordinate to Yb(III), leading to a tricapped trigonal prism (Fig. 8). The trigonal prism comprises O1 and O2 from *N*-oxide ligands, O4, O7 and O9 from three nitrate ions, and O12 from the MeOH molecule, whereas the three capping atoms are O3, O6 and O10 from different nitrate ions. The YbO_9 coordination environment [Yb–O 2.232(6)–2.433(7) Å] reflects the reduction in ionic radius from Gd(III) in **2** to Yb(III) in **4**. Both L^2 ligands in consecutive $\bar{1}$ sites act as end-to-end linkers, bridging the Yb(III) centers to generate a sinusoidal chain along the *a* axis with the period $|2\vec{a} + \vec{b}| = 23.5$ Å (Fig. 9). These chains are further connected through weak C–H···O hydrogen bonds: C1–H···O5a 130.7°, C1···O5a 3.11(1) Å; C4–H···O8b 151.0°, C4···O8b 3.38(1) Å; C7–H···O8c 154.9°, C7···O8c 3.40(1) Å; C11–H···O3a 153.6°, C11···O3a 3.27(1) Å; and C12–H···O11c 155.8°, C12···O11c 3.30(1) Å (a: $-x, -y+2, -z$; b: $x-1, y, z$; c: $-x+1, y+1/2, -z+1/2$), generating a three-dimensional framework (Fig. 10). In contrast, with the flexible L^1 ligand, $Yb(NO_3)_3$ forms a complex $\{[Yb(NO_3)_3(L^1)_{1.5}]\cdot H_2O\}_\infty$ showing an interpenetrating weave pattern of three two-dimensional (6,3) nets [13].

4. Conclusion

The building units of the coordination networks in compounds **1**–**3** are all binuclear, whereas that in compound **4** is mononuclear. For the Yb(III) ion of smaller size in **4**, only nine oxygen atoms enter into the coordination sphere, making more space available for the chelating bidentate nitrate groups, which is reflected by the significantly larger O–Ln–O bond angles (51.9°–52.6°) than those in **1**–**3** (46.2°–48.6°). Pair-wise comparison of structure **1** with **2**, and **4** with $\{[Yb(NO_3)_3(L^1)_{1.5}]\cdot H_2O\}_\infty$ [13], demonstrates the versatile coordination behavior of the flexible 1,2-bis(4-pyridyl)ethane-*N*,*N*′-dioxide (L^1), which bridge the Ln(III) ions in different modes, leading to various topological structures. On the other hand, the rigid *trans*-1,2-bis(4-pyridyl)ethene-*N*,*N*′-dioxide (L^2) yields less complex polymeric structures with Ln(III) ions. In all such compounds studied to date, the *N*-oxide group of L^1 and L^2 servers as a donor to one or two Ln(III) centers, and its potential to coordinate three metal centers needs to be further explored. As polypyridines are important ligands for d-block metal ions, poly(pyridine-*N*-oxides) may be expected to become equally versatile for f-block metal ions in coordination network assembly.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 211536–211539 for compounds **1**–**4**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336033; e-mail: deposit@ccdc.cam.uk or www:http://www.ccdc.cam.ac.uk).

Received 3 September 2003; accepted 30 September 2003

Abstract

Polystyrene-supported hydrogermanes (**1**–**4**) were prepared by functionalization of polystyrenes or functionalization of a styrene followed by polymerization. The hydrogermanes, **1**–**4**, reduced organic halides with or without a catalyst to give alkanes under mild conditions in the order: C–I>C–Br>C–Cl. The hydrogermanes, **1**–**4**, were easily separated after use by filtering and could be regenerated with lithium aluminum hydride after their reactions with organic halides.

Keywords: Polystyrene supported; Hydrogermane; Reduction; Recycle

1. Introduction

Reduction of organic halides by hydrostannanes and hydrosilanes in the presence of radical initiators has been investigated extensively and the synthetic utility of these reductions, especially with hydrostannanes, has been widely established [1–9]. The reduction of organic halides involving halogen-abstraction reaction by organostannyl and organosilyl radicals is a radical-chain process described as below [4].

$$R_3E\bullet + R'X \rightarrow R_3EX + R'\bullet$$

$$R'\bullet + R_3EH \rightarrow R'H + R_3E\bullet \quad E = Si, Ge, Sn$$

The radical-chain process by organostannyl radicals is very efficient even at low temperatures [10,11]. However, the tin compounds are toxic and cause disposal problems. Hydrosilanes are possible alternative compounds since organosilyl radicals are better halogen-abstracting reagents than their tin counterparts, and they have no toxic character. However, organosilanes are poor hydrogen atom donors toward organic radicals and do not support radical-chain reactions, except at elevated temperatures [12,13]. Moreover, the isolation of products in the reduction of organic halides by hydrostannanes and hydrosilanes in solutions is difficult. Recently, reduction of organic halides by hydrogermanes has also been of considerable interest from the viewpoint of moderate reactivity combined with selectivity and good hydrogen atom donors as compared with hydrostannanes and hydrosilanes [4,14–20]. In the course of our investigations on the structure and reactivity of organogermyl radicals we have undertaken preparation of polymer-supported hydrogermanes. These hydrogermanes are insoluble in common organic solvents and would easily be separated after use by filtering and would be recyclable. The polymer-supported hydrogermanes would also retain their integrity during chemical reactions. While the organic syntheses, their application and characterization of polymer-supported hydrostannanes have been reported [21–30], there is no report on analogues of germanium so far.

In this paper, we describe the synthesis of several polystyrene-supported hydrogermanes (**1**–**4**) and their reduction of organic halides.

2. Results and discussion

2.1. Preparation of polystyrene-supported hydrogermanes

Polystyrene-supported hydrogermanes were prepared by several methods. Diethyldichlorogermane (Et_2GeCl_2) in THF was treated with one molar amount of poly(4-vinylphenyllithium) at 20 °C for 4 h to afford poly (4-vinylphenyldiethylchlorogermane). The poly(4-vinylphenyllithium) was prepared by the reaction of polystyrene in cyclohexane with a diethylether solution of butyllithium (BuLi) with *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (TMEDA) at 65 °C for 6.5 h. The poly (4-vinylphenyldiethylgermane) (**1**) was obtained by reduction of the polystyrene-supported chlorogermane with lithium aluminum hydride (LAH). The polystyrene-supported chlorogermane and hydrogermane **1** were insoluble in common solvents. The polystyrene-supported hydrogermane **1** was analyzed by FT-IR (νGe–H: 2018 cm^{-1}) and XPS spectra (Ge content: 3.8 $mmol\,g^{-1}$, degree of functionalization = 0.28). The poly(4-vinylbenzyldiethylgermane) (**2**), in which the germyl moiety was separated from the aromatic ring by methylene, was prepared by a similar method to that of **1**. The treatment of Et_2GeCl_2 with one molar amount of poly(4-vinylbenzyllithium), which was prepared by the reaction of poly(4-vinylbenzyl chloride) with a diethylether solution of BuLi/TMEDA at 50 °C for 2 h, gave poly(4-vinylbenzyldiethylchlorogermane). The polystyrene-supported hydrogermane **2** was prepared by reduction of the corresponding chlorogermane with LAH.

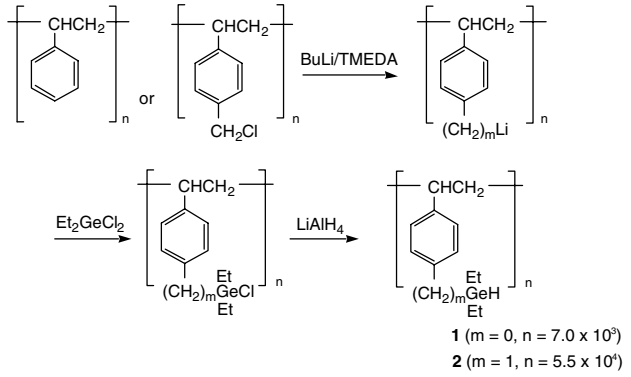
The polymer-supported hydrogermane **2** was also insoluble in common solvents and was analyzed with FT-IR (νGe–H: 2015 cm^{-1}) and XPS spectra (Ge content: 3.8 $mmol\,g^{-1}$, degree of functionalization = 0.28). The preparation of polystyrene-supported hydrogermane, **1**–**2** is outlined as Scheme 1.

Poly(4-vinylybenzyl chloride) reacted with trichlorogermane ($HGeCl_3$) and triethylamine (Et_3N) in chloroform under reflux conditions for one day to give poly (4-vinylbenzyltrichlorogermane). The poly(4-vinylbenzyltrichorogermane) was reduced with LAH to give poly(4-vinylbenzylgermane) (**3**). The third polystyrene-supported hydrogermane **3** was analyzed by FT-IR spectra (νGe–H: 2063 cm^{-1}). Flame atomic absorption and oxygen bomb combustion analyses of the polymer-supported hydrogermane **3** revealed that the degree of functionalization with the germane group was 0.55. The preparation of polystyrene-supported germanium hydride **3** is outlined as Scheme 2. The hydrogermane **3** was insoluble in common solvents.

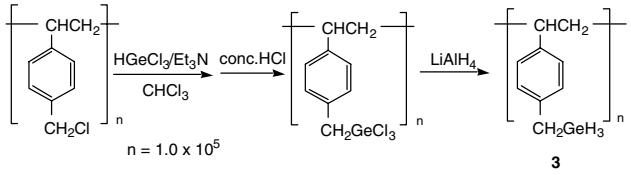
Nefedov and co-workers have reported that benzyl chloride reacts with $HGeCl_3$ in the presence of Et_3N to afford benzyltrichlorogermane [31].

p-Vinylphenethyldiethylchlorogermane was prepared by hydrogermylation of *p*-divinylbenzene with diethylchlorogermane ($Et_2(Cl)GeH$) with a catalytic amount of azobis(isobutyronitrile) (AIBN) at 60 °C for 10 h. Without purification, the crude *p*-vinylphenethyldiethylchlorogermane in octyl alcohol was directly polymerized in water containing methyl cellulose at 30 °C for 18 h to afford poly(4-vinylphenethyldiethylchlorogermane). The poly(4-vinylphenethyldiethylgermane) (**4**) was obtained by reduction of the polystyrene-supported chlorogermane with LAH (see Scheme 3).

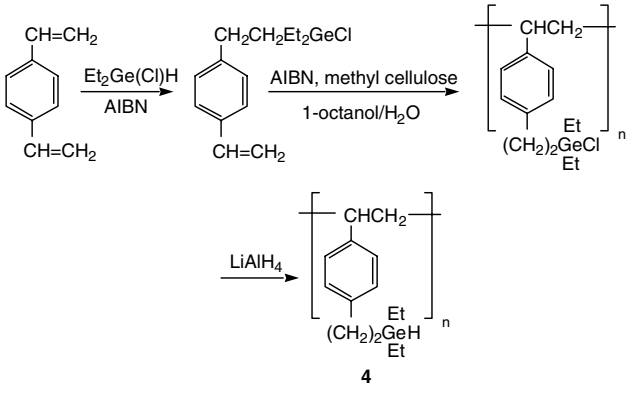
The polystyrene-supported hydrogermane **4**, in which the germyl group was separated from the aromatic ring by two methylene units, was identified by FT-IR (νGe–H: 2000 cm^{-1}) and XPS spectra (Ge content: 4.0 $mmol\,g^{-1}$, degree of functionalization = 0.30). The polymer-supported hydrogermane **4** was insoluble in common solvents. The molecular weight of **4** could not be determined by GPC relative to polystyrene standard.



Scheme 1.



Scheme 2.



Scheme 3.

The content of germanium atoms in the polystyrene-supported hydrogermanes is low. This is because the carbon–carbon chains of polystyrene are distributed closely to each other and there are few chances of functionalization in polystyrenes.

2.2. Reduction of organic halides with 1–4

The polymer-supported hydrogermanes **1**–**4** and halogermanes are insoluble in common organic solvents. Therefore, the reagents can easily be separated after use simply by filtering after their reactions with organic substrates, and then they can be regenerated by LAH.

Polystyrene-supported germanium hydrides **1**–**4** are capable of reducing organic halides simply by heating without free-radical initiators in contrast to the behavior of hydrosilanes. The uncatalyzed reduction of organic halides with hydrogermanes has been explained in terms of a radical-chain process. The reductions of organic halides with polymer-supported hydrogermanes **1**–**4** were examined in the absence of solvents by heating with di-*tert*-butyl peroxide (DTBP) and without radical initiators. Tables 1–3 summarize the results of the reduction of organic halides. Products analyses were carried out by using GC and GC–MS spectroscopy using authentic samples. The yields of products were determined by GC with an internal standard method taking into account the germanium content of the polystyrene-supported hydrogermanes **1**–**4**.

Tables 1 and 2 show the results of reduction of octyl and aryl halides with polystyrene-supported organogermanium hydrides **1**–**4** catalyzed by DTBP and by only heating. Organic halides were clearly reduced to the corresponding reduction products. No coupling products were detected. The reactivity of the halogen atoms falls in the sequence: I>Br>Cl for **1**–**4**. The ease of reaction decreases in the order: octyl halides > aryl halides. These features are in accord with those found in homolytic reduction of organic halides with trialkylgermanes previously reported [15,16]. The yields of reduction products for octyl and aryl halides are low, except for octyl iodides and the polystyrene-supported hydrogermane **3** system. This is because steric crowding around the germanium atoms in **1**–**4**, in which the germyl group was not well separated from the aromatic ring, will cause a decrease in the reactivity of germanium hydride. The high yield of octane by reduction of octyl iodide with the hydrogermane **3** is attributed to the trihydrogermane (GeH_3). The low yields of reduction products for octyl and aryl bromides and chlorides are explained by the low reactivity of the (halo)dihydrogermanes ($Ge(X)H_2$) produced by reduction of the organic halides with the GeH_3 in **3**, as well as the steric crowding around the germanium atoms. The signals of $Ge(X)H_2$ were confirmed by IR spectroscopy.

[c] At 130 °C for 20 h without DTBP.

Table 3 summarizes the results of reduction of benzyl halides, phenethyl bromide and polyhalobenzenes with polystyrene-supported hydrogermanes **1**–**4**. The reduction of benzyl bromides and phenethyl bromide with the hydrogermane **3** without free-radical initiators afforded the corresponding hydrocarbon in good yields. The GeH_3 in **3** took part in the reduction of organic halides. The reduction of polyhalobenzenes with polymer-supported hydrogermanes **1**–**4** was also examined. Polyhalobenzenes are reduced by a stepwise method, which makes it possible to carry out the selective reduction of polyhalides. *o*-Bromochlorobenzene and *o*-dibromobenzene were reduced with **1**, **2**, **4** stepwise to afford chlorobenzene and bromobenzene, respectively. The hydrogermane **3** reduced *p*-bromochlorobenzene and *p*-iodochlorobenzene to afford chlorobenzene selectively.

The extent of regeneration of polystyrene-supported hydrogermanes **1**–**4** after several reactions is 90%.

[c] At 130 °C for 20 h without DTBP.

In conclusion, we have shown polystyrene-supported hydrogermanes **1**–**4** reduce organic halides under mild conditions. Advantages of the polymer-supported **1**–**4** are easier process, clean and simple work-up of the products and use of recyclable reagents.

3. Experimental

3.1. General methods

The NMR spectra were obtained on a Varin Unity Inova 400 MHz, JEOL JNM-MY 60 MHz, and GX 270 MHz NMR spectrometer. The GC–MS spectra were measured on a JEOL LMS-DX 303 mass spectrometer. The IR spectra were recorded with a Shimadzu FT IR 4200 spectrometer. Gas chromatography was performed on a Shimadzu GC 8A with a 1 m 20% SE column and 1 m 30% Apiezon L column. GPC was performed on a JAL HPLC.

3.2. Materials

Diethyldichlorogermane [32] and diethylchlorogermane [33] were prepared as reported in the literature. Polystyrene, poly(4-vinylbenzyl chloride), *p*-divinylbenzene, trichlorogermane, TMEDA, octyl alcohol, organic halides, AIBN, DTBP, lithium aluminum hydride, methylcellulose and butyllithium were commercially available.

3.3. Preparation of poly(4-vinylphenyldiethylchlorogermane)

To a cyclohexane solution (10 ml) of polystyrene ($M_w = 7.0 \times 10^3$, 1.0 g, 0.01 mol) in a three-necked flask fitted with a condenser, mechanical stirrer and pressure equalizing dropping funnel, TMEDA (1.5 ml) and then butyllithium in diethylether (1.28 N, 11.7 ml, 0.015 mol) were added under an argon atmosphere. The reaction mixture was stirred at 65 °C for 6.5 h. After removal of the liquid phase, the polymer was washed with THF. The washing THF was removed. To the crude poly(4-vinylphenyllithium) in new THF (8 ml), diethyldichlorogermane (Et_2GeCl_2) (2.20 g, 0.01 mol) was added slowly. The resulting mixture was quenched with anhydrous ethanol and then filtered. After drying in vacuo at 60 °C the poly(4-vinylphenyldiethylchlorogermane) weighed 1.2 g.

3.4. Preparation of poly(4-vinylphenyldiethylgermane) (*1*)

To poly(4-vinylphenyldiethylchlorogermane) (1.2 g) in THF (1.5 ml) lithium aluminum hydride (LAH) (0.152 g, 4.0 mmol) suspended in THF (8 ml) was added. The reaction mixture was refluxed with stirring for 1 h. The resulting mixture was quenched with anhydrous ethanol and then filtered. After drying in vacuo at 40 °C the poly(4-vinylphenyldiethylgermane) weighed 1.1 g. Polystyrene bands (cm^{-1}): [34,35] aromatic C–H stretchings, 3010; aliphatic C–H stretchings, 2950, 2920 and 2890; aromatic C–C stretchings, 1490; weak in-plane aromatic C–H bending bands, 1090 and 1020; out-of-plane C–H aromatic bending bands, 830. Other bands (cm^{-1}): Ge–H stretching, 2018. XPS spectra revealed the germanium content in **1** was 3.8 mmol g^{-1}. The degree of functionalization was 0.28.

3.5. Preparation of poly(4-vinylbenzyldiethylchlorogermane)

To a cyclohexane solution (1 ml) of poly(4-vinylbenzyl chloride) ($M_w = 5.5 \times 10^4$, 2.5 g, 0.03 mmol) in a two-necked flask fitted with a condenser, TMEDA (0.1 ml) and then butyllithium in diethylether (1.0 N, 45 μl, 0.045 mmol) were added under an argon atmosphere.

The reaction mixture was stirred at 50 °C for 2 h. After removal of the liquid phase, the polymer was washed with THF. The washing THF was removed. To the crude poly(vinylbenzyllithium) in new THF (1 ml), diethyldichlorogermane (Et_2GeCl_2) (7.0 mg, 0.03 mmol) was added slowly. The resulting mixture was quenched with anhydrous ethanol and then filtered. After drying in vacuo at 60 °C the poly(4-vinylbenzyldiethylchlorogermane) weighed 2.4 g.

3.6. Preparation of poly(4-vinylbenzyldiethylgermane) (**2**)

To poly(4-vinylbenzyldiethylchlorogermane) (2.4 g) in THF (5.0 ml) LAH (0.152 g, 4.0 mmol) suspended in THF (8 ml) was added. The reaction mixture was refluxed with stirring for 1 h. The resulting mixture was quenched with anhydrous ethanol and then filtered. After drying in vacuo at 40 °C the poly(4-vinylbenzyldiethylgermane) weighed 2.1 g. Polystyrene bands (cm^{-1}): [34,35] aromatic C–H stretchings, 3015; aliphatic C–H stretchings, 2872; aromatic C–C stretchings, 1508; weak in-plane aromatic C–H bending bands, 1043 and 984; out-of-plane aromatic C–H bending bands, 762. Other bands (cm^{-1}): Ge–H stretching, 2015. XPS spectra revealed Ge content: 3.8 mmol g^{-1}. The degree of functionalization was 0.28.

3.7. Preparation of poly(4-vinylbenzyltrichlorogermane)

To a chloroform solution (10 ml) of poly(4-vinylbenzyl chloride) ($M_w = 1.0 \times 10^5$, 3.0 g, 0.03 mmol) in a two-necked flask fitted with a condenser, trichlorogermane ($HGeCl_3$) 4.8 ml (0.09 mmol) and then triethylamine (4.8 ml, 0.09 mol) were added under an argon atmosphere. The reaction mixture was refluxed with stirring at 50 °C for one day. The unreacted $HGeCl_3$ was removed by washing with HCl several times. After complete removal of chloroform, the polymer weighed 2.5 g. NMR (δ, THF-d_8) 1.20–2.18 (m, 3H), 3.35–3.84 (m, 2H), 6.23–7.28 (m, 2H).

3.8. Preparation of poly(4-vinylbenzylgermane) (**3**)

To suspended LAH (5.7 g, 0.15 mol) in THF (100 ml) poly(4-vinylbenzyltrichlorogermane) (2.5 g) in THF (20 ml) was added. The reaction mixture was refluxed with stirring for 4 h. The resulting mixture was hydrolyzed with water. The resulting polymer was filtered. After drying in vacuo at 40 °C the poly(4-vinylbenzylgermane) weighed 1.8 g. Polystyrene bands (cm^{-1}): [34,35] aromatic C–H stretchings, 3010; aliphatic C–H strechings, 2920 and 2851; aromatic C–C stretchings, 1508. Other bands (cm^{-1}): Ge–H stretching, 2063. Flame atomic absorption and oxygen bomb combustion analyses of the hydrogermane **3** revealed that the degree of functionalization with the germane group was 0.55.

3.9. Preparation of poly(4-vinylphenethyldiethylgermane) (**4**)

p-Divinylbenzene (55/45 mixture of *p*-isomer/*m*-isomer) (1.3 g, 0.01 mol) and AIBN (0.03 g, 0.2 mmol) were placed in a two-necked flask fitted with a condenser and pressure equalizing dropping funnel. To this mixture diethylchlorogermane ($Et_2(Cl)GeH$) (1.7 g, 0.01 mol) was added. The reaction mixture was stirred at 60 °C. The progress of hydrogermylation was checked by GC. After the disappearance of $Et_2(Cl)GeH$, 1-octyl alcohol (4.5 ml) was added. The octyl alcohol solution of 4-vinylphenethyldiethylchlorogermane was transferred to a water containing methyl cellulose (0.03 g). After stirring at 30 °C for 1 h, the reaction mixture was refluxed with stirring for 18 h. The reaction mixture was collected on a filter and washed with methanol, acetone, and toluene. After drying under vacuum, 1.41 g of poly(4-vinylphenethyldiethylgermane) (**4**) was obtained. Polystyrene bands (cm^{-1}): [34,35] aromatic C–H stretchings, 3005; aliphatic C–H stretchings, 2850 and 2750; aromatic C–C stretchings, 1600, 1510 and 1480; weak in-plane aromatic C–H bending bands, 1020; out-of-plane C–H aromatic bending bands, 700. Other bands (cm^{-1}): Ge–H stretching, 2000. XPS spectra revealed Ge content: 4.0 mmol g^{-1}. The degree of functionalization was 0.30. The molecular weight of **4** could not be determined by GPC relative to polystyrene standard.

3.10. Reactions of organic halides with polystyrene-supported hydrogermanes **1**–**4**

As a representative example, the reaction of octyl iodide with polystyrene-supported hydrogermane **3** is described. A mixture of octyl iodide (0.2 g, 0.8 mmol) and **3** (0.2 g, 0.002 mmol) was heated at 130 °C for 20 h. After washing the reaction mixture with a small amount of benzene, octane was identified by GC and GC–MS spectroscopy using authentic samples. The yield of octane was determined by GC with an internal standard method taking into account the germanium content of the polystyrene-supported hydrogermane **3**.

Received 21 July 2003; accepted 3 October 2003

Abstract

The reaction of the in situ prepared LLi ($L = Et_2NCH_2CH_2NC(Me)CHC(Me)NCH_2CH_2NEt_2$ with $LnBr_3$ (Ln = Y, Sm, and Yb) led to the solvent and alkali salt free dibromoderivative of type $LLnBr_2$ (Ln = Y, **1**, Sm, **2**, and Yb, **3**). Compounds **1**–**3** were characterized by X-ray crystallography, elemental analysis, and NMR (**1**), and their structural features were correlated with those of other compounds bearing the same ligand.

Keywords: Lanthanides; Yttrium; Diketiminato

1. Introduction

The efforts of the last years to expand the chemistry of lanthanides beyond the well-known cyclopentadienyl derivatives have brought into the light a large plethora of new complexes [1–10]. In view of the current interest in these compounds as precatalysts [11–13] we have initiated studies in new ligand systems.

Ligands containing the β-diketiminato backbone offer possibilities of stabilisation for unusual bonding situations which have been exploited for various main group and transition metal complexes [14–18]. In comparison with this relatively well developed field, the area of β-diketiminato based complexes of early transition metals and lanthanides remains rather unexplored [19,20].

Previously we reported the synthesis and structural characterization of novel derivatives of scandium $LScX_2$ (X = Cl, Br), praseodymium, $LPrX_2$ (X = Cl, Br, BH_4), $LHoI_2$, $LErI_2$, and of $LTbX_2$ (X = Br, CH_2SiMe_3; $L = Et_2NCH_2CH_2NC(Me)CHC(Me)NCH_2CH_2NEt_2$), that belong to a new class of lanthanide complexes containing a β-diketiminato-based ligand which possesses two pendant arms (Fig. 1) [21–24]. The variety of surprising compounds synthesized involving the derivatives of this ligand [24–27] convinced us to extend the chemistry of the monoanionic precursor to other rare earth metals. Herein we present our recent results in this direction namely complexes with lanthanides and yttrium of the Group 3 elements using ligand L. Moreover, we provide details on structural aspects of β-diketiminato-based complexes of these elements.

2. Experimental

All operations involving air and moisture sensitive compounds were performed using standard Schlenk line and dry box techniques under purified nitrogen atmosphere. $SmBr_3$ and YBr_3 were prepared following the procedures described in the literature [28]. Diethylether, toluene and pentane were dried from appropriate drying agents, Na/benzophenone (diethylether), Na/K alloy (toluene, pentane) and distilled under nitrogen prior to use. C_6D_6 was dried over Na/K alloy and degassed. ^1H and ^{13}C NMR spectra were recorded at ambient temperature on a Bruker AM 200. Chemical shifts are reported in

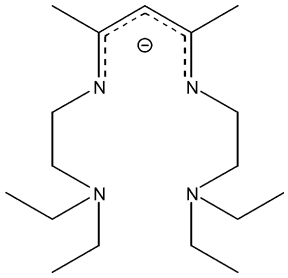

Fig. 1. Monoanionic, β-diketiminato ligand L^- used in this study.

δ units downfield from tetramethylsilane with the solvent as the reference signal. Mass spectra were recorded on a Finnigan MAT 8230 instrument, and elemental analyses were carried out at the Analytical Laboratory of the Institute of Inorganic Chemistry of the University of Göttingen. Melting points were determined in sealed capillary tubes under nitrogen and are uncorrected.

3. Preparation

$LYBr_2$ (**1**). 50 cm^3 of dry diethyl ether were added to 2.85 g (1 mmol) of LH in a 100 cm^3 Schlenk flask. The mixture was cooled to −78 °C and a solution of 6 cm^3 (1.6 M, 9.6 mmol) LiMe in diethylether was added dropwise. The reaction was stirred for 2 h at −78 °C, and then stirred overnight at room temperature until the methane evolution had ceased. The solvent was removed and toluene (50 cm^3) was added. Finally the solution was added dropwise to a suspension of 3.29 g (1 mmol) YBr_3 in toluene (25 cm^3) in a 100 cm^3 Schlenk flask. Then, the reaction mixture was refluxed overnight. The suspension was hot filtered, the solvent removed and the crude product was washed with pentane (50 cm^3) to yield 4.71 g (86.6%) of $LYBr_2$. Large colourless crystals were obtained cooling the mother liquor at −26 °C.

Complexes **2** and **3** can be prepared in a similar manner using $SmBr_3$ and $YbBr_3$, respectively, instead of YBr_3.

4. General aspects of X-ray data collection, structure determination, and refinement for complexes 1–3

Crystal, data collection, and refinement parameter are given in Table 1. Data for crystal structures of **1**–**3** were collected on a Stoe Image Plate IPDS II-System.

All structures were solved by direct methods (SHELXS-97) and refined against F^2 using SHELXL-97 [29]. Heavy atoms were refined anisotropically. Hydrogen atoms were included using the riding model with U_{iso} tied to U_{iso} of the parent atoms. Crystal data collection details, and the solution and refinement procedures are summarized in Table 1.

5. Results and discussion

$LLnBr_2$ (Ln = Y: **1**; Ln = Sm: **2**; Ln = Yb: **3**). Reaction of $LnBr_3$ with 1 equiv of LLi at reflux temperature yields tetrahydrofuran, dichloromethane and toluene respectively soluble complexes of general composition $C_{17}H_{35}N_4LnBr_2$ (Ln = Sm: yellow **2**; Ln = Yb: violet **3**) and $C_{17}H_{35}N_4LnBr_2{\cdot}C_7H_8$ (Ln = Y: colourless **1**) in good yields. Crystals of **1**–**3** suitable for X-ray studies were obtained by slow evaporation followed by refrigeration for several h at −26 °C (Fig. 2). It has to be noticed that these compounds do not have in the coordination sphere either solvent molecules or lithium halide which makes them more appropriate for further reactions.

Selected bond distances and angles for compounds **1**–**3** are listed in Table 2. In compounds **1**–**3** both pendant arms of the ligand are coordinated to the metal centre and all four nitrogen atoms and the metal atom are in the same plane. For the complex **3** (see Fig. 3) a local distortion can be observed due to the different orientation of one of the ethyl groups from one of the arms. The coordination number at the metal ion is in every case *six* and the geometry around the metal atom is *pseudooctahedral* which led, as a direct consequence, to the nonequal Ln–Br bond lengths. Nevertheless, these bond lengths are in the range of those for previously reported compounds [30c]. However, in every case the coordination number and the oxidation state of the metal ion centre finely tune the Ln–Br bond lengths. For instance the Y–Br bond length is 2.79 Å (av) [30] in Na_3YBr_6, which is comparable to that in **1** (see Table 2). The Ln–N bond lengths of the pendant arms are longer than those of the backbone, due to the coordinative and covalent character involved in different bonding modes. As far as the Ln–N (β-diketiminato) bond length is

concerned it has to be said that only samarium β-diketiminato derivatives are known [20]. The Ln–N bond lengths are similar to those in **2**. In several studies it has been shown that a β-diketiminato ligand can act as either a donor of 4 electrons, in this case the nature of the bonds is σ, or a donor of 6 electrons, in this case the description of the bonds is 2σ–π [19,31]. Information whether there is predominantly 2σ or 2σ–π bonding between the ligand and metal ion can be deduced from the deviation of the metal ion from the NC_3N backbone plane. As it can be seen from Table 3 there is a correlation between the electrophilicity of the metal ion and the deviation from the plane with the exception of the yttrium. It can be rationalized that the deviation from the plane correlates with the electrophilicity of the cation. As a consequence, the smallest deviation is found in the complex **2** (0.07 Å) which correlates with the size of Sm^{3+} that has the biggest ionic radius from this series. Furthermore, the influence on the Ln–Br as well as on Ln–N bond lengths can be observed (see Table 2) and they follow the same tendency as for Ln^{3+} ionic radii. Additionally, it can be pointed out that the 'bite' of a β-diketiminato ligand is big enough to accommodate any metal ion in NC_3N plane, at least the metals from this study. On the other hand, it has also been demonstrated that the bulkiness of the substituents on the β-diketiminato backbone can account for the deviation of the metal ion as well [19] but for the **1**–**3** complexes this is not the case.

6. Conclusions

This study has shown that the ligand L functions as an ancillary system for samarium and ytterbium, as well as yttrium thereby providing an easy access to a novel class of β-diketiminato lanthanide complexes. A subsequent investigation of the reaction chemistry of these systems is currently under way.

7. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with CCDC Nos.: 175027, 175028 and 175029. Copies of the information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033, E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction between the bridged bis(imido) complexes $\{[(CH_2)_n(2\text{-}C_6H_4N)_2]MoCl_2(dme)\}$ ($n = 1, 2$); dme = 1,2-dimethoxyethane) and one equivalent of potassium hydridotris(3,5-dimethylpyrazolyl)borate (KTp′) in refluxing thf gives $\{[(CH_2)_n(2\text{-}C_6H_4N)_2](Tp')MoCl\}$ ($n = 1$ (**1**), $n = 2$ (**2**)) as red crystalline solids in good yields. Similarly, the reaction between $[Mo(NAr)_2Cl_2(dme)]$ or $[Mo(NAr)(NBu^t)Cl_2(dme)]$ (Ar = 2,6-$Pr^i_2C_6H_3$) and KTp′ gives green [Tp′Mo(NAr)$_2$Cl] (**3**) or brown/black [Tp′Mo(NAr)(NBu^t)Cl] (**4**), respectively. X-ray crystal structures of the compounds **1**, **3** and **4** have been determined. All have octahedral structures with *fac* coordination for the tridentate Tp′ ligands and near-linear imido groups.

Keywords: Tris(pyrazolyl)borate; Bis(imido); Molybdenum; Synthesis; Structures

1. Introduction

Bis(imido) molybdenum chemistry is relatively well developed and attracts attention as it provides an entry into well-defined metathesis catalysts [1,2]. We have previously described a number of *ansa*-bis(imido) complexes, containing various sizes (7–9) of molybdacyclic ring, of the form $\{[(CH_2)_n(2\text{-}C_6H_4N)_2]MoCl_2(dme)\}$ ($n = 1, 2$) and $[(NCMe_2CH_2\text{-}2\text{-}C_6H_4N)MoCl_2(dme)]$, isolobal analogues of the *ansa*-zirconocenes [3,4]. In other studies, we and others have been investigating the 'softness' of the angle associated with the imido bond. Near-linear angles in the range 150–180° are frequently observed and can be influenced by interligand steric interactions as well as crystal packing forces [5,6]. These results encouraged us to look at the use of the bulky tris(3,5-dimethylpyrazolyl)hydroborate (Tp′) ligand. Here we report the synthesis, characterisation and crystal structures of several bis(imido) molydenum(VI) complexes containing the Tp′ ligand. A number of transition metal imido species containing hydridotris(pyrazolyl)borate type ligands have previously been reported [7–14].

2. Results and discussion

2.1. Bridged bis(imido) complexes

Interaction of $\{[(CH_2)(2\text{-}C_6H_4N)_2]MoCl_2(dme)\}$ with one equivalent of KTp′ in refluxing thf yields, after work-up, red prisms of $\{[(CH_2)(2\text{-}C_6H_4N)_2](Tp')MoCl\}$ (**1**) in good yield (ca. 65%). In contrast to the Cp de-

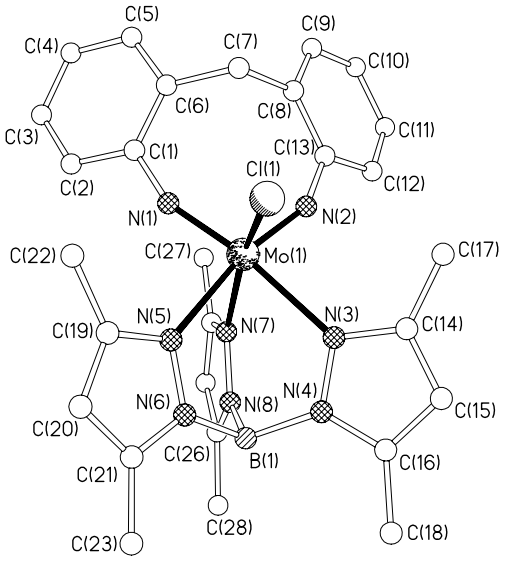

Fig. 1. Molecular structure of **1** without H atoms.

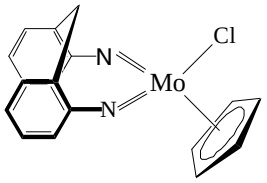
rivative **I** [3,4], where both *endo* and *exo* isomers are observed in solution (^{1}H NMR), for the bulkier Tp′ only the sterically more favourable *endo* isomer is isolated. Hence, the ^{1}H NMR of **1** exhibits signals at 5.65 and 5.87 ppm (ratio 1:2), and four methyl signals at 1.45, 2.40, 2.44 and 2.70 ppm (ratio 3:3:6:6) consistent with two sets of equivalent pyrazole rings. The two protons of the methylene bridge give rise to two doublets centred at 3.63 and 6.10 ppm ($^2J = 12.8$ Hz). The molecular structure of compound **1** · 2MeCN (obtained on recrystallisation of **1** from a saturated acetonitrile solution) was investigated by a single-crystal X-ray diffraction study (Fig. 1, Table 1).



I Endo isomer (for exo isomer Cp and Cl are interchanged)

The molybdenum centre is coordinated by one chloro and five nitrogen atoms in a pseudo-octahedral arrangement. One face of the coordination polyhedron is formed by the three N atoms of the Tp′ ligand; owing to the *trans* influence of the imido ligands, two of the Mo–N bonds formed by the Tp′ group are considerably longer than the third [2.332(2) Å for Mo–N(3) and 2.319(2) Å for Mo–N(5) as opposed to 2.179(2) Å for Mo–N(7)]. Similar behaviour has been described for the complexes [Tp′Mo(N^{t}Bu)$_2$Cl] and [Tp′Mo(NNPh$_2$)$_2$Cl] [7–15]. Compared to the respective values observed for the compound [MoCl$_2$\{[2,2′-(N$_2$)–C$_6$H$_4$]$_2$CH$_2$\}(dme)], the bond parameters of the two imido bonds of **1** seem

to reflect the steric pressure of the bulky Tp′ ligand, leading to a slight compression of the bis(imido) moiety: the N(1)–Mo–N(2) bond angle is 98.23(11)° as opposed to 100.7(5)° for [$MoCl_2${[2,2′-(N_2)–C_6H_4]$_2CH_2$}(dme)], and the Mo–N bonds are marginally elongated [1.755(2) and 1.765(2) Å as opposed to 1.725(7) Å].

Similarly, treatment of {[$(CH_2)_2$(2-$C_6H_4N)_2$]$MoCl_2$(dme)} with KTp′ affords red {[$(CH_2)_2$(2-$C_6H_4N)_2$](Tp′)MoCl} (**2**) in good yield (ca. 60%). As in **1**, solution studies of **2** (^{1}H,^{13}C NMR) are consistent with a 6-coordinate structure containing two sets of equivalent pyrazole rings. The four protons of the ethanediyl bridge appear as an AA′BB′ pattern at δ 3.44 and 3.73 ppm.

2.2. Arylimido complex

The reaction of KTp′ with one equivalent of [Mo(NAr)$_2$Cl$_2$(dme)] (Ar = 2,6-Pr$^i_2$C$_6$H$_3$) gave, after work-up, the green crystalline complex [Tp′Mo(NAr)$_2$Cl] (**3**) in ca. 70% yield. NMR spectra for **3** are consistent with the solid-state structure (Fig. 2, Table 1); the two equivalent pyrazolyl rings are *trans* to the imido ligands with the unique third pyrazolyl ring *trans* to the chloro ligand. The Pr^i groups of the arylimido ligand give rise to two septets (2 × 2H) and four doublets (4 × 6H) reflecting the restricted rotation about the C–N bond and their diastereotopic nature. Within the core geometry the N(1)–Mo–N(2) angle has opened up to 105.87(8)° to accommodate the two bulky arylimido groups. These imido groups are essentially equivalent, with bond lengths of Mo–N 1.7740(18) Å [N(1)] and 1.7805(17) Å [N(2)] and angles Mo–N(1)–C(1) = 173.06(16)° and Mo–N(2)–C(13) = 168.25(16)°; the softness of this angle has been noted previously [5,6]. The Mo–N(pyrazolyl) bonds *trans* to the two imido ligands [2.3278(18) and 2.2880(18) Å are longer than that *trans* to the chloro ligand [Mo–N(5) = 2.1915(18) Å], reflecting the relative *trans* influences of the imido and chloro groups.

2.3. Mixed-imido complex

A similar reaction with the mixed-imido complex [Mo(NAr)(NBu^t)Cl$_2$(dme)] affords brown–black prisms of [Tp′Mo(NAr)(NBu^t)Cl] (**4**). Crystals of **4** suitable for an X-ray determination were grown from acetonitrile at room temperature. The asymmetric unit comprises two independent molecules of the metal complex and two molecules of acetonitrile; the metal complex is a racemic mixture (exactly 50:50%) of *R* and *S* molecules, although the crystal structure itself is non-centrosymmetric. The molecular structure of one of the molecules is shown in Fig. 3, and selected bond lengths and angles in both are given in Table 1. The molybdenum possesses a pseudo-octahedral geometry, coordinated by four different groups. The two imido ligands are considered essentially linear [angles at N 159.9(3)°–177.2(3)°] and exert a *trans* influence on the Mo–N (pyrazolyl) bonds, the longest of which is 2.380(3) Å *trans* to the *tert*-butylimido group.

As in **3**, solution NMR studies indicate steric congestion about the arylimido ligand such that there is restricted rotation.

In conclusion, complexes **1**–**4** described herein are members of a family of pseudo-octahedral complexes having the same structural motif **I**, for which the Tp′ ligand coordinates facially with two elongated Mo–N bonds *trans* to the multiply bonded imido groups and a somewhat shorter bond *trans* to the chloro ligand.

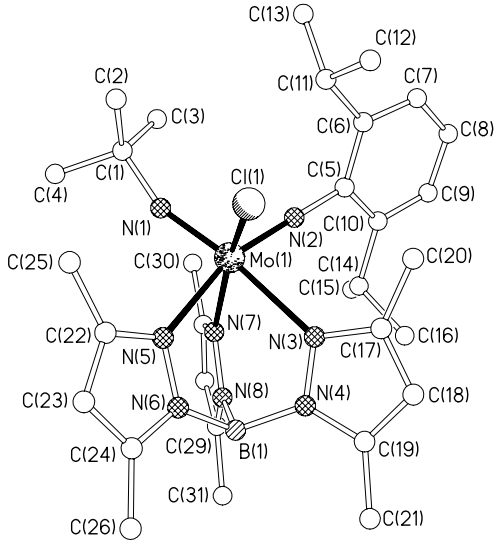

Fig. 3. The structure of one molecule of **4** without H atoms.

3. Experimental

3.1. General

All manipulations were carried out under an atmosphere of nitrogen using standard Schlenk and cannula techniques or in a conventional nitrogen-filled glove-box. Solvents were refluxed over an appropriate drying agent, and distilled and degassed prior to use. Elemental analyses were performed by the microanalytical services of the Department of Chemistry at Durham, Imperial College and Medac Ltd. NMR spectra were recorded on a Varian VXR 400 S spectrometer at 400.0 MHz (^{1}H) and 75.0 MHz (^{13}C); chemical shifts are referenced to the residual protio impurity of the deuterated solvent; IR spectra (nujol mulls, KBr windows), Perkin–Elmer 577 and 457 grating spectrophotometers. The ligand [$(CH_2)(2\text{-}C_6H_4NH_2)_2$] was prepared by the previously published procedure [16,17]. The ligand [$(CH_2)_2(2\text{-}C_6H_4NH_2)_2$] was obtained as its diphosphate salt and extracted from aqueous solution into ethyl acetate, dried ($MgSO_4$) and recrystallized from isopropyl alcohol. 2,6-Diisopropylaniline was distilled prior to use and stored in the dark. [$Mo(NAr)_2Cl_2(dme)$] and [$Mo(NAr)(NBu^t)Cl_2(dme)$] were prepared by literature methods [18,19]. All other chemicals were obtained commercially and used as received unless stated otherwise.

3.2. [$(CH_2)(2\text{-}C_6H_4N)_2$](Tp′)MoCl (1)

THF (20 cm^3) was added to {[$(CH_2)(2\text{-}C_6H_4N)_2$]$MoCl_2(dme)$} (0.5 g, 1.11 mmol) and KTp′ (0.38 g, 1.12 mmol) in a thick-walled 'rotaflo' ampoule. After refluxing for 12 h, the volatiles were removed in vacuo and the residue was extracted with hot MeCN (ca. 25 cm^3), affording on cooling deep red cubes of **1** (0.45 g, 65%). Found: C, 54.7; H, 5.7; N, 19.6%. $MoClN_8C_{28}H_{32}\cdot 2MeCN$ requires C, 54.5; H, 5.4; N, 19.9%. IR: 2254w, 2272w, 1625w, 1587w, 1540s, 1488w, 1463s, 1447s, 1413s, 1377s, 1370s, 1301w, 1279m, 1261m, 1218s, 1197s, 1160w, 1112m, 1074s, 1043, 980w, 969m, 872w, 855s, 812s, 783s, 764s, 748s, 721w, 692m, 673w, 665m, 661m, 655m, 598m, 508m. ^{1}H NMR ($CDCl_3$): δ 1.45, 2.40 (2 s, 2×3 H, pz-CH_3), 2.44, 2.70 (2 s, 2×6 H, pz-CH_3), 3.63 (d, 1 H, $^2J = 12.8$ Hz, CH_aH$_b$), 5.65 (s, 1 H, pz-CH), 5.87 (s, 2 H, pz-CH), 6.10 (d, 1 H, $^2J = 12.8$ Hz, CH$_a$H$_b$), 6.70–6.72 (m, 2 H, Ar–H), 7.03–7.12 (m, 4 H, Ar–H), 7.60–7.62 (m, 2 H, Ar–H); ^{13}C{^{1}H} NMR($CDCl_3$): chemically inequivalent pyrazol rings A and B (ratio 2/1), δ 12.5 (A):13.3 (B) (5-CH_3), 13.4 (B):14.8 (A) (3-CH_3), 35.2 (CH_2), 106.6 (A):106.7 (B) (C-4), 120.5, 126.2, 127.7, 130.0 (aryl = CH), 143.3 (A):145.6 (B) (C-3), 152.8 (A):152.9 (B) (C-5), 153.0 (= CCH_2), 156.1 (aryl = CN).

3.3. [$(CH_2)_2(2\text{-}C_6H_4N)_2$](Tp′)MoCl (2)

By a procedure analogous to that described for **1**, use of {[$(CH_2)_2(2\text{-}C_6H_4N)_2$]$MoCl_2(dme)$} (1.0 g, 2.16 mmol) and KTp′ (0.72 g, 2.14 mmol) afforded **2** as red blocks (0.8 g, 58%). Found: C, 54.7; H, 5.4; N, 18.3%. $MoClBN_8C_{29}H_{34}\cdot\frac{1}{2}MeCN$ requires C, 54.8; N, 5.4; N, 18.1%. IR: 2727w, 2540w, 2246w, 1659w, 1534w, 1544s, 1413s, 1306m, 1279m, 1262m, 1203s, 1155m, 1089m, 1069s, 1041s, 983m, 958m, 872w, 855m, 810s, 786s, 768s, 758m, 744s, 723m, 690m, 648m, 585w, 568w, 555w, 532w, 486m, 473m, 416s. ^{1}H NMR ($CDCl_3$): δ 1.98 (s, 3 H, pz-CH_3), 2.01 (s, 1.5H, 0.5MeCN), 2.42 (s, 6 H, pz-CH_3), 2.46 (s, 3 H, pz-CH_3), 2.57 (s, 6 H, pz-CH_3), 3.44 (AA′BB′, 2H, CH_2), 3.73 (AA′BB′, 2H, CH_2), 5.78 (s, 1 H, pz-CH), 5.84 (s, 2 H, pz-CH), 6.89–6.91 (m, 2 H, Ar–H), 7.07–7.18 (m, 4 H, Ar–H), 7.35–7.37 (m, 2 H, Ar–H). ^{13}C{^{1}H} NMR ($CDCl_3$): chemically inequivalent pyrazol rings A and B (ratio 2/1), δ 12.6 (A):13.3 (B) (5-CH_3), 15.3 (B):15.9 (A) (3-CH_3), 35.9 (CH_2), 106.9 (C-4), 125.3, 125.9, 128.7, 129.6, 143.1, 144.0, 145.9, 151.7, 152.8 (aryl C1), 155.0 (aryl CN).

3.4. [Tp′Mo(NAr)$_2$Cl] (3)

By a procedure analogous to that described for **1**, use of [$Mo(NAr)_2Cl_2(dme)$] (1.0 g, 1.65 mmol) and KTp′ (0.55 g, 1.64 mmol) afforded **3** as deep green prisms. Concentration and cooling of the mother-liquor afforded further crops. Overall yield 70%. Found: C, 60.1; H, 7.0; N, 14.9%. $MoBClN_8C_{39}H_{56}\cdot 1/2MeCN$ requires C, 60.1; H, 7.2; N, 14.9%. IR: 2359w, 2342w, 1543m, 1417m, 1315m, 1258s, 1242m, 1211s, 1174m, 1110m, 1097m, 1078m, 1062m, 1042m, 983w, 954m, 934w, 903w, 876w, 859w, 814m, 793m, 781m, 745m, 724s, 695w, 664w, 651w, 630w, 565w, 541w, 482w, 472w, 439w, 423w, 415w. ^{1}H NMR ($CDCl_3$): δ 0.34 (6H, d, $^3J_{HH}$ 6.4 Hz, CHMe_2), 0.56 (6H, d, $^3J_{HH}$ 6.8 Hz, CHMe_2) 1.41 (6H, d, $^3J_{HH}$ 6.8 Hz, CHMe_2), 1.42 (6H, d, $^3J_{HH}$ 6.8 Hz, CHMe_2), 1.98 (sept, 2H, $^3J_{HH}$ 6.8 Hz, CHMe_2), 2.23 (s, 6H, pz-CH_3), 2.24 (s, 3H, pz-CH_3), 2.35 (s, 6H, pz-CH_3), 2.50 (s, 3H, pz-CH_3), 4.25 (sept, 2H, $^3J_{HH}$ 6.8 Hz, CHMe_2), 5.68 (s, 2H, pz-CH), 5.91 (s, 1H, pz-CH), 6.83–6.89 (m, 4H, aryl H), 7.14 (dd, 2H, ^2J 7.2 Hz, ^3J 2.0 Hz, aryl H). ^{13}C{1H} NMR ($CDCl_3$): chemically inequivalent pyrazol rings A and B (ratio 2/1), δ 12.5 (A):12.7 (B) (5-CH_3), 15.3(A):16.3(B) (3-CH_3), 24.2, 24.7, 24.9, 26.6, 27.2, 28.4, 107.9(A):108.5(B) (C-4), 123.2, 124.9, 142.1, 142.7, 143.3, 144.7, 153.2, 154.7.

3.5. [Tp′Mo(NAr)(NBu^t)Cl] (4)

By a procedure analogous to that described for **1**, use of [$Mo(NAr)(NBu^t)Cl_2(dme)$] (0.75 g, 1.11 mmol) and KTp′ (0.38 g, 1.12 mmol) afforded **4** as brown–black

3.6. X-ray crystallography

Table 2 gives crystal data and other information on the structure determination and refinement for **1** · 2MeCN, **3** and **4** · MeCN. All measurements were made at 160K on a Siemens SMART CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) [20]. Cell parameters were refined from the observed ω angles of all strong reflections in each complete data set. Intensities were integrated from several series of narrow-frame exposures (0.3° in ω) covering more than a hemisphere of data in each case. Semi-empirical absorption corrections were applied, based on repeated and symmetry-equivalent reflections. The structures were solved by heavy-atom (**1** and **3**) or direct (**4**) methods, and refined by full-matrix least-squares on F^2 values of all measured data [21]. Non-hydrogen atoms were assigned anisotropic displacement parameters; isotropic hydrogen atoms were included with riding-model constraints. No disorder was detected. For the non-centrosymmetric structure of **4** · MeCN, the absolute structure parameter refined to −0.01(2), confirming the correct assignment [22].

4. Supplementary material

Crystallographic data for the structural analysis of **1** · 2MeCN, **3**, and **4** · MeCN have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 216483, 216484 and 216485, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ,

Foreword

Polyhedron Symposia-In-Print, number 26 Scorpionate and Related Ligands

The correct choice of ligands is of critical importance to the inorganic chemist. This Special Issue of POLYHEDRON is devoted to a particularly important class of ligands – so-called "Scorpionate Ligands" – and is dedicated to their creator, Jerry Trofimenko. Scorpionate ligands have a rather humble origin with the synthesis of simple pyrazolyboron compounds by Trofimenko at DuPont in the 1960s. However, Trofimenko quickly realized that some of these compounds, namely the anionic poly(pyrazolyl)borate derivatives, had the ability to be effective ligands (*via* coordination through the pyrazolyl nitrogen atoms) for a variety of metals while he paved a pathway for others to follow. Applications of poly(pyrazolyl)borate ligands are now very wide spread, covering areas that include bioinorganic chemistry, organometallic chemistry, and materials chemistry. In part, the large success of the poly(pyrazolyl)borate ligand system is due to the ability to tailor the ligands with a multitude of substituents, thereby varying the electronic and steric properties at a metal center. More recent developments of the Scorpionate system have included the incorporation of groups that provide sulfur and phosphorus donors which complement the nitrogen donors of poly(pyrazolyl)borate ligands. This issue of POLYHEDRON presents a compilation of articles that feature the applications of Scorpionate and related ligands as a means of paying due homage to the person that started it all. Thanks Jerry!

Scorpionates: genesis, milestones, prognosis

Swiatoslaw Trofimenko *

Department of Chemistry and Biochemistry, The University of Delaware, Newark, DE 19716, USA

Received 5 May 2003; accepted 6 August 2003

Abstract

The development of the polypyrazolylborate/scorpionate ligand system is traced from its inception, through its early and later stages of development, primarily on the basis of the author's experiences and contributions.

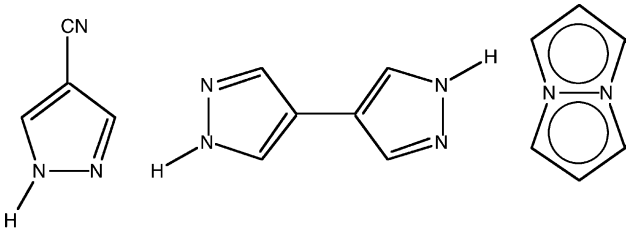
Keywords: Scorpionates; Polypyrazolylborates; Coordination chemistry; Nitrogen ligands

1. Introduction

Polypyrazolylborate/scorpionate chemistry is a very large, and still growing area. Since its inception until now, there have been about 2000 papers published on polypyrazolylborates, and complexes of seventy elements of the periodic table have been reported. A number of reviews of this area exist covering time-spans, or concentrating on certain elements, or unified by some other feature. However, in this article I would like to recount, on a personal basis, some background and little-known details, as to how this whole field came into being, focusing on my personal experiences and contributions.

2. History

When I joined the Du Pont company at the end of 1959, this was still the heady time of cyanocarbon research, and my initial assignment was to prepare the first percyanoalkane, which I did, synthesizing hexacyanoethane [1]. Shortly thereafter, I developed the first practical synthesis of what was called "cyanoform" [2], and which actually turned out to be dicyanoketeneimine, rather than tricyanomethane [3]. This led to the synthesis of 4-cyanopyrazole, **1**, my first direct experience with this ring system, which I found rather attractive [4]. Other contributions to pyrazole chemistry included 4,4′-bipyrazolyl [5], **2**, made via 1,1,2,2-ethanetetracarboxaldehyde [6], as well as pyrazolo[1,2a]pyrazole, or 3a, 6a-diazapentalene, **3**, an intriguing ligand whose coordination chemistry has not been explored at all [7,8].



1 **2** **3**

My contact with boron came from working in the group of Earl Muetterties on photochemical nucleophilic substitution reaction in perhalogenated polyhedral boranes, mainly $B_{12}X_{12}^{2-}$ [9,10]. At the time, it was standard policy in the Du Pont Central Research Department that each chemist was absolutely expected, in addition to the assigned project, to explore on a part-time basis some unrelated new area of chemistry. In later years this practice was no longer observed.

3. Earliest developments

It was in this search for something novel, that I decided to work on boron–pyrazole chemistry. What made me

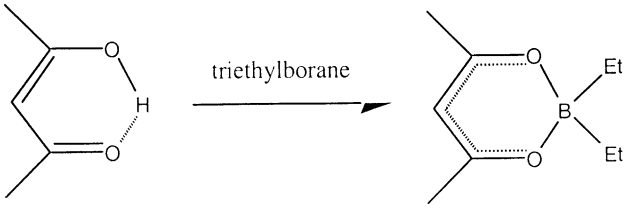
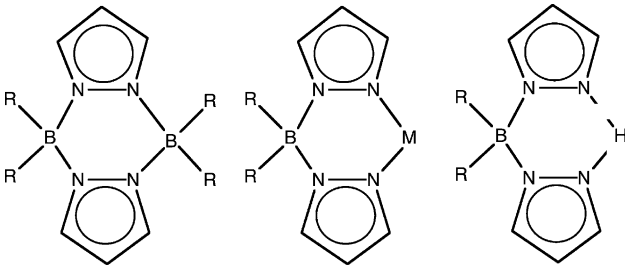
select this area? Around that time, Fred Hawthorne had published a communication on the reaction of triethylborane with acetylacetone, which yielded a rather stable compound, **4**, in which the diethylboryl group had taken the place of the chelated hydrogen bridge [11]. In other words, the diethylboryl cation took on a metalloid role.



4

I thought that it would be rather interesting to explore such BR_2 bridging in intermolecular context, the hydrogen-bridged pyrazole dimer being the molecule of choice. Considering the three possible bridging moieties: hydrogen, metal and a BR_2 group, one arrives at six different possibilities for the two bridges. If we fix one BR_2 group to act as a hinge, then at the other side one could have another BR_2 group, a metal or a hydrogen. These combinations can be readily recognized now as a pyrazabole, **5**, a scorpionate metal complex, **6**, and a scorpionate free acid, **7**, respectively.



5 **6** **7**

My first attempt in this area was to prepare tris (pyrazolyl)borane which, as a 1,3-dipole, was expected to dimerize to 4,4,8,8-tetrakis(pyrazolyl)pyrazabole, and this just had to be a good difunctional chelating agent.

$$2\,B(pz)_3 \rightarrow (pz)_2B(pz)_2B(pz)_2 \qquad (1)$$

And so I set out to make this compound by bubbling BCl_3 into molten pyrazole. This generated lots of HCl and heat, and when the reaction subsided, I dissolved everything in water, and added to the strongly acidic solution ferric chloride. It was gratifying to see an immediate formation of bright dark red color; moreover the product could be extracted into chloroform, from which red crystals could be obtained. However, elemental analysis was consistent with a species $B(pz)_4FeCl_2$, involving four (rather than the expected three) pyrazolyl groups per boron atom, and so the first assumption was that we had a bidentate chelated $FeCl_2$ species, $(pz)_2B(pz)_2FeCl_2$. Soon, however, I realized hat the red material was the complex ion pair $Fe[B(pz)_4]_2^+$ $[FeCl_4]^-$, involving the $[B(pz)_4]$ ligand chelating in κ^3 fashion, since the $[FeCl_4]^-$ ion could be readily replaced with hexafluorophosphate, maintaining the cation intact. That the iron was octahedrally coordinated followed not only from spectroscopic data, but also from Stuart–Briegleb models, which showed that the $B(pz)_2M$ entity was in a deep boat conformation, and that the third pz group could also readily coordinate to the metal ion. The structure of this very first polypyrazolylborate complex was not determined until very recently (Fig. 1) [12]. It was also quite surprising that the B–N bond was not cleaved in this strongly acidic medium.

As for 4,4,8,8-tetrakis(pyrazolyl)pyrazabole, the original target molecule of this experiment, it was synthesized at a later date by the reaction of pyrazole

$$2\,Me_3N{-}BH_3 + 6\,Hpz \rightarrow (pz)_2B(pz)_2B(pz)_2 + 2\,Me_3N + 6\,H_2 \qquad (2)$$

with trimethylamine–borane and, yes, it was a good bisbidentate chelating agent forming, inter alia, the cationic complex $[(\eta^3\text{-allyl})Pd(pz)_2B(pz)_2B(pz)_2Pd(\eta^3\text{-allyl})]^{2+}$ [13].

But my attention was now directed at the novel ligand system of polypyrazolylborates, which I proceeded to prepare in a much more civilized manner, by the reaction of pyrazole with borohydride ion, making in this fashion via temperature control bis, tris-, and tetrakis-pyrazolylborates, exploring their coordination chemistry with first-row metal ions, isolating via acidification the free acids, and using those to prepare otherwise unavailable tetraalkylammonium salts [14,15]. I also showed that 1,2,4-triazole forms the $HB(trz)_3$ ligand, and that its $Co[HB(trz)_3]_2$ complex is water soluble, in contrast to the hydrophobic $Co[HB(pz)_3]_2$. In studying the reaction of KBH_4 with variously substituted pyrazoles, it turned out that the reaction of 3,5-dimethylpyrazole, and

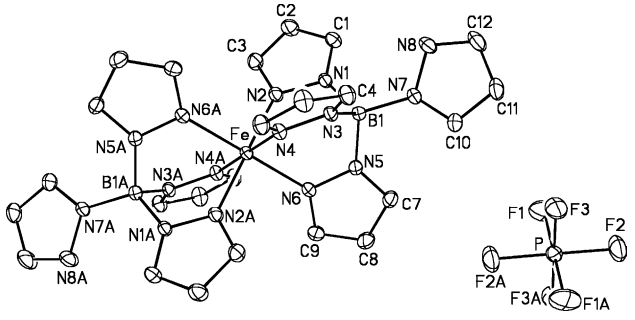


Fig. 1. View of the complex $Fe[B(pz)_4]_2PF_6$.

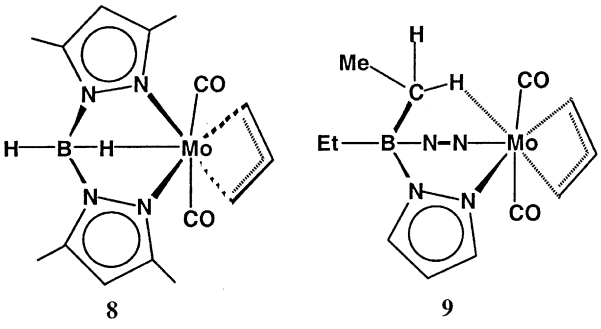
of other 3,5-disubstituted pyrazoles, stops at the tris-stage [16]. Don Eaton and Peter Jesson joined the effort, studying the physical aspects of the novel compounds, and finding interesting examples of spin equilibria in the iron(II) complexes [17–19]. This early work was featured in the C&E News [20]. Du Pont management was sufficiently impressed by my discovery to let me work on polypyrazolylborates full time, and also providing me with a full-time technician (in those days two chemists normally shared one technician on a half-time basis).

Next came the exploration of polypyrazolylborates in complexes containing additional other ligands: carbonyls, olefins, η^3-allyls [21,22], nitrosyls, arylazo groups [23], in other words the world of half-sandwiches was entered, and it became clear that in many ways the new tris(pyrazolyl)borate ligands, being uninegative tricoordinate six-electron donors, resembled the Cp ligand, while the bis-ligands could be considered analogues of acetylacetonate ion although, unlike M[acac]$_2$ complexes, the M[R$_2$B(pz)$_2$]$_2$ compounds were always monomeric. In an interesting reaction of allyl bromide with the anions {Mo[H$_2$B(3,5-Me$_2$pz)$_2$](CO)$_4$}$^-$ and {Mo[Et$_2$B(pz)$_2$](CO)$_4$}$^-$, there were obtained what appeared to be 16-electron complexes of surprising stability, Mo[H$_2$B(3,5-Me$_2$pz)$_2$](CO)$_2$(η^3-allyl), **8**, and Mo[Et$_2$B(pz)$_2$](CO)$_2$(η^3-allyl), **9**, respectively [24,25]. A structure determination of **8** showed that the pseudo-axial B–H formed a bridge to the metal, thus achieving an 18-electron configuration [26]. This was not entirely unexpected, in view of other known examples of B–H bridging.



8 9

-N=N- is the hidden pyrazolyl group

More interesting was **9** where the ethyl group should have had no affinity for the metal. Yet in its NMR spectrum one of the ethyl methylenes was shifted into the hydridic range, and unusually low-frequency C–H stretch peaks were observed in the IR. These features disappeared upon coordination of a donor molecule. Stuart–Briegleb models indicated that in **9** the pseudo-axial methylene hydrogens would indeed be sitting on top of the metal. When I gave a seminar at MIT on this new chemistry, I asked if someone would do an X-ray structure to confirm the presence of this unusual bonding. Al Cotton agreed, and later on demonstrated that there is indeed an interaction – now called "agostic" – but between only one of the methylene hydrogens and the metal [27]. In solution, however, the two methylene hydrogens exchanged rapidly on the NMR time scale. So these were not 16-electron complexes after all, and only in the case of Mo[Ph$_2$B(pz)$_2$](CO)$_2$(η^3-allyl) was there a true 16-e structure [28]. The agostic theme was later revisited in the octahedral cobalt complex Co[(cyclooctane-1,5-diyl)B(pz)$_2$]$_2$ which contained two agostic C–H–Co bonds [29].

But apart from the above studies, most of the research in this area by myself and by others, was with the tridentate trispyrazolylborate ligands [HB(pz)$_3$] and, especially, with [HB(3,5-Me$_2$pz)$_3$]. Jon McCleverty and Joe Templeton, each carved out large specialty research areas involving [HB(3,5-Me$_2$pz)$_3$] complexes of low-valent Mo and W, while John Enemark and Charlie Young in Melbourne used the same ligand in high-valent Mo and W chemistry related to various enzymes.

Even at this early stage it became apparent that just modest steric effects played a significant role in the chemistry of polypyrazolylborate ligands. For instance, while the [Mo[HB(pz)$_3$](CO)$_3$]$^-$ anion reacted readily at room temperature with allyl halide, [Mo[HB(3,5-Me$_2$pz)$_3$]CO$_3$]$^-$ was totally inert. In the reaction with diazonium salts, the former gave arylazo derivatives, but the latter only the (η^2-COAr) compounds.

$$[\mathrm{Mo[HB(pz)_3](CO)_3}]^- + \text{allyl bromide} \rightarrow \mathrm{Mo[HB(pz)_3](CO)_2}(\eta^3\text{-allyl}) \quad (3)$$

$$[\mathrm{Mo[HB(3,5\text{-}Me_2pz)_3]CO_3}]^- + \text{allyl bromide} \rightarrow \text{no reaction} \quad (4)$$

$$[\mathrm{Mo[HB(pz)_3](CO)_3}]^- + [\mathrm{ArN_2}]^+ \rightarrow \mathrm{Mo[HB(pz)_3](CO)_2(N{=}NAr)} \quad (5)$$

$$[\mathrm{Mo[HB(3,5\text{-}Me_2pz)_3](CO)_3}]^- + [\mathrm{ArN_2}]^+ \rightarrow \mathrm{Mo[HB(pz)_3](CO)_2}(\eta^2\text{-COAr}) \quad (6)$$

4. Hiatus and second generation of scorpionates

My work on polypyrazolylborates ended in 1973 when I was transferred from Central Research to other departments, working on olefin polymerization catalysis, market development and, finally, to the International Department: overseas, first to Geneva/Switzerland, then to Warsaw/Poland, as manager of the DuPont office. When the Russians invaded Afghanistan, the Du Pont manager of the Moscow office was pulled back to Warsaw, bumping me all the way to Parkersburg, West Virginia. This was a plant site, where my test tube was a

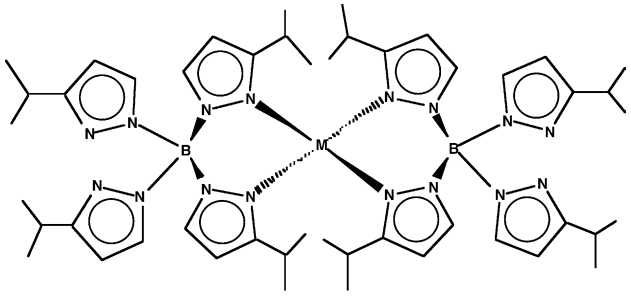
100-gallon nylon autoclave. It was there, that I was soon able to work intermittently on the second generation of trispyrazolylborate ligands, synthesizing those with 3-t-butyl and 3-phenyl substituents. This would have been impossible without the help from my colleagues at Central Research, especially Jeff Thompson. It was truly gratifying to see how steric effects introduced a new dimension in the coordination chemistry of polypyrazolylborates. Finally, in 1985, I was transferred back to Wilmington, and was able to publish the "second generation" ligand work [30,31]. From that point on it was possible to continue a little bit of polypyrazolylborate research, but it was on the margin of other projects in various departments. Under these circumstances I had to reconcile myself with being a gunsmith rather than a hunter, i.e., synthesizing new ligands, but letting others use them to do their exciting research. During this time a fruitful collaboration with Arnie Rheingold commenced and is continuing to this day, despite his departure from Delaware to the West Coast. My move to the University of Delaware after retirement from Du Pont in 1996 enabled me to resume scorpionate work within the group of Klaus Theopold as a Visiting Scholar. It is there that I wrote the book "Scorpionates: The Coordination Chemistry of Polypyrazolylborate Ligands" [32], and developed a number of novel scorpionates. But back to the earlier days.

Dave Curtis came up in 1983 with the very useful abbreviation "Tp" for the trispyrazolylborate ligand, $HB(pz)_3$ [33,34], and I built on this, introducing in my 1993 review a systematic abbreviation system which could be adapted to most types of substitution on the Tp ligand, and which greatly facilitated writing chemical formulas for Tp complexes [35]. In the case of the most commonly used ligand, Tp^{Me2}, an alternative and preferred abbreviation, became Tp*. In that review I also coined the term "scorpionates". It was clear to me that a term for this ligand class was needed which would permit the reader to visualize its coordinative behavior, since no such insight was offered by the cumbersome systematic name "poly(pyrazol-1-yl)borates". In looking for an analogy in nature, the South-American three-toed sloth came to mind first, whose Latin name is "Bradypus tridactylus", and the term "bradypate" did not sound bad at all. Unfortunately, the three claws of this sloth were all curved in the same direction, and thus did not reflect the coordinative behavior of the Tp ligand. Then it occurred to me that the scorpion would be an almost ideal analogue, especially, when taking into account that the sting (the third coordinating site) is not absolutely mandatory, but optional – as happens in the case of complexes where the Tp ligand is only κ^2.

The second generation polypyrazolylborates proved to be quite popular, and accounted for a number of striking new developments in coordination chemistry, such as stabilizing monomeric alkylmagnesium, alkylzinc and alkylberyllium species, novel oxygen complexes, and zinc-based enzyme models, this work being associated with Ged Parkin, Klaus Theopold and Heinrich Vahrenkamp.

A distinctly different family of Tp ligands contained a 3-isopropyl substituent [36,37]. It was intermediate in steric hindrance between the 3-t-butyl and 3-methyl ligands, and had a number of interesting features. On the one hand it permitted isolation of LMX complexes, on the other it also formed octahedral L_2M compounds, although this was always accompanied by ligand rearrangement, which could be borotropic or metallotropic, converting one 3-isopropyl substituent per ligand to the 5-isomer. This, at times bothersome feature, could be circumvented by using a Tp ligand derived from 3,5-diisopropylpyrazole, which precluded such rearrangement, or made it degenerate [38]. The 3,5-diisopropyl Tp ligand was used extensively by the late Nobumasa Kitajima, and is favored today by his successor, Munetaka Akita.

Another unusual feature was the coordination behavior of tetrakis(3-isopropyl)pyrazolylborate, which coordinated only in κ^2 fashion. However, unlike other bispyrazolylborate ligands, which formed square planar complexes with Ni, Cu and Cr, and tetrahedral with Co, Fe and Zn, this ligand gave exclusively tetrahedral complexes **10** across the whole first row of transition metals.



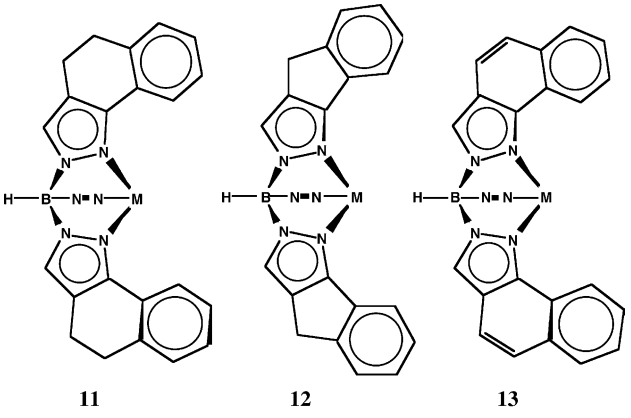
10

We compared this behavior with a series of tetrakis ligands containing 3-cycloalkyl groups ranging from cyclopropyl to cyclohexyl [39–42]. Those with cyclohexyl and cyclopentyl substituents behaved like their isopropyl analogues. The cyclopropyl substituent showed no steric effect, and acted like the parent Tp and pzTp, respectively. Cyclobutyl was special: its tris ligand permitted the isolation of both, tetrahedral LMX complexes, and also of unrearranged octahedral L_2M species. Even the L_2M complexes from its tetrakis ligand were also octahedral.

A long-standing puzzle in the scorpionate area begged to be solved: it appeared, on the basis of some

indirect evidence, that in polyindazolylborates indazole was bonding to boron anomalously through the *more hindered* nitrogen atom, contrary to expectations. We checked this out, and structurally characterized indazolylborate complexes based on a variety of substituted indazoles. It turned out that indazole itself, and indazoles with substituents in the 3, 4, 5, and 6 positions, or any combination thereof, formed the more hindered B–N bond, while indazoles with a 7-substituent formed exclusively the less hindered B–N bond [43–45]. In fact, 7-t-butylindazole formed the most sterically hindered homoscorpionate ligand with a cone angle of over 280°.

In the Tp^{Ph} ligand the phenyl group was freely rotating which was sometimes desirable, and sometimes not. It was, therefore, of interest to modify this ligand so that the phenyl would be in a fixed rotameric disposition. To achieve coplanarity with the pyrazolyl ring, we tethered the phenyl group to the 4-position by a variety of tethers [46]. An ethene tether, **11**, did not provide strict coplanarity, as it zig-zagged across the pyrazolyl ring placing the phenyl group at an angle of about 20°. A methylene tether, **12**, achieved coplanarity, but at the same time pulled back the phenyl group, increasing the "bite" of the ligand. Strict coplanarity without bite change was obtained with an ethyne tether, **13**, making each pyrazolyl arm totally rigid.



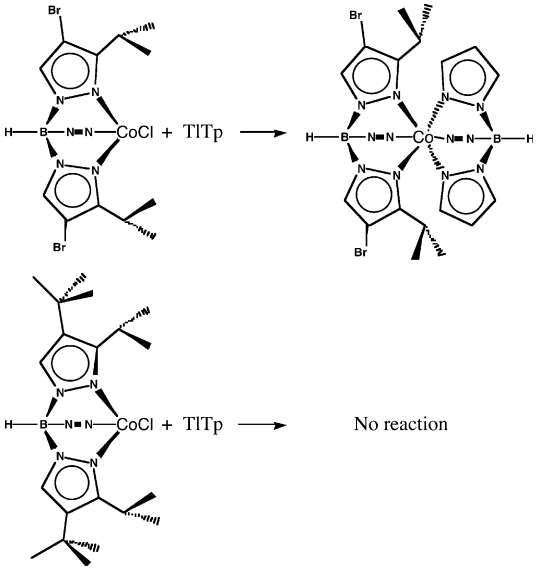
11 **12** **13**

(-N=N- is the third, hidden pyrazolyl group)

This resulted in altered chemistry. While the 3-phenyl Tp ligand permitted the formation of a normal $Mo[Tp^{Ph}](CO)_2(\eta^3$-methallyl) complex, in which the ligand was κ^3, the analogous complex with the ethyne tether did form a similar complex, but in it the ligand was κ^2, with an agostic B–H–Mo bond to achieve an 18-electron structure. Coordination of the third pyrazolyl arm was prevented by the steric interference of the η^3-methallyl group [47].

To make the 3-phenyl group orthogonal to the pyrazolyl plane, I tried to prevent its rotation by using a 3-mesityl [48], or also a 3-(9-anthryl) substituent [49]. The mesityl group was indeed orthogonal in a number of structurally characterized complexes. It was interesting that in the synthesis of this ligand a mixture was obtained containing 85% of the 3,3,5 ligand, and only 15% of the symmetric 3,3,3. However, heating the Tl salt of this mixture above 240 °C, converted everything to the 3,3,3 isomer! In the ligand with the 9-anthryl substituent, the anthryl group deviated from orthogonality, because of non-bonding interference of the peripheral hydrogens of the anthryl groups.

In an attempt to control the rotameric disposition of asymmetric 3-substituents by the presence of bulky 4-substituents, the coordination chemistry of 3-tolyl and 3-isopropyl Tp ligands which also contained a t-butyl group in the 4-position was studied [50]. The effect of the 4-t-butyl group was not major in the case of the 3-tolyl group, as it still could partially swing back-and-forth. However, the 3-isopropyl group became locked into a rigid rotameric conformation with its two methyl groups forking towards the coordinated metal, and thus behaving like a t-butyl group. $Tl[Tp^{iPr,4tBu}]$ also showed the largest Tl^{203}–C^{13} coupling, 218 Hz, surpassing those found in all the known $Tl[Tp^{tBu,R}]$ ligands. Moreover, its reactions did not resemble those of other Tp ligands with a 3-isopropyl substituent, as shown below:



Another interesting new Tp ligand was based on tribromopyrazole [51]. The cone angle of Tp^{Br3} was similar to the popular Tp*, but the ligand was electronically quite different due to the nine electron-withdrawing bromine atoms. It was also the only known Tp ligand devoid of C–H bonds, and thus very suitable for the IR study of coordinated hydrocarbon ligands. Its copper(I) complex was remarkably active in C–H activation catalysis, as was shown by Pedro Pérez [52].

Wishing to extend the dencity of the Tp ligand beyond three by including additional donor atoms on the

3-substituent, we and Jon McCleverty prepared independently the same N6 hexadentate ligand, Tp^{Py} and found it to form beautiful icosahedral $M[Tp^{Py}]_2$ cationic complexes with trivalent lanthanides and actinides [53]. We also synthesized a hexadentate N3O3 ligand, by placing 3-carboxypyrrolidido substituents on Tp [54]. The lanthanide complexes of this ligand showed in solution all pyrazolyl arms NMR-equivalent, but in the crystal one ligand was κ^6, and the other one only κ^4 with an uncoordinated pyrazolyl arm, so that the coordination around the metal ion was 10, as there was no agostic B–H–M bonding. However, when the 3-substituent was carboxy-t-butylamido, both ligands were κ^6 in the crystal [55]. The $Tp^{CONHtBu}$ ligand, while uninegative by itself, has the potential for deprotonation of one, two or even three amido hydrogens, and thus increasing its charge from minus one to minus four. This aspect of its chemistry is still to be explored.

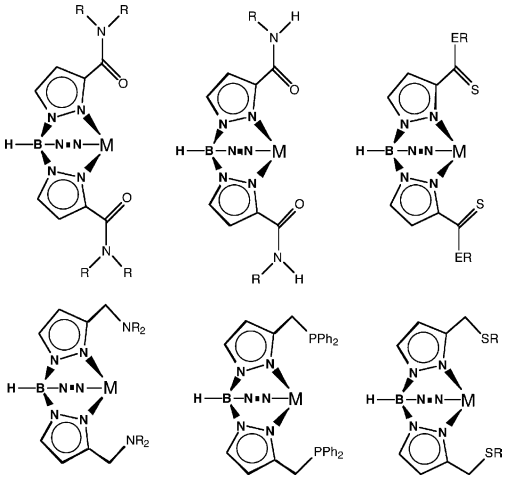
5. Non-classical scorpionates

Although polypyrazolylborates are the oldest and classical examples of the scorpionate ligand system, related scorpionate ligands may be derived from them by replacement of either the central boron, or of pyrazole. A number of such examples have been covered [35], and new ones are appearing ever more frequently. Neutral ligands are best exemplified by geminal polypyrazolylalkanes, which were introduced back in 1970, [56] and are currently being studied in detail by Dan Reger.

In recent years a veritable cornucopia of boron-based scorpionate ligands has emerged. They are generally of the type $[Ph_2B(CH_2Z)_2]^-$ and $[PhB(CH_2Z)_3]^-$, where Z can be a variety of donor functionalities. Examples of Z = SR for $[Ph_2B(CH_2Z)_2]^-$ [57], and for $[PhB(CH_2Z)_3]^-$ [58], of Z = PPh_2 for $[Ph_2B(CH_2Z)_2]$ [59,60], for $[PhB(CH_2Z)_3]^-$ [61,62], and for Z = NMe_2 [63], have already been reported, while those with Z = OR, SeR and AsR_2 are still unknown. Furthermore, one can envisage ligands containing more than one type of donor arms, such as Z_2Z', and Z,Z′,Z″. In addition, coexistence of CH_2Z arms on boron with pyrazolyl or other azolyl groups is also possible, and ligands of the type $[PhB(CH_2SR)_2(pz)]^-$ have also been prepared [64]. The chelate ring size is another adjustable variable, leading to ligands such as $[RB(CH_2Z)_2(ER)]^-$, where E = O, S, Se, or appropriate phosphino or amino functionalities. Related polyrazolylborate examples, containing two pyrazolyl bridges and one dimethylamino [65], or arylmercapto [66], or alkoxy bridge [67], have been reported earlier. While chelates derived from the above ligands involve five- and six-membered rings between boron and the coordinated metal, other similar ligands lead to eight-membered rings. They are hydrotris(mercaptoimidazolyl)borate [68,69], and the related hydrotris(thioxotriazolyl)borate [70]. The former contains twisted eight-membered rings in its complexes, which are always sulfur bonded, while the latter is ambidentate and bonds either through sulfur (with bismuth or tin), or through nitrogen (sodium or manganese). A still different ligand, dihydrobis(thioxotriazolinyl)borate, bonds in tridentate fashion through two sulfurs plus an agostic hydrogen bond [71].

6. Prognosis

So where do we go from here? As someone quipped: ''predictions are difficult, especially about the future''. Nevertheless, I will venture a guess in what areas is further growth likely to occur. First of all, the ''classical'' polypyrazolylborates, while mature ligands, still have room for expansion, especially as heteroscoropionates, containing pyrazolyl arms with additional donor atoms, some of which are shown as homoscorpionates below.



The potential of ligands that can range from tridentate to hexadentate with charges from −1 to −4, i.e. those containing deprotonatable 3-CONHR, or similar substituents, should not be underestimated. The synthesis of Tp ligands with different pyrazoles is another sub-area that may be explored [72].

The area of non-classical scorpionates will surely experience growth, including ligands containing also one or two pz^x groups, in view of the rich portfolio of available diversely substituted pyrazoles. Finally, I am also still hoping that someone will eventually synthesize the dinegative polypyrazolylberyllate ligands, $[R_2Be(pz^x)_2]^{2-}$ and $[RBe(pz^x)_3]^{2-}$, which should yield neutral complexes of tetravalent metals, and other exciting compounds.

All in all, we are dealing with a vast and promising area, the riches of which are yet to be fully exploited by the scorpionate community.

Received 7 May 2003; accepted 6 August 2003

Abstract

The compound potassium tetrakis(2-mercaptothiazolyl)borate was prepared and characterized in solution and in the solid state. The structure crystallizes in the non-centrosymmetric space group $F\bar{4}3c$ (No. 219) with two independent molecules in the asymmetric unit. In spite of the fact that two molecules are very similar enantiomorphs, the transformation relating the two moieties does not coincide with any of those belonging to the centrosymmetric super space group $Fd\bar{3}c$ (No. 228). The packing gives rise to big holes between the tetrakis(2-mercaptothiazolyl)borate anions, of mean diameter ~9 Å, which are filled by clusters of K^+ and H_2O.

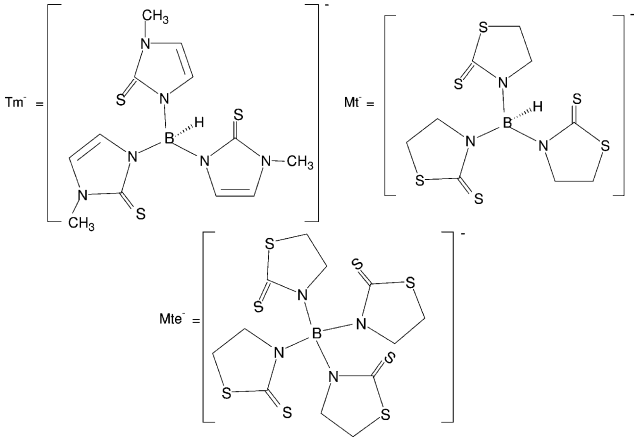
Keywords: S,N ambidentate borate ligands; Synthesis; X-ray structure; Open frame material

1. Introduction

Tripodal borate S,N ligands such as hydrotris(thioxoimidazolyl)borate, Tm^-, [1,2] and hydrotris(2-mercaptothiazolyl)borate, Mt^-, [3] are softer than the pyrzolyl analogues [4] and as such are more useful to be used as supporting ligands with soft transition metals. The tetrakis analogue offers the opportunity to bind additional metal ions and accordingly we were able to prepare tetrakis(2-mercaptothiazolyl)borate, Mte^-, as the potassium salt, that was characterized by spectroscopic methods, elemental analysis and by X-ray crystallography. According to the X-ray studies, the diameter of the cavities that are created by the packing of the anions rings, among other data, is in the range normally found for zeolite type of compounds.



2. Experimental

2.1. General comments

KBH_4 was purchased from Fluka and 2-mercaptothiazoline, from Aldrich. All the reagents were used as received. Elemental analyses (C, H, N) were performed with a Perkin–Elmer mod. PE-2400 CHN instrument.

IR spectra were recorded on a Perkin–Elmer 283B instrument. ^{1}H and ^{13}C spectra were recorded on a Bruker Avance DPX200 spectrometer operating at room temperature, using tetramethylsilane as an internal reference. ^{11}B NMR spectrum was recorded on a Bruker Avance DPX400 spectrometer operating at room temperature, using $BF_3 \cdot Et_2O$ as an internal reference.

2.2. Synthesis

2.2.1. Potassium tetrakis(2-mercaptothiazolyl)borate, KMte

Finely divided KBH_4 (0.10 g, 2.3 mmol) and 2-mercaptothiazoline (1.35 g, 11.5 mmol) were placed, together with a magnetic stirring bar, into a Schlenk flask. The flask was connected to a volumetric device and placed into a bath resting on a heating and stirring plate. The mixture was heated to 100 °C where upon evolution of H_2 commences. The temperature was controlled at 165 °C until 92.0 mmol of H_2 (203.6 mL) had been evolved. Then the mixture was allowed to cool to room temperature and dichloromethane was added. This mixture was stirred for 15 min. The solution was separated and this process was repeated three times. The remaining white solid was dried under vacuum and was washed with three 20-mL portions of THF. The solutions were collected and THF was allowed to evaporate under room temperature. $KMte \cdot 2H_2O$ was obtained in 79.9% yield. ^{1}H NMR (200 MHz, $CDCl_3$): 4.00 (t, NCH_2), 3.58 (t, SCH_2); ^{13}C NMR (200 MHz, $CDCl_3$): δ C=S not observed 51.05 (NCH_2), 33.77 (SCH_2); ^{11}B NMR (δ, $BF_3.Et_2O$): −5.21. *Anal.* Calc. (Found) for $C_{12}H_{20}BKN_4O_2S_8$: C, 25.80 (25.75); H, 3.58 (3.50); N, 10.03 (10.02)%.

2.3. Crystal structure determination

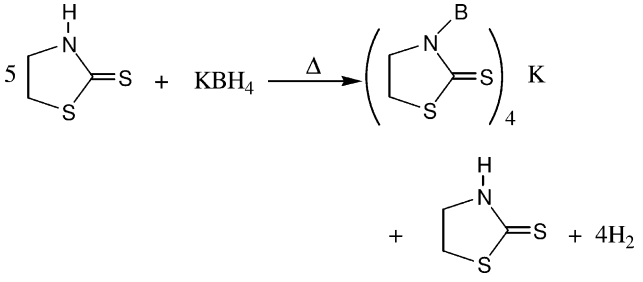
The measurement was made at 120 K on an Enraf–Nonius Kappa-CCD diffractometer (95 mm CCD camera on κ-goniostat) with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The temperature was controlled using an Oxford Cryosystem low temperature device. Data collection (φ scans and ω scans with κ offsets) were made using the COLLECT [5]; integration and scaling of the reflections was performed with the HKL DENZO-SCALEPACK system of programs [6]. The final unit cell parameters were based on all reflections using HKL SCALEPACK [6]. Absorption corrections were carried out using the multi-scan method [7]. The structures were solved using direct methods with SHELXS-97 [8]. The models were refined by full-matrix least-squares procedures on F^2 using SHELXL-97 [9]. The program WINGX was used to analyse and prepare the data for publication [10]. Crystal data, data collection procedures, structure determination methods and refinement results are summarized in Table 1. The ORTEP's were prepared using the ORTEP-3 for Windows [11].

Table 1
Crystal data and structure refinement for KMte

Formula weight	554.68
Temperature (K)	120(2)
Wavelength (Å)	0.71073
Crystal system	cubic
Space group	$F\bar{4}3c$
Unit cell dimensions (Å)	$a = 30.0302(8)$
Volume (Å^3)	27081.6(12)
Z	48
D_{calc} (Mg/m^3)	1.633
Absorption coefficient (mm^{-1})	0.993
$F(000)$	13 632
Crystal size (mm)	$0.10 \times 0.10 \times 0.10$
θ range for data collection	1.36–25.00°
Index ranges	$-35 \leqslant h \leqslant 32$, $-35 \leqslant k \leqslant 32$, $-28 \leqslant l \leqslant 35$
Reflections collected	19 207
Independent reflections	2002 [$R_{int} = 0.0500$]
Completeness to $\theta = 25.00°$	99.7%
Maximum and minimum transmission	0.9072 and 0.9072
Refinement method	Full-matrix least-squares on F^2
Data/parameters	2002/135
Goodness-of-fit on F^2	1.118
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0331$, $wR_2 = 0.0916$
R indices (all data)	$R_1 = 0.0424$, $wR_2 = 0.1108$
Absolute structure parameter	0.09(13)
Largest difference peak and hole (e Å^{-3})	0.684 and −0.244

3. Results and discussion

It is very difficult to control the volume of hydrogen evolved in such type of reactions, Eq. (1), in order to obtain the desired compound, since the temperature range where the reaction occurs, for each type of compound, bis, tris and tetrakis, is close and the reactions are done in the solid state.



(1)

Indeed, this is especially true in the preparation of the tetrakis compound, as it is always obtained as a mixture with the hydrotris compound. However, as KMte is soluble in THF, it was easily separated. It is a very hygroscopic compound. For this reason it is obtained as

$KMte \cdot 2H_2O$ by allowing a THF solution to evaporate at room temperature. The NMR data indicated that the four rings were equivalent, as just two triplets were observed for the hydrogens next to sulfur and nitrogen, at 3.58 and 4.00δ, respectively, in agreement with literature results [1], and was confirmed by the solid-state structure of the compound, as discussed below.

3.1. Molecular structure of KMte

The structure crystallizes in the non-centrosymmetric space group $F\bar{4}3c$ (No. 219) with two independent molecules in the asymmetric unit, Fig. 1. Comparison of these molecules by the method of Kabsch [12] showed them to be very similar, related by an improper orthogonal transformation and with a root mean square deviation between homologous atoms of 0.047 Å. These facts suggested that the crystal could belong to the centrosymmetric super-group $Fd\bar{3}c$ (No. 228), with just one molecule per asymmetric unit. Closer scrutiny, however, showed this not to be the case because the affin transformation relating the two moieties did not coincide with any of those belonging to the space group. It also turned out that the Flack parameter [0.08(12)] was quite sensitive to structure inversion thus permitting the assigning of the absolute structure in the non-centrosymmetric space group. An interesting crystallographic feature is the highly symmetric space group found for this compound. It is important to emphasize that in the Cambridge Structural Database (CSD) [13], only 25 of the structures deposited crystallize in the $F\bar{4}3c$ space group. This number represent less than 0.01% of the total one.

The mercaptothiazolyl ring geometry, Fig. 1, is very similar to the 1,3-thiazolidine-2-thione structure [14]. The five-member rings A and B present an envelope conformation with C(12) and C(22) in their respective flip point. The C(12), S(11) and B(1) deviate 0.497(6), 0.189(6) and 0.279(4) Å, respectively, from the least-squares plane passing through C(11), C(13), N(1) and S(12). In the same way, the C(22), S(21) and B(2) deviate 0.460(6), 0.131(6) and 0.199(4) Å, respectively, from the equivalent least-square plane passing through molecule B.

The asymmetric unit consists of one mercaptothiazolyl ring for each anion molecule A and B. The whole anions are "generated" by the symmetry $\bar{4}$ passing through the boron atom. Like the asymmetric unit the whole anion geometry of A and B are exactly the same. Fig. 2 is an ORTEP view of molecule A. The rings are bound to the boron through the nitrogen atoms N(1)–B(1) = 1.568(3) Å and N(2)–B(2) = 1.561(3) Å. The geometry around boron is an almost regular tetrahedron with a mean ∠N–B–N = 109(2)°. This value is the same for both molecules. The selected geometric parameters are showed in Table 2.

In each unit the potassium ion is coordinated to six water molecules. Four of these belong to neighbouring $K(H_2O)_6$ units. One of the K–O bond distance is shorter than the sum of the ionic radii of $K^+ + O^{2-}$, 2.73 Å [15]; K(1)–O(11) = 2.453(3) Å in molecule A and K(2)–O(21) = 2.451(3) Å in molecule B. The other K–O bond distances are longer, but still smaller than the sum of the covalent radii of K + O = 2.69 Å [16]; K(1)–O(12) = 2.890(4) Å in molecule A and K(2)–O(22) = 2.909(4) Å in molecule B. Potassium still does interact with the sulfur atoms of the anions rings. These inter-

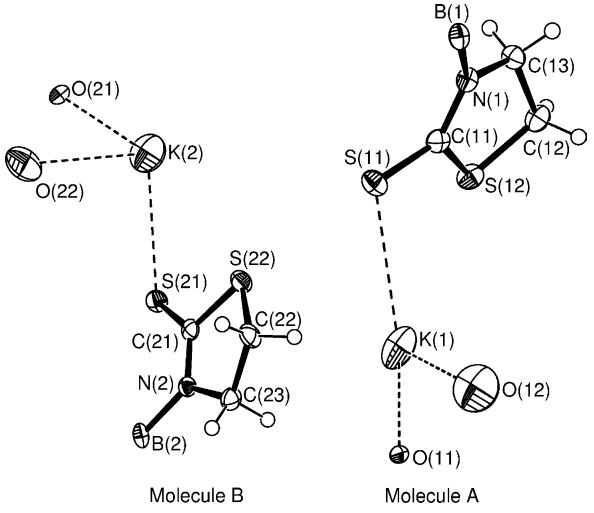


Fig. 1. An ORTEP3 view of $KMte \cdot 2H_2O$ showing the atom-labelling scheme of the two molecules present in the asymmetric unit. Displacement ellipsoids drawn at the 50% probability. H atoms are represented by circles of arbitrary size.

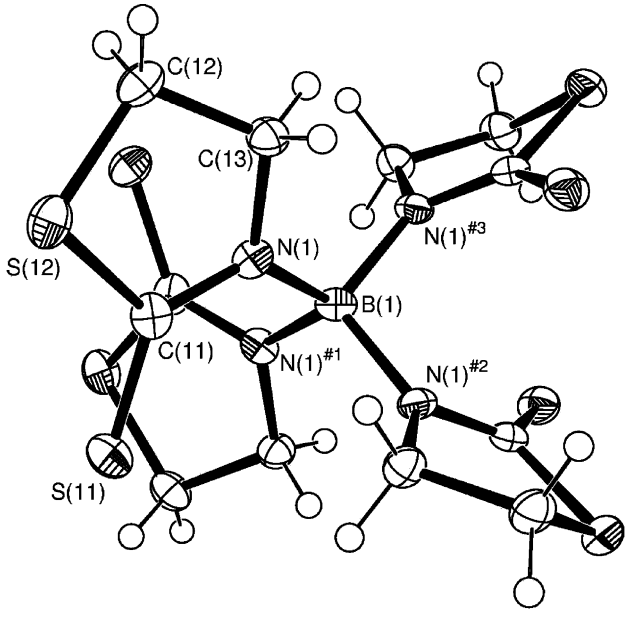

Fig. 2. A ORTEP3 view of the Mte^- anion (molecule A). Displacement ellipsoids drawn at the 50% probability. (*Symmetry codes*: #1, $-x+3/2$, $-y+3/2$, $\mathscr{Z}$; #2, $y+3/2$, x, $-z+2$; #3, y, $x+1/2$, $x+1$, $z+2$).

actions are longer than the sum of the ionic radii of $K^+ + S^{2-} = 3.17$ Å [15], and one of them is much longer than the other; K(1)–S(11) = 3.379(2) and K(1)– S(12) = 3.923(3) Å in molecule A and K(2)– S(21) = 3.388(2) and K921)–S(22) = 3.916(3) Å in molecule B. A view focusing on the potassium solvate sphere is shown in Fig. 3.

The X-ray diffraction analysis of KMt [3] revealed that there is no interaction between the potassium ion and the donor sulfur atoms. For Mte^- the same behaviour was expected. However, as stressed previously, there are interactions between potassium and the sulfur atoms. These interactions can be accounted by crystal packing effects. These effects can lead to structural differences and variations in bond distances and angle parameters for molecules belonging to the same unit cell [17]. Recently, a study that compared geometric data for crystal structures, for which more than one molecule of complex is present per crystallographic asymmetric unit, was performed [18]. This study allowed a quantification of the crystal packing effect on molecular structures. The determined metal–ligand bond distance deviations were found to be in the range 0.01–0.02 Å and for the bond angles the range was 1°–2° (or 3°). In the present work the bond distance differences (mean values), for the longer K–O bonds (K(1)–O(12) and K(2)–O(22)), within the two molecules is 0.019. Bigger deviations were found between the bond angles: e.g., O(11)–K(1)–O(12) and O(21)–K(2)–O(22), 0.28 Å. According to the previously mentioned work, these differences are due to crystal packing effects and we believe that these effects are accounted for the potassium–sulfur interactions in the present work, as they are not expected to exist, like in the Mt^- ligand [3b].

Fig. 4 is a packing of the structure on plane *ab*. In this unit cell fraction the anion generated by molecule B is in the central position. As can be observed there is an alternation between molecules A and B along the unit cell directions. Each anion is octahedrally surrounded by four other anions and two holes. When the central anion is a molecule A, the four neighbour anions are molecules B and vice versa. The big holes observed between the

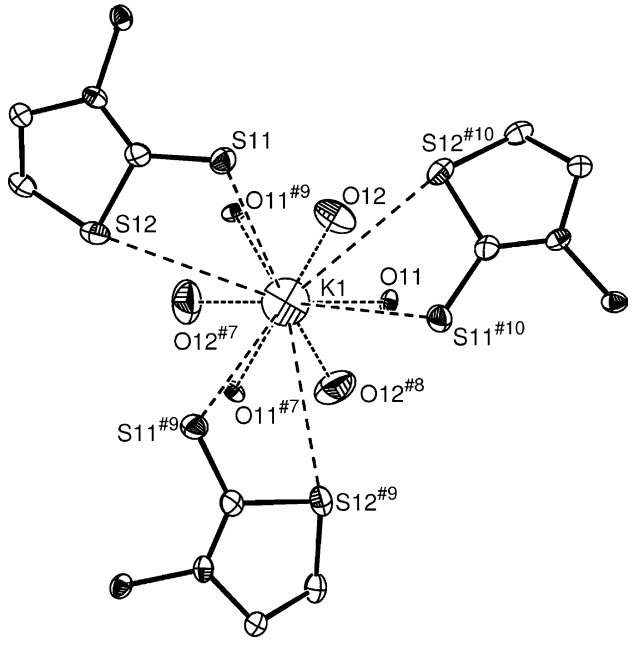

Fig. 3. A ORTEP3 view of potassium coordination environment (molecule A). Displacement ellipsoids drawn at the 50% probability. (*Symmetry codes*: #7, *y*, *z*, *x*; #8, $-z+3/2$, $x+3/2$, *y*; #9, $-z+3/2$, *x*, $-y+3/2$; #10, *y*, $-z+3/2$, $-x+3/2$).

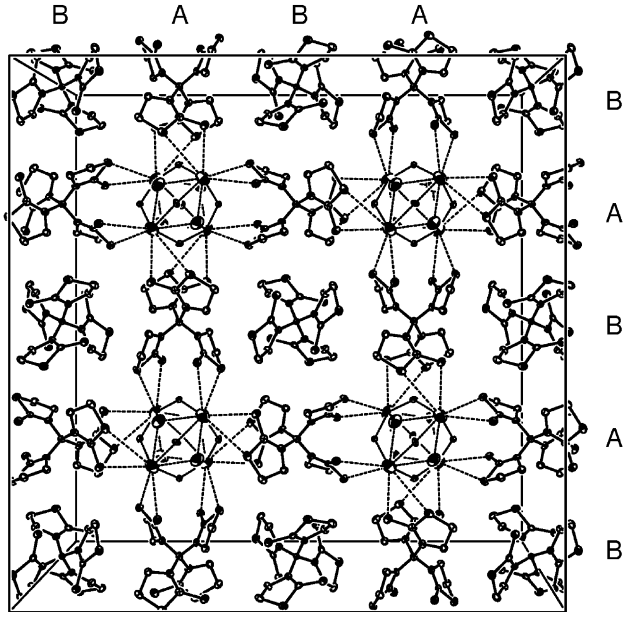

Fig. 4. Packing on plane *ab* ($-1.15 < x < 1.15$; $-1.15 < y < 1.15$; $0.12 < z < 0.38$ is shown). Displacement ellipsoids drawn at the 50% probability.

anions Mte^- have a mean diameter of ~9 Å. Each cavity is filled by a cage-shape cluster constituted by four sites containing K^+ cations and seven sites containing water's oxygens. Cluster with atoms belonged to molecule A is octahedrally surrounded by six Mte^- anions formed by atoms belonged to molecule A and vice versa. Either for molecule A or B, the separation between neighbour hole centres is about 15 Å.

4. Conclusions

The density and size of the cavities of the structure studied in the present work are similar to the ones in zeolite compounds. Also, as these, there are cations and water molecules inside the molecular cavities in order to compensate for the framework negative charge. The potassium and oxygen sites within the holes are not completely occupied. Several models were tested and the best one point to occupancies of 0.75 for K(1) and K(2), 0.5 for O(11) and O(21), and 0.75% for O(12) and O(22) sites. In spite of the non-completeness, if the whole unit cell was considered, the ratio K/Mte^- and K/H_2O are 1/1 and 1/2, respectively. Therefore, the empirical formula obtained from the present X-ray data is $K[BC_{12}H_{12}N_4S_8]\cdot 2H_2O$. The present X-ray data do not permit to find the water's hydrogens.

5. Supplementary material

A table of complete crystallographic data, tables of fractional atomic coordinates for all atoms, complete list of bond distances and angles and tables of anisotropic displacement parameters have been deposit with the Cambridge Crystallographic Data Center, CCDC No. CCDC 206571 for KMte. Abstract

This paper presents the syntheses, crystal structures and spectroscopic properties of a series of half-sandwich nickel(II) complexes with hydrotris(3,5-dimethylpyrazolyl)borate and azide or thiocyanate, [Tp*Ni(pz*)$_2$(N$_3$)] (**1**), [Tp*Ni(pz*)(SCN)(H$_2$O)] (**2**) and [Tp*Ni(SCN)(CH$_3$OH)$_2$] (**3**) (Tp*: hydrotris(3,5-dimethylpyrazolyl)borate; pz*: 3,5-dimethylpyrazole). Compound **1** crystallizes in the triclinic system, $P\bar{1}$ space group (No. 2), $a = 10.2957(11)$ Å, $b = 11.5080(12)$ Å, $c = 13.6748(15)$ Å, $\alpha = 81.993(2)°$, $\beta = 72.999(2)°$, $\gamma = 74.533(2)°$, $Z = 2$, $R_1 = 0.0454$, $wR_2 = 0.1272$. The nickel(II) ion in **1** is coordinated to six nitrogen atoms of Tp* and azide ion to form a distorted N$_6$ octahedron. The structure of **2** is roughly determined by X-ray crystal diffraction and shown two structurally independent [Tp*Ni(pz)(SCN)(H$_2$O)] units. The nickel(II) ion in **2** is six-coordinated to five nitrogen atoms of Tp*, pz*, thiocyanate and one oxygen atom of water molecule to form a N$_5$O octahedral environment. Compound **3** crystallizes in the monoclinic system, $P2_1/c$ space group, $a = 13.416(4)$ Å, $b = 11.964(3)$ Å, $c = 14.636(4)$ Å, $\beta = 96.195(5)°$, $Z = 4$, $R_1 = 0.0379$, $wR_2 = 0.1079$. The coordination environment of nickel(II) ion in **3** is better to be described as the N$_4$O$_2$ octahedron made up of three nitrogen atoms of Tp*, one nitrogen atom of thiocyanate and two oxygen atoms of coordinated methanol molecules. The half-sandwich compound [Tp*Ni(η_2-O$_2$N)(CH$_3$OH)]$_4$ (**4**), which has been previously reported in a short communication, has the nickel(II) center with N$_3$O$_3$ coordination environment. The influences of N_3^-, SCN^- and NO_2^- in all these half-sandwich nickel(II) complexes were discussed in this paper.

Keywords: Nickel(II) complexes; Crystal structures; Hydrotris(pyrazolyl)borate complexes; Coordination environment; Scorpionates

1. Introduction

The scorpionate ligand, hydrotris(pyrazolyl)borate ligand (Tp^R), is widely used in the design of functional molecules, catalysis of chiral induced asymmetric synthesis, liquid crystal materials, molecular ''electronic devices'' and biomimetic chemistry [1–3]. The half-sandwich mononuclear complexes with monohydrotris(pyrazolyl)borate ligand and small molecules or anions can be considered as the model complexes of metalloenzymes such as carbonic anhydrase (CA) [4–8], nitrite reductases (NiR) [9–11], Hemocyanin (Hc) [12,13] and blue copper proteins [14], and as the precursors for synthesis of various multinuclear model complexes [15]. Since the less hindered hydrotris(pyrazolyl)borate ligands Tp and Tp* have strong tendency to form stable and inert full-sandwich complexes [M^{II}Tp$^R_2$], the half-sandwich mononuclear complexes are relatively difficult to obtain [16,17]. However it has been found that the full-sandwich complexes [M^{II}Tp$_2$] and [M^{II}Tp*$_2$] with less hindered hydrotris(pyrazolyl)borate ligands Tp and Tp* have some reactivity under suitable conditions [18,19]. Recently, several methods to synthesize the half-sandwich complexes were summarized [18,20]. We prepared mononuclear half-sandwich nickel(II) complexes with less hindered hydrotris(3,5-dimethylpyrazolyl)borate

doi:10.1016/j.poly.2003.11.011

and nitrite, [Tp*Ni(η_2-O_2N)(CH_3OH)] (**4**) (Tp*: hydrotris(3,5-dimethylpyrazolyl)borate) by reaction of $Ni(ClO_4)_2 \cdot 6H_2O$ with KTp* and $NaNO_2$ [18]. In the complex, NO_2^- was coordinated in an asymmetric nitrito-O,O′-bidentate coordination mode and the nickel(II) ion was in N_3O_3 octahedral environment. In the present paper, we reported three novel mononuclear half-sandwich nickel(II) complexes with less hindered hydrotris(3,5-dimethylpyrazolyl)borate ligand (Tp) and azide or thiocyanate, [Tp*Ni(pz*)$_2$(N_3)] (**1**), [Tp*Ni(pz*) (SCN)(H_2O)] (**2**) and [Tp*Ni(SCN)(CH_3OH)] (**3**) (pz*: 3,5-dimethylpyrazole). The coordination environments of nickel in these complexes were N_6 (**1**), N_5O (**2**), N_4O_2 (**3**) and N_3O_3 (**4**), respectively.

2. Experimental

2.1. Materials

The scorpionate ligand KTp* was synthesized according to the literature method [19]. The purity was confirmed by IR, MS-FAB and elemental analysis. Other chemicals were reagent grade and used as received.

2.2. Physical measurements

Analyses for C, H and N were carried out on a Perkin–Elmer analyzer at the Institute of Elemental Organic Chemistry, Nankai University. Infrared spectra on KBr pellets were recorded on a Shimadzu IR-408 spectrophotometer in the range of 4000–600 cm^{-1}. UV–Vis spectroscopy in MeOH were recorded on a Shimadzu UV-2401 PC UV–Vis recording spectrophotometer in the range of 200–1000 nm. Mass spectrum analysis was performed at the Central Laboratory of Nankai University on VG ZAB-HS spectrometer.

2.3. Synthesis

2.3.1. [Tp*Ni(pz*)$_2$(N_3)] (*1*)

A solution of NaN_3 (0.6 mmol. 39.1 mg) in 1 ml water is added to 5 ml methanol solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.2 mmol, 73.1 mg). The mixture is stirring for 2 h at room temperature. A solution of KTp* (0.2 mmol, 67.3 mg) in 10 ml methanol is added to the mixture and stirred for another 10 h, and the precipitates are filtered. The green crystals suitable for X-ray structure analysis are obtained by slow evaporation of filtrate. The yield is found to be 79% based on the metal salts. *Anal*. Calc. for $C_{25}H_{38}BN_{13}Ni$ (**1**): C, 50.88; H, 6.49; N, 30.85. Found: C, 50.81; H, 6.35; N, 30.53%.

2.3.2. [Tp*Ni(pz*)(SCN)(H_2O)] (*2*)

A solution of KSCN (0.6 mmol, 58.3 mg) in 1 ml water is added to 5 ml methanol solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.2 mmol, 73.1 mg). The mixture is stirring for 2 h at room temperature. Then, 10 ml methanol solution of KTp* (0.2 mmol, 67.3 mg) is added to the mixture and stirred for 10 h, and the precipitates are filtered. The blue micro-crystals are obtained by slow evaporation of filtrate. The yield is found to be 73% based on the metal salts. *Anal*. Calc. for $C_{21}H_{32}BN_9NiOS$ (**2**): C, 47.76; H, 6.11; N, 23.87. Found: C, 47.40; H, 5.85; N, 23.60%.

2.3.3. [Tp*Ni(SCN)(CH_3OH)$_2$] (*3*)

The synthetic method of **3** is similar with **2** only the molar ratio ($Ni(ClO_4)_2 \cdot 6H_2O$: KSCN: KTp*) is different (1:1.5:1). An 1 ml aqueous solution of KSCN (0.3 mmol, 30.1 mg) is added to 5 ml methanol solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.2 mmol, 73.1 mg). The mixture is stirring for 2 h at room temperature. A solution of KTp*(0.2 mmol, 67.3 mg) in 10 ml methanol is added to the mixture and stirred for 10 h, and the precipitates are filtered. The yield is found to be 58% based on the metal salts. *Anal*. Calc. for $C_{18}H_{30}BNiN_7O_2S$ (**3**): C, 45.22; H, 6.28; N, 20.51. Found: C, 45.26; H, 6.35; N, 20.58%.

2.4. X-ray crystallography

Intensity data for single crystals of complexes **1**, **2** and **3** were collected on a BRUKER SMART 1000 CCD detector with graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods using the program SHELXS 97 [21] and subsequent Fourier difference techniques, and refined anisotropically by full-matrix least-squares on F^2 using SHELXL-97 [22].

A green single crystal of **1** having the approximate dimensions $0.30 \times 0.20 \times 0.15$ mm was mounted on a glass fiber. Cell parameters were determined from a least-squares refinement on the setting angles from 25 centered reflections in the range from 1.56° to 25.03° at 298(2) K. The intensities of the $\pm hkl$ reflections were measured up to $\theta_{max} = 25.03°$; the ω–2θ scan technique was employed. The index range was $-12 \leqslant h \leqslant 10$, $-11 \leqslant k \leqslant 13$ and $-16 \leqslant l \leqslant 15$. No absorption correction was made during processing. Crystal parameters and structure refinements were summarized in Table 1. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were set in calculated positions and refined as riding atoms with a common fixed isotropic thermal parameter. The residual maximum and minimum in the final Fourier difference maps were 0.379 and −0.242 e $Å^{-3}$. The value of the goodness-of-fit is 1.040.

The single crystal structure analysis of **2** was carried out. Unfortunately, the single crystals are sensitive to X-ray and the intensity of standard reflections strongly declined. The present results obtained from a crystal having the approximate dimensions $0.40 \times 0.30 \times 0.30$ mm. The intensities of the $\pm hkl$ reflections were

$-14 \leqslant k \leqslant 14$ and $-17 \leqslant l \leqslant 14$. Crystal parameters and structure refinements were summarized in Table 1. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were set in calculated positions and refined as riding atoms with a common fixed isotropic thermal parameter. The residual maximum and minimum in the final Fourier difference maps were 0.417 and −0.455 e $Å^{-3}$. The value of the goodness-of-fit was 1.045.

3. Results and discussion

3.1. Synthesis of the complexes

The scorpionate ligand KTp* can easily form full-sandwich complexes [MTp*$_2$]. The full-sandwich complexes [MTp*$_2$] as well as other substituted complexes [$M^{II}Tp_2^{R1,R2}$] have been considered stable and inert. Although the full-sandwich complexes have the abilities to induce some reactivity in suitable conditions [18,19], it is still the main problem to obtain the half-sandwich mononuclear complexes. Recently, several methods to synthesize the half-sandwich complexes were summarized: (i) the use of bulky substituents (R); (ii) the addition of a Tp^R salt to an excess amount of metal salt; and (iii) the use of salts with a bidentate ligand such nitrate and carboxylate [20]; and (iv) the use of the TpTl salts for the preparation of TpM complexes [3,23]. Combining (ii) and (iii), we prepared **4** by reaction of excess amount of $Ni(ClO_4)_2 \cdot 6H_2O$ with KTp* and $NaNO_2$. In the complex, NO_2^- was in an asymmetric nitrito-O,O′-bidentate coordination mode. For **1**, **2** and **3**, the metal salt $Ni(ClO_4)_2 \cdot 6H_2O$ was firstly added into NaN_3 or KSCN and then reacted with KTp*. The expected mononuclear half-sandwich complexes containing one Tp* ligand and one N_3^- or SCN^- ligand were obtained. For **1** and **2**, one or two pz*, which came from the partly decomposition of KTp* during reaction, were also coordinated to the nickel ion. Similar phenomenon was observed in other complexes with hydrotris(pyrazolyl)borate and hydrotris(pyrazolyl)methane ligands [24–27].

3.2. Structural description

The structures of all complexes have been determined by single-crystal X-ray diffraction. Selected bond lengths and angles of **1**, **2** and **3** were listed in Table 2.

The ORTEP drawing of **1** was shown in Fig. 1. The Ni(II) ion in **1** was coordinated to six nitrogen atoms, three from Tp* ligand, two from two pz* ligands and one from azide ion, to form a distorted octahedron. The average bond lengths of Ni–N(Tp*) and Ni–N(pz*) were 2.094 and 2.158 Å, respectively. The bond length of Ni–N(N_3) is 2.117 Å. In **1**, N(13) of N_3^- was connected by weak intermolecular hydrogen bond with hydrogen atoms of two pyrazole ligands of adjacent complex molecule to form a quasi-dimeric structure. The molecular packing was shown in Fig. 2. The nearest Ni···Ni distances was 8.280 Å. The hydrogen bond lengths of N(8)–H(8)···N(13) and N(10)–H(10)···N(13) were 2.136 and 2.138 Å while the angles of N(8)–H(8)–N(13) and N(10)–H(10)–N(13) were 158.79° and 159.66°, respectively. The hydrogen bond lengths and angles were listed in Table 3.

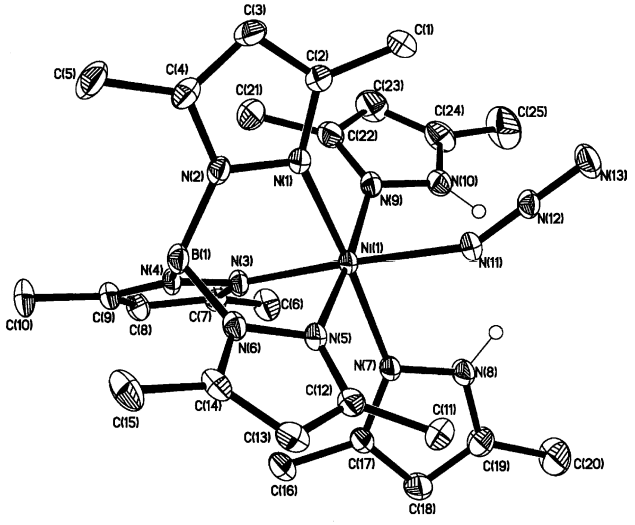

Fig. 1. ORTEP drawing of [Tp*Ni(pz*)$_2$(N_3)] (**1**).

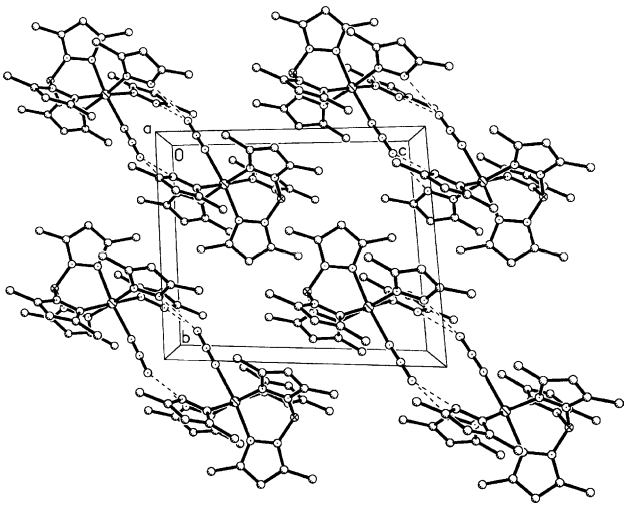

Fig. 2. Molecular packing of $[Tp^*Ni(pz^*)_2(N_3)]$ (**1**).

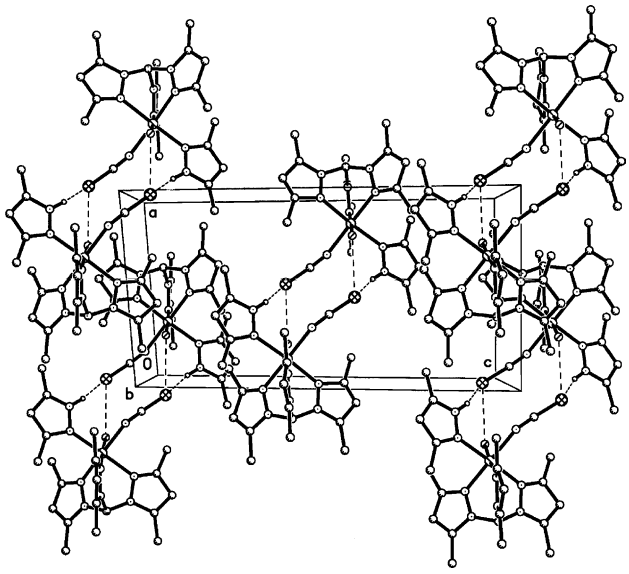

Fig. 4. Molecular packing of $[Tp^*Ni(pz^*)(SCN)(H_2O)]$ (**2**).

The structure of **2** consisted two structurally independent [Tp*Ni(pz*)(SCN)(H_2O)] units and was shown in Fig. 3. The Ni(II) ion in **2** was coordinated to three nitrogen atoms from Tp*, one nitrogen atom from pz*, one nitrogen atom from thiocyanate and one oxygen atom from water molecule to form the N_5O octahedral environment. The average bond lengths of Ni–N(Tp*) and Ni–N(pz*) were 2.083 and 2.096 Å, respectively. The bond length of Ni–N(SCN) and Ni–O(H_2O) were 2.067 and 2.147 Å, respectively. S(1) and S(2) of SCN^- were connected by weak intermolecular hydrogen bonds with hydrogen atoms on pyrazole ring of adjacent complex molecules, and O(1) and O(2) of water molecules were connected by weak intermolecular hydrogen bond with hydrogen atoms of pyrazole to form a quasi-dimeric structure. The molecular packing was shown in Fig. 4. The nearest Ni···Ni distances was 7.360 Å.

The ORTEP drawing of **3** was shown in Fig. 5. The coordination environment of Ni(II) ion in **3** was better to be described as N_4O_2 octahedron. The Ni(II) ion was coordinated with four nitrogen atoms of Tp*, thiocyanate and two oxygen atoms of methanol molecules. The average bond length of Ni–N(Tp) was 2.083 Å. The bond lengths of Ni–N(SCN) and Ni–O(CH_3OH) were 2.054 and 2.161 Å, respectively. S(1) of NCS^- was connected by weak intermolecular hydrogen bond with hydrogen atoms of O(2) in adjacent complex molecule to form a quasi-dimeric structure. The molecular packing was shown in Fig. 6. The nearest Ni···Ni distances

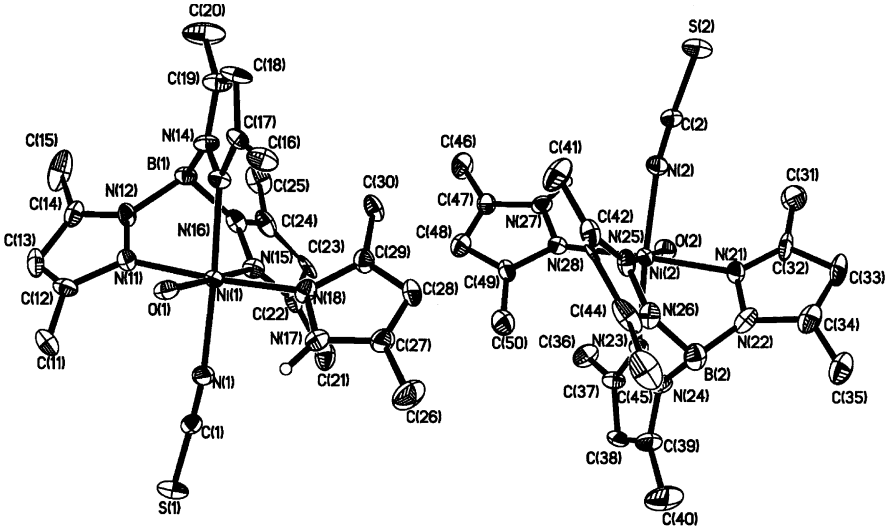

Fig. 3. ORTEP drawing of $[Tp^*Ni(pz^*)(SCN)(H_2O)]$ (**2**).

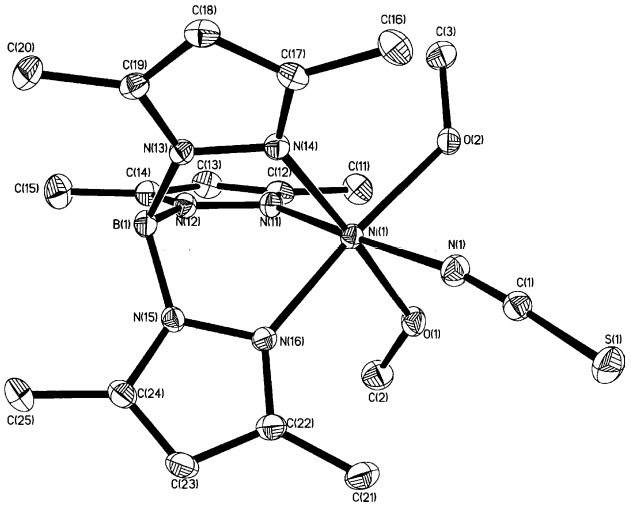

Fig. 5. ORTEP drawing of $[Tp^*Ni(NCS)(CH_3OH)_2]$ (**3**).

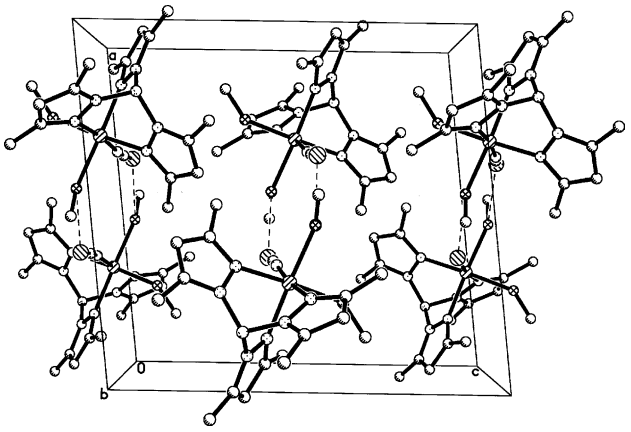

Fig. 6. Molecular packing of $[Tp^*Ni(NCS)(CH_3OH)_2]$ (**3**).

was 7.420 Å. The hydrogen bond length and angle of O(2)–H(2D)···S(1) were 2.630 Å and 126.74°, respectively. The hydrogen bond lengths and angles were also listed in Table 3.

The average bond lengths of Ni–N(Tp*) and Ni–N(pz*) of **2** and **3** were shorter than that of **1**, but longer than that of analogous $[Tp^*Ni(\eta^2\text{-}O_2N)(CH_3OH)]$ (**4**) previously reported [18]. The bond length of Ni–N(N_3) in **1** was longer than Ni–N(SCN) of **2** and **3**. The bond length of Ni–O(H_2O) in **2** was shorter than Ni–O(CH_3OH) in **3** and longer than that of **4**. The average bond lengths of these complexes became shorter with the decreasing numbers of coordinated oxygen atoms. The nickel(II) ions were in N_6-coordinated environment for **1**, N_5O-coordinated environment for **2**, N_4O_2-coordinated environment for **3** and N_3O_3-coordinated environment for **4**, which were shown in Fig. 7. The intermolecular hydrogen bonds were found for all complexes and to form quasi-dimeric structure. Selected structural parameters were listed in Table 4.

3.3. Spectroscopic properties

The IR spectra of complexes **1**–**4** were very similar for the ligand Tp* and the data were listed in Table 5. The typical stretch frequency of ν_{B-H} moved from 2430 cm^{-1} in the free ligand to 2510 cm^{-1} for **1**, 2520 cm^{-1} for **2**, 2485 cm^{-1} for **3** and **4**, respectively. The stretch frequency of $\nu_{N\equiv N}$ of N_3^- and $\nu_{C\equiv N}$ of SCN^- were observed at 2090 cm^{-1} for **1**, 2110 cm^{-1} for **2** and 2085 cm^{-1} for **3**, respectively.

The UV–Vis spectra of complexes **1**–**4** were also similar and the data were listed in Table 5. In the UV range, three strong absorptions appeared. They can be assigned

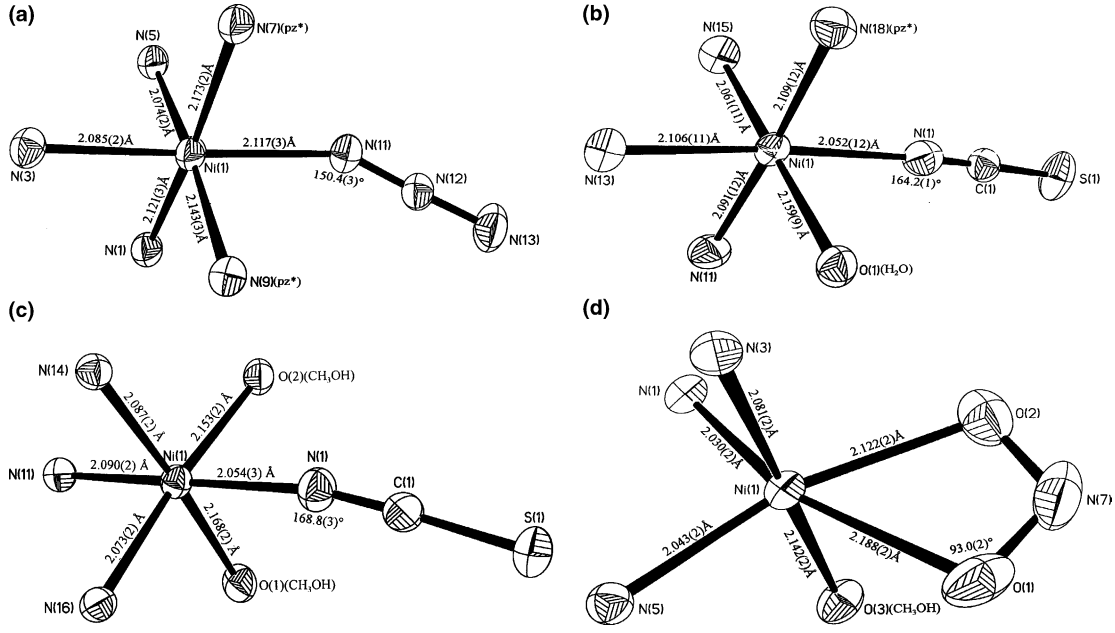

Fig. 7. Coordination environment of **1**, **2**, **3** and **4**: (a) $[Tp^*Ni(pz^*)_2(N_3)]$ (**1**); (b) $Tp^*Ni(pz^*)(SCN)(H_2O)]$ (**2**); (c) $[Tp^*Ni(NCS)(CH_3OH)_2]$ (**3**); (d) $[Tp^*Ni(\eta^2\text{-}O_2N)(CH_3OH)]$ (**4**).

β		0.55	0.77	0.79	0.84
$1-\beta$		0.45	0.23	0.21	0.16

to ligand transition bands. In the visible region two relative strong bands can be observed. They can be assigned to spin allowed d–d transition bands of Ni(II)(d^8), $\nu_3(^3T_{1g}(P) \leftarrow {}^3A_{2g})$, $\nu_2(^3T_{1g}(F) \leftarrow {}^3A_{2g})$, respectively. The small band appeared between ν_1 and ν_2 (ca. 13 300 cm^{-1}) can be assigned spin-forbidden d–d transition band of Ni(II)(d^8), $\nu_4(^1E_g \leftarrow {}^3A_{2g})$. The $\nu_1(^3T_2 \leftarrow {}^3A_{2g})$ band was not observed completely in the experimental region (200–1000 nm). The ligands-field constants Dq, B', β and ν_1 were calculated by using observed bands ν_2 and ν_3 [28] and the results were listed in Table 5. The Dq values of all complexes were larger than that of $[Ni^{II}(H_2O)_6]^{2+}$ (850 cm^{-1}). The B' of the complexes were less than that of free Ni(II) ion (1041 cm^{-1}), showing some covalent bonding of Ni(II) in the complexes.

4. Conclusions

Reaction of M(II) with hydrotris(pyrazolyl)borate ligands easily obtained stable full-sandwich complexes $[M^{II}Tp^R_2]$ because of the strong coordination ability of the ligands. These $[M^{II}Tp^R_2]$ complexes have been considered stable and inert. In this paper, we prepared three new half-sandwich nickel(II) complexes with monotris(pyrazdyl)borate ligands and azide or thiocyanate, [Tp*Ni(pz*)$_2$(N_3)] (**1**), [Tp*Ni(pz*)(SCN)(H_2O)] (**2**) and [Tp*Ni(NSC)(CH_3OH)$_2$] (**3**) by reaction of excess amount of $Ni(ClO_4)_2 \cdot 6H_2O$ with KTp* and NaN_3 or KSCN. The synthetic route described here impeded the full-sandwich complexes formation effectively. Compared with [Tp*Ni(η^2-O_2N)(CH_3OH)] **(4)** which was published previously, we can clearly see that the structures of all complexes were six-coordinated octahedral environment, with N_6 for **1**, N_5O for **2**, N_4O_2 for **3** and N_3O_3 for **4**. The different coordination environments made for different results, the bonds in four complexes, so did the intermolecular hydrogen bonds.

Received 11 May 2003; accepted 14 August 2003

Abstract

The structure of Tp″Rh(NBD) complex was determined by X-ray crystallography (Tp″ = hydrobis(3-phenyl-5-isopropylpyrazolyl)(3,5-dimethylpyrazolyl)borate, NBD = 2,5-norbornadiene). The Tp″ was found to be κ^3 coordinated to rhodium(I). Two independent molecules of Tp″Rh(NBD) were found in triclinic crystals with Rh–N(pz) distances in the region of 2.113(3)–2.307(3) Å. On the other hand the same Tp″ ligand was demonstrated to be coordinated in κ^2 fashion in Tp″Rh(COD) (COD = 1,5-cyclooctadiene) by variable temperature 1-D and 2-D ^{1}H NMR measurements. The intramolecular exchange between coordinated and uncoordinated 3-phenyl-5-isopropylpyrazolyl residues occurs with $\Delta G^{\neq} = 42.2$ kJ/mol as it was calculated from the ^{1}H NMR studies.

1. Introduction

Heteroscorpionate trispyrazolylborates (Tp″) are tripodal anionic ligands of potentially C_s symmetry [1]. The symmetry of the ligands can be preserved in their metal ion complexes, when Tp″s are coordinated in κ^3 fashion. The κ^3 hapticity resulting in effective C_s symmetry of the complexes was observed in the series of high-spin cobalt(II) complexes of the general formula Tp″Co(NCS) [2–8].

In case of Tp″Rh(LL) complexes (where LL = $(CO)_2$ or COD), the Tp″ ligands are coordinated in κ^2 fashion [9]. Fluxional behavior of those complexes was studied in detail by variable-temperature ^{1}H NMR spectroscopy. The homoscorpionate Tp″ ligands are in most cases κ^2-bonded in their Tp″Rh(LL) complexes ([9] and references [6–16] cited therein). However, there are three examples of κ^3 hapticity in rhodium complexes with trispyrazolylborates and ancillary ligands (LL) other than mentioned: Tp^{Me}Rh(NBD) [10], Tp^{Me2}Rh(PEt_3)(C_2H_4) [11], TpRh(PPh_3)[($CCOOCH_3$)$_2$] [12], and Tp^{iPr2}Rh(NBD) [13], in which the N(pz)–Rh bond lengths fall into the region of 2.12–2.27 Å. Here we report on the structure of another complex, in which the Tp″ ligand bearing two sterically demanding 3-phenyl substituents is coordinated in κ^3 fashion in Tp″Rh(NBD), while κ^2 hapticity is found in Tp″Rh(COD) analogue as can be concluded on the basis of variable temperature 1-D and 2-D ^{1}H NMR experiments.

2. Experimental

2.1. Syntheses

The sodium salt of hydrobis(3-phenyl-5-isopropylpyrazolyl)(3,5-dimethylpyrazolyl)borate (NaTp″) was synthesized as before [7]. The Tp″Rh(NBD) (**1**) and Tp″Rh(COD) (**2**) complexes were synthesized upon

addition of 120 mg of NaTp″ dissolved in toluene into the equimolar amounts of $[(COD)RhCl)]_2$ [14] or $[(NBD)RhCl)]_2$ [15] in toluene. The reaction mixtures were stirred at room temperature for 4 h under atmosphere of nitrogen, filtrated by passing through short bed of celite, the solvent was partially removed, the solutions layered with heptane and allowed to stand at 4 °C until formation of yellow crystals of **1** (yield 85%) or **2** (yield 80%).

2.2. Analytical data

1: Elemental analysis: Calc. for $C_{36}H_{42}N_6BRh$ (MW 672.48): C, 64.30; H, 6.29; N, 12.50. Found: C, 64.55; H, 6.16; N, 12.43%.

^{1}H NMR (toluene-d_8, 298 K): 8.01 (4H, m, *o*-H(3-Ph)); 7.25 (4H, m, *m*-H(3-Ph)); 7.16 (2H, m, *p*-H(3-Ph)); 6.31 (2H, s, 4-H(3-Ph,5-*i*Prpz)); 5.58 (1H, s, 4-H(3,5-diMepz)); 3.33 (6H, septet + broad singlet, C*H*(5-*i*Pr) + 2′, 3′, 5′, 6′-H(NBD)); 2.94 (2H, s, 1′, 4′ –H(NBD)); 2.31 (3H, s, 3(5)-CH_3); 2.14 (3H, s, 5(3)-CH_3); 1.29 (6H, d, $J_{(CH_3–CH)} = 6.6$ Hz, 2×CH_3(5-*i*Pr)); 1.21(6H, d, $J_{(CH_3–CH)} = 6.6$ Hz, 2×CH_3(5-*i*Pr)); 0.59 (2H, s, 7′-H(NBD)).

IR (KBr): *ν*(BH) 2534, 2474 cm^{-1}.

2: Elemental analysis: Calc. for $C_{37}H_{46}N_6BRh$ (MW 688.53): C, 64.54; H, 6.73; N, 12.21. Found: C, 64.62; H, 6.86; N, 12.13%.

^{1}H NMR (toluene-d_8, 273 K): 8.10 (4H, m, *o*-H(3-Ph)); 7.25 (4H, m, *m*-H(3-Ph)); 7.10 (2H, m, *p*-H(3-Ph)); 6.45 (2H, s, 4-H(3-Ph,5-*i*Prpz)); 5.56 (1H, s, 4-H(3,5-diMepz)); 4.10 (4H, s, 1′, 2′, 5′, 6′-H(COD)); 3.19 (2H, septet, C*H*(5-*i*Pr)), 2.34 (3H, s, 5-CH_3); 2.22 (3H, s, 3-CH_3); 1.87 (4H, s, 3′, 4′, 7′, 8′-H_{exo} (COD)); 1.39 (6H, d, $J_{(CH_3–CH)}) = 6.6$ Hz, 2×CH_3(5-*i*Pr)); 1.20 (10H, d, $J_{(CH_3–CH)}) = 6.6$ Hz, 2×CH_3(5-*i*Pr) + overlapped s, 3′, 4′, 7′, 8′-H_{endo} (COD)).

IR (KBr): *ν*(BH) 2478 cm^{-1}.

2.3. Methods

The ^{1}H NMR spectra were recorded with Bruker AMX 300 spectrometer. Standard COSY and NOESY experiments were performed with repetition time 1.0 and mixing time 0.3 s (NOESY).

Crystal data are given in Table 1, together with refinement details. All measurements of crystal were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystal was positioned 65 mm from the CCD camera. 612 frames were measured at 0.75° intervals with a counting time of 20 s. Accurate cell parameters were determined and refined by least-squares fit of 5950 of the strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o (formerly Kuma Diffraction Wrocław, Poland) programs. The structure was solved by direct methods (program SHELXS-97 [17]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 [17] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps. During refinement they were fixed.

3. Results and discussion

The heteroscorpionate ligand used in these studies, composed of two 3-phenyl-5-isopropylpyrazolyl and 3,5-dimethylpyrazolyl residues ($[HB(3\text{-}Ph,5\text{-}iPrpz)_2(3,5\text{-}diMepz)]^-$) is more sterically demanding in comparison with homoscorpionates Tp^{Me} [10], Tp [11], or Tp^{Me2} [12], which coordinate in κ^3 fashion to the rhodium(I) metal ion in their Tp′Rh(LL) complexes. On the other hand it is probably slightly less demanding than Tp^{iPr2}, which forms Tp″Rh(diene) complexes with κ^3 hapticity, when dien = NBD and κ^2 hapticity in case of diene = COD [13]. Other sterically demanding Tp′ ligands, like Tp^{Ph} [18] and $Tp^{4\text{-}OMePh}$ [19], as well as $[HB(pz)_4]^-$ [20] coordinate in κ^2 fashion in their Tp′Rh(diene) complexes. We have synthesized two compounds: $[HB(3\text{-}Ph,5\text{-}iPrpz)_2(3,5\text{-}diMepz)]Rh(NBD)$ (**1**) and $[HB(3\text{-}Ph,5\text{-}iPrpz)_2(3,5\text{-}$

diMepz)]Rh(COD) (**2**) in which the coordination mode of Tp″ ligand is κ^3 and κ^2, respectively.

The structure of **1** was elucidated crystallographically. There are two independent molecules of **1**. The views of the molecules are shown in Fig. 1 together with relevant bond lengths and angles around metal ion. The Rh–N(pz) distances fall into the region of 2.113(3)–2.307(3) Å (average value 2.24 Å), which is typical for other κ^3-Tp″Rh(NBD) complexes [10–13] and apparently longer in comparison with those for κ^2-Tp″Rh(NBD) ones (average value of Rh–N(pz) is equal 2.08 Å) [18–20].

The ^{1}H NMR spectrum of **1** (Fig. 1(b)) is composed of two 4-H(pz) resonances of relative 2:1 intensity ratio throughout broad range of temperature (down to 193 K) indicating the effective C_s symmetry of the molecule. Thus, the ligand remains coordinated in κ^3 fashion in solution or is in fast exchange between κ^2 and κ^3 mode. The resonances from methyl groups of 5-ispopropyl substituents are diastereotopically split into two doublets due to local chirality in **1**. The mutual rotation of Tp″ and NBD ligands in **1** is fast at the time-scale of the ^{1}H NMR even at the lowest temperature available in toluene-d_8 solvent as can be concluded from the presence of three resonances from NBD throughout the studied temperature range.

The crystals of **2** suitable for X-ray analysis could not be obtained. Therefore, the detailed analysis of the

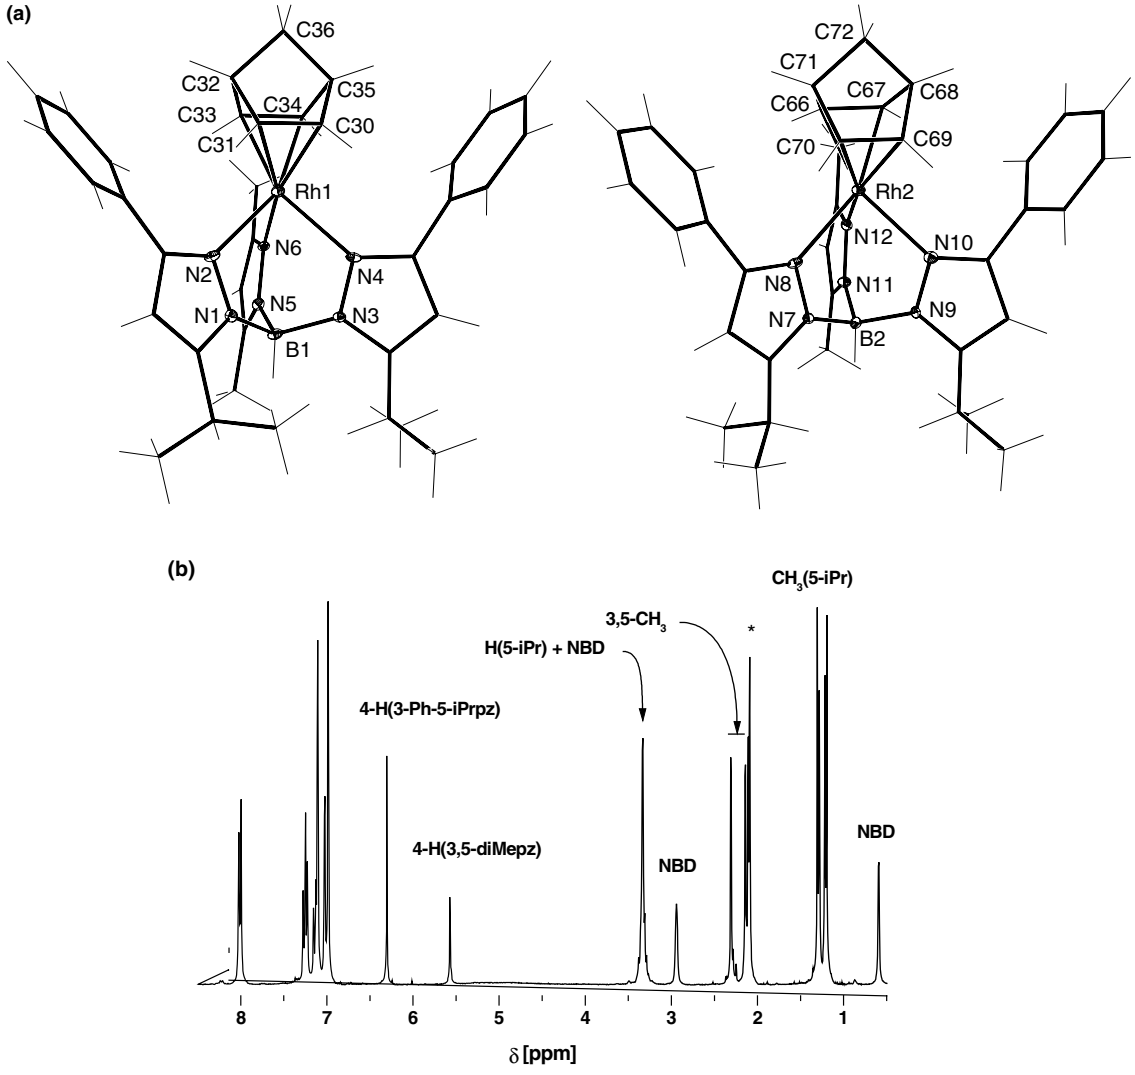

Fig. 1. (a) View of two independent molecules of **1**. Selected bond lengths (Å) and angles (°): Rh(1)–N(2), 2.299(3); Rh(1)–N(4), 2.290(3); Rh(1)–N(6), 2.113(3); Rh(1)–C(30), 2.169(4); Rh(1)–C(31), 2.157(4); Rh(1)–C(33), 2.078(4); Rh(1)–C(34), 2.069(4); N(4)–Rh(1)–N(2), 88.15(12); N(6)–Rh(1)–N(4), 83.26(13); N(6)–Rh(1)–N(2), 83.59(12); C(34)–Rh(1)–C(31), 79.34(16); C(33)–Rh(1)–C(30), 79.55(17) and Rh(2)–N(8), 2.307(3); Rh(2)–N(10), 2.282(4); Rh(2)–N(12), 2.136(3); Rh(2)–C(66), 2.087(4); Rh(2)–C(67), 2.082(4); Rh(2)–C(69), 2.166(4); Rh(2)–C(70), 2.177(4); N(10)–Rh(2)–N(8), 87.26(12); N(12)–Rh(2)–N(8), 85.07(12); N(12)–Rh(2)–N(10), 83.35(13); C(67)–Rh(2)–C(70), 79.44(17); C(66)–Rh(2)–C(69), 79.85(17). (b) ^{1}H NMR spectrum of **1** in toluene-d_8 at 298 K. The residual peak from solvent (q, C*H*D$_2$) is labeled with asterisk. The peaks from norbornadiene are labeled as NBD.

variable temperature ^{1}H NMR experiments was performed for **2** in toluene-d_8. The spectrum of **2** at ambient temperature reflects the effective C_s symmetry of **2**. However, the spectrum changes dramatically upon decrease of temperature; the coalescence point observed at 223 K clearly indicates that a chemical exchange between coordinated and uncoordinated pyrazolyl residues becomes slow at the time-scale of the method. Further decrease of temperature results in decrease of symmetry of the spectrum consistent with slow exchange between coordinated and uncoordinated 3-Ph-5-*i*Prpz residues. Three resonances of 4-H(pz) and four resonances from olefinic COD hydrogens are observed at 193 K (resonances a–d at lower trace at Fig. 2).

These features were already observed in case of other heteroscorpionate complexes: [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]Rh(COD) and [HB(3-Ph,5-Mepz)$_2$(3,5-diEtpz)]Rh(COD) [9], in which the Tp″ ligands are coordinated in κ^2 fashion, and attributed to slow exchange between coordinated and uncoordinated 3-Ph,5-Mepz moiety. The ^{1}H-^{1}H COSY and NOESY experiments showed the cross-peaks within a $\Longleftrightarrow$ b and c $\Longleftrightarrow$ d pairs of olefinic protons of COD, similarly as it was found for [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]Rh(COD) and [HB(3-Ph,5-Mepz)$_2$(3,5-diEtpz)]Rh(COD) [9]. Thus, the scalar coupling within a $\Longleftrightarrow$ b and c $\Longleftrightarrow$ d pairs of signals in COSY spectrum and concomitant EXSY cross-peaks between the same diagonal peaks in NOESY spectrum clearly confirm that effective C_1 symmetry of the ^{1}H NMR spectrum of **2** at 193 K is consistent with slow exchange between coordinated and uncoordinated 3-Ph,5-*i*Prpz residues. For this interconversion the $\Delta G^{\neq} = 42.2$ kJ/mol has been calculated. The obtained value of energy of activation is very close to those found in other similar systems, in which the coordinated and uncoordinated 3-Ph,5-Mepz residues interchanged with $\Delta G^{\neq} = 41.1$ kJ/mol in case when third, slowly exchanging pyrazolyl residue was 3,5-diEtpz and $\Delta G^{\neq} = 43.2$ kJ/mol in case of 3-Me,5-Phpz as third, coordinated pyrazolyl moiety [9].

The heteroscorpionate [HB(3-Ph,5-*i*Prpz)$_2$(3,5-diMepz)]$^-$ ligand serves a borderline example of steric demand towards the Rh(diene) counterpart, similar to homoscorpionate Tp$^{i\mathrm{Pr}2}$ [13]. The hapticity of Tp″ depends on the rhodium-centered diene cone angle. Tp″ coordinates in κ^2 fashion in case of diene = COD (average value of α for Tp″Rh(COD) complexes is 93.4° [9]), while κ^3 coordination mode occurs for diene = NBD ($\alpha = 79.5°$ in **1**) in solid state at 100 K. However, it should be emphasized that according to the IR spectral criterion proposed by Akita et al. [21] based on the position of ν(BH) the presence of two distinct bands at 2534 and 2474 cm^{-1} (of relative intensity about 2:1 both in KBr and in chloroform solution) for **1** suggests that at ambient temperature the [HB(3-Ph,5-*i*Prpz)$_2$(3,5-diMepz)]$^-$ ligand is coordinated in two ways: κ^3 and κ^2 mode, while in case of **2** (one ν(BH) band at 2478 cm^{-1}) the ligand remains coordinated in κ^2 mode both in solid state and in solution throughout the entire range of temperatures.

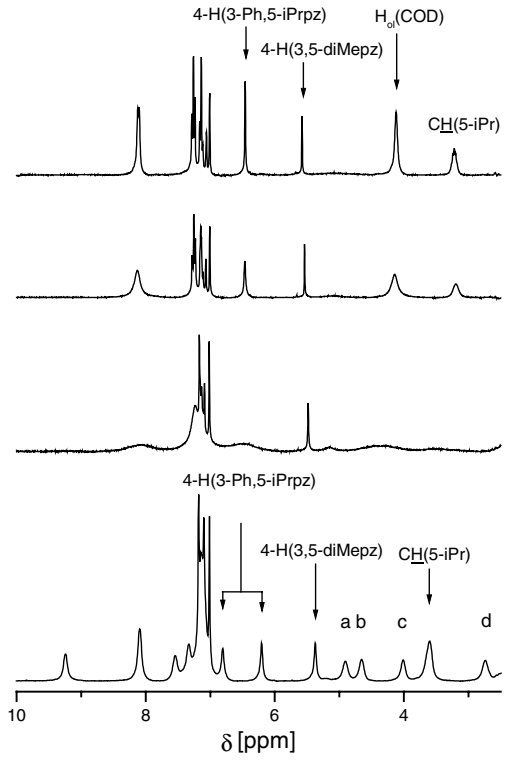

Fig. 2. The relevant fragments of ^{1}H NMR spectra of **2** in toluene-d_8 taken at temperature (from top to bottom): 273, 253, 223, and 193 K, respectively. The resonances labeled with H$_{ol}$(COD) (top trace) and a, b, c, d (bottom trace) belong to 1′, 2′, 5′, and 6′ H(COD).

4. Supplementary data

Crystallographic data for the structures reported in this paper (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 209564. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge 1EZ, UK (fax: +44-1223-336033; deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Dedicated to Dr. Swiatoslaw Trofimenko in recognition of his important contribution to inorganic chemistry

Abstract

O_2-treatment of the labile cationic aquo-Ru(II) complexes, $Tp^{iPr2}(L)_nRu(OH_2)_{3-n}(OTf)(THF)_x$ [L = bipy (**1d**), py (**2**), THF (**3**)], results in oxidation of the metal center to give the mononuclear hydroxo-Ru(III) complexes, $[Tp^{iPr2}(bipy)Ru^{III}(OH)](OTf)$ (**4**), $Tp^{iPr2}(py)Ru^{III}(OH)(OH_2)(OTf)(THF)_2$ (**5**), and the dinuclear Ru(II)–Ru(III) and Ru(III)–Ru(III) mixed aquo-hydroxo complexes bridged by the Ru–O···H···O–Ru hydrogen-bonding interactions, $Tp^{iPr2}Ru^{II}(OH)_2(OH_2)_4(OTf)Ru^{III}Tp^{iPr2}$ (**6**) and $(Tp^{iPr2}Ru)_2(OH)_2(OH_2)_4(OTf)_2$ (**7**).

1. Introduction

Hydrotrispyrazolylborates (Tp^R), so-called scorpionates, are versatile ligands, which have been used in the wide range of inorganic studies [1]. We have enjoyed the rich chemistry based on the Tp^R ligands, in particular, systematic synthetic study of O_2-complexes bearing the Tp^R ligands [2]. A variety of $Tp^RM–O_2$ complexes containing the first (V, Cr, Mn, Co, Ni) and second row metals (Rh, Pd) were prepared by way of dehydrative condensation of a hydroxo complex with H_2O_2 in addition to the classical O_2-oxidative addition to a low valent precursor, and the unique oxidizing activities of the resultant O_2-adducts were characterized. Our efforts were also devoted to the ruthenium system [3]. In previous papers we reported synthesis of a series of cationic aquo-Ru(II) complexes, $Tp^{iPr2}Ru^{II}(L)_n(OH_2)_{3-n}(OTf)(THF)_x$ **1**–**3**, [2] which were supported by hydrogen-bonding networks (Chart 1) [3a], and diphosphine complexes **1a**–**c** were subjected to oxygenation [3c]. On the basis of the labile nature of the aquo ligands in **1a**–**c** it was anticipated that they were converted into O_2-adducts upon exposure to O_2 atmosphere in a manner similar to the oxygenation of the isoelectronic η^5-C_5Me_5 systems giving the $[(\eta^5\text{-}C_5Me_5)(\text{diphosphine})Ru(\kappa^2\text{-}O_2)]^+$-type adducts [4–6]. Oxygenation of **1a**–**c**, however, did not result in the formation of O_2-adducts but one-electron oxidation of the ruthenium center, and the reaction products were dependent on the structure of the diphosphine ligand. The dppe [1,2-bis(diphenylphosphino)ethane] complex **1c** afforded the corresponding cationic hydroxo-Ru(III) complex, $[Tp^{iPr2}(dppe)Ru–OH]^+$, whereas the dppene [1,2-bis(diphenylphosphino)ethene] complex **1a** and the dppm [bis(diphenylphosphino)

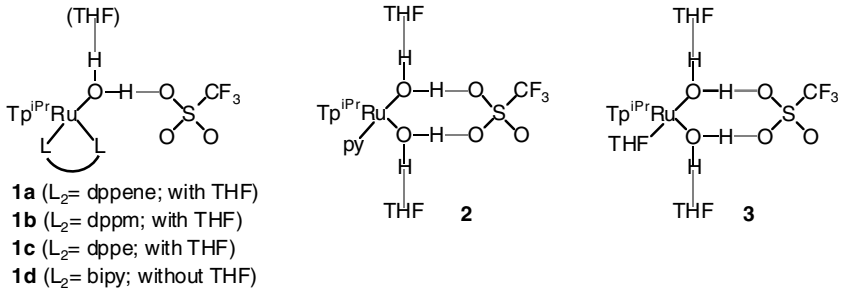

Chart 1.

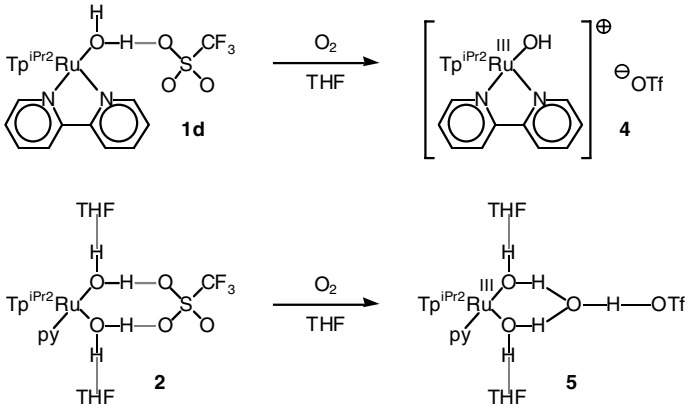
methane] complex **1b** resulted in oxidative transformations of the ancillary ligands, i.e. **1a** underwent oxidative $C(sp^3)$–$C(sp^3)$ bond cleavage of one of the isopropyl substituents of the Tp^{iPr2} ligand proximal to the metal center and **1b** was converted to the phosphine monooxide-coordinated complex. Herein we wish to report the results of oxygenation of the aquo-ruthenium(II) complexes with N-donors containing the varying number of labile oxygen ligands (OH_2 and THF): 1 (**1d**), 2 (**2**) and 3 (**3**) [Chart 1]. Although O_2-adduct was not obtained, it was revealed that the oxidized products were also supported by unique hydrogen bonding networks as found for **1**–**3**.

2. Results and discussion

2.1. Oxygenation of *1d* and *2* giving cationic mononuclear hydroxo-Ru(III) complexes

When the aquo-bipyridine complex **1d** and the diaquo-pyridine complex **2** dissolved in THF were stirred under O_2 atmosphere (1 atm), red (**4**) and yellow products (**5**) were isolated, respectively, by simple crystallization (Scheme 1). The paramagnetic properties of the products suggested formation of Ru(III) species, which were characterized by X-ray crystallography. Molecular structures of **4** and **5** are shown in Fig. 1 and their selected structural parameters are compared with those of related complexes as summarized in Table 1.

The oxygenation of the bipy complex **1d** resulted in one electron oxidation accompanied by deprotonation to give the mononuclear hydroxo-Ru(III) complex, $[Tp^{iPr2}(bipy)Ru–OH]OTf$ **4**, as observed for the O_2-treatment of the dppe complex **1c** [3c]. Complex **4** adopts an octahedral coordination geometry with the κ^1-OH, κ^2-bipy and κ^3-Tp^{iPr2} ligands as judged by the angles made by adjacent ligands close to the right angle: 85.5(2)–98.6(2)°. The Ru1–O1 length [1.969(3) Å] and the Ru–N(Tp^{iPr2}) distances [2.066(4)–2.085(5) Å] are considerably shorter than those [Ru–O: 2.158(5) Å; Ru–N: 2.157(5)–2.229(3) Å] in the dppe derivative, $[Tp^{iPr2}(dppe)Ru^{III}–OH]PF_6$ (obtained from **1c** [3c]). The shortening of the coordination bonds in **4** may be related to the electron donating ability of the bipy ligand stronger than that of the dppe ligand. In contrast to the other complexes described in this paper, no hydrogen bonding interaction with any other components (even with the TfO anion as in **1d**) is present. This should be also caused by the reduced acidity of the OH proton induced by the electron donation from the bipy ligand. In accord with this consideration, the Ru(II/III) redox potential of **4** (−0.62 eV; reversible) was much lower than that of $[Tp^{iPr2}(dppe)Ru^{III}–OH]PF_6$ (−0.25 V).



Scheme 1.

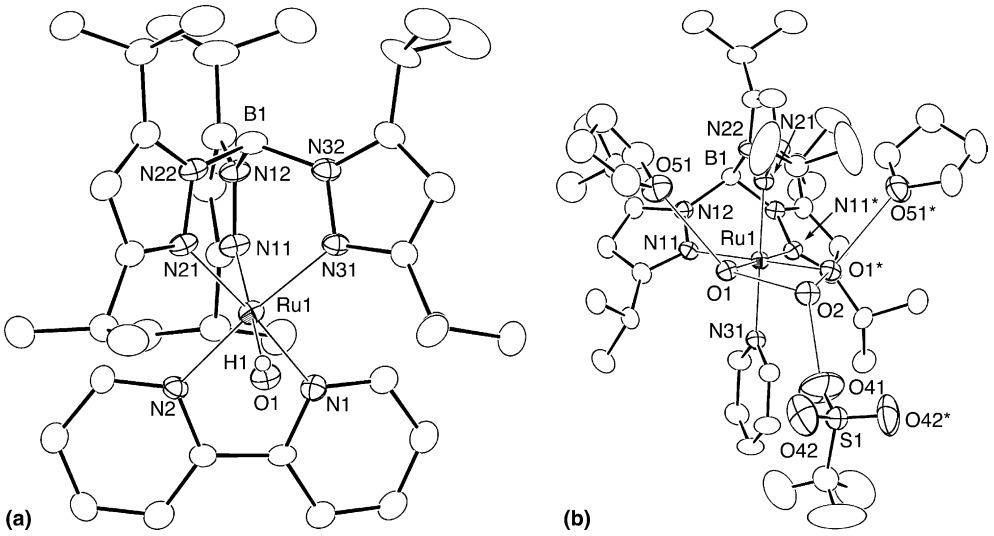


Fig. 1. ORTEP drawings for (a) the cationic part of **4** and (b) **5**. Thermal ellipsoids are drawn at the 30% probability level.

