Abstract

2,3-Dimethyl-2,3-butanediol (pinacol, L^1), 2,5-dimethyl-2,5-hexanediol (L^2) and 2,2,7,7-tetramethyl-3,6-di-*tert*-butyl-3,6-octanediol (L^3) were reacted with uranyl nitrate hexahydrate. Whereas L^1 acts as a bidentate chelating ligand, giving the 1/1 anhydrous complex $[UO_2L^1(NO_3)_2]$ in which the nitrate ions are in *cis* geometry, L^2 and L^3 are second-sphere ligands which are hydrogen bonded to the water and nitrate oxygen atoms of the $[UO_2(NO_3)_2(H_2O)_2]$ moiety. In the three cases, hydrogen bonded assemblages, either discrete, two- or three-dimensional, are obtained. The crystal structures of two forms of uncomplexed L^3 are also described.

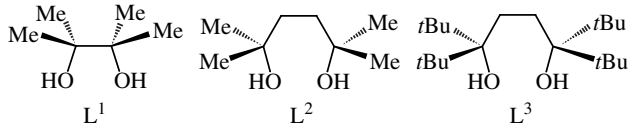
1. Introduction

The complexation of uranium by 1,2-diols and 1,2-diolates is largely unexplored from a structural viewpoint. To the best of our knowledge, the unique example involving a 1,2-diol is the mononuclear complex *bis*(hydroxylamido)(1,2-ethanediol)dioxouranium(VI), in which the diol is a chelating ligand with both hydroxyl groups bound to the metal atom [1]. Two 1,2-diolate complexes emerged in uranium(IV) chemistry as intermediates in the McMurry reaction [2]. The first one, a tetrahydrofuran solvate of the mononuclear uranium (IV) *bis*(benzopinacolate), $[U(O_2C_2Ph_4)_2(thf)_2]$, resulted from the coupling of benzophenone with UCl_4 in the presence of Na(Hg) [3]; the other one, obtained by treating acetone with the UCl_4–Li(Hg) system, is the uranium(IV) monopinacolate complex $[\{UCl_3(hmpa)_2\}_2(\mu\text{-}OCMe_2CMe_2O)]$, which is a binuclear complex with the pinacolate, in *anti*-conformation, bridging the two metallic centres [4]. The complexation properties of 1,4-diols towards uranyl ions are yet unknown, in contrast with those of acyclic or cyclic (calixarenes) polyphenoxides, which are well documented [5].

We report herein the crystal structures of the air-stable complexes of uranyl nitrate hexahydrate with three aliphatic 1,2- and 1,4-diols: 2,3-dimethyl-2,3-butanediol (pinacol, L^1), 2,5-dimethyl-2,5-hexanediol (L^2) and 2,2,7,7-tetramethyl-3,6-di-*tert*-butyl-3,6-octanediol (L^3), represented in Scheme 1, as well as two crystal structures of L^3, either unsolvated or as a methanol solvate (the crystal structures of L^1 and L^2 have been reported previously [6,7]). In these uranyl complexes, the diol can act as a first- or a second-sphere ligand. In all cases, the propensity of these molecules to form extended hydrogen bonded assemblages is illustrated.



Scheme 1. The diols L^1, L^2 and L^3.

2. Results and discussion

2.1. Uncomplexed diol L^3

Two forms of the 1,4-diol L^3, either as a methanol solvate (**1a**) or unsolvated (**1b**) were obtained by crystallization from methanol and tetrahydrofuran, respectively. The crystal structures differ by the conformation of the diol and the assemblage of molecules through hydrogen bonds. In compound **1a**, the diol is in a *syn*-conformation, with a stabilizing intramolecular hydrogen bond (Fig. 1, Table 1). Moreover, the methanol molecule is both a hydrogen bond donor and acceptor, which results in the formation of a 12-membered, centrosymmetrical ring. The formation of such rings with a "homodromic" arrangement of hydrogen bonds, displaying σ-bond cooperativity and leading to a clustering of polar groups, is a well-known phenomenon [8]. The centrosymmetrical diol in compound **1b** is in the *anti*-conformation (Fig. 2), which favours the formation of intermolecular hydrogen interactions only (the hydroxy protons, necessarily disordered, were not located, but the presence of hydrogen bonds can be inferred from the O···O distances). In contrast with the isolated dimers in **1a**, infinite zigzag chains parallel to the *a*-axis are formed in **1b**, in keeping with the convergent and di-

2.2. Uranyl complexes

The uranyl unit in $[UO_2L^1(NO_3)_2]$ (**2**) is bound to two nitrate groups and one L^1 diol in its equatorial plane (Fig. 3), which results in the hexagonal bipyramidal uranium environment usual for small bite bidentate ligands. The diol thus acts as a first-sphere bidentate ligand, as in *bis*(hydroxylamido)(1,2-ethanediol)dioxouranium(VI) [1]. The six donor atoms define a plane with a maximum deviation of 0.179(3) Å, the uranium atom being displaced by 0.023(2) Å from it. The mean U–O(nitrate) bond length is 2.49(2) Å (Table 2), in agreement with the mean value of 2.522(5) Å from the structures involving the $UO_2(NO_3)_2$ group reported in the Cambridge Structural Database [9]. The mean U–O(diol) bond length is 2.449(5) Å, in agreement with the value 2.47(1) Å in *bis*(hydroxylamido)(1,2-ethanediol)dioxouranium(VI). The conformation of the diol is staggered (close to *gauche*) and not *syn*, with a torsion angle O3–C1–C2–O4 of 51.9(9)°. As a result, C1 and C2 are on either side of the mean equatorial plane, with out-of-plane distances of 0.47(1) and −0.37(1) Å, respectively. Each uranyl complex is involved in four intermolecular hydrogen bonds, in which the two OH groups and two NO_3 ligands act as donors and acceptors, respectively. The two hydroxyl groups are bound to oxygen atoms of the nitrate ligands in distinct ways, as shown in Fig. 3: O3 and O3′ are hydrogen bonded to the bridging atoms O5′ and O5, respectively, so as to create a dimer around a binary axis parallel to the *b*-axis. On the other hand, the hydrogen bonds involving O4 and the terminal atom O10 link one molecule to two of its neighbours through the binary screw axis parallel to the *b*-axis, which results in the formation of sheets parallel to the *ab*-plane.

Symmetry code: ′, $1-x, y, 1.5-z$.

A much different situation arises with the 1,4-diol L^2, which gives the *bis*(aquo) complex $[UO_2(NO_3)_2(H_2O)_2]\cdot 2L^2$ (**3**). The separation between the two hydroxyl groups is too large for L^2 to act as a bidentate ligand in a κ^2 fashion. This would imply the formation of a seven-membered ring, which is an unfavourable situation due to entropy loss and for which few examples are to be

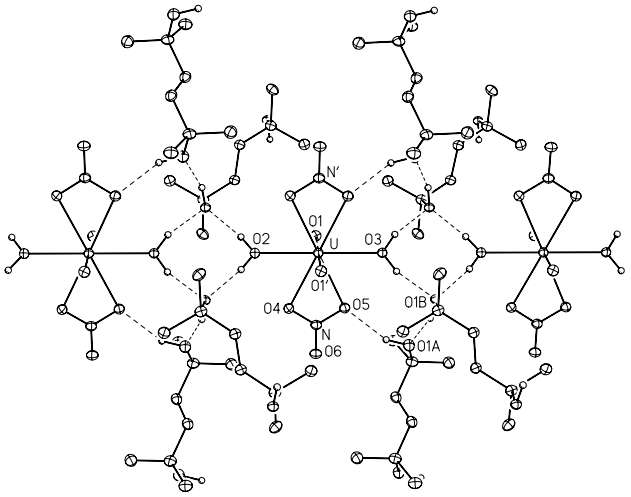

Fig. 4. View of the hydrogen bonded assemblage in compound **3**. The hydrogen atoms not involved in hydrogen bonding are omitted for clarity. Hydrogen bonds are represented as dashed lines. Displacement ellipsoids are drawn at the 20% probability level. Symmetry code: ′, $1-x, y, 1.5-z$.

found in the case of the uranyl ion, most of them with ligands more rigid than the present one [9]. In fact, L^2 is present in **3** as a second-sphere ligand, being hydrogen bonded to the first-sphere nitrate and water molecules (Fig. 4). The uranium atom and the two oxygen atoms of the water molecules (in *trans* positions) are located on the binary axis. The uranium atom is in the usual hexagonal bipyramidal environment, with a mean U–O(nitrate) bond length of 2.505(1) Å and a mean U–O(water) bond length of 2.41(2) Å, in agreement with the mean value of 2.44(3) Å from the Cambridge Structural Database. The uranium and the six equatorial donor oxygen atoms are in a plane with a maximum deviation of 0.031(2) Å. Each complex molecule is surrounded by a hydrogen bonded second-sphere of six L^2 molecules (two molecules A being bound to the nitrate ions and four molecules B to the water ligands). The two protons of each water molecule are involved in hydrogen bonds with two diols related by the binary axis (molecule B and its symmetry equivalent). Since each oxygen atom in molecule B is hydrogen bonded to two water molecules from two distinct complexes, rows of hydrogen bonded complexes along the *b*-axis are formed, which are interconnected by extended B molecules. The eight-membered hydrogen bonded ring formed by the two water and two B molecules is of an "antidromic", non-cooperative nature [8]. Each of the OH groups of molecule B acts in its turn as a donor towards one oxygen atom of another diol (molecule A), the latter being itself a donor towards the nitrate oxygen atom O5, with formation of two other symmetry-related eight-membered rings. An asymmetry is thus introduced in the second-sphere environment of the complex since the nitrate oxygen atom O4 is not involved in hydrogen bonding. Molecules A ensure the linking of the rows in a direction different from that of molecules B, the divergent nature of both diols resulting in a three-dimensional assemblage.

The last complex, $[UO_2(NO_3)_2(H_2O)_2]\cdot 4.5L^3$ (**4**), presents some common features with complex **3**, but differs in the overall assembling mode. The complex core itself is $[UO_2(NO_3)_2(H_2O)_2]$ with a *trans* geometry, as in **3**, but devoid this time of crystallographic symmetry (Fig. 5). The mean U–O(nitrate) and U–O(water) bond lengths, 2.52(1) and 2.407(6) Å, respectively, match those in **3**. The six equatorial donor oxygen atoms are in a plane with a maximum deviation of 0.046(3) Å and an out-of-plane displacement of 0.003(2) Å for the uranium atom. Each water proton is involved in a hydrogen bond with atom O1 of one L^3 molecule. However, since L^3 is not in an extended conformation, the two hydroxyl groups are not divergent as in **3**, but linked one to the other by an intramolecular hydrogen bond. The proton of the second hydroxyl group (O2) is further bound to a terminal nitrate oxygen atom. This gives rise to a circular arrangement with isolated $[UO_2(NO_3)_2(H_2O)_2]\cdot 4L^3$ assemblies held together by eight intermolecular hydrogen bonds, which, with the four intramolecular ones, make an array of twelve successive hydrogen bonds. The hydrogen bonded species thus make a 24-membered ring encircling the central uranyl complex. The second-sphere L^3 molecules, as well as the water protons to which they are bound, are either on one side (A and D) or on the other side (B and C) of the mean equatorial plane. This results in the complex having a pseudo-mirror plane containing the uranyl moiety and

the nitrogen atoms and a pseudo-binary axis containing the uranium and water oxygen atoms (C_{2h} point group). In contrast with the "homodromic" arrangement of hydrogen bonds encountered in compound **1a**, the hydrogen bonds involving the nitrate oxygen atoms are anti-cooperative in **4**, which may explain why they are significantly longer than the other ones, which are cooperative and involve only hydroxy (alcohol or water) groups. The asymmetric unit in compound **4** contains also half a L^3 molecule, the corresponding centrosymmetric diol being surprisingly isolated and not involved in any hydrogen bonding interaction.

3. Conclusion

We have reported herein the synthesis and crystal structures of novel uranyl complexes with 1,2- and 1,4-diols, which display different kinds of complexation. The 1,2-diol L^1 in a staggered conformation acts as a small-bite chelating ligand, whereas the 1,4-diols L^2 and L^3 give second-sphere complexes which both contain the central $[UO_2(NO_3)_2(H_2O)_2]$ motif, with a *trans* arrangement of the ligands in the equatorial plane. A search of the Cambridge Structural Database shows that, in molecular complexes, this moiety is frequently found in association with hydrogen bonded crown ethers, one of them being linked to each water molecule [10]. It is also found in the structure of uranyl nitrate hexahydrate $[UO_2(NO_3)_2(H_2O)_2]\cdot 4H_2O$ [11,12], in which the coordinated water molecules and the nitrate ions are involved in hydrogen bonds with the solvent water molecules, in a way reminiscent of that observed in **3** and **4**. The water molecules being able to be involved in two or three hydrogen bonds, a three-dimensional pattern is generated, as with ligand L^2 in its divergent conformation (compound **3**). The difference between compounds **3** and **4**, both involving 1,4-diols, does not seem to be related in an obvious manner to the difference in the substituents, methyl or *tert*-butyl, of the diols. In spite of synthesis procedures involving identical 1:1 diol/uranyl stoichiometries, the number of diol molecules per complex unit is different in these two compounds. This may be related to solvent effects in solution or packing effects during crystallization. In any case, it indicates that the nature of hydrogen bonded assemblages based on such flexible molecules is hardly predictable.

4. Experimental

4.1. Synthesis

2,3-Dimethyl-2,3-butanediol (pinacol, L^1), 2,5-dimethyl-2,5-hexanediol (L^2), 2,2,4,4-tetramethyl-3-pentanone and Li powder (Aldrich) were used without further purification.

4.1.1. 2,2,7,7-Tetramethyl-3,6-di-tert-butyl-3,6-octanediol (L^3)

2,2,7,7-Tetramethyl-3,6-di-*tert*-butyl-3,6-octanediol (L^3) was prepared by a modified published method [13]. A Schlenk tube equipped with a magnetic stirrer was charged with Li powder (60 mg, 8.7 mmol) in dry tetrahydrofuran (5 ml). 2,2,4,4-Tetramethyl-3-pentanone (1.24 g, 8.7 mmol) was added under argon within 2 min at room temperature and the colour of the solution turned dark brown. Ethylene (1 bar) was then immediately introduced into the Schlenk tube. After stirring for 3 h, the mixture was carefully poured into ice. The organic extract was washed with water and brine, dried with Na_2SO_4, filtered and concentrated under vacuum. The oily residue was purified by column chromatography (SiO_2, *n*-pentane), yielding the colourless 2,2,7,7-tetramethyl-3,6-di-*tert*-butyl-3,6-octanediol (520 mg, 2.9 mmol, 38%); m.p. 116 °C (lit. 115–118 °C [14]); ^{1}H NMR (200 MHz, 23 °C, ^{2}[H_8] thf): δ 0.99 (36H, s), 1.73 (4H, s), 3.01 (2H, s, in exchange with D_2O). Single crystals of $L^3 \cdot$ MeOH (**1a**) and L^3 (**1b**) suitable for X-ray crystallography were obtained by slow evaporation, in air, of solutions of L^3 in methanol and tetrahydrofuran, respectively.

4.1.2. Uranyl complexes

Single crystals of $[UO_2L^1(NO_3)_2]$ (**2**), $[UO_2(NO_3)_2(H_2O)_2] \cdot 2L^2$ (**3**) and $[UO_2(NO_3)_2(H_2O)_2] \cdot 4.5L^3$ (**4**) were obtained by slow evaporation of tetrahydrofuran solutions containing equimolar mixtures of uranyl nitrate hexahydrate and the appropriate diol.

4.2. Crystallography

The data were collected on a Nonius Kappa-CCD area detector diffractometer [15] using graphite-monochromated Mo Kα radiation (λ 0.71073 Å). The crystals were introduced in glass capillaries with a protecting "Paratone-N" oil (Hampton Research) coating. The unit cell parameters were determined from ten frames, then refined on all data. A 180° φ-range was scanned with 2° steps during data collection, with a crystal-to-detector distance fixed to 26 or 28 mm, corresponding to the temperatures of 293 and 100 K, respectively. The data were processed with DENZO-SMN [16]. The structures were solved by direct methods or Patterson map interpretation with SHELXS-97 and subsequent Fourier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [17]. Absorption effects in the uranyl complexes were corrected empirically with the program DELABS from PLATON [18]. The hydrogen atoms bound to oxygen atoms were found on Fourier-difference maps, except those in compound **1b** and that bound to O1E in compound **4**, which is not involved in a hydrogen bond and may be disordered. All the other hydrogen atoms were introduced at calculated positions. All hydrogen atoms were treated as riding atoms with a displacement parameter equal to 1.2 (OH, CH_2) or 1.5 (CH_3) times that of the parent atom. All non-hydrogen atoms were refined with anisotropic displacement parameters. Crystal data and structure refinement parameters are given in Table 3. The molecular plots were drawn with SHELXTL [19]. All calculations were performed on a Silicon Graphics workstation.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 231349–231353 for compounds **1**–**4**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of neutral palladium(II) complexes bearing non-symmetric bidentate pyrrole-iminato or salicylaldiminato chelate ligands have been synthesized, and the structure of representative complexes (**3a, 4a**, and **5a**) have been confirmed by X-ray crystallographic analysis. These palladium complexes have been investigated as catalysts for the polymerization of norbornene. Using modified methylaluminoxane (MMAO) as a cocatalyst, these complexes display high activities and produce vinyl-addition polynorborenes. Catalytic activity of up to 8.52×10^3 kg/mol$_{Pd}$ h has been observed. Wide-angle X-ray diffraction (WAXD) has been used to investigate the polymer microstructure and it has been found that they are non-crystalline.

Keywords: Neutral palladium(II) complex; X-ray crystallography; Catalyst; Methylaluminoxane; Norbornene; Vinylic polymerizaition

1. Introduction

With the boom in transition metal catalysis, there is a rapid development of a wide range of polyolefinic materials. A polymer with a certain microstructure can be easily obtained by employing a certain catalyst. Norbornene is a representative cycloolefin monomer which can be polymerized through ring-opening metathesis polymerization (ROMP), cationic (or radical) and vinylic addition polymerization mechanisms. ROMP yields poly(1,3-cyclopentylenevinylene) which retains one double bond in each polymeric repeat unit [1–3]. Cationic polymerization involves the rearrangement of the norbornene framework and generally produces moderate yields of poly (2,7-bicyclo [2,2,1] hept-2-ene) oligomers [4–7]. Free-radical processes also produce low molecular weight products [3]. In vinylic polymerization, the bicyclic structural unit remains intact and only the double bond is opened. As the vinyl-poly(norbornene) has many unique physical characteristics such as good mechanical strength, heat resistivity, optical transparency and low birefringence [8,9], many interests are focused on this kind of polymerization. The selection of catalysts is the key. Catalysts containing the metals nickel [8–16], chromium [17], titanium [18], zirconium [19–22], cobalt [23,24] and palladium [25–35] are reported in various literatures for the vinyl-type polymerization of nornornene. Nickel and palladium complexes display extremely high catalytic activity and produce high molecular weight polymers with excellent performance. Hence, our interest is keen on the well-defined complexes of nickel and palladium (see Scheme 1).

We found that neutral nickel complexes activated with methylaluminoxane display extremely high activity for the vinylic polymerization of norbornene [14,15], and Novak and co-workers [36] reported that neutral palladium complexes as catalysts for olefin and vinyl monomer polymerizations display excellent activity. This urges us to investigate if neutral palladium(II) complexes have high catalytic activity. Here, we would like to report on the synthesis of novel neutral palladium(II) complexes bearing pyrrole-iminato or

salicylaldiminato ligands and the catalysis properties for the vinylic polymerization of norbornene.

2. Experimental

2.1. General procedures and materials

All work involving air and moisture sensitive compounds was carried out using standard Schlenk techniques. NMR data of the ligands and the complexes were obtained on a Varian Unity 300 MHz spectrometer at ambient temperature, with $CDCl_3$ (ligands) or C_6D_6 (complexes) as solvent. IR spectra were recorded on a Bio-Rad FTS-135 spectrophotometer. Single-crystal X-ray diffraction data were received by P4 X-ray crystallography. The wide-angle X-ray diffraction (WAXD) spectrum was measured on a Rigaku D/Max 2500V PC with Cu Kα radiation and a wavelength of 1.54 Å.

Tetrahydrofuran (THF), benzene and diethyl ether were dried over sodium with dibenzophenone as indicator. Chlorobenzene and dichloromethane were refluxed over calcium hydride for two weeks before use. Aniline derivatives were obtained from Acros and purified by distillation before use. Triphenyphosphine, pyrrole-2-carboxaldehyde, sodium tetrachlopalladate-(II) and tetramethyltin were obtained from Aldrich and used without further purification. Pyridine was dried over sodium hydroxide and obtained by reduced distillation. Norbornene from Aldrich was refluxed with sodium, purified by reduced distillation and used as a solution in toluene. Modified methylaluminoxane (MMAO, 7% aluminum in heptane solution) was purchased from Akzo Nobel Chemical Inc. (COD)PdMeCl was prepared by the reaction of $(COD)PdCl_2$ and $SnMe_4$ according to a procedure given by Richard and co-workers [37,38]. Salicylaldehyde derivatives were prepared according to the method of Casiraghi et al. [39], and the salicylaldimines **6a**–**c** were prepared according to the procedure described by Grubbs and co-workers [40]. The pyrrole-imines **1a**–**d** were prepared according to the procedure described previously [15].

2.2. Synthesis of neutral Pd(II) complexes *3a–d, 4a, 5a and 8a–c*

A solution of ligand **1a** (0.45 g, 1.76 mmol) in THF (20ml) was added to NaH (0.12 g, 2.5 mmol). The resulting mixture was stirred at room temperature for 3 h, then filtered and the filtrate was evaporated. The solid residue was dried in vacuum. The sodium salt and (COD)PdMeCl (0.32 g, 1.2 mmol) with PPh_3 (0.32 g, 1.2 mmol) were dissolved in benzene (20 ml) in a 100 ml Schlenk flask and stirred at room temperature for 18 h. The resulting mixture was filtered by cannula filtration. The filtrate should be concentrated in a vacuum to ca. 5 ml, and then pentane (ca. 20 ml) was added. After 24 h, some yellow crystals were obtained from the solution and isolated by cannula filtration to yield 0.55 g (71.9%) of **3a**. The other complexes were prepared by the same procedure with similar yields.

chlorobenzene were added under inert gas atmosphere into a Schlenk flask with a mechanical stirrer. The reaction was started by the addition of 0.5 ml of a MMAO solution (1.0 mmol in heptane) at 30 °C. After 10 min, the reaction mixture was poured into 200 ml of acidic ethanol (ethanol/$HCl_{conc.}$ = 50/1). The polymer was isolated by filtration, washed with methanol, and dried under vacuum at 80 °C for 24 h. Total reaction volume was 11 ml, unless otherwise stated. This was achieved by variation of the amount of chlorobenzene if necessary.

3. Results and discussion

3.1. Synthesis and characterization of neutral palladium complexes

Ligands **1a–d** were prepared by the condensation of the corresponding aniline derivatives according to the procedure described previously [15], they were deprotonated using sodium hydride and the anions allowed to react with (COD)PdMeCl in the presence of neutral, two-electron donor ligands to give palladium complexes **3a–d**, and **4a**. The neutral donors ligands are necessary to stabilize the complexes. Different ligands have been used to study their effects on metal catalytic activity. Interestingly, attempts to prepare palladium complex with the acetonitrile ligand have failed and complex **5a** was obtained instead. This shows that the binding strength of the CH_3CN ligand with palladium atom is poorer than that of triphenylphosphine or pyridine, which is in accordance with the results of Novak and coworkers [36]. The general synthetic route for the kind of neutral palladium complex in this study is shown in Scheme 2. Meanwhile we have synthesized neutral palladium complexes **8a–c** bearing salicylaldiminato ligands with a similar method, which is shown in Scheme 3.

3.2. Crystal structures of complexes *3a*, *4a* and *5a*

Crystals of **3a**, **4a** and **5a** suitable for X-ray structure determination were grown from a benzene–pentane (volume ratio = 1:2) solution. The data collection and refinement data of the analysis are summarized in Table 1, the selected bond lengths and bond angles are summarized in Table 2, and the molecule structures of **3a**, **4a** and **5a** are shown in Figs. 1–3, respectively.

The Pd atom is at the center of an approximately square-planar arrangement, which is applied to all these three complexes. For **3a**, the bulky 2,6-diisopropylbenzimine filled the position *trans* to the triphenylphosphine ligand with a P–Pd–N2 angle of 175.23(11)°;

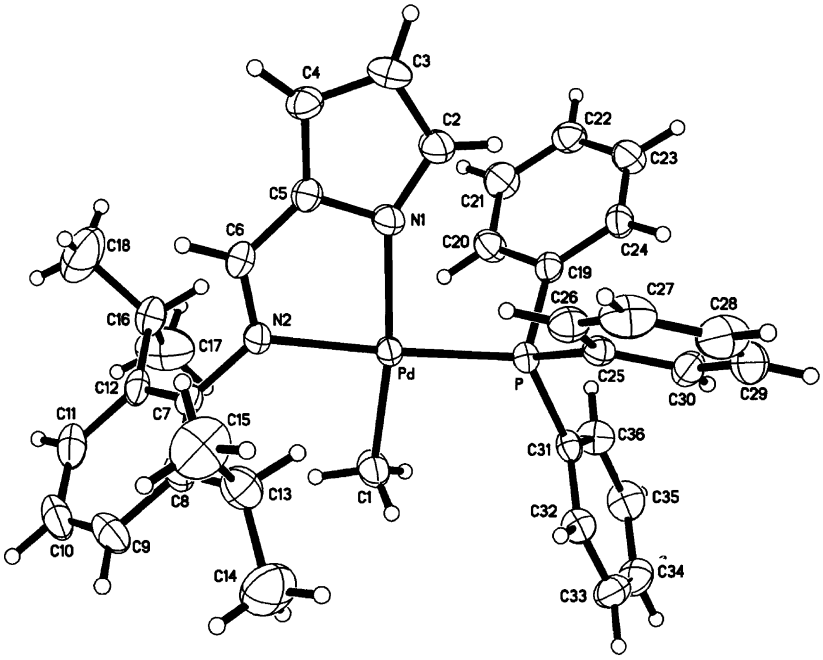

Fig. 1. ORTEP plot of the molecular structure of complex **3a**. Displacement ellipsoids are drawn at the 50% probability level.

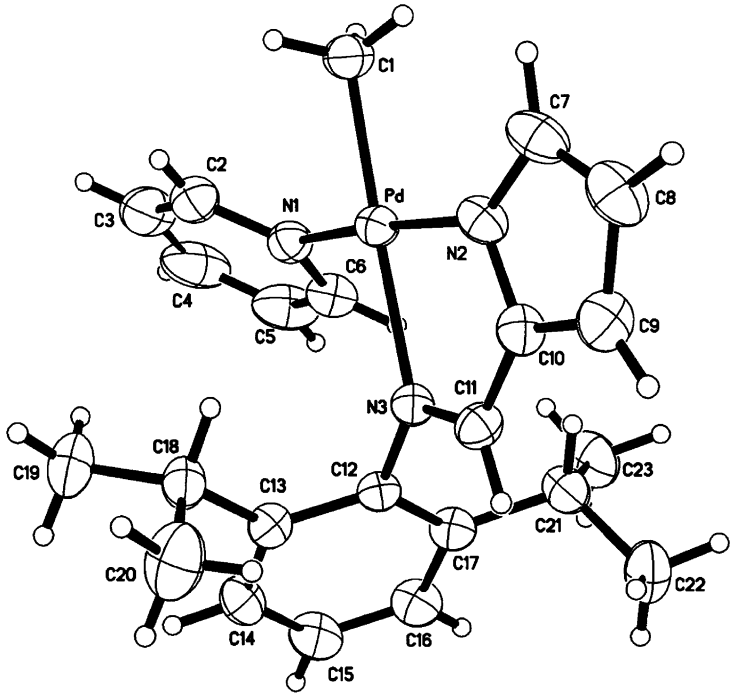

Fig. 2. ORTEP plot of the molecular structure of complex **4a**. Displacement ellipsoids are drawn at the 50% probability level.

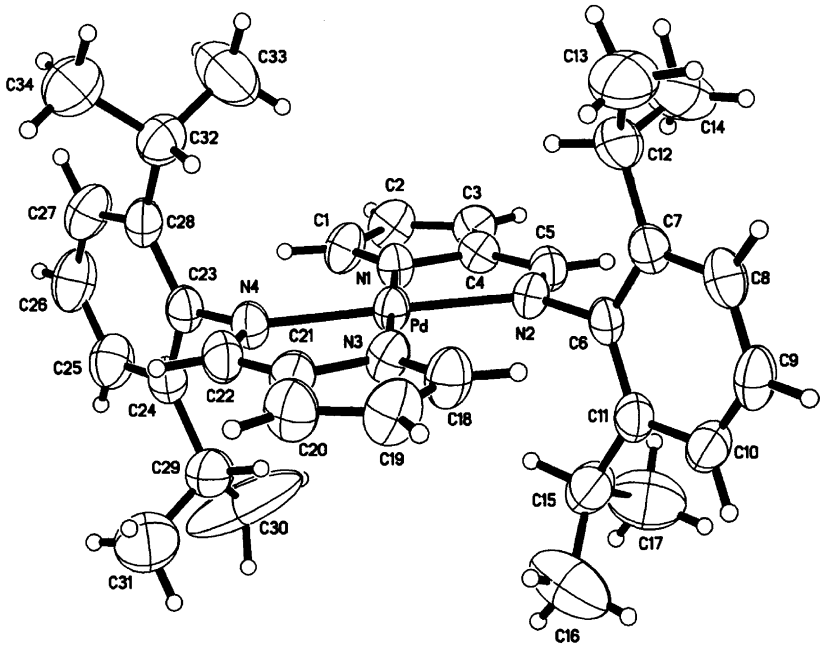

Fig. 3. ORTEP plot of the molecular structure of complex **5a**. Displacement ellipsoids are drawn at the 50% probability level.

the pyrrole group attached to Pd is in the position *trans* to the methyl ligand with a N1–Pd–C1 angle of 171.8(2)°, as shown in Fig. 1. While for **4a**, the 2,6-diisopropylbenzimine is at the position opposite to the methyl ligand with a N3–Pd–C1 angle of 172.86(10)°. The pyridine ligand lies *trans* to the pyrrole ligand through Pd with a N1–Pd–N2 angle of 174.50(9)°, as shown in Fig. 2. For **5a**, the two 2,6-diisopropylbenzimine ligands are *trans* to each other through Pd with a N4–Pd–N2 angle of 179.16(13)°, so are the two pyrrole ligands with a N1–Pd–N3 angle of 179.75(13)°, as shown in Fig. 3. From X-ray structural data by comparison of **3a** and **4a**, the Pd–C1 is sensitive to the nature of the *trans* ligand. The Pd–C1 length of **3a** is 2.022(7) Å and the Pd–C1 length of **4a** is shorter than that of **3a**, being 2.018(3) Å. This shows the ligand 2,6-diisopropylbenzimine has a stronger influence than the pyrrole ligand, according to Abu-Surrah et al. [31].

3.3. Polymerization of norbornene

Our main interest in the study of these complexes is their possible application as catalysts for the polymerization of norbornene and its derivatives. Preliminary experiments indicated that the single-component palladium complexes in the study, like single-component nickel complexes [14,15], are not able to catalyze norbornene polymerization, and MMAO alone is not able to catalyze norbornene polymerization too. From experiments, however, we found that these new neutral palladium complexes display high activities for norbornene polymerization when MMAO is used as a co-catalyst. Yet these catalysts do not work for polymerization of norbornene derivatives, which was not listed in this article.

Catalyst activities and polymer yields depended significantly on the reaction parameters applied to the polymerization of norbornene, as shown in Figs. 4–7. The concentration of norbornene should meet some requirements for good polymerization. In this system when the catalyst concentration reached 0.025 μmol/ml it did well, as shown in Fig. 4. Variation of molar ratio of MMAO to the catalyst **3c**, which is expressed here as the Al/Pd molar ratio, showed considerable effect on the polymerization reaction. When the mole ratio of Al/Pd

Norbornene polymerizations catalysted with different neutral palladium complexes[a]

Entry	Catalyst	Al/Pd (molar ratio)	Yield (g)	Activity (10^6 g/mol$_{Pd}$ h)
1	**3a**	2000	0.14	1.68
2	**3b**	2000	0.23	2.76
3	**3c**	2000	0.22	3.00
4	**3d**	2000	0.25	2.64
5	**4a**	2000	0.32	3.84
6	**5a**	2000	0.13	1.56
7	**8a**	2000	0.71	8.52
8	**8b**	2000	0.47	5.64
9	**8c**	2000	0.26	3.12

[a] 0.5 μmol catalyst, 2.443 g norbornene, $V_{total} = 11$ ml, polymerization reaction for 10 min at 30 °C.

was 1500/1, the catalyst activity reached 1.01×10^7 g polym/mol$_{Pd}$ h, as shown in Fig. 5. On increasing the mole ratio of norbornene/Pd, while other conditions were kept constant, the catalyst activity of the catalyst **3c** grew, reaching 1.0×10^7 g polym/mol$_{Pd}$ h when the mole ratio of norbornene/Pd equalled 70 000, as shown in Fig. 6.

Meanwhile, the catalyst activity of the catalyst **8a** has been examined by varying the polymerization temperature, which is shown in Fig. 7. The catalyst activity first reached a peak and then gradually decreased with the increase of temperature, which means that to get high catalytic activity, polymerization reaction should be at the proper temperature.

The polymerization results using complexes **3a**–**d**, **4a**, **5a** and **8a**–**c** activated with MMAO are summarized in Table 3. From the results, we can see that the neutral palladium complexes bearing salicylaldiminato ligands displayed higher catalytic activities than those bearing pyrrole-imine chelate ligands. According to entries 1–4, with increasing the bulk in the *ortho* position of nitrogen atom of aniline, the polymerization activities decline, which means the bulkier the volumes of the substituents, the harder the insertion of norbornene. This is similar to some neutral nickel complexes [15].

The poly(norbornene)s obtained are insoluble in choloform, benzene, chlorobenzene, 1,2-dichlorobenzene, *N*,*N*-dimethylformamide and *N*,*N*-dimethylacetamide, which is different from polymers got with neutral nickel catalysts [14,15]. The molecular weights of the polymers obtained could not be determined because of their insolubility, which is similar to the result reported by Hu and co-workers [16]. FTIR analyses of the poly(norbornene)s were performed. In the range of 1600–1670 cm^{-1} no absorption is observed which means the catalytic polymerization is via vinyl addition

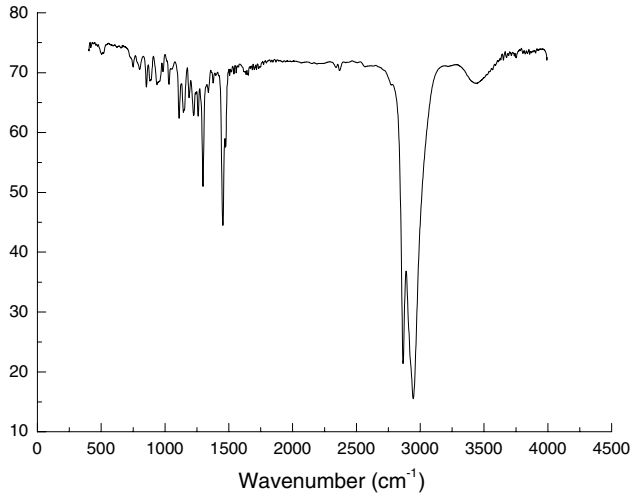

Fig. 8. FTIR spectrum of polynorbornene catalyzed by complex **3d**.

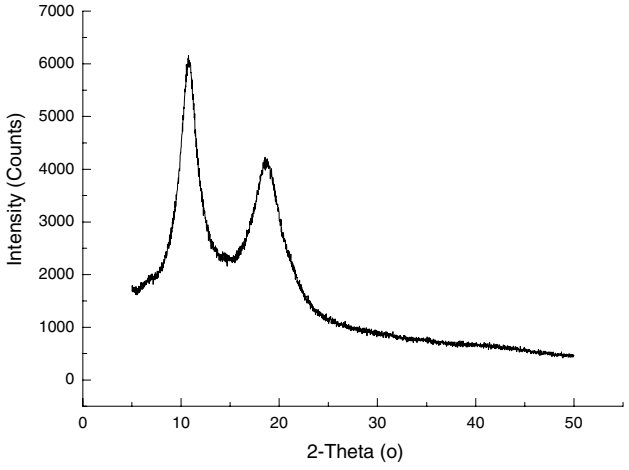

Fig. 9. WAXD plot of polynorbornene catalyzed by the catalyst **3d**.

polymerization, as shown in Fig. 8. WAXD has been employed to get information on the conformation of the polymer obtained. As shown in Fig. 9, we can see two peaks in the figure, 2θ equals 10.759 at peak 1, while 18.899 at peak 2. Haselwender et al. [41] and Zhao et al. [42] reported similar results which mean peak 1 is the reflection of the interchain or intersegment distance of the polymer, while peak 2 is the reflection of the intrachain distance. No traces of Bragg reflection, which is characteristic of a crystalline region were detected. Therefore, the polymer is non-crystalline.

4. Conclusions

In this article, several novel neutral palladium(II) complexes have been synthesized. The crystal structures of some of these complexes have been confirmed by X-ray analysis. High catalytic activities can be reached using these complexes activated with MMAO for vinyl-polymerization of norbornene. The complexes bearing salicylaldiminato ligands have more excellent activity than those bearing pyrrole-imine ligands for norbornene polymerization. IR analysis of the polymers identifies the polymerization is via vinyl addition mechanism. WAXD measurement implies the polymers are non-crystalline.

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Center as supplementary publication numbers CCDC-219639, CCDC-219640 and CCDC-219641. Copies of the data can be obtained on application to: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The metathetical reactions of cyclic telluranes: $C_4H_8TeI_2$, $C_5H_{10}TeI_2$, $C_8H_8TeI_2$, with AgX (X = Cl, Br) yield $C_4H_8TeCl_2$ (**1**), $C_4H_8TeBr_2$ (**2**), $C_5H_{10}TeBr_2$ (**3**), $C_8H_8TeCl_2$ (**4**) and $C_8H_8TeBr_2$ (**5**). Reactions of $C_4H_8TeI_2$ or $C_8H_8TeI_2$ with $[Et_4N]CI$ give X-ray quality crystals of $C_4H_8TeCl_2$ (**1**) and $C_8H_8TeCl_2$ (**4**). The X-ray structures of **1**–**5** reveal that in each case the primary geometry around Te is distorted pseudo trigonal bipyramidal where two Cl or Br atoms are at the axial positions whereas the three equatorial positions are occupied by two $-CH_2-$ groups of the cycle and, apparently, one stereochemically active electron lone pair. The Te···Cl and Te···Br secondary bonds in **1**–**5** act as crystal structure directors yielding zig-zag 2D-stairs in **1** and zig-zag 2D-ribbons in **2**, trimeric molecular aggregates in **3** and 3D-supramolecular networks in **4** and **5**. The supramolecular associations of these cyclic telluranes **1**–**5** are compared with the supramolecular associations in their precursors and in acyclic telluranes.

Keywords: Cyclic telluranes; Metathetical reactions; Intermolecular; Secondary bonding; Supramolecular networks

The concept of Te···X (X = Cl, Br, I, O, N, S) secondary bonds (non covalent interactions) was first coined by Alcock [1]. King et al. [2] described C–Te···X as 3c–4e bond in organotellurium compounds. The secondary bonds have now become a common place in organotellurium chemistry and the two important organizational tools in supramolecular chemistry are noncovalent interactions [3] and hydrogen bonds [4]. The design of organometallic supramolecular systems that can utilize these forces is a growing field [5]. King et al. [2] reviewed the supramolecular associations in organotellurium complexes formed through Te···S secondary bonds and Drake et al. [6], Dakternieks et al. [7] and others [8] utilized Te···S secondary bonds in the design of supramolecular associations in organotellurium dithio-carbamates, -carbonates and -phosphates. We are developing supramolecular organotellurium chemistry based on Te···X and C–H···O hydrogen bonds and recently we reported supramolecular associations induced by intermolecular Te···O [9] Te···I [10] and C–H···O hydrogen bonds [11] in acyclic and cyclic organotellurium compounds. However supramolecular associations through Te···Cl and Te···Br secondary bonds, to our knowledge, are restricted to only acyclic telluranes [12–16] and there is none on cyclic telluranes. De Matheus et al. [12] reported Te···Cl bonds in *cis*-[(4-$PhOC_6H_4)_2$ $TeCl(\mu\text{-}Cl)]_2$ and Bird et al. [13] reported Te···Br secondary bonds in *cis*- and *trans*-$[ArTeBr(\mu\text{-}Br)]_2$ and $[ArTeBr(\mu\text{-}I)]_2$ (Ar = 4-$MeOC_6H_4$ and 4-$EtOC_6H_4$). Alcock and Harrison [14] reported Te···Cl secondary bonds in Ph_2TeCl_2 and Te···Cl secondary bonds in Me_2TeCl_2 were reported by Ziolo and Troup [15] We reported Te···Br secondary bonds in Me_2TeBr_2 [16] and Chan and Einstein [17] reported corrugated sheets in Me_2TeI_2 through Te···I secondary

bonds. We therefore, in the present study report the synthesis of cyclic telluranes $C_4H_8TeCl_2$ (**1**), $C_4H_8TeBr_2$ (**2**), $C_5H_{10}TeBr_2$ (**3**), $C_8H_8TeCl_2$ (**4**) and $C_8H_8TeBr_2$ (**5**) and describe the formation of trimeric molecular aggregates, zig-zag 2D-stairs, -ribbons and 3D-supramolecular networks in **1**–**5** through intermolecular Te···Cl and Te···Br secondary bonds. We also compare the supramolecular associations in **1**–**5** with the supramolecular associations present in their precursors ($C_4H_8TeI_2$, $C_5H_{10}TeI_2$ and $C_8H_8TeI_2$). It is observed that when I is replaced by Cl or Br, more or less, the nature of supramolecular associations remains almost the same. This is in contrast to the drastic modification of the nature of supramolecular associations in these cyclic telluranes when I is replaced by carboxylate groups [9]. We also observe that both cyclic telluranes (**1**–**5**) and acyclic telluranes viz. $(CH_3)_2TeX_2$ (X = Cl,Br,I) contain ordered supramolecular associations [15–17].

1. Results and discussion

The complexes (**1**–**5**) have been synthesized by metathetical reactions of ($C_4H_8TeI_2$ [18], $C_5H_{10}TeI_2$ [19a], $C_8H_8TeI_2$ [20]) with freshly prepared silver salts AgX (X = Cl, Br) or $[Et_4N]Cl$. Metathetical reactions with $[Et_4N]Cl$ have not been so far reported in case of organotellurium iodides. Moreover it is interesting to note that this method affords X-ray quality crystals, which are not obtained when exchange is carried out with silver salts. Previously solids of $C_4H_8TeCl_2$ and $C_4H_8TeBr_2$ have been obtained by the reduction of $C_4H_8TeI_2$ to C_4H_8Te(II) which is a pale yellow oil of repulsive odour and then subsequent reaction of C_4H_8Te(II) with chlorine or bromine [18]. $C_5H_{10}TeBr_2$ was obtained by Morgan and Burgess [19a] as a by-product in the reaction of Aluminium telluride and pentamethylene dibromide at 160–190 °C under 25–30 mm pressure. It was also obtained by Farrar and Gulland [19b] by the reaction of sodium telluride solution with pentamethylene dichloride then by addition of bromine and crystallisation of crude product from pet. ether. Solids of $C_8H_8TeCl_2$ and $C_8H_8TeBr_2$ were obtained by the reduction of $C_8H_8TeI_2$ to C_8H_8Te(II) and its subsequent reaction with SO_2Cl_2 or Br_2 [21]. $C_8H_8TeCl_2$ and $C_8H_8TeBr_2$ have also been synthesised through exchange reactions of $C_8H_8TeI_2$ with AgCl or AgBr and characterized through (^{13}C, ^{125}Te)NMR data only [22]. There is so far no X-ray structural report on these $C_4H_8TeCl_2$ (**1**), $C_4H_8TeBr_2$ (**2**), $C_5H_{10}TeBr_2$ (**3**), $C_8H_8TeCl_2$ (**4**) and $C_8H_8TeBr_2$ (**5**) compounds.

Important bond lengths and bond angles for **1**–**5** are listed in Tables 2–6. The crystal structures of **1**, **2** and **3** are shown in Figs. 1, 3 and 5 and their supramolecular associations are shown in Figs. 2, 4 and 6, respectively. The crystal structures of **4** and **5** are shown in Figs. 7 and 9 and their supramolecular associations are shown in Figs. 8 and 10, respectively.

1.1. Description of the structure of $C_4H_8TeCl_2$ (1)

In telluracyclopentane 1,1-dichloride (Table 2) (Fig. 1), of the four methylene groups in the heterocycle ($C_4H_8TeCl_2$), the two methylene carbon atoms of the C_4H_8 group are bonded to the Te(IV) atom with bond distances and bond angles; Te–C(1) = Te–C(4) = 2.13 Å, C(1)–Te–C(4) = 85.3°. The four closest atoms C(1), C(4), Cl(1), Cl(2) in the molecule provide a distorted trigonal bipyramidal geometry around Te atom with the chlorine atoms in the apical positions [Te–Cl(l) = 2.53 Å, Te–Cl(2) = 2.52 Å]. A stereochemically active electron lone pair apparently occupies the fifth coordination position in the equatorial plane. The Cl(2)–Te–Cl(1) angle of 174.16° deviates from linearity with the chlorine atoms pushed away from the equatorial electron lone pairs [9–11,23–25].

The monomeric unit of the molecule is symmetrically connected to its neighbouring molecule through Te···Cl (3.614 Å) secondary bonds to form the dimers. These dimers are connected together through Te···Cl (3.528 Å) secondary bonds to form zig-zag-2D stairs in b direction (Fig. 2) (Table 7). The Te···Cl distances (3.528, 3.614 Å) are shorter than the sum of van der Waals radii (4.00 Å) [26] and longer than the sum of covalent radii(2.34 Å) [27] and therefore they correspond to secondary bonds [1]. With the Te···Cl, secondary bonds, the alternate tellurium atom is hexa and hepta coordinated with an unshared electron pair at the vertex situated *trans* to one of the $-CH_2$ groups attached to tellurium (the secondary bond itself is in the *trans* position to one of the $-CH_2$ group attached to tellurium). The angles Cl(1A)–Te–C(l) and Cl(lA)–Te–C(4) are 76.4° and 157.0°, respectively, and angles Cl(2B)–Te–C(1) and Cl(2B)–Te–C(4) are 159.5° and 80.7°, respectively, in the molecule. We are not aware of any closely related molecule containing Te···CI secondary bonds responsible for supramolecular associations.

1.2. Description of the structure of $C_4H_8TeBr_2$ (2)

The structure of $C_4H_8TeBr_2$ (Table 3) (Fig. 3) comprises two molecules A and B, which are present as dimers. Of the four methylene groups in the heterocycle of $C_4H_8TeBr_2$, the two methylene carbon atoms of the C_4H_8 group are bonded to the Te(IV) atom with bond distances and bond angles; Te(l)–C(l1) = 2.14 Å, Te(l)–C(14) = 2.13 Å, C(11)–Te(1)–C(14) = 84.3° in molecule A and Te(2)–C(21) = 2.15 Å, Te(2)–C(24) = 2.15 Å, C(21)–Te(2)–C(24) = 85.0° in molecule B. The four closest atoms C(11), C(14), Br(12) and Br(1A) in molecule A and C(21), C(24), Br(22), Br(2A) in molecule B

Symmetry transformations used to generate equivalent atoms.

provide a distorted TBP geometry around Te(l) and Te(2) atoms with the bromine atoms in the apical positions [Te(1)–Br(lA) = 2.74 Å, Te(l)–Br(12) = 2.77 Å in molecule A and Te(2)–Br(2A) = 2.74 Å, Te(2)–Br(22) = 2.78 Å in molecule B]. A stereochemically active electron lone pair apparently occupies the fifth coordination position in the equatorial plane. The Br(1A)–Te(l)–Br(12) angle of 173.3° in molecule A and Br (2A)–Te (2)–Br (22) angle of 175.5° in molecule B deviate from linearity with bromine atoms pushed away from the equatorial electron lone pair [9–11,23–25].

Molecule A is symmetrically connected to its neighbouring molecule through Te···Br (3.569 Å) secondary bonds and similarly molecule B is symmetrically connected to its neighbouring molecule through Te···Br (3.628 Å) secondary bonds to form the dimers. These dimers are asymmetrically connected through Te···Br (3.656, 3.836 Å) secondary bonds to form zig-zag ribbon in the a direction (Fig. 4) (Table 7). With the Te–Br secondary bonds, the coordination of each tellurium atom is octahedral with an unshared electron pair at the vertex situated *trans* to one of the $-CH_2$ group attached to tellurium (the secondary bond itself is in the *trans* position to the other $-CH_2$ group attached to tellurium). The angles Br(22)···Te(1)–C(14) and Br(22)···Te(l)–C(ll) are 89.0° and 107.6°, respectively, in molecule A and the angles Br(2B)···Te(2)–C(24) and Br(2B)···Te(2)–C(21) are 85.6° and 88.0°, respectively, in molecule B. Similar coordination environment for tellurium is found in $C_4H_8TeI_2$ [10a] and other organotellurium compounds [9–11,16] in which the unshared electron pair is *trans* to the organic group. The Te···Br distances (3.656, 3.628, 3.569, 3.836 Å) are shorter than the sum of van der Waals radii (4.15 Å) [26] and longer than the sum of covalent radii (2.51 Å) [27] and therefore correspond to secondary bonds [1]. The value of Te···Br secondary bonds is comparable to Te···Br secondary bonds present in 1-thia-4-telluracyclohexane, 4,4-dibromide ($C_4H_8STeBr_2$) [28].

1.3. Description of the structure of $C_5H_{10}TeBr_2$ (**3**)

The structure of $C_5H_{10}TeBr_2$ (Table 4) (Fig. 5) contains two independent molecules A and B. In each molecule the tellurium atom completes a cyclohexane ring with other five carbon atoms. The ring has chair conformation in both molecules due to the staggered situation of C–H bonds on neighbouring carbon atoms. In both molecules tellurium forms two normal bonds with the two neighbouring carbon atoms Te(1)–C(11) = 2.13 Å, Te(1)C(l5) = 2.16 Å, C(11)–Te(l)–C(l5) = 96.5° in molecule A and Te(2)–C(21A) = 2.17 Å, Te(2)–C(25A) = 2.17 Å, C(21A)–Te(2)–C(25A) = 96° in molecule B. Two axial bonds are formed with bromine atoms with bond distances Te(l)–Br(11) = 2.80 Å, Te(l)–Br(12) = 2.74 Å forming bond angle Br(1l)–Te(1)–Br(l2) = 175.93° in molecule A and Te(2)···Br(21) = 2.82 Å, Te(2)–Br(22) = 2.75 Å forming bond angle Br(21)–Te(2)–Br(22) = 176.52° in molecule B. The configuration around tellurium atom in both molecule A and molecule B approximates a distorted trigonal bipyramid with C(11), C(15) and unshared lone pair of electrons in equatorial position and Br(l1) and Br(12) in axial position in molecule A and C(21A), C(25A) and an unshared lone pair of electrons in equatorial positions and Br(21), Br(22) in axial positions in molecule B. The conformations adopted by the cyclohexane rings in the two molecules are same. The average C–C–C angles are 113° and 112.2°, respectively, in molecules A and B. The

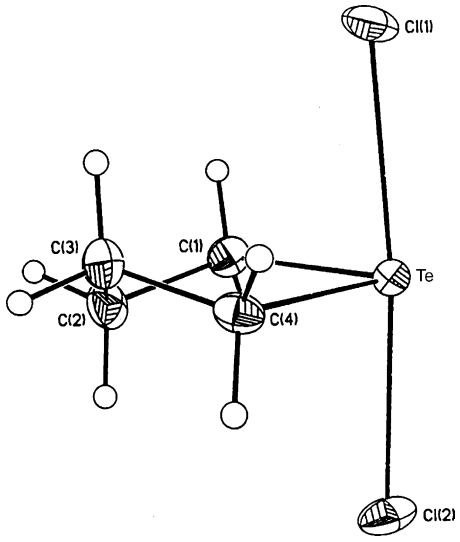

Fig. 1. Crystal structure of **1**.

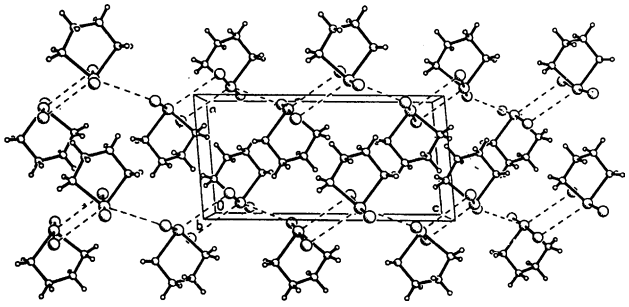

Fig. 2. Zig-zag 2-dimensional stairs for **1** in the b direction linked by Te···Cl secondary bonds.

molecule of $C_5H_{10}TeBr_2$, with bond distances Te(l)–Br(21) = 3.645 Å and Te(2A)–Br(12) = 3.778 Å (Table 4). In this way Te···Br secondary bonds form trimeric molecular aggregates (Table 7).

Despite our repeated crystallizations by varying different solvents and temperatures it was not possible to obtain X-ray quality crystals of $C_5H_{10}TeCl_2$. Among telluracyclohexane derivatives, the X-ray structure of $C_5H_{10}TeBr_2$, in the present investigation, is second one (earlier we reported the first X-ray structure of $C_5H_{10}TeI_2$ [10a] of telluracyclohexane series).

*1.4. Description of the structure of $C_8H_8TeCl_2$ (**4**)*

The X-ray structure analysis of $C_8H_8TeCl_2$ (Table 5) (Fig. 7) reveals it to have a distorted TBP geometry about the Te(IV) atom. Two axial positions are occupied by two chlorine atoms with the same bond length Te–Cl = 2.54 Å. The two methylene carbon atoms are bonded to the tellurium atom with equal Te–C bond lengths of 2.10 Å and bond angles; C(l)#l–Te–C(1) = 87.5°, C(1)#l–Te–Cl = 87.2°, C(1)–Te–Cl = 86.8°

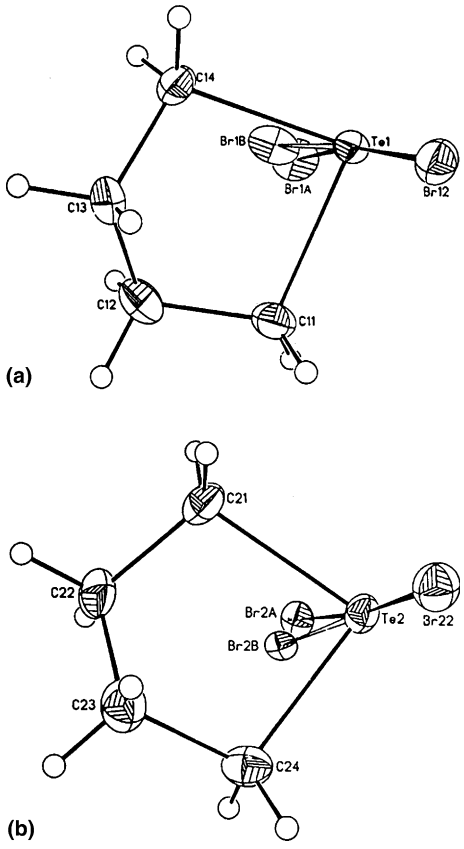

Fig. 3. Crystal structure of **2**.

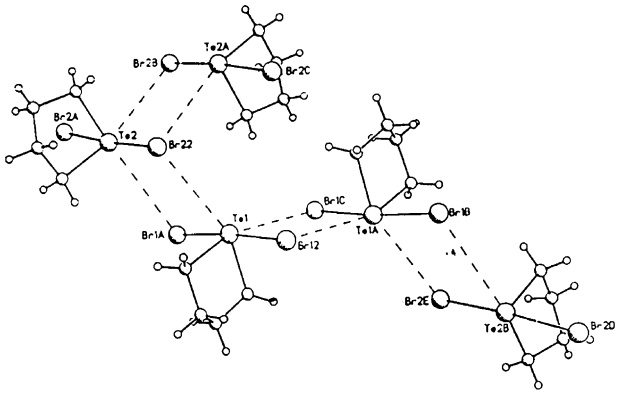

Fig. 4. Zig-zag 2-dimensional ribbon for **2** in the a direction linked by Te···Br secondary bonds.

(Table 5). The fifth coordination position in the equatorial plane is apparently, occupied by a stereochemically active electron lone pair. The bond angle Cl–Te–Cl#1 of 171.63° deviates considerably from linearity with both chlorine atoms pushed away from the equatorial lone pair of electrons [9–11,23–25].

In the unit cell, the molecules of $C_8H_8TeCl_2$ are interlinked through Te···Cl (3.495 Å) secondary bonds and leads to the formation of a three dimensional supramolecular networks in which hexa- and hepta-coordinated telluriums are present. The 3D- supramolecular networks are further assisted by cooperative participation of lesser known weak $C(sp^2)$–H···Cl hydrogen bonds [10b,11,30] (C–H = 0.93 Å, H···Cl = 2.89 Å, C···Cl = 3.802(8) Å, ∠CHCl = 165.9°) (Fig. 8).

*1.5. Description of the structure of $C_8H_8TeBr_2$ (**5**)*

The X-ray structure analysis of $C_8H_8TeBr_2$, (Table 6) (Fig. 9) reveals that the C_8H_8 group is symmetrically bonded to the Te(IV) atom with two same Te–CH_2 bond lengths of 2.13 Å. The coordination geometry formed by the four closest atoms C(1), C(1)#1, Br, Br#1 is approximately trigonal bipyramidal. The Br atoms are at the apical positions with the same Te–Br bond lengths of 2.70 Å and the two carbon atoms in the equatorial plane are bonded through the bond angles C(1)–Te–C(l)#l = 86.6°, C(1)–Te–Br#1 = 88.0°, C(1)–Te–Br = 88.1°. A stereochemically active electron lone pair apparently shares the fifth coordination position, in the equatorial plane. The Br–Te–Br#l angle of 174.67° deviates considerably from linearity with both bromine atoms pushed away from the equatorial tellurium lone pair of electrons [9–11,23–25].

In the unit cell (Fig. 10), the molecules of $C_8H_8TeBr_2$ are interconnected through Te···Br (3.547 Å) secondary bonds and lead to the formation of a three dimensional supramolecular network in which hexa and hepta coordinated tellurium are present.

On comparing the supramolecular associations present in $C_8H_8TeCl_2$, $C_8H_8TeBr_2$ with those present in $C_8H_8TeI_2$ [10a] (Te···I = 3.66–3.67 Å), it is observed that the three dimensional supramolecular networks assisted by Te···Cl, Te···Br and Te···I secondary bonds are present in $C_8H_8TeCl_2$, $C_8H_8TeBr_2$ and $C_8H_8TeI_2$. The Te···X (X = Cl, Br, I) secondary bond lengths follow the order Te···I > Te···Br > Te···CI (Table 7).

We conclude that by the replacement of iodine in the precursors ($C_4H_8TeI_2$, $C_5H_{10}TeI_2$, $C_8H_8TeI_2$) with bromine or chlorine the nature of the the supramolecular association remains almost the same in $C_4H_8TeCl_2$ (**1**), $C_4H_8TeBr_2$ (**2**), $C_5H_{10}TeBr_2$ (**3**), $C_8H_8TeCl_2$ (**4**), $C_8H_8TeBr_2$ (**5**) which is obvious as in all these the crystal structure directors are Te···halogen (X) [X = I, Br, Cl] secondary bonds (Table 7). This is contrary to the earlier perceptions that the intermolecular bonding decreases as one goes from iodides to bromides to chlorides in organotellurium halides [28]. The retention of more or less same type of supramolecular association in **1**–**5** vis a vis the supramolecular associations in their precursors is also in contrast to the drastic modification of supramolecular associations when I is replaced in $C_4H_8TeI_2$ (2D-zig-zag ribbons), $C_5H_{10}TeI_2$ (trimeric molecular aggregates) and $C_8H_8TeI_2$ (3D-supramolecular networks) with $OCOC_6H_5$ group [C_4H_8Te-$(OCOC_6H_5)_2$

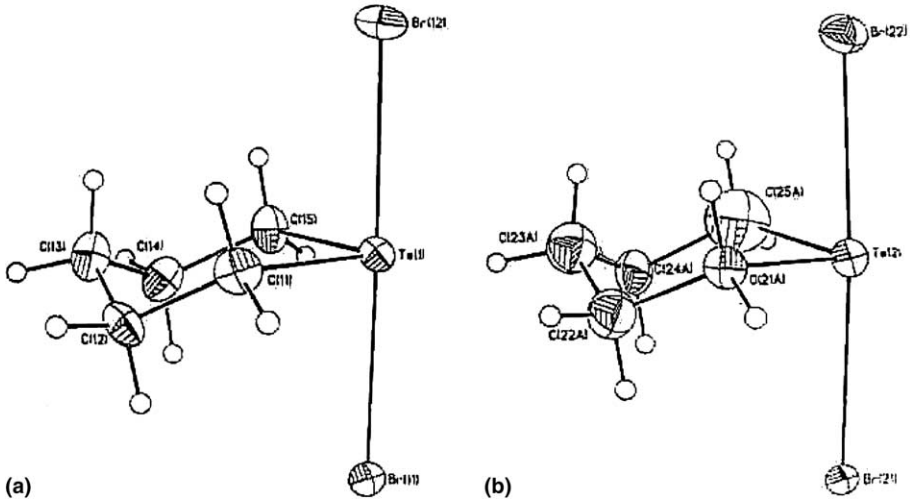

Fig. 5. Crystal structure of **3**.

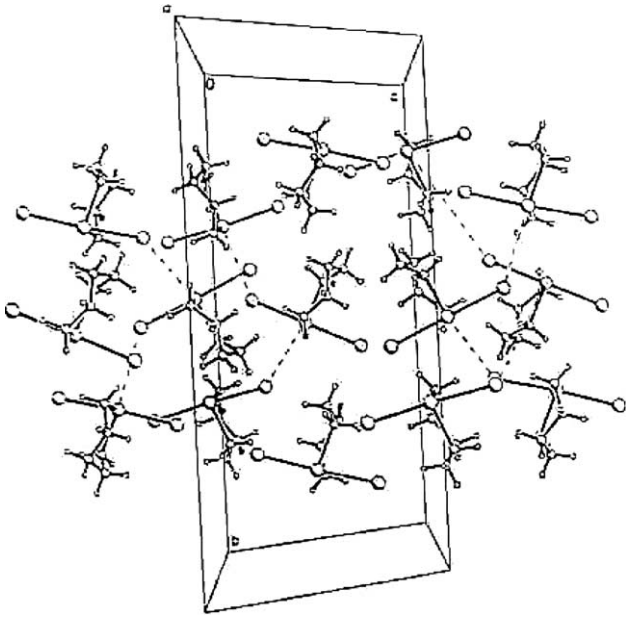

Fig. 6. Trimeric molecular aggregates of **3** linked by Te···Br secondary bonds.

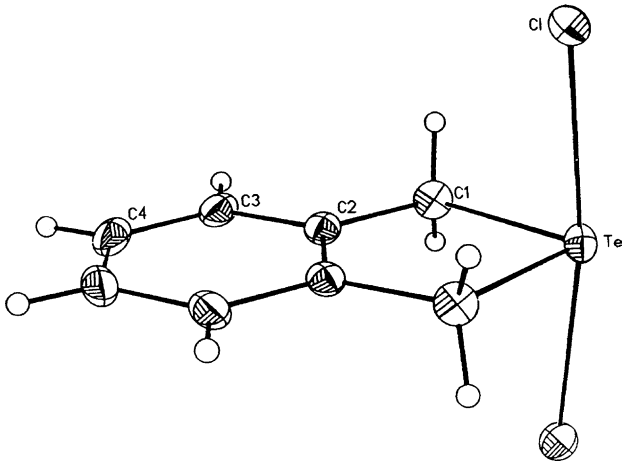

Fig. 7. Crystal structure of **4**.

(polymeric zig-zag chains), $C_5H_{10}Te$- $(OCOC_6H_5)_2$ (polymeric zig-zag chains) and $C_8H_8Te(OCOC_6H_5)_2$ (stairs)] [9a,9c].

1.6. Comparative supramolecular associations in cyclic telluranes and acyclic telluranes

In the past the supramolecular associations in simplest acyclic telluranes viz. Me_2TeI_2, Me_2TeBr_2 and Me_2TeCl_2 were not discussed properly. For example in Me_2TeCl_2 only Te···Cl secondary bonds were discussed [15] and in Me_2TeBr_2 only Te···Br secondary bonds were quoted by us [16] while in Me_2TeI_2 the

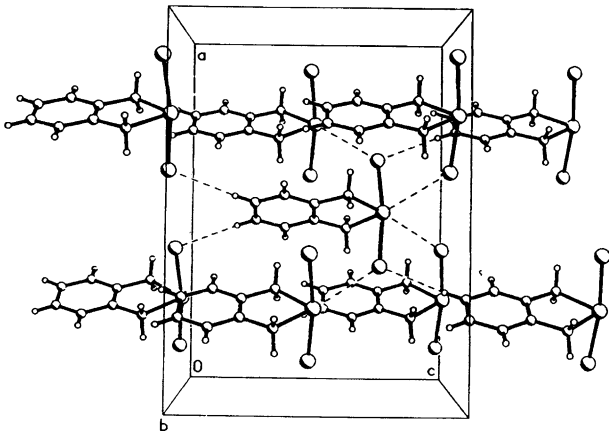

Fig. 8. Dimensional network of **4** linked by Te···Cl secondary bonds and weak $C(sp^2)$–H···Cl hydrogen bonds.

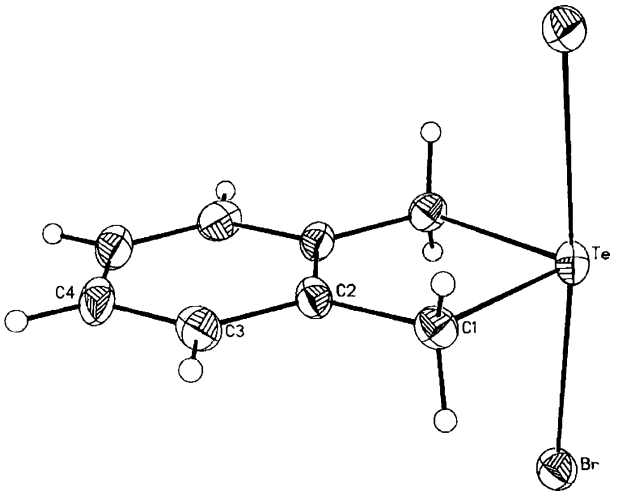

Fig. 9. Crystal structure of **5**.

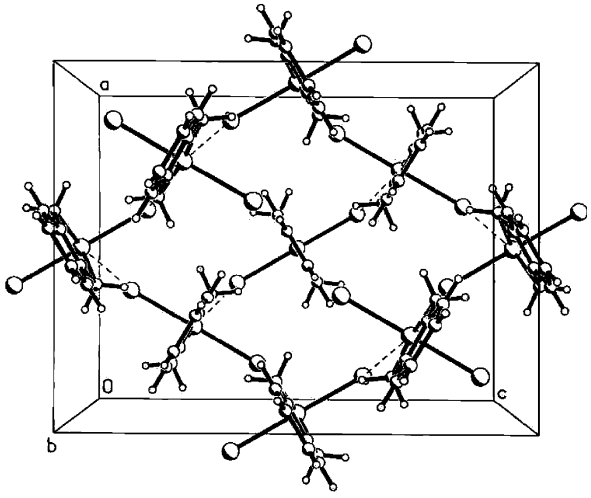

Fig. 10. Dimensional network of **5** linked by Te···Br secondary bonds and weak C(sp^2)–H···Br hydrogen bonds.

Te···I secondary bonds (3.65–4.02 Å) were quoted resulting in corrugated sheets type of supramolecular associations [17]. On the closer look at the X-ray structure of Me_2TeCl_2 [15] and its connectivity with other molecules it is apparent that Me_2TeCl_2 molecules are interconnected through Te···Cl secondary bonds (3.41–3.47 Å) resulting in zig-zag chain type supramolecular associations in Me_2TeCl_2. In our report on Me_2TeBr_2 [16] we did not discuss the supramolecular association in Me_2TeBr_2 but it is evident that Me_2TeBr_2 molecules are interconnected through Te–Br secondary bonds. (3.54–3.62 Å) resulting in dimers and these dimers are interconnected through Te···Br secondary bonds resulting in tetranuclear species (Fig. 11).

In summary, in the present investigation we have, for the first time, been successful in utilizing Te···Cl, Te···Br secondary bonds in the formation of a variety of supramolecular associations in cyclic telluranes (**1**–**5**)

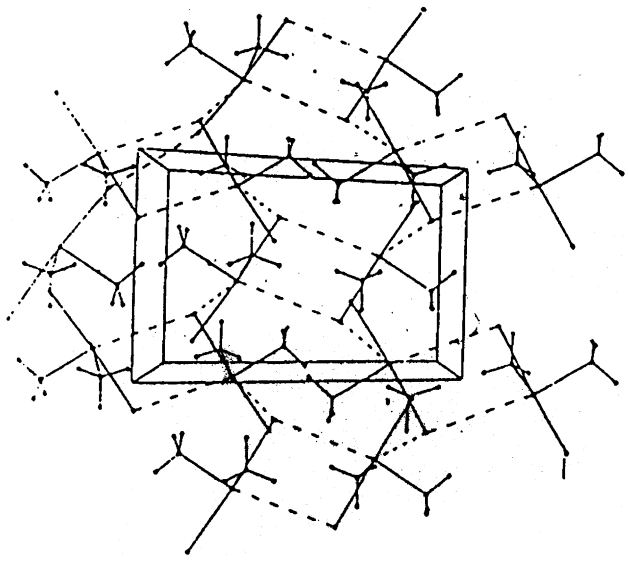

Fig. 11. Tetranuclear species of Me_2TeBr_2 linked by Te···Br secondary bonds.

which they do in almost the same way as Te···I secondary bonds do. Overall Te···X (X = Cl, Br, I) secondary bonds act as crystal structure directors resulting in ordered supramolecular associations in cyclic telluranes. These supramolecuar associations are significantly different from the supramolecular associations in cyclic telluranes where Te···O secondary bonds act as crystal structure directors. When cyclic systems attached to tellurium are changed to acyclic systems while the ligand is halide group, the pattern of the supramolecular association is again changed.

On the basis of the above available data (just about a dozen X-ray structures, considered in the present investigation) it is difficult to make any general comment but it appears that both (a) the organic group attached to tellurium and (b) the ligand attached to tellurium contribute and largely determine the nature and pattern of the supramolecular associations in organotellurium compounds and, for deeper insight into these aspects of supramolecular chemistry, the study prompts further researches in the area.

2. Experimental

1,4-diiodobutane, 1,5-diiodopentane, α,α′-dibromoxylene, Te metal and NaI were procured from Aldrich and used as such. 2-Methoxyethanol, benzene and acetone were purified and dried by standard procedures. The (precursors) cyclic telluranes viz. $C_4H_8TeI_2$ [18] (reaction of 1,4-diiodobutane with Te metal in the temperature range 130–140 °C), $C_5H_{10}TeI_2$ [19a] (reaction of 1,5-diiodopentane with Te metal at 150 °C) and $C_8H_8TeI_2$ [20] (reaction of α,α′-dibromoxylene, Te metal and NaI in 2-methoxyethanol at 100–110 °C) were

prepared by the literature methods. The complexes (**1**–**5**) were synthesized by the metathetical reactions of these cyclic telluranes with freshly prepared AgX(X = Cl, Br) or commercially procured $[Et_4N]Cl$ (Aldrich). The actual experimental work up and characterization data of each complexes (**1**–**5**) is given below.

2.1. Preparation of the compounds

2.1.1. 1,1,2,3,4,5-hexahydro-l,1-dichlorotellurophene, $C_4H_8TeCl_2$ (*1*)

$C_4H_8TeI_2$ (1g, 2.28 mmol) and $[Et_4N]Cl$ (0.76g, 4.56 mmol) were refluxed in dry chloroform (40 cm^3) for 5 h. The insoluble material was filtered off and the filtrate was reduced to ~15 cm^3. To the filtrate was added petroleum ether (60–80 °C). Yellow solid separated which on recrystallisation with acetone: pet. ether (60–80 °C) (1:1) solvent mixture twice gave dull white crystals of $C_4H_8TeCl_2$. [Yield: 0.07 g (12%) based on $C_4H_8TeI_2$], m.p. 120 °C. $C_4H_8Cl_2Te$ (M = 254.60) requires: C, 18.85; H, 3.14; Te, 50.11. Found: C, 18.80; H, 3.12; Te, 50.08%. ^1H NMR spectrum (in $CDCl_3$+DMSO-d_6 at 60 MHz): $\delta = 4.02$ m (4H, $TeCH_2$–); $\delta = 3.22$ m (4H, CCH_2–). The insoluble material on analysis, did not correspond to expected anionic complex $[Et_4N]^+[C_4H_8TeI_2Cl]^-$. The reaction of $C_4H_8TeI_2$ with AgCl (1:2 molar ratio) in chloroform did not give X-ray quality crystals of **1**.

2.1.2. 1,1,2,3,4,5-hexahydro-l,1-dibromotellurophene, $C_4H_8TeBr_2$ (*2*)

To an acetone solution (30 cm^3) of $C_4H_8TeI_2$ (2 g, 4.57 mmol) was added freshly prepared AgBr (1.72 g, 9.15 mmol). The mixture was stirred at room temperature for 2 h and filtered to remove AgI and unreacted AgBr. The filtrate was concentrated to give yellow solid, which on recrystallisation with acetone twice and on slow evaporation after 24 h yielded orange square crystals of $C_4H_8TeBr_2$. Yield: 0.70 g (45%), m.p. 100 °C. $C_4H_8Br_2Te$ ($M = 343.6$) requires: C, 13.96; H, 2.32; Te, 37.13. Found: C, 13.88; H, 2.21; Te, 37.02%. ^1H NMR spectrum (in $CDCl_3$ + DMSO-d_6 at 60 MHz): $\delta = 3.78$ m (4H, $TeCH_2$); $\delta = 2.90$ m (4H, CCH_2–).

2.1.3. 1,1,2,3,4,5,6-heptahydro-1,1-dibromotellurane, $C_5H_{10}TeBr_2$ (*3*)

To an acetone solution (30 cm^3) of $C_5H_{10}TeI_2$ (1.18 g, 2.61 mmol) was added freshly prepared AgBr (0.98 g, 5.25 mmol). The mixture was stirred at room temperature for 3 h and filtered to remove AgI and unreacted AgBr. The filtrate was concentrated under reduced pressure. A layer of petroleum ether (40–60 °C) was laid. Yellow needle shaped crystals were obtained after 24 h, which corresponded to $C_5H_{10}Br_2Te$. Yield: 0.16g (17%), m.p. 72 °C. $C_5H_{10}Br_2Te$ ($M = 357.6$) requires: C, 16.77; H, 2.79; Te, 35.68. Found: C, 16.65; H, 2.75; Te, 35.62% ^1H NMR spectrum (in $CDCl_3$ at 300 MHz): $\delta = 3.66$ t (4H, $TeCH_2$–); $\delta = 2.21$ m (4H, CCH_2–); $\delta = 1.90$ m (2H, CCH_2CH_2).

2.1.4. 1,3-Dihydro-2-λ^4-benzotellurole-2,2-diyl dichloride, $C_8H_8TeCl_2$ (*4*)

$C_8H_8TeI_2$ (2 g, 4.12 mmol) and $[Et_4N]Cl$ (1.36 g, 8.24 mmol) were refluxed in dichloromethane (20 cm^3) for 4 h. The insoluble material was filtered off and filtrate reduced to ~5 cm^3 when pale yellow crystals of $C_8H_8TeCl_2$ (**4**) [Yield: 0.30 g (24%) based on $C_8H_8TeI_2$]; m.p. 180 °C. $C_8H_8Cl_2Te$ ($M = 302.6$) requires: C, 31.72; H, 2.64; Te, 42.16. Found: C, 31.68; H, 2.44; Te, 42.12%. ^1H NMR spectrum (in $CDCl_3$ at 300 MHz): $\delta = 5.07$ m (4H, $TeCH_2$–); $\delta = 7.32$ m (4H, C_6H_4) (and black crystals m.p. 140 °C) appeared. The NMR (^1H, ^{13}C, ^{125}Te) analysis of black crystals in DMSO did not correspond to the expected $[Et_4N]^+[C_8H_8TeI_2Cl]^-$ complex. The reaction of $C_8H_8TeI_2$ with AgCl (1:2 molar ratio) in dichloromethane did not give X-ray quality crystals of **4**.

2.1.5. 1,3-Dihydro-2-λ^4-benzotellurole-2,2-diyl dibromide, $C_8H_8TeBr_2$ (*5*)

$C_8H_8TeI_2$ (2 g, 4.12 mmol) and AgBr (1.56 g, 8.30 mmol) were stirred in acetone (30 cm^3) for 4 h. The precipitated AgI and unreacted AgBr were filtered off and the excess solvent was distilled off to give pale yellow needles of $C_8H_8TeBr_2$. Yield: 0.60 g (37%). m.p. 250 °C dec. $C_8H_8Br_2Te$ ($M = 391.6$) requires: C, 24.51; H, 2.04; Te, 32.58. Found: C, 24.45; H, 2.03; Te, 32.48%. ^1H NMR spectrum (in $CDCl_3$ at 300 MHz): $\delta = 5.40$ m (4H, $TeCH_2$–); $\delta = 7.36$ m (4H, C_6H_4).

2.2. Crystal structure determinations

Crystals (**1**–**5**) were mounted on a Bruker P4 diffractometer using graphite monochromatic Mo Kα (0.71073 Å). The unit cells were determined from 25 randomly selected reflections using the automatic search index and least square refinement. The data were corrected for Lorentz, polarization and absorption effects. The data were monitored by measuring three reflections at every 97 reflections. The structures were solved by the routine heavy atom method SHELXS-97 [31] and Fourier methods and refined by full-matrix least-squares using the SHELXL-97 program [31] with the non-hydrogen atoms anisotropic and hydrogen atoms having fixed isotropic thermal parameters of 0.08 Å (Table 1).

3. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 222539 for $C_4H_8TeCl_2$ (**1**),

226695 for $C_4H_8TeBr_2$ (**2**), 226696 for $C_5H_{10}TeBr_2$ (**3**), 222541 for $C_8H_8TeCl_2$ (**4**) and 222540 for $C_8H_8TeBr_2$ (**5**). Abstract

The planar dihydroxo-bridged $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2]\cdot 2H_2O$ **(1)** and the roof-shaped trihydroxo-bridged $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl\cdot 3H_2O$ **(2)** (in which dpyam = di-2-pyridylamine) dinuclear copper(II) compounds have been synthesized and their crystal structures determined by X-ray crystallographic methods. All of compounds are being centrosymmetric molecule. Compound **1** contains a dinuclear $[I(dpyam)Cu(\mu\text{-}OH)_2Cu(dpyam)I]^+$ unit with a strictly planar CuO_2 network, dihedral angle between the CuO_2 planes of 180°. Each copper(II) ion is in a tetrahedrally distorted square pyramidal coordination geometry of the CuN_2O_2I chromophore with a dihedral angle 19.3° between the CuN_2 and CuO_2 planes. In the dinuclear $[(dpyam)Cu(\mu\text{-}OH)_3Cu(dpyam)]^+$ unit of compound **2**, the triply bridged Cu(II) ions show a distorted square pyramidal coordination. The fifth apical ligand is a longer bonded bridging OH^- group, at distance of 2.433(4) Å, which joins the basal CuN_2O_2 planes in a roof-shaped configuration with a dihedral angle of 142.5°. The Cu–Cu distance is 2.803(7) Å.

1. Introduction

In the last three decades, the dinuclear doubly bridged copper(II) compounds with nitrogen donor ligand and monoatomic bridges have been received much attention especially the di-μ-hydroxo-bridged copper(II) systems which have been studied widely both from experimental and theoretical points of view, since the magnetostructural correlations described by Hatfield et al. [1] for the Cu–O–Cu bridging angle and spin coupling constant ($2J$) between the metal centers. More recently, these correlations have been extended by Ruiz et al. [2,3]. However, the structure characterized of the triply bridged copper(II) compounds containing nitrogen donor didentated chelate ligand and monoatomic bridges are less reported. So far only a few closely related structures, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Cl_2\cdot 2H_2O$ [4], $[Cu_2(dpyam)_2(\mu\text{-}OMe)_2(\mu\text{-}Cl)]Cl\cdot MeOH$ [5] and $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Br_2\cdot 2H_2O$ [6] (in which dpyam = di-2-pyridylamine) are reported in the literature. In order to extend the investigation on this series of compounds an attempt has been made to prepare the novel planar di-μ-hydroxo-bridged copper(II) compound, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2]\cdot 2H_2O$ **(1)**, and the novel dinuclear copper(II) compounds containing three monoatomic bridges with homospecies, $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl\cdot 3H_2O$ **(2)**. Their IR, EPR and electronic spectra have been investigated and discussed, along with structural and spectral comparisons with those of other relevant compounds.

2. Experimental

2.1. Materials and measurements

Di-2-pyridylamine were purchased as commercial chemicals from Aldrich. All reagents are commercial grade

materials and were used without further purification. Elemental analyses (C, H, N) were determined on a Perkin–Elmer PE 2400 CHNS/O Analyzer by Microanalytical Service of Science and Technological Research Equipment Center, Chulalongkorn University.

IR spectra were recorded on a Biorad FTS-7/PC FT-IR and a Perkin–Elmer Spectrum One FT-IR spectrophotometer for compounds **1** and **2**, respectively as KBr disc in the 4000–450 cm^{-1} spectral range. Solid-state (diffuse reflectance) electronic spectra were measured as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer, over the range 8000–18000 cm^{-1}. The X-band powder EPR spectra were obtained on polycrystalline samples at room temperature and 77 K with a JEOL RE2X electron spin resonance spectrometer by Microanalytical Service of Science and Technological Research Equipment Center, Chulalongkorn University.

2.2. Synthesis of compound *1*

2.2.1. $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2]\cdot 2H_2O$ (*1*)

The hot aqueous solution (5 ml) of KI (0.166 g, 1.0 mmol) was added to a hot aqueous solution (5 ml) of $Cu(NO_3)_2\cdot 3H_2O$ (0.121 g, 0.5 mmol). Then a hot acetone solution (8 ml) of dpyam (0.086 g, 0.5 mmol) was added to the mixture yielding a green solution. Its color became greenish-blue by slow addition of an aqueous solution (10 ml) of NaOH (0.020 g, 0.5 mmol) and the blue precipitate formed in a few minutes. The precipitate was filtered off and recrystallized in a hot aqueous solution. After two weeks, blue-plate crystals of compound **1** were obtained. *Anal.* Calc. for $C_{20}H_{24}Cu_2I_2N_6O_4$: C, 30.28; H, 3.05; N, 10.59. Found: C, 30.35; H, 3.12; N, 10.40%.

2.3. Synthesis of compound *2*

2.3.1. $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl\cdot 3H_2O$ (*2*)

This compound was prepared by adding a hot acetone solution (10 ml) of dpyam (0.171 g, 1.0 mmol) to a hot aqueous solution (30 ml) of $CuCl_2\cdot 2H_2O$ (0.170 g, 1.0 mmol) yielding a turquoise green solution. Its color became blue by slow addition of an aqueous solution (10 ml) of NaOH (0.039 g, 1.0 mmol). This solution was allowed to evaporate at room temperature. After several days, bluish-purple crystals of compound **2** were obtained which were filtered off, washed with mother liquor and air-dried. *Anal.* Calc. for $C_{20}H_{27}ClCu_2N_6O_6$: C, 41.70; H, 4.72; N, 14.59. Found: C, 41.67; H, 4.81; N, 14.53%.

2.4. Crystallography

The X-ray single-crystal data for two compounds were collected at 298 and 293 K for compounds **1** and **2**, respectively on a 1 K Bruker SMART CCD area-detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of −35°. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0°, 88°, 180°) and each exposure of 40 s covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [7]. An empirical absorption correction by using the SADABS [8] program was applied, which resulted in transmission coefficients ranging from 0.741 to 1.000 for compound **1**, 0.752 to 1.000 for compound **2.**

The structures were solved by direct methods and refined by full matrix least-squares method on $(F_{obs})^2$ with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC V 6.12 software package [9]. All hydrogen atoms were located geometrically and refined isotropically except those of a hydroxo group and two molecules of lattice water for **2.**

The molecular graphics were created by using SHELXTL-PC [9] package. The crystal and refinement details for compounds **1** and **2** are listed in Table 1. Selected bond lengths and angles are given in Tables 2 and 3.

3. Results and discussion

3.1. Crystal structure of $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2]\cdot 2H_2O$ (*1*)

The structure of compound **1** consists of a centrosymmetric dinuclear $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2]$ unit and two molecules of lattice water. This unit is depicted in Fig. 1, together with the numbering scheme, with selected distances and angles listed in Table 2. Both copper(II) atoms of the complex are linked through the double hydroxo bridges. Each copper(II) atom has a distorted square pyramidal coordination, $\tau = 0.04$ (the structure index is defined as $\tau = (\beta - \alpha)/60$, where β and α are the largest coordination angles [10,11]), with the basal plane, CuN_2O_2 chromophore, comprised of two nitrogen atoms from a terminal dpyam ligand (Cu(1)–(N1) distance of 2.007(3) and Cu(1)–N(2) distance of 2.006(3) Å) and two oxygen atoms from two hydroxo groups (Cu(1)–O(1) distance of 1.967(2) and Cu(1)–O(1A) distance of 1.960(2) Å). The fifth apical coordination site of each copper(II) atom is occupied by an I atom (Cu–I distance of 3.040 Å) to complete the distorted square pyramidal CuN_2O_2I chromophore. However, the Cu–I distance is too long for even weak semi-coordination. The basal planes are slightly deviated from planarity with a distinct tetrahedral twist, evident from the dihedral angle of 19.3° between CuN_2 and CuO_2 planes. The Cu–Cu separation within the dinuclear unit is 2.988(7) Å, while the bridging Cu(1)–

[b] $[-x, 1-y, -z]$.
[c] $[1-x, 1-y, -z]$.

O(1)–Cu(1A) angle is 99.1(11)°. Each copper atom is displaced toward the apical I atom of 0.243 Å from the basal N_2O_2 plane. The dinuclear unit is exactly planar, a dihedral angle between two CuO_2 planes is 180° and that between the basal N_2O_2 planes is 180° (see Fig. 3). The bite angle of the dpyam ligand N(1)–Cu(1)–N(2) of 89.3(11)° is only slightly less than 90° but the O(1)–Cu(1)–O(1A) angle of 80.9(11)° is significantly less than 90°. The individual pyridine rings are planar, and the dpyam ligand is non-planar, dihedral angle of 27.2° occurs between the individual pyridine rings.

The lattice is further stabilized by a hydrogen bonding between the amine N and the oxygen atom of lattice water molecule with N···O contact of 2.916 Å ; between the oxygen atom of bridging hydroxo group and the oxygen atom of lattice water molecules with O···O contacts of 2.750–2.847 Å.

3.2. Crystal structure of $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl \cdot 3H_2O$ (2)

The structure of compound **2** is made up of a dinuclear $[Cu_2(OH)_3(dpyam)]^+$ cation, an uncoordinated Cl^- anion and three crystallisation water molecules. This unit is depicted in Fig. 2, together with the numbering scheme, with selected distances and angles listed in Table 3. The cation is located on a mirror plane through the three bridging OH^- groups. The whole cationic unit and the copper environment are the rooftop configuration. Compound **2** involves a triplyhydroxo-bridged structure with a square pyramidal CuN_2O_2O' chromophore, the fifth axial position is occupied by a longer bonded bridging OH^- group with a distance of 2.433(3) Å. The copper atom is displaced from the basal plane towards the apical oxygen by 0.035 Å. The Cu(1)–N(1) and Cu(1)–N(2) distances are

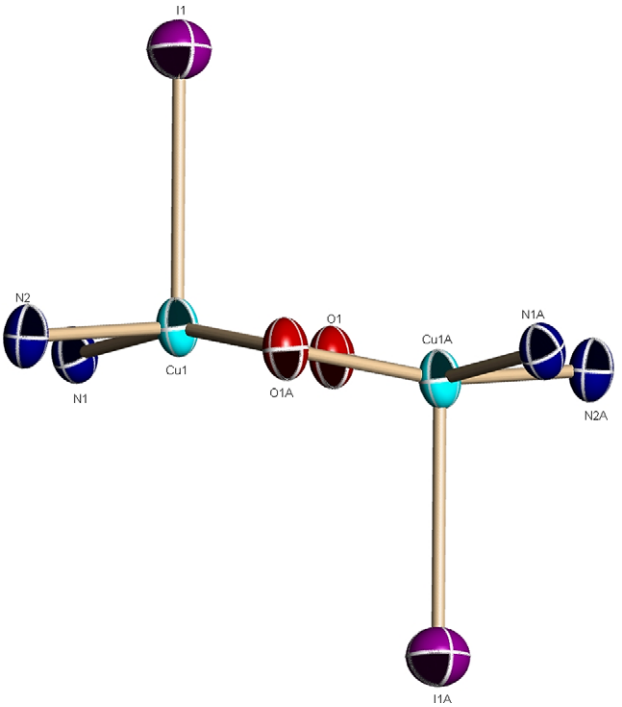

Fig. 3. The chromophore of $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2] \cdot 2H_2O$ (**1**).

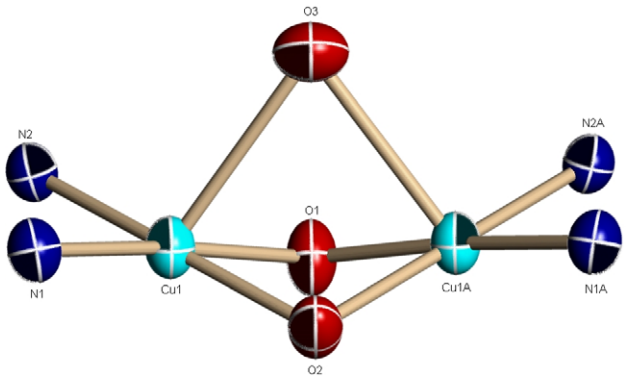

Fig. 4. The chromophore of $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl \cdot 3H_2O$ (**2**).

1.995(3) and 2.006(3) Å, respectively. The average Cu–O (hydroxo bridge) distance of 1.948 Å is slightly shorter and very close to those observed in the corresponding di–hydroxo bridged copper(II) dimers [5,6,12,13]. The CuN_2O_2 chromophore is planar with a slight tetrahedral twist, dihedral angle of 2.8° between the CuN_2 and CuO_2 planes, but the Cu_2O_2 network is not planar, a dihedral angle between the CuO_2 planes is 142.5° (see Fig. 4). The Cu–Cu distance is 2.803(1) Å. The bridging Cu–O(1)–Cu and Cu–O(2)–Cu angles are 92.4(2)° and 91.7(2)°, respectively, which are not in the range normally found for the planar dihydroxo-bridged copper(II) dimers. The dpyam ligand as a whole is nearly planar and involves a dihedral angle of 9.1° between the individual pyridine rings.

The lattice is stabilized by a hydrogen bonding between the amine N and the chloride atom with N···Cl distance of 3.252 Å and between the oxygen atom of bridging hydroxo group and the chloride atom with O···Cl contacts of 3.176–3.228 Å.

3.3. Spectral characterization

The infrared spectra of compounds **1** and **2** show a broad band at 3460 and 3400 cm^{-1}, respectively which can be assigned to the bridging OH vibrations of the hydroxo bridge and/or lattice water.

The electronic diffuse reflectance spectrum of compound **1** shows a broad band centered at 15 120 cm^{-1}. This observed single broad peak is consistent with the tetrahedrally distorted square pyramidal stereochemistry and assigned to be the $d_{z^2}, d_{xy}, d_{xz}, d_{yz}, \rightarrow d_{x^2-y^2}$ transition [14,15]. The reflectance spectrum of **2** displays a broad band and a lower energy shoulder at the frequencies of 17 800 and 14 600(sh) cm^{-1}. The relatively higher energy of this triply bridged dimer is unusual for the square pyramidal geometry. However, they are consistent with those observed for the relevant bipy complexes [16] and the $d_{xy}, d_{yz} \rightarrow d_{x^2-y^2}$ and $d_{xz}, d_{z^2} \rightarrow d_{x^2-y^2}$ transitions are assigned for a broad band and a lower energy shoulder, respectively.

The X-band polycrystalline EPR spectrum of compound **1**, at room temperature, displays a weak signal at ~320 mT ($g_i = 2.078$), while a triplet state signal at ~100–160 mT ($g_i = 6.964$) is not observed properly. The former feature is most certainly from a monomeric Cu(II) impurity, which is always present in dinuclear species. Compound **2** exhibits an intense signal at ~101 mT ($g_i = 6.695$) and a weaker signal at ~307 mT ($g_i = 2.220$). The latter is attributed to the monomeric impurity while the former is usually attributed to intramolecular exchange interaction between copper(II) ions, $\Delta Ms = \pm 2$ transition [17,18].

Compound **1** is planar (dihedral angle of 180° between the CuO_2 planes) and involves the Cu–O–Cu angle of 99.1° expecting a moderate antiferromagnetic coupling ($J = -116$ cm^{-1}) following Hodgson and Hatfield's linear relationship [1,18]. However, the experimental value of singlet-triplet energy gap ($2J$) would be smaller than the predicted value. The difference could be due to the deviation from planarity of the CuN_2O_2 plane with a tetrahedral twist between CuN_2 and CuO_2 planes, which may reduce the orthogonality of the copper(II) $d_{x^2-y^2}$ (or d_{xy}) orbital with the bridging hydroxo groups [4]. The most relevant compound $[Cu_2(dpyam)_2(\mu\text{-}OH)_2Br_2] \cdot 4H_2O$ also involves a double hydroxo bridge and an observed J value of -48.6 cm^{-1}, while the predicted value was as high as -116 cm^{-1} [6]. On the other hand compound **2** has the roof-shaped hydroxo bridge network with a dihedral angle of 142.5° between the CuO_2 planes and the Hatfield's linear relationship, which arises from studies of planar $Cu_2(OH)_2$ cores, is not valid then. The related structure, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Br_2 \cdot 2H_2O$ compound exhibits $J = -0.6$ cm^{-1}.

3.4. Structure comparison

There are five dihydroxo-bridged copper(II) dimers containing the dpyam ligand: $[Cu_2(dpyam)_2(\mu\text{-}OH)_2Br_2] \cdot 4H_2O$ **(3)**, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(FBF_3)_2]$ **(4)**, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(ONO_2)_2]$ **(5)**, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Cl_2 \cdot 2H_2O$ **(6)** and $[Cu_2(dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Br_2 \cdot 2H_2O$ **(7)** have been structurally reported [4–6,12]. In the known dimer structures, three copper environments are observed: rhombic coplanar [19], CuN_2O_2, square-based pyramidal, CuN_2O_2X [18,20], and elongated rhombic octahedral [21,22], $CuN_2O_2X_2$. Compounds **1**, **3, 4** and **5** involve the planar dihydroxo-bridged copper(II) dimer, all exhibit the square pyramidal CuN_2O_2X chromophore geometry. Compound **1** involves the square-based pyramidal CuN_2O_2I chromophores which are very comparable to the CuN_2O_2Br, CuN_2O_2F and CuN_2O_2O' chromophores in **3**, **4** and **5**, respectively. The fifth axial distances of 3.040(5) Å in compound **1** are much longer than those of 2.803(2) and 2.804(2), 2.745(7), 2.400(1) and 2.500(1) Å in

compounds **3**, **4** and **5**, respectively. The marked tetrahedral twists of the CuN_2O_2 chromophores in compound **1** and also in compounds **3**, **4** and **5** (dihedral angle of 19.3°, 21.8° and 21.4°, 24.0°, 20.7° and 16.7°, respectively) are less usual. However, the Cu_2O_2 network in these compounds is planar and the planarities of both the CuN_2O_2 chromophore and the Cu_2O_2 unit for each compound are not many different. Consequently, the Cu–Cu separation of 2.988(7) Å in compound **1** is more similar in compounds **3**, **4** and **5** (2.993(2); 2.919(5) and 2.954(2) Å, respectively). The Cu–O–Cu bridging angle of 99.1 Å in compound **1** is comparable to that of compounds **3**, **4** and **5** (98.1° and 100.1°, 99.3°, 99.4° and 98.9°, respectively). There are a significant difference observed in the Cu to N_2O_2 mean plane distances, those of compounds **1** and **3** (0.243, 0.273 Å, respectively) are longer than those of compounds **4** and **5** (0.022; 0.079 and 0.142 Å, respectively) arising from a very weak interaction in the sixth position of the chromophore provided from the other F atom of the BF_4^- group in compound **4** and the other O atom of the NO_3^- group in compound **5**. However, these sixth distances are between 3.0–4.0 Å. The structural data of compounds **1**, **3**, **4** and **5** have revealed that the bigger in the bite N–Cu–N angle (98.3°, 88.6° and 88.9°, 99.3°, 98.9° and 99.4°, respectively), the bigger the bridging Cu–O–Cu angle is observed. Consequently, the Cu–O–Cu angles in the parent dpyam complexes are bigger (>97.5°) than those of the corresponding bipy complexes (<97.5°). This feature is also observed in other corresponding dimers involving the other terminal ligand. This concludes that the terminal ligand other than the anion and solvent molecule influences the magnitude of the Cu–O–Cu angle.

The most interesting and unusual feature in structure of compound **2** is that this is the triply bridged dinuclear compound with a roof-shaped bridge, the dihedral angle between the CuO_2 planes is far from 180°. Each hydroxo group is symmetrically bound, with Cu–O(1) bond slightly shorter than Cu–O(2) bond. The bridging angles in compound **2** are significantly less than those found in the planar dihydroxo-bridged copper (II) dimers and are not in the usual range 95°–105°, normally found for these dimers [23–25]. So far, compound **2** represents the second structurally characterized examples of a triply bridged dinuclear copper(II) compound containing three monoatomic bridges with homospecies. The first one has been pointed out for the known $Cs_3[Cu_2Cl_7\ (H_2O)_2]$ compound [26], containing three Cl^- anions bridging two copper atoms separated by 3.45 Å. The related structures of the roof-shaped dinuclear copper(II) containing three monoatomic bridges are $[Cu_2\ (dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Cl_2 \cdot 2H_2O$ **(6)** and $[Cu_2\ (dpyam)_2(\mu\text{-}OH)_2(\mu\text{-}OH_2)]Br_2 \cdot 2H_2O$ **(7)** and $[Cu_2(dpyam)_2(\mu\text{-}OMe)_2(\mu\text{-}Cl)]Cl \cdot MeOH$ **(8)**. The cations present in compounds **2**, **6**, **7** and **8** show a similar structure, they exhibit the metal centres in a square pyramidal configuration with in-plane configuration of a dpyam ligand and of two bridging O atoms and involve in similar CuO_2Cu roof-top angles (142.5°, 140.6°, 135.8°, 144.3°, respectively). Also the in-plane Cu–N and Cu–O distances are similar to each other and the Cu–Cu separations are quite comparable (2.803, 2.797, 2.849, 2.792 Å, respectively). The cations differ, however, in the nature of the fifth bridging ligand, which is a hydroxo group in compound **2**, a water molecule in compounds **6** and **7**, and a bigger chloride anion in compound **8**.

4. Conclusion

In comparison to the planar di-μ-hydroxo-bridged complexes significant differences are observed. The dihedral angle between the CuO_2 planes of the dihydroxo-bridged dimers becomes near 180°, while their CuN_2O_2 chromophores are not planar with a distinct tetrahedral twist (except that for the octahedral geometry). On the other hand, the planarity of the square planes for each CuN_2O_2 chromophore with a slight tetrahedral twist is observed in the triply bridged dimers. Due to bending in the molecule, the Cu–Cu distances (2.792–2.849 Å) in the triply bridged complexes are significantly shorter than those of the planar dihydroxo-bridged complexes (2.870–3.000 Å). However, these distances are typical in the range previously observed, 2.80–3.00 Å [1,27]. There is an additional remarkable difference observed, the bridging Cu–O–Cu angles (91.0°–94.7°) in the roof-shaped dimers are significantly smaller than 95.0° while in the planar dihydroxo-bridged dimers, these angles are in the range 95.0°–104.1°.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no.CCDC-223620, 223621, for structures 1 and 2, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (international) +44-1223-336-033, e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of salicylketimines (2-[(2,6-diisopropylphenylimino)ethyl]phenol, 2-[(2,6-diisopropylphenylimino)ethyl]naphthol and 2-[(2,6-diisopropylphenylimino)(phenyl)-methyl]phenol), and their nickel complexes of general forms [(salicylketiminato)-Ni(PPh_3)(Ph)] and [(salicylketiminato)$_2$Ni] were synthesized and characterized. The formation of monophenyl-nickel(II) complexes versus the corresponding bis(sal)Ni(II) complexes depends on the fine tuning of the reaction work up and is affected by the substituent at the ketimine. Salicylketimines were thus found to form more readily the bis(sal)Ni(II) complexes than salicylaldimines. The molecular structures of the complexes were determined by X-ray crystallography and in all of them Ni has a nearly ideal square-planar coordination sphere.

Keywords: Nickel(II) complexes; Schiff bases; Salicylketimine ligands; X-ray crystallography

1. Introduction

Until middle of 1990s, only few reports were introduced utilizing late transition metal complexes as catalyst precursors for polymerization of α-olefins [1]. This could be due to the fact that these catalysts generally exhibited low activities for olefin polyinsertion. In addition, β-hydride elimination steadily competed with the chain growth resulting in the formation of oligomers [2]. However, in 1995 new nickel(II)- and palladium(II)-based catalysts bearing bulky diimine ligands were reported for ethene polymerization, and few years later also iron(II) was successfully applied as a metal centre with bis(imino)pyridine ligands [3]. These complexes, after methylaluminoxane (MAO) activation, produced high molecular weight polymers with a high activity. Moreover, due to their tolerance towards polar functionalities, these systems are viewed as promising alternatives to Ziegler-Natta and metallocene catalysts. By now, late transition metals as olefin polymerization catalysts have been extensively reviewed, and possibilities to apply them even in acrylate polymerization have been demonstrated [4].

The MAO-activated cationic catalysts are, anyhow, electrophilic and hence sensitive to protic solvents and polar monomers. For this reason, there has been a substantial interest in developing new, less oxophilic, catalysts for olefin polymerization [5]. Shell higher olefin process (SHOP) offers an intriguing insight for catalytic activity of neutral nickel catalysts used for ethylene oligomerization [6] and recently novel salicylaldimine based Ni(II) complexes as catalysts for homo and co-polymerization of olefins were described by DuPont [7] and Grubbs and co-workers [8]. The most active systems contain either electron-withdrawing nitro substituents on the aromatic ring or bulky substituents at C-3, a 9-anthracenyl group being the most effective [activity of

doi:10.1016/j.poly.2004.03.018

1.3×10^5 mol ethylene/(mol Ni h)]. It has been reported that the neutral salicylaldiminato nickel(II) complexes work as a single component catalysts or require only a phosphine scavenger such as [Ni(COD)$_2$] (COD: 1,5-cyclooctadiene) to act as catalysts for homo- and copolymerization of ethylene [8]. However, MAO as activator surprisingly turned out to be essential to initiate the homopolymerization of norbornene [9].

Recently, we and other research groups have found that penta-coordinated iron(II) complexes with tridentate ketimine ligands (2,6-bis(imino)pyridyl derivatives) are an order of magnitude more active, as ethylene polymerization catalysts, than their aldimine analogues [3,10]. As an augmentation to our studies upon both the coordination chemistry of heteroatom-containing ligands [11,12] and their catalytic application [4f,10a,13], we now report the synthesis of new nickel(II) complexes with salicylketimine Schiff base ligands. The new compounds were characterized by methods of elemental analysis, IR-, MS-, ^{1}H-, ^{13}C- and ^{31}P-NMR spectroscopy. Furthermore, the complexes were subjects to X-ray structure analysis.

2. Experimental

2.1. Materials

All reactions were carried out under argon by using standard Schlenk techniques. Reagent grade chemicals were purchased from commercial suppliers and used as received unless otherwise stated. *trans*-[(PPh$_3$)$_2$Ni((Ph)Cl] was prepared according to literature [14]. The hydrocarbon and ether solvents were purified by distillation over LiAlH$_4$.

2.2. Physical measurements

Elemental analyses were performed at the Departments of Chemistry of the Universities of Konstanz and Ulm or at the Department of Pharmacy at University of Helsinki with an EA 1110 CHNS-O CE instrument. ^{1}H-, ^{13}C- and ^{31}P-NMR spectra were recorded using a Varian Gemini 200 or a Bruker AMX 400 spectrometer. Infrared spectra were measured on a Perkin–Elmer Spectrum One spectrometer using ATR sampling assessor. Mass spectra were acquired using a JEOL JMS-SX102 mass spectrometer (EI) or Bruker ion trap 3000+ MS equipped with Agilent's AP-MALDI ion source (proto 3).

2.3. Synthesis of ligands

2.3.1. 2-[(2,6-Diisopropylphenylimino)ethyl]phenol (**4**)

A solution of 2-hydroxyacetophenone (3.2 g, 23.9 mmol), 2,6-diisopropylaniline (4.7 g, 23.9 mmol) and five drops of HCOOH in methanol were stirred together with ca. 5 g of Na_2SO_4 at 200 °C in a closed steel autoclave for 24 h. The reaction mixture was then cooled, filtered and the filtrate was evaporated to dryness. The residue was purified with column chromatography on silica with 1:5 mixture of diethylether/hexane as eluent. Yield: 46%. *Anal.* Calc. for $C_{20}H_{25}NO$: C, 81.31; H, 8.53; N, 4.74. Found: C, 81.22; H, 8.54; N, 4.75%. ^{1}H NMR (200 MHz, $CDCl_3$): $\delta = 1.15$ (dd, 12H, $J_{HH} = 1.8$ Hz, $^3J_{HH} = 7.0$ Hz, CHCH_3), 2.19 (s, 3H, N=CCH$_3$), 2.78 (sept, 2H, $^3J = 7.0$ Hz, CHMe$_2$), 6.91 (m, 1H, H–Ar), 7.05 (m, 1H, H–Ar), 7.18 (b, 3H, H–Ar), 7.41 (m, 1H, H–Ar), 7.65 (m, 1H, H–Ar), 14.95 (s, 1H, OH) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): $\delta = 17.6$, 23.1, 23.6, 28.3, 118.0, 118.3, 119.1, 123.2, 125.1, 128.9, 133.1, 138.0, 142.3, 162.4, 172.1 ppm. IR: $\nu = 1608$ cm^{-1} (C=N).

2.3.2. 2-[(2,6-diisopropylphenylimino)ethyl]naphthol (**5**)

The compound was prepared and purified as described above (Section 2.3.1). Yield: 48%. *Anal.* Calc. for $C_{24}H_{27}ON$: C, 83.44; H, 7.87; N, 4.05. Found: C, 83.39; H, 7.88; N, 4.03%. ^{1}H NMR (200 MHz, $CDCl_3$): $\delta = 1.17$ (d, 12H, $^3J_{HH} = 7.0$ Hz, CHCH_3), 2.28 (s, 3H, CCH$_3$), 2.89 (sept, 2H, $^3J = 7.0$ Hz, CHMe$_2$), 7.14 (m, 1H, H–Ar), 7.24 (m, 3H, H–Ar), 7.52 (m, 3H, H–Ar), 7.73 (m, 1H, H–Ar), 8.53 (m, 1H, H–Ar), 17.08 (s, 1H, OH) ppm. ^{13}C NMR (50 MHz, $CDCl_3$): $\delta = 17.2$, 22.8, 23.9, 28.5, 110.56, 115.8, 123.5, 124.7, 126.4, 127.2, 129.1, 136.5, 139.1, 140.6, 167.4, 172.3 ppm. IR: $\nu = 1596$ cm^{-1} (C=N).

2.3.3. 2-[(2,6-diisopropylphenylimino)(phenyl)methyl]-phenol (**6**)

The compound was prepared as described for **4** (Section 2.3.1). The isolated residue was purified with column chromatography using petroleum ether/ethylacetate (8:1) solvent mixture as eluent. Isolated yield: 6%. *Anal.* Calc. for $C_{25}H_{27}ON$: C, 83.99; H, 7.61; N, 3.92. Found: C, 82.29; H, 7.66 N, 3.86%. ^{1}H NMR (200 MHz, $CDCl_3$): $\delta = 1.08$ (d, 6H, $^3J_{HH} = 8.0$ Hz, CHCH_3), 1.17 (d, 6H, $^3J_{HH} = 8.0$ Hz, CHCH_3), 2.97 (sept, 2H, $^3J = 8.0$ Hz, CH Me$_2$), 6.81 (m, 1H, H–Ar), 7.03 (m, 2H, H–Ar), 7.16 (b, 5H, H–Ar), 7.30 (m, 3H, H–Ar), 7.43 (m, 1H, H–Ar), 14.76 (s, 1H, OH). IR: $\nu = 1605$ cm^{-1} (C=N). MS(EI): 357 (M$^+$), 280 (M$^+$ − Ph).

2.4. Synthesis of complexes

2.4.1. {Phenyl)(triphenylphosphine)(2-[(2,6-diisopropylphenylimino) ethyl]phenoxy)}-nickel(II) (**7**)

A solution of ligand **4** (0.65 g, 2.2 mmol) in THF was added to excess amount of NaH (0.18 g, 7.5 mol) at 0 °C. The mixture was stirred for 1 h at room temperature, filtered and evaporated. The pale yellow residue was washed with *n*-pentane and dried. Yield of the sodium salt Na-**4** was 98%. To a solid mixture of

Na-**4** (0.30 g, 0.94 mmol) and *trans*-[$(PPh_3)_2$Ni((Ph)Cl] (0.62 g, 0.90 mmol), 20 ml of benzene was added at 0 °C. The mixture was stirred at room temperature for 6 h and then filtered. After concentrating the filtrate to ca. 3 ml, the product was precipitated as orange powder upon addition of *n*-pentane (30 ml). The solid was isolated by cannula filtration, then washed with pentane and dried. Isolated yield: 30%. *Anal.* Calc. for $C_{44}H_{44}NNiOP$: C, 76.31; H, 6.40; N, 2.02. Found: C, 76.86; H, 6.41; N, 2.04%. ^{1}H NMR (200 MHz, C_6D_6): $\delta = 1.05$ (d, 6H, $^3J_{HH} = 6.8$ Hz, *i*Pr–CH_3), 1.21 (d, 6H, $^3J_{HH} = 6.8$ Hz, *i*Pr–CH_3), 1.83 (s, 3H, N=CCH_3), 3.84 (sept, 2H, $^3J_{HH} = 6.8$ Hz, *i*Pr–CH), 6.29–7.70 (m, 27H, Ar–H). ^{31}P NMR (200 MHz, C_6D_6): $\delta = 23.8$ ppm. IR: $\nu = 1598$ cm^{-1} (C=N).

2.4.2. {Phenyl)(triphenylphosphine)(2-[(2,6-diisopropylphenylimino)ethyl]naphthoxy)}-nickel(II) (*8*)

The sodium salt of the ligand (Na-**5**) and the corresponding complex were prepared following the same procedure used above (Section 2.4.1). The product was purified by recrystallization from 1:5 benzene/*n*-pentane solvent mixture at −20 °C and collected as orange crystals. Isolated yield: 39%. *Anal*. Calc. for $C_{48}H_{46}NNiOP$: C, 77.63; H, 6.24; N, 1.89. Found: C, 77.64; H, 5.90; N, 1.54%. ^{1}H NMR (200 MHz, C_6D_6): $\delta = 1.10$ (d, 6H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH_3), 1.24 (d, 6H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH_3), 1.97 (s, 3H, N=CCH_3), 3.89 (sept, 2H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH), 6.25–7.69 (m, 29H, Ar–H). ^{13}C NMR (50 MHz, $CDCl_3$): $\delta = 23.6$, 24.7, 25.1, 29.4, 114.2, 116.7, 121.8, 124.0, 124.5, 125.8, 126.4, 127.1, 127.3, 127.8, 128.3, 128.5, 128.7, 130.2, 131.7, 131.9, 132.2, 135.0, 135.1, 137.4, 138.7, 140.8, 147.9, 164.2, 169.5 ppm. ^{31}P NMR (200 MHz, C_6D_6): $\delta = 24.3$ ppm. IR: $\nu = 1597$ cm^{-1} (C=N).

2.4.3. Bis[{2-(2,6-diisopropylphenylimino)(phenyl)methyl}phenoxy]nickel(II) (*9*)

The sodium salt of the ligand **6** was prepared as described above (Section 2.4.1). A solution of Na-**6** (0.53 g, 1.40 mmol) in benzene (30 ml) was added to a suspension of *trans*-[$(PPh_3)_2$Ni((Ph)Cl] (0.88 g, 1.27 mmol) in the same solvent (20 ml). The reaction took soon a deep red color and was stirred at room temperature for 6 h and then filtered. After concentrating the filtrate to ca. 3 ml, the product was precipitated upon addition of *n*-pentane (30 ml). The solid was isolated by cannula filtration then washed with *n*-pentane and dried. The isolated product was crystallized from toluene/*n*-hexane 1:5 mixture to give orange crystals suitable for X-ray structure analysis. Isolated yield was 32%. ^{1}H NMR (200 MHz, C_6D_6): $\delta = 1.24$ (d, 12H, $^3J_{HH} = 6.6$ Hz, *i*Pr–CH_3), 2.13 (d, 12H, $^3J_{HH} = 6.6$ Hz, *i*Pr–CH_3), 3.87 (sept, 4H, $^3J_{HH} = 6.6$ Hz, *i*Pr–CH), 5.68 (m, 2H, H–Ar), 6.11 (m, 2H, H–Ar), 6.56–7.20 (m, 10H, H–Ar) ppm. IR: $\nu = 1599$ cm^{-1} (C=N).

2.4.4. Bis[(2-(2,6-diisopropylphenylimino)ethyl)phenoxy]nickel(II) (*10*)

The compound was prepared as described in Section 2.4.3. Crystals suitable for single crystal X-ray analysis were formed upon recrystallization from benzene/*n*-pentane (1:5) solvent mixture. ^{1}H NMR (200 MHz, C_6D_6): $\delta = 1.13$ (d, 12H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH_3), 1.73 (m, 18H, *i*Pr–CH_3, N=CCH_3), 4.08 (sept, 4H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH), 5.77 (m, 2H, Ar–H), 6.33 (m, 2H, Ar–H), 6.83–7.25 (m, 10H, Ar–H) ppm. MS(EI): 647 (M^+), 358 ($M^+ - (N \cap O)$). IR: $\nu = 1602$ cm^{-1} (C=N).

2.4.5. Bis[(2-(2,6-diisopropylphenylimino)ethyl)naphtoxy]nickel(II) (*11*)

A solution of Na-**5** (0.52 g, 1.42 mmol) in benzene (30 ml) was added to a suspension of *trans*-[$(PPh_3)_2$Ni((Ph)Cl] (0.88 g, 1.27 mmol) in the same solvent (20 ml). The reaction took soon a deep red color and was stirred at room temperature for 6 h, after which it was treated as in Section 2.4.3. Yield 86%. *Anal.* Calc. for $C_{48}H_{52}N_2O_2Ni$: C, 77.11; H, 7.01; N, 3.74. Found: C, 75.02; H, 6.93; N, 3.65%. ^{1}H NMR (200 MHz, C_6D_6): $\delta = 1.13$ (d, 12H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH_3), 1.39 (d, 12H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH_3), 1.72 (s, 3H, N=CCH_3), 4.60 (sept, 2H, $^3J_{HH} = 7.0$ Hz, *i*Pr–CH), 6.14 (m, 2H, H–Ar), 6.76–7.46 (m, 16H, H–Ar) ppm. MS(AP-MALDI): 746 (M^+). IR: $\nu = 1591$ cm^{-1} (C=N).

2.5. X-ray crystal structure determination for the complexes 7–*10*

Single crystals of the compounds were selected for the X-ray measurements and mounted on the glass fibre using the oil drop method [15a]. Data were collected at 120(2) (**7**, **10**) and 173(2) (**8**, **9**) K using Nonius KappaCCD diffractometer. The intensity data were corrected for Lorentz and polarization [15b] effects and for absorption by multi-scan method [16]. The structures were solved by direct methods (SHELXS 97). The refinements and graphics were done using SHELXL 97 and SHELXTL/PC program package, respectively. All non-hydrogen atoms were refined anisotropically. The H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. The cell parameters and the specific data collections parameters are summarized in Table 1.

3. Results and discussion

3.1. Ligand and complex synthesis

The synthesis of the ligands (**4**–**6**) and their nickel complexes (**7**–**11**) are shown in Scheme 1. Preparation of the desired salicylketimines turned out to proceed with

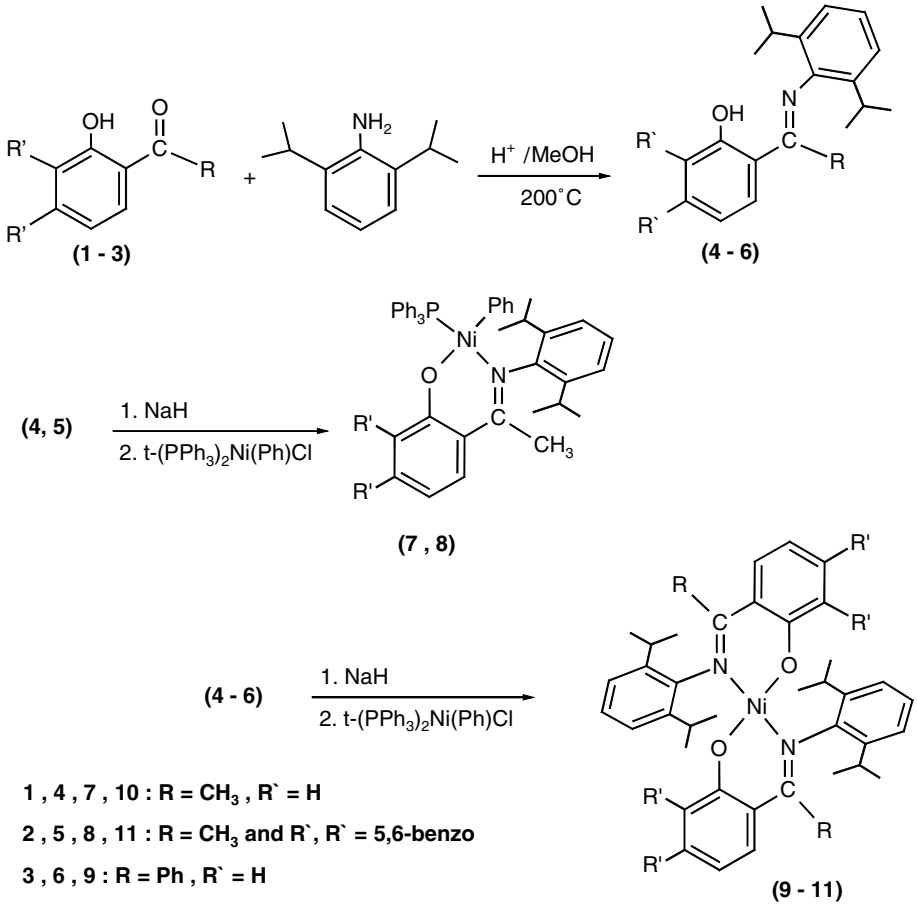
negligible yields, even with extended refluxing periods. Therefore, ligands **4**, **5** and **6** were prepared in methanol at 200 °C in a closed steel autoclave in the presence of Na_2SO_4 and a catalytic amount of formic acid. After purification by column chromatography, ligands **4** and **5** were isolated with nearly 50% yields, but with only 6% yield for ligand **6**. After deprotonation of the ligands with an excess of NaH in THF, the corresponding sodium salts were allowed to react with *trans*-[$(PPh_3)_2$-Ni((Ph)Cl], either by addition of the reaction solvent (benzene) to a solid mixture of the two reactants at low temperature or by addition of a solution of the corresponding sodium salt to a suspension of the nickel precursor. The former method favours the formation of monophenyl-nickel(II) complexes **7** and **8**, while the latter method leads to the formation of the bis(sal)Ni(II) complexes **9**–**11**.

^{1}H NMR spectra of the ligands are similar to those of the corresponding salicylaldimines [8], except for a singlet (**4** and **5**) which appears at 2.19–2.28 ppm that can be attributed to the ketimine methyl group. Upon complexation, this singlet is shifted upfield to 1.83–1.97 ppm. The septet which is due to CH protons of the isopropyl groups is shifted down field (from that in the spectra of ligands **4** and **5** (2.78 and 2.89 ppm)) to 3.84–3.89 ppm as observed for **7** and **8**. In the case of the bis(sal) complexes, this septet is further shifted to 3.87, 4.08 and 4.60 ppm for **9**, **10** and **11**, respectively. The signals of the triphenylphosphine ligand in the ^{31}P NMR spectra of complexes **7** and **8** are observed at 23.8–24.3 ppm. The IR spectra of **4**, **5** and **6** show bands at 1608, 1596 and 1605 cm^{-1}, respectively, which are ascribed to C=N group. After complexation, these bands are correspondingly found at 1598 and 1597 cm^{-1} for the monophenyl complexes (**7** and **8**) and 1599, 1602 and 1591 cm^{-1} for the bis(sal)-Ni(II) complexes (**9**–**11**), respectively. The IR spectra of all the studied complexes are in good agreement with previous reports of analogous compounds [9].

The reaction of Na-**5** with *trans*-[$(PPh_3)_2$Ni((Ph)Cl] was monitored by ^{1}H NMR. When benzene was added to a solid mixture of the reacting materials, only the monophenyl complex **8** was detected. This complex was purified by recrystallization from 1:5 benzene/*n*-pentane solvent mixture at −20 °C which gave orange crystals. However, when a slight excess of a solution of the sodium salt of **5** in benzene was added to a suspension of nickel precursor at ambient temperature, the bis(sal)-Ni(II) complex **11** was obtained as a major product and only a trace amount of **8** was observed in ^{1}H NMR. Ligand **4** behaved similarly upon complexation, both the monophenyl complex (**7**) and the bis(sal)Ni(II) (**10**) could be isolated.

In its isolated form complex **8** was found to be quite stable in solution at room temperature. According to ^{1}H NMR, no decomposition or transformation to the corresponding bis(sal)–Ni(II) species was detected even after 8 h room temperature and after 50 h the molar ratio of **11**:**8** was found to be 1:15. In the case of the



Scheme 1. Synthesis of ligands (**4**–**6**) and complexes (**7**–**11**).

salicylaldimines, the formation of bis(sal)Ni(II) complexes usually require more harsh reaction conditions [17]. In order to form the desired bis(sal)Ni(II) complex [17b], the neutral phenyl substituted salicylaldiminato Ni(II) complex had to be stirred at 50 °C first with vinyl chloride (VC) for four days in toluene and then to continue stirring for another four days in *n*-hexane at 50 °C. The complexation occurred via tetrahedral Ni complex bearing a Cl instead of the Ph ligand, where Cl–Ni bond was formed by 1,2-insertion of VC into Ni–Ph bond followed by β-Cl elimination.

With the salicylketimine ligands, the formation of the bis(sal) complexes can take place spontaneously. Moreover, in the reaction of Na-**6** with *trans*-[$(PPh_3)_2$-Ni((Ph)Cl], the bis(sal)Ni(II) complex (**11**) was the predominant product. It seems that the presence of the phenyl group on the ketimine carbon of the ligand increased the tendency to form a bis(sal) complex. The reason for this particular behaviour remains unclear but it could be due to *trans* influence of the ketimine site, thus allowing a faster dissociation of the second PPh_3 ligand. So, in addition to fine tuning of the reaction conditions, also different substituents on the ketimine carbon may affect on the complexation behaviour of these salicylketimine ligands.

Surprisingly, the monophenyl salicylketiminato based Ni(II) complexes **7** and **8** turned out to be catalytically inactive in homopolymerization of ethene or norbornene when [$Ni(COD)_2$] or BF_3 were applied as phosphine scavengers, even at elevated temperatures (up to 60 °C) and pressures (up to 40 bar).

3.2. Crystal structures of the complexes

For further investigation of structural features of the complexes, crystals of complexes **7** and **8**, suitable for X-ray structure determination, were grown from 1:5 benzene/*n*-pentane mixture at −20 °C and crystals of complexes **9** and **10** were obtained at ambient temperature. The coordination sphere of complex **8** was found to be similar to that of **7**. Also, the coordination spheres of bis(sal)Ni(II) complexes **9** and **10** were found to be alike. Data collection and the refinement of data of **7**–**10** (Figs. 1–4) are summarized in Table 1. [1]

In the solid state, complex **7** has a square-planar geometry. The Ni atom is approximately 0.01 Å out of the

[1] The molecular structure of **11** was also determined. It was found similar to that of **10** and is thus left from discussion here but the data is included in the supplementary material.

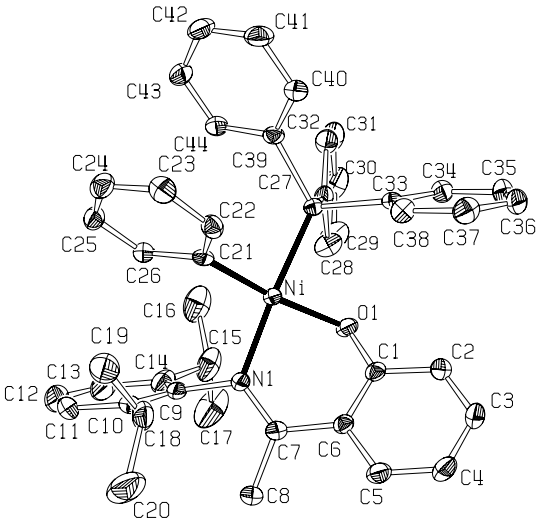


Fig. 1. ORTEP plot of the molecular structure of compound **7**. Displacement ellipsoids are drawn at 50% probability level.

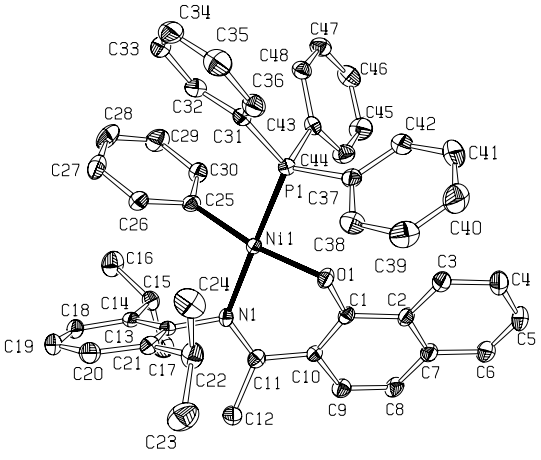

Fig. 2. ORTEP plot of the molecular structure of compound **8**. Displacement ellipsoids are drawn at 50% probability level.

plane of the donor atoms. The bulky 2,6-diisopropylphenylimine occupies the *trans* position to the triphenylphosphine ligand with almost a linear N1–Ni–P1 angle (172.17(5)°) (Table 2). The phenyl group attached to Ni lies in *trans* position to O1 with an O1–Ni–C21 angle of 171.73(7)°. The Ni–O1, Ni–N1 and Ni–C21 bond distances in complex **7** are similar to those for known nickel complexes [18].

The Ni–P1 bond distance (2.185(1) Å) is only a bit longer than those in Grubbs' nickel-based complex (2.172(2) Å) and in Cavell's [Ni(PPh_3)(*o*-tolyl)(N–O)] complexes with N–O bidentate pyridinecarboxylate ligands (*d*(Ni–P) 2.1653(2) Å) [18d]. But, it is clearly shorter than that in nickel(II) salicylaldiminato complexes bearing naphthyl instead of phenyl group *cis* to PPh_3 (2.200(1) and 2.198(2) Å) [9].

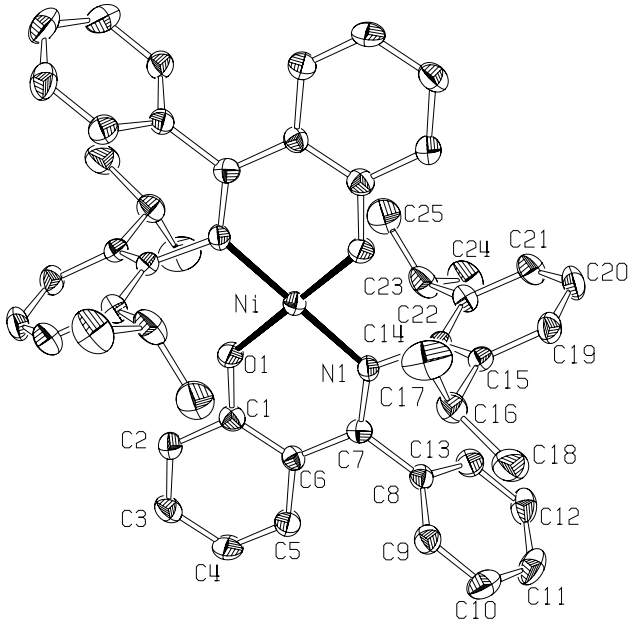

Fig. 3. ORTEP plot of the molecular structure of compound **9**. Displacement ellipsoids are drawn at 50% probability level.

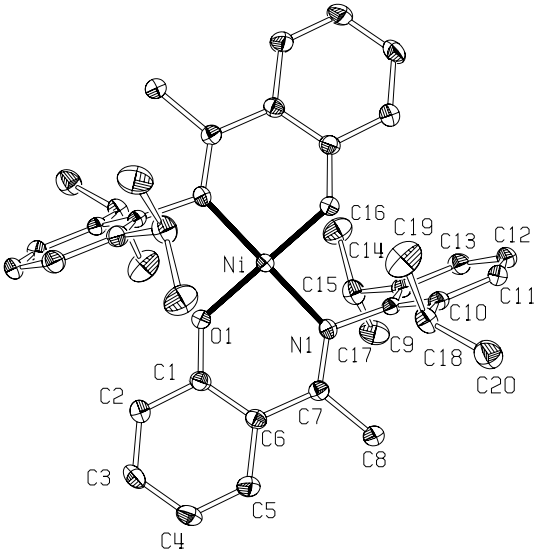

Fig. 4. ORTEP plot of the molecular structure of compound **10**. Displacement ellipsoids are drawn at 50% probability level.

Complex **9** forms a square planar complex, at which nickel lays in the symmetry centre of the molecule and thus in the plane of the four donor atoms (Table 1, Fig. 3). The bond angles and distances are similar to those found for **10** (Table 1, Fig. 4), where the average Ni–O distance (1.808 Å) is somewhat shorter, and the Ni–N distance (1.926) is somewhat longer than those in the bis(salicylaldiminato) complexes which were reported by Jordan and co-workers (Ni–O 1.846 Å, Ni–N 1.899 Å) [17b] and Knoch et al. (1.856, 1.899 Å) [17a].

4. Conclusions

A method for the synthesis of salicylketimine ligands was developed by condensation of a ketone with an amine in methanol at 200 °C in a closed steel-autoclave. The complexation behaviour of these ligands towards *trans*-[$(PPh_3)_2$Ni((Ph)Cl] was investigated. Two types of Ni(II) complexes could be isolated and characterized, the monophenyl(salicylketimine)Ni(II) complexes and the corresponding bis(salicylketimine) Ni(II) complexes. It was found that salicylketimine ligands form readily the bis(sal)Ni(II) complexes.

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC 230868 (**7**), CCDC 230869 (**8**), CCDC 230871 (**9**), CCDC 230870 (**10**) and CCDC 230872 (**11**). Abstract

The reactions of polymeric complex $[Ru(CO)_2Cl_2]_n$ with triphenyl phosphine chalcogenide ligands Ph_3PX; X = O(**a**), S(**b**), Se(**c**) in 1:1 (Ru:L ratio) molar ratio gives five-coordinate complexes of the type $[Ru(CO)_2Cl_2(Ph_3PX)]$(**1a**–**c**) while 1:2 (Ru:2L ratio) molar ratio produces six-coordinate $[Ru(CO)_2Cl_2(Ph_3PX)_2]$(**2a**–**c**) complexes. The complexes **1a**–**c** and **2a**–**c** exhibit two equally intense ν(CO) bands in the range 2059–1989 and 2050–1980 cm^{-1}, respectively, indicating *cis*-disposition of the two terminal carbonyl groups. The values of ν(CO) frequencies irrespective of the complexes, in general, follow the order: $Ph_3PO > Ph_3PS > Ph_3PSe$ which may be ascribed in terms of "Soft–Hard" (Ru(II)–O) and "Soft–Soft" (Ru(II)–S/Se) interactions. The ν(PX) bands of the complexes observed in the range 1173–538 cm^{-1} are 19–41 cm^{-1} lower than those of the corresponding free ligands indicating the formation of Ru–X bonds. The molecular structure of the complex $[Ru(CO)_2Cl_2(Ph_3PS)_2]$ was determined by single X-ray crystallography. The crystal is monoclinic, space group Cc; $a = 11.4990$ Å, $b = 17.3966$ Å, $c = 18.4788$ Å; $\alpha = 90°$, $\beta = 98.160°$, $\gamma = 90°$. In the molecule, the Ru(II) atom occupies the center of a slightly distorted octahedral geometry which consists of two *trans*-S atoms of two Ph_3PS ligands, two *cis*-CO groups and two *cis*-chlorides. The complexes have also been characterized by elemental analysis, ^1H, ^{13}C and ^{31}P NMR spectroscopy.

Keywords: Ruthenium(II) carbonyl complexes; Tertiary phosphine chalcogenides; "Soft–Hard" and "Soft–Soft" interactions; X-ray crystal structure; Octahedral structure

1. Introduction

The chemistry of rhodium and ruthenium metal complexes of unsymmetrical chelating phosphines functionalized with chalcogen donors like $Ph_2P(CH_2)_nP(X)Ph_2$ ($n = 1$–4, X = O, S, Se), $Ph_2PC_6H_4COOMe$, $Ph_2P(CH_2)_nOR$ (R = CH_3, C_2H_5) has gained much importance because of their structural novelty, reactivity and catalytic applications [1–7]. In contrast, monodentate tertiary phosphines functionalized with chalcogen donors such as Ph_3PX (X = O, S, Se) received less attention although the chemistry of such ligands is potentially important and well established. There are reports of some complexes with platinum metals [8–15], but to the best of our knowledge, only a few reports [16–21] are there on ruthenium(II) complexes. This prompted us to synthesize, characterize and to study coordination chemistry of ruthenium(II) carbonyl complexes with these chalcogen donors ligands.

In the present communication, we report the synthesis, spectroscopic characterization and structural investigation of some ruthenium(II) carbonyl complexes derived from the reaction of $[Ru(CO)_2Cl_2]_n$ with Ph_3PX; X = O, S, Se and the effect of "Soft–Hard" and "Soft–Soft" nature of the chalcogenide ligands on ν(CO) frequency is discussed. In order to the determine detailed geometry, an X-ray diffraction study was undertaken for one of the sulfide complexes.

2. Experimental

2.1. General methods

All the solvents used were distilled under nitrogen prior to use. Carbon and hydrogen analyses were done on a Perkin–Elmer 2400 elemental analyzer. Chloride analyses were performed by standard analytical method [22]. FT-IR spectra of range 4000–400 and 400–200 cm^{-1} were recorded using Perkin–Elmer 2000 and Perkin–Elmer 883 spectrophotometer, respectively, in KBr disc. NMR data were recorded on a Bruker DPX 300 MHz spectrometer and the ^1H and ^{31}P NMR chemical shifts were quoted relative to $SiMe_4$ and 85% H_3PO_4 as internal and external standard, respectively, using $CDCl_3$ and d_6-acetone as solvent. Melting points were determined with a BUCHI B-540 apparatus. $RuCl_3 \cdot 3H_2O$ was purchased from M/s Arrora Matthey Ltd., Kolkata, India. Analytically pure Ph_3P and elemental sulfur, selenium were purchased from M/S Aldrich, USA and used without further purification. The ligands, Ph_3PX, X = O, S, Se were prepared by the literature method [23–25]. The starting complex $[Ru(CO)_2Cl_2]_n$ was prepared by passing CO through a refluxing solution of $RuCl_3 \cdot 3H_2O$ in ethanol for about 24 h [26–29].

2.2. Synthesis of metal complexes

2.2.1. $[Ru(CO)_2Cl_2(Ph_3PX)]$ (**1a**–**c**), X = O, S, Se

0.044 mmol of $[Ru(CO)_2Cl_2]_n$ was dissolved in 10 cm^3 methanol and to this 0.044 mmol of corresponding ligands **a**–**c** in 10 cm^3 dichloromethane was added. The reaction mixture was stirred at room temperature for about 2 h and the solvent was evaporated under vacuum. The solid compound so obtained was washed with diethyl ether and recrystallized from dichloromethane solution.

2.2.2. $[Ru(CO)_2Cl_2(Ph_3PX)_2]$(**2a**–**c**), X = O, S, Se

0.044 mmol of $[Ru(CO)_2Cl_2]_n$ was dissolved in methanol (10 cm^3) and to this 0.088 mmol of corresponding ligands **a**–**c** in 10 cm^3 dichloromethane was added. The reaction mixture was stirred at room temperature for about 2.5 h and the solvent was evaporated under reduced pressure to generate a solid compound which was washed with diethyl ether and finally recrystallized from dichloromethane solution.

Analytical data and physical properties of the complexes are shown in Table 1.

2.3. X-ray crystallography

A crystal of the complex **2b** suitable for X-ray crystallographic analysis was developed from a CH_2Cl_2-hexane solution. Data collection was performed using a Bruker SMART diffractometer, full sphere of data with

0.3° slices, room temperature, Mo Kα radiation and empirical absorption corrections. All non-hydrogen atoms were refined anisotropically with the hydrogen atoms being refined in idealized geometries. The structure refinements were done by full matrix least square on F^2 using SHELXTL97 computer program [30]. The crystal data and structure refinement for the complex are listed in Table 2.

3. Results and discussion

Reaction of polymeric $[Ru(CO)_2Cl_2]_n$ with one molar equivalent (Ru:L = 1:1) of the ligands (**a**–**c**) affords five-coordinate 16 electron species of the type $[Ru(CO)_2Cl_2(Ph_3PX)]$(**1a**–**c**) (Scheme 1) where X = O, S, Se. The IR spectra (Table 3) of the complexes show two equally intense *ν*(CO) bands in the range 1980–2060 cm^{-1} attributing *cis*-disposition of the two terminal carbonyl groups [31,32]. The positions of the *ν*(CO) bands lie in the sequence $Ph_3PO > Ph_3PS > Ph_3PSe$. The reason of variation in *ν*(CO) frequency may be explained in terms of "Soft–Hard" and "Soft–Soft" interactions between the metal atom and the chalcogen donors. S and Se donors being "Soft" in complexes **1b** and **1c**, they interact strongly with "Soft" ruthenium(II), in contrast to the "Hard" oxygen in the complex **1a**. Because of the "Soft–Soft" interaction, the electron density increases on the central metal atom which leads to donate more d_π-electrons to the antibonding π^* orbital of the CO [7,32] and consequently reduces the C–O bond order, which in turn lowers the *ν*(CO) frequency. The *ν*(PX) (X = O, S, Se) bands in the complexes **1a**–**c** occur at 1173, 590, 538 cm^{-1}which are 27, 41, 20 cm^{-1} lower than their corresponding free ligands indicating the formation of bonds Ru–O, Ru–S and Ru–Se, respectively [9]. The *cis*-disposition of the two chlorides in the complexes is corroborated by the presence of two *ν*(RuCl) bands in the range 246–330 cm^{-1} [29]. The ^1H NMR spectra of the complexes show a set of multiplets in the *δ*7.26–7.85 ppm range assigned to the phenyl groups of triphenyl chalcogenide ligands. No appreciable shift is observed between coordinated and free ligand proton environment as the protons are remote from the coordinating chalcogen atom. The ^{31}P {H} NMR spectra of the complexes **1a**–**c** (Table 3) exhibit singlet resonance at *δ* 43.88, 48.24, 32.43 ppm, respectively, while their corresponding free ligand values occur at *δ* 30.37, 44.54, 36.53 ppm. Compared to the free ligands, the phosphorus atoms of the complexes show a small down field shift (3.70–13.51 ppm) because the phosphorus atoms are already attached with the chalcogen donor in the ligands. ^{13}C NMR data of the complexes **1a**–**c** are given in Table 3. The principal interest is on the carbonyl carbon and the ^{13}C NMR values are found to be a singlet at 182, 184, 186 ppm of the complexes **1a**–**c** respectively. Similar to the complex $[RuCl_2(PPh_3)_3]$ [33], these 16-electron complexes are assumed to show no steric barrier for H-coordination of a phenyl ring to block the 6th coordination site and the probable structure of the complexes are shown in Fig 1(a), although we could not develop suitable crystal for X-ray study.

Reaction of **1a**–**c** with one molar equivalent of ligands **a**–**c** yields six-coordinate 18 electron species of the type $[Ru(CO)_2Cl_2(Ph_3PX)_2]$(**2a**–**c**) (Scheme 1); X = O, S,

[a] Free Ph_3PO, 1200 cm^{-1}; Ph_3PS, 631cm^{-1}; Ph_3PSe, 558 cm^{-1}.
[b] Free Ph_3PO, 30.37 ppm; Ph_3PS, 44.54 ppm; Ph_3PSe, 36.53 ppm.

Se. The complexes **2a**–**c** can also be synthesized directly by reacting $[Ru(CO)_2Cl_2]_n$ with ligands **a**–**c** in 1:2 molar ratio. As in the complexes **1a**–**c**, the position and nature of ν(CO) and ν(RuCl) IR bands (Table 3) are in agreement with the mutual *cis*-disposition of the terminal carbonyl groups and the two chlorides. Similar to the complexes **1a**–**c**, the ν(PX) (X = O, S, Se) bands in complexes **2a**–**c** also show considerable lower values (19–40 cm^{-1}) suggesting coordination via chalcogen donor sites. The ^{31}P {H } NMR spectra of **2a**–**c** also show one singlet resonance showing a small shift in the range 3.67–13.50 ppm. The ^{13}C NMR spectra (Table 3) of the complexes show characteristics signals for carbonyl and phenyl carbon atoms. Thus on the basis of IR and NMR data, Fig. 1(b) is the most probable structure of the complexes **2a**–**c**.

In order to confirm the structures and to determine the detailed geometry, we tried to grow crystals of the complexes. A good crystal suitable for X-ray structural determination was obtained for the complex **2b**. IR and NMR data are well agreed with this molecular structure of the complex. The arrangements and numbering of the atoms in the crystal are shown in Fig. 2 and the important bond lengths and bond angles are given in Table 4. In the molecule, the ruthenium atom has a slightly distorted octahedral coordination with two Ph_3PS ligands occupying two *trans*-octahedral sites via two sulfur atoms, two *cis* CO groups and two *cis*-chlorides. This atomic arrangement is sterically less hindered and is apparently preferred because both the bonded sulfur atoms of the ligands are *trans* to each other. The bond lengths Ru–Cl "2.432, 2.449 Å", Ru–CO "1.836, 1.865 Å" and Ru–S "2.414, 2.426 Å" are closely similar to those observed previously in $[Ru(CO)_2(BzIPPh_2)Cl_2]$ (Ru–Cl, "2.428, 2.430 Å"; Ru–CO, "1.858, 1.869Å") [34] and $[\eta^6$-$MeC_6H_4Pr^iRu\{\eta^3$-$(SPPh_2)_2CMe$–C,S,S′}]PF_6 (Ru–S, "2.421, 2.449 Å") [35]. The basal Ru–Cl(2) and Ru–C(38) bond lengths are 2.449 and 1.865 Å while their corresponding apical bonds Ru–Cl(1) and Ru–C(37) are little shorter (2.432 and 1.836 Å, respectively). This shortening of the apical bonds may be due to a steric effect [34]. The bond angles for C(37)–Ru–Cl(1), C(38)–Ru–Cl(2) and S(2)–Ru–S(1) are 177.7°, 179° and 163.32°, respectively.

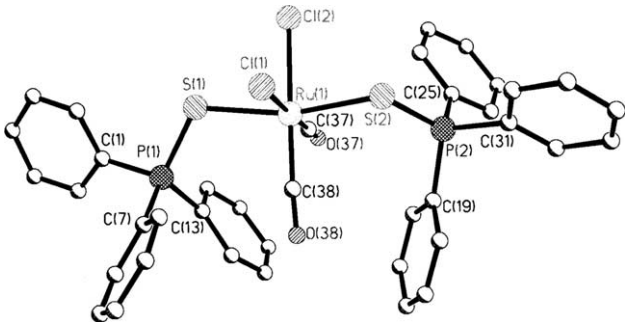

Fig. 2. Molecular structure of $[Ru(CO)_2Cl_2(PPh_3S)_2]$ (**2b**).

Table 4
Selected bond lengths (Å) and bond angles (°) of the complex **2b**

Bond lengths	
Ru–C(37)	1.836(13)
Ru–C(38)	1.865(14)
Ru–S(2)	2.414(3)
Ru–S(1)	2.426(3)
Ru–Cl(1)	2.432(4)
Ru–Cl(2)	2.449(3)
Bond angles	
C(37)–Ru–C(38)	93.2(5)
C(37)–Ru–S(2)	100.5(4)
C(38)– Ru–S(2)	91.2(3)
C(37)– Ru–S(1)	92.0(4)
C(38)–Ru–S(1)	99.2(3)
S(2)–Ru–S(1)	163.32(10)
C(37)–Ru–Cl(1)	177.7(4)
C(38)–Ru–Cl(1)	89.0(4)
S(2)–Ru–Cl(1)	80.17(11)
S(1)–Ru–Cl(1)	86.96(12)
C(37)–Ru–Cl(2)	86.5(4)
C(38)–Ru–Cl(2)	179.0(4)
S(2)–Ru–Cl(2)	87.92(11)
S(1)–Ru–Cl(2)	81.76(10)
Cl(1)–Ru–Cl(2)	91.26(13)

The large deviation from 180° for S(2)–Ru–S(1) is probably due to steric requirement to get a stable structure [36], where the uncoordinated phenyl rings are oriented away from the plane containing chlorides, CO groups and the metal centre. The angles C(37)–Ru–C(38), C(37)–Ru–S(2), C(38)–Ru–S(2), C(37)–Ru–S(1), C(38)–Ru–S(1), C(38)–Ru–Cl(1), S(2)–Ru–Cl(1), S(1)–Ru–Cl(1), C(37)–Ru–Cl(2), S(2)–Ru–Cl(2), S(1)–Ru–Cl(2) and Cl(1)–Ru–Cl(2) exhibit different values in the range 80.17°–100.5° with the deviation from 90° (Table 4). This indicates that there may be significant inter and intra atomic interactions amongst the bonding atoms and with the bulky phenyl rings which cause such deviations.

Abstract

Reactions of singly-bonded dimolybdenum complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(CO)_6]$ (**I**, R = CH_3CO; **II**, R = C_6H_5CO; **III**, R = CH_3O_2C; **IV**, R = $C_2H_5O_2C$) with diphenylditelluride in the presence of $^nBu_4NI$ were investigated. Although complex **I** reacted with diphenylditelluride in refluxing xylene to give both mononuclear complex **1** $[(\eta^5\text{-}C_5H_5)Mo(CO)_3Te]$ and dinuclear complex **2** *cis*/ae-$[(\eta^5\text{-}CH_3COC_5H_4)_2Mo_2(\mu\text{-}Te)_2(\mu\text{-}TePh)_2]$, reactions of complexes **II**, **III** and **IV** with diphenylditelluride under the same conditions only afforded dinuclear complexes *cis*/ae-$[(\eta^5\text{-}RCC_5H_4)_2Mo_2(\mu\text{-}Te)_2(\mu\text{-}TePh)_2]$ (**3**, R = C_6H_5CO; **4**, R = CH_3O_2C; **5**, R = $C_2H_5O_2C$). All the new complexes have been characterized by elemental analyses, ^1H NMR, ^{13}C NMR and IR spectroscopies. Crystal structures of complexes **1** and **5** have been determined by X-ray diffraction analyses.

1. Introduction

The chemistry of transition metal complexes containing both Group 6 metals and chalcogenido ligands has been extensively studied not only because of their importance to biology and catalysis [1,2], but also because of their novel structures and widespread use for the synthesis of organometallic compounds, and particularly organometallic clusters, during the last two decades [3–5]. However, considerably less is known about the complex chemistry of the tellurium [6]. Recently, the author has found that triply-bonded dimolybdenum complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(CO)_4]$ ($\eta^5\text{-}RC_5H_4$ = parent and substituted cyclopentadienyls) and excess diphenylditelluride in the presence of Cp_2TiX_2 (X = Cl, Br) form novel quadruply-bridged complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(\mu\text{-}X)(\mu\text{-}TePh)_3]$ [7,8]. To further extend this methodology, I have investigated the reaction of singly-bonded dimolybdenum complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(CO)_6]$ (**I**, R = CH_3CO; **II**, R = C_6H_5CO; **III**, R = CH_3O_2C; **IV**, R = $C_2H_5O_2C$) with diphenylditelluride in the presence of $^nBu_4NI$. Interestingly, unexpectedly this reaction affords a terminal tellurido organomolybdenum complex **1** $[(\eta^5\text{-}C_5H_5)Mo(CO)_3Te]$ and quadruply-bridged dimolybdenum complexes **2**–**5** *cis*/ae-$[(\eta^5\text{-}RC_5H_4)_2Mo_2(\mu\text{-}Te)_2(\mu\text{-}TePh)_2]$. To my knowledge, these complexes are the unprecedented examples [9–12], herein I wish to report on such an unexpected reaction.

2. Experimental

All reactions were carried out under purified dinitrogen atmosphere using standard Schlenk techniques. Xylene was distilled from Na/benzophenone under

doi:10.1016/j.poly.2004.03.015

dinitrogen atmosphere. Singly-bonded dimolybdenum complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(CO)_6]$ (**I**, R = CH_3CO; **II**, R = C_6H_5CO; **III**, R = CH_3O_2C; **IV**, R = $C_2H_5O_2C$) and Ph_2Te_2 were prepared according to the literature methods [13,14]. Progress of the reactions was monitored periodically by TLC. The products were separated by preparative TLC (silica gel H, 10–40 μm) and further recrystallized from deoxygenated solvents (CH_2Cl_2/petroleum ether). NMR spectra were determined on a Bruker Avance 300 spectrometer using TMS as an external standard in $CDCl_3$. IR spectra were recorded on a Perkin–Elmer 402 as KBr disks in the range of 400–4000 cm^{-1}. Analyses for C and H were performed on an Elementa Vario EL III instrument. Melting points were measured on a Yanagimoto apparatus.

2.1. Syntheses of complexes *1* and *2*

A 100 ml Schlenk flask fitted with a magnetic stir-bar, a rubber septum and a reflux condenser topped with a nitrogen inlet tube was charged with 0.574 g (1 mmol) of complex **I** $[(\eta^5\text{-}CH_3COC_5H_4)_2Mo_2(CO)_6]$ and 0.819 g (2 mmol) of Ph_2Te_2 in 40 ml of xylene. The mixture was stirred at 110 °C for 1 h, then 0.739 g (2 mmol) of $^nBu_4NI$ was added and further refluxed for 4 h. The resulting brown mixture was evaporated to dryness under vacuum, the residue obtained thus was subjected to preparative TLC using CH_2Cl_2 as an eluant. The first main band afforded 0.173 g (23.2%) of complex **1** as a brown solid; m.p. 110–113 °C. *Anal.* Calc. for $C_8H_5MoO_3Te$: C, 25.78; H, 1.35. Found: C, 25.80; H, 1.56%. IR (KBr disk): terminal carbonyl 2036.38 (vs), 1962.42 (vs, sh), 1939.75 (vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 5.615 (s, 5H, C_5H_5). ^{13}C NMR (300MHz, $CDCl_3$): δ 236.030, 219.876 (CO); 93.889 (C_5H_5). The second main band gave 0.487 g (45.5%) of complex **2** as a brown solid; m.p. 148 °C. *Anal.* Found: C, 29.31; H, 2.24. Calc. for $C_{26}H_{24}Mo_2O_2Te_4$: C, 29.17; H, 2.26%. IR (KBr disk): acetyl carbonyl 1659.21 (vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.024–7.070 (2m, 10H, $2C_6H_5$); 5.522, 5.582, 5.717, 5.911 (4s, 4× 2H, $2C_5H_4$); 2.135 (s, 6H, $2CH_3$). ^{13}C NMR ($CDCl_3$): δ 199.049 (CO); 138.292, 127.864, 127.284 (TeC_6H_5); 93.880, 92.086, 86.119, 85.579, 79.503 (C_5H_4); 26.590 (CH_3).

2.2. Synthesis of complex *3*

The similar reaction of 0.698 g (1 mmol) of complex **II** $[(\eta^5\text{-}C_6H_5COC_5H_4)_2Mo_2(CO)_6]$, 0.819 g (2 mmol) of Ph_2Te_2 and 0.739 g (2 mmol) of $^nBu_4NI$ in 40 ml of xylene furnished 0.514 g (43%) of complex **3** as a brown solid; m.p. 160 °C. *Anal.* Found: C, 36,27; H, 2.41. Calc. for $C_{36}H_{28}Mo_2O_2Te_4$: C, 36.19; H, 2.36%. IR (KBr disk): benzoyl carbonyl 1629.57 (vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 6.938–7.464 (3m, 20H, $4C_6H_5$); 5.514, 5.587, 5.911, 6.028 (4s, 4× 2H, $2C_5H_4$). ^{13}C NMR ($CDCl_3$): δ 194.844 (CO); 139.120, 138.240, 138.070, 131.187, 127.951, 127.633, 127.580, 127.244 (TeC_6H_5); 93.009, 91.736, 87.331, 85.111, 79.620 (C_5H_4).

2.3. Synthesis of complex *4*

The similar reaction of 0.610 g (1 mmol) of complex **III** $[(\eta^5\text{-}CH_3O_2CC_5H_4)_2Mo_2(CO)_6]$, 0.819 g (2 mmol) of Ph_2Te_2 and 0.739 g (2 mmol) of $^nBu_4NI$ in 40 ml of xylene furnished 0.527 g (47.8%) of complex **4** as a brown solid using CH_2Cl_2 as an eluant; m.p. 146–148 °C. *Anal.* Calc. for $C_{26}H_{24}Mo_2O_4Te_4$: C, 28.32; H, 2.19. Found: C, 28.44; H, 2.43%. IR (KBr disk): ester carbonyl 1707.19 (vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.211–7.634 (m, 10H, $2C_6H_5$); 5.699–6.084 (m, 8H, $2C_5H_4$); 3.678 (s, 6H, $2CH_3$). ^{13}C NMR ($CDCl_3$): δ 169.709 (CO); 138.447, 127.984, 127.647, 127.133 (TeC_6H_5); 91.800, 87.008, 85.837, 84.931, 79.985 (C_5H_4); 51.569 (CH_3).

2.4. Synthesis of complex *5*

The similar reaction of 0.638 g (1 mmol) of complex **IV** $[(\eta^5\text{-}C_2H_5O_2CC_5H_4)_2Mo_2(CO)_6]$, 0.819 g (2 mmol) of Ph_2Te_2 and 0.739 g (2 mmol) of $^nBu_4NI$ in 40 ml of xylene furnished 0.505 g (44.7%) of complex **5** as a brown solid using CH_2Cl_2/petroleum ether (2:1) as an eluant; m.p. 174–176 °C. *Anal.* Calc. for $C_{28}H_{28}Mo_2O_4Te_4$: C, 29.74; H, 2.50. Found: C, 29.49; H, 2.47%. IR (KBr disk): ester carbonyl 1709.26 (vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.293–7.629 (2m, 10H, $2C_6H_5$); 5.743–6.015 (3m, 8H, $2C_5H_4$); 4.163 (q, $^3J_{HH} = 6.9$ Hz, 4H, $2CH_2$); 1.201 (t, $^3J_{HH} = 6.9$ Hz, 6H, $2CH_3$). ^{13}C NMR ($CDCl_3$): δ 169.42 (CO); 138.15, 137.33, 128.73, 128.05, 126.83 (TeC_6H_5); 94.74, 89.30, 87.22, 82.15 (C_5H_4); 60.71 (CH_2); 15.28 (CH_3).

2.5. Crystal structure determination

Dark-brown single crystals for X-ray determination were obtained by slow evaporation of the solutions from $CH_2Cl_2$and petroleum ether of complexes **1** and **5** at ca. 5 °C. For each of complexes **1** and **5**, a selected single crystal was mounted on a glass fibre with epoxy resin. Measurements of diffraction intensity of single crystals of complexes **1** and **5** were carried out on an Enraf-Nonius CAD4 diffractometer. The data were collected using the $\omega - 2\theta$ scan mode. The structures were solved by direct methods and refined by full-matrix least-squares refinement with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were placed in their calculated positions, assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. All computations were carried out using the SHELEXTL PC Program Package [15]. Crystal data and details of data collection and structure refinement are summarized in Table 3.

3. Results and discussion

3.1. Syntheses of complexes 1–5

It was found that reaction of singly-bonded dimolybdenum complexes $[(\eta^5\text{-}RC_5H_4)_2Mo_2(CO)_6]$ (**I**, R = CH_3CO; **II**, R = CH_3O_2C; **III**, R = CH_3O_2C; **IV**, R = $C_2H_5O_2C$) and two molar amount of diphenylditelluride in the presence of $^nBu_4NI$ in refluxing xylene for 4 h resulted in complete disappearance of the singly-bonded material and the formation of products as shown by TLC analysis. After the solvent had been removed, the residue was subjected to preparative TLC to afford the corresponding complexes $[(\eta^5\text{-}C_5H_5)Mo(CO)_3\text{-}Te]$ (**1**) and *cis*/ae-$[(\eta^5\text{-}RC_5H_4)_2Mo_2(\mu\text{-}Te)_2(\mu\text{-}TePh)_2]$ (**2**, R = CH_3CO; **3**, R = C_6H_5CO; **4**, R = CH_3O_2C; **5**, R = $C_2H_5O_2C$) as dark brown crystalline solids in 23–48% yield. All the new complexes have been characterized by elemental analyses, ^1H NMR, ^{13}C NMR and IR spectroscopies, especially by single crystal X-ray diffraction crystallography. Therefore, the reaction undoubtedly provides a useful method for synthesizing Mo_2Te_4 core-containing complexes.

3.2. Spectroscopies of complexes 1–5

The ^1H NMR spectrum of complex **1** displays a singlet at 5.615 ppm for its cyclopentadienyl ring, its ^{13}C NMR spectrum shows the corresponding absorption at 93.889 ppm for the cyclopentadienyl ring and 219.876 and 236.030 ppm for the terminal carbonyls.

The ^1H NMR spectra of complexes **2** and **4** exhibit one singlet at 2.135 and 3.678 ppm for their methyl groups, whereas that of complex **5** displays one triplet at 1.201 ppm and one quartet at 4.163 ppm for its ethyl group ($^3J_{HH} = 6.9$ Hz). The ^1H NMR spectrum of complex **3** displays four broad singlets in the range of 5.514–6.028 ppm for the cyclopentadienyl ring and three multiplets in the range of 6.938–7.464 ppm for the benzene rings. In addition, complexes **4** and **5** show one to three multiplets in the range of 5.743–7.634 ppm for the substituted cyclopentadienyl rings and the phenyl groups, whereas complex **2** displays four singlets in the range of 5.522–5.911 ppm for the substituted cyclopentadienyl rings. ^{13}C NMR spectra of complexes **2** and **4** exhibit one absorption at 26.590 and 51.569 ppm assigned to their methyl groups, respectively, whereas that of complex **5** displays two absorptions at 15.280 and 60.710 ppm due to its ethyl group. The complexes except complex **1** show four to five absorptions in the range of 79.503–94.740 ppm for the substituted cyclopentadienyl rings and the phenyl groups in the range of 127.133–139.120 ppm. In addition, these also display the corresponding absorption for their ketonic (199.049 and 194.844 ppm) or ester carbonyls (169.709 and 169.420 ppm).

The IR spectrum of complex **1** displays three strong absorption bands at 1939.75, 1962.42 (sh) and 2036.38 cm^{-1}, while those of complexes **2**–**4** exhibit one respective absorption band in the range of 1629.57–1709.26 cm^{-1} for their ketonic or ester carbonyls.

3.3. Crystal structures of complexes 1 and 5

To determine the two types of structures mentioned above, the author carried out single crystal X-ray diffraction analyses for complexes **1** and **5**. Crystal structures

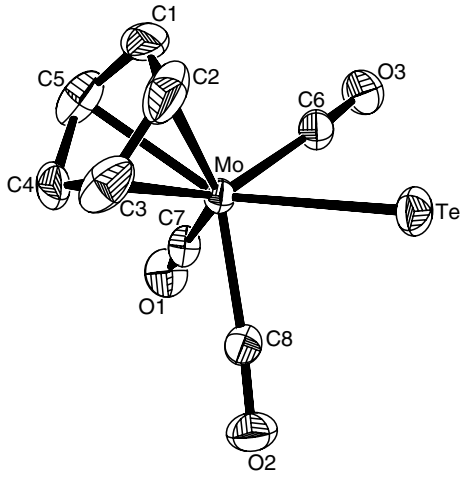

Fig. 1. Molecular structure of complex **1**. The atoms are drawn with 30% probability ellipsoids. Hydrogen atoms are omitted for clarity.

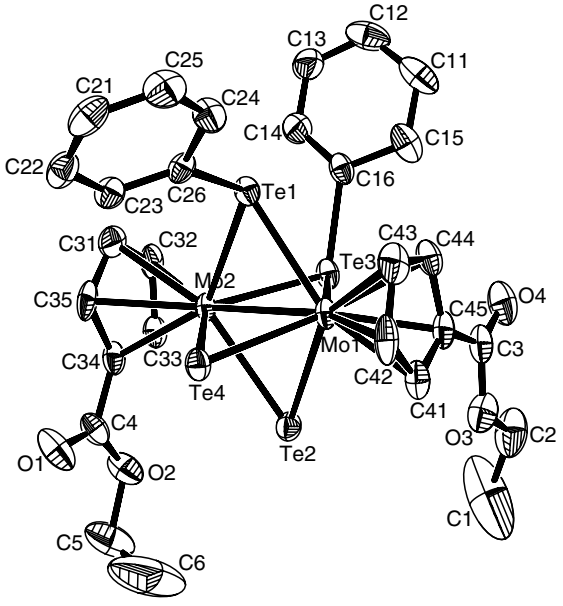

Fig. 2. Molecular structure of complex **5**. The atoms are drawn with 30% probability ellipsoids. Hydrogen atoms are omitted for clarity.

of complexes **1** and **5** are shown in Figs. 1 and 2, whereas the selected bond lengths and angles of complexes **1** and **5** are listed in Tables 1 and 2.

As seen from Fig. 1, complex **1** is monomeric and displays the commonly observed piano-stool conformation with the corresponding angles 75.8(3) (C(6)–Mo–Te), 129.2(2) (C(7)–Mo–Te), 76.0(2) (C(8)–Mo–Te), 77.3(3) (C(6)–Mo–C(7)), 112.8(3) (C(6)–Mo–C(8)) and 76.0(3)° (C(7)–Mo–C(8)). The distance of center of Cp to Mo is 1.98 Å which is close to that of $[(\eta^5\text{-}C_5H_5)Mo(CO)_3SeCH_2Ph]$ [16]. The Mo–Te bond length (2.832(1) Å) indicates an Mo–Te single bond, comparable with the corresponding bond length (2.811(2)–2.829(2) Å) in the complex $[(\eta^5\text{-}CH_3O_2CC_5H_4)_2Mo_2(CO)_4(\mu\text{-}TePh)_2]$ [8], which is also supported by the crystal structure of complex **5** (Tables 1 and 2). Against expectations, although complex **1** has a monovalent terminal telluride, it is extremely stable, it melts at 110 °C without decomposition!

Maximum peak and hole (e Å^{-3})	0.808 and −0.564	1.219 and −1.209

For convenience, the stereoisomers of $[(\eta^5\text{-}RC_5H_4)_2M_2(\mu\text{-}E)_2(\mu\text{-}E'R')_2]$ (E, E′ = S, Se, Te; M = Cr, Mo, W) may be described by the following terminologies. The *trans* and *cis* refer to the two naked E atoms or the two E′ atoms with substituents (R′) with respect to the M–M vector, *anti* and *syn* refer to the mutual orientations of the two substituents (R′) with respect to their attached planar $M_2E'_2$ ring, whereas a and e refer to the mutual orientations of the two substituents (R′) with respect to their attached butterfly $M_2E'_2$ skeleton. Accordingly, bridged complexes with the above general formula may have five isomers, viz. *trans*/*anti*, *trans*/*syn*, *cis*/aa, *cis*/ae and *cis*/ee. The X-ray analysis has revealed that complex **5** is a *cis*/ae isomer as shown in Fig. 2. The four bridged atoms in complex **5** form a plane, which is parallel to the two substituted cyclopentadienyl ring planes and bisects the Mo–Mo vector perpendicularly. The non-bonding distances between the bridged atoms are 3.248, 3.363, 3.469 and 3.566 Å. These distances fall in the range of the sum of van der waals radii of two Te atoms (4.4 Å) and indicate a weak interation between the bridging atoms [7,8]. Complex **5** is a d^2–d^2 dimer and would have a $\sigma^2\delta^2$ electronic configuration [17]. This suggests a double bond present between the two Mo(IV) atoms, which is consistent with the 18 valence-electron rule. It is worth noting that the Mo–Mo bond length of 2.731(1) Å in complex **5** is greater than that in the complex *trans*/*syn*-$[(\eta^5\text{-}C_5H_5)_2Mo_2(\mu\text{-}Se)_2(\mu\text{-}SePh)_2]$ (2.653(2) Å) [16] and very close to the Mo–Mo single bond length in $[(\eta^5\text{-}CH_3O_2CC_5H_4)_2Mo_2(\mu\text{-}Cl)(\mu\text{-}TePh)_3]$ (2.735(1)–2.756(3) Å) [8,9]. The Mo–Te bond lengths differ greatly because of the different coordination numbers of tellurium. In the case of the tellurido bridge, the values are 2.817(1) (Mo(1)–Te(2)) and 2.830(1) Å (Mo(2)–Te(2)), whereas the corresponding Mo–TePh bond lengths are 2.740(1) (Mo(1)–Te(1)) and 2.720(1) Å (Mo(2)–Te(1)). Therefore, the bonding situation is different from complexes *trans*/*syn*-$[(\eta^5\text{-}C_5H_5)_2Mo_2(\mu\text{-}Se)_2(\mu\text{-}SePh)_2]$, *trans anti*- and *trans*/*syn*-$[(\eta^5\text{-}C_2H_5O_2CC_5H_5)_2Mo_2(\mu\text{-}Se)_2(\mu\text{-}SeCH_2Ph)_2]$ in which the Mo–Se (naked) bond lengths are shorter than those of the Mo–Se (selenolato) bonds [9,11,16]. The phenyltellurolato Te atoms display almost tetrahedral bond angles (Mo(1)–Te(3)–C(16), 109.7(3)° and Mo(2)–Te(3)–C(16), 112.1(3)°), whereas the angles belonging to the Mo_2Te_4 core are acute (Mo(1)–Te(1)–Mo(2), 60.02(3)° and Mo(1)–Te(2)–Mo(2), 57.84(3)°) (Table 2). In addition, the two phenyl groups bonded to Te atoms are all bent toward the directions far away from the $C_2H_5O_2C$ substituents in order to minimize the steric repulsions between them.

4. Supplementary material

Full crystallographic data (CCDC 216750 for complex **1** and CCDC 216751 for complex **5**) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http//www.ccdc.cam.ac.uk).

Abstract

Two new one-dimensional polymeric azido- and thiocyanato-bridged cadmium (II) complexes of 1-alkyl-2-(arylazo)imidazoles [RaaiR′ (where R = H (**a**), Me (**b**); R′ = Me (**1/3/5**), Et (**2/4/6**)] are described in this work. The 1D chain structures of these complexes have been confirmed by X-ray diffraction studies of $[Cd(HaaiEt)(N_3)_2]_n$ (**4a**) and $[Cd(MeaaiEt)(SCN)_2]_n$ (**6b**). The azide (N_3^-) acts as end-on (μ-1,1; EO) and the thiocyanate (SCN^-) as end-to-end (μ-1,3; EE) double bridging agents, respectively. The π–π interactions amongst inter-chain aromatic-heterocycles generate a uniform sheet. The coordination environment of the cadmium in all these complexes is distorted octahedral. The ligand, RaaiR′, is an unsymmetric N,N′-chelator and the distortion in the octahedral geometry is mainly due to the small chelate bite angle.

1. Introduction

Supramolecular metal complexes formed by self-assembly are a frontier field in research because of their potential applications in catalyses, molecular recognition, molecular electronics and photonic materials etc. Weak forces such as hydrogen bonding, π-stacking, dipole-dipole attractions and van der Waals forces are used to assemble molecular components selectively into complex structural motifs [1–4]. For this purpose, a metal template, appropriate organic blocker and a bridging agent are necessary. The pseudohalides, especially, azide [5,6] and ambidentate thiocyanate [7] are interesting bridging agents which form a variety of networks with various transition and non-transition metals. In transition metal complexes the structural and electronic versatility of these bridgers have been used to explore magnetic materials, photo-devices, liquid crystals, catalysts and other functional materials [8–13]. However, the corresponding non-transition metal complexes are still few [14–20]. The majority of the development in the non-transition metals are with the Group 12 metals: zinc, cadmium and mercury. Because of border-line acidity, cadmium(II) prefers to bind both hard and soft donors which thus widens its scope to study crystal engineering [7,14–20].

Apparently the organic blocker has little role relative to bridging agents in the influence of physical, chemical and magnetic properties of the coordination polymer. However, subtle change in steric and electronic effects of the blocking agent significantly influence the structure, geometry and properties of the polymer [14–23]. So, choice of blocking agent is equally important with the bridging group in the network construction and thereof

the properties of the molecules. The use of different heterocyclic-N donor ligands such as pyridine, polypyridine and their substituted derivatives are well established [17–24], but no such work has been initiated with unsymmetrical ligands having azo-N and heterocyclic-N donor centers. Here arylazoheterocycles function as organic end-capping chelators.

For the last few years this group has been engaged in exploring the chemistry of such a ligand system with transition and non-transition metal ions. Major growth has been directed in the field of transition metal chemistry [25–28]. Non-transition metal complexes of arylazoimidazoles have also been reported from our group [29–34]. In this article we describe the syntheses and characterization of new polynuclear cadmium(II) azido and thiocyanato bridged complexes with 1-alkyl-2-(arylazo)imidazole (RaaiR′) ligands.

2. Experimental

2.1. Materials

Imidazole was purchased from Aldrich. Cd(II) acetate dihydrate, sodium azide and ammonium thiocyanate were obtained from Loba Chemicals, Bombay, India. All other chemicals and solvents were reagent grade and used as received. 2-(Arylazo)-imidazole (RaaiR′) was prepared by the reported procedure [25].

Warning: Cadmium and its compounds are toxic [35,36], and sodium azide is a potential explosive. Only small amounts should be prepared and handled with due care.

2.2. Physical measurements

Microanalytical (C,H,N) data were obtained from a Perkin–Elmer 2400 CHNS/O elemental analyzer. Spectroscopic data were obtained using the following instruments: UV–Vis and reflectance spectra, JASCO UV/Vis/NIR model V-570; IR (KBr disk, 4000–200 cm^{-1}), JASCO FT-IR model 420 spectrophotometer, and ^1H NMR, Bruker 400 MHz FT-NMR spectrometer.

2.3. Synthesis of $[Cd(HaaiEt)(N_3)_2]_n$ (**4a**)

1-Ethyl-2-(phenylazo)imidazole (0.05 g, 0.25 mmol) in MeOH (10 ml) was added dropwise to a stirred methanolic solution (10 ml) of $Cd(OAc)_2 \cdot 2H_2O$ (0.065 g, 0.25 mmol) at room temperature (298 K). To the resulting mixture a methanolic solution of NaN_3 (0.033 g, 0.50 mmol) was added very slowly. The orange-red solution was left undisturbed for two weeks. Bright orange-red crystals were obtained which were then washed with water and finally dried in vacuo. The yield was 0.10 g (65%).

All other complexes were prepared by the same procedure. The yields varied from 60% to 65%.

2.4. Synthesis of $[Cd(MeaaiEt)(SCN)_2]_n$ (**6b**)

The complex was prepared by the addition of a methanolic solution (10 ml) of 1-ethyl-2-(*p*-tolylazo)imidazole (0.054 g, 0.25 mmol) to a methanolic solution (10 ml) of $Cd(OAc)_2 \cdot 2H_2O$ (0.065 g, 0.25 mmol) at room temperature (298 K). To the resulting solution a methanolic solution (10 ml) of NH_4SCN (0.038 g, 0.50 mmol) was added in drops. The orange-red solution was left undisturbed for two weeks. Bright orange-red crystals were obtained which were then washed with water and finally dried in vacuo. The yield was 0.11 g (65%).

All other complexes were prepared by the same procedure. The yields varied from 60% to 65%.

2.5. X-ray diffraction study

Suitable single crystals of complexes **4a** and **6b** were mounted on a Siemens CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.711073$ Å)

radiation. The crystallographic data are listed in Table 1. The unit cell parameters and crystal-orientation matrices were determined for the two complexes by least squares refinements of all reflections. The intensity data were corrected for Lorentz and polarisation effects and an empirical absorption correction were also employed using the SAINT program for both complexes. Reflection data were assumed applying the condition $I > 2\sigma(I)$ for the complexes. The structures were solved by direct methods and followed by successive Fourier and difference Fourier syntheses. Full-matrix least-squares refinements on F_0^2 were carried out using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms. During refinement, the pendant C11 atom of the ethyl group of the imidazole moiety was found to be disordered over two positions (C11A/C11B) with the occupancy ratio 0.6/0.4. Hydrogen atoms were constrained to ride on the respective carbon or nitrogen atoms with isotropic displacement parameters equal to 1.2 times the equivalent isotropic displacement of their parent atom in all cases. All calculations were carried out using SHELXS97 [37], SHELXL97 [38], PLATON99 [39], ORTEP-3 [40] programs.

3. Results and discussion

3.1. Synthesis and spectral characterisation

Four 1-alkyl-2-(arylazo)imidazole ligands (RaaiR′, where R = H (**a**), Me (**b**); R′ = Me (**1**), Et (**2**)) are used in this work. They are unsymmetrical N,N′-bidentate chelator where N and N′ refer to N(imidazole) and N(azo) donor centers, respectively. Upon reaction of a methanolic solution of $Cd(OAc)_2 \cdot 2H_2O$, RaaiR′ and NaN_3 in 1:1:2 mole proportion, red-orange crystalline products of composition $[Cd(RaaiR')(N_3)_2]_n$ have been isolated. $[Cd(RaaiR')(SCN)_2]_n$ complexes were synthesized by the same procedure using ammonium thiocyanate in methanol. Microanalytical data support the composition of the complexes (Table 2) and in two cases the structures have been established by single crystal X-ray diffraction studies.

The complexes are insoluble in non-polar solvents and common polar solvents indicating their polymeric nature, but they are fairly soluble in DMSO and DMF. The complexes are non-conducting. The solution electronic spectra in DMSO exhibit three major transitions at 450–465, 380–390 and 355–375 nm. The reflectance spectra show only two broad absorptions at 450–470 and 360–390 nm. Free ligands show absorption below 400 nm and are assigned to intraligand charge transfer transitions [26]. Thus longer wavelength absorption is related to metal-to-ligand charge transfer transitions. Cadmium(II), a $3d^{10}$ metal ion, and RaaiR′, π-acidic ligands with low-lying vacant orbitals dominated by the

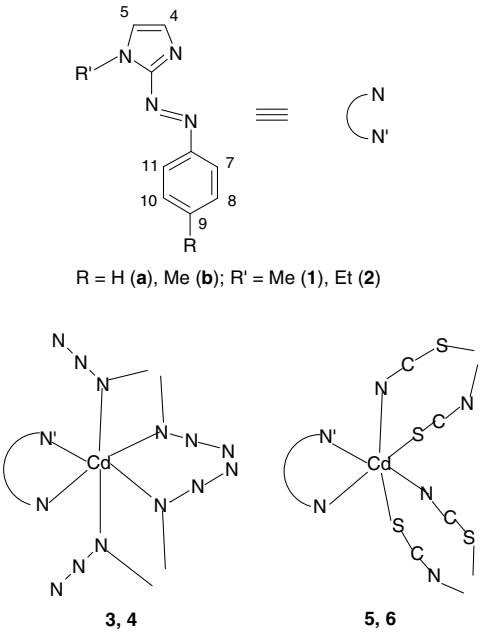
azo (N=N) group [31], may involved in metal-to-ligand charge transfer transitions. Data in Table 2 reveal that $[Cd(RaaiR')(SCN)_2]_n$ (**5**, **6**) absorb at higher energy (450–460 nm) relative to $[Cd(RaaiR')(N_3)_2]_n$ (**3**, **4**) (460–470 nm). This is reasonable because of the strong preference of Cd(II) for the S donor center of the thiocyanate group.

Infra-red spectra of the complexes are very informative. The IR spectra of **3/4** exhibit a strong doublet corresponding to $\nu_{as}(N_3)$ at 2060–2070 and 2030–2040 cm^{-1}. The IR spectra of the thiocyanato compounds, $[Cd(RaaiR')(SCN)_2]_n$ (**5/6**), show a sharp strong band at 2070–2090 cm^{-1} and weak diffused shoulders at 2100–2120 cm^{-1}. These are referred to ν(CN) of bonded SCN. Medium to strong bands observe at 775–785 and 655–765 cm^{-1} have been assigned to ν(CS). The band position and splitting pattern are corroborated with bridging N,S-thiocyanato groups [19]. The ν(NCS) appear at 450 and 400 cm^{-1}.

The ^{1}H NMR spectra of the complexes have been used to determine the coordination mode of RaaiR′. The spectra are assigned (Table 3) on the basis of spin–spin interaction, effect of substituents and on comparing with free ligand values. The spectra are recorded in DMSO-d_6 and the atom numbering pattern is shown in Scheme 1. Imidazole protons 4-H and 5-H appear as singlet that may be due to rapid proton exchange in DMSO. The protons are in general downfield shifted indicating the coordination to Cd(II). The 4-H proton suffers significant downfield shifting ($\Delta\delta = 0.4$–0.5 ppm) with reference to the free ligand value [25,26]. This indicates preferential binding of imidazole-N to Cd(II) (which is also supported from Cd–N bond distance data, vide infra). 4-H is closer to the azo group which is an electron withdrawing agent. Thus 4-H is downfield shifted. Aryl-H (7-H–11-H) signals appear in their usual positions: 7,11-H appear at the most downfield position because of their closeness to the electron withdrawing azo function and 8,10-H suffer significant upfield shifting by the substitution of an electron donating –Me group [26].



Scheme 1.

3.2. Molecular structures

3.2.1. [Cd(HaaiEt)(N$_3$)$_2$]$_n$ (**4a**)

A perspective view of **4a** is shown in Fig. 1 and selected bond parameters are listed in Table 4. The cadmium atom is in a distorted octahedral environment with CdN_6 coordination. HaaiEt acts as an unsymmetric N,N′ chelating ligand. Azido (N_3) groups act as end-on (μ-1,1 EO) double bridging agent with two neighbouring cadmium atoms. The bridging Cd_2N_2 unit constitutes a parallelogram unit with bond length Cd(1)–N(8), 2.290(3), Cd(1)–

		Cd(1)^{i}–N(8)–N(9)	121.00(2)

Symmetry code: $i = 1 - x, 2 - y, -z$; $ii = -x, 2 - y, -z$.

N(8)^{i}, 2.398(3) Å and bond angles, Cd(1)–N(8)–Cd(1)^{i}, 107.34(12)°, N(8)–Cd(1)–N(8)^{i}, 72.66(12)° ($i = 1 - x$, $2 - y, -z$; $ii = -x, 2 - y, -z$). The small chelate angle (∠N(1)–Cd(1)–N(3), 67.41(11)°) may cause the structural distortion. The bridge angles (e.g., ∠Cd(1)–N(5)–Cd(1)^{ii}, 102.69(12)°; Cd(1)–N(8)–Cd(1)^{i}, 107.34(12)°) lie in the reported angular range [7]. A 1D neutral chain is running along the a-direction by repeating the Cd_2N_2 unit. Each chelating ligand per metal ion in two adjacent Cd centers coordinates in two different ways. Two N′ (N(azo)) approach closer together or away from each other. The distortion in the CdN_6 coordination is supported by six unequal Cd–N bond distances. The longest distance is Cd–N(azo) (Cd–N(1), 2.551(3) Å) which is less than the sum of the van der Waals radii of N(azo) and Cd(II), indicating the existence of covalent interaction between Cd(II) and N(azo) [41]. The shortest distance is 2.290(3) Å and is observed for one of the Cd–N(azido) [Cd(1)–N(8)], bonds (Table 4). The N=N bond length is 1.259(5) Å which is slightly elongated ($\Delta d \sim 0.01$ Å) compared to that of the free ligand value [42]. Two neighbouring Cd-centres are in an angular arrangement with the central Cd atom and make an angle of 131.72(2)°.

3.2.2. *[Cd(MeaaiEt)(SCN)$_2$]$_n$ (**6b**)*

A perspective view of **6b** is shown in Fig. 2 and selected bond parameters are listed in Table 5. The structure consists of neutral chains of cadmium atoms linked by four SCN bridges. The octahedral coordination around Cd consists of a chelate ring from MeaaiEt, Cd(N,N′) type (MeaaiEt is an unsymmetric N,N′-chelator 1-ethyl-2-(*p*-tolylazo)imidazole), and four SCN bridges. Thiocyanate (SCN) acts as a μ-1,3 N,S-type double bridging agent with two neighbouring cadmium centres. Thus, each complex molecular fragment shows an octahedral CdN_4S_2 coordination arrangement. Thiocyanate (SCN) is an ambidentate ligand and has a schizophrenic preference to Cd(II) exhibiting both S and N bonding modes [43]. Out of four SCN groups around the Cd centre two are S-bonded and two are N-bonded. Thus double bridged NCS forms an eight membered puckered ring structure. Each Cd centre is associated

with two eight membered rings and one five membered chelate ring from MeaaiEt. The two eight membered rings are not equivalent; one of them suffers severe distortion in which Cd is deviated from planarity by 0.27 Å, the S and N are deviated by −0.27 and 0.34 Å, respectively, from the mean plane. These two rings make a dihedral angle of 55.74(7)°. The chelate ring is a good plane and the pendant phenyl ring is almost planar with the chelate ring (dihedral 3.62(14)°).

The two sets of μ-(N,S)-thiocyanato bridges are not equivalent which is evident from their bond parameters data (Table 5). The two Cd–S bond distances differ by 0.073 Å while the two Cd–N distances differ insignificantly (0.004 Å). The Cd–S(2) bond *trans* to the Cd–N(imidazole) (Cd–N(3)) is shorter than the second Cd–S(1) bond length. Other distances about SCN (C–N, C–S) differ only by 0.003–0.006 Å. The bridging SCN does not show deviation from linearity (∠S–C–N, av. 178.8°). MeaaiEt forms a strained chelate ring around cadmium; the chelate angle is 66.95(7)°. The Cd–N(MeaaiEt) distances differ significantly. Because of matching softness character of Cd(II) and imidazole-N, the Cd–N(imidazole) (Cd–N(3), 2.293(2) Å) bond length is substantially lower than the Cd–N(azo) (Cd–N(6), 2.615(2) Å) length and the difference is 0.32 Å. The azo N=N bond length, 1.267(3) Å, is slightly elongated from that of the free ligand value (1.250(1) Å) [42]. The chelate ring strain may be the reason for the inequivalence of the two μ-(N,S)-thiocyanato group double bridges about Cd(II). Two neighbouring Cd centers in the bridging head of one Cd are not in the same phase and these three Cd centers extend an angular arrangement of 131.94(1)°. The versatile bridging nature of the SCN ligands gives a 1D polymeric chain along the *b*-axis. The Cd–Cd separations are 5.4770(5) and 5.8426(5) Å.

3.2.3. Supramolecular sheet

The 1D chains are self-assembled into molecular sheets via π–π interactions between aromatic rings and are described in Figs. 3 and 4. The chelated arylazoimidazole in the molecular unit of each chain is projected into the space provided by two neighbouring molecular units of adjacent chains. This natural penetration is meaningful and we find some π–π interaction with the aromatic rings. The aryl ring (Ar) of one chelated molecule in one 1D chain interacts with imidazole ring (Imz) from the adjacent molecule of a neighbouring chain. Thus, Imz(A)–Ar(B) (A stands for one 1D chain and B stands for the adjacent 1D chain) are separated by 4.34 Å for $[Cd(HaaiEt)(N_3)_2]_n$ and 4.05 Å for $[Cd(MeaaiEt)(SCN)_2]_n$. The Ar rings are also under π–π interaction and their separations are 3.95 and 3.94 Å for $[Cd(HaaiEt)(N_3)_2]_n$ and $[Cd(MeaaiEt)(SCN)_2]_n$, respec-

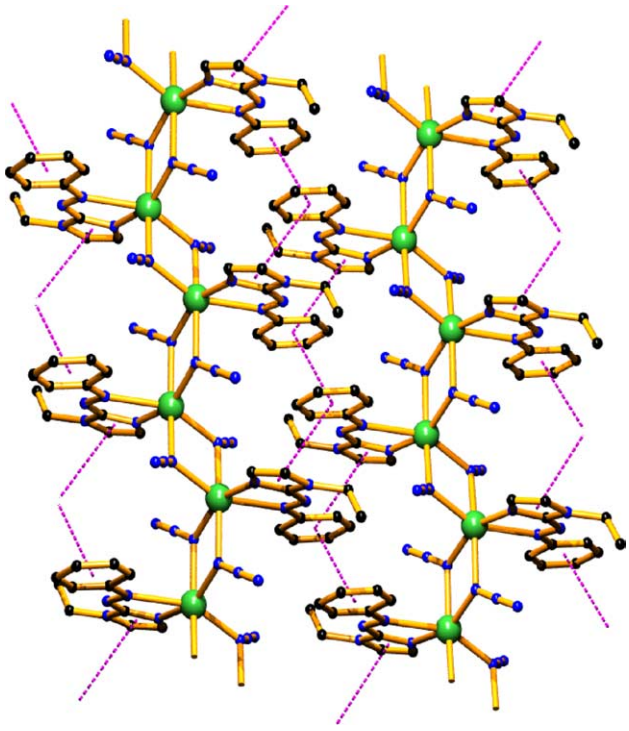

Fig. 3. Supramolecular sheet via π–π interaction in $[Cd(HaaiEt)(N_3)_2]_n$ (**4a**).

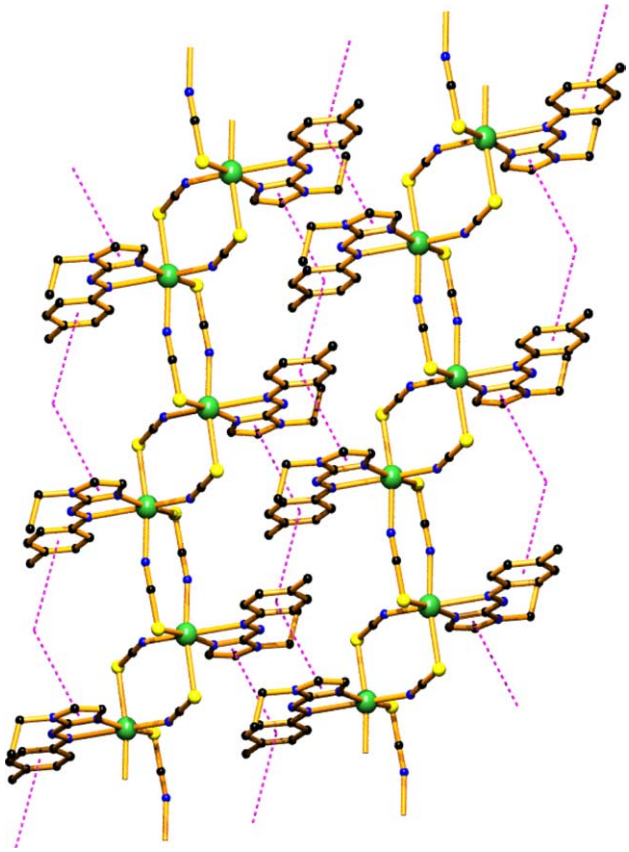

Fig. 4. Supramolecular sheet via π–π interaction in **6b**.

tively. The non-covalent interaction is thus associated with –Imz(A)–Ar(B)–Ar′(A)–Imz′(B)– [′ refers to the second molecule in the respective chain] and thus adjacent chains generate a sheet. The Ar–Ar interaction is stronger than the Imz–Ar interaction as is evident from the Cg–Cg distance data. However, the strength of the π–π interaction is about to same between the Ar–Ar system in the two classes of molecules irrespective of the substituent in the rings, while Imz–Ar interaction is stronger in $[Cd(MeaaiEt)(SCN)_2]_n$ than $[Cd(HaaiEt)(N_3)_2]_n$. The reason is unclear at present and may be due to a difference in their bridge pattern (EO in the azido compound and EE in the thiocyanato system) and the strain in the bridged motif (four membered ring in Cd-azido and eight membered in the Cd-SCN system).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 216059 for $[Cd(HaaiEt)(N_3)_2]_n$ (**4a**) and CCDC No. 216060 for $[Cd(MeaaiEt)(SCN)_2]_n$ (**6b**). Abstract

In aqueous solution with tetrabutylammonium hydrogensulfate cocatalyst, rhodium complexes like *cis*-[$Rh(CO)_2(amine)_2$](PF_6) (amine = 4-picoline, 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) promote the oligomerization and, to a lesser extent, the hydrocarboxylation of CO/ethylene. Higher rates for both the production of alternating polyketones and propionic acid are observed in wet tetrabutylammonium hydrogensulfate medium. An in situ FT-IR spectroscopy study confirms that five coordinated rhodium species of the type *trans*-[$Rh(CO)_3(amine)_2$]$^+$ are formed under catalytic conditions. The data are discussed in terms of a potential catalytic cycle, and the formation of propionic acid and ketones is determined to come from the hydrolysis and hydrogenolysis of the Rh-acyl intermediates formed under the catalytic conditions.

1. Introduction

Catalytic hydrocarboxylation of ethylene (Eq. (1)) and higher olefins under CO/water to carboxylic acids catalyzed by cobalt pyridine complexes [1–4], the co-oligomerization of CO/ethylene to polyketones (Eq. (2)) catalyzed by palladium complexes bearing nitrogen and phosphorous donor ligands [5–9] and palladium-promoted copolymerization in water [10–14] have been studied in detail. On the other hand, the use of water in some of the above described processes is due to its environmental friendly characteristic, cheapness and for its promoting effect, which has been related to the formation of active metal-hydride species [15], an important first step in the catalytic cycle, via a reaction closely related to the water gas shift reaction [16]. Also, in the literature exist few examples of CO/ethylene co-oligomerization [17–20] and copolymerization [21] reaction promoted by a rhodium system and an example of homogeneous catalytic carboxylation reaction carried out in salty medium [22]. However, little is known about the hydrocarboxylation or the co-oligomerization of CO/ethylene promoted in aqueous media by rhodium complexes bearing nitrogen donor ligands. We wish to report our preliminary observations on the reaction of carbon monoxide and ethylene by the rhodium(I) complexes *cis*-[$Rh(CO)_2(amine)_2$](PF_6) (amine = 4-picoline, 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) in water with tetrabutylammonium hydrogensulfate (40/2.5, w/w) cocatalyst and, by comparison, in wet, liquid, tetrabutylammonium hydrogensulfate/H_2O (80/40, w/w).

$$n(CH_2{=}CH_2) + nCO{+} \rightarrow H(-CH_2CH_2CO-)_nCH_2CH_3 \quad (2)$$

2. Experimental

2.1. Materials

Pyridine (py), methyl pyridines (4-picoline (4-pic), 3-picoline (3-pic) and 2-picoline (2-pic)) and dimethyl pyridine (2,6-lutidine (2,6-lut)) were obtained from Aldrich and distilled over KOH. Tetrabutylammonium hydrogensulfate ($(CH_3(CH_2)_3)_4N(HSO_4)$, 97%) from Aldrich was used as received. Water was distilled. CaO containing ethyl violet as indicator from Carlo Erba was used as received. CO (Rivoira) and ethylene (Praxair) were used as received. The complexes of the type *cis*-$[Rh(CO)_2(amine)_2](PF_6)$ (amine = 4-picoline, 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) were synthesized and characterized as reported by Denise and Pannetier [23] and their IR spectra in chloroform demonstrated their identity and purity (two strong bands in the $\nu_{(CO)}$ region at 2095 and 2020 cm^{-1}).

2.2. Instrumentation

Organic products were analyzed on a Dani Model 8400 gas chromatograph (equipped with a flame ionization detector and a 2 m × 1/8 in. Carbowax W (80–100 mesh) packed column, using He (Rivoira) as carrier gas) on a Hewlett-Packard 6890/5973 GC/MS coupled system (fitted with a 5% phenylmethyl siloxane column (30 m × 25 μm × 0.25 m) using He as carrier gas (1 mL/min)) on a Varian Gemini 200 ^1H NMR, on a Perkin–Elmer Model FT-IR 1725-X and on a Paragon 500 FT-IR instruments. The potentiometric titrations and determinations of pH were performed on a Crison model 2001 pH-meter.

2.3. Catalyst testing

Catalytic runs were carried out in a 400 mL mechanically stirred stainless steel autoclave charged with 40.0 g of H_2O (2.22 mol), 1.5×10^{-4} mol of the rhodium complex and tetrabutylammonium hydrogensulfate in the range 2.52 g (7.4 mmol)–80.00 g (235.6 mmol). The reaction vessel was charged firstly with 20.0 g of ethylene and then with 20.0 g of CO (total pressure = 88 atm) and warmed at 150 ± 1 °C by mean of a circulating oil bath. These pressure and temperature were chosen in order to average the previous reported systems based on $Rh_4(CO)_{14}$/organic solvents [16–20]. At the end of the reaction time, the amounts of formed CO_2 and propionic acid were determined by the increase in weight of a glass column packed with CaO where the pre-dried gases of the reaction were passed through and by potentiometric titration of an aliquot of the yielded catalytic mixture with NaOH (0.1 M), respectively. For the potentiometric titration, an aliquot (typically, 2.0 g) of the previously shacked catalytic mixture was diluted in 10 mL of water and then titrated with a 0.1 M NaOH solution. Two inflection points were observed, the first corresponding to $[(CH_3(CH_2)_3)_4NHSO_4]$ (pH range 2–4) and the second corresponding to propionic acid (pH range 7–11). Propionic acid concentration ([propionic acid] (mol)) was calculated by the following expression [propionic acid] = [(volume (L) of NaOH consumed until the second inflection point of titration curve) − (volume (L) of NaOH consumed until the first inflection point)]*([NaOH] (mol/L))*[(total weight (g) of the catalytic mixture)/(weight (g) of the titration aliquot)]. The other organic products were extracted with diethyl ether and subjected to column chromatography on silica gel with diethyl ether/*n*-hexane 9:1. The three major separated fractions were penta-3-one, octane-3,6-dione and undecane-3,6,9-trione which were identified by ^1H NMR, IR and GC-MS [24,25]. The extent of the co-oligomerization was established on the base of produced CO_2 (Eq. (3)), while the amount of single ketones were not quantitatively determined.

3. Results and discussion

3.1. Catalysis studies

The *cis*-$[Rh(CO)_2(amine)_2][PF_6]$ (amine = 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) complexes were investigated as precursors for catalytic CO/ethylene reactions in water containing 6% of tetrabutylammonium hydrogensulfate. All the complexes were active for both ethylene hydrocarboxylation (Eq. (1)) and ethylene/CO co-oligomerization (Eq. (3)). The relative extent of the two competing catalytic reactions can be established by the TOF(C_2H_5COOH) and the TOF(CO_2) (TOF = moles of product/moles of rhodium/24 h). The results are shown in Table 1. All the five solutions left after cooling the reactor show two liquids phases. The upper organic phase is dark-red, and the aqueous phase has a pale-yellow color. Also, control experiments show that the activity toward the hydrocarboxylation and hydrocarbonylation of ethylene under CO was not observed when the same aqueous solution of tetrabutylammonium hydrogensulfate was tested under similar experimental conditions in the absence of any of the carbonylaminerhodium(I) complexes.

$$n(CH_2{=}CH_2) + nCO + H_2O \rightarrow CH_3{-}CH_2{-}C(O){-}\mathbf{R} + CO_2 \quad (3)$$

Run	Amine (pK_a)	Wt. CO_2 (g)	TOF(CO_2)[b](% of CO conversion to CO_2)	Mol of propionic acid (selectivity, %)	TOF (propionic acid)[b] (yield %)
1	2,6-Lut[c] (6.75)	0.53	305 (2)	0.006 (33)	152 (1)
2	4-Pic[c] (6.00)	2.55	1473 (8)	0.022 (27)	558 (3)
3	2-Pic[c] (5.97)	2.17	1252 (7)	0.013 (21)	330 (2)
4	3-Pic[c] (5.52)	2.35	1356 (7)	0.014 (21)	356 (2)
5	Py[c] (5.27)	2.10	1211 (7)	0.014 (23)	356 (2)
6	3-Pic[d] (5.52)	5.03	19 878 (16)	0.193 (63)	33 565 (27)

[a] $Rh = 1.5 \times 10^{-4}$ mol; $H_2O = 40.0$ g; $CO = C_2H_4 = 20.0$ g (88 atm); $T = 150 \pm 1$ °C for 6.3 h.
[b] TOF(product) = mol product/mol Rh/24 h.
[c] $[(CH_3(CH_2)_3)_4N][HSO_4] = 2.52$ g (7.4 mmol).
[d] $[(CH_3(CH_2)_3)_4N][HSO_4] = 80.00$ g (235.6 mmol); 0.92 h.

for $n = 2$, $\mathbf{R} = CH_2–CH_3$; (penta-3-one).
for $n = 3$, $\mathbf{R} = CH_2–CH_2–C(O)–CH_2–CH_3$; (octane-3,6-dione).
for $n = 4$, $\mathbf{R} = CH_2–CH_2–C(O)–CH_2–CH_2–C(O)–CH_2–CH_3$; (undecane-3,6,9-trione).

The ketones products penta-3-one, octane-3,6-dione and undecane-3,6,9-trione come from the catalytic stepwise co-oligomerization of the CO/ethylene mixture (Eq. (3)). No attempts were made to quantify separately the yields of the each ketone. However, a 65% of penta-3-one and 35% of octane-3,6-dione was observed in one of the fractions (which contained only these two ketones), based on ^1H NMR signals.

In aqueous solution containing 5.9% of hydrogensulfate salt, the TOF(CO_2) followed the order: 3-pic (1356) > 2-pic (1252) > py (1211) > 2,6-lut (305) under the same catalytic conditions, based on CO_2 produced (Table 1).

Further, propionic acid (Eq. (1)) was separated after a treatment of the resulting aqueous phase of the catalytic solution, first with diethyl ether/H_2O, later with K_2SO_3/H_2O and finally with H_2SO_4/diethyl ether. The ^1H NMR δ_H ($CDCl_3$) = 0.949 (t, 3H, CH_3), 2.254 (q, 2H, CH_2Me) and 4.667 ppm (s, 1H, OH), and the GC-MS (molecular ion peak and base peak at $m/e = 74$) of this fraction are similar to a pure sample of propionic acid. The amount of propionic acid formed was determined by potentiometric titration.

The reactivity toward propionic acid formation for this Rh/amine system proved also to be dependent on the nature of the heterocyclic nitrogen ligand coordinated to the rhodium center (Table 1), for example the TOF(propionic acid) (24 h^{-1}) values for these carbonyl rhodium complexes followed the order: 3-pic (356) = py (356) > 2-pic (330) > 2,6-lut (152) under the same catalytic conditions.

The results show the positive effect of amine basicity on the ketones and to a lesser extent on propionic acid production, which increases with pK_a augmentation of the amine ligand in absence of steric effect (present in the 2-picoline and 2,6-lutidine); namely, 3-picoline displays the highest activity. However, reaction rates decreased markedly with increasing steric hindrance of the coordinated amine as shown by the lower activity of 2-picoline and 2,6-lutidine. These results suggest a critical steric parameter, which can be viewed as the effect of competition for binding to the catalytic center, which is more affected by steric constraints than by electronic effects. For example, the coordination of the ethylene to the rhodium center is a crucial step [17], and it can be inhibited in some degree by the effective block of methyl groups in *ortho* position to nitrogen atom of the aromatic ring and consequently decreasing the catalytic activity. Also, the blocking effect can prevent or decrease the rate of other elementary reactions of the catalytic cycle, which require an open coordination site on the metal center. This kind of blocking has been illustrated by Vallarino and Sheargold [26] on the solid state isomerism and intermetallic interactions in the square planar rhodium(I), $[RhX(CO)_2(amine)]$ (X = Cl, Br, amine = 2-picoline, 2,6-lutidine, etc.) complexes, that can be rationalized in terms of the steric hindrance of the amino ligand which effectively prevent interactions between adjacent Rh(I) centers. The methyl group of these ligands when coordinated to the metal ion effectively blocks the axial position of the square planar environment. For example, complexes in which the amine ligand has a highly hindered N-donor atom are obtained in the non-stack form while the stacked form is common for non-hindered ligands.

A test was performed by using as a catalytic precursor the complex *cis*-$[Rh(CO)_2(4\text{-pic})_2](PF_6)$ (bearing a less crowed 4-picoline ligand) to confirm this hypothesis. Under similar reactions conditions the TOF(CO_2) and TOF(propionic acid) values for this R(4-pic) system are 1473 and 558 (24 h^{-1}), respectively. It can be observed that overall TOF (TOF(CO_2) plus TOF(propionic acid)) of the Rh(4-pic) system (2031 (24 h^{-1})) is 4.4 times more active than the Rh(2,6-lut) system (457 (24 h^{-1})) and 1.3 times more active than the Rh(2-pic) system (1582 (24 h^{-1})). A plot of total TOF/day values vs. pK_a of the protonated base for the sterically and non-sterically

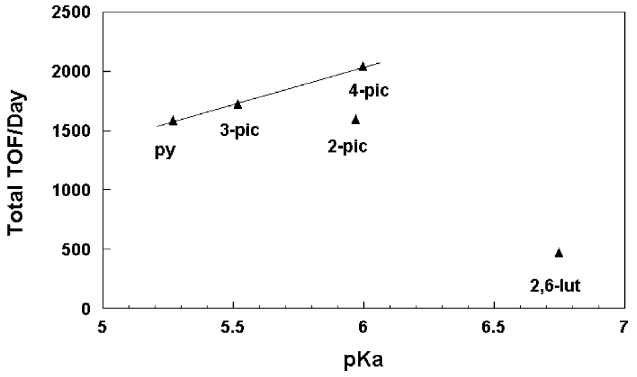

Fig. 1. Plot of total TOF/day vs. pK_a (BH^+) of pyridines and substituted pyridines. (Line drawn for illustrative purposes only.)

hindered pyridines used is shown in Fig. 1. The total TOF day values followed as 4-pic (2031) > 3-pic (1712) > 2-pic (1582) > py (1567) > 2,6-lut (457). Apparently the catalytic activity observed in these systems is the consequence of a fine balance between electronic and sterical factors. However, it can be seen that the sterical factor predominates over the electronic influence.

In these studies it was observed that all the catalytic solutions have undergone some pH changes. For example, the freshly prepared solution from *cis*-[Rh(CO)$_2$(amine)$_2$](PF$_6$)/aqueous tetrabutylammonium hydrogensulfate (0.2 M) gave a pH value of 1.29, while the catalytic solutions formed under a continuous heating (6.3 h), at 150 °C under CO/ethylene atmosphere gave a pH value of 1.49–1.56.

A remarkable result related to the ketone and propionic acid formations catalyzed by the Rh/3-pic system is observed when the concentration of the [$(CH_3(CH_2)_3)_4NHSO_4$] salt increased from 2.52 g (5.9%) to 80 g (66.7%). As observed in Table 1, the TOF(CO_2) and TOF(propionic acid) reaches the highest values of 19 878 (16% conversion in 6.3 h) and 33 565 (24 h)$^{-1}$ (selectivity ca. 63% at 27% conversion in 6.3 h), respectively, under a wet liquid tetrabutylammonium hydrogensulfate medium. These results suggested that the salty medium stabilize the ionic Rh catalytic species formed under the reaction conditions, therefore enhancing the reactivity. The approach related to the use of salty medium can constitute an alternative reaction media in comparison to the more recently reported ionic liquid [27]. Furthermore, the evaluation with the Rh/3-pic system in wet liquid tetrabutylammonium hydrogensulfate was made long before the discovery for us of the most active Rh/4-pic system. No attempt was made to evaluate the Rh/4-pic system in wet liquid tetrabutylammonium hydrogensulfate.

3.2. FT-IR characterization studies

The FT-IR spectra of recently prepared KBr pellets of *cis*-[Rh(CO)$_2$(amine)$_2$](PF$_6$) (amine = 4-picoline, 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) show two strong bands in the ν_{CO} region before being exposed to CO in agreement to the results reported by Denise and Pannetier [23]. On the contrary, the in situ FT-IR spectrum of the active Rh(amine)$_2$/R_4NHSO_4 catalyst solution, after being exposed to CO/ethylene, displays one strong band and a weak satellite at higher frequency in the ν_{CO} region (Table 2). Probably, under the catalytic conditions at high pressure a CO molecule is coordinated to starting *cis*-dicarbonyl rhodium complex forming the *trans*-[Rh(CO)$_3$(amine)$_2$]$^+$ (Eq. (4)), where both amine ligands are in *trans*-position. This ν_{CO} spectrum is typical for M(CO)$_3$L$_2$ system with D_3h form on the grounds of selection rules [28]. The single strong band in the *trans* complex is assigned the e' mode and the weak shoulder is probably the a_1' mode made weakly infrared-active by asymmetry of the ligands. Attempts to isolate and characterize the rhodium products after a catalytic run were unsuccessful due to the unstable nature of the rhodium catalytic species. The Rh species are only stable under the catalytic conditions.

$$\textit{cis}\text{-}[Rh(CO)_2(amine)_2]^+ + CO \rightarrow \textit{trans}\text{-}[Rh(CO)_3(amine)_2]^+ \quad (4)$$

3.3. Mechanistic consideration

The products of these reactions may be explained by the mechanism illustrated in Schemes 1 and 2. The overall mechanism is similar to the one proposed by Bianchini et al. [12] for the CO/ethylene alternating copolymerization and terpolymerization catalyzed by water soluble Pd(II)–Na_2DPPPDS catalyst. However, there are some important differences. First, Bianchini

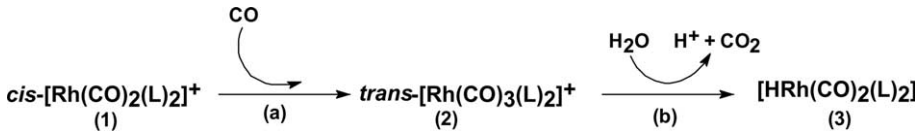
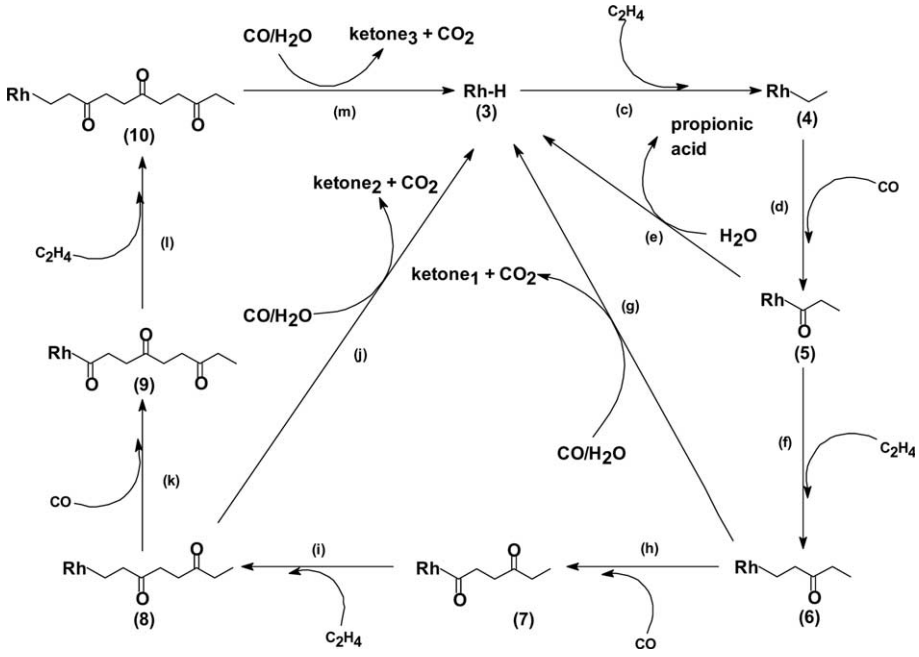


Scheme 1.



Scheme 2. Ketone$_1$ = penta-3-one; ketone$_2$ = octane-3,6-dione; ketone$_3$ = undecane-3,6,9-trione.

et al. did not observe in their system formation of propionic acid. The formation of propionic acid implies the hydrolysis of Rh–C bonds in the propagation unit Rh–$C(O)CH_2CH_3$ as one of the termination steps. Second, they suggested that the production of CO_2 goes via insertion of CO into Pd–OH bonds to give Pd–COOH. Proposed here is that the production of free CO_2 goes via decarboxylation of Rh-hydroxycarbonyl species formed by nucleophilic attack of water on coordinated CO under water gas shift reactions (WGSR) conditions [29]. The results of the TOF values (Table 1) suggest that termination steps by hydrolysis affording propionic acid are faster than the termination step by in situ hydrogenolysis to affording ketones by factor range of 2.0–3.8.

The catalytic precursors *cis*-$[Rh(CO)_2(L)_2]^+$ (**1**, L = amine) suffer diverse transformations before forming the catalytic $[HRh(CO)_2(L)_2]$ species (**3**). Namely, their reaction with CO to form the tricarbonyl-rhodium *trans*-$[Rh(CO)_3(L)_2]^+$ complex (Eq. (4)), which under CO/H_2O is gradually transformed (steps a–b) in the neutral complex Rh–H (**3**) (Scheme 1). The characterization by in situ ^1H NMR spectroscopic studies of rhodium hydride intermediates (Rh–H) formed by the transformation of the rhodium(I) complex, *cis*-$[Rh(CO)_2(py)_2](PF_6)$ dissolved in aqueous pyridine, under water gas shift reaction conditions has been reported [30].

In Scheme 2, the CO and amine ligands of the starting rhodium complex (**3**) are omitted for clarity. The propionic acid formation (step e) and ketones (steps g, j and m) arise by hydrolysis and hydrogenolysis, of the Rh-acyl intermediates, respectively. The oligomerization may proceed by a single mode of chain growth involving alternate insertion of CO and ethylene (C_2H_4) forming intermediate Rh-acyls [20]. The Rh-acyl species are terminated by reaction with the CO/H_2O couple affording CO_2 and the corresponding ketones. The formation of propionic acid may be facilitated by the coordinated pyridine. It has been proposed that pyridine has vacant antibonding π-orbitals, capable of accepting the electrons coming from rhodium-back donation, lowering the electron density on the Rh center [17,31]. Accordingly, the pyridine coordinated σ-acyl complex (**5**) may be easily attacked by nucleophillic OH^- group (coming from H_2O) given propionic acid (step e). The hydrogenolysis of the Rh-acyl intermediates, which leads to ketone formation (steps g, j and m), comes probably from *intra*-hydrogen transfer from Rh–H species formed under conditions similar to the WGSR [30]. Namely, nucleophilic attack by OH^- on a

coordinated carbonyl ligand of the $[Rh(CO)_2(L)_2(acyl)]$ complexes (**6**, **8** and **10**) would afford the anionic rhodium hydroxycarbonyl $[Rh(CO)_2(CO_2H)(L)_2(acyl)]^-$ complexes and a H^+ (Eq. (5)).

$$[Rh(CO)_2(L)_2(acyl)] + H_2O \rightarrow Rh(CO)(CO_2H)(L)_2(acyl)]^- + H^+ \quad (5)$$

Decarboxylation of rhodium hydroxycarbonyl intermediate would generate a rhodium hydride complex $[HRh(CO)(L)_2(acyl)]^-$ and CO_2 (Eq. (6)).

$$[Rh(CO)(CO_2H)(L)_2(acyl)]^- \rightarrow [HRh(CO)(L)_2(acyl)]^- + CO_2 \quad (6)$$

Reductive elimination of hydride-acyl complex affords the corresponding ketones and the coordinative unsaturated $[Rh(CO)(L)_2]_-$ complex according to Eq. (7). The accumulate negative charge on the hydride-acyl complex favors the migration of the coordinate H to the Rh–C bonds.

$$[HRh(CO)(L)_2(acyl)]^- \rightarrow [Rh(CO)(L)_2]^- + \text{ketone} \quad (7)$$

Protonation of the later anionic complex by H^+ (coming from Eq. (5)) and carbonylation by CO (Eq. (8)) would give the starting $[HRh(CO)_2(L)_2]$ complex (**3**) to get catalytic cycle closed.

$$[Rh(CO)(L)_2]^- + H^+ + CO \rightarrow [HRh(CO)_2(L)_2] \quad (8)$$

All the last four reactions, (5)–(8) lead to the formation of the starting (**3**) complex, CO_2, and ketones (Eq. (9)).

$$[Rh(CO)_2(L)_2(acyl)] + CO + H_2O \rightarrow [HRh(CO)_2(L)_2] + CO_2 + \text{ketone} \quad (9)$$

The electronic and steric effects of the coordinate amine can control all or some of these catalytic key steps.

Finally, analyses of the effects of varying the CO pressure, Rh concentration and temperature on the activity of these complexes, which are important parameters for the carbonylation reaction are in progress, and they will be reported elsewhere.

4. Conclusions

In this study, propionic acid and the ketones (penta-3-one, octane-3,6-dione and undecane-3,6,9-trione) were synthesized by a hydrocarboxylation of ethylene and by a stepwise alternating co-oligomerization of CO/ethylene, respectively. Both reactions were catalyzed by *cis*-$[Rh(CO)_2(amine)_2](PF_6)$ complexes in a salty medium of tetrabutylammonium hydrogensulfate. It can be seen a remarkable increment on the ketone and propionic acid formations catalyzed by the Rh/3-pic system when the concentration of the tetrabutylammonium hydrogensulfate salt increased. On the other hand, the reaction rates decreased markedly with increasing steric hindrance of the coordinated amine. Our approach related to the use of salty medium can constitute another alternative reaction media to propionic acid and ketones synthesis. Such a catalytic system contains a high concentration of the *trans*-$[Rh(CO)_3(amine)_2]^+$ complex, characterized by IR, which is formed by coordinative addition of one CO molecule to the starting *cis*-$[Rh(CO)_2(amine)_2]^+$ complex, under the catalytic reaction conditions.

Abstract

The crystal structures of three bis(dpyam)copper(II) complexes, $[Cu(dpyam)_2(NO_2)](NO_2)$ (**I**) and $[Cu(dpyam)_2(O_2CH)](ClO_4)$ (**II**) and $[Cu(dpyam)_2(ONO_2)](BF_4)$ (**III**) have been determined by X-ray analysis. In **I**, the copper atom and the asymmetrically bonded nitrito group lie on a crystallographic C_2-axis. The nitrito group is clearly disordered about the C_2-axis giving a square pyramidal *cis*-distorted octahedral ($4 + 1 + 1^*$) chromophore rather than a pseudo-regular *cis*-distorted octahedral chromophore. In **II** and **III**, a distortion of the *cis*-distorted CuN_4O_2 chromophore towards a square pyramidal ($4 + 1 + 1^*$) stereochemistry is also present. The polycrystalline EPR spectra of **I**–**III** together with the high asymmetry in geometry of the CuN_4O_2 chromophores are suggesting that all complexes appear to be near the static distortion limit of the fluxional CuN_4O_2 chromophore geometry. The electronic reflectance spectra of the three complexes involve two bands at the same intensity corresponding to a *cis*-distorted octahedral geometry.

