mal parameters and refined using a riding model. They were used for structure factor calculation only. Selected crystallographic data are given in Table 1. Perspective views of the complexes were obtained by ORTEP [27].

3. Results and discussion

3.1. Synthesis and general properties

Complexes **1** and **2** are prepared in high yield by reacting [$Cu_2L(O_2CMe)$] with the respective *ortho*- and *para*-aminobenzoate ligand in methanol. The complexes show a visible spectral band near 640 nm in MeOH, assignable to the d–d transition. The infrared spectra display characteristic bands for the amino group near 3450 and 3350 cm^{-1}. The IR spectral band for the imine group [ν(C=N)] is observed near 1640 cm^{-1}.

3.2. Crystal structures

The molecular structures of **1** and **2** are obtained from single crystal X-ray crystallographic studies. Selected bond distances and angles are listed in Table 2 and the ORTEP views are given in Figs. 1 and 2. Complex **1** is a discrete dimeric species in which the metal atoms are bonded to a pentadentate Schiff base and a carboxylate ligand. The Schiff base provides the endogenic alkoxo bridge, while the carboxylate displays three-atom bridging mode in the {Cu_2(μ-OR)(μ-O_2CR)} core. Each copper has $CuNO_3$ square-planar coordination geometry. The Cu···Cu distance and Cu–O–Cu angle are 3.472(1) Å and 131.02(18)°, respectively. The copper atoms are deviated by ∼0.01 Å from the basal plane. The alkoxo oxygen atom O(2) has a planar geometry as the sum of three angles is ∼359°. The pendant *o*-amino group is involved in moderately strong intramolecular hydrogen bonding interaction with the oxygen atom O(4) of the carboxylate [N(3)···O(4), 2.65(1) Å].

Complex **2** with *p*-aminobenzoate ligand forms a one-dimensional coordination polymer in which the [$Cu_2L(O_2CC_6H_4$-*p*-$NH_2)$] units are linked via axial coordination of the amino group of one unit to the copper center of another dimeric unit. The Cu(1) atom has a square pyramidal (4 + 1) coordination geometry, while the Cu(2) atom is square planar. The Cu···Cu distance and Cu–O–Cu angle are 3.511(1) Å and 132.20(17)°, respectively. The Cu(1) atom is deviated by ∼0.1 Å from the basal plane due to the formation of the axial bond. The polymeric structure of **2** displays an isotactic arrangement of the Cu(2) atom protruding to one side of the polymeric chain that contains the Cu(1) atom. The polymeric structure of **2** is significantly different from its isonicotinate analogue $Cu_2L(O_2CC_5H_4N)$] in which the Cu_2L^+ units are covalently linked by the

pyridine nitrogen atom of the isonicotinate ligand to give a syndiotactic arrangement of the copper ions protruding outside the chain [28].

3.3. Magnetic properties

The variable temperature magnetic susceptibility data for the complexes in the temperature range 300–18 K show an antiferromagnetic (AF) behavior of the complexes (Fig. 3). The magnetic moment values (per copper) of ~1.7 μ_B at 300 K and ~0.3 μ_B at 18 K indicate significant AF spin–spin coupling in the asymmetrically dibridged dicopper(II) core. A theoretical fitting of the magnetic susceptibility data for **1** gave the singlet–triplet energy separation ($-2J$) of 130 cm^{-1} with the singlet as the ground state. Complex **1** is a discrete dimeric species and the observed magnitude of the exchange coupling constant compares well with that of the precursor complex (-170 cm^{-1}) [7]. The nature and magnitude of the magnetic exchange interaction in the {Cu_2(μ-OR)(μ-

$O_2CR)\}$ core primarily depends on the Cu–O–Cu angle. The magnitude of $-2J$ in such a core is generally small due to counter-complimentary nature of overlap of the magnetic orbitals [4,5,7].

The magnetic behavior of the 1D chain coordination polymer **2** is similar to those observed for the discrete dicopper(II) complexes with a $\{Cu_2(\mu\text{-}OR)(\mu\text{-}O_2CR)\}$ core. Complex **2** has been modeled as an isolated dimeric species and good theoretical fitting of the magnetic susceptibility data is obtained using modified Bleaney–Bowers expression [23,24]. The $2J$ value is -150 cm^{-1} with a θ value of 6 K. While an antiferromagnetic coupling is predominant in the dicopper(II) unit having a large Cu–O–Cu angle of 132°, a positive value of θ suggests the presence of minor ferromagnetic interaction involving the dimeric units through the axial bond. The involvement of the $d_{x^2-y^2}$ orbital of the Cu(1) atom and the d_{z^2} orbital of the adjacent copper atom along the chain could promote weak ferromagnetic interaction. The magnetic behavior of **2** is significantly different from that of the isonicotinate complex $[Cu_2L(O_2CC_5H_4N)]_x$ for which the magnetic data do not show any good fit with the Bleaney–Bowers expression. The magnetic model assumes the isonicotinate complex as an equimolar mixture of copper atoms belonging to an antiferromagnetically coupled one-dimensional Heisenberg chain with the other copper atoms outside the chain behaving like paramagnetic centers [28]. The 1D chain of **2** magnetically behaves like the discrete dimeric complex **1**.

In summary, two new Schiff base copper(II) complexes having asymmetrically dibridged dicopper(II) cores are prepared and structurally characterized. The *o*-aminobenzoate complex is discrete dimeric in nature. The *p*-aminobenzoate species shows the formation of a one-dimensional coordination polymer. The dicopper(II) cores in the complexes show antiferromagnetic magnetic exchange. The magnetic interaction between two copper centers along the 1D chain in **2** is weakly ferromagnetic in nature.

Abstract

Starting from $Ba[Ba(1,3\text{-pdta})] \cdot 2H_2O$ (where 1,3-pdta is the 1,3-propanediaminetetraacetate ion) two new hexadentate complexes: $[Mg(H_2O)_6][Mg(1,3\text{-pdta})] \cdot 2H_2O$ (**1**) and $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)] \cdot 2H_2O$ (**2**) have been prepared and characterized. The complexes differ in coordination numbers and geometry, and in coordinative bond distances. They also display dramatically different packing patterns: while the structural units of (**1**) consist of discrete $[Mg(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ octahedra arranged in the solid-state in a close packed fashion, the crystals of (**2**) are composed of one-dimensional chains of ligand-bridged coordination complexes, such that no discrete complex units exist. The calcium(II) ion (Ca1), coordinated with the 1,3-pdta ligand and two symmetry-related water molecules, forms an irregular square-antiprismatic structure, which is not common for the M-1,3-pdta system. The coordination polyhedron formed around the counter ion (Ca2) can best be described as a dodecahedron. Six-membered diamine chelate rings in complexes (**1**) and (**2**) are found to be in *twist-boat* and distorted *chair* conformations, respectively. Infrared and solid-state ^{13}C NMR spectra of Ba-, Mg- and Ca-1,3-pdta complexes have also been presented.

1. Introduction

The metal ion (M) complexes with edta-type ligands (edta is the ethylenediaminetetraacetate ion) exhibit a variety of coordination numbers (C.N.) and geometries [1]. Factors that govern the stereochemistry of this type of complex have been considered by different authors [2–4]. According to Yamamoto et al. [2], the elements that dictate the structural types of M-edta complexes include d-electron configuration and the size of the central metal ion (M). When the ionic radius of the metal ion, [5] with other than spherically symmetric electron configurations, exceeds the size of a "critical" ionic radius, [2,4] a C.N. of six is preferred by ligand field stabilization. In some cases, edta cannot easily span the large

doi:10.1016/j.poly.2004.05.019

ion as a hexadentate ligand and the complex is expected to contain pentadentate edta having one carboxylate arm dechelated and a monodentate ligand occupying the sixth position. However, for M-edta complexes, where the ionic radius of M, [5] with d^0, d^5 (high-spin) or d^{10} configurations, exceeds the size of the "critical" ionic radius, [2,4] the C.N. can be expected to increase to 7. Seven-coordinate metal complexes, which adopt in most cases either a pentagonal-bipyramidal (PB) or mono-capped trigonal-prismatic (CTP) structure, have attracted an increasing interest of coordination chemists, [4] because they are relatively rare and play key roles in associative substitution reactions of the by-far more common six-coordinate, octahedral metal complexes.

The theory that treats the role of chelate ring size to be a very important factor in determining the coordination number and geometry, and the complex stability, has been reported by Hancock [3]. He has established that the ligand edta which is capable of forming only five-membered chelate rings, favours coordination with larger metal ions with an ionic radii of about 1.0 Å. The M-edta system is of minimum strain when the M–N bond length is 2.5 Å and the N–M–N bond angle is 69°. This is consistent with a coordination number higher than six and indeed there are several examples of complexes of the $[M(edta)(H_2O)]^{n-}$ type (M = Mg(II), [6,7] Mn(II), [8] Fe(II), [4] Co(II), [9] Fe(III), [10] V(III) [11] and Ca(II) [12]). In contrast to this, a six-membered diamine ring of 1,3-pdta (1,3-pdta is the 1,3-propanediaminetetraacetate) was found to have minimum strain when the metal ion (M) is small with a M–N bond distance of 1.6 Å and a N–M–N bond angle of 109.5° [3].

All hexadentate $[M(1,3\text{-pdta})]^{n-}$ (M = Co(III), [13] Cr(III), [14] Rh(III), [14] Fe(III), [2,15] V(III), [16] Cu(II), [17,18] Ni(II) [19] and Co(II) [20]) complexes known so far, adopt more or less distorted octahedral geometry. Comparing the X-ray data [1,19,20] of edta and 1,3-pdta complexes it has been found that the hexadentate 1,3-pdta ligand containing a lengthened diamine chain, with respect to edta, is able to form less strained octahedral systems with metal ions of different size.

The aim of the present work was to investigate the stereochemical properties of 1,3-pdta complexes with spherically symmetric metal ions of different size. For this purpose two hexadentate complexes, $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**) (C.N. = 6) and $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**2**) (C.N. = 8) were prepared, and characterized. The structural characteristics of **1** and **2** were studied by single-crystal X-ray crystallography, and spectral infrared and solid-state ^{13}C NMR characterizations for these and the $[Ba(1,3\text{-pdta})]^{2-}$ complex have also been given.

2. Experimental

All commercially obtained reagent-grade chemicals were used without further purification. The preparation of barium (1,3-propanediaminetetraacetato)barium(II) dihydrate, $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$, has been reported elsewhere [17,21].

2.1. Preparation of hexaaquamagnesium(II) (1,3-propanediaminetetraacetato)magnesium(II) dihydrate, $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (1)

$MgSO_4\cdot 6H_2O$ (4.56 g, 20.0 mmol) was dissolved in 160 cm^3 of water. To this solution, solid $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g, 10.0 mmol) was added and the reaction mixture was stirred with heating for 9 h at 90 °C. During this time the volume of the reaction mixture was kept at about 160 cm^3 by adding distilled water. The precipitated $BaSO_4$ was removed by filtration, and the volume of filtrate was reduced to 25 cm^3. After cooling at room temperature, the solution was left to stand in a refrigerator overnight. The colorless crystals of $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**) were filtered, washed with ethanol, then ether, and air-dried. Yield: 4.36 g, 88%. Recrystallization of the compound was easily achieved from hot water and cooling the solution at room temperature. *Anal.* Calc. for $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), $Mg_2C_{11}H_{30}N_2O_{16}$ (FW = 494.99): C, 26.69; H, 6.11; N, 5.66. Found: C, 26.84; H, 5.91; N, 5.70%.

2.2. Preparation of (aqua)(1,3-propanediaminetetraacetato)calcium(II)-triaquacalcium(II) dihydrate, $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (2)

$CaSO_4\cdot 1/2H_2O$ (2.90 g, 20.0 mmol) was dissolved in 1200 cm^3 of water. Into this solution solid $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g, 10.0 mmol) was added, and the reaction mixture was stirred with heating for 18 h at 90 °C. During this time, the volume of the reaction mixture was reduced to 400 cm^3 and the precipitated $BaSO_4$ was removed by filtration. The volume of the filtrate was reduced to 200 cm^3 and then cooled at room temperature. The white compound $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**2**) (2.23 g) was collected by filtration and air-dried. The volume of mother liquor was reduced to 80 cm^3. After cooling at room temperature, 10 cm^3 of ethanol was added and the solution was left to stand at room temperature for several days. From this solution an additional amount of $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**2**) (1.12 g) was precipitated, then filtered and air-dried. Yield: 3.35 g, 68%. The complex was recrystallized from a water solution left to stand in a desiccator over methanol for several weeks. The recrystallized

product was checked by elemental microanalyses and IR spectroscopy, and the obtained results were equal to those for the precipitates obtained before recrystallization. *Anal.* Calc. for $[Ca(H_2O)_3Ca(1,3\text{-}pdta)(H_2O)] \cdot 2H_2O$ (**2**), $Ca_2C_{11}H_{26}N_2O_{14}$ (FW = 490.50): C, 26.94; H, 5.34; N, 5.71. Found: C, 27.10; H, 5.24; N, 5.71%.

2.3. Physical measurements

The IR spectra in the solid-state were recorded on a JASCO FT/IR-5300 spectrophotometer using KBr pellets. Solid-state ^{13}C NMR spectra were recored on a Varian Infinityplus-400 spectrometer at 100.4 MHz, using CP/MAS. Spinning speeds of 8 kHz and a contact time of 1 ms were used. Elemental microanalyses for carbon, hydrogen and nitrogen were done by the Department of Chemistry, University of Belgrade, Serbia.

2.3.1. Crystallographic data collection and refinement of the structures

The crystal data for (**1**) and (**2**) and the parameters of data collection are summarized in Table 1. The intensity data were measured with a KM4CCD kappa-geometry diffractometer [22] using graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 293(2) and 150(2) K for (**1**) and (**2**), respectively. The structures were solved by direct methods using SHELXS97 [23] and refined by least-squares techniques with SHELXL97 [24]. The intensity data were corrected for Lp effects as well as for absorption. Anisotropic thermal parameters were employed for the non-hydrogen atoms. All of the water hydrogen atoms were located in the Fourier map, while the remaining H atoms were placed at calculated positions. The H-atom positions were refined in a so called "riding model" with the atomic displacement parameters 30% higher than the displacement parameters for the atom to which the H atoms were bonded. A Siemens Stereochemical Workstation was used to prepare drawings [25].

3. Results and discussion

The influence of metal ion radius and d-electron configuration on the geometry of the complex is precisely defined for the M-edta system [2,4]. However, this effect on the geometry of complexes with ligands containing lengthened chains with respect to edta has not been explored yet. The reason for this may lie in the fact that crystallographic data for such systems are limited. The crystal structures of these hexadentate $[M(1,3\text{-pdta})]^{n-}$ complexes, for which coordinates are available through the Cambridge Crystallographic Database, [1] can roughly be divided into two series, depending on the valence of the central metal atom. All so far reported $[M(1,3\text{-pdta})]^{2-}$ complexes crystallize in the space group, Pnna, forming an isomorphic series, [17–20] while the majority of $[M(1,3\text{-pdta})]^{-}$ complexes crystallize in either $P2_12_12_1$[14,15a,16] or $C222_1$ [13] space groups, again displaying an identical packing pattern within the series. The packing pattern in the $[M(1,3\text{-pdta})]^{2-}$ series can be characterized as constituting of discrete complexed cations and anions of octahedral geometry arranged in the crystal in a close packed fashion and connected via numerous hydrogen bonds. On the other hand, in the $[M(1,3\text{-pdta})]^{-}$ series, the cations and anions are connected via carboxylate bridges. The complex anions are situated in layers perpendicular to the 16 Å direction, while the cations and water molecules are arranged in between these layers. The crystal structure containing the $[Fe(1,3\text{-pdta})]^{-}$ unit, [2,15b] that crystallizes in space group $P2_1/n$ and therefore seems to be an exception to this generalization, possesses similar unit cell parameters and displays a very similar packing pattern as the remaining $[M(1,3\text{-pdta})]^{-}$ crystals.

Our main interest in this work was to investigate the influence of metal ion radius on the geometry of the M-1,3-pdta system. To prepare the model complexes, metal ions of varying size (Mg(II) (0.86 Å) [5] and Ca(II) (1.14 Å) [5]) were chosen for which a C.N. 6 is not preferred by ligand field stabilization. Comparison of the coordinative behavior, of calcium and magnesium from data deposited in the CSD [26] has revealed that although both cations display some similarities in their coordinative behavior, such as formation of highly ionic coordinative bonds and a marked preference for oxygen donor atoms, they do differ in their coordination numbers which in the case of Mg(II) is fairly strictly confined to 6, while for Ca(II) the coordination numbers 6 and 8 are readily accessible. In the synthetic reactions of the dibarium complex of 1,3-pdta with magnesium or calcium sulfates two new hexadentate complexes were obtained ($[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**) and $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**2**)). The X-ray analyses of these revealed that 1,3-pdta-chelated Mg(II) and Ca(II) metal ions are significantly different in coordination number and geometry.

3.1. Crystal structure of $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (1)

The crystal of the studied complex (**1**) appears to be isomorphic with the other (1,3-propanediaminetetraacetato)metal(II) complexes: $[M(H_2O)_6][Cu(1,3\text{-pdta})]\cdot 2H_2O$ (M = Mg(II) [17] or Mn(II) [18]), $[Mg(H_2O)_6][Ni(1,3\text{-pdta})]\cdot 2H_2O$ [19] and $[M(H_2O)_6][Co(1,3\text{-pdta})]\cdot 2H_2O$ (M = Mg(II) or Co(II)) [20]. The ORTEP diagram of $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**) is depicted in Fig. 1 where the numbering scheme adopted for the respective atoms is also given. Selected bond distances and bond angles for complex (**1**) are listed in Table 2. The structural unit in the crystal structure of (**1**) consists of $[Mg(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ octahedra, and two water solvent molecules, all of which lie on a special position in the unit cell. The highest symmetry (C_2) axis of the complex anion passes through the Mg1and C2 atoms and bisects the N1–Mg1–N1^{i} bond angle (where the symmetry code i = x, $0.5-y$, $-0.5-z$) making the two out-of-plane glycinate rings (R rings), as well as the two in-plane (G rings), identical. In this structure, the six-membered 1,3-propanediamine ring (T ring) adopts a flexible *twist-boat* conformation with the average torsion angle moduli of 44.0°. The R rings are almost flat, while the G-rings are much more puckered and are halfway between *envelope* and *twist* conformations. The mean deviation from octahedral angles (average

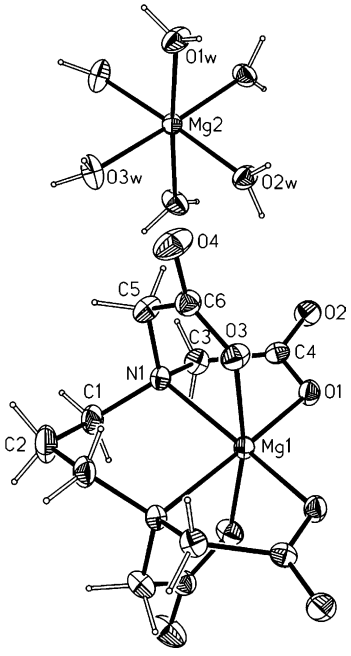

Fig. 1. The ORTEP drawing of the $[Mg(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ octahedra. As the molecules are situated on a two-fold symmetry axis, generation of the second half of the complex anion and cation requires the symmetry operations x, $0.5-y$, $-0.5-z$ and x, $0.5-y$, $0.5-z$, respectively.

(ΔO_h)) for $[Mg(1,3\text{-pdta})]^{2-}$ equals 7.4°, which indicates the nearly regular octahedral geometry of the complex anion.

Table 3 lists bond lengths to the metal(II) atoms observed in a series of isomorphic crystals for complexes of the $[M^{II}(H_2O)_6][M^{II}(1,3\text{-pdta})]\cdot 2H_2O$ type and the mean deviation from octahedral angles (average (ΔO_h) parameter). The closest to the ideal regular octahedral geometry is displayed by the $[Ni(1,3pdta)]^{2-}$ complex anion in which the Ni–N and Ni–O_R bonds are equal in length. On the contrary, in the Mg(II) complex, the Mg–N bond lengths are significantly longer than the corresponding Mg–O bonds, in line with the observation that for edta-like complexes of predominantly electrostatic binding metal ions the interactions of such metals with amine nitrogens are relatively weak.

Similar to other crystal structures of divalent metal ions with the 1,3-pdta ligand, [17–20] the discrete $[Mg(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ octahedra alternate in the crystal in such a way that each complex anion is surrounded by six complex cations situated at the corners of a distorted octahedron and vice versa. As a result, not only the first but also the second metal coordination sphere displays nearly octahedral geometry. Such an alternating arrangement of the cationic and anionic species might indicate nearly spherical charge distribution on each of the complex units, which is consistent with their first coordination sphere being close to a regular octahedron.

The packing in the structure is determined by an extended network of relatively strong hydrogen bonds predominantly involving water molecules (coordinated to Mg2 or two water solvent molecules) and carboxylate oxygens. The two coordination polyhedra are connected via hydrogen bonds in three dimensions.

3.2. Crystal structure of $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (2)

The crystal structure of (**2**) consists of infinite one-dimensional chains of ligand-bridged coordination complexes connected by hydrogen bonds, such that no discrete complexes exist. The ORTEP diagram of the $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]$ unit is presented in Fig. 2, where the numbering scheme adopted for the respective atoms is also given. Selected bond distances and bond angles for complex (**2**) are listed in Table 2.

The Ca1 has eightfold coordination with the hexadentate 1,3-pdta ligand and two symmetry-related water molecules O1W and O1W^{iii} (where the symmetry code iii = $1-x$, $1-y$, $2-z$). Distribution of the values of the valence angles around the Ca1 metal center resembles a set of values expected for the ideal square antiprism (70.5°, 109.5°, 82.1° and 160.5°), thus the coordination polyhedron formed around Ca1 may be described as distorted square antiprism. Conformations of the chelate rings are found to be *twist* or *envelope* for the glycinates and a distorted *chair* for the six-membered diamine ring. Two symmetry related calcium ions Ca1 and Ca1^{iii} are

Table 3

[c] Average of two independent measurements.

bridged by water molecules (O1W and O1W^{iii}) around the center of symmetry at (1/2 1/2 0), and in this way two complex units are joined into a dimer. The distance between two metal centers in the dimer is 4.281(1) Å . By sharing both oxygen atoms of the C(5) and C(7) carboxylate groups, the two Ca1 and Ca1^{iii} ions join in a bidentate fashion to the same two Ca2 ions (at distances of 4.632 and 4.704 Å) forming a tetramer structure. Further, Ca2 and Ca2^{v} (where the symmetry code v = $1-x$, $2-y$, $2-z$) are bridged by carbonyl oxygen atoms O4^{iii} and O4^{iv} (where the symmetry code iv = x, $1+y$, z) around the center of symmetry at (1/2 0 0). The two Ca2 metal centers approach each other at a distance of only 3.829(1)Å . In this way the tetramers are joined together by coordination bonds into one-dimensional chains parallel to the *b*-axis (Fig. 3). Within the chains the C(5) and C(7) carboxylate groups act as a bridge between metal centers: the C(5) carboxylate bridging two metal centers and C(7) carboxylate bridging three metal centers. Interactions between the neighboring polymeric chains include not only numerous hydrogen bonds but also dipolar interactions between antiparallel C(10)=O(8) groups around the symmetry center at 0 1/2 0 (Table 4). The two crystal water molecules (O5W and O6W) serving as hydrogen bond donors and acceptors connect the polymeric chains in three dimensions. Distances and angles for all hydrogen bonds that participate in the structure and geometrical parameters describing dipolar carbonyl interactions are listed in Table 4.

The coordination number of Ca2 is eight and the coordination polyhedron is very irregular in shape and may best be described as a dodecahedron. The Ca2 ion is surrounded by five oxygen atoms (O1, O2, O3^{iii}, O4^{iii} and O4^{iv}) which belong to three different but symmetry-related 1,3-pdta ligands, and by three water molecules (O2W, O3W and O4W). Two carboxylate groups of 1,3-pdta are coordinated in a bidentate fashion (over O1, O2, O3^{iii} and O4^{iii} oxygen atoms) to Ca2, and two carbonyl oxygens (O4^{iii} and O4^{iv}) are shared between two Ca2 ions.

A complex of a metal ion that is fairly large in size, such as Ca(II), with the 1,3-pdta ligand is much less favored with respect to that of edta [3,27]. Despite this, complex **2** is similar in structure to the three known crystal structures containing $[Ca(edta)]^{2-}$, units [12a–c]. For each edta-chelated Ca(II), the coordination number is also eight and the coordination polyhedron is approximately square-antiprismatic [12a–c]. In Ca(II)-edta, the two sites that supplement the C.N. 8 (in addition to the six sites occupied by the hexadentate edta ligand) are filled by a water molecule and a symmetry-related edta oxygen atom [12a,b] or by two water molecules [12c]. A noticeable difference in the stereochemistry of the three $[Ca(edta)]^{2-}$ anions is observed in the conformation of the ethylenediamine ring, which for the same configuration of the complex isomer adopts in two cases the λ conformation [12a,c] and in one case the δ conformation [12b].

3.3. Comparative stereochemistry and strain analysis of edta-type complexes

The critical radii between C.N. = 6 and 7 are successfully used to predict the coordination numbers of edta complexes in cases where the central metal ions have one of the spherically symmetric configurations (d^0, high-spin d^5 and d^{10}) [2,4]. For trivalent metal ions, the C.N. changes from 6 to 7 around Fe(III) (0.785 Å), [5] and for divalent metal ions around Zn (II) (0.88 Å) [5] or Mg(II) (0.86 Å) [5]. However, judging from an electronic point of view the metal ions with d^1, d^2, low-spin d^3, low-spin d^4, high-spin d^6 or high-spin d^7 configurations are also able to form seven-coordinate edta complexes [4]. Structural parameters reflecting the geometry of complexes with edta and 1,3-pdta ligands, containing metal ions that are common for both type of ligands, are presented in Table 5. The restriction was also imposed on metal ions that may form edta complexes of C.N. higher than six. The $[M(edta)(H_2O)]^{n-}$ (M = V(III) (**3**), Fe(III) (**4**), Mg(II) (**5** and **6**) and Co(II) (**7**)) complexes listed are of C.N. = 7 and adopt either PB or CTP structure, while complexes of Mg(II) (**1**), V(III) (**9**), Fe(III) (**10**) and Co(II) (**11**) with the 1,3-pdta ligand (which differs from edta in the length of the diamine chain) are all of C.N. = 6 and adopt an octahedral structure. This indicates that the critical ionic radii for the M-1,3-pdta system should be greater than that for edta. This well

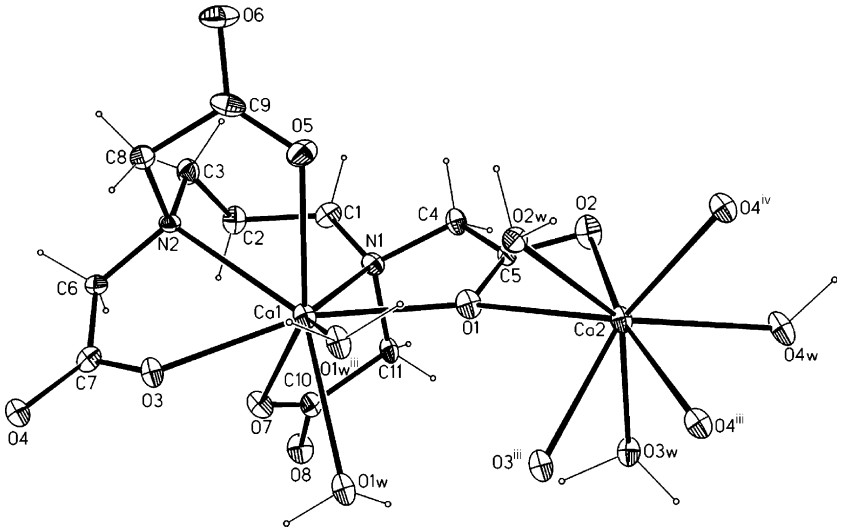

Fig. 2. Coordination sphere around two independent calcium ions (Ca1 and Ca2). The 1,3-pdta ligand is bound to other symmetry-related metal ions by five O atoms: O1, O2, O3 and O4 (the latter is bound to two different Ca^{II} ions). Symmetry codes: iii = $1-x$, $1-y$, $2-z$ and iv = x, $y+1$, z.

pronounced tendency within the two series is perturbed by the complex of Ca(II) which is of C.N. = 8 and has square-antiprismatic geometry with both the edta (complex (**8**)) and 1,3-pdta ligands (complex (**2**)) (Table 5).

The edta complexes listed in Table 5 exhibit nearly an ideal coordination geometry of the ethylenediamine rings as evidenced by N–M–N bond angles close to the value of 69° which is obtained for the energy minimized coordination [3]. With respect to the value of 69°, the N–M–N bond angle in the $[Co(edta)(H_2O)]^{2-}$ (**7**) complex shows the maximum deviation of +9.7° among the edta complexes listed. The minimum deviation of the N–M–N bond angle was registered for $[Ca(edta)(H_2O)]^{2-}$ (**8**) complexes of C.N. = 8 and equals, on average, −0.5°. A six-membered chelate ring involving 1,3-propanediamine as a ligand was found to be of minimum strain when the N–M–N bond angle equals 109.5° [3]. For the $[M(1,3\text{-pdta})]^{n-}$ [M = Co(III), Cr(III), V(III), Fe(III), Rh(III), Ni(II), Cu(II), Co(II) and Mg(II)] complexes, which adopt a nearly octahedral structure, the N–M–N bite angle was found to be in the range 92.2°–99.0° [19,20]. These values are closer to the value of an ideal octahedral bond angle rather than that of a tetrahedral one. For both series of complexes (edta and 1,3-pdta), with the exception for complex (**7**), the mean M–O distances are shorter than the mean M–N distances. In addition, the mean M–O distances for the 1,3-pdta series increase systematically with an increasing size of the ionic radii. It might also be interesting to note that Ca(II) complexes with edta and 1,3-pdta ligands contain almost identical metal–ligand bond lengths.

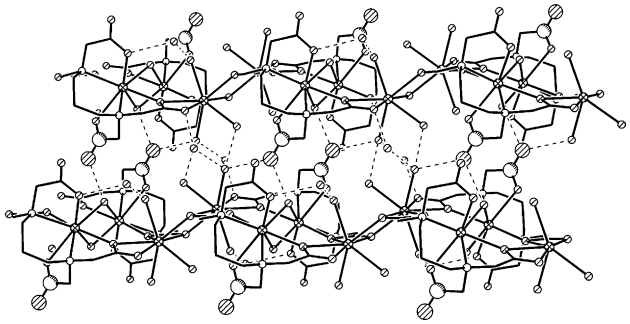

Fig. 3. Infinite one-dimensional chains parallel to the *b*-axis joined together by hydrogen bonds and carbonyl dipolar interactions in the crystal structure of complex (**2**). View along *x*-axis. Atoms constituting carbonyl groups involved in dipolar iteractions are drawn as bigger circles.

The effect of chelation on the distortion of the tetrahedral bonding geometry of the nitrogen atoms is much greater for $[M(edta)]^{n-}$ than for $[M(1,3\text{-pdta})]^{n-}$ octahedral systems [19]. However, an increase of the C.N. from 6 to 7 releases this strain and, accordingly, in the $[M(edta)(H_2O)]^{n-}$ systems of CTP or PB geometry and in the octaheral $[M(1,3\text{-pdta})]^{n-}$ complexes the strain formed around chelating N atoms seems comparable. As can be seen in Table 5, the total deviation from the tetrahedral values of the six bond angles around the N atoms measured for seven-coordinate edta complexes ((**3**)–(**7**)) varies from 8° to 17°, while for 1,3-pdta complexes ((**1**), (**9**)–(**11**)) it is somewhat greater and covers the range from 11° to 21°. For the two square-antiprismatic structures it was observed that the strain formed around chelating N atoms in $[Ca(edta)(H_2O)]^{2-}$ (**8**) is much less than that in $[Ca(1,3\text{-pdta})(H_2O)]^{2-}$ (**2**) (12° *vs.* 28°). Of all complexes considered in Table 4, $[Ca(1,3\text{-pdta})(H_2O)]^{2-}$ (**2**) contains the most strained bonds around chelating nitrogen atoms indicating possible C–N bond rupture in substitution reactions.

3.4. Spectral characteristics of the complexes

In this paper the $[Ba(1,3\text{-pdta})]^{2-}$ complex has been used in the simple method for preparation of the corresponding magnesium and calcium complexes. To compare these complexes with structurally investigated complexes of known X-ray structure, their infrared (IR) and solid-state ^{13}C NMR spectra have been recorded. No signal in the solid-state ^{13}C NMR spectrum of the 1,3-pdta-Ca complex was observed. The IR spectrum of $[Mg(1,3\text{-pdta})]^{2-}$ in the carboxylate region for coordinated glycinates showed only one very strong band at 1596 cm^{-1} indicating that all glycinate rings in this complex are equivalent. However, in accordance with its lower symmetry $[Ca(1,3\text{-pdta})(H_2O)]^{2-}$ showed two bands, a very weak one at 1638 cm^{-1} and a strong one at 1587 cm^{-1}, both assigned to the asymmetric carbonyl stretching vibrations of non-equivalent glycinate rings. In this region two bands have also been observed for $[Ba(1,3\text{-pdta})]^{2-}$ (a shoulder at 1600 cm^{-1} and a very strong band at 1568 cm^{-1}) indicating that glycinate rings in this system should also be non-equivalent. The solid-state ^{13}C CP/MAS NMR spectra of $[Mg(1,3\text{-pdta})]^{2-}$ and $[Ba(1,3\text{-pdta})]^{2-}$ are presented in Fig. 4. On the basis of their chemical shifts, the lowest-field peaks (C1) at ~180 ppm can be assigned to the carboxy-

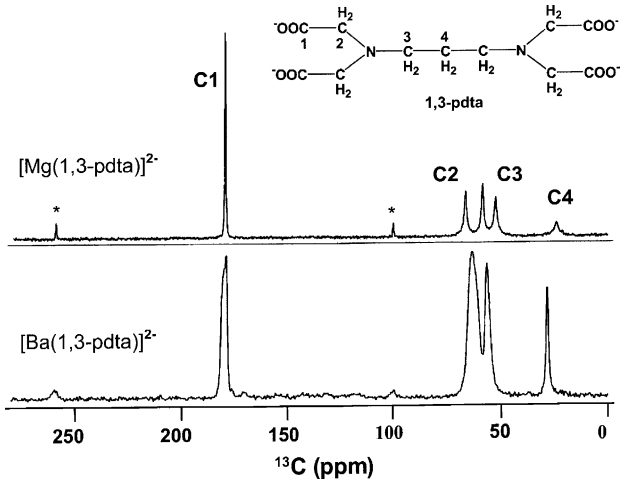

Fig. 4. Solid-state CP/MAS ^{13}C NMR spectra of $[Mg(1,3\text{-pdta})]^{2-}$ and $[Ba(1,3\text{-pdta})]^{2-}$. The assignments together with the structure of 1,3-pdta are also shown. The peaks marked with "*" are spinning side-bands.

lates and the peaks (C2) at 66.6 and 58.6 ppm for $[Mg(1,3\text{-pdta})]^{2-}$ and the very broad peak at 63.0 ppm for $[Ba(1,3\text{-pdta})]^{2-}$ can be assigned to the methylene carbons of the two pairs of non-equivalent glycinate rings in each complex. The highest field methylene resonances (C4) at 24.3 ppm for $[Mg(1,3\text{-pdta})]^{2-}$ and 27.9 ppm for $[Ba(1,3\text{-pdta})]^{2-}$ are due to the middle carbon of the propylenediamine backbone since this carbon is in the greatest shielded environment. The rest of the peaks, (C3) at 52.5 ppm for $[Mg(1,3\text{-pdta})]^{2-}$ and at 56.2 ppm for $[Ba(1,3\text{-pdta})]^{2-}$, are due to the two terminal carbons of the propylenediamine backbone. Additionally, in the carboxylate region for $[Ba(1,3\text{-pdta})]^{2-}$ two well resolved peaks (179.9 and 178.9 ppm) for the two pairs of non-equivalent rings were obtained. This is in accordance with the ^{13}C NMR spectra of 1,3-pdta complexes containing Co(III) [28] and Rh(III) [29] ions. Better resolution of these resonances for $[Ba(1,3\text{-pdta})]^{2-}$ in relation to the corresponding magnesium complex (signal at 180.2 ppm) can be explained in terms of the size differences between these two ions and the greater system strain in $[Ba(1,3\text{-pdta})]^{2-}$.

4. General conclusions

The hexadentate $[M(1,3\text{-pdta})]^{n-}$ complexes are much less distorted from a regular octahedral structure than $[M(edta)]^{n-}$ complexes, as has been evidenced by comparison of the X-ray data of the series of complexes [19]. This is due to the presence of the flexible M-1,3-propanediamine ring system, which releases the strain of the complex as a whole. Thus, it is not unexpected that all but one of the known crystal structures of M-1,3-pdta complexes are so far octahedral. The only exception is the $[Ca(1,3\text{-pdta})(H_2O)]^{2-}$ (**2**) complex, presented in this paper, which has the coordination number eight. On the other hand, M-edta complexes show varieties in stereochemistry, and the critical ionic radii between coordination number six and seven have been successfully used to predict the coordination numbers of edta complexes [2,4]. By comparing the systems of the two ligands, we came to the conclusion that the critical ionic radii for the M-1,3-pdta system should be greater than that for the M-edta system. However, the precise definition would require further X-ray studies of several new and closely related compounds.

As it follows from this study and from previous observations, six of the seven investigated crystals of transition metal(II) complexes with the 1,3-pdta ligand and divalent counter cations: $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), $[M(H_2O)_6][Cu(1,3\text{-pdta})]\cdot 2H_2O$ (M = Mg(II) [17] or Mn(II) [18]), $[Mg(H_2O)_6][Ni(1,3\text{-pdta})]\cdot 2H_2O$ [19] and $[M(H_2O)_6][Co(1,3\text{-pdta})]\cdot 2H_2O$ (M = Mg(II) or Co(II)), [20] are isomorphic. The crystal packing of these compounds is characterized by the alternating arrangement of complex cations and anions leading to an approximately octahedral surrounding in the second coordination sphere of the metal. This can be achieved because the first coordination sphere of both metals shows nearly ideal octahedral geometry and thus nearly spherical charge distribution, and the complex ions form discrete units not connected by carboxylate bridges. As a result, the packing is mostly governed by electrostatic forces. However, this way of molecular organization in the solid-state is not favoured by the homometallic complex of Ca(II) with the hexadentate 1,3-pdta ligand (**2**), which in the crystal builds one-dimensional polymeric chains such that no discrete complexes exist.

The observation that the homometallic complex of Ca(II) with the hexadentate 1,3-pdta ligand displays a different geometry and a different packing mode than all other $[M(1,3\text{-pdta})]^{2-}$ complexes may be attributed to the specific properties of the calcium ion, which is known as a "soft" cation, rather than to the properties of the ligands surrounding the metal center. This conclusion is supported by the fact that calcium(II) forms not only six- but seven-, eight- and nine-coordinated aqua ions [1].

5. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: + 44-1223-336-033; e-mail: deposit@ccdc.cam.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the Deposition No. CCDC 217531 and 217530 for complexes **1** and **2**, respectively.

Abstract

Iron(II) complexes with a combination of nitrogen-donor ligands and trithiocyanuric acid ($ttcH_3$) of the composition $[Fe(bpy)_2(ttcH)] \cdot 2H_2O$ (**1**), $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**), $[Fe(terpyCl)_2](ttcH_2)_2 \cdot H_2O$ (**3**), $[Fe(phen)_2(ttcH)] \cdot 2H_2O$ (**4**), $[Fe(nphen)_2(ttcH)] \cdot 4H_2O$ (**5**) and $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2CH_3OH \cdot 2H_2O$ (**6**), where bpy = 2,2′-bipyridine, terpyCl = 4′-chloro-2,2′:6′,2′-terpyridine, phen = 1,10-phenanthroline, nphen = 5-nitro-1,10-phenanthroline, have been prepared. The compounds, except for **6**, have been characterized by elemental analysis, ^{57}Fe Mössbauer, IR and UV–Vis spectroscopies. It has been found that the trithiocyanurate ion is either coordinated to the metal centre (**1**, **4** and **5**) or situated outside the inner coordination sphere of the iron(II) ion (**2**, **3** and **6**). The X-ray crystal structures of complexes **2** and **6** demonstrate that the ligands enforce a distorted octahedral geometry on the Fe^{II} ions with monoanionic **2** and dianionic **6** forms of uncoordinated trithiocyanuric acid. Density-functional theory (DFT) calculations (B3LYP/6-31 + G*) were used for the geometry optimisation and infrared frequencies calculations of differently protonated forms of the acid ($ttcH_3$, $ttcH_2^-$ and $ttcH^{2-}$).

1. Introduction

Trithiocyanuric acid (2,4,6-trimercapto-1,3,5-triazine, $ttcH_3$) and its trisodium salt ($ttcNa_3 \cdot 9H_2O$) are widely applied in industry, analytical chemistry and biochemistry. For example, $ttcNa_3 \cdot 9H_2O$ is used as a precipitating agent for many heavy metals from contaminated water [1], as a component of the zinc electroplating bath, in PVC floor coverings and it may be also used instead of thiourea in the bleaching of wool [2–4]. Moreover, it was found that the acid inhibits the *Toxoplasma gondii uracil phosphoribosyltransferase* enzyme in vitro better than 5-fluorouracil and emimycin, i.e. compounds showing an antitoxoplasmal activity [5,6].

At first, Beezer et al. [7] studied complexes of trithiocyanuric acid. The authors found that the formation of mononuclear, binuclear as well as trinuclear complexes depends on the molar stoichiometry of reactants (i.e. on the molar ratio between metal ions and ligands) and the pH of the water solution. Bailey et al. [8] studied

doi:10.1016/j.poly.2004.06.024

the influence of pH and different stoichiometry on the formation of Co^{II}, Cu^{II} and Cd^{II} complexes in detail. Moreover, they have found that the complexes can be used as precursors for the preparation of transition metal sulfide nanomaterials. To date, X-ray crystal structures of some complexes involving trithiocyanurate anions have been determined, e.g. $[\{Os_3H(CO)_{10}\}_3(ttc)]$ [9], $[\{Co(en)_2\}_2(ttc)](ClO_4)_3 \cdot 2H_2O$ (en = ethylenediamine) [10], $[\{Cu(PPh_3)\}_6(ttc)_2]$ (PPh_3 = triphenylphosphine) [11], $[\{Au(ttc)\}\{Au(PPhMe_2)_2\}]_2$, $[(AuPPh_3)_3(ttc)] \cdot 2DMF$ [12], $[(AuPPh_3)_3(ttc)] \cdot 2Et_2O$, $[Au_6(L)_4(ttc)_2] \cdot C_6H_5NO_2$, (L = *t*-butylcyanate) [13], $[(SnPh_3)_3(ttc)]$, $[(SnMe_3)_3(ttc)]$ [14], $Ca(ttcH_2)_2 \cdot 11H_2O$, $Sr(ttcH_2)_2 \cdot 11H_2O$, $Ba(ttcH_2)_2 \cdot 4.5H_2O$ [15], $Mg(ttcH_2)_2 \cdot 6H_2O$, $Ba(ttcH_2)_2 \cdot 7H_2O$, $Ba(ttcH) \cdot 3H_2O$ [16], $Li(ttcH_2) \cdot 2HMPA$, (HMPA = hexamethylphosphoramide) and $Li_3(ttc) \cdot 4THF$ [17,18].

Recently, we have prepared and structurally characterized a series of nickel(II) complexes containing the trithiocyanurate dianion and nitrogen-donor ligands [19]. It has been found that the nickel atom is both five- and six-coordinated in these complexes and $ttcH^{2-}$ is monodentately bonded only through a N atom or chelated via N and S atoms. All the prepared complexes are mononuclear only. Moreover, it has been found that $ttcH^{2-}$ can be also situated outside the coordination sphere of the nickel. The latter mode is preferred in the case when the coordination sphere of the central atom is completely occupied by N-donor ligands such as 1,10-phenanthroline (phen) or 2,2′-bipyridine (bpy).