The core structure of the pyridine complex **5** is also an octahedral one sitting on a crystallographic mirror plane. In addition to the κ^1-pyridine and κ^3-Tp^{iPr2} ligands, two oxygen-containing ligands (O1 and O1*) are coordinated to the metal center to complete the octahedral coordination geometry as in the starting complex **2**. The notable structural feature is the hydrogen bonding network associated with the triflate anion and the additional water and THF molecules. The distances between the oxygen ligand (O1 and O1*) and the oxygen atom of the water (O2) and THF molecules (O51, O51*) [2.6–2.8 Å] are in the range of hydrogen bonding interaction, and the water molecule (O2) is further interacted with one of the oxygen atoms of the triflate anion (O41) through hydrogen bond. There is no significant difference in the O···O separations between the Ru(III) species **5** and the aquo-Ru(II) complexes **1**–**3** [3a]. These features are consistent with the structural description as a resonance hybrid of the two canonical aquo-hydroxo-Ru(III) structures **5A** (Scheme 2).

2.2. Oxygenation of *3* leading to cationic dinuclear aquo-hydroxo-Ru(III) complexes

Complex **3** with the three labile oxygen ligands was found to be also susceptible to oxygenation to give two types of products, Ru(II)–Ru(III) species **6** and Ru(III)–Ru(III) species **7**, with the different oxidation states and with complicated hydrogen bonding networks (Scheme 3) as determined by X-ray crystallography (Fig. 2). The two products were isolated in pure forms and never obtained as a mixture but we could not determine the reaction conditions, which led to **6** or **7**, although the oxygenation was repeated many times by varying the reaction time, the amount of O_2, the concentration and so on.

Both of the complexes contain the two $Tp^{iPr2}Ru(OH_x)_3$ units connected by hydrogen bonds but the interaction modes are different as can be seen from the core structures (Fig. 3). The interunit O···O separations between the two $Tp^{iPr2}Ru(OH_x)_3$ units in the Ru(II)–Ru(II) complex **6** can be classified into two categories, those of about 2.5 Å (O11···O21, O12···O22, O13···O23) and those longer than 3.2 Å (the others). As a result, the six oxygen atoms form a trigonal-prismatic framework as can be seen from the core structure and its side view (Fig. 3). The triflate counteranion, which bridges the two oxygen atoms (O11 and O21), should support the prismatic configuration.

The interunit O···O separations for the Ru(III)–Ru(III) complex **7** imposed on a centrosymmetric site are also classified into two groups [2.668(6), 2.680(6)/2.874(6) Å] but the difference is much smaller than that for **6** (see above). Although the distance of 2.87 Å may be in the longer end for the O···O distance of hydrogen bonds and an alternative form **7A** (Chart 2) with the crown-shaped hydrogen-bonding networks may be possible, taking into account the structure of **7′** (another form of **7**; vide infra) it is concluded that (1) **7** is a dimer of the diaquo-hydroxo-Ru(III) species and (2) the three atoms (O13–O11*–O12*/O13*–O11–O12) form the wedge-shaped array through hydrogen bonds. Such ternary 1:2 interactions lead to the twisted trigonal-anitipismatic arrangement of the oxygen atoms in contrast to the trigonal-pismatic configuration observed for **6**. The H_xO···OTf and H_xO···O(THF) separations are comparable to those for the mononuclear hydroxo-aquo-Ru(III) (**5**) and aquo-Ru(II) complexes (**1**–**3**) [3a,3c] and it should be noted that the Ru(III) species **2** and **7** contain the common $Ru(O\cdots H)_2OX$ linkage [X = TfOH (**2**), $RuTp^{iPr2}$ (**7**)].

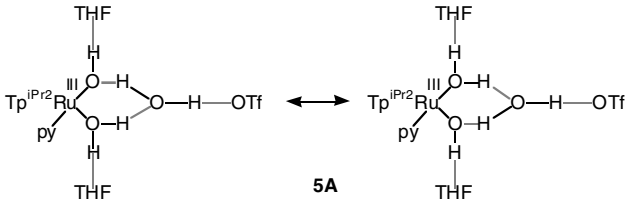
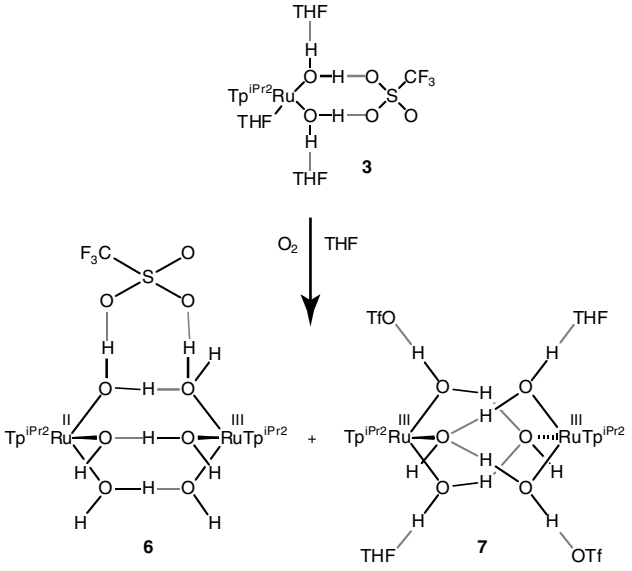


Scheme 2.



Scheme 3.

The paramagnetic properties of complexes **6** and **7** revealed that these complexes contained a Ru(III) center and in order to determine the oxidation states of the ruthenium centers CV measurements were carried out. Complex **6** showed a reversible oxidation wave at the potential of −0.80 V, which was comparable to that for the Ru(II/III) wave for the bipy derivative **4** (−0.62 V) described above, whereas complex **7** did not exhibit any significant oxidation wave in the range of 0–1.0 V. These CV features indicated that complex **6** contained a Ru(II) center but complex **7** did not; in other words, the oxidation states of the ruthenium centers in the dinuclear complexes were Ru(II)–Ru(III) (**6**) and Ru(III)–Ru(III) (**7**). The distinctive electrochemical behavior observed for **6** and **7** also revealed that the dinuclear structures were integrated in a solution, although the THF and TfO auxiliaries might be dissociated (vide infra; **6′** and **7′**).

On the basis of the above-mentioned data the hydrogen-bonding networks for **6** and **7** are characterized as follows. Taking into account the oxidation states of the central metals of **6** it is formulated as a di(μ-hydroxo)-tetra(μ-aquo)-Ru(II)–Ru(III) species, ($Tp^{iPr2}Ru^{II}$) (Tp^{iPr2}-Ru^{III})$(OH)_2(OH_2)_4(OTf)$, containing 10 protons, of which

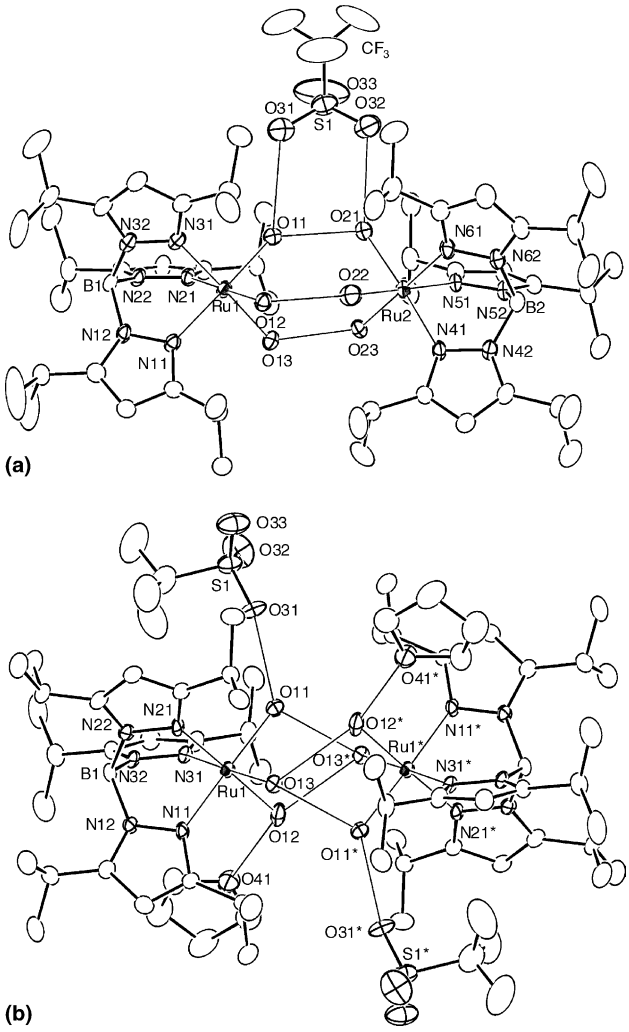


Fig. 2. ORTEP drawings for (a) **6** and (b) **7**. Thermal ellipsoids are drawn at the 30% probability level.

some should be associated with the hydrogen bonding interactions. Each one proton (in total five protons) should be present between the oxygen atoms connected by the hydrogen bonds and four of the remaining five protons should be attached to the oxygen atoms (O12,13, O22,23), which are not interacted with the triflate anion. The nine hydrogen atoms can be located by careful examination of Fourier synthesis, and the 10th proton, which cannot be located by the Fourier synthesis, is tentatively attached to the oxygen atom interacted with the triflate anion as shown in Scheme 3. Because the structural parameters for the two Tp^{iPr2}-$Ru(OH_x)_3$ moieties are essentially the same within the ranges of experimental errors, the oxidation states [Ru(II)/Ru(III)] of the particular ruthenium centers (Ru1 and Ru2) cannot be assigned.

The symmetrical structure of complex **7** as well as the presence of the two triflate conteranions clearly indicates that the oxidation states of the two ruthenium centers are the same and +3. Because each pair of the

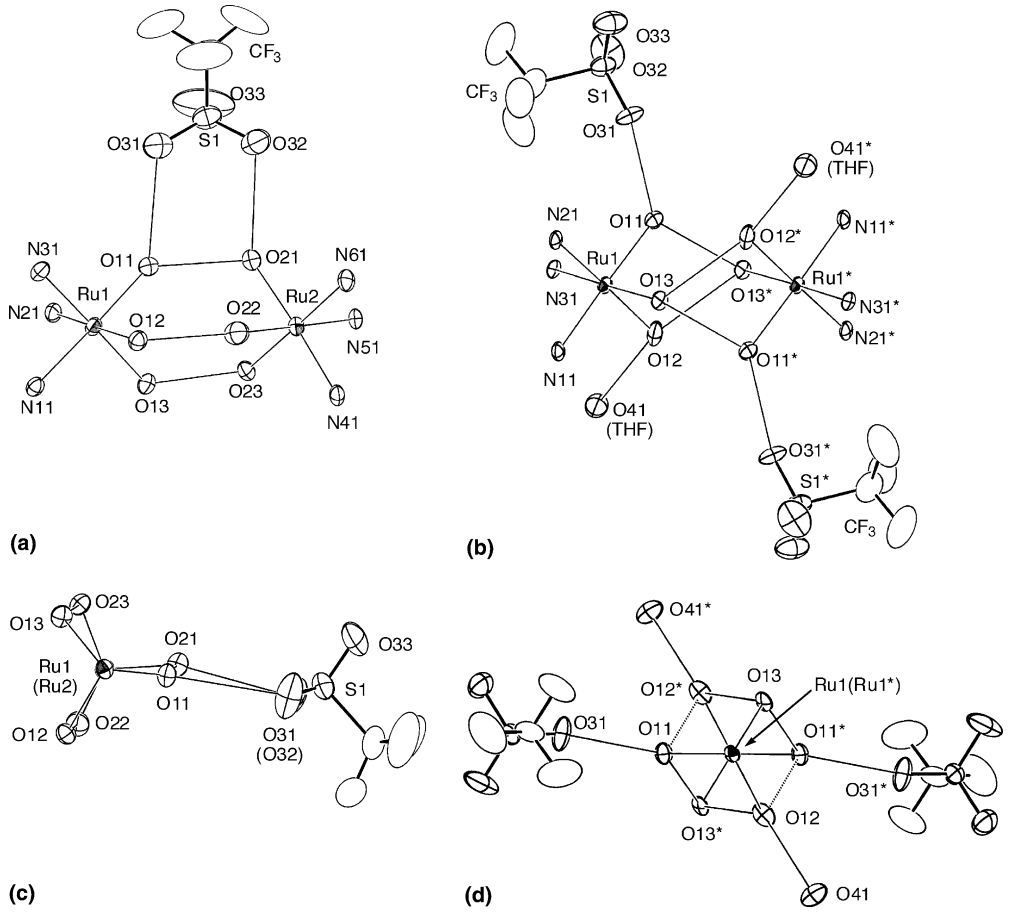

Fig. 3. Core structures of (a) **6** (side view), (b) **7** (side view), (c) **6** (a view along the Ru–Ru axis), and (d) **7** (a view along the Ru–Ru axis). Thermal ellipsoids are drawn at the 30% probability level.

hydrogen-bonded oxygen atoms should be bridged by a proton, the dinuclear system should contain 10 protons. The number of the protons is consistent with the formulation of **7** as a dimer of a hydroxo-diaquo-Ru(III) species, $(Tp^{iPr2}Ru^{III})_2(OH)_2(OH_2)_4(OTf)_2(THF)_2$ [= $\{Tp^{iPr2}Ru^{III}(OH)(OH_2)_2(OTf)(THF)\}_2$].

Let us add a note on the hydrogen bonding interactions. Changing the recrystallization solvent systems caused formation of different types of single crystals **6′** (obtained from THF–hexane) and **7′** (obtained from THF–CH_2Cl_2), which were also characterized by X-ray crystallography. Because, however, the highly disordered THF and TfO moieties hampered satisfactory refinements, the crystallographic results are not included in this paper. [3] The core structures of **6′** and **7′**, however, have been confirmed to be essentially the same as those of **6** and **7**, respectively, as schematically shown in Chart 3. Complex **6′** is formulated as $\mathbf{6}\cdot(THF)_2$ and the additional two THF molecules are found to be hydrogen-bonded to two OH moieties of one of the two $Tp^{iPr2}Ru(OH_x)_3$ fragments. Because the OH_x groups attached to a Ru(III) center should be more acidic than those attached to a Ru(II) center and therefore readily form hydrogen-bonding interactions, the oxidation state of the $Tp^{iPr2}Ru(OH_x)_3$ fragment, with which the THF molecules are interacted, is assigned to Ru(III). No significant difference is observed for the Ru–O distances

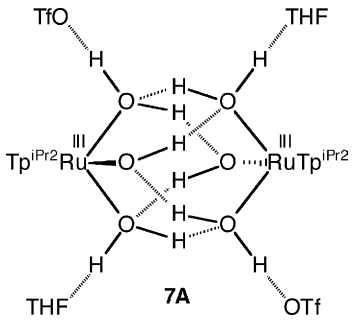

Chart 2.

[3] Crystallographic data for **6′**: $C_{69}H_{122}B_2N_{12}O_{11}F_3SRu_2$, $fw = 1608.6$, temp. −60 °C, monoclinic, space group $P2_1/c$, a = 16.990(3) Å, $b = 24.385(4)$ Å, $c = 21.378(15)$ Å, $\beta = 101.674(3)°$, $V = 8674.0(65)$ Å^3, $Z = 4$. for **7′**: $C_{80}H_{152}B_2N_{12}O_{18}F_6S_2Ru_2$, $fw = 1972.0$, temp. −60 °C, orthorhombic, space group *Pbca*, $a = 31.967(10)$ Å, $b = 17.980(2)$ Å, $c = 17.528(3)$ Å, $V = 10074(2)$ Å^3, $Z = 4$.

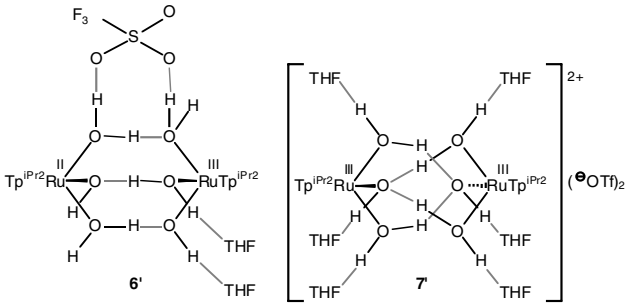

Chart 3.

of the $Tp^{iPr2}Ru^{II}(OH_x)_3$ [2.028(9)–2.06(1) Å] and $Tp^{iPr2}Ru^{III}(OH_x)_3$ fragments [2.020(9)–2.06(1) Å] as observed for **6**. The O···O separations of **6′** [RuO···ORu: 2.47–2.48 Å; RuO···O(THF): 2.81, 2.87 Å] are also similar to those in **6**. On the other hand, the composition of **7′** is found to be [**7**·(THF)$_6$]. In contrast to **7**, the triflate counteranions in **7′** are replaced by THF solvate molecules to give the separated ionic structure and all Ru–O oxygen atoms form hydrogen bonds with the six THF molecules. The features observed for the RuO···ORu separations are similar to those observed for **7**; the shorter ones (2.667, 2.707 Å) and the longer one (2.912 Å). Because six protons form hydrogen bonds with the six THF molecules, the remaining four protons integrate the dinuclear structure. It is therefore concluded that the shorter RuO···ORu linkages are retained by hydrogen bonds, whereas the longer one is not associated with hydrogen bond. This conclusion is the basis for the structural assignment as **7** (not **7A**). The six Ru–O oxygen atoms in **7′** form a trigonal-antiprismatic array similar to that in **7**. The two pairs of structures **6**/**6′** and **7**/**7′** suggest that the hydrogen-bonding interactions of the $[Tp^{iPr2}Ru(OH_X)_3]_2$ core with the THF solvates and the TfO anions may be so weak as to be dissociated in solutions but the dinuclear structure should be retained as discussed above on the basis of the electrochemical data.

The hydrated hydroxo ligand [M-(H)O···H···O(H)-M] is the bridging structural motif unique to polynuclear aquo-hydroxo complexes [7] and, to our knowledge, complexes **6** and **7** are the first examples with the multiple M–(H)O···H···O(H)–M-type hydrogen-bonding bridging interactions. It should be noted that, the O···O separations of **6** (2.4–2.5 Å) are comparable to those found for the previously reported singly or doubly bridging structures such as $[\mu\text{-}H_3O_2]_2\{Cr(bipy)_2\}_2]^{4+}$ and $[(\mu\text{-}H_3O_2)\{Ru^{III}(L)(tacn^{Me3})\}_2]^{3+}$ (L = acac, *o*-benzoquinone diimine) [7], whereas those of **7** with the ternary hydrogen-bonding interactions are substantially longer than them.

3. Conclusions

Oxygenation of a series of the labile cationic aquo-Ru(II) complexes, $Tp^{iPr2}Ru(L)_n(OH_2)_{3-n}(OTf)(THF)_x$ [L/n/x = bipy/2/0 (**1d**), py/1/2(**2**), THF/0/2 (**3**)], which

Scheme 4.

contain the hydrogen-bonding interactions between the acidic aquo ligand and donor (**D**), results in oxidation of the metal center(s) to give the mono- and dinuclear species **4**–**7** containing a Ru(III) center. The bipy complex **1d** with the only one labile ligand gives the simple hydroxo-Ru(III) complex **4**, whereas complexes **2** and **3** afford **5**–**7** with the unique hydrogen-bonding networks and, in particular, complex **3** with the three labile ligands produce the dinuclear species **6** and **7** with the multiple hydrated aquo bridges, M–(H)O···H···O(H)–M.

A combination of one electron-oxidation and deprotonation causes conversion of the aquo-Ru(II) species **A** into the hydroxo-Ru(III) species **B** and **C** resulting from formal displacement of the H···***D*** moiety by the ***H–X*** fragment (Scheme 4). The ***H–X*** fragment could be an acidic component in the reaction mixture, i.e. H_2O associated with the OTf and $RuTp^{iPr2}$ moieties. When ***H–X*** and/or ***D*** in **B** and **C** are metal components [$Tp^{iPr2}Ru(OH_x)$], the dinuclear structures result from the multiple hydrogen-bonding interactions. In the case of **7**, interaction with the two ***H–X*** fragments leads to the ternary hydrogen-bonding interaction. The bridging interaction found for **7**(**E**) is a unique one as discussed above but can be regarded as a superimposed version of the precedent μ-O_2H_3 motif. The MO_3H_2 six-membered ring structural motifs in **E** and **F** are common for the $Tp^{iPr2}Ru$(III)–OH species.

The electron-donating Tp^{iPr2} ligand renders the Ru(III)-OH moiety basic enough to form hydrogen bonds with the acidic component (***H–X***) and the facial coordination of the Tp^{iPr2} ligand forces *cis*-orientation of the OH_x ligands, which leads to the dimeric structures supported by the hydrogen-bonding networks.

4. Experimental

4.1. General methods

THF and hexane (Na–K alloy), CH_2Cl_2 (P_4O_{10}) and acetone ($KMnO_4$-molecular sieves) were treated with appropriate drying agents, distilled, and stored under argon. IR spectra were obtained on a JASCO FT/IR 5300 spectrometer. CV measurements ($E_{1/2}$ vs. Ag/Ag^+; in THF; NBu_4PF_6) were done with a BAS 100B/W(CV-50W) machine. The starting complexes were prepared according to the reported methods [3a].

4.2. Preparation of *4* (Oxidation of *1d*)

A Schlenk tube containing a THF solution (10 mL) of **1d** (103 mg, 0.12 mmol) was evacuated and then filled with O_2 gas (1 atm). After the mixture was stirred magnetically for 4 h, the solution was concentrated under reduced pressure. Addition of hexane followed by cooling at −20 °C gave **4b** (80 mg, 0.099 mmol, 78% yield) as red needles. IR 3580 (m sh, ν_{OH}), 3488 (m br, ν_{OH}), 3082 (w), 2971 (vs), 2933 (s sh), 2870 (s), 2555 (m, ν_{BH}), 1537 (s), 1473 (s), 1449 (m), 1428 (s), 1392 (s), 1367 (m), 1278 (vs), 1181 (s), 1156 (s), 1058 (s), 1032 (vs), 796 (w), 779 (m), 665 (m), 639 (s), 568 (m). *Anal*. Calc. for $C_{41}H_{61}BN_8O_5F_3SRu$: C, 52.01; H, 6.49; N, 11.83. Found: C, 51.55; H, 6.53; N, 11.83%.

4.3. Preparation of *5* (Oxidation of *2*)

A THF solution (5 mL) of $\mathbf{2}\cdot(THF)_{2.5}$ (72 mg, 0.071 mmol) was stirred under O_2-atmosphere (1 atm) for 30 min. After removal of the volatiles under reduced pressure the residue was dissolved in acetone and then hexane was added. Concentration under reduced pressure followed by cooling at −20 °C gave **5** (44 mg, 0.048 mmol, 67% yield) as yellow plates. IR 3588 (m sh, ν_{OH}), 3384 (m br, ν_{OH}), 2971 (vs), 2933 (s sh), 2871 (s), 2550 (m, ν_{BH}), 1636 (m br, δ_{OH}), 1608 (m), 1537 (s), 1474, (s sh), 1427 (m), 1395 (s), 1366 (m), 1288 (vs), 1225 (s sh), 1179 (vs), 1157 (vs), 1057 (vs), 1032 (vs), 897 (w br), 829 (w), 796 (m), 766 (m), 699 (m), 662 (m), 629 (s), 575 (m). *Anal*. Calc. for $C_{41}H_{72}BN_7O_8F_3SRu$: C, 49.64; H, 7.32; N, 9.88. Found: C, 49.81; H, 7.14; N, 10.17%.

4.4. Oxidation of *3* (Formation of *6*)

A THF solution (10 mL) of **3** (150 mg, 0.14 mmol), was stirred under O_2 atmosphere (1 atm) for 4 h. After filtration through a Celite pad haxane was added and the resulting solution was cooled at −20 °C to give **6** (88 mg, 0.057 mmol, 80% yield) as yellow brown plates. IR 3639 (w, ν_{OH}), 3406 (w br, ν_{OH}), 2968 (vs), 2931 (s sh), 2870 (m), 2546 (m, ν_{BH}), 1630 (w br, δ_{OH}), 1538 (s), 1474 (s), 1395 (s), 1364 (m), 1289 (s), 1253 (s), 1180 (vs), 1156 (s sh), 1056 (s), 1032 (s), 794 (s), 765 (w), 663 (m), 638 (s), 535 (w), 491 (w). *Anal*. Calc. for $C_{55}H_{102}B_2N_{12}O_9F_3SRu_2$: C, 47.58; H, 7.41; N, 12.11. Found: C, 47.71; H, 7.38; N, 12.09%.

4.5. Oxidation of *3* (Formation of *7*)

A THF solution (10 mL) of **3** (75 mg, 0.072 mmol) was stirred under O_2 atmosphere (1 atm) for 4 h. Work up as described for **6** gave **7** (55 mg, 0.033 mmol, 91% yield) as brown crystals. IR 3422 (w, ν_{OH}), 2970 (vs), 2872 (s), 2544 (w, ν_{BH}), 1631 (w br, δ_{OH}), 1538 (s), 1474 (s), 1429 (m), 1394 (s), 1366 (m), 1251 (s), 1180 (vs), 1058 (s), 1034 (vs), 797 (m), 639 (m). *Anal*. Calc. for $C_{64}H_{118}B_2N_{12}O_{14}F_6S_2Ru_2$: C, 45.71; H, 7.07; N, 10.00. Found: C, 46.01; H, 7.39; N, 9.85%.

THF), and **7** (THF–hexane) were obtained by recrystallization from the solvent systems described in the parentheses and mounted on glass fibers. The crystallographic data are summarized in Table 2.

Diffraction measurements of **4** · acetone and **5** · THF were made on a Rigaku RAXIS IV imaging plate area detector with Mo Kα radiation ($\lambda = 0.71069$ Å) at −60 °C. All the data collections were carried out at r.t. Indexing was performed from 3 oscillation images which were exposed for 4 min. The crystal-to-detector distance was 110 mm. Data collection parameters (the detector swing angle/the number of oscillation images/the exposed time) were as follows: 7°/21/45 min (**5** · THF), 6°/24/40 min (**4** · acetone). Readout was performed with the pixel size of 100 μm × 100 μm. Neutral scattering factors were obtained from the standard source [8]. In the reduction of data, Lorentz, polarization, and empirical absorption corrections were made [9].

Diffraction measurements of **6** · $2CH_2Cl_2$ · THF and **7** were made on a Rigaku AFC5S and AFC7R automated four-circle diffractometer, respectively, by using graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). The unit cell was determined and refined by a least-squares method using 20 independent reflections. Data were collected with an ω-2θ scan technique. If $\sigma(F)/F$ was more than 0.1, a scan was repeated up to three times and the results were added to the first scan. Three standard reflections were monitored at every 100 measurements. All data processing was performed on a FACOM A-70 computer (**6** · $2CH_2Cl_2$ · THF) and a Venturis FX 5133 computer (**7**). Neutral scattering factors were obtained from the standard source [8]. In the reduction of data, Lorentz, polarization, and empirical absorption corrections (Ψ scan) were made.

The structures were solved by a combination of the direct methods (SHELXL 87 [10a]) and Fourier synthesis (DIRDIF [11]). Least-squares refinements were carried out using SCHELEXL97 [10b] linked to TEXSAN [12]. Details of the refinements were as follows. **5** · THF: All the non-hydrogen atoms except for the THF solvate (refined isotropically) were refined anisotropically. The methyl hydrogen atoms were refined by using riding models. Hydrogen atoms attached to the THF solvate were not included in the refinement and the other hydrogen atoms were fixed at the calculated positions. **4b** · acetone and **7**: All the non-hydrogen atoms were refined anisotropically and the hydrogen atoms were fixed at the calculated positions. **6** · $2CH_2Cl_2$ · THF: All the non-hydrogen atoms except for the THF solvate (refined isotropically) were refined anisotropically and the highly disordered oxygen atom (O91) of the THF solvate was fixed at the final stage of the refinement. Hydrogen atoms attached to the THF solvate and one of hydrogen atoms attached to the O11 atom were not included in the refinement and the other hydrogen atoms were fixed at the calculated positions.

5. Supplementary material

Crystallographic data for the structural analysis of compounds **4**–**7**, have been deposited with the Cambridge Crystallographic Data Centre [CCDC Nos. 209824(**4**)–209827(**7**)]. Copies of the information may be

Abstract

Reaction of the copper(II) complex of $Bp^{Ph,4CN}$ with $Rh_2(CF_3COO)_4$ results in coordination of the CN groups of the Bp ligand to Rh and the formation of a coordination polymer. This material has been characterized by IR and EPR spectroscopy and electrospray mass spectrometry.

1. Introduction

The past 35 years of research in scorpionates has shown the tremendous versatility of these ligands made possible by virtue of the wide variety of substituents that can be relatively easily attached to the pyrazole carbon atoms. The chemist has, thereby, extraordinary control over the coordination geometry, electronic characteristics, and chemical reactivity of the metal center. This versatility, however, has primarily been achieved using alkyl and aryl substituents, relying largely on steric effects to promote changes in the electronic properties of the coordinated metal. An example is the series of complexes Tp_2Fe, Tp^*_2Fe and Tp^{Ph}_2Fe in which the increasing steric bulk of the substituent in the 3-position results in a progression from a spin-crossover complex that is low-spin at room temperature to a spin-crossover complex that is high-spin at room temperature to a complex that remains high spin at all temperatures [1]. Scorpionate ligands incorporating strongly electron-withdrawing or donating substituents have received comparatively little attention. A few people, most notably Dias and coworkers, have employed bis(3,5-trifluoromethyl)pyrazole, reporting scorpionate complexes that show interesting electronic and reactivity properties [2]. Recently, reports have come out of our group [3] and that of Trofimenko [4] concerning bispyrazolylborate ligands containing the CN substituent in the 4-position of the pyrazole ring.

Aside from its electron-withdrawing character, the cyano group offers a feature that is interesting from a structural standpoint, namely the ability of the cyano group, itself, to coordinate to a metal ion. The cyanoscorpionate complexes are thus candidates to be components of coordination polymers in which two cyanoscorpionate complexes are linked up by binding of the cyano groups on each to a second metal complex. The only examples of scorpionate-based polymers involving the coordination of a functional group on a pyrazole substituent to another metal ion involve the pyridyl-substituted Tp ligands of Vahrenkamp and coworkers [5]. In these ligands, the same metal ion is coordinated both by the pyrazole N atoms of one ligand and the pyridyl N atoms of neighboring ligands.

Our previous work and that of Trofimenko represent two extremes in the continuum of cyanoscorpionate ligands. Trofimenko reported the synthesis of the parent bis(4-cyanopyrazolyl)borate, Bp^{4CN}. The reaction of this ligand with transition metal salts results in an immediate

doi:10.1016/j.poly.2003.11.008

precipitation of intractable solids. These materials show multiple CN stretching bands in the IR spectra. The implication is that, along with coordination of the metal ion to the pyrazole N atoms, the cyano groups also coordinate to the metal ions, resulting in a polymeric material in which a given metal ion is potentially bound to the pyrazole N atoms of one Bp^{4CN} ligand and to the CN group of another. Characterization of these materials was possible only after the addition of ancillary ligands, resulting in the isolation of heteroleptic complexes containing the Bp^{4CN} ligand as well as other ligands. This work clearly demonstrated the feasibility of making cyano-substituted scorpionate ligands and also indicated that the cyano substituent on the pyrazole ring could act as a ligand to another metal ion.

We reported the synthesis of $Bp^{Ph,4CN}$ and its complexes with Co^{2+} and Cu^{2+}. As has been well documented over the last 35 years, the presence of bulky substituents in the 3-position of the pyrazole rings restricts access to the metal [6] and lessens the chance of oligomerization via coordination to the scorpionate-bound metal. The phenyl group has been shown to be a substituent of intermediate steric bulk, allowing for facile isolation of 4- and 5-coordinate complexes with a 1:1 Tp:metal stoichiometry [6a,6d], but also allowing for the preparation of complexes with a 2:1 Tp:metal stoichiometry [1b]. Indeed, the phenyl group in the 3-position of $Bp^{Ph,4CN}$ allowed for the isolation of homoleptic complexes of the form $Bp^{Ph,4CN}{}_2M$ with both Co^{2+} and Cu^{2+} [3]. These complexes showed little structural variations from analogous complexes made with non-cyano-substituted Bp ligands.

2. Results and discussion

With the information from the Trofimenko work confirming the ability of the CN group to serve as a ligand to a transition metal, isolation of the $Bp^{Ph,4CN}{}_2M$ complexes provided a material with which to attempt the rational preparation of a coordination polymer – one in which a metal is bound in the pyrazole pocket and a second metal is bound to CN groups from different $Bp^{Ph,4CN}$ ligands. The first attempt was made using the $Rh_2(CF_3COO)_4$ dimer, which is well known to bind organonitrile ligands [7]. Combination of a yellow methylene chloride solution of $Bp^{Ph,4CN}{}_2Cu$ with a green methylene chloride solution of $Rh_2(CF_3COO)_4$ results in the immediate deposition of a red powder. IR spectroscopy of this powder (Fig. 1) shows peaks attributable to both the scorpionate ligand and the rhodium dimer, including B–H stretches at 2415 and 2480 cm^{-1}, very similar to those apparent in $Bp^{Ph,4CN}{}_2Cu$. Most important, however, is the appearance of a new CN stretch at 2260 cm^{-1} in addition to the stretch at 2229 cm^{-1} seen in both $KBp^{Ph,4CN}$ and $Bp^{Ph,4CN}{}_2Cu$. This

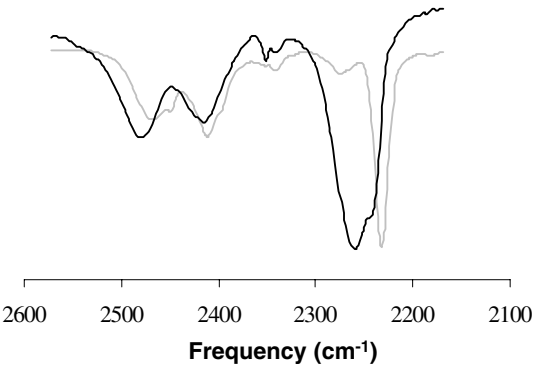

Fig. 1. IR spectra of $Bp^{Ph,4CN}{}_2Cu$ (gray) and the reaction product with $Rh_2(CF_3COO)_4$ (black) showing the B–H and C–N stretching regions.

shifted CN stretch mirrors that seen by Trofimenko at 2262 cm^{-1} in the initial polymeric materials isolated by addition of Bp^{4CN} to divalent metal ions and indicates binding of the CN group to the axial position of the Rh dimer.

Although the red powder is insoluble in methylene chloride, it can be dissolved in more coordinating solvents such as acetonitrile, acetone, and THF to give blue or green solutions. The EPR spectra taken in THF solution and in the solid state are essentially identical with those of the $Bp^{Ph,4CN}{}_2Cu$ starting material, indicating that, not surprisingly, there is no interaction between Cu ions. It is most likely that the solvent breaks up the polymer into smaller, more tractable species by replacing the nitrile coordinated to the Rh atom. ESI-MS characterization of the THF solutions (Fig. 2), however, reveals that some amount of oligomerization remains even after the material is dissolved. The spectra, in negative ion detection mode, show a peak at $m/z = 761$ which corresponds to $Bp^{Ph,4CN}{}_2Cu$. In addition, peaks are observed at $m/z = 1418$ and 2075, which correspond to $Bp^{Ph,4CN}{}_2Cu\text{-}Rh_2(CF_3COO)_4$ and $Bp^{Ph,4CN}{}_2Cu\text{-}(Rh_2(CF_3COO)_4)_2$, respectively [8]. This correlates very well with the elemental analysis performed on the original red powder, which corresponds to a stoichiometry of two rhodium dimers per $Bp^{Ph,4CN}{}_2Cu$ complex. It should be noted that one $Bp^{Ph,4CN}{}_2Cu$ complex contains four CN groups which could potentially coordinate to Rh. MS–MS experiments run on the 1418 peak show fragmentation to give the $Bp^{Ph,4CN}{}_2Cu$ peak at $m/z = 761$.

Although it has not yet been possible to crystallographically characterize either the red powder or the material dissolved in coordinating solvents, the evidence from mass spectrometry and IR spectroscopy as well as the insolubility of the red material in non-coordinating solvents indicate at least oligomerization and possibly polymerization by coordination of the CN substituent on a pyrazole ring to the Rh atom of the $Rh_2(CF_3COO)_4$ dimer, as schematized in Fig. 3.

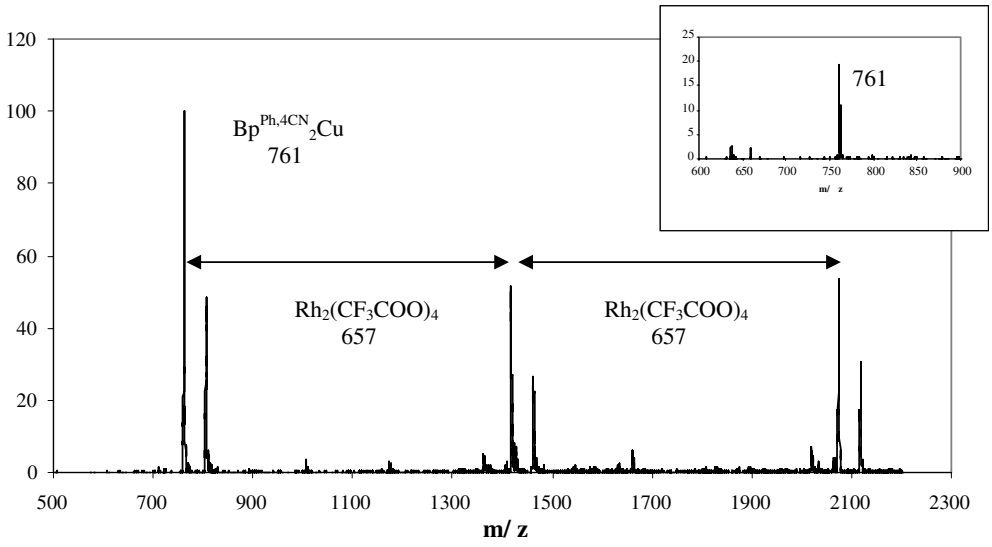

Fig. 2. ESI-MS of the reaction product of $Bp^{Ph,4CN}{}_2Cu$ and $Rh_2(CF_3COO)_4$ dissolved in THF. The inset shows the MS–MS experiment performed on the $m/z = 1418$ peak.

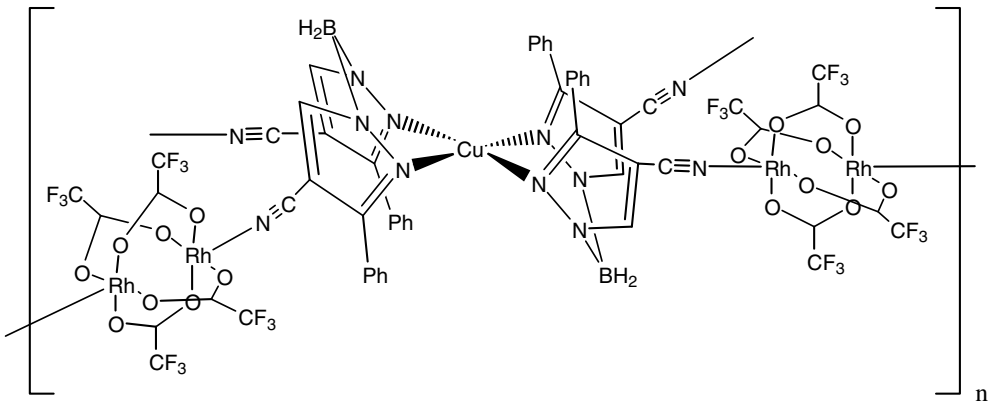

Fig. 3. Proposed structure of the polymer formed by reaction of $Bp^{Ph,4CN}{}_2Cu$ and $Rh_2(CF_3COO)_4$.

3. Conclusions

Using scorpionate ligands substituted by CN at the 4-position and by the relatively bulky phenyl group at the 3-position, it is possible to rationally produce a coordination polymer with coordination of one metal ion in the pyrazole pocket and a second metal ion to the cyano group.

4. Experimental

$KBp^{Ph,4CN}$ and $Bp^{Ph,4CN}{}_2Cu$ were synthesized as previously reported [3]. $Rh_2(CF_3COO)_4$ was purchased from Strem Chemicals and used as received. Solvents were purchased from Fisher Scientific and used as received. IR spectra were obtained on a Nicolet Avatar 360 FTIR. Electrospray Mass Spectrometry was performed on a Finnigan LCQ DECA spectrometer. EPR spectra were obtained on a Bruker EMX 6/1 spectrometer. Elemental Analysis was performed by M-H-W Laboratories, Phoenix, AZ.

To a yellow solution of $Bp^{Ph,4CN}{}_2Cu$ in CH_2Cl_2 is added a green solution containing 2 molar equivalents of $Rh_2(CF_3COO)_4$ in CH_2Cl_2. A red powder is deposited immediately, which is isolated by filtration and washed with CH_2Cl_2. IR (KBr disc, cm^{-1}): 2480 (w, B–H), 2415 (w, B–H), 2260 (m, CN), 1668 (s), 1193 (s), 1156 (s), 859 (m), 786 (m), 738 (m), 697 (w). ESI-MS (THF solution, negative ion detection mode, m/z): 761 $(Bp^{Ph,4CN}{}_2Cu)^-$, 1418 $((Bp^{Ph,4CN}{}_2Cu)\,Rh_2(CF_3COO)_4)^-$, 2074 $((Bp^{Ph,4CN}{}_2Cu)(Rh_2(CF_3COO)_4)_2)^-$. EPR (solid, 298 K, X-band): $g_{||} = 2.23$, $A_{||}^{Cu} = 590$ MHz; EPR (THF solution, 298 K, X-band): $g = 2.15$, $A^{Cu} = 210$ MHz, $A^N = 55$ MHz. Elemental *Anal.* Calc. for $C_{56}H_{28}N_{12}O_{16}F_{24}B_2Cu_1Rh_4$-$((Bp^{Ph,4CN}{}_2Cu)(Rh_2(CF_3COO)_4)_2)$: C, 32.37; H, 1.36; N, 8.09. Found C, 32.16; H, 1.12; N, 7.92%.

[8] Each of the peaks in the mass spectrum has a second peak associated with it at M + 46. While we have been unable to determine the identity of this peak, it appears to be associated with the $Bp^{Ph,4CN}{}_2Cu$ starting material, as a peak at $m/z = 807$ is evident in the mass spectrum of this compound.

New heteroscorpionate ligands with hydrogen bond donor and acceptor groups: synthesis, characterization and reactivity with divalent Co, Zn and Ni ions

Zahida Shirin, Carl J. Carrano *

Department of Chemistry, Southwest Texas State University, San Marcos TX 78666, USA

Received 14 May 2003; accepted 5 September 2003

Abstract

Three new N_2O heteroscorpionate ligands designated L6OH, L7OH and L9OH, containing either appended hydrogen bond donating or accepting residues have been synthesized and characterized. Metal complexes of these ligands with Co(II) and Ni(II) have been characterized by X-ray crystallography. A facile decomposition pathway leading to C–N bond cleavage and isolation of metal pyrazole complexes was also identified.

1. Introduction

Tris(pyrazolyl)borate (Tp) or "scorpionate" ligands have wide application in coordination, organometallic and bioinorganic chemistry [1]. These ligands have become particularly important in the development of biomimetic coordination chemistry of metalloproteins. Despite their advantages, the tris(pyrazolyl)borate ligands are completely symmetric with three nitrogen donors and many metalloproteins active site do not have such monofunctional binding sites. Our major contribution to this field has been the introduction of a family of tripodal N_2X ligands which contain all the biologically relevant donor atoms and are isostructural and isoelectronic with Tp [2,3]. With these we have begun to investigate how donor atom identity affects the properties of the metal center in a series of isostructural and isoelectronic complexes, i.e., *the inorganic chemists equivalent of site-directed mutagenesis*.

However in metalloproteins the structure of the active site has a role beyond just providing the necessary ligands to connect the metal cofactor to protein. It also controls the secondary coordination sphere (microenvironment) around the metal ion. This microenvironment often has a significant role to play in controlling the reactivity of the metal ion. Of the various interactions that proteins use to modify the secondary coordination sphere, perhaps the most important is hydrogen bonding. It is used to control structure, assist in recognition and activation of exogenous substrates or stabilize reactive intermediates. While the use of sterically restricted ligands to control the size and shape of metal binding cavities is well established, it has proven more difficult, despite its importance, to incorporate hydrogen bonding into synthetic small molecule binding site analogs. However, some recent successes in using hydrogen bonding, sterically restricted, metal binding cavities prepared by relatively simple synthetic schemes have become evident [4–7]. Using 5′-ester substituted pyrazoles we have also described a first generation of a simple H-bond accepting Tp ligands that simultaneously provides both steric bulk and hydrogen bonding groups, which can be directed towards the center of a metal binding cavity. The presence of strong intramolecular H-bonding between the ligand carbonyls and water molecules leads to the stabilization of discrete, well

doi:10.1016/j.poly.2003.11.007

characterized, divalent metal aquo complexes of the general type in $[Tp^{CO_2Et,Me}M(L)_x]^+$ where M = Co(II), Ni(II), Mn(II), Zn(II) or Cu(II), L = H_2O, OAc^-, OH^-, or various amino acids, and $x = 2$ or 3 depending on the metal [8,9]. These complexes are both, unprecedented in Tp chemistry, and good structural models for enzymes of the vicinal oxygen chelate (VOC) superfamily [10].

In this work, we describe our initial efforts to combine hydrogen bonding capabilities with the unsymmetrical donor set of our heteroscorpionates to produce a new generation of such ligands.

2. Experimental

All syntheses and crystallizations were carried out under Ar using standard Schlenk or dry box techniques. Solvents dichloromethane and acetonitrile were distilled under argon over CaH_2 while diethyl ether was distilled from Na/benzophenone. 3-Methyl-5-carboxyethylpyrazole was prepared as previously described [8]. All other reagents and solvents were purchased from commercial sources and used as received unless otherwise noted.

2.1. Synthesis of ligands

*L6OH (**1**)*. 3-Methyl-5-carboxyethylpyrazolyl ketone (8.78 g, 26.20 mmol) was dissolved in a minimum amount of anhydrous DMF and placed in a 100 ml round bottom flask which was purged and filled with argon. Salicylaldehyde (3.20 g, 26.20 mmol) and a catalytic amount (0.1 g) of anhydrous $CoCl_2$ were added to the flask. The mixture was then heated at 100 °C for 30 h under Ar. DMF was removed under reduced pressure and the solid mass dissolved in CH_2Cl_2, washed with water thrice, with saturated sodium chloride solution and finally dried over anhydrous $MgSO_4$. CH_2Cl_2 was removed to produce a pale yellow oil. The oil was triturated with pentane and stirred overnight to yield a white microcrystalline solid. This solid was collected by filtration, washed with pentane and dried in vacuo. Yield: 5.4 g (50%) *Anal.* Calc. for $C_{21}H_{24}N_4O_5$: C, 61.16; H, 5.86; N, 13.58. Found: C, 60.84; H, 5.83; N, 13.43%. ^{1}H NMR ($CDCl_3$) δ 8.59 (s, 1H, O*H*), 7.91 (s, 1H, –C*H*–), 7.09 (t, 1H, $J = 7.9$ Hz, Ar*H*), 6.78 (d, 1H, $J = 7.8$ Hz, Ar*H*), 6.74 (t, 1H, $J = 7.6$ Hz, Ar*H*), 6.66 (d, 1H, $J = 8$ Hz, Ar*H*), 6.55 (s, 2H, Pz*H*), 4.26 (q, 4H, $J = 7.2$ Hz, –OCH_2), 2.09 (s, 6H, Pz–CH_3), 1.28 (t, 6H, $J = 7.2$ Hz, –CH_3). ^{13}C NMR ($CDCl_3$) δ 162.29, 154.62, 143.05, 141.90, 130.86, 128.09, 120.34, 119.71, 116.35, 109.41, 72.55, 60.93, 14.13, 11.40.

*L7OH (**2**)*. L6OH (1.0 g, 2.42 mmol) was dissolved in 20 ml of 2.0 M methylamine in THF. To this was added 0.02 g of tetraethylammonium cyanide and the mixture was stirred at 50 °C for 4 days. The white precipitate that separated from the solution was filtered, washed with THF, and dried under vacuo. Yield: 0.58 g (63%) *Anal.* Calc. for $C_{19}H_{22}N_6O_3$: C, 59.68; H, 5.80; N, 21.97. Found: C, 59.51; H, 5.78; N, 21.63%. ^{1}H NMR ($CDCl_3$) δ 9.97 (s, 1H, O*H*), 7.81 (s, 2H, –N*H*–), 7.80 (s, 1H, –C*H*–), 7.24 (t, 1H, $J = 7.4$ Hz, Ar*H*), 6.88 (d, 1H, $J = 7.8$ Hz, Ar*H*), 6.80 (t, 1H, $J = 7.4$ Hz, Ar*H*), 6.75 (d, 1H, $J = 7.2$ Hz, Ar*H*), 6.49 (s, 2H, Pz*H*), 2.71 (s, 3H, NHCH_3), 2.70 (s, 3H, NHCH_3), 2.14 (s, 6H, Pz–CH_3). ^{13}C NMR ($CDCl_3$) δ 163.22, 156.56, 147.57, 142.66, 132.02, 129.89, 122.46, 120.33, 116.83, 108.09, 71.60, 27.11, 12.58. A second, generally minor product was also isolated and identified by ^{1}H and ^{13}C NMR as the mixed ester amide substituted complex and designated L8OH (**3**).

*L9OH (**4**)*. This ligand was synthesized as described previously for L6OH using 3-*tert*-butyl-2-hydroxy-5-methylbenzaldehyde in place of salicylaldehyde. (80% Yield): ^{1}H NMR ($CDCl_3$) δ 8.59 (s, 1H, O*H*), 7.91 (s, 1H, –C*H*–), 7.09 (t, 1H, $J = 7.9$ Hz, Ar*H*), 6.78 (d, 1H, $J = 7.8$ Hz, Ar*H*), 6.74 (t, 1H, $J = 7.6$ Hz, Ar*H*), 6.66 (d, 1H, $J = 8$ Hz, Ar*H*), 6.55 (s, 2H, Pz*H*), 4.30 (q, 4H, $J = 7.2$ Hz, –OCH_2), 2.09 (s, 6H, Pz–CH_3), 1.28 (t, 6H, $J = 7.2$ Hz, –CH_3). ^{13}C NMR ($CDCl_3$) δ 162.29, 154.62, 143.05, 141.90, 130.86, 128.09, 120.34, 119.71, 116.35, 109.41, 72.55, 60.93, 14.13, 11.40.

2.2. Synthesis of Co and Ni complexes

*[L9OHCoBr$_2$]·CH$_2$Cl$_2$ (**5**)*. A solution of L9OH (0.20 g, 0.41 mmol) in 10 ml anhydrous MeOH was treated with solid $NaOCH_3$ (0.02 g, 0.41 mmol) under Ar atmosphere. To the clear solution, solid $CoBr_2$ (0.09 g, 0.41 mmol) was added. The mixture was stirred for 3 h and the MeOH removed under reduced pressure. The solid mass was dissolved in CH_2Cl_2 and filtered. The filtrate was concentrated and layered with hexane whereupon blue crystals separated out. These were filtered, washed and dried under vacuo. Yield: 0.20 g (60%). *Anal.* Calc. (Found) for $C_{27}H_{37}N_4O_6CoBr_2Cl_2$: C, 40.78 (40.16); H, 4.69 (4.80); N, 7.04 (7.33)%.

*[(L7O)Co]$_2$(BF$_4$)$_2$·2DMF (**6**)*. A solution of L7OH (0.20 g, 0.52 mmol) in 10 ml anhydrous DMF was treated with solid KH (0.02 g, 0.52 mmol) under Ar atmosphere. After gas evolution ceased, solid $Co(BF_4)_2 \cdot 6H_2O$ (0.18 g, 0.52 mmol) was added. The resulting purple solution was stirred for 3 h and filtered to remove a small amount of insoluble material. The filtrate was concentrated under reduced pressure. Layering a CH_3CN solution of the complex with diethyl ether caused the separation of purple crystals which were filtered, washed with ether and dried under vacuo. Yield: 0.42 g (68%). *Anal.* Calc. (Found) for $C_{44}H_{56}N_{14}O_8Co_2B_2F_8$: C, 44.03 (43.79); H, 4.70 (4.75); N, 16.33 (16.26)%. ^{1}H NMR (DMF-d_5) 62.52(s), 60.69(s), 38.73(s), 36.09(s), 13.72(s), 8.08(s),

3.56(s), 2.87(dd, $J_1 = 77.8$ Hz, $J_2 = 14$ Hz), −5.23(s), −24.28(s), −27.42(s).

[(L7O)Co]$_2$Br$_2$·2DMF (7). This compound was prepared as described for [(L7O)Co]$_2$(BF$_4$)$_2$·2DMF using $CoBr_2$ as the cobalt precursor (60%). *Anal.* Calc. (Found) for $C_{44}H_{56}N_{14}O_8Co_2Br_2$: C, 44.54 (44.19); H, 4.76 (4.75); N, 16.52 (16.36)%.

[(L7O)Ni]$_2$(ClO$_4$)$_2$·2DMF (8). This complex was synthesized following the same method used for the corresponding Co complexes, using $Ni(ClO_4)_2 \cdot 6H_2O$ as the metal precursor. X-ray quality crystals were grown from DMF/ether, (62%). *Anal.* Calc. (Found) for $C_{44}H_{56}N_{14}O_{16}Ni_2Cl_2$: C, 43.13 (43.38); H, 4.61 (4.78); N, 16.00 (16.09)%.

[pz$^{Me,\,CONHCH_3}$PyCoBr]$_2$·DMF (9). This complex was prepared by gentle warming of a pyridine solution of **7**. Upon cooling blue–green crystals of the title complex appeared which where characterized solely by X-ray crystallography.

2.3. Physical methods

Elemental analyses were obtained from Quantitative Technologies, Inc., White house, NJ. All samples were dried in vacuo prior to analysis. The presence of solvates was corroborated by FTIR, ^{1}H NMR or X-ray crystallography. ^{1}H and ^{13}C NMR spectra were collected on a Varian UNITY INOVA 400 MHz NMR spectrometer. Chemical shifts are reported in ppm relative to an internal standard of TMS. The ^{13}C quaternary carbon peaks that are not observed are a result of either poor solubility and/or overlapping signals. Electrospray mass spectra (ESI-MS) were recorded on a Finnigan LCQ ion-trap mass spectrometer equipped with an ESI source (Finnigan MAT, San Jose, CA). A gateway PC with Navigator software version 1.2 (Finnigan Corp., 1995–1997), was used for data acquisition and plotting. Isotope distribution patterns were simulated using the program IsoPro 3.0. IR spectra were recorded as KBr disks or in solution on a Perkin–Elmer Spectrum One FTIR spectrometer equipped with a Dell Optiplex PC. Electronic spectra were recorded using a Cary 50 spectrophotometer.

2.4. X-ray crystallography

Crystal, data collection, and refinement parameters for **1** and **5**, **6**, **8** and **9** are given in Table 1. Crystals of all complexes were sealed in thin-walled quartz capillaries, mounted on either Siemens P4 diffractometer with a sealed-tube Mo X-ray source ($\lambda = 0.71073$ Å) controlled via PC computer (data collected at 293 K) or a Nonius Kappa CCD diffractometer (data collected at 153 K). For the Siemens system automatic searching (Siemens XSCANS 2.1), centering, indexing, and least-squares routines were carried out for each crystal with at least 25 reflections in the range, $20° \leqslant 2\theta \leqslant 25°$ used to determine the unit cell parameters. During the data collection, the intensities of three representative reflections were measured every 97 reflections, and any decay observed was empirically corrected for by the software during data processing. We thank Dr. Vincent Lynch, Department of Chemistry University of Texas at Austin for data collection on the CCD diffractometer. The structures were all solved using direct methods or via the Patterson function, completed by subsequent difference Fourier syntheses, and refined by full-matrix least-squares procedures on F^2. All non-hydrogen atoms were refined with anisotropic displacement coefficients with hydrogens treated as idealized contributions using a riding model except were noted. All software and sources of the scattering factors are contained in the SHELXTL 5.0 program library (G. Sheldrick, Siemens XRD, Madison WI). Detailed crystallographic data including complete bond distances and angles for **1**, **5**, **6**, **8**, and **9** are on deposit at the CCDC as numbers CCDC 210363–210367.

3. Results and discussion

3.1. Ligand synthesis and characterization

The synthesis, in multigram quantities, of the ester-substituted heteroscorpionate ligands designated L6OH and L9OH (Fig. 1) required only two steps. The initial step involved treatment of two equivalents of 3-methyl-5-carboxyethyl)pyrazole with phosgene in THF in the presence of triethylamine as an acid scavenger to give di(3-methyl-5-carboxyethylpyrazolyl) ketone. Reaction of one equivalent of the ketone with an equivalent of the appropriate salicylaldehyde, either as a solution in dry DMF or as a melt, in the presence of 1% anhydrous $CoCl_2$ gave, after standard workup, the desired heteroscorpionate ligands. Conversion of the ester ligand L6OH to the amide ligand L7OH used a transamidation reaction in THF employing a large excess of methylamine and tetrabutylammonium cyanide as a catalyst. The desired product complex precipitated from solution after 72 h of reaction at 50 °C. A generally minor contaminant, but which in one case was the major product, was the unsymmetrical mixed ester-amide ligand designated L8OH. However as a reliable synthesis for this species was not forthcoming it was not pursued further. Attempts to prepare the corresponding 5-carboxyamido substituted ligand from L9OH were unsuccessful.

In addition to the standard methods for structure verification (elemental analysis, ^{1}H and ^{13}C NMR etc.) ligand L6OH was characterized by X-ray crystallography. The structure of L6OH revealed the presence of a unique and strongly hydrogen bonded water molecule in the crystal lattice. The hydrogen atoms of the water

integrating for two protons at 0.055 ppm. This peak was absent in crystals that had been dried under vacuum. If it corresponds to the unique water seen in the X-ray structure remains to be determined.

3.2. Metal complex chemistry

Despite our hopes that the hydrogen bond accepting ester-substituted heteroscorpionate ligands would stabilize interesting new complexes such as those we characterized for the homoscorpionate Tp analogs, such species were not forthcoming. In general the phenolate group proved to be a poor donor for divalent metals such as Ni, Co or Zn and the only species we could structurally characterize even in the presence of base designed to deprotonate the phenolate oxygen, were protonated, tetrahedral, dihalo complexes of which **5** (Fig. 3) is a representative example. No evidence for any hydrogen bonding interactions stabilized by the appended ester groups was evident.

We next turned our attention to the amide containing ligand L7OH. In this case treatment of a solution of the anion of the ligand (prepared by deprotonation of the phenol with KH in DMF) with the bromide, tetrafloroborate or perchlorate salts of Co(II), Ni(II) or Zn(II) produced a series of highly crystalline, isostructural complexes of the type shown in Fig. 4 for **6**. These dinuclear complexes of stoichiometry M_2L_2 have the ligand functioning in an unexpected pentadentate fashion rather than the more usual tridentate mode. In this mode, one pyrazole nitrogen and one amide carbonyl oxygen from each or the two ligands bind to metal with the phenolate oxygens functioning as a bridges to a second metal center. Each metal is thus six coordinate overall with M···M distances on the order of 3.0 Å.

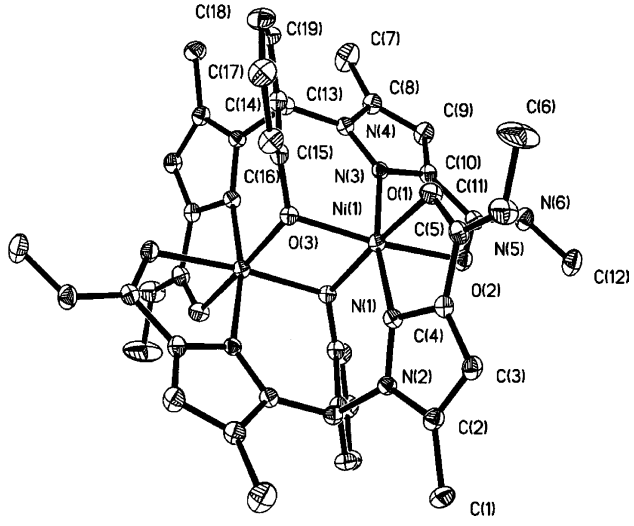

Fig. 4. ORTEP diagram for the cationic portion of **6** showing the atomic labeling for the crystallographically unique half of the molecular dimer. Thermal ellipsoids are at the 30% probability level.

In an initial attempt to grow larger crystals we uneventfully recrystallized both the tetrafloroborate and perchlorate salts of the Co(II) complex from DMF/pyridine. However upon gentle heating of the bromide salt there was a color change from purple to greenish-blue during which time the complex dissolved. Upon slow cooling crystals reappeared which were different from those of the starting complex. X-ray crystallography showed them to be that of the dinuclear 4 + 6 decomposition product **9** (Fig. 5) where the C–N bond between the pyrazole and the bridgehead carbon has been broken. In this structure one Co(II) is tetrahedrally coordinated to two bromides and a pyrazole nitrogen from each of two different 3-methyl-5-carboxamidopyrazole ligands. The second Co(II) is six coordinate with

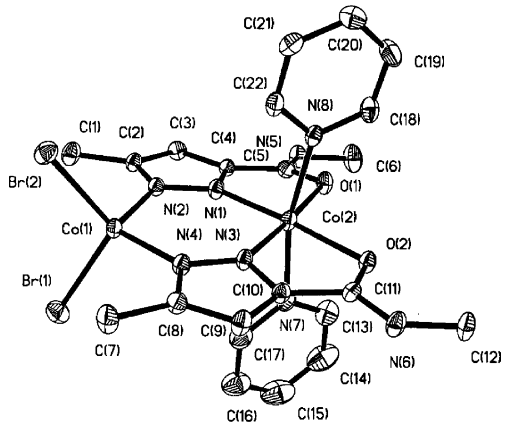

Fig. 5. ORTEP diagram for the decomposition product **9** showing complete atomic labeling. Thermal ellipsoids are at the 30% probability level.

each of the two pyrazoles functioning as bidentate ligand coordinating through a second pyrazole N and the amide carbonyl. The fifth and sixth axial coordination sites are filled by two pyridine nitrogens from the solvent. Bromide clearly plays a part in driving the decomposition reaction as the perchlorate and tetrafloroborate salts do not show this behavior unless bromide is added to the reaction mixture. No reaction takes place (as monitored by paramagnetic NMR spectroscopy) until the reaction mixture is heated. In the absence of pyridine an analogous DMF adduct is obtained showing that its presence is not required for reaction.

4. Conclusions

Several new heteroscorpionate ligands containing either appended hydrogen bond donating or accepting residues have been synthesized and characterized. Although the few metal complexes that we have examined thus far do not show the interesting intra or intermolecular hydrogen bonding interactions we were looking for, our exploration of their potentially rich coordination chemistry continues.

5. Supplementary information

Complete crystallographic data for compounds **1**, **5**, **6**, **8**, and **9**. These data under accession numbers CCDC 210363–210367, can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Complexes bearing an enantiopure N,N,O scorpionate ligand derived from (−)-menthone

Liv Peters, Nicolai Burzlaff *

Fachbereich Chemie der Universität Konstanz, Universitätsstraße 10, Fach M728, D-78457 Konstanz, Germany

Received 15 May 2003; accepted 12 August 2003

Abstract

Starting from (−)-menthone an enantiopure chiral tripod ligand is obtained via C_2 symmetric bis(menthylpyrazol-1-yl)methane bpm^{4menth} (**2c**) by introducing a carboxylate donor at the bridging carbon atom. A prochiral centre but no additional stereo centre is formed at this carbon atom resulting in a homochiral tripod ligand bpa^{4menth}H (**3**). As first examples, the complexes [Ru(bpa^{4menth})Cl(PPh$_3$)$_2$] (**4**), [Mn(bpa^{4menth})(CO)$_3$] (**5**) and [Re(bpa^{4menth})(CO)$_3$] (**6**) bearing this enantiopure scorpionate ligand were synthesized. Single-crystal X-ray structure analyses of bpm^{4menth} (**2c**), bpa^{4menth}H (**3**) and [Re(bpa^{4menth})(CO)$_3$] (**6**) are reported, too.

1. Introduction

Bis(pyrazol-1-yl)acetic acids which represent a new class of "heteroscorpionate" ligands have attracted in recent years an increasing interest. These ligands, which were introduced to coordination chemistry by A. Otero in 1999 [1], are related to the tris(pyrazol-1-yl)methane system, where one of the pyrazolyl groups has been replaced by a carboxylate. Two different synthetic routes for the syntheses of these ligands have been established so far: (a) Deprotonation of bis(pyrazol-1-yl)methanes at the methylene group with *n*-BuLi followed by reaction with carbon dioxide yields lithium salts of the bis(pyrazol-1-yl)acetates. These can either be used directly for further reactions [1] or after acidic workup be isolated as bis(pyrazol-1-yl)acetic acids [2]. This synthetic route is restricted to bis(pyrazol-1-yl)methanes bearing substituents in position 5 of the pyrazol-1-yl groups, since otherwise the deprotonation would take place at this position [3]. (b) In an alternative route dibromoacetic acid reacts under phase transfer conditions with base and unsubstituted pyrazole or 3,5-dimethylpyrazole to the bis(pyrazol-1-yl)acetates. After an acidic workup the targeted bis(pyrazol-1-yl)acetic acids are obtained, namely bis(pyrazol-1-yl)acetic acid (bpzaH) and bis(3,5-dimethylpyrazol-1-yl)acetic acid (bdmpzaH) [2,4].

The coordination chemistry of various bis(pyrazol-1-yl)acetato ligands has been exploited for several transition metals. Examples out of group 4 [5], group 5 [1], group 6 [6], group 7 [4,7], group 8 [2,8,9], group 11 [10] and group 12 [2,11,12] have been published so far. Recent reports focused on chiral though racemic examples out of the class of bis(pyrazol-1-yl)acetato tripod ligands [1c,11]. Usually the chirality originates from two different pyrazolyl donor groups, that are bound to the acetic acid, e.g. (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid (bpa^{tBu2,Me2}H) (Fig. 1(a)) [11]. [1] To avoid extraordinary long abbreviations the abbreviation system for Tp and benzopyrazolylborates Tp^{Bo} ligands introduced by S. Trofimenko was transferred to this problem. A superscript of 3 or 4 preceding "menth" indicates a 3,4- or 4,5-fusion of the menthyl group to the pyrazole. This resulted in the abbreviations bpa^{tBu2,Me2}H, bpm^{4menth} (2c), bpa^{4menth}H (3) and bpa^{4menth} for the anion of **3**. Following these rules bis(camphorpyrazol-1yl)acetic acid is now abbreviated as bpa^{4cam}H instead of bpa^{cam2}H, as we did in a former publication [9]. For further details see: S. Trofimenko, Scorpionates – The Coordination Chemistry of Polypyrazolylborate Ligands, Imperial College Press, London (1999) pp. 5.

(a) *rac* bpa$^{t\mathrm{Bu2,Me2}}$H **(b)** (+)-bpa$^{4\mathrm{cam}}$H

Fig. 1. Chiral tripod ligands.

For asymmetric induction enantiomers have to be separated, and the enantiomeric purity has to be validated. Such a separation of enantiomers often is an elaborate, low-yield process. In addition a stable configuration of the stereogenic centres has to be assured. If one of the donor groups is chiral and enantiopure or derived from the *chiral pool*, the problem is converted into a separation job of diastereomers, but still elaborate. To overcome these problems, we introduced a general concept to obtain new enantiopure facially binding tripod ligands from C_2 symmetric precursors. Recently we presented a first example for this concept derived from (+)-camphor (Fig. 1(b)) [9]. We now wish to report on a second example derived from (−)-menthone.

2. Results and discussion

Many chiral bidentate ligands exhibit C_2 symmetry as a common feature [13]. If the C_2 axis of such a ligand goes through a tetrahedral bridging atom connecting two identical enantiopure donor groups Y*, any additional group Z at this atom will cause no additional stereo centre, but a prochiral centre (Fig. 2(a)) [14]. (*S*, *S*)-Trihydroxyglutaric acid is an often cited textbook example for such a prochiral compound [14]. Inversion of configuration at C3 in (*S*, *S*)-trihydroxyglutaric acid (Fig. 2(b)) yields the identical compound.

Therefore, enantiopure tripod ligands can be obtained from C_2 symmetric precursors in a direct synthesis by applying this concept. No additional separation of enantiomers or diastereomers is necessary. As a first example for this concept, we recently reported on bis(camphorpyrazol-1-yl)acetic acid (bpa$^{4\mathrm{cam}}$H) (Fig. 1(b)), its direct synthesis in four steps starting from (+)-camphor and its coordination properties as an enantiopure scorpionate ligand [9], 1. In enantiomerically pure C_3 symmetric tripod ligands often pyrazoles derived from (−)-menthone are used instead of camphorpyrazolyl groups [15,16]. Therefore, we took an interest in a C_2 symmetric bis(menthylpyrazol-1-yl)methane reported by Togni and Venanzi [17]. Three structural isomers of bis(menthylpyrazol-1-yl)methane (**2a**, **2b** and **2c**) are formed by coupling of (2*R*, 5*R*)-menthylpyrazole **1** with CH_2Cl_2 in a two-phase system [17]. A reaction with CH_2Cl_2 as reactant and only solvent is higher in yield compared to the two-phase procedure by Togni and Venanzi. All three structural isomers can be separated by column chromatography and additional crystallisation steps. Crystallisation from pentane afforded colourless crystals of bpm$^{4\mathrm{menth}}$ (**2c**). A single-crystal X-ray diffraction experiment proves the desired constitution of **2c** (Fig. 3).

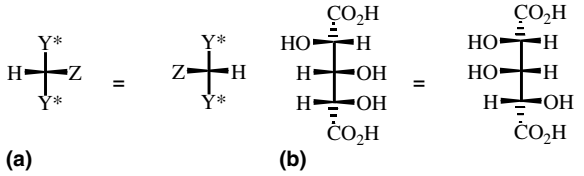

Fig. 2. Prochiral centre of (*S*, *S*)-trihydroxyglutaric acid [14].

By analogy to Otero's synthesis of bis(3,5-dialkylpyrazol-1-yl)acetic acids [1], deprotonation at the bridging carbon atom and subsequent reaction with carbon dioxide introduces a carboxylate group at this position. As mentioned above, the structural isomer bpm$^{3\mathrm{menth}}$ (**2a**) would be deprotonated also at the pyrazolyl C5 by *n*-BuLi, due to missing substituents here [3]. Therefore, only isomer **2c** out of the two C_2 symmetric isomers **2a** and **2c** can be used for this reaction sequence. Acidic workup yields the enantiopure bis(menthylpyrazol-1-yl)acetic acid bpa$^{4\mathrm{menth}}$H (**3**) (Scheme 1).

For the (2*R*, 5*R*)-menthylpyrazolyl groups two sets of signals are found in the ^{1}H and ^{13}C NMR spectra. A strong IR band at 1759 cm^{-1} and a ^{1}H NMR signal at 13.05 ppm indicate the carboxylate group. Crystals of **3** suitable for X-ray structure determination were obtained from CH_3CN (Fig. 4, Tables 1 and 2). Bond distances and bond angles of **3** are in good agreement with those reported earlier for chiral bis(camphorpyrazol-1-yl)acetic acids bpa$^{4\mathrm{cam}}$H [9].

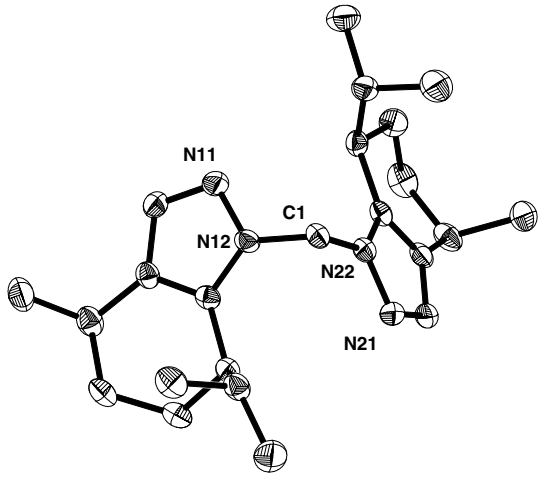

Fig. 3. Molecular structure of bpm$^{4\mathrm{menth}}$ (**2c**); thermal ellipsoids at 50% probability level.

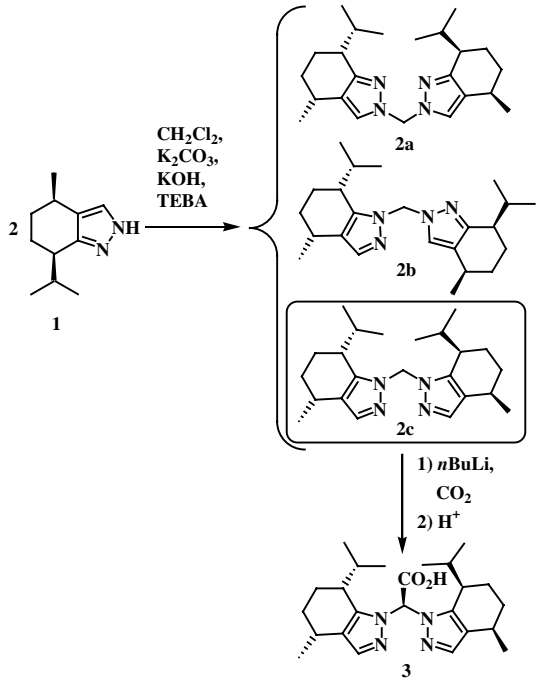

Scheme 1. Synthesis of bis(menthylpyrazol-1-yl)acetic acid.

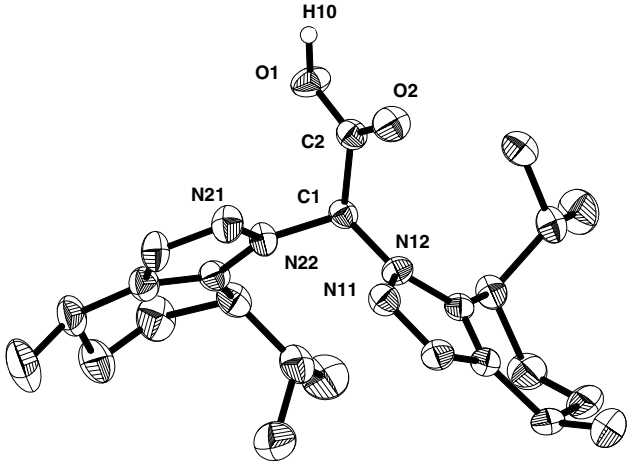

Fig. 4. Molecular structure of bpa^{4menth}H (**3**); thermal ellipsoids at 50% probability level.

Bis(pyrazol-1-yl)acetato ligands are tripodal ligands that are as useful in coordination and organometallic chemistry as hydrido(trispyrazol-1-yl)borate (Tp) and its analogues [4]. As an example we reported recently the formation of the ruthenium complexes [Ru(L)Cl(PPh$_3$)$_2$] (L = bpza, bdmpza, bpa^{4cam}) by reaction of the potassium carboxylates with [RuCl$_2$(PPh$_3$)$_3$] [8,9]. A similar reaction of the potassium salt of bpa^{4menth}H (**3**) with [RuCl$_2$(PPh$_3$)$_3$] yields [Ru(bpa^{4menth})Cl(PPh$_3$)$_2$] (**4**) (Scheme 2). An asymmetric carboxylate IR signal $\nu_{as} = 1670$ cm^{-1} and the MH$^+$ = 1071 peak in the FAB mass spectrum indicate the coordination of the ligand. As in [Ru(bpa^{4cam})Cl(PPh$_3$)$_2$] [9], two sets of signals in the ^{1}H and ^{13}C NMR spectra are observed for the (2*R*, 5*R*)-menthylpyrazolyl groups. Two sets of signals in these spectra and two doublets in the ^{31}P NMR

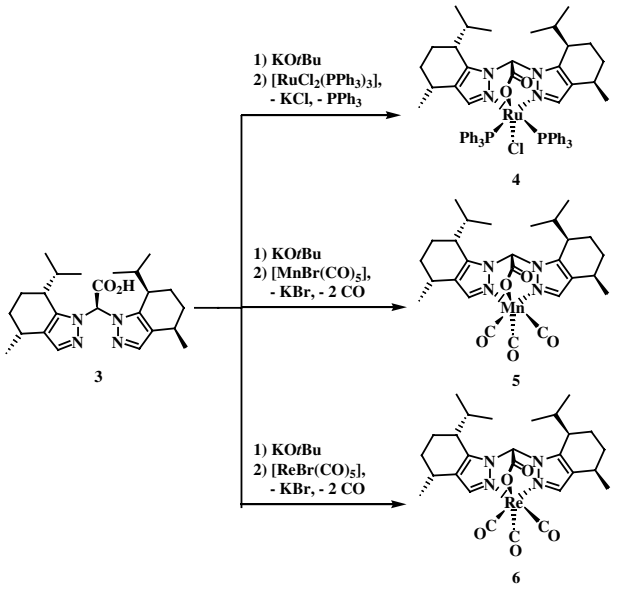

Scheme 2. Syntheses of complexes bearing bis(menthylpyrazol-1-yl)acetato ligands.

spectrum at 38.4 and 42.9 ppm ($^2J_{P,P} = 35.6$ Hz and 32.4 Hz) are reasonable for two PPh_3 ligands in a chiral environment. According to cross coupling observed in the COSY and ROESY spectra, three singlets in the ^1H NMR spectrum are assigned to the two pyrazol C(3)H protons (^1H NMR: 6.78 and 6.95 ppm; ^{13}C NMR: 142.2 and 142.8 ppm) and the bridging CH proton (^1H NMR: 6.32 ppm; ^{13}C NMR: 71.4 ppm). A rather similar distribution of these signals was observed for the symmetric ruthenium complex $[Ru(bpza)Cl(PPh_3)_2]$ [^1H NMR: 6.61 ppm ($C_{bridge}H$), 6.87 ppm ($2 \times C_{pz}(3)H$)], in which both PPh_3 ligands are *trans* to the pyrazolyl groups [8]. Therefore, a geometry with both PPh_3 ligands *trans* to the pyrazolyl groups is assumed for complex **4**.

Another example for the similarity between bis(pyrazol-1-yl)acetato ligands, Tp and Cp ligands, which we reported previously, is the formation of tricarbonyl complexes $[Mn(L)(CO)_3]$ and $[Re(L)(CO)_3]$ (L = bpza, bdmpza) starting from the pentacarbonyl complexes $[MnBr(CO)_5]$ and $[ReBr(CO)_5]$ [4]. By reaction of these pentacarbonyl complexes with potassium bis(menthylpyrazol-1-yl)acetate K[bpa^{4menth}] we were now able to obtain chiral bis(menthylpyrazol-1-yl)acetato tricarbonyl complexes [Mn(bpa^{4menth})$(CO)_3$] (**5**) and [Re(bpa^{4menth})$(CO)_3$] (**6**) (Scheme 2). K[bpa^{4menth}] was produced in situ from the acid and potassium *tert*-butylate. CO evolution was observed during the reactions, and the progress of the reactions was monitored by IR spectroscopy. The complexes **5** and **6** are rather stable and can be stored for days as solids under aerobic conditions. Asymmetric carboxylate IR signals (**5**: $\nu_{as} = 1680$ cm^{-1}, **6**: $\nu_{as} = 1685$ cm^{-1}) and MH^+ peaks in the FAB mass spectra indicate the formation of the targeted complexes. As in **4** two sets of signals in the ^1H and ^{13}C NMR spectra are observed for the (2*R*, 5*R*)-menthylpyrazolyl groups. The NMR signals of **5** are rather broad, some of its ^{13}C NMR signals are covering each other, some are not observed. The IR signals of **5** and **6** are those of unsymmetrical "piano stool" type complexes with single A_1 and two E signals each. These CO absorptions (**5**: $\nu(CO) = 2037$, 1943 and 1920 cm^{-1}, **6**: $\nu(CO) = 2025$, 1918 and 1900 cm^{-1}) are almost identical to those of the previously reported complexes $[Mn(bdmpza)(CO)_3]$ and $[Re(bdmpza)(CO)_3]$ [4]. Therefore, the electron donation properties of the bpa^{4menth} ligand are similar to those of bdmpza, which is a slightly less electron donating ligand compared to the cyclopentadienyl ligand Cp. This implies a future reactivity of **5** and **6** similar to $[MnCp(CO)_3]$ and $[ReCp(CO)_3]$. A strong, broad IR signal at 3570 cm^{-1} indicates a water adduct of **5**. This is supported by the elemental analysis of **5**, which fits to an adduct $\mathbf{5} \times 2\,H_2O$. Crystals of **6** suitable for X-ray structure determination were obtained from acetone (Fig. 5). Selected distances and angles are summarised in Tables 1 and 2

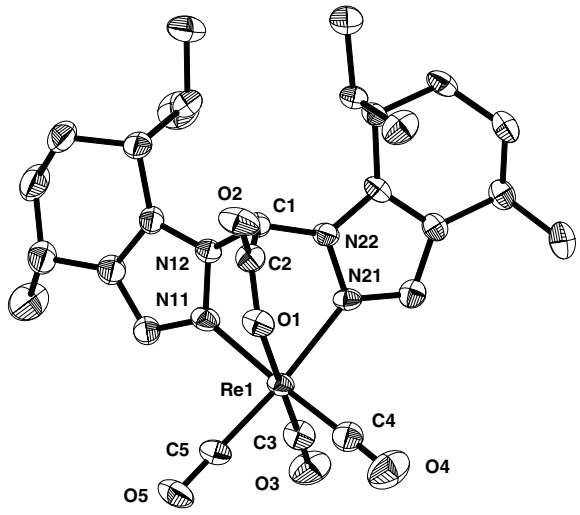

Fig. 5. Molecular structure of [Re(bpa^{4menth})$(CO)_3$] (**6**); thermal ellipsoids at 50% probability level.

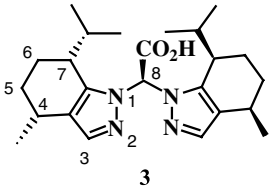

3

Fig. 6. Numbering scheme applied for the assignment of the NMR data.

(see also Fig. 6). A possible *trans* influence of the pyrazolyl acceptors onto the metal-carbonyl bonds is not indicated by the three the Re–C distances. Such a *trans* influence was reported earlier for the complexes [Re(bpza)$(CO)_3$] and [Re(bdmpza)$(CO)_3$] [4]. Nevertheless, the distances and angles of these complexes are in good agreement with those of **6**.

Our results show that new enantiopure facially binding tripod ligands can be obtained from certain C_2 symmetric precursors by adding a third donor, e.g. a carboxylate donor group, onto the bridging carbon atom. No additional stereo centre but a prochiral centre is formed. By applying this concept, a homochiral ligand is obtained by a simple separation of structural isomers (here **2a**, **2b** and **2c**). No additional separation of enantiomers or diastereomers is necessary. Future work to extend this concept will focus on the conversion of other C_2 symmetric ligands derived from the *chiral pool*.

3. Experimental

3.1. Materials

All organometallic experiments were carried out in Schlenk tubes under argon atmosphere. The solvents

were dried by standard procedures, distilled and stored under argon. $[RuCl_2(PPh_3)_3]$, $[MnBr(CO)_5]$ and $[ReBr(CO)_5]$ were prepared according to literature [18–20]. Hydrated ruthenium trichloride (35–40% Ru) was a generous gift of the Degussa AG. (−)-Menthone was used as purchased. Bpm^{4menth} (**2c**) was prepared and isolated in analogy to the procedure reported earlier by A. Togni and L. M. Venanzi [17], but with CH_2Cl_2 as solvent and reagent. **2c** was separated from a crude mixture of **2a**, **2b** and **2c** (60 mmol) via column chromatography with pentane/ethyl acetate (7:2, v/v) on silica (30 cm, ∅ 9 cm). R_f (pentane/ethyl acetate, 7:2, v/v, silica 60 plate, $KMnO_4$ stain) = 0.88 (**2c**), 0.55 (**2b**) and 0.40 (**2a**).

3.2. Instrumentation

Micro crystalline precipitates were separated by filtration or centrifugation with a Hettich Rotina 46 R Schlenk tube centrifuge. IR: Biorad FTS 60, CaF_2 cuvets (0.1 mm). ^1H NMR and ^{13}C NMR: Bruker AC 250, δ values relative to TMS. ^{31}P NMR: JEOL GX 400. Two-dimensional NMR experiments: Bruker DRX 600 (Avance). EI MS and FAB MS: modified Finnigan MAT 312. Elemental analyses: Analytical Laboratory of the Fachbereich Chemie. A modified Siemens P4 diffractometer was used for X-ray structure determinations.

3.3. Ligand synthesis

*$Bpa^{4menth}H$ (**3**).* A solution of bpm^{4menth} (**2c**) (2.13 g, 5.78 mmol) in THF (50 mL) was treated with *n*-BuLi (~1.6 M in hexane, 5.50 mL, 8.80 mmol) at −70 °C. The solution was allowed to warm to −40 °C over a period of 2 h and finally flushed with a flow of CO_2 for 15 min. At ambient temperature the solvent was removed in vacuo and the residue dissolved in water (30 mL). The aqueous solution was acidified with HCl (6 M) to pH 1–2 and extracted with Et_2O (4 × 50 mL). The combined organic layers were dried (Na_2SO_4) and concentrated in vacuo to a residue. Recrystallisation from acetonitrile yielded $bpa^{4menth}H$ **(3)** as a colourless crystal powder. Crystals suitable for X-ray structure determination were obtained from a solution in acetonitrile. Yield 982 mg (41%). m.p. 139–141 °C. $[\alpha]_D^{23} = +162.2$ ($c = 0.1$ g cm^{-3}, CH_2Cl_2). ^1H NMR (400 MHz, $CDCl_3$): $\delta = 0.69$ (d, $^3J_{H,H} = 7.0$ Hz, 3 H, CH_3), 0.86 (d, $^3J_{H,H} = 6.6$ Hz, 3 H, CH_3), 1.03 (d, $^3J_{H,H} = 6.6$ Hz, 3 H, CH_3), 1.06 (d, $^3J_{H,H} = 7.0$ Hz, 3 H, CH_3), 1.17 (d, $^3J_{H,H} = 7.1$ Hz, 3 H, CH_3), 1.23 (d, $^3J_{H,H} = 7.0$ Hz, 3 H, CH_3), 1.30–1.85 (m, 8 H, H5, H5′, H6, H6′), 1.90, 2.25 (m, 2 H, CH*i*Pr, CH*i*Pr′), 2.40–2.90 (m, 4 H, H4, H4′, H7, H7′), 6.77 (s, 1 H, CH), 7.47, 7.59 (s, 2 H, H_{pz}, H_{pz}'), 13.05 (s, br, 1 H, CO_2H). ^{13}C NMR (100.6 MHz, $CDCl_3$): δ = 18.4, 19.5, 21.0, 21.1, 21.3, 21.4 (6 × CH_3), 21.7, 23.3 (C6, C6′), 26.7, 26.8 (C4, C4′), 28.5, 29.6 (C5, C5′), 31.5, 31.8 (CH*i*Pr, CH*i*Pr′), 35.7, 36.6 (C7, C7′), 70.1 (C8), 124.0, 124.7 (C_{pz}, C_{pz}'), 137.6, 139.0 (CH_{pz}, CH_{pz}'), 142.1, 143.4 (C_{pz}, C_{pz}'), 165.3 (CO_2H). EI MS (70 eV, 150 °C): *m/z* (%) = 412 (1) [M^+], 368 (12) [M^+–CO_2], 325 (3) [M^+–CO_2–*i*Pr], 191 (68) [CH_2pz^{menth}], 178 (32) [pz^{menth}], 147 (53) [CH_2pz^{menth}–*i*Pr], 135 (100) [pz^{menth}–*i*Pr]. IR (THF): $\nu = 1759$ (CO_2H) cm^{-1}. *Anal.* Calc. for $C_{24}H_{36}N_4O_2$ (412.58): C, 69.87; H, 8.79; N, 13.58. Found: C, 69.52; H, 8.69; N 13.48%.

3.4. Complex syntheses

*$[Ru(bpa^{4menth})Cl(PPh_3)_2]$ (**4**).* $Bpa^{4menth}H$ (276 mg, 0.668 mmol) in THF (30 mL) with KO*t*Bu (68 mg, 0.606 mmol) was stirred at ambient temperature for 1 h. $[RuCl_2(PPh_3)_3]$ (500 mg, 0.521 mmol) was added, and the solvent was removed in vacuo after 1 h. The residue was washed with H_2O (2 × 10 mL) and pentane (2 × 20 mL) and dried in vacuo. The residue was dissolved in Et_2O (2 mL), precipitated by adding pentane (20 mL) and filtered off to afford $[Ru(bpa^{4menth})Cl(PPh_3)_2]$ (**4**) as yellow-greenish crystal powder. Yield 245 mg (44%). m.p. 210 °C (dec.). $[\alpha]_D^{23} = +10.7$ ($c = 0.1$ g cm^{-3}, CH_2Cl_2). ^1H NMR (600 MHz, $CDCl_3$): $\delta = 0.56$ (d, $^3J_{H,H} = 6.8$ Hz, 3 H, CH_3*i*Pr), 0.79 (d, $^3J_{H,H} = 6.8$ Hz, 3 H, CH_3), 0.90 (d, $^3J_{H,H} = 6.8$ Hz, 3 H, CH_3), 0.92 (d, $^3J_{H,H} = 6.6$ Hz, 3 H, CH_3), 1.07 (d, $^3J_{H,H} = 6.8$ Hz, 3 H, CH_3), 1.09 (d, $^3J_{H,H} = 6.8$ Hz, 3 H, CH_3), 1.20–1.90 (m, 8 H, H5, H5′, H6, H6′), 2.02 (m, 2 H, CH*i*Pr, CH*i*Pr′), 2.10–3.00 (m, 4 H, H4, H4′,H7, H7′), 6.32 (s, 1 H, CH), 6.78, 6.95 (s, 2 H, H_{pz}, H_{pz}'), 7.00–7.50 (m, 30 H, PPh_3). ^{13}C NMR (150.9 MHz, $CDCl_3$): δ = 18.6, 19.2, 20.4, 21.0, 21.1, 21.7 (6 × CH_3), 21.8, 23.0 (C6, C6′), 26.3, 26.5 (C4, C4'), 27.8, 28.9 (C5, C5′), 31.6, 32.0 (CH*i*Pr, CH*i*Pr′), 35.0, 38.5 (C7, C7′), 71.4 (C8), 123.4, 123.7 (C_{pz}, C_{pz}'), 126.8 (d, $^3J_{C,P} = 8.7$ Hz, *m*-PPh_3), 126.9 (d, $^3J_{C,P} = 8.7$ Hz, *m*-PPh_3), 128.3 (s, *p*-PPh_3), 128.4 (d, $^4J_{C,P} = 1.0$ Hz, *p*-PPh_3), 134.5 (d, $^2J_{C,P} = 9.1$ Hz, *o*-PPh_3), 134.9 (d, $^2J_{C,P} = 8.8$ Hz, *o*-PPh_3), 135.2 (d, $^1J_{C,P} = 39.1$ Hz, *i*-PPh_3), 135.7 (d, $^1J_{C,P} = 38.3$ Hz, *i*-PPh_3), 142.2, 142.8 (CH_{pz}, CH_{pz}'), 143.5, 144.8 (C_{pz}, C_{pz}'), 166.2 (CO_2^-). ^{31}P NMR (161.9 MHz, $CDCl_3$): δ = 38.4 (d, $^2J_{P,P} = 35.6$ Hz), 42.9 (d, $^2J_{P,P} = 32.4$ Hz). FAB MS: *m/z* (%) = 1071 (30) [M^+], 1036 (66) [M^+–Cl], 810 (100) [MH^+–PPh_3], 775 (47) [MH^+–PPh_3–Cl]. IR (THF): $\nu = 1670$ (CO_2^-) cm^{-1}; *Anal.* Calc. for $C_{60}H_{65}ClN_4O_2P_2Ru$ (1072.67): C, 67.18; H, 6.11; N, 5.22. Found: C, 67.16; H, 6.30; N, 5.05%.

*$[Mn(bpa^{4menth})(CO)_3]$ (**5**).* $Bpa^{4menth}H$ (447 mg, 1.08 mmol) in THF (50 mL) with KO*t*Bu (121 mg, 1.08 mmol) was stirred at ambient temperature for 30 min. $[MnBr(CO)_5]$ (298 mg, 1.08 mmol) was added, the reaction mixture was heated under reflux and checked by IR on a regular basis. After 4 h the reaction was completed, and the solvent was removed in vacuo. The

residue was washed with H_2O (2×10 mL) and Et_2O (50 mL) and dried in vacuo to afford [Mn(bpa^{4menth})$(CO)_3$] (**5**) as yellow crystal powder. Yield 470 mg (79%). m.p. 235 °C (dec.). $[\alpha]_D^{23} = +88.2$ ($c = 0.1$ g cm^{-3}, CH_2Cl_2). ^{1}H NMR (250 MHz, $CDCl_3$): $\delta = 0.77$ (d, $^3J_{H,H} = 5.8$ Hz, 3 H, CH_3), 0.87 (s, br, 3 H, CH_3), 1.09 (s, br, 6 H, $2 \times CH_3$), 1.22 (d, $^3J_{H,H} = 6.4$ Hz, 3 H, CH_3), 1.29 (d, $^3J_{H,H} = 6.7$ Hz, 3 H, CH_3), 1.35–2.40 (m, 10 H, H5, H5′, H6, H6′, CH*i*Pr, CH*i*Pr′), 2.50–3.10 (m, 4 H, H4, H4′, H7, H7′), 6.32 (s, br, 1 H, CH), 7.81, 7.86 (s, 2 H, H_{pz}, H_{pz}′). ^{13}C NMR (62.9 MHz, $CDCl_3$): $\delta = 18.4$, 18.8, 20.8, 20.9 ($6 \times CH_3$), 21.4, 22.4 (C6, C6′), 26.2, 26.3 (C4,C4′), 28.3, 28.9 (C5, C5′), 31.9, 32.3 (CH*i*Pr, CH*i*Pr′), 35.6, 37.6 (C7, C7′), 69.6 (br, C8), 124.6, 124.9 (C_{pz}, C_{pz}′), 142.2, 142.3 (CH_{pz}, CH_{pz}′), 144.1, 144.3 (C_{pz}, C_{pz}′), 193.6, 194.1, 194.6 ($3 \times CO$). FAB MS (NBOH): *m*/*z* (%) = 551 (15) [MH$^+$], 467 (40) [MH$^+$–3 CO], 423 (100) [MH$^+$–3 CO–CO_2]. 3.5. X-ray crystal structure and analysis

Single crystals of **2c**, **3** and **6** were mounted with Paratone N on glass fibres. A modified Siemens P4 diffractometer was used for data collection (graphite monochromator, Mo K_α radiation, $\lambda = 0.71073$ Å, scan rate 4–30° min^{-1} in ω). The structures were solved and refined using the SHELX-97 program package (refined with full-matrix least-squares against F^2) [21]. A weighting scheme was applied in the last steps of the refinement with $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ and $P = [2F_c^2 + \mathrm{Max}(F_o^2, 0)]/3$. Hydrogen atoms were included in their calculated positions and refined in a *riding model*. One molecule CH_3CN co-crystallised per asymmetric unit in **3**. The carboxylate proton of **3** was found and refined isotropically. All details and parameters of the measurements are summarised in Table 3. Structure pictures were prepared with the program Diamond 2.1e [22].

4. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-210441 (bpm^{4menth}) (**2c**), CCDC-210441 ($bpa^{4menth}H \times CH_3CN$) (**3** × CH_3CN), and CCDC-210443 [$Re(bpa^{4menth})(CO)_3$] (**6**). These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44)1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk).

Abstract

A range of complexes of Ce and Nd have been prepared to compare the chemistry of the non-reducible $[(Tp^{Me2})_2LnX]$ (Ln = Ce, Nd) with that reported previously for the redox-active samarium ion. The chloride $[(Tp^{Me2})_2NdCl]$ is a useful starting material for the preparation of the seven coordinate $[Nd(Tp^{Me2})_2OAr]$ (Ar = C_6H_4-4-X; X = H, Bu^t, Br, Ph, OMe, F, Me) and $[Nd(Tp^{Me2})_2NPh_2]$. Crystal structures of $[Nd(Tp^{Me2})_2Cl]$ and $[Nd(Tp^{Me2})_2NPh_2]$ are isostructural with those of the analogous samarium species. The eight coordinate species $[Nd(Tp^{Me2})_2(\beta\text{-dike})]$ (β-dike = $(RC{=}O)_2CH$, R = Me, Ph; Bu^t) and their cerium analogues (R = Ph, Bu^t) have also been prepared. The complexes are fluxional, the extent of this behaviour depending on the steric bulk of the substituents. The structure of $[Nd(Tp^{Me2})_2(Bu^tCO)_2CH]$ has been determined. Finally, in efforts to prepare a neodymium hydride, the unexpected borohydride $[Nd(Tp^{Me2})_2(H_2BEt_2)]$ has been isolated serendipitously and structurally characterized.

1. Introduction

The past few years have witnessed the rapid growth of interest in the lanthanides. This is part driven by a perception of the rare earths as representing a "last frontier" in the periodic table. At the same time the potential applications of the lanthanides in catalysis, diagnostics, and materials chemistry have provided a powerful impetus to this work. A key theme which has underpinned these developments is the observation that kinetic stabilization of the metal centre through the use of bulky ancillaries is critical to the isolation of well-defined species. Although cyclopentadienyls and their derivatives still dominate the field, chemistry using other carbocyclic systems have been developed [1] and nitrogen donor alternatives have been used by a growing number of workers [2]. The pyrazolylborates (Tp) [3] have proved extremely effective in providing a well-defined coordination sphere for the lanthanides. Both first and second-generation Tp ligands [3b,3c] have been explored to generate both sandwich and half-sandwich systems which are resistant to ligand redistribution and which afford mononuclear products. In the case of sandwich complexes, use of the easily accessible Tp^{Me2} ligand has led to a rich divalent reactivity being uncovered for divalent samarium. $[Sm(Tp^{Me2})_2]$ has been shown to react by electron transfer with oxidizers including O_2 [4], azobenzene [5], dichalcogenides [6,7], metal-metal bonds [8,9] etc. to give trivalent species. Hydrides [10] and hydrocarbyls [15] are attractive synthetic targets for catalyst studies. Unfortunately, with Tp^{Me2} ligands no hydrides have been observed and only two complexes containing Sm–C bonds have been prepared: the acetylide, $[Sm(Tp^{Me2})_2CCPh]$, and the cyclopentadienyl, $[Sm(Tp^{Me2})_2(\eta^5\text{-}C_5H_5)]$ by redox transmetallation with mercury phenylacetylide [11] and

doi:10.1016/j.poly.2003.11.014

thallium cyclopentadienide [12], respectively. The weak basicity of these ligands, however, precludes many protonolysis reactions. Attempts to use other mercury reagents in analogous reaction have failed and metathesis methods have been equally unsuccessful usually as a result of reduction of the metal to the highly insoluble complex $[Sm(Tp^{Me2})_2]$ [13,14]. Here we present analogous chemistry to that of samarium using the non-reducible lanthanides Ce and Nd together with attempts to prepare hydrides and hydrocarbyls.

2. Results and discussion

Reaction of $NdCl_3$ with either Na or KTp^{Me2} in THF leads to the formation of the pale blue complex $[Nd(Tp^{Me2})_2Cl]$ (**1**) in variable yields although the use of $NdCl_3(THF)_2$ proved to be a rather more reliable.

$$NdCl_3 + 2KTp^{Me2} \rightarrow [Nd(Tp^{Me2})_2Cl] + 2KCl$$

Like its samarium analogue **1** dissolves in THF and aromatic solvents, but not in petroleum ether, and give simple, though paramagnetically shifted ^1H spectra consistent with a fluxional coordination sphere. The Eu analogue **1-Eu** may be prepared analogously, has similar solubility, and is obtained in similar yield. **1-Eu** can be reduced readily to the known insoluble orange divalent complex $[Eu(Tp^{Me2})_2]$ by stirring with sodium chips [14]. Attempts to prepare the analogous complex with yttrium, $[Y(Tp^{Me2})_2Cl]$, was not successful – no significant soluble products were isolated apart from dimethylpyrazole, indicating extensive decomposition.

Compound **1** is a useful starting material for a range of derivatives. Reaction of **1** with NaOAr ($Ar = C_6H_4$-4-R) gives seven coordinate phenoxides, $[Nd(Tp^{Me2})_2OAr]$ ($Ar = C_6H_5$ (**2a**); C_6H_4-4-Bu^t (**2b**); C_6H_4-4-Br (**2c**); C_6H_4-4-Ph (**2d**); C_6H_4-4-OMe (**2e**); C_6H_4-4-F (**2f**); C_6H_4-4-Me (**2g**)) analogous to the samarium complexes some of which have been crystallographically characterized and have been or will be reported elsewhere [13,17].

$$Nd(Tp^{Me2})_2Cl + NaOAr \rightarrow Nd(Tp^{Me2})_2OAr + NaCl$$

Complexes **2a**–**2g** were isolated by pumping down the filtered reaction mixture and were only characterized by their ^1H NMR spectrum. The aryloxides are fluxional in solution giving simple spectra with a 9:9:3 pattern of singlets for the Tp^{Me2} resonances and two broadened and very strongly shifted resonances for the *ortho* and *meta* hydrogens of the phenyl groups, respectively. The ortho protons were particularly striking as they generally appear around +45 ppm as a very broad hump in the baseline only visible after long accumulation times. The spectrum of **2a** ($Ar = C_6H_5$) was invariant down to −90 °C, apart from the typical Curie dependence of the chemical shifts Scheme 1.

Metathesis of **1** with $NaNPh_2$ in THF results in the isolation of $[Nd(Tp^{Me2})_2NPh_2]$ (**3**).

$$[Nd(Tp^{Me2})_2Cl] + NaNPh_2 \rightarrow [Nd(Tp^{Me2})_2NPh_2] + NaCl.$$

In striking contrast to its samarium analogue [13], which is a fairly intense red colour, **3** displays the pale blue/lilac typical of Nd(III) species. This suggests that the red colour in $[Sm(Tp^{Me2})_2NPh_2]$ arises from a LMCT transition from the amide to the more reducible metal centre. Like its samarium analogue, **3** gives a more complex spectrum than **2**, indicating a non-fluxional C_2 symmetric coordination sphere – the phenyl groups of the amide ligand presumably prevent the methyl groups of the Tp^{Me2} ligands from rotating around the Sm-B axis and thereby effectively lock the coordination sphere. The spectra were assigned on the basis of the integrals and the line widths of the methyl groups in the 3-positions which are expected to be significantly broader than those in the 5-position. Curiously, the *ortho* hydrogens of the NPh_2 were quite sharp, showing a normal 6 Hz coupling to their neighbours. The *meta* and *para* protons, on the other hand, were strongly broadened by the neodymium centre.

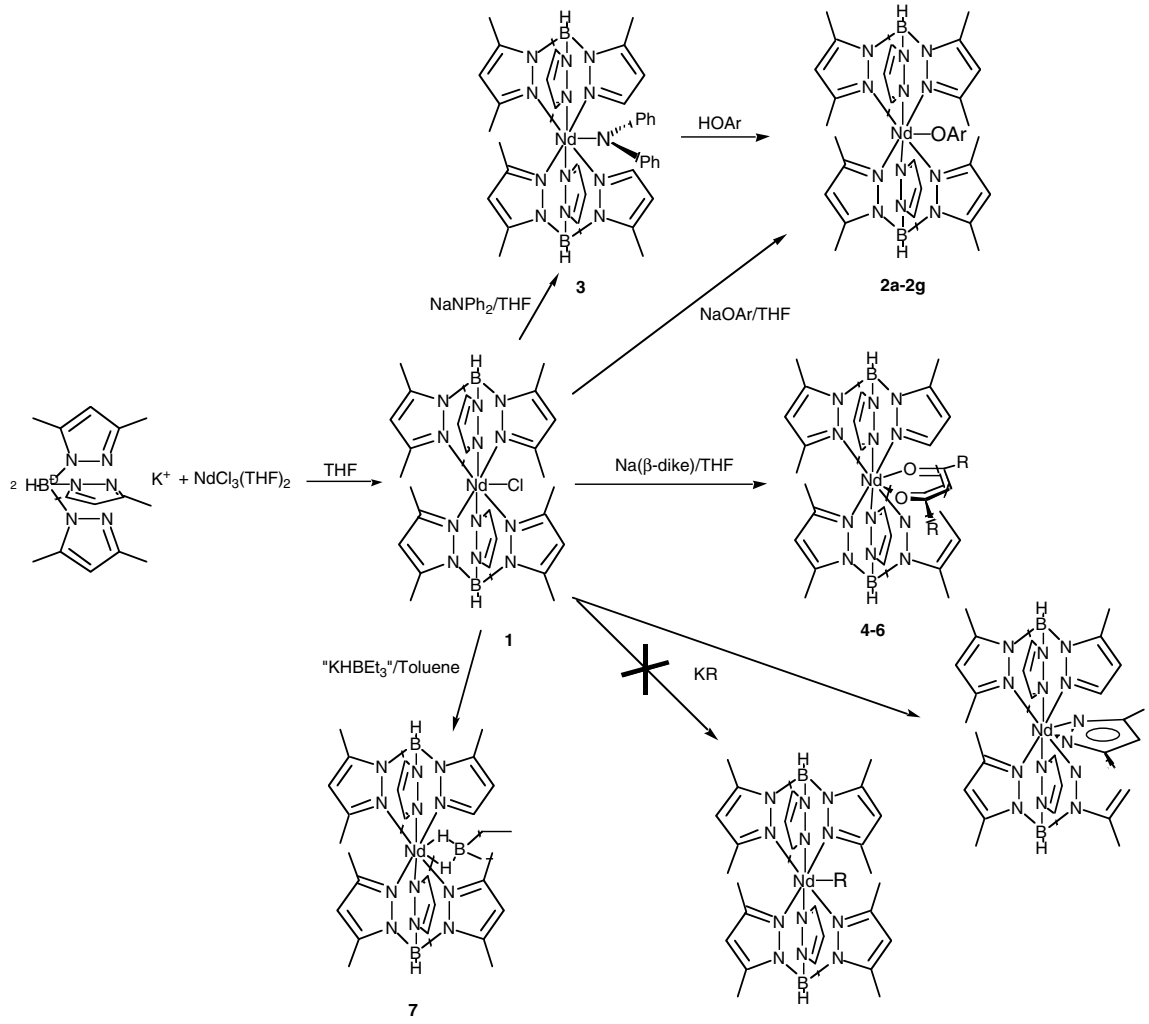
By contrast to the synthesis of the NPh_2 derivative, attempts to prepare the corresponding $N(SiMe_3)_2$ complex by metathesis of **1** in THF using $KN(SiMe_3)_2$ were not successful and gave greenish mixtures of products indicative of Tp^{Me2} decomposition. Attempts to prepare the corresponding diethylamide complex by metathesis with $LiNEt_2$ resulted in recovery of starting material and significant amounts of $LiTp^{Me2}$. Such transfers of Tp ligands from rare earths to lithium or magnesium have been reported sporadically and presumably reflect the size mismatch between the large lanthanide centre, the rather tight Tp ligand [3,15] and the stronger, more covalent bonding in the latter metals.

Metathesis of **1** with sodium β-diketonates in THF results in the isolation of eight-coordinate complexes $[Nd(Tp^{Me2})_2(\beta\text{-dike})]$ (β-dike = $(RC{=}O)_2CH$, R = Me, **4-Nd**; R = Ph, **5-Nd**; R = Bu^t, **6-Nd**)

$$[Nd(Tp^{Me2})_2Cl] + Na(\beta\text{-dike}) \rightarrow [Nd(Tp^{Me2})_2(\beta\text{-dike})] + NaCl.$$

As with the previous compounds, the diketonates are soluble in THF and aromatic solvents and moderately air stable.

The acac complex, **4-Nd** (R = Me) gave an unreadable ^1H NMR spectrum at room temperature with a mixture of sharp and broad peaks. On cooling to 203 K the spectrum separated into 11 broad peaks, indicating that the eight-coordinate molecule has C_2 symmetry but it is fluxional at room temperature on the NMR time-



Scheme 1.

scale. The corresponding greenish dbm complex (R = Ph), **5-Nd**, on the other hand, is close to the slow exchange limit at room temperature and gives 13 fairly sharp lines, again consistent with C_2 symmetry. Cooling the sample results in sharper lines. The dpm (R = Bu^t) complex, **6-Nd**, is static at room temperature.

For comparison purposes the corresponding cerium complexes, [(Tp^{Me2})$_2$Ce(β-dike)] (β-dike = (RC=O)$_2$CH; dbm, R = Ph, **5-Ce**; dpm, R = Bu^t, **6-Ce**). were also prepared by metathesis starting, however, from the triflate, [Ce(Tp^{Me2})$_2$OTf] [16], which in our hands is more easily prepared than the chloride.

$$[Ce(Tp^{Me2})_2OTf] + Na(\beta\text{-dike}) \rightarrow [Ce(Tp^{Me2})_2(\beta\text{-dike})] + NaOTf.$$

While the ^{1}H NMR spectrum of **6-Ce** is fairly sharp and readable at room temperature, that of the dbm complex, **5-Ce**, is rather broad and sharpens up on cooling to −40 °C. In both cases the static spectrum indicates a C_2 symmetric molecule. Assignment of these spectra was made with the aid of EXSY spectra which, by correlating the exchange pathways, allowed unambiguous assignment of the methyl peaks to the 3- or 5-positions, respectively. Contrary to what has been observed for the less sterically crowded analogous Tp systems, there is no indication that and of the species **4**, **5**, and **6** exchange by anything other than an intramolecular mechanism [18].

We attempted to convert **1** to the corresponding fluoride, the samarium analogue of which has been prepared previously by redox chemistry [14], and which we hoped might prove an even more useful starting material. Unfortunately, metathesis with both KF and AgF led only to the recovery of the starting material.

A number of attempts were made to introduce a hydride or a hydrocarbyl group into the metal coordination sphere, all of which were unsuccessful. The reaction of **1** with an aged sample of potassium superhydride, "KHBEt$_3$" in toluene, a reagent which has been used

previously by Takats to prepare hydride complexes [15], resulted instead in the isolation of crystals of the unexpected complex $[Nd(Tp^{Me2})_2(H_2BEt_2)]$ which was crystallographically, but not spectroscopically, characterized (vide infra). Examination of the ^{11}B NMR spectrum of the potassium superhydride stock solution used in the reaction showed this to consist of a mixture of $KH_2BEt_2$and $KBEt_4$ as has been observed previously by Fryzuk [19] and Morris [20]. We do not believe that the fact that this behaviour has only ever been observed in Canada is of any great chemical significance. Thus the reaction may be seen as follows:

$$[Nd(Tp^{Me2})_2Cl] + KH_2BEt_2 \rightarrow [Nd(Tp^{Me2})_2(H_2BEt_2)] + KCl.$$

The reaction was repeated several times with an authentic sample of $KHBEt_3$ in THF (the toluene solution being no longer commercially available). Unfortunately such reactions resulted in extensive decomposition and ligand redistribution and only the fluxional pyrazolide complex $[Nd(Tp^{Me2})_2(3,5\text{-dmpz})]$ could be isolated in low yields. While frustrating, this decomposition reaction is intriguing since it may point to the formation of a transient hydride which then attacks one of the Tp^{Me2} ligands, in a manner similar to what we have proposed recently for the hydrolytic decomposition of these ligands at lanthanide centres [21]. Other attempts to prepare this elusive terminal hydride from **1** using KH, by analogy with Baudry's work [22], or by reaction with Ph_2SiH_2 and Ph_3SnH, resulted only in the recovery of the starting material.

Attempts to introduce hydrocarbyl groups into the coordination sphere using potassium reagents (e.g. KCH_2SiMe_3) simply gave greenish solutions from which, again, only small amounts of $[Nd(Tp^{Me2})_2(3,5\text{-dmpz})]$ could be recovered. Reaction of the silver acetylide cluster "$(AgBu^t)_{14}$" [23] with **1**, with a view to preparing $[Nd(Tp^{Me2})_2(C{\equiv}CBu^t)]$ by metathesis gave no detectable reaction apart from the formation of some silver metal. We presume that the stability of the silver acetylide cluster is such as to overcome the driving force provided by the precipitation of AgCl.

Thus the problem of preparing the, presumably highly reactive, hydride and hydrocarbyl species with these ancillaries remains intractable.

3. X-ray crystallography

Single crystals of compounds **1**, **3**, **6-Nd**, and **7** were obtained and their structures have been determined. Selected crystallographic and experimental details for all four structures are given in Table 1. Selected bond lengths and angles are reported in the Figure captions. Compounds **1** and **3** are very similar to their samarium counterparts reported elsewhere, **1** [13,14]. A view of the molecular structures of **1** and **3** are shown in Figs. 1 and 2. Both compounds are seven coordinate adopting a distorted pentagonal bipyramidal metal coordination sphere and show virtually identical metrical parameters as their analogues, allowing for the difference in ionic radius of the metal. We feel it is unnecessary to discuss them further.

The dpm complex, **6-Nd**, is also largely unremarkable, crystallizing with two independent molecules in the asymmetric unit. The differences between the two are insignificant. The eight-coordinate molecule shows the expected tridentate Tp^{Me2} and the bidentate dpm ligands. A view of the molecular structure of **6-Nd** is shown in Fig. 3. Although the complex does not have any crystallographically imposed symmetry, the molecule is effectively C_2 symmetric consistent with the ^1H NMR spectra. The geometry around the metal is dodecahedral, as has been observed previous for other eight-coordinate Tp^{Me2} complexes of the lanthanides [24]. This is in contrast to the Tp complexes which tend to favour square antiprismatic coordination sphere [3a]. Such differences can be attributed to minimization of contacts between the methyl groups of the Tp^{Me2} and dpm ligands. As has become typical in rare earth structures with Tp^{Me2} [3c], twisting of some of the pyrazolyl groups around the B–N bond is observed. For **6-Nd** two pyrazolyl groups on the same ligand and one on the other twist by between 23° and 26° in opposite directions to accommodate the dpm ligand in the wedge between them.

The final molecule, **7**, is rather more interesting as a result of the coordination of the unusual H_2BEt_2 ligand. A view of the molecular structure of **7** is shown in Fig. 4. The compound crystallized in the space group *C2/c* with a somewhat disordered molecule of pentane in the lattice and showed no intermolecular contacts. The molecule lies on a crystallographic C_2 axis. The two tridentate Tp^{Me2} ligands are partnered by a bidentate H_2BEt_2 ligand, a species which has only been characterized once before [20]. Formally, therefore the molecule is eight-coordinate. However, the average Nd–N distance, 2.602(6) Å, is closer to those in **1**, 2.59(1) Å and **3**, 2.582(6) than that seen for **6**, 2.634 Å, and is consistent with the fact that the bite angle of the small bidentate borohydride is fairly tight and the complex may be thought of has having an intermediate coordination number. Nevertheless one pyrazolyl groups of the Tp^{Me2} ligands shows a 35° twist, once more away from the third ligand. The Nd–B distance, 2.883(8) Å is significantly longer than that in $[Nd(C_5H_4CH_2CH_2OMe)_2(BH_4)]$, 2.66(3) Å [25], $[Nd_2(\mu\text{-}C_7H_7)(THF)_4(BH_4)_3]$, 2.68, 2.74 Å. [26] and in $[K(18\text{-crown-}6)\{Nd(C_{13}H_8)CPh_2(C_5H_4)(BH_4)_2\}]_2$, 2.641(8) Å, 2.623(7) Å [27] all of which contain tridentate BH_4 ligands. The longer distance is consistent with the bidentate binding mode

of the BH_2Et_2 ligand and the rather crowded metal centre.

4. Conclusions

A range of simple seven- and eight-coordinate complexes of cerium and neodymium have been prepared by metathesis and the structures of $[Nd(Tp^{Me2})_2Cl]$ (**1**), $[Nd(Tp^{Me2})_2(NPh_2)]$ (**3**), and $[Nd(Tp^{Me2})_2(dpm)]$, **6-Nd**, have been determined. The behaviour of these complexes is broadly similar to that of the analogous samarium complexes. Thus all the complexes are fluxional, and the extent to which the dynamics can be slowed at low temperature depends largely on the steric demand of the substituents on the non-Tp ligand. Attempts to prepare thermally stable hydrides and hydrocarbyls have foundered on the twin rocks of pyrazolyborate fragmentation or of inappropriate solubilities for the products. From one of these attempts, the unusual bis-borohydride complex $[Nd(Tp^{Me2})_2(H_2BEt_2)]$ (**7**) was isolated and its structure determined.

5. Experimental

5.1. General procedures

All preparations and subsequent manipulations were carried out using standard Schlenk line and dry box techniques in an atmosphere of dinitrogen. Oxygen-free nitrogen was further purified by passage over columns containing BASF Cu based catalyst (RE-11) at 100 °C and Aquasorb (Mallinkrodt, P_2O_5 on an inert support) or 3 Å molecular sieves and MnO. Glassware was routinely dried at 250 °C and cooled by a nitrogen atmosphere prior to use. All solvents were pre-dried over 5 Å molecular sieves or sodium wire (UCL). Hexane and pentane were washed with sulfuric acid, dried over $MgSO_4$ prior to distillation (U of A). The solvents were distilled from appropriate drying agents before use; Na (toluene, hexane, HMPA), K (benzene), K/benzophenone ketyl (THF), Na/K alloy (petroleum ether b.p. 4060 °C, pentane, diethyl ether), CaH_2 (CH_2Cl_2). The deuterated solvents for NMR (THF-d_8, benzene-d_6 and toluene-d_8) were vacuum distilled from Na/K alloy (1:3), $CDCl_3$ from P_2O_5. All solvents were degassed prior to use.

$NdCl_3$ was prepared from Nd_2O_3 by the HCl/NH_4Cl method. $NdCl_3(THF)_2$ was prepared by Soxhlet extraction of anhydrous $NdCl_3$ with THF. The THF content was confirmed by elemental analysis. The ligands, potassium and sodium hydrotris(3,5-dimethylpyrazolyl) borate (Na/KTp^{Me2}), were prepared by standard methods [28]. $NaNPh_2$ was prepared by heating $HNPh_2$ with excess NaH in THF, followed by removal of solvent. $[Ce(Tp^{Me2})_2OTf]$ was prepared by literature procedures [16].

Infrared (IR) spectra were recorded as KBr pellets on a Nicolet 205 or BOMEM MB100 FTIR spectrometer. NMR samples were prepared in the dry box and sealed under vacuum. ^1H NMR spectra in solution were recorded on Bruker AM400 FT spectrometers at 400 MHz, respectively. ^{11}B NMR spectra were recorded on the Bruker AM400 instrument at 128 MHz. Spectra were calibrated using residual proton resonances and are reported relative to tetramethylsilane (TMS). ^{11}B chemical shifts are reported relative to external F_3BOEt_2. Elemental analyses were determined by Mr. Alan Stones of the UCL Analytical Services or the Microanalytical Laboratory, Department of Chemistry, University of Alberta.

5.1.1. $[Nd(Tp^{Me2})_2Cl]$ (**1**)

$NdCl_3$ (1.50 g, 3.80 mmol) was suspended in THF (25 cm^3) in a round bottom flask. KTp^{Me2} (2.55 g, 7.58 mmol) was dissolved separately in THF (25 cm^3). The solution of KTp^{Me2} was added to the $NdCl_3(THF)_2$ over 5 minutes. The pale blue solid was seen to dissolve giving a milky pale blue solution. The suspension was stirred for 2 h and then the solvent was removed under reduced pressure. The pale blue residue was extracted with several portions of warm toluene (total volume 50 cm^3), centrifuging each time to remove undissolved salt. Concentrating the solution to 25 cm^3 and cooling to −20 °C) yielded an analytically pure pale blue powder. Yield: 1.66 g (56%). A second crop was obtained. Total yield: 1.94 g (66%). IR (KBr, cm^{-1}): 2563 (BH). ^1H NMR (C_6D_6, 298 K): −6.75 (s, 18H, 3-Me); 2.83 (s, 18H, 5-Me); 7.62 (s, 6H, CH). ^{13}C NMR ($CDCl_3$, 298 K): 11.2 (q, 3 or 5Me); 14.2 (q, 5 or 3Me); 105.4 (d, 4-C); 145.5 (s, 3- or 5-C); 149.4 (s, 5- or 3-C). *Anal.* Calc. for $C_{30}H_{44}N_{12}B_2ClNd$: C, 46.55; H, 5.73; N, 21.79. Found: C, 46.60; H, 5.71; N, 21.40%.

5.1.2. $[Eu(Tp^{Me2})_2Cl]$ (**1-Eu**)

1-Eu was prepared from $EuCl_3$ analogously to **1**. Yield: 69%. IR (KBr, cm^{-1}): 2564 (BH). ^1H NMR (C_6D_6, 298 K): 10.74 (s, 18H, 3-Me); 1.96 (s, 6H, CH); 1.86 (s, 18H, 5-Me). *Anal.* Calc. for $C_{30}H_{44}N_{12}B_2ClNd$: C, 46.55; H, 5.73; N, 21.79. Found: C, 46.60; H, 5.71; N, 21.40%.

5.1.3. $[Nd(Tp^{Me2})_2OPh]$ (**2a**)

1 (200 mg, 0.26 mmol) and NaOPh were each dissolved in THF (10 cm^3) in separate Schlenk flasks. Addition of the NaOPh to the solution of **1** resulted in a pale blue/lilac solution from which a fine white precipitate formed overnight. Removal of solvent was followed by extraction into toluene. Removal of the solvent under reduced pressure gave a pale blue solid. Yield: 110 mg (51%).

IR (KBr) 2553 cm^{-1}. ^1H NMR (C_6D_6, 298 K): −5.66 (s, 18H, 3-Me); 1.24 (s, 18H, 5-Me); 7.41 (s, 6H, 4-CH); 17.48 (br s, 1H, *p*-Ph); 21.88 (br s, 2H, *m*-Ph); 44.89 (v br s, 2H, *o*-Ph). IR (KBr): 2554 (BH) cm^{-1}. *Anal.* Calc. for

$C_{36}H_{49}N_{12}B_2ONd$: C, 51.98; H, 5.94; N, 20.21. Found: C, 50.34; H, 5.86; N 18.95%.

5.1.4. [Nd(Tp^{Me2})$_2$OPh-4-Bu^t] (**2b**)

t-Butyl phenol (39 mg, 0.26 mmol) was dissolved in THF and added dropwise to an excess of NaH suspended in THF and stirred until hydrogen evolution stopped. The filtered supernatant was added dropwise to a stirred solution of **1** (200 mg, 0.26 mmol) in THF (10 cm^3). The mixture was stirred overnight and a fine white precipitate formed. After removal of THF under reduced pressure the residue was extracted with toluene. The resulting solution was filtered and pumped down to give an oily solid. Washing with petroleum ether (b.p. 40/60) gave a pale blue powder. Yield: 100 mg (43%).

^{1}H NMR (C_6D_6, 298 K): −5.31 (s, 18H, 3-Me); 1.40 (s, 18H, 5-Me); 7.35 (s, 9H, Bu^t); 7.50 (s, 6H, 4-CH); 21.93 (br s, 2H, *m*-Ph); 44.33 (v br s, 2H, *o*-Ph). IR (KBr): 2557 (BH) cm^{-1}. *Anal.* Calc. for $C_{40}H_{57}N_{12}B_2ONd$: C, 54.11; H, 6.47; N, 18.93. Found: C, 53.02; H, 6.43; N, 18.19%.

5.1.5. [Nd(Tp^{Me2})$_2$OPh-4-Br] (**2c**)

The procedure was analogous to that of **2a**. Yield: 120 mg (44%) IR (KBr): 2550 cm^{-1}.

^{1}H NMR (400 MHz, C_6D_6, 298 K, δ ppm): −5.44 (s, 18H 3-Me), 1.31 (s, 18H 5-Me), 7.42 (s, 6H 4-CH), 21.86 (2H H_m), 44.15 (2H H_o).

5.1.6. [Nd(Tp^{Me2})$_2$OPh-4-Ph] (**2d**)

The procedure was analogous to that of **2a**. Yield: 92 mg (38%) IR (KBr): 2550, 2524.

^{1}H NMR (400 MHz, C_6D_6, 298K, δ ppm): −5.66 (s, 18H 3-Me), 0.32 (s, 18H 5-Me), 5.88 (s, 6H 4-CH), 9.75 (1H [Ph^2]H_p), 11.39 (2H [Ph^2]H_m), 14.64 (2H [Ph^2]H_o), 24.67 (2H H_m), 45.05 (2H H_o).

5.1.7. [Nd(Tp^{Me2})$_2$OPh-4-OMe] (**2e**)

The procedure was analogous to that of **2a**. Yield: 124 mg (38%) IR (KBr, cm^{-1}): 2554.

^{1}H NMR (400 MHz, C_6D_6, 298K, δ ppm): −5.00 (s, 18H 3-Me), 0.95 (s, 18H 5-Me), 3.65 (s, 3H, CH_3) 10.0 (s, 6H 4-CH), 22.0 (2H H_m), 46.0 (2H H_o).

5.1.8. [Nd(Tp^{Me2})$_2$OPh-4-F] (**2f**)

The procedure was analogous to that of **2a**. Yield: 144 mg (50%). IR (KBr, cm^{-1}): 2553.

^{1}H NMR (400 MHz, C_6D_6, 298K, δ ppm): −5.19 (s, 18H 3-Me), 1.16 (s, 18H 5-Me), 7.42 (s, 6H 4-CH), 21.68 (2H H_m), 47.50 (2H H_o).

5.1.9. [Nd(Tp^{Me2})$_2$OPh-4-Me] (**2g**)

The procedure was analogous to that of **2a**. Yield: 165 mg (51%). IR (KBr, cm^{-1}): 2553.

^{1}H NMR (400 MHz, C_6D_6, 298K, δ ppm): −5.11 (s, 18H 3-Me), 1.00 (s, 18H 5-Me), 7.42 (s, 6H 4-CH), 10.63 (s, 3H 4-CH_3Ph), 22.63 (2H H_m), 46.13 (2H H_o).

5.1.10. [Nd(Tp^{Me2})$_2$NPh$_2$] (**3**)

1 (200 mg, 0.260 mmol) was suspended in THF (6 cm^3) in a round bottom flask. $NaNPh_2$ (54 mg, 0.280 mmol) was dissolved separately in THF (4 cm^3). The solution of $NaNPh_2$ was added to the solution of **1** in four portions. The suspension was stirred for 2 h and then the solvent was removed under reduced pressure. The pale blue residue was extracted with warm toluene (2 cm^3), centrifuging to remove undissolved salt. Concentrating the solution to 2 cm^3 and cooling to −40 °C) yielded an analytically pure pale blue microcrystals of **3**. Yield: 1.66 g (56%). A second crop was obtained. Total yield: 1.94 g (66%). ^{1}H NMR (C_6D_6, 298 K: −26.72 (s, 6H, 3-Me); −6.34 (s, 2H, CH); −5.74 (s, 6H, 5-Me); −5.1 (br s, 2H, *p*-Ph); −1.84 (s, 6H, 5-Me); 2.11 (s, 2H, CH); 3.514 (s, 6H, 5-Me); 5.26 (br s, 6H, 3-Me); 6.05 (br s, 4H, *m*-Ph); 9.55 (d $J_{HH} = 6$ Hz, 4H, *o*-Ph); 19.05 (s, 2H, CH); 23.10 (br s, 6H, 3-Me). *Anal.* Calc. for $C_{42}H_{54}N_{13}B_2Nd$: C, 55.63; H, 6.00; N, 20.08. Found: C, 55.27; H, 5.72; N, 20.35%.

5.1.11. [Nd(Tp^{Me2})$_2$(acac)] (**4-Nd**)

2,4-Pentanedione (26 mg, 0.26 mmol) was added dropwise to excess NaH suspended in THF. After effervescence had subsided, the solution was filtered directly into a solution of **1** (200 mg, 0.26 mmol) in THF (10 cm^3). The resulting yellowish solution was stirred overnight. Workup as for **2a** yielded an oily greenish solid which was pure by NMR but failed to give reliable analyses.

IR (KBr, cm^{-1}): 2515. ^{1}H NMR (C_7D_8, 233 K): −35.0 (br s, 6H, 3-Me); −8.60 (s, 2H, 4-CH); −9.6 (s, 6H, 3-CH_3); −5.5 (s, 6H, 5-Me); 2.32 (s, 6H, 5-Me); 2.38 (s, 6H, 5-Me); 6.02 (s, 2H, 4-CH); 17.0 (s, 2H, 4-CH); 19.0 (s, 6H, acac-Me); 33.0 (s, 6H, 3-Me); 34.5 (s, 1H, dike-CH). *Anal.* Calc. for $C_{35}H_{51}N_{12}B_2O_2Nd$: C, 50.18; H, 6.13; N, 20.06. Found: C, 47.23; H, 6.00; N, 18.19%.

5.1.12. [Nd(Tp^{Me2})$_2$(dbm)] (**5-Nd**)

1 (200 mg, 2.60 mmol) and Na(dbm) (64 mg, 2.6 mmol) were dissolved separately in THF (10 cm^3) in Schlenk flasks under nitrogen. The yellow solution Na(dbm) solution was added dropwise to the solution of **1** with stirring to give a greenish solution. After stirring overnight the solvent was removed under reduced pressure and the residue extracted with warm toluene (2×10 cm^3). Crystallisation at −20 °C afforded a greenish solid. Yield: 0.80 g (33%).

IR (KBr, cm^{-1}): 2500. ^{1}H NMR (C_6D_6, 298 K: −21.30 (s, 6H, 3-Me); −3.09 (s, 6H, 3-CH_3); −2.03 (s, 6H, 5-Me); 0.57 (s, 6H, 5-Me); 1.00 (s, 6H, 5-Me); 3.80 (s, 2H, 4-CH); 5.20 (br s, 2H, 4-CH); 9.17 (s, 2H, *p*-Ph); 9.59 (s, 2H, *m*-Ph); 13.16 (s, 2H, 4-CH); 15.76 (s, 4H, *o*-Ph); 22.35 (br s, 6H, 3-Me); 26.56 (s, 1H, dike-CH).

Anal. Calc. for $C_{45}H_{55}N_{12}B_2O_2Nd$: C, 55.84; H, 5.73; N, 17.36. Found: C, 55.60; H, 5.69; N, 17.06%.

*5.1.13. [Ce(Tp^{Me2})$_2$(dbm)] (**5-Ce**)*

[Ce(Tp^{Me2})$_2$OTf] (500 mg, 5.66 mmol) and Na(dbm) (141 mg, 5.66 mmol) were mixed in a Schlenk flask under nitrogen, and dissolved in 20 ml of THF. The yellow solution was stirred overnight, during which time a fine white precipitate formed. The solution was filtered and the solvent removed under reduced pressure, leaving a bright orange solid. The product was then extracted with toluene. Recrystallisation afforded a bright orange crystalline solid. Yield: 0.35 g (64%).

^{1}H NMR (CD_2Cl_2, 213 K: −33.97 (s, 6H, 3-Me); −4.56 (s, 2H, 4-CH); −2.21 (s, 6H, 5-CH_3); −1.70 (s, 6H, 5-Me); −1.00 (s, 6H, 3-Me); 3.78 (s, 6H, 5-Me); 5.42 (s, 2H, 4-CH); 8.89 (s, 4H, *m*-Ph); 8.96 (s, 2H, *p*-Ph); 12.70 (s, 4H, *o*-Ph); 16.75 (s, 2H, 4-CH); 27.5 (br s, 6H, 3-Me); 35.4 (br s, 1H, dike-CH). *Anal.* Calc. for $C_{45}H_{55}N_{12}B_2O_2Ce_1$: C, 56.43; H, 5.79; N, 17.55. Found: C, 55.88; H, 6.12; N, 17.92%.

*5.1.14. [Nd(Tp^{Me2})$_2$(dpm)] (**6-Nd**)*

The compound was prepared analogously with **4**. Yield: 120 mg (50%). IR (KBr, cm^{-1}): 2527. ^{1}H NMR (C_6D_6, 298 K): −27.94 (s, 6H, 3-Me); −5.58 (s, 6H, 3-CH_3); −1.94 (s, 6H, 5-Me); 1.23 (s, 18H, Bu^t); 2.79 (s, 6H, 5-Me); 5.76 (s, 2H, 4-CH); 7.00 (s, 6H, 5-Me); 14.05 (s, 2H, 4-CH); 16.14 (s, 2H, 4-CH); 20.56 (s, 6H, 3-Me); 25.35 (s, 1H, dike-CH). *Anal.* Calc. for $C_{41}H_{63}N_{12}B_2O_2Nd_1$: C, 53.41; H, 6.88; N, 18.23. Found: C, 53.87; H, 6.23; N, 17.99%.

*5.1.15. [Ce(Tp^{Me2})$_2$(dpm)] (**6-Ce**)*

[Ce(Tp^{Me2})OTf] (0.500 g, 5.66 mmol) and Na(dpm) (0.117 g, 5.66 mmol) were mixed in a Schlenk flask under nitrogen, and dissolved in 20 cm^3 of THF. The yellow solution was stirred overnight, during which time a fine white precipitate formed. The solution was filtered and the solvent removed under reduced pressure, leaving a bright yellow solid. The product was then extracted with toluene. Recrystallisation afforded bright yellow needle crystals. Yield: 0.075 g (15%).

^{1}H NMR ($CDCl_3$, 298 K): −26.42 (s, 6H, 3-Me); 0.80 (br s, 6H, 3-CH_3); 1.46 (s, 2H, 4-CH); 2.90 (s, 6H, 5-Me); 3.30 (s, 6H, 5-Me); 4.50 (s, 2H, 4-CH); 6.54 (s, 6H, 5-Me); 7.26 (s, 18H, Bu^t); 14.80 (s, 2H, 4-CH); 17.49 (br s, 6H, 3-Me); 25.90 (s, 1H, dike-CH). *Anal.* Calc. for $C_{41}H_{63}N_{12}B_2O_2Ce_1$: C, 53.65; H, 6.92; N, 18.31. Found: C, 53.44; H, 6.77; N, 18.50%.

6. Supporting information available

Abstract

Reaction of ($Tp^{tBu,Me}$)Yb(I)(THF) with KOMes (Mes = 2,4,6-$C_6H_2Me_3$) in tetrahydrofuran (THF) at −45 °C afforded the monomeric divalent lanthanide aryloxide complex ($Tp^{tBu,Me}$)Yb(OMes)(THF) (**1**). Reaction of [($Tp^{tBu,Me}$)Yb(μ-H)]$_2$ ($Tp^{tBu,Me}$ = hydrotris(3-*tert*-butyl-5-methylpyrazolyl)borate) with HOMes in benzene at ambient temperature gave the monomeric solvent free lanthanide aryloxide complex ($Tp^{tBu,Me}$)Yb(OMes) (**2**). Dissolution of **2** in tetrahydrofuran at ambient temperature resulted in clean transformation to the solvated complex **1**. The coordinated THF ligand is persistent in non-ethereal solvents. Reaction of [($Tp^{tBu,Me}$)Yb(μ-H)]$_2$ with dipivaloylmethane (Hdpm) afforded the related β-diketonate complex ($Tp^{tBu,Me}$)Yb(dpm) (**3**). Complexes **1**–**3** have been fully characterized by spectroscopic methods and their structures were confirmed by X-ray crystallographic studies. Crystal data: $C_{38.5}H_{62.5}BN_6O_2Yb$ (**1**·0.25 C_6H_{14}): monoclinic, $C2/c$, $a = 21.526(4)$ Å, $b = 13.213(2)$ Å, $c = 31.403(7)$ Å, $\beta = 105.80(2)°$, $Z = 8$; $C_{33}H_{51}BN_6OYb$ (**2**): orthorhombic, $Pbcm$, $a = 10.5344(5)$ Å, $b = 20.3495(7)$ Å, $c = 16.3768(6)$ Å, $Z = 4$; $C_{35}H_{59}BN_6O_2Yb$ (**3**): monoclinic, $C2/c$, $a = 13.370(1)$ Å, $b = 21.134(2)$ Å, $c = 28.242(2)$ Å, $\beta = 97.356(2)°$, $Z = 8$.

1. Introduction

The organometallic chemistry of divalent lanthanides has witnessed rapid and spectacular development with the introduction of the pentamethylcyclopentadienyl ligand system to this area of chemistry [1–3]. Much of the early work focused on the incorporation of two cyclopentadienyl supporting ligands around the divalent lanthanide, thereby limiting incorporation of additional ligands to neutral donors. Synthesis of a variety of homoleptic 'LnL_2'-type systems has expanded the range of supporting environments, but still limits ligand incorporation [4]. Some of these ancillary ligands have challenged the steric saturation limit around the metal center. In extreme instances such as Sm($Tp^{tBu,Me}$)$_2$ and Yb($Tp^{tBu,Me}$)$_2$, the steric demand of the ligand limits coordination to only 5 of the 6 pyrazolyl arms of the two commonly tridentate tris(pyrazolyl)borate ligands [5]. In order to allow for greater versatility, it was naturally of

doi:10.1016/j.poly.2003.11.015

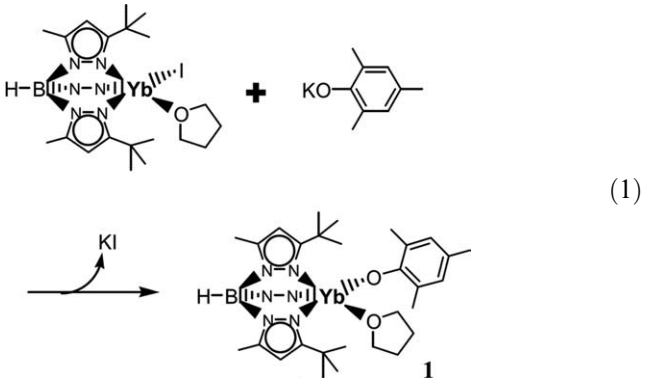
interest to investigate extensions of divalent lanthanide species to incorporate mixed anionic ligands.

Heteroleptic divalent lanthanide compounds are rare. Recent examples include some mixed C_5Me_5/ER (ER = OAr, SAr, NR^1R^2) Sm(II) complexes [6,7]. In this context, we and others have initiated an extensive investigation into the synthesis and reactivity of hydrotris(pyrazolyl)borate ($Tp^{R,R'}$) anchored lanthanide(II) complexes [8–10]. We have shown that the very bulky hydrotris(3-*tert*-butyl-5-methylpyrazolyl)borate ($Tp^{tBu,Me}$) ligand is well-suited to stabilize the mono-ligated complexes ($Tp^{tBu,Me}$)LnI(THF)$_x$ (Ln = Yb, $x = 1$; Sm, $x = 2$, 0), which proved to be good starting materials for the synthesis of heteroleptic ($Tp^{tBu,Me}$)LnER (THF)$_x$ (Ln = Sm, Yb; ER = $N(SiMe_3)_2$, CH_2SiMe_3, $CH(SiMe_3)_2$, $HBEt_3$; $x = 1$, 0) [10–12]. The subsequent isolation of solvent free [($Tp^{tBu,Me}$)YbH]$_2$, the first discrete Ln(II) hydride, is providing even greater versatility as illustrated by the recently reported alkynide, ene-diolate, and η^3-propargyl derivatives [13,14]. Here we report the synthesis and structural characterization of solvated and unsolvated heteroleptic ytterbium(II) complexes containing both pyrazolylborate and anionic oxygen donor groups.

2. Results and discussion

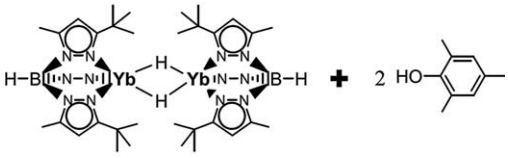
2.1. Synthesis and characterization of ($Tp^{tBu,Me}$)Yb(OMes)(THF)$_{1/0}$ (1, 2) and ($Tp^{tBu,Me}$)Yb(dpm) (3) complexes

Reaction of ($Tp^{tBu,Me}$)YbI(THF) [12] with one eq. of KOMes (Mes = 2,4,6-$C_6H_2Me_3$) in THF at −45 °C gave the heteroleptic ($Tp^{tBu,Me}$)Yb(OMes)(THF) (**1**), as a yellow-orange solid in 90% yield (Eq. (1)). The complex is air-sensitive, yet moderately stable in the solid state. Compound **1** is soluble in common aromatic and ethereal solvents. The coordinated THF molecule is retained in the former solvents but exchanges readily with bulk THF (^{1}H NMR spectroscopy). Although the coordinated THF in **1** is labile, simple trituration or heating under vacuum does not reliably produce the unsolvated complex **2**.

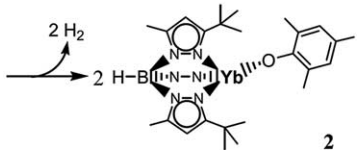


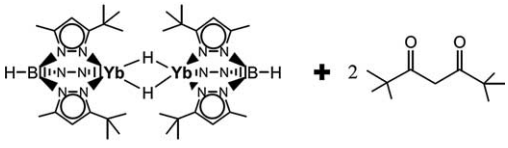
(1)

To prepare **2**, advantage was taken of our recently reported solvent free dinuclear ytterbium hydride, [($Tp^{tBu,Me}$)Yb(μ-H)]$_2$ [13,14]. This compound is proving useful for the high yield synthesis of a variety of solvent free divalent ytterbium complexes. Indeed, reaction of [($Tp^{tBu,Me}$)Yb(μ-H)]$_2$ with two eq. of HOMes (Mes = 2,4,6-$C_6H_2Me_3$) in benzene at room temperature readily gave the solvent free ($Tp^{tBu,Me}$)Yb(OMes) (**2**), as an orange solid in 98% yield (Eq. (2)). Similarly, reaction of [($Tp^{tBu,Me}$)Yb(μ-H)]$_2$ with two eq. of dipivaloylmethane in benzene at room temperature yielded the Yb(II) β-diketonate, ($Tp^{tBu,Me}$)Yb(dpm) (**3**), as a dark green solid in quantitative yield (Eq. (3)). The β-diketonate complex is relevant to the topic at hand since the ligand presents two oxygen donor functionalities and carries one negative charge, much like the aryloxide and THF ligands in **1**, but acting in tandem. Complex **3** is very soluble in a range of solvents. In addition to the common aromatic and ethereal solvents, it also dissolves in aliphatic solvents and dichloromethane. The compound does not appear to react with any of the solvents since its dark green color persists.

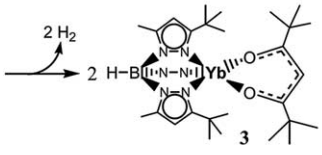


(2)





(3)



The formulations of the compounds are based on elemental analyses, IR, and multinuclear NMR data. The IR spectra of compounds **1**, **2**, and **3** showed B–H stretching vibrations at 2550, 2553, and 2550 cm^{-1}, respectively. Consistent with the κ^3 bonding of the $Tp^{tBu,Me}$ ligand, the ^{1}H NMR spectrum of **1** showed one set of signals for the $Tp^{tBu,Me}$ and OMes ligands. In C_6D_6, the coordinated THF signals appeared at 3.58 ppm and around 1.3 ppm, overlapped with the 3-^{t}Bu-pz peak. The relative integra-

tions of $Tp^{tBu,Me}$, OMes, and THF signals were in accord with the presence of one of each ligand on the ytterbium. In THF-d_8 the mesityl protons experience a more than 0.4 ppm upfield shift compared to benzene or toluene. The loss of coordinated THF resonances in THF-d_8 indicated rapid exchange between coordinated and bulk THF molecules. The ^{1}H NMR spectrum of the THF free complex **2** is surprisingly similar to that of **1**. In THF-d_8 the spectrum is identical to that observed for **1**, demonstrating rapid reaction of **2** with THF to form **1**. The ^{11}B and ^{171}Yb NMR spectra of **1** and **2**, however, show significant differences. Particularly noteworthy is the 70 ppm upfield shift of the ^{171}Yb resonance position in toluene-d_8, from 670 ppm (**2**) to 600 ppm (**1**). It is also interesting to note that the ^{171}Yb chemical shift of **1** experiences different temperature dependence in THF-d_8 than toluene-d_8. The resonance shifts upfield in THF-d_8 upon lowering the temperature whereas the opposite is seen in toluene-d_8. We have no definite explanation for this, but perhaps the larger temperature effects seen in THF-d_8 are related to the slowing down of exchange between coordinated and bulk THF. Large temperature effects were also seen by Lawless as a result of ligand exchange [15–17].

The ^{1}H and ^{13}C NMR spectra of compound **3** showed one set of resonances for both $Tp^{tBu,Me}$ and dpm ligands in the typical diamagnetic region. This observation confirmed the presence of the divalent Yb center, an important point in light of the unusual green color of complex **3**. The vast majority of Yb(II) complexes, including all $(Tp^{tBu,Me})YbL_n$ compounds reported to date, have colors ranging from red to yellow. Single peaks were also observed in the ^{11}B and ^{171}Yb NMR spectra. The ^{11}B chemical shift is similar to those of **1** and **2** further corroborating the diamagnetic nature of the complex. Surprisingly the ^{171}Yb NMR signal of **3** is highly deshielded and, at 1050 ppm, is more than 400 ppm downfield from its position in **1**. We have no rational to offer for the apparently unusual position of ^{171}Yb chemical shift.

Although leaving no doubt as to the composition of the compounds, the simple spectroscopic signatures did not resolve the details of the structures of the complexes. In particular, it was not clear whether the THF free **2** was a genuine four-coordinate Yb(II) complex and whether **3** was a simple, five-coordinate complex with a chelating dpm ligand or perhaps a dimer with bridging dpm moieties. To obtain unambiguous structures, coordination geometries, and precise metrical parameters, crystals of **1**, **2**, and **3** were subjected to single-crystal X-ray diffraction determinations.

2.2. Molecular structure of *1*, *2*, and *3*

The molecular structure and atom numbering scheme for crystalline **1**, **2**, and **3** are shown in Figs. 1, 2(a), and 3, respectively. The views are so chosen to emphasize the close structural relationship between the complexes.

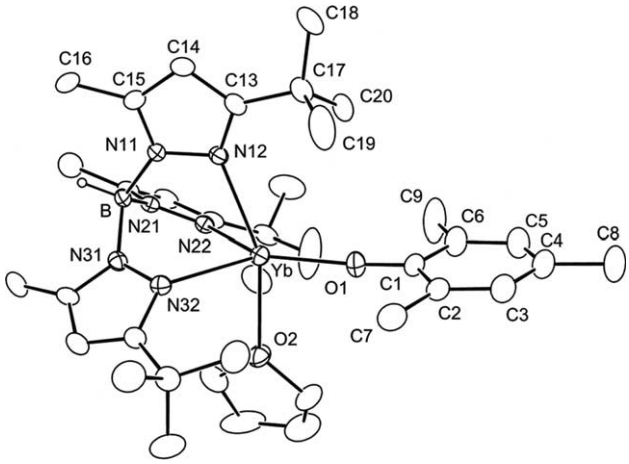


Fig. 1. ORTEP view of **1** showing the atomic numbering scheme. Drawn with 20% ellipsoids and hydrogen atoms omitted for clarity.

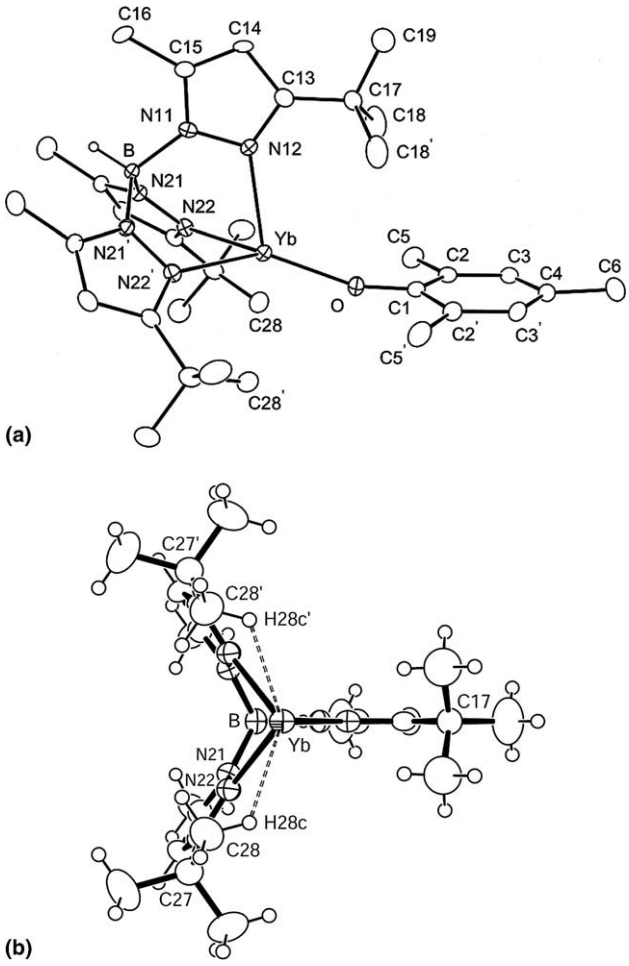

Fig. 2. (a) ORTEP view of **2** showing the atomic numbering scheme. Drawn with 20% ellipsoids and hydrogen atoms omitted for clarity. (b) ORTEP view of **2** depicting agostic Yb–H interactions. View is down Yb–B axis and OMes ligand has been omitted for clarity.

Selected bond lengths and angles are collected in Table 1 such that the corresponding metrical parameters are grouped together for ease of comparison. In this spirit,

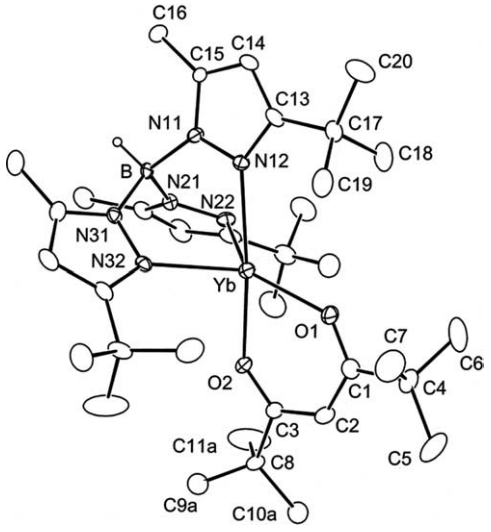

Fig. 3. ORTEP view of **3** showing the atomic numbering scheme. Drawn with 20% ellipsoids and hydrogen atoms omitted for clarity.

Table 1
Selected bond lengths (Å) and angles (°)

Parameter	**1** · $0.25C_6H_{14}$	**2**	**3**
Bond lengths			
Yb–O(1)	2.178(5)	2.168(7)	2.259(5)

C(1)–C(2)–C(3)			126.3(8)

the numbering schemes for the three complexes were kept identical as much as possible. The exception is complex **2**, which has a crystallographically imposed mirror plane of symmetry and consequently fewer independent atoms.

The structural study established that each lattice consists of discrete well separated monomeric units with no unusual intermolecular contacts. Although this was the anticipated result, based on the sterically demanding nature of the $Tp^{tBu,Me}$ ligand, alternative dimeric structures for **2** and **3** could not be ruled out on the basis of spectroscopic data.

The Yb centers in **1** and **3** are five coordinate with typical κ^3-$Tp^{tBu,Me}$ ligands and two oxygen donors completing the coordination spheres; OMes and THF in **1**, and a bidentate dpm ligand in **3**. The coordination geometry is best described as a distorted trigonal bipyramid (tbp). Two pyrazolyl nitrogens (N22 and N32) and O1 form the triangular, equatorial plane and the third nitrogen (N12) and O2 occupy the axial positions. The distortions are the result of the constraints imposed by the bite-angles of the tripodal $Tp^{tBu,Me}$ ligand. These distortions are manifest as compression of the equatorial N22–Yb–N32 angle from the ideal 120° in tbp to 90° and 94°, and a corresponding opening of the equatorial angles N22–Yb–O1 and N32–Yb–O1 to 134°/135° and 136°/131° in **1** and **3**, respectively. Similarly, the axial N12–Yb–O2 angle deviates from the ideal tbp of 180°. This value is 158.1(2)° in **1** and the deviation can be traced directly to the $Tp^{tBu,Me}$ ligand, the N12–Yb–O1 angle is 112.2(2)°, some 22° larger than the 90° expected in a rigorous tbp geometry. Indeed the oxygen of the THF ligand, O2 lies nearly orthogonal to the equatorial plane with O2–Yb–O1, O2–Yb–N22 and O2–Yb–N32 angles of 89.5(2)°, 90.3(2)°, and 83.7(2)°, respectively. It is interesting that at first glance the N12–Yb–O2 angle of 174.8(2)° seems to imply a more regular tbp geometry for **3**, but it is in fact, the combined ligand constraints of $Tp^{tBu,Me}$ and dpm that conspire to make this angle close to 180°. Indeed the N12–Yb–O1 angle, 109.4(2)°, is 19.4° larger, whereas the O2–Yb–O1 angle, 75.8(2)°, is 14.2° smaller than the requisite 90° in a regular tbp.

It is instructive to compare the distorted tbp structure of **3** to those of the analogous (Tp^{Ph})M(acac) (M = Zn, Co; acac = pentane-2,4-dionate) complexes, which Kläui and co-workers [18] described as having "a nearly regular trigonal bipyramid" as a coordination geometry. Indeed the axial angle, N12–M–O2 (same numbering as here) is virtually 180° (179.5(1)° and 179.0(1)°), and this is not a consequence of some competing distortions as seen in **3**, since the N12–M–O1 and O2–M–O1 angles are also very close to 90° (90.2(1)°/88.4(1)° and 90.0(1)°/90.7(1)°, respectively). The one distortion that is in common with **3** is in the equatorial plane with one angle about 96° and the other two around 132°. Clearly both the hydrotris(pyrazolyl)borate and the β-diketonate ligands can match the smaller transition metal better than the larger lanthanide ions, and the consequences of the latter mismatch for lanthanides has been noted recently [19,20].

Kläui and co-workers [18] noted that in the above (Tp^{Ph})M(acac) complexes the axial ligand lengths were significantly longer than the equatorial ones. Although

the same trend is seen in **3** the differences are much less pronounced; axial Yb–O2, 2.308(5) Å versus equatorial Yb–O1, 2.259(5) Å and axial Yb–N12, 2.504(5) Å versus equatorial Yb–N22/N32, 2.452(5)/2.440(5) Å, respectively. This, presumably, is the consequence of the more ionic bonding present in the lanthanide complexes compared to their transitional metal analogs. This is also manifest in the solution structure of complex **3**. The unique ligand arrangement is not preserved in solution and the compound undergoes rapid fluxionality as revealed by ^{1}H and ^{13}C NMR spectroscopy.

The coordination environment of **1**, including axial THF and two equatorial pyrazolyl ligands, is very similar to the related $(Tp^{tBu,Me})Yb(CH_2SiMe_3)(THF)$ and $(Tp^{tBu,Me})Yb(\mu\text{-}HBEt_3)(THF)$ complexes [11,12]. The Yb–O2 distance of 2.415(5) Å is significantly shorter than observed in the latter two complexes, 2.482(3) and 2.481(5) Å, respectively. This perhaps indicates that the flat aryloxide ligand simply allows closer approach of the THF or, equally likely, the stronger Yb–O2(THF) interaction is due to the diminished basicity of the aryloxide compared to $Me_3SiCH_2^-/Et_3BH^-$ ligands which gives rise to a more electron deficient metal center in **1**.

The Yb–O1(Mes) distance of 2.178(5) Å is close to the corresponding values, 2.22(1) and 2.20(2) Å, seen in five-coordinate $Yb(OAr)_2(THF)_3$ [21] and is indistinguishable from the corresponding average values, 2.14(2), 2.15(3), and 2.179(9) Å, seen in the four-coordinate complexes $Yb(OAr)_2(THF)_2$ [21], $Yb(OAr)_2(OEt_2)_2$ [21], and $Yb(OAr)_2(HMPA)_2$ [22], respectively; Ar = 2,6-*t*Bu-4-R-C_6H_2 (R = Me) in each of these complexes. The Yb–O1(Mes) distance is ca. 0.22 Å shorter than Yb–O2(THF). This bond length difference is in the 0.2–0.3 Å range observed for other ytterbium aryloxide complexes [23], and the shortening is as expected from the stronger interaction between Yb(II) and the anionic aryloxide ligand.

Turning to the solvent free $(Tp^{tBu,Me})Yb(OMes)$ (**2**) complex, its monomeric nature is in contrast to the dimeric structure of the related divalent samarium complex $[(C_5Me_5)Sm(OAr)]_2$ (Ar = 2,6-*t*Bu-4-R-C_6H_2; R = H, Me, *t*Bu) [6]. Evidently the large cone angle of $Tp^{tBu,Me}$, 243°, compared to 146° for C_5Me_5 is capable of preserving the monomeric structure [24]. Another difference between the two complexes is their reaction with Lewis bases. Although with HMPA $[(C_5Me_5)Sm(OAr)]_2$ yields the monomeric $(C_5Me_5)Sm(OAr)(HMPA)_2$, dissolution in THF led to ligand redistribution and formation of $(C_5Me_5)_2Sm(THF)_2$ and $Sm(OAr)_2(THF)$; whereas, dissolution of **2** in THF simply leads to formation of **1**.

At first glance, the structure of **2** is simply obtained by removal of the coordinated THF ligand and the coordination geometry resembles that of a distorted tbp with an open coordination site. Although subtle differences exist between the "$(Tp^{tBu,Me})Yb(OMes)$" fragment of the five-coordinate **1** and the coordinately unsaturated four-coordinate **2**, the geometry of the latter is definitely not the regular trigonal pyramidal arrangement anticipated for a coordinately unsaturated ML_3L'-type complex. Indeed the three N–Yb–O angles are not the same and neither is the B–Yb–O angle 180° as would be in a regular trigonal pyramid. The N(12)–Yb–O angle of **2**, 117.2(3)°, is somewhat greater than the corresponding angle in **1**, 112.2(2)°, but the other angles, 135.9(2)° (equal by imposed crystal symmetry), are virtually identical to those in **1**, 135.9(2)° and 133.5(2)°. The B–Yb–O angle is 167.3(3)°, some 12.7° away from linearity in a regular trigonal pyramid. Similar distortions were seen in the related "four-coordinate" $(Tp^{tBu,Me})YbN(SiMe_3)_2$ and $(Tp^{tBu,Me})YbCH(SiMe_3)_2$ complexes with L being 18.6° and 15.0° off the B–Yb axis [12]. In the latter two cases the deviations were attributed to a combination of steric and electronic factors; steric repulsion between a ^{t}Bu-Tp substituent and an $SiMe_3$ group, and attractive agostic C–H interactions between the electron deficient ytterbium and the other $SiMe_3$ moiety of the ligands as evidenced by the respective shortest $N(SiMe_3)_2$ and $CH(SiMe_3)_2$ Yb–C_{Me} separations of 3.06 and 3.08 Å. Similar combinations of factors seem to be operating in complex **2** as well. The orientation of the OMes ligand is clearly to reduce steric interactions between the mesityl ring and the 3-^{t}Bu-Tp substituents. And complex **2** displays two 2.61 Å nonbonded interactions between ytterbium and the C28/28′ hydrogen atoms, Fig. 2(b). These agostic C–H interactions serve to reduce the electron deficiency of ytterbium and may be considered as occupying the "vacant fifth" coordination sites. No such interactions are present in the THF solvated complex **1**; the closest Yb–H separation is 2.95 Å.

Comparison of the distance parameters reveals further similarities between **1** and **2**, and indeed **3**. The average Yb–N distance in **2** is 2.44(1) Å, only marginally greater than the related 2.50(2) Å average distance in **1**, and the two bracket the average Yb–N separation of 2.47(2) Å found in **3**. These distances compare favorably with the analogous Yb–N bond lengths in related $(Tp^{tBu,Me})LnL_n$ complexes [8,12,13,25,26]. The Yb–O(Mes) ligand distances for **1** and **2**, 2.178(5) and 2.168(7) Å, are again indistinguishable and further argue for the presence of agostic C–H···Yb interaction and concurrent reduced electron deficiency of Yb in **2**. As mentioned already in discussing the structure of **1**, the distances compare well with the corresponding value in divalent ytterbium aryloxide complexes.