1. Introduction

The molecular structures of the [Cu(II)(chelate)$_2$(OXO)]Y complex (chelate is 2,2′-bipyridyl (bpy) and 1,10-phenanthroline (phen) and OXO is a bidentate oxoanion such as ONO^-, ONO_2^-, $CH_3CH_2CO_2^-$, $CH_3CO_2^-$ or HCO_2^-) were classified as *cis*-distorted octahedral [1] and well characterized as fluxional copper(II) geometries [2–4]. The temperature variability in EPR spectra and in the chemical bond parameters of the CuN_4O_2 chromophore strongly evidence that vibronic coupling is operative in these complexes [5,6]. The symmetric structures with average C_2 symmetries (not static C_2 symmetries) found in the [Cu(chelate)$_2$(OXO)]Y complexes actually represent the superposition of two interconverting asymmetric structures (a 'dynamic pseudo-Jahn–Teller effect' at least at room temperature) with equally relative thermal populations of the two conformers [6,7]. The corresponding complexes of this series with the more flexible dpyam (di-2-pyridylamine) ligand have been amply characterized and investigated concerning apparent structural distortions and electronic properties in the context of the fluxional behaviour. Only four crystal structures of $[Cu(dpyam)_2(ONO)]^+$ cation distortion isomers involving the counter anions, BF_4^-, NO_3^-, ClO_4^- and NO_2^- have been reported [8,9]. The last one, $[Cu(dpyam)_2(ONO)](NO_2)$ is in surprisal, as its structure reported by Hathaway and co-workers [8] involves a regular *cis*-distorted octahedral geometry, but with unreasonable O–N–O bond angle. This unusual feature encourages us to reprepare this compound and the detailed structure redetermined. For the corresponding nitrate complex, no examples are known for a

doi:10.1016/j.poly.2004.03.020

cis-distorted octahedral structure in [Cu(chelate)$_2$-(ONO$_2$)]Y type complexes. Only the complex [Cu-(dpyam)$_2$(O$_2$CH)]- (BF$_4$) [10] has been reported for the corresponding dpyam complex with the formate oxoanion.

In the present paper, we report the synthesis, crystal structures and spectroscopic properties of three further examples of the [Cu(dpyam)$_2$(OXO)]Y complexes, [Cu(dpyam)$_2$(NO$_2$)](NO$_2$) (**I**) and [Cu(dpyam)$_2$(O$_2$CH)]-(ClO$_4$) (**II**) and [Cu(dpyam)$_2$(ONO$_2$)](BF$_4$) (**III**) which consist of NO_2^-, O_2CH^- and NO_3^- oxoanions. Complex **III** is very rare case found with the nitrate oxoanion involved in the *cis*-distorted octahedral of this series and the purpose of this paper is to examine the electronic properties of this dpyam series in the context of fluxional behaviour [11].

2. Experimental

All reagents were commercial grade materials and were used without further purification. Elemental analyses (C, H and N) were performed by the Microanalytical Service of Science and Technological Research Equipment Centre, Chulalongkorn University on a Perkin–Elmer PE2400 CHNS/O Analyzer. The infrared spectra were recorded on a Spectrum One Perkin–Elmer FT-IR spectrophotometer as KBr pellets in the 4000–450 cm^{-1} region. Solid-state (diffuse reflectance) electronic spectra were recorded as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer over the range 8000–18 000 cm^{-1}. The X-band EPR spectra were recorded on polycrystalline samples at room temperature (r.t.) and liquid nitrogen temperature (77 K) with a JEOL EPR JES-RE2X spectrometer (operating at the X-band) by the service of Scientific and Technological Research Equipment Centre, Chulalongkorn University.

2.1. Preparation

2.1.1. Preparation of [Cu(dpyam)$_2$(ONO)](NO$_2$) (*I*)

2.1.1.1. Method a. An aqueous solution (10 ml) of Cu(O$_2$CCH$_3$)$_2$ · H$_2$O (0.090 g, 0.5 mmol) was added to a solution of dpyam (0.171 g, 1.0 mmol) in methanol (5 ml), followed by an aqueous solution (10 ml) of KNO$_2$ (0.085 g, 1.0 mmol) resulting green solution. On standing for a week, green crystals of **I** were formed. They were filtered off, washed with mother liquor and air-dried. Yield approximately 90%. *Anal.* Calc. for C$_{20}$H$_{18}$N$_8$CuO$_4$: C, 48.24; H, 3.64; N, 22.50. Found: C, 48.35; H, 3.54; N, 22.53%.

2.1.1.2. Method b. The aqueous solution (40 ml) of Cu(dpyam)(NO$_2$)$_2$] (0.33 g, 1.0 mmol) was refluxed with ca. 1 g copper metal sheet and extra dpyam (0.34 g, 2.0 mmol) under an atmosphere for 8 h. After evaporation at room temperature, green crystals of **I** were obtained as the reoxygenation product of copper metal reduction. Yield approximately 88%. The complex [Cu(dpyam)-(NO$_2$)$_2$] was prepared following the previous method [12].

2.1.2. Preparation of [Cu(dpyam)$_2$(O$_2$CH)](ClO$_4$) (*II*)

The complex **II** was prepared by adding an aqueous solution (10 ml) of Cu(ClO$_4$)$_2$ · 6H$_2$O (0.370 g, 1.0 mmol) to a solution of dpyam (0.171 g, 1.0 mmol) in methanol (20 ml) after which solid HCOONa (0.035 g, 0.5 mmol) was added. The green solution was slowly evaporated at room temperature. Green crystals of **II** were deposited after several days. Yield approximately 85%. *Anal.* Calc. for C$_{21}$H$_{19}$N$_6$CuO$_6$Cl: C, 45.82; H, 3.48; N, 15.27. Found: C, 45.75; H, 3.56; N, 15.22%.

2.1.3. Preparation of [Cu(dpyam)$_2$(ONO$_2$)](BF$_4$) (*III*)

A solution of dpyam (0.272 g, 2.0 mmol) in methanol (20 ml) was slowly added to an aqueous solution (20 ml) of Cu(NO$_3$)$_2$ · 2.5H$_2$O (0.232 g, 1.0 mmol) after which solid NaBF$_4$ (0.163 g, 1.5 mmol) was added resulting green solution. Dark green needle crystals of **III** were deposited after several days. Yield approximately 90%. *Anal.* Calc. for C$_{20}$H$_{18}$N$_7$CuO$_3$BF$_4$: C, 43.30; H, 3.27; N, 17.67. Found: C, 43.24; H, 3.20; N, 17.56%.

2.2. Crystallography

Reflection data for complexes **I**–**III** were collected at 293 K on a 1K Bruker SMART CCD area-detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of −35°. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0°, 88° and 180°) and each exposure of 30, 30 and 30 s for **I**, **II** and **III**, respectively, covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [13]. An empirical absorption correction by using the SADABS [14] program was applied, which resulted in transmission coefficients ranging from 0.793 to 1.000 for **I**, 0.807 to 1.000 for **II** and 0.827 to 1.000 for **III**. The structures were solved by direct methods and refined by full-matrix least-squares method on F^2_{obs} with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC V 6.12 [15] software package. All hydrogen atoms in **I**–**III** were located by difference synthesis and refined isotropically. All non-H atoms were refined anisotropically except the perchlorate, O(4A) atom in **II** and the tetrafluoroborate, F(3) atom in **III**. The nitrite anions in **I** and the perchlorate groups in **II** are disordered with site occupancies of 0.50, for both conformers. The tetrafluoroborate groups in **III** are also disordered with site occupancies of 0.45 and

0.55 for both conformers. The molecular graphics were created by using SHELXTL-PC. The crystal and refinement details for complexes **I**–**III** are listed in Table 1. Selected bond lengths and angles are given in Tables 2–4. Figs. 1, 2 and 3 illustrate the structures of **I**, **II** and **III**, respectively, and the atom numbering scheme used.

3. Results and discussion

3.1. Crystal structures

The crystal structures of **I**–**III** consist of discrete $[Cu(dpyam)_2(ONO)]^+$, $[Cu(dpyam)_2(O_2CH)]^+$ and

$[Cu\text{-}(dpyam)_2(ONO_2)]^+$ cations and a NO_2^-, ClO_4^- or BF_4^- anion, respectively.

The $[Cu(dpyam)_2(ONO)]^+$ cation in **I**, $[Cu(dpyam)_2(O_2CH)]^+$ in **II** and $[Cu(dpyam)_2(ONO_2)]^+$ cation in **III** involve a *cis*-distorted octahedral CuN_4O_2 chromophore with an asymmetrically coordinated nitrito group, formato group and nitrato group, respectively. The copper atom in all complexes is surrounded by four nitrogen atoms from two dpyam ligands and two oxygen atoms from the coordinated anion. A terminal nitrogen of each dpyam ligand occupies the axial direction while the remaining nitrogen atoms and the oxygen atoms from OXO^- anion occupies the equatorial positions. The CuN_4O_2 chromophore in **I** has a C_2-axis of symmetry bisecting the O(1)–Cu–O(2) and N(2)–Cu–N(5) angles, but with disorder of the coordinated nitrito group. Two conformers of the asymmetrically coordinated nitrito group in **I** retain site occupancies of 0.5. Compound **I** is the second example of [Cu(chelate)$_2$(OXO)]Y complexes, where chelate = 2,2′-bipyridyl, 1,10-phenanthroline and di-2-pyridylamine, and OXO^- = nitrito, formate, acetate and propionate, reported to involve an asymmetric *cis*-distorted octahedral CuN_4OO' chromophore, although there is a crystallographic C_2 symmetry present. The first one was found recently for the corresponding dpyam complex $[Cu(dpyam)_2(ONO)](NO_3)$ [9]. This was resulted from the marked disorder of the nitrito group, compared with the previous reported pseudo-regular *cis*-distorted octahedral CuN_4O_2 chromophore of the bpy and phen ligands [6,7,16] in which the ellipsoids of the oxoanion atoms represent the superposition of one asymmetric structure with relative contributions ranging from 1:1 for the 'symmetric' structures (i.e., those with average C_2 symmetries) to approximately 1:0 for the very asymmetric structures. This has demonstrated the nature of chelate ligands on the geometric distortion and consequently, on the fluxional behaviour of the copper chromophore.

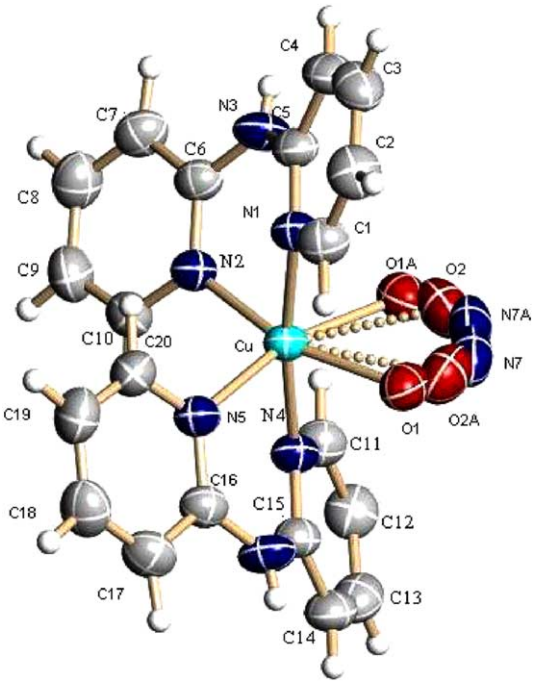

Fig. 1. The molecular structure of $[Cu(dpyam)_2(NO_2)](NO_2)$ (**I**).

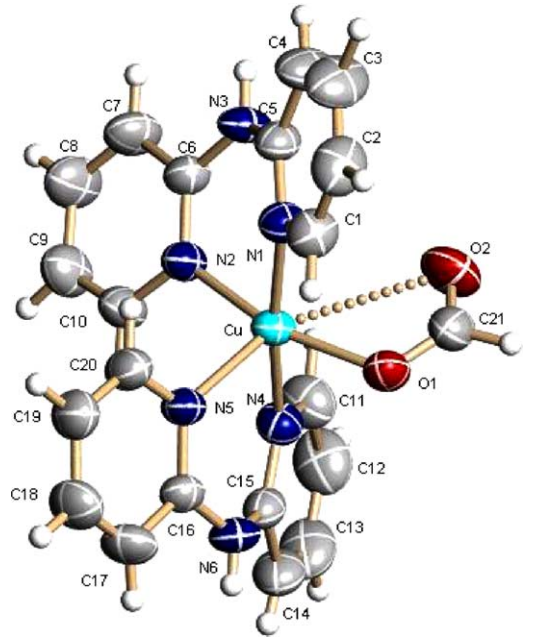

Fig. 2. The molecular structure of $[Cu(dpyam)_2(O_2CH)](ClO_4)$ (**II**).

The geometry of the CuN_4O_2 chromophore in **I**–**III** is basically five-coordinate with a second oxygen of the OXO^- anion occupying a sixth coordinating position at distance greater than 2.4 Å [2.487(2) Å for **I**, 2.892(3)Å for **II** and 2.659(3) Å for **III**] to give a $(4 + 1 + 1^*)$-type coordination.

The large O(1)–Cu–N(2) angles of 162.2(2)°, 162.8(2)° and 157.3(2)° for **I**, **II** and **III**, respectively, are

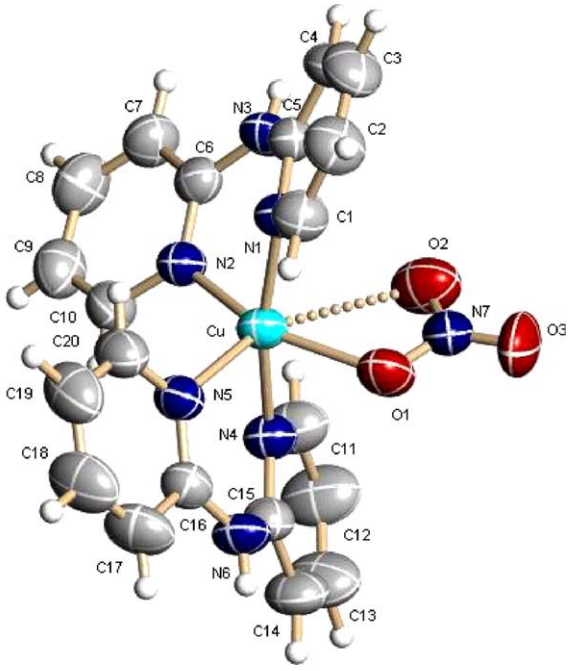

Fig. 3. The molecular structure of $[Cu(dpyam)_2(ONO_2)](BF_4)$ (**III**).

opposite the elongated Cu–N(5) direction. This could be taken as the basal angle of a square-based pyramidal geometry with elongation in the Cu–N(5) direction [17]. However, an exception case in the shorter Cu–N(5) distance compared to those of the basal plane is found in **I**. The Cu atom is displaced from the basal plane by 0.19 Å in **I**, 0.23 Å in **II** and 0.29 Å in **III**, in the direction of N(5) atom. The basal planes of three complexes also show a slight tetrahedral distortion from planarity (r.m.s.d 0.1102, 0.0685 and 0.1104 Å for **I**, **II** and **III**, respectively). The τ values ($\tau = [\{N(1)–Cu–N(4)\} - \{N(2)–Cu–O(1)\}]/60$) [18] are 0.16, 0.13 and 0.18 for **I**, **II** and **III**, respectively. All relatively close to that of a regular square pyramidal CuN_3ON' chromophore, $\tau = 0$. Hence, all structures are best described as a square pyramidal *cis*-distorted octahedral $(4 + 1 + 1^*)$, but being different in significant angular distortions. As the $\Delta O_{1,2}$ value of 0.879 Å in **II** is larger than that of 0.412 Å in **I** and 0.508 Å in **III**, **II** is more closely related to the static structure than **I** and **III**. The axial N–Cu–N angles in **I**, **II** and **III** are almost linear, 172.3(2)°, 170.5(3)° and 168.0(2)°, respectively.

The pyridine rings form dihedral angles of 28.7° in **I**, 26.2° and 25.2° in **II**, and 32.1° and 22.9° in **III** for the ligands defined by N(1)/N(2) and N(4)/N(5), respectively; the dpyam bite angles are 87.3(2)° for **I**, 88.1(2)° and 88.7(2)° for **II** and 88.6(2)° and 89.0(2)° for **III**.

The asymmetric bidentate nitrito group in **I** has no unusual bond lengths and angles, the N–O(1) distance (1.273(6) Å) involving the stronger Cu···O(1) interaction is longer than the N–O(2) distance (1.237(8) Å) involving the weaker Cu···O(2) interaction, consistent

with the more single-bond character in the N–O(1) distance. The mean N–O distance of 1.255 Å in **I**, of the nitrite group is not significant different from the 1.236 Å for the free nitrite ion, but O(1)–N–O(2) angle of 110.9(8)° in **I** is significant smaller than the 115.4° of the free ion [8,19]. The O(1)–Cu–O(2) bond angle of 52.9(2)° in **I**, agrees well with the value previously reported for the bite angle of the coordinated nitrito group found in the [Cu(chelate)$_2$(ONO)]Y complexes [20]. The Cu–O(1)–N(7) angle (107.7(6)° for **I**) is also between the value of 119.5° for the purely monodentate nitrite [21] and 93°–100° for the purely bidentate nitrite [22]. The binding mode of the nitrito group in this complex system was well investigated [20] and found that the O(1)–Cu–O(2) and O(1)–N–O(2) angles are effectively independent of the nitrito coordination mode, but clearly

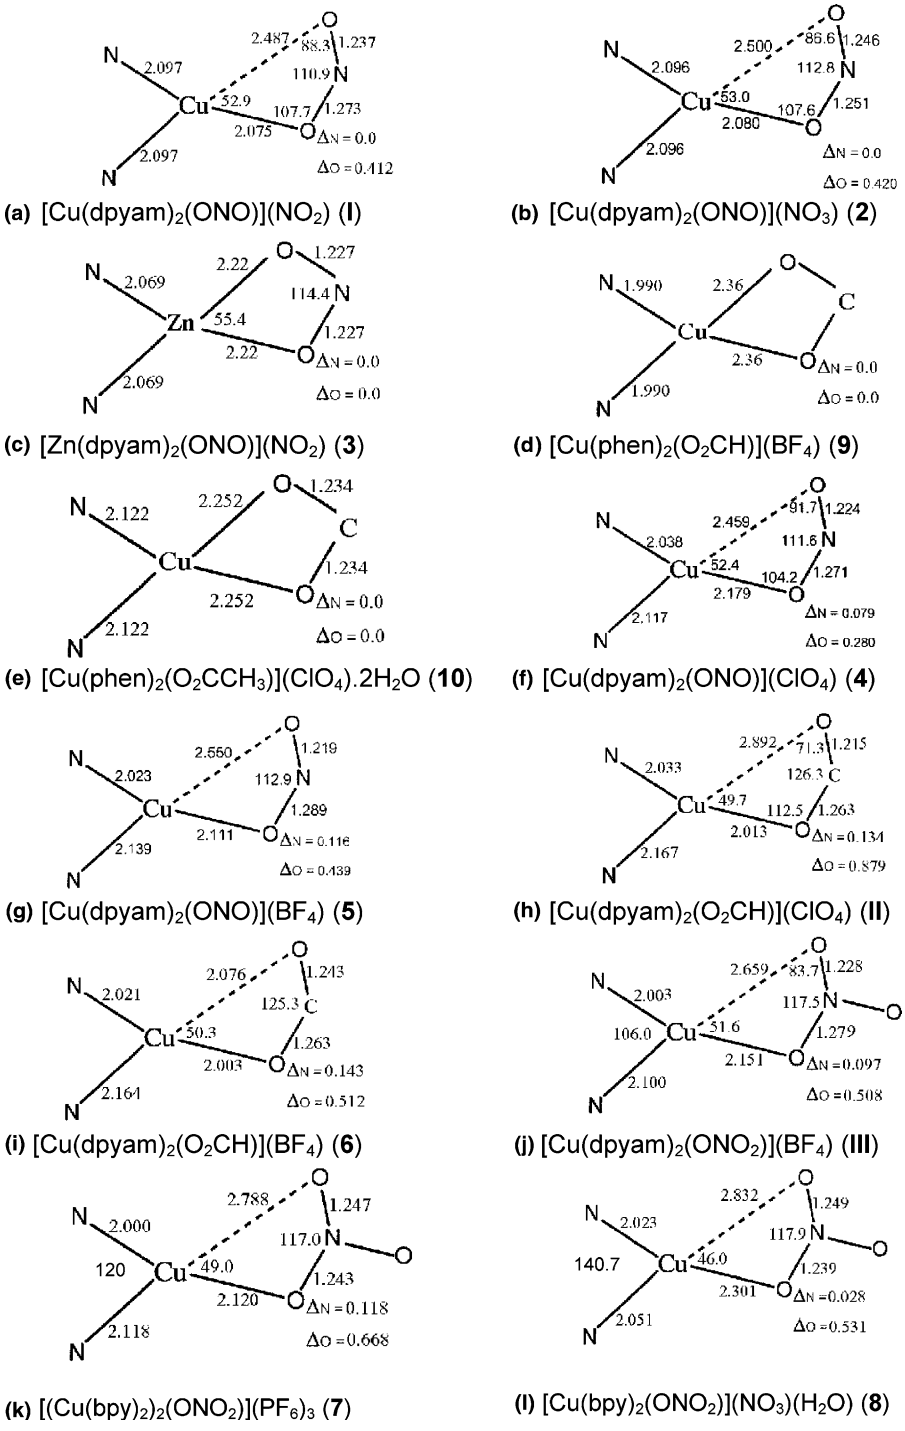

Fig. 4. Comparison of [M(chelate)$_2$(OXO)]$^+$ coordination geometries.

dependent to the Cu–O(1)–N angle. By using the correlations applied for **I**, the binding mode of the nitrito group in this complex is intermediate between monodentate and bidentate coordination.

The coordinated formato group for **II** gives asymmetric C–O distances with the C(21)–O(1) and C(21)–O(2) values of 1.263(3) and 1.215(3) Å, respectively, this is not significant different from the previous reported for coordinated carboxylato group having the C–O distance of 1.236–1.286 Å. The O–C–O angle of 126.3(3)° is usually observed in the previous reported (ranging 122.2°–126.2°) [10,23–25].

The rarely found, coordinated nitrato group in the *cis*-distorted octahedral geometry in **III** involves reasonable N–O bond lengths, mean 1.253 Å with considerable disorder in an uncoordinated O(3) atom to give a slight distortion of the N(7)–O(3A) and N(7)–O(3B) distances of 1.240(5) and 1.229(5) Å, respectively. The N–O distances of 1.279(4) and 1.228(4) Å and the O–N–O angle of 117.5(3)° which involve the coordinated O atoms are in good agreement with the values of 1.245 Å and 119.9° generally quoted for the free nitrate ion [26]. The N(7)–O(1) distance is longer than N(7)–O(2), consistent with the stronger Cu–O(1) than the Cu–O(2) bond. There is however, a significant deviation of the uncoordinated O–N–O angles from those usually found for the unsymmetrically coordinated [27] or free nitrate group [9,26]. This arises due to disorder in an uncoordinated O atom and the involvement of this uncoordinated O atom in the hydrogen bonding.

The lattice structures are stabilized by moderate to weak hydrogen bonding N–H···O(NO_2) and N–H···N(NO_2) hydrogen bonds in **I**; N–H···O(HCO_2) and N–H···O(ClO_4) hydrogen bonds in **II** and N–H···O(NO_3) and N–H···F(BF_4) hydrogen bonds in **III**]. Details of the hydrogen bondings are given in Table 6.

3.2. Structure comparison

The structures of **I**–**III** are clearly different from the equally elongated rhombic-octahedral (4 + 2) chromophore in [Cu(bpy)$_2$(S_3O_6)] [28] and [Cu(bpy)$_2$(S_4O_6)] [29] and the unequally elongated rhombic-octahedral (4 + 1 + 1*) chromophore of [Cu(bpy)$_2$(O_2ClO_2)](ClO_4) [30]. There is some similarity to the pseudo-symmetric *cis*-distorted octahedral geometries of [Cu(phen)$_2$-(O_2CMe)]Y, Y = $ClO_4^- \cdot 2H_2O$, $BF_4^- \cdot 2H_2O$ [6,7] and [Cu(phen)$_2$(HCO_2)]Y, Y = BF_4^- and ClO_4^- [2,16] with two Cu–O distances of 2.26–2.36 Å, Figs. 4(d) and (e). This geometry is typical for this complex system involving C_2 symmetric OXO group. There is a closer similarity to the [Cu(dpyam)$_2$(OXO)]$^+$ cations, where OXO^- = formate [10], acetate [10,25], propionate [31,32] and nitrite [8,9,31], all of which having a (4 + 1 + 1*)-

type coordination of the square pyramidal *cis*-distorted octahedral CuN_4OO' chromophore with the Cu–O(2) > 2.4 Å and the ΔO > 0.4 Å. From these dpyam complexes, the [Cu(dpyam)$_2$(ONO)](NO$_3$) (**2**) [9], with ΔO = 0.420 Å, Fig. 4 and Table 5, has the most similarity in distorted geometry to that of **I**, ΔO = 0.412 Å, while [Cu(dpyam)$_2$(O$_2$CH)](BF$_4$) (**6**) [10], with ΔO = 0.873 Å, Fig. 4 and Table 5, has the most similarity in distorted geometry to that of **II**, ΔO = 0.879 Å. The structure of **1**, Table 5, was first determined by Hathaway and co-workers [33,34] (1980, room temperature, visually estimated intensities) involving an average C_2 symmetry. The structure was classified as regular *cis*-distorted octahedral of fluxional CuN_4O_2 chromophore, but with an unsymmetrically coordinated nitrito group and an unacceptable high value of the O–N–O angle of 118.6° [8,20]. The detailed structural data for this compound have not been reported in the literature. Hence, the structural redetermination and a closer examination in the present work as compound **I** have confirmed that this structure should be described as a nearly static structure of an asymmetric *cis*-distorted octahedral geometry, comparable to that of **2** with ΔO = 0.420 Å, both of which involve disorder of the coordination ONO group with the static C_2 symmetry.

The nitrate complex **III** is unique and found to be the first example for the [Cu(chelate)$_2$(ONO$_2$)]Y type complex adopting an asymmetric *cis*-distorted octahedral $4+1+1^*$ geometry. When compared with the other $4+1+1^*$ distorted complexes [6,8], the present chromophore in **III** is in good agreement to that of the *cis*-distorted octahedral geometry having [Cu(chelate)$_2$(OXO)]$^+$ cation [2].The N(2)–Cu–N(5) angle of 106.1(2)° and O(1)–Cu–O(2) angle of 51.6(2)° are in usual range of 96°–113° and 50–54° found in this type of complexes, Fig. 4 and Table 5. There are only two other related nitrate complexes, [(Cu(bpy)$_2$)$_2$(ONO$_2$)](PF$_6$)$_3$ (**7**) [35] and [Cu(bpy)$_2$(ONO$_2$)](NO$_3$)(H$_2$O) (**8**) [36] previously studied, are known in the [Cu(chelate)$_2$(ONO$_2$)]Y type complexes. However, the latter adopts an asymmetrical bicapped square-pyramidal structure while the former exhibits an intermediate geometry between the asymmetric *cis*-distorted octahedral $4+1+1^*$ and the asymmetrical bicapped square-pyramidal structure, indicated following the classification of Hathaway, which based on the types of distortion from the regular *cis*-distorted geometry [36]. These complexes involve the N(2)–Cu–N(5) angle remarkably larger than 113° (140.7° for **8** and 120° for **7**) and the O(1)–Cu–O(2) angle smaller than 50° (46.0° for **8** and 49.0° for **7**).

In conclusion, the series of complexes **I**, **4**, **2**, **5** and **1**, Fig. 4 and Table 5, represent a sequence of cation distortion isomers of increasing asymmetry. The CuN_4O_2 chromophore in **I** shows significant differences from the ordered [Zn(dpyam)$_2$(ONO)]$^+$ cation of **3** [8,20], Fig. 4 and Table 5, which has static C_2 symmetry. The coordination geometries of the corresponding [Cu(chelate)$_2$(OXO)]$^+$ cations, where chelate = bpy, phen or dpyam are compared with those of the title complexes as in Fig. 4.

3.3. Spectroscopic properties

3.3.1. EPR spectra

The polycrystalline EPR spectra of **I** are isotropic at both room temperature and liquid nitrogen temperature (77 K) with $g_i = 2.165$ and 2.163, respectively, giving no information regarding to the electronic ground state and no information indicative to the fluxional behaviour [1], due to the misalignment of the CuN_4OO' chromophore. In **II**, the room temperature spectrum is isotropic with $g_i = 2.132$, with lowering the temperature to liquid nitrogen temperature the spectrum is more resolved and found to be axial [1] with $g_{\|} \approx 2.417$ and $g_{\perp} = 2.078$. In

III, the room temperature spectrum is nearly axial [1] with $g_{\|} \approx 2.314$ and $g_{\perp} = 2.093$, with decreasing the temperature to liquid nitrogen temperature the spectrum is more resolved and found to be nearly rhombic with $g_1 \approx 2.012$, $g_2 = 2.089$ and $g_3 = 2.228$, consistent with the $d_{x^2-y^2}$ ground state of a square-pyramidal *cis*-distorted octahedral CuN_4O_2 chromophore present for both complexes [2,23,37]. However, a change in EPR spectra of **II** and **III** arises due to the more resolved feature at low temperature, not due to the fluxional behaviour observed. Moreover, these complexes exhibit the high asymmetry in geometry. These suggest that a nearly static CuN_4O_2 chromophore is favourable for all three complexes.

This suggestion is supported by the non-variable-temperature (at room temperature and liquid nitrogen temperature) EPR spectra of the corresponding complexes **6**, **2** and **4** complexes [9,25] in which their structures were suggested to be near static distortion limit of the fluxional CuN_4O_2 chromophore. However, although the EPR spectra seemed to support a nearly static and a very asymmetric *cis*-distorted octahedral geometry in this dpyam system, single-crystal X-ray diffraction studies carried out at very much low temperatures are needed for the $[Cu(dpyam)_2(OXO)]Y$ complexes to prove significant changes in the bond lengths of the fluxional CuN_4O_2 chromophore, especially for the more symmetrical structures. As the more symmetrical structure is actually interconverting asymmetric structures give average, not static, C_2 structure [2]. The sensitivity of the coordination mode to temperature suggests the small difference in energy between the two conformers (extreme geometries) [2].

3.3.2. Electronic spectra

The electronic spectra of complexes **I**–**III** consist of two clearly resolved peaks with almost equal intensity at approximately 14 570 and 10 000 cm^{-1} for **I**, 14 450 and 10 050 cm^{-1} for **II** and 14 950 and 10 200 cm^{-1} for **III**, similar to those previously reported for $[Cu(chelate)_2(OXO)]Y$ complexes involving the *cis*-distorted octahedral CuN_4O_2 chromophore. The slight difference in electronic spectra of this series is due to the nearly comparable distortion of the extreme stereochemistries of the underlying static $(4 + 1 + 1^*)$ CuN_4O_2 chromophores in **I**–**III**. This arises due to the different lattice environments of the $[Cu(dpyam)_2(OXO)]^+$ cations in this series, as a consequence of the 'plasticity effects' [38,39]. The one electron energy sequence of the Cu(II) ion in the asymmetrically distorted CuN_4O_2 geometry of **I**–**III** is approximately the same as that predicted for the square-based pyramidal geometry, namely $d_{x^2-y^2} > d_{z^2} > d_{xy} > d_{xz} \approx d_{yz}$. The highest energy bands at 14 570 cm^{-1} for **I**, 14 450 cm^{-1} for **II** and 14 950 cm^{-1} for **III** may be tentatively assigned as the d_{xy}, $d_{yz} \approx d_{zx} \rightarrow d_{x^2-y^2}$ and the bands at 10 000 cm^{-1} for **I**, 10 050 cm^{-1} for **II** and 10 200 cm^{-1} for **III** as $d_{z^2} \rightarrow d_{x^2-y^2}$ transitions.

3.3.3. Infrared spectra

The most relevant feature of the infrared spectra in **I** is the evidence for the chelating nitrito coordination. It is clear that the position of IR bands distinguishes between nitro and nitrito coordination [40], but it is not possible to distinguish the symmetrical from asymmetrical bidentate nitrito coordination present in these complexes. On the basis of the structure found and a comparison with spectra of related complexes, the IR spectra of **I**–**III** have been tentatively assigned. The IR spectrum of the nitrito group in **I** appears at 1365, 1150 and 840 cm^{-1} corresponding to the $\nu_{as}(NO_2)$, $\nu_s(NO_2)$ and $\delta(NO_2)$ absorption bands, respectively. That of **II** shows bands at 1585_s and 1420, $\nu_{as}(COO)$ and $\nu_s(COO)$, respectively, a medium intensity band at 1090 and 1120 cm^{-1} is masked by a broad and strong band of ClO_4^- ion [9]. The IR spectrum of **III** shows bands at 1386_m, $\nu_{as}(NO_3)$; 1310_m, $\nu_s(NO_3)$ and 650_w, $\delta(NO_3)$, a medium intensity band at 1096 and 1020 cm^{-1} is masked by a broad and strong band of BF_4^- ion [2,7,9].

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-230772–230774 for structures **I**–**III**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) +44-1223-336-033, E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk].

Abstract

A new binuclear complex $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$, where bipy = 2,2′-bipyridine and $Me(OCH_2)Npy$ = *N*-methyl-*N*-methoxy-2pyridinamine, has been synthesized and characterized by chemical analysis, conductance measurements and IR and electronic spectroscopies. The X-ray crystal structure shows a distorted square-planar pyramidal coordination for Cu(II), determinated by two nitrogen atoms of bipy and two methoxo oxygen atoms in the equatorial plane and the pyridinic nitrogen atom of the ligand in the axial position. Magnetic susceptibility measurements (in the 2–290 K range) reveal a slightly antiferromagnetic character ($2J = -3.6$ cm^{-1}). In the Q-band EPR spectrum signals of triplet ($D > hv$) are observed.

1. Introduction

The magnetic aspects of dinuclear Cu(II) complexes, $[\{Cu(NN)(\mu\text{-}OH)\}_2]X_2$, with NN = bidentate nitrogen ligand, have been intensively studied since the magnetostructural correlations described by Hatfield et al. [1] for planar dimers of Cu(II) with the Cu_2O_2 group. More recently, these correlations have been extended and theoretically justified by Ruiz et al. [2,3].

The 2-anilinopyridine, (*N*-phenyl-2-pyridinamine, PhNHpy), is an asymmetric ligand, with two nitrogen atoms in 1,3 positions, which can coordinate as monodentate or bidentate. As monodentate ligand the coordination is established through the pyridinic nitrogen and as anionic bidentate through both nitrogen atoms [4,5].

In previous papers, we described the interaction between $[\{Cu(bipy)\}_2(\mu\text{-}OH)_2]X_2 \cdot xH_2O$ dimers, where $X^- = PF_6^-$, ClO_4^-, and the ligand PhNHpy. With the hexaflourophosphate complex, the compound $[\{Cu(bipy)(PhNHpy)\}_2(\mu\text{-}OH)_2](PF_6)_2$ was formed [6]. Each PhNHpy molecule was coordinated to a copper atom through the piridinic nitrogen atom and the hydrogen bonded to the anilinic nitrogen is involved in an hydrogen bond with the oxygen atom of a bridging OH group. In the case of the perchlorate compound, a methylene group was inserted between the anilinic nitrogen atom of the ligand and the bridging oxygen, and the $[\{Cu(bipy)\}_2\{\mu\text{-}Ph(OCH_2)Npy\}_2](ClO_4)_2$ was formed [7].

In the present work, we describe the interaction between MeNHpy and the $[\{Cu(bipy)\}_2(\mu\text{-}OH)_2](PF_6)_2 \cdot 2H_2O$ dimer. In this case, unlike the result obtained with PhNHpy and the hexafluorophosphate, the

doi:10.1016/j.poly.2004.04.013

methylene group is also inserted, and the $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$ is obtained.

2. Experimental

2.1. Synthesis

$[\{Cu(bipy)\}_2(\mu\text{-}OH)_2](PF_6)_2 \cdot 2H_2O$ was prepared according to Harris et al. [8]. The anionic form of MeNHpy was prepared, in situ. The ligand was dissolved in abs ethanol (5 ml) and metallic sodium, in stoichiometric proportion, was added. The mixture was allowed to stand 10 m before using it [9].

$[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$: a solution of $MeNpy^-$ (0.1 ml, 1 mmol) in abs ethanol (5 ml) was slowly added to a solution of $[\{Cu(bipy)\}_2(\mu\text{-}OH)_2](PF_6)_2 \cdot 2H_2O$ (0.2 g, 0.25 mmol) in methanol (80 ml). The brown mixture was refluxed during 3 h. After a time of stirring without heating until cooling to room temperature, it was again refluxed for 3 h. This process was repeated until the solution becomes green in colour. The solution was concentrated and a blue precipitate was filtered off. The green filtrate was evaporated until the formation of green crystals. These were filtered off and washed with ether. The compound was soluble in acetonitrile, methanol and nitromethane.

Yield: 25%. Elemental *Anal.* Calc. for $C_{34}Cu_2F_{12}H_{34}N_8O_2P_2$: C, 40.7; H, 3.4; N, 11.2. Found: C, 40.6; H, 3.9; N, 11.0%.

2.2. Physical measurements

C, H and N were analysed in a Leco 932-CHNS Elemental Analyzer. Conductivity measurements were made using a Metrhom E518 conductimeter. IR spectra were recorded on a Nicolet FT-IR 510 spectrometer in the range 4000–400 cm^{-1} using KBr pellets. Electronic spectra were recorded on a Schimadzu UV-265 FW spectrophotometer.

Magnetic measurements were carried out in the 300–2 K range with a magnetometer SQUID MPMS XL (Quantum Design). Diamagnetic corrections have been applied [10]. The EPR spectra were recorded on a Bruker ESP 300 spectrometer with a Bruker ER 035 M gaussmeter, Oxford ITC4 cryostat and HP 5325B frequency counter.

2.3. Crystal structure determination

The X-ray diffraction data for $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$ were collected for a prismatic green crystal on a Bruker Smart CCD diffractometer, with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation, at 296 K. A summary of the fundamental crystal data and refinement parameters are given in Table 1. Data were collected over an hemisphere of the reciprocal space by combination of the three exposure sets. Each exposure of 20 covered 0.3 in ω. The first 50 frames were recollected at the end of the data collection to monitor crystal decay. No appreciable drop in the intensities of standard reflections was observed.

Final R^a indices [$I > 2\sigma(I)$]	$R_1 = 0.0575$ (4261 observed reflections)
R^b indices (all data)	$wR_2 = 0.1694$

[a] $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2] / \sum[w(F_o^2)^2]\}^{1/2}$.

The structure was solved by Patterson (Cu atoms) and conventional Fourier techniques and refined by full-matrix least-squares on F^2 [11]. The fluoro atoms of the hexafluorophosphate groups were refined only two cycles anisotropically and in the last cycle the thermal factors has been fixed. The rest of the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in calculated positions and refined riding on the respective carbon atoms.

3. Results and discussion

3.1. Characterization

The molar conductivity of the complex in acetonitrile (285.7 Ω^{-1} cm^2 mol^{-1}) corresponds to a 2:1 elec-

trolyte [12], according to the dimeric character of the cations.

Unlike the $[\{Cu(bipy)(PhNHpy)\}_2(\mu\text{-}OH)_2](PF_6)_2$ complex [6], the IR spectrum does not show the stretching ν(O–H) and ν(N–H) bands. The ν(Cu–O) band shifts to higher frequency (491 cm^{-1}) to the original dimer $[\{Cu(bipy)\}_2(\mu\text{-}OH)_2](PF_6)_2 \cdot 2H_2O$ (487 cm^{-1}) [13].

The electronic spectra of the solution in acetonitrile exhibits, besides the ligands bands, the d-d band of Cu(II) at 638 nm ($\varepsilon_{max} = 1451$ cm^{-1} mol^{-1}).

3.2. Crystal structure

The compound $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$ consists of $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2]^{2+}$ divalent cationic dimers and $(PF_6)^-$ anions. The asymmetrical units contains two chemically identical, but crystallographically different, dimers with very slight differences. The centrosymmetric dimers consist of two sections, composed each of them, by a slightly bent bipy molecule and a $[Me(OCH_2)Npy]^-$ group bonded to a copper atom through the pyridinic nitrogen atom and to the both copper atoms through the oxygen atom. Two of such sections are linked together by the two oxygen bridges, across a centre of symmetry. Fig. 1 shows an ORTEP view of the geometry of one cation (dimer 1) with 35% probability ellipsoids. The $(PF_6)^-$ group and hydrogen atoms have been omitted for clarity. Selected interatomic distances and angles are listed in Table 2 for the two dimers.

Each copper atom has a distorted square-planar pyramidal coordination (trigonality index [14], $\tau = 0.42$) with Cu(1)–O(1) and Cu(1)–O(1A) distances of 1.926(3) and 1.984(3) Å; Cu(1)–N(1) and Cu(1)–N(2) distances of 1.987(4) and 2.018(4) Å. The fifth distance, Cu(1)–N(3), is larger, 2.296(5) Å . The copper atom rises from the basal plane to the apical N(3) by 0.308(2) Å . The Cu_2O_2 group is planar, with average angles for the two dimers of 83.2(2)° in Cu and 96.9(2)° in O atom. The Cu–O distances are asymmetrical, being the shortest that which closes the CuNCNCO ring. The Cu(1)···Cu(1A) and O(1)···O(1A) separation are 2.923(1) and 1.984(3) Å . All these results are very similar to those found for $[\{Cu(bipy)\}_2\{\mu\text{-}Ph(OCH_2)Npy\}_2](ClO_4)_2$ [7]. The bipyridine molecule are slightly bent; the angle formed by the two planar pyridyl groups being significatively different in the two dimers: 1.3° in dimer 1 and 6.4° in dimer 2.

As in $[\{Cu(bipy)\}_2\{\mu\text{-}Ph(OCH_2)Npy\}_2](ClO_4)_2$, the nitrogen atom of the reaction ligand, MeNHpy in this case, bonded to the copper atom is that belonging to the pyridine ring, N(3), and the nitrogen atom, N(4) (bonded to a methyl and to a pyridine groups) has lost its hydrogen atom to form a N–C bond with C(16). This C(16) atom is bonded to the bridging oxygen atom,

O(1). A CH_2 group is inserted between N and O. The N(4)–C(16) and C(16)–O(1) distances agree with the bond length for simple covalent bonds between these elements.

Fig. 2 shows the crystal structure of the complex viewed along the *a*-axis.

3.3. Magnetic results

The variable temperature magnetic susceptibility data have been measured in the 2–300 K temperature range. The plot of $\chi_M T$ per 2Cu(II) versus temperature is shown in Fig. 3. The $\chi_M T$ value is approximately constant (0.80 cm^3 K mol^{-1}; $\mu_{eff} = 1.79\ \mu_B$) in the range 300–50 K. Below this temperature, $\chi_M T$ decreases until 0.34 cm^3 K mol^{-1} at 2 K ($\mu_{eff} = 1.17\ \mu_B$), indicating an antiferromagnetic intradimeric interaction. The data were fitted to the Bleaney–Bowers equation modified by the inclusion of the fraction of monomeric impurity [15]: $\chi_M = [C e^x(1-\rho)/(1+3e^x)] + C\rho/4$, where $C = Ng^2\beta^2/kT$, $x = 2J/kT$, ρ is the fraction of monomeric impurity.

The fitting results were $2J = -3.6$ cm^{-1}, $g = 2.07$ and $\rho = 0.025$. This slight antiferromagnetism is intermediate between the ferromagnetism ($2J = 10$ cm^{-1}) of [{Cu(bipy)}$_2${μ-Ph(OCH$_2$)Npy}$_2$](ClO$_4$)$_2$ and the antiferromagnetism ($2J = -98$ cm^{-1}) of [{Cu(phen)}$_2${μ-Ph(OCH$_2$)Npy}$_2$](ClO$_4$)$_2$ [7]. The magnetic results and significant structural data of these compounds are collected in Table 3.

The correlation deduced by Hatfield et al. [1] between $2J$ and θ (bridging angle CuOCu) for di-μ-hydroxo planar copper dimers: $2J$ (cm^{-1}) $= -74.53\theta + 7270$ predicts ferromagnetism for $\theta < 97.5°$ and antiferromagntism for $\theta > 97.5°$. Ruiz et al. [2,3] studied the effect of other structural parameters for copper dimers with hydroxo and alkoxo bridges. These are, besides θ, the angle τ, formed between the O–O direction and the hydrogen or carbon atom bounded to the bridging oxygen atom, and the non-planarity of the Cu_2O_2 group, measured by γ (Fig. 4). High τ values are associated with lower values of θ and correspond to $2J$ more positive (ferromagnetism). For $\theta < 97.5°$ and $\tau > 40°$ a ferromagnetic effect is to be expected. The non-planarity of the Cu_2O_2 group (γ) reduces the antiferromagnetic character and enhances the influence of τ.

The data collected in Table 3 indicate that the magnetostructural correlations for copper dimers with hydroxo and alkoxo bridges are not directly applicable to theses complexes where the Cu_2O_2 group is altered by the coordinated ligand which closes a ring CuNCNCO. They are variations in the structural factors near the limit between ferro- and antiferromagnetic interaction.

3.4. EPR spectra

The X-band EPR spectrum of the powdered sample shows four signals: three derived from the triplet state

Table 3
Magnetic results and significant structural data

	Compound **1**	Compound **2**	Compound **3**
$2J$ (cm^{-1})	−3.6	10	−98
d_{Cu-Cu} (Å)	2.935	2.974	2.952
$d_{Cu-basal\ plane}$ (Å)	0.308	0.305	0.357
θ (°)	96.9	97.8	98.3
τ (°)	61.5	62.0	48.7
γ (°)	0	0	0
$2J(\theta)$[a] (cm^{-1})	48	−19	−56

Compound **1**: [{Cu(bipy)}2{μ-Me(OCH$_2$)Npy}$_2$](PF$_6$)$_2$ (this work). Compound **2**: [{Cu(bipy)}$_2${μ-Ph(OCH$_2$)Npy}$_2$](ClO$_4$)$_2$ [7]. Compound **3**: [{Cu(phen)}$_2${μ-Ph(OCH$_2$)Npy}$_2$](ClO$_4$)$_2$ [7].

[a] Calculated from $2J(\theta) = (-74.53\theta + 7270)$ cm^{-1}.

($H = 1715$, 6333 and 8285 G) and one ($H = 3315$ G) connected with the noncoupled copper.

The spectrum is similar to those observed for other copper dimers with $D > h\nu$ (D is the zero field splitting parameter) [6,7]. As it is observed for some cases, is not possible to analyse the spectra with the Wasserman et al. [16] equations for triplet state; it is not possible to do assignations corresponding to reasonable values of parameter g.

At Q-band an absorption at zero field is observed, in agreement with the condition $D > h\nu$ ($D > 1.14$ cm^{-1}).

4. Supplementary material

Further structural data have been deposited with the Cambridge Crystallographic Data Centre, CCDC 215374. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1233-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Isomorphous complexes Zn(dmid)(phen)$_2$ (**1**) and Cd(dmid)(phen)$_2$ (**2**) have been synthesized through a ligand substitute reaction. Their structures and properties have been characterized by elemental analysis, IR, UV–Vis, fluorescence and single-crystal X-ray analysis. The octahedral N_4S_2 coordination geometry, bonding, electronic structure and IR spectra of the Zn(dmid)(phen)$_2$ molecule were studied in detail using DFT and INDO/S methods. In the crystal packing, there exists a strong π–π interaction between two parallel 1,10-phenanthrolines of adjacent molecules. Complex **1** (or **2**) in the solid state exhibits an intensive fluorescence band at 539.5 nm (or 536 nm) when the excitation wavelength is 371 nm (or 370.5 nm) at room temperature.

1. Introduction

Over the past decade, dithiolene metal complexes of multi-sulfur donor ligands have attracted much interest because of their potential applications as molecular conductors, superconductors and molecular photo-devices [1,2]. Among them, metal complexes of dmit (dmit = 1,3-dithiole-2-thione-4,5-dithiolate) have been extensively investigated [3]. Through converting the thione group of the dmit ligand into a ketone group, dmid (2-oxo-1,3-dithiole-4,5-dithiolate) can be obtained. The replacement of sulfur atoms by oxygen atoms on the periphery of the ligand changes the properties of the complexes in two ways [4]: (1) the change in intermolecular interactions due to the replacement of S···S by O···O, (2) the change of electron distribution in the HOMO due to the more electronegative oxygen atoms, which do affect the intermolecular bonding and intermolecular interactions. However, metal complexes with dmid have not been studied so widely in comparison with dmit complexes, although the former have been shown to exhibit some unique properties such as electrical switching and memory function [5].

In our laboratory complexes containing both dmid and phen ligands are studied in an effort to prepare complexes with unique geometries and special physical properties. As examples of such complexes, Zn(dmid)(phen)$_2$ (**1**) and Cd(dmid)(phen)$_2$ (**2**) have been synthesized, and their crystal structures, IR spectra, UV–Vis and fluorescence are investigated in this work. To the best of our knowledge, **1** and **2** are the first two examples of mixed-ligand neutral complexes of dmid.

2. Experimental

All solvents were dried and distilled using standard methods. Reagents were obtained from commercial sources and were used without further purification. Complexes $(NEt_4)_2[Zn(dmid)_2]$ and $(NEt_4)_2[Cd(dmid)_2]$ were synthesized according to the literature procedure [6].

Elemental analysis was carried out on a Perkin–Elmer 2400|CHNSO elemental analyzer. The contents of Zn and Cd were measured through EDTA titration. The thermal analyses were performed with a Perkin–Elmer TGS-Z thermogravimetril analyzer in the range of 40–830 °C. The IR spectra were recorded with a Nicolet 170SX FT-IR spectrometer in the region 400–4000 cm^{-1} (KBr pellets). Electronic spectra were performed on a Shimadzu UV-240 spectrometer over the range of 200–700 nm. The spectra of fluorescent emission were performed on Perkin–Elmer LS 55 luminescence spectrometer in the range of 200–700 nm.

2.1. Synthesis

2.1.1. Zn(dmid)(phen)$_2$ (**1**)

Complex **1** was prepared through a ligand substitute reaction according to the following procedure. A solution of $(NEt_4)_2[Zn(dmid)_2]$ (1 mmol, 0.686 g) in 30 ml acetone was added cautiously to a solution of phen (3 mmol) in 30 ml DMF to form two clear layers in a test tube. The test tube was then allowed to stand undisturbed at room temperature for seven days without illumination, and then the red crystals of Zn(dmid)(phen)$_2$ suitable for single-crystal X-ray diffraction were obtained (0.560 g, 92% based on $(NEt_4)_2[Zn(dmid)_2]$). *Anal*. Calc. for $C_{27}H_{16}N_4OS_4Zn$: C, 53.51; H, 2.66; N, 9.24; Zn, 10.79. Found: C, 53.78; H, 2.66; N, 9.15; Zn, 10.88%. IR (KBr pellets, cm^{-1}): 1786(w), 1654(s), 1608(vs), 1512(s), 1492(w), 1446(s), 1422(vs), 1341(m), 1321(w), 1302(w), 1220(w), 1140(m), 1099(m), 974(w), 894(m), 865(m), 846(vs), 770(m), 728(s), 636(m).

2.1.2. Cd(dmid)(phen)$_2$ (**2**)

The crystals of complex **2** were prepared as described for **1** except using $(NEt_4)_2[Cd(dmid)_2]$ instead of $(NEt_4)_2[Zn(dmid)_2]$ (yield: 94%, based on $(NEt_4)_2[Cd(dmid)_2]$). *Anal*. Calc. for $C_{27}H_{16}CdN_4OS_4$: C, 49.66; H, 2.47; N, 8.57; Cd, 17.21. Found: C, 49.97; H, 2.48; N, 8.53; Cd, 17.52%. IR (KBr pellets, cm^{-1}): 1788(w), 1656(s), 1610(vs), 1512(s), 1493(w), 1441(s), 1424(vs), 1340(m), 1319(w), 1300(w), 1219(w), 1142(m), 1098(m), 968(w), 895(m), 846(vs), 771(m), 728(s), 636(m).

2.2. Theoretical calculation

All theoretical calculations were performed on a Pentium IV 1.72 GHz (80 GB, 512 MB) computer. The calculations of geometry optimization and vibrational frequencies of the gaseous Zn(dmid)(phen)$_2$ were carried out by using the B3LYP method of density functional theory with the 6-31G* basis set in GAUSSIAN-98 [7]. The calculations of electronic absorption spectra of Zn(dmid)(phen)$_2$ in the gaseous state were performed using the configuration interaction (CI) by the INDO/S method in HYPERCHEM [8]. The configuration number of CI was established by the numbers of the HOMO ($n_{OO} = 8$) and LUMO ($n_{UO} = 12$).

2.3. Crystal structure determination

The crystal data, structure solution and refinement details for the two structures determined are presented in Table 1. Relevant bond distances and bond angles for **1** and **2** are collected in Tables 2 and 3. Suitable single

crystals were mounted for data collection on a Rigaku R-axis IV equipped with Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined by a full-matrix least-squares technique procedure using anisotropic displacement parameters. All hydrogen atoms were located from difference Fourier maps, placed at calculated positions (C–H: 0.93–0.97 Å) and refined isotropically using a riding model.

3. Results and discussion

3.1. Crystal and molecular structures

Complex **1** consists of discrete molecules with a N_4S_2 six-coordinate zinc center with octahedral geometry. The metal atom is coordinated to four nitrogen atoms from two phen, and two sulfur atoms from dmid (Fig. 1). Both of the phen and dmid ligands are quite planar. The planes of the two phen ligands in complex **1** are nearly perpendicular to each other with a dihedral angle of 89.8°. The dihedral angles between the plane of dmid and the plane of phen1 (C1–C12) and of phen2 (C13–C24) are 91.5° and 105°, respectively. There are no abnormal carbon–nitrogen, carbon–sulfur or carbon–carbon bond lengths.

Through an inversion center, the plane of the phen1 (C1–C12) ligand overlaps with that of another phen1 ligand on an adjacent molecule, while the plane of the phen2 (C13–C24) ligand overlaps with that of another phen2 ligand on the other adjacent molecule. The planes of phen1 overlap through the outer-ring of phen. The distance separating the two ligands is 3.2296 Å. The planes of phen2 overlap through the middle-ring of phen. The separating distance between the two ligands is 3.4886 Å. The separation between the planes of phen indicates that the parallel phens have a strong π–π interaction [9]. The planes of dmid in **1** are different from the planes of dmid in $[Cp_2Mo(dmid)][TCNQF_4]$ and $[Cp_2W(dmid)][TCNQF_4]$ [10] which form dimers held together by dmid/dmid overlap interactions to give spin ladders. They have no apparent contact with each other just like in $(NBu_4)_2[(dmid)Ni(tto)Ni(dmid)]$ [11]. The distance separating the O atom of dmid and the plane of phen1 on an adjacent molecule is about 3.1 Å. They contact apparently through n–π interactions [9]. These two types of interaction create a three-dimensional packing system (Fig. 2).

The crystal structure of **2** is isomorphous with that of **1**. The dihedral angles between the two phen ligands, phen1 (C1–C12) and dmid, phen2 (C13–C24) and dmid are 94.2°, 106.9° and 93°, respectively. The distances of overlapping adjacent phen ligands are 3.2651 and 3.4699 Å for phen1 and phen2, respectively. The distance between the O atom of dmid and the adjacent phen1 is about 3.0 Å.

3.2. Thermal analyses

To study the thermal stability of compounds **1** and **2**, thermogravimetric analysis (TGA) was performed on the single-crystal samples. The TGA curves of the two compounds indicate that they are stable below 210 °C and one striking weight loss step occurred from 213.8 to 273.9 °C (loss 66%) for **1** and from 212.3 to 280 °C (loss

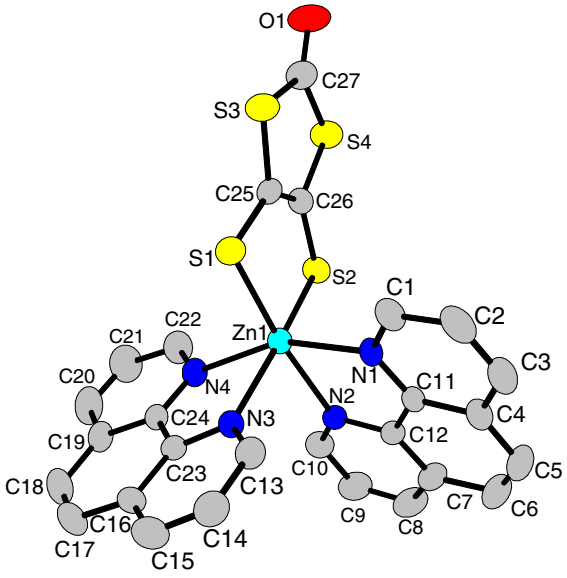

Fig. 1. Molecular structure of Zn(dmid)(phen)$_2$.

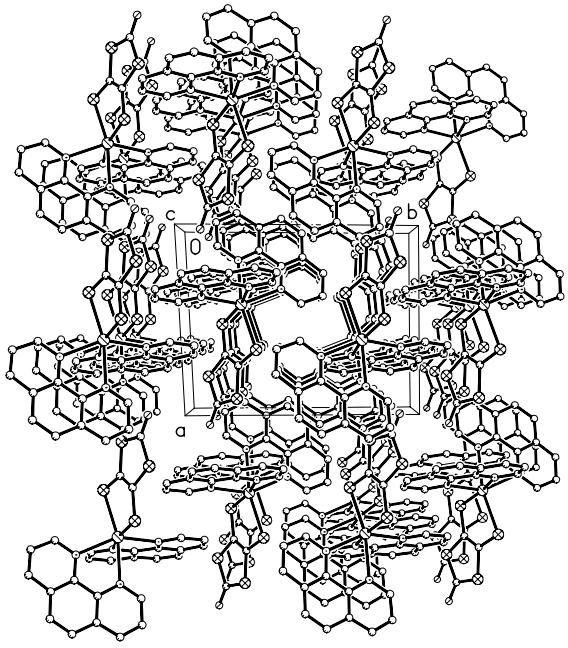

Fig. 2. The crystal packing of complex **1** facing the *ab*-plane.

64%) for **2**. The two isomorphous complexes have nearly the same thermal stability.

3.3. Infrared spectra

The IR spectra of complexes **1** and **2** are very similar to each other, except for a small shift of absorption bands. In order to explain these data, the vibrational properties of gaseous Zn(dmid)(phen)$_2$ were calculated. The geometry optimization calculations showed the molecular structure of gaseous Zn(dmid)(phen)$_2$ was similar to that of **1**, except for a C_2 symmetry. Some selected bond distances and bond angles for gaseous Zn(dmid)(phen)$_2$ are collected in Table 4. The atomic labels of Zn(dmid)(phen)$_2$ in the gaseous state were the same as complex **1**. In the band assignment, a scientific method was adopted [12]. The essentiality of this method was to give main fixed points and the crucial vibrations for each vibration mode. For example, the vibrations of S–C from dmid at 980.3 cm^{-1} are not simple stretching of S–C bonds. The C^{25}–C^{26} bond rocks in the plane of dmid while the S–C bonds stretch. So the absorption at 968 cm^{-1} observed for complex **1** could not simply be assigned to S–C stretching. The absorption at 463 cm^{-1} also could not be attributed to S–Zn stretching only. Some characteristic IR spectral data of complex **1** and the results of the calculation are presented in Table 5. Compared with the IR spectra of Zn(NCS)$_2$(phen)$_2$ [13], the observed frequencies of dmid listed in Table 5 were not found in the IR spectra of Zn(NCS)$_2$(phen)$_2$. The calculation results are in good agreement with the observed absorption frequencies.

Table 4
Selected bond lengths (Å) and angles (°) for Zn(dmid)(phen)$_2$ in the gaseous state (calculated)

Bond lengths			
Zn1–N1	1.915	Zn1–S1	2.355
Zn1–N2	2.201	Zn1–S2	2.355
Zn1–N3	2.201	S2–C26	1.772
Zn1–N4	1.915	S1–C25	1.772
O1–C27	1.228	C25–C26	1.361

S1–Zn1–S2	94.59		

3.4. Electronic absorption spectra

The electronic absorption bands measured in DMF and DMSO in the range of 190-700 nm occur at 266, 325 (shoulder), 376 and 400 nm for **1** in DMF, and at 266, 320 (shoulder), 362 and 393 nm for **1** in DMSO. The bands in the range of 300–400 nm show that they are solvent dependent and shift to higher energy with increasing solvent polarity (DMSO > DMF) [14]. They are the solvatochromic bands and support the LL′CT assignment [15]. The results of the calculation of electronic absorption spectra of gaseous Zn(dmid)(phen)$_2$ are consistent with the experimental data of electronic absorption spectra for **1** (Table 6), while the oscillator strength of the calculation is consistent with the experimental results. The theoretical spectra differ slightly

from the experimental results because the effect of the solvent has been neglected and the multiple states from the electronic repulsion and spin–orbital coupling interactions have not been taken into account in the course of the calculation. The calculation showed that the HOMO was mainly composed of the orbitals of dmid and d(Zn) atomic orbitals and the LUMO was almost exclusively orbitals of phen (Figs. 3 and 4). Like other related complexes with dithiolate and diimine ligands [16], the high-energy bands at 266 nm for **1** and **2** are assigned to the intraligand diimine transition [π (phen)–π* (phen)] and lower energy bands 300-400 nm likely involve a ligand-to-ligand charge transfer [LL′CT, π (dmid)–π* (phen)] character and the LL′CT dominates for **1** and **2**. These assignments are supported by the calculation of electronic absorption spectra.

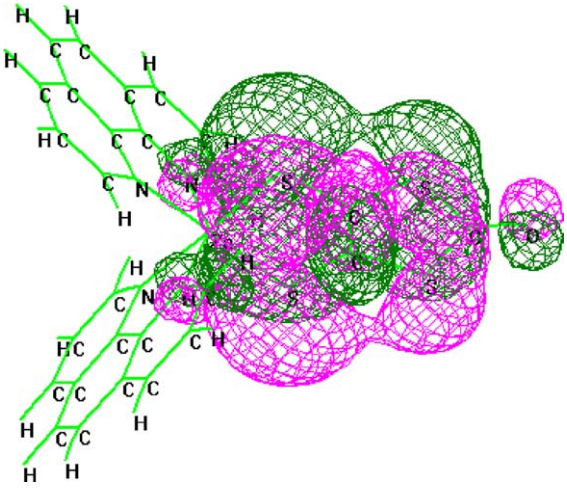

Fig. 3. HOMO, 33*b*, −7.1326 eV.

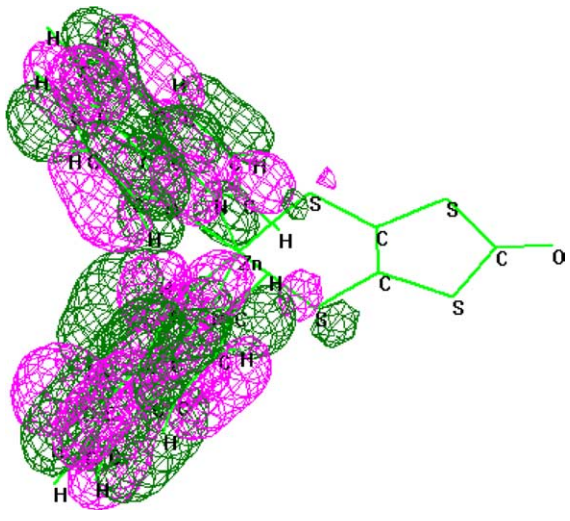

Fig. 4. LUMO, 34*b*, −1.9673 eV.

3.5. Fluorescence spectra

The fluorescent emission spectra of complexes **1** and **2** in solutions are showed in Figs. 5–7. The emissions at 417 and 435 nm in DMSO, at 407 (shoulder) and 428 nm in DMF, at 408 (shoulder) and 422.5 nm in pyridine were observed for **1**. Under the same conditions, complex **2** exhibited almost the same fluorescent emission spectrum as those of **1**, except for lower intensity. The intensity of emissions of **1** and **2** was much higher in pyridine than in DMF and in DMSO. The excitation and emission spectrum shifted to longer wavelength as the polarity of the solvent increased (DMSO > DMF > pyridine) [14]. Since the excitation wavelengths were at 351–390 nm, the emissions spectrum of **1** and **2** can be assigned to the π^*–π transition of the phen ligand to dmid ligand according to the calculation of the electronic absorption spectra. The emission behaviors of the complexes in the solid state (Fig. 8) differed from those in solution. The emissions at 484 and 538 nm were observed for both of them in the solid state. Compared with those in solution, the emissions showed large red-shifts, which were ascribed to the exciplex emissions [17]. The large red-shift revealed the strong interactions between molecules, resulting from the strong π–π stacking of the aromatic rings (Fig. 2).

Copper amino-acid complexes – towards encapsulated metal centres

Diane L. Stone, David K. Smith *, Adrian C. Whitwood

Department of Chemistry, University of York, Heslington, York, YO10 5DD, UK

Received 22 January 2004; accepted 2 April 2004
Available online 27 April 2004

Abstract

This article reports the synthesis of two novel amino-acid derivatives in which the side chain of glutamic acid (Glu) is coupled with different amines – *tert*-butylamine (ligand **A**) or a first generation 'Newkome' type dendron (ligand **B**). Consequently, ligand **B** possesses a bulkier branch than ligand **A**. Ligands **A** and **B** bind Cu^{2+} ions in solution, generating copper complexes **A–Cu** ($M_r = 508$) and **B–Cu** ($M_r = 1077$). These complexes were fully characterised and, in particular, have been investigated by electrochemical and electron spin resonance techniques to determine the extent of encapsulation of the copper ions. There were significant differences between the two complexes, indicating that Cu^{2+} may be more deeply encapsulated by ligand **B** and hence less able to interact with its surroundings. This indicates that metal ions can be sensitive reporters of even relatively small amounts of organic functionality, and emphasises the important role which protein superstructures can play in modulating the function of active metal ions.

1. Introduction

Metal ions play a dominant role in controlling the behaviour of many biologically important macromolecules [1]. By changing the metal ion, biological systems are able to achieve a wide range of different functions. However, it is also clear that a metal ion alone is not sufficient to achieve the required range of functions. It is only by carefully tuning the ligands employed, and the surrounding organic functional groups within the protein superstructure that biology can achieve selective function. Many active sites are deeply encapsulated within protein and enzyme superstructures, and this has profound effects on factors such as the microenvironmental dielectric constant experienced by the metal and its accessibility to different substrates [2].

There is currently great interest in mimicking biological systems [3], and recently, encapsulation of an active unit has been probed using dendritic molecules, in which a branched superstructure surrounds a central metal ion, with the effect of this on function being investigated [4]. There have, for example, been many studies of the effect of a dendritic microenvironment on the optical [5], redox [6–8] or catalytic [9] properties of an encapsulated active site. On encapsulation of a redox active unit, it is well-known that the electron transfer kinetics are significantly slower – a feature also observed in redox-active proteins. Furthermore, cytochromes and their dendritic mimics indicate that the encapsulated micro-environment is significantly different to that of the surrounding bulk solvent/electrolyte, leading to modification of the redox potential of the metal ion [7].

Copper complexes have considerable biological importance, but encapsulated copper centres are less well studied than encapsulated iron. Aida and co-workers reported a dendrimer capable of ligating a copper ion at its focal point, and showed that this dendrimer could react with oxygen to form a bridged bis-copper complex [10]. Multiple copper ions bound within a spherical dendrimer have also been used for O_2 binding [11]. Chow and co-workers [12] used a dendritic bis(oxazoline) ligand to bind to copper triflate and then used the

doi:10.1016/j.poly.2004.04.001

complex in Diels–Alder catalysis, while recently, functionalised bipyridine and phenanthroline ligands have been used to achieve effective encapsulation of copper ions and generate a wide range of interesting molecular architectures [13].

The coordination of amino acids to metal ions is well-known [14], with strong binding to transition metals occurring via a chelate binding mode involving both carboxylate and amine groups (Fig. 1). We therefore reasoned that the side chain of an amino acid offered a suitable point to attach functionality capable of encapsulating the bound metal ion. For this reason, we became interested in the development of synthetic amino-acid derivatives with bulky side chains. Whilst this work was in progress, Krishna and Jayaraman [15] reported some different modified amino-acid ligands and described their ability to bind and encapsulate cobalt ions.

In this paper, we report amino-acid derivatives functionalised with small, flexible branches, and illustrate their ability to bind Cu^{2+} ions. Using electrochemical and electron spin resonance (ESR) methods, we have investigated the metal complexes in order to probe the degree of isolation of the Cu^{2+} ion. We report that the copper ions were surprisingly sensitive reporter units, with their properties being modified even by the small amounts of branching used in this case. These preliminary results have significance for biological chemists interested in the role played by the organic superstructure in shielding the active sites of metalloproteins and enzymes.

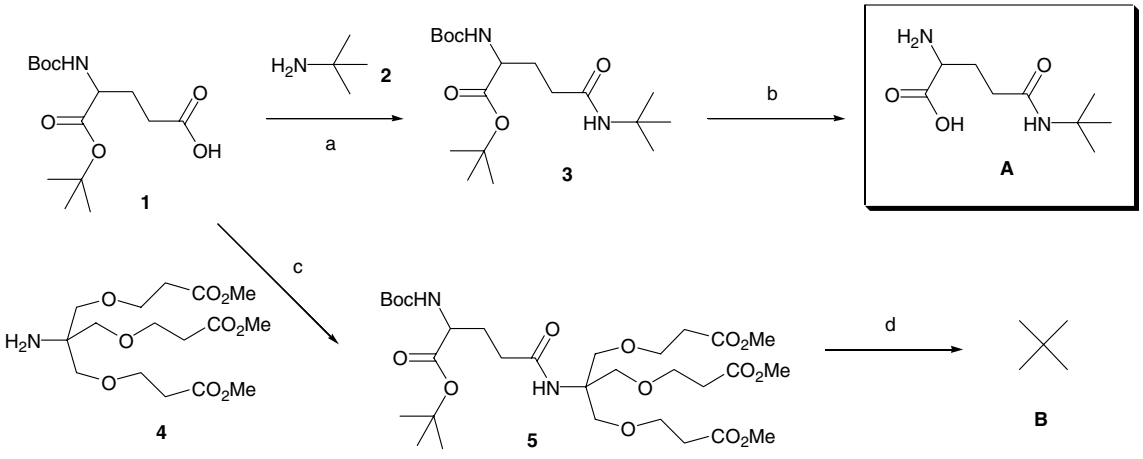
2. Results and discussion

2.1. Synthesis and characterisation of ligands *A* and *B*

Ligand **A** was prepared using standard protecting group and peptide coupling methodology (Scheme 1). The side chain of *N*-Boc, *tert*-butyl ester protected glutamic acid (**1**) was coupled with *tert*-butylamine (**2**) using 1,3-dicyclohexylcarbodiiimide (DCC), 1-hydroxybenzotriazole (HOBt) and triethylamine in CH_2Cl_2 to yield compound **3** After purification of the product by flash chromatography on silica, the product was obtained in 50% yield. The amino-acid protecting groups were then removed simultaneously. Previous literature indicated that a mild organic acid such as CF_3COOH should be sufficient, but even after stirring for 18 h the reaction was incomplete. Harsher conditions (45% HBr in acetic acid) were therefore employed and after stirring for 2 min, deprotection was complete in near quantitative yield to provide ligand **A**. This ligand was used for the synthesis of copper(II) complexes without isolation (although NMR characterisation of the ligand was achieved by performing the deprotection on one occasion in D_2O).

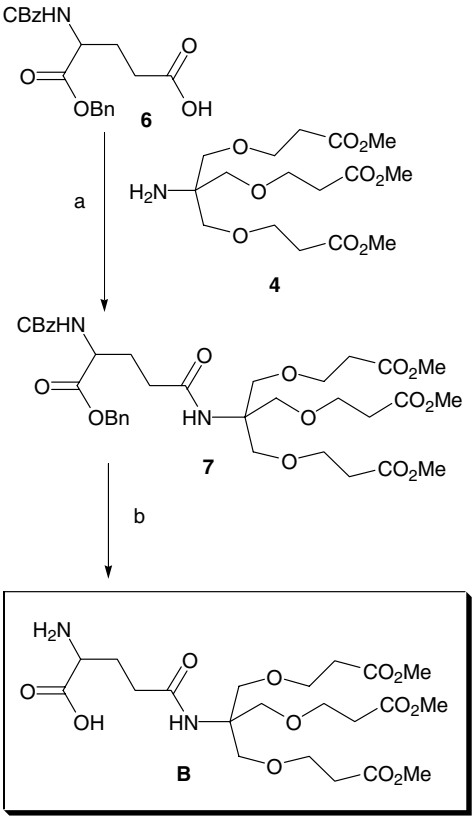
Initially, the synthesis of ligand **B** was attempted using the same approach (Scheme 1). The DCC/HOBt mediated coupling of first generation 'Newkome' type dendritic branch **4** to the protected glutamic acid **1** was very successful, providing compound **5** in 93% yield. Once again, however, CF_3COOH would not fully deprotect the amino-acid group, even on heating (the Boc group was rapidly removed but the *t*-butyl ester would not come off). Unfortunately, the alternative conditions



Scheme 1. Synthesis of **A** and attempted synthesis of **B** using Boc/*tert*-butyl ester protecting group methodology. Reagents and conditions: (a) DCC, HOBt, NEt_3, CH_2Cl_2, 50%, (b) HBr/CH_3COOH, 2 min, quant., (c) DCC, HOBt, NEt_3, CH_2Cl_2, 93%, (d) HBr/CH_3COOH, 2 min, 0%.

using HBr/CH_3COOH were too harsh, and NMR analysis of the product indicated that the methyl ester units on the branch had also been removed by acid catalysed hydrolysis (peak at $\delta = 3.65$ ppm disappeared).

An alternative strategy was therefore developed in which the amino-acid protecting groups were removed non-hydrolytically. Consequently, *N*-CBz, benzyl ester protected glutamic acid (**6**) was used as the starting material (Scheme 2). DCC/HOBt coupling of this with first generation 'Newkome' type branch **4** was performed and product **7** was purified using gel permeation chromatography (Biobeads SX-1, CH_2Cl_2). This compound was obtained in 60% yield and fully characterised. Simultaneous deprotection of the two amino-acid groups was then attempted using Pd/C under H_2 in ethanol. The reaction had to be stopped after just 30 min, because over longer time-scales, mass spectral and NMR analysis indicated that (unusually) the benzyl ester had been transesterified to an ethyl ester. We do not have a good explanation for this side-reaction, which is unexpected (EtOH is indeed normally the solvent of choice for the deprotection of benzyl esters). Nonetheless, by employing a 30-min reaction time, ligand **B** could be obtained in 93% yield and was fully characterised.



Scheme 2. Synthesis of **B** using CBz/benzyl ester protecting group methodology. Reagents and conditions: (a) DCC, HOBt, NEt_3, CH_2Cl_2, 60%, (b) H_2, 10% Pd/C, EtOH, 30 min, quant.

2.2. Synthesis and characterisation of copper complexes *A–Cu* and *B–Cu*

The usual literature technique for the preparation of copper complexes is to dissolve both the ligand and a copper salt in water, and to encourage complexation by the addition of base. This is normally followed by spontaneous precipitation or recrystallisation of the complex. For the synthesis of **A–Cu**, ligand **A** was dissolved in water which had been basified with 10% NaOH. Copper carbonate was added and the mixture stirred for 2 h. On cooling, a light blue precipitate of complex **A–Cu** was obtained in 45% yield (see Fig. 2).

The complex was analysed using electrospray mass spectrometry (ESMS) and a peak corresponding to $[M + Na]^+$ was observed at m/z 488, with an isotope peak at m/z 490. A peak was also observed at m/z 953, corresponding to $[2M + Na]^+$, with isotope peaks at m/z 955 and 957. These higher mass peaks were not,

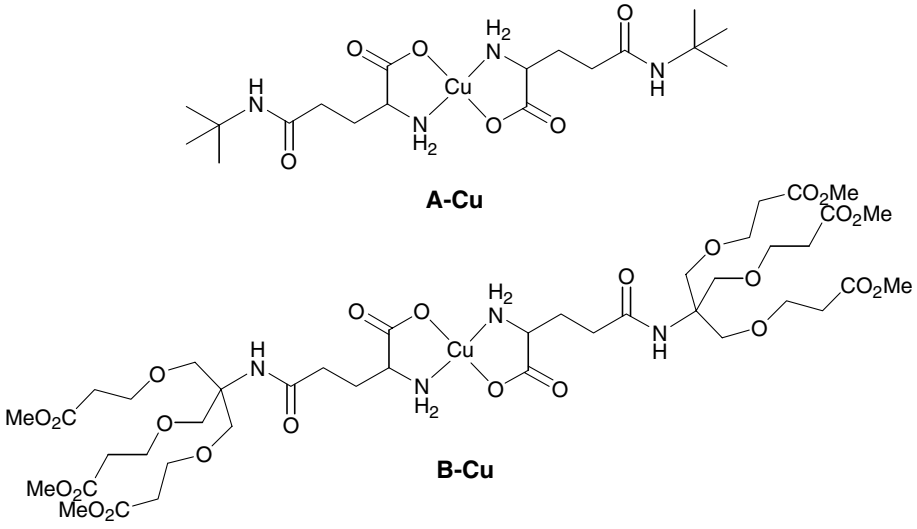


Fig. 2. Structures of complexes **A–Cu** and **B–Cu**.

however, observed by MALDI-TOF mass spectrometry. These peaks could indicate dimerisation of the complex in solution, or could alternatively be an artefact of the electrospray ionisation process – aggregation with Na^+ ions in ESMS is not uncommon. Infra red spectroscopy of the complex showed the expected ligand peaks. Elemental analysis provided a good match for the composition of the complex.

Initial attempts to synthesise complex **B–Cu** used the procedure described above. Although the reaction changed colour (from pale green to deep blue) indicating complexation may have occurred, no precipitate was formed on cooling. Attempts at recrystallisation from the liquor failed and the procedure was therefore modified. Copper carbonate and ligand **2** were dissolved in methanol and one equivalent of solid sodium hydroxide (relative to the ligand) was added to the mixture. The mixture was stirred for 6 days and a gradual colour change was observed. The product was purified by gel permeation chromatography (Sephadex LH-20, methanol). A blue band was collected from the column and evaporated to give a blue oil in 19% yield.

Complex **B–Cu** was characterised by electrospray mass spectrometry, with the major peak in the mass spectrum being observed at m/z 1100 $[M + Na]^+$, and the correct intensity isotope peak being observed at m/z 1102. Peaks corresponding to $[2M + Na]^+$ were not observed in this case. Infra red spectroscopy of the complex showed the expected ligand peaks. Elemental analysis provided a reasonable match for the composition of the complex.

2.3. Electrochemistry of copper complexes *A–Cu* and *B–Cu*

As stated in the introduction, electrochemistry is a widely used method for probing the microenvironment experienced by encapsulated redox active units [6–8]. Copper(II) is a biologically important redox active metal, with the Cu(II)/Cu(I) redox couple being implicated in the function of a wide range of enzymes. Furthermore, Cu(II) can also be oxidised to Cu(III) under very oxidising conditions. The electrochemical properties of complexes **A–Cu** and **B–Cu** were therefore investigated using cyclic voltammetry in dimethylformamide (DMF) solution.

Complex **A–Cu** was investigated at different scan rates (Fig. 3). Initially the solution was swept in the reducing direction and then subsequently swept to oxidising potentials. In each case the same components were observed in the cyclic voltammogram. The reduction peak which is tentatively assigned to the Cu(II) to Cu(I) transition was observed at a peak potential ca. −990 mV. Re-oxidation was then observed at ca. −140 mV. The large peak to peak separation and the broad reduction and oxidation peaks indicate a quasi-

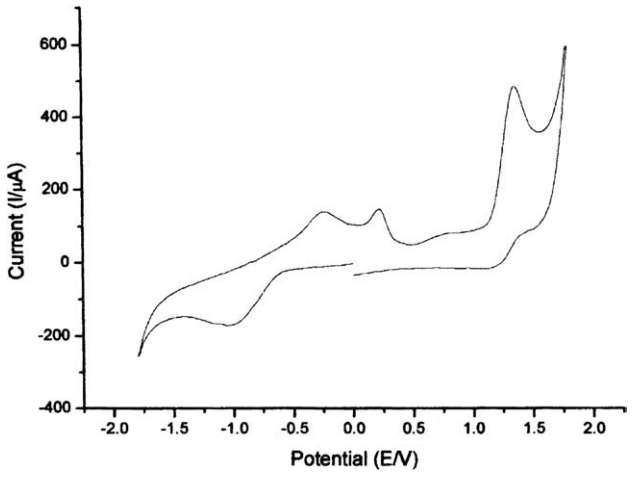

Fig. 3. Cyclic voltammogram of complex **A–Cu** (2 mM) in DMF solution with a supporting electrolyte of 0.1 M $[Bu_4N]^+[BF_4]^-$. Scan rate = 200 mV s^{-1}.

reversible process. On continued oxidation (scan rate: 200 mV s^{-1}) a sharp peak was observed at +210 mV, probably a stripping peak. Stripping peaks are typically observed following electrodeposition of metals (e.g., Cu(0) from disproportionation of decomplexed Cu(I) ion). In fact, on decreasing the scan rate to 50 mV s^{-1} the relative peak current of this peak increased significantly, while on increasing the scan rate to 500 mV s^{-1}, this stripping peak disappeared, in agreement with the above analysis. On continuing the sweep in the oxidative direction an oxidation peak was observed at ca. 1310 mV. This could correspond to the oxidation of Cu(II) to Cu(III), however, given the peak height, it is possible that ligand oxidation is also occurring. This process was irreversible. It is well-known that very robust ligands would be required if Cu(III) were to be observed as a stable species [16].

Complex **B–Cu** was then investigated using cyclic voltammetry under the same conditions of solvent and scan rate (Fig. 4). Interestingly, the Cu(II)/Cu(I) couple was significantly more reversible than for **A–Cu**. At a scan rate of 50 mV s^{-1}, the peak to peak separation was only 150 mV (rather than ca. 850 mV as observed for **A–Cu**). Furthermore, the stripping peak (observed for **A–Cu** at +210 mV) was absent. These observations indicate that the steric bulk of ligand **B** enhances the stability of the reduced complex, hence preventing the release of Cu(I) ion and its subsequent disproportionation. Complex **B–Cu** has an additional oxidation peak at ca. 1.0 V, which can tentatively be assigned to oxidation of the ligand framework. The other oxidation peak was now observed at +1370 mV, which compares with +1310 mV for complex **A–Cu**. This might reflect differences between the oxidation of the ligand structures in these two complexes although it may also indicate that the oxidation of Cu(II) to Cu(III) is thermodynamically more

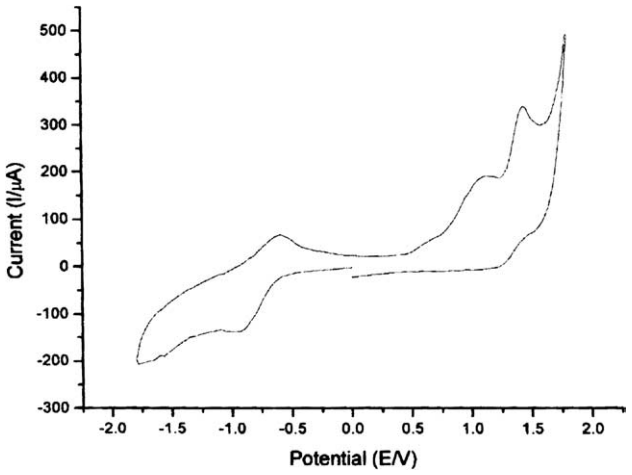

Fig. 4. Cyclic voltammogram of complex **B–Cu** (2 mM) in DMF solution with a supporting electrolyte of 0.1 M $[Bu_4N]^+[BF_4]^-$. Scan rate = 200 mV s^{-1}.

difficult for **B–Cu** than **A–Cu**. This would be in agreement with our previous observations of dendritic effects which have indicated that charge build up is disfavoured when the redox active unit is encapsulated within an organic shell, and is hence more distant from bulk solvent/electrolyte [8a,8b]. Interestingly, the comparison between **A–Cu** and **B–Cu** indicates that even relatively small amounts of organic functionalisation appear to have significant effects on the kinetics and thermodynamics of redox processes.

2.4. Electron spin resonance of copper complexes *A–Cu* and *B–Cu*

As a d^9 paramagnetic species, copper(II) is appropriate for characterisation by ESR experiments. This technique has frequently been applied for the analysis of copper complexes as well as copper ions in biological systems [17], and is a useful method of determining the geometry of a copper centre when X-ray quality crystals cannot be obtained. For a mononuclear copper(II) complex, the nuclear spin $(I = 3/2)$ means that four lines would be expected in the hyperfine splitting pattern in solution. In the case of the actual axial symmetry, the spectrum is characterised by $a_{\|}$ (G), $a_{\perp}$ (G), $\langle a \rangle$ (G), $g_{\perp}$, $g_{\|}$, $\langle g \rangle$ values, which can be obtained from the splitting pattern of the spectrum and compared with values for complexes of known geometry in order to define the composition of the equatorial coordination of the complex [18a].

ESR experiments were performed on 1 mM frozen solution of the complexes in methanol. The ESR spectrum of **A–Cu** shows the expected approximate four line hyperfine splitting (Fig. 5) The values derived from the analysis of this spectrum were $g_{\|} = 2.258$, $a = 170$ G and $g_{\perp} = 2.063$. These values are consistent with complex **A–Cu** having Jahn-Teller distorted octahedral geometry. It would be expected that the amino-acid ligands will be bound in the equatorial positions in a chelate mode, whilst there will be two more distant axial ligands.

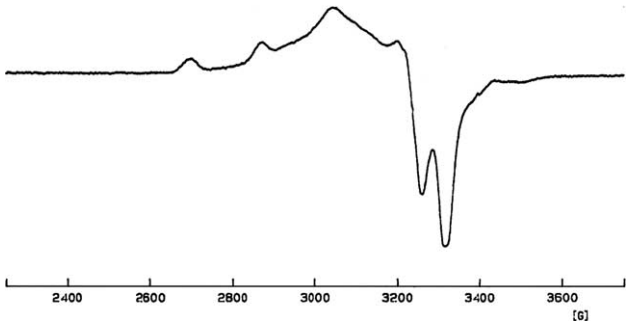

Fig. 5. ESR spectrum of complex **A–Cu** (1 mM) in frozen methanol solution.

The ESR spectrum of complex **B–Cu** was then measured (Fig. 6). The values derived from the analysis of this spectrum were $g_{\|} = 2.260$, $a = 171$ G and $g_{\perp} = 2.057$. These values are very similar to those obtained for **A–Cu** and indicate once again, an equivalent Jahn-Teller distorted octahedral geometry. This indicates that the additional steric hindrance of ligand **B** does not manifest itself through a change in coordination geometry.

Most interesting, however, was the fact that the spectrum of **B–Cu** was much sharper than that of **A–Cu**. The broadening in the ESR spectrum of **A–Cu** could possibly be caused by interaction between Cu^{2+} ions. This ESR evidence indicates that interaction between copper(II) ions may be occurring for **A–Cu**. It is well-known, for example, that carboxylate ligands can act as bridging ligands connecting two copper centres [18]. On the other hand, for complex **B–Cu**, where a more ideal ESR sepctrum with sharp well-defined peaks is observed, the copper centre will be more shielded from other copper nuclei by the ligand bulk, hence preventing copper–copper interactions.

The mediation of copper–copper interactions is of key importance in biological chemistry [19], and these

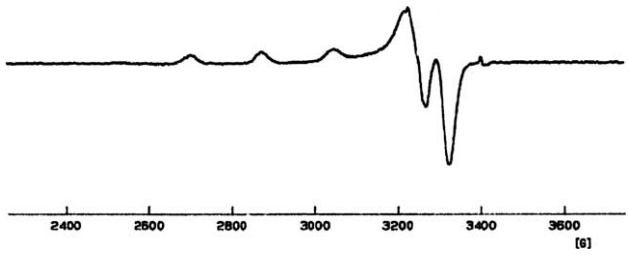

Fig. 6. ESR spectrum of complex **B–Cu** (1 mM) in frozen methanol solution.

results indicate that relatively small amounts of steric bulk (complex **B–Cu** only has approximately twice the molecular mass of complex **A–Cu**) can have a marked effect on the isolation of metal ions. The use of an organic shell to protect copper ions in this way is an important strategy in biological chemistry, and it appears that it is possible to mimic such an effect in a relatively simple manner. Work is now ongoing to extend the extent of functionalisation of these amino-acid ligands to achieve even more effective encapsulation of copper ions.

3. Conclusions

This article describes the synthesis of two novel amino-acid ligands and their characterisation. Furthermore, these ligands have been used in the assembly of two novel copper(II) complexes with different degrees of steric bulk at the periphery. These complexes have been fully characterised and subsequently investigated using electrochemical and ESR methods. The results indicate that even for these relatively small molecules, the differential encapsulation experienced by the metal ion in the two complexes is significant. This emphasises the important role which an organic superstructure can play (even in relatively small quantities) to shield and modify the properties of metal ions within metalloproteins and enzymes. Modelling the role played by the organic superstructure of metalloproteins remains a real challenge for bioinorganic chemists in the attempt to mimic the remarkable levels of function which can be obtained by highly evolved natural systems.

4. Experimental

4.1. Materials and methods

All ^{1}H and ^{13}C NMR spectra were determined either on a Jeol-E270 (270 MHz) or a Bruker AMX 500 (500 MHz) instrument, according to requirements and referenced to residual solvent. Neat IR, carried out on oil-like compounds, were measured on a Mattson Genesis Series FTIR spectrometer, whereas solid IR using KBr disks were performed using a Mattson Sirius Research FTIR spectrometer. Electrospray mass spectrometry was carried out on a Finnigan LCQ. MALDI-TOF mass spectrometry was performed at Central Science Laboratories, York. Silica column chromatography was carried out using silica gel provided by Fluorochem Ltd. (35–70 μm). Thin layer chromatography was performed on commercially available Merck aluminium backed silica plates. Preparative gel permeation chromatography was carried out using a 2 m glass column packed with Biobeads SX-1 (Biorad) eluted with CH_2Cl_2 or using standard (ca. 50 cm) columns packed with Sephadex LH-20 and eluted using MeOH. The electrochemical studies were carried out on an EG & G Princeton Applied Research potentiostat/galvanostat model 273 with a standard 3 electrode configuration, consisting of platinum working (0.5 mm diameter disk) and counter electrodes and an Ag/AgCl reference electrode. Each compound was studied at a concentration of 2 mM in a supporting electrolyte of 0.1 M $[Bu_4N]^+[BF_4]^-$ using scan rates of 50–500 mV s^{-1}. ESR experiments were performed using a Bruker ESP300 spectrometer. Elemental analysis was performed by the microanalytical lab at The University of Manchester.

4.2. Synthesis and characterisation

All protected amino acids were purchased commercially, and first generation 'Newkome' type branches were prepared according to literature methodology [20].

4.2.1. *N-(tert-Butoxycarbonyl)-L-glutamic acid 1-tert-butyl ester, 5-tert-butylamide, compound **3***

N-(*tert*-Butoxycarbonyl)-L-glutamic acid 1-*tert*-butyl ester (1.0 g, 3.3 mmol), DCC (0.68 g, 3.3 mmol) and HOBt (0.44 g, 3.3 mmol) were dissolved in dry CH_2Cl_2 (10 ml) and stirred at room temperature for 10 min. Then NEt_3 (1 ml, 7.18 mmol) and *tert*-butylamine (0.64 g, 3.3 mmol) were added as a mixture in dry CH_2Cl_2 (5 ml). The reaction was stirred under N_2 at room temperature for 2 d. After this period, CH_2Cl_2 (30 ml) was added to the mixture, which was then filtered into a separating funnel, and washed with sat. aq. $NaHCO_3$ (2×50 ml) and H_2O (2×50 ml). The organic phase was dried over $MgSO_4$, filtered and evaporated to give the crude product. This was purified by silica gel chromatography (CH_2Cl_2:MeOH, 98:2) to yield the pure product (0.591 g, 1.65 mmol, 50%). White solid; R_f 0.45 (CH_2Cl_2–MeOH 98:2); ν_{max} (KBr disk) 3338 m (NH), 2979 m and 2933 m (alkyl), 1721 m, and 1655 m (C=O), 1543 m, 1456 m, 1366 m, 1277 m and 1153 m, 1051 m, 848 s; $\delta_H(CDCl_3)$ 1.35 (9H, s, $NHC(CH_3)_3$), 1.44 and 1.46 (18H, 2s, $OC(CH_3)_3$), 1.86 (2H, m, CH_2CH_2CO), 2.15 (2H, m, CH_2CH_2CO), 4.13 (1H, t, $J = 8.5$, $CHCH_2$), 5.16 and 5.20 (1H, d, $J = 10.0$, $NHCHCH_2$), 5.80 (1H, bs, $NHC(CH_3)_3$); $\delta_C(CDCl_3)$ 28.7, 28.3, 28.0 (CCH_3), 29.3 (CH_2CH_2CONH), 33.8 (CH_2CONH), 51.2 ($NHC(CH_3)_3$), 53.6 (NHCH), 79.8 and 82.1 ($CO_2C(CH_3)_3$), 155.8 (CONH), 171.5 and 171.4 ($CO_2C(CH_3)_3$); m/z (Electrospray) $[M + Na]^+$ requires 381, found 381 (100%), 382 (19%); HRMS (CI+) ($C_{18}H_{34}N_2O_5$): found 359.2552, calculated 359.2546.

4.2.2. *L-Glutamic acid 5-tert-butylamide, ligand **A***

N-(*tert*-Butoxycarbonyl)-L-glutamic acid 1-*tert*-butyl ester, 5-*tert*-butylamide (**3**) was dissolved in hydrobromic acid (45% in acetic acid) and stirred at r.t. for 2 min.

The mixture was then added to ice water (20 ml), stirred for 10 min and evaporated to dryness. The resulting product was used without further purification for complex formation. R_f 0.0 (CH_2Cl_2–MeOH 90:10); $\delta_H(CD_3OD)$ 1.33 (9H, s, NHC(CH_3)$_3$), 2.17 (2H, m, CHCH_2CH$_2$), 2.47 (2H, t, $J = 7.0$, CHCH$_2$CH_2), 4.06 (1H, m, CHCH$_2$CH$_2$); $\delta_C(CD_3OD)$ 28.8 (C(CH_3)$_3$), 30.2 (CHCH_2), 33.2 (CH_2CONH), 52.3 (C(CH$_3$)$_3$), 53.6 (CHCH$_2$), 170.6 (CONH), 173.5 (CO_2H); m/z (Electrospray) $[M + H]^+$ requires 203, found 203 (100%).

4.2.3. Compound 5

N-(*tert*-Butoxycarbonyl)-L-glutamic acid 1-*tert*-butyl ester (**1**) (0.72 g, 2.37 mmol) was dissolved in dry CH_2Cl_2 (5 ml) then DCC (0.49 g, 2.37 mmol) and HOBt (0.32 g, 2.37 mmol) were added. The reaction was stirred under N_2 at r.t. for 5 min. Next, NEt_3 (0.5 ml, 3.59 mmol) and the first generation 'Newkome' type branch **2** (0.9 g, 2.37 mmol) in dry CH_2Cl_2 (5 ml) were added, and the mixture was stirred at r.t. under N_2 for 2 d. After this period, CH_2Cl_2 (30 ml) was added to the mixture, which was then filtered into a separating funnel and washed with sat. aq. $NaHCO_3$ (2×50 ml) and H_2O (2×50 ml). The organic phase was dried over $MgSO_4$, filtered and evaporated to give product **5** (1.47 g, 2.21 mmol, 93%). Colourless oil; R_f 0.61 (CH_2Cl_2–MeOH 90:10); ν_{max} (neat) 3370 w (NH), 2977 m and 2897 m (alkyl), 1740 s and 1675 s (C=O), 1518 s, 1438 s, 1367 s, 1254 s, 1175 s, 1112 s, 848 w; $\delta_H(CDCl_3)$ 1.41 and 1.43 (18H, 2s, C(CH_3)$_3$), 1.66 (2H, m, CHCH_2CH$_2$CO), 1.87 (2H, m, CHCH$_2$CH_2CO), 2.53 (6H, t, $J = 6.5$, CH_2CO$_2$Me), 3.67 (21H, m, CH_2OCH_2 and CO$_2$CH_3), 4.10 (1H, m, CHCH$_2$), 6.16 (1H, s, CONH); $\delta_C(CDCl_3)$ 27.9, 28.3 (OC(CH_3)$_3$), 28.7 (CHCH_2), 33.3 and 34.7 (CH_2CONH and CH_2CO_2), 53.8 (CH), 57.7 (CO_2CH_3), 59.7 (NHC(CH$_2$)$_3$), 66.7, 69.1 (CH_2OCH_2), 79.5, 81.8 (OC(CH$_3$)$_3$), 155.7 (CONH), 171.6, 172.1, 172.3 (CO_2); *m/z* (Electrospray) $[M + Na]^+$ requires 687, found 687 (100%), 688 (32%); HRMS (FAB) ($C_{30}H_{52}N_2O_{14}$): found 687.3313, calculated 687.3316.

4.2.4. Compound 7

N-(Benzyloxycarbonyl)-L-glutamic acid 1-benzyl ester (**6**) (1.00 g, 2.7 mmol) was dissolved in dry THF (10 ml), followed by the 'Newkome' type branch **4** (1.50 g, 4.0 mmol) in dry THF (10 ml). To it was added NEt_3 (1 ml, 7.0 mmol) followed by DCC (0.84 g, 4.1 mmol) and HOBt (0.54 g, 4.1 mmol) in dry THF (5 ml). The reaction was stirred under N_2 at r.t. for 72 h. The solvent was removed by evaporation and CH_2Cl_2 (50 ml) was added. The mixture was filtered, then washed with saturated aqueous $NaHCO_3$ (2×50 ml) and H_2O (2×50 ml). The organic phase was dried over $MgSO_4$ for 1 h, filtered and evaporated to give the crude product (2.684 g). The crude mixture was separated on a Biobeads gel column, and the pure product **7** was isolated (1.195 g, 1.63 mmol, 60%). Colourless oil; R_f 0.7 (CH_2Cl_2–MeOH 90:10); ν_{max} (neat) 3358 s (NH), 2952 s and 2879 s (alkyl), 1797 m, 1735 s and 1674 m (C=O), 1524 m, 1456 m, 1260 s, 1197 s, 1111 m, 744 m, 699 m; $\delta_H(CDCl_3)$ 1.98 and 2.21 (4H, m, CHCH_2CH_2), 2.50 (6H, t, $J = 6.5$ Hz, CH_2CO$_2$Me), 3.63 (21H, m, CH_2OCH_2, CO$_2$(CH_3)$_3$), 4.36 (1H, m, NHCHCH$_2$), 5.07 and 5.15 (2H and 2H, 2s, PhCH_2O), 5.84 and 5.87 (1H, d, $J = 7.5$ Hz, NHCHCH$_2$), 6.15 (1H, s, CONH), 7.31 (10H, s, C$_6H_5$CH$_2$); $\delta_C(CDCl_3)$ 27.8 (CHCH_2), 32.9 (CH_2CONH), 34.6 (CH_2CO_2Me), 51.6 (CO_2CH_3), 53.8 (CHCH$_2$), 59.6 (NHC(CH$_2$)$_3$), 66.6, 66.8, 67.1 and 69.0 (CH_2OCH_2 and OCH_2Ph), 128.0, 128.0, 128.2, 128.3, 128.4 and 128.5 (Aryl *C*H), 135.3 and 136.2 (Aryl *C*), 156.2 (CH_2CONH), 171.9, 172.1 and 172.1 (CO_2Me and CO_2CH_2); m/z (Electrospray) $[M + Na]^+$ requires 755, found 755 (100), 756 (36); HRMS (FAB) ($C_{36}H_{48}N_2O_{14}Na$): found 755.3009, calculated 755.3003.

4.2.5. Ligand B

Compound **7** (174 mg, 0.24 mmol) was dissolved in EtOH (10 ml) and 10% Pd-C (60 mg) was added. The reaction was stirred under H_2 for 30 min, and the reaction followed by TLC (90:10 CH_2Cl_2–MeOH). The mixture was filtered through Celite, and evaporated to give the product in near quantitative yield (113 mg, 0.22 mmol, 93%). Colourless oil; R_f 0.0 CH_2Cl_2–MeOH 90:10; ν_{max} (neat) 3362 w and 3261 w (NH and NH_2), 3069 w, 2953 w and 2879 w (alkyl), 1737 s and 1654 m (C=O), 1543 w, 1438 w, 1364 w, 1266 w, 1198 m, 1178 m, 1109 m, 1075 m; $\delta_H(CD_3OD)$ 2.07 (2H, m, CHCH_2CH$_2$), 2.44 (2H, m, CHCH$_2$CH_2), 2.56 (6H, t, $J = 6.0$ Hz, CH_2CO$_2$Me), 3.69 (22H, m, CO$_2$CH_3, CH_2OCH_2, CHCH$_2$); $\delta_C(CD_3OD)$ 27.2 (CHCH_2CH$_2$), 33.2 (CHCH$_2$$CH_2$), 34.8 ($CH_2CO_2$Me), 51.4 ($CH_2CO_2CH_3$), 54.9 $CHCH_2CH_2$), 60.7 (NHC(CH$_2$)$_3$), 67.2 and 68.8 (CH_2OCH_2), 127.4 (CONH), 173.2 (CO_2Me), 174.5 (CO_2H); m/z (Electrospray) $[M - H]^-$ requires 507, found 507 (100%), 508 (16%).

4.2.6. Complex A–Cu

Ligand **A** (144 mg, 0.828 mmol) was dissolved in H_2O (20 ml) and $CuCO_3$ (51 mg, 0.414 mmol) was added. The pH was measured and NaOH soln (10%) was added dropwise with stirring, until pH 11 was reached. The solution was stirred for 2 h, and a blue precipitate was formed. The solution was placed in an ice bath for 1 h and the precipitate was then collected by filtration to give complex **A–Cu** (72 mg, 0.15 mmol, 39%). Blue powder; ν_{max} (solid KBr) 3434 s and 3296 s (NH), 2968 m and 2933 m (alkyl), 1648 s (C=O), 1456 m, 1365 s, 1226 s, 1091 s; m/z (Electrospray) $[M + Na]^+$ requires 488, found 488 (90%), 490 (36%), 953 $[2M + Na]^+$ (87%), 955 (100%), 957 (34%); HRMS (FAB) ($C_{18}H_{35}N_4O_6Cu$): found 466.1851, calculated 466.1853;

Elemental analysis $C_{18}H_{34}N_4O_6Cu \cdot 2H_2O$ requires C, H, N: 43.06, 7.63, 11.16; found 43.62, 7.38, 11.10.

4.2.7. Complex *B*–Cu

Ligand **B** (305 mg, 0.60 mmol) was dissolved in MeOH (10 ml) and $CuCO_3$ (23 mg, 0.19 mmol) was added, followed by solid NaOH (22 mg, 0.60 mmol). The reaction was stirred at r.t. for 14 d. The resulting blue/green mixture was filtered twice and reduced in volume by rotary evaporation. The product was then purified over a Sephadex (LH-20) gel column with MeOH as eluent. The blue band was collected from the column and evaporated to dryness to give a blue oil (38 mg, 0.035 mmol, 19%). Blue viscous oil; ν_{max} (neat) 3297 w (NH), 2954 w, 2924 w, and 2879 w (alkyl), 1739 m and 1652 m (C=O), 1559 w, 1439 w, 1370 w, 1261 w, 1176 m; m/z (Electrospray) $[M + Na]^+$ requires 1100, found 1100 (100%), 1102 (55%), 1006 (50%); Elemental analysis $C_{42}H_{70}N_4O_{24}Cu \cdot 2H_2O$ requires C, H, N: 45.26, 6.69, 5.03; found 44.77, 6.13, 4.92.

Abstract

The chelating ligand (2,2′-$C_{12}H_8O_2$)$P(CH_2CH_2O)_4P$(2,2′-$O_2C_{12}H_8$) reacts with both $Ru(bpy)_2(O_3SCF_3)_2$ and $Mo(CO)_4(C_7H_8)$ to form the new metallacrown ether complexes *cis*-[$Ru(bpy)_2$((2,2′-$C_{12}H_8O_2$)$P(CH_2CH_2O)_4P$(2,2′-$O_2C_{12}H_8$))]$(O_3SCF_3)_2$ (**1**) and *cis*-[$Mo(CO)_4$((2,2′-$C_{12}H_8O_2$)$P(CH_2CH_2O)_4P$(2,2′-$O_2C_{12}H_8$))] (**2**). The X-ray crystal structures for both complexes indicate that the metallacrown ether ring oxygen atoms point their lone pairs towards the cavity in the *cis*-metallacrown ether ring. The effect of interactions of the metallacrown ether complex with selected monoatomic cations (Li^+, Na^+ and Hg^{2+}) on the emissive properties of the $Ru(bpy)_2^{2+}$ chromophore were studied by steady-state and time-dependent emission spectroscopy. Our results suggest that complex **1** interacts weakly with Li^+, Na^+ and Hg^{2+}, and subtle changes are observed in its photophysical properties. These changes are discussed in terms of excited-state parameters obtained from a Franck–Condon analysis of the emission spectra.

1. Introduction

The coupling of a cation binding center to a luminescent group has been successfully exploited in the past to synthesize fluoroionophores, whose emission characteristics are modulated by association with specific metal cations [1,2]. The modulation of the emissive properties of the fluoroionophore upon cation binding can originate through several mechanisms. These mechanisms include structural effects [3], exciplex formation [4], electron transfer quenching [5–7], and changes in dipole moments and π-delocalization [8]. Within the several structural families of fluoroionophores, those in which a crown ether cation receptor is attached to an organic dye are quite common [1,2]. Crown ether rings attached to inorganic fluorophores are much less frequent. Only two examples of such molecules ave been reported, one with a crown ether attached to a *fac*-[(bpy)$Re^I(CO)_3L]^+$ group [6], and the other with a crown ether attached to a $[Ru(bpy)_3]^{2+}$ center [7]. Both of these examples achieve enhanced emission quantum yields upon cation binding by suppressing electron transfer quenching of the luminescent Re(I) or Ru(II) centers.

One class of molecules that could be potentially useful inorganic fluoroionophores is metallacrown ethers. These molecules are formed by chelation of α, ω-bis(phosphorus-donor)polyether ligands to transition metals [9–21] and can bind hard metal cations or small molecules analogously to traditional organic crown ethers [22–25]. The close proximity between the binding site and the transition metal center in metallacrown ethers suggests that the spectroscopic properties of the transition metal could be strongly coupled to the binding state of the metallacrown ether.

None of the metallacrown ethers that have been studied to date have incorporated transition metal chromophores that could function as spectroscopic probes for binding. An obvious candidate for a transition metal chromophore embedded in a metallacrown ether is bis(2,2′-bipyridine)ruthenium(II), $Ru(bpy)_2^{2+}$. Tris(2,2′-bipyridine)ruthenium(II), $Ru(bpy)_3^{2+}$, and its derivatives have been of fundamental importance in developing the understanding of electron and energy transfer reactions [26–28], and in probing medium effects [26,29–32]. The popularity of $Ru(bpy)_3^{2+}$ and derived complexes in photophysical and photoinduced electron and energy transfer studies stems from their easily measured spectroscopic characteristics, long-lived emissive excited states, greatly enhanced excited-state redox potentials and well-developed synthetic chemistry. The available synthetic methodology currently allows predictable fine-tuning of the electronic characteristics of these complexes [26,33,34]. In addition, ruthenium(II) is a low-spin, d^6 transition metal and thus inert to ligand exchange. Previous work with molybdenum(0), another low-spin d^6 transition metal, has demonstrated that stable molecular metallacrown ethers can be readily formed in high yields with such transition metals [9–19].

In this paper, we report the syntheses of the first metallacrown ether containing a $Ru(bpy)_2^{2+}$ chromophore, *cis*-[$Ru(bpy)_2(C_{12}H_8O_2P(OCH_2CH_2)_4OPO_2C_{12}H_8)$]$(CF_3SO_3)_2$ (**1**), and of the closely related *cis*-[$Mo(CO)_4(C_{12}H_8O_2P(OCH_2CH_2)_4OPO_2C_{12}H_8)$] (**2**), metallacrown ether. These metallacrown ethers have been characterized by multinuclear NMR spectroscopy and X-ray crystallography. Cation binding to **2** has been evaluated using standard NMR techniques. Finally, the luminescent properties of **1** in the presence and absence of metal cations have been studied to determine if it can be used as a probe for cation binding.

2. Experimental

All reactions and purification procedures were carried out under high-purity nitrogen. All starting materials were reagent grade and were used as received. Tetrahydrofuran (THF) was distilled from sodium/benzophenone and both acetonitrile and triethylamine were distilled from calcium hydride prior to use. Deuterated NMR solvents (chloroform-d, dichloromethane-d_2) were opened and handled under a nitrogen atmosphere at all times. The *cis*-$Mo(CO)_4$(nbd) [35], 2,2′-biphenylylenephosphochloridite ester [36], and bis(2,2′-bipyridine)bis(trifluoromethanesulfonato)ruthenium(II) [37] were synthesized using the literature procedures. $[Ru(bpy)_3](PF_6)_2$ was prepared by treating an aqueous solution of $[Ru(bpy)_3]Cl_2$ (purchased from Aldrich) with concentrated aqueous ammonium hexafluorophosphate. The $[Ru(bpy)_3](PF_6)_2$ precipitate was collected by vacuum filtration, rinsed with water and dried under vacuum.

All one-dimensional $^{31}P\{^1H\}$, $^{13}C\{^1H\}$ and ^1H NMR spectra of the ligands and complexes were recorded using a Bruker ARX-300 NMR spectrometer with a quad (^1H, ^{13}C, ^{19}F, ^{31}P) 5 mm probe. The $^{31}P\{^1H\}$ NMR spectra were referenced to external 85% phosphoric acid, and both the ^{13}C and the ^1H NMR spectra were referenced to internal $SiMe_4$.

Elemental analyses were performed by Atlantic Microlabs, Norcross, GA. A solvent of crystallization is included in a calculated analysis only if the solvent was observed in the ^1H NMR spectrum of the analytical sample.

2.1. $(2,2'\text{-}C_{12}H_8O_2)P(CH_2CH_2O)_4P(2,2'\text{-}O_2C_{12}H_8)$

A solution of 10.0 g (40.0 mmol) of 2,2′-biphenylylenephosphochloridite ester in 30 ml of freshly distilled THF was added dropwise to a solution of 3.88 g (20.0 mmol) of tetraethylene glycol and 5.58 ml (40.0 mmol) triethylamine in 100 ml of tetrahydrofuran, and was stirred under nitrogen for 1 h. The solution was filtered through Celite®, under nitrogen, and evaporated to dryness to yield 12.2 g (68.2%) of crude (2,2′-$C_{12}H_8O_2$)$P(CH_2CH_2O)_4P$(2,2′-$O_2C_{12}H_8$) as a viscous, colorless oil. $^{31}P\{^1H\}$ NMR (chloroform-d): δ 140.39 (s). ^1H NMR (chloroform-d): δ 7.34 (m, 16H, Ar), 4.08 (m, 4H, CH_2), 3.66 (m, 12H, CH_2).

2.2. cis-$[Ru(bpy)_2((2,2'\text{-}C_{12}H_8O_2)P(CH_2CH_2O)_4P(2,2'\text{-}O_2C_{12}H_8))](O_3SCF_3)_2$ (**1**)

Solutions of 0.220 g (3.09 mmol) of $Ru(bpy)_2(O_3SCF_3)_2$ in 50 ml of degassed dichloromethane [1] and 0.192 g (3.09 mmol) of (2,2′-$C_{12}H_8O_2$)$P(CH_2CH_2O)_4P$(2,2′-$O_2C_{12}H_8$) in 50 ml of degassed dichloromethane were added simultaneously and dropwise to 125 ml of degassed dichloromethane over a 2 h period. This mixture was stirred for three days. The clear, red solution was then evaporated to dryness, and the residue was triturated with ether to yield an orange solid. Yield: 0.377 g (92.2%). *Anal.* Calc. for $C_{54}H_{48}F_6O_{15}S_2N_4P_2Ru$ (with four mole H_2O): C, 46.12; H, 3.98; N, 3.99; F, 8.11%. Found: C, 46.12; H, 3.78; N, 4.09; F, 8.31%. $^{31}P\{^1H\}$ NMR (dichloromethane-d_2): δ 142.85 (s).

[1] The Ru precursor was not completely soluble in the dichloromethane. However, the insoluble portion remained suspended in the solution and was efficiently added to the reaction mixture. The suspended solid gradually disappeared during the three days that the reaction mixture was stirred at ambient temperature.

2.3. cis-[Mo(CO)$_4$((2,2′-C$_{12}$H$_8$O$_2$)P(CH$_2$CH$_2$O)$_4$P(2,2′-O$_2$C$_{12}$H$_8$))] (2)

Solutions of 0.829 g (2.77 mmol) of Mo(CO)$_4$(C$_7$H$_8$) in 100 ml of degassed dichloromethane and 1.72 g (2.77 mmol) of (2,2′-C$_{12}$H$_8$O$_2$)P(CH$_2$CH$_2$O)$_4$P(2,2′-O$_2$C$_{12}$H$_8$) in 100 ml of degassed dichloromethane were added simultaneously and dropwise to 200 ml of degassed dichloromethane over a 2 h period. This mixture was stirred for 15 min. The clear, colorless solution was then evaporated to dryness and washed with hexane to yield a white powder upon filtration. Yield: 2.10 g (88.3%). *Anal.* Calc. for C$_{36}$H$_{32}$O$_{13}$P$_2$Mo: C, 52.09; H, 3.89%. Found: C, 52.18; H, 3.95%. ^{31}P{^{1}H} NMR (chloroform-d): δ 170.09 (s). ^{1}H NMR (chloroform-d): δ 7.43 (m, 2H, Ar), 7.24 (m, 14H, Ar), 4.09 (m, 4H, CH$_2$), 3.65 (m, 12H, CH$_2$). ^{13}C NMR (chloroform-d): δ 71.07 (s, C4 and C5), 70.86 (s, C3 and C6), 70.35 (bt, C2 and C7), 66.76 (bt, C1 and C8).

2.4. X-ray data collection and solution

Suitable single crystals of **1** and **2** were mounted on glass fibers with epoxy cement and aligned upon an Enraf Nonius CAD4 single-crystal diffractometer under aerobic conditions. Standard peak search and automatic indexing routines followed by least squares fits of 25 accurately centered reflections resulted in reliable unit cell parameters. These unit cell parameters indicated that both crystals belonged to the monoclinic crystal system. Systematic absences indicated that the space groups for **1** and **2** were $C2/c$ and $P2(1)/n$, respectively. In both cases, the analytical scattering factors of the complexes were corrected for both $\Delta f'$ and $i\Delta f''$ components of anomalous dispersion. The metal and phosphorus positions were located using Patterson functions, and the other non-hydrogen atoms were located in difference Fourier maps. Positional and anisotropic displacement parameters for all non-hydrogen atoms were

refined. Hydrogen atoms were not located directly but were input in calculated positions with d(C–H) = 0.96 Å. The isotropic displacement parameter of each hydrogen atom was set equal to 1.2 times the U_{eq} value of the carbon atom to which it was bonded. The Siemens SHELXTL-PC® program package was used for all crystallographic calculations [38]. The experimental details of the data collection and refinement are summarized in Table 1. Selected bond lengths and angles are given in Table 2 and selected torsion angles are given in Table 3 for each complex. ORTEP drawings of the molecules are given in Figs. 1 and 2 and ORTEP drawings of the metallacrown ether rings are shown in Fig. 3.

2.5. Optical spectroscopy

UV–Vis spectra were obtained with a Hewlett–Packard model 8453 diode array spectrophotometer. Samples of **1** for the emission studies were 3×10^{-3} M acetonitrile solutions, placed in 1.0 cm path length quartz cuvettes and bubble degassed with dry nitrogen for a minimum of 20 min. Samples with cations contained 1.1 equivalents

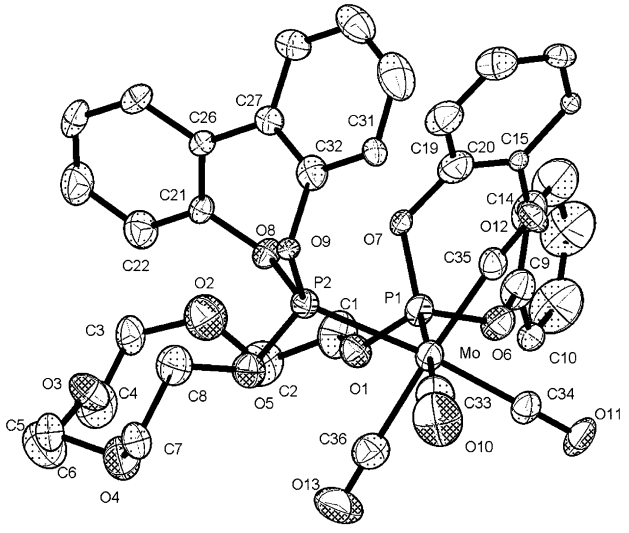

Fig. 2. Molecular structure of *cis*-[Mo(CO)$_4$((2,2′-$C_{12}H_8O_2$) P($CH_2CH_2O)_4$P(2,2′-$O_2C_{12}H_8$))] (**2**).

of $LiBF_4$, $NaBPh_4$ or $HgCl_2$, and were prepared by adding 100 μl of 0.132 M salt solution in acetonitrile to 4.0 ml of the solution of **2** in the fluorescence cell before bubble degassing. All samples were optically dilute, with absorbances below 0.65 at the excitation wavelength.

Steady-state emission spectra were recorded using a Spex Fluorolog FL3-22 fluorometer with double grating excitation and emission monochromators and a thermoelectrically cooled Hamamatsu R-928 photomultiplier tube running in photon counting mode. Emission spectra were corrected for instrument response with

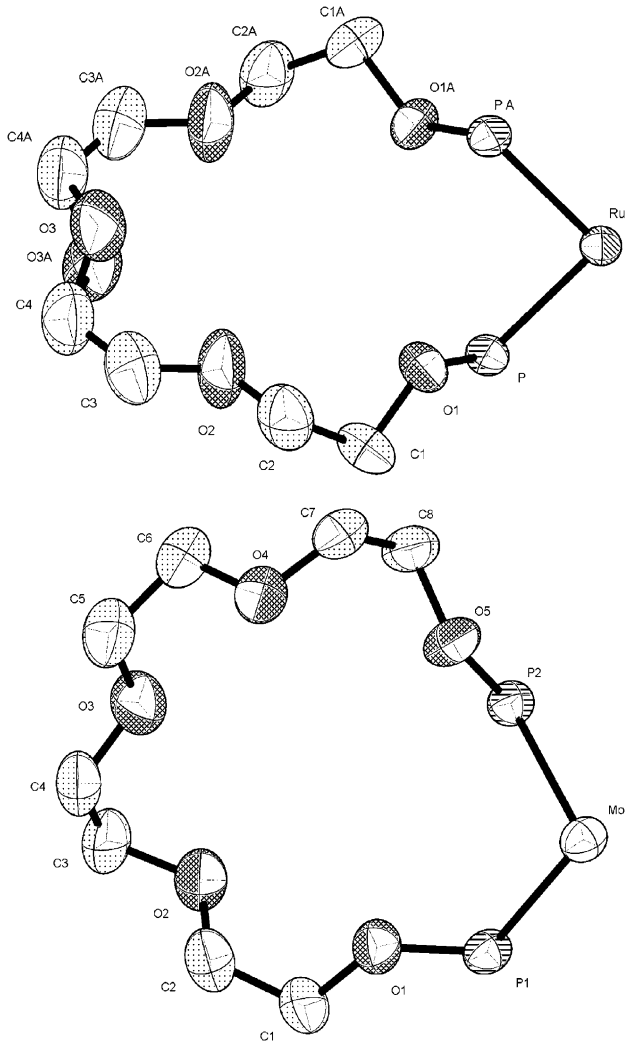

Fig. 3. Orientation of oxygen atoms suggest that the crown ether rings in both **1** and **2** are in an acceptable conformation for cation binding.

factors collected using a NIST standard lamp. All samples were excited at 400 nm. Cutoff filters were used to remove scattered excitation light when required, with cutoff wavelengths chosen well below the data collection range. Emission quantum yields were measured relative to [Ru(bpy)$_3$](PF_6)$_2$ in acetonitrile and calculated using the following equation:

$$\phi_u = \phi_s \left(\frac{I_u}{I_s}\right)\left(\frac{A_s}{A_u}\right),$$

where ϕ is the emission quantum yield, I is the integrated emission intensity, A is the sample absorbance at the excitation wavelength, and the subscripts 's' and 'u' refer to the standard and unknown samples, respectively [39].

Emission lifetimes were measured using a PTI GL3300 pulsed nitrogen laser with an attached GL301 tunable dye head. The samples were excited at 387 nm using BBQ dye (Exciton) in *p*-dioxane, and the decay was monitored at the emission maximum. Emission decays were col-

lected at a right angle to the excitation, using a McPherson 272 monochromator with a holographic grating, and a thermoelectrically cooled (−20 °C) Hamamatsu R-928 photomultiplier tube. A 400 MHz Tektronix TDS 380 oscilloscope was used to digitize the data. All lifetimes were averages of 256 laser pulses. Decay rates were determined by fitting the data to a single or double exponential model using a least-squares routine.

2.6. Emission spectral fitting

Emission spectra were fit by a one-mode Franck–Condon analysis using the following equation [39–45]:

$$I(\bar{\nu}) = \sum_{\upsilon_M=0}^{5} \left\{ \left(\frac{E_0 - \upsilon_M \hbar\omega_M}{E_0} \right)^3 \left(\frac{S_M^{\upsilon_M}}{\upsilon_M!} \right) \times \exp\left[-4\ln(2) \left(\frac{\bar{\nu} - E_0 + \upsilon_M \hbar\omega_M}{\Delta\bar{\nu}_{0,1/2}} \right)^2 \right] \right\},$$

where $I(\bar{\nu})$ is the emitted light intensity at the energy $\bar{\nu}$ in cm^{-1}, relative to the intensity of the $0 \rightarrow 0$ transition. E_0 is the energy gap between the zeroth vibrational levels of the ground and excited states. $\hbar\omega_M$ is the quantum spacing for averaged coupled vibrational modes of medium frequency. S_M is the Huang–Rhys factor reflecting nuclear distortion along the medium frequency quantum mode [46]. The relationship between the S and Q (internal) coordinates is given below, where M is the reduced mass of the vibrating system, ω is the frequency of vibration, and ΔQ is the nuclear displacement

$$S = \frac{1}{2}\left(\frac{M\omega}{\hbar}\right)(\Delta Q)^2,$$

where $\Delta\bar{\nu}_{0,1/2}$ is the full-width at half-maximum for individual vibronic lines, and it includes contributions from solvent librations and low frequency molecular modes treated classically. The parameters E_0, S_M, $\hbar\omega_M$ and $\Delta\bar{\nu}_{0,1/2}$ were optimized with a least squares minimization routine using a simplex algorithm [43]. The variance-covariance matrix, correlation matrix and standard deviations for the individual parameters were computed by means of a quadratic extrapolation at the minimum [43].

2.7. Other fits

An estimation of the cavity size of the metallacrown ether ring in complex **1** was obtained by finding the sphere that minimizes the distance between its surface and the center of all six oxygen atoms in the ring. The center coordinates (x_0, y_0, z_0 in Cartesian coordinates) and the radius (r) of the sphere were optimized by minimizing the objective function

$$ssq = \sum_{j=1}^{6} \left(\sqrt{(x_j - x_0)^2 + (y_j - y_0)^2 + (z_j - z_0)^2} - r \right)^2,$$

where x_j, y_j and z_j are the Cartesian coordinates of the jth oxygen atom of the metallacrown ring. The objective function *ssq* was minimized using Mathematica 4.2. Other non-linear fits throughout the manuscript were performed with a Gauss–Newton algorithm included in the JMP Statistical Discovery Software published by the SAS Institute.

3. Results and discussion

3.1. Syntheses of the bis(phosphepin)polyether ligand and the metallacrown ether complexes

The unsymmetrical bis(phosphepin)polyether ligand, (2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$), was prepared by the reaction of 2,2′-biphenylylenephosphochloridite ester with tetraethyleneglycol in the presence of triethylamine as shown in Fig. 4. The reaction is quantitative if dry reagents are used, as indicated by the presence of a singlet in the $^{31}P\{^1H\}$ NMR spectrum and by the correct integration ratio of aliphatic and aromatic resonances in the ^1H NMR spectra of the crude ligand. In addition, no unexplained resonances should be present in the ^1H NMR spectra of the crude ligand.

The metallacrown ethers, *cis*-[Ru(bpy)$_2$((2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$))](O_3SCF_3)$_2$ (**1**) and *cis*-[Mo(CO)$_4$((2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-O_2-

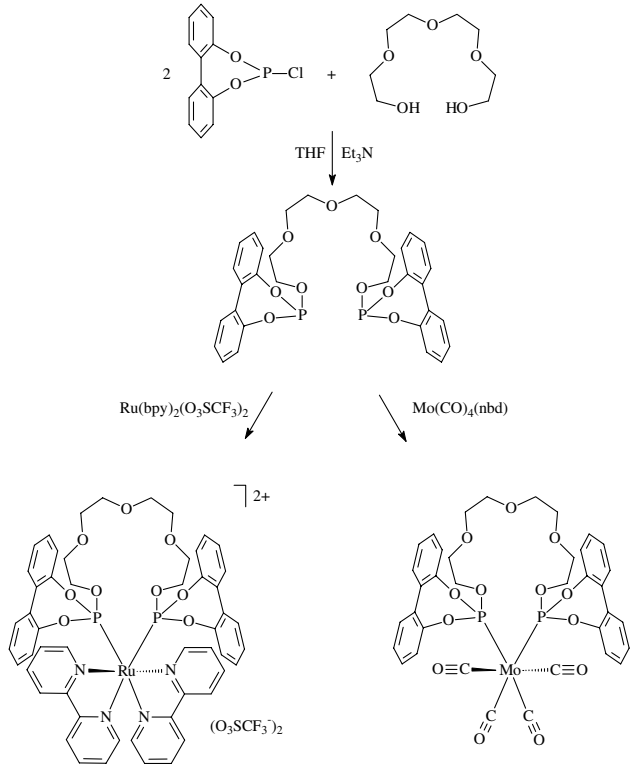

Fig. 4. Synthesis of the bis(phosphepin)polyether ligand and metallacrown ethers.

$C_{12}H_8$))] (**2**), were prepared by the reactions of the ligand with the appropriate metal precursors at moderate dilutions as shown in Fig. 4. Only the monomeric metallacrown ethers were obtained, as indicated by the presence of a singlet in the $^{31}P\{^1H\}$ NMR spectrum of each complex, and these complexes were obtained in high yields. As is the case in previously studied [1,3,2]-dioxaphosphepin ligands derived from 2,2′-biphenol, the single $^{31}P\{^1H\}$ NMR resonance for each metallacrown ether suggests that the enantiomers of the [1,3,2]-dioxaphosphepin rings are rapidly interconverting at ambient temperature [47,48].

3.2. X-ray crystal structures of *1* and *2*

The X-ray crystal structures of **1** and **2** have been determined. An ORTEP drawing of **1** (without the triflate anions) is shown in Fig. 1 and an ORTEP drawing of **2** is shown in Fig. 2. A comparison of the metallacrown ether rings in the two complexes is shown in Fig. 3.

The coordination environment of the metal in each complex is a distorted octahedron. The distortions from the ideal octahedral coordination geometry are more severe in **1** due to the small bite angle of the 2,2′-bipyridine ligand (77.84(17)°). The distortions from octahedral coordination geometry in **2** are much smaller, and they are similar to those previously observed in other metallacrown ethers containing α,ω-bis(phosphite)polyether ligands [15,19].

The [1,3,2]-dioxaphosphepin ligands in **1** and **2** are enantiomeric due to the twist of the 2,2′-biphenoxy groups [48]. The chirality of the ligands can be determined from the torsion angles about the C–C bonds of the 2,2′-biphenoxy groups, given in Table 3. When both torsion angles have the same sign, as is required by the C_2 molecular symmetry in **1** and is also observed for **2**, the enantiomer is either the *R***R** or *S***S** diastereomer. [2] Because both metallacrown ethers crystallize in centrosymmetric space groups, both the *R***R** and *S***S** diastereomers are present in each crystal.

An interesting aspect of the structures of **1** and **2** is the conformation of the metallacrown ether ring. The metallacrown ether rings in both molecules are relatively planar as shown in Figs. 1 and 2. However, the C_2 molecular symmetry in **1** means that the two halves of the ring (split at Ru and O3/O3A) have the same torsion angles. This is not the case for the metallacrown ether ring in **2**. The torsion angles of all but three of the chemically equivalent bonds in **2** (the exceptions are P2–Mo–P1–O1 and P1–Mo–P2–O5; C1–C2–O2–C4 and C8–C7–O4–C6; C2–O2–C3–C4 and C7–O4–C6–C5) are of the same magnitude but differ in sign. This indicates that the metallacrown ether ring in **2** is close to having mirror symmetry with the mirror plane passing through Mo and O3 and perpendicular to the plane of the metallacrown ether rings. This suggests that, as expected, a variety of conformations are available for metallacrown ether rings formed by cis-coordination of the bis(phosphepin)/polyether ligand in **1** and **2**.

The planar, open conformations of the metallacrown ether rings in both **1** and **2** and the orientations of the ether oxygens into the rings, shown in Fig. 3, suggest that the solid-state conformations may not be significantly different from those that could exist in complexes with hard metal cations. To determine the types of cations that could be bound by these metallacrown ethers, a non-linear least-squares optimization was used to estimate the size of a sphere that would fit into the cavity of the metallacrown ether ring in **1**. This calculation demonstrated that the oxygen atoms are relatively evenly distributed about the centroid of the ring (sphere radius = 2.64 Å; deviations: O1 = 0.094 Å, O2 = −0.29 Å, O3 = 0.20 Å) and that the distance between the center of the nearest oxygens and the center of the sphere is 2.35 Å. This distance suggests that Li^+ cations should easily fit into the cavity but that the cavity is marginally too small for a Na^+ cation [10,49] and significantly too small for a Hg^{2+} cation [10].

3.3. Cation complexation by *1* and *2*

The X-ray crystallography results suggest that both **1** and **2** should be able to bind Li^+ cations but that the binding of Na^+ and Hg^{2+} cations is less likely. These results are consistent with those reported by Powell et al. [50,51] for the closely related *cis*-$Mo(CO)_4(Ph_2PO(CH_2CH_2O)_4PPh_2)$ metallacrown ether, which was reported to bind Li^+ but not Na^+ cations. However, when either $LiBPh_4 \cdot 3dme$ (dme = dimethoxyethane) or $NaBPh_4$ are added to a solution of **2** in chloroform-d, no change is observed in either the $^{31}P\{^1H\}$ or ^1H NMR spectra of the solution. This suggests that either strong binding is not occuring or that binding of the cations does not have a measurable effect on either the $^{31}P\{^1H\}$ or ^1H NMR spectra [12].

To further probe cation binding by **2**, a catalytic amount of solid $HgCl_2$was added to a chloroform-d solution of **2**. In all previous studies, this addition has caused a rapid *cis–trans* isomerization of the *cis*-$Mo(CO)_4$(phosphorous-donor ligand)$_2$ center [18]. However, in case of **2**, no isomerization is observed even after several days at ambient temperature. This behavior is unprecedented and suggests that the cation binding abilities of metallacrown ethers derived from

[2] Throughout this paper, *R** and *S** are used to refer to the relative conformations of the 2,2′-biphenyl groups. The first conformation referred to in a molecule is designated *R** by convention.

(2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$) are quite different from those of other metallacrown ethers, even those derived from $Ph_2P(CH_2CH_2O)_4PPh_2$ that have the same ring size and number of oxygens.

3.4. Photophysical properties of cis-[Ru(bpy)$_2$((2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$))](O$_3$SCF$_3$)$_2$ (1)

Because the $Ru^{II}(bpy)_2$ chromophore group in complex **1** is an integral part of the metallacrown ring, we expected that its excited state properties could be dependent on the binding state of the ring. The modulation of the excited state parameters of **1** through interactions with cations was assessed by measuring the steady-state and time-dependent emissive characteristics of **1** and of mixtures of **1** and either $LiBF_4$, $NaBPh_4$ or $HgCl_2$ in acetonitrile.

Fig. 5 shows the UV–Vis absorption spectrum of **1** in acetonitrile. As can be seen in the inset in Fig. 5, the lowest energy absorption is a shoulder at about 350 nm. This transition probably corresponds to the $d\pi(Ru) \rightarrow \pi^*(bpy)$ metal-to-ligand (MLCT) transition of the $Ru^{II}(bpy)_2^{2+}$ group. This absorption is blue-shifted by 100 nm with respect to the equivalent MLCT transition in $Ru(bpy)_3^{2+}$ and it is significantly weaker (MLCT at 450 nm, $\varepsilon \approx 10^4$ M^{-1} cm^{-1}) [26,52]. The increased energy gap between the ground and the bpy-based MLCT excited states is probably due to the π-acidic character of the phosphepin groups attached to Ru(II) in **1**. The π-backbonding interaction between the Ru and P atoms decreases the energy of the dπ(Ru) orbitals relative to the π*(bpy) orbitals, increasing the energy required for the transition. The energy gap between the ground and bpy MLCT excited states, E_0, can be obtained from the emission spectrum of **1** and the Franck–Condon analysis of its profile as described in Section 2 (see Fig. 6). The E_0 value for **1** in acetonitrile is 17 290 cm^{-1} (Table 4) and is significantly larger than the corresponding E_0 value of 16 360 cm^{-1} for $Ru(bpy)_3^{2+}$.

Another important difference between complex **1** and $Ru(bpy)_3^{2+}$ is the significantly smaller quantum yield of emission, ϕ_{em} for **1**. In fact, as seen on Table 4, ϕ_{em} for **1** is about 18 times smaller for complex **1**. A reason for this difference is the much weaker absorption cross-section for the MLCT transition in **1**, compared to $Ru(bpy)_3^{2+}$. A decreased absorption cross-section is the consequence of a smaller transition probability for the absorption, **B**, which is proportional to the radiative decay rate, as indicated by the following equation [40,53]:

$$k_r = 8\pi\hbar c n^3 \langle \bar{\nu}^{-3} \rangle^{-1} \mathbf{B}, \quad (1)$$

where k_r is the radiative decay rate, n is the refractive index of the medium, $\bar{\nu}$ is the emission energy in wavenumbers, and $\langle \bar{\nu}^{-3} \rangle^{-1}$ is the inverse of the average value of $\bar{\nu}^{-3}$ for the emission spectrum. The value of $\langle \bar{\nu}^{-3} \rangle^{-1}$ can be calculated using Eq. (2), where I is the emission intensity in units of number of quanta per energy interval per second [40,53]

$$\langle \bar{\nu}^{-3} \rangle^{-1} = \frac{\int I(\bar{\nu})\, d\bar{\nu}}{\int I(\bar{\nu}) \bar{\nu}^{-3}\, d\bar{\nu}}. \quad (2)$$

As the emission quantum yield is the ratio of the observed radiative rate to the sum of all radiative and non-radiative decay channels (Eq. (3)), a decrease in k_r results in a decrease in ϕ_{em}

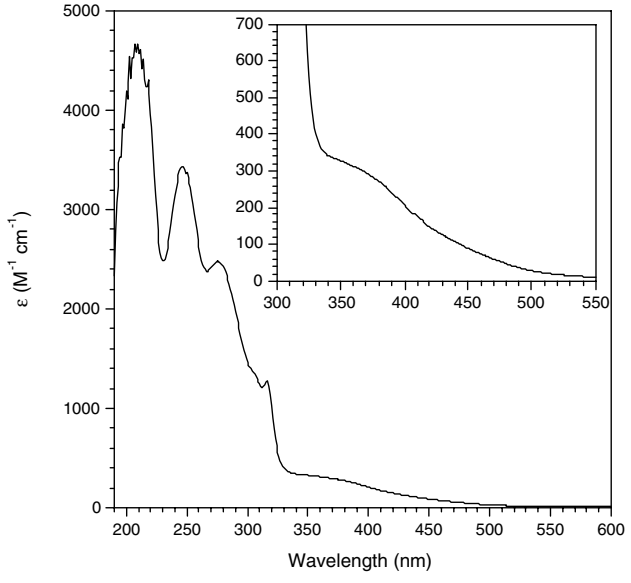

Fig. 5. UV–Vis absorption spectrum of *cis*-[Ru(bpy)$_2$((2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$))](O$_3$SCF$_3$)$_2$ (**1**) in acetonitrile. The inset shows a magnification of the lowest energy transition.

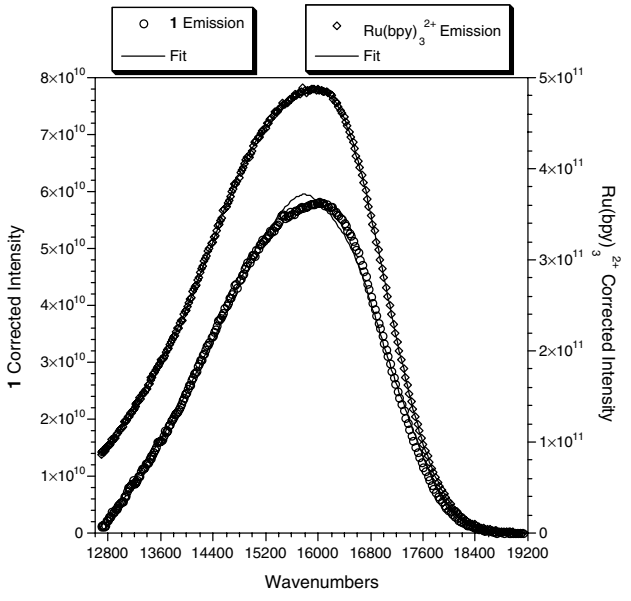

Fig. 6. Emission spectra of *cis*-Ru(bpy)$_3$(PF$_6$)$_2$ and [Ru(bpy)$_2$((2,2′-$C_{12}H_8O_2$)P(CH_2CH_2O)$_4$P(2,2′-$O_2C_{12}H_8$))](O$_3$SCF$_3$)$_2$ (**1**) in acetonitrile with excitation at 400 nm. The solid lines correspond to the Franck–Condon fits (see text).

Table 4
Photophysical properties for $Ru(bpy)_3^{2+}$ and complex **1** in acetonitrile at 25 °C with different ions added (1.1 equivalents)

[a] A_1 and A_2 are the pre-exponential parameters for the emission lifetime fits, see Eq. (4). Their values have been normalized to A_1.
[b] ϕ_{em} is the emission quantum yield.
[c] Data taken from [39].

$$\phi_{em} = \frac{k_r}{\sum k_r + \sum k_{nr}}. \quad (3)$$

The emission decay observed for complex **1** was not single exponential but could be satisfactorily fit to the double exponential function in Eq. (4). The fit parameters A_n and τ_n are listed in Table 4

$$D(t) = A_1 \exp\left(-\frac{t}{\tau_1}\right) + A_2 \exp\left(-\frac{t}{\tau_2}\right). \quad (4)$$

The principal lifetime for **1**, $\tau_1 = 974$ ns is quite comparable to the excited state lifetime of 855 ns for $Ru(bpy)_3^{2+}$. [3] The minor lifetime for **1**, $\tau_2 = 43$ ns is probably associated with a weak and broad emission observable at about 500 nm in Fig. 7. We are currently uncertain regarding the origin of this emission, but as can be observed in Fig. 7, its intensity is sharply dependent on the addition of cations to the solution of complex **1**. This emission may possibly originate from the biphenol groups of the phosphepin groups in complex **1**, as discussed below.

The results from the Franck–Condon profile analysis of the emission spectra are listed in Table 4. There are some very striking differences in the parameters obtained for complex **1** and $Ru(bpy)_3^{2+}$. As can be seen in Fig. 6, the quality of the fit for the emission spectrum of $Ru(bpy)_3^{2+}$ is higher than for the emission spectrum of **1**. We believe that this is due to the overlap of the short-lived emission, discussed above, with the major emission component at 620 nm. Due to this problem, the fit parameters for **1** may contain systematic errors and correlations and should be interpreted carefully. However, the difference in the parameters for **1** and $Ru(bpy)_3^{2+}$ are too large to be explained by fitting problems. As indicated earlier, the energy gap (E_0) for complex **1** is 930 cm^{-1} larger than for $Ru(bpy)_3^{2+}$ due to the π-acid nature of the phosphepin groups. Unexpectedly, the vibrational spacing for the average, medium-frequency coupled vibrational mode ($\hbar\omega_M$) for **1** is nearly half the value seen for $Ru(bpy)_3^{2+}$. $\hbar\omega_M$ is an average of all the molecular vibrational modes coupled to the electronic transition from the excited state to the ground state. The degree of participation of an individual vibrational mode into this average is gauged by the amount of distortion (S) that the molecule undergoes along that mode as a result of the electronic transition, as seen in the following equation:

$$\hbar\omega_M = \frac{\sum_j S_j \hbar\omega_j}{\sum_j S_j}. \quad (5)$$

The 1350 cm^{-1} value of $\hbar\omega_M$ observed for $Ru(bpy)_3^{2+}$ is largely dominated by medium-frequency breathing modes of the bpy ligands, as the occupancy of the π^*(bpy) orbitals changes during the electronic transition. The 760 cm^{-1} value of $\hbar\omega_M$ observed for **1** suggests that bpy breathing modes are much less important in the deactivation of the excited state and lower frequency

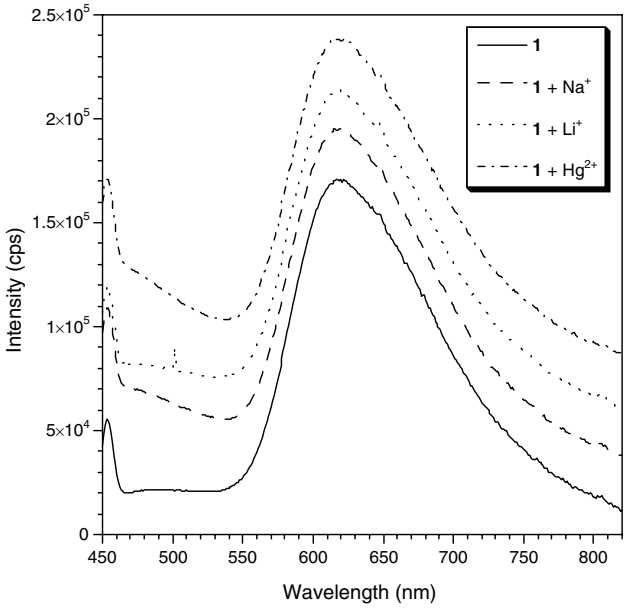

Fig. 7. Emission spectra of *cis*-$[Ru(bpy)_2((2,2'\text{-}C_{12}H_8O_2)P(CH_2CH_2O)_4P(2,2'\text{-}O_2C_{12}H_8))](O_3SCF_3)_2$ (**1**) in acetonitrile with different cations added (1.1 equivalents). The spectra have been offset for clarity. The sharp peaks at 455 nm are water Raman signals.

[3] We estimated the participation of a given component in the double exponential decay by integrating $D(t)$. The integral for a given component is the product of the pre-exponential factor (A) and the lifetime (τ), and it is proportional to the number of photons emitted through that channel.

modes are dominating. These lower frequency modes could involve bending motions of the polyether ring and the phosphepin groups. This significant difference in the value of of $\hbar\omega_M$ could also indicate that the nature of the lowest-lying excited state for **1** is not purely a bpy-based MLCT state, but that the bis(phosphite) ligand may have a significant participation as well. The much larger value of S_M observed for **1** implies a larger degree of excited state distortion and a larger inner-sphere reorganizational energy ($\lambda_i = S_M\hbar\omega_M$; $\lambda_i = 2130$ cm^{-1} for **1** and 1490 cm^{-1} for $Ru(bpy)_3^{2+}$). Finally, the bandwidth for a vibronic line, $\Delta\bar{\nu}_{0,1/2}$, is 720 cm^{-1} smaller for **1** that it is for $Ru(bpy)_3^{2+}$. The reduced value of $\Delta\bar{\nu}_{0,1/2}$ observed for **1** may be a reflection of of a decreased outer-sphere reorganizational energy (λ_o). Ruling out specific solvent effects, a decrease in λ_o may be caused by a decrease in the dipole moment difference between the ground and excited states in **1**. All of the differences in the spectral fitting parameters between **1** and $Ru(bpy)_3^{2+}$ discussed above are consistent with a significantly different electronic and vibrational structure for the lowest-lying excited state of **1**.

When adding different ions to an acetonitrile solution of **1**, subtle changes are observed in the emission spectrum and the excited state lifetime. The results are summarized on Table 4. In general, the long-lived and short-lived components of the emission decay become shorter as cations are introduced into the solution. Also, the emission quantum yield is slightly decreased, by an average of 11%, upon addition of cations. The observed changes are overall small and not particularly specific to the identity or charge of the cation added to the solution. However, the changes in the emission properties of **1** are observable, despite the fact that the interactions between the complex and cations appear to be very weak. Considering the spectral fitting parameters on Table 4, it appears that the presence of the cations produces a slight increase in the energy gap (E_0). Such a change is plausible if the interaction of a cation with the metallacrown ether increases the overall π-acidity of the diphosphite ligand. The vibrational spacing ($\hbar\omega_M$) also shows a tendency to decrease as cations are added to the sample. Again, this could be caused by a weak interaction between the cation and the metallacrown ether. If, as argued above, the metallacrown ether vibrational modes are coupled to the electronic transition, a structural change caused by an interaction with a cation could alter the value of $\hbar\omega_M$ through changes in both vibrational frequencies and excited-state distortions (see Eq. (5)). Another interesting change is the reduction of the bandwidth, $\Delta\bar{\nu}_{0,1/2}$, upon addition of cations to the sample of **1**. A decrease in $\Delta\bar{\nu}_{0,1/2}$ would indicate a reduction in λ_o due to either a loss of specific solvent effects, or a decrease in the dipole moment change during the electronic transition. Another possibility that cannot be ruled out is the change in ionic strength of the medium.

The emission spectra for **1** with different cations added, shown in Fig. 7, exhibit a secondary emission between 450 and 550 nm. This emission is dependent on the identity of the cation added to **1**, and appears to be most intense for Na^+ and Hg^{2+}, and weakest in the absence of a cation. We believe that this emission corresponds to the τ_2 component of the emission decay, and because of its high energy, it could correspond to an emission from the biphenol moieties of the phosphepin groups of **1**. If this is indeed the origin of this emission, its dependence on the presence and nature of the cations added to the sample could arise from structural changes in the metallacrown ether. As the metallacrown ether ring distorts to interact with a cation, the planarity of the biphenol group could be increased, lowering the energy of its emission. This interpretation for the secondary emissions seen in Fig. 7 is still speculative, and they will be studied in more detail in the near future due to their dependency on the presence and nature of cations.

4. Conclusions

This manuscript demonstrates how a chromophoric group, $Ru^{II}(bpy)_2^{2+}$, can be easily incorporated into a metallacrown ether ring. The interactions between the metallacrown ether ring and monoatomic cations in this type of compound could be exploited for sensing applications, as the coordination of the cation can modulate the photophysical properties of the neighboring chromophore. Unfortunately, complex **1** described here seems to interact only weakly with the selected cations, and its emission appears to be *quenched* by interacting with them. Ideally, a cation sensor should be specific, have a large equilibrium constant for the formation of the metallacrown ether–cation complex, and be luminescent in the complexated form. However, as a first example of a $Ru^{II}(bpy)_2^{2+}$-containing metallacrown ether, complex **1** provides important insight into the design of more effective cation sensors. First, specificity and metallacrown ether–cation complex stability issues can be addressed by systematically varying the length of the polyether portion of the metallacrown ring, and by changing the linkage to the phosphorus atoms. Both phosphite and phosphine linkages are possible in designing the chelating ligand. Second, the detailed nature of the emitting state in the metallacrown ether complex must be understood. We are currently planning on deleting the biphenol groups on the chelating ligand to eliminate their possible emission and simplify the spectroscopic measurements. Concurrently, we are also planning on exploiting the cation dependence of the putative biphenol emission in related complexes. Finally, we believe that chromophore-containing metallacrown ethers have great potential for sensing

applications due to their synthetic versatility and their possibilities for chromophore–host interactions.

Received 9 December 2003; accepted 5 April 2004

Abstract

A family of bis-imidazole ligands based on the parent bis(imidazol-2-yl)methane structure, and which can mimic multi-histidine coordination in biological systems, have been complexed to Mn(II), Cu(II) and Zn(II) centres. Five complexes were characterised by X-ray crystallography. A common structural feature of the ligands is that the two imidazole rings, which have a single spacer tetrahedral carbon atom between them, form stable, six-membered *N*,*N*′ chelate rings with the metals.

1. Introduction

The imidazole function of histidine is a ubiquitous ligand in Zn(II) and Cu(II) metalloproteins. In these enzymes the three-dimensional structure of the peptide chains effectively brings together two or more distant imidazole moieties close enough to simultaneously bind the central metal ion. Thus, there is great interest in bis-imidazole ligands which can mimic multi-histidine co-ordination in biological systems [1,4]. The present study centres on the synthesis and structural characterisation of Mn(II), Cu(II) and Zn(II) complexes of the *N*,*N*′ chelating ligands, bis(imidazol-2-yl)methane (2-BIM), bis(-1-methyl-1H-imidazol-2-yl)methane (2-BIM(Me)), bis(1-benzyl-1H-imidazol-2-yl)methanol (2-BIM(Bz)OH), 3-(2-{[1-(2-cyanoethyl)-1H-imidazol-2-yl]methyl}-1H-imidazol-1-yl)propanenitrile (2-BIM(CN)) and 1-(2,4-dichlorobenzyl)-2-{[1-(2,4-dichlorobenzyl)-1H-imidazol-2- yl] methyl}-1H-imidazole (2-BIM(ClBz)) (Fig. 1). A common structural feature of the ligands is that the two imidazole rings have a single spacer tetrahedral carbon atom and are able to form a stable six-membered chelate ring to the metal centre. Although a number of metal complexes of 2-BIM and a few of its derivatives have already been reported [1–18], relatively few of these [1,8,9,14,16,17] have been structurally characterised.

2. Results and discussion

In general, the Mn(II), Cu(II) and Zn(II) complexes were all prepared in a similar manner with the particular metal perchlorate salt being reacted with the bis-imidazole ligand in either a 1:2 or 1:3 molar ratio. All of the complexes were essentially insoluble in water. The X-ray crystal structure of $[Zn(2\text{-}BIM)_2](ClO_4)_2$ is shown in Fig. 2 and important bond lengths and angles are given in Table 1. The Zn(II) ion sits on a 2-fold axis (site symmetry 2) and the geometry is significantly distorted from regular tetrahedral. The Zn–N1–N4 plane is inclined at 66.50(5)° to the Zn–N1A–N4A plane and within each 2-BIM ligand the five-membered rings are inclined at 16.8(1)° to each other. Hydrogen-bonding involving the

perchlorate anion and the amine groups of the cation link the ions into puckered two-dimensional sheets (Fig. 3). The bidentate coordination mode of the 2-BIM ligands in the complex is the same as that found in the structurally characterized Cu(II) analogue $[Cu(2\text{-}BIM)_2(ClO_4)_2]$ [1] in which the metal sits in a square plane of 4N and with weak bonding interactions with an oxygen atom from each of the apical perchlorate ions. As expected, the mean metal–N bond distances in $[Zn(2\text{-}BIM)_2](ClO_4)_2$ and $[Cu(2\text{-}BIM)_2(ClO_4)_2]$ are very similar.

Mn(II), Cu(II) and Zn(II) complexes containing the ligand 2-BIM(Me) were synthesised and the latter two structurally characterised (Figs. 4 and 5, and Tables 2 and 3). $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2$ and $[Zn(2\text{-}BIM(Me))_2](ClO_4)_2$ are isomorphous. The metal ion (site symmetry 222) lies at the intersection of three two 2-fold axes, one passing through the methylene carbon atoms, one bisecting the N1–N1b and N1a–N1c vectors and one

bisecting N1–N1c and N1a–N1b. Each ligand is essentially planar but the two structures differ in the interplanar angle between the two ligands. The value for the zinc complex (64.02(2)°) shows it is further along the path from square planar to tetrahedral than the copper analogue (59.22(2)°).

For the 2-BIM(CN) ligand Mn(II), Cu(II) and Zn(II) complexes were prepared and the latter was structurally characterized. The X-ray crystal structure of $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot 0.5MeCN$ (Fig. 6 and Table 4) shows the asymmetric unit to contain two independent

$[Zn(2\text{-}BIM(CN))_2]^{2+}$ cations, four perchlorate anions and one molecule of acetonitrile solvate. The two cations differ principally in the orientation of the "tails"; these are *anti* on both ligand molecules bonded to Zn2 but one ligand bonded to Zn1 has the tail *syn*. The geometry at the metal ion in each case is approaching tetrahedral but the small bite angle of the ligand leads to significant distortion. One of the perchlorate anions is disordered and this has been modelled as 50% occupancy of two sites related by rotation about one of the Cl–O bonds.

The X-ray crystal structure of $[Cu(2\text{-}BIM(Bz)OH)_2(H_2O)_2](ClO_4)_2$ (Fig. 7 and Table 5) shows the cation to be centrosymmetric with the Cu(II) ion having tetragonal geometry and site symmetry $\bar{1}$, being coordinated by

Symmetry transformations used to generate equivalent atoms: #1 $-x+1, -y+1, -z+1$.

the 4N atoms from the two bidentate 2-BIM(Bz)OH ligands and two axial water molecules. The alcohol groups of the 2-BIM(Bz)OH ligands are each hydrogen-bonded to one of the coordinated water molecules and these have further hydrogen bonds to the perchlorate anion and to the alcohol group of a neighboring cation. The H-bonding links the complexes into one-dimensional chains (parallel to the *a*-axis) and there are additional H-bonding interactions between the chains.

Although the Mn(II), Cu(II) and Zn(II) complexes of the 2-BIM(ClBz) ligand were synthesised and characterised using IR and microanalytical data none of these provided crystals suitable for X-ray crystallographic analysis.

Prompted by the antitumor activity reported for the Pt(II) complex $[Pt(2\text{-}BIM(Me)OH)Cl_2]$ [16] and the use of the diiron(II) complex $[Fe_2(HCO_2)_4\{\text{-}BIM(Me)OMe(Ph)\}_2]$ to model features of polyiron-oxo proteins [18] we have already initiated the next phase of our studies with the bis-imidazole ligands. A number of the ligands have been complexed to silver(I) to give novel dimeric complexes and these have been shown to exhibit good antimicrobial activity in vitro [19].

3. Experimental

Chemicals were purchased from commercial sources and, unless specified, were used without further purification. Literature methods were used to prepare 2-BIM [20,21], 2-BIM(Me) [22], BIM(Bz)OH [23], 2-BIM(CN) [19] and 2-BIM(ClBz) [19]. Infrared spectra of solids (in a KBr matrix) were recorded in the region 4000–400 cm^{-1} on a Nicolet FT-IR Impact 400D infrared spectrometer and ^1H NMR spectra were run on a Bruker Avance 300 MHz instrument. Microanalytical data were provided by the Microanalytical Laboratory, National University of Ireland, Cork, Ireland.

3.1. $[Zn(2\text{-}BIM)_2](ClO_4)_2$

A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.62 g, 1.67 mmol) in methanol (5 cm^3) was added to a stirred solution of 2-BIM (0.5 g, 3.37 mmol) in methanol (15 cm^3). The resulting clear solution was stirred for 1 h and then sat aside to slowly evaporate at room temperature. The product formed as colourless crystals. The solid was filtered off, washed with methanol and allowed to air dry. Yield: 0.2 g (21%). The complex was soluble in acetonitrile and methanol and was insoluble in water. *Anal*. Calc.: C, 30.4; H, 2.88, N, 20.00. Found: C, 30.00; H, 2.82; N19.91%. IR: 3215, 1632, 1574, 1498, 1402, 1281, 1095, 932, 868, 746, 624 cm^{-1}. ^1H NMR (ppm DMSO): 12.88 (4H, s), 7.30 (4H, s), 6.75 (4H, s), 4.39 (4H, s).

3.2. $[Mn(2\text{-}BIM(Me))_3](ClO_4)_2 \cdot 2H_2O$

A solution of $Mn(ClO_4)_2 \cdot 6H_2O$ (0.137 g, 0.38 mmol) in methanol (3 cm^3) was added to a solution of 2-BIM(Me) (0.2 g, 1.14 mmol) in methanol (10 cm^3) and the mixture stirred for 1 h at room temperature. The precipitated white solid was filtered off, washed with methanol and dried in air. Yield: 0.18 g (58%). The complex was soluble in acetonitrile and hot acetone and was insoluble in water. *Anal*. Calc.: C, 39.61; H, 4.92; N, 20.53. Found: C, 39.52; H, 4.48; N, 20.69%. IR: 3432, 2927, 1640, 1510, 1406, 1289, 1092, 956, 898, 812, 763, 658, 624, 461 cm^{-1}.

3.3. $[Cu(2BIM(Me))_2](ClO_4)_2 \cdot H_2O$ and $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2$

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.21 g, 0.57 mmol) in methanol (3 cm^3) was added to a solution of 2-BIM(Me) (0.2 g, 1.14 mmol) in methanol (10 cm^3) and the mixture stirred for 1 h at room temperature. The precipitated blue solid $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2 \cdot H_2O$ was filtered off, washed with MeOH and diethyl ether and then air-dried. Yield: 0.3 g (57%). The complex was soluble in acetonitrile and was insoluble in water. *Anal*. Calc.: C, 34.15; H, 4.14; N, 17.70. Found: C, 34.08; H, 3.61; N, 17.29%. IR: 3511, 3138, 1529, 1415, 1300, 1108, 980, 811, 766, 628, 483 cm^{-1}. A sample of the anhydrous complex $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2$ suitable for X-ray analysis was obtained following the same method above except replacing the solvent MeOH with MeCN. Bright blue crystals of the product formed when the reaction solution was allowed to slowly evaporate in air.

3.4. $[Zn(2\text{-}BIM(Me))_2](ClO_4)_2$

A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.21 g, 0.56 mmol) in methanol (3 cm^3) was added to a stirred solution of 2-BIM(Me) (0.2 g, 1.14 mmol) in methanol (10 cm^3). The mixture was stirred for 1 h at room temperature and the white product was filtered off, washed with methanol and allowed to air dry. The solid was recrystallised from a 1:1 acetonitrile:acetone mixture. Yield: 0.19 g (54%).

The complex was soluble in acetonitrile and hot acetone and was insoluble in water. *Anal.* Calc.: C, 35.04; H, 3.89; N, 18.17. Found: C, 34.70; H, 3.92; N, 17.99%. IR: 3460, 3138, 2958, 1529, 1421, 1338, 1300, 1102, 981, 936, 772, 627, 477 cm^{-1}. ^1H NMR (ppm DMSO): 7.23 (4H, s), 6.58 (4H, s), 4.32 (4H, s), 3.65 (12H, s).

3.5. $[Cu(2BIM(Bz)OH)_2(H_2O)_2](ClO_4)_2$

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.21 g, 0.57 mmol) in methanol (3 cm^3) was added to a stirred solution of 2-BIM(Bz)OH (0.4 g, 1.16 mmol) in methanol (10 cm^3). The mixture was stirred for 4 h at room temperature, giving a purple solid product. The solid was filtered off, washed with methanol and air-dried. The complex was recrystallised from acetonitrile. Yield: 0.38 g (65%). The complex was soluble in acetonitrile and was insoluble in water. *Anal.* Calc.: C, 51.09; H, 4.49; N, 11.35. Found: C, 51.01; H, 4.47; N, 11.43%. IR: 3344, 3138, 1714, 1504, 1459, 1364, 1287, 1114, 968, 926, 836, 714, 628 cm^{-1}.

3.6. $[Mn(2\text{-}BIM(CN))_3](ClO_4)_2 \cdot 2H_2O$

$Mn(ClO_4)_2 \cdot 6H_2O$ (0.14 g, 0.39 mmol) in methanol (3 cm^3) was added to a solution of 2-BIM(CN) (0.3 g, 1.18 mmol) in methanol (7 cm^3) and the mixture stirred for 1 h at room temperature. The resulting white precipitate was filtered off, washed with methanol and then dried in air. Yield: 0.21 g (51%). The complex was soluble in acetonitrile and hot acetone and was insoluble in water. *Anal.* Calc.: C, 44.49; H, 4.40; N, 23.95. Found: C, 44.85; H, 4.02; N, 23.58%. IR: 3447, 3138, 2264, 1542, 1510, 1421, 1293, 1108, 958, 916, 756, 627 cm^{-1}.

3.7. $[Cu(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot 2H_2O$

$Cu(ClO_4)_2 \cdot 6H_2O$ (0.14 g, 0.39 mmol) in methanol (3 cm^3) was added to a solution of 2-BIM(CN) (0.2 g, 0.79 mmol) in methanol (7 cm^3) and the mixture was stirred for 1 h at room temperature. The precipitated purple solid was filtered off, washed with methanol and then dried in air. Yield: 0.21 g (66%). The complex was soluble in acetonitrile and was insoluble in water. *Anal.* Calc.: C, 38.49; H, 3.97; N, 20.72. Found: C, 39.35; H, 3.44; N, 20.52%. IR: 3434, 3151, 2984, 2264, 1708, 1632, 1511, 1427, 1376, 1294, 1096, 974, 919, 753, 627 cm^{-1}.

3.8. $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot H_2O$ and $[Zn(2BIM(CN))_2](ClO_4)_2 \cdot 0.5MeCN$

$Zn(ClO_4)_2 \cdot 6H_2O$ (0.21 g, 0.56 mmol) in methanol (3 cm^3) was added to a solution of 2-BIM (CN) (0.3 g, 1.18 mmol) in methanol (10 cm^3) and the reaction mixture stirred at room temperature for 1 h. The white precipitate of $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot H_2O$ was filtered off, washed with methanol and then air dried. Yield = 0.33 g (70%). The complex was soluble in acetonitrile and was insoluble in water. *Anal.* Calc.: C, 39.48; H, 3.83; N, 21.26. Found: C, 39.62; H, 3.33; N, 20.49%. IR: 3524, 3151, 2984, 2264, 1632, 1517, 1421, 1357, 1300, 1102, 981, 919, 820, 759, 628, 474 cm^{-1}. ^1H NMR (ppm DMSO): 7.47 (4H, s), 6.78 (4H, s), 4.56 (8H, t), 4.5 (4H, s), 3.17 (8H, t). Recrystallising $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot H_2O$ from acetonitrile afforded crystals of $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot 0.5MeCN$ suitable for X-ray studies.

3.9. $[Mn(2\text{-}BIM(ClBz))_2](ClO_4)_2 \cdot 5H_2O$

$Mn(ClO_4)_2 \cdot 6H_2O$ (0.05 g, 0.14 mmol) was added to a solution of 2-BIM(ClBz) (0.2 g, 0.43 mmol) in methanol (7 cm^3) and the mixture stirred for 1 h. The resulting white precipitate was filtered off, washed with methanol and then air-dried. Yield: 0.16 g (89%). The complex was soluble in hot acetonitrile and insoluble in water. *Anal.* Calc.: C, 39.53; H, 3.32; N, 8.78. Found: C, 39.57; H, 2.73; N, 8.59%. IR: 3445, 1590, 1480, 1393, 1276, 1116, 1012, 953, 864, 830, 744, 701, 627, 556, 507 cm^{-1}.

3.10. $[Cu(2\text{-}BIM(ClBz))_2](ClO_4)_2 \cdot H_2O$

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.08 g, 0.22 mmol) in methanol (3 cm^3) was added to a stirred solution of 2-BIM(ClBz) (0.2g, 0.43 mmol) in methanol (10 cm^3). The mixture was stirred for 1 h at room temperature, giving a blue solid product. The solid was filtered off, washed with methanol and air-dried. Yield: 0.08 g (31%). The complex was soluble in hot acetonitrile and was insoluble in water. *Anal.* Calc.: C, 41.58; H, 2.80; N, 9.24. Found: C, 41.63; H, 2.52; N, 8.99%. IR: 3461, 2923, 1595, 1560, 1517, 1482, 1448, 1390, 1351, 1297, 1102, 977, 862, 843, 821, 752, 625, 554 cm^{-1}.

3.11. $[Zn(2\text{-}BIM(ClBz))_2](ClO_4)_2$

A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.08 g, 0.21 mmol) in methanol (3 cm^3) was added to a stirred solution of 2-BIM(ClBz) (0.2 g, 0.43 mmol) in methanol (7 cm^3). The mixture was stirred for 1 h at room temperature and the white product was filtered off, washed with methanol and allowed to air dry. Yield: 0.17 g (65%). The complex was soluble in hot acetonitrile and was insoluble in water. *Anal.* Calc.: 42.14; H, 2.67; N, 9.36. Found: C, 42.05; H, 2.57; N, 9.08%. IR: 3119, 1590, 1560, 1517, 1478, 1395, 1351, 1302, 1107, 980, 862, 843, 816, 755, 625, 554 cm^{-1}. ^1H NMR (ppm DMSO): 7.87 (4H, d, 2.0 Hz), 7.51–7.53 (8H, m), 6.86–6.95 (8H, m), 5.60 (8H, s), 4.43 (4H, s).

3.12. X-ray crystallography

All of the data were collected at 150 K on a Bruker SMART 1000 diffractometer using Mo Kα radiation

($\lambda = 0.71073$Å) (Table 6). The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using all the reflections [24]. All non-hydrogen atoms were refined with anisotropic atomic displacement parameters and hydrogen atoms bonded to carbon were inserted at calculated positions. In $[Zn(2\text{-}BIM)_2](ClO_4)_2$ the hydrogen bonded to nitrogen was located and refined with a fixed isotropic thermal parameter; in $[Cu(2\text{-}BIM(Bz)OH)_2(H_2O)_2](ClO_4)_2$ hydrogen atoms bound to oxygen were located from difference maps and not further refined. $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2$ and $[Zn(2\text{-}BIM(Me))_2](ClO_4)_2$ are isomorphous and in each case the perchlorate ion is disordered about a 2-fold axis passing through the chlorine and one oxygen atom. The asymmetric unit of $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot 0.5CH_3CN$ contains two independent $[Zn(2\text{-}BIM(CN))_2]^{2+}$ cations, four perchlorate anions and a single acetonitrile solvate; one of the perchlorate ions is disordered and this has been modelled as 50% occupancy of two sites related by rotation about one of the Cl–O bonds.

4. Supplementary data

X-ray supplementary data for $[Zn(2\text{-}BIM)_2](ClO_4)_2$, $[Cu(2\text{-}BIM(Me))_2](ClO_4)_2$, $[Zn(2\text{-}BIM(Me))_2](ClO_4)_2$, $[Zn(2\text{-}BIM(CN))_2](ClO_4)_2 \cdot 0.5MeCN$ and $[Cu(2\text{-}BIM(Bz)OH)_2(H_2O)_2](ClO_4)_2$ are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, England (fax: +44-1223-336033, E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), on request quoting the deposition numbers CCDC 218894, CCDC 218895, CCDC 218896, CCDC 218897 and CCDC 218898, respectively.

Abstract

A novel family of carboxylic acid modified Mg species has been synthesized through the reaction of $Mg(OEt)_2$ with a series of sterically varied carboxylic acids (HORc) where HORc = HO_2CMe (HOAc), HO_2CCHMe_2 (HOPc), HO_2CCMe_3 (HOBc) and $HO_2CCH_2CMe_3$ (HONc). The resultant products were isolated as $[Mg(OAc)_2]_3(HOAc)_2(H_2O)_2 \cdot 2(HOAc)$ (**1**), $[Mg(OPc)_2(HOPc)]_6$ (**2**), $Mg(OBc)_2(HOBc)_4$ (**3**) and $[Mg(ONc)_2(HONc)]_6$ (**4**). Compound **1** is trinuclear wherein the two terminal octahedral (Oh) bound Mg metal centers possess one terminal water, one terminal, one unidentate bridging and two bidentate bridging OAc ligands that symmetrically bind to the central Oh bound Mg cation. The water in **1** is believed to be generated in situ through an esterification process. In contrast, each of the six Mg atoms of **2** or **4** adopt a trigonal bipyramidal geometry by coordinating one terminal and four bidentate bridging ORc ligands that yield a ring (diameter 6.54 Å for **2** and 6.57 Å for **4**) of bridging ORc ligands. Compound **3** binds two terminal OBc ligands and four terminal HOBc ligands to yield a monomeric complex with no water present. Standard analytical data were obtained but did not add significant amounts of information concerning the bulk properties of **1**–**4**. Differential scanning calorimetry and thermal analysis indicated the melting point of these species was tunable.

1. Introduction

Magnesium alkoxides ($Mg(OR)_2$) have been available for study since the early 1900s [1–3] and have found use in several applications, such as Ziegler-Natta catalyst support precursors [4] and reagents for organic synthesis [5,6]. Although they are widely used, only a handful of structurally characterized $Mg(OR)_2$ complexes had been reported. Therefore, we synthesized and characterized a novel family of sterically hindering aryloxide derivatives "$Mg(OAr)_2(solv)_x$" (OAr = series of substituted phenoxides [13] and phenyl bearing alkoxide ligands [14]). The nuclearity of these compounds was controlled by altering the steric bulk of the substituents and the Lewis basicity of the solvent. The tailoring of other properties of these compounds was of interest. In particular, we were concerned with synthesizing low melting point Mg species to generate controlled mono-dispersed, spherical particles through dispersion routes. The previously investigated "$Mg(OR)_2(solv)_x$" species decompose prior to melting and thus were of no use for dispersion investigations [7–14].

We have previously reported a highly soluble, low-melting carboxylic acid (HORc)-modified Sr precursor, $[Sr(ONc)_2(HONc)_4]_2$ [15] (HONc = $HO_2CCH_2CMe_3$, *tert*-butyl acetic acid). This phenomenon was attributed to the excess bound HONc which upon heating, yielding a pool of solvent from the free HONc, which could dissolve the remaining species. Therefore, it was of interest to investigate the utility of this approach to generate low melting point "$Mg(ORc)_2$" precursors. While a number of these compounds have been reported in the literature, the majority possess coordinated H_2O [16–36], with few systematic structural variations present that could be used to discern structure-property relationships. For this

doi:10.1016/j.poly.2004.04.005

family of compounds, the ORc ligand has been observed to bind in a number of different manners, some of which are shown in Fig. 1.

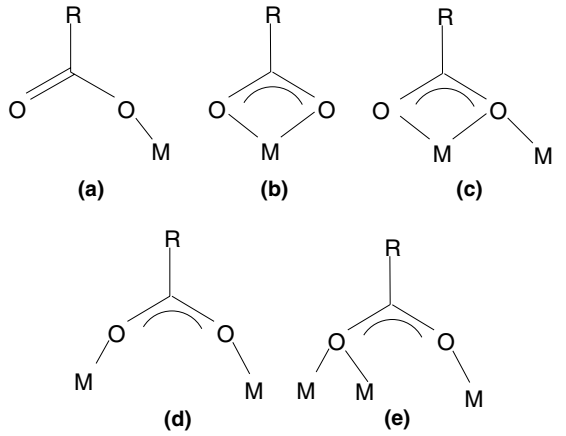

Fig. 1. Schematic representation of select binding modes of carboxylate ligands: (a) terminal, (b) unidentate, (c) unidentate bridging, (d) bidentate bridging, (e) unidentate, bidentate bridging.

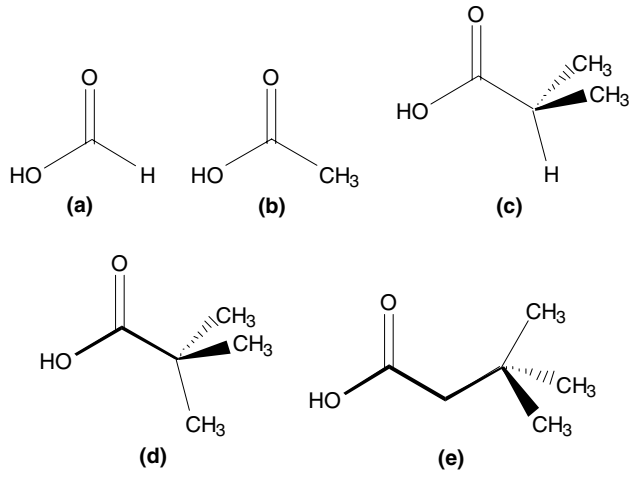

Fig. 2. Schematic representation of the sterically varied carboxylate ligands investigated: (a) formic acid (HOFc), (b) acetic acid (HOAc), (c) *iso*-butyric acid (HOPc), (d) trimethyl acetic acid (HOBc) and (e) *tert*-butyl acetic acid (HONc).

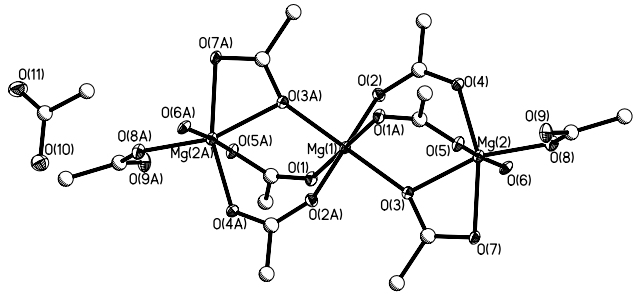

Fig. 3. Structural plot of **1**. Thermal ellipsoids for Mg and O drawn at 30%.

Therefore, we chose to synthesize a series of $Mg(ORc)_2$ compounds using simple organic carboxylate modifiers that systematically increased in steric bulk: formic acid (HO_2CH, HOFc), acetic acid (HO_2CCH_3, HOAc), *iso*-butyric acid (HO_2CCHMe_2, HOPc), trimethyl acetic acid (HO_2CCMe_3, (HOBc) and *tert*-butyl acetic acid ($HO_2CCH_2CMe_3$, HONc). A schematic representation of the HORc compounds is shown in Fig. 2. The $Mg(ORc)_2$ compounds were synthesized through the modification of $Mg(OEt)_2$ with excess HORc, as shown in Eq. (1). The reaction was run neat to minimize any solvent influences on the final structures. The following novel species were isolated:

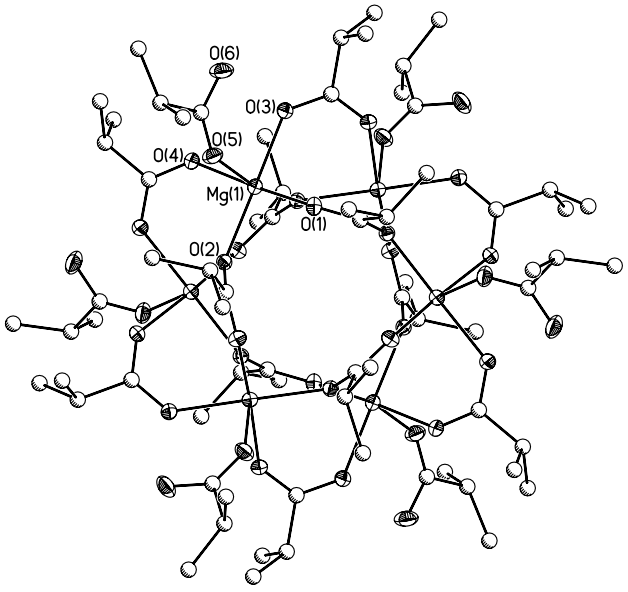

Fig. 4. Structural plot of **2**. Thermal ellipsoids for Mg and O drawn at 30%.

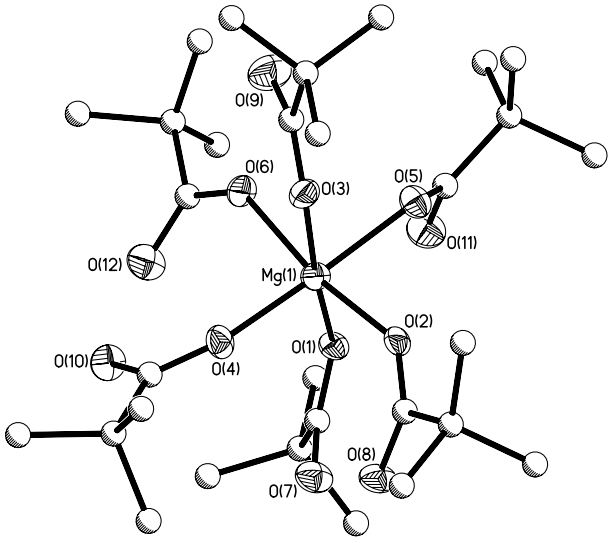

Fig. 5. Structural plot of **3**. Thermal ellipsoids for Mg and O drawn at 30%.

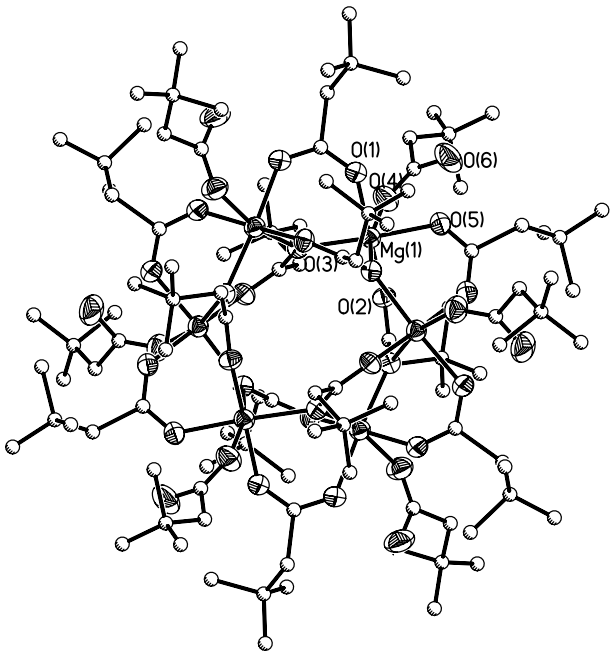

Fig. 6. Structural plot of **4**. Thermal ellipsoids for Mg and O drawn at 30%.

$[Mg(OAc)_2]_3(HOAc)_2(H_2O)_2$2(HOAc) (**1**), $[Mg(OPc)_2(HOPc)]_6$ (**2**), $Mg(OBc)_2(HOBc)_4$ (**3**) and $[Mg(ONc)_2(HONc)]_6$ (**4**) and these are shown in Figs. 3–6, respectively. The structure of the formic acid derivative, $[Mg(OFc)_2(H_2O)_2]_n$, has been reported in the literature [30,42,43], and will not be discussed further here.

$$Mg(OEt)_2 + (xs)HORc \rightarrow Mg(ORc)_2 \cdot nHORc + 2HOEt \quad (1)$$

The synthesis and characterization of **1**–**4** will be discussed in detail. The utility of these compounds in melt-dispersion processing for the control of particle morphology is currently under investigation.

2. Experimental

All compounds described below were handled with rigorous exclusion of air and water using standard Schlenk line and glove box techniques. HOFc (Aldrich) and HOAc (Fisher) were freshly distilled from the appropriate drying agents immediately prior to use [37]. The following chemicals were used as received (Aldrich): $Mg(OEt)_2$, HOPc, HOBc, HONc.

FT-IR data were obtained on a Bruker Vector 22 Instrument using KBr pellets under an atmosphere of flowing nitrogen. Elemental analysis was performed on a Perkin–Elmer 2400 CHN-S/O Elemental Analyzer. Differential scanning calorimetry (DSC) profiles were recorded on a Perkin–Elmer DSC 7 calorimeter. Samples were heated at a rate of 10 °C min^{-1} from 25 to 500 °C under a flow of 25 ml min^{-1} dry nitrogen or dry air. Thermal gravimetric analysis/differential thermal analysis (TGA/DTA) profiles were recorded on a TA Instruments SDT 2960 Simultaneous DTA-TGA balance. Samples were heated at a rate of 5 °C min^{-1} from 25 to 650 °C under a flow of 100 ml min^{-1} dry air and then held at 650 °C for 30 min. Visual confirmation of melting points (below 350 °C) were made using a bench top Electrothermal® melting point apparatus.

All NMR samples were prepared from dried crystalline materials that were handled and stored under an argon atmosphere. The $^{13}C\{^1H\}$ solid state cross-polarized magic angle spinning (CP-MAS) NMR spectra were obtained on a Bruker AMX400 spectrometer, at a frequency of 100.63 MHz using a 4 mm broadband probe spinning at 4 kHz. The CP-MAS spectra were acquired using a standard CP sequence with high power ^1H decoupling, 10 s recycle delay, a 1 ms contact time and 64–256 scan averages.

For the solution NMR spectra, **1** was dissolved in D_2O, while **2**–**4** were dissolved in toluene-d_8 at saturated solution concentrations. All solution NMR spectra were obtained on a Bruker DRX400 spectrometer at 399.87 and 100.54 MHz for ^1H and ^{13}C experiments, respectively. A 5 mm broadband probe was used for all experiments. ^1H NMR spectra were obtained using a direct single pulse excitation with a 10 s recycle delay and 8 scan average. The $^{13}C\{^1H\}$ NMR spectra were obtained using a WALTZ-16 composite pulse ^1H decoupling, a 5 s recycle delay and a $\pi/4$ pulse excitation.

Due to the similarity of synthetic procedures, a general description is presented for each reaction with individual variations noted in the respective section. To a pre-weighed sample of $Mg(OEt)_2$, the appropriate HORc was added until the majority of $Mg(OEt)_2$ was dissolved. The reaction was then heated with stirring until the solution became clear and then was allowed to cool to room temperature and sit until crystals formed. If crystal growth did not occur, some of the volatile fraction was removed via rotary evaporation and the reaction allowed to stand at room temperature. This process was repeated as often as necessary until X-ray quality crystals formed. All other characterizations were carried out on the bulk powder materials.

$[Mg(OFc)_2(H_2O)_2]_n$. Used $Mg(OEt)_2$ (0.234 g, 2.04 mmol) and HOFc (11.2 g, 243 mmol). Yield: 0.27 g (100%). FTIR (KBr pellet, cm^{-1}) 3386(m, br), 2934(w), 2906(w), 2882(w), 1678(m), 1639(s), 1612(s), 1418(m), 1407(m), 1352(s), 1069(w), 796(m). ^1H NMR (399.9 MHz, D_2O) δ 8.25 (1 H, s, OOC*H*,), 4.65 (s, O*H*$_2$). $^{13}C\{^1H\}$ NMR (100.54 MHz, D_2O) δ 170.2 (O_2*C*H). Elemental Analysis calc. for $C_2H_6MgO_6$: C, 15.97; H, 4.02. Found: C, 19.80; H, 2.54%.

$[Mg(OAc)_2]_3(HOAc)_2(H_2O)_2 \cdot 2(HOAc)$ (**1**). Used $Mg(OEt)_2$ (0.220 g, 1.92 mmol) and HOAc (5.184 g, 86.3 mmol). Yield: 0.454 g (100%). FTIR (KBr pellet, cm^{-1}) 3019 (w, br), 2936 (w), 1716 (m), 1601 (s), 1421 (s), 1344

(m), 1230 (w), 1054 (m), 1028 (m), 672 (m), 621 (m). ^{1}H NMR (399.9 MHz, D_2O) δ 1.78 (s, OOCCH_3), 4.65 (s, OH_2). ^{13}C{^{1}H} NMR (100.54 MHz, D_2O) δ 178.9 (O_2CCH_3), 21.5 (O_2CCH_3). Elemental Analysis calc. for $C_{20}H_{38}Mg_3O_{22}$: C, 34.15; H, 5.44. Found: C, 34.23; H, 4.71%.

[Mg(OPc)$_2$(HOPc)]$_6$ (**2**). Used Mg(OEt)$_2$ (0.214 g, 1.87 mmol) and HOPc (5.070 g, 57.5 mmol). Yield: 0.373 g (69%). FTIR (KBr pellet, cm^{-1}) 2972 (m), 2931 (w), 2874 (w), 1697 (w), 1591 (m), 1473 (m), 1427 (m), 1374 (w), 1361 (w), 1308 (w), 1256 (w), 1163 (w), 1098 (m), 782 (w), 657 (w), 558 (w). ^{1}H NMR (399.9 MHz, toluene-d$_8$) δ 8.82 (5.7H br s, $HO_2CCH(CH_3)_2$), 2.00 (6.6H, br s, $O_2CCH(CH_3)_2$), 1.92, 1.88 (9.7H, br s, $O_2CCH(CH_3)_2$). ^{13}C{^{1}H} NMR (100.54 MHz, toluene-d$_8$) δ 184.9 ($O_2CCH(CH_3)_2$), 35.3 ($O_2CCH(CH_3)_2$), 20.2 ($O_2CCH(CH_3)_2$). Elemental Analysis calc. for $C_{12}H_{22}MgO_6$: C, 50.30; H, 7.74. Found: C, 49.55; H, 7.34%.

Mg(OBc)$_2$(HOBc)$_4$ (**3**). Used Mg(OEt)$_2$ (0.214 g, 1.87 mmol) and HOBc (4.830 g, 47.3 mmol). Yield: 0.650 g (55%). FTIR (KBr pellet, cm^{-1}) 2969 (s), 2933 (w), 2874 (w), 2588 (w, br), 1686 (s), 1647 (s), 1479 (s), 1453 (w), 1400 (s), 1354 (s), 1210 (s), 1091 (w), 1026 (w), 874 (m), 795 (m), 604 (w), 501 (w), 532 (m). ^{1}H NMR (399.87 MHz, toluene-d$_8$) δ 13.1 (2.6H, s, br, $HO_2CC(CH_3)_3$), 1.18 (55H, mult., $O_2CC(CH_3)_3$). ^{13}C{^{1}H} NMR (100.54 MHz, toluene-d$_8$) δ 186.8 ($O_2CC(CH_3)_3$), 39.3 ($O_2CC(CH_3)_3$), 27.6 ($O_2CC(CH_3)_3$). Elemental Analysis calc. for $C_{30}H_{58}MgO_{12}$: C, 56.74; H, 9.21. Found: C, 56.31; H, 8.66%.

[Mg(ONc)$_2$(HONc)]$_6$ (**4**). Used Mg(OEt)$_2$ (0.202 g, 1.77 mmol) and HONc (5.304 g, 45.7 mmol). Yield: 0.689 g (39%). X-ray quality crystals were grown from hot dodecane. FTIR (KBr pellet, cm^{-1}) 2960 (s), 2914 (w), 2875 (m), 1703 (m), 1604 (s), 1466 (m), 1440 (m), 1387 (m), 1367 (m), 1302 (w), 1275 (w), 1236 (w), 1196 (w), 1144 (w), 1047 (w, br), 815 (m), 736 (m), 643 (m). ^{1}H NMR (399.87 MHz, toluene-d$_8$) δ 12.3 (v-br, $HO_2CCH_2C(CH_3)_3$), 2.04 (6H, multiplet, $O_2CCH_2C(CH_3)_3$, $J_{H-H} = 2.2$ Hz), 1.05 (27H, $O_2CCH_2C(CH_3)_3$). ^{13}C{^{1}H} NMR (100.54 MHz, toluene-d$_8$) δ 182.3, 180.4 ($O_2CCH_2C(CH_3)_3$), 51.2, 50.2 ($O_2CCH_2C(CH_3)_3$), 31.3, 30.8 ($O_2CCH_2C(CH_3)_3$), 30.4, 30.1 ($O_2CCH_2C(CH_3)_3$). Elemental Analysis calc. for $C_{18}H_{34}MgO_6$: C, 58.4; H, 9.2. Found: C, 58.5; H, 9.6%.

General X-ray crystal structure information [38]. Each crystal was mounted onto a thin glass fiber from a pool of Fluorolube^{TM} and immediately placed under a liquid N_2 boil-off stream, on a Bruker AXS diffractometer. The radiation used was graphite monochromatized Mo Kα radiation ($\lambda = 0.7107$ Å). The lattice parameters were optimized from a least-squares calculation on carefully centered reflections. The final crystal determination was solved using SMART Version 5.054 software, SAINT+ 6.04 (1/19/01), SHELXTL 5.1 (10/29/98), XSHELL 4.1 (11/08/2000) and SADABS (Ver. 2.03) software.

Each structure was solved using direct methods. This procedure yielded the heavy atoms, along with a number of the C atoms. Subsequent Fourier synthesis yielded the remaining C atom positions. The hydrogen atoms were fixed in positions of ideal geometry and refined within the XSHELL software. For H atoms on OH groups, the H atoms were located via difference Fourier mapping. These H atoms had their positions and

$R_1 = \sum ||F_o| - |F_c|| / \sum |F_o| \times 100$.
$wR_2 = [\sum w(F_o^2 - F_c^2)^2 / \sum (w|F_o|^2)^2]^{1/2} \times 100$.

isotropic displacement parameters refined. These idealized hydrogen atoms had their isotropic temperature factors fixed at 1.2 or 1.5 times the equivalent isotropic U of the C atoms to which they were bonded. The final refinement of each compound included anisotropic thermal parameters on all non-hydrogen atoms. Data collection parameters for **1**–**4** are given in Table 1.

The maximum θ angle for dataset integration was selected to optimize the data/parameter ratio, completeness of dataset coverage and reasonable residual errors during refinement. Although the data are not of the highest quality, the general usefulness concerning the connectivity of the structures can prove valuable and is the main focus of this paper. The problems associated with the structures are mainly due to difficulties in obtaining statistically useful data at higher θ angles (above 23°). Any variations in the handling of the individual crystals are described below.

$Mg(OBc)_2(HOBc)_4$ (**3**). Due to the instability of the refinement, all C atoms were refined with isotropic temperature factors only. Additionally, SADI bond length restraints were placed on all O–C and C–C bonds to force them to be equal ($\sigma = 0.04$ Å). Disordering of one of the acid groups (O6/O12, C26, C27, C28/C29/C30) was modelled by reducing the occupancies of the methyl carbons C28/C29/C30 to 0.5 and locating additional methyl carbons C28′/C29′/C30′, which were also fixed at 0.5 site occupancy. Due to the complication of the disorder, the hydrogens were left off this disordered acid group but counted in the chemical formula. In order to achieve charge balance, it is assumed that two of the acid groups are deprotonated. Since the H atoms could not be located they were not included in the figure but were included in the final chemical formula. Due to the uncertainties in structure refinement, the conformation of **3** given in Table 1 has a relatively large margin of error; therefore, we will only discuss the connectivity, which is unequivocally established.

$[Mg(ONc)(HONc)]_6$ (**4**). Data for compound **4** was collected under ambient nitrogen atmosphere since any cooling under the liquid nitrogen purge caused the crystal to crack.

3. Results and discussion

We have characterized several novel HORc-modified Mg compounds (**1**–**4**) that are unusual in comparison to existing members of this family of compounds. The synthesis, solid state and solution state characteristics of **1**–**4** are described below. The binding modes available and the carboxylate ligands that were used are shown in Figs. 1 and 2, respectively. The investigation of structure-property as it applies to the melting point of these compounds was also explored.

3.1. Synthesis

The HORc-derivatives of Mg were synthesized by dissolving $Mg(OEt)_2$ in an excess of the appropriate HORc (Eq. (1)). These reactions were stirred with heating, if necessary, until a clear solution resulted. The mixtures were allowed to sit until crystals formed. If a solution did not yield crystals, part of the volatile portion was removed by rotary evaporation and again the reaction mixture was allowed to sit. X-ray quality crystals were isolated for **1**–**4** and their structures are shown in Figs. 3–6, respectively. For each, there were no alkoxide ligands present in the final material. A number of these species did retain water that is believed to be formed through an esterification reaction pathway. Surprisingly, no oxo species were generated from the water by-product, as is often observed for HORc-modified metal alkoxide species [39,40].

3.2. Solid state

While a great deal of research has been conducted involving $Mg(ORc)_2$ complexes, no systematic structural studies of these "simple" compounds has been proffered. A series of furan-substituted carboxylate structures were reported forming dimeric and polymeric structures dependant on the orientation of the furan ring [16]. Monomeric $Mg(ORc)_2 \cdot (H_2O)_{n.}$ species were isolated using mandelic acid [17], malonic acid [18,19] or aromatic substituted carboxylates (ORc-OAr) [20–26] (a polymeric $[Mg(ORc\text{-}OAr)_2(H_2O)_2]_\infty$ species was also isolated) [27]. Salt species were isolated for the polycarboxylates such as oratic acid (H-Or) $[Mg(H_2O)_6^{+2}][Mg(Or)^{-1}]_2$ [28] and citric acid (H-OCit) $\{[Mg(H_2O)_6^{+2}][Mg(OCit)^{-1}]_2 \cdot 2H_2O\}_n$ [29]. A few structures of simple organic carboxylic acid derivatised Mg species have been reported including $[Mg(OFc)_2(H_2O)_2]_n$ [30], $Mg(OAc)_2 \cdot 4H_2O$ [31–34], $[Mg(O\text{-}n\text{-}Bc)_2(H_2O)_4]_2 \cdot HO\text{-}n\text{-}Bc$ where O-*n*-Bc = $O_2C(CH_2)_2(CH_3)$ [36], and $[Mg(OPyn)_2(H_2O)]_n$, where OPyn = O_2CCCH. Interestingly, until recently with the isolation of $Mg_3(OPc)_6(solv)_2$ (solv = THF or HMPA) [35], $Mg_3(O_2CC{\equiv}CPh)_6(THF)_2$ [35], and $Mg_3(O_2C{\equiv}CSiMe_3)_6(HMPA)_4$ [41], where THF = tetrahydrofuran and HMPA = hexamethyl phosphoramide, water was found coordinated to the Mg metal centers for each carboxylate species reported independent of the solvent utilized.

Therefore, crystal structures of the simple carboxylates generated from solvent free environment were obtained to elucidate the structural arrangements unhindered by solvent, polydentate ligands or other complexing agents. The thermal ellipsoid plots of **1**–**4** are shown in Figs. 3–6, respectively. Table 1 lists the data parameters for **1**–**4**.

The compound $[Mg(OFc)_2(H_2O)_2]_n$ [30,42,43] is a polymeric structure wherein there are two unique

octahedrally (Oh) bound Mg metal centers. The equatorial OFc ligands bridge from one Mg(1) to four individual Mg(1′) metal centers. The two axial Mg(1) OFc ligands bridge to different Mg(2) metal centers that are shifted 1/2 unit cell along the b-axis. Mg(2) is equatorially bound by OFc ligands from Mg(1) cations and fills its coordination sphere by binding four water molecules. Due to the bite angle of the OFc ligand, the Mg(2) cations are tilted in opposite orientations relative to each other which leads to an AB/AB/AB packing.

In contrast to $[Mg(OFc)_2(H_2O)_2]_n$, compound **1** is trinuclear with a C_2 axis of symmetry. All of the Mg metal centers are six-coordinated in a psuedo-Oh geometry binding a variety of ligands. Each terminal Mg coordinates one H_2O and one terminally bound HOAc molecule. In addition, there are two bidentate-bridging and one unidentate-bridging OAc ligands (Fig. 1) that bridge to the central Mg. This structure is similar in arrangement as was noted for the HMPA adduct of $Mg_3(ORc)_6(HMPA)_2$ where $ORc = O_2CC{\equiv}CSiMe_3$ [41] or OPc [35]; however, for **1** HOAc solvent molecules are used to fill the coordination sphere of the terminal Mg. Two additional molecules of HOAc are located in the unit cell (only one is shown in Fig. 3).

Surprisingly, by increasing the steric bulk on the pendant hydrocarbon chain of the carboxylic acid, the species isolated, **2**, was not isostructural with the previously isolated trinuclear species [35]. Instead, a hexanuclear species was isolated that does not incorporate any H_2O. Each Mg adopts a trigonal biplanar (TBP) geometry coordinating one terminal HOPc and four OPc ligands to form a six-membered ring (Fig. 4). The carboxylate ligands bridge equally between adjacent and alternating Mg metal centers forming a ring with a diameter of 6.54 Å. The depth of the ring is about 1/2 the *c*-axis or ~6 Å, forming a cubic volume of ~805 Å^3. A hexanuclear structure was previously observed for the carbamide complex, $Mg_6(O_2CNEt_2)_{12}$ which indicates there are more similarities between these ligands than was previously expected [35,44]. An identical structural arrangement was noted for **4** with a central ring diameter of 6.57 Å.

Further increases in the steric bulk of the ORc ligand yielded the mononuclear Mg species **3**. Each metal center of **3** is Oh bound by monodentate HOBc and OBc ligands (Fig. 5). Again, *no* H_2O was found bound to the metal centers and *none* of the ligands are present in a bidentate manner. While there are numerous monomeric $Mg(ORc)_2$ species present in the literature, the majority of these utilize water to stabilize the structure [20–23,33,34] (e.g., $Mg(OAc)_2(H_2O)_4$) [33,34] or combine polydentate ORc ligands with coordinated H_2O [17,25,26] (e.g., Mg(1,2-dioxydiacetato-O,O′,O″,O‴-benzene)$(H_2O)_3$) [25].

Compound **4**, shown in Fig. 6, was isostructural with **2**.

Metrical data of **1**–**4** are consistent with each other and the literature values [16–36]. The Mg – Mg distances are av. 3.53 Å, the O–C–O range from 121.0 to 126.7° for both bridging and terminal ORc ligands. The unidentate bridging OAc ligand of **2** has the smallest angle of 118.2° due to the constrained bite angle. The Mg–O distances are within a relatively small range (2.00–2.25 Å) when the variety of ligands and binding types are taken into consideration. The angles are slightly distorted from ideal Oh or TBP due to the constraints of the ORc ligands.

Attempts to demonstrate that the bulk powders were uniform and a single product were complicated by the inclusion of the free HORc, which makes complete characterization of these compounds difficult since the ligands and bound acid are difficult to distinguish from each other. Elemental analyses of **1**–**4** were consistent with the empirical formula of the single crystal structures. Since each of these samples were handled in the ambient atmosphere, it appears that **1**–**4** are relatively air stable.

For each sample, the FT-IR spectra of **1**–**4** reveal OH peaks around 3000 cm^{-1} due to the bound HORc and in some instances the H_2O. For the aqueous species, this peak is much broader than the HORc bound compounds. For each sample, the bound acids have a shift of ~200 cm^{-1} in comparison to the free HORc and much stronger stretches, indicative of coordination to the Mg metal center. There was no specific stretch that was conclusively associated with Mg–O.

CP-MAS ^{13}C NMR data was collected on the bulk samples of **1**–**4** to verify that the bulk powder was identical to the single crystal. Table 2 lists the resonances observed for the various samples. Compounds **1** and **4** have the same general structure type wherein each has two non-equivalent bridging and one terminal ORc indicating two types of carboxylate species that can be observed in the solid state. For **1**, four types of OAc ligands were observed whereas for **4**, three types of ONc ligands were recorded. The variations in the crystal structure and observed ^{13}C CP-MAS NMR data for **1** can be attributed to increased asymmetry of the crystalline material due to the reduction in averaging typi-

Table 2
CP MAS NMR data for **1**–**4**

Compound	^{13}C (δ ppm)
1	186.1, 184.2, 179.7, 178.5 ($O_2\mathit{C}CH_3$)
	23.61, 22.82, 21.25, 20.86 ($O_2C\mathit{C}H_3$)
2	186.9, 182.9 ($O_2\mathit{C}CH(CH_3)_2$)
	36.2, 34.7 ($O_2C\mathit{C}H(CH_3)_2$)
	22.8, 20.5, 19.1 ($O_2CCH(\mathit{C}H_3)_2$)

4	183.8, 182.9, 179.9 ($O_2\mathit{C}CH_2C(CH_3)_3$)
	52.1, 49.4 ($O_2C\mathit{C}H_2C(CH_3)_3$)
	31.8 ($O_2CCH_2\mathit{C}(CH_3)_3$)
	30.6, 29.6 ($O_2CCH_2C(\mathit{C}H_3)_3$)

cally noted for solution species. For **2**, two quaternary and methylene, but three types of methyl resonances were observed. The observance of two complete sets of resonances is consistent with the terminal and bridging OPc ligands. The multiple resonances noted in the methyl region are most likely due to inequivalencies of "locked out" methyl groups of the OPc ligand. As expected for **3**, only one set of resonances were observed for the OBc derivative; however, each resonance was present as a multiplet. Again, packing inequivalancies associated with the OBc/HOBc ligands would account for the multiple resonances. In general, it appears that the solid state powders were consistent with the single crystal structures collected.

3.3. Solution phase NMR

Dried crystals of **1** were dissolved in D_2O, while **2**–**4** were dissolved in toluene-d_8 to determine the solution behavior of these compounds. In the ^1H NMR spectrum of **1** only one set of sharp peaks for the ligands was observed. For **2**–**4**, resonances associated with the bound HORc and ORc ligands were observed. The ^{13}C NMR spectra for **1**–**4** show little information except for the carboxylic acid region wherein for each sample the number of carboxylates is directly related to the solid state structure. From these data, little information pertaining to the structure of these compounds is readily obtained except for the presence of the various ligands.

3.4. Thermal properties

The thermal decompositions of $[Mg(OFc)_2(H_2O)_2]_n$, and **1**–**4** were investigated by TGA/DTA (25–650 °C, air) and DSC (25–500 °C, air or N_2). The DSC data were consistent with the TGA/DTA data for each sample. Table 3 tabulates some of the thermal data obtained on these compounds.

For the H_2O coordinated species ($[Mg(OFc)_2(H_2O)_2]_n$ and **1**), the loss of both the coordinated species (water and HORc) and the bound ORc were easily observed. The bulk powder form of $[Mg(OFc)_2(H_2O)_2]_n$ exhibited a total weight loss in the TGA of 69.5%, which is clearly delineated into the loss of one water molecule per Mg center below 150 °C and loss of two formate groups per Mg between 330 and 440 °C. The loss of a water molecule was accompanied by a broad endotherm in the DTA, centered at 135 °C, concomitant with a desorption process, and the loss of OFc was accompanied by a sharp exotherm peaking at 430 °C. For **1**, a total weight loss of 82.4% was observed with the stepwise loss of solvating HOAc (<90 °C), coordinated water and HOAc (90–130 °C) and finally the loss of coordinated OAc in three stages: one OAc (per 3 Mg unit cell) at 315–320 °C, four OAc at 325–345 °C and one OAc at 360–420 °C. Each of the weight losses was associated with a thermal event; coordinated solvents revealed small endotherms and the bound OAc ligands produced sharp exothermic peaks in the 300–440 °C range.

Table 3
Thermophysical properties of $[Mg(OFc)_2(H_2O)_2]_n$ and **1**–**4**

Compound	Wt. loss[a] (%)	Melting point[b] (°C)
$[Mg(OFc)_2(H_2O)_2]_n$	69.5	440
1	82.4	322
2	90.5	129
3	98.4	140
4	93.8	198

[a] Temperature range 25–600 °C.
[b] Determined by Differential scanning calorimetry (DSC) under N_2.

For the non-aqueous species (**2**–**4**), the loss of HORc versus ORc were less clearly distinguished. On heating of **2**, the coordinated HOPc was lost in several steps up to 365 °C in the TGA, accompanied by a broad endotherm in the DTA. This process also initiated the loss of OPc ligands, which were completely removed by 430 °C, accompanied by a large exotherm. Compound **3** displayed a loss of coordinated HOBc in the range before 160 °C, as evidenced by a weight loss and corresponding endotherm. Above 300 °C, a second sharp weight loss occurred, which was assigned to the loss of ligated OBc and was accompanied by a broad exotherm. No further weight loss or thermal events were observed above 430 °C. The low temperature region of the DSC trace of **3**, recorded under N_2, is shown in Fig. 7(a). The material initially melts at approximately 140 °C (small endotherm), then exhibits three further sharp endothermic events above 190 °C. Note that the boiling point of HOBc is 163 °C, thus the latter three peaks are assigned to melting points of $Mg(OBc)_2.nHOBc$ species where $n < 4$ as the amount of "solvating" HOBc decreases steadily due to vaporization above 163 °C. Multiple melting points were also observed visually in an Electrothermal Melting Point Apparatus, but could not be resolved satisfactorily. Fig. 7(b) indicates the cyclability of melting **3** (provided the boiling point of HOBc is not exceeded), where **3** was subjected to three heating/cooling cycles between 120 and 150 °C. Note that the endotherm representing melting shows little change in intensity or peak position on repeated melting/solidifying. This result shows that **3** may be subjected to fusion/solidification processing without loss of meltability. Attempts to cycle the melting event above 163 °C were unsuccessful, as HOBc vaporized too easily. For **4**, loss of coordinated HONc was observed over the range of 50–170 °C (endothermic) while between 300 and 440 °C, a sharp exotherm accompanied the combustion of the remaining ONc groups. No further weight loss or thermal events were observed above 400 °C. In general, the compounds appear to be relatively thermally stable and should initiate a melt prior to decomposition, as was observed (Table 3). The total weight loss observed in the

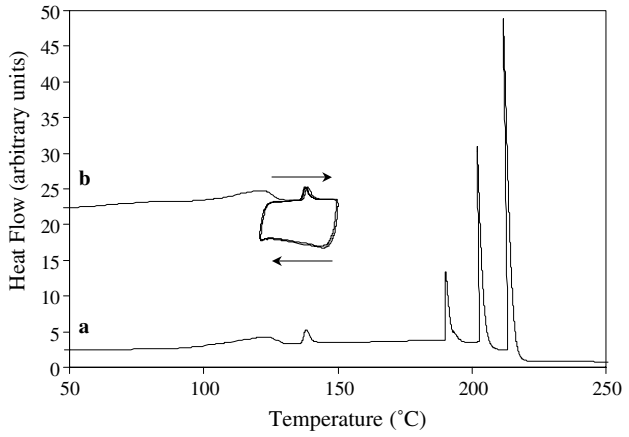

Fig. 7. Differential scanning calorimetry trace of **3** under N_2: (a) low temperature region; (b) initial melting point cycled three times. Arrows indicate heating and cooling cycles. Positive heat flow = endothermic event.

TGA up to 600 °C for **3** and **4** approximated 100%, indicating that the Mg-carboxylates were volatile which may be exploitable for metallo-organic chemical vapor deposition (MOCVD) processes.

4. Summary and conclusion

We have characterized a novel family of $Mg(ORc)_2$ complexes, the structural aspects of which are dictated by the changes in the steric bulk of the pendant hydrocarbon chain along with the rapidity with which the acids undergo esterification. The structures vary from organized polymeric complexes ($[Mg(OFc)_2(H_2O)_2]_n$), short oligomeric chains (**1**), hexanuclear rings (**2** and **4**), to monomeric species (**3**). The nuclearity of the resultant molecule appears to diminish with increased steric bulk; however, the presence of water and free HORc complicate the final structures observed by filling potential oligomerization sites. The water is thought to be generated by an esterification mechanism that is often observed when HORc are mixed with $M(OR)_x$. The expanded structural types observed for this new family of compounds are in line with carbamato derivatives and allow for more direct comparison between the two sets of precursors. The melting point properties of these compounds have been altered mainly due to the presence of the free acids bound to the metal centers, which act as a pool of solvent to aid in dissolution. This tailored property is being exploited to generate size-tunable spherical particles through a simple fluid dispersion processing method. These results will be published separately.

Abstract

The synthesis and characterization of a series of ternary Co(III) complexes which could act as simple model systems for the study of non-covalent interactions involving aromatic residues is reported. Such interactions are important to the discriminatory processes associated with molecular recognition in chemical and biochemical systems, but are relatively poorly understood due to the inherent complexity of the majority of systems. The species reported in this paper are Λ-β$_1$-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ (picchxn = *N*, *N*′-di(2-picolyl)-1,2-diaminocyclohexane; trp = the anion of tryptophan) and Δ-α-, Λ-β$_1$- and Λ-β$_2$-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$. A single-crystal X-ray study of the Δ-α- and Λ-β$_2$-*R*-trp complexes has demonstrated that the molecular cation of each adopts a conformation where intramolecular π–π interactions involving the indole group and a pyridyl ring occur in the solid state. 2D-ROESY and ^{1}H NMR experiments of these diamagnetic complexes have established that these interactions persist in solution, as is also the case with the Λ-β$_1$-*S*-trp cation. Except for the Λ-β$_2$-*R*-trp species, all possess various combinations of NH–π interactions as well, and these too serve to influence markedly the rotamer distributions in several instances. Equilibrium rotamer populations determined using NMR have enabled the energetics of the system to be evaluated. NMR measurements also show that the rotamer populations are relatively unchanged at elevated temperatures, and that the non-covalent interactions which dictate both the solid state and solution configurations of these complexes persist in a variety of solvents. It is shown for *R*-trp that combined NH–π and π–π interactions provide the driving force for octahedral inversion of both Λ-β$_1$ and Λ-β$_2$ diastereoisomers to the Δ-α form. The unprecedented stabilization of this species is rationalized in terms of a hierarchy of competing non-covalent aromatic interactions.

1. Introduction

Weak, non-covalent bonding interactions, which include classical and non-classical hydrogen bonding [1], hydrophobic association [2], aromatic ring stacking [3], π-facial [4] and electrostatic interactions [5], are often overlooked when describing the structure and reactivity of molecules. During the past decade, a consistent picture of their importance to the discriminatory processes associated with molecular recognition and self-assembly in chemical and biochemical systems has emerged [6]. What is yet to be drawn is a consistent picture of these relatively poorly understood attractive forces [2a,5,7]. This is understandable taken in the context of biochemical systems, where non-covalent interactions play vital roles in processes such as protein–ligand recognition [8], enzymatic activity [9], antigen–antibody binding [10], and the determination of three-dimensional structure [11]. Such systems are inherently complex, with

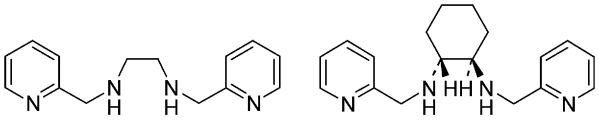
doi:10.1016/j.poly.2004.04.016

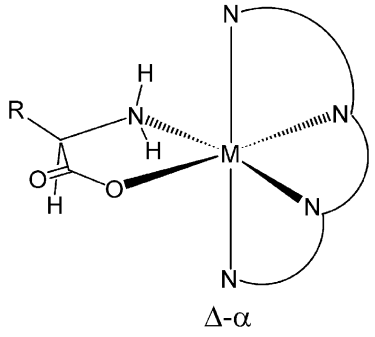
multiple weak interactions acting in synergy to facilitate discrimination. This in turn gives rise to a need for simple model systems suitable for studying these interactions.

We have chosen to focus our study on NH–π [4a,8,12] and π–π interactions [2,3], as their wider significance to the molecular recognition and stabilization of molecular structures has been recognized [13]. In this paper, we report the synthesis and characterization of a series of ternary Co(III) complexes which could act as simple model systems for studying these interactions. An important feature of the model complexes is that they possess manageable numbers of non-covalent interactions and can be studied in detail. The molecular design rationale of the reported complexes is based on a previous exploration of the stereochemistry and stability of ternary Co(III) complexes containing ligands based on *picen* (**1**, 1,6-di(2-pyridyl)-2,5-diazahexane) [14]. A chiral analogue of this ligand, *picchxn* (**2**, *N*,*N*′-di(2-picolyl)-1,2-diaminocyclohexane) has been singled out for focused studies [15] concerning chiral inductions during the reactions of other coordinated ligands, the resolution of amino acids, and aspects of stereospecific coordination behaviour. *N*,*N*′-Dimethylated analogues of these ligands enforce α geometry (Fig. 1) at Co(III) [16], but ligand **2** has been supposed to form more stable β complexes (Fig. 2) with Co(III), on the basis of the isolation of many β Co(III) complexes of *R*,*R*-picchxn containing a wide variety of bidendates [17].



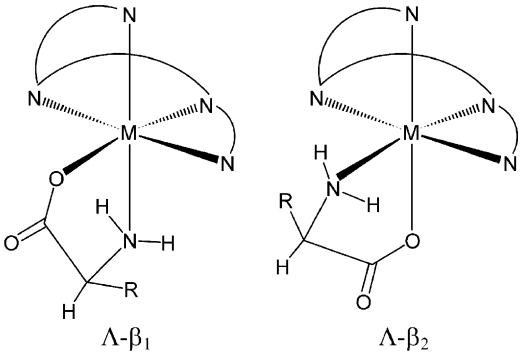
1 **2**

Indeed, the isolation of an α complex, Δ-α-[Co(*R*,*R*-picchxn)(AbuH)]$^{2+}$, $AbuH_2$ = 2-amino-2-butylpropandioic acid, was attributed to kinetic effects in that it was shown to quickly epimerize in DMSO solution to the corresponding Λ-β_1 diastereoisomer [18]. In related complexes containing aromatic amino acids, intramolecular π–π interactions between the amino acid side-chain and a pyridyl ring of the tetradentate have been identified for certain stereochemical combinations. A first example was found [19] in the structure of Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-ABzH)]$^{2+}$, $ABzH_2$ = 2-amino-2-benzylpropandioic acid, in which the π–π interaction was seen to stabilize the transition state involved in the decarboxylation of the substituted aminomalonic acid to yield phenylalanine. Subsequently, in an exploration of ternary Co(III) complexes containing phenylalanine and *N*,*N*′-dimethyl analogues of **1**, **2** and related ligands, it was shown [20] that such π–π interactions are quite general in the solid state, as revealed by a series of single-crystal X-ray structures, and, more intriguingly, the interactions persisted in solution. In the case of Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-ABzH)]$^{2+}$, the unusual situation of an NH proton of the aminoacidate lying between the interacting aromatic rings was noted in terms of chemical shift effects in the NMR, but it was not apparent at the time that the fragment was not innocent with respect to its bonding contribution [19]. A similar combination of π–π and bifurcated NH–π interactions is also evident in the analogous ternary complex containing α-methyl-*S*-tryptophan [21], and in other related complexes [20].



Δ-α

Fig. 1. Representation of the Δ-α coordination topology for octahedral complexes of *R*,*R*-picchxn containing a bidentate aminoacidate ligand.



Λ-β_1 Λ-β_2

Fig. 2. The two kinds of octahedral β distereoisomers, β_1 or β_2 are illustrated for the Λ-complex of *R*,*R*-picchxn.

We now recognize the fact that NH–π interactions also represent important stabilizing forces in this class of molecules, and have explored this in a series of coordination complexes of Co(III), *R*,*R*-picchxn and *R*- or *S*-tryptophan. These NH–π bonds are strong enough to stabilize α isomers of *R*,*R*-picchxn with Co(III), resulting in the isolation of an unprecedented stable α complex with *R*-tryptophan, as reported in this work. Further, we have been able to estimate the energetic contributions of the interactions to bonding by a combination of structural and solution studies, described below. It is concluded that in an appropriate environment [8,22], NH–π bonds can be much stronger than attractive π–π interactions in these complexes and can be as strong as normal hydrogen bonds.

2. Experimental

2.1. General procedures

NMR studies were carried out with Varian Unity*inova*-500 (500 MHz), *Mercury*-400 (400 MHz) and Unity*plus*-300 (300 MHz) spectrometers with DMSO-d_6 (98.5%), D_2O (99.9%), benzene-d_6 (99.6%) and pyridine-d_5 (99%) as solvents. Chemical shifts (δ) are given in ppm relative to TMS (DMSO) and TSP sodium salt (D_2O) as internal standards for ^1H and ^{13}C spectra. Chemical shifts are positive if the signal was shifted to higher frequencies than the standard. Unless otherwise indicated, all experiments were performed at 25 °C. Electronic spectra were recorded on a Perkin–Elmer Lambda EZ-210 spectrophotometer and circular dichroism spectra (CD) on a Jasco J-810 spectropolarimeter. Λ-β-[Co(*R*,*R*-picchxn)Cl_2]$ClO_4 \cdot 0.5H_2O$ was synthesized as previously described [23]. Crystals of the three salts of the complexes containing the *R*-aminoacidate that were obtained were suitable for X-ray analysis.

2.2. Caution

Perchlorate salts are potentially explosive and should be handled with care. However, we have not experienced any problems with the synthesis and manipulation of these compounds.