The complexes of iron(II) with 2,2′-bipyridine and 1,10-phenantholine and their derivatives are of general interest to coordination chemists [20]. In these compounds, the iron(II) ions with octahedral surroundings can be either in a low-spin ($S = 0$) or in a high-spin ($S = 2$) ground state. It is well known that the $[Fe(bpy)_3]^{2+}$ and $[Fe(phen)_3]^{2+}$ complex cations are mostly low-spin, but their magnetochemical behaviour also depends on the counter-ion used, e.g. the $[Fe(bpy)_3](BF_4)_2 \cdot 2H_2O$ complex exhibits a thermally induced low-spin to high-spin crossover [21]. The substitution of one bpy or phen ligand by a monodentate N-donor ligand in similar complexes can also lead to the formation of compounds where transition from a low-spin to a high-spin state can be observed. The spin-crossover behaviour, which can be either thermally or light induced, was intensively studied on the $[Fe(bpy)_2X_2]$ and $[Fe(phen)_2X_2]$ complexes, where $X = NCS^-$ or $NCSe^-$ [21].

The aim of this work was to prove the coordination abilities of the trithiocyanurate ion to iron(II). In this study, we used the combination of $ttcH_3$ and N-donor organic molecules as ligands. Here, we report X-ray structures of two iron(II) complexes: $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**) and $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2CH_3OH \cdot 2H_2O$ (**6**). It was also our interest to find if the presence of the trithiocyanurate ion in the iron(II) complexes can cause their spin-crossover behaviour.

2. Experimental

2.1. General procedures

The chemicals and solvents were purchased from Aldrich co. and Lachema co. and were used as received. The C, H, N, S analyses were carried out on an EA 1108 instrument (FISONS). IR spectra (400–4000 cm^{-1}) were recorded on a Nexus 670 FTIR spectrometer (ThermoNicolet) using KBr pellets. The diffuse-reflectance spectra (11000–35000 cm^{-1}) were obtained on a Specord M40 (Carl Zeiss, Jena) using the nujol technique. The transmission Mössbauer spectra were recorded using a Mössbauer spectrometer in constant acceleration mode with a $^{57}Co(Rh)$ source. A cryostat with closed He-cycle (Janis Research Company, USA) was used as the basis of a refrigerating system that allowed measurements in the 15–300 K temperature range. Isomer shift parameters are related to metallic iron (with a calibration temperature of 300 K).

2.2. Preparation of the complexes **1**–**6**

2.2.1. Preparation of $[Fe(bpy)_2(ttcH)] \cdot 2H_2O$ (**1**)

2,2′-Bipyridine (bpy) (320 mg, 2 mmol) in 15 ml of EtOH was added to an aqueous solution (10 ml) of $(NH_4)_2Fe(SO_4)_2 \cdot 6H_2O$ (390 mg, 1 mmol). The mixture was stirred at room temperature for 3 h. The white solid that formed was filtered off. Consecutively, a solution of $ttcNa_3 \cdot 9H_2O$ (400 mg, 1 mmol) in water (5 ml) was added dropwise to the red filtrate. Then, the mixture was stirred for 2 h, and a red microcrystalline product was separated by filtration, washed with EtOH and dried under an infra lamp at 40 °C. Yield: 498 mg, 86%. *Anal.* Calc.: C, 47.7; H, 3.7; N, 16.9; S, 16.6. Found: C, 47.6; H, 3.5; N, 16.6; S, 17.0%. IR (cm^{-1}): 401w, 423m, 456m, 488w, 616w, 658w, 720w, 734m, 772s, 874m, 966w, 1021w, 1134s, 1188w, 1227s, 1323w, 1343w, 1443s, 1468vs, 1529s, 1603m, 1632m, 1723w, 1738w, 2855w, 2925m, 3072w, 3103w, 3452vs. UV–Vis (cm^{-1}): 18700, 20200, 28600. Mössbauer spectrum (300 K): doublet with isomer shift (i.s.) = 0.29 ± 0.01 mm s^{-1}, quadrupole splitting (q.s.) = 0.33 ± 0.01 mm s^{-1}, half-width of the spectral line (Γ) = 0.26 ± 0.01 mm s^{-1} and relative spectrum area (A) = 100%.

2.2.2. Preparation of $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**)

A suspension of iron(II) oxalate dihydrate (180 mg, 1 mmol) and bpy (320 mg, 2 mmol) in water (50 ml) was stirred with heating until all the yellow iron(II) oxa-

late salt disappeared. After cooling, an aqueous solution (5 ml) of $ttcNa_3 \cdot 9H_2O$ (400 mg, 1 mmol) was added dropwise with stirring to the reaction mixture. The mixture was filtered off to remove a small amount of red precipitate, which was discarded, and the filtrate was left for crystallization. Dark red needle like crystals suitable for X-ray analysis were obtained after one week. They were filtered off, washed with a small amount of EtOH and dried in air. Yield: 270 mg, 58%. *Anal.* Calc.: C, 55.9; H, 4.9; N, 16.0; S, 8.5. Found: C, 55.7; H, 4.6; N, 16.0; S, 8.2%. IR (cm^{-1}): 423m, 457w, 473m, 551w, 571w, 620m, 639w, 657w, 668w, 734m, 766vs, 772vs, 852s, 898w, 991w, 1020w, 1040w, 1067w, 1122m, 1187vs, 1250m, 1269w, 1314m, 1427s, 1454vs, 1559m, 1581m, 1602s, 1622m, 1636m, 1698w, 2041w, 2907m, 3021w, 3048m, 3065m, 3409s. UV–Vis (cm^{-1}): 18300, 19850, 28800. Mössbauer spectrum (300 K): doublet with i.s. = 0.29 ± 0.01 mm s^{-1}, q.s. = 0.34 ± 0.01 mm s^{-1}, Γ = 0.25 ± 0.01 mm s^{-1}, A = 100%.

2.2.3. Preparation of $[Fe(terpyCl)_2](ttcH_2)_2 \cdot H_2O$ (3)

$Fe(ClO_4)_2 \cdot 6H_2O$ (125 mg, 0.34 mmol) was dissolved in EtOH (50 ml) and 1 ml of 0.1 M $HClO_4$ and iron chips were added. Then, 4′-chloro-2,2′:6′,2′-terpyridine (terpyCl) (140 mg, 0.5 mmol), dissolved in 20 ml of EtOH, was added to the solution with stirring at room temperature. The color of the reaction mixture turned to violet immediately and a violet precipitate was formed. Consecutively, $MeNO_2$ (10 ml) was added until all the precipitate disappeared. After that a solution of $ttcNa_3 \cdot 9H_2O$ (200 mg, 0.5 mmol) in 10 ml of EtOH:water (1:1) mixture was added. A small amount of the precipitate was removed and a dark violet crystalline product, obtained from solution after two days, was filtered off, washed with EtOH and dried in air. Yield: 82 mg, 34%. *Anal.* Calc.: C, 45.0; H, 2.7; N, 17.5; S, 20.0. Found: C, 44.8; H, 2.8; N, 17.4; S, 20.2%. IR (cm^{-1}): 420w, 458s, 483m, 541s, 567m, 619w, 652w, 670w, 690w, 719s, 728m, 751s, 787s, 828m, 874vs, 965w, 1019w, 1034w, 1057w, 1132vs, 1232vs, 1283m, 1346s, 1394vs, 1424vs, 1460vs, 1529vs, 1600vs, 1631s, 1737m, 1776w, 1849w, 2015w, 2112w, 2344w, 2361m, 2849vs, 2911vs, 3063s, 3410s. UV–Vis (cm^{-1}): 17200, 19400, 28000. Mössbauer spectrum (300 K): doublet with i.s. = 0.20 ± 0.01 mm s^{-1}, q.s. = 0.96 ± 0.01 mm s^{-1}, Γ = 0.28 ± 0.01 mm s^{-1}, A = 100%.

2.2.4. Preparation of $[Fe(phen)_2(ttcH)] \cdot 2H_2O$ (4)

The procedure similar to that used for the preparation of **1** was applied, only 1,10-phenanthroline monohydrate (400 mg, 2 mmol) was used instead of 2,2′-bipyridine. Yield: 364 mg, 58%. *Anal.* Calc.: C, 51.7; H, 3.4; N, 15.6; S, 15.3. Found: C, 51.6; H, 3.5; N, 15.2; S, 16.1%. IR (cm^{-1}): 435w, 409w, 420w, 458m, 483w, 530m, 558w, 620m, 671w, 722s, 775m, 845vs, 876s, 967w, 998m, 1040w, 1057w, 1133vs, 1188s, 1233vs, 1344s, 1425vs, 1485vs, 1527vs, 1578m, 1631s, 1985w, 2059w, 2247w, 2291w, 2362w, 2922m, 3070s, 3431vs. UV–Vis (cm^{-1}): 19100, 20400, 28800. Mössbauer spectrum (300 K): doublet *I* with i.s. = 0.29 ± 0.01 mm s^{-1}, q.s. = 0.24 ± 0.01 mm s^{-1}, Γ = 0.28 ± 0.01 mm s^{-1}, A = 71.1%; doublet *II* with i.s. = 0.25 ± 0.01 mm s^{-1}, q.s. = 0.83 ± 0.01 mm s^{-1}, Γ = 0.29 ± 0.01 mm s^{-1}, A = 28.9%.

2.2.5. Preparation of $[Fe(nphen)_2(ttcH)] \cdot 4H_2O$ (5)

5-Nitro-1,10-phenanthroline (440 mg, 2 mmol) in EtOH (100 ml) was added with stirring to an aqueous solution (10 ml) of $(NH_4)_2Fe(SO_4)_2 \cdot 6H_2O$ (390 mg, 1 mmol). Then, $ttcNa_3 \cdot 9H_2O$ (400 mg, 1 mmol) with 1 ml of 1 M HCl in water:EtOH (1:1) mixture was added dropwise to the solution. A dark violet product, which appeared during the addition of the solution of $ttcNa_3$, was filtered off, washed with EtOH and dried under an infra lamp at 40 °C. Yield: 482 mg, 64%. *Anal.* Calc.: C, 43.0; H, 3.1; N, 16.7; S, 12.8. Found: C, 43.1; H, 2.8; N, 16.2; S, 12.5%. IR (cm^{-1}): 409w, 420w, 428w, 458m, 482w, 505w, 538w, 618m, 657w, 669w, 721s, 734m, 755w, 810m, 843m, 859m, 907w, 1002w, 1039w, 1064w, 1130s, 1189m, 1232m, 1350s, 1420s, 1458vs, 1514s, 1534vs, 1579w, 1630m, 1684w, 2925w, 3090s, 3456vs. UV–Vis (cm^{-1}): 17900, 21600, 29000. Mössbauer spectrum (300 K): doublet *I* with i.s. = 0.29 ± 0.01 mm s^{-1}, q.s. = 0.27 ± 0.01 mm s^{-1}, Γ = 0.27 ± 0.01 mm s^{-1}, A = 20.0%, doublet *II* with i.s. = 0.35 ± 0.01 mm s^{-1}, q.s. = 0.64 ± 0.01 mm s^{-1}, Γ = 0.29 ± 0.01 mm s^{-1}, A = 80.0%.

2.2.6. Preparation of $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2CH_3OH \cdot 2H_2O$ (6)

$Fe(ClO_4)_2 \cdot 6H_2O$ (250 mg, 0.68 mmol) was dissolved in 50 ml of MeOH and 1 ml of 0.1 M $HClO_4$ and iron chips were added. A solution of 1,10-phenanthroline monohydrate (400 mg, 2 mmol) dissolved in 10 ml of MeOH was added to this mixture, with stirring at room temperature. The color of the reaction mixture turned into red immediately. Finally, a solution of $ttcNa_3 \cdot 9H_2O$ (400 mg, 1 mmol) in water (5 ml) was added. A red precipitate (its composition was identical to $[Fe(phen)_2(ttcH)] \cdot 2H_2O$ (**4**), as was proven by elemental analysis) was filtered off and the filtrate was left to stand at room temperature for crystallization. A small amount of red crystals was obtained after two weeks. The crystals were characterized only by a single crystal X-ray analysis. Yield: 77 mg, 12%.

2.3. X-ray crystallography

Diffraction experiments for complexes $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**) and $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2CH_3OH \cdot 2H_2O$ (**6**), were carried out on a

four circle κ-axis KUMA KM-4 diffractometer using graphite-monochromated MoK_α radiation (λ = 0.71073 Å) at 120(2) K. Data collections for both complexes were performed using a CCD detector (KUMA Diffraction, Wroclaw). KUMA KM4RED software was used for data reduction. Both structures were solved by direct methods [22]. All non-hydrogen atoms of **2** and **6** were refined anisotropically by the full-matrix least-squares procedure [SHELXL-97] [23] with weight: $w = 1/[\sigma^2(F_o^2) + (0.050P)^2 + 10.000P]$ for **2** and $w = 1/[\sigma^2(F_o^2) + (0.075P)^2 + 3.000P]$ for **6**, where $P = (F_o^2 + 2(F_c^2)/3$. The O(1), O(5) and O(7) atoms in **2** are disordered. All H-atom positions, except for one hydrogen atom of O(7) in **2**, were located from Fourier difference maps. In **6**, two methanol molecules are disordered over two positions and their hydrogen atoms were not found in the Fourier difference maps. All remaining hydrogen atoms were localized and their parameters were refined. The largest peak and hole on the final difference map for **2** and **6** were 0.711 [0.11 Å from H(7W)] and −0.425 [0.46 Å from O(7)] e Å^{-3}, and 0.550 [0.79 Å from N(5)] and −0.606 [0.61 Å from C(41)] e Å^{-3}, respectively. Important crystallographic parameters are given in Table 1.

2.4. Computational details

The geometry optimisations and infrared frequency calculations of differently protonated *thion*-forms of the trithiocyanuric acid ($ttcH_3$, $ttcH_2^-$ and $ttcH^{2-}$) were performed employing hybrid density functional B3LYP as implemented in the Gaussian98W [24] and Spartan'02 [25] programs. All calculations were performed with the 6-31 + G* basis set and the theoretical infrared frequencies were not scaled.

3. Results and discussion

3.1. Infrared and electronic spectra

The experimental vibrational frequencies with their relative intensities are given in Section 2.2. In general, the IR spectra of the iron(II) complexes **1**–**5** are quite similar. It is typical that the IR spectra of iron complexes having aromatic heterocycles such as bpy or phen as ligands contain several bands in the regions 1400–1600 and 700–900 cm^{-1}, which are connected with the ring modes [ν(C–C) and ν(C–N)] and the ring deformation vibrations, respectively [20]. For instance, the bands

observed in the IR spectrum of the free bpy ligand at 1414, 1452, 1456 and 1578 cm^{-1} are shifted to higher frequencies upon coordination and are observed at 1427, 1454, 1559 and 1581 cm^{-1} in the spectrum of **2**. The peaks connected with the ring deformation of the aromatic N-donor heterocycles are observed in the IR spectra of all the complexes at ca. 620, 720, 775, 845 and 870 cm^{-1} [26]. The bands observed near 3060 and 3450 cm^{-1} can be connected with $\nu(C_{ar}–H)$ and $\nu(N_{ttc}–H)$ vibrations, respectively. At this point, it is necessary to mention that the interpretation of IR spectra is somewhat difficult in connection with the fact that many vibrations can be overlapped. However, based on the DFT/6-31 + G* calculated infrared frequencies (see Section 3.4), we can conclude that the bands connected with the ν(C–N) and ν(C–S) vibrations of the 2,4,6-trimercapto-1,3,5-triazine ring are observed in IR spectra of the complexes **1**–**5** at 1514–1559 and 1172–1227 cm^{-1}, and 845–874 and 420–435 cm^{-1}, respectively.

The diffuse-reflectance spectra of **1**–**5** are also very similar. The bands observed in the 17200–19100 cm^{-1} range may be associated with d–d transitions or identically, and more probably, like the bands with the maxima recorded in the regions of 19850–21600 and 27500–30000 cm^{-1}, with metal-to-ligand charge transfer (MLCT) transitions [27].

3.2. Mössbauer spectroscopy

The hyperfine parameters of the room temperature ^{57}Fe Mössbauer spectra of the iron(II) complexes **1**–**5** are given in Section 2. The experimental data were fitted by a least squares procedure with Lorentzian profiles used to determine the line positions, widths and relative spectra areas. The continuous lines represent the computer's fitted data. Fig. 1 demonstrates the room temperature Mössbauer spectra of complexes **1** and **2**. The spectra are almost identical with a distinct doublet with an isomer shift i.s. = 0.29 mm s^{-1} and quadrupole splitting parameter q.s. = 0.33 and 0.34 mm s^{-1}, respectively. The value of the isomer shift is typical for octahedral complexes of iron(II) in the low-spin state. For example, the isomer shifts measured for $[Fe(bpy)_3]Cl_2$ and $[Fe(bpy)_3](ClO_4)_2$ are 0.33 and 0.30 mm s^{-1}, respectively [28,29]. The octahedral coordination of iron(II) in the complex **2** was unambiguously confirmed by X-ray analysis.

The room temperature Mössbauer spectrum of complex **3** (Fig. 2) consists of a doublet with a relatively low value of isomer shift (0.20 mm s^{-1}) corresponding to low-spin iron(II). In the structure of this complex, two 4′-chloro-2,2′:6′,2′-terpyridines are probably coordinated to the central atom in a meridional fashion, as in complex $[Fe(terpy)_2](ClO_4)_2$ [30]. This type of coordi-

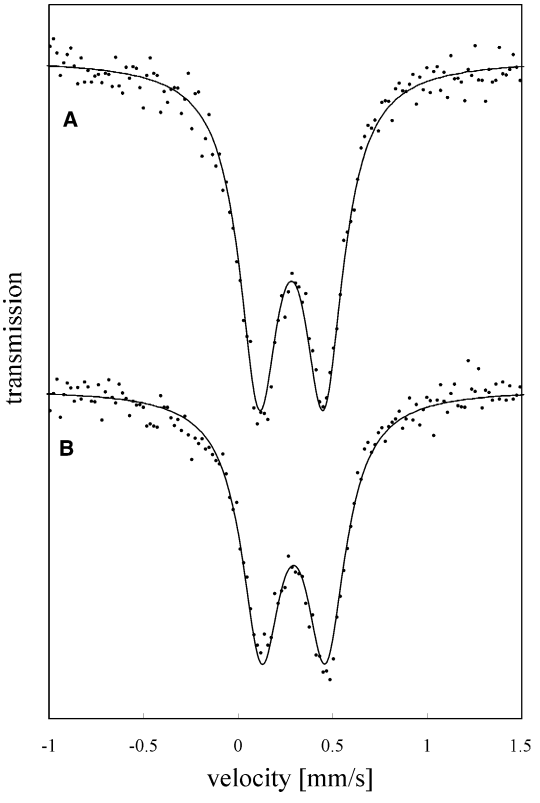

Fig. 1. Room temperature Mössbauer spectra of the complexes **1** (A) and **2** (B). I.s. are related to metallic iron. The solid line results from least-squares fitting of the data to the theoretical equation.

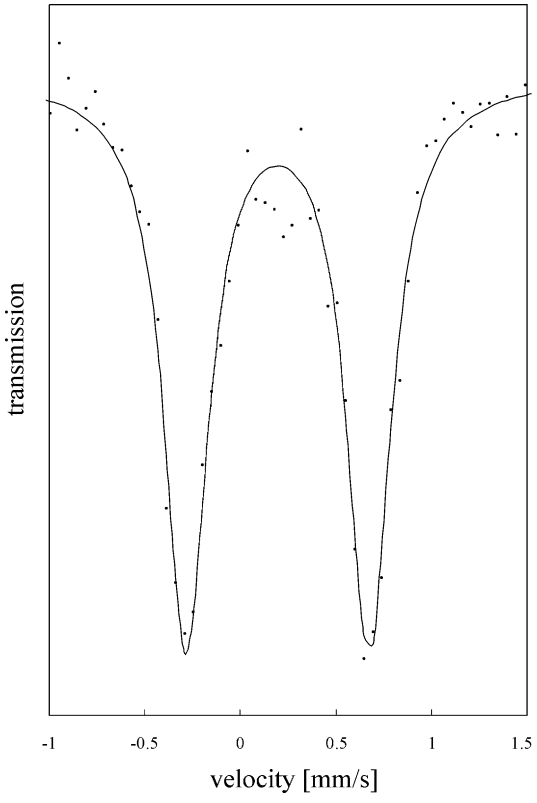

Fig. 2. The room temperature Mössbauer spectrum of complex **3**.

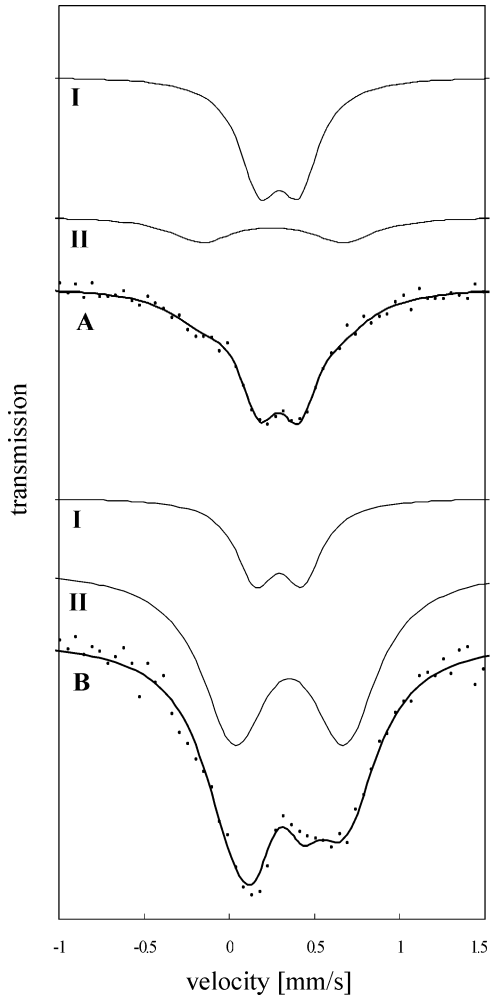

Fig. 3. The room temperature Mössbauer spectra of the complexes **4** (A) and **5** (B) with the results of their mathematical deconvolution (curves I, II).

nation leads to a lowering of the symmetry in the iron environment resulting in the relatively high value of the quadrupole splitting (0.96 mm s^{-1}).

The room temperature Mössbauer spectra of the complexes **4** and **5** are composed of two doublets corresponding to two non-equivalent coordination modes of iron (see Fig. 3). In the spectrum of **4** (Fig. 3A), the doublet *I* with relative spectrum area $A = 71.1\%$ shows hyperfine parameters well comparable to those found for complexes **1** and **2**. Therefore, we can suggest that this doublet also corresponds to octahedrally coordinated low-spin iron(II), where iron is coordinated by four N-atoms of two phen ligands and S and N atoms of trithiocyanurate(2-). The doublet *II* ($A = 28.9\%$) has a significantly higher q.s. value (0.83 mm s^{-1}) indicating distortion from the octahedral coordination geometry. We assume that the trithiocyanurate anion is coordinated to iron(II) only via a N atom as in the case of [Ni (taa)(ttcH)] {taa = tris-(2-aminoethyl)amine} [31] or in $[Cu(PPh_3)_2(ttcH_2)]$ [32]. Two doublets in the room temperature Mössbauer spectrum of complex **5** (Fig. 3B) can be interpreted as well as in the former case. However, the relative spectral areas proved the higher content of iron atoms with a distorted octahedral environment ($A_{II} = 80\%$) in comparison with complex **4**. The higher tendency towards the distorsion of the octahedral Fe environment in the case of complex **5** can be assigned to the effect of NO_2 groups although the influence of water of crystallization cannot be excluded. The low temperature Mössbauer spectra (25 K) of the complexes **4** and **5** are very similar (the spectrum of complex **4** is depicted in Fig. 4) and show only one component with a high value of i.s. = 0.40 mm s^{-1} due to the temperature shift and q.s. = 0.17 mm s^{-1}. It is evident that the distortion is eliminated by temperature lowering as can be deduced on the basis of the absence of second doublet in the spectrum. The subsequent heating to room temperature caused the repeated appearance of two doublets in the spectrum that indicates a thermally induced reversible character of the structural ordering.

In general, the obtained results are in good accordance with the literature data for iron(II) low-spin complexes [21]. The found values of q.s. parameters indicate the differences in the symmetry of central atom environment and reflect the non-equivalent coordination modes of individual complexes.

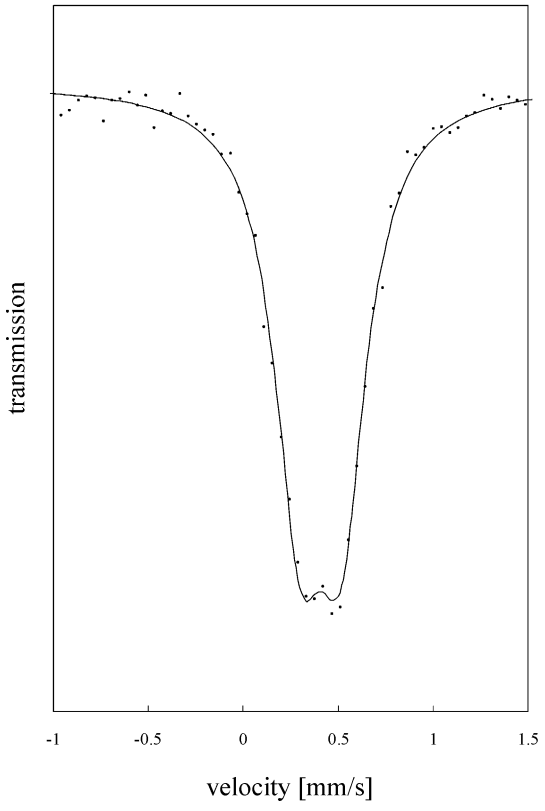

Fig. 4. The Mössbauer spectrum of complex **4** measured at 25 K.

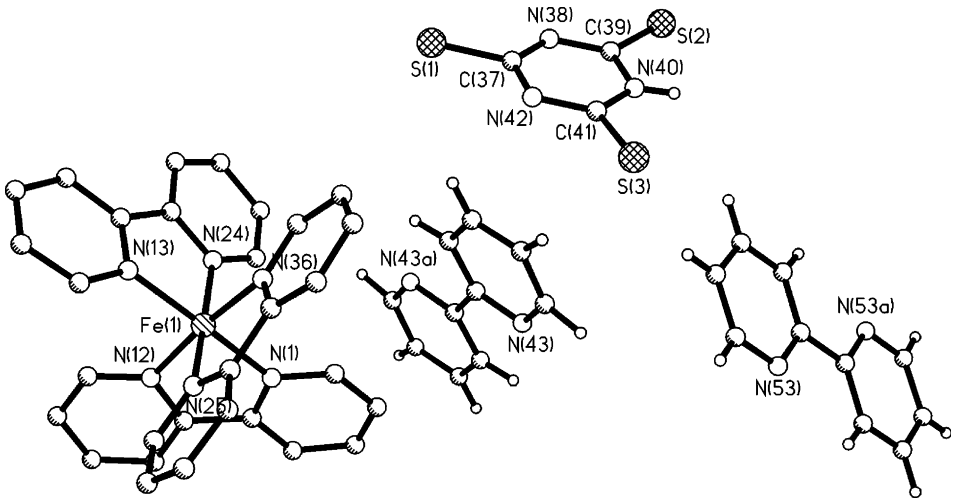

Fig. 5. Molecular structure of $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**). Solvent water molecules and the hydrogen atoms of coordinated bpy ligands are omitted for clarity.

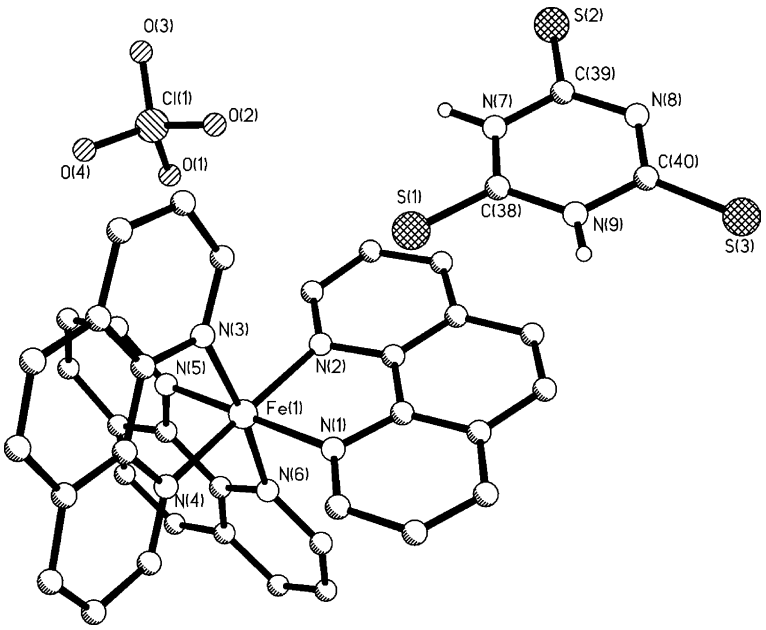

Fig. 6. Molecular structure of $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2CH_3OH \cdot 2H_2O$ (**6**). Molecules of solvents as well as hydrogen atoms of phen ligands are omitted for clarity.

3.3. X-ray structures

The molecular structures of **2** and **6** are shown in Figs. 5 and 6. Selected bond lengths and angles for the complexes are listed in Table 2. Both structures consist of hexacoordinated $[Fe(N–N)_3]^{2+}$ cations (N–N = bpy or phen) and uncoordinated trithiocyanurate anions. There are also seven water molecules and two bpy (in **2**) and one perchlorate anion, two water and two methanol molecules (in **6**) in the crystal lattices. Both iron(II) ions in **2** and **6** are coordinated in distorted octahedral arrangements. The Fe–N bond lengths are quite comparable and vary from 1.9715(17) to 1.9834(16) Å (in **2**) and from 1.973(2) to 1.985(2) Å (in **6**). In both structures, the trithiocyanurate anions are situated outside the coordination sphere of the central atom. However, the extent of deprotonation of the anion is different. Only one hydrogen atom at the N(40) position of the triazine ring was located in **2** (see Fig. 5), while two protons were found in **6** (see Fig. 6). It is evident that a different manner of deprotonation causes the changes in bond lengths and angles of the trithiocyanurate anion. The C–S bond distances in **2** {1.7213(19), 1.708(2), 1.7091(19) Å} are intermediate between single and double bonds (a typical value for the single C–S bond length equals 1.81 Å), whilst the C–S bond

Table 2
Selected bond lengths [Å] and angles [°] in the vicinity of the central atom for $[Fe(bpy)_3](ttcH) \cdot 2bpy \cdot 7H_2O$ (**2**) and $[Fe(phen)_3](ttcH_2)(ClO_4) \cdot 2\text{-}CH_3OH \cdot 2H_2O$ (**6**)

distances in **6** (1.678(3), 1.665(3), 1.682(3) Å) are more characteristic for C=S double bonds (a typical value for the double C=S bond ranges from 1.61 to 1.68 Å [18]). The bond angles of the triazine rings lie in the ranges of 116.15(16)°–125.80(17)° (for **2**) and 115.7(2)°–123.2(3)° (for **6**). The actual value of the angles inside the triazine ring strongly depends on the extent of deprotonation as well as on the protonation site.

3.4. DFT calculations

The DFT/6-31 + G* optimised structures of differently protonated *thion*-forms of the trithiocyanuric acid ($ttcH_3$, $ttcH_2^-$ and $ttcH^{2-}$) are shown in Fig. 7. The comparison of the calculated interatomic parameters with the experimental data (X-ray) [33] is presented in Table 3. Overall, the calculations gave a good agreement with the experimental data. The differences between experimental and theoretical bond lengths and angles for $ttcH_3$, $ttcH_2^-$ and $ttcH^{2-}$, expressed as an average absolute deviation, were the following (Spartan'02/Gaussian98W): 0.012/0.011 Å and 1.38°/1.38° for $ttcH_3$, 0.014/0.013 Å and 1.89°/1.73° for $ttcH_2^-$, and 0.016/0.014 Å and 1.42°/1.41° for $ttcH^{2-}$, respectively. As for theoretical infrared vibrational frequencies, we have focused our attention on interpretation of the bands belonging to ν(C–N),ν(C–S), δ(CNH) and δ(CNC) vibrations. The B3LYP calculations predicted two C–N stretching bands at 1573.8 and 1279.4 cm^{-1} (for $ttcH_3$), 1539.3 and 1209.3 cm^{-1} (for $ttcH_2^-$), and 1514.5 and 1175.1 cm^{-1} (for $ttcH^{2-}$). The experiment is consistent in finding one strong and one medium strong band at 1577 and 1260 cm^{-1}, as measured for $ttcH_3$ using the KBr technique. On the other hand, the calculated bands at 922.1 and 444.7 cm^{-1} (for $ttcH_3$), 886.4 and 431.5 cm^{-1} (for $ttcH_2^-$), and 842.3 and 411.3 cm^{-1} (for $ttcH^{2-}$) can be assigned to ν(C–S). The bands observed in the IR spectrum of $ttcH_3$ at 892 and 458 cm^{-1} can be connected with the same vibration. The theoretical bands at 1385.0 cm^{-1} (for $ttcH_3$), 1294.0 cm^{-1} (for $ttcH_2^-$) and 1236.7 cm^{-1} (for $ttcH^{2-}$) are attributable to δ(CNH), while the bands at 988.7 cm^{-1} (for $ttcH_3$), 975.4 cm^{-1} (for $ttcH_2^-$) and 961.3 cm^{-1} (for $ttcH^{2-}$) can be assigned to δ(CNC). In conclusion, we can state that although the values of calculated infrared frequencies are non-scaled, a good agreement between theoretical and experimental data has been found.

Abstract

A novel 3D malonato-bridged copper(II) complex of formula Cu(mal)(pz)$_2$ (**1**) (mal = malonate dianion; pz = pyrazole) has been prepared and characterized by elemental analyses, IR, electronic and EPR spectroscopies, TG analysis, single crystal X-ray diffraction and magnetic susceptibility. **1** crystallizes in the tetragonal space group *I4(1)*, a = 9.4951(16) Å, b = 9.4951(16) Å, c = 12.620(4) Å, V = 1137.8(5) Å^3, Z = 4. The 3D framework of the title compound is formed by the connection of malonate bridges. Magnetic characterization of **1** suggests that the complex exhibits overall a weak ferromagnetic coupling with an antiferromagnetic interaction in the very low temperature range.

1. Introduction

Pronounced attention has currently been paid to the crystal engineering of 2D and 3D metal–ligand coordination polymers due to their fascinating network topologies and potential applications as functional materials [1,2]. Dicarboxylic acids are capable of binding metals to form new types of polymers and oligomers, which can considerably influence the magnetic, optical or catalytic properties of the ultimate product [3]. Among the dicarboxylates, the major studies have been done on oxalate and terephthalate and a few examples with malonate, fumarate, maleate, adipate, etc. [4–15]. The malonate exhibits a rather flexible stereochemistry and variable mode of binding with metal ions in the crystalline state. Research works using malonate as a bridging ligand in copper(II) complexes have shown the versatility of this ligand [6,7,16–23]. Its versatility as a ligand is illustrated by the variety of its coordination modes when acting as a bridge, the most common being the so-called *syn–syn*, *syn–anti* and *anti–anti* modes (Scheme 1). In addition, the adoption of bidentate and/or bridging coordination modes makes this ligand very appropriate in designing mono- and polynuclear species. In order to design high-dimensional (2D or 3D) copper(II) malonate complexes and to gain a better understanding of the correlation between structure and magnetism, we selected the malonate dianion as a linker and pyrazole as the auxiliary ligand, and succeeded in obtaining the novel 3D malonato-bridged copper(II) complex Cu(mal)(pz)$_2$ (**1**). In this paper, we report the synthesis, structure, properties and characterization of **1**.

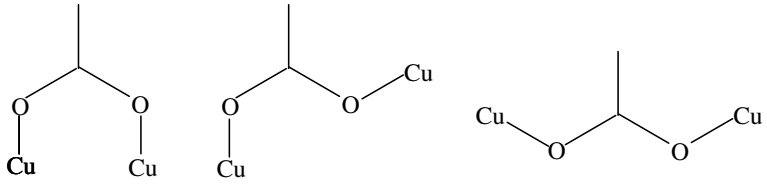

Scheme 1.

2. Experimental

2.1. Physical measurements

All the starting reagents are of A.R. grade and used as purchased. Elemental analyses (C, H, N) were performed on a Perkin–Elmer 240 analyzer. Infrared spectra on KBr pellets were recorded on a Shimadzu IR-408 spectrophotometer in the range 4000–600 cm^{-1} and the TG runs were taken on a Rigaku TG-DTA standard type thermal analysis system. The compound was heated up to 600 °C in the atmosphere of nitrogen, at a heating rate of 10 °C per min. The variable temperature susceptibility measurements were carried out with a MagLab System 2000 magnetometer in the temperature range 2–300 K at a magnetic field of 10,000 G. The electronic spectrum was measured with a Jasco-570 spectrophotometer and X-band EPR spectrum on a Bruker ER 200 D-SRC EPR spectrometer.

2.2. Synthesis

An aqueous solution of pyrazole (27 mg 0.4 mmol) was added to an aqueous solution of $Cu(NO_3)_2 \cdot 2H_2O$ (44 mg, 0.20 mmol). To this mixture an aqueous solution of Na_2(mal) (29 mg, 0.2 mmol) was added after a few minutes. This solution was stirred at room temperature for half an hour. Slow evaporation of the resulting mixture led to blue crystals of **1**. *Anal.* Calc. for $C_9H_{10}CuN_4O_4$: C, 35.82; H, 3.31; N, 18.56. Found: C 35.72; H, 3.44; N, 18.63%.

Table 1
Crystallographic data and structure refinement for **1**

Formula	$C_9H_{10}CuN_4O_4$
Formula weight	301.75
Crystal system	tetragonal
Space group	*I*4(1)
Unit cell dimensions	
a (Å)	9.4951(16)
b (Å)	9.4951(16)
c (Å)	12.620(4)

R_1, wR_2 (all data)	0.0334, 0.0533

2.3. X-ray crystal structure determination

The crystal data were collected with a Bruker Smart 1000 CCD diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by the $\omega - 2\theta$ scan technique at 293(2) K. A total of 3254 reflections were measured to give 969 independent reflections ($R_{int} = 0.0391$). The structure was solved by direct methods using the SHELXS-97 [24] program. Data were corrected for Lorentz and polarization effects. The final refinement was performed using SHELXL-97 [25] by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The crystal data and structure refinement details for **1** are given in Table 1.

3. Results and discussion

3.1. Crystal structure

The coordination environment of the copper(II) ion, with the atom numbering scheme, is shown in Fig. 1. The selected bond lengths and angles are listed in Table 2. The copper(II) ion displays a slightly distorted octahedral coordination environment with the two chelated oxygen atoms (O(1), O(1a)) of one malonate ligand and two nitrogen atoms (N(1), N(1a)) from two pyrazole ligands in the equatorial plane, while two bridging oxygen atoms (O(1w), O(2w)) from two different malonate ligands occupy the axial positions. Both the distances Cu(1)–O(1w) and Cu(1)–O(2w) are the same (2.516 Å), which can be considered as weakly coordinated bonds. The value of the equatorial Cu–O bond distances is 1.948 Å. These structural parameters are within the range observed in previous malonate-contain-

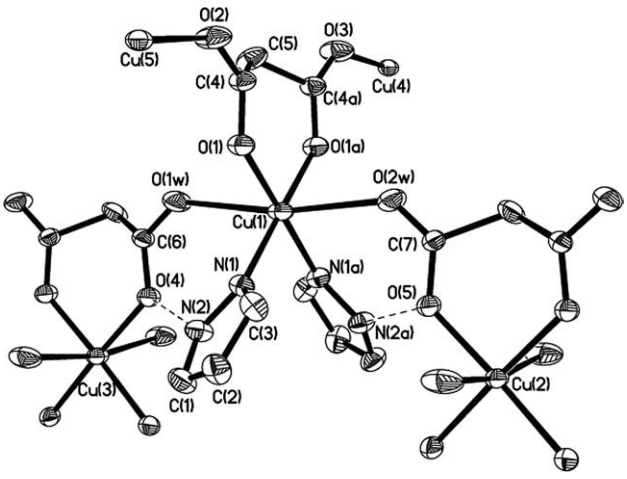

Fig. 1. Perspective diagram of the complex **1** with thermal ellipsoids at 30% probability (Symmetry codes: a = $-x + 1$, $-y + 0$, $z + 0$).

a = $-x + 1$, $-y + 0$, $z + 0$.

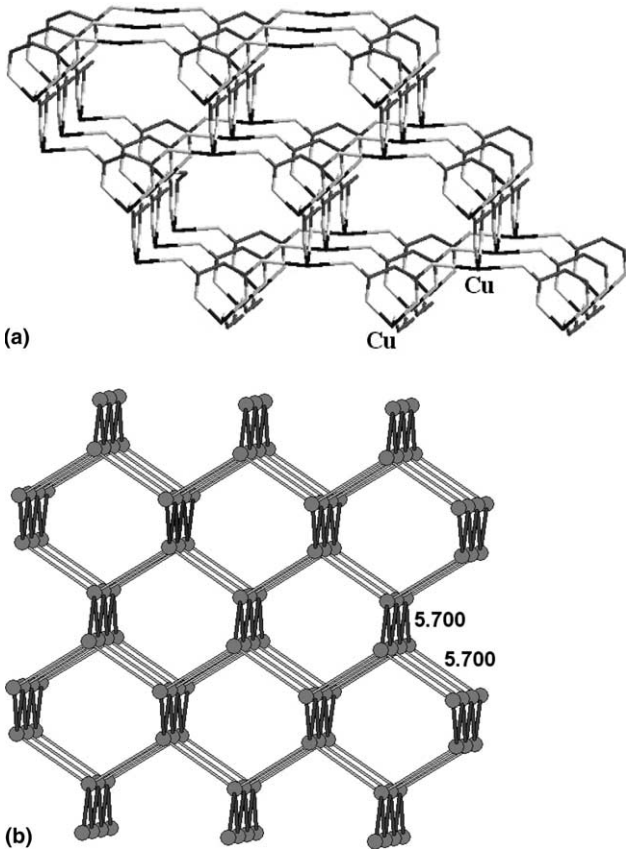

Fig. 2. (a) A perspective view of the 3D framework of **1** (the pyrazole ligands are omitted for clarity). (b) Projection of **1** showing the honeycomb-like structure based on the topology of Cu–Cu connections viewed along the a axis (C, H, O and N atoms are omitted for clarity).

ing copper(II) complexes [18]. Each malonate group adopts simultaneously bidentate (O(1), O(1a) toward Cu(1)) and bis-monodentate coordination modes (through O(3) toward Cu(4) and O(2) toward Cu(5)), and it exhibit an envelope conformation. In addition, the carboxylate-bridges exhibit a *syn–anti* conformation (Cu(1)–O(2w)–C(7)–O(5)–Cu(2)), which connect an equatorial site of one copper atom with an apical site of the adjacent copper atom.

The dihedral angle between the basal plane defined by O(1), O(1a), (N(1), N(1a) and the plane defined by O(1w), O(2w), O(4), O(5) is nearly a right angle (92.2°). The angle (O(1)–Cu(1)–O(1a)) subtended at the copper atom by the chelating malonate group is 80.3°, which is smaller than that previously reported [b]. The value of the O(1w)–Cu(1)–O(2w) bond angle (170.05°) reflects the slightly distorted octahedral surrounding at Cu(1). The average C–O bond distance is 1.241 Å and the O–C–O bond angles are the same (125.11°). Nevertheless, its unique 3D topological architecture, shown in Fig. 2(b), is worth mentioning. Each copper atom is six-connected with four malonate bridged copper atoms and two pyrazole bridged Cu atoms. If the pyrazole bridges are omitted, the four-connected network can be viewed as a metal-apex 3D honeycomb-like structure from the *a* axis, based on the topology of Cu–Cu connections. Each copper atom is connected with one copper in a *syn–anti* conformation with Cu···Cu separations of 5.700 Å. The nitrogen atoms of the pyrazole ligand link the oxygen atoms of malonate via hydrogen bonds (N(2)···O(4) = N(2a)···O(5) = 2.790 Å), which contribute to the stabilization of the crystal structure. Thus, the 3D framework of the title compound is formed by the connection of malonate in orthogonal directions as shown in Fig. 2(a).

3.2. Spectrospic properties

The IR spectrum of **1** shows the main bands as followed: 3275m, 1590s, 1405m, 1350m, 1150w, 1135w, 1050m, 1040m, 930w, 860w, 750m, 720m cm^{-1}, of which the 1590 cm^{-1} band belongs to the C═O stretching vibration of the malonate group, appearing as a strong

band. The medium bands at 1405 and 1350 cm^{-1} are assigned to the absorption of the C=C and C=N groups of the pyrazole ligand, which are shifted to considerable lower frequencies compared with the uncoordinated ligand [26,27].