Interestingly, the Yb–O–C1 angle of 162.1(7)° in **2** differs by more than 10° from that in **1**, 173.3(6)°, and, curiously, the mesityl moiety bends further away from the "open" coordination site toward the ^{t}Bu group on C13. Although the angles are different, both values are

in the typical range observed for divalent lanthanide aryloxide complexes. [3] The variation in M–O–R angle in metal–alkoxide complexes was recently discussed by Russo et al. [27], and the near linearity of such bonds in lanthanide complexes was attributed to electrostatic repulsion between the metal and α-carbon of the alkoxide ligand, as compared to the more popularly held view that linearity of M–O–R and shortness of the M–OR bond were due to the π-type interaction between metal and oxygen donor. These authors, and others [28], noted also the softness of the bending potential and, consequently, the role of steric factors influencing the M–O–R angle. On the basis of purely electrostatic arguments, the Yb–O–C1 angle of **2** should in fact be closer to 180° than that of **1**, as the more electron deficient and hence more highly charged ytterbium of the Lewis base free **2** should lead to greater polarization of the O–C1 bond than in complex **1**. The larger charges on Yb and C1 in **2**, and the attendant increase in electrostatic repulsion should result in a more linear Yb–O–C1 angle, contrary to the experimental results. We are thus left with steric effects as being responsible for the more bent Yb–O–C(Mes) moiety in **2**. As mentioned, it is curious that the bending of the mesityl ring in **2** is not toward but away from the "empty" coordination site. It appears that the bending follows the opening up of the N12–Yb–O angle of 112.2(2)° in **1** to 117.2(3)° in **2** and in fact the non-bonding C19/C20···O1 and C18/C18′···O distances in **1** and **2**, respectively, remain fairly constant.

3. Conclusions

By exploiting the solvent free nature of divalent $[(Tp^{tBu,Me})YbH]_2$, preparation of low coordinate, solvent free, divalent lanthanide complexes is possible as illustrated by the isolation of $(Tp^{tBu,Me})Yb(OMes)$ (**2**) and $(Tp^{tBu,Me})Yb(dpm)$ (**3**). The use of the sterically demanding $Tp^{tBu,Me}$ ligand allows isolation and X-ray characterization of the coordinatively unsaturated four-coordinate complex **2**. While bulky, the $Tp^{tBu,Me}$ ligand is barely sufficient to stabilize complex **2**, which in fact features two agostic C–H···Yb interactions. It also readily and irreversibly takes up THF to form **1**. The $Tp^{tBu,Me}$ ligand optimally supports the formation of five-coordinate ytterbium(II) complexes as illustrated by the lack of reactivity complex **3** demonstrates towards polar coordinating solvents.

[3] Cambridge Structural Database Search, 2003 (April), 23 hits for divalent lanthanide aryloxide complexes. Min Ln–O–C = 150.36°; max Ln–O–C = 178.4°; average Ln–O–C = 169.2°. 4. Experimental

4.1. General

All manipulations were carried out under an inert N_2/He atmosphere in a Vacuum Atmosphere HE-553-2 Dri Lab or MBraun Unilab 2000. Glassware and solvents were treated as described previously [5]. $(Tp^{tBu,Me})YbI(THF)$ and $[(Tp^{tBu,Me})YbH]_2$ were prepared according to published procedures [12,13].

Infrared (IR) spectra were recorded on a Bomem MB/100 or Perkin–Elmer 1600 series FT spectrometer. NMR samples were prepared in a glove box and sealed under vacuum. The spectra were obtained on a Brüker AM-400 or Varian Unity 500 (^{171}Yb) FT spectrometer. Chemical Shifts are reported in ppm relative to TMS (^{1}H, ^{13}C), $F_3B\cdot OEt_2$ (^{11}B) and $Yb(C_5Me_5)_2(THF)_2$ (^{171}Yb). ^{171}Yb spectra were reproducible to within 5 ppm from sample to sample and reproducible to with 2 ppm on a given sample. Variable temperature measurements were collected on a given sample in a single sitting. Elemental analyses were performed by the Microanalytical Laboratory, Department of Chemistry, University of Alberta. Dipivaloylmethane and HO-(2,4,6-$Me_3C_6H_2$) were used as obtained from Aldrich. KO-(2,4,6-$Me_3C_6H_2$) was prepared by reaction of HO-(2,4,6-$Me_3C_6H_2$) with an excess of potassium hydride in THF.

4.2. Preparation of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})(THF)$ (1)

To a solution of $(Tp^{tBu,Me})YbI(THF)$ (400 mg, 0.50 mmol) in 5 ml THF at −45 °C was added dropwise a solution of KO-(2,4,6-$Me_3C_6H_2$) (88 mg, 0.50 mmol) in 5 ml THF at −45 °C. The mixture was stirred for 1 h while allowing it to warm to room temperature. The color of solution changed from yellow to orange. The mixture was centrifuged to remove KI, then the decanted volume was reduced under vacuum to ca. 2 ml. Cooling this solution to −45 °C followed by isolation of the precipitate gave 364 mg of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})(THF)$ (**1**) as a yellow/orange solid (Yield: 90%). IR (C_6H_6, cm^{-1}): ν_{B-H} 2550. MS (EI, 70 eV, 270 °C): m/z 735 (M^+–THF). ^{1}H NMR (THF-d_8, 25 °C, ppm): 6.50 (s, 4-OAr–*H*), 5.81 (s, 4-pz-*H*), 3.58 (s, *THF*), 2.32 (s, pz-CH_3), 2.11 (s, 2,6-OAr–CH_3), 2.03 (s, 4-OAr–CH_3), 1.34, 1.30 (s, s C(CH_3)$_3$ in 2:1 with buried *THF*). ^{1}H NMR (C_7D_8, 25 °C, ppm): 5.70 (s, 4-pz-*H*), 3.45 (s, *THF*), 2.54 (s, 2,6-OAr–CH_3), 2.43 (s, 4-OAr–CH_3), 2.20 (s, pz-CH_3), 1.45 (s, C(CH_3)$_3$, buried *THF*). ^{1}H NMR (C_6D_6, 25 °C, ppm): 7.19 (s, 4-OAr–*H*), 5.72 (s, 4-pz-*H*), 3.75 (s, *THF*), 2.61 (s, 2,6-OAr–CH_3), 2.48 (s, 4-OAr–CH_3), 2.20 (s, pz-CH_3), 1.38 (s, C(CH_3)$_3$, buried *THF*). ^{11}B NMR (THF-d_8, 25 °C, ppm): −6.8 (s). ^{171}Yb NMR (THF-d_8, 25 °C, ppm): 600 ($\Delta\nu_{1/2} = 40$ Hz). *Anal.*

4.3. Preparation of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})$ (2)

To a benzene solution of $[(Tp^{tBu,Me})YbH]_2$ (400 mg, 0.335 mmol) was added a benzene solution of HO-(2,4,6-$Me_3C_6H_2$) (91 mg, 0.668 mmol) at R.T. The color of solution changed from red to orange. After stirring for 30 min, the solvent was removed under vacuum giving 480 mg of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})$ (**2**) as a orange solid (Yield: 98%). IR (C_6H_6, cm^{-1}): ν_{B-H} 2553. ^1H NMR (C_7D_8, 25 °C, ppm): 7.13 (s, 4-OAr–H), 5.65 (s, 4-pz-*H*), 2.47 (s, 2,6-OAr–CH_3), 2.40 (s, 4-OAr–CH_3), 2.17 (s, pz-CH_3), 1.34 (s, $C(CH_3)_3$). ^1H NMR (C_6D_6, 25 °C, ppm): 5.67 (s, 4-pz-*H*), 2.56 (s, 2,6-OAr–CH_3), 2.45 (s, 4-OAr–CH_3), 2.17 (s, 5-pz-CH_3), 1.35 (s, $C(CH_3)_3$). ^{13}C NMR, APT (C_6D_6, 25 °C, ppm, ^1H cross peaks {x} from HMQC): 163.9 (3-pz-*C*), 145.7 (5-pz-*C*), 129.2 (3,5-C_6), 128, 124.7, 121.2 (1-C_6,2-C_6,4,6-C_6), 102.9 (4-pz-*C*, {× 5.67}), 32.0 ($C(CH_3)_3$), 31.2 ($C(CH_3)_3$, {× 1.35}), 21.2 (4-ArCH_3, {× 2.45}), 19.7 (2,6-ArCH_3, {× 2.56 }), 13.4 (pz-CH_3, {× 2.17}). ^{11}B NMR (THF-d_8, 25 °C, ppm): −7.9 ($\Delta\nu_{1/2} = 240$ Hz). ^{171}Yb NMR (C_7D_8, 25 °C, ppm): 670 ($\Delta\nu_{1/2} = 240$ Hz). *Anal.* Calc. for $C_{33}H_{51}BN_6OYb$: C, 54.17; H, 7.02; N, 11.48. Found: C, 54.18; H, 6.97; N, 10.61%.

4.4. Reaction of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})$ with THF

Solid **2** (205 mg, 0.335 mmol) was dissolved in 5 ml THF. The orange solution was stirred 30 min, then the solvent was removed under vacuum giving 234 mg of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})(THF)$ (**1**) as a yellow/orange solid in quantitative yield. Assignment of this product as compound **1** was confirmed by ^1H NMR. ^{171}Yb NMR (THF-d_8, 25 °C, ppm): 590 ($\Delta\nu_{1/2} = 40$ Hz) (−40 °C, 550 ppm) (−80 °C, 460 ppm). ^{171}Yb NMR (C_7D_8, 25 °C, ppm): 600 ($\Delta\nu_{1/2} = 60$ Hz) (−40 °C, 620 ppm) (−80 °C, 630 ppm).

4.5. Preparation of $(Tp^{tBu,Me})Yb\{(CH_3)_3C(O)CHC(O)C(CH_3)_3\}$ (3)

To a slurry of $[(Tp^{tBu,Me})YbH]_2$ (451 mg, 0.377 mmol) in 10 ml benzene was added 158 μl (0.755 mmol) of dipivaloylmethane at R.T. The color of solution instantly changed from red to dark green with evolution of H_2 gas. The solvent was removed under vacuum giving 603 mg of $(Tp^{tBu,Me})Yb(OCC\{CH_3\}_3)_2CH$ (**3**) as a green solid in quantitative yield. IR (C_6H_6, cm^{-1}): ν_{B-H} 2550. ^1H NMR (C_7D_8, 25 °C, ppm): 7.15 (s, small C_6H_6 impurity) 5.89 (s, piv-C*H*), 5.71 (s, 4-pz-*H*), 4.5 (s, vbr, B*H*), 2.17 (s, pz-CH_3), 1.39 (s, pz-$C(CH_3)_3$), 1.25 (s, piv-$C(CH_3)_3$). ^{13}C NMR, APT (C_6D_6, 25 °C, ppm): 198.9 (piv-O-*C*), 163.1 (3-pz-*C*), 145.4 (5-pz-*C*), 102.7 (4-pz-*C*), 91.9 (piv-*C*H), 41.5 (piv-$C(CH_3)_3$), 32.2 (pz-$C(CH_3)_3$), 31.0 ($C(CH_3)_3$), 28.7 (piv-$C(CH_3)_3$), 13.5 (pz-CH_3). ^{11}B NMR (C_7D_8, 25 °C, ppm): −7.6 ($\Delta\nu_{1/2} = 240$ Hz). ^{171}Yb NMR (C_7D_8, 25 °C, ppm): 1050 ($\Delta\nu_{1/2} = 100$ Hz). *Anal.* Calc. for $C_{35}H_{59}BN_6O_2Yb$: C, 53.91; H, 7.63; N, 10.78. Found: C, 54.44; H, 7.74; N, 10.44%.

4.6. X-ray structure determination of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})(THF)\cdot 0.25C_6H_{14}$ ($\mathbf{1}\cdot 0.25C_6H_{14}$)

Red-orange crystals of $(Tp^{tBu,Me})Yb(O\text{-}\{2,4,6\text{-}Me_3C_6H_2\})(THF)\cdot 0.25C_6H_{14}$ ($\mathbf{1}\cdot 0.25C_6H_{14}$) were obtained from a hexane solution. Data were collected on a Enraf-Nonius CAD4 automated diffractometer using Mo Kα radiation at −50 °C. Unit cell parameters were obtained using the automatic peak search and reflection indexing programs. [4] The systematic absences indicated the space group to be *Cc* (No. 9) [29] or *C*2/*c* (No. 15) [30]; the latter was chosen based on the cell volume and molecular occupancy, and was confirmed by the successful solution and refinement of the structure. The cell constants and orientation matrix were obtained from a least-squares refinement of the setting angles of 24 reflections in the range $19.6° < 2\theta < 25.5°$.

The intensity data were collected with ω scans at 6.7–1.7° min^{-1} (in θ). The scan range and aperture width were varied as a function of θ to compensate for the $\alpha_1 - \alpha_2$ wavelength dispersion: ω scan width $= (0.80 + 0.344\tan\theta)°$ and aperture width $= (3.00 + \tan\theta)$ mm.

The backgrounds for the peaks were measured by extending the scan by 25% on either side of the calculated range; this gave a peak-to-background counting time ratio of 2:1. Intensity measurements were made out to a maximum 2θ of 50.0°. Three reflections were chosen as intensity and orientation standards, and these were remeasured after every 120 min of exposure time to check on crystal and electronic stability over the course of data collection; no appreciable decay was evident.

The positions of most of the non-hydrogen atoms of ($\mathbf{1}\cdot 0.25C_6H_{14}$) were determined using the direct methods program SHELXS-86 [31], and refinement was completed using the program SHELXL-93 [32]. Hydrogen atoms were assigned positions based on the geometries of their attached carbons, and were given thermal parameters of 20% greater than those of the attached carbons. The final model for **2** refined to values of $R_1(F) = 0.0441$ (for 4466 data with $F^2 > 2\sigma(F^2)$) and

[4] Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Enraf-Nonius for the CAD4 diffractometer.

Table 2
Summary of crystallographic data

$R_1(F)$	0.0441	0.0546	0.0481
$wR_2(F^2)$	0.1341	0.1409	0.0758
Goodness-of-fit	1.058	1.122	0.774

$wR_2(F^2) = 0.1341$ (for all 7495 independent data). The highest peak in the final difference Fourier map has a density of 1.41 e Å^{-3}, and is without chemical significance.

4.7. X-ray structure determination of ($Tp^{tBu,Me}$)Yb(O-{2,4,6-$Me_3C_6H_2$}) (2)

Orange crystals of ($Tp^{tBu,Me}$)Yb(O-{2,4,6-$Me_3C_6H_2$}) (**2**) were isolated. Data were collected on a Siemens P4/RA diffractometer using Cu Kα radiation at −60 °C. [5] Unit cell parameters were obtained from a least-squares refinement of 46 reflections with $44° < 2\theta < 49.6°$. The systematic absences indicated the space group to be *Pbcm* (No. 57) [33]. The data were corrected for absorption through use of face indexes Gaussian integration. See Table 2 for a summary of crystal data and X-ray collection information.

The structure of **2** was solved using the direct methods program SHELXS-86 [31] and refinement was completed using the program SHELXL-93 [32]. Hydrogen atoms were assigned positions based on the geometries of their attached carbons, and were given thermal parameters of 20% greater than those of the attached carbons. The final model for **2** refined to values of $R_1(F) = 0.0546$ (for 1998 data with $F^2 > 2\sigma(F^2)$) and $wR_2(F^2) = 0.1409$ (for all 2477 independent data). The highest peak in the final difference Fourier map has a density of 2.47 e Å^{-3}, and is without chemical significance.

4.8. X-ray structure determination of ($Tp^{tBu,Me}$)Yb(OCC{CH_3}$_3$)CH (3)

Dark green crystals of ($Tp^{tBu,Me}$)Yb(OCC{CH_3}$_3$)$_2$CH (**3**) were isolated by concentration of a pentane solution by removal of pentane by slow diffusion into toluene at −80 °C in a closed system. Data were collected on a Bruker P4/RA/SMART 1000 CCD diffractometer using Mo Kα radiation at −80 °C. [6] Unit cell parameters were obtained from a least-squares refinement of 5419 centered reflections from the data collection. The systematic absences indicated the space group to be $C2/c$ (No. 15) [30]. The data were corrected for absorption through use of the SADABS procedure. See Table 2 for a summary of crystal data and X-ray collection information.

The structure of **3** was solved using the direct methods program SHELXS-86 [31] and refinement was completed using the program SHELXL-93 [32]. The dpm ^{t}Bu group containing quaternary carbon C8 exhibited a rotational disorder that was dealt with by refining carbon atoms C9A, C10A and C11A with an occupancy factor of 0.7. C9B, C10B, and C11B were refined with an occupancy factor of 0.3, and the pairs of carbon atoms (e.g., C9A and C9B) were rotationally opposed 180° to each other about the C3-C8 bond and were assigned common anisotropic thermal parameters. Hydrogen atoms were assigned positions based on the geometries of their attached carbons, and were given thermal parameters of 20% greater than those of the attached carbons. The final model for **3** refined to values of $R_1(F) = 0.0481$ (for 3744 data with

[5] Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Siemens.

Received 16 May 2003; accepted 11 August 2003

Abstract

Sodium salt of the fluorinated tris(pyrazolyl)borate ligand $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]^-$ has been synthesized from the corresponding pyrazole and $NaBH_4$ in high yield. It forms stable adducts with oxygen-based donors like THF and water. $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ is monomeric in the solid state whereas $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$ forms a polymeric chain structure. These tris(pyrazolyl)boratosodium adducts show intra and/or inter-molecular sodium–fluorine interactions. X-ray crystal structures of $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$ and $\{[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Na(H_2O)\}_2$ also display similar CF···Na contacts. The copper carbon monoxide complex $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$ was prepared by treating $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ with CuOTf in the presence of CO. The infra-red stretching frequency data show relatively high ν_{CO} value (2103 cm^{-1}) indicating the presence of highly electrophilic copper site on $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$. Crystal structure of 3-(CF_3),5-(Ph)PzH is also reported. It forms "tub" shaped tetramers in the solid state.

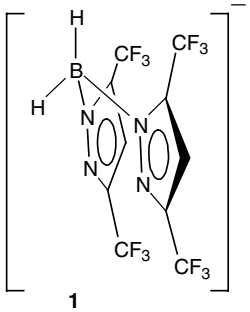
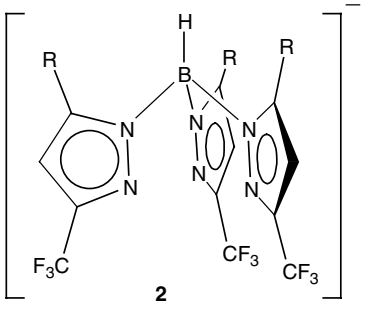
Keywords: Sodium; Copper; Tris(pyrazolyl)borate; Fluorinated; Carbonyl

1. Introduction

Fluorinated ligands play an important role in many applications [1–4]. Metal adducts of the fluorinated ligands often show very different physical and chemical properties relative to their nonfluorinated analogs. For example, polyfluorinated ligands commonly improve the volatility, oxidation resistance, thermal stability, and fluorocarbon solubility of their metal adducts. They have also been known to improve the activity and/or selectivity of certain metal-catalyzed reactions. Fluorinated ligands are highly desired for applications in fluorous-biphase and supercritical CO_2 media [5–9]. Weakly coordinating, fluorinated anions also play an important role in chemistry [10]. Consequently, there is a considerable interest in the synthesis and applications of fluorinated ligands.



1



2

Despite the importance and wide utility of poly(pyrazolyl)borate ligands, relatively little is known about their fluorinated versions [11]. Over the past few years, we have reported the synthesis and use of several poly(pyrazolyl)borates containing fluoroalkyl substituents [2,12–16]. These include $[H_2B(3,5\text{-}(CF_3)_2Pz)_2]^-$ (**1**), $[HB(3\text{-}(CF_3)Pz)_3]^-$ (**2**, where R = H), $[HB(3\text{-}(C_2F_5)Pz)_3]^-$, $[HB(3\text{-}(C_3F_7)Pz)_3]^-$, and $[HB(3,5\text{-}(CF_3)_2Pz)_3]^-$ (**2**, where $R = CF_3$). Their metal adducts show very interesting properties. For example, the copper(I) carbonyl and ethylene adducts $[HB(3,5\text{-}(CF_3)_2Pz)_3]CuCO$ [17] and $[HB(3,5\text{-}(CF_3)_2Pz)_3]Cu(\eta^2\text{-}C_2H_4)$ [16] are air

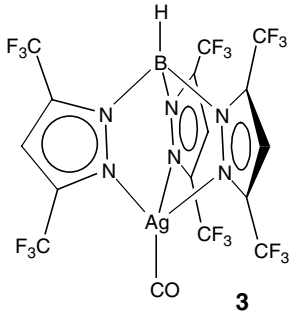
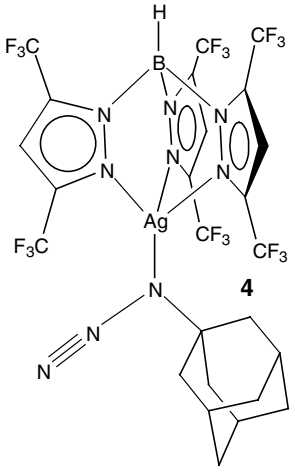
doi:10.1016/j.poly.2003.11.016

and thermally stable solids. It is also possible to obtain the corresponding silver(I) complexes [18,19]. The $[HB(3,5\text{-}(CF_3)_2Pz)_3]AgCO$ (**3**) is an example of a metal carbonyl where the bonding between the metal and the CO is essentially of σ-type (with little to no π-backbonding) [20]. Its carbonyl stretching frequency (ν_{CO} = 2178 cm^{-1}) is higher than that of free CO (2143 cm^{-1}). $[HB(3,5\text{-}(CF_3)_2Pz)_3]CuNNN(1\text{-}Ad)$ and $[HB(3,5\text{-}(CF_3)_2Pz)_3]AgN(1\text{-}Ad)NN$ (**4**) represent rare, thermally stable organo azide–metal complexes [21].



3



4

The $[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]^-$ ligand (**2** where R = CH_3), which was reported by Graham et al, has also shown to be useful in stabilizing rare, reactive and/or labile molecules like the hydrido vinyl species $[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Ir(H)(CO)(CH{=}CH_2)$ [22]. Metal adducts of fluorinated poly(pyrazolyl)borates also catalyze various transformations (e.g., $[HB(3,5\text{-}(CF_3)_2Pz)_3]Cu(\eta^2\text{-}C_2H_4)$ for aziridination; $[HB(3,5\text{-}(CF_3)_2Pz)_3]Ag(THF)$ for C–Cl bond activation; $[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Cu$ for oxidation) [16,23,24]. Overall, fluorinated poly(pyrazolyl)borates are of significant current interest, and are useful for many important applications [2,12,14–19, 21–46].

Here, we describe the synthesis of a new fluorinated tris(pyrazolyl)borate ligand $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]^-$ (**2** where R = Ph). Solid state structures of several tris(pyrazolyl)boratosodium complexes featuring oxygen-based donors like THF, Et_2O and H_2O are also reported. The ligand electronic effects were investigated using the IR spectroscopic data of the copper(I) carbonyl complex $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$.

2. Experimental

2.1. General procedures

All manipulations were carried out under an atmosphere of purified nitrogen using standard Schlenk techniques (unless noted otherwise). Solvents were purchased from commercial sources and distilled from conventional drying agents prior to use. Glassware was oven-dried at 150 °C overnight. NMR spectra were recorded at room temperature on a JEOL Eclipse 500 (^1H, 500.16 MHz; ^{19}F, 470.62 MHz; ^{13}C NMR, 125.78 MHz). Proton and carbon chemical shifts are reported in parts per million versus Me_4Si. ^{19}F NMR chemical shifts were referenced relative to an external $CFCl_3$ standard. Elemental analyses were performed at the University of Texas at Arlington using a Perkin–Elmer Model 2400 CHN analyzer. All the samples gave satisfactory CHN analysis. Benzoyl-1,1,1-trifluoroacetone, $NaBH_4$ hydrazine hydrate (55% N_2H_4 solution), and copper(I) trifluoromethanesulfonate salt $[CF_3SO_3Cu]_2 \cdot C_6H_6$ were purchased from commercial sources and used as received.

2.2. Synthesis of 3-(CF3),5-(Ph)PzH

This was synthesized from $PhCOCH_2COCF_3$ and hydrazine following a procedure slightly different from that described previously [47]. Nitrogen atmosphere is not necessary. Hydrazine hydrate (55% N_2H_4 solution 1.40 g, 24.0 mmol) was added drop wise to a solution of benzoyl-1,1,1-trifluoroacetone (4.32 g, 20.1 mmol) and ethanol in an ice bath. The reaction mixture was stirred for 4 h. Ethanol and water were removed by slow distillation to obtain 3-(CF_3),5-(Ph)PzH, which solidifies when cooled to room temperature. Sublimation under reduced pressure at 140 °C affords analytically pure 3-(CF_3), 5-(Ph)PzH. X-ray quality crystals can be obtained by recrystallization from hexane. Yield: 4.18 g, 95%; m.p. 122–123 °C (Lit. 122–123 °C); ^1H NMR (C_6D_6): δ 10.69 (br, NH), 7.01 (m, Ph), 6.98 (br m, Ph), 6.36 (s, Pz); ^{19}F NMR (C_6D_6): δ −61.6; ^{13}C NMR ($CDCl_3$): δ 145.3, 143.6 (q, $^2J(C,F)$ = 36 Hz), 129.4, 129.3, 127.9, 125.7, 121.2 (q, $^1J(C,F)$ = 270 Hz), 101.0; ^{19}F NMR ($CDCl_3$): δ −61.9.

2.3. Synthesis of [HB(3-(CF3),5-(Ph)Pz)3]Na(THF)

A mixture of 3-(CF_3),5-(Ph)PzH (5.00 g, 23.6 mmol) and $NaBH_4$ (0.288 g, 7.60 mmol) was heated at ca. 180 °C for 4 h. The reaction mixture was allowed to cool to room temperature. The excess 3-(CF_3),5-(Ph)PzH was removed by vacuum sublimation at 140 °C. The remaining solid was dissolved in warm CH_2Cl_2 containing 0.5 mL of THF, filtered over Celite, and the filtrate was collected. The solvent was removed from the filtrate under reduced pressure to obtain $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ as a colorless solid. Addition of hexane to the filtrate facilitates the precipitation of $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ as a non-sticky product. This process may also lead to the loss of some coordinated THF. X-ray quality crystals were grown from a hexane/dichloromethane mixture with a few drops of THF at −25 °C; m.p. 187–188 °C. Yield: 4.62 g, 82%. ^1H NMR ($CDCl_3$): δ 7.20 (t, 3H, Ph), 6.91 (t, 6H,

Ph), 6.87 (d, 6H, Ph), 6.43 (s, 3H, Pz), 3.83 (m, 4H, THF), 1.92 (m, 4H, THF); ^{19}F NMR ($CDCl_3$): δ −62.3. IR (KBr), cm^{-1}: 2621 (BH).

2.4. Synthesis of [HB(3-(CF$_3$),5-(Ph)Pz)$_3$]Na(H$_2$O)

A mixture of 3-(CF_3),5-(Ph)PzH (5.00 g, 23.6 mmol) and $NaBH_4$ (0.288 g, 7.60 mmol) was heated at ca. 180 °C for 4 h. The reaction mixture was allowed to cool to room temperature and the excess 3-(CF_3),5-(Ph)PzH was removed by vacuum sublimation at 140 °C. The residue was transferred to a beaker and dissolved in warm petroleum ether. The solution was filtered, and the solvent was allowed to evaporate slowly from the filtrate in open air to obtain colorless crystals of [HB(3-(CF_3),5-(Ph)Pz)$_3$]Na(H_2O); m.p. 200–201 °C. Yield: 3.91 g, 75%. ^{1}H NMR ($CDCl_3$): δ 7.18 (tt, 3H, Ph), 6.89 (br t, 6H, Ph), 6.85 (td, 6H, Ph), 6.41 (s, 3H, Pz), 1.66 (s, 2H, H_2O); ^{19}F NMR ($CDCl_3$): δ −61.6.

2.5. Synthesis of [HB(3-(CF$_3$),5-(Ph)Pz)$_3$]CuCO

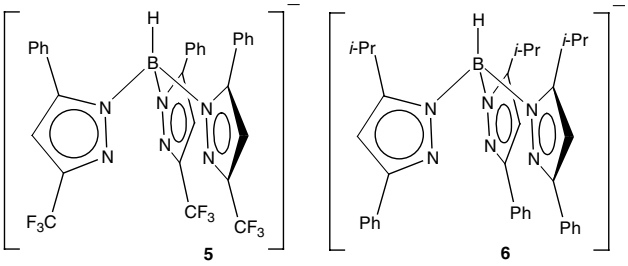
$[CF_3SO_3Cu]_2 \cdot C_6H_6$ (0.068 g, 0.135 mmol) was dissolved in THF saturated with CO. [HB(3-(CF_3),5-(Ph)Pz)$_3$]Na(THF) (0.201 g, 0.27 mmol) in THF was added to this mixture at room temperature, and stirred for about 12 h under CO atmosphere. The resulting mixture was filtered and the solvent was removed from the filtrate under reduced pressure to obtain [HB(3-(CF_3),5-(Ph)Pz)$_3$]CuCO as a white solid. It was recrystallized from THF/toluene at −25 °C; m.p: 202 °C (dec.). Yield: 0.145 g, 73%. ^{1}H NMR ($CDCl_3$): δ 7.28 (t, 3H, Ph), 6.94 (t, 6H, Ph), 6.85 (d, 6H, Ph), 6.55 (s, 3H, Pz); ^{19}F NMR ($CDCl_3$): δ −61.2; IR (KBr), cm^{-1}: 2639 (BH), 2103 (CO).

2.6. X-ray structure determination

A suitable crystal covered with a layer of hydrocarbon oil was selected and attached to a glass fiber and immediately placed in the nitrogen stream for low temperature data collections. Room temperature data were collected on crystals attached to glass fibers using epoxy glue. Structures were solved by direct methods followed by successive cycles of full-matrix least-squares refinement on F^2 and difference Fourier analysis. Software programs and the sources of scattering factors are contained in the Bruker SHELXTL 5.1 software package provided by the Bruker Analytical X-ray Instruments, Inc. Some details of data collection and refinements are given in Table 1. Selected bond distances and angles are given in Table 2.

3. Results and discussion

Several methods for the synthesis of 3-(CF_3),5-(Ph)PzH are available in the literature [47–49]. We have used one of those with some minor modifications to obtain 3-(CF_3),5-(Ph)PzH in high yield [47]. The X-ray crystal structure of 3-(CF_3),5-(Ph)PzH is depicted in Fig. 1. It adopts an interesting "tub" shaped, tetrameric structure in the solid state due to N–H···N hydrogen bonding. The (non bonded) N···N distances are 2.844, 2.854, 2.856, and 2.866 Å. The H···N distances range from 1.873 Å to 2.005 Å. N-unsubstituted pyrazoles display structures ranging from dimers, trimers, tetramers, to catemers [50]. Among these, tetrameric form is the least common. The 3,5-(CF_3)$_2$PzH, 3,5-(Ph)$_2$PzH, and 3(5)-phenyl-5(3)-methylpyrazole are examples of related pyrazoles that adopt the tertameric form in the solid state [50–53].



The sodium salt of [HB(3-(CF_3),5-(Ph)Pz)$_3$]$^-$ (**5**) was prepared by heating a mixture of 3-(CF_3),5-(Ph)PzH and $NaBH_4$ to 180 °C. It was isolated as the THF adduct and characterized using NMR and IR spectroscopy and X-ray crystallography. Fig. 2 depicts the X-ray crystal structure of [HB(3-(CF_3),5-(Ph)Pz)$_3$]Na(THF). It confirms the formation of the isomer with trifluoromethyl groups at the pyrazolyl group 3-position (rather than the 3-Ph,5-CF_3 version). [1] The B-H moiety resides in a pocket surrounded by three phenyl groups. The non-fluorinated ligand [HB(3-(Ph),5-(*i*-Pr)Pz)$_3$]$^-$ (**6**) is known [54]. In this system, the phenyl groups occupy the 3-position rather than the 5-position. Considering that the trifluoromethyl group is closer in size to an isopropyl group, these data indicate that (in the absence of adverse steric constraints) the electron rich nitrogen site of the pyrazole preferentially bonds to the boron atom during the ligand formation [55–57]. [2]

[1] We have also synthesized [HB(3-(CF_3),5-(Ph)Pz)$_3$]Tl using [HB(3-(CF_3),5-(Ph)Pz)$_3$]Na(THF) and $TlNO_3$. ^{19}F NMR signal corresponding to CF_3 groups in $CDCl_3$ appear as a doublet at δ −59.3 with $^4J(Tl, F) = 880$ Hz. Comparison of this value to ^{19}F NMR spectroscopic data of [HB(3-(CF_3),5-(thienyl)Pz)$_3$]Tl ([37]: ^{19}F NMR ($CDCl_3$): δ −60.6 with $^4J(Tl, F) = 850$ Hz) further supports the formation of tris(pyrazolyl)borate ligand isomer with CF_3 groups at the pyrazolyl ring 3-position.

[2] Although CF_3 group is larger than a methyl group and somewhat similar in size to an isopropyl group, the "effective steric bulk" of tris(pyrazolyl)borato ligands with CF_3 groups at the pyrazolyl group 3-position is much closer to the 3-methyl analog than the 3-isopropyl analog. This is evident from the cone angle data of tris(pyrazolyl)borates (see [11, p. 105]).

The Na–O bond length of 2.261(3) Å in $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ is slightly shorter than the corresponding distance of 2.303(3) Å observed for dimeric $\{[HB(3\text{-}(CF_3)Pz)_3]Na(THF)\}_2$ [15]. Although it is possible to synthesize $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(THF)$, we have not been able to obtain suitable crystals for X-ray structure determination. However, the structural data of the related diethyl ether adduct $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$ could be obtained (Fig. 3) [15]. It adopts a monomeric structure with a Na–O bond distance of 2.281(3) Å.

The sodium ion in compounds like $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$, $\{[HB(3\text{-}(CF_3)Pz)_3]Na(THF)\}_2$, and $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$ lies in a pit surrounded by three trifluoromethyl groups (“Teflon coated cavity”). These molecules show close Lewis acid–base contacts between the sodium ion and fluorine atoms of the CF_3 moieties. For example, $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$ shows several intramolecular Na···FC contacts at 2.915, 3.054, and 3.088 Å. $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$ displays similar interactions at 2.874, 3.033, and 3.195 Å. The closest Na···FC contact in $\{[HB(3\text{-}(CF_3)Pz)_3]Na(THF)\}_2$ is of an intermolecular type (2.744(3) Å).

Compounds with CF···M bonding interactions are of significant interest [58,59]. It is, however, difficult to clearly define the upper limit of the inter-atomic distance that points to a bonding interaction between a metal (in particular, hard metal ion like sodium) and fluorine of a fluorocarbon moiety [58]. Continuing revision of radii (ionic, van der Waals, covalent) further complicates this matter [60]. It has been argued that the sum of the van der Waals radii (which is 3.77 Å for Na and F combination) which is commonly used as the upper limit may over estimate the bonding interactions between a *hard metal ion* like sodium and a FC moiety. More appropriate value for the upper limit for Na···FC bonding is considered to be 3.07 Å, which is the sum of van der Waals radius of fluorine and Kollman’s ionic van der Waals radius of sodium [58]. Therefore, in all the sodium adducts illustrated in this paper, only the Na···F contacts lower than 3.07 Å are shown as bonds.

The water adduct $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$ could be obtained by allowing a petroleum ether solution of $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na$ to slowly concentrate in the open atmosphere (or using wet petroleum ether). The X-ray crystal structure (Figs. 4 and 5) shows that it is a polymeric molecule. Short intermolecular Na···FC interactions (2.848 Å) link the $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)$ units together. In addition, there is an intramolecular Na···FC contact at 3.006 Å (and two other F atoms at a distance of 3.082 and 3.256 Å). $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(H_2O)$ (Fig. 6) which was reported earlier [15] and $\{[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Na(H_2O)\}_2$ (Fig. 7) are two other examples where the coordination of water molecules to sodium centers of fluorinated tris(pyrazolyl)borates have been observed. $\{[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Na(H_2O)\}_2$ was obtained following a procedure similar to that of $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$. It has a dimeric structure. Water molecules and intermolecular Na···FC bonds (2.934 Å) hold the monomers together. In addi-

tion, there is a F–C moiety at 3.094 Å from each sodium site.

Interestingly, despite the wide utility of tris(pyrazolyl)borate salts of alkali metals, only a very few have been characterized using X-ray crystallography. The structurally characterized compounds of this type include {[HB(3,5-(CF_3)$_2$Pz)$_3$]K(DMAC)}$_2$ [12], {[HB(3-(CF_3),5-(CH_3)Pz)$_3$]K(DMAC)}$_2$ [61], {[HB(3-(CF_3),5-(CH_3)Pz)$_3$]K(CH_3CN)}$_2$ [45], [HB(3,5-(CF_3)$_2$Pz)$_3$]Na(H_2O) [15], {[HB(3-(CF_3)Pz)$_3$]Na(THF)}$_2$ [15], {[HB(3-(C_2F_5)Pz)$_3$]Na(3-(C_2F_5)PzH)} [14], [HB(3,4,5-(CH_3)$_3$Pz)$_3$]K [62], [HB(3,5-(*t*-Bu)$_2$Pz)$_3$]K(C_6H_6) [63], [HB(3,5-(*t*-Bu)$_2$Pz)$_3$]Cs [63].

The CO stretching frequency of metal carbonyl adducts serves as a good measure of relative electron density at a metal site (or the electron acceptor/back-donation ability of a metal ion). It also provides information about the donor properties of the auxiliary ligands coordinated to a metal ion. Copper(I) carbonyl adducts have been used in the study of electronic effects of tris(pyrazolyl)borates ligands [2]. ^{63}Cu NMR spectroscopic data [54] and the results from theoretical studies [64] are in good agreement with the conclusions based on CO stretching frequency data.

In order to estimate the relative electronic effects of [HB(3-(CF_3),5-(Ph)Pz_3]$^-$ ligand on metal ions, we have

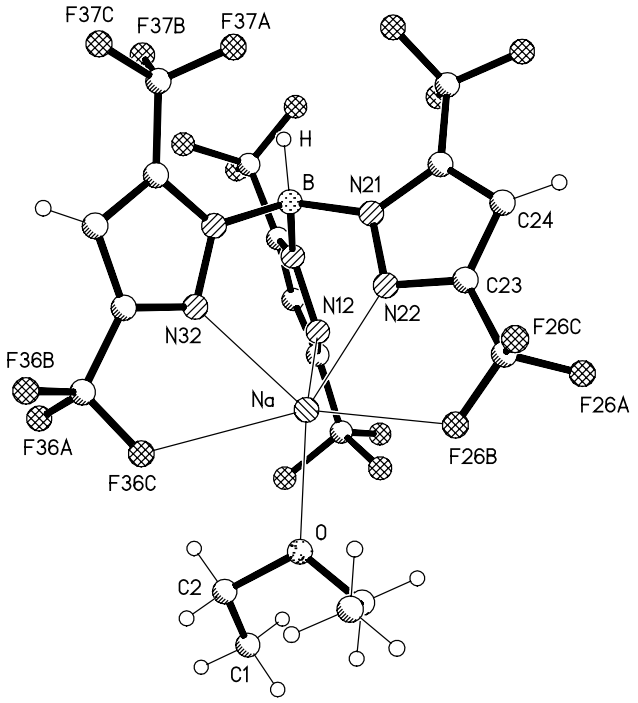

Fig. 3. Molecular structure of $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$.

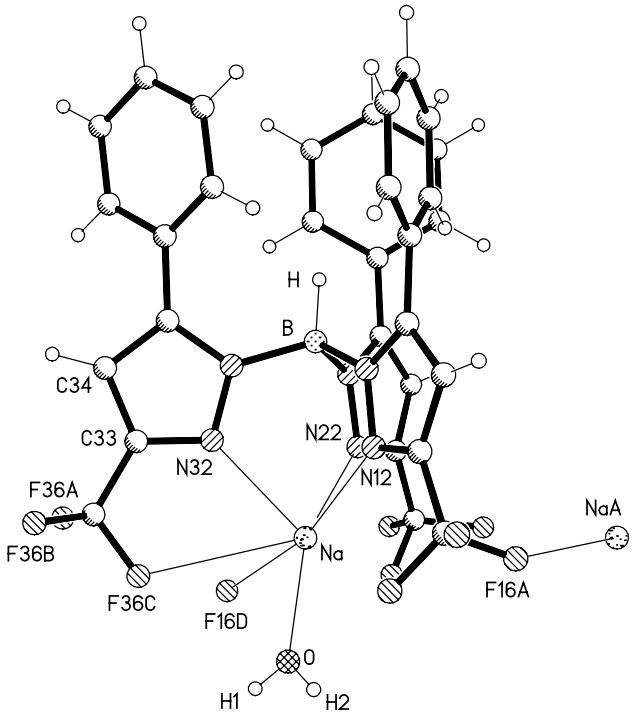

Fig. 4. A view of $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$ showing the atom numbering scheme.

synthesized and characterized the copper carbonyl adduct $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$. The X-ray crystal structure (Fig. 8) shows that it features a typical pseudotetrahedral copper site. The Cu–C–O moiety is essentially linear. The copper–CO bond length of 1.773(5) Å is well within the range reported for tris(pyrazolyl)boratocopper(I) carbonyl complexes (1.752–1.808 Å). The Cu–N bond distances of $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$ (2.049(3), 2.054(3), 2.057(3) Å) can be compared to the corresponding bond lengths in $[HB(3,5\text{-}(CF_3)_2Pz)_3]CuCO$ (2.035(3), 2.061(2), 2.061(3) Å) [17], $[HB(3,5\text{-}(Ph)_2Pz)_3]CuCO$ (2.059(6), 2.061(2),

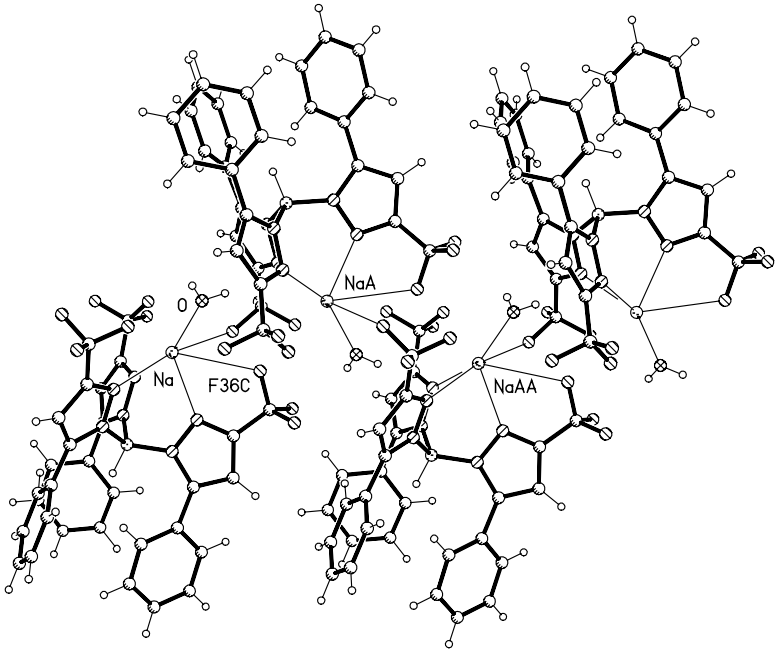

Fig. 5. Molecular structure of $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$ showing the polymeric nature.

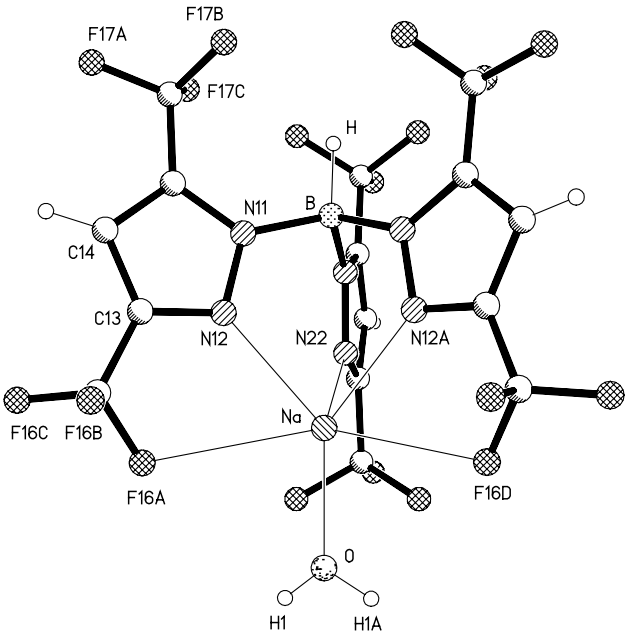

Fig. 6. Molecular structure of $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(H_2O)$ (from [15]).

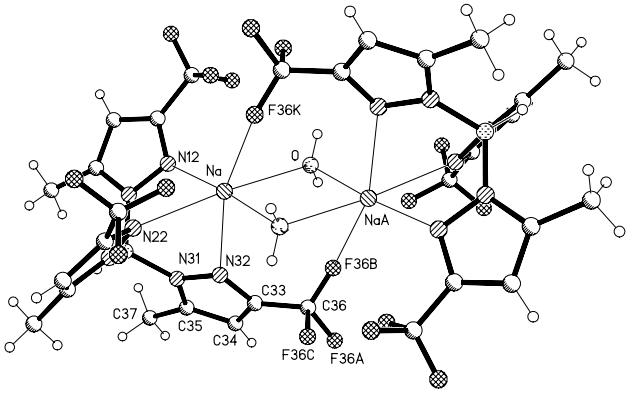

Fig. 7. Molecular structure of $\{[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Na(H_2O)\}_2$.

2.061(3) Å) [54], and $[HB(3,5\text{-}(i\text{-}Pr)_2Pz)_3]CuCO$ (2.019(5), 2.014(6), 2.022(6) Å) [65]. Overall, there is no significant difference in the Cu–N separation between the fluorinated and non-fluorinated tris(pyrazolyl)borate systems of copper(I).

The IR spectrum of $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$ shows a strong absorption band at 2103 cm^{-1} corresponding to the C–O stretching frequency. This value may be compared to the ν_{CO} data of related copper carbonyl adducts. Fig. 9 summarizes the CO stretching frequency values of closely related tris(pyrazolyl)boratocopper(I) carbonyl adducts [2,14,17,39,54,65–70]. The Cu–CO adducts of the fluorinated tris(pyrazolyl)borates display relatively high ν_{CO} values indicating the presence of fairly acidic copper sites with low back-bonding ability. This is expected based on the highly electron

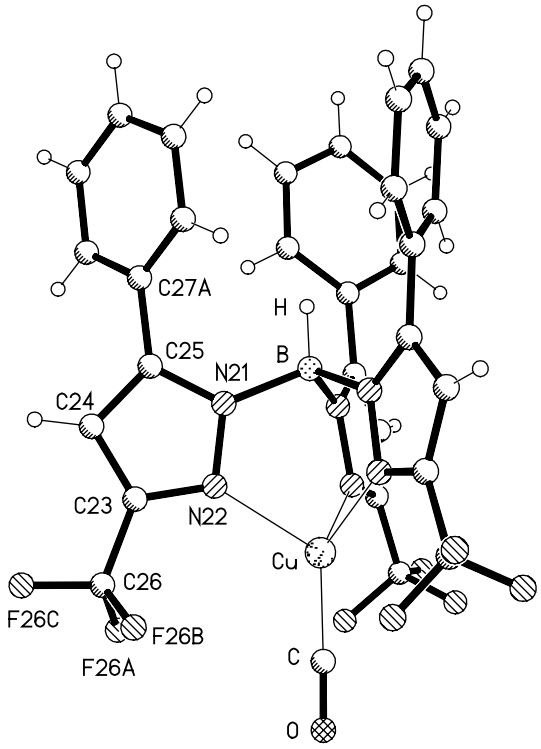

Fig. 8. Molecular structure of $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]CuCO$.

withdrawing nature of the fluorocarbon substituents present on the pyrazolyl rings.

Recently, we have reported the synthesis of copper(I) ethylene adduct $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Cu(\eta^2\text{-}C_2H_4)$ [16]. It serves as a good aziridination catalyst. Preliminary data suggest that it may also be possible to synthesize the silver carbonyl adduct $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]AgCO$ ($\nu_{CO} = 2149\ cm^{-1}$) [71]. However, so far we have not been able to obtain an analytically pure sample to confirm the identity. Thermally stable, silver carbonyl species are extremely rare [20]. $[HB(3,5\text{-}(CF_3)_2Pz)_3]AgCO$ is the only well authenticated compound of this type in the Scorpionate family [18].

Overall, the synthesis of a new fluorinated ligand is reported along with the crystal structures of several tris(pyrazolyl)boratosodium salts featuring fluorinated Scorpionates. The sodium ion in these systems resides in a pit surrounded by trifluoromethyl groups. Significant Na···FC contacts are present in the solid state as evident from the X-ray crystal structures. The IR data of the copper carbonyl complex $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]$-CuCO indicates that $[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]^-$ is a relatively poor donor to metal ions.

3.1. Supplementary material

Crystallographic data for 3-(CF_3),5-(Ph)PzH, $[HB(3(CF_3),5\text{-}(Ph)Pz)_3]Na(THF)$, $[HB(3,5\text{-}(CF_3)_2Pz)_3]Na(OEt_2)$, $\{[HB(3\text{-}(CF_3),5\text{-}(Ph)Pz)_3]Na(H_2O)\}_n$, $\{[HB(3\text{-}(CF_3),5\text{-}(CH_3)Pz)_3]Na(H_2O)\}_2$, and $[HB(3\text{-}(CF_3),5\text{-}(Ph)$

Abstract

The solvent extraction of first-series transition metal ions {Mn(II), Fe(II), Co(II), Ni(II), Cu(II) and Zn(II)} with $[B(3\text{-iPrpz})_4]^-$ (iPrpz = isopropylpyrazolyl) is reported. Although the previously reported tetrakis(pyrazolyl)borates, $[B(pz)_4]^-$ and $[B(3\text{-Mepz})_4]^-$, quantitatively extracted all the studied transition metal ions, $[B(3\text{-iPrpz})_4]^-$ extracted only Cu(II) and Zn(II). In order to elucidate the origin of the selectivity, the structures of the extracted species, $[B(3\text{-iPrpz})_4]_2Zn$ (**1**) and $[B(3\text{-iPrpz})_4]Cu(OCOCH_3)$ (**2**), were determined by single-crystal X-ray diffraction. Complex **1** has a tetrahedral geometry with each ligand having bidentate coordination. Complex **2** has a distorted square pyramidal geometry with $[B(3\text{-iPrpz})_4]^-$ having tridentate coordination and the acetate anion having asymmetric bidentate coordination. These structures of the extracted species are different from those of the previously studied tetrakis(pyrazolyl)borates, which are octahedral A_2M with each ligand having tridentate coordination (A^- = tetrakis(pyrazolyl)borate, M^{2+} = first-series transition metal ion). Because the bulky isopropyl groups at the 3-position of the pyrazolyl ring prevent octahedral geometry, the other metal ions cannot form stable and extractable complexes with $[B(3\text{-iPrpz})_4]^-$.

Keywords: Tetrakis(3-isopropylpyrazolyl)borate; Solvent extraction; Single-crystal X-ray diffraction; Zinc; Copper

1. Introduction

Poly(pyrazolyl)borates (A^-) are versatile ligands for use as metal centers of transition metal catalysts [1–10] and for mimicking metalloenzyme systems in bioinorganic chemistry [11–14]. In particular, the poly(pyrazolyl)borate incorporated a bulky substituent at the 3-position of the pyrazolyl ring known as a "tetrahedral enforcer" [15], because the bulky substituent prevents a second poly(pyrazolyl)borate ligand from coordinating the metal center and other ancillary ligands (X^-) coordinate with ease. On the other hand, a large number of A_2M complexes of transition metal ions with the poly(pyrazolyl)borates having various bulky substituents were determined by X-ray crystallography. As far as the authors know, as listed in Table 1, there are many examples of the complexes introduced phenyl, cycloalkyl groups, and so on [16–33].

We have been interested in poly(pyrazolyl)borates as extraction reagents for first-series transition metal ions {M^{2+}: Mn(II), Fe(II), Co(II), Ni(II), Cu(II) and Zn(II)} [34–36]. The parent poly(pyrazolyl)borate, $[HB(pz)_3]^-$, extracted all the studied metal ions from very acidic solution at pH <2.1 into an organic phase. $[HB(pz)_3]^-$ forms quite stable A_2M complexes because the unique trigonal structure of $[HB(pz)_3]^-$ is favorable for octahedral coordination. $[B(pz)_4]^-$ and $[B(3\text{-Mepz})_4]^-$ also quantitatively extracted all the metal ions as octahedral A_2M complexes. However, $[B(pz)_4]^-$ extracted large metal ions, such as Mn(II) and Cd(II), at higher pH than $[HB(pz)_3]^-$ due to the intraligand contact between the coordinated and non-coordinated pyrazolyl rings.

[c] Tetrahedral geometry.
[d] Square planar geometry.

$[B(3\text{-}Mepz)_4]^-$ extracted all the metal ions at higher pH compared to $[B(pz)_4]^-$ due to the interligand contact caused by the 3-methyl groups. The selectivity of these ligands for the metal ions generally followed the Irving–Williams series in stability constants; the extraction pH increased in the order of Cu(II), Ni(II), Co(II), Fe(II) and Mn(II).

Here, we report on the solvent extraction of the first-series transition metal ions with $[B(3\text{-}iPrpz)_4]^-$. $[B(3\text{-}iPrpz)_4]^-$ extracted only Cu(II) and Zn(II) of all the studied metal ions. In order to examine the steric effects of the isopropyl groups on the extraction, the structures of the extracted species, $[B(3\text{-}iPrpz)_4]_2Zn$ (**1**) and $[B(3\text{-}iPrpz)_4]Cu(OCOCH_3)$ (**2**), were examined by X-ray crystallography.

2. Experimental

2.1. General procedure

$K[B(3\text{-}iPrpz)_4]$ was synthesized as previously reported [32] and recrystallized from hot ethanol–water (1:5). All other chemicals were of reagent grade and distilled water was used throughout. Proton NMR spectra were obtained at 25 ± 1 °C with a JEOL LA-300 spectrometer. Chemical shifts (ppm) are reported downfield from TMS using the solvent chloroform-*d* ($\delta_H = 7.24$) as an internal standard. The reported ^1H coupling constants are $^3J_{HH}$ values. The metal ion concentration was determined with a HITACHI Z-8100 polarized Zeeman atomic absorption spectrometer or a Japan Jarrell Ash ICAP-500 inductively coupled argon plasma emission spectrometer. The pH was measured using a Hitachi-Horiba M-12 pH meter equipped with a glass electrode. The aqueous and organic phases were shaken with a TAITEC Bio-Shaker BR-30L.

2.2. Hydrolysis of the ligand

An aliquot of deuterium oxide (2.0 mL) at various pH was shaken with an equal volume of chloroform-*d* containing 5.0×10^{-3} M $K[B(3\text{-}iPrpz)_4]$ at 25 ± 1 °C for 10–90 min. After the two phases were separated centrifugally, the pH of the aqueous phase was measured. ^1H NMR of the two phases was measured using the JEOL LA-300.

2.3. Extraction of first-series transition metal ions

An aliquot of chloroform (10 mL) containing 1.0×10^{-3} M $K[B(3\text{-}iPrpz)_4]$ was shaken with an equal volume of an aqueous phase containing 1.0×10^{-5} M of a metal ion and 1.0×10^{-2} M of acetic acid, 2-(*N*-morpholino)ethanesulfonic acid (MES), 3-(*N*-morpholino)propanesulfonic acid (MOPS), *N*-tris(hydroxymethyl)methyl-3-aminopropanesulfonic acid (TAPS), 2-(cyclohexylamino)ethanesulfonic acid (CHES) or 3-(cyclohexylamino)propanesulfonic acid (CAPS) at 25 ± 1 °C. After the two phases were separated centrifugally, the pH of the aqueous phase was measured. The metal concentration in the aqueous phase was determined using the Z-8100 or the ICAP-500. The metal concentration in the organic phase was measured after back-extraction into 1.0 M nitric acid.

2.4. Syntheses of the complexes

2.4.1. Preparation of $[B(3\text{-}iPrpz)_4]_2Zn$ (1)

Ten milliliters of chloroform containing 2.0×10^{-3} M $K[B(3\text{-}iPrpz)_4]$ was shaken for 1 h with an aqueous solution (10 mL) at pH 8.0 containing 1.0×10^{-3} M $ZnSO_4$ and 1.0×10^{-2} M acetic acid. After centrifugation, the organic phase was evaporated to precipitate the complex. Recrystallization from a mixture of chloroform and acetonitrile in a 2:1 volume ratio gave colorless crystals suitable for X-ray diffraction. *Anal.* Calc. for $C_{48}H_{72}N_{16}B_2Zn$: C, 60.40; H, 7.52; N, 22.90. Found: C, 60.15; H, 7.64; N, 23.52%; m.p. 263–264 °C. ^1H NMR ($CDC1_3$, δ): 0.74, 1.20 (24, 24, d, d, $J = 6.8$, 7.0 Hz, Me(iPr)), 2.00, 2.95 (4, 4, m, m, CH(iPr)), 5.98, 6.09, 6.42, 7.13 (4, 4, 4, 4, d, d, d, d, $J = 2.2$, 2.6, 2.2, 2.4 Hz, 4-H (pz), 5-H(pz)). Although Trofimenko et al. [32]

prepared and characterized **1**, its X-ray structure has not been reported.

2.4.2. Preparation of $[B(3\text{-}iPrpz)_4]Cu(OCOCH_3)$ (**2**)

Ten milliliters of chloroform containing 1.0×10^{-3} M K[B(3-iPrpz)$_4$] was shaken for 1 h with an aqueous solution (10 mL) at pH 3.0 containing 1.0×10^{-3} M $CuSO_4$ and 1.0×10^{-2} M acetic acid. After centrifugation, the organic phase was evaporated to precipitate the complex. Recrystallization from methanol gave blue crystals suitable for X-ray diffraction. *Anal.* Calc. for $C_{25}H_{39}N_8BO_2Cu$: C, 54.82; H, 6.80; N, 19.67. Found: C, 54.73; H, 7.00; N, 19.71%; m.p. 145–146 °C.

2.5. X-ray crystal structure determination

Crystallographic data are summarized in Table 2. Crystals of **1** and **2** were each mounted onto a fine glass fiber with epoxy cement. The lattice parameters and intensity data were measured on a Rigaku AFC7R four-circle diffractometer with graphite monochromated Cu Kα radiation ($\lambda = 1.54178$ Å) at 20 ± 1 °C. An $\omega - 2\theta$ scan technique to a maximum 2θ value of 140° was used. An empirical absorption correction based on azimuthal scans of several reflections was applied [37]. The data were corrected for Lorentz and polarization effects, and a correction for secondary extinction was applied. The structures were solved by direct methods [38] and expanded using a Fourier technique [39]. The non-hydrogen atoms of **1** were refined anisotropically. For **2**, isotropic temperature factors were used for the nitrogen and carbon atoms of the non-coordinated pyrazolyl ring

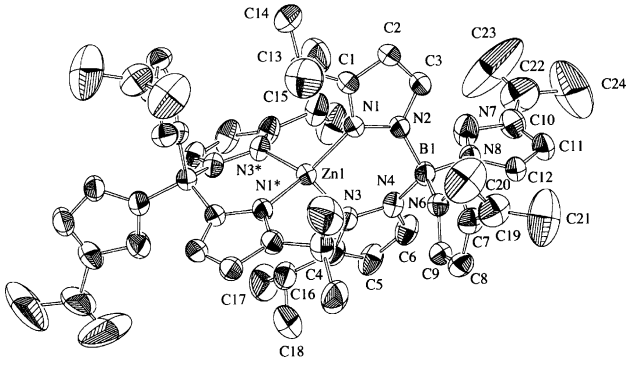

Fig. 1. ORTEP view of $[B(3\text{-}iPrpz)_4]_2Zn$ (**1**) (20% probability). Hydrogen atoms are omitted for clarity.

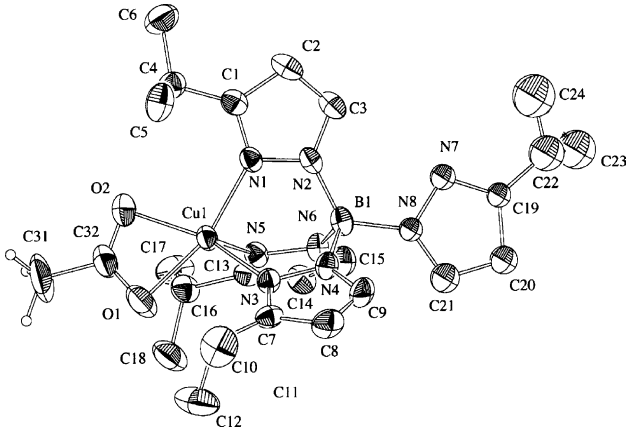

Fig. 2. ORTEP view of $[B(3\text{-}iPrpz)_4]Cu(OCOCH_3)$ (**2**) (20% probability). Hydrogen atoms are omitted for clarity except for the hydrogen atoms bonded to the carbon atom (C31).

because of disorder. Hydrogen atoms were fixed at the positions generated by calculation, while those on the non-coordinated pyrazolyl ring of **2** were not incorporated in the refinement. All calculations were performed using the TEXSAN crystallographic software package developed by Molecular Structure Corporation.

Selected bond distances and angles of **1** and **2** are shown in Table 3. Figs. 1 and 2 show ORTEP drawings of **1** and **2**, respectively.

3. Results and discussion

3.1. Hydrolysis and distribution of the ligands

It was previously reported that poly(pyrazolyl)borates hydrolyzed into pyrazoles and boric acid [34–36]. The chloroform-d solution containing $K[B(3\text{-}iPrpz)_4]$ was shaken with deuterium oxide to study the hydrolysis of $[(3\text{-}iPrpz)_4]^-$. On the basis of ^1H NMR, 5% of $[B(3\text{-}iPrpz)_4]^-$ in chloroform-*d* hydrolyzed into isopropylpyrazole after 10 min of shaking with an aqueous phase at pH 2.5–13. Twenty five percent of $[B(3\text{-}iPrpz)_4]^-$ hydrolyzed after 90 min of shaking. Although no peaks of $[B(3\text{-}iPrpz)_4]^-$ and isopropylpyrazole were observed in deuterium oxide after 10 min of shaking, one set of peaks of isopropylpyrazole was observed after 90 min. We also confirmed that the concentration of K^+ in the aqueous phase does not significantly increase after shaking. These data suggest that $K[B(3\text{-}iPrpz)_4]$ does not distribute into the aqueous phase because of the high hydrophobicity of $[B(3\text{-}iPrpz)_4]^-$, and some isopropylpyrazole distributes into the aqueous phase after hydrolysis of $[B(3\text{-}iPrpz)_4]^-$.

3.2. Extraction of first-series transition metal ions

Fig. 3 shows the relationship between the percent extraction (%*E*) of metal ions and the pH of the aqueous phase using $[B(pz)_4]^-$, $[B(3\text{-}Mepz)_4]^-$ and $[B(3\text{-}iPrpz)_4]^-$ as a ligand. $K[B(pz)_4]$ and $K[B(3\text{-}Mepz)_4]$ were initially dissolved in the aqueous phase, since they were not soluble in chloroform. Ten minutes of shaking was adopted for a comparison with $[B(pz)_4]^-$ and $[B(3\text{-}Mepz)_4]^-$, although they were not sufficient for equilibrium for $[B(3\text{-}iPrpz)_4]^-$. The %*E* values were independent of the metal ion concentrations of 3.0×10^{-5}–3.0×10^{-3} M. $[B(3\text{-}iPrpz)_4]^-$ quantitatively extracted only Cu(II) and Zn(II) ions. It should be noted that the extraction with $[B(3\text{-}iPrpz)_4]^-$ was very different from that with $[B(pz)_4]^-$ and $[B(3\text{-}Mepz)_4]^-$.

The %*E* reached a maximum value after 50 and 90 min of shaking for Cu(II) and Zn(II), respectively. In order to elucidate the extracted species, the distribution ratio (*D*) under these conditions was measured using

$$D = C_{M,o}/C_M \quad (1)$$

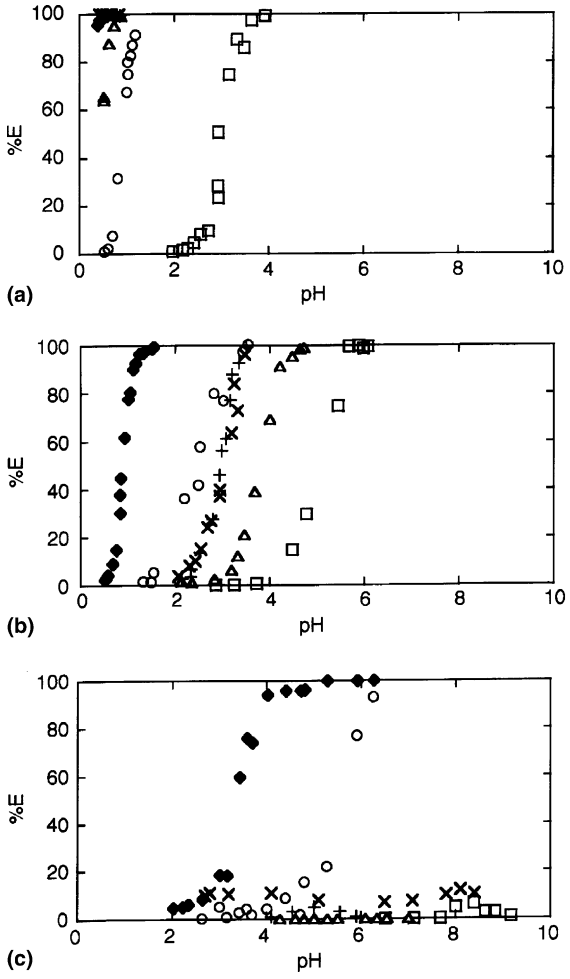

Fig. 3. Effect of pH on the percentage extraction of metal ions. The extraction time was 10 min. Key: □, Mn(II); △, Fe(II); +, Co(II); ×, Ni(II); ◆, Cu(II); ○, Zn(II). (a) $K[B(pz)_4]$; (b) $K[B(3\text{-}Mepz)_4]$; (c) $K[B(3\text{-}iPrpz)_4]$. (a,b) Aqueous phase: 1.0×10^{-2} M buffer, 1.0×10^{-4} M M^{2+}, 1.0×10^{-2} M KA (10 mL). Organic phase: chloroform 10 mL; Data taken from [34,35], respectively. (c) Aqueous phase: 1.0×10^{-2} M buffer, 1.0×10^{-5} M M^{2+} (10 mL). Organic phase: 1.0×10^{-3} M KA (chloroform 10 mL).

where C_M signifies the analytical molar concentration of the metal ion (M^{2+}) and the subscript o denotes the species in the organic phase. When an A_2M complex is formed and extracted, the overall extraction equilibrium and extraction constant (K_{ex}) of M^{2+} are described as follows:

$$M^{2+} + 2KA_o \leftrightarrow A_2M_o + 2K^+ \quad (2)$$

$$K_{ex} = [A_2M]_o[K^+]^2/[M^{2+}][KA]_o^2 \quad (3)$$

$$\log D = \log K_{ex} - 2\log[K^+] + 2\log[KA]_o \quad (4)$$

To analyze the extraction data graphically, the hydrolysis of the ligand must be taken into consideration. $[KA]_o$ is expressed as

$$[KA]_o = C_{KA}a, \quad (5)$$

where C_{KA} and a mean the initial concentration of the ligand in the organic phase and the remaining ratio of the ligand after hydrolysis, respectively. The substitution of Eq. (5) into Eq. (4) and a rearrangement result in

$$\log D - 2\log a + 2\log[K^+] = 2\log C_{KA} + \log K_{ex}. \quad (6)$$

The plot of $\log D - 2\log a + 2\log[K^+]$ versus $\log C_{KA}$ for Zn(II) gave a straight line with a slope close to 2 (Fig. 4). The $\log D$ of Zn(II) did not depend on the initial concentration of Zn(II) [$C(Zn^{2+})$]. These results suggest the validity of Eq. (2) for the extraction of Zn(II). However, the $\log D - 2\log a + 2\log[K^+]$ versus $\log C_{KA}$ plot gave a slope close to 1 for Cu(II) (Fig. 5). The $\log D$ of Cu(II) did not depend on the initial concentration of Cu(II) [$C(Cu^{2+})$]. These results suggest that the extracted species was ACuX, where X^- denotes an ancillary ligand. The extraction equation and constant are expressed as

$$Cu^{2+} + KA_o + X^- \leftrightarrow ACuX_o + K^+ \quad (7)$$

$$K_{ex} = [ACuX]_o[K^+]/[Cu^{2+}][KA]_o[X^-] \quad (8)$$

Since we used acetate as buffer in the pH range where Cu(II) was extracted, acetate is an ancillary ligand candidate.

3.3. Syntheses of the complexes

An aqueous phase containing Zn(II) or Cu(II) and an organic phase containing K[B(3-iPrpz)$_4$] were shaken to form the complexes according to Eq. (2) or Eq. (7). The pH was appropriately adjusted to produce complexes. The complexes, [B(3-iPrpz)$_4$]$_2$Zn (**1**) and [B(3-iPrpz)$_4$] Cu(OCOCH$_3$) (**2**), were obtained after evaporation of the organic phases. They dissolved into chloroform, dichloromethane and benzene, and were stable in air.

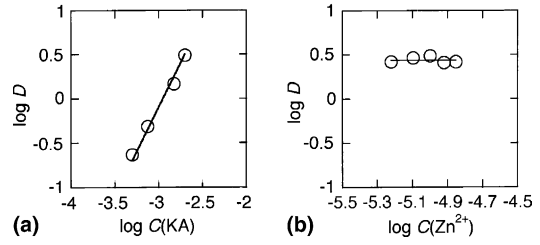

Fig. 4. Effect of $\log C_{KA}$ and $\log C(Zn^{2+})$ on $\log D$ for the extraction of Zn^{2+} with [B(3-iPrpz)$_4$]$^-$. The extraction time was 90 min. (a) pH 4.80, Zn^{2+}; 1.0×10^{-5} M, (b) C_{KA}; 1.0×10^{-3} M, pH 4.85. Solid lines, of which the slopes are 2 and 0, respectively, were obtained by a least-squares fit.

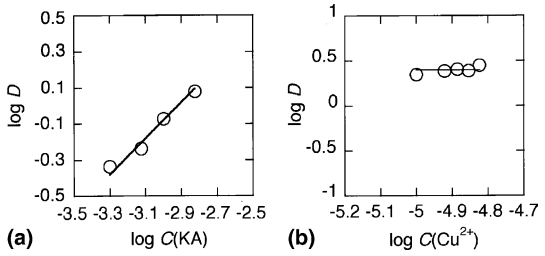

Fig. 5. Effect of $\log C_{KA}$ and $\log C(Cu^{2+})$ on $\log D$ for the extraction of Cu^{2+} with [B(3-iPrpz)$_4$]$^-$. The extraction time was 50 min. (a) pH 3.46, Cu^{2+}; 1.0×10^{-5} M, (b) C_{KA}; 1.0×10^{-3} M, pH 3.51. Solid lines, of which the slopes are 1 and 0, respectively, were obtained by a least-squares fit.

3.4. Structure of the Zn(II) complex

The zinc atom sits on a center of inversion for **1** as seen in Fig. 1. Both ligands are bidentate and the geometry about the zinc atom is a tetrahedron. The ligands coordinate to the zinc atom through the nitrogen atom in the 2-position of two of the 3-isopropylpyrazolyl rings, with the two additional rings of the ligand not coordinated to the metal atom. The metal-coordinated rings have their isopropyl groups bisecting the other chelate ring and the C–H bond oriented toward the metal ion, whereas the isopropyl groups of the non-coordinated groups are in an intermediate position. The structure of **1** resembles that of [B(3-iPrpz)$_4$]$_2$Co [32] and [B(3-iPrpz)$_4$]$_2$Ni [33]. The distances and bond angles between the zinc ion and the nitrogen atoms are nearly identical with those observed for [H$_2$B(pz)$_2$]$_2$Zn [40], which also has the Zn(II) ion coordinated by four pyrazolyl groups from two ligands. These bond distances are also typical of Zn–N distances in poly(pyrazolyl)borate complexes.

[B(pz)$_4$]$_2$Zn (**3**) and [B(3-Mepz)$_4$]$_2$Zn (**4**) are octahedral with [B(pz)$_4$]$^-$ and [B(3-Mepz)$_4$]$^-$ coordinating in a tridentate fashion by X-ray diffraction [34,35]. Only one kind of pyrazolyl ring of **3** and **4** in chloroform-*d* was observed with ^{1}H NMR, because the exchange of the coordinated and non-coordinated pyrazolyl rings in **3** and **4** was fast on the NMR time scale at ambient temperature. However, the structure observed by ^{1}H NMR for **1** indicates that [B(3-iPrpz)$_4$]$^-$ coordinates in a bidentate fashion, probably with tetrahedral geometry around the zinc atom. These facts suggest that the isopropyl group makes the exchange of pyrazolyl rings slower than the hydrogen atom and the methyl group, and that the solution structure of **1** is similar to that in the solid state.

3.5. Structure of the Cu(II) complex

As shown in Fig. 2 the [B(3-iPrpz)$_4$]$^-$ ligand and acetate anion are bonded to the copper atom in a tridentate and an asymmetric bidentate mode, respectively. The non-coordinated pyrazolyl ring stands out in the opposite direction to the copper atom. The geometry about the copper atom is best described as square pyramidal by the structural parameter $\tau = 0.11$; $\tau = (\alpha - \beta)/60°$, where α and β are the largest angles ($\alpha > \beta$) around a five-coordinate metal center, as

reported by Addison et al. [41]. The square plane consists of two nitrogen atoms from the $[B(3\text{-}iPrpz)_4]^-$ ligand and two oxygen atoms from the acetate. This structure is similar to that of $[HB(3,5\text{-}iPr_2pz)_3]Cu(O_2NO)$ [42] and $[HB(3,5\text{-}iPr_2pz)_3]Fe(OCOCH_3)$ [43].

3.6. Steric effects of 3-isopropyl group

When two $[B(3\text{-}iPrpz)_4]^-$ ligands coordinate a metal ion in a trigonal tridentate fashion, the steric repulsion around the metal ion increases by the interligand contact between the isopropyl groups, and the stability of the complexes becomes too low to be extracted into the organic phase. Thus, in order to avoid this steric repulsion, two $[B(3\text{-}iPrpz)_4]^-$ ligands coordinate the Zn(II) ion in a bidentate fashion and one $[B(3\text{-}iPrpz)_4]^-$ coordinates the Cu(II) ion in a tridentate fashion with the acetate anion having a bidentate configuration. Since the stabilities of **1** and **2** are much lower than the octahedral A_2M complexes with $[B(pz)_4]^-$ and $[B(3\text{-}Mepz)_4]^-$, the extraction pH for **1** and **2** are high. Trofimenko et al. prepared the A_2M complexes of Fe(II), Co(II), Ni(II), Cu(II) and Zn(II) with $[B(3\text{-}iPrpz)_4]^-$. They were tetrahedral in the solid state on the basis of infrared spectroscopy. It is likely that the stabilities of the A_2M complexes of Fe(II), Co(II) and Ni(II) are not sufficiently high to be extracted.

4. Conclusion

Selectivity of tetrakis(pyrazolyl)borates for first-series transition metal ions is controlled by the substituents on the 3-position of the pyrazolyl ring. All the studied metal ions form octahedral A_2M complexes with $[B(pz)_4]^-$ and $[B(3\text{-}Mepz)_4]^-$ and their stability follows the common Irving–Williams series. On the other hand, all the metal ions cannot form an octahedral A_2M complex with $[B(3\text{-}iPrpz)_4]^-$ due to the interligand contact between the isopropyl groups. Although only Zn(II) and Cu(II) form tetrahedral A_2M and square pyramidal AMX complexes, respectively, which are extracted into the organic phase, the other metal ions cannot form stable and extractable complexes. Thus, the isopropyl group changes the geometry and stability of the complexes, resulting in the unique selectivity of $[B(3\text{-}iPrpz)_4]^-$.

5. Supplementary data

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 207207 for **1** and CCDC No. 207208 for **2**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Synthesis of *meta*-$C_6H_4[C(1\text{-pyrazolyl})_2(2\text{-pyridyl})]_2$, a fixed geometry bitopic heteroscorpionate and the crystal structure of its unusual square planar silver(I) complex

Daniel L. Reger *, James R. Gardinier, Mark D. Smith

Department of Chemistry and Biochemistry, University of South Carolina, Columbia, SC 29208, USA

Received 21 May 2003; accepted 12 August 2003

Abstract

The reaction between bis(1-pyrazolyl)sulfone (prepared in situ by the reaction between NaH, Hpz, and $SOCl_2$ in THF) and $C_6H_4[C(O)(2\text{-py})]_2$ in THF catalyzed by $CoCl_2$ yields *m*-$C_6H_4[C(pz)_2(2\text{-py})]_2$ (**1**, pz = pyrazolyl, py = pyridyl) in moderate yield, along with 1-$[C(pz)_2(2\text{-py})]$-4-$[C(O)(2\text{-py})]C_6H_4$. The potentially bitopic ligand **1** reacts with $AgPF_6$ to yield $[Ag(\mathbf{1})_2](PF)_6$ (**3**), regardless of the stoichiometry of reagents used in the preparation. X-ray structural analysis of this silver complex shows that two ligands bond to a silver in a κ^2-fashion via the pyrazolyls in one $C(pz)_2(py)$ group in each ligand while the other is non-coordinated. The AgN_4C chelate rings adopt a boat conformation and the silver resides in an unusual square planar coordination environment. Non-covalent forces organize the two-dimensional structure of **3** such that it approaches a layered inorganic–organic hybrid material. Reaction of $C_6H_5[C(pz)_2(2\text{-py})]$ and $AgPF_6$ yields $\{Ag(\kappa^2\text{-}C_6H_5[C(pz)_2(2\text{-py})])_2\}(PF_6)$ (**4**). The structure is disordered but the ligands are bidentate, the nitrogen donor atoms are in a square planar coordination environment about the silver and the overall structure is similar to **3**.

1. Introduction

Current interest in coordination networks is driven in part by the desire to combine the variety in structural, physical, and spectroelectrochemical properties of both the inorganic and organic constituents with the practicality and function of zeolite-type materials [1,2]. Recent work published by Wenbin Lin's group is testament to the potential for the realization of such a goal [3,4]. Advances in the design of polytopic ligands, which serve as organic spacers between two or more metal centers, have been instrumental to this area of research. Over recent years, our group has been interested in exploring the preparation and coordination chemistry of a variety of polytopic poly(pyrazolyl)methane ligands. We have prepared bitopic tetra-(pyrazolyl) compounds that contain two bis(pyrazolyl)methane units linked by either a flexible methylene or a semi-rigid ferrocenyl group, and have explored their coordination chemistry with silver [5,6]. Additionally, we have reported on the preparation of coordination polymers that incorporate semi-rigid organic spacers based on polytopic tris(pyrazolyl)methanes of the type $C_6H_{6-n}[CH_2OCH_2C(pz)_3]_n$ ($n = 2$, 4 [7–9]; pz = pyrazolyl ring). The use of poly(pyrazolyl)methane ligands linked by *rigid* organic spacers would be of interest toward the preparation of either large metallacycles of predefined geometry or the development of coordination networks with a predictable arrangement of metal centers within the material. To this end, we have prepared $\alpha,\alpha,\alpha',\alpha'$-tetrakis(1-pyrazolyl)-$\alpha,\alpha'$-bis(2-pyridyl)-1,3-xylene, *m*-$C_6H_4[C(pz)_2\ (2\text{-py})]_2$ (**1**, py = pyridyl ring), a potentially bitopic heteroscorpionate, that can be envisioned as a 120° rigid organic spacer. In this paper we will detail the preparation of **1** and outline our initial observations regarding its coordination chemistry with silver hexafluorophosphate. For

comparison, the related chemistry involving the monotopic analogue, $C_6H_5[C(pz)_2(2\text{-py})]$ (**2**), will also be described.

2. Experimental

2.1. General

Solvents for synthetic procedures, and spectroscopic studies were dried by conventional methods and distilled under N_2 atmosphere immediately prior to use. The compound $m\text{-}C_6H_4[C(O)(2\text{-py})]_2$ was prepared as described previously [10]. All other reagents were used as received from Aldrich Chemical Co. Silica gel (0.040–0.063 mm, 230–400 mesh) used for chromatographic separations was purchased from Fischer Scientific. Silver hexafluorophosphate was stored and handled under a purified nitrogen atmosphere in a drybox. Robertson Microlit Laboratories performed all elemental analyses. Melting point determinations were made on samples contained in sealed glass capillaries by using an Electrothermal 9100 apparatus and are uncorrected. Mass spectrometric measurements recorded in ESI(+) mode were obtained on a Micromass Q-Tof spectrometer whereas those performed by using direct probe analyses were made on a VG 70S instrument. NMR spectra were recorded by using either a Varian Mercury 400 or a Varian Inova 500 instrument, as noted within the text. Chemical shifts were referenced to solvent resonances at either δ_H 7.27, δ_C 77.2 for $CDCl_3$, or δ_H 2.05, δ_C 29.8 for acetone-d_6.

2.2. Ligand preparation

The preparation of $C_6H_5C(pz)_2(2\text{-py})$ has been described previously [11], however, in this contribution an alternate purification step and additional characterization data are provided. The title bitopic derivative was prepared by using an analogous procedure. Therefore, only the quantity of reagents, solvent, reaction time, and the details of chromatographic separation are described below for each.

2.3. Preparation of $m\text{-}C_6H_4[C(pz)_2(2\text{-py})]_2$, $\alpha,\alpha,\alpha',\alpha'$-tetrakis(1-pyrazolyl)-$\alpha,\alpha'$-bis(2-pyridyl)-1,3-xylene, (*1*)

A mixture of 2.9 mmol $SO(pz)_2$ [from 0.14 g (5.9 mmol) NaH, 0.40 g (5.9 mmol) Hpz and 0.21 ml (2.9 mmol) $SOCl_2$], 0.43 g (1.5 mmol) $C_6H_4[C(O)(2\text{-py})]_2$, and 60 mg (30 mol% of $C_6H_4[C(O)(2\text{-py})]_2$) $CoCl_2$ in 80 ml THF were heated at reflux for four days. After work-up, chromatographic separation of the product mixture on SiO_2 by using Et_2O as the eluent afforded 0.16 g (0.55 mmol) $C_6H_4[C(O)(2\text{-py})]_2$ from the first pale yellow band ($R_f = 0.7$ on TLC plate) and 0.14 g (0.34 mmol) of 1-$[C(pz)_2(2\text{-py})]$-4-$[C(O)(2\text{-py})]C_6H_4$, **1a,** as a colorless solid from the second pale yellow band ($R_f = 0.3$ TLC plate). Mp 113–115 °C. IR (cm^{-1}): ν_{co} 1669 (br, vs). ^1H NMR (400 MHz, $CDCl_3$) 8.68 (d, $J = 4$ Hz, 1H, H_6-py*CO*), 8.62 (d, $J = 4$ Hz, 1H, H_6-py), 8.16 (m, 1H, aryl), 8.00 (d, $J = 8$ Hz, 1H, H_3-py*CO*), 7.98 (s, 1H, aryl), 7.85 (ddd, $J = 8$, 8, 2 Hz, 1H, H_4-py*CO*), 7.73 (ddd, $J = 8$, 8, 2 Hz, 1H, H_4-py, 7.68 (d, $J = 1$ Hz, 2H, H_3-pz), 7.56 (d, $J = 2$ Hz, 2H, H_5-pz), 7.49 (m, 2H, aryl), 7.45 (ddd, $J = 8$, 4, 1 Hz, 1H, H_5-py*CO*), 7.32 (ddd, $J = 8$, 4, 1 Hz, 1H, H_5-py), 7.24 (d, $J = 8$ Hz, 1H, H_3-py), 6.33 (d, $J = 2$ Hz, 2H, H_4-pz). ^{13}C NMR (101.62 MHz, $CDCl_3$) 193.0 (C═O), 158.3 (C_2-py), 154.9 (C_2-py*CO*), 148.9 (C_6-py*CO*), 148.6 (C_6-py), 140.9 (C_5-pz), 139.7 (C_3-aryl), 137.2 (C_4-py*CO*), 137.1 (C_4-py), 136.0 (C_1-aryl), 133.8 (C_4-aryl), 132.6 (C_3-pz), 131.9 ($C_{2,6}$-aryl), 128.1 (C_5-aryl), 126.4 (C_3-py*CO*), 124.9 (C_3-py), 124.6 (C_5-py*CO*), 123.9 (C_5-py), 106.1 (C_4-pz), 87.1 (C_α). 2.4. Preparation of $C_6H_5[C(pz)_2(2\text{-py})]$, α,α-bis(1-pyrazolyl)-α-(2-pyridyl)toluene (*2*)

A mixture of 21 mmol $SO(pz)_2$ [from 1.0 g (42 mmol) NaH, 2.9 g (42 mmol) Hpz, and 1.5 ml (21 mmol) $SOCl_2$], 3.7 g (20 mmol) 2-benzoylpyridine, and 75 mg (3 mol% of 2-benzoylpyridine) $CoCl_2$ in 20 ml THF were heated at reflux for 15 h. After work-up,

chromatographic separation of the product mixture on SiO_2 with 50% Et_2O/hexanes afforded 2.2 g (37% based on 2-benzoylpyridine) of **2** as a colorless solid from the second colorless band ($R_f = 0.4$ on TLC plate). Mp 138–139 °C (lit. 123–125 °C [11]). ^{1}H NMR (400 MHz, $CDCl_3$) 8.70 (d, $J = 4$ Hz, 1H, H_6-py), 7.73 (ddd, $J = 8$, 8, 2 Hz, 1H, H_4-py), 7.70 (d, $J = 1$ Hz, 2H, H_3-pz), 7.57 (dd, $J = 2$, 1 Hz, 2H, H_5-pz). 7.41–7.35 (m, 3H, *o*- and *p*-H of Ph), 7.31 (ddd, $J = 8$, 4, 1 Hz, 1H, H_5-py), 7.24 (d, $J = 8$ Hz, 1H, H_3-py), 7.20 (dd, $J = 8$, 2 Hz, 2H, *m*-H of Ph), 6.33 (d, $J = 2$ Hz, 2H, H_4-pz). ^{13}C NMR (101.62 MHz, $CDCl_3$) 158.7 (C_2-py), 148.8 (C_6-py), 140.7 (C_5-pz), 139.6 (C_{ipso}-Ph), 137.0 (C_4-py), 132.6 (C_3-pz), 129.4 (*o*- and *p*- of Ph), 128.2 (*m*-C of Ph), 124.3 (C_3-py), 123.7 (C_5-py), 105.8 (C_4-pz), 87.3 (C_α). Direct probe MS *m/z* (Rel. Int. %) [assgn]: 301(62) $[M]^+$, 233(100) $[M\text{-}Hpz]^+$, 223(86) $[M\text{-}py]^+$, 167(99) $[M\text{-}2Hpz]^+$, 77(28) $[Ph]^+$.

2.5. Silver hexafluorophosphate complexes

2.5.1. Preparation of {Ag(κ²-*m*-C₆H₄[C(pz)₂(2-py)]₂)₂}(PF₆), (3)

A mixture of 0.087 g (0.17 mmol) **1** and 0.042 g (0.17 mmol) $AgPF_6$ was dissolved in 15 ml of a 2:1 mixture of CH_3CN/acetone. After a reflux period of 6 h, trace gray solid was observed and solvent was removed by vacuum distillation. The resulting brown solid was washed sequentially with 5 ml each of Et_2O and hexanes. The insoluble residue was then extracted with 10 ml CH_3CN. The filtered extract was layered with 50 ml Et_2O and after allowing the solvents to diffuse overnight, the colorless crystals of $\{Ag(C_6H_4[C(pz)_2(2\text{-}py)]_2)_2\}(PF_6)$ (**3**) were isolated by filtration and were air-dried (84 mg, 78%). Mp, 205–210 °C dec. *Anal.* Calc. for $C_{60}H_{52}N_{20}AgF_6O_2P$, **3**·2 H_2O: C, 53.86 (53.98); H, 3.92 (3.53); N, 20.94 (20.81). ^{1}H NMR (400 MHz, acetone-d_6) 8.60 (d, $J = 4.5$ Hz, 2H, H_6-py), 7.89 (ddd, $J = 8$, 8, 2 Hz, 2H, H_4-py). 7.64 (d, $J = 1$ Hz, 4H, H_3-pz), 7.52 (d, $J = 2$ Hz, 4H, H_5-pz), 7.47–7.40 (m, 3H, aryl), 7.15 (dd, $J = 8$, 2 Hz, 2H, H_5-py), 7.09 (d, $J = 8$ Hz, 2H, H_3-py), 6.95 (s, 1H, aryl), 6.38 (dd, $J = 2$, 1 Hz, 4H, H_4-pz).

2.5.2. Preparation of {Ag(κ²-C₆H₅[C(pz)₂(2-py)])₂}(PF₆) (4)

A solution of 0.333 g (1.10 mmol) $C_6H_5[C(pz)_2(2\text{-}py)]$ in 10 ml THF was added by cannula to a solution of 0.139 g (0.550 mmol) $AgPF_6$ in 10 ml THF under a nitrogen atmosphere. A colorless solid precipitated within a few minutes of mixing and the resulting suspension was stirred 4 h. The product mixture was then separated by cannula filtration. The insoluble colorless solid was washed with two 5 ml portions of Et_2O and dried under vacuum to leave 0.435 g (92% yield) of $\{Ag(C_6H_5[C(pz)_2(2\text{-}py)])_2\}(PF_6)$ as a colorless solid. Crystals suitable for X-ray structural studies were grown by layering an acetone solution with Et_2O and allowing the solvents to diffuse. Mp, 175–178 °C crystals become opaque and shatter; 187–188 °C dec. to green–gray solid. ^{1}H NMR (400 MHz, acetone-d_6) 8.59 (d, $J = 4$ Hz, 1H, H_6-py), 7.98 (ddd, $J = 8$, 8, 2 Hz, 1H H_4-py), 7.62 (d, $J = 1$ Hz, 2H, H_3-pz), 7.59–7.49 (br m, 6H, H_5-pz and aryl), 7.04 (d, $J = 8$ Hz, H_3-py), 6.85–6.83 (br m, H_5-py and aryl), 6.46 (dd, $J = 2$, 1 Hz, H_4-pz). ^{13}C NMR (101.62 MHz, acetone-d_6) 157.5 (C_2-py), 150.4 (C_6-py), 142.8 (C_3-pz), 139.5, 138.9, 135.0, 131.0 (C_5-pz), 129.8, 129.7, 126.1, 125.8, 106.8 (C_4-pz), 88.0 (C_α). HRMS-ESI(+) (*m/z*): *Anal.* Calc. for $[M\text{-}PF_6]^+$, $C_{36}H_{30}N_{10}Ag^+$: 709.1702. Found: 709.1706. ESI(+) MS *m/z* (Rel. Int. %) [assgn]: 709 (100) $[AgL_2]^+$, 449 (29) $[AgL(CH_3CN)]^+$, 408 (2) $[AgL]^+$, 302 (65) $[HL]^+$, 234 (60) $[HL\text{-}pz]^+$.

2.6. Crystallography

2.6.1. X-ray structure determinations of {Ag(κ²-*m*-C₆H₄[C(pz)₂(2-py)]₂)₂}(PF₆), (3) and {Ag(κ²-C₆H₅[C(pz)₂(2-py)])₂}(PF₆)·acetone (4·acetone)

A colorless prism of **3** and a colorless prismatic crystal of **4**·acetone were each mounted onto the end of a thin glass fiber using inert oil. X-ray intensity data were measured in the dark at 190(2) K in the nitrogen cold stream of a Bruker SMART APEX CCD-based diffractometer system (Mo Kα radiation, $\lambda = 0.71073$ Å [12]. A total of 1800 raw data frames of width 0.3° in ω were collected at three different ϕ angles, with an exposure time of 15 and 20 s per frame for **3** and **4**·acetone, respectively. The data collections covered the entire sphere of reciprocal space. The first 50 frames of each were re-collected at the end of the data set to monitor crystal decay. The raw data frames were integrated into reflection intensity files using SAINT+ [12], which also applied corrections for Lorentz and polarization effects. The final unit cell parameters are based on the least-squares refinement of 6425 reflections with $I > 5(\sigma)I$ from the data set for **3** and 3377 reflections with $I > 5(\sigma)I$ from the data set for **4**·acetone. Analysis of the data showed negligible crystal decay during the data collections and no absorption corrections were applied (see Table 1).

2.6.2. Structure refinement of 3

The compound crystallized in the triclinic system; the space group $P\bar{1}$ was confirmed by successful solution and refinement of the structure. The structure was solved by direct methods followed by difference Fourier synthesis, and refined by full-matrix least-squares against F^2, using the SHELXTL software package [13]. The Ag and P atoms both lie on centers of symmetry; all other atoms are on general positions. The asymmetric unit is made up of the Ag ion, one $C_6H_4[C(pz)_2(2\text{-}py)]_2$ ligand, and half a PF_6^- anion. The PF_6^- anion is

disordered over two orientations in an 80/20 ratio. All non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were placed in calculated positions and refined as riding atoms.

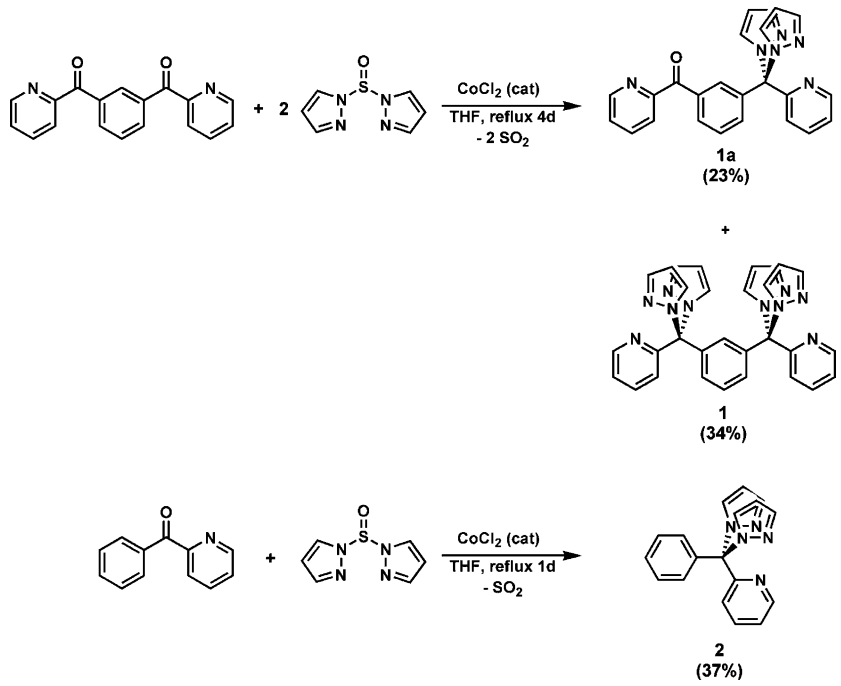
*2.6.3. Structure refinement of **4**·acetone*

This compound crystallized in the triclinic system where the space group $P\bar{1}$ was confirmed by successful solution and refinement of the structure. The structure was solved by a combination of direct methods and difference Fourier synthesis, and refined by full-matrix least-squares against F^2, using the SHELXTL software package [13]. The Ag and P atoms lie on a centers of symmetry; all other atoms are on general positions. The asymmetric unit is made up of the Ag ion, one $C_6H_5[C(pz)_2(2\text{-}py)]$ ligand, half a PF_6^- anion, and half an acetone molecule of crystallization. All components of the crystal (cation, anion, solvent) are affected by disorder. The ligand bound to Ag is disordered over all three possible κ^2, κ^0 conformations allowed by the combination of two pyrazolyl rings (pz) and one pyridyl ring (py). Only the donor rings are affected; the central methine carbon and the pendant phenyl ring behave normally. Referring to the ring numbering scheme in Figure 5a, the average composition of ring "1n" is 0.75 pz/0.25 py; that of ring "2n" is 0.75 pz/0.25 py, and that of ring "3n" is 0.50/0.50 pz/py. These values were arrived at by initially refining the pz/py composition of each ring with a free variable constrained to sum to unity (SHELX FVAR card), and then fixing the ring occupation factors at reasonable values, such that the overall composition of the ligand would be $PhC(pz)_2py$. The PF_6^- anion is rotationally disordered about one F–P–F axis in a 0.59/0.41 ratio. Finally, the acetone molecule of crystallization is disordered about an inversion center. To achieve a stable refinement, a total of 13 restraints (SHELX EADP and SADI) were employed. Eventually, all non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were placed in calculated positions and refined using a riding model. Solution and refinement in the space group $P1$ resulted in the same ligand pz/py ring and PF_6 disorder, as well as unstable ring geometries and large correlations between inversion-related atoms. Therefore, the disorder model in $P\bar{1}$ was retained.

3. Results and discussion

3.1. Syntheses of ligands

The bitopic and monotopic aryl scorpionates **1** and **2**, respectively, were prepared by the $CoCl_2$ catalyzed rearrangement reaction between bis(1-pyrazolyl)sulfone (prepared in situ by the reaction between NaH, Hpz, and $SOCl_2$ in THF) and the appropriate aryl(pyridyl)ketone in THF (Scheme 1). While the reaction to produce the monotopic derivative **2** as described in the literature proceeded smoothly (over the period of about one day), longer reaction times were necessary in order to obtain appreciable quantities of the corresponding bitopic derivative **1**. Even after four days at reflux, the starting material was only 60% consumed and the reaction produces a 1:2 mol ratio of the mono-derivatized compound **1a** and the desired bitopic compound **1**. The two products are easily separable by column



Scheme 1.

chromatography since **1** is strongly retained on silica whereas **1a** is not. It should be noted that yields of either **1** or **2** were not improved by using $CO(pz)_2$ as a replacement for $S(O)(pz)_2$. The low yields and long reaction times for the preparation of **1** and **2** can be contrasted with the preparation of $HC(pz)_2(py)$ by using similar conditions (45%, 4 h) [14]. These observations are consistent with those originally made by Thé and Peterson who indicated that the relative reactivity order for $CoCl_2$ catalyzed rearrangement of aryl carbonyls was: $PhC(O)H > PhC(O)CH_3 \gg Ph_2C(O)$ [15].

Regardless of the stoichiometry of reagents (mol ratios of 2, 1, and 0.5 were investigated), the reactions between silver hexafluorophosphate and either **1** or **2** always produced $[Ag(\mathbf{1})_2](PF)_6$ (**3**), and $[Ag(\mathbf{2})_2][PF_6]$ (**4**), respectively, as indicated from elemental analyses, mass spectral data, and X-ray diffraction studies (vide infra). The insensitivity of the product's metal:ligand mol ratio on the stoichiometry of reactants is fairly common in silver chemistry and has been reported previously for reactions between silver salts and a series of tris(pyrazolyl)methane ligands [16]. Compounds **3** and **4** are hygroscopic but otherwise air stable colorless solids that can be stored for weeks without appreciable decomposition under ambient light. Each is soluble in acetonitrile, moderately soluble in acetone, slightly soluble in methylene chloride, but insoluble in most other common (less polar) solvents. The NMR spectra of each compound in acetone-d_6 show one set of resonances that differ from those of the pure ligand by a downfield shift. This result for **3**, where the stoichiometry and solid state structure (vide infra) indicate the presence of both free and coordinated $C(pz)_2(py)$ groups, can be explained by fast exchange between coordinated and non-coordinated ends of the ligand on the NMR time scale, in accord with the known lability of silver compounds.

The results of single crystal X-ray diffraction study of **3** reveal the monotopic nature of the potentially bitopic ligand **1**. An ORTEP diagram is given in Fig. 1 and important bond distances and angles are provided in Table 2. In the solid state, two ligands are bonded to one silver in a κ^2-fashion via two pyrazolyl groups; the

Symmetry transformation: $-x+1, -y+1, -z+2$.

pyridyl part of the bonded $C(pz)_2(py)$ group is not coordinated to the silver(I). On each ligand, one of the two $C(pz)_2(py)$ groups is not bonded to a silver(I).

One striking feature of the structure is the planar coordination geometry of the nitrogen donor atoms about silver. There are two short and two longer Ag–N bonds (the silver atom resides on an inversion center) of 2.279 and 2.398 Å involving Ag–N(21) and Ag–N(11), respectfully. These distances are comparable to those found in related systems [5,6,23]. Since the sum of the four N–Ag–N angles is 360°, the coordination geometry about silver can best be described as distorted square planar where the distortion occurs as an elongation along one axis of the plane (rectangular planar coordination). An inspection of Fig. 1 would appear to suggest, using the scorpionate vernacular, that the planar arrangement is forced by the aryl group serving as a 'non-venomous' stinger. While it would be surprising to have C- rather than N-coordination, aryl coordination has been observed in other systems [26,27]. In the case of **3**, the closest contact between silver and the pyridyl ring is associated with the ipso carbon, C(31), (bottom of Fig. 1) where the corresponding Ag–C(31) bond distance of 3.193 Å is outside the 2.4–2.9 Å range found for η^1 silver(I)-arene π complexes [17–19]. As far as we are aware, there are only five other examples of tetracoordinate silver complexes that exhibit square planar coordination geometry as opposed to the more typical tetrahedral or distorted tetrahedral geometries [20,21]. The AgN_4C ring adopts a boat conformation (Fig. 2(a)). If silver is assigned to the bow and C(1) to the stern, the puckering parameters originally defined by Cremer and Pople [22] are $Q = 0.910$, $\theta = 83.1°$, and $\phi = 1.78$. The latter two values may be compared to those for an ideal boat conformation ($\theta = 90°$ and $\phi = 0$) and for an ideal half-boat ($\theta = 54.7°$ and $\phi = 0$); the puckering amplitude Q in these cases would depend on the bond lengths between the ring atoms. It should be noted that the related compound $\{Ag[(pz)_2CMe_2]_2\}(ClO_4)$ [23] contains two different AgN_4C six-member rings and each adopts a slightly distorted half-boat conformation (Fig. 2(b)). The puckering parameters $Q = 0.662$, 0.634; $\theta = 73.2°$, 72.5°; and $\phi = 6.6°$, 5.5° were determined from the data obtained from the Crystallographic Information File extracted from the Cambridge Structural Database after a phase adjustment for consistency in atom labeling and normalization to allow meaningful comparison with **3** (Reference code; SIKYOA). The difference between the boat conformation of the AgN_4C ring in **3** and the half-boat conformation in $\{Ag[(pz)_2CMe_2]_2\}(ClO_4)$ is found in the fold angles involving the respective silver atoms (and to a lesser extent those involving the carbon atoms). The fold angle can be defined as being the deviation from planarity created by the displacement of one atom (at either the bow or stern) from the four (coplanar) atoms that would represent the deck of the boat. In the case of **3**, the fold angles are the complement to those found in Fig. 2(a); that associated with silver is 32.3° whereas that associated with C(1) is 61.4°. The corresponding values in $\{Ag[(pz)_2CMe_2]_2\}(ClO_4)$ are 7.6° and 6.6° for those involving silver and 58.6° and 59.1° for those involving carbon.

Given that there does not to appear to be any significant silver(I)-π interactions in **3**, the unusual coordination environment about silver is likely due to both steric and electronic effects associated with the presence of multiple arene substituents bound to the central methane carbon. The relative orientations of the pyridyl and pyrazolyl groups in the ligands are supported by multiple intracationic CH···π interactions as shown in Fig. 3. The distances and angles associated with the CH···π interactions are given in Table 3 and are in

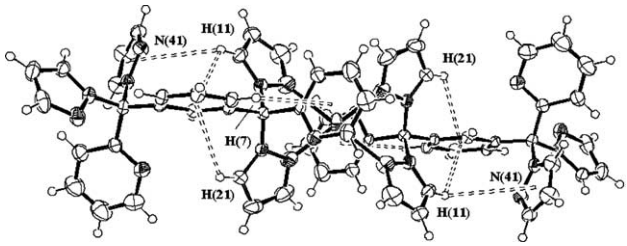

Fig. 3. View of the cation in **3** showing the intracationic CH-π interactions.

accord with accepted values [24]. Since the CH···π interactions occur within each ligand rather than spanning both ligands in the cation, the total number of CH-π bonding interactions would not change if the AgN_4C chelate rings adopted a half-boat conformation similar to those observed in {Ag[$(pz)_2CMe_2]_2$}(ClO_4). Therefore, we attribute the unusual coordination environment about silver to the forces that arrange **3** into its three dimensional supramolecular structure.

The supramolecular structure of **3** approaches that of a inorganic–organic hybrid material where the silver centers and the hexafluourophosphate anions reside in layers in the crystallographinc *ab* planes. The inorganic layers are separated by organic ligands along the *c* axis where the interlayer separation is 13.7 Å as in Fig. 4. Pyridyl rings, located above and below the AgN_4 plane also separate the cation and anions in the 'inorganic layers'. There are two types of non-covalent interactions that assist in organizing **3** in the solid state; CH···π interactions where both pyridyl rings of the ligand act as hydrogen donors and the silver bound pyrazolyl rings act as hydrogen acceptors and CH···F interactions involving the hexafluorophosphate anion and the acidic arene (pyrazolyl and pyridyl) hydrogens. Table 3

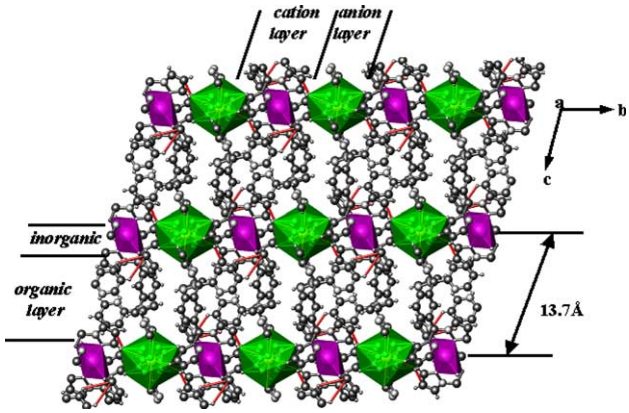

Fig. 4. Supramolecular structure of **3** emphasizing the pseudo inorganic–organic layered structure. Large (green) polyhedra are disordered PF_6^- anions whereas the small (pink) polyhedra represent coordination sphere about silver. The red lines represent intercationic CH···π interactions. The CH···F interactions that associate cationic layers are highlighted and enclosed within the green polyhedra. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

provides bond distances and angles for the non-covalent interactions that support the pseudo-layered structure. There are 12 CH···F distances involving a disordered hexafluorophosphate anion and that are shorter than the limit of 2.6 Å suggested to be indicative of weak hydrogen bonding interactions (Table 3) [25]. The result of these interactions is to organize the cationic sheets along the *bc*-plane as in Fig. 4. In particular, within a given cation containing two meta-linked ligands, the hydrogens H(32) and H(33) situated *meta*- and *para*-, respectively, to the nitrogen atom of the pyridyl ring proximal to silver on one ligand and the hydrogen at the 3-position of the silver-bound pyrazolyl rings of the second ligand are each involved in short CH···F bonding interactions with the fluorines of both components of the disordered PF_6 anion. Each hydrogen interacts with a component of the orientationally disordered hexafluorophosphate anion such that the CH···F distances are never greater than 2.6 Å. The CH···π interactions (Table 3) shown as red lines in Fig. 4 afford connectivity in a third dimension (the *a*-axis) such that the sheets depicted in Fig. 4 would stack directly on top of one another into and out of the plane of the paper, forming segregated anion and cation layers. The particular interactions that propagate along the *a*-axis occur between the pyridyl rings proximal to silver of one cation and the silver-bound pyrazolyl groups with the shorter Ag–N distance [Ag–N(21) 2.279(2)]. Those interactions involving the pyridyl rings on the 'silver-free' side of the meta-linked ligand of one cation and the silver-bound pyrazolyl group with the longer Ag–N distance [Ag–N(11) 2.398(2)] of support the overall structure (along the *c*-axis). The boat conformation of the AgN_4C rings is thought to maximize the

total number of CH···F bonding and CH···π interactions, thereby supporting the overall structure. A half-boat arrangement would place the acidic hydrogens of the pyridyl [H(32) and H(33)] and pyrazolyl groups [H(23)] at too great a distance for PF_6^- bridged CH···F interactions and would likely reduce the total number of CH···π interactions. A future report will further address the role of groups bound to the central methine carbon on the intracationic and supramolecular structure of related silver derivatives.

In an effort to determine whether the structural motif found in **3** was unique to the meta-linked ligand or was a more common framework, an X-ray structural study of $\{Ag(\kappa^2\text{-}C_6H_5[C(pz)_2(2\text{-}py)])_2\}(PF_6)$ (**4**), the monotopic derivative of **3** was undertaken and the results are given in Fig. 5. One important feature of the structure is the nature of the disorder that afflicts the nitrogen-containing heterocycles of the ligand (Fig. 5(a)). As described in the experimental, the ligand bound to silver is disordered over all three possible κ^2, κ^0 conformations allowed by the combination of two pyrazolyl and one pyridyl ring. Fig. 5(b) reveals one component of the disordered structure showing that the coordination geometry about silver is square planar, as in compound **3**. The overall structure again has the form of a pseudo-

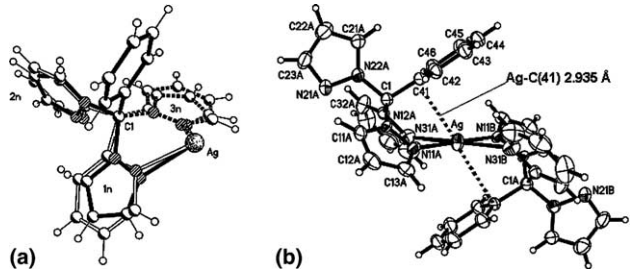

Fig. 5. Results of single crystal X-ray analysis of $Ag(\kappa^2\text{-}C_6H_5[C(pz)_2(2\text{-}py)])_2(PF_6)$ (**4**) showing (a) ligand disorder and (b) one component of the disordered structure emphasizing the square planar geometry about silver and boat conformation of AgN_4C chelate rings.

layered inorganic–organic hybrid material (Fig. 6) as in **3**, however in the current case, the separation between layers is 10.3 Å. Unfortunately, detailed analysis of any other bond distances and angles in **4** is precluded since, with the exception of the silver atom, the phenyl ring and the central methine carbon of the cation, disorder affects all components of the structure (cation, anion, and solvent).

4. Conclusions

A potentially bitopic heteroscorpionate, $m\text{-}C_6H_4[C(pz)_2(2\text{-}py)]_2$ (**1**), has been prepared by using the Peterson rearrangement reaction between two equivalents of $SO(pz)_2$ and one equivalent of $m\text{-}C_6H_4[C(O)(2\text{-}py)]_2$. The reactions between this ligand and silver hexafluorophosphate led only to a product with a 2:1 mol ratio of ligand to metal. X-ray structural analysis of this silver complex revealed that the ligand was bound to silver in a κ^2-fashion via the pyrazolyl groups, the silver resided in an unusual square planar coordination environment, and the AgN_4C chelate ring adopted a boat conformation. While a half-boat arrangement is more typical of complexes with a $C(pz)_2Ag$ chelate ring, the unusual boat conformation was proposed to be due to energetics associated with the organization of the two-dimensional structure, specifically, the CH···F interactions between the hexafluorophosphate anion and hydrogen atoms of the ligand. These non-covalent forces, coupled with CH···π interactions, organize the two-dimensional structure of **3** such that it approaches a layered inorganic–organic hybrid material. The structure of the monotopic derivative $\{Ag(\kappa^2\text{-}C_6H_5[C(pz)_2(2\text{-}py)])_2\}(PF_6)$ (**4**) was highly disordered but also revealed the bidentate nature of the $C(pz)_2(2\text{-}py)$ scorpionate moiety towards silver and a square planar arrangement for coordination environment about the metal.

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), CCDC 210455 for **3** and 210456 for **4**·acetone.

Abstract

Two Rh-dicarbonyl complexes $[Rh(\kappa^2\text{-}Tp^{PhCl})(CO)_2]$ (**1**) and $[(OC)_2Rh(\mu{:}\kappa^2,\kappa^1\text{-}Tp^{PhCl})Rh(Cl)(CO)_2]$ (**2**) have been synthesized and structurally characterized by IR and NMR spectroscopies and X-ray crystallography. Three isomeric forms have been isolated for **1**, which showed different environment on the Rh centre related with the uncoordinated third pyrazolyl arm. So, it was rotated to the equatorial position in **1**-A, but occupied the axial position in **1**-B and **1**-B′ with different orientation. As a consequence, two square-planar coordination geometries (one with the third pyrazolyl ring over the square-plane (SP1) and the other inverted with the free pyrazolyl arm away from the square-plane (SP2)) and one square pyramidal geometry (SPy) have been established for **1**-B, **1**-A and **1**-B′, respectively. The X-ray structure of **2** indicates a bridging coordination of the Tp^{PhCl} ligand, being κ^2 to the $[Rh(CO)_2]$ fragment and κ^1 to the $[Rh(Cl)(CO)_2]$ group.

1. Introduction

The ability of poly(pyrazol-1-yl)borate ligands to modify or control the steric and electronic environment about the metal centre on their coordination compounds has been focus of attention since they were discovered by Trofimenko in 1967 [1–5]. In this context, we were able to demonstrate how, in compounds of the type $[Mo(\kappa^3\text{-}Tp^{An})(NO)(X)(Y)]$ (Tp^{An} = hydridotris(3-*p*-methoxyphenylpyrazol-1-yl)borate; X = Y = CO; X = Cl, Y = NHC_6H_4-*p*-CH_3, NHC_6H_4-*p*-$N(CH_3)_2$, OC_6H_5, NHC_6H_4-*o*-CH_3), the Tp^{An} ligand generated a bowl-shape cavity in which the other co-ligands were included [6–9].

On the other hand, it has been well established the activity of the trispyrazolylborate-complexes $[M(Tp')(L_2)]$ (M = Rh, Ir; Tp′ = hydridotrispyrazol-1-ylborate ligands with substituents on the pyrazolyl rings; L_2 = 2CO, 2CNR, $2CH_2CH_2$, etc.; M = Rh, Ir) towards C–H bond activation reactions [1,10–19], which, from a mechanistic point of view, appear to be depending on the dechelation and rechelation of the Tp′ ligands [20,21]. In turns, it was also proved that denticity of the Tp′ ligands accounts for reactivity of those Rh/Ir complexes and therefore their catalytic applications [1]. Then the knowledge of the coordinative form of the Tp′

doi:10.1016/j.poly.2003.11.020

ligands for new $[Rh(Tp')(CO)_2]$ derivatives follows in increasing interest.

In this sense, it is remarkable to note that since Venanzi and co-workers [22] identified three isomeric forms for $[Rh(Tp^{3R,4R,5R})(L_2)]$ (L_2 = NBD (norbornadiene), COD (1,5-cyclooctadiene), 2CO; $Tp^{3R,4R,5R}$ = hydridotrispyrazol-1-ylborate ligands with substituents on the 3, 4 and 5 positions of the pyrazolyl group), two of them four-coordinated κ^2-$Tp^{3R,4R,5R}$ (equatorial, A, or axial, B) and the third pentacoordinated κ^3-$Tp^{3R,4R,5R}$ (C) (Fig. 1), several papers have been reported concerning with the isomerism of those Rh(I) derivatives in solution [19,23–28].

In particular the state of the art on the isomerization of $[Rh(Tp')(CO)_2]$ has been recently reported by Webster and Hall [29]. These authors have developed an excellent work concerning with predictions of structure and energy of $[Rh(Tp^{3R,5R})(CO)_2]$ (R = H, Me) by theoretical functional density calculations. The structural experimental data of different rhodium derivatives compare well with the calculated results.

Despite the variety of Rh(I) compounds studied in previous works, the structural X-ray characterization of different isomers for one determined Tp′-rhodium complex has not been produced yet. It could allow to realize a systematic study avoiding variables as the effect of the substituents on the pyrazolyl rings or the characteristics of the co-ligands.

To this proposal, and by considering our previous results on $[Rh(\kappa^2\text{-}Tp^R)(CO)_2]$ ($Tp^R = Tp^{An}$, Tp^{Ph}) (Tp^{Ph} = hydridotris(3-phenylpyrazol-1-yl)borate) [19,27], we were involved in the isolation and X-ray characterization of potential isomers of dicarbonyl Rh-complexes containing the related hydridotris(3-*p*-chlo- rophenylpyrazol-1-yl)-borate (Tp^{PhCl}) ligand.

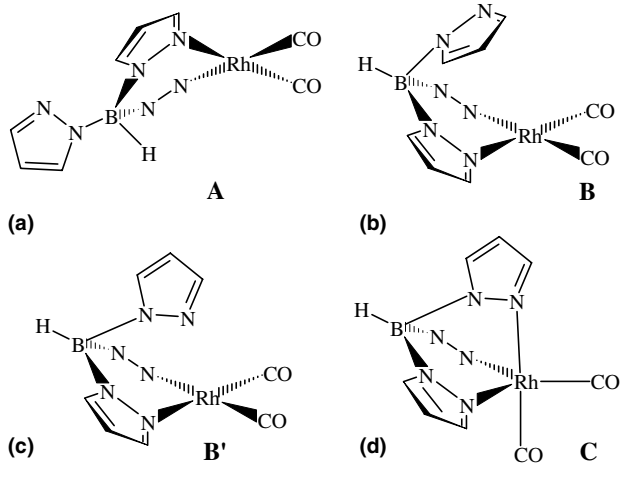

Fig. 1. Schematic representations of different geometric arrangements for $[Rh(Tp')(CO)_2]$: (a) square-planar with the third pyrazolyl arm away from the metal (SP2; isomer A); (b) square-planar with the third pyrazolyl arm over the metal (SP1, isomer B); (c) square pyramidal (SPy, isomer B′); (d) trigonal bipyramidal (TBP, isomer C).

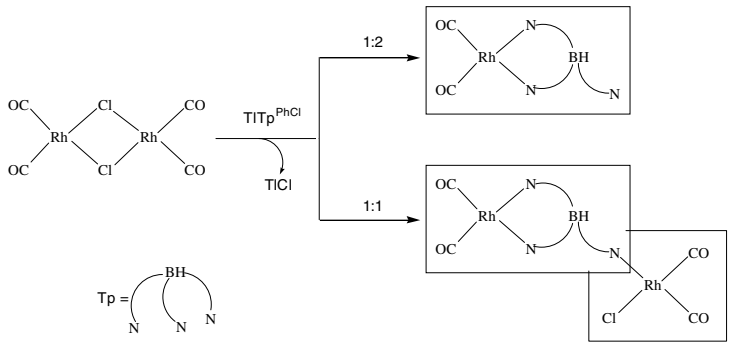
2. Results and discussion

2.1. Previous results

Stimulated for the interest of Tp′-rhodium derivatives in C–H bond activation reactions, and in particular on the knowledge of the isomers which could favour this process, we started to work, some years ago, on Rh(I) chemistry by using bulky Tp′ ligands containing aromatic substituents at the 3 position on the pyrazolyl rings as Tp^{An} and Tp^{Ph} [19,27]. So $[Rh(Tp^R)(L_2)]$ ($Tp^R = Tp^{An}$, Tp^{Ph}; L_2 = NBD, COD, 2CO) were prepared and characterized. In all cases a κ^2-Tp^R axial (B) or equatorial (A) coordination of the ligand was established (Fig. 1). Moreover two different possibilities were also found for the axial compounds. So the X-ray structure of $[Rh(\kappa^2\text{-}Tp^{Ph})(NBD)]$ evidenced a typical axial B shape, while a new axial isomer (B′) was characterized for $[Rh(\kappa^2\text{-}Tp^{An})(CO)_2]$ (Fig. 1). Both forms differ in the spacial orientation of the uncoordinated pyrazolyl arm, which gives rise to an elongated square pyramidal geometry (SPy) [1] in B′, or a square-planar coordination geometry (SP1) in B with the free pyrazolyl ring twisted related to its position in B′ and then separated from the metal. In solution both isomers (B and B′) exhibited the same ^1H NMR pattern consistent with only one set of resonances corresponding to one type of pyrazolyl rings. This feature was attributed to the presence of a very fast equilibrium between the isomeric forms. Photochemical irradiation of $[Rh(\kappa^2\text{-}Tp^{An})(CO)_2]$ resulted in a very clean intramolecular C–H bond activation [19].

During the crystallization process of $[Rh(\kappa^2\text{-}Tp^{An})(CO)_2]$, in addition to the B′ isomer, two new solid products were obtained and assigned on the basis of their IR and NMR spectra to the B isomer and to a mixture of the A and B isomers (which we were not able to separate). Surprisingly the B form containing the nitrogen atom of the uncoordinated third pyrazolyl ring closer to the Rh atom than in the equatorial A isomer exhibited the highest ν(CO) frequencies [19]. Related results were also deduced for $[Rh(\kappa^2\text{-}Tp^{Ph})(CO)_2]$ [27]. These observations, moreover the unexplained values of the ν(CO) absorption bands for the isomers, moved us to prove the identity of those isomers by X-ray determinations. Then we decided to investigate the formation of new Rh(I) carbonyl complexes containing the related Tp^{PhCl} as bulky ligand. The isolation and characterization by X-ray diffraction of three isomers (A, B and B′)

[1] The symbols used for the geometries are those indicated in a recent work published by Webster and Hall [29].



Scheme 1.

as well as a new binuclear compound containing κ^2,κ^1-Tp^{PhCl} are now presented and discussed.

2.2. Synthetic studies

The reaction of the dimer $[Rh(\mu\text{-}Cl)(CO)_2]_2$ and the thalium salt of the Tp^{PhCl} ligand in a 1:2 or 1:1 molar ratio gave rise to the new compounds $[Rh(\kappa^2\text{-}Tp^{PhCl})(CO)_2]$ (**1**) and $[(OC)_2Rh(\mu{:}\kappa^2,\kappa^1\text{-}Tp^{PhCl})Rh(Cl)(CO)_2]$ (**2**), respectively (Scheme 1). Both compounds were air-stable yellow-orange solids and characterized by analytical and spectroscopic (IR and ^1H NMR) techniques.

Complex **1** was crystallized from dichloromethane–hexane solution giving rise to three generations of crystalline solid products characterized as the **1**-A, **1**-B and **1**-B′ isomers, as it is described in the experimental part. They were identified by X-ray crystallography and IR spectroscopy (Table 1). The ^1H NMR spectra of each isomer at room temperature (Table 2) exhibited the same pattern consistent with only one set of signals of the Tp^{PhCl} ligand, which was attributed to the presence of a very fast equilibrium between them on the NMR time-scale. In agreement with these results, the IR spectra in dichloromethane solution showed the same two broad ν(CO) bands for the three isomers (Table 1). However, in solid state, the values of the ν(CO) absorption bands were different each isomer, showing the expected order to their corresponding coordination spheres (Table 1).

[a] d, doublet; br, broad signal.

Complex **2** was identified as the binuclear compound $[(OC)_2Rh(\mu{:}\kappa^2,\kappa^1\text{-}Tp^{PhCl})Rh(Cl)(CO)_2]$ which could be considered as the product of coordination of **1** to the $[Rh(Cl)(CO)_2]$ fragment (Scheme 1). Its IR and ^1H NMR spectra were consistent with the proposed formulation. So, the complex exhibited four strong ν(CO) bands both in the solid state and in dichloromethane solution (Table 1). On the other hand the ^1H NMR spectrum showed three different sets of signals for the H4 and H5 pyrazolyl protons as well as for the chlorophenyl substituents (Table 2). These NMR and IR patterns resembled to those of the samples of $[Rh(\kappa^2\text{-}Tp^R)(CO)_2]$ (R = Ph, An) previously considered as mixtures of the A and B isomers [19,27]. These features suggested us that maybe our previous assignment was wrong, the right one being that corresponding to a binuclear tetracarbonyl derivative. Then the reaction of $[Rh(\mu\text{-}Cl)(CO)_2]_2$ and Tp^{An} in a 1:1 molar ratio has now been carried out, giving rise to a solid product whose IR and ^1H NMR data are almost identical to those of the tetracarbonyl compound **2**. We are now involved in its X-ray characterization prior to establish definitive conclusions.

2.3. X-Ray crystal structure of the $[Rh(\kappa^2\text{-}Tp^{PhCl})(CO)_2]$ isomers (1-A, 1-B, 1-B′)

The X-ray structures of the **1**-A, **1**-B and **1**-B′ isomers of $[Rh(\kappa^2\text{-}Tp^{PhCl})(CO)_2]$ have been solved. Figs. 2–4 depict their molecular structures and Table 3 shows selected structural parameters.

For these three isomers, a boat conformation of the metallocycle $Rh(NN)_2B$, defined by the atoms Rh(1)N(12)N(11)B(1)N(21)N(22), was envisaged. The N(11)N(12)N(22)N(21) atoms form a plane with the highest deviation of 0.005(4), 0.020(6) and 0.011(5) Å for **1**-A, **1**-B and **1**-B′, respectively. The Rh(1) and B(1) atoms are out of this plane at distances of 0.912(1) and 0.664(7) Å (**1**-A), 0.968(1) and 0.59(1) Å (**1**-B), and 0.853(1) and 0.605(7) Å (**1**-B′).

The **1**-A and **1**-B isomers can be described as square-planar Rh complexes where the Tp^{PhCl} ligand is coordinated to the Rh atom through two of the three pyrazolyl rings. In **1**-B the uncoordinated third pyrazolyl ring is over the square-plane, but in **1**-A it is located away from the metal plane and inverted at the sp^3 boron of the Tp^{PhCl} ligand, according, respectively, to the SP1 and SP2 geometries proposed by Webster and Hall [29]. The structural core found in **1**-B′ is essentially the same that in **1**-B, but the former exhibits the N atom of the free pyrazolyl arm closer to the metal centre, so generating a square-pyramidal geometry (SPy) (Fig. 1). The dihedral angle between the metal–ligand core and uncoordinated pyrazolyl ring planes is 69.1(2)° and 79.7(2)° for **1**-B and **1**-B′, respectively. The torsion angles defined by N(31), B(1) and the two nitrogens of a single coordinated pyrazolyl ring (N(31)–B(1)–N(11)–N(12) and N(31)–B(1)–N(21)–N(22)) agree with the established geometries (−175.5(4)° and 178.2(4)° (**1**-A); −51.5(9)° and −76.3(9)° (**1**-B); −68.1(7)° and 67.2(7)° (**1**-B′)).

In all cases the sum of the angles around the Rh centre by the coordinated pyrazolic N atoms and the CO ligands was approximately 360°, indicating the planarity of the Rh(1)C(1)C(2)N(12)N(22) moiety. The Rh(1)–N(12), Rh(1)–N(22) and Rh(1)–C(1), Rh(1)–C(2) distances are almost equal suggesting a local mirror symmetry. The N(11)–B(1)–N(21) atoms form an angle of 107.4(4)°, 107.1(6)° and 109.3(5)° for **1**-A, **1**-B and **1**-B′, respectively.

The chlorophenyl substituents are twisted with their own pyrazolyl rings, being more coplanar those of the uncoordinated pyrazolyl arm. So, the corresponding dihedral angles are: 41.4(2)°, 46.9(2)° and 22.7(2)° (**1**-A); 49.0(3)°, 28.9(3)° and 6.0(2)° (**1**-B); and 51.9(2)°, 57.5(2)° and 36.4(2)° (**1**-B′).

The N(12)–Rh(1)–N(22) angles in the equatorial plane are close to 90° in the three isomers. The other two angles involving the axial pyrazolyl group N(12)–Rh(1)···N(32) and N(22)–Rh(1)···N(32) were 72.4(2)°, 91.0(2)° in **1**-B and 79.6(2)°, 82.4(2)° in **1**-B′, respectively, but 45.3(1)° and 48.8(1)° for **1**-A in agreement with the different geometry of the equatorial isomer.

The main differences between the three isomers are related to the spacial orientation of the uncoordinated third pyrazolyl arm, which occupies an axial (B or B′) or

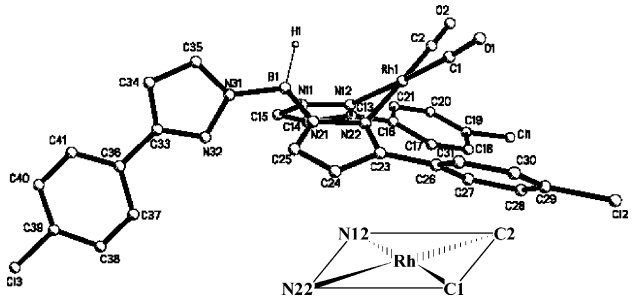

Fig. 2. PLUTO representation of compound **1**-A, showing the atomic numbering scheme. Hydrogen atoms, except that bonded to B(1), have been omitted for clarity. A schematic representation of the coordination sphere around the Rh atom is also included.

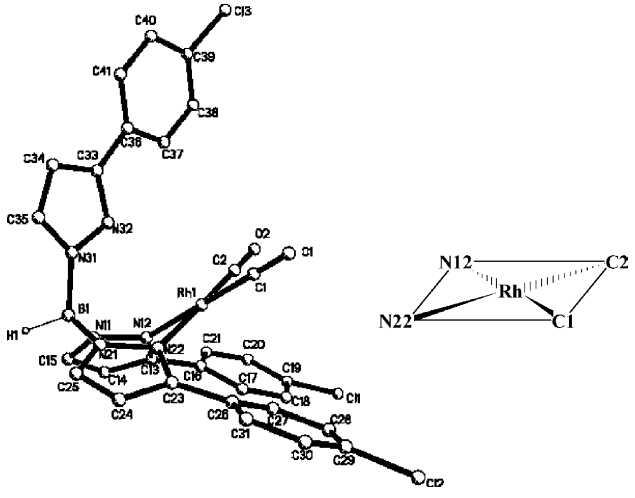

Fig. 3. PLUTO representation of compound **1**-B. Details as in Fig. 2.

equatorial (A) position. As a consequence, the Rh(1)···N(32) distances in **1**-A, **1**-B and **1**-B′ were 5.553(4), 3.100(5) and 2.599(5) Å, respectively. This distance is out or in the limit of the range of bonding interactions (sum of the van der Waals radii of Rh and N atoms is 3.15 Å) in **1**-A and **1**-B, but it agrees with a square pyramidal environment (SPy) around the metal centre in **1**-B′. Consistent with this SPy structure, the axial Rh(1)···N(32) distance was 0.468 Å longer than those on the equatorial plane and the metal was above the coordination plane by 0.123(1) Å in **1**-B′. However in **1**-A and **1**-B the metal centre was almost coplanar with the four coordinating atoms of the ligands (0.039(1) and 0.001(1) Å, respectively).

2.4. X-ray structure of $[(OC)_2Rh(\mu{:}\kappa^2,\kappa^1\text{-}Tp^{PhCl})Rh(Cl)(CO)_2]$ (**2**)

The dinuclear molecule, depicted in Fig. 5, was constituted by two metal centres, both exhibiting a square-planar geometry, bridged by a Tp^{PhCl} ligand. The Rh(1) atom has a square-planar coordination comprised by two CO ligands and a pair of pyrazolic N-donor atoms from the Tp^{PhCl} ligand acting as chelate. The third remained pyrazolyl ring coordinates to the Rh(2) atom which complete its square-planar geometry with two carbonyl and one chloride ligands. Selected bond distances and angles are presented in Table 3.

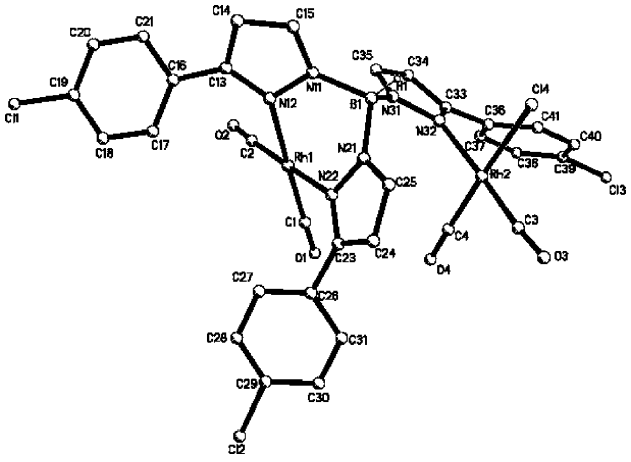

Fig. 5. PLUTO representation of compound **2**. Details as in Fig. 2.

The Rh(1)C(1)C(2)N(12)N(22) and Rh(2)N(32)C(4)C(3)Cl(4) atoms are essentially planar, the Rh(1) and Rh(2) deviating 0.014(1) and 0.012(1) Å, respectively, from the least-squares plane defined by the four corresponding remained atoms.

The observed bond distances and angles for the coordination spheres of the Rh(1) and Rh(2) atoms are almost identical to those found in **1**-A, **1**-B and **1**-B′. The Rh(2)–N(32) distance of 2.09(1) Å was slightly longer than that observed in the related four-coordinated $[Rh(Cl)(CO)_2(Hpz^R)]$ ($R = An$, $C_6H_4OC_{12}H_{25}$)

[30,31], and the Rh(2)–Cl(4) distance is also typical of Rh(I) complexes [30–33].

The chelating part of the Tp^{PhCl} ligand was symmetrically coordinated to the $[Rh(CO)_2]$ fragment. So a local mirror plane which passes through the B(1) and Rh(1) atoms lies orthogonal to the plane formed by the four nitrogen atoms of the two pyrazolyl groups involved in the bidentate coordination. The Rh(1)N(12)N(11)B(1)N(21)N(22) metallocycle adopts a boat conformation, as that observed in the mononuclear species **1**-A, **1**-B and **1**-B′. This metallocycle could be considered symmetrically divided by the above mirror plane, and consequently both carbonyl ligands and the two chlorophenyl groups were also symmetrical. In agreement the dihedral angles between the pyrazolyl rings coordinated to the Rh(1) atom and the N(11)N(12)(21)N(22) plane were almost similar (31.0(4)° and 30.2(5)°).

The dihedral angles formed by the pyrazolyl rings and their own phenyl substituents are similar (37.6(4)°, 45.9(5)° and 40.7(5)°), in contrast to those observed for the mononuclear isomers of **1** (see Section 2.3).

Despite a strict relationship between the solid state structures and the reactivity of structures in solution could not be always considered, we suggest that the **1**-A and **1**-B structures should be the best candidates to the coordination of the second metal centre, in order to accommodate the two metal fragments and at the same time to relieve the strain. In agreement with this proposal the observed Rh(1)···N(32) distance of 4.05(1) Å in **2** was intermediate to that found in **1**-A (5.553(4) Å) and in **1**-B (3.100(5) Å), and the dihedral angle formed by the free pyrazolyl ring and the coordination plane of 75.1(2)° and 69.1(2)° for **1**-A and **1**-B, respectively, was moved to 50.3(5)° in **2**.

2.5. Structural comparison of $[Rh(Tp')(CO)_2]$ complexes

To the best of our knowledge, seven Rh dicarbonyl complexes containing trispyrazol-1-ylborate ligands had been characterized by X-ray crystallography [16,18,19,28,34–36]. In addition, a new related compound containing the asymmetric hydridobis(3-phenyl-5-methylpyrazol-1-yl)(3,5-dimethylpyrazol-1-yl)borate (Tp″) has recently been reported [37], and now we present our results from three isomeric forms containing the Tp^{PhCl} ligand. Table 4 lists relevant results from these structures.

It had been proposed that the hapticity of the Tp ligands was depending on the substitution on the pyrazolyl rings [22]. However for all dicarbonyl complexes, with exception of $[Rh(\kappa^3\text{-}Tp^{3,5iPr})(CO)_2]$ (which showed some decomposition during the X-ray data collection [28,36]), it was evident that the 16-electron square-planar geometry is favoured towards the 18-electron trigonal bipyramidal structure, although the presence of free pyrazolyl arm on the axial position close to a coordinative site may lead to an elongated square pyramidal (SPy) structure, as it has now been considered for complexes $[Rh(\kappa^2\text{-}Tp')(CO)_2]$ ($Tp' = Tp^a$, $Tp^{3CF3,5Me}$, $Tp^{3Ph,5Me}$, Tp^{An}, Tp^{PhCl}).

Moreover from our actual results on $[Rh(\kappa^2\text{-}Tp^{PhCl})(CO)_2]$, we can deduce that an appropriate substitution on the pyrazolyl rings appears to be a requirement to achieve different isomers in solid state (**1**-A, **1**-B and

1-B′). They were isolated in different amounts, which could be related to factors as the kinetics of crystal growth or crystal packing effects as well as their corresponding stability. The theoretical calculations on [Rh(Tp^{3R,5R})(CO)$_2$] (R = H, Me) indicated that the SPy isomer (B′) was the most stable [29]. However, we obtained orange crystals of **1**-B′ (SPy) together with yellow crystals of **1**-B (SP1) at the first stage of the crystallization (1–2 days, T ca. 0 °C), the former being the minor form. By contrast, several days at ca. 0 °C were required to achieve light yellow crystals of **1**-A (SP2), which resulted to be the major isomer. Then it is possible to suggest that the electrowithdrawing character of the chlorophenyl substituents on the pyrazolyl rings does not favour the increasing coordination around the metal centre of the SPy geometry with respect to the square-planar compounds.

3. Concluding remarks

On the [Rh(Tp′)(CO)$_2$] chemistry, the κ² hapticity of the Tp′ ligands has been found to be the most usual feature, specially for those derivatives containing bulky substituents on the pyrazolyl groups. Several examples corresponding to SP2 (square-planar equatorial), SP1 (square-planar axial) or SPy (elongated square-pyramidal) geometries have been described [16,18,19,34,35,37]. The new compound [Rh(κ²-Tp^{PhCl})(CO)$_2$] (**1**), prepared in this work in a 1:1 Tp^{PhCl}/Rh molar ratio, provides the first example in which three isomeric forms containing κ²-Tp^{PhCl} have been isolated and structurally characterized in solid state for a single Tp′ ligand in the [Rh(Tp′)(CO)$_2$] family. Their formation appears to be depending on the crystallization process, and the bidentate κ²-Tp^{PhCl} square-planar coordination is favoured with respect to the SPy geometry, in agreement with the electronic characteristics of the Tp^{PhCl} ligand.

In addition, the coordination of Tp^{PhCl} as bridging ligand to two metal centres has been found for the complex [(OC)$_2$Rh(μ:κ²,κ¹-Tp^{PhCl})Rh(Cl)(CO)$_2$] (**2**), which was obtained when a synthetic 1:2 Tp^{PhCl}/Rh molar ratio was used. Its X-ray crystal structure shows the Tp^{PhCl} ligand bonded to both metal centres in a κ²,κ¹ fashion. It is one of the few examples exhibiting the bridging coordinative form of the Tp′-type ligands [39,40].

4. Experimental

4.1. Materials and equipment

The starting Rh-complex [Rh(μ-Cl)(CO)$_2$]$_2$ was purchased from Sigma–Aldrich and used without further

purification. Commercial reagents were used as supplied. All reaction solvents were dried and degassed according to standard methods prior to use.

Elemental analyses were carried out by the Center for Elemental Microanalysis at the Complutense University. Infrared spectra were recorded on a FTIR Nicolet Magna-550 spectrophotometer with samples as KBr discs or in dichloromethane solutions in the 4000–350 cm^{-1} region. ^1H NMR spectra were performed on a Varian VXR-300 (299.88 MHz) or a Bruker DPX-300 (300.13 MHz) spectrophotometers from $CDCl_3$ solutions. Chemical shifts δ are listed in parts per million relative to tetramethylsilane; coupling constants J are in Hertz. The ^1H chemical shifts and coupling constants are accurate to ±0.01 ppm and ±0.3 Hz, respectively.

4.2. Synthetic methods

4.2.1. Preparation of [Rh(κ²-Tp^{PhCl})(CO)$_2$] (1)

To a solution of $[Rh(\mu\text{-}Cl)(CO)_2]_2$ (0.050 g, 0.13 mmol) in dichloromethane (40 ml) was added $TlTp^{PhCl}$ (0.195 g, 0.26 mmol). The resulting yellow solution was stirred at room temperature for 15 min. The white solid (TlCl) formed is filtered through Celite. Hexane is added over the filtrate and then the solution is kept at ca. 0 °C for 1–2 days giving rise to the formation of a mixture of orange (**1**-B′) and yellow (**1**-B) crystals, which were filtered off, dried and easily separated off under a microscopy. The resulting solution was again kept at ca. 0 °C for several days yielding light yellow (**1**-A) crystals, which were filtered off and dried. *Anal.* Found: C, 49.30; H, 2.65; N, 11.80%; calc. for $C_{29}H_{19}N_6O_2BCl_3Rh$: C, 49.51; H, 2.72; N, 11.94.

4.2.2. Preparation of [(OC)$_2$Rh(μ:κ²,κ¹-Tp^{PhCl})Rh(Cl)(CO)$_2$] (2)

To a solution of $[Rh(\mu\text{-}Cl)(CO)_2]_2$ (0.050 g, 0.13 mmol) in dichloromethane (40 ml) was added $TlTp^{PhCl}$ (0.097 g, 0.13 mmol). The yellow solution was stirred for 15 min, and then filtered over Celite to eliminate TlCl. Addition of hexane led to the precipitation of a yellow solid, which was filtered off. Recrystallization in dichloromethane/diethyl ether gives rise to yellow crystals, which was filtered off, dried in vacuo and characterized as the compound **2**. *Anal.* Found: C, 41.28; H, 2.05; N, 9.10%; calc. for $C_{31}H_{19}N_6O_4BCl_4Rh_2$: C, 41.47; H, 2.13; N, 9.36.

4.3. Crystal structure determinations

Prismatic crystals of [Rh(κ²-Tp^{PhCl})(CO)$_2$] (**1**) (light yellow, **1**-A; yellow, **1**-B; orange, **1**-B′) were obtained from dichloromethane–hexane solutions at low temperature. Yellow prismatic crystals of [(OC)$_2$Rh(μ:κ²,κ¹-Tp^{PhCl})Rh(Cl)(CO)$_2$] (**2**) were obtained from dichloromethane/diethyl ether solutions.

The crystals were mounted on a Smart CCD-Bruker diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). A summary of the fundamental crystal and refinement data for the four structures is given in Table 5. The structures were solved by direct and Fourier methods. The refinement was made by full-matrix least-squares on F^2 [41]. All non-hydrogen atoms were refined anisotropically, except the O(1) and O(2) atoms for **1**-B which were refined two cycles anisotropically and in the subsequent cycle their thermal parameters were fixed. The hydrogen atoms were calculated and refined as riding on bonded carbon atom with a common isotropic displacement parameter, except that bonded to B(1) which was located as one of the first peak in a Fourier difference, and then included with different treatment: its position fixed in **1**-A, refined as riding on the boron atom in **1**-B′ and **2** or its coordinates refined in **1**-B. The largest residual peaks in the final difference map were 0.64, 0.43, 1.48 and 1.78 e $Å^{-3}$ for **1**-A, **1**-B, **1**-B′ and **2**, respectively.

5. Supplementary material

Supplementary data of the structures reported in this paper are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 211215–211218 for compounds **1**-A, **1**-B, **1**-B′ and **2**, respectively.

Acknowledgements

We are very grateful to Dr. S. Trofimenko for providing a sample of the thalium salt of the Tp^{PhCl} ligand. We also acknowledge to DGI/MCyT for the support of this work.

Interconversions of simple monodentate nitrogen donor ligands bound to Tp′ tungsten fragments

Neil J. Vogeley, Joseph L. Templeton *

W.R. Kenan Jr. Laboratories, Department of Chemistry, University of North Carolina, Chapel Hill, NC 27599-3290, USA

Received 2 June 2003; accepted 2 September 2003

Abstract

The dramatic effect of an ancillary alkyne ligand on the regioselectivity of nucleophile and electrophile additions to monodentate nitrogen ligands is illustrated by comparison of ligand based reactions characteristic of nitrogen donor ligands incorporated into $[Tp'(CO)_2W]^+$ and $[Tp'(CO)(PhCCMe)W]^+$ coordination spheres. Nitrogen ligands accessible from free nitriles and amines, including nitrile, azavinylidene, imido, imine, amido, amine, and nitrido, can be interconverted by addition of nucleophiles or electrophiles as well as by hydride abstraction or proton removal. Structural details that reveal important π-bonding interactions for multiply bonded nitrogen ligands are also discussed.

Keywords: Acetonitrile reduction; Amine oxidation; Imido; Metal-nitrogen pi bonding; Regioselectivity of nucleophile and electrophile additions

1. Introduction

This paper will compare and contrast the reaction chemistry of nitrogen ligands bound to two superficially similar tungsten(II) d^4 fragments: $[Tp'(CO)_2W]^+$ and $[Tp'(CO)(PhC{\equiv}CMe)W]^+$ (Tp′ = hydridotris(3,5-dimethylpyrazolyl)borate, Fig. 1) [1]. Both of these fragments formally count 14 electrons, but π donation from the second alkyne π orbital, $\pi_\perp$, can effectively increase the electron count to 16 for the alkyne containing metal moiety (Fig. 2) [2,3]. The comparisons here indicate that variable π donation from the alkyne ligand dictates the reaction chemistry available to other ligands coordinated to these fragments.

2. Reactivity patterns for unsaturated ligands with carbon frameworks

Reactions of unsaturated ligands built from carbon skeletons have been extensively studied [4]. Using an iron-acetylide moiety to illustrate the reaction paradigm, the acetylide unit can be reduced to an alkyl ligand by alternating addition of electrophiles and nucleophiles (Scheme 1) [5]. In this and related systems, the metal is able to house electrons pairs or share them with C_α while adhering to the 18-electron rule. It follows naturally that electrophiles will add to C_β, while nucleophiles add to C_α [6].

Addition of an electrophile to C_β of the alkynyl ligand of the starting reagent forms a vinylidene complex [5,7–11]. The vinylidene complex, $L_nM{=}C{=}CRE$, is a unique reagent with both M=C and C=C unsaturation. Two disparate reaction pathways are available to vinylidene complexes: (i) Addition of an electrophile to C_β is possible and forms a carbyne complex [10,12–17]. (ii) Addition of a nucleophile to C_α is possible and forms a vinyl complex [5,9,18]. Carbene complexes can be synthesized either by addition of a nucleophile to C_α of a carbyne complex [19–24], or by addition of an electrophile to C_β of a vinyl complex [7,8,25]. Addition of a nucleophile to the carbene carbon gives an alkyl complex [26,27].

In the iron system reported by Davison and Selegue [5], alternating addition of electrophiles and nucleophiles

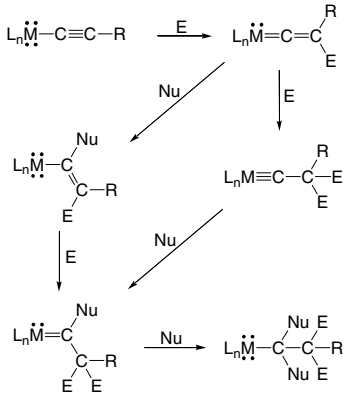

Scheme 1.

leads to the reduced alkyl ligand through a vinyl species; no carbyne is ever present in reduction of the iron-acetylide reagent.

Nitrogen ligands analogous to these carbon ligands are accessible (Fig. 3), but roadmaps for systematic interconversions among the nitrogen based ligand family remain rare. An excellent review of reactions of nitrile ligands has recently appeared [28]. We will return to a reaction scheme, similar to Scheme 1, involving nucleophile and electrophile additions to nitrogen based ligands in the summary.

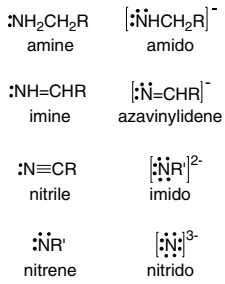

Fig. 3. Nomenclature for monodentate nitrogen donor ligands.

3. Nitrogen donor ligands bound to $[Tp'(CO)_2W]^+$

3.1. Synthesis and reactions of nitrogen ligands bound to $[Tp'(CO)_2W]^+$

Cationic imido complexes, $[Tp'(CO)_2W(\equiv NR)]^+$ (**3**), have been synthesized in two ways: (1) reduction of coordinated nitriles and (2) oxidation of amido complexes. Each of these methods has the advantage of starting from readily available reagents, either nitriles or amines.

In the first method, addition of a nucleophile to the nitrile carbon in $[Tp'(CO)_3W(NCR)]^+$ (**1**) (R = Me (**1a**), ν_{CO} = 2045, 1956 cm^{-1}), which is readily prepared by adding Ag^+ to $Tp'(CO)_3W(I)$ in CH_3CN, leads to loss of one carbonyl ligand during the formation of neutral azavinylidene complex **2** (Eq. (1)) [29]. Azavinylidene complex **2** can also be synthesized by photolysis of $Tp'(CO)_3W(H)$ in the presence of nitriles (Eq. (2)). The two infrared CO stretching frequencies of complex **2,** averaging 1926 and 1814 cm^{-1}, are in the range typical of neutral dicarbonyl tungsten(II) complexes (see Table 1).

The azavinylidene carbon is nucleophilic and electrophiles can be added at the carbon which is α to the nitrogen and β to the metal to form cationic imido complex **3** (Eqs. (1) and (2)) [29]. These imido complexes can be deprotonated to regenerate azavinylidene complex **2** [30]. Both the symmetric and antisymmetric CO stretches absorb above 2000 cm^{-1} for cationic imido complexes (**3**) (averaging 2083 and 2006 cm^{-1}, see Table 1) reflecting a dramatic decrease in electron density at the metal relative to the azavinylidene precursor. This drop in metal electron density is compatible with an increase in formal oxidation state from W(II) to W(IV) upon addition of an electrophile to the azavinylidene carbon to form an imido ligand, formally $[NR]^{2-}$.

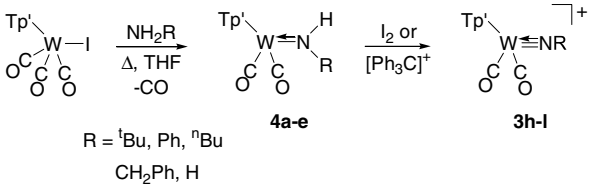
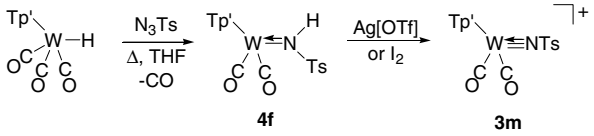
The second method for obtaining an imido complex begins by heating $Tp'(CO)_3W(I)$ in the presence of a primary amine in THF solution to form $Tp'(CO)_2W(=NHR)$ (**4a –e**) with concomitant loss of a carbonyl ligand [31]. The average CO stretching frequencies for these neutral amido complexes are 1912 and 1790 cm^{-1}, significantly lower than for analogous neutral azavinylidene complexes (**2**). The average chemical shift for the amido NH proton is about 14 ppm in the NMR spectrum (see Table 1). These $[NHR]^-$ amido ligands can be oxidized with I_2 or $[Ph_3C]^+$ via net hydride removal from nitrogen to form cationic imido complexes **3h–l** (Eq. (3)).



(3)

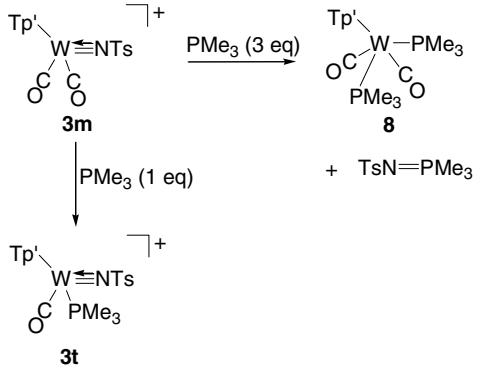
Tosylamido complex **4f** (tosyl = $SO_2C_6H_4Me$) can be synthesized by refluxing $Tp'(CO)_3W(H)$ in THF with TsN_3. Oxidation by net hydride removal with Ag[OTf] or I_2 gives tosylimido complex **3m** (Eq. (4)) [32].



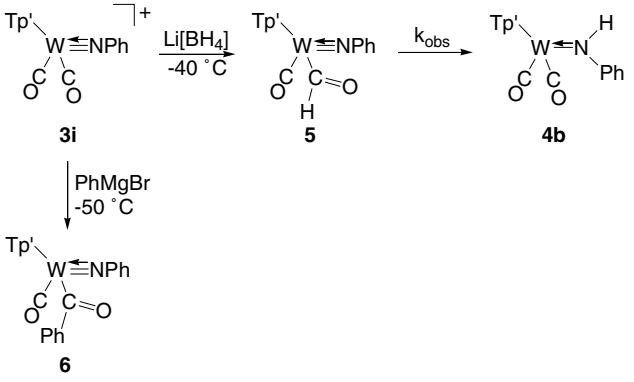
(4)

Tosylimido complex **3m** undergoes two separate reactions in the presence of four equivalents of PMe_3. Three equivalents are involved in transferring the neutral nitrene fragment, NTs, to PMe_3 forming $TsN{=}PMe_3$ and $Tp'(CO)_2W(PMe_3)_2$ (**8**) as the trapped tungsten product. The second tungsten product, $[Tp'(CO)(PMe_3)W(\equiv NTs)]^+$ (**3t**), is formed by displacement of a carbonyl ligand by one equivalent of PMe_3 (Scheme 2) [32].

Hydride reduction of $[Tp'(CO)_2W(\equiv NR)]^+$ imido complexes **3** results in formation of neutral amido complexes **4**. Addition of excess $Li[BH_4]$ to $[Tp'(CO)_2W(\equiv NPh)]^+$ (**3i**) at low temperature adds hydride to a carbonyl ligand leading to formyl complex **5** as an intermediate. Hydride migration from the formyl ligand to the imido ligand to yield phenylamido complex **4b** was monitored by ^1H NMR spectroscopy at −70°C and yielded a k_{obs} of 7.2×10^{-6} s^{-1} ($\Delta G^{\ddagger} = 16.5$ kcal/mol) (Scheme 3) [33].



Scheme 2.

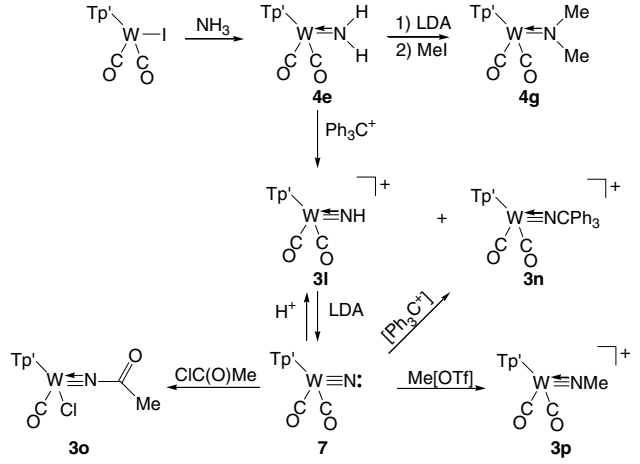


Scheme 3.

Given the high CO stretching frequencies in $[Tp'(CO)_2W(\equiv NPh)]^+$, nucleophilic attack at a carbonyl ligand by the $Li[HBEt_3]$ reagent above is easily rationalized [34]. Another example of nucleophilic addition to a carbonyl ligand is provided by addition of PhMgBr to $[Tp'(CO)_2W(\equiv NPh)]^+$ which gives phenylacyl complex **6** in good yield (Scheme 3).

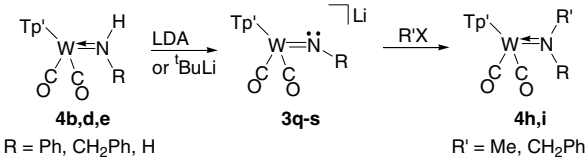
The parent amido complex, $Tp'(CO)_2W(=NH_2)$ (**4e**), can be synthesized from the 16-electron $Tp'(CO)_2W(I)$ reagent and ammonia. Amido complex **4e** has CO stretches at 1915 and 1793 cm^{-1}; the two distinct NH protons appear at 11.6 and 13.5 ppm in the ^1H NMR spectrum. Dimethylamido complex **4g** can be prepared by deprotonation of the parent amido complex **4e** with LDA (lithium diisopropylamide) followed by quenching with excess MeI. Hydride removal from parent amido complex **4e** using $[Ph_3C]^+$ forms the imido complex $[Tp'(CO)_2W(\equiv NH)]^+$ (**3l**) along with some $[Tp'(CO)_2W(\equiv NCPh_3)]^+$ (**3n**). Parent NH imido complex **3l** has CO stretches at 2092 and 2017 cm^{-1}, and the imido proton resonates at 9.8 ppm in the ^1H NMR spectrum. Deprotonation of parent imido complex **3l** affords neutral nitrido complex **7** with CO stretches at 2035 and 1938 cm^{-1}. These relatively high CO stretches reflect localization of the lone pair on the nitride nitrogen where it is not directly available to enrich the electron density at the metal. The nitrido complex can be reacted with electrophiles to give new imido complexes **3n–p** (Scheme 4) [35].

Neutral amido complexes $Tp'(CO)_2W(NHR)$ (**4b**,**d–e**) can be deprotonated with LDA or ^{t}BuLi to generate reactive anionic imido complexes **3q–s**. These imido intermediates can be trapped by $PhCH_2Br$ or MeI to give new amido complexes **4h**,**i** (Eq. (5)) [30]. The CO stretches for $[Li][Tp'(CO)_2W(\equiv NR)]$ at 1861 and 1724 cm^{-1} in the IR spectrum are much lower than for the cationic imido complexes, as expected for these cationic and anionic complexes with the same ligand set (see Table 1).



Scheme 4.

The increased π backbonding available to CO ligands in the anionic imido complexes is responsible for lowering the average CO stretching frequency 250 cm^{-1} from the related cationic imido complexes.



(5)

3.2. Orbital interactions in $[Tp'(CO)_2W]^+$ derivatives

Single-faced π-donor ligands reveal their orbital orientations indirectly but definitively through molecular geometries. X-ray structures in the solid state and NMR data in solution show that the amido fragment in $Tp'(CO)_2W(NHR)$ lies in the mirror plane of the complex. This orientation positions the nitrogen p orbital to donate electrons into the d_{yz} orbital to form the M–N π bond (Fig. 4). The two filled dπ orbitals (d_{xz} and $d_{x^2-y^2}$ in the orientation depicted in Fig. 4) are involved in backbonding to the two carbonyl ligands. In order to maximize constructive orbital overlap, the OC–W–CO angle is less than 90°. This increases the interaction of two CO π^* orbitals with the filled metal d_{xz} orbital and decreases interaction of the same CO π^* orbitals with the empty metal d_{yz} orbital [29,30]. For $Tp'(CO)_2W$ (= NHPh) (**4b**), the barrier for interconversion of the two rotamers has been determined by ^1H NMR spectroscopy at 22 °C to be 24.2 kcal/mol from the thermodynamically favored isomer, and 23.0 kcal/mol from the minor rotamer [31].

The metal–nitrogen orbital interactions in azavinylidene complexes resemble those in amido complexes. Like other cumulenes, the orientation of the pendant XR_2 group rotates by 90° with each additional double bond. The ^1H NMR spectrum of N=CRR′ complexes shows an apparent mirror plane at room temperature, but upon cooling, the spectrum changes. At low temperature, it shows distinct signals for each of the six Tp′ methyl groups indicating that rotation about the W=N=C axis has been effectively stopped on the NMR timescale and that the azavinylidene plane is oriented so that the nitrogen lone pair can donate into the empty d_{yz} orbital with R and R′ breaking the C_s symmetry (Fig. 5). The barrier for W–N–C rotation was determined to be 9.5 kcal/mol at −78°C for $Tp'(CO)_2W(=N=CHMe)$ (**2a**) [29]. The X-ray structure of $Tp'(CO)_2W(=N=C(H)CH_2Ph)$ (**2c**) shows a W=N=C bond angle of 166.6°; the benzyl group is positioned as anticipated [29].

As a cylindrically symmetrical π donor, the $[NR]^{2-}$ ligand has the capability to form a M–N triple bond; there is no rotational preference for linear imido complexes. The two sets of lone pair electrons on nitrogen are able to donate into empty dπ orbitals (d_{yz} and d_{xz}) in this tungsten(IV) d^2 system (Fig. 6). Indeed, the X-ray structure of $[Tp'(CO)_2W(NPh)][PF_6]$ (**3i**) shows an approximately linear W–N–C linkage of 171.6° [30].

Anionic imido complexes, $[Li][Tp'(CO)_2W(=NR)]$ (**3q–s**), would be expected to have a bent imido moiety. These complexes are tungsten(II) with four d-electrons. The imido ligand can form one π bond with tungsten (Fig. 7). This leaves one lone pair of electrons on nitrogen that are not needed for π bonding with tungsten.