2.3. Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$(ClO_4)_2 \cdot NaClO_4 \cdot 2H_2O$ (**3**)

It is preferable, to increase yields, to carry out the synthesis in the dark. Λ-β_1-[Co(*R*,*R*-picchxn)Cl_2]$(ClO_4) \cdot 0.5H_2O$ (0.50 g, 0.94 mmol) and *S*-trpH (0.96 g, 4.72 mmol) were stirred in water at 60 °C until the solids had dissolved. Aqueous NaOH (1 ml, 1 M) was added dropwise and the mixture cooled to room temperature. The orange solution was diluted fivefold with water and applied to a column (40×2 cm) of CM-Sephadex® C25 in the Na^+ cycle. Elution with 0.3 M aqueous NaCl resulted in a slow-moving orange band that was collected in fractions. Electronic spectroscopy showed that a single isomer was present. Solid $NaClO_4 \cdot xH_2O$ (ca. 0.15 g) was added to each fraction and the fractions stored over silica gel at room temperature under reduced pressure. After some four weeks, the complex was recovered as a microcrystalline powder from the majority of the fractions by filtration at the pump, then washing with a minimum of ice-cold water and air-drying. Yield: 0.18 g. *Anal*. Calc. for $C_{29}H_{39}Cl_3CoN_6NaO_{16}$: C, 38.03; H, 4.29; N, 9.18. Found: C, 38.21; H, 4.44; N, 9.04%. Electronic spectrum: λ_{max}/nm (H_2O) 349 (ε/M^{-1} cm^{-1} 4120), 472 (2710). CD spectrum: λ_{max}/nm (H_2O) 306 ($\Delta\varepsilon/M^{-1}$ cm^{-1} +3.6), 354 (−13.6), 487 (+25.5).

2.4. Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$(ClO_4)_2 \cdot H_2O$ (**4**)

Λ-β_1-[Co(*R*,*R*-picchxn)Cl_2]$(ClO_4) \cdot 0.5H_2O$ (1.0 g, 1.86 mmol) was dissolved in water (60 ml) at 60 °C and *R*-trpH (1.3 g, 6.4 mmol) was added. When the latter had dissolved, aqueous NaOH (2 ml, 1 M) was added dropwise and the mixture cooled to room temperature, diluted fivefold with water and chromatographed as above using aqueous 0.15 M NaCl. The main orange band that developed was collected in fractions (77×11 ml) and electronic spectra showed three isomers to be present, but pure in separate portions of the band. Fractions containing the isomer from the tail of the band were treated with solid $NaClO_4 \cdot xH_2O$ (ca. 0.15 g) and slowly evaporated over silica gel. During four weeks, orange prisms separated and these were collected at the pump, washed with ice-cold water and air-dried. Yield: 0.14 g. *Anal*. Calc. for $C_{29}H_{37}Cl_2CoN_6O_{11}$: C, 44.92; H, 4.81; N, 10.84. Found: C, 44.90; H, 4.80; N, 10.83%. Electronic spectrum: λ_{max}/nm (H_2O) 352 (ε/M^{-1} cm^{-1} 3380), 477 (1650). CD spectrum: λ_{max}/nm (H_2O) 354 ($\Delta\varepsilon/M^{-1}$ cm^{-1} +7.5), 390 (+9.2), 488 (−31.9).

2.5. Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-trp)]$(CF_3SO_3)_2$ (**5**)

Fractions from the middle of the above band were combined, reduced to dryness at 40 °C and desalted with absolute ethanol. The filtrate was reduced to dryness and taken up in water (80 ml) and to the solution was added solid CF_3SO_3K (ca. 0.8 g). Evaporation over silica gel during two weeks gave deep orange prisms that were isolated as above. Yield: 0.36 g. *Anal*. Calc. for $C_{31}H_{35}CoF_6N_6O_8S_2$: C, 43.46; H, 4.12; N, 9.81. Found: C, 43.47; H, 3.86; N, 9.70%. Electronic spectrum: λ_{max}/nm (H_2O) 351 (ε/M^{-1} cm^{-1} 3080), 480 (2710). CD spectrum: λ_{max}/nm (H_2O) 327 ($\Delta\varepsilon/M^{-1}$ cm^{-1} +4.5), 383 (+5.5), 497 (+32.7).

2.6. Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$(CF_3SO_3)Cl \cdot 4H_2O$ (**6**)

Pure fractions from the front of the above band were combined and reduced to 15 ml at 40 °C. Solid CF_3SO_3K (ca. 0.1 g) was added to the pink-orange solution, which was evaporated over silica gel for two weeks. The crimson prisms that had formed were isolated as above. These slowly lose water by efflorescence when dry, but may be protected by a coating of silicone oil, or stored in contact with the mother liquor. Yield: 0.05 g. *Anal*. Calc. for $C_{30}H_{43}ClCoF_3N_6O_9S$: C, 44.20; H, 5.44; N, 10.31. Found: C, 43.99; H, 5.79; N, 10.29%. Electronic spectrum: λ_{max}/nm (H_2O) 353 (ε/M^{-1} cm^{-1} 3370), 475 (1870). CD spectrum: λ_{max}/nm (H_2O) 349 ($\Delta\varepsilon/M^{-1}$ cm^{-1} −7.6), 467 (+39.8), 551 (−1.8).

2.7. NMR spectroscopy

Concentrations of complexes were typically 10–15 mM in DMSO-d_6 and 5–10 mM in other solvents, including mixed solvents. Broadening of resonances is observed at higher concentrations, due to intermolecular interactions. Exchangeable protons for DMSO-d_6 samples were determined by addition of D_2O 5 min prior to recording the ^1H NMR spectrum. When required, sample degassing was carried out by repeated successive freeze-thaw cycles under high vacuum. Variable-temperature ^1H NMR spectra were acquired using a 15-min equilibration period at each temperature and a recycling delay of 6 s.

Two-dimensional DQF-COSY, and TOCSY experiments employing a MLEV-17 spin lock pulse sequence with 10 and 20 ms mixing times (to give predominantly $^{2-3}J_{HH}$ and strong $^4J_{HH}$ correlations) were recorded. TOCSY experiments with mixing times between 60 and 110 ms were also recorded for obtaining relayed correlations from the entire network of spin systems. 2D data sets with 2048 data points in the t_2 dimension and 256 or 512 complex points in t_1 were collected with 16–32 scans per t_1 increment. The relaxation delay was typically 2.5–3 s. All phase sensitive 2D data sets were recorded using the protocol of States et al. [24]. For the COSY, t_1 and t_2 were multiplied by a combination of sine-bell and shifted sine-bell functions prior to 2D transformation. For the TOCSY experiments, baselines were corrected with a polynomial routine in f_1 and f_2. Spectra were zero-filled and processed with a combination of exponential and Lorentzian–Gaussian window functions. ROESY [25] spectra were recorded with a relaxation delay of 2.5–5 s for mixing times of 300, 450, 600 and 1000 ms, using a pulsed spin-lock during the mixing period. Data sets consisted of 2048 complex points in the t_2 dimension and 256 or 512 in t_1 with 32–48 scans per t_1 increment. The spectra were zero-filled and processed with Gaussian weighting functions. In all cases, ridges along f_2 were reduced by multiplying the first point in the FID by 0.4–0.75 prior to the Fourier transform, then applying a polynomial baseline correction routine. HMQC [26] spectra were recorded with the delays optimized for J_{C-H} coupling constants of 125 or 140 Hz. Data sets with 2048×256 complex

[a] $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = [2F_c^2 + \mathrm{Max}(F_o^2, 0)]/3$.
[b] $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$ and $R_w = \{[\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}\}$.

points were then processed with a combination of Gaussian and exponential weighting functions. HMBC [27] spectra were recorded with the delays optimized for a J_{nC-H} coupling constant of 8 Hz. Data workup was similar to that employed in the HMQC experiments, with the exception that data were processed with a sine-bell weighting function in absolute-value mode. All data were processed using Varian VNMR software (version 6.1C) on a Sun workstation.

2.8. X-ray crystallography

Single-crystal, high-resolution, low-temperature data of compounds **4**, **5** and **6** were collected on a Bruker SMART 1000 CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). Data were collected at 150(2) K with ω-scan increments of 0.3°. Reflections were integrated with the program SAINT [28] and merged with the program SADABS [28]. Details concerning crystal data and refinement parameters are given in Table 1. Intensities were corrected for Lorentz and polarization effects but absorption corrections were not applied. Structures were solved by direct methods and difference Fourier techniques using the SHELX-97 system [29], and refined by full-matrix least-squares methods in which the function $\sum w(F_o^2 - F_c^2)^2$ was minimized. Refinement was terminated when the minimization factor changed by <0.1% and a final difference map showed no significant residual electron density. Weighting schemes gave uniform analyses of variance in terms of F_c^2. Non-hydrogen atoms for compounds **4** and **5** were refined anisotropically. Hydrogen atoms were positioned geometrically, riding on the atoms to which they bond, with fixed isotropic thermal parameters. Data were also collected for the Λ-β_2 complex **6**, but attempts to fully refine the structure were frustrated by the fact that the anions and molecules of water of crystallization were considerably affected by disorder. However, the structure of the complex cation was fully discernible via a combination of difference Fourier maps and careful refinement steps. This allowed the complex cation to be finally refined with anisotropic thermal parameters for the non-hydrogen atoms, enabling the Λ-β_2 topology of the cation and the nature of the intramolecular π–π interaction to be established in the solid state. Hydrogen atoms for the complex cation in **6** were positioned geometrically, riding on the atoms to which they bond, with fixed isotropic thermal parameters. Three out of four waters of crystallization (as indicated by microanalysis of the efflorescent crystals) were located in partially occupied disordered sites. Our interest in this structure has been mainly focused on the confirmation of molecular structure and the conformation of the molecular cation. Plots of the molecules were made using ORTEP [30] for Windows.

3. Results and discussion

3.1. Topological considerations

The octahedral complex cations of the species reported in this paper are Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ (**3**), Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ (**4**), Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ (**5**), and Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ (**6**). The various diastereoisomers examined each have a combination of π–π and/or NH–π interactions, depending on their particular topology (Fig. 3); the Λ-β_1-*R*-trp isomer possesses one conformer of tryptophan that allows an NH–π interaction between the indole ring and a secondary amine group of the tetradentate. A secondary, non-idealized [11b] NH–π interaction involving the indole ring and an amino proton from Trp is also present in this conformer. Λ-β_2-*R*-trp, Δ-α-*R*-trp and Λ-β_1-*S*-trp isomers all have an appropriate conformer of the coordinated aminoacidate that can give rise to an intramolecular π–π interaction. In the cases of the latter two species, a bifurcated NH–π interaction involving one amino proton of the tryptophan ligand being sandwiched between the π-stacking indole and pyridyl rings, accompanies this interaction. For the Δ-α-*R*-trp complex, one amino group NH–(pyridyl) interaction remains in both of the other two conformers and a different kind of NH–π(indole) interaction is possible for one of them. The latter also obtains for another conformer of Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ and an NH–π(indole) interaction is possible for one rotamer of Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$.

3.2. Molecular structures of the complexes

The molecular structures of **3**–**6** were elucidated by NMR spectroscopy in solution, and X-ray crystallography in the solid state for compounds **4**, **5** and **6**. Through-bond ^{1}H and ^{13}C connectivities established via DQF-COSY, TOCSY, HMQC and HMBC NMR experiments enabled the complete assignment of the complexes. Through-space correlations via NOESY and ROESY measurements uniquely confirmed individual coordination topologies and dominant solution configurations of the complexes in DMSO-d_6 and D_2O solution. Full lists of ^{1}H and ^{13}C chemical shift and coupling constant data, together with observed rOe correlations (ROESY) are available as Supplementary material. A summary of the crystallographic data, experimental details and refinement results for **4**–**6** is given in Table 1. Selected bond lengths and angles in these structures are listed in Table 2.

The molecular structure of the complex cation in Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$(ClO_4)_2 \cdot H_2O$ (**4**), is shown in Fig. 4, together with the atom-labeling scheme applied both in the structural analysis and NMR studies. Numeric labels for hydrogen atoms correspond to those of

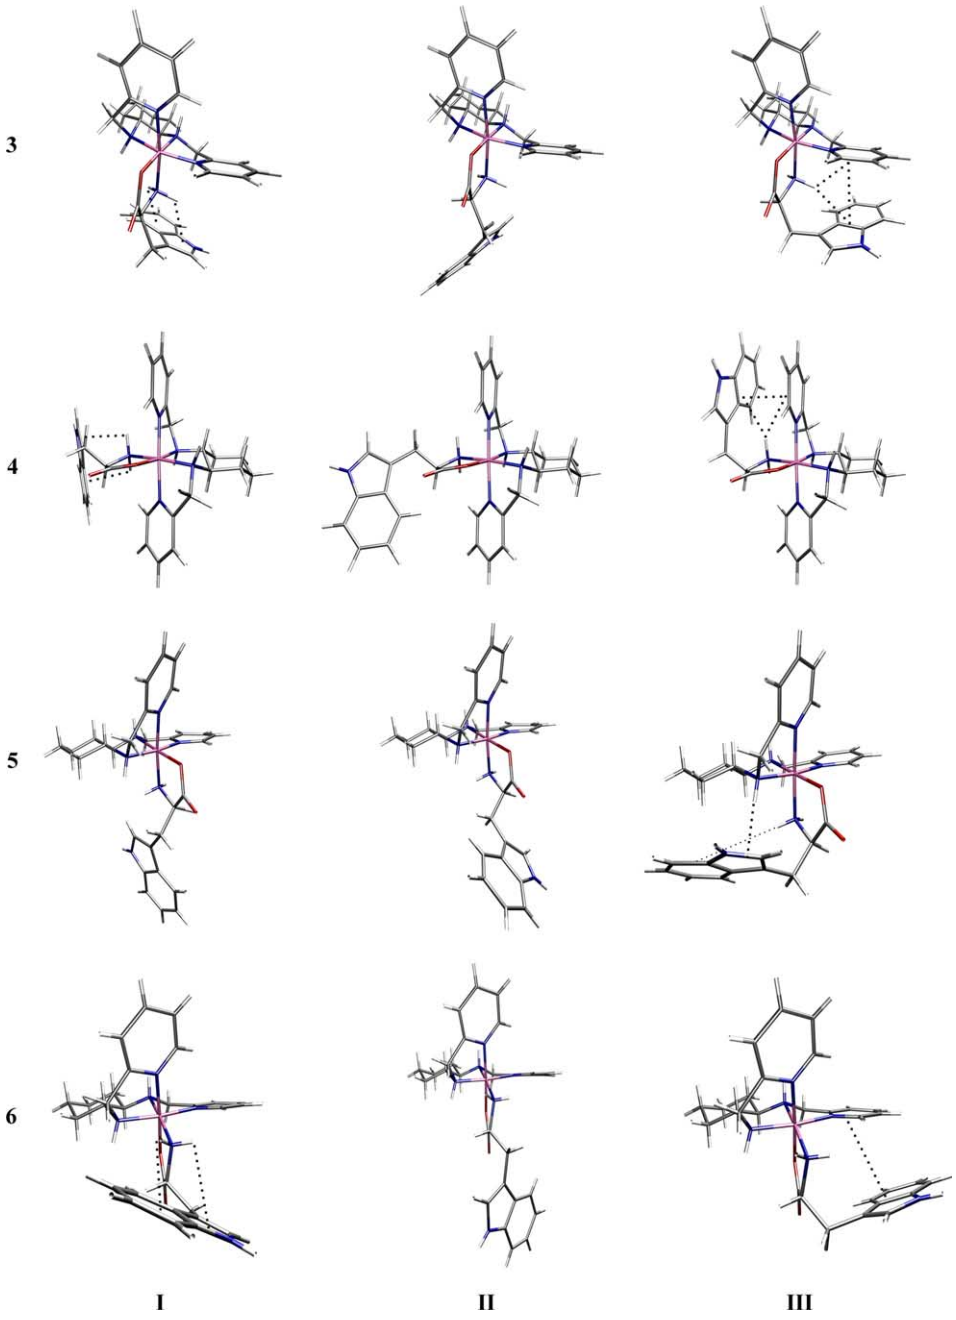

Fig. 3. Molecular conformation of the stable staggered rotamers **I**–**III** for the *R*- and *S*-aminoacidate complexes **3**–**6**. Dashed lines represent π–π and/or NH–π interactions in the individual rotamers.

the heavy atoms to which they are bonded, and where more than one hydrogen atom is bonded to a centre, it is distinguished by the suffix a, b or e. No unusual covalent bond lengths or angles were observed in the structure [13e,19–21], which clearly shows the tetradentate coordinated with α topology and the aminoacidate acting as a bidentate. In the lattice, perchlorate ions, water molecules of crystallization and the cations are linked by a hydrogen bonding network, and aromatic rings are aligned approximately parallel for adjacent cations (see Supplementary material for details of selected intermolecular contacts). Of particular note for the cation is an intramolecular π–π interaction between the indole ring of the coordinated aminoacidate and one of the pyridyl rings of the tetradentate, in a fashion akin to that observed in related structures [13e,19–21]. The conformation adopted by the molecular cation in the solid state corresponds to that of rotamer **III** in Fig. 3, as might be expected, based on a hierarchy of attractive non-covalent interactions that are possible in this species. Details of these interactions are highlighted in Fig. 5 and a summary of the intramolecular contacts is given in

Table 2

[a] The atom equivalent to N(31) in the Λ-β isomers **5** and **6** is labeled as N(3) in the Δ-α isomer **4**, in accordance with established nomenclature [16].

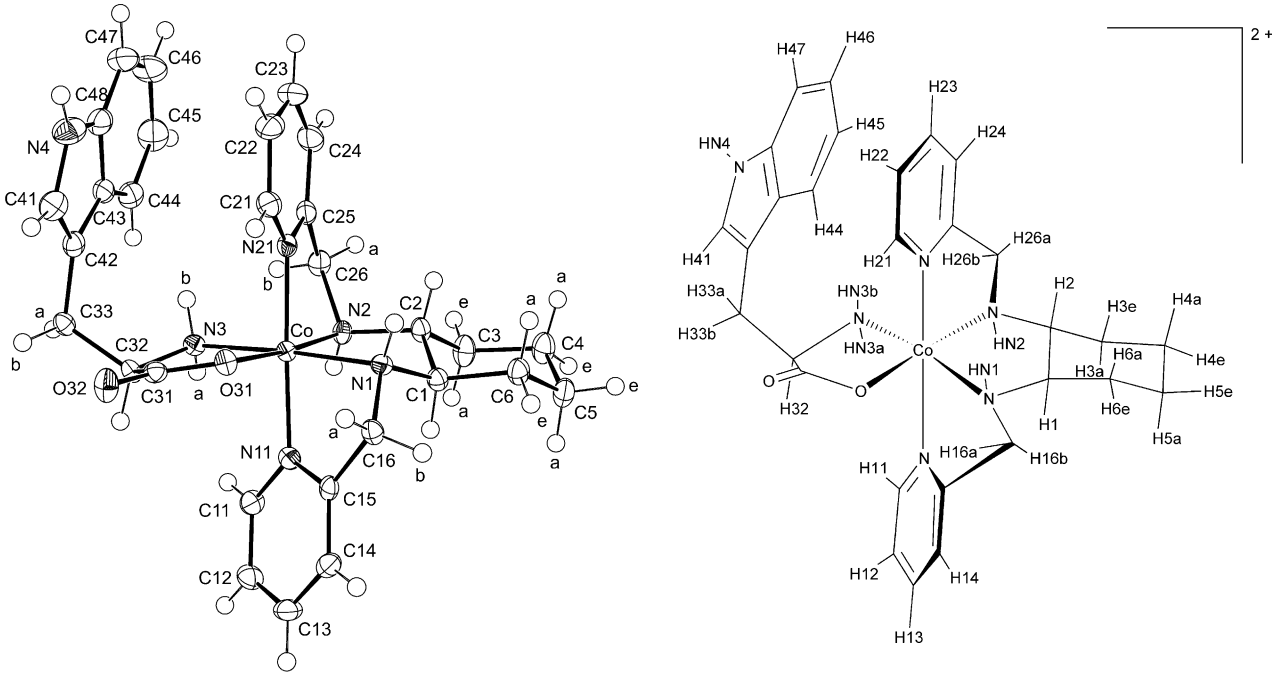

Fig. 4. Molecular structure of the Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ cation of **4**. Thermal ellipsoids are shown at the 50% probability level. The right-hand view is a line drawing of the cation.

Table 3. The two ring planes make a dihedral angle of 7.5° and the distances between the centroid of the pyridyl ring to the centroids of the five- and six-membered rings of the adjacent indole group are 3.84 and 3.58 Å, respectively. These are characteristic of attractive π–π interactions found in a variety of systems [31], and compare well with similar contacts observed in related complexes [20]. Also shown in Fig. 5 are contacts made by the amino proton *H*N3b with the two rings, between which it is sandwiched. This proton, which participates in a bifurcated NH–π interaction, is found at the unusually high-field position of 3.49 ppm in the ^{1}H NMR

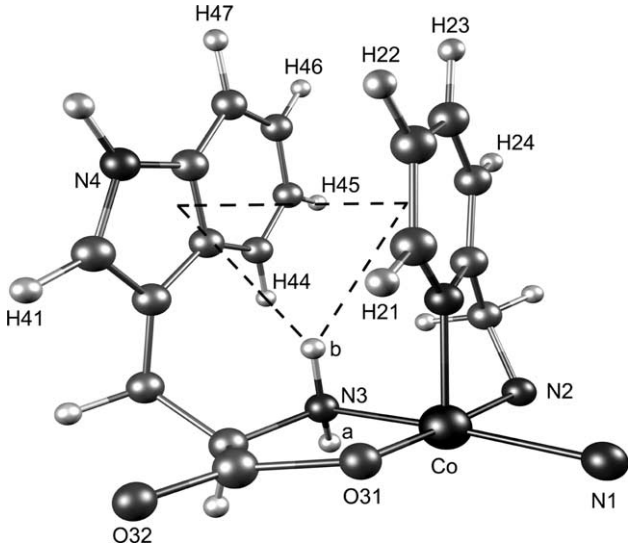

Fig. 5. Perspective view of the fragment of **4** showing the π-stacked indole and pyridyl rings. Dashed lines represent the intramolecular π–π and NH–π interactions.

spectrum recorded in DMSO-d_6 (Supplementary material). The chemical shift of *H*N3b is indicative of strong shielding effects associated with the ring current of the π-stacked aromatic rings. This non-classical hydrogen bond is not present for the geminal counterpart *H*N3a due to geometrical constraints, and accordingly this proton is observed at 6.84 ppm in DMSO-d_6. The relative chemical shifts of the two amino protons do not vary appreciably with concentration, nor under strictly anhydrous conditions (as achieved by converting the diperchlorate monohydrate **4** to the anhydrous dichloride salt via anion exchange chromatography, then dissolving this with anhydrous DMSO-d_6). This is entirely consistent with the intramolecular nature of the NH–π interaction in this complex cation.

The molecular structure of the complex cation in Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-trp)]$(CF_3SO_3)_2$ (**5**), is shown in Fig. 6. Bond lengths and angles observed in the structure are quite normal [13e,19–21], and the tetradentate coordinates with β topology with the aminoacidate acting as a bidentate in β_1 fashion. In the lattice, NH groups from the indole ring, the amino group of Trp and the tetradentate are hydrogen bonded to the oxygen atoms of the triflate ions and intermolecular ring stacking interactions range from 3.6 to 3.9 Å (see Supplementary material). A different kind of intramolecular contact is evident in the complex cation of **5** (Table 3) and involves NH–π contacts between *H*N2 and the indole group of the aminoacidate (distance of 2.41 Å from *H*N2 to the centroid of the five-membered ring). This is an example of a relatively rare *facial* interaction, noted especially in certain indole and porphyrin systems [3c], and is significantly closer than a similar contact (2.72 Å) reported for another Co(III) complex containing *S*-tryptophan and *N,N*-bis(carboxymethyl)-*S*-phenylalanine [13a]. A secondary, non-ideal [11b] NH–π interaction involving the indole ring and an amino proton from Trp is also present in this conformer. It is apparent that solid-state conformation of the cation in **5** also corresponds to that of rotamer **III** in Fig. 3. This result is consistent with the solid-state conformation adopted by the closely related species Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-tyr)]$(ClO_4)_2 \cdot 2H_2O$ [20a]. It is important to note, by way of contrast, that the analogous Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-phe)]$(ClO_4)_2 \cdot H_2O$ complex adopts the solid-state conformation equivalent to rotamer **II** for **5** (no NH–π bond) [20a]. The results, taken together, are precisely in line with the observations of Steiner and Koellner [8], who noted that Trp and Tyr are the aromatic aminoacids most frequently involved in NH–π hydrogen bonds in proteins. The order of aromatic acceptor efficiency is Trp ≫ Tyr > Phe ≫ His [8].

The molecular structure of the complex cation in Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$(CF_3SO_3)Cl \cdot 3H_2O$, **6**, is shown in Fig. 7. A high degree of disorder of the counterions and lattice water molecules in the single-crystal structure of this compound prevented full structural refinement, but the structure of the complex cation was fully discernible. In this isomer, the indole ring of Trp participates with a pyridyl ring of the tetradentate in a π–π interaction (Table 3), but no intramolecular NH–π contacts are present. The conformation adopted by the cation of **6** in the solid state corresponds to that of rotamer **III** in Fig. 3. A quasi-parallel aromatic interaction similar to that found in compound **4** is unfavoured in this diastereoisomer due to a steric clash between H44 of the indole ring and the coordinated carboxyl group. The rings adopt a hinged π-stacking arrangement with a dihedral angle of 22.1° between the ring planes, with the principal π–π interaction occurring between the pyridyl ring and the six-membered ring of the indole group. The distance between the centroids of these two rings is 3.899 Å (Table 3).

No crystals of Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$(ClO_4)_2 \cdot NaClO_4 \cdot 2H_2O$ (**3**) suitable for X-ray analysis were obtained, but spectroscopic and analytical measurements establish the nature of the complex unambiguously. The CD spectrum indicates the Λ absolute configuration at Co [15–21] and its ^1H and ^{13}C NMR spectra are in complete agreement with the assignment. Notably, H11 is observed at δ 7.71 and 7.50 in DMSO-d_6 and D_2O, respectively, in accord with previous observations of complexes for which single-crystal structures are to hand [18,19,21]. Through-bond ^1H and ^{13}C connectivities established via DQF-COSY, TOCSY, HMQC and HMBC NMR experiments have enabled the complete assignment of this complex. Through-space correlations via NOESY and ROESY measurements in DMSO-d_6 and D_2O uniquely confirmed the

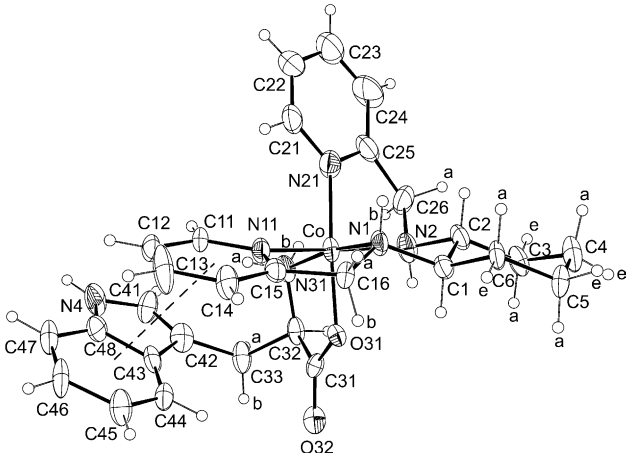

Fig. 7. Molecular structure of the Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ cation of **6** with 50% probability thermal ellipsoids. A dashed line represents the intramolecular π–π interaction.

Λ-β_1 topology and molecular structure. Full lists of ^{1}H and ^{13}C chemical shift and coupling constant data, together with observed rOe correlations (ROESY) for **3** are available as Supplementary material. The molecular structure of the complex cation of **3** is shown in Fig. 8, together with the atom-labeling scheme applied in the NMR studies. The particular conformation illustrated corresponds to the dominant species in solution, as established by measurement of rotamer populations (vide infra) and through-space correlations from ROESY spectra recorded at various mixing times (vide supra). This corresponds to rotamer **III** in Fig. 3, and is consistent with the known solid-state conformation of the analogous complex with *S*-α-methyltryp [21] and other related species [20b].

3.3. Rotamer distributions and solution structures

One- and two-dimensional NMR studies confirm the structural relationships found in the solid state for the above complexes and the nature of the Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ ion in solution. Rotamer populations (with respect to rotation about the C_α–C_β bond) for the coordinated *R*- or *S*-trp aminoacidate ligands in **3**–**6** were calculated from two vicinal coupling constants for the ABX systems present in their ^{1}H NMR spectra, using an established methodology (Eqs. (1)–(3)) [32]. Newman projections for the three stable staggered rotamers are shown in Fig. 9. The critical values used were $J_g = 2.60$ and $J_t = 13.56$ Hz [32e], which represent the values for the vicinal coupling constants between hydrogen atoms in the *trans*, J_t, and gauche position to each other, J_g, derived from various sources [32b–32e]:

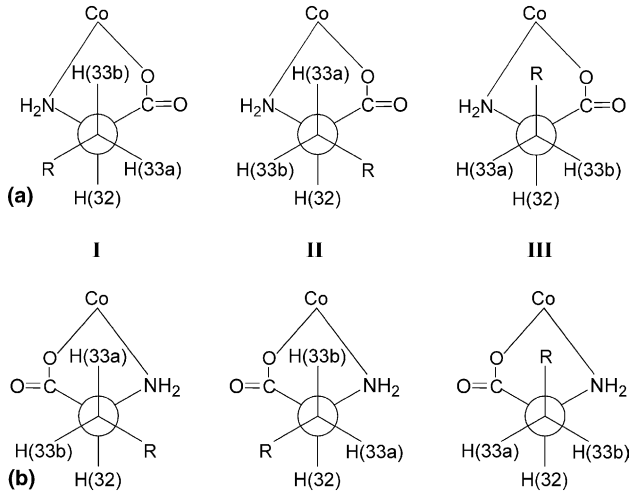

Fig. 9. Newman projections of the three staggered rotamers about the C_α–C_β bond of the coordinated aminoacidate: (a) rotamers for *R*-aa; (b) rotamers for *S*-aa.

$$p\mathbf{I} = \frac{J_{33b,32} - J_g}{J_g - J_t}, \tag{1}$$

$$p\mathbf{II} = \frac{J_{33a,32} - J_g}{J_g - J_t}, \tag{2}$$

$$p\mathbf{III} = 1 - (p\mathbf{I} + p\mathbf{II}). \tag{3}$$

It was assumed that these remained unchanged upon coordination [32a]. The relative residence times for **I** and **II** were determined from Eqs. (1) and (2), respectively, using the two measured vicinal coupling constants, $J_{33b,32}$ and $J_{33a,32}$. The residence times are normalized by

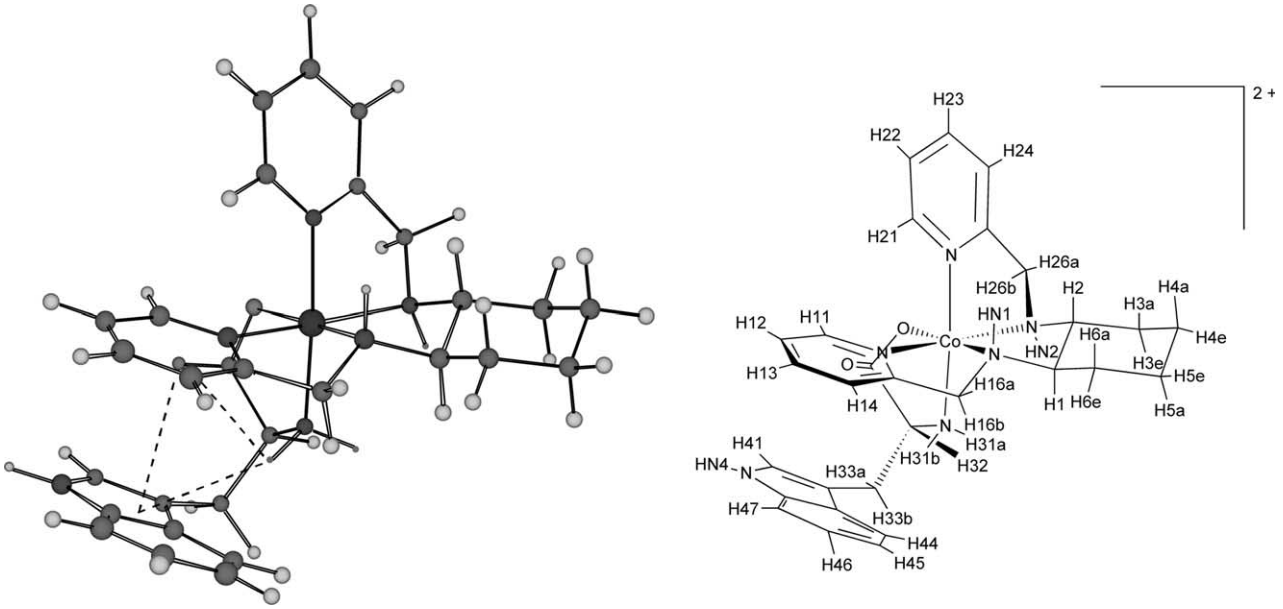

Fig. 8. Molecular structure of the Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ cation of **3**. The molecular conformation was established in solution by ROESY correlations, with dashed lines representing the intramolecular π–π and NH–π interactions. The right-hand view is a line drawing of the cation.

[a] Average values from at least three experiments.
[b] ΔG_1 is obtained from $K_1 = \mathbf{III}/\mathbf{I}$.
[c] ΔG_2 is obtained from $K_2 = \mathbf{III}/\mathbf{II}$. Dashes indicate rotamer populations that could not be evaluated due to deceptively simple ABX systems in the ^{1}H NMR spectra.

Eq. (3), enabling the population of **III** to be evaluated. Three-dimensional molecular models of the complexes (adopting conformations corresponding to the idealized rotamers) are illustrated in Fig. 3. Rotamer populations at 25 °C for **3**–**6** in various solvents are listed in Table 4. The dominant conformer in solution in all cases is **III**. As noted above, single-crystal structures of **4**–**6** have demonstrated that the molecular cation in each complex adopts a conformation corresponding to rotamer **III**, whereby attractive π–π and/or NH–π interactions dominate. These findings demonstrate the persistence of the weak non-covalent interactions in solution. The molecular conformation found in the solid state for **4** and **6** also dominates in solutions of Λ-β$_1$-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ (**3**). This is consistent with our recent observations [20b] for Λ-β$_1$-[Co(*R*,*R*-picchxn)(*S*-aa)]$^{2+}$ (aa = Tyr, *O*Me-tyr or Phe) complexes, for which the appropriate conformer possessing both intramolecular π–π and NH–π interactions dominates in solution in all cases.

It has been shown from an evaluation of the equilibrium rotamer distributions under a variety of conditions (Tables 4 and 5) that rotamer **III** is the dominant conformer in Δ-α-*R*-trp (**4**), Λ-β$_1$-*S*-trp (**3**), and Λ-β$_2$-*R*-trp (**6**). In each case, the dominant conformer is seen to exhibit an intramolecular π–π interaction (Fig. 3). The nature of the dominant conformers in **3**, **4** and **6** is further manifested in observations of rOe correlations between protons of the pyridyl and indole rings involved in π-stacking. Fig. 10 shows an expansion of the aromatic region of a ROESY spectrum of Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ in D_2O, together with a perspective view of the relevant fragment of the molecule constructed using coordinates from the single-crystal X-ray structure. Cross-peaks corresponding to close proton–proton contacts between the interacting rings (depicted by dashed lines) are highlighted in the spectrum by boxes. In the solid state, all of these interproton distances are between 3.29 and 4.55 Å in distance and thus should be and are observed in the spectrum. Through-space correlations between amino proton HN3b and protons from the indole ring of Trp were only observed at shorter mixing times ($\tau_m \leqslant 300$ ms, see Supplementary material). Spectra were acquired with sufficient mixing times to allow rOe build-up, and no evidence for the effects of spin diffusion

[a] Vicinal coupling constants in Hertz appear in the format ($J_{33a,32}$, $J_{33b,32}$) directly above populations of rotamers **I**–**III** for each given complex/solvent/temperature combination (average values from at least three separate experiments are quoted).

[b] Estimated uncertainties in the rotamer populations vary from 1% to 7% of the listed values. Dashes indicate parameters that could not be evaluated due to a deceptively-simple or obscured ABX spin system in the ^{1}H NMR spectrum at this temperature.

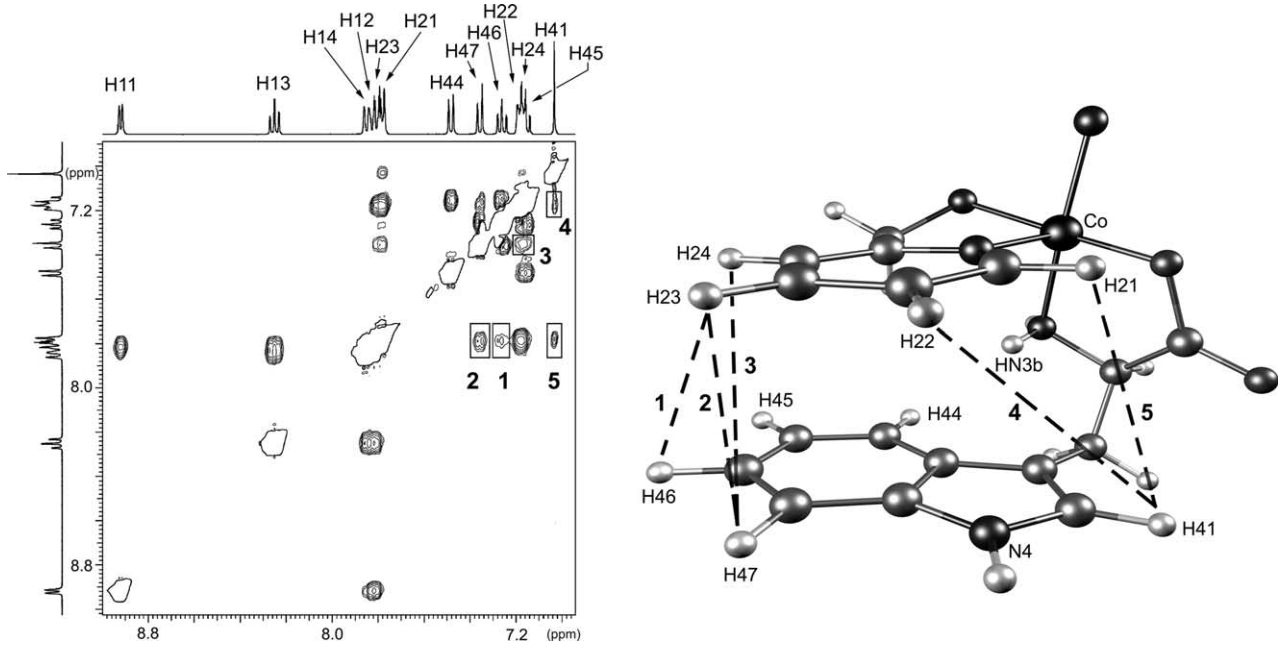

Fig. 10. ROESY spectrum of the aromatic region of Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ in D_2O (400 MHz, 1 s mixing time, 25 °C), together with a perspective view of the relevant fragment of the complex cation as determined by single-crystal X-ray measurements. The molecular conformation observed in the solid state (at right) dominates in solution (population of π stacked rotamer **III** is 0.84).

was found for the mixing times selected. Corresponding enhancements were also observed in conventional 1D nOe difference experiments in both D_2O and DMSO-d_6. Similarly, for Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ and Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$, definitive rOe cross-peaks are observed (Figs. 11 and 12, respectively). As far

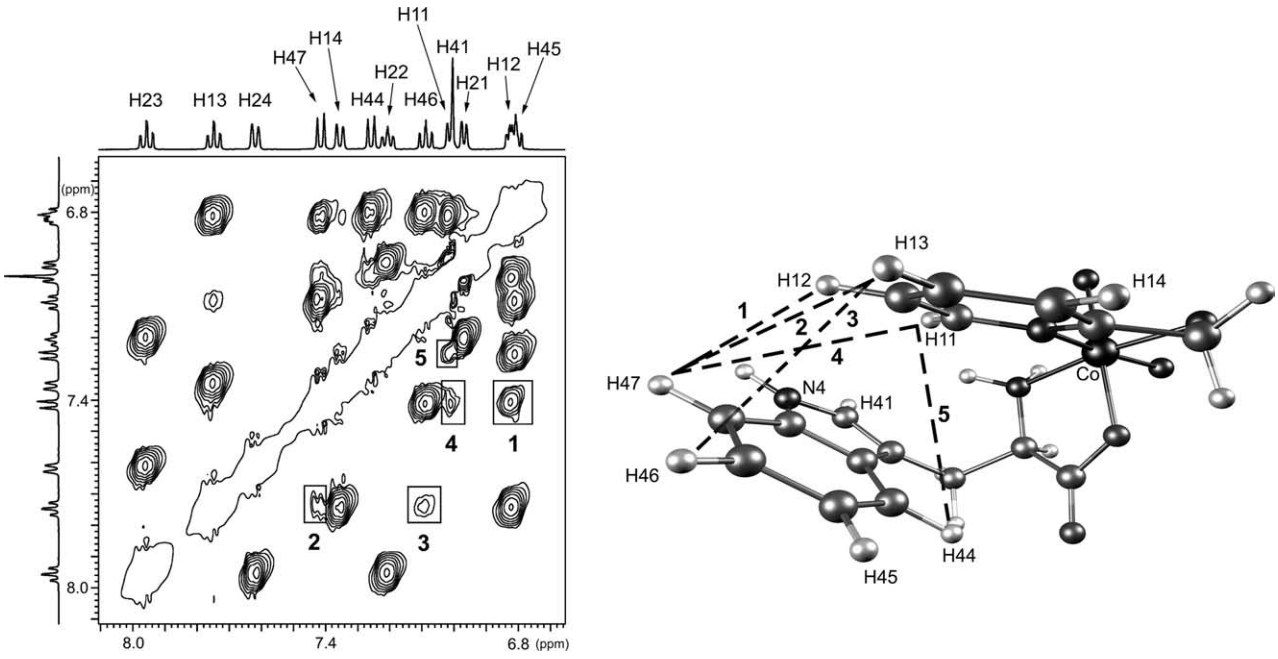

Fig. 11. ROESY spectrum of the aromatic region of the Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ cation in D_2O (400 MHz, 1 s mixing time, 25 °C), together with a view of the π-stacked rings in the solid-state structure.

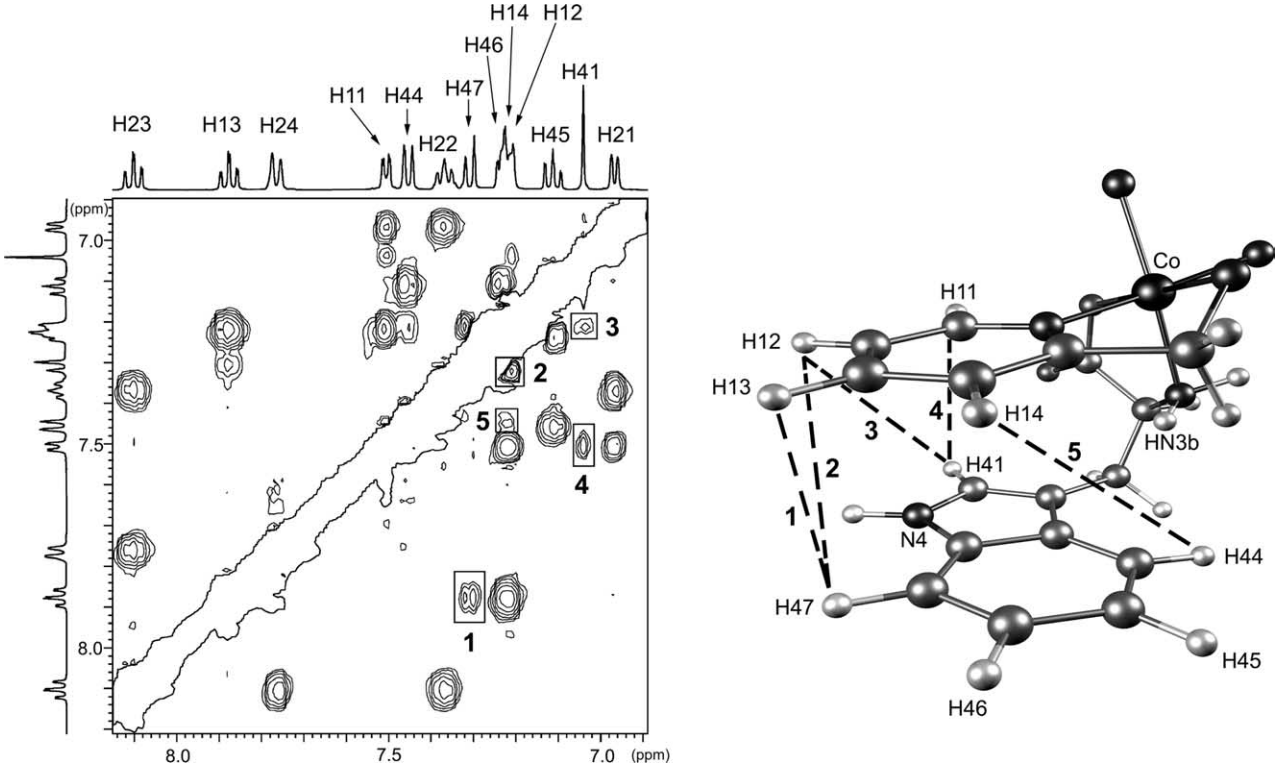

Fig. 12. ROESY spectrum of the aromatic region of the Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ cation in D_2O (400 MHz, 1 s mixing time, 25 °C). A view of the dominant molecular conformation in solution (rotamer **III**) is shown, with observed intramolecular proton-to-proton contacts (<5 Å) represented by dashed lines.

as the latter is concerned, it is true that no single-crystal structure is to hand, but the NMR evidence for the interaction is supported by its observation in the solid state for the closely related analogues Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-ABzH)]$^{2+}$ and, particularly, Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-α-methyltryp)]$^{2+}$ [19,21].

3.4. Solvent and temperature dependence of rotamer distributions as a probe of intramolecular interactions

Few studies have been undertaken with a view to establish the effects of the solvent medium on molecules known to possess weak non-covalent interactions, particularly those possessing aromatic interactions [15]. This may be because, unlike simple dipole interactions such as classical H-bonding [1], aromatic interactions are more complicated and have proven to be more difficult to study [3d]. A majority of these studies are performed in an arbitrary solvent, or rely heavily on gas-phase calculations [12], providing limited information about the effects of the medium. We have undertaken a preliminary study of the effects of various solvents on the conformation of **3**–**6**, in an effort to probe the nature of the non-covalent interactions present in these complexes and to further demonstrate the suitability of these complexes to act as model systems for such interactions. Indeed, the primary criterion of selecting suitably simple complexes (whose molecular conformation is governed by weak intramolecular π–π and NH–π interactions) has already been realized in **3**–**6**. The other important criterion that must be demonstrated experimentally is that the molecular conformation (and hence the intramolecular π–π and NH–π interactions which govern this) of the model systems be suitably sensitive to changes in the nature of the solvent. The results of our study, which include the determination and analysis of rotamer populations of **3**–**6** in a variety of solvents, are presented in Table 4. These data show that the distributions of molecular conformations for **3**–**6** (Fig. 3) are sensitive to the nature of the medium. Indeed, consistent trends in the solvent dependencies of the rotamer populations for a given complex, as well as between different complexes, are evident on inspection of our results, confirming that gross effects due to differential solvation do not play a major role in conformational discrimination in these systems. This is in accord with the structural similarity of the complexes.

It is clear that arguments invoking a general relationship between dielectric constant and conformational stability [33,34] are inadequate for explaining our observations (Table 4). For example, in **3**, **4** and **6**, the population of the π-stacked rotamer (**III**) increases significantly when aliquots of D_2O are added to a DMSO-d_6 (or predominately DMSO-d_6) solution of the complex. This observation is consistent with the hydrophobic effect [33], where the association will increase with increasing solvent polarity. However, when increasing amounts of benzene are added to a DMSO solution of **4**, **6** or **3** in particular, the population of π-stacked rotamer **III** also increases. In addition, the population of **III** for these species dissolved in pyridine is similar to that for D_2O, for which there is a substantially different dielectric constant. At 25 °C, rotamer populations for the three stable staggered rotamers of the Λ-β_1-*R*-trp diastereoisomer **5** are approximately equal in DMSO-d_6, as might be expected due to a lack of intramolecular π–π or solvent-shielded NH–π interactions in this species. Rotamer **III** becomes more populated upon addition of benzene-d_6, and in pyridine-d_6. This is consistent with the increased magnitude of so-called *buried* hydrogen bonds found in the hydrophobic (or low polarity) regions of some proteins [4b,6b,13a]. For the Λ-β_2-*R*-trp (**6**), Δ-α-*R*-trp (**4**) and Λ-β_1-*S*-trp (**3**) diastereoisomers, that is to say those which can adopt conformations yielding an intramolecular π–π interaction, these conformers predominate in all of the selected solvents. Variable-temperature ^{1}H NMR measurements recorded for **3**–**6** in DMSO-d_6 and D_2O (25–65 °C in steps of 10°, as listed in Table 5) showed that an increase in temperature to 65 °C does not perceptibly alter the relative stability of the rotamer system. Rotamer distributions showed little variation from the values at 25 °C and an analysis of the variable-temperature data indicates that ΔH^0 and ΔS^0 contributions are small; separate energetic components that contribute to the rotamer distributions cannot be discerned. However, π–π interactions are significantly enhanced in D_2O versus DMSO-d_6 (or 2:1 DMSO-d_6/D_2O), in line with expectations associated with varying solvent polarity, dielectric constant, hydrophobic bonding, and donor-acceptor ability in charge-transfer interactions [33]. Uncertainties in the rotamer populations were estimated to be in the order of between 1 to 7% of the values listed in Table 5, and are sufficiently small to permit a comparison of these values.

Relative stabilities for individual rotamers may be simply derived from an equilibrium treatment and are listed as ΔG_1 and ΔG_2 in Table 4. For example, for Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ (**4**) in D_2O, the equilibrium constants at 25 °C for Eqs. (4) and (5) are 6.5 and 28.0, respectively. Thus the intramolecular π–π interaction in **III** stabilizes this rotamer by some 4.6 and 8.3 kJ mol^{-1}, respectively. It is evident that cooperative effects involving NH–π interactions must also play a role and although absolute contributions are not readily evaluated, it is noted that the conformer that is least stable is that which has no NH–π interaction with the indole ring of Trp

$$\mathbf{I} \rightleftharpoons \mathbf{III} \quad K_1, \tag{4}$$

$$\mathbf{II} \rightleftharpoons \mathbf{III} \quad K_2. \tag{5}$$

The same set of intramolecular interactions are present in the preferred conformer of Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$, **3**, and discriminations in the equilibrium constants for Eqs. (4) and (5) in favour of **III** in this case amount to 2.4 and ca. 11 kJ mol^{-1}, respectively, in D_2O at 25 °C. Again, the least preferred rotamer is that with no possible intramolecular NH–π(indole) interaction. This is paralleled in the case of Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$, **6**, (Table 4), and the

least preferred rotamer is present in negligibly small amounts in D_2O at 25 °C; as expected, it is more populated at higher temperatures. Given the estimated errors for population distributions, discriminations for the equilibrium constants for Eqs. (4) and (5) in favour of **III** amount to 1.9 and ca. 10 kJ mol^{-1}, respectively, in D_2O at 25 °C.

A comparison of the rotamer distributions of **3**, **4** and **6** in DMSO (or DMSO/D_2O 2:1 for **4** and **6**) versus other selected solvents (Table 4), reveals that the general trend is for the population of the dominant rotamer (**III**) to increase, the population of **I** to remain about the same or increase slightly, and for the population of rotamer **II** to generally decrease, sometimes quite markedly. Inspection of Fig. 3 reveals that, for the aromatic complexes reported, rotamer **I** has possible intramolecular NH–π interactions involving the amino group and aromatic ring of the coordinate aminoacidate; in rotamer **II** the aminoacidate aromatic ring is extended such that the carbonyl group lies over the aromatic ring; rotamer **III** (favoured) corresponds to the solid state conformation of compounds **4** and **6** with combined intramolecular π–π and NH–π interactions possible. We note that for Λ-β_1-[Co(*R*,*R*-picchxn)(*R*-aa)]$^{2+}$ and Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-aa)]$^{2+}$ complexes {aa = Trp (**5**), Phe [20b,35] or Tyr [20b,35]}, that stand-alone intramolecular NH–π interactions are observed in the solid state conformation adopted by the Λ-β_1 diastereomers, and that stand-alone intramolecular π–π interactions are similarly present in Λ-β_2 diastereomers. It may be possible to rationalise these general trends of conformational preference on the basis of a hierarchy of favourable intramolecular non-covalent interactions. This, however, is further complicated by the fact that variations in rotamer distributions of a given complex from one solvent to another (Table 4) may possibly be due to the nature of any possible solute–solvent intermolecular interactions. Intermolecular solute–solvent interactions could either enhance or compete with the forces responsible for the stabilization of a particular rotamer. Such interactions are relatively poorly understood phenomena due to their complexity, and a detailed examination of the individual contributions to subtle changes in rotamer populations from solvent to solvent is not practical. However, four trends evident in Table 4 are worthy of comment. First, the intramolecular π-stacking interaction in these complexes is not disrupted by aromatic solvents (pyridine and benzene), as might be expected to be the case given the rotational isomerism involved. This is in line with the discriminatory roles undertaken by such interactions in these complexes, and would be important for conformation analyses of aromatic residues in chelated amino acids and peptides [32b,32c]. Second, the population of rotamer **II** is substantially lower in D_2O and pyridine compared with other solvents, in particular for **3**, **4** and **6**. Kobayashi et al. [32b] have suggested the possibility of attractive interactions between the carbonyl group and the aromatic ring of aromatic amino acid derivatives, and reported that the population of the rotamer with this geometry (analogous to rotamer **II** in complexes **3**–**6**) decreased as the solvent polarity is raised. This was attributed to an attractive interaction between the carbonyl group and the polar solvent molecules (such as hydrogen bonding) disrupting the carbonyl–aromatic interaction. This may well be the case in the complexes reported here. Thirdly, intramolecular NH–π interactions that occur in solvent exposed regions (such as in rotamer **I** for **3**, **4** and **6**, and rotamer **III** for **5**) are generally weaker than, and are not favoured over π–π interactions in solution. This is manifested by the observation for **5** that in pyridine-d_6 the dominant population of conformer **III** (cf. DMSO-d_6) is achieved at the expense of *both* **I** and **II**, which lack any attractive π–π or NH–π interactions. In contrast, the dominance of rotamer **III** in all other complexes is achieved primarily at the expense of **II**. This indicates a hierarchy in terms of interaction energy to be {standalone NH–π < π–π < (NH–π + π–π)}. Finally, the estimated interaction energy of the π–π interactions in these complexes (from $|\Delta G_1|$ for **3**, **4** and **6**) varies between 1.8 ± 0.2 and 4.6 ± 0.5 kJ mol^{-1} at 25 °C. In contrast, Hunter et al. [22] recently obtained values of π–π interaction energies of between 1.0 and 4.9 kJ mol^{-1} (attractive) at 22 °C by measurement of chemical double mutant cycles in hydrogen-bonded zipper complexes. Their work involved varying combinations of *substituents* on the interacting rings in deuterochloroform, as opposed to our approach of varying the solvent medium. Given this fact, the correlation between these results is quite remarkable and serves to validate our findings based on the Co(III) model systems. The estimated interaction energy of the NH–π interactions in these complexes (from $|\Delta G_2|$ for **3**–**6**, and also $|\Delta G_1|$ for **5**) varies between 0.1 ± 0.2 and 6.0 ± 0.6 kJ mol^{-1} at 25 °C (cf. a lower limit of 4.5 ± 0.5 kJ mol^{-1} at 25 °C, also reported by Hunter et al. [4d] for a molecular zipper complex), and is highly dependent of the nature of the solvent and whether the NH proton exists in a hydrophobic or a solvent-exposed region. This is precisely in accord with the postulated sensitivity of such interactions in a variety of biopolymers [4,8], and serves to thereby highlight the suitability of these complexes to act as models for studying such interactions that occur in a variety of polar or non-polar (buried) regions within a given molecule.

3.5. Charge-transfer

Charge-transfer behaviour is observed between the π-stacked rings of complexes **3**, **4** and **6** in solution. NMR evidence for this interaction arises from the strong chemical shift dependence of these ring protons

with increased population of π-stacked rotamer **III**. The population of rotamer **III** increases with increased solvent polarity upon the addition of D_2O to a DMSO-d_6 solution of **3**, **4** and **6**, primarily due to the hydrophobic effect [33].

The Hunter and Sanders rules [31b] concerning π–π interactions dictate that polarized rings are required for charge-transfer interactions, with the interacting rings exhibiting donor-acceptor character. In complexes **3**, **4** and **6**, one coordinated pyridyl ring acts as an acceptor in such an interaction. The pyridyl ring is electron deficient due to the electron-withdrawing inductive effect of the electronegative nitrogen atom, which is involved in coordination to Co(III). The relatively electron-rich indole ring is the donor ring in the π-stacking interaction. Proton resonances of the indole donor ring shift downfield, while those of the adjacent pyridyl acceptor ring move upfield as the population of rotamer **III** increases with increasing solvent polarity. Stacked ^1H NMR spectra of the aromatic region of compound **4** in DMSO-d_6, DMSO-d_6/D_2O (5:1) and D_2O at 25 °C are shown in Fig. 13. As the solvent polarity is increased, the resonances of the pyridyl acceptor (H21–H24) progressively shift upfield, while those of the indole donor (H41–H47) generally move downfield. In contrast, the proton resonances of the *trans*-axial counterpart of the pyridyl ring involved in π-stacking (H11–H14) are relatively unchanged, consistent with the fact that this pyridyl is unable to participate in π-stacking due to geometrical constraints. This donor–acceptor behaviour is also observed for the π-stacking rings in *cis*-β complexes **3** and **6**, with resonances of the pyridyl ring *cis* to its counterpart involved in π-stacking remaining relatively unchanged. Minor changes are also possible due differential solvation, which is likely to have a bigger effect on aromatic rings that have both faces exposed to bulk solvent [31]. ^1H NMR chemical shifts and chemical shift differences for the aromatic protons of **3**, **4**, and **6** in DMSO-d_6 and D_2O at 25 °C are given in Table 6. Our observations are in accordance with the Hunter and Sanders rules [31], and may be important for the study of π–π interactions in a variety of biochemical systems.

In D_2O, of course, NH protons are readily exchanged. We note in passing that over prolonged periods, one of the protons in the methylene groups attached to the pyridyl rings of the tetradentate is also exchanged for deuterium especially for β complexes. This exchange is stereospecific; in both Λ-$β_1$-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ and Λ-$β_1$-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ H16b is completely exchanged during 3 days at room temperature. In Λ-$β_2$-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$, however, both H26a and H26b exchange, the former much

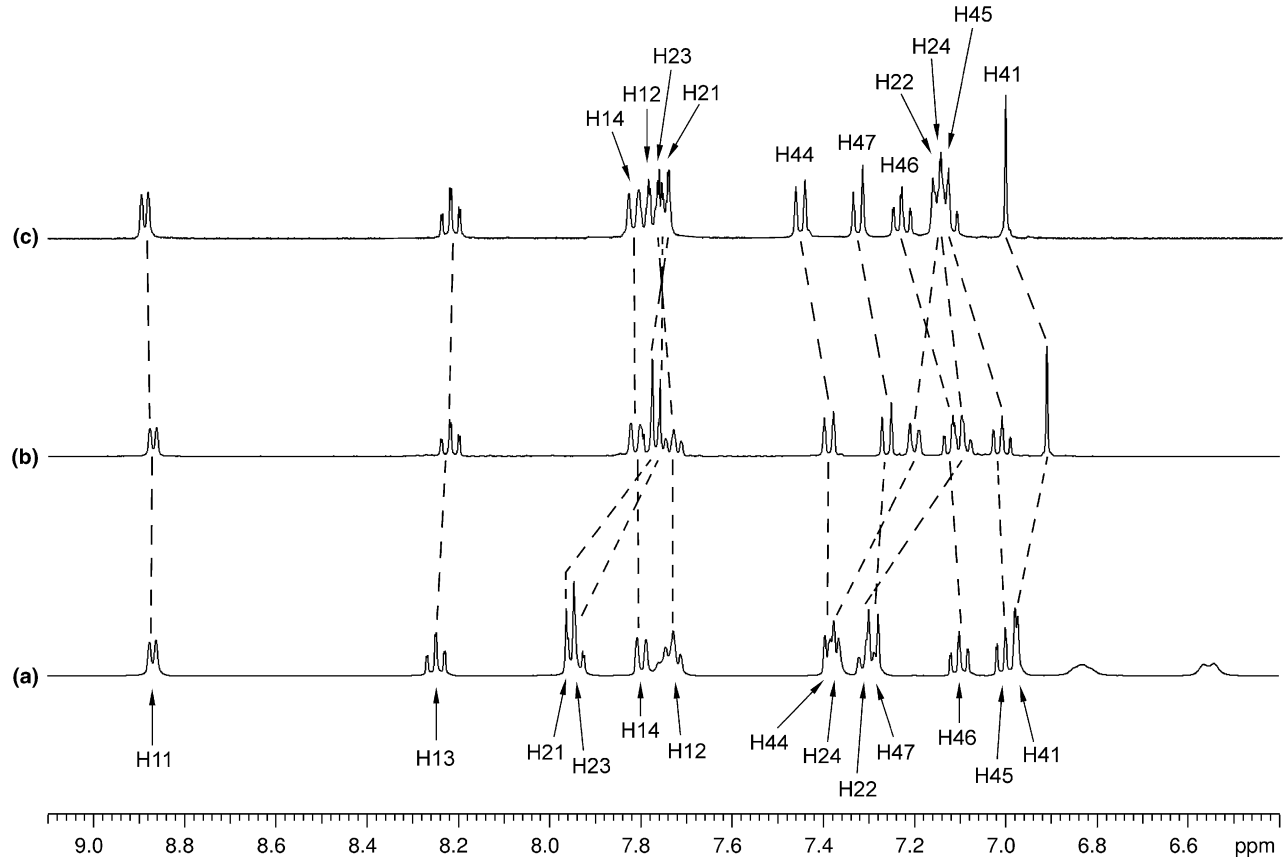

Fig. 13. Stacked ^1H NMR spectra (400 MHz) of the aromatic region of **4** at 25 °C in: (a) DMSO-d_6, (b) DMSO-d_6/D_2O (5:1), and (c) D_2O.

Table 6
^{1}H NMR chemical shift data (400 MHz) for non-exchangeable aromatic protons of **3**, **4** and **6** in DMSO-d_6 and D_2O at 25 °C

[a] $\Delta\delta = \delta$ DMSO $- \delta$ D_2O. Positive values indicate an upfield shift.
[b] Values correspond to protons of aromatic rings involved in π–π interactions.

more slowly (as is the case with the α isomer). The particular protons must be somewhat acidic, but the detailed reasons for this and the peculiar stereospecificities are not readily apparent.

3.6. Stereochemical change

Remarkably, these complexes can be epimerized under mild conditions with no discernible decomposition and this has enabled an assessment of chiral discrimination energies between diastereoisomers containing *R*-trp as well as the energetics involved in the NH–π versus π–π interactions. Rigorous degassing (oxygen) of aqueous (D_2O) solutions of the complexes in the presence of a mild base (TSP sodium salt present as a reference for the NMR is sufficient) serves to equilibrate diastereoisomer populations that can be measured by NMR integration. Oxygen must be strictly excluded during the reactions and any trace will halt the approach to equilibrium. Thus it is evident that the pattern of isomers produced during the syntheses of the complexes is in fact controlled by kinetic influences. It is noteworthy that the equilibrium mixtures can be produced by using any of the Δ-α-, Λ-β_1- or Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ species. Approach to equilibrium is characterized by a variable induction period of minutes to hours at room temperature, indicating the possible involvement of Co(II) intermediates in an autocatalytic mechanism, details of which remain to be elucidated. Nevertheless, reaction of any starting diastereoisomer in D_2O at 25 °C results in an equilibrium mixture of isomers in the ratio Δ-α:Λ-β_1:Λ-β_2 equal to 10.2:1:2.9, estimated by a careful integration of isolated signals in the aromatic region of the ^{1}H NMR spectra with a relaxation delay long enough to ensure complete relaxation of all signals. These results give in turn values for equilibrium constants for (6) and (7) at 25 °C of 10.2 ± 0.3 and 3.5 ± 0.3, respectively. Thus the Δ-α species is more stable than the Λ-β_1 and Λ-β_2-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$(aq) ions by some 5.8 ± 0.1 and 3.1 ± 0.1 kJ mol^{-1}, respectively, at this temperature

$$\Lambda\text{-}\beta_1\text{-}[\mathrm{Co}(R,R\text{-picchxn})(R\text{-trp})]^{2+}(\mathrm{aq}) \rightleftharpoons \Delta\text{-}\alpha\text{-}[\mathrm{Co}(R,R\text{-picchxn})(R\text{-trp})]^{2+}(\mathrm{aq}) \quad (6)$$

$$\Lambda\text{-}\beta_2\text{-}[\mathrm{Co}(R,R\text{-picchxn})(R\text{-trp})]^{2+}(\mathrm{aq}) \rightleftharpoons \Delta\text{-}\alpha\text{-}[\mathrm{Co}(R,R\text{-picchxn})(R\text{-trp})]^{2+}(\mathrm{aq}) \quad (7)$$

Of particular significance is the fact that no analogous Δ-α isomer could be detected in similar reactions of Λ-β_1-[Co(*R*,*R*-picchxn)(*S*-trp)]$^{2+}$ (**3**), which in the Λ-β_1 topology also possesses π–π and NH–π interactions between the indole group of the aminoacidate and the tetradentate ligand as found for Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ and topologically related complexes [19–21]. Similarly, no Δ-α isomer was found in reactions carried out under the same conditions using Λ-$\beta_{1,2}$-[Co(*R*,*R*-picchxn)(*R*,*S*-aa)]$^{2+}$ (aa = a variety of *aliphatic* aminoacidates). Since we estimate conservatively that we could detect about 1% of any isomer in the NMR, it is therefore concluded that the Δ-α configuration of the metal-tetradentate fragment is at least 15 kJ mol^{-1} more stable than the Λ-β configuration at 25 °C, for Trp complexes of appropriate topology. This is reinforced by the observation that Δ-α-[Co(*R*,*R*-picchxn)(AbuH)]$^{2+}$ epimerizes in DMSO to the corresponding Λ-β_1 diastereoisomer with no trace of the starting material at the end of the reaction [18]. The further conclusion is thus drawn that the cooperative effects of the π–π and NH–π interactions present in Δ-α-[Co(*R*,*R*-picchxn)(*R*-trp)]$^{2+}$ must also amount to at least 15 kJ mol^{-1} at 25 °C if, as seems reasonable, contributions from solvation in the diastereoisomers are comparable. The bifurcated NH–π bond, which occurs in a hydrophobic environment,

appears to contribute the bulk of this stabilization energy (given that π–π interactions are present in both Λ-β_2 and Δ-α diastereoisomers), and is equal in magnitude to some conventional hydrogen bonds [1]. In addition, it is likely that non-covalent NH–π and π–π interactions facilitate ligand reorganization in any intermediate species involved in the Λ-β_1/Λ-β_2 to Δ-octahedral inversion. The resulting equilibrium isomer distribution of Λ-β_1 < Λ-β_2 < Δ-α is consistent with the hierarchy of favourable intramolecular non-covalent interactions possible in these diastereomers {NH–π < π–π < (NH–π + π–)}, respectively. Moreover, the ligand reorganization could occur in an analogous fashion to the role of such interactions in determining conformational preference within a given diastereoisomer.

4. Conclusions

The intramolecular π–π and NH–π interactions described above for these simple molecules have, of course, a wider context, which is all the more significant in light of the measured energetics. Some of these interactions are strong and serve to reverse expected stability trends for this class of chiral complexes containing a tetradentate ligand. It seems clear that the species described lend themselves to be excellent models for weak, non-classical bonding studies for more complicated systems including various molecular recognition phenomena, enzyme-substrate interactions, metal binding sites involving tryptophan, conformation control in the tertiary structures of peptides, proteins and the like, and for the stacking of base pairs in DNA and its congeners. All of these examples [6] display combinations of such interactions and these are sometimes overlooked [36]. We suggest that, given the measured strengths of some of them in the present system, that they may play an even more significant role than has already been suggested, depending on the microscopic environment of individual cases [8,37].

5. Supplementary material

Full lists of NMR data for complexes **3**–**6** including ^{1}H NMR spectra, tabulated ^{1}H and ^{13}C NMR assignments, selected coupling constants and ROESY correlations are available from the author (PAW) on request. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-200270 (**4**), CCDC-200269 (**5**), and CCDC-200268 (**6**). These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

Reaction of a simple Schiff-base ligand bis(hydroxylbenzyl)diaminoxylene (H_2-*p*-xysal) with copper(II) perchlorate results in the formation of $Cu_2(p\text{-xysal})_2$ with a double-stranded helicate structure, constructed from two slightly different units of dinuclear Cu(II), in which all the copper(II) ions have distorted tetrahedral geometries. The two sublattices are interpenetrating where the helix axes are oriented as the monoclinic angle (116.6°). ESI-MS measurement indicates that the complex may partially dissociate in solution. The EPR spectrum in a frozen $CHCl_3$/MeOH solution shows that two different species are present. The spectrum has been satisfactory simulated with one mononuclear species and one dinuclear species. Cyclic voltammetry study shows a weakly reversible reduction wave of the Cu(II)/Cu(I) redox couple at $E_{1/2} = -0.915$ V. There are two successive oxidation waves at $E_{pa} = 0.94$ and 1.25 V. The latter one appears to be weakly reversible and it is assigned to the one electron oxidation of the phenolate group. The intra- and inter-molecular interactions are demonstrated to play important roles in the formation and the stabilization of the molecular architectures of the complex.

1. Introduction

It is well known that rationally designed complexes may give special functional properties, such as luminescence [1–3], redox activity [4] or magnetism [5–7]. Such materials can often be obtained by the self-assembly of well-defined architectures in a spontaneous or directed way. However, many factors may affect the self-assembly process, such as the nature of the coordination site, the structure of the bridging ligand, the geometric preferences of the metal ions and the weak intermolecular lattice interactions [7]. A considerable amount of molecular architectures have been assembled by means of metal–ligand interactions [8]. Among them, macrocyclic complexes formed by the self-assembly of transition metals with non-macrocyclic ligands give particular interesting physical properties and structural features [9].

Many systems formed by self-assembly processes have been reported to show interesting helical and non-helical structures by the complexation of designed ligands with metal ions [1,10]. The importance of the helicates is related to the development and the understanding of self-assembly processes in supramolecular chemistry [6,11].

In the present study, the synthesis, structural characterization and solution studies of a copper complex built from dinuclear units with a simple bis-bidentate Schiff-base ligand bis(2-hydroxybenzyl)-diaminoxylene (H_2-*p*-xysal) [12,13] are reported. The dinuclear coordination unit has a double-stranded helical structure,

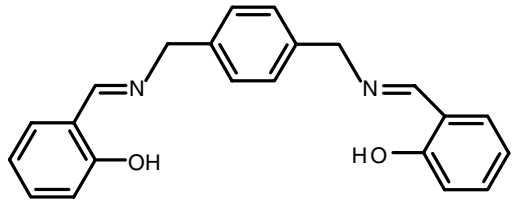

Fig. 1. The ligand bis(hydroxybenzyl)-diaminoxylene (H_2-*p*-xysal).

which is generated by coordination of two ligands twisted around two metal ions lying on the helical axis. The weak π–π and CH–π interactions between the aromatic rings of the ligands are suggested to stabilize the molecular structure and the complexation to the Cu(II) ions is the binding force which connects the two strands (see Fig. 1).

Usually Cu(II) complexes in four-coordination are found in (distorted) square-planar or tetragonal geometry. Tetrahedral geometry, on the other hand, is relatively seldom found in Cu(II) complexes, whereas it is very typical for Cu(I) complexes with four donor atoms. The present compound shows an interesting double-stranded helicate structure with a quite unusual, distorted tetrahedral coordination sphere of the copper ions. A strongly related X-ray structure has been reported recently where nitromethane molecules are present in the lattice [13]. In the present structure, no solvent molecules are included. Different methods such as ESI-MS, UV–Vis, EPR spectroscopy and cyclic voltammetry have been used to give detailed information of the solution chemistry of the complex.

2. Experimental

2.1. General remarks and physical measurements

All starting reagents and solvents were purchased from commercial sources and used as received. The ligand bis(2-hydroxybenzyl)-*p*-diaminoxylene (H_2-*p*-xylsalic) was prepared from salicylaldehyde and *p*-xylenediamine by reductive amination with $NaBH_4$ in dried methanol [12–14]. C, H, N analyses were performed on a Perkin–Elmer 2400 series II analyzer. Infrared spectra were recorded on a Perkin–Elmer Paragon 1000 spectrophotometer equipped with a Golden Gate ATR device, using the diffuse reflectance technique. X-band EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard. The ligand-field spectra of the solid compounds were recorded in the range of 200–2000 nm on a Perkin–Elmer Lambda 900. Electrospray ionization mass spectra (ESI-MS, positive ion) in MeOH/$CHCl_3$ solutions were recorded on a Thermo Finnigan AQA apparatus. UV–Vis–NIR spectrometer in the diffuse reflectance mode with MgO as a reference. The cyclic voltammetry measurements were performed with an Autolab PGstat10 potentiostat controlled by GPES4 software. A three-electrode system was used, consisting of a glassy carbon (GC) working electrode, a platinum (Pt) auxiliary electrode and a Ag/AgCl reference electrode. All potentials are given versus Ag/AgCl. The experiments were carried out in MeOH/$CHCl_3$ solutions at room temperature under argon. Magnetic susceptibility measurements (5–300 K) were carried out using a Quantum Design MPMS-5S SQUID magnetometer, in a 1 kG applied field. Data were corrected for the experimentally determined contribution of the sample holder. Corrections for the diamagnetic responses of the complex, as estimated from Pascal's constants, were applied [15].

2.2. Synthesis

A solution of copper(II) perchlorate (0.56 g, 1.5 mmol) in methanol (15 mL) was added to the ligand (0.52 g, 1.5 mmol) and NaOH (1.20 g, 3.0 mmol) in methanol (20 mL), and a brown precipitation was produced quickly. The solution was filtered and the precipitate was washed with methanol and diethylether. It was then purified on silica gel 60 with dried chloroform (300 mL) as eluent. A clear brown solution was obtained and slow evaporation in air at room temperature led to blue rectangular-shaped needle crystals after several days. Yields 34% (0.21 g). *Anal.* Calc. $C_{44}H_{36}Cu_2N_4O_4$ (811): C, 65.1; H, 4.5; N, 6.9. Found: C, 64.7; H, 4.7; N, 7.0%. IR (solid) $\nu = 1621$, 1597, 1442, 1400, 1343, 1323, 1149, 1126, 903, 760, 751, 731, 611 cm^{-1}. UV–Vis–NIR (solid): $\lambda = 373$, 474, 635 nm. EPR (solid, room temperature): $g_z = 2.07$, $g_{x,y} = 2.01$.

2.3. X-ray crystallography

A crystal was selected and mounted on a glass fibre, using the oil-drop method and data were collected on a Nonius KappaCCD diffractometer (graphite-monochromated Mo Kα radiation, $\omega - 2\theta$ scans) at 193 K. The intensity data were corrected for Lorentz and polarization effects, for absorption (ψ-scan absorption correction) and extinction. The structures were solved by direct methods. The programmes COLLECT [16], SHELXS-97 [17], SHELXL-97 [18] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. The weighted *R* factor, *wR*, and goodness of fit *S* are based on F^2, the conventional *R* factor is based on *F*, with *F* set to zero for negative F^2. All non-hydrogen atoms were refined anisotropically. The H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Crystallographic data are collected in Table 1. Residual electron density was between −0.53 and 0.69 e $Å^{-3}$. Molecular

3. Results and discussion

3.1. X-ray structure determination

It appears that the structure details of the title compound are quite similar to those in crystal structure previously reported for a nitromethane containing product [13]. Because a different crystalline composition has been obtained in the present study, we do report its molecular structure briefly and focus especially on solution chemistry studies. The dinuclear copper coordination entity of formula $[Cu_2(p\text{-xysal})_2]$ (where *p*-xysal is the dehydronated bis(2-hydroxybenzyl)-diaminoxylene) was obtained by reaction of one equivalent of H_2-*p*-xylsalic, two equivalents of NaOH and one equivalent of copper(II) perchlorate in methanol, followed by silica gel purification using chloroform as an eluent. Blue prismatic crystals suitable for single-crystal X-ray analysis were obtained after several days by slow evaporation of the solution under air. A molecular plot of two independent and slightly different units of the complex together with the used atom-labeling scheme is depicted in Fig. 2.

The unit cell of the title compound includes two independent crystallographic units, each of which consists of two symmetry-related (C_2-axis) copper(II) ions and two di-dehydronated ligands, shared by two metal centers. Each copper ion is coordinated by two oxygen donor atoms of dehydronated phenolate moieties and two imine nitrogen donor atoms, originating from two ligands. The crystal structure represents in fact a dinuclear double-stranded helicate with a C_2-axis passing through the helical axis. The tetradentate ligands adopt a bis-bidentate binding mode with two phenolate units separated by a xylene spacer. The wrapping of the strands results from a helical twist between the two coordinated bidentate binding units. Fig. 3 shows the turns of the helix of $[Cu_2(p\text{-xysal})_2]$. In the unit cell, equal amounts of right-handed and left-handed helices do occur. In Fig. 2, the helicate on the left appears to have an "arc" configuration and its assembly in Fig. 3 may be influenced by this [20]. There does appear to be an S shape aggregation pattern in Fig. 3(b), which is one of the possible aggregate patterns for an "arc" configuration.

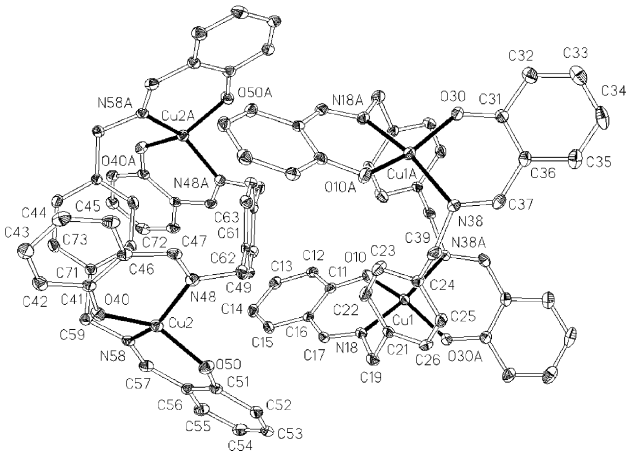

Fig. 2. Thermal ellipsoid plot (50% probability level) of two units of the dinuclear copper complex $[Cu_2(p\text{-xysal})_2]$ showing the crystallographic numbering scheme; hydrogen atom have been omitted for clarity.

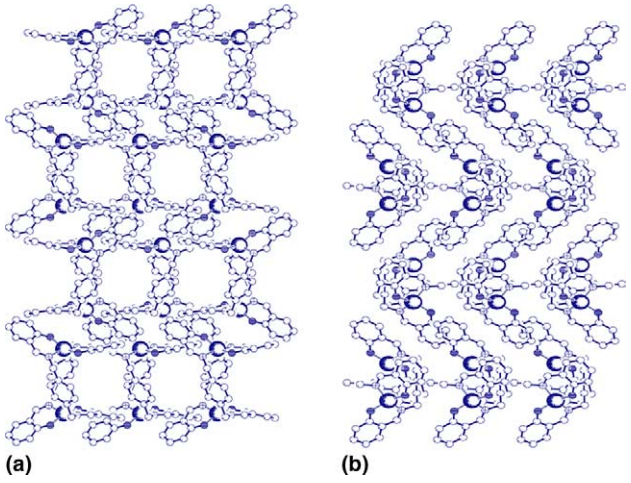

Fig. 3. Projection view along the a axis of the two independent units of the double-stranded helicates showing the turns of the helices. (a) crystal packing of the unit containing of Cu1 and Cu1a; (b) crystal packing of the other unit containing Cu2 and Cu2a.

In regard to the four-coordinated geometry of the copper ions, the discrimination between square-planar and tetrahedral geometries is partially parameterized by the angle θ, the dihedral angle between the two CuNO planes, which are 90° for a tetrahedral (D_{2d}) structure and 0° for a planar structure (D_{2h}). For the Cu1 ion, the dihedral angle between the planes O10–Cu1–N18 and O30a–Cu1–N38a is equal to 40.69(13)° [32.8(1)° for the complex in literature [13]]. For the Cu2 ions, the dihedral angle between the planes O40–Cu2–N48 and O50–Cu2–N58 is 44.52(14)° [35.9(1)° for the complex in literature [13]]. These values indicate that the coordination spheres around the copper ions can be best described as a heavily distorted tetrahedron with a CuN_2O_2 chromophore. It should be emphasized that such double-stranded helicate structures, based on four coordinated metal ions with a tetrahedral geometry, are often encountered for Cu(I) complexes [21]. However, most often the coordination geometry around the copper(II) ions in double-stranded helicates is based on a distorted octahedron [22].

The average Cu–N and Cu–O distances in the complex are 1.968(7) and 1.902(7) Å, respectively, for the Cu1 ion, and 1.960(8) and 1.904(2) Å for the Cu2 ion. The angles N/O–Cu–N/O are varying in the range of 90.65(10)°–158.52(12)°. The largest angular deviation from the regular tetrahedral geometry (109°) is 49.52° and 39.2° for the N18–Cu1–N38a (158.52°) and for N58–Cu2–N45 (148.20°). The crystal structure reveals a rather large intermetallic distance associated with the xylene spacer with 7.365 Å for the Cu1–Cu1a couple and 7.454 Å for the Cu2–Cu2a couple. Shorter intermolecular Cu–Cu contacts occur in the lattice (6.88 and 7.45 Å). Crystallographic information and selected bond lengths and angles are presented in Tables 1 and 2. (The crystal data that reported in [13] are included in Tables 1 and 2 to allow comparison).

The metal–ligand interactions lead to a ligand twisting. The flexibility of the ligand facilitated by the xylene spacer group is an important factor controlling the molecular architecture. It is worth noting that internal macrocyclic cavities are generated between the xylene groups and the coordinated phenolate units. For the cavity containing the Cu1 and Cu1a ions, the distance between ring centroids of the two benzene planes is 5.2523 Å. The dihedral angle between them is 67.63° [39.7(1)° for the complex in literature [13]]. For the cavity containing Cu2 and Cu2a, the dihedral angle between these two rings is 90°, which indicate that these two rings are strictly perpendicular to each other. These kinds of cavities may be of significance in host–guest chemistry [23].

It is interesting that the aromatic rings stack with adjacent ones from another ligand by inter-strand face to face interactions. The crystal packing of the complex is stabilized by the π–π interactions between the aromatic rings, with the shortest inter-planar ring–ring distances being 3.984 Å. These phenyl rings are stacked with each other with a dihedral angle of only 0.03°. The distances are larger than the standard distances for strong π–π stacking interactions between two aryl rings (3.35 Å for graphite [24,25]). In addition, the molecules pack together through a combination of π–π stacking and CH–π interactions [25,26]. It might be suggested that these interactions play important roles in the molecular assembly. Fig. 4 shows the crystal packing of the complex and the interactions between intermolecules. It can be seen that two independent units appear to be interpenetrating networks.

Table 2
Crystal data of $[Cu_2(p\text{-xysal})_2]$ and the crystalline complex containing nitromethane molecules [13]

3.2. UV–Vis and ESI-MS

The ligand-field spectrum of the complex in the solid state (diffuse reflectance) shows three absorption bands above 300 nm, centred at approximately 373 nm

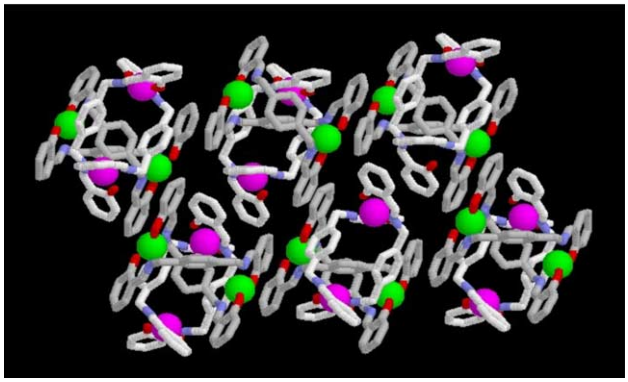

Fig. 4. Perspective view exhibiting the π–π stacking of the aromatic rings of the two units in the complex $[Cu_2(p\text{-xylsal})_2]$. Cu(II) ions are presented as large spheres.

(26.8×10^3 cm^{-1}), 474 nm (21.1×10^3 cm^{-1}) and 635 nm (15.7×10^3 cm^{-1}). The absorption at 474 nm is likely to be due to charge transfer from the nitrogen atoms to the copper ions [27]. The transition in the visible region of the electronic spectrum of this complex is a much less intense absorption at 635 nm, which is assigned to d–d transitions. The UV spectrum of the complex in a methanol:chloroform (3:7) solution shows absorptions at 271 nm ($\varepsilon = 1.6\times10^5$ M^{-1} cm^{-1}), 305 nm ($\varepsilon = 4.2\times10^4$ M^{-1} cm^{-1}), 373 nm ($\varepsilon = 5.8\times10^4$ M^{-1} cm^{-1}), and 438 nm ($\varepsilon = 680$ M^{-1} cm^{-1}) and 610 nm ($\varepsilon = 110$ M^{-1} cm^{-1}) as shoulder peaks. The difference with the solid-state spectra suggests a change in geometry upon dissolution. The intensity of the absorptions at 373 and 438 nm clearly precludes it originating from d–d transitions, hence this feature is assigned as being due to a phenolate oxygen to Cu^{II} charge-transfer (CT) transition [2,28].

The ESI-MS spectrum of the complex has been obtained in a methanol:chloroform (3:7) solution. The most intensive peak at m/z 345 corresponds to the free ligand. The peak at m/z 811.21 (relative abundance 17% to the peak at m/z 345.26) is the molecular ion peak of the targeted complex. The peak at m/z 406.12 is tentatively assigned to mononuclear species $[CuL]^+$ containing one copper ion and one ligand (the experimentally observed isotopic pattern is in a very good agreement with the theoretic result of isotope pattern calculation). However, the formation of $[Cu_2L_2]^{2+}$ can also not be excluded, since the resolution of the mass spectra is not good enough to discriminate between these two species with our experimental setup. Further studies are needed to give more detailed information. The solvent mixture of MeOH and $CHCl_3$ employed ensues from the poor solubility of the complex in pure methanol and the poor resolution of the EPR signal in pure chloroform.

3.3. EPR and magnetic susceptibility studies

The X-band EPR spectrum of the complex as a polycrystalline powder at room temperature exhibits one exchange-narrowed signal, probably caused by a dipolar interaction between the copper ions on a relatively close distance in the helical chains (Cu–Cu1a: 7.365 Å; Cu2–Cu2a: 7.45 Å; Cu1–Cu2: 8.972 Å; Cu1a–Cu2: 8.883 Å). Apparent g_z and $g_{x,y}$ values are 2.07 and 2.01, respectively. No hyperfine splitting is resolved, and no $\Delta M = \pm2$ signal, typical for dinuclear species, could be detected. The resolution does not improve upon cooling to 77 K.

The best resolved frozen-solution spectrum could be obtained in a mixture of $CHCl_3$:MeOH in 7:3 ratio (Fig. 5(b)). Now the presence of two different species in solution, as suggested by mass-spectroscopic measurements, can be clearly evidenced from the EPR spectrum. The spectrum can be best regarded as an overlap of a

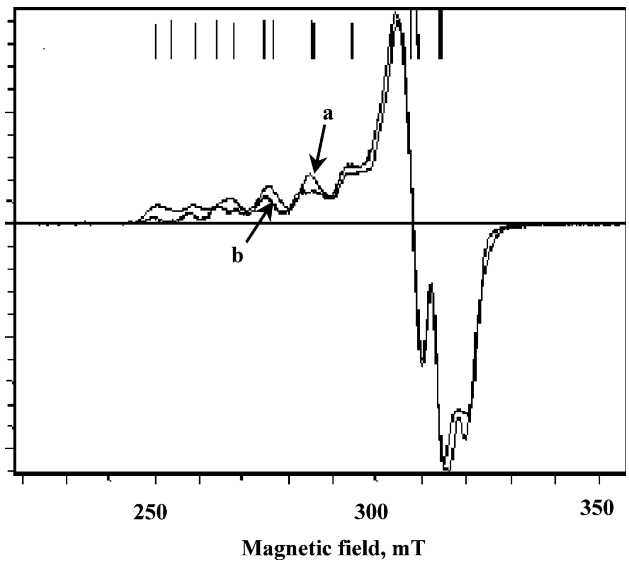

Fig. 5. X-band EPR spectrum of the complex $[Cu_2(p\text{-xysal})_2]$, recorded at 77 K in $CHCl_3$:MeOH (7:3) solution (a) and the simulated curve (b) see text for further details. Field on horizontal axis is in mT.

rhombic spectrum, derived from a mononuclear species, and a typical axial triplet spectrum ($\Delta M = \pm1$) of a dinuclear Cu(II) species. No half-field signal ($\Delta M = \pm2$), derived from a dinuclear species, could though be detected. In both cases, the ^{63,65}Cu hyperfine splitting in the g_z region is observed, although some lines are hidden due to the overlapping of two spectra with each other, or with those in the $g_{x,y}$ region. The spectrum could be satisfactory simulated [29] (Fig. 5(a)), considering two non-interacting species, one mononuclear and one dinuclear, in an approximate ratio of 1:1. The simulated parameters for the mononuclear species X are $g_x = 2.10$, $g_y = 2.11$, $g_z = 2.41$, $A_x = A_y = 0$, $A_z = 105$ Gauss). These parameters are typical for elongated rhombic octahedral CuO_6 chromophores [30] and are very close to the values observed for Cu(II) ions in a frozen methanol solution. Thus, these results suggest a partial dissociation of the complex in solution, leading to the formation of mononuclear Cu(II) species, and coordination of solvent (MeOH) molecules to the metal ions. The simulated parameters for the dinuclear species Y are $g_x \approx g_y \approx 2.07$, $g_z = 2.35$, $A_x = A_y = 0$, $A_z = 88$ Gauss, and the zero-field splitting parameter $D = 0.050$ cm^{-1}.

Magnetic susceptibility measurements have been performed on powdered crystals of the complex in the temperature range 5–300 K at 0.1 Tesla. Values for χ have been calculated for dinuclear species.

At 300 K, the χT for the complex is 0.80 cm^3 K mol^{-1}, which corresponds to an effective magnetic moment of 2.53 μB. This value is in a good agreement with the theoretically predicted one for two uncoupled Cu(II) ions ($S = 1$). This value remains almost constant upon cooling down to 5 K, as the compound exhibits a Curie–Weiss behavior over the whole temperature range. Thus,

no magnetic interaction is detected between two copper ions, which is not surprising because of the large distance between them, and thus the absence of possible exchange pathways and only dipolar exchange leading to exchange narrowing is observed. The Curie constant C is 0.42 cm^3 K mol^{-1}, resulting in a g value of 2.12. This value is fairly close to the one determined experimentally from the EPR measurements. The Curie–Weiss temperature θ is 0 K, as one would expect for such virtually uncoupled systems.

3.4. Cyclic voltammetry

The electrochemical behavior of the compound has been studied in a MeOH/$CHCl_3$ solution with tetrabutylammonium perchlorate as the supporting electrolyte in the potential range −2.0–1.8 V by cyclic voltammetry. While scanning towards the negative range of potentials, a weakly reversible reduction wave at $E_{1/2} = -0.915$ V ($\Delta E_p = 0.19$ V, $v = 0.1$ mV s^{-1}) was assigned to the Cu(II)/Cu(I) redox couple. In the anodic part of the CV curve, two successive oxidation waves at $E_{pa} = 0.94$ and 1.25 V are observed. The latter of these appears to be very weakly reversible ($\Delta E_p = 0.35$ mV, $v = 0.1$ mV s^{-1}), whereas the first one is fully irreversible. A very small reduction peak at $E_{pc} = 0.90$ V can be observed, which corresponds to $E_{pa} = 1.25$ V. These peaks are tentatively assigned to the one-electron oxidation of the phenolate group [31] (see Fig. 6).

It should be realized that coordination complexes of four-coordinated Cu(II) and Cu(I) with the same ligand, sharing the same distorted tetrahedral geometry, are rare. Due to the similar coordination spheres of Cu(I) and Cu(II) sites, the electron transfer rates between these two oxidation states are supposed to be very fast [32]. Taking into account that the two copper(II) ions in the complex have a distorted tetrahedral geometry, it is interesting to compare the redox potential of Cu(II)/Cu(I) complex couple in the complex with the values previously found in case of the Cu(I) and Cu(II) complexes sharing the same tetrahedral geometry. In the latter complexes the reduction of Cu(II) to Cu(I) oxidation state usually occurs at quite high potentials [33] (values as high as 0.92 V versus Ag/AgCl were found in some cases [34]), indicating a high stability of Cu(I) state. In our case, however, the reduction of Cu(II) to Cu(I) state takes place at much lower potential ($E_{pc} = -1.0$ V versus Ag/AgCl electrode), and is only weakly reversible. This behavior is not surprising, as the double positive charge of Cu(II) ion in the initial complex is compensated by two negatively charged ligands; thus, the reduction of Cu(II) to Cu(I) state is probably accompanied by the release of one of the two dehydronated ligands. Therefore an isolation of the respective Cu(I) complex, sharing the same coordination sphere and donor set, appears to be impossible.

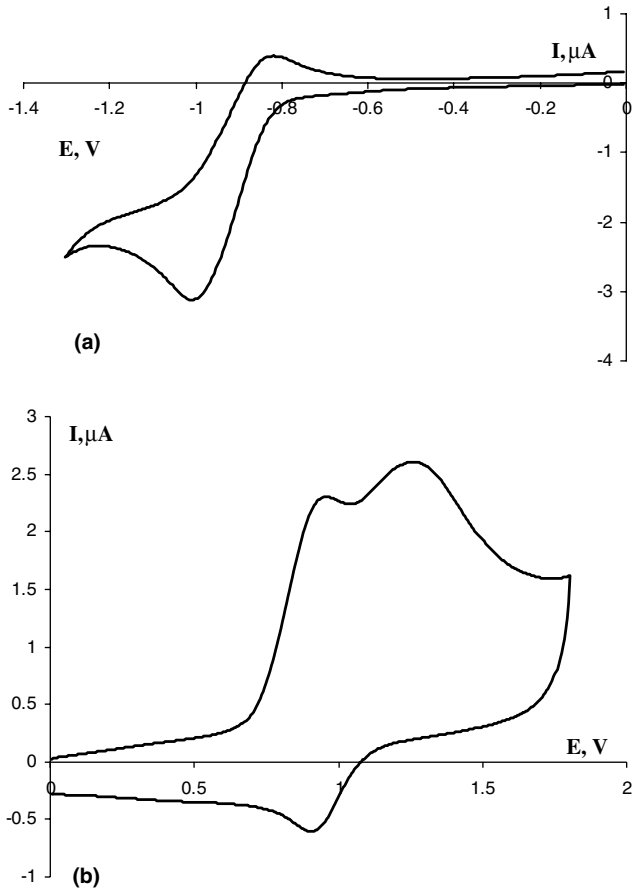

Fig. 6. Cyclic voltammograms for a solution of the complex in MeOH/$CHCl_3$ + 0.1 M TBAP, working electrode (WE): Pt (diameter 5 mm); (a) scans between −1.4 and 0 V; (b) scans between 2.0 and 0 V.

4. Conclusions

In conclusion, a dinuclear copper complex has been obtained in a tetradentate coordination mode with heavily distorted tetrahedral geometry around copper with the ligand ions. The ligands twist with each other in the molecule and allow formation of the double-stranded helical dinuclear complex by self-assembly. The cavities between the xylene spacers rings may be suitable for host–guest interactions as the nitromethane-containing copper complex found in [13]. The EPR spectrum of the frozen MeOH/$CHCl_3$ solution indicates there are two different species and the spectrum can be best simulated as one mononuclear and one dinuclear species in the solution. Cyclic voltammetry measurements indicate that the reduction of Cu(II)–Cu(I) occurs at $E_{1/2} = -0.915$ V with weakly reversible peaks. It is supposed that the intra- and inter-molecule interactions play important roles in the formation of the molecular architectures and the stabilization of the complex. Further studies by changing the bridging ligands to increase the π–π interactions are currently in progress and are likely to give better insights into the factors affecting the self-assembly process.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures have been deposited with the Cambridge Crystallographic Data Centre as publication no. CCDC-225176 for the title structure. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; [Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk, or www: http://www.ccdc.cam.ac.uk].

Abstract

The synthesis and spectroscopic characterization of new substituted porphyrinate complexes are reported. The investigated compounds are represented by the formula (Porph)M(Cl) where Porph are T*p*FPP, TPyP, β-Cl_4TPP, β-Cl_8TPP or β-Cl_4TPP, and M = In or Tl.

UV–Vis and NMR spectroscopies of the title complexes confirm the proposed molecular formula and are described extracting all plausible information. The study is completed by three X-ray structures of (β-Cl_4TPP)Tl(Cl), (β-Cl_4TPP)In(Cl) and (T*p*FTPP)Tl(Cl).

Compounds (β-Cl_4TPP)Tl(Cl) and (β-Cl_4TPP)In(Cl) are isostructural and they were treated in a similar way. The chloride substituents on the porphyrin core were found to be disordered in both compounds and they were refined anisotropically with occupation factors free to vary. The porphyrin core is saddle distorted while there is no twist distortion as judged by the large values of the dihedral angles formed between the phenyl rings and the $C_{20}N_4$ mean plane. In compound (T*p*FTPP)In(Cl), the dihedral angles between the pentafluorophenyl rings and $C_{20}N_4$ are very close to the ideal value of 90°.

Keywords: Metalloporphyrins; Indium; Thallium

1. Introduction

Porphyrin complexes of the main group III_B are ideal model compounds since they show considerable flexibility of the core geometries depending on the peripheral substitution and on axial ligation [1–9].

Meso-substitution as well as β-halogenation on the porphyrin core is expected to alter their spectroelectrochemical properties. Investigations have been carried out to probe the electronic structures of these systems by different approaches involving spectral and redox potential data as well as semi-empirical calculations. For β-halogenated porphyrins with more than four halogens, the electronic effects of the peripheral substituents causes a decrease of the basicity of the porphyrin ring, a red shift of the Soret band transition energy and a decrease in HOMO–LUMO energy gap [10–18].

Metal ions incorporated into perhalogenated complexes are mainly copper, zinc and nickel [10,12,14,16–18] as far as concerns the four coordinated ions, while iron complexes have also been reported due to the enhanced catalytic activity of these systems [11,18,19].

Recently the X-ray study of a lanthanide perhalogenated complex has been published [14]. It has been suggested that the metal ion and its environment influence the redox potential of these systems.

Based on a recently published procedure [14] we achieved the synthesis of halogenated In(III) and Tl(III) complexes. Their physicochemical features are compared with those of *meso*-substituted derivatives. Metallation with In or Tl offers a unique probe to study the influence of peripheral substituents and/or of the central metal on their physicochemical properties. A work correlating the ^{205}Tl NMR chemical shifts to the basicity of the ring, the axial ligation and the oxidation state has already been published by our group [20]. Monomeric thallium complexes provide ^{205}Tl signals from approximately 2850–2700 ppm following a decreasing order of basicity, while in the case of dimeric complexes (with a Rh:→Tl metal bond, typical +1 oxidation state of Tl) the signal is shifted more than 2000 ppm to the region of 180–200 ppm [21].

Finally, part of our research interest is the formation of single metal–metal bonded porphyrinic complexes. Monomeric metalloporphyrins of In or Tl are excellent precursors for the synthesis of new metal–metal bonded dimers. The nature of the monomeric complexes is expected to influence dramatically the properties of the formed dimers.

2. Experimental

2.1. Materials

All chemical were reagent grade and were used without further purification except as noted. Basic type I alumina was activated at 150 °C for at least 24 h.

2.2. Syntheses

The synthesis of free bases followed previously published procedures [14,22]. The preparation of thallium(III) complexes was based on Abraham's method [23]. The preparation of In complexes was based on the "acetate method" [24].

2.2.1. Syntheses of (Porph)Tl–Cl complexes

(T*p*FPP)TlCl (**1**): 0.1 mmol of (T*p*FPP)H_2 and 1 mmol of $Tl^{III}(CH_3COO)_3 \times 11/2H_2O$ were dissolved in 100 ml THF. The reaction mixture was refluxed for 24 h. After cooling, THF was removed and the solid residue was dissolved in CH_2Cl_2 and washed with a saturated aqueous solution of NaCl. Chromatographic separation of the crude product was performed on a SiO_2 column (4 cm × 3 cm). The metallated product was eluted with CH_2Cl_2/C_6H_{14} (4/6 v/v) as eluents (yield: 60%).

(TPyP)TlCl (**2**): The same reaction process as mentioned above was followed. The product was recovered after recrystallization from a mixture of CH_2Cl_2/C_6H_{14} (1/3 v/v), (yield: 94%).

(β-Cl_4TPP)TlCl (**3**): The reaction was performed as for compound **1**. A column of SiO_2 (4 cm × 3 cm) was used for the chromatographic separation. The desired product was eluted with CH_3OH/CH_2Cl_2 (50/50 v/v-20/80 v/v) as eluents, (yield: 65%).

(β-Br_4TPP)TlCl (**4**): The preparation of the crude product was the same as described above. The column separation was performed on SiO_2 (4 cm × 3 cm). The desired metalloporphyrin derivative was eluted with CH_2Cl_2, (yield: 67%).

(β-Cl_8TPP)TlCl (**5**): The reaction conditions mentioned before were also followed for the synthesis of the crude product **5**. The chromatographic separation was performed on SiO_2 column (6 cm × 4 cm). The product was eluted with toluene/hexane (8/2 v/v), (yield: 60%).

2.2.2. Syntheses of (Porph)In–Cl complexes

(T*p*FPP)InCl (**6**): 0.15 mmol of (T*p*FPP)H_2, 1.5 mmol of $InCl_3$ and 16 mmol of CH_3COONa were dissolved in 50 ml of glacial acetic acid. The reaction mixture was refluxed for 24 h. The solvent was removed under reduced pressure and the solid residue was dissolved in CH_2Cl_2. The solution was extracted from an aqueous solution of $NaHCO_3$ (5% w/v). The organic phase was washed two times with a saturated aqueous solution of NaCl and dried over $MgSO_4$. The solvent was removed and the solid residue was purified. A chromatographic separation was performed on SiO_2 (6 cm × 3 cm). With CH_2Cl_2/hexane (4/6 v/v) the free base was eluted. Increasing gradually the polarity of the solvents to CH_2Cl_2/hexane (8/2 v/v) the metalloporphyrin was eluted, (yield: 85%).

(TPyP)InCl (**7**): The previous synthetic route was also performed for compound **7**. Basic Al_2O_3 (5 cm × 3 cm) (Grade 1) was used in order to perform the chromatographic separation. With CH_2Cl_2/MeOH (200/5 v/v) the desired product was collected, (yield: 87%).

(β-Cl_4TPP)InCl (**8**): The preparation followed the previously described method for complex **6**. The chromatographic separation was performed on basic Al_2O_3 (5 cm × 3 cm) (Grade 1). The metalloporphyrin was eluted with a mixture of CH_2Cl_2/MeOH (7/3 v/v), (yield: 70%).

(β-Br_4TPP)InCl (**9**): The preparation was the same as described above. The crude product was chromatographed on SiO_2 (5 cm × 4 cm). The elution of the metallated porphyrin was achieved with toluene, (yield: 60%).

(β-Cl_8TPP)InCl (**10**): The reaction conditions were the same but with THF as reaction solvent due to low solubility of (β-Cl_8TPP)H_2 in the glacial acetic acid. The chromatographic separation was achieved on SiO_2 (6

cm × 4 cm) and the product was eluted with CH_2Cl_2, (yield: 70%).

3. Instrumentation and methods

^1H NMR and ^{13}C NMR spectra were recorded on a Bruker AMX-500 MHz NMR spectrometer using chloroform-D_3 as a solvent. Resonances in the ^1H NMR were referenced versus the residual proton signal of the solvent.

Absorption spectra were collected on a Perkin–Elmer Lamda 6 grating spectrophotometer.

Crystals suitable for X-ray diffraction were obtained by slow evaporation of a saturated toluene solution for compounds **3** and **8** and of a saturated solution of a mixture of 1:1 $CHCl_3$/toluene for compound **6**.

3.1. Data collection and X-ray crystal structure determination

A single crystal with approximate dimensions 0.20 × 0.20 × 0.50 mm for **3,** and 0.10 × 0.10 × 0.30 mm for **8** were mounted in air. Diffraction measurements for **3** and **8** were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the range $1° < 2\theta < 23°$. Intensity data were recorded using $\theta - 2\theta$ scans. Three standard reflections were monitored every 97 reflections over the course of data collection and showed less than 3% variation and no decay. Lorentz polarization and ψ-scan absorption corrections were applied using Crystal Logic software. The structures of **3** and **8** were solved by direct methods using SHELXS-86 [25] and refined by full-matrix least-squares techniques on F^2 with SHELXL-93 [26].

A single crystal of **6**, with approximate dimensions 0.20 × 0.40 × 0.60 mm, was mounted in air on a Siemens-Bruker P4 diffractometer equipped with a rotating anode generator, graphite-monochromated Cu Kα radiation being used for all operations. Cell dimensions were determined from the angular settings of 30 reflections with $32° < \theta < 55°$. Intensity data were recorded by ω–2θ scans and three standards monitored every 90 min revealed an overall 14% intensity decay, which was accounted for at data reduction time. A ψ-scan absorption correction was applied. Structure solution and refinement were performed with SHELX [25,26].

A summary of crystallographic data for **3**, **6** and **8** is given in Table 1.

Compounds **3** and **8** are isostructural and they were treated in a similar way. The chloride substituents on the porphyrin core were found disordered in both **3** and **8** and they were refined anisotropically with occupation factors free to vary. The chlorine substitution on the

pyrroles of the porphyrin skeleton is unsymmetrical in both **3** and **8**. The distribution of the chloride ions is unsymmetrical because there are two pyrrole rings, which are monosubstituted, one that is doubly substituted and one unsubstituted. In compound **3,** there is 64% probability of the presence of chlorine substituents in C_2, C_7, C_{12}, C_{13} and 36% probability of the presence of the substituents in the remaining C_β atoms of the porphyrin. The corresponding probabilities in compound **8** are 60% in C_2, C_7, C_{12}, C_{13} and 40% in the remaining C_β positions. In both **3** and **8**, all the non-hydrogen atoms were refined anisotropically, except those of the toluene solvent molecule, which were refined isotropically. The toluene molecule was found disordered over two orientations and was refined with occupation factors of a total sum of one. All H atoms were introduced at calculated positions as riding on bonded atoms; no H atoms for the toluene solvent molecule were included in the refinement.

In the model for the structure of **6** all the non-hydrogen atoms were refined anisotropically and the hydrogen atoms, both of the TPP ring and of the solvent molecules, were in calculated positions, riding. Presence of solvate molecules in the structure was modelled by two benzene molecules: one was distributed over two orientations whose complementary occupancy factors were refined and the other one, lying in proximity of an inversion centre, was assigned a fixed 0.50 occupancy factor value.

4. Results and discussion

4.1. NMR

The title complexes are fully characterized by ^{1}H NMR and ^{13}C NMR, while for the case of pentafluoroporphyrins ^{19}F NMR experiments were performed.

By the performance of ^{1}H NMR we observed the characteristic differentiation of *ortho*- and *ortho′*-protons. There is only one exception for the case of octahalogenated complexes (Table 2). In the case of Tl complexes a scalar coupling of pyrrolic protons with the Tl nucleus is observed, which is measured close to 75 Hz.

Taking advantage of the 100% natural abundance of spin 1/2 ^{19}F and its high gyromagnetic ratio, ^{19}F NMR experiments were performed. Five separate signals were observed (Table 3). The porphyrin ring current and the position of the fluorine atoms related to the porphyrin ring differentiate them. The furthest downfield signals, which appeared as two doublets, are attributed to *ortho*-F and to ortho′-F ($J = 23.5$ Hz). The fluorine atom at the *para* position appeared as a triplet. Metallation mainly effects the chemical shifts of *ortho*-F, *ortho′*-F and *meta*-F compared to the free base [27].

^{13}C- NMR signals spread in a 200 ppm region (Table 4). Assignment was based on heteronuclear experiments (HMQC, HMBC). We can distinguish two major groups for carbon frequencies. The aromatic carbons resonate between 130 and 170 ppm and the methinic carbons in the region of 90–120 ppm. The chemical data does not present any unexpected information in respect to other metalloporphyrinic derivatives. However the chemical shifts for C_{ph} are sensitive to the number of the halogen atoms: 140.18 ppm for (β-Cl_4TPP)TlCl to 144.2 ppm for (β-Cl_8TPP)TlCl.

C_β are the most sensitive carbon atoms to substitution. For tetrahalogenated complexes C_β provide two signals, one which is attributed to C_β-H and one to C_β-X (X = Cl, Br). In the case of (β-Cl_4TPP)TlCl, C_β–Cl resonate at 135.34 ppm. The signal at 133.72 ppm was assigned through heteronuclear experiments to C_β-H and for the tetrabrominated analogue at 134.2 ppm. In the case of octahalogenated complexes C_β–Cl is dishielded at 137.86 ppm for (β-Cl_8TPP)TlCl.

4.2. UV–visible spectroscopy

The position (β-pyrrole or *meso*) of the substitution is the factor which affects more or less in each case the spectrochemical properties of the macrocycle (Table 5).

λ_{max} (nm), $\log \varepsilon$ ($dm^{-1}\,mol^{-1}\,cm^{-1}$).

Theoretical as well as experimental work concerning the tetraphenyl porphyrin has demonstrated that the relative ordering of the a_{1u} and a_{2u} orbitals is particularly sensitive to *meso*-substitution [28]. The a_{1u} orbital localizes electron density predominantly on C_α whereas a_{2u} electron is concentrated on the *meso* position. So, an electron-withdrawing group such as a perfluorophenyl group at the *meso* position is expected to lower the energy of the a_{2u} orbital with respect to a_{1u} [15].

In the case of halogenated complexes semi-empirical AM1 and spectroscopic calculation revealed that both the electronic properties of the halogen and the distortion of the macrocycle results in a reduced HOMO–LUMO energy gap [10,12,14,18,29]. On the other hand theoretical calculations relative to the influence of metal–porphyrin interactions on the energy of the frontier orbital revealed that mainly the a_{2u} orbital sensed the metal perturbation which places considerable electron density on the pyrrole nitrogen, while a_{1u} has nodes through the nitrogen and cannot interact directly with the metal [28c,30].

The porphyrinic complexes **1**, **2**, **6** and **7** which are *meso* substituted possess spectral features of ''normal'' type porphyrins [31] (Table 5) with no significant shifts of λ_{max} relative to the corresponding tetraphenyl derivatives [2].

Metallation of tetrahalogenated porphyrin results in bathochromically shifted bands. The intensity of the α band increases relative to the tetraphenyl complexes of In and Tl. This observation is more pronounced in the case of octahalogenated complexes where the intensity ratio of the molar absorptivities (β/α) is reduced. To a first approximation the β/α value correlates with the stabilization of the central metal [32]. The porphyrin ring with a large β/α value stabilizes the central metal. This is in good agreement with the reduced electron density for the octahalogenated complexes.

The *Soret* band of the octa-halogenated complexes (**5**, **10**) is red shifted relative to the free base, in contrast to the four coordinated complexes which possess blue-shifted *Soret* bands. [10,16]. The difference in λ_{max} of the *Soret* band between octahalogenated complexes **5**, **10** and the *meso* substituted **1**, **2**, **6**, **7** reflect the reduced HOMO–LUMO energy gap expected in view of the ring distortion as well as to the inductive effect of the halogen atoms.

The differences observed concerning the λ_{max} of the *Soret* band for the two series of In and Tl complexes with the same porphyrinic ligand can be attributed to the different electronegativity values of the two metals. More electronegative metals lower the a_{2u} orbital [28c,30b]. In addition, the ionic radii of the two metals play an important role. The size of the ionic radius of Tl (1.05 Å) leads to an out of the Δ_{4N} plane displacement which is larger than that for the In complexes [33] and it is also observed in the present X-ray structures.

4.3. Description of the structures

The molecular structures of compounds **3**, **6** and **8** are shown as ORTEP plots in Figs. 1–3 respectively. Selected bond distances and angles are listed in Table 6, structural characteristics of the porphyrin core of all the three structures are given in Table 7. Compounds **3** and **8** are the corresponding thallium(III) and indium(III) complexes of tetrachloro-tetraphenylporphyrin and are isostructural, so they will be discussed together. In both compounds, the coordination geometry about the metal is square pyramidal with the four nitrogen atoms of the porphyrin defining the equatorial plane and the chloride ion occupying the apical position. The M–N bond distances range from 2.199(6) to 2.220(6) Å for **3** (average value 2.210 Å) and from 2.150(7) to 2.163(7) Å for **8**

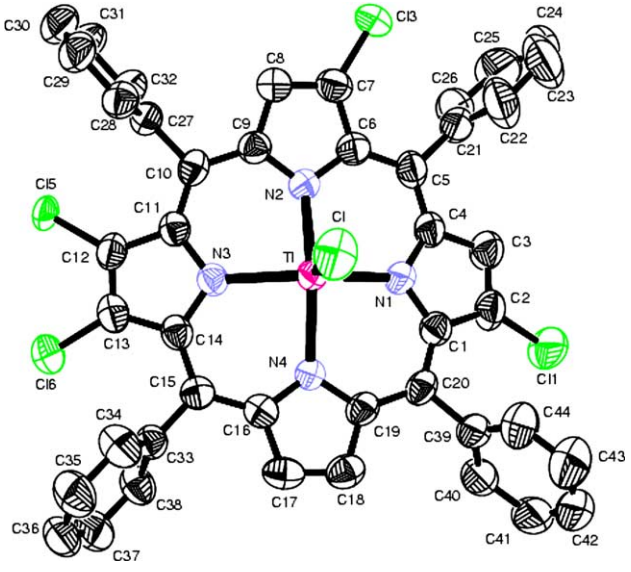

Fig. 1. ORTEP plot of (β-Cl_4TPP)TlCl (**3**).

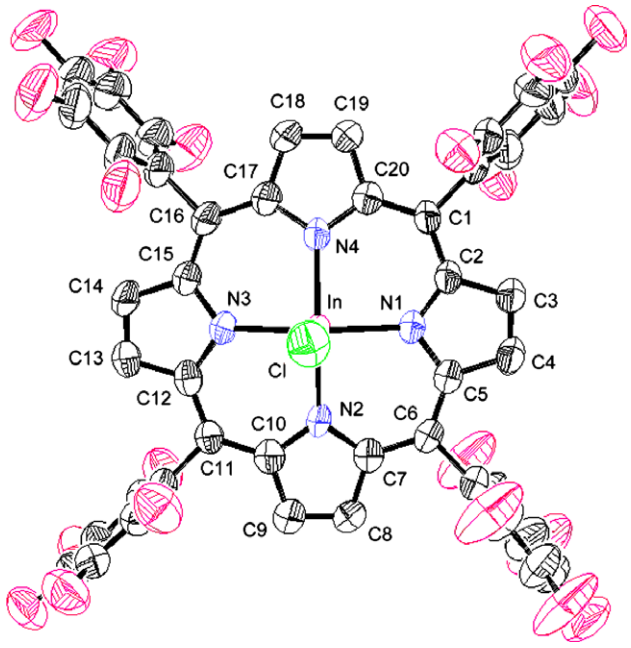

Fig. 2. ORTEP plot of (T*p*FPP)InCl (**6**).

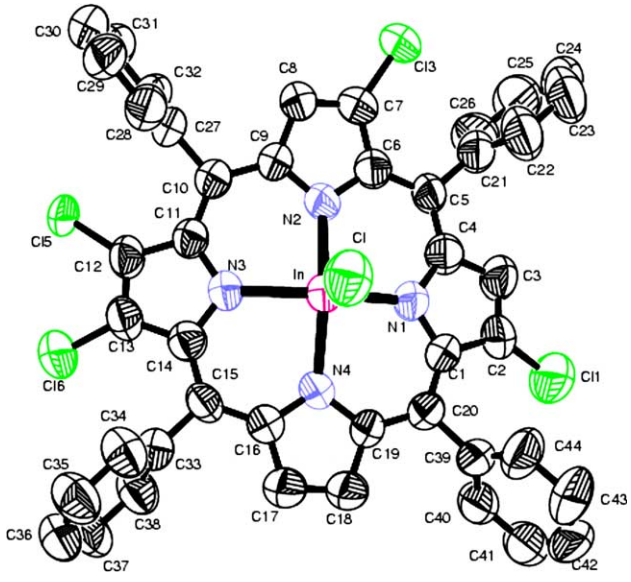

Fig. 3. ORTEP plots of (β-Cl_4TPP)InCl (**8**).

(average value 2.158 Å). The M–Cl bond lengths are 2.442(2) and 2.367(3) Å for **3** and **8** respectively. The metal ion lies 0.70 and 0.58 Å in **3** and **8** respectively, out of the equatorial plane of the square pyramid toward the axial chloride ligand. The presence of the metal ions along with the substitution on the C_β and C_m atoms of the porphyrin results in the distortion of the porphyrin core. The presence of the chlorine atoms on C_β carbon atoms of the porphyrin skeleton in both **3** and **8** results in the saddling distortion of the ligand, expressed by the mean absolute displacement of the C_β atoms from the $C_{20}N_4$ mean plane (0.39 Å for C_2, C_7, C_{12}, C_{13} in both **3** and **8**).

	10.85, 9.21	10.85, 8.43	3.33, 7.28
Phenyls	76.71, 72.74	76.66, 72.41	74.96, 89.58
	66.70, 65.10	67.55, 64.12	87.23, 73.55

Average absolute displacement of selected atoms of the porphyrin from the $C_{20}N_4$ mean plane.
[a] Average absolute value of C(2), C(7), C(12) and C(13) displacements.
[b] Average absolute value of C(3), C(8), C(13) and C(18) displacements.
[c] Average absolute value of C(4), C(9), C(14) and C(19) displacements.
[d] Average absolute value of Cl(1), Cl(3), Cl(5) and Cl(6) displacements.

The average absolute displacement of the corresponding chlorine atoms bonded to C_β atoms is 0.69 Å (for Cl_1, Cl_3, Cl_5, Cl_6 in both **3** and **8**). On the other hand, the average absolute displacement of the C_m atoms from the porphyrin core (0.081 and 0.094 Å in **3** and **8** respectively) along with the rather large values of the dihedral angles formed between the phenyl rings and the $C_{20}N_4$ mean plane (65.10°–76.71° and 64.12°–76.66° in **3** and **8** respectively) indicate that there is no twist distortion of the porphyrin skeleton. The pyrrole rings are planar within experimental error and they are tilted alternatively up and down with respect to the porphyrin core mean plane by 9.21°–12.69° in **3** and 8.43°–12.33° in **8**.

In compound **6**, the nitrogen atoms of the tetra(pentafluorophenyl)porphyrin define the equatorial plane of the square pyramidal geometry about the indium(III) ion while the apical position is occupied by the chloride ion. The metal ion lies 0.63 Å out of the equatorial plane towards the axial ligand. The In–N bond distances range from 2.135(5) to 2.161(5) Å (average value 2.148 Å), and the In–Cl bond length is 2.360(2) Å. The lack of substitution on the C_β atoms of the porphyrin skeleton is reflected in the small average absolute displacement of these atoms from the $C_{20}N_4$ mean plane (0.097 and 0.101 Å for C_3, C_8, C_{13}, C_{18} and C_4, C_9, C_{14}, C_{19} respectively) and the small dihedral angles formed between the pyrrole rings and the $C_{20}N_4$ mean plane (3.33°–7.28°). The average absolute displacement of the C_m atoms is also very small (0.061 Å for C_1, C_6, C_{11}, C_{16}) despite the pentafluoro-phenyl substituents. The absence of C_β-substituents in the porphyrin skeleton is also reflected in the large dihedral angles formed between the pentafluoro-phenyl rings and the $C_{20}N_4$ mean plane (73.55°–89.58°) due to the minimization of the steric effects. These values are very close to the ideal value of 90°, which is expected in the non-substituted porphyrins.

5. Concluding remarks

All these complexes could be used as precursors for the synthesis of new metal–metal bonded derivates with

Rh–In or Rh–Tl bonds in order to modify the properties of the metallic bond, stability and/or reactivity. The position of substitution (β or *meso*) and the number of halogen atoms (tetra- or octahalogenated complex) impose a pronounced effect on the spectroelectrochemical features of the dimers, which will be discussed in detail in a future article [34].

6. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Center, CCDC 221431-221333. Abstract

The crystal structure of a novel polymeric copper(II) complex with 2-thiopheneacetic acid is presented and the vibrational spectra are discussed. The copper(II) atoms and coordinating carboxylate oxygen atoms form the $[Cu_2O_8]$ dinuclear units typical for other carboxylates of this metal. The units are directly linked via two, relatively short Cu–O interactions and form polymeric chains along the b axis. A structural two- and threefold disorder has been found for the thiophene rings. The IR and Raman spectra of the title complex and free ligand are interpreted with help from literature data and deuteration effects. The absorption bands that are related to Cu–Cu core vibrations have been localized by a ^{63}Cu–^{65}Cu labelling technique.

1. Introduction

Several thiophene derivatives are known to show biological activities in point of pharmaceutical and clinical aspects. The major role of 2-thiophene carboxylates is connected with drug production. Some of these derivatives have been widely studied to focus on a family of semisynthetic cephalosporins (first-generation antibiotics), antiallergic, antimigraine and intestinal antibacterial agents as well as for influenza treatment [1]. From the clinical point of view, thiophene carboxylates have also been interesting for treatment of osteoporosis as the inhibitors of bone resorption in the tissue culture [2,3]. It has been found that the biological activities of the discussed compounds are considerably increased when they are bonded into metal complex molecules. For example, such effects have been observed for Co(II), Ni(II), Cu(II) and Zn(II) chelates with several ligands including 2-thiophenecarboxylic acid tested on some selected fungi [4]. The biological aspect concerns the wider research area of transition metal complexes with thiophene containing ligands. In recent years, the influence of Co(II), Ni(II) and Cu(II) complexes with 2-thiophenecarboxylic acid has received increasing attention as potential anticancer drugs [5]. Thus, the preparation of new naturally occurring metal complexes, which have promising biological activity, is an important aim of current chemical and medical investigations.

In the presented work, the structure of a new copper(II) complex with 2-thiopheneacetic acid is presented. This compound belongs to the large group of copper(II) carboxylates containing a very characteristic, dinuclear $[Cu_2O_8]$ unit, where each copper(II) atom is coordinated by four oxygen atoms from carboxylate groups acting in a *syn*, *syn* bridging mode Scheme 1. In most cases, the copper(II) apical position (along the Cu–Cu direction) is occupied by CH_3COOH [6] or by additional ligands, being frequently the solvent molecules of H_2O [7–11], methanol [6], DMF [6], dioxane [12,13] as well as by

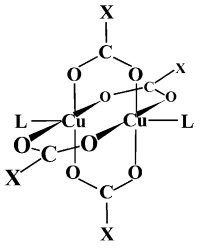

Scheme 1. The Cu(II)–Cu(II) core.

specially introduced substances e.g. pyridine [14–18], pyrazine [19], picoline [20–24], urea [16,25] and quinoline [26,27]. There are far fewer complexes where the copper atoms in the dinuclear unit are additionally coordinated by oxygen atoms of neighbouring $[Cu_2O_8]$ units, which results in a polymeric chain structure with Cu···O interactions. Such structures have been found so far for copper(II) complexes with propionic [28] and butanoic [29] acids. Here, we present another complex with a similar polymeric structure, together with its vibrational spectra, where the special metal isotope technique has been applied for detection of copper–oxygen vibrations.

2. Experimental

2.1. Preparation of the $[Cu_2(TAA)_4]_n$ complex

The ligand, 2-thiopheneacetic acid (HTAA), 98% was purchased from Sigma–Aldrich. The copper(II) chloride used was of analytical reagent grade.

The complex was prepared by neutralization of a 5 cm^3water solution containing 0.2 mmol of 2-thiopheneacetic acid with freshly precipitated $Cu(OH)_2$. The excess metal hydroxide was filtered off and the supernatant was left for crystallization at room temperature. After few days green crystals were collected, washed with water and dried in air. (Found: C, 41.44; H, 3.02; S, 18.47; $C_{12}H_{10}O_4S_2Cu$ Calc. C, 41.67; H, 2.91; S, 18.54%; melting point (m.p.) ca. 170 °C decomp.).

The complex analogues substituted with pure ^{63}Cu and ^{65}Cu isotopes were produced exactly as the compound with copper of natural abundance.

2.2. Spectral measurements

The IR spectra were collected on Perkin–Elmer FTIR 2000 and 1600 spectrometers with 0.5 and 2 cm^{-1} resolution for FIR and MIR regions, respectively. Samples were measured as Nujol mulls sandwiched between polyethylene plates and using the standard KBr pellet technique.

Raman spectra were measured on a T64000 Jobin-Yvon instrument equipped with Ar–Kr laser excitation and using the 514.5 nm line.

2.3. X-ray structure determination

For the X-ray structure determination, the data were collected on a KUMA KM4CCD diffractometer equipped with Mo Kα radiation ($\lambda = 0.71073$ Å). The structure was solved using the direct method option in

the SHELXS-97 program [30] and developed using least-squares refinement and Fourier difference synthesis in the SHELXL-97 program [31]. The thiophene rings in two crystallographically different ligand forms were disordered and modelled using two or three sets of positions. For this procedure the ring distances and angles were restrained to constant values and the occupancy of two or three alternate orientations were constrained to unity. The refined occupancy was 0.851(5) and 0.149(5) for one ligand form, and 0.486(17), 0.304(5) and 0.210(17) for the second form. The hydrogen atoms were placed in geometrically calculated positions. Crystallographic parameters and structural refinement are summarized in Table 1. Selected structural parameters and best planes were calculated using the PARST97 package [32]. Diagrams were generated using ORTEP3 for Windows [33].

3. Results and discussion

3.1. Description of the structure

The core of the title compound is a dinuclear unit composed of two copper atoms and four bidentate anions forming *syn*, *syn* bridges between the metals (Fig. 1). Following the inversion symmetry, the oxygen atoms of opposite carboxylate groups form a quasi-plane together with the Cu–Cu unit. Both planes intersect along the Cu–Cu line forming a dihedral angle equal to 89.7(1)°. The copper atoms are situated in a coordination center of approximately square pyramidal shape. The four oxygen atoms of acetate anions form a base equatorial plane, and the Cu atom is 0.1717(6) Å above this plane. The apical position is occupied by a carboxylate oxygen atom from a neighbouring $[Cu_2(COO)_4]$ unit. The basal Cu–O distances are different and vary between 1.929(3) and 2.006(3) Å (Table 2). The fifth Cu–O bond, being a link between two $[Cu_2(COO)_4]$ units, is much longer and equals 2.190(3) Å.

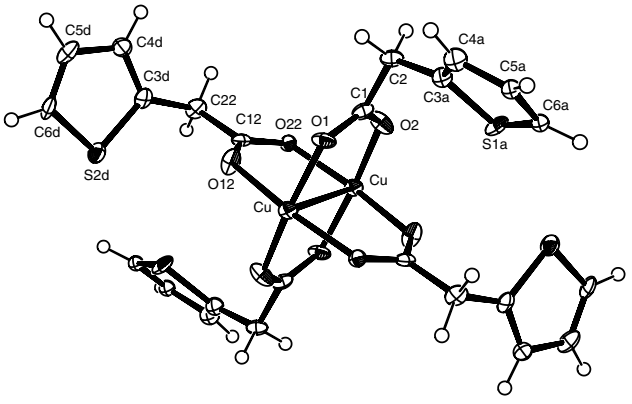

Fig. 1. View of the $[Cu_2(TAA)_4]$ unit with the atom labelling scheme and 50% probability thermal ellipsoids for non-hydrogen atoms. Atoms related by the inversion center are not labelled.

The Cu–Cu distance of 2.5867(15) Å is comparable to the respective values observed for other dinuclear copper acetates such as simple $[Cu(CH_3COO)_2(CH_3COO)]_2$ (2.581(1) Å [6]) or its analogs with water (2.6143(17) Å [7], 2.616(1) Å [8]), methanol (2.596(1) Å [6]), DMF (2.614(1) Å [6]), pyrazine (2.583(1) Å [19]) and α- or β-pyridine (2.645(3) Å [16], 2.641(1) Å [15] and 2.628(1) Å [16], 2.630(3) Å [14]) as side ligands attached along the Cu–Cu direction. Among many other dinuclear copper(II) carboxylates, similar Cu–Cu distances were found for formic (2.58(1) Å [12]), propionic (2.5634(4) Å [13], 2.578(4) Å [28] and 2.630(2) Å [18]), 2-phenylpropionic (2.589(1) Å [11]), butanoic (2.565 Å [29]), 2-thiophenecarboxylic (2.607(2) Å [9]) and 3- or 2-furancarboxylic (2.612(2) Å [9] and 2.638(1) Å [10]) acids. The symmetry of the $[Cu_2O_8]$ unit is C_i, but the distortion from the D_{4h} symmetry is rather small; the O–Cu–O angles deviate a maximum of 0.84° from a right angle, the Cu–O bond lengths differ less than 0.08 Å (~4%) and the dihedral O–Cu–Cu–O angles, measured for oxygen atoms belonging to the same carboxylate group, are a maximum of 0.3°.

As a consequence of the observed bond lengths within the Cu–O–C–O–Cu rings, the O–C–O angles are approximate 5° greater than the ideal value typical for sp^2 carbon atom hybridization. This atom is 0.038(4) Å displaced from the O1–Cu–Cu–O2 plane. The attached carbon atoms of the methylene groups are located approximately in the planes of the respective bridging rings. The C–CH_2–C angles attain values between 105(1)° and 120(3)°. These differences result from the existence of two geometrically different ligand forms and also from positional disorder of the thiophene rings. This disorder is different for two thiopheneacetic ligands as has been shown in Fig. 2, where the asymmetric unit is presented. In one case the thiophene rings are almost parallel but are rotated approximately along the C22–C3 direction forming an angle of 172(1)° between the ring best planes. In the second ligand, the disorder is more complicated. In addition to two orientations similar to those described above, a third quasi-parallel orientation has been found. The thiophene ring planes corresponding to the discussed three orientations form dihedral angles of 6(1)° (a and c indexed rings) and 173(1)° (a and b rings). Besides, the rings are shifted which causes the C1–C2–C3 angles to vary from 105.2° to 115.4°, whereas the C2–C3–S1 angles are between 119.8° and 123.3°. For the twofold disordered rings, similar angles are 113.8°, 120° and 114.6°, 121.2°, respectively. The rings are twisted with respect to the O–Cu–Cu–O planes, forming dihedral angles of approximately 80° and 62° for three- and twofold disordered

thiophene units. The different ring orientation is accompanied by changes in the C2–C3(a, b, c) or C22–C3(d, e) bond lengths. In the former case, the C2–C3 distances deviate up to 0.1 Å, whereas those of C22–C3 differ by 0.07 Å.

In the crystal structure, the dinuclear units are arranged in polymeric chains running parallel to the b axis. Within the chain, the units are linked by two apical Cu···O22 interactions of 2.190(3) Å to give a zigzag chain of copper atoms (Fig. 3). Copper and oxygen atoms engaged in the discussed link form a planar parallelogram with the Cu–O22···Cu angle equal to 99.83°. Similar chain structures have been found for anhydrous copper(II) propionate [28] and butyrate [29]. In these compounds, the Cu···O distances equal 2.28(1) and 2.245(no esd) Å, respectively. Thus, the complex presented here exhibits the shortest Cu···O link among those known so far. The polymeric chains are well separated, with the shortest contacts found between C5d^{i}–H5d^{i}, C6e^{i}–H6e^{i} (i: $1/2-x$, $1/2+y$, $1/2-z$) groups and O1 atoms. In these interactions the carbon–oxygen

distances are 3.214(10) and 3.126(46) Å, whereas the C-H-O angles equal about 130°.

3.2. Vibrational spectra

The IR and Raman spectra of the discussed complex and free ligand have been compared in Fig. 4. The most noticeable change in IR band positions is observed for two strong ligand absorptions at 1701 and 1242 cm^{-1}. Upon coordination these bands shift to 1596 and 1285 cm^{-1}, respectively, which suggests their origin is from coordinating carboxylate group vibrations. The 105 cm^{-1} downshift of the 1701 cm^{-1} band well corresponds to the lowering of the C=O bond order caused by copper(II) coordination. Such a change is confirmed by X-ray data of the complex where all carbon–oxygen bond lengths are almost the same, within the range of 1.25 and 1.28 Å (Table 2). These distances are about 0.05 Å longer than those which are typical for the carboxylic C=O group [34]. A similar, but opposite difference is obtained when C–O bond lengths measured here are compared with those of the carboxylic C–OH group [34]. The last effect demonstrates the strengthening of the C–OH bond upon coordination and well corresponds to the positive shift of the 1242 cm^{-1} band assigned to the stretching ν(C–OH) vibration. The two recently discussed bands are frequently accompanied by another, less characteristic, absorption ranging between 1400 and 1450 cm^{-1} [35] for which the contribution of the δ(OH) mode is postulated [36]. Since this region is also occupied by thiophene ring vibration (observed for pure thiophene at 1409 cm^{-1} [36]) and $\delta(CH_2)$ mode, the coupling with the δ(OH) vibration has been utilized in the experimental detection of the third ν(COO) band. On O-deuteration of the HTAA ligand, monitored that in the discussed region, only the band at 1422 cm^{-1} is markedly shifted (to 1387 cm^{-1}) upon deuteration. Thus, this ligand absorption and corresponding 1415 cm^{-1} band in the spectrum of the complex would be the best candidates for the recently discussed transition. However, the 7 cm^{-1} difference between these band positions suggests that the contribution of the C–O vibrations is rather low in this transition where probably the modes of neighbour C–C and CH_2 groups contribute significantly. The H–D substitution also pointed the 1335 and 1293 cm^{-1} bands (not included in Table 3) as predominantly due to δ(OH) vibration. The δ(OH) counterpart has appeared as new band at 1057 cm^{-1}, which gives the H/D frequency ratio equal to 1.26 and 1.22.

As results from the location of the thiophene rings, the vibrations of these units should be much less affected by metal coordination. The comparison of the ligand and complex IR spectra shows several bands at similar positions easily comparable with normal vibrations observed for pure thiophene [37]. For nine vibrations of thiophene skeleton (listed in Table 3 as 2, 5, 11, 14, 15, 16, 21, 22 and 23) the respective wavenumbers observed for thiophene, HTAA and the complex differ by no more than 35 cm^{-1}. In the complex spectrum some

vibrations split into two or more bands (numbered in Table 3 as 8, 10, 14, 15, 17, 19 and 20). This effect is probably due to the presence of two independent ligand forms in the asymmetric unit and their structural two- or threefold disorder. Since the thiophene ring skeletons are very similar, the observed splitting may be related to bending vibrations of the CH groups or C1–C2–C3–C4 subunits, whose geometry is affected by skeletal disorder, and their vibrations may contribute in these transitions. The remaining thiophene modes are mainly due to displacements of hydrogen atoms and they preserve their positions after complexation with an accuracy similar to that of the skeletal vibrations. The stretching ν(C–H) vibrations of the thiophene units are observed in the $[Cu_2(TAA)_4]_n$ IR spectrum as broad absorptions with four distinct maxima at 3106, 3095, 3084 and 3072 cm^{-1}. Three of these maxima at 3106, 3095 and 3072 cm^{-1} well correspond to those observed for the HTAA ligand (3103, 3082 and 3070 cm^{-1}) and thiophene (3126, 3098 and 3086 cm^{-1}) [37]. The additional 3095 cm^{-1} band in the complex spectrum is probably related to an overtone or combination transition. In the Raman

spectrum of the complex, the above transitions are disturbed by luminescence, but are better seen in the corresponding spectrum of the HTAA ligand together with $\nu(CH_2)$ vibrations at 2962 and 2909 cm^{-1}. In the region below 2500 cm^{-1} this spectrum is strongly obscured by luminescence, and only the most intense transitions could be located there. These transitions mainly result from thiophene ring vibrations and appear at very similar wavenumbers as in the IR spectrum.

The most interesting transitions observed in the far-IR region are generated by stretching vibrations of copper–oxygen bonds. For copper(II) carboxylates of the structure with dimeric D_{4h} $[Cu_2O_8]$ units, two (Cu–O) ($A_{2u} + E_u$) vibrations are expected to be IR active. In the literature, those transitions were detected in the region between 300 and 400 cm^{-1} [38]. In the comparable area (420–260 cm^{-1}), the spectrum of the complex investigated here shows five mostly medium intensity bands (415, 385, 300, 285, 275 cm^{-1}) being candidates for the discussed vibrations. In the same range, the ligand shows three bands at 402, 306 and 275 cm^{-1}, which to some extent may be preserved in the spectrum of the complex. In order to distinguish the bands, which are related to the vibrations of the copper coordination sphere, the ^{63}Cu–^{65}Cu labelling technique was applied. This experiment demonstrated that bands at 415 and 385 cm^{-1} are the most sensitive (2.0 and 1.0 cm^{-1}, respectively) for isotope substitution and can be attributed to ν(Cu–O) modes, corresponding to the D_{4h} symmetry discussed before. However, as has been formerly concluded, the $[Cu_2O_8]$ unit shows small distortion from D_{4h} symmetry (the real symmetry is C_i) and more ν(Cu–O) vibrations can be IR active. Some of these modes contribute, together with bending ones, in seven other bands showing the isotope effects. As results from the X-ray data, each copper atom of the $[Cu_2O_8]$ unit forms an additional bond with one of the oxygen atoms of neighbouring unit. This bond is approximately 0.26 Å longer than those of the $[Cu_2O_8]$ unit and the energy of the corresponding vibration should be lower than in the recently presented ν(Cu–O) modes. The metal isotope substitution monitored for this vibration, the 149 cm^{-1} band, exhibited a 2.0 cm^{-1} shift.

In the discussed complex, the inversion center is located between the copper atoms, which causes in some symmetric vibrations the metal may be displaced and isotope effects can appear in the Raman spectrum. Such effects were generally not observed in the Raman scattering, except for a small shift of the 193 cm^{-1} band, but this does not exclude the contribution of copper–oxygen vibrations in particular Raman bands. Such assignment has been proposed in Table 3 for Raman bands not corresponding to 306 and 275 cm^{-1} ligand transitions. The intense band at 214 cm^{-1} could be compared with the IR, metal sensitive band at 222 cm^{-1}, but that band and those below 200 cm^{-1} may also result from lattice vibrations usually scattering strongly for molecular crystals.

4. Supplementary data

Crystallographic data for the structural analysis of the $[Cu_2(TAA)_4]_n$ complex have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 229653. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033); e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk.

Complexation of uranium(VI) with glycerol 1-phosphate

Astrid Koban *, Gert Bernhard

Institute of Radiochemistry, Forschungszentrum Rossendorf e.V., P.O. Box 510119, D-01314 Dresden, Germany

Received 16 December 2003; accepted 13 April 2004
Available online 1 June 2004

Abstract

The complex formation of uranium(VI) with glycerol 1-phosphate was determined by potentiometric titration, and TRLFS spectroscopy. Two complexes with a metal-to-ligand stoichiometry of 1:1 and 1:2 were found by potentiometry in the pH range 3–8, and the stability constants were calculated for $I = 0.1$ M ($NaClO_4$) and $T = 25$ °C to be $\log \beta_{11} = 6.23 \pm 0.09$ for $UO_2(C_3H_7O_3PO_3)$ and $\log \beta_{12} = 10.22 \pm 0.13$ for $UO_2(C_3H_7O_3PO_3)_2^{2-}$.

The TRLFS spectra at pH = 4 show an increase of the fluorescence intensity, connected with a red shift of the emission spectra. But contrary to the potentiometric measurements only the 1:1 complex $UO_2(C_3H_7O_3PO_3)$ could be detected under the specific experimental conditions. The main fluorescence emission bands and the lifetime of this complex were determined. The complex stability constant at $I = 0.1$ M ($NaClO_4$) and $T = 25$ °C was calculated to be $\log \beta_{11} = 6.15 \pm 0.05$.

Keywords: Uranium; Glycerol phosphate; Complex formation; Potentiometric titration; TRLFS

1. Introduction

Interactions of metal ions with phosphate esters play an important role in many biological processes. Glycerol 1-phosphate is widely distributed in biological systems, as constituent of phospholipids or as intermediate of metabolism or other biochemical processes like the biosynthesis of lecithin's [1]. Because of its simple and clear structure glycerol 1-phosphate can serve as model for the interaction of cations with more complex biological systems, such as phospholipids.

The understanding of the interaction of radioactive metals with biological systems on the molecular level is of great importance in view of the distribution of radioactive elements via the food chain from sources like nuclear waste disposal. There are very few data about the interactions of uranyl(VI) with bioligands in the literature. Only a couple of studies concerning the complex behavior with some amino acids [2] and nucleosides [3] are to be find. Several investigations of bio-systems like microorganisms and plants with various analytical and spectroscopic methods show that the phosphate group seems to be quite effective for uranium binding [4–7]. The complex behavior of uranium with inorganic phosphates and some organic phosphate esters was examined by different methods and some complex stability constants and spectroscopic data are well known [8–11]. However, except for the complexation of uranyl(VI) with various sugar phosphates [12,13], no investigations of the complex behavior of uranium with biorelevant organic phosphate esters have been published up to now. Therefore, we present the results of uranyl(VI) complexation with glycerol 1-phosphate ($C_3H_7O_3PO_3^{2-}$), studied by potentiometric titration, and time-resolved laser-induced fluorescence spectroscopy (TRLFS). The spectroscopic characterization of the system is the major task of our studies to get useful data sets for comparison with biological systems to understand the binding behavior of actinides in natural systems. Beside this equilibrium constants were determined to enlarge the basis for modeling the transport and binding mechanisms of actinides in bio-systems.

2. Experimental

2.1. Solutions and reagents

Glycerol 1-phosphate disodium salt hexahydrate was purchased from Fluka (analytical grade), the ligand stock solutions were prepared freshly for each experiment. The stock solutions of UO_2^{2+} were made from $UO_2(NO_3)_2 \cdot 6H_2O$ (Merck, p.A.). The ionic strength was kept constant by adding a $NaClO_4$ stock solution ($NaClO_4 \cdot H_2O$, Merck, p.A.). All stock solutions were prepared with deionized water. Necessary pH adjustments were made with $HClO_4$ or NaOH.

2.2. Potentiometric titration

The potentiometric titration experiments were carried out at a starting volume of 50 ml with two different uranyl concentrations (1×10^{-4} and 5×10^{-4} M) and glycerol 1-phosphate concentrations (5×10^{-4} M and 10^{-3} M) each. The corresponding glycerol 1-phosphoric acid was performed in situ by adding appropriate equimolar ratios of $HClO_4$ to the starting solution. The ionic strength was kept constant at 0.1 M ($NaClO_4$). All solutions were prepared with carbonate free deionized water under nitrogen atmosphere in a glove box. The samples were titrated in a thermostatic vessel at 25.0 ± 0.1 °C under nitrogen atmosphere in a pH range from 3 to 8 with 0.01 M NaOH (carbonate free, Merck, Titrisol) by an automatic titrator (GP Titrino 736, Metrohm, Germany) and monitored by the accompanying software (TiNet 2.2). The pH values were measured with a Schott BlueLine 11 pH combination electrode with a platinum diaphragm, the electrode was calibrated for each experimental run with NBS buffers at pH 4.01 and 6.87 (Schott). A detailed description of the titration procedure is given in [12].

Five measurements for determination of the dissociation constants of the ligand and 12 measurements for determination of the complex stability constants were accomplished. The measured titration data were analyzed with the Hyperquad least squares program, version 2.1 [14].

2.3. TRLFS measurements

The TRLFS measurements were performed at a total uranyl concentration of 10^{-5} M as a function of the ligand concentration at $pH = 4.00 \pm 0.05$. The spectra were recorded at 25 ± 2 °C using a pulsed Nd:YAG laser system (Spectron Laser Systems, SLM 400, Rugby, UK). The excitation wavelength of the uranyl fluorescence was 266 nm with a pulse energy of 0.2–0.5 mJ. The TRLFS spectra were measured from 450 to 600 nm, averaging six spectra with 100 laser pulses each and a gate time of 1 μs. The time-resolved fluorescence emission was detected using a 270 mm spectrometer (Spex 270M, Jobin–Yvon) in combination with a ICCD camera (Spectrum One, Jobin–Yvon). All functions of the laser spectrometer are computer controlled, the control software was provided from Jobin–Yvon. A detailed description of the TRLFS system is given in [15].

3. Results and discussion

3.1. Potentiometric titration

For studying the complexation behavior of glycerol 1-phosphate with uranyl(VI), it is necessary to know the acid dissociation constants of the ligand. Some data are available in the literature [10,16–21], but they differ both in values and experimental conditions. However, due to the self consistency, we determined our own pK_a values (see Table 1). Our measured value of $pK_{a1} = 2.26 \pm 0.14$ is very closed to those of André et al. [18] ($pK_{a1} = 2.28$). Other values (i.e., $pK_{a1} = 1.30$ [21]) and some values of pK_{a2} (i.e., 6.07 [16], 6.11 [17], 6.22 [18], 6.66 [20]) are more or less far away from our results ($pK_{a2} = 6.57 \pm 0.03$), but this is probably due to different definition of the constant and different experimental conditions and measuring methods.

The complexation of uranium(VI) with glycerol 1-phosphate was studied in the pH range from 3 to 8 for the general complex equilibrium

$$xUO_2^{2+} + yC_3H_7O_3PO_3^{2-} + zH^+ \rightleftharpoons (UO_2)_x(C_3H_7O_3PO_3)_yH_z^{(2x-2y+z)+} \quad (1)$$

The highest pH value we could study was limited by hydrolysis of uranium(VI); the higher the uranium concentration the lower the useable pH value. The titration measurements with the highest uranium and ligand concentration (5×10^{-4} M U(VI), 1×10^{-3} M glycerol 1-phosphate) could only be analyzed up to $pH = 4.75$.

Table 1
Summarized formation constants of the uranyl(VI) glycerol 1-phosphate system at $T = 25$ °C, $I = 0.1$ M ($NaClO_4$); $\beta_{xyz} = [(UO_2)_x(C_3H_7O_3PO_3)_yH_z]/[UO_2]^x[C_3H_7O_3PO_3]^y[H]^z$

Species	xyz	$\log \beta_{xyz}$[a]	Method
$C_3H_7O_3PO_3H^-$	011	6.57 ± 0.03[b]	Potentiometry
$C_3H_7O_3PO_3H_2$	012	8.83 ± 0.17[c]	
$UO_2(C_3H_7O_3PO_3)$	110	6.23 ± 0.09	Potentiometry
		6.15 ± 0.05	TRLFS
$UO_2(C_3H_7O_3PO_3)_2^{2-}$	120	10.22 ± 0.13	Potentiometry

[a] Errors are equal to 2σ.
[b] $\log \beta_{11} = pK_{a2}$.
[c] $\log \beta_{12} = pK_{a1} + pK_{a2}$.

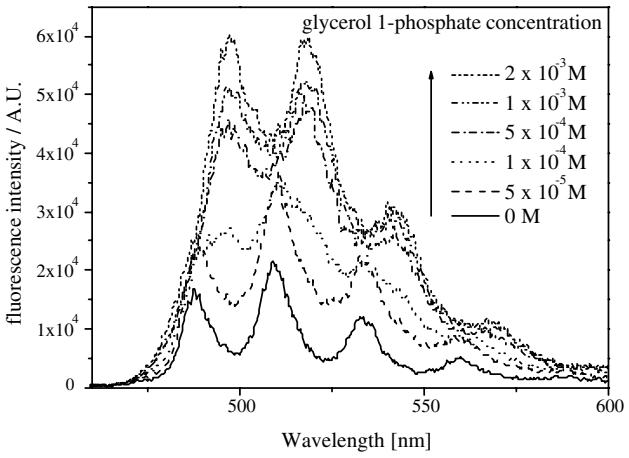

Fig. 1. TRLFS spectra of uranium(VI) (10^{-5} M) as a function of the glycerol 1-phosphate concentration at pH = 4.

Because all potentiometric titration experiments were carried out under CO_2 free and carbonate free conditions (cf. Section 2.2), the formation of uranyl carbonate complexes can be excluded. The appropriate uranyl hydroxides [10,11] were accounted for in all the refinements.

Two complexes with a metal-to-ligand ratio (M:L) of 1:1 and 1:2 could be observed. The equilibrium constants were determined to be $\log\beta_{11} = 6.23 \pm 0.09$ for $UO_2(C_3H_7O_3PO_3)$ and $\log\beta_{12} = 10.22 \pm 0.13$ for $UO_2(C_3H_7O_3PO_3)_2^{2-}$ (see Table 1). Besides at almost all titration curves any other complexes with a 1:3 or 2:3 stoichiometry or protonated species could be fitted to improve the fit parameter. Thus still more species seems to exist in this system. Further investigations are necessary to validate this presumption.

3.2. TRLFS measurements

Fig. 1 shows the fluorescence spectra of uranium(VI) as a function of the concentration of glycerol 1-phosphate at pH = 4. With increasing ligand concentration we notice a strong increase in fluorescence intensity, connected with a red shift of about 9 nm compared to the uranyl ion.

The TRLFS spectra show tri-exponential decays indicating a mixture of three species. The lifetimes are (averaged about all measurements) 155 ± 30, 800 ± 160 ns, and 7 ± 3 μs. The lifetime of 7 μs with a very low but constant intensity can be assigned to uranyl hydroxide, which is always present in small amounts under such experimental conditions. The intensity of the second lifetime (800 ± 160 ns) decreases with increasing ligand concentration, whereas the intensity of the shortest lifetime (155 ± 30 ns) increases. A lifetime of 800 ± 160 ns seems to be quite short for UO_2^{2+}(aq), but test solutions of UO_2^{2+}(aq) at pH = 4 and 1 under same conditions showed lifetimes of 761 ± 46 ns (pH = 4) and 784 ± 31 ns (pH = 1), respectively. Therefore we assign the lifetime of 800 ± 160 ns to the free uranyl ion and the lifetime of 155 ± 30 ns to the uranyl(VI) glycerol 1-phosphate complex.

To estimate the stoichiometry of this complex the series of measurements was investigated according to the complex formation reaction

$$UO_2^{2+} + nC_3H_7O_3PO_3H_2 \rightleftharpoons UO_2(C_3H_7O_3PO_3)_n^{(2-2n)+} + 2nH^+ + \log\beta_{1n}^* \quad (2)$$

A slope analysis for reaction (2) was made using the mass action law in its transformed linear form (Eq. (3))

$$\log\frac{[\text{complex}]}{[UO_2^{2+}]_{\text{free}}} = n\log[\text{ligand}]_{\text{free}} + \log\beta_{1n}^* + 2n\text{pH}. \quad (3)$$

The concentrations of the free uranyl ion were determined on the basis of the measured absorption spectra using conventional peak deconvolution. These data were used to calculate the corresponding concentrations of the complex and the non complexed ligand. This well established method for analyzing fluorescence spectra [22] is described detailed in [12]. The slope of 1.24 ± 0.04 indicates a predominant formation of the 1:1 complex $UO_2(C_3H_7O_3PO_3)$. Taking into account the dissociation of glycerol 1-phosphoric acid, the complexation reaction can be written as follows:

Table 2
Fluorescence emission bands of some uranyl compounds and uranium complexes in biosystems

	Fluorescence emission bands (nm)						References
U(VI) model compounds							
UO_2^{2+} (aq)	471.3	488.9	510.5	533.9	559.4	585.5	[15]

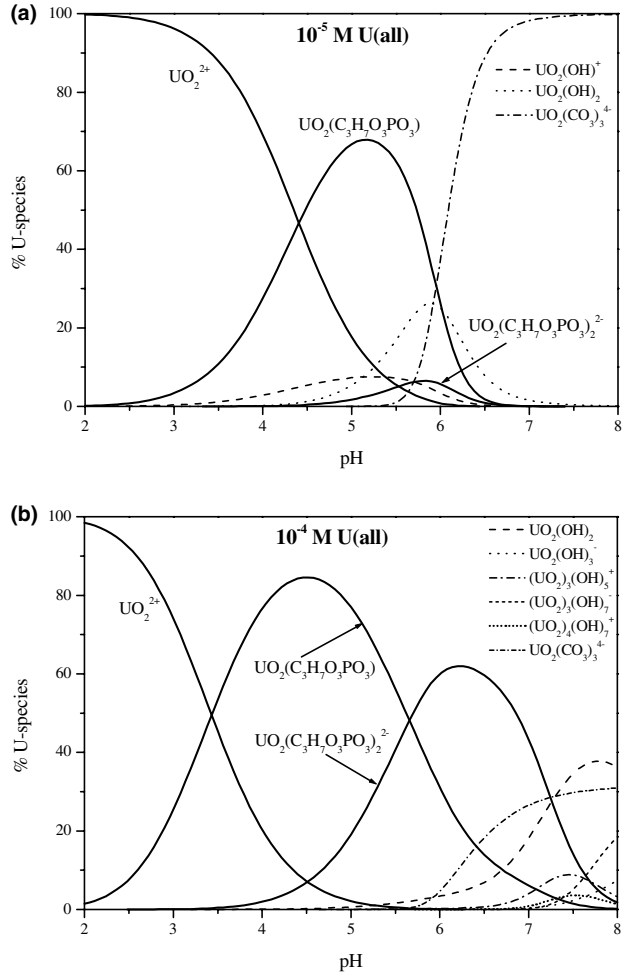

Fig. 2. Speciation of uranium(VI) in aqueous solution in dependence of the uranium and glycerol 1-phosphate concentration (10^{-4} M carbonate each): (a) 10^{-5} M U(VI), 10^{-4} M glycerol 1-phosphate; (b) 10^{-4} M U(VI), 10^{-3} M glycerol 1-phosphate. Only species $\geqslant 1\%$ were included.

$$UO_2^{2+} + C_3H_7O_3PO_3^{2-} \rightleftharpoons UO_2(C_3H_7O_3PO_3) + \log\beta_{11} \quad (4)$$

with consideration of the pH and pK_a values (from potentiometric titration, see Table 1) the complex stability constant of $UO_2(C_3H_7O_3PO_3)$ results to be $\log\beta_{11} = 6.15 \pm 0.05$.

The spectra of the uranyl glycerol 1-phosphate complex can be isolated from the composite spectra using conventional peak deconvolution. The peak maxima of the complexed uranyl species are located at 497, 518, 543, 569, and 599 nm (see Table 2). It was not possible to detect any other uranyl glycerol 1-phosphate species. Under that for TRLFS measurements optimal experimental conditions (low uranium(VI) concentrations at about 10^{-5} M and pH values up to 4), where the uranyl hydroxide species do not disturb the measurements, other complexes do not form or only in so small ratios, that they cannot be isolated from the spectra for characterization (see for example Fig. 2(a)).

4. Conclusions

The combination of potentiometric and spectroscopic methods for the investigation of the complex behavior between uranium(VI) and glycerol 1-phosphate results in a detailed characterization of this system over a wide pH and concentration range. Two different complexes, the complexes with a metal-to-ligand ratio of 1:1 and 1:2, could be detected with potentiometric titration. This method is used however with relatively high uranium concentration ratios ($1–5 \times 10^{-4}$ M). TRLFS is applied at lower uranium concentrations (10^{-5} M), which comes the biological situation more near. Under that experimental conditions only the 1:1 complex could be found and characterized. These results are in accordance with the findings made by the complexation of uranium(VI) with several sugar phosphates [12,13].

Potentiometric measurements indicate the existence of further complexes in this system. To validate this presumption UV–Vis and EXAFS measurements were done at higher uranium concentrations (10^{-3} M). But in this concentration ranges no reasonable investigations of this complex system were possible, because the solutions are only short time stable, even under cooling. Decomposition and precipitation occurs rapidly. Further investigations are necessary to identify the precipitate and to understand this complex system completely.

To estimate the relevance of the characterized complexes in bio-systems with alternating conditions concerning, for instance, the concentration of CO_2, pH value, ionic composition and ionic concentrations, Fig. 2 shows two examples of the speciation of uranium(VI) in an aqueous solution with tenfold excess of glycerol 1-phosphate and 10^{-4} M carbonate each. The speciation was done with the program Species 1.2 (Academic Software). The following uranyl species were used to obtain the speciation (additionally to the glycerol phosphates): $UO_2(OH)^+$ ($\log\beta_{11(I=0.1)} = -5.385$), $UO_2(OH)_2$ ($\log\beta_{12(I=0.1)} = -10.517$), $UO_2(OH)_3^-$ ($\log\beta_{13(I=0.1)} = -19.201$), $UO_2(OH)_4^{2-}$ ($\log\beta_{14(I=0.1)} = -32.578$), $(UO_2)_2(OH)^{3+}$ ($\log\beta_{21(I=0.1)} = -2.487$), $(UO_2)_2(OH)_2^{2+}$ ($\log\beta_{22(I=0.1)} = -5.838$), $(UO_2)_3(OH)_4^{2+}$ ($\log\beta_{34(I=0.1)} = -12.357$), $(UO_2)_3(OH)_5^+$ ($\log\beta_{35(I=0.1)} = -16.2$), $(UO_2)_3(OH)_7^-$ ($\log\beta_{37(I=0.1)} = -31.438$), $(UO_2)_4(OH)_7^{2+}$ ($\log\beta_{47(I=0.1)} = -22.767$), UO_2CO_3 ($\log\beta_{11(I=0.1)} = 7.22$), $UO_2(CO_3)_2^{2-}$ ($\log\beta_{12(I=0.1)} = 16.0$), $UO_2(CO_3)_3^{4-}$ ($\log\beta_{13(I=0.1)} = 26.5$), $(UO_2)_3(CO_3)_6^{6-}$ ($\log\beta_{36(I=0.1)} = 42.25$), $(UO_2)_2CO_3(OH)_3^-$ ($\log\beta_{213(I=0.1)} = -17.75$), $(UO_2)_3CO_3(OH)_5^-$ ($\log\beta_{315(I=0.1)} = -16.46$) [10,11]. The uranyl glycerol 1-phosphate complexes dominate over a wide uranium concentration and pH range, which

underlines the importance of this type of ligands for the complexation of heavy metals in biological systems. The formation of mixed uranyl carbonate glycerol phosphate complexes were not included in the model because there are no data available for these complexes (cf. capture 3.1).

The characteristic main emission bands received at TRLFS measurements can be used for comparison with biological samples, in order to be able to interpret the binding properties. Table 2 summarizes TRLFS data of some investigated model compounds and uranium-contaminated biosystems [4,6,7,13,15,23]. The similarity of the main emission bands with the glycerol 1-phosphate system and other organic phosphate esters substantiates the former experiences, that to organic structures bound phosphate groups dominate the uranium binding in biosystems [4–7].

Abstract

The reaction of 2,4-bis(4-methoxyphenyl)-1,3,2,4-dithiadiphosphetane-2,4-disulfide (Lawesson's Reagent, LR) with $NiCl_2$ or $Co(CH_3COO)_2$ in methanol or ethanol gives novel sulfur-rich complexes: $C_{16}H_{20}NiO_4P_2S_4$ (**1**), $C_{18}H_{24}NiO_4P_2S_4$ (**2**) and $C_{24}H_{30}CoO_6P_3S_6$ (**4**). With the presence of ethylenediamine under the same conditions, complex $C_{24}H_{48}N_6NiO_4P_2S_4$ (**3**) is also obtained. These four novel sulfur-rich complexes were characterized by IR and X-ray crystallography, which indicate that the solvent can influence the crystal structure of complexes in the reaction between LR and metal.

1. Introduction

There is much literature that reports that 2,4-bis(4-methoxyphenyl)-1,3,2,4-dithiadiphosphetane-2,4-disulfide (Lawesson's Reagent, LR, see Scheme 1) is a most effective thiation reagent for ketones, carboxamides, esters, *S*-substituted thioesters and a variety of other compounds [1–4]. LR can also participate in the preparation of many thiophosphoryl complexes [5,6]. It has been reported by Shabana and Atrees [7] and Fahmy [8] that thiophosphoryl compounds are of potential interest as fungicides, insecticide and herbicides. In order to study the influence of the thiophosphoryl metal on their biological activity, research of the syntheses and crystal structures of these thiophosphoryl metal compounds has an important role.

It has been reported that the P–S bonds in LR can easily be cleaved to offer $MeOC_6H_4PS_2$ as a ligand [9]. We found that LR can decompose into an alcohol derivative when heated in alcohol solvent (see Scheme 2).

Although a great deal of work has been reported [10–12] on thiophosphoryl compounds, these four complexes have not been reported before. We studied the syntheses and crystal structures of some metal complexes with $MeOC_6H_4P(OR)S_2$ ($R = CH_3-$ or C_2H_5-) using the direct reaction of LR with transition metal salts. In this paper, the syntheses and crystal structures of three nickel(II) and one cobalt(II) complex are reported.

2. Experimental

2.1. Materials and physical measurements

All chemicals except Lawesson's Reagent were of reagent analytical grade, purchased from Zhengzhou

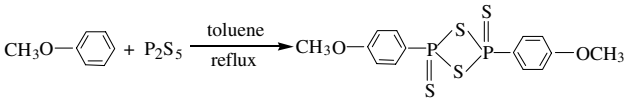
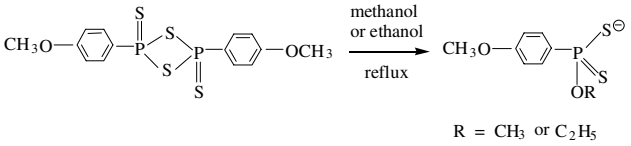


Scheme 1. Lawesson Reagent.



Scheme 2. The thermal decomposition reaction of Lawesson's Reagent in alcohol solvent.

Chemical Reagent Company and were used without any purification. Lawesson's Reagent ($R = p$-$MeOC_6H_4$) was prepared as described in the literature [13]. The single crystal structures were measured on a Rigaku-Raxis-IV X-ray diffractometer and IR spectra were recorded on a FTS-40 infrared spectrophotometer as KBr pellets in the range 4000–400 cm^{-1}.

2.2. Preparation of complexes *1*, *2*, *3* and *4*

Complex ***1***. 5 ml of 0.02 M solution of LR in methanol and 5 ml of 0.02 M solution of $NiCl_2$ in methanol were put into sealed vials, respectively, which were connected via a thin tube full of anhydrous ethanol. Purple crystals of complex **1** suitable for X-ray analysis were obtained in about three days.

Complex ***2***. With the same method mentioned above, purple crystals of complex **2** suitable for X-ray analysis were got using the mixed solution of ethanol and DMF (1:1, v/v).

Complex ***3***. 3.0 ml (0.04 mol) of ethylenediamine and 8.10 g (0.02 mol) of LR were refluxed in 180 ml anhydrous toluene at 110 °C with stirring for about 6 h. After cooling to room temperature, insoluble materials were filtered off. Then the reaction mixture was concentrated to about 20 ml with a vacuum rotary evaporator. This 20 ml oil liquid was diluted with 80 ml methanol, and 5 ml of the diluted solution and 5ml methanol solution of $NiCl_2$ (0.2 mmol) were mixed and run into a small vial and allowed to evaporate slowly at room temperature. Filtered, washed with anhydrous ethanol and dried naturally, pink crystals of **3** suitable for single-crystal X-ray diffraction analyses were obtained in about two weeks.

Complex ***4***. Complex **4** can be obtained by the method used in the preparation of complex **1**. 5 ml of 0.02 M solution of LR in methanol and 5 ml of 0.02 M solution of $Co(CH_3COO)_2 \cdot 4H_2O$ in methanol were put into sealed vials, respectively, which were connected via a thin tube full of anhydrous ethanol. Red crystals of **4** suitable for X-ray analysis were obtained in about three days.

2.3. X-ray crystallography

Intensity data of these complexes were measured with a Rigaku-Raxis-IV X-ray diffractometer using mono-

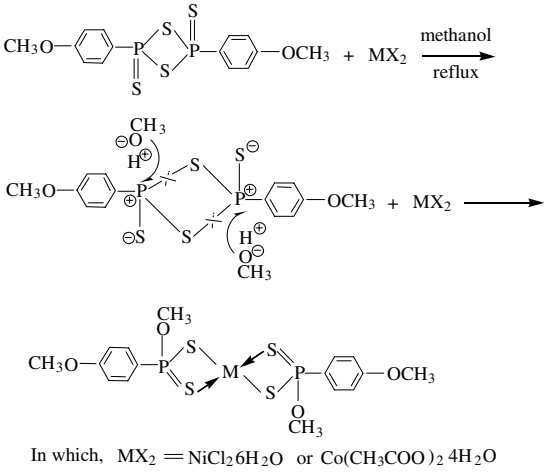
chromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Raw data were corrected and the structures were solved using the SHELXL-97 program. Non-hydrogen atoms were located by direct phase determination and subjected to anisotropic refinement. The full-matrix least-squares calculation on F^2 was applied on the final refinement. Details of the crystal structure determination are summarized in Table 1. Full atomic data are available as a file in CIF format.

The IR spectra of the four complexes contain the expected bands due to the C_6H_4OMe groups. LR has two bands at 1267(s) and 1293(m) cm^{-1} due to ν_{as}(C–O–C) and a band at 2837(w) cm^{-1} of $\nu_s(CH_3)$. All these bands can be observed in complexes **1**–**4**. In the IR spectra of complex **1**, there are bands present at 1004(s), 1010(s), 1025(m) 829(w), 792(s), 666(m) and 644(m) cm^{-1} for ν_s(P–S). In that of complex **4**, the bands at 1025(m), 789(s) and 663(m) are for ν_s(P–S). All these are consistent with the literature [12]. As far as the IR spectra of the complex **3** is concerned, the bands at 3280(s) cm^{-1} for $\nu_{as}(NH_2)$, 2975(w) cm^{-1} for $\nu_{as}(CH_2)$, and 1028(vs) cm^{-1} for ν_s(CN) are also consistent with the literature [14] (s, strong; m, medium; w, weak; vs, very strong).

3. Results and discussion

3.1. The possible reaction mechanism of LR with transition metals

When Lawesson's Reagent and transition metals react in alcohol solvent the four above-mentioned complexes were obtained. The possible reaction mechanism, as shown in Scheme 3, may have one self-coordinating catalyst course. The sulfur atoms of the LR molecule have a strong coordinating tendency with the metal ion and the P–S bond of LR may easily be cleaved [9]. When Lawesson's Reagent was heated in alcohol solvent with transition metals, the fragment $CH_3OC_6H_4PS_2$, cleaved from LR, was produced and some alcohol molecules (such as methanol) were deprotonated in order to keep the phosphorus atoms with a five valence state. Finally, the fragments $CH_3OC_6H_4PS_2$ connect with a deprotonated alcohol molecule and coordinate to the metal ion. Therefore, the four title complexes (as shown in Scheme 3) are formed.



Scheme 3. The possible reaction mechanism of LR with transition metals.

3.2. The crystal structure description of complexes *1*, *2*, *3* and *4*

Crystallographic data and structure refinement for complexes **1**–**4** are given in Table 1. For complex **1**, it can be seen from Fig. 1 that the structural unit contains a crystallographic center of symmetry at the center of the four-member rings, and is therefore planar. Four sulfur atoms from two $MeOC_6H_4P(OCH_3)S_2$ ligands describe a parallelogram environment around the nickel atom, as is shown in these angles: S2AA–Ni1A–S2A = 180°, S1A–Ni1A–S1AA = 180° and S2AA–Ni1AA–S1A = 91.25°. Selected bond distances and angles for complex **1** are shown in Table 2. The two benzene rings of a certain crystal unit are parallel. The triangle P1A–S1A–S2A and another P1AA–S1AA–S2AA in the same unit lie *trans*-parallel along the central four-member ring S1A–S2A–S2AA–S1AA plane, and the dihedral angle is 19.2°.

From Figs. 1 and 2, it can be found that the molecular structure of complex **2** is similar to that of complex **1**. The only difference lies in the fact that the OCH_3 in complex **1** is replaced by OC_2H_5 in complex **2**. The nickel–sulfur bond lengths in complex **2** {2.2257(17) Å for Ni1A–S1AA and Ni1A–S1A; 2.2237(17) Å for Ni1A–S2AA and Ni1A–S2A} are a little shorter than those of complex **1** {2.2307(13) Å for Ni1A–S2AA and Ni1A–S2A; 2.2426(13) Å for Ni1A–S1AA and Ni1A–S1A}. Selected bond distances and angles for complex **2** are shown in Table 3.

As for complex **3**, it is in fact the complex $Ni(II)(en)_3^{2+}$ (en = ethylenediamine). The $MeOC_6H_4P(C_2H_5O)S_2$ can be seen as a substituted thiophosphate group which exists in the crystal structure as an electron-balancing anion. It can be seen from Fig. 3 that for every nickel(II), such as Ni1, three ethylenediamines offer four nitrogen atoms N1, N2, N4 and N5, existing in the equatorial geometry and forming a parallelogram, with the other two nitrogen atoms N3 and N6 from two ethylenediamines occupying the axial sites. So the Ni(II) ion is six-coordinated, in the center of a distorted

So the Co(II) ion is six-coordinated, in the center of a distorted octahedron. Selected bond distances and angles are shown in Table 5.

3.3. Discussion

Through the research of the syntheses and crystal structures of these four novel sulfur-rich complexes, we found that the product can be influenced by the sort of solvent used in the preparation of such complexes of LR derivatives. For example, when the solvent is methanol or ethanol, the deprotonated methanol or ethanol can attack the phosphorus atom of LR, and the product cleaved from LR containing methoxy or ethoxy was produced. It is suggested that when LR is heated in a solvent containing an active proton, solvation decomposition can easily take place.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic

Available online 4 May 2004

Abstract

The reaction of triphenyltin hydroxide with 2-furanyl, 2-furanvingl, 2-(5-terbutyl) furanyl, 2-(5-benzoyl) furanyl, 2-pyridinyl, 4-pyridinyl, 3-indolyl, 3-indolmethyl, 3-indolethyl and 3-indolpropyl carboxylates in 1:1 stoichiometry yields triphenyltin esters of heteroaromatic carboxylic acids Ph_3SnO_2CR. All compounds are characterized by elemental analysis, IR and ^1H NMR. The crystal structure of the triphenyltin ester of 4-pyridinyl carboxylic acid (**6**) is determined by single crystal X-ray diffraction. In compound (**6**), the tin atom is rendered five-coordinate in a trigonal bipyramidal structure by coordinating with the 4-pyridinyl carboxlate group. The resulting structure is a linear polymer containing Sn–O bond lengths of 0.2160(5)–0.2166(5) nm and Sn–N bond lengths of 0.2512(6)–0.2612(6) nm.

1. Introduction

Organotin esters of carboxylic acid are widely used as biocides, fungicides and as homogeneous catalysts in industry [1–4]. Recently, pharmaceutical properties of organotin esters of carboxylic acid have been investigated for their antitumor activity [5,6]. In general, the biocidal activity of organotin compounds is influenced greatly by the structure of the molecule and the coordination number of the tin atom(s) [7,8]. Studies on organotin compounds containing carboxylate ligands with an additional donor atom (e.g., N, O or S) that are available for coordinating to the tin atom, have revealed that new structural types may lead to different activity [9,10]. As an extension of our studies of organotin esters of carboxylic acid with additional donor atoms residing on the carboxylate ligand [11], we have synthesized and structurally characterized a series of triorganotin compounds derived from 2-furanyl, 2-furanvingl, 2-(5-terbutyl)furanyl, 2-(5-benzoyl)furanyl, 2-pyridinyl, 4-pyridinyl, 3-indolyl, 3-indolmethyl, 3-indolethyl and 3-indolpropyl carboxylic acids and determined the crystal structure of $[Ph_3SnO_2CC_5H_4N \cdot 0.5H_2O]_\infty$. The results of these studies are reported herein.

2. Experimental

2.1. General procedures

All reactants were reagent grade. Infrared spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs. ^1H NMR spectra were obtained on Mercury Plus-400 NMR spectrometer, chemical shifts are given in parts per million relative to Me_4Si in $CDCl_3$ solvent. Elemental analyses were performed with a PE-2400 II elemental apparatus. Tin was estimated as SnO_2. X-ray measurements were made on a Bruker Smart-1000 CCD diffractometer with graphite monochromated Mo Kα (0.071073 nm) radiation.

2.2. Synthesis of triphenyltin esters of heteroaromatic carboxylic acids

Heteroaromatic carboxylic acids (1.2 mmol) were added to a benzene solution of Ph_3SnOH (1.0 mmol). Then the mixture was refluxed for 5 h, with water formed during the reaction being removed azeotropically with a Dean and Stark apparatus. The clear solution obtained after filtration was evaporated in vacuum to give a white solid. The products were recrystallized from acetone–hexane to give colorless crystals (see Scheme 1 for compounds R).

$$Ph_3SnOH + RCOOH \rightarrow Ph_3SnOOCR$$

2.3. Crystallographic measurements of $Ph_3SnO_2CC_5H_4$-N-4 · 0.5H_2O

A colorless crystal having approximate dimensions of 0.50 mm × 0.50 mm × 0.20 mm was mounted on a glass capillary. All measurements were made on a Bruker Smart 1000 CCD diffractometer with graphite monochromated Mo Kα (0.071073 nm) radiation. The data were collected at room temperature (298 ± 2 K) using the $\omega - 2\theta$ scan technique to a maximum 2θ value of 52.9°. The crystal structure belongs to orthorhombic crystal system, with space group $P2_12_12$, $a = 1.4882(3)$, $b = 2.3802(5)$, $c = 1.2366(2)$ nm, $\alpha = \beta = \gamma = 90°$, $Z = 4$, $V = 4.3805(15)$ nm^3, $D_c = 1.459$ g/cm^3, $\mu = 1.187$ mm^{-1}, $F(000) = 1928$. The structure was solved by direct method and differential Fourier map using the SHELXL-97 program, and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically. The positions of hydrogen atoms were calculated and refined isotropically. The weighting scheme was $w = 1/[s^2(F_o^2) + (0.0720P)^2 + 0.0000P]$, $p = (F_o^2 + 2F_c^2)/3$. The refinement was converged to the final $R = 0.0540$, $wR = 0.1237$, $(\Delta/\sigma)_{max} = 0.001$ and $S = 0.999$. In the final difference map, the residuals are 1.074 and −1.238 e/Å^3.

3. Results and discussion

3.1. Physical properties

Physical data for compounds **1**–**10** are listed in Table 1. All compounds are colorless crystals. They are soluble in many organic solvents such as CCl_4, $CHCl_3$, C_6H_6, $(CH_3)_2CO$, but are insoluble in hexane, petroleum ether and water.

3.2. Analyses of spectroscopies

3.2.1. IR spectra

The characteristic IR spectral data of compounds **1**–**10** are shown in Table 2. The assignment of IR bands of these compounds has been determined by a comparison with the IR spectra of related organotin compounds, carboxylates and Ph_3SnOH. It is worth noting that the difference Δv between v^{as}(COO) and v^{s}(COO) is important because these frequencies can be used to determine the type of bonding between the metal and carboxylate ligand [1,12]. Generally triorganotin esters of carboxylic

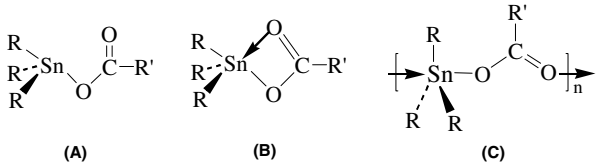


Scheme 2.

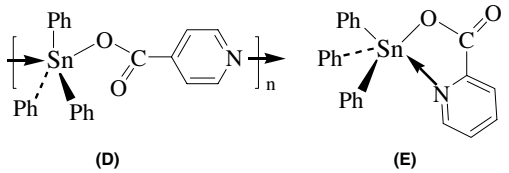
acid adopt three types of structures in the solid state (as shown in Scheme 2).

The magnitude of $\Delta\nu$ [ν^{as}(COO)–ν^{s}(COO)] of 170–199 cm^{-1} for compounds **1**–**3** and **7**–**10** is approximately equal to that for the corresponding sodium salt of the carboxylic acids. This information indicates the presence of bidentate carboxylate groups [1–4]. So it is impossible for these compounds to be structure **A**. The IR spectra of these compounds in CCl_4 are also studied in order to find out whether the ligand linkage of the C=O bond to the tin atom is intra-molecular or inter-molecular [1,13]. Because in solution the inter-molecular bond of a five-coordinated organotin polymer which belongs to structure **C** is destroyed, the polymeric structure is decomposed into mono-molecules and as a result, the $\Delta\nu$ value increases greatly [14,15]. However, the $\Delta\nu$ value for compounds with structure **B** and structure **A** do not change obviously when they are determined in solvent [14]. The results showed that the magnitude of $\Delta\nu$ 292–308 cm^{-1} in CCl_4 is much greater than that in KBr for compounds **1**–**3** and **7**–**10** (shown in Table 2). This fact reveals that the structure of these compounds might be structure **C**, not be structure **B**. The magnitude of 277–311 cm^{-1} for compounds **4**–**6** strongly indicates the unidentate bonding of the carboxylate groups, and the result in KBr is similar to that in CCl_4. But the structures of compounds **5** and **6** are different from structure **A**. One obvious feature of the IR spectra in the compounds at 484 and 483 cm^{-1} is the similarity of the stretching band arising from Sn–N [15]. Because the inter-molecular bond of Sn ← N will break in solvent, while the intra-molecular bond of Sn ← N is not influenced basically by solvent [14], whether Sn ← N of an organotin compound is inter-molecular or intra-molecular may be deduced. It is shown that the N hetero atom on the pyridine group in the carboxylate group coordinates to the tin atom [15]. In CCl_4 solution, this band is not observed in compound **6**. This indicates that the Sn ← N bond breaks up for the compound in CCl_4 solution, Thus it is proved that compound **6** contains an inter-molecular Sn ← N bond and exists as a polymer [15]. However, this difference is not observed for compound **5**. Since the intra-molecular coordination bond is not influenced by solvent [14], the Sn ← N bond existing in the compound with structure **E** can also be observed in solution. So it is possible for compound **6** to be structure **D** and compound **5** to be structure **E** [15] (see Scheme 3).

3.2.2. ^1H NMR spectra

The ^1H NMR spectra of compounds **1**–**10** are given in Table 3. It is shown that the chemical shifts of the protons on the phenyl groups of compounds **1**–**10** exhibit signals at about 7.21–7.68 ppm as multiplets.

The chemical shifts of the protons of heteroaromatic rings of compounds **1**–**10** exhibit signals in the range 6.10–8.82 ppm as multiplets (see Table 3). In compounds **1**–**4** and **7**–**10**, they are similar to that of the corresponding free heteroaromatic acid but in compounds **5** and **6** they obviously increase to be higher values than that of the corresponding free heteroaromatic acid. This finding may be consistent with previous studies that suggest that only pyridine type N atoms, present in the carboxylate R′ group, coordinate to Sn, and there is no evidence of intra- or inter-molecular coordination to Sn by the O atoms of furanyl groups



Scheme 3.

Table 3
^{1}H NMR data (ppm) for compounds **1**–**10**

Compound	^{1}H NMR
1	7.25–7.68 (16H, m, Ph-H, 5-furan-H), 7.11 (1H, d, 3-furan-H), 6.53 (1H, d, 4-furan-H)
2	7.19–7.65 (17H, m, Ph-H, 5-furan-H, C=$CHCO_2$), 6.91 (1H, d, 3-furan-H), 6.64 (1H, d, 4-furan-H), 6.38 (1H, d, C=CHAr)
3	7.21–7.67 (15H, m, Ph-H,), 6.10 (1H, d, 3-furan-H), 7.87 (1H, d, 4-furan-H), 1.33 (9H, s, CH_3)
4	7.94 (2H, br, 2,3-furan-H), 7.20–7.64 (20H, m, Ph-H)
5	8.21 (1H, br, 3-pyridine-H), 7.90 (1H, d, 6-pyridine-H), 7.51 (1H, d, 4-pyridine-H), 7.24–7.69 (16H, m, Ph-H, 5-pyridine-H)
6	8.82 (2H, d, 2,6-pyridine-H), 7.84 (2H, d, 3,5-pyridine-H), 7.35–7.75 (15H, m, Ph-H)
7	8.02 (1H, s, N–H), 7.21–7.67 (16H, m, Ph-H, 2-indole-H), 6.84–7.18 (4H, m, indole-H)
8	8.00 (1H, s, N–H), 7.22–7.62 (16H,m, Ph-H, 2-indole-H), 6.78–7.17 (4H, m, indole-H), 3.62 (2H, s, $ArCH_2CO_2$)
9	7.95 (1H, s, N–H), 7.23–7.66 (16H, m, Ph-H, 2-indole-H), 6.72–7.20 (4H, m, indole-H), 2.91 (2H, br, CH_2CO_2), 2.23 (2H, br, $ArCH_2$)
10	7.97 (1H, s, N–H), 7.21–7.69 (16H, m, Ph-H, 2-indole-H), 6.75–7.18 (4H, m, indole-H), 2.72 (2H, t, CH_2CO_2), 2.05 (2H, t, $ArCH_2$), 1.52 (2H, m, CH_2)

[10]. In addition, the presence of the N–H proton signal in the spectra of compounds **7**–**10** supports that the indolyl group N atom is not coordinated to the Sn atom.

3.2.3. X-ray crystal structure of $Ph_3SnO_2CC_5H_4N$-4·0.5H_2O (**6**)

Selected bond distances and angles are listed in Table 4. The molecular structure is shown in Fig. 1. Fig. 2 shows the packing of the molecules in the unit cell as seen in a projection onto its face.

In $[Ph_3SnO_2CC_5H_4N \cdot 0.5H_2O]_\infty$ **6**, two kinds of tin atoms with different chemical environments can be found. Each molecule of compound **6** in the unit cell possesses an unequivocally polymeric structure, but this structure differs from the tributyltin 2-(5-*tert*butyl) furanylcarboxylate [8] and tribenzyltin 2-(5-*tert*butyl)furanylcarboxylate [8]. Each tin atom is rendered five-coordinate in a trigonal bipyramidal structure by coordination of the nitrogen atom from a 4-pyridinyl carboxylate group from an adjacent molecule. The central tin atoms are surrounded axially by one oxygen atom and one nitrogen atom, and equatorially by three carbon atoms of the phenyl groups. The intra-molecular Sn(1)–O(1) and Sn(2)–O(3) bond distances are 0.2166(5) and 0.2160(5) nm, which are longer than that in $\{[^nBu_2Sn(2\text{-pic})]_2O\}_2$ [7] (0.20544 and 0.2110 nm), but are shorter than those in $Me_3SnO_2CC_5H_4N \cdot H_2O$ (0.218 and 0.221 nm) [16]. The Sn(1)–O(2) and Sn(2)–O(4) distances are 0.3237 and 0.3311 nm, which are much greater than the sum of the van der Waals radii for Sn and O of 0.280 nm. It is shown that the O(2) and O(4) atoms do not make any significant contacts with the Sn atom. The Sn(1)–N(2) and Sn(2)–N(1)#1 distances, 0.2512(6) and 0.26612(6) nm, are greater than the sum of the covalent radii of Sn and N (0.215 nm), but are considerably less than the sum of the van der

Table 4

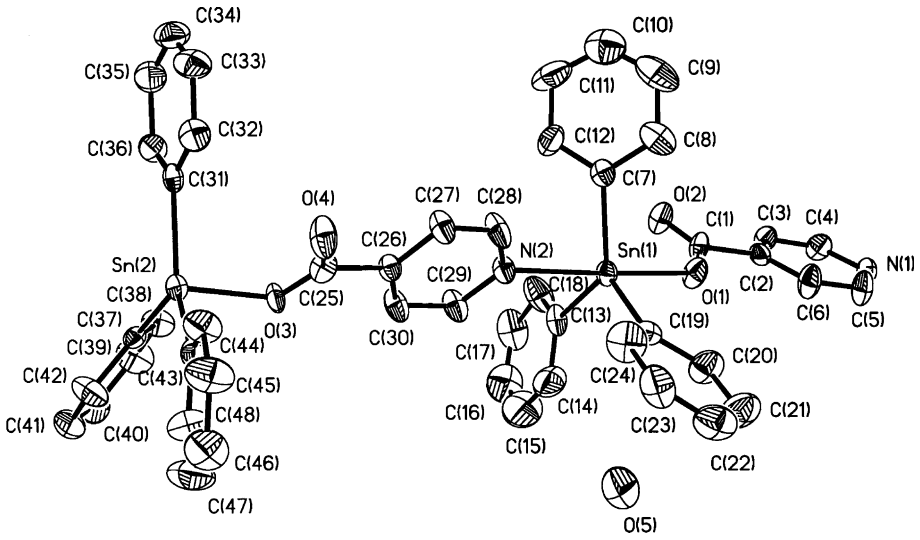

Fig. 1. The molecular structure of compound **6**.

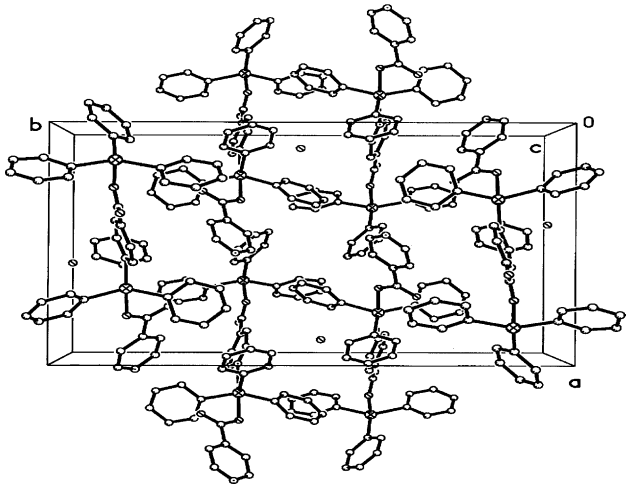

Fig. 2. Projection of compound **6**.

Waals radii (0.375 nm) [17] and should be considered as bonding interactions. In this connection it is relevant to note the Sn–N bond distances found in three other crystal structures of organotin compounds containing the pyridine carboxylate ligand. In polymeric $[Me_2SnCl(2\text{-pic})]_n$ [18] the two unique Sn–N bond distances are 0.250(3) and 0.247(2) nm, in polymeric $[Me_2Sn(2\text{-pic})_2]_n$ [9] the two Sn–N bond distances are 0.2507(4) and 0.2477(4) nm and in dicarboxylato tetraorganostannoxane $\{[^nBu_2Sn(2\text{-pic})]_2O\}_2$ [7] the two Sn–N bond distances are 0.2550(5) and 0.3150(5) nm. In compound **6**, the distortions from true trigonal bipyramidal symmetry are reflected in the interatomic angles. For instance around the Sn(1) atom of compound **6** the angles of C(7)–Sn(1)–O(1) 93.2(3)°, C(13)–Sn(1)–O(1) 96.2(3)°, C(19)–Sn(1)–O(1) 89.9(3)°, C(7)–Sn(1)–N(2) 84.9(3)°, C(13)–Sn(1)–N(2) 88.0(2)°, C(19)–Sn(1)–N(2) 88.2(3)°, all are not 90°, and only one approximates to 90°. The angle of O(1)–Sn(1)–N(2), 175.8(2)°, shows that the atoms O(1), Sn(1) and N(2) are nearly linear. The Sn(2) atom is similar to the Sn(1) atom and it has a distorted trigonal bipyramidal structure too.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 200373 for compound **6**. Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1233-336-033; E-mail: deposit@ccdc.cam.ac.uk, or www: http://www.ccdc.cam.ac.uk).

Abstract

Two new azido derivatives of quadridentate Schiff base manganese(III) complexes have been synthesized and characterized structurally and magnetically. X-ray structure analysis revealed that both complexes viz. $[Mn_2(L1)_2(N_3)_2]$ (**1**) and $[Mn_2(L2)_2(N_3)_2]$ (**2**), where $H_2L1 = N,N'$-(1,1-dimethylethylene)-bis-(salicylaldiimine) and H_2L2 = bis(*o*-hydroxyacetophenone)-ethylenediimine exist as phenoxo-bridged dimer. The magnetic susceptibility of the complexes has been measured in the 5–300 K range. At room temperature the Mn^{III} ions in complexes **1** and **2** possess an $S = 4$ ground state. The global magnetic interaction in complex **1** is found to be ferromagnetic, while for complex **2** it is anti-ferromagnetic.

1. Introduction

Studies on metal assembled complexes of manganese have attracted considerable attention in recent time due to their various interesting properties like biomimetism, catalysis, molecular magnetism, etc. Manganese takes part in several essential life processes [1]. One of the most famous examples is the tetranuclear manganese cluster of the oxygen evolving complex (OEC) present in the photosystem II of green plants [2]. Dinuclear manganese clusters are present in several metalloproteins such as manganese catalase, manganese ribonucleotide reductase, etc. [3,4]. Attempts have been made to mimic the catalase activity of metalloprotein using dinuclear Mn^{III} Schiff base complexes [5]. A family of Mn^{III} Schiff base complexes also catalyzes many important reactions such as C–H bond activation, olefin epoxidation, hydroxylation, etc. [6,7]. Such complexes with chiral ligands are also employed in asymmetric catalytic reactions [7]. Exchange between two or more paramagnetic centers is the crucial criteria in manifestation of molecular magnetism. The role of bridging ligands that gives a suitable mechanism for super exchange between metal ions is important in this context. Pseudohalogens are versatile ligands for making such bridges [8–10]. Amongst them azide is the most efficient ligand with regard to super-exchange pathways between paramagnetic centers. The versatility and efficiency of azide lies on its functionality as a terminal monodentate, or bridging bi, tri and tetradentate ligand [11]. Manganese(III) Schiff bases are known to serve the required paramagnetic building block for multidimensional extended architecture. The Mn^{III} with this ligand environment could afford a ground state $S = 2$ for the monomeric entity, while $S = 4$ for dimeric forms and so on. A lot of dimeric Mn^{III} Schiff base complexes

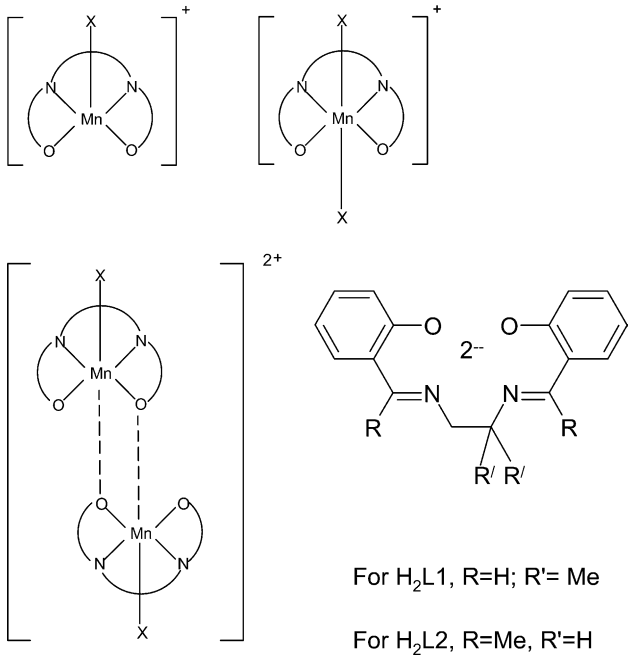

Scheme 1.

exhibiting antiferromagnetic interaction has been reported by several researchers [12–17]. But ferromagnetically coupled dimers are still scanty in the literature [18–20]. These complexes often dimerize by virtue of the formation of Mn–O–Mn* (Mn* belongs to a neighboring monomeric unit) bridge (Scheme 1) through phenoxo group present in a Schiff base [21]. In most of the cases phenoxo bridges are weak. In order to functionalize the metal centers further the azido adducts of Mn^{III} Schiff base complexes are prepared in the present study.

We report here the synthesis, structure and magnetic properties of two new azido adducts of Mn^{III} complexes containing quadridentate Schiff base ligands.

2. Experimental

2.1. Materials and synthesis

All chemicals and solvents used during the synthesis were of AR grade.

Caution!! *Azide derivatives are potentially explosive, only a small amount of materials should be prepared, and it should be handled with proper care.*

The H_2L1 was synthesized by mixing 1,1-dimethylethylenediamine with salicylaldehyde in a 1:2 molar ratio in methanol. The H_2L2 was also produced in the same method by mixing ethylenediamine with *o*-hydroxyacetophenone. The method of preparation of ligands that were followed in this study is given in [22a,22b], respectively.

2.1.1. $[Mn_2(L1^{2-})_2(N_3)_2]$ (**1**)

A methanol solution (40 ml) of H_2L1 (0.276 g, 0.932 mmol) was added to a methanol solution (20 ml) of manganese(III) acetate dihydrate (0.25 g, 0.933 mmol). After stirring the resulting brown solution for 30 min, sodium azide (0.061 g, 0.934 mmol) dissolved in minimum volume of water was added. Before filtration, the mixture was stirred for another 30 min. The filtrate was left to stand for two days at room temperature. Dark brown crystals were collected by suction filtration, washed with a minimum amount of methanol and dried in vacuo. (Yield ca. 70%.) *Anal.* Calc. for $C_{18}H_{18}MnN_5O_2$: C, 55.2; H, 4.6; N, 17.9. Found: C, 54.8; H, 4.7; N, 17.6%. IR(KBr): ν(C=N), 1635 cm^{-1}; ν(azide), 2080 cm^{-1}.

2.1.2. $[Mn_2(L2^{2-})_2(N_3)_2]$ (**2**)

The same preparation procedure as that presented for **1** was used for **2** using H_2L2 instead of H_2L1. (Yield ca. 80%.) *Anal.* Calc. for $C_{18}H_{18}MnN_5O_2$: C, 55.2; H, 4.6; N, 17.9. Found: C, 54.9; H, 4.5; N, 17.5%. IR(KBr): ν(C=N), 1601 cm^{-1}; ν(azide), 2040 cm^{-1}.

2.2. Physical measurements

The instruments used for IR and UV–Vis spectral measurement and CHN analyses were the same as reported earlier [23]. The magnetic susceptibility of complexes **1** and **2** was measured in the 5–300 K temperature range with a Quantum Design MPMS-XL SQUID susceptometer under a 1 T field. Diamagnetic corrections were estimated from Pascal constants.

2.3. X-ray crystallography

The crystal data of **1** and **2** and data collection parameters are summarized in Table 1. A black plate crystal of **1** was placed on a Rigaku AFC7S diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). The lattice parameters were obtained from a least-squares refinement of diffractometer setting angles of 12 reflections with $15.38° < 2\theta < 22.26°$. Data were collected at 300 K using the ω scan mode. The structure was solved by direct methods [24] and expanded using Fourier techniques [25]. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. All calculations were performed using the TEXAN [26a] crystallographic software package.

Intensity data of **2** were collected on a Bruker P4 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Accurate cell parameters were obtained by least-squares refinement of diffractometer setting angles of 38 reflections with $2.07° < \theta < 14.89°$. Data were collected at 160 K using the ω scan mode. The crystal structure was solved by conventional Patterson and Fourier methods and re-

fined by a full-matrix least-squares method with SHELXS-97 and SHELXL-97 [26b]. All non-hydrogen atoms were assigned to ideal positions and refined using a riding model.

3. Results and discussion

3.1. Description of the structures

The structure of the complexes **1** and **2** with atom numbering scheme is given in Figs. 1 and 2. The selected bond distances and angles of the complexes **1** and **2** are gathered in Table 2. These are comparable with other phenolato-bridged complexes [27]. Both complexes are the phenoxo-bridged dimers. Complexes **1** and **2** possess the same empirical formula and are ligand isomers. The quadridentate Schiff base forms the equatorial plane in these complexes. One of the axial positions of the coordination environment of Mn^{III} is occupied by a terminal azide, while the remaining axial position of the octahedron is connected to a phenoxo group of the neighboring monomeric unit which forms the bridge in the Mn_2^{III} dimer. The geometry around Mn^{III} in this molecule is best described as a tetragonally elongated octahedron. The other half of the dimer is related by a center of inversion to the first half described above (Figs. 1 and 2). The distance of Mn–O_{bridge} bonds were found to be 1.88(1) and 2.87(1) Å in complex **1**, whereas these are 1.912(4) and 2.375(5) Å in complex **2**. The [$Mn_2(\mu$-$O_2)$] diamond core in both complexes consists of

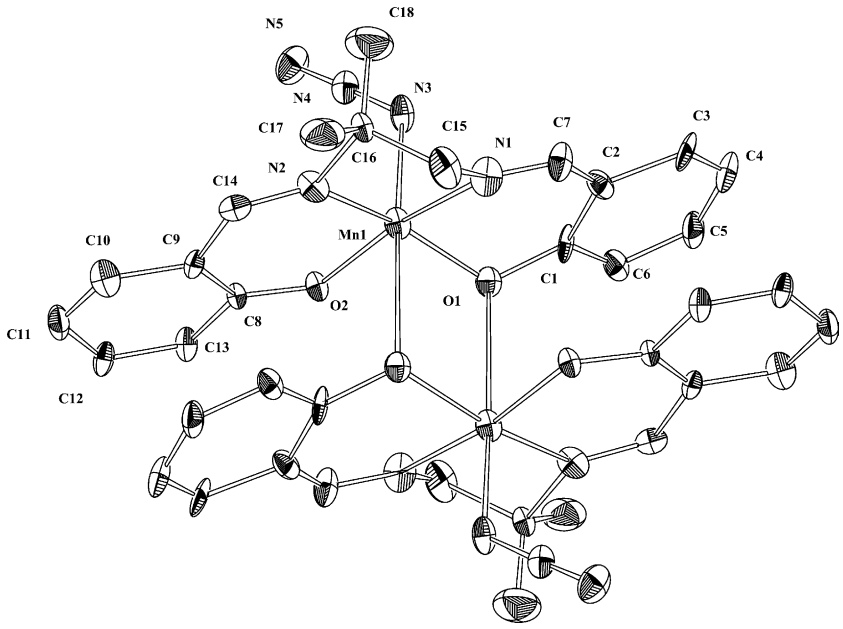

Fig. 2. ORTEP diagram of the complex **2** with the atom numbering scheme.

two significantly unequal Mn–O_{bridge} bonds. But the difference between two Mn–O_{bridge} bond distances is more prominent in complex **1** than in the complex **2**. There is also a difference between bridged and non-bridged Mn–O bond distances, obviously the Mn–O_{bridge} bond is longer than the other Mn–O bond. The Mn–Mn* distances and Mn–O–Mn* angles are 3.611(1) and 3.341(2) Å and 96.76° and 101.83°, respectively, for complexes **1** and **2**.

3.2. Magnetic properties

The variable temperature magnetic susceptibility of complexes **1** and **2** was measured in the range 5–300 K. A μ_{eff} (BM) versus T plot is given in Fig. 3, while the plots of χ_M versus T are given in Figs. 4 and 5 for complexes **1** and **2**, respectively. The μ_{eff} values of **1** and **2** are 6.99 and 6.89 BM, respectively, at 300 K. This suggests both the dimeric complexes possess an $S = 4$ ground state at room temperature. On lowering of temperature the μ_{eff} values of complex **1** remains almost unaltered up to ca. 100 K, then gradually increased to a value of 8.08 BM. On the other hand the μ_{eff} versus T plot for complex **2** shows a sharp downward turn at ca.

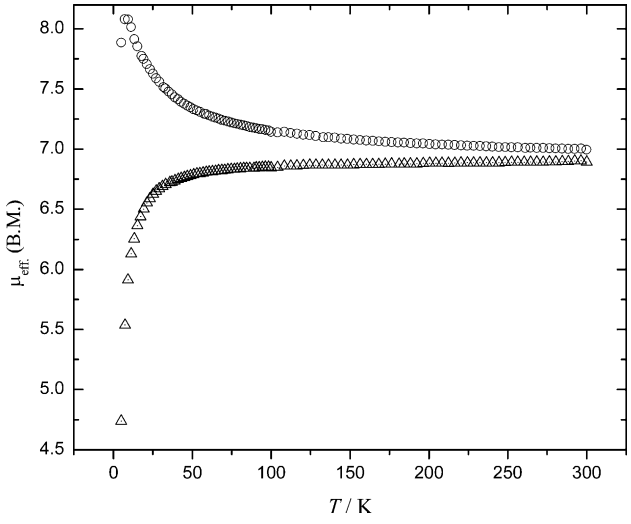

Fig. 3. A plot of μ_{eff} (BM) vs. T (K) for complex **1** (○) and **2** (△).

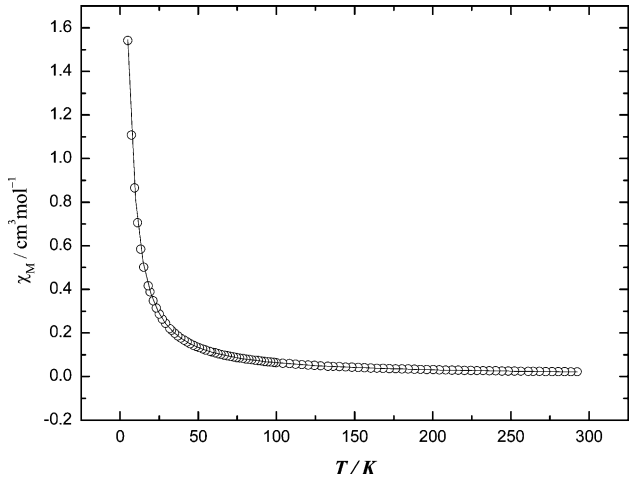

Fig. 4. A plot for complex **1** of temperature dependence of χ_M ($cm^3\ mol^{-1}$) vs. T (K). The solid lines are theoretical fits based on Eq. (I).

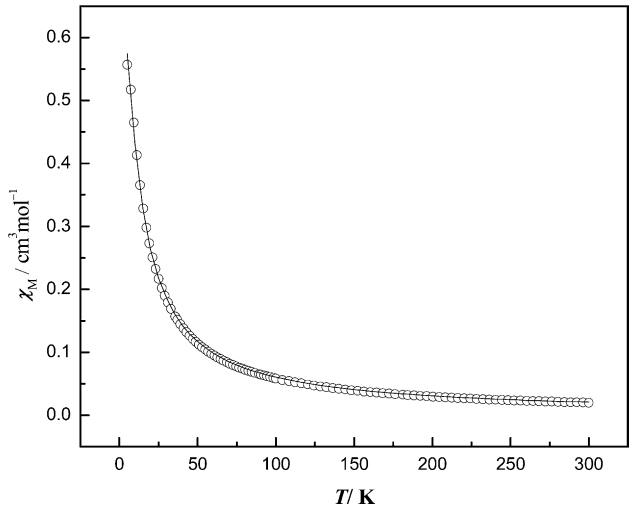

Fig. 5. A plot for complex **2** of temperature dependence of χ_M ($cm^{-3}\ mol^{-1}$) vs. T (K). The solid lines are theoretical fits based on Eq. (II).

50 K and reaches a value of 4.73 BM at 5 K. Besides, the Curie–Weiss plot (not shown) $[\chi^{-1}(T)]$ afforded the Curie (C) and Curie–Weiss (θ) constants 5.99 emu $mol^{-1}\ K^{-1}$, 4.77 K and 5.95 emu $mol^{-1}\ K^{-1}$, −2.39 K, for complex **1** and **2**, respectively. All these are indicating that the overall magnetic interaction between the Mn^{III} ions in complex **1** is ferromagnetic, whereas an antiferromagnetic coupling is operative in complex **2**.

Eqs. (I) and (II) were used for calculating the susceptibilities of complex **1** and **2**, respectively. For a ferromagnetic dimer with $S = 4$ ground state, the equation is as follows [28,29]:

$$\chi = [2Ng^2\beta^2/k(T-\alpha)][A/B],$$
$$A = 30 + 14\exp(-8J/kT) + 5\exp(-14J/kT) + \exp(-18J/kT),$$
$$B = 9 + 7\exp(-8J/kT) + 5\exp(-14J/kT) + 3\exp(-18J/kT) + \exp(-20J/kT). \quad \text{(I)}$$

For an antiferromagnetic dimeric system the equation can be written as [30]:

$$\chi = [2Ng^2\beta^2/kT][A/B],$$
$$A = \exp(J/kT) + 5\exp(3J/kT) + 14\exp(6J/kT) + 30\exp(10J/kT),$$
$$B = 1 + 3\exp(J/kT) + 5\exp(3J/kT) + 7\exp(6J/kT) + 9\exp(10J/kT). \quad \text{(II)}$$

The terms N, g, β and k have their usual meaning. The best fit of the magnetic data was obtained with the following set of parameters $J = 1.32\ cm^{-1}$, $g = 1.995$, $R = 2.52 \times 10^{-6}$ and $\alpha = -1.33$ for complex **1** (Fig. 4). The α term is introduced in the susceptibility equation (I) to account for the intradimer interaction for which the decrease of μ_{eff} in the very low temperature region was observed (Fig. 3). For complex **2** the fitting of the magnetic data afforded $J = -0.55\ cm^{-1}$, $g = 2.04$ and $R = 1 \times 10^{-5}$ (Fig. 5), where $R = \sum(\chi_{M_{obs}} - \chi_{M_{calc}})^2 / \sum(\chi_{M_{obs}})^2$.

The studies of magneto-structural correlation including theoretical calculations of phenoxo-bridged Mn^{III} complexes are sparse in the literature [31]. DFT calculations show that the phenoxo-bridged complexes of Cu^{II} and Ni^{II} are usually antiferromagnetic in nature [31]. Recently, Miyasaka et al. have studied a series of Mn^{III} Schiff base complexes structurally and magnetically [20]. Magneto-structural correlation of these complexes show that factors like Mn–O* [O* denotes the symmetry (−X,

$-Y$, $-Z$) related phenoxo oxygen] distances, stereo-electronic character of the Schiff base, Jahn–Teller distortion have considerable influences on the characteristics of the magnetic coupling in these dimers. The Mn–O* distances are relatively longer in the case of complexes having ferromagnetic interaction, while their antiferromagnetic counterparts have shorter Mn–O* distances (Table 3). The electronic configuration of a Jahn–Teller elongated Mn^{III} ion is $t_{2g}^3e_g^1(d_z2^1)$ with a $^5B_1$ ground state [32]. The methyl group being electron releasing enhances the J–T orbital splitting. Thus the Jahn–Teller elongation increases the possibility of the orthogonality between e_g and $d\pi$ orbitals in Mn^{III} ions; as a result, a ferromagnetic interaction is favored in such cases. Both of these factors are more pronounced in complex **1** than in **2**, which might be leading the former to show a ferromagnetic coupling. It is apparent from a cursory look at Table 3 that ferromagnetic coupling predominates for a complex with smaller Mn–O–Mn* angles ($\angle$Mn–O–Mn* $\approx 96°$). Although no theoretical calculations are reported so far on the magneto-structural correlation of such Mn^{III} dimers, DFT calculation of oxo-bridged model complex $[(NH_3)_4Mn^{II}(\mu\text{-}O)_2(NH_3)_4]$ shows that J value is maximum at around $\angle$Mn–O–Mn $\approx 97°$ [31].

It is noteworthy that the azido derivatives of Mn^{III} quadridentate Schiff base complexes were synthesized in anticipation of azide being an efficient and versatile bridging ligand which would rather form a stronger bridge between metal ions and would functionalize Mn^{III} further to give a polymetallic assembly. This is indeed happened in the case of other Schiff base complexes [9,10]. Instead in the present case Mn^{III} ions prefer to form phenoxo-bridged dimers keeping the azides in the terminal positions. Although more complex and dynamic situations are encountered in metalloproteins, it is tempting to mention that the manganese catalase which consists of Mn_2^{III} moieties shows the same preference by not forming Mn^{III}–Mn^{III} bridges through azide which is often found in other metalloproteins [33,34] when azide is used as a ligand to study the interaction between small molecules and the metal centers of proteins [35].

Abstract

X-ray structures of new $[ReCl_3(pzH)_2(PPh_3)]$ and $[ReCl_3(3,5\text{-}Me_2pzH)_2(PPh_3)]$ complexes (pzH = pyrazole) have been determined, and the geometric parameters of $[ReCl_3(pzH)_2(PPh_3)]$ have been examined using density functional theory (DFT) method. The UV–Vis spectra of the complexes have been discussed on the basis of the electronic transitions of $[ReCl_3(pzH)_2(PPh_3)]$ calculated with time-dependent DFT method (TDDFT).

Keywords: Rhenium complexes; Pyrazole ligand; X-ray structure; DFT calculations

1. Introduction

The noticeable growth of interest in the rhenium coordination chemistry is connected with the favourable nuclear properties of ^{186}Re and ^{188}Re nuclides, which make the radioisotopes useful for diagnostic nuclear medicine and applications in radioimmunotherapy [1,2]. Although pyrazole and its derivatives have a special place among N-donor ligands, the number of rhenium complexes containing these ligands is limited [2–6].

Previously, we investigated the reactivity of oxorhenium(V) species – $[ReO(OEt)X_2(PPh_3)_2]$, $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)(OAsPh_3)]$ (X = Cl or Br) – towards pyrazole (pzH) and 3,5-dimethylopyrazole (3,5-Me_2pzH) under various reaction conditions. The products of these syntheses include: (i) mononuclear $[ReOX_2\{\eta^2\text{-}N_2C_3H_3C(CH_3)_2O\}(PPh_3)]$ complexes with $C_3H_3N_2C(CH_3)_2O^-$ anion obtained in the addition reaction of pyrazole and acetone and (ii) dinuclear Re(V) compounds of types $[\{Re(O)X(PPh_3)\}_2(\mu\text{-}O)(\mu\text{-}pz)_2]$, $[\{Re(O)X_2(3,5\text{-}Me_2pzH)_2\}_2(\mu\text{-}O)]$, $[\{Re(O)Br(3,5\text{-}Me_2pzH)\}_2(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2]$, $[\{Re(O)X(PPh_3)\}_2(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2]$ and $[\{Re(O)X(PPh_3)\}(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2\{Re(O)X(3,5\text{-}Me_2pzH)\}]$ (X = Cl or Br) [7,8].

Here, we report the synthesis and X-ray structure of the two mononuclear Re(III) $[ReCl_3(pzH)_2(PPh_3)]$ (**1**) and $[ReCl_3(3,5\text{-}Me_2pzH)_2(PPh_3)]$ (**2**) complexes and the results of the density functional theory (DFT) calculations for **1**. The UV–Vis spectra of **1** and **2** are discussed basing on the electronic transitions of **1**, calculated using the time-dependent DFT method (TDDFT).

2. Experimental

2.1. General procedure

The reactions were carried out under argon atmosphere. All solvents were of reagent grade and were used as received. Ammonium perrhenate, Ph_3P and pyrazole (pzH) were purchased from Aldrich and used as

received. $[Re(MeCN)Cl_3(PPh_3)_2]$ and $[ReOCl_3(PPh_3)_2]$ complexes and 3,5-Me_2pzH were prepared according to the literature methods [9–11].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 800–220 nm in deoxygenated dichloromethane solution. The magnetic susceptibility was determined with a superconducting quantum interference device (SQUID, Quantum Design) magnetometer. Elemental analyses (C, H and N) were performed on a Perkin–Elmer CHN-2400 analyser.

2.2. Preparation of $[ReCl_3(pzH)_2(PPh_3)]$ (**1**)

2.2.1. Method A (**1a**)

$[ReOCl_3(PPh_3)_2]$ (1 g, 1.20 mmol) and pzH (0.54 g, 8 mmol) in diisopropyl ketone (60 cm^3) were refluxed for 2 h. The starting material gradually dissolved and the colour of the reaction solution changed from green to dark brown. The volume of the reaction solution was condensed to 20 cm^3 and reddish-orange microcrystalline solid was formed by an addition of 100 cm^3 of diethyl ether. The product was washed with EtOH and cold ether, and dried in vacuo.

2.2.2. Method B (**1b**)

$[Re(MeCN)Cl_3(PPh_3)_2]$ (1 g, 1.20 mmol) and pzH (0.54 g, 8 mmol) in chloroform (80 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the colour of the reaction solution became dark red. After 3 h, the reddish-orange microcrystalline solid started to participate. The volume was condensed to 10 cm^3, diethyl ether (100 cm^3) was added and reddish-orange microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried in vacuo.

The crystals of **1a** and **1b** suitable for X-ray investigation were obtained by recrystallization from a mixture of acetonitrile and dichloromethane (yield 80%).

The solvents used for the reactions and recrystallization were not dried, so some water was present in the reaction systems and water molecule was found in **1b** structure.

2.3. Preparation of $[ReCl_3(3,5\text{-}Me_2pzH)_2(PPh_3)]$ (**2**)

$[Re(MeCN)Cl_3(PPh_3)_2]$ (1 g, 1.20 mmol) and 3,5-Me_2pzH (0.77 g, 8 mmol) in chloroform (80 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the colour of the reaction solution became dark red. After 3 h, the reddish-orange microcrystalline solid started to participate. The volume was condensed to 10 cm^3, diethyl ether (100 cm^3) was added and reddish-orange microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried in vacuo. The crystals of **2** suitable for X-ray investigation were obtained by recrystallization from a mixture of acetonitrile and dichloromethane (yield 85%).

IR(KBr, cm^{-1}) 3384 (s), 3354 (s) 3138 (w), 3055 (m), 2922 (m), 1567 (s) 1482 (m), 1465 (w), 1432 (s), 1395 (m), 1372 (m), 1275 (s) 1177 (m), 1149 (m), 1091 (s), 1031 (s), 999 (w), 813 (w), 800 (m), 744 (s), 694 (s), 650 (m), 644 (m), 555 (w), 524 (s), 511 (s), 497 (s), 448 (m). *Anal.* Calc. for $C_{28}H_{31}N_4Cl_3PRe$: C, 45.01; H, 4.18; N, 7.50. 2.4. Crystal structures determination and refinement

The X-ray intensity data were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector with 24, 32 and 40 s exposure time (for compounds **1a**, **1b** and **2**, respectively) was used and the whole Ewald sphere (up to $2\theta = 50°$) was collected. The unit cell parameters were determined from least-squares refinement of the setting angles of 8345°, 6543° and 5421° (respectively, as above) of strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [12] were applied. The structures was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as ''riding'' on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. SHELXS 97 [13], SHELXL 97 [14] and SHELXTL [15] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

The crystals of **1a** have the diffused electron density originated from multipositional disordered solvent water molecule around special position 0, 1/2 and 1/2. This effect was repeatable for all measured crystals in the sample. In the crystals of **1b** it can be found slightly dynamically disordered water molecule that is also statically disordered in two symmetry equivalent positions.

The N2/C21 and N4/C24 atoms in structure of **1** were distinguished on the basis of anisotropic parameters. Changing the carbon atoms to nitrogen and vice versa

cause anisotropic displacement parameters to be senseless.

2.5. Computational details

GAUSSIAN 03 program [16] was used in the calculations. The geometry optimization was carried out using the DFT method with the use of B3LYP functional [17,18]. The electronic spectrum was calculated with the TDDFT method [19].

LANL2DZ basis set [20] was used on the rhenium atom, 6-31G(d) on the chlorine, nitrogen, phosphorus and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations.

3. Results and discussion

Two different routes have been employed for the preparation of **1**. The refluxing of $[ReOCl_3(PPh_3)_2]$ with pzH in diisopropyl ketone gives the complex **1** in moderate yield. The well-known capacity of PPh_3 to interact with the Re≡O bond in the rhenium(V) oxo-complexes explains the course of the reaction between $[ReOCl_3(PPh_3)_2]$ and pyrazole:

$$2[ReOCl_3(PPh_3)_2] + 2N_2C_3H_4 \rightarrow [ReCl_3(pzH)_2(PPh_3)] + OPPh_3$$

A higher yield of **1** has been reported for the substitution reaction:

$$[ReCl_3(MeCN)(PPh_3)_2] + 2pzH \rightarrow [ReCl_3(pzH)_2(PPh_3)] + MeCN + PPh_3.$$

The complex **2** has been obtained in the reaction of $[ReCl_3(MeCN)(PPh_3)_2]$ with 3,5-Me_2pzH. The excess of pyrazole and 3,5-Me_2pzH used in the reactions ensure the maximum yield of the complexes.