The electronic spectrum of complex **1** shows a strong absorption at 43 500 cm^{-1} ($\varepsilon = 4.5 \times 10^3$ L mol^{-1} cm^{-1}) and a weak absorption at 14 000 cm^{-1} ($\varepsilon = 344$ L mol^{-1} cm^{-1}). The former may be assigned to an intra-ligand and/or change-transfer transition in the copper(II) chromophore and the latter is the d–d transitions of copper(II) ions in a distorted octahedral environment.

The EPR spectrum of complex **1** measured on a polycrystalline power at 110 K shows an isotropic signal centered at $g = 2.15$, line width 198 G. Two g values ($g_{\|}$, $g_{\perp}$) correspond to a tetragonally ligand field formed by an elongated octahedron. The computer simulation gave the ESR parameters ($g_{\|} = 2.19$, $g_{\perp} = 2.08$ as shown in Fig. 3.

3.3. TG analysis

The TG curve of compound **1** is shown in Fig. 4. The TG curve of **1** exhibits three steps of weight losses. The first weight loss is 45.6% from 230 to 240 °C, which is assigned to the loss of pyrazole groups. The whole weight loss of the second and the third stage is 26.1% from 260 to 500 °C. The second loss of weight is due to the start of decarboxylation of the malonate ligand and finally the metal oxide is formed as expected, which is in agreement with the calculated weight loss value (71.7%).

3.4. Magnetic properties

Fig. 5 describes the temperature variation of the effective magnetic moment μ_{eff}. The μ_{eff} value of the title complex is 1.79 BM at room temperature, which is a slightly higher than the spin-only value of one copper(II) ion (1.73 BM), due to mixing of angular momentum from excited states via spin–orbit coupling. The μ_{eff} value increases smoothly upon cooling, to 1.83 BM at 8 K, then decreases to 1.72 BM at 3 K. This curve is typical of overall weak ferromagnetic coupling with antiferromagnetic coupling between chains in the very low temperature range. The magnetic behavior within the chain may be described by the series expansion for the Heisenberg model ($H = -2J\sum_i \hat{S}_i\hat{S}_{i+1}$) for ferromagnetically coupled $S = 1/2$ ions, which was derived by Baker et al. [28] (Eq. (1)). Taking into account the interaction between chains, the magnetic susceptibility expansion involving a mean field correction is given by Eq. (2) [29].

$$\chi_{\text{Chain}} = \frac{Ng^2\beta^2}{4KT}\left\{\frac{1.0 + 5.7979916x + 16.902653x^2 + 29.376885x^3 + 29.832959x^4 + 14.036918x^5}{1.0 + 2.7979916x + 7.0086780x^2 + 8.6538644x^3 + 4.5743114x^4}\right\}^{2/3}, \quad (1)$$

$$\chi = \frac{\chi_{\text{Chain}}}{1 - (ZJ'/Ng^2\beta^2)\chi_{\text{Chain}}}, \quad (2)$$

where $x = 2J/KT$, J is the interaction parameter between two copper(II) centers. ZJ' is the exchange parameter between the chains and the rest of the symbols have their usual meanings. Magnetic data were well fitted to Eqs. (1) and (2) with $g = 2.07$, $J = +0.32$ cm^{-1}, $ZJ' = -0.02$ cm^{-1} and $R = 5.76 \times 10^{-3}$, where R is the agreement factor: $R = \sum(\chi_{obsd} - \chi_{calcd})^2/\sum\chi_{obsd}^2$. The small value of J indicates a weak ferromagnetic exchange interaction between copper(II) ions within the chain. The decrease of

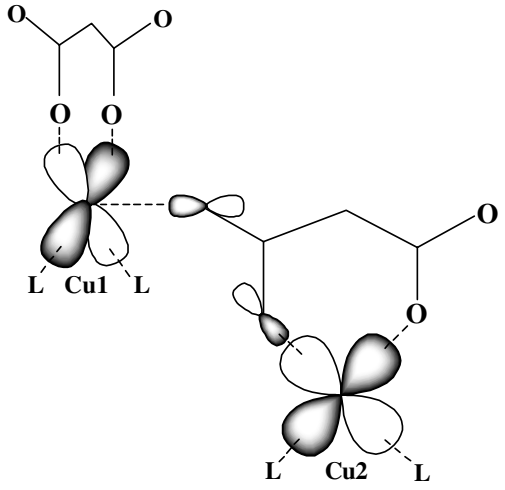

Scheme 2.

the values of the effective magnetic moment below 8 K is due to the antiferromagnetic interaction between the chains.

Details of the magneto-structural correlation of carboxylato-bridged copper(II) complexes have been well explored [18e,22], and it is found that the magnetic interaction between metal centers is dependant on the relative position of the carboxylato bridge of the malonate with respect to the copper(II) ions: equatorial–equatorial (strong antiferromagnetic interaction), equatorial–apical (weak ferromagnetic interaction) and apical–apical (negligible interaction). The crystal structure shows that the copper(II) ion is in an elongated octahedral coordination environment. One of the bridging oxygen atoms (O(2w)) is in an axial position to Cu(1), the other bridging oxygen (O(5)) is in an equatorial position of Cu(2). Scheme 2 shows the relative orientation (equatorial–apical) of the malonato-bridge with respect to the copper(II) ions in the title complex. Since the exchange pathway involves an equatorial position on one copper ($d_{x^2-y^2}$ orbital) and an axial position on the other copper atom (d_{z^2}), this would lead to a ferromagnetic interaction between the copper(II) ions within the chain.

Abstract

Three Ag(I) coordination polymers with flexible long-chain multi-nitrile ligands, $[Ag(TDPN)(NO_3)]_n$ (**1**), $[Ag(TDPN)(ClO_4)]_n$ (**2**) (TDPN = β,β′- thiodipropionitrile), $[Ag_2(TCEB)(NO_3)_2]_n$ (**3**) (TCEB = 1, 2, 3, 4-tetrakis (2-cyanoethoxy)butane) have been synthesized and structurally characterized by IR spectra and X-ray crystallography. In particular, TCEB is a meso compound. Single-crystal X-ray analysis shows that it contains two chiral carbon atoms with *R*- and *S*-configurations. The structures of **1**, **2** and **3** consist of a 1-D ladder-like chain, a 2-D boxlike network and a 3-D framework of $CdSO_4$ topology, respectively. IR spectra of the free and coordinated CN groups, the correlation between the counter anions and the topological structures, and the photoluminescent properties of complexes **1–3** are also discussed.

1. Introduction

Self-assembly of metal-based supramolecules has attracted considerable interest in current coordination chemistry owing to their potential as functional materials [1]. Much effort has been devoted to the investigation of multi-dimensional networks based primarily on linking metal centers with rigid bridging components, such as 4,4′-bipyridine [2]. Far less common is the use of flexible bridging ligands in the construction of extended networks. However, the use of flexible ligands is attractive because the flexibility and conformation freedom of such ligands offer the possibility for the construction of novel frameworks with tailored properties and functions. On the other hand, Ag(I) as a soft acid, being inclined to coordinate to soft base such as *S*- and unsaturated *N*-containing ligands, is a favorable and fashionable building block and connecting node for coordination polymers [3]. For example, Carlucci et al. reported a series of silver coordination architectures with flexible long-chain dinitrile ligands. However, the architectures of coordination polymers constructed by silver ions and flexible long-chain multi-nitrile ligands with ether or thioether groups, have not been reported to our knowledge.

A major challenge in crystal engineering using flexible building blocks is the predictability of the polymeric network topology, which may depend on several factors such as the coordination geometry and the oxidation state of the metal centers [5], the metal-to-ligand ratio [6], the nature of the ligands used [7] and the presence of solvents [8] and/or counter anions [4,9]. In particular,

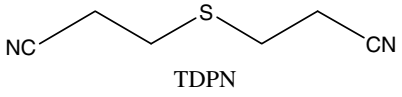
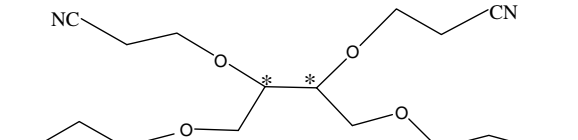
counter anions exert an important influence on the self-assembly of silver salts and flexible ligands. Herein, we report our recent successful results in the construction of three Ag(I) coordination polymers with flexible multi-nitriles TDPN and TCEB, and the effects of counter anions on the coordination modes of the ligands and the geometries of the Ag(I) ions are also discussed in detail.



TDPN



TCEB

2. Experimental

2.1. Materials and physical measures

All reagents were commercial grade and were used as received. Elemental analyses for C, H, N were determined on an Elementar Vario EL-III analyzer. IR spectra were measured as KBr pellets on a Nicolet Magna 750 FT IR spectrometer in the range of 400–4000 cm^{-1}. Fluorescence measurements were made on an Edinburgh Analytical Instrument FLS920.

2.2. Syntheses of the complexes

2.2.1. Synthesis of $[Ag(TDPN)(NO_3)]_n$ (1)

TDPN (1 mmol) was dissolved in CH_3CN (20 ml), then $AgNO_3$ (1 mmol) was added. The resulting mixture was stirred at 50 °C for 30 min and then filtered. Colorless block crystals were obtained after slow evaporation at room temperature for two days. Yield: 68% (on the basis of silver). *Anal.* Calc. for $C_6H_8N_3O_3SAg$: C, 23.24; H, 2.60; N, 13.55; S, 10.34. Found: C, 23.13; H, 2.46; N, 13.59; S, 10.61%. IR (cm^{-1}): 2933w, 2426w, 2395w, 2251m, 1763m, 1626w, 1385vs, 1284w, 1238w, 904w, 825m.

2.2.2. Synthesis of $[Ag(TDPN)(ClO_4)]_n$ (2)

TDPN (1 mmol) was dissolved in CH_3CN (20 ml), then $AgClO_4$ (1 mmol) was added. The resulting mixture was stirred at 50 °C for 30 min and then filtered. Colorless block crystals were obtained after slow evaporation at room temperature for five days. Yield: 63% (on the basis of silver). *Anal.* Calc. for $C_6H_8N_2O_4SClAg$: C, 20.74; H, 2.32; N, 8.06; S, 9.23. Found: C, 20.75; H, 2.60; N, 7.87; S, 9.12%. 2.3. Crystal structure determination

Measurements were made on a Siemens SMART platform diffractometer with graphite monochromatized Mo Kα ($\lambda = 0.71073$ Å) radiation. Data reductions and cell refinements were performed with SMART CCD software [10]. The structures were solved by direct methods with the SHELXTL-97 program [11]. Absorption corrections were carried out using SADABS [12]. Crystallographic data for complexes **1**–**3** and TCEB are listed in Table 1. Selected bond lengths and bond angles for complexes **1**–**3** are summarized in Table 2.

3. Results and discussion

3.1. IR spectra

The main absorption peaks in the IR spectra of complexes **1**–**3**, TDPN and TCEB are listed in Table 3. The presence of characteristic bands around 2250 cm^{-1} indicates that the complexes all contain CN groups. As shown in Table 3, we found that the ν_{CN} values of coordinated CN groups of complexes **1**–**3** are the same as those of the corresponding ligands. Therefore, the silver ions exert no influence on the ν_{CN} values. In addition, complexes **1** and **3** show the same absorption at 1385 cm^{-1}, which should be assigned to $\nu_{NO_3^-}$. According to the result of $[Ag(EDTPN)(ClO_4)]_n$ reported by Min et al., the strong absorption peak at 1088 cm^{-1} corresponds to $\nu_{ClO_4^-}$ [4].

3.2. Fluorescence spectra

The fluorescence emission spectra for complexes **1** and **2**, and complex **3** in the solid-state are shown in Figs. 1 and 2, respectively. It can be observed that the intense emission for complex **1** occurs at 426 nm ($\lambda_{max} = 363$ nm) and complex **2** at 436 nm ($\lambda_{max} = 371$ nm), while the intense emission for complex **3** occurs at 440 nm ($\lambda_{max} = 368$ nm). These emissions may be assigned to the CN groups in the TDPN and TCEB ligands to Ag ion charge-transfer bands (LMCT). It is notable that a blue shift (10 nm) occurs in complex **1**, although complexes **1** and **2** are constructed by the same metal ion and ligands. We assume that the different topological structures and metal coordination environments are mostly responsible for the blue shift.

Table 3
IR spectra data for complexes **1**–**3** T(DPN) and TCEB

Compound	ν_{CN} (cm^{-1})	ν_{anion} (cm^{-1})
1	2251	1385
2	2251	1088
3	2247	1385
TDPN	2251	
TCEB	2247	

*3.2.1. Crystal structures of complexes **1** and **2***

Fig. 3 shows an ORTEP view of the coordination sphere of the Ag(I) ion and atom labelling in $[Ag(TDPN)(NO_3)]_n$ **(1)**. TDPN as a flexible multi-functional ligand contains rich structural information in which both nitrile nitrogen and sulfur atoms can act as donors to coordinate to Ag ions. As shown in Fig. 3, two TDPN ligands exhibit a "W" and an inverse "W" motif. Two nitrogen atoms and one sulfur atom occupy the summit of the "W" motif, and then coordinate to the three different Ag ions. The two motifs are linked with two Ag ions, thus a 20-membered ring is formed in which the S···S distance is 3.541(2) Å and the Ag···Ag distance is 10.224(6) Å. Each silver ion exhibits tetrahedral coordination geometry and is surrounded by two N atoms (Ag(1)–N(1) 2.398(6), Ag(1)–N(2) 2.221(5) Å) and one S atom (Ag(1)–S(2) 2.497(1) Å) from two different TDPN ligands, as well as one O atom from the nitrate anion (Ag(1)–O(1) 2.447(5) Å). In the whole structure, each Ag ion is linked with three TDPN ligands, and each TDPN binds three Ag ions. Therefore, **1** is a 1-D ladder-like coordination polymer, which propagates along *c*-axis (Fig. 4).

An ORTEP drawing of **2** is represented in Fig. 5. Similar to complex **1**, the silver ion also displays tetrahedral coordination geometry. In contrast to complex **1**, the coordination sites are defined by two N atoms (Ag(1)–N(1)#1 2.283(6), Ag(1)–N(2)#2 2.303(6) Å) and two S atoms (Ag(1)–S(1) 2.5437(15), Ag(1)–S(1)#3 2.635(2) Å) from four different TDPN ligands (Fig. 5). As a result, S atoms in complex **2** act as μ_2-bridges to complete the tetrahedral coordination geometry. Similar to complex **1**, a 20-membered ring is also observed in complex **2** (Fig. 5), although the motif is distinct from that of **1**. As each TDPN ligand binds four different Ag(I) ions and each Ag(I) is linked with four TDPN ligands, whole structure becomes a box-like 2-D layer, as shown in Fig. 6. The uncoordinated perchlorate ions are located between the layers to balance the electric charge (Fig. 7).

*3.2.2. Crystal structures of complex **3** and TCEB*

Figs. 8 and 9 show ORTEP diagrams of complex **3** and TCEB, respectively. It is notable that TCEB is a *meso* compound as it possesses two chiral carbon atoms, *R*-C8 and *S*-C8# 1(Fig. 8). Space groups *P*2(1)/*c* of TCEB and complex **3** also confirm that they are achiral. TCEB, acting as a symmetrical tetra-dentate ligand, has a volute motif. It seems a good ligand to coordinate to metal ions, but, to our surprise, a search of the Cambridge Crystallographic Database revealed that metal TCEB complexes do not exist. The X-ray crystallography of complex **3** shows that the silver ion in **3** also displays a tetrahedral coordination geometry, being coordinated by two cyano groups from two different TCEB ligands and two O atoms from two different ni-

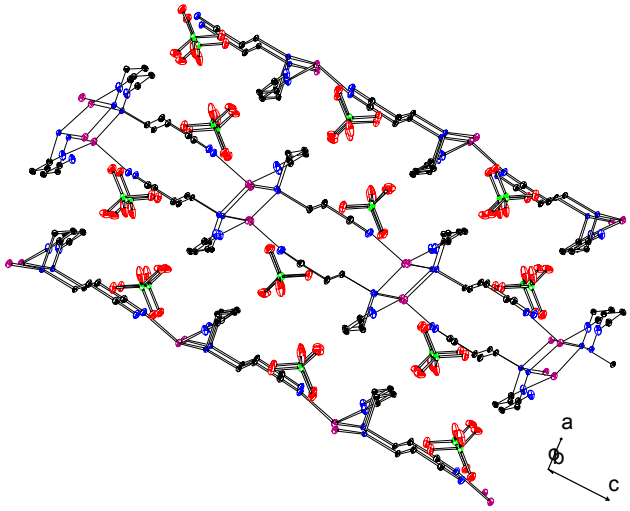

Fig. 7. The side view of the packed structure of **2**, showing the position of ClO_4^- anions.

trate ions. The Ag–N bond distances are 2.209(4) and 2.239(4) Å. For the coordinated nitrate anions, the two Ag–O bond distances are 2.395(4) and 2.660(4) Å. Each TCEB acts as a μ_4-bridge to link four silver ions, and each nitrate ion acts as a μ_2-bridge to link two Ag(I) ions, which gives rise to a 3-D network as shown in Fig. 10. Evidently, complex **3** exhibits a 3-D inorganic–organic hybrid coordination architecture, in which inorganic layers are constructed by rare

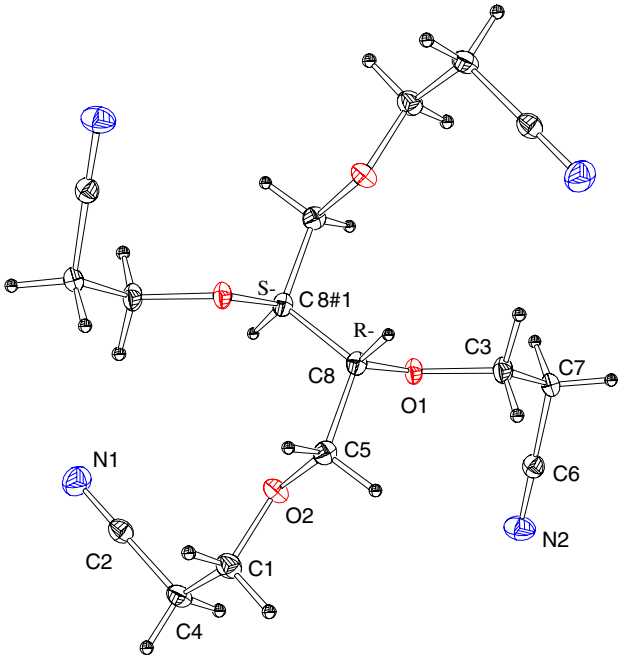

Fig. 8. An ORTEP drawing of TCEB with atomic numbering scheme. Symmetry mode: (# 1) $1-x, 1-y, -z$.

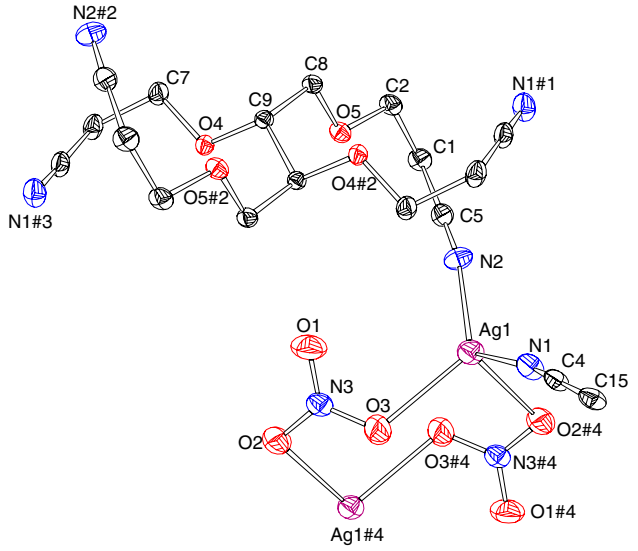

Fig. 9. An ORTEP drawing of $[Ag_2(TCEB)(NO_3)_2]_n$**3** with atomic numbering scheme. Symmetry modes: (#1)x, $-1/2-y$, $-1/2+z$; (#2) $2-x$, $-y$, $1-z$; (#3) $2-x$, $1/2+y$, $3/2-z$; (#4) $1-x$, $1-y$, $2-z$.

eight-membered silver nitrate rings with an Ag···Ag distance of 4.463(1) Å, while organic layers are formed by TCEB ligands. In addition, the 3D network of **3** could be simplified to a 4-connected network if the $Ag_2(NO_3)_2$ dimer is simplified to the baricenter and the ligand becomes another four-connected center. The overall topology could be described as a simple single (not interpenetrated) uninodal four-connected net of $CdSO_4$ topology. Compared to the S atoms of TDPN in complex **1** and **2**, the O atoms of TCEB in **3** do not participate in coordination to the Ag^+ ions. This indicates that the order of affinity to Ag ions can be ranked as S > O, which is in accord with conventional wisdom that a soft acid, such as Ag^+ ions, is inclined to coordinate to a soft base such as a *S*-ligand [4].

4. Conclusion

It is interesting that although complexes **1** and **2** are both synthesized by the self-assembly of silver salts with the same ligand TDPN, X-ray analysis reveals that they display completely different topological structures, which are an infinite one-dimensional array with a ladder-like chain structure (Fig. 4) and a box-like layer structure (Fig. 6), respectively. Different anions thus exert an important influence on the assembly of metal–organic frameworks, including their topologies and dimensionality. Such a phenomenon was observed in the self-assembly of other silver coordination architectures [4]. We have used a *meso* ligand to construct a novel complex **3** with a four-connected net of $CdSO_4$ topology. The IR spectra for the three title complexes and their ligands TDPN and TCEB show that free and coordinated CN groups have virtually the same ν_{CN} value. In addition, the fluorescence spectra for complexes **1**–**3** indicate that they may be good blue-light emitting materials since they are insoluble in common polar and non-polar solvents.

In summary, three silver coordination polymers have been synthesized and characterized. The present study shows that the counter anion plays an important role in the construction of coordination architectures from silver salts and flexible multi-nitriles.

5. Supplementary data

CCDC Nos. 236187 and 236190 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/data_request/cif, by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336033.

Synthesis and characterization of cobalt(III) complexes with sinambic amplector ligands

Clint A. Sharrad, Lawrence R. Gahan *

Chemistry Department, The University of Queensland, Brisbane, Qld 4072, Australia

Received 25 May 2004; accepted 24 June 2004
Available online 28 August 2004

Abstract

The synthesis of the hexadentate ligand 5,6-dimethyl-2,2,9,9-tetra(methyleneamine)-4,7-dithiadecane (1,2-$Me_2EtN_4S_2$amp) is reported. The diastereiosomers were separated as cobalt(III) complexes using cation exchange chromatography. The *rac* and *meso* isomers were characterized by NMR (^{13}C, ^{1}H, ^{59}Co), ESI-MS, UV–Vis spectroscopy and cyclic voltammetry. Single crystals of [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)] $Cl_2(ClO_4) \cdot 2H_2O$ were characterized by X-ray diffraction. The low-temperature (11 K) absorption spectra of the complexes have been measured in Nafion films and from the observed positions of both spin-allowed $^{1}A_{1g} \rightarrow {}^{1}T_{1g}$ and $^{1}A_{1g} \rightarrow {}^{1}T_{2g}$ and spin forbidden $^{1}A_{1g} \rightarrow {}^{3}T_{2g}$ bands, octahedral ligand-field parameters (10Dq, *B* and *C*) were determined. These results, in conjunction with the ^{59}Co NMR data, are used to further explore the relationship between the ^{59}Co magnetogyric ratio (γ_{Co}) and the product of the nephelauxetic ratio and the wavelength of the $^{1}A_{1g} \rightarrow {}^{1}T_{1g}$ transition ($\beta(\Delta E)^{-1}$) for complexes of mixed donor nitrogen–thioether ligands.

Keywords: Multidentate ligand; Cobalt(III); Sinambic; ^{59}Co NMR

1. Introduction

A new class of mixed donor nitrogen–thioether ligands, known as *amplectors* (amp), with a tetrapodal branched topology has been developed [1–3]. A series of cobalt(III) complexes, $[Co(RN_4S_2amp)]^{3+}$, have been synthesized and characterized where the hinge moieties (R) include straight chain (R = Et, Pr, Bu) and aromatic entities (R = Xy) [1,2] (Chart 1). Our interest in these and other mixed donor nitrogen–thioether complexes has focussed on structural, electronic, ^{59}Co NMR and electrochemical properties [1–8]. The amplector complexes can be used also as templates for the synthesis of encapsulated structures with larger cavities [1].

The use of 2,3-butanethiol in the readily adaptable amplector synthetic methodology allows for the possible introduction of chirality into the ligand structure by forming 5,6-dimethyl-2,2,9,9-tetra(methyleneamine)-4,7-dithiadecane (1,2-$Me_2EtN_4S_2$amp; Chart 1). This expansion of the class of hexadentate amplectors results in the formation of a sinambic (Latin: *without rotation*) ligand, the term sinambic ligands used to describe bidentates with rotationally non-equivalent donor atoms [9–11]. The terminology is applicable to these amplector ligands as the chiral carbons are located within the dithio-hinge moiety. This paper reports the preparation and characterization of the sinambic ligand and the cobalt(III) complexes which were separated into their diastereoisomeric forms and characterized.

2. Experimental

2.1. Physical measurements

NMR (^{13}C, ^{1}H and ^{59}Co) spectroscopy, cyclic voltammetry, mass spectrometry, solution and Nafion film UV-Vis spectroscopy were performed as described previously [1–4]. The chemical shifts of ^{13}C NMR spectra (D_2O) for the metal complexes are reported in parts per million (δ_C) as positive downfield and negative upfield of the internal reference 1,4-dioxane, as described previously [1–3]. Where necessary, peak positions in UV–Vis spectra were determined using Peakfit [12] obtaining a correlation coefficient (R^2) greater than 0.997.

Analytical HPLC was performed with a Shimadzu HPLC system comprised of a Shimadzu LC-10ATvp liquid chromatograph, Shimadzu FCV-10ALvp low-pressure gradient flow control valve, Shimadzu DGU-14A degasser, Shimadzu SCL-10Avp system controller and a Shimadzu SPD-10Avp UV–Vis detector. A Waters Protein-Pak SP 5PW (7.5 mm × 7.5 cm) analytical column was used. All eluent solutions were prepared using Milli-Q water and were degassed and filtered through an all-glass filter unit fitted with a 0.45 μm membrane (Millipore MF type membrane). All metal complex solutions (Milli-Q H_2O) were passed through syringe filters (pore size 0.2 μm) prior to injection. The column was prepared by an initial washing with water (30 min, 0.5 cm^3/min) followed by the eluent (60 min, 0.5 cm^3/min). Metal complex solutions (5–50 μL; Hamilton 250 μL syringe) were injected into the injector assembly unit. Chromatograms were recorded from 0 to 90 min at two detection wavelengths. Concentrations of metal complex solutions were adjusted so that all absorbance readings were below 2.0.

2.2. Ligand synthesis

2,3-Butanedithiol was purchased from Aldrich Chemical Company and used without further purification.

2.2.1. 5,6-dimethyl-2,2,9,9-tetra(methyleneamine)-4,7-dithiadecane (1,2-$Me_2EtN_4S_2$amp)

The synthetic methodology for 1,2-$Me_2EtN_4S_2$amp was essentially identical to that described for the analogous ligand 2,2,9,9-tetra(methyleneamine)-4,7-dithiadecane (EtN_4S_2amp) but replacing 1,2-ethanedithiol in the latter synthesis with 2,3-butanedithiol in the former [1–3]. In all steps of the synthesis of 1,2-$Me_2EtN_4S_2$amp, the same reagents, solvents and methodologies were employed as described for EtN_4S_2amp, and on the same scale.

2.3. Preparation of cobalt(III) complexes

Caution: Although the perchlorate salts described in this work do not appear to be sensitive to shock or heat these materials, like all perchlorates, should be treated with caution.

2.3.1. [Co(rac-1,2-$Me_2EtN_4S_2$amp)] $Cl_2(ClO_4)\cdot 2H_2O$

Cobaltous nitrate hexahydrate (13.1 g) in methanol (200 cm^3) was added dropwise to a stirred solution of

1,2-$Me_2EtN_4S_2$amp (13.1 g) in methanol (300 cm^3). A stream of air was bubbled through the ligand solution for the duration of the metal addition and the aeration continued for a further four hours. The solvent was removed under reduced pressure, the residue dissolved in water and the solution filtered. The filtrate was diluted to 2 l and loaded on Dowex cation exchange resin (50W × 2 (200–400 mesh) H^+ form). The column was washed with water and 1 M HCl to elute minor products. The major red band was eluted with 3 M HCl. The solvent was removed under reduced pressure to give a red residue, which was dissolved in water (500 cm^3) and loaded onto Sephadex C-25 cation exchange resin (Na^+ form). The column was washed with water then 0.2 M NaCl to elute a series of minor pink and purple products followed by a red-brown band. A major orange band was eluted with 0.3 M NaCl. The orange eluent was loaded onto Dowex cation exchange resin and washed with 1 M HCl. The orange band was eluted with 3 M HCl and the solvent removed to give an orange solid. HPLC of a small sample of the orange compound resolved two compounds when eluted with 0.1 M Na_2SO_4 adjusted to pH 4 with H_2SO_4 (see Fig. 1). The orange solid was dissolved in water (500 cm^3) and loaded onto Sephadex cation exchange resin. The orange band was eluted with 0.1 M Na_2SO_4, adjusted to pH 4 with H_2SO_4. The orange band was collected in three approximately even fractions as band separation was not clearly evident. Fraction 3 was loaded onto Dowex cation exchange resin, washed with 1 M HCl and eluted with 3 M HCl. The solvent was removed from the eluent under reduced pressure to give an orange solid. Analytical HPLC showed the fraction consisted of predominantly one compound. A small amount of the compound predominant in Fraction 1, subsequently identified as [Co(*meso*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$, was eluted immediately before the major product. The orange solid was dissolved in a minimum volume of aqueous $NaClO_4$, and the solution left to stand overnight to give orange crystals (0.3 g). (Found: C, 27.87; H, 6.28, N, 9.30%. $[C_{14}H_{34}N_4S_2Co]Cl_2(ClO_4)\cdot 2H_2O$ requires: C, 28.60; H, 6.52; N, 9.53%.) UV–Vis spectrum [λ_{max}, nm (ε_{max}, L mol^{-1} cm^{-1}) in H_2O]: 475 (390), 284 (16000), 232 (15000). ^{13}C NMR (D_2O): δ_C −49.9 (–CH_3*(hinge)*); −43.0 (—CH_3); −29.0 (–CH_2–S); −26.5 (C_q); −21.9, −20.0 (–CH_2–N); −11.3 (—CH—S). ^1H NMR (D_2O): δ_H 1.07 (–CH_3, s); 1.67 (–CH_3*(hinge)*, d); 2.3–3.3 (–CH_2–, m) ; 3.52 (—CH—S, m). ^{59}Co NMR (H_2O): δ_{Co} 5579 ($\nu_{1/2}$ = 630 Hz). ESI-MS: Calc. for [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ − $2H^+$, *m/z* 379; found, *m/z* 379 (65%). Calc. for [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ − H^+, *m/z* 190; found, *m/z* 190 (100%).

2.3.2. [Co(meso-1,2-$Me_2EtN_4S_2$amp)]Cl $(ClO_4)_2\cdot 3H_2O$

Fraction 1 of the initial Sephadex purification from the synthesis of [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ was loaded onto Dowex cation exchange resin and washed with 1 M HCl. The orange band was eluted with 3 M HCl and the solvent was removed under reduced pressure. Analytical HPLC showed the fraction consisted of predominantly one compound. A small amount of

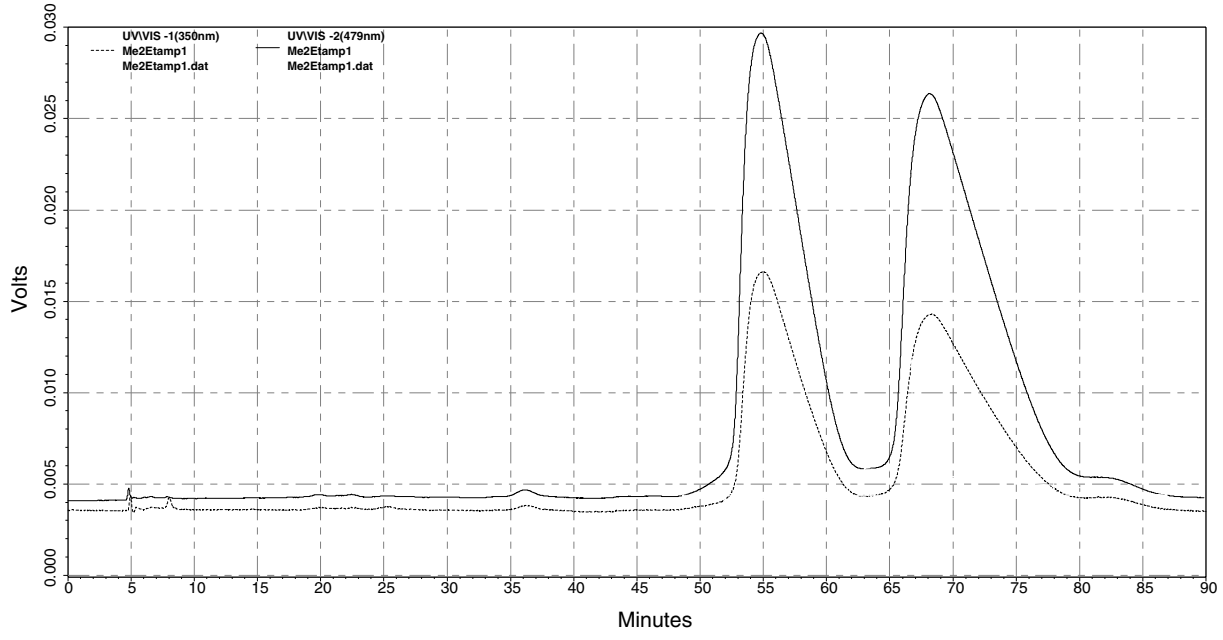

Fig. 1. HPLC trace of the crude orange product from the synthesis of [Co(1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ (eluent: 0.1 M Na_2SO_4, pH 4; detection wavelengths: 479 and 350 nm; flow rate = 0.5 cm^3/min; column: Waters Protein-Pak SP 50PW).

the compound predominant in Fraction 3, subsequently identified as [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$, was eluted immediately after the major product. The orange solid was dissolved in a minimum volume of aqueous $NaClO_4$ and the solution allowed to stand for several days to give orange crystals (0.2 g). ($[C_{14}H_{34}N_4S_2Co]Cl(ClO_4)_2 \cdot 3H_2O$ requires: C, 25.10; H, 6.02; N, 8.37. Found: C, 24.89; H, 5.68; N, 8.20%.) UV–Vis spectrum [λ_{max}, nm (ε_{max}, L mol^{-1} cm^{-1}) in H_2O]: 481 (350), 289 (11 000), 234 (10 000). ^{13}C NMR (D_2O): δ_C −55.8, −52.0 (–CH_3*(hinge)*); −43.0, −42.9 (–CH_3); −32.4, −31.6 (–CH_2–S); −25.7, −25.5 (C_q); −21.9, −20.8, −20.7, −20.4 (–CH_2–N); −18.4, −11.7 (–CH–). ^{1}H NMR (D_2O): δ_H 1.08, 1.08 (–CH_3, s); 1.50, 1.76 (–CH_3*(hinge)*, d); 2.3–3.3 (–CH_2–, m); 3.68, 3.72 (–CH–, m). ^{59}Co NMR: δ_{Co} 5661 ($\nu_{1/2}$ = 370 Hz). ESI-MS: Calc. for $[Co(meso-1,2-Me_2EtN_4S_2amp)]^{3+} - H^+ + {}^{35}ClO_4^-$, *m*/*z* 479; found, *m*/*z* 479 (100%). Calc. for [Co(*meso*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ − 2H$^+$, *m*/*z* 379; found, *m*/*z* 379 (89%).

2.4. X-ray crystallography

For diffractometry a crystal of the metal complex was mounted onto glass fibres with Supa Glue. Lattice parameters were determined by least squares fits to the setting parameters of 25 independent reflections, measured and refined on an Enraf-Nonius CAD4 diffractometer using graphite-monochromated Mo Kα radiation.

The structure was solved by heavy-atom methods (direct methods) and refined using full-matrix least-squares on F^2. Programs used were SIR-92 [13] for solution, SHELXL-97 [14] for refinement and *ORTEP-3 for Windows* [15] for plotting. Crystal data are given in Table 1. The geometry of the complex cation [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ is displayed in Figs. 2 and 3 with crystallographic atom numbering schemes. Selected bond lengths and bond angles are given in Table 2.

3. Results and discussion

3.1. Nomenclature

The nomenclature employed for amplector ligands synthesized from straight chain dithiols will be used [1,2]. The abbreviated nomenclature for the amplector (amp) ligand can be considered in terms of the donor set and a hinge moiety connecting them. Thus, for 1,2-$Me_2EtN_4S_2$amp (*5,6-dimethyl-2,2,9,9-tetra(methyleneamine)-4,7-dithiadecane*) the hinge derived from 2,3-butanedithiol is abbreviated to 1,2-Me_2Et, where Et refers to the ethyl link between thio donors. The 1,2-Me_2 prefix refers to the methyl groups bonded to each of the methine carbons of the ethyl hinge. The two diastereoisomeric forms of the ligand, upon complexation, are referred to as *rac*-1,2-$Me_2EtN_4S_2$amp and *meso*-1,2-$Me_2EtN_4S_2$amp.

3.2. Synthesis

The synthetic methodology reported previously for this type of ligand [1–3] employing straight chain and substituted dithiols has been utilized in this work. Thus, the reaction sequence employed is essentially that described for the EtN_4S_2amp analogue [1]; however, a diastereomeric mixture of 2,3-butanedithiol was employed instead of 1,2-ethanedithiol. The desired ligand 1,2-$Me_2EtN_4S_2$amp was reacted with a cobalt(II) salt and air in methanol and, after initial purification with Dowex resin, cation exchange chromatography of the crude mixture of the Co(III) complex using Sephadex resin resulted in the isolation of an orange band in a similar manner to the purification of [Co(EtN_4S_2amp)]$^{3+}$ [1].

The NMR spectrum of this material indicated that it consisted of a mixture of isomers. High performance liquid chromatography of this material using a Waters Protein-Pak SP 5PW (cation exchange) column, eluting with Na_2SO_4 (adjusted to pH 4), indicated that two complexes were present (Fig. 1). Assuming that the extinction coefficients for both complexes are similar at the detection wavelengths used, the peak areas obtained for the HPLC trace suggested the complexes are present in approximately equivalent amounts. Preparative scale chromatography of this orange band with a Sephadex cation column (0.1 M Na_2SO_4, pH 4; H_2SO_4) gave two bands. The complexes were separately crystallized as mixed chloride/perchlorate salts by the addition of $NaClO_4$ to an aqueous solution. The first eluted complex was found to be [Co(*meso*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ by microanalysis and NMR spectroscopy while the [Co(*rac*-1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ isomer was eluted second. No evidence from either the HPLC or preparative scale chromatography separations indicated the resolution of *lel* and *ob* isomers [16] for [Co(1,2-$Me_2EtN_4S_2$amp)]$^{3+}$ for both *rac* and *meso* ligands. Attempts to resolve the racemic complex into stereoisomers using sodium $(+)_{589}$-tartrate as eluent on a column of Sephadex SP C25 cation exchange resin (Na^+ form) were unsuccessful.

The chemistry of Co(III) complexes with chiral carbons in disubstituted ethyl dithio-chelate rings is limited, but the chemistry of analogous diamine chelate rings is more extensive. Examples include numerous complexes with the bidentate 2,3-butanediamine ligand [8,17–20], straight chain tetradentate ligands like 5,6-dimethytriethylenetetraamine (5,6-dmtrien) and 5,6-dimethyl-3,7-diaza-2,9-diaminodecane (tmtrien) [21], and branched ligands like 2,3-butanediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid (H_4bdta) [22].

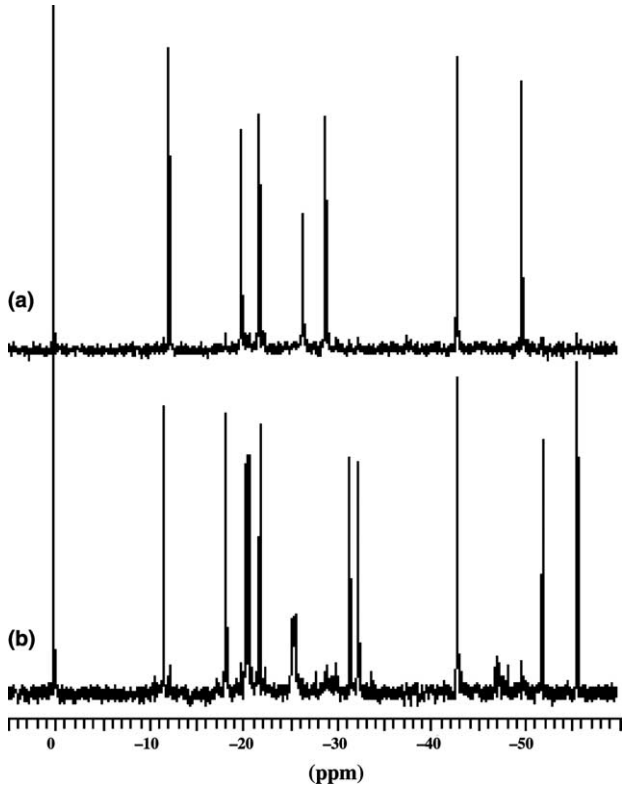

Fig. 4. ^{13}C NMR spectra of $[Co(1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ in D_2O: (a) *rac* isomer, (b) *meso* isomer (δ_C 0 ppm – 1,4-dioxane).

3.3. NMR spectroscopy

The ^{13}C NMR spectrum of $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ (Fig. 4(a)) exhibits seven resonances for this symmetric molecule which has a C_2 rotation axis bisecting the dithio-hinge and the cobalt centre. The methyl carbon resonance in the dithio-hinge (δ_C −49.9 ppm) is shifted upfield relative to the apical methyl carbon resonance (δ_C −43.0 ppm). The methine carbons on the dithio-hinge display a resonance (δ_C −12.3 ppm) which is shifted significantly downfield compared to resonances of methylene carbons adjacent to thioethers for both this complex (δ_C −29.0 ppm) and $[Co(EtN_4S_2amp)]^{3+}$ (δ_C −28.4, −27.5 ppm) [1]. The remaining ^{13}C resonances of $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ are found to have similar shifts to those for the analogous resonances of $[Co(EtN_4S_2amp)]^{3+}$ [1].

The ^{13}C NMR spectrum of $[Co(meso\text{-}Me_2EtN_4S_2amp)]^{3+}$ (Fig. 4(b)) displays 14 resonances and is characteristic of an asymmetric molecule. In comparison to the *rac* isomer, the ^{13}C NMR signals for the *meso* isomer can be considered as ''pairs'' of resonances for each type of carbon atom present. The greatest difference in chemical shift within a single ''pair'' of signals is seen for the chiral methine carbons (δ_C −11.7, −18.4 ppm). The difference between shifts within a ''pair'' of resonances decreases with decreasing proximity to the chiral carbons.

3.4. X-ray crystal structure

The structure of $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]Cl_2(ClO_4)\cdot 2H_2O$ (Fig. 2) consists of the molecular cation, two chloride anions, a perchlorate anion and two water molecules. The structure of the molecular cation is similar to that of $[Co(EtN_4S_2amp)]^{3+}$ [1]. The cation adopts the *lel* conformation [16] for the dithio-chelate ring (Fig. 3) as for the Co(III) complexes of amplectors with straight chain dithio-hinges. The chiral carbons of the dithio-hinge both adopt the *S* (or *R*) configuration while the coordinated thioethers are *R* (or *S*). Thus, the methyl groups of the dithio-chelate ring are equatorial with the average plane of this chelate ring. When both thioethers are *R*, the dithio-chelate ring has the δ conformation for the *lel* form. Conversely, for its mirror image, the dithio-chelate ring has the λ conformation and both thioether donors are *S* for the *lel* form. The *ob* conformation would require one thioether donor to adopt the *R* configuration while the other thioether donor would have the *S* configuration. The remaining six-membered chelate rings all adopt the unsymmetrical skew-boat conformation [23].