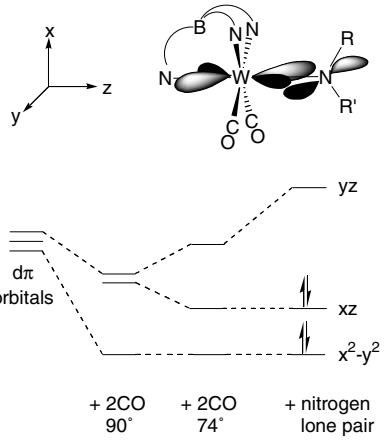


Fig. 4. Orbital interactions in $Tp'(CO)_2W(NRR')$.

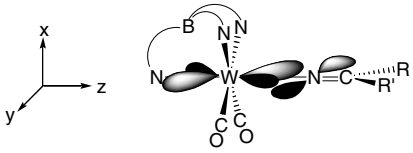

Fig. 5. Orbital interactions in $Tp'(CO)_2W(=N=CRR')$.

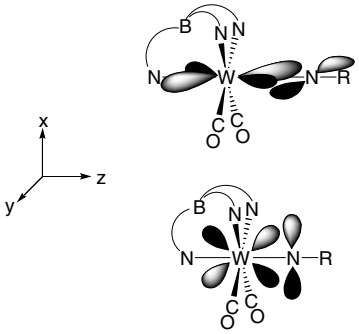

Fig. 6. Orbital interactions in $[Tp'(CO)_2W(\equiv NR)]^+$.

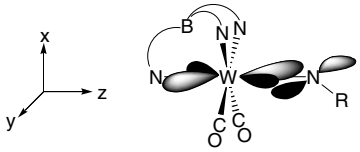

Fig. 7. Orbital interactions in $[Li][Tp'(CO)_2W=NR]$.

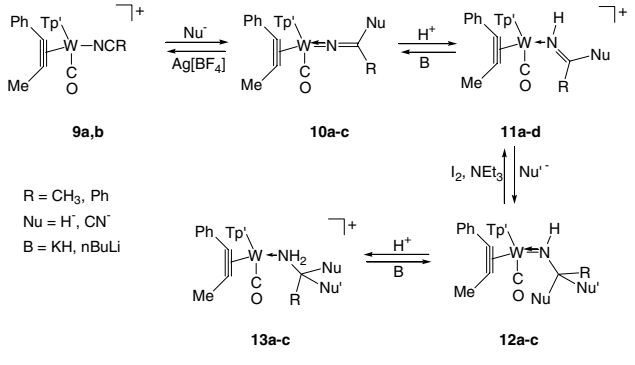
It is possible that this lone pair of electrons is available for lithium coordination forming a lithium amido type structure.

4. Nitrogen donor ligands bound to [Tp′(CO)(PhCCMe)W]$^+$

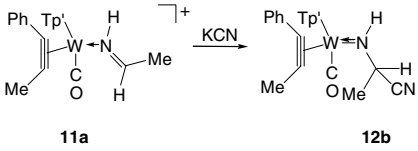
4.1. Synthesis and reactions of nitrogen ligands bound to [Tp′(CO)(PhCCMe)W]$^+$

Addition of a nucleophile to the nitrile carbon in [Tp′(CO)(PhCCMe)W(NCMe)]$^+$ (**9a**) ($\nu_{CO} = 1940\ cm^{-1}$) gives corresponding azavinylidene complexes **10a**,**b** *without the loss of a ligand* (Scheme 5). Recall that nucleophile addition to the nitrile of [Tp′(CO)$_3$W(NCR)]$^+$ promoted loss of one carbonyl ligand, so the reactivity patterns of these two tungsten(II) d^4 nitrile complexes diverge immediately. The azavinylidene complexes can be protonated at nitrogen, thus utilizing the M–N π electrons, to form cationic imine complexes **11a**,**b**. Note that the regiochemistry of electrophile addition is reversed relative to Tp′(CO)$_2$W(=N=CR$_2$) which adds electrophiles to the azavinylidene *carbon*, rather than to the nitrogen. Addition of a nucleophile to the imine carbon in [Tp′(CO)(PhCCMe)W(NH=CRR′)]$^+$ then leads to neutral amido complexes **12a**,**b** which can be protonated at nitrogen to give coordinated amine complexes **13a**,**b** [36,37]. Note that the sites for addition of nucleophiles and electrophiles to this M–N–C linkage are reversed relative to the M–C–C template.

Nucleophilic addition of [CN]$^-$ to [Tp′(CO)(PhCCMe)W(NH=CHMe)][BF$_4$] (**11a**), obtained from reduction of coordinated acetonitrile (Scheme 5), occurs diastereoselectively to form amido complex **12b** (Eq. (6)) [37]. The ability to resolve the enantiomers of the chiral fragment (see below) leads to the possibility for the synthesis of single enantiomer amine products. Diastereoselective addition of nucleophiles to imines coordinated to chiral metal complexes has been observed in other systems [38,39].



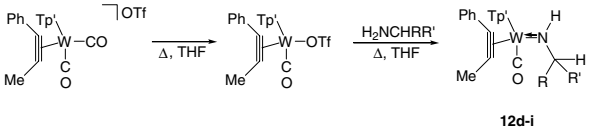
Scheme 5.



(6)

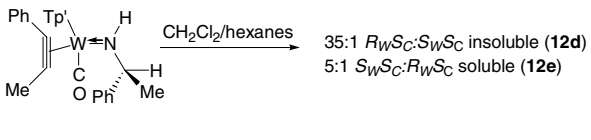
The reverse scheme, stepwise oxidation of an amine ligand, has been demonstrated with [Tp′(CO)(PhCCMe)W(NH$_2$CH$_2$Ph)]$^+$ (**13c**) as the initial reagent (Scheme 5) [40]. Deprotonation of the benzylamine ligand gives amido complex **12c**. The amido ligand can be oxidized by iodine in the presence of triethylamine to form imine complex **11c**,**d** by net hydride removal from the amido carbon. The imine complex can be deprotonated generating azavinylidene complex **10c,** which can in turn be oxidized by Ag[BF$_4$] to yield benzonitrile complex **9b**.

Amido complexes can also be synthesized directly from the corresponding free amines and [Tp′(CO)$_2$(PhCCMe)W][OTf]. Heating a solution of [Tp′(CO)$_2$(PhCCMe)W][OTf] in THF leads to the loss of one carbonyl ligand and to coordination of the triflate counterion. Addition of a primary amine and continued heating forms amido complexes **12d–i** (Eq. (7)). This method provides convenient access to a wide variety of amido complexes (**12d–i**) ($\nu_{CO} \approx 1850\ cm^{-1}$, ^{1}H NMR: 5.5–7.8 ppm, N*H*) which can then be converted (via Scheme 5) to amine (**13d–i**) ($\nu_{CO} \approx 1917\ cm^{-1}$, ^{1}H NMR: 2.5–5.5 ppm, NH_2), imine (**11e–h**) ($\nu_{CO} \approx 1931\ cm^{-1}$, ^{1}H NMR: 8.9–11 ppm, N*H*), or azavinylidene (**10d–g**) ($\nu_{CO} \approx 1887\ cm^{1}$) complexes (see Table 2) [41,42].



(7)

Enantiomers of chiral derivatives of the [Tp′(CO)(PhCCMe)W]$^+$ fragment have been separated. Synthesis of (*S*)-α-methylbenzylamido complex **12d**,**e** from (*S*)-α-methylbenzylamine allows for fractional recrystallization of the diastereomers. The R_WS_C diastereomer **12d** is recrystallized from CH_2Cl_2/hexanes, while the S_WS_C diastereomer **12e** is left in solution (Eq. (8)) [41].



(8)

Cationic amine complexes **13d**,**e** can be obtained by protonation of amido complexes **12d**,**e**, and the amine ligand can be removed as the ammonium salt in the presence of excess acid and acetonitrile to give single

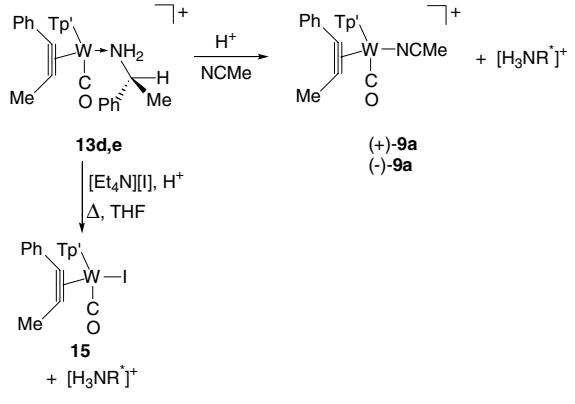
enantiomers of nitrile complex **9a**. The enantiomers of Tp′(CO)(PhCCMe)W(I) (**15**) can be obtained by refluxing the resolved amine complexes (**13d**,**e**) in THF with $[NEt_4][I]$ and acid (Scheme 6) [37,41].

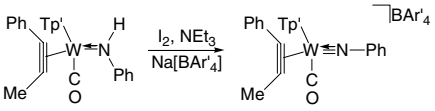
Using (+)-**9a** or (−)-**9a** in the stepwise reduction of acetonitrile gives Tp′(CO)(PhCCMe)WNHCH(CN)(CH_3) (**12b**) as a single enantiomer. The amine fragment can then be cleaved by HBF_4 in the presence of acetonitrile to recover one enantiomer of the amine and the same enantiomer of **9a** that was used as the starting reagent. This demonstrates the configurational stability of the $[Tp'(CO)(PhCCMe)W]^+$ fragment.

Aniline is much less basic than alkylamines, and of course the resultant phenylamido complex (**12i**)



Scheme 6.

(synthesized according to Eq. (7)) has no β hydrogen on the amido ligand. With hydride removal from carbon off the table as an option, oxidation using iodine in the presence of triethylamine does not give an imine complex, but rather cationic phenylimido complex **14a** results from net hydride removal at nitrogen (Eq. (9), BAr'_4 = tetrakis[3,5-bis(trifluoromethyl)phenyl]borate) [43]. The CO stretch for this imido complex is at 2087 cm^{-1} indicating low electron density at the metal which is compatible with oxidation of the metal to tungsten(IV) d^2. In this case, the amido reactivity options are constrained so that the phenylamido ligand relinquishes a hydride just as amido ligands do in the dicarbonyl case of Section 3.



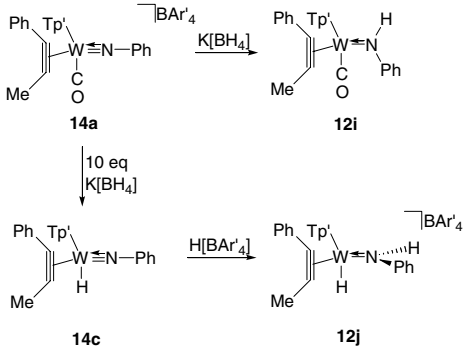
12i **14a** (9)

The imido complex [Tp′(CO)(PhCCMe)W(≡NPh)]$^+$ (**14a**) adds one equivalent of hydride from K[BH_4] to yield amido complex **12i**. Reduction with excess hydride does not generate the amido complex, but rather imido–hydride complex **14c** is obtained instead, reflecting replacement of CO by hydride. The imido ligand is now nucleophilic and can be protonated at nitrogen to give cationic amido-hydride complex **12j** (Scheme 7) [43]. This cationic tungsten(IV) amido complex displays an NH chemical shift of 10.8 ppm which is downfield relative to neutral tungsten(II) amido complexes (Table 2).

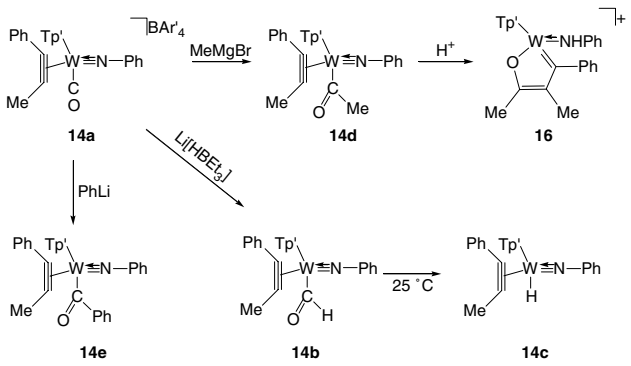
Nucleophilic addition of Me^-, Ph^-, or H^- to phenylimido complex **14a** occurs at the carbonyl ligand to generate acyl complexes. Methylacyl complex **14d** inserts the adjacent alkyne into the metal-acyl bond to form metallafuran complex **16**. Formyl complex **14b** deinserts CO to give imido–hydride complex **14c** (Scheme 8) [43].

4.2. Orbital interactions in [Tp′(CO)(PhCCMe)W]$^+$ derivatives

In these tungsten(II) d^4 systems, both of the two filled dπ orbitals, d_{xz} and d_{yz}, are utilized in π backbonding to



Scheme 7.



Scheme 8.

CO. The alkyne $\pi^*_{\parallel}$ orbital can further lower the energy of d_{xz}, while $\pi_{\perp}$ is able to donate into the lone empty d_{xy} orbital. These bonding interactions orient the alkyne parallel to the CO axis. Since there is only one empty dπ orbital, the nitrogen lone pair on either an amido or an azavinylidene ligand has to compete with alkyne π donation. Due to π donation into d_{xy} from nitrogen, the plane of the amido ligand is *parallel* to the CO axis. In turn, the cumulene alternation guideline implies that the azavinylidene plane will be *perpendicular* to the CO axis (Fig. 8) [37].

X-ray structures for Tp′(CO)(PhCCMe)W(=N=CMePh) (**11f**) and Tp′(CO)(PhCCMe)W(NHCHMeEt) (**12f**) indeed show the expected alternating orientations for azavinylidene and amido ligands [42]. The W=N=C angle of the azavinylidene fragment is slightly bent at 165.4° [42]. Heating a solution of Tp′(CO)(PhCCMe)W(=N=CMePh) (**11f**) (7:1 ratio of rotamers) to 100 °C in an NMR tube showed no broadening of the signals indicating a barrier for W–N–C rotation in this azavinylidene complex of greater than 19 kcal/mol [42]. The dπ interactions in alkyne complexes are significantly

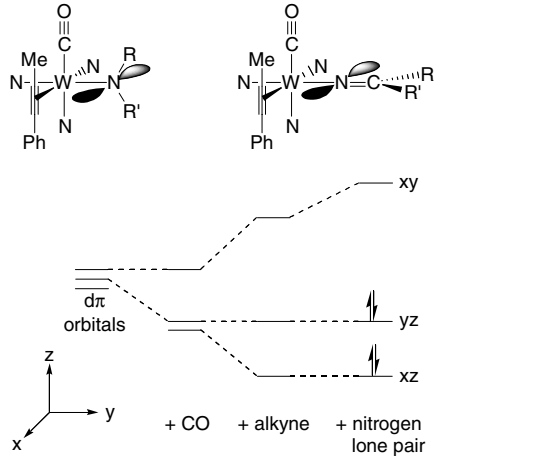


Fig. 8. Orbital interactions in Tp′(CO)(PhCCMe)W(NHR) and Tp′(CO)(PhCCMe)W(=N=CR_2).

restricted relative to the dicarbonyl derivatives, and this is reflected in the difficulty of azavinylidene rotation here which contrasts with the ease of rotation in the analogous $Tp'(CO)_2W(=N=CR_2)$ dicarbonyl complex where a barrier of only 9.5 kcal/mol was observed.

It is noteworthy that in the cationic tungsten(IV) amido-hydride complex **12j** with only two dπ electrons, the alkyne and the amido ligands can find separate vacant dπ orbitals to serve as acceptor sites in order to form two 2-center-2-electron π bonds. Stated differently, both the alkyne and the amido ligands must be net four-electron donor ligands for the metal to adhere to the 18-electron rule. The alkyne and amido ligands do not compete for donation to the metal in this system because there are two empty dπ orbitals. While the geometry was not discussed in the initial report [43], the consequence of this is that the amido ligand would be expected to rotate by 90° relative to the d^4 complexes so that it should be oriented perpendicular to the alkyne triple bond (Fig. 9).

The pivotal factor in the chemistry of the $[Tp'(CO)(PhCCMe)W]^+$ fragment is the ability of the alkyne ligand to donate either two or four electrons which allows chemistry to occur at the nitrogen ligand without the loss of an ancillary ligand. In amido and azavinylidene complexes the lone pair of electrons on the nitrogen donor atom competes with the $\pi_\perp$ electron pair of the adjacent alkyne ligand for the single empty metal dπ orbital. Changes in electron donation from the alkyne ligand are reflected in the ^{13}C NMR spectrum [44,45].

When the alkyne donates four electrons, as in cationic imine and amine complexes, the resonances of the alkyne carbons appear around 215 ppm (see Table 2). When $\pi_\perp$ donation competes with the lone pair on the nitrogen ligand, as in neutral amido and azavinylidene complexes, the alkyne carbon resonances move upfield: alkyne carbons in amido complexes appear around 170 ppm, while alkyne carbons in azavinylidene complexes appear near 160 ppm (see Table 2).

These data indicate that an alkyne ligand in an azavinylidene complex donates less electron density from $\pi_\perp$ than in a similar amido complex, or stated differently, 'an amido ligand is a stronger π donor than an azavinylidene ligand'. The donor ability of amido and azavinylidene ligands is also evident in the CO stretching frequencies of their analogous complexes. The carbonyl ligand in amido complexes absorbs near 1850 cm^{-1}, while those in azavinylidene complexes absorb near 1890 cm^{-1}.

In the cationic amido-hydride complex **12j,** the alkyne carbons appear the farthest downfield (about 250 ppm) indicating that the alkyne is a four-electron donor in this tungsten(IV) d^2 complex. The alkyne carbons of phenylimido complex **14a** appear the farthest upfield (near 140 ppm), suggesting that the alkyne is tending toward two-electron donor behavior in response to strong π donation from the cylindrically symmetrical π-donor ligand $[NPh]^{2-}$.

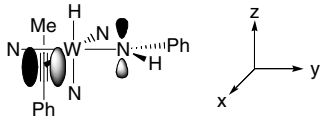

Fig. 9. Orbital interactions in $[Tp'(H)(PhCCMe)W(NHPh)][BAr'_4]$ (**12j**).

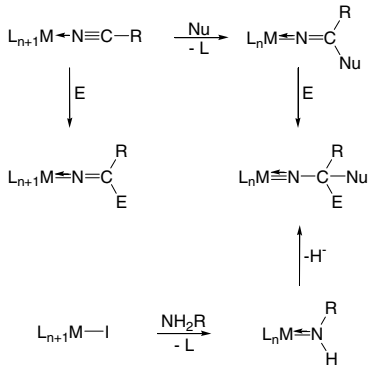
5. Summary

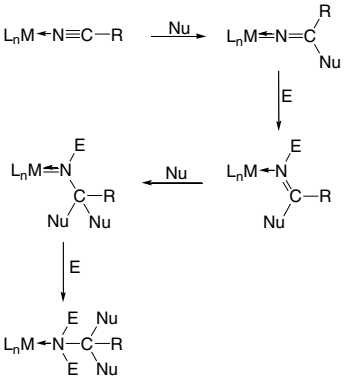
Interconversions among monodentate nitrogen donor ligands depend on the ancillary ligands. With classic two-electron donor ligands completing the coordination sphere, nitrogen lone-pair electrons with π character are immutably linked to the metal in a π bond, and they are therefore unavailable for ligand based reactions. Consequently, addition of electrophiles to an azavinylidene complex is directed to C_β leading to the formation of an imido complex. With a variable electron donor alkyne in the coordination sphere, the nitrogen lone pair with M–N π character is not essential for bonding with the metal, and as a result, these electrons are available for reaction with electrophiles. This allows protonation to occur at nitrogen and leads to the synthesis of imine and amine complexes in the stepwise reduction of a coordinated nitrile.

We can now describe a general reaction scheme starting from a metal nitrile complex, comparable to a metal acetylide, with classic two-electron donor ancillary ligands completing the coordination sphere. Addition of a nucleophile to C_β (β with respect to the metal) of the nitrile ligand leads to an azavinylidene complex and allows a second pair of nitrogen electrons to donate to the metal to form an M–N π bond to supplement the original M–N σ bond. Note that adherence to the 18-electron rule will require concomitant loss of a ligand in order to provide an acceptor orbital for N to M π donation in these azavinylidene complexes (Scheme 9). After ligand loss, the second nitrogen lone pair is required in order to maintain an 18-electron count at metal and consequently directs incoming electrophiles to C_β, utilizing the electrons from the N–C double bond [46,47]. A metal lone pair can then replace the π electrons at nitrogen forming an M–N triple bond. The metal is formally oxidized upon formation of an imido complex.

Imido complexes can also be accessed starting from free amines and a metal iodide complex. The first reaction forms an amido complex and is accompanied by loss of a ligand to accommodate π donation from the



Scheme 9.



Scheme 10.

amido lone-pair electrons. The amido complex can then be oxidized to the imido complex via net hydride removal from the NHR ligand. In a reaction revealing the dual sites suitable for lone pair electrons in nitrogen based ligand chemistry, addition of electrophiles to C_β of coordinated nitriles has recently been observed to give azavinylidene complexes; no ligand is lost in this reaction (Scheme 9) [48].

If one of the classic two-electron donor ligands in the reagent coordination sphere is replaced with a variable electron donor ligand such as an alkyne [36] or nitrosyl [36,49], the regioselectivity of the electrophile additions can be altered (Scheme 10). Concentrating on the alkyne as the adjacent variable π-donor ligand, the nitrogen can now either house its lone pair or share it with the metal via π donation – no loss of a ligand is required. The alkyne can either act as a lone π donor in a 2-center-2-electron π donor scheme with $\pi_\perp$ or it can act in concert with the nitrogen lone-pair electrons to form a 3-center-4-electron π bond. Flexible donation from the alkyne's $\pi_\perp$ orbital incites competition with the nitrogen lone pair for π donation into a metal dπ orbital. Electrophiles can add directly to nitrogen in such systems and this allows complete reduction of the nitrile ligand to an amine ligand [50].

Abstract

The osmium(III) aniline complex $TpOs(NH_2Ph)Cl_2$ (**$Os^{III}NH_2Ph$**) is formed on heating the triflate complex $[Cp^*_2Fe][TpOs^{III}(OTf)Cl_2]$ in the presence of aniline [Tp = hydrotris(1-pyrazolyl)borate]. It can also be prepared by reduction and protonation of the osmium(IV) anilido complex $TpOs(NHPh)Cl_2$ (**$Os^{IV}NHPh$**). The X-ray structure of **$Os^{III}NH_2Ph$** shows pseudo-octahedral molecules with an Os–N(aniline) bond length of 2.168(7) Å. Unlike most Os(III) coordination complexes, **$Os^{III}NH_2Ph$** is oxidized by O_2, yielding **$Os^{IV}NHPh$**. This reaction occurs readily in the presence of catalytic base. Under these conditions, the reaction proceeds by a stepwise mechanism of pre-equilibrium proton transfer (PT) forming **$Os^{III}NHPh^-$**, which then reacts with O_2 by outer-sphere electron transfer (ET). **$Os^{III}NH_2Ph$** is essentially air stable in the presence of acid, because this PT–ET mechanism is prevented.

1. Introduction

Amine complexes of ruthenium and osmium are one of the classic systems of coordination chemistry, extensively studied by Taube and his students, and others [1]. For osmium complexes, the most stable oxidation state is typically +3. Os(II) complexes without π-acid ligands are quite reducing and air sensitive (e.g., $Os(NH_3)_6^{2+}$), while Os(IV) complexes are usually very oxidizing (cf., $OsCl_6^{2-}$). The hydrotris(1-pyrazolyl)borate (Tp) ligand is a ''hard'' donor, in some ways similar to amines and halides. The osmium(IV) complex $TpOsCl_3$, for instance, is substitution inert and a good outer-sphere oxidant, much like $OsCl_6^{2-}$ [2]. The osmium(III) complex $TpOs(NH_3)Cl_2$ follows this pattern, as it is air stable and difficult to reduce or oxidize ($E_{1/2}$: $Os^{IV/III}$, +0.65 V; $Os^{III/II}$, −1.32 V (irrev.) vs. $Cp_2Fe^{+/0}$ in MeCN [2]).

Described here is the surprising result that the osmium(III) aniline complex $TpOs(NH_2Ph)Cl_2$ (**$Os^{III}NH_2Ph$**) is quite air sensitive in the presence of even trace amounts of base. To our knowledge, this is only the second report of dioxygen-oxidation of an osmium(III) complex to generate osmium(IV), the first being a brief mention by Taube and coworkers that $Cs[Os(NH_3)Cl_5]$ can be prepared using O_2 [3]. Mechanistic studies of this unusual reaction are presented. Oxidations of metal complexes by O_2 (autoxidations) are of particular importance because of the strong interest in using metals to catalyze aerobic oxidations [4]. We have found that O_2 can deliver oxidative equivalents in unusual nucleophilic aromatic substitution reactions of the osmium(IV) anilido complex $TpOs(NHPh)Cl_2$ (**$Os^{IV}NHPh$**) [5,6]. **$Os^{III}NH_2Ph$** was briefly reported in this context [5].

The oxidation of **$Os^{III}NH_2Ph$** to **$Os^{IV}NHPh$** by O_2 is thermodynamically possible because it involves loss of a proton as well as an electron. Such coupling of proton and electron transfers is critical in a wide range of chemical processes, as shown, for instance, by Meyer and coworkers for ruthenium and osmium polypyridyl complexes [7]. Proton, electron, and hydrogen atom self-exchange reactions involving **$Os^{III}NH_2Ph$** and **$Os^{IV}NHPh$** are described elsewhere [8]. In the autoxidation of **$Os^{III}NH_2Ph$**, proton transfer (PT) is critical to the mechanism as well as the thermodynamics, as the preferred pathway involves stepwise proton and then electron transfers.

2. Experimental

2.1. General considerations

All manipulations were performed under an inert atmosphere using standard vacuum line and nitrogen-filled glove box techniques, unless otherwise noted. NMR spectra were acquired on Bruker DRX-500 spectrometers at 298 K. Temperature calibration of the NMR probes was accomplished by Van Geet's method [9]. Proton NMR chemical shifts were referenced to the residual ^{1}H NMR signals of the deuterated solvents and are reported vs. TMS. IR spectra were obtained as CH_2Cl_2 solutions in a ZnSe solution cell, or as KBr pellets, using a Perkin–Elmer 1720 FTIR spectrophotometer. Elemental analyses were performed by Atlantic Microlab, Inc. in Norcross, Georgia. Absorption spectra were obtained using a HP 8453 UV–Vis spectrophotometer equipped with a temperature-controlled multicell apparatus. Kinetic data were obtained using this HP spectrophotometer or with an OLIS rapid scanning monochromator equipped with an OLIS USA stopped-flow apparatus. Cyclic voltammetry measurements were made with a BAS CV-27. The electrochemical cell typically contained a ~5 mM solution of analyte in acetonitrile (0.1 M $^nBu_4NPF_6$), a $Ag/AgNO_3$ reference electrode, a platinum disk working electrode and a platinum wire auxiliary electrode. Ferrocene was used as an internal standard.

2.2. Materials

All solvents used for the syntheses were degassed and dried according to standard procedures [10]. Acetonitrile was used as obtained from Burdick and Jackson (low-water brand) and stored in an argon-pressurized stainless steel drum plumbed directly into a glove box. Deuterated solvents were purchased from Cambridge Isotope Laboratories, degassed, dried, and distilled by vacuum transfer prior to use. MeCN-d_3 was dried by successively stirring over CaH_2, followed by P_2O_5 and again over CaH_2 to remove trace acids. Reagents were typically purchased from Aldrich and used as received unless otherwise noted. Anilines were distilled from KOH or CaH_2 under reduced pressure and thoroughly degassed prior to use. Sodium naphthalenide was prepared by literature methods [11]. $TpOs(NHPh)Cl_2$ (**$Os^{IV}NHPh$**) [12], $TpOs(OTf)Cl_2$ [2,13], $TpOs(N)Cl_2$ [14] and $[^nBu_4N]^+[TpOs(NHPh)Cl_2]^-$ (**$Os^{III}NHPh^-$**) [8] were prepared according to published procedures. Purity was checked by ^{1}H NMR spectroscopy.

2.3. $TpOs(NH_2Ph)Cl_2$ ($Os^{III}NH_2Ph$)

A glass flask with a Teflon stopcock was charged with $TpOs(OTf)Cl_2$ (20 mg, 32 μmol), Cp^*_2Fe (11 mg, 34 μmol) and CH_2Cl_2 (5 ml). Aniline (15 μl, 160 μmol) was added to the resulting mint-green solution and the reaction mixture was heated at 76 °C for 14 h. CH_2Cl_2 was removed under vacuum and the faint orange product was dissolved in 8 ml C_6H_6 and decanted off the insoluble green $Cp^*_2Fe^+OTf^-$. Following removal of C_6H_6 by sublimation, the solids were washed twice with pentane to remove excess aniline. Small, light orange crystals were obtained by slow diffusion of pentane into a saturated CH_2Cl_2 solution. The crystals were dried in vacuo and quickly washed with minimal MeCN to give **$Os^{III}NH_2Ph$** in moderate yield (10 mg, 17 μmol, 53%). The entire procedure was strictly anaerobic. **$Os^{III}NH_2Ph$** can be purified by silica gel chromatography under argon using 1:1 hexane-CH_2Cl_2 to 10:1 CH_2Cl_2-acetone. ^{1}H NMR (MeCN-d_3): [all resonances are broad, full-width half-maximum (FWHM) 68–1100 Hz; NH_2Ph peaks assigned by comparison with materials prepared from $NH_2C_6D_5$ or $ND_2C_6D_5$] δ 3.3 (1H), 1.7 (2H), −7.7 (2H, NH_2Ph); 64.2 (2H, N<u>H</u>$_2$Ph); 26.4 (1H); 7.6 (1H); 5.1 (2H); −0.8 (2H); −3.4 (1H); −48.2 (2H); −51.1 (1H). IR (CH_2Cl_2): 2504 (m, ν_{B-H}); 1493 (m), 1406 (s), 1309 (m), 1211 (s), 1188 (w), 1118 (s), 1071 (w), 1046 (vs), 987 (w), 654 (w), 615 (m, all Tp); 1602 (w); 1569 (w); 788 (w). *Anal.* Calc. (Found) for $C_{15}H_{17}BCl_2N_7Os$: C, 31.76 (31.76, 31.92); H, 3.02 (2.84, 2.87); N, 17.28 (17.18, 17.35).

2.4. pK_a of $Os^{III}NH_2Ph$

A quartz cuvette with a resealable Teflon valve was charged with 2.8 ml of a MeCN solution containing 91% **$Os^{III}NH_2Ph$** and 9% **$Os^{IV}NHPh$** (by ^{1}H NMR) for a total $[Os] = 3.2 \times 10^{-4}$ M. A 9.9×10^{-2} M solution of quinuclidine ($pK_a = 19.51$ [15]) in MeCN was prepared such that 8 μl corresponded to 1 molar equivalent of base per **$Os^{III}NH_2Ph$**. Absorption spectra were acquired over a range of quinuclidine concentrations, from 1–130 molar equivalents based on **$Os^{III}NH_2Ph$**, yielding K_{eq} and therefore the desired pK_a. Extinction coefficients for **$Os^{III}NHPh^-$** were determined by stoichiometric addition of DBU ($pK_a = 24.32$ [16]) in MeCN to **$Os^{III}NH_2Ph$** solutions under similar conditions and agree with those obtained from isolated samples of **$Os^{III}NHPh^-$**. Addition of >1 equiv DBU results in no further observed spectral changes. **$Os^{IV}NHPh$** is unaffected by quinuclidine under these conditions.

2.5. Stopped flow kinetics of $Os^{III}NHPh^-$ and O_2

A 0.23 mM solution of **$Os^{III}NHPh^-$** in degassed MeCN was loaded into one mixing syringe in the stopped flow apparatus. Oxygen gas was bubbled for 20 min through a separate sample of MeCN, which was subsequently loaded into the other mixing syringe. The data for the obtained runs were fit at 406.7 nm for a rise–fall

(A → B → C) mechanism using the OLIS software. The A → B phase was assigned as consumption of **Os^{III}-NHPh**$^{-}$, based on the spectrum at the end of this phase. B → C apparently is due to further reactions of the initial products.

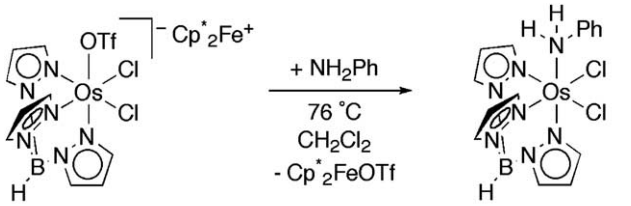
2.6. Crystal structure of $Os^{III}NH_2Ph$

A red, prism-shaped crystal $0.23 \times 0.08 \times 0.06$ mm was grown by slow evaporation of an acetonitrile-d_3 solution of **Os^{III}NH$_2$Ph** and mounted on a glass capillary with oil. Data were collected at −143 °C with one set of φ scans. Crystal-to-detector distance was 30 mm and exposure time was 40 s per degree for all sets. The scan width was 1.0°. Data collection was 95.2% complete to 28.30° in θ. A total of 12,455 partial and complete reflections were collected of which 3619 reflections were symmetry independent and the $R_{int} = 0.060$ indicated that the quality of data was of better than average quality. The data were integrated and scaled using hkl-2000, a program that applies a multiplicative correction factor (S) to the observed intensities (I). S is calculated from the scale and B factor determined for each frame, which has the form: $S = (e^{-2B(\sin^2\theta)/\lambda^2})$/scale. Solution by direct methods (SIR97) produced a complete heavy atom phasing model consistent with the proposed structure. All hydrogen atoms, except the two on N7 were placed using a riding model. The latter two were located from the Fourier difference map and their locations refined isotropically by full-matrix least-squares (SHELXL-97). All non-hydrogen atoms were refined anisotropically. The one restraint used is a floating origin restraint, which is generated automatically by the SHELXL-97 program. This restraint effectively fixed the X-ray 'center of gravity' of the structure in the polar axis direction.

3. Results

3.1. Synthesis and characterization

The Os(III) aniline complex TpOs(NH$_2$Ph)Cl$_2$ (**Os^{III}NH$_2$Ph**) is obtained from [Cp*$_2$Fe][TpOs^{III}(OTf)-Cl$_2$] and aniline (≈5 equiv.) in CH$_2$Cl$_2$ at 76 °C (Eq. (1); Tp = hydrotris-[1-pyrazolyl]borate). As described earlier in the preparations of



(1)

other TpOs^{III}(L)Cl$_2$ complexes, heating is required to displace triflate from the anionic [TpOs^{III}(OTf)Cl$_2$]$^-$ [2]. This illustrates the remarkable substitution inertness of these TpOs complexes. Kirchner and coworkers have previously shown the strongly substitution inert character of TpRu complexes [17]. **Os^{III}NH$_2$Ph** is also substitution inert, as it is stable to excess triflic acid in MeCN-d_3 solution for at least days at ambient temperatures [8]. **Os^{III}NH$_2$Ph** can be purified by recrystallization or by anaerobic chromatography on silica.

The single crystal X-ray structure of **Os^{III}NH$_2$Ph** contains isolated molecules with pseudo-octahedral coordination (Fig. 1). Crystallographic parameters and selected bond lengths and angles are collected in Tables 1 and 2. The Os–N(7) distance of 2.168 (7) Å is close to those in the *ortho-t*-butylaniline and ethylamine analogues [8,14]. These Os–N(aniline) distances are substantially longer than the ≈1.9 Å Os^{IV}-anilide distances in **Os^{IV}NHPh** and related complexes [8,14]. The orientation of the aniline ligand in **Os^{III}NH$_2$Ph** is such that the osmium atom lies well out of the plane of aromatic ring, as indicated by the Os–N(7)–C(10)–C(11) torsion angle of 103.7(9)°. This contrasts with the structures of Os(IV) anilide derivatives where the osmium, the nitrogen, and the aromatic ring are close to coplanar, with Os–N–C–C dihedral angles near 0° or 180°. The coplanar conformation allows π-conjugation from Os to N to the aromatic ring, and **Os^{IV}NHPh** is probably best described as having an Os=N double bond [5,6,19]. The aniline complex **Os^{III}NH$_2$Ph** simply contains a dative Os←N bond.

The characterization of **Os^{III}NH$_2$Ph** as an Os(III) aniline complex is supported by spectroscopic and analytical data. ^{1}H NMR spectra contain broad, paramagnetically shifted resonances (δ 64 to −51 ppm,

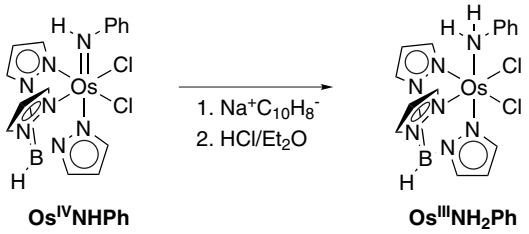
N(3)–Os–N(5)	87.7(2)		

FWHM 68–1100 Hz) consistent with a low-spin d^5 configuration. Phenyl resonances for **$Os^{III}NH_2Ph$** were assigned by comparison with deuterium-labeled materials prepared from $[Cp^*_2Fe]^+[TpOs(OTf)Cl_2]^-$ and NH_2Ph-d_5 or ND_2Ph-d_5.

Deprotonation of **$Os^{III}NH_2Ph$** with DBU (1,8-diazabicyclo[5.4.0]undec-7-ene) in acetonitrile ($pK_a = 24.32$ [16]) gives the Os(III) anilide complex $[TpOs(NHPh)Cl_2]^-$ (**$Os^{III}NHPh^-$**). The $^nBu_4N^+$ salt of this anion has previously been prepared by reduction of **Os^{IV}(NHPh)** with sodium naphthalenide and cation exchange [8]. Titrations of **$Os^{III}NH_2Ph$** with quinuclidine in acetonitrile (1–130 molar equiv; $pK_a = 19.51$ [15]) were monitored at 406 and 582 nm (the λ_{max} values for **$Os^{III}NHPh^-$**). Concentrations of each species were calculated from the absorbances and used to determine K_{eq} at each point in the titration. Addition of pK_{eq} to the pK_a of quinuclidine gives pK_a [**$Os^{III}NH_2Ph$**] $= 22.5 \pm 0.1$. The relatively small error reflects the good agreement in calculated pK_a values at each titration point.

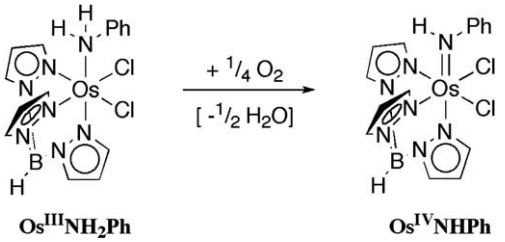
The N–H bond dissociation enthalpy in **$Os^{III}NH_2Ph$** is calculated via a thermochemical cycle [18] to be D(N–H) $= 66 \pm 1$ kcal mol^{-1} using the pK_a above and the reported quasi-reversible $Os^{IV/III}$ redox couple for **$Os^{IV}NHPh$** at −1.05 V vs. $Cp_2Fe^{+/0}$ in MeCN (referenced internally) [8,19]. Application of this cycle assumes that the entropy difference between **$Os^{III}NH_2Ph$** and **$Os^{IV}NHPh$** is negligible. The thermochemical cycle mirrors an alternative preparation of **$Os^{III}NH_2Ph$**, by sequential reduction and protonation of **$Os^{IV}NHPh$** using sodium naphthalenide then HCl/Et_2O (Eq. (2)). Cyclic voltammograms of **$Os^{III}NH_2Ph$** show an irreversible oxidation wave at +0.48 V. The irreversibility is presumably due to rapid deprotonation of the highly acidic **$Os^{IV}NH_2Ph^+$** formed [19].



(2)

3.2. Reaction of $Os^{III}NH_2Ph$ with O_2

Exposure of solutions of **$Os^{III}NH_2Ph$** in MeCN-d_3 or chloroform-d to 1 atm O_2 shows complete loss of the characteristic ^{1}H NMR resonances for **$Os^{III}NH_2Ph$** with concomitant growth of resonances for the Os(IV) anilide **$Os^{IV}NHPh$** (Eq. (3)).



(3)

Concentrations of **$Os^{IV}NHPh$** and **$Os^{III}NH_2Ph$** are determined by integration against an internal standard and the sum of the concentrations is constant throughout the reaction indicating that no other osmium-containing products are formed. (Resonances for **$Os^{IV}NHPh$** and **$Os^{III}NH_2Ph$** are not shifted or broadened significantly during the reaction because H-atom exchange between these species is slow [8].) Quantitative conversion of **$Os^{III}NH_2Ph$** to **$Os^{IV}NHPh$** with O_2 has also been observed by UV–Vis spectroscopy, monitoring the change from light orange **$Os^{III}NH_2Ph$** to dark red

$Os^{IV}NHPh$. To balance Eq. (3) the H-atom removed from **$Os^{III}NH_2Ph$** is presumed converted to H_2O but this has not been observed by NMR.

^1H NMR kinetic data for the disappearance of **$Os^{III}NH_2Ph$** and simultaneous appearance of **Os^{IV}-NHPh** are fit well by an integrated first order rate expression (an example is shown Fig. 2). This indicates that reaction is first order in **$Os^{III}NH_2Ph$**. The derived rate constants, however, are irreproducible between samples of **$Os^{III}NH_2Ph$**. Reactions with O_2 are slow using samples of **$Os^{III}NH_2Ph$** that were purified by recrystallization, and have been scrupulously kept anaerobic. These reactions take weeks to reach completion. In contrast, complete conversion to **$Os^{IV}NHPh$** under 1 atm O_2 in <10 h is observed for samples of **$Os^{III}NH_2Ph$** that have been chromatographed or have briefly been exposed to air. Similar irreproducible rates have also been observed for other reactions of **$Os^{III}NH_2Ph$**, both its self-exchange with **$Os^{IV}NHPh$** and its reaction with TEMPO [8]. In these cases as well, the preparative route to **$Os^{III}NH_2Ph$** is the critical variable [8]. Trace acid impurities appear to be present when strictly anaerobic conditions are maintained during synthesis of **Os^{III}-NH_2Ph**. Samples that are exposed briefly to atmospheric conditions or are isolated from chromatography on silica under argon have trace base impurities.

Experiments with added reagents confirm that the O_2 oxidation is catalyzed by bases and slowed by acid. MeCN solutions of **$Os^{III}NH_2Ph$** containing sub-stoichiometric Et_2NH (0.3–0.5 equiv) react with 1 atm O_2 in seconds, with the color change from orange to dark red indicating conversion to **$Os^{IV}NHPh$**. Complete conversion to **$Os^{IV}NHPh$** is observed upon acquisition of an initial ^1H NMR spectrum (≈12 min). The second order rate constant under these conditions can be estimated as $k_3 \geqslant 10\ M^{-1}\ s^{-1}$, based on a half life of less than ≈10 s ($k_{obs} \geqslant 10^{-1}\ s^{-1}$) and $[O_2] = 8$ mM in MeCN at 1 atm O_2 [20]. Conversely, samples of **$Os^{III}NH_2Ph$** isolated from silica gel, that would normally react quickly with air, are stable for days under 1 atm O_2 when pretreated with acetic acid or sub-stoichiometric HCl/Et_2O.

4. Discussion

Air oxidation of **$Os^{III}NH_2Ph$** to **$Os^{IV}NHPh$** (Eq. (3)) is not typical of Os(III) complexes. It is unexpected given the high redox potential of **$Os^{III}NH_2Ph$** ($E_{p,a} = +0.48$ vs. $Cp_2Fe^{+/0}$ in MeCN) and the oxidizing nature of related Os(IV) complexes [2,13]. This reaction is downhill only because a proton is transferred as well as an electron. Using the N–H bond strength of 66 kcal mol^{-1} in **$Os^{III}NH_2Ph$** and tabulated heats of formation for O_2, H· and H_2O (using ΔH_f° values from [21], the autoxidation of **$Os^{III}NH_2Ph$** is enthalpically favored by 20 kcal mol^{-1} (Eq. (4)).

$$\Delta H^\circ = -20\ \text{kcal mol}^{-1}\ \text{for}$$

$$\textbf{Os}^{\textbf{III}}\textbf{NH}_2\textbf{Ph} + 1/4\ O_2(g) \rightarrow \textbf{Os}^{\textbf{IV}}\textbf{NHPh} + 1/2\ H_2O\ (l) \quad (4)$$

The formal removal of H· from **$Os^{III}NH_2Ph$** by O_2 to form **$Os^{IV}NHPh$** could occur by concerted H· transfer (HAT) or by initial electron transfer (ET) (Scheme 1). Proton-coupled ET processes such as this could, in general, also occur by initial PT. However, O_2 does not act as a base in solution. Scheme 1 (and Scheme 2 below) show only initial mechanistic steps, leading to $O_2^{\cdot-}$ or $HO_2^{\cdot}$, because the subsequent reactions leading to water should be fast. ET from **$Os^{III}NH_2Ph$** to O_2, the vertical line in Scheme 1, is very unfavorable: it is uphill by ≈1.6 V or $\Delta G^\circ \cong +37$ kcal mol^{-1}. This is based on $E_{1/2}$ for $O_2^{0/\cdot-}$ of −1.11 V and the +0.48 V $E_{p,a}$ for **$Os^{III}NH_2Ph$** (both vs. $Cp_2Fe^{+/0}$ in MeCN) [22]. Concerted HAT

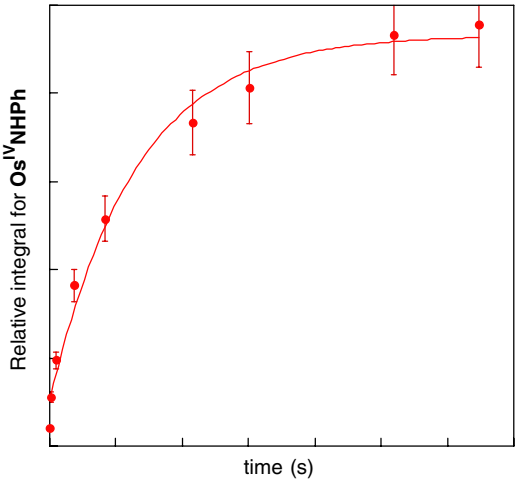


Fig. 2. First order fit for the appearance of **$Os^{IV}NHPh$** as a function of time from reaction of **$Os^{III}NH_2Ph$** with O_2 in chloroform-d at 298 K.

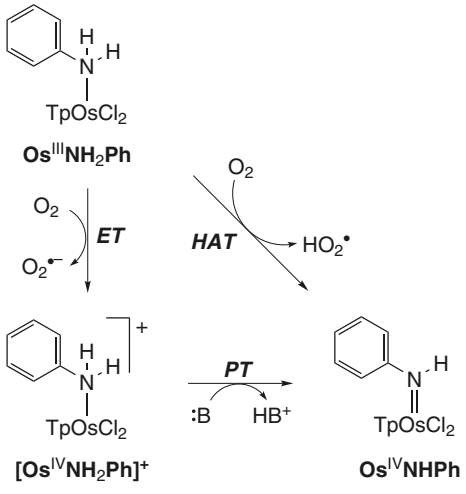
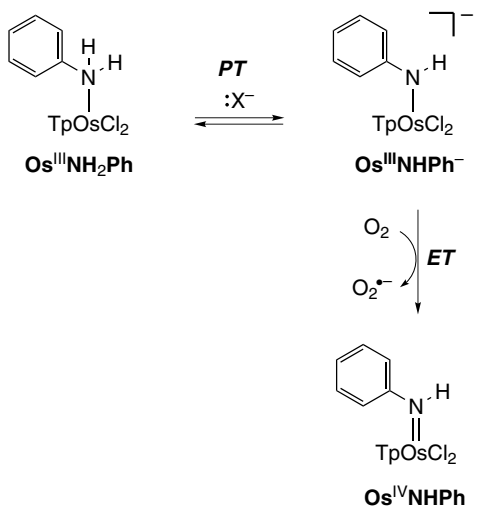


Scheme 1. Possible mechanisms for uncatalyzed net H· transfer from **$Os^{III}NH_2Ph$** to O_2.



Scheme 2. Mechanism for base-catalyzed oxidation of $\mathbf{Os^{III}NH_2Ph}$ by O_2.

from $\mathbf{Os^{III}NH_2Ph}$ to O_2, the diagonal in Scheme 1, is similarly quite uphill. Addition of H· to O_2 makes a 51.6 kcal mol^{-1} O–H bond in $HO_2^{\cdot}$ [21,23], so HAT from $\mathbf{Os^{III}NH_2Ph}$ to O_2 has $\Delta H^{\cdot}(\cong \Delta G^{\cdot}) = +14$ kcal mol^{-1}. This indicates a very slow rate, since HAT from $\mathbf{Os^{III}NH_2Ph}$ to TEMPO· (2,2,6,6-tetramethyl-1-piperidnyloxyl) is 4 kcal mol^{-1} *downhill* and still occurs fairly slowly, with $k_{HAT} = 4 \times 10^{-2}$ M^{-1} s^{-1}. These arguments explain why the uncatalyzed reaction of $\mathbf{Os^{III}NH_2Ph}$ and O_2 is very slow and $\mathbf{Os^{III}NH_2Ph}$ is stable to air for days in the presence of added acid. Both possible initial steps are very unfavorable.

Addition of a catalytic base to $\mathbf{Os^{III}NH_2Ph}$, however, leads to very rapid reaction with O_2. This is because a new pathway is now accessible: initial PT followed by ET (Scheme 2). The base rapidly generates a small equilibrium amount of $\mathbf{Os^{III}NHPh^-}$, which is much easier to oxidize, with an $Os^{IV/III}$ redox potential couple of −1.05 V (vs. $Cp_2Fe^{+/0}$ in MeCN [19]). This dramatic shift in redox potential results from the $N\ p_\pi - Os\ d_\pi$ antibonding interaction in $\mathbf{Os^{III}NHPh^-}$ and the Os–N π bond that is formed in $\mathbf{Os^{IV}NHPh}$ [8,19]. ET from $\mathbf{Os^{III}NHPh^-}$ to O_2 (Eq. (5)) is roughly isoergic

$$\mathbf{Os^{III}NH_2Ph^-} + O_2 \rightarrow \mathbf{Os^{IV}NH_2Ph} + O_2^- \quad E = +0.06\ \text{V} \tag{5}$$

($\Delta G^\circ = +1.3$ kcal mol^{-1}, $K_5 = 0.1$). Reaction 5 has been examined directly: isolated ^{n}Bu$_4$N[$\mathbf{Os^{III}NHPh}$] [8] reacts very rapidly with O_2 in MeCN solution to give an uncharacterized mixture of products. Monitoring the reaction by stopped-flow gives a tentative rate constant $k_5 = (3.3 \pm 0.5) \times 10^4$ M^{-1} s^{-1} (see Section 2).

In more quantitative terms, Scheme 2 implies the rate law in Eq. (6). As noted above, the reaction of $\mathbf{Os^{III}NH_2Ph}$ (10 mM) with Et_2NH (5 mM) and O_2 (8 mM) gives $\mathbf{Os^{IV}NHPh}$ with $k_3 \geqslant 10$ M^{-1} s^{-1}. Under these conditions, rapid pre-equilibrium PT gives $[\mathbf{Os^{III}NHPh^-}] = [Et_2NH_2^+] = 0.09$ mM based on $K_{eq} = 1.6 \times 10^{-4}$ ($\Delta pK_a = -3.8$ for $\mathbf{Os^{III}NH_2Ph}$ + Et_2NH). Following Eq. (6),

$$-\frac{[\mathbf{Os^{III}NH_2Ph}]}{dt} = K_{eq,PT}k_5[\mathbf{Os^{III}NH_2Ph}][O_2]\frac{[\text{base}]}{[\text{Hbase}^+]} \tag{6}$$

$k_3 = K_{eq,PT}k_5[Et_2NH][Et_2NH_2^+]^{-1}$. If we take, for simplicity, $[Et_2NH_2^+]$ to be constant through the reaction (consistent with the observed pseudo-first order kinetics), the observed k_3 implies that $k_5 \geqslant 10^4$ M^{-1} s^{-1}. This is consistent with the k_5 directly measured by stopped flow, supporting the mechanism in Scheme 2.

The value of k_5 is reasonably close to that estimated using the Marcus cross-relation (Eq. (7)) [24].[1] Electron self-exchange between $\mathbf{Os^{III}NHPh^-}$ and $\mathbf{Os^{IV}NHPh}$ occurs with

$$k_{Os/s.e.} = k_{XY} = \sqrt{k_{XX}\ k_{YY}\ K_{XY}\ f_{XY}} \tag{7}$$

$(5.5 \pm 0.8) \times 10^4$ M^{-1} s^{-1} at 298 K in MeCN-d_3 [8]. To our knowledge, the O_2/O_2^- self-exchange rate constant in acetonitrile has not been reported. The value in water has been established to be $k_{O_2+O_2^-/H_2O} = 450 \pm 160$ M^{-1} s^{-1} [25], after a period of some uncertainty [26]. Using this value, the value K_5 above and $f = 1$, k_5(calculated) $= 1.6 \times 10^3$ M^{-1} s^{-1}, compared to the measured $k_5 \geqslant 10^4$ M^{-1} s^{-1}. Better agreement would require that the O_2/O_2^- self-exchange rate be faster in MeCN than in water, $k_{O_2+O_2^-/MeCN} \cong 10^5$ M^{-1} s^{-1}.

5. Conclusions

The hydrotris(1-pyrazolyl)borate osmium(III) aniline complex $TpOs(NH_2Ph)Cl_2$ ($\mathbf{Os^{III}NH_2Ph}$) has been prepared by substitution of aniline for triflate and by reduction and protonation of the osmium(IV) anilido complex $TpOs(NHPh)Cl_2$ ($\mathbf{Os^{IV}NHPh}$). Surprisingly, $\mathbf{Os^{III}NH_2Ph}$ is air sensitive, reacting with O_2 to give $\mathbf{Os^{IV}NHPh}$. This reaction is catalyzed by bases. In the presence of base, formation of $\mathbf{Os^{IV}NHPh}$ from $\mathbf{Os^{III}NH_2Ph}$ and O_2 proceeds by a stepwise mechanism of initial PT to give $\mathbf{Os^{III}NHPh^-}$, which then reacts with O_2 by outer-sphere ET. In the presence of acid, when the concentration of $\mathbf{Os^{III}NHPh^-}$ is suppressed, the PT–ET mechanism is effectively shut-off. The stepwise mechanism is attractive in this system because the individual PT and ET steps have small intrinsic barriers while HAT is intrinsically slow [8].

[1] $\ln f_{XY} \cong \frac{(\ln K_{XY})^2}{4\ln(\frac{k_{XX}k_{YY}}{Z^2})}$. Corrections to Eq. (7) to account for the energy required to bring together the reactants and products (work terms) are not needed here as both the reactants and products have one uncharged species.

The origin of the unusual air sensitivity of $\mathbf{Os^{III}NH_2Ph}$ vs. Taube-type coordination complexes is not the Tp ligand, but rather the involvement of an aniline ligand. Aniline is much more acidic than ammonia or alkylamines, so a pathway involving deprotonation is much more facile. Deprotonation of the Os(III) complex lowers the redox potential dramatically, because the $\mathbf{Os^{III}NHPh^-}$ is destabilized by a π conflict between the anilide p_π and Os t_{2g} orbitals while $\mathbf{Os^{IV}NHPh}$ is stabilized by d–p π bonding. With this low redox potential, ET to dioxygen is roughly thermoneutral and proceeds rapidly.

A short ride on scorpionates: from d- to f-elements

António Paulo, João D.G. Correia, Maria P.C. Campello, Isabel Santos *

Departamento de Química, Instituto Tecnológico e Nuclear, Estrada Nacional 10, P-2686-953 Sacavém Codex, Portugal

Received 3 June 2003; accepted 8 September 2003

Abstract

This paper presents an overview of progress involving group 7 elements and actinides with scorpionate ligands. This includes oxides, polyhydrides and carbonyls of group 7 elements and any type of compounds of actinides (III) and (IV). Synthetic procedures, reactivity and structural data are reviewed.

Keywords: Scorpionate ligands; Technetium; Rhenium; Uranium

1. Introduction

All along the periodic table, a rich coordination chemistry has been developed based on the hard scorpionate ligands [1]. Such diversity is due to the easy tunning of the electronic, steric and coordinating properties of scorpionates, achieved by changing the nature of the groups attached to the boron atom (R) and/or by introducing various sterically bulky and/or coordinating groups in the 3- and 5-positions of the pyrazolyl ring (Scheme 1) [1].

Due to their scientific interests, the authors of this manuscript decided to participate in this special issue of Polyhedron with a *short ride on scorpionates*, focused on group 7 elements and actinides. Particular emphasis is given to oxides, polyhydrides and carbonyls of group 7 elements, while for the actinides any type of compound will be reviewed. From group 7, rhenium will be the most extensively described, as oxides, polyhydrides and carbonyls anchored by scorpionates were mainly studied with this element, with a view on stoichiometric or catalytic transformation of substrates [2]. Similar to rhenium, the chemistry of technetium scorpionates is much more limited. This is certainly due to its radioactive nature, although the element is quite relevant to nuclear medicine. Manganese, due to its electronic properties, tends to form mainly homoleptic compounds, which will not be discussed here, but were reviewed elsewhere [1]. Due to accessibility and safety reasons, uranium has been the more extensively studied actinide, and these studies involved mainly U(III) and (IV) compounds anchored by homo- and heteroscorpionates of the first and second generation.

This contribution updates two previous reviews by I. Santos and coworkers [3] one on rhenium poly(pyrazolyl)borates and the other covering both the 4f- and 5f-element chemistry [4]. Special attention will be given to more recent achievements, but to provide some context to the current work, some overlap between this review and its predecessors is unavoidable.

2. Group 7 scorpionate complexes

2.1. M(VII) trioxides

Air-stable M(VII) trioxides [Tp′MO_3] (M = Re, Tp′ = Tp (**1a**), pzTp (**1b**), Tp*(**1c**), PhTp (**1d**); M = Tc, Tp′ = Tp (**1a′**), Tp*(**1c′**)) have been prepared by reacting M_2O_7 (M = Re, Tc) with sodium or potassium salts of the corresponding homoscorpionates [5–9]. Conversion of Re_2O_7 to $ReO_3(O_2CCF_3)$, followed by reaction with KTp*, is an even more efficient alternative for the synthesis of **1c** (Scheme 2) [10].

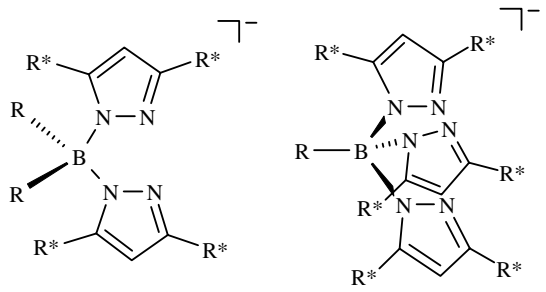


Scheme 1.

Compounds **1a** and **1a′** are also accessible, although in moderate yields, by nitric acid oxidation of $[TpMOCl_2]$ (**3a**) (M = Re, Tc) or by reacting $[MO_4]^-$ (M = Re, Tc) with excess of NaTp in an acidified alcoholic solution [11,12].

The structures of complexes **1a**, **1b** and **1d** were determined by X-ray diffraction analysis, and found to be almost superimposable. The metal center is six-coordinate by three oxygen atoms and the nitrogens of the tridentate homoscorpionate. The coordination geometry around the metal is pseudo-octahedral and within each compound the Re–N distances (mean values: 2.231(3) Å (**1a**), 2.217(6) Å (**1b**) and 2.222(7) Å (**1d**)) are almost identical. The Re–O bond distances of ca. 1.712(2) Å (**1a**), 1.714(6) Å (**1b**) and 1.710(8) Å (**1d**) are consistent with conventional double bonds [5,7,8]. In the IR spectra of the M(VII) trioxides (M = Re, Tc) the stretching vibrations associated with the M=O bonds appear in the range 890–944 and 853–921 cm^{-1} for the Re and Tc complexes, respectively [5–9]. The solution ^1H NMR spectra of **1a**–**d** are consistent with the respective molecular structure indicating a static behavior for these compounds and precluding, in the case of **1b**, the involvement of the fourth uncoordinated pyrazolyl ring in any scrambling process [7].

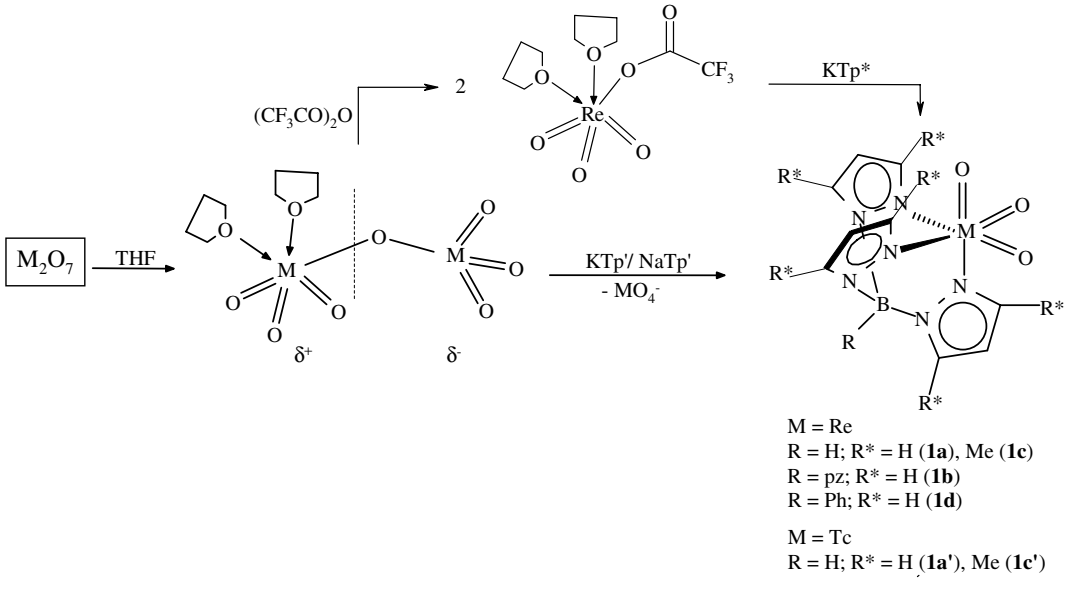
2.2. M(V) oxides

2.2.1. Key compounds

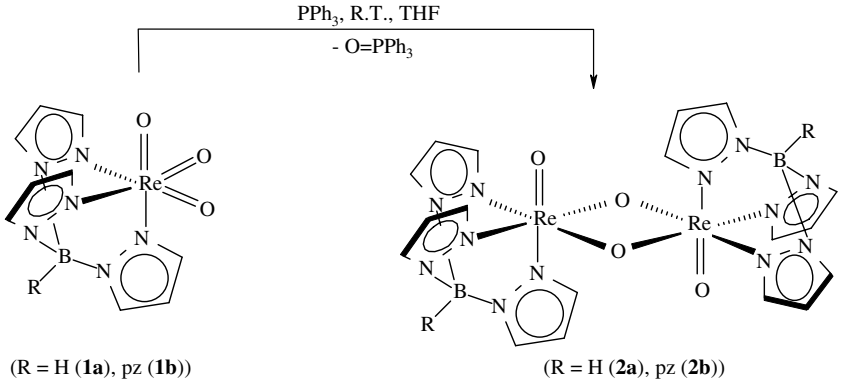
As would be expected for complexes with the metal in the highest oxidation state, the chemistry of the trioxides **1a**–**d** is dominated by reductive/deoxygenation processes, that led to a certain number of monomeric or dimeric key compounds as entry into Re(V) chemistry, namely $[Tp'ReO(\mu\text{-}O)]_2$ (Tp′ = Tp (**2a**), pzTp (**2b**)), $[Tp'ReOCl_2]$ (Tp′ = Tp (**3a**), pzTp (**3b**), Tp* (**3c**)), [Tp*ReO(OH)Cl] (**4**) and [TpReO(Cl)I] (**5**).

The dimers, $[Tp'ReO(\mu\text{-}O)]_2$ (Tp′ = Tp (**2a**), pzTp (**2b**)), were obtained by reacting $[Tp'ReO_3]$ (Tp′ = Tp (**1a**), pzTp (**1b**)) with PPh_3 in THF (Scheme 3) [13,14]. Interestingly, this type of compound was never identified when the scorpionate involved was Tp*. In this case, Gable et al. [15–17] considered the fragment $\{Tp^*ReO_2\}$ as being the reduced species, which does not dimerize due to the steric bulkiness of the Tp* ligand.

The formulation of **2a**,**b** was mainly based on the spectroscopic properties and reactivity of these compounds. In particular, their IR and mass spectra were consistent with the presence of the $[ReO(\mu\text{-}O)]_2$ unit [13,14]. Compounds **2a**,**b** are rare examples of scorpionate rhenium complexes exhibiting fluxional behavior in solution. Static ^1H NMR spectra could be obtained at low temperature, presenting patterns compatible with the tridentate coordination mode of the scorpionates and with a six-coordination environment around the metal [13,14].

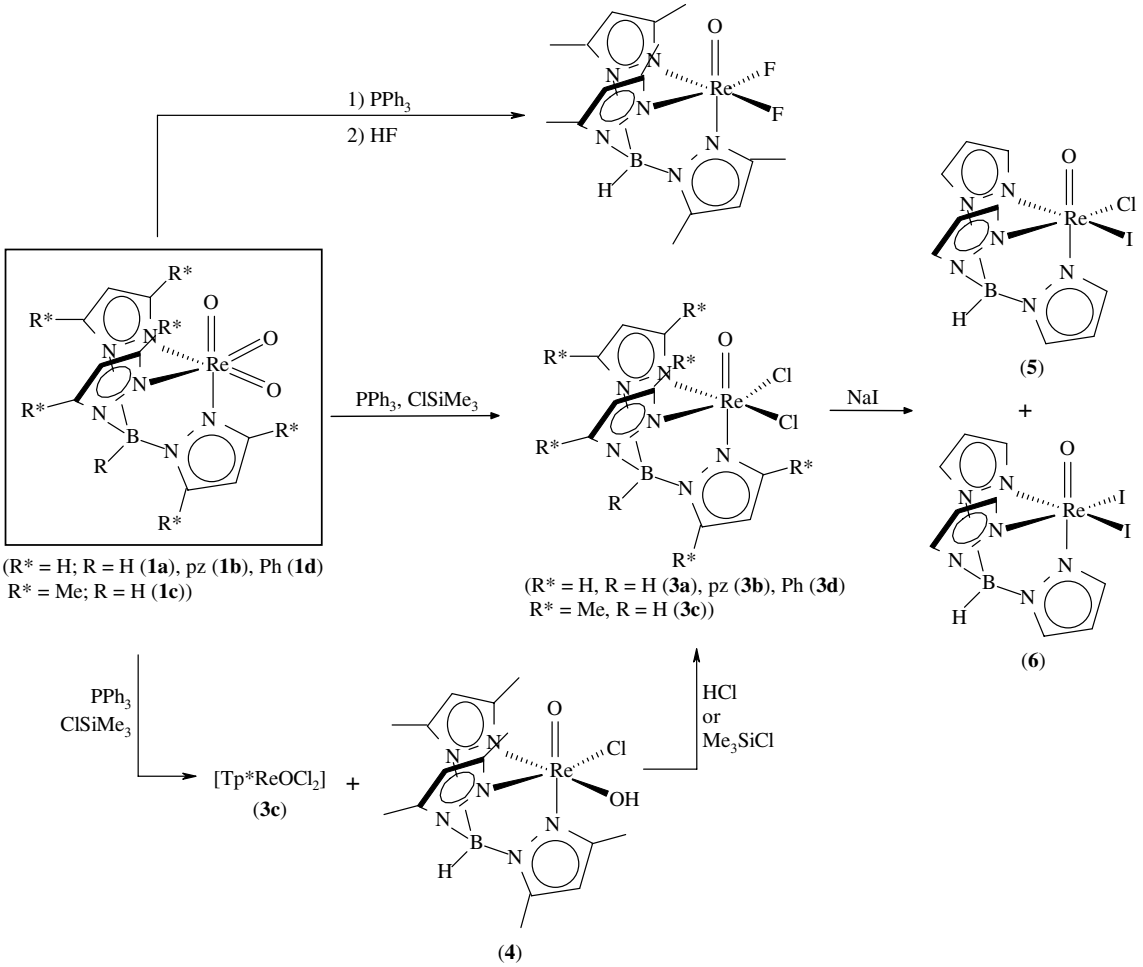


Scheme 2.



Scheme 3.

As shown in Scheme 4, the oxo-dichlorides [Tp′ReOCl$_2$] (Tp′ = Tp (**3a**), pzTp (**3b**), Tp* (**3c**), PhTp (**3d**)) were synthesized by simultaneous treatment of [Tp′ReO$_3$] (**1a–d**) with PPh$_3$ and chlorotrimethylsilane [6–8,10,18,19]. However, during the formation of **3c** hydrolysis also occurs and compound **3c** is obtained contaminated with [Tp*ReO(OH)Cl] (**4**) [6]. Treatment of this mixture with further Me$_3$SiCl or HCl, in a second reaction step, led to the pure oxodichloride **3c** [10,18]. Moreover, optimal conditions for the synthesis of the hydroxychloride [Tp*ReO(OH)Cl] (**4**), a useful precursor for the synthesis of mixed halide Re(V) derivatives, were also described [10]. Compound [Tp*Re(O)F$_2$] was also prepared by reduction of **1c** with PPh$_3$, followed by



Scheme 4.

addition of aqueous HF. In contrast, all the efforts to prepare oxo-difluorides anchored by Tp have failed [20]. The iodide derivatives [TpReO(Cl)(I)] (**5**) and [TpReOI$_2$] (**6**) were prepared by reacting **3a** with sodium iodide (Scheme 4). Replacement of iodide in compound **5** by triflate gave the mixed halide-triflate [TpReO(Cl)(OTf)] [21,23]. Several mixed halides and triflates of the type [Tp*ReO(X)Cl] (X = Br, I, F) and [Tp*ReO(Y)(OTf)] (Y = OH, F, Cl) were also prepared by reacting, respectively, [Tp*ReO(OH)Cl] (**4**) with HX and [Tp*Re(O)Y(F)] with Me_3SiOTf [10,20].

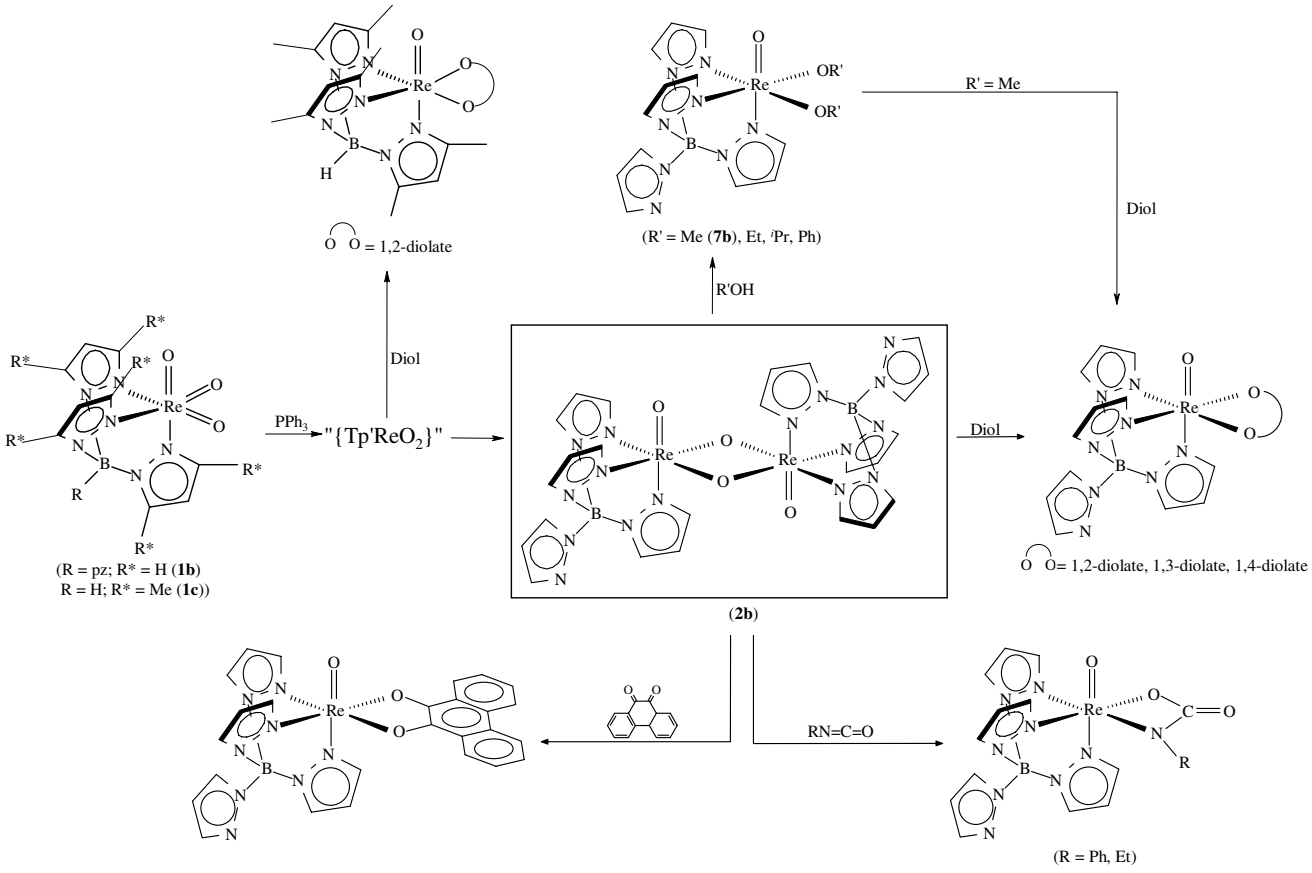
The original synthesis of the key compounds, [TpMOCl$_2$] (M = Re, **3a**, M = Tc, **3a′**), involved reaction of $[MO_4]^-$ with excess KTp in aqueous HCl solution and took advantage of the reducing properties of the Tp$^-$ ligand [11,24]. By contrast, the reduction of $[ReO_4]^-$ with KTp*, in the presence of HCl, is accompanied by decomposition of the ligand with formation of the dimer [ReOCl$_2$(Hpz^{Me_2})$_2$]$_2$(μ-O) [25]. This symmetric dimer, mixed with the binuclear oxo-bridged asymmetric isomer [{Re(O)Cl(Hpz^{Me_2})$_3$}(μ-O){Re(O)Cl$_3$(Hpz^{Me_2})}] was also identified in the reaction of KTp* with [N^{n}Bu$_4$][ReOCl$_4$] [18]. When the metal is Tc, the precursor [N^{n}Bu$_4$][TcOX$_4$] (X = Br, Cl) reacts with excess Tp yielding [TpTcOX$_2$] as the main product [26]. The isoelectronic sulfido complexes [TpMSCl$_2$] (M = Re, Tc) have been directly prepared from **3a** and **3a′** by atom transfer from B_2S_3, without degradation of the ancillary scorpionate [27–29].

2.2.2. Derivative chemistry of M(V) scorpionate oxides

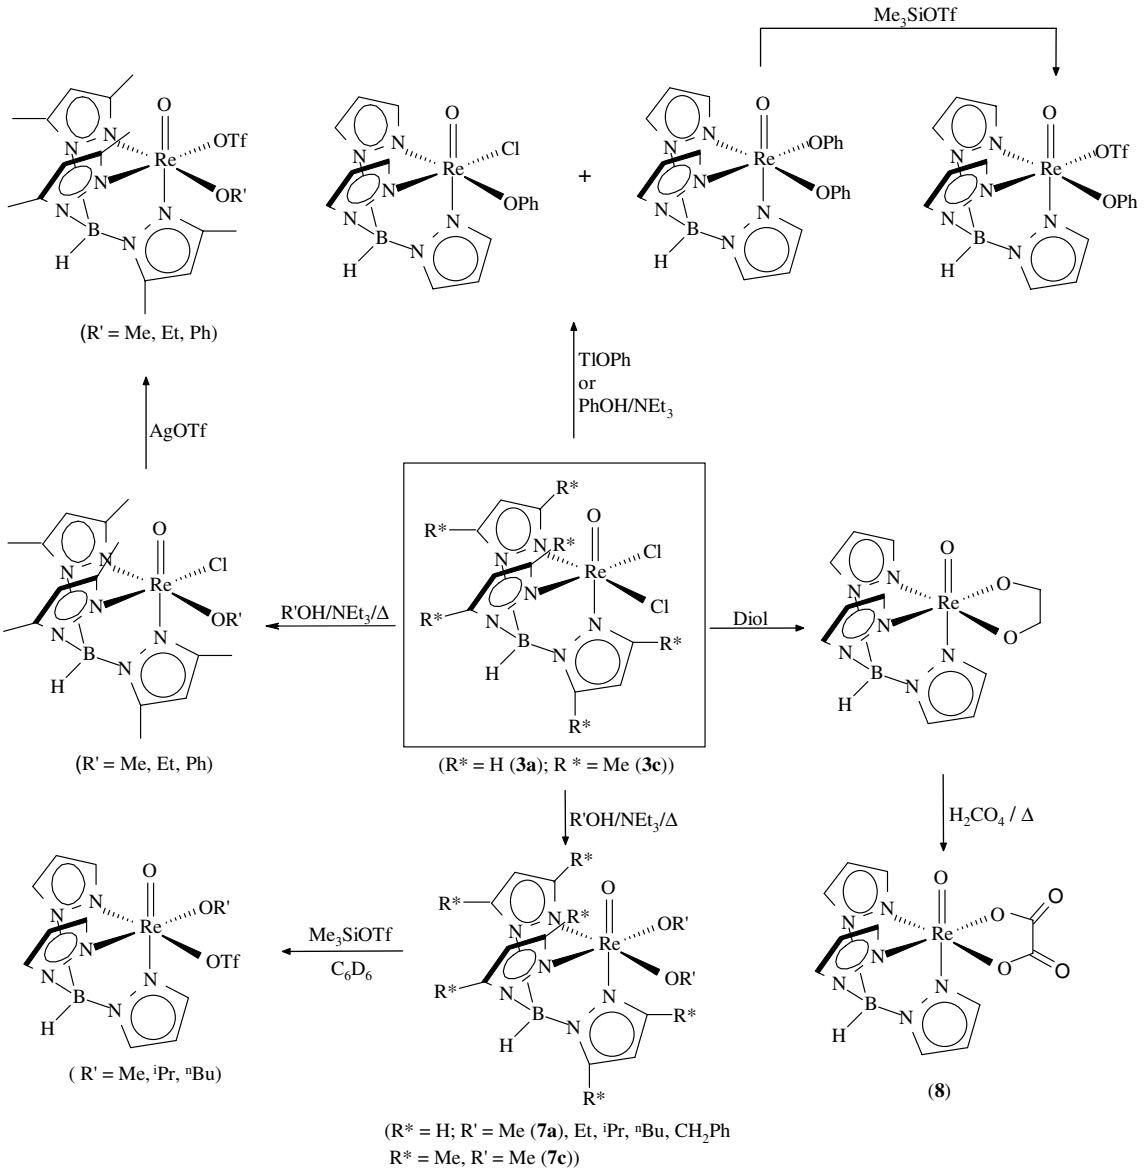
2.2.2.1. Complexes with oxygen donor co-ligands. Several oxocomplexes with alkoxides, diolates or other oxygen donor co-ligands have been isolated using the dinuclear compounds [Tp′ReO(μ-O)]$_2$ (Tp′ = Tp(**2a**), pzTp (**2b**)) or the in situ generated {Tp*ReO$_2$} fragment as starting materials [13–15]. The reaction of the bis-metoxide [(pzTp)ReO(OMe)$_2$] (**7b**) with diols is also a quite convenient approach for the synthesis of diolates (Scheme 5) [30].

Preparation of this type of compounds was also achieved using the monomeric dichlorides [Tp′ReOCl$_2$] (Tp′ = Tp (**3a**), Tp* (**3c**)) as precursors (Scheme 6) [10,31]. However, comparatively to the synthetic procedures depicted in Scheme 5, this synthetic route is time consuming, demands high temperatures and the use of deprotonating agents.

While the alkoxide derivatives [Tp′ReO(OR′)$_2$] (Tp′ = Tp, pzTp) are somewhat air and moisture sensitive, decomposing mainly to the dimers [Tp′ReO(μ-O)]$_2$ (Tp′ = Tp (**2a**), pzTp (**2b**)), the bisalkoxides anchored by



Scheme 5.



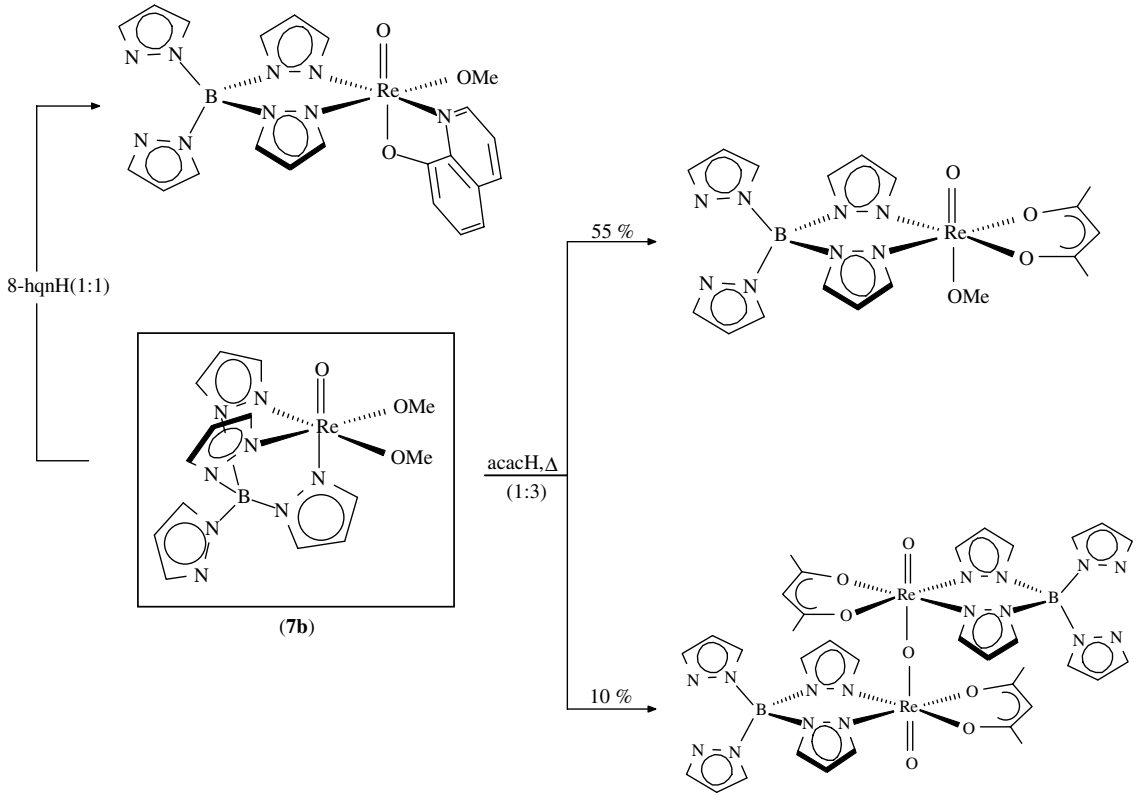
Scheme 6.

Tp* are stable in solution, even after several days [10,13,31]. Vicinal diolates of the type [Tp′ReO(O∩O)] (Tp′ = Tp, pzTp, Tp*) are air and water resistant but their thermolysis regenerates [Tp′ReO$_3$] (Tp′ = Tp (**1a**), pzTp (**1b**), Tp* (**1c**)) and the corresponding alkene [12,15,30,33]. In contrast, the complexes [(pzTp)ReO{O(CH$_2$)$_n$O}] ($n = 3, 4$) hardly eliminate the corresponding olefin under the same conditions [30]. The oxalate [TpReO(C$_2$O$_4$)] (**8**) is also thermally robust [33].

Characterization of this family of compounds, in some cases, also included X-ray structural analysis: [(pzTp)ReO(OPh)$_2$], [(pzTp)ReO(OMe)$_2$] (**7b**), [TpReO(OTf)$_2$], [TpReO(C$_2$O$_4$)] (**8**) and [(pzTp)ReO{O(CH$_2$)$_2$O}]. All are monomeric and the metal is six-coordinate, displaying a distorted octahedral coordination geometry. The homoscorpionate occupies one triangular face of the coordination polyhedron and the oxygen atoms of the two alkoxides or diolate are in the equatorial plane [13,30,32–34].

The nucleophilicity of the Re=O functionality in some of these alkoxide and diolate derivatives allowed the synthesis of the stable Lewis acid–metal complex adducts [TpRe{OB(C$_6$F$_5$)$_3$}(OEt)$_2$], [TpRe{OB(C$_6$F$_5$)$_3$}(OCH$_2$CH$_2$O)], and [TpRe{OB(C$_6$F$_5$)$_3$}(C$_2$O$_4$)], which were prepared by reacting the corresponding monoxocompounds with the strong Lewis acid B(C$_6$F$_5$)$_3$ [35].

Corroborating the versatility of the pzTp systems, reactions of [(pzTp)ReO(OMe)$_2$] (**7b**) with protic oxygen donor substrates, potentially bidentate and uninegative, promoted a haptotropic change of the anchor scorpionate from κ^3-pzTp to κ^2-pzTp (Scheme 7) [36].



Scheme 7.

The bidentate coordination of pzTp in [(κ^2-pzTp)ReO(acac)(OMe)] and [(κ^2-pzTp)ReO(acac)]$_2$(μ-O) was confirmed by X-ray crystallography. In these six-coordinate octahedral complexes, the oxo groups occupy the axial sites and the κ^2-pzTp and acac ligands lie in the equatorial plane. The dimeric structure of [(κ^2-pzTp)ReO(acac)]$_2$(μ-O) is centrossymmetric, with a quasi linear O=Re–O–Re=O group. The bridging Re–O bond length, 1.910(1) Å, is normal for rhenium complexes containing this type of moiety [36].

2.2.2.2. Complexes with nitrogen-donor co-ligands. Re(V) oxo amido derivatives of the type [TpReOCl(NRR′)] have been isolated by reacting [TpReOCl$_2$] (**3a**) with excess of the corresponding amines (Scheme 8). These oxo-amidos are unstable in solution, decomposing in the presence of air to [TpReO$_3$] (**1a**), and exist in solution as conformational isomers, most likely due to restricted rotation about the Re–N bond [37].

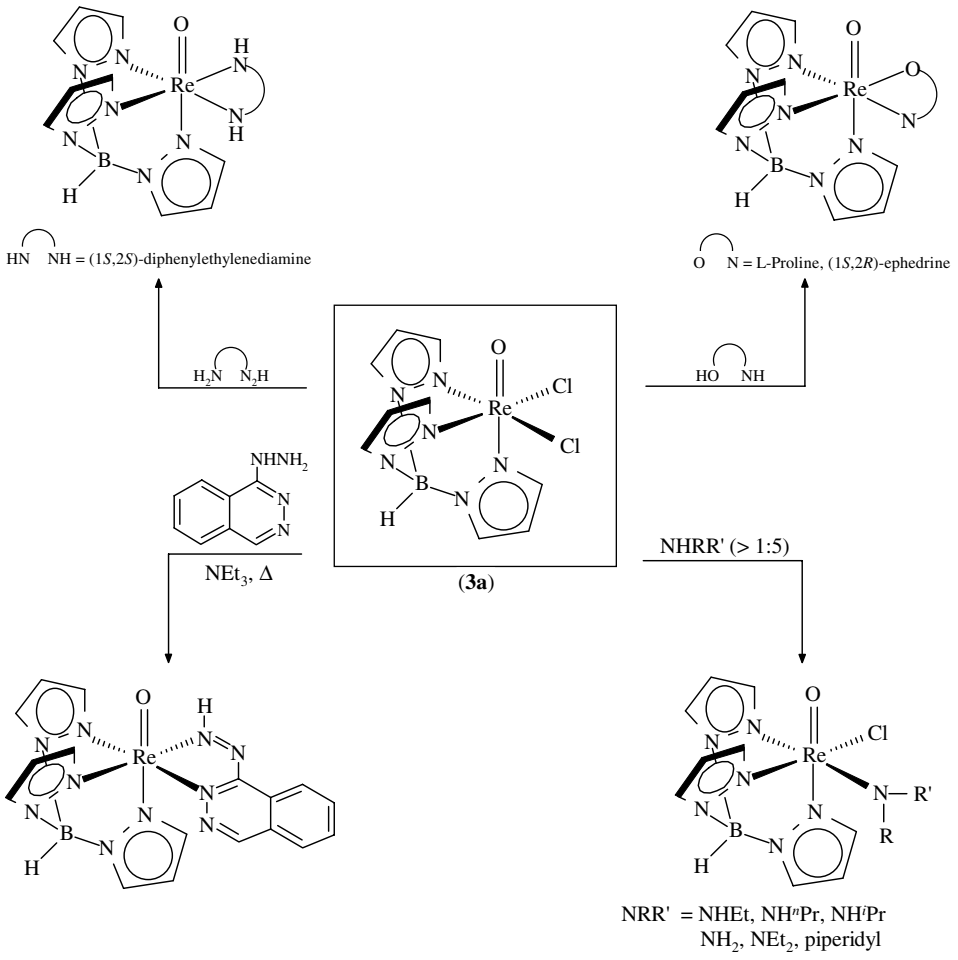
Compound **3a** was also used as precursor in the synthesis of metallacycles of the type [TpReO(κ^2-N–X)] (X = N, O) [38,39]. Some of these compounds contain chiral and bidentate ligands of the type alcoholate or amidate, derived from (1*S*,2*R*)-ephedrine, (1*S*,2*S*)-diphenylethylenediamine, and L-proline (Scheme 8) [38].

Monomeric and dimeric derivatives containing metal–nitrogen bonds were prepared by reacting [(pzTp)ReO(μ-O)]$_2$ (**2b**) or [(pzTp)ReO(OMe)$_2$] (**7b**) with diamines or pyrazoles (Scheme 9) [36]. Diamines react with **2b** or **7b** yielding the monomeric metallacycles [(pzTp)ReO(HN$^\frown$NH)], while reactions of **2b** with pyrazoles afforded dimeric species with bridging pyrazolides. **7b** also reacts with pyrazoles and forms the monomeric **9a**,**b**, which slowly dimerize in solution to **10a**,**b**, releasing pyrazole and methanol (Scheme 9) [36].

The crystal structure of **10a** consists of two independent "{κ^2-(pzTp)ReO}" units triple bridged by an oxygen and two pyrazolide ligands. The O=Re–O–Re=O unit is quite bent (Re–O–Re, 125.4(3)°) due to the steric requirements of the two bridging pyrazolides [36]. This quite unusual structure was also found in the recently described [{κ^2-H(F)Bpz$_2$}Re(O)]$_2$(μ-pz)$_2$(μ-O), obtained by refluxing [TpReOI$_2$] with excess of NaF in acetonitrile [20].

Re(V) imido compounds of general formula [TpRe(NTol)X$_2$] were synthesized by reacting [TpReOX$_2$] (X = Cl (**3a**), I (**6**)) with *p*-toluidine (Scheme 10) [37,40]. Based on [TpRe(NTol)X$_2$] (X = Cl, I) several Re(V) imido alkyl and aryl derivatives have been prepared by methatesis reactions (Scheme 10) [40].

The imido group being isoelectronic with the oxo ligand produces similar types of complexes, as far as general structural patterns are concerned. However, from the electronic point of view the imido derivatives



Scheme 8.

are more electron-rich compounds. This trend was confirmed by electrochemical studies performed on a series of imido and oxo-complexes of the type [TpRe(NTol)(X)(Y)] and [TpReO(X)(Y)] (X, Y = triflate, halide, alkyl, aryl). Consistently, the oxo-complexes act as inner-sphere oxidants, reacting as electrophiles towards PPh_3, in contrast with the imido congeners [41].

2.2.2.3. Complexes with sulfur donor-co-ligands. Mono- or bis-thiolates and dithiolates have been synthesized by reacting [TpReOCl$_2$] (**3a**) and the corresponding mono- or bidentate thiols in the presence of deprotonating agents and/or under reflux (Scheme 11) [19,28,39]. Thiophenolates [Tp*ReO(OH)(SPh′)] were also obtained by treatment of [Tp*ReO(Cl)(OH)] (**4**) with the corresponding thiol [6].

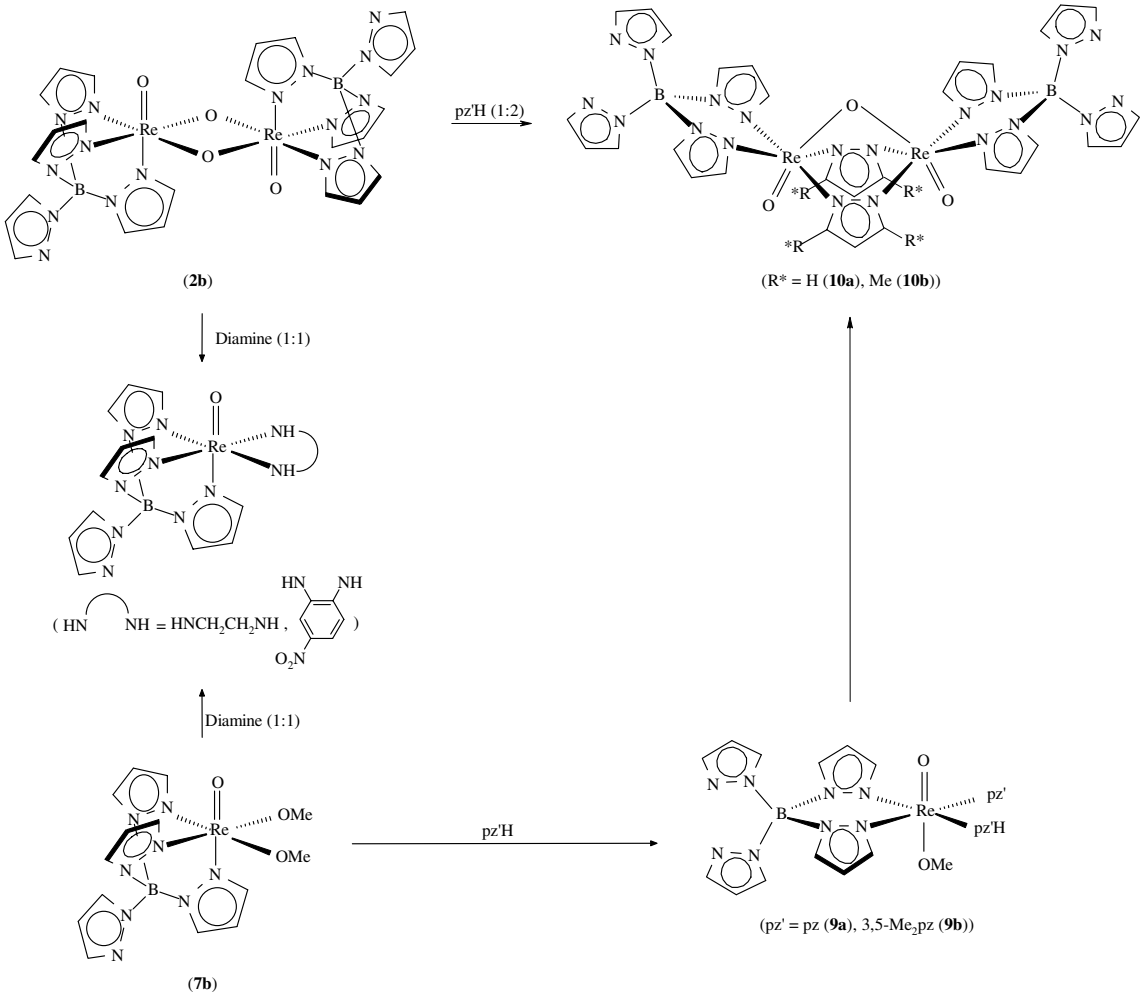
A faster and cleaner procedure for the preparation of thiolate derivatives is the reaction of the dinuclear compound [(pzTp)ReO(μ-O)]$_2$ (**2b**), or the in situ generated {Tp*ReO$_2$} unit, with thiols, 2-mercaptopyridine, 2-mercaptoalcohols or dithiol (Scheme 12) [13,17,42,43].

The compounds [TpReOCl(SPh)], [TpReO(SCH$_2$CH$_2$S)], [Tp′ReO(SPh)$_2$] and [Tp′ReO(2-S-py)$_2$] (Tp′ = Tp, pzTp) were structurally characterized. All are six-coordinate by a κ^3-Tp′, an oxo group and two monodentate or one bidentate co-ligand, displaying an octahedral coordination geometry [13,19,28,39,43].

An interesting result, which confirmed the haptotropism of pzTp, was the identification of the complex [(κ^2-pzTp)ReO{κ^2-(C$_5$H$_4$NS)}(OMe)], obtained by reacting [(pzTp)ReO(OMe)$_2$] (**7b**) with 2-mercaptopyridine. As shown by the solid state structural analysis, the metal is six-coordinate by the κ^2-pzTp, the κ^2-pyS and by a metoxide group coordinate *trans* to the oxo (Scheme 12) [43].

2.2.2.4. Complexes with hydrocarbyl co-ligands. Oxo alkyl or aryl derivatives were prepared by reacting [Tp′ReOCl$_2$] (Tp′ = Tp (**3a**), Tp* (**3c**)) with different alkylating agents (Scheme 13) [10,32,44].

The outcome and yield of these reactions depend on the nature of the scorpionate and also on the alkylating agent. It was found that the Tp* system was more resistant to reduction, making possible the use of



Scheme 9.

Grignard reagents in the arylation. Mayer and co-workers [10] considered that steric factors, more than electronic ones, are responsable for the greater stability of the Tp* organometallic derivatives. Substitution of the halide in [Tp′ReO(X)(R′)] (Tp′ = Tp; X = Cl, R′ = Me, Et, ^{n}Bu, Ph; X = I, R′ = Ph and Tp′ = Tp*, X = Cl, R′ = Et, Ph) by reaction with silver triflate led to [Tp′ReO(OTf)(R′)] [10,32,44]. Unlike the reactions with complexes containing the Tp* ligand, in the case of Tp complexes the reactions require some days for completion, but excess of AgOTf cannot be used due to separation problems.

Some of these organometallic Re(V) oxides were characterized by single crystal X-ray diffraction analysis. The complexes adopt a distorted octahedral geometry with the rhenium atom displaced toward the oxo ligand, similar to other oxo Re(V) scorpionate compounds containing different co-ligands [10,44].

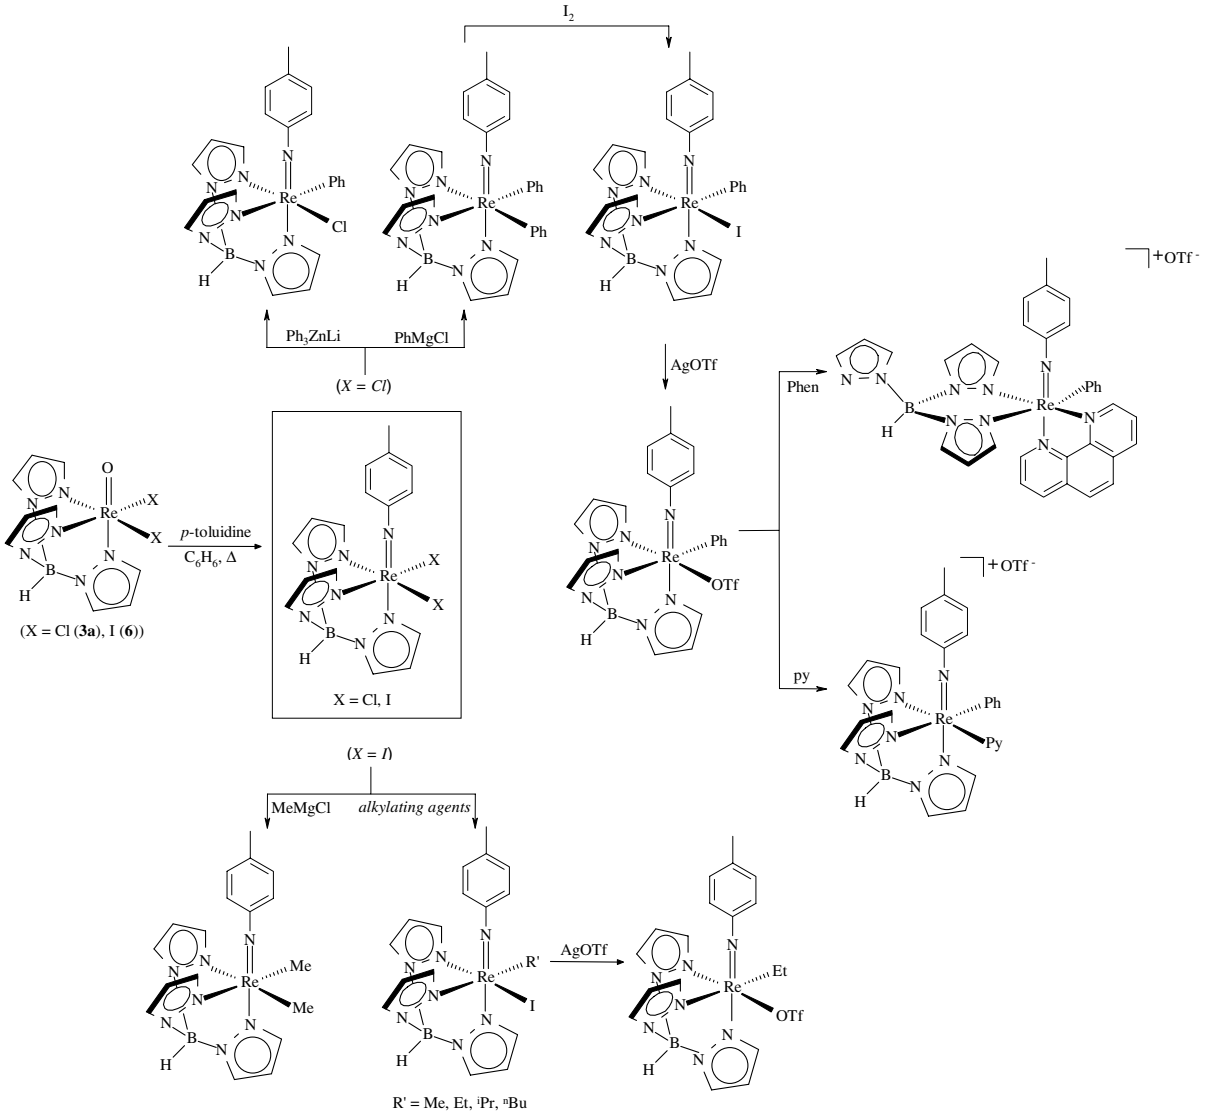
2.2.3. *trans*-Dioxocomplexes

trans-Dioxo derivatives, of general formula *trans*-[(κ^2-Tp′)ReO_2L_2] (**11**–**16**), were obtained by reducing [Tp′ReO_3] (Tp′ = Tp (**1a**), pzTp (**1b**), PhTp (**1d**)) with PPh_3 in the presence of σ donors such as pyridines, imidazoles or diphosphines (L) (Scheme 14) [8,45,46]. The stability of this unusual class of compounds depends on the scorpionate and on the neutral co-ligand. Santos et al. found a higher stability for the pzTp system and identified the dimers [Tp′ReO(μ-O)]$_2$ (**2**) as the major decomposition products.

The synthesis of **11**–**16** was considered to be consistent with the formation of the electronic and coordinatively unsaturated "{Tp′ReO_2}" fragment, which does not dimerize in the presence of neutral σ donor ligands but yields **11**–**16**. The $\kappa^3 \Longleftrightarrow \kappa^2$-haptotropism of the scorpionates facilitates the process [8,45,46].

The structural analysis of some *trans*-dioxocomplexes (**11c**, **13**, **15a**, **15b**) confirmed the κ^2-coordination mode of the scorpionate ligands and the presence of the *trans*-ReO_2 unit. The Re–O bond distances (1.751–1.773) are typical of Re(V) *trans*-dioxocomplexes and are compatible with a certain double character [45,46].

During recrystallization of **15a** a slight decomposition occurred and a pzH molecule of solvation per



Scheme 10.

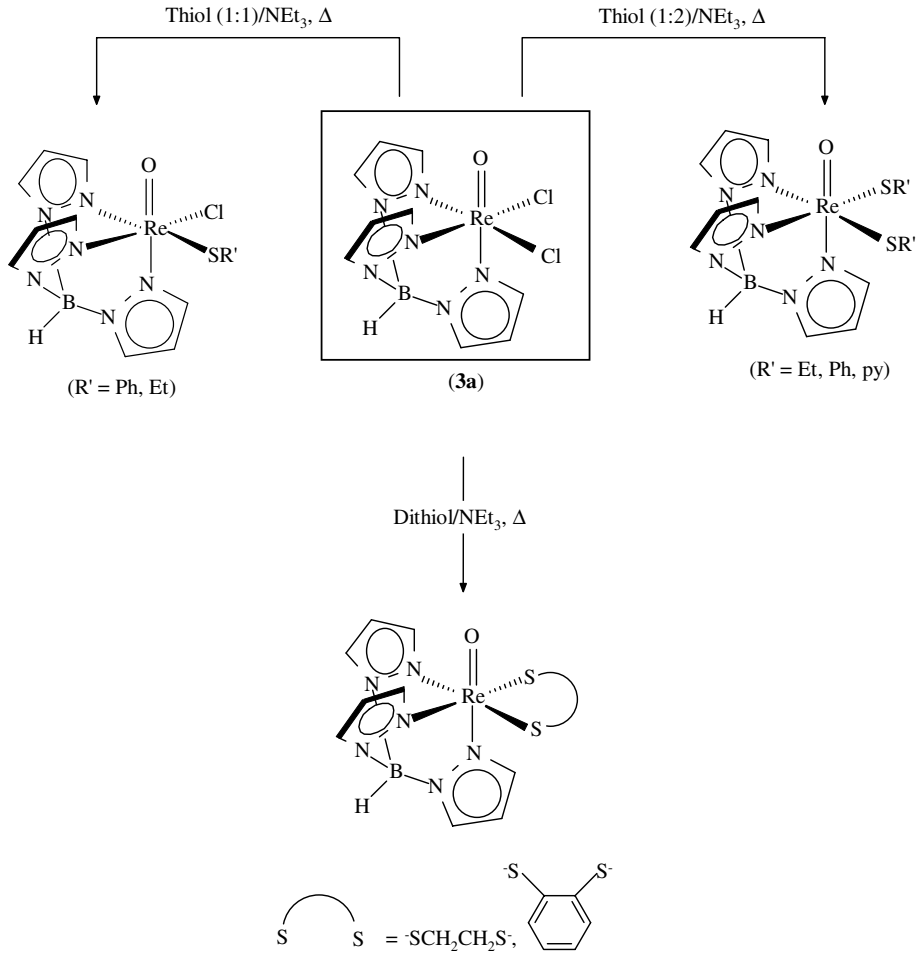
asymmetric unit appears in the crystal structure. Another indication for the relative instability of **15a** is the formation of *trans*-$[ReO_2(dmpe)_2]$ [Tp] (**17**), due to the replacement of Tp by dmpe moiety. The crystal structure of **17** consists of *trans*-$[ReO_2(dmpe)_2]^+$ cations and Tp anions, representing a rare example of a d-transition complex with a scorpionate acting as counter-ion [46].

The ^1H NMR spectra of the dioxocomplexes anchored by κ^2-pzTp show abnormally highfield shifted H(3/5) resonances for the two uncoordinated pyrazolyl rings. This behavior is typical of Re(V) oxocomplexes with κ^2-pzTp ligand, and rendered ^1H NMR spectroscopy a powerful tool in assigning the denticity of the pzTp ligand [36,45].

When the synthesis of *trans*-$[(\kappa^2\text{-pzTp})ReO_2(py)_2]$ was tried using *trans*-$[ReO_2(py)_4]Cl$ as starting material, an oxygen attack at the boron atom was observed and a mixture of two compounds anchored by asymmetric κ^2-heteroscorpionates was obtained (Scheme 15) [45].

Reactions of the starting material *trans*-$[ReO_2(py)_4]Cl$ with Bp or Bp* were also studied. No degradation of the scorpionates was observed and the resulting compounds were the anions *trans*-$[(Bp')_2ReO_2]^-$ ($Bp' = Bp$, Bp*), with *trans*-$[ReO_2(py)_4]^+$ as counter ion (Scheme 15). These anionic complexes react readily with the electrophilic substrates $ClXMe_3$ ($X = Si$, Sn), affording $[(Bp')_2ReO(OXMe_3)]$ and providing an easy entry into the chemistry of bis-Bp′ oxocompounds (Scheme 15) [47].

Unusual cationic mono-oxocomplexes of general formula $[(\kappa^2\text{-pzTp})ReO(OSiMe_3)(L)_2]Cl$ were also synthesized by reacting *trans*-$[(\kappa^2\text{-pzTp})ReO_2(L)_2]$ with trimethylsilyl chloride (Scheme 16). In solution, the cationic complexes with monodentate σ-donor ligands



Scheme 11.

rearrange to the neutral compounds [(κ^2-pzTp)ReO(O-$SiMe_3$)Cl(L)]. The use of dmpe improved considerably the stability of the cationic species, preventing such rearrangement (Scheme 16) [48].

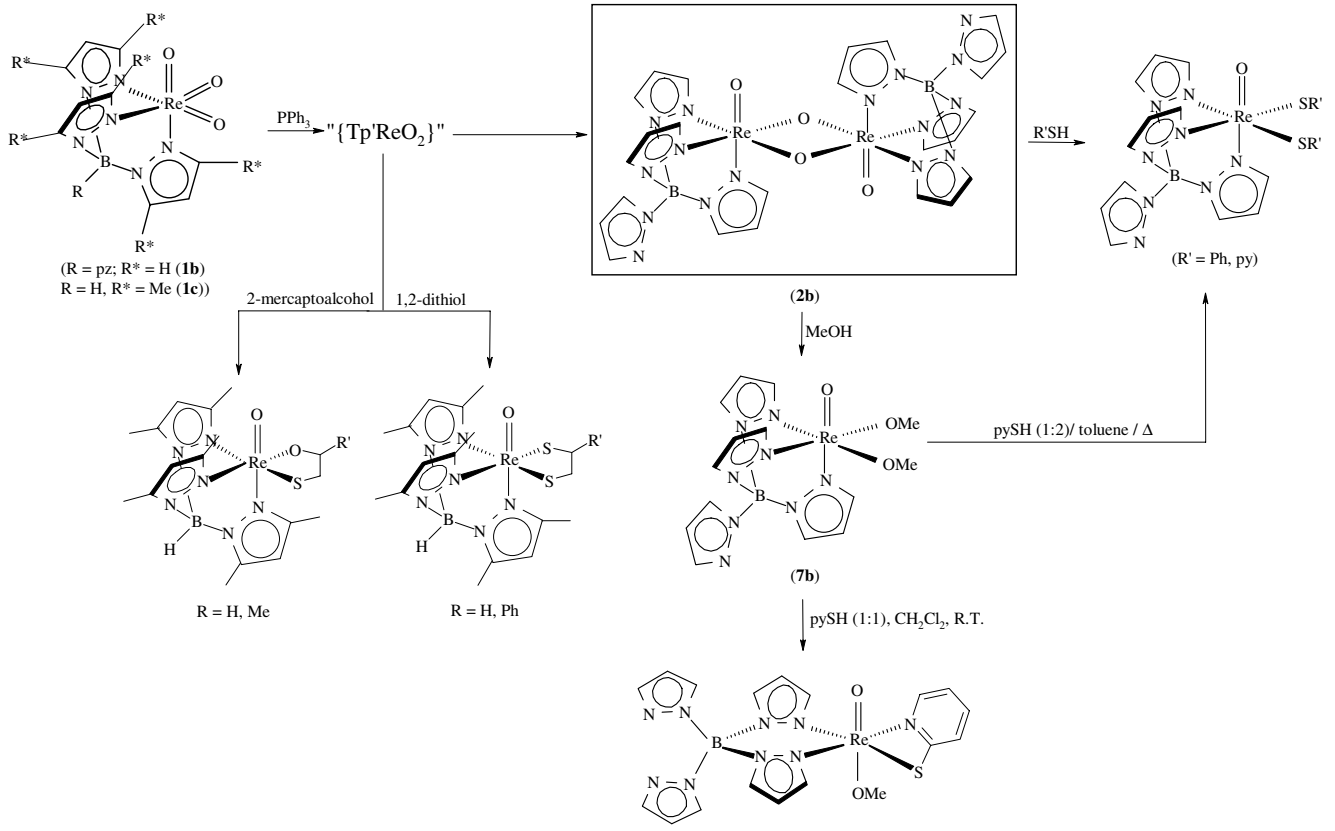
2.2.4. Oxygen transfer reactions

Re(III) monomeric adducts of the type [Tp′ReX_2L] (Tp′ = Tp, X = Cl, L = PPh_3, py, 3-hexyne, $OPMe_3$; X = Br, L = py, Meim, $OPEt_3$; Tp′ = pzTp, X = Cl, L = PPh_3, $PEtPh_2$, PEt_2Ph, PEt_3) or the pyridine adducts [TpReCl(X)py] (X = OPh, NEt_2) were obtained by deoxygenation of [Tp′$ReOX_2$] or [TpReOCl(X)] (X = OPh, NEt_2) with tertiary phosphines or phosphites, respectively (Scheme 17) [34,37,49,50].

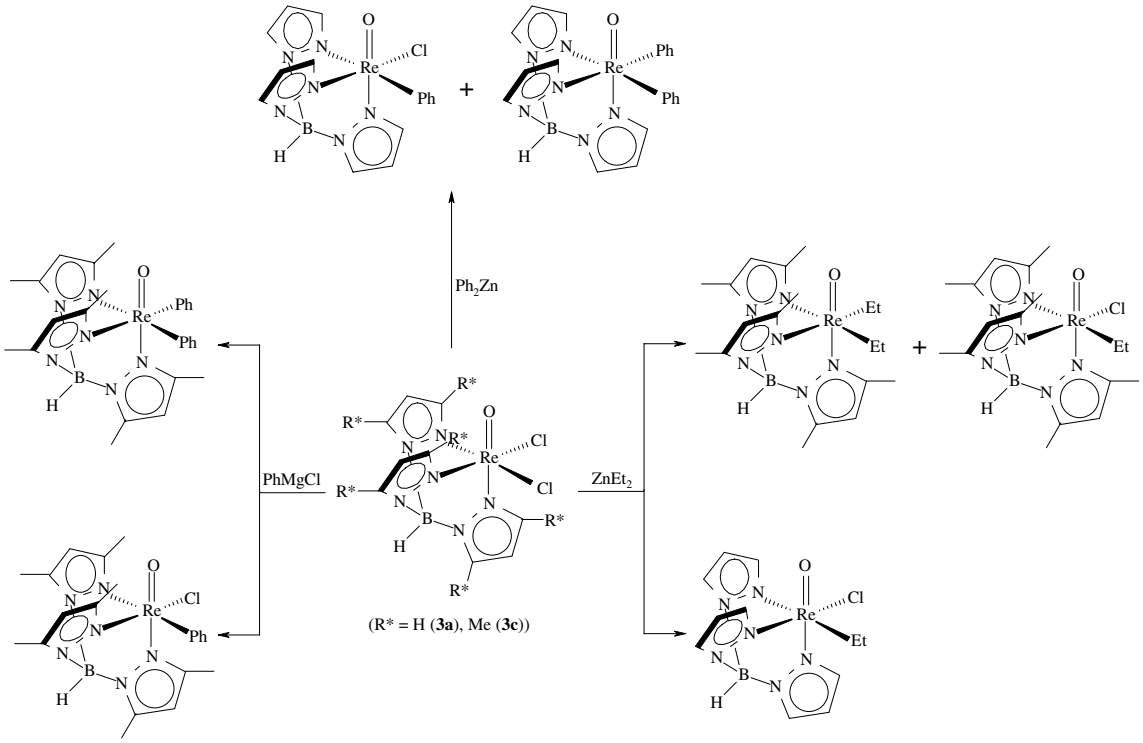
When oxygen abstraction in [$TpReOCl_2$] (**3a)** is carried out with PMe_3, in the presence of 2,2-bipyridine and thallium triflate, the complex formed is cationic and has been formulated as [TpRe(κ^2-bipy)(Cl)][OTf]. Further reduction of this cationic compound with Zn/Hg in the absence or presence of cyclopentene yields [TpRe(κ^2-bipy)(Cl)] and [TpRe(κ^2-bipy)(η^2-cyclopentene)], respectively [51]. The paramagnetic [(pzTp)$ReCl_3$] has also been identified in the reaction of [$ReOCl_3(PPh_3)_2$] with K(pzTp) in CH_2Cl_2. This compound was considered to be formed through a Re(III) intermediate species, which is unstable and easily oxidized by the solvent (Scheme 18) [30].

The octahedral Re(III) complexes, anchored by Tp or pzTp, and [(pzTp)$ReCl_3$] are all paramagnetic and present relatively sharp but shifted resonances in the ^{1}H NMR spectra [30,34,37,49–51]. As confirmed by X-ray structural analysis, the compounds [$TpReCl_2$(py)], [TpReCl(OPh)(py)] and [(pzTp)$ReCl_2(PEt_2Ph)$] are six-coordinate, displaying an octahedral coordination geometry, with facial and symmetrical coordination of the κ^3-Tp′ ligand. This symmetrical coordination is different from what is observed in the analogous Re(V) oxo complexes, where exists a strong *trans* influence of the oxo group [21,34,49].

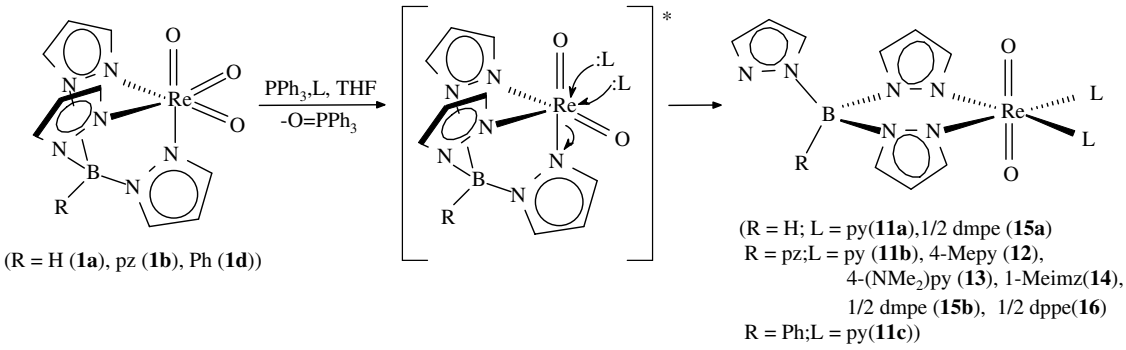
Mayer et al. described the first *cis*-[$TpReO_2X$] compounds (X = Cl (**18a**), Br (**18b**), I (**18c**)) obtained by oxidation of oxotriflates with a stoichiometric amount of pyridine *N*-oxide (Scheme 19). On the basis of electronic arguments, the *trans* configuration would be more stable for these d^1-dioxocomplexes, but the facial disposition imposed by the κ^3-Tp is certainly responsible



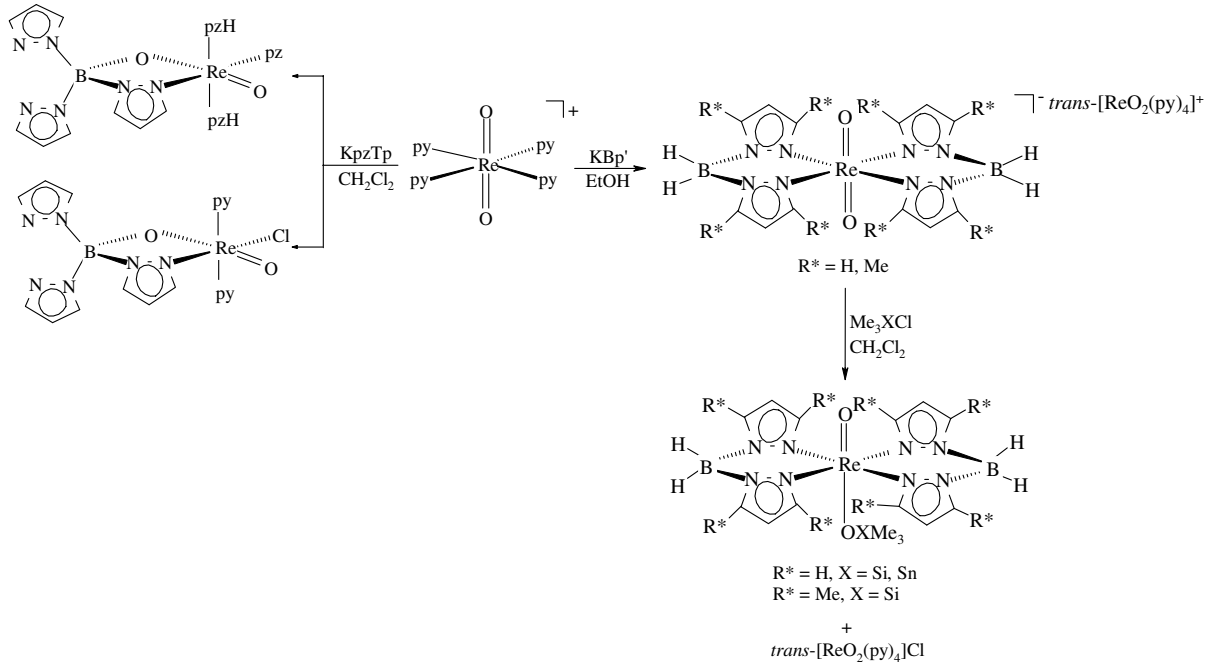
Scheme 12.



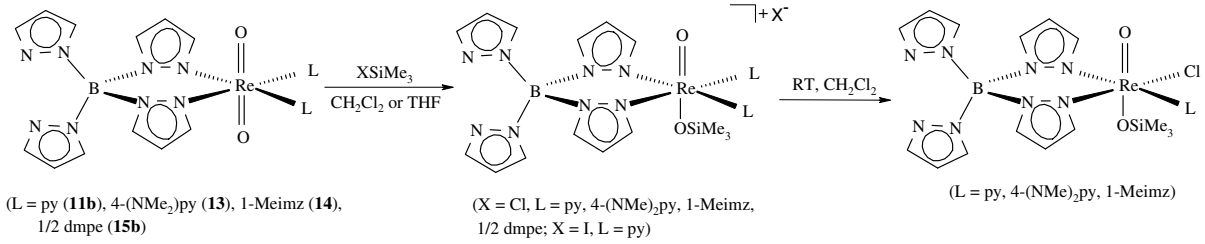
Scheme 13.



Scheme 14.



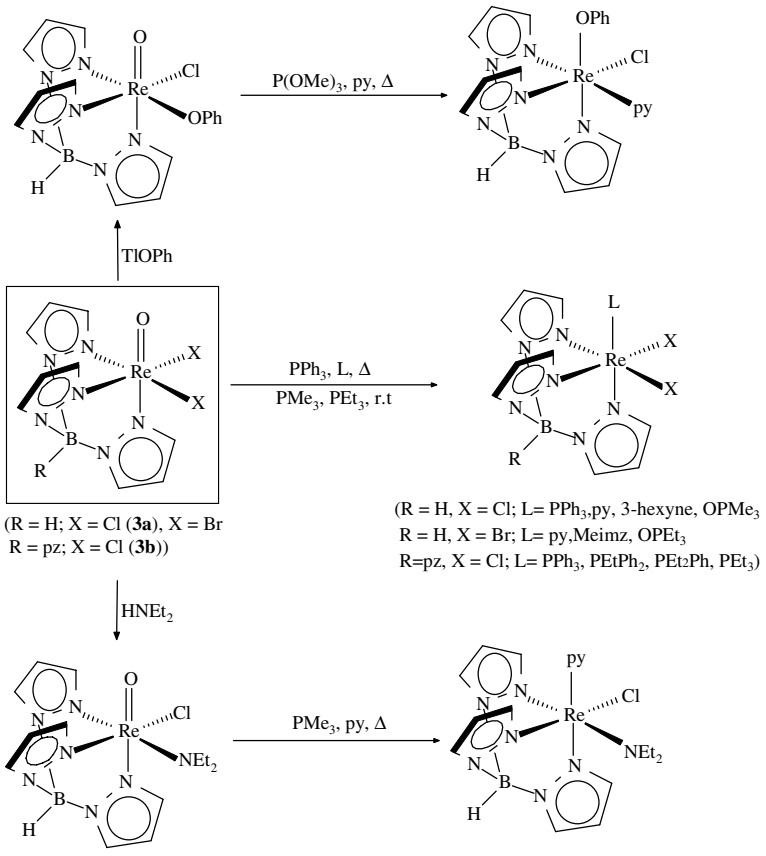
Scheme 15.



Scheme 16.

for the formation of this unusual Re(VI) *cis*-dioxo complexes [23]. The paramagnetic nature of compounds **18** results in very broad and uninformative ^{1}H NMR resonances, but the X-ray structural analysis of **18a** demonstrated that the two oxo ligands are in a *cis*-arrangement, with the homoscorpionate ligand coordinating in a tridentate and facial way. The Re–O bond lenghts of 1.797(11) and 1.741(10) Å are longer than the typical Re–O triple bonds (1.69(3) Å), but compare well with the Re–O bond distances found in *trans*-dioxo complexes (ca. 1.76(2) Å) [8,45–47]. Compounds **18** are not particularly reactive, being fairly air stable and only slightly water sensitive. As solids or in solution, *cis*-[TpReO$_2$X] (**18**) slowly disproportionate to [TpReO$_3$] (**1a**) and [TpReOX$_2$] [23].

The formation of 18 was considered to go through cationic Re(VII) intermediates [TpReO$_2$X]$^+$ (X = Cl, Br, I), which undergo rapid one electron reduction [23].



Scheme 17.

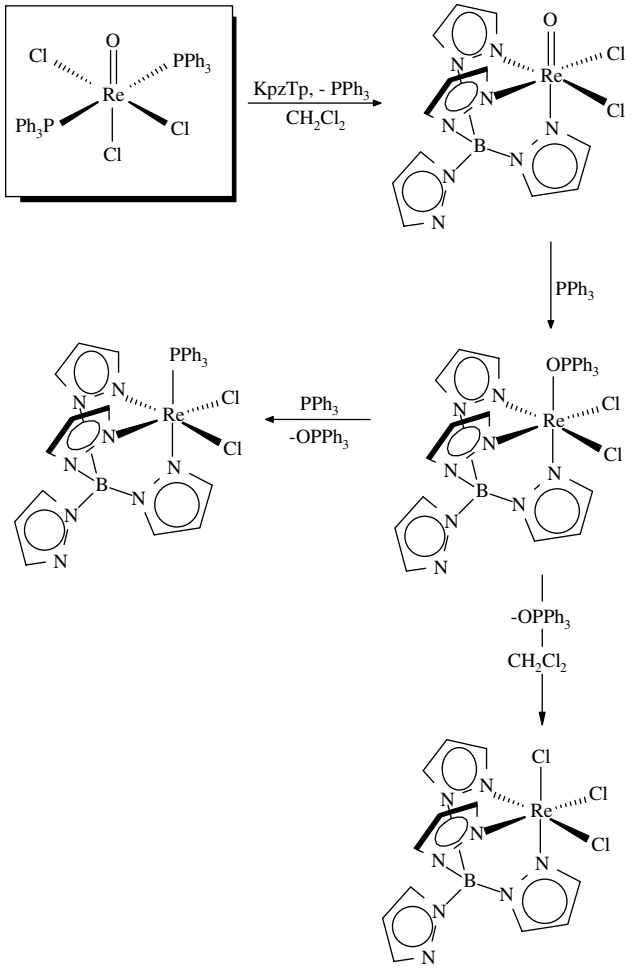
Mayer and coworkers [10,31,32,44] also claimed that the related Re(VII) dioxo cations $[Tp'ReO_2Y]^+$ ($Tp' = Tp$, Tp*; Y = aryl, alkyl, hydroxyde, alkoxide) are the key reactive species in the reactions of $[TpReO(OR')_2]$ or $[Tp'ReOY(OTf)]$ with py-O and Me_2SO. The fate of the strongly electrophilic $[Tp'ReO_2Y]^+$ cations, which were never isolated, is quite dependent on the nature of the co-ligands. Alkoxides, alkyl and hydroxy complexes are in general oxidized by py-O or Me_2SO to $[Tp'ReO_3]$ and to the corresponding aldehydes or ketones [10,31,44]. The exception is the oxidation of [Tp*ReO(OTf)(Et)] with Me_2SO, which is not accompanied by release of the expected acetaldehyde [10].

During studies of the oxidation of [Tp′ReO(Ph)OTf] ($Tp' = Tp$, Tp*) with Me_2SO or pyridine *N*-oxide, Mayer and coworkers [10,32] reported the first clear examples of a thermal [1,2]-migration of an aryl group from a metal center to an oxo-ligand (Scheme 20). According to these authors, the phenyl ligand in the Re (VII) intermediates $[Tp'ReO_2(Ph)]^+$ ($Tp' = Tp$, Tp*) migrates to a neighbouring oxo group, forming novel rhenium(V) complexes. However, the nature of the final complexes depends on the scorpionate and on the oxygen atom donor. When Me_2SO is used as oxidant, the reactions proceed with formation of the phenoxide complexes [Tp′ReO(OPh)(OTf)] both for the Tp and Tp* systems. By contrast, the oxidation of [TpReO (Ph)OTf] with py-O led to the formation of a phenoxide and a catecholate, while [Tp*ReO(Ph)OTf] yields a complex mixture of products, which does not include [Tp*ReO(OPh)(OTf)] (Scheme 20) [10,32].

Gable and Brown [16] reduced the compounds $[Tp*ReO_3]$ and $[pzTpReO_3]$ with PPh_3 or $P(OEt)_3$, and evaluated the in situ generated species $\{Tp'ReO_2\}$ ($Tp' = Tp^*$, pzTp) in catalytic oxygen transfer reactions. For the Tp* system, they found efficient catalytic oxygen transfer from epoxides to the stoichiometric phosphorus reductant with consequent deoxygenation of the epoxyde and formation of the corresponding olefin. The catalytic reaction is stereospecific and proceeds more rapidly with *cis*- vs. *trans*-alkenes. These authors also found that the use of Tp* or pzTp has a significant influence on the rate and efficiency of the catalytic cycle, the rate being severely retarded by the presence of pzTp. The higher rate of epoxide deoxygenation achieved with Tp* was considered to be due to the larger steric bulk of Tp*, which disfavor dimerization of the catalytically active $\{Tp*ReO_2\}$ species [16].

2.2.5. Photochemical reactions

Photochemical activation of the complex $[TpReO(C_2O_4)]$ (**8**), by irradiation with UV light, induces reac-



Scheme 18.

tivity towards different substrates (Scheme 21) [33,52]. The authors considered the photochemical process taking place through the reactive transient {TpReO} and with release of CO_2 and CO. The trapping of the intermediate {TpReO} by oxidants like DMSO, $CHCl_3$ and phenanthrenequinone, yielded stable rhenium(V) or rhenium(VII) products (Scheme 21). The starting oxo-oxalate reacts also with the photochemically generated transient yielding the dimer **19**. The reaction with dioxygen was also studied, and the peroxo {TpReO(η^2-O_2)} was formulated as the possible intermediate. This intermediate, which was never isolated, reacts further affording the rhenium(VII) trioxo [$TpReO_3$] [33].

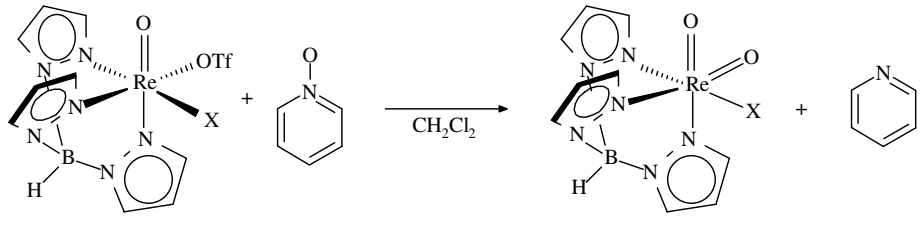
Most of the Re(V) and Re(VII) compounds indicated in Scheme 21 can be obtained either by a photochemical reaction or by a chemical pathway. However, the metallacycle [TpReO($C_9HF_{12}NO_4$)] (**20**) can only be prepared by photolysis of **8**. The formation of **20** results from a condensation of two $(CF_3)_2C{=}O$ molecules and one CH_3CN molecule [52].

Photolysis of [TpReO(Cl)I] (**5**) or [$TpReOI_2$] (**6**) in aromatic hydrocarbons promotes C–H activation of the solvents giving the oxo aryls [TpReOCl(Ph′)] or [$TpReO(Ph')_2$] (Scheme 22). At least one iodide ligand appears to be needed for arylation, as [$TpReOCl_2$] (**3a**) is unreactive [22].

Another interesting result, and a quite rare process in the chemistry of metal transition complexes, is the formation of Re alkoxides by photochemical aryl-to-oxo and alkyl-to-oxo migration in [TpReOCl(Ph)] and [TpReOCl(Et)], respectively. For the phenyl derivative the type of isolated products depends on the reaction conditions (Scheme 23) [22,49]. In the absence of coordinating substrates, photolysis of [TpReOCl(Ph)] in benzene yields two new paramagnetic compounds tentatively assigned as the two diastereomers of the asymmetric [{TpRe(OPh)Cl}(μ-O){TpRe(Ph)(Cl)}] (Scheme 23) [49]. Photolysis in neat CH_3CN or in benzene solutions containing pyridine or Me_3PO produce the paramagnetics adducts [TpReCl(OPh′)(L)] (L = CH_3CN, Me_3PO, py) (Scheme 23), while photolysis in the presence of Me_2SO proceeds with formation of a diamagnetic oxo-phenoxide [TpReOCl(OPh)], due to oxygen atom transfer from Me_2SO. Mechanistic studies showed that the phenyl to oxo migration occurs predominantly via an intramolecular [1,2]-shift. Mayer and coworker [49] also reported that photolysis of the oxo alkyl [TpReOCl(Et)], in the presence of pyridine, gave [TpReCl(OEt)(py)], but the net ethyl migration seems to involve free ethyl radicals.

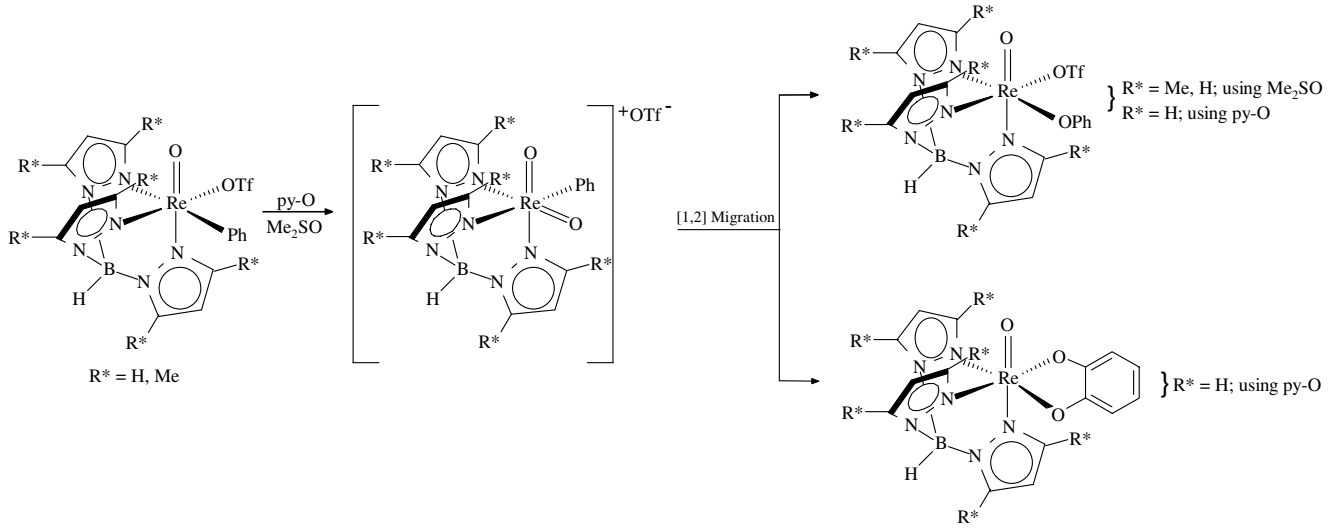
2.3. Hydrides and oxo-hydrides

Crabtree et al. [53] reported the complexes [$TpReH_6$] and [$TpReH_4(PPh_3)$] which were prepared by reacting $LiAlH_4$ with [$TpReOCl_2$] (**3a**) and

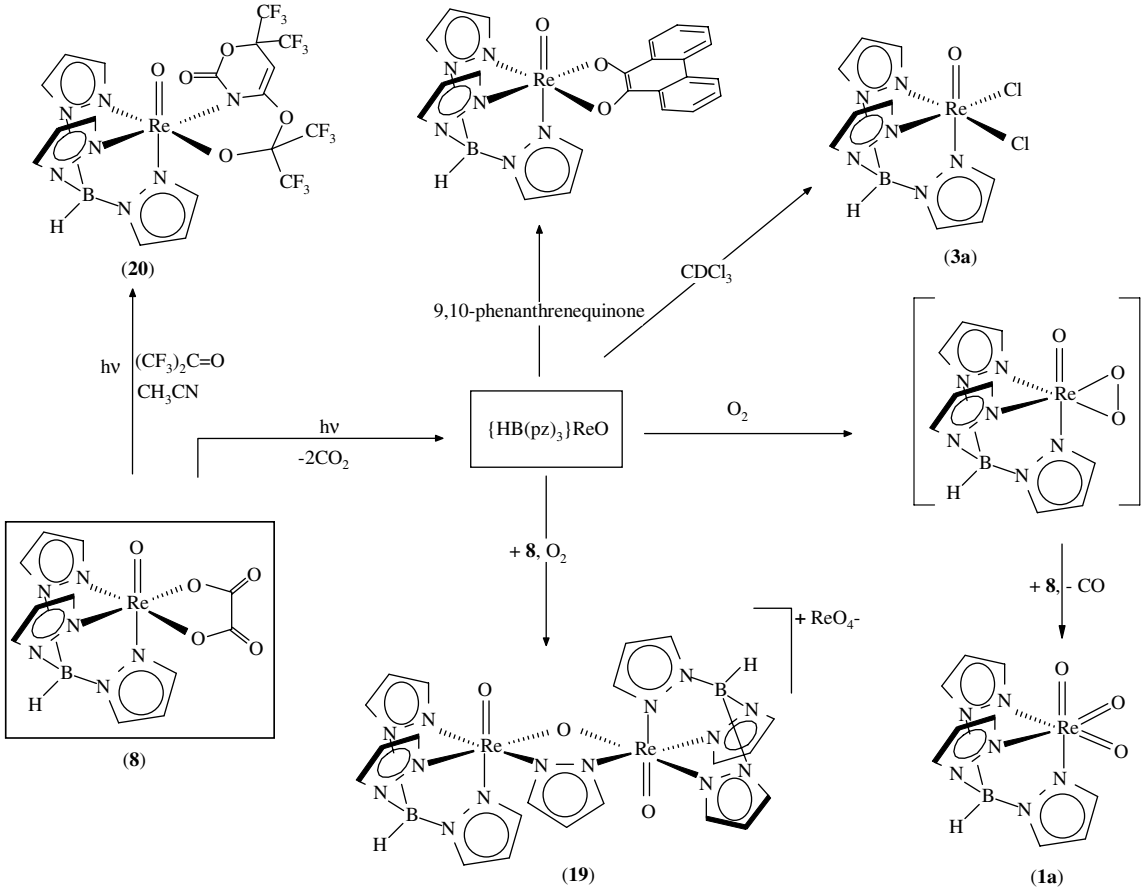


(X = Cl, Br, I) (X = Cl (**18a**), Br (**18b**), I (**18c**))

Scheme 19.



Scheme 20.



Scheme 21.

[TpReCl$_2$(PPh$_3$)], respectively. Based on T_1 and J_{H-D} measurements, a classical character has been proposed for both hydrides.

Santos et al. described a novel route for preparing Re(III) (**21**) and Re(V) (**22**) hydride complexes, which is based on the reaction of [ReOCl$_3$(PPh$_3$)$_2$] with hetero-scorpionates, using alcohols as the solvent (Scheme 24). These authors also studied the reaction of [ReOCl$_3$(PPh$_3$)$_2$] with Na[Ph$_2$Bp] in methanol. In this case, as expected, no hydrides were formed and, from a mixture of oxocomplexes, it was possible to isolate [ReO(OMe){κ^2-Ph$_2$B(OMe)(pz)}$_2$] [54].

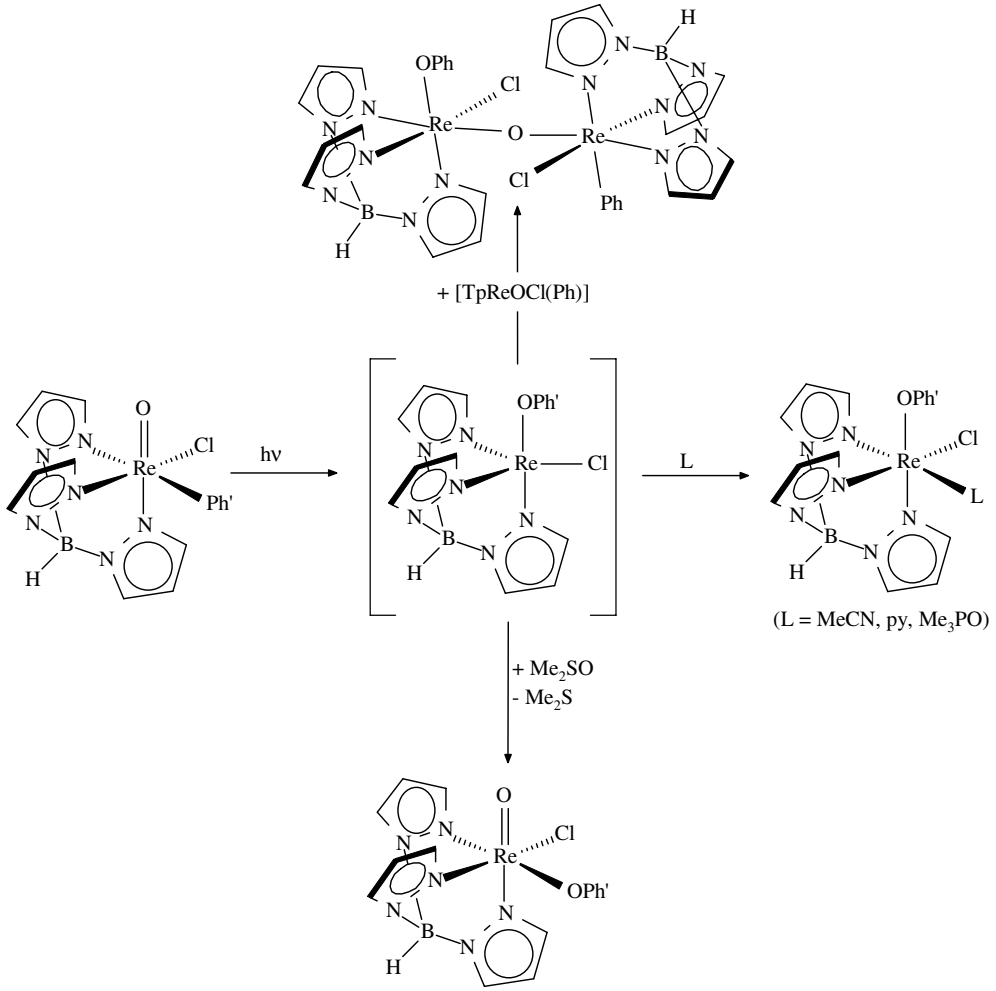
(**6**)

Scheme 22.



(L = MeCN, py, Me_3PO)

Scheme 23.

The crystal structures of **21a** and **22b** were determined, but the hydride ligands were not located by X-ray. The structural parameters of these hydrides were tentatively assigned by a combination of X-ray diffraction and Molecular Orbital calculations of ab initio and Extended Hückel (EHMO) type [54]. The structures of **21a** and **22b** are the first examples of Re(III) and Re(V) hydrides anchored by asymmetric heteroscorpionates, coordinated in a κ^3-(*N*,*N*,*O*) fashion. The spectroscopic, structural and theoretical studies performed on **21** and **22** indicated a classical character for these hydrides [54].

Recently, Mayer and coworkers [55] reported the quite unusual oxo-hydrides [Tp*ReO(H)Cl] (**23**), [Tp*ReO-$(H)_2$] (**24**) and [TpReO(H)Cl] synthesized by reacting [Tp*ReO(OMe)Cl], [Tp*ReO$(OMe)_2$] or [TpReO(OEt)-Cl] with BH_3·THF in toluene at low temperatures (Scheme 25). Prolonged reactions of [Tp*ReO$(OR')_2$] ($R' = OMe$, OEt) with excess BH_3·THF afford Tp*ReH_6 as the only isolable rhenium product [10].

Complex **23** yields [Tp*ReO(H)(OTf)] (**25**) by metathesis with AgOTf in benzene/CH_2Cl_2 [10,55]. Compound **25** is six-coordinate and displays a distorted octahedral coordination geometry, with the hydride ligand in one of the octahedral sites (Re–H, 1.69 Å) [10].

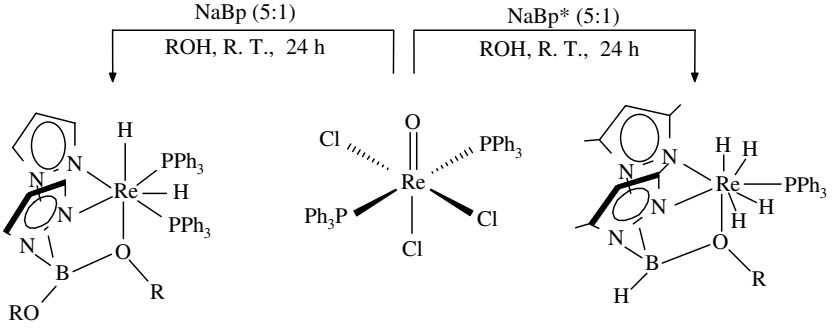
Compound **25** reacts with $CDCl_3$, acetaldehyde, ethylene and propylene affording [Tp*ReO(Cl)(OTf)], [Tp*ReO(OEt)(OTf)], [Tp*ReO(CH_2CH_3)(OTf)] and [Tp*ReO$(CH_2CH_2CH_3)$(OTf)], respectively [10]. The triflate ligand in **25** is easily displaced by pyridine yielding the cationic compound [Tp*Re(O)H(py)][OTf]. This cation is also formed, together with [Tp*ReO_3] (**1c**), when **25** is treated with pyridine *N*-oxide. Using Me_2SO as the oxygen atom transfer reagents, **25** is oxidized mainly to [Tp*ReO_3]. By analogy with phenyl-to-oxo migrations, the mechanism proposed for these oxidation reactions involves a [1,2]-migration of the hydride to an oxo ligand in [Tp*$ReO_2H]^+$, via the intermediate [Tp*Re(O)(OH)(OTf)], which is further oxidized to **1c**.

2.4. Carbonyl complexes

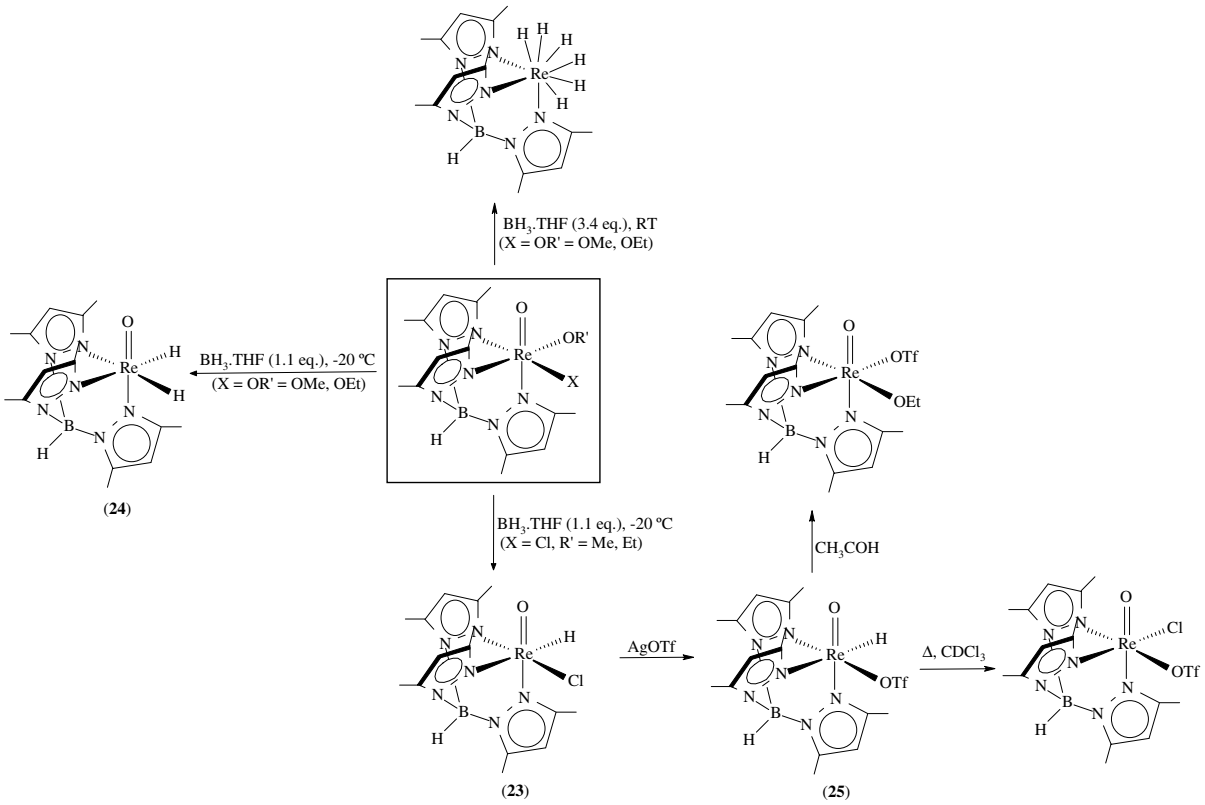
In the late 1960, the tricarbonyl compounds [Tp′Mn$(CO)_3$] (Tp′ = Tp, pzTp) were the first reported group 7 scorpionate complexes [56,57]. Subsequently, several research groups extended the chemistry of homoscorpionate tricarbonyl complexes to Tc and Re. The structurally characterized [Tp′M$(CO)_3$] (M = Tc, Re; Tp′ = Tp*, Tp) were synthesised by reaction of the starting materials [M$(CO)_5$Br] or [M$(CO)_4$(μ-Cl)]$_2$ with the sodium or potassium salts of the correspondent Tp′ ligands [58–60]. The tridentate and facial coordination of the scorpionates, and the facial arrangement of the CO ligands are common structural features of the [Tp′M$(CO)_3$] (M = Mn, Tc, Re; Tp′ = Tp, Tp*) complexes [60].

By contrast, the chemistry of group 7 heteroscorpionate carbonyl complexes is much more limited, being almost restricted to [BpM$(CO)_3$(pzH)] (M = Mn, Re) [61]. In these compounds, the three CO ligands are facially coordinated and the three remaining coordination sites are occupied by the bidentate dihydrobis(pyrazolyl)borate and a pyrazole, arising from partial fragmentation of the Bp ligand [61]. Interestingly, a similar reaction with Na[H_2B(tim^{Me})$_2$], a soft congener of Bp, yields almost quantitatively a tricarbonyl complex with the heteroscorpionate coordinating through the two thione sulfurs and one robust agostic B–H···Re interaction [62].

Ultraviolet irradiation of complexes [Tp′M$(CO)_3$] (M = Mn, Tc, Re) in THF led to the adducts [Tp′M$(CO)_2$(THF)] [59,63,64]. In these complexes, the THF ligand is quite labile and easily replaced by other donors with formation of compounds of general formula [Tp′M$(CO)_2$(L)] (M = Mn, Tc, Re) (Scheme 26) [59,63,64]. Complexes [Tp′M$(CO)_2$(THF)] (M = Tc, Re) react also with N_2 forming the dinuclear species [Tp′M$(CO)_3]_2$(μ-N_2) (M = Tc, Tp′ = Tp*; M = Re, Tp′ = Tp) (Scheme 26) [66,67]. Complex [Tc(κ^3-



Scheme 24.



Scheme 25.

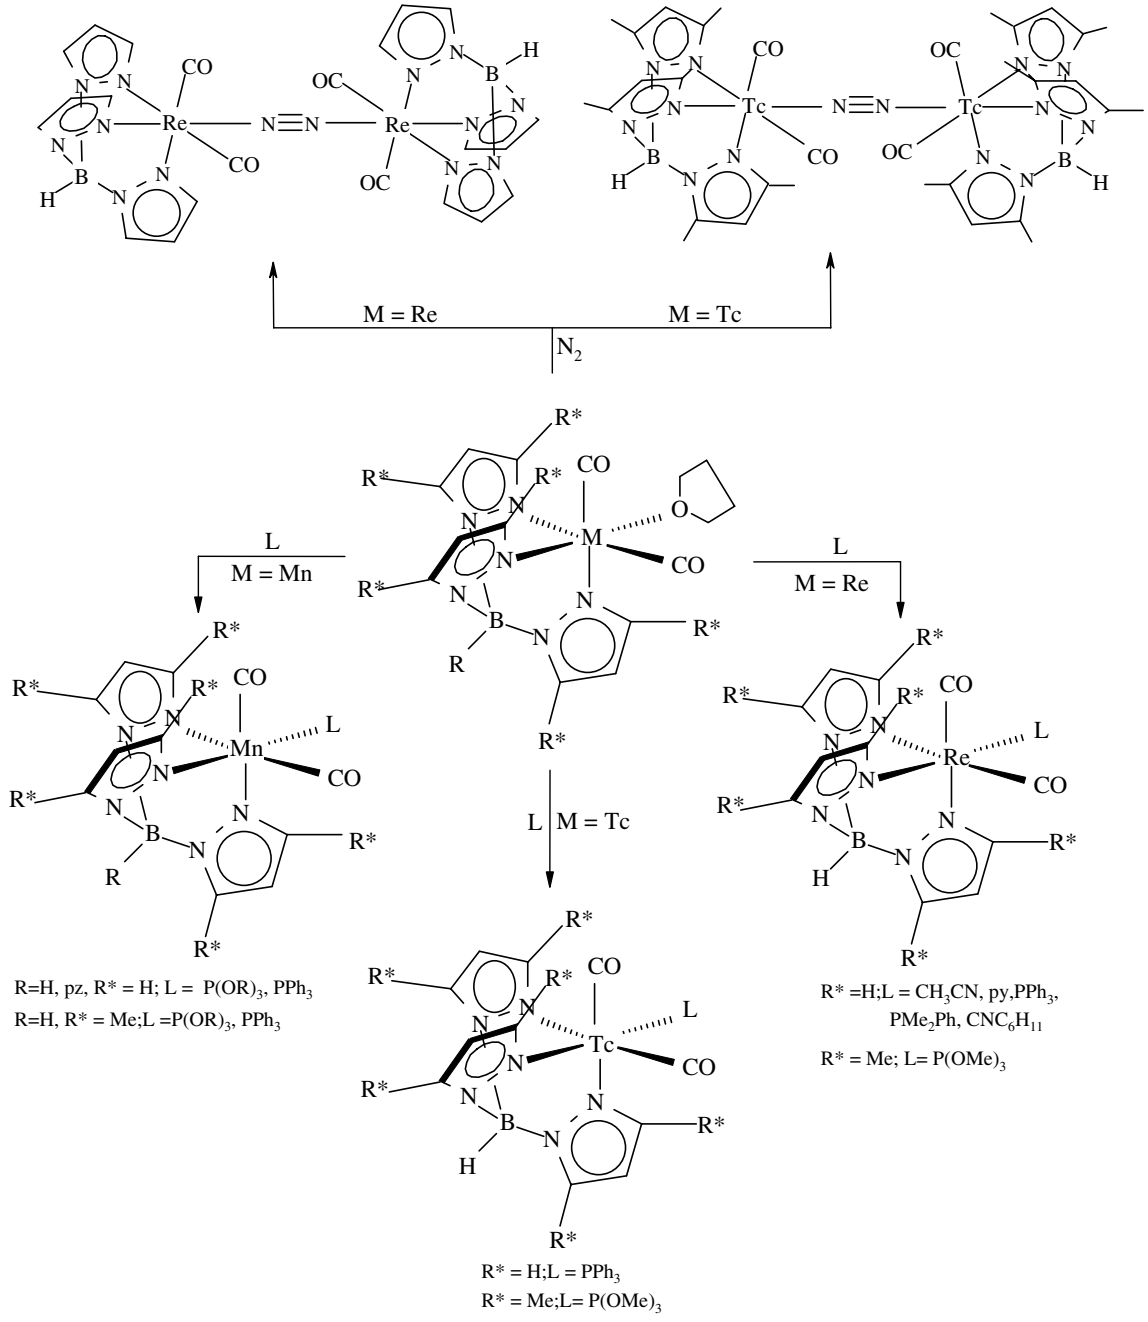
Tp)$(CO)_2(PPh_3)$] was alternatively prepared by a metathesis reaction of $[TcCl(CO)_2(PPh_3)_2]$ with KTp [65].

The monomeric di(carbonyl) complexes [Tp′M$(CO)_2$-(L)] (M = Mn, Tc, Re) are six-coordinate, and present an approximately octahedral coordination geometry. The most relevant structural parameter is the shortening of the M–N bond *trans* to the neutral co-ligand (L = THF, PR_3, $P(OR)_3$) [59,64,65]. The dinitrogen-bridged bimetallic complexes [Tp′M$(CO)_3]_2(\mu\text{-}N_2)$ (M = Tc, Tp′ = Tp*; M = Re, Tp′ = Tp) were also structurally characterized, and a different orientation for the scorpionates in the Re and in the Tc compounds was found (Scheme 26). These dimers are unique examples of structurally characterized dinitrogen bridged ditechnetium or dirhenium complexes, and the M(μ-N_2)M moieties are best described as possessing M–N single and N–N triple bonds [66,67].

Recently, Harman and coworkers studied the reactivity of [TpRe$(CO)_2$(THF)] (**26**) towards unsaturated substrates, namely cyclopentene, furan, thiophene, naphthalene and *N*-methylpyrrole, in order to stabilize monomeric complexes containing η^2-bound aromatic ligands (Scheme 27). The postulated monomeric or dimeric structures for the products, and the coordination mode of the unsaturated substrates were based on IR and NMR spectroscopy [67].

To avoid the dimerization process observed in these reactions, Harman and coworkers replaced one of the CO ligands in the fragment {TpRe$(CO)_2$} by a weaker π-acid or stronger σ-donor ligand. Consequently, the resulting fragments, {TpRe(CO)(L)} (L = ^{t}BuNC, PMe_3, NH_3, 1-Meimz), were more π-basic and were able to bind a series of aromatic molecules, without undergoing dimerization or oxidative addition reactions (Schemes 28 and 29) [50,68,69]. Among the more π-basic compounds, [TpRe(CO)(1-Meimz)(η^2-C_6H_6)] (**27**) proved to be remarkably versatile for the direct synthesis of organometallic derivatives with a variety of unsaturated substrates coordinated in a π-fashion to the metal center (Scheme 29). The authors found that, under nitrogen, the rate of dissociation of the dihapto-coordinate aromatic ligand decreases as the fragment becomes more electron-rich, while the stability to air shows a somewhat inverse trend [50,68–73].