3.1. X-ray structure

A perspective drawings of **1** and **2** are given in Figs. 1 and 2, respectively. The rhenium atom of the both

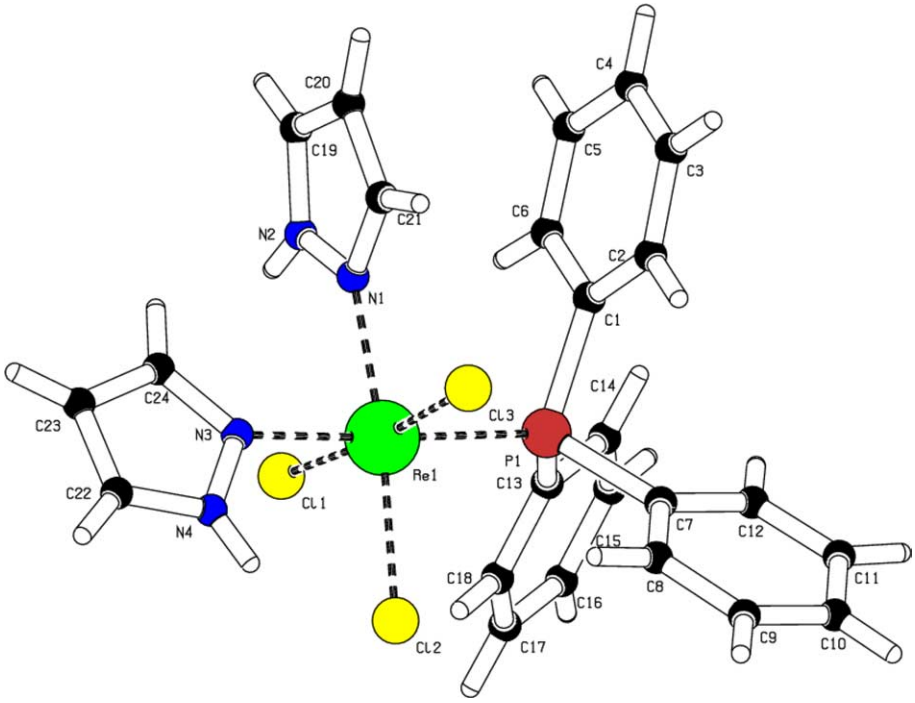

Fig. 1. The molecular structure of **1**.

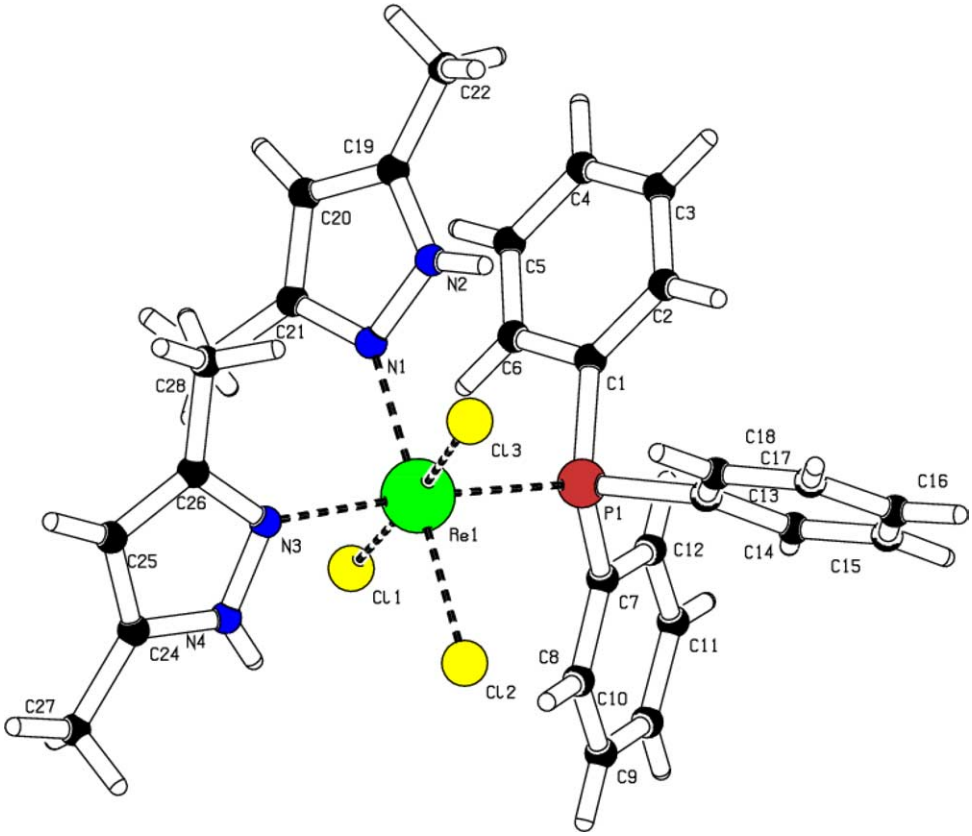

Fig. 2. The molecular structure of **2**.

complexes is in distorted octahedral environment with three chlorine ligands in *mer* geometry, two N-donor ligands (pzH or 3,5-Me_2pzH) in *cis* position to each other and one PPh_3 molecule occupying *trans* position to N(3) atom. Table 1 presents crystal data and structural refinement for **1a**, **1b** and **2**. The most important bond lengths and angles for compounds **1a**, **1b** and **2** are reported in Table 2. A notable *trans* influence of triphenylphosphine ligand is observed in both complexes; the Re–N(3) bond lengths are longer in comparison with the corresponding Re–N(1) distances. The Re–N, Re–Cl and Re–P bond lengths are unexceptional, they agree well with appropriate values found previously in similar rhenium compounds [7,8,21–23].

The weak intramolecular and intermolecular hydrogen bonds [24–26] of **1** and **2** are presented in Table 3.

3.2. Infrared data

The strong bands in the range assignable to N–H vibrations (3400–3100 cm^{-1}) in the IR spectra of **1** and **2** confirm the coordination of pyrazoles ligands in the neutral monodentate form. The characteristic bands of the C=C and C=N stretching modes, observed at 1640 and 1558 cm^{-1} in uncomplexed pyrazole and at 1663 and 1595 cm^{-1} in uncomplexed 3,5-dimethylpyrazole, are shifted to considerable lower frequencies.

3.3. Magnetochemical measurements

Magnetic susceptibilities of **1** were recorded over the temperature range 5–300 K. Temperature dependence of the molar magnetic susceptibility for **1** is presented in Fig. 3. The observed room-temperature effective magnetic moment 1.2 BM is typical of the rhenium(III) mononuclear complexes. It consistent with low-spin rhenium(III) (d^4) ions in O_h field [27] and arises because of the large spin–orbit coupling ($\xi = 2500$ cm^{-1}) [28].

3.4. The optimized geometry and molecular orbitals of *1*

The geometry of **1** was optimized in triplet and singlet states using the DFT method with the B3LYP functional. The energy of the singlet state is of 16.3 kcal higher. The optimized geometric parameters of the triplet state are gathered in Table 2. The optimized geometry of **1** is in good agreement with the experimental one and the largest differences are found for Re–Cl bond distances.

The selected HOMO and LUMO orbitals with α-spin for **1** are depicted in Fig. 4. The following orientation of the axes has been used for determination of the MO characters: the *z*-axis goes along Cl(1)–Re–Cl(3) linkage and *x* goes through the N(3)–Re–P(1) bonds. The rhenium d_π atomic orbital (d_{xz}, d_{yz} and d_{xy}) and π orbitals of chlorine ligands in anti-bonding arrangement make main contributions into the HOMO-2, HOMO-1 and

#2: $x-1,y,z$.

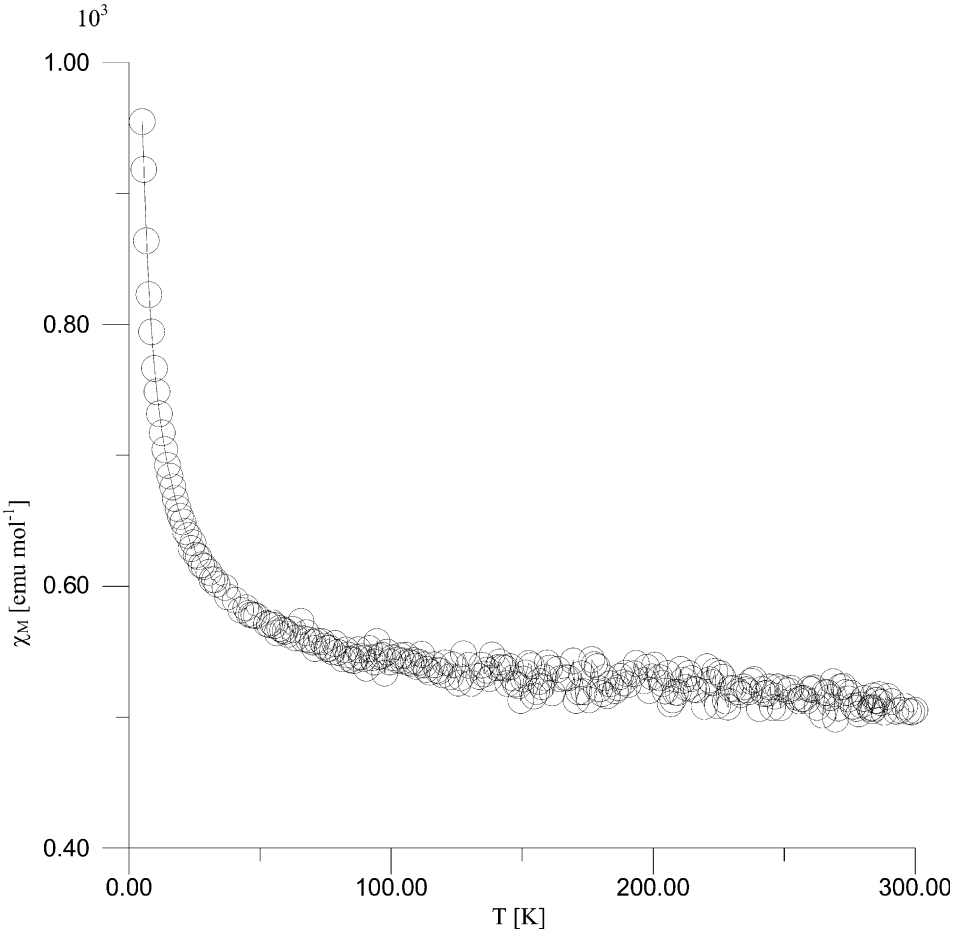

Fig. 3. Temperature dependence of the molar susceptibility for **1**.

HOMO with α-spin and HOMO, LUMO and LUMO + 1 with β-spin. The HOMO orbitals have also the antibonding contribution from the pyrazole ligands. The lower lying orbitals are π orbitals of the phenyl groups and pyrazole ligands. HOMO-11 and HOMO-5 with α-spin and HOMO-9 and HOMO-3 with β-spin

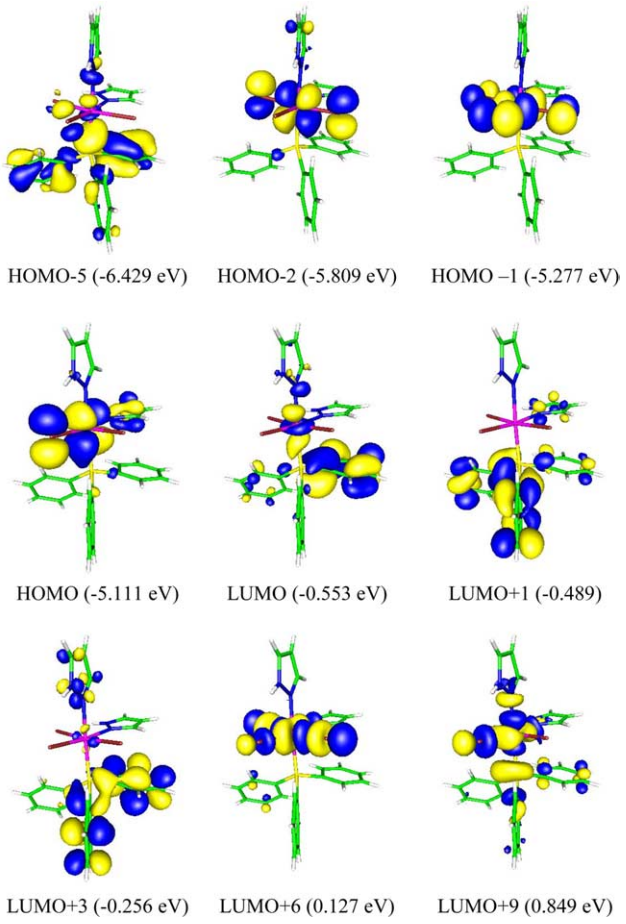

Fig. 4. The selected HOMO and LUMO orbitals with α-spin for **1**.

have a substantial contribution from the free electron pairs on the phosphorus atom. The LUMO+6 with α-spin and the LUMO+10 with β-spin are the antibonding orbital of $d_{z2} - \sigma_{Cl}$ character. The LUMO+9 with α-spin and the LUMO+11 with β-spin are the antibonding orbital of $d_{x^2-y^2} - \sigma_{Cl} - \sigma_N - \sigma_P$ character. LUMO, LUMO + 3 and LUMO + 1 with α-spin, and LUMO+2 and LUMO+3 with β-spin have large participation of p phosphorus orbitals.

3.5. UV–Vis spectra of *1* and *2* and electronic spectrum of *1* from the TDDFT calculations

The complexes under investigation are high spin systems. The calculations with TDDFT method for open-shell organic, inorganic and organometallic molecules are still limited but a few studies have already appeared and supported the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [29–33]. There are also several works performed with this method for 5d-metal (including rhenium complexes) in which good correlations between experimental and calculated results have been confirmed [34–40].

The energy and molar absorption coefficients of experimental absorption bands of **1** and **2** are presented in Table 4. The spin-allowed triplet–triplet electronic transitions of **1** calculated with the TDDFT method are presented in Table 5. Except for the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.01 are listed. The UV–Vis spectrum of **1** was calculated only to 260 nm. Nevertheless, on the basis of the calculated transitions for PPh_3 and [$ReCl_3(pzH)_3$] [41], it can be assumed that the experimental bands of **1** and **2** at energy below 240.0 nm correspond to intraligand $\pi \rightarrow \pi^*$ transitions in phosphine and pyrazole ligands. The solution spectra of pyrazole and PPh_3 exhibit intense absorption band at 231.6 and 217.6 nm, respectively, which can support this assignment.

The assignment of the calculated transitions to the experimental bands was based on the criterion of the energy and oscillator strength of the calculated transition. The long-wave experimental bands are of low intensity and they are compared to the calculated long-wave transitions with small oscillator strengths. The remaining absorption experimental bands are of much higher intensity and they are compared to the calculated transitions with high oscillator strengths.

The longest wave experimental bands of **1** and **2** (at 507.3 and 547.8 nm, respectively) may be attributed to the calculated transitions of $\pi_{Cl} \rightarrow d$ and $\pi_{Ph} \rightarrow d$ character (at 407.4 and 401.0 nm) and $d \rightarrow \pi^*_{Ph}$ character (at 404.5 nm) with small oscillator strengths. The transitions from π_{Ph} to metal d orbitals are mediated by phosphorus.

The next experimental bands of **1** and **2** (at 390.8 and 379.6 nm, respectively) can be assigned to the calculated transitions at 385.5 and 381.4 nm. They have MLCT ($d \rightarrow \pi^*_{pzH}$) character with small contribution of d–d

Table 4
The energy and molar absorption coefficients of experimental absorption bands for **1** and **2**

Band position (nm)	Band position (eV)	ε
1		
507.3	2.44	350
390.8	3.17	1040
331.1	3.74	1620
263.8	4.70	2200

200.1	6.20	7200
2		
547.8	2.26	400
379.6	3.27	1220
338.4	3.66	3700
269.0	4.61	5470
229.0	5.41	8910
213.0	5.82	7330

ε, molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$).

Table 5
The most important electronic transitions calculated with the TDDFT method for **1**

The most important orbital excitations		λ (nm)	E (eV)	f
α-spin	β-spin			
	H-5(π_{Cl}) → L(d)	407.4	3.04	0.0004
	H-2(π_{Ph}) → L(d)			
	H(d_{xy}) → L + 3(π^*_{Ph})	404.5	3.06	0.0028
	H(d_{xy}) → L + 8(π^*_{Ph})			
	H-3 (n_P + π_{Ph}) → L(d)	401.0	3.09	0.0080
	H(d_{xy}) → L + 4(π^*_{pzH})	385.5	3.22	0.0113
H(d_{xy}) → L + 6(d_{z2})	H(d_{xy}) → L + 2(π^*_{Ph})	381.4	3.25	0.0046
	H(d_{xy}) → L + 10(d_{z2})			
	H-1(π_{Ph}) → L(d_{xz})	376.1	3.30	0.0035
	H-4(π_{Ph}) → L(d_{xz})	355.3	3.49	0.0039
H(d_{xy}) → L(π^*_{Ph})		352.7	3.52	0.0033
	H-5(π_{Cl}) → L + 1(d_{yz})	351.2	3.53	0.0194
	H-2(π_{Ph}) → L + 1(d_{yz})			
H(d_{xy}) → L + 1(π^*_{Ph})		314.7	3.94	0.0266
H(d_{xy}) → L + 2(π^*_{pzH})		305.6	4.06	0.0491
	H-10(π_{Cl} + π_{pzH}) → L + 1(d_{yz})	283.7	4.37	0.0217
	H-9(π_{Cl} + π_{pzH} + π_{Ph} + n_p) → L + 1(d_{yz})			
	H-9(π_{Cl} + π_{pzH} + π_{Ph} + n_p) → L + 1(d_{yz})	280.9	4.41	0.0204
	H-6(π_{Ph}) → L + 1(d_{yz})			
H-2(d_{xz}) → L + 3(π^*_{Ph})	H-13(π_{pzH}) → L(d_{xz})	277.0	4.48	0.0253

electronic transitions. Owing to the small oscillator strengths, the three calculated transitions at 376.1, 355.3 and 352.7 nm of π_{Ph} → d and d → π^*_{Ph} character do not contribute significantly to the overall shape of the spectrum. In the experimental spectrum such small transitions are hidden under the more intense ones.

The experimental bands of **1** and **2** at 331.1 and 338.4 nm, respectively, are attributed to the calculated transitions at 351.2, 314.7 and 305.6 nm. The first one is a π_{Cl} → d(LMCT) transition, the two others have d → π^*_{pzH}(MLCT) character.

The absorption bands recorded at 263.8 and 269.0 nm for **1** and **2**, respectively, are assigned to the calculated transitions at 283.7, 280.9 and 277.0 nm with large oscillator strengths. They are of LMCT (π_{pzH} → d, π_{Cl} → d and π_{Ph} → d) character.

The LUMO + 1 and LUMO + 3 with α-spin and LUMO + 2 and LUMO + 3 orbitals with β-spin have a substantial admixture of phosphorus orbitals so the transitions from metal to π^*_{Ph} orbitals are mediated by phosphorus.

Abstract

The complex $[Ni(Tr^{Me,o\text{-}Py})_2]$ (**2**) {$Tr^{Me,o\text{-}Py}$ = hydrotris[1,4-dihydro-4-methyl-3-(2-pyridyl)-5-thioxo-1,2,4-triazolyl]borate} was synthesized and characterized by UV–Vis spectroscopy, ESI-mass spectrometry and X-ray crystallography. Complex **2** crystallizes in the tetragonal *I*-42d space group. The metal presents a slightly distorted octahedral geometry (N_4S_2 co-ordination) bound by two ligands that behave in the S,N/N′ co-ordination mode: one of the three arms of each tripod is bound to the metal with the thioxo group, the second chelates N/N′ with the triazoline and pyridine nitrogen atoms and the third does not participate in the metal co-ordination. Ni/$Tr^{Me,o\text{-}Py}$ complexation was studied by collecting visible spectra of 16 batch samples (10 ml) containing a fixed concentration of metal (9.994×10^{-4} mol dm^{-3}) with increasing concentrations of ligand up to Ni/L = 1/3 (L = $Tr^{Me,o\text{-}Py}$). For a Ni/L ratio of 1/2, ≈38% of NiL^+ and ≈56% of NiL_2 are present with respect to the total Ni(II) concentration. Conductivity (Λ_M range 112–55 ohm^{-1} cm^2 mole^{-1} in acetonitrile and Λ_M range 15–8 ohm^{-1} cm^2 mole^{-1} in DMF) and ESI-mass spectrometry results are consistent with a partial dissociation of **2** in acetonitrile and DMF solutions according to the equilibrium $NiL_2 = NiL^+ + L^-$ in agreement with the spectrophotometric titration results. Cyclic voltammetry performed on acetonitrile solutions of **2** reveals the electrochemical activity of the $Tr^{Me,o\text{-}Py}$ ligand, which undergoes irreversible oxidation and reduction processes at potential > +0.7 and ∼0 V, respectively. The occurrence of the Ni(II)/Ni(III) and Ni(II)/Ni(I) electrochemical events could not be determined.

1. Introduction

The introduction of the second generation of the hydrotris(pyrazolyl)borate ligand (Tp) was aimed at the study of the steric hindrance influence on the chemical properties of the Tp-metal complexes [1]. The steric bulk on the C^3 position of the pyrazolyl ring has a dramatic effect on the co-ordination geometry of the first row transition metal ions. In fact, tetrahedral geometry and ligand to metal ratio of 1:1 are usually found especially if the substituent on the pyrazolyl C^3 position is a *t*-Butyl group [2]. More recently, after the introduction of the softer hydrotris(methylthioxoimidazolyl)borate ligand (Tm) [3], the steric hindrance on the thioxoimidazolyl rings has been used as a 'tetrahedral enforcer' in order to obtain synthetic models of the liver alcohol dehydrogenase active site in which the zinc cation is in a tetrahedral and sulphur rich environment [4]. Another liver alcohol dehydrogenase model complex has been reported, in which the mixed hydro[pyrazolylbis(thioxoimodazolyl)]borate ligand (S,S,N donor) presents aromatic ring systems favouring the tetrahedral co-ordination at the metal [5].

A new development of the Tp chemistry has been obtained by the synthesis of ligands bearing donor groups on the pyrazolyl C^3 position in order to expand the co-ordination capabilities of the ligand and generate new co-ordination geometries [6]. A relevant example is offered by the [CoL][PF_6] (L = hydrotris[3-(2-pyridyl)pyrazol-1-yl]borate) complex in which the metal exhibits a trigonal prismatic geometry [7]. Despite many examples of Tp N-donor podand ligands with heavy metals and lanthanide cations, relatively few mono-nuclear structures with first row transition metals have been reported. The reason for this has been ascribed to the large cavity that such ligands present, resulting in the preferred formation of poly-nuclear species when small cations are involved [7,8].

At present time no structures of Tm ligand exhibiting a podand donor group have been described, and it seemed interesting to us to investigate the co-ordination capabilities of a tripodal ligand having a thioxo group and an N,N chelating system on every arm. This could be obtained by using a thioxotriazoline-3-(2-pyridyl) precursor for the synthesis of the tripodal ligand, Scheme 1. From a previous work it was apparent how the hydrotris(thioxotriazolyl)borate ligand could behave as an S_3 or N_3 donor depending on the nature of the metal ion [9]. The introduction of a 2-pyridyl group on the thioxotriazoline moiety may render the co-ordination modes of this ligand more unpredictable as they may span from the S_3, $(N/N')_3$ to the mixed $S_x(N/N')_{3-x}$ ($x = 1, 2$).

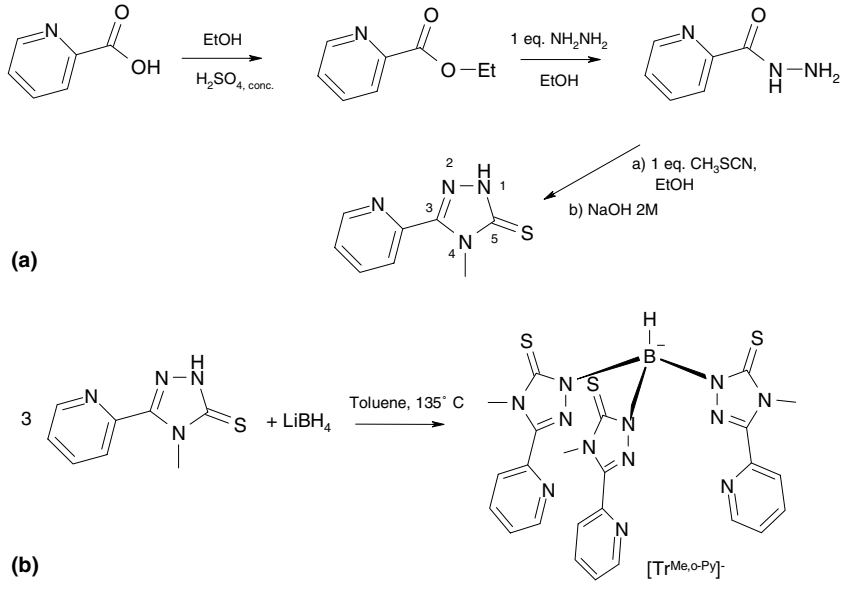
Nickel complexes have attracted much interest in bio-inorganic chemistry [10] as nickel has been shown to be present at the catalytic core of urease [11], [NiFe] hydrogenase [12], methyl-CoM reductase [13], carbon monoxide dehydrogenase [14], acethyl CoA synthase [15] and nickel superoxide dismutase [16]. With the exception of urease, which is an hydrolytic enzyme, the catalytic activity of nickel enzymes is essentially due to the redox activity of the nickel centers and to the accessibility of the +1, +2 and +3 metal oxidation states. The redox properties of those enzymes are controlled by the presence of S (cysteinate) and N donor atoms at the nickel sites and various metal complexes have been prepared in order to mimic the redox activity of [NiFe] hydrogenase [17].

Here we wish to report the synthesis, structure, complexation studies and electrochemical properties of the [$Ni(Tr^{Me,o\text{-}Py})_2$] complex {$Tr^{Me,o\text{-}Py}$ = hydrotris[thioxotriazolyl-3-(2-pyridyl)]borate}, in which the ligand exhibits the S,N/N′ coordination mode. We can anticipate that the redox activity of $Tr^{Me,o\text{-}Py}$ narrows the potential windows at which the metal-based redox processes can be observed. In fact, irreversible oxidation and reduction peaks occur at +0.72 and ~0 V, respectively, attributable to the ligand electrochemical activity.

2. Experimental

Solvents were dried and distilled before use. The compound 1,4-dihydro-4-methyl-3-(2-pyridyl)-5-thioxo-1,2,4-triazole has been prepared according to published procedures [18]. All other reagents are commercially available (Sigma–Aldrich) and were used as received.

The ^1H and ^{13}C NMR spectra were recorded on a Bruker Avance 300 spectrometer. Chemical shifts are reported in ppm referenced to residual solvent protons (DMSO-d_6, CD_3CN).



Scheme 1.

Mass spectra were obtained with a Micromass ZMD spectrometer. The mixtures were analyzed in negative and positive ionization modes by direct perfusion in ESI-MS interface; injection flow-rate = 20 μl/min; desolvation temperature = 150 °C; source block temperature = 80 °C; cone and desolvation gas flow-rates = 1.6 and 8.0 l/min, respectively; capillary = 3.0 kV; cone = 30 V; extractor = 3 V. Spectra were registered with a scansion time of 6 s.

Infrared spectra were recorded using KBr pellets from 4000 to 400 cm^{-1} on a Perkin–Elmer FT-IR Nexus spectrometer. Elemental analyses (C, H, N) were performed with a Carlo Erba EA 1108 automated analyser. Conductivity measurements were performed on a Crison microCM 2202 conductometer operating at 25 °C.

Cyclic voltammetry experiments were performed in a three-electrode cell with a Pt-disk as working electrode, a Pt-rod as counter electrode and a Ag/AgCl/KCl 0.1 M as reference electrode, by using a computerized electrochemical workstation consisting of an Autolab PGSTAT 20 potentiostat (Ecochemie, The Netherlands) controlled by the GPES 4.9 software. All measurements have been conducted in oxygen-free solutions, previously purged with N_2 for 2 min.

Magnetic susceptibility measurements were performed following Evans' method [19] using precision-made coaxial tubes (Wilmad). Cyclohexane (5% by volume) was used as internal standard in DMF-d_7. Molar susceptibilities were calculated according to

$$\chi_M = \left(\frac{3\Delta f}{2\pi f m} + \chi_0 + \frac{(d_0 - d_s)}{m}\chi_0\right)M, \quad (1)$$

where Δf is the susceptibility shift (Hz), f is the operating radio frequency (300×10^6 Hz) of the spectrometer, m is the concentration of the paramagnetic substance (grams per milliliter), χ_0 is susceptibility of the pure solvent and M is the solute molecular weight; d_0 and d_s are the densities of the pure solvent and solution, respectively. The third term in Eq. (1) has been neglected in the calculation [20]. The value of χ_0 was estimated from Pascal's constants [21]. χ_M values were corrected for the ligand diamagnetic susceptibility derived from Pascal's constants (-198×10^{-6} cgs unit).

Visible spectra were recorded on a Perkin–Elmer Lambda 25 spectrophotometer (range 200–1100 nm) using matched cells of 4 cm pathlength. Stock solutions of $Li(Tr^{Me,o\text{-}Py})$ (9.990×10^{-3} mol dm^{-3}) and of $NiCl_2 \cdot 6H_2O$ (9.994×10^{-3} mol dm^{-3}) in DMF were prepared by weight and used immediately. Complexation was studied by collecting visible spectra of 16 batch samples (10 ml) containing a fixed concentration of metal (9.994×10^{-4} mol dm^{-3}) with increasing concentrations of ligand up to Ni/L = 1/3 ($L = Tr^{Me,o\text{-}Py}$). Absorption spectra of both ligand and metal solutions were registered and used as fixed spectra. Stability constants were calculated by means of the SPECFIT program [22].

2.1. $[Li(Tr^{Me,o\text{-}Py})]$ (**1**)

Under an atmosphere of purified nitrogen, 1,4-dihydro-4-methyl-3-(2-pyridyl)-5-thioxo-1,2,4-triazole (5.00 g, 26.00 mmol) and lithium tetrahydroborate (0.189 g, 8.67 mmol) were mixed together in 80 ml of toluene in a round bottomed flask connected to a reflux condenser and to an oil bubbler. The yellow suspension was stirred at 135 °C for four days. The mixture was filtered, washed with hot toluene (3 × 20 ml), THF (2 × 20 ml) and vacuum dried yielding a pale yellow product (2.52 g, 49%). *Anal.* Calc. for $C_{24}H_{22}BN_{12}S_3Li$: C, 48.65; H, 3.74; N, 28.37. Found: C, 49.15; H, 3.42; N, 27.86%. ESI-MS (CH_3CN/MeOH, 1/1) m/z, %: 1177.4, 3, $[L_2Li]^-$; 1193.2, 7, $[L_2Na]^-$; 585.1, 100, $[L]^-$. IR data (KBr disks cm^{-1}): 3074w, 3048w, 2945w, 2531w [ν(B-H)], 1591s, 1476s, 1408s, 1337s, 1264s, 1074s, 1006m, 799s, 697m. ^1H NMR (300 MHz, DMSO-d_6) δ (ppm): 3.65 (s, 9H, CH_3), 5.18 (b, 1H, B-*H*), 7.31 (m, 3H, Py), 7.63 (t, $J = 7.8$ Hz, 3H, Py), 7.79 (d, $J = 7.8$ Hz, 3H, Py), 8.56 (d, $J = 4.5$ Hz, 3H, Py) (b = broad). ^{13}C NMR (75 MHz, DMSO-d_6) ppm: 32.35 (CH_3), 123.71 (CH, Py), 123.86 (CH, Py), 136.95 (CH, Py), 146.70 (C quat.), 147.29 (C quat.), 148.56 (CH, Py), 170.90 (C = S).

2.2. $[Ni(Tr^{Me,o\text{-}Py})_2]$ (**2**)

A mixture of $NiCl_2 \cdot 6H_2O$ (0.125 g, 0.526 mmol) and **1** (0.306 g, 0.516 mmol) in methanol (30 ml) was heated to reflux. A green precipitate formed after few minutes. After 1 h the mixture was allowed to cool to room temperature and filtered. The green solid was washed with 5 ml of hot methanol, vacuum dried and collected (0.207 g, 65%). *Anal.* Calc. for $C_{48}H_{44}B_2N_{24}S_6Ni$: C, 46.88; H, 3.61; N, 27.34. Found: C, 46.00; H, 3.89; N, 26.88%. ESI-MS (CH_3CN/MeOH, 1/1) m/z, %: positive ion mode, 1267.8, 100, $[(NiL_2)K]^+$, 1252.9, 20, $[(NiL_2)Na]^+$, 643, 70, $[NiL]^+$, 585.5, 8, $[L]^+$; negative ion mode, 585.1, 15, $[L]^-$. IR data (KBr disk, cm^{-1}): 3048w, 2947w, 2920w, 2512w [ν(B-H)], 1607m, 1590m, 1512m, 1474s, 1404s, 1342s, 1215m, 1076s, 802m, 793m. ^1H NMR (300 MHz, CD_3CN) δ (ppm): 3.58, 7.20, 7.56, 7.97, 8.33, 8.77, all signals were broad. The product was recrystallized from a dimethylsulfoxide solution from which crystals suitable for X-ray structure determination were obtained, corresponding to $[Ni(Tr^{Me,o\text{-}Py})_2] \times 1.4$ DMSO (**2a**).

2.3. X-ray crystallography

A summary of data collection and structure refinement for **2a** are reported in Table 1. Single crystal data were collected with a *Bruker AXS Smart 1000* area detector diffractometer (Mo Kα; $\lambda = 0.71073$ Å). Empirical absorption correction was applied using the program SADABS [23] (maximum and minimum absorption

$R_1 = \sum ||F_o| - |F_c||/|F_o|, wR_2 = [\sum[w(F_o^2 - F_c^2)^2]/[w(F_o^2)^2]]^{1/2}, w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = [\max(F_o^2, 0) + 2F_c^2]/3$.

correction coefficient: 1.000 and 0.790). The structure was solved by direct methods (SIR97) [24] and refined with full-matrix least-squares (SHELXL-97) [25], using the Wingx software package [26]. Non-hydrogen atoms were refined anisotropically; the B-*H* hydrogen atom was found and refined whereas the remaining hydrogen atoms were placed at their calculated positions. DMSO solvent molecules were severely disordered and were treated using the SQUEEZE PLATON program giving approximately 11 DMSO molecules per unit cell (469 electrons/cell) [27]. The pyridine ring of the sulfur-co-ordinated triazoline was found disordered in two positions with site occupancy factors of 0.5. The crystal was twinned (Flack parameter 0.46(2) [28]) and was refined with the Twin law 100, 010, 00–1. The programs Parst [29,30] and ORTEP for Windows [31] were also used. Full tables of bond lengths and angles, atomic positional parameters, isotropic and anisotropic displacement parameters are given in the Supplementary material.

3. Results and discussion

The synthesis of the thioxotriazoline and of the $Tr^{Me,o\text{-}Py}$ ligand is outlined in Scheme 1. This procedure allows for the synthesis of thioxotriazolines variously substituted in the third and fourth positions by using appropriate carboxylic acids and isothiocyanates as starting materials. The $[Ni(Tr^{Me,o\text{-}Py})_2]$ complex was prepared in methanol by reacting $[Li(Tr^{Me,o\text{-}Py})]$ and $NiCl_2\cdot 6H_2O$ and even if equimolar amounts of the reagents were employed, a complex of ligand/metal ratio of 2/1 was always recovered. This complex can be recrystallized from dimethylformamide, dimethylsulfoxide and acetonitrile. The X-ray structural analysis performed on crystals obtained from each one of these solvents revealed the same molecular structure together with crystallization solvent molecules.

3.1. Crystal structure of $[Ni(Tr^{Me,o\text{-}Py})_2]$

The ORTEP diagram of the complex is depicted in Fig. 1. Selected bond lengths and angles are reported in Table 2. The complex is octahedral and the metal lies on a crystallographic C_2 axis co-ordinated by four nitrogen and two sulfur atoms from two different ligands. The overall co-ordination is of the type N_4S_2 and the two

[a] $= 1 - x + 1/2, y, -z + 3/4$.

sulfur atoms are in *cis* position. The complex is chiral but both enantiomers are present in the structure. The Ni–S distance is of 2.396(1) Å and the Ni–N distances [2.118(3) (*N*-triazoline) and 2.098(3) (*N*-pyridine) Å] are nearly equivalent despite the triazoline nitrogen atom is *trans* to the thioxo group. Every arm of the ligand displays a different behaviour, as one is S co-ordinated, the second is chelating N,N′ whereas the third is not involved in the metal co-ordination. The thioxo group that is bound to the metal presents C=S bond length longer than the other two thioxo groups, Table 2. In the complex, the two ligands are arranged in a *mer* configuration with the free arms facing each other. This results in an unusual co-ordination mode if the $Tr^{Me,o\text{-}Py}$ ligand is compared to the Tp and Tm ligands, which usually act as N_3 and S_3 tripods, respectively. The reason can be ascribed to the presence of the pendant 2-pyridyl group, which introduces an additional binding site for every arm of the ligand. One of the alternative co-ordination modes of $Tr^{Me,o\text{-}Py}$ could have been the $(N/N')_3$ trigonal prismatic, where each arm of the ligand would chelate the metal through the pyridine and triazoline nitrogen atoms, as described for hydrotris[(2-pyridyl)pyrazolyl)borato [6,7]. Nevertheless, there are two major drawbacks for the trigonal prismatic geometry: (a) no sulphur atom would be involved in the metal binding and (b) this scenario is more likely for bigger metals such as the lanthanides that possess an appropriate dimension to be located into the ligand pocket, whereas for the first row transition metals, poly-nuclear complexes are preferentially formed [6,7,8b]. In the present case, the contemporary presence of the thioxo groups and the N/N′ chelating system seem to dictate the S,N/N′ ligand co-ordination giving rise to a dissymmetric ligand binding. Additional results with other metal ions are necessary to draw definitive conclusions about the co-ordination properties of $Tr^{Me,o\text{-}Py}$.

The formation constants for the complexes NiL^+ and NiL_2 were determined by collecting visible spectra of DMF solutions containing different Ni/L ratios. The obtained log β values are: $\log \beta_{[NiL]} = 3.99(6)$ and $\log \beta_{[NiL2]} = 7.47(4)$. A representative distribution diagram is reported in Fig. 2 and the calculated spectra for the complexes are reported in Fig. 3. For a Ni/L ratio of 1/2, as in the case of **2** dissolved in DMF, the concentration of the species with respect to the total Ni(II) concentration is as follow: $[NiL^+] \approx 38\%$ and $[NiL_2] \approx 54\%$.

In order to better understand the complex behaviour in solution, the molar conductivity of **2** has been measured in dry acetonitrile (concentration range $= 1.2 \times 10^{-5}$–4.9×10^{-5} M) and DMF (concentration range $= 2.4 \times 10^{-4}$–9.8×10^{-4} M) giving molar conductivity Λ_M in the range 112–55 $ohm^{-1}\,cm^2\,mole^{-1}$ (acetonitrile) and 15–8 $ohm^{-1}\,cm^2\,mole^{-1}$ (DMF), respectively. This is in accordance with the spectrophotometric titrations, which indicate a partial dissociation of **2** in DMF, according to the following equilibrium:

$$NiL_2 \leftrightarrows NiL^+ + L^-$$

The Λ_M values are in fact smaller than the lower limit of the range reported for 1:1 electrolytes in acetonitrile and DMF [32] but they are too high for a complex behaving as a non-electrolyte. This is also confirmed by ESI-MS spectrometry performed on one of the samples (conc. $= 2.4 \times 10^{-5}$ M, acetonitrile as solvent) used for the conductivity measurements, which shows the peaks corresponding to the ionic species NiL^+ and L^-, together with the un-dissociated form NiL_2 (see Section 2).

Magnetic moment (μ_{eff}) of 3.6 B.M has been observed for DMF-d_7 solutions of **2** over the 296–335 K temperature range. This unusually high value for a Ni(II) ion in an octahedral field may be explained considering the dissociation equilibrium where the NiL^+ species is in a tetrahedral geometry. This can be achieved

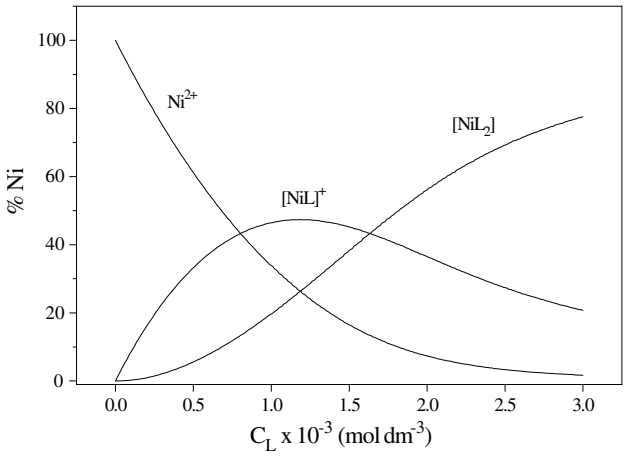

Fig. 2. Distribution diagram of the Ni/L system ($L = Tr^{Me,o\text{-}Py}$) as a function of the ligand concentration ($C_{Ni} = 1 \times 10^{-3}$ mol dm^{-3}).

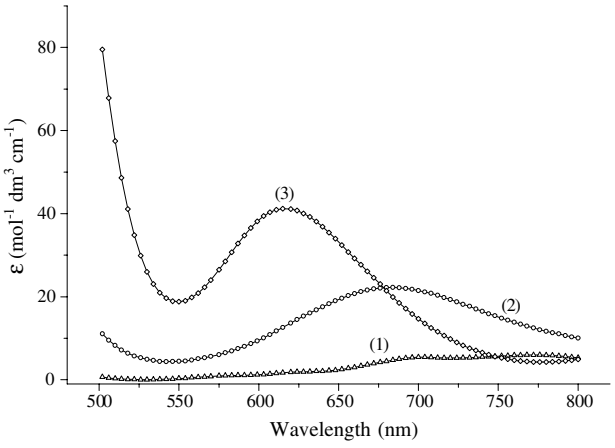

Fig. 3. Calculated spectra of the species Ni^{2+} (1), $[NiL]^+$ (2), $[NiL_2]$ (3).

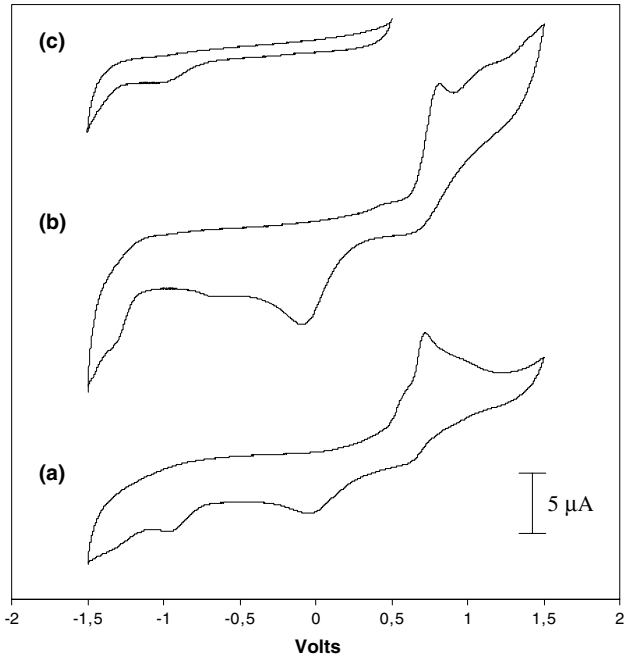

Fig. 4. Cyclic voltammograms (third scans) of saturated solutions of **1** (a) and **2** (b,c) in acetonitrile containing $TBABF_4$ as supporting electrolyte (0.1 M). Reference electrode: Ag/AgCl/KCl 0.1 M. Scan rate: 0.1 V/s.

by substitution of a ligand molecule in NiL_2 with a DMF solvent molecule. In fact, reported literature values of μ_{eff} for octahedral Ni(II) complexes fall in the range 2.8–3.3 B.M. whereas for tetrahedral Ni(II) complexes this range is usually 3.0–4.0 B.M. due to a greater spin-orbit coupling [21a,33]. According to the distribution diagram (Fig. 2), upon dissolution of **2** in DMF, the NiL^+ species occurs in ≈38% of the total metal and it may be reasonable to assume that it is a $NiL(DMF)^+$ complex exhibiting a tetrahedral geometry.

Cyclic voltammograms (acetonitrile solutions) for **1** and **2** were recorded in the −1.5 to +1.5 V potential window and starting from the Open Circuit Potential (OCP), Fig. 4. The voltammograms of **1** shows two irreversible oxidation waves at +0.72 and +1.10 V whereas for **2** these processes occur at +0.82 and +1.10 V. It seems that in the Ni(II) complex the ligand is more stabilized as it is oxidized at a slightly higher potential. The irreversible reduction process at ∼0 V is not observed when the scans are operated in the −1.5/+0.5 V potential window (Fig. 4c) and it can be concluded that it corresponds to the reduction of a species generated during the oxidation processes at potentials above +0.75 V. Furthermore, holding the potential at +0.8 V for 5 min and reversing the scan toward the cathodic direction increases only the peak at ∼0 V and confirms this assumption. From the comparison of the voltammograms of **1** and **2** it emerges that (a) the electrochemical processes are mainly due to ligand oxidation/reduction and (b) the potential window where metal-based redox processes can be observed with this ligand is limited approximately to the 0/+0.8 V range. Unfortunately, the position of the Ni(II)/Ni(III) and Ni(II)/Ni(I) couples cannot be determined. This is not surprising as in many octahedral Ni(II) complexes exhibiting mixed N/S coordination the Ni(II)/Ni(III) couple is usually found at potentials greater than +0.8 V and the Ni(II)/Ni(I) couple appears at negative potentials [17a,34], values at which the $Tr^{Me,o\text{-}Py}$ ligand is already electrochemically active.

4. Supplementary material

Listings of atomic coordinates of the non-hydrogen and hydrogen atoms, anisotropic displacement parameters and bond lengths and angles for **2a** are given in the supplementary materials. Abstract

Trinuclear $Ni_3S_4N_3$ clusters were obtained from (1*S*,2*S*)-1-monothiasulfato-1-phenyl-2-(methylammoniumyl)propane (tpmp). Three homochiral ligand molecules together with three Ni^{II} ions give rise to a cone-shaped cluster topped by a μ_3-sulfide ion. Each Ni^{II} is in a distorted planar geometry. X-ray structural studies showed that in three cases the three phenyl groups form the rim of a cage which contains R-OSO_3 ($R = C_2H_5$, C_3H_7) or nitrate anions. The alkyl sulfates were generated during the synthesis reaction, and are hydrogen-bonded through the oxygen atoms to the amine nitrogen atoms. The corresponding compound with the methyl sulfate anion ($MeOSO_3$) reacts with Fe^{III} nitrate to form a similar compound in which the nitrate anion occupies the cavity and its crystals were analyzed by X-ray diffraction.

1. Introduction

The chemistry and structure of nickel complexes with sulfur ligands has attracted much interest due to the biological functions of nickel–sulfur sites in enzymes [1–10]. Most of the synthetic models of such enzymes contain mono- and binuclear nickel(II) compounds with thiolate, thioester and amines [11–16]. However, some examples are known which contain trinuclear clusters and clusters of higher nuclearity [17]. We have been interested in optically active aminoalcohol and aminothiol pseudoephedrine derivatives, because of the influence of their stereochemistry on the coordination properties [18–21]. Their flexibility and the presence of different potential coordinating sites permit the formation of mono- and trinuclear coordination compounds. The *threo* stereochemistry of the pseudoephedrine derivative is important in the formation of the trinuclear complex since *erythro* isomers do not form analogous compounds [22,23]. Therefore, we investigated the coordination behaviour of 1(*S*),2(*S*)-1-monothiosulfato-1-phenyl-2-methylammoniumylpropane (tpmp) towards nickel(II), including the influence of the solvent in the synthesis reaction, and found that trinuclear nickel [17,24–29] derivatives were formed. Here, we discuss the formation and structures of new four optically active compounds $[Ni_3(pmp)_3(\mu_3\text{-}S)]$ (CH_3OSO_3) (**2**), $[Ni_3\text{-}(pmp)_3(\mu_3\text{-}S)]$ $(C_2H_5OSO_3)$ (**3**), $[Ni_3(pmp)_3(\mu_3\text{-}S)]$ $(C_3H_7OSO_3)$ (**4**) and $[Ni_3(pmp)_3(\mu_3\text{-}S)](NO_3)$ (**5**). parent compound, ephedrine, without sulfur was designated pmp.

2. Experimental

2.1. General remarks

All chemicals were reagent grade (Aldrich) and used without further purification. Solvents (Baker) were dried by standard procedures and freshly distilled under dinitrogen before use. IR spectra of solid samples in KBr pellets (4000–400 cm^{-1}) were obtained using a Perkin–Elmer 599B FT-IR spectrometer. UV–Vis spectra (diffuse reflectance, 40 000–4000 cm^{-1}) were recorded on a Cary-5E spectrometer. Elemental analyses were carried out with a Fisons EA 1108 analyser. Magnetic susceptibility measurements of powdered samples at room temperature were recorded on a Johnson–Matthey DG8 5HJ balance using the Gouy method. A Jeol GSX-270 spectrometer was used to obtain ^{1}H and ^{13}C NMR spectra, and a Bruker 300 for ^{15}N NMR spectra.

Details of the X-ray structural analysis, crystal data and refinement are given in Table 1. Diffraction data for compounds **3** and **5** were collected on a Nonius kappa CCD diffractometer in the hemisphere-scan mode and compound **4** on a Siemens-P4 diffractometer with CCD. The structures were solved and refined using standard methods [30,31], Crystals for compound **3** and SHELXL-97 for **4** and **5** without restrains or constraints, applying an adequate weighting scheme and an extinction correction during the least-squares cycle. Non H-atoms were refined anisotropically, while H-atoms were refined using a riding model and fixed isotropic thermal parameters. No significant residuals were observed in the final difference maps. The chiral character of the space groups were confirmed on the basis of Wilson's statistics and successful refinement. The absolute configurations were determined from refinement of the Flack parameter [32], $[Ni_3(pmp)_3(\mu_3\text{-}S)](C_2H_5OSO_3)$ (**3**) yielding $x = 0.10(3)$, $[Ni_3(pmp)_3(\mu_3\text{-}S)](C_3H_7OSO_3)$ (**4**) yielding $x = 0.04(3)$, $[Ni_3(pmp)_3(\mu_3\text{-}S)](NO_3)$ (**5**) yielding $x = 0.005(12)$, and the expected configuration for the pmp moiety.

[a] R_{int}, R_1, wR_2, and S are defined as follows: $R_{int} = \sum |F_o^2 - \langle F_o^2 \rangle| / \sum F_o^2$, $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$, $wR_2 = \left[\sum w(F_o^2 - F_c^2)^2 / \sum (wF_o^2)^2\right]^{1/2}$, $S = \left[\sum w(F_o^2 - F_c^2)^2 / (m-n)\right]^{1/2}$.

2.2. Synthesis of (1S,2S)-1-monothiasulfato-1-phenyl-2-(methylammoniumyl)propane, (tpmp) (1) [33]

To a solution of (1*S*,2*S*)-1-chloro-1-phenyl-2-(methylamino)propane hydrochloride (4.49 g, 19.9 mmol) in dry ethanol (40 cm^3), sodium thiosulfate (3.78 g, 23.9 mmol) was added and the mixture was heated under reflux for 3 h. Then the reaction mixture was cooled to 0 °C and the sulfate derivative allowed to precipitate. It was filtered off and washed with ethanol and cold water. Yield 3.26 g, 75%, m.p. 180–182 °C. IR (ν_{max}/cm^{-1}) 1228 ($\nu_{as}RS–SO_3^-$), 1026 ($\nu_sRS–SO_3^-$), 1200 ($\nu_{as}R_2NH_2^+$). Found: C, 44.7; H, 6.0; N, 5.25; S, 24.0. $C_{10}H_{15}NO_3S_2$ requires: C, 46.0; H, 5.80; N, 5.35; S, 24.5%. $[\alpha]_D = -146.3°$ ($c = 15.0$ mg/10 cm^3, DMSO, $b = 1$ dm).

2.3. Synthesis of [Ni3(pmp)3(μ3-S)](CH3OSO3) (2)

To a solution of tpmp (2.012 g, 7.7 mmol) in methanol (50 cm^3) was added a solution which contained $Ni(CH_3COO)_2 \cdot 4H_2O$ (1.918 g, 7.7 mmol) in methanol (50 cm^3). The mixture was stirred to obtain an homogeneous solution. After 15 days, dark brown crystals were isolated. Yield 0.33 g, 15%. IR (ν_{max}/cm^{-1}) 1237 ($\nu_{as}RO–SO_3^-$), 1007 ($\nu_sRO–SO_3^-$), 1211 ($\nu_{as}R_2NH_2^+$), 579 (νM–S). Found: C, 43.60; H, 5.99; N, 4.80; S, 19.10. $C_{31}H_{45}N_3Ni_3O_4S_5$ requires: C, 43.28; H, 5.27; N, 4.88; S, 18.64%.

2.4. Synthesis of [Ni3(pmp)3(μ3-S)] (C2H5OSO3) (3)

A solution of $Ni(CH_3COO)_2 \cdot 4H_2O$ (0.266 g, 1.07 mmol) in ethanol (20 cm^3) was added to a stirred solution of tpmp (0.264 g, 1.07 mmol) in ethanol (30 cm^3). The mixture was stirred at room temperature for 30 min and filtered, and dark-brown crystals were obtained from the filtrate. Yield 0.040 g, 15%. IR (ν_{max}/cm^{-1}) 1016 ($\nu_sRO–SO_3^-$), 1236 ($\nu_{as}RO–SO_3^-$), 1206 ($\nu_{as}R_2NH_2^+$), 577 (νM–S), Found: C, 43.80; H, 5.45; N, 4.80; S, 18.60. $C_{32}H_{47}N_3Ni_3O_4S_5$ requires: C, 43.95; H, 5.42; N, 4.81; S, 18.34%.

2.5. Synthesis of [Ni3(pmp)3(μ3-S)] (C3H7OSO3) (4)

This compound was prepared analogously to **3**, using propanol as solvent. Yield 0.162 g, 30%. IR (ν_{max}/cm^{-1}) 1037 ($\nu_sRO–SO_3^-$), 1234 ($\nu_{as}RO–SO_3^-$), 1203 ($\nu_{as}R_2NH_2^+$), 577 (νM–S). Found: C, 44.50; H, 5.50; N, 4.70; S, 18.20. $C_{33}H_{49}Ni_3N_3O_4S_5$ requires: C, 44.6; H, 5.55: N, 4.75; S, 18.10%.

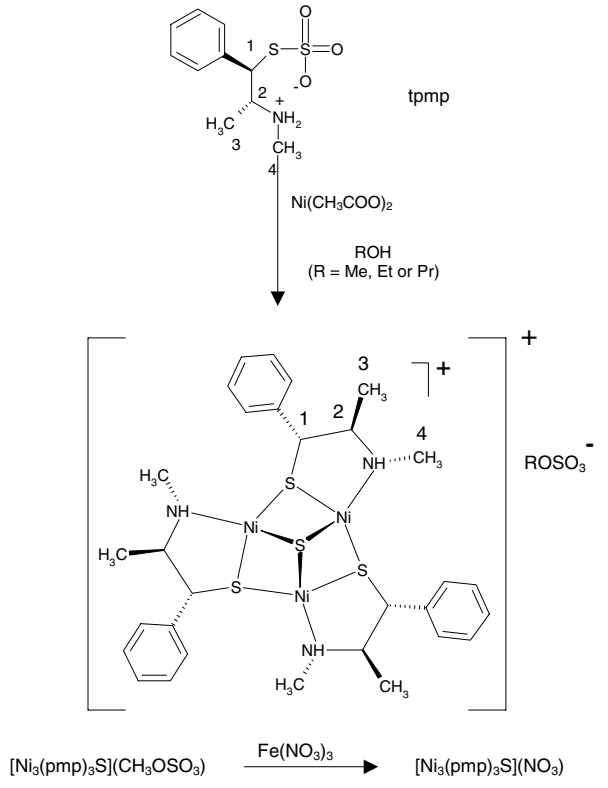
2.6. Synthesis of [Ni3(pmp)3(μ3-S)](NO3) (5)

A solution of $[Ni_3(pmp)_3(\mu_3\text{-}S)](CH_3OSO_3)$ (72 mg, 84 mmol) in $CHCl_3$ (4.0 cm^3) was added to a stirred solution of $Fe(NO_3)_3 \cdot 9H_2O$ (80 mg, 20 mmol) in ethanol (4.0 cm^3). The mixture was stirred at room temperature and then the excess of metal salts were filtered. Dark-brown cubic crystals were obtained from the filtrate. The yield was very low, 12.2 mg (18%), and was not enough to carry on further spectroscopic characterization. Found: C, 44.75; H, 5.25; N, 6.80; S, 15.80. $C_{30}H_{42}Ni_3N_4O_3S_4$ requires: C, 44.4; H, 5.20; N, 6.90; S, 15.8%.

3. Results and discussion

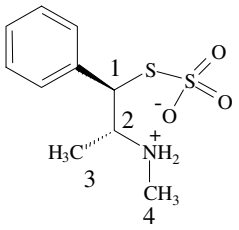
Scheme 1 shows the synthetic routes used in this work. During the synthesis of our new complexes, the alcohol solvents react with the tpmp to cleave the S–S bond and generate the anions $ROSO_3^-$ (R = Pr, Et or Me) and a cationic cluster. The positive charge should be delocalized on the Ni_3S_4 core. All four new compounds were analysed as $[Ni_3(pmp)_3(\mu_3\text{-}S)]X$ ($X^- = NO_3$ or $ROSO_3$, where R is Me, Et or Pr).

The IR spectrum of tpmp shows the ν_{as} and ν_s modes of the $RO–SO_3^-$ group at 1228 and 1026 cm^{-1}. These shifted to 1211 and 1007 cm^{-1} for **2**, 1236 and 1016 cm^{-1} for **3**, and 1234 and 1037 cm^{-1} for **4**. All three compounds (**2**–**4**) have bands assignable to ν(M–S) at ca. 578 cm^{-1}.



Scheme 1. General synthesis of triangular trinuclear $Ni_3S_4N_3$ clusters obtained from (1*S*,2*S*)-1-monothiasulfato-1-phenyl-2-(methylammoniumyl) propane (tpmp) and $Ni(CH_3COO)_2$.

Table 2
^{1}H NMR and ^{13}C NMR chemical shifts (δ, ppm) in $CDCl_3$ for compounds **3**–**5**



Compounds	H1	H2	H3	N–CH_3	C_6H_5
tpmp	4.42(d, $J = 8.7$ Hz)	3.81(m)	1.06(d, $J = 6.5$ Hz)	2.34	7.26–7.35
3	4.81	2.49	1.00	2.26	7.24–7.37
4	4.86 (d, $J = 11.1$ Hz)	2.46	1.00 (d, $J = 6.2$ Hz)	2.28	7.23–7.40
5	4.88	2.49	1.01	2.23	7.28–7.39
Compounds	C1	C2	C3	C4	C_6H_5
	54.7	59.0	13.9	31.1	$C_i = 138.8$, $C_o = 128.6$ $C_m = 129.2$, $C_p = 128.2$
3	54.1	72.2	15.2	41.1	$C_i = 141.0$, $C_o = 128.4$ $C_m = 128.8$, $C_p = 127.7$
4	54.1	72.2	15.6	41.0	$C_i = 141.1$, $C_o = 128.4$ $C_m = 128.7$, $C_p = 127.6$
5	54.2	72.3	15.7	41.1	$C_i = 141.1$, $C_o = 128.5$ $C_m = 128.8$, $C_p = 127.7$

Complexes **2**–**4** are diamagnetic in the solid state and in solution, and have comparable ^{1}H and ^{13}C NMR spectra (Table 2) [33]. An HETCOR experiment was carried out to correctly assign the chemical shifts for all compounds. Protons have similar shifts in the tpmp ligand and its coordination compounds. Signals for C2 and C3 are shifted to higher frequency on coordination of the amine to the nickel, by 13.2 and 10.0 ppm with respect to tpmp. There are new signals at 55.9 ppm for **2**, 64.3 and 15.3 ppm for **3** and 70.6, 23.0 and 10.6 ppm for **4** which were assigned to alkyl sulfate groups. The ^{15}N NMR spectra show only one signal characteristic of the quaternary amino group for each compound, at −364.2, −349.5 and −363.9 ppm for **2**, **3** and **4**, respectively.

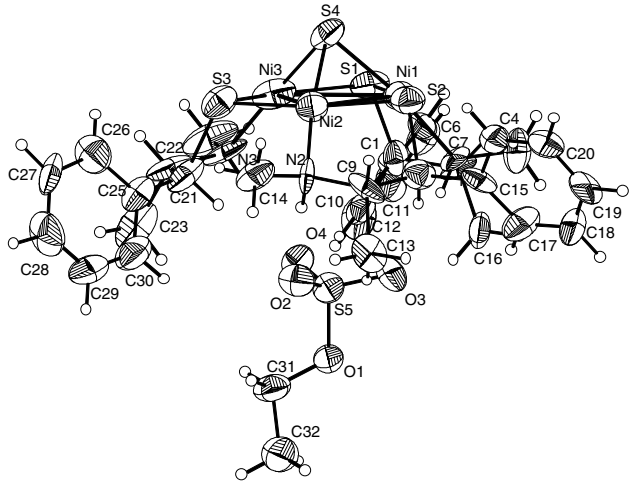


Fig. 1. ORTEP diagram for compound of $[Ni_3(pmp)_3(\mu_3\text{-}S)](C_2H_5OSO_3)$ (**3**). Displacement ellipsods are drawn at the 50% probability level and hydrogen atoms are shown as small spheres of arbitrary radii. The ethylsulfate molecule is on the rim of the cage formed by the three phenyl groups.

3.1. Crystal structures

The crystal structures of compounds **3** and **5** are presented in Figs. 1 and 2. Compound **4** has a structure very similar to that of **3**. Selected bonds distances and angles for all three structures are listed in Tables 3 and 4.

All the compounds contain the same $Ni_3S_4N_3$ cluster, Fig. 3, formed from three nickel atoms arranged in an equilateral triangle, which is capped on one face by a μ_3-sulfide ion. This core has three pendant five membered rings forming a cone shaped molecule with the capped sulfur at the apex. Each triangular edge is also bridged by a sulfur atom, which is part of the thia-pseudoephedrine, pmp. In every case, each nickel atom is also bonded to the nitrogen atom of the pmp. Since compound **5** is formed directly from compound **2**, it is likely that **2** possesses the same structure.

The phenyl groups of the three pmp molecules are so oriented as to form a cylindrical cavity which is closed at one end by the Ni_3S_4 cluster. In all three

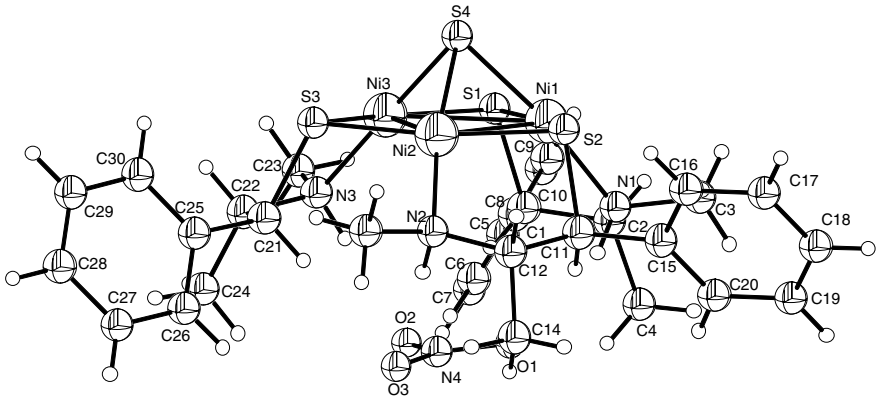

Fig. 2. ORTEP diagram for compound of $[Ni_3(pmp)_3(\mu_3\text{-}S)](NO_3)$ **5**. Displacement ellipsods are drawn at the 50% probability level and hydrogen atoms are shown as small spheres of arbitrary radii. The nitrate anion is lodged in the cavity.

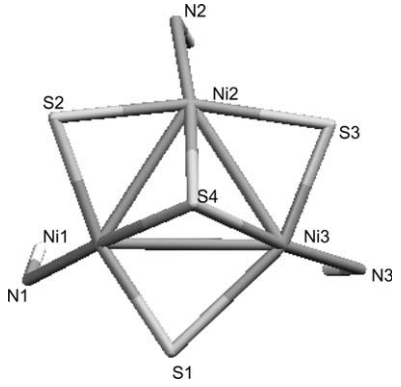

Fig. 3. Scheme showing the $Ni_3S_4N_3$ cluster in compound $[Ni_3(pmp)_3(\mu_3\text{-}S)]$ $(C_3H_7OSO_3)$ **4**.

structures the counter ion, $EtOSO_3^-$, $PrOSO_3^-$ or NO_3^-, is bound into the cavity by strong hydrogen bonds [34]. For example, in compound **4** each oxygen atom is hydrogen bonded to a N–H (N–H···O 2.089–2.149 Å) and also interacts with a benzylic C–H hydrogen (C–H···O 2.472–2.717 Å). Compound **5** (Fig. 4), contains a planar nitrate group (N–O 1.232(6)–1.248(6) Å; O–N–O 118.0(5)–121.6(5)°) with shorter N–H···O and C–H···O hydrogen bonds (2.111–2.185 and 2.370–2.413 Å, respectively).

There are at least nine compounds, including those described here, that contain the Ni_3S_4 nucleus, with the ligands (*R*,*S*)-2-[(2-mercapto-1-methylamino)ethylphenol)] [24], SMe [25], SPh [26,27], *t*-butylthiolato [28] and *o*-$(SCH_2)_2C_6H_4$) [29]. Nevertheless all nine have very similar geometries, the special characteristic of the pseudoephedrine in our compounds is its potential for hydrogen-bonding that allows the binding of the oxoanions within the cavity.

The Ni_3S_4 cluster is not significantly different in any of the compounds (**3**–**5**) or those cited in the literature. The three nickel atoms and the capping sulfur atom form a distorted tetrahedron, but perhaps the structure

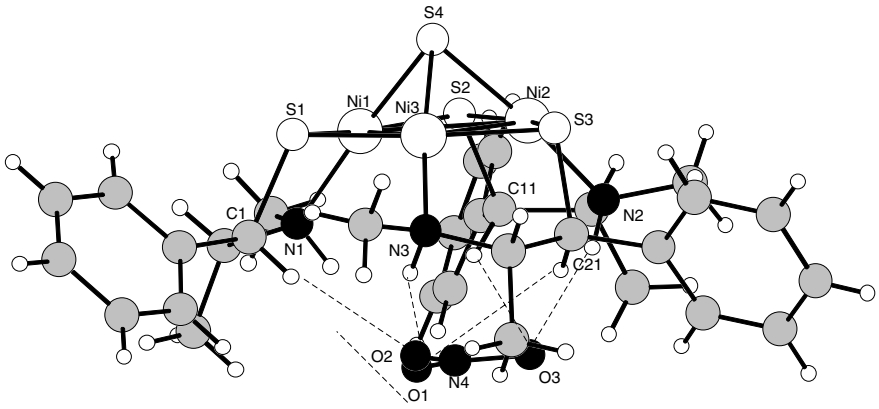

Fig. 4. Scheme of $[Ni_3(pmp)_3(\mu_3\text{-}S)](NO_3)$ **5** showing the principal hydrogen bonds between the N–H and C–H groups of pmp and oxygen atoms of the nitrate anion.

is best described as a relatively planar Ni_3S_3 array capped upon one side by a μ_3-S ion bonded directly to all three nickel ions. This has the effect of forcing other ligands attached to the nickels out of the Ni_3S_3 plane and in a direction away from the capping sulfide. This occurs with large ligands such as our own, as well as with small ligands such as SMe [25]. The three bridging sulfur atoms are little removed from the plane of the nickel atoms, so that a single plane contains not just the three nickel ions but the complete Ni_3S_3 moiety. With monodentate ligands the Ni_3S_3 unit is trigonal [25–29]. However, when bidentate ligands bridge the two positions, they introduce some distortion and two different S–Ni bond lengths, the S–Ni bonds of the five membered chelate ring being the shorter, for example 2.171(4) and 2.219(4) for the compound with (*R*,*S*)-2-[(2-mercapto-1-methylamino)ethylphenol] [24] The distances observed in our compounds are 2.158(3) and 2.513(3) Å for **3**, 2.152(3) and 2.393(3) Å for **4**, and 2.150(1) and 2.242(1) Å for **5**.

The reported Ni-μ_3S distances are all within the range 2.166(1)–2.196(3) Å, which is not a large variation, and are similar to those of our compounds. In fact, for all the recorded compounds where the μ_2-S atoms may or may not be a part of a chelating system and where the other donor atom on the nickel may be S or N or C, this range scarcely changes. The coordination about the nickel can be described as approximately square-planar. The angle S(apex)–Ni–X (X = S, C or N) in every case is of the order of 170°, which is also consistent with roughly square–planar geometry at the nickel atoms.

The Ni_3 moiety forms an equilateral triangle, the maximum variation from 60° observed in any of the examples with the Ni_3S_4 core being 2° Fig. 3. This implies some Ni–Ni bonding, which is consistent with the observed metal ion separations, none being very different from 2.75 Å. This distance is between twice the reported covalent radius of nickel(II) (1.16×2–1.21×2 Å) and twice the van der Waals radius (1.60×2 Å) [35].

4. Compound synthesis

The syntheses of all the compounds so far described, including our own, have at least one factor in common. Although all the compounds contain the capping sulfide ion, in no case was sulfide an original reactant. It must be generated in the reaction mixture. The yields of Ni_3S_4 complexes are always relatively small, less than 30% so that the reactions are not clean. In another respects, the synthesis described in the literature differ from ours. All use thiols as the source of the sulfur ligands as well as (presumably) sulfide. Our systems use a thiosulfate, tpmp, and alcohols as solvents rather than the more usual acetonitrile. It seems probable that the nickel(II) induces thiosulfate solvolysis, yielding the alkyl sulfate and the formation of a thiazolidine, where the metal ion is part of the ring system [33].

The *S*,*S* conformations at C(1) and C(2) of the initial ephedrine propane skeleton are maintained in the complexes. The cavity in our materials should be able to act as an anion trap through strong hydrogen bonding. In fact, we have already obtained compound **5** from compound **2** by treatment with $Fe(NO_3)_3$ which is essentially an anion exchange reaction. We are currently testing this kind of reaction further.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre. The relevant CCDC references are 228424, 228425 and 22842. Copies of this information may be obtained free of charge from The Director, CCDC, 12

Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Magnesium porphyrazinate substituted with eight (1-naphthylmethylthio)groups on the peripheral positions has been synthesized by cyclotetramerization of 1,2-bis(1-naphthylmethylthio)maleonitrile in the presence of magnesium butanolate. The metal-free derivative was obtained by its treatment with trifluoroacetic acid and further reaction of this product with copper(II) acetate, zinc(II) acetate and cobalt(II) acetate led to the metal porphyrazinates (M = Cu, Zn, Co). These new compounds have been characterized by elemental analysis, together with FT- IR, ^{1}H NMR, UV–Vis and EPR spectral data.

1. Introduction

Porphyrins, phthalocyanines, tetrabenzoporphyrins and porphyrazines, which can be denoted as tetrapyrrole derivatives, receive extensive attention because of both theoretical studies and applications in advanced materials science [1]. Among this group, porphyrins are important not only from biological aspect but also for coordination chemistry, catalysis and material science. Phthalocyanines that are completely synthetic materials are used in electrophotography, optic data collection, gas sensor, liquid crystal, laser technology and the photodynamic therapy of tumors as well as their classical fields as pigments and dyes. Tuning of the properties of phthalocyanines has been generally achieved through changes in the nature and bonding pattern of the substituents [2–5].

In contrast to the structural similarity between phthalocyanines and porphyrazines, the latter have been relatively less studied compared to the phthalocyanines [6–8]. Starting with octakis(alkylthio) porphyrazine derivatives by Hoffman [9], in which the presence of soft S donor atoms play an important role in affecting the solid-state interactions, an extensive series of derivatives with physical and chemical properties comparable to those of phthalocyanines have been reported. Peripherally-functionalized porphyrazines have the potential to exhibit novel optical, magnetic and electronic properties. The transition metal ion in the inner core offers new ways to induce, modify and to control molecular properties. Metalloporphyrazines have been also proven to exhibit optical limiting effects comparable with phthalocyanine and naphthalocyanine derivatives [10].

During the last decade, we have been heavily engaged with the preparation of new porphyrazines in parallel with phthalocyanine analogues [11–15]. Substitution of various groups on the peripheral positions of porphyrazines has been accomplished either starting with an unsaturated dinitrile precursor with this group attached at the beginning (e.g., dimethylaminoethylthio- [16], tosylaminoethylthio- [17], etc.) or a porphyrazine with reactive functional groups has been prepared at first and then additional groups (e.g., ferrocene [18], benzo-15-crown-5 [19], pyridine [13], etc.) have been incorporated by further condensation reactions.

Recently, we have reported a new group of compounds containing an aromatic phthalocyanine core at the center and four electron rich naphthoxy-substituents on the periphery with the aim of observing the consequences of the combination of these electron-rich units in the same molecule. Here in the present work, the target molecule is a further step to include a porphyrazine core with eight naphthyl units attached to the peripheral positions through methylthio bridges [20].

2. Experimental

IR spectra were recorded on a Mattson 1000 FT-IR spectrophotometer by using KBr pellets, electronic spectra on a Unicam UV–Vis spectrophotometer. Elemental analyses were performed at the Instrumental Analysis Laboratory of TUBITAK Marmara Research Center. Proton NMR spectra were recorded on a Bruker 250 MHz spectrometer using TMS as the reference. EPR spectra of (**3c**) and (**3e**) as powder form and as chloroform solution were registered by a conventional X-band ($v = 9.5$–9.8 GHz) Bruker EMX model spectrometer employing an ac magnetic modulation technique.

The disodium salt of dithiomaleonitrile (**1**) was prepared according to the previously reported procedures [21].

2.1. Synthesis of 1,2-bis(1-naphthylmethylthio)maleonitrile (2)

Disodium salt of dithiomaleonitrile (**1**) (1.12 g, 6 mmol) was mixed with 1-(chloromethyl)-naphthalene (2.65 g, 15 mmol) in methanol (50 ml) and refluxed under nitrogen for about 6 h. When MeOH was evaporated, the remaining oily product was treated with $CHCl_3$ to remove insoluble salts by filtration. The $CHCl_3$ solution was extracted several times with 15% Na_2SO_4 solution and then dried over anhydrous Na_2SO_4 overnight. After evaporation of the solvent the remaining oily product was extracted with refluxing *n*-hexane to remove any excess 1-(chloromethyl)-naphthalene. The product was very soluble in chloroform and dichloromethane. Yield: 1.90 g, 75%. FT-IR (KBr), ν_{max}/(cm^{-1}): 3055 (H–Ar), 2930–2852 (CH_2), 2212 (C≡N), 1520, 1214, 1162, 1042, 782 cm^{-1}; ^{1}H NMR (d-chloroform 250 MHz): 7.92–7.79 (m, 3H, Ar–H), 7.56–7.35 (m, 4H, Ar–H), 4.67 (s, 2H, S–CH_2). UV–Vis. ($CHCl_3$) λ_{max}/(nm): 285.

2.2. [2,3,7,8,12,13,17,18-Octakis(1-naphthylmethylthio)-porphyrazinato] Mg(II) (3a)

Mg turnings (6 mg, 0.25 mmol) and a small I_2 crystal were refluxed in *n*-BuOH (15 ml) for about 8 h to obtain $Mg(BuO)_2$. 1,2-Bis(1-naphthylmethylthio)maleonitrile (211 mg, 0.5 mmol) was added to the this solution and the mixture was refluxed for about 12 h. The blue-green product was filtered, washed with ethanol and water and dried. The crude product was dissolved in $CHCl_3$ and filtered. The $CHCl_3$ solution was dried over anhydrous Na_2SO_4. When the solvent was evaporated, dark blue-green product was obtained. Finally, pure porphyrazine was obtained by chromatography on silica gel using methanol/chloroform (1:50) mixture as eluent. The product was very soluble in chloroform, soluble in dichloromethane, acetone and toluene, but insoluble in *n*-hexane. Yield: 150 mg (70%). FT-IR (KBr), ν_{max}/(cm^{-1}): 3055 (H–Ar), 2927–2850 (CH_2), 1526, 1210, 1161, 1035, 782 cm^{-1}. ^{1}H NMR (d-chloroform 250 MHz): 8.11–7.37 (m, 7H, Ar–H), 5.40 (br s, CH_2–S).

2.3. [2,3,7,8,12,13,17,18-Octakis(1-naphthylmethylthio) H^{21}, H^{23} porphyrazine] (3b)

3a (171 mg, 0.1 mmol) was dissolved in minimum amount of trifluoroaceticacid (~3 ml) and stirred for 3 h at room temperature. When the reaction mixture was added to ice drop-by-drop and neutralized with 25% ammonia solution, precipitation occurred and it was filtered. The precipitate was extracted into the chloroform and the chloroform solution was extracted with water twice. After drying over anhydrous Na_2SO_4, the solvent was evaporated to obtain violet colored metal-free porphyrazine. The crude product was purified by chromatography on silica gel using methanol/chloroform (1:30) mixture as the eluent. Yield: 110 mg (65%). FT-IR (KBr), ν_{max}/(cm^{-1}): 3326 (N–H), 3055 (H–Ar), 2923–2855 (CH_2), 1522, 1212, 1168, 1044, 782 cm^{-1}. ^{1}H NMR (d-chloroform 250 MHz): 7.65–6.91 (m, 7H, Ar–H), 5.41 (br s, 2H, CH_2–S), −2.21 (br s, 2H, NH).

2.4. General procedure for metallo porphyrazines (3c–3e)

3b (169 mg, 0.1 mmol) in $CHCl_3$ (10 ml) was stirred with the metal salt [$Cu(OAc)_2$ (181.6 mg, 1 mmol), $Zn(OAc)_2$ (183.4 mg, 1 mmol) or $Co(OAc)_2$ (177 mg, 1 mmol)] in ethanol (15 ml) and refluxed under nitrogen for about 4 h. Then, the precipitate composed of the crude product and the excess metal salt was filtered. The precipitate was treated with $CHCl_3$ and the insoluble metal salts were removed by filtration. The filtrate was reduced to minimum volume under reduced pressure and then added into *n*-hexane (150 ml) drop by drop to realize the precipitation. Finally, pure porphyrazine derivatives were obtained by chromatography on silica gel using methanol/chloroform (1:50) mixture as the eluent.

[2,3,7,8,12,13,17,18-Octakis(1-naphthylmethylthio)-porphyrazinato] Cu(II) ***(3c)***. Yield: 58 mg (33%). FT-IR (KBr), ν_{max}/(cm^{-1}): 3055 (H–Ar), 2925–2854 (CH_2), 1522, 1213, 1162, 1039, 782 cm^{-1}.

[2,3,7,8,12,13,17,18-Octakis(1-naphthylmethylthio)-porphyrazinato] Zn(II) ***(3d)***. Yield: 67 mg (38%). FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3055 (H–Ar), 2922–2853 (CH_2), 1528, 1211, 1161, 1035, 782 cm^{-1}. ^1H NMR (d-chloroform 250 MHz): 8.29–7.35 (m, 7H, Ar–H), 4.72 (s, 2H, CH_2–S).

[2,3,7,8,12,13,17,18-Octakis(1-naphthylmethylthio)-porphyrazinato] Co(II) ***(3e)***. Yield: 75 mg (43%). FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3055 (H–Ar), 2932–2855 (CH_2), 1521, 1219, 1168, 1033, 782 cm^{-1}.

3. Results and discussion

The starting point for a novel porphyrazine structure with eight (1-naphthylmethylthio) groups bound to the periphery through flexible methylthio-chains is 1,2-bis-(1-naphthylmethylthio)maleonitrile (**2**) which was obtained from disodium salt of dithiomaleonitrile (**1**) and 1-(chloromethyl)naphthalene (Scheme1). The oily product (**2**) was obtained in relatively high yield (75%). The presence of bulky electron-donating S-groups is expected to give porphyrazines absorbing electromagnetic radiation just in the same range as phthalocyanines [10,13–16]. Conversion of bis(1-naphthylmethylthio)-maleonitrile into porphyrazine was achieved by the template effect of magnesium butanolate. Cyclotetramerization gave the blue-green octakis(1-naphthylmethylthio) porphyrazinatomagnesium (**3a**) (Fig. 1). It is very soluble in chloroform and soluble in dichloromethane, acetone and toluene, but insoluble in apolar hydrocarbon solvents such as *n*-hexane.

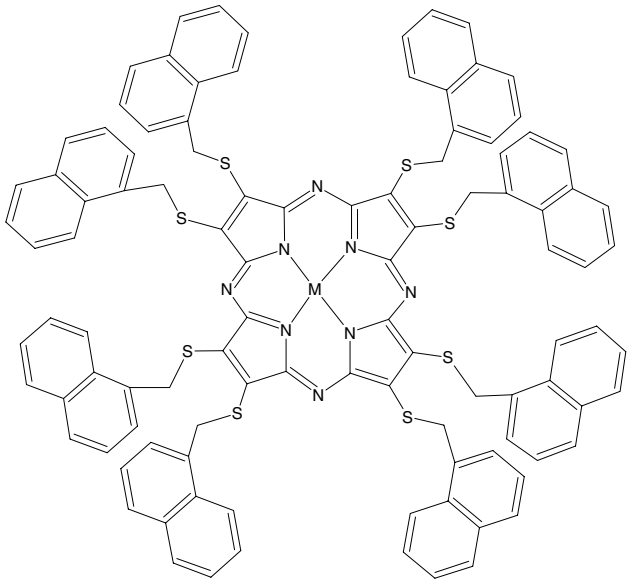

Fig. 1. Octakis (1-naphthylmethylthio) substituted porphyrazines (M = Mg (**3a**); 2H (**3b**); Cu (**3c**); Zn (**3d**); Co (**3e**)).

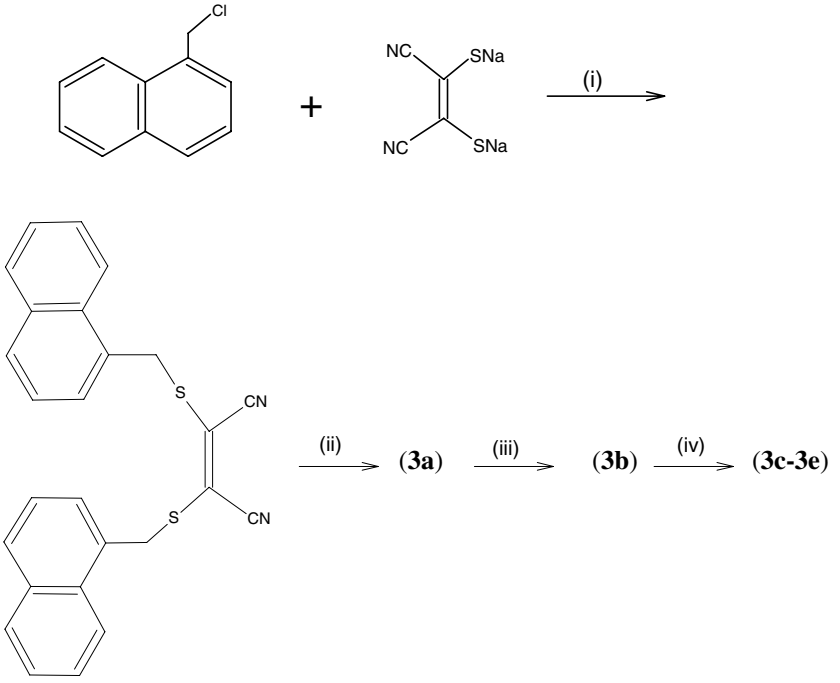
Elemental analyses correspond closely with the values calculated for (**2**, **3a**–**3e**) (Table 1). In the FT-IR spectrum of bis(1-naphthylmethylthio)maleonitrile (**2**) stretching vibration of C≡N is observed at 2212 cm^{-1}, the aromatic and aliphatic C–H peaks are around 2850–3055 cm^{-1} and the characteristic substituted naphthalene peak at 782 cm^{-1}. These values comply with those reported in the literature for similar compounds [20]. After conversion of dinitrile derivative (**2**) to porphyrazine (**3**), the sharp C≡N vibration around 2212 cm^{-1}



Scheme 1. (i) Methanol; (ii) Mg turnings, I_2, *n*-BuOH; (iii) CF_3CO_2H; (iv) EtOH and $Cu(OAc)_2$, $Zn(OAc)_2$, or $Co(OAc)_2$.

Table 1
Elemental analyses results of the porphyrazines[a]

Compound	C	H	N
2	73.65 (73.90)	4.45 (4.29)	6.49 (6.63)
3a	72.60 (72.86)	4.36 (4.23)	6.30 (6.54)
3b	73.68 (73.82)	4.65 (4.41)	6.78 (6.62)
3c	71.46 (71.22)	4.27 (4.14)	6.14 (6.39)
3d	70.94 (71.15)	4.28 (4.13)	6.12 (6.38)
3e	71.12 (71.41)	4.30 (4.15)	6.56 (6.41)

[a] Required values are given in parentheses.

disappeared. The N–H stretching absorption of the inner core of the metal-free porphyrazine (**3b**) was observed around 3326 cm^{-1}. FT-IR spectra of all porphyrazines derivatives (**3a**–**3e**) showed the aromatic and aliphatic C–H peaks are around 2850–3055 cm^{-1} and a characteristic substituted naphthalene peak at 782 cm^{-1} [20].

The N–H protons of the metal-free porphyrazine (**3b**) were also identified in the ^1H NMR spectrum with a broad peak at $\delta = -2.21$ ppm, presenting the typical shielding of inner core protons, which is a common feature of the ^1H NMR spectra of metal-free porphyrazines [7,12,18,19]. In the ^1H NMR spectra of diamagnetic porphyrazines **3a**, **3b**, **3d** two different types of protons are clearly seen: A multiplet around 7–8 ppm corresponding to naphthyl-protons and a singlet at 5.40 ppm (**3a**), 5.41 ppm (**3b**) or 4.72 ppm (**3d**) for methylene protons. The ratio of the integral values 7:2 also confirms the proposed structure.

Electronic spectra are especially useful to establish the structure of the porphyrazines (**3a**–**3e**). UV–Vis spectra of porphyrazine core are dominated by two intense bands, the Q band around 660 nm and the B band in the near UV region of around 355 nm, both correlated to $\pi \rightarrow \pi^*$ transitions [6,7]. The presence of an electron donating group on the periphery causes a bathochromic shift on Q bands. UV–Vis spectra of metallo-porphyrazines (**3a**, **3c**–**3e** in $CHCl_3$) prepared in the present work exhibited intense single Q band absorption of the $\pi \rightarrow \pi^*$ transitions around 643–676 nm and B bands in the UV region around 335–377 nm. For metal-free derivative (**3b**), Q band is split into two peaks at 643 and 707 nm as a consequence of the change in the symmetry of porphyrazine core from D_{4h} (in the case of metallo derivatives) to D_{2h}. Here, in the case of porphyrazines with appending (1-naphthylmethylthio) substituents in addition to these absorptions of the porphyrazine core, an intense absorption due to the $\pi \rightarrow \pi^*$ transition of naphthalene groups appeared for all these porphyrazines derivatives (**3a**–**3e**) in the UV region at about 287–289 nm [20] (Table 2).

The room temperature first-derivative EPR spectra taken from powder and solution forms of Cu(II) and Co(II) porphyrazine samples (**3c**, **3e**) are shown in Figs. 2 and 3, respectively. As seen in the figures, the first

signals are from the powder forms and they have both parallel and perpendicular parts with hyperfine splitting. The signals have a characteristic and anisotropic main curve that satisfies an axial symmetry for the compounds. Here $g_{\|}$ and $g_{\perp}$ denote effective g-values when the applied dc field is parallel ($B_{\|}$) and perpendicular ($B_{\perp}$) to the symmetry axis of the crystalline field around the paramagnetic center, respectively. As it is well known, for statistically and randomly oriented powders,

the absorption corresponding to $g_{\perp}$ is more intensive than that corresponds to $g_{\|}$. This kind of spectrum is characteristic for a conventional powdered sample containing a paramagnetic ion with an axially symmetric g factor with $g_{\|} > g_{\perp} > g_e$ ($g_e = 2.0023$) and with hyperfine splitting [22,23]; that is, the local symmetry of the paramagnetic center giving this signal should be axial. The EPR spectrum of chloroform solution of Cu(II) porphyrazine (**3c**) (Fig. 2) is a little different from that of powder form. The hyperfine splitting can not be seen clearly. The reason for the lack of hyperfine splitting is probably due to superimposition and line broadening in the spectrum. Also, in the EPR spectrum of chloroform solution of Co(II) porphyrazine (**3e**) (Fig. 3), the signal maintains its axial symmetry character with $g_{\perp} > g_{\|}$. However, when we compare this spectrum with the previous one taken from the powder form, there are important changes at both parallel and perpendicular parts of the spectrum. The well resolved hyperfine peaks superimpose and cannot be seen at both parts of the spectrum. Also, the line width of the overall spectrum decreases. These changes observed in the EPR spectra of both samples can be attributed to the axial symmetry and highly anisotropic *g*-value. The *g*-values obtained for the copper(II) and cobalt(II) porphyrazines (**3c**) and (**3e**) closely follow those reported for other monomeric tetrapyrrole derivatives of the same paramagnetic metal centers [24–27].

In conclusion, new porphyrazines surrounded with eight bulky naphthylmethyl groups have been described; high electron density on the substituents results with a second absorption in the ultraviolet region of comparable intensity as the intense B band of porphyrazines.

Abstract

The synthesis and characterization of a Zn(II) complex with 5-ethyl-2-amino-1,3,4-thiadiazole (eatz) are described. The crystal structure of $[Zn(eatz)_2(OAc)_2]$ was determined by X-ray diffraction. The crystal belongs to the monoclinic system and the structural unit is a distorted tetrahedron. In this complex, eatz acts as a monodentate ligand coordinating through the thiadiazole N atom to Zn(II), and the crystal structure is mainly stabilized by both intra- and intermolecular hydrogen bonds. Thermal analysis reveals that the complex $[Zn(eatz)_2(OAc)_2]$ decomposes in three transitions to give $Zn(CN)_2$ as the end product at 650 °C in N_2 atmosphere. The thermal decomposition kinetic analysis of the title complex indicates that the first transition is a double-step reaction with the main reaction being an *n*th auto-catalysis one. A biological activity study shows that both the ligand and the complex have good antimicrobial activities against *Staphylococcus aureus*.

1. Introduction

The chemistry of thiadiazoles, their derivatives and related compounds is of great interest in chemistry owning to their bioactivity of certain plant growth regulating effects as well as antimicrobial activity [1,2]. As a series of superior ligands, thiadiazoles and their derivatives can coordinate to many metal ions with nitrogen or sulfur atoms from the five-membered ring. In particular *N*,*N*′-linkage ligands, such as 1,3,4-thiadiazoles, are very versatile ones that are able to bridge a wide range of inter-metallic separations through two close adjacent N donors [3]. These complexes have received considerable attention for the past few years due to their specific structures, characteristics and reactivities, as well as their special biological activities, exceptional pharmacological properties and potential industrial applications [4,5]. 1,3,4-thiadiazoles, which have special structures and properties, have been widely reported in the fields of synthesis and structural studies by spectroscopic analysis. But single crystal structures of 1,3,4-thiadiazole complexes with metals and their thermal analysis are rare in the literature. Up until now there have been no reports on the single-crystal structure, thermal decomposition and biological activity of the complex $[Zn(eatz)_2(OAc)_2]$, eatz = 5-ethyl-2-amino-1,3,4-thiadiazole. We have synthesized the ligand, 5-ethyl-2-amino-1,3,4-thiadiazole:  , and

the complex $[Zn(eatz)_2(OAc)_2]$. A single crystal of the complex was obtained and the crystal structure was determined by X-ray diffraction. In the present paper, we report the single crystal structure and the thermal behaviour of the complex $[Zn(eatz)_2(OAc)_2]$. The kinetic parameters for the first transition of $[Zn(eatz)_2(OAc)_2]$ decomposition have been calculated by employing both integral and differential methods and a kinetic equation has been given. In addition, bioactivity experiments of the complex and the ligand are also reported.

2. Experimental

2.1. Materials and measurement

The ligand, 5-ethyl-2-amino-1,3,4-thiadiazole, was prepared by the method described in the literature [6]. All chemicals used were of analytic reagent grade and used without further purification.

The single crystal structure was measured on a Rigaku-Raxis-IV X-ray diffractometer. The thermal behaviours were measured on NETZSCH TG209 and DSC204 instruments. The IR spectra were recorded on a Nicolet IR-470 spectrometer using KBr pellets in the range of 4000–400 cm^{-1}.

2.2. Synthesis of the complex $[Zn(eatz)_2(OAc)_2]$

0.391g (3.03 mmol) of 5-ethyl-2-amino-1,3,4-thiadiazole was added with continuous stirring to 60 ml of an acetonitrile solution containing 0.133 g (1.5 mmol) of $Zn(CH_3COO)_2 \cdot 2H_2O$. Five drops of 1 $mol1^{-1}$ HOAc solution were added to the above-mentioned solution to keep pH $\approx$ 5. The resultant solution was heated on an electro-magnetic stirring apparatus to reflux for 4 h. After a few days, 0.326 g (Yield 49.2%) poor yellow crystals of the title complex, suitable for X-ray diffraction, were obtained by being filtrated, washed with cooled water and dried under vacuum. *Anal.* Calc. for $C_{12}H_{20}N_6O_4S_2Zn$: C, 37.30; H, 5.43; N, 32.41. Found: C, 37.44; H, 5.58; N, 32.76%.

2.3. X-ray crystallography

A selected crystal of $[Zn(eatz)_2(OAc)_2]$ was mounted on a Rigaku-Raxis-IV X-ray diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at 293(2) K. 3534 reflections were measured over the ranges $2.56° \leqslant 2\theta \leqslant 27.52°$, $-13 \leqslant h \leqslant 10$, $-34 \leqslant k \leqslant 34$, $-10 \leqslant l \leqslant 10$, yielding 2017 unique reflections. Raw data were corrected and the structure was solved using the SHELX-97 program. Non-hydrogen atoms were located by direct phase determination and subjected to anisotropic refinement [7]. The full-matrix least-squares calculations on F^2 were applied on the final refinement. The refinement converged at $R_1 = 0.0423$ and $wR_2 = 0.0943$ values for reflections with $I > 2\sigma(I)$. Details of crystal structure determination are summarized in Table 1. Full atomic data are available as a file in CIF format.

2.4. Thermal analysis

The thermal decomposition experiments in nitrogen atmosphere with a flow rate of 20 ml min^{-1} were carried out using NETZSCH TG 209 and DSC 204 instruments. In these experiments, the complex $[Zn(eatz)_2(OAc)_2]$ was pre-triturated and pretreated in pure nitrogen atmosphere at 85 °C for 1 h to remove acetonitrile solvent completely. An Al crucible was used for DSC measurement and Al_2O_3 crucibles for TG to hold about 3–5 mg of the samples, respectively. The heating rate for thermal decomposition employed was 10 °C min^{-1}, and the rates for kinetic analysis were 5, 10, 15 and 30 °C min^{-1}, respectively.

Extinction coefficient	0.0036(8)
Largest difference peak and hole (e Å^{-3})	0.549 and −0.407

2.5. Biological tests of the ligand and the complex $[Zn(eatz)_2(OAc)_2]$

Antimicrobial activity of the complex and the ligand eatz was qualitatively determined by a modified disc diffusion method [8] with a suspension of *Staphylococcus aureus* 1 ml in agar medium. Ethanol solutions of the complex and the ligand were prepared with concentrations of 0.0155 mmoll^{-1}.

3. Results and discussion

3.1. Crystal structure of $[Zn(eatz)_2(OAc)_2]$

Selected bond distances and angles of the complex $[Zn(eatz)_2(OAc)_2]$ are listed in Table 2. The ORTEP drawing and the packing diagram of the unit cell of $[Zn(eatz)_2(OAc)_2]$ are presented in Fig. 1(a) and (b), respectively.

In the complex $[Zn(eatz)_2(OAc)_2]$, the Zn(II) ion is linked to two thiadiazole N atoms and two acetate O atoms, and both eatz and OAc^- are coordinated to the Zn(II) ion as monodentate ligands. The lengths of Zn–O bonds (1.947(5) and 1.971(5) Å) are slightly shorter than those of Zn–N bonds (2.027(5) and 2.043(5) Å), and the maximum and minimum values of the bond angles around the Zn(II) ion are 123.0(3)° (O(3)–Zn(1)–O(1)) and 99.4(2)° (O(3)–Zn(1)–N(5)), respectively, indicating that the configuration of the structural unit of $[Zn(eatz)_2(OAc)_2]$ is very distorted from the ideal tetrahedral geometry. This severe distortion could be due to the difference in coordinate ability and steric hindrance between eatz and OAc^- ligands, as well as the stronger bonding of acetate O atoms to the Zn(II) ion than that of thiadiazole N atoms, because of the negative charge on the O atoms from OAc^-. There are complicated intra- and intermolecular hydrogen bonds in the crystal structure of $[Zn(eatz)_2(OAc)_2]$ (bonding details are given in Table 3). The tridimensional network of hydrogen bonds provides an extra stability for the crystal. Although the two thiadiazole rings of the neighboring units in different planes have a large overlap and are close to parallel to each other (the interplane angle is 1.4°), the distance between them is 4.221 Å, which is bigger than the maximum value for which π–π interactions are accepted. As a result, the structure is

primarily stabilized by intra- and intermolecular hydrogen bonds.

3.2. Thermal decomposition

The TG and DSC curves of the title complex are shown in Fig. 2. The relatively smaller endothermic peak at 130 °C involving a ΔH value of 7.6 J g^{-1}, without mass loss associated in TG, is linked to the break of intra- and intermolecular hydrogen bonds. The endothermic peak at 150 °C without mass loss, and giving a ΔH value of 98.9 J g^{-1}, is due to the phase change of the complex. The sharp exothermic peak at 215 °C involving a ΔH value of 894.5 J g^{-1}, with a mass loss of 32.2%, may be assigned to the breaking of thiadiazole rings with the generation of NCS^- and accompanied by the formation of the $H_2[Zn(NCS)_2(OAc)_2]$ complex. The replacement of eatz by NCS^- gives rise to the more stable coordinate bond of Zn–NCS^- than that of Zn-eatz. The calculated mass loss (31.7%) for this thermal event agrees with that revealed by the TG curve (32.2%) at 217 °C. The broad shallow exothermic peak between 217 and 295 °C, giving a ΔH value of 228.3 J g^{-1} and accompanied by mass loss in TG, may mainly correspond to the breaking of Zn–OAc bonds and the decomposition of $H_2[Zn(NCS)_2(OAc)_2]$ into $Zn(NCS)_2$, with the release of CO, H_2O and H_2 [9]. The successive mass loss in TG from 300 to 650 °C may be caused by the gradual elimination of carbon as well as the decomposition of $Zn(NCS)_2$ into $Zn(CN)_2$, and the removal of sulfur. The total mass loss of 72.0% at 650 °C is quite close to the theoretical mass loss (73.4%) calculated by taking $Zn(CN)_2$ as the final product.

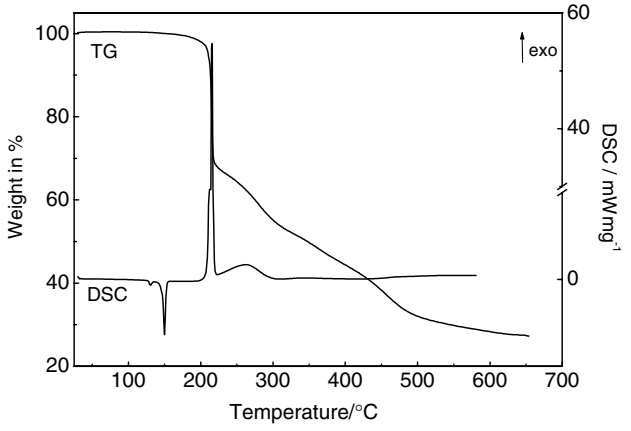

Fig. 2. TG–DSC curves of $[Zn(eatz)_2(OAc)_2]$.

The characterization frequencies of the IR spectra of the complex $[Zn(eatz)_2(OAc)_2]$ and the decomposed product at 217 °C are listed in Table 4. The peaks at 1523 and 1500 cm^{-1} in the IR spectrum of the complex, which are assigned to the characteristic vibration band of the 1,3,4-thiadiazole rings, disappear in the spectrum of the decomposed product and a new characteristic absorption peak of NCS^- appears at 2081 cm^{-1}. These results justify that the breakage of the thiadiazole ring is accompanied by the formation of NCS^-. The result of IR spectra agrees with that of the thermal analysis.

3.3. Non-isothermal kinetics of the first transition of the complex $[Zn(eatz)_2(OAc)_2]$ decomposition

3.3.1. Model-free estimation of activation energy

A series of dynamic scans with different heating rates results in a set of data which exhibits the same degree of conversion (α) at different temperatures. Based on this, two methods are developed by Friedman as well as Ozawa–Flynn–Wall to determine the kinetic parameters without having to presuppose a certain model. Fig. 3 shows the TG curves of the title complex measured in N_2 atmosphere with the heating rate of 5, 10, 15 and

Table 4

d, doublet; s, strong.

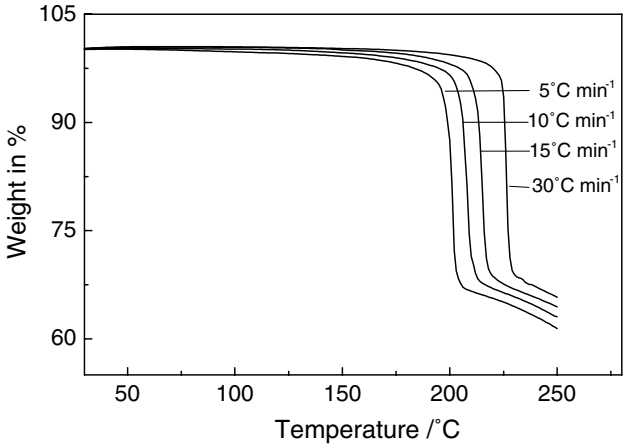

Fig. 3. TG curves of $[Zn(eatz)_2(OAc)_2]$ with different heating rates (°C min^{-1}).

30 °C min^{-1}, respectively. The basic data (β, α, T) taken from the TG curves are used in the equations below:

Ozawa–Flynn–Wall equation [10,11]:

$$\ln \beta = \ln\left(\frac{AE}{R}\right) - \ln\ g(\alpha) - 5.3305 - 1.052\frac{E}{RT}, \qquad (1)$$

where β is the heating rate, α degree of conversion, $g(\alpha)$ mechanism function, E activation energy, A pre-exponential factor and R gas constant. Friedman equation [12]:

$$\ln\left(\frac{d\alpha}{dt}\right)_{\alpha=\alpha j} = \ln[Af(\alpha)_j] - \frac{E}{RT}, \qquad (2)$$

where $d\alpha/dt$ is the rate of conversion, and $f(\alpha)$ mechanism function.

It can be seen from Eqs. (1) and (2) that the graphs ln β versus $1/T$ and ln ($d\alpha/dt$) versus $1/T$ both show straight lines with slopes $m_{(1)} = -1.052E/R$ and $m_{(2)} = -E/R$. The slopes of these straight lines are directly proportional to the reaction activation energy (E). The calculation results using the NETZSCH Thermokinetic Analysis Program [13] are shown in Table 5.

From Table 5, it can be seen that the values of E calculated by using different methods are comparable although the values obtained by the Friedman method lie on the low side. It can also be seen that the activation energy is not a constant, which indicates that the first transition of the thermal decomposition of the complex $[Zn(eatz)_2(OAc)_2]$ is a two-step reaction. The first step is a pre-reaction with $E_1 = 209.09 \pm 40.63$ kJ mol^{-1}, and the second step is the main reaction with average $\bar{E}_2 = 130.5 \pm 8.25$ kJ mol^{-1}.

3.3.2. Estimation of the kinetic model by means of multiple linear regression

From Table 5 it can be seen that the main reaction of the decomposition process comprises 96% of the total mass loss, while the pre-reaction only comprises less than 4%. For this reason, the determination of kinetic parameters and mode type for the main reaction can be turned into a problem of multiple linear regression (MLR) by an appropriate transformation. Selecting mechanism functions $f(\alpha)$ of different reaction types [14,15], given in Table 6, the calculated TG curves were obtained by plotting $\ln[(d\alpha/dt)/f(\alpha)]$ versus $1/T$ using the ACHAR equation [16]:

$$\ln\frac{d\alpha/dt}{f(\alpha)} = \ln\frac{A}{\beta} - \frac{E}{RT}. \qquad (3)$$

The calculated curves were fitted to the experimental curves by using the MLR method and corrected with least squares (LSQ). The fitting results for different reaction types are also given in Table 6.

Considering the fitting quality (characterized by the correlation coefficient), regression parameter and activation energy E from OFW analysis, it can be seen from Table 6 that the mechanism of Cn is more suitable for this reaction. That means the first thermal

$K_{CI} = 3.0967$, $K_{Cn} = 3.5354$.

decomposition transition of the complex $[Zn(eatz)_2(OAc)_2]$ preferably proceeds mainly as an nth reaction with auto-catalysis through the reactants, the order is 1.23 with $E = 129.9$ kJ mol^{-1}, lg $A = 9.55$ s^{-1} and the kinetic equation of the main reaction is:

$$d\alpha/dt = A\exp(-E/RT)(1-\alpha)^n(1+k\alpha),$$

where $n = 1.23$, $K = 3.5354$.

The result of the kinetic analysis above can also illuminate the rapid rate of decomposition of the complex during the first transition. Being an nth reaction with auto-catalysis, the main reaction is started by a pre-reaction, the reaction type of which cannot be estimated because of its smallness. It is the pre-reaction that induces the main reaction to occur so rapidly that the complex loses more than 31% of its mass within a temperature range of less than 5 °C.

3.4. Qualitative antimicrobial assay results

The results of antimicrobial activities of the complex $[Zn(eatz)_2(OAc)_2]$ and the free ligand, eatz, together with the result of the blank as a comparison, are listed in Table 7, as evaluated by the diameter of the growth inhibition zone. It can be seen that both the complex and the ligand showed a clear inhibition zone 15 mm above against *Staphylococcus aureus*, and the differences in the zone diameter between them are not obvious. These results indicate that eatz and $[Zn(eatz)_2(OAc)_2]$ are very effective against *S. aureus*.

Both the ligand and the complex have similar antimicrobial activities suggesting that the coordination of eatz with the Zn(II) ion and the formation of the complex $[Zn(eatz)_2(OAc)_2]$ do not change the biologic activity of eatz obviously. This indicates that the active group in eatz and $[Zn(eatz)_2(OAc)_2]$ is the 1,3,4-thiadiazole ring. The mechanism of antimicrobial action of these compounds still needs further investigating and the assay results above would provide basic data for the pharmacological research of thiadiazoles and their complexes.

Table 7
Results for antimicrobial assay[a] (diameter in mm)

Sample	I	II	III
Blank	8	8	8
eatz	23	24	26
$[Zn(eatz)_2(OAc)_2]$	22	22	26

[a] Diameter of 15 mm and above considered active.

Abstract

Mononuclear molybdenum(VI) $[MoO_2L_2]$ (**1a**, **1b**, **2a**, **2b**) and dinuclear molybdenum(V) $[Mo_2O_4(L^{1b})_2(CH_3OH)_2]$ (**3b**) complexes have been prepared by the reaction of $[MoO_2(acac)_2]$ or $[Mo_2O_3(acac)_4]$ (acac = acetylacetonate ion), respectively, with the appropriate β′-hydroxy-β-enaminones (**HL**). Also, two isomeric enaminones ($\mathbf{HL^{1a}}$ and $\mathbf{HL^{1b}}$) have been prepared by the reaction of ethyl 2-hydroxy-4-(4-hydroxy-6-methyl-2H-pyran-2-on-3-yl)-4-oxo-2-butenoate (**ehmpb**) and *o*-anisidine. All the prepared molybdenum(VI) complexes are built up of mononuclear molecules with *cis*-MoO_2^{2+} cores, while the dinuclear molybdenum(V) complex contains a $Mo_2O_4^{2+}$ core. In all complexes ligand **L** is coordinated in a didentate fashion to molybdenum through two oxygen atoms and not through the nitrogen atom. One neutral solvent molecule CH_3OH in the molybdenum(V) complex, acting as a monodentate ligand, completes the octahedral coordination of each Mo atom. All compounds have been characterized by means of chemical analyses, IR and one- and two-dimensional NMR spectroscopy. The molecular and crystal structures of the molybdenum(VI) (**1a**), molybdenum(V) (**3b**) complexes and of ligand $\mathbf{HL^{1b}}$ have been determined by a single crystal X-ray diffraction method.

1. Introduction

A series of 2-pyrone derivatives and their metal complexes have received significant attention due to their enzyme-inhibiting properties [1–4]. Similarly, the discovery of the insuline-enhancing (or insuline-mimetic) properties of oxovanadium compounds has stimulated numerous investigations concerning the syntheses, characterization and biological relevance of such complexes [5–9]. Some studies have shown that molybdenum(VI) complexes also exhibit such properties [10].

We have recently published the syntheses and structures of several isomeric enaminones containing a 4-hydroxy-2-pyrone ring, obtained by the reaction of ethyl 2-hydroxy-4-(4-hydroxy-6-methyl-2*H*-pyran-2-on-3-yl)-4-oxo-2-butenoate and the corresponding amines (*n*-butyl amine, aniline, *p*-anisidine and α-naphthyl amine) [11–13]. We have also described the preparation of several dinuclear molybdenum(V) complexes of the general formula $[Mo_2O_4L_2D_2]$ obtained by the reaction of various isomeric β′-hydroxy-β-enaminones and $[Mo_2O_3(acac)_4]$ [14–16].

☆ This paper is a part of our studies on molybdenum complexes with enaminones containing a 4-hydroxy-2-pyrone ring.

doi:10.1016/j.poly.2004.03.025

In the continuation of our previous research we report here the synthesis of new ligands (HL^{1a} and HL^{1b}), and novel molybdenum(VI) $[MoO_2L_2]$ (**1a**, **1b**, **2a**, **2b**) and molybdenum(V) $[Mo_2O_4(L^{1b})_2(CH_3OH)_2]$ (**3b**) complexes with β′-hydroxy-β-enaminones (Scheme 1).

The molecular structures of a molybdenum(VI) complex (**1a**), the molybdenum(V) complex (**3b**), as well as of one ligand isomer (HL^{1b}) have been determined by a single crystal X-ray diffraction method.

The ligands and complexes have also been characterized by means of chemical analyses, high-resolution NMR spectroscopy and IR spectroscopy.

2. Experimental

All chemicals were of reagent grade and used as purchased. The starting complexes $[MoO_2(acac)_2]$ [17] and $[Mo_2O_3(acac)_4]$ [18] were prepared as described in the literature. Ethyl 2-hydroxy-4-(4-hydroxy-6-methyl-2H-pyran-2-on-3-yl)-4-oxo-2-butenoate (**ehmpb**) and the corresponding enaminones HL^{2a} and HL^{2b} (Scheme 2) were prepared according to the already described procedure [11–13]. Methanol was dried using magnesium turnings and iodine and then distilled. Dichloromethane was dried over P_2O_5.

C, H and N analyses were provided by the Analytical Services Laboratory of Rudjer Bošković Institute, Zagreb. Molybdenum was determined according to the method described in the literature [19]. Infrared spectra were recorded in KBr with an FTIR 1600, Fourier transform spectrophotometer in the 4500–450 cm^{-1} region. Elemental analyses, yields and selected IR data are given in Table 1.

2.1. Synthesis of enaminones and complexes

2.1.1. Synthesis of enaminones (HL^{1a}, HL^{1b})

A mixture of equimolar amounts (2.5 mmol) of **ehmpb** and *o*-anisidine in ethanol (20 mL) was warmed up under reflux for 1 h. The reaction mixture was cooled overnight. The formed yellow precipitate (HL^{1a}) was collected by filtration and purified by recrystallization from ethanol (m.p. = 195–196 °C). The filtrate was evaporated to half of its volume and allowed to stand at room temperature for 3–4 days. The yellow-orange crystals of HL^{1b} were collected and recrystallized from ethanol (m.p. = 146–147 °C).

2.1.2. Synthesis of the molybdenum(VI) complexes $[MoO_2L_2]$ (**1a**, **1b**, **2a**, **2b**)

$[MoO_2(acac)_2]$ (0.1 g, 0.31 mmol) was suspended in dry methanol (30 mL) and the appropriate ligand (0.31

mmol) was added. The mixture was warmed up for 15 h. Complexes **1a** or **2a** were deposited during warming of the reaction mixture, while the complexes **1b** or **2b** were obtained when the solution was evaporated to one-third of its volume and left overnight. The obtained products were filtered off, washed with cold methanol and dried.

*2.1.3. Synthesis of the molybdenum(V) complex $[Mo_2O_4(L^{1b})_2(CH_3OH)_2]$ (**3b**)*

$[Mo_2O_3(acac)_4]$ (0.25 g, 0.39 mmol) was suspended in dry dichloromethane (25 mL) and ethyl 4-(4-hydroxy-6-methyl-2*H*-pyran-2-on-3-yl)-2-(2-methoxyanilino)-4-oxo-2-butenoate (**HL^{1b}**) (0.39 mmol) was added. The mixture was gently warmed up for 1 h, the solution was filtered off and methanol (30 mL) added to the filtrate. Upon standing at room temperature for 10 days, the obtained orange-red crystalline product was filtered off, washed with cold alcohol and dried.

2.2. X-ray crystallography

Whereas the single crystals of **HL^{1b}** and **3b** were grown by slow evaporation of solutions obtained from the above-described preparations, the single crystal of **1a** was obtained by evaporation from a mixture of methanol and dichloromethane. Intensity data for structures **HL^{1b}**, **1a** and **3b** were collected at 150 K on a Nonius Kappa CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and reduced using the DENZO programme [20]. The structures of all

complexes were solved by Patterson and Fourier methods using the SHELXS-97 [21] programme. The refinements were performed by the full-matrix least-squares method assuming anisotropic temperature factors for all non-H atoms using SHELXL-97 [22].

Hydrogen atoms attached to carbon atoms in all structures were generated on geometrical grounds. Hydrogen atoms H1 (bonded to N1) and H4 (bonded to O4) in structure **HL^{1b}** were found in a difference Fourier map and their positions were refined, while hydrogen atoms H1 (bonded to N1) and H2 (bonded to N2) in structure **1a**, and H1 (bonded to N1) and H8 (bonded to O8) in structure **3b** were also located in a difference Fourier map but their positions were kept fixed during the refinement.

Crystal parameters, data collection details and the results of refinements are summarized in Table 2. Selected bond lengths and angles are listed in Tables 3 and 4, and hydrogen bond parameters in Table 5.

All calculations were performed on an IBM THINKPAD microcomputer (Pentium II processor, 300 MHz). The molecular structure drawings were prepared using ORTEP [23] and PLATON [24].

2.3. NMR spectroscopy

NMR experiments were carried out on a Bruker Avance DRX500 spectrometer operating at 500.13 MHz for ^{1}H, with a 5-mm diameter inverse detection probe and a *z*-axis gradient coil. The spectra of the ligands (**HL^{1a}** and **HL^{1b}**) and of all molybdenum(VI) complexes (**1a**, **1b** and **2a**) were recorded in chloroform-d_1. The spectrum of the molybdenum(V) complex (**3b**) was recorded in acetone-d_6. All experiments were performed at ambient temperature. TMS was used as the internal standard. ^{1}H NMR experiments were executed with a spectral width of 10 000 Hz, 65 K data points and 8–16 scans. The sample concentration was 20 mg mL^{-1}. The digital resolution was 0.15 Hz per point. In ^{13}C APT NMR spectra, the spectral width was 31 446 Hz, number of data points 65 K and number of scans 9000–10 000 per spectrum. The digital resolution was 0.48 Hz per point.

Two-dimensional absolute value gradient selected COSY spectra were recorded under the following conditions. The spectral width was 6660 Hz in both domains, 2K data points were applied in the time domain and 256 increments were collected for each data set with linear prediction and zero filling to 1K. The relaxation delay was 1.5 s. Spectra were processed with sine window functions. The digital resolution was 3.3 Hz per point in the f2 domain and 26.0 Hz per point in the f1 domain. The number of scans was 4.

Absolute value HMQC and HMBC spectra were recorded with a relaxation delay of 1.5 s and 8–16 scans per increment. The spectral width was 6600 Hz in acquisition domain f2 and 31000 Hz in time domain f1. Data were collected into a 1024×256 acquisition matrix and processed using a $2K \times 1K$ transformed matrix with zero filling in the f1 domain. Sine multiplication was performed prior to Fourier transformations. In HMBC spectra the delay for long range couplings was set to 60 ms.

3. Results and discussion

3.1. Synthesis of complexes

In the course of our research on molybdenum complexes with enaminones, we have prepared novel molybdenum(VI) and molybdenum(V) complexes with polydentate β′-hydroxy-β-enaminones (Scheme 1). The complexes of the general formula $[MoO_2L_2]$ (**1a**, **1b**, **2a**, **2b**) were prepared by the reaction of $[MoO_2(acac)_2]$ with the appropriate enaminone. They were orange-red crystalline solids slightly soluble in dichloromethane and chloroform. Their solutions are quite sensitive to moisture changing colour from orange to blue.

The new molybdenum(V) complex $[Mo_2O_4(L^{1b})_2(CH_3OH)_2]$ (**3b**) was prepared in a similar way as $[Mo_2O_4L_2D_2]$, already described in the literature [13–16]. The complex was very soluble in coordinating solvents such as dmf, dmso, picoline and py, and slightly soluble in acetone, methanol and ethanol.

All complexes were characterized by IR spectroscopy and selected spectral data are given in Table 1. Two bands at 1726–1721 and 1644–1671 cm^{-1} can be attributed to the stretching vibrations of the carbonyl groups belonging to the ester $COOC_2H_5$ and 2-pyrone, respectively. The stretching frequencies at 1572–1585 cm^{-1}, attributed to the coordinated C···O, groups were observed at lower values comparing to those found in the free ligands. The intense bands in the regions 929–934 and 906–907 cm^{-1} were assigned to the ν_{asym} and ν_{sym} $Mo–O_{(terminal)}$ stretching frequencies, respectively. In the spectra of the molybdenum(V) complex, the single strong absorption maximum at about 962 cm^{-1} belongs to $Mo–O_{(terminal)}$, while the band at 720 cm^{-1} belongs to the $Mo–O_{(bridging)}$ stretching frequency. The remaining frequencies in the IR spectra are due to the vibrations within the ligands.

3.2. Crystal structure

3.2.1. Crystal structure of *HL^{1b}*

The molecular structure of compound HL^{1b} can be described as consisting of three structural fragments: a 2-pyrone ring substituted at position 6 by a methyl group, a delocalized central enaminone part and a N-substituent (phenyl ring with a methoxy group at position 2) (Fig. 1). The compound exists in the crystalline state in the enamine form (C=C–N–H) with a C8=C9 bond distance value of 1.377(5) Å and C9–N1 of 1.354(4) Å. The difference Fourier map clearly exhibits one position of a H atom (O4–H4 = 1.05(5) Å) revealing the presence of the (N–C=C–C–OH) exo–enol tautomeric form. All available O–H and N–H protons participate in hydrogen bonding. A six-membered ring formed in the β-diketone fragment is established by the resonance assisted O–H···O hydrogen bond of a very short distance, O4···O3 of 2.418(4) Å. Another six-membered heterocyclic ring containing N–H (0.85(5) Å), where H is found in the difference Fourier map, is formed by the N–H···O intramolecular hydrogen bond (N1···O4 = 2.637(4) Å).

The N-substituent shows torsion flexibility due to rotation around the single $Nsp^2–Csp^3$ bond. The value of the C9–N–C13–C14 torsion angle of 21.43(6)° in structure HL^{1b} is smaller than the values already observed in this class of compound [12,14]. Twisting around the $Nsp^2–Csp^3$ bond is reduced due to the formation of the additional intramolecular hydrogen bond, N1···O7 = 2.600(4) Å.

Symmetry code: i $= -x + 1/2, -y + 1/2, -z$.

The bond lengths and angles of the phenyl ring, the ethoxy-carbonyl group, as well as the pyrane ring are within expected values [25].

3.2.2. Crystal structure of *1a*

The crystal structure of compound **1a** is built up of mononuclear complex molecules $[MoO_2(C_{19}H_{18}O_7N)_2]$, with two didentate ligands **L^{1a}** coordinated to the *cis*-MoO_2^{2+} core (Fig. 2). The ligand itself is the same as described in 3.2.1. but with position 6 of the 2-pyrone ring is substituted by an ethoxycarbonyl group instead of a methyl group. The molybdenum(VI) atom is octahedrally coordinated by two terminal oxo-oxygen ligands and four oxygens from the two didentate ligands. The Mo–O distances, as already observed, indicate their dependence upon the bond order as well as their position in the molybdenum coordination sphere, i.e., *cis* or *trans* to the terminal O atoms. Consequently, the two Mo–O_{trans} bonds, amounting to 2.157(2) and 2.159(2) Å, are significantly longer than the Mo–O_{cis} bonds, amounting to 1.996(2) and 1.999(2) Å.

The characteristic bond lengths C*x*08–C*x*09 ($x = 1$ or 2) of 1.398(5) and 1.399(5) Å, and N*x*–C*x*09 of 1.339(5) Å in both cases, are indicative of the enamine

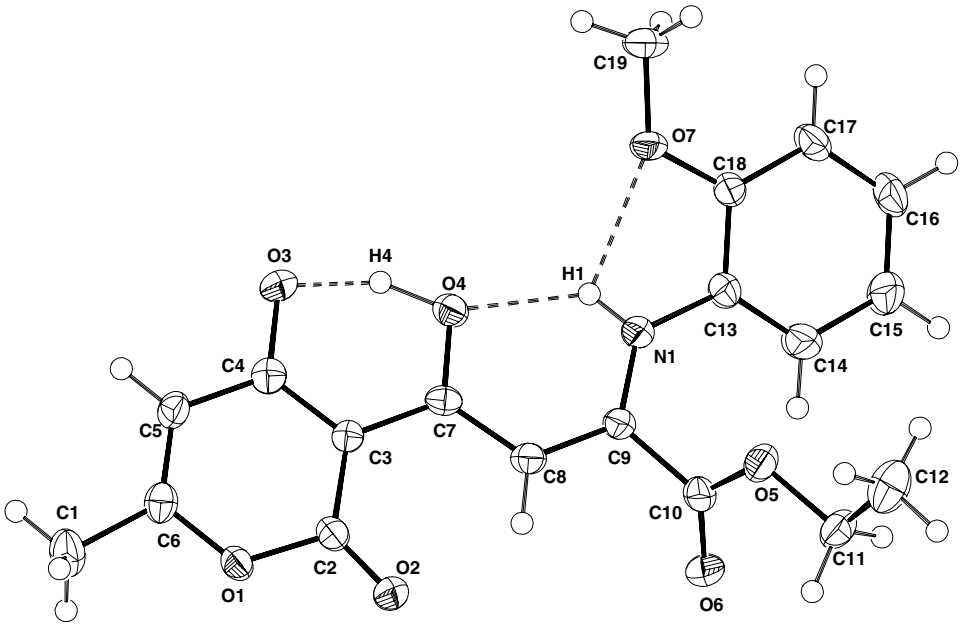

Fig. 1. Molecular structure of ligand molecule **HL[1b]**. The dashed lines indicate intramolecular hydrogen bonds. Ellipsoids are shown at the 50% probability level.

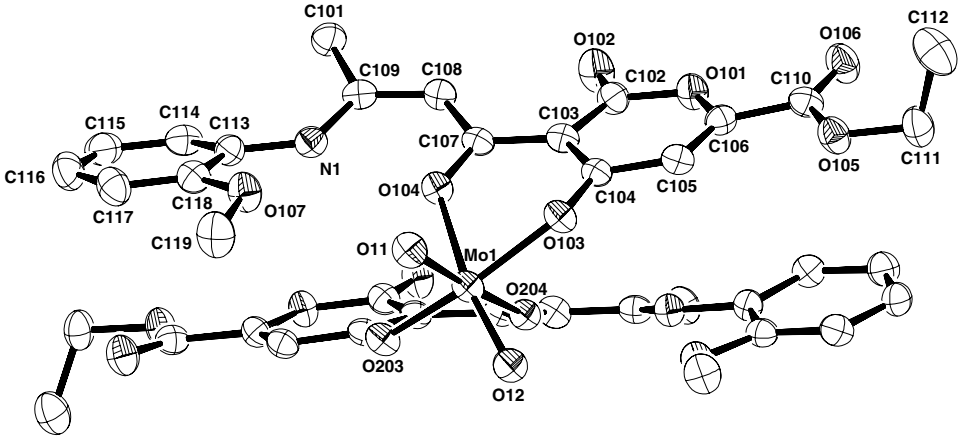

Fig. 2. Molecular structure of complex molecule **1a** showing the atom numbering scheme. Hydrogen atoms as well as the analogous labelling of lower part of the molecule are omitted for clarity. Ellipsoids are shown at the 50% probability level.

C=C–N–H form of the ligand. Due to the slight rotation around the single N–C bond, the ligands are not planar, with C*x*09–N*x*–C*x*13–C*x*14 ($x = 1$ or 2) torsion angles of 33.5(6)° and 24.5(6)°. Such a conformation is stabilized with strong intramolecular N–H···O hydrogen bonds, thus forming an additional six-membered heterocyclic ring in the enaminonic fragment of the ligand [N1···O104 = 2.647(4) Å, N2···O204 = 2.650(4) Å] and a five-membered ring with the N-substituent, [N1···O107 = 2.565(4) Å, N2···O207 = 2.552(4) Å]. Moreover, the ester groups adopt different conformations, with torsion angles C*x*05–C*x*06–C*x*10–O*x*05 ($x = 1$ or 2) of 3.6(5)° and −178.8(3)°, and C*x*10–O*x*05–C*x*11–C*x*12 of 84.4(4)° and −79.0(4)°.

3.2.3. Crystal structure of *3b*

The complex molecule $[Mo_2O_4(C_{19}H_{18}NO_7)_2(CH_3OH)_2]$, with a crystallographically imposed two-fold axis, contains a $[Mo_2O_4]^{2+}$ core, two didentate **L[1b]** ligands and two molecules of methanol (Fig. 3). Each molybdenum atom is coordinated with six oxygen atoms: one terminal oxo-O at 1.679(1) Å, two bridging oxo-O at 1.930(1) and 1.940(1) Å, two oxygen atoms from the didentate ligand at 2.097(1) and 2.177(1) Å and a oxygen atom from the methanol

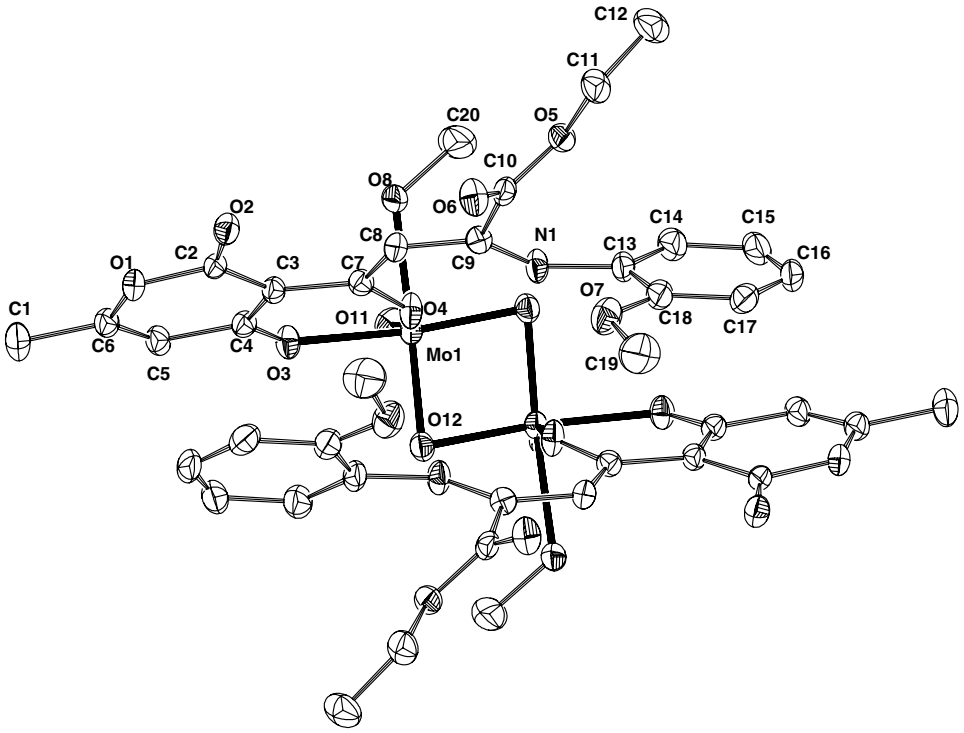

Fig. 3. Molecular structure of complex molecule **3b** showing the atom numbering scheme. Hydrogen atoms are omitted for clarity. Ellipsoids are shown at the 50% probability level.

molecule at 2.190(1) Å. The Mo–Mo distance of 2.5491(4) Å corresponds to a single bond between two molybdenum atoms [26,27]. The characteristic bond length C8═C9 of 1.380(3) Å and C9–N1 1.345(3) Å as in **1a** are indicative of the enamine C═C–N–H form of the ligand.

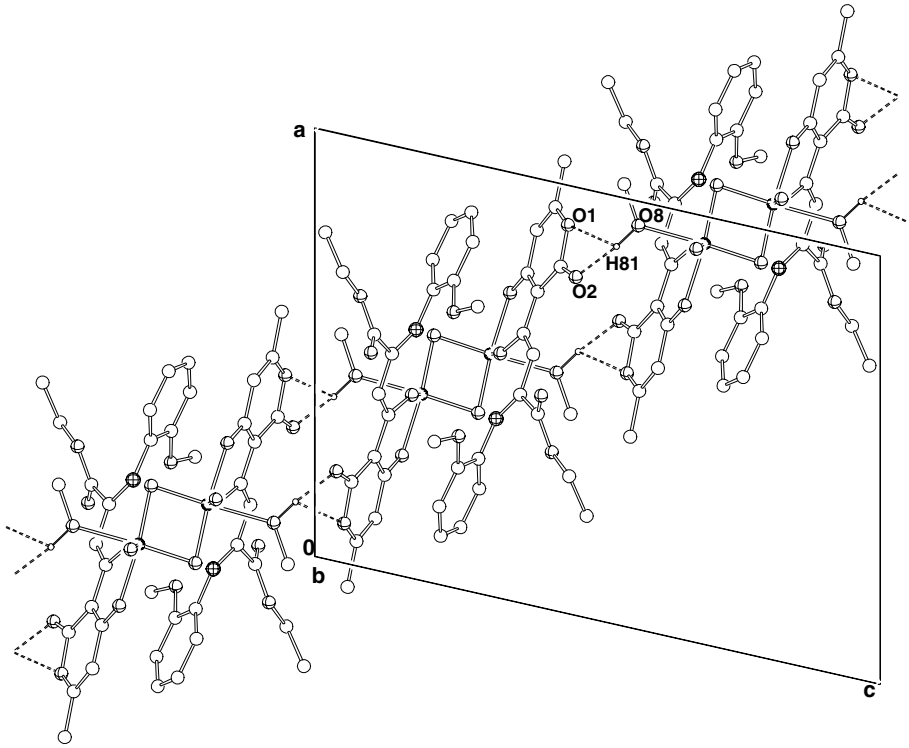

Fig. 4. Packing of **3b** complex molecules in the unit cell viewed down the *b*-axis. The hydrogen bonds are indicated by dashed lines. Chains of molecules are formed along the (1 0 1) direction.

Table 6
^{13}C chemical shifts (ppm) of carbons C-4 and C-7 for the ligands and their complexes in $CDCl_3$

Molecule	HL^{1a}	1a	Δ^*	HL^{1b}	1b	Δ^*	HL^{2a}	2a	Δ^*	HL^{2b}	$HL^{1b\#}$	$3b^{\#}$	Δ^*

C-4	180.86	174.91	5.95	180.71	173.91	6.80	179.71	175.31	4.40	181.93	181.78	178.07	3.71

[#] In acetone-d_6.
[*] Δ (ppm) = $\delta_{Ligand} - \delta_{Complex}$.

According to the value of the C9–N1–C13–C14 torsion angle: −138.7(2)°, the N-substituent has significant flexibility around the N–C single bond.

A six-membered heterocyclic ring containing N–H is formed by the strong intramolecular hydrogen bond N–H···O [N1···O4 = 2.602(2) Å] which is reinforced with π-delocalization along the heterodienic O=C–C=C–NH moiety.

Complex molecules are interconnected through intermolecular hydrogen bonds between the coordinated methanol molecule and the 2-pyrone oxygen [O8···O1^{i} = 3.019(2) Å] and the keto-oxygen from the 2-pyrone ring [O8···O2^{i} = 2.662(2) Å; i = $-x + 1/2, -y + 1/2, -z$]. In such a way chains of molecules are formed along the (1 0 1) direction (Fig. 4). The crystal structure is additionally stabilized by C–H···O hydrogen bonds with C···O distances ranging from 2.856(2) to 3.430(3) Å.

3.3. NMR spectroscopy

The molybdenum complexes were characterized by the combined use of one- (^1H and APT) and two-dimensional (COSY, HSQC and HMBC) NMR spectra. Both proton and carbon chemical shifts resemble those previously reported for related compounds [14–16]. A complete and unambiguous atom assignment of the complex **2b** was not possible in $CDCl_3$ or acetone-d_6 owing to its very low solubility. In order to increase solubility, we added small amounts of DMSO but the complex underwent rapid decomposition.

The absence of a hydroxyl proton resonance and significant shifts of the respective carbon signals confirm the formation of complexes between molybdenum and the ligands (Scheme 2). For illustration, only chemical shifts of carbons C-4 and C-7 (being the two interacting sites) of both the ligands and the complexes are given in Table 6, together with their chemical shift differences Δ (ppm). It is clearly seen that in all complexes larger changes of chemical shift are observed for the C-7 atom (up to 14 ppm), than for C-4 (up to 7 ppm). Both effects are upfield and arise from the electron redistribution upon complexation with molybdenum. The changes in chemical shifts of the other atoms are smaller and alternate in sign. This is in accordance with the results obtained for similar compounds [14–16]. The significant downfield shifts of the amine protons in the range 10.5–12.5 ppm and the relatively broad nature of these signals are due to the formation of strong intramolecular hydrogen bonds in solution, as observed also in the solid state.

4. Supplementary material

CCDC Nos. 231337, 231338 and 231339 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; or deposit@ccdc.cam.ac.uk).

Abstract

A series of dinuclear iron (III) complexes with carboxylate bridges, of the type $[Fe_2L_2(H_20)_4](NO_3)_2(H_2O)_m$ ($m = 1$–3), where L = Schiff base derived from L-α-amino acids and salicylaldehyde have been prepared and characterised by different spectroscopic techniques, magnetic susceptibility, conductivity, and electrochemical measurements. The dimeric iron complexes contain hexa-coordinated iron (III), with the metal ion surrounded by water molecules, the salicylidenimine ligand, and the bridging carboxylate groups. The inequivalence of the iron atoms is detected by Mössbauer spectroscopy and this is reflected by the presence of two overlapping quadrupole doublets ($\delta_1 \sim 0.52$–0.67 mm s^{-1}, $\delta_2 \sim 0.64$–0.80 mm s^{-1}, $\Delta E_{Q1} \sim 0.38$–0.80 mm s^{-1}, and ΔE_{Q2} (~ 0.68–1.01 mm s^{-1}), with an approximate intensity ratio of 1:1 for all complexes. The magnetic susceptibilities of the complexes were determined over the temperature interval 5–300 K and revealed a decrease in the effective magnetic moment with decreasing temperature. The plots of the reciprocal of the molar susceptibility versus temperature indicate that the two iron (III) ions are very weakly antiferromagnetically coupled ($-J \sim 0.09$–0.21 cm^{-1}). Electrochemical studies show that the first two peaks can be assigned to two consecutive one-electron reduction process, affording $Fe^{II}Fe^{III}$ and $Fe^{II}Fe^{II}$. The comproportionation constant K_c at 298 K is in the 5.3×10^3–2.5×10^4 range. The values obtained are in agreement with an intermediate electron coupling between redox sites.

1. Introduction

Proteins use a limited set of metal ions to mediate a variety of processes. Often the same metal centre can have a variety of roles, for example, polymetallic centres occur in numerous metalloproteins, carry out a variety of functions including electron transfer, hydroxylation of methane, the generation of amino acid radicals, hydrolysis of phosphate esters, and dioxygen transport. Furthermore, proteins that contain carboxylate-bridged diiron centres form a class of enzymes that activate molecular oxygen for diverse biological functions. These include the oxygen carrier hemerythrin, the R2 subunit of the ribonucleotide reductase, and the iron storage protein ferritin among others [1–3].

How a protein is able to fine-tune the properties of metal ions to accomplish such different functions, such as the selectivity and efficiency of these reactions, are important questions that with the development of bio-omimetics inorganic compounds have been answered in the last years [1–3]. The magnetical, electrochemical, and spectroscopical studies of these analogous synthetic systems provide important information about redox and spin states of the iron centre or centres, magnitude of exchange interaction, and the ligand environment, which have a profound influence on the functional properties [2–5].

The use of Schiff bases, derived from amino acids, as model systems has been due mainly to the participation

doi:10.1016/j.poly.2004.03.024

of similar biological compounds in key metabolic reactions. Furthermore, carboxylate-bridged diiron centres are encountered at the active sites of several proteins that bind or activate dioxygen [2,3]. The metal ions bonded to this kind of ligands promote the above-mentioned reactions by maintaining the planarity of the conjugated system [4,5].

Complexes with Schiff bases derived from salicylaldehyde and α-amino acids constitute simple models which make possible the study and the elucidation of the mechanisms of the above-mentioned reactions. These models also allow the correlation between structures and the magnetic, electronic, and optical properties of the metal sites present in biological systems [6–10].

2. Experimental

The reagents salicylaldehyde, L-glycine, L-alanine, L-valine, L-leucine, L-isoleucine, and L-phenylalanine were purchased from Merck (analytical grade) and were used without further purification.

The ligands were synthesised after introducing important modifications [11] to the method described by Heinert and Martell [12]. The amino acid was added to a solution of potassium hydroxide (1 mmol) in *i*-propanol. The amino acid was stirred with gentle warming until it had completely dissolved. The salicylaldehyde (1 mmol) was added and the reaction mixture was refluxed for 3 h. The mixture was then cooled and the product was filtered, and washed with ethanol and petroleum ether. The compounds were recrystallised from methanol and ether and dried in vacuo. (Yield 73–91%). All the ligands were prepared according to the procedure described above and were isolate as potassium salts. The Schiff bases synthesised by this method are solids of different shades of yellow and they were characterised by elementary analysis, FTIR, UV–Vis, and ^{1}H NMR spectroscopic methods [11].

The Fe(III) complexes were prepared as described by Casella et al. [13], introducing some modifications [11]. The ligand (0.001 mol) was dissolved in methanol at room temperature and 0.001 mol of potassium hydroxide was added. $Fe(NO_3)_3 9H_2O$ (0.001 mol) was added directly to the solution. The reaction mixture was left for 5–6 h at room temperature with stirring and under a nitrogen atmosphere. The KNO_3 formed was filtered off and the solution was concentrated. Finally, the product was concentrated under vacuum at room temperature to induce the precipitation, then it was filtrated and washed with *n*-hexane. A dark violet solid was obtained and was dried under vacuum. All the complexes were prepared according to the procedure described previously. The complexes synthesised by this method are dark amorphous solids of violet color with molecular formulae $[Fe_2L_2(H_2O)_4](N0_3)_2(H_2O)_{1-3}$ (Yields 70–80%).

Metal microanalyses of the complexes were performed with a Shimadzu atomic absorption spectrophotometer, model AA-6200. The infrared spectra (KBr pellets) were recorded on a Bruker, model AMX300 spectrophotometer. The Mössbauer spectra of these complexes as fine powder samples were obtained in a conventional spectrometer with constant acceleration. The source was 10 mCi ^{57}Co in a Pd matrix. The γ-ray detection was carried out with a Reutes–Stokes detector connected to an Ortec amplifying and selecting system. A 1024 channel Canberra multichannel analyser was used for the data acquisition. The reported isomer shift values are relative to sodium nitroprusside. Electrochemical studies were done with a PAR 173 potentiostat and PAR 175 programmer equipped with a Model 179 digital coulometer. Polarographic measurements were done with BAS CV27 cyclic voltammetry equipment. Molar conductance was measured at 25 °C on a Radiometer model CDM-83 conductimeter with a CDC-304 electrode. Electronic spectra were recorded on a Unicam II UV–Vis spectrophotometer. Variable temperature (5–300 K) magnetic susceptibility data were obtained with a SHE Model 906 SQUID type susceptometer–magnetometer and calibrated with $Hg[Co(NCS)_4]$. The diamagnetic corrections were calculated from Pascal's constants.

3. Results and discussion

The complexes synthesised in this work are amorphous solids of dark violet colour, with molecular formulae $[Fe_2L_2(H_2O)_4](N0_3)_2(H_2O)_m$ $(m = 1–3)$. The complexes were characterised by elementary analysis, FTIR, UV–Vis, and Mössbauer spectroscopy methods and conductivity, electrochemical, and magnetic measurements. The dimeric iron complexes contain hexacoordinated iron (III), with the metal ion surrounded by water molecules and the salicylidenimine ligand coordinated through the iminic nitrogen and the phenolic oxygen. Both metal ions are bridged by the carboxylate

groups of the amino acids residue, Fig. 1. The physical characteristics of the complexes are summarised in Table 1. In general, the complexes are highly insoluble in most organic solvents of low polarity, and although they are soluble in water, they decompose releasing the free ligand.

3.1. Magnetic susceptibilities

The magnetic susceptibilities of the $[Fe_2(L_2(H_2O)_4](NO_3)_2(H_2O)_m$ set were determined over the temperature range 5–300 K. The plot of the reciprocal of the molar susceptibility versus temperature for Fe–SA–Ala complex is shown in Fig. 2 and is similar for the rest of the complexes. The alanine complex, for example, has an effective magnetic moment per molecule (μ_{eff}), which slightly decreases from $7.10\mu_B$ at 300 K to $7.03\mu_B$ at 60 K, after which there is a major decrease to $5.85\mu_B$ at 5 K. The trend is similar for the rest of the complexes. The μ_{eff} values at 300 K for complexes are lower than the theoretical value of $8.37\mu_B$ for effective moment of two independent high spin iron (III) ions ($S = 5/2$). The decrease of μ_{eff} at lower temperatures indicates that two high-spin iron (III) centres are weakly antiferromagnetically coupled [14].

The magnetic susceptibility of the binuclear iron (III) complexes was analysed using the van Vleck equation [14] with a spin exchange Hamiltonian, $H = -JS_1S_2$, where $S_1 = S_2 = 5/2$. All the calculations were performed using a least-squares minimisation routine,

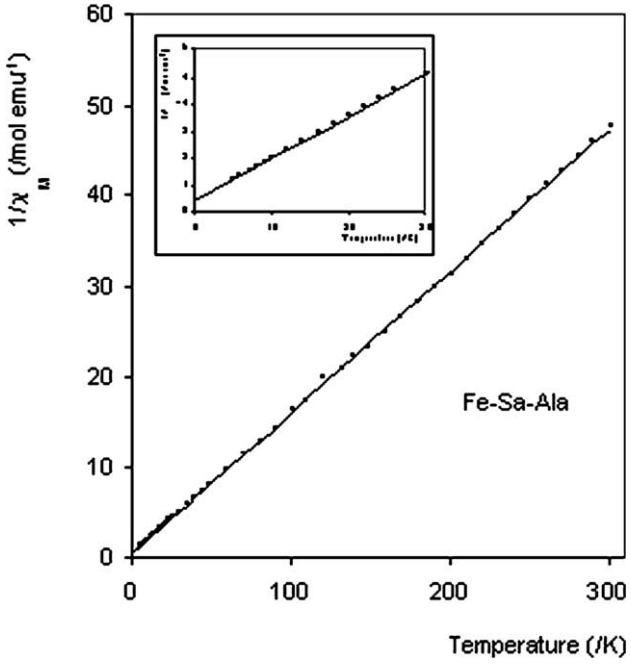

Fig. 2. Temperature dependence of the reciprocal molar susceptibility of Fe–SA–Ala.

Table 2
Magnetic parameters for dinuclear iron (III) complexes

Complexes	μ_{eff} (300 K) dimeric complex (μ_B)	g	$-J$ (cm^{-1})	R	θ (K)
Fe–SA–Gly	7.05	2.37	0.12	4.2×10^{-6}	−1.46
Fe–SA–Ala	7.10	2.37	0.21	2.1×10^{-5}	−2.68
Fe–SA–Val	6.86	2.18	0.16	3.1×10^{-4}	−4.27
Fe–SA–Leu	6.71	2.20	0.15	6.1×10^{-5}	−2.36
Fe–SA–Ile	7.00	2.19	0.12	4.8×10^{-4}	−5.14
Fe–SA–Fen	7.24	2.39	0.09	5.6×10^{-5}	−1.66

where $SSQ = \sum_i [(\chi_i^{obs} - \chi_i^{calc})/\chi_i^{obs}]^2$. We report the parameter $R = SSQ/(n-p)$, where n is the number of experimental data points and p is the number of parameters allowed to vary in the minimisation routine. The final magnetic parameters for the different complexes are summarised in Table 2. For all complexes, a very small negative value was obtained for J (−0.09 to −0.21 cm^{-1}), indicating that the two iron (III) ions are very weakly antiferromagnetically coupled [14]. The g values were somewhat greater than expected for ferric ions. We attribute this to the difficulty of fitting them when the J values are so small. These values are comparable with those reported for other tris-carboxylate-bridged complexes $[Fe_2(O_2CH)_4(BIPhMe)_2]$ [15], in which the J value is −0.16 cm^{-1}. Other complexes derived from $[Fe_2(salen)_2L_2]$, where L = oxalate and squarate as bridging ligands have J values of −7.1 and −0.39 cm^{-1}, respectively [16]. For bis-carboxylate complexes such as $[Fe_2(O_2CCH_3)_2L_2](ClO_4)_2$, where L = *N*,*N*′-dimethyl-*N*,*N*′-bis-(2-pyridylmethylethane)-1,2-diamine, the value of the antiferromagnetic exchange coupling constant is also very small, J value, i.e., −1.5 cm^{-1} [15].

The magnetic properties of carboxylate-bridged di-iron (III) complexes depend significantly on the nature of the bridging ligands. For example, the values for J vary between −13 and −26 cm^{-1} for hydroxo and alkoxo carboxylate-bridged complexes [17–20].

3.2. Mössbauer spectroscopy

Mössbauer spectra for all complexes were recorded at 4, 298 and 300 K. Fig. 3 shows a representative spectrum and theoretical least-squares fit of the data. The parameters obtained for the series of carboxylate-bridged iron (III) complexes, derived from salicylaldehyde and the different α-amino acids, are summarised in Table 3. The values of the chemical shifts are referred to sodium nitroprusside.

The spectra of all the complexes show two overlapping doublets that are revealed by shoulders in each spectrum, and by the width and asymmetry of the obtained signals [11]. The integrated absorption intensities of the two spectral subcomponents show a 1:1 ratio, and consequently, the relative proportion of iron in both sites is the same. The above indicates the presence of two inequivalent iron (III) centres in the dinuclear complexes.

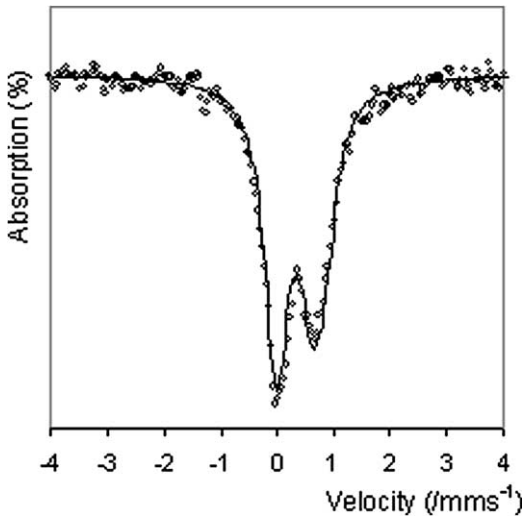

Fig. 3. Mössbauer spectrum for Fe–SA–Ala at 300 K.

The isomer shifts are similar for both doublets ($\delta_1 \sim 0.60$ mm s^{-1}, $\delta_2 \sim 0.70$ mm s^{-1}), as expected for very similar ligand environment for the iron centres, and the values correspond to high spin Fe(III) [21–23]. In all the complexes, the second site shows a higher quadrupolar splitting value ($\Delta E_Q = 0.68$–1.01 mm s^{-1}), that is indicative of a variation in the electric field gradient, probably caused by greater distortions of the octahedral geometry at this site [23,24]. The Mössbauer spectra at room temperature show an asymmetric doublet. At lower temperature this asymmetry is partially lost, but a slight asymmetry is retained even at 4 K. The asymmetry of the lines is probably due to Gol'danskii–Karyagin and spin–spin relaxation combined effects, since it disappears partially with decreasing temperature [21,24]. The isomer shift values of 0.50 mm s^{-1} and quadrupolar splitting in order to 0.9 mm s^{-1} are in accord with pseudo-octahedral system, with a N,O coordination sphere and carboxylate bridges, like in $[Fe_2O(O_2CH_3)_2(Me_3TACN)](ClO_4)_2$ (Me_3TACN = 1,4,7-trimethyl-1,4,7-triazacyclo-nonane) [25]. These parameters are similar for those derived from iron ions in hemerythrin forms,

Table 3
Mössbauer parameters for dinuclear iron complexes at 77 and 300 K

Complexes	Temperature (K)	I.S.[a] ($mm\,s^{-1}$)		ΔE_Q[b] ($mm\,s^{-1}$)		A_1/A_2[c]

[c] Area ratio.

in which a coordination sphere also formed by nitrogen and oxygen atoms and carboxylate bridges is present [26]. On the other hand, the difference in ΔE_Q values for sites 1 and 2 is indicative of different local symmetries for the two ferric sites, producing the splitting of the T_{2g} orbital triplet by crystal field distortion. The values indicate a lower symmetry for site 2 compared to site 1 [18a]. Since the quadrupolar splitting values are not significantly different, the ferric ions at both sites must have a pseudo-octahedral arrangement [23,24]. It is also possible to consider that the dinuclear iron (III) complexes synthesised in this work have a more symmetric conformation at 77 K than at 298 K.

Although big fluctuations do not exist in the value of the isomer shift, this value increases as the amino acid side chain increases. A higher electronic density on the metal atom could also explain these fluctuations. The fact that these differences are small may be due to retrodonation effects of ligand to metal donation, thus leaving a constant electron density on each iron atom [11,27,28].

3.3. Cyclic voltammetry

The electrochemistry of the dinuclear complexes was studied by cyclic voltammetry. Cyclic voltammetry of the complexes was recorded in DMF with [TBA][PF_6] as supporting electrolyte, in the potential range +1.3 to −1.8 V versus SCE. The redox parameters are summarised in Table 4. In all cases, three redox processes

Table 4

Fe–SA–Ile	I	−0.30	−0.36	0.06	−0.32	0.75	5.25×10^3
	II	−0.52	−0.59	0.07	−0.54	1.34	
	III	−1.09	−1.20	0.11	−1.18	1.34	
Fe–SA–Fen	I	−0.31	−0.38	0.07	−0.30	1.32	1.69×10^4
	II	−0.50	−0.57	0.07	−0.55	2.05	
	III	−1.05	−1.17	0.12	−1.12	1.16	

[a] Potential values are in volts and referred to SCE. $\Delta E = E_{pa} - E_{pc}$; $E_{1/2} = (E_{pa} + E_{pc})$. E_{pa} and E_{pc} are the anodic and cathodic peak potentials, respectively.

were observed at essentially identical potentials. This result is indicative of a similar electronic environment for the iron in all complexes. The first and second processes can be ascribed to successive redox reactions with approximately $E^1_{1/2} = -0.3$ V and $E^2_{1/2} = -0.6$ V versus SCE,

$$[Fe_2L_2(H_2O)_4]^{2+} \overset{E^1_{1/2}}{\underset{-e^-}{\overset{+e^-}{\rightleftharpoons}}} [Fe_2L_2(H_2O)_4]^{+} \overset{E^1_{1/2}}{\underset{-e^-}{\overset{+e^-}{\rightleftharpoons}}} [Fe_2L_2(H_2O)_4] \quad (1)$$

where L = Schiff base ligand.

Both couples were quasireversible, and with potential separations (ΔE^1, ΔE^2) between 60 and 70 mV, indicating a one-electron transfer per dimer. The ratio $i_p/v^{1/2}$ was constant in accord with a diffusion-controlled process.

The first two peaks can be assigned to two consecutive one-electron reduction process, affording $Fe^{II}Fe^{III}$ and $Fe^{II}Fe^{II}$ species, similar to those observed for other binuclear carboxylate-bridged iron (III) complexes [29–31].

The separation between redox potentials $E^1_{1/2}$ and $E^2_{1/2}$ ($\Delta E_{1,2} = E^1_{1/2} - E^2_{1/2}$) is between 0.22 and 0.29 V. The comproportionation constant K_c at 298 K for Eq. (2) were calculated using Eq. (3) and are in the 5.3×10^3–2.5×10^4 range (Table 3),

$$Fe^{III}Fe^{III} + Fe^{II}Fe^{II} \overset{K_c}{\rightleftharpoons} 2Fe^{II}Fe^{III} \quad (2)$$

$$K_c = \exp\left(\frac{\Delta E_{1,2} nF}{RT}\right). \quad (3)$$

The K_c values obtained are in agreement with an intermediate electron coupling between redox sites, which is indicative of a moderate charge delocalisation between metal centres, class II, Robin–Day classification [32–34].

The third redox process with $E^3 1/2 = -1.10$ V (versus SCE) involves more than one electron and may be attributed to the reduction of the Fe^{II}–Fe^{II} species [35,36]. The analysis of the polarographic waves indicates that the electron ratio between the first two reduction processes and the third reduction process is 1:1:2.

3.4. Spectroscopy data

Infrared data were recorded in KBr pellets at room temperature. The vibrational data for all dinuclear iron complexes and the free ligand are summarised in Table 5. For all complexes it can be seen that the vibration of the –C=N bond in the complexes is displaced toward lower energy, in comparison to the free ligand; the opposite is observed for the –C–O (phenolic) group [37]. On the other hand, the symmetric and asymmetric stretching absorption bands associated with the carboxylate group show a decrease in energy for both bands. Furthermore, since the difference between these bands is about 170 cm^{-1}, it may be assumed that the carboxylate group is bridging the two metal atoms [38]. At lower energy, an absorption is present around 800–810 cm^{-1}, and this can be assigned to chelate ring vibrations, since it is not present in the free ligand [39]. Around 645–680 cm^{-1}, the band corresponding to out-of-plane vibrations, δO–C–O of the carboxylate bridge can be identified [40]. The absorptions at approximately 560 and 450 cm^{-1} were assigned to the metal–ligand vibrations Fe–N and Fe–O, respectively, in agreement with Nakamoto [39]. These bands are of low intensity and are not present in the free ligand spectrum. The spectra of all the complexes showed a broad band at 3400 cm^{-1} due to lattice water. The single absorption at 1445 cm^{-1} is indicative of an ionic nitrate group [41].

In agreement with infrared data and reported assignments for similar Schiff bases, it is possible to infer that these dimeric complexes have six-coordinated structures in which the metal ion is coordinated to water oxygen, phenol oxygen, imine nitrogen, and carboxylate oxygen, the latter group bridging both iron atoms (Fig. 1).

The low solubility of the complexes in a great variety of solvents allowed the electronic spectra to be recorded

Table 5

only in methanol. The electronic spectra of the complexes are strongly dominated by the electronic transitions due to the iron-salicylaldiminate chromophores. The charge transfer bands from phenolate to the metal (causing the red-purple color of the complexes) are of intermediate intensity and appear near 450 nm. These bands correspond to a charge transfer from the pπ orbital of phenolic oxygen to the dπ orbital of the iron [42]. The absorption bands between 230 and 260 nm are assigned to π–π^* transitions of benzenoid type [30,38]. The absorption bands near 295 and 420 nm have been assigned to the π–π^* and n–π^* transitions, originating mainly in the azomethine chromophore [32,38]. The other bands near 320 and 480 nm should correspond to ligand–metal charge transfer bands [37].

4. Conclusions

By Mössbauer spectroscopy, it is possible to identify two different sites for iron. For the whole series of complexes derived from salicylaldehyde and different α-amino acids, the isomer shift and quadrupolar splitting for both sites correspond to high spin Fe(III). The quadrupolar splitting for these two sites is different, due to different distortions at each iron centre with a pseudo octahedral arrangement. The values of chemical shift and quadrupolar splitting are similar to those shown by iron nuclei in biological compounds with N and O coordination spheres and with carboxylate bridges. The observed weak antiferromagnetic interactions are in agreement with other iron polynuclear complexes with carboxylate bridges.

From the cyclic voltammetry measurements, it was possible to determine two redox couples which identified the process of reduction of Fe(III) to Fe(II) and one redox couple for the reduction of iron II. Polarographic measurements indicate that for the reductions of iron (III), there is one electron involved and the reduction of Fe(II) is related to a two-electron transfer.

From the results obtained by infrared, electronic, and Mössbauer spectroscopy, besides the electrochemical, conductimetric, and magnetic measurements, the structures of dimeric complexes with Schiff bases derived from α-amino acids and salicylaldehyde (Fig. 1) are confirmed.

Abstract

The hydrothermal reactions of H_3TMA (or Na_3TMA) with metal acetate yield three novel coordination polymers $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)]\cdot H_2O$ (**1**), $Cd_2Na_2(TMA)_2(H_2O)_4$ (**2**) and $[Cd_2Co(TMA)_2(H_2O)_4]\cdot 2H_2O$ (**3**) (TMA = trimesic acid, PRZ = piperazine). The three Cd(II) centers in **1** are bridged by TMA ligands and a μ_3-O atom of coordinated hydroxide to generate a sandwich-liked tri-layer motif. These motifs with a Cd_3O core are further interlinked by hydrogen bond interactions to stack in a 3D coordination framework with a porous dimension of ca. 7.5×5.5 Å. Complex **2** is a three-dimensional polymer based on tetranuclear heterometallic clusters. The centrosymmetric tetranuclear heterometallic cluster contains a Cd_2Na_2 parallelogram cluster core. These clusters are connected through the coordination of carboxylate oxygen atoms of TMA ligands to form a 3D coordination framework. Complex **3** represents the first structural characterization of a trimesate complex containing two different transitional metals. Each TMA^{3-} ligand in the $Cd_2Co(C_9H_3O_6)_2(H_2O)_4$ structure unit of **3** binds to other three structure units, resulting in a 3D coordination polymer. The three complexes exhibit strong fluorescent emission bands at 420 nm (λ_{ex} = 314 nm) for complex **1**, 424 nm (λ_{ex} = 314 nm) for complex **2**, and 419 nm (λ_{ex} = 308 nm) for complex **3** in the solid state at room temperature. The preliminary magnetic property of complex **3** has been investigated.

1. Introduction

The construction of inorganic coordination polymers with unusual electrical, magnetic, optical and catalytic properties is currently considered as one of the most important issues [1–3]. Hydrogen bonding and coordinative metal–ligand interactions are two principal methods for the construction of extended structural coordination polymer solids. The assembly of a wide variety of 1D, 2D and 3D extended porous metal–organic supramolecular polymers exhibiting unusual ion exchange, neutral guest exchange and selective adsorptive behavior from hydrogen bonding interactions has still to reach a new level as a hot subject [4], and yet the construction of extended metal–organic architectures from metal–ligand interactions has been widely studied. For example, some very interesting functional coordination solids with cyclic or porous structures based on metal ions and bridging ligands containing N-donors have been prepared [5–7]. Another approach to novel porous networks involves the reaction

doi:10.1016/j.poly.2004.04.018

of organic ligands containing O-donors such as multicarboxylates with alkaline earths or transition metal ions under hydrothermal conditions [8]. As a building block to construct some porous or cyclic coordination polymer, the trimesic acid (H_3TMA) ligand exhibits a variety of coordination fashions and holds the capability of generating coordination architectures of diverse sizes and shapes. Although there have been a lot of reports [9–14] on infinite 1D, 2D and 3D coordination polymers assembled by trimesate, however, so far as we know, most of them contain a single metal atom, whereas those constructed by two different metal atoms and TMA ligands are very rare, with the reported compound [NaCu-$TMA(H_2O)_4]\cdot 2H_2O$ [10b]. In this paper, we report three novel compounds of metal-trimesate $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)]\cdot H_2O$ (**1**), $Cd_2Na_2(TMA)_2(H_2O)_4$ (**2**)

and $[Cd_2Co(TMA)_2(H_2O)_4]\cdot 2H_2O$ (**3**), measuring their strong fluorescence emissions in the solid state at room temperature, based on diverse coordination architectures.

2. Experimental

2.1. Materials

All analytical grade chemicals and solvents were purchased commercially and used without further purification.

2.2. Preparations

2.2.1. Na_3TMA

Na_3TMA was synthesized according to the chemical reaction equation: $H_3TMA + 3NaOH \rightarrow Na_3TMA + 3H_2O$.

2.2.2. $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)]\cdot H_2O$ (**1**)

0.134 g (0.502 mmol) cadmium(II) acetate dihydrate, 0.106 g H_3TMA (0.504 mmol), 0.0493 g (0.254 mmol) piperazine hexahydrate ($C_4H_{10}N_2\cdot 6H_2O$) and 12 ml water were loaded into a 23 cm^3 Teflon-lined stainless-steel vessel, which was then sealed and placed in a programmable furnace. The resulting mixture was heated at 100 °C h^{-1} to 160 °C and held at that temperature for 10 h, then cooled to 140 °C at 4 °C h^{-1} and held for 5 h, followed by further cooling at the same rate to room temperature to give a 44.67% yield of **1** (0.207 g) based on Cd, as primrose yellow crystals which were collected by mechanical isolation and washed with water (3 × 10 ml) and absolute alcohol (3 × 10 ml), then dried at 40 °C. *Anal.* Calc. for $Cd_3C_{22}H_{26}N_2O_{17}$, $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)]\cdot H_2O$: C, 28.47; H, 2.80; N, 3.02; O, 29.34. Found: C, 28.21; H, 2.85; N, 3.12; O, 29.45%. FT-IR (KBr pellet, 4000–400 cm^{-1}): 3380(vs, br), 3244(vs, sh), 2364(m), 1612(vs, sh), 1561(vs, sh),

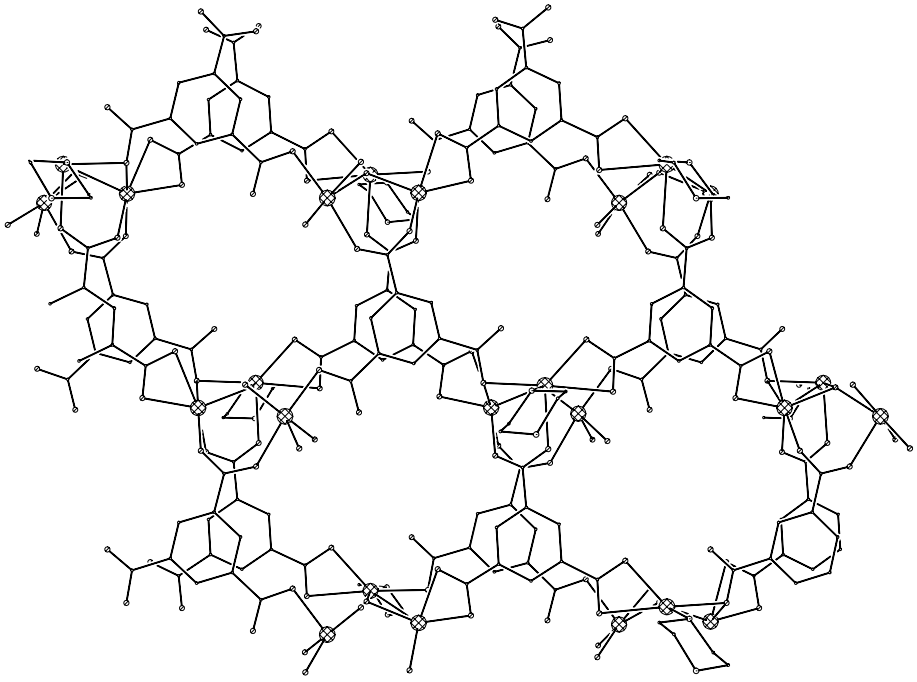

Fig. 3. The 3D porous structure of **1** along the *b*-axis. All hydrogen atoms are omitted for clarity.

2.3. Physical measurements

Infrared spectra were measured on a Perkin–Elmer FT-IR 2000 spectrometer using KBr pellets in the 4000–400 cm^{-1} region. Elemental analyses were carried out by an EA1112 CHNS elemental analyzer. Fluorescent data were collected on an Edinburgh FL-FS920 TCSPC system, thermal gravimetric analysis (TGA) was tested under nitrogen with a heating rate of 10 °C min^{-1} using a Perkin–Elmer TGA-7 Thermal Analysis system. The magnetic susceptibility was measured on a SQUID magnetometer.

2.4. Crystal structure determination

Crystals of a suitable size for the three title compounds were mounted on glass fibers. Intensity data were collected with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and the ω scan mode, using a Rigaku R-AXIS RAPID Weissengberg IP diffractometer. The structures were solved by direct methods using SHELXS-97 [15] and refined by full-matrix least-squares calculations with SHELXL-97 [16]. All non-hydrogen atoms in the three title complexes were refined with anisotropic thermal parameters. Most of the hydrogen atoms in the three complexes were located in calculated positions or found from difference Fourier maps.

3. Results and discussion

3.1. A summary of coordination fashions for the TMA ligand

As mentioned above, TMA has a great ability to construct different coordination frameworks with metal ions using various coordination fashions. We now summarized fifteen coordination models in Fig. 1, three (Fig. 1, M–O) of which are discovered first in this work. It is noticeable that one carboxylic group of TMA contains a bridging μ_3-O atom in coordination pattern N.

3.2. Structures

The crystallographic data of complexes **1**, **2** and **3** are given in Table 1.

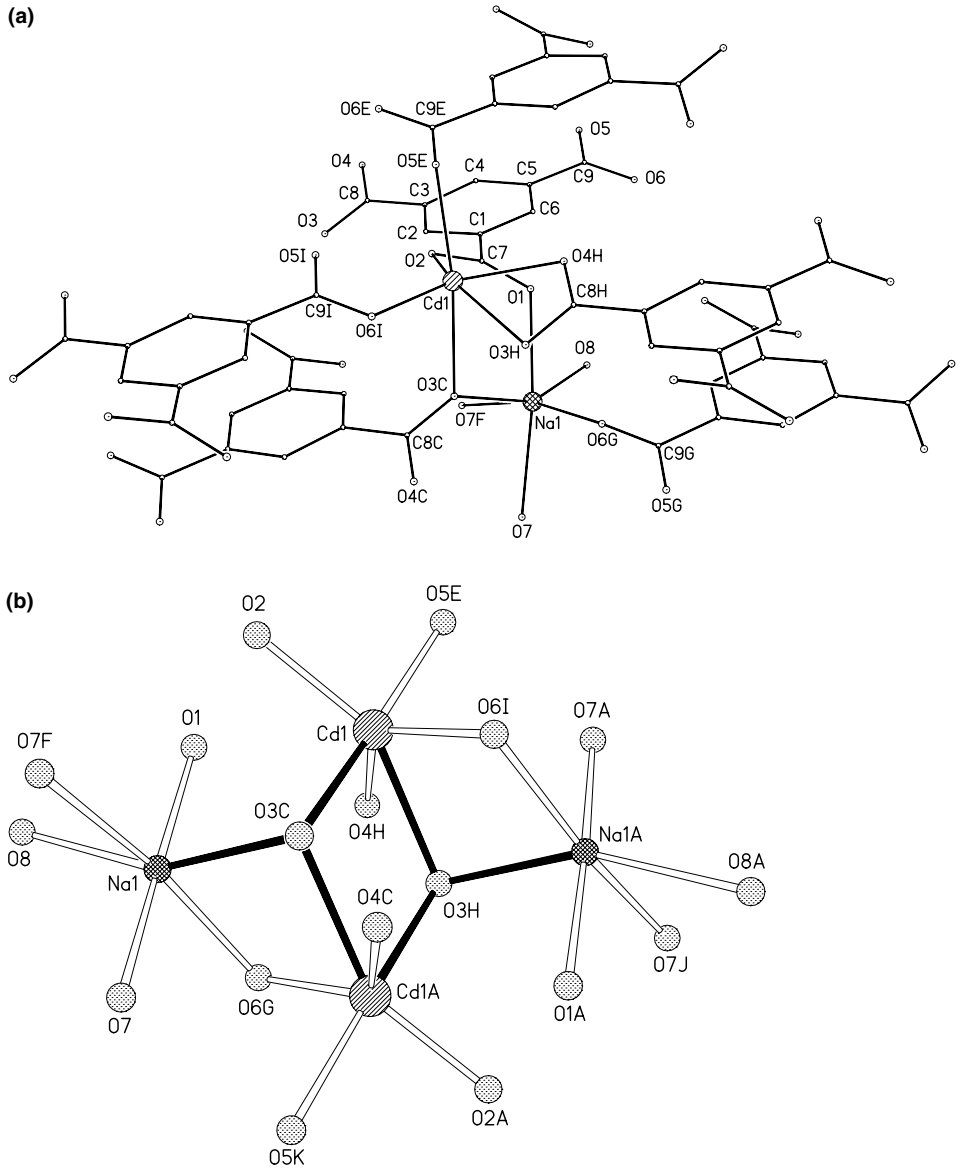

Fig. 4. (a) The local coordination environments of Cd1 and Na1 in **2**. Symmetry codes: C, $-x+1,-y+1,-z$; E, $-x+1,-y+1,-z+1$; F, $-x,-y+1,-z$; G, $-x,-y+1,-z+1$; H, $x-1,y+1,z$; I, $x,y+1,z-1$. (b) The Cd_2Na_2 core in the tetranuclear cluster unit. Symmetry codes: A, $-x,-y+2,-z$; C, $-x+1,-y+1,-z$; E, $-x+1,-y+1,-z+1$; F, $-x,-y+1,-z$; G, $-x,-y+1,-z+1$; H, $x-1,y+1,z$; I, $x,y+1,z-1$; J, $x,y+1,z$; K, $x-1,y-1,z-1$.

3.2.1. $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)]\cdot H_2O$ (1)

As shown in Fig. 1, L and M, the TMA ligand has two coordination fashions in complex **1**. In one fashion (Fig. 1, L), the three carboxylate groups of the TMA ligand bind to metal ions adopting unidentate, bidentate and bridging unidentate patterns. In the other fashion (Fig. 1, M), the three carboxylate groups of the TMA ligand link to metal ions using bidentate and chelating bis-bidentate forms. The local coordination environment of the three Cd(II) centers is described in Fig. 2. The trinuclear Cd_3O core, which is constructed by three Cd(II) centers and a capped μ_3-O atom (O16 from a coordinated hydroxide ion), fabricates the principal architecture of complex **1**. Selected bond lengths and bond angles are listed in Table 2. Bond lengths of Cd1–O16, Cd2–O16 and Cd3–O16 are 2.263(3), 2.203(3) and 2.303(3) Å, respectively; and distances of Cd···Cd separation are 3.3629(4) Å (Cd1···Cd2), 3.6612(4) Å (Cd2···Cd3) and 4.1762(5) Å (Cd1···Cd3). The bond angles of Cd1–O16–Cd3, Cd3–O16–Cd2, Cd2–O16–Cd1 and the interatomic angles of Cd3···Cd1···Cd2 and Cd1···Cd2···Cd3 are 132.3(1)°, 108.7(1)°, 97.7(1)°, 56.9(0)° and 72.8(0)°, respectively.

The Cd1 atom is coordinated by four oxygen atoms (O1, O2, O3A, O12B), a capped μ_3-O atom (O16) and a nitrogen atom (N1) from a PRZ molecule, forming a distorted octahedral geometry. The O1 and O2 atoms come from a chelating bidentate carboxylate group

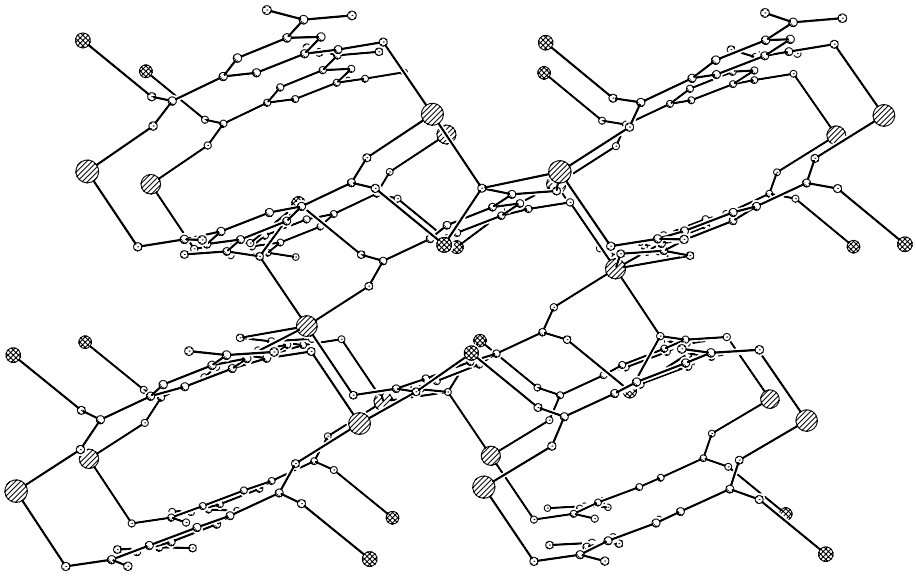

Fig. 5. The 3D structure of compound **2**. All the hydrogen atoms and coordinated water molecules on the Na atoms are omitted for clarity.

(Fig. 1, M) of the first TMA ligand; O3A atom comes from a bidentate carboxylate group (Fig. 1, M) of the second TMA ligand; whereas the atom O12B comes from the bridging unidentate carboxylate group (Fig. 1, L) of the third TMA ligand. Similar to Cd1, besides being coordinated by the capped unitary μ_3-O atom (O16), the six-coordinated Cd2 atom is coordinated by three oxygen atoms [O4A and (O5B, O6B)], which come from two different bidentate and chelating bidentate carboxylate groups (Fig. 1, M) of two separate TMA ligands; meanwhile, it is bound to two oxygen atoms (O10A and O12B) from two diverse bidentate and bridging unidentate carboxylate groups (Fig. 1, L) of two separate TMA ligands. The Cd3 atom is also six-coordinated by the capped unitary μ_3-O atom (O16), three terminal coordinated water molecules (O13, O14 and O15), as well as two oxygen atoms (O8 and O9A) from two different unidentate and bidentate carboxylate groups (Fig. 1, L) of two

separate TMA ligands. The non-coordinated nitrogen atom (N2) of piperazine is protonated. The rudimental building block of compound **1** is constructed by two TMA ligands with two diverse coordination fashions, three Cd(II) centers, a protonated PRZ molecule as well as a capped unitary μ_3-O atom (from an hydroxide ion). As shown in Fig. 3, the rudimental building blocks are interlinked along the *ac*-plane to yield a sandwich-like tri-layer molecular motif subunit with a porous dimension of ca. 7.5×5.5 Å (based on nuclei separation). These independent 2D sandwich-like sheet subunits are further interconnected by hydrogen bond interactions (Table 3) between layers to stack in a 3D coordination framework.

3.2.2. $Cd_2Na_2(TMA)_2(H_2O)_4$ (**2**)

Complex **2** is a three-dimensional polymer based on tetranuclear heterometallic clusters. Selected bond lengths and angles in **2** are listed in Table 4.

The coordination fashion of the TMA ligand in **2** is depicted in Fig. 1, N, where the TMA ligand possesses three different carboxylate groups of bidentate, bridging bidentate and chelating/bridging bidentate bonding modes. Different from complex **1**, complex **2** contains two diverse metal ions [Cd(II) and Na(I)], which is rare in all coordination polymers of TMA [10b]. Fig. 4(a) reveals the local coordination environment around the Na(I) and Cd(II) centers. The metal atoms (Cd1 and Na1) are in distorted octahedral geometry. The Na1 atom is coordinated by six oxygen atoms (O1, O3C, O6G, O7, O7F and O8), three of which (O1, O3C and O6G) come from a bidentate carboxylate group, a chelating/bridging bidentate carboxylate group and a bridging bidentate carboxylate group (Fig. 1, N) of three separate TMA ligands, respectively; the remaining oxygen atoms (O7, O7F and O8) come from three terminal water molecules. The Cd1 atom is coordinated by six oxygen atoms (O2, O3C, O3H, O4H, O5E and O6I), of which atom O2 comes from a bidentate carboxylate group of TMA; O3C, O3H and O4H come from two chelating/bridging bidentate carboxylate groups of two separate TMA ligands; whereas the O5E and O6I atoms come from two bridging bidentate carboxylate groups of two separate TMA ligands.

The tetranuclear heterometallic cluster in complex **2** and its parallelogram Cd_2Na_2 cluster core are shown in Fig. 4(b). The centrosymmetric tetranuclear cluster is constructed from two Cd atoms (Cd1 and Cd1A, symmetry code A: $-x, -y+2, -z$), two Na atoms (Na1 and Na1A), eight TMA ligands and four-coordinated water molecules. Two longer Cd–Na edges of 3.826(1) Å (Cd1–Na1 and Cd1A–Na1A) and two shorter Cd–Na edges of 3.642(1) Å (Cd1–Na1A and Cd1A–Na1) construct a parallelogram Cd_2Na_2 cluster core, angles of Na1A–Cd1–Na1 and Cd1–Na1–Cd1A being 114.99(2)° and 65.01(2)°, respectively. The symmetrical center $(0, 1, 0)$ is between the two Cd atoms and between the two Na atoms in the tetranuclear cluster Cd_2Na_2 core. There are two μ_3-O atoms from carboxylate groups (O3C and O3H) in the cluster core. These tetranuclear heterometallic clusters are connected through the coordination of carboxylate oxygen atoms of TMA ligands, forming a 3D polymer (Fig. 5). A 3D polymer based on tetranuclear heterometallic clusters is rarely found in all known coordination polymers of TMA complexes [10b].

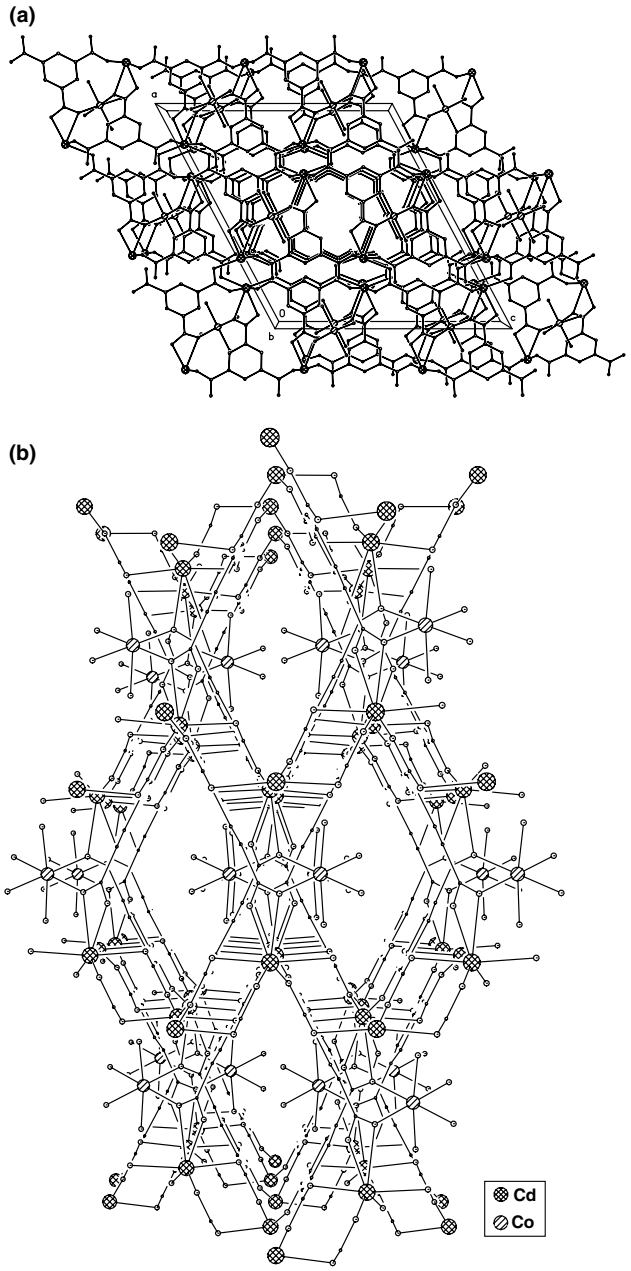

Fig. 7. (a) The 3D structure of **3** along the *b*-axis. (b) The 3D structure of **3** viewed down the *c*-axis showing the channel. All the hydrogen atoms are omitted for clarity.

As given in Table 5, there are several intermolecular hydrogen bonds between the TMA ligands and the coordinated water molecules.

3.2.3. $[Cd_2Co(TMA)_2(H_2O)_4]\cdot 2H_2O$ (3)

The selected bond lengths and bond angles of complex **3** are shown in Table 6. To our knowledge, complex **3** is the first trimesate containing two different transitional metals. As illustrated in Fig. 6, the coordination sphere in **3**, $Cd_2Co(C_9H_3O_6)_2(H_2O)_4$, has a crystallographic symmetry C_2, in which Co1 atom is on the twofold rotation axis 2[0 1 0], and two $Cd(C_9H_3O_6)$ groups and four-coordinated water molecules (O7, O8, O7A, and O8A, symmetry code A: $1-x, y, 1/2-z$) are on the two sides of the axis 2[0 1 0].

Each TMA^{3-} ligand in the coordination sphere $Cd_2Co(C_9H_3O_6)_2(H_2O)_4$ bridges to three other coordination spheres, resulting in a 3D coordination polymer (see Fig. 7(a) and (b)). There is a channel with dimensions of ca. 6.5×6 Å (based on nuclei separation) in the 3D framework, and the Co(II) coordination spheres are located in the 1D channels (see Fig. 7(b)).

The coordination fashion of the TMA ligand in **3** is illustrated in Fig. 1, O. The six-coordinated Cd1 and Co1 centers have a distorted octahedral geometry. The Cd1 atom is coordinated by six oxygen atoms from a chelating/bridging bidentate carboxylate group (O1, O2) and four different bidentate carboxylate groups (O3A, O4B, O5C, O6D) of five separate TMA ligands. The Co1 atom is coordinated by six oxygen atoms (O1, O1A, O7, O7A, O8, O8A), two of which (O1 and O1A) come from two different chelating/bridging bidentate carboxylate groups of two separate TMA ligands, the remaining four (O7, O7A O8 and O8A) come from four terminal coordinated water molecules.

As shown in Table 7, there are several intermolecular hydrogen bonds between the O–H group of coordinated water molecules and the carboxylate oxygen atoms.

3.3. Elemental analysis and TGA measurement

The elemental analysis data for the three complexes are consistent with the formulas of $[Cd_3(TMA)_2(HPRZ)(H_2O)_3(OH)]\cdot H_2O$ (**1**), $Cd_2Na_2(TMA)_2(H_2O)_4$ (**2**), and $[Cd_2Co(TMA)_2(H_2O)_4]\cdot 2H_2O$ (**3**). The TGA data of complex **1** indicates two obvious weight losses. The first weight loss starts at ca. 103–151 °C to give a total weight loss of ca. 11.2%, corresponding to loss of one guest H_2O molecule and one PRZ molecule per formula unit. The second weight loss starts at ca. 314–462 °C to give a total weight loss of ca. 52.4%, corresponding to loss of $4H_2O$ molecules and two TMA molecules per formula unit, which indicates that the framework of complex **1** is stable. The TGA data of complex **2** shows an obvious weight loss starting at ca. 100–150 °C to give a total loss of ca. 9.5%, corresponding to loss of $4H_2O$ molecules per formula unit. TMA removal starts at ca. 355–492 °C, which sug-

Table 7
Hydrogen-bonding geometry (Å, °) in **3**

D–H···A	D–H	D···A	D–H···A
O(7)–H(4w)···O(3)#1	0.724	2.927(3)	136.6
O(7)–H(4w)···O(6)#2	0.724	2.975(3)	115.2

O(8)–H(5w)···O(5)#3	0.878	2.739(3)	159.4
O(8)–H(6w)···O(1w)#4	0.934	2.701(3)	164.9
O(1w)–H(1w)···O(2)	1.003	2.710(3)	161.7

Symmetry codes: #1, $-x, 1+y, 1/2-z$; #2, $1-x, 1-y, -z$; #3, $-1/2x, y+1/2, z$; #4, $x, 1-y, z+1/2$.

gests that TMA ligands are strongly coordinated with the metal centers to form a stable architecture. Similar to complex **2**, the TGA of compound **3** exhibits an obvious weight loss starting at ca. 80–200 °C, to give a total loss of ca. 13.3% which corresponds to loss of $6H_2O$ molecules per formula unit. TMA removal starts at ca. 350–512 °C, which accounts for the framework of **3** being rather stable, too.

3.4. Spectroscopy and fluorescent properties

The IR spectra of these complexes show the characteristic bands of the TMA ligand at 1622–1551 cm^{-1} for the asymmetric vibration $\nu_{as}(COO^-)$ and at 1441–1367 cm^{-1} for the symmetric vibration $\nu_s(COO^-)$, and the broad bands of water at 3215–3442 cm^{-1}. In the three complexes, the absence of the expected characteristic bands at 1730–1690 cm^{-1} attributed to the protonated carboxylate groups accounts for the complete deprotonation of H_3TMA ligands in the course of the hydrothermal reactions [17]. For complex **1**, the presence of characteristic bands at 1027–997 cm^{-1} are assigned to absorption vibrations of the PRZ ligand.

The emission spectra of complexes **1**–**3** in the solid state at room temperature are depicted in Fig. 8. It can be observed that intense emissions occurring at 420 nm (Fig. 8(a), $\lambda_{ex} = 314$ nm) for **1**, 424 nm (Fig. 8(b), $\lambda_{ex} = 314$ nm) for complex **2**, and 419 nm (Fig. 8(c), $\lambda_{ex} = 308$ nm) for complex **3** are attributed to the ligand-to-metal charge-transfer (LMCT) bands. It is worthy of statement that complex **1** exhibits a quenching of the fluorescence with $\tau = 3.47$ ns, which suggests that complex **1** may be an excellent candidate for potentially photoactive material.

3.5. Magnetic investigation of complex 3

The magnetic susceptibility of complex **3** was measured in the 5–300 K temperature range and is shown as

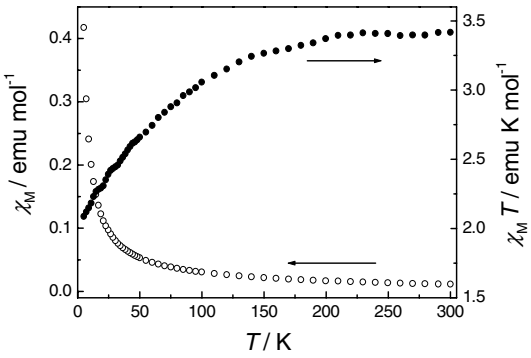

Fig. 9. The χ_M and $\chi_M T$ vs. T plots for complex **3**.

χ_M and $\chi_M T$ versus T plots in Fig. 9. The experimental $\chi_M T$ value of the complex at room temperature is ca. 3.41 emu mol^{-1} K per Cd_2Co unit, indicating significant contributions from the orbital momentum, typical of the Co(II) ion ($^4T_{1g}$) in an octahedral field. Upon cooling, the χT value decreases monotonously and reaches 2.09 emu mol^{-1} K at 5 K. Since the Co(II) ions are well isolated from one another by the TMA ligand and the Cd(II) ions, the magnetic interaction between Co(II) ions should be negligible. The temperature-dependent behavior should be mainly due to the combination of spin-orbit coupling and low-symmetry ligand field effects that cause splitting of the $^4T_{1g}$ levels [18,19].

3.6. Reaction condition dependence of structures

As illustrated in Fig. 1, the TMA ligand has a considerable variety of coordination fashions when it reacts with metal ions, and the resulting coordination polymer solids usually possess 1D, 2D or 3D structural characteristics. Yaghi et al. [9c] described that the dimensionality of the resulting coordination framework topology constructed by metal ions and TMA is extremely dependent on the deprotonation level of H_3TMA. Another noticeable experimental phenomenon

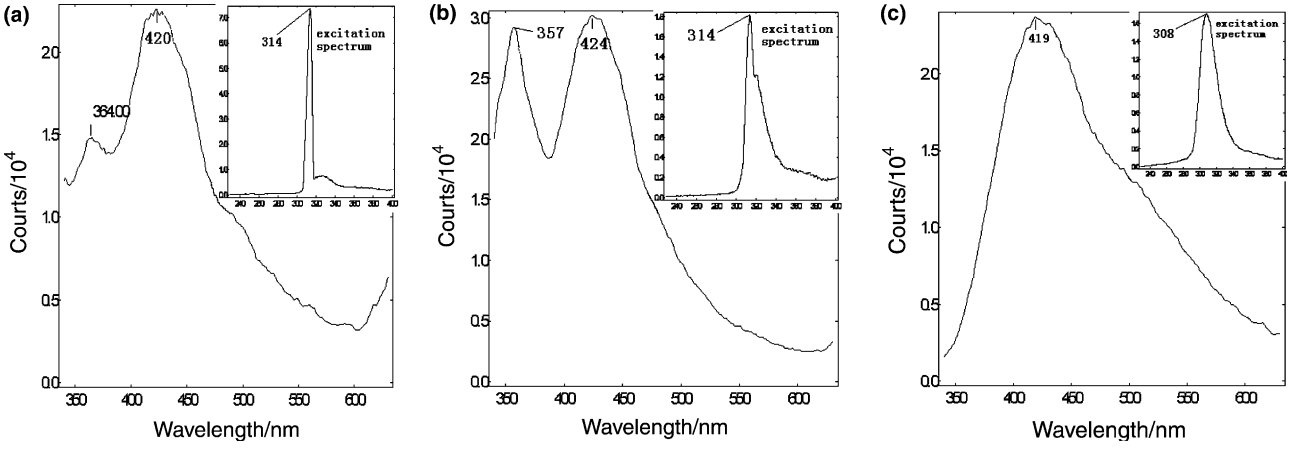

Fig. 8. Solid-state emission spectra for complexes **1**–**3**: (a) complex **1**; (b) complex **2**; (c) complex **3**.

is that different polymer solids constructed by TMA and metal ions are often obtained synchronously in the same reaction vessel under hydrothermal condition, which indicates the mechanisms of those reactions are very complex. Of course, the temperature, crystallisation time, pH value and cooling rate are also important influential factors on the structures of the resulting coordination solids. Revelation of the microscopic reaction mechanisms of H_3TMA may lead to new strategies for inorganic synthetic chemistry and design of supramolecular hosts.

It has now been demonstrated that the three novel title polymer solids with 3D porous frameworks have been synthesized through hydrothermal reactions of TMA with transition metal ions. The title complexes **2** and **3** contain two different metal centers in the coordination architectures. Similar to zeolitic properties, the TGA data of the three title compounds indicate the backbones of the polymers are very stable. The intense fluorescent emissions show that the title complexes could have roles as potential photoactive materials. The experimental $\chi_M T$ value of complex **3** at room temperature is ca. 3.41 emu mol^{-1} K per Cd_2Co unit. Upon cooling, the χT value decreases steadily and reaches 2.09 emu mol^{-1} K at 5 K.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 214205 for compound **1**, 214204 for compound **2** and 214203 for compound **3**. Abstract

A mixture of dicyanopolyynes having the general formula N≡C–(C≡C)$_n$–C≡N with $n = 2$, 3 and 4 is formed and collected in a simple apparatus when graphite electrodes are arced in liquid nitrogen. As secondary products regular polyynes, i.e. hydrogen-terminated polyynes with the general formula H–(C≡C)$_n$–H with $n = 4$, 5 and 6 are formed together with the cyanopolyynes. It is shown that the hydrogen for carbon chain end-capping is supplied by the plasmalysis of traces of water present in the liquid nitrogen while nitrogen end groups of cyanopolyynes derive from the plasmalysis of molecular nitrogen. This study has confirmed the key role played by the graphite electrodes as the source of elemental carbon under the form of sp-hybridized carbon chains which are then terminated by atoms derived from the medium where the electric arc is struck. The analysis of the reaction products was made by electronic absorption spectroscopy and the separation and identification of the molecular species produced was made with a liquid chromatographic analysis (HPLC) coupled with a diode-array (DAD) detector. The importance of the polyynes and their role as a class of carbon allotropes has been discussed.

1. Introduction

The concept of allotropy sometimes appears too limited when applied to the richness of chemical structures that have been observed or theorized for elemental carbon [1]. In fact, elemental carbon occurs in a plethora of forms and mixed structures. For this reason it is convenient to classify carbon allotropes and other forms of carbon based on the degree of hybridization as proposed by Heimann et al. [2]. According to the proposed classification (see Fig. 1), there are three fundamental carbon allotropes: diamond, graphite and polyynes. In each of these elemental forms the carbon atoms are sp^3, sp^2 and sp hybridized, respectively.

Fullerenes, carbon nanotubes and related structures (see Fig. 1) are considered intermediate forms of carbon in this classification, because of the deviation from planarity imposed by the curved surfaces observed in these molecules; the carbon hybridization is no longer pure sp^2 but an intermediate value between sp^2 and sp^3 [3].

Acetylenic chains like H–(C≡C)$_n$–H are constituted by a sequence of sp hybridized carbon atoms. If the chain is relatively short and terminated with hydrogen atoms or with other groups, it is called a polyyne chain. In such a case it is an almost linear carbon chain although deviations from linearity have been observed experimentally in some cases [4]. However, when a polyyne chain is closed into a ring, we obtain a cyclopolyyne which again is no longer bonded by purely sp hybridized carbon. The distortion from linearity introduces a higher degree of hybridization and hence the carbon atoms are at an intermediate level of hybridization between sp and sp^2. Carbyne is instead an ideal form of solid elemental carbon made by sp-hybridized

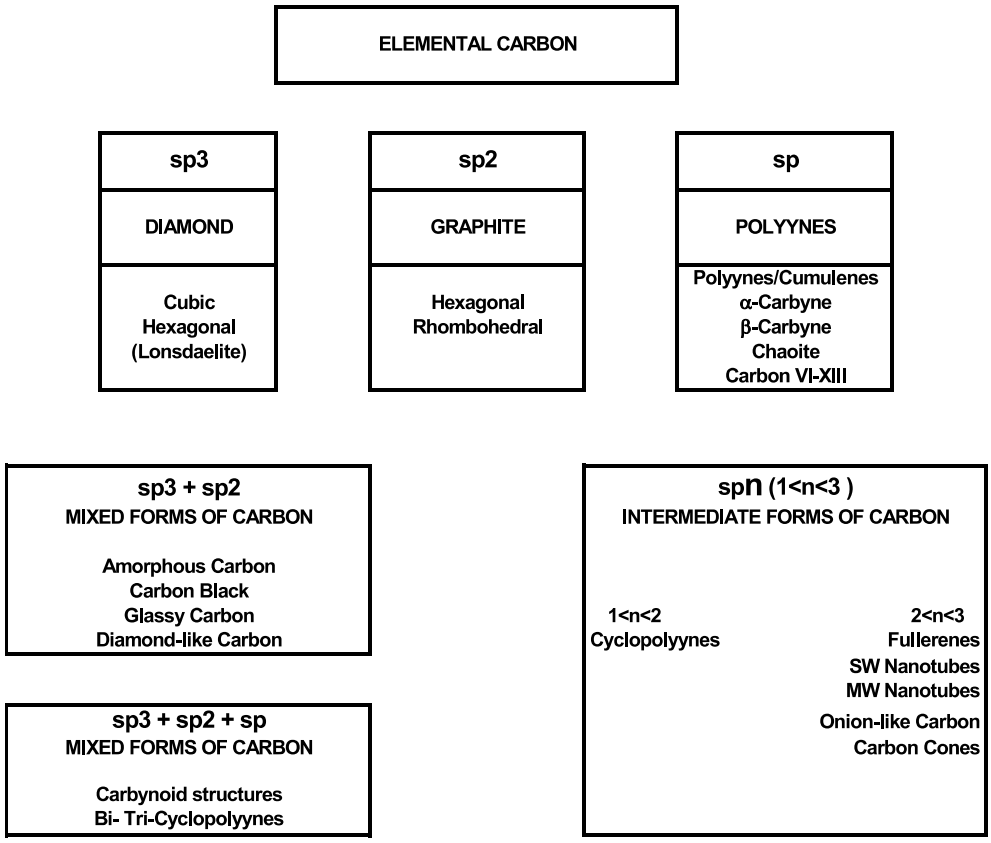

Fig. 1. Carbon allotropes and other forms of carbon. Elaborated and updated by the author; after Heimann et al. [2].

carbon chains whose length is so high that they can be considered infinite. By using the language of polymer chemistry, it is possible to state that polyynes are oligomeric forms of sp-hybridized carbon atoms which have been synthesized and observed experimentally essentially in solution and in vapour phase, while carbyne is a high polymer made again by sp-hybridized carbon atoms but it has never been produced in pure form experimentally. Instead of carbyne, several times carbynoid structures have been obtained as results of attempted synthesis of carbyne. The distinction between carbyne and carbynoid structures was proposed by Heimann [5] and is useful to distinguish between ideal and real sp-carbon solid. In fact, the literature is confusing since often the synthesis of carbyne has been reported while actually the synthesis was of carbynoid structures [5]. Carbynoid structures are essentially made by carbyne chains or, better, by polyyne chains or domains embedded in a carbonaceous matrix of mixed forms of carbon or stabilized by certain metal ions.

It is possible to talk about mixed forms of carbon when carbon atoms with different types of hybridization occur simultaneously in the same solid. Examples of mixed forms of carbon are the already mentioned carbynoid structures where it is possible to detect the coexistence of hybridized sp, sp^2 and sp^3 carbon atoms [6]. Other examples of mixed forms of carbon are represented by diamond-like carbon and glassy carbon.

Probably the carbonaceous solids closest to carbyne were synthesized under special conditions for instance by Kavan and co-workers [7], by Ravagnan et al. [8] and by Tanuma and Palnichenko [9].

Based on the preceding discussion, polyynes are a class of molecules which simultaneously can be viewed as a class of carbon allotropes, exactly as fullerenes are: a special class of molecules made exclusively by elemental carbon.

The bulk synthesis of polyynes belonged to the realm of organic chemistry and was achieved in 1972 [10] by a complex, impressive and elegant synthetic procedure. Recently, we have shown that a polyynes mixture can be easily synthesized in one shot and in relatively bulk quantities when an electric arc is struck between two graphite electrodes submerged in a solvent like methanol, acetonitrile or *n*-hexane [11–14]. The graphite electrodes play a key role in the polyynes synthesis as will be discussed elsewhere [15]. Moreover the temperature and the nature of the solvent also seem to be important in the arc synthesis. For instance, when acetonitrile was used as solvent, polyynes chains having up to 18 carbon atoms were obtained, provided that the arc between the graphite electrodes was struck in the solvent cooled at

−40 °C [12,13]. In acetonitrile the polyynes series was accompanied by a monocyanopolyynes series described by the general formula H–(C≡C)$_n$–C≡N [12,13]. Instead, when *n*-hexane was used as solvent at room temperature, although the polyynes series with chains having the maximum length of 16 carbon atoms were the dominant products, significant traces of polycyclic aromatic hydrocarbons (PAH) and other by-products were found in the solution [15].

To maximize the beneficial effects of the low temperatures, which permit the synthesis of the longest polyynes chains and to reduce the solvent interference, which tends also to produce by-products, we have studied the products formed in the electric arc between graphite electrodes submerged in liquid nitrogen. The present work is a complete account of our investigation on this specific subject.

2. Experimental

Graphite rods 6 mm diam. × 150 mm length (99.999% purity) used as electrodes were obtained from Aldrich. All solvents used were analytical or high performance liquid chromatographic (HPLC) grades from Fluka or Riedel de Haen. Liquid nitrogen was supplied by SIAD gas tecnici (Italy).

The electric arc was conducted using DC current. The DC power supply was from KERT (Italy) model Cosmo 3000 (0–30 V and 0–10 A). The electronic absorption spectra were recorded on a Shimadzu UV160A spectrophotometer on filtered solutions in *n*-octane. The solution containing the crude mixture of polyynes in *n*-octane was filtered through a PVDF Acrodisc® membrane having a pore size of 0.45 μm, to remove carbon particles suspended in the solvent, before recording electronic spectra or before running HPLC analysis.

The HPLC analysis of the solutions was conducted on an Agilent Technologies System Model 1100 equipped with a diode-array detector (DAD) and a C-8 column Zorbax Eclipse XDB-C8. A mixture of CH_3CN/water 80/20 v/v was used as the mobile phase and pumped at a rate of 1.5 ml/min into the HPLC column. Further details on the analysis can be found in previous works [12–14].

2.1. The electric arc in liquid nitrogen between graphite electrodes

A three-necked round bottomed Duran flask of 100 ml equipped with two graphite electrodes arranged in a "V" geometry was filled with liquid nitrogen and immersed in liquid nitrogen in a Dewar flask. The third neck of the flask was fitted with a valve connected with a Drechsel tube (a gas washing bottle) of 250 ml filled with 100 ml of *n*-octane.

The electric arc was ignited and sustained at 9.5 A and 15–30 V (DC current) by putting in contact and by moving slightly up and down the two graphite electrodes submerged in liquid nitrogen in the three-necked flask. The bright light of the arc can be easily observed and the heat generated by the arc caused the partial vaporization of the liquid nitrogen, which was forced to bubble into the gas washing bottle attached to the reaction flask. The products formed in the electric arc were forced to pass into the octane solvent outside the reactor and hence were trapped in the solvent. Periodically samples of the *n*-octane solution were collected and analyzed by electronic absorption spectroscopy and by HPLC–DAD analysis. The following polyynes were identified based on the retention time and the electronic spectra: C_6N_2, C_8H_2, C_8N_2, $C_{10}H_2$, $C_{10}N_2$.

2.2. Electric arc between graphite electrodes submerged in n-octane

To create a "blank" or a reference to the products formed by the carbon arc in liquid nitrogen, we have arced also graphite electrodes directly in *n*-octane at 10 A under the same conditions described elsewhere [12,14] for *n*-hexane. Indeed the products were practically the same as detected and reported previously for *n*-hexane [12–14], namely, a polyynes mixture with polyyne C_8H_2 as the most abundant component (see the spectrum in Fig. 2(a)).

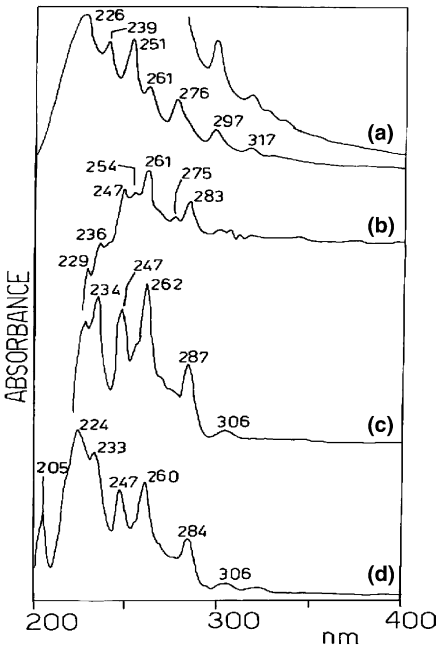

Fig. 2. Electronic absorption spectra of polyynes mixtures. (a) Polyynes obtained by arcing graphite directly into *n*-octane. (b) Initial spectrum of the polyynes mixtures produced from the graphite arc in liquid nitrogen and trapped in *n*-octane at the beginning of the experiment. (c) Same as (b) but after prolonged arcing in liquid nitrogen. (d) Same as (c) at the end of the experiment; a final total concentration of polyynes estimated at about 8×10^{-6} M was achieved.

2.3. The electric arc between graphite electrodes submerged in water

The arc was conducted between graphite electrodes submerged in distilled water at 10 A. The electronic absorption spectrum of the crude aqueous solution of polyynes and other products showed the following absorption bands: 200, 215 and 226 nm as the most intense. Other weaker bands were observed at 238, 246, 250, 259, 274, 284, 300 and 323 nm.

The HPLC–DAD analysis revealed the presence of the following polyynes: C_4H_2, C_6H_2, C_8H_2 and $C_{10}H_2$. Polyyne C_8H_2 was by far the most abundant product.

3. Results and discussion

3.1. General remarks

At atmospheric pressure, carbon sublimes above 3500 °C. The complex nature of carbon vapour has been known since the end of the fifties of the last century [16,17]. The mass analysis of the carbon vapour formed in an electrical discharge between graphite electrodes has revealed all ions from C_1 up to C_{33}^+ and C_{35}^- [17,18]. Alternatively, the laser ablation of graphite by a ruby laser produced a series of species ranging from C_1 to C_{10}, the most abundant being C_2 and C_3 [16,19]. The properties of the carbon vapour have been studied theoretically by using molecular orbital theory computations. The results indicate the growth of linear polyatomic molecules essentially of the polyyne type. Extrapolation of the calculations to liquid carbon shows that this should consist of essential long chains of carbon atoms [16]. The laser vaporization of graphite [20] confirmed the earlier results, namely odd and even clusters were obtained up to C_{38}, but only even clusters above that value. It was shown later [21] that the carbon clusters larger than C_{38}, having only even numbers of carbon atoms, are made by fullerenes with a neat predominance of C_{60} and C_{70}. Conversely, the clusters having less than 38 carbon atoms have been assigned to polyynes and/or cyclopolyynes which are considered the precursors of fullerenes which, in fact, by a crosslinking reaction yield fullerenes [22,23] as it has been postulated and also demonstrated by using appropriate precursors [21]. High intensity laser ablation of graphite and other carbonaceous substrates produces also higher homologues of C_{60} and C_{70} fullerenes [24,25].

3.2. Formation of polyynes from an electric arc in liquid nitrogen between graphite electrodes

Recently we have shown that an electric arc between two graphite electrodes in a solvent produces polyyne solutions in the given solvent. The basic mechanism proposed involves carbon vaporization from the graphite electrodes under the high temperature produced by the electric arc, estimated to be above 4000 °C [11–14] and thus above the vaporization point of elemental carbon. Carbon is vaporized from the electrodes in the form of polyyne chains and then is quenched into the solvent surrounding the plasma ball of the arc. Thus, polyyne solutions are obtained.

When the graphite electrodes are arced in liquid nitrogen the polyynes formed in the arc are quenched into the very cold reservoir of the liquid nitrogen surrounding the plasma ball. During arcing, part of the liquid nitrogen vaporizes to dissipate the heat generated by the electric arc. When the liquid nitrogen vaporizes, a continuous stream of gaseous nitrogen drags the polyynes, which presumably are insoluble but are embedded in liquid nitrogen, outside the reactor (see Section 2) into the gas washing bottle connected to the reactor and filled with a solvent (*n*-octane). When nitrogen bubbles into the bottle, it releases the polyynes into the *n*-octane solvent, which acts as a trap. In fact in Fig. 2 it is possible to observe the typical polyyne spectrum from the octane solution used as a trap for these molecules. As reported and discussed in our earlier works [11–14], the polyynes are characterized by very peculiar electronic absorption spectra which permit their easy identification. When the polyynes are in a mixture they show spectra composed of several bands as reported in Fig. 2(a) obtained by arcing graphite electrodes directly into *n*-octane [11–14].

Fig. 2(b) shows the initial spectrum of the polyyne mixtures produced from the graphite arc in liquid nitrogen at the beginning of the experiment. Under these conditions, the initial concentration of polyynes was estimated from their optical density in the spectrum to be around 10^{-7} M in the *n*-octane trap. Furthermore, the spectrum in Fig. 2(b) of the polyynes produced from the arc in liquid nitrogen shows a different band pattern than the mixture of polyynes produced by arcing graphite electrodes directly into *n*-octane (compare Fig. 2(b) with Fig. 2(a)). In particular in Fig. 2(b) we can observe two main bands at 261 and 283 nm while the most intense bands in Fig. 2(a) are located at 226, 239 and 251 nm. Since the end groups of polyyne chains are affected by the nature of the solvent where the graphite arc is struck, and since we know that usually the polyynes are hydrogen-terminated when the arc is made in hydrocarbon solvents like *n*-hexane or *n*-octane and they are also cyano-terminated when the arc is made in acetonitrile, these spectral differences can be taken as a first hint that the polyynes formed in liquid nitrogen are nitrogen and hence cyano-terminated.

From our previous works on polyynes, we know the electronic absorption spectra of a series of monocyanopolyynes and from literature [26,27] we know the spectrum of the dicyanopolyyne C_8N_2 whose maximum

wavelength absorption band lies just at 261 nm. In principle, it is quite obvious to expect to produce nitrogen-terminated polyynes by arcing graphite in liquid nitrogen since the high temperatures of the electric arc may cause the plasmalysis of molecular nitrogen into atomic nitrogen which in its turn can easily form cyano-groups with carbon vapour and hence can terminate the polyyne chains into dicyanopolyynes:

$$N{\equiv}C{-}(C{\equiv}C)_n{-}C{\equiv}N$$

It is fascinating to think that similar synthetic processes leading to these or similar molecules are known to occur in the outflow of certain carbon-rich giant stars in the space [28].

By continuing arcing in liquid nitrogen with graphite electrodes, it is possible to accumulate the reaction products into the octane trap. This is illustrated in Fig. 2(c) where the bands become more intense and better defined as a function of the arcing time. In particular in Fig. 2(c) the concentration of the polyynes can be estimated at about 2.5×10^{-6} M. Arcing was stopped when all the liquid nitrogen in the reaction flask was consumed, i.e. disappeared by vaporization. The final spectrum of the products collected is shown in Fig. 2(d), with a final total concentration of polyynes estimated at about 8×10^{-6} M.

The crude *n*-octane solution, after filtration, was chromatographed in the HPLC apparatus (see Section 2). The complex polyynes mixture formed by arcing graphite directly into liquid nitrogen was resolved into six main components whose electronic absorption spectra are shown all together in Fig. 3. The three main components are easily and definitively identified from their electronic absorption spectra and are, respectively, C_6N_2, C_8N_2 and $C_{10}N_2$ (see below for further details), the former being the most abundant followed by the other two in lower concentrations. Other minor components detected were hydrogen-terminated polyynes C_8H_2, $C_{10}H_2$ and $C_{12}H_2$ in decreasing concentration and in general at much lower concentration than the corresponding dicyanopolyynes ($C_{12}H_2$ is not shown in Fig. 3).

The individual spectra of the molecular species separated by the liquid chromatographic analysis are shown in Fig. 4, following their retention time (R_t) from the bottom to top of Fig. 4. The first molecular species eluted with a $R_t = 1.55$ min was identified as C_6N_2 from its absorption spectrum ($\lambda_m = \mathbf{235}$, 222, 213 and 205 nm) in comparison to the well known [11–14] spectrum of C_8H_2 which eluted immediately after the species with a $R_t = 1.64$ min ($\lambda_m = \mathbf{227}$, 218 and 208 nm). It can be observed that both C_6N_2 and C_8H_2 have similar molecular weight (about 100 versus 98 Da, respectively), but from our previous study on polyynes and cyanopolyynes [12–14] we know that at more or less equal molecular weight the nitrogen-capped polyynes have a shorter retention time than the hydrogen-capped polyynes. Thus, the assignment appears correct. The

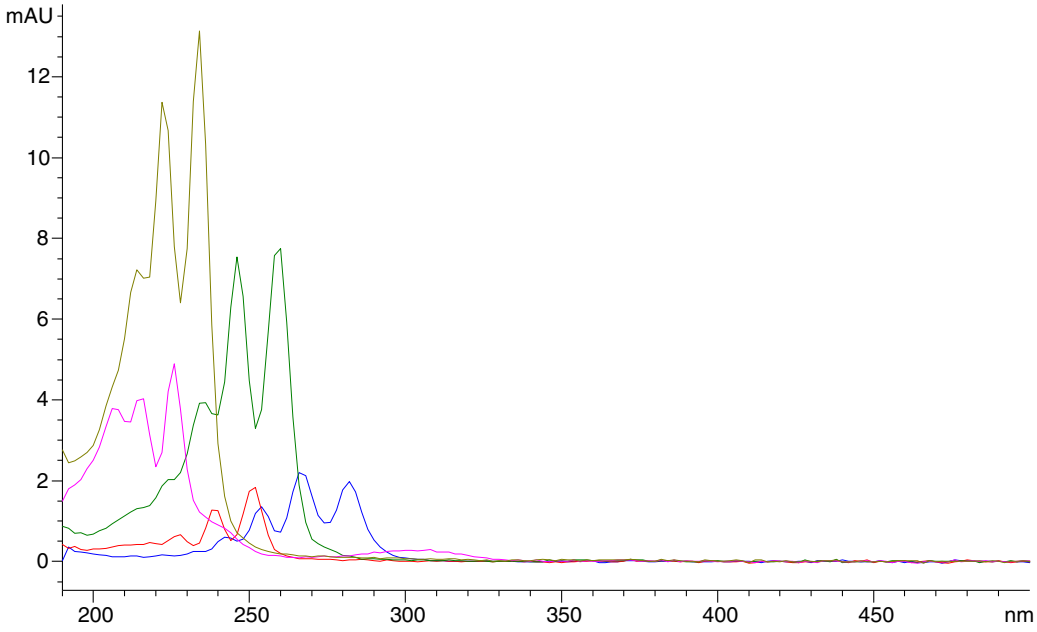

Fig. 3. Electronic absorption spectra of the polyynes formed from graphite arcing in liquid nitrogen. The liquid chromatographic analysis (HPLC) was able to separate the mixture into its components. The electronic spectrum of each component eluted was recorded by the diode-array detector (DAD). The three main components are easily and definitively identified from their electronic absorption spectra and are, respectively, C_6N_2, C_8N_2 and $C_{10}N_2$. The spectra of these three dicyanopolyynes in the figure are easily identifiable from the longest wavelength absorption band lying at 233, 260 and 283 nm, respectively. There are also two other minor components in the figure: the hydrogen-terminated polyynes C_8H_2 and $C_{10}H_2$. Furthermore, $C_{12}H_2$ has also been identified although at very low concentration (not shown in the figure).

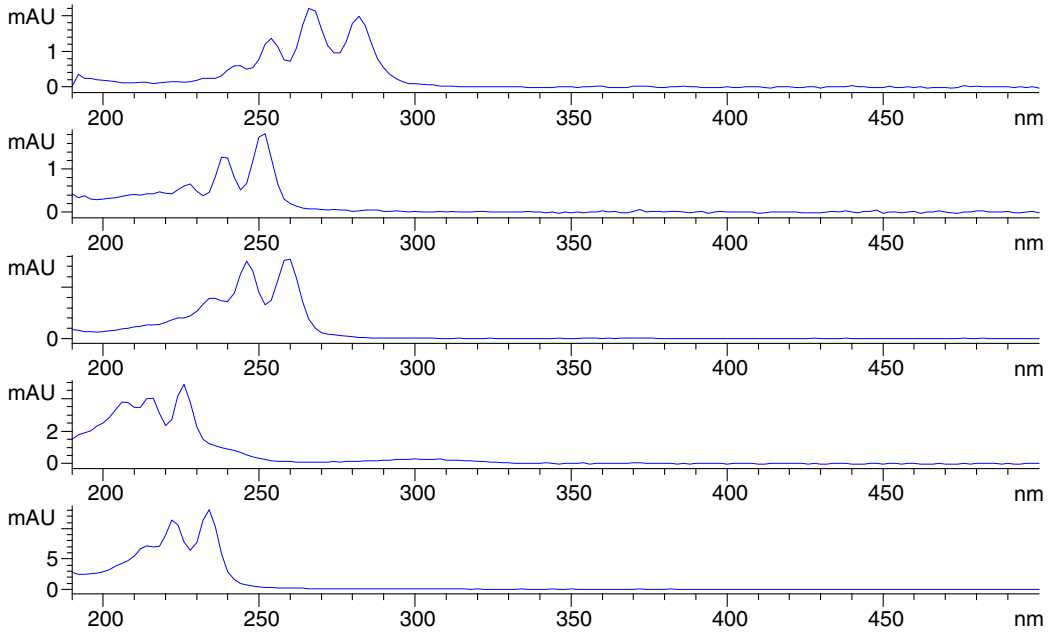

Fig. 4. Individual spectra of each molecular species separated by the liquid chromatographic analysis. From bottom to top of the figure it is possible to distinguish the spectrum of C_6N_2 with $R_t = 1.55$, then C_8H_2 with $R_t = 1.64$ followed by C_8N_2 ($R_t = 1.87$), $C_{10}H_2$ ($R_t = 2.11$) and $C_{10}N_2$ ($R_t = 2.39$).

next compound eluted with a $R_t = 1.87$ min is C_8N_2, which has been recognized from the band pattern of its spectrum which matches that reported in literature for this compound [26,27] (λ_m (found) = **260**, 247, 233, 223 and 214 nm; λ_m (literature [26]) = 261, 248, 236, 225 and 215 nm). After C_8N_2 with a molecular weight of about 124 Da, the hydrogen-capped polyyne $C_{10}H_2$ is eluted, having a molecular weight of 122 Da and a $R_t = 2.11$ min. Its spectrum matches completely the known [12–14] band pattern of this compound (λ_m = **251**, 239, 227 and 218 nm). Finally, the detection of $C_{10}N_2$ occurs at a $R_t = 2.39$ min and the spectrum is characterized by λ_m = 303, 283, **268**, 253, 243 and 232 nm. In all the spectral wavelengths reported, the most intense band is written in bold. It is also important to underline that in the assignments reported here we have been guided also by the typical retention times we have measured in earlier works for hydrogen-capped polyynes of monocyanopolyynes as reported in Table 1.