Selected bond lengths and bond angles for $[Co(rac\text{-}Me_2EtN_4S_2amp)]Cl_2(ClO_4)\cdot 2H_2O$ are shown in Table 2. The coordination bond lengths are typical for both Co(III)-amine and Co(III)-thioether bonds [24–27]. In comparison to $[Co(EtN_4S_2amp)]^{3+}$ [1], the Co–N and Co–S bonds of $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ are slightly shorter. The S–Co–S bite angle for $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ (88.29(3)°) is slightly smaller than that of $[Co(EtN_4S_2amp)]^{3+}$ (88.72(7)°) [1]. The structural parameters of $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ and $[Co(EtN_4S_2amp)]^{3+}$ show only minor differences suggesting there is little steric hindrance from the methyl groups of the 1,2-dimethylethyl dithio-hinge.

3.5. Electrochemistry

The cyclic voltammograms of the cobalt(III) complexes of the diastereoisomers of $1,2\text{-}Me_2EtN_4S_2amp$ (Fig. 5) exhibit irreversible $Co^{3+/2+}$ redox couples as is the case for all the other cobalt(III) amplector complexes studied to date [1,2]. The cathodic peak attributed to the $Co^{3+/2+}$ couple for $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ (−412 mV, versus Ag/AgCl) is clearly shifted to a more negative value in comparison to that for $[Co(EtN_4S_2amp)]^{3+}$ (−330 mV, versus Ag/AgCl)) [1]. The difference in potential and the differences in the structural properties between $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ and $[Co(EtN_4S_2amp)]^{3+}$ suggest a preference for the smaller Co(III) ion in the former complex.

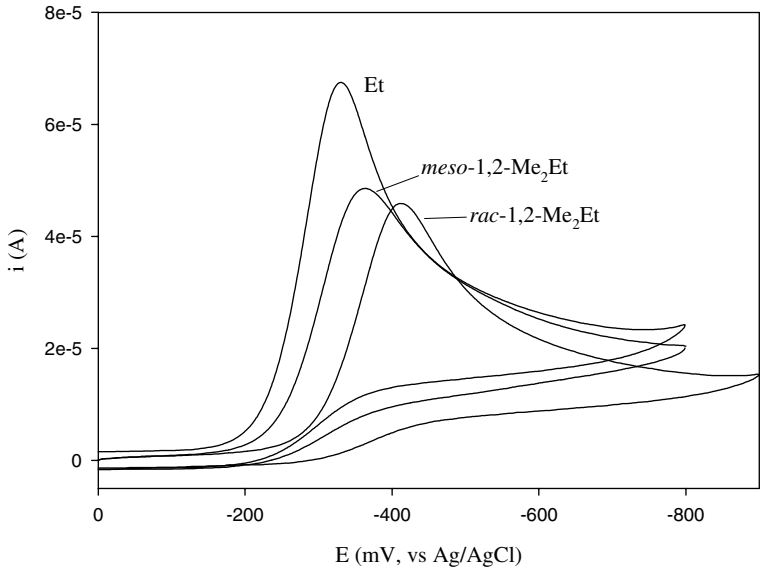

Fig. 5. Cyclic voltammograms of $[Co(RN_4S_2amp)]^{3+}$ (R = Et, *meso*-1,2-Me_2Et, *rac*-1,2-Me_2Et, pH < 2.5; Glassy C working electrode, 100 mV/s).

The cathodic peak for the $Co^{3+/2+}$ couple of [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ (−364 mV, versus Ag/AgCl) falls between those for [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ and $[Co(EtN_4S_2amp)]^{3+}$. The difference in redox potentials for the diastereoisomers of [Co(1,2-Me_2Et-N_4S_2amp)]$^{3+}$ is of similar magnitude to the $Co^{3+/2+}$ couples observed for other diastereoisomeric complexes such as [Co(salbn)] (salbn = *N*,*N*′-butane-2,3-diylbis(salicylideneiminato)) [28].

3.6. UV–Vis spectroscopy

The room temperature aqueous solution UV–Vis spectra of [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$Cl_2(ClO_4)$ and [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$Cl(ClO_4)_2$ were recorded. The spectra are typical of low spin Co(III) systems, with no spin forbidden transitions observed. For each spectrum, the peak attributed to the $^1A_{1g} \rightarrow {}^1T_{1g}$ transition is clearly seen. The higher energy $^1A_{1g} \rightarrow {}^1T_{2g}$ transition is observed as a shoulder upon an intense charge transfer band for both complexes.

Spectra recorded in Nafion film at low temperature (11 K) for [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ and [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ are similar to those of $[Co(EtN_4S_2amp)]^{3+}$ although the $^1A_{1g} \rightarrow {}^1T_{2g}$ transition is less obscured by the charge transfer band for the complexes with the dimethyl substituted hinge [1].

The observation of one spin forbidden band ($^1A_{1g} \rightarrow {}^3T_{2g}$) for both [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ and [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ complexes allows for the unique determination of spectrophotometric parameters 10Dq, *B* and *C* using perturbation equations described previously [7]. The equations assume O_h symmetry and are corrected for configuration interaction. The complexes $[Co(EtN_4S_2amp)]^{3+}$, [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ and [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ are found to have similar B values (551, 535 and 549 cm^{-1}, respectively; Table 3) as expected. It is clearly evident that the Racah parameter $C \approx 6B$ as previously reported [1,2,4,7,8,25]. 10 Dq for these complexes is essentially constant, as expected, and supports previous observations that this parameter is relatively insensitive for mixed nitrogen–thioether cobalt(III) complexes [4,7,8].

3.7. ^{59}Co NMR resonances and line-widths

^{59}Co resonances for the ethyl hinged amplector complexes are found within the relatively narrow chemical shift range of 5570–5670 ppm ($[Co(EtN_4S_2amp)]^{3+}$, δ_{Co} 5638 ppm; [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$, δ_{Co} 5579 ppm; [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$, 5661 ppm) and have similar ^{59}Co NMR chemical shifts to other Co(III) complexes with N_4S_2 donor sets (5000–6500 ppm) [2]. The linewidths of the ^{59}Co NMR resonances are known to be dependent upon electric field gradients at the cobalt nucleus and departures from strict octahedral symmetry about the cobalt atom cause line broadening [29]. The ^{59}Co linewidth of [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ ($\nu_{1/2}$ = 630 Hz) is similar to that of $[Co(EtN_4S_2amp)]^{3+}$ ($\nu_{1/2}$ = 740 Hz), whilst that of [Co(*meso*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ ($\nu_{1/2}$ = 370 Hz) is decidedly less than that of the *rac* isomer. This is a somewhat surprising result as the *meso* isomer is asymmetric by ^{1}H and ^{13}C NMR spectroscopy while [Co(*rac*-1,2-$Me_2EtN_4S_2amp$)]$^{3+}$ and $[Co(EtN_4S_2amp)]^{3+}$ both exhibit a C_2 rotation axis. The ^{59}Co NMR linewidth is not only seen to be dependent on the symmetry of the donor set but also the rigidity of the ligand structure, as the

encapsulated complexes have a markedly larger ^{59}Co linewidth than the branched precursor complexes.

3.8. Correlation between the ^{59}Co chemical shift and $E(^1A_{1g} \rightarrow {}^1T_{1g})$

Griffith and Orgel [30] showed that for low spin d^6 systems the $^1T_{1g}$ state can mix with the ground state ($^1A_{1g}$) on exposure to a magnetic field. They predicted that the paramagnetic screening constant σ_p was inversely proportional to $\Delta E_{(^1A1g \rightarrow {}^1T1g)}$, the energy separation of the $^1T_{1g}$ and $^1A_{1g}$ states [30]

$$\sigma_p = -32\beta_M^2 \langle r^{-3} \rangle \Delta E^{-1}_{(^1A_{1g} \rightarrow {}^1T_{1g})}, \quad (1)$$

where r is the distance of a given 3d electron from the cobalt nucleus and β_M is the Bohr magneton. The theoretical expression for the magnetogyric ratio, γ, as a function of screening constants is given by [31]

$$\gamma = \gamma_o(1 - \sigma_d - \sigma_p), \quad (2)$$

where σ_d and σ_p are diamagnetic and paramagnetic screening constants, respectively. Experimentally, $\gamma = \gamma_S(1 + \delta_{Co})$ where γ_S, the magnetogyric ratio of $[Co(CN)_6]^{3-}$, is 10.1057 MHz T^{-1} and δ_{Co} is the ^{59}Co chemical shift. Assuming $\langle r^{-3} \rangle$ to be constant, it was expected that γ would be inversely proportional to $\Delta E_{(^1A_{1g} \rightarrow {}^1T_{1g})}$. Freeman et al. [32], the first to investigate whether such a correlation existed using homoleptic and mixed donor cobalt(III) complexes, concluded that a linear correlation between ^{59}Co chemical shifts and the wavelength of the $^1A_{1g} \rightarrow {}^1T_{1g}$ transition existed for symmetrical complexes. Deviations from the best fit line for symmetrical structures were observed for asymmetric complexes and those with 3rd and 4th period ligators [32]. The difference was attributed to increases in the covalency of the coordination sphere delocalizing the cobalt d-electron shell, thus decreasing $\langle r^{-3} \rangle$. Introduction of the nephelauxetic ratio, β_{Racah} ($= B_{complex}/B_{free\ ion}$)

$$\sigma_p \alpha \beta_{Racah} \Delta E^{-1}_{(^1A_{1g} \rightarrow {}^1T_{1g})}$$

was proposed to rationalize the observed deviations from linearity [33].

The series of non-orthoaxial complexes $[Co(EtN_4S_2amp)]^{3+}$, $[Co(meso\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$, $[Co(rac\text{-}1,2\text{-}Me_2EtN_4S_2amp)]^{3+}$ and the $N_{6-x}S_x$ ($x = 1, 2, 3$) complexes [5–8] for which both spin-allowed and spin-forbidden transitions are observed permits unique determination of β and therefore an examination of the relationship between γ_{Co} and $\beta\Delta E^{-1}$ [2]. The plot of $\gamma(^{59}Co)$ and $\beta_{Racah}(\Delta E)^{-1}$ for these complexes (Table 3, Fig. 6) results in a linear relationship ($r^2 = 0.93$) with an intercept of 10.047 MHz T^{-1}, giving $\gamma_0(^{59}Co)$ as 10.049 ± 0.013 MHz T^{-1} ($\sigma_d = 0.0021$) [32]. Independently determined values of γ_0 (the magnetogyric ratio of the bare cobalt nucleus) include 10.054 ± 0.002 MHz T^{-1} [34,35].

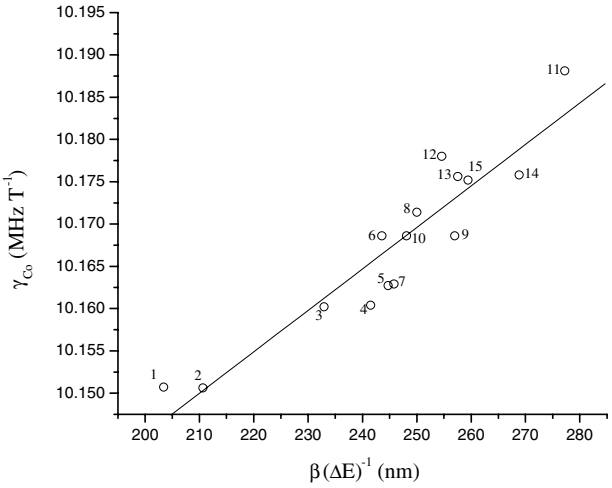

Fig. 6. Plot of ^{59}Co magnetogyric ratio vs $\beta(\Delta E)^{-1}$ for the series of complexes with N_6, N_5S, N_4S_2 and N_3S_3 donors (see Table 3 for data; the solid line represents the line of best fit).

4. Conclusions

The amplector synthetic methodology has been shown to be readily adapted to allow the formation of ligands possessing substituents on the dithio-chelate ring – in this case resulting in an example of a sinambic ligand. The complexes characterized in this work have permitted the further investigation of the spectroscopic characteristics of mixed donor (sulfur–nitrogen) multidentate ligands. Future work will investigate the inclusion of more elaborate functional groups (e.g primary amine) on the dithio-hinge presenting the possibility for further synthetic elaboration.

5. Supplementary material

Crystallographic data for $[Co(rac\text{-}1,2\text{-}Me_2Et\text{-}N_4S_2amp)]Cl_2(ClO)_4 \cdot 2H_2O$ (CCDC 239514) have been deposited with the Cambridge Crystallographic Data Centre. Three-dimensional porous frameworks constructed by transition metal ions and isoorotic acid

Chang-Yan Sun, Lin-Pei Jin *

Department of Chemistry, Beijing Normal University, Xinjiekou Road, Beijing 100875, PR China

Received 31 May 2004; accepted 25 June 2004
Available online 25 August 2004

Abstract

Four new coordination polymers, $[M(Hiso)(H_2O)_3]_n$ (M = Co (**1**); M = Ni (**2**)) and $\{[M_2(Hiso)_2(bipy)_2(H_2O)_4]\cdot 2(bipy)\}_n$ (M = Co (**3**); M = Ni (**4**)) (H_2iso = isoorotic acid, bipy = 4,4′-bipyridine), were synthesized by hydrothermal reactions and characterized by single-crystal X-ray diffraction. The four complexes all comprise 1D chains that are further interlinked via hydrogen bonds, resulting in the formation of 3D frameworks. There are small channels in **1** and **2** and two kinds of larger channels in **3** and **4**, in which free bipy molecules residue. In **1** and **2**, the $Hiso^{2-}$ anions act as tridentate ligands to link metal ions; in **3** and **4**, the $Hiso^{2-}$ anions act as bidentate ligands and the metal ions are bridged by bipy.

Keywords: Isoorotic acid; Co(II) and Ni(II) complexes; Hydrothermal synthesis; Hydrogen bonds; Supramolecular frameworks

1. Introduction

The rational self-assembly of supramolecular frameworks using noncovalent forces such as hydrogen bonds and π–π stacking interactions is a rapidly expanding field due to their fascinating crystal structures, electronic, optical and magnetic properties, and potential applications [1–5]. Hydrogen bonding, as the strongest and most directional intermolecular force, has been intensively investigated in organic crystalline solids [6–9]. Attempts have been made to combine both metal–ligand coordination bonds and hydrogen bonds in the crystal engineering of porous metal–organic hybrid materials. For example, the construction of a porous solid from hydrogen bonded metal complexes of 1,3,5-benzenetricarboxylic acid with interesting properties has been achieved by Yaghi, and Munakata has described the design of 3D supramolecular channel-like copper compounds that host a variety of anions by changing the hydrogen-bonding modes and distances [10,11]. This approach provides a means to control the rigidity of a supramolecular framework joined by metal–ligand interactions by selectively incorporating more flexible hydrogen bonds between molecules. This should promote crystalization since hydrogen-bonded structures form reversibly and exhibit slower kinetics for nucleation and growth of crystals than coordination polymers.

In this work, we used transition metal ions, 4,4′-bipyridine (bipy) and a multifunctional ligand, namely, isoorotic acid (5-carboxyuracil acid, H_3iso) to construct coordination complexes. Bipy is an efficient ligand to link transition metal ions. The choice of H_3iso was driven by following factors. First, H_3iso possesses multiple coordination sites and can bond to metal ions with versatile coordination modes. Moreover, it can act as a hydrogen bond donor or acceptor. Finally, there are only a few reports on the coordination chemistry of H_3iso [12–16].

Hydrothermal synthesis has been employed extensively to obtain single crystals because the properties and the interactions of the reactants are quite different from those under conventional conditions [17–20]. Herein, we report the hydrothermal syntheses and structures of four new complexes $[M(Hiso)(H_2O)_3]_n$ (M = Co (**1**), Ni (**2**)) and $\{[M_2(Hiso)_2(bipy)_2(H_2O)_4]\cdot 2(bipy)\}_n$ (M = Co (**3**), Ni (**4**)).

2. Experimental

2.1. Materials and apparatus

All reagents were used as received without further purification. The C, H, N microanalyses were carried out with a Vario EL elemental analyzer. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. Thermogravimetric analyses were conducted on a ZRY-2P Thermal Analyzer using a heating rate of 10 °C/min from room temperature to 900 °C.

2.2. Synthesis

2.2.1. $[Co(Hiso)(H_2O)_3]_n$ (*1*)

A mixture of H_3iso (0.017 g, 0.1 mmol), $CoCl_2\cdot 6H_2O$ (0.048 g, 0.2 mmol), NaOH aqueous solution (0.35 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml), heated to 120 °C for 72 h, and then cooled at 5 °C/3 h to 100 °C, followed by slow cooling to room temperature. Red crystals were obtained, washed with water and ethanol, and dried in air. Yield: 0.02 g (74.9%). *Anal*. Calc. for $C_5H_8N_2O_7Co$: C, 22.47; H, 3.00; N, 10.49. Found: C, 22.35; H, 2.74; N, 10.31%. IR data (KBr pellet, cm^{-1}): 3480m, 1646s, 1571m, 1526m, 1404s, 1386m, 1325m, 1297m, 1028m, 887w, 670m.

2.2.2. $[Ni(Hiso)(H_2O)_3]_n$ (*2*)

The synthesis of complex **2** followed the same procedure as for complex **1**. Yield: 0.022 g (82.4%). *Anal*. Calc. for $C_5H_8N_2O_7Ni$: C, 22.49; H, 3.00; N, 10.49. Found: C, 22.33; H, 2.75; N, 10.35%. IR data (KBr pellet, cm^{-1}): 3483m, 1646s, 1571m, 1528m, 1404s, 1386s, 1325m, 1295m, 1209m, 883w, 675m.

2.2.3. $\{[Co_2(Hiso)_2(bipy)_2(H_2O)_4]\cdot 2(bipy)\}_n$ (*3*)

A mixture of H_3iso (0.017 g, 0.1 mmol), $CoCl_2\cdot 6H_2O$ (0.024 g, 0.1 mmol), bipy (0.016 g, 0.1 mmol), NaOH aqueous solution (0.18 ml, 0.65 mol l^{-1}) and deionized water (5 ml) was sealed in a Teflon-lined stainless vessel (25 ml), heated to 120 °C for 72 h, and then cooled at 5 °C/3 h to 100 °C, followed by slow cooling to room temperature. Red crystals were obtained, washed with water and ethanol, and dried in air. Yield: 0.02 g (35.6%). *Anal*. Calc. for $C_{50}H_{44}N_{12}O_{12}Co_2$: C, 53.44; H, 3.92; N, 14.97. Found: C, 53.48; H, 3.52; N, 14.90%. IR data (KBr pellet, cm^{-1}): 3414m, 2920m, 1611s, 1564m, 1536m, 1477m, 1402s, 1376m, 1310m, 1294m, 816m, 660m, 609w.

2.3. X-ray diffraction determination

Diffraction intensities for the four complexes were collected at 293 K on a Bruker SMART 1000 CCD diffractometer employing graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). A semi-empirical absorption correction was applied using the SADABS program [21]. The structures were solved by direct methods [22] and refined by full-matrix least squares on F^2 using SHELXS-97 and SHELXL-97 programs, respectively [22,23]. Non-hydrogen atoms were refined anisotropically. All hydrogen atoms were initially located in a difference Fourier map. The O–H distances were then fixed at 0.85 Å and Uiso(H) of the hydrogen atoms of H_2O was 1.5 times of Ueq(O) in the next refinement. The crystallographic data for complexes **1**–**4** are listed in Table 1, and selected bond lengths (Å) and bond angles (°) in Tables 2 and 3.

3. Results and discussion

3.1. Description of the structures

Complexes **1** and **2**, **3** and **4** are two isomorphous pairs. Because of the different radii of the Co(II) and Ni(II) ions, there are corresponding differences in the distances of M–O and M–N (M = Co or Ni), but only the structures of **1** and **3** will be described in detail.

3.1.1. $[Co(Hiso)(H_2O)_3]_n$ (*1*)

As shown in Fig. 1, the Co(II) ion is six-coordinated and surrounded by two oxygen atoms from one $Hiso^{2-}$ anion, one nitrogen atom from another $Hiso^{2-}$ anion and three aqua ligands. In this complex the $Hiso^{2-}$ anion acts as a tridentate ligand through O(1), O(3) and N(2). This kind of coordination mode has not been reported before. The bridging $Hiso^{2-}$ anions link the Co(II) ions into infinite polymeric zigzag chains parallel to the *c*-axis. The Co···Co distance in the chain is 7.574 Å (7.488 Å for Ni) and the Co–Co–Co angle is 151.2° (151.5° for Ni).

In **1**, the amido groups, the carbonyl oxygen atoms, the carboxylate groups and the aqua ligands are all involved in hydrogen bonds. The amido groups and the aqua ligands act as hydrogen bonding donors, while the carboxylate and the carbonyl oxygen atoms act as hydrogen bonding acceptors. There are O_w–H···O_w (a), O_w–H···O_{cc} (b), O_w–H···O_{uc} (c), O_w–H···O_c (d) and N–H···O_c (e) hydrogen bonds between the chains (O_w, water molecule oxygen atom; O_{cc}, coordinating carboxyl oxygen atom; O_{uc}, uncoordinating carboxyl oxygen atom; O_c, uncoordinating carbonyl oxygen atom), resulting in the formation of a 3D-supramoleclar structure (see Fig. 2). There are two kinds of channels (A and B) in the structure, but they are too small for any host molecules to reside. The geometry of the hydrogen bonds is shown in Table 4. There is a weak π–π stacking interaction between the pyramidine rings at a distance of 3.76 Å, which stabilizes the complex.

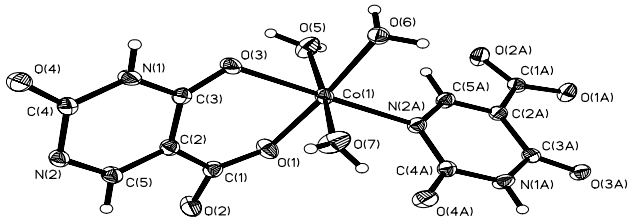

Fig. 1. The coordination environment of the Co(II) ion in complex **1** with 50% thermal ellipsoids.

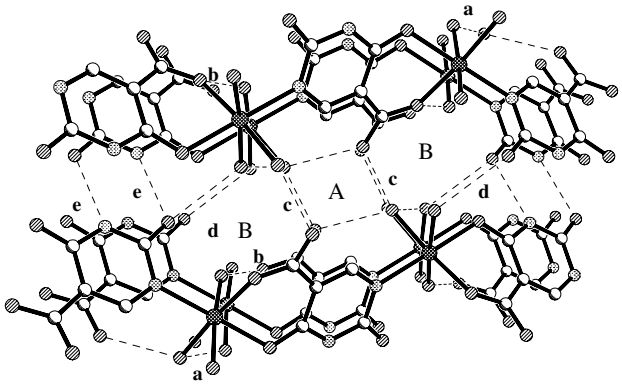

Fig. 2. 3D network constructed by hydrogen bonds of complex **1** viewed along the a axis, all hydrogen atoms are omitted for clarity.

3.1.2. $\{[Co_2(Hiso)_2(bipy)_2(H_2O)_4]\cdot 2(bipy)\}_n$ (*3*)

There are two kinds of metal coordination environments in **3**, as shown in Fig. 3. Although Co(1) and Co(2) are both six-coordinate and their coordination geometries can be described as distorted octahedrons, the coordination environments around them are different. Co(1) is coordinated by four oxygen atoms belonging to two $Hiso^{2-}$ anions and two nitrogen atoms from two bipy molecules, while Co(2) is coordinated by two nitrogen atoms of bipy and four aqua ligands. Co(1) and Co(2) are in the center of symmetry and are connected by bipy at a separation of 11.365 Å (11.288 Å for Ni). In complex **3**, the $Hiso^{2-}$ anion acts as a bidentate ligand through O(1) and O(3). It is worth noting that although N(2) in the $Hiso^{2-}$ anion is deprotonated, it is not coordinated as in **1** and **2** owing to the strong coordination ability of bipy to Co(II) ions. There are two kinds of bipy that have different roles in the structure (see Fig. 3). One kind of bipy bridges Co(II) ions and the dihedral angle of the two pyridine rings of this bipy is 6.1°; while the other

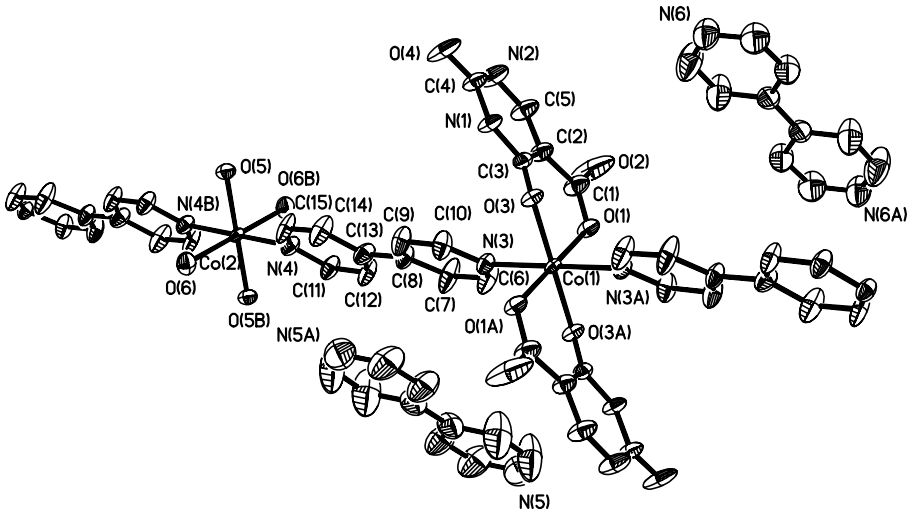

Fig. 3. The coordination environments of Co(II) ions in complex **3** with 50% thermal ellipsoids, all hydrogen atoms are omitted.

kind, with the two pyridine rings being coplanar, is free and does not take part in coordination.

As shown in Fig. 4, the octahedral Co(II) ions are bridged into 1D infinite chains by bipy, and the $Hiso^{2-}$ ligands stay up and down the chains. The uncoordinating carbonyl oxygen atoms and amido groups of $Hiso^{2-}$ ligands form hydrogen bonds with the aqua water molecules of the adjacent chain (O_w–H···O_c and O_w–H···N hydrogen bond), building a rhomboid-type 2D network. The rhomboid-grid dimensions are about 11.365 × 9.579 Å (see Fig. 4, 11.288 × 9.570 Å for Ni). Furthermore, the uncoordinating carboxylate oxygen atoms of $Hiso^{2-}$ ligands also form hydrogen bonds with the aqua water molecules of the adjacent chain (O_w–H···O_{uc}

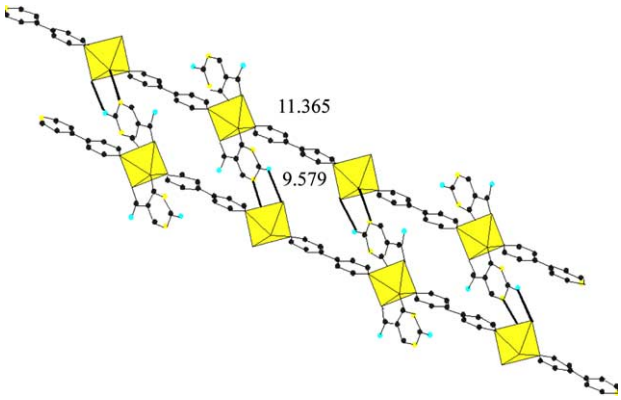

Fig. 4. Rhomboid-type 2D network of complex **3** viewed along the [1 1 0] direction. The thick line represents hydrogen bonds, and all hydrogen atoms are omitted for clarity.

hydrogen bonds), building a similar rhomboid-grid of 11.365 × 6.348 Å (11.288 × 6.345 Å for Ni). The 3D supramolecular structure of complex **3** is shown in Fig. 5. Free bipy molecules residue in the channels. The details of the hydrogen bonds are listed in Table 4.

Comparing the structures of **1** and **3**, several differences are noted: (1) In complex **1**, there is only one kind of metal environment, while in complex **3** there are two. The different coordination environments of Co(II) ions help to form the ordered packing. (2) In complex **1**, $Hiso^{2-}$ acts as a tridentate ligand, coordinating through the carboxylate group, carbonyl oxygen and deprotonated amido group; while in complex **3**, $Hiso^{2-}$ acts as a bidentate ligand, coordinating through the carboxylate group and carbonyl oxygen, but the amido group is left to form hydrogen bonds. (3) The channels in complex **3** are much larger than those in complex **1**. This must be attributed to the introduction of bipy, which acts as a bridging ligand to link the metal ions, leaving $Hiso^{2-}$ anions to form hydrogen bonds and resulting in the formation of large channels.

3.2. Thermal analyses

Thermogravimetric analyses of the four complexes were carried out to examine their thermal stabilities. The data for **1**–**4** are listed in Table 5. The complexes **1** and **2** lost their aqua ligands at the first weight loss, while **3** and **4** lost their free bipy molecules. Taking **1** and **3** as examples, the TGA curves show that the first weight loss of 18.7% from 206 to 258 °C corresponds to the loss of three aqua water molecules in complex **1** (calcd 18.8%) and the first weight loss of 28.1% from 131 to 219 °C corresponds to the loss of two free bipy molecules in complex **3** (calcd 27.8%). Increasing temperature led to further decomposition of **1** and **3** at 276 and 342 °C. The final pyrolysis was completed at 615 and 537 °C, respectively, giving CoO powder.

4. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 218806, 218807, 234940 and 234939 for **1**–**4**, respectively. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-

Abstract

Various conformations of bis(methoxycarbimido)amine, $[HN{=}C(OCH_3)]_2NH$ (Hmici), and of it anion, $[HN{=}C(OCH_3)]_2N^-$ ($mici^-$), have been optimized at MP2 level of theory. Their electronic structures have been investigated in terms of Mulliken population analysis and topological analysis of electron density. The experimentally observed conformations are not the most stable ones and the determining role of the central atom for the geometry and electronic structure of Hmici and $mici^-$ complexes may be concluded. The preferential methoxy group positions may be explained by energy arguments of the free ligands. Shielding (especially by methoxy groups) should increase the electron density at the central H atom in Hmici.

1. Introduction

Transition metal compounds with dicyanamide (or dicyanimide) bridges exhibit interesting magnetic properties [1]. Dicyanamide anions, $[N(CN)_2]^-$, form both mono- and multinuclear complexes with various metals [2] but no compound of this type with its neutral form has been found in the Cambridge Structural Database (CSD) [3]. Neutral dicyanamide molecules exist in solutions only [2]. Depending on the reaction conditions, the hydrolysis of dicyanamide salts may result in various products. If not accounting for polymerisation products, it proceeds in several steps.

In the first hydration step, a cyanourea H_2N–CO–NH–CN is obtained. Only a single tetranuclear Ag complex of its anionic form [4] has been found in the CSD.

In the second step, a biuret H_2N–CO–NH–CO–NH_2 is formed. Only mononuclear complexes of its neutral form are known (such as $[Cu(biuret)_2]^{2+}$ [5], $[Co(biuret)_3]^{3+}$ [6] and $[Ni(biuret)_2]^{2+}$ [7]).

In methanolic solutions, the third solvation step may be observed [1]. It results in the formation of neutral bis(methoxycarbimido)amine, HN–$C(OCH_3)$–NH–$C(OCH_3)$–NH, (Hmici) or its anion, [HN–$C(OCH_3)$–N–$C(OCH_3)$–$NH]^-$, ($mici^-$). On the contrary to the previous compounds, mononuclear complexes of both forms are known.

$[Cu(mici)_2]$ has a square-planar structure (Fig. 1) [8,9]. An attempt to replace the central atom by its reaction with CoS in dimethylsulfoxide led to the formation of $[Co(mici)_3]$ [10] whereas FeS caused the formation of $[Fe(Hmici)_2(H_2O)(SO_4)] \cdot 2H_2O$ [11]. The same neutral ligand is bonded in bis(bis(methoxycarbimido)amine)-copper(II) tetrakis(biuret)dibromide methanol acetonitrile solvate [12] (Fig. 2). It is interesting that the methoxy groups in the planar anionic $mici^-$ (in the complexes with Cu(II) [8,9] and Co(III) [10]) and in the neutral Hmici ligand (in the complexes with Cu(II) [12] and

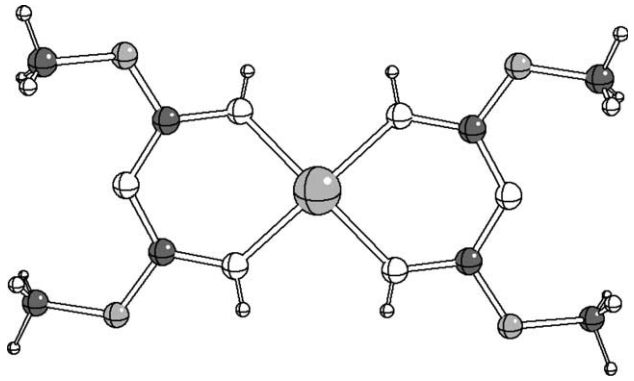

Fig. 1. Structure of $[Cu(mici)_2]$ [8,9].

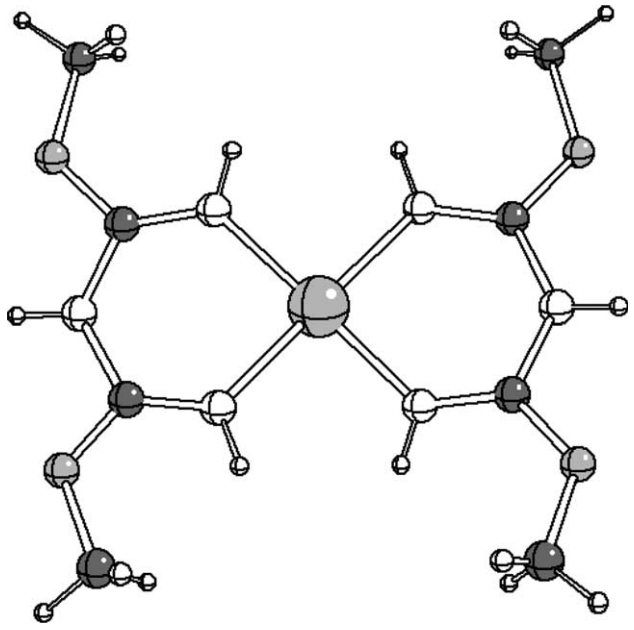

Fig. 2. Structure of $[Cu(Hmici)_2]^{2+}$ in bis(bis(methoxycarbimido)amine)copper(II) tetrakis(biuret)dibromide methanol acetonitrile solvate [12].

Fe(II) [11]) are in opposite positions (compare Figs. 1 and 2).

It is evident that the relative stability of transition metal complexes with Hmici and $mici^-$ ligands should depend on a delicate balance between intrinsic properties of the complex (such as electronic structure) and environmental influences of the solvent (such as pH). Experimental data on Hmici powder (confirmed by NMR measurements) obtained from a DMSO solution at various conditions indicate its existence in (at least) two forms, one of them sublimating at room temperature [13]. Unfortunately, no quantum-chemical studies on this type of molecule have been found in the literature. Very recently, a HF/6-31G* study [14] of substituted 1,3-diazabuta-1,3-dienes (such as HN=CR–N=CH–NH_2, R = H or NH_2) in various conformations has been published. Geometry optimizations confirmed the earlier observation that there is a delicate balance between π conjugative effects (forcing the molecule to planarity) and 1,4-steric repulsions, and this balance determines the conformational preferences in these systems. Under solvent conditions the electron delocalisations in these systems get reduced and the torsional angles in non-planar structures are larger than in the gas phase. π Donating substituents (at both carbons) increase the conjugation in the π frame of the diazadienes.

The aim of our study is to investigate mutual relations between geometry and electronic structure of $mici^-$ and Hmici ligands (the shielding by methoxy and imine groups, π-bond signification, etc.) within a suitable series of conformations. This might help to explain the reasons of preferential methoxy group positions as well as the role of transition metals in the solvation.

2. Method

Ab initio molecular MP2 orbital calculations were performed using the standard GAUSSIAN94 program package [15] with Dunning's correlation consistent cc-pVDZ basis sets [16]. The geometries of all the systems under study (Table 1) were optimized using the Berny algorithm [17] with standard accuracy. The electronic structure was evaluated in terms of Mulliken population analysis (gross atomic charges for atoms and overlap populations for bonds).

Using the AUG-cc-pVDZ basis set [16,18], a topological analysis of electron density [19] has been elaborated (AIM2000 program package [20]) and the results have been evaluated in terms of electron density ρ, density Laplacian L and bond ellipticity ε at bond critical points (BCP) as well as in terms of atomic volumes and atomic charges evaluated using the electron density integrated over atomic basins (up to the 0.001 e/$bohr^3$ level).

3. Results and discussion

Studied conformations of $mici^-$ (A1–A6 models, see Fig. 3) and Hmici (B1–B6 models, see Fig. 4) systems (for the atoms notation see Scheme 1) differ in N(2) (and H(2)) atom shielding by methoxy and imine groups. For the sake of simplicity, the equivalent atoms (with the same numbers – see Scheme 1) are symmetry related (by a mirror plane or C_2 symmetry axis) in the starting conformations and full geometry optimizations started from planar structures. The optimized geometries are presented in Figs. 3 and 4 and Tables 1 and 2. According to our results all systems are planar except A4 and B4 ones. Non-planar A4 and B4 systems contain two planar subsystems with torsion angles of ca. 70° about the central N(2)–C(1) bond. This indicates significant π character of C–N and C–O bonds. The C(1)–N(2), C(1)–O and N(1)–H(1) bonds are longer than their

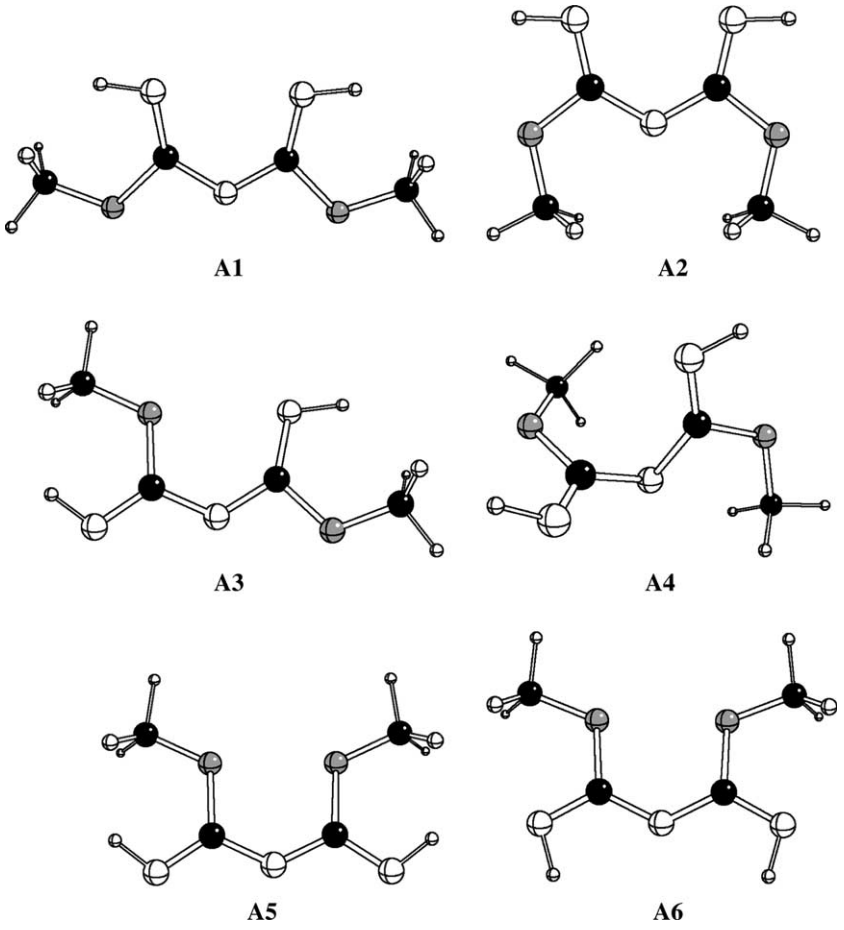

Fig. 3. Investigated conformations of the anionic form of bis(methoxycarbimido)amine, HN=C(OCH$_3$)–N–C(OCH$_3$)=NH$^-$ (mici$^-$).

C(1)–N(1), C(Met)–O and N(2)–H(2) counterparts, respectively. The longer C–N and C–O bonds are shortened and the shorter ones lengthened (i.e., the bonds length alternation is lower) in mici$^-$ in comparison with Hmici. The geometries of our systems are significantly influenced by mechanical strain due to non-bonding interatomic interactions. The flexibility of C(1) atoms is higher than of N(2) ones, as may be deduced from N(1)–C(1)–N(2) and C(1)–N(2)–C(1′) bond angles (their deviations from 120°), respectively. The same data indicate that the interatomic repulsion decreases in the order O–O′ > O–N(1′) > N(1)–N(1′) for the planar structures. C(1)–O–C(Met) bond angles in mici$^-$ are nearly constant whereas in Hmici they are influenced by the interaction of the methyl group with H(1) or H(2) atoms.

Energy data (Table 3) exhibit the lowest values for A6 and B6 systems. The differences in zero-point energy (ZPE) corrections are one order lower than in MP2 energies and cannot cause any changes in the relative stability of the systems under study. Nevertheless, only planar A1/B1 and non-planar A4/B4 geometries have not any imaginary frequencies and may be ascribed to energy minima. The remaining ones should decrease in energy on account of their planarity.

According to our results, the geometries A1 and B2 observed in experimental structures are not the most

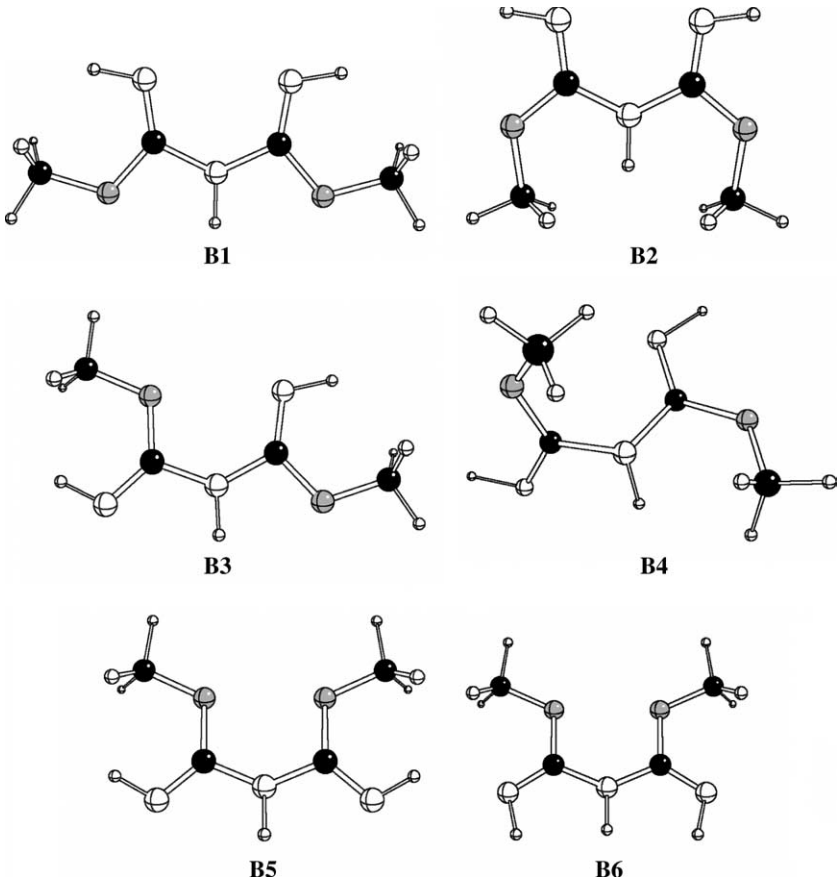

Fig. 4. Investigated conformations of the neutral bis(methoxycarbimido)amine, HN=C(OCH$_3$)–NH–C(OCH$_3$)=NH (Hmici).

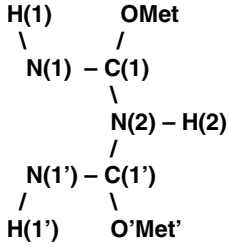

Scheme 1. Schematic description of neutral bis(methoxycarbimido)-amine.

stable ones. It implies a determining role of the central atom for the geometry and electronic structure of our ligands.

Electronic structural characteristics are usually described in terms of Mulliken population analysis (MPA). However, MPA results for our systems using the aug-cc-pVDZ basis are evidently incorrect (negative bond orders, negative H charges) and so cc-pVDZ data are presented. Nevertheless, the trends in MPA data (gross atomic charges and overlap populations) and in

the corresponding characteristics of topological analysis of electron density (atomic charges and BCP electron density, ρ_{BCP}) within the aug-cc-pVDZ basis may be different (Tables 4–6).