X-ray diffraction analysis was performed on the different [TpRe(CO)(L)(η^2-L_π)] (L = ^{t}BuNC, PMe_3, py, NH_3, 1-Meimz) complexes [50,69,70]. In all, the coordinate double bond of the aromatic ligand (L_π) is oriented perpendicular to the rhenium carbonyl bond, in order to optimize π-back-bonding. [50,69,70]. Due to their asymmetric character, the [TpRe(CO)(L)(η^2-L_π)] compounds exist in solution as two diastereomers, which undergo a non-dissociative interconversion (Scheme 30). The author claims that such interconversion occurs via both interfacial and intrafacial migrations. NOE and 2D NMR techniques allowed the

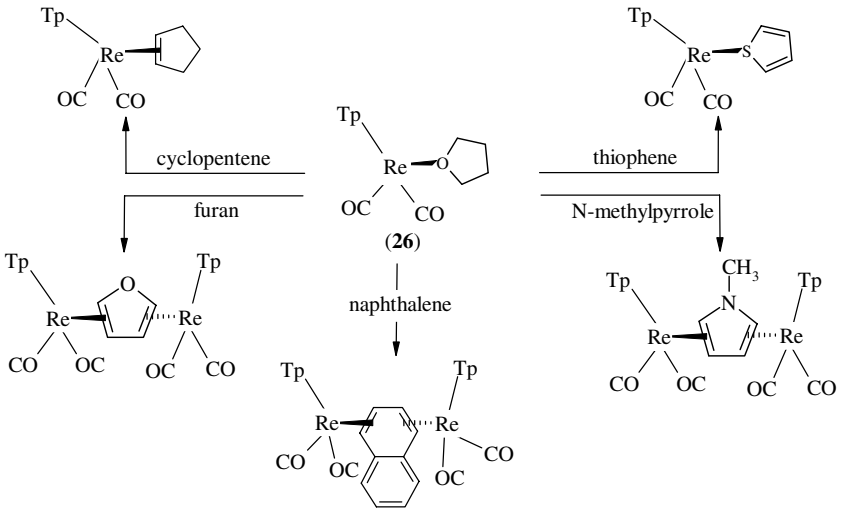


Scheme 26.

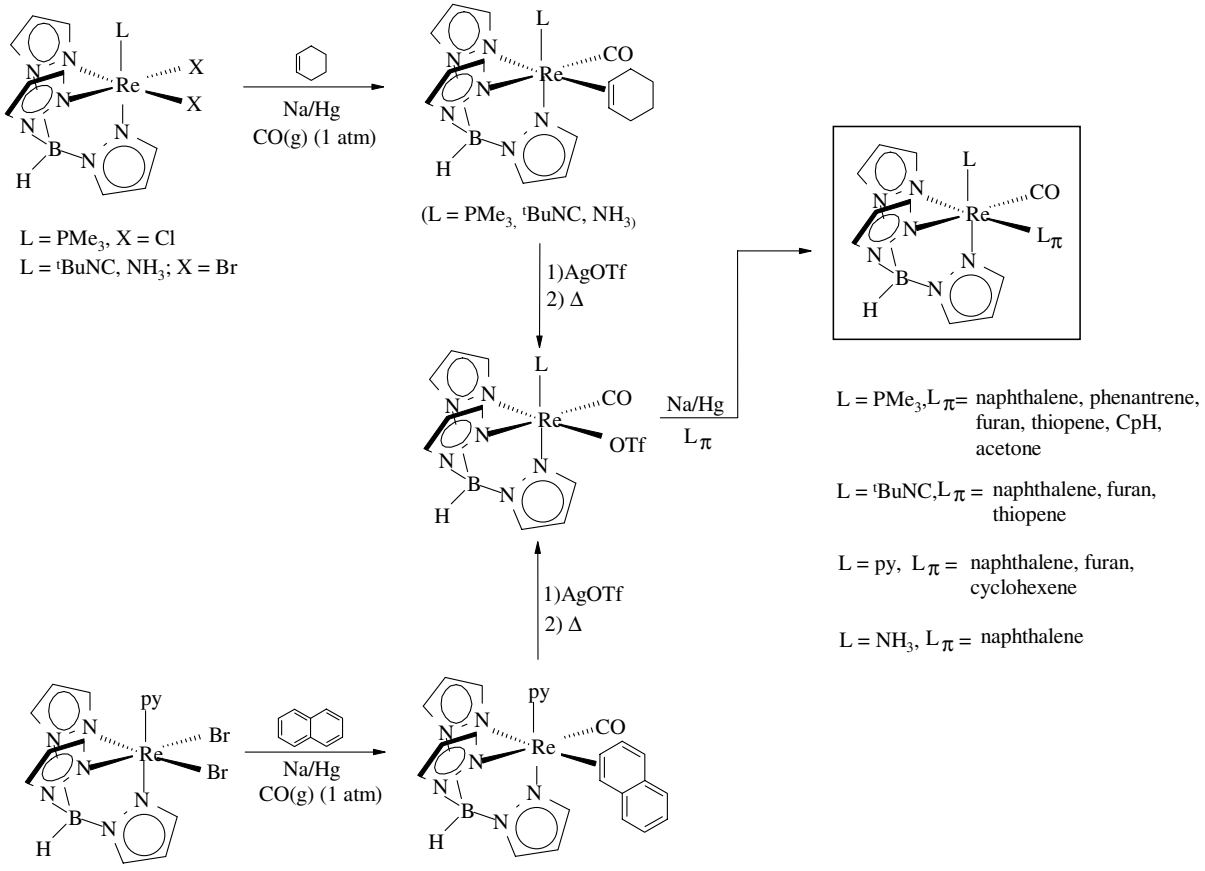
identification of each diastereomer and ^{1}H NMR spin transfer experiments were used to calculate the rate and free energy of activation for the isomerization processes [74]. The diastereoselectivity exhibited by these systems is very much dependent on the nature of the L and L_π ligands, being governed by the relative steric interaction of L and *trans* pyrazole ring with the L_π (Scheme 30).

Due to the volume of PMe_3, a single diastereomer predominates in complex [TpRe(CO)(PMe_3)(η^2-naphthalene)] (**A**, Scheme 30) [50,74]. The resolution of racemic [TpRe(CO)(1-Meimz)(η^2-benzene)] into the *R* and *S* enantiomers was achieved using (*R*)-α-pinene as a chiral auxiliary and based on an elaborated series of redox and substitution reactions [75].

The η^2-coordination of the aromatic substrates to the π-basic metal fragments [TpRe(CO)(L)] is accompanied by the disruption of the aromaticity through π-back-bonding. For example, the crystal structure of [TpRe(CO)(1-Meimz)(η^2-benzene)] (**27**) shows dearomatization to such an extent that the uncoordinated portion of the benzene ring closely resembles cyclohexadiene [70]. This dearomatization explains why **27** undergoes a



Scheme 27.

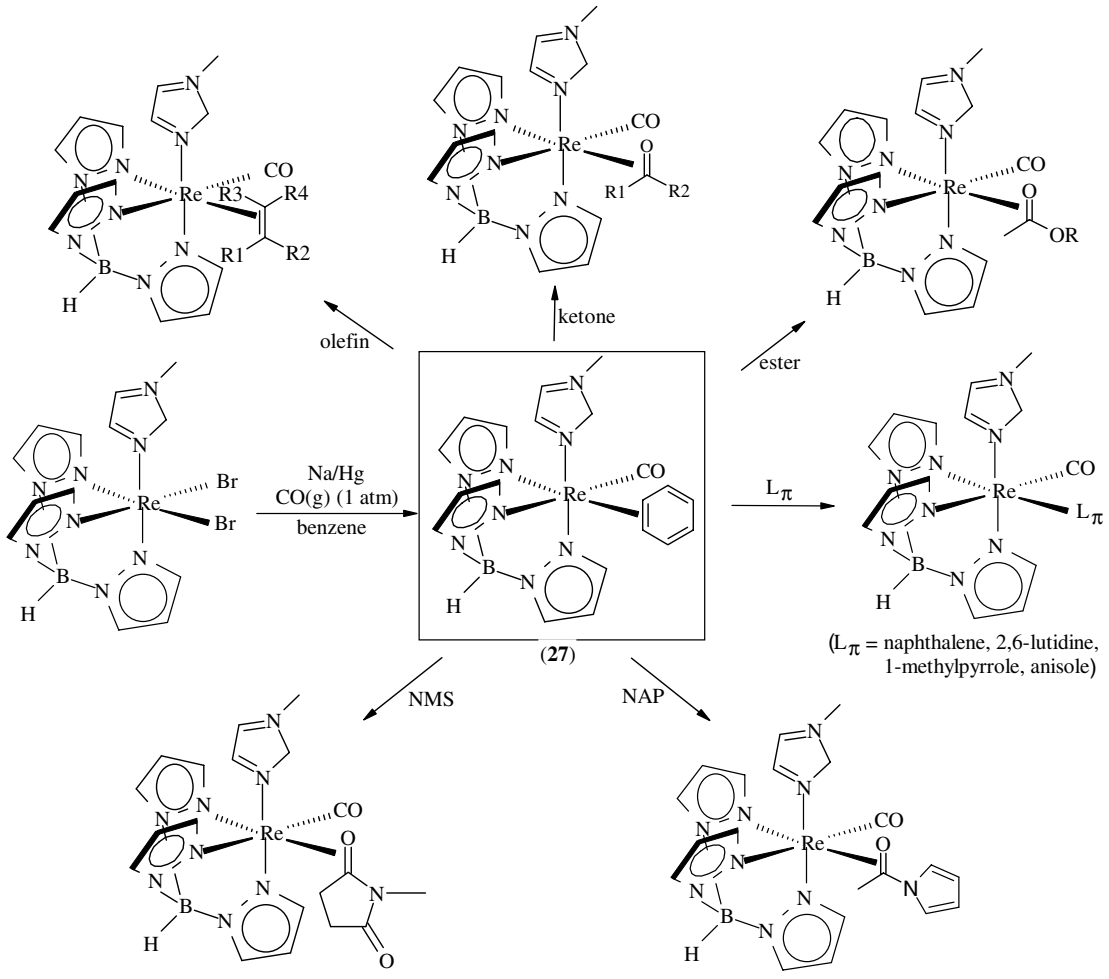


Scheme 28.

Diels-Alder cyclo-addition with *N*-methylmaleimide (NMM) with a specific rate that is 60% faster than that observed for cyclohexadiene (Scheme 31) [76].

X-ray crystallographic analysis of the complex from the cyclo-addition process, **28**, confirmed that the reaction occurs exclusively at the arene face non-coordinated to the metal with exclusive *endo* selectivity. Oxidation of the metal center promotes decomplexation with liberation of bicyclo[2.2.2]-octadiene and/or octenone products, depending on the oxidation conditions (Scheme 31) [76].

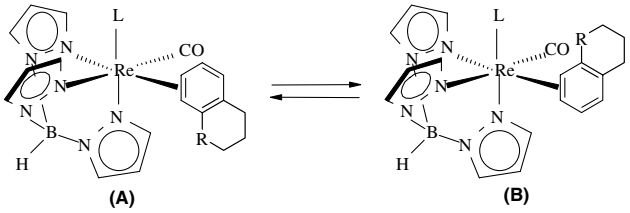
Coordination of furans to the fragments {TpRe(CO)(L)} (L = ^{t}BuNC, PMe_3, 1-Meimz) activates these heterocycles towards cycloaddition reactions with dif-



Scheme 29.

ferent dienophiles. When the furan is bound through the 4,5-positions it undergoes [2 + 2] cyclizations, while [3 + 2] cycloaddition reactions occur when the heterocycle is bound through the 3,4-positions [77].

The acid-catalysed addition of methanol to the coordinated furan in complexes [TpRe(CO)(L)(η^2-furan)] (L = ^{t}BuNC, PMe_3, py, 1-Meimz) was also evaluated. In traditional organic reactions methanol attacks at the 3-position of furan, but in these Re(I) systems the reactions occur at the 2-position, and two diastereomers of η^2-coordinated 2-methoxy-2,3-dihydrofurans are formed (Scheme 32) [78].



Scheme 30.

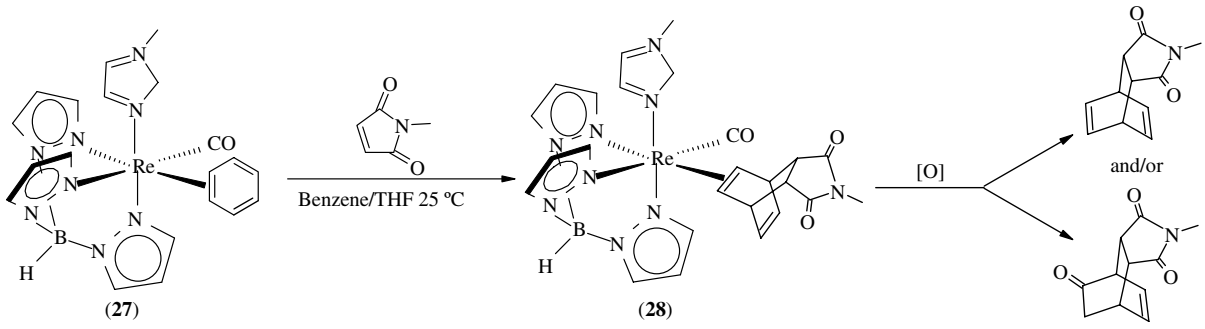
The complexes [TpRe(CO)(L)(η^2-naphthalene)] (L = PMe_3, NH_3, py, 1-Meimz) undergo tandem electrophilic/nucleophilic addition reactions, by sequential treatment with triflic acid and a siloxypropene derivative, leading to 1,4- or 1,2-addition products (Scheme 33) [79]. The regioselectivity of these reactions depends on the nature of the co-ligand L. The key for the regiocontrol seems to be the formation of single 1H-naphthalenium intermediates and its orientation relatively to the CO bond, as depicted in Scheme 33. The PMe_3 complex promotes predominantely the 1,4-addition products, while all the other favor the 1,2-addition [79].

3. 5f-Element scorpionate complexes

3.1. Trivalent complexes

3.1.1. Bis- and mono-homoscorpionates

The unique and fully characterized Pu complex is the dimer [PuCl(μ–Cl)(κ^3-Tp*)(Me_2pzH)]$_2$, which has been isolated in good yield by reacting $PuCl_3$ and NaTp*, in



Scheme 31.

	A:B

PMe_3	2:1
py	1:1
1-Meimz	1:3

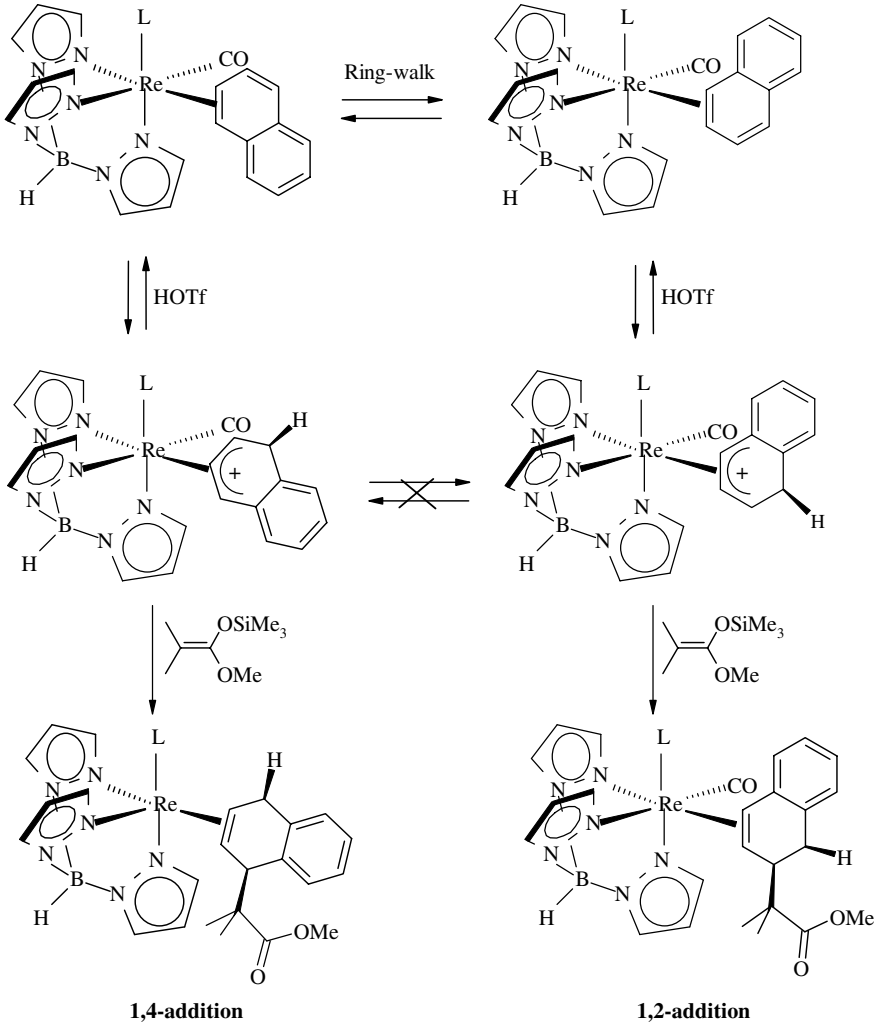
Scheme 32.

refluxing THF during 2 weeks. The synthesis of another plutonium(III) compound, $[PuTp_3]$, was also mentioned, but no details were given [2,80].

Bis- and mono-Tp* U(III) complexes have been synthesized by metathesis of $[UI_3(THF)_4]$ or $[UCl_3(THF)_x]$ in THF (Scheme 34). The iodide derivatives $[(\kappa^3\text{-Tp*})_2UI]$ (**29**) and $[(\kappa^3\text{-Tp*})UI_2(THF)_2]$ (**30**) were fully characterized, including X-ray crystallographic analysis [81,82]. The chloride compound was never characterized in the solid state and its formulation was based on spectroscopic data, as well as on the reactivity towards unsaturated substrates (Scheme 34) [83,84].

Compound **29** readily undergoes iodide abstraction with $TlBPh_4$ to form $[(\kappa^3\text{-Tp*})_2U(THF)]$ $[BPh_4]$ (**31**) [81]. This cation is stable in the solid state but tends to decompose in THF solution. X-ray structural characterization of **29**, **30** and **31** showed that these compounds are seven-coordinate, displaying a distorted capped octahedral coordination geometry. An interesting feature in **29** is the different coordination mode of the two Tp* ligands: one ligand binds normally through three nitrogen atoms, while the other contains one pyrazolyl ring bonded to uranium through both of its nitrogen atoms [82,85].

Takats et al. demonstrated the utility of $[(\kappa^3\text{-Tp*})UI_2(THF)_2]$ as precursor for further derivatization, and by metathesis $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}I]$, $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}_2]$, $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}\{CH(SiMe_3)_2\}]$ and $[(\kappa^3\text{-Tp*})U\{CH(SiMe_3)_2\}_2(THF)]$ were synthesized. The



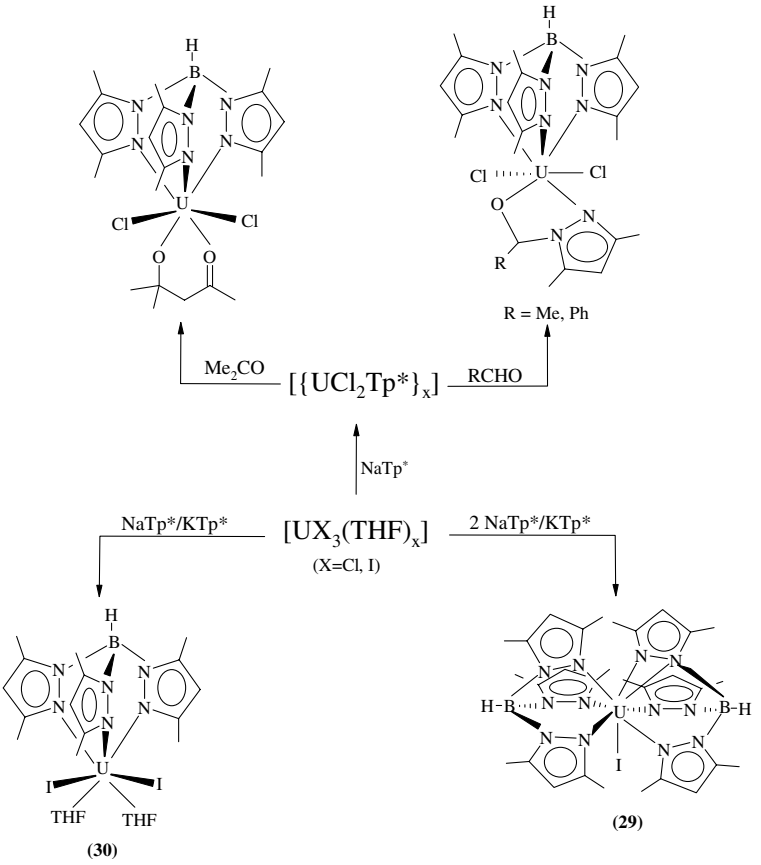
Scheme 33.

bis-amido, bis-alkyl and mixed amido-alkyl derivatives are five- or six-coordinate, displaying trigonal bipyramidal and distorted octahedral coordination geometries [85]. In contrast to $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}I]$, compounds $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}_2]$ and $[(\kappa^3\text{-Tp*})U\{CH(SiMe_3)_2\}_2(THF)]$ are thermally unstable in solution and the decomposition process is solvent dependent [85].

Taking advantage of the possibility of introducing different substituents in the 3-position of the pyrazole ring, the podand $Tp^{2\text{-py}}$ ligand has been synthesized. Takats et al. has shown that $[UI_3(THF)_4]$ reacts with $KTp^{2\text{-py}}$ in the 1:2 ratio in THF yielding the homoleptic $[(Tp^{2\text{-py}})_2U]I$. This complex is 12-coordinate by the six nitrogen atoms of the pyrazolyl rings and by the six nitrogen atoms of the pyridyl groups, displaying an unusual icosahedral coordination geometry [86].

Recently, Santos and coworkers [87] have shown that $[UI_3(THF)_4]$ reacts with $KTp^{i\text{Pr}2}$ in THF yielding $(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(THF)_{2\text{–}3}]$. This compound is unstable in solution, the main decomposition product being $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(Hpz^{i\text{Pr}2})]$ (**32**) [87a]. Interestingly, when $[UI_3(THF)_4]$ is treated with $KTp^{i\text{Pr}2}$ in toluene in the presence of other Lewis bases, different from THF, stable mono-$Tp^{i\text{Pr}2}$ complexes can be prepared. These quite robust compounds of general formula $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(L)_x]$ ($L = OPPh_3$, $x = 1$; L = bipy, $x = 1$; L = py, $x = 2$; $L = Hpz^{t\text{Bu,Me}}$, $x = 2$) were obtained in relatively high yields (65–75%) (Scheme 35). The compounds $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(OPPh_3)]$, $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(bipy)]$, $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(py)_2]$ and $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(Hpz^{i\text{Pr}2})]$ are six- or seven-coordinate, depending on the steric bulk of the neutral co-ligand.

The six-coordinate compound $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(OPPh_3)]$ displays an octahedral coordination geometry, while the seven-coordinate $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(bipy)]$ and $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(py)_2]$ display, respectively, distorted capped octahedral and pentagonal bipyramidal geometries. Initially, $[(\kappa^3\text{-}Tp^{i\text{Pr}2})UI_2(Hpz^{i\text{Pr}2})]$ (**32**) was considered as six-coordinate, by the three nitrogen atoms of the $\kappa^3\text{-}Tp^{i\text{Pr}2}$, two iodides and one nitrogen of the $Hpz^{i\text{Pr}2}$. However, a careful analysis of the relevant structural parameters has shown an additional interaction between



Scheme 34.

the metal and one hydrogen atom of one ^{i}Pr(3) of the Tp$^{i\mathrm{Pr}2}$. This seven-coordinate compound displays a capped octahedral coordination geometry with the axial position defined by the hydrogen atom of the ^{i}Pr group interacting with the metal (U–H, 3.06 Å) and by the nitrogen atom of Hpz$^{i\mathrm{Pr}2}$ [87a].

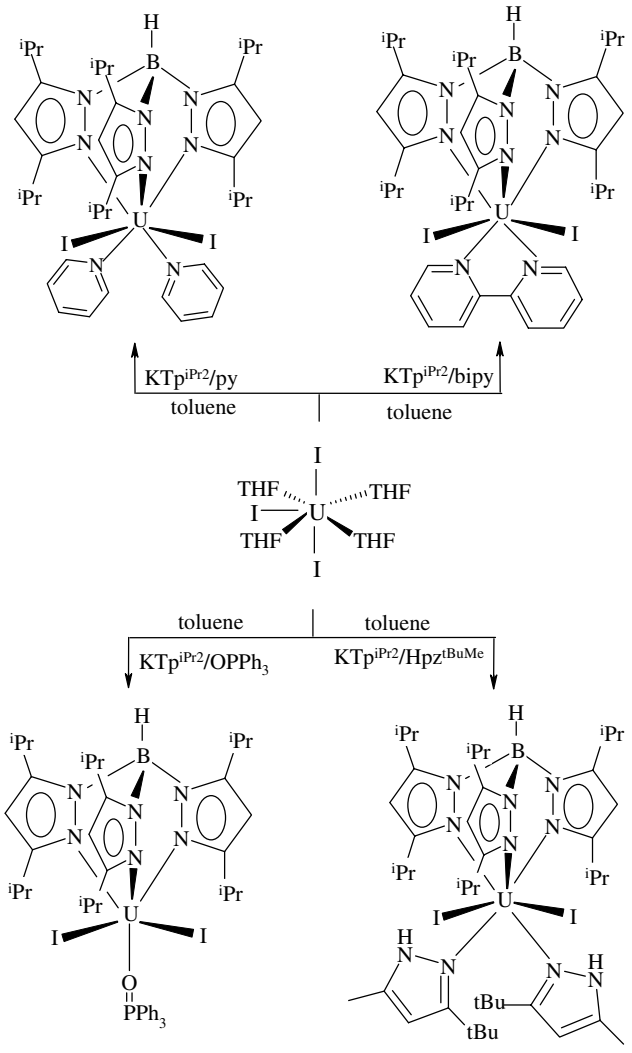
3.1.2. Tris-, mono- and bis-heteroscorpionates

Uranium tricloride or uranium triiodide react with KBp, KBp*, NaPh$_2$Bp and KBp$^{i\mathrm{Pr}2}$ in a 1:3 ratio yielding [(κ^3-Bp)$_3$U(THF)], [(κ^3-Bp)$_3$U], [(κ^2-Ph$_2$Bp)$_3$U] and [(κ^3-Bp$^{i\mathrm{Pr}2}$)$_3$U, respectively (Scheme 36) [87–90].

These homoleptic and monomeric compounds present high solubility in toluene and *n*-hexane. In all the six nitrogen atoms of the three ligands are arranged in a trigonal prismatic geometry around the U(III) center. For [(κ^3-Bp)$_3$U(THF)], [(κ^3-Bp*)$_3$U] and [(κ^3-Bp$^{i\mathrm{Pr}2}$)$_3$U] each of the three rectangular faces of the trigonal prism is capped by an agostic B–H$\cdots$U interaction, leading in the case of [(κ^3-Bp*)$_3$U] and [(κ^3-Bp$^{i\mathrm{Pr}2}$)$_3$U] to formally nine-coordinate compounds and in the case of [(κ^3-Bp)$_3$U(THF)] to a 10-coordinated compound, due to the presence of the THF molecule. The [(κ^2-Ph$_2$Bp)$_3$U] compound is six-coordinate by the nitrogen atoms of the three κ^2-Ph$_2$Bp ligands, and displays a trigonal prismatic geometry, with a C_{3h} molecular symmetry. The long U$\cdots$B distances observed in [(Ph$_2$Bp)$_3$U] (mean value of 3.817 Å) excludes any interaction of the metal with the phenyl groups [90].

Since the bulky and symmetrical substituents in the 3-position of the Bp ligand can be expected to avoid the formation of homoleptic compounds, Santos et al. studied the chemistry of U(III) with KBp$^{t\mathrm{Bu,Me}}$. In fact, metathesis of [UI$_3$(THF)$_4$] with KBp$^{t\mathrm{Bu,Me}}$ in THF yields the first mono-Bp$^{t\mathrm{Bu,Me}}$ f-element compound [(κ^3-Bp$^{t\mathrm{Bu,Me}}$)UI$_2$(THF)$_2$] (**33**) (Scheme 36) [90]. In **33** the THF is easily replaced by OPPh$_3$, bipy, Hpz$^{t\mathrm{Bu,Me}}$ or Hpz$^{\mathrm{Me}_2}$, and the resulting seven-coordinate compounds all retain the agostic B–H$\cdots$U interaction.

The molecular structure of these ''half-sandwich'' complexes and their dynamic behavior in solution indicated a metal center relatively unprotected from incoming ligands. Therefore, the possibility of preparing bis-Bp$^{t\text{-}\mathrm{Bu,Me}}$ complexes was a challenge and has been studied. It was found that [UI$_3$(THF)$_4$] reacts with KBp$^{t\text{-}\mathrm{Bu,Me}}$ in a 1:2 ratio in toluene yielding the unprecedented [{κ^3-H$_2$B(pz$^{t\text{-}\mathrm{Bu,Me}}$)(pz$^{\mathrm{Me},t\text{-}\mathrm{Bu}}$)}$_2$UI] (**34**). Compound **34** has been formed due to an isomerization of the Bp′ ligand promoted by the metal center [91]. Taking into account that these arrangements are sterically driven processes, this result encouraged the synthesis of the novel asymmetric K[H$_2$B(pz$^{t\text{-}\mathrm{Bu,Me}}$)(pz$^{\mathrm{Me}2}$)]



Scheme 35.

ligand, which was expected to have steric properties adequate for the preparation of bis-$Bp^{R,R'}$ U(III) complexes by metathesis. This has been achieved, and the complex $[\{\kappa^3\text{-}H_2B(pz^{tBu,Me})(pz^{Me_2})\}_2UI]$ (**35**) has been synthesized by metathesis [91]. Compounds **34** and **35** are seven-coordinate by two tridentade asymmetric heteroscorpionates (κ^3-N,N,H) and an iodide ligand, both displaying pentagonal bipyramidal coordination geometries [91]. In these studies, the vulnerability of the scorpionates to fragmentation [2,92] led to the formation of the dimeric compound $[(\kappa^3\text{-}Bp^{tBu,Me})UI(Hpz^{t\text{-}Bu,Me})]_2(\mu\text{-}I)_2$ [91].

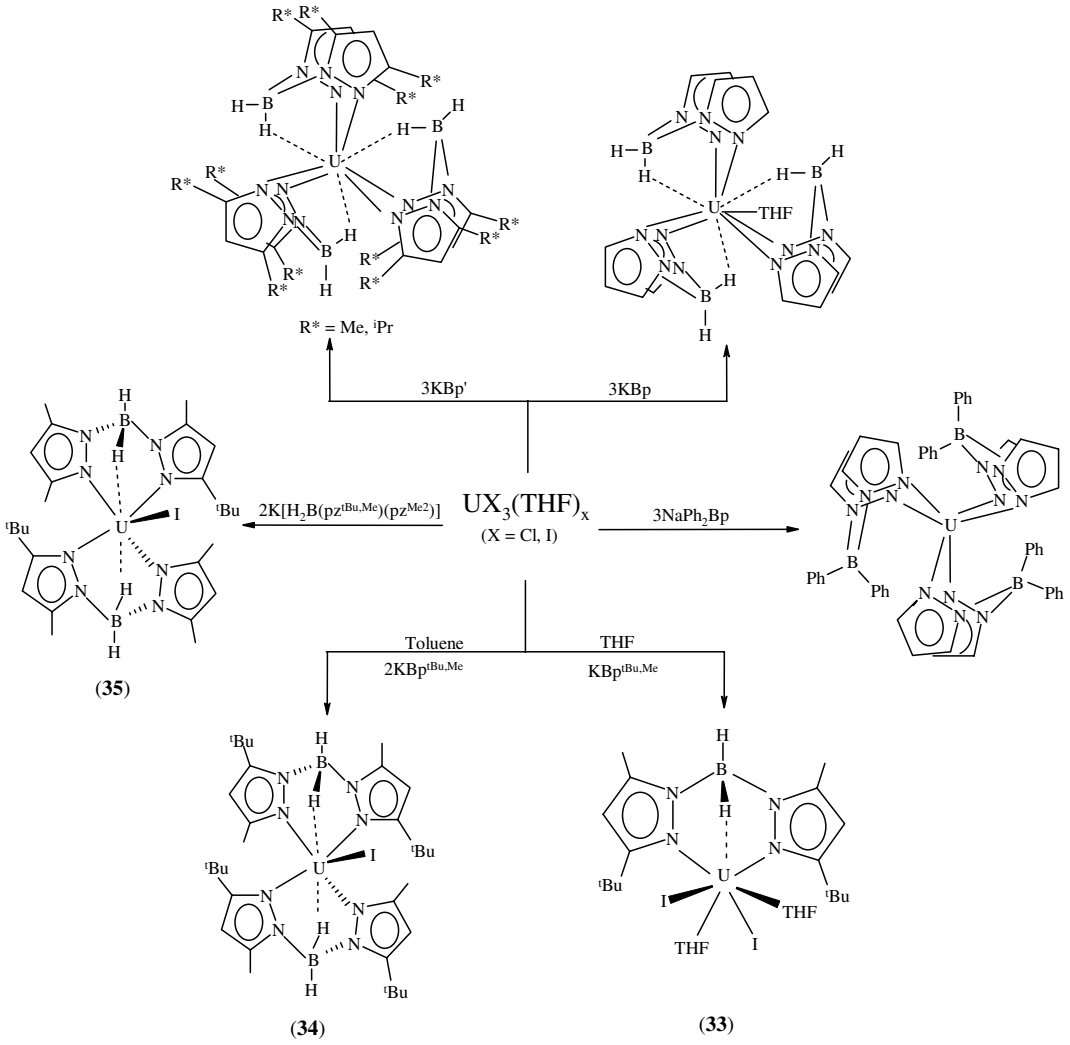
3.2. Tetravalent complexes

3.2.1. Bis and mono-homoscorpionates

The tetrachlorides, MCl_4 (M = Th, U, Np), react with KTp or KpzTp yielding the bis-Tp′ complexes $[(\kappa^3\text{-}Tp)_2AnX_2]$ (X = Cl and An = U, Th, Np; X = Br, An = Th) and $[(\kappa^3\text{-}pzTp)_2UCl_2]$ [4,93]. However, the same type of reaction with bulkier ligands, such as Tp* or Tp^{Ms}, allowed the stabilization of the mono-complexes $[(\kappa^3\text{-}Tp^*)AnCl_3(THF)]$ (An = U, Th, Np) and $[(\kappa^3\text{-}Tp^{Ms^*})UCl_3]$, respectively (Scheme 37) [4,94].

The utility of compounds $[(\kappa^3\text{-}Tp)_2MX_2]$ (M = U, Th, X = Cl; M = U, X = I) and $[(\kappa^3\text{-}pzTp)_2UCl_2]$ for further derivatization has been demonstrated, and several alkyl, amido, thiolate and alkoxide derivatives have been prepared [4,93,95,96]. The reactivity of some U(IV) hydrocarbyl derivatives towards protic substrates, acetone, acetonitrile and iodide was also studied [95,96]. The outcome of the reactions depends on the nature of the alkyl group, as well as on the nature and stoichiometry of the reactants [95,96]. These studies have shown a less rich derivative chemistry for $[(\kappa^3\text{-}pzTp)_2UCl_2]$ than for $[(\kappa^3\text{-}Tp)_2UCl_2]$. In order to get a better insight on these differences, extended Hückel molecular orbital (EHMO) studies have been performed. The analysis of the frontier orbitals did not show any significant differences between Tp and pzTp ligands. However, the calculations indicated that stereochemical interaction affects the reactivity of the complexes stabilized by Tp or pzTp. It was found that the maximum overlap population between these ligands and the uranium metal center is achieved at a bite distance of 3.05 Å for both ligands. This value is ideal for Tp, but for pzTp this distance is energetically unfavorable due to the repulsive interactions between *ortho* hydrogens of the pyrazolyl rings, that are in the same plane. The most favorable bite distance found for the pzTp ligand is 2.85 Å. This feature on its own makes all complexes anchored by pzTp more unstable than their Tp counterparts [93,96]. EHMO calculations provided also some information on the bonding capabilities of the fragment "$[(\kappa^3\text{-}Tp)_2M]$" compared to "$[M(Cp^*)_2]$" and also on the vulnerability of the scorpionate ligands to nucleophilic attack [95].

A significant amount of structural and solution NMR data exists for compounds containing the $[Tp_2'U]$ moiety. In the solid state all are eight-coordinate by two κ^3-Tp′ ligands (Tp′ = Tp, pzTp) and by two monodentate co-ligands, all displaying square antiprismatic coordination geometries, distorted towards bicapped trigonal prism or dodecahedral [4,93,95,96]. In solution all the compounds are fluxional, but static spectra, in accord with the solid state structure, were obtained for most of them, depending on the bulkiness of the co-ligands and/or the coordination number of the metal [4,93,95,96]. For the uranium compounds anchored by pzTp, variable temperature NMR studies revealed that at high temperatures two distinct dynamic processes exist: one intramolecular dissociative process, which promotes the exchange between coordinated and uncoordinated rings, and a non dissociative process involving interconversion of the common eight-coordinate polyhedra (SAP $\Longleftrightarrow$ DD $\Longleftrightarrow$ BCTP).



Scheme 36.

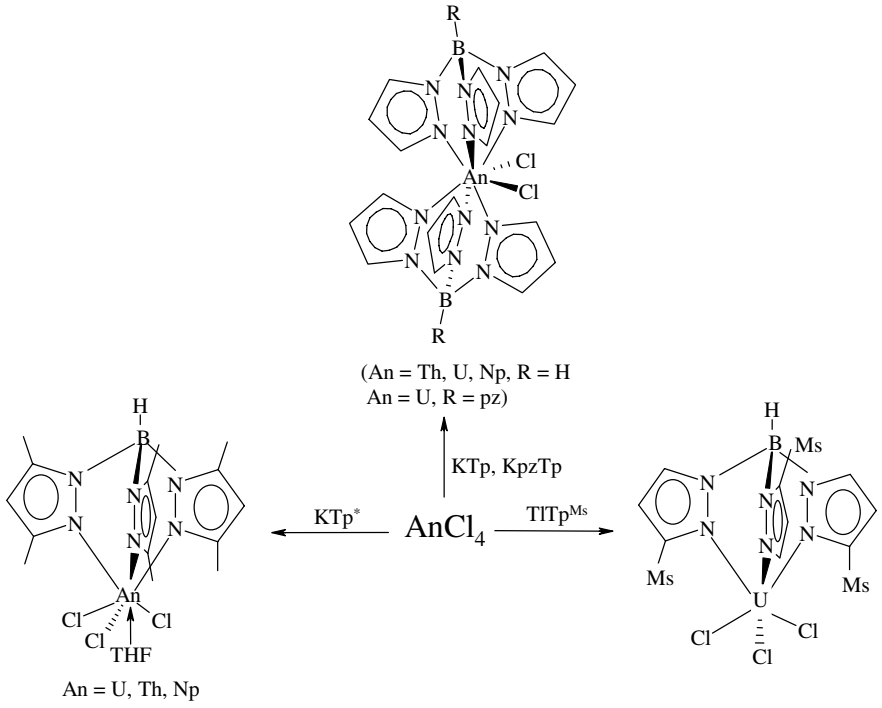
The replacement of one, two or three chlorides in $[(\kappa^3\text{-Tp*})AnCl_3(THF)]$ has also been possible, and a large number of alkoxide, amido, thiolate and alkyl derivatives were isolated and characterized The reactivity of some alkyl derivatives towards several unsaturated substrates was also evaluated [4,84,97]. This family of compounds can be six- or seven-coordinate, and presents a static behavior in solution [4,97].

Recently, Marques and coworkers [94] reported the complex $[(\kappa^3\text{-Tp}^{Ms^*})UCl_3]$, as well as some derivative chemistry (Scheme 38).

An interesting result was the characterization of the symmetrical complex $[U(\kappa^3\text{-Tp}^{Ms})Cl_3]$, which has been obtained during the recrystallization of an amido derivative. It has also been found that nitriles, isocyanides and acetone do not insert into the U–C bond of $[(\kappa^3\text{-TpMs*})U(C_6H_4CH_2NMe_2)Cl_2]$, but acetone reacts with this compound yielding the aldolate $[(\kappa^3\text{-TpMs*})U\{\eta^2\text{-}(OC(Me)_2CH_2C(=O)Me\}Cl_2]$ [94]. This reactivity is comparable to the one observed for the analogous $[(\kappa^3\text{-Tp*})UCl_3(THF)]$ [4]. Based on NMR results, the authors considered the Tp^{Ms^*} a poorer electron donor than Tp*, and a less sterically demanding ligand. This last feature being due to the rearrangement of the Tp^{Ms} ligand during formation of the complex. The X-ray analysis of $[(\kappa^3\text{-Tp}^{Ms^*})UCl_3]$, $[(\kappa^3\text{-Tp}^{Ms})UCl_3]$ and $[(\kappa^3\text{-Tp*})U\{N(SiMe_3)_2\}Cl_2]$ revealed that the uranium center has octahedral geometry with the ligand coordinating in its usual κ^3-mode [94].

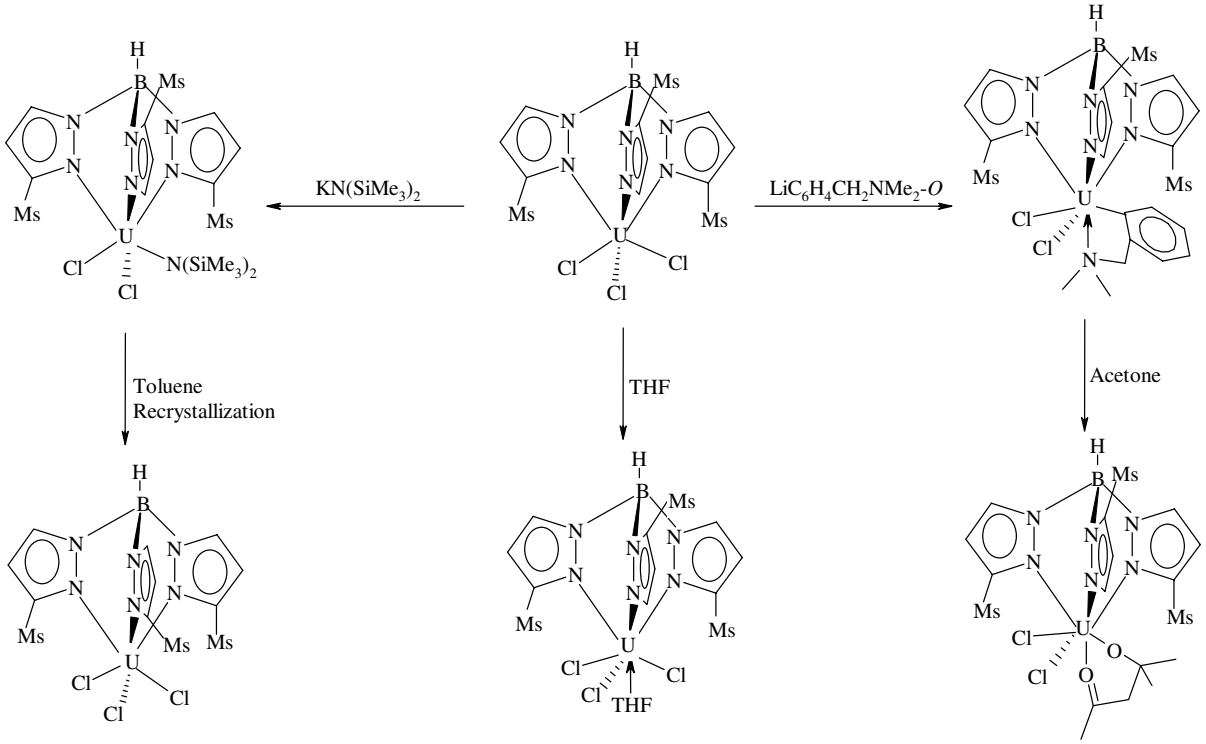
4. Final remarks

In the last few years a resurgence of interest in the chemistry of rhenium scorpionates is clear from the plethora of contributions and a variety of complexes, mainly anchored by Tp, pzTp and Tp* and with metal in the oxidation states +VII to +I, have been isolated. Using high valent oxides, several oxygen transfer reactions have been studied, allowing the stabilization of unusual neu-



Scheme 37.

tral and anionic Re(V) *trans*-dioxocomplexes anchored by pzTp or Bp′, and Re(VI) cationic *cis*-dioxocompounds anchored by Tp. Thermal and photochemical migration of alkyl or aryl groups from the metal to the oxo ligand have also been reported, for the first time. Catalytic oxygen transfer reactions have been studied using Re(V) oxides anchored by Tp* and pzTp, and a significant effect of the scorpionate ligand on these transfers was found.



Scheme 38.

A relatively *old compound*, a Re(I) dicarbonyl, has been reinvestigated and an impressive synthetic chemistry around it has been developed. Modulation of the electronic properties of the Re(I) metallic center allowed the stabilizing of rare monomeric η^2-aromatic compounds. A series of reactions involving selective transformation of the organic substrates has been described.

Among the actinides, uranium is still the most studied element and, in the last few years, its chemistry has been extended to the so called second generation of homo and heteroscorpionates. For U(III) it has been clearly shown that the type of compounds formed depends not only on the bulkiness but also on the symmetry of the 3-R substituents. The first mono-heteroscorpionate and bis-asymmetric heteroscorpionate complexes have been described and characterized, confirming the importance of modulating the steric profile of the ligand. This recently described U(III) chemistry certainly has opened a new avenue for heteroscorpionates as ancillary ligands.

5. Abbreviations

acac	acetylacetonate
An	actinides
BCTP	bicapped trigonal prismatic
bipy	bipyridine
Bp	dihydrobis(pyrazolyl)borate
Bp′	substituted dihydrobis(pyrazolyl)borate
Bp*	dihydrobis(3,5-dimethylpyrazolyl)borate
$Bp^{tBu,Me}$	dihydrobis(3-*tert*-butyl-5-methylpyrazolyl)borate
Bu	butyl (superscript n or *t* for normal or tertiary)
Cp*	pentamethylcyclopentadienyl
CpH	cyclopentadiene
DD	dodecahedral
dmpe	1,2-bis(dimethylphosphino)ethane
DMSO	dimethyl sulfoxide
dppe	1,2-bis(diphenylphosphino)ethane
Et	ethyl
$Hpz^{tBu,Me}$	3-*tert*-butyl-5-methylpyrazole
Hpz^{Me_2}	3,5-dimethylpyrazole
8-hqnH	8-hydroxyquinoline
IR	infrared
Me	methyl
1-Meimz	1-methylimydazole
NAP	*N*-acetylpyrrole
NOE	nuclear overhauser effect
NMM	*N*-methylmaleimide
NMR	nuclear magnetic resonance
NTol	*p*-tolylimido
OTf	triflate, OSO_2CF_3
Ph	phenyl
Ph′	substituted pheny
Ph_2Bp	diphenylbis(pyrazolyl)borate
PhTp	phenyltris(pyrazolyl)borate
Pr	propyl (superscript *i* or *n* for iso or normal)
py	pyridine
py-O	pyridine *N*-oxide
pzH	pyrazole
pz′H	substituted pyrazole
pzTp	tetrakis(pyrazolyl)borate
R.T.	room temperature
SAP	square antiprismatic
2-S-py	pyridine-2-thiolate
THF	tetrahydrofuran
tim^{Me}	1-methyl-2-mercaptoimidazole
Tp	hydrotris(pyrazolyl)borate
Tp*	hydrotris(3,5-dimethylpyrazolyl)borate
Tp^{Ms}	hydrotris(3-mesitylpyrazolyl)borate
Tp^{Ms}*	hydrotris(5-mesitylpyrazolyl)borate

Abstract

The complex [RuH(κ^3-bpzmPhO)(cod)] (**1**) was synthesized by the reaction of [RuH(cod)(NH_2NMe_2)$_3$][BPh_4] with the potassium salt of 2-phenoxy-bis(pyrazol-1-yl)methane (bpzmPhOK). This ligand adopts a κ^3-*N*, *N*, *O* coordination on the metal center that is reminiscent of the situation usually observed in trispyrazolylborate complexes. Complex **1** exists in solution as a mixture of two diastereoisomers that are in equilibrium. The reaction of **1** with different phosphines (PMe_3, PMe_2Ph, $PMePh_2$ and PPh_3) has been studied. The reaction product depends not only on the nature of the phosphine but also on the complex:L ratio and the temperature. Diphosphine derivatives of stoichiometries [RuH(κ^1-*O*-bpzmPhO)(cod)L_2] (L = PMe_3, PMe_2Ph) and [RuH(κ^3-bpzmPhO)L_2] (L = PMe_3, PMe_2Ph, $PMePh_2$, PPh_3) were prepared. Similarly, tetraphosphine derivatives of formula [*cis*-*O*,*H*-RuH(κ^1-*O*-bpzmPhO)L_4] (L = PMe_3, PMe_2Ph) were obtained. The complex with PMe_2Ph can be transformed into the respective *trans* isomer by heating the solution. The reaction of **1** with five equivalents of PMe_3 gives rise to a pentaphosphine derivative with complete decoordination of the anionic bpzmPhO ligand. This ligand exhibits hemilabile behavior that involve a reversible coordination of the pyrazole fragments. Proton transfer reactions from HBF_4 to **1** have also been studied both in acetone-d_6 and in methanol-d_4. In all of these processes the proton is selectively transferred to the oxygen of the bpzmPhO ligand, which remains coordinated through at least the *N*-donor centers. Three hydride derivatives are formed in these reactions and they differ either in the relative orientation of the ligands or in the coordination of the OH group of the ligand.

1. Introduction

Homo- and heteroscorpionate borate ligands have been widely used in coordination chemistry [1]. In recent years analogues of the boron-based scorpionates have been prepared and used as ligands. [1] For instance, bis- and tris(pyrazol-1-yl)methane compounds potentially offer analogous coordination modes to those found in the classical scorpionates [2]. In contrast with the classical systems, the methane derivatives are neutral and consequently the metal–ligand interaction is weaker. The introduction of charged groups in the spacer carbon is an interesting possibility in terms of improving the coordination ability of these ligands and, on the other hand, involves the possibility of introducing a hemilabile role for this ligand in the resulting complexes.

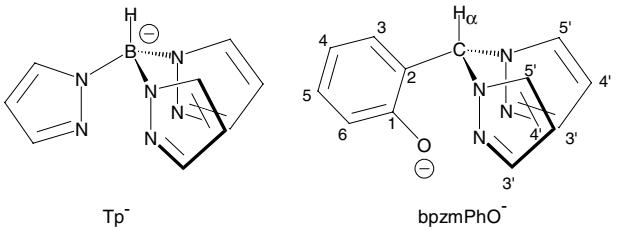

Scheme 1.

In recent years we [3] and others [4] have prepared bis(pyrazol-1-yl)methane derivatives bearing additional functionalized groups in the spacer carbon between the two pyrazoles. The previously described (2-hydroxyphenyl)bis(pyrazol-1-yl)methane is an example of this family of ligands [5]. The ligand is easily prepared by the Peterson method [6] and offers the possibility of deprotonating the phenol group, which transforms it into an anionic compound ($bpzmPhO^-$) that is reminiscent of the original scorpionates (Scheme 1). However, in the anionic form the charge is mainly located at the oxygen, a situation that increases the coordination ability of this atom. In this way, this potentially *NNO*-ligand could stabilize the same complexes as the boron-based scorpionates but the different electronic character of the donor atoms could lead to asymmetrization of the coordination sphere of the metal.

Carrano et al. used the anionic form of this ligand to prepare Co [5,7], Ni [7a,7b,8], V and Fe [7c], Zn, Cu and Mn [7a,7b] complexes. The introduction of substituents in the pyrazole rings or the phenol (or thiol) groups makes the formation of mononuclear species less favorable when bulky ancillary ligands are also coordinated to the metal center. As a consequence, in the work described here we preferred to use the unsubstituted ligand to stabilize mononuclear ruthenium compounds with three main goals in mind: (i) to explore the coordination ability of the three donor atoms of this ligand; (ii) to analyze the potential hemilability of the ligand in substitution processes with different phosphines; (iii) to evaluate the role of the phenoxy group, which is, in principle, in competition with the hydride ligand bonded to the Ru center, in proton transfer reactions.

2. Results and discussion

2.1. Synthesis and characterization of complexes *1a* and *1b*

The new hydride derivative [RuH(bpzmPhO)(cod)] (**1**) which is the starting material for the work described in this paper, can be obtained by reaction of bpzmPhOK with $[RuH(cod)(NH_2NMe_2)_3][BPh_4]$ or [RuClH(bpzm)(cod)] according to Eqs. (1) and (2), respectively. Reaction (2) is slightly less convenient because it requires the separation of the displaced bpzm (see Section 3).

$$[RuH(cod)(NH_2NMe_2)_3][BPh_4] + bpzmPhOK \rightarrow \underset{(\mathbf{1})}{[RuH(bpzmPhO)(cod)]} + KBPh_4 + 3NH_2NMe_2 \quad (1)$$

$$[RuClH(bpzm)(cod)] + bpzmPhOK \rightarrow \mathbf{1} + KCl + bpzm \quad (2)$$

cod = 1,5-cyclooctadiene, bpzm = bis(pyrazol-1-yl)methane.

In the hydride region of the ^1H NMR spectrum of complex **1**, two resonances (−3.64 ppm, d, $J = 2.9$ Hz and −6.84 ppm, s) are observed (see Table 1). This is due to the presence of two isomers whose ratio (**1a**:**1b**) changes with the solvent (acetone-d_6, 1:1; methanol-d_4, 2:1), meaning that the two species are in equilibrium. The assignment of the ^1H NMR resonances of the two isomers (except the aliphatic cod signals) was made on the basis of NOE and ^1H–^1H COSY spectra (acetone-d_6). The ^1H and $^{13}C\{^1H\}$ NMR spectra of isomer **1a** (Tables 1 and 2) show signals for two types of pyrazole ring and four distinct resonances for the olefinic CH groups of the cod ligand (C_1 symmetry). The hydride signal at −3.64 ppm exhibits a NOE with two olefinic protons. Considering all these data, the structure shown in Scheme 2 is proposed for this compound. Two lines are observed for the hydride signal and this is unexpected. However, it was confirmed that the resonance is indeed a doublet after the same coupling constant was observed in spectra acquired using 300, 200 and 80 MHz spectrometers. In addition, the COSY spectra show a correlation between this signal and an aliphatic cod proton (2.21 ppm). The coupling was confirmed when selective irradiation of the cod signal was observed to transform the hydride resonance into a singlet. This coupling can be explained in terms of a distortion of the octahedral geometry, which has been determined by X-ray diffraction for other complexes with the RuH(cod) fragment [9], resulting in the hydride group coming into close proximity with the cod ligand.

The ^1H and $^{13}C\{^1H\}$ NMR spectra of **1b** (Tables 1 and 2) exhibit signals for one type of pyrazole ring and a cod group with C_s symmetry. This data, along with the NOE observed between the hydride resonance (−6.84 ppm) and one type of olefinic cod proton (2H), allowed the structure of this isomer to be determined (see Scheme 2).

The reactivity of **1a/b** with different phosphines and the addition of HBF_4 was explored and the results of these studies will be discussed in the following sections.

2.2. Reaction of *1alb* with phosphines

The reaction of **1a/b** with phosphines of different basicity and, more importantly, different levels of steric

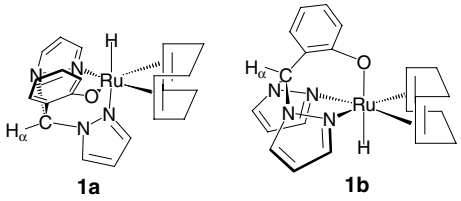
[a] Room temperature. All signals are singlets. Solvent, acetone-d_6.

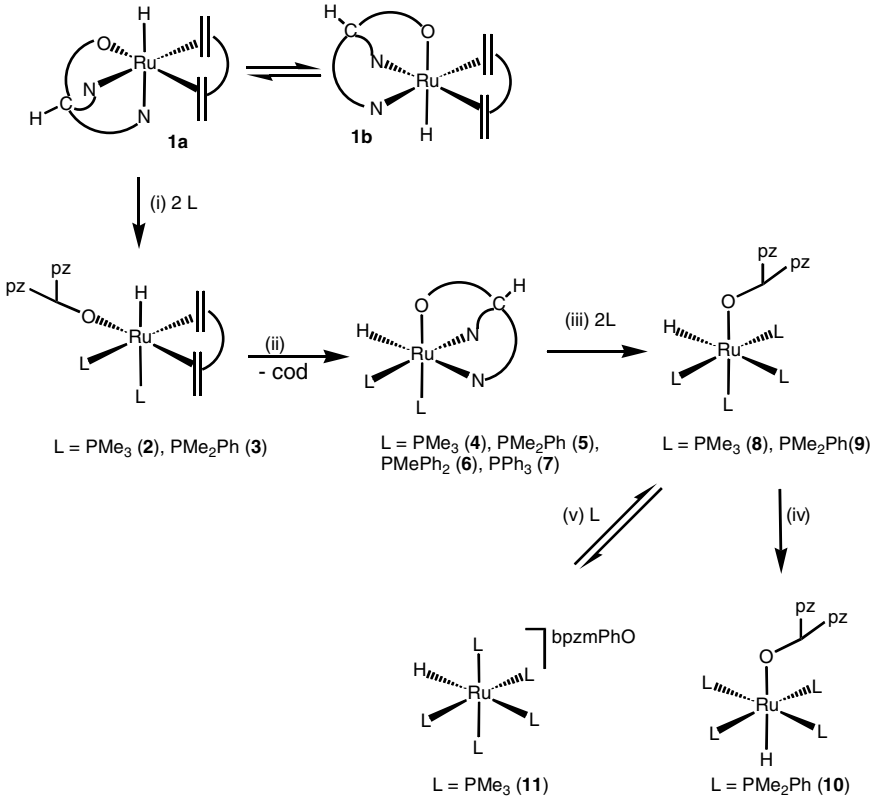


Scheme 2.

hindrance (L = PMe_3, PMe_2Ph, $PMePh_2$, PPh_3) in a range of complex:L ratios and temperatures was studied. Although all possible stoichiometries were not assessed, the preliminary results provide evidence that the most labile functions to be displaced were those on the pyrazole groups and the cod ligand. It was therefore decided that complex:L ratios of 1:2 and 1:4 would be the most suitable for further study. The reactions were carried out in an NMR tube using benzene-d_6 as solvent and reaction progress was monitored by ^1H and $^{31}P\{^1H\}$ NMR spectroscopy. The product was isolated when only one species was detected.

The discussion that follows is based on the processes outlined in Scheme 3 and the nature of the reaction product is essentially dependent on the whole range of factors described above. It must be emphasized that the whole series of steps reflected in Scheme 3 is not complete for any of the phosphines used. However, the scheme is a reasonable general pathway for the reactions observed.

As shown in Scheme 3, reaction of **1a/b** with small phosphines, i.e., PMe_3 and PMe_2Ph, is the most versatile route. A complex:L ratio of 1:2 at room temperature (step i) led to complexes **2** and **3**, which formally can be



Scheme 3.

considered as the result of the displacement of the pyrazole groups from isomer **1a**, although the possibility of a direct reaction of **1b** with the phosphines followed by rapid rearrangement can not be excluded. Interestingly, when solutions of **2** or **3** were heated at 70 °C, the elimination of cod was observed with the concomitant recoordination of the pyrazole groups to give **4** or **5** (step ii). This behavior implies partial decoordination of the hemilabile ligand, which allows coordination of a second ligand (phosphine, in our case) that can induce the displacement of a third one (cod, in this case) with recoordiantion of the former. To the best of our knowledge, this behavior is very rarely observed [10]. The main conclusion to be drawn from these results is that **2** and **3** can be considered as products of kinetic control while **4** and **5** are the thermodynamically stable species' for this stoichiometry. Complex **5** could be isolated whereas **4** appeared in the solutions as the minor component of a mixture with the tetraphosphine derivative **8** and unidentified compounds with resonances in ^{1}H and ^{31}P NMR.

Bulkier phosphines such as $PMePh_2$ and PPh_3 did not react at room temperature but heating the reaction solutions (70 °C) did give the isolable products **6** and **7**, respectively. These compounds are isostructural with complexes **4** and **5**. The fact that species' of similar structure to **2** or **3** were not obtained with $PMePh_2$ or PPh_3 could be due to the high temperature required for the reactions to occur.

The use of a complex:L ratio of 1:4 with the different phosphines provided the conclusions that only the smallest phosphines (PMe_3 and PMe_2Ph) gave tetraphosphine derivatives and for PMe_2Ph this reaction was only possible above 50 °C (room temperature for PMe_3). Complexes **8** and **9** were initially obtained in these reactions (step iii). Both the cod and the pyrazole groups were displaced, with the bpzmPhO remaining coordinated as a monodentate *O*-donor ligand. When solutions of **9** were heated at 70 °C this complex evolved to give the more symmetrical isomer **10** (step iv), which, despite being the major component of the mixture, could not be isolated as a pure species and was characterized only by NMR.

The smallest phosphine, PMe_3, was even able to remove completely the bpzmPhO ligand from the metallic center when a complex:L ratio of 1:5 was used at room temperature (step v), although in this reaction competition between the two ligands was observed that gave mixtures of **8** and the pentaphosphine derivative **11**. The analogous isomer to **10** was not observed with PMe_3. However, the formation of this derivative as a transient intermediate, with a mutually *trans* disposition of the bpzmPhO and H ligands (hydride has a high *trans* influence), could explain the total displacement of the phenoxy group in **8** to give **11**. Nevertheless, **10** does not react with an excess of PMe_2Ph, even after heating, possibly due to steric factors. The complete decoordination of bpzmPhO by incoming ligands, as observed in the reaction with PMe_3 to give **11**, is an infrequent process but does have a precedent in the chemistry of trispyrazolylborate complexes [11].

It can be concluded that: (i) the displacement reactions from **1a/b** can be controlled by the complex:L ratio and temperature; (ii) the final product also depends on the nature of the phosphine; (iii) the ease of substitution is in the order: pyrazoles > cod > bpzmPhO ligand; (iv) the bpzmPhO ligand shows a hemilabile behavior in these reactions.

The most relevant aspects concerning the characterization of complexes **2**–**11** are discussed below.

The stretching vibrations for the terminal Ru–H bonds were observed in the expected regions of the IR spectra (1973–2025 cm^{-1}).

Complexes **2**–**11** were characterized by ^{1}H (except **4** – which is present as a minor component with **1** and **8**), $^{31}P\{^{1}H\}$ (see Tables 1, 3 and 4) and $^{13}C\{^{1}H\}$ NMR spectroscopy (except **2**–**4**, which are too unstable or could not be isolated) (see Table 4).

The resonances in the ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra for the pyrazole rings provide valuable information about the symmetry of the complexes. For example, the existence of two distinct pyrazoles is deduced for complexes **2**, **3**, **5**–**7** but only one pyrazole is present in **8**–**11**. One of the most noticeable differences between **2** and **3** and the rest of the phosphine complexes is the existence of cod resonances. The cod signals in the ^{1}H NMR spectra of **2** and **3** show the expected pattern for a local C_1 symmetry and more than two different olefinic resonances (in fact three out of the four expected) are observed.

The hydride chemical shifts are very sensitive to the environment, and particularly to the ligand situated in the *trans* position (δ, *trans* to phosphine ca. −1 ppm, **2**–**3**; *trans* to a pyrazole group, between −13 to −15.5 ppm, **4**–**7**). The electronic enrichment of the metallic center induces a corresponding shift to lower frequency of the hydride resonance for the tetra- and pentaphosphine derivatives **8**–**11** and the *trans* effect of the ligand is also observed for this series of complexes (δ, *trans* to phosphine ca. −8 ppm, **8**–**9** or ca. −12 ppm, **11**; *trans* to phenoxy group ca. −18.7 ppm, **10**). The expected multiplicities were observed for the hydride resonances and the coupling constants were in the expected range (*trans* J_{PH}, 70–100 Hz; *cis* J_{PH}, ca. 30 Hz).

The $^{31}P\{^{1}H\}$ NMR spectra of diphosphine derivatives **2**–**7** (see Table 4) show two different resonances with the expected shift to higher frequencies due to the coordination. The J_{PP} coupling constants are indicative of a *cis*-arrangement for both phosphines (J_{PP} = 26–41 Hz). As expected, the tetraphosphine derivatives **8** and **9** give rise to three resonances while only one, although broad, is observed for **10**. A doublet and a quintet, in the corresponding spectrum, are due to the pentaphosphine derivative **11**.

2.3. Reaction of *1alb* with HBF_4

This reaction was analyzed in acetone-d_6 and methanol-d_4.

The addition of one equivalent of HBF_4 to **1a/b** (equimolecular amount of HBF_4 and **1a/b**) in acetone-d_6 was carried out at −80 °C and monitored by ^1H NMR from −80 to 50 °C. Two hydride singlets in a 4:1 ratio (**12a**:**12b**) were observed at −80 °C (see Fig. 1). A resonance at 9.83 ppm was observed for the major component **12a**, indicating the protonation of the oxygen atom. A C_s symmetry for the complex was deduced. The following NOEs between different signals (indicated with arrows in Scheme 4) were observed for **12a** (−10 °C): (i) H_α and H'_5; (ii) H_α and OH; (iii) the hydride signal and one olefinic cod resonance; (iv) the hydride signal and H_3 of the phenoxy group. The NOEs of (ii) and (iv) reflect the fact that the OH group is not coordinated to the metal center. The low proportion of **12b** meant that it was not possible to observe and assign all resonances for this species. However, it is worth mentioning that a quartet observed at 4.95 ppm was assigned to a molecule of Et_2O (from the HBF_4 solution) coordinated to the Ru center in this derivative. Considering all these data, the structures proposed for the two derivatives are indicated in Scheme 4. Protonation of the phenoxy group and its decoordination makes possible the formation of these

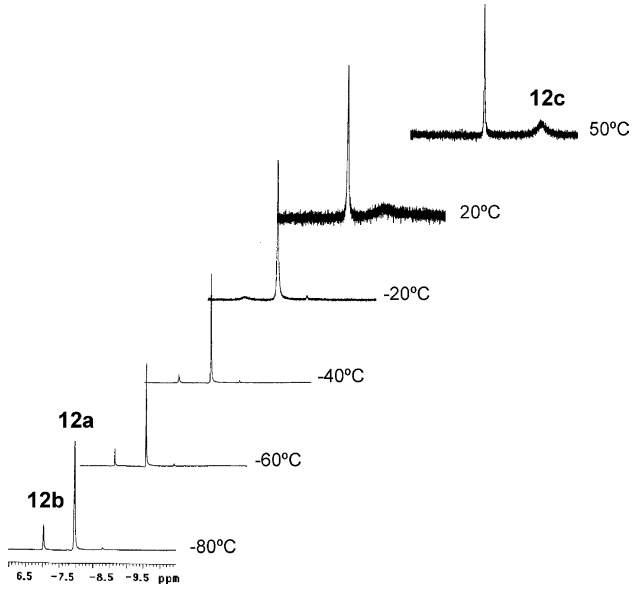

Fig. 1. Variable ^1H NMR spectra of **12a**,**b**,**c** in the hydride region.

two complexes, which mainly differ in the relative disposition of the phenol group with respect to the hydride. We must emphasize that a boat-to-boat inversion of either of these two species' does not lead to the skeleton of the other.

When the temperature of the sample was raised, the resonances of **12b** broadened (clearly observed for the hydride, H_α and Et_2O signals). However, the resonances of **12a** remained sharp. At −10 °C, the resonances of **12b** were not observed. At 10 °C, a new and broad hydride signal appeared (**12c**) (see Fig. 1). At higher temperatures this signal became less broad and at 50 °C the approximate ratio **12a**:**12c** was 1:0.8. A decrease in the temperature to 20 °C indicated that the process is reversible. On the basis of these data it is proposed that **12b** easily interconverts with **12c** in such a way that an increase in temperature favors the latter derivative. A C_s symmetry was deduced for **12c**. We propose the structure indicated in Scheme 4 for this derivative and believe that the equilibrium involves coordination–decoordination of the Et_2O molecule and the OH group. In fact the stated resonances for the Et_2O coordinated on **12b** disappeared when the formation of **12c** was completed. Displacement of the Et_2O molecule must be favored for entropic reasons. In any case, the Ru–O bond must be labilized by the high *trans* influence of the hydride ligand (in both **12b** and **12c**). Considering the stated change of the **12a**:**12b** + **12c** ratio with temperature, the transformation of **12a** into the pair **12b**–**12c** is also possible although less rapid than the transformation between **12b** and **12c**. The ^1H NMR resonances of **12a** (two temperatures) and **12c** (50 °C) are given in Table 5.

The proton transfer evolved in a similar way when carried out in methanol-d_4, with the formation of complexes **13a**,**b**,**c** as depicted in Scheme 4. However, several differences must be pointed out for this system: (i) as expected, a signal for the OH group was not observed in the spectra as a consequence of the rapid proton exchange with the medium; (ii) the three products of the reaction were separately observed in the ^1H NMR spectrum at −90 °C in a 4:1:0.5 ratio (**13a**:**b**:**c**), which implies a relative stabilization of species **13c** in comparison to **12c** in the respective mixtures.

On the other hand, the hydride (also the H_α proton) resonances of **13b** and **c** coalesced (see Fig. 2) as a consequence of the equilibrium that arises due to the competition for the coordination between the OD group of the phenol ring and that of methanol. The free energy of activation calculated at 0 °C is 55.9 kJ mol^{-1}.

The ^1H resonances of **13a** at −90 °C are shown in Table 5.

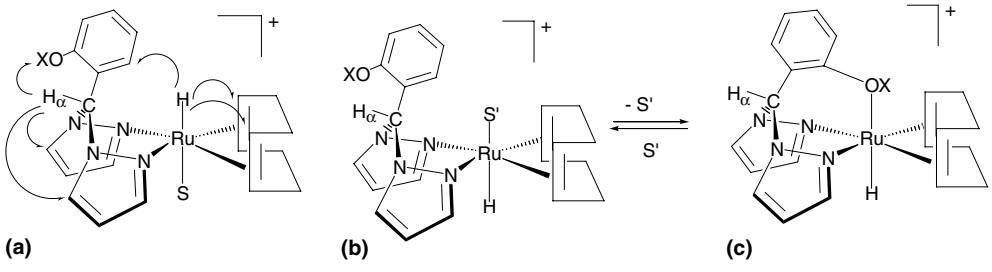
It can be concluded that the proton transfer from HBF_4 to **1a/b** is selective and occurs on the oxygen atom of the phenoxy group. The previous attack onto the Ru–H bond (kinetic control) with the formation of a dihydrogen compound, acid enough to be transformed onto the final products (thermodynamic control) can not be ruled out, although none evidence of such a pathway can be deduced from the spectra. The acid character of some dihydrogen complexes of Ru [12] and the kinetic control of the proton transfer over the Ru–H bonds of some complexes [13] is well reported.

An isomerization process, at least for isomer **1a**, must take place in these proton transfer processes and gives products with C_s symmetry. Considering the coordination mode of the bpzmPhO ligand, the main reaction products show a κ^2-*NN* coordination (**a** and **b**) with two different configurational dispositions that orientate the phenol group towards (forms **a**) or away from (forms **b**) the hydride ligand. The latter configuration means that the phenol group has an orientation suitable for coordination to the metal center (which leads to isomers of type **c**) but this coordination is in competition with the solvent (methanol or ether, isomers of type **b**). The hydride ligand apparently does not participate in the process.

3. Experimental

3.1. General comments

All manipulations were carried out under an atmosphere of dry oxygen-free nitrogen using standard Schlenk techniques. Solvents were distilled from the



X = H, S = acetone, S' = diethyl ether **12**
X = D, S = S' = methanol-d_4 **13**

Scheme 4.

appropriate drying agents and degassed before use. $[RuH(cod)(NH_2NMe_2)_3][BPh_4]$ [14], [RuClH(cod)-(bpzm)] [15] and the bpzmPhOH ligand [5] were prepared as described in the literature. PMe_3 (1 M solution in toluene), PMe_2Ph, $PMePh_2$ and PPh_3 were used as purchased from Aldrich. HBF_4 was used as a solution 54 wt% in diethyl ether (Aldrich). Elemental analyses were performed with a Perkin–Elmer 2400 microanalyzer. IR spectra were recorded as KBr pellets with a Perkin–Elmer PE 883 IR spectrometer. ^{1}H, ^{31}P{^{1}H} and ^{13}C{^{1}H} spectra were recorded on a VARIAN UNITY 300 spectrometer. Chemical shifts (ppm) are given relative to TMS. Coupling constants are given in Hz. bs = broad singlet, d = doublet, m = multiplet, pt = pseudo-triplet, q = quintet, t = triplet. COSY spectra: standard pulse sequence with an acquisition time of 0.214 s, pulse width 10 ms, relaxation delay 1 s, number of scans 16, number of increments 512. The NOE difference spectra were recorded with the following acquisition parameters: spectral width 5000 Hz, acquisition time 3.27 s, pulse width 18 ms, relaxation delay 4 s, irradiation power 5–10 dB, number of scans 240. For variable temperature spectra the probe temperature (±1 K) was controlled by a standard unit calibrated with a methanol reference. Free energies of activation were calculated [16] from the coalescence temperature (T_c) and the frequency difference between the coalescing signals (extrapolated at the coalescence temperature) with the formula $\Delta G_c^{\ddagger} = aT\,[9.972 + \log(T/\delta v)]$, $a = 1.914 \times 10^{-2}$. The estimated error in the calculated free energies of activation is ±1.0 kJ mol^{-1}.

3.2. Preparations

3.2.1. bpzmPhOK

This salt was prepared according to a modified method of that described by Carrano and co-workers [7b] for the sodium salt. A solution of bpzmPhOH (111.5 mg, 0.4 mmol) and ^{t}BuOK (56.1 mg, (0.4 mmol) in THF (15 ml) was stirred during 1 h. The solvent was evaporated to dryness and the resulting white solid was washed with diethylether (2 × 8 ml). Yield: 70%.

*3.2.2. [RuH(κ³-bpzmPhO)(cod)] (**1**)*

To a solution of [RuH(cod)(NH_2NMe_2)$_3$][BPh_4] (200 mg, 0.28 mmol) in THF (30 ml) at room temperature one equivalent of the ligand bpzmPhOK (78 mg, 0.28 mmol) was added. The mixture was stirred overnight, and the resulting suspension was filtered off in order to eliminate the $KBPh_4$ formed. The solution was evaporated to dryness, and the resulting white solid was washed with hexane (10 ml). Yield: 65%.

Another way to synthesize this complex is starting from [RuClH(cod)(bpzm)]. To a suspension of [RuClH(bpzm)(cod)] (125 mg, 0.32 mmol) in THF, one equivalent of the ligand bpzmPhOK (88 mg, 0.32 mmol) was added, and the mixture was stirred at room temperature for 10 h. The solution was filtered off in order to eliminate the KCl formed and evaporated to dryness, and the resulting white solid was washed with ether (2 × 10 ml). Yield: 50%. *Anal.* Calc. for $C_{21}H_{24}N_4ORu$: C, 56.11; H, 5.38; N, 12.46. Found: C, 56.11; H, 5.34; N, 12.16%. IR (KBr): 2045 cm^{-1} (*ν* Ru–H).

*3.2.3. [RuH(κ¹-O-bpzmPhO)(cod)(PMe_3)$_2$] (**2**)*

The reaction has been done in an NMR tube. To a solution of [RuH(bpzmPhO)(cod)] (**1**) (18 mg, 0.04 mmol) in 0.5 ml of benzene-d_6 two equivalents of PMe_3 (80 μl, 1 M in toluene, 0.08 mmol) were added. The solution was stirred at 20 °C and the reaction evolution was monitored by ^1H and $^{31}P\{^1H\}$ NMR. After that, the solution was put into a Schlenk and evaporated to dryness, and the resulting yellow solid was washed with hexane (2 × 10 ml). Approximate yield: 70%. *Anal.* Calc. for $C_{27}H_{42}N_4OP_2Ru$: C, 53.90; H, 7.04; N, 9.31. Found: C, 53.90; H, 6.99; N, 9.44%. IR (KBr): 2003 cm^{-1} (*ν* Ru–H).

*3.2.4. [RuH(κ¹-O-bpzmPhO)(cod)(PMe_2Ph)$_2$] (**3**)*

The reaction has been done in an NMR tube. To a solution of [RuH(bpzmPhO)(cod)] (**1**) (20 mg, 0.04 mmol) in 0.5 ml of benzene-d_6 two equivalents of PMe_2Ph (12.7 μl, 0.08 mmol) were added. The yellow solution was stirred at 20 °C and the reaction evolution was monitored over 2 h by ^1H and $^{31}P\{^1H\}$ NMR. After that, the solution was put into a Schlenk and the solvent was evaporated. The resulting yellow solid was washed with 10 ml of hexane. Approximate yield: 69%. *Anal.* Calc. for $C_{37}H_{46}N_4OP_2Ru$: C, 61.23; H, 6.39; N, 7.72. Found: C, 61.45; H, 6.46; N, 7.53%. IR (KBr): 2025 cm^{-1} (*ν* Ru–H).

*3.2.5. [RuH(κ³-bpzmPhO)(PMe_2Ph)$_2$] (**5**)*

When a solution of the complex **3** (15 mg, 0.021 mmol) is heated at 50 °C into an NMR tube in benzene-d_6 for 30 min, complex **5** was obtained. After that, the solution was put into a Schlenk and the solvent was evaporated. The resulting yellow solid was washed with 10 ml of hexane. Yield: 95%. *Anal.* Calc. for $C_{29}H_{34}N_4OP_2Ru$: C, 56.40; H, 5.55; N, 9.07. Found: C, 56.32; H, 5.12; N, 9.05%. IR (KBr): 1948 cm^{-1} (*ν* Ru–H).

*3.2.6. [RuH(κ³-bpzmPhO)($PMePh_2$)$_2$] (**6**)*

To a solution of [RuH(bpzmPhO)(cod)] (**1**) (200 mg, 0.44 mmol) in toluene (15 ml) two equivalents of the ligand $PMePh_2$ (165 μl, 0.88 mmol) were added, and the mixture was heated at 70 °C for 20 min. The pale yellow solution was evaporated to dryness, and the resulting yellow solid was washed with 10 ml of hexane. *Anal.* Calc. for $C_{39}H_{38}N_4OP_2Ru$: C, 63.15; H, 5.16; N, 7.55. Found: C, 63.25; H, 5.99; N, 7.45%. IR (KBr): 2021 cm^{-1} (*ν* Ru–H).

*3.2.7. [RuH(κ³bpzmPhO)(PPh_3)$_2$] (**7**)*

To a solution of [RuH(bpzmPhO)(cod)] (**1**) (125 mg, 0.28 mmol) in acetone (10 ml) two equivalents of PPh_3 (146 mg, 0.56 mmol) were added. The mixture was heated at 70 °C for 1 h and a suspension was formed. A pale yellow solid was obtained after filtration at room temperature and it was washed with hexane (2 × 10 ml). Yield: 80%. *Anal.* Calc. for $C_{39}H_{38}N_4OP_2Ru$: C, 67.97; H, 4.89; N, 6.47. Found: C, 68.16; H, 4.99; N, 6.24%. IR (KBr): 1944 cm^{-1} (*ν* Ru–H).

*3.2.8. [RuH(κ¹-O-bpzmPhO)(PMe_3)$_4$] (**8**)*

The reaction has been done in an NMR tube. To a solution of [RuH(bpzmPhO)(cod)] (**1**) (18 mg, 0.04 mmol) in 0.5 ml of benzene-d_6 four equivalents of PMe_3 (160 μl, 1 M in toluene, 0.16 mmol) were added. The solution was stirred at 20 °C and the reaction evolution was monitored for 1 h by ^1H and $^{31}P\{^1H\}$ NMR. After that, the solution was evaporated to dryness in a Schlenk. The resulting orange solid was washed with 10 ml of hexane. Approximate yield: 73%. *Anal.* Calc. for $C_{25}H_{48}N_4OP_4Ru$: C, 46.51; H, 7.49; N, 8.68. Found: C, 46.32; H, 7.58; N, 8.82%. IR (KBr): 1973 cm^{-1} (*ν* Ru–H).

*3.2.9. [cis-O,H-RuH(κ¹-O-bpzmPhO)(PMe_2Ph)$_4$] (**9**)*

The reaction has been done in an NMR tube. To a solution of [RuH(bpzmPhO)(cod)] (**1**) (20 mg, 0.04 mmol) in 0.5 ml of benzene-d_6 four equivalents of PMe_2Ph (25.4 μl, 0.16 mmol) were added. The solution was stirred and heated at 50 °C for 20 min, and the reaction evolution was monitored by NMR. After that, the solution was put into a Schlenk and evaporated to dryness, and the yellow solid was washed with 10 ml of diethyl ether. Approximate yield: 74%. *Anal.* Calc. for $C_{45}H_{56}N_4OP_4Ru$: C, 60.46; H, 6.31; N, 6.27. Found: C, 60.40; H, 6.27; N, 6.31%. IR (KBr): 1957 cm^{-1} (*ν* Ru–H).

*3.2.10. [trans-O,H-RuH(κ¹-O-bpzmPhO)(PMe_2Ph)$_4$] (**10**)*

A solution of **9** in 0.5 ml of benzene-d_6 in an NMR tube was heated at 70 °C and the reaction evolution was monitored by NMR until complete transformation into **10**. **10** was spectroscopically characterized by NMR.

*3.2.11. [RuH(PMe_3)$_5$] (bpzmPhO) (**11**)*

To a solution of [RuH(bpzmPhO)(cod)] (**1**) (200 mg, 0.44 mmol) in 20 ml of toluene five equivalents of PMe_3 (2.2 ml, 1 M in toluene, 2.2 mmol) were added, and the mixture was stirred at 20 °C for 30 min. The solution was evaporated to dryness, obtaining an orange solid. Complex **11** is not obtained as a single product but only in a mixture with complex **8**. IR (KBr): 1983 cm^{-1} (ν Ru–H).

*3.2.12. General procedure to the formation of complexes **12a–c** and **13a–c***

A solution of [RuH(bpzmPhO)(cod)] (**1**) (18 mg, 0.04 mmol) in 0.5 ml of acetone-d_6 or methanol-d_4 in a NMR tube was cooled to −90 °C. A solution of $HBF_4 \cdot Et_2O$ (54 wt%) was added (3.6 μl, 0.04 mmol). This tube was introduced in the NMR probe previously cooled at −90 °C. The evolution of the reaction was monitored by ^1H NMR with an increasing of temperature up to 50 °C (increments of 10° except in the proximity of the coalescence temperature where the increments were of 1°).

A chromogenic penta-aza scorpionand for nickel(II) and copper(II) ions

Luigi Fabbrizzi *, Maurizio Licchelli, Antonio Poggi, Donatella Sacchi, Cristina Zampa

Dipartimento di Chimica Generale, Università di Pavia, via Taramelli 12, 27100 Pavia, Italy

Received 5 June 2003; accepted 3 September 2003

Abstract

The nickel(II) and copper(II) complexes of a new scorpionand in which the side chain has been functionalized with the powerful chromophore 4-amino-7-nitro-benzo-2-oxa-1,3-diazole have been prepared. The pendant arm of the new ligand undergoes pH-dependent complexation/decomplexation to the metal centre, with simultaneous deprotonation of the aniline nitrogen atom of the pendant arm, thus inducing drastic modifications of the spectral features of the chromophore and a sharp colour change. The pK_a values observed for both complexes change according to the metal promoting the deprotonation, being lower for the Ni complex than for the Cu species, because of the different coordination geometries adopted by the two ions.

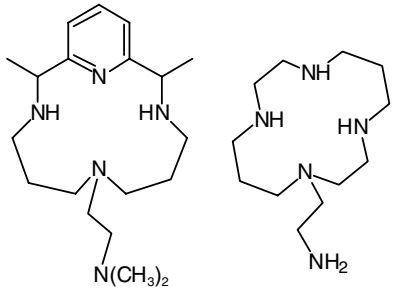
Keywords: Scorpionands; Chromophores; Copper(II); Macrocycles; Nickel(II)

1. Introduction

There exist two-component ligands which consists of a multidentate macrocycle and of a covalently linked side-chain containing a further donor group. Classical examples are provided by penta-aza ligands **1** [1], and **2** [2]. Each system contains a 14-membered ring which can include a transition metal ion, e.g. Ni^{II}, Cu^{II}. In each complex, the metal centre is firmly incorporated by the tetra-aza-macrocycle, according to a square stereochemical arrangement, in which the four nitrogen atoms of the ring are coplanar with the metal centre. In this situation, the metal is especially resistant to the demetallation due to the so-called *kinetic macrocyclic effect* [3]. In particular, the tetra-aza-macrocyclic complex persists indefinitely in a strongly acidic solution, even if the processes of metal extrusion and protonation of the nitrogen atoms would be very favoured from a thermodynamic point of view. However, the M^{II}–N bond itself (with both amine and pyridine donor atoms) is intrinsically labile: thus, inertness derives from the steric constraints imposed by the cyclic ligand.



1 **2**

On the other hand, ligands **1** and **2** contain a fifth binding site, the nitrogen atom belonging to the ethylamine side-chain covalently linked to the macrocycle. In particular, the amino group of the side chain binds one of the axial positions of the coordination polyhedron, either an octahedron or a square pyramid. It should be noted that the interaction of the metal ion with the axially bound amine nitrogen atom does not suffer from any steric constraint and is therefore labile. Thus, it should happen that, on acidification, the amino group is protonated and removed from coordination. The change

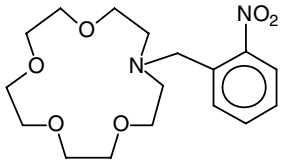
doi:10.1016/j.poly.2003.11.024

is quickly reversible and addition of standard base relocates the pendant arm on the axial position. The complexation/decomplexation of the pendant arm, driven by the protonation/deprotonation of the amino group is illustrated in Scheme 1.

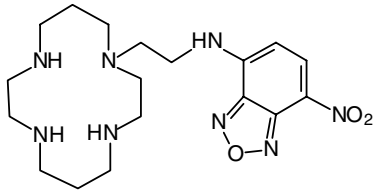
Ligands **1** and **2** have been given the current name of *scorpionands*, by considering that they firmly chelate an individual (the metal ion), which can be stung from the top, at command, by an aggressive tail. Metal scorpionate complexes are interesting systems which consist of a fixed part (the rigid tetra-aza ring) and of a mobile portion (the flexible pendant arm). Taking profit from a chemical input (the addition of either H^+ or OH^-), the pendant arm can be alternatively located between two distinct positions: either axially bound to the metal centre or far away from it in order to minimise the electrostatic repulsions with the ammonium ion. In this sense, scorpionate complexes of the type described are suitable systems for generating controlled molecular motions and, as they convert energy (that of an acid–base reaction) into a repeteable movement, they can be considered the prototypes of elementary molecular machines.



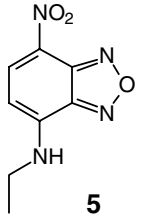
3

Analogous systems exist in the realm of crown ethers. In the ligand **3**, a side chain containing a 2-nitrobenzene fragment is covalently linked to the nitrogen atom of a 15-crown-NO_4 [4]. Under unperturbed conditions, the pendant arm is bound very weakly to the sodium ion encircled by the crown. However, if the nitro group undergoes one-electron electrochemical reduction, the $NO_2^{\bullet -}$ anion radical that forms establishes a rather strong interaction with the alkali metal ion. In this case, alternate reduction/oxidation of the nitro group induces formation-breaking of a coordinative bond, according to a mode reminiscent of that observed with scorpionate complexes. It should be mentioned that Authors gave systems like **3** the name of lariat ethers [5] taking inspiration from the shape of the ligand (a lasso which takes a metal ion). Therefore, the following convention is being currently followed: a multidentate chelate (possibly cyclic) with a pendant arm is called *scorpionand* if the donor atoms are nitrogens, or *lariat* if the donor atoms are oxygens.

In the case of scorpionands, complexation/decomplexation of the pendant arm may induce a variety of effects, which are essentially related to the versatile behaviour of the transition metal centre incorporated by the macrocycle. For instance, complexation–decomplexation may induce a variation of the spin state of a Ni^{II} centre, with a concomitant colour change (blue-to-yellow) [2]. A colour change (red-to-blue) is observed also in the case of Cu^{II} scorpionate complexes [6]. Moreover, the pendant arm can be equipped with a further functionality, whose properties vary depending whether the side-chain is bound or not bound to the metal. For instance, a fluorescent fragment was covalently linked through a $–CH_2–$ fragment to the pendant amine group of **2**: it was observed that coordination of the pendant arm quenched the emission of the fluorophore, which was restored on decomplexation, thus giving rise to an unprecedented mechanical switch of fluorescence [7].

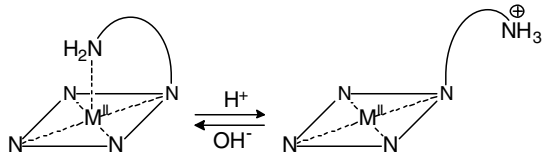


4



5

We consider now a new type of scorpionand, in which the pendant arm has been equipped with a powerful chromophore: in particular, the 4-amino-7-nitro-benz-2-oxa-1,3-diazole (7-nitrobenzofurazan or NBD) fragment [8] was directly linked to the side-chain of macrocycle **2**, to give **4**. It will be shown that the pendant arm of **4** undergoes pH-dependent complexation–decomplexation to Ni^{II} and Cu^{II}, according to a process which induces a drastic modification of the colour and of the spectral features of the chromophore.



Scheme 1. Protonation–deprotonation equilibrium for the scorpionate complexes of ligand **2**.

2. Experimental

2.1. General remarks

Unless otherwise stated, commercially available reagent grade chemicals (Sigma–Aldrich) were used as received. 1,4,8,11-tetraazacyclotetradecane, cyclam, was prepared according to literature method [9].

UV–Vis spectra were recorded on a Hewlett–Packard 8453 diode array or on a Varian Cary 100 spectrophotometer. NMR spectra were recorded on a Bruker AMX400 spectrometer.

Mass spectra were obtained using an LCQ DECA ion trap mass spectrometer equipped with electrospray ionization (ESI) ion source and controlled by Xcalibur software 1.1 (Thermo-Finnigan).

Potentiometric determinations were performed in a thermostatted cell on aqueous solutions (20 ml, made 0.05 M in $NaClO_4$, 25 °C) containing [Ni(**4**)]$(ClO_4)_2$, [Cu(**4**)]$(ClO_4)_2$ or the reference compound **5** (10^{-4}M) and an excess of standard $HClO_4$, by addition of standard aqueous NaOH (a Radiometer automatic titration apparatus was used). The pH scale was calibrated prior to each experiment according to the Gran method [10]. Refinement of the potentiometric data was made through the Hyperquad package [11].

Spectrophotometric titrations were performed on aqueous solutions (10 ml, made 0.05 M in $NaClO_4$, 25 °C) of the metal complexes or of the reference compound **5** ($1.0–5.0 \times 10^{-5}$ M) adjusted at pH ~2.0 by adding small amounts of a standard solution of $HClO_4$. Subsequently, additions of standard solutions (0.1 or 1.0 M) of NaOH were made until a basic pH (~12.0) was attained. Absorption spectra were taken after each addition of base. In each experiment the overall addition was limited to about 200 μl, so that volume variation was not significant.

Safety note: Perchlorate salts of metal complexes are potentially explosive and should be handled with care. In particular, they should never be heated as solids [12].

2.2. Synthesis of N-ethyl-7-nitrobenzo-2-oxa-1,3-diazol-4-amine (*5*)

A solution of 4-chloro-7-nitrobenzo-2-oxa-1,3-diazole (NBD chloride, 0.5 g, 2.5 mmol) in toluene was added to a refluxing mixture of Cs_2CO_3 (0.48 g, 1.47 mmol) and ethylamine (0.2 ml, 2.5 mmol) in toluene. The reaction was monitored by TLC (Al_2O_3, CH_2Cl_2, $R_f = 0.40$). After 3 h the solvent was removed at the rotary evaporator, the residue treated with MeOH, and the precipitate isolated by filtration; yield 81%. *Anal.* Found: C, 46.01; H, 3.73; N, 27.03. Calc. for $C_8H_8N_4O_3$: C, 46.16; H, 3.87; N, 26.91%. ^{1}H-NMR (400 MHz, CD_3CN): δ(ppm) = 8.6 (d, 1H, *H–Ar*), 7.5 (s, 1H, *NH*), 6.4 (d, 1H, *H–Ar*), 3.6 (m, 2H, CH_2), 1.4 (t, 3H, CH_3).

2.3. Synthesis of N-(2-bromoethyl)-7-nitrobenzo-2-oxa-1,3-diazol-4-amine (*6*)

Bromoethylamine ·HBr (0.27 g, 1.3 mmol) and NaOH (0.12 g, 3 mmol) were dissolved in ethanol (10 ml) and added dropwise to a refluxing solution of NBD chloride (0.26 g, 1.3 mmol) in ethanol (10 ml), under magnetic stirring. The reaction was monitored by TLC (Al_2O_3, CH_2Cl_2). After 5 h the resulting green solution was cooled to room temperature and the solvent was evaporated in vacuo, leaving a red residue. The crude product was purified by liquid chromatography (Al_2O_3, CH_2Cl_2, $R_f = 0.51$); yield 60%. *Anal.* Found: C, 33.31; H, 2.52; N, 19.43. Calc. for $C_8H_7BrN_4O_3$: C, 33.47; H, 2.46; N, 19.52%. ^{1}H-NMR (400 MHz, d_6-DMSO): δ(ppm) = 9.5 (s, 1H; *NH*), 8.5 (d, 1H, *H–Ar*), 6.5 (d, 1H, *H–Ar*), 3.7 (t, 2H, CH_2Br), 3.3 (t, 2H, CH_2N).

2.4. Synthesis of *4*

Cyclam (1.07 g, 5.3 mmol) was dissolved in hot toluene (40 ml) and **6** (0.223 g, 0.78 mmol) was added. The resulting mixture was refluxed for 2 h, then it was cooled at room temperature and the white precipitate (excess cyclam and its hydrobromide salt) was filtered off. The solvent was removed and the residue treated with diethyl ether: an orange product was obtained; yield 73%. *Anal.* Found: C, 52.96; H, 7.56; N, 27.39. Calc. for $C_{18}H_{30}N_8O_3$: C, 53.19; H, 7.44; N, 27.57%. MS (ESI): *m/z*: 407.4 [M+H$^+$].

2.5. Synthesis of metal complexes, [Ni(*4*)]$(ClO_4)_2$ and [Cu(*4*)]$(ClO_4)_2$

Nickel(II) complex: $Ni(ClO_4)_2 \cdot 6H_2O$ (4.5 mg, 0.012 mmol) dissolved in MeOH was added to a solution of **4** (5 mg, 0.012 mmol) in MeOH. A red precipitate formed quickly and was isolated by filtration; yield 93%. *Anal.* Found: C, 32.84; H, 4.32; N, 17.09. Calc. for $C_{18}H_{30}Cl_2NiN_8O_3$: C, 32.56; H, 4.55; N, 16.87%. MS (ESI): *m/z*: 563.2 [M-ClO_4^-]$^+$, 463.3 [M-ClO4$^-$–$HClO_4$]$^+$.

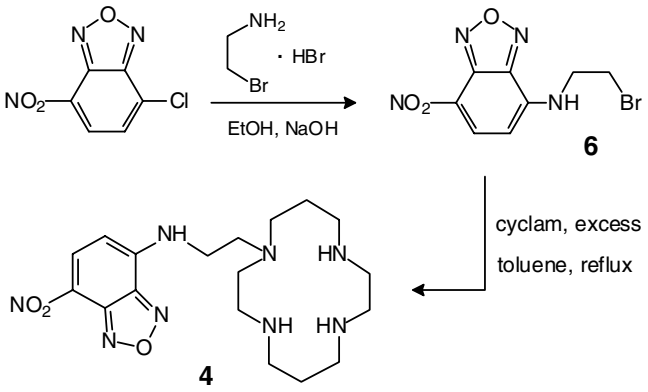
Copper(II) complex: the same procedure but $Cu(ClO_4)_2 \cdot 6H_2O$ (4.6 mg, 0.012 mmol) was used; purple–red product; yield 95%. *Anal.* Found: C, 32.47; H, 4.39; N, 16.88. Calc. for $C_{18}H_{30}Cl_2CuN_8O_3$: C, 32.32; H, 4.52; N, 16.75%. MS (ESI): *m/z*: 568.1 [M-ClO_4^-]$^+$, 468.2 [M-ClO4$^-$–$HClO_4$]$^+$.

3. Results and discussion

3.1. Synthesis of scorpionand *4*

The synthesis of cyclam derivatives containing a substituent group on a nitrogen atom has been recently performed by triprotection of the cyclic tetraamine followed by a specific reaction involving the free amino group [13]. Such a procedure afforded very pure products after the final deprotection step.

However, the protection/deprotection procedure was not necessary in the synthesis of scorpionand **4**, which was prepared, with satisfactory yield and purity, according to a shorter synthetic pathway, as depicted in Scheme 2.



Scheme 2. Synthesis of scorpionand **4**.

In the first step, the commercially available 4-chloro-7-nitro-benzo-2-oxa-1,3-diazole (NBD chloride) was converted into bromoethylamino-NBD (intermediate **6**) by performing an aromatic nucleophilic substitution in boiling ethanol.

The chromophore-containing pendant arm was then appended onto the macrocyclic framework by reaction of **6** with cyclam (fivefold excess) in boiling toluene. The excess of the cyclic tetraamine affords a double advantage: (i) it addresses the reaction toward the formation of the mono-functionalised macrocycle, minimizing the probability of polysubstitution; (ii) it neutralises the hydrobromic acid generated from the reaction, avoiding the addition of a further basic reactant. The scorpionand **4** was easily isolated by cooling the reaction mixture since both excess cyclam and cyclam hydrobromide are insoluble in toluene at room temperature.

Nickel(II) and copper(II) complexes were prepared by addition of stoichiometric amounts of the corresponding perchlorate salts to methanol solutions containing the scorpionand **4**.

3.2. pH-controlled complexation–decomplexation of the pendant arm

A solution of the $[Ni^{II}(\mathbf{4})](ClO_4)_2$ complex, acidified with standard acid to pH 2 and made 0.05 M in $NaClO_4$, was titrated with standard NaOH. The titration curve disclosed a single deprotonation event, with a $pK_a = 7.83 \pm 0.05$, to be ascribed to the acid–base equilibrium: $[Ni^{II}(LH)]^{2+} \rightleftarrows [Ni^{II}(L)]^{+} + H^{+}$, where LH = **4**. Titration with base induces decolorisation of the orange–yellow solution and a drastic change of the absorption spectrum, as shown in Fig. 1.

In particular, the strong band at 475 nm ($\varepsilon = 9100$ $M^{-1}\,cm^{-1}$) decreases, while a new band develops at 394 nm ($\varepsilon = 7180$ $M^{-1}\,cm^{-1}$, limit value at pH 12). Quite interestingly, on increasing pH the molar absorbance of the new band superimposes well with the concentration profile of the $[Ni^{II}(L)]^{+}$ species, as shown in Fig. 2. This indicates that colour and spectral changes are associated

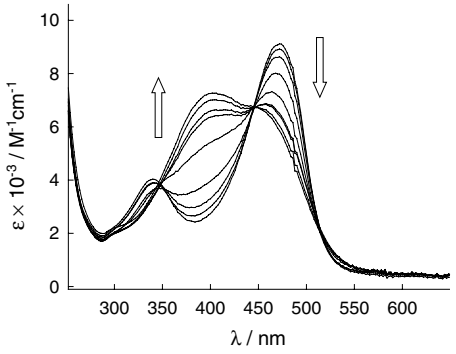


Fig. 1. Absorption spectra of $[Ni^{II}(\mathbf{4})](ClO_4)_2$ in water (1.3×10^{-5} M), measured during a titration with NaOH (pH range: 2–12).

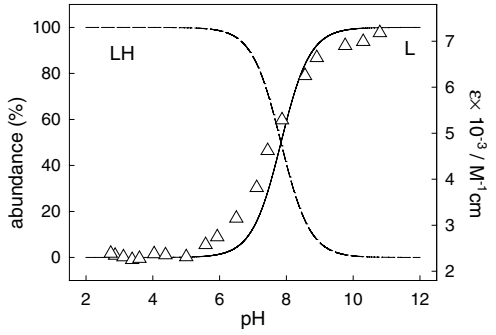

Fig. 2. Right vertical axis, distribution curves of the species present at equilibrium for the nickel(II) complex of scorpionand **4**. Left vertical axis (Δ) molar absorbance measured at 394 during the titration experiment.

to the deprotonation process. It is suggested that deprotonation involves the aniline nitrogen atom of the pendant arm. This hypothesis is supported by the behaviour of the chromogenic fragment **5**, which can be considered as an isolated analogue of the pendant arm, without the appended macrocycle. **5** behaves as a monoprotic acid with $pK_a = 10.75 \pm 0.03$. Moreover, the absorption spectrum shows a pH dependence very similar to that observed with the $[Ni^{II}(\mathbf{4})]^{2+}$ complex (see Fig. 3), with the band at 470 nm ($\varepsilon = 11,150$ $M^{-1}\,cm^{-1}$) which decreases, while a new band forms and develops

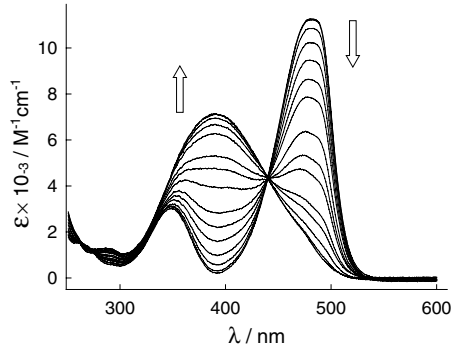

Fig. 3. Absorption spectra of **5** in water (2.4×10^{-5} M) measured during a titration with NaOH (pH range: 2–12).

at 394 nm ($\varepsilon = 7190\ M^{-1}\,cm^{-1}$, limit value at pH 12). Note that in the present case, spectral changes have to be necessarily ascribed to the deprotonation of the amine group.

Therefore, the $[Ni^{II}(L)]^+$ species should be considered as a scorpionate complex, with the deprotonated aniline group coordinated to one of the axial positions of the octahedron. Occurrence of the apical coordination of the pendant arm is demonstrated by the fact that the pK_a value is about three log units lower than that of the reference system **5**. The greater acidity of the aniline group in the $[Ni^{II}(L)]^+$ scorpionate complex has to be ascribed to the exothermic contribution of the metal-deprotonated aniline nitrogen atom. Indeed, this effect is rather moderate. In this connection, it has to be noted that in the case of the Ni^{II} complex with system **2**, the pK_a for the scorpionate (2.8) [2] was 10 orders of magnitude lower than that of the isolated side chain ethylamine (pK_a = 10.8). On the other hand, for system **1**, the difference of pK_a values between the Ni^{II} scorpionate complex (6.2) [1b] and the isolated side chain, *N*,*N*-dimethyl-ethyl-amine (p$K_a \cong 11$) was distinctly lower, probably due to the steric effects exerted by the two methyl groups on the nitrogen atoms that reduced the intensity and the exothermicity of the interaction with the metal. Such a steric repulsive effect must be especially important in the case of the scorpionate complex with **4**, due to the presence of the bulky 7-nitrobenzo[1,2,5]oxadiazole substituent, which is directly bound to the nitrogen atom of the pendant arm. This situation accounts for the low value of ΔpK_a.

An analogous behaviour has been observed in the case of copper(II). Potentiometric titration disclosed the occurrence of an acid–base event with pK_a = 8.78 ± 0.12. Moreover, electronic spectra showed a sharp dependence upon pH. Fig. 4 displays the spectra of an aqueous solution of $[Cu^{II}(\mathbf{4})](CF_3SO_3)_2$, recorded over the 2–12 pH range. It is seen that, on increasing pH, the absorption spectrum changes in the 320–520 nm range and, in particular, the band centred at 475 nm, due to the 4-amino-7-nitro-benz-2-oxa-1,3-diazole chromophore, decreases. Quite interestingly the molar absorbance of this new band superimposes well on the concentration profile of the deprotonated species $[Cu^{II}(L)]^+$. It is therefore suggested that also in the present case the aniline group of the pendant arm deprotonates and simultaneously coordinates the Cu^{II} centre in one of the two available apical positions. Notice that ΔpK_a (about 2) is smaller than that observed for the Ni^{II} complex: this may be due to the fact that the Cu^{II} ion in an octahedral geometry is sensitive to the Jahn–Teller effect and tends to form octahedrally elongated complexes. Thus, the longer distance and the diminished Cu^{II}-deprotonated aniline interaction reduce the exothermic contribution due to the apical metal–ligand interaction, with a consequent lower decrease of pK_a with respect to the isolated side-chain.

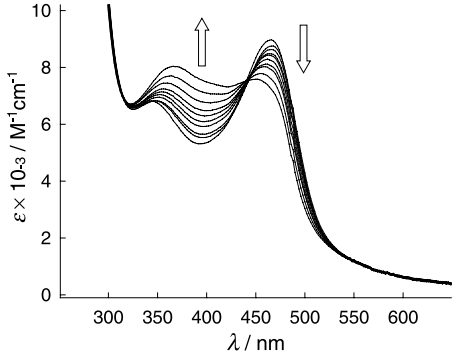

Fig. 4. Absorption spectra of $[Cu^{II}(\mathbf{4})](ClO_4)_2$ in water (2.5×10^{-5} M) measured during a titration with NaOH (pH range: 2–12).

4. Conclusions

This work has introduced a new class of scorpionands, in which the pendant arm has been equipped with a chromophore. In particular, the nitrogen atom of the pendant arm is an essential part of the chosen chromogenic fragment. It may happen that coordination of the metal ion may favour an acid–base event (in the present case deprotonation of the aniline group), with a drastic modification of the spectral features and a sharp colour change. Choice of suitable chromophores and coordinating groups of the pendant arm (amine, aniline, carboxamide, sulphonamide) may give rise to a variety of chromogenic scorpionands, whose activity (complexation–decomplexation of the side-chain) can be displayed over a wide pH range.

Dedicated to the ever enthusiastic Jerry Trofimenko

Abstract

In an effort to obtain suitable starting materials, the synthesis and crystal structure of hydrotris(3,5-dimethylpyrazolyl)borato (Tp^{Me2}) tantalum(III) complexes are reported. Reaction of KTp^{Me2} with $[TaCl_2(tht)]_2(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (**1**) (tht = tetrahydrothiophene) gives the X-ray characterized unsymmetrical $(Tp^{Me2}Ta)(TaCl_3)(\mu\text{-}Cl_2)(\mu\text{-}tht)$ (**2**) in fair yield. This doubly bonded Ta=Ta complex [2.6791(5) Å, diamagnetic, 18e per Ta] is a rare example of an unsymmetrical $Ta_2X_6L_3$ complex. The X-ray structure of $Tp^{Me2}TaCl_2(PhC{\equiv}CMe)$ (**3**) is also reported. It has the (4e)-alkyne in the symmetry plane of the molecule. The *trans* effects of tht and phenylpropyne are discussed. **1** is inert towards the reaction with a second equivalent of KTp^{Me2}.

Keywords: Hydrotris(pyrazolyl)borate; Scorpionate ligands; Tantalum; Metal–metal multiple bond; Alkyne complex; Tetrahydrothiophene complex

1. Introduction

During the last few years, we have been endeavouring a diverse organometallic chemistry of Tp′NbXX′(alkyne) complexes (Tp′ = a susbstituted hydrotris(pyrazolyl)borate, X and/or X′ = Cl, alkyl, CO, etc.) [1], with a particular emphasis on the steric and electronic effects leading to various agostic interactions and on their consequences [2]. However, the development of a rich scorpionate-based chemistry of the heavier group 5 metals (Nb, Ta) has long been hampered by the lack of straightforward, efficient syntheses of suitable starting materials. The early literature in the field pointed to facile in situ decomposition of the compounds by hydrolysis, redox processes, B–N bond cleavage or to the undesired synthesis of ionic complexes [1]. Simple routes to $TpNbCl_4$ or $Tp^{Me2}NbCl_4$ were highly dependent on experimental conditions, and by-products formation precluded the development of these species as useful starting materials [3]. A recent reliable synthesis of the simple niobium(IV) complex $Tp^{Me2}NbCl_3$ [4], which was characterized by an X-ray diffraction, involves Tp^{Me2} exchange between the tin complex $Tp^{Me2}SnCl(n\text{-}Bu)_2$ and $NbCl_4(thf)_2$. The case of tantalum is even more striking. The tin route leads to a cationic Ta(V) complex $[Tp^{Me2}TaCl_3][TaCl_6]$ [4]. Oxo and imido complexes [5] have been prepared but in the case of Tp^{Me2}, $Tp^{Me2}Ta(=NAr)Cl_2$ was formed along with the salt $[HB(Me_2Pz)_3BH][TaCl_4(=NAr)(Me_2PzH)]$ from KTp^{Me2} and $Ta(=NAr)Cl_3(thf)_2$ [6]. The pre-fonctionallized complexes $TaMe_3Cl_2$, $Ta(=CH^tBu)Cl_3(thf)_2$ and $TaCl_3(dme)(PhC{\equiv}CMe)$ reacted quite cleanly with KTp^{Me2} leading to $Tp^{Me2}TaMe_3Cl$ [7], $Tp^{Me2}Ta(=CH^tBu)Cl_2$ [8], and $Tp^{Me2}TaCl_2(PhC{\equiv}CMe)$ [9], respectively. Given our interest in Tp′-based group 5 chemistry, we have been seeking for a convenient route to tantalum derivatives that might lead to simple halo complexes useful for further derivatization. We describe herein some of our observations in this field. The synthesis and X-ray crystal structures of $Tp^{Me2}TaCl_2(PhC{\equiv}CMe)$ [9] and of the new dimer $Tp^{Me2}Ta(\mu\text{-}Cl)_2(\mu\text{-}tht)TaCl_3$, which exhibits a formal Ta=Ta double bond, are reported.

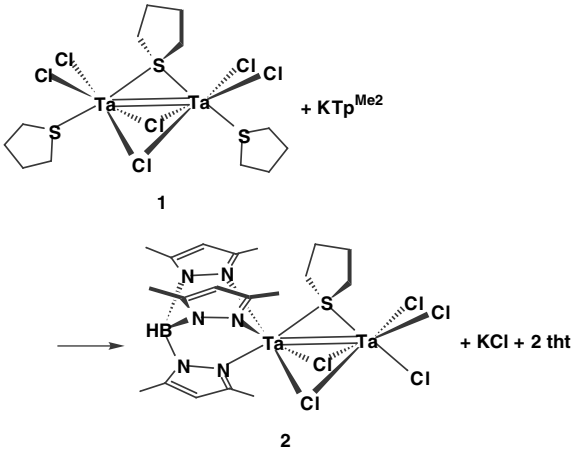
2. Results and discussion

2.1. Syntheses

Given the problems inherent in the use of tantalum(V) derivatives, we looked for a simple Ta(III) starting material akin to the readily available $[NbCl_3(dme)]_n$ (dme = 1,2-dimethoxyethane) [10]. However, such a simple complex does not exist for tantalum. For Ta(III), apart from $TaCl_3(PMe_3)_3$ [11], it appears that among the few useful complexes, all have a dimeric structure of the general type $Ta_2X_6L_3$ or $Ta_2X_6L_4$ [12]. Note that $TaCl_3(PMe_3)_3$ readily converts to $Ta_2Cl_6(PMe_3)_4$ [13]. Thus, one of the simplest and readily available tantalum(III) complex is the dimer $[TaCl_2(tht)]_2(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (**1**) (tht = tetrahydrothiophene) [14]. One equiv of KTp^{Me2} reacted with dark red **1** in dichloromethane to give the new dinuclear species $(Tp^{Me2}Ta)(TaCl_3)(\mu\text{-}Cl_2)(\mu\text{-}tht)$ (**2**) (Eq. (1)) as plum purple crystals in 72% yield.



(1)

2 has been characterized by elemental analysis, ^1H NMR spectroscopy and an X-ray diffraction analysis (see below). The ^1H NMR methine and methyl signals of Tp^{Me2} appear as 1:2 and 3:3:6:6 singlets indicating a plane of symmetry in **2**. The tht protons appear as four multiplets, three of them being obscured by Tp^{Me2} methyl signals. During the synthesis of **2**, one chloride is removed as KCl, but also two equivalents of tht are displaced. Thus the bridging core does not change when going from **1** to **2**, but the two ends of the dimer have rearranged. This is due to the fact that Tp^{Me2} is an L_2X ligand that coordinates facially, whereas in **1** the terminal parts of the dimer are identically formed by two X and one L ligand. Indeed, one could describe **2** as having two tantalum(III), a $TaCl_3$ adduct of $Tp^{Me2}TaCl_2(tht)$ with a Ta=Ta double bond to account for diamagnetism. Attempts to use **2** as a source to other $Tp^{Me2}Ta$ complexes have been hampered by its high stability. Refluxing **2** in thf with one equivalent of KTp^{Me2} with or without excess tht did not lead to any reaction. Excess tht was introduced in the hope of forming $Tp^{Me2}TaCl_2(tht)$ since only one tht for two tantalum is present in **2**. $Tp^{Me2}TaCl_2(tht)$ could have been a very promising starting material. It is interesting to note that several vanadium(III) $Tp'VCl_2(L)$ complexes have been synthesized [14]. In all cases, L is indeed a 2e-donor so that the resulting $Tp'VCl_2(L)$ complex is a 14 electron high spin complex, as expected for a first row transition metal. Related complexes with either Nb or Ta have never been formed. Apparently the preference for a low-spin situation with the heavier metals precludes the formation of such species. Similarly, we have not been able to make the low spin vanadium(III) $Tp'VCl_2$(alkyne) akin to the known (4e)-alkyne 16 electron Nb [15] or Ta [9] analogs.

The synthesis and spectroscopic characterization of $Tp^{Me2}TaCl_2(PhC{\equiv}CCH_3)$ (**3**) has been described previously [9]. Just like in the niobium case [15], its starts from $TaCl_3(dme)(PhC{\equiv}CCH_3)$ and KTp^{Me2}, but the formation of $[HB(C_3N_2Me_2H)_3BH][TaCl_6]$ as a by-product limits the yield to ca. 40%. This is in line with previous observations in related systems (see above). The X-ray crystal structure of **3** is described in the following section.

2.2. X-ray structures

A plot of the X-ray molecular structure of **2** is displayed in Fig. 1 and associated metric parameters are collected in Table 1. This ditantalum species, being formally an unsymmetrical $M_2L_3X_6$ i.e., $L_2XM(\mu\text{-}LX_2)MX_3$, exists as a confacial bioctahedron, just like

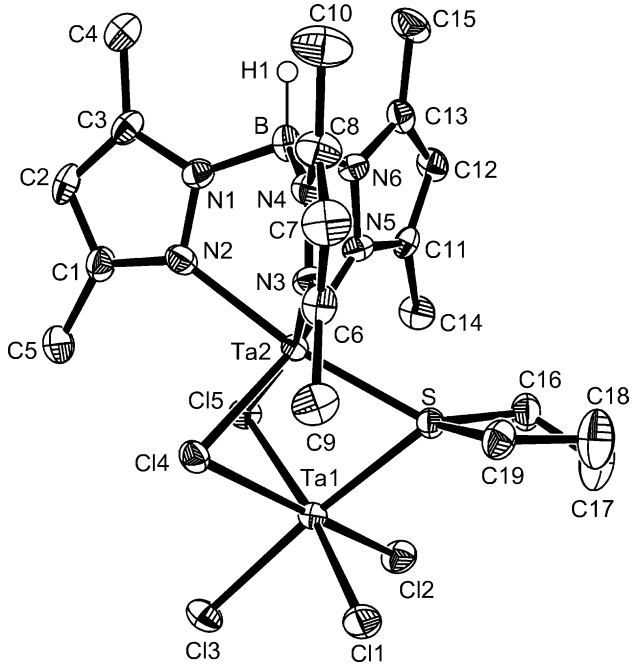


Fig. 1. Plot of the molecular structure of $Tp^{Me2}Ta(\mu\text{-}Cl)_2(\mu\text{-}tht)TaCl_3$ (**2**).

Table 1
Selected bond lengths (Å) and angles (°) for (Tp^{Me2}Ta)($TaCl_3$)(μ-$Cl)_2$(μ-tht) (**2**)

Bond lengths			
Ta(1)–Ta(2)	2.6791(5)	Ta(2)–Cl(5)	2.4662(16)
Ta(1)–Cl(1)	2.3763(14)	Ta(2)–N(2)	2.247(5)
Ta(1)–Cl(2)	2.3700(15)	Ta(2)–N(3)	2.161(5)
Ta(1)–Cl(3)	2.4477(14)	Ta(2)–N(5)	2.165(4)
Ta(1)–Cl(4)	2.5023(14)	Ta(1)–S	2.4293(14)
Ta(1)–Cl(5)	2.5283(14)	Ta(2)–S	2.4098(14)
Ta(2)–Cl(4)	2.4697(13)		
Bond angles			
Ta(1)–Cl(4)–Ta(2)	65.21(3)	Ta(1)–S–Ta(2)	67.23(4)
Ta(1)–Cl(5)–Ta(2)	64.86(4)		

its symmetrical $M_2L_3X_6$ ($LX_2M(\mu\text{-}LX_2)MLX_2$) parent **1**, with X being either Cl or Br [12,16,17]. The shared face consists in all these cases of two X (Cl in **2**) and one L ligand (tht). The Ta–Ta distance of 2.6791(5) in **2** is statistically identical with that (2.681(1) Å) in $[TaCl_2(tht)]_2(\mu\text{-}Cl)_2(\mu\text{-tht})$ **1** [16], consistent with a bond order of 2 (taking into account the diamagnetism of **2** and a formal 18e count for each Ta atom) [12]. The effect of the unsymmetry of the two ends can be probed by examining the bond lengths and angles for key ligands in the bridge and in terminal positions. Indeed in symmetrical **1**, tht ligands are *trans* to one another, whereas in **2**, the bridging tht has a *trans* Cl and a *trans* N. The Ta(1)–Cl(3) distance of 2.4477(14) Å *trans* to tht is 0.075 Å longer than to the two other identical terminal Ta–Cl_t bonds (2.373 Å average). These Ta–Cl_t are fully comparable with those in **1** (2.368 Å average). Similarly, the *trans*-influence of the bridging tht is observed on Ta(2). The Ta(2)–N(2) bond length is 2.247(5) Å, 0.084 Å longer than the two other Ta–N bonds between Ta and Tp^{Me2} nitrogens (2.163 Å average). The bond lengths between the bridging ligands and Ta(1), which bears the three chloro ligands, are all slightly longer than those with Ta(2) which bears Tp^{Me2}. For the chloro bridges, the Ta–Cl bond lengths in **1** (2.503 Å average) are in between those for Ta(1) and Ta(2). For tht, the Ta–S bonds of 2.390 Å (average for **1**) are slightly longer than those in **2**. The angles about the chloro-bridges are marginally larger in **2** than in **1** (64.90(6)°, 64.63(6)°) whereas those about the tht are ca. 1° smaller, consistent with the variations observed for the bond lengths. Overall, the structure of **2** remains very similar to that of **1**, apart from the observed *trans*-influence of the tht ligand.

A plot of the X-ray molecular structure of **3** is displayed in Fig. 2 and associated metric parameters are collected in Table 2. As observed for the niobium analogue [15b], the whole phenylpropyne sits in the molecular mirror plane, with the phenyl ring oriented proximal to the pyrazole rings of Tp^{Me2}. All geometrical parameters for the Nb and Ta compounds are very similar. In **3**, the elongated coordinated C–C bond of the

alkyne, the short Ta–C bonds and the bent back angles between the alkyne substituents and the coordinated C–C bonds are in accord with a (4e)-donor description [17]. These parameters are typical of other (4e)-donor alkyne Tp^{Me2} [15b], or the numerous examples of Cp′ [18] or non-Cp′ [19] complexes of either Nb or Ta. The orientation of the alkyne has been discussed in Tp′ and Cp′ derivatives. As suggested by Extended Huckel [20,21] or more recent DFT calculations [18], the orientation of the alkyne is mainly due to steric interactions. Whereas steric interactions drive the alkyne in the molecular symmetry plane (perpendicular conformation) in Tp′ complexes [20], orbital interactions have been invoked to explain this same perpendicular orientation in dimethyl derivatives but not in dichloro derivatives of Cp′ [18]. In any instances, the barrier to alkyne rotation remains low unless a bulky Cp′ or Tp′ ligand is used. Finally, one can compare the *trans* influence of tht and alkyne ligands in **2** and **3**. In **3**, the Ta–N bond *trans* to

the alkyne is ca. 0.113 Å longer than the other two, whereas it is 0.084 Å longer *trans* to the tht in **2**.

2.3. Conclusion

In an effort to extend the range of readily available Tp′Ta complexes, we have synthesized and fully characterized one mononuclear alkyne complex and one dinuclear tht complex. The latter was found to be very stable towards further derivatization. Although its reactivity hence its possible use as starting material are quite deceptive, the dinuclear complex exhibits an unprecedented unsymmetrical structure among the $M_2L_3X_6$ complexes.

3. Experimental

All reactions and workup procedures were performed under an atmosphere of dry dinitrogen using conventional vacuum line and schlenk tube techniques. Dichloromethane, *n*-hexane and tht were dried and distilled by refluxing over calcium dihydride under dinitrogen. Tantalum pentachloride was used as received from commercial sources. ^{1}H NMR data were acquired on a Bruker AM 250. Elemental analyses were performed in the Analytical Service of our laboratory. $[TaCl_2(tht)]_2(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (**1**) [14], $Tp^{Me2}TaCl_2(PhC{\equiv}CCH_3)$ (**3**) [9] were prepared according to literature procedures.

3.1. $(Tp^{Me2}Ta)(TaCl_3)(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (2)

Dichloromethane (60 mL) was added to a mixture of solid $[TaCl_2(tht)]_2(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (**1**) (1.00 g, 1.2 mmol) and KTp^{Me2} (0.40 g, 1.2 mmol). The resulting dark red slurry was refluxed for 2 h and then filtered through Celite to give a deep plum purple solution. Hexane (20 mL) was added and solvents were slowly removed under vaccum until incipient crystallization. The solution was left at −30 °C overnight. $(Tp^{Me2}Ta)(TaCl_3)(\mu\text{-}Cl)_2(\mu\text{-}tht)$ (**2**) was then obtained as orange microcrystals that were collected by filtration and washed with hexane. A second batch of crystals was obtained similarly from the

Sulfur atom transfer reactions of tungsten(VI) and tungsten(IV) chalcogenide complexes

Aston A. Eagle, Robert W. Gable, Simon Thomas, Stephen A. Sproules, Charles G. Young *

School of Chemistry, University of Melbourne, Vic. 3010, Australia

Received 10 June 2003; accepted 22 August 2003

Dedicated to Jerry Trofimenko, whose remarkable contributions to scorpionate chemistry have inspired and sustained our research in Group 6 chemistry

Abstract

The sulfur, oxygen and chlorine atom transfer reactions of thio-W(VI) and -W(IV) complexes containing monodentate and ambidentate dithiophosphinate co-ligands are examined. Systems featuring monodentate ligands are complicated by the instability of the W(IV) species; significantly and in contrast to observations in thio-Mo chemistry, thio-W(VI) complexes such as Tp*WS_2Cl fail to react with cyanide. Dithiophosphinate systems are more tractable and amenable to full description. The oxo-thio and bis(thio) complexes, Tp*$WOS(S_2PPh_2$-*S*) and Tp*$WS_2(S_2PPh_2$-*S*) [Tp* = hydrotris(3,5-dimethylpyrazol-1-yl)borate] undergo sulfur atom transfer to tertiary phosphines to produce Tp*$WO(S_2PPh_2$-*S*,*S*′) and Tp*$WS(S_2PPh_2$-*S*,*S*′), respectively, and phosphine sulfides. The X-ray crystal structures of Tp*$WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$ and Tp*$WS(S_2PPh_2)$ have been determined. Both complexes possess six-coordinate, distorted-octahedral tungsten centers ligated by tridentate *fac*-Tp*, terminal thio (W = S = 2.139–2.143 Å) and mono- or bidentate dithiophosphinate ligands, respectively. The W(IV) complexes, Tp*$WE(S_2PPh_2)$ (E = O, S), react with sulfur atom donors to produce thio-W(VI) complexes, Tp*$WES(S_2PPh_2)$ but with oxygen atom donors to yield mixtures of Tp*$WOE(S_2PPh_2)$ and Tp*$WES\{SP(O)Ph_2$-*S*}. The latter result from oxygen atom transfer to phosphorus with concomitant sulfur atom transfer from phosphorus to tungsten. Catalytic sulfur atom transfer by thio-W complexes is demonstrated for the first time.

1. Introduction

Group 6 oxo compounds are versatile catalysts in industry and biology. Metal oxides and mixed-oxides have important industrial applications in inter alia hydrogenation, oxidation, condensation, epoxidation, isomerization and polymerization processes [1–3]. In biology, pterin-containing Mo and W enzymes such as sulfite oxidase, nitrate reductase, dimethyl sulfoxide reductase and aldehyde oxidoreductase catalyze a range of net oxygen atom transfer (OAT) reactions crucial to all life and to global bio-geo-chemical cycles [4–7]. For the aforementioned enzymes there is strong evidence for mechanisms involving direct OAT between Mo and substrate [4–7]. Consequently, there has been intense interest in the OAT chemistry of Mo and W; indeed, Mo lies at the epicenter of OAT chemistry and all important enzyme models feature reactions of this type. These reactions have been comprehensively reviewed [6,8]. For kinetic as well as thermodynamic reasons, clean OAT reactions are much less common in W(VI)/W(IV) chemistry [6,8]. Tungsten dithiolene complexes are an exception, as they generally undergo facile OAT inter-converting stable and isolable species [9–13]. The kinetic inertness of W(VI) toward OAT is evident from detailed investigations of the reactions of

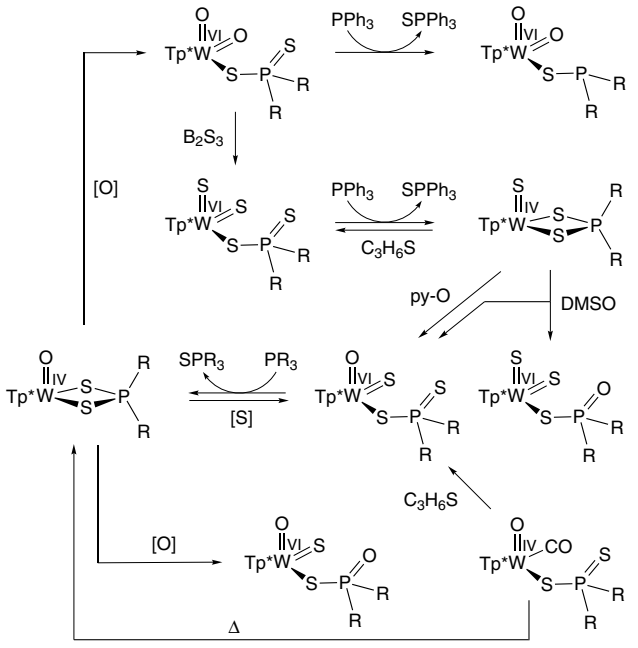
doi:10.1016/j.poly.2003.11.026

$[MO_2(mnt)_2]^{2-}$ [M = Mo, W; mnt = $S_2C_2(CN)_2^{2-}$] with phosphites, which are characterized by rate constants $k_{Mo}/k_W \sim 10^2$–10^3 [9]. The large bond dissociation enthalpy for W=O moieties (ca. 138–160 kcal mol^{-1}, cf. ca. 98 kcal mol^{-1} for Mo=O units) reduces the thermodynamic driving force for OAT from W(VI) [14].

Certain W-enzymes (or states thereof) are proposed to contain thio- or sulfhydryl-W active sites [15,16]; consequently, the atom transfer chemistry of thio- and oxo-thio-W complexes is fundamental to a complete understanding of these enzymes. This paper examines the sulfur atom transfer (SAT) reactions of thio-W complexes containing the hydrotris(3,5-dimethylpyrazol-1-yl)borate ligand (Tp*). Reactions of this kind are only sparsely represented in the literature [17,18]. Examples of SAT *to* W(II) centers include the reactions of $WCl_2(PMe_3)_4$, $Tp^*W(S_2CNR_2)(CO)_2$ (R = alkyl) and Tp*WX(CO)(MeCN) (X = monoanion) with thiiranes to give $WSCl_2(PMe_3)_3$ [19] (and related mononuclear complexes [20]), $Tp^*WS(S_2CNR_2)$ [21] and Tp*WSX(CO) [22], respectively. Phosphine sulfides also serve as sulfur atom donors to W(II), reacting, for example, with $WCl_2(PMePh_2)_4$ to form $WSCl_2(PMePh_2)_3$ and dinuclear species [23]. We are unaware of any example of SAT *to* mononuclear oxo- or thio-W(IV) complexes. Like OAT [8], SAT *from* thio-W(VI) species is generally not clean or complete. Thus, the reaction of WSX_4 with PPh_3 results in the formation of $W(PPh_3)(SPPh_3)X_4$ (X = Cl, Br) [24] while $Cp^*WS_2(R)$ (R = Me, CH_2SiMe_3) [25], $WS(OBu^t)_4$ [26] and *trans*-$WS_2(PMe_3)_4$ [27] are unreactive toward phosphines. SAT reactions are catalyzed by disulfido species such as $[WO(S_2)(mnt)_2]^{2-}$ [28] and $MoO(S_2)(S_2CNEt_2)_2$ [29,30] but thio-W catalysts for SAT have not been reported.

We have described the synthesis, characterization and electrochemical properties of the complexes Tp^*WO_2X, Tp*WOSX and Tp^*WS_2X (X = monoanion) [31–33]. The thio-W(VI) complexes are reduced at potentials similar to their dioxo-Mo(VI) analogues, which are avid participants in OAT [6]. Moreover, preliminary studies of related oxo-thio-Mo(VI) species have revealed preferential SAT vs. OAT in these systems [34–36]. This paper reports that thio-W(VI) and -W(IV) Tp* complexes participate in stoichiometric as well as catalytic SAT reactions. The stability of the various complexes is dictated by the nature of the co-ligand, complexes containing ambidentate dithiophosphinate ligands being the most stable and tractable. The report includes the X-ray crystal structures of $Tp^*W^{VI}S_2(S_2PPh_2\text{-}S)$ and $Tp^*W^{IV}S(S_2PPh_2\text{-}S,S')$, two complexes that are interconverted by direct SAT reactions. We also describe the first systems for SAT catalysis by high-valent thio-W species. The principal outcomes of the investigation are summarized in Scheme 1.



Scheme 1.

2. Experimental

2.1. Materials and methods

The compounds Tp^*WS_2Cl [37], $Tp^*WO_2(S_2PPh_2)$ [31] and $Tp^*WE(S_2PPh_2)(CO)$ (E = O, S) [22] were prepared by literature methods. Unless stated, all reactions were performed under an atmosphere of pure dinitrogen using standard Schlenk techniques and dried, deoxygenated solvents. Infrared spectra were obtained on Jasco A-302 or Perkin–Elmer 983G infrared spectrophotometers using pressed KBr discs. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded using Varian FT Unity300 or INOVA 400WB spectrometers and were referenced to internal (solvent) chloroform (δ_H 7.26) or benzene (δ_H 7.15) and external H_3PO_4 (δ_P 0), respectively. Electronic spectra were recorded on a Hitachi 150–20 UV spectrophotometer. Electron impact (70 eV) mass spectra were obtained on a Jeol AX 505H mass spectrometer. Column chromatography was performed using Merck Artikel 7734 Kieselgel 60. Microanalyses were performed by Atlantic Microlabs, Norcross, Georgia, USA.

2.2. Syntheses

2.2.1. Tp*WSCl(py)

A mixture of Tp^*WS_2Cl (0.241 g, 0.415 mmol) and PPh_3 (0.120 g, 0.456 mmol) was treated with pyridine (6 ml) and stirred for 30 min. The initial green color changed to deep blue in 2 min. The solvent was removed under vacuum and dry methanol (10 ml) was added to

the sticky residue. The resulting crystals were filtered and washed with methanol and cyclohexane. Yield 0.184 g (71%).

Anal. Unstable. IR (KBr): 2920s, 2845m, *ν*(BH) 2545w, 1625w, 1585w, 1540s, 1475m, 1440s, 1410s, 1380m, 1355s, 1200s, 1150w, 1100w, 1065s, 1040s, 985m, 950w, 935w, 910w, 855m, 810s, 785s, 780m, 755m, 715w, 690s, 640m, 590w,br, 515w, *ν*(W=S) 470m, 440w, 370w, *ν*(W–Cl) 330w cm^{-1}. Mass spectrum, *m/z*: 532 (9%) $[M–Me_2pz]^+$.

2.2.2. Tp*WOS(S_2PPh_2)

Method 1. A deep green solution of Tp*WO(S_2PPh_2) (0.200 g, 0.268 mmol) in benzene (15 ml) was treated with propylene sulfide (100 μl, 1.43 mmol), then refluxed for 2 days. The resulting yellow solution was reduced to dryness, dissolved in CH_2Cl_2 and column chromatographed on silica gel using 3:2 CH_2Cl_2/hexane as eluent. The bright orange band was collected. The compound was recrystallized from CH_2Cl_2/hexane or CH_2Cl_2/methanol, filtered, washed with methanol and dried in vacuo. Yield 0.191 g (92%). A similar reaction between Tp*WO(S_2PPh_2) (0.100 g, 0.134 mmol) and sulfur (0.100 g, 3.12 mmol) in refluxing benzene for 1 h yielded the same compound upon similar work-up (yield 79%).

Method 2. A solution of Tp*WS(S_2PPh_2)(CO) (0.82 g, 1.04 mmol) and pyridine *N*-oxide (0.40 g, 4.21 mmol) in toluene (60 ml) was heated at reflux for 48 h. The reaction mixture was then reduced to dryness and the residue was column chromatographed on silica gel/CH_2Cl_2 and the orange fraction collected. The product was isolated as above. Yield 0.32 g (38%).

Method 3. A solution of Tp*WS(S_2PPh_2) (0.200 g, 0.262 mmol) and pyridine *N*-oxide (0.026 g, 0.275 mmol) was refluxed in 1,2-dichloroethane (15 ml) for 20 h. The brown solution was evaporated to dryness and passed down a silica gel column using 3:2 CH_2Cl_2/hexane as eluent. The first green band yielded Tp*WS_2Cl (0.016 g, 10%) upon concentration and precipitation with MeOH. A slow-moving orange band was then eluted with CH_2Cl_2, concentrated and treated with MeOH to precipitate Tp*WOS(S_2PPh_2). Yield 0.017 g (8%). A similar reaction between Tp*WS(S_2PPh_2) (0.105 g, 0.138 mmol) and dimethyl sulfoxide (0.100 ml, 1.41 mmol) in refluxing benzene (15 ml) for 2 h yielded brown Tp*-WS_2{$SP(O)Ph_2$} (61 mg) and orange Tp*WOS(S_2PPh_2) (0.019 g, 18%) upon work-up. The analytical sample was isolated as the dichloromethane hemisolvate.

Anal. Calc. for $C_{27}H_{32}BN_6OPS_3W \cdot 0.5CH_2Cl_2$: C, 40.24; H, 4.05; N, 10.24; S, 11.72. Found: C, 40.04; H, 4.06; N, 10.15; S, 12.06%. 2.2.3. Tp*WS_2(S_2PPh_2)

A red solution of Tp*WS(S_2PPh_2) (0.105 g, 0.138 mmol) and propylene sulfide (100 μl, 0.143 mmol) in benzene (10 ml) was refluxed for 20 h. The resulting brown solution was reduced to dryness and the residue was recrystallized from CH_2Cl_2/hexane, then CH_2Cl_2/MeOH to give brown crystals of product. These were filtered, washed with methanol and dried in vacuo. Yield 0.085 g (78%). The complex was also prepared in the reaction of Tp*WO_2(S_2PPh_2) with boron sulfide [33]. Characterization data are available in the literature [33].

2.2.4. Tp*WO(S_2PPh_2)

Method 1. An orange solution of Tp*WOS(S_2PPh_2) (0.198 g, 0.254 mmol) in benzene (15 ml) was treated with a solution of PMe_2Ph (0.15 g, 1.09 mmol) in toluene (2 ml) and stirred for 20 min at room temperature. The resulting green solution was reduced to dryness and column chromatographed on silica gel using 3:2 CH_2Cl_2/hexane as eluent. The green band was collected and reduced to dryness. The residue was recrystallized from CH_2Cl_2/hexane, then CH_2Cl_2/EtOH to produce green crystals, which were filtered, washed with EtOH and vacuum dried. Yield 0.097 g (51%). A similar reaction between Tp*WOS(S_2PPh_2) and PPh_3 in refluxing benzene for 4 days yielded the same compound upon work-up (yield 57%).

Method 2. A red solution of Tp*WO(S_2PPh_2)(CO) (0.871 g, 1.12 mmol) was refluxed in benzene (15 ml) for 15 min and the resulting deep green solution was reduced to dryness. The residue was recrystallized and the product isolated as above. Yield 0.757 g (90%).

Anal. Calc. for $C_{27}H_{32}BN_6OPS_2W$: C, 43.45; H, 4.32; N, 11.26; S, 8.59. Found: C, 43.40; H, 4.37; N, 11.29; S, 8.49%. IR (KBr): 3050w, 2960w, 2920m, *ν*(BH) 2540m, 1540s, 1445s, *ν*(Ph) 1430s, 1410s, 1375m, 1365s, 1205s, 1160w, *ν*(Ph) 1095s, 1065s, 1035m, 990w, 980w, *ν*(W=O)

945s, 855m, 815m, 780m, 745m, 705s, 695s, 650m, 630m, 605m, $\nu(PS_2)$ 560s, 475m, 420w, 355w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.16, 2.24 (each s, 3H, CH_3), 2.52, 2.83 (each s, 6H, $2CH_3$), 5.50 (s, 1H, CH of Tp), 5.96 (s, 2H, 2CH of Tp*), 7.57 (m, 6H, Ph), 8.03 (m, 4H, Ph). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 85.30. Mass spectrum, *m/z*: 746 (54%) $[M]^+$. Electronic spectrum (CH_2Cl_2): λ_{max} 805 (sh, 30), 630 (400), 438 nm (ε 1830 M^{-1} cm^{-1}).

2.2.5. Tp*WS(S$_2$PPh$_2$)

A benzene (15 ml) solution of $Tp^*WS_2(S_2PPh_2)$ (0.270 g, 0.340 mmol) and PPh_3 (0.107 g, 0.408 mmol) was refluxed for 19 h. The resulting red solution was reduced in vacuo to ca. 1 ml, and dry methanol (8 ml) was added with stirring. The orange solid was filtered in air, and washed with dry MeOH. A second crop of red crystals was obtained by enriching the filtrate in hexane. Yield 0.218 g (84%).

Anal. Calc. for $C_{27}H_{32}BN_6PS_3W$: C, 42.53; H, 4.23; N, 11.03; S, 12.62. Found: C, 42.63; H, 4.23; N, 11.04; S, 12.53%. IR (KBr): 2955w, 2920m, ν(BH) 2545m, 1540s, 1445s, ν(Ph) 1430s, 1415s, 1375m, 1360s, 1300w, 1205s, 1180w, 1155w, ν(Ph) 1095s, 1065s, 1045w, 1035s, 995w, 980w, 870w, 855m, 815m, 785m, 755w, 745m, 705s, 690s, 645w, 630w, 605w, $\nu(PS_2)$ 565s, ν(W=S) 490s, 435w, 345w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.60 and 2.90 (each br, 9H, $3CH_3$), 5.89 (s, 3H, 3CH of Tp*), 7.40 (m, 2H, Ph), 7.60 (m, 4H, Ph), 8.10 (m, 4H, Ph). Mass spectrum, *m/z*: 762 (4%) $[M]^+$. Electronic spectrum (CH_2Cl_2): λ_{max} 865 (50), 455 nm (ε 1340 M^{-1} cm^{-1}).

2.2.6. Tp*WOS{SP(O)Ph$_2$}

Method 1. A solution of $Tp^*WO(S_2PPh_2)$ (0.100 g, 0.134 mmol) in benzene (8 ml) was prepared in air, then stirred for 6 days in a capped vial. The resulting orange mixture was reduced to dryness, dissolved in CH_2Cl_2 and eluted on a silica gel column with 3:2 CH_2Cl_2/hexane. The first two orange bands were collected and enriched in hexane to precipitate products. The first band yielded $Tp^*WOS(S_2PPh_2)$ (0.012 g, 17% based on S), the second $Tp^*WOS\{SP(O)Ph_2\}$ (0.020 g, 20%). The final light yellow band containing $Tp^*WO_2(S_2PPh_2)$ was eluted with 1:1 THF/hexane, and cream crystals were obtained by hexane enrichment (0.027 g, 27%).

Method 2. A benzene (15 ml) solution of $Tp^*WO(S_2PPh_2)$ (0.100 g, 0.134 mmol), NBu_4NO_3 (0.045 g, 0.147 mmol), and sulfamic acid (0.100 g, 1.03 mmol) was refluxed for 2 h. The resulting solution was worked up as above, to yield $Tp^*WOS\{SP(O)Ph_2\}$ (0.032 g, 31%) and $Tp^*WO_2(S_2PPh_2)$ (0.040 g, 39%).

Method 3. A solution of $Tp^*WO(S_2PPh_2)$ (0.125 g, 0.167 mmol) in benzene (12 ml) was treated with tetramethylene sulfoxide (18.1 μl, 0.201 mmol), then refluxed for 21 h. The resulting orange solution was worked up as above, to yield $Tp^*WOS\{SP(O)Ph_2\}$ (0.097 g, 76%) and $Tp^*WO_2(S_2PPh_2)$ (0.021 g, 16%).

Anal. Calc. for $C_{27}H_{32}BN_6O_2PS_2W$: C, 42.54; H, 4.23; N, 11.02; S, 8.41. Found: C, 42.64; H, 4.24; N, 10.96; S, 8.35%. IR (KBr): 2960w, 2925m, ν(BH) 2555m, 1540s, 1445s, ν(Ph) 1430s, 1415s, 1380s, 1360s, 1305w, 1205s, 1185m, 1155w, ν(P=O) 1110s, 1080s, 1075s, 1040s, ν(W=O) 940s, 890s, 870w, 855s, 815m, 790m, 750m, 725s, 715s, 695s, 655s, 545m, 510m, ν(W=S) 480s, 400w cm^{-1}. ^1H NMR ($CDCl_3$): δ 1.66, 2.20, 2.35, 2.37, 2.38, 2.84 (each s, 3H, CH_3), 5.68, 5.71, 5.99 (each s, 1H, CH of Tp*), 7.35 (m, 5H, Ph), 7.50 (m, 1H, Ph), 7.61 (m, 2H, Ph), 7.81 (m, 2H, Ph). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 85.21. Mass spectrum, *m/z*: 667 (4%) $[M–Me_2pz]^+$, 730 (2%) $[M–S]^+$.

2.3. Crystal structures

Yellow-brown crystals of $Tp^*WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$ and red crystals of $Tp^*WS(S_2PPh_2)$ were grown by diffusion of hexane into dichloromethane solutions of the complexes. Crystals of dimensions $0.03\times0.18\times0.46$ mm and $0.13\times0.27\times0.27$ mm, respectively, were chosen for examination.

A summary of the crystal data is given in Table 1. In this section, data for $Tp^*WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$ are followed in parentheses by the corresponding data for $Tp^*WS(S_2PPh_2)$. Accurate unit cell parameters were obtained by a least squares procedure from the setting angles of 25 reflections, $16.0° < 2\theta < 24.2°$ ($21.2° < 2\theta < 27.6°$). Intensity data were collected using an Enraf-Nonius CAD-4MachS single crystal X-ray diffractometer using the ω:2θ scan method. A total of 3752 (7722) reflections were measured, $4° \leqslant 2\theta \leqslant 50°$ ($4° \leqslant 2\theta \leqslant 52°$), of which 3492 (6011) were unique (R_{int} 0.019; 0.022) with 3113 (4625) having $I \geqslant 2\sigma(I)$. Three intensity control reflections, monitored every 9600 s X-ray exposure time, showed a 2% (no significant) variation in intensity; the data were corrected in accordance with

Table 1

ρ_{calcd} (g cm^{-3})	1.654	1.651
R	0.0282	0.0263
wR	0.0515	0.0621

$R = \sum ||F_o| - |F_c|| / \sum F_o$ and $wR = [\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}$.

these variations as well as for Lorentz and polarization effects, but not for extinction. Absorption corrections, evaluated by Gaussian integration [38], were applied to the data, the maximum and minimum transmission factors being 0.8927 and 0.5115 (0.6751 and 0.5581).

The structures were solved using a combination of Patterson, direct methods and difference synthesis [39,40], and refined with a full-matrix least-squares refinement procedure. All hydrogen atom sites were found on a difference electron-density map; all were included at calculated positions and refined using the riding model. For $Tp^*WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$, the dichloromethane molecule was found to be disordered over a site of two-fold symmetry, and was modelled by assigning one component to have the carbon atom lying on the two-fold axis, with the chlorine atoms equally disposed around the two-fold axis, and a second component with one chlorine atom lying on the two-fold axis, with the carbon and chlorine atoms equally disposed around it. Both components were restrained to geometrical estimates with a refinable occupancy factor assigned.

Final refinements, on F^2 and using all data, were carried out with anisotropic displacement factors applied to each of the non-hydrogen atoms and isotropic for the hydrogen atoms and for the atoms of the dichloromethane molecule. A weighting scheme of type $[\sigma^2(F_o^2) + (aP)^2 + bP]^{-1}$, where $P = (F_o^2 + 2F_c^2)/3$ and where a and b were 0.0191 and 13.9650 (0.0254 and 1.8353) was used. At convergence, $R\ [I \geqslant 2\sigma(I)] = 0.0282$ (0.0263) and wR (all data) = 0.0515 (0.0621). For $Tp^*WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$, the absolute configuration was determined; the Flack absolute structure factor [41] refined to a value of 0.00(1). In the final difference map the maximum and minimum peak heights were 0.594 and −0.480 (1.021 and −0.810) e $Å^{-3}$, close to the W atom.

The atomic scattering factors for all atoms were those incorporated in the SHELXL-93 program [40]; corrections were made for anomalous dispersion. Calculations were carried out on a Vaxstation 4000 VLC computer system. Distances and angles for the two structures are given in Tables 2 and 3. Figs. 1 and 2 were prepared from the output of ORTEP-II and thermal ellipsoids are drawn at the 50% probability level [42].

3. Results and discussion

3.1. Sulfur atom transfer from thiotungsten(VI) centers

Oxo-thio- and bis(thio)-W(VI) complexes undergo SAT to tertiary phosphines yielding oxo- and thio-W(IV) complexes, respectively, and phosphine sulfides. Nucleophilic attack by phosphine at the terminal thio ligand is consistent with a sulfur based π^* LUMO [33] and, in the case of oxo-thio species, expectations based on bond dissociation enthalpies (W=S, ca. 82–92 kcal mol^{-1}; W=O, 138–160 kcal mol^{-1}) [14,17]. The observation is also in accord with the outcomes of similar reactions in oxo-thio-Mo chemistry [34–36,43]. The stability of the W-containing products is critically dependent on the conditions of the reaction, particularly the solvent and the nature of the co-ligand (vide infra). While the chemistry observed generally parallels the OAT chemistry of Tp^*MoO_2X complexes [6], the instability of W(IV) species containing monodentate co-ligands limits their clean isolation and full characterization. These difficulties are ameliorated by the presence of stabilizing ambidentate ligands (vide infra).

In pyridine, green Tp^*WS_2Cl reacts rapidly with PPh_3 to produce $SPPh_3$ and blue, air-sensitive Tp*WSCl(py). The instability of the complex toward loss of pyridine, in solution and the solid state, prevented complete characterization. The compound's IR spectrum exhibited medium intensity ν(BH) and ν(W=S) bands at 2545 and 470 cm^{-1}, respectively. The

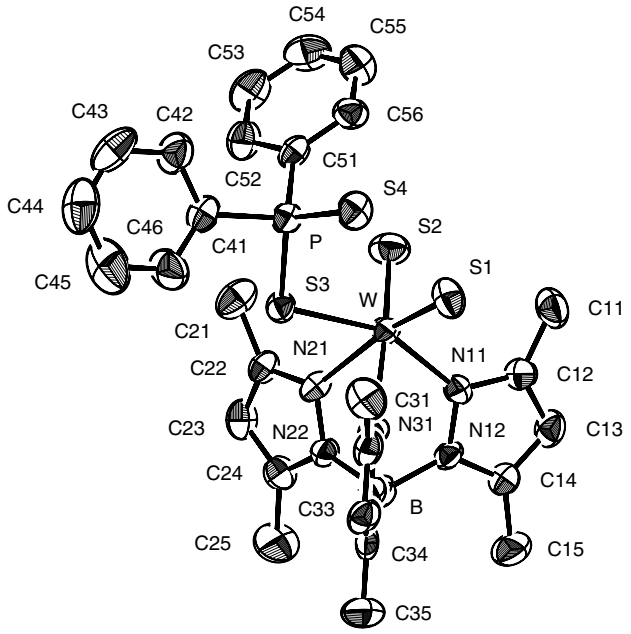

Fig. 1. Molecular structure and atom numbering scheme for $Tp^*WS_2(S_2PPh_2)$. The numbering schemes for the pyrazole ring containing N(31) (unlabelled) parallels those shown for the rings containing N(11) and N(21). Hydrogen atoms have been removed for clarity.

observation of bands at 1625, 1585, 1475, 1150, 755 and 690 cm^{-1} (absent from the spectrum of Tp^*WS_2Cl) were consistent with pyridine ligation. The mass spectrum of

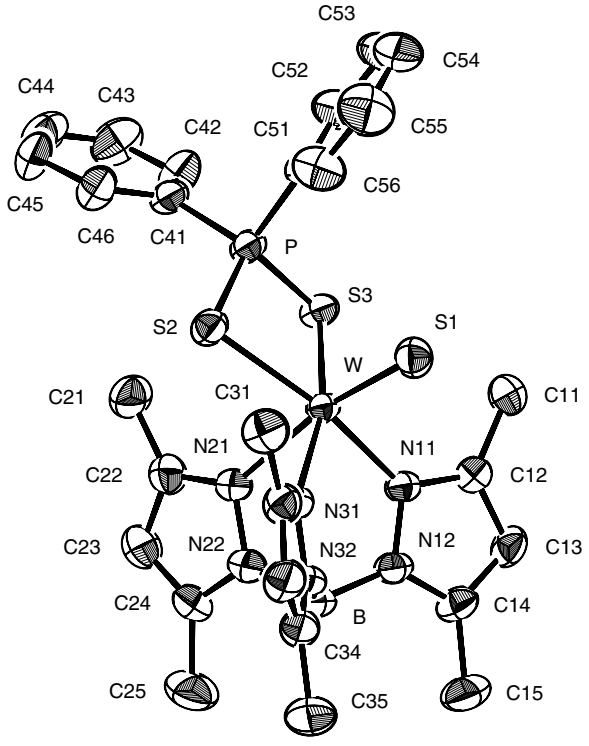

Fig. 2. Molecular structure and atomic numbering scheme for $Tp^*WS(S_2PPh_2)$. Hydrogen atoms have been removed for clarity.

$Tp^*WSCl(py)$ lacked a molecular ion but contained a strong $[M–Me_2pz]^+$ ion at *m/z* 532 (9%); the loss of an Me_2pz is a common fragmentation pattern for complexes of Tp*. The ^1H NMR spectrum of $Tp^*WSCl(py)$ exhibits broad features typical of fluxional oxo- and thio-W(IV) Tp* complexes [21]. The conversion of the compound to Tp^*WOSCl or $Tp^*WS(S_2CNEt_2)$ upon reaction with dimethyl sulfoxide or NaS_2CNEt_2, respectively, supported the proposed formulation. Aspects of this work were previously described [33].

The reactions of Tp^*WS_2X (X = Cl, SPh) with PPh_3 or PMe_2Ph in pyridine or 2,6-lutidine (lut) yielded intensely colored Tp*WSX(solvent). Here, the air-sensitivity of the complexes and persistent contamination by phosphine sulfide prevented full characterization. In light of the isolation of phosphine oxide intermediates in related OAT reactions [44], the generation of phosphine sulfide complexes cannot be excluded nor at this time confirmed. Purple Tp*WS(SPh)(py) and Tp*WS(SPh)(lut) are soluble and moderately stable in CH_2Cl_2 producing dichroic (blue-grey/red) solutions. The former is also solvatochromic, producing green solutions in hexane. Attempts to prepare MeCN complexes such as Tp*WSX(MeCN) by heating Tp^*WS_2X and PPh_3 in MeCN were unsuccessful (cf. clean reactions in oxo-Mo systems [45,46]). The reaction of Tp^*WS_2Cl with PPh_3 in dichloromethane resulted in the generation of orange Tp^*WSCl_2 in 77% yield via consecutive SAT and solvent-based chlorine atom abstraction reactions. The complex was characterized by IR (ν(BH) 2555 cm^{-1}, ν(W=S) 515 cm^{-1}) and EPR ($g = 1.731$) spectroscopy. Chlorine atom abstraction reactions are also observed in related oxo-Mo systems [45].

Green Tp^*WS_2Cl failed to react with NEt_4CN in benzene even after days under reflux. No visible reaction occurred between Tp^*WS_2Cl and NaCN/18-crown-6 in refluxing toluene over two hours but all Tp^*WS_2Cl was consumed after 15 h; numerous products were detected by TLC (silica, 1:1 THF/hexane) but none could be isolated or characterized. Cyanide does not react with $Cp^*WS_2(R)$ (R = Me, CH_2SiMe_3) at room temperature [25]. Tungsten enzymes vary in their response to cyanide. *Pyrococcus furiosus* aldehyde oxidoreductase and *Desulfovibrio gigas* aldehyde dehydrogenase are deactivated by cyanide [47] but, *Thermococcus litoralis* formaldehyde ferredoxin oxidoreductase [16] and *P. acetylenicus* acetylene hydratase [48] are less sensitive to the anion. The formylmethanofuran dehydrogenases from *Methanobacterium thermoautotrophicum* [49] and *M. wolfei* [50] and the aldehyde oxidoreductase from *Thermococcus* sp. ES-1 [51] are unaffected by cyanide. Deactivation of xanthine oxidase [4,5] and $[MoOS]^{2+}$ model complexes [34–36,43] by cyanide is a key indicator of the presence of a terminal thio ligand at Mo. By analogy, it is implicit that, cyanide-stable W enzymes are devoid of W–SH or W=S ligands. However, our results

suggest that, W=S groups can be unusually stable in the presence of cyanide. Hence, the inability of cyanide to deactivate W enzymes cannot be taken as strong evidence for the absence of thio ligands. Aspects of this work were previously described [33].

Tungsten(IV)/(VI) complexes containing dithiophosphinate co-ligands were more stable and amenable to study than the monodentate ligand complexes above. As was the case for Tp*WOSCl (vide supra), orange Tp*WOS(S_2PPh_2) [52] underwent SAT (rather than OAT) to tertiary phosphines, producing air-stable Tp*WO(S_2PPh_2) and SPR_3 according to Eq. (1). Similarly, yellow-brown Tp*WS_2(S_2PPh_2) [33] reacted with one equivalent of PPh_3 in refluxing benzene to yield dark red Tp*WS(S_2PPh_2) and $SPPh_3$ (Eq. (2)).

$$\mathrm{Tp^*WOS(S_2PPh_2\text{-}\mathit{S}) + PR_3 \rightarrow Tp^*WO(S_2PPh_2\text{-}\mathit{S},\mathit{S}') + SPR_3} \quad (1)$$

$$\mathrm{Tp^*WS_2(S_2PPh_2\text{-}\mathit{S}) + PPh_3 \rightarrow Tp^*WS(S_2PPh_2\text{-}\mathit{S},\mathit{S}') + SPPh_3} \quad (2)$$

The oxo-W(IV) complex can also be prepared by thermal decarbonylation of Tp*WO(S_2PPh_2-*S*)(CO) [22] in benzene. The compounds are freely soluble in chlorinated solvents but insoluble in alcohols and alkanes. The oxo-W(IV) complex is moderately air-stable as a solid but air-sensitive in solution, yielding Tp*WO_2(S_2PPh_2) and Tp*WOS{$SP(O)Ph_2$} upon lengthy exposure to air. The thio-W(IV) complex is air-sensitive and decomposes over several days in the solid state, faster in solution. Only Tp*WO(S_2PPh_2) is stable toward column chromatography on silica gel. The IR spectra of Tp*WO(S_2PPh_2) and Tp*WS(S_2PPh_2) exhibit medium intensity ν(BH) bands at 2540–2545 cm^{-1} and strong ν(W=E) (E = O, S) bands at 945 and 490 cm^{-1}, respectively. The bidentate dithiophosphinate ligand gives rise to strong bands at ca. 1430 and 1100 and 560–565 cm^{-1}, which are associated with phenyl [53] and $\nu(PS_2)$ vibrational modes, respectively. The room temperature ^{1}H NMR spectrum of Tp*WS(S_2PPh_2) consisted of broad resonances indicative of (undetermined) fluxional processes; similar behavior is observed for Tp*WO(S_2CNEt_2) and Tp*WS(S_2CNEt_2) [21]. In contrast, the ^{1}H NMR spectrum of Tp*WO(S_2PPh_2) exhibited six sharp methyl and methine Tp* resonances, indicative of a non-fluxional molecule with C_s symmetry.

The sluggish reactions of the dioxo-W(VI) complexes, Tp*WO_2X, with PPh_3 have already been mentioned in the literature [31,54]. Interestingly, Tp*WO_2(S_2PPh_2) reacts with PMe_2Ph in refluxing toluene to produce at least seven species (by thin layer chromatography). One of the major products, an orange compound, has been tentatively characterized as the phosphinothiolate (thiophosphinite) complex, Tp*WO_2($SPPh_2$), on the basis of IR data indicating the presence of oxo ($\nu(WO_2)$ 940 and 905 cm^{-1}) and phenyl groups (1430 and 1100 cm^{-1}) but the absence of PS_2 and P=O units. SAT from P rather than OAT from W is consistent with relative W=O (138–160 kcal mol^{-1}) and P=S (ca. 82–92 kcal mol^{-1}) bond dissociation enthalpies. Mononuclear phosphinothiolate complexes of Ti, Zr and Hf have been reported and the crystal structure of $Cp_2Ti(SPCy_2)$ determined [55]. Full characterization of the W complex is underway.

3.2. Atom transfer to oxo- and thiotungsten(IV) centers

The reactions of Tp*WSCl(py) with dimethyl sulfoxide or Tp*WS(SPh)(py) with dioxygen produced Tp*WOSX via OAT. An alternative but less reliable synthesis of Tp*WOSCl, involving the direct sulfurization of Tp*WO_2Cl, has been reported [32,37].

Green Tp*WO(S_2PPh_2) reacts cleanly with sulfur or propylene sulfide ([S]) in refluxing benzene to produce Tp*WOS(S_2PPh_2) (Eq. (3)); the yields and reaction times are 79% in ca. 30 min and 92% in ca. 3 days, respectively, for the two reagents. The product was identified by IR (ν(W=O) 930s, ν(P=S) 643s, ν(P–S) 525s, ν(W=S) 485m cm^{-1}) and ^{1}H NMR spectroscopy. The reaction contrasts with the formation of $[WO(S_2)(mnt)_2]^{2-}$ rather than $[WOS(mnt)_2]^{2-}$ when $[WO(mnt)_2]^{2-}$ reacts with sulfur [28].

$$\mathrm{Tp^*WO(S_2PPh_2) + [S] \rightarrow Tp^*WOS(S_2PPh_2)} \quad (3)$$

$$\mathrm{Tp^*WS(S_2PPh_2) + MeCH(S)CH_2 \rightarrow Tp^*WS_2(S_2PPh_2) + MeCH{=}CH_2} \quad (4)$$

No reaction was observed between Tp*WO(S_2PPh_2) and excess thiophene over two days in refluxing benzene. The steric bulk of Tp* is likely to prevent the η^5-coordination of thiophene required for desulfurization [56]. SAT to Tp*WS(S_2PPh_2) provides an efficient alternative route to Tp*WS_2(S_2PPh_2) [33] (Eq. (4)) but rather forcing conditions are required for the reaction (benzene reflux). The analogous reaction with elemental sulfur fails to produce Tp*WS_2(S_2PPh_2). These reactions are to our knowledge the first examples of the oxidation of W(IV) by SAT leading to the generation of oxo-thio and bis(thio)-W(VI) centers.

The reactions of Tp*WS(S_2PPh_2) with oxygen atom donors are not as straightforward. Thus, the reaction of Tp*WS(S_2PPh_2) with dimethyl sulfoxide produces two products, orange Tp*WOS(S_2PPh_2) (18%) and brown Tp*WS_2{$SP(O)Ph_2$} (65%). The latter was characterized by IR (ν(BH) 2560m, phenyl modes 1435 and 1100s, ν(P=O) 1035s, $\nu(WS_2)$ 495m and 475s, $\nu(PS_2)$ absent) and ^{1}H NMR spectroscopy (C_s symmetry indicated). The generation of Tp*WS_2{$SP(O)Ph_2$} is consistent with OAT to P with concomitant SAT from P to W. The

reaction of Tp*WS(S_2PPh_2) with pyridine *N*-oxide in refluxing 1,2-dichloroethane (18 h) also gave disappointing yields (8%) of Tp*WOS(S_2PPh_2) (and other intractable products).