The formation of polyynes in the electric arc in liquid nitrogen represents a clear indication that the elemental carbon for the polyynes chains is supplied essentially from the graphite electrodes and not from the solvent. This result is quite expected since we know that the electric arc in vacuum conditions between graphite electrodes produces polyynes ions. Furthermore, Hirsch and colleagues [26,27] have shown that the electric arc between graphite electrodes under Kratschmer–Huffman conditions [29] in a reduced pressure of cyanogen (C_2N_2) produces a mixture of dicyanopolyynes whose main components are C_8N_2 and $C_{10}N_2$ (respectively, 55% and 35%). Also $C_{12}N_2$, $C_{14}N_2$ and $C_{16}N_2$ were detected [26,27].

Table 1
HPLC retention times of the dicyanopolyynes versus other polyynes

$R_t = 1.55$ for C_6N_2 in comparison to $R_t = 1.547$ for HC_7N [12–14]
$R_t = 1.64$ for C_8H_2 as already found in [12–14]
$R_t = 1.87$ for C_8N_2 in comparison to $R_t = 1.89$ for HC_9N [12–14]
$R_t = 2.11$ for $C_{10}H_2$ as already found in [12–14]
$R_t = 2.39$ for $C_{10}N_2$ in comparison to $R_t = 2.41$ for $HC_{11}N$ [12–14]

In the products of the electric arc in liquid nitrogen (Fig. 3), we can estimate from the chromatographic analysis that C_6N_2 represents approximately 50% (by mol.) of the mixture followed by C_8N_2 with about 25% and $C_{10}N_2$ with about 5%. The remaining products are essentially C_8H_2, $C_{10}H_2$ and $C_{12}H_2$.

The hydrogen-terminated polyynes formed in minor quantities in our synthesis derive their hydrogen end-groups from the plasmalysis of the humidity present in the reactor and in the liquid nitrogen. Therefore, they must be regarded merely as secondary products. In the next section, we demonstrate experimentally that the hydrogen-terminated polyynes are formed from the water plasmalysis. In fact, in our electric arc in liquid nitrogen we have excluded the presence of any organic solvent but not the presence of humidity. Therefore, the arc between graphite electrodes in liquid nitrogen involves necessarily also the plasmalysis of small amounts of water which supplies the hydrogen necessary for end-capping the polyynes chain.

3.3. Polyynes from the electric arc from graphite electrodes in water

As reported in our previous works [11–14] when arcing between graphite electrodes is conducted in organic solvents usually hydrogen-capped polyynes are obtained. In general, it is believed at present that the hydrogen end capping is derived from the solvent plasmalysis. Under special conditions e.g. in acetonitrile, monocyanopolyynes are produced together with normal hydrogen-terminated polyynes. The solvent plasmalysis caused by the electric arc generates atomic hydrogen, which then reacts with the diradicalic carbon chains produced by carbon vaporization from the electrodes.

In Section 3.2, the electric arc in liquid nitrogen produces cyanopolyynes as expected but also hydrogen-terminated polyynes, which are rather unexpected unless we should admit that traces of water play the role of the supplier of hydrogen atoms during the plasmalysis caused by the electric arc. In Section 2.3, we have clearly demonstrated that when the submerged electric arc between graphite electrodes is struck under distilled water, it is possible to observe the typical electronic spectrum of a mixture of polyynes in water. Furthermore, the liquid chromatographic analysis permits to separate and identify all the hydrogen-terminated polyynes series normally observed in organic solvents like methanol and *n*-hexane (see Fig. 5). Thus, it is demonstrated that the hydrogen atoms in a system of graphite electrodes and water are supplied by the plasmalysis of the water molecules. Consequently, it is now clear that the hydrogen-terminated polyynes observed as secondary products in the arcing experiment in liquid nitrogen derive from the humidity and traces of water present in the liquid nitrogen itself and in the reactor.

4. Conclusions

Polyynes represent the oligomers of carbyne, which is thought as a carbon chain of very high molecular weight: a high polymer. Although carbyne has not yet been produced in pure form and remains a limiting structure, polyynes can be produced in bulk quantity by certain multistep synthetic routes or by the electric arc between graphite electrodes submerged in organic solvents or in liquids. Polyynes are thus a class of molecules made exclusively by a chain of sp-hybridized carbon atoms and represent a class of molecules which can be regarded as a class of carbon allotropes. Of course, carbon chains of any length must be terminated by end groups to ensure stability, otherwise we are dealing with diradical chains. The simplest end groups are hydrogen atoms:

$$H–(C{\equiv}C)_n–H$$

When arcing is made between graphite electrodes submerged in organic solvents, the elemental carbon is supplied from the vaporization of the graphite electrodes under the high plasma temperature produced by the high speed electron impacts on the surface of the electrodes. The nature of the solvent does not seem to play any role in the elemental carbon supply. This has been demonstrated in the present work, where the polyynes have been formed in an "inorganic" liquid: liquid nitrogen

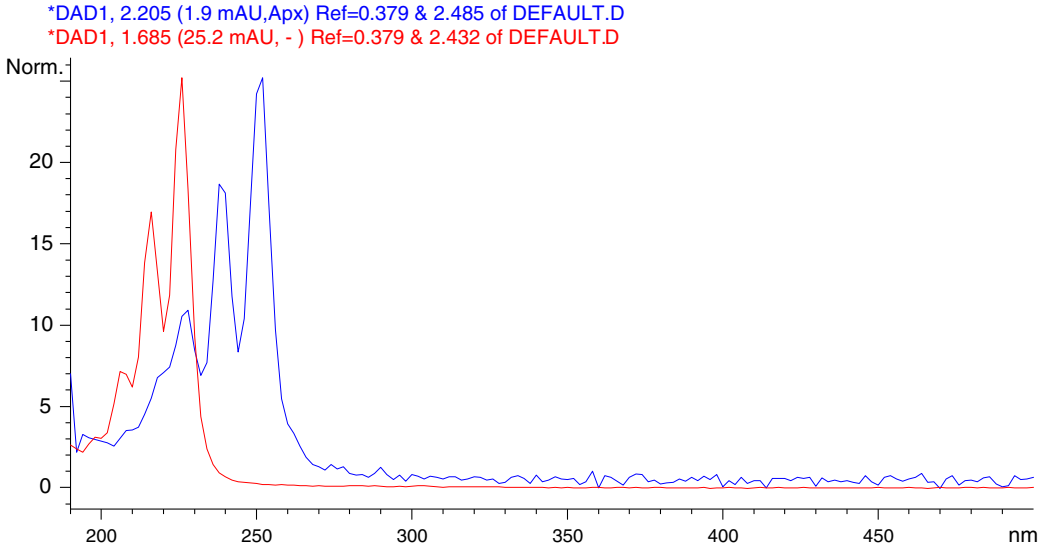

Fig. 5. Hydrogen-terminated polyynes C_8H_2 and $C_{10}H_2$ produced by arcing graphite electrodes in pure distilled water as identified by HPLC–DAD analysis of the mixture. The former polyyne was the dominant product.

instead of the organic solvents used previously, provided that graphite electrodes were used. Obviously, by arcing electrodes of other elements than carbon in liquid nitrogen no polyynes must be expected [15].

Concerning the end-groups of the polyynes, the medium where the graphite electrodes are arced seems instead to be of great importance. We have shown that in liquid nitrogen the polyynes are nitrogen terminated:

$$N{\equiv}C{-}(C{\equiv}C)_n{-}C{\equiv}N$$

The nitrogen end groups derive necessarily from the plasmalysis in the electric arc of molecular N_2 into atomic nitrogen. The nitrogen atoms react with the polyynes carbon chains produced from the graphite electrodes yielding the cyanopolyynes. However, even in liquid nitrogen the formation of cyanopolyynes is accompanied by the formation of hydrogen-terminated or regular polyynes. We have demonstrated that these secondary products are formed from the plasmalysis of traces of water present in liquid nitrogen and in the reactor. The resulting hydrogen atoms then terminate the carbon chains. In fact, if the graphite electrodes are arced submerged in distilled water regular polyynes are formed easily in detectable quantities, exactly as it happens by arcing graphite electrodes in organic solvents like methanol or *n*-hexane [11–14]. In these last two cases the hydrogen atoms are supplied from the plasmalysis of these solvents and regular polyynes are obtained [11–14].

This study has shown the easy access to cyanopolyynes in solution with a simple apparatus. The availability of cyanopolyynes will permit us to study their chemistry and physical properties, which until now have been explored mainly on a theoretical basis. It is expected that the end-capping of polyynes chains with cyano groups must give a significant stability to these molecules. Cyanopolyynes are present in the interstellar and circumstellar shells of carbon rich stars [28,29] as well as in the interstellar medium, and are thought to contribute to certain spectral features of the interstellar medium [30]. Furthermore, cyanopolyynes are known to be present in the atmospheres of the giant plants of the solar system and also on Titan, the giant moon of Saturn [31]. The results of the present work may be used to explain the easy formation of these complex molecules in space and can be also used in laboratory simulations and studies of the interstellar conditions with a very easy access to these species.

Abstract

Hydroxyapatite (HAp) was synthesized through the decomposition of a Ca(EDTA) complex in presence of phosphate ions. Ion concentrations are much higher than previously reported. This route allows the formation of HAp at temperatures below 140 °C and at different pH values. Phase identification, crystallinity and morphology of the obtained products were studied via FTIR, SEM, XRD and EDS.

1. Introduction

Hydroxyapatite (HAp) is the main inorganic constituent of bone tissue. Synthetic HAp has been successfully used for synthetic bone, metal coatings and other materials of biomedical interest [1–4]. A number of different methodologies for producing synthetic calcium phosphates are available in the literature, ranging from updates of long-known techniques, to reports on novel synthetic routes, including solution processes, hydrothermal systems, bio-mimetic systems and sol–gel methods, among others [5–18]. The preparation of homogeneous HAp precipitates via decomposition of chemical complexes through chelating agents are simple processes, particularly associated with hydrothermal reactions. These kind of processes have been used to produce HAp whiskers and coatings on metals and ceramic materials. Chelates including EDTA, citric acid and lactic acid have been tested [19–24]. Our group has recently succeeded in synthesizing SiO_2–HAp composites by decomposing the Ca(EDTA) complex under reflux conditions. In addition, HAp coatings on metals with orthopedic interest have been produced at temperatures below 150 °C [25–28].

The production of Hap through homogeneous solutions of complexed calcium yields a versatile synthetic route, which allows to experiment with different temperatures, pH conditions and concentrations of both calcium and phosphate ions. The present work shows the results of synthesizing HAp through the decomposition of the Ca(EDTA) complex in presence of phosphate ions, at concentrations five times larger than previously reported [19–24]. HAp has been produced at temperatures of 140 °C or lower. Besides, the formation and morphology of the precipitates is studied as a function of pH.

2. Experimental

2.1. Calcium/EDTA/phosphate solution

Complexed solutions were prepared with $CaCl_2 \cdot 2H_2O$ (Riedel-de Haën, analytical grade), Na_2

EDTA · $2H_2O$ (Aldrich Chemical Co., analytical grade), and K_2HPO_4 (Riedel-de Haën, analytical grade). One liter of the solutions were prepared as to obtain $CaCl_2$ 0.25 M, Na_2 EDTA 0.25 M and K_2HPO_4 0.15 M at pH values of 5.0, 7.0 and 9.0. Two hundred millilitres of the calcium/EDTA/phosphate solution at the mentioned pH values were refluxed until the production of a precipitate was observed. Solutions were also heated in a Mini-reactor Parr up to 120 and 140 °C during 4 h.

2.2. Characterization

Sample morphology and constituent elements were determined through a Low Vacuum Scanning Electron Microscope, JEOL-5900LV (LV-SEM), equipped with an energy dispersive X-ray analysis probe, Oxford (EDS) and a Hitachi S-570 with an Aspe model Sirius 10/7.5 EDS. Samples were fixed to the aluminum holder via adhesive carbon foil and secondary electrons were employed. FTIR was performed in a Perkin–Elmer Spectrum 1000. XRD was carried out in a Siemens D5000 and a Rigaku Mini Flex.

3. Results and discussion

The calcium/EDTA/phosphate solution at pH 5.0 was refluxed until a precipitate was observed after at least 20 h. Figs. 1–3 show a series of SEM micrographs showing the different morphologies obtained for pH 5.0 under the three different conditions, i.e.: reflux, 120 and 140 °C. In the solid obtained under reflux, Fig. 1, bars are present with sizes of the order of 10 μm long and 1 μm in diameter and platelets of various sizes, ranging between 1/2 and 2 μm. When the solution is heated to 120 °C, the solid obtained, Fig. 2, consists mostly of platelets with sizes ranging from 1.5 to 3 μm, in addition several needles about 1 μm long are present. The solid obtained when the solution is heated to 140 °C, Fig. 3, presents different morphology to those previously described. Crystallites resemble clustered thin blades between 2 and 3 μm long. Fig. 5 shows the corresponding X-ray diffractograms, which clearly show that the nature of the solid precipitated obtained depends on temperature. The one corresponding to the refluxed solution (the lowest in Fig. 5) shows the presence of monetite and HAp as a minority phase. The one for the solid obtained at 120 °C clearly indicates that HAp is now more abundant and, for that obtained with the reactor at 140 °C, HAp is the main phase. It is important to point out that no report on the production of HAp at temperatures below 150 °C and pH 5.0 in so short period of time is available in the literature. Thus, the presence of much higher concentrations of calcium and phosphate ions achieved in this work allow the formation of HAp under these conditions. It is also important to emphasize that

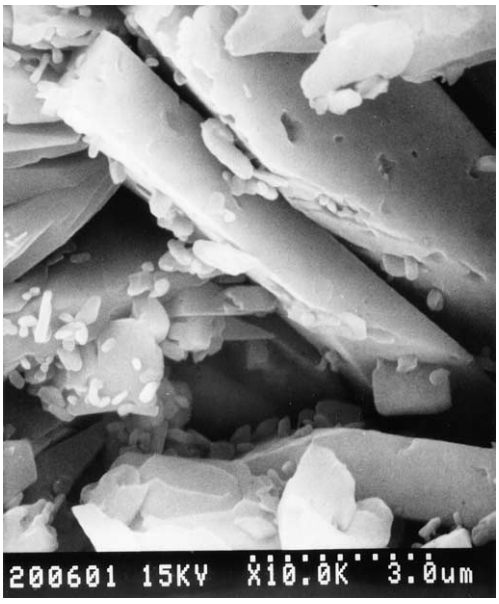

Fig. 1. Morphology and size for the solid obtained as precipitates at pH 5.0 and at reflux temperature.

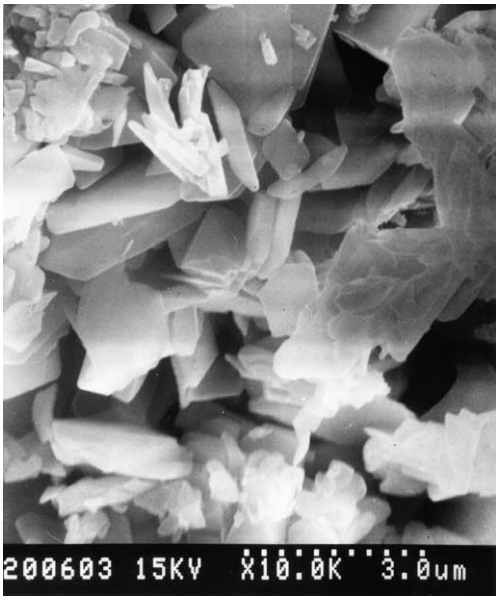

Fig. 2. Morphology and size for the solid obtained as precipitates at pH 5.0 and 120 °C.

the solubility diagram for calcium phosphates shows that at pH values smaller or equal to 5.0, HAp becomes less stable than dicalcium phosphate. Therefore, the HAp phase exposed to more acidic conditions may coexist with this compound [29,30].

Table 1 summarizes the Ca/P ratio for the solids obtained at different pH values and temperatures. For pH 5.0, the increase in this ratio with increasing temperature confirms that the solid obtained is richer in HAp as temperature is raised. However, the Ca/P ratio

Fig. 3. Morphology and size for the solid obtained as precipitates at pH 5.0 and 140 °C.

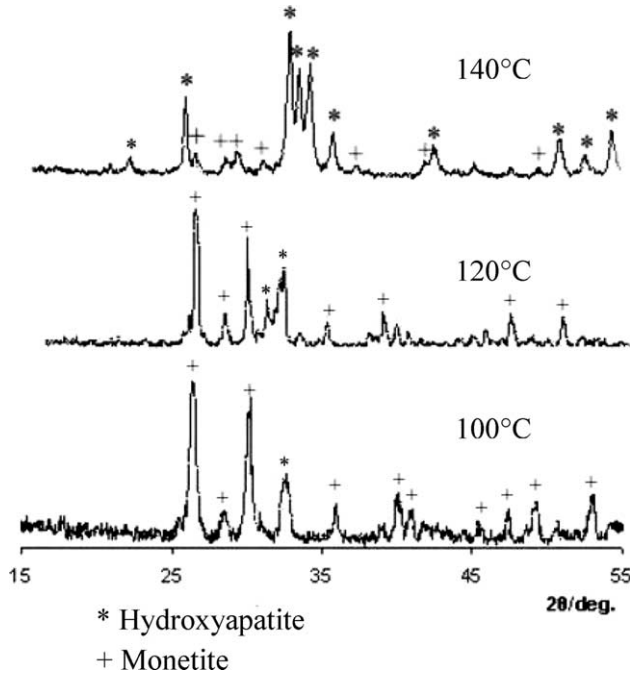

Fig. 5. X-ray diffractograms for samples prepared at pH 5.0. Temperatures are indicated above each spectra.

Table 1
Ca/P ratio for solids obtained at different pH values and temperatures by decomposition of a Ca–EDTA complex in presence of phosphate

Temperature (°C)	Ca/P (pH 5)	Ca/P (pH 7)	Ca/P (pH 9)
100	1.01	1.57	1.59
120	1.14	1.57	1.60
140	1.41	1.59	1.61

for the solid produced at 140 °C (1.41) is well below the stoichiometric ratio for HAp (1.67); this is a consequence of monetite still being present.

The solids precipitated at pH 7.0 after 96 h under reflux and for the solution heated up to 120 and 140 °C in the reactor were analyzed with scanning microscopy. Under these three conditions elongated crystallites between 5 and 10 μm are found. The image for the 140 °C case is shown in Fig. 4. X-ray diffractograms for these

Fig. 4. Morphology and size for solids obtained as precipitates at pH 7.0 and 140 °C.

Fig. 6. Morphology and size for solids obtained as precipitates at pH 9.0 and reflux temperature.

powders prove HAp to be the only phase present. XRD spectra are very similar for these samples and for those prepared at pH 9.0, the solid obtained at pH 9.0 and 140 °C is shown in Fig. 7. In Table 1, the Ca/P ratio for pH 7.0 varies between 1.57 and 1.60 showing a calcium-deficient HAp; this is typical for HAp obtained from decomposition of complexes.

It was necessary to reflux the calcium/EDTA/phosphate solution at pH 9.0 for 120 h in order to obtain a precipitate. The solid from the refluxed solution presents elongated crystallites 0.1 m in diameter and about 1.5 μm long, Fig. 6. It is important to mention that the use of complexing agents for the production of HAp via hydrothermal methods has traditionally being associated to the production of whiskers (about 15 μm in length) [29]. In this case, however, with much larger concentrations of calcium and phosphate, at reflux temperature, the size of the crystallites is significantly smaller. After heating for 4 h at 120 and 140 °C, the crystals consist of needles about 12 μm long, resembling those synthesized at pH 7.0 but some groups grow up from a common origin, see Fig. 7. Powder X-ray diffractograms show, for all samples obtained at pH 9.0, that the only phase is Hap, Fig. 8 shows the one corresponding to reflux at 140 °C.

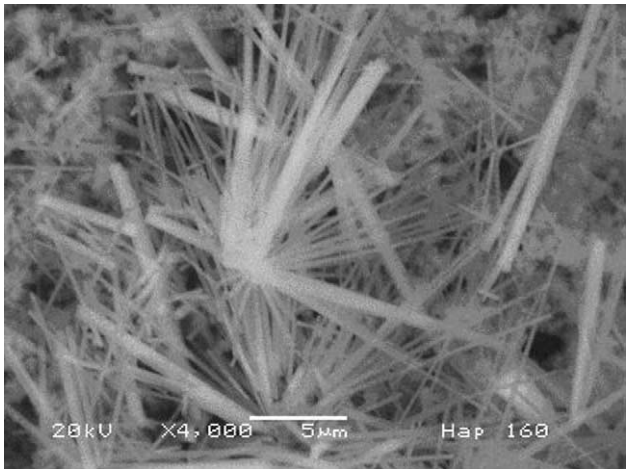

Fig. 7. Morphology and size for solids obtained as precipitates at pH 9.0 and 140 °C.

IR spectra for samples prepared at pH 7.0 and 9.0 show all bands corresponding to the PO_4^{3-} and to OH^-. A weaker band from 1400 to 1500 cm^{-1} shows the presence of traces of CO_3^{2-}. A signal at around 859 cm^{-1} shows the HPO_4^{2-} functional group.

From Table 1 it is evident that those solids with HAp as the only present phase (pH 7.0 and 9.0), are not stoichiometric but calcium-deficient. Several theories have being develop to explain this phenomenon. They consider: (a) the presence of other phases like amorphous calcium phosphate or octacalcium phosphate, (b) the absorption of phosphate species by the surface, (c) lattice defects combinations, (d) Ca^{2+} and OH^- vacancies and (e) the substitution of some phosphate groups by HPO_4^{2-} [31,32]. The presence of IR bands corresponding to CO_3^{2-} and HPO_4^{2-} in these samples could support the last model.

4. Conclusions

HAp has been prepared by a hydrothermal method under reflux and at 120 and 140 °C during 4 h at pH values of 7.0 and 9.0; by decomposition of a Ca–EDTA complex. At pH 5.0 there is a direct influence of temperature on the solid obtained; at reflux the main component of the solid is monetite. When temperature is raised, HAp phase becomes predominant. The

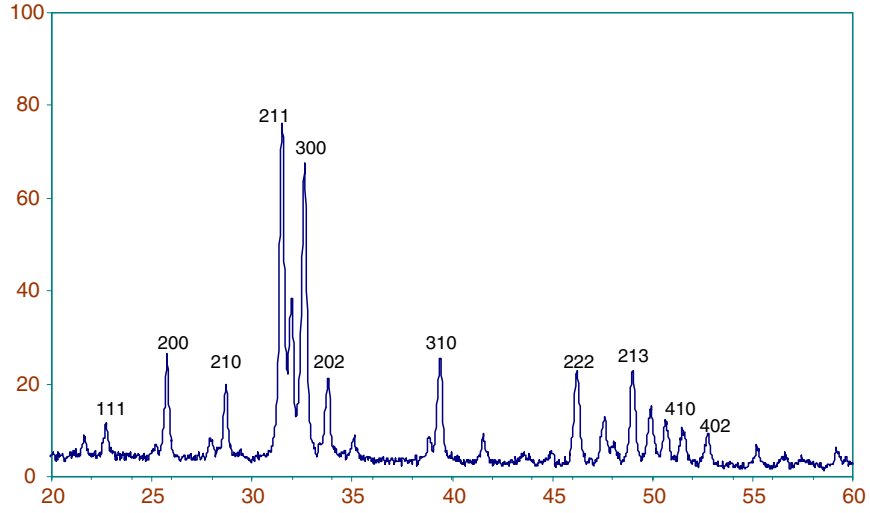

Fig. 8. X-ray diffractograms for sample prepared at pH 9.0 and 140 °C. It is totally alike to those obtained for all samples prepared at pH 7.0 and 9.0.

morphology of the solid synthesized at pH 5.0 changes with temperature, from plate like monetite to thin blades of HAp mixed with monetite. For crystals produced at pH 7.0 the morphology is elongated, with sizes between 5 and 10 μm which do not change significantly with temperature,. The crystals corresponding to pH 9.0 are all elongated with sizes varying from 1.5 μm in length and 0.1 μm in diameter for reflux temperature to about 12 μm for temperatures of 120 and 140 °C. It is important to remark that in order to obtain a solid at reflux temperatures, rather long reaction times were needed, which became even longer with increasing pH. An increase of 20 °C has the effect of reducing to 4 h the time needed to obtain a solid for the different pH values studied.

The Ca/P ratio increases with temperature for pH 5.0, this fact is explained by the formation of HAp in larger quantities. It reaches up to 1.41, due to the presence of monetite in the solid. This ratio varies from 1.57 to 1.61 for pH 7.0 and 9.0. The crystallites obtained are calcium-deficient for all pH values and temperatures investigated, this could be related to the presence of HPO_4^{2-} for all samples, as shown by its bands in the IR spectra.

Abstract

Crystal structure and minimum energy calculations show that 2,5-bis(2-pyridyl)-1,3,4-thiadiazole exists in the solid state in one of two minimum energy forms. Uncomplexed, both nitrogen atoms of the pyridyl rings facing in the direction of the sulfur atom of the five-membered hetero ring in the planar molecule. Two different single crystal structures of zinc complexed to this ligand with a Zn/ligand ratio of 1/2 show a rotation of one of the pyridyl rings of each ligand molecule to allow complexation of the metal to the pyridyl nitrogen atom of this ring and the near diazole nitrogen atom. Axial coordination to water molecules completes the octahedral geometry at zinc.

1. Introduction

There is interest in dimeric metal complexes with close metal–metal contacts and appropriate bridging atoms for their magnetic properties [1–7]. These properties may be modified by the character of the bridging species and by the geometry of the metal atoms and bridging species. 1,2,4-Triazoles (1A, 1B), 1,3,4-oxadiazoles (1C) and 1,3,4-thiadiazoles (1D) with *o*-pyridine substitution at the carbon positions of the hetero ring (Scheme 1) have been used as bridging ligands capable of enforcing suitable geometry and proximity of metal atoms, while providing a σ overlap superexchange pathway. Structural parameters such as magnitude of the M–N=N angles, coplanarity of the extended π network of the ligand with the metal, and conformation of N7 and N13 nitrogen atoms play a role in determination of the magnitude and type of magnetic interaction.

When the pyridyl nitrogen atoms face in the same direction as the N1 and N2 positions and the four nitrogen atoms bond to two metal atoms (Scheme 1D), metal–metal distances of about 4 Å are seen [8]. However, one pyridine ring may rotate 180° to bond to a metal atom along with the nitrogen atom in the 4 position. A second metal is found on the opposite side of the ligand, bound to the nitrogen atom of the remaining pyridine ring and to the near nitrogen of the oxadiazole ring [9]. In this conformation, metal–metal interactions are absent.

We have recently reported the structures of monomeric complexes of Co(II), Ni(II) and Cu(II) with the neutral 2,5-bis(2-pyridyl)-1,3,4-thiadiazole derivative

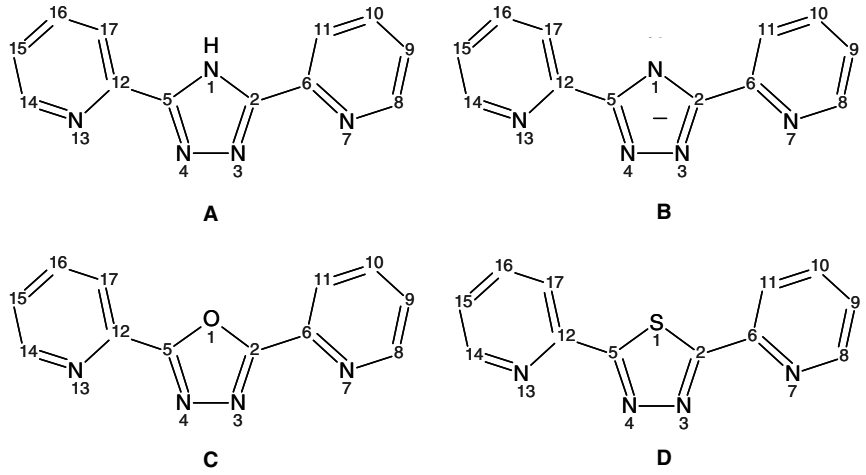

Scheme 1.

[10]. We report here the structures of the uncomplexed ligand 1D (structure I) along with the monomeric zinc (diaquo-2,5-bis(2-pyridyl)-1,3,4-thiadiazole) cationic complexes with zinc tetrachloride (**II**) and perchlorate (**III**) as counter ions. Comparison of the energy-minimized structure [11] of the solid-state uncoordinated ligand and of the two monomeric zinc(2,5-bis(2-pyridyl)-1,3,4-thiadiazole)$_2$ complexes permits an evaluation of the relative importance of conformation and planarity in complex formation. From this information, the potential of the ligand as a bridging unit may be evaluated.

2. Experimental

2.1. Synthesis

2.1.1. Ligand (*I*)

2,5-Bis(2-pyridyl)-1,3,4-thiadiazole (**I**) was synthesized as described previously [12,13]. M.p., 218 °C. ^{1}H NMR (200 MHz, dmso): δ (ppm) 7.60 (t, 2H, $J = 7.5$ Hz), 8.05 (t, 2H, $J = 7.7$ Hz), 8.31 (d, 2H, $J = 7.9$ Hz), 8.71 (d, 2H, $J = 5.1$ Hz). ^{13}C NMR (200 MHz, $CDCl_3$): δ (ppm) 157.32, 150.30, 144.72, 137.7, 124.04, 118.76. *Anal.* Calc. for $C_{12}H_8N_4S$: C, 60.00; H, 3.33; N, 23.33; S, 32.00. Found: C, 60.11; H, 3.21; N, 23.36; S, 32.06%.

2.1.2. $[ZnL_2(H_2O)_2](ZnCl_4)(H_2O)_2$ (*II*)

$ZnCl_2$ (1.5 mmol, 0.2 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand (**I**) dissolved in 8 ml of ethanol. The solution was filtered and after 24 h, the colorless compound (**II**) crystallized at room temperature. Crystals (**II**) were washed with water and dried under vacuum. *Anal.* Calc. for $C_{24}H_{24}N_8O_4S_2Cl_4Zn_2$: C, 34.93; H, 2.91; N, 13.58; S, 7.76; Cl, 17.20. Found: C, 34.99; H, 2.99; N, 13.51; S, 7.72; Cl, 17.39%.

2.1.3. $[ZnL_2(H_2O)_2](ClO_4)_2$ (*II*)

$Zn(ClO_4)_2$, $6H_2O$ (1.5 mmol, 0.56 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand (**I**) dissolved in 8 ml of ethanol. The solution was filtered and after 24 h, the colorless compound (**III**) crystallized at room temperature. Crystals were washed with water and dried under vacuum. *Anal.* Calc. for $C_{24}H_{20}N_8O_{10}S_2Cl_2Zn$: C, 36.91; H, 2.56; N, 14.35; S, 8.20; Cl, 9.09. Found: C, 36.87; H, 2.59; N, 14.43; S, 8.26; Cl, 9.21%.

2.2. Crystal structure determinations

Single crystals of **I**, **II** and **III** were mounted on a Brucker AXS SMART three-circle diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å), equipped with a CCD two-dimensional detector [14]. Data (Table 1) were corrected for Lorentz, polarization, background and decomposition effects. Atomic positions were determined using SHELXS [15] and refined using full-matrix least-squares [16]. Hydrogen positions were calculated and included in the final cycles of refinement in constrained positions and with fixed isotropic thermal parameters. Absorption corrections were not made due to the small value of the absorption coefficients (Table 1). Extinction was refined for all three structures but was minimal. Tables 2–4 present the bond angles and distances for **I**, **II** and **III**, respectively.

2.3. Theoretical calculations

All quantum theoretical calculations were performed with SPARTAN PRO V. 1.05 software package for PC (Irvine Inc.) using ab initio Hartree–Fock 6-21G** basis set at RHF (Restricted Hartree–Fock) level. Prior full ab initio optimization, the three conformers were optimized with semi-empirical PM3 method.

3. Discussion

2,5-Bis(2-pyridyl)-1,3,4-thiadiazole (**I**) (L = ligand) exists with the 2-pyridyl rings relatively coplanar with the central 1,3,4-thiadiazole ring, rotation angles 4.9° and 2.8°. Both pyridyl nitrogen atoms are found on the sulfur side of the 1,3,4-thiadiazole ring (Fig. 1) [17].

Minimum energy calculations at the Hartree–Fock level using the 6-31G** basis set (Spartan [11]) show a difference of 11.7 kcal/mol between this and the local minima form with both pyridyl nitrogen atoms rotated to the 'azide side' of the five-membered ring. The conformation with a single pyridyl ring rotated to the 'azide side' is at an intermedial level in energy (5.4 kcal/mol greater than the local minimum form). All three energy-minimized conformations show total coplanarity of all atoms with a calculated dihedral angle of 0.02°.

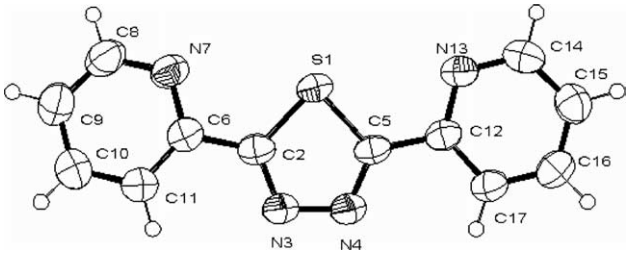

Fig. 1. Projection view of 2,5-bis(2-pyridyl)-1,3,4–thiadiazole (**I**) (thermal ellipsoids are shown at the 50% probability level).

Complexes **II** and **III** show zinc(+2) in octahedral coordination. Each zinc(+2) atom exists on a center of symmetry and is coordinated to two molecules of ligand L and to two molecules of water. Coordination to the ligands (**I**) is achieved by interaction with the nitrogen atom of a single pyridyl ring and with the near nitrogen of the azide group. Zn–N, 2.078(4) and 2.129(5) Å (**II**), 2.080(4) and 2,155(4) Å (**III**) (Figs. 2 and 3). The nitrogen atom of the remaining pyridyl ring is rotated to the sulfur side of the thiadiazole ring. In **II**, both pyridyl rings, complexed and uncomplexed, display near coplanarity with the central thiadiazole ring (0.9° and 3.2°, respectively). However in **III** the complexed pyridyl ring displays an interplanar angle of 4.3° with the thiadiazole ring, whereas the noncomplexed ring subtends an angle of 20.9°, a significant rotation from coplanarity. Thus the ligand, L, is seen in a conformation close to that of the form of intermediate energy. In that conformation,

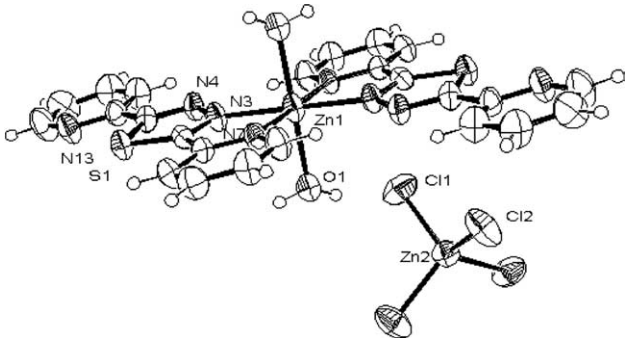

Fig. 2. Projection view of $[ZnL_2(H_2O)_2](ZnCl_4)(H_2O)_2$ (**II**) (thermal ellipsoids are shown at the 50% probability level).

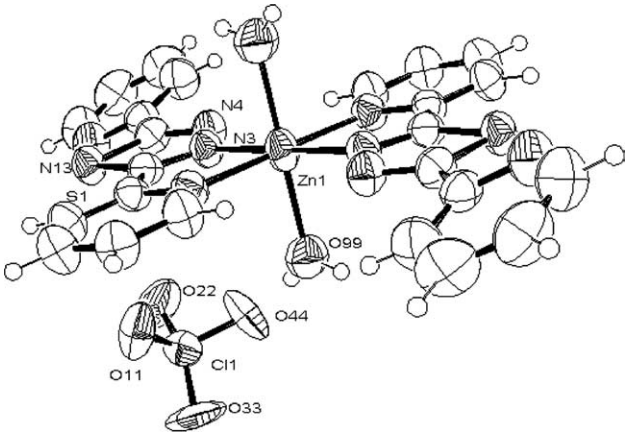

Fig. 3. Projection view of $[ZnL_2(H_2O)_2](ClO_4)_2$ (**III**). Only one of the two disordered sets of oxygens of ClO_4 are represented for clarity (thermal ellipsoids are shown at the 50% probability level).

it is not capable of complexing to two metal atoms in close proximity.

Important to potential overlap mechanisms of dimeric complexes of these ligands are the N3–Zn1–N7 and N3–Zn1–N7′ angles which should be close to the 90° angle between $d_{x^2-y^2}$ orbitals which are normally found in the equatorial plane. These angles are 77.67(17)° and 102.33(17)° in **II** and 78.02(17)° and 101.98(17)° in **III**, far from the ideal 90° value. Similarly M–N=N angles may be used to evaluate an overlap of greater efficiency. Values approaching 120° seen in dimers with effective orbital overlap between metal atoms. In **II** and **III**, these angles are 130.7(3)° (**II**) and 131.9(3)° (**III**), larger than ideal.

The water molecules are found in axial positions and at distances which substantiate the lack of axial distortion, Zn–O, 2.129(5) Å (**II**) and Zn–O 2.163(4) Å (**III**).

The counter ion, $ZnCl_4$ in **II** is well ordered. Hydrogen bonding links bound and unbound water molecules and also the unbound water molecule and N13. In **III**, the ClO_4 moiety shows disorder over more than two sets of positions. Refinement was unstable when attempts were made to introduce more than two sets of disordered oxygen positions. Hydrogen bonding links the two hydrogen atoms of the bound water molecule to oxygen atoms of each of the disordered ClO_4 groups.

Consideration of the solid-state structures seen for coordinated and uncoordinated 2,5-bis(2-pyridyl)-1,3,4-thiadiazole shows that the ligand is likely to maintain a coplanar or near coplanar conformation when coordinated. The rotation of a single pyridyl ring nitrogen atom to the 'azide side' of the five-membered hetero ring to bind one metal atom is accomplished without energy penalty. The rotation of the second pyridyl ring to provide bidentate binding to a second metal atom involves a relatively small energy cost. However, potentially effective orbital overlap between two bound metal atoms and thus significant magnetic interaction when 2,5-bis(2-pyridyl)-1,3,4-thiadiazole serves as a bridging ligand seem impeded by unfavorable M–N–N and N–M–N angles.

4. Supplementary material

The supplementary material has been sent to the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) as supplementary material No. SUP 200909–200911 and can be obtained by contacting the CCDC (quoting the article details and the corresponding SUP number).

Abstract

New β-aminovinylketones with heterocyclic 1,2-benzothiazine-1,1-dioxide and antipyrine moieties (LH) and their 3d-metal (Co^{II}, Ni^{II}, Cu^{II}, Zn^{II}) chelates have been synthesized. Two types of chelates can be obtained based on the coordination of the LH ligand, depending when an available carbonyl (C=O) group of the antipyrine fragment is coordinated (M = Co, Ni) or not (M = Cu) to the metal center. The molecular structure of compound **5b** was obtained by X-ray diffraction, indicating that the ligand **2b** forces the complex to adopt a highly distorted tetracoordinate square planar structure. Details on the synthesis and characterization of these complexes are discussed.

1. Introduction

Although β-aminovinylketones have been subject of permanent interest in coordination chemistry [1–4], a relatively small number of their metal-chelate complexes, specially those containing heterocyclic fragments attached to the amino functionality, have been reported to the date [4–12]. Among them, the complexes based on azomethine derivatives of 1,2-benzothiazine-1,1-dioxide β-diketones are of especial interest due to their chances to act as anti-inflammatory drugs [13] as well as their potential as interesting ambidentate ligands [6–8]. According to previous studies by several other research groups, which includes X-ray diffraction analysis, molecules such as piroxicam, **1** [4-hydroxy-2-methyl-*N*-(2-pyridyl)-2H-1,2-benzothiazine-3-carboxamide-1,1-dioxide] a non-steroidal anti-inflammatory drug widely used for arthritis treatment can act as mono- [7] or bidentate [6,8] ligands.

As a contribution to the development of this research area, we have synthesized a series of ligands derived from the β-aminovinylketone, **2a**–**2c**, which can be considered as being potentially a mono (O)-, bi (N,O)- or tri (N,O,O)-dentate ligand, depending on the number of donor atoms bound to the metal center [14,15].

2. Experimental

2.1. Materials

β-Diketones **3a**–**3c** were synthesized from a known procedure [16]. 4-Aminoantipyrine, **4** was purchased from Aldrich and used as supplied. Metal acetates and pure metals in the form of foils or wire were purchased from Aldrich.

2.2. Instrumentation

^{1}H NMR spectra were recorded in a UNITY (Varian) 300 MHz instrument at room temperature and using DMSO-d_6 as solvent (TMS as internal reference). Melting points were determined in a MeltTemp apparatus. Infrared spectra were registered in vaseline oil using a Specord IR-75 spectrophotometer. Magnetochemical studies were carried out on a Quantum Design MPMS-5S SQUID apparatus using the Faraday's method at 21 °C. TESWARE (Sigma–Aldrich, model PS500-1) power supply was used for the electrolysis experiments.

2.3. Synthesis of the ligands

The β-aminovinylketones, **2a**–**2c**, were obtained by Schiff-base condensation of the corresponding *N*-*R*-1,2-benzothiazine-1,1-dioxide, **3** (a β-diketone, where R = H, Me, Et), with a small excess of 4-amino-2,3-dimethyl-1-phenylpyrazolone-5 (4-aminoantipyrine), **4**. The general procedure is illustrated as follow: In a round bottom flask, a mixture of 0.01 mol of (III) and 0.015 mol of (IV) was heated up to 180 °C and kept at this temperature before total elimination of water (30–40 min). After cooling the reaction mixture, 10 mL of acetonitrile were added and the mixture was refluxed; a precipitate formed and was filtered after cooling. The recovered solid was recrystalized from *i*-propanol, and dried at vacuum at 150 °C. Analytical data. Compound **2a**: R = H ($C_{26}H_{22}N_4O_4S$). NMR (DMSO-d_6, ppm): 1.95 (CH_3, s, 3H); 2.8 (CH_3N, s, 3H); 7.20–8.20 (Ar, m, 14H); 8.85 (NH, s, 1H); 12.2 (NH, s, 1H). Calculated: C, 64.18; H, 4.56; N, 11.51. Found: C, 63.90; H. 5.10; N, 11.65%. Compound **2b**: R = CH_3 ($C_{27}H_{24}N_4O_4S$). NMR (DMSO-d_6, ppm): 1.95 (CH_3, s, 3H); 2.8–3.0 (CH_3N, s, 3H); 2.8 (CH_3, s, 3H); 7.20–8.20 (Ar, m, 14H); 12.2 (NH, s, 1H). Calculated: C, 64.78; H, 4.83; N, 11.90. Found: C, 64.10; H, 5.00; N, 11.69%. Compound **2c**: R = CH_2CH_3 ($C_{28}H_{26}N_4O_4S$). NMR (DMSO-d_6, ppm): 0.5 (CH_3CH_2, t, 3H); 1.95 (CH_3, s, 3H); 2.8–3.0 (CH_3N, s, 3H); 2.8–3.0 (CH_2CH_3, q, 2H); 7.20–8.20 (Ar, m, 14H); 12.2 (NH, s, 1H). Calculated: C, 65.35; H, 5.09; N, 10.90. Found: C, 64.80; H, 5.39; N, 10.75%.

2.4. Synthesis of metal-chelates

2.4.1. Chemical synthesis (A)

The complexes were synthesized by refluxing for a short time (10–20 min) 0.001 mol of the ligand **2a**–**2c** and 0.0005 mol of the corresponding hydrated metal acetate ($Co(OAc)_2 \cdot 4H_2O$, $Ni(OAc)_2 \cdot 4H_2O$, $[Cu(OAc)_2 \cdot H_2O]_2$ or $Zn(OAc)_2 \cdot 2H_2O$) in methanol (15 mL). The solids obtained, usually crystalline, were filtered, washed with hot methanol, and dried at 150 °C. Analytical and physical-chemical data for compounds **5a**–**5c** **6a**–**6c** **7b, 7c** and **8c** are presented in Table 1.

2.4.2. Direct electrochemical synthesis (B)

The electrochemical cell consisted on a Zn cathode (counter electrode) and a sacrificial anode (M = Cu, Zn, working electrode). To avoid the formation of a mixture of products, sometimes obtained during conventional electrochemical synthesis [17], the experiment was carried out without using any of the common supporting electrolytes. According to [9] in order to provide an electron carrier in the electrochemical cell, the sodium salt of the corresponding ligand was generated in situ and used as supporting electrolyte. It was obtained by the reaction of 2 mg of metallic sodium and 0.001 mol of the ligands **2a**–**2c** in 25 mL of a methanol. The electrolysis was carried out at fixed voltages during 2.5 h (M = Zn) or 1.5 h (M = Cu). The applied voltage varied with the time, as the in situ generated supporting electrolyte was consumed, and it was optimal at 30 V. The applied current ranged from 10 to 20 mA. After electrolysis, the solid products were filtered and washed with hot methanol. Analytical and physical–chemical data for compounds **6a′**, **6c′** and **8c′** are presented in Table 1.

3. Results and discussion

β-Aminivinylketones **2a**–**2c**, containing an antipyrine fragment, were synthesized following a classic technique of interaction of β-diketones with primary amines [3,18]. However, in contrast with previously reported similar syntheses in low-boiling solvents [3], harder conditions (fusion of reagents occurred at 180 °C) are needed to carry out the reaction when the β-diketones **3a**–**3c** and aminoantipyrine **4**, are used (Scheme 1).

This transformation can take place in two different routes depending on the reaction site, so it can generate any of two tautomers **2a**–**2c** or **2a′**–**2c′**, or both.

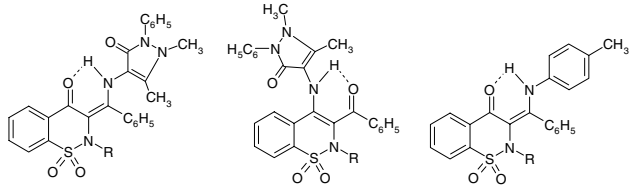
2c (R=CH_2CH_3)

Scheme 1.



(a) **2a-c** (b) **9**

It can be guessed than the structure of compounds **2a**–**2c** can be represented by tautomer (a) on analogy with other β-aminovinylketones for which the aminoketone tautomer with similar structure are mostly obtained [19], as well by comparison with compound **9** whose structure has been proved by X-ray diffraction analysis to be almost exclusively as tautomer (a) [20].

In accordance, IR and NMR data for compounds **2a**–**2c** agree with that supposition. The IR spectra (see Table 1) show several absorption bands corresponding to different vibrational modes for C═O (antipyrine, 1663–1673 cm^{-1}) [21], SO_2 (1180, 1327 cm^{-1}), and N–H (~3200–3450 cm^{-1}) groups [22]. The presence of a wide low-intense band at 3000–3500 cm^{-1} (max. at ~3400 cm^{-1}), as well as signals corresponding to a NH fragment at 12.2 ppm in the ^1H NMR spectra, suggest the existence of an intra-molecular hydrogen bond of the type N─H···O═C─ as occurs in tautomer (a).

According to elemental analysis data (see Table 1), the synthesized compounds have the general composition ML_2 (where LH is the pro-ligand **2a**–**2c** and L is the corresponding deprotonated ligand), which is typical for describing other previously synthesized metal-chelates of aliphatic and aromatic β-aminovinylketonates [1–4], β-diketonates of 1,2-benzothiazine-1,1-dioxide [10,23], and 3-carboxamido-4-hydroxy-1,2-benzothiazine-1,1-dioxide [6]. The chelate structure of the described complexes is confirmed by disappearance of the typical vibrational bands for secondary amino group in the IR spectra of the complexes (for the pure ligand, LH, **2a**–**2c**, the NH group vibrational band appears at 3300–3450 cm^{-1}) and also is supported by the ^1H NMR data of the zinc complex.

The tautomeric form of ligands **2a**–**2c** (a) should be considered as an ambidentate ligand [4,14,24,25], which can act as bi- or tridentate ligands with or without participation of the C═O group of the antipyrine fragment in binding with the metal. In this sense, the structures of the novel coordination compounds can be represented as shown in Scheme 2.

Complexes **5a**, **5b**, **5c**, **7b** and **7c** should adopt an octahedral geometry according with IR and magnetochemical data (see Table 1). A shift of the C═O vibrational band of the antipyrine fragment [21,24–30] of around 20–60 cm^{-1}, in comparison with the free ligands was observed. The magnetochemical information for these coordination compounds (where $M = Co^{2+}$, Ni^{2+}) indicate that they are high-spin complexes, as should be expected for octahedral complexes [31].

In contrast, complexes **6a**, **6a′**, **6b**, **6c**, **6c′**, **8c** and **8c′** present two absorption bands corresponding to vibrational stretching modes of the non-coordinated and coordinated C═O group of the antipyrine fragment. Small prismatic green crystals of 6c, suitable for X-ray diffraction analysis, were grown by slow evaporation from a methanolic solution (monoclinic system; $a = 15.565(4)$ Å, $b = 25.911(4)$ Å, $c = 13.821(3)$ Å; $\beta = 99.25(2)°$; $V = 5501(2)$ $Å^3$; $\mu = 1090.7$; $F(000) = 2268$; $\rho_{calc} = 1.317$ g/cm^3; $\mu_{Mo} = 0.53$ mm^{-1}; $Z = 4$; space group = $P2_1/c$). X-ray data indicates that the oxygen atom of one antipyrine fragment is oriented toward the metal center (Cu). However, the interatomic distance

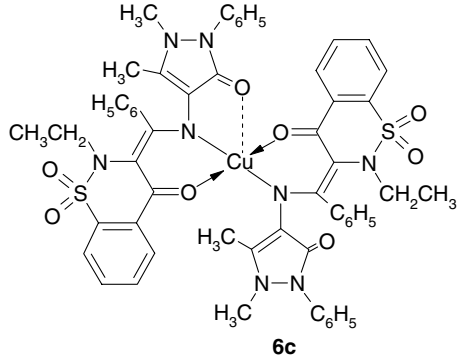
C=O···Cu of 3.41 Å [32], is too large to be considered a coordination bond (Fig. 1). Furthermore, the tetrahedral geometry is highly distorted, as evidenced by the 47° dihedral angle between the planes formed by the Cu(1)O(1)N(1) and Cu(1)O(1′)N(1′) planes, being more precisely an intermediate structure between a tetrahedral and a square planar arrangements. Table 2 contains selected bond distances and angles for compound **6c**. The magnetochemical data (Table 1) is in agreement with a tetracoordinated system and is supports the idea of a mononuclear structure for compound **6c**.



6c

Cu(1)–O(1)	1.875(9)
Cu(1)···O(4′)	3.41(2)
Cu(1)–N(1′)	1.93(1)
Cu(1)–O(1′)	1.928(9)
Cu(1)–N(1)	1.93(1)
O(1) Cu(1)N(1′)	93.0(4)
O(1′)Cu(1)N(1)	91.4(5)

4. Conclusions

The synthesis, by conventional chemical as well as by direct electrochemical methods, of 12 new coordination complexes of three early unknown-aminovinylketonates with 1,2-benzothiazine-1,1-dioxide fragments and a coordinatively active antipyrine substituent has been reported. It was shown that, depending on the metal nature, the studied ligand system may behave as an ambidentate ligand, forming metal-chelates with both distorted tetrahedral (Cu^{2+} and Zn^{2+}) or octahedral (Co^{2+} and Ni^{+}) geometries around the metal center. Spectrophotometrical and magnetochemical studies, as well as X-ray diffraction for one compound, support our findings. Further studies on other systems is currently undergoing.

Abstract

The colourless neutral Mo(VI) complexes $[MoO_2Cl_2(OPMe_3)_2]$, $[MoO_2Cl_2(L\text{–}L)]$ (L–L = $Ph_2P(O)CH_2P(O)Ph_2$, $Ph_2P(O)CH_2CH_2P(O)Ph_2$ and $o\text{-}C_6H_4(P(O)Ph_2)_2$) have been obtained in good yield by reaction of MoO_2Cl_2 with the ligand in anhydrous CH_2Cl_2 solution. The corresponding light yellow bromo species were obtained from reaction of a CH_2Cl_2 solution of the phosphine oxide ligand with MoO_3 and HBr. The complexes have been characterised by IR, ^1H, $^{31}P\{^1H\}$ and where possible by ^{95}Mo NMR spectroscopy and trends in the spectroscopic data are discussed. Crystal structures of $[MoO_2X_2(OPMe_3)_2]$ (X = Cl or Br) and $[MoO_2Br_2\{o\text{-}C_6H_4(P(O)Ph_2)_2\}]\cdot 2CH_2Cl_2$ are also described. Each of the compounds adopts a distorted octahedral geometry at Mo(VI) with *trans* halo ligands, a *cis* dioxo unit and with the O-bound phosphine oxide ligands completing the coordination environment.

Keywords: Molybdenum; ^{95}Mo NMR; X-ray structures; Phosphine oxide

1. Introduction

Molybdenum coordination chemistry continues to be the subject of much research effort. This is in part due to the occurrence of Mo in the active sites of biologically important species, the molybdoenzymes [1]. Further interest derives from the ability to vary the Mo oxidation state from Mo(VI) to Mo(0) (and even Mo(–II)) under ligand control. Molybdenum(VI) oxo complexes are also of interest as oxo transfer agents [2] and as catalyst precursors, e.g., in the selective epoxidation of olefins [3].

We have been interested for some time in the synthesis and properties of coordination complexes involving hard, high oxidation state acceptors with soft ligands, such as chalcogenoethers and phosphines and arsines. Recent examples include the preparations, spectroscopic and structural properties of complexes involving six-, seven- and eight-coordinate Ti(IV), Zr(IV) and Hf(IV) with these types of ligand, for example the eight-coordinate $[TiX_4\{o\text{-}C_6H_4(EMe_2)_2\}_2]$ (X = Cl or Br; E = P or As) and $[MCl_4\{MeE'(CH_2)_2\text{-}E'Me\}_2]$ (M = Zr or Hf; E′ = S or Se), the seven-coordinate $[MCl_4([9]aneS_3)]$ and the octahedral dinuclear $[(ZrCl_4)_2\{\mu_2\text{-}MeS(CH_2)_3SMe\}_2]$ [4–7]. In an extension of this work, we are now attempting to investigate the properties of rare examples of complexes of Mo(VI) based upon the MoO_2X_2 (X = Cl or Br) core, with neutral Group 15 and 16 ligands. We are not aware of any molybdenum(VI) dioxo complexes with phosphine and arsine ligands. The only reported thioether complexes involving the MoO_2X_2 unit are those of the macrocyclic [14]aneS$_4$ (1,4,8,11-tetrathiacyclotetradecane)

and [18]aneS$_6$ (1,4,7,10,13,16-hexathiacyclooctane) [8], and there are no selenoether or telluroether derivatives.

Under some conditions reaction of the quite strongly oxidising [MoO_2Cl_2(solvent)$_2$] (solvent = dmso or dmf) with phosphines results in oxidation and oxygen atom transfer to afford the corresponding phosphine oxide and reduction to Mo(IV) [9]. A number of phosphine oxide complexes of Mo(VI) have also been reported, however in many cases the data are quite old and rather fragmented and spectroscopic data are limited. Structurally characterised examples include [MoO_2X_2-(OPPh$_3$)$_2$] (X = Cl or Br), [MoO_2Cl_2(OPMePh$_2$)$_2$], [MoO_2Br_2{$Ph_2P(O)CH_2P(O)Ph_2$}], [MoO_2Cl_2{$Ph_2P(O)$-$(CH_2)_3P(O)Ph_2$}] and [MoO_2Cl_2{$(CH_2P(O)(CH_2CH_2O$-Me)$_2$)$_2$}] [10–16]. Therefore, in our preliminary work we have investigated a series of Mo(VI) complexes with phosphine oxide ligands, including ^{95}Mo NMR spectroscopic data where possible. We report here the synthesis and spectroscopic properties of [MoO_2X_2(OPMe$_3$)$_2$], [MoO_2X_2{$Ph_2P(O)CH_2P(O)Ph_2$}], [MoO_2X_2{o-C_6H_4(P(O)Ph$_2$)$_2$}] and [MoO_2Cl_2-{$Ph_2P(O)(CH_2)_2P(O)Ph_2$}]. The crystal structures of [MoO_2X_2(OPMe$_3$)$_2$] (X = Cl or Br) and [MoO_2Br_2{o-C_6H_4(P(O)Ph$_2$)$_2$}]$\cdot$ 2CH_2Cl_2 are also described and compared with the related literature compounds.

2. Results and discussion

Reaction of MoO_2Cl_2 with two molar equivalents of L (L = OPMe$_3$ or OPPh$_3$) or one molar equivalent of L–L (L–L = $Ph_2P(O)CH_2P(O)Ph_2$, $Ph_2P(O)CH_2CH_2P(O)$-Ph_2 or o-C_6H_4(P(O)Ph$_2$)$_2$) in anhydrous CH_2Cl_2, followed by concentration of the solvent in vacuo, affords the six-coordinate [$MoO_2Cl_2L_2$] or [MoO_2Cl_2(L–L)], respectively, as white solids in good yield. The corresponding bromo derivatives [MoO_2-Br_2L_2] and [MoO_2Br_2(L–L)] (L–L = $Ph_2P(O)CH_2P(O)$-Ph_2 and o-C_6H_4(P(O)Ph$_2$)$_2$) were obtained as light yellow solids from reaction of MoO_3, L or L–L and concentrated HBr in CH_2Cl_2/EtOH. The products were characterised by IR, ^{1}H, ^{31}P{^{1}H} and (where possible) ^{95}Mo NMR spectroscopy and analysis.

IR spectra (Table 1) show two peaks in the range 900–960 cm^{-1}, indicative of the *cis*-dioxo unit and either one or two P=O stretching vibrations significantly to low frequency of the uncoordinated phosphine oxide, consistent with coordination to the metal centre. The spectra for the chloro and bromo complexes are very similar, although the spectra of the chloro complexes exhibit a reasonably strong peak at ca. 320 cm^{-1} which is not evident in the bromo species and is therefore attributed to ν($MoCl_2$) of a *trans*-$MoCl_2$ unit. A peak at ca. 235 cm^{-1} in the bromo complexes is tentatively assigned to ν($MoBr_2$) of a *trans*-$MoBr_2$ unit.

The products are air stable solids, most of which show modest solubility in CH_2Cl_2, $CHCl_3$ and acetone without degradation. They are rather more soluble in O-donor solvents such as dmf, however ^{31}P{^{1}H} NMR studies show that the monodentate phosphine oxide ligands are readily displaced by the dmf, while the diphosphine dioxide ligands are displaced more slowly (1–2 h).

The ^{1}H NMR spectra of the compounds are generally not very informative, but confirm the presence of the coordinated L or L–L. Although the OPPh$_3$ complexes have been reported previously, ^{31}P{^{1}H} and ^{95}Mo NMR spectroscopic data on these are not known. The ^{31}P{^{1}H} NMR spectra for each of the compounds in this study reveal a single resonance ca. 10 ppm to high frequency of the uncoordinated phosphine oxide, indicating the presence of a single isomer for each, and that there is no significant chelate ring effect in the bidentate ligand species between the six-membered ring present in [MoO_2X{$Ph_2P(O)CH_2P(O)Ph_2$}] and the seven-membered rings in the other L–L complexes (Table 1). The coordination shifts in these compounds are similar to those observed in other hard, early transition metal

complexes with phosphine oxide ligands, for example yttrium(III) halide complexes [17]. The $^{31}P\{^{1}H\}$ NMR shifts of the Mo-chloro complexes are consistently to high frequency of the bromo analogues by ca. 1 ppm. This very small difference suggests that the electronic environment at Mo(VI) is little influenced by X and L (or L–L), but is probably dominated by the Mo-dioxo unit as expected.

The ^{95}Mo isotope (15.7%, $D_c = 0.489$), although quadrupolar ($I = 5/2$), has proved to be a useful and informative spectroscopic probe in diamagnetic Mo-containing complexes, with the chemical shift showing significant dependence on the Mo oxidation state, the ligand set around the metal and the coordination geometry [18,19]. ^{95}Mo NMR spectroscopy has been widely used to study zero-valent molybdenum carbonyl complexes, however, despite offering a direct probe of the electronic environment at the metal centre, there have been fewer studies on Mo(VI) coordination complexes.

^{95}Mo NMR spectra were obtained for the $OPPh_3$ and $OPMe_3$ ligand complexes in this work from solutions in CH_2Cl_2, as well as for $[MoO_2X_2(dmf)_2]$ for comparison and are in the range observed for other Mo(VI) complexes (Table 1) [18]. The $[MoO_2Cl_2L_2]$ species each show a single broad resonance (137 ppm for $L = OPPh_3$ and 149 ppm for $L = OPMe_3$). The corresponding resonances for the bromo analogues are observed at 171 ppm for $L = OPPh_3$ and 179 ppm for $L = OPMe_3$. The linewidths are approximately 350–400 Hz for these compounds. The ^{95}Mo NMR nucleus appears to be much more sensitive than ^{31}P to both the halide and the phosphine oxide ligand in these complexes, although the chemical shift range for ^{95}Mo is substantially larger than for ^{31}P. These shifts compare with $\delta(^{95}Mo) = 157$ and 216 for $[MoO_2Cl_2(H_2O)_2]$ and $[MoO_2Br_2(H_2O)_2]$, respectively [20]. This inverse dependence of $\delta(^{95}Mo)$ upon the halide is also consistent with that seen in other molybdenum-dioxo complexes with halide co-ligands [18]. The resonances for the phosphine oxide species are also to low frequency of $[MoO_2X_2(dmf)_2]$ for a given X.

The diphosphine dioxide ligand complexes were not sufficiently soluble in non-coordinating CH_2Cl_2 solution to observe the ^{95}Mo NMR resonance, and attempts to obtain the spectra from freshly prepared solutions of these compounds in dmf resulted in partial dissociation of the diphosphine dioxide ligand and resonances associated with $[MoO_2X_2(dmf)_2]$. This was confirmed from $^{31}P\{^{1}H\}$ NMR spectra recorded after the ^{95}Mo NMR spectra which revealed resonances associated with free L–L.

Attempts to obtain electrospray, APCI or FAB mass spectra for these compounds gave peaks consistent L or L–L, but no Mo-containing species were evident.

In order to confirm the structures of the new complexes and to establish bond length and angle distributions, X-ray crystallographic studies were undertaken on four examples. Crystals were obtained as described in Section 3. The structures of $[MoO_2X_2(OPMe_3)_2]$ (X = Cl or Br), although not isostructural, each show (Figs. 1 and 2, Table 2) distorted octahedral coordination to Mo(VI) through two *cis* oxo groups, two *trans* X ligands and two *cis* $OPMe_3$ ligands. Other than *d*(Mo–X), which increase as a consequence of the larger size of Br over Cl, there are no significant differences in the bond lengths and angles around the Mo centre in these compounds. The O–Mo–O angles in the *cis*-dioxo unit are 102.21(14)° and 102.72(13)°, whereas the O–Mo–O angle involving the $OPMe_3$ ligands are much more acute (78.77(10)° and 78.31(9)°).

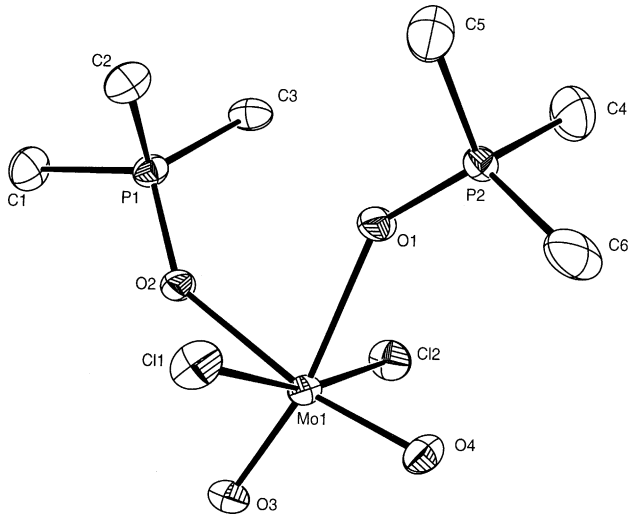

Fig. 1. View of the structure of $[MoO_2Cl_2(OPMe_3)_2]$ with numbering scheme adopted. Ellipsoids are shown at the 40% probability level and H atoms are omitted for clarity.

The X-ray structure of $[MoO_2Br_2\{o\text{-}C_6H_4(P(O)Ph_2)_2\}]\cdot 2CH_2Cl_2$ shows (Fig. 3 and Table 3) a similar distorted octahedral arrangement to the $OPMe_3$ complexes above, with similar bond lengths and angles around the molybdenum ion. In this species, the diphosphine dioxide ligand forms a seven-membered chelate ring, with the O–Mo–O angle involved in this chelate ring = 76.22(14)°, almost identical to the corresponding angle in the $OPMe_3$ complexes above. This suggests that the $o\text{-}C_6H_4(P(O)Ph_2)_2$ ligand can adjust its bite angle to accommodate the preference of the central metal fragment. These structures are very similar to those of other reported phosphine oxide complexes involving the MoO_2X_2 unit [12–16].

Very small, weakly diffracting crystals of $[MoO_2Cl_2\text{-}\{Ph_2P(O)CH_2P(O)Ph_2\}]\cdot 1/2Me_2CO$ [1] were also

[1] Crystal data for $[MoO_2Cl_2\{Ph_2P(O)CH_2P(O)Ph_2\}]\cdot 1/2Me_2CO$: MW = 644.25; monoclinic, space group $P2_1/c$, $Z = 4$, $a = 9.2075(4)$, $b = 20.4599(13)$, $c = 15.7724(10)$ Å, $\beta = 104.217(3)°$, $V = 2880.3(2)$ Å^3, $Z = 4$; 6492 unique data, giving $R_1 = 0.0853$, $wR_2 = 0.1990 (I > 2\sigma(I))$ based upon 327 independent parameters and $S = 1.005$.

examined. The structure determination confirms that the coordination environment at Mo is very similar (Fig. 4) to that reported previously for $[MoO_2Br_2\{Ph_2P(O)CH_2P(O)Ph_2\}]$. However, the quality of the structure determination was poorer than for the other structures described, with higher *R*-factors and esds, precluding detailed comparisons of the geometric parameters.

Studies on the preparation and properties of MoO_2X_2 complexes incorporating soft phosphine, arsine, thioether and selenoether ligands are now underway in our laboratories. The results described here provide useful comparative data since as we have already noted, oxo-transfer from Mo(VI) to P(III) is a possible decomposition pathway in this chemistry.

3. Experimental

Infrared spectra were recorded as Nujol mulls between CsI plates using a Perkin–Elmer 983G spectrometer over the range 4000–200 cm^{-1}. ^1H NMR spectra were recorded using a Bruker AM300 spectrometer. $^{31}P\{^1H\}$ and ^{95}Mo NMR spectra were recorded using a Bruker DPX400 spectrometer operating at 162.00 or 26.08 MHz, respectively, and are referenced to external 85% H_3PO_4 and 1 mol dm^{-3} aqueous $Na_2[MoO_4]$, respectively. Microanalyses were undertaken by the University of Strathclyde microanalytical service.

Solvents were dried prior to use and all preparations were undertaken using standard Schlenk techniques under a N_2 atmosphere. MoO_2Cl_2, $OPMe_3$ and $OPPh_3$ were obtained commercially (Aldrich), while the other phosphine oxides were obtained by oxidation of the parent phosphine by the literature method [21]. MoO_3 was obtained by heating $[NH_4]_6[Mo_7O_{24}]\cdot 4H_2O$ in a furnace at ca. 250 °C to constant weight. $[MoO_2X_2(OPPh_3)_2]$ (X = Cl or Br) were obtained by the literature method [10].

3.1. Preparation of $[MoO_2Cl_2(OPMe_3)_2]$

MoO_2Cl_2 (0.17 g, 0.85 mmol) with $OPMe_3$ (0.16 g, 1.74 mmol) were stirred in CH_2Cl_2 (5 cm^3) under N_2 for ca. 2 h. The resulting white precipitate was filtered, washed with hexane and dried in vacuo. Yield 0.32 g, 97%. *Anal.* Calc. for $C_6H_{18}Cl_2MoO_4P_2$: C, 18.8; H, 4.7. Found: C, 18.7; H, 5.0%. ^1H NMR ($CDCl_3$): δ 1.83 (d, $J = 13.2$ Hz, Me) ppm.

3.2. Preparation of $[MoO_2Cl_2\{Ph_2P(O)CH_2P(O)Ph_2\}]$

Method as above to give a white solid. Yield 76%. *Anal.* Calc. for $C_{25}H_{22}Cl_2MoO_4P_2$: C, 48.8; H, 3.6. Found: C, 48.3; H, 3.4%. ^1H NMR ($CDCl_3$): δ 7.35–7.85 (m, 10H, Ph), 3.75 (t, 2H, CH_2) ppm.

3.3. Preparation of $[MoO_2Cl_2\{Ph_2P(O)CH_2CH_2P(O)Ph_2\}]$

Method as above to give a white solid. Yield 88%. *Anal.* Calc. for $C_{26}H_{24}Cl_2MoO_4P_2\cdot 0.25CH_2Cl_2$: C, 48.5; H, 3.8. Found: C, 48.4; H, 3.8%.

3.4. Preparation of $[MoO_2Cl_2\{o\text{-}C_6H_4(P(O)Ph_2)_2\}]$

Method as above to give a white solid. Yield 78%. *Anal.* Calc. for $C_{30}H_{24}Cl_2MoO_4P_2\cdot 0.25CH_2Cl_2$: C, 52.0; H, 3.5. Found: C, 51.9; H, 3.5%. ^1H NMR ($CDCl_3$): δ 7.20–7.60 (m, aromatic CH) ppm.

3.5. Preparation of $[MoO_2Br_2(OPMe_3)_2]$

To a flask containing MoO_3 (0.12 g, 0.83 mmol) in concentrated HBr (0.5 cm^3) was added $OPMe_3$ (0.16 g, 1.73 mmol) in ethanol. The resulting mixture was stirred under N_2 overnight. The resulting precipitate was filtered, washed with hexane and dried in vacuo to give a light yellow solid. Yield 0.20 g, 71%. *Anal.* Calc. for $C_6H_{18}Br_2MoO_4P_2$: C, 15.5; H, 4.1. Found: C, 15.3; H, 3.8%. ^1H NMR ($CDCl_3$): δ 1.88 (d, $J = 12.5$ Hz, Me) ppm.

3.6. Preparation of $[MoO_2Br_2\{Ph_2P(O)CH_2P(O)Ph_2\}]$

Method as above to give a light yellow solid. Yield 73%. *Anal.* Calc. for $C_{25}H_{22}Br_2MoO_4P_2$: C, 42.6; H, 3.2. Found: C, 42.6; H, 3.3%. ^1H NMR (CD_2Cl_2): δ 7.30–7.90 (m, 10H, Ph), 3.80 (t, H, CH_2) ppm.

3.7. Preparation of $[MoO_2Br_2\{o\text{-}C_6H_4(P(O)Ph_2)_2\}]$

Method as above to give a yellow solid. Yield 65%. *Anal.* Calc. for $C_{30}H_{24}Br_2MoO_4P_2$: C, 47.0; H, 3.2. Found: C, 46.5; H, 3.6%. ^1H NMR ($CDCl_3$): δ 7.20–7.65 (m, aromatic CH) ppm.

3.8. X-ray crystallography

Details of the crystallographic data collection and refinement parameters are given in Table 4. Colourless crystals of $[MoO_2Cl_2(OPMe_3)_2]$ and light yellow

Table 4

crystals of $[MoO_2Br_2(OPMe_3)_2]$ and $[MoO_2Br_2\{o\text{-}C_6H_4\text{-}(POPh_2)\}]\cdot 2CH_2Cl_2$ were obtained by cooling a solution of the appropriate complex in CH_2Cl_2. Extremely small and weakly diffracting crystals of $[MoO_2Cl_2\text{-}\{Ph_2P(O)CH_2P(O)Ph_2\}]\cdot 1/2Me_2CO$ were obtained by cooling a solution of this complex in Me_2CO. Data collection used a Nonius Kappa CCD diffractometer ($T = 120$ K) with graphite monochromated Mo Kα X-radiation ($\lambda = 0.71073$ Å). Structure solution and refinement were routine [22–24], except for the $[MoO_2Cl_2\{Ph_2P(O)CH_2P(O)Ph_2\}]$ where the difference map indicated the presence of two partially occupied and disordered Me_2CO solvent molecules in asymmetric unit. This was modelled reasonably successfully to give two 25% occupied molecules disordered over one site. Selected bond lengths and angles are given in Tables 2 and 3.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 230190 ($[MoO_2Br_2\{o\text{-}C_6H_4(P(O)Ph_2)_2\}]\cdot 2CH_2Cl_2$), 230191 ($[MoO_2Cl_2\text{-}(OPMe_3)_2]$) and 230192 ($[MoO_2Br_2(OPMe_3)_2]$). Abstract

The four title compounds have been synthesized and characterized by ^1H, ^{13}C and ^{31}P NMR spectroscopy and their identities confirmed by elemental analysis and X-ray crystallography. $Bu^t_2P(E)NHPr^n$ [E = Se (**1**); E = Te (**2**)] and $Ph_2P(E)NHPr^n$ [E = Se (**3**)] were prepared by the metathesis reaction of $LiNHPr^n$ with the appropriate chlorophosphine in diethylether at −78 °C, followed by reaction with elemental selenium or tellurium at reflux temperatures. (**1**) and (**2**) are isostructural with P═Se 2.1163(14) Å and P═Te 2.3642(13) Å. In (**3**) a P═Se bond length of 2.1159(10) Å is observed. (**4**) was prepared by the additional of two equivalents of diethylchlorophosphine to the dilithium salt of *n*-propylamine.

1. Introduction

Over the past several years, there has been a great deal of interest in the design and synthesis of precursors suitable for the chemical vapor deposition of metal chalcogenides [1]. These have included several investigations into the properties of ligands that can coordinate to suitable metal fragments to produce volatile materials that deposit thin films in a clean manner [2,3].

One such class of ligands that have been investigated is the aminophosphine chalcogenides of the general formula $R_2P(E)–NHR'$ (R and R′ = alkyl/aryl groups). By altering the R/R′ groups it was found that the volatility of any subsequently formed metallo-complexes could be changed. Bochmann et al. [4] have synthesized and characterized a series of seleno- and telluro-aminophosphines and some associated Ti, Zn and Cd complexes. In a later paper, they investigated the chemical vapor deposition potential of these materials [5] and determined that at temperatures generally above 150 °C (sublimation temperatures) and under reduced pressures (10^{-6} mbar), films of cadmium telluride, zinc telluride or cadmium selenide could be deposited and readily identified by X-ray diffraction. Compared to arene chalcogenato compounds [6], the zinc and cadmium complexes of phosphinochalcogenic amines showed better volatility and stability as suitable single-source precursors for metal selenides and tellurides.

In this paper, we present the synthesis and characterization of some seleno- and telluro-aminophosphines, whose reactions with main group elements and transition metals are part of an ongoing investigation.

2. Results and discussion

The chalogenophosphinic amides presented in this paper were prepared through a metathesis reaction of

doi:10.1016/j.poly.2004.04.028

the corresponding lithium amide and di(alkyl/aryl)chlorophosphine. Further reaction with the elemental chalcogen (selenium or tellurium) at refluxing solvent temperatures resulted in the formation of the title compounds as depicted in Scheme 1.

The isolated compounds were obtained in moderate to high yields (60–80%) as white microcrystalline powders (selenium derivatives) or pale yellow powders (tellurium derivatives). The spectroscopic and analytical data for (**1**–**4**) are presented in Section 3. These compounds are generally air stable although the tellurium analogs have a tendency to decompose, depositing elemental tellurium, upon exposure to warm, humid air. The selenium compounds are stable in solution indefinitely at −20 °C, but the tellurium compounds should be handled only in oxygen free solvents. We also prepared $Ph_2P(Te)NHPr^n$ but the compound was too unstable for us to grow crystals.

The molecular structures of **1**–**3** show the expected geometries for molecules of this type. The central phosphorus atom lies in a distorted tetrahedral environment coordinated to a chalcogen atom, an amino nitrogen atom and two carbon atoms of the alkyl/aryl substituents. We were also able to prepare compound **4** through a double substitution by two equivalents of diethylchlorophosphine on dilithium *n*-propylamide followed by oxidation with selenium. To our knowledge, this is the first time such a doubly substituted amide has been structurally characterized.

2.1. $Bu^t_2P(Se)NHPr^n$

The structure of this compound is shown in Fig. 1 together with the atom notation used. The central phosphorus atom lies in a distorted tetrahedral environment surrounded by two carbon atoms of the *tert*-butyl groups, an amine nitrogen group and a selenium atom with bond distances P=Se [2.1163(14) Å], P–N

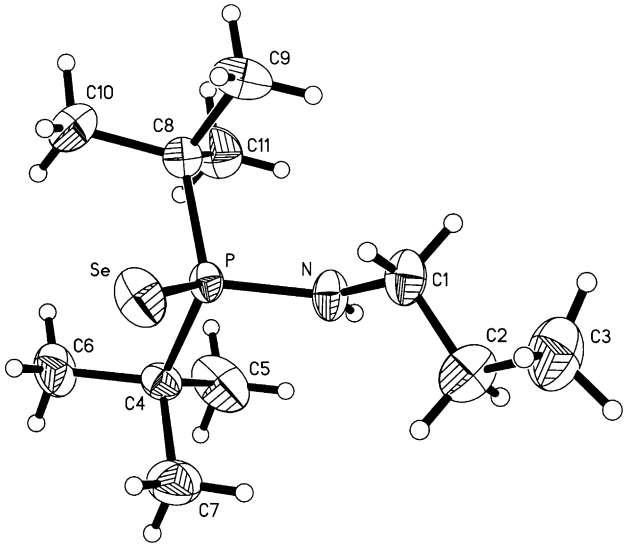

Fig. 1. Molecular structure of $Bu^t_2P(Se)NHPr^n$ showing atomic numbering.

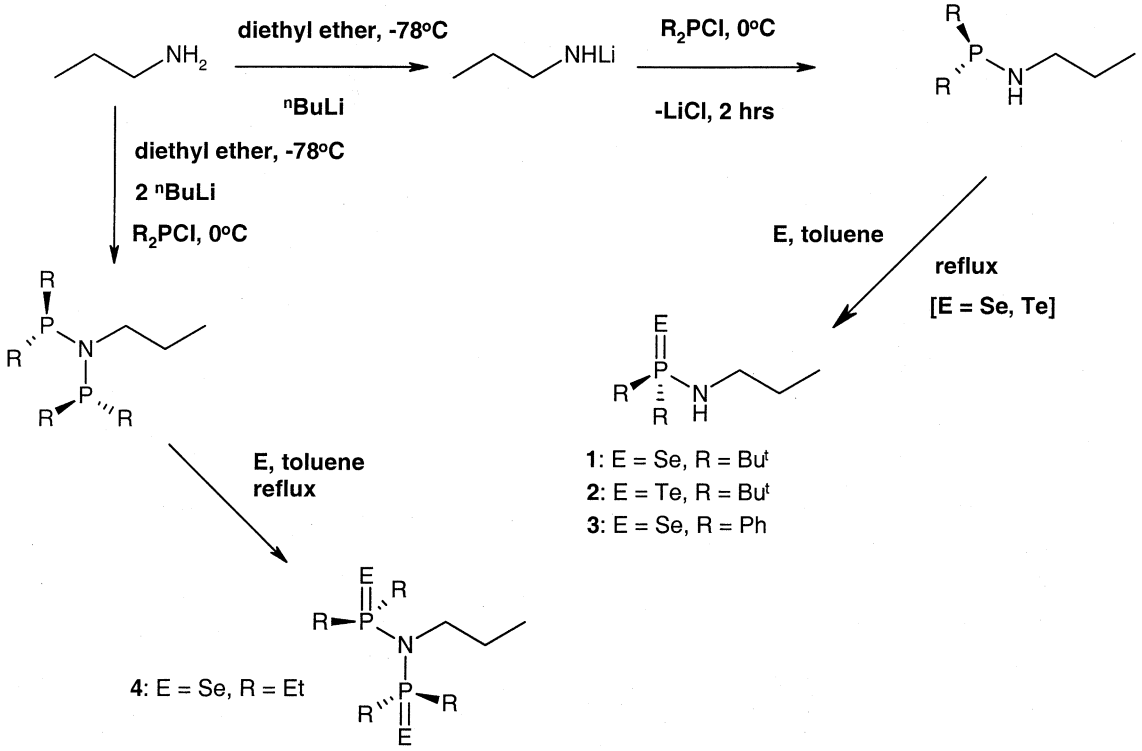

Scheme 1. Synthesis of chalcogenoic aminophosphines.

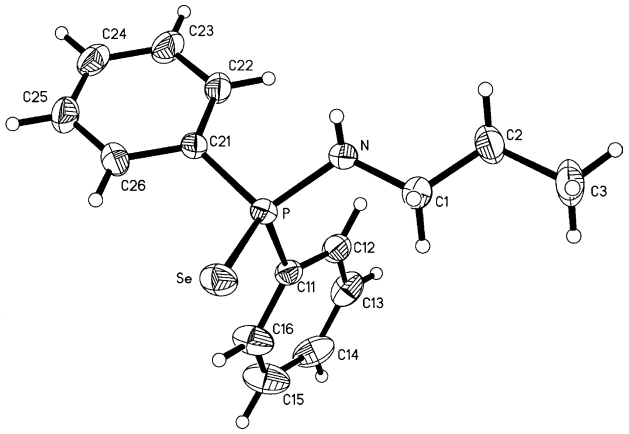

Fig. 2. Molecular structure of $Bu^t_2P(Te)NHPr^n$ showing atomic numbering.

[1.649(4) Å], and P–C_{ave} [1.857 Å]. These molecular dimensions are very similar to those described by Bochmann in the related $Bu_2P(Se)NHPr^i$ structure [4].

2.2. $Bu_2P(Te)NHPr^n$

The structure of this compound is shown in Fig. 2. As with compound **1** above, the aminophosphine has been chalcogenated, this time with tellurium. There are only a few known P=Te compounds that have been crystallographically characterized. These include a related structure reported by Bochmann et al. [4], Bu_2P-(Te)NHCy in which a P=Te distance of 2.371(1) Å is found. In a related, but disordered structure of $Ph_3PTe{\cdot}PPh_3$ [7] the phosphorus–tellurium bond distances are 2.27–2.42 Å. For comparison purposes, it is interesting to note that the P=Te distance in the tungsten carbonyl complex, $[W(CO)_5(Bu^t_3PTe)]$ is 2.439(2) Å [8]. Interestingly enough, in his discussion of phosphine telluride bond lengths in known crystal structures, Gilheany [9] indicates that the bond length of 2.368 Å in Bu^t_3PTe is probably not typical of tertiary phosphine tellurides and that this corresponds to a bond order of 1.5 according to the covalent radii of Schomaker and Stevenson.

2.3. $Ph_2P(Se)NHPr^n$

Fig. 3 shows the atomic labeling and molecular structure of compound **3**. This compound was prepared by the metathesis reaction of Ph_2PCl with lithium *n*-propylamine in diethylether followed by addition of selenium at reflux temperatures. Some considerable deviations away from the tetrahedral bonds angles are found, most probably due to the steric requirements of the two phenyl groups. A review of the bond lengths and angles found in triaminophosphine selenides and tellurides, in particular their deviation away from the ideal structure, has recently been published [10].

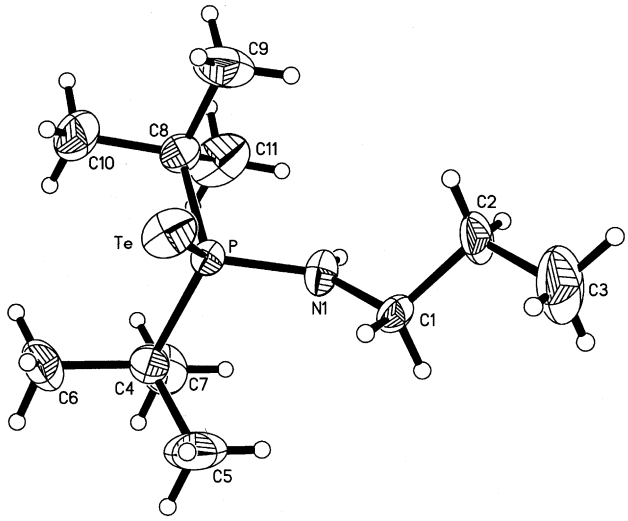

Fig. 3. Molecular structure of $Ph_2P(Se)NHPr^n$ showing atomic numbering.

2.4. $\{Et_2P(Se)\}_2NPr^n$

The structure of this doubly substituted primary amine is shown in Fig. 4. The addition of two molar equivalents of *n*-butyl lithium to *n*-propylamine followed by treatment with two equivalents of diethylchlorophosphine and oxidation with selenium yielded the title compounds which was readily obtained as

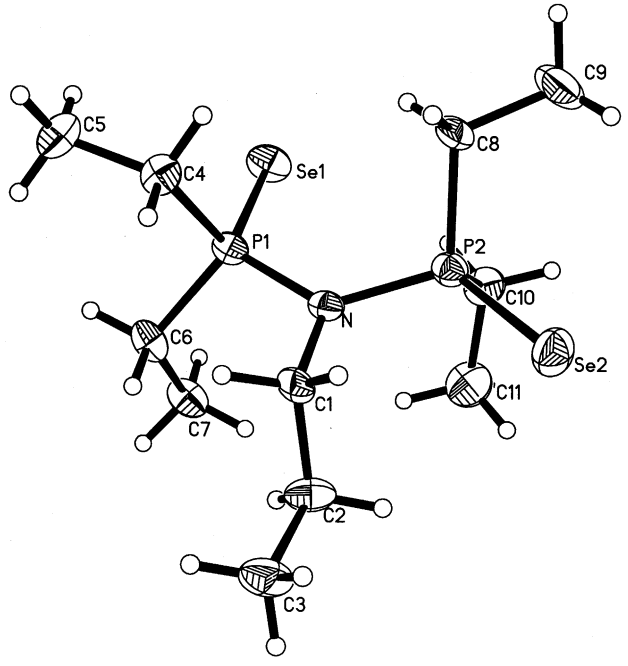

Fig. 4. Molecular structure of $\{Et_2P(Se)\}_2NPr^n$ showing atomic numbering.

colorless crystals. The two selenium atoms lie in an anti-arrangement. Both P=Se bonds distances are typical of the range observed in phosphine selenides (2.09–2.11 Å) [9]; the less bulky nature of the alkyl groups in this study, compared with the Ph and Bu^t substituents in **1** and **3**, give rise to a less strained tetrahedral environment around the two phosphorus atoms.

3. Experimental

3.1. General and instrumental

NMR spectra were obtained on a Bruker AMX-360 spectrometer and recorded in $CDCl_3$ except where noted. ^1H NMR were recorded at 360 MHz, ^{13}C at 90.6 MHz and ^{31}P at 161.9 MHz (using an external H_3PO_4 reference). Et_2PCl (Strem), Ph_2PCl (Strem) and Bu^t_2PCl (Aldrich), *n*-butyllithium (1.6 M in hexanes, Aldrich) and *n*-propylamine were used as received. All solvents (toluene, diethylether and hexanes) were dried and purified using standard reagents and distilled from a dry nitrogen atmosphere prior to use. All reactions were carried out using Schlenk techniques under an atmosphere of argon. Elemental analyzes were performed at Atlantic Microlab. Inc. (Norcross, GA).

3.2. Synthesis of $Bu^t_2P(Se)NHPr^n$ (**1**)

To a cooled solution (−78 °C) of *n*-propylamine (0.46 mL, 5.6 mmol) in diethylether (10 mL) was added *n*-butyllithium (1.6 M in hexane; 3.52 mL, 5.6 mmol). After allowing the reaction to slowly warm to room temperature, a thick white precipitate of $LiNHPr^n$ formed which was stirred for 1 h. The precipitate was cooled back to 0 °C and di-*t*-butylchlorophosphine (1.09 mL, 5.6 mmol) was added via syringe. The reaction immediately became clear and colorless and was stirred at room temperature for 2 h during which time a small amount of precipitate formed. The precipitate was allowed to settle and the solution filtered onto elemental selenium (0.44 g, 5.7 mmol) through a Whatman 1μm on-line filter. Toluene (10 mL) was added and the mixture was refluxed for 2 h until all the selenium had been consumed. Whilst hot, the solution was again filtered through a Whatman filter and allowed to cool. Large colorless block crystals formed directly at −10 °C suitable for X-ray structure determination. Yield: 1.55 g, 81%. M.p.: 150–2 °C. *Elem. Anal.* Calc. for $C_{11}H_{26}NPSe$ ($M_w = 282.26$) C: 46.80; H 9.30. Found: C 46.78; H 9.24%. ^1H NMR: 0.88 (t, 3H, $CH_3CH_2CH_2$); 1.29 (d, 18H, $J(PH) = 15.6$ Hz, $C(CH_3)_3$); 1.48 (d of q, 2H, $CH_3CH_2CH_2$); 1.77 (s, br, 1H, NH); 3.03 (q, 2H, $CH_3CH_2CH_2$); ^{13}C NMR 11.2 (s, $CH_3CH_2CH_2$); 25.6 (d, $J(PC) = 5$ Hz $CH_3CH_2CH_2$); 27.7 (s, ^{t}Bu); 40.8 (d, $J(PC) = 46.3$ Hz, CMe_3); 45.9 (s, $CH_3CH_2CH_2$) $^{31}P\{^1H\}$ NMR: 98.74 ppm (s, $J(PSe) = 731$ Hz).

3.3. Synthesis of $Bu^t_2P(Te)NHPr^n$ (**2**)

An analogous procedure to that described above was used. Amounts used: *n*-propylamine (0.42 mL, 5.1 mmol); *n*-butyllithium (1.6 M in hexane; 3.2 mL, 5.2 mmol); di-*t*-butylchlorophosphine (0.97 mL, 5.1 mmol); Te powder (0.65 g, 5.1 mmol). The reaction was refluxed for 3 h and then filtered. Recrystallization from diethylether gave small colorless block crystals. Yield: 1.66 g, 67%. M.p.: 150 °C (dec). *Elem. Anal.* Calc. for $C_{11}H_{26}PNTe$ ($M_w = 330.91$) C: 39.93; H 7.92. Found: C 39.82; H 7.95%. ^1H NMR: 0.93 (t, 3H, $CH_3CH_2CH_2$); 1.33 (d, 18H, $J(PH) = 19.0$ Hz, $C(CH_3)_3$); 1.53 (d of q, 2H, $CH_3CH_2CH_2$); 1.71 (s, br, 1H, NH); 3.05 (q, 2H, $CH_3CH_2CH_2$); ^{13}C NMR 11.6 (s, $CH_3CH_2CH_2$); 25.6 (d, $J(PC) = 7$ Hz $CH_3CH_2CH_2$); 28.6 (s, ^{t}Bu); 40.2 (d, $J(PC) = 34.0$ Hz, CMe_3); 50.1 (s, $CH_3CH_2CH_2$); $^{31}P\{^1H\}$ NMR: 85.02 (s, J (PTe) = 1784 Hz).

3.4. Synthesis of $Ph_2P(Se)NHPr^n$ (**3**)

An analogous procedure to that described above was used. Amounts used: *n*-propylamine (0.50 mL, 6.0 mmol); *n*-butyllithium (1.6 M in hexane; 3.8 mL, 6.0 mmol); diphenylchlorophosphine (1.11 mL, 6.0 mmol); Se powder (0.46 g, 6.0 mmol). The reaction was refluxed for 2 h and then filtered. Small colorless block crystals were obtained from the reaction liquors. Yield: 2.03 g, 67%. M.p.: 126–131 °C. *Elem. Anal.* Calc. for $C_{15}H_{18}NPSe$ C: 55.90; H 5.64. Found: C 55.90; H 5.56%. ^1H NMR: 0.94 (t, 3H, $CH_3CH_2CH_2$); 1.61 (d of q, 2H, $CH_3CH_2CH_2$); 2.27 (s, br, 1H, NH); 2.87 (q, 2H, $CH_3CH_2CH_2$); 7.19–7.52 (m, Ph, 10H); ^{13}C NMR: 11.9 (s, $CH_3CH_2CH_2$); 24.8 (d, $J(PC) = 12$ Hz $CH_3CH_2CH_2$); 44.6 (s, $CH_3CH_2CH_2$); 128.4–134.5 (m, Ph); $^{31}P\{^1H\}$ NMR: 58.10 (s, $J(PSe) = 739$ Hz).

3.5. Synthesis of $\{Et_2P(Se)\}_2NPr^n$ (**4**)

To a cooled solution of *n*-propylamine (0.2 mL, 2.4 mmol) in diethylether (10mL) was added two equivalents of *n*-butyllithium (1.6 M in hexane; 3.0 mL, 4.8 mmol) forming a white precipitate. This was stirred for 2 h at room temperature and then cooled to ca. −20 °C. Diethylchlorophosphine (0.58 mL, 4.8 mmol) was introduced via a syringe and a vigorous exothermic reaction occurred. The reaction was allowed to warm to room temperature, stirred for 1 h and then filtered onto selenium powder (0.37 g, 4.8 mmol) suspended in dry toluene (10 mL). The reaction was refluxed for 1 h until the selenium had been consumed and then filtered while still hot. Cooling to −20 °C for 3 weeks yielded large colorless block crystals. Yield: 0.68 g, (67%). M.p.:

67–70 °C. *Elem. Anal.* Calc. for $C_{11}H_{27}NP_2Se_2$ ($M_w = 393.20$) C: 33.60; H 6.92. Found: C 33.86; H 6.90%. ^{1}H NMR: 0.79 (t, 3H, $CH_3CH_2CH_2$); 1.17 (d of t, 12H, CH_3CH_2P); 1.63 (d of q, 2H, $CH_3CH_2CH_2$); 2.87 (d of d of q, 8H, CH_3CH_2P); 3.41 (q, 2H, $CH_3CH_2CH_2$); ^{13}C NMR: 7.7 (s, PCH_2CH_3); 10.3 (s, N–$CH_2CH_2CH_3$); 26.0 (s, N–$CH_2CH_2CH_3$); 29.7 (d, $J(PC) = 54.9$ Hz P–CH_2CH_3); 51.3 (s, N–$CH_2CH_2CH_3$); ^{31}P{^{1}H} NMR: 83.92 (s, $J(PSe) = 745$ Hz).

3.6. Structure determinations

Crystal data are given in Table 1, together with some data collection and refinement parameters.

The following general method was used: Diffracted intensities were collected on an Enraf–Nonius CAD-4 operating in the ω–2θ scan mode, using graphite-monochromated Mo Kα radiation. Final unit cell dimensions were determined from the setting angles of 25 accurately centered reflections. Crystal stability during the data collection was monitored by measuring the intensities of three standard reflections every 2 h. Data were collected at a constant rate, 5.17° min^{-1} in ω, with a scan range of $1.30 + 0.34 \tan\theta$. The data were corrected for Lorentz, polarization and X-ray absorption effects, the latter by a numerical method based on the measurements of six crystal faces.

The structure was solved by direct methods and successive difference Fourier syntheses were used to locate all non-hydrogen atoms using SHELXTL Version 5.03 [11]. Refinements were made by full-matrix least-squares on all F^2 data using SHELX-97 [12]. Anisotropic thermal parameters were included for all non-hydrogen atoms. All hydrogen atoms were included in calculated positions and allowed to ride on their parent nitrogen or carbon atoms with fixed isotropic thermal parameters ($U_{iso} = 1.2U_{iso}$ of the parent atom, or $U_{iso} = 1.5U_{iso}$ of the parent for CH_3 hydrogens).

Some differences in the individual methods for solving the crystal structures **1**–**4** are given below.

For **1**: The *n*-propyl group was disordered with the methylene carbons (C1, C2 and C1a, C2a) occupying two distinct sites in a 70:30 ratio. Insignificant residual electron density in the difference Fourier synthesis was found near the Se atom.

For **2**: The C1 and C2 atoms of the *n*-propyl group were found to be disordered over two distinct sites in a 60:40 ratio. The C–C distances were restrained in the minor component. Insignificant residual electron density in the difference Fourier syntheses was found near the Te atom.

For **3**: Diffracted intensities were collected on an Enraf–Nonius CAD-4 operating in the ω–$5/3\theta$ scan mode. Data were collected at a constant rate, 5.17° min^{-1} in ω, with a scan range of $1.10 + 0.34 \tan\theta$. The data were corrected for Lorentz, polarization and X-ray absorption effects, the latter by a numerical method based on the measurements of seven crystal faces. Insignificant residual

electron density in the difference Fourier syntheses was found near the Se atom.

For **4**: Diffracted intensities were collected on an Enraf–Nonius CAD-4 operating in the ω–4/3θ scan mode. Data were collected at a constant rate, 5.17° min^{-1} in ω, with a scan range of $1.15 + 0.34 \tan\theta$. The data were corrected for Lorentz, polarization and X-ray absorption effects, the latter by a semi-empirical method based on azimuthal scans of ψ-data. Insignificant residual electron density in the difference Fourier syntheses was found near the Se atoms.

Some of the significant bond distances and angles are given in Table 2.

3.7. Spectroscopy

All of the new ligands were fully characterized using multi-nuclear NMR spectroscopy. The ^{1}H and ^{13}C NMR spectra are as expected for this type of organophosphorus compound. As is typical of P(V)═E compounds, ^{31}P chemical shifts occurred in the δ 20–100 ppm range, depending on the exact nature of the R and amino groups [13]. Bochmann reported a value [4] of δ 97.6 ppm for $Bu^{t}_{2}P(Se)NHPr^{i}$. As indicated in the literature, coupling constants of $^{1}J_{PSe}$ 700–800 Hz are often seen for E = Se [14], and closer to 1500–2000 Hz for E = Te [15,16].

4. Conclusions

In this work, we have shown that the synthesis of chalcogenoic aminophosphines can be readily achieved through a facile synthetic route giving moderate to high yields of the desired products. We have established that a variety of alkyl and aryl groups can be used to prepare these compounds and that ^{31}P NMR spectroscopy is a useful technique for their characterization. We are currently probing the reactions of these ligands (neutral and deprotonated) with a variety of transition metal and main group halides.

5. Supplementary data

CCDC Nos. 236222–236225 [236222 (**4**); 236223 (**3**); 236224 (**2**) and 236225 (**1**)] contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif, by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033.

Acknowledgements

M.D.R. thanks the NSU CURIA for generous financial support of this project and UW – Fox Valley for travel monies. M.A.C expresses his thanks to Dr. Gary White (Society of Physics Students) for his support in this undergraduate research. We are grateful to Dr. Paul Jelliss (Baylor University) for assistance in obtaining the NMR spectra and to Professor Bob Angelici (Iowa State University) for computing facilities.

Received 4 March 2004; accepted 21 April 2004

Abstract

The synthesis of metallo derivatives (Ni, Zn) of phthalocyanines obtained from a 4,5-dicyanobenzomonoazacrown ether substituted with a long alkoxyphenyl chain (**5a, 5b**) are described. The new compounds have been characterized by elemental analysis, IR, NMR and electronic spectroscopy, and mass spectra. The thermal stabilities of the pc compounds were determined by thermogravimetric analysis. The mesogenic properties of these new materials were studied by differential scanning calorimetry (DSC), optical microscopy and X-ray diffraction patterns of the mesophases.

1. Introduction

Phthalocyanines (Pcs) have been under systematic study more than 70 years; however, researchers are still interested in this class of compounds [1]. There is great interest in designing and using phthalocyanine (pc) compounds and their metal derivatives as materials in chemical sensors, liquid crystals, catalysis, nonlinear optics, optical data storage and nanotechnology. Substituted pc derivatives can also be used for photodynamic cancer therapy and other processes driven by visible light. Phthalocyanine derivatives offer a very wide choice of molecular physicochemical properties by changing the type of metal complex and/or the nature of substituent [1–4].

Phthalocyanines are well-known as a disc-like molecule and form a one-dimensional columnar structure in condensed phases. The first thermotropic discotic liquid crystalline pc was reported in 1982 [5] and since then numerous liquid crystalline pc derivatives have been synthesized with the aim of producing more easily controllable macroscopic structures [6]. It has recently been found that numerous phthalocyanine derivatives exhibit thermotropic or lyotropic mesomorphism [7–17]. The liquid crystalline properties of these compounds depend on the number, position and character of peripheral substituents and the nature of the central complex-forming ion. For example pcs, when peripherally substituted with alkyl [7], alkoxy [8], alkoxymethyl [5], oligo(ethyleneoxy) [10–12], alkylthia [13], oligo (ethyleneoxy)thia [14] or even ''crowned'' [15,16] groups form thermotropic discotic liquid crystals. Most of the liquid crystals based on pc or porphyrins contain alkyl side chains [17]. Although a number of benzo-15-crown-5 substituted pcs have been shown to form discotic mesophases [15,16] and there are no pcs showing mesogenic properties, which contain monoazacrown ether moieties.

Aza-crown ether-substituted pcs have been previously described in the literature [18–22]. Different substituents have been introduced on the nitrogen atom of the aza-crown moiety to improve the solubility, liquid crystal properties and the intrinsic amphiphilic character of these pcs.

Recently we have essentially focused on the synthesis of new pcs exhibiting gas sensor [23–25] and liquid crystal properties [13,14,27,28]. Pc films have been proven to be used as photoconductors and gas sensors in molecular electronic devices and ordered pc films are more sensitive than disordered pc films [25,26]. In this study, pcs with monoazacrown ether moieties on the periphery containing a long alkyloxyphenyl N-pivotal group were synthesized for investigation of their liquid crystalline behaviour. These compounds contain a central pc core, four monoaza 15-crown-5 rings and a total of four 3,4,5-tri(decyloxy) phenyl N-pivotal groups.

2. Experimental

2.1. Materials

4,5-Dibromomonoazabenzo-15-crown-5 (**1**) [18] and 3,4,5-tri(decyloxy)-1-benzenecarbonyl chloride (**2**) [29] were prepared according to the literature procedures. All other reagents and solvents were reagent-grade quality, were obtained from commercial suppliers, and were dried as described in Perrin and Armarego [30] before use.

2.2. Measurements

Elemental analyses were obtained from a Carlo Erba 1106 Instrument. Infrared spectra in KBr pellets were recorded on a Bio-Rad FTS 175C FT-IR spectrophotometer. Optical spectra in the UV–Vis region were recorded with a Shimadzu 2001 UV Pc spectrophotometer using 1 cm pathlength cuvettes at room temperature. The mass spectra were acquired on an LCQ-ion trap (Thermofinnigan, San Jose, CA, USA), equipped with an electrospray source and were recorded on a VG Zab Spec GC–MS spectrometer using the liquid secondary ion mass spectrometer (LSIMS). Electrospray full scan spectra, in the range of m/z 50–2000 amu or m/z 2000–3000 amu, were obtained by infusion through fused silica tubing at 2–10 μl min^{-1}. The solutions were analyzed in the positive mode. The LCQ calibration (m/z 50–2000) was achieved according to the standard calibration procedure from the manufacturer (mixture of caffeine, MRFA and Ultramark 1621). An ES-Tuning Mix solution (Agilent) was used to calibrate the spectrometer between 2000 and 3000 amu. The temperature of the heated capillary of the LCQ was set to the range of 180–200 °C, the ion spray voltage was in the range of 1–7 kV with an injection time of 5–200 ms. ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Bruker 500 MHz spectrometer using TMS as an internal reference. Thermogravimetric analyses were carried out on a Mettler Toledo Star^e Thermal Analysis System at a rate of 10 °C min^{-1} in a nitrogen flow (50 ml min^{-1}). Transition temperatures were determined with scan rates of 10 °C min^{-1} using a Mettler Toledo Star^e Thermal Analysis System/DSC 822^e System differential scanning calorimeter calibrated with indium from 3 to 4 mg samples under a nitrogen atmosphere. Optical textures were observed with the polarizing microscope Leitz Wetzler Orthoplan-pol equipped with the hot stage Linkam TMS 93 and temperature-controller Linkam LNP. X-ray measurements were performed with Cu Kα-radiation using a Rigaku Kristalloflex diffractometer (D_{max} 2200) at 30 °C.

2.3. Synthesis

2.3.1. 4,5-Dibromo-1,2-[7-(3,4,5-tri-decyloxyphenyl-1-carbonyl)-7-aza-1,4,10,13-tetraoxatridecamethylene]-benzene (3)

3,4,5-Tri(decyloxy)-1-benzenecarbonyl chloride (**2**) (0.93 g, 1.54 mmol) was added to a mixture of 4′,5′-dibromomonoazabenzo-15-crown-5 (**1**) (0.60 g, 1.41 mmol) and Et_3N (0.29 g, 2.82 mmol) in CH_2Cl_2 (10 ml) and stirred at room temperature. After 18 h, the crude mixture was washed with water (3 × 10 ml) and the organic solution was dried with anhydrous Na_2SO_4. The solvent was removed and the crude mixture was further purified by column chromatography (Silica gel, CH_2Cl_2) to afford of **3** as a white solid. Yield: 1.31 g (93%); mp. 53 °C. *Anal.* Calc. for $C_{51}H_{83}Br_2NO_8$: C, 61.41; H, 8.36; N, 1.41. Found: C, 61.38; H, 8.38; N, 1.40%. IR (KBr): ν_{max} (cm^{-1}) 3047, 2927–2857 (CH_2, CH_3), 1634 (C=O), 1583, 1487, 1455, 1354, 1252, 1175 (C–O–C), 1135 (C–N), 1056 ($C_{ar}O$–CH_2), 1013, 927, 843, 803, 765. MS (LSIMS): m/z (%) 998 (70) [M^+], 573 (100) [$M^+-3(C_{10}H_{21})$], 433 (76), 153 (27). ^1H NMR ($CDCl_3$): δ 0.87 (t, 9H, CH_3), 1.40 (m, 42H, CH_2), 1.76 (m, 6H, CH_2), 3.54–4.06 (m, 22H, CH_2O), 6.57 (s, 2H, CH_{ar}), 7.05 (s, 2H, CH_{ar}). ^{13}C NMR ($CDCl_3$, APT): δ 14.04 (CH_3), 22.83–31.87 (CH_2), 69.15–73.40 (CH_2O), 105.31 ($C_{ar}H$), 115.33 (C_{ar}–Br), 118.06 ($C_{ar}H$), 131.35 (C_{ar}–C=O), 139.12 (C_{ar}–$OC_{10}H_{21}$), 148.89 (C_{ar}–OCH_2CH_2O), 153.103 (C_{ar}–$OC_{10}H_{21}$), 172.11 (C=O).

2.3.2. 4,5-Dicyano-1,2-[7-(3,4,5-tri-decyloxyphenyl-1-carbonyl)-7-aza-1,4,10,13-tetraoxatridecamethylene]-benzene (4)

A mixture of **3** (0.73 g, 0.73 mmol), CuCN (0.20 g, 2.17 mmol) and dry DMF (4.50 ml) were heated to reflux for 18 h under argon. After cooling to room temperature, the solvent was removed and the reaction mixture was diluted with ammonium hydroxide solution (25%) and air bubbled through the mixture for 18 h. Then the mixture was filtered and the precipitate was washed with water until it became neutral. The precipitate crude product was further purified by column chromatography (Silica gel, CH_2Cl_2) to afford of **4** as a white solid. Yield: 0.32 g (50%); mp. 84 °C. *Anal.* Calc.

3. Results and discussion

The starting compound 4,5-dibromomonoazabenzo-15-crown-5 (**1**), 3,4,5-tri(decyloxy)-1-benzenecarbonyl chloride (**2**) were obtained as described in the literature [18,29], respectively. 4,5-Dibromomonoazabenzo-15-crown-5 (**1**) was treated with **2** to prepare the dibromo monoazacrown ether substituted with a long alkyloxyphenyl chain (**3**). This reaction was carried out in the presence of triethylamine as the base in dichloromethane at room temperature and the yield was relatively high (93–97%). Dibromo compound (**3**) was treated with CuCN in dimethylformamide (DMF) to prepare the corresponding dinitrile derivative (**4**). The synthetic pathways are shown in Fig. 1.

The preparation of pc derivatives from aromatic dinitriles might be carried out under different reaction conditions [1]. For various substituted dinitriles, the reactions in the presence of strong nitrogen bases such as 1,8-diazabicyclo [5.4.0] undec-7-ene (DBU), or 15-diazabicyclo [4.3.0] non-5-ene (DBN) in 1-hexanol are the most efficient ones in comparison to other methods [31–33]. In addition, these reactions are easily to perform and the conditions are relatively mild, together with a relatively high yield of pure pcs. Therefore, the pc derivatives (**5a** and **5b**) were obtained from the reaction of the dicyano compound (**4**) in the presence of the corresponding metal salt and DBU in 1-hexanol at reflux temperature.

Spectral investigations on the newly synthesized intermediates and pcs are in accordance with the proposed structures. Comparison of the IR spectra of each step gave some hints as to the nature of the product. In the IR spectrum of **3**, CH_2, CH_3 groups gave absorptions at 2927, 2856 cm^{-1} and the amidic C=O group stretched around 1635 cm^{-1}. The IR spectrum of **4** was easily verified with the sharp C≡N vibrations around 2229 cm^{-1}. The IR spectra of **5a** and **5b** are very similar.

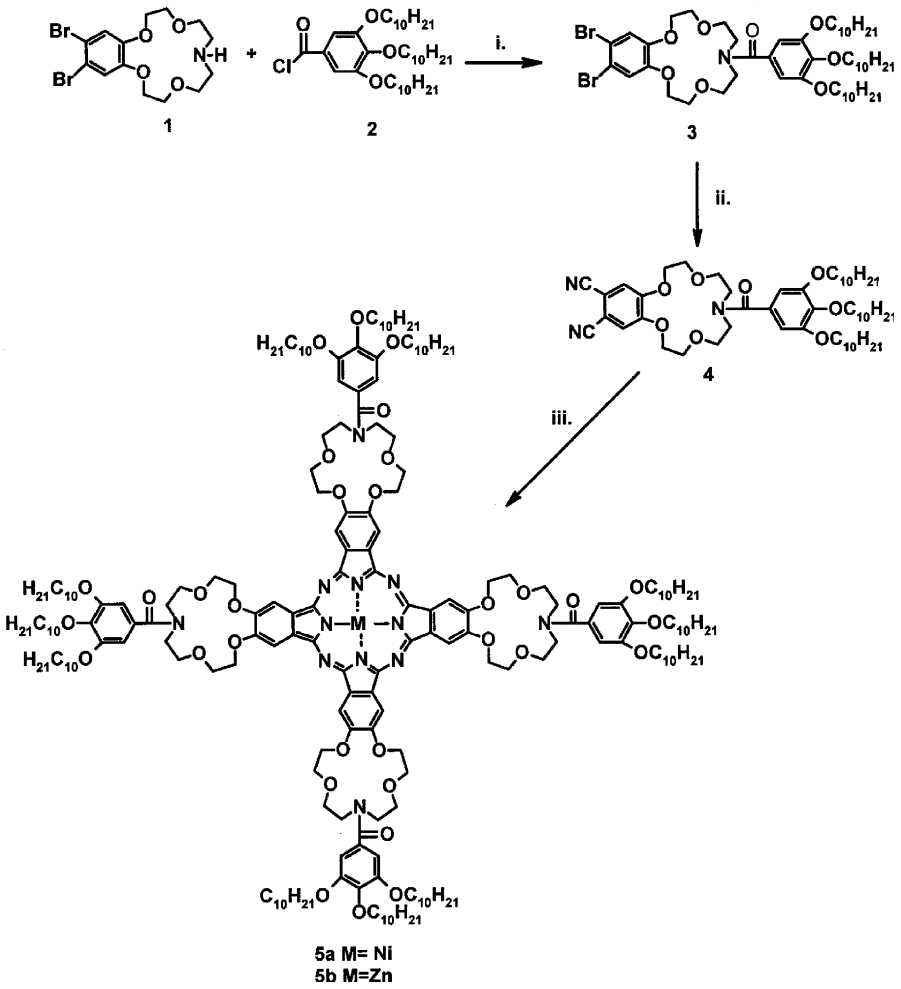

Fig. 1. Synthetic pathway for the preparation of **3**, **4**, **5a** and **5b**. (i) Triethylamine, dichloromethane. (ii) CuCN, DMF, reflux. (iii) DBU, 1-hexanol and metal salt.

In the ^{1}H NMR spectrum of **3**, the aromatic protons of the benzo group of the monoaza crown ether and the benzo group of the substituted alkyl chain give singlets at 6.57 and 7.05 ppm, respectively. The ^{1}H NMR spectrum of **4** indicates the aromatic protons of the benzo group of the monoaza crown ether at 6.5 ppm, shifting 0.7 ppm because of the CN substitution. A common feature of the ^{1}H NMR spectra of the pcs (**5a** and **5b**) is the broad absorptions when compared with that of the cyano derivatives.

In the ^{13}C APT (Attached Proton Test) NMR spectrum of **4**, the nitrile carbons appeared at 107.80 ppm. The ^{13}C NMR spectra of **5a** and **5b** indicate C=N carbons at 130.70 and 131.55 ppm, respectively.

A close investigation of the mass spectra of the dibromo (**3**) and dinitrile (**4**) derivatives and pcs (**5a, 5b**) confirmed the proposed structures. The mass spectra of **5a** and **5b** were obtained by the Electron Spray technique and the molecular ion peaks at m/z: 3618 for **5a** and m/z: 3624 for **5b** were observed. The mass spectra of **3** and **4**, obtained by the LSIMS technique show molecular ion peaks for these molecules. In the mass spectra of **3** and **4** the region of the molecular ion and of the bigger fragment ions are shown together with the corresponding leaving groups. In the mass spectra of **3** and **4**, in addition to the [M^{+}] peaks at 998 and 889, respectively, fragment ions corresponding to the loss of 3($C_{10}H_{21}$) [M^{+}−425] for **3** and [M^{+}−(425+Na)] for **4** were easily identified.

In the electronic spectra of the pcs (**5a** and **5b**) intense Q absorption bands were observed at 667 and 674 nm, respectively, with weaker absorptions at 601 and 609 nm, respectively. Weaker absorptions on the higher energy side of the Q bands are generally observed in the case of metallophthalocyanines, indicating the presence of aggregated species together with the monomeric ones which are essentially responsible for the intense absorption occurring in the main Q bands [34]. B band absorptions of the pcs (**5a** and **5b**) were observed at 312 and 355 nm, respectively (Fig. 2). Although the NiPc (**5a**) and ZnPc (**5b**) have a typical spectral pattern in the UV–Vis region for pcs, only the NiPc (**5a**) showed a new

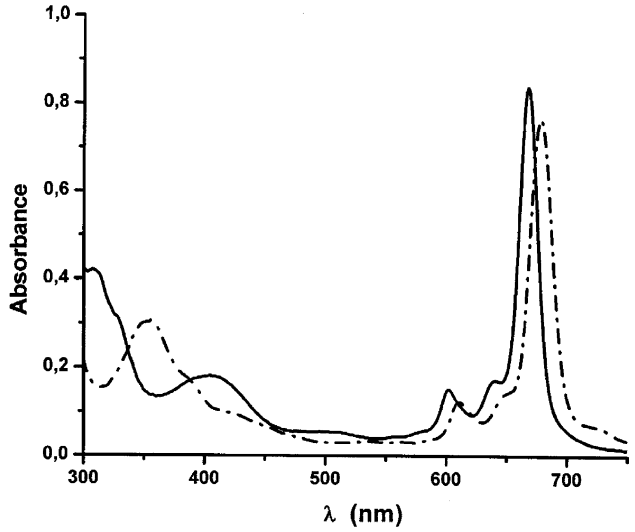

Fig. 2. Absorption spectra of **5a** (—) and **5b** (- - -) in chloroform at 3.76×10^{-6} M concentration.

absorption band at 405 nm in addition to a B band. This new absorption band due to the effect of the metal can be characteristically observed for a number of Ni Pcs [19,22,28]. For pcs complexed with metals having partially filled d orbitals, further bands are sometimes observed which can be ascribed to metal-to-ligand charge transfer (MLCT) or ligand-to-metal charge transfer (LMCT) transitions. So the spectrum of NiPc shows three transitions in the region of the B and N bands which are not present in the zinc analogue [35].

Although the thermal stability of pcs is well known, the pc compounds are not stable above 320 °C. The initial and main decomposition temperatures of **5a** and **5b** are 320 and 396 °C, respectively.

3.1. Characterization of the mesophases

3.1.1. Thermotropic phase-behaviour

The phase transition behaviours of pcs **5a** and **5b** were determined by differential scanning calorimetry (DSC) and polarizing microscopic observations. The DSC-measurement of **5a** shows an endothermic peak at about 109 °C in the vicinity which relates to the phase transition ($\Delta H = 78.1$ kJ/mol). The cooling cycle shows no peak representing a phase transition compared with the heating cycle. A phase transition is not observed at the second heating and cooling cycles nor the third cycle. However, compound **5b** shows a broad peak at about 117 °C for the first heating cycle ($\Delta H = 16.2$ kJ/mol). The cooling cycle shows a broad peak at about 111 °C ($\Delta H = 16.9$ kJ/mol). The heating cycles were interrupted before reaching any clearing point to avoid decomposition. In all cases, decomposition of the pcs are around 320–396 °C (determined by Thermal Gravimetric Analysis, TGA). We assume that the peaks of **5a** and **5b** in the heating cycles are related to the transition from the crystal phase to the mesophase and the peak of **5b** in the cooling cycle is related to the transition from the mesophase to the crystal phase. These investigations indicate that compound **5a** exhibits a thermotropic liquid crystalline behaviour over a wide temperature range, including room temperature, and compound **5b** exhibits no liquid crystalline behaviour at room temperature.

Fig. 3. Optical texture of **5a** observed at 110 °C (magnification × 25).

Fig. 4. Optical texture of **5b** observed at 118 °C (magnification × 16).

3.1.2. Optical microscopy of the thermotropic mesophase

The textures observed by polarizing optical microscopy for the compounds **5a** and **5b** are very similar to those described in the literature [12,36–38]. Good textures of the samples of the mesophases were obtained by slowly cooling (5 °C min^{-1}) from the isotropic melt, and mosaic textures appear (notice the decomposition). A phase transition from the mesophase to isotropic liquid is for **5a** and **5b** >320 °C. The textures of compound **5a** and **5b** under polarizing optical microscopy at 110 and 118 °C, respectively, are presented in Figs. 3 and 4.

Table 1
X-Ray diffraction data of compound **5a** at room temperature

Compound	Spacing (Å)		Ratio	Miller indices	Lattice constant
	$d_{calculated}$	$d_{observed}$			
5a	34.86	34.86	1	1 0 0	$a = 40.26$ Å
	20.05	20.13	$\sqrt{3}$	1 1 0	
	17.01	17.43	$\sqrt{4}$	2 0 0	
	13.19	13.17	$\sqrt{7}$	2 1 0

	7.35				
	4.46				

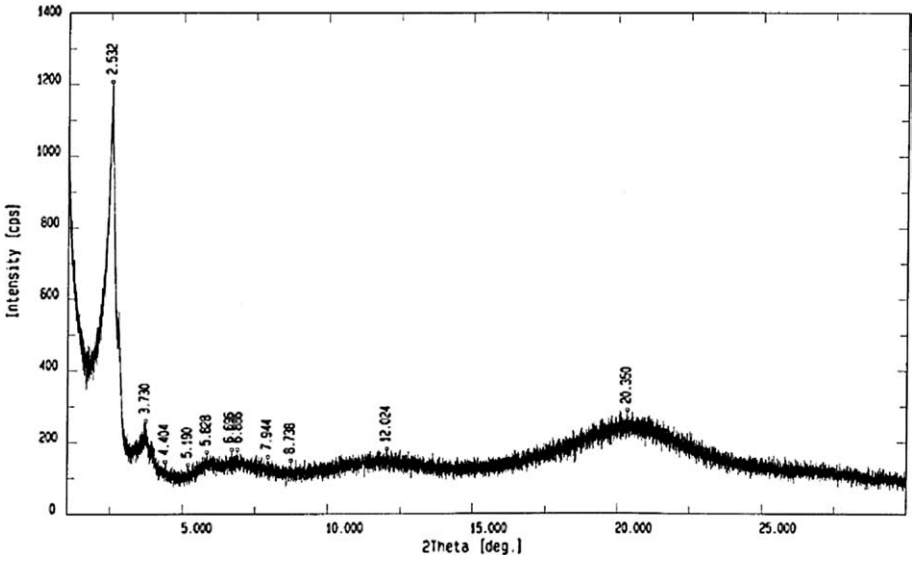

Fig. 5. X-ray diffraction pattern of complex **5a** at 30 °C.

3.1.3. X-ray diffraction

The mesophase of **5a** was identified by microscopic observation and X-ray diffraction measurements at 30 °C. The X-ray data is summarized in Table 1. Powder diffraction patterns of **5a** contain the typical reflections of a columnar mesophase of substituted pcs [17]. The low angle of the X-ray diffraction diagram of compound **5a** (Fig. 5) shows up to seven sharp Bragg reflections with a d-spacing ratio $1{:}1/\sqrt{3}{:}1/\sqrt{4}{:}1/\sqrt{7}{:}1/\sqrt{9}{:}1/\sqrt{12}{:}1/\sqrt{13}$ [5,7,10,13,14,17,39]. The lattice constant (**a**) is 40.26 Å for compound **5a**. This results suggests a two-dimensional hexagonal lattice with disk-like molecules stacked in columns in the hexagonal arrangement. In the wide angle regions the compound shows a diffuse band around 4.46 Å ($2\theta = 20.36°$) which corresponds to the melting of alkyl chains, and a band at about 3.5 Å ($2\theta \cong 25°$) which would correspond to fluctuation of the inter-disk distance in the one-dimensional molecular stack was not observed. Hence, this mesophase could be identified as a Col_h mesophase. The X-ray diffraction measurement of **5b** could not be measured at room temperature because this compound does not exhibit a mesophase at this temperature.

The diameter of the pc molecules (**5a** and **5b**) were calculated as ≈57 Å by means of semi-empirical method AM1 with full geometry optimization (GAUSSIAN 03W program package) in the gas phase. If the alkyl chains break then the diameter of the molecule is calculated as 35.8 Å. The experimental result from X-ray analysis data does not fit the corresponding theoretical result. It may be concluded that, according to the X-ray analysis data, the alkyl chains do not prefer a straight form but a frizzed form.

Abstract

Potentiometric, UV–Vis, CD and EPR studies were performed on the copper(II) complexes of oxygen and nitrogen donor ligands (monophosphono dipeptides: 1-(*N*-L-leucylamino)methylphosphonic acid – Leu–Gly(P), 1-(*N*-L-leucylamino)valylphosphonic acid – Leu–Val(P)) and a thioether sulfur donor ligands (monophosphono dipeptides: 1-*N*-(glycyloamino)-2-(*S*-benzylthio)ethanephosphonic acid – Gly–(Bz)Cys(P), D(+) and Gly–(Bz)Cys(P), D(−)). Complex formation reaction between copper(II) and dipeptides were very similar to each other, $[MLH_{-1}]^-$ being the major species in wide pH region. CD spectroscopy, however, was a very sensitive tool for the elucidation of small structural differences among peptide complexes, including the weak interaction in an axial and equatorial position of thioether residues. The complexes of the thioether donors have higher thermodynamic stability constants than the other ones.

1. Introduction

In contrast to the aminoalkylphosphonic acids complexes (see review [1] and references therein), which were intensively investigated in solution, studies on the chemistry of complex equilibria of the phosphonodipeptides containing N-terminal aminoalkylphosphonic acids with different metal ions in solution are rather poor [2–5]. Phosphonodipeptides containing terminal aminoalkylphosphonic acids have exhibited bacteriostatic ([6] and references therein) and herbicidal [7] activity. Their synthesis and properties have been reported by Kafarski et al. [8].

Besides, a good implementation of organophosphonates requires reliable data on the stability constants of the corresponding complexes. These permit modeling and prediction of the technological, environmental and pharmaco-kinetic equilibrium. So, chemical speciations based on numerical chemical equilibrium data are of extreme importance for different applications.

In earlier publications we have characterized the complex forming abilities of some aminodiphosphonic acids as iminodimethylenediphosphonic acids [1], and aminomethane-1,1-diphosphonic acids [9] with different metal ions in aqueous solutions. In the present work, our studies have been extended to various monophosphono dipeptides: 1-(*N*-L-leucylamino)methylphosphonic acid – Leu–Gly(P), 1-(*N*-L-leucylamino)valylphosphonic acid – Leu–Val(P) and 1-*N*-(glycyloamino)-2-(*S*-benzylthio) ethanephosphonic acid – Gly–(Bz)Cys(P). The aim of

doi:10.1016/j.poly.2004.04.027

the present paper was to study the influence of a thioether sulfur in the side chain on the complexing properties of Gly–(Bz)Cys(P), D(+) and Gly–(Bz)Cys(P), D(−) towards Cu^{2+} metal ion. We have chosen copper(II) (the coordination sphere of this metal ion is characterized by the phenomena of its plasticity) because of question, which still exists in the literature: does a thioether sulfur interact with Cu^{2+} or not?

Coordination properties of the ligands are important factors to understand the coordination ability of the hard–soft metals towards biological materials. Combination of different spectroscopic method was applied to identify the complexes in solution. Tentative structures for the complexes are discussed.

2. Experimental

2.1. Materials

Monophosphono dipeptides used in this study (Table 1) were obtained according to previously described procedures [10,11]. The purity and the exact concentrations of the solutions of the ligands used for potentiometric measurements were determined by the Gran method [12]. The concentration of copper(II) chloride stock solution was standardized by complexometric ethylenedinitrilotetraacetate (EDTA) titration. Carbonate-free sodium hydroxide (the titrant) was prepared and standardized against a standard potassium hydrogenphthalate solution.

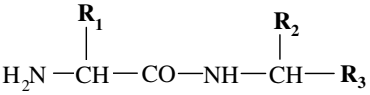
2.2. Potentiometric measurements

The stability constants of the proton and copper(II) complexes were determined by pH-metric titration of 5 cm^3 samples in water solutions. The ligand concentration was 4×10^{-3} or 2×10^{-3} mol dm^{-3} and the metal ion:ligand ratios were 0:1; 1:1; 1:1.5; 1:2 or 1:4. The ionic strength was adjusted to 0.2 mol dm^{-3} with KCl in each case. The titrations were performed over the range pH 2–11 with a carbonate-free KOH solution of known concentration (ca. 0.15 mol dm^{-3}). All titration solutions were thermostated at 25 ± 0.1 °C using a constant-temperature water-bath.

The data for the Cu^{2+}–Leu–Gly [13] and for the Cu^{2+}–Leu–Gly(P) [4] systems can be found in the literature but the stability constants were reinvestigated by us under the condition identical to those applied for other systems. In the case of Leu–Val(P), Gly–(Bz)Cys(P), D(−) and Gly–(Bz)Cys(P), D(+) our data are the first reported.

The pH was measured with a Radelkis OP-208/1 instrument with a combination pH electrode (SINGLE PORE, Hamilton) using a microburette ABU-80 (Radiometer). The electrode system was calibrated by periodic titrations of HCl solution (7.5×10^{-3} mol dm^{-3} in KCl) against standard KOH solution. The resulting titration data were used to calculate the standard

Table 1
The formulae of the studied ligands



R_1	R_2	R_3	Abbreviation
			Leu – Gly
			Leu – Gly(P)
			Leu – Val(P)
			Gly-(Bz)Cys(P), D(-) Gly-(Bz)Cys(P), D(+)

electrode potentials, E^0, and the dissociation constant for water ($pK_w = 13.73$). These values were then used to calculate the hydrogen-ion concentration [H^+] from e.m.f. readings [14]; number of titration, 3; calculations, SUPERQUAD computer program [15]. The reported standard deviations were calculated by assuming random errors.

The charges of the complexes have been omitted in the text and tables. However, for clarity, it should be mentioned that the fully deprotonated forms have negative charges L^{2-} and L^- for the monophosphono dipeptides and simple dipeptide, Leu–Gly, respectively.

2.3. UV/Vis spectroscopy

The absorption spectra were obtained on a SPECORD M40 spectrophotometer using 5-cm quartz cells at room temperature. The spectra were recorded digitally (1.5 nm) over the range 400–900 nm. The metal ion concentration was 3×10^{-3} mol dm^{-3} and concentration ratio of copper(II):ligand were 1:1 and 1:2. The individual spectra of the copper(II) complexes were calculated by means of method described in [16].

2.4. CD spectroscopy

The spectra were recorded at 25 °C on a Jasco J-715 spectropolarimeter (JASCO, Japan Spectroscopic Co.), over the range of 200–800 nm, using 1 cm and 0.1 cm cells. Samples contained 5.0×10^{-3} mol dm^{-3} ligand concentrations and 1:1.5 Cu^{2+}-to-ligands molar ratios. Such molar complex ratio exactly reflects the species distribution at the ratio 1:2, however, at the ligand concentration applied (2.5×10^{-3} mol dm^{-3} of Cu^{2+} ions) were too low to obtain readable spectra. The spectra are expressed in terms of $\Delta\varepsilon = \varepsilon_l - \varepsilon_r$, where ε_l and ε_r are molar absorption coefficients for left and right circularly polarized light, respectively.

2.5. EPR spectroscopy

Electron paramagnetic resonance (EPR) spectra were performed on a Bruker ESP 300E spectrometer at the X-band frequency (9.45 GHz) at 77 K in ethylene glycol–water (1:1 v/v) solutions. The ligand concentration was 4.0×10^{-3} mol dm^{-3} and the molar ratios of metal–ligand were 1:1 and 1:2. The spectra were analyzed by computer simulation program [17] based on resonance fields calculated according to method of Sakaguchi et al. [18].

3. Results and discussion

The acid dissociation constants of the studied monophosphono dipeptides together with those of simple dipeptide, Leu–Gly, are given in Table 2. The fully protonated form (H_3L^+) of Leu–Gly–PO_3H_2, Leu–Val–PO_3H_2 or Gly–(Bz)Cys–PO_3H_2, D(−) and Gly–(Bz)

Cys–PO_3H_2, D(+) can release three protons. The first proton of the –PO_3H_2 group is very acidic (p$K \approx 1.0$–2.0), and thus this function is fully deprotonated in the pH range studied in potentiometric titrations (2–10.5) and does not take part in metal coordination equilibria. In this connection the acidic dissociation constants of these protons are not given in Table 2. The second proton comes from the phosphonic function –PO_3H^- and the last one from the amino group –NH_3^+.

Comparison of the corresponding pK values with each other: the pK(NH_3^+) values with that of Leu–Gly, and of the pK(–PO_3H^-) values with that of Leu–Gly–PO_3H^-, shows that the pK(NH_3^+) values of the peptide-phosphonic acids are in good agreement with one another and slightly differ from that of Leu–Gly. It is seen (Table 2) that in case of the phosphonodipeptides, the –NH_3^+ group shows a higher basicity (ca. 0.3 log units) than Leu–Gly, probably because of a weak interaction with negatively charged phosphonic group (the fully deprotonated phosphonate group has a charge of 2–).

The electron donating by the R_3 substituent, which is present in the Leu–Val–PO_3H^-, results from the more basic character of the –PO_3H^- group in this molecule, if compare with Leu–Gly–PO_3H^-. The more acidic character of the –PO_3H^- group of Gly–(Bz)Cys–PO_3H^-, D(–) and Gly–(Bz)Cys–PO_3H^-, D(+) than of Leu–Gly–PO_3H^- ($\log \Delta K = 0.30$), can be explained by the electron-withdrawing effects of the R_3 substituent in the former case. The differences between the pK values of the corresponding amino groups are not as big as the differences between the pK's of the – PO_3H^- groups.

The titration curves for the systems containing copper(II) and studied ligand were evaluated by assuming the same type of complexes as were determined for the simple aliphatic dipeptides [19]. Due to the higher basicity of PO_3^{2-}, as compared to that for CO_2^-, the formation of protonated LH was also taken into account. The best fits between the measured and calculated titration curves were obtained by assuming the species given in Table 2. Formation of the [CuL_2] complex, which is not found by Herman and Lukes [4] for Cu^{2+}–Leu–Gly(P) system, is observed by us for all the phosphonodipeptides. As an illustration, the concentration distribution curves for the complexes formed in the Cu^{2+}–Leu–Gly and Cu^{2+}–Leu–Gly(P) systems are depicted in Figs. 1 and 2, and for the Cu^{2+}–Gly–(Bz)Cys(P), D(–) system in Fig. 3.

To clarify the binding modes of the complexes formed – visible, CD and EPR spectral measurements were performed (Tables 3 and 4). The analysis of the EPR spectra measured for all the systems as a function of pH and molar relation Cu:L, allows to find a specific EPR parameters which differentiate the species predicted by the potentiometric studies. In general, the EPR parameters are in some extent modified due to substitution of –CO_2^- by –PO_3H^- (or –PO_3^{2-}) group. The

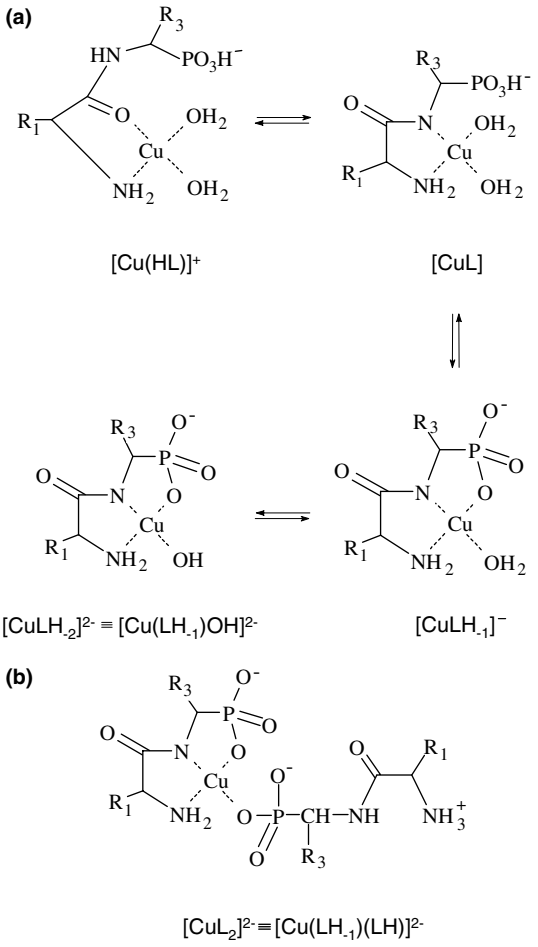
A parameters are given in 10^{-4} cm^{-1}. For all liquid solution spectra a fourth line of copper hyperfine structure exhibits hyperfine splitting of 13 G due to interaction with two nitrogen nuclei.
[a] A_{iso} is close to 15×10^{-4} cm^{-1}.
[b] $A_{\parallel}$ is close to 15×10^{-4} cm^{-1}.

complexes with phosphonodipeptides exhibit in general higher values of copper hyperfine coupling parameter A, due to a greater negative charge provided by deprotonated phosphono groups.

In the copper(II)–dipeptide–PO_3H_2 systems, the first complex formed at pH ca. 4 is [Cu(HL)]. This species is not formed with amino acid dipeptides because of the lower basicity of the carboxylate group. Taking into account a fact that the values of $\log K_{[Cu(HL)]} = \log \beta_{[Cu(HL)]} - pK_{PO_3H^-}$ of the phosphonodipeptides and of $\log \beta_{[CuL]}$ of the simple dipeptides [20,21] are about of the same order of magnitude, we can conclude that in the [Cu(HL)] species the phosphonodipeptides are coordinated to the metal ion in the same way as in the simple dipeptides, i.e. in a bidentate way, via the terminal amino and the peptide carbonyl group. This leads to the formation of the thermodynamically stable five-membered chelate ring, while the phosphonate group is still protonated, similarly to Kiss's [5] and Herman's [4] systems. The formation of this complex is evident from frozen solution EPR spectra at pH range 4.5–5.5. The signals of the species in the EPR spectra (in equilibrium with Cu^{2+}–aqua and with the signals from the next complex) correspond to the parameters $A_{\parallel} = 158 \times 10^{-4}$ cm^{-1} and $g_{\parallel} = 2.330$, which are associated with {3O, N} donor set around Cu^{2+} plane in [Cu(HL)] complex. On the other hand, the EPR spectrum of liquid solution at pH 5.3 is separated from the next spectrum and corresponds to the different parameters, than those observed at higher pH. The spectrum exhibits a hyperfine structure from two nitrogen atoms at the fourth line at high magnetic field suggesting, that in the second complex [CuL] metal ion is surrounded by two nitrogen atoms (Scheme 1).

Deprotonation of [Cu(HL)] and formation of the minor [CuL] species begins at pH below 5. The next step in the ligand dissociation and formation of the dominant species [CuLH$_{-1}$] occurs at the same pH. The loss of these two protons can presumably be ascribed to the terminal PO_3H^- and the peptide amide groups. These two processes overlap with each other (see $pK_{[Cu(HL)]}$ and $pK_{[CuL]}$ values in Table 2 and Scheme 1). If the next two consecutive deprotonations are separated by less than ca. 0.6 log units [22] a correct assignment of their pK values cannot be achieved.



Scheme 1. Tentative structures of the species formed in the Cu^{2+}–phosphonodipeptides systems at 1:1 molar ratio (a) and additional structure formed at 1:2 molar ratio (b).

Nevertheless, the $pK_{[CuL]}$ values are the same for Leu–Val(P), Gly–(Bz)Cys(P), D(−) and Gly–(Bz)Cys(P), D(+) and higher than for Leu–Gly(P) (Table 2) suggesting that substitution of C-terminal part of the phosphonodipeptide by R_3 has effect on the metal ion-binding ability of the ligands. On the other hand, all these values are distinctly higher for the complexes with Leu–Gly (Table 2), indicating that PO_3^{2-}/CO_2^- substitution makes the copper(II) ion-induced deprotonation and simultaneous coordination of the peptide amide somewhat disfavored [5].

In the first major complex $[CuLH_{-1}]$ phosphonodipeptides coordinate in a tridentate manner with {2N, O} binding mode. Besides the considerable increase in energy of the d–d transition, the change of EPR parameters is seen. An increase of $A_{\|}$ to about 180×10^{-4} cm^{-1} and decrease of $g_{\|}$ to about 2.25 may be unambiguously assigned to coordination of two nitrogen atoms in Cu^{2+} plane. This coordination mode is supported additionally by ^{14}N hyperfine splitting, which comes from two nitrogens, observed in liquid solution EPR spectra.

The CD spectra, obtained for both Cu^{2+}–Gly–(Bz)Cys(P) complexes confirm nitrogen coordination with the distinct $N\rightarrow Cu^{2+}$ CT band at around 260–270 nm. The intensity of this band increases drastically upon pH increase in comparison with that observed at pH 4.5, where only one nitrogen donor is coordinated in [Cu(HL)] species. The most probable arrangement of the donor atoms around the Cu^{2+} ion in $[CuLH_{-1}]$ can be seen in Scheme 1. The deprotonation and simultaneous coordination of the peptide–amide group are accompanied by an appreciable spectral change. Fig. 4 shows the changes in energy of the d–d transition as a function of pH for several of the Cu^{2+}–ligand systems studied. It can be seen that until pH ca. 4.5 there are small spectral changes in the copper(II)–phosphonodipeptide systems. Due to the very close overlap of the two deprotonation processes (Figs. 1–3), a correct assignment of the two pK values cannot be achieved. It is most probable that parallel deprotonation of the terminal $-PO_3H^-$ and the peptide amide take place. In the [CuL] species, ligands coordinate in a bidentate manner with $\{NH_2, N^-\}$ binding modes and in $[CuLH_{-1}]$ – in a tridentate manner with $\{NH_2, N^-, O\}$ binding modes. Besides the considerable increase in energy of the d–d transition ($\lambda_{max}\approx 625$ nm) the EPR parameters also indicate 2N coordination in these two species.

A further deprotonation process of $[CuLH_{-1}]$, leading to the formation of $[CuLH_{-2}]$ is detected potentiometrically in all studied systems. This complex is regarded as a mixed hydroxo-complex $[Cu(LH_{-1})(OH)]$, in which the water molecule in the horizontal plane is replaced by $[OH]^-$. This process is accompanied by almost no change in the d–d transition on visible spectra for all the systems studied, but the CD spectra for Gly–(Bz)Cys(P), D(−) and Gly–(Bz)Cys(P), D(+) show that the sum of d–d bands which occurs at around 670 nm splits up into three individual bands following deprotonation and formation of $[CuLH_{-2}]$. The formation of

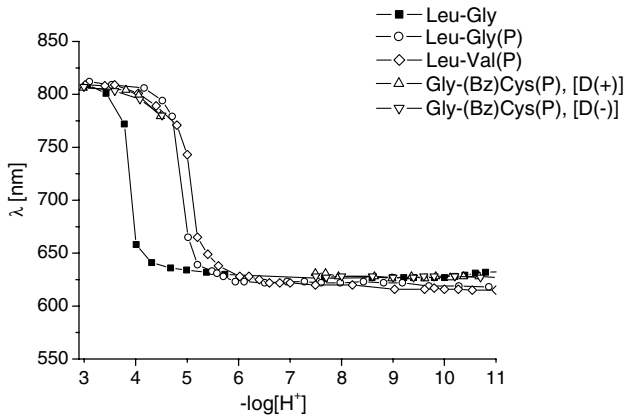


Fig. 4. Changes of the d–d absorption in the 1:1 Cu^{2+}/ligand systems as a function of $-\log[H^+]$.

the transitions at ca. 570 and 520 nm for the complexes of both ligands indicates the distortion of the tetragonal symmetry towards more tetrahedral environment, due to increasing repulsion between negatively charged ligands around copper(II) ion (Table 3).

For the systems with L = Leu–Val(P) and Gly–(Bz)Cys(P) at pH 10.5, a new EPR spectrum is observed for Cu^{2+}:L molar ratios equal to 1:1 and 1:2 indicating that the spectrum is most likely associated with formation of $[CuLH_{-2}]$ complex. A significant decrease of $A_{\|}$ values for the spectra at pH higher than 10 additionally supports a lowering of the complex symmetry upon including of OH^- into Cu^{2+} coordination sphere. The effect appears to be smaller in the case of the ligand with $R_3 = H$.

Ligands Gly–(Bz)Cys(P), D(−) and Gly–(Bz)Cys(P), D(+) are more effective chelating agents than other ones. This is reflected in the pH value of complexation of 50% of Cu^{2+}, which is about 30% for other ligands (Fig. 3) and also in the higher basicity-adjusted stability constants, $\log \beta_{[CuLH-1]} - \sum pK$ (Table 2). Taking these into account, comparison of the $[Cu(Leu–Val(P)H_{-1})]$ species and $[Cu(Gly–(Bz)Cys(P)H_{-1})]$ complexes still reveals a difference in stabilities of about 0.98 log units. The presence of an aromatic ring (e.g. Bz) in the C-terminal residue gives generally a more stable $[MLH_{-1}]$ species [23]. This stabilizing effect is often attributed to an interaction between the metal ion and the aromatic ring [24–27]. In the case of both Gly–(Bz)Cys(P) ligands, this effect may also arise from the interaction of thioether sulfur in an axial position with the copper(II) center. As an evidence for this, the formed complexes exhibit a distinct band in CD spectra in the region 320–330 nm. A similar band was previously observed in the absorption spectra for a set of thioether ligands and was assigned to $S \rightarrow d_{x^2-y^2}$ charge transfer transition [28]. Also, a wide range of studies focused on copper(II) binding to a variety of oligopeptides containing methionyl residue revealed the possibility of S–Cu^{2+} interactions [29–33]. Methionine itself was reported to act as tridentate ligand for copper(II) ions but only at low temperatures and at low pH values [29]. This type of chelation was verified in comparison to norleucine, which possesses a similar hydrophobic side chain [30]. Moreover, dipeptides and tripeptides containing methionine gave with Cu^{2+} ions similar CT bands in UV–Vis and CD spectra, assigned to the $S \rightarrow Cu^{2+}$ transition, regardless the position of thioether group [31,32]. The CT band in CD spectra was relatively weak [31] and the analogous band in UV–Vis existed only at acidic and neutral pH [32]. In our experiments, the intensity of the band between 320 and 330 nm in CD spectra for both Gly–(Bz)Cys(P) ligands arises with the change of the complex stoichiometry from $[CuLH_{-1}]$ to $[CuLH_{-2}]$.

However, the benzyl ring may also participate in complex stabilization through an interaction in an axial position with Cu^{2+} center. Such phenomenon may compete with thioether sulfur coordination. It was proved for both methionyl sulfur and phenyl aromatic ring in Met–Phe and Phe–Met ligands to exhibit similar potency towards their copper complexes stabilization [33]. This occurred through the distortion of the carboxylic oxygen–copper(II) bond, which is energetically weak, by sulfur donor or phenyl residue. In the case of Gly–(Bz)Cys(P), both benzyl ring and thioether group can stabilize the complex by competition with the phosphonic oxygen towards copper ion coordination in an axial position. A distinct CT transition band observed at around 320 nm suggests that this is rather S–Cu^{2+} interaction. The inspection of (Table 4) (X-EPR) reveals that liquid- and frozen-state EPR spectra of all the complexes formed by both Cu^{2+}–Gly–(Bz)Cys(P) ligands are in small extent but consequently different as compared to those observed for the remaining Cu^{2+}–phosphonodipeptides. The change in the EPR parameters [slightly decreased $A_{\|}$ (and A_{iso}) and increased $g_{\|}$ (and g_{iso})] at pH range of dominant contribution of $[CuLH_{-1}]$ is opposite the change observed [32] due to coordination of methionine sulphur in the *xy*-plane of copper. This tendency supports the binding of thioether sulfur at an axial position and the weakness of the equatorial ligand bonds.

In the presence of excess of the ligand a species with $[CuL_2]$ composition is also formed in all studied systems in the pH range 6–8. Our results concerning the system with Leu–Gly(P) are not consistent with those reported by Herman and Lukes [4]. The formation of 1:2 complex was not observed by them. For other systems, contrary to [5] and [4], the $[CuL_2]$ species is regarded as a $[Cu(LH_{-1})(HL)]$ complex. Because deprotonation of the amide function takes place around pH 5, tridentate and monodentate binding of the ligands is possible. So, binding mode of this species can be interpreted as $\{NH_2, N^-, PO_3^{2-}, PO_3^{2-}\}$, see Scheme 1.

The calculations performed with use of the complex stabilities, $\log K_{[CuL]}/K_{[CuL_2]}$, show the decreasing ability to form the bis-complexes as the size of R_3 increases (Table 2).

Deprotonation of the $[CuL_2]$ species starting at pH 5.5 and giving $[CuL_2H_{-1}]$ is overlapped by deprotonation process of dominant $[CuLH_{-1}]$ species, accompanied by formation $[CuLH_{-2}]$, which concentration reaches about 80% at pH ca. 10.5. It is noteworthy that similarly to the complex with Leu–Gly, the greatest content of $[CuL_2H_{-1}]$ is predicted potentiometrically at pH about 9 for both L = Gly–(Bz)Cys(P), in contrast to other phosphono dipeptides. In this case the species $[CuL_2H_{-1}]$ are separated from $[CuL_2]$. The signals of the corresponding EPR spectra are shifted into slightly lower values of $g_{\|}$ and higher values of $A_{\|}$ suggesting a stronger donor character of the ligands; this effect may be diminished by a simultaneous distortion of the complex geometry.

4. Conclusion

Because of the more basic character of the phosphonic group, PO_3^{2-}/CO_2^- substitution leads to the formation of various protonated 1:1 and 1:2 complexes in copper(II)–monophosphono dipeptides systems in compare to system with Leu–Gly (see Table 2).

From the comparative analysis of the stability and the spectroscopic (UV–Vis, CD and EPR) data, it has been established that the coordination in $[CuLH_{-1}]$, the major species in the studied systems, is realized by the $\{PO_3^{2-}, NH_2, N^-\}$ donor set. Both ligands Gly–(Bz)Cys(P) are more effective chelating agents than other ones. In this case both benzyl ring and thioether group can stabilize this complex by competition with the phosphonic oxygen towards copper ion coordination in an axial position. A distinct CT transition band observed at around 320 nm suggests that this is rather S–Cu^{2+} interaction. In addition the inspection of X-EPR reveals that liquid- and frozen-state EPR spectra of all the complexes formed by both Cu^{2+}–Gly–(Bz)Cys(P) ligands are in small extent but consequently different as compared to those observed for the remaining Cu^{2+}–monophosphono dipeptides.

Abstract

The syntheses and structural characterization of two new chiral coordination polymers, Cu(nic)$_2$(H_2O)·CH_3OH (nic = nicotinate) (**1**), and Co(nic)$_2$·H_2O (**2**), which were prepared by reactions of nicotinic acid with $CuCl_2 \cdot 2H_2O$ and $Co(NO_3)_2 \cdot 6H_2O$, respectively, are reported. Single-crystal X-ray crystallography structure determinations show that complexes **1** and **2** crystallize in the chiral space groups $P3_221$ and $C2$, respectively. The Cu(II) centers in **1** adopt a slightly distorted square pyramidal geometry, while the Co(II) centers in **2** exhibit a distorted octahedral coordination geometry. The metal centers in **1** and **2** coordinate to both the pyridyl and carboxylate groups to form 3-D and 2-D framework structures, respectively. Complex **1** exhibits open channels that are occupied by removable CH_3OH molecules, while complex **2** shows planar molecular grids.

1. Introduction

Recently, great effort has been devoted to the self-assembly of organic and inorganic molecules in the solid state because it extends the range of new solids with desirable physical and chemical properties [1]. The range and variety of self-assembled inorganic structures that can be constructed relies on suitable metal–ligand interactions and hydrogen bondings, and the various types of polymeric structures include 1-D, 2-D and 3-D network structures [2]. Chiral coordination polymers containing nicotinate ligands [3], which display optical properties [3a], were the subject of several studies during recent years. Despite some recent progress for the synthesis of chiral coordination polymers, the ability to predict and control the supramolecular assembly of these molecules remains an elusive goal, and much more work is required to understand the effects of the metal center and ligand on the patterns of the molecular structure in the solid state. During our investigation on the reactions of transition metal (II) complexes with nicotinic acid, we have obtained two chiral polymeric complexes which show 3-D and 2-D framework structures. The syntheses and crystal structures of Cu(nic)$_2$(H_2O)·CH_3OH (nic = nicotinate) (**1**), and Co(nic)$_2$·H_2O (**2**), form the subject of this report.

2. Experimental

2.1. General procedures

All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated

doi:10.1016/j.poly.2004.04.026

by refluxing over the appropriate reagents before use. The visible absorption spectra were recorded on a Hitachi U-2000 spectrophotometer. IR spectra were obtained from a Jasco FT/IR-460 plus spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer.

2.2. Materials

The reagents $CuCl_2 \cdot 2H_2O$, $Co(NO_3)_2 \cdot 6H_2O$ and nicotinic acid were purchased from Aldrich Chemical Co. and used as received.

2.3. Preparation of the $Cu(nic)_2(H_2O)$ (1)

$CuCl_2 \cdot 2H_2O$ (0.43 g, 2.52 mmol) was added to a methanolic solution (25 ml) containing nicotinic acid (0.75 g, 6.09 mmol). The mixture was then heated to reflux for 6 h until some blue solid began to precipitate. The solid was filtered out, washed with diethylether (2×10 ml) and dried under vacuum to give a blue powder. Yield: 0.75 g (91%). UV–Vis (DMF): 438 nm ($\varepsilon = 1406.2\ M^{-1}\,cm^{-1}$). *Anal.* Calc. for $C_{13}H_{14}CuN_2O_6$ ($M_w = 357.80$), C, 44.24; H, 3.09; N, 8.60. Found: C, 43.75; H, 3.01; N, 9.08%. IR (KBr disk): 1636(m), 1560(s), 1543(s), 1508(w), 1457(m), 1384(s), 1307(w), 1191(m), 762(m), 683(m), 669(w), 651(m), 472(w). Dark blue crystals suitable for X-ray crystallography were obtained by slow diffusion of CH_3OH into a DMF solution of **1**.

2.4. Preparation of $Co(nic)_2$ (2)

$Co(NO_3)_2 \cdot 6H_2O$ (0.29 g, 1.0 mmol) was added to a CH_2Cl_2 solution (20 ml) containing nicotinic acid (0.25 g, 2.0 mmol). The mixture was then refluxed for 48 h to afford a red solution and a red solid. The precipitate was filtered and washed with ether (3×10 ml) and then dried under reduced pressure to give a dark red solid. Yield: 0.28 g (92%). UV–Vis (DMF): 382 nm ($\varepsilon = 1045.8\ M^{-1}\,cm^{-1}$). *Anal.* Calc. for $C_{12}H_8CoN_2O_4$ ($M_w = 303.14$), C, 47.55; H, 2.66; N, 9.24. Found: C, 47.54; H, 3.03; N, 9.67%. IR (KBr disk): 1385(s), 1192(s), 1048(s), 828(m), 756(s), 698(m), 451(w). Red crystals suitable for X-ray crystallography were obtained by slow diffusion of ether into a $MeOH/H_2O$ solution of **2**.

3. X-ray crystallography

The diffraction data for complexes **1** and **2** were collected at 25 °C on Bruker AXS P4 and Siemens CCD diffractometers, respectively, which were equipped with graphite-monochromated Mo K_α ($\lambda_\alpha = 0.71073$ Å) radiation. Data reduction was carried out by standard methods with the use of well-established computational procedures [4]. The structure factors were obtained after Lorentz and polarization correction. The positions of some of the heavier atoms, including the copper atom, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [5]. The CH_3OH molecule was found to be disordered, and the occupancies for the carbon and the oxygen atoms were set to be 0.5. The final residuals of the final refinement were $R_1 = 0.0552$, $wR_2 = 0.1490$. The crystallographic procedures for **2** were similar to those for **1**. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1.

4. Results and discussion

4.1. Syntheses

The complex $Cu(nic)_2(H_2O)$ (nic = nicotinate) (**1**), was prepared by reaction of $CuCl_2 \cdot 2H_2O$ with nicotinic acid in refluxing methanol while the complex $Co(nic)_2$ (**2**), was prepared by reaction of $Co(NO_3)_2 \cdot 6H_2O$ with nicotinic acid in refluxing CH_2Cl_2. Their structures have been determined by spectroscopic methods and by X-ray crystallography.

4.2. Structure of 1

A single crystal X-ray structural analysis of **1** reveals the formation of a complex of stoichiometry $Cu(nic)_2(H_2O) \cdot CH_3OH$. Complex **1** conforms to the chiral space group $P3_221$. Fig. 1 shows the coordination geometry about the Cu metal center, which adopts a slightly distorted square pyramidal coordination geometry with the bond angles only slightly deviated from 90° or 180°. The Cu atom is bonded to two *trans* pyridyl nitrogen atoms (Cu–N = 2.032 (6) Å) and two *trans* oxygen atoms of the monodentate carboxylate groups (Cu–O = 1.964 (4) Å) in the equatorial plane. The dihedral angles of the two *trans* pyridyl rings that coordinated to the Cu atom through the nitrogen atoms is 83.0°, while that of the other set is 18.1°. The Cu atom is also bonded to one H_2O ligand (Cu–O = 2.332 (1) Å) in the axial position to complete the distorted-square-pyramidal coordination geometry. Noticeably, each bidentate nicotinate ligand links two Cu(II) metal centers, and all the ligands extend approximately along the *c*-axis to form an infinite helical chain (Fig. 2, top). The most striking feature of this complex is that the infinite helices form a two-dimensionally extended hexagonal array with open pores (9.1×11.3 Å) that accommodate the water molecules that are coordinated to the Cu(II) atoms and the non-coordinating methanol molecules. The open channels are further linked through the nico-

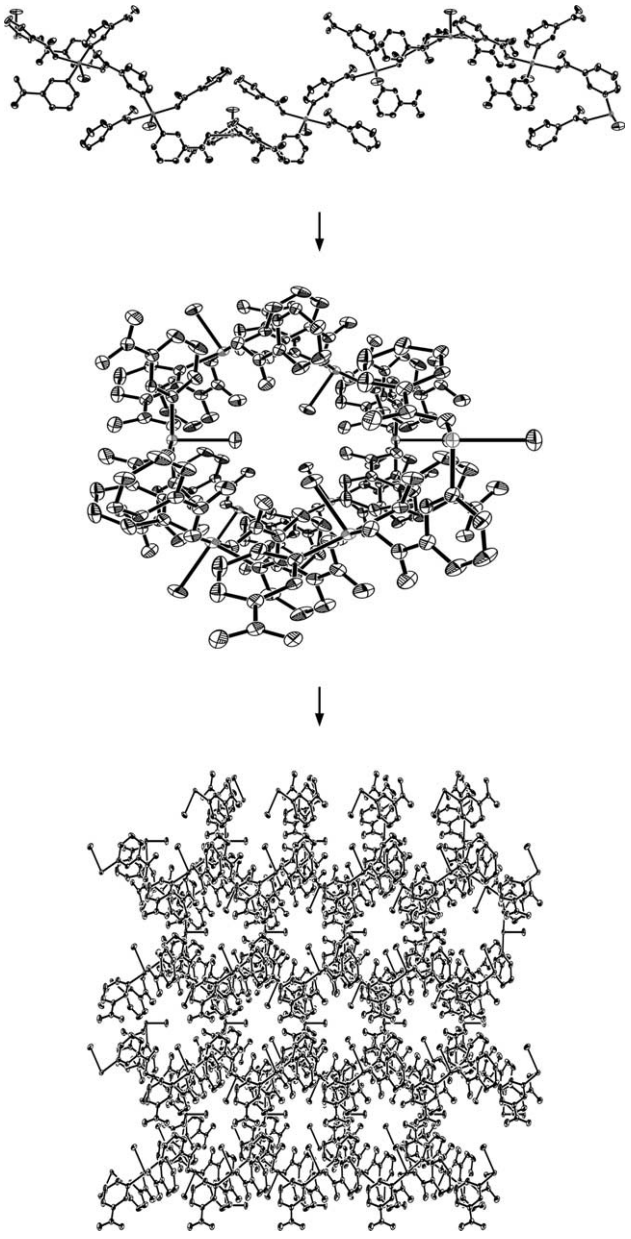

Fig. 2. A helical chain with *P* configuration formed by the bidentate nicotinate groups and Cu centers running along the *a* axis (top), Chiral channel formed by the helical chain running along the *c* axis (middle) and the polymeric structure of **1** (bottom).

tinate groups to form a 3-D framework structure (Fig. 2, bottom). It is also seen from Fig. 2 that the water molecules are all pointing to the centers of the pores. This helical structure is in marked contrast to the one found in the complex $[Cu(pzca)(Me_2CO)_{0.5}](BF_4)$ (pzca = 2-pyrazinecarboxamide) where the cavities are occupied by the BF_4^- anions [6]. It is also noted that helical coordination polymers with large chiral cavities have been prepared by dissolving $[Ni(acetate)_2]$ and benzoic acid in MeOH and layering with a solution of 4,4′-bipyridine in MeOH [7].

4.3. Structure of **2**

A single X-ray structural analysis of crystals of **2**, obtained by slow diffusion of ether into a MeOH solution of **2**, reveals the formation of a complex of stoichiometry $Co(nic)_2 \cdot H_2O$. Complex **2** was solved in the chiral space group *C*2. Fig. 3 shows the coordination geometry about the Co metal center. The cobalt metal center, which resides on a crystallographic 2-fold axis, adopts a distorted octahedral coordination geometry with the bond angles significantly deviated from 90° or 180° (Table 2), presumably due the chelation of the bidentate carboxylate groups to the Co metal center. The Co atom is bonded to two *cis* pyridyl nitrogen atoms (Co–N = 2.075 (6) Å) and two *cis* bidentate carboxylate groups (Co–O = 2.059 (6) and 2.291 (7) Å). The carboxylate groups are coordinated to the metal centers in unsymmetrical fashions. All the Co metal centers in complex **2** are chiral and have the same handedness Δ. Adjacent Co atoms are linked to each other through the pyridyl nitrogen atoms and the oxygen atoms of the bidentate carboxylate groups to form the two-dimensional square grid, Fig. 4(a). The complex shows void space with a Co–Co separation of 7.748 Å. The cavities are occupied by the solvent molecules and the squares are further linked through extensive C–H- - -O hydrogen bondings (H- - -O = 2.523 Å; ∠C–H–O = 130.5°), Fig. 4(b). The square grids in complex **2** are in contrast to those found in the chiral complex Zn(nicotinate)$_2$ where the pyridine rings of the nicotinate groups intrude into the square cavities to result in interdigitation of the 2-D square networks [3].

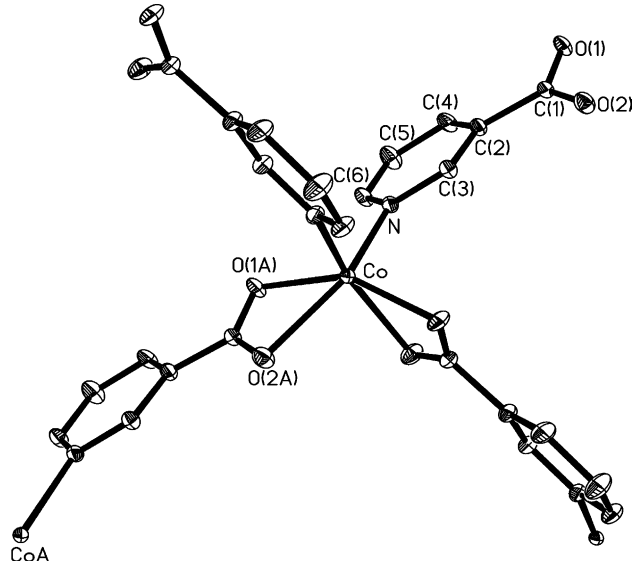

Fig. 3. An ORTEP drawing showing the coordination geometry of the cobalt metal center. Ellipsoids are scaled to enclose 20% of the electron density.

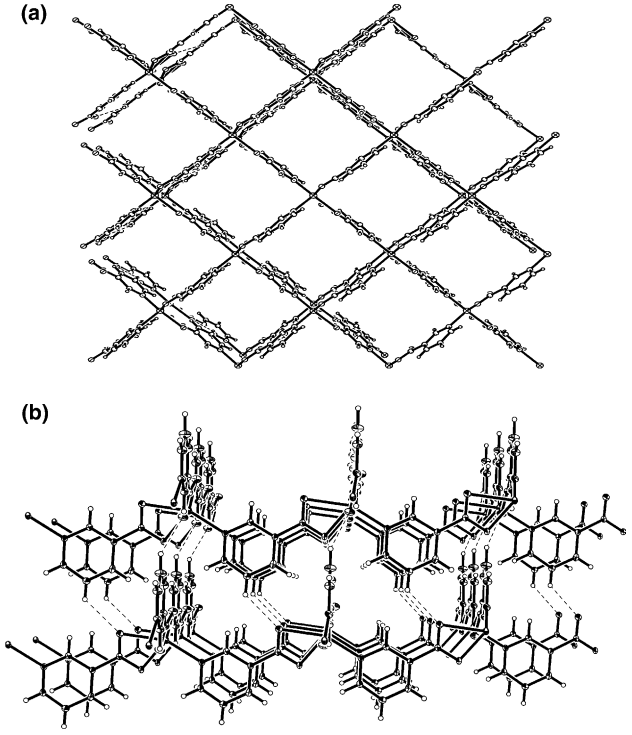

Fig. 4. (a) The polymeric structure of **2**. The solvent molecules which occupy the cavities are removed for clarity. (b) A diagram showing the interactions among the square grids of **2**.

Complexes **1** and **2** make interesting comparisons with the mononuclear complexes $Cu(nic)_2(H_2O)_4$ and $Co(nic)_2(H_2O)_4$ [8] and the three-dimensional Cu(II) coordination polymer $Cu(nic)_2$ [9,10]. The complexes $Cu(nic)_2(H_2O)_4$ and $Co(nic)_2(H_2O)_4$ were prepared by the reactions of $CuCl_2 \cdot 2H_2O$ and $CoCl_2 \cdot 6H_2O$, respectively, with nicotinic acid in NaOH solution (pH = 6) at 60 °C. The coordination spheres of these two mononuclear complexes are octahedral, with two pyridyl nitrogen atoms and two aqua oxygen atoms in the equatorial positions and two aqua oxygen atoms in the axial positions. The complex $Cu(nic)_2$ was synthesized by treating copper nitrate with nicotinic acid under hydro(solvo)thermal conditions, and the Cu(II) centers adopt a coordination geometry intermediate between square pyramidal and trigonal bipyramidal. The tridentate nicotinate groups (with bridging carboxylate) link doubly carboxylate bridged Cu(II) dimers into a pleated-sheet structure through the coordination of their pyridyl nitrogen atoms, while the bidentate nicotinate groups link adjacent Cu centers to form zigzag chains along the *a*-axis and thus cross-link the pleated sheets formed by the Cu centers and tridentate nicotinate groups to result in a complex 3-D framework structure [9]. A complex of the same formula of $Cu(nic)_2$ has also been prepared by reacting $Cu(NO_3)_2 \cdot 2.5H_2O$ with nicotinic acid in the mole ratio of 2:1 for three days at 170 °C under hydrothermal conditions [10].

The two main factors that govern the structures of **1** and **2** and all the complexes mentioned above are the coordination of the H_2O molecules and the role of the metal centers in influencing the coordination geometry. It is clearly seen that changing the metal center and introducing the water molecule can drastically modify the structures of the coordination polymers.

4.4. Thermal properties

Complex **1** is very stable in air at ambient temperature and almost insoluble in common solvents such as water, alcohol, acetonitrile, chloroform, methanol and acetone. Complex **2** is also stable in air at room temperature but soluble in methanol. Thermal gravimetric analyses (TGA) were carried out to examine the thermal stability of **1** and **2**. The samples were heated up in air at 1 atm pressure with the heating rate of 20 °C min^{-1}. The TGA curve shows that **1** is stable up to 120 °C. A total weight loss of 16.3% occurred in the temperature range 120–230 °C, presumably due to the removal of the guest methanol molecules and the bonded H_2O molecules per formula unit (Calc. 16.4%), and a sharp weight loss occurred in the temperature range 230–320 °C, consistent with the removal of nicotinate ligands and decomposition of the framework. The TGA curve shows that **2** is stable up to 100 °C. A total weight loss of 5.6% occurred in the temperature range 100–150 °C, corresponding to the removal of the guest H_2O molecules per formula unit (Calc. 5.9%), and a sharp weight loss occurred in the temperature range 380–420 °C, consistent with the removal of nicotinate ligands and

decomposition of the framework. Their T_m values have been measured by using differential scanning calorimetry (DSC), and these are 107.2° and 134.9° for complexes **1** and **2**, respectively.

5. Supplementary material

Crystallographic data (CIF files) for the structures **1** and **2** have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 226294 and 228646, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 12 January 2004; accepted 28 April 2004

Abstract

This work presents the synthesis of the complex $[Fe(\mathbf{L})_2](PF_6)_2 \cdot H_2O$ ($\mathbf{L}$ = 2,6-bis[1-(3-pyrrol-1-yl-propylimino)ethyl]pyridine (Fig. 1) and its characterization through elemental and thermal analysis, X-ray diffraction and UV–Vis, IR and ^{1}H NMR spectra. The use of this compound in the preparation of modified electrodes is also described. The best electrochemical parameters to achieve optimum film formation have been established and the effects of both the upper-limit of the applied scanning potential (E_{aul}) and the number of scans on the efficiency of film formation have been investigated. Film surface morphology has been characterized by atomic force microscopy.

1. Introduction

Chemically modified electrodes have been the subject of considerable attention since their inception about 27 years ago [1]. This is due to their potential application in electrochromic devices, electrocatalysis, electroanalysis and in the design of molecular electronic devices [2]. With the deliberate immobilization of a modifier agent onto an electrode surface, it is hoped that the physicochemical properties of the modifier will be transferred to the electrode surface. This modification seeks to dictate and control the behavior of the electrode/solution interface [2]. The electrochemical polymerization and precipitation of films directly onto an electrode surface offer some advantages when compared with the deposition of chemically preformed polymers. Electropolymerization allows the deposition of insoluble polymers, uniform coating on irregular surfaces and easy electrochemical control of the film thickness. The electrochemical polymerization of the pyrrole group is convenient for carrying out the coating of electrode surfaces by non-passivating polymer films containing active centers, especially transition metal complexes [3].

This work presents the synthesis of the complex $[Fe(\mathbf{L})_2](PF_6)_2 \cdot H_2O$ ($\mathbf{L}$ = 2,6-bis[1-(3-pyrrol-1-yl-propylimino)ethyl]pyridine (Fig. 1) and its characterization through elemental and thermal analysis, X-ray diffraction and UV–Vis, IR and ^{1}H NMR spectra. The use of this compound in the preparation of modified electrodes is also described. The best electrochemical parameters to achieve optimum film formation have been established and the effects of both the upper limit of the applied scanning potential (E_{aul}) and the number of scans on the efficiency of film formation have been investigated. Film surface morphology has been characterized by atomic force microscopy.

2. Experimental

2.1. Materials

2,6-Diacetylpyridine, *N*-(2-cyanoethyl)pyrrole, lithium aluminium hydride and dichloromethane (DCM) were obtained from Aldrich Chemical Co., Ltd. Tetrabutylammonium perchlorate (TBAP) was purchased from Fluka. All other reagents and solvents were of the highest purity grade available from Merck, Mallinckrodt and Sigma Chemical Co., Ltd. and were used without prior purification.

2.2. Synthesis of the ligand

N-(2-cyanoethyl)pyrrole was reduced to *N*-(3-aminopropyl)pyrrole with $LiAlH_4$ in dry diethyl ether through a procedure described in the literature [4]. The product was purified by distillation under reduced pressure. Yield 62%.

^{1}H NMR in $CDCl_3$: δ 1.12 (s, 2H, NH_2); δ 1.87 (q, 2H,); δ 2.67 (t, 2H); δ 3.94 (t, 2H); δ 6.12 (t, 2H); δ 6.64 (t, 2H).

IR: $\nu(NH_2)$ 3365, 3293 cm^{-1}.

2.3. Synthesis of the complex $[Fe(L)_2](PF_6)_2 \cdot H_2O$

The complex was synthesized through Schiff-base condensation between 2,6-diacetylpyridine (143.4 mg, 0.88 mM) and *N*-(3-aminopropyl)pyrrole (219.4 mg, 1.77 mM), in the presence of ferrous ammonium sulfate (172.4 mg, 0.44 mM) and dry ethanol (10 mL), under nitrogen atmosphere. The mixture was stirred at 70 °C for 3 h and filtered through a fine filter. The desired complex was precipitated from the filtrate by adding 2 mL of saturated aqueous NH_4PF_6 to it. The precipitate was collected, washed with cold water and dried under vacuum. Yield 68%. Results from CHN elemental analysis were in good agreement with the expected theoretical composition for $[Fe(C_{46}H_{58}N_{10})](PF_6)_2 \cdot 1H_2O$ (M quelate) = 1114.81 g mol^{-1}. Calc.: C, 49.56; H, 5.42; N, 12.56. Found: C, 49.17; H, 5.03; N, 12.18%.

2.4. Characterization

Elemental analysis was performed on a Carlo Erba Elemental Analyzer model EA1110. ^{1}H NMR spectra were obtained in $CDCl_3$ solutions in a Bruker 300 MHz spectrometer model DPX 300. UV–Vis spectra were obtained in quartz cells by using a 8452A Hewlett–Packard spectrophotometer. Thermogravimetry (TG) and differential thermal analysis (DTA) experiments were performed by using a module of thermal analysis, SDT 2960, from TA Instruments under dynamic atmosphere of oxygen and nitrogen with a heating rate of 20 °C min^{-1} from 40 to 1200 °C. The residual oxide was characterized through DXR using a Siemens D 5000 diffractometer with Cu Kα radiation, submitted to 40 KV, 30 mA and 0.05° s^{-1} step. The oxide was placed on a proper support and exposed to radiation from 4° to 70° (2θ). Differential scanning calorimetry (DSC) curves were obtained by using a DSC 2910 from TA Instruments under nitrogen dynamic atmosphere, at a heating rate of 20 °C min^{-1} from 40 to 600 °C. IR spectra were recorded on a 1600 FT Perkin–Elmer spectrophotometer as KBr discs. Electrochemical experiments were conducted on a PAR model 273 Potentiostat/Galvanostat. Cyclic voltammetric experiments were carried out in conventional three-compartment glass cells under argon atmosphere using a glassy-carbon disc working electrode (0.08 cm^2 area), a platinum wire auxiliary electrode and a saturated calomel reference electrode (SCE). The glassy-carbon electrode was polished to a mirror finish with different grades of alumina as low as 0.05 μm and ultrasonically cleaned before the experiments. All experiments were done in dichloromethane 0.1 M in TBAP.

Apparent surface coverages (Γ_T^{APP}, mol cm^{-2}) were calculated using the equation $\Gamma_T^{APP} = Q/nFA$ (where n is the number of transferred electrons, F is Faraday's constant, A is the electrode area in cm^2 and Q is the charge (area) under the cyclic voltammetric oxidation $Fe^{II/III}$ wave at 50 mV s^{-1}.

The surface morphology of the electrodeposits was analyzed by AFM in a Nanoscope IIIa electronics (Digital Instruments, Inc.). Polymer films of different thickness were grown on indium/tin oxide electrodes (1 cm^2) by cycling (20 and 50 times) the potential (0–1.25 V). One modified electrode was cycled between 0 and −2.0 V to deactivate the polymer. The electrodes were removed from the electrochemical cell after electrodeposition, washed with anhydrous dichloromethane and dried under vacuum. During AFM measurements, considerable search was done to find images on various parts of the surface. The images that were found in several parts of the film will be shown herein.

3. Results and discussion

The free ligand (L) was prepared by heating a solution of 2,6-diacetylpyridine and *N*-(3-aminopropyl)pyrrole (1:2 equivalents) at reflux in dry benzene for 2 h. Upon removal of the solvent by roto-evaporation, the ligand was collected as a yellow oil. However, a carbonyl containing material, probably due to the unreacted 2,6-diacetylpyridine, remained in the reaction product, as detected by ^{1}H NMR spectrum. Sub products of this condensation were not observed when it was performed in the presence of ferrous ammonium sulfate, yielding the complex straightforwardly.

The IR spectrum of the complex showed one band at ca. 1648 cm^{-1}, assigned to the ν(C=N) imine bond stretch. No ν(C=O) or $\nu(NH_2)$ signals were observed, indicating that no unreacted reagents remained in the sample. The sharp bands at 840 and 558 cm^{-1} were assigned to the hexafluorophosphate ion.

The electronic spectrum of $[Fe(\mathbf{L})_2]^{2+}$ in dichloromethane solution shows two absorption bands in the visible region (494 and 597 nm) characteristic of metal-to-ligand charge-transfer transitions (MLCT) in iron(II)–diimine complexes [5]. The electronic spectra of this complex is very similar to that reported by Wieghardt and coworkers [6]. for iron(II) complexes containing the ligand 2,6-bis[1-(4-methoxyphenylimino) ethyl]pyridine. The intense bands observed in the region from 219 to 292 nm are assigned to internal ligand transitions of the type $\pi \rightarrow \pi^*$ [7] and $n \rightarrow \pi^*$ [8] type.

The TG curves for $[Fe(\mathbf{L})_2]^{2+}$ under oxygen and nitrogen (Fig. 2(a)) shows the first mass loss step to be between 40 and 165.5 °C, which is related to the dehydration of 1 H_2O per mol of the compound. This thermal event displays the endothermic peaks at 133.0 and 91.8 °C in DTA (Fig. 2(b)) and DSC (Fig. 2(c)) curves, respectively.

The complex shows distinct thermal behavior depending on the employed atmosphere. Under oxygen, the thermal decomposition of the ligand occurs in two consecutive steps: between 187.5–461.4 °C and 462.3–833.7 °C (Fig. 2(a)), corresponding to the exothermic peaks at 297.4 and 573.7 °C (Fig. 2(b)). These events result in the formation of 14.25% of a Fe(III) oxide residue above 834.0 °C. Such oxide corresponds to $FePO_4$ in the hexagonal phase and it is generated because of the oxidizing atmosphere (calculated 13.53%), as revealed by the X-ray diffraction pattern.

Under nitrogen, the compound shows a mass loss of 46.81% between 230.5 and 440.4 °C (Fig. 2(a)), with a wide endothermic peak around 255.2 °C and another one defined at 363.9 °C in the corresponding DSC curve (Fig. 2(c)). This thermal event may be due to the decomposition of propylpyrrole and ethyl groups that were not coordinated to the metal (calculated 46.74%). The remaining complex shows subsequent continuous

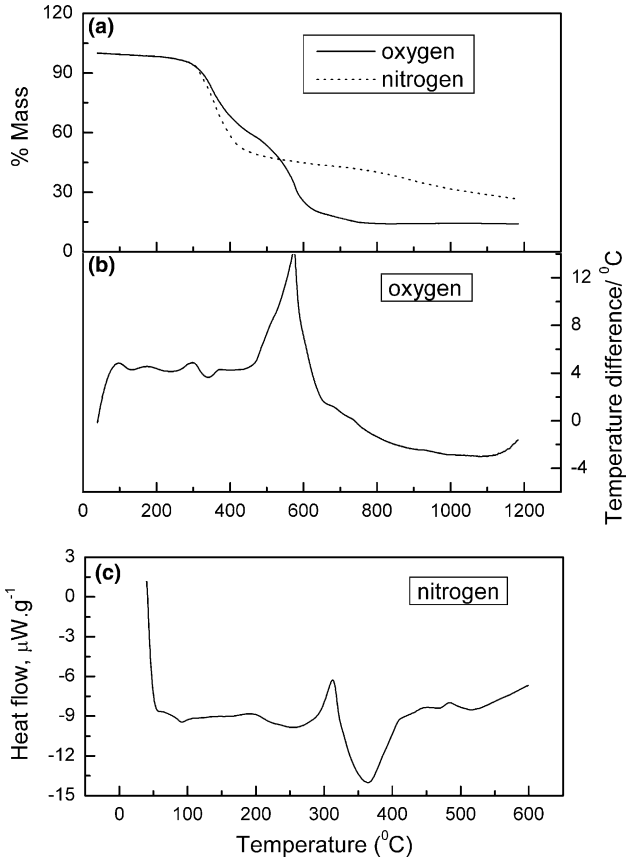

Fig. 2. Thermal analysis of the $[Fe(\mathbf{L})_2](PF_6)_2 \cdot 1H_2O$ under oxidant and inert atmospheres at 20 °C min^{-1}: (a) TG curves; (b) DTA curve; (c) DSC curve.

$$[Fe^{II}L_2{}^0]^{2+} \underset{+e}{\overset{-e}{\rightleftharpoons}} [Fe^{II}L_0L_1]^{+} \underset{+e}{\overset{-e}{\rightleftharpoons}} [Fe^{II}L_2{}^1]^{0}$$

Scheme 1.

mass loss up to 1200 °C, forming a carbonaceous compound as residue. The acquisition of the DSC curve was necessary because the DTA one does not show adequate resolution due to the low reaction enthalpies observed under nitrogen atmosphere.

The electrochemical behavior of 1.0 mM $[Fe(\mathbf{L})_2]^{2+}$ in dichloromethane 0.1 M in TBAP was investigated by cyclic voltammetry on a glassy-carbon electrode (Fig. 3). The voltammogram shows two redox pairs corresponding to two quasi- reversible one-electron reductions ($E^1_{1/2} = -0.98$ V; $E^2_{1/2} = -1.34$ V) that must be ligand-centered as depicted in Scheme 1 [6].

Upon oxidation, the cyclic voltammogram shows two overlapped waves with peak potential values of 1.21 and 1.35 V, which can be ascribed to the reversible $Fe^{II/III}$ oxidation and irreversible pyrrole oxidation, respectively. This was also earlier observed for a similar iron complex [9]. The plot of i_p versus $v^{1/2}$ (square root of the scan rate), was linear for both peaks in the 20–500 mV s^{-1} range, indicating that both charge-transfer reactions are diffusion controlled in this interval. For higher scan rates, there is total overlap so only one peak is observed, and the peak potential shifts anodically as the scan rate increases.

The oxidative electrodeposition of $[Fe(\mathbf{L})_2]^{2+}$ in anhydrous dichloromethane is shown in Fig. 4. The continuous current increase in the cyclic voltammetric peaks during repeated potential scans from 0.0 to 1.25 V indicates film growth on the electrode surface. As described by Deronzier and Moutet [10], the poor reversibility of the $Fe^{II/III}$ couple suggests that pyrrole groups are catalytically oxidized by electrogenerated Fe(III) species. The parent cobalt complex $[Co(\mathbf{L})_2]^{2+}$ has the Co(II)/Co(III) couple potential at 0.38 V, far from the pyrrole function oxidation potential. Attempts to electropolymerize this complex were unsuccessful, supporting the suggestion above. Visual inspection of the electrode also shows the deposition of a purple film. The film is not dissolved upon subsequent anodic or cathodic potential sweeps; i.e., it is not simply the result of the precipitation of an insoluble monomeric $Fe(\mathbf{L})_2$-based complex. In agreement with the work of Vilas-Boas et al. [11] and references therein, one can conclude that the product of $[Fe(\mathbf{L})_2]^{2+}$ oxidation is a polymeric material.

The modified electrode transferred to clean electrolyte solution exhibits only one redox couple with diffusional shape at $E_{1/2} = 1.26$ V (which is an average value between $Fe^{II/III}$ and pyrrole oxidations). Broad waves, normally associated with conducting polypyrrole, are not observed in the voltammogram. These results demonstrate that only the electroactivity of the iron complex is maintained (Fig. 5). In the case of a chemically stable redox species and an electrochemically reversible system, the voltammetric behavior of an electrode coated with a monolayer of a redox couple is characterized by symmetrical anodic and cathodic waves with a difference in the peak potential values (ΔE_p) close to zero. Surface-confined redox couples with slow charge-transfer kinetics, on the other hand, exhibit higher ΔE_p values which increase with the scan rate. For relatively thicker films, further deviations from the monolayer behavior normally occur, indicating the appearance of some mass transport limitations in the film. Note that for $[Fe(\mathbf{L})_2^{2+}]_n$ films, even in the case of low coverage and low scan rates, the cyclic voltammetry waves exhibited peak potential separations greater than 200 mV and diffusional shape, thus indicating a relatively slow charge transfer rate from the interface between the electrode substrate and the $Fe^{II/III}$ redox centers through the film.

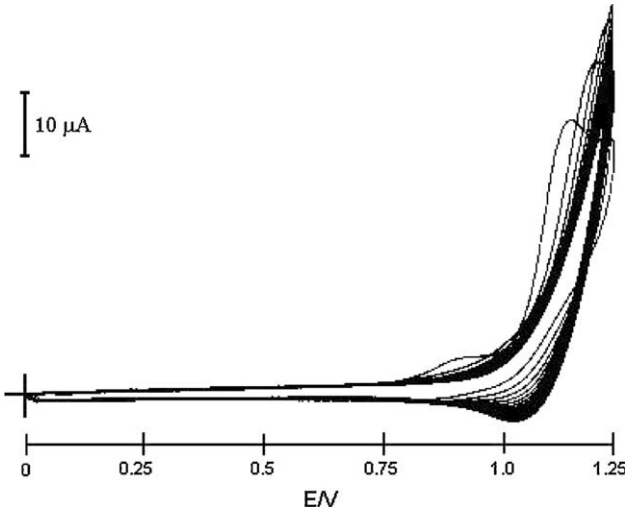

Fig. 4. Cyclic voltammogram showing deposition of poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ onto a glassy-carbon electrode in dichloromethane 0.1 M in TBAP, scan rate = 100 mV s^{-1}.

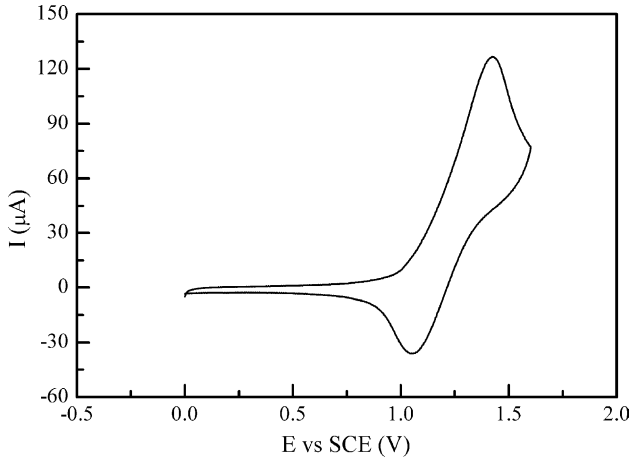

Fig. 5. Cyclic voltammogram of a poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$-coated glassy-carbon electrode in dichloromethane 0.1 M in TBAP, scan rate = 100 mV s^{-1}.

The successful growth of polypyrrole films from substituted pyrroles requires carefully controlled experimental conditions. No electropolymerization is observed at monomer concentrations below 0.5 mM. A determining factor for successful electropolymerization is solvent choice. Electropolymerization does not occur in acetonitrile, *N*,*N*-dimethylformamide and propylene carbonate, for example. The choice of an appropriate scan upper-limit potential also determines the electropolymerization success. In order to establish the optimum parameters for efficient polymer film electrodeposition, E_{aul} was systematically changed from 0.70 to 1.6 V versus SCE (five cycles), with scans always beginning at 0.0 V. The $Fe^{II/III}$ couple peak intensities were monitored in clean electrolyte solutions. Fig. 6 shows the modified electrode apparent surface coverage (Γ_T^{APP} mol cm^{-2}) in a clean electrolyte solution (no monomers) as a function of E_{aul}. Electrochemical polymerization does not occur for potentials below 0.95 V. Above this potential, a nearly linear continuous increase in the apparent surface coverage is observed, reaching a maximum at 1.25 V. The value of Γ_T^{APP} increases with successive scans, indicating continued polymer deposition on the electrode. The value of Γ_T^{APP} abruptly decreases at upper-limits (beyond 1.25 V), so this potential has been established as the optimum upper-limit potential for growing polymeric films on glassy-carbon electrode surfaces.

It was observed that the number of cycles affects Γ_T^{APP} values. In order to improve electrodeposition efficiency, experiments were conducted to investigate the relationship between film formation and the number of voltammetric scans for an E_{aul} of 1.25 V. A plot of Γ_T^{APP} versus the number of cycles (Fig. 7) reveals an increase in the apparent surface coverage for up to 20 cycles,

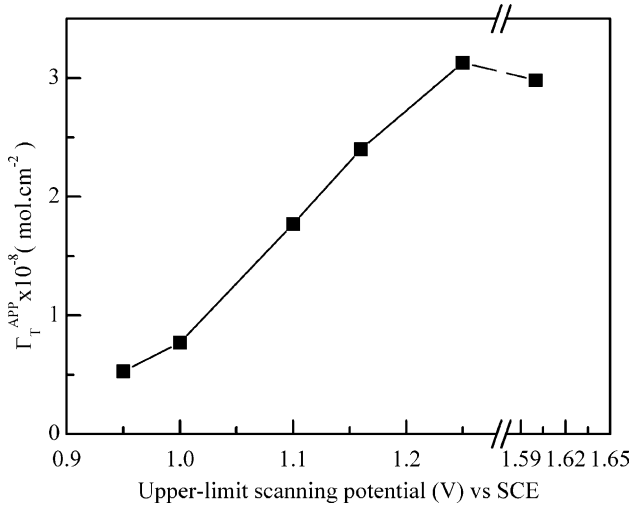

Fig. 6. Plot of Γ_T^{APP} vs. upper-limit scanning potential for poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ in dichloromethane 0.1 M in TBAP; glassy-carbon electrode, scan rate = 50 mV s^{-1}.

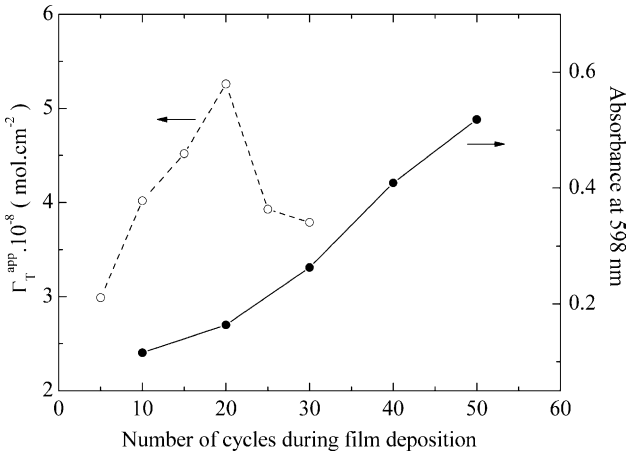

Fig. 7. Plot of Γ_T^{APP} vs. number of potential sweep voltammetric cycles of poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ (—) for an upper-limiting potential of 1.25 V; glassy-carbon electrode, dichloromethane 0.1 M in TBAP, scan rate = 50 mV s^{-1}. Absorbance at 598 nm vs. number of potential sweep voltammetric cycles of poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ (– – –) in dichloromethane. Films were deposited on ITO electrode in the same conditions as for glassy-carbon electrode.

followed by a decrease in the coverage. Each point was obtained from a modified electrode grown from freshly prepared monomer solution which was then transferred to a clean electrolytic solution (no monomers). Franco et al. [12] observed the same behavior for polypyrrole films functionalized with ruthenium and they attributed it to film formation with relatively poor charge transfer kinetics. The above experiment was repeated using an ITO working electrode for the electrodeposition. Each freshly modified electrode was copiously washed with dichloromethane and the electronic spectrum was acquired in the same solvent. The spectrum shows the same absorption bands obtained for the monomer in solution, suggesting that intact $[Fe(\mathbf{L})_2^{2+}]$ complex is incorporated into the deposited film. The absorbance at 598 nm almost linearly increases with the number of cycles (up to 50 cycles), indicating that an increasing number of layers is being deposited (Fig. 7). These results are clearly in contrast with those obtained before, where maximum surface coverage was obtained with 20 cycles, as discussed above. An explanation for that can be given as follows. An electrode coated with a redox polymer film exhibiting diffusive charge transport may do so at a fast, slow or intermediate rate with respect to the experimental time scale. If the charge transport rate is significantly faster than the experimental time scale, the oxidized/reduced site concentration ratio Γ_o/Γ_r will be uniform throughout the film and will be in thermodynamic equilibrium with the applied electrode potential. Cyclic voltammetric current–potential peaks will thus have a symmetrical shape in this case. If on the other hand, the diffusive charge transport is small, the cyclic voltammetric response will quantitatively be

the same as when reactants freely diffuse to the electrode from an infinite volume of solution. In other words, the depletion layer of the diffusion profile never reaches the cell wall. In the case of a coated electrode, the "cell" dimension is the thickness of the polymerized film itself, which is quite small. For films that present diffusional shape, as the one observed in Fig. 5, the electrochemical charge diffusion rate through the polymer must be very slow in comparison with diffusion rates common to electrolyte solutions. So it is obvious, that a good deal of electroactive Fe^{II} sites remains unoxidized as the potential is swept through the peak. This happens even more frequently at fast sweep rates and on thicker films, misleading the measured charge under the voltammetric wave. In our case, it is believed that estimated surface coverage values higher than $\sim 5 \times 10^{-8}$ mol cm^{-2} are significantly smaller than the real ones due to charge transport limitations imposed by film thickness. This is supported by AFM studies (see below).

The stability of the films has been checked by repetitive potential cycling in both anodic and cathodic sides. $[[Fe(\mathbf{L})_2]^{2+}]_n$ films exhibit low stability toward electrochemical cycling between the Fe(II) and Fe(III) states. For example, 42% of the integrated anodic peak current is lost after cycling a film 10 times between 0 and 1.6 V at 100 mV s^{-1}. After only one cathodic cycle in the 0–2.0 V range, all electroactivity is lost and no electrochemical response is observed at all.

Electrodes coated with $[[Fe(\mathbf{L})_2]^{2+}]_n$ films have been examined by cyclic voltammetry in the presence of ferrocene, which undergoes one-electron oxidation at less positive potentials than the Fe(II)/Fe(III) couple inside the film ($E_{sol} = 0.62$ V and $E_{pol} = 1.330$ V, respectively). These experiments were done with five electrodes (5, 10, 15, 20, 25 cycles) prepared by cycling the potential (0–1.25 V, 50 mV s^{-1}) in a 10^{-3} M solution of $[Fe(\mathbf{L})_2]^{2+}$ in dichloromethane 0.1 M in TBAP. They were washed with dichloromethane and transferred to a solution of ferrocene 4×10^{-3} M in clean supporting electrolyte. It is know that ferrocene may be oxidized at the electrode/polymer interface after diffusion through a continuous polymer film. Alternatively, it may be oxidized at a polymer film/solution interface, a process that requires either redox conduction through the film or an electronically conducting film. In the case of redox-conductivity-mediated electron transfer, irreversible oxidation of the solution species will occur at or near E_{pol}. For electron transfer mediated by an electronically conducting film, reversible oxidation will occur at or near E_{sol} [9].

A cyclic voltammogram for a solution of 4×10^{-3} M ferrocene at an electrode freshly coated with 3.95×10^{-8} mol cm^{-2} (10 cycles) of $[Fe(\mathbf{L})_2]^{2+}$ is shown in Fig. 8.

Ferrocene seems unable to penetrate the film, even the thinnest one (5 cycles), once the normally reversible wave at E_{sol} is completely suppressed. Similar behavior has been reported for cobaltocene and ferrocene at polypyrrole films [2]. On the other hand, the wave at E_{pol} is enhanced in the presence of ferrocene, while the cathodic wave in the reverse scan is reduced. This effect is qualitatively indicative of concurrent electrocatalytic oxidation of ferrocene by Fe^{3+} species inside the film [3]. For thicker films, there is no increase in the oxidation current in the presence of ferrocene, but the cathodic wave is again reduced. In summary, for an electrode modified with $[[Fe(\mathbf{L})_2]^{2+}]_n$, the most likely pathway for ferrocene oxidation in solution is via redox conduction through the film, which can in turn be classified as a redox polymer.

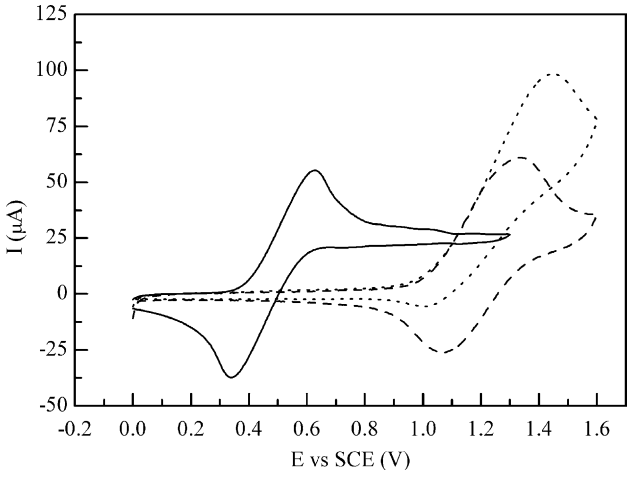

Fig. 8. Cyclic voltammogram of 4×10^{-3} M ferrocene in dichloromethane 0.1 M in TBAP (scan rate = 100 mV s^{-1}): (—) bare glassy-carbon electrode; (– – –) glassy-carbon coated with 3.95×10^{-8} mol cm^{-2} (10 cycles) of $[[Fe(\mathbf{L})_2]^{2+}]_n$; (. . .) glassy-carbon/poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ without ferrocene.

Atomic force microscopy was used to provide information concerning polymer morphology. Values of roughness and film thickness are listed in Table 1. It can be observed that there is an increase in roughness and film thickness values with the number of voltammetric scans. Films without electrochemical activity present smaller values than electroactive ones.

A typical 3-D AFM image of an electrochemically active film is shown in Fig. 9. The image reveals that the surface morphology is granular, indicating that the nuclei growth rates are essentially equal or comparable in directions parallel or perpendicular to the electrode surface [13]. From the observation of the AFM image, it is clear that nuclei are formed in large number and different sizes. No channels or holes are observed and the film surface is substantially rough with small and large nuclei in conical form. The 3-D image of a film without electrochemical activity is shown in Fig. 10.

Such images were obtained to verify if any alteration in film morphology would be responsible for the loss of electrochemical response. From Fig. 10, it can be ob-

Table 1

Roughness (nm)	152	74	309	238

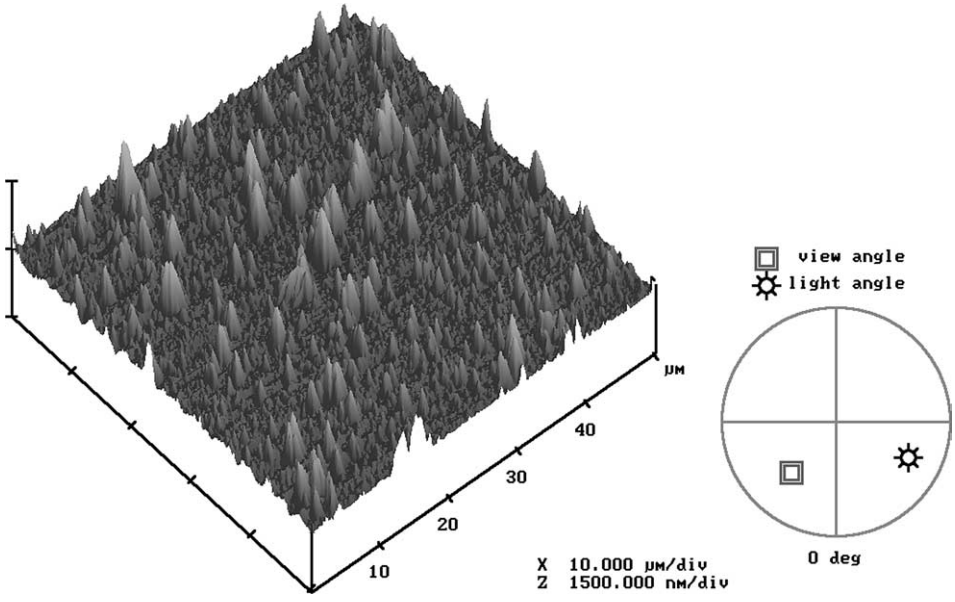

Fig. 9. AFM image of the surface morphology of a poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ film deposited on ITO, prepared by 20 voltammetric scans (0–1.25 V). 3-D view, scan scale: 10 μm.

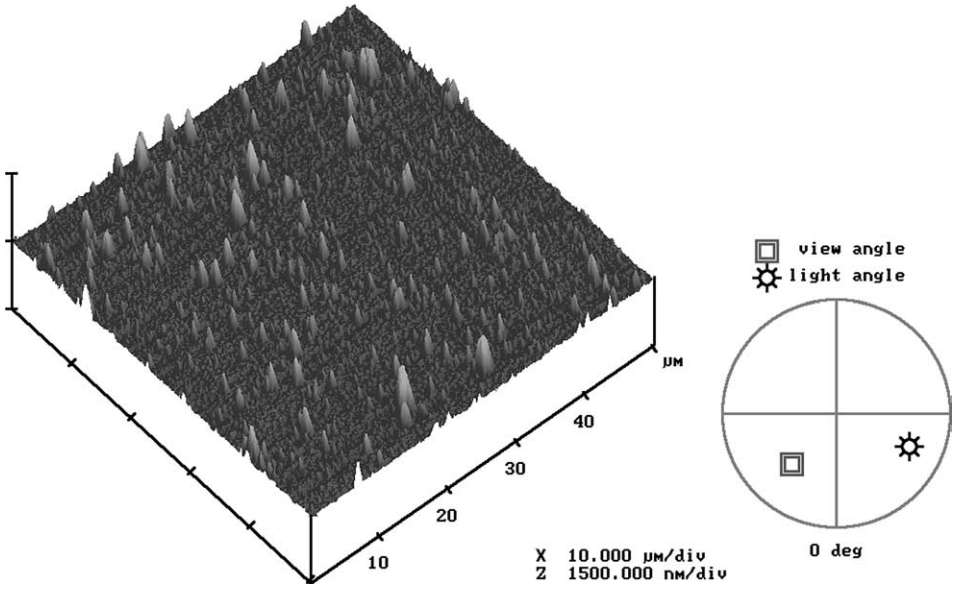

Fig. 10. AFM image of the surface morphology of a poly-$[[Fe(\mathbf{L})_2]^{2+}]_n$ film deposited on ITO, prepared by 20 voltammetric scans (0–1.25 V) followed by one scan in the cathodic direction (0 to −2.0 V). 3-D view, scan scale: 10 μm.

served that film morphology for the non-active film is about the same as for the active one. Although some film has been lost, it is clear that it still is on the electrode surface and the complete absence of electrochemical activity cannot be attributed to morphology modification or film destruction. Therefore, we suppose

that Fe(II) and/or ligand reduction modifies the complex coordination environment in an irreversible way, although there is no evidence to support such suggestion.

4. Conclusions

In the complex synthesis, the condensation between 2,6-diacetylpyridine and *N*-(3-aminopropyl)pyrrole in the presence of ferrous ions in a template reaction mode gives better results than the reaction between the free ligand and the metal ions.

Through TG, DTA and DSC curves, the composition of the complex could be established as being $[Fe(\mathbf{L})_2]^{2+}$ monomers that show distinct thermal behaviors under oxygen and nitrogen atmospheres. There is no formation of $FePO_4$ as residual oxide in the former case. Elemental analysis supports this composition.

Results reported herein demonstrate the successful preparation of modified electrodes by electropolymerization of the pyrrole-substituted Schiff-base iron complex using the potentiometric technique and an adequate solvent. The established optimum conditions are: tetrabutylammonium perchlorate 0.1 M in dichloromethane as solvent, 1.25 V as upper-limit potential and 20 as maximum number of electropolymerization cycles. From the results of our electrochemical studies carried out in the presence of ferrocene, the film can be classified as a redox polymer.

AFM analysis showed neighboring globular deposits under the experimental conditions. Surface morphology is maintained for films with or without electrochemical activity.

This work is an initial study in the coordination chemistry of iron(II) Schiff-base complexes bearing a pyrrole unit and a study on the nucleation and growth mechanism of $[Fe(\mathbf{L})_2]^{2+}$ is currently under investigation in our laboratory.

Abstract

The reaction of copper dichloride dihydrate, heterocyclic diimine (bipy, phen) and bidentate diamine (en) ligands under mild conditions affords two novel supramolecular complexes containing $Cu^{II}N_4Cl$ chromophores, $[Cu(en)(bipy)Cl][OH]\cdot(H_2O)_3$ (**1**) (en = ethylenediamine, bipy = 2,2′-bipyridine) and $[Cu(phen)_2Cl][OH]\cdot(CH_3OH)_2\cdot(H_2O)_6$ (**2**) (phen = 1,10-phenanthroline). Complex **1** involves a $Cu^{II}N_4Cl$ chromophore with a regular square based pyramidal stereochemistry, while complex **2** involves a regular trigonal bipyramidal one. To our knowledge, **1** is the first example of a $Cu^{II}N_4X$ complex generated from mixed ligands. Both of the two compounds were constituted through hydrogen bonding and π–π interactions between the heterocyclic rings. The magnetic properties of **2** were studied in the temperature range 5–300 K. The results reveal the occurrence of a weak antiferromagnetic coupling with $J = -1.9\ cm^{-1}$.

1. Introduction

The penta-coordinated copper(II) complexes comprising of both molecules of bidentate diimine, 2,2′-bipyridine (bipy) and 1,10-phenanthroline (phen), and one monodentate co-ligand have been attracting great interest for their diverse stereo and physicochemical properties [1–8]. The molecular structures of five-coordinate copper(II) complexes show an extensive variability, ranging from regular trigonal bipyramidal (RTBP) to regular square based pyramidal (RSBP) with most complexes displaying a structure that is intermediate between the two extremes. In such materials, interesting properties and potentials in spectroscopy, electrochemistry, biological activity and magnetism, etc. can be introduced from either the inorganic species or the organic linker molecules [9–15]. Therefore, the evaluations for correlations of stereochemistry with the corresponding properties are of fundamental importance for these copper(II) complexes. Although many five-coordinated copper(II) complexes are well documented, the presence of a mixed ligand compound has been rarely observed [8]. Here we describe the synthesis and crystal structures of two novel supramolecular complexes containing $Cu^{II}N_4Cl$ chromophores, $[Cu(en)(bipy)Cl][OH]\cdot(H_2O)_3$ (**1**) (en = ethylenediamine, bipy = 2,2′-bipyridine) and $[Cu(phen)_2Cl][OH]\cdot(CH_3OH)_2\cdot(H_2O)_6$ (**2**) (phen = 1,10-phenanthroline). To the best of our knowledge, compound **1** is the first example of a $Cu^{II}N_4X$ ($X = Cl^-$, Br^-, I^-) complex generated from mixed ligands and **2**

provides a novel case of a dimeric unit formed through weak hydrogen bonding C–H···Cl and π–π interactions between phen rings. The magnetic properties of compound **2** are also investigated. The results indicate that the magnetic behavior of the compound obeys the Curie–Weiss law over the whole temperature range and weak antiferromagnetic coupling can be observed between the copper(II) ions.

2. Experimental

2.1. Materials and physical techniques

All chemicals were of analytical reagent grade quality, obtained from commercial sources and used without further purification. IR spectra were recorded on a FTS-40 spectrophotometer with pressed KBr pellets in the 400–4000 cm^{-1} region. Elemental analyses (C, H and N) were carried out on a Carlo-Erba 1106 elemental analyzer. The thermogravimetric analyses were performed on a NETZSCH TG 209 system at a rate of 10 °C min^{-1} in nitrogen atmosphere over the range 30–700 °C. DSC traces were obtained with the aid of a NETZSCH DSC 204 calorimeter at 10 °C min^{-1} in N_2 over the range 20–400 °C. Variable-temperature magnetic susceptibility data were obtained on a Quantum Design MPMS-5 SQUID magnetometer in the temperature range 5–300 K with an applied field of 500 G. Diamagnetic corrections were calculated from Pascal's constants [16].

2.2. Synthesis of the complexes

2.2.1. Synthesis of $[Cu(en)(bipy)Cl][OH]\cdot(H_2O)_3$ (**1**)

Copper dichloride dihydrate (0.0850 g, 0.5 mmol) dissolved in 20 cm^3 of water was allowed to react with 20 cm^3 of a methanolic solution of 2,2′-bipyridine (0.1562 g, 1.0 mmol), and stirred for 10 min. Into the resulting solution was poured slowly 10 cm^3 of a methanolic solution of ethylenediamine (0.030 g, 0.5 mmol), the entire mixture was stirred for 30 min and then allowed to evaporate slowly in an open atmosphere. After a few weeks, clear blue purple blocks of **1** suitable for X-ray structural study were obtained. These crystals were separated, washed with ethanol, and dried (yield: 82%, based on $CuCl_2\cdot H_2O$). *Anal.* Calc. for $C_{12}H_{23}ClCuN_4O_4$: C, 37.31; H, 6.00; N, 14.50. Found: C, 37.45; H, 5.98; N, 14.54%. IR (ν, cm^{-1}): 3384 (s, br), 3222 (s), 3135 (s), 2948 (m), 2889 (m), 1632 (m), 1610 (m), 1601 (s), 1567 (m), 1481 (m), 1441(m), 1327 (w), 1132 (m), 1056 (s), 1031 (m), 775 (s), 732 (s), 662 (m), 524 (m), 419 (m).

2.2.2. Synthesis of $[Cu(phen)_2Cl][OH]\cdot(CH_3OH)_2\cdot(H_2O)_6$ (**2**)

Into an aqueous solution (5 cm^3) of $CuCl_2\cdot 2H_2O$ (0.0425 g, 0.25 mmol) was poured slowly 20 cm^3 of a methanolic mixture of 1,10-phenanthroline monohydrate (0.0991 g, 0.5 mmol) and pyrazine (0.020 g, 0.25 mmol). The entire mixture was stirred for 30 min at 70 °C and allowed to evaporate slowly in an open atmosphere. After a few weeks, clear blue prismatic crystals of **2** suitable for X-ray structural study were obtained. These crystals were separated, washed with methanol, and dried (yield: 76%, based on $CuCl_2\cdot H_2O$). *Anal.* Calc. for $C_{26}H_{37}ClCuN_4O_7$: C, 50.65; H, 6.05; N, 9.09. Found: C, 50.58; H, 6.02; N, 9.12%. IR (ν, cm^{-1}): 3529 (m), 3382 (m), 3327 (m), 1627 (m), 1605 (w), 1585 (m), 1518 (s), 1495 (m), 1428 (s), 1426 (m), 1342 (w), 1228 (w), 1151 (w), 1103 (w), 869 (m), 853 (s), 778 (w), 722 (s), 648 (w), 629 (w), 430 (m).

2.3. X-ray crystallography

Crystal data and experimental details for compounds **1** and **2** are contained in Table 1. All measurements were made on a Rigaku RAXIS-IV imaging plate area detector with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Prismatic single crystals were selected and mounted on a glass fiber. All data were collected using the ω–2θ scan technique and corrected for Lorenz-polarization effects. A correction for secondary extinction was applied. The two structures were solved by direct methods and expanded using Fourier techniques. All non-hydrogen atoms were described anisotropically; hydrogen atoms were included but not refined. The final cycle of full-matrix least-squares refinement was based on 3156 observed reflections and 200 variable parameters for **1**, 3561 observed reflections and 308 variable

parameters for **2**. All calculations were performed using the SHELXL-97 crystallographic software package [17]. Selected bond lengths and bond angles are listed in Table 2.

3. Results and discussion

3.1. Preparation of complexes

The self-assembly reaction of $CuCl_2 \cdot H_2O$ and the chelating bidentate ligands (bipy, en, phen) in H_2O–MeOH is an effective route for preparation of novel penta-coordinated copper(II) complexes containing $[Cu^{II}N_4X]^+$ and OH^-. Although it has the same cation as $\{[Cu(phen)_2Cl][OH] \cdot 6H_2O\}_2$ (**3**) [13], complex **2** obtained the hydroxide counter-ions in a quite different way. The structure of **3** was gained by treating $CuCl_2 \cdot 2H_2O$ with phen (1:2 metal-to-ligand ratio) in H_2O–EtOH and using NaOH to adjust the pH. In our synthesis (but not in compound **3**s) it appears that the (unincorporated) pyrazine molecules and non-coordinating methanol solvent used are critical in influencing the product. When the experiment was performed in the absence of pyrazine, extremely unstable crystals which turned opaque immediately under ambient atmosphere were obtained, a property distinctly different from the air-stable **2**. Similar results were obtained for complex **1**, all attempts to obtain a $Cu^{II}N_4Cl$ complex failed in a water solution instead of H_2O–MeOH.

3.2. Infrared spectra

The infrared spectrum of compound **1** exhibits characteristic bands for both 2,2′-bipyridine and ethylenediamine ligands. The presence of the bipy ligand is confirmed by bands due to the skeletal vibrations of the pyridine ring at 1610, 1567, 1481 and 1441 cm^{-1}. In addition, the band at 775 cm^{-1} can be assigned to the CH out-of-plane bend of the pyridine ring (four adjacent H). Moreover, the peaks at 3384, 3222, 3135 and 1601 cm^{-1} are the characteristic bands of N–H(en), and the bands in the region 3300–3500 cm^{-1} are assigned to the stretching vibrations, ν(O–H), of the hydroxyl groups. The slight variation of O–H(H_2O) and N–H(en) vibrations for these complexes is probably mainly due to the hydrogen bonds. The Cu–N stretching is tentatively assigned at 419 cm^{-1}.

In the IR spectrum of complex **2**, the aromatic C=C and C=N stretching vibration absorptions of the phen ring appear at 1627, 1585, 1518 and 1428 cm^{-1}. The band at 853 and 722 cm^{-1} is assigned to the CH out-of-plane bend (two adjacent H), ring breathing and deformation absorptions of coordinated 1,10-phenanthroline. Meanwhile the peaks at 3529 (ν_{O-H}) and 1426 (ν_{bend}) cm^{-1} are the characteristic bands of H_2O, which indicates the existence of molecular lattice water. In addition, the new band at ca. 430 cm^{-1} was recorded which shows the stretch vibrating frequency of the Cu–N coordinated bond [18].

3.3. Thermal behavior

The thermogravimetric analyses of compounds **1** and **2** show the occurrence of three consecutive processes, namely dehydration, ligand pyrolysis and inorganic residue formation. The DSC and TGA analysis for **1** shows that the lattice water molecule is lost at ~89 °C as indicated by a weight loss of 12.10% (Calc. 13.99%) corresponding to three moles of water per formula unit. As the temperature increases simultaneous en and 2,2′-bipy ligand pyrolyses occurs between 146 and 271 °C with a total weight loss of 57.70% (Calc. 55.99%), by the occurrence of endothermic and exothermic peaks overlapping with each other. Thermogravimetric analysis of **2** indicates that the thermal decomposition of **2** is initiated between 99 and 112 °C by a weight loss of 27.10%, corresponding to the loss of six water and two methanol molecules (Calc. 27.93%). The six water molecules are released before the temperature of 112 °C which suggests that these water molecules are the crystallized ones instead of the coordinated ones. There is a further 58.0% weight loss in two continuous steps in the 278–384 °C range, which compares with the calculated loss (58.45%) for the two phen molecules.

3.4. Crystal structures

3.4.1. $[Cu(en)(bipy)Cl][OH] \cdot (H_2O)_3$ (**1**)

Compound **1** consists of discrete monovalent complex cations, hydrogen bonded separate hydroxide ions and solvent H_2O molecules. An ORTEP drawing of the unit with the atomic numbering scheme is depicted in

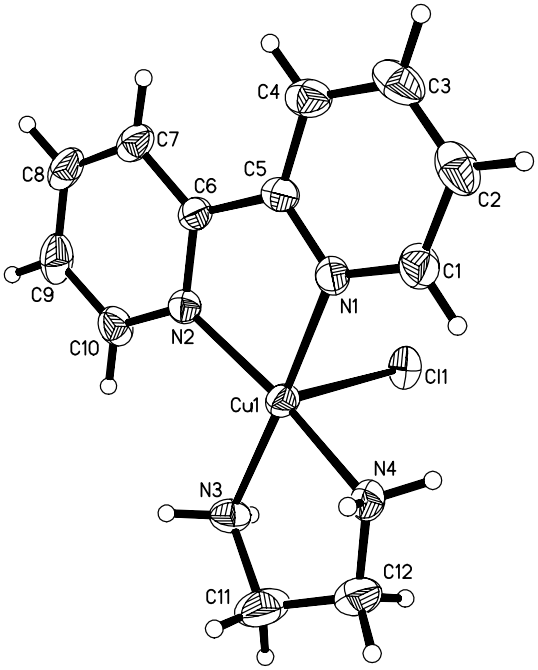

Fig. 1. Structural unit of $[Cu(en)(bipy)Cl]^+$ with atom numberings, showing 30% thermal ellipsoids.