Our results (Tables 4 and 5) indicate that N(2) are more negative than N(1) atoms whereas H(2) and C(1) are more positive than H(1) and C(Met) atoms (in agreement with the observed H(2) dissociation), respectively. In anionic systems, the electron density at N(1), N(2), O and C(1) atoms increases but decreases at C(Met) atoms in comparison with neutral molecules. Shielding (especially by methoxy groups) should increase H(2) electron density. As expected, volumes of atomic basins exhibit reverse trends (higher electron densities correspond to lower atomic volumes). Significant changes in atomic volumes of N(2) in mici$^-$ and H(2) in Hmici are not caused by mechanical strain but by space restrictions of the shielding methoxy groups (compare N(2) in mici$^-$ – see Table 5). The changes in H(1) volumes may be explained analogously. On the other hand, mechanical strain explains the (smaller) changes in C(1) volumes.

As indicated by overlap populations as well as by ρ_{BCP} values (Tables 4 and 6), N(1)–C(1) bonds are stronger than C(1)–N(2) ones in all systems. C(1)–O bonds are stronger than O–C(Met) ones in neutral Hmici molecules. In anionic mici$^-$, C(1)–N(2) and O–C(Met) bonds are stronger whereas N(1)–C(1) and C(1)–O ones are weaker than in neutral Hmici. These trends are in agreement with the bond lengths (Table 1) and Laplacian BCP electron densities (Table 6, longer bond lengths correspond to weaker bonds and a less negative Laplacian). Nevertheless, analogous C–O and N–H bond length trends have been confirmed by the above electronic characteristics in neutral Hmici molecules only.

Ellipticity ε data (Table 6) confirm the π character of all C–N bonds whereas the remaining ones correspond to typical σ bonds. Ellipticity of N(1)–C(1) bonds is significantly higher than of C(1)–N(2) ones. In neutral Hmici molecules, a non-vanishing π contribution to C(1)–O bonds may be observed. Ellipticities in mici$^-$ are lower (especially in N(1)–C(1) bonds) than in neutral Hmici molecules (except non-planar structures) in agreement with lower bond length alternations in mici$^-$.

4. Conclusions

Finally it may be concluded that mici$^-$ and Hmici are typical examples of the failure of traditional MPA treatment to electronic structure investigations using basis sets with polarization and diffusion functions. Higher flexibility of C(1) atoms than of the central N(2) ones reflects the unusual electron structure of our ligands (especially mici$^-$). Shielding the central H(2) atom in Hmici causes its protection against splitting not only sterically, but also by increasing its electron density (less positive H(2) charge). Comparison of our results with experimental structural data on transition metal complexes shows that preferential methoxy group positions may be explained by energy arguments of the free ligands, but their formation should be conditioned by complexation with transition metals (in agreement with [1]). In further studies, solvent influences are to be considered. Quantum-chemical studies on individual solvation stages as well as on transition metal complexes of these ligands are in progress.

Abstract

New complexes of bipodal thiophosphorylated thioureas $\{[(i\mathrm{PrO})_2\mathrm{P(S)NC(S)NH}]_2\mathrm{Z}\}\mathrm{M}$, where Z = *m*-$C_6H_4$, *p*-$C_6H_4$, M = Co, Ni, Zn, Cd have been prepared and characterized. The crystal and molecular structures of Cd(II), Z = CH_2CH_2 and Pd(II), Z = $(CH_2CH_2)_2O$ complexes have been determined by single crystal X-ray diffraction analyses. Both complexes are binuclear in the solid state with a M_2L_2 stoichiometry. The cadmium and palladium atoms are four-coordinated and have the configuration of a slightly distorted tetrahedron for cadmium and a distorted square plane for palladium. Metal-containing macrocycles are formed as well as two spirocycles.

1. Introduction

We have recently reported the syntheses and complexing properties of bipodal thiophosphorylated thioureas $[(i\mathrm{PrO})_2\mathrm{P(S)NHC(S)NH}]_2\mathrm{Z}$, where Z = $(CH_2)_2$, $(CH_2)_7$, $(CH_2)_2O(CH_2)_2$, $(CH_2)_2O(CH_2)_2O(CH_2)_2$, and some properties of the chelate complexes formed by these ligands with a series of metal ions [1,2].

In this paper, we report on the synthesis of the bis-urea $[(i\mathrm{PrO})_2\mathrm{P(S)NHC(S)NH}]_2\mathrm{Z}$ complexes with Co(II), Ni(II), Zn(II) and Cd(II) (Z = *m*-C_6H_4, *p*-C_6H_4), together with the X-ray study of the bis-urea $[(i\mathrm{PrO})_2\mathrm{P(S)NHC(S)NHCH_2}]_2$ and the complexes with the cadmium(II) ion (**1**) (Z = CH_2CH_2) and the palladium(II) ion (**2**) (Z = $(CH_2CH_2)_2O$).

2. Experimental

2.1. Synthesis of $[(iPrO)_2P(S)NHC(S)NH]_2$-*m*-C_6H_4 (**3**)

A solution of *m*-phenylenediamine (2.163 g, 0.02 mol) in anhydrous benzene (50 ml) was added dropwise under stirring to a benzene solution (25 ml) of diisopropylthiophosphoryl isothiocyanate (9.572 g, 0.04 mol). The mixture was heated to 60 °C and stirred for 2 h. The solvent was removed in vacuum. A colourless precipitate was crystallized from benzene. Yield: 8.33 g (~71%), m.p. 122 °C. *Anal.* Calc. for $C_{20}H_{36}N_4O_4P_2S_4$: C, 40.95; H, 6.14; P, 10.58. Found: C, 41.58; H, 6.25; P, 10.30%. ^{1}H NMR (C_6D_6) 1.33 (d, 24H, CH_3, $^3J_{HH}$ 6.1 Hz), 4.78 (d, sept, 4H, OCH, $^3J_{HH}$ 6.3 Hz, $^3J_{POCH}$ 10.7 Hz), 6.86 (d, 2H, NHP(S), $^2J_{PH}$ 9.8 Hz), 7.24 (t, 1H, *m*-C_6H_4, $^3J_{HH}$ 8.2 Hz), 7.46 (d. d, 2H, *m*-C_6H_4, $^3J_{HH}$ 7.8 Hz, $^4J_{HH}$ 1.9 Hz), 8.14 (m, 1H, *m*-C_6H_4), 9.68 (s, 2H, C_6H_4NH). $^{31}P\{^1H\}$ NMR (ppm), 53.5. IR (cm^{-1}):

2.2. Synthesis of [(iPrO)$_2$P(S)NHC(S)NH]$_2$-p-C$_6$H$_4$ (4)

A solution of diisopropylthiophosphoryl isothiocyanate (9.572 g, 0.04 mol) in anhydrous benzene (25 ml) was added dropwise under stirring to a solution of *p*-phenylenediamine (2.163 g, 0.02 mol) in 50 ml of benzene heated to 60 °C. The mixture was refluxed with stirring for 3 h. *n*-Hexane (30 ml) was added, the mixture cooled down to 0 °C and then a white solid precipitated. The precipitate was crystallized twice from benzene. Yield: 8.8 g (~75%), m.p. 139 °C. *Anal*. Calc. for $C_{20}H_{36}N_4O_4P_2S_4$: C, 40.95; H, 6.14; P, 10.58. Found: C, 41.09; H, 6.25; P, 10.18%. ^{1}H NMR (C_6D_6) 1.22 (d, 12H, CH_3, $^3J_{HH}$ 6.0 Hz), 1.25 (d, 12H, CH_3, $^3J_{HH}$ 6.4 Hz), 4.90 (d, sept, 4H, OCH, $^3J_{HH}$ 6.2 Hz, $^3J_{POCH}$ 10.6 Hz), 6.50 (d, 2H, NHP(S), $^2J_{PH}$ 8.4 Hz), 7.83 (s, 4H, C_6H_4), 10.19 (s, 2H, C_6H_4*NH*). ^{31}P{^{1}H} NMR (ppm), 53.28. IR (cm^{-1}): 3360(s) (NH), 3110(s) (NH), 1565(s) (S═C─N), 1335(m) (C═S), 980(vs) (POC), 655(m) (P═S).

2.3. Synthesis of [(iPrO)$_2$P(S)NHC(S)NHCH$_2$]$_2$ (5)

The compound was prepared as described above for **3** from ethylenediamine (1.202 g, 0.02 mol, as an acetonitrile solution, 15 ml) and diisopropylthiophosphoryl isothiocyanate (9.572 g, 0.04 mol) in benzene (25 ml) to give 7.54 g (~70%, after crystallization from benzene) of **5** as colourless crystals. M.p. 111 °C. *Anal*. Calc. for $C_{16}H_{36}N_4O_4P_2S_4$: C, 35.67; H, 6.74; P, 11.50. Found: C, 35.64; H, 6.67; P, 11.09%. ^{1}H NMR (C_6D_6) 1.404 (d, 12H, CH_3, $^3J_{HH}$ 6.2 Hz), 1.409 (d, 12H, CH_3, $^3J_{HH}$ 6.3 Hz), 3.97 (m, 4H, CH_2CH_2), 4.88 (d. sept, 4H, OCH, $^3J_{HH}$ 6.3 Hz, $^3J_{POCH}$ 10.4 Hz), 7.53 (d, 2H, NHP(S), $^2J_{PH}$ 8.3 Hz), 8.35 (br. s, 2H, CH_2*NH*). ^{31}P{^{1}H} NMR (ppm), 51.46. IR (cm^{-1}): 3440(s) (NH), 1560(s) (S═C─N), 1315(m) (C═S), 1010(vs) (POC), 640(m) (P═S).

2.4. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-m-C$_6$H$_4$Co} (6)

A suspension of **3** (1.173 g, 2 mmol) in anhydrous ethanol (20 ml) was mixed with an ethanol solution of potassium hydroxide (0.224 g, 4 mmol). To the resulting potassium salt, a water (20 ml) solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.579 g, 2.2 mmol) was added dropwise with vigorous stirring. The mixture was stirred at room temperature for a further 3 h and left overnight. The resulting complex was extracted with methylene chloride, washed with water and dried over $MgSO_4$. Then the solvent was removed in vacuum. A green precipitate was precipitated from methylene chloride by *n*-hexane. Yield: ~41%, m.p. 156 °C. *Anal*. Calc. for $C_{20}H_{34}CoN_4O_4P_2S_4$: C, 37.29; H, 5.28; P, 9.63; Co, 9.15. Found: C, 37.67; H, 5.72; P, 9.32; Co, 8.86%. ^{31}P{^{1}H} NMR (acetone; ppm; width at half height, Hz; integral intensity, %), 56.46 (58 Hz, 64.6%), 58.632 (79 Hz, 35.4%). IR (cm^{-1}): 3350(s) (NH), 1550(s) (SCN), 970(br, vs) (POC), 560, 580 (m) (P═S).

2.5. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-m-C$_6$H$_4$Ni} (7)

This was prepared similarly to compound **6** by using $Ni(NO_3)_2 \cdot 6H_2O$. Yield: ~45%, m.p. 140 °C. *Anal*. Calc. for $C_{20}H_{34}N_4NiO_4P_2S_4$: C, 37.30; H, 5.28; P, 9.63; Ni, 9.12. Found: C, 37.22; H, 5.68; P, 9.98; Ni, 9.95%. ^{31}P{^{1}H} NMR (CH_2Cl_2; ppm; width at half height, Hz; integral intensity, %), 51.20 (187 Hz, 51.3%), 53.05 (58 Hz, 36.6%), 54.40 (90 Hz, 12.1%). IR (cm^{-1}): 3345(s) (NH), 1545(s) (SCN), 975(br, vs) (POC), 573, 589(m) (P═S).

2.6. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-m-C$_6$H$_4$Zn} (8)

This was prepared similarly to compound **6** by using $ZnCl_2$. Yield: ~84%, m.p. 150 °C. *Anal*. Calc. for $C_{20}H_{34}N_4O_4P_2S_4Zn$: C, 36.94; H, 5.23; P, 9.53; Zn, 10.06. Found: C, 37.16; H, 5.17; P, 9.24; Zn, 9.76%. ^{31}P{^{1}H} NMR ($(CD_3)_2CO$; ppm), 56.24. ^{1}H NMR ($(CD_3)_2CO$; ppm): 1.478 (d, 12H, $^3J_{HH}$ 5.5 Hz); 1.482 (d, 12H, $^3J_{HH}$ 6.0 Hz), 4.92 (d. sept, 4H, $^3J_{POCH}$ 9.9 Hz; $^3J_{HH}$ 6.1 Hz), 7.44 (m, 3H, Ph); 8.15 (m, 1H), 9.59 (br. d, 2H, $^4J_{PNCNH}$ 7.8 Hz). IR (cm^{-1}): 3340(br, s) (NH), 1520(s) (SCN), 1000(b, vs) (POC), 569, 595(m) (P═S).

2.7. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-m-C$_6$H$_4$Cd} (9)

This was prepared similarly to compound **6** by using $Cd(CH_3COO)_2 \cdot H_2O$. Yield: ~69%, m.p. 146–147 °C. *Anal*. Calc. for $C_{20}H_{34}CdN_4O_4P_2S_4$: H, 4.88; P, 8.88. Found: H, 5.59; P, 8.20%. ^{31}P{^{1}H} NMR ($(CD_3)_2CO$; ppm), 55.54. ^{1}H NMR ($(CD_3)_2CO$; ppm): 1.496 (d. 12H, $^3J_{HH}$ 6.5 Hz); 1.471 (d, 12H, $^3J_{HH}$ 6.5 Hz), 4.92 (d. sept, 4H, $^3J_{POCH}$ 10.2 Hz; $^3J_{HH}$ 6.1 Hz), 7.39 (m, 3H, Ph), 8.30 (m, 1H, Ph), 9.64 (br. d, 2H, NH, $^4J_{PNCNH}$ 8.2 Hz). IR (cm^{-1}): 3200(br, s) (NH), 1490(s) (SCN), 1005(br, vs) (POC), 573, 594(m) (P═S).

2.8. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-p-C$_6$H$_4$Co} (10)

A suspension of 1.173 g (2 mmol) of [(*i*PrO)$_2$P(S)NHC(S)NH]$_2$-*p*-C$_6$H$_4$ in anhydrous ethanol (20 ml) was mixed with an ethanol solution of potassium

hydroxide (0.224 g, 4 mmol). To the resulting potassium salt, a water (20 ml) solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.579 g, 2.2 mmol) was added dropwise with vigorous stirring. The resulting complex was extracted with methylene chloride as a suspension and then the organic phase was washed with water (20 ml). The solvent was removed in vacuum. The residue was dried over $MgSO_4$ as an acetone solution and the solvent was removed in vacuum. A green solid was precipitated from acetone by *n*-hexane and dried in vacuum at 50 °C. Yield: 66%, m.p. 190–200 °C, decomposes. *Anal*. Calc. for $C_{20}H_{34}CoN_4O_4P_2S_4$: C, 37.29; H, 5.28; P, 9.63; Co, 9.15. Found: C, 36.60; H, 5.38; P, 11.94; Co, 11.37%. $^{31}P\{^1H\}$ NMR (CH_2Cl_2; ppm; width at half height, Hz); 169.54 (341 Hz). IR (cm^{-1}): 3360(br, s) (NH), 1504(s) (SCN), 1000(br, vs) (POC), 568(m) (P═S).

2.9. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-p-C$_6$H$_4$Zn} (11)

This was prepared similarly to compound **10** by using $ZnCl_2$. Yield: ~65%, m.p. 305 °C, decomposes. *Anal*. Calc. for $C_{20}H_{34}N_4O_4P_2S_4Zn$: C, 36.94; H, 5.23; P, 9.53; Zn, 10.06. Found: C, 36.60; H, 5.22; P, 9.89; Zn, 10.04%. $^{31}P\{^1H\}$ NMR ($(CD_3)_2CO$; ppm), 56.39. ^1H NMR ($(CD_3)_2CO$; ppm): 1.475 (d, 24H, $^3J_{HH}$ 6.2 Hz), 4.90 (d. sept, 4H, $^3J_{POCH}$ 10.2 Hz; $^3J_{HH}$ 6.1 Hz), 7.79 (s, 4H, Ph), 9.577 (d, 2H, NH, $^4J_{PNCNH}$ 8.2 Hz). IR (cm^{-1}): 3280(br, s) (NH), 1500(s) (SCN), 980(br, vs) (POC), 575(m) (P═S).

2.10. Synthesis of {[(iPrO)$_2$P(S)NC(S)NH]$_2$-p-C$_6$H$_4$Cd} (12)

This was prepared similarly to compound **10** by using $Cd(CH_3COO)_2 \cdot H_2O$. Yield: ~20%, m.p. 175 °C. *Anal*. Calc. for $C_{20}H_{34}CdN_4O_4P_2S_4$: C, 34.46; H, 4.88; P, 8.88; Cd, 16.12. Found: C, 34.71; H, 4.56; P, 9.06; Cd, 16.71%. $^{31}P\{^1H\}$ NMR ($(CH_3)_2CO$; ppm), 55.29. IR (cm^{-1}): 3220(br, s) (NH), 1510(s) (SCN), 980–1000 (POC), 568(m) (P═S).

2.11. Physical measurements

Infrared spectra (Nujol) were recorded on a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^1H and ^{31}P spectra were recorded

2.12. Crystal structure determination and refinement

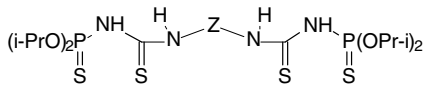
The crystals of **1** were obtained from the mixture of dichloromethane and *n*-hexane (1:13) and the crystals of **2** via the slow evaporation of solvent from a dichloromethane solution. At room temperature the crystals of **2**, taken from the saturated solution, lose solvents molecules and destroy themselves.

The X-Ray diffraction data for the crystals of **1** and **2** were collected on a CAD4 Enraf-Nonius automatic diffractometer using graphite monochromated Mo Kα (0.71073 Å) radiation. Molecules of **2** and **5** in the crystals are in special positions. The details of crystal data, data collection and the refinement are given in Table 1. The stability of the crystals and the experimental conditions were checked every 2 h using three control reflections, while the orientation was monitored every 200 reflections by centreing two standards. No significant decay was observed. An empirical absorption correction based on ψ-scans was applied. The structures were solved by direct methods using the SIR 92 [3] program and refined using the SHELXL-97 program [4]. For the crystals (**1**, **2**, **5**) all non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms were idealised. All figures were made using the program PLATON [5].

3. Results and discussion

3.1. Synthesis

Ligands were prepared by the addition reaction of bis-amines $H_2N–Z–NH_2$ to diisopropoxythiophosphoryisothiocyanate $(iPrO)_2P(S)NCS$.



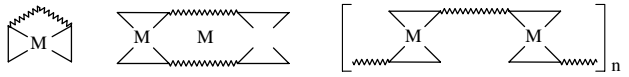
3–5

Complexes of $[(iPrO)_2P(S)NHC(S)NH]_2(m\text{-}C_6H_4)$ and $[(iPrO)_2P(S)NHC(S)NH]_2(p\text{-}C_6H_4)$ with Co(II), Ni(II), Zn(II) and Cd(II) **6–12** were prepared by the following procedure: the ligands were converted to their potassium salts, followed by interaction with inorganic salts of the corresponding metals. The obtained compounds are crystalline solids, soluble in most polar solvents. According to elemental analyses, they have a ratio M/L = 1:1. Complexes of bis-urea $[(iPrO)_2P(S)NHC(S)NH]_2(p\text{-}C_6H_4)$ are unstable in solution, in the presence of moisture, alcohols and air oxygen.

3.2. IR and NMR spectroscopy

The IR spectra of **1**, **2**, **6–12** exhibit absorptions at 450–300 cm^{-1}, which correspond to the stretching vibration of M–S bonds. The absorption band of the P=S group is shifted from 630–655 cm^{-1} in the parent ligands to 560–595 cm^{-1} in the complexes. The strong infrared absorption observed for all complexes in the region 1490–1570 cm^{-1} was assigned to the group vibrations of the SCN fragment. The signal of the C(S)NHP(S) group proton is absent in NMR ^1H spectra. The signal of the ZNH proton is shifted upfield with respect to the same signal of free ligands. High $^4J_{PNCNH}$ coupling constants, about 8 Hz, were noted previously for the complexes of *N*-diisopropoxyphosphoryl-*N*′-phenyl thiourea [6]. Such a high constant can be explained by the almost planar bond arrangement in the PNCNH backbone and by the accordance of this fragment configuration to the so-called *W*-criterion [7]. ^{31}P NMR spectra of complexes **1**, **2**, **6–9**, **11** and **12** each show a resonance in the region 51–59 ppm. As a rule the signals are shifted downfield with respect to the parent ligands. Obtained IR and NMR spectral data are evidence of the chelate knot formation with participation of C=S and P=S groups and the metal cation. Due to the presence of the paramagnetic centres, the signals for the ^1H NMR spectrum of cobalt and nickel complexes **6**, **7** and **10** are broadened and their number increased, this makes assignment of the signals much more complicated.

Divalent metals can form complexes of 1:1 ML **A** and 2:2 M_2L_2 **B** compositions with such a kind of bipodal ligands. Formation of oligomeric or polymeric compositions M_nL_n (**C**) is also possible.



A **B** **C**

Thus, there is the possibility of an equilibrium in solution between all described types of complexes. We suppose that the equilibrium state depends first of all on the bridging chain Z length and secondly on the nature of the metal.

The ^{31}P NMR spectra of cobalt and nickel complexes **6**, **7** and **10** show several (up to three) signals of different intensities and widths at half height, which correspond to the different metal cation environments in the complexes. Such behaviour is common of the other complexes of bipodal thiophosphorylated thiourea [1]. The nickel cation has a *cis*-square-planar coordination environment in a dimer **B** and a *trans*-square-planar in an oligomer **C**. Nickel can also stay tetrahedral. Moreover, Ni(II) cations can be coordinated by lone pair donors,

such as nitrogen or oxygen, which are present in the ligand molecules. Different signals in the phosphorus spectrum of **7** can be due to any of proposed forms. Cobalt(II) cations are usually tetrahedral, but they can also form adducts with donor molecules.

^{31}P NMR spectra of complexes **1**, **8**, **9**, **11** and **12** exhibit only one signal. Cd(II) and Zn(II) cations are diamagnetic and their signals in ^{31}P NMR spectra are less sensitive to the environment of the metal cation. That is why both forms can have the same chemical shift.

In contrast to nickel, palladium(II) does not give a tetrahedral form or adducts and *cis*- and *trans*-isomers have different signals in spectra, as shown for the complex of *N*-diisopropoxythiophosphoryl-*N*′-phenylthiourea with Pd(II) [6]. Nonetheless, the ^{31}P spectrum of compound **2** shows a single resonance, which could correspond to the binuclear complex as the only form present in solution.

3.3. Crystal structure of *5*

Ligand **5** has been studied by X-ray analysis in order to compare its structure with the structures of **1** and **2**. The crystal structure of **5** is shown in Fig. 1, selected values of bond lengths, bond and torsion angles are given in Table 2. The NC(S)N fragment is almost planar, which is evidence of the resonance between the nitrogen lone pair and the double C=S bond. The conformation of the P–N–C–N fragment is almost shielded, torsion ∠P(1)–N(1)–C(1)–N(2) = 8.5(1)°. The NH group protons stay in an anti-disposition. The molecule has an inversion centre (see Table 3).

In the crystals of bisthiourea intra- and inter-molecular H-bonds of the NH···S type were found. Their parameters are presented in Table 3. Intermolecular H-bonds form endless chains. In the crystal these chains are oriented parallel to each other, along the *OY* axis.

3.4. Crystal structures of *1* and *2*

Figs. 2 and 3 show the structures of **1** and **2**, respectively, selected values of bond lengths, bond and torsion angles are given in Tables 4 and 5. For compound **1** only the data concerning one chelate knot are presented. The second one has a very similar geometry. According to the X-ray data these complexes are of M_2L_2 structure.

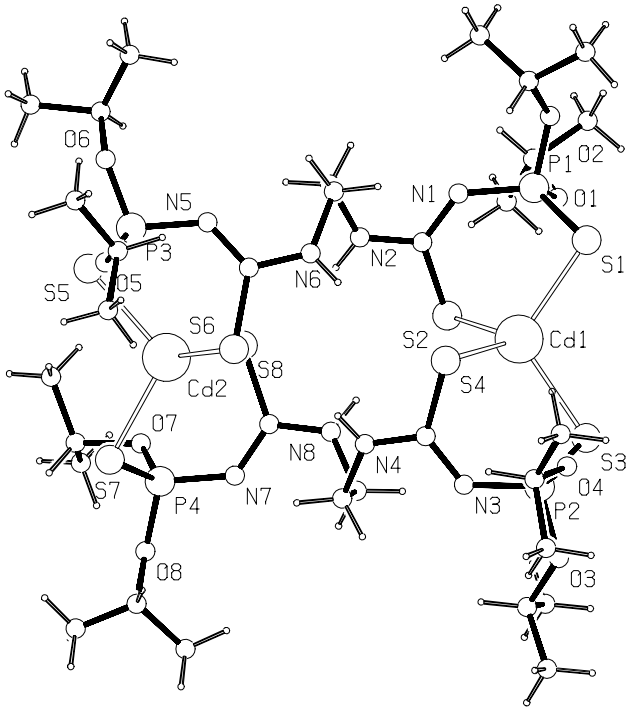

Fig. 2. Molecular structure of complex **1**.

Each ligand "tail" covers only its own metal atom. The coordination sphere of the metal includes a second ligand molecule. The structures of the described complexes are similar to the structures of the complexes of *para*-phenylene bis(imines) and *para*-phenylene methylpyridines [8,9]. In the crystal of compound **1** there is only the independent molecule in the asymmetric part of the lattice. In compound **2** the molecule is in a special position respective to the centre of symmetry. The cadmium and palladium atoms are four-coordinated and have the configuration of a slightly distorted tetrahedron for cadmium and a distorted square plane for palladium. The tetrahedral configuration of the cadmium atoms in compound **1** resembles those previously found in imidobis-seleno-$[Ph_2P(Se)NP(Se)Ph_2]_2Cd$ [10] and -thiophosphinyl $[iPr_2P(S)NP(S)iPr_2]_2Cd$ [11] cadmium complexes. They have a bis-chelate structure with a tetrahedral configuration of the central atom.

In compound **1** the Cd–S(C) bond lengths range from 2.527(1) to 2.536(1) Å, and Cd–S(P) bond lengths range from 2.503(2) to 2.523(1) Å. This reveals the equalization of the metal bond lengths with either the thiophosphoryl or the thiocarbonyl sulfur atoms. The values of the P–S (1.990 Å mean) and C–S (1.760 Å mean) bond

lengths also correspond to the values intermediate between double (P═S 1.91–1.92 Å, C═S 1.68 Å in the thioureas) and the single (P–S 2.05–2.11 Å, C–S 1.751 Å) bonds [12]. The P═S bonds order stays in agreement with IR spectroscopy observations. Meanwhile, the C–N and P–N bonds are shorter on comparison with those in the free ligand **5** (C–N 1.382(7), P–N 1.684(5) Å). This picture is characteristic for the complexes discussed.

The metal-containing heterocycles CdSPNCS have the conformation of a non-symmetric boat, with the most deviation of P and S(C) atoms from the mean square planes of these fragments (Table 6).

In complex **2** the palladium atom has a distorted square-planar configuration. The deviations of the S(1) and S(4a) atoms from the plane S(1)S(2)S(3a)S(4a) are −0.147(2) and −0.154(2) Å, respectively, S(2) and S(3a) atoms are 0.158(2) and 0.154(2) Å, respectively. The palladium atom deviates from the plane S(1)S(2)S(3a)S(4a) by 0.0305(6) Å. The Pd–S(C) and Pd–S(P) bond lengths are within the usual limits for bonds of these kinds. For example, in the complex $[PhC(S)NP(S)(O\textit{i}Pr)_2]_2Pd$ (**13**) Pd–S(C) is 2.310 Å and Pd–S(P) is 2.341 Å [13]. The Pd–S(P) bond lengths in the compounds $Pd[(EtO)_2P(S)NP(S)Ph_2]_2$ (**14**) [14], $Pd[\{(PhO)_2P(S)\}_2N]_2$ [15], $Pd[\{\textit{i}Pr_2P(S)\}_2N]_2$ [16] are in the range 2.325–2.351 Å. The Pd–S(C) bond lengths in the complex $Pd[Et_2NC(S)NC(O)Ph]_2$ (**15**) are 2.310–2.315 Å [17]. The values of the bond lengths also show the equalization of the bond lengths, but in contrast to complex **1**, there is an evident difference between the bonds M–S(P) and M–S(C) in complex **2**.

The metal-containing six-membered heterocycle Pd(1)S(1)P(1)N(1)C(1)S(2) is in a ''sofa'' conformation. The conformation of the second metal-containing heterocycle Pd(1)($-x$, $-y$, $1-z$)S(3)P(2)N(3)C(2)S(4) is a non-symmetric boat, see Table 7. The conformation of the SCNPS backbone in **1** and **2** is similar: the NC(S)NP fragment is almost planar and the phosphoryl sulfur is deviated from its least-square plane. Torsion S–P–N–C angles range from 67.3(4)° to 72.3(5)° for **1** and 23.2(8)° to 48.4(7)° for **2**. The values of torsion angles in compounds **1** and **2** show that these deviations are higher in the cadmium complex **1**.

Table 6
Deviations (Å) from the mean-square planes CdSPNCS in **1**

Atoms in plane	Deviation	Atoms in plane	Deviation	Atoms in plane	Deviation	Atoms in plane	Deviation

Table 8
Parameters of intramolecular H-bonds of the complex **1**

Bond	d(D–H)	d(H···A)	d(D···A)	∠(DHA)
N2–H2···S8	0.86	2.66	3.504(3)	168.0
N4–H4···S6	0.86	2.69	3.529(4)	167.0
N6–H6···S4	0.86	2.82	3.662(4)	167.0
N8–H8···S2	0.86	2.63	3.477(3)	170.0

Bond lengths in Å and bond angles in degrees.

In the crystal of complex **1** intramolecular H-bonds of the NH···S type were found (Fig. 4). In contrast to complex **1**, in the crystal of complex **2** both inter- and intramolecular H-bonds take place (Fig. 5). The H-bonds parameters of complexes **1** and **2** are presented in Tables 8 and 9. As a result of hydrogen bonding in **2** centrosymmetric dimers are formed. Since the first molecule of the dimer lies in the local symmetry centre, the second molecule is linked to another dimer's molecule. Finally, due to this interaction the dimers are linked into endless chains.

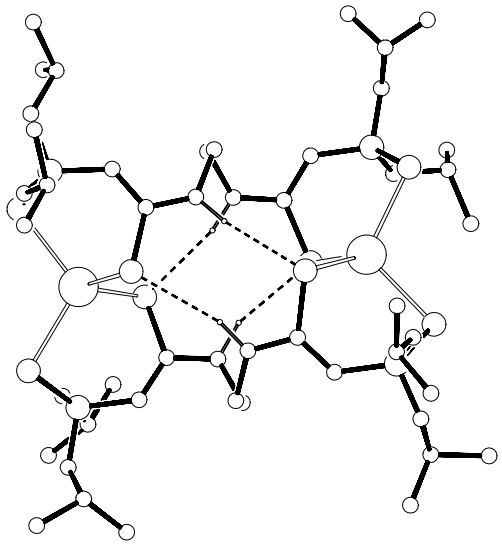

Fig. 4. H-bonds in complex **1**.

The nature of the close chemical environment of the central atom imposes a major impact on the chelate knot structure. If these atoms are the same then the square-planar complexes of "soft" metals with anionic ligands of the [A(X)NB(Y)] type have, as a rule, a *trans*-structure: **13** [13], **14** [14], [PhNHC(S)NP(S)(O*i*Pr)$_2$]$_2$Ni [18], [Pr$_2$NC(S)NP(S)(OPh)$_2$]$_2$Ni [19], [MeNHC(S)NP(S)Ph$_2$]$_2$Ni [20], [(EtO)$_2$P(S)NP(S)Ph$_2$]$_2$Pt [14], [Me$_2$P(S)NP(S)Ph$_2$]$_2$Ni [21], [Et$_2$NC(S)NC(S)Ph]$_2$Ni [22]. The only exception is the complex {[H$_2$NC(S)NP(S)Ph$_2$]$_2$Pt}(Et$_2$O) [23]. If $X \neq Y$ the *cis*-structure is preferable due to the *trans*-influence: **15** [17], [Et$_2$NC(S)NC(O)Ph]$_2$Cu [24], [Ph$_2$P(Se)NP(O)Ph$_2$]$_2$Pd [25], [(*i*PrO)$_2$P(O)NC(S)Ph]$_2$Cu [26], [(*i*PrO)$_2$P(O)NC(S)NEt$_2$]$_2$Cu [27]. The central atom's surroundings affects in turn the structure of the macrocyclic complexes with bipodal ligands. For example the dimer

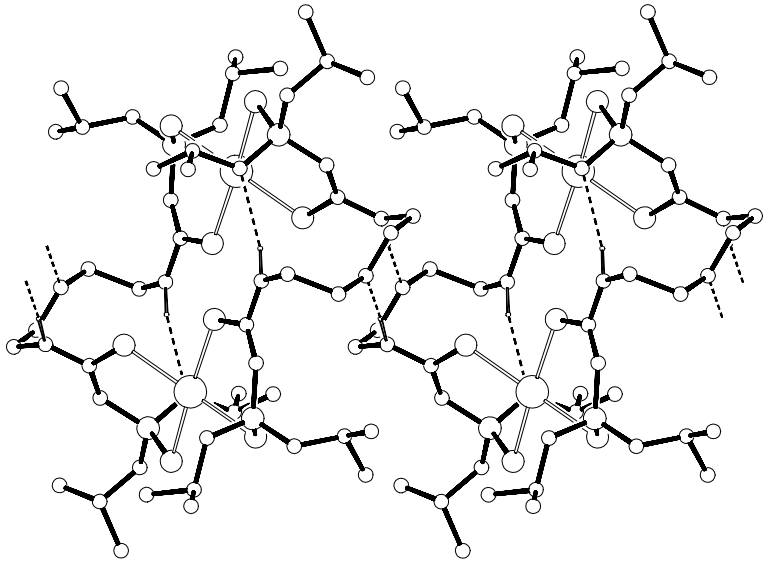

Fig. 5. H-bonds in complex **2**.

Bond lengths in Å and bond angles in degrees.

and trimer complexes with bipodal *O*,*S*-acylthioureas have the *cis*-structure only [28,29].

Ligands having coordinating atoms with similar donor abilities can form both *cis*- and *trans*-isomers depending on slight peculiarities like the entropy of an isomer, steric preferences, polarity of media. Hence, it is evident, why the complexes with *S*,*S*-bipodal ligands form both polymers [1,2] and dimers as in this case. When there is a tendency to form chelate molecules with a *trans*-structure, the minimal accepted size for the cyclic molecule $(ML)_n$ should be $n = 4$.

The results of the presented work are in a good agreement with the data published by Kluiber and Lewis [30], Kobuke and Satoh [31], – both the dimeric complexes **1** and **2** are formed with ligands that contain less than 7 atoms in the bridging chain Z.

Abstract

Reaction of Na[CuL] (H_3L = the Schiff base derived from 5-bromosalicylaldehyde and glycylglycine) with $Ln(NO_3)_3$ leads to the formation of the title complexes $[Ln(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ (Ln = La (**1**) and Ce (**2**)), which contain ring-like hexanuclear $[Ln_2(H_2O)_{10}(CuL)_4]^{2+}$ cations. The Ln(III) cations in **1** and **2** are coordinated by five water molecules, one carbonyl oxygen and three carboxylic oxygen atoms, and the copper(II) cations are coordinated by one phenolic oxygen, one carboxylate oxygen atom, one deprotonated amide nitrogen atom and one imino nitrogen atom. Complex **1** exhibits a ferromagnetic interaction and **2** exhibits an antiferromagnetic interaction in the solid state.

Keywords: Cu(II)–Ln(III) complexes; Dipeptides; Carboxylate bridge; Hexanuclear cations; Crystal structures; Magnetic properties

1. Introduction

Study on the synthetic methods, structures and properties of heterometallic compounds consolidated by carboxylate groups is currently of interest because of the magnetic interaction between transition and rare-earth ions in bridged systems, and their possible application in production of high temperature superconductors [1–4]. Heterometallic compounds ligated by carboxylate groups have not been well documented [5–7]; some examples of heteronuclear Cu–Ln (Ln = lanthanide) compounds have recently been uncovered [8–15]. This may be attributed to the fact that Cu and Ln have different coordination capabilities. Therefore heteronuclear Cu–Ln compounds have commonly been synthesized with hetero-donor ligands, comprising two types of ligating atoms (such as N and O) coordinated each to Cu and Ln atoms, respectively.

Some transition metal complexes of Schiff bases derived from amino acids and peptides comprising two types of ligating atoms (such as N and O) have interesting coordination capabilities (especially as carboxylate-bridged ligands) to metal ions [16–21]. We have recently found that the stable $[CuL]^-$ (H_3L = 5-bromosalicylideneglycylglycine) core can be used as a ''metallo-ligand'' to bind other hard metal ions such as Ba^{II} to form a heterometallic complex [22,23], thus providing a new synthetic route for heterometallic complexes in metal carboxylate chemistry. Since the lanthanide^{III} ions are very similar to hard barium ions in coordination chemistry, the above-mentioned interesting strategy can also

be applied to the preparation of carboxylate-bridged heterometallic hexanuclear $Cu_4^{II}Ln_2^{III}$ compounds. Herein we described their preparation and magnetic properties, and the crystal structure of $[Ln(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$.

2. Experimental

2.1. Materials and methods

All reagents were commercially available and used as received. Elemental analyses (H, C, N) were performed on a Perkin–Elmer 240 analytical instrument. FT-IR spectra were recorded on a Bruker vector22 spectrophotometer as KBr pellets in the 4000–400 cm^{-1} region. Magnetic measurements were performed on a Quantum Design MPMS-7 SQUID magnetometer and an Oxford MagLab2000 System in the temperature range 2–300 K and under an applied external magnetic field of 2–3 T. Diamagnetic corrections were estimated on the basis of Pascal's constants.

2.2. Preparation of compounds

2.2.1. $Ln(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ (1–2)

These complexes were all prepared using the same method as described in detail for complex **1** as an example (Scheme 1): glycylglycine (10 mmol), 5-bromosalicylaldehyde (10 mmol) and LiOH (20 mmol) were dissolved and refluxed in MeOH/H_2O (v:v = 1:1). $CuCl_2\cdot 2H_2O$ (10 mmol) was then added to the solution and the resulting solution was adjusted to pH 9–11. Last excess $LaCl_3$ (15 mmol) was added. A violet precipitate was obtained, which can be recrystallized from hot water (90 °C). The filtrate was allowed to evaporate slowly at room temperature. After several days violet red crystals, which were suitable for X-ray diffraction were obtained. Yield: 78%. *Anal.* Calc. for $C_{33}H_{48}O_{24}N_6Br_3Cu_3La$: C, 26.7; H, 3.3; N, 5.7. Found: C, 26.6; H, 3.3; N, 5.6%. IR (KBr, cm^{-1}): ν_{sh}(COO) 1686, ν(C=N) 1646s, ν_{as}(COO) 1600 and ν_s(COO) 1403. MS ($[C_{11}H_8N_2O_4BrCu]^-$, *m/z*): 375.7.

2: violet red crystals. Yield: 80%. *Anal.* Calc. for $C_{33}H_{50}N_6O_{25}Br_3CeCu_3$: C, 26.4; H, 3.4; N, 5.6. Found: C, 26.7; H, 3.4; N, 5.7%. IR (KBr, cm^{-1}): ν_{sh}(COO) 1688, ν(C=N) 1645s, ν_{as}(COO) 1599 and ν_s(COO) 1400 (see Table 1).

2.3. X-ray crystallography

A summary of the data collection and structure refinement is listed in Table 2. Data were collected on a Bruker SMART 1000 diffractometer equipped with a CCD detector and graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. The structure solution by direct methods revealed the metal atom coordinates and subsequent difference Fourier methods yielded the positions of all remaining non-H atoms and all of the hydrogen atoms. All other non-H atoms were refined anisotropically by full-matrix least-squares calculations using SHELXTL version 5.1 [24]. For the two complexes all the hydrogen atoms were found in difference Fourier maps, assigned fixed isotropic displacement parameters 1.2 times the equivalent isotropic *U* value of the attached atoms and allow to ride on their respective parent atoms.

3. Results and discussion

3.1. Crystal structures

3.1.1. $La(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ (1)

The crystal structure of **1** consists of a centrosymmetric hexanuclear $[La_2(H_2O)_{10}(CuL)_4]^{2+}$ ring-like cation,

Symmetry code: (i) $1-x,-y,-z$; (ii) $-x,2-y,-$z.

two [CuL]$^-$ anions and lattice water molecules. An ORTEP view of the hexanuclear cation in **1** is shown in Fig. 1. The coordination environment of the copper(II) centers is approximately square-planar. The Schiff base ligand is deprotonated and acts as a triple negatively charged quadridentate ONNO chelate, coordinated to

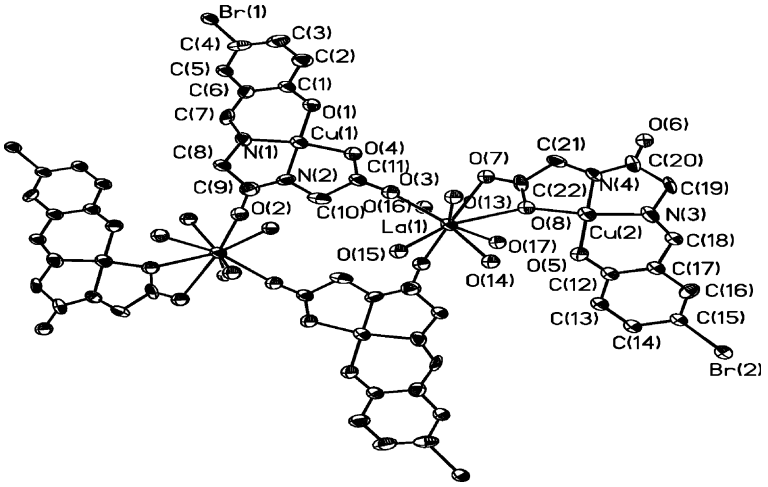

Fig. 1. An ORTEP view of the crystal structure of $[La_2(H_2O)_{10}(CuL)_4]^{2+}$ showing the 50% probability thermal ellipsoid.

the copper(II) atom via one phenolic oxygen (O(1)), one deprotonated amide nitrogen atom (N(2)), one imino nitrogen atom (N(1)) and one carboxylate oxygen atom (O(4)). The value of 1.444(9) Å for the C(8)–N(1) bond, shorter than the usual C–N single bond, and the double bond C(7)–N(1) length of 1.298(9) Å agree well with the values of Schiff base type I [25]. The C(9)–N(2) bond length is 1.342(10) Å and the C(10)–N(2) bond length is 1.444(9) Å. The best-fit least-squares plane through the four basal and Cu atoms shows these atoms to be nearly coplanar. The O(1)–Cu(1)–N(2) angle of 177.6(3)° is nearly linear. The N(1)–Cu(1)–O(4) bond angle is 167.6(3)°. The phenyl ring [C(1)–C(6)] and the C(1), C(6), C(7), N(1), O(1), Cu(1) chelate ring are almost coplanar with a small dihedral angle of 0.3°. There are three types of $[CuL]^-$ subunits in the crystal. $[Cu(3)L]^-$ act as a counter ion; $[Cu(1)L]^-$ coordinate to La(III) through one carboxylate oxygen (O(3)) and one carbonyl oxygen (O(2)), and $[Cu(2)L]^-$ coordinates to La(III) though two carboxylate oxygens (O(7), O(8)).

La(III) is 9-coordinated by five water molecules (O(13), O(14), O(15), O(16), O(17)), three carboxylic oxygen atoms (O(3), O(7), O(8)) and one carbonyl oxygen $(O(2)^i$; symmetry code (i): $1-x,-y,-z$). The La–O(water) distances, ranging from 2.525(5) to 2.587(5) Å, are similar to reported values [26]. The La–O(carboxylic oxygen) distances range from 2.433(5) to 2.633(5)Å. The La–O(carbonyl oxygen) distances is 2.385(5) Å. The $[CuL]^-$ and the lanthanum ions join together to form a ring structure. The nearest La–La distance is 8.093 Å.