The oxygen atom donors dioxygen, tetramethylene sulfoxide (TMSO) and NBu_4NO_3 react with Tp*WO(S_2PPh_2) to give Tp*WO_2(S_2PPh_2) in 27%, 16% and 39% yields, respectively. The unexpectedly low yields are associated with the generation of a second product, orange, air-stable Tp*WOS{$SP(O)Ph_2$}, in 20%, 76% and 31% yield, respectively. The infrared spectrum of this complex contained a medium intensity ν(BH) band at 2555 cm^{-1} and strong phenyl group, ν(W=O) and ν(W=S) bands at 1430, 940 and 480 cm^{-1}, respectively. The strong ν(P–S) band of Tp*WOS(S_2PPh_2) at 525 cm^{-1} was conspicuously absent and new bands were present at 1110, 725, 545, and 510 cm^{-1}. The strong band at 1110 cm^{-1} is assigned to the ν(P=O) mode. The ^1H NMR spectrum was indicative of molecular C_1 symmetry and the retention of both phenyl groups. Mass spectra contained peak clusters at *m*/*z* 528, 730 and 667 (ca. 2–4%) assignable to $[Tp^*WOS]^+$, $[Tp^*WO\{SP(O)Ph_2\}]^+$ and $[M–Me_2pz]^+$ fragments, respectively. Aerial oxidation of Tp*WO(S_2PPh_2) also led to Tp*WOS(S_2PPh_2) (17% based on sulfur). Formation of the dioxo complex is proposed to result from direct OAT to the W center while the generation of oxo-thio species occurs through OAT to P with concomitant SAT from P to W. The distinctly different product distributions observed for the smaller (dioxygen, NO_3^-) vs. larger (TMSO) oxidants are consistent with restricted access of TMSO to the W vs. P centers. Pure Tp*WO(S_2PPh_2) is quite stable in refluxing benzene (for over two days) under nitrogen, and *did not* spontaneously produce *cis*-$[WOS]^{2+}$ complexes.

3.3. Crystal structures

The structures of Tp*WS_2(S_2PPh_2) and Tp*WS(S_2PPh_2) were determined by X-ray diffraction and views of the molecules are shown in Figs. 1 and 2, respectively. Selected bond distances and angles are given in Tables 2 and 3, respectively.

Mononuclear, six-coordinate Tp*WS_2(S_2PPh_2) exhibits a distorted-octahedral coordination geometry comprised of *cis* thio, monodentate $S_2PPh_2^-$ and tridentate *fac*-Tp* ligands. The W=S bond distances of 2.137(2) and 2.139(2) Å are at the short end of the range established for W=S bonds (mean 2.153 Å) [57,58] but similar distances pertain to related complexes, including Tp*WS_2(OPh) (2.130(4) Å) [33] and Cp*WS_2(CH_2SiMe_3) [25]. The W–S(3) distance of 2.418(2) Å is typical of monodentate dithiophosphinate species and close to equivalent bond distances in Tp*WE(S_2PPh_2-*S*)(CO) (E = O, S) [59]. The thio ligands exert a strong *trans* influence on the W–N(21) and W–N(31) bonds, lengthening them significantly with respect to the W–N(11) bond. The S(1)–W–S(2) angle of 102.38(9)° is close to the corresponding angle for Tp*WS_2(OPh) (102.9(1)°) and enhances favorable π-interactions between the thio ligand and metal orbitals [33]. The W–S(3) and W–N(11) vectors are inclined away from the thio ligands producing an S(3)–W–N(11) angle of 156.8(2)°. The W atom lies 1.043(2) Å out of the plane defined by S(1), S(2) and S(3) but 1.509(4) Å out of the plane defined by the N(*n*1) atoms; these parameters highlight the distorted nature of the octahedral geometry.

The monodentate dithiophosphinate ligand adopts a partially extended conformation with S(4)···S(1) and S(4)···S(2) intramolecular contacts of 3.237(3) and 5.013(3) Å, respectively. The former is inside the van der Waals distance of 3.7 Å [60], the latter well outside this distance. A very weak interaction is indicated by the spatial conjunction of the sulfur atoms observed here and in Tp*WOS(S_2PPh_2) [52]. The P–S(4) bond distance is significantly shorter than that of P–S(3) [1.953(3) vs. 2.085(3) Å], a reflection of double bond character in the terminal P=S unit. Similar differences in P–S distances are observed in other monodentate dithiophosph(in)ate ligand complexes, e.g., Tp*MoO_2\{$S_2P(OEt)_2$-*S*\} [61] and Tp*WOS(S_2PPh_2-*S*) [52], as well as $[R_2P(S)]_2S_2$ (R = Me, ^{i}Pr) [62] and the free acid, HS_2PPh_2 [63]. A fully extended structure is observed in the related oxo-Mo species, Tp*MoO_2\{$S_2P(OEt)_2$\} [61]. The other bond distances and angles within the dithiophosphinate and Tp* ligands are unexceptional.

Molecules of Tp*WS(S_2PPh_2) are also mononuclear and six-coordinate, with a distorted octahedral coordination sphere comprised of terminal thio, bidentate $S_2PPh_2^-$ and tridentate *fac*-Tp* ligands. The W–S(1) bond length of 2.1426(12) Å is similar to those found in other mononuclear thio-W(IV) complexes, including Tp*WS(S_2CNEt_2) (2.153(2) Å) [21], WS(S_2CNEt_2)(η^4-C_4Ph_4H) (2.103(4) Å) [64], WS(PhC≡CPh)(S_2CNEt_2)($SCNEt_2$) (2.138(5) Å) [65] and WS(S_2CNEt_2)$_2$(PhC≡CPh) (2.147(2) Å) [66]. The bidentate $S_2PPh_2^-$ ligand is symmetrically bound to tungsten with average W–S and P–S distances of 2.463(1) and 2.026(2) Å, respectively. The S–W–S and S–P–S angles of the dithiophosphinate ligand are 80.32(4)° and 103.22(6)°, respectively. The *trans* influence of the W=S group results in a lengthening of the W–N(21) bond by ca. 0.19 Å compared to the other W–N bonds. The W atom lies 0.288(1) Å out of the plane defined by S(2), S(3), N(11) and N(31) toward the terminal thio ligand. Finally, the P atom is swivelled slightly toward the thio ligand as a result of steric interactions, the dihedral angle between the W, S(2), S(3) and S(2), S(3), P planes being 25.00(5)°. The structure is most closely related to those determined for Tp*MoO\{$S_2P(OEt)_2$\} [61] and Tp*WS(S_2CNEt_2) [21].

3.4. Catalytic SAT reactions

The interconversion of thio-W(IV) and -(VI) complexes by SAT raises the possibility of catalytic SAT. With this aim in mind, we have briefly assessed the capacity of several complexes to catalyze Eq. (5) in dry, deoxygenated benzene.

$$PPh_3 + MeCH(S)CH_2 \rightarrow SPPh_3 + MeCH{=}CH_2 \qquad (5)$$

The reactions were conveniently monitored by ^{31}P NMR spectroscopy, activity being indicated by the replacement of the resonance of PPh_3 (δ 1.3) with that of $SPPh_3$ (δ 46.8). Reactions were performed at room temperature, with a 1:1 mole ratio of PPh_3:C_3H_6S (0.13 mmol each/sample) with 0.1 mole equivalent of W catalyst. A blank reaction was also monitored, giving 85% conversion to products after 43 weeks. The reaction was accelerated by addition of Tp*WS_2X (X = Cl, OPh, SPh). The thiophenolate complex catalyzed 82% conversion to products over a 10 week period but improved catalytic activity, 56% conversion in 16 days, was noted for Tp*WS_2(OPh). The best catalyst was found to be Tp*WS_2Cl, which effected 95% conversion in just 3 days. The active catalyst in this system is unclear as there is in situ ^1H NMR evidence for the presence of a dinuclear species (possibly from the comproportionation of Tp*WS_2Cl and Tp*WSCl(solv)) in this system. Attempts to isolate and characterize the species are underway. Present studies have been hampered by a degree of polymerization in the propylene sulfide used and more effective sulfur atom donor reagents are now under investigation. Future investigations will also examine the use of bulkier trispyrazolylborate ligands to maintain mononuclearity, although this does not appear to be pre-requisite for catalysis. The results to date hold great promise for the development of fully functional SAT catalysts based on terminal thio-W chemistry.

4. Summary

Reduction of oxo-thio- and bis(thio)-W(VI) complexes with phosphines results in the formation of oxo- and thio-W(IV) species, respectively. The products of the reactions of Tp*WS_2Cl or Tp*WOSCl with phosphines are unstable even in the presence of coordinating solvents. In contrast, the ambidentate $S_2PPh_2^-$ ligand stabilizes Tp*WE(S_2PPh_2) (E = O, S), the products of the reactions of Tp*WES(S_2PPh_2) with phosphines, through chelation. The one-electron redox potentials of the thio-W(VI) complexes, as well as the products obtained from reactions with phosphines, are directly comparable with those observed for analogous dioxo-Mo(VI) complexes, and clear parallels exist in the oxygen and sulfur atom transfer capabilities of dioxo-Mo(VI) on one hand and oxo-thio- and bis(thio)-W(VI) centers on the other. If W-enzymes contain thio-W centers and operate by direct atom transfer, then sulfidation rather than oxidation of the substrate would be predicted on the basis of the results reported here. This is at odds with the observed net OAT chemistry of the enzymes (unless an initially formed thio species is hydrolyzed to give the observed product).

The tungsten(IV) complexes Tp*WE(S_2PPh_2) (E = O, S) react cleanly with sulfur atom donors to give the thio-W(VI) complexes, Tp*WES(S_2PPh_2), while reaction with oxygen atom donors gave a mixture of Tp*WOE(S_2PPh_2), through OAT to W, and Tp*WES {$SP(O)Ph_2$}, through OAT to P and concomitant SAT from P to W. In general, reduction of W(VI) to W(IV) was effective through sulfur rather than oxygen atom transfer while oxidation of W(IV) to W(VI) is readily achieved by either oxidant (the complications associated with the phosphorus-containing ligand notwithstanding). Catalysis of SAT has been demonstrated and will be further developed with both thio-W and -Mo systems.

5. Supplementary data

Full details of data collections and structure determinations have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 211 896 [for Tp*$WS_2(S_2PPh_2)\cdot 0.5CH_2Cl_2$] and 211 897 [for Tp*$WS(S_2PPh_2)$]. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Poly(mercaptoimidazolyl)borate chemistry and the predominance of κ^3-*S*,*S*,*H* over κ^2-*S*,*S* or κ^3-*S*,*S*,*S* coordination modes: unexpected formation of square pyramidal Ni(II) complexes

Abstract

The paramagnetic nickel(II) complexes [(dppe)Ni(L)]X (L = Bm^R or Tm^R) have been readily prepared from the appropriate 1,2-bis(diphenylphosphino)ethane adducts Ni(dppe)X_2 (X = Cl, Br) and the thallium(I) reagents Tl(Bm^R) (R = Me, Bu^t) or Tl(Tm^R) (R = Me, Bu^t, *p*-Tol), and isolated as carmine to deep purple solids in 75–95% yield. X-ray diffraction studies of [(dppe)Ni(Bm^{Me})]Cl and [(dppe)Ni($Tm^{p\text{-Tol}}$)]Cl revealed the presence of a weak pseudo-axial Ni···H–B interaction and an overall square pyramidal geometry in each complex. As such, the cationic complexes $[(dppe)Ni(L)]^+$ are the first structurally characterized species having $[NiP_2S_2H]$ cores and resemble a number of transient species that play a key role in the catalytic cycle of [NiFe] hydrogenases.

1. Introduction

The versatility of the tris(pyrazolyl)borate (scorpionate) ligand system is evident from the nearly 200 members of this family of ligands that have been prepared simply by varying the number and nature of the substituents on either the boron center or the pyrazolyl rings [1–3]. A number of neutral analogues of Tp ligands have also been developed over the years by replacing the boron atom by a different element, e.g., carbon or silicon to produce the corresponding tris(pyrazolyl)methanes [4] or tris(pyrazolyl)silanes [5] (Fig. 1). Interest in the design of more polarizable (i.e., softer) analogues of Tp ligands, prompted by potential applications in bioinorganic and organometallic chemistry, has also arisen within the last decade. In this regard, whereas Riordan introduced the poly(thioether)borates [6,7] and Reglinski originated the tris(mercaptoimidazolyl)borates [8], Peters and Nocera disclosed almost simultaneously the tris(phosphino)borates [9,10] (Fig. 2).

The Tm^R ligands, in conjunction with the related bis(mercaptoimidazolyl)borates (Bm^R) [11], have been particularly appealing for the design of synthetic models for the active centers in the small but conspicuous group of known sulfur-rich metalloenzymes. For example, Parkin and coworkers [12,13] and Vahrenkamp and coworkers [14] have independently prepared several (Tm^R)ZnX complexes (X = halide, alkoxide, thiolate, etc.) in their quest to better understand the structure and function of sulfur-rich zinc enzymes such as liver alcohol dehydrogenase (LADH) and 5-aminolevulinate dehydratase (ALAD). In turn, we have synthesized a series of novel nickel(II) complexes Ni(Bm^R)$_2$ (R = Me, Bz, Bu^t, *p*-Tol) (Fig. 3) [15] as structural models for the nickel center in [NiFe] hydrogenases [16]. The active site in these enzymes consists of a dinuclear nickel–iron

complex in which the nickel atom is surrounded by four cysteine groups in a geometry that has been described as either square pyramidal with a missing basal ligand or octahedral with two adjacent coordination vacancies (Fig. 4) [17]. The $Ni(Bm^R)_2$ complexes, having $[NiS_4H_2]$ cores and slightly distorted octahedral geometries resulting from the unexpected presence of two Ni···H–B interactions, constitute unprecedented structural mimics that resemble the nickel coordination environment in the active form of [NiFe] hydrogenases.

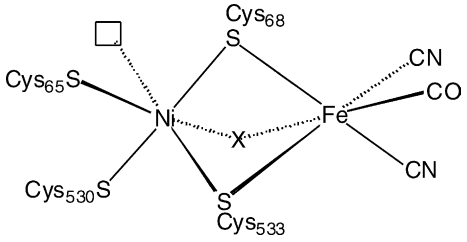

Fig. 4. Representation of the active site in the [NiFe] hydrogenase extracted from *D. gigas* showing the vacant coordination site (open square) and the additional bridging oxo or hydroxo ligand (×) present only in the oxidized (inactive) form of the enzyme.

Seeking to extend our synthetic efforts to the Tm^R ligand system and to investigate the reactivity (i.e., redox chemistry) of a *single* thiolate group bound to nickel in these metalloenzymes, we set out to prepare unusual tetrahedral complexes of the form $(Tm^R)NiSR$. However, the synthesis of such attractive species remains elusive to date since every attempt to access suitable $(Tm^R)NiX$ precursors (X = halide) has yielded instead the homoleptic derivatives $Ni(Tm^R)_2$ as the only isolable nickel products [18,19]. Undeterred by these results, we envisioned that the use of a starting material containing a chelating diphosphine such as 1,2-bis(diphenylphosphino)ethane (dppe) may prevent the addition of a second $[Tm^R]^-$ group to nickel and plausibly generate useful complexes such as $(dppe)Ni(Tm^R)X$, all while preserving the required soft donor ligand set around the metal center. We describe in this paper the synthesis and characterization of the unexpected nickel(II) complexes that are isolated from the reactions of $Ni(dppe)X_2$ (X = Cl, Br) [20] with a variety of poly(mercaptoimidazolyl)borate ligands. These studies will provide insight into the relative affinities of the nickel(II) center for the κ^3-*S*,*S*,*H*, κ^2-*S*,*S*, or κ^3-*S*,*S*,*S* coordination modes that these ligands may exhibit.

2. Results and discussion

2.1. Syntheses of nickel complexes

Nickel(II) products of stoichiometry (dppe)Ni(L)X ($L = Bm^R$ or Tm^R) were readily prepared by reacting equimolar dichloromethane solutions of Ni(dppe)X_2 (X = Cl, Br) and the corresponding thallium(I) reagents Tl(Bm^R) (R = Me, Bu^t) or Tl(Tm^R) (R = Me, Bu^t, *p*-Tol) (Eq. (1)), and isolated as carmine to deep purple solids in ca. 75–95% yield after the appropriate work-up. The use of the sodium reagents Na(Bm^R) or Na(Tm^R) was not nearly as effective and their reactions with Ni(dppe)X_2 produced lower yields of the desired species or, more often, intractable mixtures of unidentified products. All the (dppe)Ni(L)X complexes are air-stable materials, generally soluble in polar solvents such as dichloromethane, chloroform, acetonitrile, acetone, methanol, and dimethyl sulfoxide (DMSO) but insoluble in aliphatic or aromatic hydrocarbons or diethyl ether.

$$\mathrm{Ni(dppe)X_2 + Tl(L) \xrightarrow[\substack{L=Bm^R,Tm^R\\ R=Me,Bu^t,p\text{-}Tol\\ X=Cl,Br}]{CH_2Cl_2} (dppe)Ni(L)X + TlX} \quad (1)$$

The 10 new (dppe)Ni(L)X complexes were characterized by a combination of analytical and spectroscopic techniques, including elemental analyses (CHN) and IR, UV/Vis, and ^{1}H NMR spectroscopies. Their paramagnetism ($\mu_{eff} = 3.0$–$3.2\ \mu_B$) is consistent with $S = 1$ ground states (i.e., two unpaired electrons) and is reflected in solution by broad albeit not significantly contact-shifted signals (relative to the free Bm^R or Tm^R ligands) in their ^{1}H NMR spectra. Electrospray ionization mass spectrometry (ESI-MS) was also used to investigate the nature of the (dppe)Ni(L)X complexes in solution. For example, the positive ion mass spectrum of a dilute acetonitrile solution of (dppe)Ni(Bm^{Me})Cl (Fig. 5) showed only the set of peaks ($m/z = 695$) with the expected isotopic distribution corresponding to the [(dppe)Ni(Bm^{Me})]$^+$ fragment. This observation is in agreement with the fact that loss of a halide is the most common ionization pathway for transition metal complexes containing halide ligands [21]. The complexes were further characterized in acetonitrile solution by UV/Vis spectroscopy. The spectra of (dppe)Ni(L)X ($L = Bm^R$, Tm^R; R = Me, Bu^t; X = Cl, Br) show intense charge-transfer bands at ca. 273 nm ($\varepsilon = 29.4$–$44.7 \times 10^3 M^{-1}\ cm^{-1}$), while those of the $Tm^{p\text{-Tol}}$ derivatives are red-shifted to 302 nm, presumably a consequence of the π influence of the aryl substituents. In addition, all the complexes also exhibit much weaker ($\varepsilon = 1700$–$2700\ M^{-1}\ cm^{-1}$) spin-allowed d–d transitions at ca. 505 nm. Significantly, the overall resemblance in the electronic absorption data for both the Bm^R and Tm^R series of compounds suggests that all the complexes have similar structures in solution (vide infra). The (dppe)Ni(L)X complexes were also characterized in the solid state using FT-IR spectroscopy and their IR spectra, obtained as KBr pellets, typically show several ν_{B-H} bands of medium and weak intensity in the approximate range 2050–2400 cm^{-1}. This situation reflects not only subtle differences in packing effects among similar compounds but also hints at the presence of both terminal and bridging B–H bonds, with the latter likely to be 3-center-2-electron Ni···H–B interactions of the type often seen in other Bm^R and, to a lesser degree, Tm^R complexes [15,22–29].

Despite all the analytical and spectroscopic data described above, the exact nature of the (dppe)Ni(L)X compounds remained uncertain. In particular, the coordination number of nickel and the overall geometry of the complexes could vary depending on the coordination mode of the specific Bm^R and Tm^R ligand (e.g., κ^3-*S*,*S*,*H* versus κ^3-*S*,*S*,*S*). In addition, the potential presence of the halides as counterions, rather than directly bound to nickel, would lead to the formation of cationic complexes. We envisioned that complete and unequivocal structural elucidation would only be derived from X-ray crystallography and therefore we set out to structurally characterize at least one representative for each of the Bm^R and Tm^R series of compounds.

2.2. Molecular structures of [(dppe)Ni(L)]Cl ($L = Bm^{Me}$, $Tm^{p\text{-Tol}}$)

Single crystals suitable for X-ray diffraction studies of [(dppe)Ni(Bm^{Me})]Cl and [(dppe)Ni($Tm^{p\text{-Tol}}$)]Cl were obtained at room temperature by slow diffusion of pentane into dichloromethane solutions of the complexes. Unexpectedly, both [(dppe)Ni(L)]Cl complexes are pentacoordinated and exhibit in the solid state molecular geometries that can be best described as distorted square pyramidal (Figs. 6 and 7), as reflected also in trigonality indexes (τ) of 0.24 and 0.21 for $L = Bm^{Me}$ and $Tm^{p\text{-Tol}}$, respectively. [1] Selected bond lengths and angles are given in Table 1. The nickel atom in [(dppe)Ni(Bm^{Me})]Cl is coordinated to the two phosphino groups of the chelating diphosphine and the two thione sulfurs of the [Bm^{Me}]$^-$ ligand, which also displays a pseudo-axial Ni···H–B interaction towards the metal center (vide infra). The structure of [(dppe)-Ni($Tm^{p\text{-Tol}}$)]Cl is analogous, except that the third mercaptoimidazolyl arm in the [$Tm^{p\text{-Tol}}$]$^-$ ligand is not

[1] The trigonality index $\tau = (\beta - \alpha)/60$, where β and α are the largest and second-largest interligand angles, has been used to estimate the degree of structural distortion from the ideal square pyramidal ($\tau = 0$) and trigonal bipyramidal ($\tau = 1$) geometries in five-coordinate complexes. See A.W. Addison, T.N. Rao, J. Reedijk, J. van Rijn, G.C. Verschoor, J. Chem. Soc., Dalton Trans. (1984) 1349.

bonded to the metal. Significantly, a search of the Cambridge Structural Database (CSD version 5.24, November 2002) [30] revealed that the [(dppe)Ni(L)]Cl complexes are the first structurally characterized five-coordinated nickel compounds having [NiP_2S_2H] cores. As such, they represent coordination environments that bear resemblance to those in certain species proposed to play a key role in the catalytic cycle of [NiFe] hydrogenases (e.g., those having [NiS_4H] cores) [31,32]. It is also worth noting that related examples of distorted square pyramidal Ni(II) complexes displaying [NiP_2S_2X] central moieties (X = Br, I) are known [33,34], as are some elegant dinuclear nickel–iron compounds containing [NiP_2S_2Cl] fragments [35,36] that have been prepared with the same goal in mind.

The Ni–S bond distances in both [(dppe)Ni(L)]Cl complexes, in the range 2.246(2) to 2.296(2) Å, are shorter than those observed in the distorted octahedral complexes Ni(Bm^{Me})$_2$ (2.362(2) and 2.390(2) Å) [15] and Ni(Tm^{Me})$_2$ (2.440(1)–2.483(1) Å) [19] a phenomenon that is likely to be a consequence of the lower coordination number in the square pyramidal derivatives. However, the average Ni–P bond length in the [(dppe)-Ni(L)]Cl complexes (2.168 Å) is virtually identical to the mean value found in the CSD for such bonds in a variety of dppe complexes of nickel (2.174 Å). The Ni···H distances in [(dppe)Ni(L)]Cl, 1.99(4) and 2.15(4) Å for L = Bm^{Me} and $Tm^{p\text{-}Tol}$, respectively, while slightly

longer than those in $Ni(Bm^{Me})_2$ (1.863(9) Å) [15], are still comparable to the values observed in the limited number of structurally authenticated nickel(II) complexes presenting Ni···H–B interactions (Table 2) [37–42]. On the other hand, the latter are all clearly longer than the Ni–H bond lengths (ca. 1.37–1.65 Å) found in bona fide terminal hydride complexes of nickel [38, 43–46].

3. Conclusions

Two series of heteroleptic nickel(II) complexes, $[(dppe)Ni(Bm^R)]X$ and $[(dppe)Ni(Tm^R)]X$ (X = Cl, Br) have been readily prepared in high yield. The successful use of the thallium(I) compounds $Tl(Bm^R)$ and $Tl(Tm^R)$ as clean poly(mercaptoimidazolyl)borate ligand transfer reagents, as opposed to their sodium counterparts, demonstrates their value and applicability under certain reaction conditions. As established by X-ray diffraction studies, the square pyramidal complexes [(dppe)Ni(L)]X exhibit virtually identical coordination environments at the metal centers, including the presence of pseudo-axial Ni···H–B interactions, and they are the first examples of structurally characterized species having $[NiP_2S_2H]$ cores. Since Tm^R ligands, unlike their Bm^R counterparts, are capable of adopting a κ^3-*S*,*S*,*S* coordination mode, it is important to note that the preferred κ^3-*S*,*S*,*H* bonding scheme observed in all of these Ni(II) complexes, independently of the bulk of the R substituents, may stem from electronic rather than steric considerations. Reactivity studies of the cationic $[(dppe)Ni(L)]^+$ complexes towards a variety of nucleophiles and a more detailed investigation of the κ^3-*S*,*S*,*H* versus κ^2-*S*,*S* or κ^3-*S*,*S*,*S* binding modes often seen in poly(mercaptoimidazolyl)borate ligands are currently under way.

4. Experimental

4.1. General considerations

All reactions were performed in the air, solvents were purified and degassed by standard procedures, and all commercially available reagents were used as received. Whereas $Ni(dppe)X_2$ (X = Cl, Br) were synthesized as reported [20], the thallium reagents $Tl(Bm^R)$ and $Tl(Tm^R)$ were prepared following a combination of literature procedures [23,47,48]. ^1H NMR spectra were obtained on General Electric QE 300 or Varian Gemini (300 MHz) FT spectrometers. Chemical shifts (δ) are reported in parts per million relative to $SiMe_4$ ($\delta = 0$ ppm) and were referenced internally with respect to the solvent resonance (δ 2.49 ppm for d_5-DMSO); coupling constants are given in hertz (Hz). IR spectra were recorded as KBr pellets on a Thermo Mattson Satellite 3000 FT-IR spectrophotometer and are reported in cm^{-1}; relative intensities of the absorptions are indicated in parentheses (vs = very strong, s = strong, m = medium, w = weak). UV-Vis spectra were obtained using a Varian Cary 300 Bio spectrophotometer. Electrospray ionization mass spectra were obtained on a PerSeptive Biosystems Mariner ESI-TOF mass spectrometer by direct infusion using dilute acetonitrile solutions and a flow rate of 10 μL/min. Magnetic susceptibility measurements on solid samples were obtained using a Johnson Matthey magnetic susceptibility balance at room temperature and standard diamagnetic correction factors were applied to the data [49]. Elemental analyses were determined by Desert Analytics (Tucson, AZ) or Atlantic Microlab, Inc. (Norcross, GA).

4.2. Synthesis of $[(dppe)Ni(Bm^{Me})]Cl$

A stirred solution of $Ni(dppe)Cl_2$ (0.178 g, 0.337 mmol) in CH_2Cl_2 (10 mL) was treated with a suspension of $Tl(Bm^{Me})$ (0.150 g, 0.338 mmol) in the same solvent (20 mL), resulting in the formation of a purple-brown solution and a white precipitate (TlCl). The suspension was stirred for 15 min and filtered. Concentration of the

filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a purple-brown solid, which was isolated by filtration and dried in vacuo for 18 h (0.178 g, 72%); m.p. = 170 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 3.16 (s, 6H, CH_3), 6.85 (br s, 4H, imidazole *H*), 7.3–8.3 (m, 20H, C_6H_5), CH_2 and H_2B not located. IR data (cm^{-1}): 2946 (w), 2401 (w), 2266 (w), 2115 (w), 1561 (m), 1551 (m), 1467 (m), 1435 (s), 1407 (w), 1384 (s), 1372 (s), 1323 (w), 1274 (m), 1202 (s), 1157 (w), 1122 (w), 1100 (s), 1027 (w), 998 (w), 815 (w), 747 (m), 715 (w), 691 (s), 530 (vs), 485 (m), 341 (m), 327 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 273 (43.5), 507 (1.8). *Anal.* Calc. for $C_{34}H_{36}BClN_4NiP_2S_2$: C, 55.8; H, 5.0; N, 7.7. Found: C, 55.4; H, 5.5; N, 6.8%.

4.3. Synthesis of [(dppe)Ni(Bm^{Me})]Br

A stirred solution of Ni(dppe)Br_2 (0.903 g, 1.461 mmol) in CH_2Cl_2 (10 mL) was treated with a suspension of Tl(Bm^{Me}) (0.649 g, 1.463 mmol) in the same solvent (20 mL), resulting in the formation of a purple solution and a white precipitate (TlBr). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a purple solid, which was isolated by filtration, washed with pentane (10 mL), and dried in vacuo for 18 h (1.126 g, 99%); m.p. = 138 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 3.16 (s, 6H, CH_3), 6.83 (s, 2H, imidazole *H*), 6.86 (s, 2H, imidazole *H*), 7.2–8.1 (m, 20H, C_6H_5), CH_2 and H_2B not located. IR data (cm^{-1}): 3050 (m), 3014 (w), 2983 (w), 2943 (w), 2400 (m), 2233 (m), 2196 (m), 2046 (w), 1584 (w), 1571 (w), 1555 (m), 1466 (s), 1435 (s), 1419 (w), 1388 (s), 1328 (w), 1306 (w), 1198 (s), 1157 (m), 1102 (s), 1011 (w), 1026 (w), 998 (w), 876 (m), 812 (m), 747 (m), 692 (s), 651 (w), 616 (w), 530 (s), 485 (m), 439 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 273 (29.4), 506 (2.0). *Anal.* Calc. for $C_{34}H_{36}BBrN_4NiP_2S_2$: C, 52.6; H, 4.7; N, 7.2. Found: C, 51.6; H, 4.8; N, 6.8%.

4.4. Synthesis of [(dppe)Ni(Bm$^{t\text{-}Bu}$)]Cl

A stirred solution of Ni(dppe)Cl_2 (0.150 g, 0.284 mmol) in CH_2Cl_2 (25 mL) was treated with a solution of Tl(Bm$^{t\text{-}Bu}$) (0.150 g, 0.284 mmol) in the same solvent (10 mL), resulting in the formation of a purple solution and a white precipitate (TlCl). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a purple solid, which was isolated by filtration and dried in vacuo for 3 h (0.214 g, 92%); m.p. = 147 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 1.37 [s, 18H, C(CH_3)$_3$], 6.97 (s, 2H, imidazole *H*), 7.00 (s, 2H, imidazole *H*), 7.2–8.0 (br s, 20H, C_6H_5), CH_2 and H_2B not located. IR data (cm^{-1}): 2973 (m), 2881 (w), 2408 (w), 2362 (m), 2343 (w), 2224 (m), 2080 (w), 1655 (w), 1561 (w), 1509 (w), 1481 (m), 1434 (m), 1402 (w), 1375 (vs), 1307 (m), 1260 (w), 1231 (w), 1194 (s), 1167 (w), 1149 (m), 1102 (s), 1068 (w), 1028 (w), 998 (w), 931 (w), 879 (w), 811 (w), 749(w), 713 (w), 692 (w), 529 (s), 485 (m), 355 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 273 (33.3), 295 (35.4), 509 (2.2). $\mu_{eff} = 3.1\ \mu_B$. *Anal.* Calc. for $C_{40}H_{48}BClN_4NiP_2S_2$: C, 58.9; H, 5.9; N, 6.9. Found: C, 58.0; H, 6.1; N, 6.6%.

4.5. Synthesis of [(dppe)Ni(Bm$^{t\text{-}Bu}$)]Br

A stirred solution of Ni(dppe)Br_2 (0.117 g, 0.189 mmol) in CH_2Cl_2 (10 mL) was treated with a solution of Tl(Bm$^{t\text{-}Bu}$) (0.100 g, 0.190 mmol) in the same solvent (20 mL), resulting in the formation of a purple solution and a white precipitate (TlBr). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a purple solid, which was isolated by filtration and dried in vacuo for 18 h (0.153 g, 94%); m.p. = 169 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 1.37 [s, 18H, C(CH_3)$_3$], 6.96 (s, 2H, imidazole *H*), 7.00 (s, 2H, imidazole *H*), 7.2–8.0 (br s, 20H, C_6H_5), CH_2 and H_2B not located. IR data (cm^{-1}): 2974 (m), 2934 (w), 2881 (w), 2408 (m), 2345 (w), 2227 (m), 2083 (w), 1561 (w), 1480 (m), 1434 (s), 1418 (w), 1402 (w), 1375 (vs), 1307 (w), 1259 (w), 1231 (w), 1194 (s), 1167 (w), 1102 (s), 1066 (w), 1029 (w), 998 (w), 878 (w), 812 (m), 748 (m), 713 (s), 691(s), 651 (w), 529 (s), 485 (m), 354 (m), 342 (m). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 272 (44.7), 509 (1.8). *Anal.* Calc. for $C_{40}H_{48}BBrN_4NiP_2S_2$: C, 55.8; H, 5.6; N, 6.5. Found: C, 54.8; H, 5.9; N, 5.9%.

4.6. Synthesis of [(dppe)Ni(Tm^{Me})]Cl

A stirred solution of Ni(dppe)Cl_2 (0.128 g, 0.242 mmol) in CH_2Cl_2 (20 mL) was treated with a suspension of Tl(Tm^{Me}) (0.135 g, 0.243 mmol) in the same solvent (50 mL), resulting in the formation of a carmine solution and a white precipitate (TlCl). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a carmine solid, which was isolated by filtration and dried in vacuo for 1 h (0.158 g, 77%); m.p. = 165 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 3.07 (br s, 9H, CH_3), 7.08 (s, 3H, imidazole *H*), 7.2–7.9 (m, 23H, imidazole *H* + C_6H_5), CH_2 and *H*B not located. IR data (cm^{-1}): 3054 (w), 3007 (w), 2981 (w), 2360 (w), 2335 (w), 2271 (w), 1559 (w), 1466 (m), 1436 (s), 1406 (w), 1387 (m), 1372 (m), 1324 (w), 1273 (w), 1204 (s), 1158 (w), 1125 (w), 1100 (s), 1025 (w), 988

(w), 875 (w), 817 (w), 803 (w), 748 (m), 715 (m), 692 (m), 668(w), 614 (w), 530 (vs), 484 (w), 473 (w), 419 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 266 (29.8), 504 (1.7). $\mu_{eff} = 3.2$ μ_B. *Anal.* Calc. for $C_{38}H_{40}BClN_6NiP_2S_3$: C, 54.1; H, 4.8; N, 10.0. Found: C, 53.3; H, 4.9; N, 9.9%.

4.7. Synthesis of [(dppe)Ni(Tm^{Me})]Br

A stirred solution of Ni(dppe)Br_2 (0.167 g, 0.270 mmol) in CH_2Cl_2 (12 mL) was treated with a suspension of Tl(Tm^{Me}) (0.150 g, 0.270 mmol) in the same solvent (10 mL), resulting in the formation of a carmine solution and a white precipitate (TlBr). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a carmine solid, which was isolated by filtration and dried in vacuo for 18 h (0.182 g, 76%); m.p. = 169 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 3.10 (br s, 9H, CH_3), 7.08 (s, 3H, imidazole *H*), 7.36 (s, 3H, imidazole *H*), 7.4–7.9 (m, 20H, C_6H_5), CH_2 and *H*B not located. IR data (cm^{-1}): 3049 (m), 3006 (w), 2367 (w), 2344 (w), 2268 (w), 1560 (w), 1466 (m), 1435 (s), 1407 (w), 1385 (s), 1323 (w), 1273 (m), 1203 (vs), 1157 (w), 1123 (w), 1100 (s), 1027 (w), 997 (w), 816 (w), 747 (m), 715 (w), 702 (w), 691 (s), 530 (vs), 485 (m). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 273 (34.3), 502 (2.4). *Anal.* Calc. for $C_{38}H_{40}BBrN_6NiP_2S_3$: C, 51.4; H, 4.5; N, 9.5. Found: C, 51.1; H, 4.5; N, 9.1%.

4.8. Synthesis of [(dppe)Ni($Tm^{t\text{-}Bu}$)]Cl

A stirred solution of Ni(dppe)Cl_2 (0.105 g, 0.199 mmol) in CH_2Cl_2 (17 mL) was treated with a solution of Tl($Tm^{t\text{-}Bu}$) (0.135 g, 0.198 mmol) in the same solvent (10 mL), resulting in the formation of a deep purple solution and a white precipitate (TlCl). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a deep purple solid, which was isolated by filtration and dried in vacuo for 18 h (0.164 g, 85%); m.p. = 134 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 1.45 [br s, 27H, C(CH_3)$_3$], 7.19 (s, 3H, imidazole *H*), 7.2–7.8 (m, 23H, imidazole $H + C_6H_5$), CH_2 and *H*B not located. IR data (cm^{-1}): 3051 (w), 2965 (m), 2926 (w), 2366 (w), 2222 (w), 1727 (w), 1570 (w), 1482 (w), 1434 (m), 1402 (m), 1363 (s), 1307 (w), 1261 (m), 1192 (m), 1165 (m), 1100 (m), 1028 (w), 998 (w), 930 (w), 879 (w), 820 (w), 794 (w), 746 (m), 714 (m), 691 (m), 617 (w), 598 (w), 562 (w), 529 (m), 483 (m), 440 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 275 (34.8), 506 (2.0). *Anal.* Calc. for $C_{47}H_{58}BClN_6NiP_2S_3$: C, 58.2; H, 6.0; N, 8.7. Found: C, 57.6; H, 6.2; N, 8.8%.

4.9. Synthesis of [(dppe)Ni($Tm^{t\text{-}Bu}$)]Br

A stirred solution of Ni(dppe)Br_2 (0.122 g, 0.197 mmol) in CH_2Cl_2 (12 mL) was treated with a solution of Tl($Tm^{t\text{-}Bu}$) (0.135 g, 0.198 mmol) in the same solvent (10 mL), resulting in the formation of a deep purple solution and a white precipitate (TlBr). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a deep purple solid, which was isolated by filtration and dried in vacuo for 18 h (0.191 g, 96%); m.p. = 154 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 1.46 [s, 27H, C(CH_3)$_3$], 7.20 (s, 3H, imidazole *H*), 7.2–7.8 (m, 23H, imidazole $H + C_6H_5$), CH_2 and *H*B not located. IR data (cm^{-1}): 3050 (w), 2974 (m), 2925 (w), 2368 (w), 2222 (w), 1570 (w), 1482 (w), 1435 (m), 1403 (w), 1364 (s), 1307 (w), 1261 (m), 1227 (w), 1190 (m), 1165 (m), 1100 (m), 1028 (w), 998 (w), 931 (w), 879 (w), 819 (w), 794 (w), 747 (w), 713 (m), 691 (m), 617 (w), 599 (w), 529 (s), 482 (m), 440 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 275 (33.6), 509 (2.0). *Anal.* Calc. for $C_{47}H_{58}BBrN_6NiP_2S_3$: C, 55.6; H, 5.8; N, 8.3. Found: C, 55.6; H, 5.4; N, 7.1%.

4.10. Synthesis of [(dppe)Ni($Tm^{p\text{-}Tol}$)]Cl

A stirred solution of Ni(dppe)Cl_2 (0.149 g, 0.282 mmol) in CH_2Cl_2 (20 mL) was treated with a suspension of Tl($Tm^{p\text{-}Tol}$) (0.222 g, 0.283 mmol) in the same solvent (15 mL), resulting in the formation of a brown-purple solution and a white precipitate (TlCl). The suspension was stirred for 15 min and filtered. Concentration of the filtrate under reduced pressure to ca. 5 mL and addition of pentane (30 mL) resulted in the separation of a deep purple solid, which was isolated by filtration and dried in vacuo for 2 h (0.241 g, 80%); m.p. = 159 °C (dec). ^{1}H NMR data (in d_6-DMSO): δ 2.35 (s, 9H, CH_3), 6.8–7.9 (m, 38H, imidazole $H + C_6H_5 + C_6H_4$Me), CH_2 and *H*B not located. IR data (cm^{-1}): 3138 (w), 3049 (w), 2919 (m), 2852 (w), 2367 (w), 2345 (w), 1610 (w), 1515 (vs), 1483 (w), 1435 (m), 1413 (m), 1348 (s), 1303 (m), 1245 (w), 1178 (s), 1101 (s), 1023 (w), 998 (w), 955 (w), 878 (w), 818 (m), 747 (m), 713 (s), 7691 (s), 615 (w), 577 (w), 564 (w), 529 (m), 484 (w). UV/Vis [MeCN, λ_{max} (nm), $\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})]: 302 (36.1), 502 (2.5). $\mu_{eff} = 3.2$ μ_B. *Anal.* Calc. for $C_{56}H_{52}BClN_6NiP_2S_3$: C, 62.7; H, 4.9; N, 7.8. Found: C, 61.5; H, 5.1; N, 7.8%.

4.11. Synthesis of [(dppe)Ni($Tm^{p\text{-}Tol}$)]Br

A stirred solution of Ni(dppe)Br_2 (0.200 g, 0.324 mmol) in CH_2Cl_2 (15 mL) was treated with a suspension of Tl($Tm^{p\text{-}Tol}$) (0.254 g, 0.324 mmol) in the same solvent (15 mL), resulting in the formation of a carmine solution and a white precipitate (TlBr). The suspension was

Table 3
Crystallographic data for [(dppe)Ni(L)]Cl

	$L = Bm^{Me}$	$L = Tm^{p\text{-Tol}}$
Formula	$C_{39}H_{48}BClN_4NiP_2S_2$	$C_{56}H_{52}BClN_6NiP_2S_3 \cdot CH_2Cl_2$

Found: C, 60.4; H, 5.0; N, 7.6%.

4.12. X-ray structure determinations

X-ray diffraction data were collected on a Bruker P4 diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å) and equipped with a SMART CCD detector. A summary of crystal data collection and refinement parameters for [(dppe)Ni(L)]Cl ($L = Bm^{Me}$, $Tm^{p\text{-Tol}}$) is given in Table 3. The structures were solved using direct methods and standard difference map techniques, and were refined by full-matrix least-squares procedures on F^2 using SHELXTL (version 6.10) [50]. Hydrogen atoms on carbon were included in calculated positions.

5. Supplementary data

Crystallographic data (excluding structure factors) for [(dppe)Ni(L)]Cl ($L = Bm^{Me}$, $Tm^{p\text{-Tol}}$) have been deposited with the Cambridge Crystallographic Data Centre with CCDC No. 212127 and 212128, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk http://www.ccdc.cam.ac.uk).

Acknowledgements

We thank the Camille and Henry Dreyfus Foundation, Inc. for a Henry Dreyfus Teacher-Scholar Award to D.R., Research Corporation for a Cottrell College Science Award, the donors of the Petroleum Research Fund, administered by the American Chemical Society, and The University of North Carolina at Charlotte for support of this research. H.M.A. is particularly grateful to the Thomas D. Walsh Tuition Fellowship for financial assistance and we also thank Professor Pat Desrochers (University of Central Arkansas) for his communication of results prior to publication.

Tris(imidazolyl) cadmium and zinc complexes: structural and spectroscopic characterization of M–OH_2 motifs

Janis K. Voo, Christopher D. Incarvito, Glenn P.A. Yap, Arnold L. Rheingold, Charles G. Riordan *

Department of Chemistry and Biochemistry, University of Delaware, Newark, DE 19716, USA

Received 12 June 2003; accepted 6 September 2003

Dedicated to Jerry Trofimenko, colleague and friend, for his contributions to tripodal coordination chemistry

Abstract

The tris(imidazolyl) cavitand ligand, 1,3,5-triethyl-2,4,6-tris[*N*-methyl-imidazol-2-yl-thiomethyl]benzene, TriMIm, is used to prepare monomeric aqua complexes of cadmium and zinc with the general formula, $[(TriMIm)M(OH_2)]X_2$ ($M = Cd$, $X = BF_4$; $M = Zn$, $X = BF_4$ or NO_3). The molecular structures of each species are characterized by trigonal pyramidal metal ion coordination and hydrogen-bonding between the bound water molecule and the non-coordinating counter ions. The binuclear zinc hydroxo-bridged complex, $[\{(TriMIm)Zn\}_2(\mu\text{-}OH)](BF_4)_3$, has been characterized by X-ray diffraction methods.

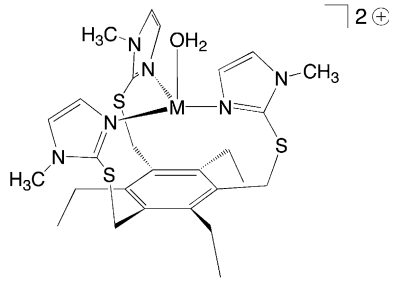
1. Introduction

The tris(pyrazolyl)hydroborato ligand, $[Tp^{R,R'}]$, developed by Jerry Trofimenko more than 35 years ago [1,2] has found great utility as a scaffold for modeling a number of important metallobiochemistry motifs [2–4]. The tripodal $[N_3]$ donor environment of the ligand mimics the nitrogen-rich ligation sphere found at the active site of numerous non-heme proteins. Leading examples include Kitajima's dicopper peroxo complex [5], $[(Tp^{2iPr})Cu]_2(O_2)$ and Parkin's and Vahenkamp's $[Tp^{R,R'}]Zn(OH)$ species [6]. The former was prepared and authenticated as a structural and spectroscopic precedent of the oxygenated form of the O_2-binding protein hemocyanin in advance of evidence of such $\mu\text{-}\eta^2\text{:}\eta^2\text{-}O_2$ coordination at the protein active site [7]. The mononuclear zinc hydroxide species provided the opportunity to assess the inherent nucleophilicity, and more recently, basicity [8] of a $[N_3]Zn(OH)$ species. Inherent in each of these examples is the utility of systematic variation of the pyrazole substituents in controlling structure and reactivity at the attendant metal complexes, clearly one of the strengths of the [Tp] ligand family.

Recently, we have prepared a new tris(imidazolyl)-based cavitand ligand and reported aspects of its coordination chemistry with copper(I) [9]. The ligand, TriMIm, [1] is preorganized to ligate a single metal ion in a trigonal planar array of imidazoles. The enforced geometry is distinct from the [Tp] ligands where more acute N–M–N angles are observed. Herein, we report the synthesis and structural characterization of cadmium- and zinc-aqua complexes, $[(TriMIm)M(OH_2)]^{2+}$.



$[(TriMIm)M(OH_2)]^{2+}$

2. Experimental

2.1. Materials

2-Mercapto-1-methylimidazole, NaH, $MgSO_4$, $Cd(BF_4)_2 \cdot 6H_2O$, $Cd(NO_3)_2 \cdot 4H_2O$, $Zn(BF_4)_2 \cdot xH_2O$, and $Zn(NO_3)_2 \cdot 6H_2O$ were used as supplied by commercial vendors. $[Cu(MeCN)_4]BF_4$ [10], and TriMIm [9] were prepared according to literature procedures. Pentanes, tetrahydrofuran, and diethyl ether were freshly distilled from sodium/benzophenone. Methylene chloride was freshly distilled from calcium hydride. Acetone was freshly distilled over $MgSO_4$. Acetonitrile (UV Grade) was purchased from Burdick and Jackson and stored over 4 Å molecular sieves and stored under N_2. Deuterated solvents were purchased from Cambridge Isotope Laboratories, dried over 4 Å molecular sieves and stored under N_2.

2.2. Physical methods

Proton and carbon NMR spectra were recorded either on a Bruker AC-250, AM-250, or DRX-400 NMR spectrometer. Chemical shifts were referenced to the residual protio solvent signal. Chemical shifts are quoted in δ (ppm) and coupling constants in Hz. Infrared spectra were recorded on a Mattson Genesis Series FT-IR spectrophotometer under dinitrogen purge at ambient temperature, unless stated otherwise. FT-IR samples were prepared as KBr pellets. Melting points were determined with a Melt-Temp melting point determination apparatus and are reported uncorrected. Elemental analyses (C, H, N) were performed by Desert Analytics, Inc., Tucson, AZ.

2.3. Synthesis of [(TriMIm)Cd(OH_2)](BF_4)$_2$ (**1**)

To a stirred solution of $Cd(BF_4)_2 \cdot 6H_2O$ (196 mg, 0.5 mmol) in distilled water, 0.5 ml, was added a solution of TriMIm (272 mg, 0.5 mmol) in acetone, 3 ml, at ambient temperature. The colorless solution was stirred overnight during which time it turned cloudy. Removal of volatiles under reduced pressure followed by extraction into acetonitrile, 1 ml, and filtration through Celite gave a colorless solution. Removal of solvent under reduced pressure yielded a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 200 mg, 48%. Mp (dec.) 296–300 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K): δ 0.9 (t, 9H, ^3J(HH) 7.5 Hz, CH_2CH_3), 1.1 (m, 3H, CH_2CH_3), 2.1 (m, 3H, CH_2CH_3), 3.7 (d, 3H, ^2J(HH) 15 Hz, SCH_2), 4.0 (s, 9H, NCH_3), 4.2 (d, 3H, ^2J(HH) 15 Hz, SCH_2), 7.1 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)C*H*CHN}), 7.6 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (100 MHz, CD_3CN, 298 K): δ 15.6, 21.9, 34.1, 36.4, 127.5, 131.0, 133.2, 141.4, 143.8. FT-IR (KBr) $\upsilon_{OH} = 3475$ and 3530 cm^{-1}. *Anal.* Calc. for $C_{27}H_{38}N_6S_3OCdB_2F_8$: C, 38.4; H, 4.53; N, 9.95. Found: C, 38.7; H, 4.36; N, 10.0%.

2.4. Synthesis of [(TriMIm)Cd($NCCH_3$)](BF_4)$_2$ (**2**)

To a stirred solution of $Cd(BF_4)_2 \cdot 6H_2O$ (374 mg, 0.95 mmol) in distilled water, 0.8 ml, was added a solution of TriMIm (515 mg, 0.95 mmol) in acetonitrile, 5 ml, at ambient temperature. The colorless solution was stirred overnight. Removal of volatiles under reduced pressure followed by extraction into acetonitrile, 10 ml, and filtration through Celite gave a colorless solution. Removal of solvent under reduced pressure yielded a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 500 mg, 61%. Mp, 252–256 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K): δ 0.9 (t, 9H, ^3J(HH) 7.5 Hz, CH_2CH_3), 1.1 (m, 3H, CH_2CH_3), 1.9 (s, 3H, $NCCH_3$), 2.1 (m, 3H, CH_2CH_3), 3.7 (d, 3H, ^2J(HH) 15 Hz, SCH_2), 4.0 (s, 9H, NCH_3), 4.2 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 7.1 (d, 3H, ^3J(HH) 2.0 Hz, {CN(Me)C*H*CHN}), 7.6 (d, 3H, ^3J(HH) 2.0 Hz, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (100 MHz, CD_3CN, 298 K): δ 15.6, 21.9, 34.1, 36.5, 127.5, 131.0, 133.2, 141.4, 143.8. FT-IR (KBr) $\upsilon_{CN} = 2286$ cm^{-1}. *Anal.* Calc. for $C_{29}H_{39}N_7S_3CdB_2F_8$: C, 40.1; H, 4.53; N, 11.3. Found: C, 40.0; H, 4.57; N, 11.4%.

2.5. Synthesis of [(TriMIm)Cd(ONO_2)](NO_3) (**3**)

To a stirred solution of $Cd(NO_3)_2 \cdot 4H_2O$ (118 mg, 0.38 mmol) in acetonitrile, 20 ml, was added a solution of TriMIm (213 mg, 0.39 mmol) in acetonitrile, 5 ml, at ambient temperature. The colorless solution was stirred overnight. Filtration through Celite and removal of volatiles under reduced pressure yielded a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 210 mg, 68%. Mp, 202–206 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K): δ 0.9 (t, 9H, ^3J(HH) 7.3 Hz, CH_2CH_3), 1.1 (m, 3H, CH_2CH_3), 2.0 (m, 3H, CH_2CH_3), 3.7 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 4.0 (s, 9H, NCH_3), 4.2 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 7.1 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)C*H*CHN}), 7.5 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (62.5 MHz, CD_3CN, 298 K): δ 15.8, 21.6, 34.2, 36.2, 126.8, 131.6, 132.6, 140.8, 142.4. *Anal.* Calc. for $C_{27}H_{36}N_8S_3O_6Cd$: C, 41.7; H, 4.67; N, 14.4. Found: C, 41.1; H, 4.73; N, 13.5%.

2.6. Synthesis of [(TriMIm)Zn(OH_2)](BF_4)$_2$ (**4**)

To a stirred solution of $Zn(BF_4)_2 \cdot xH_2O$ (133 mg, 0.56 mmol) in distilled water, 0.5 ml, was added a solution of TriMIm (300 mg, 0.56 mmol) in methylene chloride, 8 ml, at ambient temperature. The colorless

solution was stirred overnight during which time it turned cloudy gradually. Removal of volatiles under reduced pressure followed by extraction into acetonitrile, 2 ml, and filtration through Celite gave a colorless solution. Removal of solvent under reduced pressure resulted in a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 240 mg, 60%. Mp (dec.) 276–280 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K): δ 0.9 (t, 9H, ^3J(HH) 7.5 Hz, CH_2CH_3), 1.2 (m, 3H, CH_2CH_3), 2.0 (m, 3H, CH_2CH_3), 3.7 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 4.0 (s, 9H, NCH_3), 4.2 (d, 3H, ^2J(HH) 15 Hz, SCH_2), 7.1 (s, 3H, {CN(Me)C*H*CHN}), 7.5 (s, 3H, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (62.5 MHz, CD_3CN, 298 K): δ 16.0, 21.7, 34.2, 36.3, 126.9, 131.4, 131.7, 141.2, 143.4. FT-IR (KBr) $\upsilon_{OH} = 3445$ cm^{-1}. *Anal.* Calc. for $C_{27}H_{38}N_6S_3OZnB_2F_8$: C, 40.7; H, 4.80; N, 10.5. Found: C, 40.9; H, 4.87; N, 10.6%.

2.7. Synthesis of [(TriMIm)Zn(OH$_2$)](NO$_3$)$_2$ (5)

To a stirred solution of $Zn(NO_3)_2 \cdot 6H_2O$ (127 mg, 0.43 mmol) in acetonitrile, 50 ml, was added a solution of TriMIm (230 mg, 0.43 mmol) in acetonitrile, 5 ml, at ambient temperature. The colorless solution was stirred overnight. Filtration through Celite and removal of volatiles under reduced pressure yielded a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 230 mg, 72%. Mp, 206–210 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K): δ 0.9 (t, 9H, ^3J(HH) 7.5 Hz, CH_2CH_3), 1.2 (m, 3H, CH_2CH_3), 2.0 (m, 3H, CH_2CH_3), 3.7 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 4.0 (s, 9H, NCH_3), 4.2 (d, 3H, ^2J(HH) 14 Hz, SCH_2), 7.2 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)C*H*CHN}), 7.5 (d, 3H, ^3J(HH) 1.5 Hz, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (62.5 MHz, CD_3CN, 298 K): δ 16.0, 21.6, 34.3, 36.2, 126.3, 131.5, 132.0, 140.6, 143.3. FT-IR (KBr) $\upsilon_{OH} = 3398$ cm^{-1}. *Anal.* Calc. for $C_{27}H_{38}N_8S_3O_7Zn$: C, 43.3; H, 5.12; N, 15.0. Found: C, 43.8; H, 5.15; N, 14.9%.

2.8. Synthesis of [{(TriMIm)Zn}$_2$(μ-OH)](BF$_4$)$_3$ (6)

To a stirred solution of $Zn(BF_4)_2 \cdot xH_2O$ (440 mg, 1.84 mmol) in distilled water, 2 ml, was added a solution of TriMIm, (1.0 g, 1.85 mmol) in acetone, 50 ml, at ambient temperature. The colorless solution was stirred overnight during which time it turned cloudy. Removal of volatiles under reduced pressure followed by extraction into acetonitrile, 10 ml, and filtration through Celite gave a colorless solution. Removal of solvent under reduced pressure yielded a white solid, which was collected on a glass frit and washed with diethyl ether and pentanes. Yield: 830 mg, 60%. Mp (dec.) 280–284 °C. ^{1}H NMR (250 MHz, CD_3CN, 298 K) δ 0.8 (t, 18H, ^3J(HH) 7.5 Hz, CH_2CH_3), 1.1 (m, 6H, CH_2CH_3), 1.9 (m, 6H, CH_2CH_3), 3.7 (d, 6H, ^2J(HH) 14 Hz, SCH_2), 3.9 (s, 18H, NCH_3), 4.1 (d, 6H, ^2J(HH) 15 Hz, SCH_2), 6.3 (s, 6H, {CN(Me)C*H*CHN}), 7.1 (s, 6H, {CN(Me)CHC*H*N}). ^{13}C{^{1}H} NMR (62.5 MHz, CD_3CN, 298 K): δ 15.9, 21.6, 34.1, 36.0, 126.1, 126.7, 131.1, 139.8, 143.4. FT-IR (KBr) $\upsilon_{OH} = 3450$ cm^{-1}. *Anal.* Calc. for $C_{54}H_{73}N_{12}S_6OZn_2B_3F_{12}$: C, 43.5; H, 4.94; N, 11.3. Found: C, 43.9; H, 5.08; N, 11.2%.

2.9. X-ray structural solution and refinement

Suitable crystals were selected and mounted on glass fibers with epoxy cement. Data were collected on a Siemens P4 diffractometer equipped with a SMART CCD detector with graphite Mo Kα radiation (Kα $\lambda = 0.7107$ Å). The unit cell parameters and orientation matrices were determined by harvesting reflections from three orthogonal sets of 15 frames using 0.3°ω scans. The systematic absences in the diffraction data are uniquely consistent with the reported space group for the compound identified. Crystallographic analysis (direct methods) of the reduced data using the SHELXTL (version 5.1) package of programs located all non-hydrogen atoms, which were refined anisotropically using the conventional full-matrix least-squares method. Hydrogen atoms were treated as idealized contributions, except for the hydrogen atoms on O1 in **1**, which were located in the difference Fourier map. In **2**, the coordinated CH_3CN was found to be disordered over two positions. Attempts to model the disorder were not successful due to insufficient data resolution.

3. Results and discussion

3.1. Synthesis of Cd and Zn aqua complexes

Reaction of equimolar mixtures of TriMIm and a hydrated metal salt in the appropriate solvent yielded the corresponding monomeric metal aqua complex, [(TriMIm)M(OH$_2$)]X$_2$ (M = Cd, X = BF$_4$ (**1**); M = Zn, X = BF$_4$ (**4**), and M = Zn, X = NO$_3$ (**5**)), in moderate to good yields as a white, microcrystalline solid. The materials possess good solubility in acetone, acetonitrile, and methanol but, are only sparingly soluble in hydrocarbons and chlorinated solvents. Spectroscopic (^{1}H, ^{13}C NMR, FT-IR) and combustion analytical data (experimental) support the indicated compositions, which were verified by X-ray diffraction analyses.

Judicious selection of the reaction solvent is required to generate the desired complexes with differing behavior observed between Zn and Cd. TriMIm complexation reactions with Zn favor formation of the aqua complexes, **4** and **5**, even in the donor solvent acetonitrile. However, the analogous reaction in acetone yields the hydroxo-bridged dimer, **6**.

The Cd-aqua complex **1** was prepared in acetone. When the same reaction was conducted in acetonitrile, with BF_4^- as counter ion, the Cd–$NCCH_3$ adduct, **2**, was generated. However, the reaction in acetonitrile with $Cd(NO_3)_2$ as the metal source yielded the O-nitrato complex, **3**. It appears that the fates of the reactions are driven by insolubility of the products.

3.2. Molecular structures

The molecular structures of the aqua complexes **1**, **4** and **5** are depicted in Fig. 1 with crystallographic data collected in Table 1. Relevant, selected metric parameters are contained in Table 2. Each complex consists of a monomeric core, coordinated to three imidazolyl nitrogens of the TriMIm and one water molecule. The geometry at each divalent ion can be described as trigonal pyramidal with the three nitrogens defining the basal plane and the oxygen in the apical position. The imidazolyl rings are all canted in the same direction inducing an asymmetry to the structures that is maintained in solution as evidenced in the ^1H NMR spectra recorded at room temperature. That is, there are two enantiomers that differ in the handedness of the canting (clockwise versus counter clockwise). In contrast, the three coordinate Cu(I), [(TriMIm)Cu]BF_4, exhibited facile interconversion between the two diastereomers with $\Delta G^{\ddagger} = 13$ kcal/mol [9]. The sum of the three N–M–N angles is essentially 360°, thus requiring the metal and three nitrogens to be coplanar. The deviations of the individual N–M–N angles from 120° are small, less than 3.5°. The Cd–OH_2 distance of 2.340(2) Å in **1** is within the range of values reported for the limited number of four coordinate Cd aqua complexes, 2.31–2.38 Å. The distance is somewhat shorter than that of 2.41(1) Å found for [Cd(TPA)(OH_2)(NO_3)]NO_3 [11]. The two zinc aqua complexes, differing only in the identity of the counter anions, show similar molecular structures despite crystallizing in distinct space groups. Further, while the Zn–N distances are all approximately 2.00 Å, the Zn–OH_2 distances differ by 0.10, 2.130(4) Å for **4** and 2.033(1) Å for **5**. The clear difference in Zn–OH_2 distances reflect the variable degrees of hydrogen-bonding between the bound water and the anions. The nitrate ion is a better H-bond acceptor than tetrafluoroborate thus, more effectively polarizing the O–H bond and consequently, shortening the Zn–O distance.

The Zn–O distances in **4** and **5** are significantly longer than those found in two recently characterized [N_3]Zn(OH_2) complexes in which [N_3] is either [$Tp^{tBu,Me}$] [8] or the tris(imidazolyl) calix[6]arene [12,13]. The latter two complexes exhibit Zn–O distances below 2.00 Å, despite Zn–N distances of approximately 2.00 Å, similar to **4** and **5**. In contrast, the Zn–O distances reported for the (presumably) aqua forms of the enzymes carbonic anhydrase II (2.05(2) Å) [14] and adamalysin II (2.35(2) Å) [15] are similar to **4** and **5**. Further, the geometries of these complexes are best described as pseudo-tetrahedral, with more acute N–Zn–N angles.

formed between the bound water and each of the counter anions. In **1** the H-bonding interactions were established clearly by locating the hydrogen atoms in the difference Fourier maps. In **4** and **5**, the hydrogen atoms were not located, but they were inferred by the characteristically short heavy atom distances, Table 2, and supported by FT-IR spectroscopic data, detailed in the following section. In complexes **1** and **4** the distances between the aqua oxygen and one of the fluorides of the BF_4^- are similar, with each distance below 2.9 Å. For comparison, in the Cu(II) aqua complex, [Cu(pmdien)(OH_2)F]BF_4, the O–FBF_3^- distance is 2.87 Å [16]. In the nitrato complex, **5**, the two nitrates are located at the same distance from the aqua ligand as required by the imposed crystallographic symmetry. The O1---O2 distance is 2.779(2) Å. H-bonding to Zn–OH_2 units is common to the three other structurally authenticated [N_3]Zn(OH_2) species that predate this report. In the Tp supported examples of Vahrenkamp [17] and Parkin [8], novel H-bond acceptors, [$Tp^{Ar,Me}$]Zn(OH) and $(C_6F_5)_3BOH$, respectively are required, with O---O distances in the range of 2.4–2.5 Å. In contrast, Reinaud's calix[6]arene derivative [13] shows the Zn-bound aqua ligand H-bound to a second water molecule in the heart of the calix[6]arene cavity with a O---O distance of 2.539(7) Å. The exceptional stability of this Zn aqua complex has been ascribed to the unique combination of the calixarene cavity and the H-bonding to a second water molecule. Identification of complexes **4** and **5** demonstrates clearly that neither special counter ions nor novel hydrophobic ligand cavity environments are requisite to stabilize [N_3]Zn(OH_2) motifs. It is plausible the enforced trigonal pyramidal geometry in the [(TriMIm)M(OH_2)]$^{2+}$ ions modulates the Lewis acidity of the metals permitting for the isolation of aqua, as opposed to hydroxo, adducts. Deprotonation of the zinc-aqua complexes is elicited facilely by changing the reaction conditions as described later.

The aqua ligand in **1** is replaced with acetonitrile by changing the reaction solvent from acetone to acetonitrile. A thermal ellipsoid representation of [(TriMIm)Cd($NCCH_3$)](BF_4)$_2$, (**2**) is contained in Fig. 2. Selected bond lengths and angles are given in Table 2. The environment of the Cd ion is that of a trigonal pyramid, with the imidazolyl nitrogens lying in the basal plane and an acetonitrile nitrogen in the axial position. The Cd–$NCCH_3$ distance of 2.328(5) Å is within the range of distances for the limited number of crystallographically defined Cd–$NCCH_3$ derivatives. The three imidazolyl donors and the Cd constitute a trigonal plane with the sum of the three N–Cd–N angles of 359.9°. The Cu–N_{Im} average distance in **2** at 2.190(7) Å is similar to that observed in the aqua derivative **1** at 2.184(3) Å. The acetonitrile ligand is positioned on the three-fold axis as indicated in the narrow range of N(7)–Cd–N_{Im} angles, 87.5(2)°–94.2(2)°.

The nitrato complex **3** prepared by reaction of $Cd(NO_3)_2 \cdot 6H_2O$ and TriMIm in acetonitrile indicates that the nitrato ligand binds to Cd preferentially over H_2O and CH_3CN, the latter two ligands binding only

when BF_4^- is the counter ion. The structure of [(TriMIm)Cd(NO_3)](NO_3), (**3**) is depicted in Fig. 2 with selected metric parameters contained in Table 2. Of interest is the coordination mode of the nitrato group as such ligands can coordinate via unidentate, bidentate and anisobidentate modes. The Cd–O distances are 2.342(9) and 2.731 (9) Å while the Cd–O–N angles are 87.7(8)° and 107.4(8)°.

Parkin and coworkers proposed that the nature of the interaction between the bicarbonate intermediate and the metal ion influences the efficiency of carbonic anhydrase enzymes [18–23]. Accordingly, metals showing greater tendency to form bidentate bicarbonate intermediates are anticipated to be slow catalysts. As there are significant synthetic challenges in isolating mononuclear bicarbonate adducts, metal nitrates have been pursued as structural analogs due to the similar coordination modes available to nitrates and bicarbonates. The criteria established to classify the nitrato coordination mode rely on the differences in M–O interaction as defined by the differences in the two M–O distances and M–O–N angles [24]. The values determined for **3** are in accord with anisobidentate nitrato coordination. Comparison with a number of Cd(NO_3) complexes, Table 3, reveals **3** shows the greatest degree of asymmetry in nitrato binding. The trigonal planar coordination defined by the TriMIm accounts for this observation, as it is not sufficiently flexible to accommodate neither the trigonal bipyramidal nor square pyramidal geometries required for (more) symmetric nitrato coordination.

The zinc hydroxo dimer, **6**, was produced via the simple change of reaction solvent from acetone to acetonitrile. While a similar change in the synthesis of the

Fig. 2. Structures of the cations of **2**, **3** and **6**.

corresponding Cd complexes resulted in isolation of **2**, such a solvento species was not evident for Zn. Presumably, the higher polarity of the acetonitrile permits for generation of **6**. X–ray structural analysis provided unequivocal evidence for the hydroxo-bridged dimer, **6**, Fig. 2. Selected bond angles and distances are listed in Table 2. Each Zn ion lies in the basal plane defined by the three imidazolyl nitrogens, where the sums of N–Zn(1)–N′ and N–Zn(2)–N′ angles are 355.8(4)° and 355.1(3)°, respectively. Both zinc atoms are bridged by a hydroxo group with a substantially linear Zn(1)–O(1)–Zn(2) angle of 160.0(2)°. The steric demands of the TriMIm ligand require that the single atom bridge forms with the wide M–O–M angle. The bridging hydroxide is symmetric with Zn–O distances of Zn(1)–O(1), 1.95(1) Å and Zn(2)–O(1), 1.94(1) Å. The Zn–O distances support assignment of the bridging group as hydroxide. Although the hydrogen atom of the bridging unit was not located in the difference Fourier map, its presence was supported further by the identification of three BF_4^- per cation as required for charge balance and by infrared analysis, ν(OH) at 3450 cm^{-1}. Unlike the aqua complexes, the hydroxide does not appear to participate in hydrogen bonding with a BF_4^- anion as the closest O- - - F distance is 4.19(1) Å.

As the Zn-aqua complex is formed exclusively in acetone, it is likely the first species generated in acetonitrile. However, due to the higher polarity of the latter solvent, the aqua complex then ionizes to a mononuclear Zn–OH. While the identity of the base has not been established, TriMIm could serve this role. Under acidic conditions the free acid form, $[H_3TriMIm]^{3+}$, is accessible. The $[(TriMIm)Zn(OH)]^+$, reacts subsequently with a second Zn-aqua complex to generate the binuclear product. The presence of a $[N_3Zn]_2$–OH unit serves as a model compound for the hydrolytic function of hydroxo bridging zinc enzymes such as aminopeptidase and phospholipase C [25].

3.3. Spectroscopic data for metal aqua complexes

Proton and C-13 NMR spectroscopic data were consistent with the indicated formulations for **1**, **4** and **5**. However, even in aprotic solvents proton signals for the bound water were not evident. Infrared spectra of solid samples prepared as KBr pellets revealed broad features ascribed to the ν(OH) modes above 3400 cm^{-1}. Similar features were absent from the spectra of **2** and **3** further supporting the assignment. In **1** the band is split due to solid state effects with values of 3530 and 3475 cm^{-1}. The single broad ν(OH) bands for **4** and **5** occur at 3445 and 3398 cm^{-1}, respectively. The relative ordering for the Zn aqua species is consistent with stronger H-bonding between the bound water and the nitrato anion in **5**, as stronger H-bonds exhibit shifts to lower energy.

Despite the apparent acidity of the metal aqua complexes, attempts to generate the conjugate metal hydroxo species via deprotonation have failed. Addition of a range of bases including NEt_3, $LiNEt_2$, KOH, KOEt, and BuLi, resulted in either direct replacement of the aqua ligand or other, more catastrophic degradation to ill-defined species. Alternatively, efforts to generate **4** via

Carbon–hydrogen bond activation of chloroalkanes by a rhodium trispyrazolylborate complex

Andrew J. Vetter, William D. Jones *

Department of Chemistry, University of Rochester, Rochester, NY 14627, USA

Received 20 June 2003; accepted 28 August 2003

Abstract

The trispyrazolylborate complex fragment [Tp′Rh(CNneopentyl)], generated photochemically from the carbodiimide complex, reacts with chloro-substituted alkanes to give primary C–H oxidative addition products. Little reactivity is seen of the carbon–chlorine bond except when chlorine is in the β-position of the alkyl group.

Keywords: Trispyrazolylborate; C–H activation; Rhodium

1. Introduction

The activation of C–H bonds of alkanes and arenes by coordinatively unsaturated metal complexes is a well-studied area of organometallic chemistry [1]. A number of complexes shown to be successful in alkane activation are Cp or Cp* metal complexes [2–4]. More recently, however, the analogous trispyrazolylborate complexes [5] have been shown to also activate a variety of C–H bonds in aliphatic and aromatic hydrocarbons [6–11]. Despite these many investigations, there are only a few examples that look at the activation of hydrocarbons that already contain reactive functional groups ([12], for examples of C–H activation in aryl halides, see [13]), perhaps because of a belief that the functional group would prove more reactive than the C–H bond. In this report, the reactions of a number of monochloroalkanes with the reactive fragment [Tp′Rh(CNneopentyl)] are investigated.

2. Experimental

2.1. General

All operations were performed under a nitrogen atmosphere, either in a Vacuum Atmospheres Corporation Glove Box or on a high vacuum line using modified Schlenk techniques. Benzene-d_6 was purchased from the Cambridge Isotope Labs and distilled under vacuum from dark purple solutions of benzophenone ketyl and stored in ampules with Teflon-sealed vacuum line adaptors. 1-Chloropentane, 2-chloropentane, and 2-chloropropane were purchased from Aldrich Chemical Co., distilled and dried over 4A molecular sieves. 3-chloropentane was prepared according to a published procedure [14]. Preparation of Tp′Rh(L)(η^2-PhN=C=NCH$_2$C(CH$_3$)$_3$) (**1**), Tp′Rh(L)Cl$_2$ (**2**), and neopentylisocyanide (L), have been previously reported [15–17]. All NMR spectra were recorded on a Bruker AMX400 or Bruker AVANCE 400 spectrometer. Chemical shifts are reported in ppm relative to tetramethylsilane and referenced using chemical shifts of residual solvent resonances (C_6D_5H, δ 7.15).

2.2. Preparation of Tp′Rh(L)HCl (3)

5.7 mg (0.010 mmol) of Tp′Rh(CNCH$_2$C(CH$_3$)$_3$)Cl$_2$ was dissolved in 0.75 ml of C_6D_6. To this solution was added 1.7 mg (0.0076 mmol) of Cp_2ZrH_2 in increments of 3 equal amounts with stirring for 20 min in between additions. Intermediate ^{1}H NMR spectra showed the conversion of **2** into **3**. The reaction mixture was stirred an additional 30 min, after which a ^{1}H NMR spectrum showed the formation of **3**. For **3**, ^{1}H NMR

(C_6D_6): δ Rh–H: −13.40 (d, $J = 11.5$ Hz, 1H); Tp′Me: 2.074 (s, 3H), 2.120 (s, 3H), 2.207 (s, 3H), 2.286 (s, 3H), 2.862 (s, 3H), 2.869 (s, 3H); TpCH: 5.499 (s, 2H), 5.803 (s, 1H); CNR: 0.655 (s, 9H), 2.554 (s, 2H). For Tp′Rh(L)Cl_2 (**2**), ^{1}H NMR (C_6D_6): 2.033 (s, 6H), 2.106 (s, 3H), 2.735 (s, 6H), 3.241 (s, 3H), 5.491 (s, 2H), 5.522 (s, 1H), 2.688 (s, 2H), 0.793 (s, 9H).

2.3. Activation of 1-chloropentane: Tp′Rh(L)(H)($CH_2CH_2CH_2CH_2CH_2Cl$) (*4*)

A bright yellow solution of 9.7 mg of **1** in 0.75 ml of 1-chloropentane was irradiated with $\lambda > 345$ nm for 20 min at −20 °C. The solution changes to a tan color upon photolysis. The volatiles were removed under vacuum at 0 °C, leaving a brown oily solid. The resulting solid was dissolved in C_6D_6 and a ^{1}H NMR spectrum was taken immediately showing a single C–H bond activated product, **4**. ^{1}H NMR (C_6D_6): δ Rh–H: −14.92 (d, $J = 24.5$ Hz, 1H); Tp′Me: 2.197 (s, 3H), 2.211 (s, 3H), 2.295 (s, 3H), 2.374 (s, 3H), 2.544 (s, 3H), 2.566 (s, 3H); Tp′CH: 5.656 (s, 1H), 5.661 (s, 1H), 5.843 (s, 1H); CNR: 0.653 (s, 9H), 2.647 (s, 2H); CH_2Cl: δ 3.219 (t, $J = 6.8$ Hz, CH_2Cl). The remaining CH_2 resonances for the alkyl group were highly split and obscured, δ 1.0–2.3.

2.4. Activation of 3-chloropentane: Tp′Rh(L)(H)($CH_2CH_2CHClCH_2CH_3$) (*5*)

The activation of 3-chloropentane was identical to that of 1-chloropentane except that 7.1 mg of **1** was dissolved in 0.75 ml of 3-chloropentane. The ^{1}H NMR spectrum in C_6D_6 shows evidence for two products assigned as diastereomers in a 1:1 ratio. For Tp′Rh(L) (H)(CH_2CH_2-$CHClCH_2CH_3$) (**5**) (two diastereomers present), ^{1}H NMR (C_6D_6): δ Rh–H: 14.92 (d, $J = 24$ Hz, 2H); Tp′Me: 2.184 (s, 3H), 2.197 (s, 6H), 2.203 (s, 3H), 2.282 (s, 3H), 2.287 (s, 3H), 2.364 (s, 6H), 2.519 (s, 3H), 2.532 (s, 3H), 2.606 (s, 6H); Tp′CH: 5.626 (s, 1H), 5.645 (s, 1H), 5.654 (s, 2H), 5.821 (s, 1H), 5.839 (s, 1H); CNR: 0.652 (s, 9H), 0.667 (s, 9H), 2.638 (s, 2H), 2.651 (s, 2H); CH_2CH_3: 1.010 (t, $J = 7.3$ Hz, 3H), 1.017 (t, $J = 7.3$ Hz, 3H); CHCl: 3.93 (m, 1H), 4.00 (m, 1H); the remaining CH_2 resonances for the alkyl group were highly split and obscured.

2.5. Activation of 2-chloropentane: Tp′Rh(L)(H)($CH_2CH_2CH_2CHClCH_3$) (*6*) and Tp′Rh(L)HCl (*3*)

The procedure was identical to that for activation of 1-chloropentane except that 10.5 mg of **1** was dissolved in 0.75 ml of 2-chloropentane and irradiated at −20 °C. The volatiles were removed under vacuum, and examination by GC showed the presence of 1-pentene. The non-volatiles were dissolved in C_6D_6. Both Tp′Rh(L) HCl (**3**) and a CH activated product **6** were observed by ^{1}H NMR spectroscopy in a 1:2.5 ratio. The C–H activation product **6** was assigned as the terminal 4-chloropentyl derivative (two diastereomers present). For **6** (two diastereomers present), ^{1}H NMR (C_6D_6): δ Rh–H: 14.915 (d, $J = 24.8$ Hz, 1H), −14.909 (d, $J = 24.8$ Hz, 1H), Tp′Me: 2.194 (s, 3H), 2.201 (s, 3H), 2.208 (s, 6H), 2.286 (s, 3H), 2.293 (s, 3H), 2.378 (s, 6H), 2.537 (s, 3H), 2.560 (s, 3H), 2.578 (s, 3H), 2.611 (s, 3H); Tp′CH: 5.659 (s, 4H), 5.835 (s, 1H), 5.845 (s, 1H); CNR: 2.691 (s, 2H), 2.731 (s, 2H), 0.677 (s, 9H), 0.680 (s, 9H); $CHClCH_3$: 1.082 (d, $J = 6.1$ Hz, 3H), 1.031 (d, $J = 6.1$ Hz, 3H), 3.98 (m, 1H), 4.06 (m, 1H); the remaining CH_2 resonances for the alkyl group were highly split and obscured.

2.6. Activation of 2-chloropropane

The photolysis of 2-chloropropane was identical to that of 1-chloropentane except that 5.1 mg of **1** was dissolved in 0.75 ml of 2-chloropropane and irradiated at −20 °C for 20 min. Hydridochloride **3** was observed as well as the dichloride **2** in roughly a 3:1 ratio.

2.7. Activation of 1,1,1-trichloroethane

The photolysis of 1,1,1-trichloroethane was identical to that of 1-chloropentane except that 4.9 mg of **1** was dissolved in 0.75 ml of 1,1,1-trichloroethane and irradiated at −20 °C for 20 min. The only product observed was the dichloride **2**. A control experiment demonstrated that hydridochloride **3** reacts rapidly with 1,1,1-trichloroethane to give **2**.

2.8. Activation and quench of 1-chloropentane: Tp′Rh(L)(Cl)($CH_2CH_2CH_2CH_2CH_2Cl$) (*4-Cl*)

A bright yellow solution of 10 mg of **1** was dissolved in 0.75 ml of 1-chloropentane. The solution was cooled to −20 °C and photolyzed for 20 min. The resulting tan solution was quenched in vacuo with CCl_4 and kept at −20 °C for 2 h. Solvent was removed yielding a yellow-brown solid. A ^{1}H NMR spectrum shows Tp′Rh(L)(Cl)($CH_2CH_2CH_2CH_2CH_2Cl$) (**4-Cl**) and **2** in a 4:1 ratio, respectively. For **4-Cl**, ^{1}H NMR (C_6D_6): δ Tp′Me: 2.092 (s, 3H), 2.156 (s, 3H), 2.220 (s, 3H), 2.345 (s, 3H), 2.775 (s, 3H), 2.949 (s, 3H); Tp′CH: 5.574 (s, 1H,), 5.627 (s, 1H), 5.704 (s, 1H); CNR: 0.712 (s, 9H), 2.632 ('d' of AB quartet, $J = 3.8$ Hz, 2H); $RhCH_2$: 3.34 (m, 1H), 3.16 (m, 1H); CH_2Cl: 3.157 (t, $J = 6.8$ Hz, 2H), the three remaining CH_2 resonances for the alkyl group were highly split and obscured, δ 1.3–2.0.

2.9. Activation and quench of 3-chloropentane: Tp′Rh(L)(Cl)($CH_2CH_2CHClCH_2CH_3$) (*5-Cl*)

Activation and quench was identical to that of 1-chloropentane except that 9.7 mg of **1** was photolyzed in 0.75 ml of 3-chloropentane. Quenching in vacuo with

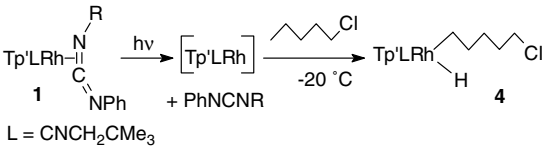
CCl_4 and removal of volatiles afforded a yellow-brown solid. A ^{1}H NMR spectrum shows two products assigned as diastereomers in a 1:1 ratio and about 20% **2**. For **5-Cl**, ^{1}H NMR (C_6D_6): δ Tp′Me: 2.057 (s, 3H), 2.080 (s, 3H), 2.152 (s, 3H), 2.165 (s, 3H), 2.206 (s, 3H), 2.210 (s, 3H), 2.442 (s, 3H), 2.493 (s, 3H), 2.770 (s, 3H), 2.775 (s, 3H), 2.879 (s, 3H), 2.954 (s, 3H); Tp′CH: 5.550 (s, 1H), 5.559 (s, 1H), 5.586 (s, 1H), 5.619 (s, 1H), 5.695 (s, 2H), CNR: 0.703 (s, 9H), 0.710 (s, 9H), 2.601 (s, 2H), 2.628 (s, 2H). CH_2CH_3: 1.063 (t, $J = 7.3$ Hz, 3H), 0.874 (t, $J = 7.5$ Hz, 3H); CHCl: 4.12 (br m, 2H); Rh–CH_2: 3.2–3.5 (br m, 4H), the remaining CH_2 resonances for the alkyl group were highly split and obscured.

2.10. Activation and quench of 2-chloropentane

The exact procedure was followed as for 1-chloropentane except that 8.0 mg of **1** was dissolved in 0.75 ml of 2-chloropentane. Removal of the solvent leaves a yellow-brown solid. ^{1}H NMR spectroscopy shows three products: Tp′Rh(L)(Cl)($CH_2CH_2CH_2CHClCH_3$) (**6-Cl**) (two isomers), and Tp′(L)Cl_2 (**2**) in a 1:1:1 ratio. For **6-Cl** (two diastereomers present), ^{1}H NMR (C_6D_6): δ Tp′Me: 2.068 (s, 3H), 2.080 (s, 3H), 2.155 (s, 3H), 2.167 (s, 3H), 2.218 (s, 6H), 2.407 (s, 3H), 2.426 (s, 3H), 2.779 (s, 3H), 2.785 (s, 3H), 2.946 (s, 3H), 2.980 (s, 3H); Tp′CH: 5.703 (s, 2H), 5.644 (s, 1H), 5.611 (s, 1H), 5.579 (s, 2H); CNR: 0.726 (s, 9H), 0.755 (s, 9H), 2.654 (s, 2H), 2.675 (s, 2H); $CHClCH_3$: 1.270 (d, $J = 6.6$ Hz, 3H), 1.248 (d, $J = 6.5$ Hz, 3H), 2.86 (m, 1H), 3.92 (m, 1H); $RhCH_2$: 3.29 (m, 2H). The remaining CH_2 resonances for the alkyl group were highly split and obscured.

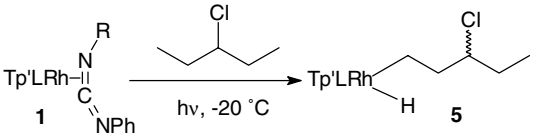
3. Results and discussion

The fragment [Tp′Rh(L)] (L = neopentyl isocyanide), generated cleanly by irradiation of the carbodiimide complex Tp′Rh(L)(PhN=C=Nneopentyl) (**1**), is known to react selectively with the terminal C–H bonds of linear alkanes [15–17]. Importantly, activation of the internal secondary C–H bonds has been demonstrated *not* to occur. In looking at the reaction of this fragment with chloroalkanes, it was expected that the reactive C–Cl bond would undergo oxidative addition to the Rh^I fragment to give Tp′Rh(L)(*n*-alkyl)Cl in light of the ubiquitous reactivity of four-coordinate d^8 Rh(I) and Ir(I) complexes with alkyl halides. It was found, however, that irradiation of **1** in neat 1-chloropentane gives a single product that displays a hydride resonance in the ^{1}H NMR spectrum at δ −14.92 (d, $J = 24.5$ Hz), indicating that a selective C–H bond activation had occurred (Eq. (1)). The presence of six Tp′ methyl and three Tp′ methine resonances was diagnostic for an asymmetric Tp′Rh(L)XY product. The observation of a triplet at δ 3.219 ($J = 6.8$ Hz) indicated the presence of a terminal CH_2CH_2Cl group, and the product was assigned as Tp′Rh(L)($CH_2CH_2CH_2CH_2CH_2Cl$)H (**4**). No evidence for activation of the C–Cl bond or other positions on the hydrocarbon was seen. The hydride product could be converted to its stable chloride derivative (**4-Cl**) by treatment with CCl_4. **4-Cl** displayed a similar set of resonances in the ^{1}H NMR spectrum. Neither **4** nor **4-Cl** could be crystallized suitably for structure determination. **4Cl** displays characteristic multiplet resonances for the α-CH_2Rh protons at δ 3.2 [18]. The alkyl hydride **4** appears to have a stability towards reductive elimination of chloropentane comparable to that of the *n*-pentyl hydride complex studied earlier ($\tau_{1/2} = 2$ h at 22 °C) [15–17].



(1)

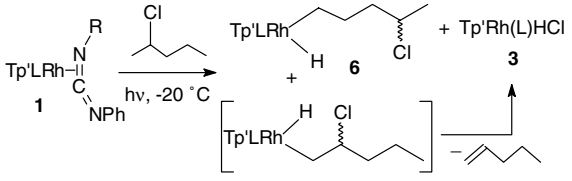
The irradiation of a solution of **1** in 3-chloropentane also leads to a C–H bond activation product, **5**. A single hydride resonance is observed just as for **4** at δ −14.92 (d, $J = 25$ Hz). However, examination of the Tp′ region of the spectrum shows evidence for *two* products. It was recognized that terminal activation of 3-chloropentane should yield two diastereomers of **5** due to the presence of chiral centers both at rhodium and at the γ-carbon of the pentyl chain (Eq. (2)). Confirmation of this possibility was obtained by the observation of two distinct triplets ($J = 7.3$ Hz) at δ 1.017 and 1.010 for the terminal methyl groups and two multiplets at δ 3.93 and 4.00 for the CHCl groups. Distinct *t*-butyl resonances for the isocyanide ligands were also observed. Once again, no activation of the C–Cl or other C–H bonds is seen. The hydride **5** could be converted to the stable chloride derivative **5-Cl**, but once again the product resisted attempts to produce X-ray quality crystals. Hydride complex **5** undergoes reductive elimination of 3-chloropentane over a period of several hours, similar to other alkyl hydrides of the type [15–17].



(2)

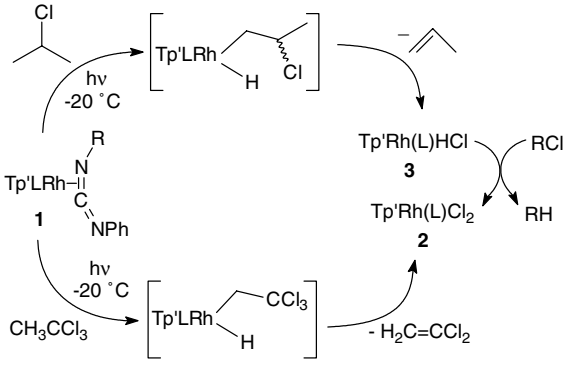
The photochemical reaction of **1** with 2-chloropentane was examined next. It was anticipated that two products would form resulting from the activation of either terminal methyl group, with each regioisomer existing as a pair of diastereomers. Upon irradiation of **1** in 2-chloropentane, two hydride resonances are seen inthe ^{1}H NMR spectrum in a 2.5:1 ratio. The minor resonance is

for the compound, Tp′Rh(L)HCl (**3**), not previously reported, but easily prepared by the titration of **2** with Cp_2ZrH_2. **3** displays a doublet at −13.40 with an unusually small Rh–H coupling constant ($J = 11.5$ Hz), along with characteristic Tp′ resonances. The second hydride belongs to a C–H bond activation product assigned as diasteriomers of $Tp'Rh(L)(CH_2CH_2CH_2CHClCH_3)H$ (**6**) (Eq. (3)). Two sets of Tp′ resonances are observed in a 1:1 ratio and two doublets are seen for the terminal methyl groups at δ 1.082 and 1.031. The CHCl methines appear as multiplets at δ 3.98 and 4.06. While no activation of the opposite end of the 2-pentylchloride is seen (position 1), it is proposed that this isomer did indeed form in the reaction, but that rapid β-chloride elimination leads to the formation of **3** and 1-pentene. 1-Pentene could be identified by GC examination of the volatiles removed from the initial solution. Treatment of **6** with CCl_4 leads to the formation of the chloro derivative, **6-Cl**. The observation of a 2.5:1 ratio of **6**:**3** therefore implies that a CH_3-CH_2-methyl group is 2.5× more reactive than a CH_3–CHCl–methyl group.



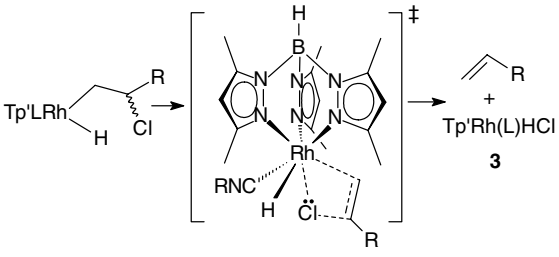
(3)

As further evidence for the occurrence of β-chloride elimination in β-chloro substituted alkyl hydrides, a solution of **1** in 2-chloropropane was irradiated. The ^1H NMR spectrum of this reaction shows the formation of **3** and **2** in a 3:1 ratio, but no C–H activation products (Eq. (4)). Propene was identified in the GC of the solution. Similarly, irradiation of a solution of **1** in 1,1,1-trichloroethane yields only **2**. In both of these reactions, the formation of **2** is believed to occur by reaction of **3** with chloroalkane, as confirmed by control experiments. In comparison, the earlier described reaction of **1** with 2-chloropentane showed formation of **3**, but not **2**, implying that **3** is less reactive with 2-chloropentane than 2-chloropropane.



(4)

One issue that remains to be addressed is the mechanism of β-chloride elimination to generate **3**. The intermediate alkyl hydride complexes in these reactions are formally d^6 octahedral Rh(III) species, which should be inert towards ligand loss. Yet β-elimination of the chloro group would be expected to require an adjacent vacant site, by analogy to the well-established need for a vacant site in β-hydride elimination from an alkyl group [19]. Either these intermediates are indeed labile (η^3-Tp′ → η^2-Tp′), which seems unlikely, or β-chloride elimination does not require an adjacent vacant site. Perhaps the presence of a pair of electrons on the chlorine permits this elimination by way of a direct attack at the metal to displace the incipient olefin that is formed, as indicated in Eq. (5). Such β-chloroalkyl compounds may indeed be inherently unstable towards elimination. A search of the literature showed *no examples* of stable rhodium compounds containing simple β-chloroalkyl ligands (for rhodium, β-chlorofluoroalkyls and β-chloroacetyls are known. For Rh and $IrCl_2(CF_2CF_2Cl)(CO)(PEt_3)_2$, see [20]; for $Rh(COCH_2Cl)Cl_2(CO)(PEt_3)_2$, see [21]; for $RhCl_2(PPh_3)_2$(COCHClMe), see [22]. For iridium, β-chloroalkyls are known. For $IrHCl(CO)(PPh_3)_2(CH_2CCl_2Ph)$, see [23]; for $Ir(PEt_2Ph)_2(CO)Cl_2(CH_2CHClMe)$, see [24]; for $[Re_7C(CO)_{21}Ir(C_8H_{14})(CO)(CH_2CH_2Cl)Cl]^{2-}$, see [25]), yet examples with α-chloroalkyl [26–28] and γ-chloroalkyl ligands were found [29,30]. Indeed the β-chloroalkyl group represents the 'missing link' in the polymerization of vinyl chloride to polyvinylchloride (PVC). Most attempts to polymerize vinylchloride via olefin insertion into a metal-alkyl have failed due to the tendency for β-chloride elimination to occur faster than insertion [31–33].



(5)

4. Conclusions

The reactive fragment [Tp′Rh(CNR)] is found to react with chlorinated alkanes to give terminal methyl group C–H activation products exclusively. If the alkane has chlorine substitution β to the methyl group, then activation is followed by rapid β-elimination to give Tp′Rh(L)HCl and the corresponding olefin. In no case is C–Cl oxidative addition observed.

Abstract

The syntheses and structures of a series of $(N,C^{2\prime}$-(2-*para*-tolylpyridine))$_2$Ir(LX) [$(tpy)_2$Ir(LX)] and $(N,C^{2\prime}$-(4′,6′-difluorophenylpyridine))$_2$Ir(LX) [$(dfppy)_2$Ir(LX)] are reported, where LX are pyrazolyl and pyrazolyl-borate ligands. Reaction of the dichloro-bridged dimer [$(tpy)_2$Ir(μ-Cl)]$_2$ with excess pyrazolyl-borate ligands forms a protonated-dipyrazolyl Ir complex, $(tpy)_2$Ir(pz_2H). The Ir bound chloride in [$(tpy)_2$Ir(μ-Cl)]$_2$ presumably facilitates the hydrolysis of pyrazolyl-borate. Thus, the syntheses of Ir complexes with bis(pyrazolyl)borates, e.g., $(tpy)_2$Ir(pz_2Bpz$_2$) and $(tpy)_2$Ir(pz_2BEt$_2$) require the chloride abstraction by CF_3SO_3Ag before pyrazolyl-borate is added to the reaction solution. $(tpy)_2$Ir(pz_2H), $(tpy)_2$Ir(pzH)$_2$(CF_3SO_3), $(tpy)_2$Ir(pz_2Bpz$_2$) and $(tpy)_2$Ir(pz_2BEt$_2$) have been structurally characterized by X-ray crystallography. The two pyrazolyl rings of $(tpy)_2$Ir(pz_2H) are nearly coplanar (dihedral angle, 12°), due to the presence of N–H···N hydrogen bond (N···N distance of 2.56 Å), while the two pyrazolyl rings of $(tpy)_2$Ir(pzH)$_2$(CF_3SO_3) are not coplanar (pz–pz dihedral angle, 47°). Unlike other η^2-pyrazolyl-borate complexes, the $(tpy)_2$Ir(pz_2BEt$_2$) exhibits a rare *quasi*-chair conformation adopted by $\overline{\text{Ir–N–N–B–N–N}}$ the ring, rather than the more common boat conformations which have been observed previously. Similarly, the $\overline{\text{Ir–N–N–B–N–N}}$ cycle of $(tpy)_2$Ir(pz_2Bpz$_2$) adopts a *half*-chair conformation, more flattened than the typical boat conformation. While the choice of pyrazolyl-borate ligand does not change the structural properties of the "$(tpy)_2$Ir" fragment, it markedly affects the photophysical properties of both $(tpy)_2$Ir(pz_2BR$_2$) and $(dfppy)_2$Ir(pz_2BR$_2$) complexes. The pyrazolyl-borate ancillary ligands affect the absorption and emission energies of these complexes by tuning the HOMO (highest occupied molecular orbital) energies. The electron-withdrawing ancillary ligands, e.g., $pz_2Bpz_2^-$, decrease the electron density on the iridium, stabilizing the metal-centered HOMOs.

1. Introduction

Since their introduction in 1967, poly(pyrazolyl)borate ligands have been widely used as auxiliary ligands in coordination, organometallic, and bioinorganic chemistry [1–4]. Due to their relative ease of synthesis, complexes with pyrazolyl-borates of almost all metals of the periodic table have been synthesized. The ligating properties of pyrazolyl-borates and substituted pyrazolyl-borates have therefore been well established and extensively explored [2–17]. The poly(pyrazolyl)borate complexes have been used to investigate a wide range of topics including catalysis for C–H bond activation [13], models for enzymatic reactions [6,17], metal extraction [2,12], and biomedical applications [6], to name but a few [2–7]. There has been little reported, however, on the use of these ligands to influence the photophysical properties of metal complexes [15].

During the last two decades cyclometalated Ir(III) complexes, because of their interesting photophysical properties, have attracted attention for a potential range of applications [8–22]. These applications include sensitizers for outer-sphere electron-transfer reactions [23,24], photocatalysts for CO_2 reduction [24,25], photooxidants and singlet oxygen sensitizers [26]. We have

recently found that the high luminescent quantum yields and comparatively short phosphorescent lifetimes of these Ir complexes make them ideal emissive dopants in organic light emitting devices (OLEDs) [27–29]. OLEDs prepared with these phosphors have the highest efficiency to date, giving internal quantum efficiencies approaching 100% [30]. Both homoleptic Ir tris cyclometalates, $(CN_2)Ir$, and heteroleptic Ir complexes, $(CN)_2Ir(LX)$, have been incorporated into highly efficient OLEDs [19,27,28,31], where CN is a general abbreviation used hereafter for a cyclometalating ligand and LX is an anionic ancillary ligand, such as β-diketonate, 2-picolinic acid and *N*-alkylsalicylimine. In this paper, we expand the list of ancillary ligands to include a series of pyrazolyl and pyrazolyl-borates, with the ultimate goal of investigating their influence on the photophysics of these cyclometalated complexes. This report provides syntheses, structures and gives a preliminary account of the photophysical properties of a series of cyclometalated Ir(III) complexes with pyrazolyl and pyrazolyl-borates ancillary ligands. Two different cyclometalating ligands were used to prepare the $(CN)_2Ir$ (pyrazolylborate) complexes, i.e., $N,C^{2\prime}$-(2′-*para*-tolylpyridyl) (abbreviated as *tpy*) and $N,C^{2\prime}$-(4′,6′-difluorophenyl-pyridyl) (abbreviated as *dfppy*) (Fig. 1). The types of products formed in reactions between pyrazolyl-borate anions and the Ir chloride precursors were found to depend strongly on the presence of chloride ligand. The X-ray structures, as well as some photophysical properties of these Ir complexes, are discussed. The η^2-pyrazolyl-borate ligands adopt conformations that differ from orientations more commonly observed for these ligands. Comparisons of selected $(tpy)_2Ir(LX)$ complexes, in their absorption spectra and room temperature emission spectra, demonstrate that the new Ir complexes with pyrazolyl ancillary ligands can have different photophysical properties, e.g., absorption energies of the lowest-energy transition and emission energies, than $(tpy)_2Ir(acac)$ having the same "$(tpy)_2Ir$" fragment. A similar trend is also observed for $(dfppy)_2Ir$ (LX) complexes.

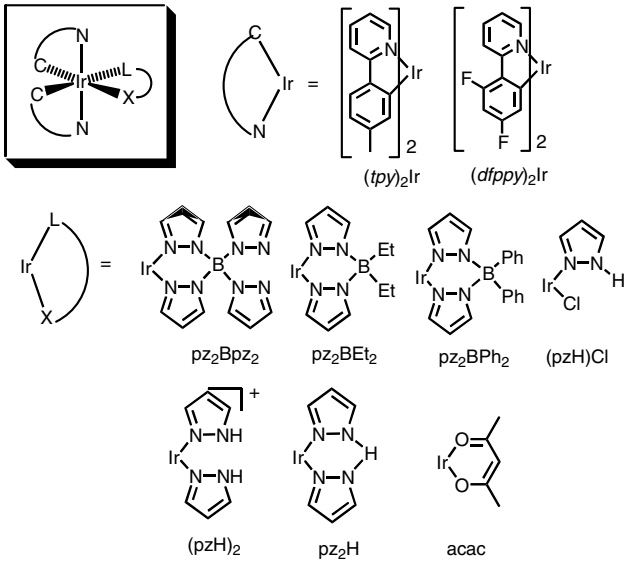

Fig. 1. Abbreviations of iridium complexes used through out the paper.

2. Experimental

2.1. Equipment

Photoluminescent spectra were measured using a Photon Technology International fluorometer. NMR spectra were recorded on Bruker AC 250 MHz, AM 360 MHz, AMX 500 MHz instruments. The Microanalysis Laboratory at the University of Illinois, Urbana-Champaign, performed all elemental analysis.

2.2. X-ray crystallography

The crystallographic data for the four structures reported here have been deposited in the Cambridge Database [$(tpy)_2Ir(pz_2BEt_2)$, CCDC #213343; $(tpy)_2Ir(pz_2H)$, CCDC #213345; $(tpy)_2Ir(pzH)_2(CF_3SO_3)$, CCDC #213346 and $(tpy)_2Ir(pz_2Bpz_2)$, CCDC #213344)]. X-ray diffraction data for $(tpy)_2Ir(pz_2BEt_2)$, $(tpy)_2Ir(pz_2H)\cdot CHCl_3$ and $(tpy)_2Ir(pzH)_2(CF_3SO_3)$ were collected at room temperature, 296(2) K on a Bruker SMART APEX CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$Å) while the data of $(tpy)_2Ir(pz_2Bpz_2)$ were collected at 273(2) K. The cell parameters for the Ir complexes were obtained from the least-squares refinement of spots (from 60 collected frames) using the SMART program. A hemisphere of the crystal data was collected up to a resolution of 0.75 Å and the intensity data was processed using the SAINT PLUS program. All calculations for the structure determination were carried out using the SHELXTL package (version 5.1) [32]. Initial atomic positions were located by Patterson methods using XS, and the structures of $(tpy)_2Ir(pz_2BEt_2)$ were refined by least-squares methods using SHELX 93 with 6983 independent reflections and within the range of $\Phi = 1.57°$ to 27.51° (completeness 95.9%). For $(tpy)_2Ir(pz_2H)$, $(tpy)_2Ir(pzH)_2(CF_3SO_3)$ and $(tpy)_2Ir(pz_2Bpz_2)$, the data are $\Phi = 1.61°$ to 24.71° (completeness 99.9%), $\Phi = 1.68°$ to 23.25° (completeness 100.0%) and $\Phi = 1.45°$ to 27.63° (completeness 91.8%), respectively. Absorption corrections were applied by using SADABS [33]. Calculated hydrogen positions were input and refined in a riding manner along with the attached carbons. A summary of the refinement details and resulting factors are given in Table 1.

2.3. Synthetic section

2′,4′-Difluorophenylpyridine was prepared by Suzuki coupling reaction with commercially available 2,4-difluorophenyl boronic acid and 2-bromopyridine [34]. The compounds sodium diethylbis(1-pyrazolyl)borate [35,36], potassium tetrakis(1-pyrazolyl)borate [1] and the cyclometalated Ir(III) μ-chloro-bridged dimers $[(tpy)_2Ir(\mu\text{-}Cl)]_2$ and $[(dfppy)_2Ir(\mu\text{-}Cl)]_2$ [37] were prepared following published procedures. Potassium diphenylbis(1-pyrazolyl)borate was purchased from STREM Chemical Co. Silver trifluoromethylsulfonate (AgOTf) and all other materials were purchased from Aldrich Chemical Co. and used without further purification.

2.3.1. Synthesis of $(tpy)_2Ir(pz_2BX_2)$ (X=pz, Et, Ph) complexes

2.3.1.1. General procedure. $[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (1.0 g, 0.89 mmol) was dissolved in 50 ml of CH_2Cl_2 and a solution of 2.1 equiv. AgOTf (0.48 g, 1.9 mmol) in 50 ml of MeOH was added to yield a cream-colored slurry. After stirring for 2 h at room temperature, the slurry was centrifuged to precipitate the AgCl. The clear decantate was evaporated to dryness to yield a yellow oily residue. The residue was dissolved in 50 ml CH_3CN and was treated with 3–4 equiv. of either $K(pz_2BX_2)$ (X = Ph, pz) or $NaBEt_2pz_2$. The solution was refluxed under N_2 for 18 h, and then cooled to room temperature. The colored precipitate was filtered, dissolved in 50 ml CH_2Cl_2 and refiltered. The filtrate was collected and evaporated to dryness to yield a crude product. The yellow $(tpy)_2Ir(pz_2Bpz_2)$ product was purified by recrystallization in $MeOH/CH_2Cl_2$ while the yellow $(tpy)_2Ir(pz_2BPh_2)$ or $(tpy)_2Ir(pz_2BEt_2)$ products were purified by chromatography on a silica/CH_2Cl_2 column.

2.3.1.2. $(tpy)_2Ir(pz_2Bpz_2)$: iridium(III) bis(2′-para-tolylpyridinato-N,C$^{2\prime}$)η^2-tetrakis(1-pyrazolyl)borate (yield 73%). ^{1}H NMR (360 MHz, CD_2Cl_2), ppm: 7.75 (d, $J = 7.9$ Hz, 2H), 7.68 (s, 2H), 7.58 (ddd, $J = 7.8$, 7.8, 1.5 Hz, 2H), 7.51 (d, $J = 7.8$ Hz, 2H), 7.28 (d, $J = 4.4$ Hz, 2H), 7.06 (d, $J = 2.4$ Hz, 2H), 6.93 (s, 2H), 6.80 (d, $J = 7.8$ Hz, 2H), 6.71 (ddd, $J = 6.3$, 6.3, 1 Hz, 2H), 6.24 (d, $J = 1.5$ Hz, 2H), 6.17 (s, 2H), 6.07 (s, 2H), 5.99 (s, 2H), 2.08 (s, 6H). *Anal.* Calc. for $(tpy)_2Ir(pz_2Bpz_2)\cdot 0.5CH_2Cl_2$: C, 51.56; H, 3.91; N, 16.47. Found: C, 51.76: H, 3.76; N, 16.16%.

2.3.1.3. $(tpy)_2Ir(pz_2BEt_2)$: iridium(III) bis(2′-para-tolylpyridinato-N,C$^{2\prime}$)diethylbis(1-pyrazolyl)borate (yield 41%). ^{1}H NMR (360 MHz, $CDCl_3$), ppm: 7.73 (d,

$J = 7.8$ Hz, 2H), 7.70 (dd, $J = 2.4$, 1.0 Hz, 2H), 7.57 (ddd, $J = 7.8$, 7.8, 1.5 Hz, 2H), 7.46 (d, $J = 7.8$ Hz, 2H), 7.06 (dd, $J = 5.8$, 1.0 Hz, 2H), 6.81 (ddd, $J = 5.8$, 5.8, 1.5 Hz, 2H), 6.72 (m, 4H), 6.03 (m, 4H), 2.07 (s, 6H) 0.51 (t, $J = 5.4$ Hz, 6H), 0.61–0.45 (m, 4H). *Anal*. Calc. for $(tpy)_2Ir(pz_2BEt_2)$: C, 55.81; H, 4.96; N, 11.49. Found: C, 55.48; H, 4.67; N, 11.34%.

2.3.1.4. $(tpy)_2Ir(pz_2BPh_2)$: iridium(III) bis(2′-para-tolylpyridinato-N,$C^{2'}$)diphenylbis(1-pyrazolyl)borate (yield 51%). ^{1}H NMR (360 MHz, CD_2Cl_2), ppm: 7.72 (d, $J = 8.2$ Hz, 2H), 7.56–7.47 (m, 4H), 7.24–7.00 (m, 10H), 6.83 (dd, $J = 1.9$, 1 Hz, 2H), 6.77 (dd, $J = 8.2$, 1.9 Hz, 2H), 6.60 (dd, $J = 8.2$, 1.5 Hz, 2H), 6.51 (m, 2H), 6.02 (dd, $J = 2.4$, 2.4 Hz, 2H), 5.99 (d, $J = 1.9$ Hz, 2H), 2.07 (s, 6H). *Anal*. Calc. for $(tpy)_2Ir(pz_2BPh_2)$ $0.5CH_2Cl_2$: C, 58.65; H, 4.29; N, 9.66. Found: C, 58.23; H, 4.29; N, 9.32%.

2.3.2. Synthesis of $(tpy)_2Ir(pzH)Cl$: (chloro)bis(2′-para-tolylpyridinato-N,$C^{2'}$)(pyrazole)iridium(III)

$[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (0.1 g, 0.09 mmol) was dissolved in 10 ml of CH_2Cl_2 and 8 equiv. pyrazole (0.05 g, 0.74 mmol) was added to yield a cream-colored slurry. After the slurry was stirred for overnight at room temperature, the colored precipitate was filtered off. The crude product was washed with 2×10 ml CH_2Cl_2, followed by ether and hexane, then dried under the vacuum to yield yellow $(tpy)_2Ir(pzH)Cl$ (0.09 g, 80%). ^{1}H NMR (360 MHz, acetone-d_6), ppm: 13.2 (s, 1H), 9.77 (d, $J = 6.5$ Hz, 1H), 8.01 (d, $J = 8.3$ Hz, 1H), 7.98 (d, $J = 8.3$ Hz, 1H), 7.94 (d, $J = 1.8$ Hz, 1H), 7.83 (m, 2H), 7.73 (d, $J = 5.5$ Hz, 1H), 7.60 (d, $J = 7.4$ Hz, 1H), 7.53 (d, $J = 8.3$ Hz, 1H), 7.25 (ddd, $J = 6.5$, 6.5, 1.8 Hz, 1H), 7.14 (ddd, $J = 6.5$, 6.5, 1.8 Hz, 1H), 6.71 (s, 1H), 6.70 (d, $J = 5.5$ Hz, 1H), 6.57 (d, $J = 8.3$ Hz, 1H), 6.30 (s, 1H), 6.15 (s, 1H), 6.01 (s, 1H), 2.84 (s, 3H), 2.80 (s, 3H). *Anal*. Calc. for $(tpy)_2Ir(pzH)Cl$: C, 51.30; H, 3.83; N, 8.86. Found: C, 50.69; H, 3.45; N, 8.51%.

2.3.3. Synthesis of $(tpy)_2Ir(pzH)_2(CF_3SO_3)$: bis(2′-para-tolylpyridinato-N,$C^{2'}$)bis(pyrazole)iridium(III) trifluoromethylsulfate

$[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (0.1 g, 0.09 mmol) and 2.1 equiv. AgOTf (0.05 g, 1.9 mmol) was dissolved in 10 ml of CH_2Cl_2 followed by 8 equiv. pyrazole (0.05 g, 0.74 mmol) to yield a cream-colored slurry. The slurry was stirred for 2 h at room temperature and the colored precipitate collected by filtration and dissolved in 30 ml acetone and refiltered. The acetone filtrate was evaporated to dryness to yield yellow $(tpy)_2Ir(pzH)_2(CF_3SO_3)$ (0.1 g, 70%). ^{1}H NMR (360 MHz, acetone-d_6), ppm: 12.26 (s, 2H), 8.84 (d, $J = 6.5$ Hz, 2H), 8.05 (d, $J = 8.0$ Hz, 2H), 7.97 (ddd, $J = 7.1$, 7.1, 1.8 Hz, 2H), 7.86 (s, 2H), 7.63 (s, 2H), 7.56 (d, $J = 8.0$ Hz, 2H), 7.38 (ddd, $J = 6.0$, 6.0, 1.8 Hz, 2H), 6.70 (d, $J = 8.0$ Hz, 2H), 6.42 (s, 2H), 6.24 (s, 2H), 2.84 (s, 6H). *Anal*. Calc. for $(tpy)_2Ir(pzH)_2CF_3SO_3$: C, 45.75; H, 3.47; N, 10.33. Found: C, 45.47; H, 3.15; N, 10.01%.

2.3.4. Synthesis of $(tpy)_2Ir(pz_2H)$: bis(2′-para-tolylpyridinato-N,$C^{2'}$)(pyrazolato)(pyrazole) iridium(III)

This complex can be prepared by four different methods.

Method A. $[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (0.2 g, 0.18 mmol) was dissolved in 25 ml of CH_2Cl_2 followed by 4 equiv. $NaBEt_2pz_2$ (0.16 g, 7.2 mmol) and the solution was stirred for overnight at room temperature. The resultant slurry was filtered and the filtrate was collected and evaporated to dryness. The crude product was washed with 3×10 ml methanol. Recrystallization in CH_2Cl_2/MeOH gave a yellow product (0.07 g, yield 30%). ^{1}H NMR (500 MHz, $CDCl_3$), ppm: 19.9 (s, 1H), 7.76 (d, $J = 5.5$ Hz, 2H), 7.72 (d, $J = 7.4$ Hz, 2H), 7.66 (d, $J = 1.8$ Hz, 2H), 7.55 (ddd, $J = 7.4$, 7.4, 1.8 Hz, 2H), 7.46 (d, $J = 7.4$ Hz, 2H), 6.83 (ddd, $J = 6.5$, 6.5, 1.8 Hz, 2H), 6.71 (d, $J = 7.4$ Hz, 2H), 6.64 (d, $J = 1.8$ Hz, 2H), 6.12 (s, 2H), 6.07 (dd, $J = 1.8$, 1.8 Hz, 2H), 2.08 (s, 6H). *Anal*. Calc. for $(tpy)_2Ir(pz_2H)$: C, 54.28; H, 4.10; N, 12.66. Found: C, 53.62; H, 3.85; N, 12.28%.

Method B. $[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (0.1 g, 0.09 mmol) was dissolved in 20 ml of CH_3CN followed by 4 equiv. $KBpz_4$ (0.14 g, 4 mmol). The solution was refluxed for 2 days under N_2 and was then evaporated to dryness under reduced pressure. The crude product was recrystallized in CH_2Cl_2/MeOH to give $(tpy)_2Ir(pz_2H)$ in 80% yield.

Method C. $(tpy)_2Ir(pzH)_2(CF_3SO_3)$ (0.2 g, 0.25 mmol) was added to 30 ml $CHCl_3$. After addition of 0.2 g MeONa, the solution was heated up to 70 °C for 2 h. The cooled solution was filtered and the filtrate was collected and evaporated to dryness. Recrystallization in CH_2Cl_2/MeOH gave $(tpy)_2Ir(pz_2H)$ (0.13 g, 80%).

Method D. $[(tpy)_2Ir(\mu\text{-}Cl)]_2$ (0.2 g, 0.18 mmol) was dissolved in 25 ml of CH_2Cl_2 followed by 4.4 equiv. pyrazole (0.05 g, 0.8 mmol) and 0.05 g MeONa. The solution was stirred for overnight at room temperature and the crude product was collected by filtration. The crude product was recrystallized in CH_2Cl_2/MeOH to give $(tpy)_2Ir(pz_2H)$ in 90% yield.

2.3.5. Synthesis of $(dfppy)_2Ir(acac)$: iridium(III) bis(4′,6′-difluorophenylpyridinato-N, $C^{2'}$) acetylacetonate

The compound was prepared according to a previously reported method [19], $[(dfppy)_2Ir(\mu\text{-}Cl)]_2$ (0.1 mmol), 0.3 mmol of 2,4-pentanedione, and 0.1 g sodium carbonate were refluxed under N_2 atmosphere in 1,2-dichloroethane for 12 h. After cooling to room temperature, the reaction mixture was evaporated to dryness. The pure yellow product (yield 80%) was obtained by chromatography in a silica/CH_2Cl_2 column.

^{1}H NMR (500 MHz, $CDCl_3$), ppm: 8.42 (d, $J = 5.6$ Hz, 2H), 8.23 (d, $J = 8.4$ Hz, 2H), 7.78 (ddd, $J = 7.4$, 7.4 Hz, 1.4 Hz, 2H), 7.17 (ddd, $J = 6.5$, 6.5, 1.4 Hz, 2H), 6.31 (ddd, $J = 8.4$, 8.4, 2.4 Hz, 2H), 5.63 (dd, $J = 3.7$, 2.4 Hz, 2H), 5.23 (s, 1H), 1.79 (s, 6H). *Anal.* Calc. for (*dfppy*)$_2$Ir(acac): C, 48.28; H, 2.85; N, 4.17. Found: C, 48.20; H, 2.61; N, 3.90%.

2.3.6. Synthesis of (dfppy)$_2$Ir(pz$_2$H): bis(4′,6′-difluorophenylpyridinato-N,C$^{2'}$)(pyrazolato)(pyrazole)iridium(III)

This yellow compound was prepared analogous to the synthesis of (*tpy*)$_2$Ir(pz$_2$H) (method D), and was obtained after recrystallization from MeOH/CH_2Cl_2 in 70% yield. ^{1}H NMR (360 MHz, $CDCl_3$), ppm: 20.01 (s, 1H), 8.19 (d, $J = 8.3$ Hz, 2H), 7.76 (dd, $J = 5.8$, 1.0 Hz, 2H), 7.68 (d, $J = 1.9$ Hz, 2H), 7.65 (dd, $J = 8.3$, 8.3Hz, 2H), 6.92 (vt, $J = 6.3$ Hz, 2H), 6.67 (d, $J = 1.9$ Hz, 2H), 6.41 (m, 2H), 6.12 (dd, $J = 1.9$, 1.9 Hz, 2H), 5.71 (dd, $J = 8.3$, 2.4 Hz, 2H). *Anal.* Calc. for (*dfppy*)$_2$Ir(pz$_2$H): C, 47.52; H, 2.71; N, 11.88. Found: C, 47.40; H, 2.49; N, 11.54%.

2.3.7. Synthesis of (dfppy)$_2$Ir(pz$_2$Bpz$_2$): iridium(III) bis(4′,6′-difluorophenylpyridinato-N,C$^{2'}$)η^2-tetrakis(1-pyrazolyl)borate

This yellow-greenish compound was prepared analogous to the synthesis of (*tpy*)$_2$Ir(pz$_2$Bpz$_2$), and was obtained after recrystallization from MeOH/CH_2Cl_2 in 60% yield. ^{1}H NMR (360 MHz, $CDCl_3$), ppm: 8.15 (d, $J = 8.3$ Hz, 2H), 7.72 (s, 2H), 7.60 (vt, $J = 7.8$ Hz, 2H), 7.28 (s, 2H), 7.13 (d, $J = 2.4$ Hz, 2H), 6.92 (d, $J = 1.5$ Hz, 2H), 6.74 (d, $J = 6.3$ Hz, 2H), 6.44 (m, 2H), 6.23 (vt, $J = 2.4$ Hz, 2H), 6.18 (s, 2H), 6.03 (s, 2H), 5.55 (dd, $J = 8.8$, 2.4 Hz, 2H). *Anal.* Calc. for (*dfppy*)$_2$Ir(pz$_2$Bpz$_2$): C, 47.95; H, 2.84; N, 16.45. Found: C, 47.65; H, 2.40; N, 16.05%.

3. Results and discussion

3.1. Synthesis and structure

Cyclometalated chloride-bridged Ir(III) dimers, [(CN)$_2$Ir(μ-Cl)]$_2$, can be readily converted to emissive, monomeric complexes by treating the dimer with acetylacetone and base [Eq. (1)] [19]. However, the related reaction, treating [(*tpy*)$_2$Ir(μ-Cl)]$_2$ with an excess of $Na^+pz_2BEt_2^-$, does not lead to the desired product, i.e. (*tpy*)$_2$Ir(pz$_2$BEt$_2$), but rather a protonated dipyrazolyl complex, (*tpy*)$_2$Ir(pz$_2$H), is formed in good yield (30%, Eq. (2)). This unexpected reaction product was characterized by a proton NMR spectrum that displays a sharp low-field singlet ($\delta = 19.9$ ppm) that is consistent with the presence of a strong N–H···N hydrogen bond. This chemical shift for the bridging proton is similar to those observed for iridium [38], osmium [39] and rhodium complexes [40], having the "pz$_2$H" ligand. In addition to spectroscopic and analytical characterization, the identity of (*tpy*)$_2$Ir(pz$_2$H) was confirmed by an X-ray crystal structure analysis, vide infra. A similar transformation was observed when [(*tpy*)$_2$Ir(μ-Cl)]$_2$ was treated with an excess of KBpz$_4$ in acetonitrile [Eq. (3)], giving (*tpy*)$_2$Ir(pz$_2$H) in high yield (80%). While we have not carried out a complete survey of pyrazolyl-borate ligands and solvents, it appears that the decomposition of the pyrazole borate ligand, and reaction to give (*tpy*)$_2$Ir(pz$_2$H), is not related to a solvent specific process

$$[(tpy)_2\mathrm{Ir}(\mu\text{-Cl})]_2 + \text{excess acacH} \xrightarrow[C_2H_4Cl_2,\text{reflux}]{Na_2CO_3} (tpy)_2\mathrm{Ir}(\text{acac}) \quad (1)$$

$$[(tpy)_2\mathrm{Ir}(\mu\text{-Cl})]_2 + \text{excess } Napz_2BEt_2 \xrightarrow[CH_2Cl_2,\mathrm{RT}]{} (tpy)_2\mathrm{Ir}(pz_2H) \quad (2)$$

$$[(tpy)_2\mathrm{Ir}(\mu\text{-Cl})]_2 + \text{excess } KBpz_4 \xrightarrow[CH_3CN,\text{reflux}]{} (tpy)_2\mathrm{Ir}(pz_2H) \quad (3)$$

Once the identity of (*tpy*)$_2$Ir(pz$_2$H) was established, efforts were made to prepare the complex by direct reaction between [(*tpy*)$_2$Ir(μ-Cl)]$_2$ and pyrazole. However, when [(*tpy*)$_2$Ir(μ-Cl)]$_2$ is treated with excess pyrazole in CH_2Cl_2 solution, the only observable product is (*tpy*)$_2$Ir(pzH)Cl. The proton NMR spectrum of (*tpy*)$_2$Ir(pzH)Cl shows a sharp low-field singlet ($\delta = 13.2$ ppm), suggesting the presence of a strong hydrogen bond (N–H···Cl) which stabilizes the complex against further substitution. A [OsCl(pzH)(H)(≡CCH$_2$Ph) (P^{i}Pr$_3$)$_2$]BF$_4$ complex was found to have a similar hydrogen bond between the pzH and Cl ligands and displays a similar proton resonance for the pyrazole bound proton ($\delta = 12.4$ ppm) [39]. Although pyrazole does not displace the bound chloride, addition of CF_3SO_3Ag to the reaction mixture abstracts the Ir bound chloride and leads to the formation of (*tpy*)$_2$Ir(pzH)$_2$(CF_3SO_3). Subsequent treatment of this dipyrazole cation with sodium methoxide yields the desired (*tpy*)$_2$Ir(pz$_2$H). Alternately, (*tpy*)$_2$Ir(pz$_2$H) can be prepared directly by reacting the dimer, [(*tpy*)$_2$Ir(μ-Cl)]$_2$, with excess pyrazole and NaOMe, without the need for the silver salt [Eq. (4)]. A similar synthetic method was reported for the synthesis of [Os(pz$_2$H)(H)(=C=CHPh) (P^{i}Pr$_3$)$_2$ [39]

$$[(tpy)_2\mathrm{Ir}(\mu\text{-Cl})]_2 + \text{excess pzH} \xrightarrow[CH_2Cl_2,\mathrm{RT}]{NaOMe} (tpy)_2\mathrm{Ir}(pz_2H) \quad (4)$$

It was initially suspected that the mere presence of chloride ion was responsible for the decomposition of pyrazolyl-borate, giving the protonated-dipyrazolyl ligand. Experiments showed that Na(pz$_2$BEt$_2$) partially

decomposes when heated with excess NMe_4Cl in either CD_2Cl_2 or CD_3CN. However, the rate of this decomposition reaction is markedly lower than the rate of $(tpy)_2Ir(pz_2H)$ formation [Eq. (2)]. Moreover, although we see chloride-mediated decomposition of the pyrazolyl-borate ligands, this is not commonly observed reaction. A wide range of metal complexes with poly (pyrazolyl)borate ligands have been prepared through the direct reaction between a metal chloride and the pyrazolyl-borate ligand [2,12,15,35]. For example, metal chlorides of first-row of transition metals react with $KBpz_4$ in aqueous solution, efficiently forming metal pyrazolyl-borate complexes [1,2,12]. For these complexes, however, the halide ligands are rapidly lost by solvolysis, leading to a metal-solvento complex, analogous to $(tpy)_2Ir(H_2O)_2^+$, which react cleanly, without pyrazolyl-borate decomposition. In light of that fact, we postulate that the presence of an Ir bound chloride ligand promotes the decomposition of the pyrazolyl-borate. Based on the previous reports that the ligating solvents, i.e., acetonitrile and DMF, do not dissociate the chloride from the Ir complex [18,24], it is plausible that the Ir dimer reacts with $pz_2BEt_2^-$ via a $(tpy)_2IrCl[\eta^1\text{-}pzB(pz)Et_2]^-$ intermediate, in a manner analogous to the formation of $(tpy)_2Ir(pzH)Cl$. Intramolecular attack of chloride at the pyrazolyl-borate ligand could then lead to cleavage of the pz-B bond.

It was found possible to prepare the desired pyrazolyl-borate complexes in good yields provided that the complex is chloride-free prior to the addition of the pyrazolyl-borate ligand. The removal of chloride can be accomplished by treating the dimer with CF_3SO_3Ag to first produce $(tpy)_2Ir(H_2O)_2(CF_3SO_3)$ [24]. This chloride-free Ir complex reacts with $K(pz_2BX_2)$ (X = pz, Ph) or $Na(pz_2BEt_2)$ in acetonitrile solution, forming the corresponding $(tpy)_2Ir(pz_2BX_2)$ complexes with yields of 40% to 70%

$$[(tpy)_2Ir(\mu\text{-}Cl)]_2 \xrightarrow[CH_2Cl_2/MeOH]{AgOTf} (tpy)_2Ir(H_2O)_2(CF_3SO_3) \xrightarrow[CH_3CN,\ reflux]{excess\ KBpz_4} (tpy)_2Ir(pz_2Bpz_2) \quad (5)$$

The same synthetic method can be applied to other cyclometalated complexes. For example, $(dfppy)_2Ir(pz_2H)$ and $(dfppy)_2Ir(pz_2Bpz_2)$ are prepared in a similar manner as given in Eqs. (4) and (5), respectively, in high yield.

3.2. Crystal structures

Single crystals of $(tpy)_2Ir(pz_2H)$, $(tpy)_2Ir(pz_2Bpz_2)$ and $(tpy)_2Ir(pz_2BEt_2)$ were prepared by slow evaporation of chloroform, while single crystals of a fourth compound, $(tpy)_2Ir(pzH)_2(CF_3SO_3)$, were prepared via slow evaporation of acetone. Molecular plots of $(tpy)_2Ir(pz_2H)$, $(tpy)_2Ir(pzH)_2(CF_3SO_3)$, $(tpy)_2Ir(pz_2Bpz_2)$ and $(tpy)_2Ir(pz_2BEt_2)$ are shown in Figs. 2 and 3. Crystallographic data are given in Table 1. Selected bond lengths for six Ir complexes with the same "tpy_2Ir" fragment, including *mer*–$Ir(tpy)_3$ [42] and $(tpy)_2Ir(acac)$ [19], are reported in Table 2. All of these complexes have an octahedral coordination geometry around Ir, retaining the *cis*-C,C *trans*-N,N chelate disposition of the chloride-bridged precursor complex, $[(tpy)_2Ir(\mu\text{-}Cl)]_2$. For the two *trans*-N,N atoms, the N–Ir–N angles in these complexes are between 172° and 175°. The Ir–C and Ir–N bond lengths among these $(tpy)_2Ir(LX)$ (LX = pyrazolyl and pyrazolyl-borate ligands) complexes are not significantly different from those reported for the "$(tpy)_2Ir$" fragment of $(tpy)_2Ir(acac)$.

In the structure of $(tpy)_2Ir(pz_2H)$, the two pyrazolyl rings are nearly coplanar, with a dihedral angle between the two pyrazolyl rings of 15°. Although we were unable to refine the position of bridging hydrogen atom of N–

H···N by X-ray crystallography, the existence of the bridging hydrogen atom could be inferred from the short $N_4\cdots N_6$ distance of 2.56 Å, consistent with a strong hydrogen bonding interaction [43]. The $Os(pz_2H)(H)(=C=CHPh)(P^iPr_3)_2$ [39], and $Rh((3,5\text{-}Me_2\text{-}4\text{-}NO_2\text{-}pz)_2H)(PPh_3)_2(H)_2$ [40] complexes have similar coordination geometries for the pz_2H ligand, with pz–pz dihedral angles of 4° and 12°, and N···N distances of 2.58 Å and 2.55 Å, respectively. In contrast to $(tpy)_2Ir(pz_2H)$, the two pyrazolyl rings of $(tpy)_2Ir(pzH)_2(CF_3SO_3)$ (Fig. 2(b)) are far from coplanar, with a 47° dihedral angle between the two pyrazoles. The two protonated nitrogen atoms of the pyrazolyl rings (N_4 and N_6) adopt an anti conformation.

The crystal structure of $(tpy)_2Ir(pz_2BEt_2)$ is presented in Fig. 3(a). The two pyrazolyl rings of this complex are nearly coplanar, with a dihedral angle (11°) similar to that found for the pyrazolyl ligands of $(tpy)_2Ir(pz_2H)$. The Ir–N–N–B–N–N ring of $(tpy)_2Ir(pz_2BEt_2)$ exhibits a *quasi*-chair conformation. The iridium atom lies 0.12(2) Å above the plane formed by the four pyrazolyl N atoms, while the boron atom is 0.43(2) Å below the same plane.

The *quasi*-chair conformation adopted by the Ir–N–N–B–N–N ring of $(tpy)_2Ir(pz_2BEt_2)$ is not common for metal complexes of diethyl-bis(pyrazolyl)borate. All of the other crystallographically characterized pz_2BEt_2 metal complexes show boat like conformations of the M–N–N–B–N–N ring, where M is a metal atom [44–47]. In some cases the boat conformation has been cited as evidence for a possible agostic interaction between the metal ion and the methylene proton from the pz_2BEt_2 ligand nearby [44]. However, boat conformations have also been observed for complexes where agostic interactions are not likely [45–47]. The other reported metal complexes of $pz_2BEt_2^-$ also show more marked deviations from the N_4 plane than those observed for $(tpy)_2Ir(pz_2BEt_2)$, i.e., boron atoms of the reported complexes lie 0.67–0.76 Å above the four nitrogen plane and the metal atoms range from 0.58 to 1.11 Å above the same plane. The complexes in which the metal shows the largest deviation from the N_4 plane (0.97 and 1.11 Å) have strong agostic interactions, stabilizing the boat conformation [45]. The two pyrazolyl rings of the agostic $pz_2BEt_2^-$ complexes have dihedral angles >70°, whereas the two pyrazolyl rings of $(tpy)_2Ir(pz_2BEt_2)$ are nearly coplanar. The relatively high dihedral angle for the agostic interactions is necessary to maximize the metal–pyrazolyl bonding interaction in the boat conformer. It therefore appears that the steric constraints of octahedral coordination sphere around the Ir atom, along with the absence of any agostic interaction to stabilize the boat conformation, leads to the rare *quasi*-chair conformation in $(tpy)_2Ir(pz_2BEt_2)$, with nearly coplanar pyrazolyl rings.

Fig. 3(b) shows the crystal structure of $(tpy)_2Ir(pz_2Bpz_2)$. Similar to $(tpy)_2Ir(pz_2BEt_2)$, the dihedral angle between the two coordinated pyrazolyl rings is relatively small, 17°. The Ir–N–N–B–N–N ring of $(tpy)_2Ir(pz_2Bpz_2)$ is in a *half*-chair conformation, where the iridium atom is in the least square plane of four

nitrogen atoms (Ir is 0.04(3) Å below the plane), while the boron atom lies 0.48(3) Å above the same plane. As expected, the two non-coordinated pyrazolyl rings of the η^2-pz_2Bpz_2 ligand are not coplanar, having a dihedral angle of 81°. The *half*-chair conformation is also more flattened than the typical boat conformation of the M–N–N–B–N–N ring [2]. The heights of boron atoms above the four nitrogen planes of η^2-pz_2Bpz_2 complexes fall within a fairly narrow range, i.e., in a range 0.56–0.67(6) Å, greater than is observed for $(tpy)_2Ir(pz_2Bpz_2)$ [17,48–51].

3.3. Photophysical properties

Fig. 4 shows absorption spectra of three different $(tpy)_2Ir(LX)$ complexes, i.e. $(tpy)_2Ir(pz_2Bpz_2)$, $(tpy)_2Ir(pz_2H)$ and $(tpy)_2Ir(acac)$, and the room temperature emission spectra of $(tpy)_2Ir(pz_2Bpz_2)$, $(tpy)_2Ir(pz_2H)$, $(tpy)_2Ir(pzH)Cl$, and $(tpy)_2Ir(acac)$ are shown in Fig. 5. Although all of them have the same "$(tpy)_2Ir$" fragment, there is a clear blue shift in the lowest energy absorption band as well as the maximum emission wavelength (λ_{max}), as the ancillary ligand is changed. Figs. 4 and 5 demonstrate that different ancillary ligands clearly influence the photophysical properties of $(tpy)_2Ir(LX)$ complexes. For example, $(tpy)_2Ir(pz_2Bpz_2)$ has the highest emission energy among all of $(tpy)_2Ir(LX)$ complexes, and its absorption band, ascribed to an MLCT transition [19], is the highest in energy among all of $(tpy)_2Ir(LX)$ complexes. Previous investigations have shown that the HOMOs (highest occupied molecular orbitals) of these Ir complexes are largely metal-centered, while the LUMOs (lowest unoccupied molecular orbitals), are primarily localized on the pyridyl rings of the cyclometalating ligands [52–54], thus the ancillary ligand is not directly involved in the lowest energy excited state. However, the ancillary ligand can alter the excited state energy by modifying the electron density at the metal center. A net electron-withdrawing ancillary ligand will pull electron density away from the iridium atom, thereby stabilizing the metal orbitals and lowering the HOMO energy, whereas the LUMO of the $(tpy)_2Ir(LX)$ complexes, localized on the pyridyl rings, is expected to be largely unaffected in energy. Consequently, the HOMO-LUMO gap should increase for stronger electron-withdrawing ancillary ligands, leading to a blue shift in both absorption and emission. [1] Substituting fluorine in the 4′, 6′-positions of the phenyl-

[1] Electrochemical studies of $(tpy)_2Ir(LX)$ complexes showed that the reduction potentials of $(tpy)_2Ir(LX)$ are largely unaffected, i.e., the reduction potentials of $(tpy)_2Ir(LX)$ stay in a narrow range between −2.62 and −2.68 V, while the oxidation potentials vary by as much as 400 mV between two different LX ligands, i.e., the oxidation potential of $(tpy)_2Ir(pz_2Bpz_2)$ is 310 mV higher than that of $(tpy)_2Ir(acac)$. The electrochemical properties of $(tpy)_2Ir(LX)$ complexes will be discussed in detail in a subsequent publication.

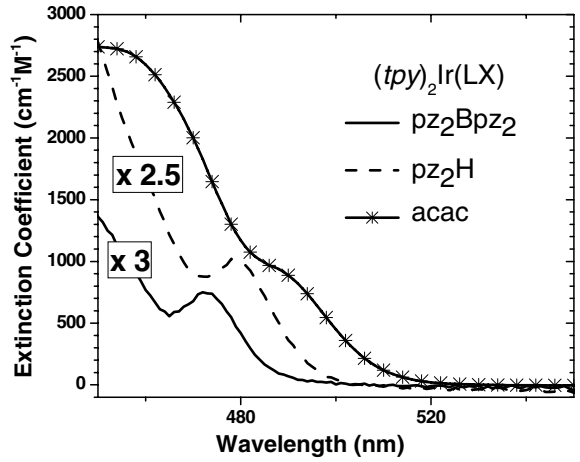

Fig. 4. Absorption spectra of $(tpy)_2Ir(pz_2Bpz_2)$, $(tpy)_2Ir(pz_2H)$ and $(tpy)_2Ir(acac)$ complexes in CH_2Cl_2.

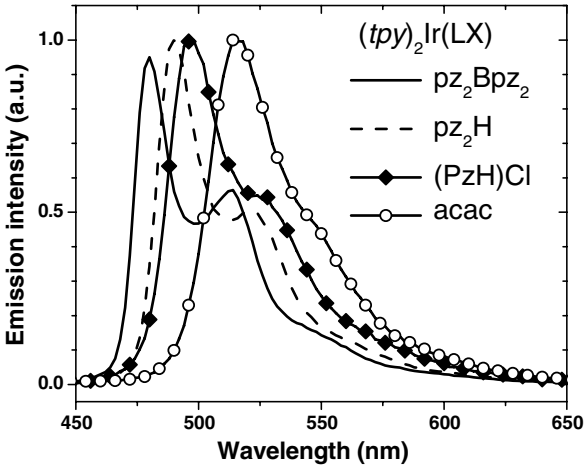

Fig. 5. Room temperature emission spectra of $(tpy)_2Ir(pz_2Bpz_2)$, $(tpy)_2Ir(pz_2H)$, $(tpy)_2Ir(pzH)Cl$, and $(tpy)_2Ir(acac)$ complexes in 2-MeTHF.

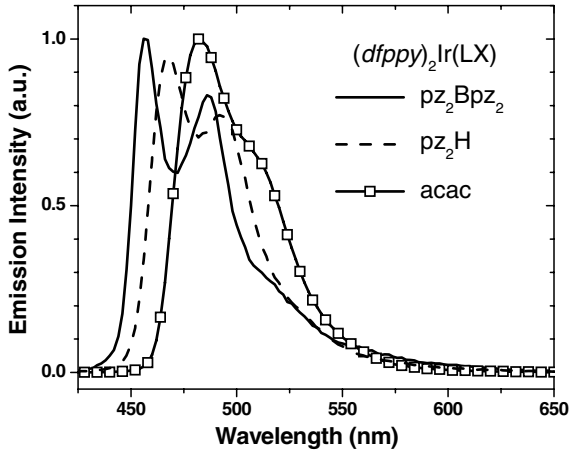

Fig. 6. Room temperature emission spectra of $(dfppy)_2Ir(pz_2Bpz_2)$, $(dfppy)_2Ir(pz_2H)$, and $(dfppy)_2Ir(acac)$ complexes in 2-MeTHF.

pyridyl ligand leads to a further blue shift in the emission energy, as expected from the luminescent properties of related tris-cyclometalated complexes [22,42,54]. The room temperature emission spectra of $(dfppy)_2$Ir(pz_2Bpz_2), $(dfppy)_2$Ir(pz_2H), and $(dfppy)_2$Ir (acac) are shown in Fig. 6. As observed for the *tpy* complexes, the $pz_2Bpz_2^-$ ligand blue shifts the emission spectra of $(dfppy)_2$Ir(LX) complexes relative to the other pyrazolyl ligands.

4. Conclusion

We have reported the synthesis and characterization of a family of organometallic Ir pyrazolyl and pyrazolylborate complexes. The pyrazolyl-borate complexes were prepared from dimer of chloride-bridged complexes [i.e., $((tpy)_2Ir(\mu\text{-}Cl))_2$] by first extracting the chloride ion with Ag^+ followed by treatment with the desired pyrazolylborate ligand, to give $(tpy)_2Ir(pz_2BR_2)$, R = Et, Ph, pz. The same synthesis can be applied to other cyclometalated complexes, e.g., $(dfppy)_2$Ir(LX). If the chloride is not removed by silver ion prior to treatment with the pyrazolyl-borate ligand, extensive ligand decomposition is observed. Crystallographic studies showed that the organometallic fragments of these complexes are not significantly affected by the choice of pyrazolyl ancillary ligands. Unlike other reported η^2-pyrazolyl-borate complexes, the $(tpy)_2Ir(pz_2BR_2)$ complexes show rare *half*-chair or *quasi*-chair conformations for the Ir–N–N–B–N–N ring, rather than the most common boat conformations that have been observed previously. While the choice of pyrazolyl-borate ligand does not change the structural properties of the "$(tpy)_2$Ir" fragment, it does markedly affect the photophysical properties of both $(tpy)_2Ir(pz_2BR_2)$ and $(dfppy)_2$Ir (pz_2BR_2) complexes. The pyrazolyl-borate ancillary ligands affect the absorption and emission energies of these complexes by tuning the metal (HOMO) orbital energies.

Many of the Ir complexes reported here are highly emissive at room temperature. For example, $(dfppy)_2$Ir (pz_2Bpz_2) is very useful as emissive dopant in blue phosphorescent OLEDs. Devices have been fabricated with $(dfppy)_2Ir(pz_2Bpz_2)$ doped films which have external efficiencies of >8%, and spectra that closely match the emission spectrum shown in Fig. 6 [55]. The tetrakis(pyrazolyl)borate ligand also offers the possibility of expanded coordination. The non-coordinated pyrazoles of $(tpy)_2Ir(pz_2Bpz_2)$ can be used to bind a second metal center [15,41]. Related dinuclear organometallic complexes have been reported for Pd and Ru complexes, but not, thus far, for photoactive metal fragments such as the Ir complexes reported here. The ability to make homo-metallic and hetero-metallic complexes of this type may lead to further applications of cyclometalated Ir complexes, such as photosensitizers [56] and donor–acceptor dyads [57].

5. Supporting information available

Tables of crystal data, atomic coordinates, bond distances, bond angles, and anisotropic displacement parameters for $(tpy)_2Ir(pz_2H)$, $(tpy)_2$ $Ir(pzH)_2(CF_3SO_3)$, $(tpy)_2Ir(pz_2BEt_2)$, and $(tpy)_2Ir(pz_2Bpz_2)$, as well as the corresponding CIF files are available on request from the authors.

Received 25 June 2003; accepted 8 October 2003

Abstract

The electronic structures of the potassium salts of the homoscorpionates hydrotris(3,5-dimethylpyrazol-1-yl)borate (Tp*, **1**), hydrotris(4-chloro-3,5-dimethylpyrazol-1-yl)borate (Tp^{*Cl}, **2**) and hydrotris(3,5-bis(trifluoromethyl)pyrazol-1-yl)borate ($Tp^{(CF_3)_2}$, **3**) are compared using gas-phase photoelectron spectroscopy and density functional theory (DFT). DFT calculations also are reported for the generic scorpionate potassium (hydrotris(pyrazol-1-yl)borate) (KTp). This is the first such experimental probe of the electronic structure of halogen containing scorpionate ligands and subtle differences in the ionizations from the frontier orbitals in the photoelectron spectra of **1** and **3** are observed that give insight into the influence of substituents upon metal–scorpionate bonding. Distinct assignments of the ionizations from the nitrogen σ-donor orbitals (σ_N) and σ_{BH} molecular orbitals are possible experimentally by the use of variable (He I and He II) excitation energies. The experimentally observed first ionization energy of **3** is stabilized by ~2.0 eV relative to **1** due to the strong electron withdrawing effect of the trifluoromethyl groups. The photoelectron spectroscopic studies of $NaTp^{(CF_3)_2}$ further confirm the assignments of ionizations from σ_N orbitals for **3** associated with the *a* and *e* sets in C_3 symmetry. The X-ray crystal structure of **2** as the (μ-aqua)$_3$(potassium hydrotris(4-chloro-3,5-dimethylpyrazol-1-yl)borate)$_2$ dimer is also reported.

1. Introduction

Scorpionates based on polypyrazolylborates are a well-known class of ligands with very rich coordination chemistry [1–3]. One of the most symmetric (C_{3v}) of these, hydrotris(pyrazol-1-yl)borate (Tp), is a generic tridentate monoanionic ligand (Fig. 1). Symmetrically substituted Tp ligands (Fig. 1) that conserve pseudo-C_3 symmetry and coordinate to a metal center in a tridentate fashion are called homoscorpionates. Complexes of the Tp-based ligands are known for most of the metals in the periodic table. Substitutions at the 3, 4 and 5 positions of the pyrazole in the Tp framework allow both steric and electronic control of metal centers by restricting the number and the positions of vacant coordination sites [4–6], the size and/or shape of the substrates [7] and by stabilizing electron rich [8,9] or electron poor [6,10] metal centers. One example of such substitution at the 3 and 5 positions of the pyrazole ring is the trifluoromethyl (CF_3) group. The resulting

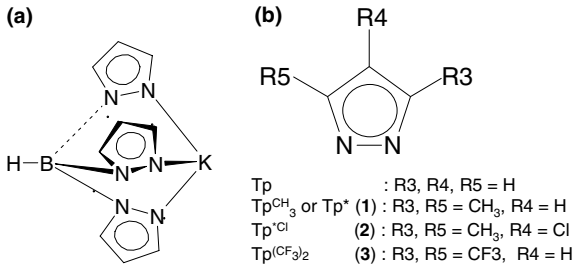

Fig. 1. (a) A generic tripodal scorpionate ligand hydrotris(pyrazol-1-yl)borate; KTp. (b) Examples of substitutions at 3 and 4 positions of the pyrazole ring. These substitutions retain the C_3 symmetry of the adducts.

hydrotris(3,5-bis(trifluoromethyl)pyrazol-1-yl)borate ($Tp^{(CF_3)_2}$) ligand is structurally similar to its methylated analogue hydrotris(3,5-dimethylpyrazol-1-yl)borate (Tp*), and therefore, allows perturbations of ligand electronic effects without significant perturbations in steric factors. Polyfluorinated ligands such as $Tp^{(CF_3)_2}$ commonly improve the volatility and oxidation resistance of their metal complexes [11,12]. They have very electrophilic metal centers relative to their hydrocarbon analogues (Tp*) [11,12].

Another widely accepted family of ligands in organometallic chemistry is the derivatives of the cyclopentadienyl (η^5-$C_5H_5^-$, Cp) ligands. The Tp and the Cp ligands are both monoanionic and formally six-electron donors, but one notable difference lies in the mode of their ligation to metals. The Cp-based ligands involve a π-type interaction with the metal centers whereas the Tp-based ligands are primarily σ-donors, with the exception of the recent report of a η^5-$Tp^{CF3,CH3}$ potassium π-bonding interaction by Gorun et al. [13]. Bergman and co-workers [14] have compared the relative electron-donating abilities of Tp and Cp and found a lack of generalization as any comparison varies with the identity of the metal, its oxidation state and other ligands present. Pioneering research work in the area of C–H bond activation by Jones and Feher [15] and Tellers and Bergman [16] has compared the differences in reactivity of related Tp and Cp transition metal complexes. A recent theoretical study of methane activation by $TpRe(CO)_2$ and $CpRe(CO)_2$ compounds reported by Cundari and co-workers [17] reveals that the Tp framework is more stereoelectronically flexible than Cp.

Previous photoelectron spectroscopic studies have been reported on the metal complexes of the Cp-based ligands and their electronic structure perturbation due to direct halogen (F, Cl) substitutions on the Cp rings [18]. However, the Cp ligands involving CF_3 substitutions are very difficult to synthesize and their metal adducts are rare in the literature. The analogous $Tp^{(CF_3)_2}$ ligands are well known [11,12] and they form stable metal adducts.

Na^+ or K^+ salts of the Tp-based ligands are used in almost all ligand transfer reactions for the synthesis of the transition metal adducts of these scorpionates. Previous structural characterization and computational work have been applied to these salts. Reglinski et al. have compared the Tp and the trismethylimazolyl borate (Tm) ligands by X-ray crystallography and ab initio calculations and found a clear difference in behavior on going from hard nitrogen donor atoms in Tp to soft sulfur donor atoms in Tm [19]. The X-ray crystal structures of the Na^+ or K^+ salts of several Tp-based ligands are known and have provided the starting geometry for our computational studies. The molecular structure of hydrotris(4-chloro-3,5-dimethylpyrazol-1-yl)borate (Tp^{*Cl}) is presented here. Fewer than 15 structures of metal adducts of Tp^{*Cl} are included in more than four hundred complexes containing scorpionate ligands that are reported in the Cambridge Structural Database (CSD).

Sterically demanding bulky ligands like the scorpionates discussed here are used to facially coordinate a metal and prevent the polynucleation of metal complexes. Several complexes of these ligands have been used in bioinorganic model chemistry [1,10]. One of the questions in this ligand chemistry is whether the ligand itself is chemically innocent. For example, Tp* ligands have been used to stabilize the oxo-molybdenum complexes that are minimum molecular models for the pyranopterin molybdenum and tungsten enzymes. EPR studies of the paramagnetic molybdenum center in these complexes [4,5] show very small ^{14}N superhyperfine interactions from the trispyrazolylborate nitrogen atoms. The Tp-based ligands are also silent for electronic absorption and MCD spectroscopies [20–22] and thus allow spectroscopic investigations of other coordinated biologically relevant functional groups/ligands and of the metals in the model complexes. A technique capable of assessing the metal and ligand characters of orbitals and studying the electronic structure of small molecules is gas-phase photoelectron spectroscopy using multiple energy ionization sources [23]. Photoelectron spectroscopic studies of the Mo adducts of the homoscorpionate Tp* have been reported earlier by our group [24,25] and others [26]. All of these studies found that the Tp* ligand has a very prominent signature in the 8–11 eV region of the photoelectron spectra of these Mo complexes, which could allow electronic structure studies of scorpionate ligands. However, these previous studies were focused on metal–sulfur ionizations that are located at lower ionization energies than the Tp*-based ionizations, and no attempts were made to explore the origin of the Tp* signatures (referred to as the "forest region" in these earlier studies). A series of photoelectron spectroscopic and computation studies using density functional theory were done to understand metal–halide interactions in $(Tp^*)MoO(X)_2$ (X = F, Cl, Cr, I) [27]. The importance of

understanding of the electronic structure of Tp* is illustrated by photoelectron spectroscopic studies of (Tp*)MoO(qdt) (qdt = quinoxaline dithiolate), where the Tp*-based ionizations overshadow the metal and sulfur-based ionizations [26]. Previous related photoelectron spectroscopy studies have investigated the electronic structure of pyrazole [28], several compounds containing the BH_4^- group [29a], poly(triazolyl)borato ligands [29b], and the parent Tp ligand [30,31]. Fragalà and coworkers [30,31] utilized a combination of semi-empirical theoretical calculations (complete neglect of differential overlap; CNDO) and photoelectron spectroscopy and found that in the scorpionate–metal adducts, the ionizations of the ligand-based molecular orbitals are generally unaffected by the nature of the central metal [31]. However, a detailed comparison among homoscorpionates using high-level density functional theory (DFT) and experimental gas-phase photoelectron spectroscopy has not been described. This report is the first gas-phase photoelectron spectroscopic investigation of the electronic structures of halogen containing scorpionates. The reported experimental and computational findings quantitates the electron withdrawing effects of CF_3 and Cl substituents on the Tp and Tp* ligand.

2. Experimental

2.1. General

All reactions were carried out under an inert atmosphere of argon using standard Schlenk techniques and a high-vacuum/gas double line setup. All glassware was dried in an oven at 150 °C and Schlenkware was further purged by repeated evacuation and inert gas flushes prior to use. Benzene and toluene were distilled from Na/benzophenone; triethylamine was distilled from Na/K amalgam [32]. The prepurified solvents were subsequently transferred and stored under N_2 over fresh drying agents. These solvents were freshly distilled under nitrogen prior to use, thoroughly degassed by repeated freeze–thaw–pump cycles, and transferred to reaction vessels via steel cannulae under a positive pressure of inert gas. Compounds **1**–**3** were prepared according to the literature procedures [2,3,11,12,33]. All of these compounds were purified by Soxhlet extraction and by sublimation as required. Mass spectra were recorded on a JEOL HX110 high-resolution sector instrument utilizing fast atom bombardment (FAB) ionization in a matrix of 3-nitrobenzyl alcohol (NBA). IR spectra (4000–400 cm^{-1}) were collected on a Nicolet Avatar ESP 360 FT-IR spectrophotometer in KBr disks or as dichloromethane solutions (between NaCl plates) at room temperature. Solvent background corrections were made in all cases. ^1H NMR ($CDCl_3$) spectra were acquired on a Bruker DRX-500 spectrometer operating at a ^1H frequency of 500.13 MHz using a 5 mm Nalorac triple-resonance 3-axis gradient probe. Chemical shifts were referenced to residual $CHCl_3$ at 7.24 ppm.

2.2. X-ray crystallography

2.2.1. Crystal structure of 2

A colorless block of **2** was mounted on a glass fiber for structure determination using a Bruker SMART 1000 CCD detector X-ray diffractometer. The X-ray quality crystals were obtained from hexanes. Key parameters for the structure determination are also summarized in Table 1. The structure was solved by direct methods using SHELXS in the Bruker SHELXTL (Version 5.0) software package. Refinements were performed on F^2 by full-matrix least squares with anisotropic displacement parameters for all the non-hydrogen atoms (using SHELXL and illustrations were made using XP). Hydrogen atoms were added at idealized positions, constrained to ride on the atom to which they are bonded and given thermal parameters equal to 1.2 or 1.5 times U_{iso} of that bonded atom. Scattering factors and anomalous dispersion were taken from International Tables vol. C, Tables 4.2.6.8 and 6.1.1.4 [34,35].

2.3. Photoelectron spectroscopy

Photoelectron spectra were recorded using an instrument that features a 36-cm radius, 8-cm gap hemispherical analyzer [36] and custom-designed excitation source, sample cells, and detection and control electronics that have been described in more detail [24]. The difference between the argon $^2P_{3/2}$ ionization at 15.759 eV and the methyl iodide $^2E_{1/2}$ ionization at 9.538 eV was used to calibrate the ionization energy scale. The argon $^2P_{3/2}$ ionization also was used as an internal calibration lock of the absolute ionization energy throughout data collection. During data collection the instrument resolution (measured using fwhm of the argon $^2P_{3/2}$ peak) was 0.020–0.035 eV. All data are intensity corrected with an experimentally determined instrument analyzer sensitivity function.

All samples sublimed cleanly with no detectable evidence of decomposition products in the gas phase or as a solid residue. The potassium and sodium salts of these ligands are hygroscopic and usually crystallize as a dimer with bridging water molecules. Contamination from the water of crystallization was observed in the photoelectron spectrum, but disappeared with time. Therefore, upon sublimation only the monomer is likely to be present in the gas phase. The sublimation temperatures were (°C, 10^{-4} Torr, monitored using a "K" type thermocouple passed through a vacuum feedthrough and attached directly to the sample cell) 210–225° for compound **1,** 195–230° for compound **2** and 50–60° for compound **3**.

Largest difference peak and hole (e Å^{-3})	0.334 and −0.252
RMS difference density (e Å^{-3})	0.063

For the photoelectron spectroscopy data presented in Figs. 3–7, the vertical length of each data mark represents the experimental variance of that point. The valence ionization bands are represented analytically with the best fit of asymmetric Gaussian peaks as described in more detail elsewhere [37]. The bands are defined with the position, amplitude, halfwidth for the high binding energy side of the peak, and the halfwidth for the low binding energy side of the peak. The number of peaks used in a fit was based solely on the features of a given band profile. The peak positions and halfwidths are reproducible to about ± 0.02 eV $\sim 3\sigma$. The parameters describing an individual Gaussian peak are less certain when two or more peaks are close in energy and overlap.

2.4. Theoretical methods

Calculations were performed on NaTp, KTp and **1**–**3** using the ADF (Amsterdam Density Functional theory calculations) package (release 2000.02). Starting geometries were obtained from crystal structures of NaTp [19] and **3** [11]. A generalized gradient approximation, with the exchange correction of Becke [38] and the correlation correction of Lee et al. [39], was used for all density functional calculations. All core levels (up to 2s for K, up to 1s for C, N, B and Na) were treated as frozen orbitals. The calculations employed triple-zeta basis sets with Slater type orbitals and a polarization function for all elements. Calculations on the ground-state molecules were performed in the spin-restricted mode. Spin-unrestricted ΔSCF (self-consistent field) calculations were performed on the proposed ion states formed by photoionization by removing one electron from the relevant orbital and comparing the total energy of the ion with that of the ground state molecule. The calculated ΔSCF energies and orbital energies were shifted by the difference between experimentally obtained and calculated energies of the highest occupied molecular orbital (HOMO) for comparison of the calculated ionization energies with the experimental ionization energies.

3. Results and discussions

3.1. Molecular structure of KTp^{*Cl}

The potassium salt of **2** was isolated as its H_2O adduct and characterized using X-ray crystallography. The

final refinement revealed that the (μ-aqua)$_3$ (potassium hydrotris(4-chloro-3,5-dimethylpyrazol-1-yl) borate)$_2$ dimer cocrystallized with unreacted 4-chloro-3,5-dimethylpyrazole. A perspective drawing of **2** is given in Fig. 2. The potassium atom is coordinated to three nitrogen atoms from pyrazole rings (Tp*^{Cl}) and three oxygen atoms of the three coordinated μ-aqua ligands. Crystal packing analysis reveals that the space group $R\bar{3}c$ imposes 32 (D_3) site symmetry on the molecule with a threefold axis passing through the two potassium atoms of the dimer and a twofold axis passing through the bridging oxygen atoms. The key bond lengths, angles and torsion angles are reported in Table 2.

The striking difference in the crystal structures of NaTp [19] and compounds **2** and **3** is the relative orientation of the pyrazole rings. The molecular structures of NaTp [19] and compound **3** feature pseudo-C_{3v} symmetry, whereas in **2** the propeller-shaped pyrazole rings reduce its symmetry to pseudo-C_3. The B–N–N–metal torsion angle containing nitrogen atoms of the same pyrazole ring is a sensitive parameter for this deviation and should be 0.0° for ideal C_{3v} symmetry. This torsion angle in **2** is −28.7°. This value is in contrast with the published structures of the Mo ([40] torsion angles of 3.72°, −4.68° and −15.83°) and Rh ([41], torsion angles of 4.07°, −0.94° and −2.72°) complexes of Tp*^{Cl}, and indicates that a large deviation from C_{3v} symmetry might be occurring due to the larger size of the potassium ion. The reported (Tp*^{Cl})$_2$Cu structure [42] also has a propeller-shaped arrangement of pyrazole rings (torsion angles of 17.15°, 24.92°, −15.54° and 17.54°, 25.60°, 19.07°). The Cl–C bond length of 1.728(2) in **2** is comparable to those of 1.724, 1.720 and 1.721 Å in the (Tp*^{Cl})Rh adduct and 1.697, 1.714 and 1.719 Å in the (Tp*^{Cl})Mo adduct.

3.2. Gas-phase photoelectron spectroscopy

The gas-phase photoelectron spectra of **1**–**3** recorded with a He I photon source (21.2 eV) are shown in Fig. 3. There are several differences among these spectra that result from the changes in substituents on the pyrazole rings. In the ionization energy region greater than ∼12 eV the main differences among these three spectra are due to the addition or removal of ionizations associated with the C–Hσ bonds of the CH_3 substituents, the C–Fσ bonds of the CF_3 substituents, or the halogen lone pair ionizations of the Cl and CF_3 substituents. For example, the spectrum of **2** has one moderate and one sharp feature between 10.7 and 12 eV, which is the energy region expected for Cl lone pair ionizations (X) [18], while the spectrum of **3** contains much intensity in the region of 15–18 eV due to F lone pair ionizations. In general, however, the region of the photoelectron spectra greater than ∼12 eV gives very little information for these molecules due to the large number of overlapping ionizations present.

The region of the photoelectron spectra with ionization energies below ∼12 eV contains the most information that can be used to analyze the electronic differences between these scorpionate ligands. This region of the spectra is shown in more detail in Fig. 4. The features in this region and our assignments in general agree with those of NaTp and TlTp previously reported by Fragalà and co-workers [30,31]. Each of these spectra contain at lowest ionization energy an envelope of ionizations labeled A that is fairly well separated from all other ionizations. The ionizations under bands A can be assigned to the total of six possible linear combinations of the pyrazole π-orbitals, two from each pyrazole ring, each of which has one node. In the deconvolutions shown in Fig. 4 (positions of the Gaussians used in the

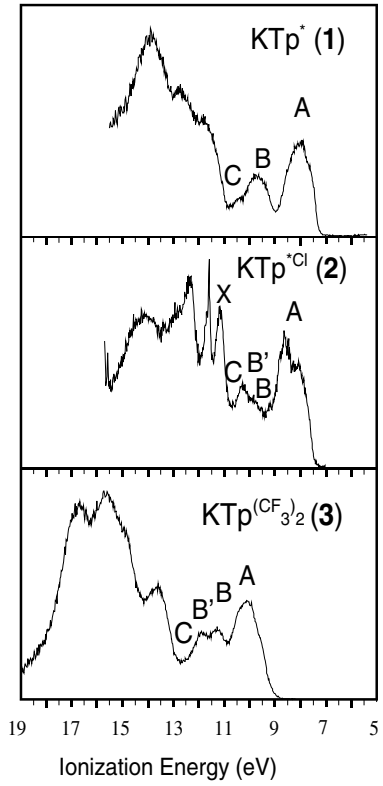

Fig. 3. The He I full photoelectron spectra of the potassium salts of: hydrotris(3,5-dimethylpyrazol-1-yl)borate, Tp* (**1**); hydrotris(4-chloro-3,5-dimethylpyrazol-1-yl)borate, Tp^{*Cl} (**2**); and hydrotris(3,5-bis(trifluoromethyl)pyrazol-1-yl)borate, $Tp^{(CF_3)_2}$ (**3**). All of the spectra have three general features labeled as bands A, B and C in the lower energy region. These bands are assigned as A: pyrazole-π ; B, B′: σ_N of the pyrazole nitrogen orbitals; C: σ_{BH} of the trispyrazole borate ligands; X: The chlorine lone pair based orbital.