Fig. 1. The complex cations possess five-coordinated environments with $Cu^{II}N_4Cl$ chromophores, namely, each of the Cu atoms is coordinated by four nitrogen atoms from one bidentate diimine (2,2′-bipy) and one bidentate diamine (en) ligand with one chloride anion forming weak Cu–Cl apex bonds. Although the hydroxide ion is geometrically oriented for potential axial Cu–O bonding, the distance (Cu–O = 2.762 Å) is greater than 2.7 Å, and the axial bonding is considered to be absent. The Cu–N bond lengths and the N–Cu–N bite angles are comparable to those found in en and bipy copper(II) structures (see Table 2) [8–10]. However, the Cu–Cl distance (2.733(2) Å) is significantly longer than that in the common $Cu^{II}N_4Cl$ complexes [9–13]. Furthermore, the largest angle around the Cu(II) center (β: N3–Cu1–N1 = 177.4(2)°) is slightly larger than the second-largest one (α: N4–Cu1–N2 = 167.6(2)°). The value of the differences between the longest and shortest Cu–N bond distances ΔCu–N is 0.030 Å. These imply that the geometries around the Cu(II) centers in **1** are of distorted square-pyramidal or trigonal-bipyramidal one. Since the angular structural index parameter, $\tau = (\beta - \alpha)/60$, is evaluated by the two largest angles ($\alpha < \beta$) in the five-coordinated geometry [19], the value of $\tau = 0.16$ seems to indicate a RSBP. The two pyridine rings in the heterocyclic diimine ligands are not coplanar. Each dihedral angle is twisted by 3.8°, similar to that of closely related compound [8–10]. The hydroxide ions appear to be loosely held in lattice holes by Coulombic forces and by weak hydrogen bonds to the chloride and bipyridine C–H groups as shown in Fig. 2.

The most interesting feature of **1** is that the inter-ionic hydrogen bonds play an important role in the crystal packing and the stability of the inclusion complex (Fig. 2). Adjacent units are cross-linked by four types of intermolecular hydrogen bonds, which stabilize the conformation with the distances of 2.369 Å for $(OH^-)O\cdots H$–C(bipy), 3.115 Å for $Cl\cdots H$–$O(OH^-)$, 2.816 Å for $Cl\cdots H$–C(bipy), 2.478 and 2.697 Å for $Cl\cdots H$–N(en). Through the interionic hydrogen bonds, the cations are linked into two-dimensional layers parallel to the crystallographic *ab*-plane with interdigitation of neighboring parallel pyridyl ligands. The bipy ligands engage in face-to-face C–H$\cdots\pi$ aromatic stacking in-

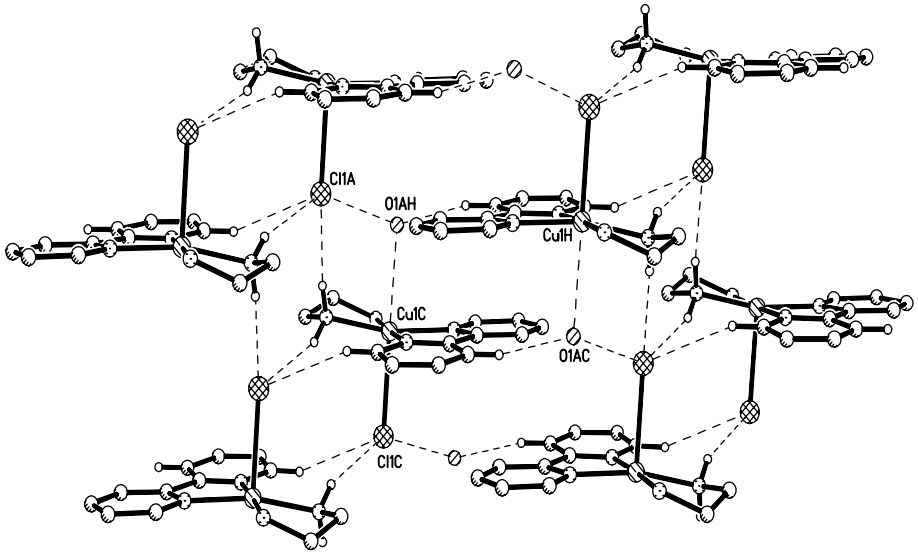

Fig. 2. The layer structure of **1** formed by hydrogen bondings. The non-hydrogen bonding H atoms have been omitted for clarity.

teractions (d(C···C) = 3.035–3.148 Å). In the crystal, the infinite considerably puckered sheets are parallel on each other along the c-axis and stack with an interpenetrating mode to give an extended three-dimensional network with spacious and straight channels, in which the hydrogen bonded H_2O molecules are sandwiched.

3.4.2. $[Cu(phen)_2Cl][OH]\cdot(CH_3OH)_2\cdot(H_2O)_6$ (2)

The X-ray structural analyses reveals that **2** consists of discrete monovalent complex cations, hydrogen bonded free hydroxide ions and solvent H_2O molecules, and that **2** additionally involves hydrogen bonded dimers of methanol. As shown in Fig. 3, the complex cations possess five-coordinated environments with $Cu^{II}N_4Cl$ cores similar to that in complex **3** [13]. Namely, each of the Cu atoms is coordinated by four N atoms from two phen frameworks and one Cl atom. The Cu–N distances of ~2.02 Å and the bite angles of ~81° of the phen ligands are close to the average values for phen copper(II) complexes (Table 2) [11]. The Cu–Cl distance (2.336(2) Å) is slightly longer, while the value of ΔCu–N (0.129 Å) is slightly shorter than that for **3**. The largest angle β(N4–Cu1–N1 = 176.1(3)°) is considerably different from the second-largest one α(N2–Cu1–N3 = 123.5(2)°). The value of the angular structural index parameter τ(0.88) shows a much more limited range of distortion from the RTBP stereochemistry (regular trigonal bipyramidal).

In crystals of **2**, no hydroxide ions are close enough to interact with the Cu(II) centers in the complex cations. However, one phen framework in the complex cation in **2** is in close proximity to that in the other complex cation accompanied by the formation of a dimeric unit. Namely, the interplane distance and angle between the neighboring two phen frameworks are ca. 3.425 Å and 0.0°, respectively, indicating the interaction between the two π-electronic systems of the phen frameworks. In addition, the Cl atoms form double hydrogen bonds with the C atoms in the phen ring of the dimer and the O atom of adjacent lattice water. The crystal lattice water molecules and hydroxyl groups are involved in the hydrogen bonding network, making the system stable. Thus, the dimers are propagated into a 2D architecture through the C–H···Cl, O–H···Cl and O–H···O hydrogen bonds (Fig. 4). A statistical analysis based on CSD suggests that C–H··· Cl contacts are within the range 2.7–3.0 Å. In this case, the C–H···Cl distance is 2.759 Å, which is in accordance with the statistical analysis. Furthermore, the C–H···Cl bond angles of **2** exhibit a directionality of 159.0°, which further suggests that the C–H···Cl hydrogen bonds are available in the structure of **2**. The remaining one of the phen rings in the $[Cu(phen)_2Cl]^+$ cation also produces π–π interactions between dimers as shown in Fig. 5. The center-to-center and interplanar distances are 3.687 and 3.426 Å, respectively. Thus, the binuclear $[Cu(phen)_2Cl]_2^{2+}$ units are linked to each other to give an extended three-dimensional network with void space, in which the hydrogen bonded hydroxide ions, solvent H_2O molecules and tetramers of methanol are sandwiched.

It is interesting that the phen components play double roles in the structure of **2**. One is acting as a ligand covalently linked to the copper centers. The adjacent phen rings are parallel to each other and cause signifi-

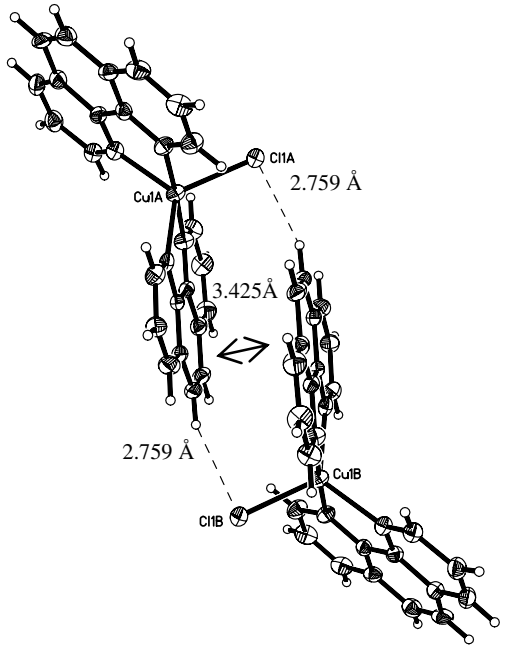

Fig. 3. Dimer structure of $[Cu(phen)_2Cl]_2^{2+}$ formed by C–H···Cl hydrogen bondings and π–π interactions.

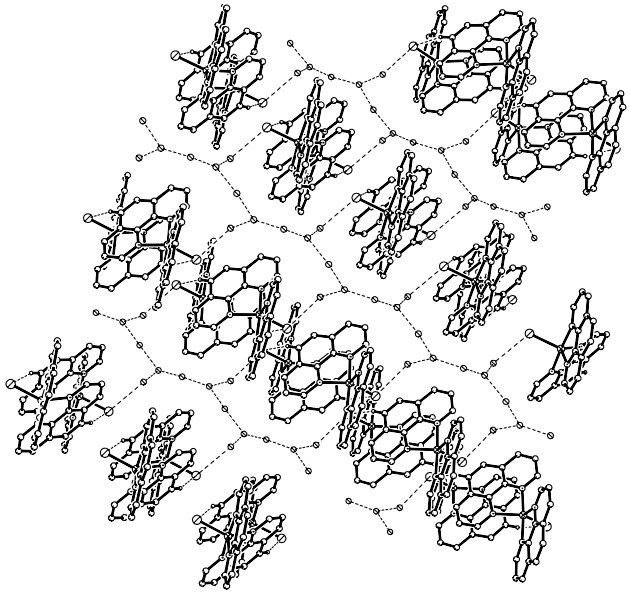

Fig. 4. The layer structure of complex **2** formed by hydrogen bonds. Hydrogen atoms have been omitted for clarity.

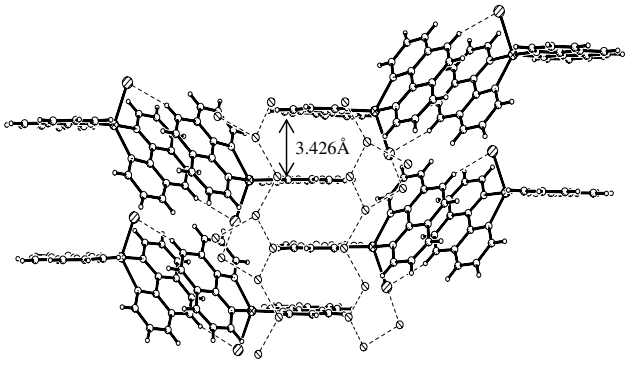

Fig. 5. The π–π interactions between the adjacent phen rings of the dimers in **2**.

cant π–π stacking interactions in and between dimers. Therefore, the dimer unit is highly strengthened by the strong π–π interactions. The other role is acting as the donors of hydrogen bonding which leads to the generation of the 3D supermolecular architecture. It is worth noting that a dimer structure constructed through C–H···Cl hydrogen bonding and π–π interactions is rare, and **2** is a new case of the RTBP stereochemistry for the $[Cu(phen)_2Cl]^+$ series of compounds.

3.5. Magnetic properties of 2

Variable-temperature magnetic susceptibility measurements were performed in the range of 5–300 K. The thermal variation of the molar susceptibility χ_M together with a plot of χ_M^{-1} versus T of complex **2** is shown in Fig. 6. The magnetic moment at 300 K ($\mu_{eff} = 2.04\ \mu_B$) per copper(II) center is higher than that expected for an isolated paramagnetic system with $S = 1/2$ ($\mu_{eff} = 1.73\ \mu_B$). By the value of magnetic moment measured at 300 K, the 2+ oxidation state of copper in **2** could be confirmed with a calculation of the spin-only magnetic moment. The increase in χ_M with decreasing temperature at very low temperatures is due to the presence of traces of monomeric paramagnetic impurity. The thermal evolution of χ_M^{-1} obeys the Curie–Weiss law, $\chi_M = C_M/(T-\theta)$, over the whole temperature range with $C_M = 0.5190$ cm^3 K mol^{-1} and $\theta = -0.302$ K. In general, the negative Weiss constant indicates an antiferromagnetic interaction between the copper ions. In addition, the variation of magnetic susceptibility with temperature for **2** can be fitted to the Bleaney–Bowers model (see Eq. (1)); J is the exchange coupling constant; N, g, β, K have their usual meanings; χ_M is expressed per mole of copper atoms, ρ is the fraction of monomeric impurity [20]

$$\chi_M = \frac{Ng^2\beta^2}{3KT}[1 + 1/3\exp(-2J/KT)]^{-1}(1-\rho) + \frac{Ng^2\beta^2}{4KT}\rho + N_a. \quad (1)$$

However, the magnetism of the dimer could not be simulated in the region between 5 and 60 K. In this temperature range the observed and calculated data diverge slightly, therefore we have concentrated our efforts in the range 60–300 K. Magnetic parameters thus determined are $g = 2.36$, $J = -1.9$ cm^{-1}, $N_a = 2.23 \times 10^{-3}$ cm^3 mol^{-1}, $\rho = 0.02$. The discrepancy factor $\sigma = [\sum(\chi_{obs} - \chi_{calc})^2 / \sum \chi_{obs}]^{1/2}$ in the least-squares fits was 1.03×10^{-4}. Obviously, the negative and small J value suggests the antiferromagnetic interaction between the copper(II) ions in the complex is very weak and C–H···Cl hydrogen bonding in the dimers does not apparently facilitate exchange between the paramagnetic atoms. Moreover, from 300 to 5 K, the slightly decreased $\chi_M T$ value is also consistent with the above conclusion.

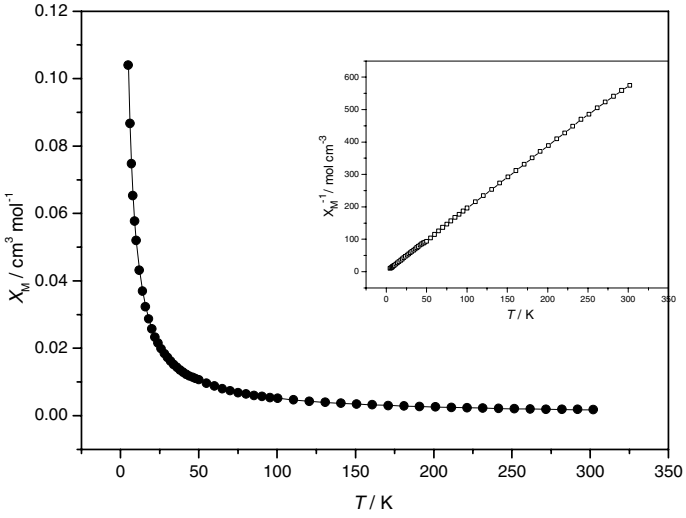

Fig. 6. Thermal variation of χ_M and χ_M^{-1} for **2**. The solid line corresponds to the best theoretical fit.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 197217 and 227506 for **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The synthesis, crystal structures, as well as the electronic and spectroscopic properties, of two new mononuclear Cu(II) isomeric compounds containing the ligand 2,2′-bi-imidazoline (biz) are reported. Both Cu(II) compounds, the blue $[Cu(biz)_2(ClO_4)_2]$ (**1**) and the violet $[Cu(biz)_2](ClO_4)_2$ (**2**), have the same stoichiometry and but differ in the location of the perchlorate anions. The basal plane of both compounds is formed by four nitrogen atoms of two dichelating biz ligands. In compound **1**, the apical position is occupied by two oxygen atoms of two perchlorate anions, resulting in an elongated octahedral geometry around the Cu ion. In compound **2**, the perchlorate anions are not coordinating to the Cu ion, resulting in a square planar geometry around the Cu atom. Both isomers show different and interesting H-bonding properties. The electronic, EPR and IR spectroscopy results are in agreement with the structural geometry. In frozen solution (at 77 K) the EPR spectrum is identical for both compounds, so in that case they have both the same geometry.

Keywords: Copper; Structure; Infrared; Hydrogen bonds; Distortion isomers

1. Introduction

The organic ligand 2,2′-bi-imidazoline (biz) (see Fig. 1) is an interesting and flexible bifunctional ligand. This heterocyclic didentate ring ligand is of special interest as it deviates from the more "flat" molecules, like bisimidazole, bipyridine or bipyrimidine, due to the fact that the steric effects at the rear side of the molecule are influenced by two acidic hydrogen atoms. These two N–H donor groups can form polymeric aggregates by hydrogen bonding [1,2].

So far X-ray structures with biz and transition metals have only been reported for a few Fe(II), Fe(III) and Co(II), Co(III) compounds [1,2], in which neutral and mono-deprotonated biz are present. With Cu(II), Ni(II) and Co(II) as transition metal ions recently X-ray structures with this ligand and the anion dicyanamide and a copper(II) azide compound have been reported by some of us [3,4]. Especially, the chemistry of the Cu(II) compounds appears to be rich.

In this study, we present the molecular and X-ray structure of two new mononuclear compounds with the same stoichiometry, a blue $[Cu(biz)_2(ClO_4)_2]$ (**1**) and a violet $[Cu(biz)_2](ClO_4)_2$ (**2**) compound. The compounds can be described as examples of the rare case of distortion isomers; in the literature only a few of such cases are reported [5–8]. The two studied compounds could be reproducible synthesized by using a different Cu–ligand ratio of Cu–L 1:2 and Cu–L 1:1 for compounds **1** and **2**, respectively.

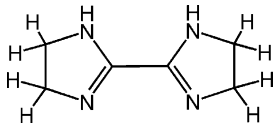

Fig. 1. Chemical structure of 2,2′-bi-imidazoline (biz).

2. Experimental

2.1. Syntheses

The ligand, 2,2′-bi-imidazoline (biz), was prepared by the method reported in the literature [9].

The compounds **1** and **2** were prepared by using a different Cu(II) ligand ratio, according to the following procedure: 1.2 mmol of the metal perchlorate salt and 2.4 mmol ligand (for the synthesis of compound **1**) or 1.2 mmol ligand (for the synthesis of compound **2**) were each dissolved in 10 ml of ethanol and 1 ml water. The ligand solution was then added slowly to the metal perchlorate solution and filtered to remove any undissolved material. Usually, after a few days to at most one week, the product separates as crystalline products. Violet crystals of compound **2** separates as a pure compound within a few days. The blue compound **1** also separates within a week, but contains always a small amount (5% at most) of the violet crystals of compound **2**. These violet crystals were easily removed by hand under the microscope obtaining in this way the pure compound **1**, which could be used for XRD, spectroscopic measurements and EPR. The crystalline products were isolated by filtration and dried in air, and characterized by elemental analysis and spectroscopic methods. Yield varies from 40% to 60%. *Anal*. Calc. for $C_{12}H_{20}Cl_2CuN_8O_8$: (Compound **1**): C, 26.3; H, 4.2; N, 20.2. Found: C, 26.7; H, 3.7; N, 20.8%. *Anal*. Calc. for $C_{12}H_{20}Cl_2CuN_8O_8$: (Compound **2**): C, 26.2; H, 3.9; N, 20.5. Found: C, 26.7; H, 3.7; N, 20.8%.

2.2. Physical measurements

C, H, N determinations were performed on a Perkin–Elmer 2400 Series II analyser. Ligand-field spectra were obtained on a Perkin–Elmer Lambda 900 spectrophotometer using the diffuse-reflectance technique, with MgO as a reference. X-band powder EPR spectra were obtained on a Jeol RE2× electron spin resonance spectrometer, using DPPH ($g = 2.0036$) as a standard.

FT-IR spectra were obtained on a Perkin–Elmer Paragon 1000 FT-IR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, resolution 4 cm^{-1}).

2.3. Crystal structure determination and refinement of the structures

The reflection intensities were measured on a four-circle Enraf-Nonius CAD-4 diffractometer using graphite-monochromated Cu Kα radiation ($\lambda = 1.54184$ Å).

The cell dimensions were determined using 25 independent reflections. Intensity data were corrected for Lorentz and polarization effects. Absorption correction was not applied. The positions of heavy atoms were determined from a Patterson map (DIRDIF) [10]. The atomic scattering factors were taken from the International Tables for X-ray Crystallography [11]. The remainder of the non-H atoms were located in subsequent difference Fourier syntheses. Hydrogen atoms were placed at calculated positions (at 0.95 Å) from their parent atoms. Full-matrix least-squares refinement on F using the XTAL 3.4 set of programs [12] with the function minimized being $\sum w(|F_o| - |F_c|)^2$ with $w = 1/\sigma^2(F)$. Positional refinement of all non-H atoms, anisotropic for the non-hydrogen atoms, fixed isotropic thermal parameters for the hydrogens. Geometric calculations and molecular graphics were performed with the PLATON package [13]. (Details are given in Table 1.)

3. Results and discussion

3.1. Description of the crystal structures of $[Cu(biz)_2(ClO_4)_2]$ (1) and $[Cu(biz)_2](ClO_4)_2$ (2)

Both structures **1** and **2** are quite similar, and are discussed together. The only important difference is the location of the perchlorate anion and the hydrogen bonding system. The structure of the complete units is depicted in Figs. 2 and 3, for structures **1** and **2**, respectively. Relevant bond length and bond angle information is given in Table 2. A centre of symmetry is located on the Cu atom.

The basal plane in both compounds is occupied by four nitrogen atoms of two dichelating biz ligands with distances of 1.977(7) and 2.021(6) Å for compound **1** and 1.965(4) and 1.982(4) Å for compound **2**. In compound **1**, the apical positions are occupied by two oxygen atoms of two perchlorate anions with a semi-coordination distance of 2.594(8) Å, resulting in a elongated octahedral geometry around the Cu ion. In compound **2**, the perchlorate anions are not coordinating to the Cu ion (shortest Cu···O contact = 3.183(4) Å), resulting in a square planar geometry around the Cu ion. This also agrees with the somewhat shorter Cu–N distances in compound **2** (averaged Cu–N distance 1.973 Å), compared to compound **1** (averaged Cu–N distance 1.999 Å). The difference in coordination of the perchlorate anion for the two compounds results mainly in a quite different lattice structure. The hydrogen bonds in compound **1** occur between the uncoordinated nitrogen atoms of the biz ligand at the rear side of the molecule and the oxygen atoms of the perchlorate anions of a neighbouring unit as bifurcated bonds with distances that vary from 2.946(12) to 3.201(14) Å. The hydrogen bonds in compound **2** exist between the uncoordinated nitrogen atoms of the biz ligand and the O3 of the uncoordinating perchlorate anion with distances of 2.941(6) and 2.938(6) Å. Details of the hydrogen bonds are given in Table 2 and in Figs. 4 and 5. The lattice is further stabilised by ring–ring contacts of imidazoline units of 4.094 and 3.784 Å, for compounds **1** and **2**, respectively.

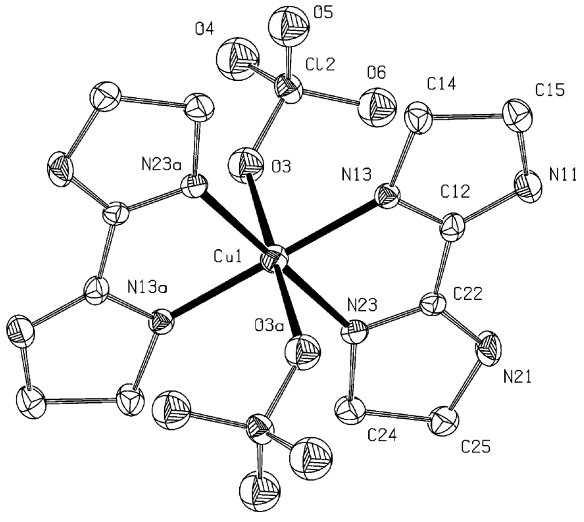

Fig. 2. Thermal ellipsoid plot at 50% probability of $[Cu(biz)_2(ClO_4)_2]$ (**1**) with atom-labelling scheme. Hydrogen atoms are omitted for clarity. Atoms marked with an "a" are generated by an inversion centre.

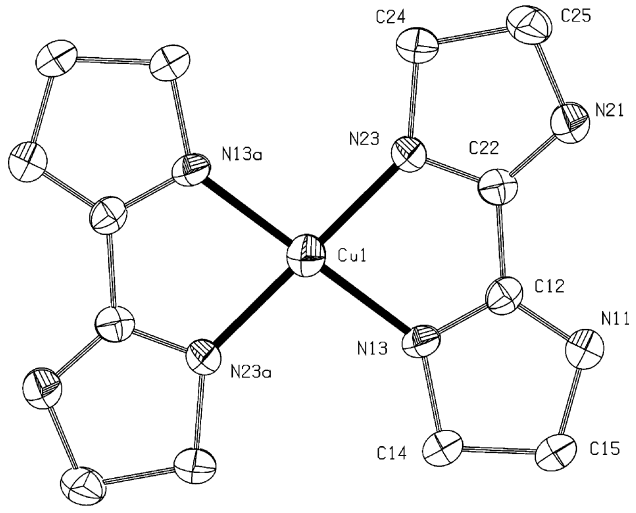

Fig. 3. Thermal ellipsoid plot at 50% probability of the cation in $[Cu(biz)_2](ClO_4)_2$ (**2**) with atom-labelling scheme. Hydrogen atoms and the uncoordinating perchlorate anions are omitted for clarity. Atoms marked with an "a" are generated by an inversion centre.

3.2. Electronic and infrared spectra

The diffuse reflectance spectra of the powdered solids are observed as broad bands at 16.3 and 17.5×10^3 cm^{-1}, for compound **1** and **2**, respectively. These band positions are to be considered as normal for a square-planar based CuN4 or $CuN_4(O_2)$ chromophore [14,15].

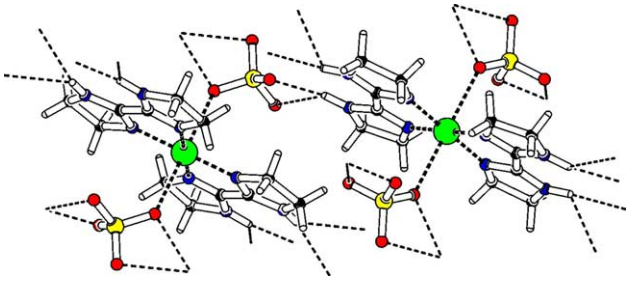

Fig. 4. Hydrogen bonds of compound **1**.

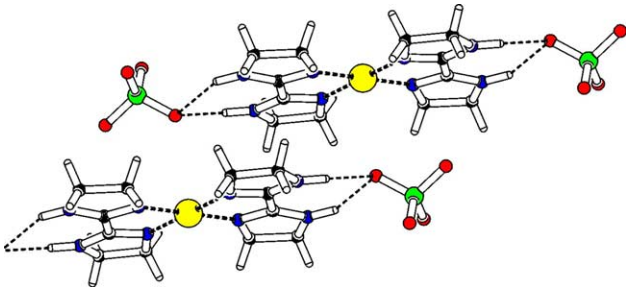

Fig. 5. Hydrogen bonds of compound **2**.

The IR spectra of compounds **1** and **2** are almost identical, except the area between 1000 and 1100 cm^{-1}, in which the strong anionic vibrations occur. These perchlorate vibrations are found around 1030 and 1066 cm^{-1} for compound **1** and around 1028 and 1091 cm^{-1} for compound **2**. Also a remarkable difference is seen in the region of the NH and OH vibrations, around 3300 cm^{-1}. Compound **1** has medium to strong peaks at 3385 and 3291 cm^{-1}, while compound **2** has only one strong broad vibration at 3306 cm^{-1}. This difference is due to the difference in the H-bonding properties (see Table 2). The two bands in compound **1** nicely agree with two different N···O contacts and calculations according to Bellamy and Owens [18] would have predicted N···O distances of 2.95 and 3.10 Å (assuming the free ligand having a NH vibration of 3450 cm^{-1} [18]). The one band at 3306 cm^{-1} for compound **2** agrees with the almost identical N···O contacts (calculated to be 2.96 Å). This is in close agreement with the observations made.

Another small difference is present in the region around 950 cm^{-1}, where medium strong CH_2 out-of-plane vibrations of the ligand occur [16]. Compound **1** has a medium strong doublet at 938 and 924 cm^{-1}, while compound **2** has a medium strong doublet shifted to 934 and 925 cm^{-1}.

3.3. EPR

X-band EPR spectra of polycrystalline powders were recorded at room temperature (RT) and in liquid nitrogen (77 K). Firstly, the difference in coordination geometry in the two Cu(II) compounds, **1** and **2**, is clearly demonstrated here. Compound **1** exhibits at RT a strong broad signal at $g_\perp$ at 2.07 with an unresolved $g_\parallel = 2.27$. At 77 K, $g_\parallel$ is more resolved and two hyperfine peaks are resolved with $A_\parallel = 18.2$ mT. Com-

pound **2**, however, gives only one strong isotropic signal at RT with $g = 2.07$, which sharpens up at 77 K, but no hyperfine is resolved. These values are in agreement with a $d_{x^2-y^2}$ ground state [14,15] and in good agreement with the square planar/octahedral topology of the CuN_4 or $CuN_4(O)_2$ chromophore [17].

In frozen solution (DMF/methanol 1:1) at 77 K, however, identical signals are obtained for both compounds. A resolved signal with $g_\perp = 2.04$, $g_\parallel = 2.24$ and $A_\parallel = 18.5$ mT. Even the superhyperfine splitting is observed with $A_{N\parallel} = 1.55$ mT. Also nine lines, though not clearly by overlap of the fourth band of the $A_\parallel$ signal, is in agreement with four nitrogen donors. So in solution both isomers must have the same geometry.

4. Concluding remarks

The research described in this paper has shown that the proper choice of the ligands, 2,2′-bi-imidazoline, can give interesting structural compounds, due to its steric properties. With Cu(II) perchlorate a blue and a violet compound could be synthesized using a different Cu:ligand ratio. These two compounds which are so-called distortion isomers, and differ in geometry by the (non) coordination of the perchlorate anion. These differences have also been observed in the IR and in the solid-state EPR. In frozen solution EPR (DMF/MeOH) the same signal is obtained and it has been concluded that in solution both isomers have the same geometry.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as Supplementary Publication Nos. CCDC-228514 and 228515, for compounds **1** and **2**, respectively.

Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223-336-033, e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk].

Abstract

Four heterometal complexes, namely $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2Mn(H_2O)_4]\cdot 2H_2O\}_n$ (**1**), $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{–}O)(nta)_2Zn(H_2O)_4]\cdot 2H_2O\}_n$ (**2**), $NH_4[La(H_2O)_9][(V^{IV}O)_2(\mu_2\text{–}O)(nta)_2]$ (**3**) and $NH_4[Nd(H_2O)_9][(V^{IV}O)_2(\mu_2\text{–}O)(nta)_2]$ (**4**), where nta = nitrilotriacetate, have been prepared and characterized by single-crystal X-ray diffraction analyses. Complexes **1** and **2** exhibit heterometallic one-dimensional chain structures formed by polymeric $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2M(H_2O)_4]^{2-}$ anions (M = Mn, Zn). Moreover, the one-dimensional chains are further linked together through hydrogen bonding into a three-dimensional framework. Compounds **3** and **4** display discrete units, however, these molecules are built up into three-dimensional structures through hydrogen bonding.

1. Introduction

Contemporary interest in the coordination chemistry of oxovanadium (IV), oxovanadium (V) and dioxovanadium (V) derives from their important biological and medicinal applications [1]. Recently, inorganic–organic hybrid materials based on vanadium oxides have attracted much attention. Therefore, the discovery of new vanadium oxide complexes especially possessing one-, two- or three-dimensional structures and the rational design of such solid materials remain an important and very active subject. In view of this point, some novel vanadium oxide complexes with polymeric structures have been prepared through the use of organically templated metal coordination subunits [2] or bridging organic ligands [3] as structural directors.

As one of the important derivatives of glycine, nitrilotriacetate (nta) can act as a potential bifunctional ligand with variable multi-dentate coordination modes. For instance, a series of nta complexes of transition metals have been isolated and structurally characterized [4]. Among these numerous studies on nta complexes, vanadium nitrilotriacetate (nta) complexes have been reported over the past decades, and some crystal structures have been described: $(NH_4)_3[V_2O_3(nta)_2]\cdot 3H_2O$ [5], $Na_3[VO(O_2)(nta)]\cdot 5H_2O$ [6], $[V(nta)(H_2O)_3]\cdot 4H_2O$ [7], $Na_3[V_2O_3(nta)_2]\cdot 5H_2O$ [8], $Ba[VO(O_2)(nta)]\cdot 3H_2O$ [9], $K_2[VO(O_2)(nta)]\cdot 2H_2O$ [10], $K_2[VO(O_2)(nta)]$ [11], $K_2[VO(O_2)(nta)]\cdot 2H_2O$ [12], $(NH_4)_2[VO_2(nta)]$ [13], $K_3[V_2O_3(nta)_2]\cdot 3H_2O$ [14]. In these vanadium nta complexes, each exhibits a discrete structure. Therefore, how to design and synthesize a polymeric structure of this type of vanadium nta complex will be an interesting

doi:10.1016/j.poly.2004.05.008

work. In this paper, we present four heterometal complexes with nta ligands, $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2\text{-}Mn(H_2O)_4]\cdot 2H_2O\}_n$ (**1**), $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2\text{-}Zn(H_2O)_4]\cdot 2H_2O\}_n$ (**2**), $NH_4[La(H_2O)_9][(V^{IV}O)_2(\mu_2\text{-}O)\text{-}(nta)_2]$ (**3**) and $NH_4[Nd(H_2O)_9][(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]$ (**4**) (nta = nitrilotriacetate). In **1** and **2**, the binuclear vanadium $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ anions are linked up by $[M(H_2O)_4]^{2+}$ (M = Mn, Zn) cations into heterometallic one-dimensional chain structures. The one-dimensional chains are further linked together through hydrogen bonds into a three-dimensional structure. Although compounds **3** and **4** exhibit discrete structures, the molecules are built up into three-dimensional structures through complex hydrogen bonding.

2. Experimental

2.1. Reagents and apparatus

All chemical used during the course of this work were of reagent grade and were used as received from a commercial source without further purification. Elemental analysis (C, H, N) was performed with a Vario EL *III* CHNOS Elemental Analyzer and the inductively coupled plasma (ICP) analysis was performed on a Perkin–Elmer optima 3300 DV ICP spectrometer. The IR spectra were recorded from KBr pellets in the range of 4000–400 cm^{-1} on a FTS-40 spectrophotometer. ESR spectra were recorded on a FD-ESR-I spectrometer in an aqueous solution.

2.2. Synthesis

2.2.1. $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2Mn(H_2O)_4]\cdot 2H_2O\}_n$ (*1*)

A mixture of NH_4VO_3 (0.31 g, 2.65 mmol), H_3nta (1.20 g, 6.28 mmol), $Mn(CH_3COO)_2\cdot 4H_2O$ (0.33 g, 1.35 mmol) and H_2O (25 ml) was heated to boiling until NH_4VO_3 dissolved completely. The deep blue solution was allowed to stand at room temperature without any further disturbance for about three days to give deep blue crystals. *Anal.* Calc. for **1**: C, 19.86; H, 4.41; N, 7.72; Mn, 7.58; V, 14.05 (%). Found: C, 19.78; H, 4.36; N, 7.75; Mn, 7.39; V, 14.12 (%). IR (KBr pellet, cm^{-1}): 3498 (s), 3190 (s), 1614 (s), 1454 (m), 1398 (s), 1283 (w), 1124 (m), 1001 (m), 953 (s), 910 (s), 733 (s), 625 (s). Yield: ≈67%.

2.2.2. $\{(NH_4)_2[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2Zn(H_2O)_4]\cdot 2H_2O\}_n$ (*2*)

A mixture of NH_4VO_3 (0.28 g, 2.39 mmol), H_3nta (1.20 g, 6.28 mmol), $Zn(CH_3COO)_2\cdot 2H_2O$ (0.46 g, 2.09 mmol) and H_2O (25 ml) was heated to boiling until NH_4VO_3 dissolved completely. The deep blue solution was allowed to stand at room temperature without any further disturbance for about five days to give deep blue crystals. *Anal.* Calc. for **2**: C, 19.57; H, 4.35; N, 7.61; Zn, 8.89; V, 13.85 (%). Found: C, 19.51; H, 4.36; N, 7.52; Zn, 8.71; V, 13.23 (%). IR (KBr pellet, cm^{-1}): 3537 (s), 3383 (s), 1603 (s), 1460 (m), 1412 (m), 1385 (s), 1281 (w), 1126 (w), 958 (s), 912 (s), 746 (s), 629 (w). Yield: ≈73%.

completely. The deep blue solution was allowed to stand at room temperature without any further disturbance for about six days to give deep blue crystals. *Anal.* Calc. for **4**: C, 16.93; H, 3.99; N, 4.93 (%). Found: C, 16.86; H, 3.58; N, 4.71 (%). IR (KBr pellet, cm^{-1}): 3381 (s), 1612 (s), 1406 (s), 1375 (s), 1275 (m), 1219 (m), 1128 (m), 1007 (w), 957 (s), 916 (s), 739 (s), 629 (w). Yield: ≈68%.

2.3. Crystallography

Crystals with dimensions $0.08 \times 0.12 \times 0.21$ mm for **1**, $0.06 \times 0.10 \times 0.16$ mm for **2**, $0.11 \times 0.25 \times 0.31$ mm for **3** and $0.11 \times 0.19 \times 0.27$ mm for **4** were selected for indexing and intensity data collections at 293 K on a Siemens SMART CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. The structures were solved by direct methods, successive Fourier difference synthesis and refined by full matrix least-squares based on F^2 using the SHELXTL-97 program package. In all cases, all non-hydrogen atoms were refined anistropically. All the hydrogen atoms based on C atoms were generated theoretically, while other hydrogen atoms were not located. The crystallographic data for **1**, **2**, **3** and **4** are listed in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

Complexes **1** and **2** are isostructural compounds. Each consists of one heterometal $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2M(H_2O)_4]^{2-}$ anion, two ammonium cations and two free water molecules. A locally expanded unit for complex **1** is shown in Fig. 1. The heterometal $[(V^{IV}O)_2\text{-}(\mu_2\text{-}O)(nta)_2M(H_2O)_4]^{2-}$ anion is formed by the connection of a binuclear vanadium $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ anion and a metal $[M(H_2O)_4]^{2+}$ (M = Mn, Zn) cation. As described before [5,8,14], the binuclear $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ anion can be considered as two similar mononuclear $[(V^{IV}O)(nta)]^{-}$ anions connected together by one μ_2-O atom (O8). The two $[(V^{IV}O)(nta)]$ units are centrosymmetric via the O8 atom which is located on the special position (1/2, 0, 1/2). Each vanadium atom in the mononuclear unit is in an octahedral coordination environment. The distorted octahedron is defined by one vanadyl oxygen atom (O7), one bridging oxygen atom (O8), three carboxyl oxygen atoms (O1, O3 and O5) and one nitrogen atom. The V–O distances of **1** can be divided into three groups: (a) The V=O bond length is 1.601(5) Å, which is in the normal range of 1.56–1.63 Å for the V^{IV}=O bond length [15]; (b) The V–O μ_2 bond length is 1.8164(1) Å, showing partial multiple bond character; (c) The V–O_{nta} bond distances are 1.977(5), 1.984(6) and 2.052(5) Å. The V–N distance is 2.294(5) Å, which is slight longer than that in other analogous nta complexes, but is shorter than that in vanadium EDTA complexes [16].

In compound **1**, the tetradentate nta ligand forms three glycinate rings with the V atom. The N–V–O bond angles are 76.46(2)°, 76.5(2)° and 76.5(2)°. The N–C and C–C distances are as expected. It is worthwhile to point out that there exists one carboxyl oxygen atom (O6) coordinated to the Mn atom. Thus, the C–O bond lengths can be divided into three groups: (a) C–O_V 1.283(8), 1.279(11) and 1.261(10) Å; (b) C–O_{Mn} 1.250(9) Å; (c) C–O_{unco} 1.235(8) and 1.231(10) Å. As a bridging metal, the Mn atom is coordinated by four water molecules and two bridging O atoms. A regular octahedral MnO_6 is formed with the corresponding Mn–O6, Mn–O9 and Mn–O10 distances of 2.166(5), 2.128(5) and 2.183(5) Å, respectively.

As shown in Fig. 2, the most interesting feature of **1** is its novel one-dimensional chain structure, which is formed by the binuclear $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ ions and the bridging metal $[Mn(H_2O)_4]^{2+}$ ions. The free ammonium ions and water molecules are hydrogen bonded to the carboxylate O atoms of the neighboring nta ligands with corresponding N···O contacts of 2.795 Å and O···O contacts in the range of 2.750–3.198 Å. Thus, the one-dimensional chains are further bound together through the hydrogen bonding into a three-dimensional network (Fig. 3).

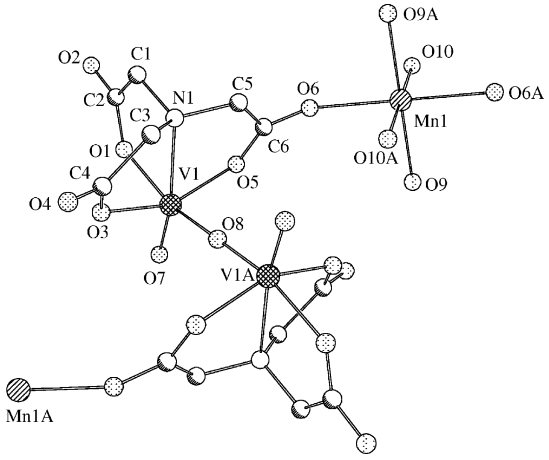

Fig. 1. The locally expanded unit of **1**, showing the structure of the heterometal $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2M(H_2O)_4]^{2-}$ anion.

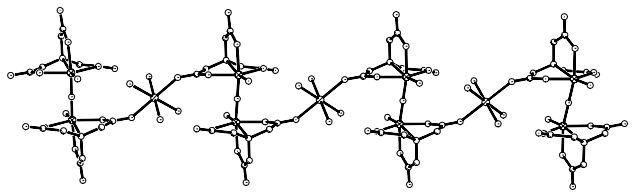

Fig. 2. The one-dimensional chain of **1** formed by the polymeric $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2M(H_2O)_4]^{2-}$ anion (viewed along the *a*-axis).

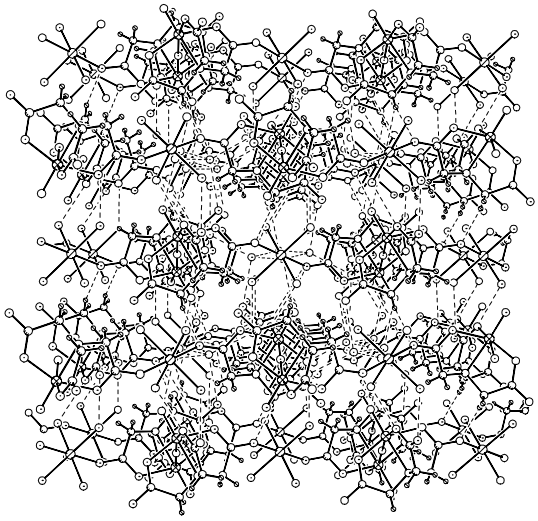

Fig. 3. Packing framework of **1** viewed along the *c*-axis. All hydrogen atoms are omitted for clarity.

As shown in Fig. 4, compound **3** contains one binuclear $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ anion unit, one $[La(H_2O)_9]^{3+}$ cation and one ammonium ion. The binuclear $[(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]^{4-}$ anion unit of **3** displays a similar structure to that of **1**, which is formed by the means of the connection of one bridging oxygen atom (μ_2-O) and two mononuclear $[(V^{IV}O)(nta)]^-$ anions. In the binuclear vanadium anion of **3**, the V=O, V–Oμ_2, and V–O_{nta} (average) bond lengths are 1.607(4), 1.8045(9) and 2.0226 (4) Å, respectively. The V–N distance is 2.297(5) Å, which is comparable to that of compound **1** (2.294(5) Å). The La ion is coordinated by nine water molecules with La–O distances in the range of 2.526(4)–2.602(4) Å.

A remarkable feature of compound **3** is that there exists hydrogen bonding between the coordinated water molecules and the binuclear vanadium units. The coordinated water molecules not only link up the adjacent binuclear vanadium clusters into a two-dimensional layer, but they also connect the two-dimensional layers

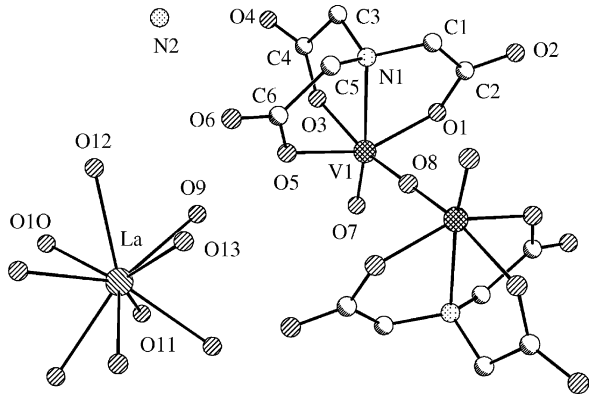

Fig. 4. The molecule structure of **3**.

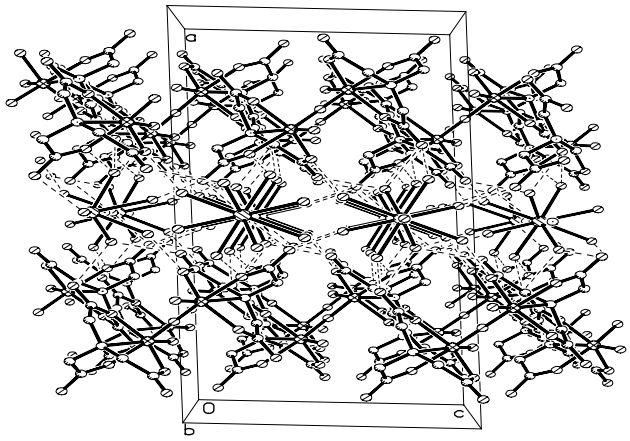

Fig. 5. Packing framework of **3**. All hydrogen atoms are omitted for clarity.

into a three-dimensional framework through hydrogen bonding (Fig. 5). The distances between the coordinated water molecules and the oxygen atoms of binuclear vanadium units are in the 2.701–3.159 Å range. However, no hydrogen bonding is involved between the ammonium cations and the binuclear vanadium units.

The structure of the Nd derivative $NH_4[Nd(H_2O)_9][(V^{IV}O)_2(\mu_2\text{-}O)(nta)_2]$ (**4**) is isomorphous with **3**. As shown in Table 2, among the metrical parameters for structures the Nd–O distances are in the range of 2.475(8)–2.556(9) Å, showing the predicted changing trend compared with the La–O counterparts. In addition, the distances involving the hydrogen bonding between the coordination water molecules and the oxygen atoms of the binuclear vanadium units are in the 2.697–3.139 Å range.

The IR spectra show that the ν(C–N) of the compounds are in the 1124–1128 cm^{-1} range (free H_3nta is at 1200 cm^{-1}), indicating the N atoms of nta ligands coordinate to V atoms. The ν_{as}(COOH) at 1725 cm^{-1} of H_3nta now red-shifts to the 1603–1614 cm^{-1} range, and the ν_s(COO) at 1340 cm^{-1} of H_3nta blue-shifts to the 1375–1398 cm^{-1} range, which confirm that the O atoms of the COO^- groups coordinate to the V atoms. Moreover, in **1** and **2**, the relative positions of the ν_{as}(COO) and ν_s(COO), $\Delta = \nu_{as}(COO) - \nu_s(COO)$, are 216 and 218 cm^{-1}, while in **3** and **4**, the relative positions (Δ) are 239 and 237 cm^{-1}, respectively. This fact indicates that there exist different coordination modes of the carboxylate groups in **1**, **2** (containing bidentate bridging) and **3**, **4** (monodentate). The bands in the 958–625 cm^{-1} range for all the compounds are attributed to the ν(V=O) and ν(V–O–V) vibrations. The EPR spectrum of **3** has been performed at room temperature, providing eight hyperfine peaks with g_o and A_o values of 1.985 and 112.62 G, respectively. The observed g tensor value is expected for oxo-vanadium (IV) ions, and eight $(2nI + 1)$ peaks are should be attributed to the coupling

of the unpaired electron ($n = 1$) with the nuclear spin ($I = 7/2$). In view of this point, we can deduce that the oxidation state of each vanadium atom in the other three compounds is in a reduced oxidation state (V^{IV}). This is also in agreement with the charge balance. Actually, all the complexes are synthesized in low pH solutions (pH < 1). When the pH values of the reaction solution are raised to above 1, the complexes cannot be obtained. Therefore it is easy to understand that the VO^{2+} ion is from the redox of the VO_3^- ion and nitrilotriacetic acid in the low pH value solution.

To date, some vanadium nitrilotriacetate complexes have been reported [5–14], however, each exhibits a discrete structure. In the reported vanadium nta complexes with alkali or alkaline-earth metal ions [6,8–12,14], the alkali or alkaline-earth metal ions only act as counter ions to balance the negative charges of the molecules. In compound **1**, the transition metal ion takes part in coordination as a bridge, playing an important role in the formation of this kind of polymeric structure. Compound **3** is synthesized in a similar aqueous solution to that of **1**, but displays a different structure feature. This might be attributed to the different influence of electronic structures of the lanthanide and transition metal on the formation of this type of complex.

4. Supplementary material

Crystallographic data for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Center as Supplementary Publication No. CCDC-233302 for **1**, CCDC-233303 for **2**, CCDC-233304 for **3** and CCDC-233305 for **4**. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax; (+44) 1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of triorganotin and triorganogermanium(IV) complexes with 1H-5-mercapto-1,2,3-triazolato, of the type $R_3MSC_2H_2N_3$ (M = Sn, R = CH_3, (**1**); C_2H_5, (**2**); *n*-C_4H_9, (**3**); C_6H_5, (**4**); M = Ge, R = CH_3, (**5**); C_2H_5, (**6**); *n*-C_4H_9, (**7**); C_6H_5, (**8**)), have been synthesized. All the complexes **1**–**8** have been characterized by elemental, IR and ^{1}H NMR analyses. Among them complexes **4** and **8** have also been characterized by X-ray crystallography diffraction analyses, which revealed that the Sn and Ge atom environments are distorted tetrahedral coordination polyhedrons, coordinated to three phenyl groups and to one sulfur atom of the ligand. The packing of complexes **4** and **8** is stabilized into a one-dimensional infinite chain by intermolecular N–H···N hydrogen bonds.

1. Introduction

Metal thiolato complexes have been extensively studied because of their ability to adopt various nuclearities and their relevance in biology, since they form the inorganic part of the biologically active centers of some metalloproteins and enzymes [1–3]. Recently, attention has been paid to the coordination chemistry of heterocyclic thiol/thione donors, which can give potential access to new compounds with unusual structures and reactivities [4]. For example, triazyl- and tetrazole-thiol organometallic derivatives have been reported. A related class of such compounds is thiosemicarbazones in which the structure unit HS–C–N–N or S=C–N–N can bond to metal ions through S or N or both atoms [5–8].

As a result of our continuing interest in the coordination of main group metals with polydentate S, N ligands [9–11], here we report the studies on the syntheses of a series of organotin and organogermanium complexes $R_3MSC_2H_2N_3$ (M = Sn, R = CH_3, (**1**); C_2H_5, (**2**); *n*-C_4H_9, (**3**); C_6H_5, 4; M = Ge, R = CH_3, (**5**); C_2H_5, (**6**); C_4H_9, (**7**); C_6H_5, (**8**)) and their characterization by elemental, IR and ^{1}H NMR analyses. X-ray crystallography analyses of the complexes **4** and **8** have also been given in the present paper.

2. Experimental

2.1. Materials and measurements

All reagents and the sodium salt of the ligand (1H-5-mercapto-1,2,3-triazole) were purchased commercially and used without further purification unless otherwise noted. The melting points were obtained with a Kofler micro-melting point apparatus and were uncorrected. Infrared-spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs and sodium chloride optics. ^{1}H NMR spectra were recorded on a JEOL-FX-90Q spectrometer using TMS as internal standard and

$CDCl_3$ as solvent. The chemical shifts are reported in ppm. Elemental analyses were performed with a PE-2400II apparatus.

2.2. Syntheses of the complexes **1–8**

2.2.1. $(CH_3)_3Sn(SC_2H_2N_3)$ (**1**)

The reaction was carried out under nitrogen atmosphere. The sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol) and trimethyltin chloride (0.199 g, 1 mmol) were added to a solution of absolute benzene (20 ml) in a Schlenk flask, stirred for 12 h at 40 °C and then filtered. The filtered solution was gradually reduced by evaporation under vacuum until a solid product was obtained. The solid was then recrystallized from ether. The white crystal complex **1** was formed. Yield, 89%. M.p.: 121–123 °C. *Anal*. Calc. for $C_5H_{11}N_3SSn$: C, 22.76; H, 4.20; N, 15.93. Found: C, 22.72; H, 4.18; N, 15.96%. IR (KBr, cm^{-1}): 3251 (br, N–H), 3052 (w, C–H), 1605 (m, C=C), 1596 (C–N), 1442 (m, N=N), 1156, 1078 (m, C–S), 560, 535 (m, Sn–C), 319 (m, Sn–S). ^1H NMR ($CDCl_3$): δ 10.9 (br, 1H, N-H), 1.53 (m, 9H, CH_3), 7.30 (s, 1H, =CH).

2.2.2. $(C_2H_5)_3Sn(SC_2H_2N_3)$ (**2**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), triethyltin chloride (0.241 g, 1 mmol) and benzene (20 ml). The colorless crystal complex **2** was obtained from *n*-hexane. Yield: 82%. M.p.: 124–126 °C. *Anal*. Calc. for $C_8H_{17}N_3SSn$: C, 31.41; H, 5.60; N, 13.74. Found: C, 31.38; H, 5.46; N, 13.79%. IR (KBr, cm^{-1}): 3250 (br, N–H), 3050 (w, C–H), 1605 (m, C=C), 1595 (C–N), 1443 (m, N=N), 1152, 1076 (m, C–S), 561, 524 (m, Sn–C), 317 (m, Sn–S). ^1H NMR ($CDCl_3$): δ 10.5 (br, 1H, N–H), 1.76 (q, 6H, $-CH_2$), 0.88 (t, 9H, CH_3), 7.28 (s, 1H, =CH).

2.2.3. $(n\text{-}C_4H_9)_3Sn(SC_2H_2N_3)$ (**3**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), tributyltin chloride (0.325 g, 1 mmol) and benzene (20 ml). The colourless crystal complex **3** was obtained from benzene. Yield: 80%. M.p.: 58–60 °C. *Anal*. Calc. for $C_{14}H_{29}N_3SSn$: C, 43.11; H, 7.50; N, 10.78. Found: C, 43.14; H, 7.53; N, 10.76%. IR (KBr, cm^{-1}): 3249 (br, N–H), 3050 (w, C–H), 1605 (m, C=C), 1595 (C–N), 1443 (m, N=N), 1152, 1076 (m, C–S), 565, 540 (m, Sn–C), 316 (m, Sn–S). ^1H NMR ($CDCl_3$): δ 10.6 (br, 1H, N–H), 1.79 (t, 6H, $-CH_2$), 1.13–1.50 (m, 12H, CH_2), 0.86 (t, 9H, CH_3), 7.28 (s, 1H, =CH).

2.2.4. $Ph_3Sn(SC_2H_2N_3)$ (**4**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), triphenyltin chloride (0.385 g, 1 mmol) and benzene (30 ml). The yellow crystal complex **4** was obtained from hexane–dichloromethane. Yield, 89%. M.p.: 128–130 °C. *Anal*. Calc. for $C_{20}H_{17}N_3SSn$: C, 53.37; H, 3.81; N, 9.33; S, 7.12. Found: C, 53.24; H, 3.76; N, 9.28; S, 6.97%. IR (KBr, cm^{-1}): 3250 (br, N–H), 3050 (w, C–H), 1605 (m, C=C), 1595 (C–N), 1443 (m, N=N), 1152, 1076 (m, C–S), 561, 533 (m, Sn–C), 317 (m, Sn–S). ^1H NMR ($CDCl_3$): δ 11.0 (br, 1H, N–H), 7.31–7.96 (m, 15H, Ph–H), 7.28 (s, 1H, =CH).

2.2.5. $(CH_3)_3Ge(SC_2H_2N_3)$ (**5**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), trimethylgermanium chloride (0.153 g, 1 mmol) and benzene (20 ml). The yellow crystal complex **5** was obtained from hexane–dichloromethane. Yield, 78%. M.p.: 120–122 °C. *Anal*. Calc. for $C_5H_{11}N_3SGe$: C, 27.57; H, 5.02; N, 19.29. Found: C, 27.40; H, 5.06; N, 19.05%. IR (KBr, cm^{-1}): 3251 (br, N–H), 3120 (w, C–H), 1608 (m, C=C), 1595 (C–N), 1445 (m, N=N), 1160, 1073 (m, C–S), 587, 505 (m, Ge–C), 455 (m, Ge–S). ^1H NMR ($CDCl_3$): δ 10.8 (br, 1H, N–H), 1.71 (s, 9H, Ge–CH_3), 7.29 (s, 1H, =CH).

2.2.6. $(C_2H_5)_3Ge(SC_2H_2N_3)$ (**6**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), triethylgermanium chloride (0.195 g, 1 mmol) and benzene (20 ml). The yellow crystal complex **6** was obtained from hexane–dichloromethane. Yield, 79%. M.p.: 119–121 °C. *Anal*. Calc. for $C_8H_{17}N_3SGe$: C, 36.97; H, 6.60; N, 16.17. Found: C, 36.94; H, 6.57; N, 16.19%. IR (KBr, cm^{-1}): 3252 (br, N–H), 3121 (w, C–H), 1608 (m, C=C), 1596 (C–N), 1443 (m, N=N), 1161, 1073 (m, C–S), 579, 516 (s, Ge–C), 457 (m, Ge–S). ^1H NMR (90 MHz, $CDCl_3$): δ 10.8 (br, 1H, N–H), 1.76 (q, 6H, Ge–CH_2), 0.88 (t, 9H, CH_3), 7.30 (s, 1H, =CH).

2.2.7. $(n\text{-}C_4H_9)_3Ge(SC_2H_2N_3)$ (**7**)

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), triphenylgermanium chloride (0.279 g, 1 mmol) and benzene (20 ml). The yellow crystal complex **7** was obtained from hexane–dichloromethane. Yield, 71%. M.p.: 49–51 °C. *Anal*. Calc. for $C_{14}H_{29}N_3SGe$: C, 48.89; H, 8.50; N, 12.21. Found: C, 48.87; H, 8.53; N, 12.19%. IR (KBr, cm^{-1}): 3250 (br, N–H), 3120 (w, C–H), 1605 (m, C=C), 1592(C–N), 1442 (m, N=N), 1162, 1073 (m, C–S), 585, 531 (m, Ge–C), 461 (m, Ge–S). ^1H NMR ($CDCl_3$): δ 10.7 (br, 1H, N–H), 1.79 (t, 6H, Ge–CH_2), 1.13–1.50 (m, 12H, CH_2), 0.86 (t, 9H, CH_3), 7.30 (s, 1H, =CH).

*2.2.8. $Ph_3Ge(SC_2H_2N_3)$ (**8**)*

The synthesis procedure was the same as in Section 2.2.1, using the sodium salt of 1H-5-mercapto-1,2,3-triazole (0.123 g, 1 mmol), triphenylgermanium chloride (0.339 g, 1 mmol) and benzene (25 ml). The yellow crystal complex **8** was obtained from hexane–dichloromethane. Yield, 73%. M.p.: 130–132 °C. *Anal*. Calc. for $C_{20}H_{17}N_3SGe$: C, 59.46; H, 4.24; N, 10.40. Found: C, 59.40; H, 4.19; N, 10.36%. IR (KBr, cm^{-1}): 3250 (br, N–H), 3120 (w, C–H), 1608 (m, C=C), 1595 (C–N), 1445 (m, N=N), 1160, 1073 (m, C–S), 591, 535 (m, Ge–C), 453 (m, Ge–S). ^1H NMR ($CDCl_3$): δ 11.2 (br, 1H, N–H), 7.33–7.74 (m, 15H, Ph–H), 7.30 (s, 1H, =CH).

*2.3. X-ray crystallographic studies of complexes **4** and **8***

All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer. The φ/ω, scan technique was employed. Corrections were applied for Lorentz and polarization effects but not for absorption, satisfying $I \geqslant \sigma(I)$. Criterion of observability was used for the solution and refinement. The structure was solved by direct methods and refined by a full-matrix least-squares procedure based on F^2 using the SHELXL-97 program system. All data were collected at 298(2) K using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and corrected for Lorentz and polarization effects but not for absorption. All non-H atoms were included in the model at their calculated positions. The positions of hydrogen atoms were calculated, and their contributions in structural factor calculations were included.

3. Results and discussion

*3.1. Syntheses of the complexes **1**–**8***

The synthesis procedure was as in the following Scheme 1:

*3.2. IR spectroscopic studies of the complexes **1**–**8***

The assignment of the IR bands of all the complexes **1**–**8** have been made by a comparison with the IR spectra of related organotin(IV) and organogermanium(IV) compounds. A new absorption band that appears at about 309–316 cm^{-1} for complexes **1**–**4** can be attributed to the vibration of the Sn–S bond, which is consistent with that detected for a number of organotin(IV)–sulfur derivatives [12], and the absorption band that appears at 453–461 cm^{-1} for complexes **5**–**8** can be attributed to the vibrations of the Ge–S bond according to the literature [13].

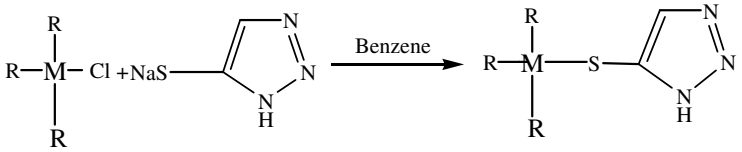
In complexes **1**–**4**, two strong or medium absorptions are observed at 560–565 and 524–540 cm^{-1}. They are due to ν_{asym} and ν_{sym} Sn–C stretching vibrations, respectively. In complexes **5**–**8**, ν_{asym} and ν_{sym} Ge–C stretching vibrations are at 579–591 and 505–535 cm^{-1}, respectively. This suggests that there are no-planar SnC_3 fragments for all the complexes **1**–**8**.

The middle intensity bands observed at 1592–1596 cm^{-1} in the spectra of all the complexes **1**–**8** have been assigned to ν(C–N), according to the literature [14], together with the absorption region ranging from 1442 to 1445 cm^{-1} attributed to the vibration of ν(N=N), which are all consistent with the free ligand. In the 2800–2600 cm^{-1} region the ligands exhibit a broad band typical of N–H stretching. In the organotin(IV) and organogermanium(IV) adducts this shifts to 3250 cm^{-1}. The position and character of the broadened N–H stretching band are consistent with the presence of a NH···N intermolecular hydrogen bond, as reported in the literature [15].

All the above data indicate the coordination of the ligand to tin or germanium only by the sulfur atom in all the complexes **1**–**8**. So it can be concluded that complexes **1**–**8** are four-coordinate, with a sulfur atom and three alkyl (or phenyl) groups bonded to the central metal atom. The conclusion well coincides with the following X-ray crystallographic analysis of complexes **4** and **8**.

*3.3. ^1H NMR data of the complexes **1**–**8***

The ^{1}HNMR spectra show that the chemical shifts of the proton on the phenyl group (Sn–C_6H_6) 7.31–7.96 ppm for **4** and (Ge–C_6H_6) 7.30–7.74 ppm for **8** and those of the methylene connected directly with tin in complexes **1**–**3** and with germanium in complexes **5**–**7**,



M=Sn, R=CH_3, **1**; C_2H_5, **2**; n-C_4H_9, **3**; C_6H_5, **4**; M=Ge, R=CH_3, **5**; C_2H_5, **6**; C_4H_9, **7**; C_6H_5, **8**

Scheme 1.

1.53–1.79 ppm, upfield shift when compared with those of their corresponding precursors. All these data are similar to those cases that appear in the literature [16], indicating there may exist coordination of the ligand to the metal atom for all the complexes. In addition, the broad resonance of the (N–H) proton appears at 10.5–11.2 ppm for all the complexes **1**–**8**.

3.4. Crystal structures of complexes *4* and *8*

The structure details of complexes **4** and **8** are shown in Figs. 1 and 2, respectively. The intermolecular hydrogen-bond packing of complexes **4** and **8** are similar, one of which is displayed in Fig. 3. Single crystal X-ray diffraction study details are shown in Table 1, and selected bond lengths and angles are listed in Table 2. The complexes **4** and **8** exhibit the tin(IV) and the germanium(IV) in a distorted tetrahedral geometry defined by three phenyl groups and one sulfur atom, which exists as a bridge between the tin or the germanium atom and the triazole ring.

For complex **4**, Sn–C bond lengths (2.121(5) to 2.135(5) Å) are comparable with the complex: triphenyl(5-mercapto-1-phen-1,2,3,4-tetralato)tin (2.120–2.127 Å) [17]. The Sn–S distance is 2.4354(15) Å, which is consistent with the sum of the covalent radii (2.42 Å) [18] and the complex $[Cy_2NeophylSnS_2P(OC_6H_4{}^tBu\text{-}4)_2]$ (2.477(3) Å) [19], and this distance is much shorter than the sum of the van der Waals' radii (4.0 Å) [18]. The S–Sn–C bond angles are more acute and the C–Sn–C bond angles are larger than the theoretical tetrahedral angle, the largest deviations occurring in S(1)–Sn(1)–C(15) [101.32(14)°] and C(15)–Sn(1)–C(9) [116.12(17)°].

For complex **8**, the germanium atom environment is similar to that of the tin atom in complex **4**. The Ge–C bond lengths (1.925(2)–1.929(3) Å) are in the normal range (1.93 Å for Ge–Cp) [20]. The Ge–S bond length (2.2406(11) Å) is a little longer than that reported in dichloro-(ferrocene-1,1′-dithiolato)-germanium (2.19 Å) [20], and is consistent with that in complex 4-$CH_3C_6H_5CS_2GePh_3$ (2.2526(8) Å) [21]. The angles around the center Ge element range from 103.00° to 113.40°, which all depart from the theoretical tetrahedral angle.

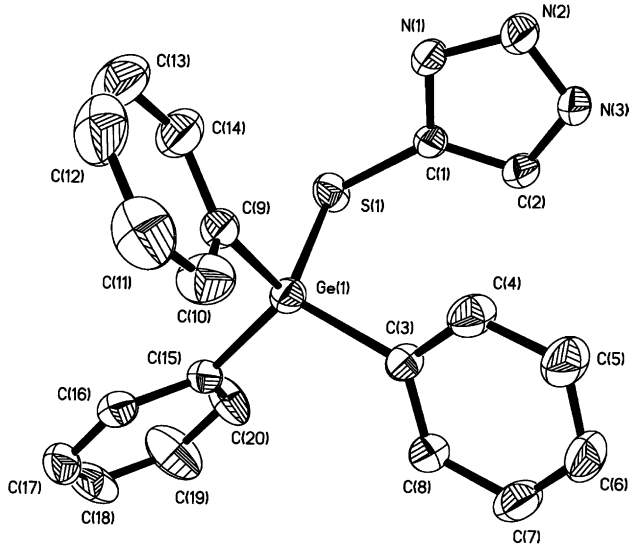


Fig. 2. SHELX view of complex **8** (30% probability thermal ellipsoids).

Furthermore, the salient feature of the superamolecular structure of complexes **4** and **8** is that of a one-dimensional hydrogen-bonded polymer, as shown in Fig. 3, in which N(3) of the triazole bonds to N(1) of a neighboring triazole through a hydrogen bond [$H(1)\cdots N(1)^i$ 1.966 Å, N(3)–$H(1)\cdots N(1)^i$ 173.93° for **4**); $H(1)\cdots N(1)^i$ 1.880 Å, N(3)–$H(1)\cdots N(1)^i$ 165.56° for **8**, (i) $X+1/2, -Y+1/2, -Z$], the parameters of which are consistent with that reported, $H(1)\cdots N(1)$ 1.92(3) Å, for the complex $[(C_6H_5)_3SnSCNH_2{=}N{-}N{=}C(CH_3)(C_6H_4\text{-}2\text{–}OH)]$ [22].

Abstract

A novel redox active (*E*,*E*)-dioxime ligand, *S*,*S*′-bis-[2(2′-ferrocenemethylaminobenzyl)]-dithioglyoxime (LH_2), containing ferrocene and flexible aminobenzenesulfanyl-moieties on the periphery has been synthesized from 2-(2′-ferrocenemethylamino)benzenethiol, which was obtained by the reduction of 2,2′-pyridylbenzothiazolidine with a large excess of $NaBH_4$. Mononuclear $(LH)_2M$ ($M = Ni^{II}$, Cu^{II}, Co^{II}, Fe^{II} and Mn^{II}), homodinuclear $(LH)_2(UO_2)_2(OH)_2$ and heterotrinuclear $(LH)_2MM'_2X_n$ ($M = Ni^{II}$ and $M' = Pd^{II}$, $X = Cl^-$, $n = 4$ and $M' = Ag^{I}$, $X = NO_3^-$, $n = 2$) complexes have been obtained with the metal:ligand ratios of 1:2, 2:2 and 3:2, respectively. Flexible ferrocenemethylaminobenzenesulfanyl moieties bearing two different heteroatoms, –S and –N, on the periphery of the *vic*-dioxime serve as weak binding sites for Pd^{II} and Ag^{I} ions. The detection of H-bonding in all complexes except the uranyl complex by IR revealed square-planar MN_4 coordination of the mono- and trinuclear complexes. The MN_4 coordination of the Ni^{II} complex was also determined by the ^1H NMR spectroscopy. The structures of the complexes were characterized by elemental analysis, ^1H NMR, IR, MS, UV–Vis spectral and cyclic voltammetry. The voltammetric analyses of the complexes showed metal, ligand, and ferrocene based signals. The redox chemistry of the complexes exhibited both M^{I} and M^{III} oxidation states of the central metals of the complexes.

1. Introduction

The importance of polytopic *vic*-dioximes containing functional sites for binding different guest species is increasing rapidly [1–6]. Their metal complexes are of current concern for their rich physcochemical, optical, catalytic, redox and medical properties [7–14]. The desired properties of the complexes can be altered by peripheral and central substitutions [5–21]. Polytopic *vic*-dioximes form polynuclear metal complexes, which exhibit novel allosteric, catalytic and sensor properties [22–24]. The oxidation states of the central metals, type and number of donor atoms, and core structures of the complexes are major factors in determining structure–function relationships of the transition metal complexes [15–21,25,26].

Although a large number of *vic*-dioxime complexes possessing core structural types, such as MN_2, MS_2, MN_4, MN_2S_2, MS_4, MN_2S_2, $MN_2S_2O_2$ and MO_4S_2, have been synthesized and characterized [15–21,27–29], the studies on complexes containing peripheral redox-active substituents are rather scarce [30]. Therefore, we are currently interested in fabricating new reactive *vic*-dioxime ligands containing multiple redox-active peripheral groups and/or external transition metal recognition sites as precursors for further applications.

In this study, as a continuity of our previous studies on *vic*-dioximes with multifunctional substituents [18–20], we reported for the first time the preparation and characterization of a novel mixed-donor *vic*-dioxime ligand, *S*,*S*′-bis-[2(2′-ferrocenemethylaminobenzyl)]-dithioglyoxime (LH_2) (**3**), containing N_2S_2 external chelating donor sites. It was synthesized from (*E*,*E*)-dichloroglyoxime and 2-(2′-ferrocenemethylamino)-benzenethiol (**2**). Compound **2** was prepared by the reduction of the condensation product, 2,2′-pyridylbenzothiazolidine (**1**), of 2-ferrocenecarboxyaldehyde and 2-aminothiophenol with a large excess of $NaBH_4$ [31,32]. Compound **3** gave *N*,*N*-coordinated planar mononuclear complexes with Ni^{II}, Cu^{II}, Fe^{II}, Co^{II} and Mn^{II} in the rigid core of the *vic*-dioxime groups as MN_4 type complexes. But, compound **3** gave *N*,*O*-coordinated dinuclear complexes with $UO_2{}^{II}$ as MN_2O_2 type complex. We also isolated heterotrinuclear complexes of $(LH)_2MM'_2X_n$ with Pd^{II} ($n = 4$) and Ag^{I} ($n = 2$), having one metal ion for each dithioamino-substituted benzenoid group.

The stability of the oxidation states of the metal center in these complexes depends on the metal coordination environment [33,34]. The ability of donor atoms to stabilize reduced and/or oxidized forms of metal has sparked interest in their role in bioinorganic systems. Hence, for a better understanding of their properties, the investigation of redox behavior has a vital importance. Although various oximes and their metal and non-metal compounds have been studied extensively, electrochemistry of *vic*-dioximes is scarce [18–20]. Therefore, the redox properties of the complexes synthesized in this study were investigated by cyclic voltammetry.

2. Experimental

All reagents and solvents were of reagent-grade quality and obtained from commercial suppliers. (*E*,*E*)-Dicholoroglyoxime was prepared by a reported procedure [31,32]. ^{1}H NMR spectra were recorded on Bruker 200 and 250 MHz spectrometers. FT-IR spectra were recorded on a Mattison 1000 FT-IR spectrometer using KCl pellets, and electronic spectra on a Unicam UV2 spectrophotometer. The elemental analyses were performed using a Carlo Erba 1106 Instrument. Mass spectra were recorded on a VG Zabspec GSMS Spectrometer by the EI and LSIMS methods (MNBA matrix: *meta*-nitrobenzylalcohol). The metal contents of the complexes were determined with a Hitachi 180-80 Atomic Absorption Spectrophotometer in solution prepared by decomposition of the compounds in aqua regia followed by dilution with water. The homogeneity of 2-(2′-ferrocenemethylamino)benzenethiol (**2**) and **3** were tested by TLC (SiO_2, $CHCl_3$:MeOH).

Cyclic voltammetric (CV) and controlled potential coulometric (CPC) measurements were carried out at 25 ± 1 °C with a Princeton Applied Research Model 273 potentiostat controlled by an external PC, using the computer program, HEADSTRT. The Origin 6.0 graph program was used to evaluate HEADSTRT data, to draw voltammograms and to analyze them. The working electrode was a Pt plate with an area of 1.0 cm^2 and a Pt-spiral wire served as the counter electrode in the voltammetric measurements. A saturated calomel electrode (SCE) was employed as the reference electrode. Ferrocene was used as an internal reference and the potentials are also reported with respect to the Fc/Fc^+ couple. Dimethylsulfoxide (DMSO) over molecular sieves was employed as the solvent. Electrochemical grade tetraethylammonium perchlorate (TEAP) (0.1 mol dm^{-3}) was employed as the supporting electrolyte. High-purity nitrogen was used for deaeration and to maintain a nitrogen blanket for at least 15 min prior to each run. For CPC studies, a platinum gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge, a SCE as reference, and a model 377/12 Synchronous stirrer were used.

2.1. Synthesis

2.1.1. S,S-Bis-[2(2′-ferrocenemethylaminophenyl)]-dithioglyoxime(LH_2) (3)

[2-(2′-Ferrocenemethylamino)]benzenethiol (**2**) (0.50 g, 1.87 mmol) was dissolved in 30 cm^3 absolute ethanol under nitrogen. Then anhydrous $NaHCO_3$ (0.157 g, 1.87 mmol) was added and the mixture was stirred for about half an hour at room temperature. To this solution, (*E*,*E*)-dicholoroglyoxime (0.046 g, 0.291 mmol) in 15 cm^3 ethanol was added dropwise. The reaction mixture was stirred for 1 h at this temperature and then 4 h at reflux temperature. During the reaction, the mixture was monitored by TLC (chloroform/MeOH; 98:2 v/v). After the mixture had been filtered to separate the NaCl formed, the solvent was removed under reduced pressure until a volume of about 10–15 cm^3 remained. The yellowish mixture was taken up in $CHCl_3$, washed successively with H_2O, 5% $NaHCO_3$ and then H_2O to remove any thiol or inorganic reagents, dried with Na_2SO_4, and finally evaporated under reduced pressure to give a yellow oily residue. The crude product was purified by chromatography on silica gel (MeOH:$CHCl_3$ 2/98 v/v) and dried in vacuo to give the pure compound. This compound is soluble in THF, DMSO, DMF and hot ethanol, and slightly soluble in diethyl ether. Yield: 0.55 g (40.29%); m.p.: 196 °C. IR (Thin film, cm^{-1}): 3380 (s, NH), 3240 (N–OH), 3068, 3019 (Ar-H), 2963, 2924, 2854 (Aliph-H), 1729 (O–H···O), 1606 (C=C), 1587 (C=N), 1566, 1497, 1476, 1448, 1409 (Fc), 1383 (Ar-skel-vib), 1314–1279, 1251, 1174, 1159, 1105, 1032, 1005 (br, st, N–O and Fc), 924, 817 (Fc), 742 (st), 668. ^{1}H NMR (250 MHz, DMSO-d_6) δ: 9.97 (s, 2H, =N–OH, D-exchangeable), 7.62 (dd, $^3J = 7.5$ Hz, 2H, C_6H_4

ortho to SCH_2), 7.44 (dt, $^3J = 7.0$ Hz, 2H, C_6H_4 *meta* to SCH_2), 7.25 (d, $^3J = 7.0$ Hz, 2H, C_6H_4 *para* to NH), 6.62–6.48 (dd, $^3J = 7.8$ Hz, 2H, C_6H_4 *ortho* to NH), 5.84 (s, br, 2H, –NH, D-exchangeable), 4.82 (2H, t, $^3J = 5.0$, C_5H_4), 4.68 (2H, t, $^3J = 5.2$, C_5H_4), 4.27 (s, 2H, NH–CH_2), 4.11 (2H, s, $^3J = 5.2$, C_5H_5), UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 375(sh) (2.2), 338(sh), (2.8), 262 (11.34). MS (LSIMS,*m*-NBA): m/z (%) = 731.2 $[M + 1]^+$ (5), 711.4 $[(M–H_2O)]^+$ (5), 673.2 $[(M–Cp)]^+$ or $[(M–Fe)]^+$ (10), 543.4$[(M–Fc)]^+$ (3), 536.2 $[(M–FcCH_2)]^+$, 394.7 $[(M–FcCH_2C_7H_5NS)]^+$ (4), 358.4 $[(M–2Fc)]^+$ (7), 213.3 $[(M–FcCH_2C_7H_5NS–Fc)]^+$ (13), 234.3 (50), 157. 0 $[(DCGO)]^+$ (45).

2.2. Mononuclear complexes: $(LH)_2M$ ($M = Ni^{II}$ (**4**), Cu^{II} (**5**), Co^{II} (**6**), Fe^{II} (**7**) and Mn^{II} (**8**))

2.2.1. $(LH)_2Ni$ (**4**)

To a solution of LH_2 (**3**) (0.050 g, 0.068 mmol) in 20 cm^3 THF, a solution of $Ni(NO_3)_2 \cdot 6H_2O$ (0.010 g, 0.034 mmol) in 10 cm^3 THF was added by dropwise. The complex started to precipitate after a distinct change in color and a decrease in pH had been observed. The mixture was stirred for 2 h at 40 °C to complete the reaction. An equivalent amount of $(C_2H_5)_3N$ was then added dropwise to adjust the pH of the mixture to about 6–7 and complete the precipitation of the complex. After the mixture had been cooled to room temperature and stored in a deep-freeze for 1–2 h, a red-brown precipitate was isolated by successive centrifugation. The product was filtered off, washed with H_2O, MeOH and Et_2O, and finally dried in vacuo. It is soluble in DMSO, DMF and pyridine, and insoluble in methanol, THF and diethylether. Yield: 0.017 g (32.95%); m.p.: >200 °C. IR (Thin film, cm^{-1}): 3376 (–NH), 3073, 3028 (Ar-H), 2974, 2924 (Aliph-H), 1728 (O–H···O bridge), 1632 (C=C), 1586 (C=N), 1504, 1458, 1412, 1291, 1212, 1161, 1065 (N–O), 838, 750, 653, 519. ^{1}H NMR (200 MHz, DMSO-d_6) $\delta = 15.34$ (s, 2H, O–H···O), 7.47(dd, $^3J = 7.5$Hz, 4H, Ar-H, H3), 7.22(dt, $^3J = 6.5$ Hz, 4H, C_6H_4, H5), 6.76 (dt, $^3J = 6.8$ Hz, 4H, C_6H_4, H6), 6.48 (dd, $^3J = 6.4$ Hz, 4H, C_6H_4, H4), 5.84 (s, br, 2H, –NH, D-exchangeable), 4.81(2H, t, $^3J = 5.0$, C_5H_4), 4.68 (2H, t, $^3J = 5.2$, C_5H_4), 4.23 (s, 2H, NH–CH_2), 4.01 (2H, s, $^3J = 5.2$, C_5H_5). UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 426(sh) (1.8), 365(sh) (3.8), 264 (10.14). MS (LSIMS, *m*-NBA): $m/z = 1517.3$ $[M + 1]^+$ (3), 1572.3 $[(M + Fe)]^+$ (5), 1499.2 $[M + H_2O]^+$, 1458.2 $[M–Ni]^+$, 1331.7 $[M–Fc]^+$ (3), 1145.3 $[M–2xFc]^+$ (3), 1089.9 $[M–2Fc\text{-}Ni]^+$ (5), 825.7 $[M–2FcCH_2\text{-}C_7H_5NS]^+$ (6), 715.3 (5), 692.3 (10), 676.4 (100), 663.3 (20), 621.4 (10), 583.4 (15), 509.2 (5), 453.2 (8), 337.2 (5), 227.2 (15), 175.1 (20), 157. 0 $[(DCGO)]^+$ (15).

2.2.2. $(LH)_2Cu$ (**5**)

This brown complex was prepared by following the same procedure as described for the preparation of **4**, starting from **3** (0.050 g, 0.068 mmol) and $Cu(NO_3)_2 \cdot 6H_2O$ (0.010 g, 0.034 mmol). This compound is soluble in DMF, DMSO and pyridine, and insoluble in THF, alcohol, hexane and diethyl ether. Yield: 0.20 g (38.66%); m.p.: >200 °C. IR (Thin film, cm^{-1}): 3373 (–NH), 3060, (Ar-H), 2963, 2926 (Aliph-H), 1757 (O–H...O bridge), 1630 (C=C), 1580 (C=N), 1501, [1462–1380] (alip-skel-vib and Fc), 1284, 1106 (Fc), 1032, (N–O), 827 (Fc), 745, 672, 618, 497(Fc), 482 (Fc). UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 387(sh) (1.86), 340(sh) (2.4), 261 (12.26). MS (LSIMS, *m*-NBA): m/z (%) = 1523.3 (15) $[M + 3]^+$, 1485.3 $[M–2H_2O]^+$, 1335.8 $[M–Fc]^+$ (5), 1187.9 $[M–FcCH_2C_7H_5NS]^+$ (7), 1153.3 $[M–2Fc]^+$ (3), 829.4 (10), 682.3 (30), 563.3 (12), 457.2 (15), 311.2 (10), 147.4 (5), 228.0 (20), 157.3 $[(DCGO)]^+$ (35), 136.0 (25).

2.2.3. $(LH)_2Co$ (**6**)

The preparation method as described for **4** gave the brown complex, **6**, as powder, starting from **3** (0.050 g, 0.068 mmol) and $Co(NO_3)_2 \cdot 6H_2O$ (0.010 g, 0.034 mmol). This compound is soluble in DMF, DMSO and pyridine, and insoluble in THF, alcohol, hexane and diethyl ether. Yield: 0.025 g (48.47%); m.p.: >200 °C. IR (Thin film, cm^{-1}): 3376 (–NH), 3063 (Ar-H), 2968, 2928 (Aliph-H), 1771 (O–H···O bridge), 1626 (br, C=C), 1589 (C=N), 1508, [1458, 1406 (Fc), 1317] (alip-skel-vib), 1261, 1161, 1063, 1033 (N–O), 1001 (Fc), 942, 823 (Fc), 752, 598, 517 (S–CH_2). UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 378(sh) (2.0), 309(sh) (4.65), 264 (12.12).

2.2.4. $(LH)_2Fe$ (**7**)

This red-brown complex **7** was prepared by following the same procedure as described for the preparation of **4**, starting from **3** (0.050 g, 0.068 mmol) and $Fe(NO_3)_2 \cdot 6H_2O$ (0.010 g, 0.034 mmol). This compound is soluble in DMF, DMSO, pyridine and quinoline, and insoluble in THF, alcohol and diethyl ether. Yield: 0.025 g (48.56%); m.p.: >200 °C. IR (Thin film, cm^{-1}): 3343 (–NH), 3035 (Ar-H), 2967, 2923 (Aliph-H), 1774 (O–H···O bridge), 1638 (br, C=C), 1568 (C=N), 1500, [1460, 1441, 1405 (Fc), 1384] (alip-skel-vib), 1275, 1174, 1106, 1015 (N–O), 1003 (Fc), 926, 828 (Fc), 753, 668, 582, 500, 482 (S–CH_2 and Fc). UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 384(sh) (8.2), 308(sh) (3.13), 264 (10.80).

2.2.5. $(LH)_2Mn$ (**8**)

A preparation method similar to that used for compound **4** gave the brown complex, **8** as powder, starting from **3** (0.050 g, 0.068 mmol) and $MnCl_2 \cdot 4H_2O$ (0.007 g, 0.034 mmol). This compound is soluble in DMF, DMSO, pyridine, quinoline and insoluble in THF, alcohol and diethyl ether. Yield: 0.014 g (27.22%); m.p.: >200 °C. IR (Thin film, cm^{-1}): 3347 (–NH), 3055 (Ar-H), 2965, 2926 (Aliph-H), 1819 (O–H···O bridge), 1630 (C=C), 1589 (C=N), [1501, 1460, 1400 (Fc) 1384] (alip-

skel-vib), 1316, 1281, 1161, 1105 (Fc), 1033 (N–O), 1005 (Fc), 820 (Fc), 748, 669, 617, 561 (S–CH_2). UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 412(sh) (2.18), 359 (sh) (5.14), 262 (9.08).

2.3. Dinuclear uranyl complex $[(LH)_2(UO_2)_2(OH)_2]$ (9)

A solution of $UO_2(NO_3)_2 \cdot 6H_2O$ (0.068 g, 0.166 mmol) in 15.0 cm^3 THF was slowly added with stirring to a solution of **3** (0.100 g, 0.136 mmol) in 15.0 cm^3 THF at room temperature. The color of the solution immediately turned into orange. The pH of the mixture was about 4–5. $(C_2H_5)_3N$ was added to the mixture to adjust the pH of the mixture and to complete the precipitation after the mixture had been heated on water-bath for 1 h. Finally, the mixture was centrifuged several times with THF and Et_2O and the product dried in vacuo to afford an orange powder. This compound is soluble in DMF, DMSO, pyridine and quinoline, and insoluble in THF, alcohol and diethyl ether. Yield: 0.023 g (16.64%); m.p: >200 °C. IR (Thin film, cm^{-1}): 3256 (N–OH), 3067, (Ar-H), 2971, 2925 (Aliph-H), 1642 (C=C), 1576 (C=N), 1515, 1453, 1407 (st, Fc), 1370, 1253, 1068, 1025 (N–O), 1003 (st, Fc), 908 (st, O=U=O), 816 (Fc), 738, 666, 535, 523, 440. UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 412(sh), 378(sh), 283 (sh), 264 (10.12). ^{1}H NMR (250 MHz, DMSO-d_6) $\delta = 10.45$ (s, 1H, N–OH, D-exchangeable), 10.22 (s, 1H, N–OH, D-exchangeable), 7.38 (dd, $^3J = 6.5$ Hz, 4H, Ar-H, H3), 7.08 (dt, $^3J = 6.5$ Hz, 4H, C_6H_4, H5), 6.66 (dt, $^3J = 6.0$ Hz, 4H, C_6H_4, H6), 6.51 (dd, $^3J = 6.0$ Hz, 4H, C_6H_4, H4), 5.92, 5.84 (s,s br, 2H, –NH, D-exchangeable), 4.82 (2H, t, $^3J = 6.0$ Hz, C_5H_4), 4.64 (2H, t, $^3J = 6.2$ Hz, C_5H_4), 4.22 (s, 2H, NH–CH_2), 4.12 (2H, s, $^3J = 6.0$ Hz, C_5H_5).

2.4. Heterotrinuclear complexes $[(LH)_2MM'_2X_n$ ($M = Ni^{II}$ and $M' = Pd^{II}$, $X = Cl^-$, $n = 4$ and $M' = Ag^I$, $X = NO_3^-$, $n = 2$) (10, 11)

The mononuclear nickel complex, **4**, (0.05 g, 0.033 mmol) was dissolved in DMF–water (5.0:0.3 cm^3). An excess $Na_2[PdCl_4] \cdot 3H_2O$ or $AgNO_3$ in the same solvent was added. The color became brown-black while stirring for 2 h at 60–70 °C and some precipitation occurred. After adding ethanol to the mixture, the precipitates were separated by filtration and washed successively with hot water, ethanol and diethylether to yield brown-black products $[Ni(LH)_2 (PdCl_2)_2]$ and $[Ni(LH)_2 (AgNO_3)_2]$.

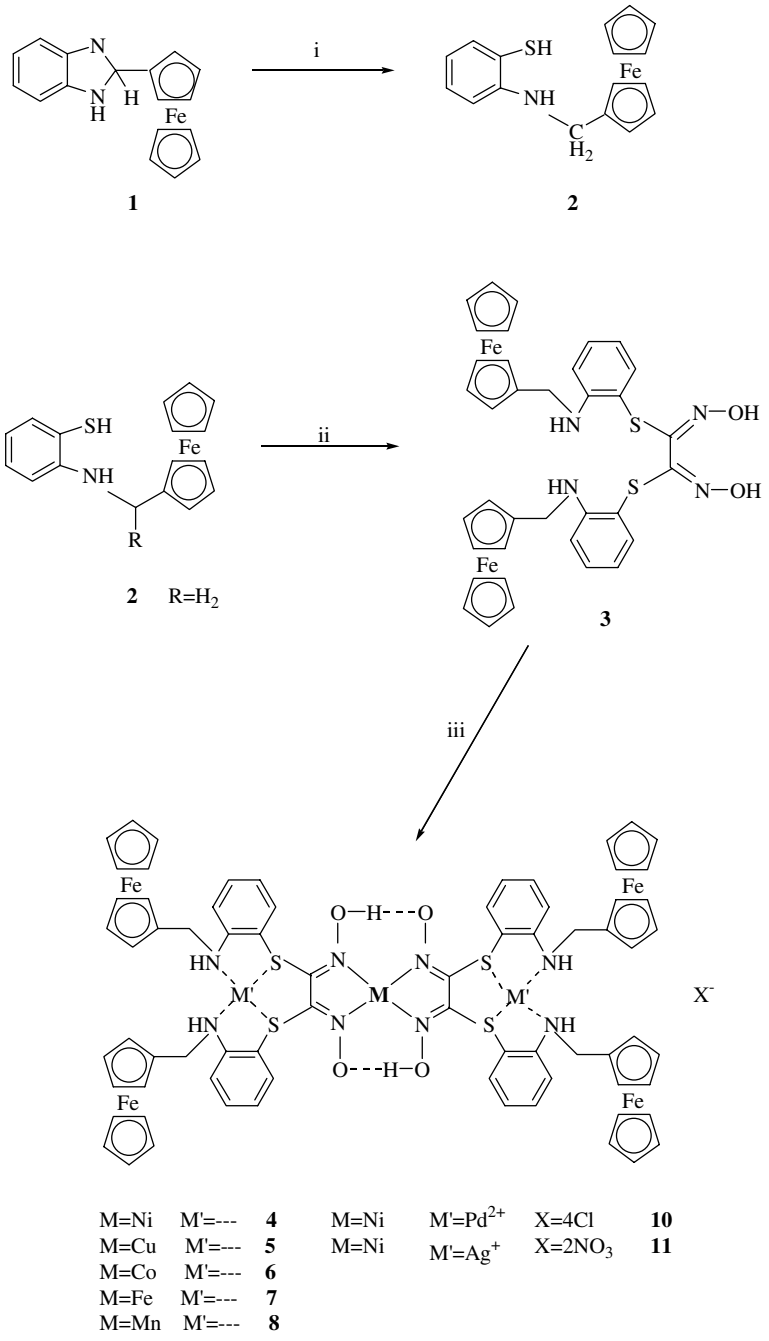
Complex **10**: Yield: 0.025 g (40.49%); ν_{max} 3343 (–NH), 3055, 3019 (Ar-H), 2988, 2945 (Aliph-H), 1713 (O–H···O bridge), 1612 (C=C), 1577 (C=N), 1498, 1443, 1409, 1280, 1156, 1051 (N–O), 886, 714, 648, 512. UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 403 (1.92), 363(sh) (3.2), 264 (11.08). MS (FAB): 1871 $[M]^+$ (5), 1873 $[M]^+$ (3), 1836.3 $[M–PdCl_2]^+$ (4), 1517 $[(LH)_2M]$ (5), 1431 $[(LH)_2M–2Fc]$, 1154 (10), 833.5 (10), 231.0 (20), 157.0 $[DCGO]^+$ (55).

Complex **11**: Yield: 0.034 g (55.48%), ν_{max} 3340 (–NH), 3082, 3013 (Ar-H), 2975, 2933 (Aliph-H), 1702 (O–H···O bridge), 1604 (C=C), 1595 (C=N), 1498, 1443, 1385, 1280, 1132, 1103 (N–O), 1078, 976, 879, 828, 710, 658, 534. UV–Vis (in DMSO) λ_{max}/nm ($\log \varepsilon$): 398(sh) (1.7), 352(sh) (4.04), 264 (9.40). MS (FAB): 1857 $[M]^+$ (3), 1685.3 $[M–AgNO_3]^+$ (4), 1517 $[(LH)_2M]$, 1483.1 (5) 1325.1 (8), 1150.7 (15), 835.5 (17), 675.3 (25), 322.0 (30), 224.4 (45),157.0 $[DCGO]^+$ (75).

3. Results and discussion

2-(2′-Ferrocenemethylamino)benzenethiol (**2**) was prepared by a two-step reaction sequence according to the previously reported procedure [31,32]. Compound **3** was prepared by the reaction of the mixture of **2** and (*E*,*E*)-dichlorodioxime [35,36] in THF at reflux temperature in the presence of $NaHCO_3$ (Scheme 1). It was isolated in a moderate yield after chromatography with silica gel. Mononuclear $(LH)_2M$ ($M = Ni^{II}$ (**4**), Cu^{II} (**5**), Co^{II} (**6**), Fe^{II} (**7**) and Mn^{II} (**8**)) (Scheme 1), and dinuclear uranyl complexes $(LH)_2(UO_2)_2(OH)_2$ (**9**) (Fig. 1) of the *vic*-dioxime were prepared with a metal/ligand molar ratio of 1:2 and 2:2, respectively, in moderate yield by treating the metal(II)nitratehexahydrate, except **8** where manganese(II)chloridetetrahydrate was used, with the ligand in THF in the presence of basic Et_3N [13–21]. These products were isolated as pure species via spontaneous precipitation. Further precipitation was achieved by adding Et_3N to the crude product after the first precipitation. The formation of mono-, di- and trinuclear complexes with **3** depends on the tendency of the metal ion to coordinate to the "hard" and/or "soft" sites of the ligand. In trinuclear complexes, two metal ions are coordinated by the two nitrogen and two sulfur atoms of each peripheral site whereas the third metal ion is coordinated by the *N*,*N*′ atoms of each oxime group in the two ligand molecules (Scheme 1). The acidity of peripheral –NH donors in **3** coming from the condensation between ferrocenecarboxyaldehyde and 2-aminothiophenol is rather low when compared with that of amides because of their position far away from oxime groups [37]. Therefore, the trinuclear complex was obtained without deprotonation of these –NH groups under the basic conditions in DMF.

The routes for the synthesis of **3** are given in Scheme 1. The structural formula of **3** and its complexes (**4**, **5**, **6**, **7**, **8** and **9**) were deduced by elemental analysis, IR, ^{1}H NMR, UV–Vis spectroscopic and mass spectral data. The colors, yields and elemental analyses of **3** and its complexes are listed in Table 1. In the IR spectrum of **3**, the –[NOH] stretching absorption was observed at 3240



Scheme 1. (i) MeOH, $NaBH_4$, HCl; (ii) MeOH, $NaHCO_3$, DCGO, reflux; (iii) $MX_2 \cdot 6H_2O$ ($M = Ni^{II}$, Cu^{II}, Co^{II}, Fe^{II}; $X = NO_3$; $M = Mn^{II}$, $X = Cl$), Et_3N, THF.

cm^{-1} while the [ν(SH)] band for **1** at 2519 cm^{-1} is not observed. The missing of N–OH stretching band at ca 3200 cm^{-1} in the IR spectrum of **3** together with the existence of a H-bridge (O–H···O) at near 1700–1850 cm^{-1} and the shifting of –C=N and –N–O stretches in the IR spectra of the complexes provide support for MN_4-type coordination in the complexes. While the ν(N–O) stretching vibrations for the ligand shifted to slightly higher frequencies, ν(C–N) stretching vibrations shifted to slightly lower frequencies upon complexation. On the other hand, in the IR spectrum of the uranyl complex **9** [ν(O=U=O)], [ν(N–O)] and [ν(N–OH)] frequencies were observed at 908, 1025 and 3256 cm^{-1}, respectively, as strong bands which are consistent with the dimeric structure. Characteristic ferrocene frequencies were also detected at 816, 1003 and 1407 cm^{-1}. These values are also in harmony with the previously reported dithioglyoxime derivatives [14–20,27–29].

The ^1H NMR data gave reasonable information about the proposed structures of the *vic*-dioxime ligand

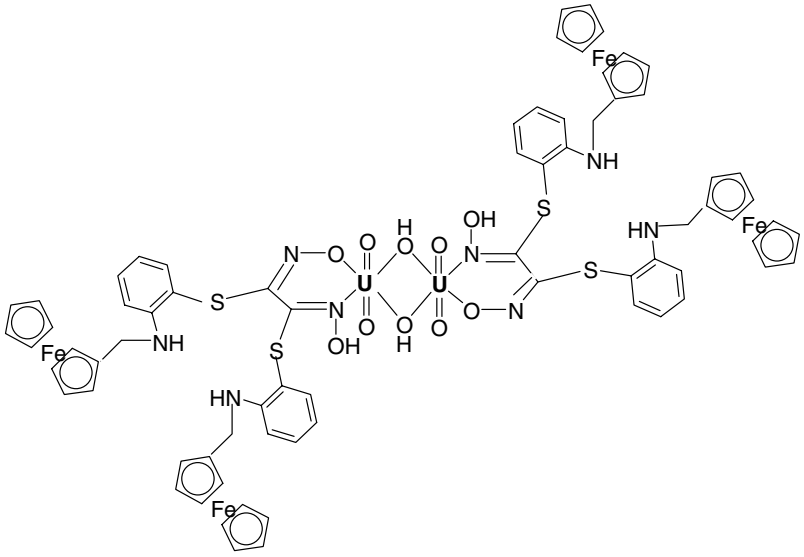


Fig. 1. Binuclear uranyl complex (**9**).

Table 1
Analytical and physical data for LH_4 and its complexes

Compounds	Color	Calc. (Found) %				
		C	H	N	Fe	M

and its metal complexes. The resonances due to the –N–OH, –NH, ferrocene and S-donor of the benzene moiety were the most dominant signals indicating the formation of **3**. The ^1H NMR spectrum of **3** in DMSO exhibited D_2O-exchangeable signals for the N–OH and NH protons at 9.97 and 5.84 ppm, respectively. These signals are indicative of the *anti*-isomer form of the *vic*-dioxime. The singlets, which belong to NH and N–OH, disappeared after addition of D_2O. In addition, the signals resulting from the moieties in **3** were observed as a double-doublet at 7.44, a double-triplet at 7.25, a doublet at around 6.62–6.48, and a double-doublet at around 4.82–4.68 for benzene, at 4.11 for ferrocene and at 4.24 ppm for N–CH_2. The ^1H NMR spectrum of complex **4** confirms the hydrogen-bridged structure. The existence of an intra-molecular H-bridge was observed by a new signal at lower field, $\delta = 15.34$ ppm, in addition to the second deuterium-exchangeable-NH protons. The signal from the deuterium-exchangeable O–H$\cdots$O group disappeared upon addition of D_2O. The shifts and changes in the intensity of certain peaks in the NMR spectra of **4** and **9** as compared to **3** are consistent with the coordination of **3**. The signals for the ferrocene, methylene and benzene in **4** and **9** are similar with those of **3** with small shifts. The NMR spectrum of **9** contained two peaks for the oxime N–OH group at low field ($\delta = 10.45$, 10.22 ppm, s, 1H, N–OH, D-exchangeable), which can be attributed to the magnetic anisotropy of the uranyl ion, as discussed in previous works [18–20]. It is known that the uranyl ion enhances the chemical shift differences between non-equivalent protons.

The UV–Vis spectra of the ligand and its complexes (**4**, **5**, **6**, **7**, **8** and **9**) in DMF showed two or three absorption bands between 260 and 550 nm. These bands are assigned to both a charge transfer transition from the metal to π^* anti-bonding orbital of the ligand and a spin-allowed π–π^* transition of the ligand. The general character of these spectra are very similar to that of the corresponding complexes of symmmetrically disubstituted dioximate ligands. This is probably due to the fact that metal to ligand charge transfer and ligand to metal charge transfer transitions have similar energy differ-

ences. The d^8 metal ion, Pd^{II} exhibits a preference for square planar geometry with dithioether complexes [37]. The decrease in the intensities of π–π^* and n–π^* transitions indicates the coordination to the peripheral sulfur and nitrogen atoms [17–21,38]. Consequently, the two PdS_2N_2 planes are directed out of the plane of the *vic*-dioxime complex as expected, which causes decomposition of aggregates of the planar *vic*-dioxime molecule in solution. The metal contents of the trinuclear complexes were determined quantitatively by atomic absorption spectrophotometry.

The mass spectra of **3**, **4**, **5**, **10** and **11** were obtained by the LSIMS technique using *m*-NBA (*meta*-nitrobenzylalcohol) as the matrix and they showed molecular ion peaks at $m/z = 731.2$ $[L + 1]^+$ for **3**, $m/z = 1517.3$ $[2L + M + H]^+$ for **4**, $m/z = 1523.3$ $[2L + M + 3H]^+$ for **5**, 1871 $[M]^+$ for **10** and 1857 $[M]^+$ for **11**. These data confirm the proposed structures and obey the rules of dithiosubstituted *vic*-dioxime and its complexes in addition to major fragments.

The electrochemical properties of **4**–**9** were investigated using voltammetric techniques. The results are summarized in Table 2. With the controlled potential coulometry studies, complete electrolysis of the solution at the working electrode at constant potential ($E_{p,c}$ of the redox couple) was achieved, and the time integration of the electrolysis current was recorded and the charge, Q, at the end of the electrolysis was calculated using the current-time response of the solution. Faraday's law was used to estimate the number of electrons transferred. The number of electrons was found to be two for the U(VI)/U(V) couple of **9** and one for all other redox processes.

Figs. 2 and 3 show the cyclic voltammograms of **4** and **7**, respectively. The first reduction and first oxidation processes for these complexes (Ic/Ia and IIIa/IIIc in Figs. 2 and 3) take place on the metal center of the complexes, whose voltammetric data are given in Table 2. For both **4** and **7**, the second reduction process corresponds to the oxime moieties and the second oxidation process to Fc/Fc^+. Addition of ferrocene compound into the solution of **4** gives an oxidation signal almost at the same potential with the couple at $E_{1/2} = 0.466$ V indicating that the second one of these oxidations corresponds to the ferrocene substituents attached to the oxime moieties. ΔE_p and $\partial E_p/\partial \log v$ values indicated that for both complexes the metal-based processes have quasi-reversible character while the ferrocene oxidation processes have reversible behavior. The redox chemistry of the Ni^{II} (**4**) and Fe^{II} (**7**) complexes exhibit both M(III)/M(II) and M(II)/M(I) redox couples. It is clearly stated in the literature that oxime containing metal

complexes give redox signals involving both higher and lower oxidation states of the metal depending on the coordination environment of metal center [39,40].

In the CV measurements upon scanning cathodically at the negative potential side, with the exception of **5**, all complexes display first a one-electron peak assigned to the reduction of the metal center of the complexes and then an irreversible oxime-based reduction peak without the corresponding anodic wave. As shown in Fig. 4(b), **5** has a different redox behavior compared to the others. It displays two one-electron totally irreversible reduction peaks at −0.730 and −1.130 V without the corresponding anodic waves during the reverse scan. Since the first reduction wave is irreversible, the first electron transfer step is probably being rapidly followed by a chemical reaction which gives a daughter product which is responsible for the second irreversible process. It also displays a third reduction peak with the corresponding anodic wave at $E_{1/2} = -1.330$ V which can be attributed to the oxime moieties. The oxidation process of **5** (IVa in Fig. 4(a)) had an adsorption behavior. Direct proportionality of the anodic peak current with scan rate provided evidence for the adsorption character of this process. This adsorption behavior was also observed previously in our works involving voltammetric behaviors of various copper-oxime complexes [18–20]. Although the ferrocene substituents are redox active within the accessible potential range of the DMSO/TBAP solvent system, their voltammetric signal was not observed. This signal probably coincides with the adsorption peak having a high-current, and cannot be observed.

Figs. 5 and 6 indicate the CVs of **6** and **8**, respectively. These complexes give a one-electron M^{II}/M^{I} couple (Ic/Ia) with a high peak separation probably due to a slow charge transfer process. The peak separation value of the Ic/Ia couple of **6** is considerably high ($\Delta E_p = 0.470$ V at 0.100 V s^{-1}). However, the $\partial E_p/\partial \log v$ value for this couple (−0.020 V) is indicative of a quasi-reversible character of the process. ΔE_p of the Ic/Ia couple of **8** is also very high (0.565 V at 0.100 V s^{-1}) while the $\partial E_p/\partial \log v$ value (−0.015 V) is within the range for a quasi-reversible peak character. In the case of **6**, the Co^{II}/Co^{I} couple is followed with an irreversible oxime reduction peak (IIc) at −1.070 V, while this peak was not observed with **8**. The redox peak of the oxime reduction

for **8** is probably weak and it is difficult to resolve it from the background current of the CV. Both **6** and **8** also show a reversible oxidation couple corresponding to Fc/Fc^+. The ferrocene signal of **6** is considerably higher than those of the other complexes. This is probably due to the coincidence of the Co(II)/Co(III) and Fc/Fc^+ redox processes.

Fig. 7 represents the cyclic voltammograms of **9** at different scan rates. Complex **9** displays a reversible reduction couple assigning to $U^{VI}O_2/U^{V}O_2$ at $E_{1/2} = -0.508$ V followed by an irreversible reduction of the oxime moieties at −1.140 V and two oxidation couples at 0.460 V (IIIa/IIIc) and at 0.730 V (IVa/IVc). Addition of ferrocene compound into the solution of **9** give an oxidation signal almost at the same potential with the couple at $E_{1/2} = 0.460$ V indicating that first one of these oxidations corresponds to the ferrocene substituents attached to the oxime moieties. Moreover, addition of ferrocene does not change remarkably the position of other voltammetric signals indicating the absence of any considerable substituent effect on the potentials of the oxime and metal based redox processes. The second oxidation signal is attributed to the oxime

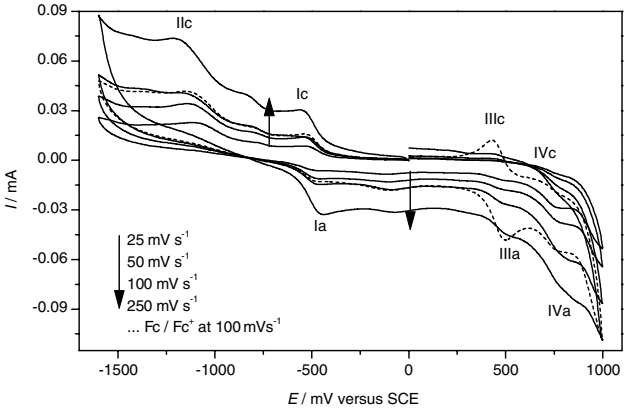

Fig. 7. Cyclic voltammograms of $[(UO_2)_2(LH)_2(OH)_2]$ (**9**) in DMSO–TBAP at various scan rates.

moieties, and observed only for the uranyl complex. For the other complexes, this signal is probably out of the accessible potential window of the DMSO/TBAP solvent system, and thus cannot be monitored.

4. Conclusion

The present work introduces the preparation, characterization and electrochemical properties of a novel *vic*-dioxime ligand and its mono and dinuclear metal complexes which were substituted peripherally with redox active ferrocenyl and ionophore aminothiophenyl moieties. The external aminobenzylthio moieties provided the complexes with the capability of binding various metal ions. Electron donating nitrogen or sulfur atoms render the chelating centers very electron rich. This makes this family of molecules ideally suited for the development of new charge-transfer complexes and as precursors to magnetic or conductive materials. Voltammetric results showed that the metal-oxime complexes indicated metal, ligand and ferrocene based signals. The electrochemistry of the oxime containing metal complexes clearly showed that the reduction of the oxime moiety in non-aqueous media is very difficult due to the polarization of the hydroxyl groups, so the redox signals involving the oxime moiety were observed after central metal-based redox processes and at considerably negative potentials. Addition of ferrocene into the complex solutions did not change remarkably the position of other voltammetric signals indicating the absence of any considerable substituent effect on the potentials of the oxime and metal-based redox processes.

Abstract

The condensation of acetylacetone with benzoylhydrazine in a 1:2 mol ratio in methanol to prepare acetylacetone bis(benzoylhydrazone) (H_3bbhac) resulted in the formation of the cyclized product 1-benzoyl-3,5-dimethyl-5-(1′-benzoylhydrazido)-pyrazoline (bzpyzn). The pyrazoline structure has been confirmed by X-ray crystallography. In methanol, treatment of bzpyzn with $Ni(O_2CCH_3)\cdot 4H_2O$ in a 1:1 mol ratio under aerobic conditions results in the pyrazoline ring opening and formation of a complex with the deprotonated acetylacetone bis(benzoylhydrazone) ($bbhac^{3-}$). The room temperature magnetic moment (1.71 μ_B) of [Ni(bbhac)] is consistent with an $S = 1/2$ spin state. However, the EPR spectral features indicate that [Ni(bbhac)] is on the borderline between an authentic nickel(III) complex and a nickel(II) stabilized ligand radical. In our attempts to grow single crystals of [Ni(bbhac)], the transformation of the central –CH= moiety of the acetylacetone residue in $bbhac^{3-}$ to a keto group has been realized. The molecular structure of the resulting nickel(II) complex of the formula [Ni(bbhacO)] has been determined by X-ray crystallography.

1. Introduction

The chemistry of trivalent nickel complexes has been the subject of considerable interest due to the important roles played by nickel(III) in catalytic and biological processes [1–4]. Ligands containing N-coordinating deprotonated amide functionality are well known to stabilize higher-valent (>+2) late first transition series metal ions [5]. Schiff bases derived from semicarbazides and acyl- or aroylhydrazines contain this high oxidation state promoting amide functionality that can coordinate a metal ion through the O atom. Thus these ligands provide the scope to study the effect of the amide protonation state on the structural and physical properties of the complexes, which is rather intricate for amide-N coordinated species. We have been working on these aspects of transition metal complexes with tridentate acyl- or aroylhydrazones [6–11]. In the present work, we have reported the results obtained in our attempt to prepare a similar tetradentate Schiff base acetylacetone bis(benzoylhydrazone) (H_3bbhac) and to explore the nickel coordination chemistry with it. Deprotonation of the two amide functionalities and the active methylene group of H_3bbhac will produce the trianionic planar N_2O_2 donor ligand $bbhac^{3-}$ which in principle can stabilize nickel(III). To synthesize H_3bbhac we have reacted benzoylhydrazine and acetylacetone in a 2:1 mol ratio. However, a new cyclized product 1-benzoyl-3,5-dimethyl-5-(1′-benzoyl-hydrazido)pyrazoline (bzpyzn) has been isolated instead of H_3bbhac. Formation of substituted pyrazolines from semicarbazide or thiosemicarbazide and 1,3-diketones (in a 2:1 mol ratio) has been reported before [12–14]. It has been shown that in the presence of transition metal ions (Cu^{2+}, Zn^{2+}) under anaerobic conditions, the pyrazoline derived from thiosemicarbazide and acetylacetone undergoes ring

doi:10.1016/j.poly.2004.05.002

opening and neutral complexes of the general formula [ML] are formed where H_2L is the acetylacetone bis(thiosemicarbazone) [14]. It is also observed that under aerobic conditions, the central methylene group of the acetylacetone residue of the ligand in [ML] (Ni, Cu, Zn) is oxidized to a keto group [14,15]. The reaction of bzpyzn with $Ni(O_2CCH_3)\cdot 4H_2O$ under aerobic condition causes a similar pyrazoline ring opening in bzpyzn. However, this ring opening leads to the formation of a formal nickel(III) complex [Ni(bbhac)], of the intended ligand instead of the nickel(II) complex of the oxidized ligand, as observed for acetylacetone bis(thiosemicarbazone). Interestingly in solution under wet conditions, the methine fragment in [Ni(bbhac)] gets oxidized to a keto group leading to the formation of a new nickel(II) complex of the formula [Ni(bbhacO)]. Herein, we describe the synthesis and physical properties of bzpyzn, [Ni(bbhac)] and [Ni(bbhacO)]. Solid state molecular structures of bzpyzn and [Ni(bbhacO)] have been determined by X-ray crystallography.

2. Experimental

2.1. Materials

The chemicals and the solvents used in this work were of analytical grade, available commercially and were used without further purification.

2.2. Physical measurements

Microanalytical (C, H, N) data were obtained with a Perkin–Elmer Model 240C elemental analyzer. Infrared spectra were collected by using KBr pellets on a Jasco-5300 FT-IR spectrophotometer. Solution electrical conductivities were measured with a Digisun DI-909 conductivity meter. Room temperature (300 K) solid state magnetic susceptibility was measured by using a Sherwood Scientific magnetic susceptibility balance. $Hg[Co(NCS)_4]$ was used as the standard. A diamagnetic correction (-186×10^{-6} emu mol^{-1} for [Ni(bbhac)]), calculated from Pascal's constants [16], was used to obtain the molar paramagnetic susceptibility. EPR spectra were recorded on a Jeol JES-FA200 spectrometer. A Shimadzu 3101-PC UV/vis/NIR spectrophotometer was used to record the electronic spectra. Proton NMR spectra of bzpyzn (in $CDCl_3$) and [Ni(bbhacO)] (in $(CD_3)_2SO$) were recorded on a Bruker 200 MHz spectrometer using $Si(CH_3)_4$ as an internal standard.

2.3. Synthesis of 1-benzoyl-3,5-dimethyl-5-(1′-benzoylhydrazido)pyrazoline (bzpyzn)

To a methanol solution (25 ml) of benzoylhydrazine (545 mg, 4 mmol) 0.21 ml of acetylacetone (205 mg, 2.05 mmol) was added. The mixture was refluxed for 6 h followed by evaporation to about 1/5th of the original volume on a rotary evaporator. It was then cooled to room temperature. The white solid thus obtained was collected by filtration and recrystallized from methanol. Yield, 430 mg (64%). A single crystal suitable for X-ray structure determination was selected from this material. *Anal*. Calc. for $C_{19}H_{20}N_4O_2$: C, 67.84; H, 5.99; N, 16.65. Found: C, 67.55; H, 5.82; N, 16.53%. Selected IR bands (cm^{-1}): 3277(s), 1659(s), 1605(s), 1572(m), 1537(m), 1489(w), 1456(s), 1427(s), 1375(s), 1329(s), 1306(m), 1134(m), 1105(m), 1061(w), 1026(m), 993(m), 934(w), 910(s), 862(s), 789(s), 708(s), 638(w), 488(m). ^{1}H NMR (200 MHz) data in CD_3OD (δ): 1.88 (s, 3H, 5-CH_3); 1.98 (s, 3H, 3-CH_3); 2.90 and 3.22 (2H, CH_AH_B, $J_{AB}=18$ Hz); 5.30 (s, 1H, 5-NH); 7.38–7.50 (m, 6H, aromatic protons); 7.73–7.84 (m, 4H, aromatic protons); 8.27 (s, 1H, NHN*H*). Electronic spectral data in CH_3OH (λ (nm) (ε ($M^{-1}\,cm^{-1}$))): 322 (1760), 264sh (9700), 225 (24 600).

2.4. Synthesis of [Ni(bbhac)]

To a methanol solution (20 ml) of bzpyzn (572 mg, 1.7 mmol) a methanol solution (20 ml) of $Ni(O_2CCH_3)\cdot 4H_2O$ (425 mg, 1.7 mmol) was added dropwise over a period of 5 min. with stirring in air. The mixture was stirred for another 5 h. The green solid that precipitated was collected by filtration, washed thoroughly with methanol and dried in vacuum over anhydrous $CaCl_2$. Yield, 500 mg (75%). *Anal*. Calc. for $C_{19}H_{17}N_4O_2Ni$: C, 58.21; H, 4.37; N, 14.29. Found: C, 57.85; H, 4.25; N, 14.07%. ESI mass spectrum: highest m/z at 392 ($[M]^+$). Selected IR bands (cm^{-1}): 1632(m), 1597(m), 1539(w), 1472(s), 1412(s), 1379(s), 1279(m), 1215(w), 1171(m), 1117(w), 1086(s), 1009(s), 920(s),

880(s), 787(m), 731(m), 698(s), 534(w). Electronic spectral data in CH_2Cl_2 (λ (nm) (ε ($M^{-1}\,cm^{-1}$))): 772 (130), 644 (640), 595sh (330), 439 (4 600), 372sh (4 580), 346 (5 860), 267 (9 440). μ_{eff} (μ_B) at 300 K: 1.71.

2.5. Synthesis of [Ni(bbhacO)]

[Ni(bbhac)] (100 mg, 0.25 mmol) was dissolved in 25 ml of dichloromethane–acetonitrile (1:1) mixture and left in air at room temperature for slow evaporation. The initial green colour of the solution slowly became brown and in about 4–5 days a brown crystalline solid separated. The complex was collected by filtration and dried in air. Yield, 30 mg (29%). A single crystal suitable for X-ray structure determination was selected from this material. *Anal*. Calc. for $NiC_{19}H_{16}N_4O_3$: C, 56.06; H, 3.96; N, 13.76. Found: C, 55.84; H, 3.73; N, 13.51%. Selected IR bands (cm^{-1}): 1649(m), 1591(m), 1541(s), 1491(m), 1443(w), 1368(s), 1242(w), 1208(w), 1169(m), 1138(w), 1067(w), 1026(m), 955(w), 924(w), 870(w), 787(w), 700(s), 599(m), 474(w). ^1H NMR (200 MHz) data in $(CD_3)_2SO$ (δ): 2.35 (s, 3H, CH_3); 7.46 (m, 3H, phenyl); 7.93 (m, 2H, phenyl). Electronic spectral data in CH_3CN (λ (nm) (ε ($M^{-1}\,cm^{-1}$))): 577sh (95), 398sh (3 670), 364 (6 830), 269 (7 330), 223 (8 100).

2.6. X-ray crystallography

For each of the two compounds, bzpyzn and [Ni(bbhacO)], the crystal was mounted at the end of a glass fibre and covered with a thin layer of epoxy. The data were collected on an Enraf-Nonius Mach-3 single crystal diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by the ω-scan method. Unit cell parameters of bzpyzn and [Ni(bbhacO)] were determined by the least-squares fit of 25 reflections having 2θ values in the range 18°–22° and 19°–29°, respectively. In each case, the stability of the crystal was monitored by measuring the intensities of three check reflections after every 1.5 h during the data collection. No decay was observed in either case. An empirical absorption correction was applied to the data of [Ni(bbhacO)] based on the ψ-scans of three reflections. The compounds bzpyzn and [Ni(bbhacO)] crystallize in *Pbca* and $P\bar{1}$ space groups, respectively. The structures were solved by using direct methods and refined by full-matrix least-squares procedures on F^2. In each case, the asymmetric unit contains a single molecule of the compound. For both structures all the non-hydrogen atoms were refined using anisotropic thermal parameters. The hydrogen atoms were included at calculated positions by using a riding model and were used for the structure factor calculation, but were not refined. Calculations were done using the programs of WINGX [17] for data reduction and absorption correction, and SHELX-97 programs [18] for structure solution and refinement. The ORTEX6a [19] and PLATON [20] packages were used for molecular graphics. Significant crystal data are summarized in Table 1.

Table 1
Crystallographic data for bzpyzn and [Ni(bbhacO)]

Compound	bzpyzn	[Ni(bbhacO)]
Chemical formula	$C_{19}H_{20}N_4O_2$	$C_{19}H_{16}N_4O_3Ni$

3. Results and discussion

3.1. Synthesis and characterization of bzpyzn

Reaction of 1 mol equivalent of acetylacetone with 2 mol equivalents of benzoylhydrazine in methanol produced a white product in good yield. The elemental analysis data for this compound are consistent with the formula $C_{19}H_{20}N_4O_2$ for the desired acetylacetone bis(benzoylhydrazone) (H_3bbhac). However, as it is known that this type of reaction leads to cyclized 3,5-substituted pyrazolines [12–14], we have determined the molecular structure of bzpyzn by single crystal X-ray crystallography. The structure obtained confirms the cyclization reaction and formation of the pyrazoline derivative (Fig. 1). Selected bond parameters are listed in Table 2. The intramolecular bond distances are comparable to other similar structurally characterized compounds [13,14,21,22]. In the solid state, a one-dimensional assembly of the bzpyzn molecules is formed via intermolecular hydrogen bonding (Fig. 2). The oxygen atom (O2) of the benzoyl group attached to N3 and one of the hydrazide protons of the benzoylhydrazide group attached to C3 (Fig. 1) are involved in the hydrogen bonding. The N1···O2 distance and N1–H···O2 angle are 2.871(2) Å and 160.0(2)°, respectively.

The infrared spectrum of bzpyzn shows a strong peak at 3277 cm^{-1}, possibly due to the N–H groups [23]. Two

strong peaks observed at 1659 and 1605 cm^{-1} are assigned to the C=O and C=N stretches, respectively [22,23]. The electronic spectrum of bzpyzn in methanol solution displays three strong absorptions in the range 322–225 nm. The proton NMR spectrum of bzpyzn in $CDCl_3$ solution is consistent with the pyrazoline structure. The 5-methyl and 3-methyl protons appear as singlets at 1.88 and 1.98 δ, respectively. As observed in other similar compounds [12–14,22], the methylene group protons of bzpyzn are diastereotopic and observed as an AB type quartet centred at 3.06 δ. Each of the two N–H group protons appear as a singlet. They are observed at 5.30 and 8.27 δ. The aromatic protons appear as two multiplets centred at 7.44 and 7.78 δ.

3.2. Formation of [Ni(bbhac)] by ring opening of bzpyzn

Under aerobic conditions, reaction of 1 mol equivalent of bzpyzn with 1 mol equivalent of $Ni(O_2CCH_3)\cdot 4H_2O$ in methanol results in the formation of a green solid. In the infrared spectrum of this green solid there is no peak near 3300 cm^{-1} attributable to an N–H group. The strong peak at 1659 cm^{-1} displayed by free bzpyzn, due to the C=O stretch, is also absent. The non-appearance of the N–H and C=O stretches is consistent with the ring opening of bzpyzn and complexation of the metal ion by the tetradentate N_2O_2 donor $Hbbhac^{2-}$ (H represents the active methylene proton) or $bbhac^{3-}$. Two medium intensity peaks observed at 1632 and 1597 cm^{-1} are most likely due to the deprotonated O-coordinating amide functionalities and the C=N moieties of the tetradentate ligand [6–11,24]. The complex is electrically non-conducting in CH_2Cl_2 solution. The elemental analysis data are consistent with the formula [Ni(bbhac)]. It has been reported that in the presence of oxygen or iodine, oxidative C–C coupling involving the central C-atom of the acetylacetone residue in complexes with similar tetradentate Schiff bases leads to dinuclear species [25–27]. Although [Ni(bbhac)] has been isolated in the presence of air, the ESI mass spectral data indicates that the complex is mononuclear. Furthermore, oxidation of the –CH= moiety of the acetylacetone residue to a keto group and the formation of [Ni(bbhacO)] (vide infra) also supports the mononuclear nature of [Ni(bbhac)]. The electronic spectrum

of the complex in CH_2Cl_2 solution displays several absorptions in the range 772–267 nm. The three weak absorptions at 772, 644 and 595 nm are most likely due to d–d transitions [28]. The remaining intense bands are likely to be due to ligand-to-metal charge transfer and intra-ligand transitions.

The solid state magnetic moment (1.71 μ_B) of [Ni(bbhac)] at 300 K indicates an $S = 1/2$ spin state. A non-innocent nature of the ligands in complexes with tetradentate Schiff bases derived from acetylacetone has been noted before [25–27]. Thus, to resolve the ambiguity between an authentic nickel(III) complex and a nickel(II) stabilized ligand radical system we have examined the EPR spectral features of [Ni(bbhac)] (Fig. 3). At room temperature (300 K) in the powdered phase the complex displays an isotropic signal centred at $g = 2.01$. The peak-to-peak width for this signal is 70 G. At low temperature (115 K) this signal becomes rhombic and the corresponding g values are 2.02, 2.01 and 1.98. Like the solid sample, a dichloromethane solution of the complex at room temperature also displays a similar isotropic signal at $g = 2.01$. However, the peak-to-peak width (17 G) for this signal is significantly smaller compared to that in the solid state spectrum (Fig. 3). The spectrum of the complex in frozen (115 K) dichloromethane solution is again rhombic in character (g values are 2.02, 2.01 and 1.98). However, in this spectrum the lowest field signal is well resolved and the highest field signal is significantly broadened compared to the corresponding signals observed in the spectrum obtained from the solid sample of the complex at the same temperature (Fig. 3). The observed g values are very close to those for a nickel(II) stabilized ligand radical species [29–31]. However, the peak-to-peak width for the isotropic signal observed at room temperature in the solid state spectrum is rather large for a ligand radical system [31]. Although the room temperature isotropic signal displayed by the dichloromethane solution of [Ni(bbhac)] is sufficiently narrow, it is devoid of any nitrogen hyperfine structure to suggest a ligand radical system. In addition, at low temperature both solid state and frozen solution spectra are rhombic in character. Such rhombic spectra are not unusual for square-planar nickel(III) complexes, due to distortion from the square-planar geometry or weak coordination at the apical site [32,33]. Considering all the EPR features it is difficult to describe [Ni(bbhac)] as a genuine nickel(III) species or a nickel(II) stabilized ligand radical system. Thus the best description for [Ni(bbhac)] may perhaps be that it is border-line between the two possible situations. However, the typical rhombic nature of both low temperature solid state and frozen solution spectra suggests that [Ni(bbhac)] may be slightly biased towards the nickel(III) side.

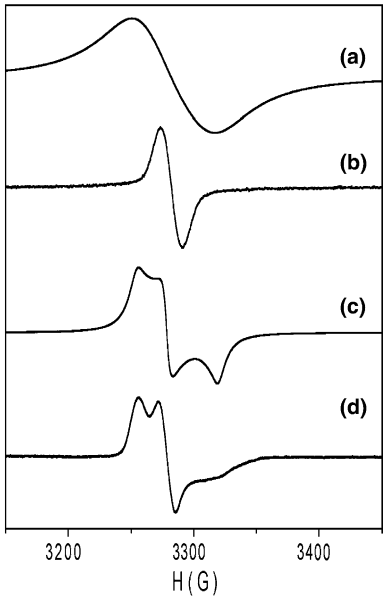

Fig. 3. EPR spectra of [Ni(bbhac)]: (a) in powder phase at 300 K; (b) in dichloromethane solution at 300 K; (c) in powder phase at 115 K; (d) in frozen (115 K) dichloromethane solution.

3.3. Isolation and characterization of [Ni(bbhacO)]

Slow evaporation of a green dichloromethane–acetonitrile (1:1) solution of [Ni(bbhac)] in air produces a brown crystalline substance. However, if the same procedure is performed using dry solvents under moisture free atmosphere in the presence or absence of oxygen, the unchanged [Ni(bbhac)] is recovered as a green amorphous material. Interestingly [Ni(bbhac)] also remains unchanged in wet solvent under dinitrogen atmosphere. Thus, the brown complex is formed in the presence of both water and oxygen. Solid state magnetic susceptibility measurements with this brown crystalline substance indicate the diamagnetic character of this material. In acetonitrile solution, this new species is electrically non-conducting. Thus the brown complex is most likely a neutral square-planar nickel(II) complex. In the electronic spectrum, the complex displays a weak absorption at ~577 nm. This absorption has been assigned to the spin-allowed d–d transition ($^1A_{1g} \rightarrow {}^1A_{2g}$). Four more absorptions observed in the range 398–223 nm are possibly due to ligand-to-metal charge transfer and intra-ligand transitions. The proton NMR spectrum of the complex displays only three signals. The singlet observed at 2.35 δ, corresponding to three protons, has been assigned to the methyl group. The multiplets centred at 7.46 and 7.93 δ correspond to three and two protons, respectively. These signals are assigned to the phenyl ring protons. Observation of only one methyl group and one phenyl ring in the NMR spectrum suggests that both halves of the tetradentate ligand in the complex are magnetically equivalent, at least on an NMR time-scale. There is no signal assignable to

methylene or N–H groups. The infrared spectrum of the solid also does not display any peak that could be associated with the N–H group. The absence of an N–H group indicates deprotonation of the amide functionalities in the ligand. However, one medium intensity peak observed at 1649 cm^{-1} is very likely to be due to a C=O group. The origin of another medium intensity peak at 1591 cm^{-1} is most likely the C=N moieties of the ligand. As mentioned before, under aerobic conditions square-planar bivalent 3d metal ion complexes of the formula [ML] (H_2L = acetylacetone bis(thiosemicarbazone)), the central methylene of the acetylacetone residue of L^{2-} gets oxidized and a keto group is formed [14,15]. The infrared spectrum and other physical properties indicate that the brown material obtained from [Ni(bbhac)] is possibly a similar square-planar nickel(II) complex with the oxidized ligand $bbhacO^{2-}$.

We have determined the X-ray structure of the brown complex to confirm the above conjecture. The structure reveals that indeed the middle C-atom of the acetylacetone residue has been oxidized with the formation of a keto group (Fig. 4). The molecule is a square-planar nickel(II) species having a tetradentate dianionic ligand ($bbhacO^{2-}$). Selected bond parameters are listed in Table 3. Intra-ligand bond distances and angles are unexceptional and consistent with the deprotonation of both amide functionalities and C9–O3 being a keto group [6–11,22,34,35]. The ligand binds the metal ion via two amide-O atoms and two imine-N atoms providing an N_2O_2 square-plane around the metal ion. In this process, it forms two five- and one six-membered chelate ring. The chelate bite angles for the five membered rings are essentially identical (84.77(9)° and 84.69(9)°), and are smaller than that (97.40(10)°) of the six-membered ring. There is no displacement of the nickel(II) centre from the N_2O_2 square plane. The maximum deviation from the mean plane formed by NiN_2O_2 is 0.0055(11) Å for O1 (Fig. 4). However, the molecule as a whole is not perfectly planar. The two phenyl ring planes are slightly tilted from the mean plane constituted by the rest of the molecule. The dihedral angles thus formed are very similar (7.43(15)° and 7.17(14)°). The angle between the two phenyl ring planes is 10.96(18)°. The Ni–N(imine) distances (1.836(2) and 1.841(2) Å) are very similar. The same is true for the Ni–O(amide) distances (1.8418(19) and 1.8479(19) Å). These distances are comparable with the distances observed for square-planar nickel(II) complexes having imine-N or deprotonated amide-O coordinating atoms [22,26,27,34,35].

[Ni(bbhacO)] does not have any good conventional hydrogen bond donor. However, intermolecular C–H···π interactions [11,36–38] lead to the self-assembly of [Ni(bbhacO)] molecules into a one-dimensional array in

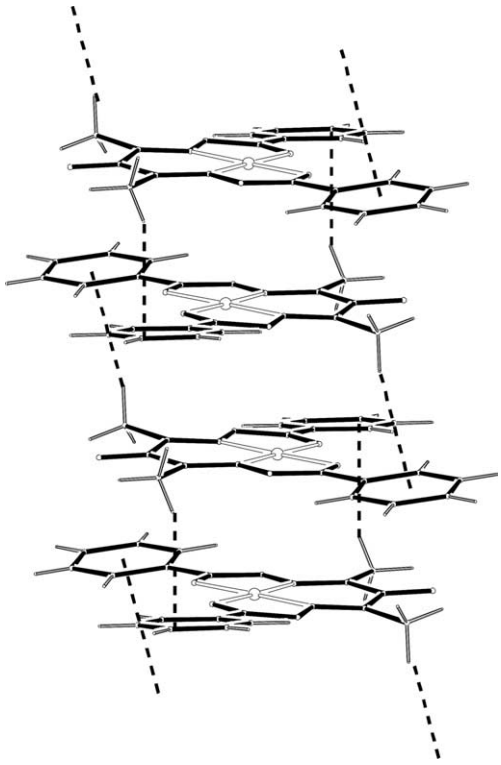

Fig. 5. One-dimensional ordering of the [Ni(bbhacO)] molecules via C–H···π interactions.

the crystal lattice. In this one-dimensional arrangement, two methyl group C–Hs of each molecule are interacting with the phenyl rings of the two adjacent molecules in a reciprocal manner (Fig. 5). Thus, both methyl groups and both phenyl rings of every molecule are involved in these interactions. The H···centroid (cg) distances are 2.801 and 2.952 Å for C18–H···cg (of C12–C17 ring) and C19–H···cg (of C1–C6 ring) interactions, respectively. The corresponding C–H···cg angles are 137.2° and 125.4°, respectively. The Ni···Ni distance for the pair of molecules involved in C18–H···cg interactions is 4.142 Å and that for the pair of molecules involved in C19–H···cg interactions is 3.586 Å . The differences in the structural parameters associated with the two C–H···π interactions and the tilted nature of the two phenyl rings compared to the rest of the molecule (vide supra) are possibly responsible for the alternating short and long Ni···Ni distances in the chain-like arrangement of the metal ions.

4. Conclusion

Our objective was to study the nickel coordination chemistry with the Schiff base acetylacetone bis(benzoylhydrazone) (H_3bbhac) containing two higher oxidation state promoting amide functionalities. In our attempt to prepare this Schiff base from acetylacetone and benzoylhydrazine, we have isolated a new substituted pyrazoline. Treatment of this pyrazoline with nickel acetate tetrahydrate leads to metal ion assisted pyrazoline ring opening and the formation of a neutral complex of the formula [Ni(bbhac)], having the intended ligand. The molecular formula and the magnetic moment of [Ni(bbhac)] are consistent with the +3 formal oxidation state of the metal ion in this complex. However, the EPR spectral characteristics of this complex indicate a border-line situation between a nickel(III) species and a nickel(II) stabilized ligand radical species. In wet dichloromethane–acetonitrile solution, the –CH═ moiety of the ligand in [Ni(bbhac)] gets oxidized to –C(═O)– and a square-planar nickel(II) complex of the formula [Ni(bbhacO)] is formed. Considering the border-line nature of [Ni(bbhac)] and the need of moisture for this transformation to take place, a possible mechanism for this oxidation could be as follows: shift of the unpaired electron from the nitrogen atom to the methine carbon of the ligand, followed by homolytic cleavage of the C–H bond and addition of water to form –CH(OH)–, and finally a $2e^-$, $2H^+$ oxidation to the keto group by oxygen. Similar mechanisms have been suggested for platinum(IV) and Ru(III) assisted conversion of a methine group to a keto group in guanine [39,40].

Although the oxidation of the methylene group to a keto group for the complexes [ML] of the deprotonated acetylacetone bis(thiosemicarbazone) (H_2L) in the presence of oxygen has been observed before [14,15], nothing has been reported about the nature of the intermediate involved during the formation of [MLO] from [ML]. In this work, we have been able to isolate and establish the nature of this intermediate which provides us with some clues about the possible pathways for the transformation to the final complex of the oxidized ligand. We are currently investigating the chemistry of other transition metal ions with the same ligand and those prepared from 3-substituted 2,4-pentanediones for a better understanding of the intricacies involved in this ligand oxidation process.

5. Supplementary material

Crystallographic data have been deposited with the Cambridge Crystallographic Data centre (deposition numbers are CCDC-233762 and CCDC-233763 for bzpyzn and [Ni(bbhacO)], respectively). Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1233-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The X-ray structure of a new paramagnetic $[ReCl_3(pzH)_3]$ complex (pzH = pyrazole) has been determined and its geometric parameters have been examined using the density functional theory (DFT) method. The UV–Vis spectrum of the complex has been discussed on the basis of the electronic transitions of $[ReCl_3(pzH)_3]$ calculated with the time-dependent DFT method (TDDFT).

1. Introduction

Pyrazole and its derivatives possess two adjacent nucleophilic sites and their steric and electronic properties can be modified by the substituents of the heterocyclic ring. They (i) can act as monodentate, *exo*- or even *endo*-bidentate anionic ligands, (ii) can afford oligomers of different nuclearities depending on the used synthesis methods and (iii) have been shown to possess a rather wide conformational variability [1–4].

Previously, we investigated the reactivity of oxorhenium(V) species – $[ReO(OEt)X_2(PPh_3)_2]$, $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)(OAsPh_3)]$ (X = Cl or Br) – towards pyrazole (pzH) and 3,5-dimethylpyrazole (3,5-Me_2pzH) under different reaction conditions. The products of these syntheses include (i) mononuclear $[ReOX_2\{\eta^2\text{-}N_2C_3H_3C(CH_3)_2O\}(PPh_3)]$ complexes with the $C_3H_3N_2C(CH_3)_2O^-$ anion obtained in the addition reaction of pyrazole and acetone, and (ii) dinuclear Re(V) compounds of the types $[\{Re(O)X(PPh_3)\}_2(\mu\text{-}O)(\mu\text{-}pz)_2]$, $[\{Re(O)X_2(3,5\text{-}Me_2pzH)_2\}_2(\mu\text{-}O)]$, $[\{Re(O)Br(3,5\text{-}Me_2pzH)\}_2(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2]$, $[\{Re(O)X(PPh_3)\}_2(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2]$ and $[\{Re(O)X(PPh_3)\}(\mu\text{-}O)(\mu\text{-}3,5\text{-}Me_2pz)_2\{Re(O)X(3,5\text{-}Me_2pzH)\}]$(X = Cl or Br) [5,6].

Here, we report the synthesis and X-ray structure of $[ReCl_3(pzH)_3]$ complex (**1**) and the results of DFT calculations for **1**, based on B3LYP theory, carried out by using the GAUSSIAN 03 program package. The UV–Vis spectrum of the title complex is discussed based on the electronic transitions of **1**, calculated using the time-dependent DFT method (TDDFT).

Reports of $[ReX_3L_3]$ rhenium complexes with monodentate N-donor ligands (L) are restricted, and the only structurally characterized complexes of this type appear to be *mer*-$[ReFI_2(py)_3]$ [7], *mer*-$[ReCl_3(py)_3]$, *mer*-$[ReBr_3(py)_3]$ [8] and *mer*-$[ReCl_3(3,5\text{-lut})_3]$ [9].

2. Experimental

2.1. General procedure

The reaction was carried out under argon atmosphere. All solvents were of reagent grade and were used as received. Ammonium perrhenate, Ph_3P and pyrazole (pzH) were purchased from Aldrich and used as

doi:10.1016/j.poly.2004.05.003

received. The $[ReOCl_3(PPh_3)_2]$ complex was prepared according to the literature method [10].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 800–220 nm in deoxygenated dichloromethane solution. Magnetic susceptibilities were measured at 296 K by the Faraday method. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReCl_3(pzH)_3]\cdot H_2O\cdot HCl$ ($\mathbf{1}\cdot H_2O\cdot HCl$)

$[ReOCl_3(PPh_3)_2]$ (1 g, 1.20 mmol) and pzH (0.54 g, 8 mmol) in benzene (100 cm^3) were refluxed overnight. The color of the reaction mixture changed quickly from yellow-green to dark brown. The volume was condensed to 10 cm^3 and a reddish-brown microcrystalline solid was formed on addition of 100 cm^3 of diethyl ether. The product was washed with EtOH and cold ether, and dried in vacuo. Crystals of $\mathbf{1}\cdot H_2O\cdot HCl$ suitable for X-ray investigation were obtained by recrystallization from $CHCl_3$–EtOH. Yield: 55%.

IR (KBr, cm^{-1}) 3406 (m), 3341 (m), 3142 (s), 1618 (w, br), 1513 (w), 1490 (m), 1470 (m), 1405 (m), 1348 (m), 1327 (m), 1265 (m), 1241 (w), 1125 (s), 1106 (s), 1086 (m), 1052 (vs), 910 (m), 783 (s), 702 (w), 603 (m). Calc. for $C_9H_{15}N_6Cl_4ORe$: C, 19.61; H, 2.74; N, 15.24. Found: C, 19.73; H, 2.6; N, 15.30%.

2.3. Crystal structure determination and refinement

The X-ray intensity data of $\mathbf{1}\cdot H_2O\cdot HCl$ were collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector with 21 s exposure time, and a half of the Ewald sphere was collected. The unit cell parameters were determined from least-squares refinement of the setting angles of the 5023 strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [11] were applied. The structure was solved by means of the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using a full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as "riding" on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent carbon atom. SHELXS-97 [12], SHELXL-97 [13] and SHELXTL [14] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

Table 1
Crystal data and structure refinement for $\mathbf{1}\cdot H_2O\cdot HCl$

Empirical formula	$C_9H_{15}Cl_4N_6ORe$

Largest difference peak and hole (e Å^{-3})	1.508 and −1.387

2.4. Computational details

The GAUSSIAN 03 program [15] was used in the calculations. The geometry optimization was carried out using the DFT method with the use of the B3LYP functional [16,17]. The electronic spectrum was calculated with the TDDFT method [18]. The LANL2DZ basis set [19] was used on the rhenium atom, 6-31G(d) on the chlorine, nitrogen and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations.

3. Results and discussion

Refluxing the $[ReOCl_3(PPh_3)_2]$ complex with an excess of pzH in wet benzene under argon atmosphere leads to the isolation of the mononuclear $\mathbf{1}\cdot H_2O\cdot HCl$ complex. The well-known capacity of PPh_3 to interact with the Re≡O bond in rhenium(V) oxo-complexes explains the course of the reaction between $[ReOCl_3(PPh_3)_2]$ and pyrazole:

$$[ReOCl_3(PPh_3)_2] + 3N_2C_3H_4 \rightarrow [ReCl_3(pzH)_3] + PPh_3 + OPPh_3$$

3.1. Geometry and charge distribution

Complex **1** crystallizes as the solvate $\mathbf{1}\cdot H_2O\cdot HCl$. A perspective drawing of $\mathbf{1}\cdot H_2O\cdot HCl$ is shown in Fig. 1. The two groups of ligands of **1** (halide ions and pyrazole molecules) are arranged in a *meridional* fashion and the departure from the ideal octahedron is very limited. Table 1 presents crystal data and structural refinement for **1**. The most important experimental bond lengths and angles for compound **1** are reported in Table 2. The Re–N bond lengths of **1** are similar to those of [{$ReOCl_2py_2$}$_2$(μ-O)] and [{$ReOCl_2$(3,5-Me_2pzH)$_2$}$_2$(μ-O)] [20,21], and the bond distances and angles in the pyrazole rings are in good agreement with expected values [22,23].

The structure of $\mathbf{1}\cdot H_2O\cdot HCl$ is assembled via strong N–H···Cl, N–H···O, Cl–H···O, O–H···N, O–H···Cl and weak C–H···Cl [24–26] intermolecular hydrogen bonds (Table 3) into a three-dimensional network. Three pairs of intermolecular hydrogen bonds: Cl(99)–H99···O(99# $-x,-y,-z+1$), O(99)–H99B···Cl(99# $-x,-y,-z+1$); N(4)–H(4N)···O(99), O(99)–H(99A)···N(4) and Cl(99)–H(99)···O(99# $x-1,y+1,z$), O(99)–H99A···Cl(99# $x+1,y-1,z$) can be considered as double hydrogen bonds [25]. This causes the existence of three relatively short intermolecular contacts H(99)···H(99A) – 2.07 Å, H(4N)···H(99A) – 1.54 Å and H99···H99B – 1.36 Å. In the title compound strong N–H···Cl and weak C–H···Cl intramolecular hydrogen bonds can be also found (Table 3), which provides additional stabilization to the molecule conformation. In this way five-membered rings in spiro arrangement are created.

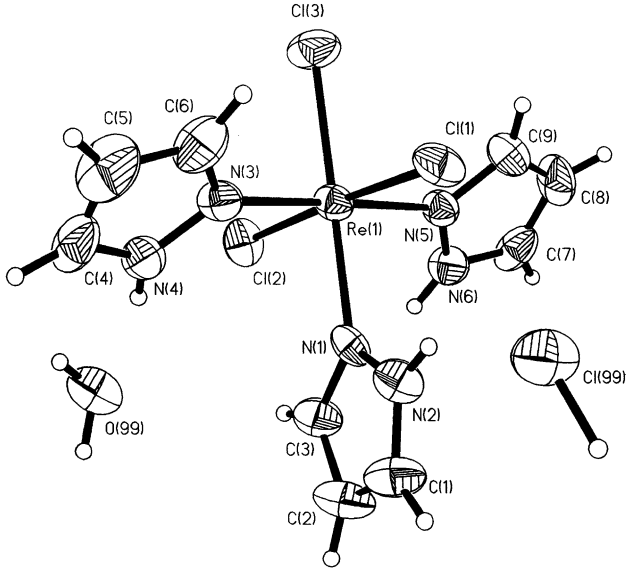

Fig. 1. The molecular structure of $\mathbf{1}\cdot H_2O\cdot HCl$.

3.2. Infrared data

The presence of strong bands in the range assignable to N–H vibrations in the spectrum of **1** confirms the coordination of pyrazoles in the neutral monodentate form. The characteristic bands of the C=C and C=N stretching modes, observed at 1640 and 1558 cm^{-1} in uncomplexed pyrazole, are shifted to considerable lower frequencies, which is consistent with the somewhat

longer C=C and C=N bonds in these complexes compared with the same distances in the uncomplexed ligand [27].

3.3. Magnetochemical measurements

Complex **1** shows a room temperature magnetic moment of 1.8 BM. This value is characteristic of mononuclear complexes with low-spin rhenium(III) (d^4) ions in an O_h field [28], and arises because of the large spin–orbit coupling ($\xi = 2500\ cm^{-1}$) [29]. A similar deviation from the expected value (2.8 BM) has been found for $[ReX_2(pymS)(PPh_3)]$ (X = Cl, Br, I) [30,31], $[ReCl_3(NCR)(PPh_3)_2]$ (R = Me, Et, Ph), $[ReCl_3(NCR)(P(p\text{-tol})_3)]$ (R = Me, Et) [32] and $[ReCl_3(\eta^3\text{-}N,N,P\text{–}N\{CH_2CH_2PPh_2\}_2\{CH_2CH_2P(O)Ph_2\})]$ [33].

3.4. The optimized geometry and molecular orbitals of *1*

The geometry of **1** was optimized in triplet and singlet states using the DFT method with the B3LYP functional, but the singlet state could not be converged. Because of that only the triplet state has been calculated, but other calculations show that the B3LYP method gives the proper ordering of spin states of rhenium complexes [34]. The optimized bond lengths and angles for **1** are presented in Table 2. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data. The largest differences between the experimental and optimized values may be noticed for Re–Cl distances in *trans* positions to each other (~0.2 Å). The elongation of the rhenium–chlorine bond lengths (up to 0.25 Å) in the B3LYP with different basis sets has been found in other rhenium–chlorine complexes [35]. The optimized length of the Re–Cl *trans* to pyrazole is in good agreement with the experimental data. The differences in the calculated and experimental Re–Cl(1,2) bonds lengths can be explained by strong hydrogen bonding involving Cl(1) and Cl(2) atoms. In the experimental structure the transfer of electron density between the hydrogen bond acceptor and donor causes its local deficiency on the chlorine atoms and thus these atoms are closer to the rhenium atom. The atomic charges calculated with the DFT method presented in Table 4 also confirm the stronger delocalizaton of the electron density of Cl(3) in comparison with Cl(2) and Cl(1) ligands.

Table 5

LUMO + 8	1.566	d_{x2-y2}–σ_{pzH}–σ_{Cl}	1.470	π*(pzH)
LUMO + 9	1.698	π*(pzH)	1.497	π*(pzH)

3.5. Molecular orbitals

The energies and characters of the selected MOs for **1** are presented in Table 5. The following orientation of the axes has been used for determination of the MO characters: the *z* axis goes along the Cl(1)–Re–Cl(2) linkage and *x* goes through the N(3)–Re–N(5) bonds. Several HOMOs and LUMOs of **1** with α and β spins are depicted in Fig. 2. The rhenium d_π atomic orbital (d_{xz}, d_{yz} and d_{xy}) and π orbitals of the chlorine ligands, in anti-bonding arrangement, make the main contributions into the HOMO-2, HOMO-1 and HOMO with α-spin and HOMO, LUMO and LUMO + 1 with β-spin. The α LUMO orbital has predominantly π^*(pzH) character. The LUMO + 3 with α-spin and the LUMO + 5 with β-spin are antibonding orbitals of d_{z2}–σ_{Cl} character. The LUMO + 6 with α-spin is the antibonding orbital of $d_{x^2-y^2}$–σ_{Cl}–σ_{pzH} character.

3.6. Electronic spectrum from the TDDFT calculations

The electronic absorption spectrum of **1** is typical of mononuclear rhenium(III) complexes [30,31]. The solution spectrum of **1** exhibits two intense absorption bands at 269 and 226 nm and some weaker absorptions in the low energy range 520–380 nm.

Considering the significant elongation of the Re–Cl distances in *trans* positions to each other, the spin-allowed triplet–triplet electronic transitions of **1** were calculated with the TDDFT method using the experimental data. The assignment of the calculated transitions to the experimental absorption bands was based on the criterion of the energy and oscillator strength of the calculated transition. Due to the complex character of the MOs of **1**, only the main contributions were taken into consideration for the discussion of the electronic transitions. The assignments of the calculated transitions to the experimental absorption bands are presented in Table 6.

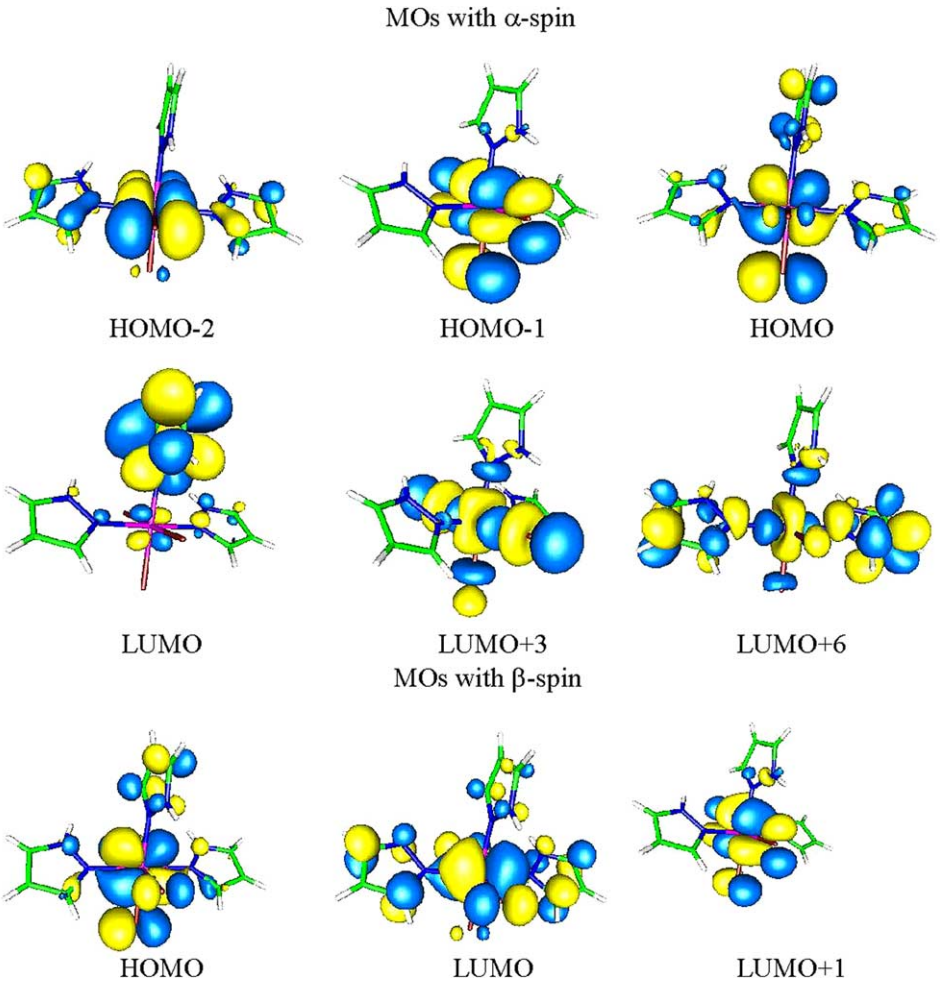

Fig. 2. The selected HOMO and LUMO orbitals with α and β spins for **1**. Positive values of the orbital contour are represented in blue (0.03 a.u.) and negative values in yellow (−0.03 a.u.). (For interpretation of the references to color in this figure legend, the reader is referred to web version of this article.)

$H-5(\pi_{pzH}) \rightarrow L+2(\pi^*_{pzH})$	$H-3(\pi_{pzH}) \rightarrow L+2(\pi^*_{pzH})$				

The experimental bands at 518 and 465 nm are attributed to the calculated transitions at 475.1 and 439.2 nm, respectively. The experimental band at 412.9 nm is assigned to the calculated transitions at 394.2, 377.0 and 375.8 nm. All these transitions have MLCT ($d \rightarrow \pi^*_{pzH}$) character with a small contribution of d–d electronic transitions.

The absorption band at 391.0 nm can be assigned to the calculated transitions in the range 365–328 nm. They have MLCT ($d \rightarrow \pi^*_{pzH}$) and LMCT ($\pi_{Cl} \rightarrow d$) character.

The experimental band at 268.8 nm with $\varepsilon = 2250$ is ascribed to the calculated transitions with large oscillator strengths at 288 and 278 nm of LMCT ($\pi_{pzH} \rightarrow d$ and $\pi_{Cl} \rightarrow d$) character.

The absorption band at 224 nm is attributed to the calculated transition at 228.8 nm. This transition consists mainly of the $\pi \rightarrow \pi^*$ excitations in the pyrazole ligands (intra-ligand LL). We expect additional $\pi \rightarrow \pi^*$ transitions to be found in the calculation at higher energies, but it is outside the range of our calculated spectrum, and it is not of significant interest to the present work. The solution spectrum of pyrazole exhibits an intense absorption band at 231.6 nm, which supports this assignment.

4. Supplementary data

Supplementary data for $C_9H_{15}Cl_4N_6ORe$ are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number 224809.

Abstract

The complexes $[ML_2A_2]$ or $[ML_2B]$ where M = Pd or Pt, L = 5-phenyl-1,3,4-oxadiazole-2-thione ion, A = tertiary monophosphines and B = tertiary diphosphines have been used effectively to prepare bimetallic complexes of the type $[A_2M(\mu\text{-}L)_2M'Cl_2]$ or $[BM(\mu\text{-}L)_2M'Cl_2]$, where M′ = Co, Pd or $SnCl_2$. The prepared complexes were characterized by elemental analysis, magnetic susceptibility, IR and UV–Vis spectral data. $^{31}P\text{–}\{^1H\}$ NMR data have been applied to characterize the produced linkage isomers.

1. Introduction

The metal complexes of some heterocyclic thiones attract much attention. The interactions of heavy metals such as platinum and gold with N,S-donor atoms have been recognized for their anticancer properties with the potential to develop metal based drugs [1–6]. Recently, some research works involving platinum(II) and palladium(II) ions with 8-thiotheophylline and dppm to give homo- and heterobimetallic complexes have been published [7,8]. Other related works on platinum(II) or (IV) complexes with tertiary phosphines and ligands containing sulfur have been also published recently [9,10]. However, metal complexes containing bis-tertiary phosphines and heterocyclic-2-thiones are rare [11].

In our recent work [12,13], we reported the preparation of some palladium(II) and platinum(II) complexes containing mixed ligands; tertiary monophosphines or diphosphines and 5-phenyl-1,3,4-oxadiazole-2-thione (LH). We found that the tertiary monophosphines or diphosphines reacted with the chelated complexes of the above ligand (L) to give complexes in which L behaves as a monodentate ligand coordinated to the metal centre through either S, N or mixture of both (Fig. 1).

In the present work, we used the uncoordinated end of the ligand (L) in the complexes $[ML_2A_2]$ and $[ML_2B]$ to build up some new types of heterobimetallic complexes bridged by L, i.e., $[A_2M(\mu\text{-}L)_2M'Cl_2]$ and $[BM(\mu\text{-}L)_2M'Cl_2]$, where M = Pt or Pd; M′ = Co, Pd or $SnCl_2$; A = $PMePh_2$; B = $Ph_2P(CH_2)_nPPh_2$ {$n = 1$, dppm; $n = 2$, dppe; $n = 3$, dppp; $n = 4$, dppb} and L = 5-phenyl-1,3,4-oxadiazole-2-thione (–H) (Fig. 1). To the best of our knowledge, this work is novel.

2. Experimental

2.1. General

$^{31}P\text{–}\{^1H\}$ NMR spectra were performed in the laboratories of Prof. Dr. Wilhelm Keim, Insitute for Techische Chemie der RWTH Achen, Worringer Weg 1, D-52074 Achen, Germany. IR spectra were recorded on a PYE-Unicam SP3-300s spectrophotometer in the 200–4000 cm^{-1} range using CsI discs. Electronic spectra were

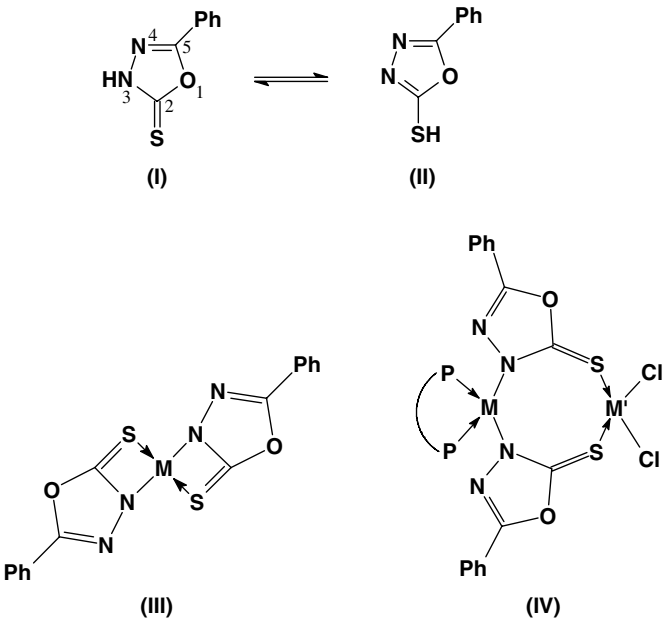

Fig. 1. The ligand 5-phenyl-1,3,4-oxidiazole-2-thione (LH), its tautomeric forms (I) and (II) and the suggested structure of its bis(chelated) complexes (III) and the bridging bimetallic complexes (IV), M = Pd or Pt, M′ = Co, Pd or $SnCl_2$, P···P = 2PMePh$_2$, dppm, dppe, dppp or dppb.

obtained using a Perkin–Elmer lambda 9 spectrophotometer. Elemental analyses were carried out on a CHN Analyzer, type 1106 (Carlo Erba). Magnetic measurements were recorded on a Bruker BH6 instrument at room temperature following the Faraday method. Conductivity measurements were made on a conductivity meter type CDM 83 70. Melting points were measured on an Electrothermal 9300 melting point apparatus.

2.2. Starting materials

The compounds K_2PtCl_4, $Na_2PdCl_4 \cdot 3H_2O$, $PdCl_2$, $CoCl_2$, $SnCl_4 \cdot 5H_2O$, $PMePh_2$, dppm, dppe, dppp and dppb were commercial products and used as supplied. The ligand 5-phenyl-1,3,4-oxadiazole-2-thione (LH) its potassium salt (LK) [14], *trans*-[$PdCl_2$ $(DMSO)_2$], *cis*-[$PtCl_2(DMSO)_2$] [15], [PdL_2]$\cdot H_2O$, [PtL_2], [PdL_2 (dppm)]$\cdot H_2O$, [PtL_2(dppm)], [PdL_2(dppe)], [PtL_2(dppe)] [12], [$PdL_2(PMePh_2)_2$] and [$PtL_2(PMePh_2)_2$] [13] were prepared according to the literature.

2.3. [PdL_2(dppp)] (**4**) and [PdL_2(dppb)] (**5**)

These complexes were prepared by a method similar to that reported for the preparation of [PdL_2-(dppm)]$\cdot H_2O$ [12].

2.4. [PtL_2(dppp)] (**9**) and [PtL_2(dppb)] (**10**)

These complexes were prepared by a method similar to that reported for the preparation of [PtL_2(dppm)] [12].

2.5. [$(PMePh_2)_2Pd(\mu$- L)$_2CoCl_2$]$\cdot 2H_2O$ (**11**)

Solid $CoCl_2$ (0.05 g, 0.38 mmol) was added to a solution of [$PdL_2(PMePh_2)_2$] (0.15 g, 0.17 mmol) in chloroform (15 ml). The yellow solution turned green. The mixture was stirred at room temperature for ca. 10 h. The unreacted $CoCl_2$ was removed by filtration and the green filtrate was evaporated to dryness. Diethylether was added and the green solid was filtered off and dried under vacuum (yield, 0.13 g, 75%).

The following complexes were prepared and isolated by a similar method: **13**, **17**, **20**, **23**, **25**, **28** and **31**.

2.6. [$(PMePh_2)_2Pd(\mu$-L)$_2PdCl_2$] (**12**)

Solid *trans*-[$PdCl_2(DMSO)_2$] (0.13 g, 0.38 mmol) was added with stirring to a solution of [$PdL_2(PMePh_2)_2$] (0.2 g, 0.23 mmol) in chloroform (15 ml). The mixture was stirred at room temperature for ca. 8 h, then filtered. The filtrate was evaporated to dryness and diethylether was added. The orange–brown solid thus formed was filtered off and dried in vacuum (yield, 0.23 g, 95%).

The following complexes were prepared and isolated by a similar method: **15**, **18**, **21**, **24**, **26**, **29** and **32**.

2.7. [$(PMePh_2)_2Pd(\mu$-L)$_2SnCl_4$] (**13**)

Solid $SnCl_4 \cdot 5H_2O$ (0.07 g, 0.22 mmol) was added with stirring to a clear yellow solution of [$PdL_2(PMePh_2)_2$] (0.14 g, 0.16 mmol) in chloroform (12 ml). The mixture was stirred at room temperature for ca. 10 h, then filtered. The filtrate was evaporated to dryness

and diethylether was added. The resulting yellow solid was filtered off and dried in vacuum (yield, 0.13 g, 71%).

The following complexes were prepared and isolated by a similar method: **16**, **19**, **22**, **27**, **30** and **33**.

3. Results and discussion

3.1. Synthesis of the complexes

We reported previously that the reaction of *cis*-$[PtCl_2(B)]$ {B = $Ph_2P(CH_2)PPh_2$ (dppm) and $Ph_2P(CH_2)_2PPh_2$ (dppe)} with the potassium salt of the ligand 5-phenyl-1,3,4-oxadiazole-2-thione (LK) or the reaction of *trans*-$[PtL_2]$ with dppm or dppe gave complexes of the type $[PtL_2(B)]$ which was a single linkage isomer when B = dppm [12]. From the *J*(Pt–P) value (2714 Hz), we believed that this was the S-bonded isomer. When B = dppe, two linkage isomers in the ratio 1:1 were obtained, the S-bonded isomer with a low *J*(Pt–P) value (2346 Hz) and the N-bonded isomer with high *J*(Pt–P) value (3088 Hz). Now, we have extended this series to include the ligands $Ph_2P(CH_2)_3PPh_2$ (dppp) and $Ph_2P(CH_2)_4PPh_2$ (dppb). From the $^{31}P–\{^1H\}$ NMR data, we found that for the complex $[PtL_2(dppp)]$, a single isomer is obtained and from its *J*(Pt–P) value (3023 Hz), we believed that it is the N-bonded isomer.

Treatment of a solution of $[ML_2(PMePh_2)_2]$ or $[ML_2(B)]$ (B = dppm, dppe, dppp or dppb) with solid $CoCl_2$, *trans*-$[PdCl_2(DMSO)_2]$ or $SnCl_4 \cdot 5H_2O$ in chloroform yielded heterobimetallic complexes of the type $[(PMePh_2)_2M(\mu\text{-}L)_2M'Cl_2]$ or $[(B)M(\mu\text{-}L)_2M'Cl_2]$.

3.2. Characterization of complexes

The complexes were identified by elemental analysis, $^{31}P–\{^1H\}$ NMR, IR, UV–Vis spectra, magnetic susceptibility and conductivity measurements and their data are listed in Tables 1–4.

The synthesised heterobimetallic complexes are stable in the solid state as well as in solution except for the cobalt complexes which showed some instability in aqueous or alcoholic solvents. For this reason, these solvents were avoided in the preparation and characterization of the cobalt complexes Although the molar conductivities of the complexes in acetonitrile are greater than those in chloroform (Table 3), due to the higher dielectric constant of acetonitrile, nevertheless the values in both solvents are too low to suggest that they are non-electrolytes [16].

3.2.1. IR spectra and magnetic moments

The IR spectra of the prepared complexes (Table 2) showed weak to strong bands at ca. 1550, 1435, 960 and 775 cm^{-1}, which may be assigned to the thioamide vibrational bands I, II, III and IV, respectively [17]. The IR spectra of the Pd–Co or Pt–Co complexes showed two medium to strong bands at around 310–330 cm^{-1}, assigned to *ν*(Co–Cl) in an octahedral environment (complexes **11**, **17**, **20**, **25**, **28** and **31**), or a single strong band at around 310 or 315 cm^{-1} for square planar and tetrahedral cobalt complexes (complexes **14** and **23**) [18]. The far IR spectra of the Pd–Sn complexes showed a strong single band at around 310–330 cm^{-1} assigned to (Sn–Cl) [19], while the IR spectra of the Pd–Pd complexes (**12**, **15**, **18**, **21** and **24**) showed in each case two medium intensity bands at 350, 290 or 310, 290 cm^{-1}, respectively, which are assigned to (Pd–Cl) in a *cis*-arrangement [20]. Other IR data are given in Table 2.

The magnetic susceptibility measurements for the prepared complexes indicated that all of them are diamagnetic except for some of the cobalt complexes (**11**, **17**, **20**, **23**, **25**, **28** and **31**). The magnetic susceptibility value of complex **23** is 4.5 BM, which on the basis of this value and the spectral data was assigned to have a tetrahedral geometry [21]. The values 4.9–5.2 BM for the remaining cobalt complexes suggest an octahedral arrangement around cobalt(II), which compare very well with reported values for octahedral complexes of cobalt(II) (4.7–5.2 BM) [22–24].

3.2.2. $^{31}P–\{^1H\}$ NMR spectra

The $^{31}P–\{^1H\}$ NMR data of some of the prepared complexes are given in Table 4.

The spectrum of $[PtL_2(dppm)]$ showed a singlet at $\delta P - 49.2$ ppm with associated platinum satellites, *J*(Pt–P) = 2714 Hz. The negative value of the δP indicates that dppm behaves as a chelating ligand [25]. The low *J*(Pt–P) value suggests that the *trans*-atom is a sulfur rather than a nitrogen atom [8]. The sulfur atom has the ability to compete with the phosphorus atom on back donation from the platinum. Therefore, it lowers the *J*(Pt–P) value. The small volume occupied by dppm permits the ligand (L) to bond through the preferable sulfur atom. This makes the ligands occupy a bigger volume [26]. The $^{31}P–\{^1H\}$ NMR spectrum of $[(dppm)Pt(\mu\text{-}L)_2PdCl_2]$ showed a singlet at $\delta P - 63.0$ ppm associated with platinum satellites, *J*(Pt–P) = 3106 Hz; i.e., 392 Hz higher than that of the starting complex $[PtL_2(dppm)]$, indicating a single isomer and that the bridging ligand (L) is bonded to platinum via the sulfur end, while it is bonded to palladium via the nitrogen end.

We reported in our recent work that the $^{31}P–\{^1H\}$ NMR spectrum of $[PtL_2(dppe)]$ showed two singlets at δP 48.1 and 48.8 ppm in the ratio of 1:1, each associated with platinum satellites, *J*(Pt–P) = 3088 and 2346 Hz, respectively, assigned to the linkage N-bonded and the S-bonded isomers, respectively [12]. Reaction of the isomeric mixture with *trans*-$[PdCl_2(DMSO)_2]$ gave a single heterobimetallic isomer at δP 42.4 ppm with *J*(Pt–P) = 3727 Hz, i.e., 639 Hz higher than that of the starting complex $[PtL_2(dppe)]$. The *J*(Pt–P) value

[a] Complexes melt with decomposition.

indicated that it is the N-bonded isomer *cis–cis*-$[(dppe)Pt\{\mu\text{-}L(NS)\}_2PdCl_2]$. However, the difference in J(Pt–P) values, i.e., 392 Hz in the case of the dppm complex and 639 Hz in the case of dppe may be explained on the basis of the strain presented by the dppm chelate ring which is not present in the dppe and dppp chelate rings.

The $^{31}P\text{–}\{^1H\}$ NMR spectrum of $[PtL_2(dppp)]$ showed a singlet at $\delta P - 1.92$ ppm with $J(Pt\text{–}P) = 3023$ Hz, indicating the presence of a single isomer. The J(Pt–P) value indicates that it is the N-bonded isomer. Reaction of this complex with *trans*-$[PtCl_2(DMSO)_2]$ gave the heterobimetallic complex *cis–cis*-$[(dppp)Pt\{\mu\text{-}L(NS)\}_2PdCl_2]$ as indicated from the δP which is −4.37 ppm and J(Pt–P) which is 3375 Hz.

The above trend of changing the point of attachment of the ligand 5-phenyl-1,3,4-oxadiazole-2-thione from an S-bonded, in the presence of the dppm ligand, to a 1:1 mixture of the S- and N-bonded with dppe, to an N-bonded in the presence of dppp reflects the steric effect exerted by the diphosphine ligands on the type of linkage isomer produced. This trend is in consistent with that reported for the complexes $[Pd(SCN)_2\{Ph_2P(CH_2)_nPPh_2\}]$ $n = 1$, 2 or 3 [26].

On the other hand, the $^{31}P\text{–}\{^1H\}$ NMR spectrum of *trans*-$[PdL_2(PMePh_2)_2]$ showed two singlets at δP 13.5 and 12.4 ppm in the ratio of 80% and 20%, respectively. No coupling between the two signals was observed which indicates the presence of two compounds. We believe that these are, probably, due to the two linkage isomers, the S-bonded and the N-bonded 5-phenyl-1,3,4-oxadiazole-2-thione. The possibility of having an S,N-bonded isomer is ruled out since the complex we obtained has a *trans*-configuration and not the *cis*-one. The *cis*-isomer should give an AX spin system (doublet of doublets) in the ^{31}P NMR spectrum and in our case we found only two singlets in the spectrum. Several attempts carried out to grow a crystal of the complex for X-ray analysis were unsuccessful. On treatment of this isomeric mixture with *trans*-$[PdCl_2(DMSO)_2]$, a mixture of linkage heterobimetallic isomers of the type *trans*-$[(PMePh_2)_2Pd(\mu\text{-}L)_2PdCl_2]$ were observed, as shown

[c] These are listed here for comparison.

from the $^{31}P–\{^1H\}$ NMR spectrum. The spectrum of this heterobimetallic mixture showed two singlets at δP 23.0 and 23.6 ppm in the ratio of 65% and 35%, respectively. We believe that these correspond to the S-bonded and N-bonded heterobimetallic isomers, i.e., *cis–cis*-$[(PMePh_2)_2Pd\{\mu\text{-}L(SN)\}_2PdCl_2]$ and *cis–cis*-$[(PMePh_2)_2Pd\{\mu\text{-}L(NS)\}_2PdCl_2]$, respectively.

The $^{31}P–\{^1H\}$ NMR spectrum of $[PdL_2(dppm)]$ showed a singlet at $\delta P - 39.2$ ppm while that of the bimetallic complex $[(dppm)Pd(\mu\text{-}L)_2PdCl_2]$ showed it to be at $\delta P - 53.3$ ppm. The negative sign of the chemical shifts indicate again that dppm behaves as a chelating ligand in both the mononuclear and the binuclear complexes [25]. Other $^{31}P–\{^1H\}$ NMR data of the other palladium complexes are given in Table 4.

Acknowledgements

We thank Prof. Dr. Wilhelm Keim, Institute for Technische Chemie der RWTH Aachen, Worringer Weg1, D-52074 Aachen, Germany, for his help in obtaining the $^{31}P–\{^1H\}$ NMR data.

Abstract

The complexes $[Me_2(Indo)SnOSn(Indo)Me_2]_2$, (**1**) $[Bu_2(Indo)SnOSn(Indo)Bu_2]_2$, (**2**), where Hindo is indomethacin, have been prepared and structurally characterized by means of ^{119}Sn Mössbauer, vibrational, and NMR (^1H and ^{13}C) spectroscopy. The crystal structures of the complexes $[Me_2(Indo)SnOSn(Indo)Me_2]_2 \cdot 2C_4H_8O_2$, **3** and **2** have been determined by X-ray crystallography. Each structure is centro-symmetric and features a central rhombus Sn_2O_2 unit with two additional tin atoms linked at the O atoms. Pairs of tin atoms are bridged by bidentate carboxylate ligands and by a monoatomic bridging oxygen. C–H→ π, π → π, stacking interactions, inter and intramolecular hydrogen bonds stabilize the structures **2** and **3**. Complexes **2** and **3** are self-assembled via π → π, C–H-π and stacking interactions.

1. Introduction

Indomethacin (1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1Hindole-3-acetic acid), Hindo, scheme 1, is one of the most potent of the clinically used non-steroidal anti-inflammatory drugs, NSAIDs, and interferes with prostaglandin synthesis by direct inhibition of the two cyclooxygenase enzyme systems, Cox-I and Cox-II. Inhibition of the Cox-II system results in anti-inflammatory action, while inhibition of the Cox-I enzyme system results in anti-inflammatory action as well as gastric irritation [1,2]. It was proposed that Hindo binds to Arg 120 of both the COX-I and COX-II enzymes by a carboxylate bridge and by slow and time-dependent reaction, competing with arachidonic acid for the COX site, and blocking the COX action of the enzyme [3,4]. A Cu(II) dimer of indomethacin with low toxicity is commercially available in Australasia, South East Asia and South Africa in a variety of oral pharmaceutical dosage forms for veterinary use [4–6]. Additional interest in NSAIDs lies in their possible therapeutic benefits in the prevention of various cancers including colorectal and lung cancers [7] and even in the treatment of Alzheimer's disease [8]. It was found that, indomethacin and mefenamic, at non-toxic levels, significantly increased the cytotoxicity of the anthracyclines, doxorubicin, daunorubicin and epirubicin, as well as teniposide, VP-16 and vincristine [9]. The crystal structure of Copper(II) dimers of Indomethacin have been reported [10,11].

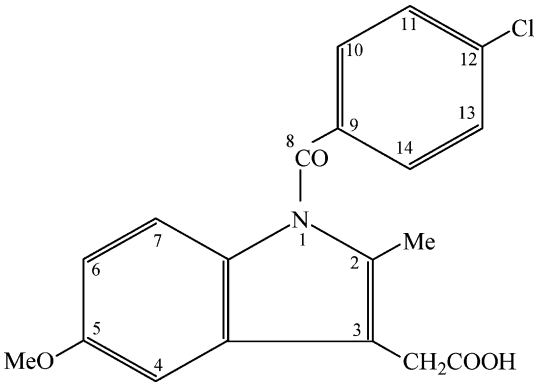

Scheme 1.

Organotin(IV) carboxylates form an important class of compound and have received increasing attention in recent years, not only because of their intrinsic interest but owing to their varied applications [12,13]. Investigations have been carried out to test their anti-tumour activity and it has been observed that indeed several diorganotin and triorganotin species show potentiality as anti-neoplastic and anti-tuberculosis agents [14–16].

Given the pharmacological importance of indomethacin acid and the potential biological activity of organotin carboxylates, it was thought of interest to explore the chemistry of organotin/indomethacin compounds. As a continuation of our studies of biological organotin chemistry and on the coordination chemistry and anti-inflammatory properties of NSAIDs such as diclofenac, tolfenamic acids and lornoxicam [17–21], we report here the synthesis and spectral characterization of $[R_2(Indo)SnOSn(Indo)R_2]_2$ (where $R = CH_3$, **1**, Bu, **2**, Indo is the deprotonated indomethacin. The complexes have been structurally characterized in the solid state by means of ^{119}Sn Mössbauer and vibrational spectroscopy and in solution by ^{1}H and ^{13}C NMR spectroscopic studies and electrochemical measurements. The crystal and molecular structures of **2** and $[Me_2(Indo)SnOSn(Indo)Me_2]_2 \cdot 2C_4H_8O_2$, **3** are also described, these being the first structures of organometallic indomethacin acid derivatives to be reported.

2. Experimental

2.1. Physical measurements

The reagents (Aldrich, Merck) were used as supplied while the solvents were purified according to standard procedures. Indomethacin was a gift from "Genepharm S.A". C, H, and N analyses were carried out by the microanalytical service of the University of Ioannina. Melting points were determined in open capillaries and are uncorrected. Infrared and far-infrared spectra were recorded on a Nicolet 55XC Fourier transform spectrophotometer using KBr pellets (4000–400 cm^{-1}) and nujol mulls dispersed between polyethylene disks (400–40 cm^{-1}). The ^{1}H (250.13 MHz), and ^{13}C (62.90 MHz) NMR spectra were recorded on a Bruker AC-250 spectrometer. Samples were dissolved in $CDCl_3$ or DMSO-d6 and spectra were obtained at room temperature with the signal of the free DMSO or $CHCl_3$ (at 2.49 and 7.24 ppm, respectively) as a reference. 2D ^{1}H–^{1}H shift correlated spectra (COSY), 2D ^{13}C–^{1}H shift correlated spectra (HETCOR) and 2D long-range ^{13}C–^{1}H shift correlated spectra (COLOC) of indomethacin were performed. Mössbauer spectra were recorded on finely ground materials at 80.0 K using an Air Liquid cryostat. The $Ca^{119}SnO_3$ source (15mCi New England Nuclear) at room temperature was moved in a constant acceleration mode with a triangular wave form. Suitable computer programs were employed in the fitting procedure of the experimental spectra to Lorentzian line shapes. The estimated errors on the Mössbauer parameters are ±0.01 mm/s. Electrochemical measurements were made using an AUTOLAB PGSTAT30 potentiostat with a platinum microsphere as working electrode, a platinum wire auxiliary electrode and an Ag/AgCl reference electrode in a three electrode configuration. Ferrocene was added at the end of each experiment and

used as an internal standard. All potentials are reported relative to a Ag/AgCl reference electrode and ferrocenium/ferrocene (Fe^{+}/Fc, $E_{1/2} = 0.173$ V in DMF); under the experimental conditions used (scan rate 100 mV s^{-1}). Et_4NClO_4 (0.1 M) was used as supporting electrolyte, the solutions were 1×10^{-3}M in complex, and carried out under a dinitrogen atmosphere.

2.2. Preparation of the complexes

2.2.1. Synthesis of [Me_2(Indo)SnOSn(Indo)Me_2]$_2$ 1,2:3,4-di-μ_2-1-(4chlorobenzoyl)-5-methoxy-2-methyl-1H-Indole-3-acetato-O,O-1,3-bis-1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-Indole-3-acetato-μ_3-oxo-tetrakis[di-methyltin(IV)] (**1**)

Me_2SnO, (0.164 g, 1 mmol) was added to a solution of Hindo (0.357 g, 1 mmol) in benzene (50 cm^3) and the reaction mixture was refluxed overnight with azeotropic removal of water via a Dean–Stark trap. The resultant clear solution was rotary evaporated under vacuum to a small volume, chilled and triturated with diethyl ether to give a yellow solid. The powder was redissolved (suspended) in dry diethyl ether and the same procedure was repeated twice. The yellow powder was filtered and dried in vacuum over silica gel. M.p. 192–194 °C; Yield 92%. IR: 1614 ν_{as}(COO), 1362 ν_{sym}(COO), 1560 ν_{as}(COO), 1402 ν_{sym}(COO), 588, 575, 547 ν(Sn–C), 645br v(SnOSn), 314, 279 νSn–O(COO);). *Anal.* Calc. for $C_{84}H_{84}Cl_4N_4O_{18}Sn_4$: C, 49.1; H, 4.1; N, 2.7. Found: C, 48.7; H, 4.4; N, 2.6%. Crystals of [Me_2(Indo)SnOSn(Indo)Me_2]$_2 \cdot 2C_4H_8O_2$ (**3**) suitable for X-ray analysis were obtained by slow evaporation of a fresh *n*-C_6H_{12}/$CHCl_3$/$C_4H_8O_2$ solution of **1**.

2.2.2. Synthesis of [Bu_2(Indo)SnOSn(Indo)Bu_2]$_2$, 1,2:3,4-di-μ_2-1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-Indole-3-acetato-O,O-1,3-bis-1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-Indole-3-acetato-μ_3-oxo-tetrakis[di-n-butyltin(IV)] (**2**)

Di-*n*-butyl oxide (0.250 g, 1 mmol), Hindo (0.3578 g, 1 mmol) and 40 ml of benzene were refluxed overnight with azeotropic removal of water via a Dean–Stark trap. The resulting clear solution was rotary evaporated under vacuum to a small volume, chilled and triturated

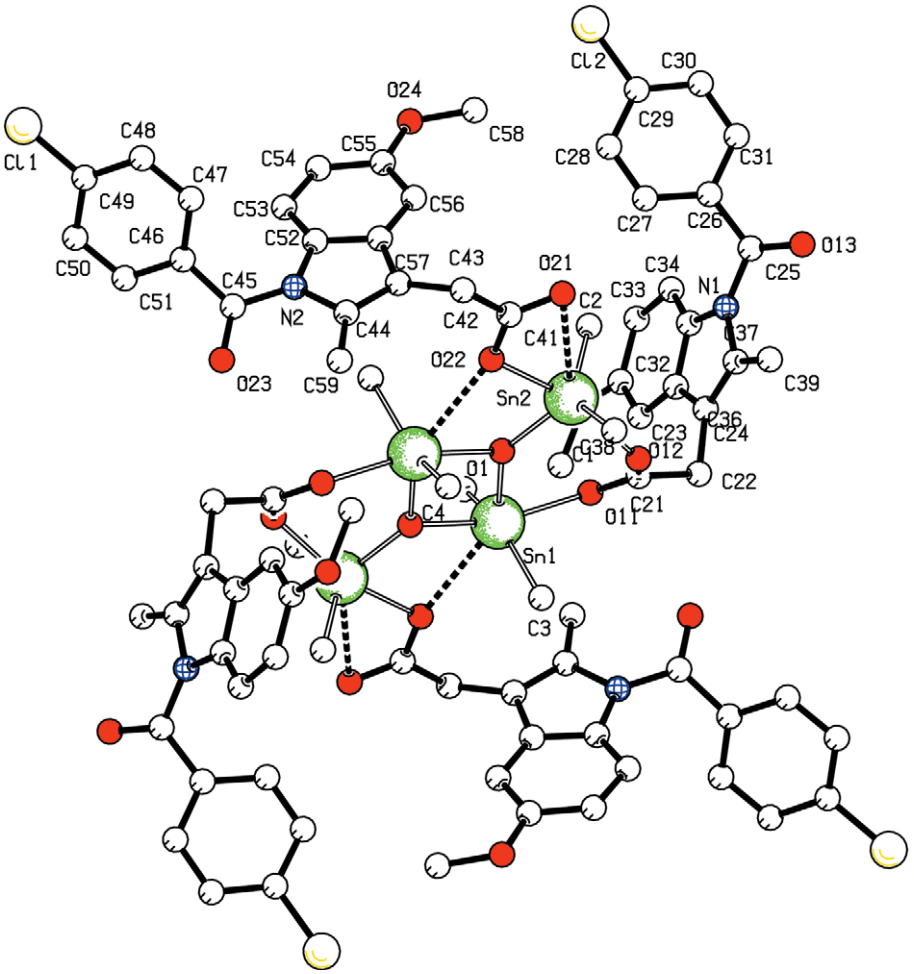

Fig. 1. Perspective view of [$Me_2SnLOLSnMe_2$]$_2$ (**1**) showing the atomic numbering scheme.

with diethyl ether to give a yellow solid. The powder was redissolved (suspended) in dry diethyl ether and the same procedure was repeated twice. The light yellow powder was dried in vacuo over silica gel. 180–183 °C; Yield, 85%. IR: 1622 v_{as}(COO), 1369 v_{sym}(COO), 1566 v_{as}(COO), 1402 v_{sym}(COO), 564, 545 v(Sn–C), 640, 635br v(SnOSn), 295, 277 vSn–O(COO); *Anal*. Calc. for $C_{108}H_{132}Cl_4N_4O_{18}Sn_4$: C, 54.2; H, 5.5; N, 2.3. Found: C, 54.4; H, 6.1; N, 2.1%. Crystals of (**2**) suitable for X-ray analysis were obtained by slow evaporation of a fresh *n*-C_6H_{12}/$CHCl_3$ solution of **2**.

2.3. X-ray crystallography

Crystal data for **2** and **3** are given in Table 1, together with refinement details. All measurements of crystals were performed in low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystal was positioned at 65 mm from the CCD camera. Six hundred and twelve frames were measured at 0.75° intervals with a counting time of 20 s. Accurate cell parameters were determined and refined by least-squares fit of 2100 the strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o (formerly Kuma Diffraction Wroclaw, Poland) programs. The structure was solved by direct methods (program SHELXS-97 [11]) and refined by the full-matrix least-squares method on all F^2 data using the using the WinGX version of SHELXL-97 programs [22,23]. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps but were not refined. Molecular graphics were performed from PLATON2001 [24,25].

3. Results and discussion

3.1. Crystal structures of 3 and 2

Compounds **1** and **2** are obtained by azeotropic removal of water produced by the reaction between the diorganotin oxide and indomethacin in the molar ratio 1:1. Recrystallization of **1** from a fresh *n*-C_6H_{12}/$CHCl_3$ solution gives the adduct $C_4H_8O_2$, **3**. The molecular structures of **3** and **2** are shown in Figs. 1 and 2 and selected interatomic parameters are collected in Table 2. Compounds **3** and **2** are centrosymmetric dimers built up around the planar cyclic Sn_2O_2 unit. The two oxygen

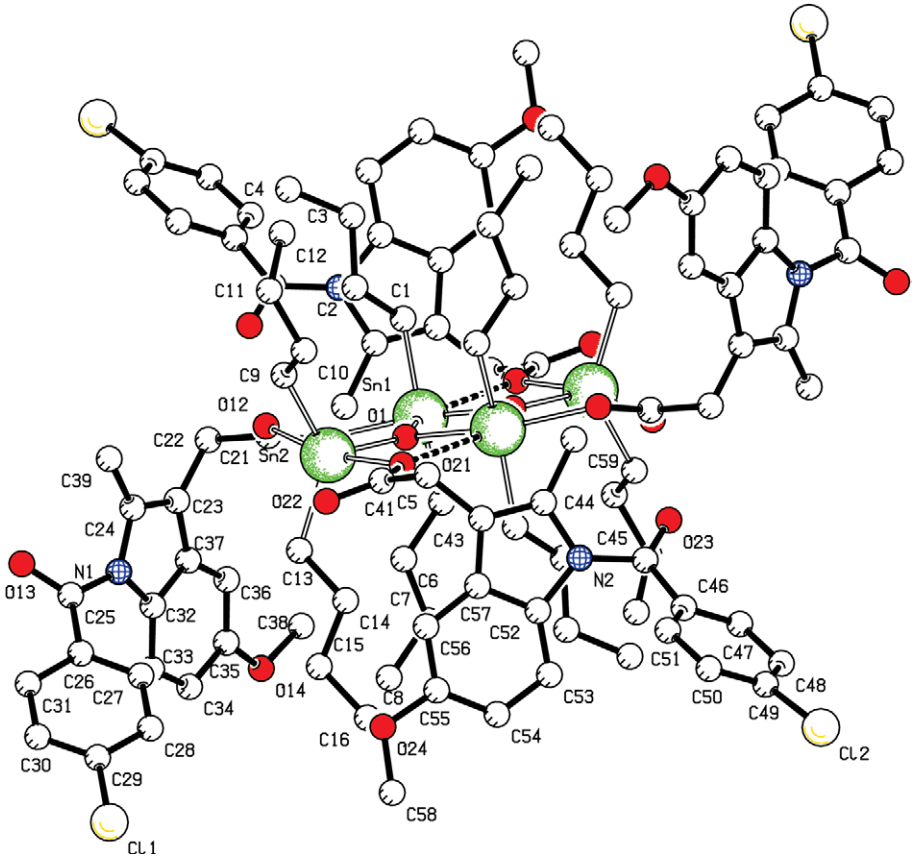

Fig. 2. Perspective view of $[Bu_2SnLOLSnBu_2]_2$ (**2**) showing the atomic numbering scheme.

atoms O(1) and O(1a) are triply bridging, each linking one exo-cyclic (Sn(2) or Sn(2a)) and two endo-cyclic (Sn(1) and Sn(1a)) atoms (see Fig. 3). The additional links between the endo- and exo-cyclic Sn atoms are provided by two bidentate bridging carboxylate ligands that form symmetrical bridges (Sn(1)–O(11) 2.262(3) Å and Sn(2)–O(12) 2.2361(3) Å for **3** and Sn(1)–O(11) 2.242(4) Å and Sn(2)–O(12) 2.243(4) Å) for **2**. Each exocyclic Sn atom is also coordinated by an anisobidentate chelating carboxylate ligand (Sn(2)–O(22) 2.176(3) Å and Sn(2)–O(21) 2.874(3) Å for **3** and Sn(2)–O(22) 2.178(4) Å and Sn(2)–O(21) 2.970(6) Å for **2**. The distance of O(22) atoms from endocyclic Sn are 2.741(3) and 2.752(5) for **3** and **2** respectively. The Sn–O distance of 2.741(3)–2.970(6) Å is considered long to indicate significant bonding interactions, however, the range of distances Sn–O of 2.61–3.02 Å, has been confidently reported for intramolecular bonds [26,27]. It is considered that the close approach of 2.970(6) Å is long for primary Sn–O bonding, but represent a type of secondary interaction. The coordination number around each tin is six for **3** and five and six around Sn(1) and Sn(2) respectively for **2**. Analysis of the shape determining angles for **2**, using the approach of Reedijk and coworkers [28], yields τ ($(\alpha - \beta)/60$) value of 0.54 for Sn(2) ($\tau = 0.0$ and 1.0 for *SP* and *TBP* geometries respectively). The metal co-ordination geometry is therefore described as very distorted trigonal bipyramidal with the O(21) and O(12) atoms occupying the axial positions and O(1), C(13) and C(9) the equatorial

[b] $1-x, 1-y, 1-z$.

positions. For **3** and **2** the bond distances involving the bridging carboxylate ligand differ by only 0.024 and 0.002 Å respectively indicating a nearly symmetrical bridge, while the variations in the C–O bond distances, 0.002 and 0.025 Å suggest charge delocalization over the carboxylato group. The two rings of indole, the five and six-membered rings, are nearly planar, the dihedral angle is 3.6(3)° and 2.7(4)° for **3** and **2** respectively. The dihedral angles between the planes of the two phenyl rings are 62.2(2)° and 64.1(2)° for **3** and 63.2(4)° and 63.5(4)° for **2** and for the bidentate bridging and the anisobidentae chelating ligands respectively. The conformation of the co-ordinated indomethacin is similar to the two adducts and is similar to the structure of indomethacin. The dihedral angle of indomethacin between the planes of the two phenyl rings and the two rings of indole is 67.3(9)° and 2.0(8)° respectively [29]. The crystal structure of **3** shows ring stacking interactions. The monomers are stacked by double strong $\pi \rightarrow \pi$ interactions (C(2)–C(4)N(1) → C(4A)–C(9A), C(4A)–C(9A) → C(2)–C(4)N(1); the two rings of indole, the six and five-membered C(4A)–C(9A) and C(2)–C(4)N(1) 'face' the rings C(2)–C(4)N(1) and C(4A)–C(9A) respectively at a distance of 3.915(4) Å. These $\pi \rightarrow \pi$ interactions play an important role in the stabilization of the stacked molecular units. Weaker $\pi \rightarrow \pi$ and C–H→ π interactions play a role in the stabilization of the units. The crystal structure of **2** exhibits weak $\pi \rightarrow \pi$ and C–H→ π interactions, Table 3, in this case complex **2** is self-assembled via C–H→ π and $\pi \rightarrow \pi$ stacking interactions [30]. The overall geometry found in **2** and **3** allowing for differences in chemistry, is similar to compounds with the general formula $[R_2(R'CO_2)SnOSn(O_2CR')R_2]_2$ [31]. View of the crystal packing for **2** is shown in Fig. 4.

3.2. Spectroscopy

3.2.1. Infrared spectroscopy

Hindo displays a very broad, intense O–H stretching absorption in the region of 3300–2500 cm^{-1} with weaker and much sharper C–H stretches superimposed. The absence of the O–H absorption bands of the carboxylic acid in the IR spectra of **1** and **2** are indicative of carboxylato group binding. All the complexes exhibit characteristic IR spectra due to the ligand vibration modes. The major characteristic of the IR spectra is the frequency of the υ_{asym}(COO) and υ_{sym}(COO) stretching

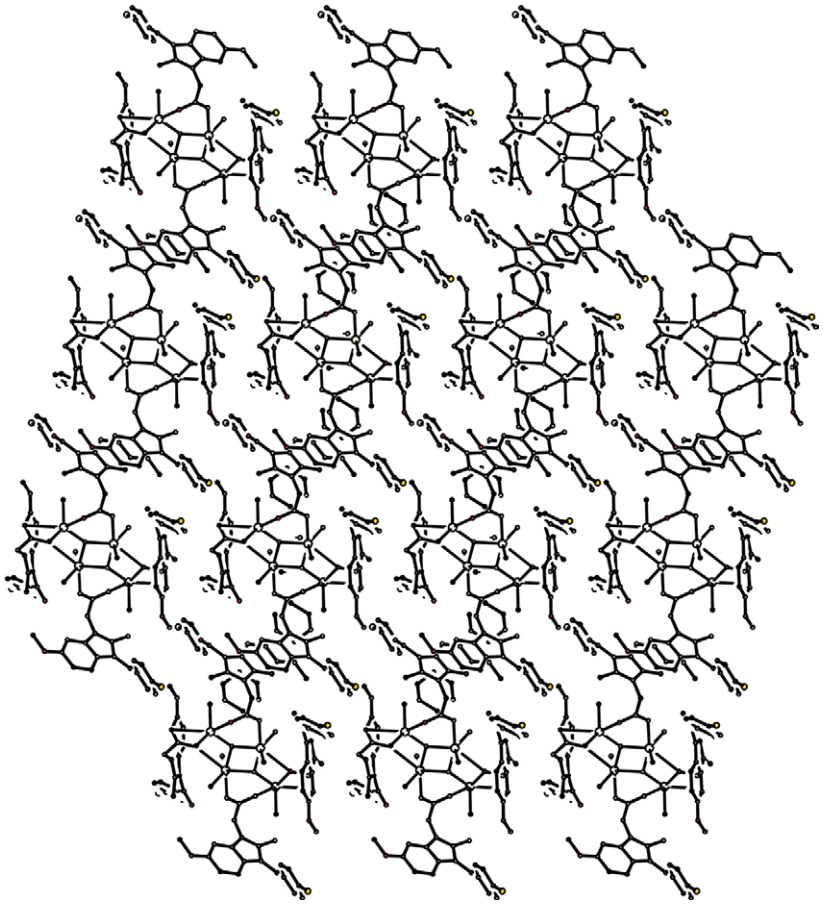

Fig. 3. Packing diagram of the complex of $[Me_2SnLOLSnMe_2]_2$ (**1**) viewed along the α axis.

vibrations. The frequency of these bands depends upon the co-ordination mode of the carboxylato ligand. The ν_{as}(COO) and ν_{sym}(COO) bands appear at ~1630–1560 cm^{-1} and ~1400–1370 cm^{-1} respectively. The ν_{as}(COO) and ν_{sym}(COO) bands appear at 1614, 1560 cm^{-1} and at 1394, 1402 cm^{-1}, respectively, for **1**. The difference, Δ [ν_{as}(COO)−ν_{sym}(COO)] between these frequencies for **1** is close to that found for aniso-bidentate (252 cm^{-1}) and bridging bidentate carboxylato groups (158 cm^{-1}). The ν_{as}(COO) and ν_{sym}(COO) bands appear at 1622, 1566 cm^{-1} and at 1369, 1401 cm^{-1}, respectively, for **2**. The difference, Δ [ν_{as}(COO)−ν_{sym}(COO)] between these frequencies for **2** is close to that found for aniso-bidentate (253 cm^{-1}) and bridging bidentate carboxylato groups (163 cm^{-1}). Two bands at 600–620 for **1** and **2**, are assigned to $\nu_{as,sym}(SnO)_2$, indicating non-linear O–Sn–O moieties, while the bands at 320–280 cm^{-1} are assigned to the tin-oxygen (COO) stretching modes. The absorption bands at 580–540 cm^{-1} are attributed to ν(Sn–C) stretching modes [18–20,32].

3.2.2. Mössbauer spectra

The Mössbauer spectra of **1** and **2** consist of a clearly asymmetric doublet that can be fitted only by assuming it derives from the overlap of two doublets due to two different tin sites present in a 1:1 atomic ratio. For both complexes, the two doublets present very similar values for the isomer shift, while the quadrupole splitting values are rather different indicating different contributions to the electric field gradient due to the lattice. The fitting of the experimental data points by two overlapping Lorentzian doublets for **1** and **2**, shows the occurrence of two distinct crystallographic environments around tin atoms, present in a 1:1 ratio. The hyperfine values for **1** are: $\delta = 1.51$, 1.46 $mm\,s^{-1}$; $\Delta E_Q = 3.76$, 2.88 $mm\,s^{-1}$; and for **2** are: $\delta = 1.50$, 1.44 $mm\,s^{-1}$; $\Delta E_Q = 3.63$, 2.86 $mm\,s^{-1}$. The very similar values for the isomer shift are indicative of the comparable electronic density at the two tin sites for both complexes.

From the quadrupole splitting values (ΔE_Q) and the point-charge model formalism, the relation $\Delta E_Q = 4[R](1 - 3\sin^2\theta\cos^2\theta)^{1/2}$ gives an estimate of θ, where 180°–2θ is the R–Sn–R bond angle [33]. In **1**, the bond angles calculated for the two tin sites are 151.8° for the high ΔE_Q value and 132.1° for the low ΔE_Q value. The X-ray crystal structure for this compound indicates C–Sn–C bond angles of 142.4(2)° and 135.1(2)°. For **2** similar results are confirmed by the X-ray diffraction analysis where the experimental values, 146.2(3)° and 134.0(3)°, are very close to the theoretical ones, 146.9° and 131.4°.

3.2.3. NMR spectra

The ^1H and ^{13}C NMR data for indomethacin (scheme 1) and the complexes **1** and **2** are summarized in Table 4. Complete assignment of the indomethacin

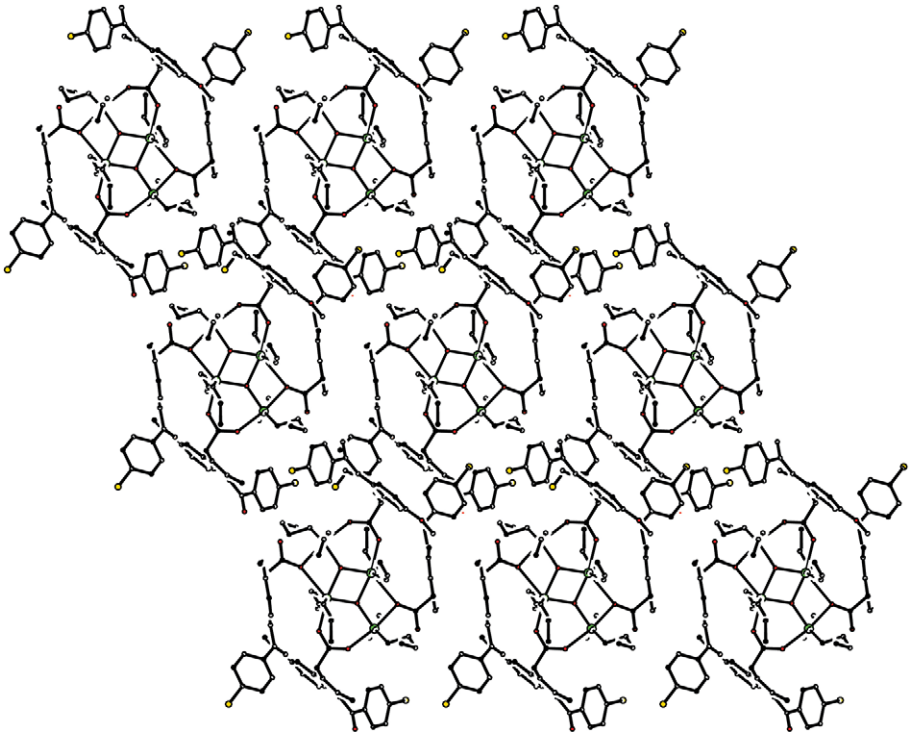

Fig. 4. Packing diagram of the complex of $[Bu_2SnLOLSnBu_2]_2$ (**2**) viewed along the α axis.

resonances in $CDCl_3$ has been based on ^1H (250.13 MHz), ^{13}C (62.90 MHz), 2D ^1H–^1H shift correlated spectra (COSY), 2D ^{13}C–^1H shift correlated spectra (HETCOR) and 2D long range ^{13}C–^1H shift correlated spectra (COLOC) and on previously reported data [34]. In **1** and **2**, most of the proton atoms of indomethacin show upfield shifts upon interaction of the ligand with organotin. These shifts mainly lie close to 0.1 ppm. When looking only at the proton resonances, no clear conclusion can be drawn concerning the possible coordination site of the metal. The ^{13}C NMR spectra of the complexes synthesized reveal major changes in the exocyclic carboxylic group, indicative of metal interaction through the carboxylic group. The latter exhibits either a major downfield shift (4.2 ppm in **1**) or a considerably broadened signal accompanied by a significant downfield shift for the methylene carbon attached to the carboxylato group, as observed in complex **2**. The ^1H NMR resonances of **2** are broadened in comparison to the free ligand and exhibit small upfield shifts, with the greatest shift (0.18 ppm) demonstrated by the CH_2 peak. In the ^{13}C NMR spectrum of **2**, the greatest shifts are observed for the C(3a) (2.5 ppm, downfield) and CH_2 (+2.3 ppm, downfield) atoms. Negligible shifts ranging between 0.0 and 0.9 ppm are found for the other carbon atoms. It is worth mentioning that the peak corresponding to the carboxyl group remains unshifted. However, upon interaction with the metal, it exhibits considerable loss in intensity and broadening. Keeping this in mind and taking also into consideration the shifts exhibited by the neighboring atoms (C(3a) and CH_2), interaction of the metal with the carboxyl group is infered. In both the ^1H and ^{13}C NMR spectra of complex **2**, two peaks of equal height appear for the methyl group of dibutyltin (IV). It is presumed that two types of tin centres are present. This is confirmed by the crystal structure of **2**. The greatest shift at **1** is exhibited by the CH_2 peak implicating coordination through the carboxyl group of the ligand. Two peaks of equal height appear for the methyl group of dimethylltin(IV), reflecting the presence of two types of tin centres. This is confirmed by the crystal structure of **3**. No J ($^{119/117}Sn$–^1H) fine couplings could be observed for **1** and **2**.

3.3. Electrochemical measurements

The ability of the complexes to gain or to lose electrons was studied in anhydrous DMF solution by cyclic voltammetry. The ligand exhibits irreversible reduction peaks at −0.618 and −1.130 V. Complex **1** shows irreversible reductions at −0.610 and −1.123 V, while complex **2** at −0.613 and −1.189 V. The electrochemical data suggest that the reduction of **Hindo**, **1** and **2** might be regarded as being more or less centered on the ligand system [20]. The electron transfers from the platinum cathode and is directed to the π^* LUMO orbital. The first reduction potential of **1** is less negative than **2** and decreased in the order **1** < **2** < **Hindo**.

Abstract

New mixed-ligand copper(II) complexes of empirical formulas [Cu(pysme)(sac) (CH_3OH)] and $[Cu(6mptsc)(sac)]_2$ have been synthesized and characterized by conductance, magnetic, IR and electronic spectroscopic techniques. X-ray crystallographic structure analyses of these complexes indicate that in both complexes the copper(II) ions adopt a five-coordinate distorted square-pyramidal geometry with an N_3SO donor environment. The Schiff bases are coordinated to the copper(II) ions as tridentate NNS chelates via the pyridine nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. In the monomeric [Cu(pysme)(sac)(MeOH)] complex, the saccharinate anion acts as a monodentate ligand coordinating the copper(II) ion via the imino nitrogen atom whereas in the dimeric $[Cu(6mptsc)(sac)]_2$ complex, the sac anion behaves as a bridging bidentate ligand providing the imino nitrogen donor atom to one of the copper(II) ions and the carbonyl oxygen as a weakly coordinated axial ligand atom to the other Cu(II) ion. In both complexes, the copper(II) ions have distorted square-pyramidal environments. The distortion from an ideal square-pyramidal geometry is attributed to the restricted bite angles of the planar tridentate ligand.

1. Introduction

Saccharin (*o*-sulfobenzoimide) is a commercially important artificial sweetener and is widely used as a food additive [1]. The saccharinate anion (sac^-) is also an interesting polyfunctional ligand since it has several potential donor atoms and consequently, its coordination chemistry with several metal ions has been studied in some detail [1–5].

In view of the interesting coordination chemistry of both the saccharinate anion and tridentate Schiff bases derived from *S*-alkyl- and *S*-aryldithiocarbazates and thiosemicarbazide [6–10], which are also analogues of the well-known experimental anticancer drug, pyridine-2-aldehydethiosemicarbazone [11], we report here the synthesis, characterization and X-ray crystal structures of two new mixed-ligand copper(II) complexes [Cu(pysme)(sac)(MeOH)] and $[Cu(6mptsc)(sac)]_2$ which contain both coordinated saccharinate anion and tridentate NNS ligands.

2. Experimental

2.1. Materials and instrumentation

The electronic spectra were recorded both in the solid state (as Nujol mulls) and in solution on a Shimadzu UV-3100 spectrophotometer. The IR spectra were recorded as KBr discs on either a Perkin–Elmer 1600 FT IR spectrometer or a Perkin–Elmer 2000 spectrometer. Conductance measurements were made by means of a CMD 400 conductivity meter. Magnetic susceptibilities were measured with a Sherwood Scientific magnetic susceptibility balance calibrated with $HgCo(NCS)_4$. Diamagnetic corrections were applied using Pascal's constants.

2.2. Preparation of the Schiff bases

These bases were prepared by literature methods [12,13].

2.3. Preparation of the complexes

The complexes were prepared by the following general method: $[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ [4] (0.6 mmol) dissolved in boiling methanol (25 ml) was mixed with a solution of the appropriate Schiff base (0.6 mmol) in the same solvent (25 ml) and the resulting mixture was heated on a water bath for 40 min. On standing overnight in a refrigerator, the mixture yielded crystalline complexes suitable for X-ray work (yield: 40–60%). *Anal.* Calcd. for [Cu(pysme)(sac)(CH_3OH)] ($C_{16}H_{16}N_4O_4S_3$Cu): C, 37.84; H, 3.39; N, 11.77. Found: C, 38.01; H, 2.97; N, 11.74%. *Anal.* Calcd. for $[Cu(6mptsc)(sac)]_2$ ($C_{30}H_{26}N_{10}O_6S_4Cu_2$): C, 37.64; H, 3.20; N, 15.20. Found: C, 37.64; H, 3.18; N, 15.03%.

2.4. X-ray crystallography

A crystal of the appropriate complex was mounted on a glass fibre. Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf–Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $2° < 2\theta < 50°$. An empirical absorption correction (ψ scans) and data reduction were performed with the WINGX [14] suite programmes. The structures were solved by direct methods with SHELX86 [15] of programmes and refined by full-matrix least-squares analysis with SHELXL97 [16]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were restrained at calculated positions using a riding model. Drawings of the molecules were produced with ORTEP3 [17]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1.

3. Results and discussion

The Schiff bases (Fig. 1(a); R = H, CH_3; X = SCH_3 or NH_2) although, in principle, could exhibit thione (**1a**)

(**1a**; thione form; R =H, CH_3 X = SCH_3 or NH_2) (**1b**;thiol form)

Fig. 1. The thione (**1a**) and thiol (**1b**) forms of the Schiff bases (**1a**: thione form; R = H, CH_3, X = SCH_3 or NH_2) (**1b**: thiol form).

and thiol (**1b**) tautomerism, our previous studies have shown that, in the solid state, they remain in the thione forms (**1a**) [12,13]. However, in boiling methanol, they readily react with $[Cu(H_2O)_4(sac)_2]\cdot 2H_2O$ yielding mixed-ligand complexes of empirical formula $[Cu(NNS)(sac)(MeOH)_x]$ (NNS = anionic form of the Schiff base; sac^- = the saccharinate anion; $x = 1, 0$). These complexes are quite stable in the atmosphere and could be kept in a desiccator for a long period of time without any sign of decomposition. Their molar conductance values in MeCN fall in the range 18–19 $\Omega^{-1}\,cm^2\,mol^{-1}$. These values, although significant, are much lower than that shown by 1:1 electrolytes in this solvent [18]. The conductivity data indicate that the sac^- ligands remain predominantly coordinated to the copper(II) ions as uninegatively charged ligands in MeCN. The IR spectra of the complexes do not exhibit the *v*NH bands of the free ligands supporting deprotonation of the ligands during coordination with the copper(II) ion. An examination of the IR data in Table 2 also shows that the Schiff bases are coordinated to the copper(II) ions via the azomethine nitrogen atoms (shift of *v*C=N and *v*N–N bands of the free ligands at ca. 1584–1559 and 1046–1076 cm^{-1}, respectively), the thiolate sulfur atom (splitting of the $vCSS_a$ bands of the free ligands in the spectrum of the [Cu(pysme)(sac)(MeOH)] complex) and the pyridine nitrogen atoms (shift of the pyridine ring vibration from ca. 634 to ~647 cm^{-1}).

The room temperature magnetic moments of 1.88 B.M. for [Cu(pysme)(sac)(CH_3OH)] and 1.85 B.M. for $[Cu(6mptsc)(sac)]_2$ indicate that they are magnetically dilute in nature. The electronic spectra of the copper(II) complexes, in addition to showing the intra-ligand $n \Rightarrow \pi^*$ bands in the range 369–358 nm and $\pi \Rightarrow \pi^*$ in the 293–254 nm range, display a $S \Rightarrow Cu^{II}$ charge-transfer band in the 406–430 nm range and a weaker d–d band in the range 600–620 nm. The presence of a $S \Rightarrow Cu$ LMCT band at ca. 406–430 nm in the electronic spectra of the present copper(II) complexes is strong evidence that the Schiff bases are coordinated to the copper(II) ions via the thiolate sulfur atom. Such LMCT bands are quite common in the electronic spectra of copper(II) complexes of tridentate NNS thiosemicarbzone ligands [19,20]. The appearance of a d–d band at ca. 600–620 nm in their electronic spectra is consistent with a five-ccordinate geometry and is similar to that observed for $[\{Cu(pytsc)(CH_3COO)\}_2]$ (λ_{max} = 640 nm) which also contains five-coordinate copper(II) ions [21].

3.1. The crystal structure of the [Cu(pysme)(sac)(MeOH)] complex

A thermal ellipsoid drawing of the structure indicating atom numbering scheme is shown in Fig. 2. Bond lengths and bond angles are given in Table 3. The complex crystallizes as a five-coordinate monomeric species. As indicated from the physicochemical results, the copper(II) ion adopts a distorted square-pyramidal geometry with the equatorial donor atoms being the pyridine nitrogen atom (N3), the azomethine nitrogen atom (N2) and the sulfur atom (S1) from the

O(1)′ symmetry operation $2-x, 1-y, 2-z$.

tridentate dithiocarbazate Schiff base plus the nitrogen N(4) from the saccharinate ion. The methanol ligand coordinates weakly in the apical site through O(1), which is typical of similar five-coordinate complexes [21]. The Schiff base is coordinated to the copper(II) ion in its iminothiolate form. While coordinating in this form, the negative charge generated upon deprotonation of the NH proton is delocalized across the S1–C1–N1 group as indicated by the intermediate C1–N1 {1.312(4) Å} and C1–S1 bond distances {1.710(3) Å}. These bonds may be compared with the true double bond seen in C3=N2 {1.273(3) Å} and C=S bonds are found in the (metal free) methylpyruvate Schiff base of *S*-methyldithiocarbazate {1.652(6) Å} [22], methylpyruvatethiosemicarbazone hemihydrate {1.684(4) Å} [23] and pyridine-2-carboxaldehydethiosemicarbazone {1.698(3) Å} [24].

The Cu–S {2.2951(9) Å}, Cu–$N_{azomethine}$ {1.958(2) Å} and Cu–N_{py} {2.062(2) Å} bond distances compare well with those of the analogous five-coordinate square-pyramidal copper(II) complex, [Cu(pytsc)(sac)(H_2O)] (pytsc = anionic form of the pyridine-2-carboxaldehydethiosemicarbazone), whose structure has been confirmed by X-ray diffraction [25]. The saccharinate ion is coordinated to the copper(II) ion via the deprotonated imino nitrogen atom. The Cu–N_{sac} distance {1.967(2) Å} also compares well that found in the above mixed-ligand copper(II)-thiosemicarbazone–saccharinate complex. The geometry of the complex is distorted square-pyramidal as a consequence of the restricted bite of the tridentate Schiff base ligand.

3.2. The crystal structure of the [Cu(6mptsc)(sac)]$_2$ complex

The structure shows that, in contrast with [Cu(pysme)(sac)(MeOH)] which is a monomer, the complex [Cu(6mptsc)(sac)]$_2$ is a centrosymmetric dimer. The symmetry related copper(II) ions adopt a five-coordinate geometry with the unique thiosemicarbazone ligand coordinating in its deprotonated thiolate form via the pyridine nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom, while the saccharinate anion behaves as a bridging bidentate ligand providing an imino nitrogen donor atom to one copper(II) ion and the carbonyl oxygen donor to the second copper(II) ion. The structure of the dimer, [Cu(6mptsc)(sac)]$_2$ with atom numbering scheme adopted is shown in Fig. 3. The important bond lengths and angles are listed in Table 3. The resulting coordination spheres, (CuN_3SO) are similar to that found in the monomeric [Cu(pysme)(sac)(MeOH)] complex. The delocalization of electrons in the thiosemicarbazide chain is again reflected in the intermediate C1–N1 {1.333(7) Å} and C1–S1 bond lengths {1.715(5) Å}. The Cu–S {2.2741(19) Å}, Cu–$N_{azomethine}$ {1.961(4) Å}, Cu–N_{py} {2.123(4) Å} and Cu–N_{sac} {1.992(4) Å} bond distances compare well with those of other five-coordinate mixed-ligand copper(II)–saccharinate complexes containing tridentate thiosemicarbazones as co-ligands. However, the apical Cu–O_{sac} bond length {2.276(4) Å} is longer than that found in other O-bonded saccharinate complexes such as in [Cu(sac)(NH_3)$_4$] [3], indicating weaker copper(II)–carbonyl oxygen interaction in the present dimer. Of course these variations in the strength of axial coordination are relatively minor perturbations on the

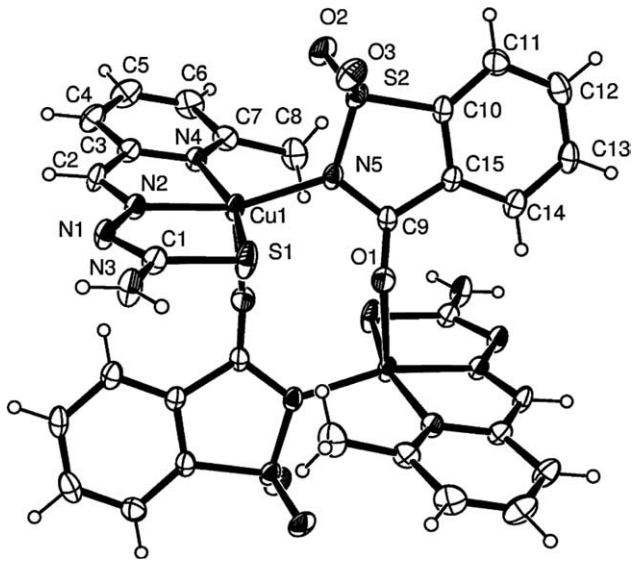

Fig. 3. The structure of $[Cu(6mptsc)(sac)]_2$.

over-riding axial elongation that ensues from the electronic (Jahn–Teller) effect inherent to five- and six-coordinate Cu(II) complexes, and they are correlated with changes in the equatorial ligands as well. The stereochemistry adopted by each copper(II) ion in the dimer is a distorted square-pyramid as a result of the restricted bite size of the ligand.