In the packing scheme of the compound, intermolecular and intramolecular hydrogen bonds plays a very important role. The hydrogen atoms of water are involved in both intra- and intermolecular hydrogen bonds, bonding with the carbonylic, carboxylic and phenolic oxygen of the Schiff base ligand. The intermolecular bonds have $\cdots$O distances ranging from 1.87 to 2.87 Å. The molecules are linked by the extensive hydrogen bonding to form a three-dimensional network in the solid state.

$[Ce(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ (**2**). The crystal structure of complex **2** is isomorphic to that of **1**, only small metric differences being observed for the two complexes. Owing to the slightly smaller radius of Ce^{III} than that of La^{III} [27], all the metal–ligand bonds in **2** are slightly shorter than the corresponding bonds in **1**, as compared in Table 2, however the bond angles in both are almost the same.

3.2. Magnetic properties of $[La(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ (*1*)

The temperature dependency of magnetic susceptibilities $\chi_m T$ for **1** measured at 10 kOe field using a SQUID magnetometer are shown in Fig. 2. The $\chi_m T$ value at room temperature (2.252 emu K mol^{-1}) is very close to the expected value of 2.25 emu K mol^{-1} for six non-interacting spin-only Cu^{II} ions (La^{III} is a diamagnetic ion). As the temperature is decreased from 300 to 14.1 K, the values of $\chi_m T$ show a gradual increase, indicating a ferromagnetic coupling. After passing though a maximum of 5.13 emu K mol^{-1} at 14.1 K, $\chi_m T$ shows an abrupt decrease, suggesting a weak antiferromagnetic coupling between the ferromagnetic units. Ferromagnetic ordering is demonstrated further by the field dependence of isothermal magnetization performed at 1.9 K (inset of Fig. 2). The magnetization at 1.9 K increases very rapidly in low fields, and reaches the saturation value of ca. 25846 emu G mol^{-1} at 60 kOe.

For complex **2**, The $\chi_m T$ value at room temperature (3.36 emu K mol^{-1}) is slightly smaller than the calculated value (3.86 emu K mol^{-1}) for two Ce^{III} and six spin-only Cu^{II}. As the temperature decreases, the $\chi_m T$ value first decreases slowly between 300 and 21 K (3.09 emu K mol^{-1}) and then drops very rapidly to

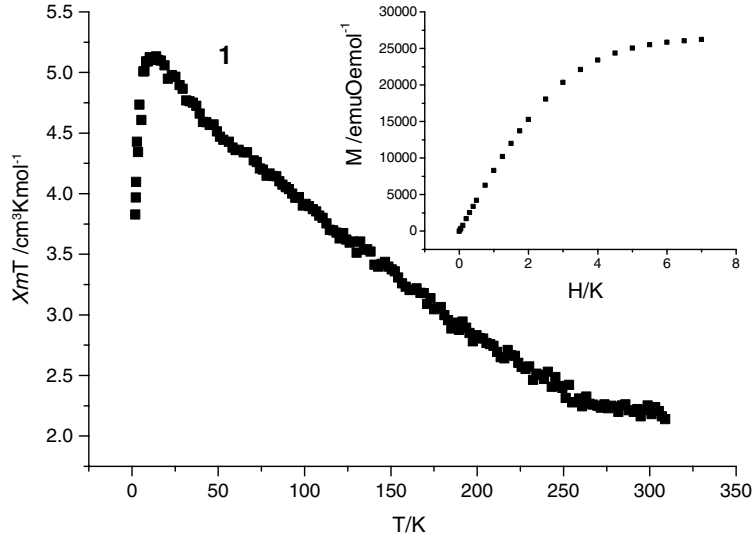

Fig. 2. Temperature dependence of $\chi_m T$ for a powder sample of $[La(H_2O)_5(CuL)_2]_2[CuL]_2\cdot 16H_2O$ (**1**). The field dependence of magnetization M for $[La(H_2O)_5(CuL)_2]_2[CuL]_2\cdot 16H_2O$ at 1.9 K is given in the inset.

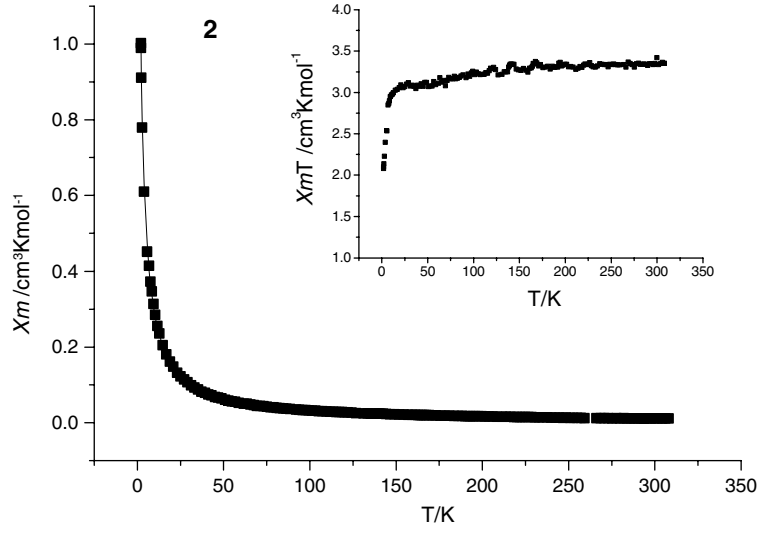

Fig. 3. Temperature dependence of χ_m for a powder sample of $[Ce(H_2O)_5(CuL)_2]_2[CuL]_2\cdot 16H_2O$ (**2**). The $\chi_m T$ vs T plot is given in the inset.

2.08 emu K mol^{-1} at 2 K (see Fig. 3). Fitting the data to the Curie–Weiss law gives $C = 3.22$ emu K mol^{-1}, $\theta = -1.17$ K with a final agreement factor $R = 2.0 \times 10^{-5}$ $[R = \sum(\chi_m^{obs} - \chi_m^{calc})^2 / \sum(\chi_m^{obs})^2]$, showing antiferromagnetic interactions.

4. Conclusion

In summary, we have prepared two novel hexanuclear complexes $[Ln(H_2O)_5(CuL)_2][CuL]\cdot 8H_2O$ constructed from the "metallo ligand" $[CuL]^-$ and the rare-earth ions La or Ce, and have reported their magnetic properties. Many fascinating structures will be assembled by the versatile building block $[CuL]^-$.

5. Supplementary data

CCDC 225171 and 225172 contain the supplementary crystallographic data for this paper. Abstract

Six silver(I) complexes with a new type of ligand, 4′,5′-diaza-9′-(4,5-disubstituted-1,3-dithiol-2-ylidene)fluorene (L^n, n = 1, Me; 2, Et; 3, Bu substituted) have been obtained. Two of the complexes $[Ag(L^1)_2]ClO_4$ (**1**) and $[Ag(L^1)_2]SO_3CF_3$ (**4**) have been structurally characterized by single-crystal X-ray diffraction. All of the Ag(I) ions are coordinated linearly by two ligands and the cations take planar structures. These planes are further assembled into one dimensional columns by Ag–Ag weak bonds, π–π stacking and Ag···N interactions. The UV–Vis and fluorescence spectra of the complexes were studied and the ligand-centered energy levels are not changed dramatically when the complexes are formed.

1. Introduction

The research on metal complexes with bipyridine and 1,10–phenanthroline ligands has attracted great interest due to their long-standing application in electronic and luminescent photochemistry [1,2]. Several efforts were reported to tune the physical and chemical properties of the π system through chemical modification of the phenanthroline [3–6]. 1,10-Phenanthroline behaves as a σ chelator donor/π acceptor ligand, which implies that the low-lying π^* orbits are an attractive target for modifying the electrochemical or excited state properties of the corresponding complexes. Furthermore, great efforts on crystal engineering have been reported to design and prepare supramolecules or complexes having π···π stacking [7–9]. Recently much more attention has been paid to silver(I) compounds [10–13]. In view of these facts, we became interested in the ligands 4′,5′-diaza-9′-(4,5-disubstituted-1,3-dithiol-2-ylidene)fluorene, which are a derivative of bipyridine and has a similar structure to 1,10-phenanthroline (Scheme 1) [14,15]. Besides, these ligands have a conjugated dithiole moiety that changes the relative levels of the π orbitals, compared with those of phenanthroline and bipyridine. In this paper, we present the synthesis, spectroscopic properties and crystal structures of a series of Ag(I) complexes with this type of diaza fluorene. These complexes are expected to be a new molecular system.

2. Experimental

2.1. Materials and methods

The reagents L^1, 4′,5′-diaza-9 ′-(4,5-bis(methylthio)-1,3-dithiol-2-ylidene) fluorene; L^2, 4′,5′-diaza-9′-(4,5-bis-(ethylthio)-1,3-dithiol-2-ylidene)fluorene; L^3, 4′,5′-diaza-9′-(4,5-bis(butylthio)-1,3-dithiol-2-ylidene)fluorene were prepared according to the literature [16–19]. Acetonitrile was dried and distilled by a standard method before use. Elemental analyses of C, H and N were performed using an EA1110 elemental analyzer. The IR spectra were recorded as KBr discs on a Nicolet Magma 550 FT-IR spectrometer. ^{1}H NMR spectra were measured by an UNITYNOVA-400 spectrophotometer. UV–Vis spectra were recorded using a Shimadzu UV-240 spectrometer. The fluorescence spectra were recorded on a RF-540 fluorescent photometer.

2.2. Synthesis of the complexes

2.2.1. $[Ag(L^1)_2]ClO_4 \cdot 2CH_2Cl_2$ (1)

To an acetonitrile solution (1 ml) of $AgClO_4 \cdot H_2O$ (0.1 mmol, 20.76 mg) was slowly dropped a dichloromethane solution (15ml) of the ligand L^1 (0.1 mmol, 36 mg). The mixture was stirred for 30 min at room temperature. After that, an orange precipitate formed which was filtrated, washed with the solvents, and finally dried in vacuum over silica gel (Yield 61%). *Anal.* Calc. for $C_{34}H_{28}AgCl_5N_4O_4S_8$: C, 37.30; H, 2.58; N, 5.12. Found: C, 37.12; H, 2.38; N, 5.49%.

2.2.2. $[Ag(L^2)_2]ClO_4 \cdot CH_2Cl_2$ (2)

Complex **2** was synthesized by a similar procedure as for complex **1** (Yield 69%). Anal. Calc. for $C_{37}H_{34}AgCl_3N_4O_4S_8$: C, 41.55; H, 3.20; N, 5.24. Found: C, 41.50; H, 3.23; N, 5.41%.

2.2.3. $[Ag(L^3)_2]ClO_4 \cdot CH_2Cl_2$ (3)

Complex **3** was also synthesized by a similar procedure as for complex **1** (Yield 60%). Anal. *Calc.* for $C_{45}H_{50}AgCl_3N_4O_4S_8$: C, 45.74; H, 4.27; N, 4.74. Found: C, 45.40; H, 4.19; N, 4.62%.

2.2.4. $[Ag(L^1)_2]SO_3CF_3 \cdot 1/2\,CH_2Cl_2$ (4)

To an acetonitrile solution (1 ml) of $AgSO_3CF_3$ (0.05 mmol, 13.7 mg) was slowly dropped a dichloromethane solution (8 ml) of the ligand L^1 (0.05 mmol, 18 mg). The mixture was stirred for 30 min at room temperature. After that, an orange precipitate formed which was filtrated, washed with the solvents, and finally dried in vacuum over silica gel (Yield 65%). *Anal.* Calc. for $C_{33.5}H_{25}AgCl_1F_3N_4O_3S_9$: C, 39.43; H, 2.47; N, 5.49. Found: C, 39.93; H, 2.39; N, 5.54%.

2.2.5. $[Ag(L^2)_2]SO_3CF_3 \cdot 1/2\,CH_2Cl_2$ (5)

Complex **5** was synthesized by a similar procedure as for complex **4** (Yield 62%). *Anal.* Calc. for $C_{37.5}H_{33}AgCl_1F_3N_4O_3S_9$: C, 41.84; H, 3.07; N, 5.21. Found: C, 41.99; H, 3.14; N, 5.20%.

2.2.6. $[Ag(L^2)_2]SO_3CF_3 \cdot CH_2Cl_2$ (6)

Complex **6** was also synthesized by a similar procedure as for complex **4** (Yield 68%). *Anal.* Calc. for $C_{46}H_{50}AgCl_2F_3N_4O_3S_9$: C, 44.84; H, 4.06; N, 4.55. Found: C, 44.75; H, 4.09; N, 4.57%.

2.3. X-ray crystallography

X-ray crystallographic data for complexes **1** and **4** were obtained using a Rigaku Mercury CCD area detector with graphite monochromated Mo Kα (λ = 0.71070 Å) radiation. The data of **1** have been reported as a letter [15]. The data of **4** were collected at a temperature of 193.15 K to a maximum 2θ value of 55.0° using ω scans. An empirical absorption correction was applied and the structure was solved by the SHELXS-97 software package. The non-hydrogen atoms were refined anisotropically and hydrogen atoms were added theoretically. The final cycle of full-matrix least-squares refinement on F^2 was based on all unique reflections of **4**. The weighted *R*-factor and goodness-of-fit *S* are based on F^2 and conventional *R*-factors are based on *F*. Calculations were performed using the SHELXL-97 software package. Table 1 lists relevant crystallographic data for complex **4** and details of data collection. Table 2 lists the selected bond lengths and angles and the important

interaction distances for **4** (shorter than the sum of Van der Waals radii). Disorder was found for one Cl atom of the solvent, one F and one O atom of the anion. For the same reason, the H atoms of dichloromethane could not be located.

3. Results and discussion

3.1. Synthesis of the compounds

The ligands were prepared according to the literature [16–19] and were characterized before being used. These molecules, L^n ($n = 1$–3), have part of a TTF (tetrathiafulvalene) moiety and showed quasi-reversible one-electron redox behavior [19]. Due to the ligands having good solubility only in dichloromethane, the complexes of $[Ag(L^n)_2]ClO_4 \cdot mCH_2Cl_2$ (**1**–**3**) and $[Ag(L^n)_2]SO_3CF_3 \cdot mCH_2Cl_2$ (**4**–**6**) was synthesized by reaction of the ligands L^n with $AgClO_4$ or $AgSO_3CF_3$ in mixed solvents of acetonitrile and dichloromethane. Although complex **1** has been reported previously as a communication for discussion of the conversion of molecular configuration in the solid state and in solution [15], it is still mentioned here for the integrity of the silver complexes. The red single crystals suitable for X-ray diffraction were obtained from the filtrate of a diluted reaction solution at room temperature under ambient conditions. X-ray crystal structure determination showed that solvent molecules CH_2Cl_2 are included in the crystals, but they are lost quickly when the crystals are separated from the mother liquid for a period. Thus the elemental analysis was carried out immediately after the micro-crystal powders were separated.

3.2. Structural descriptions

The crystal structure of $[Ag(L^1)_2]ClO_4 \cdot 2CH_2Cl_2$ (**1**) and $[Ag(L^1)_2]SO_3CF_3 \cdot 1/2\,CH_2Cl_2$ (**4**) are shown in Fig. 1. In **1**, the silver ion is coordinated linearly by two nitrogen atoms from two ligands. It is noteworthy that although the linear coordinated planar structure of $[Ag(L^1)_2]^+$ in **4** is similar to that of **1**, the crystal structure of **4** is quite different from **1**. Two types of silver

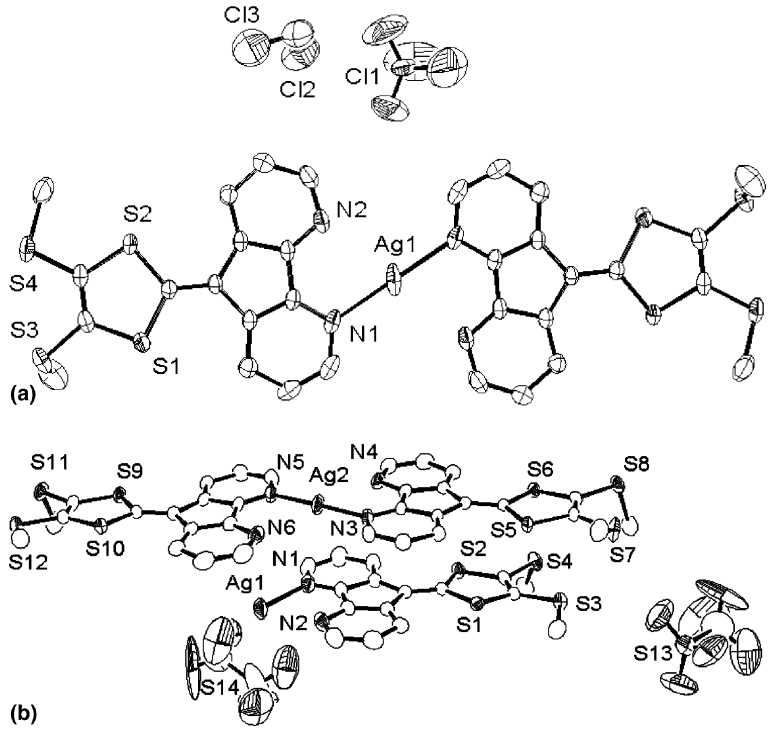

Fig. 1. ORTEP view of $[Ag(L^1)_2]ClO_4 \cdot 2CH_2Cl_2$ (**1**) (a) and $[Ag(L^1)_2]SO_3CF_3 \cdot 1/2\,CH_2Cl_2$ (**4**) (b), showing the selected atom labels. Non-H atoms are shown as 50% probability displacement ellipsoids. The solvent is omitted for clarity for **4**.

centers were found within the compound. Ag(1) is coordinated linearly by two ligands via N(1) and N(1′) atoms with an inversion center. The two Ag(1)–N(1) distances of **4** are equivalent (2.200 Å) and the two other Ag–N distances are 2.727 Å, longer than the coordination bonds. Ag(2) is also linearly coordinated by two N atoms from two ligands, but they are not equivalent in the operation of crystallographic symmetry, due to the methylthio groups of the two ligands being orientated on the same side of the ion's plane (Fig. 1(b)). The distances of Ag(2)–N(3) and Ag(2)–N(5), 2.193 and 2.200 Å, respectively, are approximately equivalent to the Ag(1)–N(1) distance. The other Ag–N distances are 2.714 Å for Ag(2)–N(6) and 2.732 Å for Ag(2)–N(4). Although linear coordination is very common for Ag(I) complexes, it is not for 2,2′-bipyridine and phenanthroline complexes. In contrast, a number of four coordinated Ag(I) complexes are reported [11,12]. Burke has indicated that complexes of the type $[M(bpy)_2]^{n+}$ and $[M(phen)_2]^{n+}$ are unable to adopt a square-planar configuration because of steric interaction between α-H atoms [13]. For the same reason most octahedral $[M(bpy)_2X_2]^{n+}$ and $[M(phen)_2X_2]^{n+}$ ions take on a *cis*-structure rather than a *trans*-one. Thus the planar structure of $[Ag(L)_2]^+$ is unusual and it is benefited by the linear coordination of the Ag(I) ion and the intermolecular interactions of the extended molecular planes. The linear coordination keeps away from the steric hindrance of the α-H atoms of the two ligands and the planar structure can be further stabilized by the layered close-packing with strong interactions.

In complex **4**, three $[Ag(L^1)_2]^+$ cations form a unit in which two form a pair which is interconnected by a weak Ag(2)···Ag(2′) bond (3.56 Å) and the other is independent (Fig. 2) with a Ag(1) to Ag(2) separation of 4.307 Å. All the molecules are found in columns propagated in the direction of the *a* axis and displaying three distinct forms of intermolecular interaction of Ag···C (3.40 Å), Ag···N (3.28 Å) and C···C (3.34–3.38 Å). It is interesting that unlike the structure of **1**, in which the Ag···S and C···C interactions act continuously along the column, the interactions in **4** only exist within the planes of Ag(1) and Ag(2) and there is no interaction within the Ag(2) planes except the weak

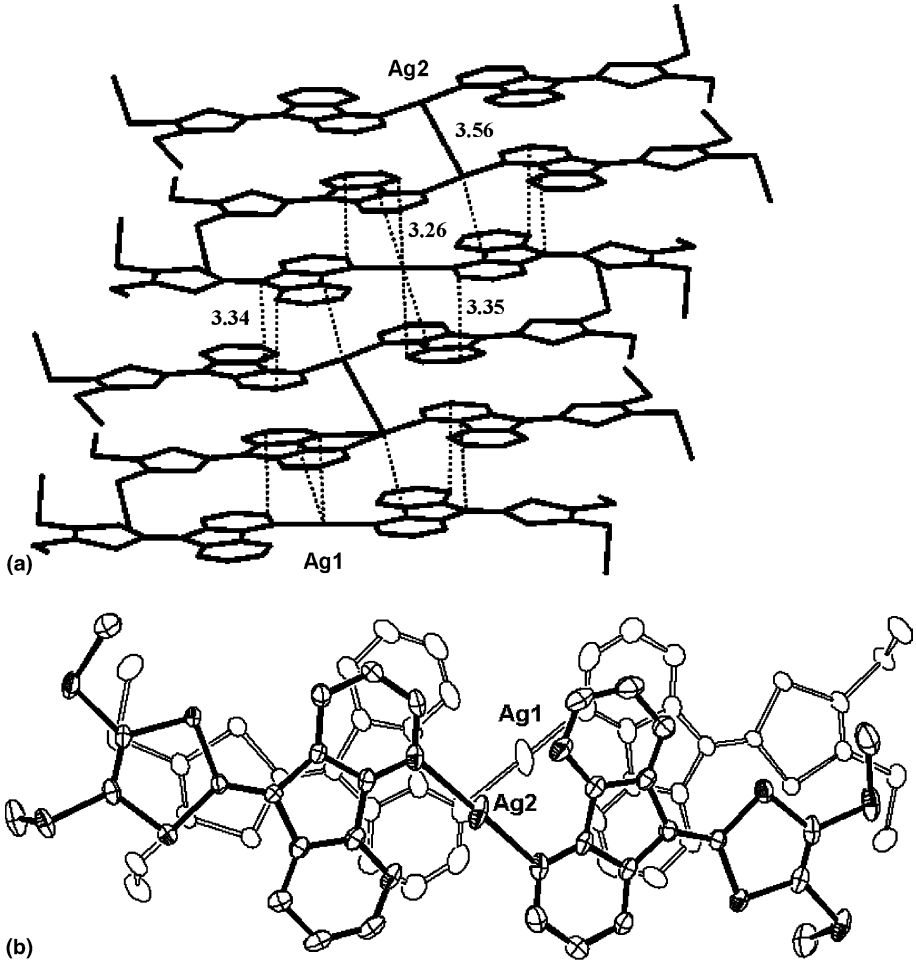

Fig. 2. (a) Molecular packing of **4** within a column, the dashed lines are used to represent inter-planar π–π stacking and Ag···N interactions. (b) Top view of the two units of $[Ag(L^1)_2]^+$ showing the overlap areas.

Ag···Ag bond. Fig. 2 shows the alternant interaction structure and a top view of the planes of Ag(1) and Ag(2) showing the overlap areas.

3.3. Spectral properties

The ^{1}H NMR spectra and signal assignments of ligands L^1–L^3 and the complexes **1**–**6** in $CDCl_3$ are summarized in Table 3. As an example, for complex **4** two doublet signals at 8.81 and 8.28 ppm are assigned to ^{1}H at 1′, 8′ and 3′, 6′ ring sites of the fluorene, respectively (Scheme 1). The signal at 7.60 with a quartet-split is assigned to the ^{1}H at 2′ and 7′ ring sites. The signals below 3.10 ppm are attributed to the alkyl groups. The general downfield shifts can be attributed to the coordination of the ligands with the positive silver ion. All the chemical shifts of the aromatic protons of **4**–**6** are somewhat larger than those of **1**–**3**, which might have arisen from the polarized anion.

The important IR vibration bands and their assignments are given in Table 4. The ν(C=N) band at 1540 cm^{-1} for the free ligand L^n is somewhat shifted to lower energy in the case of the complexes $[Ag(L^n)_2]ClO_4$ and $[Ag(L^n)_2]SO_3CF_3$, due to the coordination of the imino group in the pyridyl ring. The same results were also found for the C=C vibration bands at about 1480 cm^{-1}. In contrast to the C=N and C=C bands, the S–C–S vibrations at about 856 cm^{-1} are enhanced on the formation of the complexes. The ClO_4^- vibrations of **1**–**3** were observed at around 1090 cm^{-1}, and the $SO_3CF_3^-$ vibrations of the complexes **4**–**6** were observed at around 1265 cm^{-1}, which confirms the presence of the counterions.

The UV–Vis spectral data of phenanthroline, the ligands and their complexes in dichloromethane have been measured. In contrast to the spectrum of phenanthroline (no absorption bands above 300 nm) a strong absorption band at about 410–415 nm appeared when the ligand was modified with the extended and conjugated dithiole structure. An intramolecular charge transfer, from dithiole to the bipyridine moieties, is attributed to the new absorption. The representative spectra of L^3 (R = Bu) and complex **3** are given in Fig. 3. This new absorption band red shifts to 420–435 nm on the formation of the complex, which is due to the influence of the electron withdrawing property of the Ag(I) ion. Since the tail of this band develops over 500 nm, these complexes are red in color in contrast to the yellow ligands.

Fluorescence spectra show that the ligand emits a strong fluorescence at 365 nm (λ_{ex} 300 nm, $CHCl_3$). This fluorescence band is still observed and does not change

Table 4
Characteristic IR bands of the ligands and their complexes (cm^{-1})

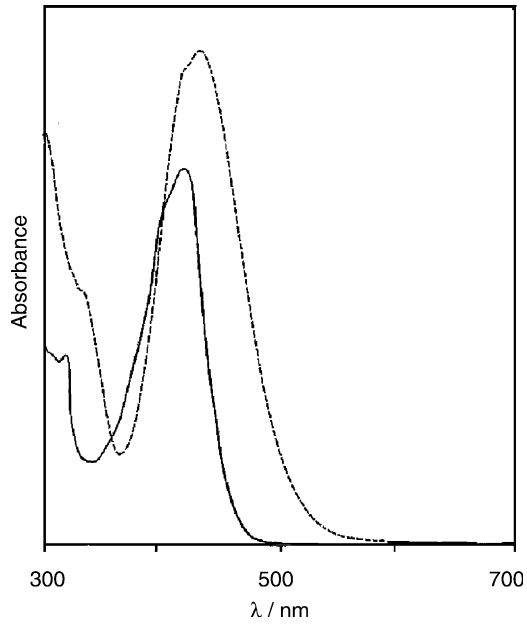

Fig. 3. UV–Vis spectra of the ligand L^3 (solid line) and complex **3** (dash-line) in dichloromethane.

when the complex is formed (ligand centered π–π emission). This result has been explained by the tetrahedral configuration of the complex in solution [15]. On the other hand, the emission spectra in the visible range are dramatically different (Fig. 4). Although self-absorption should also be considered at about 400–480 nm for both the ligands and the complexes, the weak emission above 550 nm is clearly a new band which can be assigned to the fluorescence of the Ag(I) ion of the d^{10} metal. However the energy level of the complexes and the assignment of the emission bands need to be studied further.

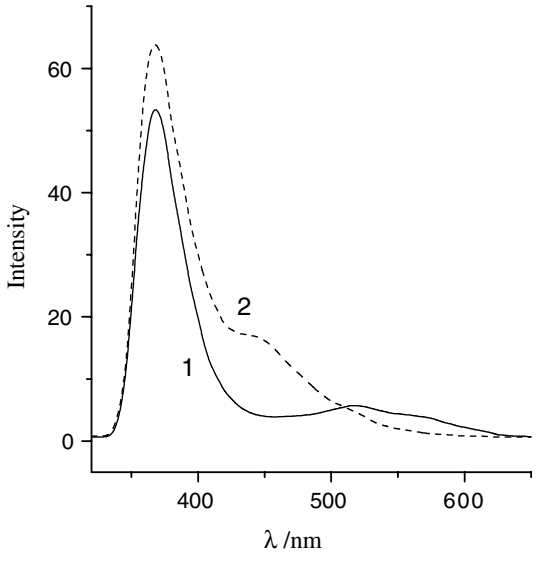

Fig. 4. Fluorescence spectra of ligand L^3 (line 2) and complex **3** (line 1) in trichloromethane (λ_{ex} 300 nm).

4. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 209123 and 228492 for compounds **1** and **4**, respectively. These data can be obtained free of charge via www: http://www.ccdc.cam.ac.uk or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033, or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

$Ln(ClO_4)_3$ and $Ni(ClO_4)_2$ self-assemble in the presence of amino acids (glycine, L-alanine or L-threonine) to form seven novel heptanuclear octahedral clusters {$LnNi_6$} (Ln = La, Pr). X-ray structures are reported for $Na[LaNi_6(Gly)_{12}](ClO_4)_4(H_2O)_{11}$ (**1**), $Na_5[LaNi_6(Gly)_{12}](ClO_4)_8(H_2O)_{10}$ (**2**), $Na[PrNi_6(Gly)_{12}](ClO_4)_4(H_2O)_{11}$ (**3**), $[LaNi_6(Gly)_{12}][Ni(im)(H_2O)_5]\cdot(ClO_4)_5(H_2O)_5$ (**4**) and $[LaNi_6(Gly)_{12}][Ni(NCS)_3(H_2O)_3][Ni(NCS)_2(H_2O)_4]\cdot(ClO_4)_2(H_2O)_6$ (**5**). L-Alanine and L-threonine were used as ligands to synthesize $[LaNi_6(Ala)_{12}](ClO_4)_3\cdot(H_2O)_{15}$ (**6**) and $[LaNi_6(Thr)_{12}](ClO_4)_3\cdot(H_2O)_{15}$ (**7**). In the $[LnNi_6(Gly)_{12}]^{3+}$ ions, the Ln^{3+} ion is in the center of the octahedral cage formed by six nickel atoms and coordinates to 12 carboxylate oxygen atoms. Its coordination polyhedron may be best described as an icosahedron. Complexes **1, 3** and **4** exhibit ferromagnetic interactions.

1. Introduction

Sparked by the structural diversity and interesting luminescence and magnetic properties found and proposed for 3d–4f clusters [1], interest in their rational synthesis has been increasing rapidly since the pioneering work of Gatteschi [2]. Up until now many heterometallic compounds of transition metals and rare earth metals have been synthesized with pyridones [3], Schiff-base [4], oxalato [5], oximates [6] or oxamides [7], cyano groups [8] and carboxylic acids [9] as ligands. However, despite extensive research on low-nuclearity 3d–4f complexes, only a few studies have focused on the design and synthesis of high-nuclearity compounds of 3d–4f clusters [9a,10].

Amino acid is one of the most important biological ligands. Research on the coordination of metal–amino acid complexes has contributed to our understanding of the function of metal ions in organisms. Up until now many Ln–amino acid complexes [11] and 1:1 or 1:2 transition metal–amino acid complexes [12] with a mononuclear or chain structure motif have been synthesized, though only recently a series of poly-nuclear lanthanide clusters with amino acid as the ligand were reported [13]. Recently we also showed that amino acid is a useful ligand for the construction of poly-nuclear copper clusters [14]. But until now, only three reports have focused on the 3d–4f-amino acid system, which are the $LnNi_6$ octahedral complex [15], the series of

$LnNi_6$ trigonal prismatic complexes [16] and the 32-nuclearity complex $\{La_6Cu_{26}\}$ reported by our group [10c]. The difficulty in obtaining this kind of complex may be attributed to the fact that 3d and 4f ions have distinctly different chemical behavior and the difficulty of seeking a suitable pH window so that the ligand can use both amino and carboxylate groups to coordinate to 3d and 4f metal ions. As amino acid ligands have a variety of coordinated modes, their use for the synthesis of 3d–4f heteronuclear compounds can lead to structures much more complex and intriguing than those of simple carboxylic acids [10c,16].

Up until now there are five kinds of heptanuclear 3d–4f clusters with the general formula of LnM_6 (M = transition metal) with the wheel ($LnCu_6$) [17], trigonal prismatic ($LnCu_6$ or $LnNi_6$) [16,18] and octahedral ($LnNi_6$) [15] structure motifs. Yukawa et al. [15] have synthesized an octahedral $SmNi_6$ cluster by the reaction of Sm^{3+} and bis(L-prolinato)nickel(II) in a non-aqueous medium, but the crystal is unstable. In this paper we report a series of octahedral $LnNi_6$ clusters obtained by the reaction of Ln^{3+}, Ni^{2+} and amino acid (glycine, L-alanine or L-threonine) in aqueous solution. The crystals obtained are very stable in air. The effect of solvent, the ionic radii of the lanthanide ions and other small molecular ligands, such as imidazole and SCN^-, on the synthesis are discussed. The magnetic behaviours were also studied.

2. Experimental

2.1. Materials and instrumentation

$Ln(ClO_4)_3 \cdot 6H_2O$ was synthesized by dissolving lanthanide oxide in an excess amount of perchloric acid. Other starting materials were of reagent grade and used without further purification. Elemental analyses were carried out by the Elemental Analysis Laboratory of our Institute. Magnetic measurements were carried out with a Quantum Design PPMS model 6000 magnetometer.

2.2. Synthesis of the complexes

2.2.1. $Na[LaNi_6(Gly)_{12}](ClO_4)_4(H_2O)_{11}$ (1)

To an aqueous solution (10 ml) of $La(ClO_4)_3 \cdot 6H_2O$ (0.545 g, 1 mmol), $Ni(ClO_4)_2 \cdot 6H_2O$ (2.184 g, 6 mmol) and glycine (0.90 g, 12 mmol) were added. Then the pH value of the reaction mixture was carefully adjusted to about 6.6 by slow addition of 0.1 M NaOH solution. After 2 h of stirring, the solution was filtered to remove a small amount of precipitate formed due to hydrolyzation of metal ions, and placed in a desiccator filled with phosphorus pentaoxide. Blue crystals were obtained about one month later. Yield: 0.76 g, 38%. *Anal*. Calc. for $C_{24}H_{70}Cl_4LaN_{12}NaNi_6O_{51}$: C, 14.42; H, 3.53; N, 8.41. Found: C, 14.32; H, 3.63; N, 8.58%.

2.2.2. $Na_5[LaNi_6(Gly)_{12}](ClO_4)_8 \cdot (H_2O)_{10}$ (2)

The above procedure was repeated except that the proportion of the reactants was controlled to be La^{3+}:Ni^{2+}:Gly = 1:9:9. Yield: 1.26 g, 51%. *Anal*. Calc. for $C_{24}H_{68}Cl_8LaN_{12}Na_5Ni_6O_{66}$: C, 11.67; H, 2.77; N, 6.80. Found: C, 11.46; H, 2.83; N, 6.51%.

2.2.3. $Na[PrNi_6(Gly)_{12}](ClO_4)_4 \cdot (H_2O)_{11}$ (3)

The above procedure was repeated except that $Pr(ClO_4)_3 \cdot 6H_2O$ was used and the proportion of the reactants was controlled to be Pr^{3+}:Ni^{2+}:Gly = 1:6:12. Yield: 0.71 g, 36%. *Anal*. Calc. for $C_{24}H_{70}Cl_4N_{12}NaNi_6O_{51}Pr$: C, 14.41; H, 3.53; N, 8.40. Found: C, 14.12; H, 3.43; N, 8.14%.

2.2.4. $[LaNi_6(Gly)_{12}][Ni(im)(H_2O)_5](ClO_4)_5(H_2O)_5$ (4)

The above procedure was repeated except imidazole was added and the proportion of the reactants was controlled to be La^{3+}:Ni^{2+}:Gly:im = 1:6:12:3. Yield: 0.66 g, 30%. *Anal*. Calc. for $C_{27}H_{72}Cl_5LaN_{14}Ni_7O_{54}$: C, 14.85; H, 3.32; N, 8.98. Found: C, 14.80; H, 2.95; N, 8.74%.

2.2.5. $[LaNi_6(Gly)_{12}][Ni(NCS)_3(H_2O)_3][Ni(NCS)_2(H_2O)_4] \cdot (ClO_4)_2 \cdot (H_2O)_6$ (5)

The above procedure was repeated except NaSCN was added and the proportion of the reactants was controlled to be La^{3+}:Ni^{2+}:Gly:SCN = 1:6:6:3. Yield: 0.56 g, 25%. *Anal*. Calc. for $C_{29}H_{74}Cl_2LaN_{17}Ni_8O_{45}S_5$: C, 15.69; H, 3.36; N, 10.72. Found: C, 15.43; H, 3.17; N, 10.32%.

2.2.6. $[LaNi_6(Ala)_{12}](ClO_4)_3 \cdot (H_2O)_{15}$ (6)

The above procedure was repeated except L-alanine was used and the proportion of the reactants was controlled to be La^{3+}:Ni^{2+}:Ala = 1:6:12. Yield: 0.87 g, 41%. *Anal*. Calc. for $C_{36}H_{102}Cl_3LaN_{12}Ni_6O_{51}$: C, 20.43; H, 4.86; N, 7.94. Found: C, 20.67; H, 5.16; N, 8.02%.

2.2.7. $[LaNi_6(Thr)_{12}](ClO_4)_3 \cdot (H_2O)_{15}$ (7)

The above procedure was repeated except L-threonine was used and the proportion of the reactants was controlled to be La^{3+}:Ni^{2+}:Thr = 1:6:12. Yield: 0.87 g, 35%. *Anal*. Calc. for $C_{48}H_{126}Cl_3LaN_{12}Ni_6O_{63}$: C, 23.28; H, 5.13; N, 6.79. Found: C, 23.18; H, 5.02; N, 6.94%.

2.3. X-ray crystallography

Intensity data for the five complexes **1**–**5** were collected at 293(2) K on a Siemens Smart/CCD area-detector diffractometer with Mo Kα radiation ($\lambda = 0.71073$

Å). Data reduction and unit cell refinement were performed with Smart-CCD software [19a]. An absorption correction using SADABS software was applied [19b]. The structures were solved by direct methods using SHELXS-97 [20] and refined by full-matrix least squares using SHELXL-97 [20]. Anisotropic displacement parameters were refined for all non-hydrogen atoms. Hydrogen atoms of the methylene and amine groups of the amino acid have been placed in calculated positions (AFIX 23) and refined with a riding model. No attempt was made to locate the hydrogen atoms of water. The crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis of the complexes

Until now many Ln–amino acid complexes [11] and 1:1 or 1:2 transition metal–amino acid complexes [12] with a mononuclear or chain structure motif have been synthesized below pH 1–4. We have now developed a high pH synthesis procedure and have successfully prepared a series of 3d–4f heptanuclear clusters. During the synthesis process, we observed an interesting phenomenon controlled mainly by the ionic radii of the lanthanide ions. We have tried many times and various molar ratios of reagents to synthesize a $\{LaNi_6\}$ trigonal prismatic cluster, but failed [16]. In our attempted synthesis of $\{LnNi_6\}$ octahedral clusters in aqueous solution, only $\{LaNi_6\}$ and $\{PrNi_6\}$ octahedral clusters could be obtained though we have tried La^{3+}, Pr^{3+}, Nd^{3+}, Sm^{3+}, Eu^{3+}, Gd^{3+} and Er^{3+}. The ionic radii of the lanthanide ions were presumed to play an important role in the synthesis. Of the lanthanide ions, La^{3+} has the largest ionic radius (1.50 Å, 12-coordinated) [21]. In this system it prefers a stable 12-coordinated icosahedral configuration regardless of the molar ratios of reagents employed. For those lanthanide ions following Pr^{3+}, their ionic radii are not large enough to satisfy a 12-coordinate icosahedral configuration, so only $\{LnNi_6\}$ trigonal prismatic clusters have been obtained. Previously a heptanuclear octahedral cluster was synthesized with Sm^{3+} as the central ion and bis(L-prolinato)nickel(II) as the "ligand" in acetonitrile [15]. Thus the solvent can also affect the synthesis of the octahedral cluster, as the coordination ability of water to Ln^{3+} is superior to a non-aqueous solvent molecule. The competition of solvent effect and ionic radii effect account for the fact that $\{LnNi_6\}$ (Ln = Nd–Lu) octahedral clusters cannot be synthesized in aqueous solution.

In order to build new clusters, we tried to introduce some small molecular ligand, such as imidazole or SCN^- into the system, but failed. The $\{LnNi_6\}$ octahedral cluster is so stable that it does not take up any additional ligand.

3.2. IR spectra

Using **1** as an example, the complex has two ν_s(N–H) peaks at about 3350 and 3298 cm^{-1}, compared with 3130 and 3105 cm^{-1} of the free glycinato ligand. The spectrum of **1** also shows two strong peaks at ca. 1414 and 1578 cm^{-1} which may be assigned to stretching vibrations ν_{sym}(COO) and ν_{asym}(COO) of the carboxylate group of glycine. The strong bands at 1090 and 625 cm^{-1} may be assigned to the vibrations of ClO_4^-. The presence of water molecules was proven by the strong and broad OH resonance at 3300–3500 cm^{-1}. The spectra of other complexes were found to be similar to that of **1**, except that **4** has several peaks at about 1621 and 1537 cm^{-1} which may be attributed to the presence of imidazole and **5** has strong peak at about 2083 cm^{-1} (ν(SCN)).

3.3. Description of structures

X-ray diffraction analyses indicate that complexes **1**–**5** all have the same heptanuclear octahedral $\{LnNi_6\}$ cation. In the cations, all the lanthanide atoms sit on crystallographic centres of symmetry and thus the entire clusters are centrosymmetric. The structure of the cation of **1** is shown in Fig. 1 as an example. Selected bond distances and bond angles of **1** are shown in Table 2. The La^{3+} ion is situated in the center of a large octahedral cage formed by six Ni^{2+} ions with La···Ni distances and Ni···Ni distances of about 3.6950(0.0009)–3.7019(0.0009) and 5.2309(0.0013)–5.2424(0.0013) Å, respectively, compared with those observed in the $\{SmNi_6\}$ cluster (3.7 and 5.23 Å, respectively) [15] and the $\{LaNi_6\}$ cluster with imino-carboxylate as the ligand [18a] (3.63 and 5.12–5.15 Å, respectively).

The coordination polyhedron of the O_{12} coordinated centered La^{3+} ion, as shown in Fig. 2, may be best described as an icosahedron. The 12 carboxyl oxygen atoms from 12 glycinato ligands coordinate to the central lanthanide ion with distances of about 2.692–2.761 Å. The average nearest neighboring O···O distance is about 2.745–2.980 Å and the angles between two adjacent metal–ligand bonds are in the range of 61.49–65.80° (see Table 3).

Each Ni atom has an N_2O_4 donor set which consists of two amino nitrogen atoms and four carboxyl oxygen atoms from four glycinato ligands. The Ni–O and Ni–N distances are about 2.04–2.07 Å. For Ni(1), small deviations of bond angles from 180° of the idealized octahedral geometry are found for angles O(1)–Ni(1)–N(2) [174.8(2)°], O(3)–Ni(1)–N(1) [174.5(2)°] and O(6A)–Ni(1)–O(8) [176.5(2)°], implying it has a slightly distorted octahedral configuration. Other Ni ions show similar behavior.

In the cation, each glycinato ligand adopts a η^4-coordination mode, being bound to two Ni^{2+} and one La^{3+}

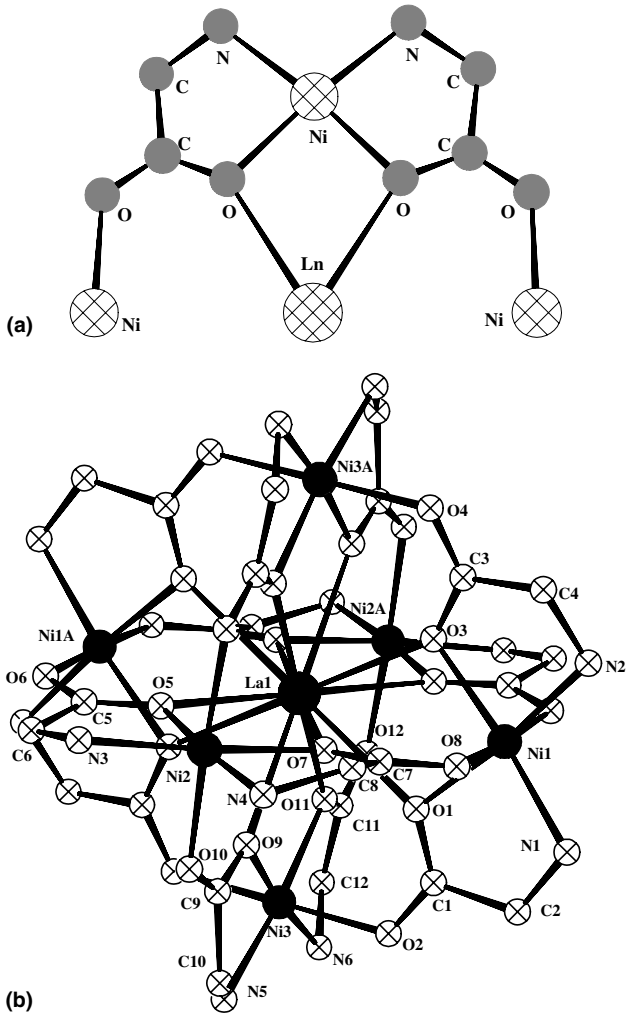

Fig. 1. (a) The structure of the $Ni(Gly)_2$ unit. (b) A perspective view of the $\{LaNi_6\}$ cation of **1** with the atom numbering scheme. Symmetry code: A = $-x + 2$, $-y$, $-z + 1$.

ion (as shown in Scheme 1). The N–Ni–O angles in the five-membered chelate rings formed in the η^4-coordination mode are about 82°.