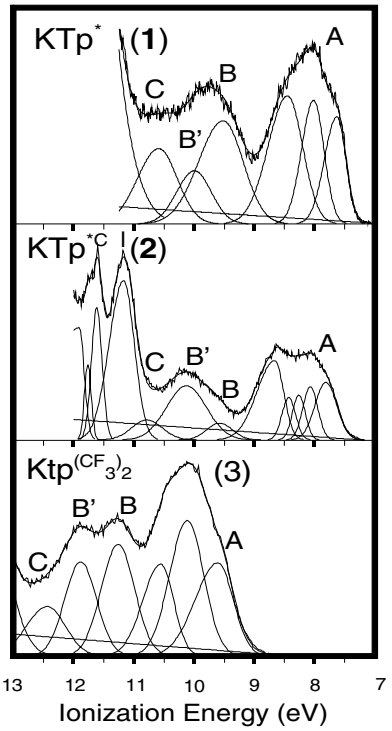

Fig. 4. The He I close up photoelectron spectra of KTp* (**1**); KTp^{*Cl} (**2**); and $KTp^{(CF_3)_2}$ (**3**). Bands A, B and C are assigned as in Fig. 3.

deconvolutions are listed in Table 3), bands A can be modeled with three Gaussians for **1** and **3**, but the shape of band A for **2** is different and deconvolution requires at least five Gaussians to fully describe the shape of the band. This extra structure is typical for π ionizations with halide substituents due to the sharpening of the ionizations with an admixture of lone pair character and also the presence of additional vibrational fine structure on the ionizations [18]. As the substituents are varied the ionizations under band A shift in energy but the spread of the ionizations does not change dramatically, indicating that all the ionizations under band A are approximately shifting by the same amount. If the position of the lowest energy Gaussian that is used to model the band is used as a measure of the shift, the total stabilization of band A from **1** to **3** is 1.98 eV, indicative of a very strong electron withdrawing effect of the trifluoromethyl substitutions.

In each of the photoelectron spectra the ionizations labeled as bands B and C are due to the σ_N and σ_{BH} molecular orbitals. Band C is not observed clearly because of proximity to other ionizations. According to group theory, for scorpionate ligands in C_3 symmetry the σ_N orbitals transform as *e* and *a* sets. The *a*-symmetry σ_N orbitals have the proper symmetry to overlap with the empty s orbital on K and therefore will be expected to be stabilized relative to the *e*-symmetry σ_N orbitals. In Fragalà and co-workers [30] previous study on NaTp there were two distinct bands in this energy region, and they assigned the *e*-symmetry σ_N ionization at lower ionization energy followed by the overlapping *a*-symmetry σ_N and σ_{BH} ionizations. In contrast, the spectra of **1**–**3** reported here all require three Gaussians to model the shape of the ionization envelope in this region.

To aid in the assignment of these ionizations, data were also collected on **1** and **2** with a He II excitation source (40.8 eV), which will change the relative intensity of ionizations depending upon the atomic character of the molecular orbitals with which they are associated [23,43,44]. A comparison of the He I and He II spectra of **1** is shown in Fig. 5. The most distinct difference between the spectra collected with different ionization sources is that the band labeled C decreases in intensity dramatically in the He II spectrum, as would be expected for the σ_{BH} ionization. The assignment of these ionizations of **1** is then that band B is the *e*-symmetry σ_N ionization, band B′ is the *a*-symmetry σ_N ionization and band C is the σ_{BH} ionization. Some splitting of the *e*-symmetry σ_N ionizations would be expected if the symmetry is lower than C_3, but any such splitting is not large enough to be experimentally observed. The He I

Table 3

9.58, 10.13	9.66, 10.25			band B, σ_N
10.78	10.41			band C, σ_{BH}
K(Tp$^{(CF_3)_2}$) (**3**)				
9.61–10.55[a]	9.61–10.13	6.93	8.78	band A, pyrazole-π
11.26, 11.88	10.66–11.23			band B and B′, σ_N
12.44	11.88			band C, σ_{BH}

[a] Range of experiment I.E. values for Band A are taken from the positions of Gaussians used to deconvolute the data. This does not imply that these values are vertical ionization energies.
[b] Eigenvalues were shifted so the HOMO eigenvalue matches the position of the lowest energy Gaussian used to deconvolute the experimental data.

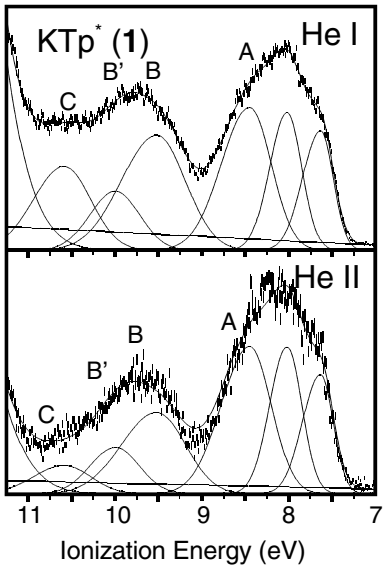

Fig. 5. The He I and He II close up spectra of KTp*. Ionizations associated with molecular orbitals with hydrogen contributions decrease in relative intensity with the He II source.

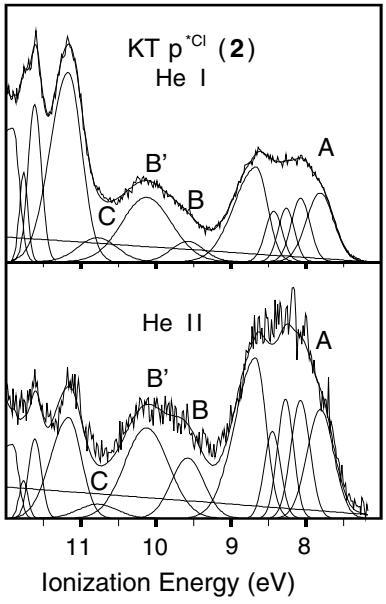

Fig. 6. The He I and He II close up spectra of K(Tp*^{Cl}). Ionizations associated with molecular orbitals with chlorine contribution decrease in relative intensity with the He II source.

and He II spectra of **2** shown in Fig. 6 can be assigned in a similar fashion, with the σ_{BH} ionization (C) assigned as the small shoulder on the high energy side of the band from 9.5 to 11 eV.

The σ_N and σ_{BH} ionizations also shift as the substituents on the pyrazole rings are varied. All three ionizations are stabilized for **2** as compared to **1**, and only slightly more than the pyrazole π ionizations under band A. In **3**, band C (σ_{BH}) shifts to higher ionization energy due to the electron withdrawing effect of the trifluoromethyl groups on the pyrazole rings.

Fragalà and co-workers [30] have reported changes in the position and the intensity of the σ_N ionizations for unsubstituted MTp as M is changed from Na to Tl. They have observed that the *a*-symmetry σ_N ionization is stabilized in the Tl complex due to the more covalent interaction of the nitrogen σ-donors orbitals with the softer Tl atom than with the relatively harder Na atom. The ionization of the nitrogen σ-donor orbitals (bands B and B′) for Tp* is shifted to higher ionization energy in the photoelectron spectra of molybdenum complexes [24,25] than for **1**, consistent with a more covalent nature of the interaction with the Mo metal center with the nitrogen-donor orbitals as compared to the K^+ cation. To further evaluate the effect that differences in metals have on the σ-donor abilities of more electron withdrawing scorpionate ligands, a photoelectron spectrum

was collected of $Na(Tp^{(CF_3)_2})$ for comparison to $K(Tp^{(CF_3)_2})$. Fig. 7 shows a stack plot of the close-up spectra of these Na and K adducts of $Tp^{(CF_3)_2}$. A slight shift to higher energy of bands B and B′ is observed in $Na(Tp^{(CF_3)_2})$ in comparison to $K(Tp^{(CF_3)_2})$, which is counterintuitive to the expectation that K^+ complexes should be more covalent than complexes containing the harder Na^+, but is consistent with the fact that Na^+ is more electronegative than K^+. These shifts might be due to the strong electron withdrawing effect of CF_3 in $Tp^{(CF_3)_2}$ resulting in electron deficient nitrogen atoms σ-bonded to the metal. These electron deficient (harder) σ-donor nitrogen atoms can interact better with hard Na^+ relative to K^+. The bands A, B and B′ are destabilized by 0.1, 0.28 and 0.62 eV, respectively, in the photoelectron spectrum of $K(Tp^{(CF_3)_2})$ in comparison to $Na(Tp^{(CF_3)_2})$. A significant destabilization of B′ from the Na to the K adduct is further evidence of its assignment to the *a* set of symmetric σ-donor nitrogen orbitals, which is the right symmetry to have overlap bonding with the unfilled symmetric metal s orbitals and hence is affected the most by metal substitution.

3.3. Computational results

Geometry optimization of NaTp beginning from the reported crystal structure [19] converged without significant changes in the geometry. We used this ligand geometry as a starting point for the geometry optimization of the KTp, **1** and **2**. Geometry optimization of **3** started with the crystal structure coordinates [11]. A similar pattern of molecular orbitals was calculated for KTp and for compounds **1**–**3**. The results for KTp are generalized and discussed below in detail, with representative molecular orbitals plotted in Fig. 8. The lowest unoccupied molecular orbital (LUMO), has primarily metal s character (Fig. 8(a)), and is well isolated (4.216 eV in KTp) from the filled ligand-based molecular orbitals. The highest occupied and several lower energy molecular orbitals that are closely spaced in energy (HOMO to HOMO-5) are primarily pyrazole-π in character, as shown by the molecular orbital plots for the HOMO and HOMO-1 in Figs. 8(b) and (c). These orbitals correspond to the ionizations under band A of the photoelectron spectra for **1**–**3** (Fig. 3).

These pyrazole-π orbitals are separated by 0.68 eV from the next group of molecular orbitals that comprise mainly the σ-donor nitrogen orbitals of the pyrazole rings. These σ-donor nitrogen orbitals are *e* and *a*-symmetry orbitals in C_3 symmetry. The orbital with the correct symmetry to interact with the metal-s orbital (K 4s) is plotted in Fig. 8(d). A third type of calculated molecular orbital is 0.68 eV more stable than the σ-donor combination of the nitrogen orbitals discussed above. This molecular orbital is σ_{BH} in character (Fig. 8(e)) and corresponds to the ionization occurring under band C in Figs. 3–6 for **1**–**3**.

The computed molecular orbital energies and ΔSCF estimate of calculated ionization energies for removal of an electron from **1** to **3** are reported in Table 3, and plots of the HOMO of each of these molecules are shown in Fig. 9. The calculated HOMO for **2** (Fig. 9) has significant chlorine character (~20%). This corroborates well with the experimental finding of the halogen character in frontier molecular orbitals of **2** discussed earlier. The substitution of CF_3 in **3** results in a very strong electron

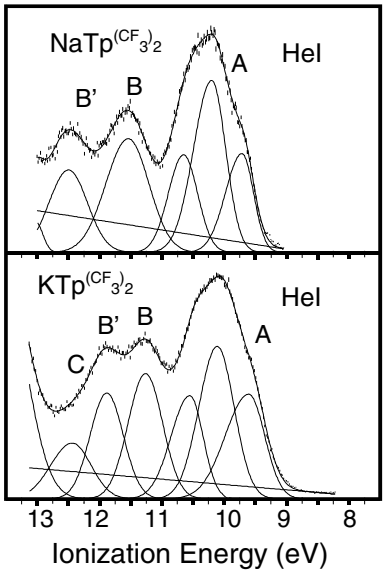

Fig. 7. He I close-up photoelectron spectra of $Na(Tp^{(CF_3)_2})$ (top) and $K(Tp^{(CF_3)_2})$ (bottom). The bands are assigned as A: pyrazole-π; B, B′: σ_N (*e*-symmetric and *a* symmetric combinations, respectively) of the pyrazole nitrogen orbitals; C: σ_{BH} of the trispyrazole borate ligand.

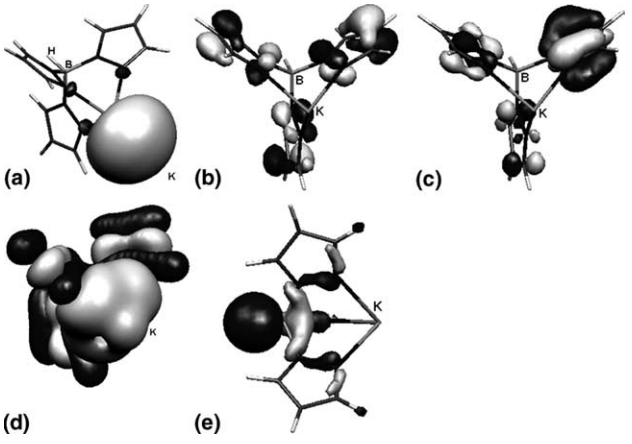

Fig. 8. Molecular orbital plots (at 0.05 cutoff levels unless stated) of KTp. (a) Lowest unoccupied molecular orbital (LUMO) is primarily metal in character (at 0.03 cutoff levels). (b) The highest occupied molecular orbital (HOMO) is primarily pyrazole-π in character. (c) HOMO-1 is again pyrazole-π in character. (d) An example of the pyrazole σ-donor (σ_N) molecular orbital (at 0.008 cutoff levels). (e) The hydrotris(pyrazol-1-yl)borate σ_{BH} molecular orbital.

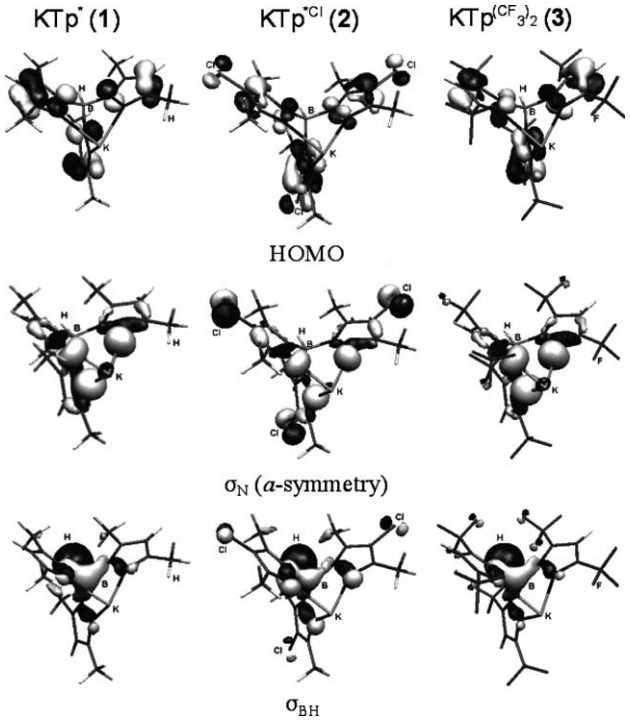

Fig. 9. Comparison of the highest occupied molecular orbitals (HOMO), σ_N (*a*-symmetric) and σ_{BH} orbitals of compounds **1**–**3** (at 0.05 cutoff levels).

withdrawing effect and stabilizes the pyrazole-π based molecular orbitals (HOMO) by 2.27 eV relative to **1**. This calculated shift compares very well with the corresponding experimentally obtained value of ~2.0 eV. The σ_{BH} and σ_N (*a*-symmetry) orbitals for **1**–**3** also are plotted in Fig. 9 for comparison. The methyl or trifluoromethyl substitutions, for **1** and **3**, at the 3 and 5 positions of pyrazole ring do not significantly change the nature of the σ_{BH} and σ_N orbitals.

Finally, we note that the Mulliken charges at the potassium atom for compounds **1**, KTp, **2**, **3** (0.88, 0.91, 0.89 and 0.99, respectively) correspond very well to the electron withdrawing properties of the substitutions in these compounds. The Mulliken charge at the metal center in compound **3** (0.99) contrasts with that of 0.88 in **1** and confirms the experimental findings of us and others [11] of a very electropositive metal center in the metal adducts of $Tp^{(CF_3)_2}$. Thus, the homoscorpionates discussed here offer a variety of possibilities for the modification of the steric and the electronic properties by variations of the substitution at the 3, 4 and 5 positions of the pyrazole rings.

4. Conclusions

The general shape of the low energy ionizations bands A, B, and C in the photoelectron spectra of **1**–**3**, is not greatly affected by the nature of the metal ions as reported here and by others [31]. However, substitutions at the 3, 4 and 5 positions of the pyrazole ring can shift the ionization energies of the bands significantly, as especially shown by the CF_3 substitutions, and can perturb the distributions of the orbitals, as shown most clearly by the Cl substitutions.

The scorpionates discussed in this work are coordinated to the metal through the nitrogen atoms of the pyrazole rings and this σ-bonding is modulated by electron density at the metal center or vice versa. The electronic structure of scorpionate ligands presented here includes distinct assignments of σ_{BH} and σ_N (*a* and *e*-symmetry) orbitals confirmed experimentally for the first time. This will help in understanding the electronic structure of scorpionate-based transition metal complexes utilized in bioinorganic modeling and organometallic catalysis. The shift in the positions of band B might be an indicator of the extent of σ-bonding of these scorpionate ligands upon coordination with transition metals and will be a topic of discussion in later studies [45].

5. Supporting information

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), CCDC No. 213807 for compound **2**.

Acknowledgements

Authors thank Dr. P.J. Desrochers, at University of Central Arkansas for a sample of $K(Tp^{*Cl})$. Support by the National Institutes of Health (Grant GM-37773 to JHE) and the National Science Foundation (Grant CHE-0078457 to DLL and Grant CHE 9610374 for the X-ray diffractometer) is gratefully acknowledged. The determination of the structure of $K(Tp^{*Cl})$ was a special class project of MEA in Chemistry 517.

Preparation and ligand substitution reactions of $Tp^{Ms}Ru(COD)H$ including intramolecular ligand metalation

Chandi Pariya, Christopher D. Incarvito, Arnold L. Rheingold, Klaus H. Theopold *

Department of Chemistry and Biochemistry, Center for Catalytic Science and Technology, University of Delaware, Newark, DE 19716-2522, USA

Received 25 June 2003; accepted 30 August 2003

Dedicated to S. Trofimenko, inventor of scorpionates and esteemed colleague

Abstract

Reaction of $[RuH(COD)(NH_2N(CH_3)_2)_3]BPh_4$ (COD = 1,5-cyclooctadiene) with $Tp^{Ms}Tl$ (Tp^{Ms} = hydrotris(3-mesitylpyrazolyl)borate) yielded $Tp^{Ms}Ru(COD)H$ (**1**). Treatment of **1** with CO afforded acyl complex $Tp^{Ms}Ru(CO)_2C(O)C_8H_{13}$ (**2**) via intramolecular olefin insertion followed by CO addition and insertion. In contrast, reaction of **1** with acetonitrile was accompanied by C–H activation of a ligand methyl group and H_2 elimination, ultimately producing $Tp^{Ms@}Ru(NCCH_3)_2$ (**3**) as the final product. The molecular structures of complexes **1**–**3** have been determined by single crystal X-ray diffraction methods.

Keywords: Ruthenium; Scorpionate; Tris(pyrazolyl)borate; Hydride; C–H activation

1. Introduction

Tris(pyrazolyl)borate ligands with bulky substituents in the 3-position of the pyrazolyl rings – i.e. homoscorpionates of the second generation – have provided a plethora of interesting organometallic and coordination compounds [1,2]. For example, we have used the $Tp^{R,Me}$ ligands (R = ^{t}Bu, ^{i}Pr) in our exploration of the dioxygen chemistry of cobalt and chromium [3–12], and Moro-Oka et al. [13–20] have extensively used the Tp^{iPr2} ligand. In an attempt to extend our work to second row metals, we encountered unexpected difficulties in preparing ruthenium complexes of the $Tp^{tBu,Me}$ ligand, and were thus forced to pursue alternatives. A consideration guiding our choice was the desire to exclude C–H bonds from the immediate vicinity of any metal bound oxygen atom. We reasoned that the sterically enforced orthogonality between the pyrazolyl rings and mesityl ring planes of Tp^{Ms} (Tp^{Ms} = hydrotris(3-mesitylpyrazolyl)-borate) [21,22] would keep the vulnerable benzylic C–H bonds out of harm's way and present the aromatic π-system to any reactive groups bound to ruthenium. Herein we describe the facile preparation of a starting material for $Tp^{Ms}Ru$ chemistry and some observations bearing on our working hypothesis.

2. Results and discussion

We have found that the reaction of $[RuH(COD)(NH_2\text{-}N(CH_3)_2)_3]BPh_4$ (COD = 1,5-cyclooctadiene) [23] with $Tp^{Ms}Tl$ is an efficient method for the synthesis of $Tp^{Ms}Ru(COD)H$ (**1**, see Scheme 1). The use of the ruthenium dimethylhydrazine complex was first reported by Kirchner and co-workers [24] for the synthesis of TpRuCl(COD) (Tp = hydrotris(pyrazolyl)borate), but it has not been widely employed. Complex **1** can also be made by the reaction of RuH(COD)(bpm)Cl (bpm = *bis* (pyrazolyl)methane) [25] with $Tp^{Ms}Tl$, as described earlier for the synthesis of Tp*RuH(COD) (Tp* = hydrotris(3,5-dimethylpyrazolyl)borate) and $Tp^{iPr,4Br}RuH$ (COD) ($Tp^{iPr,4Br}$ = hydrotris(3-isopropyl-4-bromopyrazolyl)borate) [26–29]. The formulation of complex **1** is based on spectroscopic and analytical data and it has been confirmed by an X-ray crystal structure determination.

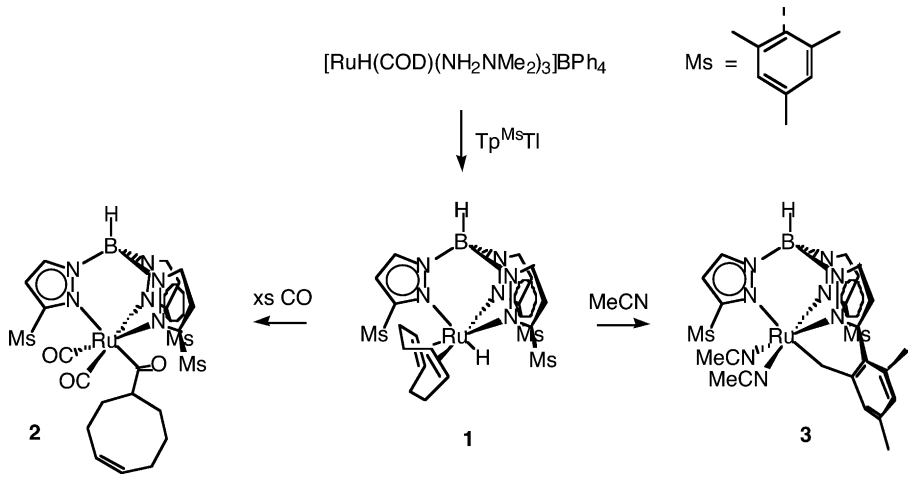

Scheme 1.

The result of the structure determination is shown in Fig. 1, and selected interatomic distances and angles are listed in Table 1. The complex features six-coordinate ruthenium in roughly octahedral coordination geometry. The hydride ligand was located, but the structural parameters associated with it must of course be viewed with some suspicion. However, the effect of the hydride is clearly seen in its *trans* influence upon one of the pyrazolyl groups. Thus the Ru(1)–N(1) bond distance (2.450(5) Å) is considerably longer than the other two Ru–N bonds (2.215(5) and 2.252(5) Å). The latter are more typical of TpRu(II) complexes. Other notable features of the structure include the significant lengthening of the olefinic C=C double bonds (1.421(9) and 1.400(10) Å) due to π-backbonding from the electron rich metal, and the near orthogonality of the mesityl planes and the pyrazolyl rings. The latter gives the $Tp^{Ms}Ru$ fragment its characteristic bowl shape.

The solid state IR spectrum of **1** showed the ν_{Ru-H} and ν_{B-H} vibrations at 2087 and 2444 cm^{-1}, respectively. The ^1H NMR spectrum (in C_6D_6) shows the presence of a Tp^{Ms} ligand, a COD and a signal at $\delta = -6.88$ ppm with an integrated intensity of one hydrogen per Tp^{Ms} ligand; the latter was assigned to the hydrido ligand. These data are in agreement with the solid state structure. **1** is soluble in most common organic solvents and its solutions decompose upon exposure to air.

As our interest in **1** was chiefly its utility as precursor for other complexes, we subjected it to reactions aimed at removing the COD ligand. Unfortunately, **1** did not react directly with either N_2O or O_2 at room temperature, and prolonged heating of these reactions led to decomposition. By contrast, exposure to an excess of carbon monoxide at room temperature resulted in the quantitative conversion of **1** to a new organometallic compound (**2**). The IR spectrum of **2** exhibited three

C(40)–C(41)–C(42)	122.7(6)	C(41)–C(42)–C(43)	123.3(6)

resonances in the carbonyl stretching frequency range; two of these (at 2040 and 1970 cm^{-1}) were consistent with terminal carbonyls, whereas the third (at 1661 cm^{-1}) indicated the presence of an acyl moiety. Furthermore, the ^1H NMR spectrum of **2** indicated the loss of the metal hydride functionality, but showed resonances of the eight-membered ring. A proposed structure of **2** that is entirely consistent with the spectroscopic data, namely $TpMsRu(CO)_2C(O)C_8H_{13}$, is shown in Scheme 1. This assignment was also confirmed by a crystal structure determination by X-ray diffraction. The molecular structure of **2** is shown in Fig. 2, while selected interatomic distances and angles are listed in Table 2. Once again, the ruthenium exhibits octahedral coordination, with the angles between *cis*-ligands ranging from 84.0(2)° to 96.1(2)°. This time, however, the Ru–N distances are much more similar (2-197(5)–2.252(5) Å); they as well as the Ru–C bonds are entirely unexceptional. It should be noted that the cyclooctenyl group is disordered over two positions; this has been modeled and Fig. 2 only shows one of the two arrangements. Accordingly, the bond distances in the ring are of low accuracy, but there can be no doubt that one of them is a double bond.

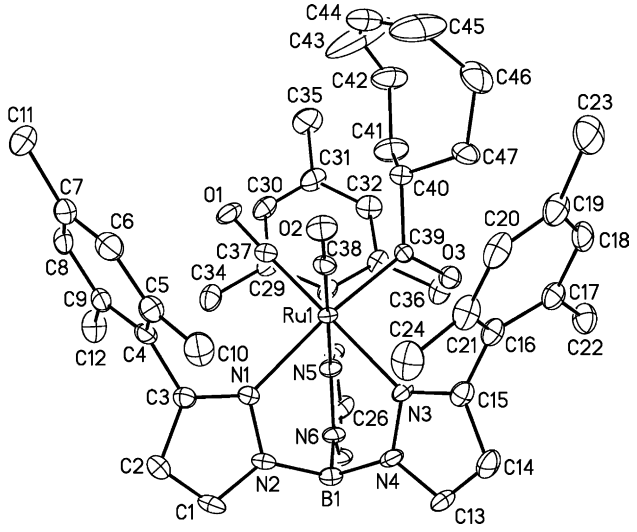

Fig. 2. The molecular structure of $Tp^{Ms}Ru(CO)_2C(O)C_8H_{13}$ (**2**); only one of the two disordered conformers is shown.

The formation of **2** implies an insertion of one of the double bonds of COD into the ruthenium hydride to form an alkyl complex. Trapping of this coordinatively unsaturated species with CO, followed by a migratory CO-insertion and trapping again delivers **2**. While the exact sequence of these individual mechanistic steps remains uncertain, they are clearly implicated in their aggregate by the final product. Based on these observations it seemed reasonable to suggest a rate determining equilibration between **1** and its less stable alkyl olefin complex isomer. Evidence for such a mechanism might be gathered from a reaction with a trapping reagent less likely to undergo insertion into the metal–carbon σ-bond. This was our intent when we reacted **1** with an excess of acetonitrile. However, this reaction took an entirely different path.

1 is very poorly soluble in acetonitrile. However, on refluxing a suspension of **1** in acetonitrile under argon the starting material dissolved and within a few minutes the solution changed color from yellow to green and finally a green microcrystalline powder of **3** precipitated. The ^1H NMR spectrum of **3** was consistent with a molecule lacking any symmetry, as indicated by the large number of proton resonances; furthermore, it no longer showed a resonance attributable to a hydride. The IR spectrum showed two bands at 2255 and 2238 cm^{-1}, which indicated the presence of coordinated acetonitrile. The nature of **3** was ultimately revealed by a crystal structure determination; its result is depicted in Fig. 3 and selected interatomic distances and angles are listed in Table 3. **3** is the apparent product of a C–H activation of one of the ortho-methyl groups of a mesityl substituent. Elimination of H_2 and replacement of the COD ligand with two coordinated acetonitrile molecules complete the transformation of **1**–**3** (abbreviated $Tp^{Ms@}Ru(NCMe)_2$ to indicated the functionalized

ligand). The coordination geometry about ruthenium is once again close to octahedral, with the angles between *cis*-ligands spanning the range of 81.12(10)°–100.37(9)°. The metalation of the mesityl methyl does not appear to create any unusual strain; thus, the Ru(1)–C(34) bond is of normal length (2.113(3) Å) and the bond angle at C(34) (Ru(1)–C(34)–C(29), 109.82(18)°) approximates the ideal tetrahedral angle. Naturally, the mesityl plane is turned somewhat from the perpendicular position with respect to the pyrazole ring. The nitriles are coordinated in the common 'end-on' fashion. The solid state structure is in complete accord with the complicated solution spectrum, which indicates that the molecule is static on the NMR time scale in solution. Most importantly, the formation of **3** suggests that the mesityl substituents of the Tp^{Ms}-ligand are subject to facile attack by metal bound ligands. This does not bode well for the stabilization of highly oxidizing intermediates containing $Tp^{Ms}M$ fragments.

3. Conclusions

With the synthesis of TpMsRu(COD)H (**1**) we have devised a convenient entry into the chemistry of the $Tp^{Ms}Ru(II)$ fragment. Ligand substitution reactions of **1** are facile and mechanistically diverse. Depending on the entering group, the COD ligand may be retained in some form (as in **2**) or completely lost (as in **3**). The causes for this mechanistic divergence are not clear at this juncture. A novel and unexpected feature of this chemistry was the ready metalation of the Tp^{Ms}-ligand at an ortho-methyl group. This observation would seem to disqualify this particular scorpionate from consideration as an 'oxidation resistant' ligand. However, we have reason to believe that it is useful for less severe chemistry.

4. Experimental

4.1. General procedures

The preparation and handling of all compounds was performed in oven-dried glassware with exclusion of air and moisture under nitrogen or argon atmosphere, using standard vacuum line and Schlenk techniques. All solvents were dried and distilled under a nitrogen atmosphere prior to use. C_6D_6 was predried with Na and stored under vacuum over Na/K (1:3) alloy. $RuCl_3 \cdot x H_2O$ was purchased from Strem Chemical Co. 1,5-cyclooctadiene (COD) and *N*,*N*-dimethyl hydrazine were purchased from Aldrich Chemical Co and Fisher Scientific Co, respectively. $Ru(COD)Cl_2$ [30] and $[RuH(COD)(NH_2\text{-}N(CH_3)_2)_3]BPh_4$ [23] were synthesized by literature procedures. NMR spectra were recorded on Bruker AM 250 and AC250 spectrometers. FT-IR spectra were run using a Mattson Alpha Centauri spectrometer. Combustion analyses were obtained from Oneida Research Services, Whitesboro, NY or Schwarzkopf Microanalytical Laboratory, Woodside, NY.

4.2. Preparation of $Tp^{Ms}Ru(COD)H$ (*1*)

Solid $[RuH(COD)(NH_2N(CH_3)_2)_3]BPh_4$ (2.32 g, 3.27 mmol) was added to a suspension of $Tp^{Ms}Tl$ (2.54 g, 3.29 mmol) in 100 ml of THF. The reaction mixture was stirred for 12 h at room temperature, over which time a white precipitate separated. The color of the solution changed from colorless to yellow. The resulting yellow solution was filtered and evaporated to dryness. The product was extracted with pentane and filtered. Removal of solvent under reduced pressure gave 1.67 g (66%) of **1** after drying. Recrystallization of **1** from pentane gave crystals suitable for X-ray analysis. ^1H NMR (250 MHz, C_6D_6): $\delta = 7.86$ (s, 1H, 5-H), 7.59 (s, 2H, 5-H), 6.93 (s, 2H, 3′,5′-H), 6.80 (s, 2H, 3′,5′-H), 6.70

(s, 2H, 3′,5′-H), 6.04 (s, 1H, 4-H), 5.79 (s, 2H, 4-H), 3.40 (s, 4H, olefin H of COD), 2.58 (s, 6H, 2′-CH_3), 2.22 (d, 6H, 6′-CH_3), 2.13 (d, 9H, 4′-CH_3), 1.92 (s, 6H, 2′, 6′-CH_3), 1.55 (m, 4H, H of COD), 1.12–1.04 (m, 4H, H of COD) and −6.88 (s, 1H); IR (KBr): $\nu_{B-H} = 2444$ cm^{-1}, $\nu_{Ru-H} = 2087$ cm^{-1}. Elemental analysis Calc. for $C_{44}H_{53}N_6BRu$ ($M = 777.83$): C, 67.94; H, 6.87; N, 10.80. Found: C, 67.74; H, 6.81; N, 10.94%.

4.3. Preparation of $Tp^{Ms}Ru(CO)_2C(O)C_8H_{13}$ (2)

A pentane (20 ml) solution of Tp^{Ms}RuH(COD) (**1**) (350 mg, 0.45 mmol) was prepared in the glovebox. The reaction flask attached with needle valve was set up in the high vacuum line. The solution was frozen in liquid N_2 and flask was evacuated. Repeated freezing and evacuation was performed to make sure the solution is completely free from N_2. Then the solution was placed under 1 atm of CO at ambient temperature for 10 h. During this time light yellow crystals appears. After a brief evacuation to remove excess CO the flask and contents were transferred to a glovebox. It was filtered and the solvent was removed in vacuo. The combined amount of product shows the reaction is virtually quantitative. The product was recrystallized from ether: yield 374 mg (96%). ^{1}H NMR (250 MHz, C_6D_6): $\delta = 7.54$ (s, 1H, 5-H), 7.51 (s, 2H, 5-H), 6.96 (s, 2H, 3′,5′-H), 6.75 (d, 4H, 3′,5′-H), 5.93 (s, 1H, 4-H), 5.78 (m, 2H,4-H), 5.58 (m, 1H, olefin H of cyclooctene), 5.35 (m, 1H, olefin H of cyclooctene), 2.36 (s, 3H, 2′-CH3), 2.28 (s, 3H, 6′-CH3), 2.21 (d, 6H, 2′-CH3), 2.11 (d, 6′-CH3), 2.06 (d, 9H, 4′-CH3), 1.74 (m, 4H, H of cyclooctene), 1.17 (m, 2H, H of cyclooctene), 0.95 (m, 2H, H of cyclooctene), 0.75 (m, 2H, H of cyclooctene), 0.05 (m, 1H (H of cyclooctene); IR (KBr disk): $\nu_{B-H} = 2458$, $\nu_{C\cong O} = 2040$, 1970; $\nu_{C\cong O} = 1661$ cm^{-1}. *Anal.* Calc. for $C_{47}H_{53}N_6BO_3Ru$ ($M = 861.36$): C, 65.48; H, 6.20; N, 9.80. Found: C, 65.38; H, 6.37; N, 9.86%.

4.4. Preparation of $Tp^{Ms}@Ru(CH_3CN)_2$ (3)

A suspension of Tp^{Ms}Ru(COD)H (**1**, 200 mg, 0.26 mmol) in 15 ml of acetonitrile was refluxed for 4 h. Within half an hour all starting material dissolved and the clear yellow solution turned green. A green solid precipitated out from the homogeneous solution. The reaction mixture was cooled to room temperature and filtered. The product was dried under vacuum to give pure **3** (93 mg, yield: 48%). A small amount was recrystallized from CH_3CN and diethyl ether to get crystals suitable for the X-ray crystal structure determination. ^{1}H NMR (250 MHz, C_6D_6): $\delta = 7.99$ (m, 1H), 7.80 (m, 1H), 7.65 (m, 1H), 7.12 (s, 1H), 6.84 (s, 1H), 6.71 (s, 1H), 6.62 (s, 1H), 6.57 (s, 2H), 6.42 (m, 1H), 6.14 (m, 1H), 5.90 (m, 1H), 3.53 (d, 1H, $J_{HH} = 10$ Hz) 2.38 (s, 3H), 2.26 (s, 6H), 2.13 (m, 9H), 2.00 (s and d, 4H), 1.80 (s, 3H) 1.30 (s, 3H), 0.80 (s, 3H). IR (KBr disk): $\nu_{B-H} = 2473$, $\nu_{C=N} = 2255$, 2238 cm^{-1}. *Anal.* Calc. for $C_{40}H_{45}N_8BRu$ ($M = 749.74$): C, 64.08; H, 6.05; N, 14.95. Found: C, 63.62; H, 5.75; N, 14.93%.

4.5. Crystallographic structure determinations

Crystal, data collection, and refinement parameters are given in Table 4. Suitable crystals for data collection were selected, mounted with Paratone oil and flash cooled to the data collection temperature. All data were collected at 173 K with a Siemens P4/CCD diffractometer

Table 4

with graphite-monochromated Mo Kα X-radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and were completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures. The cyclooctene moiety in **2** was found to be severely disordered and was modeled using two contributing structures having a 50/50 site occupancy distribution, with restrained 1,2 and 1,3 C–C distances and with common displacement parameters for chemically equivalent carbon atoms. The hydride ligand, H(1), was located in the difference map of **1**; all other hydrogen atoms were treated as idealized contributions excepting those on the disordered cyclooctene moiety which were ignored. All non-hydrogen atoms were refined with anisotropic displacement coefficients. All software and sources of the scattering factors are contained in the SHELXTL (5.1) program library (G. Sheldrick, Siemens XRD, Madison, WI).

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 212260 for compound **1**, CCDC No. 212259 for compound **2**, and CCDC No. 212261 for compound **3**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

We report the synthesis and structure of arsenic (III) and tin(IV) adducts of the hydrotris(methimazolyl)borate anion (Tm^{Me}). Both species are found to be $[E(\kappa^3Tm^{Me})_2]^{n+}$ anions (E = As, $n = 1$; E = Sn, $n = 2$). Comparisons are made between each of these species and the compounds formed with their heavier and larger group partners bismuth and lead. Due to the remarkable flexibility in the soft scorpionate ligand we were unable to form a charge-separated species analogous to that reported by Parkin for the phenyl analogue (Tm^{Ph}). Attempts to prepare the tin(II) adduct curiously produced the tin(IV) product $[Sn(\kappa^3Tm^{Me})_2][Tm^{Me}]_2$ even when the reaction was carried out under inert atmospheres.

1. Introduction

The hydrotris(pyrazolyl)borate anion (Tp), first reported in 1966 [1,2], has found great favour with synthetic inorganic chemists, and since the initial reports an extensive family of poly(pyrazolyl)borate ligands has been gradually developed. Concurrent with these developments, the synthetic community have generated examples of poly(pyrazolyl)borate complexes of every d-block element [3]. With few exceptions these ligands are easy to prepare and they readily support transition metals during changes in their oxidation state and co-ordination sphere. They have thus been found to be highly versatile ligands, which repeatedly appear as a chemical component of new materials, reagents and catalysts [3].

While the chemistry of the poly(pyrazolyl)borates with transition metals is extensive and continues to expand, reports of their complexes with the softer, lower main group elements are few [3] principally due to the hard donor character of the Tp ligand. However, the more recent syntheses of soft hydrotris(thiaimidazolyl)borate (Tm^R) analogues of Tp has enabled workers to study the co-ordination chemistry of the lower main group in a C_3 environment relatively simply. Thus far compounds of thallium(I/III) [4–7], tin(IV) [8,9], lead(II) [10,11] and bismuth(III) [8,12] have been reported and a number of structural motifs have been observed (Fig. 1). The (thiaimidazolyl)borate anions would seem to have a distinct preference for the κ^3 co-ordination mode. Examples of the simple 1:1 Tm^R:E species include those of thallium(I), lead(II) (**1a**) and tin(IV) (**1b**) [5–8,10], with the 2:1 Tm^R:E (**2**) complexes being represented by bismuth(III) [8,12]. However, alternative structural motifs may be isolated if the conditions are carefully manipulated. Where non-exchangeable bulky alkyl groups are present at the central atom (e.g., triscyclohexyl-tin(IV)) it was found [9] that the ligand is restricted to a simple monodentate co-ordination mode (**3**). A similar contrast in motifs is observed in the chemistry of lead(II), which has been shown to adopt two distinct structural types [10,11]. In the presence of non-co-ordinating anions simple salts such as $[Pb(\kappa^3\text{-}Tm^{Ph})][ClO_4]$ (**1a**) are obtained [10]. However, when the ratio of ligand to metal is increased to 2:1 an intriguing bis-thiaimidazolylborate adduct (**4**) is obtained [11] where one ligand is κ^3, typical of the 1:1 adducts, but the second ligand is inverted, weakly associating with the metal fragment through three thione donors and the hydrogen atom on the

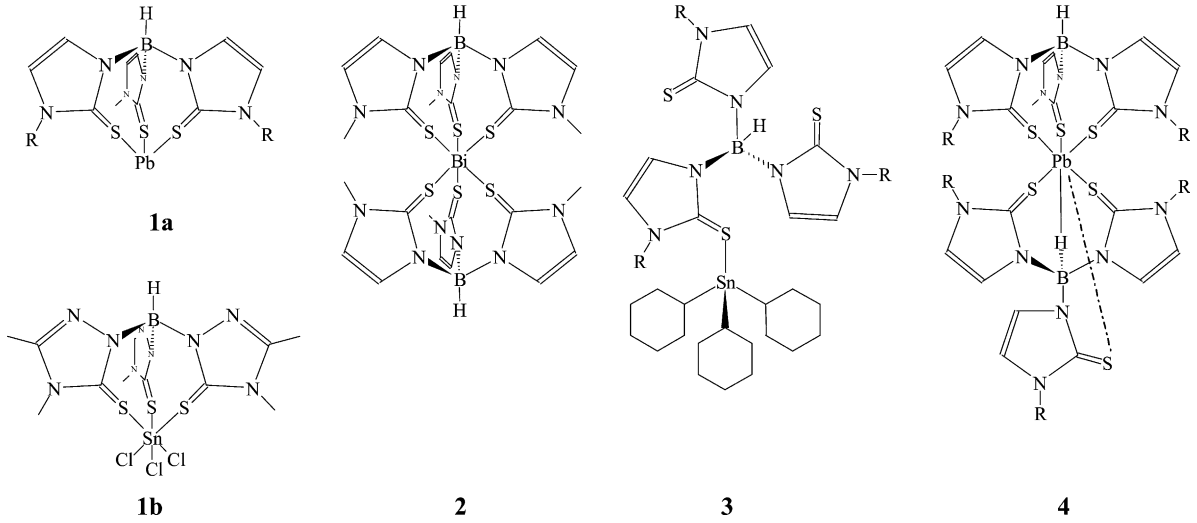

Fig. 1. The reported structural motifs of the thiaimidazolylborates with the elements from groups 13–15.

boron. That lead adopts this fascinating structure has been ascribed to the increased steric bulk of the Tm^R ligand (R = phenyl) which prevents the close approach of the two scorpionate ligands in a facial mode. The metal hydrogen interaction displayed by **4** has subsequently been observed in a number of other structures [13,14] and its has been the subject of some discussion. It has been described variously as an inverse hydrogen bond ($H^- \rightarrow M$), as an agostic interaction and as an electrostatic interaction, but as yet no consensus has been reached.

The contrast in the structures of "$[Pb(Tm^{Ph})_2]$" [10,11] and $[Bi(Tm^{Me})_2]$ [8,12] is very evident and is presumably driven by the steric effect of the phenyl substituents. In almost all of the bis-κ^3-Tm^{Me} adducts with metals the S–M–S angles between the two coordinated scorpionates is found to be less than 90°. This effect is seen also in six coordinate thiourea complexes of lead [15] and bismuth [16] and is thus not unique to soft scorpionates. However, this observation further supports the hypothesis that the motif displayed by **4** may result from steric hindrance. Although Parkin et al have been successful in structurally characterising two Tm^{Ph} lead species [10,11] we remain unsuccessful in our attempts to fully characterise the parent Tm^{Me} lead species [12] and an argument based on steric effects cannot conclusively be made. As such, it was postulated that by decreasing the size of the central atom we could increase the steric interactions between the Tm^{Me} ligands. The implications are that moving from the sixth period elements into the fourth period (namely arsenic) we should increase the preference of the complexes formed to adopt structures analogous to those reported for lead (**1a** and **4**) over those reported for bismuth (**2**). The comparison between bismuth and tin and lead would be best served if the structural aspects of tin chemistry were expanded further and we have thus included these species in this report.

2. Experimental

Unless otherwise stated, all chemicals were commercially obtained. Sodium hydrotris(methimazolyl)borate (NaTm) was prepared by published methods [17]. No precautions were taken to exclude air or moisture.

2.1. Reaction of AsI_3 with NaTm

Arsenic(III) iodide (0.110 g, 0.24 mmol) was dissolved in chloroform (5 ml) and a solution of $NaTm^{Me}$ (0.181 g, 0.48 mmol) in chloroform (15 ml) was added. After stirring for 24 h the resulting orange solid was filtered off. Recrystallisation from DMF by vapour diffusion with diethyl ether yielded red-orange crystals. Yield: 90 mg; 41%. Found: C, 31.78; H, 3.66; N, 17.34. Expected for $C_{24}H_{32}AsB_2IN_{12}S_6$: C, 31.89; H, 3.54; N, 18.59. ^1H NMR (400.1 MHz; δ DMSO-d_6): 7.4 (s, 1H, –CH=), 7.1 (s, 1H, –CH=), 3.6 (s, 3H, $-CH_3$). IR (KBr disc) $\nu_{(B-H)}$ 2433 cm^{-1}.

2.2. Reaction of $SnBr_2$ with NaTm

Tin(II) bromide (0.14 g, 0.5 mmol) was suspended in acetone (50 ml) to which was added NaTm (0.375 g, 1.0 mmol). The mixture was allowed to stir for 1 h after which time the solvent was removed at reduced pressure (16 mmHg) to help nucleate the sodium bromide. The solid obtained was recrystallised from DMF/ether using vapour diffusion to produce orange crystals. Yield: 50% based on $[Sn(Tm^{Me})_2]_2[Tm^{Me}]_2 \cdot DMF \cdot H_2O$. Found: C, 38.17; H, 4.70; N, 21.25. Expected for

$C_{51}H_{73}N_{25}S_{12}B_2O_2Sn$: C, 37.93; H, 4.56; N, 21.68. ^{1}H NMR (400.1 MHz;δ d_6-dmso): 7.8 (d, 1H, –CH=, $J_{H–H}$ 2 Hz, $J_{Sn–H}$ 8.8 Hz), 7.6 (d, 1H, –CH=, $J_{H–H}$ 2 Hz, $J_{Sn–H}$ 8.8 Hz), 6.8 (d, 1H, –CH=, $J_{H–H}$ 2 Hz), 6.4 (d, 1H, –CH=, $J_{H–H}$ 2 Hz), 3.65 (s, 3H, $–CH_3$), 3.4 (s, 3H, $–CH_3$), 2.91 (s, 3H, DMF), 2.75 (s, 3H, DMF). IR (KBr disc) $\nu_{(B–H)}$ 2468 cm^{-1}.

2.3. Reaction of SnI_4 with NaTm

Tin(IV) iodide (0.31 g, 0.5 mmol) dissolved in dichloromethane (15 ml) was added drop-wise to a suspension of NaTm (0.375 g, 1.0 mmol) in dichloromethane (10 ml). The mixture was allowed to stir for 1 h after which time the solvent was removed at reduced pressure (16 mmHg) to help nucleate the sodium iodide. The orange solid was extracted with warm dichloromethane (2×50 ml), filtered and the solvent volume reduced to 25 ml. The yellow solid obtained was recrystallised from DMF by vapour diffusion with diethyl ether.

The orange solid remaining in the filter funnel was extracted with DMF (5 ml), filtered through celite and placed in a vapour diffusion chamber with diethyl ether. Yellow crystals suitable for X-ray diffraction were obtained overnight. Yield: 200 mg; 36%. Found: C, 27.08; H, 3.34; N, 15.32. Expected for $C_{24}H_{32}N_{12}S_6B_2SnI_2$: C, 26.81; H, 3.00; N, 15.63. ^{1}H NMR (400.1 MHz; δ $CDCl_3$): 7.8 (d, 1H, –CH=, $J_{H–H}$ 2 Hz, $J_{Sn–H}$ 8.8 Hz), 7.6 (d, 1H, –CH=, $J_{H–H}$ 2 Hz, $J_{Sn–H}$ 8.8 Hz), 3.6 (s, 3H, $–CH_3$). IR (KBr disc) $\nu_{(B–H)}$ 2468 cm^{-1}.

2.4. X-ray crystallography

Crystals were coated in mineral oil and mounted on glass fibres. Data were collected at 123 K on a Nonius Kappa CCD diffractometer using graphite monochromated Mo Kα radiation. The heavy atom positions were determined by Patterson methods and the remaining atoms located in difference electron density maps. Full matrix least-squares refinement was based on F^2, with all non-hydrogen atoms anisotropic. While hydrogen atoms were mostly observed in the difference maps, they were placed in calculated positions riding on the parent atoms. *Notes*. $[As(Tm^{Me})_2]I \cdot 2DMF \cdot Et_2O$: the diethyl ether molecule is disordered over two sites. $[Sn(Tm^{Me})_2]I_2 \cdot Et_2O$: the diethyl ether molecule site is only partially occupied and not particularly well defined. The molecule is set at 50% occupation and refined isotropically. $[Sn(Tm^{Me})_2]_2[Tm^{Me}]_2 \cdot DMF \cdot \frac{1}{2}H_2O$: the free Tm^{Me} ligand is disordered over two equally occupied sites and both the DMF and water molecule sites are partially occupied (set at 50% and 25%, respectively). The structure solution and refinement used the program SHELX 97 [18] and the graphical interface WinGX [19]. A summary of the crystallographic parameters is given in Table 1. Selected metrical parameters are reported in Table 2.

3. Results and discussion

The reactions of the halides of the main group elements arsenic and tin with NaTm are effected with ease. In each case the initial reactions were conducted using excess ligand to allow the species to adopt their favoured configuration. From the reaction of arsenic triiodide we obtained the $[As(\kappa^3\text{-}Tm^{Me})_2]^+$ cation, i.e., a sandwich motif (Fig. 1), iso-structural with the cation previously reported [12] for its heavier group 15 partner viz. $[Bi(\kappa^3\text{-}Tm^{Me})_2]^+$, (Table 2). The arsenic atom is situated within an almost regular S_6 octahedral environment. Consistent with other bis κ^3 motifs the intra ligand ∠S–E–S angles are slightly more obtuse than the inter ligand ∠S–E–S angles. The non-bonded distance between the bridgehead boron and chelated main group cation is shorter for arsenic than for bismuth by a distance commensurate with the difference in their covalent radii (1.20 versus 1.42 Å) indicating that the eight membered rings ($BN_2C_2S_2E$) are flexing to accommodate smaller and larger cations, respectively. This is exemplified in the ∠H–B–N–C torsion angles, which are a measure of the twist of the heterocycle plane from the H–B…E plane. The torsion angles, and thus the twist. are found to be lower for the smaller central arsenic cation.

Although the interaction of sulphur with arsenic(III) has an established importance in biological chemistry [20], the range of structurally characterised compounds are limited especially those which have a high coordination number AsL_xS_n $(n = 2-6, \times + n > 3)$. Although a range of tris–dithiocarbamate adducts have been reported [21] they provide a poor comparison with the cation generated here as they form three highly constrained four membered rings, with significant asymmetry in the As–S distances (i.e., 2.35–2.82 Å) and ∠S–As–S angles. Perhaps the best comparison is with the arsenic adduct of the bis-molybdosulfido cubane of Hernandez-Molina [22] (Table 2). Considering the disparate nature of these two ''ligands'' the bond distances are similar but with the cubane As–S distances being slightly shorter due to the greater charge on the sulphur in the vertices of the cubes. The cubane motif constrains the angles to such an extent that the inter ligand angles are now smaller than 90° whereas the intra ligand angles rise to values greater than 90°.

Our attempt to change the structural motif of the group 15 Tm adducts by simply moving to a smaller cation has been thwarted by the Tm ligand system. The impressive flexibility of the eight membered chelates would seem to be able prevent the pendant methyl groups from a adopting sterically compromising positions which would prevent the formation of the the bis κ^3-Tm^{Me} species and could possibly lead to the formation of charge a separated anion similar to that reported for lead [11]. There is no evidence in the NMR to suggest that there is any fluxionality in this system in solution as is found with the pyrazolylborato adducts of arsenic [23]. Thus the integrity of the bis κ^3-Tm motif would seem to be assured in solution also.

A simple rationalisation of the chemistry of observed for arsenic and bismuth would be that the charge on the central atom may preclude the inversion of one of the Tm ligands and thus the formation of the charge separated species. Thus since we have had little success in retrieving a structure of lead (II) with Tm [12], we turned our attention to tin(IV) and tin(II) again in a further attempt to increase the influence of steric bulk around a smaller central atom (Sn versus Pb).

In contrast to the structures observed by Bailey et al. [8] (**1b**) and Santini et al. [9] (**3**), our reaction with stannic iodide produced yet another bis κ^3-Tm motif in formation of the $[Sn(\kappa^3\text{-}Tm^{Me})_2]^{2+}$ cation (Fig. 2). Unlike arsenic, tin has a greater propensity to adopt an S_6 coordination environment. Examples exist for the ubiquitous dithiocarbamates [24] and dithiolenes [25]. It is thus curious that this motif has not been reported previously by other workers. On comparison with the structure of $[As(\kappa^3\text{-}Tm^{Me})_2]^+$ above (Fig. 1, Table 1) the ∠S–Sn–S angles are found to follow a similar pattern, with the intra ligand angles being larger than the inter ligand angles by a substantial amount (6°). Considering the similarities in the covalent radii for the two ions, the similarity in the E–S distances, the E…B distance, the S…S distances and torsion angles (∠HBNC) is again not surprising.

Although Bailey et al. [8] and Santini et al. [9] have looked at the high oxidation state complexes of tin, the compounds of tin(II) remain unexplored. From our initial reactions in acetone we retrieved a curious tin(IV) product $[Sn(Tm^{Me})_2]_2[Tm^{Me}]_2$ in good yield. Crystal-

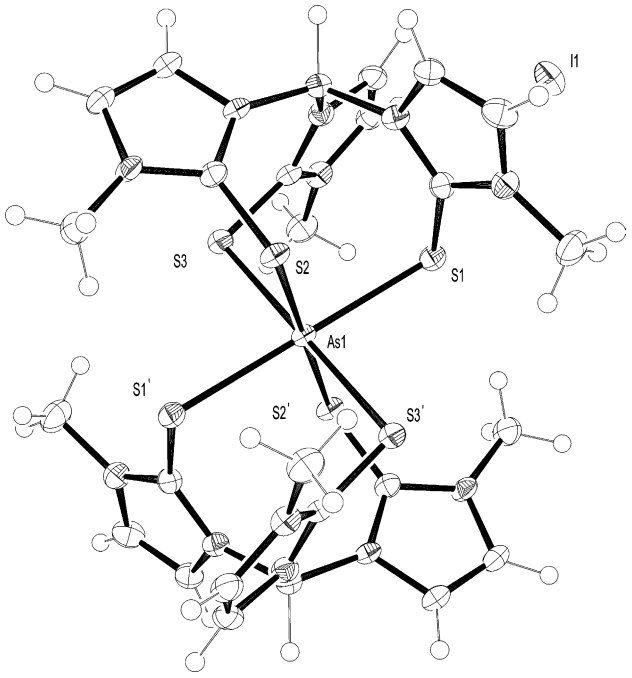

Fig. 2. The X-ray crystal structure of $[As(\kappa^3\text{-}Tm^{Me})_2]^+$ cation. The key bond distances are given in Table 2.

lography reveals that the structure of the $[Sn(\kappa^3\text{-}Tm^{Me})_2]^{2+}$ motif is isostructural with that obtained from the reaction with stannic iodide (Fig. 3) and confirms the presence of a non coordinated ligand. The facile oxidation of tin(II) was surprising. However, on repeating the reaction under anaerobic conditions we continued to isolate the Tin(IV) adduct. NMR/IR analysis provided no evidence for the presence of a tin(II) complex, but again confirmed the presence of the $[Sn(Tm^{Me})_2]^{2+}$ cation (with $^{117/119}Sn$ satellites) and of the non-coordinated ligand. In general one would expect the soft scorpionate

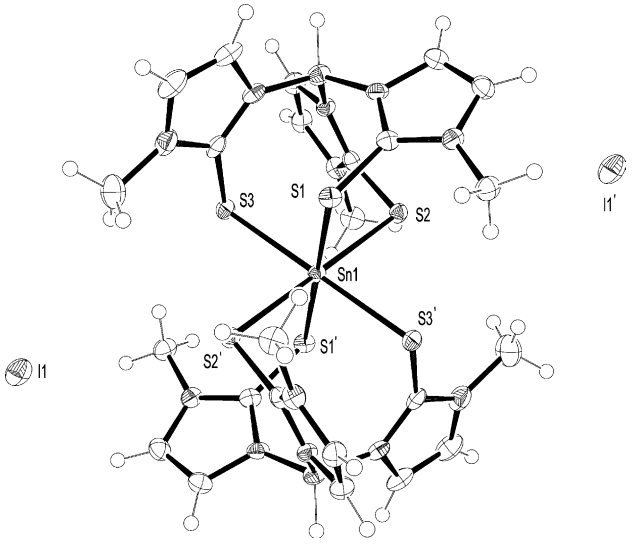

Fig. 3. The X-ray crystal structure of the $[Sn(Tm^{Me})_2]^{2+}$ cation.

ligand to support tin(II) in preference to tin (IV) and consequently it is curious that the Tin(II) adducts of the pyrazolylborates (viz. $\kappa^3Tp\kappa^2TpSn(II)$, $\kappa^3TpSnCl$) have been reported [26,27]. Similarly although a range of unstable six coordinate $TpSnX_3$ (X = Cl, Me, pz_3) species [23,28,29] are isostructural with **1b**, a motif similar to that shown in Fig. 2 remains absent. Thus it seems that our understanding of the structural preferences and redox properties of tin in a hard and soft coordination environment is not yet complete.

4. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 215615–215617. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Received 30 June 2003; accepted 3 September 2003

Abstract

A comprehensive survey of the syntheses and of spectroscopic, analytical and structural data of silver(I), copper(I), and copper(II) complexes containing scorpionate and related ligands and prepared by this group has been reported. This review outlines the possible strategies that can be used in this field for the synthesis of analogous complexes. Statistical analyses of structural features are reported as a function of (1) the steric and electronic properties of the scorpionate ligand, (2) the steric and electronic properties of eventual ancillary ligands, and (3) the nature of the counter-ion. The most important results obtained in this field have been also summarized.

Abbreviations

We have employed the method of representing the tris(pyrazolyl)borate ligands proposed by Curtis [1,2] and the rules recently described by Trofimenko for the "second generation" scorpionates [3]. However a more detailed list of abbreviations employed is below.

HAz	azole
Bn	benzyl
Bp^x	dihydrobis(pyrazolyl)borate
cy	cyclohexyl
dppm	bis(diphenylphosphino)methane
dppe	1,2-bis(diphenylphosphino)ethane
dppp	1,3-bis(diphenylphosphino)propane
dppb	1,4-bis(diphenylphosphino)butane
dppf	4,4′-bis(diphenylphosphino)ferrocene
Hbtz	1,2,3-benzotriazole
Him	imidazole
Hmimt	1-methy-2-mercaptoimidazole
Hpz^x	pyrazole
Htz	1,2,4-triazole
Me	methyl
Mes	2,4,6-trimethylphenyl
Ph	phenyl
pz^oTp^x	tetrakis(pyrazolyl)borate
Tm	hydrotris(3-methyl-2-thioxo-1-imidazolyl)borate
Tp^x	tris(pyrazolyl)borate
Tpms	tris(pyrazolyl)methanesulfonate

1. Introduction

Since the first report of Trofimenko [4], poly(pyrazolyl)borates (Fig. 1) and in particular tris(pyrazolyl)borates (Tp^x), have been extensively employed as anionic σ-donor ligands in a wide variety of metal complexes [3]. They form stable complexes in which they often act as tridentate, facial, five-electron donors (covalent formalism for electron counting [5]). These ligands are extremely versatile because the number of pyrazolate groups and the substituents thereon or at the B center can be easily modified in order to obtain ligands with different steric and electronic profiles. They have been extensively used to prepare complexes of main and transition group metals and are particularly useful for the synthesis of monomeric derivatives in which the coordination sphere about the metal can be carefully controlled.

Modifications of poly(pyrazolyl)borates can be made by changing the substituents on the hererocyclic ring or also by replacement of the pyrazolyl with triazolyl [6,7], imidazolyl [8], methimazolyl [9,10], thioether [11,12], thiazolyl and benzothiazolyl [13] and mercaptotriazolyl

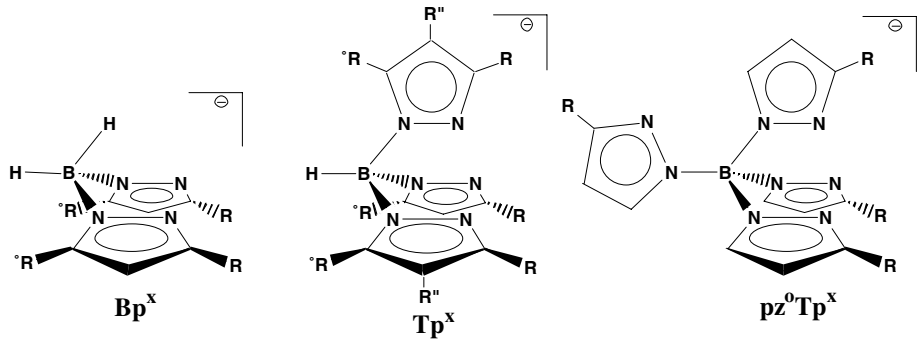

Fig. 1.

moieties [14,15]. Another important variation can be effected by replacement of the boron bridging atom with carbon [16], silicon [17], or phosphorus [18,19].

Poly(pyrazolyl)alkanes (Fig. 2) $[R^*_nC(pz^x)_{4-n}]$ ($n = 0$, 1 or 2, $R^* = H$ or a generic substituent), for example, are stable and flexible polydentate ligands isoelectronic and isosteric with poly(pyrazolyl)borate. They can be prepared readily and in good yields by the procedures reported by Reger [20] and Elguero [21]. Various substituents may replace each hydrogen atom, so that electronic and steric effects can be varied nearly at will. These molecules are generally very stable towards chemical attack, for example, against both oxidizing and reducing agents.

Copper is the center of active sites of many metalloenzymes and metalloproteins, such as hemocyanin and nitrite reductase. In such metalloenzymes and metalloproteins, each copper atom is coordinated by the three nitrogen atoms of three imidazoles or histidine groups of proteins. In 1973 the use of the Tp anion has permitted isolation of the first copper carbonyl complex TpCu(-CO) [22]. Recently, interest in copper poly(pyrazolyl)borate complexes has been aroused by their resemblance to the active sites in some copper-containing metalloproteins, Tp^{iPr2} and Tp^{Ph2} being useful in the revealing the mode of dioxygen binding at the copper site of hemocyanin [23,24], while Tp^{tBu} and Tp^{Ph2} have assisted the development of models for nitric oxide adducts of mononuclear copper in nitrite reductase [25–28]. $[Cu(Tp^*)(C_2H_4)]$ has also been reported as a catalyst for carbene and nitrene transfer to form cyclopropanes, cyclopropenes, and aziridines [29]. Very recently a series of $[Cu(Tp^x)]$ derivatives, generated in situ, has been reported to catalyze the cyclopropanation of terminal olefins as well as the industrially important 2,5-dimethyl-2,4-hexadiene [30,31].

Dias and coworkers in 1996 reported some group 11 metal complexes of fluorinated tris(pyrazolyl)borates [32] and very recently has described the synthesis of $[Ag(Tp^{(CF3)2})\{OC(OCH_3)\}_2CN_2]$ which features a diazoalkane moiety with Ag–O (rather than Ag–N) interactions [33]. The stability of this compound suggests that the metal–oxygen bonded species may also play an important role in metal-mediated activation of diazoketones.

On the basis of the increasing interest in this field and on the potential applications of silver and copper scorpionate complexes we have started a systematic investigation concerning the reactivity of scorpionate-like ligands towards silver(I), copper(I) and copper(II), in the presence of auxiliary ligands such as phosphines, isonitriles or neutral monodentate azoles. Here we report a survey of the results obtained by us in the last decade. A summary of the most relevant molecular pa-

2. Results

2.1. Copper poly(pyrazol-1-yl)borates

2.1.1. Bis(pyrazol-1-yl)borates (Bp^x) derivatives

Dihydrobis(pyrazolyl)borate and other scorpionate copper(I) (triaryl)phosphino complexes $[Cu(Bp^x)(PR'_3)_2]$ were firstly reported by Bruce and coworkers [34–37], and further spectroscopically investigated by us in 1995 [38]. These compounds have been only recently structurally characterized [39]. Monophosphine $[Cu(Bp^x)(PR'_3)]$ adducts may be obtained with sterically hindered donors such as P(*o*-tolyl)$_3$, the copper centre in these cases achieving three-coordination by way of bidentate chelation of the ligand (κ^2-hapticity), whereas less sterically hindered phosphines such as $PMePh_2$ and PPh_3 allow the attainment of 1:2 $[Cu(Bp^x)(PR'_3)_2]$ adducts (Scheme 1). Dias has recently reported that fluorinated Bp^x ligands yield compounds of similar stoichiometry but with the scorpionate acting as N,H-donor [40].

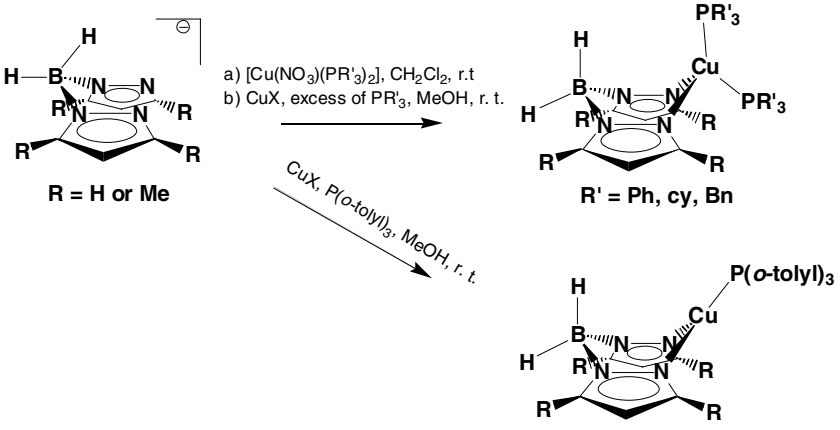
It has been previously reported that $[M(Bp^x)(L)_2]$ may be subject to boat inversion [41]. In the ^{31}P NMR spectrum of our $[Cu(Bp^x)(PR'_3)_2]$ complexes only one sharp peak is observed, indicating that, unless there is fortuitous synchronicity, the boat inversion is operating at room temperature.

2.1.2. Tris(pyrazol-1-yl)borates (Tp^x) derivatives

The first systematic investigation of triaryl- [42] and tricyclohexylphosphine [43] copper(I) complexes containing anionic tris(pyrazol-1-yl)borates, prepared from the metathetic and displacement reaction (1) in chlorinated solvents, was reported seven years ago.

$$[Cu(NO_3)(PR'_3)_2] + MTp^x \rightarrow [Cu(Tp^x)(PR'_3)] + PR'_3 + MNO_3 \quad (M = Na \text{ or } K, R = cy \text{ or aryl}) \quad (1)$$

Four-coordinate Cu(I) species, in a tetrahedral configuration strongly distorted because of the bulky PR'_3 and Tp^x ligands, were always obtained (Fig. 3). We have



Scheme 1.

R' = Ph, Bn, cy, *o*-tolyl, *m*-tolyl, *p*-tolyl, Mes

Fig. 3.

found that these compounds can be prepared more efficiently by using a Cu(I) starting material such as [CuBr(Me_2S)] or [$Cu(C_6H_6)_{0.5}(O_3SCF_3)$]$_2$ [39]. The [$Cu(Tp^x)(PR'_3)$] complexes are generally soluble in chlorinated solvents, acetone and DMSO in which they are non-electrolytes. They are air-stable but decompose in solution in accordance with non-ionic equilibria such as (2), followed by disproportionation of the well known polynuclear complexes [44–46] to copper metal and copper(II) species (3). Attempted reactions of [$Cu(Tp^x)(PR'_3)$] with imidazole, pyrazole, bipyridyl or phenanthroline were unsuccessful, the starting materials always being recovered.

$$n[Cu(Tp^x)(PR'_3)] \rightarrow [Cu(Tp^x)]_n + nPR'_3 \quad (2)$$

$$2[Cu(Tp^x)]_n \rightarrow n[Cu(Tp^x)_2] + nCu \quad (3)$$

Kitajima reported that displacement of the carbonyl group in a mononuclear copper complex [$Cu(Tp^*)(CO)$] with PPh_3 can afford [$Cu(Tp^*)(PPh_3)$] quantitatively. The reaction of [$Cu(Tp^*)(PPh_3)$] with an excess amount of PhIO results in the formation of a μ-oxo dinuclear copper(II) complex [$Cu(Tp)]_2O$ which immediately converts to a bis(μ-hydroxo) dinuclear species [$Cu(Tp)]_2(\mu\text{-}OH)_2$ [47].

Volatility studies, electrospray mass spectra and IR in vapour phase have been carried out for selected [$Cu(Tp^x)(PR'_3)$] complexes [48,49]. The volatility has been related to structural features and molecular parameters of the copper(I) complexes. These compounds are much more volatile than copper(I) pyrazolonates [48] and seem to be promising precursors for thin film deposition as the heterocyclic rings in the ligand are not involved in the conjugation and do not contain additional donor centres. XRD data of films obtained from metal organic chemical vapor deposition MOCVD on [$Cu(Tp^x)(PR'_3)$] [48] and [$Cu(Bp^x)(PR'_3)_n$] ($n = 1$ or 2) complexes [49] have been also reported.

By using the water-soluble P-donor ligand 4-(diphenylphosphane)benzoic acid, some water-soluble copper(I) complexes [$Cu(Tp^x)\{PPh_2(4\text{-}C_6H_4COOH)\}$] have recently been obtained [50] which have been investigated by chemiluminescence techniques in order to evaluate their superoxide scavenging activity.

A series of $Cu(Tp^x)_2$ derivatives ($Tp^x = Tp^{Me3}$, Tp^{4Me}, Tp^{*Cl}, Tp^{3Me}) were synthesised and spectroscopically characterized in 1999 [51]. These complexes, with the metal in a strongly distorted octahedral environment (Fig. 4) (X-ray studies), have been also characterized by fast atom bombardment spectrometry and magnetic susceptibility measurements.

2.1.3. Tetrakis(pyrazol-1-yl)borate (pz^oTp^x) derivatives

Tetrakis(pyrazolyl)borate copper(I) bis(triaryl)phosphino species [$Cu(pz^oTp^x)(PR'_3)_2$] (Fig. 5(a)) were reported in 1995 [38] and characterized by way of IR, ^1H, ^{13}C and ^{31}P NMR measurements. These compounds are more stable in solution with respect to the analogous Tp^x and Bp^x derivatives. They are fluxional in solution, all pyrazolyl groups being equivalent down to −60 °C. Selected [$Cu(pz^oTp^x)(PR'_3)_2$] derivatives have been characterized by IR in the gas phase across a wide temperature range, confirming the stability of these species and suggesting the molecular structure in vapour to be similar to that previously determined by single crystal X-ray studies. The dependence of the volatility on the number of the pyrazolyl moieties has been discussed, the pz^oTp^x derivatives being more volatile with respect to Bp^x and Tp^x derivatives containing the same phosphine.

More recently monophosphine [$Cu(pz^oTp^x)(PR'_3)$] (Fig. 5(b)–(c)) species have been reported as well [39] with two different structurally authenticated arrays: (i) [$Cu(pz^oTp^{Me})(Pcy_3)$], with a three coordinate $PCu(N)_2$ coordination environment and the donor with κ^2-hapticity and (ii) [Cu(pzTp)(P(*p*-tolyl)$_3$)], with a four coordinate $PCu(N)_3$ metal core and the scorpionate with κ^3-hapticity.

The strongly distorted octahedral $Cu(pz^oTp^{Me})_2$ and $Cu(pz^oTp^{4Me})_2$ have been also described. In these compounds the ligands act as tripodal N_3-donors; complexation of the fourth pyrazole ring and formation of

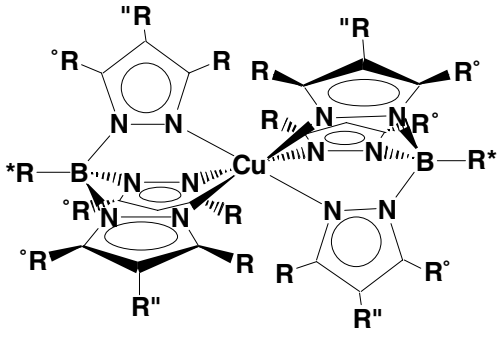

Fig. 4.

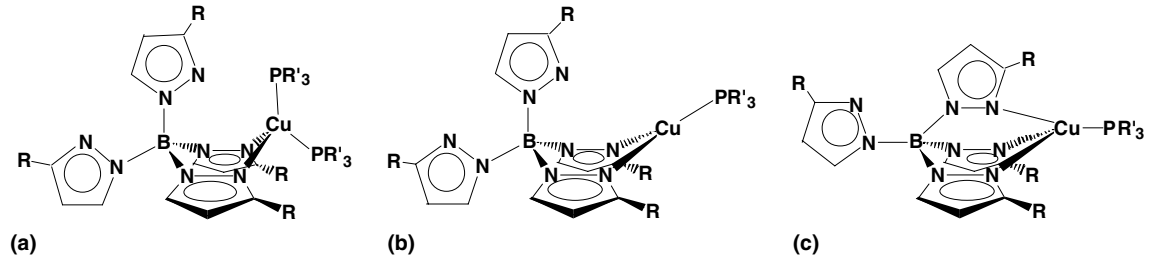

Fig. 5.

polynuclear or oligonuclear species has never been observed [51].

2.2. Copper poly(triazol-1-yl)borates

Although a cobalt complex of hydrotris(1,2,4-triazolyl)borate was reported by Trofimenko in 1967 [52], the chemistry of poly(triazolyl)borate ($H_nB(tz)_{4-n}$) species (Fig. 6) has remained undeveloped. Two features make them attractive candidates for further examination: they should be electron-withdrawing relative to their pyrazole-based counterparts, and the properties of metal complexes should differ accordingly; the exo ring nitrogen atoms of triazole-based ligands may bridge between metal centers, thereby creating coordination polymers with interesting solid state structural and optical properties as recently shown by Janiak [53]. We have recently reported several copper(I) coordination polymers as well as mononuclear copper complexes derived from poly(1,2,4-triazolyl)borate ligands and triorganophosphines [54]. The structurally authenticated arrays fall into four different types (Fig. 7): (a) discrete mononuclear bis(triazolyl)boratebis(triorganophosphine) copper(I) species; (b) discrete mononuclear tris(triazolyl)borate-(triorganophosphine)copper(I) species, with CuN_3P coordination spheres; (c) one dimensional polynuclear species containing bis(triazolyl)borate wherein the triazolyl groups are coordinated throughout both N2 and N4 within CuN_3P coordination spheres; (d) one-dimensional polynuclear species containing tris(triazolyl)borate, wherein one of the triazolyl rings is uncoordinated and the other two bridge through the N to successive copper atoms. Two $[Cu(H_nB(tz)_{4-n})\{PPh_2(4\text{-}C_6H_4COOH)\}]$ ($n = 1$ or 2) have been also reported [50].

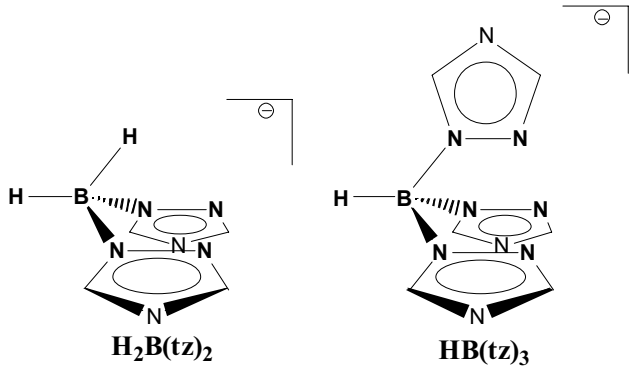

Fig. 6.

2.3. Copper poly(benzotriazol-1)borates

A series of copper(I)$(PR'_3)_n$ ($n = 1$ or 2) complexes of $\{H_xB(btz)_{4-x}\}$ (Fig. 8) ($x = 1$ or 2) has been synthesised and characterized by X-ray studies, and by IR and NMR spectroscopy [55]. 1:1:1 and 1:2:1 Cu:PR'_3:$\{H_xB(btz)_{4-x}\}$ species were afforded, depending on the

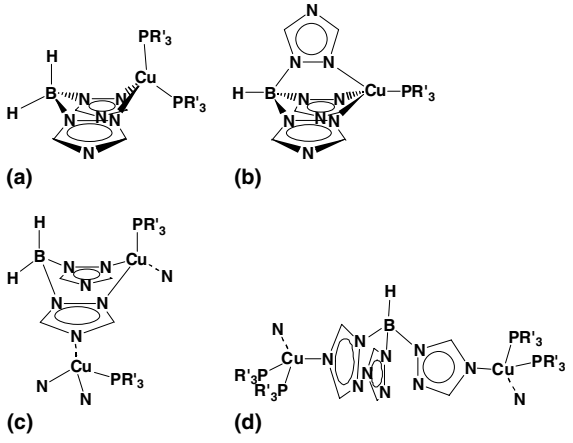

Fig. 7.

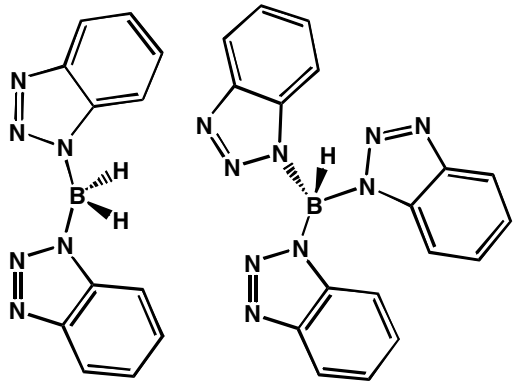

Fig. 8.

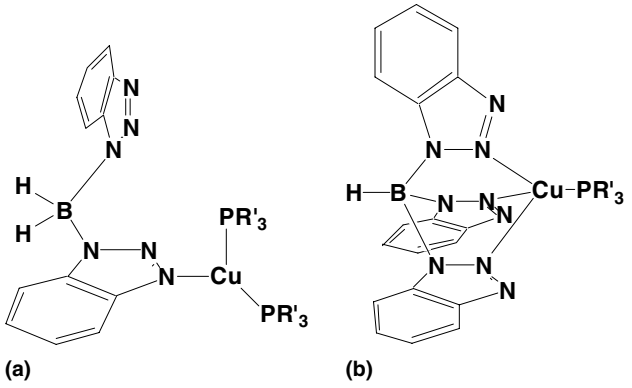

Fig. 9.

nature of the P-donor, and in some cases, on the reaction conditions employed. All species are of limited stability in solution and fluxional at room temperature. The $\{H_xB(btz)_{4-x}\}$ ligand is able to coordinate in uni-, bi- or tri-dentate fashion, coordination occurring not only through the three N2 atoms, but also through one N3 atom. Two structurally authenticated arrays were found: (i) $[Cu\{H_2B(btz)_2\}(PBn_3)_2]$ with a three coordinate P_2CuN coordination sphere and the donor coordinated throughout only one N3 atom (Fig. 9(a)); (ii) $[Cu\{HB(btz)_3\}\{P(m\text{-tolyl})_3\}]$ with a four coordinate $PCuN_3$ coordination sphere, and the $\{HB(btz)_3\}$ acting as tripodal donor by way of all N2 atoms (Fig. 9(b)).

A copper(II) derivative, $[Cu\{HB(btz)_3\}_2]$, has also been reported and characterized by IR and EI MS spectra [56].

2.4. Copper(I) hydrotris(3-methyl-2-thioxo-1-imidazolyl)borates

1:1:1 $[Cu(Tm)(PR'_3)]$ triorganophosphine copper(I) complexes containing the anionic, potential S_3-donor face-capping ligand hydrotris(3-methyl-2-thioxo-1-imidazolyl)borate Tm^- [9] (Fig. 10) were synthesised from

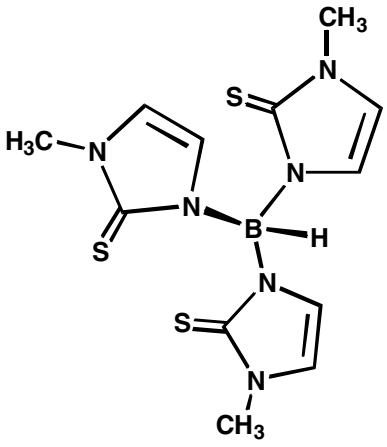

Fig. 10.

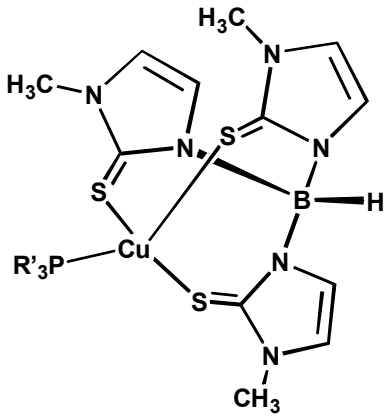

Fig. 11.

K(Tm), CuCl and the corresponding P-donor [57]. The copper atoms are tetracoordinated, the Tm^- behaving as a tripodal donor (Fig. 11). In the absence of P-donors Cu(I) salts react with K(Tm) yielding a possibly polynuclear $[Cu(Tm)]_n$ species which is unreactive toward NH_3, CS_2, H_2O and CO, but reacts with pyridine yielding [Cu(Tm)(py)]. $[Cu(Tm)]_n$ reacts with H_2O_2 yielding the poorly soluble $[Cu(mimt)]_n$ (Hmimt = 3-methyl-1-imidazoline-2-thione) upon breaking of the B–N bond in the mercaptoimidazolylborate ligand.

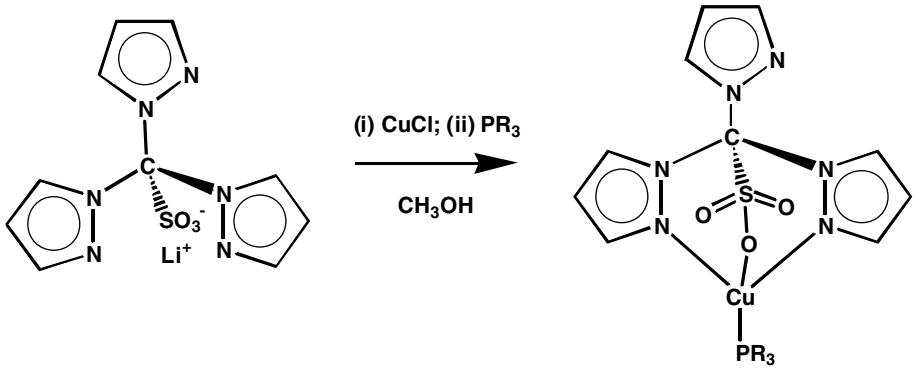
2.5. Copper(I) heteroscorpionate derivatives

Interest in the coordination chemistry of new heteroscorpionates monoanionic ligands, N-, O- or S-donor is increasing. Some recent papers report the synthesis of the tris(pyrazol-1-yl)methane sulfonate ligand (Tpms) [58] which is highly water soluble and stable over a wide pH range ligand. Its interaction with CuCl in the presence of PR'_3 has provided a series of new copper(I) coordination compounds of formula $[Cu(Tpms)(PR'_3)]$ (Scheme 2) and also a copper(II) species $[Cu(Tpms)_2]$ when R is cyclohexyl. [Cu(Tpms)(PPh_3)] is the first example of structurally characterised complex containing Tpms coordinated to a metal ion in an unusual κ^3-N,N′,O fashion [59].

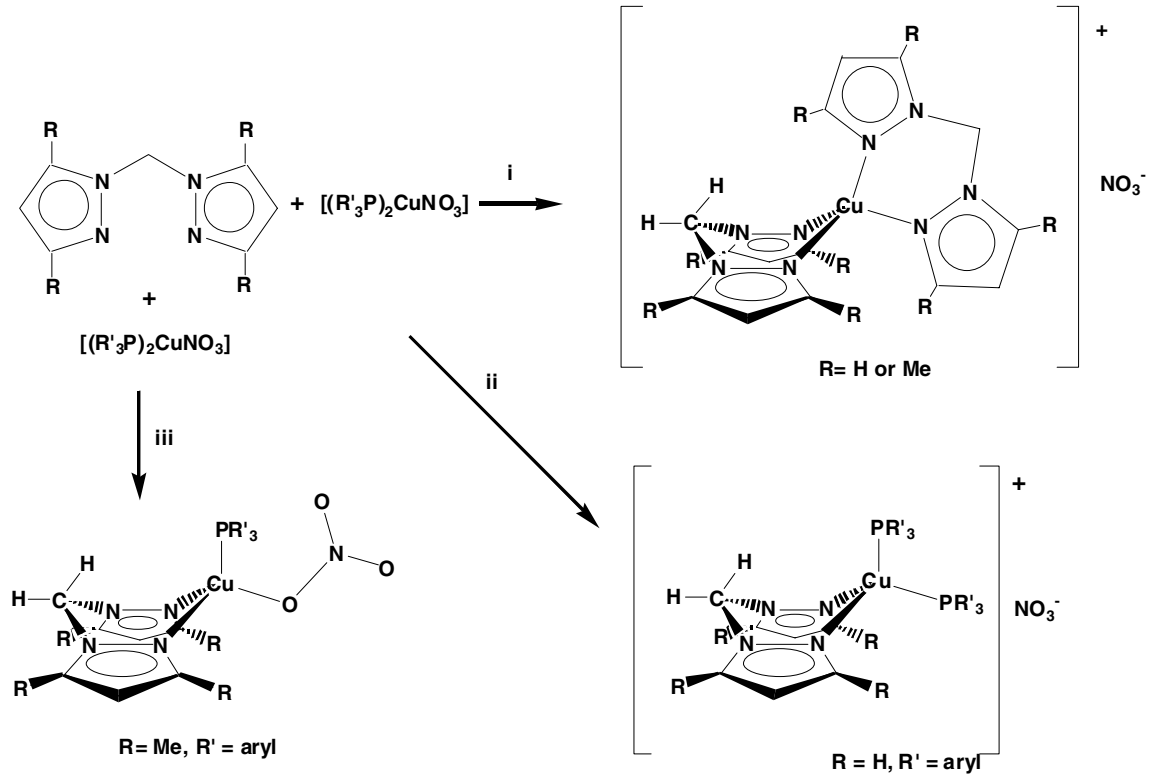
2.6. Copper poly(azol-1-yl)alkanes

2.6.1. Bis(azolyl)alkane derivatives $\{(Az)_2CH_2\}$

The interaction of a bis(azol-1-yl)alkane $(Az)_2CH_2$ (Az = pyrazole or triazole) with $[CuX(PR'_3)_2]$ (X = NO_3, BF_4, ClO_4, halide) [60,61] can yield ionic $[Cu\{(Az)_2CH_2\}(PR'_3)_2]^+X^-$ or neutral $[CuX\{(Az)_2CH_2\}(PR'_3)]$ derivatives upon displacement of X^- or PR'_3, respectively, from the copper coordination sphere. The stoichiometry and structure of the complexes are dependent on the nature of the substituent on the azolyl group and also on the nature of the counter-ion X. As an example in the Scheme 3 [60] the reaction of $[CuNO_3(PR'_3)_2]$



Scheme 2.

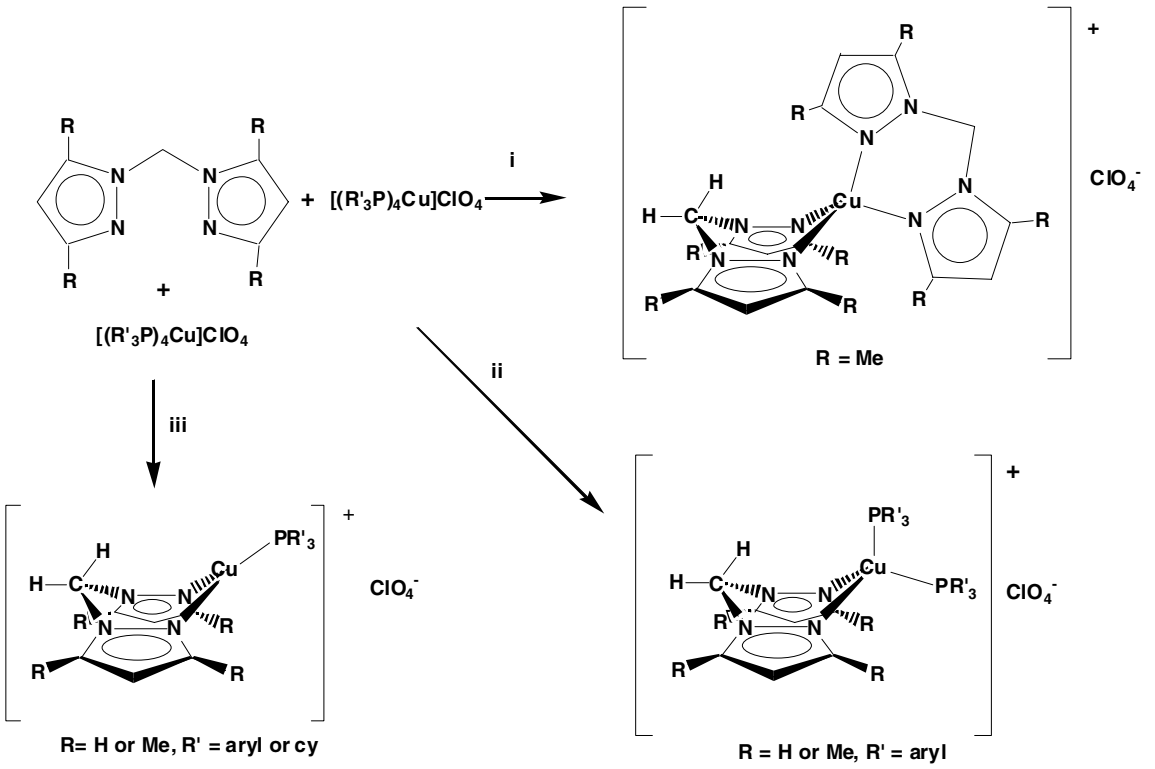


Scheme 3.

with several $(pz^x)_2CH_2$ is described. Displacement of the nitrate is observed with the less hindered and less basic ligands of the family such as pz_2CH_2. Nevertheless, one PR'_3 may be displaced from $[CuNO_3(PR'_3)_2]$ by the more bulky and more basic $(pz^*)_2CH_2$. By contrast, no difference in behaviour has been observed with the arsine and stybine derivatives $[CuNO_3(AsPh_3)_3]$ and $[CuNO_3(SbPh_3)_3]$ which always yield $[CuNO_3\{(pz^x)_2CH_2\}(EPh_3)]$ derivatives. Displacement of all the phosphine ligands to yield $[Cu\{(pz^x)_2CH_2\}_2]^+X^-$ is possible although forcing conditions are required, i.e. strong excess of the N_2-donor ligand in refluxing benzene. The compounds $[Cu\{(Az)_2CH_2\}_2]^+X^-$ can be more efficiently prepared from $[CuNO_3(SbPh_3)_3]$ taking advantage of the decreasing strength of the metal-E bond in the sequence P, As and Sb. The reactivity of the bis(azol-1-yl)alkanes towards $[Cu(PR'_3)_4]ClO_4$ [61] is summarized (Scheme 4).

2.6.2. Tris(pyrazol-1-yl)methanes derivatives $\{HC(pz^x)_3\}$

The interaction of CuX_2 ($X = ClO_4$, NO_3, Cl, Br, O_2CCH_3) with excess of tris(pyrazol-1-yl)methane



Scheme 4.

$HC(pz^x)_3$ yielded $[CuX_2\{(pz)_3CH\}]$, $[\{CuX_2\}_3\{(pz)_3CH\}_2]$ or $[\{Cu\{(pz)_3CH\}_2\}]X_2$ depending on the substituents on the azolyl moiety and, more particularly, on the nature of the counter-ion [62]. All complexes have been characterized by analytical and spectroscopic measurements (IR, UV, and conductivity measurements) and also in the case of the strongly distorted octahedral $[\{Cu\{(pz)_3CH\}_2\}]X_2$ species, by X-ray diffraction studies.

2.7. Silver(I) poly(pyrazol-1-yl)borate

2.7.1. Bis(pyrazol-1-yl)borates derivatives

Silver(I) derivatives containing triorganophosphine and bis(pyrazolyl)borates were synthesised in 2000 by the reaction of $AgNO_3$ with K(Bp) and K(Bp*) in the presence of PR'_3 in methanol [63]. They have been characterized both in the solid and solution state through analytical and spectroscopic measurements. They are air- but not solution-stable. The structures of $[Ag(Bp)(PPh_3)_2]$, $[Ag(Bp^*)(Pcy_3)]$ and $[Ag(Bp^*)(PEtPh_2)]$ have been determined by X-ray crystallographic studies. In these compounds Bp and Bp* are bidentate, with their silver(I) centres adopting tetrahedral (a) or trigonal geometries (b) (Fig. 12). The ^{31}P NMR data show that the bis(triorganophosphino)derivatives are more stable than the mono-organophosphino species and that the stability decreases with increasing cone angle of the P-donor.

We have also investigated the reactivity of K(Bp) and K(Bp*) toward $AgNO_3$ in the presence of bidentate diphosphines such as dppm, dppe, dppp, dppb and dppf. The ^1H and ^{31}P NMR spectra have been interpreted

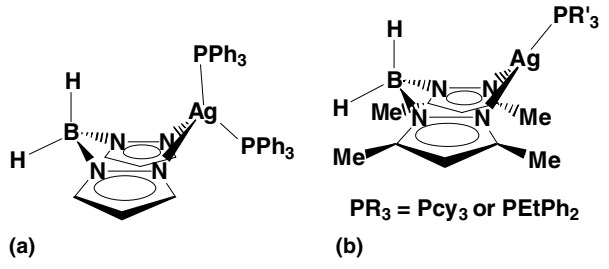


Fig. 12.

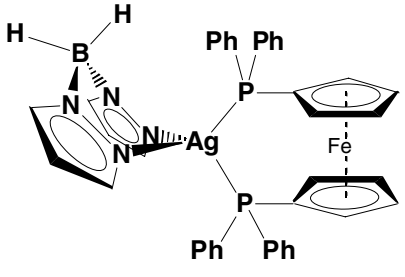

Fig. 13.

with equilibria that involve mono- and di-nuclear species, or the presence of 1:1 and 1:2 silver:diphosphine adducts. The structure of [Ag(Bp)(dppf)] as determined by single crystal X-ray studies indicates the Bp to be bidentate, with the silver centre in a distorted tetrahedral geometry (Fig. 13) [64].

No derivative containing Bp^x and CNR ligands simultaneously coordinated to silver(I) has been to date reported.

2.7.2. Tris(pyrazol-1-yl)borates derivatives

The silver derivatives $[Ag(Tp^*)]_2$, $[Ag(Tp^{4Br})]_2$, and $[Ag(Tp)_2]$ [65], have been synthesised and characterized by IR and NMR spectroscopy. The complexes $[Ag(Tp^*)]_2$ and $[Ag(Tp^{4Br})]_2$ are fluxional with a pyrazolyl ring exchange process occurring rapidly at 293 K, but not at 193 K, whereas $[(Ag(Tp)_2]$ and the crystalline form of $[Ag(Tp^*)]_2$ are not fluxional even at room temperature. The structure of $[Ag(Tp^*)]_2$ as described by McCleverty and coworkers [66] and substantiated by our own work, despite substitution, is not that of its copper(I) homologue, with no bridging pyrazolate units, but rather, that of the unsubstituted parent $[Cu(Tp)]_2$ [44–46] with $N_2M(\mu\text{-}N)$ metal atom environments (Fig. 14), presumably a consequence of greater flexibility contingent upon the incorporation of the larger (silver) metal atom.

Trialkyl- and triaryl-phosphine silver(I) derivatives containing anionic tris(1*H*-pyrazolyl)borates $[Ag(Tp^x)(PR'_3)]$ were prepared from AgX (X = OTf or NO_3), PR'_3 (R′ = Ph, Bn, cy, *o*-, *m*-, *p*-tolyl, Mes) and MTp^x, Tp^x = Tp [67], Tp^{4Br}, Tp^* [68], Tp^{Ph2} [69]; M = Na or K). These air-stable, light sensitive complexes, are non-electrolytes in dichloromethane and acetone, and have been characterized through analytical and spectral measurements. The X-ray diffraction studies show that the silver atom adopts a distorted tetrahedral geometry. $[Ag(Tp^x)(PR'_3)]$ (Fig. 15(a)) generally decompose in acetone solution, even with strict exclusion of oxygen and light. Comparison of the Ag–N bond lengths suggests the bonding of Tp^x to the $Ag(PR'_3)^+$ fragment to be similar despite the steric and electronic differences of the supporting ligand PR'_3. The magnitude

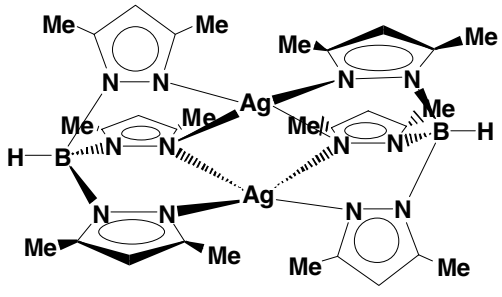

Fig. 14.

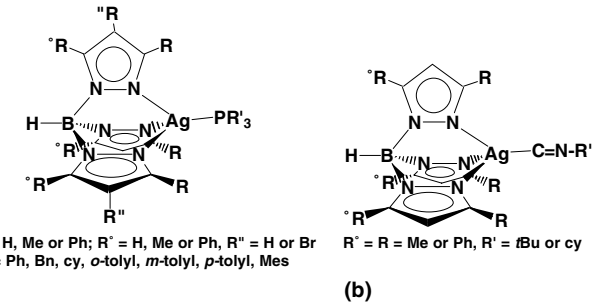

Fig. 15.

of the silver–phosphorus coupling constant and the ^{31}P chemical shift indicate that the structure and the stability of complexes in solution is strongly dependent on the Tolman cone angle and pK_a of PR'_3. We have also found that, in $[Ag(Tp^x)(PR'_3)]$, it is possible to displace the PR'_3 donor from the Ag(I) center with a more basic triorganophosphine, but not with a neutral N-donor mono or bidentate, such as imidazoles, pyrazoles or phenanthroline.

Despite the large number of papers describing Group 11 poly(pyrazol-1-yl)borate derivatives, relatively little attention has been devoted to systems which also contain small unsaturated molecules such as CO and CNR [70–75]. Complexes of the formula $[Ag(Tp^x)CNR]$ ($Tp^x = Tp^*$ or Tp^{Ph2}; R = cy or *t*Bu) (Fig. 15(b)) have been generally obtained independently under the reaction conditions employed when the reaction between Tp^* and silver salts was carried out in the presence of isonitrile ligands [76], no derivatives being obtained when the unsubstituted Tp was used. Those $[Ag(Tp^x)CNR]$ structurally characterized are all unsolvated mononuclear arrays with tripodal Tp^x and unidentate CNR making up the four coordinate environment of the silver atom.

2.7.3. Tetrakis(pyrazol-1)borate derivatives

A systematic investigation of the interaction between silver(I) and the anionic tetrakis(pyrazol-1-yl)borates pzTp and pz^oTp^{Me} was reported in 1998 [77]. These complexes are generally more stable in solution than the analogous derivatives obtained with Bp and Tp ligands. At room temperature, in $CDCl_3$ solution the six-membered AgN_4B rings formed by pzTp and pz^oTp^{Me} are fluxional, probably undergoing a rapid dissociation-reassociation mechanism (boat–boat flip), whereas at low temperature a process which equilibrates only three pyrazolyl rings, with the fourth remaining uncoordinated, is likely. Room-temperature single crystal structural characterizations showed that the scorpionate ligand may be bidentate or tridentate, with a three- or four-coordinate array about the silver. The variation in the silver(I) coordination number and environment in various combinations of various degrees of steric inter-

action among the above entities has been explored and structures similar to those described for Cu(I) have been found [77]. The interaction of pzTp and pz^oTp^{Me} with silver(I) in the presence of chelating bidentate diphosphines was also investigated [64].

The silver(I) tetrakis(pyrazol-1-yl)borates $[Ag(pzTp)]_n$ and $[Ag(pz^oTp^{Me})]_n$ have been also reported and their spectroscopic features and reactivity toward imidazole described [65].

The silver isonitrile derivatives [Ag(pzTp)CNR] and $[Ag(pz^oTp^{Me})(CNR)_x]$ ($x = 1$ or 2) have been successfully synthesised. They exhibit a fluxional behaviour in solution with a pyrazolyl ring exchange process occurring rapidly even at 218 K. Reaction of $[Ag(pz^oTp^{Me})(CNcy)_2]$ with Hmimt and ImH yield $[Ag(mimt)]_n$ and $[Ag(pz^oTp^{Me})(CNcy)(ImH)]$, respectively, whereas reaction of [Ag(pzTp)(CN^{t}Bu)] with ImH yields [Ag(pzTp)(ImH)] [76].

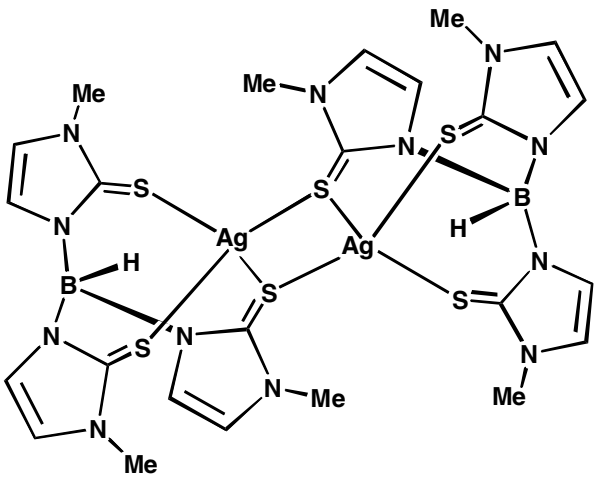

Fig. 17.

2.8. Silver(I) hydrotris(3-methyl-2-thioxo-1-imidazolyl)borates

1:1:1 $[Ag(Tm)(PR'_3)]$ triorganophosphine silver(I) complexes were synthesised in methanol from K(Tm), $AgNO_3$, and the corresponding PR'_3 donor [78]. In [Ag(Tm)(Pcy_3)] (Fig. 16) the silver atom are tricoordinated, with the donor Tm behaving as an S_2-donor. A short Ag···B distance suggests the existence of a two-electron B–H···Ag agostic interaction. The syntheses of the 1:1:2 $[Ag(Tm)(PEtPh_2)_2]$ and the 2:2:1 $[Ag_2(Tm)_2P(m\text{-tolyl})_3]$ were also reported. The complex $[Ag(Tm)]_2$, obtained in methanol from the methathesis reaction of $AgNO_3$ with K(Tm), in the chloroform solvate form $[Ag(Tm)]_2 \cdot 2CHCl_3$ [65], has been shown to be dinuclear, the core of the dimer (Fig. 17) being a four-membered $Ag(\mu\text{-}S)_2Ag$ ring, the two sulfur atoms of the bridging mercaptoimidazolyl rings coordinating two silver atoms in somewhat unsymmetrically mode. The B–H groups of the Tm ligand is disposed with the hydrogen atom projecting into the Ag_2S_2 ring. The silver coordination environment is completed by two sulfur atoms from the remaining mimt rings.

2.9. Silver(I) poly(imidazolyl)borates

The anionic dihydrobis(imidazolyl)borates $[H_2B(im)_2]^-$ and tetrakis(imidazolyl)borate $[B(im)_4]^-$ (Fig. 18) react with $AgNO_3$ in the presence of PR'_3 yielding binuclear $[Ag(PR'_3)_2\{(im)BX_2(im)\}]_2$ (X = H or im) (Fig. 19(a)) or polymeric compounds $[Ag(PR'_3)\{(im)BX_2(im)\}]_n$ compounds (Fig. 19(b)) [79]. Solution data are consistent with a partial dissociation of complexes, occurring through breaking of both Ag–N and Ag–P bonds. In particular the ^{31}P NMR data indicate that the structure and stability are strongly dependent on the stoichiometry and on the Tolman cone angle of the phosphorus donor ligand. $[Ag\{(im)BH_2(im)\}(Pcy_3)]_n$ is a single stranded polymer containing three-coordinate silver atoms ($PAgN_2$ core), while in $[Ag\{(im)B(im)_2(im)\}(Pcy_3)_2]_2$ the silver atoms are four-coordinate with P_2AgN_2 cores.

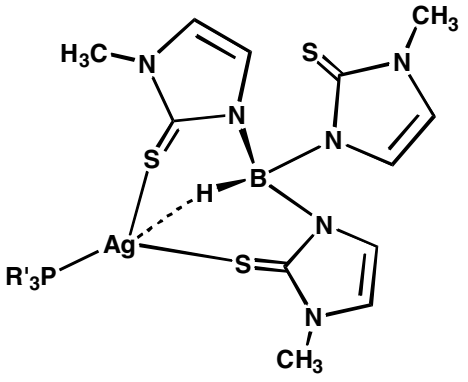

Fig. 16.

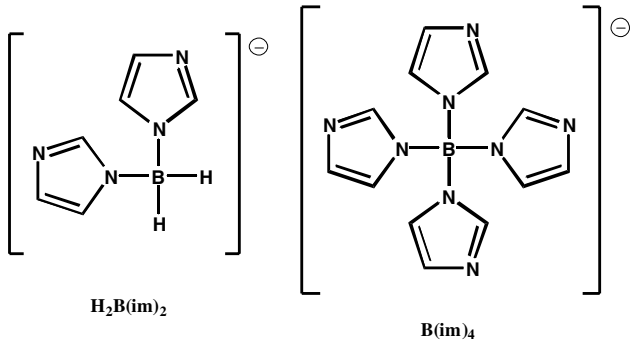

Fig. 18.

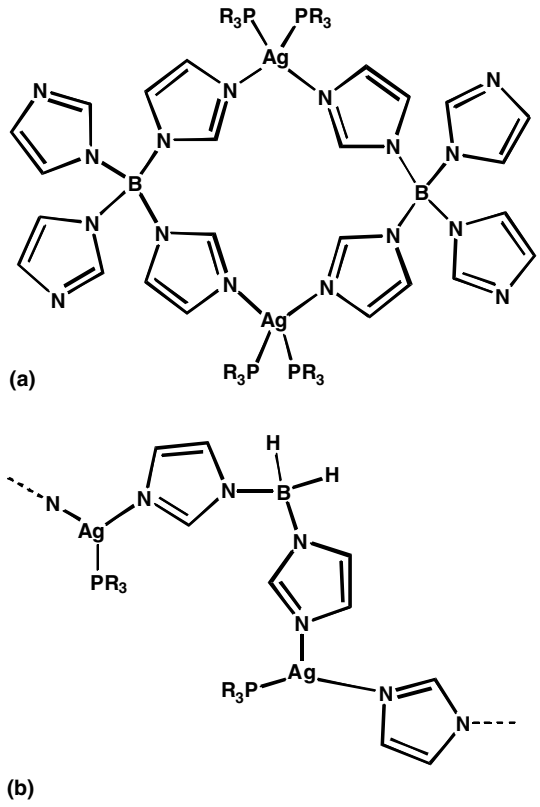

Fig. 19.

2.10. Silver poly(azolyl)alkanes

2.10.1. Bis(pyrazolyl)alkanes

Bis(pyrazolyl)-methanes and -ethanes react with AgX species ($X = NO_3$, ClO_4, O_3SCF_3, O_3SCH_3, O_2CCH_3, BF_4) yielding complexes of different stoichiometry dependent on the nature of X [80,81]. The bis(pyrazolyl)alkane/silver ratio rises from 0.5 in $[(Ag(O_3SCH_3))_2\{(pz^{4NO2})_2(1,2\text{-}C_2H_4)\}]$ [81] to 2 in the distorted tetrahedral $[Ag\{(pz)_2CMe_2\}_2]ClO_4$ (Fig. 20) [80]. The $(pz)_2CH_2$ ligand reacts with $AgNO_3$ yielding a 1:1 neutral species whereas with $Ag(O_2CCH_3)$ a polynuclear $[Ag(pz)]_n$ species is formed, presumably following hydrolysis of the acetate and breaking of the bridging C-N bond in the organic ligand.

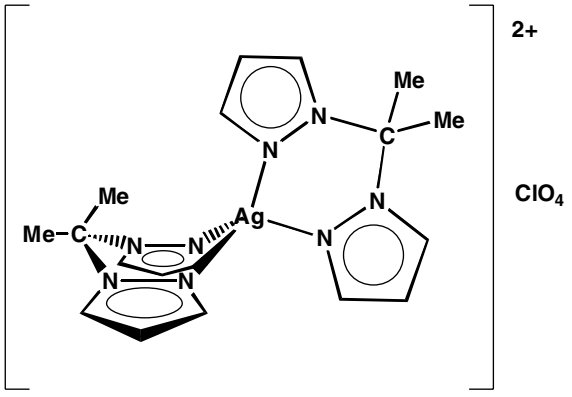

Fig. 20.

2.10.2. Tris(pyrazolyl)alkanes

The reaction of AgX ($X = ClO_4$, NO_3, O_3SCH_3) with excess of tris(pyrazolyl)methane ligand $(pz^x)_3CH$ ($Hpz^x = Hpz$, Hpz^{4Me}, Hpz*, Hpz^{Me3}) yields 1:1, 2:1 or 3:2 complexes. The ligand to metal ratio is dependent on the number and disposition of the methyls on the azole ring and primarily on the nature of the counter-ion X. IR, NMR and conductivity measurements have been reported for all complexes. $Ag(NO_3):(pz)_3CH$ 1:1 crystallizes with two formula units devoid of crystallographic symmetry as the asymmetric unit of the complex which is an infinite, unsolvated, two dimensional polymer, lying parallel to the *ac* plane. The Ag(2) atom in Fig. 21 has a tris(bidentate) environment due to a pairs of pyrazolate N from each of the independent $(pz)_3CH$ ligands and approximately bidentate nitrate, whereas Ag(1) is five-coordinated by three pyrazolate from three independent pz_3H and one bidentate nitrate [82]. In $Ag(NO_3):(pz)_3CH$ 1:2, each ligand behaves as a tripod, the silver atom being in a strongly distorted octahedral environment (Fig. 22) [82,83].

2.10.3. Bis(triazol-1-yl)methanes

Only few examples of triazolylalkane complexes have been to date reported, because of the ready formation of polymeric insoluble species. We have had success in the synthesis of a series of soluble silver complexes containing the tz_2CH_2 ligand [84]. The structure of $AgNO_3:tz_2CH_2$ 1:1 is based on a silver atom essentially linearly coordinated from different rings of different

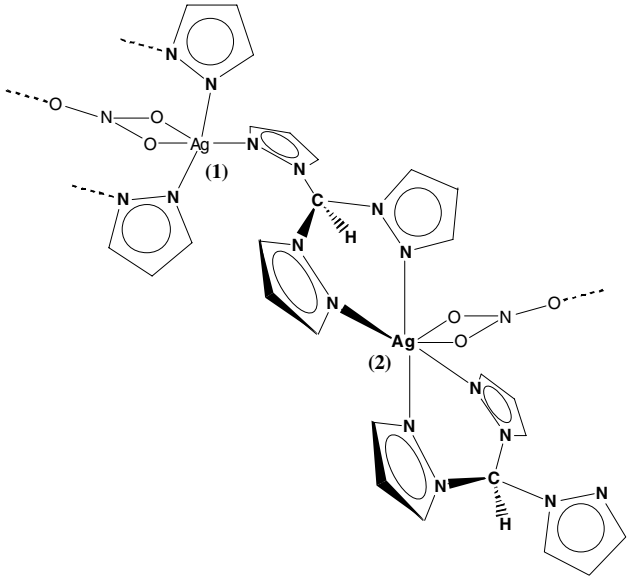

Fig. 21.

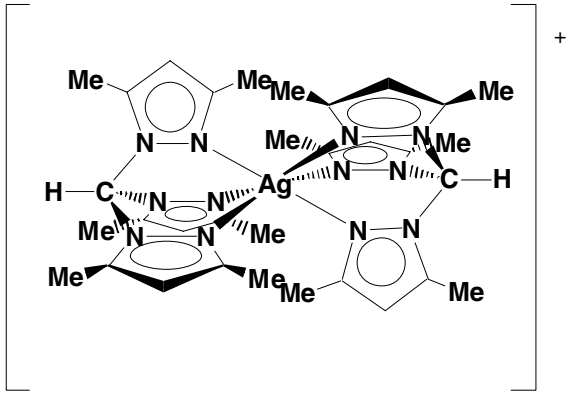

Fig. 22.

ligands. Polymer strands overlaid with juxtaposed silver atoms have the latter weakly bridged by only one of the nitrate oxygen atoms which interacts significantly, further feeble cross-linking in the third dimension occurring by way of another nitrogen atom (Fig. 23(a)). The character of the silver(I) nitrite:tz_2CH_2 (1:1) adduct is quite different, two formula units comprising the asymmetric unit of the structure. The coordination of the first silver is quasi linear as in the nitrate counterpart. Perturbation of the coordination occurs through the approach of a nitrogen of another triazolyl group and a nitrite nitrogen, but the remainder of the coordination sphere of the latter is made up of a pair of nitrite chelates (Fig. 23(b)). The 4:3 adduct between tz_2CH_2 and silver(I) triflate is devoid of metal-anion interactions, with concomitant increase in salt ligand stoichiometry. One AgO_3SCF_3:(tz_2CH_2) (3:4). MeCN formula unit comprises the asymmetric unit of the structure with the $(Ag_3(tz_2CH_2)_4)^{3+}$ cation array polymeric (Fig. 23(c)).

3. Conclusions

A summary of the most important results obtained in this field by other researchers was reported in Table 2. From the reaction of scorpionate-like ligands with Cu and Ag more than five hundred new derivatives have

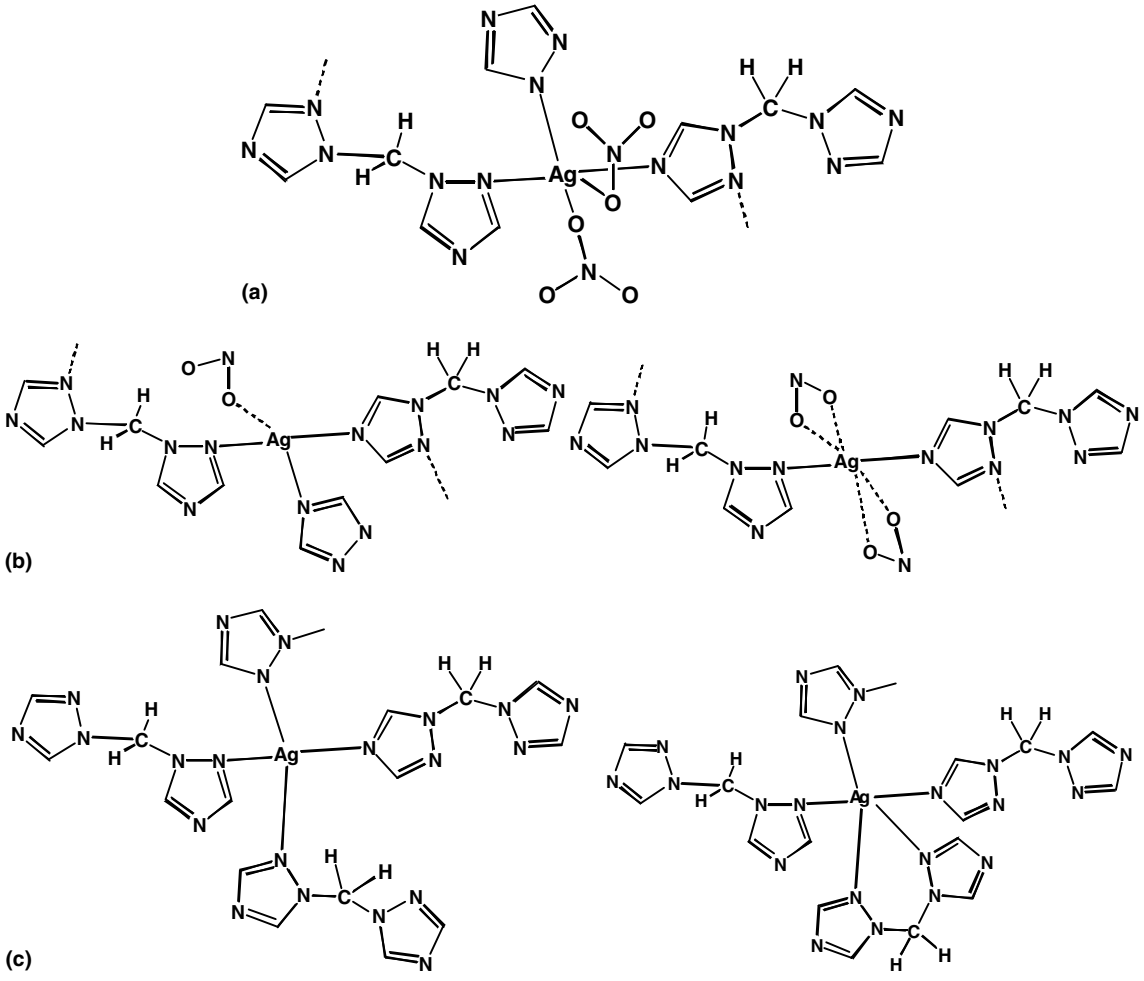

Fig. 23.

Table 2
The most important results in the field of Cu and Ag scorpionates

Results	Author	Reference
First homoscorpionate $(Tp^x)_2Cu$	Trofimenko	[85,86]
First X-ray crystal structure determination of $(Tp^x)_2Cu$	Kitajiima	[87]
First stable Cu^I carbonyl complex TpCu(CO)	Bruce	[10,34–37]
Synthesis of the dimer $[Tp^xCu]_2$	Bruce	[88]
X-ray crystal structure determination of $[Tp^xCu]_2$	Marks	[44,45]
Synthesis and investigation of the chloro-bridged dimer $[Tp^xCuCl]_2$	Roundhill	[89]
TpCu(L) as models for the blue copper proteins	Marks/Kitajima	[90–92]
Tp^{Ph}Cu(pterin) as model for the active metal site in phenylalanine hydroxylase	Perkinson	[93]
Dinuclear TpCu(II) peroxo complexes	Kitajima	[23,24,47,94]
Tp^xCu derivatives as models for the active site of the plastocyanin	Marks	[95]
Copper complexes of optically active Tp	Tolman	[96]
Theoretical characterisation of TpCuCl complexes	LLedós	[97]
Tp copper nitrosyl derivatives as models for nitric oxide adducts	Tolman	[25–28]
Copper(I) ethylene adducts of fluorinated Tp^x a aziridinanation catalysts	Dias	[98]
Tp- and Bp-Cu complexes as catalysts for the olefin cyclopronation	Pérez	[29,99,100]
$TpCu(PR_3)$ as precursor for the metal organic vapor deposition	Dahmen	[101]
A TpCu(L) complex as model for the copper center of galactose oxidase	Pierpont	[102]
TpCu(Nitronyl Nitroxide-Semiquinone) complexes	Shultz	[103]
$[Tp^{Ph}]$CuX-catalyzed dehydration of HCO_3	Cheng	[104]
TpCu-catalyzed carbene insertion into OH-bonds: conversion of alcohols into ethers	Pérez	[105]
Ternary TpCu(II) complexes containing N–N-donor heterocyclics	Chakravarty	[106]
TpCuX as catalyst for the insertion of diazo compounds into nitrogen-hydrogen bonds of amines and amides	Pérez	[107]
Cu...H interactions in hindered TpCu(I) complexes	Stavropoulos	[108]
Homoleptic copper complexes with cyano substituted scorpionate ligands	Eichhorn	[109]
Design of enzyme-like active site with fluorinated Tp ligands	Gorun	[110–112]
Reactivity of Cu-$HC(pz^x)_3$ derivatives toward O_2	Murray	[113]
First silver complexes of structure $(Tp^x)Ag(L)$ (L = P-donor or isonitrile)	Bruce	[114–116]
Fluorinated $(Tp^x)Ag$ derivatives as ligand transfer agent.	Dias	[117]
Activation of alkyl halides via a Ag–Tp catalyzed carbene insertion process	Dias	[118]
A sandwich six-coordinate derivative of silver(I) with $HC(3,5\text{-}Me_2pz)_3$	Reger	[83]
Synthesis and characterization of Cu and Ag complexes of $HC(pz^x)_3$	Reger	[119]
Synthesis of coordination polymers by using $HC(pz^x)_3$	Reger	[120]
Structure of the first binary complex $(Tp^x)Ag$	Ward	[66]
Encapsulation of a trinuclear silver(I) cluster by a hexadentate podand scorpionate	McCleverty	[121]
Ethyelene oxide and Propylene sulfid complexes of AgTpx	Dias	[122]
A coordination polymers derived from Ag and $HB(tz)_3$	Janiak	[48]

been synthesised. The coordination number ranges from 3, in sterically hindered complexes, to 6 in polynuclear species containing coordinating O-donor counter-ions as nitrate. The most common geometries observed are the trigonal planar and the tetrahedral (Table 1). The following cores for the metal coordination environment have been structurally characterized: MN_3P, MN_2P, MNP_2, MN_2P_2, MN_6, MN_4, MS_4, MS_2P, MS_3P, MN_4O_2, MN_4O, MN_2O_3, MN_2O_2, MN_5, MN_2O_3, MN_3C, $MNHP_2$.

Our work also demonstrated that from the reaction of copper(I) or silver(I) salts with anionic poly(pyrazolyl)borates neutral mononuclear complexes have been generally obtained in the presence of auxiliary ligands, such as phosphines and isonitriles. On the other hand poly(pyrazolyl)borates interact with silver(I) and copper(I) yielding dinuclear species where the metal obtains its classical maximum coordination number (4) through bridging coordination of the nitrogen ligands. The hapticity of the donor is strongly dependent on the number of pyrazolyl groups, Tp^x being generally tridentate, Bp^x uni- or bidentate, pz^oTp^x, bi- or tri-dentate. The coordination environment can be determined by a careful choice of the substituents on the azolyl ring and on the nature and steric hindrance of the auxiliary ligands. Finally poly(pyrazolyl)borates interacts with copper(II) yielding sandwich-type $Cu(Tp^x)_2$ and $Cu(pz^oTp^x)_2$ complexes.

Ionic mononuclear compounds can be generally synthesised by using poly(pyrazolyl)alkane ligands. The metal complexes formed by $R^*C(pz^x)_3$ and $R^*_2C(pz^x)_2$ are generally less stable than those obtained with the analogous anionic counterparts Bp^x and Tp^x. In the presence of coordinating counterions such as NO_3 poly(azolyl)alkanes seems able to form neutral polynuclear silver species. In these compounds the metal expands its classical coordination number (4) until to six, whereas derivatives containing non-coordinating anions such as ClO_4 or triflate, are generally cationic mononuclear or polynuclear species.

Polynuclear species can be also readily produced by using ligands such as $HB(tz)_3$ and $H_2C(tz)_2$ characterized by an exo-ring nitrogen able to bridge between metal centers, whereas $H_2B(im)_2$ and $B(im)_4$ seem efficient molecules for the synthesis of both dinuclear and polynuclear complexes depending on the reaction conditions, and on the steric properties (cone angle) of the auxiliary ligands. S-donor ligands such as Tm stabilize Cu and Ag complexes in the low oxidation state also through supplementary M–H interaction, but their reaction with Cu(II) yields, upon reduction of the metal by the S-donor, insoluble Cu(I) species.

Abstract

Two related heteroscorpionate N_2S(thiolate) ligands L^1 and L^2 have been employed in the synthesis of new zinc(II) and iron(II) complexes. These ligands contain two imidazolyl donors and one alkylthiolate donor connected by a central carbon atom. The ligand L^1 was reacted with $ZnBr_2$ to give the trinuclear zinc complex $[(L^1)_3Zn_3Br_2]Br$ (**1**). The X-ray structure of **1** reveals one of the zinc ions to be coordinated by two L^1 ligands in a tripodal arrangement resulting in a distorted octahedral geometry, while the other two zinc ions are both held in a distorted tetrahedral geometry and are coordinated to another molecule of L^1 in an unusual tridentate, multibridging coordination mode. Modification of L^1 to include phenyl substituents on the imidazole groups leads to L^2, and these substituents cause quite a different result to be obtained in the reaction with $ZnBr_2$. The combination of L^2 and $ZnBr_2$ leads to the dimeric zinc complex $(L^2)_2Zn_2Br_2$, (**2**). Characterization of **2** by X-ray diffraction shows this complex to be a dimer with a central $Zn_2(\mu\text{-}SR)_2$ rhomb. Each zinc ion is found in a distorted tetrahedral geometry coordinated by L^2 in a bidentate, N,S fashion. The ^1H NMR spectrum of **2** provides strong evidence this structure is retained in solution. In comparison, reaction of L^2 with $FeCl_2$ leads to the monomeric complex $(L^2)_2Fe^{II}$ (**3**), which has each ligand coordinated in the same bidentate, N,S bonding mode. Interestingly, the methoxy groups of the two ligands in **3** are close enough to the iron center for a possible bonding interaction, suggesting an unexpected N_2O coordination mode.

1. Introduction

A variety of metalloproteins rely on a single metal ion cofactor bound to the protein by a combination of His_xCys_y amino acid ligands. Examples include zinc proteins such as the matrix metalloproteinases [1], zinc fingers [2], alcohol dehydrogenase [3], farnesyl transferase [4] and spinach carbonic anhydrase [5], as well as the blue copper proteins [6] and the non-heme iron enzymes nitrile hydratase [7] and peptide deformylase (PDF) [8]. We have specifically targeted the metal active site of the latter enzyme for synthetic modeling because we find it especially intriguing from an inorganic point of view; it utilizes an iron(II) center in vivo yet belongs to the mononuclear zinc(II) enzyme family in terms of both structure and function [8b]. In order to mimic the active site of PDF, which has a His_2Cys donor set coordinated to an M(II) ion in all of its known derivatives (M(II) = Fe(II), Zn(II), Co(II), Ni(II)), we have made efforts to synthesize ligands with mixed nitrogen/alkylthiolate donor sets. Accordingly, we recently prepared a simple linearly disposed N_2S(thiolate) ligand called PATH, which has led to the synthesis of a novel series of

doi:10.1016/j.poly.2003.11.034

monomeric, pseudotetrahedral N_2S(thiolate) complexes ((PATH)$M^{II}L$; M = Zn, Co) [9–11]. These complexes have served as structural models for the generalized $(His)_2(Cys)M^{II}L$ active site of PDF, and recently we have shown that a PATH-Zn(II) complex generated in water acts as a functional model complex by catalyzing the hydrolysis of an ester substrate [12].

At the same time, we have also pursued the construction of scorpionate ligands bearing an N_2S(thiolate) donor set. The tris(pyrazolyl)borate (Tp) family of scorpionate ligands has proven remarkably useful for the construction of many enzyme model complexes, especially models of the zinc enzyme family [13–16]. Their incredible success has spurred the development of many variations, including systems in which the pyrazolyl N groups have been replaced by sulfur donors. Such systems include thioether [17] and methimazolyl-containing [18–20] ligands. However, to our knowledge there are as yet no boron-based scorpionate ligands bearing a sulfur donor derived from an alkylthiolate group, most likely because of the synthetic difficulties of installing an alkylthiolate appendage. We have turned to a carbon-centered framework as a synthetically feasible alternative to the boron-centered systems. Herein we describe the coordination behavior of the scorpionate ligands L^1H and L^2H (Fig. 1). Both of these ligands rely on a central carbon atom in place of boron to link the imidazolyl and alkylthiolate donors into a tripodal framework [21]. The ligand L^1H was originally synthesized by Bosnich over 20 years ago for use in the preparation of models of blue copper proteins [22]. Still, little is known about its coordination chemistry, and to our knowledge no X-ray structures of complexes containing L^1 have been reported to date. The synthesis of the ligand L^2H was previously communicated by some of us [23].

We report here the first X-ray structure of any transition metal complex of the scorpionate ligand L^1. In addition, the first iron(II) complex of L^2 has been synthesized and crystallographically characterized, and a new dinuclear zinc(II) complex of L^2 has been characterized by both ^1H NMR spectroscopy and X-ray crystallography, allowing for a comparison between solution and solid-state structures. These different structures reveal that the L^1/L^2 framework can adopt three different coordination modes, including the expected tripodal N_2S bonding mode.

2. Experimental

2.1. Materials and general methods

No special precautions were taken for the synthesis of **1**. All synthetic procedures for complexes **2** and **3** were carried out by using a dry-box or Schlenk techniques. For the synthesis of complex **3**, MeOH and CH_2Cl_2 were dried by refluxing over CaH_2 for 18 h and then distilled. Traces of oxygen were removed from these solvents by 3 cycles of freeze–pump–thaw. Ligands L^1H [22] and L^2H [23] were prepared as described in the literature. All other chemicals used in the experiments were of analytical grade from commercial sources and used without further purifications.

2.1.1. Synthesis of $[(L^1)_3Zn_3Br_2]Br$ (**1**)

Methanol (15 mL) was added to L^1H (0.050 g, 0.178 mmol), NaOMe (0.011 g, 0.196 mmol) and $ZnBr_2$ (0.044 g, 0.196 mmol) to yield a clear yellow solution. Overnight a white precipitate formed and the solution was filtered. This precipitate was dissolved by addition of 2 mL of hot CH_3CN. Crystals suitable for X-ray diffraction were obtained by diffusion of Et_2O into a CH_3CN solution of **1**. Yield <2%.

2.1.2. Synthesis of $[(L^2)_2Zn_2Br_2]$ (**2**)

To a solution of L^2H (0.1 g, 0.17 mmol) in CH_2Cl_2 (10 mL) was added NaOH (0.008 g, 0.19 mmol) in MeOH, and then the mixture was bubbled with argon for 30 minutes to make sure that the solution was oxygen-free. An amount of $ZnBr_2$ (0.039 g, 0.17 mmol) was dissolved in MeOH (5 mL) and bubbled with argon for 30 minutes. The methanolic solution of $ZnBr_2$ was added dropwise to the solution of deprotonated ligand and the reaction mixture was stirred for 18 h under argon. The complex **2** precipitated from the reaction mixture as a white powder, which was filtered, washed with Et_2O and dried under vacuum. Yield: 0.07 g, 56%. Crystals suitable for X-ray diffraction were obtained by diffusion of Et_2O into a CH_2Cl_2 solution of **2**. *Anal.* Calc. for $C_{74.5}H_{71}N_8O_2S_2Zn_2Br_2Cl$ [**2** · $(CH_2Cl_2)_{0.5}$]: C, 59.63; H, 4.77; N, 7.47. Found: C, 59.40; H, 4.91; N, 7.29%. ^1H NMR ($CDCl_3$, ppm): 7.56–7.11 (m, 40H, C_6H_5); 3.51 (s, 6H, N–CH_3); 3.26 (s, 6H, N–CH_3); 2.74 (s, 6H, O–CH_3); 1.93 (s, 12H, C–CH_3).

2.1.3. Synthesis of $(L^2)_2Fe$ (**3**)

A 2 mL solution of NaOH (0.009 g, 0.23 mmol) in MeOH was added to L^2H (0.06 g, 0.1 mmol) dissolved in CH_2Cl_2 (3 mL) and the mixture was stirred for 30 minutes. The solution of deprotonated ligand was then added to a solution of $FeCl_2$ (0.014 g, 0.11 mmol) in 3 mL MeOH, which was then stirred for 18 h to get a green precipitate. This precipitate was dissolved by addition of 2 mL CH_2Cl_2 to the reaction mixture. To the

resulting clear green solution, 3 mL of MeOH was added and colorless crystals were obtained by storing this solution at −20 °C for four days. Yield 0.03 g, 45%. IR of $\mathbf{3}\cdot(CH_3OH)_2$ (KBr, cm^{-1}): 3479, 3051, 2975, 2915, 1603, 1504, 1463, 1443, 1367, 1262, 1229, 1179, 1125, 1075, 1027, 1001, 966, 930, 775, 697, 671, 648, 569, 530. For comparison the IR of L^2H is as follows (KBr, cm^{-1}): 3062, 2925, 1602, 1504, 1443, 1375, 1303, 1240, 1178, 1128, 1080, 1026, 964, 776, 698, 666, 627, 528. *Anal.* Calc. for $C_{76}H_{78}N_8O_4S_2Fe[\mathbf{3}\cdot(CH_3OH)_2]$: C, 70.90; H, 6.11; N, 8.70. Found: C, 71.35; H, 5.79; N, 8.97%.

2.2. Physical measurements

Elemental analyses were performed at Atlantic Microlab, Inc. (Norcross, GA). ^1H NMR spectrum in $CDCl_3$ was recorded on a Varian Unity Plus 400 spectrometer (400 MHz) at ambient probe temperature with tetramethylsilane as the internal reference. IR spectra were recorded on a Bruker Vector 22 IR spectrometer as KBr disks.

2.3. X-ray crystallography

Diffraction intensity data were collected with a Bruker Smart Apex CCD (**1** and **3**) and a SMART-1000 CCD (**2**) diffractometer with graphite monochromated Mo Kα radiation. Crystal data, data collection, and refinement parameters for all structures are given in Table 1. The structures were solved using direct methods, completed by subsequent difference Fourier syntheses, and refined by full matrix least-squares procedures on F^2. SADABS absorption corrections were applied to **1** and **3** (T_{min}, $T_{max} = 0.390$, 0.699 (**1**) and 0.898, 0.924 (**3**)). In the case of **2**, an analytical absorption correction was applied. Minimum and maximum transmission factors were 0.746 and 0.932, respectively. All non-hydrogen atoms were refined with anisotropic displacement coefficients, and hydrogen atoms were treated as idealized contributions in a riding group model.

In the crystal structure of **2** there is a disordered CH_2Cl_2 molecule. It was refined isotropically with occupancy factors of 0.125 for four chlorine atoms, 0.25

for two chlorine atoms and the occupancy factor of 0.5 for the carbon atom to give half a CH_2Cl_2 molecule per dimer unit while the remaining non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in idealized positions but not refined.

In the crystal structure of **3**, there are six MeOH solvent molecules. Two of those MeOH molecules are involved in weak hydrogen bonding with the thiolate sulfur atoms. The other four highly disordered MeOH molecules were treated as diffuse contributions with the SQUEEZE program (A. Spek, Platon software package). Corrections of the X-ray data by SQUEEZE found 159 e^-/unit cell which is close to the required value of 144 e^-/unit cell for four MeOH molecules. All samples of **3** examined diffracted weakly and diffusely, almost certainly a result of the loosely fixed solvent molecules, resulting in a rather high final *R* factor.

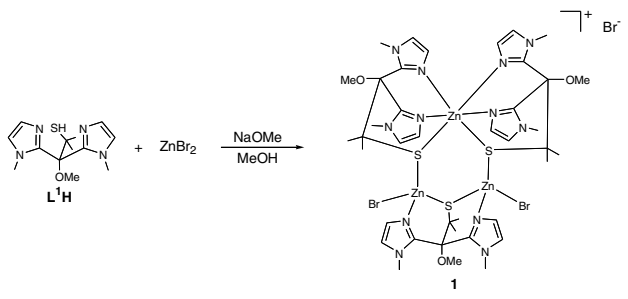
All software and sources of scattering factors for **1** and **3** are contained in the SHELXTL (5.10) program package (G. Sheldrick, Bruker XRD, Madison, WI). For **2** all calculations were performed using the TEXSAN crystallographic software package of Molecular Structure Corporation (TEXSAN *for Windows version 1.05*: Crystal Structure Analysis Package, Molecular Structure Corporation (1997–1998)).

3. Results and discussion

3.1. Synthesis of $[(L^1)_3Zn_3Br_2]Br$ (1)

The heteroscorpionate N_2S(thiolate) ligand L^1H, shown in Fig. 1, was originally prepared over 20 years ago for use in the synthesis of "blue copper" protein model complexes [22]. We recognized L^1 to be an intriguing example of a tripodal ligand with an alkylthiolate donor, which also had the added advantage of containing biomimetic imidazole donors. To our knowledge the blue copper modeling work was the only published account discussing L^1, and there were as yet no crystallographically characterized compounds containing L^1. As pointed out in the Introduction, heteroscorpionate ligands bearing an alkylthiolate donor are extremely rare, and thus we were compelled to see if we could develop the coordination chemistry of this system. We reacted L^1 with a Zn(II) source to determine its coordination behavior with this ion, and obtained a trinuclear zinc complex in which L^1 displays two distinct bonding modes.

For the synthesis of $[(L^1)_3Zn_3Br_2]Br$ (**1**), the three starting materials L^1H, NaOMe, and $ZnBr_2$ are dissolved together in MeOH, as shown in Scheme 1. The ligand L^1H is freely soluble in MeOH, unlike L^2H, and therefore the use of CH_2Cl_2 can be avoided, in contrast to the synthesis of **2** and **3** (vide infra). Initially a clear solution is obtained, but after 18 h a small amount of white precipitate is formed and isolated by filtration. This solid has limited solubility, but can be redissolved in hot CH_3CN. From Et_2O/CH_3CN a very small amount of **1** can be obtained as X-ray quality crystals. Attempts to scale up the reaction or obtain subsequent crops of **1** led to the formation of yellow oils or solids which could not be re-crystallized to give more **1**. Thus the yield of **1** is extremely low, and sometimes no crystals of **1** form, but the few crystals that were obtained by this method were utilized for X-ray crystallography. The low yield of **1** precluded us from obtaining other characterization data on **1**.



Scheme 1.

3.2. Crystal structure of $[(L^1)_3Zn_3Br_2]Br$ (1)

An ORTEP view of **1** is shown in Fig. 2. Crystallographic data are summarized in Table 1. Selected bond distances and angles are given in Table 2. Structural characterization of **1** has revealed a trinuclear zinc complex that crystallizes in the monoclinic space group $P2_1/c$. The metal:ligand ratio is 1:1, but the overall structure is much less symmetric than the simple formula

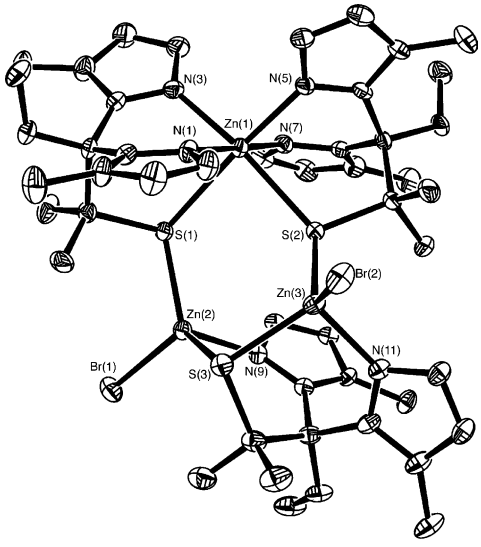


Fig. 2. Thermal ellipsoid plot of the cation of **1** at 40% probability. Hydrogen atoms are omitted for clarity.

implies. The ligands exhibit two distinct coordination modes. One of the zinc centers, Zn(1), is bound by two ligands each through the expected tripodal N_2S coordination. The geometry at this zinc center is best described as distorted octahedral with *cis* angles ranging from 83° to 101° and *trans* angles ranging from 170° to 177°. The two sulfur atoms are in a *cis* arrangement. The Zn(1)–N(im) distances range from 2.055(3) to 2.141(3) Å. In the case of the longer Zn(1)–N(im) distances (Zn(1)–N(7) = 2.141(3) Å and Zn(1)–N(1) = 2.091(3) Å), the imidazoles are *trans* to one another, while the imidazoles with shorter bond distances (Zn(1)–N(5) = 2.055(3) Å and Zn(1)–N(3) = 2.068(4) Å) are *trans* to the sulfur atoms. From these distances it is reasonable to conclude that N(7) and N(1) lie on axial positions while N(5) and N(3) lie on equatorial positions in the distorted octahedral geometry. All of these Zn–N(im) distances are reasonable compared to other octahedral zinc complexes containing imidazole donors [24,25]. Interestingly, the Zn(1)–S distances of Zn(1)–S(1) = 2.6697(11) Å and Zn(1)–S(2) = 2.5110(12) Å are quite long for a typical Zn–S bond, and considerably longer than the distances from the thiolate sulfur atoms to the respective tetrahedral zinc(II) ions: Zn(2)–S(1) 2.3115(12) Å and Zn(3)–S(2) 2.2843(11) Å. This observation is counterintuitive to the expectation that the Zn–S bonds of the chelate ring should be shorter than the bridging Zn–S bonds. However, this same trend is observed for two other trinuclear zinc complexes, $[(MBPA)_4Zn_3]I_2$ (MBPAH = *N*-(2-mercaptoisobutyl)-(picolyl)amine)[26] and $[Zn\{Zn(L^3)_2\}_2](ClO_4)_2$ (L^3 = 2-[(2-pyridylmethyl)amino]ethanethiolate) [27], both of which have 6-coordinate and 4-coordinate zinc(II) ions bridged by thiolate ligands. In these compounds the sulfur distance to the six-coordinate zinc ion is significantly longer than the sulfur distance to the four-coordinate zinc center ($[(MBPA)_4Zn_3]I_2$: $Zn_{octahedral}$–S = 2.545(3) Å, $Zn_{tetrahedral}$–S = 2.365(3) Å; $[Zn\{Zn(L^3)_2\}_2](ClO_4)_2$: $Zn_{octahedral}$–S = 2.538(3)–2.596(3) Å, $Zn_{tetrahedral}$–S = 2.346(3)–2.363(3) Å). In both of the latter complexes the thiolate donor is also part of a chelate ring that includes the octahedral zinc ion. The considerably longer $Zn_{octahedral}$–S distances are likely a consequence of the increase in coordination number compared to a tetrahedral zinc site.

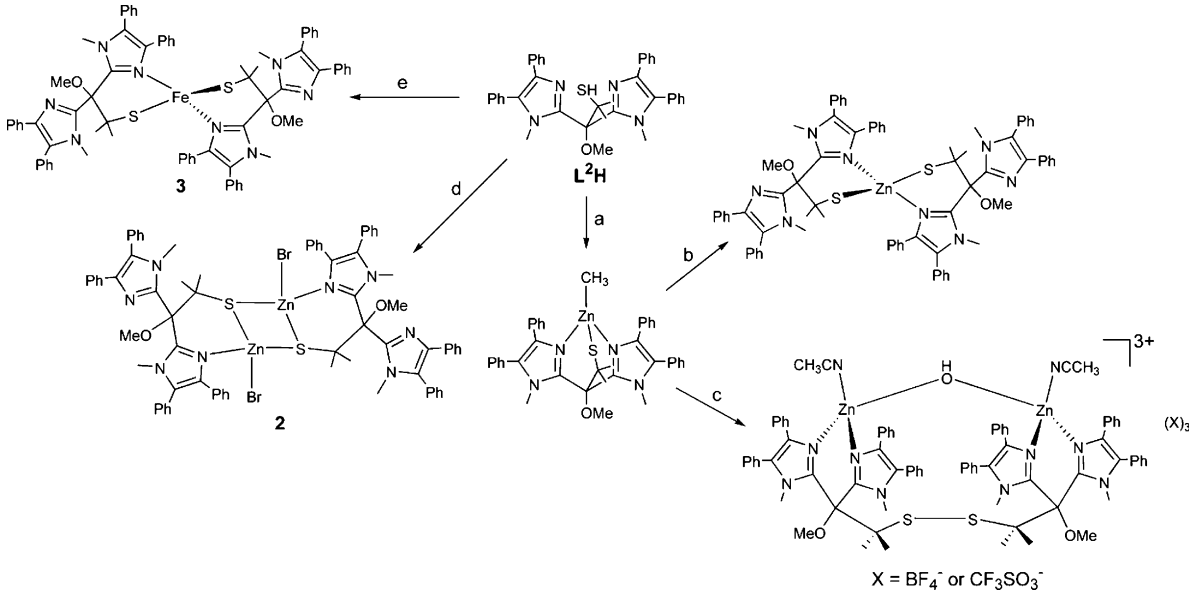
The tetrahedral zinc centers Zn(2) and Zn(3) are not only bridged by sulfur atoms to the octahedral zinc ion, but are also connected to each other by the thiolate arm of a third ligand. Each of these four-coordinate zinc ions is also bound by a separate imidazole donor from the same ligand. Thus the imidazolyl groups together with the bridgehead carbon atom also participate in bridging the dinuclear zinc fragment. This (im)-C-(im)-type bridge has been observed previously for the related N_3 scorpionate ligand tris[2-(1-methylimidazolyl)methoxymethane (timm), which has three imidazolyl donors connected by a central C_3 symmetric carbon atom. The dimeric complexes of formula $[Cu(timm)]_2[BF_4]_2$ [28] and $[Pd_2Cl_2(timm)_2]Cl_2$ [29] have structures which show the ligand bound to one metal ion through two imidazole rings while the third imidazole group coordinates to the other metal ion of the dimer. Interestingly, the unusual "1 + 2" assembly of an octahedral zinc ion bridged to a dinuclear fragment of two tetrahedral zinc ions has been seen before for another N_2S(thiolate) scorpionate ligand, but in this case the tetrahedral zinc ions are bridged by a $(PhO)_2PO_2^-$ ligand [21b]. The fourth site of each distorted tetrahedral zinc center in **1** is occupied by a bromide ion. The Zn–N(im) distances for the four-coordinate zinc sites are 2.026(3) and 2.034(4) Å. These Zn–N lengths are slightly shorter than those found for the octahedral zinc site, as to be expected from the lower coordination number of the

tetrahedral centers. The angles around the two four-coordinate zinc ions are distinct, ranging from 90.9°–123.1° for Zn(2) to 99.9°–121.5° for Zn(3), making them both rather distorted from ideal tetrahedral geometry.

3.3. Coordination behavior of L^2

Although L^1 exhibited the desired tripodal bonding mode in complex **1**, it also demonstrated a propensity to form both 2:1 octahedral complexes as well as thiolate-bridged oligomers. Given these results, we sought methods for synthetically modifying L^1 to incorporate steric bulk near the metal center during tripodal coordination, thereby favoring monomeric $(N_2S)ZnL$ complexes. Modification of the imidazole groups was the most synthetically feasible method of achieving this goal given the stepwise synthesis of L^1H [22], and thus we targeted the diphenyl-substituted analog L^2H, shown in Fig. 1. The synthesis of L^2H has been communicated previously, and in the same work L^2 was shown to react with $Zn(CH_3)_2$ to give the neutral, monomeric zinc alkyl complex $(L^2)ZnCH_3$, as seen in Scheme 2 [23]. The synthesis of this complex demonstrated that L^2 coordinates in the desired tridentate facial mode to give a tetrahedral $(N_2S)ZnL$ complex. This complex was prepared as a possible starting material for the formation of $(L^2)ZnOH$ by reaction with water. However, upon reaction of $(L^2)ZnCH_3$ with water in toluene, a redistribution of ligand:metal stoichiometry took place along with a rearrangement of the N_2S bonding mode of L^2 to a bidentate N,S mode, resulting in the formation of a four-coordinate N_2S_2–Zn complex. Alternatively, if $(L^2)ZnCH_3$ was reacted under acidic conditions (HBF_4 or CF_3SO_3H in CH_3CN), the rearranged $Zn–N_2S_2$ product was not obtained, but instead the dinuclear complexes $[(L^2)_2Zn_2(CH_3CN)_2(\mu\text{-}OH)](X)_3$ ($X = BF_4^-$, $CF_3SO_3^-$) were isolated and crystallographically characterized [23]. During the formation of these dimers an undesirable intramolecular disulfide linkage had formed. These synthetic observations are summarized in Scheme 2.

In continuing our efforts to determine the coordination behavior of L^2, we have reacted L^2 with the metal salts $ZnBr_2$ and $FeCl_2$, as shown in Scheme 2. The syntheses of **2** and **3** were carried out under the strict exclusion of air to prevent the possible oxidation of the thiolate ligand to a disulfide and in the case of **3**, to prevent oxidation of the Fe(II) product. The ligand L^2H is freely soluble in CH_2Cl_2 but only sparingly soluble in MeOH. Thus, L^2H was first dissolved in CH_2Cl_2 and then deprotonated by the addition of NaOH in MeOH in the synthesis of both **2** and **3**. For **2**, a solution of $ZnBr_2$ in MeOH was added dropwise to the solution of L^2 whereas for **3** the addition was reversed and ligand was added to metal. Complex **2** precipitates from the reaction mixture as a white powder. After workup this powder was shown to be pure **2** by its ^1H NMR spectrum. Complex **2** is freely soluble in CH_2Cl_2, and recrystallization of **2** from vapor diffusion of Et_2O into CH_2Cl_2 gave the crystals that were used for the structural determination. In the case of **3**, a precipitate also forms in the reaction mixture, but this precipitate is not isolated and instead is simply recrystallized directly by the addition of CH_2Cl_2 to the reaction mixture to redissolve the solid. X-ray quality crystals of **3** are obtained after storage of this mixture at −20 °C.



Scheme 2. Conditions: (a) 1.4 $Zn(CH_3)_2$, toluene, rt, 3 h. (b) 30 H_2O, toluene, rt, 6 d. (c) 2 HBF_4 (aq.) or 2 CF_3SO_3H, CH_3CN, rt, 24 h. (d) 1.1 NaOH, MeOH; 1 $ZnBr_2$, MeOH; 18 h. (e) 2.2 NaOH, MeOH; 1.1 $FeCl_2$, MeOH; 18 h.

3.4. Crystal structure of $[(L^2)_2Zn_2Br_2]$ (2)

An ORTEP view of **2** is shown in Fig. 3. Crystallographic data are summarized in Table 1. Selected bond distances and angles are given in Table 3. Complex **2** crystallizes in the triclinic $P(\bar{1})$ space group. The dimer does not sit on an inversion center, and therefore all bonds and angles are crystallographically unique. A CH_2Cl_2 molecule of 1/2 occupancy was located per dimeric unit. Both zinc centers have a distorted tetrahedral geometry and are bridged by two sulfur atoms from two ligand molecules to give a Zn_2S_2 rhomb. In addition to the bridging thiolates, a nitrogen atom from one of the *N*-methyl-4,5-diphenylimidazole rings coordinates each zinc atom. A bromide ion completes the coordination sphere of each zinc atom. Each ligand has one imidazole moiety that is free and not coordinated to a zinc atom, and thus each ligand binds in a bidentate N,S fashion through one nitrogen atom and one μ-sulfur atom. As pointed out in Section 3.3, evidence for this type of bonding mode has been obtained previously for L^2. In comparison, the dimeric complexes of the N_3 scorpionate ligand timm, $[Cu(timm)]_2[BF_4]_2$ [28] and $[Pd_2Cl_2(timm)_2]Cl_2$ [29], described previously in Section 3.2, have structures which show a bidentate N,N bonding mode. Thus, the bidentate bonding mode of these carbon-centered scorpionate ligands is not unique to mixed N/S systems, and is seen for the homoleptic N_3 systems as well.

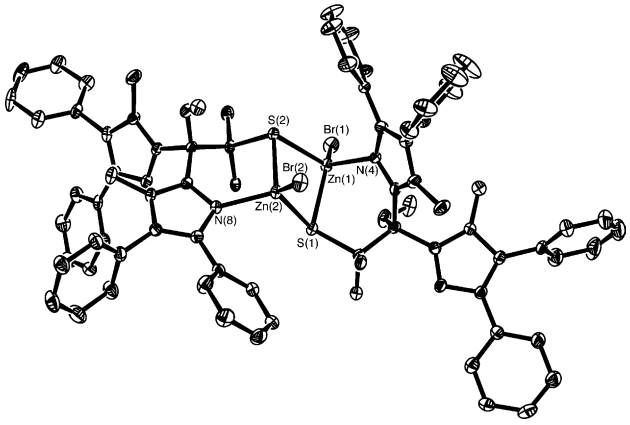


Fig. 3. Thermal ellipsoid plot of **2** at 40% probability. Hydrogen atoms are omitted for clarity.

Table 3
Bond lengths (Å) and angles (°) for **2**

Bond lengths	
Br(1)–Zn(1)	2.3706(9)
Br(2)–Zn(2)	2.3573(9)
Zn(1)–S(1)	2.3400(13)
Zn(1)–S(2)	2.3807(13)
Zn(1)–N(4)	2.061(3)
Zn(2)–S(1)	2.4034(13)
Zn(2)–S(2)	2.3787(13)
Zn(2)–N(8)	2.050(4)
Bond angles	
Br(1)–Zn(1)–S(1)	114.89(4)
Br(1)–Zn(1)–S(2)	122.77(4)
Br(1)–Zn(1)–N(4)	111.00(9)
S(1)–Zn(1)–S(2)	94.84(4)
S(1)–Zn(1)–N(4)	99.19(10)
S(2)–Zn(1)–N(4)	110.77(10)
Br(2)–Zn(2)–S(1)	113.12(4)
Br(2)–Zn(2)–S(2)	129.23(4)
Br(2)–Zn(2)–N(8)	117.78(10)
S(1)–Zn(2)–S(2)	93.25(4)
S(1)–Zn(2)–N(8)	104.66(10)
S(2)–Zn(2)–N(8)	94.06(10)
Zn(1)–S(1)–Zn2	82.92(4)
Zn(1)–S(2)–Zn(2)	82.59(4)

The Zn–S distances of **2** range between 2.3400(13) and 2.4034(13) Å, which is within the range of other $Zn_2(\mu\text{-}SR)_2$ complexes [30–34], such as the homoleptic complex $[(Et_4N)_2Zn_2(SEt)_6]$ [33] where d(Zn–S) = 2.394(1) and 2.456(1) Å, or $[Zn_2(CH_3)_2(\{SC_6H_4(R)\text{-}CH(Me)NMe_2\}\text{-}2\})_2$, where the zinc ions are bound by an N,S chelate ring and d(Zn–S) ranges between 2.389(1) and 2.453(2) Å [34]. The carbon atoms attached to each thiolate bridge are on opposite sides of the Zn_2S_2 plane, as are the bromine atoms, and thus **2** can be classified in the *anti* form [33]. The Zn(1)–N(4) and Zn(2)–N(8) distances of 2.061(3) and 2.050(4) Å, respectively, are close to other $Zn_{tetrahedral}$–$N_{imidazole}$ distances [35–37]. The Zn–Br distances of 2.3573(9) and 2.3706(9) Å are also unexceptional [9,35,38]. The angles around the zinc centers range from 82.59(4)°–129.23(4)°, which indicates a significant distortion from tetrahedral geometry. The dihedral angle between the two planes defined by $Zn(1)S_2$ and $Zn(2)S_2$ is 19.3°, giving a slight V shape to the Zn_2S_2 unit. In the literature this dihedral angle is found to vary from 0° for $[(Et_4N)_2Zn_2(SEt)_6]$ [33] to 29.18° for $[(Me)Zn(SBu^t)(cis\text{-}C_6H_{15}N_3)]_2$ where $(cis\text{-}C_6H_{15}N_3)$ = 1,3,5-trimethylhexahydro-1,3,5-triazine [39]. The reasons for the variance in this fold angle are not clear. The distance between the two zinc atoms in **2** is 3.141 Å which is also in the normal range for $Zn_2(\mu\text{-}SR)_2$ complexes [33].

3.5. ^1H NMR spectrum of $[(L^2)_2Zn_2Br_2]$ (2)

The ^1H NMR spectrum for **2** in $CDCl_3$ provides good evidence that the dinuclear structure obtained from X-ray crystallography remains intact in solution. The resonances for the phenyl protons of **2** appear as a complex multiplet in the region δ 7.11–7.56 ppm, and do not provide much structural information. However, for the N–CH_3 substituents, two distinct singlets are observed at 3.51 and 3.26 ppm, consistent with the two different types of imidazole groups in the dimer. We assign the upfield peak at 3.26 ppm to the non-coordinated imidazole group, whereas the peak at 3.51 ppm is assigned to

the imidazole group bound to the zinc(II) ion. The latter assignment is based on the ^{1}H NMR spectra for $(L^2)ZnCH_3$ and $[(L^2)_2Zn_2(CH_3CN)_2(\mu\text{-}OH)](X)_3$ ($X = BF_4^-$, $CF_3SO_3^-$), both of which have only the coordinated type of imidazolyl group (Scheme 2) and exhibit downfield-shifted N–CH_3 resonances of δ 3.87 and 3.95 ppm, respectively [23]. A similar pattern to that of **2** was seen for $(L^2)_2Zn$, which exhibited two peaks at 2.95 and 3.87 ppm, presumed to be the free and bound imidazole groups, respectively [23]. Curiously, the free ligand itself, L^2H, gives rise to a relatively downfield N–CH_3 resonance of 3.53 ppm. However, the precedent for a coordinated N–CH_3 peak being significantly downfield-shifted is clear from the former data. The singlet at 2.74 ppm in the spectrum of **2** is assigned to the O–CH_3 resonance, which is close to the same peak found for $(L^2)_2Zn$ (O–CH_3: δ 2.57 ppm), yet quite distinct from that of $(L^2)ZnCH_3$ (3.57 ppm) or $[(L^2)Zn\text{–}(\mu\text{-}OH)\text{–}Zn(L^2)]^{3+}$ (3.56 ppm). Finally, the gem-dimethyl protons for **2** appear as a singlet at δ 1.93 ppm, which is downfield of the same resonance found for the free ligand L^2H (1.60 ppm) or for $(L^2)ZnCH_3$ (1.64 ppm), in which L^2 is bound in a tripodal mode. Thus the ^{1}H NMR spectrum of **2** appears to be quite characteristic of the bonding mode of L^2 (N,S versus N,N,S for $(L^2)ZnCH_3$ and N,N for $[(L^2)Zn\text{–}(\mu\text{-}OH)\text{–}Zn(L^2)]^{3+}$).

3.6. Crystal structure of $(L^2)_2Fe$ (3)

An ORTEP view of **3** is shown in Fig. 4. Crystallographic data are summarized in Table 1. Selected bond distances and angles are given in Table 4. This complex crystallizes in the triclinic space group $P(\bar{1})$. The ferrous ion adopts a distorted tetrahedral geometry and is coordinated by two ligand molecules through one imidazole and one thiolate donor, which makes the complex neutral in charge. As observed in the case of **2**, the other imidazole donor from each ligand molecule remains uncoordinated, demonstrating the preference for an N,S binding mode over an N_2S mode for L^2. The two MeOH molecules found in the lattice appear to be involved in hydrogen bonding with separate thiolate sulfur atoms.

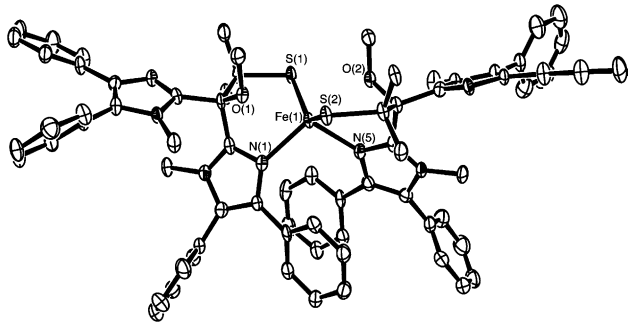

Fig. 4. Thermal ellipsoid plot of **3** at 40% probability. Hydrogen atoms are omitted for clarity.