Given the very similar solution electronic spectra of $[Cu(6mptsc)(sac)_2]$ and [Cu(pysme)(sac)(MeOH)] and the lability of the metal ions, we wished to investigate whether the solid state structural differences identified crystallographically persisted in solution. EPR spectroscopy is a particularly powerful technique for the discrimination of monomeric and dimeric copper(II) complexes. Dipole–dipole coupling between neighbouring Cu(II) ($S = 1/2$) centres in a dimeric configuration leads to completely different EPR spectra to those found in isolated mononuclear analogues. The 77K EPR spectrum of 1 mM solution of $[Cu(6mptsc)(sac)]_2$ in DMF is characteristic of a monomeric Cu(II) complex with the spin Hamiltonian parameters $g_z = 2.205$ ($A_z = 168$ G), $g_x = g_y = 2.057$ ($A_x = A_y = 20$ G) obtained by spectral simulation. The spectrum of [Cu(pysme)(sac)(MeOH)] measured under identical conditions was the same. The A_z value (hyperfine coupling constant ^{65,67}Cu $I = 3/2$) is consistent with a distorted square-pyramidal coordination environment and a $d_{x^2} - d_{y^2}$ ground state [26]. Furthermore, the spectra are unlike those seen for genuine dinuclear five-coordinate copper(II) complexes [27,28], so the dimeric solid-state structure of $[Cu(6mptsc)(sac)]_2$ clearly does not persist in DMF solution. Presumably the competitive O-donor DMF occupies the axial coordination site in place of the O-bound sac^- ligand seen in the crystal structure.

4. Conclusions

The reaction of $[Cu(sac)_2(H_2O)_4]$ with tridentate sulfur–nitrogen chelating agents such the pyridine-2-carboxaldehyde Schiff base of *S*-methyldithiocarbazate or the 6-methyl-2-pyiridinecarboxaldehydethiosemicarbazone in methanol proceeds smoothly yielding crystalline mixed-ligand copper(II) complexes containing both coordinated saccharinate ion and deprotonated NNS donor ligands. The formation of a monomeric five-coordinate [Cu(pysme)(sac)(MeOH)] complex with an N-bonded saccharinate ligand and a dimeric $[Cu(6mptsc)(sac)]_2$ complex in which each of the saccharinate ions behaves as a bidentate chelating agent providing a nitrogen donor atom to one copper and the carbonyl oxygen donor atom to the other, demonstrates the versatility of the saccharinate anion as a polyfunctional ligand. In both the monomeric and dimeric complexes the $Cu–N_{sac}$ and $Cu–N_{imine}$ bonds are shorter than the $Cu–N_{py}$ bond.

5. Supplementary data

Crystallographic data for the structure analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 204485 for [Cu(pysme)(sac)(MeOH)] and 204491 for $[Cu(6mptsc)(sac)]_2$. Copies of these information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-123-333-6033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

New tin(IV) complexes of empirical formula, Sn(SNNNS)I_2 (SNNNS = anionic form of the 2,6-diacetylpyridine Schiff bases of *S*-methyl- or *S*-benzyldithiocarbazate) have been prepared and characterized by a variety of physico-chemical techniques. The structure of Sn(dapsme)I_2 has been determined by single crystal X-ray crystallographic structural analysis. The complex has a seven-coordinate distorted pentagonal-bipyramidal geometry with the Schiff base coordinated to the tin(IV) ion as a dinegatively charged pentadentate chelating agent via the pyridine nitrogen atom, the two azomethine nitrogen atoms and the two thiolate sulfur atoms. The ligand occupies the equatorial plane and the iodo ligands are coordinated to the tin(IV) ion at axial positions. The distortion from an ideal pentagonal bipyramidal geometry is attributed to the restricted bite size of the pentadentate ligands.

Keywords: Tin(IV) complexes; Dithiocarbazates; 2,6-diacetylpyridine Schiff bases of *S*-alkyldithiocarbazates; Seven-coordinate tin(IV) complexes

1. Introduction

Schiff bases formed from *S*-alkyl- and *S*-aryldithiocarbazates and heterocyclic aldehydes and ketones contain both hard 'nitrogen' and soft 'sulfur' donor atoms and consequently, they are capable of forming stable complexes with a wide variety of metal ions some of which have been shown to exhibit interesting physico-chemical properties and potentially useful chemotherapeutic properties [1–10]. Although a large number of studies involving complexes of these ligands with transition metal ions have been reported, there have been fewer studies on complexes of these ligands with main group elements such as tin. We have previously reported some transition metal complexes of the 2,6-diacetylpyridine Schiff bases of *S*-methyl- [11] and *S*-benzyldithiocarbazates [12,13]. The 2,6-diacetylpyridine Schiff base of *S*-benzyldithiocarbazate has been shown to act as an interesting chelating agent yielding a novel dinuclear pyridine-nitrogen-bridged nickel(II) complex whose structure has been determined by X-ray diffraction [12]. Recently we have also reported a novel binuclear zinc(II) complex in which the mode of coordination of the ligand is entirely different from that found in the dimeric nickel(II) complex [2]. The related 2,6-diacetylpyridinebis(thiosemicarbazone) has also been found to act as a versatile chelating agent producing zinc(II) complexes with different geometry

doi:10.1016/j.poly.2004.05.010

depending on the nature of the zinc(II) salts and reaction conditions used in the preparation of the complexes [13]. In view of very little work done on tin complexes of Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid and as part of our ongoing work on metal-dithiocarbazates, we report here the first examples of two seven-coordinate tin(IV) complexes of the 2,6-diacetylpyridine Schiff bases of *S*-methyl- and *S*-benzyl esters of dithiocarbazic acid together with the X-ray crystal structure of the Sn(dapsme)I_2 complex.

2. Experimental

2.1. Reagents

All chemicals were of analytical reagent grades and used without any further purification. Tin(IV) iodide was prepared according to the published procedure [14]. The ligands were prepared as described in our previous papers [11,12]. All physical measurements and analytical procedures used in the present work were similar to those described previously [1].

2.2. Preparation of the complexes

Tin(IV) iodide (0.18 g; 0.3 mmol) dissolved in boiling absolute ethanol (20 ml) was mixed with a boiling solution of the appropriate Schiff base (0.3 mmol) in a mixture of ethanol (20 ml) and dichloromethane (250 ml). The mixture was refluxed for 5 h and then left to stand overnight. The crystals of the tin complexes which had formed were then filtered off, washed with cold ethanol and dried in a desiccator over silica gel. Yield: 50–60%. Crystals of Sn(dapsme)I_2 suitable for X-ray analysis were obtained during preparation of the complex. *Anal.* Calc. for $C_{13}H_{15}N_5S_4SnI_2$: C, 21.04; H, 2.02; N, 9.40%. Found: C, 21.25; H, 1.95; N, 9.09%. *Anal.* Calc. for $C_{23}H_{25}N_5OS_4SnI_2$: C, 32.92; H, 2.75; N, 7.68%. Found: C, 32.46; H, 2.32; N, 6.60%.

2.3. Crystallography

For the compound Sn(dapsme)I_2 cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf-Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $2° < 2\theta < 50°$. Empirical absorption correction (ψ scans) and data reduction were performed with the WINGX [15] suite of programmes. The structures were solved by direct methods with SHELX-86 and refined by full-matrix least-squares analysis with SHELXL-97 [16]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions.

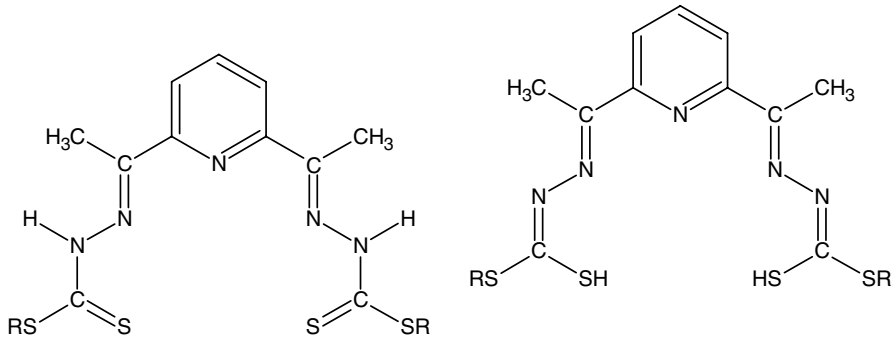
The drawing of the molecule (Fig. 2) was produced with ORTEP3 [17]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1 and selected bond lengths appear in Table 4.

3. Results and discussion

Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid possess the thioamide –NH– C(S)– functional group and consequently, they are capable of exhibiting thione-thiol tautomerism. In the solid state, the 2,6-diacetylpyridine Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate (Fig. 1(a); R = –SCH_3, SCH_2-C_6H_5), have previously been found to remain soley as the thione tautomer. In solution, they however, can exist as an equilibrium mixture of both the thione (**1a**) and thiol (**1b**) tautomers. Their ^{1}H NMR spectra in DMSO-d_6 show a broad signal at ≈12.60 ppm attributable to the resonance of the sec. NH proton. The appearance of the –NH– signal at ≈13 ppm and the absence of any signal at ≈4.00 ppm which can be attributed to the –SH proton, indicate that in DMSO, both the Schiff bases also remain in their thione forms. The presence of the N(H) signal at ≈12.60 ppm in the ^{1}H NMR spectra also indicates that the sec. NH protons are probably intermolecularly hydrogen bonded with a thione sulfur of another molecule or the NH protons participate in hydrogen bonding with the solvent DMSO. Although the Schiff bases remain in thione forms both in the solid state and in solution, in an ethanolic solution and in the presence of tin(IV) iodide, they quickly convert to the thiol forms with the con-



(**1a; R=CH_3, $CH_2C_6H_5$**) **(1b)**

Fig. 1. The thione (**1a**) and thiol (**1b**) forms of the Schiff bases.

comitant formation of tin(IV) complexes of their deprotonated mercaptide forms. This behaviour has been found to be common with almost all Schiff bases derived from *S*-alkyldithiocarbazates [1–10]. Thiosemicarbazones, which are structurally similar to Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid, do not always deprotonate in neutral media and consequently, their complexes of in both protonated [18–21] and deprotonated [22,23] forms have been prepared. There are also interesting examples of complexes in which both protonated and deprotonated forms of a thiosemicarbazone ligand have been found to be present in the same complex [24]. In contrast with thiosemicarbazones, Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid, almost invariably coordinate in their deprotonated forms even in the presence of mineral acids.

Reaction of tin(IV) iodide with the Schiff bases in a mixture of absolute ethanol and dichloromethane afforded beautiful bright orange coloured crystalline tin(IV) complexes of empirical formula, Sn(SNNNS)I_2 (SNNNS = anionic form of the Schiff bases) which are quite stable in the atmosphere and could be stored in a desiccator over anhydrous silica gel for a long period of time without any sign of decomposition. These complexes are sparingly soluble in methyl cyanide, chloroform and dichloromethane but dissolve readily in DMSO. Their molar conductances in DMSO are in the range 34.8–36.8 $ohm^{-1}\,cm^2\,mol^{-1}$, indicating that there is substantial dissociation of the complexes in this solvent but the conductivity values are much lower than those shown by 1:1 electrolytes in this solvent. The conductivity data, therefore, support coordination of the ligands to the tin(IV) ion in their deprotonated anionic forms and that the two iodide ions are also coordinated to the tin(IV) ion.

Table 3 lists the main IR bands of the ligand and their tin complexes. The IR spectra of the ligands when compared with those of the tin complexes indicate that the νNH bands of the free ligands disappear in the spectra of the complexes supporting deprotonation of the ligand during coordination with the tin ion. Coordination of the azomethine nitrogen to the tin atom is indicated by the shift the the νC=N bands of the free H_2dapsme ligand from 1617 to 1596 cm^{-1} in the spectrum of Sn(dapsme)I_2. However, in the IR spectrum of Sn(dapsbz)I_2 the νC=N band of the free H_2dapsbz ligand at 1600 cm^{-1} does not exhibit any shift after coordination. This is not surprising since the C=N band is expected to couple with other bands and therefore, its shifting will be dependent on how much it is in combination with other bands. However, support in favour of coordination of H_2dapsbz to the tin(IV) ion via the azomethine nitrogen atoms comes from the shift of the νN–N bands of the free ligand to higher wave numbers in the spectra of the tin complex [25]. The splitting of the ν_aCSS band of the ligand at $\approx$959 cm^{-1} in the IR spectra of the complexes indicates coordination of the ligands to the tin ion via one of the sulfur atoms [26]. Coordination via the pyridine nitrogen atom is also indicated by the shift of the pyridine ring breathing vibration of the ligands at 697–700 cm^{-1}.

The electronic spectra of the Schiff bases and their tin(IV) complexes are shown in Table 3. The spectra of the ligands exhibit bands in the range 389–345 and 264–256 nm assignable to the $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions, respectively. In addition to the intra-ligand bands, a shoulder appears at 410–420 nm in the spectra of the complexes which could be attributed to the $S \rightarrow Sn^{IV}$ charge-transfer band. Such CT bands are quite common in the electronic spectra of metal complexes of thiosemicarbazones [27,28].

The ^{1}H and ^{13}C NMR spectral data for the ligands and their tin complexes in DMSO-d_6 are compiled in Table 2. The changes in the spectra of the ligands upon complexation with the tin(IV) ion are closely related to those observed for other Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid, when they are coordinated to metal ions via the thiolate sulfur, the azomethine nitrogen and pyridine nitrogen atoms. In the ^{1}H NMR spectra of the complexes the following changes are observed: (i) The N(H) signal at ≈12.65 ppm of the free ligand disappears as a result of their deprotonation during coordination and (ii) the protons attached to the pyridine ring are deshielded as a result of coordination via the pyridine nitrogen atom but the –N=C(CH_3) protons are not affected even though coordination via the azomethine nitrogen atom occurs. In the ^{13}C NMR spectra, the carbon atom of the thiocarbonyl group undergoes a significant shielding effect on coordination to the tin(IV) ion. This is in contrast with the ^{13}C NMR spectra of the seven-cordinate tin(IV) complex of the related 2,6-diacetylpyridine thiosemicarbazone where a very little shift of this signal was observed [29]. The carbon atoms of the methyl groups (attached to the carbon atom of the azomethine group) are deshielded on coordination with the tin atom similar to that found in related tin complexes [30].

3.1. The structure of Sn(dapsme)I_2

Symmetry transformation $-x, y, -z + 1/2$.

symmetry, with the rotation axis passing through the Sn atom and the pyridyl N3 atom. Selected bond lengths and angles are given in Table 4. The structure shows that the complex is monomeric and the tin(IV) ion is in a seven-coordinate pentagonal bipyramidal environment being ligated by the two iodide ions at apical positions and the planar pentadentate SNNNS coordinated Schiff base in its deprotonated thiolate form through the thiolate sulfur atoms, the two azomethine nitrogen atoms and the pyridine nitrogen atom. The two Sn–N distances [Sn(1)–N(2) = 2.354(5) and Sn(1)–N(3) = 2.280(6)] are slightly higher than the sum of the non-polar covalent radii 2.15 Å indicating strong tin(IV)-nitrogen interaction. However, as found in other tin(IV) complexes of related pentadentate thiosemicarbazone ligands [29,30], the Sn–N_{py} bond distance [2.280(6) Å] in the present complex is shorter than the Sn–$N_{azomethine}$ distance [2.354(5) Å]. The higher basicity of the azomethine nitrogen atoms relative to that of the pyridine nitrogen atom should lead to shorter M–$N_{azomethine}$ distances than the M–N_{py} distances. This has in fact been observed in most four-, five- and six-coordinate metal complexes of thiosemicarbazones [31–33] and dithiocarbazates [1]. The shorter Sn–N_{py} distance compared with the the Sn–$N_{azomethine}$ distance in the present complex as well as in other related seven-coordinate tin(IV) complexes may be due to the geometric requirement of the structure in which the tin(IV) ion bonds with the pyridine nitrogen atom in such a way that it prevents the closer approach of the two imine nitrogen atoms. The Sn–S distance [2.563(2) Å] is longer than the sum of the covalent radii (2.42 Å) but it is considerably shorter than the van der Waals radii (4.0 Å) [34] suggesting a fairly strong bond. For the purpose of comparison, the Sn-donor atom distances of Sn(dapsme)I_2 together with those of other seven-coordinate complexes of related pentadentate chelating agents are shown in Table 5. The

[Sn(dapcheximtsc)Bu_2]	2.6924(6) 2.6924(6)	2.437(5) 2.437(5)	2.415(6)	2.148(10) 2.170(8)		[40]

Hadaptsc, monodeprotonated form of the 2,6-diacetylpyridinebis(thiosemicarbazone); H_2dapsc, neutral form of the 2,6-diacetylpyridinebis(semicarbazone); dapsme, doubly deprotonated form of the 2,6-diacetylpyridine Schiff base of *S*-methyldithiocarbazate; H_2daptsz-Me, Bis(4-*N*-methylthiosemicarzone)-2,6-diacetylpyridine; dapcheximtsc, doubly deprotonated form of 2,6-diacetylpyridine bis(3-hexamethyleneiminylthiosemicarbazone).

data indicate that all these complexes have comparable tin-donor atom distances irrespective of the oxidation state of the tin atom. An examination of bond distances in the dithiocarbazate chain shows that the C(1)–S(1) bond {1.719(6) Å} is longer than than that observed in free *S*-benzyldithiocarbazate [35] and other Schiff bases derived from related dithiocarbazates [36], being intermediate between 1.82 Å for a single and 1.56 Å for a double bond. While coordinating in its iminothiolate form, the negative charge generated upon deprotonation of the thiol group is delocalized across the coordinated N(1)–C(1)–S(1) group as supported by the intermediate (single/double bond) N(1)–C(1) distance [1.309(7) Å].

The coordinated dapsme^{2-} ligand presents an almost ideal pentagonal array of donor atoms. The five-membered chelate rings each have bite angles (Table 4) within 3° of their ideal value (72°). The N_3S_2 coordination core is approximately planar with deviations of 0.139 Å for S(1) and −0.099 Å for N(2) from the SnN_3S_2 least squares plane (where Sn(1) and N(3) lie on the plane). The symmetry related iodo ligands are distorted somewhat away from linear *trans*-conformation (168.24(3)°).

4. Conclusions

The 2,6-diacetylpyridine Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazates, like most Schiff bases derived from *S*-alkyl esters of dithiocarbazic acid, remain as the thione tautomer in both the solid state as well as in solution but, in the presence of tin(IV) iodide they convert to the iminothiol form, deprotonate and coordinate with the tin(IV) ion as a dinegatively charged pentadentate SNNNS chelating agent. The tendency of the ligands to deprotonate even in a neutral solution may be attributed to the extra stability gained by them through π-electron delocalization along the –C–N–N–C–S–chains in the two arms of these ligands. The ready formation of stable 1:1 metal-ligand complexes with tin(IV) iodide with the elimination of HI indicates that these ligands are capable of coordinating with non-transition metals like tin even though they have both soft sulfur donor atoms in their backbones. The adoption of a distorted pentagonal-bipyramidal geometry by the Sn(SNNNS)I_2 complexes is due to the restricted bite sizes of the ligands.

5. Supplementary materials

Full crystallographic data (CCDC No. 237458) for Sn(dapsme)I_2 have been deposited at the Cambridge Crystallographic Data Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Treatment of $Cd(NO_3)_2 \cdot 4H_2O$ with two equivalents of NH_4NCS in combination with two equivalents of imH [imH = imidazole] or one equivalent of pfan [pfan = ((pyridin-2-yl)formylidene)aniline] results neutral 1D polymers of the type $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**) or $[Cd(pfan)(NCS)(SCN)]_n$ (**2**). X-ray structure determinations show that in both polynuclear **1** and **2**, octahedral Cd^{II} ions occupy centre of symmetry with a CdN_4S_2 chromophore. The metal ions are linked through N and S atoms of NCS^- alternately in doubly bridged end-to-end fashion; two mutually *trans* N atoms of monodentate imH units complete hexacoordination of each metal centre in **1**. Similar NCS-bibridging chain is present in **2** with one bidentate (N,N) Schiff base chelator (pfan) in *cis* orientation. The 1D chains in **1** are further engaged in intermolecular hydrogen bonding (N–H···S) between N of imH and coordinated S of NCS^- along with aromatic π–π stacking of imH moieties that constrain the 1D chains to lie in *bc*-plane, which are further linked via C–H···π interactions. In **2**, 1D chains participate in two kinds of π–π interactions. Supramers **1** and **2** display intraligand $^1(\pi–\pi^*)$ fluorescence and intraligand $^3(\pi–\pi^*)$ phosphorescence in glassy solutions (MeOH at 77 K).

1. Introduction

The construction [1] of sophisticated inorganic–organic hybrid [2] supramolecular networks [3] based on organised strong covalent interactions [4] and extensive lateral weak non-covalent forces like hydrogen bonding [5], π–π stacking [6] and C–H···π interactions [7] is an area of great activity due to fabrication of functional materials [8–13] utilizing the wide variety in properties associated with each suitably tailored component. Among the weak forces, hydrogen bonding is a general protocol for structure directing master key interaction, and has been widely used towards crystal design [5,14,15]. On the contrary, less attention [6,7,16,17] has been paid to cooperative weaker π···π and C–H···π interactions, which may tune topology [18] effectively and untangle the intrigue interactions in peptide and protein structures and associated properties [19]. Recently, we have established the composition tailored superstructures [20] on luminous zinc(II)azides containing a tailored diimine, 2,2′-dipyridylamine (dpa) with active amine (–NH–) hydrogen and aromatic π rings. In continuation of our research on congeneric cadmium, we have investigated its binding with

thiocyanate in combination with a monodentate blocker, imidazole (imH), and bidentate Schiff base chelator, ((pyridin-2-yl)formylidene)aniline (pfan), with or without active hydrogen on ligand network coping with possible H-bonding, face-to-face $\pi\cdots\pi$ and/or edge-to-face C–H$\cdots\pi$ interactions due to the presence of aromatic π-rings towards preparation of metallosupramolecules of different aggregates. Polynuclear cadmium complexes in which the metal centres are in close proximity has received much attention due to study of electronic and optoelectronic properties [21] towards designing of new inorganic materials [22]. Thiocyanate is a putative ambidentate ligand, which results in different molecular architectures through its versatile ligation modes [23]. Imidazole [24] with its active –NH– hydrogen and aromatic π-ring, is a versatile blocker and the interest in its chemistry arises from the use as ionic liquids [25] and in different compounds from a biological and pharmacological applications [26]. Schiff bases [27,28] have recently been focussed by the coordination chemists due to their preparational accessibilities, structural varieties and varied denticities. The present work stems from our interest to build new crystalline aggregates in cadmium bound states with such bridging units. Successfully we have prepared and X-ray crystallographically characterized two one-dimensional (1D) coordination polymers of the type $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**) and $[Cd(pfan)(NCS)(SCN)]_n$ (**2**). **1** and **2** exhibit fascinating self-assembled structural topologies via cooperative H-bonds and aromatic face-to-face $\pi\cdots\pi$ and edge-to-face C–H$\cdots\pi$ interactions (in **1**) or via $\pi\cdots\pi$ interactions (in **2**). In this paper an emphasis has been made to show how use of such intermolecular cooperative forces may be harnessed to engineer novel crystalline architectures.

2. Experimental

2.1. Materials

High purity imidazole (SRL, India), aniline (E. Merck, India), pyridine-2-carboxaldehyde (Lancester, UK), cadmium nitrate tetrahydrate (E. Merck, India) and ammonium thiocyanate (E. Merck, India) were purchased from respective concerns and used as received. The Schiff base (pfan) was prepared [28b] by condensing pyridine-2-carboxaldehyde with aniline in dehydrated alcohol in the 1:1 molar ratio. After 8 h reflux the reaction solution was evaporated under reduced pressure to a gummy mass, which was dried and stored in vacuo over $CaCl_2$ for subsequent use. Yield: 0.137 g (70%). *Anal.* Calc. for $C_{12}H_{10}N_2$: C, 79.10; H, 5.53; N, 15.37. Found: C, 78.98; H, 5.46; N, 15.65%. IR (KBr, cm^{-1}): ν(C=N), 1590 cm^{-1}. UV–Vis (λ, nm): 254, 390. All other chemicals and solvents were AR grade and were used as received.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a JASCO FTIR model 420 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry MeOH was used as solvent. Ground state absorption and steady-state fluorescence measurements were made with a JASCO model V-530 UV–Vis spectrophotometer and Hitachi model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photomultiplier tube were, respectively, used as the excitation source and the fluorescence detector.

2.3. Preparation of the complexes

The complexes were prepared using 1:2:2 and 1:1:2 mole ratio of the metal, ligand and thiocyanate for **1** and **2**, respectively. The typical syntheses are described below.

2.3.1. $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**)

Solid imH (0.136 g, 2 mmol) was added slowly to $Cd(NO_3)_2\cdot 4H_2O$ (0.308 g, 1 mmol) dissolved in methanol (10 cm^3). To this, a methanol solution (5 cm^3) of NH_4NCS (0.152 g, 2 mmol) was added (5 cm^3). The resulting colourless solution was filtered and was kept for slow evaporation. After seven days colourless crystals that were separated, was collected by filtration, washed with toluene and dried in vacuo over silica gel indicator. Yield: 0.095 g (80%). *Anal.* Calc. for $C_8H_8N_6S_2Cd$ (**1**): C, 26.34; H, 2.21; N, 23.04. Found: C, 26.52; H, 2.31; N, 22.31%. IR (KBr, cm^{-1}): ν(N–H) 3310; ν(CN), 2120, 2106. Λ_M (MeOH, Ω^{-1} cm^2 mol^{-1}): 5; UV–Vis (λ, nm): 311.

2.3.2. $[Cd(pfan)(NCS)(SCN)]_n$ (**2**)

Pfan (0.182 g, 1 mmol) in MeOH (10 cm^3) was added dropwise to a solution of $Cd(NO_3)_2\cdot 4H_2O$ (0.308 g, 1 mmol) in the same solvent (10 cm^3). To the resulting yellowish brown mixture, aqueous solution (5 cm^3) of NH_4NCS (0.152 g, 2 mmol) was added slowly. The final mixture was filtered and the supernatant liquid was kept in air for slow evaporation. After about a week compound **2** was separated which was collected by filtration, washed with toluene and dried in vacuo over silica gel

indicator. Yield: 0.093 g (70%). *Anal.* Calc. for $C_{14}H_{10}N_4S_2Cd$ (**2**): C, 40.94; H, 2.45; N, 13.64. Found: C, 40.68; H, 2.57; N, 13.52%. IR (KBr, cm^{-1}): ν(CN), 2120, 2104. Λ_M (MeOH, Ω^{-1} cm^2 mol^{-1}): 5; UV–Vis (λ, nm): 328.

2.4. X-ray crystallographic analyses

Single crystals of the title complexes were obtained by slow evaporation of methanol (**1**) and 4:1 methanol–water (**2**) solutions of the reaction mixtures at room temperature (298 K). Suitable colourless crystals were mounted on a Siemens SMART CCD (**1**) and Bruker-AXS SMART APEX/CCD (**2**) diffractometers equipped with a graphite-monochromator and Mo Kα ($\lambda = 0.71073$ Å) radiation. Diffraction data for both **1** and **2** were measured using the ω-scan method. Crystal data, data collection parameters and the results of analyses can be found in Table 1. The intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was employed using the SAINT [29] and SADABS [30] program for crystal **1**, and no absorption correction was made for **2**. The structures were solved by direct methods and the structure solution and refinement were based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic U values 1.2 times that of the atom to which they are bonded. The final difference Fourier map showed the highest residual electron density of 1.091 e $Å^{-3}$ at a distance of 0.62 Å from Cd(II) atom for **2**, having no chemical significance. All crystallographic calculations were conducted with SHELXL-97 [31], ORTEP-32 [32], PLATON programs [33] for **1** and the SHELXTL v.6.1 program package [34] for **2**.

3. Results and discussion

3.1. Synthesis and formulation

The coordination polymer $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**) was prepared as a colourless powder through one-pot reactions of a 1:2:2 molar ratio of the metal nitrate, organic blocker and the pseudohalide from methanolic solutions. The other polymer $[Cd(pfan)(NCS)(SCN)]_n$ (**2**) was obtained with a 1:1:2 molar ratio of cadmium nitrate tetrahydrate, pfan and ammonium thiocyanate, respectively, in aqueous alcohol. The compounds have been characterized by microanalytical (C, H and N) results, IR, UV–Vis spectral data and other physicochemical properties. The air-stable moisture-insensitive complexes $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**) and $[Cd(pfan)(NCS)(SCN)]_n$ (**2**) are soluble in common organic solvents like, methanol, ethanol, dichloromethane, dimethylformamide and dimethylsulfoxide. In methanol both behave as non-electrolytes as is evident [35] from their low conductivity values (ca. 5 Ω^{-1} cm^2 mol^{-1}). The IR spectra show two strong peaks at 2120, 2106 cm^{-1} in

1 and 2120, 2104 cm^{-1} in **2**, which are assigned to ν_{as}(CN) stretching vibrations [36]. The position (>2100 cm^{-1}) and number of signals strongly suggest mutual *cis* alignment as well as N- and S-coordinated bridging nature of the bound thiocyanates. The X-ray diffraction study confirms this hypothesis. The solution of **1** in MeOH is colourless and exhibits absorption at 311 nm while the faint yellow solution of complex **2** displays bands at 328 nm. Reflectance spectra [**1**: λ, 310 nm; **2**: λ, 325 nm] in nujol and electronic spectra in MeOH solutions are akin in both complexes reflecting similar gross structure and electronic structure in solid state and in solution in each case.

3.2. Structure

The structural analyses show that **1** and **2** consist of strong 1D covalent chains cooperated by weak N–H···S hydrogen bonding, π···π stacking and C–H···π interactions in **1** and two kinds of π···π interactions in **2**. The ORTEP diagrams of part of the chains with atom labeling scheme, perspective view of the 2D sheets and arrangement of these sheets are shown in Figs. 1–3 (for **1**) and Figs. 4–6 (for **2**), respectively. Selected interatomic bond distances and bond angles of **1** and **2** are set in Tables 2 and 3, respectively. The significant hydrogen bonding, π···π interaction and C–H··· interaction parameters can be found in Table 4 following the criteria of Janiak [37].

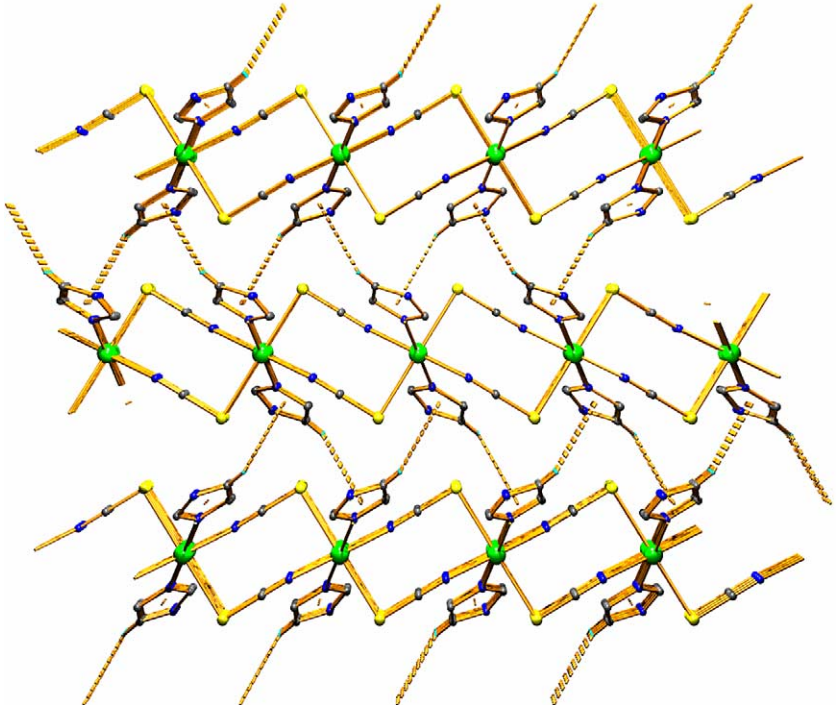

Fig. 3. C–H···π in **1** interactions among the supramolecular sheets.

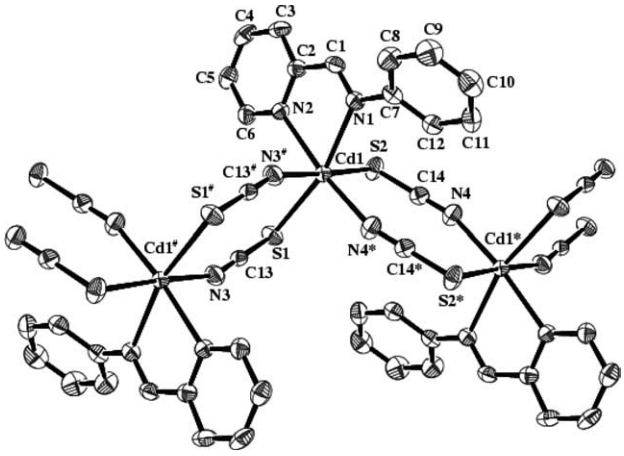

Fig. 4. ORTEP plot of $[Cd(pfan)(NCS)(SCN)]_n$ (**2**) with atom numbering scheme and 40% probability ellipsoids for all non-hydrogen atoms.

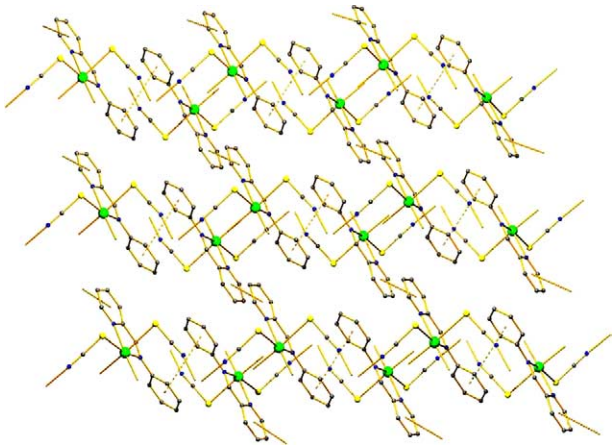

Fig. 6. $\pi\cdots\pi$ interactions in **2** among the supramolecular sheets.

Complex **1** is made up of 1D chains along *c*-axis. The coordination environment around each cadmium(II) is best described as distorted octahedron with CdN_4S_2 chromophore (Fig. 1) in a *trans*,*trans*,*trans* geometry of imH nitrogens and nitrogen and sulphur atoms of coordinated NCS^-. Each cadmium(II) is attached to four NCS^- bridges and two pendant imH ligands. The metal ion occupies centre of inversion. Two N atoms (N1, $N1^a$) of pendant imH ligands and two N atoms ($N3^c$, $N3^b$) of bridging NCS^- form the equatorial plane. The *trans* axial positions are occupied by the two symmetry related S atoms. The distortion of each cadmium(II) is reflected from the *cisoid* angles [87.80(5)°–92.20(5)°] (Table 2). The eight-membered Cd–$(SCN)_2$–Cd rings adopt chair conformation. The intrachain Cd···Cd separation is 5.769 Å.

The polymeric chains of $[Cd(imH)_2(NCS)(SCN)]_n$ (**1**) pack alongside each other to give a 2D sheet-like structure in *bc*-plane. Closest 1D chains are arranged side by side to facilitate a weak N–H···S hydrogen bond (Table 4). The 2D sheets are further stabilised by a

face-to-face π···π interactions from two terminal imH rings of two closest chains (Fig. 2). Every such sheet is further locked by a C–H···π interaction (Table 4) to generate an aesthetically pleasant solid state continuum (Fig. 3).

In **2** cadmium(II) centres are linked by bibridged end-to-end thiocyanato ligands resulting a 1D polymeric infinite chain (Fig. 4) which is composed of [Cd(pfan)-(NCS)(SCN)] monomer where the metal centres are coordinated by both N and S in *cis* position. Each cadmium(II) ion is linked with two of its neighbouring symmetry related counterparts (Cd1*), by two end-to-end thiocyanate ligands, and effectively each metal centre is ligated with four bridging pseudohalides producing two eight-membered loops. Similar to **1**, the eight-membered Cd–$(SCN)_2$–Cd loops adopt chair conformation. Octahedral coordination around each metal centre is completed through binding to one bidentate pfan chelator forming a five-membered loop. This feature makes the polymeric structure unique. One nitrogen atom (N1) from bidentate Schiff base chelator, one nitrogen atom ($N3^{\#}$) and two sulphur atom (S1, S2) of the three NCS^- define the equatorial plane around cadmium. The *trans* axial sites are occupied by nitrogen atom (N2) from bidentate organic blocker and fourth nitrogen (N4*) of the bridging thiocyanate. Deviation of cadmium(II) from the mean plane formed by four equatorial atoms (N1, $N3^{\#}$, S1, S2) is about 0.1713 Å. The Cd–N bond lengths are shorter than the bridging Cd–S distances (Table 3) and are consistent with the corresponding values of cadmium(II)thiocyanato bridging system [23]. Cd1-N1 [imine] distance is slightly greater than Cd1–N2 [pyridine] bond length. Angles in the equatorial plane are close to the ideal 90.00° and lie within a close range [86.21(3)°–93.73(8)°]. *Trans* axial angle N2–Cd1–N4* shows slight deviation from ideal 180.00°. The dihedral angle between the planar pyridine and benzene moieties of pfan ligand is 47.3(2)°. The nearest neighbouring Cd···Cd distances within the chain are 5.908 and 5.795 Å.

The chains of $[Cd(pfan)(NCS)(SCN)]_n$ (**2**) pack alongside each other to give a sheet-like structure (Fig. 5) in *bc*-plane containing only π···π interactions. Here, two pyridyl rings from two closest chains are linked through face-to-face π-interactions (Table 4). The 2D sheets are further locked by another weaker face-to-face π···π interactions from two terminal benzene rings (Fig. 6), where the π-interactions (Table 4) are mainly responsible for the formation of solid state.

Recent literature on π···π interactions in metal complexes containing pyridyl-type ligands [38,39] shows that such non-covalent interaction plays an important role on crystal packing, and aromatic N-heterocycles are well suited for fabricating congregated π···π motifs because of their low π-electron density. Likewise, the presence of two N atoms in imH blocker in **1** facilitates such relatively stronger non-covalent interactions as compared to that in **2**.

3.3. Luminescence spectra

The spectroscopic data in methanol solutions and glasses are listed in Table 5. **1** shows emission spectrum at 348 nm while compound **2** has a band at 395 nm at 298 K (Fig. 7). These are assignable to intraligand $^1(\pi–\pi^*)$ fluorescence. **2** has very weak fluorescence; the lifetimes are 2.04 ns (**1**) and 2.42 ns (**2**), respectively. Though complex **1** shows overall stronger weak interaction, this higher lifetime in **2** may be due to the presence of a stronger π···π interactions (pyridyl–pyridyl), which is mainly responsible for fluorescence. In

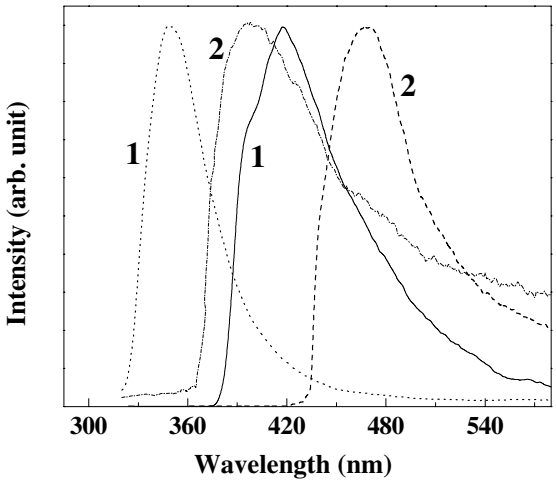

Fig. 7. Fluorescence of **1** in MeOH solution at 298 K (·····), phosphorescence in MeOH glassy solution (——); fluorescence of **2** in MeOH solution at 298 K (–·–·–), phosphorescence in MeOH glassy solution (- - - - -).

Table 5
Photophysical data for **1** and **2**

Sample	Absorption (λ (nm))	Emission (λ (nm))		Lifetime (ns)
		Fluorescence[a]	Phosphorescence[b]	
1	311	348	417	2.04
2	328	395	470	2.42

[a] In MeOH at room temperature (298 K).
[b] In MeOH at 77 K.

glassy solutions (77 K) a red shift is observable (417 nm for **1** and 470 nm for **2**) which is presumably due to $^3(\pi$–$\pi^*)$ phosphorescence.

4. Conclusion

Two new inorganic organic composite luminous polymers are synthesised through single-pot reactions of the building components with preassigned ratios. The C–H(imH)$\cdots\pi$ interaction in **1** indicates acidity of C–H proton of imH ring. No such hydrogen bonding in **2** indicates less acidity of the C–H proton in pfan Schiff base. The presence of more than one hetero N in imH compared to single N in pyridine ring of pfan facilitates such weak force, and topology is engineered accordingly. Structures **1** and **2** represent the reliability of combinations of strong/weak interactions in crystal engineering because of the concomitant predictability of the crystal design. This work reflects that a combination of a moderate to strong interaction and a weaker interaction seems to result synthon robustness giving variable architectures. In the future, we will expand the types of networks through change of organic blocker, metal template and bridging unit.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-217234 (**1**) and 211535 (**2**). Copies of this information can be obtained, free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Available online 3 July 2004

Abstract

4,13-Diaza-18-crown-6 is shrouded by two *p*-sulfonatothiacalix[4]arenes in the presence of trivalent lanthanide ions in two different types of arrangements: (4,13-diaza-18-crown-6){(4,13-diprotodiaza-18-crown-6) ⊂ {[La(H_2O)$_8$(*p*-sulfonatothiacalix[4]arene)$^{4-}$]$^-$}$_2$} · 17H_2O **(1)** and (4,13-diprotodiaza-18-crown-6){[Eu(NO_3)(H_2O)$_7$]$^{2+}$}$_2$}{(4,13-diprotodiaza-18-crown-6) ⊂ [(*p*-sulfonatothiacalix[4]arene)$^{4-}$]$_2$} · 17H_2O **(2)**. In complex **1**, one sulfonato group of thiacalixarene ligates to the La^{3+} ion, but in complex **2,** the *p*-sulfonatothiacalixarene does not directly coordinate to the Eu^{3+} ion which exists as [Eu(NO_3)(H_2O)$_7$]$^{2+}$ but acts as a second-sphere ligand through hydrogen bonding. In both complexes, thiacalixarenes form irregular bi-layer structures in which the exo-capsule diaza-18-crown-6 traverses the hydrophobic layers.

Keywords: Sulfonatothiacalixarene; Capsules; Diaza-18-crown-6; Lanthanide ions

1. Introduction

Water-soluble calix[*n*]arenes have been widely investigated and are becoming increasingly important in the field of supramolecular chemistry and crystal engineering, showing interesting inclusion properties and a wide range of metal coordination complexes both in solution and in the solid state [1]. *p*-Sulfonatocalix[4]arene is a highly versatile tecton, generating various structural motifs which include 'molecular capsules' [2–7], 'ferris wheels' [8], hydrogen bonded polymers [9], 2-D coordination polymers [9–11], as well as nanometer scale spheres and tubules [12].

Similar to *p*-sulfonatocalix[4]arene, Na_4[thiacalix[4]arene tetrasulfonate] · ethanol · 8H_2O also shows a bi-layer structure in the solid state [13] and the thiacalixarene unit adopts the cone configuration. It is also shown to form large molecular assemblies with highly complex supramolecular architectures in the presence of suitable guest molecules. In our recent studies, we focused on the supramolecular chemistry of water-soluble *p*-sulfonatothiacalix[4]arene [14–17]. In this paper, we report the formation of ionic capsules where the di-protonated 4,13-diaza-18-crown-6 is shrouded by two *p*-sulfonatothiacalix[4]arenes in the presence of lanthanide ions.

2. Experimental

2.1. Materials and methods

4,13-Diaza-18-crown-6 [18] and tetrasodium *p*-sulfonatothiacalix[4]arene [13] were synthesized by literature methods. All other reagents were commercially available and used without further purification.

C, H and N were determined using an Elementar Vario EL analyzer. The UV spectra in aqueous solution were measured using a GBC Cintra 10e UV–Vis spectrophotometer. The IR spectra were recorded on a

Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique in the 400–4000 cm^{-1} regions.

2.2. Preparation of (4,13-diaza-18-crown-6){(4,13-diprotodiaza-18-crown-6) ⊂ {[La(H_2O)$_8$(p- sulfonatothiacalix[4]arene)$^{4-}$]$^-$}$_2$}·17H_2O (1) and (4,13-diprotodiaza-18-crown-6){[Eu(NO_3)(H_2O)$_7$]$^{2+}$}$_2${(4,13-diprotodiaza-18-crown-6) ⊂ [(p-sulfonatothiacalix[4]arene)$^{4-}$]$_2$}·17H_2O (2)

4,13-Diaza-18-crown-6 (26 mg, 0.1 mmol) and tetrasodium *p*-sulfonatothiacalix[4]arene (45 mg, 0.05 mmol) were dissolved in deionized water (5 mL), and the solution was acidified up to pH ≈ 2 with perchloric acid, to which 0.2 mmol $Ln(NO_3)_3$ ($Ln^{3+} = La^{3+}$, Eu^{3+}) was added. After several days, large crystals suitable for X-ray diffraction analysis were formed. The crystals quickly cracked when removed from the mother liquor. UV (in water): $\lambda_{max}/nm(\varepsilon_{max}/dm_3\,mol^{-1}\,cm^{-1}) = 208$ (9.07×10^4), 305 (1.45×10^4) (for complex **1**), λ_{max}/nm ($\varepsilon_{max}/dm_3\,mol^{-1}\,cm^{-1}) = 208$ (1.04×10^5), 305 (1.60×10^4) (for comp1ex **2**). IR: sulfonate absorptions: $\nu = 1221$, 1146, 1037 cm^{-1} (for comp1ex **1**), $\nu = 1221$, 1145, 1037 cm^{-1} (for comp1ex **2**). Elem. *Anal*. Calc. for $C_{36}H_{62}LaN_2O_{31.5}S_8$: C, 30.40; H, 4.40; N, 1.97. Found: C, 30.11; H, 4.26; N, 2.11% (the analytical data is only for the samples having lost five water molecules during transport), *Anal*. Calc. for $C_{36}H_{54}EuN_3O_{30}S_8$: C, 30.51; H, 3.85; N, 2.97. Found: C, 30.15; H, 3.99; N, 2.59% (the analytical data is only for the samples having lost 8.5 water molecules during transport).

2.3. X-ray data collections and structure determinations

X-ray data were collected at 293(2) K on a Bruker SMART 1000 CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). The crystals were sealed in a glass capillary with a few drops of mother liquor in order to prevent cracking owing to solvent loss. The structures were solved by direct methods and refined by full-matrix least-square techniques on F^2 using the SHELXL-97 program. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms on the crown ether and the thiacalixarene were placed at their calculated positions and assigned with isotropic displacement parameters. The hydrogen atoms on the water molecules could not be located. A number of lattice water molecules were disordered and were given partial occupancies. The experimental details for X-ray data collection of the complexes are presented in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

The complexes were prepared by mixing the corresponding lanthanide ion (III) nitrates, 4,13-diaza-18-crown-6 and tetrasodium *p*-sulfonatothiacalix[4]arene in an aqueous solution, with the pH adjusted to 2 (see Scheme 1).

The structure of complex **1** is shown in Fig. 1. It consists of several structural components: the anionic capsule {(4,13-diprotodiaza-18-crown-6) ⊂ {[La(H_2O)$_8$

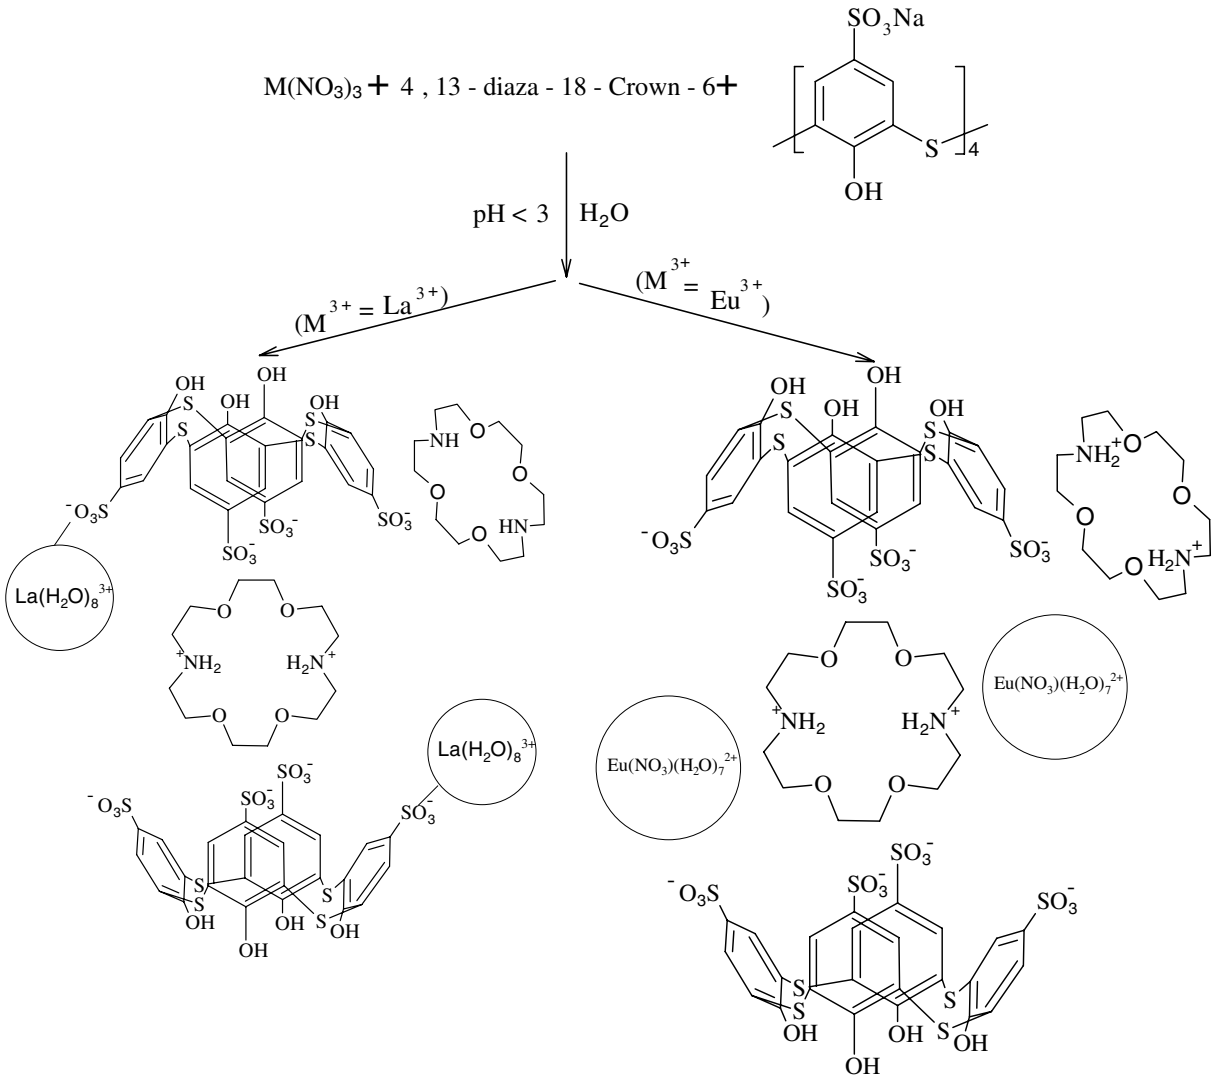
(*p*-sulfonatothiacalix[4]arene)$^{4-}$]$^{-}$}$_2$}, one disordered exo-capsule diaza-crown ether, and two water molecules hydrogen bonded to the crown ether, along with several disordered lattice water molecules. An oxygen atom of a sulfonato group coordinates to a lanthanum ion at a La–O bond distance of 2.503 Å. The metal ion is also ligated to eight aqua ligands at an average La–O bond distance of 2.544 Å. The cation is ligated in a distorted mono-capped tetragonal *anti*-prismatic geometry.

A di-protonated diaza-crown ether is sandwiched by two thiacalixarenes, each of which has two sulfonato groups disordered in an 'up–down' fashion forming a capsule. There is a water molecule on either side of the di-protonated diaza-crown ether guest molecule. This is reminiscent of the capsule created by the di-protonated diaza-crown ether and *p*-sulfonatocalix[4]arene [7], but in the present structure, the water molecules hydrogen are bonded to two *trans* oxygen atoms of the crown ether with O···O distances of 2.874 and 3.093 Å, not to the di-protonated nitrogen atoms.

In the present structure, the splaying effect of the thiacalixarene is observed, which is the decisive factor in



Scheme 1.

the formation of an 'ion capsule'. The dihedral angles between the two splaying aromatic rings and the plane of the four phenolic oxygens are 146.8° and 138.3°. The other two are 118° and 105.4°. There are also hydrogen bonds from the lattice water molecules to the sulfonato groups of the two thiacalixarenes with O···O distances from 2.742 to 2.921 Å.

There is an exo-capsule crown ether which is interspersed between columns of 'up–down' thiacalixarenes, so an irregular bi-layer assembly is formed (see Fig. 2). The interactions between the adjacent thiacalixarenes are not π–π stacking, but are hydrogen bonds between the sulfonato groups and the phenolic groups or hydrogen bonds mediated by lattice water molecules. The interaction between the thiacalixarene and the exo-capsule crown ether are hydrogen bonds bridged by lattice water molecules.

The structure of complex **2** is shown in Fig. 3. It consists of several structural components: the anionic capsule {(4,13-diprotodiaza-18-crown-6) ⊂ [(*p*-sulfonato-thiacalix[4]arene)$^{4-}$]$_2$}, one exo-capsule di-protonated diaza-crown ether and two $[Eu(NO_3)(H_2O)_7]^{2+}$ ions, along with several disordered lattice water molecules. The Eu^{3+} ion is not bound directly to any sulfonato groups, but exists as the $[Eu(NO_3)(H_2O)_7]^{2+}$ ion, forming part of the secondary coordination sphere through hydrogen bonding. This is different from that of complex **1**. A NO_3^- anion coordinates to Eu^{3+} as a bidentate ligand, at an average Eu–O bond distance of 2.518 Å. The metal ion is also ligated to seven aqua ligands at an average Eu–O bond distance of 2.443 Å. There is extensive hydrogen bonding from the ligated water molecules of the europium ion to sulfonato groups of the two thiacalixarenes in the nearest 'ionic capsule' with hydrogen bonding MO···OS distances of 2.968 and 2.975 Å.

In this structure, a disordered di-protonated diaza-18-crown-6 is at the core of the 'ionic capsule'. In

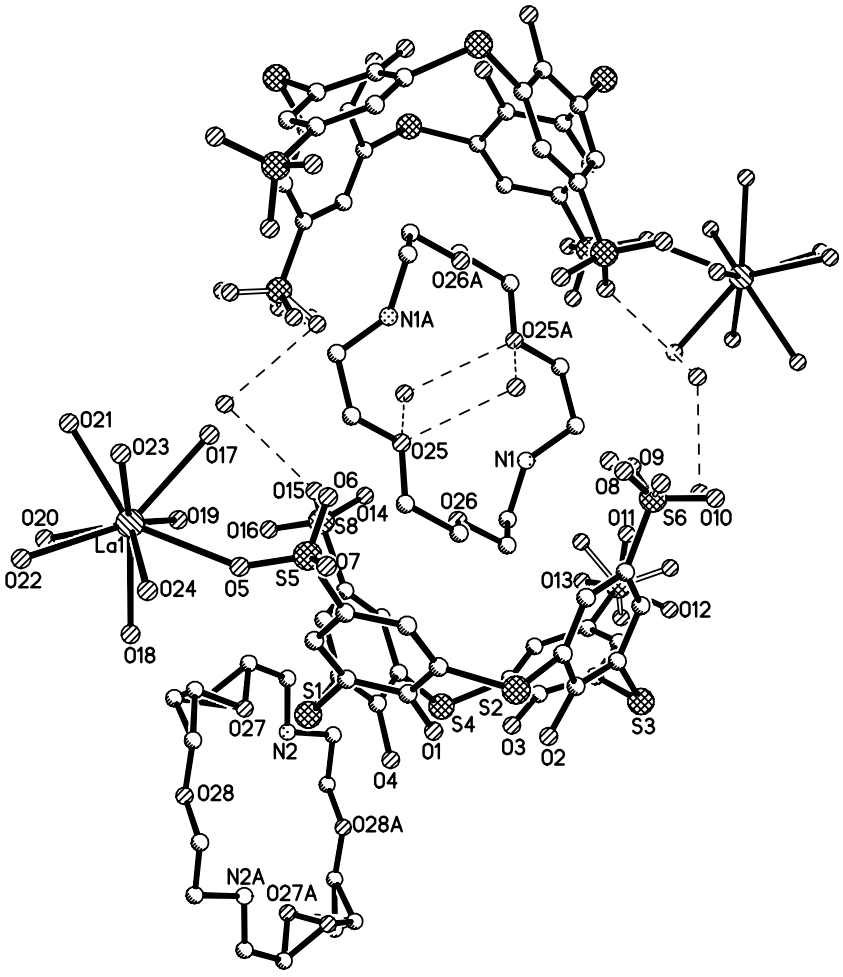


Fig. 1. An 'ionic capsule' in **1**; dashed lines indicate hydrogen bonds (hydrogen atoms and lattice water molecules have been omitted for clarity).

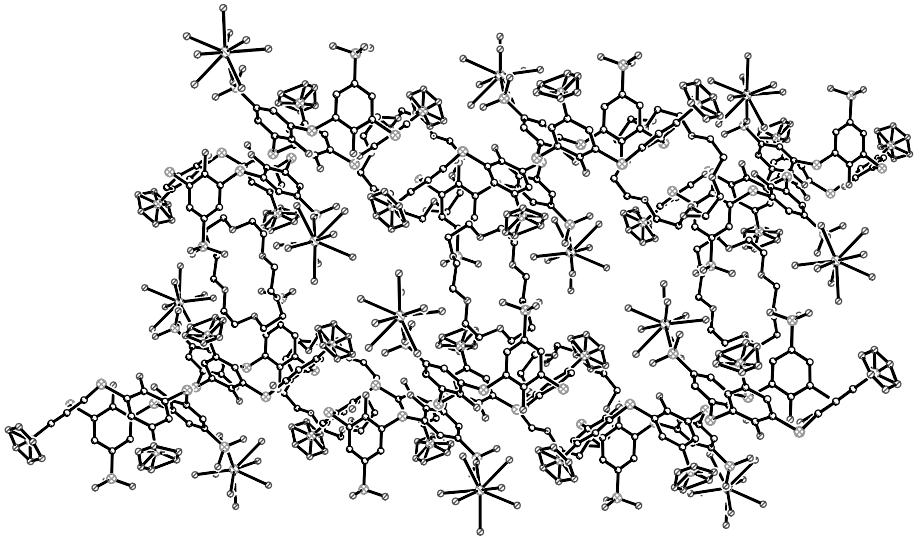

Fig. 2. Projection of **1,** showing the bi-layer packing.

addition to the splaying effect (the dihedral angles between the two splaying aromatic rings and the plane of the four phenolic oxygens are 141.4° and 134°, the other two are 113.9° and 109.8°), the hydrogen bonds between the di-protonated nitrogen atoms of the crown ether and the disordered sulfonato groups of the two

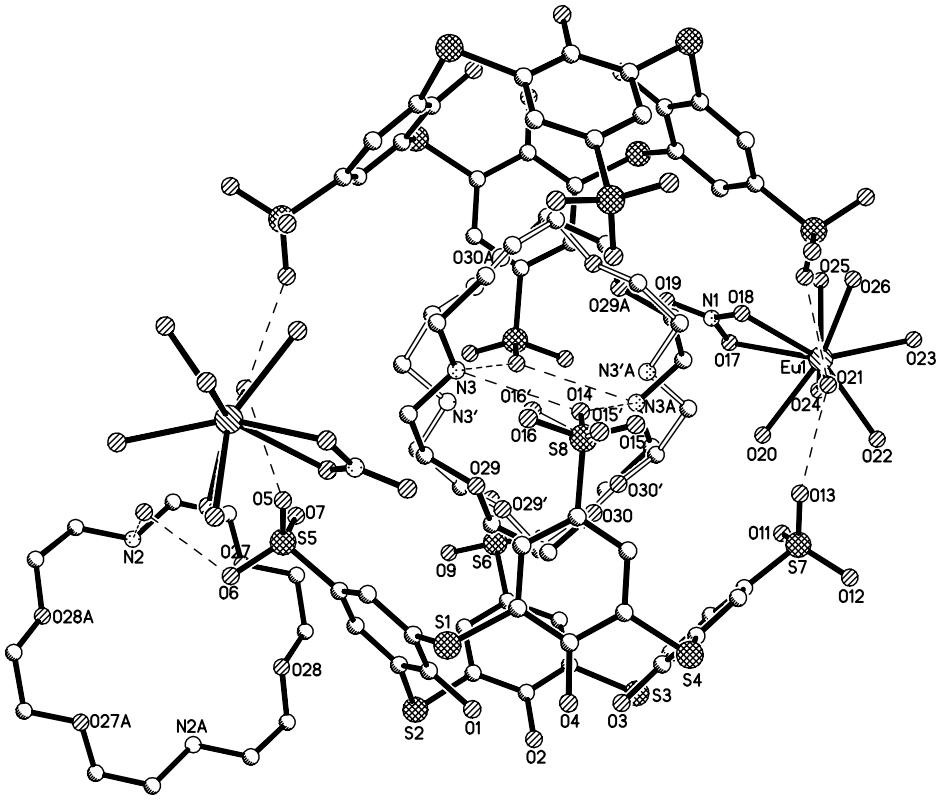

Fig. 3. An 'ionic capsule' in **2**; dashed lines indicate hydrogen bonds (hydrogen atoms and lattice water molecules have been omitted for clarity).

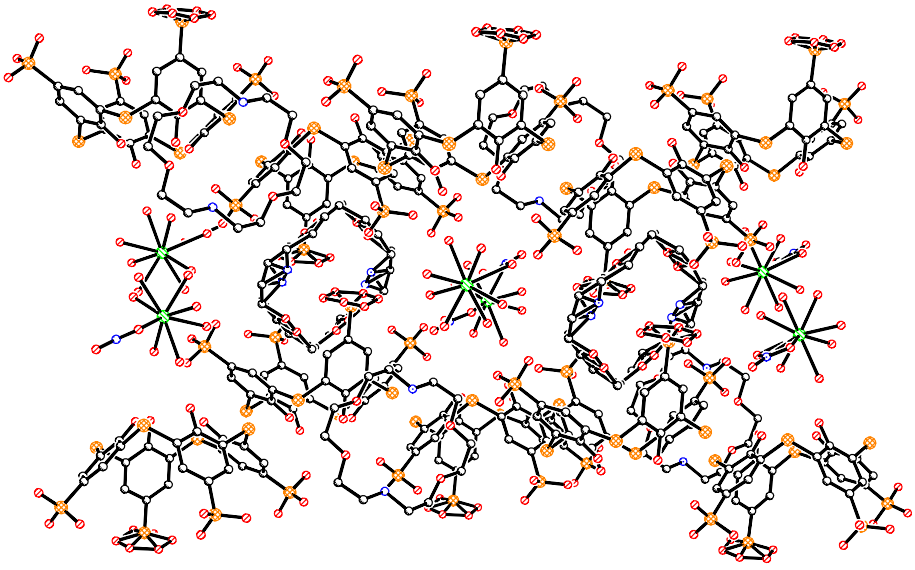

Fig. 4. Projection of **2**, showing the bi-layer packing.

thiacalixarenes which form the shell of the capsule stabilize the ionic capsule assembly. The distances of N···O range from 2.673 to 3.067 Å.

Similar to complex **1**, as an exo-capsule di-protonated diaza crown ether intersperses into the hydrophobic layer, a particular bi-layer structure is formed (see Fig. 4).

4. Conclusion

In both complexes, the 4,13-diaza-18-crown-6 is shrouded by two thiacalixarenes in the presence of trivalent lanthanide ions to form an ionic capsule. In addition to forming 'ionic capsules', the diaza-crown ethers can also insert into the hydrophobic layers via a

variety of supramolecular interactions. These are similar to the related complexes of transition metal ions ($M^{2+} = Co^{2+}$, Ni^{2+}, Cu^{2+}) with 4,13-diaza-18-crown-6 and *p*-sulfonatothiacalix[4]arene [17]. But the coordination modes of the cations with the *p*-sulfonatothiacalix[4]arenes in the lanthanide ionic complexes are different from that in the related transition metal ionic complexes in which the thiacalixarenes coordinate to transition metal ions through phenolic groups and a bridging sulfur atom at the base due to the fact that the bridging sulfur atom tends to bind the transition metal ions.

5. Supplementary data

CCDC-230797 (complex **1**) and CCDC-230796 (complex **2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge, CB2 1EZ, UK [fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Abstract

Reaction of $ZnCl_2$ with *R*,*R*-bmbcd (= *N*,*N*′-bis(4-methoxy-benzyl)-cyclohexane-1,2-diamine) **1** in ethanol yields the chiral [$ZnCl_2$(*R*,*R*-bmbcd)] **2**, which crystallizes in the monoclinic space group $P2_1$. The Zn atom has a distorted tetrahedral geometry involving two nitrogen atoms of *R*,*R*-bmbcd and two chloro ligands with the range of bond lengths, 2.066(2)–2.2289(9) Å. The result of the catalytic enantioselective reduction of acetophenone promoted by *R*,*R*-bmbcd:$Zn(OTf)_2$ = 1:1 mole ratio in the presence of catecholborane for 48 h at 0 °C give (*S*)-(−)-1-phenylethanol in 48% ee with 77% yield.

Keywords: *trans*-1,2-Diaminocyclohexane; Crystal structure; Zinc complex; Catalytic enantioselective reduction

1. Introduction

Catalytic asymmetric synthesis is a key technique for preparing optically active substances in biologically medical science and fine chemicals [1]. Enantioselective syntheses such as the alkylation of aldehydes [2], the epoxidation of olefines [3] and the asymmetric reduction of ketones [4] have been extensively studied. In particular, asymmetric alkylation of aldehydes with dialkylzinc in the presence of chiral bidentate ligands such as diol [5], aminoalcohol [6], diamine [7], ditriflamide [2,8], diaminocyclohexane [9] have been well-established as contrasted with the asymmetric reduction of ketones. The Kobayashi and co-workers [2a] has obtained highly optically pure alcohols by using a (*R*,*R*)-*trans*-1,2-diaminocyclohexane derivative containing an electron withdrawing group in the presence of $Ti(O^iPr)_4$. Recently, the Walsh and co-worker [10] has worked to optimize the enantioselectivity of the catalyst by varying the achiral ligands, described as chiral environment amplifications, which is a modular approach to asymmetric catalysis. Enantioselective reduction of α-alkoxy ketones in the presence of $Zn(OTf)_2$ and bis-oxazolines afforded the chiral alochols in good yields and high ee's [11], but the extended studies for enantioselective reduction of α-alkoxy ketones are limited.

The enantiomeric purity of a chiral auxiliary in asymmetric catalysis is a major factor for alkylation of benzaldehyde. The reaction rate is also considerably influenced by the enantiomeric purity, and is significantly faster with pure chiral auxiliaries than with the racemic ones [12]. The structure of the catalyst in the asymmetric reduction of ketones can be a key parameter for the development of a better catalyst, providing the coordination environments at the centre atom, the reaction mechanism and the steric effect. Diaminocyclohexane derivatives involving functional groups such as hydrogen, isopropyl, isobutyl, etc., are not satisfied with the enantioselective reduction of ketones by comparing with the enantioselective reduction of aldehydes. However, the enantioselective reduction of acetophenone to secondary alcohols with polymethylhydrosiloxane (PMHS) was carried out with high yields and ee's in the

doi:10.1016/j.poly.2004.04.033

presence of chiral zinc catalysts [13] or chiral titanocene [14]. More recently, we have reported our results for the catalytic reduction of acetophenone using the $Zn(OTf)_2$ and N,N'-bis(3,5-dimethylpyrazolylmethyl)-L-alanine-methylester system, in which (*S*)-(−)-1-phenylethanol was obtained in low yield and ee [15].

Optically pure 1,2-diaminocyclohexane derivatives have been extensively utilized as chiral reagents, auxiliary catalysts and chiral ligands in various asymmetric synthetic routes [16]. However, these ligands are rare in the asymmetric reduction of ketones. The studies of the enantiomeric reduction of acetophenone activated by diaminocyclohexane derivatives bearing secondary and tertiary diamine bidentate ligands under mild conditions have not been reported. Herein, we have synthesized optically pure *R*,*R*-bmbcd and its complex of $ZnCl_2$, and describe its catalytic reduction of acetophenone by considering its structural property and the steric effect through the function of the methoxy-benzyl group.

2. Experimental

2.1. General remark

All reagents were of reagent grade and solvents were freshly distilled prior to use. ^{1}H NMR spectra were recorded on a Varian 300-NMR Spectrometer at ambient temperature and chemical shifts were referenced to internal tetramethylsilane. HPLC with a chiralcel OD-H (0.46 cm $\Phi \times 25$ cm) column was used for measurement of ee. Elemental analyses were performed at the Chemical Analysis Laboratory of the Center for Scientific Instruments of Kyungpook National University.

2.2. Syntheses of the compounds

2.2.1. *N,N'-bis(4-methoxy-benzyl)-cyclohexane-1,2-diamine (R,R-bmbcd),* **1**

Absolute ethanol was added to *trans*-*R*,*R*-1,2-diaminocyclohexane (19.81 g, 0.17 mol) until it was completely dissolved. *p*-Anisaldehyde (43.077 ml, 0.347 mol) was added and the yellow solution was stirred at room temperature for two days. The solvent was then removed under reduced pressure to obtain a thin yellow solid. This solid was recrystallized in diethyl ether to give colorless crystals (55.00 g, 90%). To a solution of the colorless crystals an ice bath (16.81 g, 0.0478 mol) in dry THF, in an ice bath, was slowly added $LiAlH_4$ (1 M solution in THF, 143.904 ml, 3 equiv.) by syringe. This solution was refluxed for 24 h, cooled to room temperature and then distilled water (12 ml) and 2 M NaOH (30 ml) were added. After filtering, the solvent was removed under reduced pressure, the remaining solid was extracted with CH_2Cl_2, dried with $MgSO_4$, filtered, and then the solvent was evaporated to give a thin yellow solid. This solid was recrystallized in diethyl ether to give colorless crystals (13.60 g, 80%). *Anal.* Calc. for $C_{22}H_{30}N_2O_2$: C, 74.54; H, 8.53; N, 7.90. Found: C, 74.57; H, 8.49; N, 7.87%. ^{1}H NMR ($CDCl_3$); δ 7.2 (d, 4H, Ph, $J = 8.7$ Hz), 6.8 (d, 4H, Ph, $J = 8.4$ Hz), 3.77 (s, 6H, OCH_3), 3.84–3.56 (dd, 4H, CH_2, $J = 13.2$ Hz), 2.22 (m, 2H, CHA), 2.12 (m, 2H, CHA), 1.74 (m, 2H, CHA), 1.69 (m, 2H, CHA), 1.20 (m, 1H, CHA), 1.01 (m, 1H, CHA).

2.2.2. *$ZnCl_2$(R,R-bmbcd),* **2**

To a solution of $ZnCl_2$ (0.7900 g, 5.79 mmol) in ethanol (10 ml) was added dropwise a solution of **1** (2.0548 g, 5.796 mmol) in ethanol (25 ml). The mixture was stirred overnight at ambient temperature. The white precipitate that formed was filtered off and washed several times with *n*-hexane and diethyl ether. The white solid was recrystallized from methanol to obtain colorless crystals (2.625 g, 92%). *Anal.* Calc. for $C_{22}H_{30}Cl_2N_2O_2Zn$: C, 53.84; H, 6.16; N, 5.71. Found: C, 53.82; H, 6.16; N, 6.18%. ^{1}H NMR ($CDCl_3$); δ 7.4 (d, 4H, Ph, $J = 8.7$ Hz), 6.8 (d, 4H, Ph, $J = 8.4$ Hz), 3.73 (s, 6H, OCH_3), 3.99–3.82 (dd, 4H, CH_2, $J = 13.2$ Hz), 2.46 (m, 4H, CHA), 2.08 (m, 2H, CHA), 1.85 (m, 2H, CHA), 1.26 (m, 1H, CHA), 1.13 (m, 1H, CHA).

2.3. Crystal structure determination of **2**

A colorless single crystal of **2** suitable for X-ray analysis was sealed in a thin walled glass capillary and mounted on an Enraf-Nonius CAD-4 diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell dimensions with estimated standard deviations were determined by least-squares using 25 well-centered reflections in the range of 10°–13°. A total of 2469 unique reflections were collected using the ω–2θ scan mode. The intensities of the reflections were corrected for Lorentz and polarization effects. Crystal data, data collection, and refinement for the complex are listed in Table 1. Data reduction was carried out using a MOLEN program package; a decay correction based on the intensities of three standard reflections measured every hour was performed; empirical absorption corrections were applied based on Ψ scans [17]. The structure in $P2_1$ for the complex was determined by direct methods and refined by full-matrix least-squares using SHELXS-97 and SHELXL-97 program packages [18,19] using reflections with $I > 2\sigma(I)$. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were constrained by using riding models. The final cycle of the refinement yielded $R = 0.021$ and $wR = 0.057$. Selected bond distances and bond angles are given in Table 2.

2.4. Catalytic enantioselective reduction of acetophenone

The flame-dried Schlenk flask was charged with the chiral ligand **1** (0.078 mmol), $Zn(OTf)_2$ (0.078 mmol) and

dry CH_2Cl_2 (2 ml) under nitrogen atmosphere via syringe. The mixture was stirred for 30 min, cooled to 0 °C and then acetophenone (0.078 mmol) was added. The mixture was then stirred for 5 min and catecholborane (100 μl, 0.94 mmol) was added. The procedures were same as the methods used in the previous paper [15]. The enantiomeric excess was measured by HPLC (a chiral OD column), affording (*S*)-(−)-1-phenylethanol in 48% ee with 77% yield.

3. Results and discussion

3.1. Synthesis and chemical properties

The pure optical material, diaminocyclohexane derivative **1**, which was afforded from the cyclohexyldiimine derivative by reduction with $LiAlH_4$, gives in quantitative yield a colorless solid. It is soluble in polar solvents and insoluble in non-polar solvents such as hydrocarbons.

The reaction of $ZnCl_2$ with **1** afforded **2** in a high yield as white crystals after the usual workups. The chiral Zn(II) complex is readily soluble in polar solvents such as alcohols, yet poorly soluble in most polar solvents such as chloroform and THF.

3.2. Crystal structure of complex 2

The crystal structure of the chiral Zn(II) complex **2**, for getting binding information of the catalytic species, is confirmed by X-ray analysis as shown in Fig. 1. The central Zn atom is coordinated by two nitrogen atoms from a bidentate *R*,*R*-bmbcd and two chloro atoms in a distorted tetrahedral arrangement. The bond distances Zn–N(1) and Zn–N(2) are 2.066(2) and 2.092(2) Å, respectively, which are comparable to those in related compounds of the type $ZnCl_2$(L), i.e., 2.029(3) and 2.157(3) Å in $ZnCl_2$(Clemizole) where Clemizole is 1-(*p*-chloro-phenylmethyl)-2-(1-pyrrolidinylmethyl)benzimidazole [20], 2.006(3) and 2.008(3) Å in $ZnCl_2$(1,2-dimethylimidazole)$_2$ [21], and 2.050(3) and 2.074(3) Å in $ZnCl_2$(quinoline) [22]. The bond distances Zn–Cl(1) and Zn–Cl(2) [2.2289(9) and 2.2036 (8) Å] are close to those of similar complexes which are in the range of 2.196(2)–2.2509(8) Å [20–22]. The long bond distances of Zn–Cl are comparable with the bond distances of Zn–N, giving rise to those reported for the $ZnCl_2N_2$ core. The bond angles of N–Zn–Cl are in the range of 108.43(7)°–113.32(7)°, which are distorted from ideal tetrahedral geometry as a consequence of the opening of the two chloro ligands. The bond angle N(1)–Zn–N(4) [85.66(9)°] is smaller than that [89.5(1)°] found in $ZnCl_2$(2,2′-bis(pyrazolyl-1-ylpropane) and that [109.3(1)°]

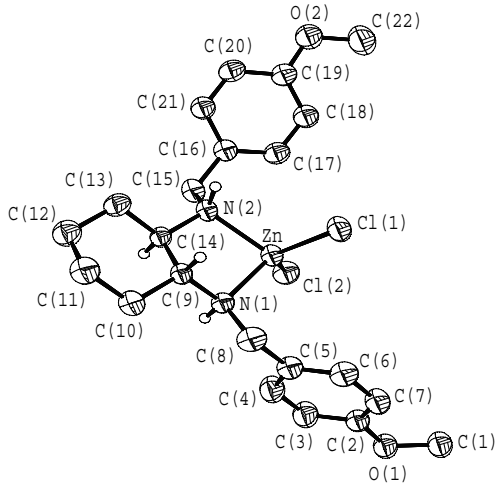

Fig. 1. Crystal structure with the labelling scheme for compound **2**.

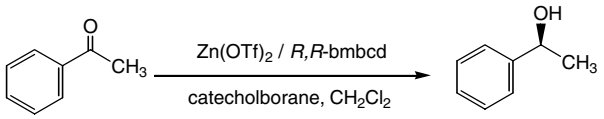
in $ZnCl_2$(quinoline)$_2$ [21], but larger than that [81.7(1)°] in $ZnCl_2$(Clemizole) [20]. The bond angle of 121.42(3)° for Cl(1)–Zn–Cl(2) is quite similar to that [120.18(6)°] found in $ZnCl_2$(Clemizole) [20] and is larger than that [114.54(7)°] in $ZnCl_2$(bdmpame) (bdmpame = *N*,*N*-bis(3,5-dimethylpyrazolylmethyl)-L-alaninemethyl ester) [15], that [114.59(8)°] in $ZnCl_2(MeImOH)_2$ (MeImOH = 2-hydroxymethyl-1-methylimidazole) [23], and that [115.47(5)°] in $ZnCl_2$(quinoline)$_2$ [21].

3.3. Catalytic enantioselective reduction of acetophonone

Recently, the enantioselective reduction of ketones prompted by chiral zinc complexes has been well-established, and very high enantioselectivity has been accomplished by using various chiral diimine ligands [11,13]. We have investigated the catalytic enantioselective reduction of acetophenone (Eq. (1)) using in situ $Zn(OTf)_2$/*R*,*R*-bmbcd as the catalyst.



(1)

The reaction was carried out under the standard set of conditions described in Section 2. The enantiomeric excess of the catalytic reduction was moderate to give 48% ee with 77% yield. The enantioselective reduction of acetophenone using lithiated α-stannylbenzyl sulfide or α-lithio benzyl 2-pyridyl sulfide with *N*,*N*,*N*′,*N*′-tetramethyl-cyclohexane-1,2-diamine as the chiral ligand show 1% ee in 8% yield and 21% ee in 70% yield, respectively [24]. The low enantiomeric excess may be explained by the lack of stereoselective control of the functional groups at the reaction center, coupled with the fact that the blocking from the steric hinderance of the methyl or dimethyl groups the near chiral center washes out any chiral discrimination formed in the catalyst.

4. Conclusions

We have attempted to establish the synthesis and characterization of *R*,*R*-bmbcd and its Zn complex **2**. In particular, the catalytic enantioselective reduction of acetophenone promoted by $Zn(OTf)_2$ with *R*,*R*-bmbcd in the presence of catecholborane as reductant has shown that a chiral cyclohexane-1,2-diamine derivative **1** is an exploratory precursor. The zinc catalyst of the new chiral 1,2-diaminocyclohexane derivative ligand, through the steric effect of functional groups and the enhancement of the absolute stereoselective control, could give significant enantiometric excess. We are currently investigating in this area.

Abstract

The complex $[VO(didadf)(H_2O)](BF_4)_2$ (didadf = diiminediaminediphenolate ligand) has been prepared from a vanadium(II) salt under strict inert atmosphere conditions and characterized by analytical, magnetic and spectroscopic methods (EPR, FTIR, UV–Vis), cyclic voltammetry as well as by spectroelectrochemistry. These techniques along with the mass spectrum (FAB^+) were important to understand the nature and the redox properties of the metal ion complex.

1. Introduction

Selectivity, inertia, high thermodynamic stability and structural flexibility of their metal complexes have proved macrocycles to be suitable ligands to produce specific metal–ion environments [1,2]. The macrocyclic ligand tetraiminediphenolate (tidf) was first prepared by Pilkington and Robson [3] by a template reaction involving 4-methyl-2,6-diformylphenol, 1,3-diaminepropane, lead acetate and lead nitrate (magnesium and other transition metal salts can also be employed) [1b].

Tidf binds metal ions such as copper(II), nickel(II), cobalt(II), iron(II), manganese(II), lead(II) and zinc(II) giving either mono- or di-nuclear complexes [4]. All metal(II) mononuclear complexes have both uncoordinated diimine nitrogen atoms protonated, so the complexes have a total charge of 2+. Transmetallation reactions from Mg^{II} or Pb^{II} compounds allow the preparation of new mononuclear complexes that are good starting materials for binuclear macrocycle compounds, as recently reported by our group [5].

In contrast to other first row transition elements [6], the chemistry of vanadium-macrocyclic complexes has not been extensively investigated, up to the present time. In this work, we report the synthesis of the $[VO(didadf)(H_2O)](BF_4)_2$(didadf = diiminediaminediphenolate ligand) complex and its characterization by means of elemental analysis, mass spectrometry, magnetochemistry, EPR, FTIR and UV–Vis spectroscopy, cyclic voltammetry and spectroelectrochemistry. This compound was obtained from the reaction between $[V(H_2O)_6]^{2+}$ and tidf under severe inert atmosphere conditions through an unusual hydrogenation reaction. The didadf ligand can form two complexes, by coordinating to the central phenolate groups and either two amine or two imine groups in the lateral positions, as shown in Scheme 1. A detailed assignment of the spectra and the electrochemical behavior is provided, and the reaction steps for the formation of the complex are discussed.

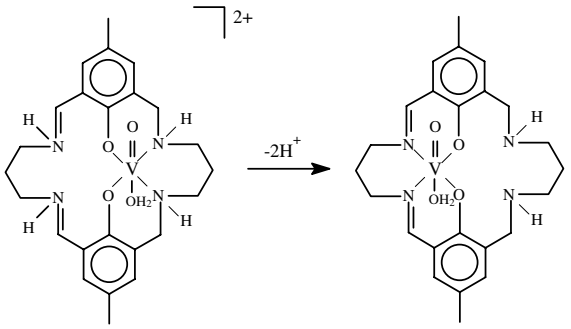

Scheme 1. The oxovanadium complexes.

The relative stability of the two possible complexes was evaluated theoretically, based on molecular mechanics (MM^+) and semiempirical methods (ZINDO/S).

2. Experimental

2.1. Physical measurements and instrumentation

X-band electron paramagnetic resonance (epr) spectra were recorded on a Bruker ESP300-E instrument from acetonitrile solutions of the complex (1×10^{-2} mol L^{-1}) at room-temperature.

The mass spectrum (FAB^+ technique) was recorded on a VG Autospec spectrometer (Fisons Instruments) equipped with a CsI gun at 25 kV in 3-nitrobenzyl alcohol as the matrix.

Magnetic susceptibility measurements were carried out in the solid state at room-temperature using a MKII magnetic susceptibility balance from Johnson–Matthey. Corrections for the diamagnetism of the ligands were applied by the use of Pascal constants [10].

Infrared spectra were obtained with a Bomen Hartmann and Braun MB series spectrophotometer in the region 4000–400 cm^{-1} as nujol mulls spread on KBr windows.

Electronic spectra in the UV–Vis range (190–820 nm) were obtained on a Hewlett–Packard Model 8452A diode-array spectrophotometer in acetonitrile solutions.

Cyclic voltammetry was carried out with a Princeton Applied Research Potentiostat (PARC) model 273A. A platinum disc electrode was employed for the measurements at $I = 0.1$ mol L^{-1}, kept constant with $TEAClO_4$ (tetraethylammonium perchlorate). $Ag/AgNO_3$ ($[Ag^+] = 0.01$ mol L^{-1} in an MeCN solution of $TEAClO_4$ 0.1 mol L^{-1}) and a platinum wire were used as reference and auxiliary electrodes, respectively. Typical experiments were conducted with a 3.0×10^{-3} mol L^{-1} complex concentration in acetonitrile solutions at ambient temperature.

Spectroelectrochemical measurements were performed with the PARC potentiostat attached to a diode-array spectrophotometer, from ≈1 mmol L^{-1} complex and 0.1 mol L^{-1} $TEAClO_4$ acetonitrile solutions. A three-electrode system was designed for a thin layer cell of 0.025 cm internal optical path length. A gold minigrid was used as transparent working electrode in the presence of a small Ag/AgCl (1 mol L^{-1}) reference electrode and a platinum auxiliary electrode.

Microanalyses were done under dinitrogen by MEDAC Ltd. laboratories in Egham, Surrey, UK.

Molecular modelling calculations were carried out for the two possible forms of the $[VO(didadf)(H_2O)](BF_4)_2$complex, using the HYPERCHEM 7.1 package, from Hypercube Inc., Gainesville, FL, USA. Geometry optimization was carried out using the MM^+ method, with a gradient of 1×10^{-5} kcal as a convergence criterion, in combination with SCF calculations performed at the RHF level using the ZINDO/S method. In this case, default parameters were employed for single CI excitations in an active space involving 20 frontier molecular orbitals (10 highest occupied and 10 lowest unoccupied MOs).

2.2. Materials

Magnesium acetate tetrahydrate, magnesium nitrate (Mallinckrodt), 4-methyl-2,6-diformylphenol (Aldrich) and 1,3-diaminopropane (Merck) were used as supplied. Methanol (Merck) was degassed exhaustively before use. $[V(H_2O)_6](BF_4)_2$ was prepared as described previously [7]. The complex $[VO(acac)_2]$ (acac = acetylacetonate) was prepared according to Fernelius [8].

2.3. Synthesis

2.3.1. $[Mg_2(tidf)](NO_3)_2 \cdot 4H_2O$

This compound was prepared by an adaptation of the synthesis described by Mohanta et al. [9] for a less symmetric macrocyclic ligand. To a boiling solution containing magnesium acetate tetrahydrate (1.63 g, 7.5 mmol), magnesium nitrate (1.95 g, 7.5 mmol) and 4-methyl-2,6-diformylphenol (2.50 g, 15 mmol) in methanol (80 mL) was added a solution (50 mL) of 1,3-diaminopropane (1.13 g, 15 mmol) in methanol, over a period of 4 h. The mixture was refluxed for 2 h. After cooling to room-temperature, diethyl ether was added to the bright yellow solution and a colorless solid was removed by filtration and discarded. The solution was concentrated under vacuum and an orange-yellowish solid was obtained, filtered-off, washed with diethyl ether/methanol (1:1) and vacuum-dried. Yield 95% (4.69 g). *Anal.* Calc. for $C_{24}H_{34}N_6O_{12}Mg_2$: C, 44.54; H, 5.30; N, 12.99. Found: C, 43.50; H, 5.77; N, 12.32%.

2.3.2. $[VO(didadf)(H_2O)](BF_4)_2$

This product was prepared in a nitrogen-saturated glove-box. $[V(H_2O)_6](BF_4)_2$ (1.36 g, 4.0 mmol) was dissolved in 30 mL of methanol. The resulting purple

solution was added to a yellow suspension of $[Mg_2(tidf)](NO_3)_2 \cdot 4H_2O$ (1.22 g, 2.0 mmol) in 80 mL of methanol. The system was stirred for 1 h and a reddish solid was filtered-off, washed with methanol and dried under vacuum. Yield was 58% (0.84 g). *Anal*. Calc. for $C_{24}H_{30}N_4O_4B_2F_8V$: C, 43.49; H, 4.53; N, 8.45. Found: C, 43.55; H, 4.94; N, 8.50%.

3. Results and discussion

3.1. Electron paramagnetic resonance and magneto chemistry

The eight-line epr spectrum of $[VO(didadf)(H_2O)](BF_4)_2$ at room-temperature (Fig. 1) is typical of a single species in which the unpaired electron in a d_{xy} orbital is coupled to the nuclear spin of the vanadium nucleus with $I = 7/2$, ruling out the occurrence of any mixture of species. The values of $g = 2.014$ and $A = 100$ G are very similar to those observed for other $V^{IV}ON_2O_2$ systems [11].

The room-temperature magnetic moment of $[VO(didadf)(H_2O)](BF_4)_2$ is 1.78, consistent with the spin only value predicted for a VO^{2+} ($S = 1/2$) species [12].

3.2. Mass spectrum

FAB^+ mass spectrum of the vanadyl complex shows a base peak (intensity of 100%) at $m/z = 470$ assigned to the molecular ion $\{[VO(didadf\text{-}H)]\}^+$ (didadf-H = the macrocyclic ligand with the loss of a hydrogen ion), produced by the dissociation of a water molecule and a proton.

3.3. Infrared spectrum

IR spectrum of $[VO(didadf)(H_2O)](BF_4)_2$ exhibits very intense bands at 1644 and 1555 cm^{-1} assigned to ν(C=N) and ν(C–O) and, respectively. A band at 870 cm^{-1} with strong intensity was attributed to ν(V=O). This ν(V=O) band was reported at 844 cm^{-1} for the tetraaminediphenolate complex $[VO(tadf)] \cdot H_2O$ (tadf = tetraaminodiphenolate) [13], in which case intermolecular V=O···V=O interactions were observed. The bands at 3480 and 3558 cm^{-1} assigned to ν(O–H) are in agreement with the microanalysis as these results support the presence of a water molecule in the composition of the complex. Other important bands occurs at 1050(s) cm^{-1} (ν_s(B–F)), 770(m) and 544(m) cm^{-1} (δ(B–F)) in accordance with the positive charge of the ion complex.

3.4. Spectroelectrochemistry

UV–Vis spectra of $[VO(didadf)(H_2O)](BF_4)_2$ show bands at 212 and 265 nm (Fig. 2) assigned to π–π^* transitions, also seen in the magnesium complex $[Mg_2(tidf)](NO_3)_2 \cdot 4H_2O$. The strong absorption band at 395 nm was tentatively assigned to a ligand-to-metal

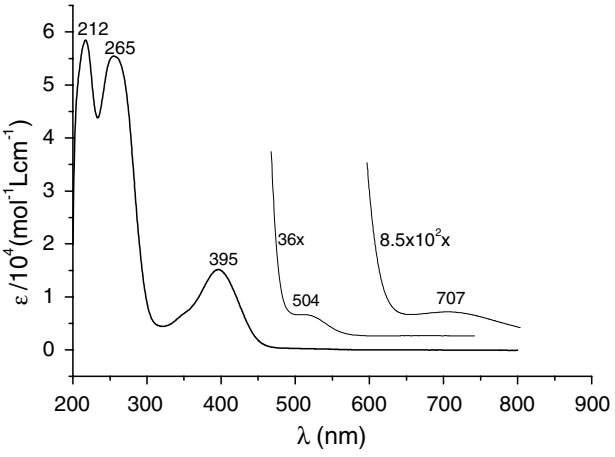

Fig. 2. UV–Vis spectra of $[VO(didadf)(H_2O)]^{2+}$ in CH_3CN.

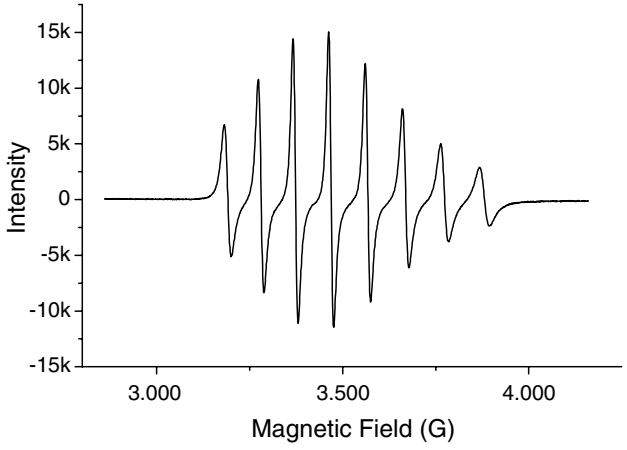

Fig. 1. The epr spectrum of $[VO(didadf)(H_2O)](BF_4)_2$ in CH_3CN at room-temperature.

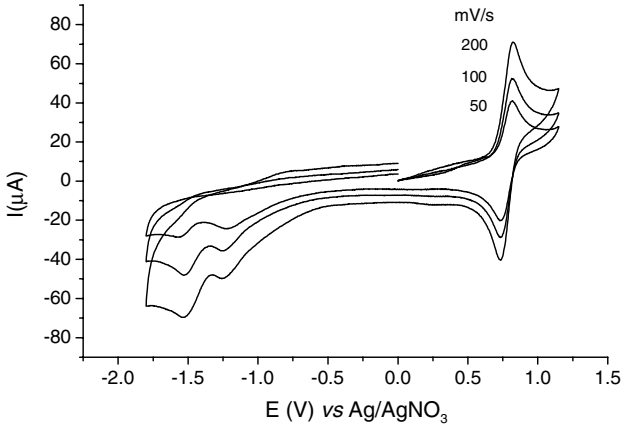

Fig. 3. Cyclic voltammograms of $[VO(didadf)(H_2O)]^{2+}$ (3 mmol L^{-1}), 0.10 mol L^{-1} $TEAClO_4$ in CH_3CN.

charge transfer transition, since it is not observed in the magnesium complex. The bands at 504 nm and 707 nm have intensities ($\varepsilon = 433$ and 18 $L\,mol^{-1}\,cm^{-1}$) compatible with d–d transitions (d_{xy} to $d_{x^2-y^2}$ and to (d_{yz}, d_{xz}), respectively), similar to the ones seen at 584 and 707 nm in the $[VO(acac)_2]$ complex and at 520 and 820 nm in $[VO(tadf)]\cdot H_2O$ [13]. Cyclic voltammograms of $[VO(didadf)(H_2O)](BF_4)_2$ show typical reversible behavior between −0.75 and 1.25 V with a formal reduction potential $E^f = 0.80$ V versus Ag/Ag^+ (1.30 versus SHE) and assigned to the $V^{IV/V}$ process (Fig. 3), and two irreversible waves below −1 V, ascribed to the successive reduction of the macrocyclic ligand.

Spectroelectrochemical measurements between 0.68 and 0.90 V (Fig. 4(a)) shows a decrease in the intensity of the band at 395 nm, accompanying the reversible oxidation of the vanadium(IV) center. An interesting observation is that this process is followed by a second electrochemical reaction in the 0.90–0.98 V range (Fig. 4(b)), not apparent in the cyclic voltammograms. This process can be ascribed to the oxidation of the didadf ligand, since a similar behavior was also observed in the electrochemistry of the magnesium complex $[Mg_2(tidf)](NO_3)_2\cdot 4H_2O$ at 1.1 V. These two processes exhibit rather close E^fs, giving rise to a single reversible wave in the cyclic voltammograms. The two-step process can also be observed by reversing the potentials in the spectroelectrochemical experiments, as shown in Fig. 4(c). The band at 395 nm is regenerated in the catodic scan between +0.90 and +0.1 V consistent with a

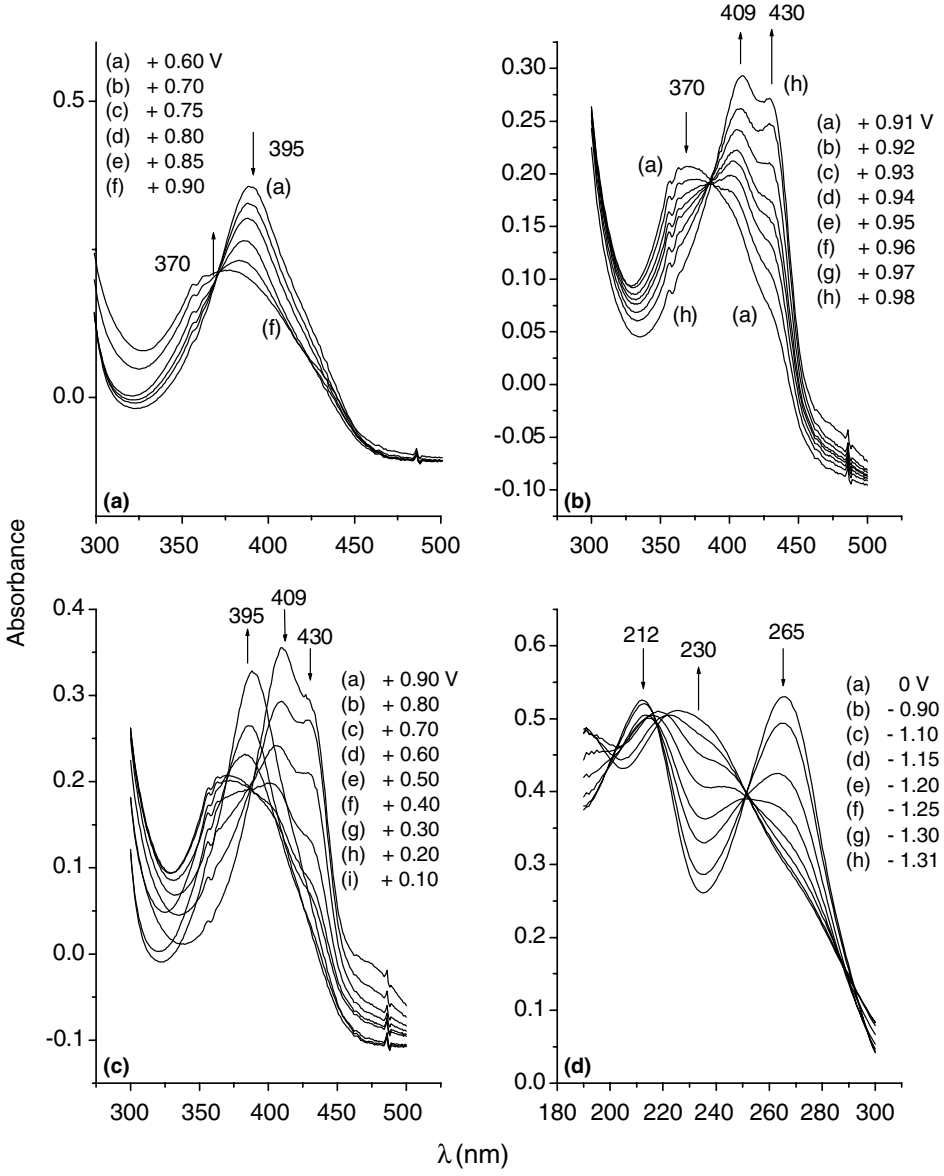

Fig. 4. Spectroelectrochemistry of $[VO(didadf)(H_2O)]^{2+}$ (≈1 mmol L^{-1}), 0.10 mol L^{-1} $TEAClO_4$ in CH_3CN. Oxidation process starting from +0.60 V (a) and +0.91 V vs Ag/Ag^+ (b), and the reduction of the VO^{IV} complex starting from +0.90 V (c) and 0 V (d).

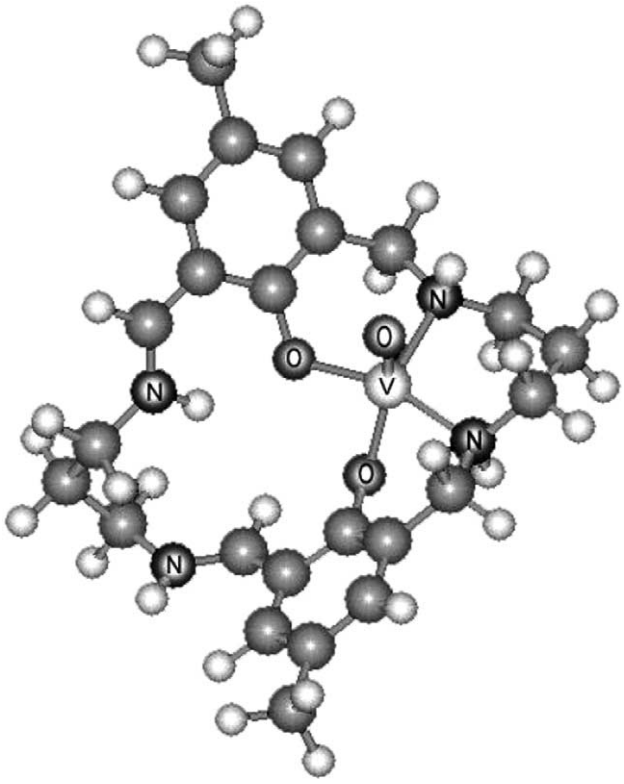

Fig. 5. Molecular simulation (MM^{+}) for the most stable complex.

thermodynamic reversibility of the two processes involved.

The π–π^{*} bands at 212 and 265 nm tend to vanish at very negative potentials, 0 to −1.31 V (Fig. 4(d)) as a new band, with the same assignment, appears at 230 nm. This behavior occurs in a range of potentials where an irreversible reduction of the ligand didadf with Ep_c at −1.3 V (Fig. 3) is observed.

3.5. Molecular mechanics MM^{+}

The corresponding structures generated by (MM^{+}/ZINDO) molecular simulation exhibit strong distortions from the planar configuration, with the vanadyl center in an intermediate geometry between square pyramidal and trigonal bipyramid, as shown in Fig. 5. However, according to ZINDO/S calculations, the complex where the vanadyl ion is bound to the two-amine groups is thermodynamically favored with respect to the diimine species. This is also in agreement with the hard acid behavior of the V^{IV} ion, in relation to the strong donor amine group and the predominantly acceptor diimine group. The protonation of the imines is not unusual in the chemistry of the tidf macrocycle, and was reported in the crystal structure investigation of the $[Fe(tidf)(CH_3OH)_2](NO_3)_2$ complex [5b].

4. Conclusions

Our attempts to prepare the vanadium(II) complex always ended up with oxovanadium(IV) complex in a high yield, even using strict inert atmosphere conditions (glove-box with $[O_2] < 0.1$ ppm and solvents thoroughly degassed. Apparently there was no oxidation of the starting solution of vanadium(II) as it maintained its original purple color until the reaction with $[Mg_2(tidf)](NO_3)_2 \cdot 4H_2O$. A possible explanation is summarized in Scheme 2, where it is believed that vanadium(II) reduces the macrocyclic ligand. This would be supported by the presence of the weak band at 3090 cm^{-1} assigned to ν(N–H) in the infrared spectrum of the product. The expected band at ca. 1600 cm^{-1} due to the δ(N–H) mode is masked by the strong and broad band at 1644 cm^{-1} attributed to ν(C=N).

Facile synthesis and structures of infinite one-dimensional silver(I) coordination polymers

Alexandra L. Pickering, Geoffrey J.T. Cooper, De-Liang Long, Leroy Cronin *

Department of Chemistry, Joseph Black Building, University of Glasgow, University Avenue, Glasgow G12 8QQ, UK

Received 17 March 2004; accepted 7 June 2004

Abstract

The synthesis and characterization of the isolated, infinite tubular coordination polymers $\{[Ag(cis\text{-tach})]ClO_4\}_\infty$ (**1**), $\{[Ag(trans\text{-tach})]ClO_4\}_\infty$ (**2**) and $\{[Ag(cis\text{-tach})]BF_4\}_\infty$ (**3**) has been achieved with the isomers *cis,cis*-1,3,5-triaminocyclohexane and *cis,trans*-1,3,5-triaminocyclohexane. Each new material has been fully characterized by single crystal X-ray diffraction, NMR, IR and elemental analysis. Compounds **1**–**3** form definite channels by the trigonal planar coordination of silver(I) metal centres to rigid, aliphatic triamino ligands, forming $4^2 \cdot 6$ topological networks.

1. Introduction

Since their discovery in 1991 [1], carbon nanotubes have become of increasing interest due to their uniqueness in size, shape and extraordinary physical properties. Experiments are emerging that investigate the properties of carbon nanotubes, whose structural properties are determined by such features as length, diameter and chirality. Such studies have shown carbon nanotubes to be extremely robust materials, and research into the construction of fibre-composite materials using carbon nanotubes is underway [2]. However, production of single (SWNT) [3–6] and multiple (MWNT) [7] walled carbon nanotubes is both expensive and challenging. Coordination polymers are attractive alternatives as the self-assembly of polynuclear, functional materials provides a flexible and facile route to systems more traditionally formed using a covalent approach [8,9]. This methodology uses coordinative or weaker forces to build-up networks of specific topologies, and has been successful in creating a great number of functional materials that contain channels within a higher dimensionality array [10–13], and a much smaller number that exist as isolated one-dimensional polymers [14–16]. We have recently published the first synthesis of infinite, isolated silver(I) coordination tubes by incorporating a pre-organized, tridentate ligand system that is flexible enough to 'wrap' its number of arms to form a tubular network [17].

We herein report the extended synthesis of a variety of silver(I) nanotubes using the isomerically related ligands *cis,cis*-1,3,5-triaminocyclohexane (*cis*-tach) and *cis,trans*-1,3,5-triaminocyclohexane (*trans*-tach) (Fig. 1). The ligand system in each case has combined rigidity due to the cyclohexane backbone and flexibility due to the primary aliphatic amino groups. The formation of the tubular networks appears to be a function of the nitrogen donor geometry combined with anion effects, and as such comprise a novel synthetic route to the construction of the isolated nanotubes $\{[Ag(cis\text{-tach})]ClO_4\}_\infty$ (**1**), $\{[Ag(trans\text{-tach})]ClO_4\}_\infty$ (**2**) and $\{[Ag(cis\text{-tach})]BF_4\}_\infty$ (**3**).

cis,cis-1,3,5-triaminocyclohexane *cis,trans*-1,3,5-triaminocyclohexane

Fig. 1. Ligand geometry facilitating network formation.

2. Experimental

2.1. Materials and physical measurements

Ligands *cis,cis*- and *cis,trans*-1,3,5-triaminocyclohexane were synthesized according to literature methods [18]. All other solvents and reagents were used as purchased without further purification. NMR spectra were measured in D_2O on a Bruker DPX-400 (400 MHz ^1H, 100 MHz ^{13}C). Infrared spectra were obtained from samples prepared as KBr discs in the 650–4000 cm^{-1} range using a Jasco FTIR-410 spectrometer. Elemental analyses were performed on a CE-440 Elemental Analyser.

2.2. Synthesis of compounds **1–3**

2.2.1. Synthesis of [Ag(cis-tach)]ClO_4 (**1**)

Silver perchlorate (40 mg, 0.19 mmol) in methanol (3 ml) was added dropwise to a methanolic solution of *cis,cis*-1,3,5-triaminocyclohexane (50 mg, 0.39 mmol) and stirred at room temperature for 1 h, during which white precipitate occurred. Water (5 ml) was added and the mixture stirred for a further 30 min. The resulting cloudy solution was filtered and the clear colourless filtrate yielded colourless needle-like crystals suitable for diffraction by diffusion with ethanol. Yield: 20 mg (0.06 mmol, 32%) $[Ag(C_6H_{15}N_3)]ClO_4$ (334.98); Found (Calc.)%: C 20.99 (21.49), H 4.32 (4.49), N 11.98 (12.48); ^1H NMR (ppm) 0.96 (q, 3H, *J* 11.62 Hz), 2.19 (dt, 3H, *J* 3.83, 11.42 Hz), 3.12 (m, 3H); ^{13}C NMR (ppm) 40.154 (CH_2), 47.124 (CH); FTIR (wavenumbers in cm^{-1}) 3332 (m), 3284 (m), 2919 (w), 2850 (w), 1581 (m), 1457 (w), 1378 (m), 1199 (m), 1074 (s), 1047 (s), 948 (m), 921 (m), 856 (w).

2.2.2. Synthesis of [Ag(trans-tach)]ClO_4 (**2**)

Silver perchlorate (53 mg, 0.25 mmol) in methanol (3 ml) was added dropwise to a methanolic solution of *cis,trans*-1,3,5-triaminocyclohexane (65 mg, 0.51 mmol) and stirred at room temperature for 1 h, during which a small amount of white precipitate occurred. The cloudy solution was filtered through a cotton wool plug until clear. The clear colourless filtrate yielded pale brown, block-like crystals suitable for diffraction by slow evaporation over two months. Yield: 41 mg (0.12 mmol, 48%). $[Ag(C_6H_{15}N_3)]ClO_4$; Found (Calc.)%: C 21.38 (21.49), H 4.69 (4.55), N 11.65 (11.72); ^1H NMR (ppm) 1.15 (q, 1H, *J* 11.60 Hz), 1.42 (tt, 2H, *J* 3.93, 12.81 Hz), 1.88 (d, 2H, *J* 13.61 Hz), 2.17 (dt, 1H, *J* 1.80, 11.86 Hz), 3.23 (tt, 2H, *J* 3.83, 11.68 Hz), 3.47 (quin, 1H, *J* 3.41 Hz); ^{13}C NMR (ppm) 37.96 (CH_2), 44.53 (CH_2), 45.19 (CH), 45.73 (CH); FTIR (wavenumbers in cm^{-1}) 3332 (m), 3282 (m), 2904 (w), 2389 (w), 1716 (m), 1579 (m), 1454 (w), 1365 (m), 1351 (m), 1211 (w), 1187 (w), 1068 (s), 993 (s), 970 (s), 875 (m), 844 (m), 806 (m).

2.2.3. Synthesis of [Ag(cis-tach)]BF_4 (**3**)

Silver(I) tetrafluoroborate (75 mg, 0.39 mmol) in water (3 ml) was added dropwise to a solution of *cis,cis*-1,3,5-triaminocyclohexane (100 mg, 0.78 mmol) in methanol (2 ml) and the solution stirred for 1 h. The resulting clear, colourless solution was filtered and single crystals suitable for X-ray diffraction were grown by diffusion of ether. Yield: 116 mg (0.358 mmol, 46%). $[Ag(C_6H_{15}N_3)]BF_4$; Found (Calc.)%: C 22.32 (22.25), H 4.65 (4.66), N 12.74 (12.97); ^1H NMR (ppm) 1.03 (q, 3H, *J* 11.60 Hz), 2.17 (dt, 3H, *J* 3.53, 11.34 Hz), 3.15 (tt, 3H, *J* 3.73, 11.05 Hz); ^{13}C NMR (ppm) 39.195 (CH_2), 47.096 (CH); FTIR (wavenumbers in cm^{-1}) 3372 (w), 3347 (m), 3301 (w), 2923 (m), 2852 (m), 2237 (w), 1587 (s), 1459 (s), 1382 (m), 1359 (m), 1290 (w), 1261 (w), 1201 (s), 1074 (s), 948 (m), 923 (m), 856 (w), 806 (m).

2.3. X-ray crystallography

Suitable single crystals of **1**–**3** were prepared and the crystals were mounted on a thin glass fibre using Fomblin oil. X-ray intensity data were measured at 150 K on a Nonius Kappa-CCD diffractometer [λ(Mo Kα) = 0.7107 Å]. Structure solution and refinement for **1**–**3** was carried out with SHELXS-97 [19] and SHELXL-97 [20] via WinGX [21]. Corrections for incident and diffracted beam absorption effects were applied using empirical [22] and numerical methods [23]. None of the crystals showed evidence of crystal decay during data collection. Compounds **1**–**3** crystallized in the space group $P2_1/c$, as determined by systematic absences in the intensity data, intensity statistics and the successful solution and refinement of the structures. All structures were solved

by a combination of direct methods and difference Fourier syntheses and refined against F^2 by the full-matrix least-squares technique. Crystal data, data collection parameters and refinement statistics for **1**–**3** are listed in Table 1. Relevant interatomic bond distances and bond angles for **1**–**3** are given in Table 2.

3. Results and discussion

3.1. Structural analysis of compounds *1*–*3*

Crystallization of a methanolic mixture of *cis,cis*-1,3,5-triaminocyclohexane with $AgClO_4$ and $AgBF_4$ and *cis,trans*-1,3,5-triaminocyclohexane with $AgClO_4$ results in the formation of infinite one-dimensional coordination polymers. Each structure contains a metal to ligand ratio of 1:1 and the asymmetric unit in each case consists of one ligand, one silver(I) ion and one counter ion. None of the structures presented here contain solvent molecules (see Fig. 2).

Both the trigonal planar silver(I) ions and the tridentate amino ligands can be seen as three-coordinate units, which self-assemble to form $4^2 \cdot 6$ topological networks. The macrocycles formed upon coordination facilitate a tubular structure with a definite channel. The channels found in compounds **1**, **2** and **3** are not large enough to encapsulate a further molecule, having dimensions of 5.4, 5.3 and 5.6 Å, respectively. The isolated one-dimensional polymers together form an extensive three-dimensional hydrogen-bonded network linked via interactions between the coordinating amino groups and the counter ions (Fig. 3).

The manner in which these rigid ligands facilitate the formation of tubular networks is dependent upon their coordination geometry. The molecule *cis*-tach is a tripodal ligand, where the three equatorial amino residues can wrap around the walls of the channel (Fig. 4(a)). *trans*-Tach, on the other hand, has the ability to coordinate in a linear polymer via the two equatorial groups along a chain (Fig. 4(b)), and further coordination via the axial amino group connects to a silver(I) centre of a second chain and forms the tubular structure (Fig. 4(c)). The macrocyles formed in each case by two silver(I) ions and two ligands consist of 12 atoms and have an inversion centre.

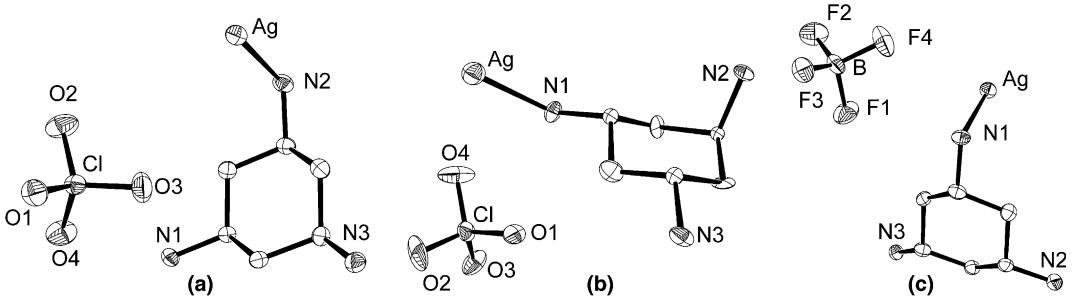

Fig. 2. Asymmetric unit of **1 (a)**, **2 (b)** and **3 (c)**. Note the coordination environment of the silver ion lies between T-shaped planar and trigonal planar, with the Ag ion being ligated to three amino groups of different tach ligands.

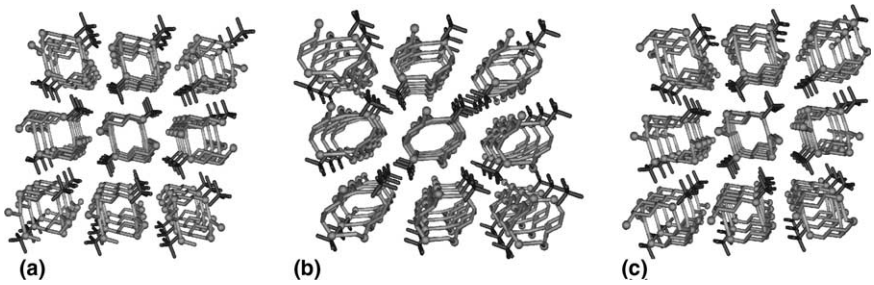

Fig. 3. Three-dimensional hydrogen bonded networks of (a) compound **1**, (b) compound **2** and (c) compound **3** showing isolated coordination polymers. The anions are shown by the black tetrahedra and the nitrogen atoms of the tach-based ligands are shown as spheres.

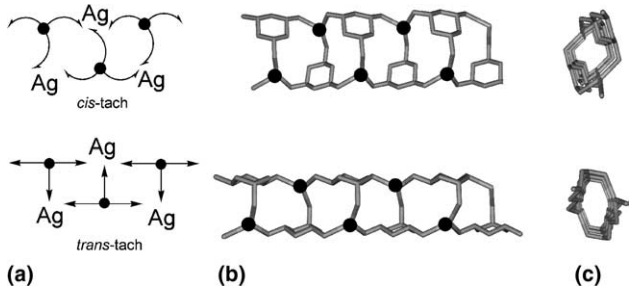

Fig. 4. (a) Ligand motifs of *cis*- and *trans*-tach shown as black dots with arrows. (b) Macrocycle formation utilizing the different ligand geometries with the silver ions show as black dots. (c) End-on view of tubes showing channels.

3.2. Conclusions

We have investigated the synthesis of a number of infinite one-dimensional coordination polymers of aliphatic triamino ligands with a variety of silver(I) salts in order to determine whether such ligand systems can be used as building blocks in the rational design of new functional materials. The isomeric ligands *cis,cis*-1,3,5-triaminocyclohexane and *cis,trans*-1,3,5-triaminocyclohexane have aliphatic amino groups, the direction of which have been proven to provide valuable freedom in the self-assembly process. The construction of these infinite tubular polymers from metal–ligand systems that posses a degree of pre-organization and a number of arms that can 'wrap' can be seen as a noteworthy development in the self-assembly of nanotubular compounds. We are currently extending this work by investigation into the coordination of our rigid amines with other metals and also via derivatization of the amino residues in order to enlarge the channel dimensions and increase the functionality of the materials.

4. Supplementary material

Crystallographic data (X-ray data in *.cif files) for structures **1**–**3** have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 233831 for compound **1**, CCDC No. 233832 for compound **2** and CCDC No. 233833 for compound **3**. Copies of this information may be obtained from the Director, CCDC, 12 Union Road, Cambridge, CB21EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Is bipyridine planar in metal complexes?

Alan Hazell *

Department of Chemistry, Aarhus University, Langelandsgade 140, DK-8000 Århus C, Denmark

Received 22 April 2004; accepted 8 June 2004
Available online 3 July 2004

Abstract

Deviations from planarity of the bipyridine ligand are discussed in terms of bow and twist angles and an S-shaped deformation. The angle φ between the best-planes through the pyridine moieties is related to the bow and twist angles by $\varphi \sim \sqrt{(\theta_B^2 + \theta_T^2)}$. The values are compared with the results of crystal structure determinations. A further deviation from ideality is the in-plane distortion of the ligand that is seen to decrease with increasing metal–nitrogen distances.

Keywords: Bipyridine; Distortions

1. Introduction

Bipyridine, $C_{10}H_8N_2$, is a very popular complexing agent. In the uncoordinated molecule the nitrogen atoms are *trans* [1], whereas in the vast majority of metal complexes studied by X-ray diffraction they are *cis* (the Cambridge Structural Data Base [2] contains 2506 *N*,*N*′ complexes, three *N*,*C* complexes and one *N*,*C*,*N*′,*C*′ complex). The ligand is often regarded as either being planar or that the two pyridine moieties are twisted about the central C–C single bond. In the latter case crystallographers are then often asked for the angle between the planes, φ, this angle is then claimed to be the twist angle, θ_T. In practice the distortion from planarity is more complex [3,4] with a bow distortion, θ_B, and an S-shaped distortion. There is also an in-plane distortion, θ_P. These distortions are shown in Fig. 1 for real structures.

In most cases, the deformation is a combination of these effects and the purpose of this paper is to describe a simple method of decomposing the deformation into the individual components.

2. Calculation of the distortion angles

Atomic positions are usually given by a set of fractional coordinates obtained by X-ray diffraction, these are then converted to orthogonal coordinates, in Å, relative to the centre of gravity of the ligand. These are then transposed to the inertial axial system, with *x* parallel to the long dimension of the bipyridine and *z* perpendicular to the best plane through the ligand. The various deformation angles are then obtained by examining the projections down the inertial axes. The pyridine moieties are considered to be planar.

2.1. The in-plane distortion, θ_P

The angle, θ_P, is the angle between the two lines through the pyridine rings in the *xy* projection, Fig. 1(a), these are calculated as the mean of vectors 1–2, 3–4, and 5–6 for the left hand pyridine and similarly for the right hand pyridine. The required angle is then the angle between these two lines. Since the atoms of the pyridine ring lie almost on a circle a 'best straight line' cannot be calculated.

2.2. The bow distortion, θ_B, and S-shaped distortions

The best straight lines, $ax + c = z$, through each of the two pyridine rings in projection have gradients θ_1

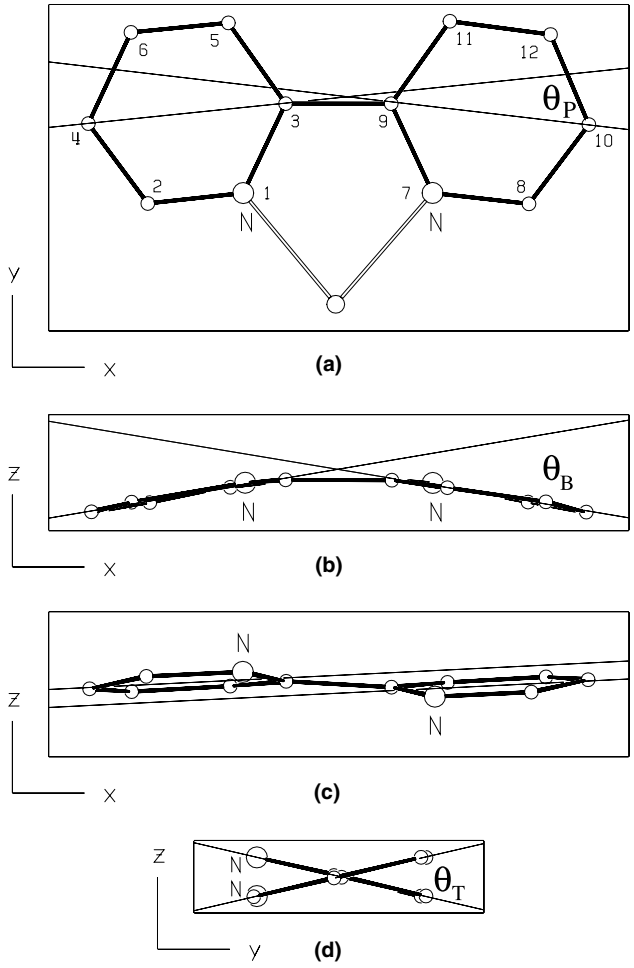

Fig. 1. Distortions in bipyridyl ligands, (a) in-plane, θ_P, Refcode HAJZOH01, (b) bow form, θ_B, Refcode JOYWAV (c) S-shaped, Refcode FUPQUEM, (d) twist, θ_T, Refcode JEVWAI. The Refcodes refer to the Cambridge Structural Data Base [2].

and θ_r and make intercepts c_l and c_r with the z-axis. For a pure bow distortion, Fig. 1(b), $\theta_l = -\theta_r$ and $c_l = c_r$ whilst for a pure S-shaped distortion, Fig. 1c, $\theta_l = \theta_r$ and $c_l = -c_r$. For a combination of the two effects $\theta_B = \theta_l - \theta_r$ and $d_z = c_l - c_r$, d_z is the separation of the two parallel lines along the z-axis. The perpendicular distance between the lines is $d_s = d_z \cos((\theta_l + \theta_r)/2)$.

The S distortion is generally small and in Fig. 1(c) the z-axis has been drawn on double the scale of the x-axis. For structures with a 2-fold axis through the bipyridine ring, $\theta_B = 0$.

2.3. The twist distortion, θ_T

This is the angle between the two best lines through the pyridine rings in the yz projection, Fig. 1(d). For structures with a mirror plane perpendicular to the bipyridine ring, $\theta_T = 0$.

3. Comparison with observed values

The Cambridge Structural Data Base [2] contains 2506 N,N' coordinated bipyridyl ligands, many of these are poorly determined, so only those in which the average σ(C–C) was smaller than 0.005 Å were considered, this reduced the number to 563 this number was further reduced to 551 by rejecting three structures which clearly contained errors, e.g., bond lengths differing by more than 0.2Å from expected values. The pyridine rings are usually not coplanar, Fig. 2.

The values of θ_T range from 0.0° to 26.1° and for θ_B from 0.0° to 19.8°, a plot, Fig. 3, of θ_T versus θ_B shows that in many cases both distortions occur.

There is a high concentration of points on the axes, those where the distortions are constrained to be zero by the crystallographic symmetry are shown with filled circles. The angle φ between the pyridine rings is seen to be $\sqrt{(\theta_B^2 + \theta_T^2)}$. The parameter d_s is in the range 0–0.127 Å, 90% of the values being less than 0.053 Å. This is a small distortion, $d_s = 0.05$ Å corresponds to the central C–C bond making an angle of 1.9° with the plane through a pyridine ring. For all of these distortions the absolute value is given since the sign has no meaning.

The in-plane angle, θ_P, differs from the other distortions in that here the sign has been retained, all the angles are positive, i.e., the nitrogen atoms are displaced towards the metal atom. Fig. 4, shows that θ_P lies in the range 2.9°–12.5° with a mean value of 7.8° and decreases with increasing metal–nitrogen distance.

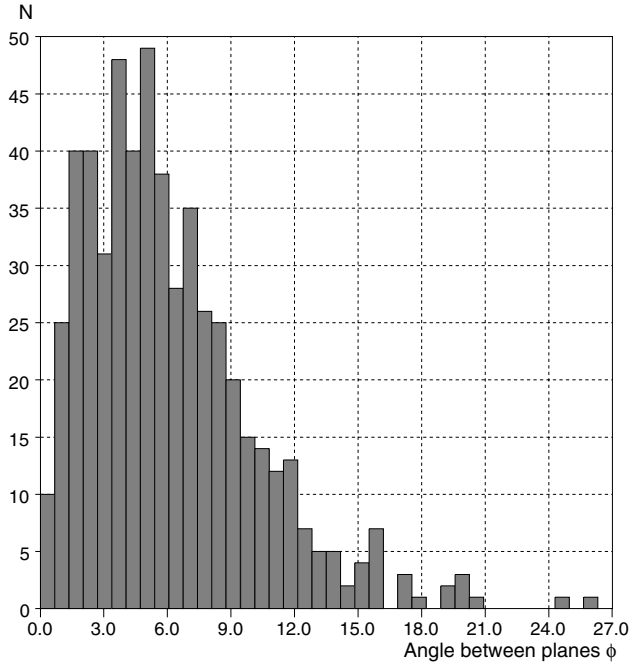

Fig. 2. The angle, φ, between the best planes through the pyridine moieties.

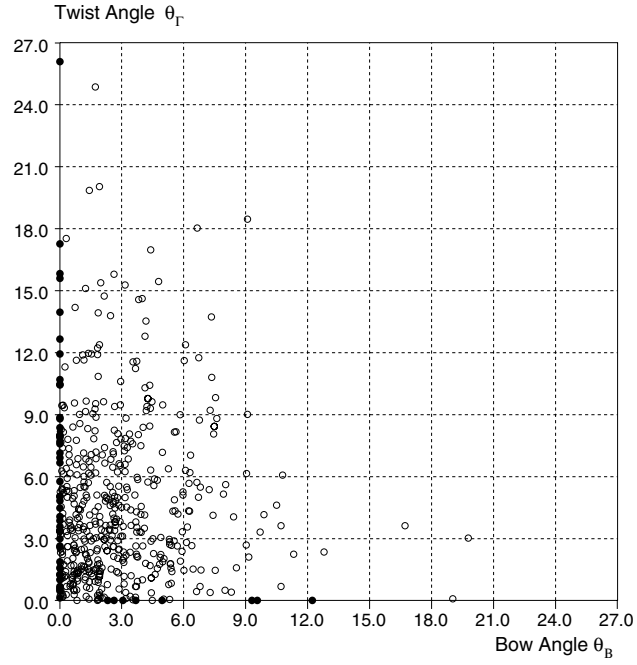

Fig. 3. The bow angle, θ_B, vs. the twist angle, θ_T. Points representing structures where one of the angles is exactly zero from symmetry considerations are shown as filled circles.

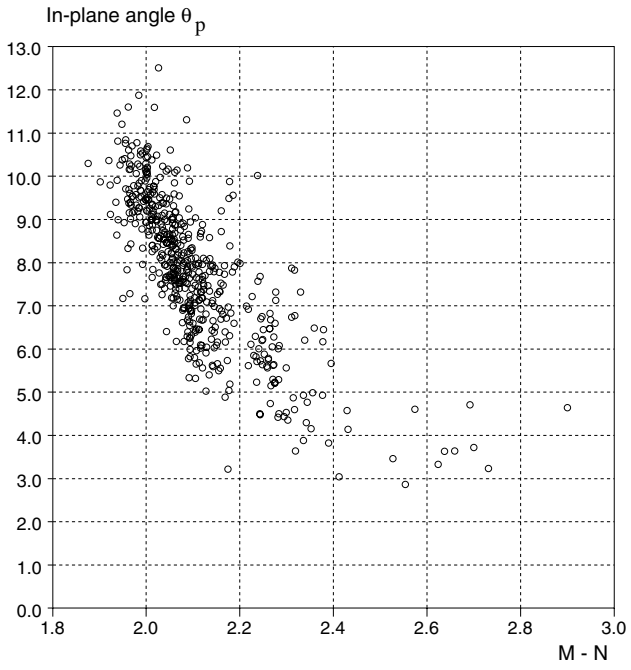

Fig. 4. The in-plane distortion, θ_P, plotted against the mean M–N distance.

There is however a large scatter and the correlation coefficient is only 0.77. In the free bipyridine [1], the CCN angle involving the central bond is 118.26° that would give an in-plane distortion of 3.5°. The in-plane distortion of the Mbipy group is a combination of distortions of the CCN and of the MNC angle, and the sum of these distortions $(240° - \theta_{CCN} - \theta_{MNC})$ correlates inversely with M–N, the correlation coefficient is 0.96. The M–N distance for which there would be no in-plane distortion is 2.72 Å.

4. Conclusions

The answer to the question in the title is that bipyridine is seldom planar in metal complexes and that the deviation from planarity can be described in terms of bow and twist deformations and to a lesser extent in terms of an S-shaped distortion. There is also an in-plane deformation, which is far from negligible.

Hydrothermal synthesis and characterization of the first examples of lanthanide(III) isoorotates with a 3D supramolecular network

Chang-Yan Sun, Lin-Pei Jin *

Department of Chemistry, Beijing Normal University, Xinjiekou Road, Beijing 100875, PR China

Received 10 February 2004; accepted 25 May 2004
Available online 3 July 2004

Abstract

The first examples of lanthanide(III) isoorotates were synthesized by hydrothermal reactions and characterized by single crystal X-ray diffraction. Isoorotate ions (H_2iso^- and $Hiso^{2-}$) act as bidentate ligands and coordinate to the Ln(III) ions through the carboxylate oxygen and the adjacent carbonyl oxygen, forming a stable six-membered ring. But in the Pr(III) complex, $Hiso^{2-}$ acts as a tetradentate ligand, and in addition to the formation of the six-membered ring, another carbonyl oxygen atom and a deprotonated amido nitrogen atom are involved in coordination. There are O–H···O, N–H···O and/or N–H···N hydrogen bonds, and/or π–π stacking interactions in these complexes, resulting in the formation of 3D supramolecular networks.

1. Introduction

It is well known that orotic acid (6-carboxyuracil, H_3oro) plays a significant role in many biological processes, since this compound is the only effective precursor of pyrimidine bases of nucleic acids in living systems [1]. Also, it has been extensively used in medicine for the treatment of some pathologies [2]. The coordination chemistry of this compound has been intensively investigated. Isoorotic acid (5-carboxyuracil, H_3iso), the isomer of orotic acid, has not received so much attention yet, although it exhibits anticancer, antibacterial and antihypertensive properties and is an interesting species from a medical and pharmacological point of view [3]. Apart from that, isoorotic acid possesses fascinating coordination characteristics: first, it is an interesting multidentate ligand capable of coordinating to metal ions through the nitrogen atoms, the two carbonyl oxygen atoms and the carboxylate oxygen atoms; second, the carboxylic and amido hydrogens may be completely or partially removed, so that metal complexes of H_2iso^-, $Hiso^{2-}$ and/or iso^{3-} are formed; and third, it can act not only as a hydrogen-bond acceptor, but also a hydrogen-bond donor, depending on the deprotonated groups. Because of the different position of the carboxylate group in orotic acid and isoorotic acid, we expect that there are many differences in their coordination behavior. Previous studies on the coordination chemistry of isoorotic acid mainly focused on transition metals [4–10] and those on lanthanide ones were by and large neglected. With the above consideration in mind, we report the synthesis and characterization of the first examples of lanthanide complexes with isoorotic acid.

2. Experimental

2.1. Materials and apparatus

All reagents were used as received without further purification. The C, H, N microanalyses were carried out with a Vario EL elemental analyzer. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. Thermogravimetric

analyses were conducted on a ZRY-2P Thermal Analyzer using a heating rate of 10 °C/min from room temperature to 900 °C.

2.2. Synthesis

Tb(Hiso)(H2iso)(H2O)4·3H2O (1). A mixture of H_3iso (0.017 g, 0.1 mmol), $TbCl_3 \cdot 6H_2O$ (0.038 g, 0.1 mmol), an aqueous solution of NaOH (0.2 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml) and heated at 140 °C for 72 h. The vessel was then cooled at 10 °C/3 h to 100 °C, followed by slow cooling to room temperature. Colourless crystals were obtained by filtration, and washed with water and ethanol. Yield: 0.019 g (64%). *Anal.* Calc. for $C_{10}H_{19}N_4O_{15}Tb$: C, 20.20; H, 3.20; N, 9.43. Found: C, 20.05; H, 3.03; N, 9.23%. IR (KBr, cm^{-1}): 3378s, 1625s, 1552m, 1469m, 1426m, 1370s, 1304m, 1192m, 1142m, 1011m, 919m, 812m, 653m, 584m.

Yb(Hiso)(H2iso)(H2O)4·3H2O (2). The synthesis of complex **2** followed the same procedure as for **1**, but using $YbCl_3 \cdot 6H_2O$. Yield: 0.012 g (39.5%). *Anal.* Calc. for $C_{10}H_{19}N_4O_{15}Yb$: C, 19.73; H, 3.12; N, 9.21. Found: C, 19.61; H, 2.92; N, 9.06%. IR (KBr, cm^{-1}): 3418s, 1626s, 1548m, 1470m, 1427m, 1384s, 1304m, 1196m, 1142m, 1010m, 919m, 812m, 653m, 584m.

Pr2(Hiso)(H2iso)4(phen)2(H2O)2·5H2O (3). A mixture of H_3iso (0.017 g, 0.1 mmol), $PrCl_3 \cdot 6H_2O$ (0.036 g, 0.1 mmol), phen·H_2O (0.02 g, 0.1 mmol), an aqueous solution of NaOH (0.2 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml) and heated at 140 °C for 72 h. The vessel was then cooled at 10 °C/3 h to 100 °C, followed by slow cooling to room temperature. Colourless crystals were obtained by filtration, and washed with water and ethanol. Yield: 0.023 g (74.5%). *Anal.* Calc. for $C_{49}H_{44}N_{14}O_{27}Pr_2$: C, 38.11; H, 2.85; N, 12.70. Found: C, 38.35; H, 2.56; N, 12.34%. IR (KBr, cm^{-1}): 3428s, 3073m, 2969m, 2798m, 1716m, 1643s, 1559m, 1422s, 1384s, 1300m, 1198m, 1142m, 1101m, 1046m, 846m, 812m, 648m, 567m.

Eu(Hiso)(H2iso)(phen)2·2H2O (4). The synthesis of complex **4** followed the same procedure as for **3**, but using $EuCl_3 \cdot 6H_2O$. Yield: 0.031 g (72.3%). *Anal.* Calc. for $C_{34}H_{25}N_8O_{10}Eu$: C, 47.60; H, 2.92; N, 13.07. Found: C, 47.47; H, 2.60; N, 13.07%. Tb(Hiso)(H2iso)(phen)2·2H2O (5). A mixture of H_3iso (0.017 g, 0.1 mmol), $TbCl_3 \cdot 6H_2O$ (0.038 g, 0.1 mmol), phen·H_2O (0.02 g, 0.1 mmol), an aqueous solution of NaOH (0.3 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml), and heated at 120 °C for 72 h. The vessel was then cooled slowly to room temperature. Colourless crystals were obtained by filtration, and washed with water and ethanol. Yield: 0.023 g (74.5%). *Anal.* Calc. for $C_{34}H_{25}N_8O_{10}Tb$: C, 47.22; H, 2.89; N, 12.96. Found: C, 46.63; H, 2.66; N, 12.85%. IR (KBr, cm^{-1}): 3451s, 3061m, 2927m, 1637s, 1545m, 1515m, 1496m, 1418s, 1342m, 1301m, 1257m, 1103m, 1049m, 847m, 731m, 638m.

Yb(Hiso)(H2iso)(phen)2·2H2O (6). The synthesis of complex **6** followed the same procedure as for **5**, but using $YbCl_3 \cdot 6H_2O$. Yield: 0.016 g (36.4%). *Anal.* Calc. for $C_{34}H_{25}N_8O_{10}Yb$: C, 46.43; H, 2.85; N, 12.75. Found: C, 45.68; H, 2.64; N, 12.42%. IR (KBr, cm^{-1}): 3464s, 3062m, 2926m, 1636s, 1544m, 1513m, 1473m, 1420s, 1379m, 1302m, 1256m, 1103m, 996m, 848m, 730m, 638m.

Yb(Horo)(OH)(H2O) (7). A mixture of H_3oro (0.017 g, 0.1 mmol), $YbCl_3 \cdot 6H_2O$ (0.039 g, 0.1 mmol), an aqueous solution of NaOH (0.2 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml), and heated at 160 °C for 72 h. The vessel was then cooled slowly to room temperature. Colourless crystals were obtained by filtration, and washed with water and ethanol. Yield: 0.011 g (30.4%). *Anal.* Calc. for $C_5H_5N_2O_6Yb$: C, 16.57; H, 1.38; N, 7.73. Found: C, 16.84; H, 1.26; N, 7.65%. IR (KBr, cm^{-1}): 3373m, 3113m, 1631s, 1486m, 1425s, 1374m, 1346m, 1320m, 1162m, 1018m, 848s, 798m, 723m, 620m.

2.3. X-ray diffraction determination

Diffraction intensities for the complexes were collected at 293 K on a Bruker SMART 1000 CCD area detector diffractometer employing graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) in ϕ and ω scan modes. Semi-empirical absorption correction was applied on the complexes using the SADABS program [11]. The structures were solved by direct methods [12] and refined by full-matrix least squares method on F^2 using SHELXS-97 and SHELXL-97 programs, respectively [12,13]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in geometrically calculated positions. The crystallographic data for complexes **1**–**7** are listed in Table 1, and selected bond lengths (Å) and bond angles (°) in Tables 2–5.

3. Results and discussion

3.1. Description of the structures

Compounds **1** and **2** are isomorphous, while **4**, **5** and **6** are isomorphous, too. Only the structures of **2, 3, 6** and **7** will be described in detail. It is noted that the site occupancy of hydrogen atoms on N(2) and N(2A) for **1** and **2**, and on N(4) and N(4A) for **4**–**6**, is 0.5.

Symmetry transformations used to generate equivalent atoms: #1 $-x+1, -y+1, -z$.

In the complex, the isoorotate group (H_2iso^- or $Hiso^{2-}$) acts as a bidentate ligand through the carboxylate group and the adjacent carbonyl oxygen, forming a stable six-membered ring. This is the same as in the Mn(II) [5], Zn(II) [7], Fe(II) [8] and Mg(II) [10] complexes with H_2iso^-. The Yb–O distances range from 2.285 to 2.360 Å and the average value is 2.333 Å (2.371 Å for **1**).

There are several kinds of hydrogen bonds in **2**: (1) the O_w–H$\cdots O_{cc}$ hydrogen bond between the coordinating water molecule (O_w) and the coordinating carboxyl oxygen (O_{cc}); (2) the O_w–H$\cdots O_c$ hydrogen bond between the coordinating water molecule and the uncoordinating carbonyl oxygen (O_c); (3) the O_w–H$\cdots O_w$ hydrogen bond among the coordinating water molecules; (4) the N–H$\cdots O_c$ hydrogen bond between the amido group and the uncoordinating carbonyl oxygen. All these hydrogen bonds link the moieties into a 2D layer structure along the ab plane, as shown in Fig. 2. The lattice water molecules in **2** can form hydrogen bonds with the aqua ligands, uncoordinating carbonyl oxygen and coordinating carboxyl oxygen, which connect the 2D layer into a 3D supramolecular architecture [14]. The details of the hydrogen bonds are listed in Table 6.

*$Pr_2(Hiso)(H_2iso)_4(phen)_2(H_2O)_2\cdot 5H_2O$ (**3**).* The coordination environments of the Pr(III) ions in **3** are shown in Fig. 3. Both Pr(III) ions are coordinated by four oxygen atoms (O(1), O(4), O(5), O(8) or O(1A), O(4A), O(5A), O(8A)) from two H_2iso^- anions, one oxygen atom (O(9) or O(9A)) from one coordinated water molecule and two nitrogen atoms (N(1), N(2) or N(1A), N(2A)) from one chelating phen molecule. For Pr(1), one oxygen atom (O(13)) and one nitrogen atom (N(7)) from one $Hiso^{2-}$ anion occupy the last two sites to complete the nine-coordination. On the other hand, for Pr(1A) they are O(10) and O(11) from the $Hiso^{2-}$

Symmetry transformations used to generate equivalent atoms: #1 $-x+1, y, -z+1/2$.

anion. The $Hiso^{2-}$ anion is disordered and its occupancy is 0.5. The average distance of Pr–O is 2.498 Å, while that of Pr–N is 2.676 Å. In the complex, the coordination modes of H_2iso^- and $Hiso^{2-}$ anions are different. The H_2iso^- anion acts as an O,O-chelating bidentate ligand, the same as in complexes **1** and **2**, while the $Hiso^{2-}$ anion acts as a tetradentate ligand. In addition to the formation of a six-membered ring, another carbonyl oxygen and one deprotonated amido nitrogen are involved in the coordination. So one $Hiso^{2-}$ anion bridges two Pr(III) ions. This coordination mode has not been reported before. The separation between Pr(1) and Pr(1A) is 8.717 Å.

The dinuclear $Pr_2(Hiso)(H_2iso)_4(phen)_2(H_2O)_2$ is the building block of **3**. Every two such building blocks are linked by O_w–H···O_c hydrogen bonds, forming a grid of 10.239×8.717 Å (Fig. 4a). There are N–H···O_c, O_w–H···O_{uc}, O_w–H···O_{uc} and O_w–H···O_w hydrogen bonds between the grids, resulting in the formation of a 3D supramolecular structure, as shown in Fig. 4b. The details of the hydrogen bonds are depicted in Table 6. All phen molecules are perfectly parallel to each other and the average distance between two adjacent phen planes is 3.58 Å, indicating the existence of π-aromatic interactions.

*$Yb(Hiso)(H_2iso)(phen)_2 \cdot 2H_2O$ (**6**)*. There is only one metal environment in **6** as shown in Fig. 5. The Yb(III) ion is eight-coordinated and is surrounded by four nitrogen atoms belonging to two chelating phen molecules and four oxygen atoms from two isoorotate groups. The distances of Yb–O are 2.222 and 2.272 Å, and those of Yb–N are 2.513 and 2.544 Å. The average distance of Yb–O is 2.247 Å, which is much shorter than that of Yb–N (2.529 Å). The dihedral angle between two phen molecules is 35.8°. In the complex, the isoorotate groups (H_2iso^- or $Hiso^{2-}$) also act as bidentate ligands as in **1** and **2**, but leading to a different architecture.

A 3D supramolecular network (see Fig. 6) results from the hydrogen bonds among the amido groups (N–H···N), and the hydrogen bonds between the amido group and the uncoordinating carbonyl oxygen (N–H···O_c), the lattice water and the uncoordinating carbonyl oxygen (O–H···O_c), the lattice water and the uncoordinating carboxyl oxygen (O–H···O_{uc}).The details of the hydrogen bonds are shown in Table 6.

*$Yb(Horo)(OH)(H_2O)$ (**7**)*. The structure of **7** is similar to that of $Gd(Horo)(OH)(H_2O)$ [15], which is a coordination polymer with a 3D network. Each Yb(III) ion is coordinated to one nitrogen and seven oxygen atoms, of which three oxygen atoms come from OH^- groups, three from different orotate ligands and one from a coordinating water molecule. In the complex, the orotate group acts as a tetradentate ligand, coordinating

through two carbonyl oxygen, one carboxylate oxygen and one deprotonated amido nitrogen.

Comparing the structures of **2** and **7**, we can see some differences: (1) **2** is mononuclear while **7** is a 3D coordination polymer. This is the result of the different coordination modes of isoorotate and orotate anions. The former coordinates to metal atoms through the carboxylate group and the adjacent carbonyl oxygen, forming a stable six membered ring, while the latter acts as a bridging ligand to link the metals. (2) The position

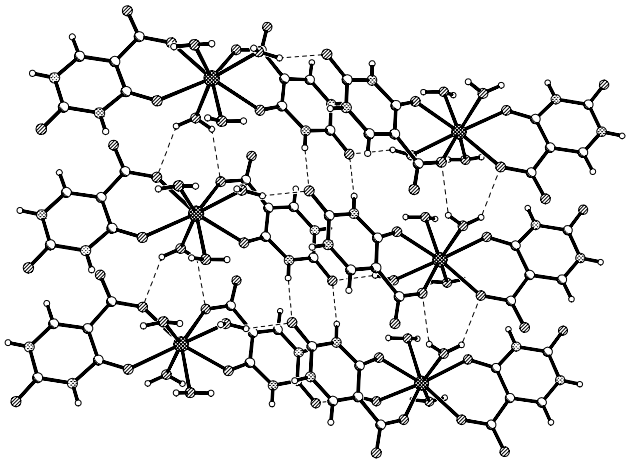

Fig. 2. The 2D layer structure of complex **2** viewed along the *c*-axis.

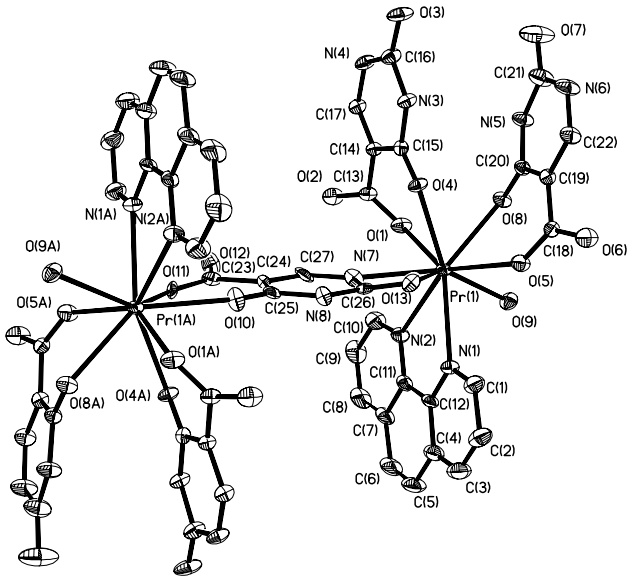

Fig. 3. The coordination environments of Pr(III) ions in **3** with 30% thermal ellipsoids, all hydrogen atoms and lattice water molecules are omitted for clarity.

of carboxylate is important for the deprotonation of the amido group. In **2**, H_3iso only loses one hydrogen atom of the carboxylate group; while in **7**, H_3oro loses two hydrogen atoms, including one hydrogen of the carboxylate group and one hydrogen of the adjacent amido group, so that $Horo^{2-}$ coordinates to the metal ion through the carboxylate oxygen and the adjacent deprotonated amido nitrogen, forming a five membered ring.

Phen is a versatile ligand to construct supramolecular structures, as it is often involved with π–π stacking interactions and C–H···O hydrogen bonds. When phen was introduced to the mixture of H_3iso and lanthanide

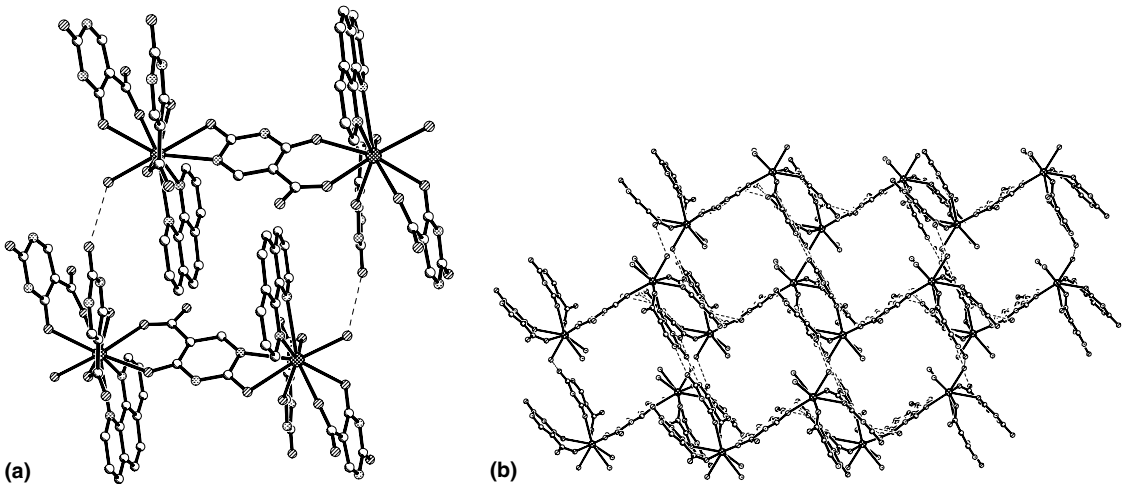

Fig. 4. (a) The grid formed by the O_w–H$\cdots$$O_c$ hydrogen bonds; (b) The 3D supramolecular network of **3** viewed along the *b*-axis, carbon atoms of phen molecules and all the hydrogen atoms are omitted for clarity.

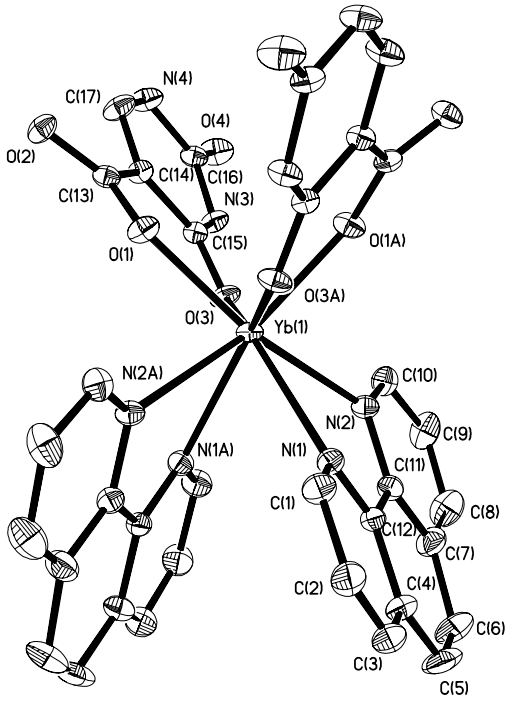

Fig. 5. Asymmetric unit of the complex **6** with 30% thermal ellipsoids; two lattice water molecules and all hydrogen atoms are omitted for clarity.

ions, different results were obtained. In **3**, there are weak π–π stacking interactions between phen molecules as expected. But in complexes **4**–**6**, two phen molecules coordinate to one lanthanide ion. In order to decrease the steric hindrance, the phen molecules are separated with a large distance and there are no π–π stacking interactions.

From **3** to **6**, with increasing atomic number, the mean distance of Ln–O bonds are in the following order:

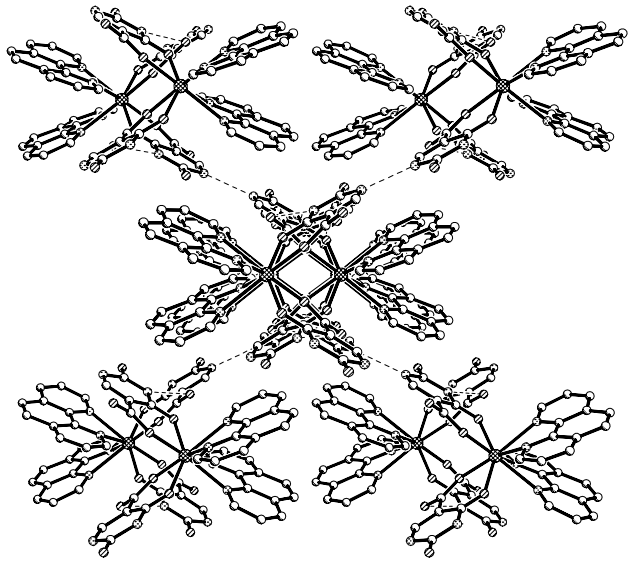

Fig. 6. The 3D supramolecular network of **6** viewed along the *c*-axis.

Pr–O (2.498 Å) > Eu–O (2.320 Å) > Tb–O (2.304 Å) > Yb–O (2.247 Å); the mean Ln–N bond distances are 2.676, 2.605, 2.584 and 2.529 Å for Pr, Eu, Tb and Yb, respectively. This is consistent with the lanthanide contraction.

3.2. Thermal analyses

Thermogravimetric analyses of the seven complexes were carried out to examine their thermal stabilities. The data of the thermogravimetric analyses for **1**–**7** are listed in Table 7. The complexes **1**–**6** lost their coordinated or/and lattice water molecules at the first weight loss, while complex **7** began to decompose above 250 °C.

Table 7
Thermogravimetric analyses data of **1**–**7**

	Dehydration temperature (°C)	Loss of water: Cacl. (Found) (%)	Further decomposition temperature (°C)
1	84–168	21.2 (20.8)	258
2	75–177	20.7 (20.4)	260
3	48–199	5.8 (5.5)	232
4	69–141	4.2 (3.8)	291
5	63–160	4.2 (3.6)	310
6	64–151	4.1 (3.8)	320
7			250

From Table 7 we can see that the dehydration temperature for **1–6** ranges from 48 to 199 °C. They further decompose beyond 230 °C. Taking **2** as an example, the TGA curve shows that the first weight loss of 20.4%, which occurs between 75 and 177 °C, corresponds to the loss of four coordinated and three crystal water molecules (calculated: 20.7%). Further decomposition of **2** occurs above 260 °C, whereas for **3** the first weight loss of 5.5%, from 48 to 199 °C, corresponds to the loss of five crystal water molecules (calculated: 5.8%) and further decomposition occurs above 232 °C.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 227488 to 227494 for **1**–**7**, respectively. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail:deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Abstract

This paper shows the characteristics of a coordinated compound formed by zinc(II) and di-2-pyridyl ketone salicyloylhydrazone (DPKSH). The synthesized complex shows the formula: $Zn(DPKSH)_2$. Elemental analysis, electron ionization and electrospray mass spectra indicated the 1:2 metal/ligand molar ratio. The IR spectra show that DPKSH is coordinated to zinc(II) through the oxygen from the enolic or the phenolic group as the *v*CO frequency was suppressed and the *v*CO (phenolic) band was shifted to higher frequency in the IR spectrum of the complex. Two other interactions can be attributed to the nitrogens from the azo and the pyridine groups. Thermal decomposition and differential scanning calorimetry (DSC) are different for the ligand and the complex. The overall formation constants were obtained in ethanolic solution 50% (V/V), at pH 4.5 and 25 °C, resulting in $\beta_1 = 1.07\times10^5$ and $\beta_2 = 1.05\times10^{10}$. The molar absorptivies of the 1:1 (ε_1) and 1:2 (ε_2) complexes (Zn(II):DPKSH) were found to be 1.1×10^4 and 4.5×10^4 ($M^{-1}cm^{-1}$), respectively.

1. Introduction

Hydrazones are azomethines characterized by the triatomic grouping C═N–N and they are interesting substances because some of them may play an important role in the treatment of several diseases, such as tuberculosis. Such an activity is directly attributed to the formation of stable chelates with transition metals that catalyze the corresponding physiological processes [1–3]. Such compounds are often synthesized and are widely used in analytical chemistry, chiefly as colorimetric or fluorimetric reagents or in liquid–liquid extraction methods combined with atomic absorption, colorimetric or fluorimetric methods for the determination of metallic ions [4–17]. In these chelates the aroylhydrazones ($R^1R^2CN_2(H)C(O)R^3$) may behave as a bidentate, tridentate or tetradentate ligand when R^1, R^2 and/or R^3 have a donor atom in an appropriate position [1,2,17–19]. When R^1 and R^2 are pyridine groups and R^3 is an

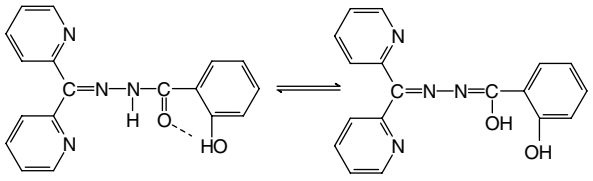
o-hydroxy-phenolic group, the result is di-2-pyridyl ketone salicyloylhydrazone (DPKSH).

Di-2-pyridyl ketone salicyloylhydrazone is a reagent soluble in different organic solvents but only slightly soluble in water. In aqueous/ethanolic solutions, DPKSH shows tautomeric structures (I and II) [20] and it may be coordinated to the metallic ion through the nitrogen atoms either alone or in combination with an oxygen atom, of the enolic or phenolic group. Neutral metallic complexes are formed in many cases.



(I) ketonic form (II) enolic form

Recently, complexes of zinc(II) with DPKSH were used to develop a highly sensitive spectrophotometric method [16]. The highest sensitivity was achieved in 50% (V/V) ethanol–water solvent and pH 4.5, maintained with acetic acid/acetate buffer. The main advantages of this method consist of low detection limit (8.1 $\mu g\,L^{-1}$), high sensitivity (4.8×10^{4} $L\,mol^{-1}\,cm^{-1}$ at 376 nm) and the use of simple instrumentation with the possible application in field analysis.

For a better understanding of the bonds, structure and stoichiometry of DPKSH/Zn(II) complexes, as well as the knowledge of some spectroscopic, thermal and thermodynamic properties, a thorough report on the experiments and the results obtained from DPKSH and the DPKBH/Zn(II) complex is provided.

2. Experimental

2.1. Reagents and solutions

All reagents and solvents were of analytical grade from Merck. A standard solution of Zn(II) was prepared by dissolving reagent-grade $ZnSO_4\cdot7H_2O$ in de-ionized water and sulfuric acid. The final pH was adjusted to ≈2.5 in order to avoid the hydrolysis of the metallic ion and the zinc(II) concentration was determined by titration with a standard EDTA solution [21].

The synthesis of DPKSH was performed in accordance with the procedure outlined by Garcia-Vargas et al. [20]. After synthesis, the melting point of the product was verified to be 179 °C and its absorption spectrum was checked and compared with previously reported values [20]. The DPKSH stock solution was prepared by dissolving the reagent in ethanol and may be stored for 30 days.

The complex was obtained by reacting the zinc hydrated salt and the ligand (molar ratio 1:2) in ethanol. This molar ratio was achieved by mixing 50 mL of each solution: 2×10^{-2} $mol\,L^{-1}$ Zn(II) and 4×10^{-2} $mol\,L^{-1}$ DPKSH. After a slow evaporation of this solvent, the complex was dried under vacuum over anhydrous calcium chloride leading to a yellow solid.

The electrospray ionization spectra were recorded from a solution of the complex in ethanol/methanol 40/60% (v/v). Another electrolyte was not added because the synthesis was carried out in presence of buffer solution (acetic acid/potassium acetate).

The necessary experimental data for the application of the continuous variations [22,23] or Job's method are made up of the absorbances related to solutions with different ligand molar fractions, varying the concentrations of both Zn(II) and DPKSH, but keeping the sum of the ligand and the metal ion concentrations constant at 1.0×10^{-4} $mol\,L^{-1}$. Such solutions are obtained from complementary volumes of equimolar solutions where the total volume is constant. The stoichiometry of the Zn(II)/DPKSH complexes was determined by using a series of solutions having a constant sum of the DPKSH and Zn(II) concentrations, in 50% ethanol–water and at pH 4.5. The molar ratio was varied from 0 to 1 and the absorbance values were measured at $\lambda = 376$ nm.

The necessary absorbance measurements to determine the overall formation constants [24] of the complexes were obtained at 376 nm. Three series of solutions with 1.10×10^{-5}, 1.52×10^{-5} and 2.01×10^{-5} $mol\,L^{-1}$ Zn(II) were prepared with different ligand concentrations ranging from 0.01×10^{-5} to 5.0×10^{-5} $mol\,L^{-1}$, in 50% EtOH/water, at pH 4.5.

2.2. Apparatus

All spectrophotometric measurements were carried out on a Hitachi model U-3000 spectrophotometer using 1.00 cm quartz cells. The pH measurements were performed with a Metrohm 654 pH meter equipped with a Metrohm glass electrode of which the Ag/AgCl reference was filled with 3 $mol\,L^{-1}$ NaCl. FTIR spectra (4000—500 cm^{-1}; KBr pellets) were recorded on a Perkin–Elmer 1750 series FTIR spectrophotometer. The electron ionization spectra were obtained from a Hewlett Packard HP 5988A. The electrospray mass spectra were obtained from Platform II Micromass in high capillary and cone tension (2.90 kV and 53 V, respectively). A CHN Elemental Analyser instrument from Perkin–Elmer, model 2400 was used to determine the C, H and N percentages both in DPKSH and the Zn(II)/DPKSH complex. The percentage of oxygen in the ligand was calculated by difference and the Zn(II) percentage present in the complex was obtained from TG experiments. Thermogravimetry (TG) and derivative thermogravimetry (DTG) curves were obtained on a model TGA-50

Thermogravimetric Analyzer in the temperature range 25–900 °C with a heating rate of 10 °C min^{-1} under dynamic air atmosphere (ca. 50 mL min^{-1}) and with a sample weighing 3.1–3.2 mg in a Pt crucible. Differential scanning calorimetry (DSC) curves were obtained on a DSC50 cell (Shimadzu) in the temperature range 25–600 °C with a heating rate of 10 °C min^{-1}, under dynamic nitrogen atmosphere (ca. 50 mL min^{-1}) with a sample weighing in the range of 0.9–1.3 mg in an Al crucible. The DSC system was calibrated with indium (m.p. = 156.6 °C; $\Delta H_{fus.}$ = 28.54 J g^{-1}) and zinc (m.p. = 419.6 °C).

3. Results and discussion

DPKSH is a crystalline and very light yellow solid and the Zn(II)/DPKSH complexes obtained as previously described have a darker yellow color. The main IR frequencies for DPKSH and Zn(II)/DPKSH are summarized in Table 1. IR spectrum of the complex differs significantly from that of the free ligand. The ν(N–H) at 3059 cm^{-1}, δ(C═O) at 1636 cm^{-1} (amide I) and δ(C–O) phenolic group at 1133 cm^{-1}, observed for the ligand, are suppressed in the spectrum [25–27] of the complex. The shift of the carbonyl stretching mode to lower frequencies is in accordance with coordination through the oxygen. The band at 1583 cm^{-1} (amide II) is shifted to a higher frequency and intensity in the complex (1593 cm^{-1}). The band due to the phenolic group from the ligand at 1133 cm^{-1} [25] is shifted to a higher frequency (1151 cm^{-1}) in the complex. These observations suggest that DPKSH is coordinated to Zn(II) through the oxygen from the enolic (amide I) or phenolic group (C–O 1133 cm^{-1}) and through nitrogens of one of the pyridines and from the principal chain (amide II).

Electron ionization spectra of the ligand and the Zn(II)/DPKSH complex were registered in a range of m/z from 0 to 400. Main fragments found for DPKSH are indicated in Table 2. The base peak was found at m/z = 169 for both the ligand and the complex. The molecular ion peak at m/z = 318 corresponds to the formula weight of the ligand. The peak m/z = 121 was found for the ligand but it was not observed for the Zn(II) complex. In the spectrum of the complex the molecular ion peak formed at m/z = 350 probably corresponds to its formula weight when z = 2 ($Zn(C_{18}H_{13}N_4O_2)_2$, 700 g mol^{-1}).

The mass spectrum with electrospray ionization [28–30] was obtained. The cluster registered at m/z = 701, corresponds to the protonated complex $[Zn(C_{18}H_{13}N_4O_2)_2H]^+$ and confirms the composition of the Zn(II)/DPKSH complex with a 1:2 ratio of Zn(II)/ligand. A peak at m/z = 723 may be related to the species $[Zn(DPKSH)_2Na]^+$ and the presence of Na is probably due to a very common electrode contamination. A cluster at m/z = 739 was also observed and it can be correlated to the $[Zn(DPKSH)_2K]^+$ species. The presence of K is probably explained by the use of buffer solution (acetic acid/potassium acetate) in the synthesis of the complex.

Table 3 shows the elemental analysis results for DPKSH and its complexes with Zn(II). These data are in excellent compliance with the calculated C, H and N percentages for the ligand and the respective complex of Zn(II) considering the 1:2 stoichiometry $[Zn(DPKSH)_2]$. The calculation was made considering

121		**11**

the formula weight of the DPKSH being equal to 318.3 and 317.3 g mol^{-1} for the ligand coordinated to Zn(II) ions as an anion ($[C_{18}N_4H_{13}O_2]^-$).

The concordance between the experimental and theoretical percentages of C, N and H found for the ligand shows the absence of water molecules. Considering the elemental analysis data (Table 3) for the complex it is possible to confirm the presence of a water molecule in the composition, namely $Zn(DPKSH)_2 \cdot H_2O$.

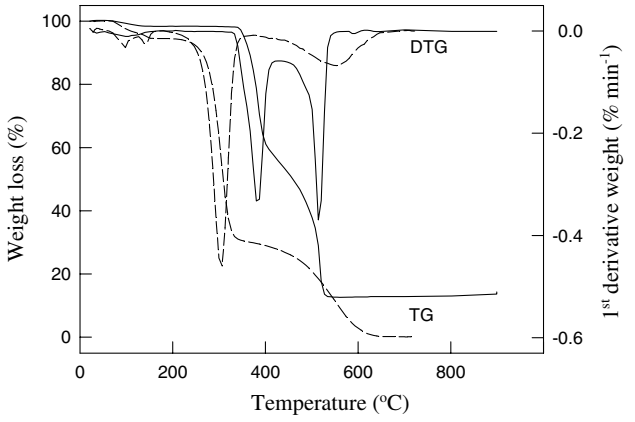

Fig. 1. TG/DTG curves: for (– – –) DPKSH ($m = 3.134$ mg) and (—) $Zn(DPKSH)_2$ ($m = 3.271$ mg). Both of the curves were obtained in air atmosphere (ca. 50.0 mL min^{-1}) and a heating rate of 10 °C min^{-1}.

Fig. 1 shows TG/DTG curves for the ligand and the Zn(II) complex. Thermal decomposition of DPKSH occurs in three main steps, with DTG peaks at 91 and 146 (related to dehydration), 295 and 493 °C. The weight loss observed between 50 and 160 °C may be attributed to an intramolecular reaction that involves the loss of a water molecule as the TG curve shows a mass variation of 5.41%. Considering this probable reaction, the mass loss calculated corresponds to 5.67%, which is quite similar to the experimental value.

TG/DTG curves of the complex show a mass loss of 2.6% over temperatures ranging from 30 to 200 °C that corresponds to the complex dehydration, indicating the presence of one coordinated water molecule. The anhydrous species is stable thermally up to ≈350 °C. In a temperature range from 350 to 730 °C, the thermal decomposition occurs at two distinctive stages. The mass loss between 350 and 430 °C with a DTG peak at 383 °C and $\Delta m = 43.9\%$ corresponds to the elimination of one molecule of DPKSH (calculated value, 45.5%). The mass loss observed in a range from 430 to 730 °C with a DTG peak at 515 °C was found to have a $\Delta m = 42.8\%$ and it corresponds to the final decomposition resulting in ZnO (Table 3).

Table 3
Elementary analysis of DPKSH and the Zn(II)/DPKSH complex

DPKSH				$Zn(DPKSH)_2 \cdot H_2O$		
%	Calculated	Experimental	Error %	Calculated	Experimental	Error %
C	67.9	67.7	−0.3	60.22	60.3	+0.1
H	4.43	4.54	2.4	3.93	3.99	+1.5
N	17.6	17.6		15.61	15.6	−0.1
H_2O				2.51	2.61	+3.8
ZnO				11.3	11.1[a]	−1.8

[a] Calculated from TG/DTG curves.

Considering the total decomposition of the [Zn(DPKSH)$_2$] complex and the formation of ZnO as a residue at 730 °C, the experimental value (11.1%) conforms to the calculated value (11.3%). This good agreement is another evidence of the coordination of two molecules of DPKBH to the Zn(II) cation and confirms the proposed stoichiometry for this complex.

Comparison between TG/DTG curves of the ligand and the complexes shows a higher thermal stability for the complex, as the mass losses after its dehydration begin at 350 for the complex and at 200 °C for the ligand. The higher stability of the ligand – when coordinated to Zn(II) – may be attributed to ligand–metal interactions.

DSC curves of DPKSH and [Zn(DPKSH)$_2$H$_2$O] are shown in Fig. 2. As it can be seen, the DSC curve profiles of the ligand and complex are quite different. Some endothermic events observed for DPKSH at the lower temperature range (<160 °C) may also be associated to the intramolecular reaction (water molecule loss) proposed on the TG curve basis. The anhydrous DPKSH shows an intense sharp endothermic peak between 169 and 189 °C and, $\Delta H = 36$ kJ mol^{-1} which corresponds to the melting of DPKSH. The onset temperature, 179 °C, is in agreement with the melting temperature range indicated in the literature (172–174 °C) [20]. Above 297 °C, several exothermic events can be seen and they are related to thermal decomposition processes. The DSC curve of the complex shows a sharp endothermic peak which characterizes the melting process at 336 °C with $\Delta H = 60$ kJ mol^{-1}. After the complex melts, some exothermic events are observed and the thermal decomposition is associated with a gradual mass loss process.

The molar ratio relative to the maximum of the Job's curve corresponds to the more favorable species present in the equilibrium [22,23]. That molar ratio is obtained from the intersection between the tangents of the curve.

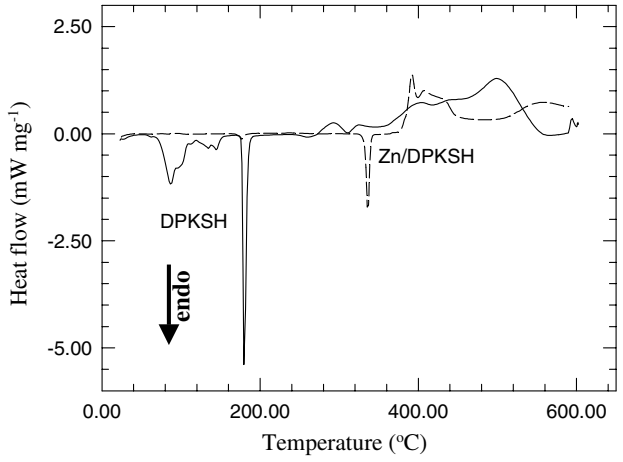

Fig. 2. DSC curves of the ligand DPKSH and Zn(DPKSH)$_2$ obtained in dynamic nitrogen atmosphere (ca. 50.0 mL min^{-1}) and heating rate of 10 °C min^{-1}, with mass 1.365 and 0.9220 mg, respectively.

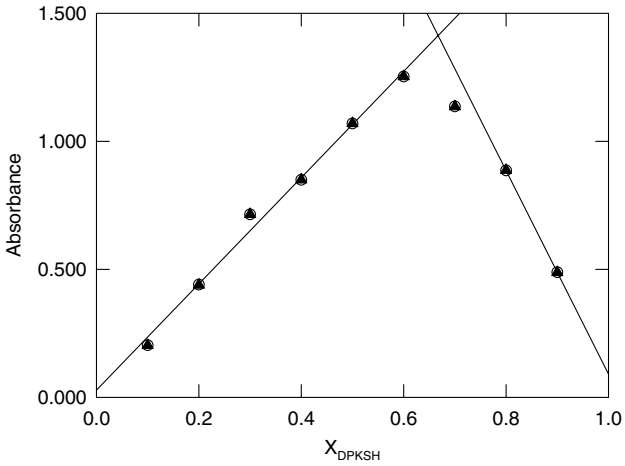

Fig. 3. Values of absorbance vs. molar fraction of the ligand, $C_{DPKSH}/(C_{Zn(II)} + C_{DPKSH})$. Pathlength = 1 cm, $\lambda = 376$ nm, pH 4.5. $C_{DPKSH} + C_{Zn(II)} = 1.00 \times 10^{-4}$ mol L^{-1} in ethanol/water 50% (v/v).

Fig. 3 shows the absorbances at $\lambda = 376$ nm for several solutions with different molar ratios. The maximum absorbance was found at a molar ratio equal to 0.67 and this value corresponds to a 1:2 metal/ligand ratio or the coordination of two molecules of DPKSH to Zn(II).

In order to obtain the stability constants of the complexes [24] formed by Zn(II) and DPKSH, absorbances were measured at 376 nm for three different total metal concentrations with variable ligand-to-metal ratios. Median molar absorptivities ($\bar{\varepsilon}$) were obtained as follows:

$$\bar{\varepsilon} = \frac{A}{C_{Zn} \cdot b} \quad (1)$$

where A is the measured absorbance, C_{Zn} is the analytical molar concentration of Zn(II) and b is the pathlength (cm) of the spectrophotometric cell.

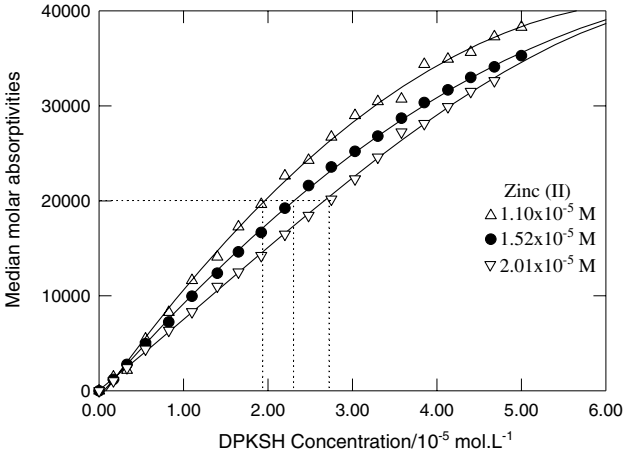

Fig. 4. Experimental data of median molar absorptivities vs. analytical concentrations of DPKSH for Zn(II) at three different concentrations. Calculated curves from stability constants and individual molar absorptivities. An example of three corresponding solutions is showed by the dashed lines.

Fig. 4 shows the data obtained for three representative Zn(II) concentrations: 1.10×10^{-5}, 1.52×10^{-5} and 2.01×10^{-5} mol L^{-1}. Considering the favorable changes in the absorbance with variable metal and ligand concentrations, the spectrophotometric method of corresponding solutions [11,12] was employed to determine the overall formation constants.

With the available experimental data ($\bar{\varepsilon}$, C_{Zn} and C_L), the average ligand number, $\bar{n}$, and the free ligand concentrations, [DPKSH]=[L], were determined according to Eq. (2) in which a plot of C_{DPKSH} versus C_{Zn} should yield a straight line with an intercept that corresponds to the free ligand concentration and a slope that corresponds to the $\bar{n}$ value.

$$C_{DPKSH} = [DPKSH] + \bar{n}C_{Zn} \quad (2)$$

Considering the region (Fig. 4) where the variation of the median molar absorptivities is the maximum, Eq. (2) can be used to obtain a set of $\bar{n}$ and [DPKSH] values. The average ligand number – $\bar{n}$ – according to Eq. (3) is related to [DPKSH].

$$\bar{n} = \frac{C_L - [L]}{C_M} = \frac{\beta_1[L] + 2\beta_2[L]^2}{1 + \beta_1[L] + \beta_2[L]^2} \quad (3)$$

A nonlinear variation of $1/\bar{n}$ versus [DPKSH] shows the existence of more than one species at equilibrium. A weighted least-square analysis of the data Eq. (3) yields *overall stability constants* for the 1:1 (β_1) and 1:2 (β_2) complexes, being $\beta_1=(1.07\pm0.02)\times10^5$ and $\beta_2=(1.05\pm0.01)\times10^{10}$. The individual formation constants are $K_1=1.07\times10^5$ and $K_2=9.81\times10^4$.

Calculation of the individual molar absorptivities (ε_1 and ε_2) for the respective complexes was simplified due to the low number of species present at equilibrium. Eq. (1) can be rewritten as:

$$\bar{\varepsilon} = \frac{\varepsilon_0 + \varepsilon_1\beta_1[L] + \varepsilon_2\beta_2[L]^2}{1 + \beta_1[L] + \beta_2[L]^2} \quad (4)$$

Here ε_0 was experimentally determined and corresponds to the Zn(II) molar absorptivity in the absence of DPKSH. A weighted least-square analysis of the data ($\bar{\varepsilon}$, [L], $\varepsilon_0=0$) yields Eq. (4) the molar absorptivities ($M^{-1}cm^{-1}$) of the Zn(II)/DPKSH 1:1 and 1:2 complexes of $\varepsilon_1=(1.1\pm0.3)\times10^4$ and $\varepsilon_2=(4.5\pm0.1)\times10^4$ L $mol^{-1}cm^{-1}$, respectively. The last molar absorptivity (ε_2) is in excellent agreement with the slope of the analytical curve by Gaubeur et al. 4.83×10^4 L $mol^{-1}cm^{-1}$ [16]. This means that the use of excess of ligand in the spectrophotometric method [16] leads to the predominance of the 1:2 species.

The distribution diagram of the species is presented in Fig. 5. It shows that in the range of concentrations employed to determine the stability constants, the Zn(II)DPKSH 1:1 species predominates. Even though the [$Zn(DPKSH)_2$] concentration is low, the determination of the respective stability constants is possible due to the fact that the K_1/K_2 ratio is favorable.

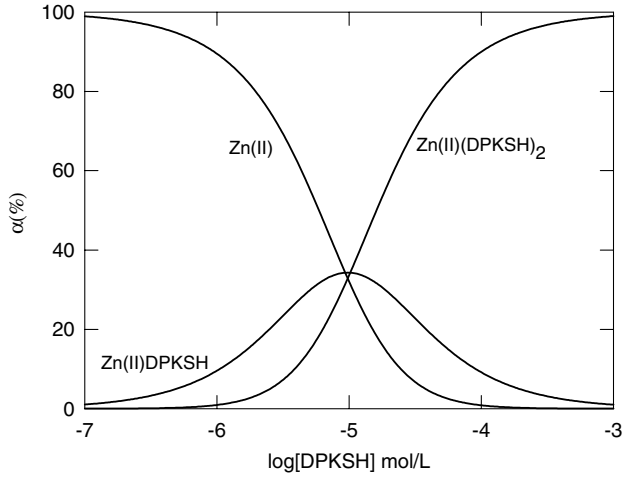

Fig. 5. Distribution diagram for the species present in the system Zn(II)-DPKSH. $T=25.0\pm0.1$ °C, pH 4.5 and 50% ethanol.

Abstract

The reaction of ammonium pyrrolidinedithiocarbamate with $SnPh_2Cl_2$ and $SnPh_3Cl$ produced in good yield the compounds $[Sn\{S_2CN(CH_2)_4\}_2\{C_6H_5\}_2]\cdot$toluene (**1**) and $Sn\{S_2CN(CH_2)_4\}\{C_6H_5\}_3$ (**2**). They were fully characterised by multinuclear NMR [^1H,$^{13}C\{^1H\}$ and $^{119}Sn\{^1H\}$] and ^{119}Sn Mössbauer spectroscopies. In addition the structure of **1** was determined, and **2** was revised by X-ray crystallographic studies. Finally, thermal decomposition experiments were carried out for both compounds in nitrogen and the residues were characterised by X-ray powder diffraction (XRD), X-ray electron probe microanalysis (EPMA), scanning electron microscopy (SEM) and ^{119}Sn Mössbauer spectroscopy. The results clearly indicate the formation of a mixture of γ-Sn_2S_3 and SnS, both orthorhombic phases.

Keywords: Pyrolysis; Organotin derivatives; Tin sulfide

1. Introduction

Tin sulfides are narrow-bandgap semiconductors with special optical and electronic properties [1]. Tin sulfides have three main phases: (i) SnS_2, (ii) SnS that exhibit layer structures and (iii) Sn_2S_3 which is a mixed valence Sn(II)/Sn(IV) compound with the same local order as the former sulfide, but with a ribbon-like structure [2]. Tin(II) sulfide displays a distorted rock-salt arrangement which is isostructural to GeS (orthorhombic, *Pbnm* group). Six sulfur atoms surround each tin centre with three short Sn–S bonds within the layer and three long bonds to the sulfur of the next layer [3,4].

Tin sulfides might encounter applications as low-cost green materials for photovoltaic devices either replacing cadmium chalcogenides, which have been banned in many countries because of their toxicity, or else as substitute to the expensive silicon-based sensors. Their preparation methods require high temperature reactions (more than 300 °C) or special reactors [5,6]. Atmospheric pressure chemical vapour deposition (APCVD) and pyrolysis using unsymmetrical organotin dithiocarbamates complexes, like $[(CH_3)_3Sn(S_2CN(C_4H_9)CH_3)]$ and $[(CH_3CH_2CH_2CH_2)Sn(S_2CN(C_4H_9)CH_3)]_3$, or heteroleptic thiolate/dithiocarbamate derivatives, $(Et_2NCS_2)(RS)_2$-Sn (R = Cy, CH_2CF_3), have already been reported [7–9].

However, either the decomposition temperatures are still too high or the process goes on in complicated many step mechanisms. Therefore the search for more appropriate single source precursors for Sn–S based materials is still justified.

The work reported here is part of a more general study performed by our research team concerning precursors for tin sulfide and oxide powders, which is still under investigation [10,11]. So far we have employed organotin derivatives such as $Sn_4S_4R_6$ and $Sn_4O_4R_6$ {R = methyl (Me), *n*-butyl or phenyl}. We found those economically attractive not only because of the facile preparation method but also due to their air stability, however, the decomposition temperatures are still high. In order to explore other promising starting materials and check the viability as a good precursor, we have also an interest in tin-containing dithiocarbamates complexes, and herein we describe the first outcomes of our investigations.

2. Experimental

2.1. Instrumentation and techniques:

IR spectra were obtained as KBr plates on a Mattson Galaxy Model ST 3000 spectrometer in the 4000–400 cm^{-1} range. NMR spectra were record in $CDCl_3$ at 25 °C on a Brucker Avance DRX 400. The values were referenced to internal $SiMe_4$ and $SnMe_4$. C, H, N analyses were performed using a Perkin–Elmer Model PE 2400 CHN.

Thermal decomposition of **1** and **2** were carried out in a tube furnace in N_2 atmospheres up to 500 °C for **1** and 750 °C for **2** using a heating rate of 5 °C/min and a gas flux of 100 ml/min.

XRD patterns were collected with Rigaku Geigerflex equipment by using Ni-filtered Cu Kα radiation ($\lambda = 1.5418$ Å) and a graphite monochromator in the diffracted beam. A scan rate of 4 °/min was applied to record a pattern in the 2θ range of 4–80°.

^{119}Sn Mössbauer measurements were performed on conventional apparatus with the samples at liquid N_2 temperature and a $CaSnO_3$ source kept at room temperature, for compounds **1** and **2** and both the residues in order to identify the Sn oxidation state and number of different sites.

The scanning electron microscopies (SEM) were taken in JEOL JSM-840A equipment and the samples were previously covered with a thin gold layer. The X-ray electron probe microanalyses (EPMA) were carried out in a JXA 89000 RL wavelength /energy dispersive combined microanalyser with samples covered with a thin film of carbon deposited by sputtering.

The intensity data for the X-ray crystallographic determination of **1** were collected at 293(2) K on an Enraf-Nonius Kappa CCD diffractometer with Mo Kα, $\lambda = 0.71073$ Å, radiation. Programs used: COLLECT, HKL Denzo-Scalepack, WINGX, SHELXS-97 [12], SHELXL-97 and ORTEP-3 [13] and the refinements were carried out on F^2 using SHELXL-97 software [14]. Further details are given in Table 1. All non-H atoms were refined anisotropic. The carbons' H atoms were positioned stereochemically and were refined with fixed individual displacement parameters [U_{iso} (H) = 1.2U_{eq} (C)] using the SHELXL riding model.

2.2. Synthesis of $[Sn\{S_2CN(CH_2)_4\}_2\{C_6H_5\}_2]\cdot$toluene (1)

$[NH_4][(CH_2)_4NCS_2]$ (1.32 g, 8 mmol) was dissolved in 20 cm^3 of ethanol and added dropwise to a solution of $(C_6H_5)_2SnCl_2$ (1.38 g, 4 mmol) in the same solvent. The mixture was stirred for two hours and then the solvent was removed by filtration and a white solid, $(C_6H_5)_2Sn[S_2CN(CH_2)_4]_2$, was obtained. The ammonium salt was removed by washing the product with hot water (80 °C). X-ray quality colourless crystals were obtained by cooling a dichloromethane/toluene solution of the compound. Yield: 85%. M.p. 222.5–223.1 °C. IR (cm^{-1}, KBr): 990 and 1050 (s, ν_{C-S}), 1560 (s, ν_{C-N}). ^1H NMR (δ, $CDCl_3$): 1.95–2.01; 3.60–3.66 (t); 7.23–7.90

3. Results and discussion

Compounds **1** and **2** were isolated as mixture-free derivatives and after re-crystallisation they showed acceptable melting points, as well as satisfactory elemental analyses. They were obtained as air- and moisture-stable white crystalline solids, readily soluble in polar organic solvents.

Compound **1** was studied by X-ray crystallography and the results are displayed in Table 1. It is shown that the crystalline compound possesses a very disordered molecule of toluene in its structure (Fig. 1).

Table 2 comprises selected bond lengths and angles. A similar derivative, $[Sn\{S_2CN(CH_2)_4\}_2Me_2]$, previously published, crystallises as orthorhombic in the *Pmmn* space group [15]. In this compound, the Sn atom lies at the centre of an almost perfect octahedron with a plane of symmetry, containing the R group and the metal centre, and dividing equally the two ligands. Compound **1** has kept the hexacoordination and the pseudo-octahedral geometry, but the crystals have grown in the triclinic system with the space group $P\bar{1}$. Unlike the published derivative, which displays two sets of Sn–S bonds, 2.518(1) and 2.9938(1) Å, all four Sn–S distances in **1** are different. There are three slightly different short bonds, S(22)–Sn 2.5727(13), S(12)–Sn 2.5864(14) and S(11)–Sn 2.6850(17) Å, and a long one S(21)–Sn 2.9495(16) Å, which seems not to remain in solution as will be discussed later. Apart from the longer bond, the former bonds correlate very well with those observed for the methyl derivative. Because of the lack

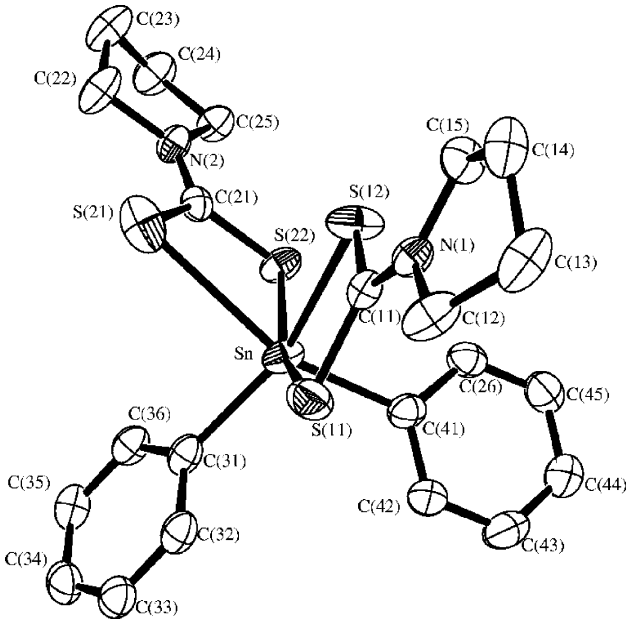

Fig. 1. The Molecular structure of **1** and the atom numbering scheme.

of symmetry, two Sn–C bond lengths are observed, Sn–C(41) 2.166(5) Å and Sn–C(41) 2.156(6) Å, for the Sn–phenyl interactions. The S–Sn–S angles, S(22)–Sn–S(12) 89.77(5)°, S(22)–Sn–S(11) 157.20(5)°, S(12)–Sn–S(11) 67.55(5)° are close to those found in the literature. We have also reviewed the X-ray crystallographic structure of **2** and the data does not differ from the reported structure [16]. The Sn(IV) displays a geometric arrangement between tetrahedral and bipyramidal trigonal.

The ^1H NMR of **1** and **2** revealed signals for the organic groups. Besides the expected resonances for the R groups the ^{13}C spectra revealed first and second-order $^{119}Sn–^{13}C$ couplings. Unlike other reported examples found in the literature, which normally describe more than one isomer in solution, detected by ^{119}Sn NMR experiments, in our case only one signal was observed, δ −500 $^1J(^{13}C–^{19}Sn) = 811$Hz for **1** and −174 $^1J(^{119}Sn–^{13}C) = 606$ Hz for **2**. The latter signal appeared upfield compared to the former because of the higher coordination number of the Sn(IV) centre in compound **2**.

Table 2
Selected bond lengths (Å) and angles (°) for **1**

C(31)–Sn	2.156(6)	S(12)–Sn	2.5864(14)
C(41)–Sn	2.166(5)	S(21)–Sn	2.9495(16)

S(22)–Sn–S(12)	89.77(5)	S(22)–Sn–S(11)	157.20(5)

Table 3
^{119}Sn Mössbauer parameters[a] (isomer shift (IS), quadrupole splitting (QS), area and width) obtained at liquid nitrogen temperature for the compounds **1** and **2** and their respective residues obtained in N_2

Material	Sn site	IS (mm s^{-1})	QS (mm s^{-1})	Area (%)	Width (mm s^{-1})
1	Sn(IV)	1.09	1.72	100	0.90
2	Sn(IV)	1.26	1.65	100	0.90
Residue of **1**	Sn(II)	3.31	1.03	88	0.90
	Sn(IV)	0.17	0.59	12	0.90
Residue of **2**	Sn(II)	3.08	1.07	77	0.90
	Sn(IV)	0.14	0.56	21	0.90

[a] The errors associated to IS, QS and width are ±0.05 mm s^{-1} and 1% for the area.

It is possible to estimate the C–Sn–C bond angle employing methods encountered in the literature, which correlates the angle with the first-order coupling constant between ^{119}Sn and ^{13}C, in solution [17]. The methods have provided a C–Sn–C angle for compound **1** ranging from 154.57° to 157.34°, in disagreement with the experimental data, 107.58(19)°. Either because the structure of **1** in solution differs drastically from that in the solid state, or the reported methods do not apply to this system. The latter could be justified by the dissociation of the long Sn–S bond, discussed in the X-ray results, effecting a change in the coordination of the metal.

The ^{119}Sn Mössbauer parameters, isomer shift (IS) and quadrupolar splitting (QS) obtained for compounds **1** and **2** indicate a strong dependence upon the coordination number, hybridisation and symmetry around the Sn(IV) nucleus. The IS for **1**, 1.09 mm s^{-1} is smaller than that for **2**, 1.65 mm s^{-1}, Table 3, suggesting higher coordination, as attested by the X-ray and ^{119}Sn-NMR spectroscopic results. It is consistent with a smaller contribution of *s* electrons to the hybridisation scheme at the tin atom in **1** as compared to **2**. The quadrupole splitting parameters 1.30 and 1.80 mm s^{-1} points to a lower symmetry for complex **1**. These data match perfectly with other known values for penta and hexacoordinated Sn(IV) derivatives [18].

*3.1. Thermal decomposition of **1** and **2** and characterisation of the residues*

The thermogravimetric curves of **1** and **2**, Fig. 2, shows that the decomposition processes begin at 207 and 233 °C (±2 °C), respectively, and at about 350 °C both materials have been consumed. The presence of one more phenyl group in the structure of **2** increases its T_d (temperature of decomposition) by approximately 26 °C. In both cases, the decomposition take place in a pseudo-single step and the decomposition temperatures are lower than those found for organotin sulfides, reported by us, which have been considered a promising single source precursor [10a].

The residue obtained after the pyrolysis of **1** and **2** carried out in a tube furnace in N_2 were chemically and structurally characterised. The EPMA results, Fig. 3, clearly indicate the presence of Sn and S as major elements in the residues. However, a tiny amount of oxygen has also been revealed, which might be due to the formation of SnO_2 as a much lesser product. It has possibly originated from the N_2, which was not completely free from moisture or oxygen, however, it is much smaller than the quantity of carbon, employed to cover the sample.

The diffraction patterns of the residues, Fig. 4, suggested the formation of γ-Sn_2S_3 and SnS, both orthorhombic phases, in view of the diffraction lines. The lines of SnO_2, which is quite sensitive to this technique, were not detected. A poor crystallinity of the sample has rendered low quality XRD patterns for residue **1**. Nevertheless, lines at 2θ/° 27.19, 31.80, 31.46 and 38,99 assigned to γ-Sn_2S_3 and SnS were identified. A better diffractogram was obtained for **2** and it was possible to connect the lines at 2θ/° 31.61 (201), 31.86 (131), 25.94 (101), 27.22 (140) and 38.94 (301) to γ-Sn_2S_3 (JCPDS-ICCD 1996 card no. 39-0354). Likewise, those diffractions at 2θ/° 31.50 (111), 31.73 (040), 25.94 (110), 27.36 (021), 30.46 (101) and 39.24 (131) were attributed to SnS (JCPDS-ICCD 1996 card no.

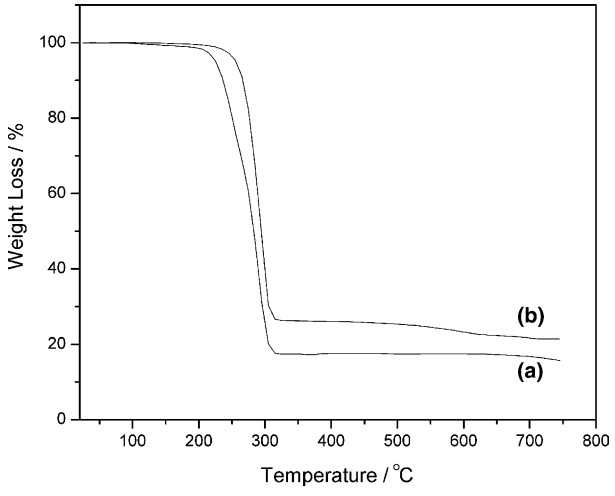

Fig. 2. The thermogravimetric curves of **1** (a) and **2** (b) in nitrogen.

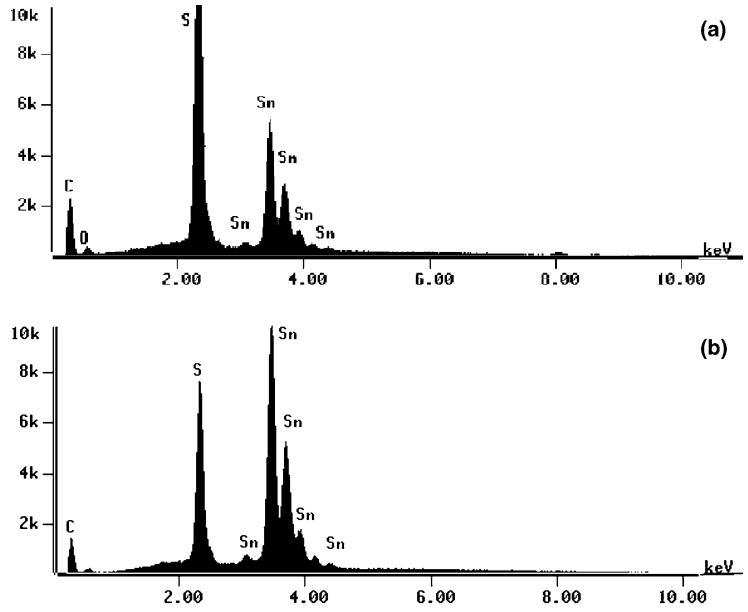

Fig. 3. The X-ray electron probe microanalysis (EPMA) of the residue of **1** (a) and **2** (b).

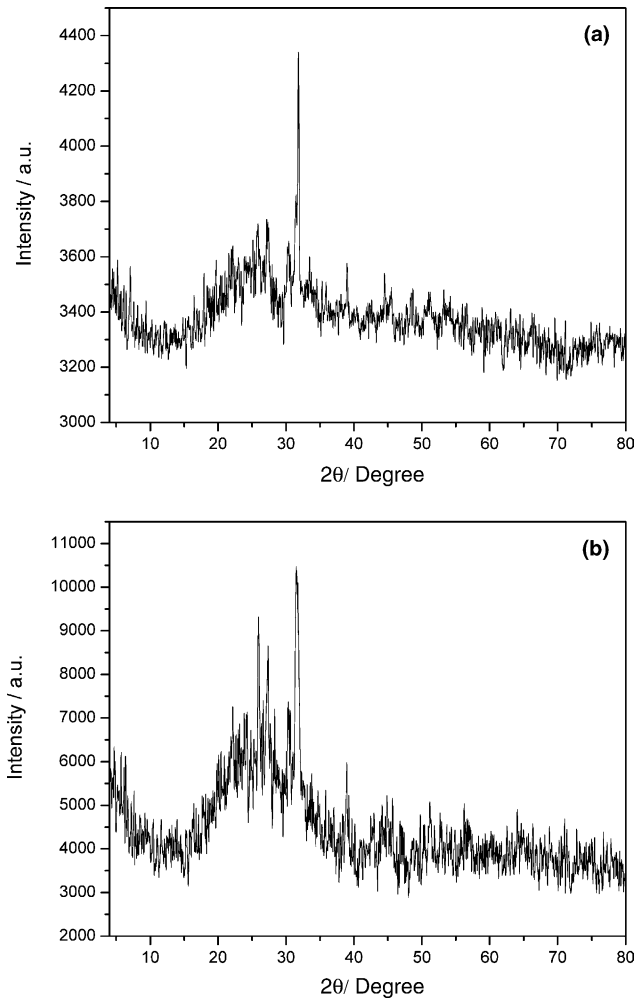

Fig. 4. The X-ray powder diffraction patterns of the residue **1** (a) and **2** (b).

30-13790). The respective Miller indexes are indicated in parenthesis.

The ^{119}Sn Mössbauer spectra were important to confirm the results of XRD and EPMA, Fig. 5. The experiments have clearly shown the presence of two Sn sites corresponding to Sn(II) and Sn(IV) in the residues, in the form of SnS and Sn_2S_3. Since the amount of SnO_2 is not detectable, it is not absurd to assume that all the Sn nuclei exist as tin-sulfides. For the residue of **1** there are two sets of signals, IS 3.31 mm s^{-1}, QS 1.03 mm s^{-1} and IS 0.17 mm s^{-1}, QS 0.59 mm s^{-1}. Similarly, for **2** IS 3.08 mm s^{-1}, QS 1.07 mm s^{-1} and IS 0.14 mm s^{-1}, QS 0.56 mm s^{-1} are observed. The Mössbauer parameters for both residues are in good agreement with similar data reported in one of our previous works [10a]. It is important to observe that a smaller amount of Sn(II) was produced in the decomposition of **2** (area = 77%) compared to the residue of **1** (area = 88%). In either case there is more SnS than the required amount to match the Sn_2S_3 stoichiometry. It is possible that a mixture of the two sulfides is present, which the ^{119}Sn Mössbauer experiments cannot reveal. We have also performed the same study on a standard of Sn_2S_3 and the same pattern of two set of signals with IS = 3.35 mm s^{-1}, QS = 0.97 mm s^{-1} for Sn(II) and IS = 0.46 mm s^{-1}, QS = 0.88 mm s^{-1} for Sn(IV) was encountered.

The scanning electron micrographs showed that layered and ribbon-like crystals basically compose the residues, Fig. 6. It is a very common characteristic of SnS and Sn_2S_3 systems. The SEM images have revealed the particle size of microns and also confirmed the low crystallinity of the samples, as pointed out by the XRD diffractograms.

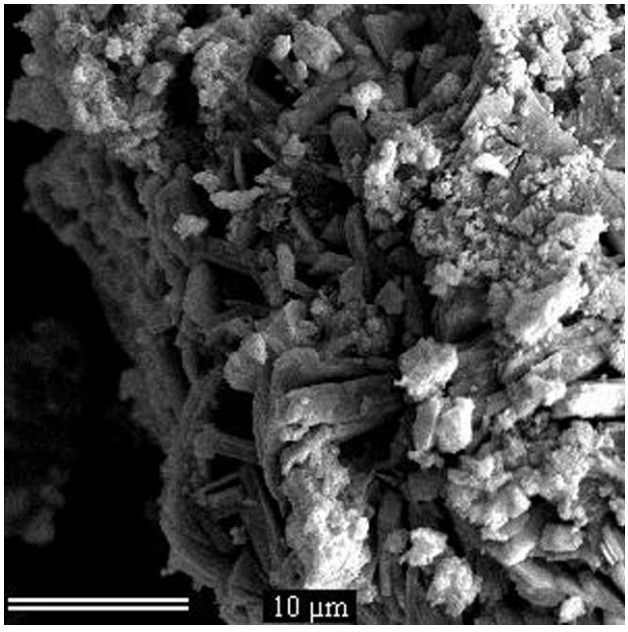

Fig. 6. The scanning electron microscopy (SEM) image of the residue of **1**.

4. Conclusions

We have described in this paper the synthesis, characterisation and thermal decomposition of two dithiocarbamate tin-based derivatives. The versatility of compounds **1** and **2** has been proved as single source precursor for SnS and Sn_2S_3. They were obtained by a pyrolysis experiment in N_2 in sharp steps at a much lower temperature compared to other compounds. Only a negligible amount of SnO_2 was revealed by EPMA, and was not detected in the XRD or in ^{119}Sn Mössbauer experiments.

5. Supplementary data

Crystallographic data for the structural analysis for complex **1** have been deposited at the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, and are available on request quoting the deposition number CCDC-236258.

Abstract

Charge transfer compounds with the general formula $(TTF)_4CuX_2$ (TTF=tetrathiafulvalene; X = NCS, NO_3, Cl, Br, NCO and NO_2) were prepared by the reaction of excess TTF with the precursor $Cu(Sp)X_2$[Sp = (–)-sparteine] complexes in dichloromethane. The TTF radical patterns were observed in EPR spectra and a signal attributable to Cu(II) was not detected in the solid state for the prepared compounds, indicating that there is charge transfer from the TTF donors to the copper metal(II) ions and that the copper center in $(TTF)_4CuX_2$ is in a diamagnetic Cu(I) state. The powdered electrical conductivities of some $(TTF)_4CuX_2$ (X = NCS, NO_3, Cl and Br) compounds are in the semiconductor region ($\sigma_{r.t} = 10^0$–10^1 S cm^{-1}), whereas the other compounds (X = NCO and NO_2) are in the insulator range ($\sigma_{r.t} < 10^{-4}$ S cm^{-1}) at room temperature. The electrical conductivities of the prepared six compounds are closely related to the charge transfer rate from TTF to $Cu(Sp)X_2$ in the formation of $(TTF)_4CuX_2$ and the reduction potential of the precursor $Cu(Sp)X_2$ complexes.

Keywords: Tetrathiafulvalene; Copper(II); Charge transfer compounds; Electrical conductivity

1. Introduction

Tetrathiafulvalene (TTF) is an excellent electron donor for the purpose of forming a wide class of electrical conductive materials ranging from insulators to superconductors [1,2]. Its electrical properties depend on the degree of charge transfer (stoichiometry) as well as the stacking mode of TTFs in the resulting charge transfer compounds [3]. For example, in TTF compounds with copper(II) halides, the partially ionized $(TTF)n^{+1}Cu(I)X_2$ ($n = 4/3$–$7/3$, X = Cl, Br) exhibits $\sigma_{rt} = 10^{-1}$–10^{+1} S cm^{-1} [4], whereas the completely ionized $(TTF)^{+1}Cu(I)Cl_2$ has been reported to be an insulator, $\sigma_{rt} = 10^{-4}$–10^{-5} S cm^{-1} [5]. In those compounds, the composition of TTF is dependent on the reaction conditions such as the solvent used, the ratio of the reactants, and other conditions.

Previously we proposed a convenient method for the preparation of $(TTF)_nCuX_2$ charge transfer compounds of varying ratios of TTF to copper using copper halides complexes [6]. $(TTF)_4CuX_2$ (X = Cl, Br) and $(TTF)_2CuX_2$ compounds were obtained using $Cu(Sp)X_2$ [Sp = (–)-sparteine, $C_{15}H_{26}N_2$] and $Cu(nic)X_2$ [nic = (–)-nicotine, $C_{10}H_{14}N_2$] respectively with excess TTF in dichloromethane. In this work, we expand this method of preparing TTF complexes with variable

counter ions of the copper metal; $(TTF)_4CuX_2$ (X = NCS, NO_3, Cl, Br, NCO and NO_2) were prepared using $Cu(Sp)X_2$ complexes as the precursors. The composition of TTF was constant, independent of the counter ions of the copper metal in the prepared compounds; therefore, we examined the conductivity of the prepared $(TTF)_4CuX_2$ in terms of the nature of the counter anions and the difference of the reduction potential of $Cu(Sp)X_2$ compounds, since the reduction potential of the electron acceptor also plays an important role in the strength of the ionicity of the charge transfer compounds [7]. The rates of electron transfer from TTF to the copper(II) metal center in the reaction of TTF with $Cu(Sp)X_2$ complexes are also investigated here, and the correlation of the charge transfer rate with the conductivity is an interesting further step since both the electrochemical and kinetic properties of $Cu(Sp)X_2$ complexes are known to be related to the copper coordination geometry [8–15].

2. Experimental section

2.1. Synthesis

All reagents and solvents were obtained commercially from either Aldrich or Sigma Chemicals and the precursor copper(II)-sparteine $Cu(Sp)X_2$ complexes were synthesized by a method reported previously [8]. The $(TTF)_4Cu(NO_3)_2$ complex was prepared from the direct reaction of TTF with $Cu(Sp)(NO_3)_2$. A solution of $Cu(Sp)(NO_3)_2$ (0.3 mmol) in 40 ml of dichloromethane was added dropwise to 20 ml of TTF (1 mmol) dichloromethane solution. The solution changed to a dark purple color immediately. The resulting mixture was stirred for approximately 2 h and then refrigerated overnight. The deep purple precipitates were isolated by filtration and washed several times with dichloromethane. The microcrystalline precipitates were dried in a vacuum at room temperature. Other $(TTF)_4CuX_2$ (X = NCS, Cl, Br, NCO and NO_2) type complexes were obtained by an analogous method using the corresponding $Cu(Sp)X_2$ complexes. All of the prepared compounds are stable in air. Elemental analyses were performed by the Korean Basic Science Center (Busan Branch). *Anal.* Calc. for $(TTF)_4Cu(NCS)_2$: C, 31.32; H, 1.62; N, 2.81. 2.2. Physical measurements

The electrical conductivities for the prepared compounds were determined with compressed pellets using a two-electrode system connected to a potentiostat at room temperature. The EPR spectral measurements were carried out for powered samples both at room temperature and at 77 K using an ESP-300S EPR spectrometer at the X-band frequency. The field modulation frequency was 100 kHz and DPPH was used as a reference. Cyclic voltammograms were recorded on an EG& PAR Inc. model 273 Potentiostat and a Galvanostat with a model BD X–Y recorder (Kipp & Zonen). The charge transfer rates from TTF to $Cu(Sp)X_2$ complexes was followed by the use of a Union Giken RA-401 stopped-flow spectrophotometer. All of the kinetic runs were carried out at 25 °C and 0.1 M ionic strength. The rate of formation of the charge transfer complexes was determined spectrophotometerically at 580 nm. The total concentration of [TTF] was 100-fold in excess over that of $[Cu(Sp)X_2]$ and the pseudo-first order condition was maintained. Pseudo-first order rate constants were evaluated using the conventional $\ln(A_t - A_\infty)$ vs. time plot and were linear for about 90% of the reaction times for most of the experiments. All of the test solutions were purged with dried nitrogen gas before each run.

3. Results and discussion

$(TTF)_4CuX_2$ (X = NCS, NO_3, Cl, Br, NCO and NO_2) complexes were prepared from the reaction of TTF with the copper(II)-sparteine $Cu(Sp)X_2$ complexes. The reaction of TTF with $Cu(Sp)X_2$ is interesting in that sparteine is replaced by TTF molecules. Fraenkel et al. [16] reported on the kinetics of the complexation of magnesium complexes with the sparteine ligand, in which one of the two nitrogen atoms in sparteine bound to the metal ion can be replaced by a solvent molecule in solution. The complex with sparteine bound by two nitrogen atoms is in equilibrium with a complex with a monodentate sparteine and a coordinated solvent molecule. It is likely that sparteine in $Cu(Sp)X_2$ could dissociate in the reaction with a strong reductant such as TTF, through this equilibrium. In all of the prepared compounds, the composition of TTF was always four per copper atom, provided that excess TTF in dichloromethane was used.

The powdered electrical conductivities of the compounds at room temperature are summarized in Table 1. On the basis of the electrical conductivity, the prepared compounds can be divided into two groups. One is the compounds, $(TTF)_4CuX_2$ (X = NCS, NO_3, Br and Cl), the electrical conductivities of which are in the semiconductor region ($\sigma_{r.t} = 10^0$–10^1 $S\,cm^{-1}$), and

$(TTF)_4Cu(NO_2)_2$	~0	2.006	2.009

[a] EPR parameters were obtained at 77 K.
[b] Ref. [6].

the other group (X = NCO and NO_2) are insulators ($\sigma_{r.t} < 10^{-4}\ S\,cm^{-1}$) at room temperature.

The powdered EPR spectra for each compound exhibit a sharp singlet at around $\langle g\rangle \sim 2.006$ at room temperature. The EPR line shapes for each compounds exhibit good resolution for parallel ($g_{\parallel}$) and perpendicular ($g_{\perp}$) components at 77 K, except for $(TTF)_4Cu(NCO)_2$, and the results are summarized in Table 1. It is well known that the g values of sulfur radicals in which unpaired electrons are localized on the sulfur atoms are ~2.03, which is somewhat larger than the value of 2.003 of carbon radicals because of the larger spin–orbital coupling constants of sulfur atoms [17]. The observed g values for $(TTF)_4CuX_2$ are nearly equal to that of TTF^{+} radicals in solution ($\langle g\rangle = 2.00838$), indicating that the EPR signals arose from the unpaired electrons distributed on TTF stacks in $(TTF)_4CuX_2$ and that they have the same spin density as a TTF moiety. No EPR signals attributed to the Cu(II) metal ions were detected in any case, indicating that the copper center in $(TTF)_4CuX_2$ is in the diamagnetic Cu(I) state in the solid state; therefore the compounds are formulated as $(TTF)_4{}^{+1}Cu(I)X_2$. The partially ionized $(TTF)_4{}^{+1}$ oxidation state was confirmed by IR spectral investigations. The CS stretch band in the TTF ring (ν_{16}) of the prepared compounds was observed in the range of 821–828 cm^{-1}, which are higher than the value of 781 cm^{-1} for the TTF molecule and lower than the value of 836 cm^{-1} for TTF^{+1} free radicals [18].

We examined the correlation between the electrical conductivity and both the stability of $(TTF)_4CuX_2$ and the rate of charge transfer from TTF to the copper(II) metal in the reaction in order to examine how the nature of the counter anion in $(TTF)_4CuX_2$ affects the electrical conductivity.

Fig. 1 shows the electronic absorption spectra of TTF, $Cu(Sp)(NCS)_2$ and $(TTF)_4Cu(NCS)_2$, respectively. A new intense band appears at 580 nm in $(TTF)_4Cu(NCS)_2$, which is considered to arise from the charge transfer from the sulfur atom in TTF to the copper metal ion ($b_{2g} \rightarrow b_{1u}$) [19]. These charge transfer bands of all of the prepared compounds with an initial concentration of $[TTF]_0 = 5.0\times10^{-3}$ M and $[Cu(Sp)X_2]_0 = 2.5\times10^{-4}$ M centered at 580 nm at 298 K are also shown in a box in Fig. 1. The absorption intensities depend on the type of precursor copper complex used. The absorption intensities are parallel to the electrical conductivities of the charge transfer compounds produced. This result shows that the electrical conductivity increases as the quantity of charge transfer compound produced increases, suggesting that the more stable charge transfer compound exhibits the higher electrical conductivity.

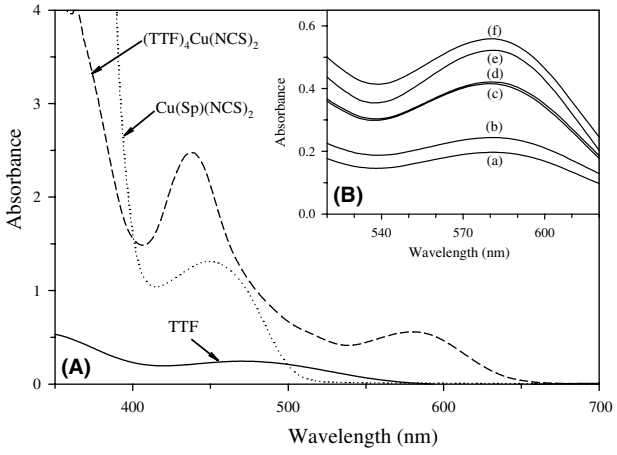

Fig. 1. (A) Electronic absorption spectra of the charge transfer complex, TTF and precursor complex $Cu(Sp)(NCS)_2$, A new intense band appears when TTF reacts with $(TTF)_4Cu(NCS)_2$. (B) The charge transfer bands centered at 580 nm are shown in a box. (The initial concentrations of $[TTF]_0 = 5.0\times10^{-4}$ M and $[Cu(Sp)X_2]_0 = 2.5\times10^{-4}$ M at 298 K, The absorption intensities are different depending on the type of precursor complexes used.) (a) $(TTF)_4Cu(NCO)_2$, (b) $(TTF)_4Cu(NO_2)_2$, (c) $(TTF)_4CuBr_2$, (d) $(TTF)_4CuCl_2$, (e) $(TTF)_4Cu(NO_3)_2$ and (f) $(TTF)_4Cu(NCS)_2$.

We measured the charge transfer rate from TTF to the copper metal ion for the following reaction.

$$4TTF + Cu(Sp)X_2 \rightarrow (TTF)_4CuX_2 + Sp$$

when $Cu(Sp)X_2$ and TTF are mixed in acetonitrile in a stopped-flow system, a very rapid increase in the absorption of 580 nm was observed. The pseudo-first order k_{obs}

[a] The k_2 values were evaluated from the equation $k_{obs} = k_2$[TTF] at 25 °C and 0.1 M ionic strength.
[b] Working electrode: Pt disk (ϕ = 1.6 mm). Reference electrode: Ag/Ag^+ electrode. Concentration: 0.5 mM. Supporting electrolyte: 0.1 M TBAP in CH_3CN. Scan rate: 100 mV/s. $E_{1/2}$ for the ferrocium/ferrocene couple is at +0.47 V vs. Ag/AgCl under the experimental conditions.
[c] ΔE_p is defined as E_{pa}–E_{pc}.

values for the above reaction were determined from the $\ln(A_t - A_\infty)$ vs. time plot which yields a good straight line. The second order rate constants k_2, for $k_{obs} = k_2$ [TTF], were evaluated from the plot of the k_{obs} values vs. [TTF] concentrations. The slope gives the second order rate constant k_2 value and the evaluated k_2 values are also summarized in Table 2. The k_2 values vary appreciably depending on the nature of anions in the precursor copper complexes. The highest value was observed for $(TTF)_4Cu(NCS)_2$. The $(TTF)_4Cu(NO_3)_2$ and $(TTF)_4CuBr_2$ complexes show relatively higher values than those of $(TTF)_4CuCl_2$, and $(TTF)_4Cu(NO_2)_2$. The softer sulfur and bromide donor atoms can stabilize the +1 state of the copper metal ion more efficiently than the oxygen atom.