The structure of the $\{LaNi_6\}$ cation of **2** is same as that of **1**, though **2** crystallizes in a different space group. Another structural difference between **1** and **2** is that **2** has more Na^+ and ClO_4^- ions. Compounds **3** and **1** are isomorphous. Complex **4** has two kinds of cations, and one is the $\{LaNi_6\}$ cluster, the other is $[Ni(im)(H_2O)_5]^{2+}$ (Fig. 3(a)). In the latter, the Ni^{2+} ion is six-coordinated, with an octahedral NO_5 donor set which consists of one nitrogen atom from imidazole and five aqua ligands. The Ni–O and Ni–N distances are in the range of 2.03–2.14 Å. Compound **5** contains the complex anion $[Ni(NCS)_3 \cdot (H_2O)_3]^{-1}$ and the neutral complex $[Ni(NCS)_2 \cdot (H_2O)_4]$ as well as $[LaNi_6(Gly)_{12}]^{3+}$. In $[Ni(NCS)_3 \cdot (H_2O)_3]^{-1}$ and $[Ni(NCS)_2 \cdot (H_2O)_4]$, the Ni^{2+} ions adopt a distorted octahedral configuration and coordinate to nitrogen and oxygen atoms.

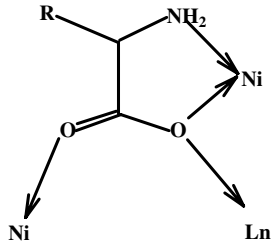
Angle B (max)	118.53(15)	119.22(11)	118.53(13)	118.44(11)	118.48(11)	118.0(2)
Angle C	180	180	180	180	180	180

Note: Angle A is O–Ln–O, where O are adjacent vertices of a triangular icosahedron face, e.g. O(9)–La(1)–O(1) in Table 2. Angle B is O–Ln–O, where O are the unshared vertices of a pair of edge sharing icosahedron faces, e.g. O(1)–La(1)–O(11) in Table 2. Angle C is O–Ln–O, where O are vertices with the longest distance between themselves.



Scheme 1. The η^4-coordination mode of amino acid.

We also obtained well-shaped blue crystals of **6** and **7**. Complex **6** crystallizes in the tetragonal system ($a = b = 27.5708(3)$, $c = 40.3522(7)$ Å) and **7** belongs to the cubic system with $a = b = c = 33.696(8)$ Å. Because of the weak intensities, we only obtained incomplete structures, which indicated both to have an analogous $\{LaNi_6\}$ heptanuclear octahedral metal skeleton.

3.4. Magnetic properties

Temperature dependent magnetic susceptibilities of complexes **1**, **3** and **4** were measured in the range 2–300 K at 10 kOe. Fig. 4 shows the $\chi_M T$ versus T curves for **1** and **3**. At 300 K, the $\chi_M T$ values for **1**, **3** and **4** are 8.35($LaNi_6$), 9.79 ($PrNi_6$), 9.68 $cm^3\,mol^{-1}\,K$ ($LaNi_7$), respectively, larger than the expected values (7.46 $cm^3\,mol^{-1}\,K$ for **1**, 9.06 $cm^3\,mol^{-1}\,K$ for **3**, 8.70 $cm^3\,mol^{-1}\,K$ for **4**) for one Ln^{III} ion with a free-ion state and six or seven spin only Ni^{II} ions ($S = 1$, $g = 2.23$).

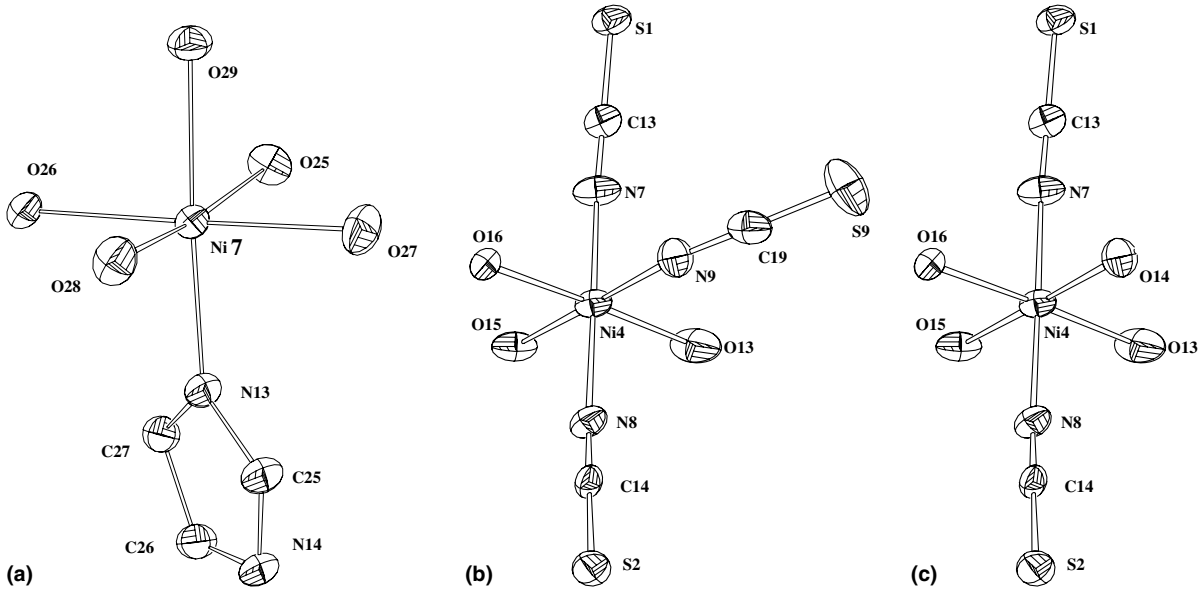


Fig. 3. ORTEP drawing of the complex species in **4** and **5** with the atom numbering scheme (ellipsoids at 25% probability). (a) $[Ni(im)(H_2O)_5]^{2+}$; (b) $[Ni(NCS)_3(H_2O)_3]^-$; (c) $[Ni(NCS)_2 \cdot (H_2O)_4]$.

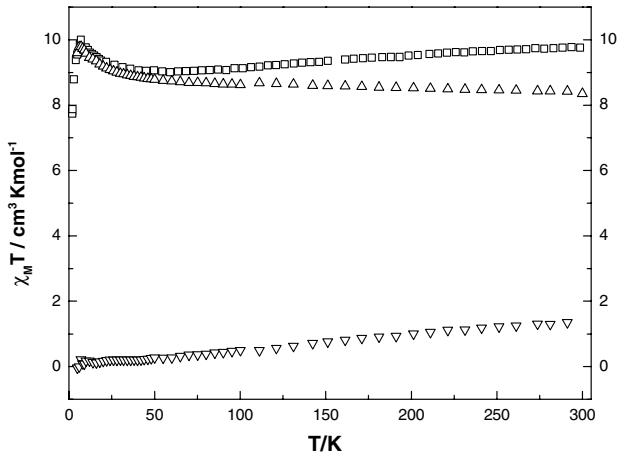

Fig. 4. Plots of $\chi_M T$ vs T for **1** (△) and **3** (□), and for the difference $\Delta\chi_M T = \chi_M T$ (**3**) $- \chi_M T$ (**1**) (▽).

Upon cooling, the $\chi_M T$ value for **1** increase slightly when the temperature is cooled to about 60 K and more rapidly up to about 7 K, where it reaches a maximum of 9.79 cm^3 mol^{-1} K. This phenomenon corresponds to a ferromagnetic interaction. Further decreasing of $\chi_M T$ below 7 K may be due to anisotropic effects, like zero field splitting or spin orbit coupling. This Ni–Ni ferromagnetic interaction in the $LaNi_6$ cluster is also confirmed by the positive Weiss constants ($\theta = 2.35$ K), determined by data in the temperature range 10–300 K. Ferromagnetic coupling was also observed in a similar heptanuclear $NaCu_6$ compound [22]. With the decreasing temperature, $\chi_M T$ for **3** first decreases slowly, reaches 9.35 cm^3 mol^{-1} K at 150 K, and then remains almost constant down to ca. 60 K, where it begins to increase smoothly until reaching a maximum of 10.00 cm^3 mol^{-1} K at ca. 6 K. It shows an overall ferromagnetic interaction, compared with the antiferromagnetic interaction in the $\{PrNi_6\}$ trigonal prismatic cluster [16].

As **1** and **3** are isomorphous, we can deduct the Ni···Ni interaction by subtracting the $\chi_M T$ (**1**) from $\chi_M T$ (**3**), similarly to that done by Kahn and Costes [23]. The $\Delta\chi_M T$ is the sum of the Pr···Ni interaction and the crystal field effect of the Pr^{3+} ion (as shown in Fig. 4). Pr^{3+} ion has a $^3H_4$ ground state and is not a Kramers ion. The crystal field alone can resolve degeneracy to give a non-magnetic ground state [24]. $\Delta\chi_M T$ decreases slowly with decreasing temperature and tends to zero as the temperature approaches absolute zero, suggesting that the Pr···Ni interaction may be small or negligible. As the crystal field effect will also decrease the $\chi_M T$ value upon cooling and we cannot obtain an isostructural $\{PrZn_6\}$ cluster, we cannot tell the nature of the Pr···Ni interaction based on the experiments. The $\chi_M T$ versus T curve of **4** is similar to that of **3** and also shows an overall ferromagnetic interaction with positive Weiss constants ($\theta = 1.53$ K).

4. Conclusion

In summary, a family of seven novel heptanuclear octahedral clusters $\{LnNi_6\}$ have been synthesized, among which five have been characterized by X-ray structure analysis. Previous studies [10c,14,16] and this work together show that under high pH conditions, amino acids have the unique ability in adopting different coordination modes to co-existing different transition metal ions and lanthanide ions to form high-nuclearity 3d–4f-amino acid clusters. Future work will be aimed at the synthesis of high-nuclearity Ln–V, Ln–Cr clusters with novel structures using amino acid ligands.

5. Supplementary data

CCDC 225803-225807 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk).

Abstract

The phosphine complexes bu^i_3PMX (**2a**: M = Cu, X = Cl, **2b**: M = Cu, X = I, **2c**: M = Ag, X = Cl, **2d**: M = Au, X = Cl) were synthesised in high yields from bu^i_3P and MX. Their reaction with $[Li\{\mu\text{-}N(R)C(bu^t)C(H)R\}]_2$ (R = $SiMe_3$) gave the monomeric complexes $bu^i_3PCuN(R)C(bu^t) = C(H)R$ (**3a**) and $bu^i_3PMC(H)RC(bu^t) = NR$ (**3b**: M = Ag, **3c**: M = Au) in moderate to high yields. All compounds were fully characterised by multinuclear NMR spectroscopy, microanalysis [not $bu^i_3PCuN(R)C(bu^t) = C(H)R$ (**3a**) and $bu^i_3PAgC(H)RC(bu^t) = NR$ (**3b**)] and for **2c**, **2d** and **3c** by single crystal X-ray diffraction. The bonding mode in the 1-azaallyl complexes **3a**–**c** was found to depend strongly on the metal ion, with **3a** being an enamide complex and **3b** and **3c** iminoalkyl complexes.

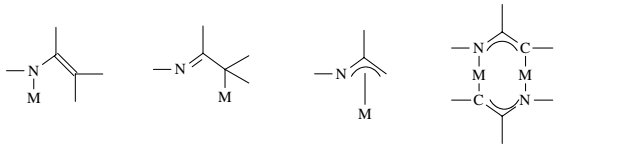
Keywords: Group 11 phosphine complexes; 1-azaallyls; X-ray crystallography; Iminoalkyl bonding mode

1. Introduction

Metal η^3-allyl complexes have been studied extensively and found numerous applications in organic chemistry [1]. 1-Azaallyl complexes in contrast had initially attracted much less interest and have only become popular in the last decade with a recent review [2] summarising the field. The ligands steric and electronic properties have given access to complexes with the metal in an unusual oxidation state or coordination number. Another feature of interest is the ligands flexibility in adopting different bonding modes as shown in **I**–**IV** depending on the substituents on the ligand, the nature of the metal and the presence or absence of a neutral co-ligand(s) [2].



I η^1-enamide complex; II η^1-iminoalkyl complex; III η^3-azaallyl complex; IV μ^2-bridging complex

As part of our continuing investigations into the chemistry of the 1-azaallyl ligand in the context of Group 11 metals we have previously reported the bridged (**IV**), dimeric complexes $[CuLL']_2$ [L′ = $RNC(bu^t)CHR$] [3], $[MLL'']_2$ [4] [M = Cu, Au, LL″ = RNC(Ph)CR_2], the monomeric phosphine adduct Ph_3PCuLL' [3] and a lithium cuprate $(dme)_3LiCu(LL')_2$ (dme = 1,2 dimethoxyethane; R = $SiMe_3$) [3]. It was shown that Ag and Au analogues of $[CuLL']_2$ were

doi:10.1016/j.poly.2004.07.008

not stable and attempts to their synthesis led to the reduction of the Group 11 metal precursor by the ligand transfer reagent $[LiLL']_2$ [5]. The sterically more demanding ligand LL″ [6] provided access to $[AuLL'']_2$ [4] but a silver analogue remained elusive. In this paper we report the synthesis, solid and solution structures of a series of phosphine stabilised Group 11 metal 1-azaallyl complexes bu^i_3PMLL' and their metal halide precursors.

2. Experimental

2.1. Reagents and general procedures

All manipulations were carried out under argon, using standard Schlenk techniques. Solvents were distilled from drying agents and degassed. The NMR spectra were recorded in C_6D_6 at ambient probe temperature using the following Bruker instruments: DRX 400 (^{1}H, 400.13 MHz, ^{31}P, 162.0 MHz), DXP 300 (^{1}H, 300.13; ^{13}C 75.5 MHz) or AC200 (^{1}H, 200.13 MHz) and referenced internally to residual solvent resonances (chemical shift data in δ). ^{13}C NMR spectra were all proton-decoupled. Elemental analyses were determined by the Institute for Soil, Climate and Water, Pretoria, South Africa. The following abbreviations are used throughout this section: bs = broad singlet, d = doublet, dd = doublet of doublet, m = multiplet, s = singlet. Coupling constants (J) are given in Hz. Me_2SAuCl [7] was synthesised according to the literature [8].

2.2. Synthesis of phosphine complexes

2.2.1. Synthesis of bu^i_3PCuCl (**2a**)

(a) bu^i_3P (0.64 cm^3, 2.53 mmol) was added to a suspension of CuCl (0.25 g, 2.53 mmol) in thf (20 cm^3). The initially yellow, later colourless solution was stirred for 3 h at room temperature. The solvent was removed in vacuo and the residue extracted into hexane. The solution was filtered of some dust and the solvent was then removed from the filtrate to give a colourless, viscous oil, that was sufficiently pure for further reactions.

(b) bu^i_3P (0.80 cm^3, 3.16 mmol) was added to acetonitrile (25 cm^3) followed by the addition of CuCl (0.38 g, 3.84 mmol). The resulting mixture was stirred overnight to give a colourless solution. After keeping the reaction mixture for two days at −20 °C colourless crystals of bu^i_3PCuCl (**2a**) (0.35 g, 30%) were isolated. ^{1}H NMR (C_6D_6): δ = 1.02 [d, CHMe_2, 18H, $^3J_{H-H}$ = 6.6 Hz], 1.22 [dd, CH_2, 6H, $^2J_{P-H}$ = 10.5 Hz; $^3J_{H-H}$ = 6.6 Hz], 2.03 (m, CHMe$_2$, 3H); ^{13}C NMR (C_6D_6): δ = 24.0 (s, CHMe_2), 26.3 (br s, CHMe$_2$), 37.5 (br s, CH$_2$); ^{31}P NMR (C_6D_6): δ = −25.1.

2.2.2. Synthesis of bu^i_3PCuI (**2b**)

CuI (0.38 g, 2.00 mmol) was dissolved in 25 cm^3 acetonitrile. The solution was cooled to 0 °C and 0.50 cm^3 (2.00 mmol) bu^i_3P were added. Immediately a colourless precipitate formed that was isolated by removing all volatiles in vacuo to give 0.82 g of crude material. Recrystallisation from diethyl ether (25 cm^3) at −60 °C gave colourless crystals of bu^i_3PCuI (**2b**) (0.53 g, 67%). (Found: C, 36.48; H, 6.97. $C_{12}H_{27}CuI$ requires C, 36.70; H, 6.93%); ^{1}H NMR (C_6D_6): δ = 1.05 [d, CHMe_2, 18H, $^3J_{H-H}$ = 8.8 Hz], 1.39 [dd, CH_2, 6H, $^2J_{P-H}$ = 9.6 Hz; $^3J_{H-H}$ = 9.4 Hz], 2.05 (m, CHMe$_2$, 3H); ^{13}C NMR (C_6D_6): δ = 25.3 [d, CHMe_2, $^3J_{C-P}$ = 7.8 Hz], 26.0 [d, CHMe$_2$, $^2J_{C-P}$ = 3.8 Hz], 36.7 [d, CH$_2$, $^1J_{C-P}$ = 36.7 Hz]; ^{31}P NMR (C_6D_6): δ = −29.6.

2.2.3. Synthesis of bu^i_3PAgCl (**2c**)

A mixture of AgCl (0.29 g, 2.00 mmol) and bu^i_3P (0.50 cm^3, 2.00 mmol) was stirred in 25 cm^3 acetonitrile overnight. After filtration and cooling the filtrate to −20 °C colourless crystals of bu^i_3PAgCl (**2c**) (0.61 g, 87%) were obtained. (Found: C, 42.14; H, 8.10. $C_{12}H_{27}AgCl$ requires C, 41.70; H, 7.87%); ^{1}H NMR (C_6D_6): δ = 1.08 [d, CHMe_2, 18H, $^3J_{H-H}$ = 8.4 Hz], 1.30 [dd, CH_2, 6H, $^2J_{P-H}$ = 9.7 Hz; $^3J_{H-H}$ = 9.6 Hz], 2.02 (m, CHMe$_2$, 3H); ^{13}C NMR (C_6D_6): δ = 25.0 (m, CHMe_2), 26.9 (br s, CHMe$_2$), 37.8 (m, CH$_2$); ^{31}P NMR (C_6D_6): δ = −15.6 [d, ^1J = 599.4 Hz]; ^{31}P NMR (C_7D_8) (−15 °C): δ = −16.1 [dd, $^1J(^{31}P-^{107}Ag)$ 592.2 Hz; $^1J(^{31}P-^{109}Ag)$ 683.3 Hz].

2.2.4. Synthesis of bu^i_3PAuCl (**2d**)

Me_2SAuCl (1.00 g, 3.4 mmol) was dissolved in thf (approx. 25 cm^3) at room temperature and 0.87 g (4.3 mmol) bu^i_3P was added. The resulting mixture was stirred for 2 h. The solution was concentrated to 2/3 of its volume and stored at −20 °C to give colourless crystals of bu^i_3PAuCl (**2d**) (1.31 g, 89%). (Found: C, 33.34; H, 6.29. $C_{12}H_{27}AuCl$ requires C, 33.15; H, 6.26%); ^{1}H NMR (C_6D_6): δ = 0.86 [d, CHMe_2, 18H, $^3J_{H-H}$ = 6.7 Hz], 1.09 [dd, CH_2, 6H, $^2J_{P-H}$ = 10.4 Hz;$^3J_{H-H}$ = 6.7 Hz], 1.56 (m, CHMe$_2$, 3H); ^{13}C NMR (C_6D_6): δ = 24.6 [d, CHMe_2 $^3J_{C-P}$ = 19.0 Hz], 26.3 (s, CHMe$_2$), 36.7 [d, CH$_2$, $^1J_{C-P}$ = 74.5 Hz]; ^{31}P NMR (C_6D_6): δ = 11.9.

2.2.5. Synthesis of $bu^i_3PCuN(R)C(bu^t)=C(H)R$ (**3a**)

(a) bu^i_3P (0.29 cm^3, 1.18 mmol) was dissolved in hexane (12 cm^3) and added dropwise at −40 °C to a solution of $[CuN(R)C(bu^t)=CHR]_2$ (0.36 g, 0.58 mmol). The reaction mixture was allowed to warm up to room temperature and stirred for 1.5 h to give a yellow reaction mixture that was filtered. The filtrate was concentrated and cooled to −60 °C to give colourless crystals of $bu^i_3PCuN(R)C(bu^t)=CHR$ (**3a**) (0.29 g, 48%).

(b) A solution of $LiC(H)RC(bu^t)NR$ (0.40 g, 1.60 mmol) in hexane (10 cm^3) was added to a solution of

bu^i_3PCuCl (**2a**) (0.48 g, 1.60 mmol) in hexane (20 cm^3) at −20 °C. The reaction mixture was allowed to warm up to room temperature and stirred for 6 h to give a pale yellow, slightly turbid solution. Filtration of the reaction mixture and concentration of the filtrate gave after cooling to −60 °C colourless crystals of **3a** (0.51 g, 63%). Isolation of the crystals by removal of the mother liquor led to a slow decomposition of the sample as evident by the crystals turning brown and becoming sticky. ^{1}H NMR (C_6D_6): δ = 0.45 (s, Si*Me*$_3$, 9H), 0.49 (s, Si*Me*$_3$, 9H), 0.94 [d, CH*Me*$_2$, 18H, $^3J_{H-H}$ = 6.6 Hz], 1.38 [dd, C*H*$_2$, 6H, $^2J_{P-H}$ = 16.8 Hz; $^3J_{H-H}$ = 3.4 Hz], 1.41 (s, C*Me*$_3$, 9H), 1.66 (m, C*H*Me$_2$, 3H), 4.95 (s, C*H*, 1H); ^{13}C NMR (C_6D_6) δ = 2.3 (s, NSi*Me*$_3$), 5.1 (s, CSi*Me*$_3$), 25.0 [d, CH*Me*$_2$, $^3J_{C-P}$ = 8.3 Hz], 26.2 [d, *C*HMe$_2$, $^2J_{C-P}$ = 3.0 Hz], 32.0 (s, C*Me*$_3$), 37.0 [d, *C*H$_2$, $^1J_{C-P}$ = 24.5 Hz], 40.0 (s, *C*Me$_3$), 103.1 (s, *C*H), 177.8 (s, *C*N); ^{31}P NMR (C_6D_6) δ = −19.2.

2.2.6. Synthesis bu^i_3PAgC(H)RC(bu^t)=NR (**3b**)

A solution of LiC(H)RC(bu^t)NR (0.38 g, 1.52 mmol) in hexane (10 cm^3) was added dropwise to a solution of (bu^i)$_3$PAgCl (**2c**) (0.45 g, 1.3 mmol) in hexane (10 cm^3) at −60 °C. The reaction mixture was kept at that temperature for 20 min and then slowly warmed to room temperature. The reaction mixture was stirred for 6 h at room temperature to give a yellow solution with a fine black precipitate. The solvent was removed in vacuo to give a blackish/white solid that was found to be light and temperature sensitive. The solid was extracted with hexane (30 cm^3), it was filtered and the pale brown filtrate was concentrated (to approx. 4 cm^3) and cooled to −60 °C to give after several days slightly brownish, highly sensitive crystals of **3b** (0.42 g, 58%). ^{1}H NMR (C_6D_6): δ = 0.51 (s, Si*Me*$_3$, 9H), 0.54 (s, Si*Me*$_3$, 9H), 0.92 [d, CH*Me*$_2$, 18H, $^3J_{H-H}$ = 6.5 Hz], 1.05 (bs, C*H*$_2$, 6H), 1.43 (s, C*Me*$_3$, 9H), 1.63 (bs, C*H*Me$_2$, 3H), 3.50 (s, C*H*, 1H); ^{13}C NMR (C_6D_6): δ = 2.8 (s, CSi*Me*$_3$), 4.6 (bs, NSi*Me*$_3$), 24.6 [d, CH*Me*$_2$, $^3J_{C-P}$ = 9.0 Hz], 26.7 [d, *C*HMe$_2$, $^2J_{C-P}$ = 5.9 Hz], 31.5 (s, *C*Me$_3$), 37.5 [d, *C*H$_2$, $^1J_{C-P}$ = 15.1 Hz], 41.7 (s, *C*Me$_3$), 60.1 (s, *C*H), 189.8 (s, *C*N); ^{31}P NMR (C_6D_6): δ = −17.4 (bs).

2.2.7. Synthesis bu^i_3PAuC(H)RC(bu^t)=NR (**3c**)

To a solution of (bu^i)$_3$PAuCl (**2d**) (0.68 g, 1.56 mmol) in diethyl ether (40 cm^3) was added dropwise a solution of LiC(H)RC(bu^t)NR (0.39 g, 1.56 mmol) in diethyl ether (20 cm^3) at −60 °C. Initially a white precipitate was formed that redissolved at −40 °C to give a colourless solution once the reaction mixture had reached room temperature. After stirring for 1 h at room temperature a fine colourless precipitate started to form. The reaction mixture was stirred overnight and the solvent removed in vacuo to give a colourless solid. Extraction with hexane (30 cm^3) and filtration gave a colourless solution that was concentrated and cooled to −20 °C. A first crop of crystals (0.18 g, 0.4 mmol, 26%) was identified as starting material **2d**. Concentration of the mother liquor and cooling to −60 °C gave colourless crystals of **3c** (0.68 g, 68%). (Found: C, 44.03; H, 7.61; N 2.05. $C_{24}H_{55}AuNPSi_2$ requires C, 44.91; H, 8.64; N 2.18%); ^{1}H NMR (C_6D_6): δ = 0.45 (s, Si*Me*$_3$, 9H), 0.49 (s, Si*Me*$_3$, 9H), 0.98 [d, CH*Me*$_2$, 18H, $^3J_{H-H}$ = 8.0 Hz], 1.15 [dd, C*H*$_2$, 6H, $^2J_{P-H}$ = 9.6 Hz; $^3J_{H-H}$ = 6.8 Hz], 1.39 (s, C*Me*$_3$, 9H), 1.88 (m, C*H*Me$_2$, 3H), 3.01 [d, C*H*, 1H, $^3J_{P-H}$ = 10.9 Hz]; ^{13}C NMR (C_6D_6): δ = 2.1 (s, CSi*Me*$_3$), 3.0 (bs, NSi*Me*$_3$), 24.9 [d, CH*Me*$_2$, $^3J_{C-P}$ = 8.05 Hz], 26.4 (s, *C*HMe$_2$), 30.7 (s, C*Me*$_3$), 38.3 [d, *C*H$_2$, $^1J_{C-P}$ = 47.2 Hz], 42.3 (s, *C*Me$_3$), 50.3 [d, *C*H, $^2J_{C-P}$ = 56.3 Hz], 193.7(s, *C*N); ^{31}P NMR (C_6D_6): δ = 21.4.

2.3. Crystal structure determination

Intensity data were collected on a Bruker SMART 1K CCD area detector diffractometer with graphite monochromated Mo Kα radiation (50 kV, 30 mA). The collection method involved ω-scans of width 0.3°. Data reduction was carried out using the program SAINT+ [9] and face indexed absorption corrections were made using the program XPREP [9].

The crystal structures were solved by direct methods using SHELXTL [10]. Non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full matrix least-squares calculation based on F^2 using SHELXTL. Hydrogen atoms were located from the difference map and then positioned geometrically and allowed to ride on their respective parent atoms. The isobutyl groups of compound **2c** exhibited very large thermal vibration as indicated by the large thermal ellipsoids. Attempts to apply a disorder model proved to be unsuccessful. Several low temperature collections were attempted on crystals grown from various solvents without success due to a phase transition at around −70 °C. A data collection at −50 °C was found to be of lower quality than the presented room temperature data. Bond lengths and angles from **2d** were used as restraints in the final structure solution of **2c**. Compound **3c** was found to be disordered in a ratio of 0.9379(8):0.0621(8) although only a partial refinement on the minor component was possible. Only the equivalent atoms of Au, P, C2, C13, C17 and C21 were refined as a rigid body on the disordered component, with the occupancies of the two components being summed to unity. This was necessary as a refinement of the major component only would lead to a residual peak of about 9 e $Å^{-3}$ corresponding to the Au atom from the minor component.

Further crystallographic data are summarised in Table 1. Diagrams and publication material were generated using SHELXTL [10], PLATON [11] and ORTEP3 [12].

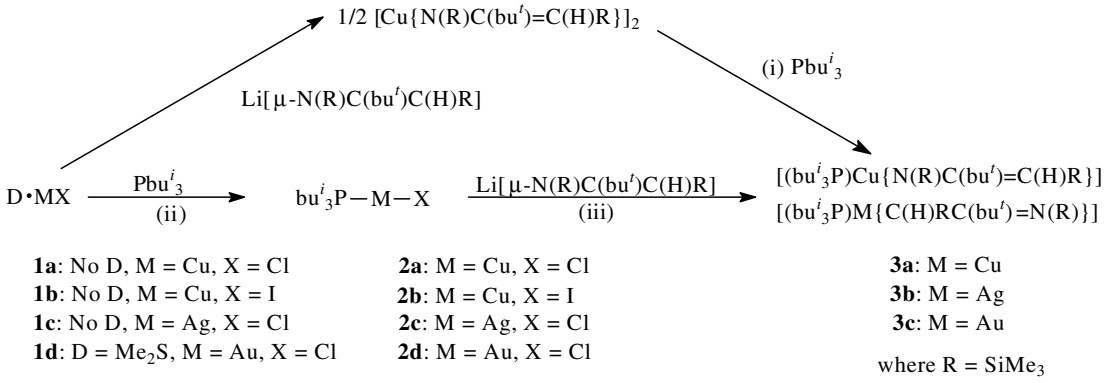
3. Results and discussion

3.1. Synthesis

Ph_3PCuLL' had previously been synthesised by the addition of stoichiometric amounts of triphenylphosphine to the dimeric complex $[CuLL']_2$ [LL′ = RNC(bu^t)CHR, R = $SiMe_3$] [3] [cf. (i) in Scheme 1]. The same synthetic route gave the copper complex bu^i_3PCuLL' (**3a**) in moderate yield [(i) in Scheme 1] but was not applicable for the Ag and Au analogues as the respective parent compounds [MLL′] were not accessible. It was, therefore, decided to first synthesise the easily accessible and stable phosphine adducts bu^i_3PM-X (**2a**–**d**) from the metal halides and free phosphine [(ii) in Scheme 1], which were then reacted with $[LiLL']_2$ [5] to give the 1-azaallyl complexes bu^i_3PMLL' (**3a**–**c**) [(iii) in Scheme 1]. Pbu^i_3 was selected as the phosphine of choice as its sterically demanding alkyl groups were expected to convey stability to the metal complexes as well as solubility in non-polar solvents. Preliminary experiments involving the treatment of $(Me_2S)AuCl$ with PPh_3 and subsequent reaction with $[LiLL']_2$ [5] led to the NMR-spectroscopically characterised complex Ph_3PAuLL' but attempts to purify the product by recrystallisation were unsuccessful. The bu^i_3P-derivatives (**3a**–**c**) were in contrast obtained after recrystallisation from hexane as colourless, air- and moisture sensitive crystals in moderate to high yields. While **3c** was indefinitely stable at room temperature in an inert gas atmosphere, the copper (**3a**) and especially the silver analogue (**3b**) were found to be sensitive to light and heat, depositing metal from dissolved and solid samples of the complex even at low temperatures. An attempt to synthesise the aurate complex $(dme)_3LiAu(LL')_2$ from **3c** and a second equivalent of $[LiLL']_2$ [5] in the presence of dme was not successful and led to the recovery of the starting materials.

3.2. NMR-spectroscopic studies and solution behaviour

It had been shown previously that ^1H and ^{13}C NMR spectroscopy is a powerful tool to distinguish different



Scheme 1. Synthesis of Group 11 metal 1-azaallyl complexes.

Table 2
Selected NMR-spectroscopic data of 1-azaallyl metal complexes

Compound	CH (^{1}H)	CH (^{13}C)	CN (^{13}C)	^{31}P	Bonding mode	Ref.

LL′ = C(H)RC(bu^t)NR.

bonding modes in 1-azaallyl complexes [3,13]. Table 2 summarises NMR-spectroscopic data of **3a**–**c** and some related metal complexes featuring the LL′ ligand. Previously a signal at low frequency in the ^{1}H ($\delta \approx 3$) and ^{13}C ($\delta \approx 50$) NMR spectrum for CH and a signal at high frequency for CN ($\delta \approx 190$) was found to be indicative for an iminoalkyl metal complex (**II**) while the reverse situation with signals for CH at high frequency [$\delta \approx 5$ (^{1}H), 100 (^{13}C)] and CN at low frequency [$\delta \approx 180$ (^{13}C)] were observed for enamide metal complexes (**I**). In line with this interpretation the copper phosphine complexes Ph_3PCuLL' and bu^i_3PCuLL' (**3a**) may be classified as enamide complexes (**I**) with a direct bond between Cu and N and no direct contact to CH while the heavier analogues bu^i_3PAgLL' (**3b**), Ph_3PAuLL' and bu^i_3PAuLL' (**3c**) are better described as iminoalkyl complexes (**II**).

Further support for this classification comes from the ^{1}H and ^{13}C NMR spectra of **3c** that show doublets for the CH group of the 1-azaallyl ligand with coupling constants ^3J(P,H) and ^2J(P,C) of 10.9 (10.5 for Ph_3PAuLL') and 56.3 Hz, respectively, as a consequence of coupling to P. Coupling constants for ^3J(P,H) in the region of 4–16 Hz and ^2J(P,C) around 100 Hz have been reported for other phosphine alkyl complexes [14–18].

The silver complex **3b** in contrast showed singlets in the ^{13}C NMR ($\delta = 24.6$) and the ^{1}H NMR spectrum ($\delta = 3.50$). The latter was broad and probably not resolved due to additional J(Ag,C) coupling and the occurrence of exchange between **3b** and free bu^i_3P formed from the decomposition of the silver complex. Similar observations have previously been described for phosphine gold complexes $RAuPR'_3$ (R = alkyl, R′ = alkyl, aryl) where the doublet of the HCAu-fragment either broadens significantly [18] or else collapses to a sharp singlet [17] as a consequence of the addition of small quantities of free phosphine to the metal complexes.

A noteworthy observation is the appearance of two overlapping doublets [attributable to unequal $^1J(^{31}P–^{109}Ag)$ and $^1J(^{31}P–^{107}Ag)$ coupling constants] in the $^{31}P\{^1H\}$ NMR spectrum at near ambient temperature (298 K). This is unusual for monodentate phosphine silver complexes, since rapid ligand exchange usually precludes the observation of P–Ag spin–spin coupling. For example, for a series of $XAg\{P(p\text{-tol})_3\}_n$ complexes (where $n = 2$–4 and X = a range of counter-anions), the ligands were labile in all the complexes studied so that P–Ag spin–spin coupling was not resolved above −70 °C [19]. Where ligands are too sterically encumbered to

participate in the association process believed to be involved in the exchange, most notably, $XAg(PMe_3)_2$ and $XAg(Pbu^t_3)_2$, well resolved P–Ag spin–spin coupling is exhibited at ambient temperature [20,21].

Consistent with the copper complexes being enamide complexes (**I**) no coupling was observed in their ^1H or ^{13}C NMR spectrum. The solid state structures of Ph_3PCuLL' [3], $(dme)_3LiCuLL'_2$ [3] and bu^i_3PAuLL' (see below) lend the above arguments further support.

The distinction between an η^3-1-azaallyl (**III**) and an iminoalkyl metal complex (**II**) on the basis of NMR spectroscopy is, however, more ambiguous as may be deduced from the close similarity of the NMR-spectrum (cf. Table 2) of $Ph_3PNi(I)LL'$ [22] as an example for an η^3-1-azaallyl complex (**III**) and the discussed iminoalkyl metal complexes (**II**).

The observed difference in bonding modes between Cu- and Ag/Au-azaallyl complexes, respectively, may be explained on the basis of HSAB theory [23] with the softer, larger metal ion [Ag(I), Au(I)] having a preference for the softer atom (C^-) of the bidentate 1-azaallyl ligand and the harder cation [Cu(I)] binding preferentially to the harder atom (N^-).

3.3. Solid state structures of complexes *2c*, *2d* and *3c*

Copper- and silver phosphine halides of monodentate phosphines are frequently found to aggregate in the solid state into dimers or higher molecular species by increasing the coordination number of the metal via additional metal halogen bonds [24,25]. Gold analogues in contrast are known to show linear two coordinate metal atoms that may dimerise via relativistic Au···Au interactions [25,26]. In order to minimise steric repulsion between the phosphine substituents while at the same time maximising aurophilic interactions the dimers are arranged in a paddle-like fashion with P–Au–Au–P torsion angles close to 90° [25–27]. Mononuclear complexes in contrast are found in case of sterically demanding phosphines with cone angles [28] larger than 130°.

In line with these general trends the crystal structures of **2c** and **2d** show no surprises. $[bu^i_3PAgCl]_4$ (**2c**) crystallises as a tetramer with a cubic AgCl core that has threefold rotation symmetry (Fig. 1). The Cl–Ag–Cl and Ag–Cl–Ag angles (see Table 3) are close to 90° with the former being slightly larger [92.67(8)–94.00(6)°] than the latter [86.03(8)–87.50(6)°]. A considerable larger distortion of the cube was observed in $[(2\text{-}Py_2Ph)PAgCl]_4$ [29] and $[Ph_3PAgCl]_4$ [30]. The Ag–P and Ag–Cl distances of 2.371(2), 2.383(4) and 2.645(3), 2.648(2), 2.690(2), 2.676(3) Å, respectively, in **2c** compare well to those found in related complexes such as $[(H_{11}C_6)_3PAgCl]_4$ [31] or $[Et_3PAgCl]_4$ [32] (see also [26,27]).

bu^i_3PAuCl (**2d**) (cone angle for Pbu^i_3 143°) [28] is a monomer (shortest Au···Au contact 4.450 Å; Fig. 2(a), Table 4) in the solid state with a linear two coordinate gold atom [(P–Au–Cl 178.41(3)°]. The Au–P and Au–Cl bond distances of 2.239(1) and 2.292(1) Å are comparable to related complexes such as $(c\text{-}H_{11}C_6)_3PAuCl$ [33], $(H_7C_{10})_3PAuCl$ [8], (TPA)-AuCl (TPA = 1,3,5-triaza-7-phosphaadamantane) [27], Et_3PAuCl [34], $(NCCH_2CH_2)_3PAuCl$ [35], $2\text{-}Py_3PAuCl$ [36], Ph_3PAuCl [37] or Pr^i_3PAuCl [38] but slightly shorter than those in related silver complexes. This is thought to be a consequence of the relativistic contraction of gold [25,39]. Two monomeric units of **2d** are linked via weak CH···Cl contacts (C1–H1···C1′ 2.82 Å, Fig. 2(b)) between the Cl atom and a CH_2 group of the neighbouring phosphine (Fig. 2(b)). $(c\text{-}H_{11}C_6)_3PAuCl$ was found to associate in a similar fashion to polymeric chains (Cl···HC 2.91–3.27 Å) [33a].

Compound **3c** crystallises in the monoclinic space group $P2(1)/n$ with one molecule in the asymmetric unit (Fig. 3, Table 5). It is a monomer with a linear P–Au–C unit [P–Au–C2 178.3 (1)°] and represents to the best of

our knowledge the first example of a crystallographically characterised 1-azaallyl complex that adopts an iminoalkyl configuration (**II**) and may be best compared to the enolate complex $Ph_3PAuCH_2C(O)Ph$ [40]. The Au–P distance of 2.284(1) Å is unexceptional as is the Au–C2 distance of 2.100(5) Å that is within the range expected for a Au–C σ bond to an sp^3-hybridised C-atom [$Ph_3PAuCH_2C(O)Ph$ [40], $Ph_3PAuCH_2CH_2C(O)Ph$ [40], $Ph_3PAuC_5HPh_4$ [18], Ph_3PAuMe [41], Ph_3PAuCH_2Cl [15], Ph_3PAuCH_2SPh [15], $Ph_3PAuCH(SiMe_3)_2$ [14], ($Ph_3PAuC_{13}H_9$ [16]) but slightly longer than those found in aryl gold complexes as for example $Ph_3PAuC_6H_3(OMe)_2$-2,6 [42], $bu^{t}_{3}PAuPh$ [43], $Ph_3PAuC_4H_4O$ [44] or $Ph_3PAuC_6H_3Mes_2$-2,6 [45] (2.04–2.08 Å). The coordination geometry around C2 is a distorted tetrahedron with the angle C1–C2–Si1 (114.2°) between the two sterically most demanding groups showing the largest deviation from 109.5°. The iminoalkyl configuration is further confirmed by the C1–C2 and C2–N bond distances of 1.493(7) and 1.2666(6) Å that correspond to C–C single and CN double bonds, respectively. The sum of angles of 360° around the N atom are in line with an sp^2-hybridisation at the N.

4. Supplementary data

Full crystallographic data (CCDC No. 232066 for compound **2c**, 232067 for compound **3c** and 232068 for

compound **2d**) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; Email: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Ferrocenyldithiodiphosphetane [FcPS(μ-S)]$_2$ [Fc = Fe(η^5-C_5H_4)(η^5-C_5H_5)] reacts with the aminoethanol derivatives $HOCH_2CH_2NHMe$ and $HOCH_2CH_2NEt_2$ to give the first structurally characterised examples of zwitterionic (*O*-ethylammonium)ferrocenyldithiophosphonates, [FcP(S)S($OCH_2CH_2NHR^1R^2$)] (R^1 = H, R^2 = Me (**1**); R^1 = R^2 = Et (**2**)). **1** and **2** were characterised by elemental analyses, IR, NMR spectroscopy (^{1}H, ^{13}C (for **2**) and ^{31}P) and mass spectrometry. A crystal structure determination was carried out on **1**.

1. Introduction

Organophosphorus-containing dithiolato-type compounds are of interest due to their agricultural and industrial applications, such as insecticides, pesticides, antioxidants, additives for lubricants, solvent-extraction reagents for metals and flotation agents for mineral ores [1,2]. Reactions of [FcPS(μ-S)]$_2$ [Fc = Fe(η^5-C_5H_4)(η^5-C_5H_5)] [3] with alcohols [4–7] or sodium alkoxides [8], silanols [6,9], dienes [10,11], alkenes [11] and cyanamides [12,13] were already described.

We now report the reaction of [FcPS(μ-S)]$_2$ with methylaminoethanol and diethylaminoethanol to give the zwitterionic complexes [FcP(S)S($OCH_2CH_2NHR^1R^2$)] (R^1 = H, R^2 = Me (**1**); R^1 = R^2 = Et (**2**)), in which the H atom of the initially formed P–SH group was transferred to the amino group (Scheme 1). We also report the molecular structure of **1**, which to the best of our knowledge is the first example of this type of compounds to be structurally characterised.

2. Results and discussion

We previously observed that [FcPS(μ-S)]$_2$ [3] reacts with alcohols ROH (R = Me, Et, Pr^i, Bu^s, Bu^i) to give the corresponding ferrocenyldithiophosphonic acids [FcPS(OR)(SH)], which could, however, not be isolated in pure form, but were sufficiently pure for further reaction with nickel(II) acetate to yield the square-planar heterobimetallic trinuclear complexes [{FcP(OR)S$_2$}Ni] [7]. We have therefore now employed aminoalcohols as bifunctional reagents in an attempt to prepare the corresponding ferrocenyldithiophosphonic acids [FcPS($OCH_2CH_2NR^1R^2$)(SH)], which could act as *S*,*S*′ chelating ligands towards soft transition metals and simultaneously as amino ligands towards hard transition metals, thus enabling the synthesis of multinuclear complexes.

$R^1 = H$, $R^2 = Me$ (**1**)
$R^1 = R^2 = Et$ (**2**)

Scheme 1.