Table 4
Bond lengths (Å) and angles (°) for **3**

Bond lengths	
Fe(1)–N(1)	2.157(4)
Fe(1)–N(5)	2.157(4)
Fe(1)–S(2)	2.3363(14)
Fe(1)–S(1)	2.3480(14)
Bond angles	
N(1)–Fe(1)–N(5)	102.77(15)
N(1)–Fe(1)–S(2)	107.65(11)
N(5)–Fe(1)–S(2)	99.65(11)
N(1)–Fe(1)–S(1)	98.68(10)
N(5)–Fe(1)–S(1)	109.78(11)
S(2)–Fe(1)–S(1)	134.72(6)

The hydrogen atoms on the MeOH molecules could not be located by X-ray diffraction, but the distances between the oxygen and sulfur atoms, O(1S)–S(1) = 3.183 Å and O(2S)–S(2) = 3.167 Å, indicate an H-bonding interaction [40]. Despite these putative hydrogen bonds, the Fe–S distances of Fe–S(1) = 2.3480(14) Å and Fe–S(2) = 2.3363(14) Å, are quite normal. Interestingly, both the methoxy oxygen atoms of the ligands are oriented towards the iron(II) ion, with distances of Fe–O(1) = 2.462 and Fe–O(2) = 2.473 Å. These distances are comparable to other Fe–O(ether) distances for compounds in which an Fe–O(ether) bond has been assigned. For example, a mean Fe–O distance of 2.40 Å is found for the crown ether complex {[Fe([12]-crown-4)$_2$](PF$_6$)$_2$}[41], and $(Fe\text{–}O)_{ave} = 2.386(3)$ Å for the calixarene complex [Fe(II–H)](FeCl$_4$)$_2$ [42] [(II–H) = 5,11,17,23-tetra-*tert*-butyl-24-hydroxy-26,27,28-tris (diethyl-carbamoylmethoxy)calix-[4]arene]. These data suggest that there is a bonding interaction between the Fe^{2+} ion and the methoxy oxygen atoms, and the ligand has adopted the unexpected tripodal N_2O bonding mode. However, the angles do not support an assignment of octahedral geometry in preference to a distorted tetrahedral geometry, and therefore we conclude that this O(ether)–Fe^{II} interaction is weak at best. The Fe–N distances of 2.157(4) Å are slightly longer than the bond length of 2.095(4) Å for the related $Fe^{II}(N_2S_2)$ complex Fe(S-2,6-*i*-Pr$_2$C$_6$H$_3$)$_2$(1-MeIm)$_2$ [43]. The X-ray structures of complexes **2** and **3** together with the synthesis and spectroscopic characterization of $(L^2)_2Zn$ (Scheme 2) make it clear that L^2 has a particular preference for coordination via a bidentate N,S bonding mode.

4. Conclusions

We have succeeded in obtaining the first X-ray structure of a transition metal complex of the N_2S(thiolate) ligand L^1. This trinuclear zinc complex **1** showed that L^1 does bind in the designed tripodal mode, but also exhibits another multibridging bonding mode involving bridging imidazole and thiolate groups. The

ligand L^2 is a modified version of L^1 bearing phenyl substituents, and exhibits a third type of bidentate N,S bonding mode evidenced by the X-ray structures of the dinuclear zinc(II) complex **2** and the mononuclear iron(II) complex **3**. This bonding mode is likely favored in the case of L^2 because of a combination of strain around the central carbon atom and the weakened donor power of the imidazole groups caused by the electron-withdrawing phenyl substituents. In addition, yet another type of bonding mode may be operative in **3**; there is some evidence for a weak bond between the methoxy oxygen atom of L^2 and Fe(II), giving rise to tripodal NSO(ether)-type coordination. Clearly, further modifications to these heteroscorpionate N_2S(thiolate) ligands are necessary before they can rival the tris(pyrazolyl)borates in terms of their ability to enforce a biologically relevant monomeric, tetrahedral geometry at the metal center. The results obtained here suggest that replacing the phenyl substituents with electron-donating groups (e.g. alkyl groups), as well as increasing the steric encumbrance near the sulfur atom to discourage thiolate bridges from forming, should favor complexes of the desired nuclearity and geometry.

5. Supplementary material

The X-ray crystallographic files, in CIF format, have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 213062, 213475 and 211497 for **1**, **2**, and **3**, respectively. Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, (fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk/conts/retrieving.html) on request, quoting the deposition number.

Dedicated to Jerry Trofimenko for creating the *poly*(pyrazolyl) borate ligand system that has provided inspiration for so many other chemists, and especially myself (G.P.)!

Abstract

The tris(2-mercapto-1-arylimidazolyl)hydroborato complexes {[Tm^{Ar}]Zn(mim^{Ar})}[ClO_4], which feature tetrahedrally coordinated zinc centers in a sulfur rich environment, may be prepared by the reaction of [Tm^{Ar}]Li with $Zn(ClO_4)_2$ in the presence of 2-mercapto-1-arylimidazole (mim^{Ar}; Ar = Ph, *p*-Tol). X-ray diffraction studies demonstrate that the mim^{Ar} ligands are almost orthogonal to the Zn–S–C plane, in contrast to the almost planar arrangement that is calculated for {[Tm^{H}]Zn(mim^{H})}$^+$ and {[Tm^{H}]Zn(mim^{Me})}$^+$. The orthogonal arrangement observed experimentally for both {[Tm^{Ph}]Zn(mim^{Ph})}$^+$ and {[$Tm^{p\text{-}Tol}$]Zn($mim^{p\text{-}Tol}$)}$^+$ is a consequence of the existence of a N–H···O hydrogen bond between the N–H group of the mim^{Ar} ligand and a molecule of methanol. Evidently, the hydrogen bonding interactions in {[Tm^{Ar}]Zn(mim^{Ar})···(HOMe)}$^+$ are sufficiently strong to counter the electronic destabilization resulting from rotation of the mim^{Ar} ligand from the Zn–S–C plane. The mim^{Ph} ligand of {[Tm^{Ph}]Zn(mim^{Ph})}$^+$ may be immediately displaced by I^- to give [Tm^{Ar}]ZnI; however, {[Tm^{Ph}]Zn(mim^{Ph})}$^+$ does not react rapidly with MeI, thereby demonstrating that the zinc coordinated mim^{Ph} ligand is less susceptible to electrophilic attack than is a zinc thiolate ligand.

1. Introduction

Tetrahedrally coordinated zinc in a sulfur-ligated environment, i.e. [S_4Zn^{II}], is a prominent feature of structural and functional sites of zinc enzymes and proteins, as exemplified by the structural site of liver alcohol dehydrogenase and the functional site of the Ada DNA repair protein [1,2]. While considerable insight into the chemistry of zinc enzymes has been achieved by studying synthetic analogues that feature nitrogen rich active sites (for example, see [3]), comparatively few studies have been devoted to the chemistry of synthetic analogues with [S_4Zn^{II}] coordination environments. In this paper, we describe the synthesis, structures and reactivity of tetrahedral zinc complexes [S_4Zn^{II}] that employ tripodal tris(2-mercapto-1-arylimidazolyl)hydroborato ligands.

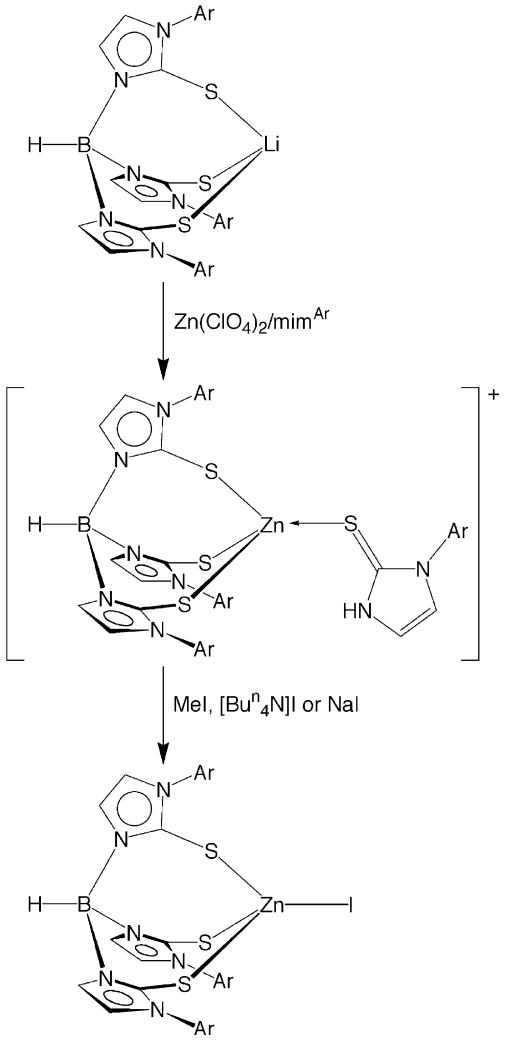
2. Results and discussion

We have previously reported the application of tris (2-mercapto-1-arylimidazolyl)hydroborato ligands, i.e. [Tm^{Ar}] for providing a [S_3] donor array to model aspects of the chemistry of zinc enzymes with sulfur-rich active sites [4]. For example, we have described the synthesis of [Tm^{Ph}]ZnSPh and have demonstrated that the phenylthiolate ligand is readily alkylated by MeI to give PhSMe and [Tm^{Ph}]ZnI ([4d], for other examples of alkylation of zinc thiolate derivatives, see [5]). Such reactivity mimics aspects of the mechanism of action of the Ada DNA repair protein which also possesses a [S_4Zn^{II}] active site [6]. A notable feature of the reaction between [Tm^{Ph}]ZnSPh and MeI is that the reaction occurs specifically at the sulfur atom of the phenylthiolate ligand, with the sulfur atoms of the [Tm^{Ph}] ligand being inert to alkylation. To address the issue of whether the inertness of the sulfur atoms of the [Tm^{Ph}] ligand is a consequence of constraints associated with the three mercaptoimidazole groups being attached to a common boron center, we sought to investigate the reactivity of {[Tm^{Ph}]Zn(mim^{Ar})}$^+$, in which the phenylthiolate ligand has been replaced by a 2-mercapto-1-arylimidazole ligand (mim^{Ar}; Ar = Ph, *p*-Tol).

2.1. Synthesis and structural characterization of {[Tm^{Ar}]Zn(mim^{Ar})}$^+$

{[Tm^{Ph}]Zn(mim^{Ph})}[ClO_4] may be prepared by the reaction of [Tm^{Ph}]Li with $Zn(ClO_4)_2$ in the presence of mim^{Ph} (Scheme 1). The *para*-tolyl derivative {[$Tm^{p\text{-Tol}}$]Zn($mim^{p\text{-Tol}}$)}[ClO_4] has likewise been synthesized (Scheme 1). Both {[Tm^{Ph}]Zn(mim^{Ph})}$^+$ and {[$Tm^{p\text{-Tol}}$]Zn($mim^{p\text{-Tol}}$)}$^+$ feature zinc centers that are coordinated to four mim^{Ar} groups, of which three are components of the [Tm^{Ar}] ligand. As such, {[Tm^{Ph}]-Zn(mim^{Ph})}$^+$ provides a means to determine whether the inertness of the sulfur atoms of the [Tm^{Ph}] ligand of [Tm^{Ph}]ZnSPh is associated with constraints imposed by attachment to the boron center.

The molecular structures of both {[Tm^{Ph}]Zn(mim^{Ph})} [ClO_4] and {[$Tm^{p\text{-Tol}}$]Zn($mim^{p\text{-Tol}}$)} [ClO_4] have been determined by X-ray diffraction (Figs. 1 and 2) and display several noteworthy features. First, the coordination geometry of the zinc is close to regular tetrahedral, with S–Zn–S bond angles in the range 103°–115° for {[Tm^{Ph}]-Zn(mim^{Ph})}$^+$ and 103°–120° for {[$Tm^{p\text{-Tol}}$]Zn ($mim^{p\text{-Tol}}$)}$^+$ (Table 1). In this regard, it is pertinent to compare the structures of {[Tm^{Ph}]- Zn(mim^{Ph})}$^+$ and {[$Tm^{p\text{-Tol}}$]-Zn($mim^{p\text{-Tol}}$)}$^+$ with that of [$Zn(SPh)_4$]$^{2-}$, a complex that may be expected to have an idealized tetrahedral zinc coordination environment. However, it has been noted by Koch and Millar that [$M(SPh)_4$]$^{2-}$ derivatives exist with two conformations that differ according to the positions of the phenyl groups; the two conformations have



Scheme 1.

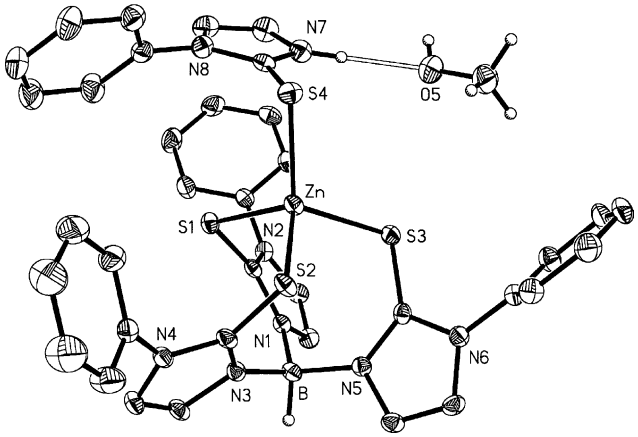


Fig. 1. Molecular structure of {[Tm^{Ph}]Zn(mim^{Ph})···(HOMe)}$^+$.

idealized S_4 and D_{2d} symmetry [7]. Steric interactions cause a distortion of the MS_4 core from tetrahedral geometry [8] such that the S_4 isomer is tetragonally compressed along the S_4 axis, while the D_{2d} isomer is tetragonally elongated.

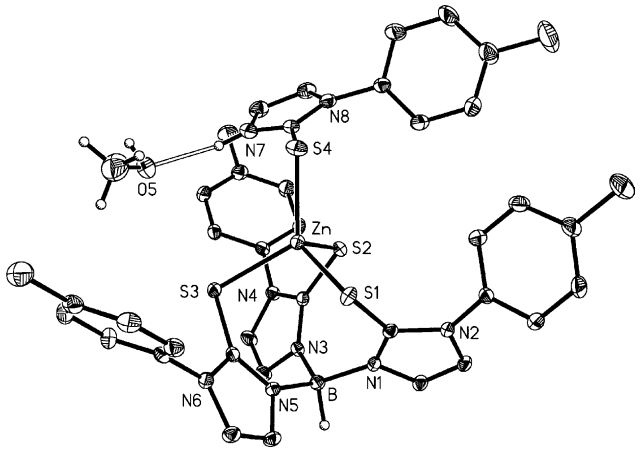

Fig. 2. Molecular structure of $\{[Tm^{p\text{-}Tol}]Zn(mim^{p\text{-}Tol})\cdots(HOMe)\}^+$.

S(2)–Zn–S(3)	102.92(5)	106.05(4)
S(2)–Zn–S(4)	112.45(4)	106.46(4)
S(3)–Zn–S(4)	114.94(5)	119.83(4)

Due to increased steric interactions, distortions from idealized tetrahedral coordination (109.5°) are expected to be greater for the D_{2d} isomer. Thus, the S–Zn–S bond angles in $[Ph_4P]_2[Zn(SPh)_4]$ with D_{2d} geometry spread the substantial range of 97°–121° [9], while those in $[Me_4N]_2$-$[Zn(SPh)_4]$ with S_4 geometry span the range 100°–117° [10]. It is, therefore, evident that $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$ (with S–Zn–S bond angles in the range 103°–115°) and $[Tm^{Ph}]ZnSPh$ (with S–Zn–S bond angles in the range 105°–115°) are better models for a tetrahedral zinc site than simple $[Zn(SPh)_4]^{2-}$. However, it should be noted that incorporation of different aryl groups can have a profound effect; thus, $[Et_4N]_2$-$[Zn(SAr)_4]$ (Ar = *o*-C_6H_4Ph) exhibits rigorous S_4 symmetry and the S–Zn–S angles are close to tetrahedral (106°–116°) [7a], whereas $[Et_3NH]_2[Zn(SAr)_4]$ (Ar = *o*-$C_6H_4pyr^{Me_2}$) deviates substantially from tetrahedral coordination (95°–119°) [11,12].

Second, the N–H protons of the mim^{Ar} ligands participate in a hydrogen bonding interaction with a molecule of methanol; the N···O distances are 2.80 Å (Ar = Ph) and 2.77 Å (Ar = *p*-Tol). Furthermore, it is noteworthy that the intermolecular N–H···O hydrogen bonding interaction with methanol is favored over an intramolecular N–H···S to one of the sulfur ligands attached to zinc. In this regard, it is worth noting that intramolecular N–H···S hydrogen bonding interactions involving Zn–S linkages have been previously observed [13], and that in one case, namely $[HC(pz^{Bu^t,\,Me})_2$-$(CO_2)]ZnS[C_6H_4$-*o*-NHC(O)Me], an intramolecular N–H···O hydrogen bond is favored over an intramolecular N–H···S hydrogen bond [13d].

Third, and of most interest to the present study, the coordination of the mim^{Ar} ligands is very similar to that of the analogous groups of the $[Tm^{Ar}]$ ligand. Specifically, not only are the Zn–S bond lengths comparable, but so are the C–S bond lengths and Zn–S–C bond angles, as summarized in Table 1. It is, therefore, evident that the attachment of the three mim^{Ar} groups to boron exerts very little perturbation on the ability of the mim^{Ar} groups to bind to zinc.

For further comparison, we have also determined the structure of $mim^{p\text{-}Tol}$, as illustrated in Fig. 3. The structure of $mim^{p\text{-}Tol}$ is analogous to that of mim^{Me} [14], consisting of a centrosymmetric N–H···S hydrogen bonded dimer, with a N···S separation (3.30 Å) that is comparable to that of mim^{Me} (3.35 Å). The diffraction study also indicates that the protons involved in the hydrogen bond interaction are attached primarily to the nitrogen [d(N–H) = 0.87 Å] and so $mim^{p\text{-}Tol}$ exists as the imidazole thione tautomer, as does mim^{Me}. Examination of the bond length data demonstrates that coordination of the $mim^{p\text{-}Tol}$ ligand is accompanied by little structural perturbation; as expected, the most significant change is associated with the C=S thione linkage, but this only increases from 1.690(2) to 1.720(5) Å upon coordination.

2.2. Reactivity of $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$

As previously noted, methyl iodide reacts with $[Tm^{Ph}]ZnSPh$ selectively at the sulfur atom of the phenylthiolate ligand and not with the sulfur atoms of the $[Tm^{Ph}]$ ligand [4d]. Since $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$ features

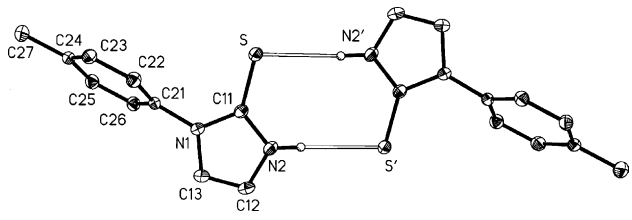

Fig. 3. Molecular structure of mim^{Ph}. Selected bond lengths (Å): S–C(11) 1.690(2), C(11)–N(1) 1.368(3), N(1)–C(13) 1.389(3), C(13)–C(12) 1.337(3), C(12)–N(2) 1.373(3), N(2)–C(11) 1.347(3), S···N(2′) 3.30 Å.

a zinc center that is coordinated to four mim^{Ph} groups, of which three are components of the $[Tm^{Ph}]$ ligand, it provides a means to determine whether the inertness of the sulfur atoms of the $[Tm^{Ph}]$ ligand of $[Tm^{Ph}]ZnSPh$ is associated with constraints imposed by attachment to the boron center. It is, therefore, notable that whereas $[Tm^{Ph}]ZnSPh$ reacts immediately with MeI to give $[Tm^{Ph}]ZnI$, the corresponding reaction of $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$ occurs over a period of days (Scheme 1). The iodide complex $[Tm^{Ph}]ZnI$ is, nevertheless, obtained immediately upon treatment of $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$ with either $[Bu^n_4N]I$ or NaI (Scheme 1). The reduced reactivity of $\{[Tm^{Ph}]Zn(mim^{Ph})\}^+$ towards MeI, as compared to that for $[Tm^{Ph}]ZnSPh$, clearly demonstrates that the coordinated mim^{Ph} ligand is less susceptible to electrophilic attack than is a zinc thiolate ligand, presumably a reflection the ''thione'' versus ''thiolate'' nature of the sulfur atoms [15].

2.3. DFT Calculations concerned with mim^R orientation and intermolecular N–H···O hydrogen bonding interactions

To address the issue pertaining to the intermolecular N–H···O hydrogen bond between the mim^{Ar} ligand and methanol, we have performed a series of DFT (B3LYP) calculations in which the aryl group of the $[Tm^{Ar}]$ ligand is replaced by hydrogen. Interestingly, the calculations indicate that while the geometry optimized structure of $\{[Tm^H]Zn(mim^H)\}^+$ is comparable to the experimental structures of $\{[Tm^{Ar}]Zn(mim^{Ar})\}^+$ in terms of the Zn–S and S–Zn–S bond lengths and angles, as illustrated in Fig. 4 and Table 2, a notable difference is concerned with the orientation of the mim^H ligand. Specifically, the mim^H ligand of $\{[Tm^H]Zn(mim^H)\}^+$ lies close to the plane defined by Zn–S–C, whereas the mim^{Ar} ligands of the experimentally determined structures of $\{[Tm^{Ar}]Zn(mim^{Ar})\cdots(HOMe)\}^+$ are almost orthogonal (Figs. 1 and 2). The ''in–plane'' Zn–mim^H geometry calculated for $\{[Tm^H]Zn(mim^H)\}^+$ is in accord with the orientations of the lone pairs in the imidazole thione mim^H. As a result of the orientation of the mim^H ligand in $\{[Tm^H]Zn(mim^H)\}^+$, the N–H hydrogen comes into proximity with one of the sulfur atoms of the $[Tm^H]$ ligand, with H···S and N···S separations of 2.37 and 3.34 Å, respectively. The N···S separation is very similar to the value of 3.30 Å described above for the hydrogen bonded dimeric structure of $mim^{p\text{-Tol}}$ (Fig. 3). It is, therefore, possible that this represents a N–H···S hydrogen bonding interaction. However, the N···S separation of 3.34 Å is longer than the separations that have been previously reported for zinc complexes with N–H···S hydrogen bonds, e.g., $[Ph(pz^{Bu^t})Bt^{Bu^t}]ZnS[C_6H_4\text{-}o\text{-}NHC(O)Bu^t]$ (2.94 Å) [5i], $[Tm^{Ph}]ZnSCH_2C(O)N(H)Ph$ (2.99 and 3.05 Å) [13c], and $Zn[S\text{–}2\text{–}C_6H_4N(H)C(O)Ph]_2(1\text{-}MeImH)_2$ (2.96 Å) [13b], such that the hydrogen bonding interaction in $\{[Tm^H]Zn(mim^H)\}^+$ must be regarded as weak. There are two principal reasons that may account for the longer N···S hydrogen bond separation in $\{[Tm^H]Zn(mim^H)\}^+$: (i) the N–H···S hydrogen bond interaction is part of a six-membered ring, whereas the hydrogen bonds in the other complexes that have been reported are components of a five-membered ring; and (ii) the sulfur of the $[Tm^H]$ ligand has thione character, whereas the other complexes have thiolate sulfurs that are likely to be more amenable to participating in a hydrogen bonding interaction. Thus, for these two reasons, the intramolecular N–H···S hydrogen bonding interaction would be expected to be weaker

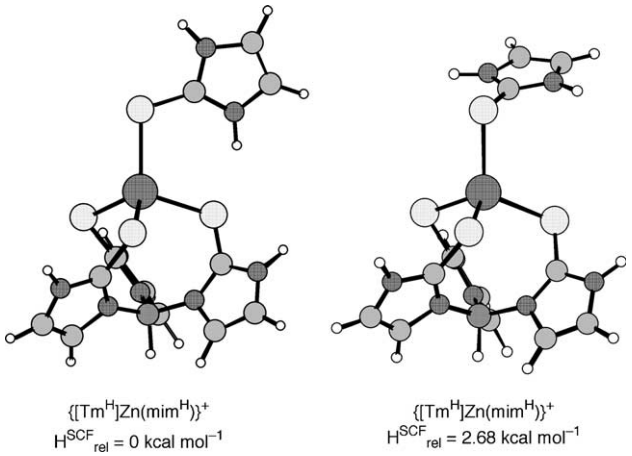

Fig. 4. Geometry optimized structure of $\{[Tm^H]Zn(mim^H)\}^+$ and that with the mim^H ligand constrained to be orthogonal to the Zn–S–C group by imposing a Zn–S–C–N torsion angle of 90°.

Table 2
Comparison of the geometries of the calculated structures of $\{[T]Zn(mim^H)\}^+$, $\{[Tm]Zn(mim^{Me})\}^+$, and $\{[Tm]Zn(mim^{Me})\cdots(HOMe)\}^+$ with those of the experimental structures for $\{[Tm^{Ph}]Zn(mim^{Ph})\cdots(HOMe)\}^+$ and $\{[Tm^{p\text{-Tol}}]Zn(mim^{p\text{-Tol}})\cdots(HOMe)\}^+$

	$\{[Tm^{Ph}]Zn(mim^{Ph})\cdots(HOMe)\}^+$ experiment	$\{[Tm^{Tol}]Zn(mim^{Tol})\cdots(HOMe)\}^+$ experiment	$\{[Tm]Zn(mim^H)\}^+$ calculated	$\{[Tm]Zn(mim^{Me})\}^+$ calculated	$\{[Tm]Zn(mim^{Me})\cdots(HOMe)\}^+$ calculated
Zn–S(Tm^R)$_{av}$ (Å)	2.35	2.35	2.45	2.45	2.45

S(mim^R)–Zn–S(Tm^R) (°)	109.6–114.9	106.5–119.8	109.6–115.0	110.0–114.8	107.7–118.3

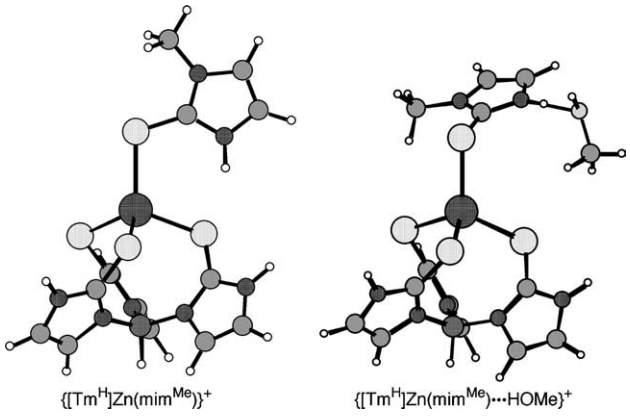

Fig. 5. Geometry optimized structure of $\{[Tm^H]Zn(mim^{Me})\}^+$ and the methanol adduct $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$.

than in the aforementioned thiolate complexes. Nevertheless, evidence which suggests that the N–H···S interaction is not insignificant is provided by the observation that the mim^H ligand does not adopt a position that bisects the S–Zn–S angle (which would minimize steric interactions), but is rather located such that one of the sulfur atoms of the $[Tm^H]$ ligand lies close to the plane of the mim^H ligand. Calculations on $\{[Tm^H]Zn(mim^H)\}^+$ with an orthogonal position for the mim^H ligand (i.e., a fixed Zn–S–C–N torsion angle of 90°) indicate that the preference for the "in-plane" position is 2.68 kcal mol^{-1} (Fig. 4).

To emulate the intermolecular N–H···O hydrogen bonding interaction with methanol, geometry optimization calculations were performed on $\{[Tm^H]Zn(mim^{Me})\}^+$ and $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$ (Fig. 5), the methyl group on the imidazole thione ligand being present to prevent an additional N–H···S hydrogen bonding interaction with the $[Tm^H]$ ligand. Significantly, while the mim^{Me} ligand of $\{[Tm^H]Zn(mim^{Me})\}^+$ adopts a similar conformation to that of mim^H in $\{[Tm^H]Zn(mim^H)\}^+$, coordination of MeOH results in rotation of the mim^{Me} ligand in $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$ to a position that closely reflects the experimentally observed geometry of $\{[Tm^{Ph}]Zn(mim^{Ph})\cdots(HOMe)\}^+$ (Fig. 5). Furthermore, the calculated N···O hydrogen bonding separation for $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$ (2.76 Å) compares favorably with the experimental values for $\{[Tm^{Ph}]Zn(mim^{Ph})\cdots(HOMe)\}^+$ (2.80 Å) and $\{[Tm^{p\text{-}Tol}]Zn(mim^{p\text{-}Tol})\cdots(HOMe)\}^+$ (2.77 Å). Thus, the N–H···O hydrogen bonding interaction in $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$ is sufficient (5.55 kcal mol^{-1}) to counter the electronically favored "in-plane" location of the mim^{Me} ligand.[1]

[1] The difference in energy between geometry optimized $\{[Tm^H]Zn(mim^{Me})\}^+$ and that of the same fragment in geometry optimized $\{[Tm^H]Zn(mim^{Me})\cdots(HOMe)\}^+$ is 3.44 kcal mol^{-1}. Thus, the magnitude of the hydrogen bonding interaction in the absence of rotation of the mim^{Me} ligand is 8.99 kcal mol^{-1}.

3. Experimental

3.1. General considerations

All manipulations were performed using a combination of glovebox, high-vacuum or Schlenk techniques [16]. Solvents were purified and degassed by standard procedures. ^1H NMR chemical shifts are reported in ppm relative to $SiMe_4$ ($\delta = 0$) and were referenced internally with respect to the protio solvent impurity. All coupling constants are reported in Hz. IR spectra were recorded as KBr pellets and are reported in cm^{-1}. C, H, and N elemental analyses were measured using a Perkin–Elmer 2400 CHN Elemental Analyzer. $[Tm^{Ph}]Li$ [4a] and mim^{Ar} [17] were synthesized as previously reported, and $[Tm^{p\text{-}Tol}]Li$ was prepared analogously to $[Tm^{Ph}]Li$.

3.2. Synthesis of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$

A mixture of $[Tm^{Ph}]Li$ (100 mg, 0.18 mmol), $Zn(ClO_4)_2\cdot 6H_2O$ (69 mg, 0.19 mmol) and mim^{Ph} (33 mg, 0.19 mmol) in MeOH (50 mL) was stirred overnight at room temperature. After this period, the mixture was filtered and the volatile components were removed from the filtrate. The resultant white product was washed with pentane (2×5 mL) and dried in vacuo to give $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ as a white solid (99 mg, 62%). *Anal.* Calc. for $C_{36}H_{30}N_8S_4BZnClO_4$: C, 49.2; H, 3.4; N, 12.8. Found: C, 49.0; H, 3.3; N, 12.5%. IR data (KBr disk, cm^{-1}): 2423 (ν_{B-H}). ^1H NMR (CD_3CN): 6.82 [br, $HB\{C_3N_2H_2(C_6H_5)S\}_3ZnS\{CN(C_6H_5)C_2H_2NH\}$], 7.02 [br, $HB\{C_3N_2H_2(C_6H_5)S\}_3ZnS\{CN(C_6H_5)C_2H_2NH\}$], 7.24–7.58 [m, $HB\{C_3N_2H_2(C_6H_5)S\}_3ZnS\{CN(C_6H_5)C_2H_2NH\}$], 10.62 [br,$HB\{C_3N_2H_2(C_6H_5)S\}_3ZnS\{CN(C_6H_5)C_2H_2NH\}$]. Crystals for X-ray diffraction were obtained from methanol.

3.3. Synthesis of $\{[Tm^{p\text{-}Tol}]Zn(mim^{p\text{-}Tol})\}[ClO_4]$

A mixture of $Zn(ClO_4)_2\cdot 6H_2O$ (98 mg, 0.26 mmol), $mim^{p\text{-}Tol}$ (50 mg, 0.26 mmol), and $[Tm^{tol}]Li$ (154 mg, 0.26 mmol) in CH_3CN (10 mL) was stirred for four days at room temperature. After this period, the mixture was filtered and the volatile components removed in vacuo from the filtrate. The resultant white product was washed with pentane (2×5 mL) and dried in vacuo to give $\{[Tm^{p\text{-}Tol}]Zn(mim^{p\text{-}Tol})\}[ClO_4]\cdot 3CH_3CN$ as a white solid (158 mg, 57%). *Anal.* Calc. for $C_{46}H_{47}BClN_{11}O_4S_4Zn$: C, 52.2; H, 4.5; N, 14.6. Found: C, 51.8; H, 4.0; N, 14.1%. IR data (KBr disk, cm^{-1}) = 2438 (ν_{B-H}). ^1H NMR (CD_3CN): 2.37 [s, $HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS\{CN(C_6H_4CH_3)C_2H_2NH\}$], 2.40 [s, $HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS\{CN(C_6H_4CH_3)C_2H_2NH\}$], 6.63 [d, $^3J_{H-H} = 2$ [3H], $HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS$-

$\{CN(C_6H_4CH_3)C_2H_2NH\}$], 6.94 [d, $^3J_{H-H} = 2$ [3H], $HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS\{CN(C_6H_4CH_3)C_2H_2$-NH}], 7.11–7.32 [m, $HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS$-$\{CN(C_6H_4CH_3)C_2H_2NH\}$], 10.62 [br,$HB\{C_3N_2H_2(C_6H_4CH_3)S\}_3ZnS\{CN(C_6H_4CH_3)C_2H_2NH\}$]. Crystals suitable for X-ray diffraction were obtained from methanol.

3.4. Reaction of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ with MeI

A solution of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ (ca. 3 mg) in $CDCl_3$ (0.5 mL) was treated with MeI (ca. 2 μl). The reaction was monitored by ^1H NMR spectroscopy, thereby demonstrating the formation of $Tm^{Ph}ZnI$ over a period of 2 days at room temperature.

3.5. Reaction of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ with NaI

A solution of $\{[Tn^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ (ca. 3 mg) in $CDCl_3$ (0.5 mL) was treated with NaI (ca. 5 mg). The reaction was monitored by ^1H NMR spectroscopy, thereby demonstrating the immediate formation of $Tm^{Ph}ZnI$.

3.6. Reaction of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ with $[Bu_4N]I$

A solution of $\{[Tm^{Ph}]Zn(mim^{Ph})\}[ClO_4]$ (ca. 3 mg) in $CDCl_3$ (0.5 mL) was treated with $[Bu_4N]I$ (ca. 5 mg). The reaction was monitored by ^1H NMR spectroscopy, thereby demonstrating the immediate formation of $Tm^{Ph}ZnI$.

3.7. X-ray structure determination

X-ray diffraction data were collected on a Bruker P4 diffractometer equipped with a SMART CCD detector and crystal data, data collection and refinement parameters are summarized in Table 3. The structures were solved using direct methods and standard difference map techniques, and were refined by full-matrix least-squares procedures on F^2 with SHELXTL (Version 5.03) [18].

3.8. Computational details

All calculations were carried out using DFT as implemented in the Jaguar 4.1 suite of ab initio quantum chemistry programs [19]. Geometry optimization was performed with the B3LYP [20] functional employing 6-31G** (H, B, C, N, O, S) and LAV3P** (Zn) basis sets [21]. The energies of the optimized structures were reevaluated by additional single point calculations on each optimized geometry using the cc-pVTZ(-f) [22] (H, B, C, N, O, S) and LAV3P** (Zn) basis sets [21].

4. Summary

In conclusion, $\{[Tm^{Ph}]Zn(mim^{Ph})\}^{+}$ and $\{[Tm^{p\text{-}Tol}]$-$Zn(mim^{p\text{-}Tol})\}^{+}$ provide examples of tetrahedrally coordinated zinc in a sulfur-ligated environment and, as such, represent models for the structural and functional sites of zinc enzymes and proteins, such as the Ada

DNA repair protein. X-ray diffraction studies demonstrate that the mim^{Ar} ligands are almost orthogonal to the Zn–S–C plane, in contrast to the almost planar arrangement that is calculated for $\{[Tm^{H}]Zn(mim^{H})\}^{+}$ and $\{[Tm^{H}]Zn(mim^{Me})\}^{+}$. The orthogonal arrangement observed experimentally is a consequence of the existence of N–H···O hydrogen bonds between the N–H group of the mim^{Ar} ligand and a molecule of methanol. Evidently, the hydrogen bonding interactions in $\{[Tm^{Ar}]Zn(mim^{Ar})\cdots(HOMe)\}^{+}$ are sufficiently strong to counter the electronic destabilization resulting from rotation of the mim^{Ar} ligand from out of the Zn–S–C plane. The mim^{Ph} ligand of $\{[Tm^{Ph}]Zn(mim^{Ph})\}^{+}$ may be immediately displaced by I^{-} to give $[Tm^{Ar}]ZnI$; however, $\{[Tm^{Ph}]Zn(mim^{Ph})\}^{+}$ does not react rapidly with MeI, thereby demonstrating that the zinc coordinated mim^{Ph} ligand is less susceptible to electrophilic attack than is a zinc thiolate ligand.

5. Supplemental material

The crystallographic data for $\{[Tm^{Ph}]Zn(mim^{Ph})\cdots(HOMe)\}$ $[ClO_4]$ (CCDC #215019), $\{[Tm^{p\text{-}Tol}]Zn(mim^{p\text{-}Tol})\cdots(HOMe)\}[ClO_4]$ (CCDC #215018), and mim^{Ph} (CCDC #215020) have been deposited with the Cambridge Crystallographic Data Centre. Copies of the information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Platinum-alkyl and hydride complexes supported by a tris(phosphino)borate ligand: structural and spectroscopic studies

J. Christopher Thomas, Jonas C. Peters *

Division of Chemistry and Chemical Engineering, Arnold and Mabel Beckman Laboratories of Chemical Synthesis, California Institute of Technology, Pasadena, CA 91125, USA

Received 30 July 2003; accepted 8 October 2003

Abstract

The synthesis and characterization of platinum-methyl and hydride complexes containing the ligand [$PhBP_3$] ([$PhBP_3$] = [$PhB(CH_2PPh_2)_3]^-$) are described. Metalation of [$PhBP_3$][TBA] (**1[TBA]**, [TBA] = [$^nBu_4N]^+$) with platinum methyl precursors provided the corresponding phosphine methyl platinum species [$PhBP_3$]$PtMe_3$ (**2**) and [[κ^2-$PhBP_3$]$PtMe_2$][TBA] (**3**). The reactivity of octahedral **2** and square planar **3** are discussed, and their X-ray diffraction structures are reported. Octahedral Pt(IV) **2** was found to be very thermally and chemically robust. In contrast, the square planar Pt(II) complex **3** demonstrated reactivity at both the platinum center and the unbound phosphine. The reaction of **3** with one equivalent of elemental sulfur provided the corresponding phosphine-sulfide [[κ^2-$PhB(CH_2P(S)Ph_2)(CH_2PPh_2)_2$]$PtMe_2$][TBA] (**4**). Similarly, the reaction of **3** with one equivalent of $BH_3 \cdot SMe_2$ generated the borane-protected complex [[κ^2-$PhB(CH_2P(BH_3)Ph_2)(CH_2PPh_2)_2$]$PtMe_2$][TBA] (**5**). Complex **5** was significantly less reactive than **3** to a variety of substrates under similar conditions; however, the reaction of **5** with additional $BH_3 \cdot SMe_2$ resulted in the formation of the platinum(I) bridged hydride species [[κ^2-$PhB(CH_2P(BH_3)Ph_2)(CH_2PPh_2)_2$]Pt($\mu$-H)]$_2$[TBA]$_2$ (**6**).

1. Introduction

Trofimenko's tris(pyrazolyl)borate ligands [1] have been widely used in mechanistic C–H activation studies. Several studies of the noble group 9 metals (Rh and Ir) have exploited the scorpionates, such as the recent works of Bergman and Harris [2], as well as that of Jones [3]. Important advances in [Tp]-supported platinum C–H activation chemistry have also emerged ([Tp] = hydrotris(pyrazolyl)borate, $[HB(pz)_3]^-$). For example, in an elegant experiment, Goldberg's group showed that the anionic complex K[[κ^2-Tp_2^{Me}]$PtMe_2$] ([Tp_2^{Me}] = hydrotris(3,5-dimethylpyrazolyl)borate) reacts with $B(C_6F_5)_3$ to generate an unobserved, presumed 3-coordinate species, "[κ^2-Tp_2^{Me}]PtMe", that then undergoes oxidative C–H bond addition to afford octahedral platinum(IV) alkyl hydride products, [κ^3-Tp_2^{Me}]Pt(Me)(R)H [4]. A number of interesting studies have followed this early report, including the isolation of a well-defined five-coordinate Pt(IV) species [5], a rare η^2-benzene adduct of platinum(II) [6], and mechanistic investigations of reductive elimination from platinum(IV) [7,8]. Given the considerable momentum behind [Tp]-supported C–H activation studies, it seemed prudent to us to begin examining other tripodal borate ligands for comparison [9]. We have therefore begun to develop the platinum chemistry of a related class of tris(phosphino)borate ligands. These latter ligands resemble the classic scorpionates by virtue of having three donor arms anchored by a borate unit so that they bind most typically in a tripodal fashion. Despite these similarities, the (phosphino)borates appear to be electronically, as well as sterically, quite distinct from [Tp]-type ligands. For example, the monoanionic (phosphino)borate complexes of platinum feature an anionic borate unit that is more spacially separated from the coordinated platinum center in both κ^3- and κ^2-binding modes

doi:10.1016/j.poly.2003.11.036

by comparison to structurally related [Tp] complexes (vide infra). Moreover, the absence of simple resonance contributors that would efficiently distribute the anionic borate charge in these (phosphino)borate complexes suggests that they can be reasonably regarded as molecular "zwitterions" [10]. Such a descriptor is not typically attributed to [Tp]-supported complexes, where resonance delocalization of the borate charge is normally presumed [11].

In the present study, we describe for the first time aspects of the platinum coordination chemistry of the tris(phosphino)borate ligand $[PhB(CH_2PPh_2)_3]^-$ (**1**, $[PhBP_3]$). We report on the synthesis and characterization of several methyl and hydride complexes of platinum supported by **1** and emphasize the electronic contribution that the anionic phosphine ligand provides.

2. Experimental

2.1. General

Unless otherwise noted, all syntheses were carried out under a dinitrogen atmosphere in the absence of water and dioxygen, using standard Schlenk or glovebox techniques. Acetonitrile, tetrahydrofuran, diethyl ether, dichloromethane, toluene, benzene, and petroleum ether were deoxygenated and dried by thorough sparging with N_2 gas followed by passage through an activated alumina column. Pentane and hexanes were deoxygenated by repeated evacuation under reduced pressure followed by introduction of dinitrogen and were dried by storing over 3-Å molecular sieves. Hydrocarbon and ethereal solvents were typically tested with a standard purple solution of sodium benzophenone ketyl in tetrahydrofuran in order to confirm effective oxygen and moisture removal. Ethanol and acetone were dried and distilled over calcium sulfate under dinitrogen. Morpholine and TMEDA were dried and distilled from CaH_2 under dinitrogen. Deuterated chloroform, benzene, dichloromethane, THF, acetonitrile, and acetone were purchased from Cambridge Isotope Laboratories, Inc. and were degassed by repeated freeze–pump–thaw cycles and dried over activated 3-Å molecular sieves prior to use. $[PhBP_3][Li(TMEDA)]$ [9a] and $(COD)PtMe_2$ [12] were prepared by literature methods. All other chemicals were purchased from commercial vendors and used without further purification. NMR spectra were recorded on Varian Mercury 300 MHz and Inova 500 MHz, and Joel 400 MHz spectrometers at ambient temperature, unless otherwise noted. ^1H and $^{13}C\{^1H\}$ chemical shifts were referenced to residual solvent as determined relative to Me_4Si (0 ppm). $^{31}P\{^1H\}$ NMR, $^{11}B\{^1H\}$ NMR, and $^{19}F\{^1H\}$ NMR chemical shifts are reported relative to an external standard (0 ppm) of 85% H_3PO_4, neat $BF_3 \cdot Et_2O$, and neat $CFCl_3$ respectively. Abbreviations for reported signal multiplicities are as follows: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; br, broad. IR spectra were recorded at 4 cm^{-1} resolution on a Bio-Rad Excalibur FTS 3000 spectrometer controlled by Win-IR Pro software using either a KBr solution cell or KBr plates. Elemental analyses were performed by Desert Analytics, Tucson, AZ. X-ray diffraction experiments were carried out by the Beckman Institute Crystallographic Facility on a Bruker SMART 1000 CCD diffractometer.

2.2. Syntheses of complexes

2.2.1. $[PhB(CH_2PPh_2)_3][^nBu_4N]$ (**1[TBA]**, $[PhBP_3][TBA]$)

The previously reported compound $[PhBP_3][Li(TMEDA)]$ [9] (20.987 g, 25.952 mmol) was dissolved in MeOH in air (50 mL). The methanolic solution was quickly filtered through diatomaceous earth and added slowly to tetra-*n*-butyl ammonium bromide (9.603 g, 28.55 mmol) dissolved in water (300 mL), yielding a white gelatinous solid which dispersed into a coarse chunky powder upon addition of Et_2O (40 mL). The mixture was stirred for 5 min, and then the solids were collected by filtration and washed sequentially with water (30 mL), Et_2O (30 mL), water (30 mL), and Et_2O (30 mL). The resulting white solids were dissolved in acetonitrile (100 mL), yielding a somewhat cloudy yellowish solution which was dried by stirring the reaction mixture over sodium sulfate for 10 min. The solution was then filtered over diatomaceous earth affording a clear yellow solution, which was concentrated by rotary evaporation and triturated with Et_2O, yielding white solid **1[TBA]** (16.453 g, 67.3%). This compound is not air or moisture stable and should be stored under inert atmosphere. ^1H NMR (400 MHz, CD_3CN): δ 7.48 (br, 2H, [*ortho*-$C_6H_5BP_3$]), 7.22 (m, 12H, aryl protons), 7.13 (m, 18H, aryl protons), 6.86 (t, 2H, [*meta*-$C_6H_5BP_3$]), 6.74 (t, 1H, [*para*-$C_6H_5BP_3$]), 3.04 (m, 8H, $[(CH_3CH_2CH_2CH_2)_4N]$), 1.57 (m, 8H, $[(CH_3CH_2CH_2CH_2)_4N]$), 1.33 (m, 8H, $[(CH_3CH_2CH_2CH_2)_4N]$), 1.08 (br, 6H, $[PhB(CH_2PPh_2)_3]$), 0.96 (t, 12H, $[(CH_3CH_2CH_2CH_2)_4N]$). $^{31}P\{^1H\}$ NMR (161.9 MHz, CD_3CN): δ −11.31. *Anal.* Calc. for $C_{62}H_{79}BNP_3$: C, 79.05; H, 8.45; N, 1.49. Found: C, 79.36; H, 8.52; N, 1.37%.

2.2.2. $[PhBP_3]PtMe_3$ (**2**)

Solid off-white $[PhBP_3][TBA]$ (263.6 mg, 0.2840 mmol) and $IPtMe_3$ (104.5 mg, 0.2847 mmol) were dissolved in THF (7 mL). The reaction mixture was stirred for 2 h and then concentrated to 4 mL. Upon standing, white solids precipitated. The supernatant was decanted, and the solids were dried under reduced pressure. Benzene (6 mL) was added, and the reaction mixture was stirred for 10 min. The cloudy solution was filtered, and volatiles were removed under reduced pressure from the

resulting solution, providing white solid **2** (193.2 mg, 73.5%). Clear, colorless block crystals suitable for X-ray diffraction were obtained from pentane diffusion into a THF solution of **2**. ^{1}H NMR (300 MHz, C_6D_6): δ 7.90 (d, 2H, [*ortho*-$C_6H_5BP_3$]), 7.54 (t, 2H, [*meta*-$C_6H_5BP_3$]), 7.36 (m, 13H, aryl protons), 6.85 (m, 18H, aryl protons), 2.01 (br, 6H, [PhB(CH_2PPh_2)$_3$]), 1.35 (d, 9H, Pt(CH_3)$_3$, $^2J_{Pt-H} = 55.5$ Hz, $^3J_{P-H} = 7.2$ Hz). ^{13}C{^{1}H} NMR (125.7 MHz, C_6D_6): δ 136.9, 133.9, 132.4, 129.5, 128.9, 124.9, 15.8 (br, [PhB(CH_2PPh_2)$_3$]), 6.5 (dd, Pt(CH_3)$_3$, $^1J_{Pt-C} = 497$ Hz, $^2J_{P-C} = 11$, 111 Hz). ^{31}P{^{1}H} NMR (121.4 MHz, C_6D_6): δ −26.01 ($^1J_{Pt-P} = 1094$ Hz). ^{11}B{^{1}H} NMR (128.3 MHz, C_6D_6): δ −11.9. *Anal.* Calc. for $C_{48}H_{50}BP_3Pt$: C, 62.28; H, 5.44. Found: C, 62.44; H, 5.67%.

2.2.3. [[κ^2-PhBP$_3$]PtMe$_2$][TBA] (3)

Solid off-white [PhBP$_3$][TBA] (1.6076 g, 1.732 mmol) was dissolved in THF (8 mL). A solution of (COD)PtMe$_2$ (577.0 mg, 1.731 mmol) dissolved in THF (1 mL) was added to the stirring [PhBP$_3$][TBA] solution, forming a colorless to pale yellow solution. After stirring the reaction mixture for 4 h, the volume of the reaction was reduced by removal of volatiles under reduced pressure. Precipitation with pentane produced off-white to pale yellow solids which were repeatedly triturated with pentane. Drying the solids under reduced pressure resulted in off-white to pale yellow solid **3** (1.8024 g, 90.3%). Clear, colorless rectangular prism crystals suitable for X-ray diffraction were grown by slow evaporation of a saturated toluene solution of **3**. ^{1}H NMR (300 MHz, acetone-d$_6$): δ 7.64 (br, 4H), 7.44 (br, 4H), 6.86–7.28 (m, 24H), 6.63 (m, 3H), 3.36 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.76 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.55 (br, 4H, [[PhB(CH_2PPh_2)(CH_2PPh_2)$_2$]PtMe$_2$]), 1.39 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.96 (t, 12H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.65 (br, 2H, [[PhB(CH_2PPh_2)(CH_2PPh_2)$_2$]PtMe$_2$]), 0.08 (t, 6H, Pt(CH_3)$_2$, $^2J_{Pt-H} = 67$ Hz, $^3J_{P-H} = 5$ Hz). ^{13}C{^{1}H} NMR (125.7 MHz, acetone-d$_6$): δ 122–148 (aryl carbons), 59.9 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 25.0 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 24 (br), 21.0 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 14.6 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 6.7 (Pt(CH_3)$_2$, $^1J_{Pt-C} = 616$ Hz, $^2J_{P-C} = 8.8$, 103 Hz). ^{31}P{^{1}H} NMR (121.4 MHz, acetone-d$_6$): δ 18.96 (s, 2P, $^1J_{Pt-P} = 1888$ Hz), −9.61 (s, 0.12P), −12.60 (s, 0.88P). ^{11}B{^{1}H} NMR (160.4 MHz, acetone-d$_6$): δ −14.10. *Anal.* Calc. for $C_{63}H_{83}BNP_3Pt$: C, 65.86; H, 7.34; N, 1.20. Found: C, 65.51; H, 7.29; N, 1.06%.

2.2.4. [[κ^2-PhB($CH_2P(S)Ph_2$)(CH_2PPh_2)$_2$]PtMe$_2$][TBA] (4)

Solid **3** (159.0 mg, 0.1379 mmol) was dissolved in THF (2 mL). While stirring the reaction mixture, a suspension of elemental sulfur (4.6 mg, 0.14 mmol of S atoms) in THF (1 mL) was added to the reaction. After 1h, the sulfur had been visibly consumed and the reaction changed color from colorless to yellow. The reaction mixture was filtered, and volatiles were removed under reduced pressure, providing pale yellow solid **4** (160.7 mg, 97.2%) in > 95% purity. Analytically pure **4** has not yet been isolated. ^{1}H NMR (300 MHz, acetone-d$_6$): δ 7.62 (br, 4H), 7.46 (br, 4H), 6.8–7.3 (m, 24H), 6.62 (m, 3H), 3.36 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.76 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.6 (br, 4H, [[PhB($CH_2P(S)Ph_2$)(CH_2PPh_2)$_2$]PtMe$_2$]), 1.39 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.96 (t, 12H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.73 (br, 2H, [[PhB($CH_2P(S)Ph_2$)(CH_2PPh_2)$_2$]PtMe$_2$]), 0.07 (t, 6H, Pt(CH_3)$_2$, $^2J_{Pt-H} = 68$ Hz, $^3J_{P-H} = 5$ Hz). ^{31}P{^{1}H} NMR (121.4 MHz, acetone-d$_6$): δ 44.44 (s, 1P), 18.37 (s, 2P, $^1J_{Pt-P} = 1875$ Hz).

2.2.5. [[κ^2-PhB($CH_2P(BH_3)Ph_2$)(CH_2PPh_2)$_2$]PtMe$_2$][TBA] (5)

Solid **3** (241.2 mg, 0.2092 mmol) was added to a fresh 2 M solution of $BH_3 \cdot SMe_2$ (104.6 μL, 0.2092 mmol) in toluene/THF. After 5 min, concentration of the reaction mixture under reduced pressure followed by addition of petroleum ether precipitated solid **5**. Analytically pure **5** was obtained from repeated washing of the solids with petroleum ether (237.6 mg, 97.3%). ^{1}H NMR (500 MHz, CD_2Cl_2): δ 7.72, 7.49, 7.0–7.4, 6.95, 6.54 (m, 35H, aryl protons), 2.96 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.50 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 1.35 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.99 (t, 12H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 0.04 (t, 6H, Pt(CH_3)$_2$, $^2J_{Pt-H} = 67$ Hz, $^3J_{P-H} = 5.5$ Hz). ^{13}C{^{1}H} NMR (125.7 MHz, CD_2Cl_2): δ 161 (br), 140.1 (m), 137.5 (d), 137.2 (d), 134.7 (m), 133.9 (m), 133.3, 132.4 (d), 129.0, 128.4, 128.0, 127.8 (d), 127.5, 127.1, 125.5, 122.3, 59.3 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 24.3 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 23.5 (br), 22.5 (br), 20.2 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 13.9 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 5.1 (dd, Pt(CH_3)$_2$, $^1J_{Pt-C} = 602$ Hz, $^2J_{P-C} = 9.1$, 102 Hz). ^{31}P{^{1}H} NMR (121.4 MHz, CD_2Cl_2): δ 18.01 (s, 2P, $^1J_{Pt-P} = 1878$ Hz), 15.30 (br, 1P). ^{11}B{^{1}H} NMR (160.4 MHz, CD_2Cl_2): δ −14.8, −30.3. *Anal.* Calc. for $C_{63}H_{86}B_2NP_3Pt$: C, 65.09; H, 7.51; N, 1.19. Found: C, 64.69; H, 7.53; N, 1.02%.

2.2.6. [[κ^2-PhB($CH_2P(BH_3)Ph_2$)(CH_2PPh_2)$_2$]Pt(μ-H)]$_2$[TBA]$_2$ (6)

Solid **3** (277.4 mg, 0.2377 mmol) was dissolved in THF (2 mL). While stirring the reaction mixture, a fresh 2 M solution of $BH_3 \cdot SMe_2$ in toluene/THF was added (250 μL, 0.500 mmol). After 15 min, the solution was concentrated to dryness under reduced pressure. The resulting solids were washed with petroleum ether [5 × 2 mL] and dried under reduced pressure, providing analytically pure **6** (268.4 mg, 99.2%). ^{1}H NMR (500 MHz, C_6D_6): δ 7.97 (br), 7.83 (m), 7.76 (br), 7.54 (br), 7.45 (d), 7.04 (br), 6.93 (m), (m, 35H, aryl protons), 2.66 (m, 8H, [($CH_3CH_2CH_2CH_2$)$_4$N]), 2.10 (br, 4H), 1.61 (br, 2H),

1.15 (m, 16H, [($CH_3CH_2CH_2CH_2$)$_4$N] and [(CH_3CH_2 CH_2CH_2)$_4$N]), 0.84 (t, 12H, [($CH_3CH_2CH_2CH_2$)$_4$N]), −3.17 (“quintet of quintets”, 2H, $[Pt(\mu-H)]_2$, $^1J_{Pt-H} = 464$ Hz, $^2J_{P-H} = 40$ Hz). $^{13}C\{^1H\}$ NMR (125.7 MHz, C_6D_6): δ 161 (br), 142.5 (br d), 141.3 (br d), 138.2 (d), 137.5 (d), 134.6 (br m), 134.2 (d), 134.0, 133.2 (d), 133.0 (d), 129.4, 128.9 (m), 127.9 (m), 126.5, 123.1, 58.8 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 24.4 ([($CH_3CH_2CH_2$ CH_2)$_4$N]), 20.2 ([($CH_3CH_2CH_2CH_2$)$_4$N]), 20 (br), 14.3 ([($CH_3CH_2CH_2CH_2$)$_4$N]). $^{31}P\{^1H\}$ NMR (121.4 MHz, C_6D_6): δ 25.69 (s, 2P, $^1J_{Pt-P} = 2959$ Hz, $^2J_{Pt-P} = 168$ Hz), 16.06 (br, 1P). $^{11}B\{^1H\}$ NMR (160.4 MHz, C_6D_6): δ −15.3, −31.1. ES–MS (CH_3CN, anion observe): Calc. for $[C_{90}H_{90}B_4P_6Pt_2]^{2-}$: 1790.5, found: 1790.9 [$M^{2-} + H^+$], 1777.1 [$M^{2-} + H^+ - BH_3$], 1763.3 [$M^{2-} + H^+ - 2BH_3$]. 2.3. X-ray crystallography

Single crystals of **2** and **3** were grown as described and were mounted on a glass fiber with Paratone N (Exxon) and transferred to the 98 K cold stream of a Bruker CCD X-ray diffraction system controlled by the SMART (v5.060) software package. Collected data were processed using SAINT+ (v6.02). No empirical absorption corrections were calculated. Structures were solved either by direct or Patterson methods using the XS program, followed by difference Fourier methods and refinements carried out with SHELXTL, both part of the SHELXTL software package (v5.1). Non-hydrogen atoms were refined anisotropically by a series of least-squares cycles. All hydrogen atoms were assigned idealized positions and refined isotropically. Crystallographic information is provided in Table 1, and interatomic distances and angles are contained in Table 2.

3. Results and discussion

3.1. Synthesis of a platinum(IV) trimethyl complex

The tridentate phosphine ligand **1** was initially reported as the lithium(TMEDA) salt, [$PhB(CH_2PPh_2)_3$][Li(TMEDA)] (**1[Li(TMEDA)]**) [9a]. Salt metathesis protocols developed in our laboratories have resulted in the useful thallium adduct, [$PhB(CH_2PPh_2)_3$]Tl (**1[Tl]**) [13] and the tetra(*n*-butyl)ammonium salt, [$PhB(CH_2$ $PPh_2)_3$][TBA] (**1[TBA]**) [14]. For the ensuing discussion of platinum chemistry supported by **1**, it was found that **1[TBA]** resulted in clean substitution onto platinum starting materials.

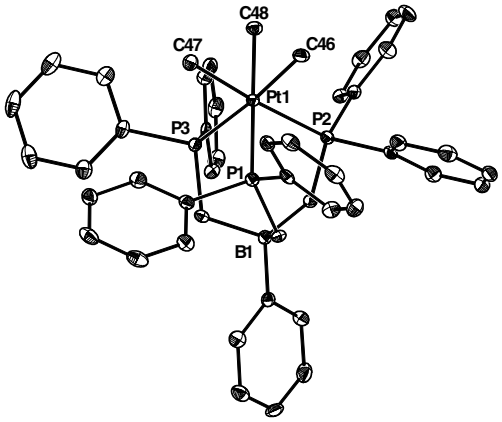

Fig. 1. A 50% displacement ellipsoid representation of **2**·**THF**. Hydrogen atoms and THF molecule are omitted for clarity.

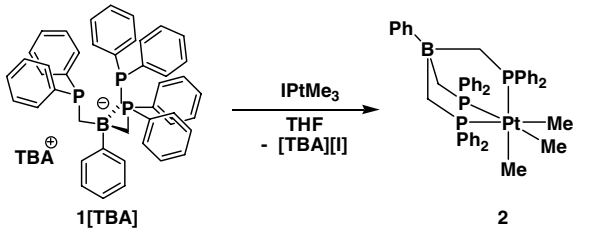
Reaction of **1[TBA]** in THF with $IPtMe_3$ led to the formation of a single product, $[PhBP_3]PtMe_3$ (**2**), as a colorless, neutral, octahedral Pt(IV) complex Eq. (1). In solution, **2** exhibited C_{3v} symmetry. Protons on the platinum-methyl groups showed coupling to both platinum ($^2J_{Pt-H} = 55.5$ Hz) and phosphorus ($^3J_{P-H} = 7.2$ Hz) in the ^1H NMR spectrum. Similarly, platinum coupling was seen for the ligand phosphines in the $^{31}P\{^1H\}$ NMR spectrum ($^1J_{Pt-P} = 1094$ Hz). Interestingly, the only other *fac*-platinum trimethyl complex supported by trialkyl phosphines that has been reported in the literature is $[(Me_2PhP)_3PtMe_3][PF_6]$ [15].

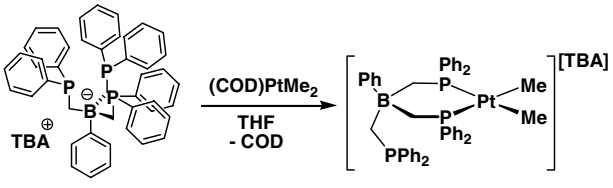


1[TBA] 2 (1)

An X-ray diffraction study carried out on a single crystal of **2** verified the structure (Fig. 1). The X-ray structure of **2** shows the tridentate *fac* coordination of ligand **1**, with P–Pt–P bond angles being very close to 90°. Space-filling models of **2** derived from the crystallographic data show that the phosphino-phenyl groups provide sufficient steric bulk to force the platinum-methyl groups slightly away from octahedral, as evidenced by the average C–Pt–C bond angle of 83.0°. Complex **2** is very robust, being stable to air, moisture, aqueous mineral acids (e.g., 12M HCl (aq)), strong Lewis acids (e.g., $B(C_6F_5)_3$, $[Ph_3C][BF_4]$), and reductants such as methyl lithium and sodium borohydride. Thermolysis of **2** in 1,3-dichlorobenzene showed that the complex was stable for several hours even at 170 °C; however, thermal decomposition occurred relatively quickly (hours) at 180 °C to provide a complex mixture of uncharacterized products. The marked stability of **2** is comparable to that observed for $[(Me_2PhP)_3PtMe_3][PF_6]$ by Clark and Manzer [15].[1] Compared to the recently structurally characterized $[Tp_2^{Me}]PtMe_3$, the Pt–C bond lengths of **2** are longer, presumably due to the greater *trans* influence of the phosphine ligands. More importantly, the Pt–B distance (3.640 Å) in **2** is much larger than for its [Tp] analogue (3.184 Å), likely providing a better through space separation of charge for **2**.

3.2. Synthesis and reactivity of platinum(II) complexes

Formation of the platinum(II)-methyl compound $[[\kappa^2\text{-}PhBP_3]PtMe_2][TBA]$ (**3**) proceeded cleanly at room temperature by the reaction of **1[TBA]** and $(COD)PtMe_2$ in THF solution (Eq. (2)). The ability to use $(COD)PtMe_2$ as a reagent is consistent with previous results using phosphine donor ligands and stands in contrast to (pyrazolyl)borate ligands which require more labile starting materials to achieve substitution [16,17].



1[TBA] 3 (2)

Examination of the ^1H and $^{31}P\{^1H\}$ NMR spectra of **3** shows the C_s symmetry of the platinum complex: the platinum-methyl protons are equivalent, with readily apparent coupling to platinum ($^2J_{Pt-H} = 67$ Hz) and phosphorus ($^3J_{P-H} = 5$ Hz). The coordinated phosphines in **3** have a very different chemical shift and platinum coupling constant ($\delta = 18.96$, $^1J_{Pt-P} = 1885$

[1] Interestingly, the authors observed high stability for $[Pt(CH_3)_3(OH_2)_3]^+$ and $[Pt(CH_3)_3(NC_2H_5)_3]^+$ as well, noting that the complexes "are quite stable and exhibit no tendency towards reductive decomposition" [15]. We presume that this is due to the electronic nature of the threefold symmetric octahedral molecules.

Hz) from those in **2** ($\delta = -26.01$, $^1J_{Pt-P} = 1093$ Hz), demonstrating a substantial change in the electronic character of the ligated phosphines between Pt(II) and Pt(IV) states. In contrast to two related $[[\kappa^2\text{-Tp}]PtMe_2]^-$ complexes, **3** exhibits smaller methyl $^2J_{Pt-H}$ values ($[[\kappa^2\text{-Tp}]PtMe_2]^-$, $^2J_{Pt-H} = 86$ Hz [16b]; $[[\kappa^2\text{-Tp}_2^{Me}]PtMe_2]^-$, $^2J_{Pt-H} = 83$ Hz [4]), consistent with stronger trans influencing phosphine donors. Relative to a series of previously prepared bidentate phosphine platinum-dimethyl compounds [18], $[E(CH_2PPh_2)_2]Pt(CH_3)_2$ (E $= Ph_2B^-$, Ph_2Si, H_2C), the phosphorus-platinum coupling constant of **3** is comparable to the anionic bis(phosphino)borate complex $[[Ph_2BP_2]PtMe_2][ASN]$ ($^1J_{Pt-P} = 1892$ Hz), and both anionic complexes have larger platinum phosphorus coupling constants than similar neutral compounds. A structurally analogous neutral Pt(II) compound, $(\kappa^2\text{-tripod})Pt(CH_3)_2$, has been previously prepared [19], though it was not thoroughly characterized nor explored further.

Examination of the $^{31}P\{^1H\}$ NMR spectrum of **3** showed two phosphine environments consistent with two phosphines ligated to a square planar platinum(II) center and one unligated phosphine. The pendant arm of the (phosphino)borate ligand in an analytically pure sample of **3** demonstrated unusual behavior. Two peaks were observed at −9.61 and −12.60 ppm whose integrated intensity corresponded to one phosphine relative to the two phosphines coordinated to platinum in the $^{31}P\{^1H\}$ NMR spectrum. Both of these signals are similar to the chemical shift of the uncoordinated ligand **1[TBA]** ($^{31}P\{^1H\}$ NMR (CD_3CN): δ −11.3). The two distinct signals suggest that there is a barrier to rotation about the phosphine-methylene (or the boron-methylene) carbon bond. The difference in chemical shifts between the two signals also suggests that a there is a modest change in the magnetic environment on the pendant phosphine depending on whether the phosphine lone pair is directed toward the metal or away from it. Two possible orientations are depicted in Fig. 2.

An X-ray diffraction experiment confirmed the structure of **3** (Fig. 3), showing that two arms of the tridentate ligand bind to platinum in a *cis* fashion to form a square planar dimethyl platinum complex while one arm of the ligand remains uncoordinated. The uncoordinated arm in the crystal lattice is oriented so that the phosphine lone pair is directed away from the metal. Examination of the bond angles around the platinum center reveals a square planar motif which has been slightly altered due to the steric demands of the aryl rings and the twisted conformation of the chelating ligand. Comparison of the bond lengths and angles observed for **3** with those observed for the related bis(phosphino)borate platinum(II) dimethyl anion $[[\kappa^2\text{-Ph}_2BP_2]PtMe_2][ASN]$ demonstrate that no significant structural changes occur by replacing the uncoordinated phosphine arm for a more innocent phenyl group pendant to boron [18]. Fortunately, the crystal structure of the related $[[\kappa^2\text{-Tp}_2^{Me}]PtMe_2]^-$ has been reported [4]. Similar to **2**, the Pt–C bond lengths (2.09 Å) are longer than for the Tp analogue (2.03 Å). The Pt–B distance in **3** is significantly longer (4.06 Å) than for its Tp analogue (3.37 Å), again suggesting a greater degree of spacial charge separation for $[PhBP_3]$-ligated complexes. It is interesting to note that for both **3** and $[[\kappa^2\text{-Tp}_2^{Me}]PtMe_2]^-$ the pendant donor is directed away from the metal center in the solid state structure. Presumably, interactions between the donor lone pair and the occupied d_z^2-type orbital results in electron-electron repulsion.

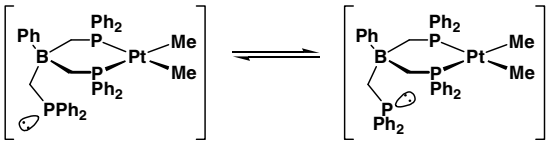


Fig. 2. Possible orientations for the pendant phosphine arm in **3**.

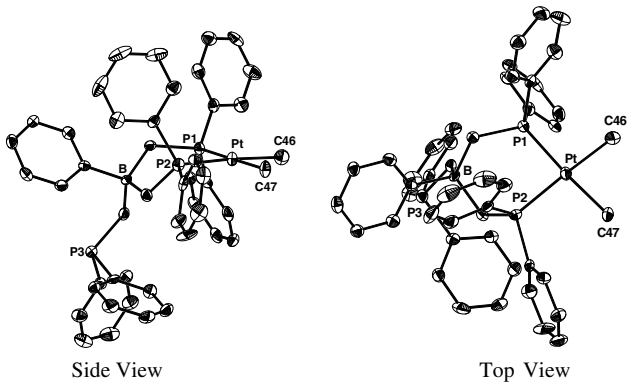

Fig. 3. A 50% displacement ellipsoid representation of **3**. Hydrogen atoms and the TBA cation are omitted for clarity.

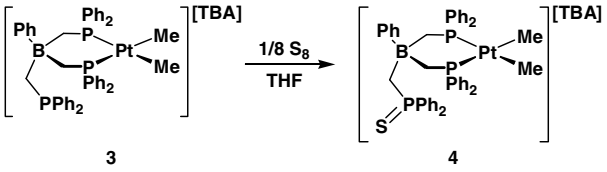
Complex **3** exhibited reactivity with dioxygen, water, protic and Lewis acids (e.g., HCl in Et_2O, HOTf, $[Et_3NH][BPh_4]$, $B(C_6F_5)_3$), and small alkyl halides such as CH_3I, CH_2Cl_2, and $CHCl_3$. In most cases, complex product mixtures were formed, as determined by $^{31}P\{^1H\}$ NMR spectroscopy. In particular, reactivity at the pendant phosphine arm was frequently observed, as evinced by new $^{31}P\{^1H\}$ NMR signals without platinum satellites. Related $[[\kappa^2\text{-Tp}]PtMe_2]^-$ species also show a wide variety of reactivity, including well-characterized reactions with H_2O, and protic and Lewis acids [4,16,20]. Reactivity at the uncoordinated pyrazolyl donor has been primarily limited to protonation [21]. The apparent contrast in reactivity of the uncoordinated donor in **3** is most likely attributed to its greater basicity and lower oxidation potential.

3.3. Protection of the unchelated phosphine

In order to sidestep undesirable reactivity at the pendant phosphine arm, phosphine protection strategies

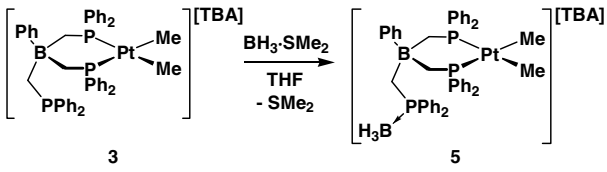
were considered. The pendant arm of the ligand reacted with one equivalent of elemental sulfur to provide a single major product Eq. (3), assigned by NMR spectroscopy as $[[\kappa^2\text{-PhB}(CH_2P(S)Ph_2)(CH_2PPh_2)_2]PtMe_2][TBA]$ (**4**). The chemical shift of a singlet at 44.4 ppm ($^{31}P\{^1H\}$ NMR) suggests an oxidized trialkylphosphine and is consistent with the $^{31}P\{^1H\}$ NMR chemical shifts of known $R_3P=S$ compounds [22]. Additionally, the $^{31}P\{^1H\}$ NMR chemical shift (18.4 ppm) and coupling ($^1J_{Pt-P} = 1875$ Hz) of the coordinated phosphines do not change significantly upon modification of the pendant arm. ^1H NMR spectra of **4** showed no significant changes as compared to **3**. Due to the difficulty in stoichiometric control of the sulfur addition, **4** was typically isolated in >95% purity. The addition of excess sulfur provides uncharacterized products.



3 4

(3)

A second protection strategy involved addition of the Lewis acid, $BH_3 \cdot SMe_2$. Using one equivalent of a 2.0 M solution of $BH_3 \cdot SMe_2$ in toluene ($BH_3 \cdot THF$ can also be used), clean formation of the BH_3-phosphine adduct **5** can be observed by $^{31}P\{^1H\}$ NMR spectroscopy Eq. (4). $^{31}P\{^1H\}$ NMR spectra show the disappearance of the peaks at −9 and −12 ppm (vide supra) and the growth of a broad peak at ca. 15 ppm. This downfield shift is expected for the formation of a phosphine-borane adduct due to the decreased shielding of the phosphorus nucleus upon borane complexation, and the broadness of the new peak results from unresolved coupling to the boron nucleus. Examination of **5** by ^{11}B NMR spectroscopy confirmed the formation of the phosphine-borane adduct with the presence of a new upfield signal (−30.3 ppm) consistent with known phosphine-borane complexes. The resonances from the platinum-bound phosphines demonstrate virtually no change in their $^{31}P\{^1H\}$ NMR chemical shift and register only a slight change in their coupling to platinum ($^1J_{Pt-P}(\mathbf{5}) = 1870$ Hz versus $^1J_{Pt-P}(\mathbf{3}) = 1885$ Hz).



3 5

(4)

Protection of the pendant phosphine arm with BH_3 provides altered reactivity with various substrates relative to the reactivity found in **3**. For example, **3** begins to react immediately when dissolved in dichloromethane, providing a mixture of products over a period of hours [10].[2] In contrast, **5** shows no spectroscopic change over 2.5 hours when dissolved in dichloromethane. Additionally, **5** shows no reaction with air and water in THF solution over several hours. These examples show that the reactivity of complex **3** is dependent upon the pendant phosphine arm, either as a site of reactivity or as a neutral donor facilitating reactivity at the platinum center. Deprotection of the pendant phosphine $\cdot BH_3$ adduct of **5** can be accomplished by heating **5** to 55 °C for several hours in the presence of excess (~200 equiv.) morpholine, a common deprotection method [23].

3.4. Reactivity of protected platinum(II) species

If **5** is allowed to react with an additional equivalent of $BH_3 \cdot SMe_2$ (or $BH_3 \cdot THF$), then clean formation of a new product is observed Eq. (5). Spectroscopic (NMR), mass spectrometric, and combustion analyses are consistent with the formation of the reduced platinum(I) dimeric species, $[[\kappa^2\text{-PhB}(CH_2P(BH_3)Ph_2)(CH_2PPh_2)_2]Pt(\mu\text{-H})]_2[TBA]_2$ (**6**). BH_3 reagents are widely known to act as reducing agents, and, in this case, it appears that BH_3 is serving as a reductant and H-atom donor. The fate of the methyl groups on platinum is unknown at this point: possible methyl containing products are methane or methylborane species, neither of which has been spectroscopically observed.

Bridging platinum(I) hydride dimers have been previously described in detail by Schwarz and Andersen [24]. The NMR spectra of **6** are consistent with their observations and those of others [24–26], including the unusual "quintet of quintets" signal for the hydrides (Table 3). The observed trends of the ^1H NMR spectroscopic data for several bisphosphine platinum(I) bridged hydrides suggest that the hydrides in **6** are *trans* to a more electron-rich bisphosphine ligand as compared to other neutral bisphosphine platinum(I) hydride dimers, based on the reduced Pt–H coupling constant. The IR data (Nujol) for **6** contain a broad peak at 2368 cm^{-1}, and two peaks at 2003 and 1966 cm^{-1}. The first of these peaks is consistent with previously observed BH_3-phosphine adducts, typically observed between 2450 and 2350 cm^{-1} [27]. The two peaks at 2003 and 1966 cm^{-1} are assigned as the Pt–H stretching modes.

[2] The unligated tris(phosphino)borate $[PhBP_3][TBA]$ also demonstrates reactivity with halide-containing solvents such as CH_2Cl_2 and $CHCl_3$.

Table 3
^{1}H NMR and IR data for bisphosphine platinum(I) dimers

Compound	δ (Pt–H) (ppm)	$^1J_{Pt-H}$ (Hz)	$^2J_{P-H}$ (Hz)	ν (Pt–H) (cm^{-1})Nujol	Ref.
6	−3.17	464	40	2003, 1966	
[(dppe)PtH]$_2$	0.30	564	42	[a]	[25b]

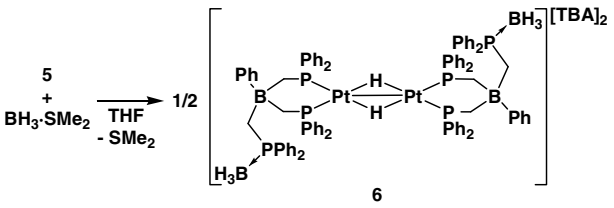
[(dcype)PtH]$_2$	0.49	512	40	1965, 1937	[24]
[(dtbpe)PtH]$_2$	0.05	570	42	1975, 1951	[24]
[(dfepe)PtH]$_2$	3.55	737	47	[b]	[26]

[a] IR data were not reported.
[b] The authors did not observe Pt–H stretching bands in the IR spectrum (see footnote 7 of [26]).



(5)

4. Conclusions

Several platinum methyl and hydride complexes containing the monoanionic tris(phosphino)borate ligand **1** have been synthesized, and preliminary investigations into their chemistry has begun. In general, a zwitterionic description for complexes ligated by **1** seems more appropriate than for related [Tp]-containing systems, given that comparative structural data often shows similar binding modes for the two ligands but greater separation between the metal center and the anionic borate for [PhBP$_3$] systems. Although the binding modes are similar between [Tp] and [PhBP$_3$], particularly notable for **3** and its [Tp] congener, we have found that much of the reactivity of the anionic dimethyl complex **3** is attributable to the unligated phosphine arm of the trisphosphine ligand. In comparison to related [Tp]-ligated platinum systems, the free phosphine donor readily participates in reactivity due to its greater basicity. Protection of the pendant phosphine arm can be achieved using either BH_3 or sulfur. The sulfur-protected complex **4** promises to be an interesting candidate for further reactivity studies based on its donor potential. Studies of the reactivity of the BH_3-protected compound **5** have shown it to be significantly less reactive than **3** under comparable conditions, demonstrating the role of the unbound phosphine in reactivity. Future studies of [PhBP$_3$]Pt systems will aim at further understanding the structural and electronic differences between analogous [Tp]- and [PhBP$_3$]-ligated complexes.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited at the Cambridge Crystallographic Data Center, CCDC Numbers 216189 (**2·THF**) and 216190 (**3**). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Ground and excited state spectral comparisons of models for sulfite oxidase

Martin L. Kirk *, Katrina Peariso

Department of Chemistry, The University of New Mexico, MSC03 2060, 1 University of New Mexico, Albuquerque, NM 87131-0001, USA

Received 1 August 2003; accepted 7 October 2003

Abstract

Determining the contributions of thiolate and ene-1,2-dithiolate donors to the underlying electronic structure of the Mo site in sulfite oxidase (SO) has been a goal pursued by inorganic chemists for almost twenty years. The use of the hydrotris(3,5-dimethyl-1-pyrazolyl)borate ligand provided the framework for the first low-symmetry oxo-molybdenum(V) models in which the oxo donor was *cis* to the dithiolene moiety of benzene-1,2-dithiolate. Recent work from the Carrano and Kirk laboratories has produced a second-generation model of the SO active site based upon the (2-dimethylethanethiol)bis(3,5-dimethylpyrazolyl)methane heteroscorpionate ligand. Use of this heteroscorpionate framework provides for an oxo-molybdenum(V) complex with both a thiolate and an ene-1,2-dithiolate in the equatorial plane. In addition to providing a good structural model, the heteroscorpionate thiolate offers a constrained O–Mo–$S_{thiolate}$–C torsion angle of ~115°, closer to that of the ~90° O–Mo–S_{Cys}–C torsion angle observed in the chicken liver SO active site than can be obtained with thiophenolate ligands. This constrained torsion angle allows for the examination of how second-coordination sphere effects influence the electronic structure of the Mo site. Here we compare and contrast the molecular and electronic structures of these first- and second-generation models of the SO active site. Additionally, the electron paramagnetic resonance (EPR) parameters for both of these models are compared with those measured for the Mo(V) form of both low pH (*lpH*) and high pH (*hpH*) forms of SO in order to determine what insight these structural models can offer about the electronic structure of the active site of SO.

1. Introduction

Pyranopterin molybdenum enzymes are ubiquitous in biology, performing such essential functions as the degradation of amino acids, nucleobases and various drugs in addition to their involvement in pro-drug activation [1]. These enzymes have previously been categorized into three families, two of which are represented in mammalian systems; the xanthine oxidase (XO) and sulfite oxidase (SO) families [1]. Members of the XO family are involved in the oxidation of simple aldehydes and the hydroxylation of purines while mammalian SO converts sulfite to sulfate, presumably via an inner sphere oxygen atom transfer process. The consensus active site structures for oxidized (SO_{ox}) and reduced (SO_{red}) SO are given in Scheme 1. Both sites are pentacoordinate, possessing an apical oxo donor and equatorial ene-1,2-dithiolate and cysteine sulfur (S_{Cys}) coordination [2–6]. The 5-coordinate site in SO_{ox} is completed by a second terminal oxo donor, which is replaced by water or hydroxide in reduced forms of the enzyme [2,3,5]. Catalysis is initiated in the reductive half-reaction, where the sulfite lone pair is proposed to attack the *equatorial* oxo donor (O_{eq}) resulting in a $2e^-$ reduction of the Mo center and a subsequent transfer of O_{eq} to the substrate to form sulfate [1,7]. The oxidative half reaction formally consists of sequential coupled electron–proton transfer steps which regenerate the oxidized active site, and the ene-1,2-dithiolene chelate has been hypothesized to play a key role in this process by modulating the reduction potential of the Mo and/or

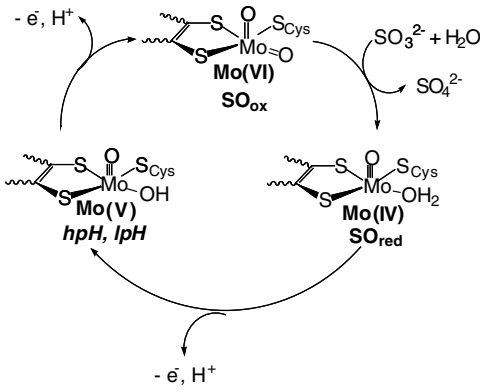

Scheme 1.

coupling the active site into hole superexchange pathways for electron transfer regeneration of SO_{ox} [8,9]. As the coordinated cysteine is essential for catalytic activity, these same roles may also be ascribed to the S_{Cys} donor as well. Charge density maps of the chicken liver enzyme indicate that electrons may be sequentially transferred out of the Mo active site following docking of the b-type heme domain [1] at the surface of the substrate access channel [10,11]. It has therefore been suggested that the S_{Cys}, which is directed toward this substrate access channel, could act as an electron transfer conduit between Mo and the b-type heme and facilitate the electron transfer regeneration process. As such, understanding the roles of the S_{Cys} and ene-1,2-dithiolate donors in reduced forms of SO has been a fundamental goal of researchers in this field.

Deconvoluting the different contributions of thiolate and ene-1,2-dithiolate donors to the underlying electronic structure of the Mo site in SO has proven to be a difficult task. Very accurate synthetic models of SO_{ox} and SO_{red} have recently been synthesized and structurally characterized. Holm and coworkers [12] have reported the synthesis and structural characterization of $(Et_4N)[MoOCl(bdt)(2,4,6\text{-}Pr^i_3\text{–}SC_6H_2)]$, however, the use of synthetic models to probe structure-property relationships that directly relate to the reduced SO active site has been hampered by the dearth of structural models that possess both ene-1,2-dithiolate and thiolate donors to molybdenum.

The synthesis and structures of new oxo-Mo(V) complexes as effective models for the one electron reduced active site of SO have also been recently reported. In these complexes, the tridentate heteroscorpionate ligand (2-dimethylethanethiol)bis(3,5-dimethylpyrazolyl)methane (L3SH) [13–15] was used to model the constrained cysteinyl sulfur (S_{Cys}) ligand environment observed in the crystal structure of the enzyme. In addition, an equatorial benzene-1,2-dithiol (bdt) provides a mimic of the ene-1,2-dithiolate chelate. As such, [(L3S)MoO(bdt)] is only the second known model compound that closely approximates the active site structure of reduced forms of SO. The incorporation of the $L3S^-$ chelate allows the O–Mo–S–C torsion angle to be effectively constrained in these new models. This is important, as bond torsions about this angle have been shown to be critical in modulating the degree of Mo–$S_{thiolate}$ covalency in oxomolybdenum thiolate complexes, affecting the overlap between the S^v p orbital [2] and the Mo $d_{x^2-y^2}$ redox orbital. The crystallographically determined O–Mo–S'_{Cys}–C torsion angle in SO is ~90° [5], which is markedly different from that found in small molecule complexes such as $[MoO(SPh)_4]^{1-}$ [16].

In this paper, we compare the structure and spectroscopic characterization of first and second generation models of the SO active site, [Tp*MoO(bdt)] and [(L3S)MoO(bdt)], respectively. These complexes allow for probing the effects of thiolate and ene-1,2-dithiolate coordination on the electronic structure of *hpH* and *lpH* SO and the respective abilities of these sulfur donor ligands to facilitate catalytically crucial ET processes.

2. Experimental

2.1. Preparation of compounds

Both [(L3S)MoO(bdt)] [17] and [Tp*MoO(bdt)] [18,19] were synthesized by literature methods.

2.2. Abbreviations

Tp* = hydrotris(3,5-dimethyl-1-pyrazolyl)borate; L3SH = (2-dimethylethane-thiol)bis(3,5-dimethylpyrazolyl)-methane; bdt = 1,2-benzenedithiolate; $S_{op}^{a',a''}$ = out-of-plane dithiolene S orbital; = $S_{ip}^{a',a''}$ in-plane dithiolene S orbital.

2.3. Electronic absorption spectroscopy

Solution electronic absorption spectra were collected using a Hitachi-3501 UV–Vis–NIR dual-beam spectrophotometer. The electronic absorption spectra were measured in 1-cm path length, black-masked, Wilmad quartz cuvettes with a Teflon stopper to prevent the introduction of O_2. The spectra for [(L3S)MoO(bdt)] was measured using dry, degassed dichloromethane as the solvent, and the spectrum for [Tp*MoO(bdt)] was measured in 1,2-dichloroethane. The measurements

[1] Vertebrate SO is a homodimer. Each half of the dimer consists of a molybdenum binding domain and a heme domain that are connected by a flexible loop region.

[2] S^v is the S p orbital that is orthogonal to the Mo–S bond and not involved in S–C σ bonding.

were repeated at a number of time points to ensure the structural stability and integrity of the complex in solution during the measurements.

2.4. Magnetic circular dichroism spectroscopy

Low temperature MCD spectra were collected on a system consisting of a Jasco J600 CD spectropolarimeter employing Hamamatsu photomultiplier tubes of either S-1 or S-20 response, an Oxford Instruments SM4000-7T superconducting magneto-optical cryostat (0–7 T, 1.4–300 K), and an ITC503 Oxford Instruments temperature controller. The spectrometer was calibrated for circular dichroism intensity with camphorsulfonic acid and the wavelength was calibrated using Nd-doped glass. All spectra were collected at 2.0 nm resolution at a temperature of 5 K in an applied magnetic field of 7 T. Samples were prepared by dispersing the solids in poly(dimethylsiloxane) and placing the mull between quartz disks. Depolarization of the incident radiation by the sample was determined by comparing the intrinsic circular dichroism of a standard Ni (+)-tartrate solution positioned in front of and then in back of each sample.

2.5. Electron paramagnetic resonance spectroscopy

Solution and frozen glass EPR spectra were measured at X-band (~9.3 GHz) using a Bruker EMX spectrometer. The room-temperature solution spectra were measured in dichloromethane. For the low temperature measurements, a 1:1 toluene–dichloromethane mixture was used as a glassing solvent, and the temperature was held at 4 K in an Oxford liquid helium flow cryostat. Simulations of the EPR spectra were performed using the program QPOW [20–22]. The enzyme and [Tp*MoO(bdt)] spectra were simulated using previously published parameters [18]. The proton hyperfine coupling has been removed in the enzyme spectral simulations for clarity and to aid in making direct comparisons with the model spectra.

3. Results and discussion

3.1. Comparing the solid state structures of [Tp*MoO(bdt)] and [(L3S)MoO(bdt)]

The structure of [Tp*MoO(bdt)] has been determined previously by Dhawan and Enemark [18]. The coordination geometry is that of a six-coordinate oxo-molybdenum complex with the sulfur atoms of the coordinated dithiolene oriented *cis* to the terminal oxo ligand. The effective symmetry of the molecule is C_s, with the mirror plane bisecting the two sulfur donors of the bdt ligand and containing the oxo-molybdenum unit. As is typical for mono oxo-molybdenum complexes, the Mo(V) ion was found to lie out of the N_2S_2 equatorial plane toward the apical oxo.

The crystal structure of [(L3S)MoO(bdt)] shows that the two pyrazolyl nitrogens and the alkyl thiolate sulfur donor of the $(L3S)^-$ ligand are facially coordinated to the Mo center [17]. An appreciable lengthening of the Mo–N(3) bond in [(L3S)MoO(bdt)] results from a strong structural *trans* effect due to the presence of the terminal oxo group, and this is reflected in the shorter Mo-oxo distance for [(L3S)MoO(bdt)] (1.657 Å) when compared to [Tp*MoO(bdt)] (1.678 Å). Thus, while the Mo–N(1) bonds average 2.178(5) Å in [(L3S)MoO(bdt)], and [Tp*MoO(bdt)] [18,23], the *trans* Mo(V)–N_{pz} bond lengths are 2.521, and 2.372 Å, respectively. Of particular interest is the very long distance recorded for the Mo–N(3) bond in the [(L3S)MoO(bdt)] derivative which is ~0.3 Å longer than the *cis* Mo–N bond. As was the case for [Tp*MoO(bdt)], the Mo atom lies above the center of a square plane consisting of atoms N(1), S(1), S(2) and S(3). Again, the oxo oxygen O(1) is orthogonal to this plane and the Mo ion lies approximately 0.3–0.4 Å out of the plane toward the oxo ligand. As anticipated, addition of a third sulfur in the equatorial plane of [(L3S)MoO(bdt)] results in Mo–$S_{dithiolene}$ bond distances that are somewhat longer, at an average of 2.405 Å, than those of [Tp*MoO(bdt)] which average 2.375 Å. This 2.40 Å Mo–S distance observed for [(L3S)MoO(bdt)] is completely consistent with the crystallographically and XAS determined Mo–S distances in the models of the SO active site published by Holm and coworkers [12,24]. Despite the increase in Mo–$S_{dithiolene}$ distance, the sulfur fold angles (the angle between the plane containing the Mo and the dithiolene sulfurs and that containing the dithiolene sulfurs and the S-bonded C atoms of the benzene-1,2-dithiolate ring) are very similar, at 23.6° in [(L3S)MoO(bdt)] and 21.3° in [Tp*MoO(bdt)] [18]. The O–Mo–S(1)–C dihedral angle in [(L3S)MoO(bdt)], which involves the alkyl thiolate donor from the L3S ligand, is 115° [17]. This angle is constrained by the chelate ring, and may be compared to the ~90° dihedral angle found in the structure of SO. The very close similarity in first coordination sphere sulfur donor atoms that exists between [(L3S)MoO(bdt)] and the enzyme is clearly evident in Fig. 1.

Fig. 1. Schematic representation of (left to right) the SO active site [5], [Tp*MoO(bdt)] [18], and [(L3S)MoO(bdt)] [17].

3.2. Electronic absorption spectra

A detailed electronic structure study of the first generation model compound [Tp*MoO(bdt)] has been previously undertaken and complete band assignments have been made [8]. The Gaussian resolved solution absorption spectrum of [Tp*MoO(bdt)] is shown in Fig. 2, and the band assignments are as follows: Bands 1 and 2, $S_{op}^{a',a''} \rightarrow d_{x^2-y^2}$; Band 3, $d_{x^2-y^2} \rightarrow d_{xz,yz}$; Band 4, $S_{ip}^{a'} \rightarrow d_{x^2-y^2}$; Band 5, $S_{op}^{a''} \rightarrow d_{xz,yz}$; Band 6, $S_{op}^{a'} \rightarrow d_{xz,yz}$. The intensities of the lowest energy charge transfer transitions are weak, which is indicative of the poor orbital overlap between out-of-plane dithiolene S orbitals and the in-plane Mo $d_{x^2-y^2}$ orbital. Band 3 is the lowest energy ligand field transition and reflects the splitting of the metal t_{2g} orbital set under the influence of a strong π^* interaction with the terminal oxo ligand. The intensity of band 4 reflects the degree of overlap between the in-plane dithiolene S orbital of a' symmetry and the Mo d_{xy} redox orbital. This overlap is of fundamental importance to hole transfer superexchange mechanisms for electron transfer regeneration involving the dithiolene chelate in pyranopterin molybdenum enzymes [8]. The intensity of bands 5 and 6 reflect dithiolene charge transfer to the higher energy, vacant, Mo $d_{xz,yz}$ orbitals and has been postulated to play a key role in modulating the reduction potential of [(Tp*)MoO(dithiolene)] [9] complexes as well as the SO_{red} site.

The electronic absorption spectra of [Tp*MoO(bdt)] and [(L3S)MoO(bdt)] are overlayed in Fig. 3 for comparative purposes. There are three distinct, lower intensity features that are clearly resolvable in the [(L3S)MoO(bdt)] spectrum, and these are observed at 9750 cm^{-1} ($\varepsilon = 400$ M^{-1} cm^{-1}), 14,792 cm^{-1} ($\varepsilon = 1020$ M^{-1} cm^{-1}) and 17,908 cm^{-1} ($\varepsilon = 630$ M^{-1} cm^{-1}) [17]. As stated earlier, three $S_{dithiolene} \rightarrow$ Mo charge transfer bands were assigned in a relatively similar energy region for [Tp*MoO(bdt)] [8]. The weak $d_{x^2-y^2} \rightarrow d_{xz,yz}$ ligand field transition cannot be assigned at this time and is almost certainly obscured beneath the ~14,800 cm^{-1} band in the [(L3S)MoO(bdt)] spectrum. By analogy with the [Tp*MoO(bdt)] spectrum, the 9750 cm^{-1} band is easily assignable as the lowest energy component of the $S_{op}^{a',a''} \rightarrow d_{x^2-y^2}$ charge transfer. A precise assignment of the 14,792 and 17,980 cm^{-1} bands is more difficult, however. Interestingly, the relative intensity of the transitions observed at 14,792 and 17,980 cm^{-1} in [(L3S)MoO(bdt)] are reversed from those observed in [Tp*MoO(bdt)]. This may be due, in part, to a dominant $L3S \rightarrow d_{x^2-y^2}$ LMCT contribution to the intensity of the 14,792 cm^{-1} band in the [(L3S)MoO(bdt)] model that is not present in the [Tp*MoO(bdt)] complex due to the fact it lacks an alkyl thiolate donor. The 17,980 cm^{-1} band is tentatively assigned as the $S_{ip}^{a'} \rightarrow d_{x^2-y^2}$ charge transfer transition. Provided that this is the correct assignment, it indicates a considerable reduction in the degree of overlap between the key in-plane dithiolene S orbital and the Mo $d_{x^2-y^2}$ redox orbital. A fundamental question that remains regarding the oxidative half reaction of SO is which S donor functions to assist in the electron transfer process whereby two electrons are shuttled sequentially from the SO_{red} site to the endogenous b-type heme. To the extent that the overlap between the dithiolene S p orbitals and Mo $d_{x^2-y^2}$ is attenuated in SO, this may result in a reduced capability for the dithiolene to effectively couple the Mo site into hole transfer superexchange pathways for electron transfer regeneration.

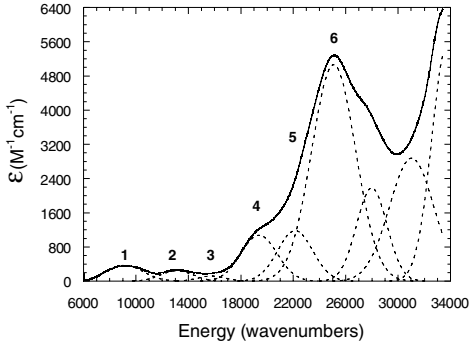

Fig. 2. Gaussian resolved electronic absorption spectrum of [Tp*MoO(bdt)]. Adapted from [8].

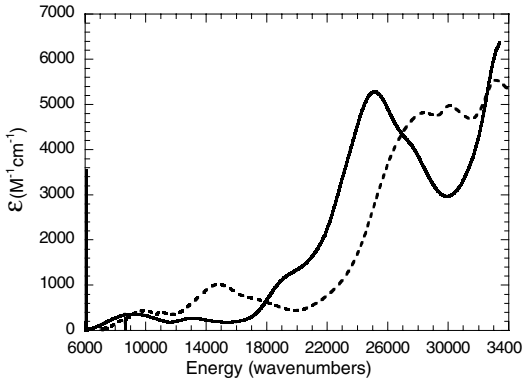

Fig. 3. Electronic absorption overlay of [Tp*MoO(bdt)] (solid line) and [(L3S)MoO(bdt)] (dashed line).

3.3. Magnetic circular dichroism spectroscopy

Given the discrepancy observed in the peak intensities in the low-energy region of the electronic absorption spectra for [(L3S)MoO(bdt)] and [Tp*MoO(bdt)], it is not surprising that there are significant differences in both the number and the intensity of the low-energy MCD features (relative to that of the high energy region of the spectrum) (Fig. 4). As discussed in the previous section, the region below 20 000 cm^{-1} is dominated by LMCT transitions from the sulfur donors to the Mo $d_{x^2-y^2}$ orbital. The increased MCD intensity in this re-

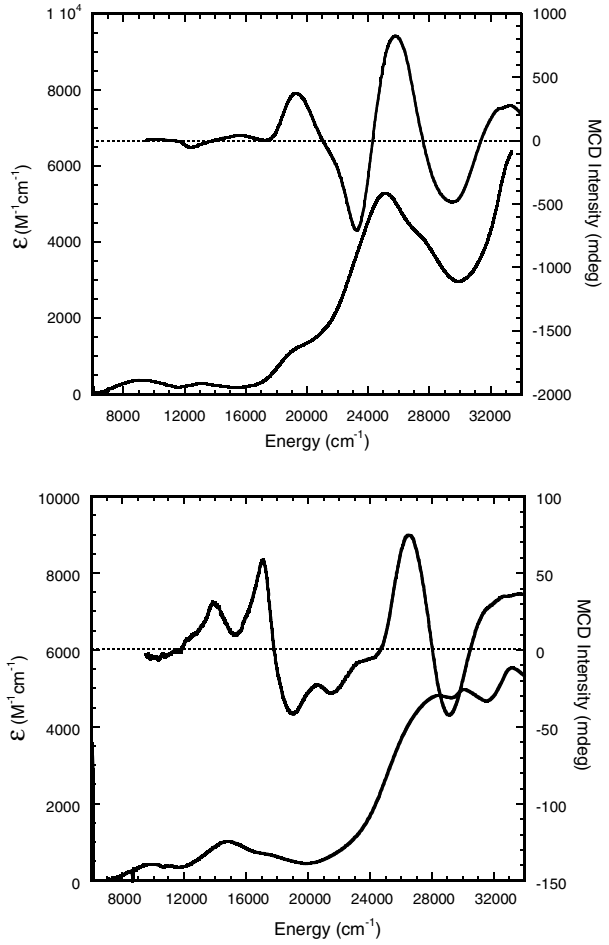

Fig. 4. Solution absorption and solid MCD overlay for [Tp*MoO(bdt)] (top) and [(L3S)MoO(bdt)] (bottom).

gion for [(L3S)MoO(bdt)] suggests an increase in out-of-state spin–orbit mixing between the $L3S \rightarrow d_{x^2-y^2}$, $S_{dithiolene} \rightarrow d_{x^2-y^2}$, and $d_{x^2-y^2} \rightarrow d_{xz,yz}$, states relative to that observed for [Tp*MoO(bdt)], especially for the transitions between 14 000 and 18 000 cm^{-1}. While the band assignments for the spectrum of [(L3S)MoO(bdt)] are not yet complete, the decreased symmetry of the [(L3S)MoO(bdt)] complex and the observed intensity increase in the low-energy MCD features indicates that the CT transitions likely arise from a linear combination of $L3S \rightarrow d_{x^2-y^2}$ and $S_{dithiolene} \rightarrow d_{x^2-y^2}$ one-electron promotions.

Despite these differences in the low-energy regions of the absorption and MCD spectra for [(L3S)MoO(bdt)] and [Tp*MoO(bdt)], the spectra above 24 300 cm^{-1} are strikingly similar. This is not entirely unexpected, since this region of the spectrum is dominated by CT transitions from the sulfur donors to the Mo $d_{xz,yz}$ orbitals. The planar geometry of the benzenedithiolate ligand allows for a large $S_{op}\pi$–Mo $d_{xy,yz}$ orbital overlap. If the constrained O_{ax}–Mo–$S_{thiolate}$–C torsion angle in [(L3S)MoO(bdt)] were closer to the ~90° O_{ax}–Mo–S_{Cys}–C torsion angle observed in SO, an increase in $S_{thiolate}$–Mo $d_{xy,yz}$ orbital overlap would be anticipated. However, the strong MCD spectral similarity between [(L3S)MoO(bdt)] and [Tp*MoO(bdt)] in the high energy region suggests that the $S_{thiolate} \rightarrow$ Mo $d_{xy,yz}$ CT transition is attenuated in [(L3S)MoO(bdt)], and this likely results from the larger 115° O_{ax}–Mo–$S_{thiolate}$–C torsion angle in [(L3S)MoO(bdt)] relative to that of the enzyme.

Understanding the electronic origin of CT contributions to the absorption and MCD spectra of [Tp*MoO(bdt)] and [(L3S)MoO(bdt)] has provided insight into the requirement of both thiolate and dithiolene donors in the first coordination sphere of SO_{red}. Interestingly, MCD spectra of the [Mo(V):Fe(II)] form of chicken liver SO show a distinct lack of low-energy CT bands [25]. While this may be due, in part, to the subtraction method employed to remove the heme signatures in the spectrum, it does suggest that, if these bands are present, they have very low intensity. This would suggest that despite the similarity in the first coordination sphere between [(L3S)MoO(bdt)] and SO_{red}, the electronic structure of the high pH MCD active SO_{red} active site is such that there is little S_{Cys}–Mo $d_{x^2-y^2}$ mixing, indicative of an ~90° O–Mo–S_{Cys}–C torsion angle also being present in the [Mo(V):Fe(II)] form of chicken liver SO. Studies are currently underway to investigate the electronic structure of SO in the absence of the heme cofactor, so that the S→Mo CT transitions may be more easily observed.

3.4. EPR spectroscopy

The EPR spectra of [(L3S)MoO(bdt)] and [Tp*MoO(bdt)], in addition to the enzyme spectra, have been analyzed using the spin-Hamiltonian given in Eq. (1), where the parameters and symbols have their usual meaning.

$$H = \beta H(g_{xx}\hat{S}_x + g_{yy}\hat{S}_y + g_{zz}\hat{S}_z) + A_{xx}\hat{S}_x\hat{I}_x + A_{yy}\hat{S}_y\hat{I}_y + A_{zz}\hat{S}_z\hat{I}_z. \quad (1)$$

We assign the *molecular* axes for [(L3S)MoO(bdt)] and [Tp*MoO(bdt)] using an orthogonal right hand coordinate frame with the molecular z along the terminal oxo and y bisecting the two sulfur donors of the dithiolene. Thus, for [Tp*MoO(bdt)] the x axis is orthogonal to the mirror plane. The anisotropic ^{95,97}Mo ($I = 5/2$; 25.38% abundance) hyperfine parameters (A_{ii}) are often difficult to determine from spectral simulations. Thus, the expression $\langle A \rangle = (A_{xx} + A_{yy} + A_{zz})/3$ has been used, which relates the isotropic solution hyperfine parameter, $\langle A \rangle$, to A_{ave}. A further complication often arises in the simulation of low-symmetry oxo-molybdenum complexes, namely the noncoincidence of the **g** and **A**(^{95,97}Mo) tensors. Thus, the Euler angles α, β, and γ are commonly used to transform the **A**(^{95,97}Mo) hyperfine

tensor onto that of the **g** frame. Metal complexes such as [(L3S)MoO(bdt)] that have very low or no symmetry (C_i or C_l) are not required to possess coincident **g** and **A**(^{95,97}Mo) tensors, while higher symmetry sites (C_s, C_2, or C_{2h}), such as the one present in [Tp*MoO(bdt)] are required to possess one coincident set of principal **g** and **A**(^{95,97}Mo) axes [26]. Understanding the electronic origin of **g** and **A** (^{95,97}Mo) tensor noncoincidence is important, as this relates directly to the degree of d orbital and charge transfer excited state mixing in low symmetry oxomolybdenum sites.

Single crystal EPR studies of oxomolybdenum complexes are quite rare and, to our knowledge, no such measurements have been performed on oxomolybdenum dithiolene complexes. However, the natural mixed isotope EPR spectra for [Tp*MoO(bdt)] [18] and [(L3S)MoO(bdt)] [17] in frozen glass matrices have recently been simulated and the spin-Hamiltonian parameters determined. These data are collected in Table 1 along with the analogous parameters for *hpH* and *lpH* SO. A comparison of these results shows that g_1 is greater than 2.00 for both of the model complexes, with [(L3S)MoO(bdt)] possessing the larger g_1 value and markedly less rhombicity in the **g** tensor. The **A**(^{95,97}Mo) tensors for both complexes are essentially axial. However, the [Tp*MoO(bdt)] complex possesses a rather unusual **A**(^{95,97}Mo) tensor with large and approximately equal A_1 and A_3 components, and coincident **g** and **A**(^{95,97}Mo) tensors. In marked contrast, [(L3S)MoO(bdt)] possesses only one large hyperfine component, A_1, and noncoincident **g** and **A**(^{95,97}Mo) tensors with $\beta = 40°$, the latter likely being a reflection of the lower point symmetry for this complex.

The values of the principal components for the **g** and **A**(^{95,97}Mo) tensors are directly related to the electronic structure of the complexes [27]. According to Eqs. (2)–(4), one may observe g_i values greater than the free electron value (2.0023) with large contributions from Δ_{gi}^{CT}, the charge transfer terms.

$$g_x = g_e - \Delta_{g_x}^{LF} + \Delta_{g_x}^{CT}, \quad (2)$$

$$g_y = g_e - \Delta_{g_y}^{LF} + \Delta_{g_y}^{CT}, \quad (3)$$

$$g_z = g_e - \Delta_{g_z}^{LF} + \Delta_{g_z}^{CT}. \quad (4)$$

The principal factors that affect **g** tensor anisotropy and, in particular, result in g_i values greater than 2.0023 for oxomolybdenum complexes are metal–ligand covalency, ligand spin–orbit coupling, and the presence of low energy L → Mo charge transfer states that mix into the ground state by the spin–orbit operator [27]. It has been empirically observed that g_1, the largest g_i component, is the one that is most affected by the $\Delta_{g_i}^{CT}$ term while the charge transfer contributions to g_2 and g_3 are minimal. Furthermore, for high symmetry oxomolybdenum halide complexes, both ground state and excited state covalency has been determined to be the dominant contributor to **g** tensor anisotropy and g_1 values greater the free electron value.

While spin–orbit mixing of charge transfer and ligand field excited states into the ground state wavefunction are important in determining **g** tensor anisotropy [27–29], the principal components of **A**(^{95,97}Mo) primarily reflect contributions from the isotropic Fermi contact and spin dipolar terms. Therefore, the ground state orbital wavefunction plays an important role in defining the principal directions of the **A**(^{95,97}Mo) tensor. Detailed electronic absorption, magnetic circular dichroism, and resonance Raman spectroscopic studies have shown that the singly occupied orbital in oxomolybdenum thiolates and dithiolenes is always orthogonal to the Mo≡O bond (i.e. the $d_{x^2-y^2}$ orbital in our coordinate frame) and A_{zz} should be oriented along this bond. The analysis of the [Tp*MoO(bdt)] frozen glass EPR spectra was based on previous studies of high symmetry oxomolybdenum complexes and single crystal experiments on a series of [(Tp*)(MoEX$_2$)] complexes (E = O, S; X = Cl, NCS) [30]. The analysis resulted in g_1 and A_1 being colinear and tentatively assigned as g_z and A_z. Both tensor components were found to be closely aligned with the Mo≡O bond. Since [Tp*MoO(bdt)] possesses effective C_s symmetry, g_2 and A_2 are fixed by symmetry, corresponding to g_x and A_{xx} and aligned perpendicular to the mirror plane. This leaves $g_3(g_y)$ and $A_3(A_y)$ bisecting the dithiolene sulfur donors in the equatorial plane of the molecule.

The unusual EPR spectral parameters for [Tp*MoO(bdt)] are all the more unique in light of a recent single crystal EPR study on the homologous series of complexes, [(Tp*)(MoOX$_2$)] (X = F, Cl, Br) [29]. This work revealed that A_{zz} is indeed oriented along

the Mo≡O bond for [(Tp*)($MoOF_2$)] and [(Tp*)($MoOBr_2$)]. However, β increases dramatically across the series ($\beta(F) = 17°$, $\beta(Cl) = 31°$, and $\beta(Br) = 57°$) indicating that M–L covalency, in concert with low energy charge transfer excited states, results in the rotation of g_{zz} off the molecular z axis. Drawing upon these studies, some preliminary tentative spectral assignments may be made for [(L3S)MoO(bdt)]. The A_{zz} hyperfine component is likely oriented along the Mo≡O bond (the molecular z axis) and g_1, assigned as g_z, is rotated away from A_{zz} by ~40° [17]. The orientations of g_2, g_3, A_2, and A_3 relative to the molecular coordinate frame have yet to be determined for this complex. Regardless, it appears that a fundamental difference in electronic structure exists between [Tp*MoO(bdt)] and [(L3S)MoO(bdt)]. One explanation for these observations is that the low energy S → Mo charge transfer states of [(L3S)MoO(bdt)] spin–orbit mix more efficiently into the ground state compared to [Tp*MoO(bdt)], and this is supported by the key differences observed in the electronic absorption spectra of these two complexes.

The EPR spectral parameters obtained for [(L3S)MoO(bdt)] and [Tp*MoO(bdt)] reflect the inherent differences in their geometric structures, ultimately influencing ground and excited state electronic structural differences as well. As the first coordination sphere of [(L3S)MoO(bdt)] is remarkably similar to that of chicken SO (Fig. 1) it might be expected that these similarities extend to their EPR spectra as well. Simulations of previously reported spectra for *hpH* and *lpH* SO clearly show that g_1 for *lpH* SO is greater than g_e [18], and quite similar to that observed for [Tp*MoO(bdt)] and [(L3S)MoO(bdt)] [17] (Fig. 5), while g_1 for *hpH* SO is significantly lowered, yielding $g_1 < g_e$ [18]. Furthermore, the hyperfine anisotropy pattern observed for [(L3S)MoO(bdt)], *hpH* SO, and *lpH* SO is similar with one large hyperfine component oriented along the Mo≡O bond and two smaller hyperfine components. Additionally, the simulations of the [(L3S)MoO(bdt)] and *lpH* SO spectra yield a similar noncoincidence of the **A**(^{95,97}Mo) hyperfine and **g** tensor components. In brief,

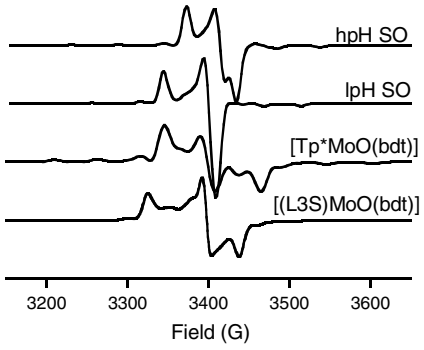

Fig. 5. EPR spectral simulations of hpH and lpH SO, and [Tp*MoO(bdt)] with the experimental spectrum of [(L3S)MoO(bdt)].

the EPR spectral parameters for [(L3S)MoO(bdt)] appear to be more closely related to those determined for SO than those for [Tp*MoO(bdt)], indicating that [(L3S)MoO(bdt)] is not only a good structural model for SO_{red} but a good electronic structural model as well. Although much can be gleaned from this type of combined analysis, the inherent ambiguities associated with spectral fitting of frozen glass EPR spectra underscore the need for detailed single crystal studies on accurate models for the one-electron reduced from of SO.

4. Summary

A geometric and electronic structural comparison of [(L3S)MoO(bdt)] and [Tp*MoO(bdt)], models for the one electron reduced site of sulfite oxidase, has been presented and discussed. EPR spectroscopy has been the technique of choice for probing the electronic structure of SO_{red}, since it is impossible to isolate 100% Mo(V) SO for electronic absorption spectroscopic studies. Thus, the relevant spin-Hamiltonian parameters have been determined for the models and directly compared with enzyme spectra.

The inherent electronic structure differences between [Tp*MoO(bdt)], and [(L3S)MoO(bdt)] are readily apparent in the EPR spectra of these complexes. Appreciable differences in g-tensor anisotropy are observed in the low temperature EPR spectra of [Tp*MoO(bdt)], and [(L3S)MoO(bdt)]. This is consistent with the fact that these complexes possess noticeably different electronic absorption spectra, which indicates that the charge transfer manifolds of these two complexes are different. Since g-tensor anisotropy is a function of both the energy of these LMCT states and their ability to spin–orbit couple with the ground state, the spectroscopic data presented for [Tp*MoO(bdt)] and [(L3S)MoO(bdt)], provide an initial basis for the interpretation of the enzyme EPR spectra. Indeed, specific spectral differences are observed between the models and the enzymes. Of particular importance is the fact that $g_1 > g_e$ for *both* [Tp*MoO(bdt)] and [(L3S)MoO(bdt)], in contrast to the fact that $g_1 < g_e$ for *hpH* SO. For [(L3S)MoO(bdt)] this is likely due to the fact that the O–Mo–$S_{thiolate}$–C dihedral angle is more obtuse than that observed in the structure of SO, where this angle was found to be ~90°. Bond torsions about this angle have been shown to be critical in modulating the degree of Mo–$S_{thiolate}$ covalency in oxomolybdenum thiolate complexes, affecting the overlap between a $S_{thiolate}$ p orbital and the Mo $d_{x^2-y^2}$ redox orbital [31].

The ability to directly examine the interplay between thiolate and dithiolene donors in [(L3S)MoO(bdt)] allows insight into possible hole superexchange mechanisms for electron transfer regeneration of the SO_{ox} site. Since the O–Mo–$S_{thiolate}$–C dihedral angle in [(L3S)MoO(bdt)] is more obtuse than that observed in

the structure of SO, akyl thiolate covalency contribution to the Mo $d_{x^2-y^2}$ orbital is increased in the model. This is evident in the intensity of the L3S $\rightarrow d_{x^2-y^2}$ LMCT band, which is of greater intensity than many of the $S_{dithiolene} \rightarrow d_{x^2-y^2}$ LMCT transitions in [Tp*MoO(bdt)]. The key point here is that the O–Mo–$S_{thiolate}$–C dihedral angle in reduced forms of SO may play a key role in the electron transfer regeneration process by acting as a switch, with dominant covalency contributions to the $d_{x^2-y^2}$ redox orbital involving the dithiolene and cysteine sulfurs being a direct function of this angle.

The results presented here demonstrate the importance of d^1 oxo-molybdenum thiolate/dithiolene electronic structure to the analysis of magnetic resonance data, since both metal–ligand covalency and the energy of low-lying LMCT states contribute significantly to the observed **g**-tensor anisotropy [27,28]. A more detailed spectroscopic and electronic structure study on these and related model complexes is currently underway in our laboratories with the primary focus of addressing specific issues regarding Mo–S bond covalency as they relate to SO mediated catalysis.

Abstract

The new copper(II)–nitrite complex $[Cu^{II}(L)(ONO)]ClO_4$ (**2**), L = [(bis(1-methylimidazol-2-yl)methyl)(2-(pyridyl-2-yl)ethyl)amine] was synthesized and characterized by cyclic voltammetry, UV–Vis spectroscopy, X-band EPR and X-ray crystallography. Complex **2** crystallizes in the monoclinic system, space group $P2_1/n$ and has the metal center in a somewhat distorted square pyramidal geometry, with three nitrogen atoms from the chelate ligand and one nitrite ion outlining the basal plane. One imidazole nitrogen from the tripodal molecule is at the apical position at 2.158(2) Å from the metal. Spectrophotometric and electrochemical experiments in water solution reveal that complex **2** readily releases the nitrite ligand in this medium ($t_{1/2} < 10$ s at 25 °C) yielding the precursor complex **1**, $[Cu^{II}(L)(S)]^{2+}$. The affinity of complex **1** for nitrite was evaluated by spectrophotometric titration, following the appearance of the Cu(II)–nitrite band at 376 nm, and by the cyclic voltammetric peak potential data. Both experiments were carried out in methanolic solution ($\mu = 0.1$ mol L^{-1}, $TBAPF_6$, $T = 25 \pm 1$ °C). The formation constant value obtained from the voltammetric experiments ($1.2 \pm 0.1 \times 10^3$ M^{-1}) agrees quite well with that from the spectrophotometric titration ($1.4 \pm 0.2 \times 10^3$ M^{-1}) and is within the range of values observed for other Cu(II)–nitrite complexes. The geometrical arrangements of the tripodal ligand and the nitrite ion coordination allows considering complex **2** a potential biomimetic structural model for type II copper in nitrite reductases.

Keywords: Cu-NIRs; Model complex; Crystalline structure; Tripodal ligand; Polyimidazole ligand

1. Introduction

Copper-containing nitrite reductases (Cu-NIRs) are a class of enzymes related to the reduction of nitrite (NO_2^-) to nitric oxide in one electron pathway [1,2]. This is one of the four classes of enzymes involved in the denitrification process, in which nitrate is gradually reduced to nitrite, gaseous nitric oxide, nitrous oxide and finally dinitrogen [1–3]. This is an anaerobic respiratory process achieved by anaerobic denitrifying which returns fixed nitrogen from the soil to the atmosphere [4]. There are two types of denitrification-associated nitrite reductases, one containing copper (Cu-NIRs) and the other an iron-heme core (Fe-NIRs) in the active site. Although the iron-containing nitrite reductases (Fe-NIRs) are the most abundant NIRs in nature, the Cu-NIRs ones show more physiological diversity, as they are found in a greater variety of ecological systems [5,6]. Cu-NIRs have been isolated from a large number of bacteria and are spectroscopically [7–10] and structurally [11–14] well characterized. Recently [15], two new mutant forms of NIRs from *Alcaligenes faecalis* (AfNIRs), D98N[NO_2^-] and H255[NO_2^-], have been structurally characterized. The D98N[NO_2^-] is a mutant AfNIR, in which Asp98 is displaced at ca. 1.00 Å in relation to the wild AfNIR. H255[NO_2^-] is another mutant AfNIR, in which His255 is replaced by Asn255,

doi:10.1016/j.poly.2003.09.036

providing significant insight in the understanding of the catalytic mechanism involved in this important environmental process [15]. The native AfNIR [13] is a green 110 kDa homotrimer, with each monomer containing one type I and one type II copper centers. Type I is coordinated to four chain amino acids (His95, Cys136, His45 and Met150) in distorted trigonal bipyramidal geometry. Type II presents a tetrahedral coordination and is bound to three histidine ligands (His100, His135 and His306) and one water molecule. In the oxidized D98N[NO_2^-] structure [8], nitrite is coordinated to the type II copper as a bidentate ligand via the oxygen atoms [Cu502–O1: 2.42 (0.05) and Cu502–O2: 2.21 (0.08) Å]. This coordination form is the same as that observed in the wild enzyme [13], in which the nitrite ion replaces the water molecule. In contrast, the structure [15] of the oxidized H255N[NO_2^-] features the binding of the nitrite through a single oxygen atom O2 [Cu502–O1: 3.60 (0.15) and Cu502–O2: 2.16 (0.05)] without the displacement of the water ligand [Cu502–503OH_2: 2.15 (0.09)]. Type II copper is therefore pentacoordinated and adopts a distorted square pyramidal geometry, in which the histidine HIS306 is at the apical position. The reduced forms of the D98[NO_2^-] and H255[NO_2^-] were also studied and in both structures nitrite adopts a similar position in the active site to that of the oxidized forms. Based on these studies, Boulanger and Murphy [15] suggested that the nitrite form mimics the electronic and structural properties of a proposed catalytic intermediate [12] in native AfNIR and that this stage is energetically accessible. In the catalytic mechanism, a protonated nitrite molecule [12] displaces the water ligand and coordinates to the type II copper prior to the electron transfer from the type I copper. Then, after the reduction of the type II copper, a pentacoordinated copper(II) transient complex is formed, which is coordinated to one hydroxyl and one nitric oxide. The protonation of the active site, the release of the NO molecule and the rebinding of the water ligand to the type II copper complete the catalytic process.

Aiming to mimic the arrangement of the histidine and the nitrite groups in the type II Cu-NIRS, we describe here a new copper(II)–nitrite complex (**2**) with a polyimidazole moiety. The copper(II)–chloride precursor complex (**1**) is only briefly discussed here, as it will be fully reported in a later paper [16]. Complex **2** presents structural features that allow us to consider it as a model for the active site of the oxidized type II copper nitrite reductases.

2. Experimental

2.1. Abbreviations

L, [(bis(1-methylimidazol-2-yl)methyl)(2-(pyridyl-2-yl)ethyl)amine]; $TBAPF_6$, tetrabutylammonium hexafluorophosphate; TEPA, tris[2-(2-pyridyl)ethyl] amine; TMBA, tris((benzimidazol-2-yl)methyl)amine; BIAP, *N*,*N*-bis(2-ethyl-5-methyl-imidazol-4-ylmethyl)aminopropane; L^{py}, 1,4-diisopropyl-7-R″-1,4,7-triazacyclononane (R″ = 6-methyl-2-pyridylmethyl); 1-BB, bis[(1-methylbenzimidazol-2-yl)methyl]amine; bdmppy, 2,6-bis[(3,5-dimethyl)pyrazol-1-yl]pyridine; dpyam, di-2-pyridylamine.

2.2. Materials

2-Methyl-2-imidazolecarboxaldehyde [17] and the [(bis(2-methylimidazol-2-yl)methyl)(2-(pyridyl-2-yl)ethyl) amine] (**L**) tripodal ligand [18] were synthesized as previously described. All reagents for syntheses and analyses were of analytical and/or spectroscopic grade and were used without further purification. In aqueous studies, deionized (Millipore) distilled water was used.

2.3. Instrumentation

Infrared spectra (KBr pellet) were taken with an FTIR Bomen MB-102 spectrometer. Elemental analysis was performed on a Perkin–Elmer elemental analyzer 2400 CHN. UV–Vis spectra were recorded on a Carry 5G UV–Vis spectrometer. Cyclic voltammograms were recorded using a Princeton Applied Research (PAR) 264A at room temperature (25 ± 1) °C and under argon atmosphere. A standard three-electrode cell was used, composed of the following electrodes: a glass carbon working, a platinum auxiliary and calomel or Ag/AgCl reference, for use in aqueous or methanolic measurements, respectively. Aqueous cyclic voltammograms (+1.2 to −0.5 V) of complexes **2** and **1** (1.0×10^{-3} mol L^{-1}) were recorded in CF_3COOH solutions (0.2 mol L^{-1}) in the pH range 4.5–8.5 (pH values were adjusted with NaOH solution, 0.1 mol L^{-1}). In the methanolic experiments, cyclic voltammograms were recorded in the +1.0 to −0.7 V range using $TBAPF_6$ [0.1 mol L^{-3}] as the supporting electrolyte and the ferrocenium–ferrocene [19] couple (Fc^+/Fc = 197 mV versus SCE, $\Delta E_p = 126$ mV) to monitor the reference electrode potential. EPR spectra were recorded on a Bruker ESP300E spectrometer at room and liquid N_2 temperatures.

2.4. Equilibrium constant determination

Spectrophotometric measurements were taken in methanol as follows: A methanolic solution of complex **1** (1.5×10^{-3} mol L^{-1}, $\mu = 0.1$ mol L^{-1} $TBAPF_6$) and a standard methanolic solution of sodium nitrite (1.8×10^{-2} mol L^{-1}) were previously prepared and pre-equilibrated at 25 ± 1 °C. A fixed volume of 2 mL complex **1** solution was placed in a cuvette, into which aliquots of the nitrite solution were added and spectrophotometric

measurements were taken after each addition until the relation [complex]:[nitrite] = 1 was reached. The equilibrium constant (K_{eq}) for the $[Cu^{II}(L)(ONO)]^+$ species was determined by the measurement of solutions containing the same concentration of complex **1**, C_x, and variable concentrations of the nitrite ligand (C'_L and C''_L). Eqs. (1) and (2) [20] were applied to calculate the K_{eq} constant, in which C'_z and C''_z are the concentration of the complex with absorbance values A_1 and A_2, respectively, at 376 nm. The absorbance values were corrected with respect to the absorbance of the precursor $[Cu^{II}(L)(S)]^+$ complex and the dilution.

$$K_{eq} = \frac{(C_x - pC'_z)C''_z}{pC'_z}, \tag{1}$$

where

$$C'_z = \frac{C_z(C''_L - pC'_L)}{p(C''_L - C'_L)} \quad \text{and} \quad C''_z : C'_z = A_2 : A_1 = p. \tag{2}$$

Potentiometric experimental data were also used to estimate the relative power of the nitrite ligand to complex with the $[Cu^{II}(L)(S)]^{2+}$ and $[Cu^{I}(L)(S)]^+$ species, since the electrochemical data correspond to the Cu(II)/Cu(I) redox system. This estimate can be achieved by means of the Leden "complexity" function, $F_0(x)_{ox,red}$ (Eq. (3)), in the presence of a defined concentration of the complexing agent [21]. In addition, estimation of the average ligand number $\bar{n}_{ox,red}$ (Bjerrum's function, Eq. (4)) [22] is also possible. These functions are readily evaluated from electrochemical data [23,24] at 25 °C.

$$F_0(x)_{ox,red} \cong \text{anti}\log\left\{ -\frac{n[(E_{1/2})_x - (E_{1/2})_s]}{0.05915} \right\} \cong 1 + (\beta_1)_{ox,red}[NO_2^-] + (\beta_2)_{ox,red}[NO_2^-]^2 + \cdots, \tag{3}$$

$$\Delta\frac{(E_{1/2})_{x',x}}{\log[X]} = \bar{n}_{ox,red}\frac{0.05915}{n}, \tag{4}$$

where the $(E_{1/2})_x$ and $(E_{1/2})_s$ are, respectively, the half-wave potentials in the complexing and non-complexing medium; n is the number of electrons involved in the Cu(II)/Cu(I) reduction process, [X] is the concentration of the complexing agent and ox,red is the Cu(II),Cu(I) oxidation states of the metal center.

From a plot $F_1(x)_{ox,red}$ versus [nitrite], the K_{ox}/K_{red} ratio can be graphically calculated [23,24] according to the following equations:

$$F_1(x)_{ox,red} = (\beta_1)_{ox,red} + (\beta_2)_{ox,red}[NO_2^-] + \cdots \tag{5}$$

$$F_1(x)_{ox,red} = \frac{F_0(x)_{ox,red} - 1}{[NO_2^-]}. \tag{6}$$

2.5. Synthesis

2.5.1. [Cu^II(L)Cl]ClO4 (1)

A solution of $CuCl_2 \cdot 2H_2O$ (0.17 g, 1 mmol, in 10 mL of ethanol) was added to an ethanolic solution of **L** (0.31 g, 1 mmol, in 10 mL) while stirring and heating. After 15 min, $NaClO_4 \cdot H_2O$ (0.12 g, 1 mmol, in 10 mL) was added resulting in a deep blue solution, from which a blue power was obtained. Monocrystals suitable for X-ray analysis were obtained from recrystallization in methanol/diisopropyl ether (5:1) solution. Yield: 0.28 g (56%). *Anal.* Calc. for $CuC_{17}H_{22}N_6O_4Cl_2$: C, 40.13; H, 4.36; N, 16.52. Found: C, 39.74; H, 4.33; N, 16.12%. $\Lambda_M = 194\ \Omega^{-1}\,cm^2\,mol^{-1}$ in CH_3CN. IR(KBr): ν(OH) 3445; $\nu(CH_{Ar}/CH_{Alif})$ 3158–2945; ν(C=N/C=C) 1602–1442; $\nu(ClO_4)$ 1096; $\delta(CH_{Ar})$ 753 in cm^{-1}.

2.5.2. [Cu^II(L)(ONO)]ClO4 (2)

Approximately 0.28 g of $NaNO_2$ (40 mmol) was added to a round-bottom flask containing a solution of the precursor complex $[Cu^{II}(L)Cl]ClO_4$ (**1**) (0.20 g, 0.40 mmol, in 30 mL of HBF_4, 0.10 mol L^{-1}). The reaction flask was sealed, stirred for 20 min and kept at 4 °C for 1 day, after which monocrystals suitable for X-ray analysis were collected. Yield: 60%. *Anal.* Calc. for $CuC_{17}H_{22}N_7O_6Cl$: C, 39.3; H, 4.27; N, 18.9. Found C, 39.3; H, 4.17; N, 18.8%. IR(KBr): $\nu(CH_{Ar}/CH_{Alif})$ 3151–2905; ν(C=N/C=C) 1603–1441; ν(N=O) 1383; ν(N–O) 1270; $\nu(ClO_4)$ 1092; $\delta(CH_{Ar})$ 761 in cm^{-1}.

Caution! Perchlorate salts with organic ligands are potentially explosive and should be carefully handled.

2.6. X-ray crystallography

Data collection, structure solution and refinement. The crystal was measured on an Enraf–Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Data were collected up to 50° in 2θ, with a redundancy of 4. The final unit cell parameters were based on all reflections. Data collection was made using the COLLECT program [25]; integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [26]. Absorption corrections were carried out using the multi-scan method [27]. The structure was solved by direct methods with SHELXS 97 [28]. The model was refined by full-matrix least-squares on F^2 with SHELXL 97 [29]. All hydrogen atoms were stereochemically positioned and refined with the riding model [29]. Hydrogen atoms of the aromatic rings and CH_2 were set isotropic with a thermal parameter 20% greater than the equivalent isotropic displacement parameter of the atom to which each one is bonded; this percentage was set to 50% for the hydrogen atoms of the methyl groups. Data collection and experimental

details for the complex are summarized in Table 1 and relevant bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. Synthesis and general characterization

The synthesis of **2** was achieved by the reaction of the precursor complex $[Cu^{II}(L)Cl]ClO_4$ (**1**) with $NaNO_2$ in a 1:1 ratio to give green single-crystals. The elemental analysis agrees quite well with the proposed $CuC_{17}H_{22}N_7O_6Cl$ formula. The infrared spectrum of **2** is mainly characterized by the skeletal ligand vibrations, the ν(N=O)/ν(N–O) stretching of the nitrite ligand and the ClO_4^- counter-ion. Although nitrite ligand vibrations can only be assigned with certainty by isotopic substitution, they are tentatively attributed here through the spectra differences between complexes **1** and **2**.

3.2. X-ray analysis

A ZORTEP [30] view of complex **2** is presented in Fig. 1. Complex **2** is a nitrite compound five-coordinated in a distorted square pyramidal stereochemistry, as the O(2) atom of the nitrite ligand is far from the metal center [Cu–O(2) = 2.76(2) Å]. This square pyramidal distortion is evidenced by the structural Addison [31] parameter ($\tau = 0.27$), which is zero for a perfectly square pyramidal geometry. As seen in Fig. 1, the tripodal ligand is coordinated in such a way that the ethylpyridine group (N2) lies in the basal plane and is *trans* to an imidazole nitrogen (N5) and mutually *cis* to the amine nitrogen (N3) and to one oxygen atom (O1) from the nitrite group. The coordination sphere is completed by the other imidazole nitrogen (N7) coordinated apically at 2.158(2) Å. The small bite angle resulting from the five-membered ring of the apical coordination, N(3)–Cu(1)–N(7) = 80.66(9)° deviates significantly from orthogonality. Consequently, the Cu^{II} ion is 0.1761(1) Å

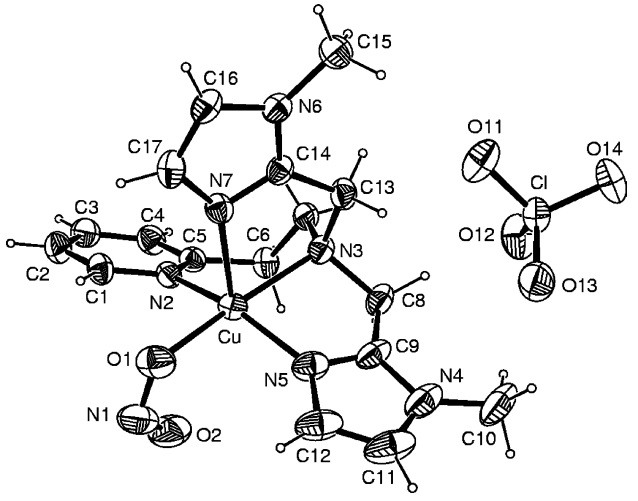

Fig. 1. The ZORTEP view of complex $[Cu(L)(ONO)]ClO_4$ (**2**), showing the atom labeling and the 50% probability ellipsoids.

above the least-square plane through N(2), N(3), O(1) and N(5). The coordination mode in complex **2** shows that the ligand undergoes a geometrical rearrangement when the nitrite group replaces the chloride ligand present in the precursor complex $[Cu^{II}(L)Cl]ClO_4$ (**1**). As in **1**, the ethylpyridine group coordinates at the apical position of the square pyramidal geometry ($\tau = 0.14$). The Cu^{II}–N_{amine} bond distance in complex **2** (Table 3) is smaller than that observed in $[Cu^{II}(L)Cl]ClO_4$ (**1**) (Table 3) and is within the range observed for other complexes given in Table 3. In complex **2**, the Cu–O(1) bond length [1.973(2) Å] is in the middle range observed (Table 3) for other copper(II)–nitrite complexes [32–38]. This bond length is a little shorter than those reported for the oxidized D98N[NO_2] and for the H255N[NO_2] enzymes (Table 3). The basal Cu–$N_{imidazole}$ bond length in complex **2** [Cu(1)–N(5): 1.963(3) Å] is the shortest of the coordination sphere and is similar to those observed for $[Cu^{II}(L)Cl]ClO_4$ (**1**) (Table 3), in which both imidazole groups also lie in the basal plane. On the other hand, the apical Cu–$N_{imidazole}$ bond length [Cu(1)–N(7): 2.158(2) Å] is the longest of the coordination sphere in complex **2**. In addition to the similarities of these bond lengths with those observed (Table 3) in complexes with imidazole ligands [33,34,36], the Cu–$N_{imidazole}$ bond length is close to the Cu–His distances reported [15] for the oxidized form of D98N[NO_2] and the oxidized form of H255N[NO_2]. As observed in Table 3, the Cu–$N_{pyridine}$ bond distance in **2** is slightly different to that in $[Cu^{II}(L)Cl]ClO_4$ (**1**), probably due to the coordination of this group in the basal plane and in the apical positions, respectively. However, the Cu–$N_{pyridine}$ bond length in $[Cu^{II}(L)Cl]ClO_4$ (**1**) is longer than those reported [32] for the $[Cu^{II}(TEPA)(NO_2)]^+$ complex, where two pyridine groups are coordinated in the basal plane (Table 3). Although the nitrite ligand in the wild copper-containing NIRs exhibits an asymmetric η^2-*O*,*O* coordination, and that in complex **2** a η^2-*O* coordination, the similarities of the Cu–$O(1)_{nitrite}$ and the Cu–$N_{imidazole}$ bond lengths with the analogous groups in the enzymes discussed above allow us to consider complex **2** as a

3.3. Electronic and EPR spectroscopies

The electronic spectrum of **2** recorded in acetonitrile solution (1.03×10^{-3} mol L^{-1}) presents two bands at 650 nm ($\varepsilon = 1.4 \times 10^2$ mol^{-1} L cm^{-1}) and 385 nm ($\varepsilon = 1.3 \times 10^3$ mol^{-1} L cm^{-1}), which are ascribed as a ligand field and a charge transfer transition, respectively, based on their molar absorption coefficients. As complex **2** presents only a broad ligand field band near 600–700 nm, it could be suggested that [39], in solution, the complex is in an octahedral coordination with a solvent molecule (S) occupying the vacant position in the first metal coordination sphere, affording the $[Cu^{II}(L)(S)ONO]^+$ species. The blue shift of the d–d transition from 687 nm ($\varepsilon = 1.2 \times 10^2$ mol^{-1} L cm^{-1}) in $[Cu^{II}(L)Cl]ClO_4$ (**1**) to 650 nm ($\varepsilon = 1.4 \times 10^2$ mol^{-1} L cm^{-1}) in **2** shows, as expected, that the nitrite ligand exhibits a stronger ligand field than the neutral acetonitrile molecule, which displaces the chloride ligand in **1** when it is dissolved [16]. As mentioned above, complex **2** also presents a charge transfer band in the near-UV region (385 nm, $\varepsilon = 1.3 \times 10^3$ mol^{-1} L cm^{-1}), with a molar extinction coefficient similar to that reported for the $[Cu(1\text{-}BB)(NO_2)]^+$ complex [36] (364 nm, $\varepsilon = 1.4 \times 10^3$ mol^{-1} L cm^{-1}). Such a result strongly suggests that the nature of this band is a nitrite–Cu^{II} charge transfer transition in copper(II)–nitrite complexes.

Spectra of **2** were also recorded in water (CF_3COOH, 0.2 mol L^{-1}, pH 7, adjusted with NaOH) and in methanolic (1.5×10^{-3} mol L^{-1}, $\mu = 0.1$ mol L^{-1} with $TBAPF_6$) solutions. In water, the spectrum presents only the d–d band at 682 nm ($\varepsilon = 1.0 \times 10^2$ mol^{-1} L cm^{-1}), which is within the same range observed for complex **1** under the same conditions (676 nm, $\varepsilon = 1.1 \times 10^2$ mol^{-1} L cm^{-1}). This fact may be indicative that the nitrite ligand is released in this medium. In methanolic solution, complex **2** exhibits spectral characteristics similar to those observed in acetonitrile (376 nm, $\varepsilon = 1.3 \times 10^3$ mol^{-1} L cm^{-1} and 648 nm, $\varepsilon = 1.7 \times 10^2$ mol^{-1} L cm^{-1}), indicating the coordination of nitrite in this medium.

The X-band EPR spectra of complex **2** in the polycrystalline state show only isotropic signals in the range of $g \cong 4.3$ (room temperature: $g_{iso} \cong 4.148$ and liquid N_2: $g_{iso} \cong 4.261$) and $g \cong 2$ (room temperature: $g_{iso} \cong 2.079$ and liquid N_2: $g_{iso} \cong 2.104$). This behavior is typical of a copper–copper interaction among close molecules [40], which may arise from the packing of the molecules in the crystalline cell. The first signal is large and not very intense corresponding to the forbidden transition $\Delta M_s = 2$. The second one is due to the allowed transition $\Delta M_s = \pm 1$ [40]. For comparison purposes, EPR spectra were also recorded in ethanol/water (1:1) solution at liquid N_2 temperature (Fig. 3) and reveals a typical spectrum of tetragonal distorted stereochemistry ($g_\parallel > g_\perp > g_e$ and high hyperfine constant $A_\parallel$) and the fitted parameters [41] for complex **2** ($g_\parallel = 2.261$, $g_\perp = 2.084$ and $A_\parallel = 163.0 \times 10^{-4}$ cm^{-1}) show a decrease in the $g_\parallel$ and an increase in the $A_\parallel$ values with respect to the precursor complex $[Cu^{II}(L)Cl]ClO_4$ (**1**) ($g_\parallel = 2.267$, $g_\perp = 2.096$ and $A_\parallel = 148.0 \times 10^{-4}$ cm^{-1}). This fact has been interpreted [42] as an increase in the delocalization of the unpaired electron, which moves away from the metal center as a consequence of the increase in the covalence of the metal–ligand bond. This agrees with the replacement of the neutral solvent molecule by the nitrite group. Comparison of EPR data for complex **2** with copper(II)–nitrite complexes is difficult as their parameters were recorded in very different media.

3.4. Electrochemical studies

The redox behavior of complex **2** was investigated in water and in methanolic solutions. In water (1.0×10^{-3} mol L^{-1}, CF_3COOH 0.2 mol L^{-1}, pH range 4.5–8.5, potential range of +1.2 to −0.7 V) complex **2** presents two redox processes: one reversible at $E_{1/2} = -235$ mV versus SCE ($\Delta E_p \approx 80$ mV, $i_{pa}/i_{pc} \approx 1.0$) and one irreversible at $E_{pc} = +970$ mV versus SCE. Both processes do not undergo significant changes (less than 5 mV) in the studied pH range. For complex **1**, the reversible Cu(II)/Cu(I) couple process, under the same experimental conditions, is observed at $E_{1/2} = -234$ mV versus SCE ($\Delta E_p \approx 82$ mV, $i_{pa}/i_{pc} \approx 1.0$), which is attributed to the presence of the $[Cu^{II}(L)(S)]^{2+}$ species in

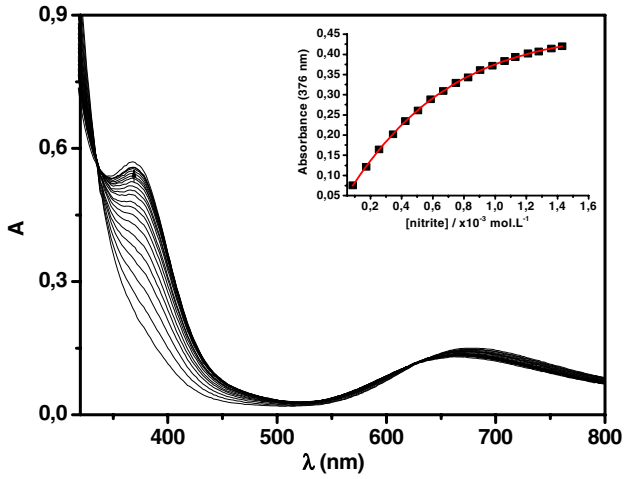

Fig. 2. Difference spectra recorded during the titration of complex **1** (1.5×10^{-3} mol L^{-1}, $\mu = 0.1$ mol L^{-1} $TBAPF_6$) with nitrite (8.0×10^{-5}–1.8×10^{-3} mol L^{-1}) in methanolic solution at 25 ± 1 °C and best fit plot (inset) of absorbance at 376 nm against nitrite concentration.

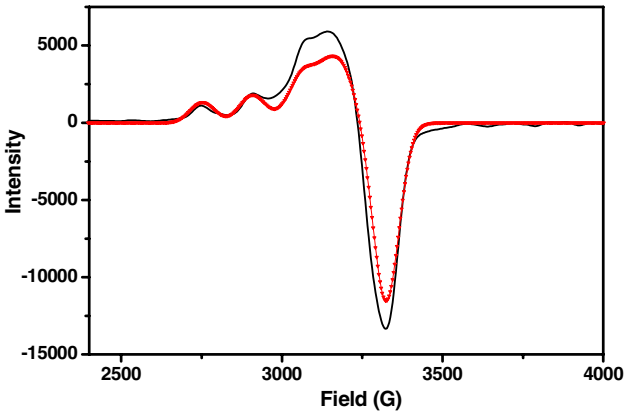

Fig. 3. X-band EPR spectrum of complex **2** in ethanol/water (1:1) at liquid N_2 temperature [solid line (experimental)/line + symbol (simulated)], recorded under the following experimental conditions: microwave frequency: 9.443669 GHz, microwave power: 16.0 mW, modulation frequency: 100.00 kHz, modulation amplitude: 1.02 G, receiver gain: 1.00×10^4 and conversion time: 81.92 ms. Fitted parameters: $g_{\|} = 2.261$, $g_{\perp} = 2.084$ and $A_{\|} = 163.0 \times 10^{-4}$ cm^{-1}.

solution. The similarity between the $E_{1/2}$ values observed for complexes **1** and **2** strongly corroborates the proposal of the releasing of the nitrite ligand by complex **2** in water solution, as discussed above for the spectrophotometric data. In view of this, the irreversible process at $E_{pc} = +970$ mV versus SCE can be attributed to the two electron oxidation process of free nitrite to nitrate in solution [43], which is upheld by the fact that the addition of $NaNO_2$ to the electrochemical solution results in an increased peak current.

Cyclic voltammograms of **2** recorded in methanolic solution show only the Cu(II)/Cu(I) redox process (Fig. 4) in the +1.0 to −0.7 V potential range ($E_{1/2} = -335$ mV versus SCE, $\Delta E_p \approx 112$ mV, $i_{pa}/i_{pc} = 0.94$). The $E_{1/2} = -335$ mV versus SCE observed in methanol for complex **2** is cathodically shifted

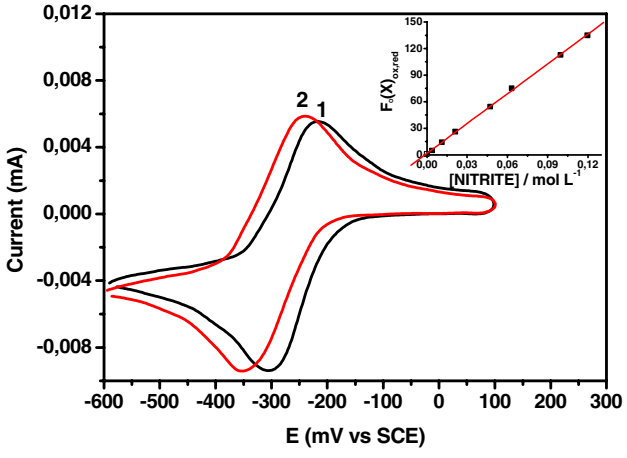

Fig. 4. Cyclic voltammogram of complexes **1** and **2**, in methanolic solution, at 25 ± 1 °C, scan rate of 20 mV s^{-1}, and the best fit plot of $F_0(x)_{ox,red}$ against nitrite concentration (inset).

with regard to the value observed for complex **1** ($E_{1/2} = -300$ mV versus SCE, $\Delta E_p \approx 87$ mV, $i_{pa}/i_{pc} = 0.82$), in which the substitution of the chloride by a solvent molecule has been proposed in pure methanol [16]. This shift of the $E_{1/2}$ value to a more negative potential is consistent with the replacement of a neutral molecule by a nitrite anion as shown by Monzani and coworkers [44] through a lowering of the Cu(II)/Cu(I) reduction potential to ca. 30 mV.

3.5. Equilibrium studies

As mentioned before, since the electrochemical data relate to the Cu(II)/Cu(I) redox process, the evaluation of the relative power of the nitrite ligand to complex with the $[Cu^{II}(L)(S)]^{2+}$ and $[Cu^{I}(L)(S)]^{+}$ species may be inferred from potentiometric experimental data. The average number of $\bar{n}_{ox,red}$ ligands for the Cu(II) and Cu(I) species was calculated as 1.06–1.04 in the 5.0×10^{-3}–1.9×10^{-1} mol L^{-1} nitrite concentration range, suggesting that no change in the coordination sphere of the copper center occurs during the one-electron transfer process. From the electrochemical data, it was also possible to calculate the K_{ox}/K_{red} ratio by plotting $F_0(x)_{Cu(II)/Cu(I)}$ against the corresponding nitrite concentration [21]. A straight line was obtained suggesting that Eq. (3) takes the form of Eq. (7) and that only the $[Cu^{II}(L)ONO]^{+}$ and $[Cu^{I}(L)ONO]$ species are present at the electrode. Thus, the K_{ox}/K_{red} ratio was calculated as equal to $(1.16 \pm 0.04) \times 10^3$ M^{-1}.

$$F_0(x)_{ox,red} \cong 1 + (\beta_1)_{ox,red}[NO_2^-] \quad (7)$$

The affinity of the nitrite ligand for complex **1**, $[Cu^{II}(L)(S)]^{2+}$, was also estimated by spectrophotometric titration of the anion with the $[Cu^{II}(L)(S)]^{2+}$complex, in methanolic solution (1.5×10^{-3} mol L^{-1}, $\mu = 0.1$ mol L^{-1} $TBAPF_6$), following the development of the near-UV charge transfer band at 376 nm (Fig. 2). Spectra recorded in the presence of variable concentrations of nitrite allowed us to utilize of the different absorption spectra of reagents and products to calculate the equilibrium constant for the following reaction:

$$[Cu(L)(S)]^{2+} + NO_2^- \rightleftharpoons [Cu(L)(ONO)]^{+} + S$$

Applying Eqs. (1) and (2) to the data of Fig. 2, the $K_{eq} = 1.4 \pm 0.5 \times 10^3$ M^{-1} value was obtained.

Combining the spectrophotometrical (K_{ox}) and the cyclic voltammetric data with K_{eq} for the reaction above, and since $K_{eq(ox,red)} = K_{ox}/K_{red}$, the value of K_{red} for the following reaction was estimated as 1.2 M^{-1}, which is consistent with the known low affinity of Cu(I) centers for nitrite ligands.

$$[Cu(L)(S)]^{+} + NO_2^- \rightleftharpoons [Cu(L)(ONO)] + S$$

Similar equilibrium study has been performed for the formation of the $[Cu(1\text{-}BB)(NO_2)]^{+}$ complex [34], being

the value of $K_{eq} = 7.5 \times 10^4$ M^{-1}. This higher affinity can be attributed to the tridentated character of the 1-BB ligand. The tetradentated ligand in 1, occupy one more coordinated site, which would decrease the metal center affinity for the nitrite ligand.

4. Conclusions

A new imidazole–copper(II) complex, of potential interest in the context of type II copper nitrite reductase biomimetic model chemistry, is reported. The tripodal ligand **L** closely reproduces the presence of three histidine residues in the active site of copper nitrite reductase. In addition, the O-nitrite coordination, the similarities of the Cu–O(1) nitrite distance, as well as the $Cu–N_{imidazole}$ bond lengths allow us to consider complex **2** as a good structural model complex for the oxidized type II copper-containing nitrite reductases.

5. Supplementary material

Crystallographic data for the structure reported here have been deposited with the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), as supplementary publication number CCDC 216312.

Received 10 July 2003; accepted 19 September 2003

Abstract

From macrobicyclic ligands having different compartments originated from their corresponding precursor compounds (PC-1: 3,4:9,10-dibenzo-1,12[*N*,*N*′-bis{(3-formyl-2-hydroxy-5-methyl)benzyl}diaza]-5,8-dioxacyclotetradecane and PC-2: 3,4:9,10-dibenzo-1,12[*N*,*N*′-bis{(3-formyl-2-hydroxy-5-methyl)benzyl}diaza]-5,8-dioxacyclopentadecane) several mono and binuclear copper(II) complexes denoted as $[CuL](ClO)_4$ and $[Cu_2L(ClO_4)](ClO_4)$ have been synthesized. Electrochemical studies vindicate that one quasireversible reduction wave ($E_{pc} = -0.80$ to -0.88 V) for the mononuclear complexes and two quasireversible one electron transfer reduction waves ($E^1_{pc} = -0.84$ to -0.94 V, $E^2_{pc} = -1.25$ to -1.40 V) for the binuclear complexes are obtained in the cathodic region. The probe of room temperature magnetic moment studies depicts the presence of an antiferromagnetic interaction in the binuclear complexes (μ_{eff} of 1.35–1.42 B.M.), which is also observed from the broad ESR spectra with a *g* value of 2.10 or 2.11. Whereas, hyperfine splitting in ESR spectra is observed for mononuclear complexes and the magnetic moment value is found to be close to the spin only value (μ_{eff} of 1.69–1.71 B.M.). A variable temperature magnetic susceptibility study of the complex was carried out and the calculated $-2J$ values for the binuclear complexes $[Cu_2L^{1a}(ClO_4)](ClO_4)$ and $[Cu_2L^{1b}(ClO_4)](ClO_4)$ are 240 and 219 cm^{-1}, respectively. The initial rate constant values of catechol oxidation using the complexes as catalysts have been found to span a domain ranging from 5.06×10^{-3} to 2.56×10^{-2} min^{-1} and the values are found to be higher for binuclear complexes than the corresponding mononuclear complexes. Spectral, electrochemical and catalytic studies support the distortion of the copper ion geometry that arises as the macrocyclic ring size increases.

1. Introduction

The rich chemistry of complexes of compartmental ligands binding two metals has been applied to the investigation of magnetic exchange interaction between the two metal ions, the stabilization of mixed-valent species and the activation of small molecules [1–5]. The success in molecular recognition promoting selective binding, transformation and transfer of large varieties of substrates has been enhanced by the development of highly preorganized macrocyclic and macropolycyclic ligands [6]. In particular, azamacrocyclic receptors are able to bind different kinds of substrates [7]. Structural factors have been shown to play a significant role to determine the strength of the interaction between the polyaza receptor and the guest molecule [8–10]. In this connection to introduce into the molecular framework a structural feature that imparts high selectivity in the recognition of different guests is one of the goals in the design of synthetic receptors. Aromatic subunits are often introduced as an integral part of the host molecules. Cyclic ligands containing aromatic rings in their backbone have received much attention [11]. Fewer efforts have been devoted to the study of macrocylic

systems containing two metal binding sites within the same macrocyclic framework mainly due to synthetic difficulties. The present work tries to rationalize the study of various macrobicyclic compartmental mono and binuclear copper(II) complexes containing aromatic subunits in the imine compartment which is associated with an electrochemical translocation process. In our previous works [12–14] we have reported the distinct properties of mono and binuclear copper(II) complexes containing aliphatic diimines.

2. Experimental

Elemental analysis was carried out on a Carlo Erba Model 1106 elemental analyzer. ^{1}H NMR spectra were recorded using a FX-80-Q Fourier transition NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–800 nm. IR spectra were recorded on a Hitachi 270–50 spectrophotometer on KBr disks in the range 4000–250 cm^{-1}. Mass spectra were obtained on a JEOL DX-303 mass spectrometer. Molar conductivity was measured by using an Elico model SX 80 conductivity bridge using a freshly prepared solution of the complex in CH_3CN. Cyclic voltammograms were obtained on a CHI600A electrochemical analyzer. The measurements were carried out under oxygen free conditions using a three electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and a platinum wire was used as the auxiliary electrode. The ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental conditions is 470 mV in DMF and ΔE_p for Fc/Fc^+ is 70 mV. Tetra(*n*-butyl)ammonium perchlorate was used as the supporting electrolyte. The room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. X-band ESR spectra were recorded at 25 °C on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference. The catalytic oxidation of catechol to *o*-quinone by the complexes was studied in a 10^{-3} M acetonitrile solution. The reaction was followed spectrophotometrically by choosing the strongest absorbance at 390 nm and monitoring the increase in the absorbance at this wavelength as a function of time. A plot of $\log(A_\infty/A_\infty - A_t)$ versus time was made for each complex and the initial rate constant for the catalytic oxidation was calculated.

2.1. Materials

5-Methylsalicylaldehyde [15], 3-chloromethyl-5-methylsalicylaldehyde [16] and 3,4:9,10-dibenzo-1,12-diaza-5,8-dioxacyclohexadecane [17,18] were prepared from the literature methods. TBAP used as supporting electrolyte in the electrochemical measurements was purchased from Fluka and recrystallised from hot methanol. (*Caution*! TBAP is potentially explosive; hence care should be taken in handling the compound). DMF and CH_3CN were obtained from E. MERCK. All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.2. Synthesis of precursor compounds

2.2.1. 3,4:9,10-Dibenzo-1,12[*N*,*N*′-bis{(3-formyl-2-hydroxy-5-methyl}benzyl)diaza]-5,8-dioxacyclotetradecane (PC-1)

A mixture of 3,4:9,10-dibenzo-1,12-diaza-5,8-dioxacyclotetradecane (0.95 g, 3.2 mmol) and triethylamine (1.32 g, 6.4 mmol) in THF was added slowly to a stirred solution of 3-chloromethyl-5-methyl salicylaldehyde (1.16 g, 6.4 mmol) in THF. After the addition was over the stirring was continued further for one more hour. The whole solution was then refluxed over a water bath for 3 h and was allowed to cool on standing at room temperature. Copious water was added to this solution to dissolve any salt obtained. Then the required compound was extracted in organic medium using chloroform. The extraction was repeated for two to three times. A pale yellow compound was obtained on evaporation of solvent at room temperature (25 °C). Light yellow crystals were obtained on recrystallization from chloroform. Yield: 1.82 g (80%), m.p.: 100 °C. Analytical data for $C_{36}H_{38}O_6N_2 \cdot CHCl_3$: Calc.: C, 60.50; H, 5.32; N, 3.92. Found: C, 60.72; H, 5.36; N, 3.98%. IR data (ν cm^{-1}): 1678 (νC=O, s), 3448 (νOH, br). ^{1}H NMR (δ ppm in $CDCl_3$): 10.0 (s, 2H, CHO protons), 7.0 (m, 12H, aromatic protons), 4.7 (m, 4H, methylene protons attached to oxygen atom), 3.8 (m, 4H, methylene protons attached to nitrogen atom), 3.5 (s, 8H, benzylic protons), 2.3 (s, 6H, aromatic CH_3 protons). Mass (EI) m/z: 594 (m^+).

2.2.2. 3,4:9,10-Dibenzo-1,12[*N*,*N*′-bis{(3-formyl-2-hydroxy-5-methyl}benzyl)diaza]-5,8-dioxacyclopentadecane (PC-2)

The compound PC-2 can be prepared from the procedure mentioned above by using 3,4:9,10-dibenzo-1,12-diaza-5,8-dioxacyclopentadecane instead of 3,4:9,10-dibenzo-1,12-diaza-5,8-dioxacyclotetradecane. Yield: 1.98 g (85%), m.p.: 112 °C. Analytical data for $C_{37}H_{40}O_6N_2 \cdot CHCl_3$: Calc.: C, 60.98; H, 5.49; N, 3.84. Found: C, 61.02; H, 5.58; N, 3.88%. IR data (ν cm^{-1}): 1677 (νC=O, s), 3435 (νOH, br). ^{1}H NMR (δ ppm in $CDCl_3$): 10.0 (s, 2H, CHO protons), 7.0 (m, 12H, aromatic protons), 4.5 (m, 4H, methylene protons attached to oxygen atom), 3.7 (m, 4H, methylene protons attached to nitrogen atom), 3.5 (s, 8H, benzylic protons),

2.5 (s, 6H, aromatic CH_3 protons), 2.0 (s, 2H, CH_2 protons). Mass (EI) m/z: 608 (m^+).

2.3. Synthesis of macrobicyclic mononuclear copper(II) complexes

[CuL^{1a}](ClO$_4$): A methanolic solution of copper(II)perchlorate hexahydrate (0.676 g, 1.8 mmol) was added to the hot solution of PC-1 (1.085 g, 1.8 mmol) in $CHCl_3$ followed by the addition of *o*-phenylenediamine (0.195 g, 1.8 mmol) in methanol. The solution was refluxed on a water bath for 24 h. After the reaction was over, the solution was filtered hot and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, a dark green compound was obtained, washed with methanol and dried in vacuum. Attempts to obtain crystals were unsuccessful. Yield: 1.21 g (77%). Analytical data for $C_{44}H_{44}O_8N_5ClCu$: Calc.: C, 60.68; H, 5.05; N, 8.04. Found: C, 60.75; H, 5.11; N, 8.13%. Selected IR (KBr): 1626 (s), 1099 (s), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 129. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 590 (181), 428 (20,500), 360 (34,200), 308 (39,700), 270 (34,200). $g_{\|} = 2.21$, $g_{\perp} = 2.06$; μ_{eff}: 1.69 B.M.

[CuL^{1b}](ClO$_4$): [CuL^{1b}](ClO$_4$) was synthesized by following the previously described procedure for [CuL^{1a}](ClO$_4$), using 1,8-diaminonaphthelene instead of *o*-phenylenediamine. The compound obtained was dark green. Yield: 1.32 g (79%). Analytical data for $C_{48}H_{46}O_8N_5ClCu$: Calc.: C, 62.60; H, 5.00; N, 7.60. Found: C, 62.69; H, 5.09; N, 7.68%. Selected IR (KBr): 1625 (s), 1098 (s), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 151. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 620 (135), 350 (13,500), 308 (38,700), 275 (33,200). $g_{\|}$: 2.19, $g_{\perp}$: 2.03; μ_{eff}: 1.70 B.M.