We reported the reduction potentials of some $Cu(Sp)X_2$ complexes for the process $Cu^{II}(Sp)X_2 + e \rightarrow Cu^{I}(Sp)X_2$ [8], and newly examined the reduction potentials of $Cu(Sp)(NCS)_2$ and $Cu(Sp)Cl_2$ to compare the stability of the precursor copper complexes. In the potential range of −1.00 to +0.50 V vs. Ag/AgCl in acetonitrile, a single peak was observed which was described as $Cu(II) + e \rightarrow Cu(I)$ [20]. The half-wave $E_{1/2}$ values for $Cu(II) \rightarrow Cu(I)$ were estimated by averaging the anionic and cathodic peak potentials, and these values are listed in Table 2. Two $E_{1/2}$ values at +0.42 V and +0.66 V were observed in the TTF molecule, and were assigned to the TTF^{+1}/TTF and TTF^{+2}/TTF^{+1} couples respectively by comparing them with the reported reduction potential of TTF [21]. It is well known that conducting material of a mixed valence state can be obtained by the reaction of donors and acceptors with moderate redox potentials, and it is proposed that the value of the difference (ΔE_{redox}) between the first oxidation potential of the donors and the first reduction potential of the acceptors must be below ≈+0.25 V in order to form a partially ionized charge transfer compound [22]. The ΔE_{redox} of $(TTF)_4Cu(NCS)_2$ is +0.19 V and those of the other prepared compounds are above +0.25 V. For example, the ΔE_{redox} of $(TTF)_4Cu(NO_2)_2$ is as large as +0.76 V. In spite of these relatively high ΔE_{redox} values, partially ionized $(TTF)_4^{1-n}$ species are formed in these compounds; however, the ΔE_{redox} value plays an important role in forming the electrical conductive materials. The compounds that have ΔE_{redox} larger than +0.66 V exhibit poor electrical conductivities, acting as insulators, in this study.

It was found that the faster the charge transfer rate from TTF to the precursor copper(II) complex in the formation of $(TTF)_4CuX_2$ as well as the higher the reduction potential of the precursor copper complexes, the higher the electrical conductivity of $(TTF)_4CuX_2$ that was produced. A quasi-linear relationship between $E_{1/2}$ and k_2 values was discovered for $(TTF)_4CuX_2$ (X = NCS, NO_3, NCO and NO_2), as seen in Table 2.

But the compounds with the anions Cl and Br deviated from this linearity, showing the relatively low k_2 values even though the electrical conductivities are in the semiconductor region. The relatively high electrical conductivities of $(TTF)_4CuCl_2$ and $(TTF)_4CuBr_2$ are attributable to the thermodynamic stability of the corresponding precursor compounds rather than the charge transfer rate in the formation of $(TTF)_4CuX_2$.

4. Conclusions

We prepared the charge transfer compounds $(TTF)_4CuX_2$ (X = NCS, NO_3, Cl, Br, NCO and NO_2) from the direct reaction of TTF with the precursor $Cu(Sp)X_2$ complexes in dichloromethane. The TTFs were partially ionized and the copper metals were reduced $Cu(II) \rightarrow Cu(I)$ in the formation of $(TTF)_4CuX_2$. The electrical conductivity increases by increasing the reduction potential of the precursor compound $Cu(Sp)X_2$ and the charge transfer rate from TTF to $Cu(Sp)X_2$. This observed result may provide useful information in the design of molecular-based conductive material with prescribed thermodynamic and kinetic

properties, even though more data is needed in order to confirm this conclusion.

Abstract

Three silver(I) coordination complexes of diaza- and dibenzo-crown ethers, $[Ag(DDAC)](CF_3SO_3)$ (**1**), $[Ag_2(DDAC)(CF_3SO_3)_2]$ (**2**) and $[Ag_2(DB24C8)(CF_3SO_3)_2]$ (**3**) have been synthesized by using different molar ratios of ligand to silver triflate salt, and characterized structurally. A large excess of DDAC ligand leads to mononuclear complex **1**, and a large excess of silver triflate gives rise to dinuclear complex **2**, based on metal–heteroatom and metal–oxygen interactions. Ligand DB24C8 coordinates two silver(I) ions to afford dinuclear complex **3**.

1. Introduction

Macrocyclic ligands have long been employed for studies involving transition metal ion recognition [1,2]. There has been tremendous development with respect to cyclic type ligands like crown ethers [3] which are able to perform specific functions. When the macrocyclic ligands are bound to polymeric supporting materials, the resulting materials can serve as ion sensors, exchange resins, metal ion extractors, phase transfer catalysts, mimics of enzyme systems and photoresponsive chromophores [4–6].

Cryptand type ligands, crown ether systems are suitable to be used in the design of complexation agents for metal ions [7–13]. We have been continuously studying dibenzo-crown ether complexes with silver(I) ions [14,15], because these silver(I) complexes used usually involve the oxygen base cavities and π-donor phenyl groups. Same as the reported example [16], two different coordination complexes can be constructed by using different molar ratios of crown ether ligand to silver(I) ion in this work. The macrocyclic crown ether and cryptand ligands were incorporated into the dimers.

In this work, two cryptand type ligands of crown ethers, N,N'-dibenzyl-4,13-diaza-18-crown-6-ether (DDAC) and dibenzo-24-crown-8-ether (DB24C8), as a continuation of our previous work [15], have been selected as ligands to synthesize three silver(I) coordination complexes, $[Ag(DDAC)](CF_3SO_3)$ (**1**), $[Ag_2(DDAC)(CF_3SO_3)_2]$ (**2**) and $[Ag_2(DB24C8)(CF_3SO_3)_2]$ (**3**). The cryptand crown ether hosts, diaza-crown ether and dibenzo-crown ether, using different coordination modes bind the guest silver(I) ions and build up distinctive molecular architectures.

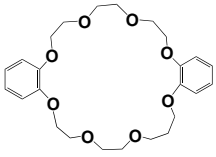
N,N'-Dibenzyl-4,3-diaza-18-crown-6-ether
(DDAC)



Dibenzo-24-crown-8-ether
(DB[24]C8)

2. Experimental

2.1. General procedures

All reactions and manipulations were performed under an argon atmosphere by using Schlenk techniques. All chemicals were reagent grade and used as supplied without further purification. Solvents were dried and distilled by using standards methods before use. Reagent grade DDAC was purchased from Tokyo Chemical Industry Co. Ltd., whereas silver perchlorate and all other chemicals were purchased from Wako Pure Chemical, Inc. and used as received. The IR spectra were measured as KBr disks on a JASCO FT/IR-8000 spectrometer at room temperature. All crystallizations of the silver complexes were performed in the dark.

2.2. Syntheses

2.2.1. [Ag(DDAC)](CF$_3$SO$_3$) (**1**)

To a toluene solution (8 ml) containing Ag(CF$_3$SO$_3$) (12.6 mg, 0.048 mmol), DDAC (106.2 mg, 0.24 mmol) was added. The mixture was stirred at room temperature for 20 min and filtered. A portion of the filtrate (2 ml) was introduced into a 7 mm glass tube and layered with *n*-hexane as a diffusion solvent. After the glass tube was sealed under argon and left standing at room temperature for one week, colorless block crystals of **1** suitable for X-ray determination were isolated. The theoretical value of elemental analysis and the isolated yield (21.4 mg, 18%) are based on the formula without THF molecules. *Anal.* Calc. for $AgSF_3O_7N_2C_{27}H_{38}$: C, 46.36; H, 5.48; N, 4.00. Found: C, 46.35; H, 5.06; N, 3.96%. Main IR bands (KBr, ν/cm^{-1}): 2858(m), 1494(w), 1452(m), 1266(s), 1145(s), 1106(s), 1030(s), 749(m), 709(m), 638(s).

2.2.2. [Ag$_2$(DDAC)(CF$_3$SO$_3$)$_2$] (**2**)

A solution of DDAC (12.8 mg, 0.03 mmol) in toluene (10 ml) was treated with Ag(CF$_3$SO$_3$) (38.8 mg, 0.30 mmol). The above procedure was repeated to yield colorless platelet single crystals of **2** (13.4 mg, yields 26%). *Anal.* Calc. for $Ag_2S_2F_6O_{10}N_2C_{28}H_{38}$: C, 34.42; H, 4.09; N, 2.81. Found: C, 35.16; H, 4.00; N, 2.93%. Main IR bands (KBr, ν/cm^{-1}): 2887(m), 2370(w), 1458(w), 1285(s), 1267(s), 1148(s), 1106(s), 1036(s), 736(m), 708(m), 638(m).

2.2.3. [Ag$_2$(DB24C8)(CF$_3$SO$_3$)$_2$] (**3**)

Similar to the previous complexes, DB[24]C8 (44.8 mg, 0.10 mmol) was added to a solution of AgCF$_3$SO$_3$ (51.4 mg, 0.20 mmol) in toluene, and yielded colorless platelet single crystals of **3** (26.9 mg, yield 28%). *Anal.* Calc. for $Ag_2S_2F_6O_{14}C_{26}H_{32}$: C, 32.42; H, 6.88. Found: C, 32.05; H, 6.56%. Main IR bands (KBr, ν/cm^{-1}): 3547(m), 2910(s), 1597(s), 1504(s), 1456(s), 1352(s), 1278(s), 1224(s), 1160(s), 1116(s), 1083(s), 1047(s), 1033(s), 951(s), 938(s), 905(m), 746(m), 634(s).

2.3. Crystallography

Single crystal X-ray data for all complexes were measured on a Rigaku/MSC Mercury CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at -123 ± 1 °C for **1** and **2**, and 26.0 ± 1 °C for **3**. Details are summarized in Table 1. Selected bond lengths and angles for the three complexes are given in Table 2.

3. Results

3.1. Syntheses and infrared spectroscopy

3.1.1. Syntheses

It is noted that in the preparations described above different metal:ligand ratios were used. Generally, coordination of an aromatic ligand to silver ions can be achieved via a stoichiometric reaction [17,18], but sometimes an excess of ligand or metal ion has to be used to obtain coordinated complexes [19–23]. In this work, the complexes presented here are prepared via reactions of excess ligand or metal ion. In the experiments, when the molar ratios of M:L were 5:1, 1:10 and 1:2 for **1**, **2** and **3**, respectively, crystallized solids were isolated at room temperature, and the different molar ratios led to different crystal structures. Reasons for the use of silver salt excesses in **3** are as follows: (i) The solvent toluene may form metal complexes in solution with silver ions [24] which partially consumes the metal salt. Thus, the preparation of silver(I) complexes in toluene sometimes requires an excess of the silver salt

different M:L ratios. Reactions similar to that described in the experimental section but performed with M:L ratios of 1:1 led to no evidence for formation of an isolable complex. In order to obtain polymeric complexes by connecting silver(I) ions and the phenyl group of DDAC besides silver(I) locating in the cavities, a large excess of silver triflate was used with L:M = 1:10 which led to dinuclear complex **2**. The effect of a different molar ratio was studied by employing a large ligand excess with L:M = 5:1. The result was the mononuclear complex **1**.

3.1.2. Infrared spectroscopy

In the IR spectra of **1**–**3**, a broad strong absorption occurs in the region 638–1254 cm^{-1}, and their peaks are shifted to slightly different frequencies compared with the normal absorption of $AgCF_3SO_3$ at 1256, 1179, 1037, and 629 cm^{-1}. This suggests that the triflate groups in these complexes are present not as ionic species, but as coordinated ones [27]. The coordination of silver(I) ions to oxygen or nitrogen atoms of diaza-crown ether and dibenzo-crown ether can also be seen by comparing the spectra of **1**–**3** with those of the two free ligands (DDAC at 1453, 1123, 1056, 749, 701 cm^{-1}, DB24C8 at 1594, 1507, 1357, 1225, 960, 740 cm^{-1}).

3.2. Description of the structures

3.2.1. Mononuclear complex [Ag(DDAC)](CF$_3$SO$_3$) (1)

Molecules of triflate anion exist independently of the complex in lattice interstices. The molecular structure of complex **1** together with the numbering scheme is shown in Fig. 1. The silver(I) ion is in a distorted tetrahedral environment, being coordinated by two nitrogen atoms and two oxygen atoms on the same side of the N–Ag–N system, in which Ag–O bond lengths are 2.598(1) and 2.686(2) Å and Ag–N bond lengths are 2.305(2) and 2.315(2) Å. The O–Ag–O and N–Ag–N angles are 63.6(4)° and 166.13(4)°, respectively. The remaining two ligand oxygen atoms are not involved in coordination, and the triflate ion only plays a charge-balance and space-filling role.

3.2.2. Dinuclear complex [Ag$_2$(DDAC)(CF$_3$SO$_3$)$_2$] (2)

An ORTEP drawing of complex **2** with the atom numbering scheme is shown in Fig. 2. The symmetric unit contains two independent dinuclear molecules each located at an inversion center. The coordination environment of each metal atom is almost tetrahedral, comprising of three oxygen atoms of which two are from DDAC and one from a triflate group, plus a nitrogen atom. The DDAC ligand thus contains two silver(I) centers in its heterocyclic hard donor cavity with Ag–O bond lengths ranging from 2.203(4) to 2.592(4) Å and Ag–N bond lengths of 2.287(4) and 2.325(4) Å. The present Ag–O bond lengths are well within the normal range 2.17–2.61 Å observed in silver(I)–crown ether complexes [15] and the Ag–N bond lengths are normal

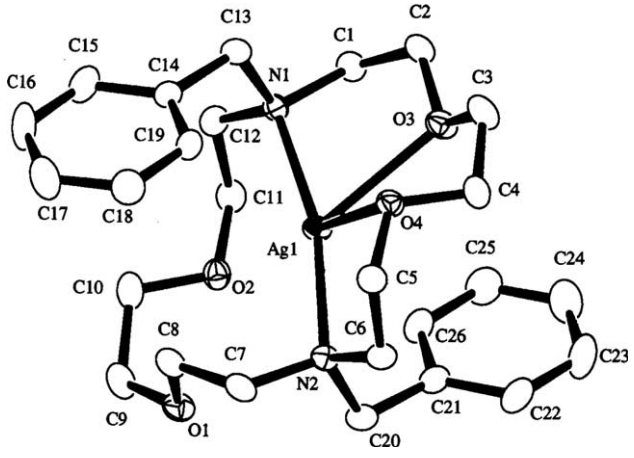

Fig. 1. ORTEP view of the molecular structure of **1**.

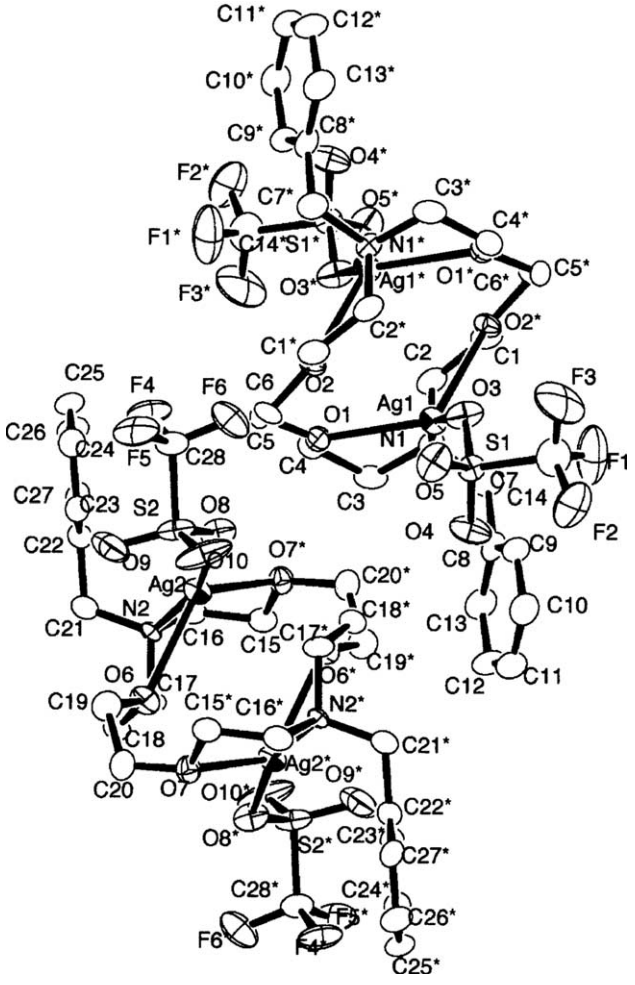

Fig. 2. Molecular structure of the dinuclear unit of **2**.

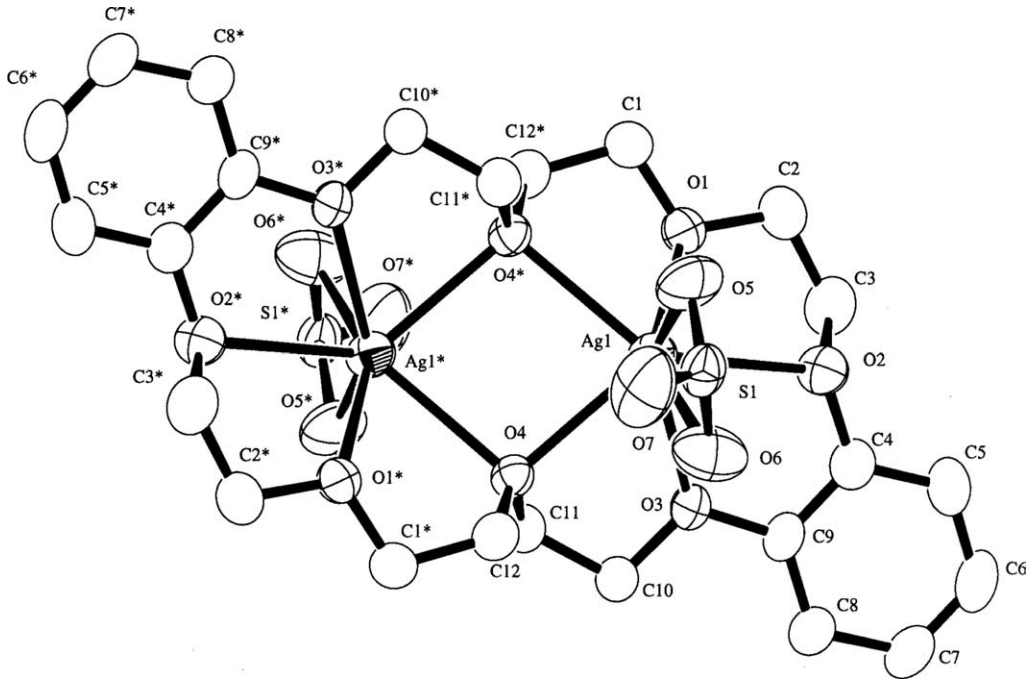

Fig. 3. Molecular structure of the dinuclear unit of **3**.

compared with those in previously reported crystate–silver(I) complexes [10].

3.2.3. Dinuclear complex $[Ag_2(DB24C8)(CF_3SO_3)_2]$ (**3**)

Fig. 3 depicts a perspective view with the atom numbering of centrosymmetric complex **3**, in which each silver(I) ion is octahedrally coordinated by two triflate oxygens with an average Ag–O length of 2.586 Å and five oxygens of the ligand with an average Ag–O bond length of 2.450 Å. Each DB24C8 host molecule contains two silver(I) ions as guests with a Ag···Ag distance of 3.95 Å. Unlike dinuclear silver(I) coordination complexes of the dibenzo-crown ether family in our previous works, [Ag(DB[18]C6)(ClO_4)](THF) [15a], the silver(I) ions are not coordinated to phenyl groups.

4. Discussion

In this work, the diaza- and dibenzo-crown ether hosts accommodate silver(I) ions as guests in their cyclic hard donor base cavities. The structures of these three silver(I) complexes display different characteristics with the cation being encapsulated in a macrocyclic environment with different L:M stoichiometries. A large excess of DDAC ligand leads to mononuclear complex **1**, and a large excess of silver triflate gives rise to dinuclear complex **2** based on metal–heteroatom and metal–oxygen interactions. DB24C8 coordinates to two silver(I) ions to afford dinuclear complex **3**.

The average Ag–O bond lengths of 2.642, 2.442 and 2.540 Å observed for **1**, **2** and **3**, respectively, are within the normal range observed in silver(I)–crown ether complexes [10]. The average Ag–N bond lengths of 2.310 Å in **1** and 2.306 Å in **2** are virtually the same and a little longer than that in the silver(I) complex of 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane, but slight shorter than that in the silver(I) complex of N-methylated (L^2) and N-benzylated 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane (L^3) [10]. In the present complexes, each silver(I) ion is not coordinated to all oxygen and nitrogen atoms as in [Ag(L^3)]PF_6 [10]. In addition, triflate oxygen atoms are not coordinated to silver(I) ions in **1**, but are coordinated to silver(I) ions in **2**, and the Ag–O bond length of silver(I) with triflate is shorter than that of silver(I) with the ligand oxygen atoms.

Furthermore, the crown ether hosts in this work are not involved in coordination of the phenyl group to silver(I) via a π interaction, as our previous work in DB18C6–Ag(I) complexes [15a] (Fig. 4). Two symmetry-related silver(I) ions can be located in the oxygen base cavity of DB24C8 without silver(I)–π interaction and π–π interaction (Fig. 4(c)). On the other hand, even though DDAC has the same size, six-membered hard donor cavity as that of DB18C6, the silver(I) guest number and coordination fashion differ distinctly. The coordination unit of DB18C6-Ag(I) complexes can involve both σ bonding at an oxygen group and silver–π as well as π–π interaction between two parallel phenyl groups (Fig. 4(a)). DDAC only contains two symmetry-related silver(I) ions in its

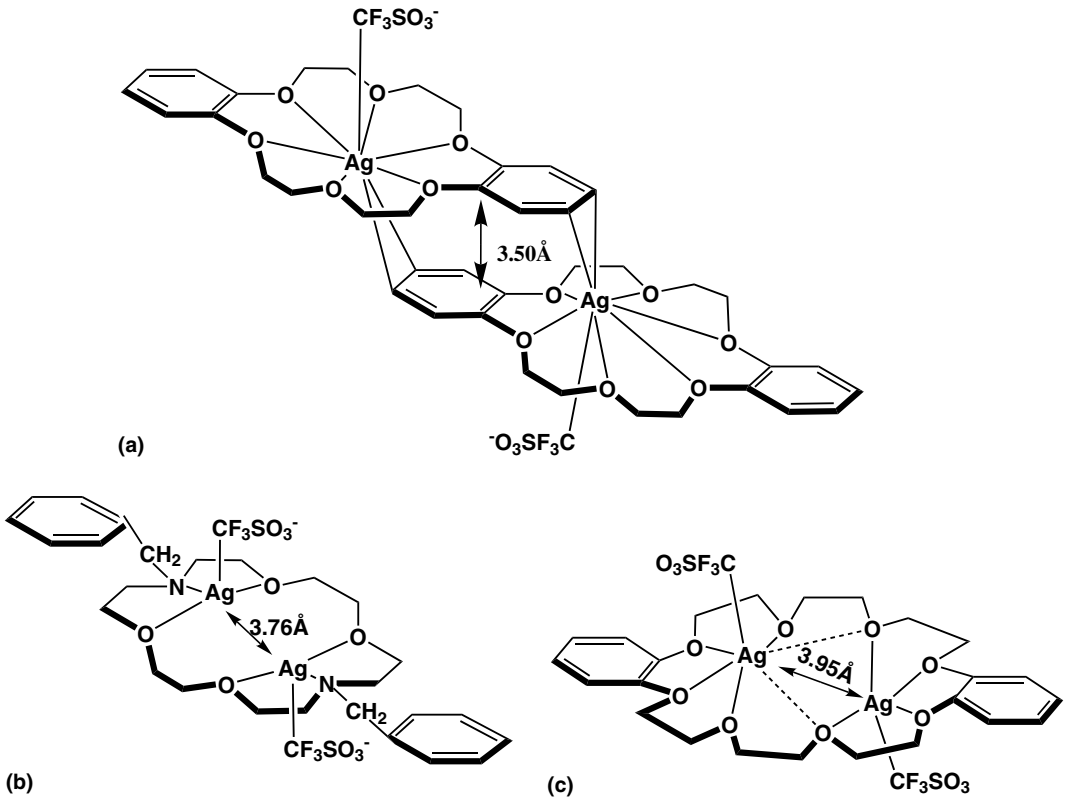

Fig. 4. Schematic view of dinuclear Ag(I) complexes with dibenzo- and diaza-crown ethers. $[Ag(DB18C6)(CF_3SO_3)]_2(acetone)_2$ (a), $[Ag_2(DDAC)(CF_3SO_3)_2]$ (b), $[Ag_2(DB24C8)(CF_3SO_3)_2]$ (c).

six-membered heterocyclic hard donor cavity without silver–π and π–π interaction (Fig. 4(b)). This case is the same as the formation of the Ag(I)–DB24C8 complex with a eight-membered hard donor cavity. This indicates that the structure construction process in the crown ether–silver(I) complex system is strongly dependent on the ligand: cavity size and the existence of heteroatoms as well as flexibility of the phenyl group.

In conclusion, with the cryptand type ligands, two distinct coordination complexes **1** and **2**, have been synthesized with different L:M stoichiometry. With regard to silver(I) complexes with diaza- and dibenzo-crown ethers (Fig. 4), there are two kinds of substantial dinuclear complexes. The ligand DB18C6 is based on the silver(I)–π interaction, in which the coordination unit involves both σ bonding at oxygen donor sites and π–π interaction between two phenyl groups. The other kind comprise dinuclear complex **2** and **3** in this work, in which two silver(I) ions occupy the cyclic or heterocyclic base cavity to coordinate to oxygen atoms without Ag(I)–π interaction or π–π interaction. It is believed that self-assembly of macrocyclic cryptand or dibenzo-crown ether compounds with transition metal ions can be constructed using stereospecific diaza- and dibenzo-crown ethers ligands (cavity size, the existence of heteroatoms as well as the flexibility of phenyl groups) and the molar ratio effect [10].

Abstract

Schiff base complex $[CuL]^-$ anions, used as metalloligands, are assembled by alkaline earth metal cations M^{2+} (M = Mg, Ca, Sr, Ba) leading to mononuclear $[Mg(H_2O)_6][CuL]_2\cdot 4H_2O$ (**1**), tri- and tetranuclear $[Ca_4(CuL)_8(H_2O)_{16}]\cdot 22H_2O$ (**2**), a 1D ladder-like polymer $\{[Sr(CuL)_2(H_2O)_3]\cdot 2H_2O\}_n$ (**3**) and a 2D layer polymer $\{[Ba(CuL)_2(H_2O)_4]\}_n$, (**4**), ($H_3L$ = *N*-2-hydroxyacetophenoneglycylglycine), depending on the radius of the alkaline earth metal cations. Single crystal X-ray diffraction analyses show that the deprotonated Schiff base ligand (L) in **1**–**4** is a triple negatively charged quadridentate ONNO chelant, coordinating to the Cu(II) atom in a square-planar geometry. Compound **1** is stacked to form a three-dimensional network consisting of $[CuL]^-$ and $Mg(H_2O)_6^{2+}$ via hydrogen bonding. In **2**, three moieties, mononuclear($[CuL]^-$), trinuclear($[Ca(CuL)_2(H_2O)_4]$) and tetranuclear($[Ca_2(CuL)_2(H_2O)_8]^{2+}$), are co-existent and are linked together by a network of hydrogen-bonding to form a three-dimensional network. In **3**, The ligand $[CuL]^-$ is assembled by the cation Sr^{2+} to form a 1D ladder-like coordination polymeric chain via Sr–O bonds. In **4**, $[CuL]^-$ coordinates to Ba(II) via the carboxylate and carbonyl oxygen atoms to form a 2D polymeric plane. Variable-temperature magnetic susceptibility measurements indicate that all complexes exhibit weak antiferromagnetic interactions between the Cu(II) paramagnetic centers.

1. Introduction

The design of metal-containing building blocks to spontaneously assembly into higher order architectures is of considerable interest in relation to their resemblance to biopolymers as well as their potential applications in catalysis and advanced materials such as magnetic, optic and electronic materials [1–8]. Recently, some stable coordination compounds containing potential bridging blocks have been used as metalloligands to bind other metal ions to form one-, two- and three-dimensional (1D, 2D, 3D) systems [9–16]. Some transition metal complexes of Schiff bases derived from amino acids and peptides comprising two types of ligating atoms (such as N and O) have interesting coordination capability (especially as carboxylate-bridged ligands) to metal ions [17–22]. These precursors are good candidates to be used as metalloligands and are particularly suitable for designing carboxylate-bridged heterometallic polynuclear complexes and constructing

doi:10.1016/j.poly.2004.06.003

extended 1D or 2D heterometallic supramolecular coordination polymers. Although carboxylate-bridged heteronuclear transition metal complexes containing multidentate ligands have been investigated with respect to their role in biological systems [23,24] and some of other areas [25–27] in recent years, the understanding of the chemistry of carboxylate-bridged heterometallic polynuclear compounds, especially for the heteronuclear complexes and polymers containing transition metals and main group metals, is very limited [28–30].

Here we report the synthesis of the novel Cu(II) Schiff base complex $K[CuL]\cdot 2.5H_2O$ (H_3L = *N*-2-hydroxyacetophenoneglycylglycine), and then use the metalloligand $[CuL]^-$ as a building block, reacting it with alkaline earth metal cations leading to a series of carboxylate-bridged heteronuclear Cu(II)–M(II) compounds $[M(CuL)_2(H_2O)_{x1}]_{x2}\cdot xH_2O$ (M = Mg, Ca, Sr, Ba) (**1**–**4**). Compound **4** has been briefly reported in a preliminary communication [31]. The present paper is devoted to the structural studies and magnetic properties of these compounds.

2. Experimental

2.1. Reagents and physical measurements

Reagent grade 2-hydroxyacetophenone (Fluka) and glycylglycine (Sigma) were used without further purification. All other reagents and solvents were analytical grade.

The IR spectra using KBr discs were recorded on a Bruker Vector 22 spectrophotometer in the 400–4000 cm^{-1} region. The UV–Vis spectra were recorded with a Shimadzu UV-3100 spectrophotometer. Elemental analyses (H, C, N) were determined using a Perkin–Elmer model 240C automatic instrument. Electrospray mass spectra were recorded on a LCQ system (Finnigan MAT, USA) using methanol/water as the mobile phase. All ESR spectra were obtained using a Bruker JES-FEIXG spectrometer with the X-band. Variable-temperature magnetic susceptibility measurements for complexes **1** and **2** were performed on a CAHN-2000 Faraday balance from 300 to 75 K, and for coordination polymers **3** and **4** were carried out with a Quantum Design MPMS SQUID magnetometer down to 2 K. Diamagnetic correction for the constituent atoms was made using Pascal's constants.

2.2. Preparation of Cu(II) Schiff base complex $K[CuL]\cdot 2.5H_2O$ (H_3L = *N*-2-hydroxyacetophenoneglycylglycine)

Glycylglycine (1.32 g, 10 mmol) was dissolved in 30 mL of aqueous ethanol (1:2 by volume mixture) containing KOH (0.56 g, 10 mmol). After cooling to room temperature, a solution of 2-hydroxyacetophenone (1.36 g, 10 mmol) in 10 mL absolute ethanol was added slowly with stirring for half an hour. An aqueous solution of copper(II) acetate (2.00 g, 10 mmol) in 10 mL was added dropwise and the resulting solution was adjusted to pH 9–10 by addition of concentrated KOH solution. After stirring at about 50 °C for 8 h and then filtering, the volume of the filtrate was reduced to ca. 5 mL in vacuo using a rotary evaporator. A large quantity of acetone was added to precipitate the violet product, which was recrystallized from water/acetone, dried in vacuo at 35 °C over P_2O_5. Yield 89%. *Anal.* Calc. for $K[Cu(C_{12}H_{11}N_2O_4)]\cdot 2.5H_2O$: C, 36.5; H, 4.1; N, 7.1. Found: C, 36.4; H, 4.1; N, 7.1%. FTIR (KBr; cm^{-1}): 3421s, 1651s, 1618s, 1343m, 1530m, 1297m. UV–Vis (in CH_3OH, λ_{max}, nm): 345, 568. ESI-MS (*m*/*z*): 310.1 $[CuL]^-$.

2.3. Synthesis of Cu(II)–M(II) (M = Mg, Ca, Sr, Ba) Schiff bases complexes

2.3.1. Synthesis of $[Mg(H_2O)_6][CuL]_2\cdot 4H_2O$ (**1**)

$K[CuL]\cdot 2.5H_2O$ (2 mmol) was dissolved in 20 mL H_2O. $MgCl_2\cdot 6H_2O$ (1 mmol) was then added to the filtrate with stirring at 25 °C for half an hour. A violet precipitate was obtained, which could be recrystallized from hot water (90 °C). The filtrate was allowed to evaporate slowly at room temperature. After several days violet red crystals, which were suitable for X-ray diffraction, were obtained. Yield 72%. *Anal.* Calc. for $C_{24}H_{42}N_4O_{18}MgCu_2$: C, 34.9; H, 5.1; N, 6.8. Found: C, 34.6; H, 5.2; N, 6.6%. FTIR (KBr; cm^{-1}): 3242s, 1640s, 1601s, 1351m, 1538m, 1292m. UV–Vis (in CH_3OH, λ_{max}, nm): 346, 567.

2.3.2. Synthesis of $[Ca_4(CuL)_8(H_2O)_{16}]\cdot 22H_2O$ (**2**), $[Sr(CuL)_2(H_2O)_3]\cdot 2H_2O$ (**3**) and $[Ba(CuL)_2(H_2O)_4]$ (**4**)

Complexes **2**–**4** were obtained using a similar method but by replacing $MgCl_2\cdot 6H_2O$ with $CaCl_2$, $SrCl_2\cdot 6H_2O$ and $BaCl_2\cdot 2H_2O$. Yield 68% for **2**; 76% for **3** and 52 % for **4**. *Anal.* Calc. for $C_{96}H_{164}N_{24}O_{70}Ca_4Cu_8$ (**2**): C, 33.5; H, 4.8; N, 9.8. Found: C, 33.4; H, 4.8; N, 9.7%. FTIR (KBr; cm^{-1}): 3453s, 1649s, 1609s, 1341m, 1538m, 1292m. UV–Vis (in CH_3OH, λ_{max}, nm): 346, 567. *Anal.* Calc. for $C_{24}H_{32}N_4O_{13}SrCu_2$ (**3**): C, 36.1; H, 4.0; N, 7.0. Found: C, 35.8; H, 4.1; N, 6.9%. FTIR (KBr; cm^{-1}): 3396s, 1658s, 1604s, 1340m, 1537m, 1290m. UV–Vis (in CH_3OH, λ_{max}, nm): 345, 566. *Anal.* Calc. for $C_{24}H_{30}N_4O_{12}BaCu_2$ (**4**): C, 34.7; H, 3.6; N, 6.7. Found C, 34.6; H, 3.6; N, 6.7%. FTIR (KBr; cm^{-1}): 3442s, 1655s, 1609s, 1340m, 1537m, 1297m. UV–Vis (in CH_3OH, λ_{max}, nm): 344, 563.

2.4. X-ray crystallography

The diffraction experiments were carried out on a Bruker AXS SMART APEX CCD diffractometer. Data were collected with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) using SMART and SAINT programs [32]. Absorption corrections were calculated and applied for each structure by using SADABS [33]. The structures were solved by direct methods and non-hydrogen atoms were anisotropically refined by full-matrix least-squares based on F^2 using SHELXTL [34]. All hydrogen atoms were included in the refinement in calculated positions, riding on their carrier atoms. The hydrogen thermal displacement parameters were fixed at 1.2 and 1.5 times the equivalent isotropic thermal displacement parameters of their internal and terminal carrier atoms, respectively. A summary of the data collection and structure refinement is listed in Table 1.

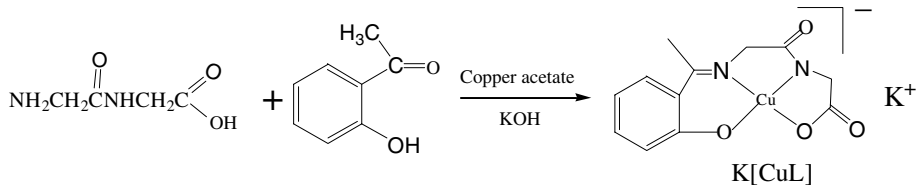
3. Results and discussion

3.1. Syntheses

Heteronuclear compounds and inorganic polymers containing main group metals are very important and present synthetic challenges [35–37]. Supramolecular self-assembly processes allow these materials to be prepared with high yield. As mentioned in the experimental (Scheme 1), the synthetic approach to prepare heteronuclear complexes is based on two major step reactions. The first step is to synthesize the complex K[CuL] in which L is a Schiff base ligand derived from 2-hydroxyacetophenone and dipeptides. The second step is using $[CuL]^-$ as a metalloligand to prepare heteronuclear complexes. The $[CuL]^-$ core with a terminal carboxylic group is easy to coordinate to the other hard (lewis acid) metal ions. As long as M^{2+} (M = Mg, Ca, Sr or Ba) were added to the solution of $[CuL]^-$, the final heteronuclear compounds were precipitated immediately. The simple general method provides a facile way to include more than one type of metal center into the system.

3.2. Crystal structure of $[Mg(H_2O)_6][CuL]_2\cdot 4H_2O$ (1)

An ORTEP plot with non-hydrogen atomic labelling is shown in Fig. 1. Selected bond distances and angles are listed in Table 2. The compound crystallizes in the centrosymmetric space group $P\bar{1}$. The unit cell of **1** consists of two $[CuL]^-$ cores, one $Mg(H_2O)_6^{2+}$ core and four water molecules. $[CuL]^-$ has approximately square-planar structure. The deprotonated Schiff base ligand is a triple negatively charged quadridentate ONNO chelant, coordinating to the Cu(II) atom via



$MCl_2 \cdot nH_2O$

M=Mg, Sr, n=6
M=Ca, n=0
M=Ba, n=2

$[M(CuL)_2(H_2O)_{x1}]_{x2} \cdot xH_2O$

1 M=Mg; X1=6; X2=1; X=4
2 M= Ca; X1=4; X2=4; X=22
3 M= Sr; X1=3; X2=1; X=2
4 M= Ba; X1=4; X2=1; X=0

Scheme 1.

one phenolic oxygen (O(1)), one deprotonated amide nitrogen atom (N(2)), one imino nitrogen atom (N(1)) and one carboxylate oxygen (O(3)). The phenyl ring [C(1)–C(6)] and the chelate ring C(6), C(1), C(7), N(1), O(1), Cu(1) are almost coplanar with a small dihedral angle of 3.7°, suggesting a large π-electron delocalization. Mg(II) lies on an inversion center and is almost octahedrally coordinated by six aqua ligands.

The anions and cations form well-separated columns along the *a*-axis in the stacking structure of **1**. Hydrogen bonds play a very important role (see supplementary material, Table S1). In the presence of water molecules, intermolecular and intramolecular hydrogen bonds result in the compound forming a 3D network.

3.3. Crystal structure of $[Ca_4(CuL)_8(H_2O)_{16}] \cdot 22H_2O$ (**2**)

Compound **2** has an interesting structure, its ORTEP view is shown in Fig. 2 with water molecules omitted for clarity. In the solid state, the compound crystallizes in the centrosymmetric space group $P\bar{1}$ and three Cu(II) containing moieties co-exist simultaneously: mononuclear ($[CuL]^-$), trinuclear ($[Ca(CuL)_2(H_2O)_4]$) and tetranuclear ($[Ca_2(CuL)_2(H_2O)_8]^{2+}$). Selected bond distances and angles are listed in Table 3. The coordination environment of the Cu(II) centers of all $[CuL]^-$ groups in the three moieties are similar to that of complex **1**.

For the trinuclear moieties, two $[CuL]^-$ are connected by Ca(2). Each calcium atom is coordinated by four carboxylate oxygen atoms (O(7), O(8), O(11), O(12)) and four water molecule oxygen atoms. The carboxylates in two $[CuL]^-$ groups chelate the calcium atom in a bidentate manner (Fig. 3(a)). The chelate rings C(25), C(30), C(31), N(5), O(9), Cu(3) and C(13), C(18), C(19), N(3), O(5), Cu(2) are almost perpendicular, with a dihedral angle of 94.1°. The chelate rings C(25), C(30), C(31), N(5), O(9), Cu(3) and C(37), C(42), C(43), N(7), O(13), Cu(4) in the mononuclear moieties are almost parallel, with a small dihedral angle of 11.7°.

In the tetranuclear moieties, two $[CuL]^-$ groups are connected by two Ca cations (Ca(1), Ca(1A)) to form a $[Ca_2(CuL)_2(H_2O)_8]^{2+}$ structure. The Ca cation has 7 coordination atoms: three carboxylate oxygen atoms (O(3), O(4), O(4A)) and four water molecule oxygens. The carboxylate group shows two different coordination modes: to one calcium in a bidentate chelating manner, to the other one in a monodentate manner (Fig. 3(b)). Ca(1) and Cu(1) are bridged by carboxylate oxygen O(3) with a Ca···Cu distance of 4.30 Å, and Ca(1)

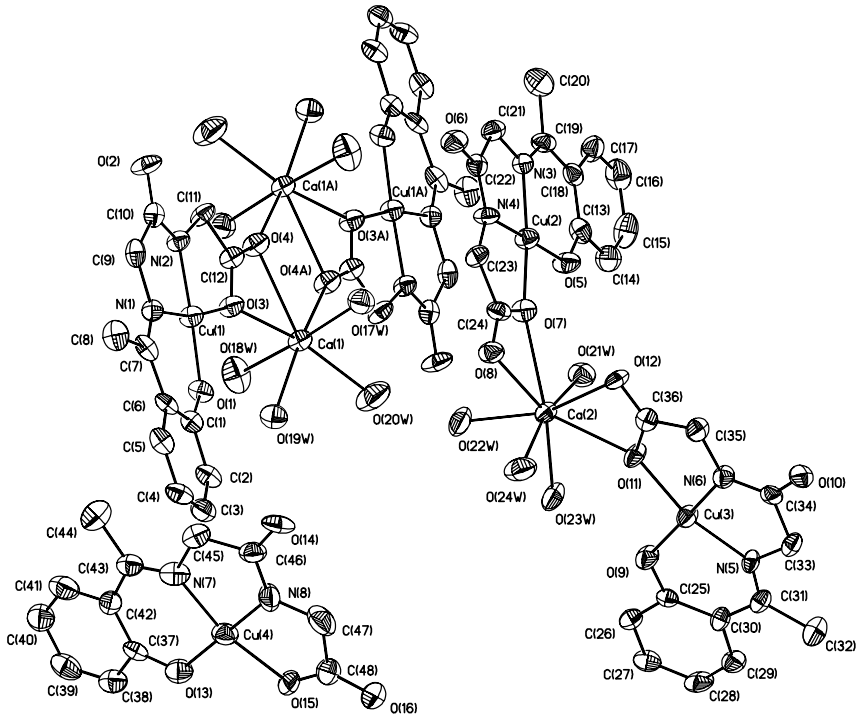

Fig. 2. ORTEP view of **2,** with lattice water molecules and hydrogen atoms omitted for clarity. Thermal ellipsoids are drawn at the 35% probability level.

and Ca(1A) are bridged by the carboxylate oxygen O(4) and O(4A). The Ca–Ca distance is longer (4.14 Å) than those of usual dimeric complexes [38]. The chelate rings C(6), C(1), C(7), N(1), O(1), Cu(1) and C(13), C(18), C(19), N(3), O(5), Cu(2) are almost parallel with a small dihedral angle of 4.7°.

The molecule packs along the *b*-axis to form a main chain that is stabilized by H-bond interactions between water molecules and their symmetric atoms (see supplementary material, Table S2). Adjacent main chains are associated by extensive H-bonds form the three-dimensional network.

3.4. Crystal structure of coordination polymer $\{[Sr(CuL)_2(H_2O)_3]\cdot 2H_2O\}_n$ (3)

The crystal structure of **3** consists of 1D coordination polymer chains and water molecules. An ORTEP view of the polymer is shown in Fig. 4(a). Selected bond distances and angles are listed in Table 4. Compound **3** crystallizes in the triclinic centrosymmetric space group $P\bar{1}$. The coordination environment of Cu(II) is similar to complex **1**. $[Cu(1)L]^-$ and $[Cu(2)L]^-$ groups are attached to Sr(II) ions by two different modes: $[Cu(1)L]^-$ through one carbonyl oxygen atom (O(2)) (Fig. 3(c)), and $[Cu(2)L]^-$ through two carboxylate oxygen atoms(O(8), O(7)) and one carbonyl oxygen atom(O(6)) (Fig. 3(d)). The carboxylate group in $[Cu(2)L]^-$ is similar to that of the tetranuclear moiety ($[Ca_2(CuL)_2(H_2O)_8]^{2+}$) in **2** and shows two different coordination

Symmetry transformations used to generate equivalent atoms: (a: $-x+1, -y+1, -z+2$.)

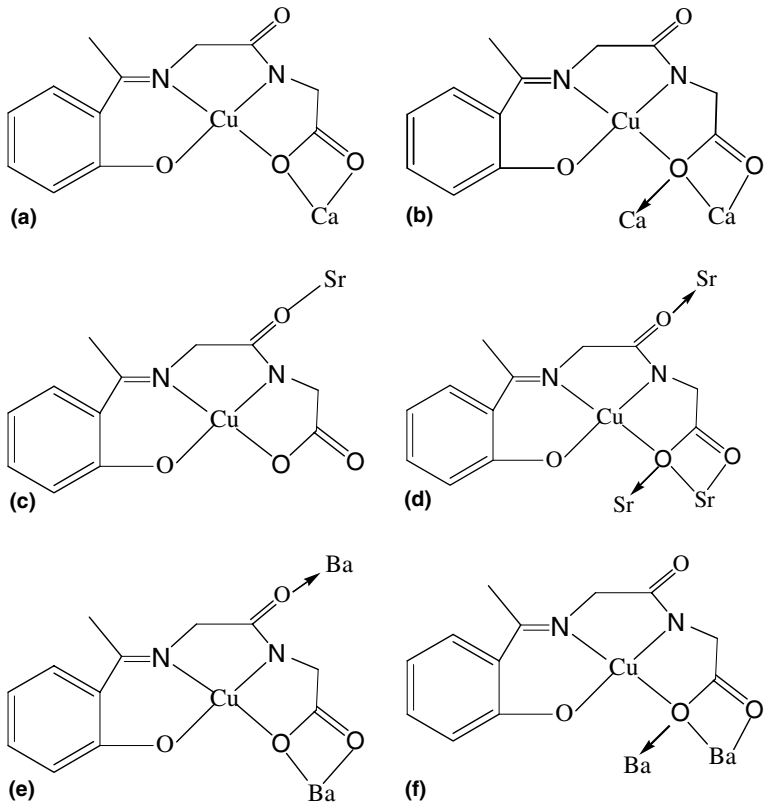

Fig. 3. Schematic diagram of the coordination behavior of the metalloligand $[CuL]^-$ in **2**–**4**

modes: to one strontium in a bidentate chelating manner, to the other one in a monodentate manner. The chelate ring planes of the two metalloligands ($[Cu(1)L]^-$ and $[Cu(2)L]^-$) are almost parallel with a small dihedral angle of 5.6°. In each unit, Sr and SrA are bridged by carboxylate oxygen atoms (O(8), O(8A)). The Sr···SrA distance is 4.34 Å.

The strontium cations in **3** are eight-coordinated as in the case of the calcium cations in the trinuclear moieties ($[Ca(CuL)_2(H_2O)_4]$) of **2**. However, the coordination environment around the strontium varies significantly to that found in **2**. Each strontium cation is coordinated by three carboxylate oxygen atoms (O(7), O(8), O(8A)), two carbonyl oxygen atoms (O(2) from the $[Cu(1)L]^-$ group and O(6B) from another $[Cu(2B)L]^-$ group, related by a symmetry operation) and three aqua ligands (O(1w), O(2w), O(3w)).

Two strontium cations link the four $[CuL]^-$ groups together via Sr–O bonds to form a new building block {[Cu(1)L][Cu(2)L]SrSr(A)[Cu(1A)L][Cu(2A)L]}. The two carbonyl oxygen atoms (O(6B) and O(6D)) from the adjacent building blocks are connected to Sr and SrA in the new building block respectively. The coordination of the symmetry-related strontium cations link the adjacent building blocks together to generate a 1D ladder-like polymeric chain along the *a*-axis (Fig. 4(b)). The intermolecular and intramolecular hydrogen bonds play an important role in the stabilization of the whole structure (Table S3, Supplementary material). Adjacent 1D chains are associated by hydrogen bonds to form 2D planes. The entire structure is held together to form a two-dimensional layer structure by van der Waals contacts.

3.5. Crystal structure of polymer $\{[Ba(CuL)_2(H_2O)_4]\}_n$ (**4**)

The crystal structure of **4** has been briefly reported in our previous communication [31]. Compound **4** crystallizes in the monoclinic centrosymmetric space group $P2_1/c$. The coordination environment of all Cu(II) ions is similar to **1**. In each unit, the metalloligand $[Cu(1)L]^-$ coordinates to Ba(II) ions through two carboxylate oxygen atoms(O(7), O(8)) in a bidentate chelating manner and one carbonyl oxygen atom (O(6)) (Fig. 3(e)), and $[Cu(2)L]^-$ has the same coordination mode as the tetranuclear moiety ($[Ca_2(CuL)_2(H_2O)_8]^{2+}$) in **2** (Fig. 3(f)). The Ba(II) ion is 10-coordinated to five carboxylate oxygen, one carbonyl oxygen (from another $[Cu(2A)L]^-$ ligand related by a symmetry operation) and four aqua ligands.

Two barium cations link the four $[CuL]^-$ metalloligands together via Ba–O bonds to form a hexanuclear building block {[Cu(1)L][Cu(2)L]Ba(1)Ba(1A)[Cu(1A)L]-

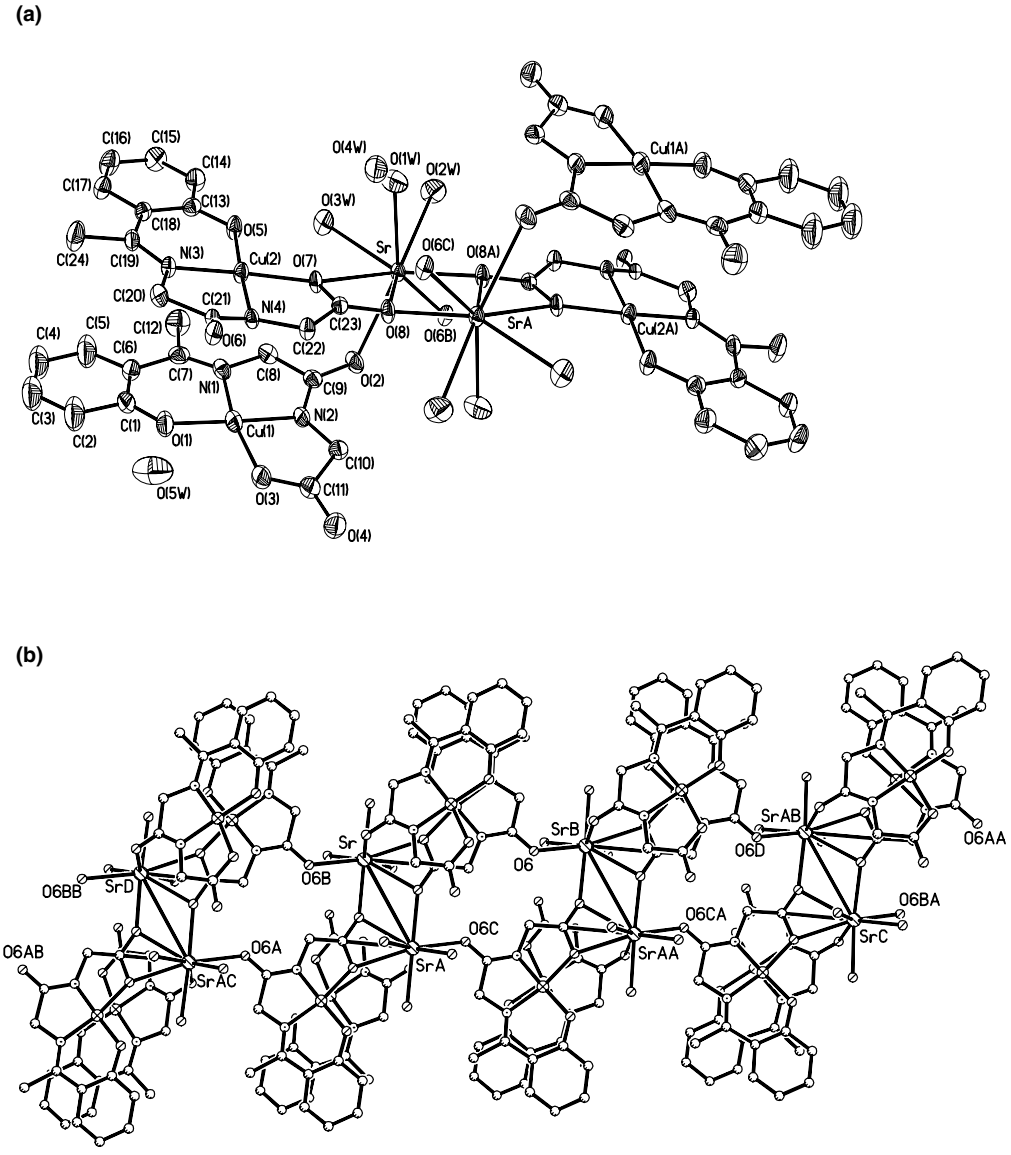

Fig. 4. (a) ORTEP view of **3**, with hydrogen atoms omitted for clarity. Thermal ellipsoids are drawn at the 35% probability level. (b) A view of the packing of the 1D ladder-like polymeric chain in **3** along the *a*-axis.

[Cu(2A)L]}. The symmetry-related Ba–O(6) bonds further join adjacent building blocks together to give an extended 2D network structure along the *bc*-plane (see Fig. 5). The intermolecular and intramolecular hydrogen bonds (Table S4, Supplementary material) and π–π interactions also potentially contribute to the stability of the whole structure. The entire structure is held together to form a 2D layer structure by van der Waals contacts.

3.6. Infrared, electronic and ESR spectra

The IR spectra of all the complexes show broad bands in the 3000–3500 cm^{-1} region, which may be ascribed to hydrogen-bonded *v*(O–H) and/or *v*(N–H), and may also include *v*(C–H). The broad bands at 1640–1658 and 1601–1618 cm^{-1} correspond to *v*(C═N) and v_{as}(COO). The symmetric carboxylate stretch, v_s(COO), probably corresponds to the medium/strong bands in the range 1340–1351 cm^{-1}. A medium band at 1530–1538 cm^{-1}, always present in the four compounds, may originate from the vibration of the *v*(Ph–)C–C(═N) bond [39] and typifies complexes derived from salicylaldehyde or 2-hydroxyacetophenone [39,40]. Medium bands in the range 1290–1297 cm^{-1} can be assigned to *v*(C–O) of the phenolic group in the complexes [41].

The UV absorption band observed at 344–346 nm in the complexes are assigned to the imino n–π^* transitions. The d–d transition spectra of the complexes show broad bands centered at 562–568 nm, being suggestive of approximate square-planar geometry at the Cu(II) ion.

Symmetry transformations used to generate equivalent atoms: (a: x, $y-1$, z; b: $-x+1$, $-y+2$, $-z+1$).

ESR spectra of complex **2** at room temperature in DMSO are shown in Fig. 6. Simulated spectra obtained by using the WINEPR SimFonia program gave good agreement. ESR spectra of complexes **1**, **3** and **4** are similar to that of complex **2**. The spectra exhibited a lineshape with five nitrogen superhyperfine (shf) structure peaks indicating ligation of two nitrogen atoms to the metal ion.

The four compounds all have similar IR, electronic and ESR spectra, which shows they have the same coordination environment around the Cu(II) ions.

3.7. Magnetic properties

The magnetic behaviours of compounds **1** and **2** showed that in the studied temperature range (75–300 K) the $\chi_M T$ (where χ_M is the molar magnetic susceptibility) values decrease regularly with cooling (see supplementary material, Fig. S1). The data can be nicely fitted to the Curie–Weiss expression $\chi_M = C/(T-\theta)$, affording $C = 0.677$ cm^3 mol^{-1}, $\theta = -12.18$ K for **1** and $C = 1.05$ cm^3 mol^{-1}, $\theta = -7.39$ K for **2**. The negative Weiss constant θ could suggest a weak antiferromagnetic interaction between the copper(II) ions in both compounds.

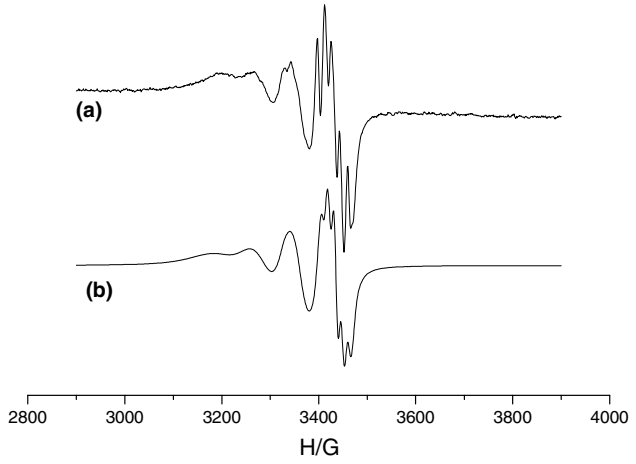

Fig. 6. Experimental ESR spectrum of **2** taken in DMSO at room temperature (a), together with the calculated curve (b).

The magnetic susceptibility of the two coordination polymers **3** and **4** was measured in the temperature range of 2–300 K on a SQUID magnetometer in an applied magnetic field of 1000 G (Fig. 7). The μ_{eff} values are equal to 2.74 (**3**) and 2.88 μ_B (**4**) at room temperature. These values are a little larger than those expected for two isolated copper(II) ions (for **3**, 2.45 μ_B, $g = 2.00$; for **4**, 2.58 μ_B, $g = 2.11$). For **3** (**4**), the $\chi_M T$ values decline gradually between 300 and ca. 11 (15) K, where the value is 0.720 (0.771) cm^3 mol^{-1} K; below 11 (15) K, it falls

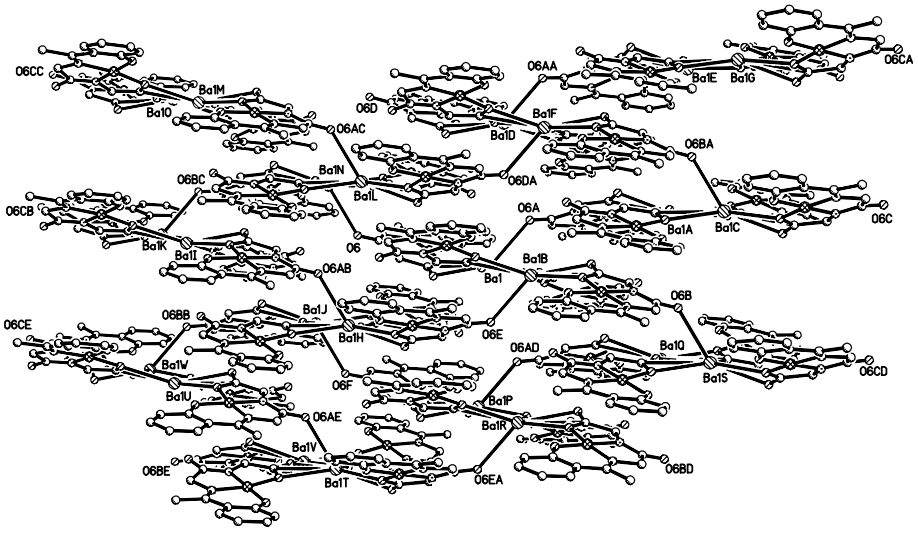

Fig. 5. A view of the packing of the 2D polymeric plane in **4** along the *a*-axis.

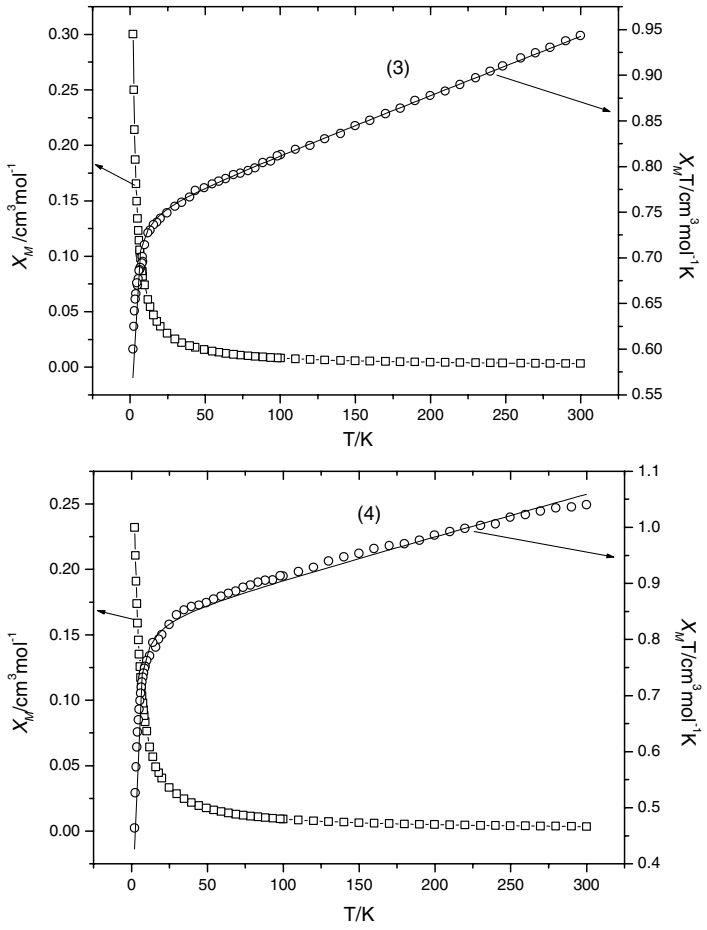

Fig. 7. χ_M (□) versus T and $\chi_M T$ (○) versus T plots for the coordination polymers **3** and **4**. The solid lines represent the best-fit curves to Eq. (1).

sharply to 0.600 (0.464) cm^3 mol^{-1} K at 2 K. These magnetic behaviors provide evidence of the presence of a weak antiferromagnetic spin-exchange interaction between two Cu(II) centres through the oxygen bridges. The experimental magnetic susceptibility data were fitted to the modified Bleaney–Bowers equation [42] for exchange-coupled dinuclear copper(II) complexes

$$\chi_M = \frac{2Ng^2\beta^2}{3kT}\left[1+\frac{1}{3}\exp(-2J/kT)\right]^{-1} + \text{Tip}. \qquad (1)$$

Here, Tip is the corrected value of temperature-independent paramagnetism and the remaining symbols have their usual meanings. A least-squares fitting procedure led to $J/k = -0.83$ K, $g = 2.00$ and Tip $= 6.5\times10^{-4}$, with an agreement factor of $R = 8.00\times10^{-5}$ (R is defined as $\sum[(\chi_M)_{obs}-(\chi_M)_{calc}]^2/\sum[(\chi_M)_{obs}]^2$) for **3** and $J/k = -1.58$ K, $g = 2.11$ and Tip $= 7.5\times10^{-4}$, with R value of 1.30×10^{-4} for **4**.

4. Conclusion

A series of heterometallic supramolecules have been constructed by a Cu(II) Schiff base complex K[CuL] (H_3L = *N*-2-hydroxyacetophenoneglycylglycine) with alkaline earth metal cations M^{2+} (M = Mg, Ca, Sr or Ba). The supramolecules are assembled by carboxylate bridges of the metalloligand $[CuL]^-$. With the ionic radii increase from Mg^{2+} to Ba^{2+}, they formed a mononuclear entity, trinuclear and tetranuclear clusters, a 1D ladder-like chain polymer and a 2D extended layer polymer. For a given M/[CuL] ratio (1:2), the coordinating behavior of the $[CuL]^-$ ligand to M can be fine tuned depending on the nature and size of the M^{2+} ions in the study. The $[CuL]^-$ ligand does not coordinate to the metal ion Mg^{2+} in **1** wherein the Mg^{2+} ion preferentially binds to water molecules, in the form of $[Mg(OH_2)_6]^{2+}$. While the $[CuL]^-$ ligands in **2** make only three and four bonds to the central calcium through the carboxylate oxygen atoms, the number of contacts with M ions are increased to five and six in **3** and **4**, respectively. The carbonyl oxygen atom of the $[CuL]^-$ ligand in **2** does not coordinate to the metal, presumably because the calcium dication has a smaller coordination sphere. Thus, five different modes of coordination of the metalloligand $[CuL]^-$ have been realized for complexes **2**–**4** (Fig. 3). The magnetic behaviours indicate that all complexes exhibit weak

antiferromagnetic interactions between the Cu(II) paramagnetic centers.

Reactions of *closo*-$[B_{12}H_{12}]^{2-}$ anion with aromatic acylchlorides: synthesis of novel 1,2-disubstituted dodecaborates $[1\text{-HO-2-ArCOB}_{12}H_{10}]^{2-}$

Abstract

Synthesis of disubstituted derivatives of the dodecahydro-*closo*-dodecaborate anion is described and the reaction mechanism is discussed. Derivatives of the $[B_{12}H_{12}]^{2-}$ anion containing hydroxyl and arylated carbonyl functions ($[1\text{-HO-2-ArCOB}_{12}H_{10}]^{2-}$) were prepared from different acylchlorides. The major advantage of these compounds is their possibility to provide two different binding sites in one molecule. These compounds are suitable for the development of new precursors for boron neutron capture therapy (BNCT).

Keywords: *closo*-Dodecaborate; Hydroxy and acyl derivatives; Disubstituted functional derivatives; Boron neutron capture therapy

1. Introduction

Our continuing interest in the chemistry of the dodecahydro-*closo*-dodecaborate anion $[B_{12}H_{12}]^{2-}$ aims towards facile, reliable and rational introduction of a broad variety of substituents [1–4]. Especially water-soluble functionalized derivatives of the dodecahydro-*closo*-dodecaborate anion are promising candidates for boron neutron capture therapy (BNCT) [5,6]. In our previous work [1], we described the reaction of $Na_2[B_{12}H_{12}]$ with various acylchlorides in acetone at room temperature, leading to a mixture of the acylated product $[B_{12}H_{11}COR]^{2-}$ and the monohydroxy derivative $[B_{12}H_{11}OH]^{2-}$.

The ratio of the products depends on the nature of the R used. The mechanism of the reaction was studied and intermediate (**A**) was characterized [1] (cf. (Scheme 1)). In this paper, we present the results of the study of the same reaction in boiling acetone.

2. Results and discussion

We found, that aromatic acylchlorides react with $Na_2[B_{12}H_{12}]$ (**1**) in boiling acetone resulting after work up with water in 1-hydroxy-2-acyl-*closo*-dodecaborates $[1\text{-HO-2-ArCOB}_{12}H_{10}]^{2-}$ (**2a**–**c**) with ca. 70% yield. In contrast the reaction with aliphatic acylchlorides in boiling acetone leads to a mixture of the acylated product and the monohydroxy derivative as at ambient temperature [1].

The structure of **2a**–**c** was determined using methods of NMR and IR spectroscopy. The $^{11}B\{^1H\}$ NMR

A

Scheme 1.

spectra of **2a**–**c** (Table 1) show 6 signals with the intensity ratio of 1:1:6:2:1:1. This pattern is not inconsistent with the expected 1:1:2:2:2:2:1:1 pattern for a $[B_{12}H_{10}XY]^{2-}$-system with 2 different substituents. The coinciding ^{11}B resonances B(3,6), B(4,5) and B(7,11) show separated ^{1}H resonances in the corresponding $^{1}H\{^{11}B\}$ NMR spectra. The two lowfield singlets at ~4.5 and ~2.7 ppm are assigned to B(1)–OH and B(2)–COAr. The assignment of B(1) and B(2) is based on the data found for the monosubstituted derivatives $[B_{12}H_{11}OH]^{2-}$ (B(1) 5.4 ppm [2]) and $[B_{12}H_{11}COR]^{2-}$ (B(1) ~3 ppm [1]). The 1,2-substitution in **2a**–**c** and assignment of the B–H-bonded (non-substituted) boron atoms is based on the ^{11}B-^{11}B-COSY NMR spectra (Scheme 2).

In the ^{1}H NMR spectra of **2a**–**c** the signals of the cation and the COAr protons were observed. The shifts of the B–H protons were determined by ^{1}H-^{11}B-2D NMR spectra (Table 1). The 5 signals in the $^{1}H\{^{11}B\}$ NMR spectra (intensity ratio of 2:2:2:2:2) correspond to disubstitution of the *closo*-dodecaborate anion. The B–H protons of B(9)–H and B(12)–H (antipodal to B(2)–COAr and B(1)–OH) show coincidence for all synthesized dodecaborates $[1\text{-HO-2-ArCOB}_{12}H_{10}]^{2-}$ (**2a**–**c**).

The ^{13}C NMR spectra of **2a**–**c** contain signals of the CO-group at ~170 ppm. These signals are shifted by approximately 5 ppm to the lower field in the comparison with signals of the corresponding monoacylated derivatives $[B_{12}H_{11}COR]^{2-}$ [1].

The IR spectra of **2a**–**c** contain the characteristic bands of CO (~1650 cm^{-1}), BH (~2500 cm^{-1}) and OH (~3425 cm^{-1}) groups. The signals of carbonyl and hydroxyl groups are shifted in the comparison with signals of monosubstituted acylderivatives $[B_{12}H_{11}COR]^{2-}$ (1675–1690 cm^{-1}) [1] and hydroxyl derivative $[B_{12}H_{11}OH]^{2-}$ (3565cm^{-1}) [2]. Such trends, as well as the corresponding shift of the carbonyl ^{13}C NMR signals, can be explained by the formation of a intramolecular hydrogen bond between the hydroxy and carbonyl groups (Scheme 3).

Earlier we studied the mechanism of the room temperature reaction of **1** with acylchlorides [1]. To understand the reason of the selective 1,2-disubstitution in the present work we studied the reaction of **1** with 4-chlorobenzoylchloride in acetone-d_6 in a NMR tube at 52 °C. We monitored the reaction by measuring ^{1}H and ^{11}B NMR spectra every 5 min and ^{13}C NMR spectra every 30 min. After heating the tube for 2.5 h the same intermediate as in the reaction at room temperature (**A**) was formed (cf. Scheme 1). The NMR data of **A** match perfectly with those obtained earlier [1].

Through further heating of the tube for additional 3 h hydrogen is evolved and **A** is nearly quantitatively transformed to the new intermediate **B**. Intermediate **B**

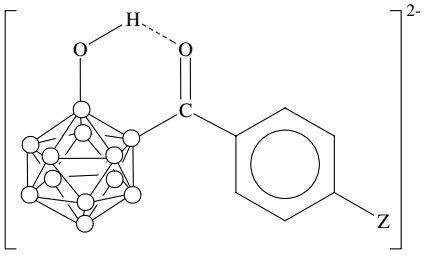
2a-c

Ar = Ph (**2a**), 4-ClC_6H_4 (**2b**), 4-BrC_6H_4 (**2c**)

Scheme 2.

is stable at room temperature for several hours. It reacts to **2b** after the addition of water. In the ^1H NMR spectrum of **B** the signals of the aromatic ring protons are shifted to lower field (8.21 and 7.72 ppm for this AX-system) compared to **A** [1]. The ^{13}C NMR spectrum shows that all signals of the aromatic ring carbons are shifted to lower field compared to **A**. The signal of C_i (C–CO–) is shifted by ca. 5 ppm (143.4 and 137.9 ppm for **A** [1]). ^{13}C NMR shift for the former carbonyl C-atom is found at 185.3 ppm (167.0 for **A** [1]). The ^{11}B NMR spectrum of **B** shows the expected 1:1:2:2:2:2:1:1 pattern for a disubstituted dodecaborate with two different substituents (5.00 and 2.9 ppm for B(1)–O– and B(2)–C^+(Ar)–). The shifts of the substituted boron atoms are close to the product **2b** (4.5 and 1.7 ppm), but both shifted to the lowfield side. The 2:2:2:2:1:1 pattern of the $^1H\{^{11}B\}$ NMR spectrum provides another convincing proof for the proposed structure of **B**. According to the data it is possible to propose a mechanism for the formation of **2** (Scheme 4).

After the elimination of hydrogen from **A** the formation of **B** through transient intermediate **I** is reasonable. All NMR data match with the proposed structure **B**. The work up of **B** with water or dry methanol only results in **2b**. This strongly supports structure **B**. If the reaction mixture contained substantial amounts of **I**, after work up with MeOH the methoxylated derivative [1-MeO-2-(4-ClC_6H_4CO)-$B_{12}H_{10}$]$^{2-}$ should be formed as well.



Scheme 3.

3. Experimental

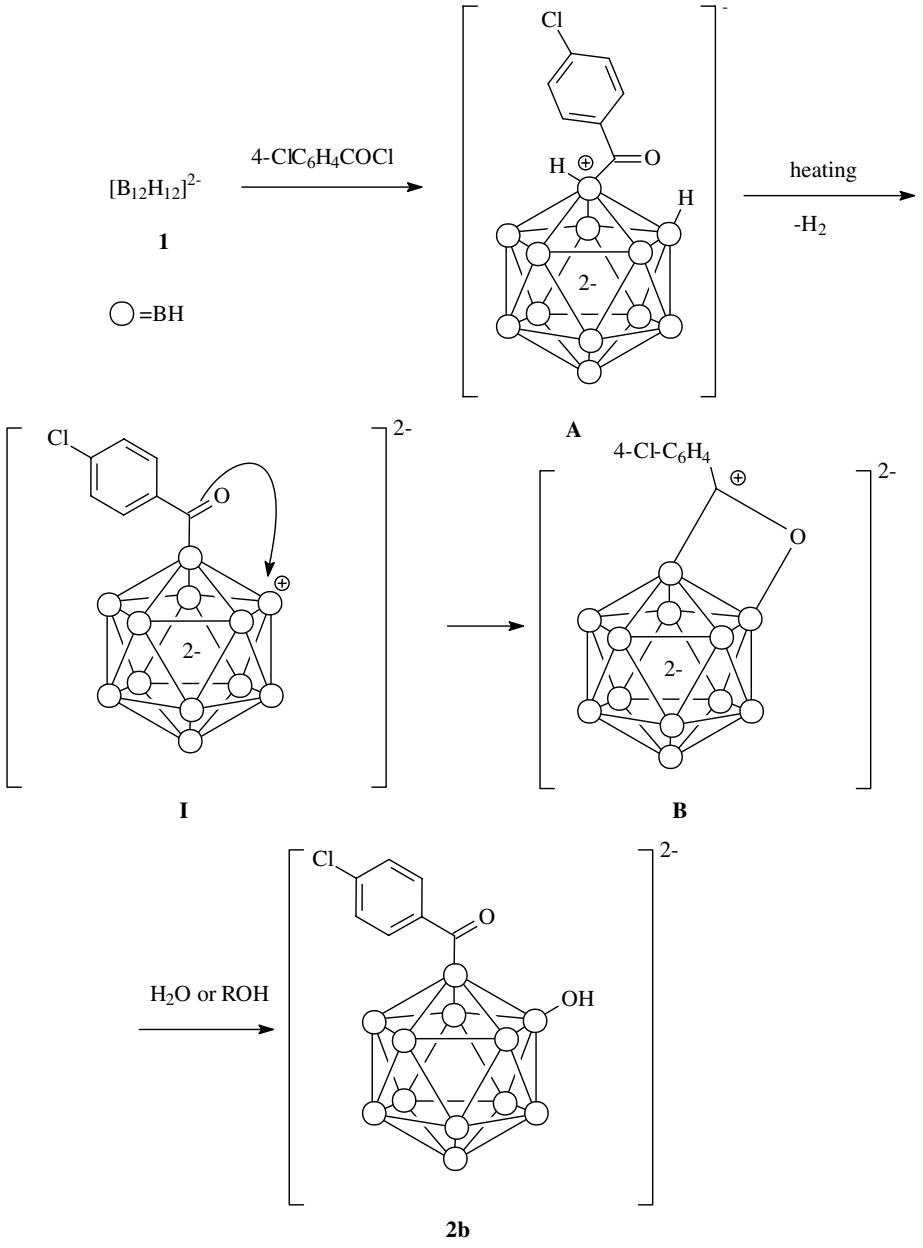
3.1. Materials and equipments

Chemicals were reagent grade and used as received from standard commercial vendors, acetone and acetone-d_6 was distilled from dry K_2CO_3, methanol was distilled from magnesium. IR spectra were recorded on NICOLET 520 FR/FT spectrometer. The ^1H, ^{13}C, and ^{11}B NMR spectra were recorded at 200.13. 50.32 and 64.21 MHz on a BRUKER-ACP-200 spectrometer in acetone-d_6/D_2O (10:1,v/v). Melting points were measured in open capillary and are not corrected.

3.2. Preparation of compounds

3.2.1. Bis-(triphenyl-n-propylphosphonium)-1-hydroxy-2-benzoyl-decahydrodo-closo-decaborate, *2a*

To a solution of 0.95 g (5.0 mmol) $Na_2[B_{12}H_{12}]$ in 50 ml absolute acetone 1.4 ml (5.2 mmol) benzoylchloride was added and the solution was refluxed for 48 h. The precipitated NaCl was filtered. To the filtrate 1.52 g (10.0 mmol) CsF in 50 ml dry MeOH was added. The precipitate formed was recovered by filtration and dissolved in 50 ml H_2O. After addition of 3.85 g (10.0 mmol) Ph_3PrPBr in 50 ml water the Ph_3PrP-salt precipitated. The solid was filtered, washed with 2×30 ml H_2O, dried in vacuum giving 3.13 g (71.7%, yield) of **2a,** m.p. = 84–85 °C. *Anal*. Calc. for $C_{49}H_{60}B_{12}O_2P_2$; C, 67.44; H, 6.93; B, 14.86. Found: C, 66.98; H, 6.94; B, 14.47%. IR (Nujol, cm^{-1}): 3401 (OH), 2499 (B–H), 1648 (C═O). ^1H NMR (ppm): 8.1–7.7 (30H, m, Ph–P), 7.6–7.3 (5H, m, Ph–CO), 3.56 (4H, m, P–CH_2), 1.81 (4H, m, P–CH_2-CH_2), 1.20 (6H, t, P–CH_2–CH_2–



Scheme 4.

CH_3). ^{13}C NMR (ppm): 171.6 (C═O), 133.6, 131.6, 130.5, 129.9 (Ph–CO), 135.8 (d), 134.2 (d), 131.0 (d), 119.5 (d, –Ph–P), 23.6 (d), 16.8 (d), 15.2 (d, –Pr–P).

3.2.2. Bis-(triphenyl-n-propyl-phosphonium)-1-hydroxy-2-(4-chlorobenzoyl)-decahydro-closo-dodecaborate ***2b***

$Na_2[B_{12}H_{12}]$ (0.95 g, 5.0 mmol) was dissolved in 50 ml absolute acetone and 0.7 ml (5.2 mmol) *p*-chlorobenzoylchlorid was added. The reaction mixture was refluxed for 24 h. The solvent was evaporated to dryness, 100 ml H_2O were added and insoluble material was filtered off. One gram NMe_4Br in 10 ml H_2O was added to precipitate by – products. After filtering, the pure product was precipitated after the addition of 3.85 g (10.0 mmol) Ph_3PPrBr in 100 ml H_2O. The precipitate was recovered by filtration, washed 2×30 ml H_2O, dried in vacuo, yielding −3.1 g (68.5%) of **2b,** m.p. = 72 °C. *Anal*. Calc. for $C_{49}H_{59}B_{12}ClO_2P_2$; C, 64.88; H, 6.56; B, 14.30. Found: C, 64.27; H, 6.59; B, 14.14%. IR (Nujol, cm^{-1}): 3447 (OH), 2495 (B–H), 1650 (C═O). ^1H NMR (ppm): 7.7 (30H, m, Ph–P), 7.43 (2H,d,1/2Ar–CO), 3.56 (4H, m, P–CH_2): 1.81 (4H, m, P–CH_2–CH_2), 1.20 (6H, t, P–CH_2–CH_2–CH_3). ^{13}C NMR (ppm): 169.5 (C═O), 138.6; 135.9, 132.3; 129.0 (4-C_6H_4–CO), 135.8 (d), 134.4 (d), 131.1 (d), 119.0 (d, –Ph–P), 23.5 (d), 17.0 (d), 15.0 (d, –Pr–P).

3.2.3. Bis-(triphenyl-n-propylphosphonuim)-1-hydroxy-2-(4-bromobenzoyl)-decahydro-closo-dodecaborate, ***2c***

2c was synthesized by the same way as **2b** from 0.95 g (5.0 mmol) $Na_2[B_{12}H_{12}]$ in 50 ml absolute acetone and 1.2 ml (5.0 mmol) 4-bromobenzoylchloride. Yield 3.22 g (67.4%) **2c**, m.p. = 83 °C. *Anal.* Calc. for $C_{49}H_{59}B_{12}BrO_2P_2$; C, 61.85; H, 6.25; B, 13.63. Found: C, 61.17; H, 6.22; B, 13.34%. IR (Nujol, cm^{-1}): 3429 (OH), 2495 (B–H), 1651 (C═O). ^1H NMR (ppm): 8.1–7.7 (30H, m, Ph–P), 7.87, 7.60 (4H, dd, 4-BrC_6H4CO), 3.57 (4H, m, P–CH_2), 1.82 (4H, m, P–CH_2CH_2), 1.18 (6H, t, P–CH_2–CH_2–CH_3), ^{13}C NMR (ppm): 169.1 (C═O), 135.8, 134.6, 131.7, 129.2 (4-BrC_6H_4–CO–), 135.5 (d); 134.1 (d), 130.9 (d), 118.5 (d, –P–Ph), 23.5 (d), 17.0 (d), 15.3 (d, –P–Pr).

3.2.4. Studies of mechanism

To a solution of $Na_2[B_{12}H_{12}]$ (71 mg, 0.37 mmol) in 0.5 ml absolute acetone-d_6 in the NMR-tube 50 μl (0.39 mmol) *p*-chlorobenzoylchloride was added. The tube was heated to 52°C for 2.5 h (formation of **A**) and than for additional 3 h. The resulting solution contained nearly quantitatively **B**. The tube was cooled to room temperature and the NMR data were taken.

^{11}B NMR (ppm): 5.0 (1B, s, B–O–), 2.9 (1B, s, B–$C(Ar)^+$–), −14.5 (2B), −15.6 (2B), −16.2 (2B), −17.0 (2B), −20.5 (1B, B(9)), −22.4 (1B, B(12)); ^1H NMR (ppm): 8.21, 7.72 (4H,dd,Ar), 3.0–0.5 (10H, broad, BH); $^1H\{^{11}B\}$NMR (ppm): 1.67 (2H), 1.51 (2H), 1.30 (2H), 1.14 (2H), 1.05 (1H), 0.96 (1H); ^{13}C NMR (ppm): 185.3 (C^+), 143.4 (C(Ar)–C^+), 137.6 (C(Ar)–Cl), 134.2, 131.5(CH)Ar)).

Abstract

The iron complex chemistry of the ligands 3-(pyrazinyl)-1,2,4-triazole (L^2H) and 1-methyl-3-(pyrazinyl)-1,2,4-triazole (L^2Me) has been investigated. The complexes $[Fe(L^2H)_3](ClO_4)_2$, $[Fe(L^2Me)_3]X_2$ ($X^- = BF_4^-$ or PF_6^-), $[Fe(L^2Me)_3](ClO_4)_2 \cdot xH_2O$ ($x = 0$ or 1) and $[Fe(L^2Me)_3]SO_4 \cdot 2H_2O$ have been isolated by complexation of the appropriate hydrated iron(II) salt by 3 equiv. of an L^2R ligand. Attempts to prepare other salts of these complexes gave intractable oil products; the autooxidation product $[\{FeCl(L^2Me)_2\}_2(\mu\text{-}O)](PF_6)_2$ slowly crystallised from one such reaction mixture, and was identified by crystallography. The single crystal structure of $[Fe(L^2Me)_3](ClO_4)_2 \cdot H_2O$ contains *mer*-six-coordinate Fe(II) centres, that are essentially fully low-spin at 150 and 296 K. The anhydrous powders $[Fe(L^2H)_3](ClO_4)_2$ and $[Fe(L^2Me)_3]Y_2$ ($Y^- = BF_4^-$, ClO_4^- or PF_6^-) undergo gradual spin-state transitions with $182 \leqslant T_{1/2} \leqslant$ ca. 400 K, that range from 61% to 100% completeness at 50 K. $[Fe(L^2Me)_3]SO_4 \cdot 2H_2O$ is high-spin above 200 K, but shows a decline in $\chi_M T$ at lower temperatures whose origin is uncertain. The single crystal X-ray structure of 1,4-dihydro-3,6-dipyrazinyl-1,2,4,5-tetrazine, a byproduct from an attempted synthesis of 5-methyl-3-(pyrazinyl)-1,2,4-triazole, is also reported.

Keywords: Iron; Spin-crossover; Crystal structure; Magnetic measurements

1. Introduction

There is continuing interest in the chemistry and physics of compounds that exhibit spin-state transitions upon cooling, irradiation and/or the application of pressure [1–3]. Since these transitions are usually accompanied by a colour change in the sample, such compounds in the solid state have potential for application in information storage and display devices [4]. In order to be useful, a thermal spin-crossover compound must exhibit an abrupt transition with a pronounced hysteresis loop, which should ideally occur close to room temperature [5,6]. Abrupt spin-state transitions are a consequence of strong, cooperative interactions between the spin centres in the solid [1–3]. Hence, it can be generalised that coordination polymers, or solids containing discrete complex molecules linked by hydrogen-bonding or strong π–π interactions, are the most likely to exhibit this property. Otherwise, the synthesis of new abrupt spin-crossover materials still involves a significant degree of trial-and-error.

During our own studies of spin-crossover Fe(II) compounds [7–11] we reported Fe(II) complexes of 3-(pyrazinyl)pyrazole (L^1), which contains both hydrogen bond-donor and -acceptor sites when coordinated to a metal ion [11]. We thought that this might result in networks of Fe complex centres linked by hydrogen bonding, which could undergo cooperative spin-state transitions. In fact, while crystals of $[Fe(L^1)_3]X \cdot n_2O$ ($X^- = BF_4^-$, $n = 2$; $X^- = ClO_4^-$, $n = 1$) do show the desired intermolecular N–H···N hydrogen bonding, they are also fully low-spin at or below room-temperature [11]. We reasoned that, in order to obtain spin-crossover

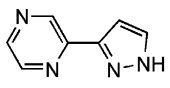
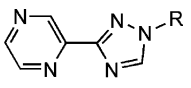
doi:10.1016/j.poly.2004.06.018

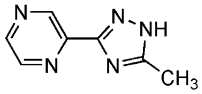
compounds from this type of system, we would need to make one or other of the heterocycles in the L^1 framework less basic. We now report an investigation of the iron(II) complex chemistry of two 3-(pyrazinyl)-1,2,4-triazole derivatives, L^2R (R = H or Me). The synthesis of these ligands, and of L^3H, has been reported by others, although only their ruthenium complex chemistry has been investigated to date [12–14]. However, several iron(II) complexes of closely related 35-(pyrid-2-yl)-1,2,4-triazoles L^4R are known, all of which undergo spin-state transitions below room temperature [15–18].



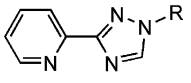
L^1



R = H, L^2H
R = CH_3, L^2Me



L^3



R = H, L^4H
R = CH_3, L^4Me

2. Experimental

All manipulations were carried out in air, using distilled water or reagent-grade solvents, and all organic and inorganic reagents were used as supplied. The syntheses of **I**, **II**, L^2H and L^2Me are modifications of the literature procedures [12]. *Caution*. While we have experienced no difficulty in handling the ClO_4^- salts in this study, metal–organic perchlorates are potentially explosive and should be handled with due care in small quantities.

2.1. Synthesis of pyrazinylamidrazone (*I*)

An ethanol (40 cm^3) solution of cyanopyrazine (10.0 g, 9.5×10^{-2} mol) and hydrazine monohydrate (4.8 g, 9.5×10^{-2} mol) was stirred at room temperature for 1 h, yielding a yellow precipitate. The reaction mixture was stored at −30 °C overnight. The solid product was then collected by filtration, washed with the minimum amount of cold ethanol and dried over P_2O_5. Yield 12.1 g (93%). Calc. for $C_5H_7N_5$: C, 43.8; H, 5.1; N, 51.1. Found: C, 44.0; H, 5.2; N, 51.1%. M.p. 127–129 °C. EI mass spectrum: *m/z* 137 (M^+), 106 (M^+–N_2H_3), 79 (M^+–$CNHN_2H_3$). ^{1}H NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 5.64 (br s, 2H, N*H*), 5.81 (br s, 2H, N*H*), 8.56 (m, 2H, pz H^5 + H^6), 9.18 (s, 1H, pz H^3).^{13}C NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 141.6 (*C*═NH), 142.1, 142.6, 143.1 (pz C^3 + C^5 + C^6), 147.5 (pz C^2).

2.2. Synthesis of pyrazinyl-N′-methylamidrazone (*II*)

A solution of cyanopyrazine (10.0 g, 9.5×10^{-2} mol) and methylhydrazine (23.8 g, 0.48 mol) in ethanol (100 cm^3) was stirred at room temperature for 1 h, yielding a yellow solution. The reaction mixture was quenched with water, and the aqueous phase extracted with Et_2O (3×50 cm^3). The organic washing were dried over $MgSO_4$, then concentrated in vacuo until the product began to precipitate. Overnight storage of the solution at −30 °C yielded fine yellow needles, which were collected by filtration and dried over P_2O_5. Yield 12.6 g (88%). Calc. for $C_6H_9N_5$: C, 47.7; H, 6.0; N, 46.3. Found: C, 47.8; H, 6.0; N, 46.3%. M.p. 106–108 °C. EI mass spectrum: *m/z* 151 (M^+), 122 (M^+–$NHCH_2$), 79 (M^+–$CNHN_2H_2$ CH_3). ^{1}H NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 2.88 (s, 3H, CH_3), 5.29 (br s, 1H, N*H*), 5.79 (br s, 2H, N*H*), 8.53 (d, 2.7 Hz, 1H, pz H^6), 8.54 (dd, 1.4 and 2.7 Hz, 1H, pz H^5), 9.13 (d, 1.4 Hz, 1H, pz H^3). 13C NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 38.3 (C_3), 140.6 (*C*═NH), 142.1, 142.8, 143.2 (pz C^3 + C^5 + C^6), 147.0 (pz C^2).

2.3. Synthesis of pyrazinyl-N′-phenylamidrazone (*III*)

Method as for **I**, using phenylhydrazine (10.3 g, 9.5×10^{-2} mol). Evaporation of the reaction mixture to dryness yielded an orange oil, which partially crystallised on standing at room temperature. Yield 18.1 g (89%). Calc. for $C_{11}H_{11}N_5$: C, 62.0; H, 5.2; N, 32.8. Found: C, 61.8; H, 5.3; N, 32.8%. EI mass spectrum: ***m/z*** 214 (M+H^+), 77 (Ph^+). ^{1}H NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 3.63 (br s, 3H, N*H*), 6.73 (m, 2H, Ph $H^{2/6}$), 7.16 (m, 3H, Ph H^{3-5}), 8.65 (dd, 1.2 and 2.6 Hz, 1H, pz H^5), 8.83 (d, 2.6 Hz, 1H, pz H^6), 9.39 (d, 1.2 Hz, 1H, pz H^3).13C NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 112.5 (Ph $C^{2/6}$), 119.8 (Ph C^4), 129.6 (Ph $C^{3/5}$), 131.5 (Ph C^1), 145.9, 147.8, 148.7 (pz C^3 + C^5 + C^6), 151.7 (pz C^2), 162.2 (*C*═NH).

2.4. Synthesis of 3-(pyrazinyl)-1,2,4-triazole (L^2H)

Pyrazinylamidrazone (2.7 g, 0.020 mol) was added in small portions, with stirring, to formic acid (9.0 g, 0.20 mol) at 0 °C. The mixture was allowed to warm to room temperature, then refluxed for 2 h. The excess formic acid was removed by evaporation under reduced pressure, and the solid residue neutralised with aqueous Na_2CO_3. Silica column chromatography using a 1:3 MeOH:CH_2Cl_2 eluent yielded the pure product as yellow-brown platelets. Yield 0.95 g (32%). Calc. for $C_6H_5N_5$: C, 49.0; H, 3.4; N, 47.7. Found: C, 49.1; H, 3.7; N, 47.7%. M.p. 210–212 °C. EI mass spectrum: *m/z*

147 (M^+), 119 (M^+–N_2). ^{1}H NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 8.50 (s, 1H, tz H^5), 8.70 (d, 2.5 Hz, 1H, pz H^6), 8.73 (dd, 1.5 and 2.5 Hz, 1H, pz H^5), 9.25 (d, 1.4 Hz, 1H, pz H^3).^{13}C NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 142.9, 144.9, 145.5 (pz C^3 + C^5 + C^6), 148.3 (pz C^2), tz C^3 and C^5 not observed [19].

2.5. Synthesis of 1-methyl-3-(pyrazinyl)-1,2,4-triazole (L^2Me)

Method as for L^2H, except pyrazinyl-*N*′-methylamidrazone (3.0 g, 0.020 mol) was used. The product was a cream powder. Yield 1.3 g (40%). Calc. for $C_7H_7N_5$: C, 52.2; H, 4.4; N, 43.5. Found: C, 52.0; H, 4.2; N, 43.3%. M.p. 174–176 °C. EI mass spectrum: *m/z* 161 (M^+), 133 (M^+–N_2), 118 (M^+–N_2CH_3). ^{1}H NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 3.98 (s, 3H, CH_3), 8.63 (s, 1H, tz H^5), 8.67 (d, 2.6 Hz, 1H, pz H^6), 8.72 (dd, 1.5 and 2.6 Hz, 1H, pz H^5), 9.21 (d, 1.5 Hz, 1H, pz H^3).^{13}C NMR spectrum ({CD_3}$_2$SO, 293 K): δ, ppm 36.6 (C_3), 142.9, 144.9, 145.1, 146.6 (pz C^3 + C^5 + C^6 + tz C^5), 145.5 (tz C^3), 159.3 (pz C^2).

2.6. Attempted synthesis of 5-methyl-3-(pyrazinyl)-1,2,4-triazole (L^3H)

Pyrazinylamidrazone (2.7 g, 0.020 mol) was added in small portions, with stirring, to acetic acid (12.0 g, 0.20 mol) at 0 °C. The mixture was allowed to warm to room temperature, then stirred for 2 h. The excess acetic acid was removed by evaporation under reduced pressure, and the solid residue neutralised with aqueous Na_2CO_3. Silica column chromatography using a 1:3 MeOH:CH_2Cl_2 eluent demonstrated the presence of several coloured products, with dark orange 1,4-dihydro-3,6-dipyrazinyl-1,2,4,5-tetrazine (**IV**) [20] being the only component to elute cleanly.^{1}H NMR spectroscopy implied that **IV** was the most abundant species in the crude product mixture (ca. 30%).

2.7. Synthesis of[Fe(L^2H)$_3$](ClO_4)$_2$ [**1(ClO_4)$_2$**]

A mixture of $Fe(ClO_4)_2 \cdot 6H_2O$ (0.38 g, 1.0×10^{-3} mol) and L^2H (0.46 g, 3.1×10^{-3} mol) in MeOH (50 cm^3) was stirred at room temperature until all the solid had dissolved. The deep red solution was filtered to remove a black impurity, and concentrated to ca. 5 cm^3. Diffusion of Et_2O vapour into this solution yielded a dark red-brown powder which was filtered, washed with Et_2O and dried in vacuo. Yield 0.29 g, 42%. Calc. for $C_{18}H_{15}Cl_2FeN_{15}O_8$: C, 31.1; H, 2.2; N, 30.1. Found: C, 31.0; H, 2.2; N, 29.7%. ESMS: *m/z* 627 [Na_5(L^2H)$_3$(OH)(OH$_2$)$_3$]$^+$, 591 [Na_5(L^2H)$_3$(OH)(OH$_2$)]$^+$, 427 [Na_2(L^2H)$_2$(OH)$_3$(OH$_2$)$_2$]$^+$, 390 [Na(L^2H)$_2$(OH$_2$)$_4$+H]$^+$, 358 [Na_2(L^2H)$_2$(OH$_2$)]$^+$, 285 [Na_3(L^2H)(OH)$_3$(OH$_2$)]$^+$, 263 [Na_2(L^2H)(OH)$_2$(OH$_2$)$_2$]$^+$, 245 [Na_2(L^2H)(OH)$_2$(OH$_2$)]$^+$, 212 [Na_2(L^2H)(OH$_2$)+H]$^+$, 148 [L^2H+H]$^+$. IR (nujol): 3460br w, 3130br w, 1606m, 1561w, 1405m, 1344m, 1297m, 1274m, 1165s, 1105br vs, 1000m, 972m, 930w, 856m, 767m, 736m, 722m, 622s, 511m cm^{-1}. ^{1}H NMR spectrum (CD_3 CN, 293 K): δ, ppm 45.5, 55.2 (both 1H, pz H^3+H^5), 108.1 (1H, tz H^5).

2.8. Synthesis of [Fe(L^2Me)$_3$](BF_4)$_2$ [**2(BF_4)$_2$**]

A mixture of $Fe(BF_4)_2 \cdot 6H_2O$ (0.34 g, 1.0×10^{-3} mol) and L^2Me (0.50 g, 3.1×10^{-3} mol) in MeCN (50 cm^3) was stirred at room temperature for 1 h. The deep red solution was filtered, and concentrated to ca. 5 cm^3. Diffusion of Et_2O vapour into this solution yielded dark red microcrystals which were filtered, washed with Et_2O and dried in vacuo. Yield 0.46 g, 63%. Calc. for $C_{21}H_{21}B_2F_8FeN_{15}$: C, 35.4; H, 3.0; N, 29.5. Found: C, 35.6; H, 3.1; N, 29.7%. IR (nujol): 3146w, 1603m, 1558s, 1512m, 1351m, 1285m, 1223s, 1151s, 1020br vs, 939m, 873w, 855s, 849s, 832m, 771s, 733m, 699s, 664s, 642m, 636m, 540m, 523m cm^{-1}.

2.9. Synthesis of [Fe(L^2Me)$_3$](ClO_4)$_2$ [**2(ClO_4)$_2$**]

A solution of $Fe(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1.0×10^{-3} mol) and L^2Me (0.50 g, 3.1×10^{-3} mol) in acetone (50 cm^3) was stirred at room temperature for 1 h. The resultant red solution was filtered, and concentrated to ca. 5 cm^3. Diffusion of Et_2O vapour into this solution gave a red microcrystalline solid which was filtered, washed with Et_2O and dried in vacuo. Yield 0.52 g, 68%. Calc. for $C_{21}H_{21}Cl_2FeN_{15}O_8$: C, 34.2; H, 2.9; N, 28.5. Found: C, 34.0; H, 3.0; N, 28.4%. ESMS: *m/z* 569 [Na_3(L^2Me)$_3$(OH)]$^+$, 423 [Na_2(L^2Me)$_2$(OH$_2$)$_3$+H]$^+$, 385 [Na_2(L^2Me)$_2$(OH)]$^+$, 303 [Na_3(L^2Me)$_3$(OH$_2$)$_3$]$^{2+}$, 259 [Na_2(L^2Me)(OH)$_2$(OH$_2$)]$^+$, 225 [Na_2(L^2Me)(OH$_2$)]$^+$, 162 [L^2Me+H]$^+$. IR (nujol): 3124w, 1597m, 1549m, 1513s, 1346m, 1296m, 1222s, 1166s, 1100br vs, 1034s, 932m, 879m, 864m, 767s, 734m, 695m, 636m, 625s, 514m cm^{-1}. ^{1}H NMR spectrum (CD_3 CN, 293 K): δ, ppm 9.6 (3H, CH_3), 41.7, 45.9 (both 1H, pz H^3 + H^5), 97.2 (1H, tz H^5).

2.10. Synthesis of [Fe(L^2Me)$_3$](PF_6)$_2$ [**2(PF_6)$_2$**]

A mixture of $FeCl_2 \cdot 4H_2O$ (0.21 g, 1.0×10^{-3} mol), L^2Me (0.50 g, 3.1×10^{-3} mol) and NH_4PF_6 (0.34 g, 2.1×10^{-3} mol) in H_2O (50 cm^3) was stirred with mild heating until all the solid had dissolved. Allowing the red solution to stand at room temperature overnight afforded a red polycrystalline solid contaminated with a small amount of white powder. Recrystallisation of this material from MeCN/Et_2O afforded dark red microcrystals which were filtered, washed with Et_2O and dried in vacuo. Yield 0.32 g, 37%. Calc. for $C_{21}H_{21}F_{12}FeN_{15}P_2$:

C, 30.4; H, 2.6; N, 25.3. Found: C, 30.7; H, 2.8; N, 25.5%. IR (nujol): 3143w, 1607m, 1559s, 1511m, 1349m, 1287m, 1220s, 1165s, 1149m, 1066m, 1046m, 1018m, 1008m, 923m, 860br vs, 770s, 735m, 701m, 645m, 634m, 558m, 522m cm^{-1}.

2.11. Synthesis of $[Fe(L^2Me)_3]SO_4 \cdot 2H_2O$ [$2SO_4 \cdot 2H_2O$]

An aqueous (50 cm^3) mixture of $FeSO_4 \cdot 6H_2O$ (0.34 g, 1.0×10^{-3} mol) and L^2Me (0.50 g, 3.1×10^{-3} mol) was stirred with mild heating until all the solid had dissolved. Slow evaporation of the resultant red solution afforded a red polycrystalline solid which was dried in vacuo and analysed without further purification. Yield 0.46 g, 66%. Calc. for $C_{21}H_{25}FeN_{15}O_6S$: C, 37.6; H, 3.7; N, 31.3. Found: C, 37.7; H, 3.7; N, 31.6%. IR (nujol): 3098w, 1634br m, 1603m, 1552w, 1536m, 1511m, 1496m, 1345m, 1294m, 1278m, 1224s, 1193s, 1146s, 1020br vs, 943m, 914m, 858s, 766m, 760m, 739s, 722m, 698m, 690m, 642m, 608m, 597m, 512m cm^{-1}.

2.12. Single crystal X-ray structure determinations

Red needles of **IV** were grown from CH_2Cl_2/MeOH. For **2(ClO$_4$)$_2$ · H$_2$O**, a mixture of $Fe(ClO_4)_2 \cdot 6H_2O$ (0.38 g, 1.0×10^{-3} mol) and L^2Me (0.50 g, 3.1×10^{-3} mol) in H_2O (50 cm^3) was stirred with mild heating until all the solid had dissolved. The resultant dark red solution was filtered, and then allowed to evaporate slowly to yield clusters of small, dark red plates. Different crystals, cleaved from these clusters, were used for the two datasets of this compound. For **3 · 1.5CH$_3$CN**, a mixture of $FeCl_2 \cdot 4H_2O$ (0.21 g, 1.0×10^{-3} mol), L^2Me (0.50 g, 3.1×10^{-3} mol) and NH_4PF_6 (0.34 g, 2.1×10^{-3} mol) in MeCN (50 cm^3) was stirred at room temperature for 1 h, yielding a red solution with a small amount of white precipitate. The solution was filtered and concentrated to ca. 5 cm^3. Diffusion of Et_2O vapour into this solution initially afforded an orange oil, which slowly crystallised over several days to yield red single crystals of the product, mixed with **2(PF$_6$)$_2$** as a red powder.

Experimental details from the structure determinations are given in Table 1. Data for **IV**, **3 · 1.5CH$_3$CN** and **2(ClO$_4$)$_2$ · H$_2$O** at 150 K were collected on a Nonius KappaCCD area-detector diffractometer, using graphite-monochromated Mo Kα radiation. The data for **2(ClO$_4$)$_2$ · H$_2$O** at 296 K were obtained from a Bruker X8 Apex diffractometer, using graphite-monochromated Mo-K_α radiation generated by a rotating anode. All the structures were solved by direct methods (SHELXS-97 [21]) and refined by full-matrix least-squares on F^2 (SHELXL-97 [22]).

2.13. Single crystal X-ray structure of IV

No disorder was detected during refinement, and no restraints were applied. All non-H atoms were refined anisotropically, while all C-bound H atoms were placed in calculated positions and refined using a riding model. The two N-bound H atoms were located in the difference map and allowed to refine freely with a common isotropic thermal parameter. A Flack parameter of 4(4) was calculated from 940 Friedel pairs, meaning that the absolute configuration of the crystal could not be determined. Hence, all Friedel opposites in the data were merged for the final least-squares refinement cycles.

2.14. Single crystal X-ray structures of 2(ClO$_4$)$_2$ · H$_2$O

The asymmetric unit contains one complex dication, two ClO_4^- anions and one water molecule, all lying on a general position. At 150 K, one ClO_4^- ion was found to be disordered over three equally occupied orientations. At 296 K both ClO_4^- anions were disordered: one over two orientations with a 0.60:0.40 occupancy ratio; and the other over three orientations with occupancies of 0.50, 0.30 and 0.20. The three disorder orientations of the latter anion contained a common, wholly occupied Cl atom. At both temperatures, this disorder was modelled using the restraints Cl–O = 1.42(2) Å and O···O = 2.32(2) Å. At 150 K, the water molecule was crystallographically ordered and wholly occupied. In the 296 K crystal, however, two partial water environments were refined with occupancies of 0.50 and 0.20. At both temperatures, all wholly occupied non-H atoms were refined anisotropically, while all C-bound H atoms were placed in calculated positions and refined using a riding model. The H atoms attached to the water molecule(s) could not be located in the difference map and so were not included in the final model although they were included in the final density calculation.

2.15. Single crystal X-ray structure of 3 · 1.5CH$_3$CN

The asymmetric unit contains one complex dication, two PF_6^- anions and one MeCN molecule lying on general positions, and a second, half occupied MeCN site that is disordered across the crystallographic inversion centre $1-x, -y, 1-z$. One of the two PF_6^- anions is disordered over three equally occupied orientations. All disordered P–F bonds were restrained to 1.59(2) Å, *cis*-F···F distances to 2.25(2) Å and *trans*-F···F distances to 3.18(2) Å. The solvent molecule on a general position is also disordered over two equally occupied sites. All the solvent C–C bonds were restrained to 1.46(2) Å, C≡N bonds to 1.13(2) Å and 1,3-C···N distances to 2.59(2) Å. All wholly occupied non-H

atoms were refined anisotropically, and all H atoms were placed in calculated positions and refined using a riding model, with the methyl group torsions allowed to refine freely.

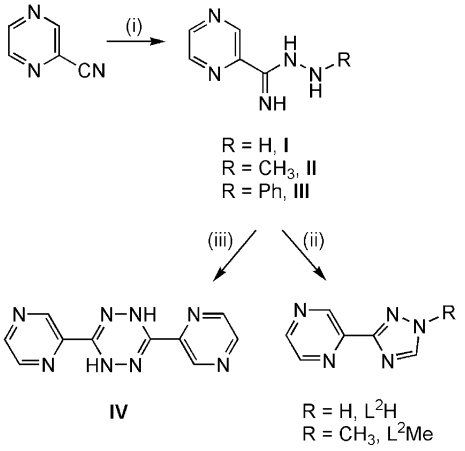
2.16. Other measurements

Infra-red spectra were obtained as Nujol mulls pressed between KBr windows, between 400 and 4000 cm^{-1} using a Nicolet Avatar 360 spectrophotometer. UV/visible spectra were obtained with a Perkin–Elmer Lambda 900 spectrophotometer, operating between 1100 and 200 nm, in 1 cm quartz cells. EI mass spectra were performed on a VG AutoSpec spectrometer while electrospray mass spectra were obtained on a Micromass LCT TOF spectrometer, employing a MeOH matrix. CHN microanalyses were performed by the University of Leeds Department of Chemistry microanalytical service. NMR spectra were run on a Bruker ARX250 spectrometer, operating at 250.1 MHz (^1H) or (^{13}C). Magnetic susceptibility measurements were obtained using a Quantum Design SQUID magnetometer in an applied field of 1000 G. Diamagnetic corrections were estimated from Pascal's constants [23].

3. Results and discussion

The ligands L^2H and L^2Me have been synthesised previously by Nieuwenhuis et al. [12], by the method shown in Scheme 1. We obtained a higher yield of the amidrazone derivative **II**, compared to these workers, by using an excess of methylhydrazine reagent and a modified work-up procedure. However the method of Nieuwenhuis et al. using a stoichiometric amount of hydrazine was followed for **I** and **III**, since separation of these crude products from an excess of hydrazine reagent proved difficult. We also obtained higher yields for the second step of the synthesis [(ii) in Scheme 1] compared to the literature method, by carrying out the reactions at reflux and through a modified work-up. Our attempts to extend this methodology to the preparation of L^2Ph were unsuccessful, with **III** being recovered largely unchanged following step (ii). Nieuwenhuis et al. [12] have also reported the synthesis of L^3H, by treatment of **I** with acetic acid. Our own attempts to replicate that reaction at reflux or at room temperature yielded 1,4-dihydro-3,6-dipyrazinyl-1,2,4,5-tetrazine (**IV**) [20] as a major product, together with several other unidentified byproducts. The identity of **IV**was unambiguously confirmed from an X-ray crystal structure (Fig.1). However, the bulk sample of **IV** also showed the correct highest molecular ion by EI mass spectrometry ($m/z = 240$) and an identical ^1H NMR spectrum to that reported previously for this compound [20], thus confirming its identity. The formation of **IV** implies that acetic acid is a weaker electrophile than **I** under the reaction conditions, so that **I** prefers to nucleophilically attack another molecule of itself [24]. In the light of this result, the synthesis of L^3H and other L^3R ligands was not pursued further. Although they are not isostructural, the molecular structure of **IV** in the crystal closely resembles that of 1,4-dihydro-3,6-dipyridyl-1,2,4,5-tetrazine [25].

The red complexes $[Fe(L^2Me)_3](BF_4)_2$ [**2(BF$_4$)$_2$**] and $[Fe(L^2Me)_3](ClO_4)_2$ [**2(ClO$_4$)$_2$**] were readily obtained by direct complexation of the appropriate ligand and hydrated Fe(II) salt in MeCN or acetone, respectively. In addition, slow evaporation of a mixture of $Fe(ClO_4) \cdot 6H_2O$ or $FeSO_4 \cdot 6H_2O$ and 3 equiv. of L^2Me in water afforded the red polycrystalline hydrates $[Fe(L^2Me)_3](ClO_4)_2 \cdot H_2O$ [**2(ClO$_4$)$_2$ · H$_2$O**] and $[Fe(L^2Me)_3]SO_4 \cdot 2H_2O$ [**2(SO$_4$) · 2H$_2$O**]. The presence of water in these materials was confirmed from a characteristic H–O–H bending vibration near 1635 cm^{-1} in their IR spectra [26]. While **2(SO$_4$) · 2H$_2$O** retains its water content in vacuo, drying **2(ClO$_4$)$_2$ · H$_2$O** in vacuo over P_2O_5 afforded analytically pure anhydrous **2(ClO$_4$)$_2$**. Finally, $[Fe(L^2Me)_3](PF_6)_2$ [**2(PF$_6$)$_2$**] was synthesised by reaction of $FeCl_2 \cdot 4H_2O$, L^2Me and NH_4PF_6 in a 1:3:2 molar ratio in water. The resultant red polycrystalline precipitate



Scheme 1. Syntheses of the ligands used in this study. (i) 1 eq. (R = H) or 5 eq. (R = Me) H_2NNHR, EtOH, RT, 2 h. (ii) **I** or **II**, HCO_2H, 0 °C → reflux, 2 h. (iii) **I**, CH_3CO_2H, 0 °C → reflux, 2 h.

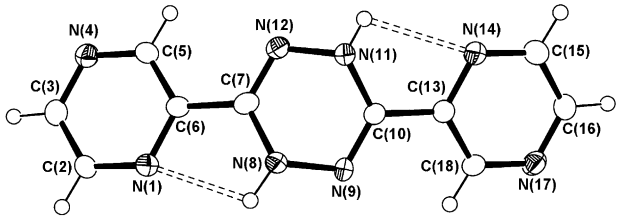


Fig. 1. View of the asymmetric unit in the single crystal structure of 1,4-dihydro-3,6-dipyrazinyl-1,2,4,5-tetrazine (**IV**). Thermal ellipsoids are at the 50% probability level and H atoms have arbitrary radii.

was recrystallised from MeCN/Et_2O to remove a white impurity, yielding an anhydrous product that contained no chloride by microanalysis (see below). Preparing salts of $[Fe(L^2H)_3]^{2+}$ proved more difficult. Solvent-free $[Fe(L^2H)_3](ClO_4)_2$ [**1(ClO$_4$)$_2$**] was obtained as a dark red-brown powder, upon reaction of $Fe(ClO_4) \cdot 6H_2O$ and 3 equiv. of L^2H in MeOH. Attempts to prepare this complex, or the BF_4^-, PF^{6-} and SO^{42-} salts of the same dication, in water or any other of the common organic solvents led only to intractable oils. Similarly, impure compounds were obtained following attempts to prepare the salts of $[Fe(L^2Me)_3]^{2+}$ by procedures different from those described above. This is discussed further below.

Complex **2(ClO$_4$)$_2$ · H$_2$O** crystallises from water as clusters of plates, from which small fragments could be cleaved for X-ray analysis. A full dataset to $2\theta = 55°$ from one such fragment was achieved at 150 K. Unfortunately, the crystals diffracted very weakly at higher temperatures. We were able to collect a complete dataset of **2(ClO$_4$)$_2$ · H$_2$O** to $2\theta = 42°$ at 296 K, using a different diffractometer fitted with a more intense, rotating anode X-ray source. Although the observed data:parameter ratio was low, this determination did show that the bond lengths and angles at Fe(1) are equal to within four standard uncertainties at the two temperatures (Table 2). Hence, only the 150 K crystal structure will be described in detail.

The $[Fe(L^2Me)_3]^{2+}$ dication in **2(ClO$_4$)$_2$.H$_2$O** has an octahedral geometry, that is slightly distorted by the bite angle of the chelating ligands (Table 2, Fig. 2). The triazole ring of the L^2Me ligand is coordinated through *N*4,

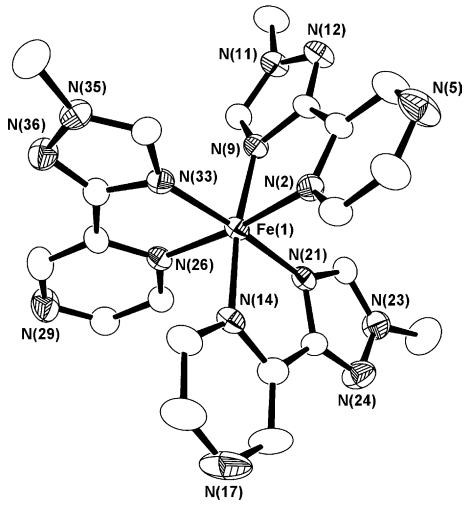

Fig. 2. View of the complex dication in the single crystal structure of $[Fe(L^2Me)_3](ClO_4)_2 \cdot H_2O$ [**2(ClO$_4$)$_2$ · H$_2$O**] at 150 K. All H atoms have been omitted for clarity. Thermal ellipsoids are at the 50% probability level. The structure of this compound at 296 K is visually indistinguishable from that shown here, and uses the same atom numbering scheme.

as is usual in iron complexes of triazole-containing chelates [17,18,27]. The complex crystallises as its *mer* isomer, which is the more commonly observed isomer for Fe(II) complexes of asymmetric heterocyclic chelates [11,17,18,28], including $[Fe(L^4H)_3](BF_4)_2 \cdot 2H_2O$ [17]. The Fe–N bond lengths clearly demonstrate that the complex is fully low spin at both 150 and 296 K (Table 2). While the H atoms of the lattice water molecule O(48) could not be located in the difference map, it is clear that the molecule is positioned to hydrogen bond to the disordered ClO_4^- anion Cl(43)–O(47) (not shown in Fig. 2), and to its symmetry equivalent Cl(43^i)–O(47^i) related by $0.5 + x$, y, $-0.5 + z$. This is evidenced by a range of O(48)···O distances between the water molecule and partial O atoms from these disordered anions, of 2.79–3.19 Å. The water molecule also accepts a C–H···O hydrogen bond from the pyrazine C–H group C(4)–H(4), with C(4)···O(48) = 3.375(5) Å, H(4)···O(48) = 2.44 Å and C(4)–H(4)···O(48) = 167.0°. Importantly, there is no hydrogen bonding to any of the non-coordinated pyrazine or triazole N atoms in the $[Fe(L^2Me)_3]^{2+}$ dication.

Variable temperature susceptibility measurements between 5 and 340 K were run on all of the complex salts prepared in this study. The sample of **2(ClO$_4$)$_2$** employed for these measurements was obtained from dried polycrystalline **2(ClO$_4$)$_2$ · H$_2$O**. All of the compounds except one (see below) undergo spin-state transitions, although these differ substantially in form (Fig. 3). Three different types of behaviour can be distinguished, which will be discussed in turn. The compounds **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** exhibit a very gradual and incomplete spin-state transition upon cooling, with a substantial residual

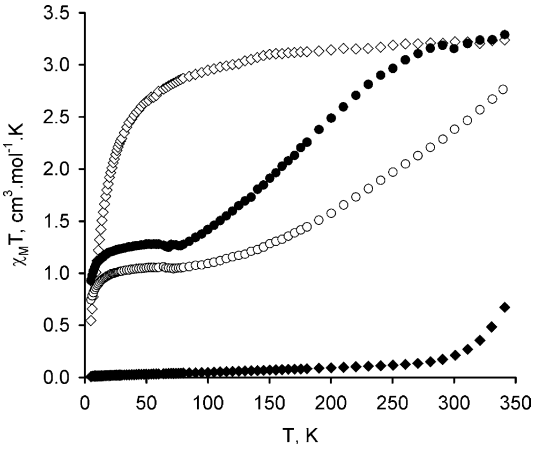

Fig. 3. Variable temperature susceptibility data from powdered **1(ClO$_4$)$_2$** (○), **2(ClO$_4$)$_2$** (●), **2(PF$_6$)$_2$** (♦) and **2(SO$_4$)·2H$_2$O** (◇). The behaviour of **2(BF$_4$)$_2$**, not shown in the figure, is very similar to that of **2(PF$_6$)$_2$**.

high-spin fraction below the transition temperature range (Table 3). A small additional decrease in $\chi_M T$ below 50 K for these compounds reflects zero-field splitting of the residual high-spin $S = 2$ manifold (Fig. 3). $\chi_M T$ for **2(ClO$_4$)$_2$** at 340 K is 3.29 cm^3 mol^{-1} K, showing that it is fully high-spin at this temperature [23]. However, **1(ClO$_4$)$_2$** shows $\chi_M T \approx 2.76$ cm^3 mol^{-1} K at 340 K, implying that this compound is in a mixture of spin-states. If $\chi_M T$ for fully high-spin **1(ClO$_4$)$_2$** is also 3.3 cm^3 mol^{-1} K, then $T_{1/2} \approx 277$ K and ca. 68% of the iron sites in this material undergo spin-crossover.

In contrast to these data, **2(BF$_4$)$_2$** (not shown in Fig. 3) is essentially diamagnetic at low temperatures, but exhibits an increase in $\chi_M T$ upon warming above ca. 200 K to reach 0.85 cm^3 mol^{-1} K at 340 K. The behaviour of **2(PF$_6$)$_2$** is similar, with $\chi_M T$ increasing from 0.09 cm^3 mol^{-1} K at 200 K to 0.68 at 340 K (Fig. 3). These data indicate that both compounds undergo a complete, high-temperature spin-state transition. The midpoint $T_{1/2}$ for both compounds is near 400 K if the $\chi_M T$ versus T curves below 340 K are extrapolated, and if $\chi_M T$ for their fully high-spin states is 3.3 cm^3 mol^{-1} K.

Finally, $\chi_M T$ for **2(SO$_4$)·2H$_2$O** is near-constant at 3.20 ± 0.05 cm^3 mol^{-1} K upon cooling to ca. 200 K, before decreasing in a smooth curve to 0.54 cm^3 mol^{-1} K at 5 K without reaching a plateau (Fig. 3). This curve can be modelled reasonably using the Curie–Weiss law for a $S = 2$ paramagnet with $g = 2.14$ and $\theta = -16.8$ K. The low-temperature decrease in $\chi_M T$ is unlikely to arise from zero-field splitting of the high-spin iron(II) spins, because the zero-field splitting constant $|D|$ obtained by fitting these data [23] is 41.7 cm^{-1}. That is an extremely high value for high-spin Fe(II) with six N-donor ligands; by comparison, $|D|$ calculated for the high-spin fractions of **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** below 80 K ranges from 7.8 to 8.7 cm^{-1}. Rather, the low-temperature decrease in $\chi_M T$ may be caused by a spin-state transition with $T_{1/2} = 15$ K and 83% completeness at 5 K. Or, it could reflect weak ($|J| = 1$–2 cm^{-1}) antiferromagnetic coupling between high-spin iron(II) centres in the solid. In the absence of any structural or Mössbauer spectroscopic data on **2(SO$_4$)·2H$_2$O**, it is impossible to distinguish between these two possibilities.

The ^{1}H NMR spectra of **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** in CD_3CN or $\{CD_3\}_2CO$ at 293 K are strongly contact-shifted, demonstrating that they are predominantly high-spin in these solvents. The spectra of **1(ClO$_4$)$_2$** both show three contact-shifted peaks, while those of **2(ClO$_4$)$_2$** show four peaks. In both cases, this is one fewer than the number of unique C-bound H environments in the relevant L^{2}R (R = H or Me) ligands. It is most likely the pyrazine *H* 6 environment that is not detected in these spectra owing to dipolar broadening, since this H atom will be the closest in space to the high-spin Fe(II) centre [29]. Importantly, the spectra of **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** in both solvents show the same number of peaks with chemical shifts that vary by up to 7 ppm between solvents. This suggests that there are only small differences between the chemical and/or magnetic structures of these compounds in different solvents. Importantly, however, electrospray mass spectra of all the complexes in this study showed substantial exchange of Na for the Fe content of the samples, to the extent that no Fe-containing molecular ions were detected under the conditions used. This shows that these complexes are in fact labile in solution, as we have previously noted for [Fe(L^1)$_3$]$^{2+}$ [11].

Some insight into our difficulties preparing other salts of [Fe(L^{2}H)$_3$]$^{2+}$ (see above) was provided by the crystallisation of [{FeCl(L^{2}Me)$_2$}$_2$(μ-O)](PF$_6$)$_2$·1.5CH$_3$CN

Table 3
Summary of the magnetic data for the spin-state transitions shown by the compounds in this study

	$\chi_M T$ (340 K) (cm^3 mol^{-1} K)	$\chi_M T$ (70 K) (cm^3 mol^{-1} K)	$T_{1/2}$ (K)	Completeness (%)
1(ClO$_4$)$_2$	2.76	1.05	≈277	≈68
2(BF$_4$)$_2$	0.85	0.03	≈385	≈100
2(ClO$_4$)$_2$	3.29	1.27	182	61
2(PF$_6$)$_2$	0.68	0.04	≈400	≈100
2(SO$_4$)·2H$_2$O[a]	3.25	2.81	15	83 [at 5 K]

$T_{1/2}$ corresponds to the temperature at which $\chi_M T = [3.3 + \chi_M T(70\text{ K})]/2$.
[a] It is uncertain whether this compound actually undergoes a spin-state transition. See text for more details.

(**3 · 1.5CH$_3$CN**) from a reaction of $FeCl_2 \cdot 4H_2O$, 3 equiv. L^2Me and 2 equiv. NH_4PF_6 in MeCN. The theoretical C, H and N microanalyses of **3** and **2(PF$_6$)$_2$** are indistinguishable within experimental error. However, from the Cl analysis of the bulk material of $1.6 \pm 0.2\%$, the products of this reaction appeared to be a mixture of these two compounds in approximately a 1:3 **3**:**2(PF$_6$)$_2$** ratio. Compound **3** is a product of the aerobic autooxidation of the Fe(II) content of the reaction mixture to Fe(III), a common feature of the iron chemistry of N-donor ligands. The molecular structure of **3** resembles those of $[\{FeCl(L)_2\}_2(\mu\text{-}O)]^{2+}$ (L = bipy, 4,4′-Me$_2$ bipy or phen) [30], bearing two *cis*-$[FeCl(L^2Me)_2]^{2+}$ moieties linked by a near-linear oxo bridge (Table 4, Fig. 4). The two octahedral Fe centres adopt a near-staggered conformation, with the torsion Cl(4)–Fe(1)···Fe(2)–Cl(29) being 87.38(5)°. This facilitates an intramolecular π–π interaction between the ligands N(17)–C(28) and N(42)–C(53) which lie 3.617(16) Å apart, with a dihedral angle of 8.60(11)° between their least squares planes. There are two apparent intramolecular C–H···Cl hydrogen bonds between the triazole C–H groups C(13)–H(13) and C(38)–H(38), and the Cl ligands bound to the opposite Fe atom (Fig. 4). This is suggested by the distances H(13)···Cl(29) = 2.86 Å and H(38)···Cl(4) = 2.81 Å, which are substantially shorter than the 3.0 Å sum of the van der Waals radii of a H and a Cl atom [31], and the angles C(13)–H(13)···Cl(29) = 152.5 and C(38)–H(38)···Cl(4) = 152.7°. These C–H···Cl contacts are also most likely to be responsible for the displacement of Fe(1) and Fe(2) out of their equatorial planes of ClN_3 ligand donors towards O(3), by 0.2688(13) [Fe(1)] and 0.2795(12) Å [Fe(2)]. The other bond lengths and angles in **3** are unexceptional.

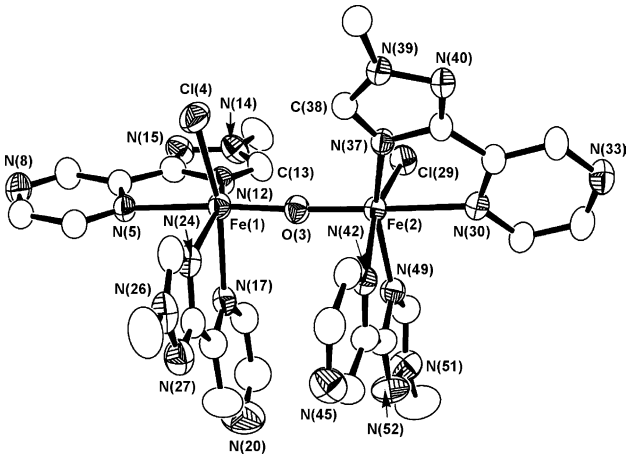

Fig. 4. View of the complex dication in the single crystal structure of $[\{FeCl(L^2Me)_2\}_2(\mu\text{-}O)](PF_6)_2 \cdot 1.5CH_3CN$ [**5 · 1.5CH$_3$CN**]. All H atoms have been omitted for clarity. Thermal ellipsoids are at the 50% probability level.

4. Concluding remarks

The only structural information we were able to gain from a $[Fe(L^2R)_3]^{2+}$ complex was from **2(ClO$_4$)$_2$ · H$_2$O**. The low-spin nature of this hydrate at 296 K is inconsistent with the spin-state transition shown by anhydrous **2(ClO$_4$)$_2$** upon cooling, but does resemble **2(BF$_4$)$_2$** and **2(PF$_6$)$_2$** which are predominantly low-spin at room temperature. With that in mind, it is a little surprising that **2(ClO$_4$)$_2$** does not show the same type of complete high-temperature spin-state transition as these other two compounds, given that the ClO_4^- counterion has the same near-spherical shape as BF_4^- and PF_6^-, and lies between them in size [32]. Notwithstanding this anomaly, the very different spin-state regimes shown by several of the complexes in this study demonstrate that spin-crossover in this system is dependent on the local environment of the $[Fe(L^2R)_3]^{2+}$ centres in their solids. While the presence (or absence) of lattice water is clearly important, in **2(ClO$_4$)$_2$ · H$_2$O** at least this influence does not arise from hydrogen bonding to the complex dications. Rather, the dominant factor controlling the different spin-state regimes in this system is probably the local steric environment about the complex dications in each material. Unfortunately more detailed explanations for the anomalous spin-state transition of **2(ClO$_4$)$_2$**, and whether or not **2(SO$_4$) · 2H$_2$O** actually undergoes spin-crossover at very low temperatures, are unclear in the absence of structural and/or Mössbauer spectroscopic data on these compounds.

The magnetochemistry of **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** strongly resembles that of many hydrated or anhydrous salts of $[Fe(L^4R)_3]^{2+}$ (R = H, Me) in showing a gradual, incomplete spin-state transition upon cooling with a large residual high-spin fraction [15–18]. In the one case where this transition been fully characterised, namely $[Fe(L^4H)_3](BF_4)_2 \cdot 2H_2O$, the incompleteness of the spin-state transition was attributed to anion/water site disorder in the crystal, which results in different molecules in the sample having different local environments [17,18]. Since we do not have structural data on **1(ClO$_4$)$_2$** and anhydrous **2(ClO$_4$)$_2$**, it is unclear whether anion disorder is also the origin of their incomplete spin-crossover. There are two other potential explanations for the incomplete spin-state transitions in this study, however. First, it might be that a fraction of the $[Fe(L^2R)_3]^{2+}$ sites in **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** contain triazole centres coordinated through *N*2 rather than *N*4. This coordination mode is unusual for mononuclear complexes of 3-pyridyl-1,2,4-triazole-type chelates, and is apparently unknown for compounds of this type containing first row transition ions [17,18,29] (the only crystallographically characterised examples have the formula $[Ru(bipy)_2(L)]^{2+}$ {L = L^4H or a 5-substituted derivative of it} [14,33]). However, linkage isomerism of the triazole donors in bulk samples of $[Fe(L^2R)_3]^{2+}$ and $[Fe(L^4R)_3]^{2+}$ cannot be ruled out. Alternatively, is that the six-coordinate Fe(II) centres in **1(ClO$_4$)$_2$** and **2(ClO$_4$)$_2$** exist as a mixture of *fac*- and *mer*-stereoisomers. That is certainly possible; for example, both *fac*- and *mer*-isomers of $[Fe(L^1)_3]^{2+}$ have been crystallised using different counterions [11]. This explanation would require that the *mer*-complex centres give rise to the residual high-spin iron fraction at low temperatures, as precedent suggests that *fac*-isomers of $[FeL_3]^{2+}$ (L = a bis-N-donor chelate) tend to favour low-spin configurations more than their corresponding *mer*-isomers [34].

5. Supplementary data

Full crystallographic data for the structure analyses in this study are available on request from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK. The CCDC deposition numbers are 236851 [**3 · 1.5CH$_3$CN**], 236852 [**IV**], 236853 [**2(ClO$_4$)$_2$ · H$_2$O** at 150 K] and 236854 [**2(ClO$_4$)$_2$ · H$_2$O** at 296 K].

Acknowledgements

The authors thank Dr. H.J. Blythe (University of Sheffield, UK) for the susceptibility data, and the EPSRC and the University of Leeds for funding.

Abstract

Two new molybdenum phosphates, $[Co(en)_3][C_4H_{12}N_2]_{0.5}[(Mo_5O_{15})(HOPO_3)_2]\cdot 3H_2O$ (**1**) (en = ethylenediamine) and $(C_4N_2H_{10})_5[Co_3Mo_{12}O_{18}(HOPO_3)_6(PO_4)_2(OH)_{12}(H_2O)_4]\cdot 9H_2O$ (**2**), have been synthesized hydrothermally. **1** is constructed from $[Mo_5P_2O_{21}(OH)_2]^{4-}$ clusters, $Co(en)_3^{3+}$ and piperazine, which are linked together through hydrogen-bonding interactions. The enantiomers of $Co(en)_3^{3+}$ in **1** are separated as Δ and Λ configurations. **2** is composed of centrosymmetric $Co[Mo_6O_9(OH)_6(HOPO_3)_3(PO_4)]_2$ clusters linked by dinuclear cobalt cations forming a three dimensional structure. The interconnected voids and channels in **2** are filled with piperazine and water molecules. The three dimensional **2** was obtained from the zero dimensional **1** under hydrothermal reaction conditions. This experiment demonstrates that molybdenum phosphates of low dimensional structure could be employed as starting materials to prepare molybdenum phosphates of high dimensional structure.

1. Introduction

The cooperative assembly of organic and inorganic components has given rise to a wide variety of new materials [1]. Among the organic–inorganic hybrid materials reported, molybdenum phosphates have become good candidates owing to their attractive characters ranging from potential applications such as catalysis and medicine [2,3] to the diversity of their structures [4–10]. The investigation of incorporating d-block elements into molybdenum phosphates [4,8–25] as stoichiometric framework constituents has resulted in metal molybdenum phosphates with remarkable structural diversities [8–10] when compared with the well-characterized building units $[P_4Mo_6O_{25}(OH)_3]^{9-}$ [11–21] and $[P_2Mo_5O_{23}]^{6-}$ [22–25]. Recently, chiral transitional metal complexes have been often used as template agents in the synthesis of phosphates since the first example was reported by Morgan et al. [26]. Some studies have demonstrated that the chirality of these complexes could be transferred to the inorganic networks through the formation of "chiral pockets" [27–30]. In 2001, Rao et al. showed that low dimensional zinc phosphates could transform into complex open-framework structures under appropriate reaction conditions [31–33]. In our experiments, $Co(en)_3Cl_3$, MoO_3, piperazine and H_3PO_4 were selected as starting materials to prepare a molybdenum phosphate $[Co(en)_3(C_4H_{12}N_2)_{0.5}(Mo_5O_{15})(HOPO_3)_2]\cdot 3H_2O$ (en = ethylenediamine) (**1**), which has a

zero dimensional structure constructed from monomers of $[Mo_5P_2O_{21}(OH)_2]^{4-}$ clusters, $Co(en)_3^{3+}$ and piperazine. Then **1** was disposed in the mother liquor and heated at a higher temperature. Another product, $(C_4N_2H_{10})_5[Co_3Mo_{12}O_{18}(HOPO_3)_6(PO_4)_2(OH)_{12}(H_2O)_4]\cdot 9H_2O$ (**2**), with a three dimensional framework was obtained.

2. Experimental

2.1. Synthesis

1 was synthesized through the hydrothermal reaction of $Co(en)_3Cl_3$, MoO_3, H_3PO_4, $C_4N_2H_{10}$ and H_2O in a molar ratio of 1.0:2.4:6.0:3.0:288.0. Typically, 0.8 g $Co(en)_3Cl_3$, 0.8 g MoO_3 and 0.6 g piperazine were dissolved in 12 ml of water, 1 ml H_3PO_4 (85 wt%) was added dropwise with stirring. After stirring for 1h, the mixture was transferred into a Teflon-lined stainless steel autoclave and heated at 413 K for 4 days under autogenous pressure. Orange rod-like crystals as a single phase (90% based on Mo) were then filtered, washed with distilled water and dried at room temperature. *Anal*. Calc. for $C_8H_{38}CoMo_5N_7O_{26}P_2$: C, 7.69; H, 3.04; N, 7.85. Found: C, 7.83; H, 2.97; N, 7.94%. The simulation of single-crystal X-ray diffraction data accords with the experimental X-ray powder diffraction data well.

2 was prepared by heating **1** (0.5 g), which was dried at room temperature for 2 days, in 10 ml of the mother liquor of **1** at 443K for 2 days. Dark red crystals were obtained as a single phase in good yield (80% based on Mo). *Anal*. Calc. for $C_{20}H_{94}Co_3Mo_{12}N_{10}O_{75}P_8$: C, 7.38; H, 2.89; N, 4.31. Found: C, 7.47; H, 2.78; N, 4.44%.

2.2. Measurements and materials

X-ray powder diffraction (XRD) data were collected on a Shimadazu XRD-6000 diffractometer with Cu Kα radiation ($\lambda = 1.5418$ Å).

Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 CHN Elemental Analyzer.

A Perkin–Elmer TGA 7 unit was used to carry out the thermogravimetric analysis (TGA) in air with a heating rate of 20 °C/min.

IR spectra were recorded in the range 400–4000 cm^{-1} on a Nicolet 5PC FT-IR spectrophotometer using KBr pellets.

2.3. X-ray crystallography

The X-ray single-crystal structure analyses of **1** and **2** were performed on a Rigaku R-AXIS RAPID diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å, graphite monochromator) in the Ψ rotation scan mode. The structure determinations were done with direct methods by using SHELXL 5.01v and refinements with full-matrix least squares on F^2. The structures were solved by direct methods and refined on F^2 by full-matrix least squares using SHELXTL-97 [34]. No adsorption correction was applied. H atoms were placed geometrically and refined using a riding model. All non-hydrogen atoms were refined anisotropically. Experimental details for the structure determinations are presented in Table 1.

3. Results and discussions

3.1. Structure of $[Co(en)_3][C_4H_{12}N_2]_{0.5}[(Mo_5O_{15})(HOPO_3)_2]\cdot 3H_2O$ (1)

In **1**, the inorganic cluster, $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ (Fig. 1), is quite similar to that reported by Burkholder and Zubieta [22] and Hedman [35]. Selected bond distances of **1** are summarized in Table 2. The structure of **1** consists of $[Co(en)_3]^{3+}$, $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ clusters, piperazine and water molecules, which construct the framework though hydrogen-bonding (Fig. 2). The structure of $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ can be considered as a ring formed by five distorted edge- and corner-sharing MoO_6 octahedra capped on both poles by a phosphate tetrahedron sharing three vertices with the ring molybdenum centers. Based on the bond parameter results from bond valence sum calculations [36], all the Mo atoms have a +6 oxidation state, which agrees with the expected value of 6.00 for Mo atoms in the $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ building block. Bond lengths of MoO_6 and PO_4 are all within the expected range.

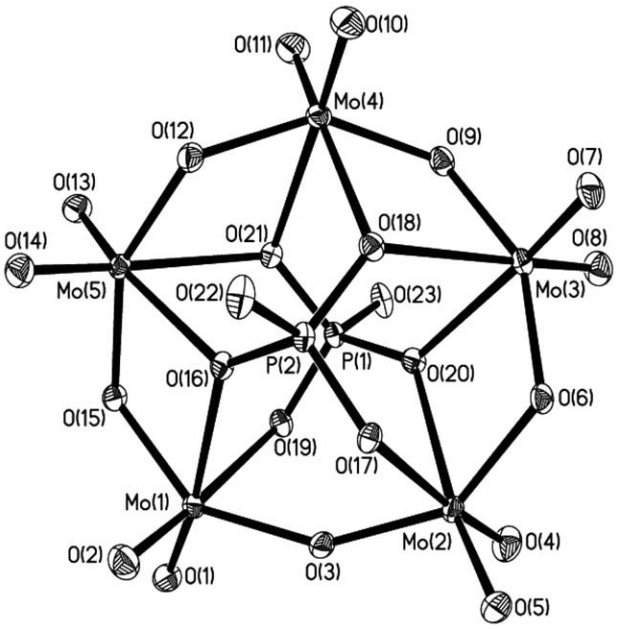

Fig. 1. The structure of $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ anionic cluster showing the atom-labelling scheme and the 50% probability displacement ellipsoids. H atoms have been omitted for clarity.

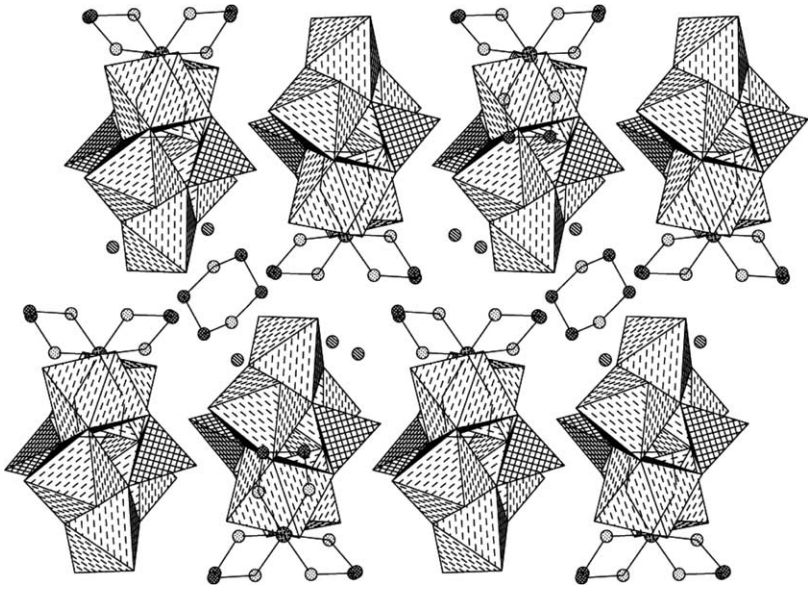

Fig. 2. Polyhedral representation of $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ anion and ball-and-stick representation of the $[Co(en)_3]^{3+}$ cations and piperazines along the *a*-axis. Water molecules and H atoms have been omitted for clarity.

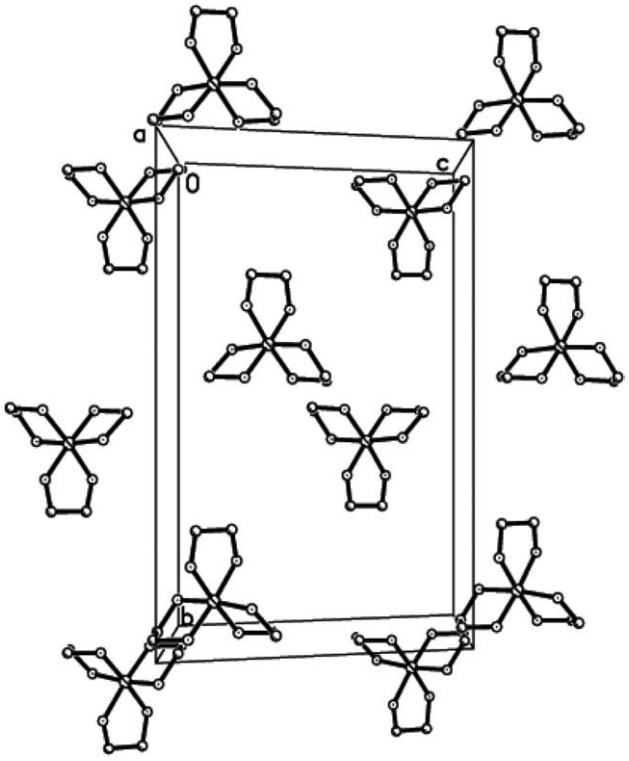

Fig. 3. Δ and Λ configurations of $[Co(en)_3]^{3+}$ pairs in alternative regions in the structure of **1**.

The metal complexes $[Co(en)_3]^{3+}$ in **1** separate the inorganic clusters of $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$. Interestingly, the enantiomers of the cobalt complexes are separated as Δ and Λ configurations and appear as pairs of enantiomers (Fig. 3). Similar results have been reported by other authors when $[Co(en)_3]^{3+}$ is used as a template in the synthesis of phosphates [26,27].

The framework of **1** is stabilized by extensive intermolecular multi-point hydrogen bonding involving inorganic clusters, $Co(en)_3^{3+}$, piperazine and water molecules. Hydrogen-bonding occurs between the P–OH groups with μ_2-O(17) and μ_2-O(19) in adjacent $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ clusters. As a result, the inorganic clusters form a chain-like structure (Fig. 4). Each amino group in $[Co(en)_3]^{3+}$ and the piperazine form extensive hydrogen bonds with oxygen atoms in the $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ luster and water molecules with N···O separation distances ranging from 2.726 to 3.320 Å. Water molecules also form hydrogen bonds with three terminal oxygen atoms O(2), O(4) and O(7) in the inorganic clusters.

3.2. Structure of $(C_4N_2H_{10})_5[Co_3Mo_{12}O_{18}(HOPO_3)_6(PO_4)_2(OH)_{12}(H_2O)_4]\cdot 9H_2O$ (**2**)

In **2,** the building block (Fig. 5) of the crystal consists of two $Co(1)_{0.5}[Mo_6O_9(OH)_6(HOPO_3)_3(PO_4)]$ (Co-$[Mo_6P_4]$) units and dinuclear Co cations in an octahedral environment. The geometry of the Co(1)-$[Mo_6O_9(OH)_6(HOPO_3)_3(PO_4)]_2$(Co$[Mo_6P_4]_2$) unit (Fig. 6) is very similar to that observed in several sodium, iron or zinc molybdenum phosphates [14–21]. Six MoO_6 in Co$[Mo_6P_4]$ units form a hexagonal ring by sharing edges, and the four phosphate tetrahedra are corner-sharing with the corresponding molybdenum octahedron. Among the four phosphate groups, three around the periphery of the ring bridge the three non-bonded Mo···Mo dimers and the one in the center bridges the three non-bonded Mo atoms from the ''inside'' of the Mo_6 ring. Bond valence sum calculations [36] indicate that all the molybdenum atoms are pentavalent, the cobalt atoms are bivalent, the phosphate atoms are pentavalent, O(1), O(3), O(4), O(13), O(23), O(26), O(28), O(29) and O(30) are oxygen atoms of OH groups, and O(8) and O(24) are oxygen atoms of water molecules. The oxidation state of all other oxygen atoms is −2. In **2,** there are three Mo–Mo bonding contacts and the Mo–Mo bond distances are 2.5898(6), 2.5914(6) and 2.5943(6) Å for Mo(1)–Mo(5), Mo(2)–Mo(3) and Mo(4)–Mo(6), respectively (Table 3).

In the structure of **2**, each Co$[Mo_6P_4]_2$ unit is coordinated to six dinuclear Co cation via six oxygen atoms of six peripheral phosphate groups, and each dinuclear Co cations in turn contacts six phosphate groups from six different Co$[Mo_6P_4]_2$ units (Figs. 6 and 7). The resulting three dimensional anionic framework delimits channels running along the [1 0 0] axes. The structure is similar to two molybdenum phosphates $(TMA)_2(NH_4)_2[Fe_2$-

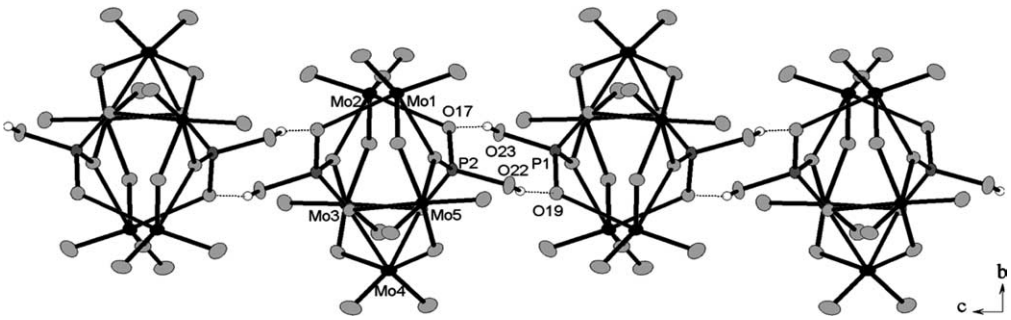

Fig. 4. View of connection of $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ clusters forming a chain-like structure by hydrogen bonds interactions shown by dotted lines.

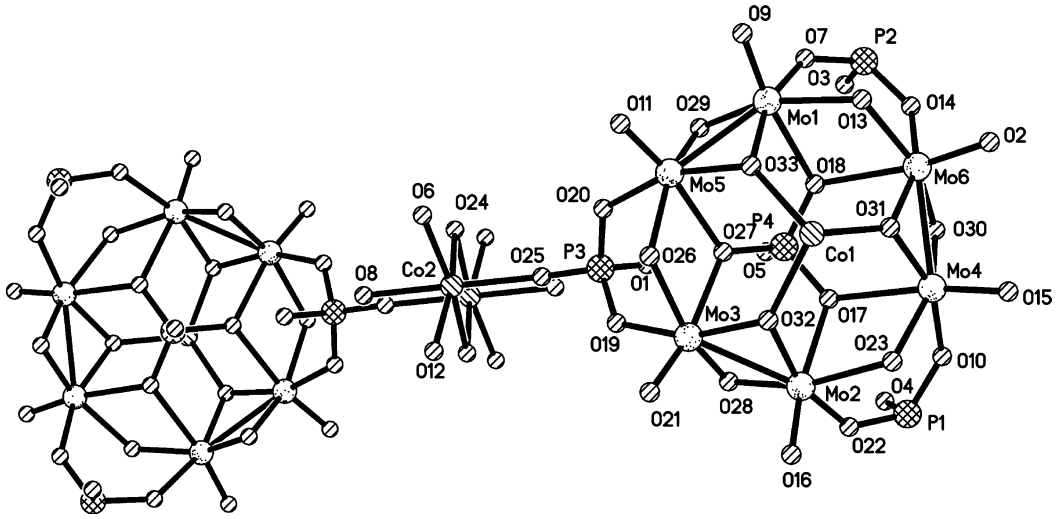

Fig. 5. Perspective view of a representative fragment of **2** showing the atom numbering scheme and the 50% probability displacement ellipsoids. H atoms have been omitted for clarity.

$Mo_{12}O_{30}(H_2PO_4)_6(HPO_4)_2]\cdot nH_2O$ [14] and $Na_{12}Co_3$-$[(PO_4)_4Mo_6O_{12}(OH)_3]_2\cdot 44H_2O$ [11]. A noteworthy feature in the structure of **2** is the presence of the dinuclear Co cations, while in other molybdenum phosphates [11–15,17,19–21] containing $[Mo_6P_4]$ building units, the three dimensional frameworks are formed through coordination of the inorganic groups with transition metal cations in the mononuclear form. The structure of **2** is stabilized by multipoint hydrogen bonds among $[(Mo_5O_{15})(HOPO_3)_2]^{4-}$ clusters, piperazine and lattice water molecules.

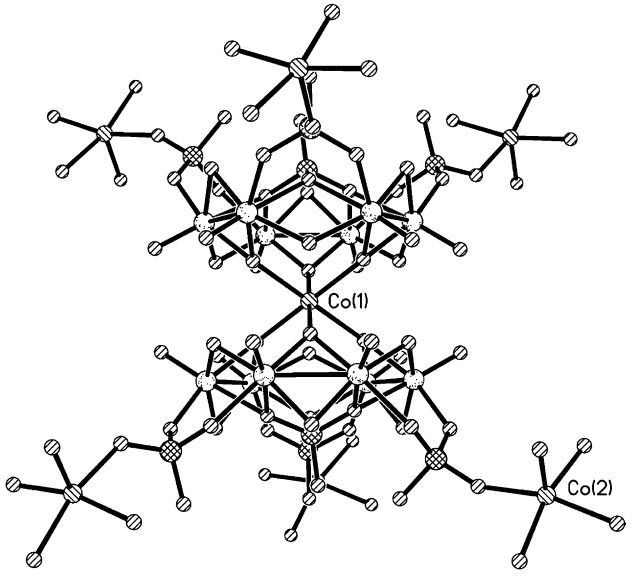

Fig. 6. Perspective view of the $Co[Mo_6P_4]_2$ building unit.

Symmetry transformations used to generate equivalent atoms: #1 $-x+1,-y+2,-z$; #2 $-x,-y+1,-z+1$; #3 $x,y+1,z$; #4 $x+1,y,z$; #5 $x,y-1,z$; #6 $x-1,y,z$.

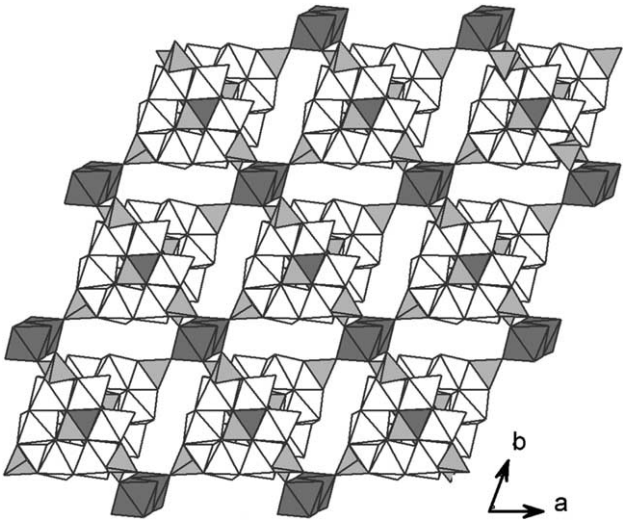

Fig. 7. Polyhedral view of the 3D network parallel to the *c*-axis in **2** showing that each $Co[Mo_6P_4]_2$ unit is coordinated to six dinuclear Co cations via six oxygen atoms of six peripheral phosphate groups, and each dinuclear Co cation in turn contacts six phosphate groups from six different $Co[Mo_6P_4]_2$ units. All C, H, N atoms and water guests are omitted for clarity.

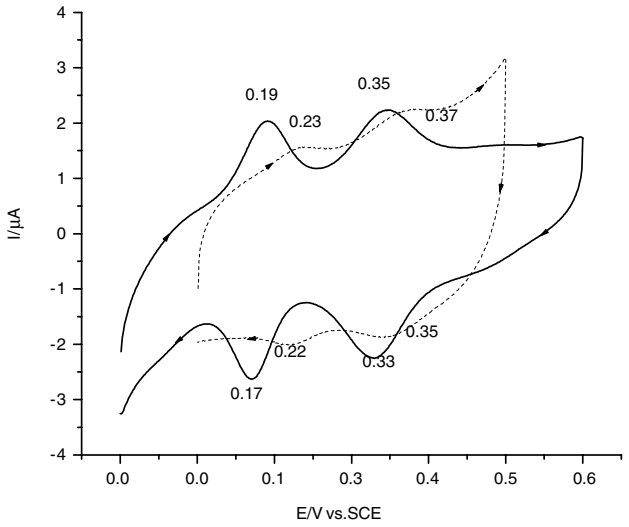

Fig. 8. Cyclic voltammograms (100 mV/s) in hydrochloric acid solution of **1** (solid line) and **2** (dashed line). Peak potentials vs. SCE are indicated.

3.3. TGA-DSC thermal analysis and IR spectra

TG analysis of **1** shows that a weight loss of about 4.0 wt% occurs below 200°C, which is attributed to the loss of water molecules in **1** (calc. 4.3 wt%). A weight loss of 20.5 wt% occurring in the temperature range 250–650 °C is attributed to the decomposition of the metal complexes and organic amines (calc. 19.4 wt%). X-ray powder diffraction analysis indicates that the crystal structure collapses upon decomposition of the metal complexes and organic amines.

TG analysis of **2** shows a weight loss of about 5.0 wt% occurring below 250 °C, which is attributed to the loss of water molecules in **2** (calc. 4.98 wt%). A weight loss of 14.0 wt% occurring in the temperature range 250–650 °C is attributed to the decomposition of the organic amines (calc. 13.35 wt%).

The IR spectrum of **1** contains characteristic bands at 927 cm^{-1} attributed to the Mo═O group, in the region of 688–407 cm^{-1} attributed to the bridging Mo–O–Mo group, in the region of 1000–1200 cm^{-1} associated to the P–O bond and in the region 1530–1340 cm^{-1} assigned to the C–C and C–N stretching vibrations of the organic amines.

The IR spectrum of **2** exhibits an absorption at 952 cm^{-1}, characteristic of ν(Mo═O), and bands at 738 and 1010 cm^{-1} which are attributed to ν(Mo–O–M) and ν(P–O), respectively. A series of bands in the 1455–1314 cm^{-1} region are assigned to the C–C and C–N stretching vibrations of the organic amines.

3.4. Electrochemistry

Complexes **1** and **2** were sampled from hydrochloric acid solution. As shown in Fig. 7, in the potential range from 0 to 700 mV, **1** exhibits two couples of reversible redox peaks at 180 and 340 mV, while **2** has two couples of quasi-reversible redox peaks at 230 and 360 mV. The peak current of **1** is thus much larger than that of **2**; this indicates that the redox ability of **1** is stronger than that of **2**. The potential separations of two couples of peaks of **1** are 20 mV, so according to the formula $\Delta ep = Ep_a - Ep_c = 57–63/n$, the two couples of peaks correspond to three-electron redox processes (see Fig. 8).

4. Conclusion

We have reported the synthesis, crystal structures, TGA-DSC thermal analysis and IR spectra of two new molybdenum phosphates **1** and **2**. It was demonstrated that the three dimensional **2** was synthesized from the zero dimensional **1** by a hydrothermal reaction. Though the mechanism of the transformation is not yet clear, the reaction temperature plays a key role for the product. Our experimental results show that novel architectures can be achieved by using a simple molybdenum phosphate cluster as a starting material.

Abstract

Hydrothermal reaction of $Pb(II)X_2$ ($X = Cl^-$, NO_3^-) and 4,4′-bipyridine in a molar ratio of 1:1 resulted in the formation of two new Pb(II) coordination polymers, $^{2}_{\infty}[PbCl_2(4,4'\text{-bipy})]$, (**1**), and $^{2}_{\infty}[Pb_2(NO_3)_4(H_2O)_2(4,4'\text{-bipy})_2](4,4'\text{-bipy})_2$, (**2**). Compound **1** crystallizes in the triclinic crystal system ($P\bar{1}$), and the stereochemically active lone pair generates a distorted structure different from the similar bromide analogue reported previously, where the Pb^{2+} lone pair is apparently not "active". Compound **2** crystallizes in the monoclinic crystal system ($P2_1/c$), with an unusual layered structure consisting of flat slabs of $\{Pb(NO_3)_{4/2}Pb(H_2O)_2(NO_3)_2\}$ bilayers linked into a 3D network via hydrogen bonds involving undulating layers of two independent uncoordinated 4,4′-bipyridine molecules.

1. Introduction

Crystal engineering, the domain of organic chemists for more than 30 years, has been refined and extended in recent years by inorganic and materials chemists to synthesize a new class of organic–inorganic hybrid materials called coordination polymers [1]. These materials represent a new and expanding research area that weds the fields of coordination chemistry, polymer synthesis and solid state chemistry by the linking of metal ions, complexes or clusters via organic ligands to create polymeric structures. The field began (ca. 1992) with studies employing 4,4′-bipyridine (4,4′-bipy), and this simple rigid bidentate ligand has been responsible for a bewildering number of compounds, primarily with first row transition elements. Despite the thousands of structures already reported with 4,4′-bipy, new M-4,4′-bipy structural motifs continue to be discovered. Indeed, the variety of structures obtained from M-4,4′-bipy systems (M = Fe, Co, Ni, Cu, Zn, Cd) is surprisingly vast [2] and hints at the yet undiscovered structural variety of other less-well characterized ligand systems. Recent coordination polymer discoveries have impacted catalysis, molecular recognition, ion exchange, luminescence, nonlinear optics and magnetism [3].

Hydrothermal synthesis as a preparative route to new coordination polymer materials is well established and can produce compounds not achievable by other routes. This technique is well-suited to solubilizing materials which are only slightly soluble at room temperature or at temperatures accessible by reflux. It also often yields crystals of high quality for single crystal X-ray diffraction analysis.

Here we report the hydrothermal synthesis and structural characterization of two new coordination polymers based on 4,4′-bipyridine and Pb(II)X_2 salts ($X = Cl^-$, NO_3^-), two novel additions to the sparse field of Pb(II)-containing coordination polymers [4].

2. Experimental

All reagents were commercially available and used without further purification. Elemental analyses were carried out by Desert Analytics Inc.

2.1. Synthesis of [$PbCl_2$(4,4′-bipy)] (1)

$PbCl_2$ (27.1 mg, 0.10 mmol), 4,4′-bipyridine (4,4′-bipy) (15.7 mg, 0.10 mmol) and 0.80 ml of distilled water were sealed in an evacuated Pyrex tube (7 mm ID, 11 cm long). The reaction was heated to 130 °C at 1 °C/min, soaked at 130 °C for 10 h, and cooled to 30 °C at 0.2 °C/min. Colorless crystals formed in the tube. *Anal.* Calc. for $C_{10}H_8N_2PbCl_2$: C, 27.66; H, 1.86; N, 6.45. Found: C, 27.34; H, 1.69; N, 6.28%.

2.2. Synthesis of [$Pb(NO_3)_2(H_2O)$(4,4′-bipy)$_2$] (2)

$Pb(NO_3)_2$ (33.0 mg, 0.10 mmol), 4,4′-bipyridine (4,4′-bipy) (15.8 mg, 0.10 mmol), and 0.80 ml of distilled water were sealed in an evacuated Pyrex tube (7 mm ID, 11 cm long). The reaction was heated to 130 °C at 1 °C/min, soaked at 130 °C for 10 h and cooled to 30 °C at 0.2 °C/min. Over the course of 24–48 h, plentiful colorless bar shaped crystals and a variety of very thin, small colorless crystals grew throughout the ampoule. The analysis of the crystalline products in multiple ampoules demonstrated that while compound **2** was the major product, small amounts of other crystalline products formed. Due to the fragility and poor crystal quality of these other products, it was not possible to fully characterize these products. Several samples were sent for elemental analysis, but the results were inconclusive due to the difficulties of getting enough pure product for analysis. The IR (cm^{-1}) results: 1590 (s), 1406 (s), 1323 (s), 1216 (m), 805 (s), clearly indicate the presence of nitrate groups coordinated to the metal.

2.3. X-ray crystallography

Crystals of each compound formed as colorless blocks (**1**) or bars (**2**). X-ray intensity data for both were measured at room temperature on a Bruker SMART APEX CCD-based diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å). [5] Raw data frame integration and Lp corrections were performed with SAINT+ [5]. Final unit cell parameters were determined by least-squares refinement of all reflections from each data set with $I > 5(\sigma)I$ (4102 for **1** and 5219 for **2**). Analysis of the data sets showed negligible crystal decay during collection. Both data sets were corrected for absorption with SADABS [5]. Patterson methods structure solution, difference Fourier calculations and full-matrix least-squares refinement against F^2 were performed with SHELXTL [6].

2.3.1. [$PbCl_2$(4,4′-bipy)] (1)

1 crystallizes in the triclinic crystal system. The space group $P\bar{1}$ was assumed and confirmed by the successful solution and refinement of the structure. The asymmetric unit consists of one Pb atom, two Cl atoms and one 4,4′-bipy ligand. All species reside on positions of general crystallographic symmetry. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were placed in geometrically idealized positions and included as riding atoms. The largest peak/hole remaining in the final difference map are +1.80/−0.72 $e^-/Å^3$ respectively, both located near Pb1.

2.3.2. [$Pb_2(NO_3)_4(H_2O)_2$(4,4′-bipy)$_2$](4,4′-bipy)$_2$ (2)

The space group $P2_1/c$ was uniquely determined by the pattern of systematic absences in the intensity data. The asymmetric unit consists of two crystallographically independent Pb centers, four nitrate anions, two 4,4′-bipy ligands coordinated to the Pb atoms, two uncoordinated 4,4′-bipy ligands and two coordinated H_2O ligands. All species are located on positions of general crystallographic symmetry. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms bound to carbon were placed in geometrically idealized positions and included as riding atoms; water hydrogens were located in difference maps and refined subject to O–H = 0.9 Å and H···H = 1.5 Å distance restraints, and $U_{eq}(H) = 1.5U_{eq}(O)$. The largest peak/hole remaining in the final difference map are +2.55/−1.68 $e^-/Å^3$ respectively, both located near Pb1.

3. Results and discussion

3.1. Crystal structure of $^2{}_\infty$[$PbCl_2$(4,4′-bipy)] (1)

Hydrothermal reaction (130 °C, 24 h) between equimolar amounts of $PbCl_2$ and 4,4-bipy yields plentiful colorless block-like crystals. Details of the X-ray data and structural refinement are in Table 1. Table 2 contains selected bond distances and angles. The details of the structure were established by single crystal X-ray diffraction, which revealed infinite two-dimensional layers parallel to the crystallographic *ab* plane (Fig. 1). The layers themselves are comprised of linear one-dimensional ribbons of composition $PbCl_{4/2}$ running along the crystallographic *a*-axis (Fig. 2). These constituent ribbons are linked into sheets by 4,4′-bipy spacers.

There is one crystallographically independent lead (II) atom, which is situated in a severely distorted octahedral coordination environment consisting of four Cl atoms (Pb–Cl1 = 2.741(2), 3.052(2) Å; Pb–Cl2 = 2.736(2), 3.005(2) Å) and two nitrogen atoms from two symmetry-equivalent 4,4′-bipy ligands (Pb–N1 = 2.557(6) Å, Pb−N2 = 2.834(6) Å). The distorted Pb environment is caused by the Pb(II) lone pair, which is clearly stereochemically active (Fig. 3). Its impact is plainly evident in the *trans* N1–Pb–N2 bond angle of 151.3(2)° and in the slight lifting of Pb out of the plane formed by the four equatorial Cl atoms ($Pb–Cl_4$ plane distance = 0.387 Å). With the exception of the stereochemical distortion at the metal center, the structural motif observed in **1** is the same as that observed in $[PbI_2(4,4'\text{-bipy})]_n$ [4a], $[PbBr_2(4,4'\text{-bipy})]_n$ [4b], $[HgBr_2(4,4'\text{-bipy})]_n$ [7] and $[MCl_2(4,4'\text{-bipy})]_n$ (M = Fe, Co) [8]. The Cl2–Pb–Cl2 angle is 87.65(5)° and the Cl1–Pb–Cl1 angle is 86.65(5)° in **1**. In the related lead-containing compounds the X1–Pb–X1 angles are 87.94(2)° for X = I and 89.22(4)° for X = Br. The distorted Pb environment caused by the stereochemically active lone pair in **1** is the reason **1** is not isostructural with $[PbX_2(4,4'\text{-bipy})]_n$ (X = Br, I). The lone pair distortion is also responsible for the non-planarity of the 4,4-bipy ligand observed in **1**. The dihedral angle between the symmetry-inequivalent pyridyl ring planes of the 4,4′-bipy ligand in **1** is 28.5°, compared to 0.0° (exactly planar) for the symmetry-equivalent pyridyl rings in the Br and I compounds. Within the layers, the 4,4′-bipy ligands stack on top of each other at a perpendicular distance of 3.69 Å, and like the related Br and I compounds, the $PbCl_2(4,4'$-bipy) layers themselves stack along the c-axis at a

distance of *c*/2 or 6.1874 Å. Our attempts to prepare either $[PbBr_2(4,4'\text{-bipy})]_n$ or $[PbI_2(4,4'\text{-bipy})]_n$ via hydrothermal synthesis have been to date unsuccessful.

3.2. Crystal structure of $^2{}_\infty[Pb_2(NO_3)_4(H_2O)_2(4,4'\text{-bipy})_2]\cdot(4,4'\text{-bipy})_2$ (**2**)

Plentiful colorless plate crystals of **2** were obtained from the hydrothermal reaction of equimolar amounts of $Pb(NO_3)_2$ and 4,4′-bipy in a sealed pyrex tube (130 °C). The structure of **2** was established by single crystal X-ray diffraction. Details of the X-ray data and structural refinement are in Table 1. Table 3 contains selected bond distances and angles. Compound **2** adopts a layered structure quite different from the rather common structural motif adopted by **1**. Two crystallographically and chemically different Pb(II) centers are present in **2**. Pb1 sits in an irregular eight-coordinate $\{PbN_2O_6\}$ environment (Fig. 4) composed of two nitrogen donors from two crystallographically inequivalent 4,4′-bipy ligands (Pb1–N1 = 2.643(7), Pb1–N11 = 2.721(7) Å); two oxygen atoms from two independent water molecules (Pb1–O1W = 2.471(7); Pb1–O2W = 2.515(7) Å) and four oxygen atoms from two independent bidentate nitrate anions (Pb1–O range = 2.742(7)–2.817(8) Å). Pb2 sits in an irregular 10-coordinate environment (Fig. 4) formed by two inequivalent 4,4′-bipy nitrogen donors (Pb2–N2 = 2.785(7); Pb2–N12 = 2.841(7) Å), and eight oxygen atoms from four chelating nitrate anions. These Pb–O distances (2.563(8)–3.068(8) Å) are in the range commonly observed in Pb–NO_3 complexes [9].

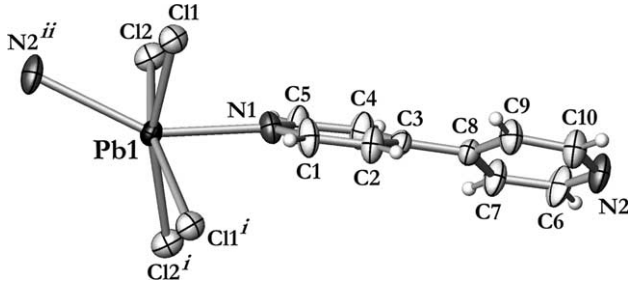

Fig. 3. Pb1 coordination environment. Displacement ellipsoids drawn at the 50% probability level.

The two inequivalent Pb centers are linked into one-dimensional chains by the two inequivalent bridging 4,4′-bipy ligands (Fig. 4). These chains run along the crystallographic [1,−2,0] direction and lie side-by-side

Symmetry transformations used to generate equivalent atoms: #1 $-x,y+3/2,-z+3/2$; #2 $-x+1,y-1/2,-z+3/2$; #3 $x,y+1,z$; #4 $-x,y-3/2,-z+3/2$; #5 $x,-y+1/2,z+1/2$; #6 $x,-y+3/2,z+1/2$; #7 $-x,y+1/2,-z+3/2$.

forming sheets in the *ab* plane. There is no direct linkage between individual unidirectional chains in these sheets; however two such sheets of chains are connected via bridging nitrates to form a bilayer of composition $[Pb_2(NO_3)_4(H_2O)_2(4,4'\text{-bipy})_2]$. The operation of the 2_1 axis causes the constituent chains of each sheet of the bilayer to crisscross at an angle of (ca. ~90°) relative to the chains in the other sheet (Fig. 5). An alternative view of the bilayers is of infinite undulating $\{Pb(NO_3)_2\}$ ribbons running parallel to the *b*-axis (Fig. 5) which are linked in a crisscross fashion by 4,4′-bipy ligands. This view highlights the inorganic–organic hybrid nature of **2**, grossly similar to that in **1**.

The two water molecules bound to Pb1 protrude to the outside surfaces of the bilayers and play a critical role in assembling the full three-dimensional hydrogen-bonded structure. The bilayer sheets lie parallel the crystallographic *ab* plane, and are interleaved by layers of 'free' (uncoordinated to Pb1 or Pb2) 4,4′-bipy molecules. These interstitial 4,4′-bipy molecules adopt a sinusoidally undulating pattern, with the extrema of the troughs and crests coinciding with the water molecules bound to Pb1, forming hydrogen bonds (Fig. 6). All four water hydrogens on the two waters on Pb1

participate in the hydrogen bonding network (Table 4). The relative positions of the two waters along the undulation direction created a slight ''phase lag'' in the sine wave chains of uncoordinated 4,4′-bipys, illustrated schematically in Fig. 6.

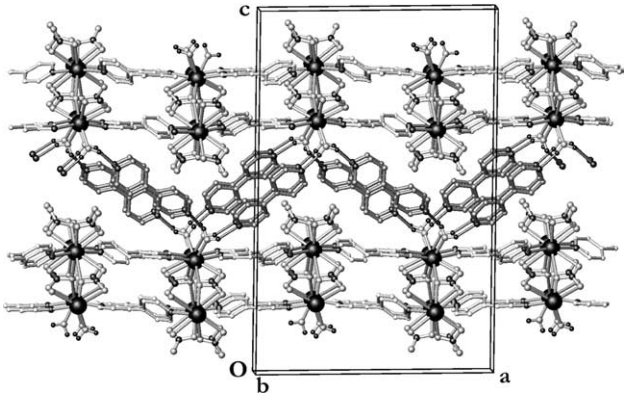

Fig. 6. View of the Pb bilayer – 4,4′-bipyridine hydrogen bonding in **2**.

4. Conclusions

Whereas the slow addition of a methanol solution of 4,4′bipy to a dimethylformamide solution of PbX_2 (X = Br, I) resulted in the formation of isostructural Pb-containing coordination polymers $[PbX_2(4,4'\text{-bipy})]_n$ (X = Br, I) [4], our hydrothermal synthesis resulted in the formation of two new lead-containing coordination polymers. Compound **1** is nearly isomorphous with the two previously reported (Br and I) compounds except for the profound distorting impact of the stereochemically active lone pair on the Pb(II) coordination environment. In an excellent discussion, Shimoni–Livny et al. list factors favoring an active lone pair in Pb(II) compounds [10]. They point out that based on a search of the Cambridge Structural Database, it is unusual for a Pb(II)

Symmetry transformations used to generate equivalent atoms: #1 $-x,y+3/2,-z+3/2$; #2 $-x+1,y-1/2,-z+3/2$; #3 $x,y+1,z$; #4 $-x,y-3/2,-z+3/2$; #5 $x,-y+1/2,z+1/2$; #6 $x,-y+3/2,z+1/2$; #7 $-x,y+1/2,-z+3/2$.

compound with several soft Cl^- ligands to show the effects of an active lone pair. However, this may be mitigated by the presence of harder ligating atoms such as nitrogen in the presence of Pb, and by attractive interactions between ligands. The π–π interactions between pyridyl rings present in compound **1** may thus also contribute to the geometry at the Pb center. Finally, the authors say inter-ligand repulsions show a tendency to favor more symmetrical Pb coordination geometries. Therefore the smaller size of Cl relative to Br and I provides a more roomy coordination environment around the Pb(II) thereby allowing the lone pair to exert a stronger stereochemical influence in **1**. Compound **2** is an interesting layered structure stuffed with free 4,4′-bipy molecules, arranged to maximize their hydrogen-bonding capability. Both structures display inorganic $\{Pb(anion)_2\}$ ribbons linked together by organic 4,4′-bipy ligands.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 234033 and 234034. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Abstract

Condensation of 2-pyridinecarboxaldehyde with several primary amines containing fluorine groups gave the corresponding pyridinecarboxaldimines (N-N′). Addition of these ligands to $[MCl_2(coe)]_2$ (M = Pd, Pt; coe = *cis*-cyclooctene) gave complexes of the type *cis*-MCl_2(N-N′) [Pd (**3**), Pt (**4**)] in moderate to high yields. All palladium and platinum complexes were examined for their potential cytotoxicities against OV2008 (human ovarian carcinoma) and the analogous cisplatin-resistant C13.

1. Introduction

Cisplatin, *cis*-$[PtCl_2(NH_3)_2]$ and a few related platinum-based complexes are currently used as anticancer agents against testicular and ovarian malignancies [1–7]. There are several limitations to platinum therapy, however, such as neural and kidney toxicity as well as intrinsic and acquired resistance of tumor cells to the drugs [1]. These complications have provided an incentive for further research into the development of platinum-based complexes with increased solubility and enhanced specificity towards cancer cells. Recent studies have shown that *cis*-amminedichloro(2-methylpyridine)platinum(II) (AMD473 or ZD0473, Fig. 1) shows considerable cytotoxicity in cisplatin-resistant cell lines [8,9]. Steric crowding from the methyl group is believed to decrease the rates of hydrolysis and substitution reactions of AMD473 by effectively shielding the platinum atom and thereby permitting high selectivity in binding to DNA [10]. The primary mechanism of action in these platinum drugs is believed to arise from the metal's interaction with DNA.

We have begun to develop AMD473 analogues by replacing the NH_3 group with a pendant imine group. Previous studies have shown that the platinum complex derived from aniline, **2** (Fig. 1), has shown considerable activity against the hormone independent human mammary carcinoma cell line MDA-MB 231 [11]. Varying the aniline functionality allows us to design compounds with a wide range of physical and chemical properties

that may provide steric congestion around the platinum atom. As well, the use of bidentate ligands prevents trans labilization and undesired displacement of the ligands by sulfur and nitrogen donors in biomolecules, interactions believed responsible for some of the adverse side effects associated with cisplatin [1–3]. We report herein our results on the synthesis and initial cytotoxicity testing of *cis*-dichloro(pyridin-2-ylcarboxaldimine)-palladium(II) and -platinum(II) compounds containing bulky fluorinated aryl groups (Fig. 2).

2. Experimental

2.1. General procedures and methods

Reagents and solvents used were obtained from Aldrich Chemicals. $PdCl_2$ and K_2PtCl_4 were purchased from Precious Metals Online Ltd. and $[PdCl_2(coe)]_2$ and $[PtCl_2(coe)]_2$ were made by established procedures [12]. Pyridinecarboxaldimine ligands were prepared as previously reported [13]. NMR spectra were recorded on a JEOL JNM-GSX270 FT NMR or Varian Mercury Plus 200 NMR spectrometer. ^1H NMR chemical shifts are reported in ppm and are referenced to residual protons in deuterated solvent at 270 and 200 MHz. ^{13}C NMR chemical shifts are referenced to solvent carbon resonances as internal standards at 68 and 50 MHz. ^{19}F NMR chemical shifts are referenced to CF_3CO_2H. Multiplicities are reported as singlet (s), doublet (d), triplet (t), quartet (q), multiplet (m), broad (br) and overlapping (ov). Infrared spectra were obtained using a Mattson Genesis II FT-IR spectrometer and are reported in cm^{-1}. Melting points were measured uncorrected with a Mel-Temp apparatus. Microanalyses for C, H and N were carried out at Guelph Chemical Laboratories Ltd. (Guelph, Ont.).

2.2. General procedure for the preparation of metal complexes

A CH_2Cl_2 (5 ml) solution of ligand (0.55 mmol) was added to the appropriate $[MCl_2(coe)]_2$ (where M = Pd or Pt) (0.25 mmol) in CH_2Cl_2 (5 ml). The reaction mixture was stirred for 5 h at room temperature and the precipitate was collected by suction filtration and washed with CH_2Cl_2 (3×5 ml) to afford the metal complex.

Fig. 2. Synthesis of palladium and platinum complexes **3**–**4**.

1H, Ar), 7.34–7.24 (ov m, 3H, Ar); $^{13}C\{^1H\}$ δ: 174.0, 161.7 (d, J_{C-F} = 245 Hz, *C*F), 156.2, 150.7, 148.8 (d, J_{C-F} = 10 Hz), 141.9, 130.6 (d, J_{C-F} = 9 Hz), 130.3, 129.9, 120.7, 115.9, (d, J_{C-F} = 21 Hz), 112.4 (d, J_{C-F} = 25 Hz); $^{19}F\{^1H\}$ δ: −112.8. IR (nujol): 2951, 2927, 2854, 1591, 1460, 1377, 1360, 1300, 1269, 1252, 1228, 1167, 1138, 980, 897, 856, 796, 771, 723, 692. *Anal*. Calc. for $C_{12}H_9N_2Cl_2FPd$: C, 38.16; H, 2.41; N, 7.42. Found: C, 38.22; H, 2.13; N, 7.25%.

2.2.3. Compound **3c**

Yield: 60% as an orange solid; m.p. 328 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.05 (d, J = 6 Hz, 1H, Ar), 8.75 (s, 1H, C(*H*)═N), 8.40 (t, J = 8 Hz, 1H, Ar), 8.20 (d, J = 8 Hz, 1H, Ar), 7.94 (t, J = 6 Hz, 1H, Ar), 7.51–7.46 (m, 2H, Ar), 7.34–7.28 (m, 2H, Ar); $^{13}C\{^1H\}$ δ: 173.4, 162.2 (d, J_{C-F} = 246 Hz, *C*F), 156.4, 150.6, 143.9 (d, J_{C-F} = 2 Hz), 141.9, 130.1, 129.7, 126.8 (d, J_{C-F} = 9 Hz), 115.6 (d, J_{C-F} = 22 Hz); $^{19}F\{^1H\}$ δ: −113.0. IR (nujol): 3109, 3041, 3016, 2920, 1597, 1579, 1498, 1479, 1308, 1296, 1242, 1228, 1196, 1157, 1103, 960, 850, 806, 795, 768, 579. *Anal*. Calc. for $C_{12}H_9N_2Cl_2FPd$: C, 38.16; H, 2.41; N, 7.42. Found: C, 37.98; H, 2.10; N, 7.10%.

2.2.4. Compound **3d**

Yield: 70% as an orange solid; m.p. 324–326 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.04 (d, J = 6 Hz, 1H, Ar), 8.97 (s, 1H, C(*H*)═N), 8.44 (t of d, J = 8, 1 Hz, 1H, Ar), 8.25 (d, J = 8 Hz, 1H, Ar), 8.01 (t of d, J = 6, 1 Hz, 1H, Ar), 7.82–7.76 (ov m, 2H, Ar), 7.61 (t, J = 8 Hz, 1H, Ar), 7.51 (d, J = 8 Hz, 1H, Ar); $^{13}C\{^1H\}$ δ: 175.2, 155.6, 151.2, 145.3, 142.1, 133.5, 130.6 (2C), 129.0, 126.8 (q, J_{C-F} = 5 Hz), 126.2, 124.5 (q, J_{C-F} = 274 Hz, *C*F_3), 122.2 (q, J_{C-F} = 30 Hz); $^{19}F\{^1H\}$ δ: −55.9. IR (nujol): 3074, 3014, 2952, 2925, 2854, 1593, 1471, 1456, 1319, 1296, 1269, 1203, 1155, 1124, 1055, 1034, 984, 768, 571. *Anal*. Calc. for $C_{13}H_9N_2Cl_2F_3Pd$: C, 36.51; H, 2.13; N, 6.55. Found: C, 36.57; H, 1.98; N, 6.54%.

2.2.5. Compound **3e**

Yield: 65% as an orange solid; m.p. 346–348 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.06 (d, J = 6 Hz, 1H, Ar), 8.85 (s, 1H, C(*H*)═N), 8.42 (t, J = 8 Hz, 1H, Ar), 8.23 (d, J = 8 Hz, 1H, Ar), 7.97 (t, J = 6 Hz, 1H, Ar), 7.85 (s, 1H, Ar), 7.80 (m, 1H, Ar), 7.77–7.68 (ov m, 2H, Ar); $^{13}C\{^1H\}$ δ: 175.0, 156.8, 151.3, 148.2, 142.5, 130.8, 130.5 (2C), 129.9 (q, J_{C-F} = 32 Hz), 129.4, 128.7 (q, J_{C-F} = 274 Hz, *C*F_3), 126.1 (q, J_{C-F} = 4 Hz), 122.0 (q, J_{C-F} = 4 Hz); $^{19}F\{^1H\}$ δ: −61.0. IR (nujol): 3074, 3014, 2953, 2854, 1593, 1450, 1362, 1329, 1238, 1184, 1159, 1117, 1068, 808, 773, 700, 658. *Anal*. Calc. for $C_{13}H_9N_2Cl_2F_3Pd$: C, 36.51; H, 2.13; N, 6.55. Found: C, 36.23; H, 2.11; N, 6.33%.

2.2.6. Compound **3f**

Yield: 65% as an orange solid; m.p. 301–302 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.06 (d, J = 6 Hz, 1H, Ar), 8.83 (s, 1H, C(*H*)═N), 8.42 (t of d, J = 8, 1 Hz, 1H, Ar), 8.22 (d, J = 8 Hz, 1H, Ar), 7.97 (t of d, J = 6, 1 Hz, 1H, Ar), 7.87 (d, J = 8 Hz, 2H, Ar), 7.63 (d, J = 8 Hz, 2H, Ar); $^{13}C\{^1H\}$ δ: 174.4, 156.3, 150.7, 150.4, 142.0, 130.4, 130.0, 129.1 (q, J_{C-F} = 35 Hz), 126.0 (q, J_{C-F} = 4 Hz), 125.6, 124.5 (q, J_{C-F} = 274 Hz, *C*F_3); $^{19}F\{^1H\}$ δ: −60.8. IR (nujol): 3074, 2870, 1460, 1377, 1186, 1169, 1107, 966, 854, 766, 721, 607. *Anal*. Calc. for $C_{13}H_9N_2Cl_2F_3Pd$: C, 36.51; H, 2.13; N, 6.55. Found: C, 36.66; H, 1.97; N, 6.45%.

2.2.7. Compound **3g**

Yield: 60% as an orange solid; m.p. 358–360 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.07 (d, J = 6 Hz, 1H, Ar), 8.98 (s, 1H, C(*H*)═N), 8.45 (t of d, J = 8, 1 Hz, 1H, Ar), 8.27 (d, J = 8 Hz, 1H, Ar), 8.24 (s, 1H, Ar), 8.19 (s, 2H, Ar), 8.00 (t of d, J = 6, 1 Hz, 1H, Ar); $^{13}C\{^1H\}$ δ: 175.7, 156.1, 150.9, 148.2, 142.1, 130.8, 130.6 (q, J_{C-F} = 34 Hz), 130.3, 126.1, 123.5 (q, J_{C-F} = 274 Hz, *C*F_3), 122.6 (q, J_{C-F} = 4 Hz); $^{19}F\{^1H\}$ δ: −61.2. IR (nujol): 3107, 3020, 2951, 2922, 2854, 1371, 1358, 1292, 1279, 1242, 1184, 1174, 1126, 970, 901, 881, 777, 702, 683. *Anal*. Calc. for $C_{14}H_8N_2Cl_2F_6Pd$: C, 33.92; H, 1.63; N, 5.65. Found: C, 33.50; H, 1.39; N, 5.43%.

2.2.8. Compound **3h**

Yield: 65% as an orange solid; m.p. 288 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.21 (s, 1H, C(*H*)═N), 9.04 (d, J = 6 Hz, 1H, Ar), 8.46 (t, J = 8 Hz, 1H, Ar), 8.34 (d, J = 8 Hz, 1H, Ar), 8.06 (t, J = 6 Hz, 1H, Ar); $^{19}F\{^1H\}$ δ: −145.4 (d, J_{F-F} = 19 Hz), −154.2 (t, J_{F-F} = 19 Hz), −162.8 (t, J_{F-F} = 9 Hz). IR (nujol): 3095, 3016, 2951, 2924, 2856, 1591, 1512, 1470, 1433, 1352, 1294, 1221, 1103, 1009, 995, 960, 885, 793, 781. *Anal*. Calc. for $C_{12}H_5N_2Cl_2F_5Pd$: C, 32.06; H, 1.12; N, 6.23. Found: C, 31.91; H, 0.83; N, 5.99%.

2.2.9. Compound **4a**

Yield: 65% as an orange solid; m.p. 282 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^1H δ: 9.51 (s, J_{H-Pt} = 92 Hz, 1H, C(*H*)═N), 9.47 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 8.47 (t, J_{H-H} = 8 Hz, 1H, Ar), 8.25 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.04 (t, J_{H-H} = 6 Hz, 1H, Ar), 7.50–7.31 (ov m, 4H, Ar); $^{13}C\{^1H\}$ δ: 175.4, 157.1, 154.9 (d, J_{C-F} = 250 Hz, *C*F), 149.8, 141.4, 135.4 (d, J_{C-F} = 12 Hz), 131.1 (d, J_{C-F} = 8 Hz), 130.8 (2C), 126.5, 124.9 (d, J_{C-F} = 4 Hz), 116.5 (d, J_{C-F} = 20 Hz); $^{19}F\{^1H\}$ δ: −120.0. IR (nujol): 2941, 2902, 2860, 1589, 1558, 1493, 1456, 1377, 1348, 1300, 1250, 1228, 1159, 1101, 937, 856, 800, 766, 739,

667, 596. *Anal.* Calc. for $C_{12}H_9N_2Cl_2FPt$: C, 30.91; H, 1.95; N, 6.01. Found: C, 30.44; H, 1.73; N, 5.68%.

2.2.10. Compound **4b**

Yield: 81% as an orange solid; m.p. 286 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.48 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 47 Hz, 1H, Ar), 9.40 (s, J_{H-Pt} = 91 Hz, 1H, C(*H*)═N), 8.45 (t, J_{H-H} = 8 Hz, 1H, Ar), 8.24 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.01 (t, J_{H-H} = 6 Hz, 1H, Ar), 7.60–7.52 (m, 1H, Ar), 7.40–7.29 (ov m, 3H, Ar); ^{13}C{^{1}H} δ: 174.0, 161.8 (d, J_{C-F} = 247 Hz, *C*F), 157.5, 149.7, 148.7 (d, J_{C-F} = 10 Hz), 141.3, 130.7, 130.5, 130.4, 121.2 (d, J_{C-F} = 3 Hz), 116.2 (d, J_{C-F} = 21 Hz), 112.7 (d, J_{C-F} = 25 Hz); ^{19}F{^{1}H} δ: −112.7. IR (nujol): 2931, 2912, 2856, 1593, 1460, 1377, 1358, 1300, 1269, 1252, 1230, 1138, 984, 897, 858, 796, 769, 694. *Anal.* Calc. for $C_{12}H_9N_2Cl_2FPt$: C, 30.91; H, 1.95; N, 6.01. Found: C, 31.27; H, 1.65; N 6.00%.

2.2.11. Compound **4c**

Yield: 85% as an orange solid; m.p. 327 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.47 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 9.34 (s, J_{H-Pt} = 93 Hz, 1H, C(*H*)═N), 8.45 (t of d, J_{H-H} = 8, 1 Hz, 1H, Ar), 8.23 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.00 (t of d, J_{H-H} = 6, 1 Hz, 1H, Ar), 7.56–7.51 (ov m, 2H, Ar), 7.39–7.33 (ov m, 2H, Ar); ^{13}C{^{1}H} δ: 172.8, 161.8 (d, J_{C-F} = 250 Hz, *C*F), 157.1, 149.1, 143.3 (d, J_{C-F} = 2 Hz), 140.7, 129.8, 129.7, 126.6 (d, J_{C-F} = 9 Hz), 115.0 (d, J_{C-F} = 23 Hz); ^{19}F{^{1}H} δ: −112.7. IR (nujol): 2951, 2939, 2914, 2852, 1462, 1377, 1298, 1244, 1228, 1157, 1101, 1059, 1039, 972, 947, 932, 920, 850, 806, 766, 752, 586. *Anal.* Calc. for $C_{12}H_9N_2Cl_2FPt$: C, 30.91; H, 1.95; N, 6.01. Found: C, 30.75; H, 1.69; N, 5.72%.

2.2.12. Compound **4d**

Yield: 75% as an orange solid; m.p. 315 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.59 (s, J_{H-Pt} = 90 Hz, 1H, C(*H*)═N), 9.48 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 8.48 (t, J_{H-H} = 8 Hz, 1H, Ar), 8.30 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.06 (t, J_{H-H} = 6 Hz, 1H, Ar), 7.88–7.79 (ov m, 2H, Ar), 7.67 (t, J_{H-H} = 8 Hz, 1H, Ar), 7.54 (d, J_{H-H} = 8 Hz, 1H, Ar); ^{13}C{^{1}H} δ: 174.9, 163.2, 156.9, 150.1, 141.5, 133.4, 131.1, 130.9, 129.4, 127.1, 126.9 (q, J_{C-F} = 5 Hz), 125.0 (q, J_{C-F} = 274 Hz, *C*F$_3$), 122.9 (q, J_{C-F} = 30 Hz); ^{19}F{^{1}H} δ: −56.2. IR (nujol): 2945, 2902, 2868, 1560, 1460, 1377, 1317, 1306, 1271, 1234, 1201, 1163, 1124, 1055, 1032, 968, 781, 762, 723, 596. *Anal.* Calc. for $C_{13}H_9N_2Cl_2F_3Pt$: C, 30.24; H, 1.76; N, 5.43. Found: C, 29.81; H, 1.69; N, 5.25%.

2.2.13. Compound **4e**

Yield: 65% as an orange solid; m.p. 336 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.48 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 9.45 (s, J_{H-Pt} = 88 Hz, 1H, C(*H*)═N), 8.47 (t of d, J_{H-H} = 8, 1 Hz, 1H, Ar), 8.26 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.02 (t of d, J_{H-H} = 6, 1 Hz, 1H, Ar), 7.90 (s, 1H, Ar), 7.85–7.75 (ov m, 3H, Ar); ^{13}C{^{1}H} δ: 174.5, 157.6, 149.7, 147.6, 141.4, 130.6, 130.5, 130.2 (q, J_{C-F} = 31 Hz), 130.0, 129.2, 128.3 (q, J_{C-F} = 274 Hz, *C*F$_3$), 126.0 (q, J_{C-F} = 4 Hz), 121.9 (q, J_{C-F} = 4 Hz); ^{19}F{^{1}H} δ: −61.0. IR (nujol): 2943, 2910, 2860, 1460, 1377, 1327, 1240, 1182, 1161, 1117, 1066, 941, 808, 771, 700, 660, 596. *Anal.* Calc. for $C_{13}H_9N_2Cl_2F_3Pt$: C, 30.24; H, 1.76; N, 5.43. Found: C, 30.20; H, 1.50; N, 5.43%.

2.2.14. Compound **4f**

Yield: 85% as an orange solid; m.p. 300 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.48 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 9.43 (s, J_{H-Pt} = 97 Hz, 1H, C(*H*)═N), 8.47 (t of d, J_{H-H} = 8, 1 Hz, 1H, Ar), 8.26 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.03 (t of d, J_{H-H} = 6, 1 Hz, 1H, Ar), 7.92 (d, J_{H-H} = 8 Hz, 2H, Ar), 7.68 (d, J_{H-H} = 8 Hz, 2H, Ar); ^{13}C{^{1}H} δ: 174.4, 157.5, 149.7, 149.5, 141.3, 130.6, 130.5, 130.2 (q, J_{C-F} = 31 Hz), 126.5 (q, J_{C-F} = 274 Hz, *C*F$_3$), 126.0 (2C); ^{19}F{^{1}H} δ: −60.8. IR (nujol): 2958, 2939, 2883, 1416, 1325, 1201, 1111, 1066, 856, 825, 808, 760, 731, 700, 685, 669, 606, 596, 515. *Anal.* Calc. for $C_{13}H_9N_2Cl_2F_3Pt$: C, 30.24; H, 1.76; N, 5.43. Found: C, 29.98; H, 1.42; N, 5.22%.

2.2.15. Compound **4g**

Yield: 60% as an orange solid; m.p. 338 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.59 (s, J_{H-Pt} = 85 Hz, 1H, C(*H*)═N), 9.49 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 40 Hz, 1H, Ar), 8.49 (t, J_{H-H} = 8 Hz, 1H, Ar), 8.31 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.27 (s, 1H, Ar), 8.25 (s, 2H, Ar), 8.05 (t, J_{H-H} = 6 Hz, 1H, Ar); ^{13}C{^{1}H} δ: 175.6, 157.4, 149.9, 148.1, 141.5, 130.9, 130.6 (q, J_{C-F} = 34 Hz), 130.4, 126.5, 123.5 (q, J = 274 Hz, *C*F$_3$), 123.1 (q, J_{C-F} = 4 Hz); ^{19}F{^{1}H} δ: −61.2. IR (nujol): 2935, 2904, 2870, 1460, 1377, 1290, 1173, 1126, 974, 900, 847, 773. *Anal.* Calc. for $C_{14}H_8N_2Cl_2F_6Pt$: C, 28.77; H, 1.38; N, 4.80. Found: C, 28.57; H, 1.16; N, 4.57%.

2.2.16. Compound **4h**

Yield: 60% as an orange solid; m.p. 302 °C (decomposition). Spectroscopic NMR data (in DMSO-d_6): ^{1}H δ: 9.85 (s, J_{H-Pt} = 82 Hz, 1H, C(*H*)═N), 9.47 (d, J_{H-H} = 6 Hz, J_{H-Pt} = 38 Hz, 1H, Ar), 8.50 (t, J_{H-H} = 8 Hz, 1H, Ar), 8.40 (d, J_{H-H} = 8 Hz, 1H, Ar), 8.14 (t, J_{H-H} = 6 Hz, 1H, Ar); ^{19}F{^{1}H} δ: −145.9 (d, J = 19 Hz), −153.6 (t, J = 19 Hz), −162.6 (t, J = 19 Hz). Found: C, 26.53; H, 0.75; N, 5.15%.

2.3. X-ray crystallography

Crystals of **3d**·**DMF** were grown from a saturated DMF solution at 20 °C. Single crystals were coated with Paratone-N oil, mounted using a glass fibre and frozen in the cold stream of the goniometer. A hemisphere of data was collected on a Bruker AXS P4/SMART 1000 diffractometer using ω and θ scans with a scan width of 0.3° and 10 s exposure time. The detector distance was 4 cm. The data were reduced [14] and corrected for absorption [15]. The structure was solved by direct methods and refined by full-matrix least-squares on F^2 [16]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located in Fourier difference maps and refined isotropically.

2.4. Cell culture

OV2008 (human ovarian carcinoma) and the analogous cisplatin-resistant cell line C13 were a generous gift from Dr. Barbara C. Vanderhyden of the Centre for Cancer Therapeutics, Ottawa Regional Cancer Centre, Ont., Canada. Both cell lines were cultured in complete RPMI-1640 medium with L-glutamine, supplemented with 5% fetal bovine serum, penicillin (50 units/ml) and streptomycin (50 mg/ml). Cells were incubated in a humidified atmosphere of 5% CO_2 at 37 °C and were subcultured twice weekly using trypsin–EDTA.

2.5. Cell growth inhibition assay

Cells were seeded in 96-well plates at a concentration of $0.1–1.0 \times 10^4$ cells/well in 200 μl of complete media and incubated for 24 h at 37 °C in a 5% CO_2 atmosphere to allow for cell adhesion. Stock solutions (15 mM) of the compounds made in DMSO were filter sterilized, then diluted to 10 mM in phosphate-buffered saline (PBS, 0.02 M phosphate, 0.11 M NaCl, pH 7.0, sterile). The 10 mM solutions were diluted to 50 μM and 1.4 mM in complete media for treatment against OV2008 and C13 cell lines, respectively, where 20 μl of compound solutions were added to 180 μl of fresh medium in wells to give final concentrations of 5 μM against OV2008 and 140 μM for C13. All assays were performed in two independent sets of quadruplicate tests. Control groups containing no drug were run in each assay, along with standards of cisplatin and a previously studied *cis*-dichloro(pyridin-2-ylcarboxaldimine)platinum(II) complex (**2**) [11].

Following 48 h of exposure, each well was carefully rinsed with 200 μl PBS buffer. MTT solution (50 μl, 1 mg/ml ddH_2O) along with 200 μl of fresh, complete media were added to each well, and plates were incubated for 45 min. Following incubation, the medium was removed and the purple formazan precipitate in each well was solubilized in 200 μl DMSO. Absorbances were measured using a VersaMax tunable microplate reader (Molecular Devices) at 570 nm. Reduction of cell proliferation was determined as a fraction of the absorbance values for each drug treatment (T) to the mean absorbance of the no-drug control (C), and calculated using the expression $1 - T/C \times 100\%$. Data from the separate trials were combined using a t test ($P < 0.05$).

3. Results and discussion

3.1. Synthesis and structure

The addition of a primary amine to commercially available 2-pyridinecarboxaldehyde to afford the corresponding pyridinecarboxaldimine ligand is a well-known route to a versatile class of bidentate ligands [17–27]. Variation of the amine therefore allows for the facile design of ligands and subsequent metal complexes with different physical and chemical properties. In this study, the metal complexes **3**–**4** (Fig. 2) were prepared by addition of the pyridin-2-ylcarboxaldimine ligands to CH_2Cl_2 solutions of $[MCl_2(coe)]_2$ (M = Pd, Pt; coe = *cis*-cyclooctene) [12,13]. Palladium complexes were also prepared because of recent interest for their anticancer potential. Compounds of the type $[Pd(en)Cl_2]$ and [Pd(en)L] (en = ethylenediamine; L = malonato, methylmalonato, dimethylmalonato and 1,1-cyclobutanedicarboxylato) were recently shown to bind to DNA in a manner similar to that proposed for cisplatin [28].

Complexes containing fluorine groups are of particular interest as substitution of hydrocarbon fragments with C–F moieties can dramatically alter the properties of biologically active compounds and can influence the metabolism and distribution of drug molecules in the body [29–31]. For instance, substitution of fluorine on the aromatic ring of the neurotransmitter norepinephrine produces large differences in its adrenergic activities [32].

In this study, complexes **3**–**4** have been characterized by a number of physical methods, including multinuclear NMR spectroscopy. A significant downfield shift in the ^1H NMR is observed for the imine sp^2 proton upon coordination of the ligand to the metal center. For instance, the singlet at δ 8.59 ppm for the free ligand derived from 2-pyridinecarboxaldehyde and 4-fluoroaniline shifts to 9.34 ppm in complex **4c**. Platinum satellites are also observed for this resonance (J_{H-Pt} = 93 Hz) upon complexation of the ligand to the metal. Similar trends are observed for the pyridine hydrogen α to the nitrogen atom as the chemical shift changes from δ 8.71 to 9.47 ppm (J_{H-Pt} = 40 Hz). The ^{19}F NMR spectra for compounds **3**–**4** are similar to analogous palladium and platinum complexes containing fluorinated imines [33–36]. For instance, three distinct resonances appear

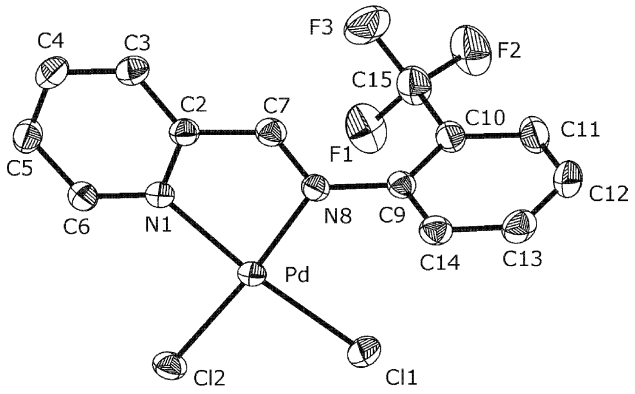

Fig. 3. A view of molecule **3d·DMF**, with displacement ellipsoids drawn at the 30% probability level. H atoms and the molecule of DMF have been omitted for clarity.

in the aromatic region for complexes **3**, **4h**, derived from pentafluoroaniline, and coupling constants are in the expected range for analogous compounds [37]. It is interesting to note, however, that metal complexes **3**, **4h** were unstable in DMSO and decomposed after ca. 12 h to give a number of unidentified products, precluding the acquisition of ^{13}C NMR data. As late metals are known to activate the C–F bond in related pentafluoropyridine [38], it is plausible that compounds **3**, **4h** are also decomposing via a similar mechanism [39,40].

Complex **3d·DMF** has also been characterized by an X-ray diffraction study (Fig. 3). Crystallographic data are given in Table 1 and selected bond lengths and angles provided in Table 2. The nitrogen–palladium bonds of 2.0296(15) Å (pyridine) and 2.0181(16) Å (imine) are similar to those reported in other imine palladium systems [41–43]. The imine C(7)–N(8) distance of 1.286(2) Å is in the range of accepted carbon–nitrogen double bonds [44]. Interesting, the aromatic ring on the imine nitrogen is almost perpendicular to the N(1)–Pd–N(8) plane (83.4°), a trend that is observed in related diimine platinum systems [45]. Indeed, this structural feature has been used to create active and selective catalyst precursors for the polymerization of α-olefins, where *ortho* substitution of the aniline group with bulky groups is believed to shield and stabilize the metal center. The structure of the related $[PtCl_2(R\text{-pea})]$ (pea = 1,(2-pyridyl)ethylamine) has been reported recently [46], where the methyl group of the backbone lies in an equatorial plane and results in a close contact between it and the pyridine, which would otherwise not be present if the methyl group were in the axial position. In the case of **3d·DMF**, a closest contact of Pd with F is 3.387 Å, where the trifluoromethyl group is canted over the plane of the metal center. This observation suggests that complexes with CF_3 groups in the *ortho* position of the imine aryl ring may shield the metal atom in a similar way to AMD473.

3.2. Cytotoxic activity

We have tested the cytotoxic activity of all the new palladium and platinum complexes against both cisplatin-sensitive and cisplatin-resistant human ovarian cells (Table 3), OV2008 and C13, respectively, at concentrations corresponding to cisplatin's IC_{50} value against either cell line [47–49]. While marginal activity was observed for palladium complexes against cisplatin-sensitive cells OV2008, most of the analogous platinum complexes showed significantly less activity. Indeed, the platinum complexes **4a** and **4h**, which contain a F group in the α position showed no activity against the cisplatin-sensitive cell line. In contrast, however, is the observation that **4d**, with a bulky CF_3 group in the α position, showed considerable activity against OV2008 while **4e** showed no activity with the CF_3 group in the *meta* position. More remarkable is that almost all palladium and platinum complexes displayed substantial activity against cisplatin-resistant cell lines C13. Only compound **4a** does not show any significant activity. Compound **3d**, with the CF_3 group in the *ortho* position of the aryl group, was significantly more active than its platinum analogue **4d**. The platinum compounds **4e** and 4**g** contain a CF_3 moiety in the *meta* position and show enhanced activities towards C13 as compared to OV2008. Interestingly, increased activities were observed for both metal complexes when the CF_3 group was bound in the *para* position (complexes **3f** and **4f** show the greatest activity against C13). While these initial studies have shown that some compounds show promise against the cisplatin-resistant cell line, further in vitro studies are needed to address the structure activity relationships in these complexes in order to design a potent drug candidate.

Table 3
Percent reduction of cell proliferation of cisplatin-sensitive (OV2008) and cisplatin-resistant (C13) cancer cells to compounds at 5 and 140 μM, respectively ($n = 8$; ±SD)

Compound	OV2008	C13
cisplatin	44 ± 11	41 ± 8
2	21 ± 3	37 ± 8
3a	25 ± 11	78 ± 8
3b	21 ± 7	31 ± 9
3c	28 ± 12	31 ± 7
3d	28 ± 10	79 ± 11
3e	20 ± 11	29 ± 16

3g	23 ± 10	39 ± 15
3h	25 ± 8	56 ± 13
4a	0	4 ± 4
4b	10 ± 16	83 ± 4
4c	26 ± 5	78 ± 7
4d	70 ± 14	28 ± 13
4e	0	81 ± 6
4f	45 ± 12	96 ± 2
4g	12 ± 9	87 ± 9
4h	0	35 ± 12

4. Conclusion

Pyridinecarboxaldimines derived from the condensation of 2-pyridinecarboxaldehyde and fluorine-containing amines have been prepared in high yields and used as ligands for palladium and platinum salts. The resulting metal complexes have shown considerable cytotoxicity against the OV2008 (human ovarian carcinoma) cisplatin-resistant C13 cell line. Future work in this area will continue to develop bulkier metal complexes containing highly fluorinated groups.

Acknowledgements

Thanks are gratefully extended to the Research Corporation (Cottrell College Science Award), NSERC, Canada Research Chair/Canadian Foundation for Innovation/Atlantic Innovation Fund programs and Mount Allison University for financial support. We also thank Roger Smith, Dan Durant and Barbie Sears (MAU) for expert technical assistance, Dr. Barbara C. Vanderhyden of the Centre for Cancer Therapeutics (Ottawa Regional Cancer Centre, Ont., Canada) for providing us with the OV2008 and C13 cell lines, and anonymous reviewers for helpful comments.

Dicopper(II) Schiff base aminobenzoates with discrete molecular and 1D-chain polymeric structures

Arindam Mukherjee, Manas K. Saha, Munirathinam Nethaji, Akhil R. Chakravarty *

Department of Inorganic and Physical Chemistry, Indian Institute of Science, Sir C. V. Raman Avenue, Bangalore 560012, India

Received 2 June 2004; accepted 23 June 2004
Available online 29 July 2004

Abstract

Dicopper(II) complexes $[Cu_2L(O_2CC_6H_4\text{-}o\text{-}NH_2)]$ (**1**) and $[Cu_2L(O_2CC_6H_4\text{-}p\text{-}NH_2)]$ (**2**) are prepared from a reaction of $[Cu_2L(O_2CMe)]$ with the corresponding aminobenzoic acid and a base in MeOH, where L is a trianionic pentadentate Schiff base ligand *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine). The complexes are structurally characterized by X-ray crystallography. The crystal structures show the presence of an asymmetrically dibridged $\{Cu_2^{II}(\mu\text{-}OR)(\mu\text{-}O_2CR)\}$ core where the endogenous monoatomic bridging alkoxo group is derived from the Schiff base and the aminobenzoate ligand displays *syn–syn* bridging mode. The Cu···Cu separation and Cu–OR–Cu bond angle in **1** and **2** are 3.472(1) Å, 131.02(18)° and 3.511(1) Å, 132.20(17)°, respectively. The *o*-aminobenzoate complex is discrete dimeric nature. The pendant *o*-amino group is involved in an intramolecular hydrogen bonding interaction with one carboxylate oxygen atom. The crystal structure of the *p*-aminobenzoate species **2** shows the formation of a one-dimensional polymeric chain resulting from the axial binding of the pendant *p*-amino group to one copper center belonging to another dimeric unit. Magnetic studies show that both the complexes are antiferromagnetic in nature giving a singlet–triplet energy separation of −130 and −150 cm^{-1} for **1** and **2**, respectively. The 1D chain complex **2** magnetically behaves like the discrete dimeric complex **1**.

1. Introduction

Binuclear copper(II) complexes are of interest as models for investigating intramolecular magnetic-exchange interactions between two metal centers in different structural motifs, viz. the ''paddle-wheel'' dicopper(II) tetracarboxylates, symmetrically dibridged hydroxo or alkoxo species, and asymmetrically dibridged complexes with a (μ-hydroxo/alkoxo)(μ-carboxylato)dicopper(II) core [1–10]. Dicopper(II) complexes are also of importance as precursors in the chemistry of supramolecular and discrete molecular high-nuclearity copper(II) complexes [11–20]. In our recent publications, we have shown that dicopper(II) complexes containing pentadentate Schiff base ligands *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine) (H_3L) or *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(acetylacetoneimine) (H_3L^1) are useful for the synthesis of high nuclearity copper(II) complexes showing interesting magneto-structural properties [16–20].

We have observed that the dicopper(II) Schiff base complexes having bridging carboxylate like *p*-hydroxycinnamate with a pendant hydroxyl group form helical supramoleclar structure due to hydrogen bonding interactions involving one phenoxo oxygen atom of the Schiff base and the hydroxyl group of the carboxylate [21]. In contrast, the *p*-hydroxybenzoate complex is a discrete tetranuclear species resulting from the self-assembly of

two dicopper(II) units [22]. The present work stems from our interest to prepare analogous dicopper(II) Schiff base (H_3L) complexes containing *o*- and *p*-aminobenzoate ligands with an aim to explore the effect of the pendant amino group on the structure and magnetic properties of the complexes. Herein we report the synthesis, crystal structure and magnetic properties of two new dicopper(II) complexes $[Cu_2L(O_2CC_6H_4\text{-}o\text{-}NH_2)]$ (**1**) and $[Cu_2L(O_2CC_6H_4\text{-}p\text{-}NH_2)]$ (**2**) having a (μ-alkoxo)(μ-carboxylato)dicopper(II) core. While **1** is discrete dimeric, **2** is a one-dimensional coordination polymer.

2. Experimental

2.1. Materials and measurements

Chemicals and reagents were procured from commercial sources and were used as received. The Schiff base *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine) (H_3L) and the precursor complex $[Cu_2L(O_2CMe)]$ were prepared following literature procedures [7]. The elemental analyses were done using Thermo Finnigan FLASH EA 1112 CHN analyser instrument. The infrared and electronic spectra were obtained from Bruker Equinox 55 and Perkin–Elmer Lamda 35 spectrometers, respectively. Variable temperature magnetic susceptibility data for the polycrystalline samples of the complexes in the temperature range 18–300 K were obtained using a Model 300 Lewis Coil Force magnetometer (George Associates Inc., Berkeley, CA), equipped with a closed cycle cryostat (Air Products) and a Cahn balance. $Hg[Co(NCS)_4]$ was used as a standard. The experimental susceptibility data were corrected for diamagnetic contributions and temperature independent paramagnetism [23]. The magnetic susceptibility data were fitted to the modified Bleaney–Bowers expression by means of a least-squares computer program [23,24]. The Hamiltonian and susceptibility equation used were: $\hat{H} = -2J\hat{S}_1\hat{S}_2$ ($S_1 = S_2 = 1/2$ for a d^9–d^9 dicopper(II)core) and $\chi_{Cu} = [Ng^2\beta^2/k(T-\theta)][3+\exp(-2J/k(T-\theta))]^{-1}(1-\rho) + (Ng_1^2\beta^2/4kT)\rho + N_\alpha$, where ρ is the fraction of paramagnetic impurity and $2J$ is the singlet–triplet energy separation. The expression used to calculate *R* value is: $R = \sum_i[\{\chi_{obs}(T_i) - \chi_{calc}(T_i)\}^2/\chi_{obs}(T_i)^2]$. The best theoretical fit gave $2J = -130$ cm^{-1}, $g = 2.06$, $\rho = 0.011$, $g1 = 2.2$, $\theta = 0$ K, $R = 6.5\times10^{-3}$ for **1** and $2J = -150$ cm^{-1}, $g = 2.19$, $\rho = 0.02$, $g1 = 2.2$, $\theta = 6$ K, $R = 7.9\times10^{-3}$ for **2**. The magnetic moments were calculated in μ_B unit ($\mu_B \approx 9.274\times10^{-24}$ JT^{-1}).

2.2. Synthesis

The complexes were prepared by a common synthetic procedure in which the *ortho*- or *para*-aminobenzoic acid (0.24 g, 1.7 mmol) taken in methanol (10 ml) was initially treated with piperidine (0.15 ml, 1.5 mmol), followed by reaction with a methanol solution of $[Cu_2L(O_2CMe)]$ (0.71 g, 1.5 mmol). The solution was refluxed for 30 min, cooled to an ambient temperature and the product, isolated as a green solid, was washed with ethanol and finally dried in vacuum over P_4O_{10} (~65% yield). *Anal.* Calc. for $C_{24}H_{21}Cu_2N_3O_5$ (**1**): C, 51.6; H, 3.8; N, 7.5. Found: C, 51.3; H, 4.0; N, 7.7%. Electronic spectral data in MeOH [λ_{max}, nm (ε, M^{-1}cm^{-1})]: 635 (370), 354 (8600), 269 (22600), 242 (42000), 222 (54000). Magnetic susceptibility data [χ_M^{corr} (per copper), cm^{3}M^{-1}]: 1.17×10^{-3} at 300 K; 0.35×10^{-3} at 18 K. Magnetic moment (μ_{eff} per copper): 1.67 μ_B at 300 K and 0.22 μ_B at 18 K. *Anal.* Calc. for $C_{24}H_{21}Cu_2N_3O_5$ (**2**): C, 51.6; H, 3.8; N, 7.5. Found: C, 51.4; H, 4.0; N, 7.6%. FT-IR (KBr phase), cm^{-1}: 3419m, 3341m, 3052w, 2925w, 2899w, 1632s, 1600s, 1587s, 1548s, 1449s, 1390s, 1349m, 1319m, 1281m, 1186m, 1167m, 1148m, 1132m, 1055w, 1027w, 966w, 858w, 792m, 758m, 698m, 625w, 587w, 513w, 475w, 437w. Electronic spectral data in MeOH [λ_{max}, nm (ε, M^{-1}cm^{-1})]: 640 (370), 364 (10100), 273 (41600), 242 (43600), 223 (50000). Magnetic susceptibility data [χ_M^{corr} (per copper), cm^{3}M^{-1}]: 1.29×10^{-3}at 300 K; 0.73×10^{-3} at 18 K. Magnetic moment (μ_{eff} per copper): 1.76 μ_B at 300 K and 0.33 μ_B at 18 K.

2.3. X-ray crystallography

Single crystals of the complexes were obtained on slow concentration of the mother liquor at room temperature. The crystals were mounted on glass fibers using epoxy cement. All geometric and intensity data for **1** were collected using an automated Enraf-Nonius CAD4 diffractometer equipped with graphite monochromated Mo Kα radiation. Intensity data were collected using a ω–2θ scan mode and the data were corrected for Lorentz-polarization effects and for absorption [25a]. Intensity data for **2** were measured in frames with increasing ω (width of 0.3°/frame) at a scan speed of 12 s/frame using a Bruker SMART APEX CCD diffractometer, equipped with a fine-focus sealed tube X-ray source. The SMART software was used for data acquisition and the SAINT software for data extraction. Empirical absorption correction was made on the data [25b]. The structures were solved by heavy atom method and refined on F^2 by full-matrix least-squares using SHELX programs [26]. All the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were generated in their calculated positions, assigned fixed ther-