However, reaction of 2,4-diferrocenyl-1,3-dithiadiphosphetane 2,4-disulfide $[FcPS(\mu\text{-}S)]_2$ with the aminoethanol derivatives $HOCH_2CH_2NHMe$ and $HOCH_2CH_2NEt_2$ in a 1:2 ratio gave the zwitterionic complexes $[FcP(S)S(OCH_2CH_2NHR^1R^2)]$ ($R^1 = H$, $R^2 = Me$ (**1**); $R^1 = R^2 = Et$ (**2**)) as yellow solids in good yield (Scheme 1).

Compounds **1** and **2** were characterised by elemental analyses (C, H, N, S), ^1H and ^{31}P NMR and IR spectroscopy and by MS. The solubility of **1** is very low, even in $CHCl_3$ and CH_3CN, in which **2** is slightly soluble. Both compounds are soluble in DMSO, but decomposition occurs with the yellow solution turning darker. Therefore, ^{13}C NMR spectra could only be obtained for **2**, but the signal of the *ipso*-C atom of the cyclopentadienyl ring could not be observed due to low solubility in $CDCl_3$. The ^1H NMR spectra of **1** and **2** are consistent with the formation of zwitterionic dithiodiphosphonates, as indicated by a broad singlet at δ 9.85 (for **1**) and 11.50 ppm (for **2**), which can be assigned to the NH proton of the ammonium group [14]. In the ^{31}P NMR spectra of **1** and **2** triplets are observed at 114.1 and 115.4 ppm ($^2J_{PH} = 14.8$ and 16.5 Hz) due to coupling to the OCH_2 protons. Due to low solubility, no NMR data are available for the starting material $[FcPS(\mu\text{-}S)]_2$ [3], but similar chemical shifts and coupling constants were observed in [FcP(S)(SH)(OR)] and $[\{FcP(OR)S_2\}_2Ni]$ [7].

In the IR spectra of **1** and **2** characteristic bands are observed for νPO (1025 or 1028 cm^{-1}), and two strong bands about at 654 or 656 cm^{-1} and 582 or 584 cm^{-1} are attributed to $\nu_{asym}(PS_2)$ and $\nu_{sym}(PS_2)$, respectively. A medium band at 2745 (for **1**) or 2697 cm^{-1} (for **2**) can be attributed to the N-H vibration in the ammonium salt [14].

In the ESI mass spectra of **1** and **2** molecular ion peaks are observed at *m/z* 355 and 397, respectively, while only fragment ions (*m/z* 121 (CpFe), 186 (Fc) and 217 (FcP)) occur in the EI mass spectrum. In the ESI mass spectrum, signals for a dimer (for **1** and **2**) and trimer (for **1**) are also observed.

Compounds **1** and **2** do not dissolve in water but dissolve in aqueous NaOH, probably with formation of the sodium salts $Na[FcP(S)S(OCH_2CH_2NR^1R^2)]$ ($R^1 = H$, $R^2 = Me$; $R^1 = R^2 = Et$). Attempts to isolate these salts by evaporating the solvent at room temperature produced only **1** or **2** and NaOH. This reaction is presently under further investigation.

Attempts to prepare transition metal complexes of **1** and **2** by reaction with nickel acetate in acetic acid/chloroform, $ZnSO_4$ in aqueous NaOH or cadmium acetate in chloroform/ethanol were unsuccessful; no reaction was observed under these conditions.

3. Molecular structure of 1

Single crystals of **1** were obtained from $CHCl_3$/CH_3CN. Compound **1** crystallises in the orthorhombic space group *Pbca* with $Z = 8$. The crystallographic data indicate that **1** is a zwitterion (Fig. 1). The P–S(1) and P–S(2) bond lengths are similar (1.975(1) and 1.993(1) Å) and longer than observed for a P–S double bond (1.94 Å) [15] as would be expected for a delocalised PS_2 fragment. The phosphorus atom has a tetrahedral coordination environment with a small O(1)–P–C(1) bond angle (97.5(1)°) and three bond angles (O(1)–P–S(1), O(1)–P–S(2) and C(1)–P–S(2)) close to the ideal value of 109.5°

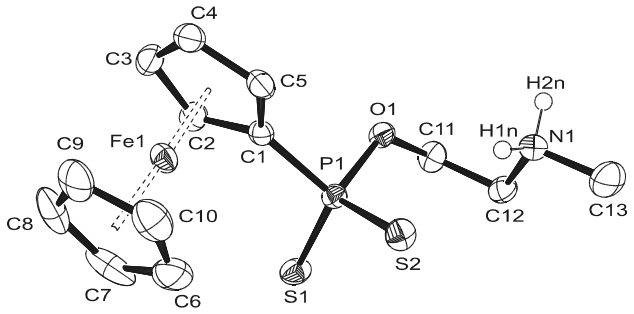

Fig. 1. Molecular structure of **1** (ORTEP, 50% probability, SHELXTL PLUS; XP) [18].

(110.03(9), 108.36(8) and 109.8(1)°). However, larger bond angles (112.5(1) and 116.91(5)°) are observed for C(1)–P–S(1) and S(1)–P–S(2), respectively, probably due to steric reasons (see Table 2).

4. Experimental

Solvents were dried and distilled prior to use by standard methods. Compounds were handled with exclusion of air and moisture. $[FcPS(\mu\text{-}S)]_2$ was prepared according to the literature procedure [16]. Elemental analyses were determined with a VARIO EL (Heraeus). The mass spectra were recorded on a MAT-8230 (EI-MS, 70 eV) or on an FT-ICR-MS Bruker-Daltonics ESI mass spectrometer (APEX II, 7 Tesla). IR spectra were recorded as KBr disks with a Perkin–Elmer 2000 FT-IR spectrometer in the range 400-4000 cm^{-1}. Melting points (Gallenkamp) are uncorrected. Methylaminoethanol and diethylaminoethanol were purchased from ACROS.

5. Syntheses

5.1. [FcP(S)S(OCH$_2$CH$_2$NH$_2$Me)] (1)

$[FcPS(\mu\text{-}S)]_2$ (0.6 g, 1 mmol) was treated with methylaminoethanol (0.18 mL, 2 mmol) in hot toluene (10 mL). The mixture was refluxed for 30 min and a yellow solid was obtained. The yellow solid was isolated by filtration and washed with toluene and diethyl ether. The product was recrystallised from chloroform/acetonitrile (2/1) and obtained as a yellow solid (0.35 g, 58%), m.p. 193–194 °C (decomp); $C_{13}H_{18}FeNOPS_2$: requires C, 43.95; H, 5.10; N, 3.90; S, 18.05. Found: C, 41.5; H, 5.15; N, 3.77; S, 21.0%. MS (ESI): *m/z* 354.99 $[M]^+$, 710.99 $[2M]^+$, 1065.99 $[3M]^+$; MS (EI): *m/z* 337 $[M - CH_3 - 2H, 100\%]^+$, 280 $[FcPS_2, 93\%]^+$, 217 $[FcP, 66\%]^+$, 184 $[Fc, 88\%]^+$, 121 $[CpFe, 88\%]^+$. δ_H ($CDCl_3$): 9.85 (br, 2H, NH_2), 4.76 (br s, 2H, C_5H_4), 4.64 (d of m, 2H, $^3J_{PH} = 14.8$ Hz, C_5H_4), 4.43 (br s, 2H, OCH_2), 4.36 (s, 5H, C_5H_5), 3.32 (br, 2H, CH_2N), 2.94 (s, 3H, CH_3). δ_P($CDCl_3$): 114.1 (t, $^3J_{PH} = 14.8$ Hz). Due to low solubility, ^{13}C NMR spectra could not be obtained. Selected IR bands (cm^{-1}): 2745 s (νNH), 1025 versus (νPO), 654 versus ($\nu_{asym}(PS_2)$), 582 s ($\nu_{sym}(PS_2)$).

5.2. [FcP(S)S(OCH$_2$CH$_2$NHEt$_2$)] (2)

$[FcPS(\mu\text{-}S)]_2$ (0.52 g, 0.9 mmol) was treated with diethylaminoethanol (0.25 mL, 1.8 mmol) in hot toluene (10 mL). The mixture was refluxed for 30 min and a yellow solid was obtained, which was isolated by filtration and washed with toluene and diethyl ether. The product was recrystallised from chloroform/acetonitrile (2/1) to give a yellow solid (0.41 g, 68%), m.p. 182–183 °C (decomp); $C_{16}H_{24}FeNOPS_2$: requires C, 48.32; H, 6.08; N, 3.52; S, 16.14. Found: C, 47.80; H, 5.83; N, 3.58; S, 16.90%. MS (ESI): *m/z* 397.5 $[M]^+$, 398.05 $[M + H]^+$, 795.09 $[2M]^+$; MS (EI): *m/z* 340 $[M - 2C_2H_5, 41\%]^+$, 248 $[FcPS, 33\%]^+$, 217 $[FcP, 35\%]^+$, 186 $[Fc, 100\%]^+$, 121 [CpFe,

5.3. X-ray crystallography

Crystallographic data for **1** are given in Table 1. Data [λ (Mo Kα) = 0.71073 Å] were collected with a Siemens CCD (SMART) diffractometer. 900 reflections were used for determination of the unit cell parameters. Empirical absorption correction with SADABS [17]. The structure was solved by direct methods (SHELXTL PLUS) [18]. H atoms were located by difference maps and refined isotropically.

6. Supplementary material

CCDC-242555 (**1**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or deposit@ccdc.cam.uk).

Abstract

The preparation of the tetradentate dianionic ligand *N,N′*-bis(3,5-di-*t*-butylsalicylidene)-4,5-dimethyl-1,2-phenylenediamine [H_2L] is described, together with the corresponding uranium complex [$UO_2(L)CH_3OH$]. H_2L has been found to selectively bind to a representative actinide (UO_2^{2+}) rather than to lanthanum (La^{3+}) due to its cavity size. Both the free ligand and uranyl complex were characterized by elemental analysis, spectroscopic methods and single-crystal X-ray diffraction. The crystal structure of [$UO_2(L)CH_3OH$] complex show that uranyl cation adopts a distorted pentagonal bipyramidal conformation, with two imine nitrogen atoms, two phenolic oxygen atoms and a methanol oxygen in the coordination sphere, together with two *trans* oxo groups. The oxo groups have a (O–U–O, 176.85(15)°) angle consistent with linear coordination and U–O bond lengths of 1.786(4) and 1.805(4) Å. The difference in the bond distances can be ascribed to the existence of a hydrogen bond between one uranyl oxygen and the O–H of a methanol of neighboring molecule. This complex has one of the highest solubilities in organic solvents of all uranium compounds, making it a potential candidate for applications in solvent extraction.

1. Introduction

One of the critical tasks in the restoration and nuclear waste is the separation of radioactive waste for disposal and for long term storage. There has been great interest in the separation of actinides (Ac) and lanthanides (Ln) in solution to aid the safe management of nuclear waste [1–3]. Many Schiff-base ligands have been designed and prepared with the aim of discriminating between Ln and Ac [4–7]. Tetradentate Schiff-base ligands are suitable for coordination to d-block transition metals due to their cavity size and planarity, but very few ligands have been found that chelate to f-block metals. One noticeable limitation in using these kinds of ligands lies in the fact that they are generally insoluble after binding to form a neutral complex [8]. The title complex is highly soluble in a range of solvents, which is likely due to the incorporation of *t*-butyl groups into the ligand.

Our research is currently focused on the synthesis of related ligands and the formation of analogous Ln^{3+} and (UO_2^{2+}) coordination complexes.

In this paper, we explore the synthesis, spectroscopic characterization, crystal structures and hydrogen bonding interactions of the first of our ligands, *N,N′*-bis(3,5-di-*t*-butylsalicylidene)-4,5-dimethyl-1,2-phenylenediamine, and its corresponding uranyl complex. This ligand has a cavity for which preliminary modelling had shown that a Ln^{3+} ion would probably not bind in the chelating mode, whereas the uranyl groups would bind.

2. Experimental

2.1. Synthesis of *N,N′*-bis(3,5-di-*t*-butylsalicylidene)-4,5-dimethyl-1,2-phenylenediamine [H_2L]

3,5-di-*t*-Butylsalicylaldehyde (4.68 g, 0.02 mol, 2 equiv.) and 4,5-dimethyl-1,2-phenylenediamine (1.32 g, 0.01 mol, 1 equiv.) were refluxed overnight in methanol (50 ml). The solution was allowed to cool to room temperature, yielding a yellow precipitate, which was filtered off and washed with diethyl ether. This solid was dissolved in a $CH_3OH/CHCl_3$ mixture and a small quantity of activated charcoal was added. The solution was heated to reflux and filtered, and the yellow crystalline compound obtained by solvent evaporation. Yield: 2.84 g (47.8%); m.p. 135 °C. *Anal.* Calc. for $C_{38}H_{52}N_2O_2$: C, 80.19; H, 9.21; N, 4.46. Found: C, 77.47; H, 8.89; N, 4.22%. FT-IR (ν_{max}/cm^{-1}): 1615 ν(C=N) and 1590 ν(C=C). MS (*m/z*): 569. ^1H NMR ($CDCl_3$): δ 8.33 (s, 2H), 7.36 (m, 2H), 7.25 (m, 2H), 7.07 (m, 2H), 2.20 (s, 6H), 1.53 (s, 6H), 1.45 (s, 15H) and 1.31 (s, 15H).

2.2. Synthesis of [$UO_2(L)CH_3OH$]

Uranyl nitrate (0.25 g, 0.0005 mol) was dissolved in the minimum amount of methanol and added to an equimolar solution of H_2L (0.284 g, 0.0005 mol) in methanol (50 ml). A red precipitate was formed, which was filtered and dried in vacuo. The crude product was recrystallized from chloroform to obtain the pure compound. Red single crystals for X-ray diffraction were grown in a $CH_3OH/CHCl_3$ mixture by solvent evaporation at room temperature over three days. Yield: 0.346 g (79%). *Anal.* Calc. for $C_{39}H_{54}N_2O_5U$: C, 53.91; H, 6.26; N, 3.22. Found: C, 53.11; H, 7.18; N, 4.04%. IR (ν_{max}/cm^{-1}): 1609 (C=N); 1533 (C=C) and 888 (O=U=O). UV/Vis (λ_{max}/nm): 398, 295.

2.3. Physical measurements

All the chemicals and solvents were of analytical grade and were used as received (Caution! *Uranyl nitrate is a weak radioactive salt and care should be taken in handling the compound*). C, H and N analyses were performed with a Perkin–Elmer 2400 series II analyzer. Infrared spectra (4000–300 cm^{-1}, resp. 4 cm^{-1}) were recorded on a Perkin–Elmer Paragon 1000 FTIR spectrometer equipped with a Golden Gate ATR device, using the reflectance technique. ^1H NMR spectra were recorded on a Bruker 300 DPX MHz spectrometer in $CDCl_3$ solution, using TMS as the internal standard. Diffuse reflectance spectra were obtained on a Perkin–

2.4. Single crystal X-ray structures

2.4.1. $(H_2L)\cdot(acetone)$ and $[UO_2(L)CH_3OH]$

The X-ray data were collected with a Nonius Kappa CCD diffractometer using graphite-monochromatized Mo Kα radiation. An initial unit cell determination was performed using the NONIUS COLLECT software suite [9] and the DIRAX [10] indexing program. A complete dataset for each compound was collected, and integrated by the HKL2000 [11] and SORTAV [12] programs. No absorption correction was applied. The ligand structure was solved using the SHELXS-86 program [13], and refined with SHELXL-97 [14]. The program PLATON [15] was used for space group determination, validation and the preparation of diagrams. An empirical absorption correction was applied using the SADABS program [16] for the Uranyl complex. The structure was solved and refined using SHELXS-97 [17], SHELXL-97 [14] for structure solution and structure refinement, respectively. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at idealized positions and allowed to ride on the connecting atom. Selected crystal data are given in Table 1.

3. Results and discussion

3.1. Ligand and metal coordination

The new tetradentate ligand *N,N′*-bis(3,5-di-*t*-butylsalicylidene)-4,5-dimethyl-1,2-phenylenediamine was synthesized from a reaction of 4,5-dimethyl-1,2-phenylenediamine with 3,5-di-*t*-butylsalicylaldehyde, using the synthetic procedure described above. Schiff-base uranyl complexes are generally soluble only in donor solvents such as DMSO and DMF, whereas the title compound is highly soluble in ethanol, methanol, chloroform, dichloromethane and acetone. This good solubility may be due to the presence of tertiary butyl groups, which will improve the solubility of the complex in less strong donor or organic solvents [18]. The IR spectrum of the ligand shows the formation of a ν(C=N) peak [19] at 1615 cm^{-1}, which, together with the disappearance of the ν(C=O) peak is indicative of a Schiff-base condensation.

The uranyl complex $[UO_2(L)CH_3OH]$ was prepared using the method described above. The IR spectrum shows subtle differences in comparison to the free ligand, with peaks at 1609 cm^{-1} ν(C=N) and 1533 cm^{-1} ν(C=C). A new peak was observed at 888 cm^{-1} due to ν(O=U=O), which indicates the presence of a linear, symmetric dioxouranium(VI) group [20]. The ligand field spectrum of the complex in the solid state

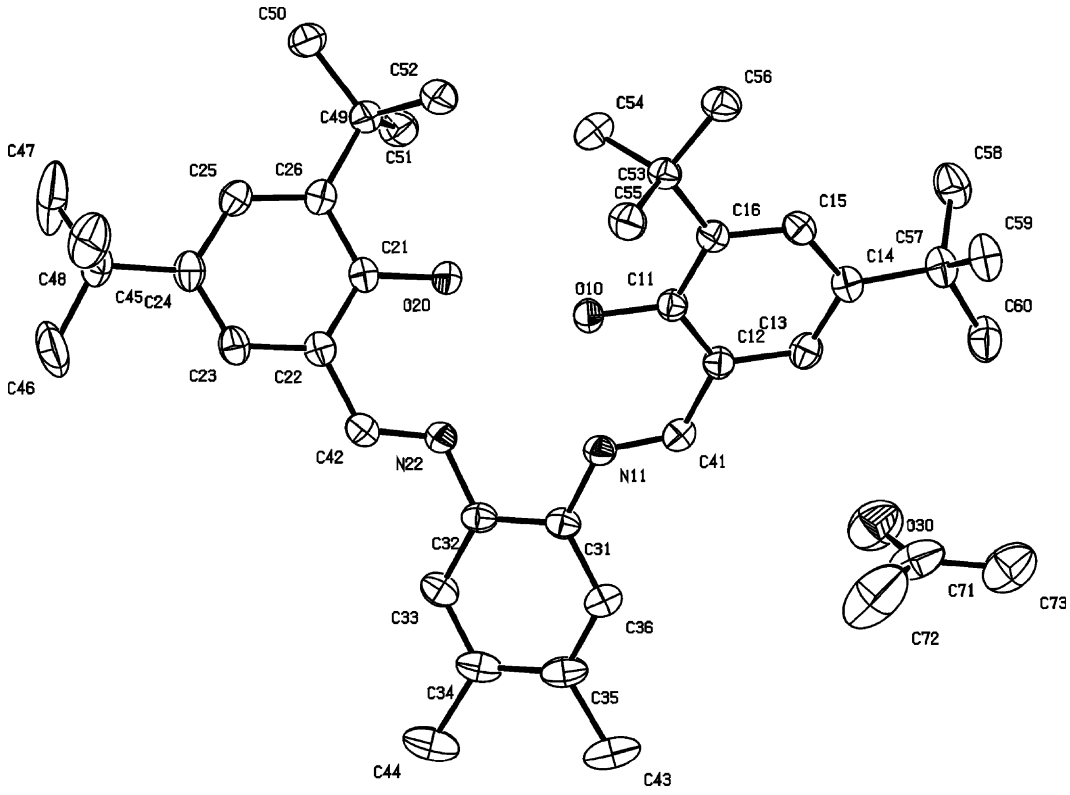

Fig. 1. Crystal structure of ligand (H_2L) and acetone, with hydrogen atoms omitted for clarity and displacement ellipsoids drawn at the 50% probability level.

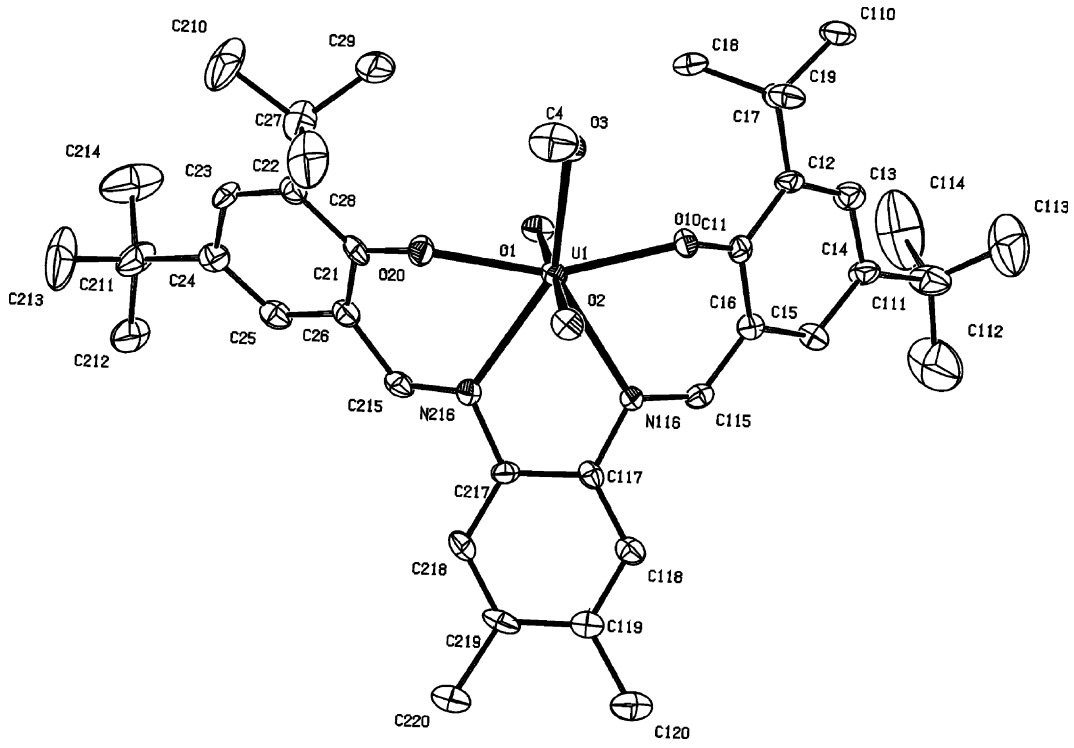

Fig. 2. Crystal structure of $[UO_2(L)CH_3OH]$ with hydrogen atoms omitted for clarity and displacement ellipsoids drawn at the 50% probability level.

shows absorptions around 398 nm with a shoulder of 295 nm, assigned to the charge transfer (phenolato-O–U) and $\pi-\pi^*$ of ligand. As expected, the proton NMR spectrum of the complex shows the imine proton shifted downfield from 8.33 to 8.86 ppm. The aromatic as well as methyl protons were found to be unaltered.

We tried to prepare lanthanide complexes by using the above method with a 1:1 mole ratio of the ligand and metal salt in methanol solvent. At the final stage after evaporation, we observed the formation of crystals of the ligand and metal salt separately. The ligand crystal was obtained with one acetone molecule. We also change the reaction conditions with different temperatures and times, and periods of 3, 6 h and overnight reflux were used. These repeated attempts to prepare lanthanide complexes starting from $LnCl_3$, $La(NO_3)_3$, $Pr(NO_3)_3$, $GdCl_3$ and $Gd(NO_3)_3$ with the same ligand were also unsuccessful, which may be due to a mismatch of its ionic size (radii, La^{3+}: 1.02 Å for 8 coordination; U^{6+}: 0.80 Å for 6–8 coordination) with the cavity of the ligand.

3.2. Crystal structures

The crystal structures of (H_2L) and $[UO_2(L)CH_3OH]$ are depicted in Figs. 1 and 2, with selected crystal data in

Table 1 and selected bond distances and angles given in Table 2.

The molecular structure of the H_2L ligand crystallized with one acetone molecule is shown in Fig. 1, which shows that in the uncoordinated ligand, the molecule is distinctly non-planar. In order to accommodate the two central O–H groups the 3,5-di-*t*-butylsalicylidene groups are displaced to opposite sides of the 4,5-dimethyl-1,2-phenylenediamine ring plane, with dihedral angles of 34.97(11)° between the C(31)–C(36) plane and C(11)–(C16) plane, and −37.39(11)° between the C(31)–C(36) plane and C(21)–(C26) plane (Fig. 1, Supplementary material).

The tetradentate dianionic ligand binds equatorially to the dioxouranium(VI) group leading to a seven-coordinated center with a distorted pentagonal bipyramidal coordination geometry. The uranium oxide coordination sphere contains two imine nitrogen atoms, two phenol oxygen atoms and a third oxygen atom from the methanol molecule. The oxo groups of the uranyl moiety lie *trans* to one another with a nearly linear O–U–O angle of 176.85(15)° and U–O bond length of 1.786(4) Å for U–O(1) and 1.805(4) Å for U–O(2). The lengthening of the U–O(2) bond length can be ascribed to the existence of a hydrogen bond, D–H···A length of 2.831(6) Å, between O(2) and the O–H group of the methanol molecule.

The uranium atom, N(116), N(216), and O(20) all lie approximately in a plane, with a maximum deviation from the mean squares plane of 0.0383(3) Å for U(1). O(10) is displaced significantly out of the plane by 0.390(4) Å. The U–N(116), U–N(216), U(1)–O(10) and

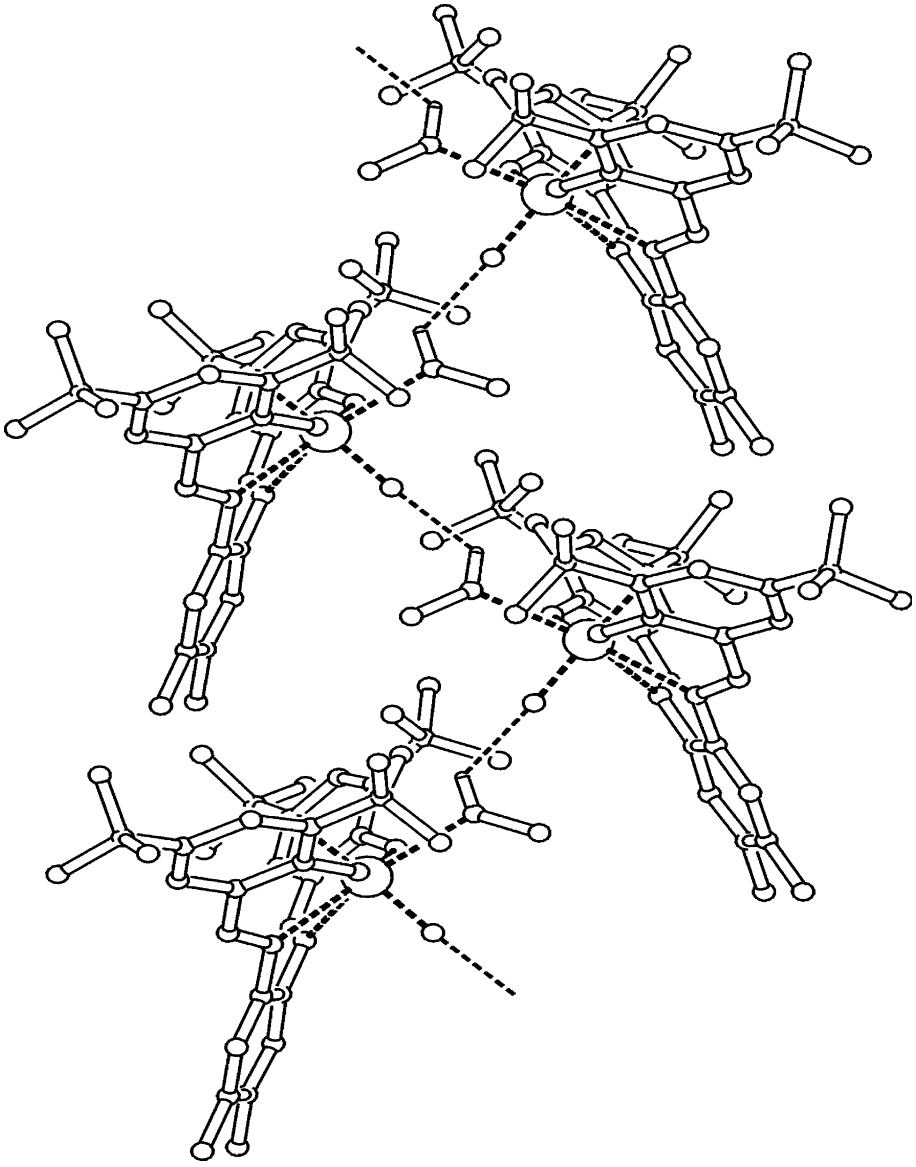

Fig. 3. Molecular packing of $[UO_2(L)CH_3OH]$ complex showing hydrogen bonded zigzag infinite chain.

U(1)–O(20) bond distances, of 2.590(4), 2.521(4), 2.228(3) and 2.240(3) Å, respectively, are in good agreement with those reported previously [8,21–23]. U–N distances are typically found to be longer than U–O distances, a behavior which can be explained by Pearson's hard and soft acid–base concept [24,25]. This concept agrees well with what is observed in the title compound, as nitrogen would be expected to be bonded less strongly to a hard acid such as (UO_2^{2+}), while oxygen has relatively higher base strength towards uranium. The methanol oxygen atom, O(3), also lies outside the main U–N–N–O plane, though on the other side to O(10), with a deviation of −0.334(4) Å. The U–O(3) bond length is 2.530(4) Å, which is comparable with related complexes in the literature [25].

The ligand is not planar, but, in contrast to the uncoordinated structure, the two 3,5-di-*t*-butylsalicylidene groups are now on the same side of the 4,5-dimethyl-1,2-phenylenediamine ring, which gives the complex a distinctive "book" appearance when viewed from the side (Fig. 2, Supplementary material). Evidently, in the five-membered ring (C117, C217, N116, N216 and U1), the small bite angle (62.88°), may enhance the planarity of chelating mode to non-binding with lanthanides.

Due to the hydrogen-bonding between the methanol molecule and O(2) the structure forms an infinite polymer with a distinctive 'zigzag' motif (Fig. 3). No π–π stacking is present, due to the unfavorable orientations of the aromatic rings in the structure.

4. Conclusions

In this paper, we have described the successful synthesis of a ligand that is suitable for coordination to the actinide (UO_2^{2+}), but not to lanthanides (La, Pr, Eu and Gd). Uranium exists as the uranyl cation (UO_2^{2+}) in aqueous solution, where the oxo groups of the uranyl moiety lie *trans* to one another with an angle that is close to linear with the uranium as the center. This linear arrangement appears to help the uranyl cation enter into the cavity of the ligand frame like a "pen" into the "cap". The uranium center is seven coordinate with a distorted pentagonal bipyramidal geometry. The lengthening of one U=O distance can be ascribed to the presence of a hydrogen bond between the oxygen and the O–H of a neighboring methanol molecule. Hydrogen bonding will lead to the sequestration of the uranium to achieve the high selectivity over competing cations in solution.

Apparently the spherical shape and the large size of the Ln(III) ions do not match with the ligand cavity, whereas the smaller size of U(VI) and the ellipsoid of the (UO_2^{2+}) fit better. This principle is now further developed for a potential use in the separation of uranium and lanthanum.

Abstract

Lanthanide bromide complexes were prepared in excellent yields by reactions of lanthanide oxides and hydrogen bromide, which was formed *in situ* from bromotrimethylsilane and water, in DME (DME = dimethoxyethane). The crystals for X-ray structural analyses were grown from DME and from THF (THF = tetrahydrofuran) solutions. Three bromine and four oxygen atoms from DME are coordinated to a central lanthanide atom in the crystal structures of lanthanide complexes $[LnBr_3(DME)_2]$ (Ln = Pr (**1**), Nd (**2**), Sm (**3**), Eu (**4**)). Crystallization from THF resulted in two types of complexes, molecular $[LnBr_3(THF)_4]$ (Ln = Pr (**5**), Sm (**6**)) and ionic $[EuBr_2(THF)_5][EuBr_4(THF)_2]$ (**7**). Complexes **1**, **4**, **5** and **7** are the first crystallographically characterized water-free complexes of praseodymium or europium tribromides.

Keywords: Lanthanide oxides; Bromotrimethylsilane; O-donor ligands; Complexes of lanthanide bromides; Crystal structure; Coordination number

1. Introduction

Lanthanide(III) halides and their complexes with simple donors such as THF [1–16] and DME [6,9,10,15,17–20] are useful starting compounds in syntheses of lanthanide complexes, organolanthanide compounds and in organic synthesis [21]. Base-free lanthanide trihalides with an extended structure (CN = 9 for Ln = La–Gd) are in many cases less appropriate starting substances than mononuclear complexes of lanthanide halides with simple donors due to their low solubility and reactivity. For example, carbamato complexes of the lighter lanthanides $[Ln(O_2CNR_2)_3]$ were successfully synthesized only by using $[LnCl_3L_n]$, while experiments using anhydrous lanthanide chlorides failed due to lower reactivity of $LnCl_3$ (Ln = La–Gd) [22]. A choice of an appropriate lanthanide halide in metathesis reactions also plays an important role. A softer iodide could be displaced by some ligands [11], but a similar reaction does not take place, if a harder chloride is used.

Crystal structures of lanthanide chloride and some iodide complexes with THF and DME have been well investigated in the past due to their broad application (references in Table 1). In the crystal structures of lanthanide chlorides with DME only two types of molecules were found, binuclear $[LnCl_3(DME)_2]_2$ and mononuclear $[LnCl_3(DME)_2]$. In the case of iodide complexes with DME are reported only crystal structures of lanthanide(II) compounds [23–27]. A higher structural diversity is characteristic for lanthanide trichloride complexes with THF where are coordination numbers from

six to eight. Several lanthanides form two (Nd, Gd) [1–3,5] or three (Yb) [1,4,10] different types of chloride complexes with THF, simultaneously revealing transitions to lower coordination numbers (Gd, Yb) [1,2,4,10]. Structural diversity diminishes along with the coordination numbers range in the THF complexes of larger halides, bromides and iodides, as seen in Table 1.

In contrast to lanthanide chloride and iodide complexes only a few bromide complexes have been described in the literature by now [15,16]. The known complexes of lanthanide bromides were prepared from $LnBr_3 \cdot 6H_2O$ (Ln = Nd, Sm) [16,28] or from metals (Ln = La, Yb) [15]. A dehydration of $LnBr_3 \cdot 6H_2O$ was done by trimethylorthoformate. The metals reacted with dibromomethane or dibromoethane in THF and DME under ultrasound conditions. We chose lanthanide oxides as starting compounds to prepare lanthanide bromide complexes with DME similar as in syntheses of lanthanide chloride complexes [29]. The new syntheses from lanthanide oxides are effective and simple by using trimethylbromosilane as bromide donor at room temperature. New THF complexes of lanthanide bromides were prepared to check the structural diversity of bromides and compare it to the well known variety of crystal structures reported for analogous chlorides. We provide additional structural data to establish at which elements occur transitions to lower coordination numbers in the series of lanthanide bromide complexes with THF and DME.

2. Experimental

2.1. General

All the manipulations were carried out under an atmosphere of purified argon using Schlenk tubes or in a dry box. Lanthanide oxides (Aldrich), bromotrimethylsilane (Aldrich) and DME (Fluka) were used as received, THF and pentane were dried over Na/K and distilled before use. When a bottle of bromotrimethylsilane (Aldrich) was opened, the substance was used within a few days. A later use is not recommended due to a partial decomposition of the reagent to bromine, which resulted in a contamination of the products and lower yields.

The samples were ground in nujol mull and IR spectra were recorded on a Perkin–Elmer 1720X instrument between 400 and 4000 cm^{-1}.

The bromine content was determined by a potentiometric titration of bromide ions with silver nitrate and lanthanide content by a gravimetric analysis. Elemental analyses were carried out on a Perkin–Elmer 2400 CHN analyzer at the University of Ljubljana (Department of Organic Chemistry).

2.2. Synthesis of $[PrBr_3(DME)_2]$ (1) and $[PrBr_3(THF)_4]$ (5)

To 0.420 g (0.622 mmol) of Pr_4O_7 were added 10.53 g (117 mmol) of DME, 7.81 g (51 mmol) of $(CH_3)_3SiBr$ and water (0.01 g, 0.56 mmol). The suspension was stirred for eight days at room temperature and after drying in vacuum 1.40 g (100% yield) of the complex **1** was gained. *Anal.* Calc. for **1**: H, 3.95; C, 17.13. Found: H, 3.97; C, 17.69%. IR (Nujol): 1311 w, 1280 w, 1260 m, 1239 w, 1187 m, 1081 vs, 1030 vs, 993 m, 914 m, 911 m, 898 m, 859 s, 822 m, 800 m, 674 w, 598 w, 551 w, 464 w cm^{-1}. Dried product was dissolved in DME and THF. Complex **1** crystallized from DME solution and **5** from THF solution during slow diffusion of pentane vapor to the solution. IR of **5** (Nujol): 1169 w, 1074 w, 1019 vs, 917 w, 863 s, 669 w cm^{-1}.

2.3. Synthesis of $[NdBr_3(DME)_2]$ (2)

To 0.460 g (1.37 mmol) of Nd_2O_3 were added 29.39 g (327 mmol) of DME, 6.80 g (44.4 mmol) of $(CH_3)_3SiBr$ and water (0.01 g, 0.56 mmol). The suspension was stirred for eight days at room temperature and after drying in vacuum 1.54 g (99.6% yield) of the complex **2** was gained. *Anal.* Calc. for **2**: H, 3.57; C, 17.03; Br, 42.5; Nd, 25.7. Found: H, 3.67; C, 16.89; Br, 42.1; Nd, 25.2%. IR (Nujol): 1259 w, 1189 w, 1086 s, 1028 vs, 998 m, 899 m, 856 m, 826 w cm^{-1}. Dried product was dissolved in DME and complex **2** crystallized during slow diffusion of pentane vapor to the solution.

2.4. Synthesis of $[SmBr_3(DME)_2]$ (3) and $[SmBr_3(THF)_4]$ (6)

To 0.540 g (1.55 mmol) of Sm_2O_3 were added g 12.79 g (142 mmol) of DME, 6.71 g (43.8 mmol) of $(CH_3)_3SiBr$ and water (0.01 g, 0.56 mmol). The suspension was stirred for nine days at room temperature and after drying in vacuum 1.68 g (95.0% yield) of the product was gained. *Anal.* Calc. for **3**: Br, 42.0; Sm, 26.3. Found: Br, 42.3; Sm, 26.9%. IR (Nujol): 1305 w, 1285 w, 1260 w, 1240 w, 1188 w, 1072 vs, 1028 s, 1017 s, 1002 m, 992 s, 974 m, 896 m, 856 s, 825 w, 550 w cm^{-1}. Dried product was dissolved in DME and in THF. Complex **3** crystallized from DME solution and **6** from THF solution during slow evaporation of the solvent. IR of **6** (Nujol): 1260 m, 1177 w, 1074 w, 1019 vs, 919 w, 862 s, 669 w cm^{-1}.

2.5. Synthesis of $[EuBr_3(DME)_2]$ (4) and $[EuBr_2(THF)_5][EuBr_4(THF)_2]$ (7)

To 0.440 g (1.25 mmol) of Eu_2O_3 were added 15.36 g (171 mmol) of DME, 7.26 g (47.4 mmol) of

$(CH_3)_3SiBr$ and water (0.01 g, 0.56 mmol). The suspension was stirred for nine days at room temperature and after drying in vacuum 1.24 g of the yellow product was gained. The traces of Eu_2O_3were observed in IR spectra of this crude product. The crude product was dissolved in DME or THF and filtered. Yellow crystals of **4** grew out of DME solution during evaporation of the solvent. *Anal.* Calc. for **4**: H, 3.52; C, 16.80. Found: H, 3.56; C, 16.85%. IR of **4** (Nujol): 1306 w, 1260 m, 1188 w, 1111m, 1084s, 1073 s, 1026 vs, 973 m, 859 s, 850 s, 826 w, 801 w, 556 w, 459 w cm^{-1}. Complex **7** crystallized from THF solution during slow evaporation of the solvent. IR of **7** (Nujol): 1170 w, 1074 w, 1040m, 1011 s, 919 m, 855 vs, 670 m cm^{-1}.

2.6. Crystal structure determination

The details of crystal data collection and refinement parameters are listed in Table 2 (**1**–**4**) and Table 3 (**5**–**7**). All studied compounds were hygroscopic. The crystals were greased on a glass thread. Diffraction data were collected on a Nonius Kappa CCD diffractometer with CCD area detector at 150(2) K. A Cryostream Cooler (Oxford Cryosystems) was used for cooling of the samples. A graphite monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å) was employed in all measurements. The structures were solved by direct methods implemented in SHELXS-97 [30] and refined by a full-matrix least-squares procedure based on F^2 (SHELXL-97) [31]. Combined general twinning by pseudo-merohedry and racemic twinning (Flack parameter 0.44(3)) [32] was considered in the refinement of the complex **4**. The twin law in SHELXL-97 for monoclinic unit cell ($\beta \sim 90°$), which emulate orthorhombic one, was employed in the refinement. All non-hydrogen atoms except one carbon atom in methyl group in complexes **4** were refined anisotropically. The calculated fraction of orthorhombic structure in **4** was 11.2(1)%. All non-hydrogen atoms in complexes **1**, **2**, **3**, **5**, **6** and **7** were refined anisotropically. The hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model except in the crystal structure of **2**, where were all hydrogen atoms located from difference Fourier syntheses.

3. Results and discussion

3.1. Syntheses

The syntheses of the lanthanide bromide complexes were achieved according to the reactions:

$$2(CH_3)_3SiBr + H_2O \rightarrow (CH_3)_3SiOSi(CH_3)_3 + 2HBr$$

$$6HBr + Ln_2O_3 + 4DME \rightarrow 2[LnBr_3(DME)_2] + 3H_2O$$

Bromotrimethylsilane reacts with water generating hydrogen bromide in situ, which reacts with lanthanide oxides in dimethoxyethane giving the lanthanide bromide complexes. The water, formed in the second reaction reacts with $(CH_3)_3SiBr$ and therefore, only a small amount of water is added (n(Ln):n(H_2O) ~ 5:1). The excess of $(CH_3)_3SiBr$ guarantees the total consumption of water. High yields were achieved by this simple method, which is carried out at room temperature. The side products, HBr and $(CH_3)_3SiOSi(CH_3)_3$, are volatile and easily removable. Crystallization of the products from DME resulted in mononuclear compounds $[LnBr_3(DME)_2]$ (**1**–**4**) and from THF in the neutral $[LnBr_3(THF)_4]$ (**5**, **6**) or ionic complex of $[LnBr_2(THF)_5][LnBr_4(THF)_2]$ (**7**). To the best of our knowledge are compounds **1**, **4**, **5** and **7** the first crystallographically characterized water-free lanthanide tribromide complexes containing Pr–Br and Eu–Br bonds.

3.2. Crystal structures of DME complexes *1*–*4*

The structures of the complexes **1**–**4** (see Fig. 1 for **1**, Table 4) consist of three bromine and four oxygen atoms from DME coordinated to the central lanthanide atom in a distorted pentagonal bipyramidal geometry. Two bromine atoms, Br1 and Br3, occupy the axial sites with Br1–Ln–Br3 angle from 166.72(1)° in **1** to 171.15(1)° in **3**. Molecules **1**–**4** have similar structures to $[LnCl_3(DME)_2]$ [6,9,15,17–20] and $[YbBr_3(DME)_2]$ [15]. On the contrary to chlorides $[LnCl_3(DME)_2]$, where all mononuclear complexes (Ln = Nd–Lu) crystallize in the same monoclinic space group with similar unit cells, different packing of molecules in the bromides resulted either in orthorhombic or monoclinic crystal system. Only the complex **3** crystallize in the same monoclinic space group as analogous chlorides, **1** and **2** are isostructural orthorhombic complexes, while monoclinic emulate

O3	2.579(2)	2.5603(14)	2.482(2)	2.52(1)
O4	2.476(2)	2.4596(15)	2.460(2)	2.43(1)
$Br_{av.}$	2.857(1)	2.845(1)	2.826(1)	2.811(6)
$O_{av.}$	2.525(8)	2.509(6)	2.468(8)	2.46(4)

orthorhombic compound in **4** (Table 2). Unit cell volumes in **1** and **2** are approximately two times larger than in **3** and **4** because of doubled *c* axes in **1** and **2**.

Average Ln–Br and Ln–O bond lengths in the series of complexes decrease as expected due to lanthanide contraction [33]. The average Ln–Br bond distances in **2** and **3** (Table 4) are similar to the Ln–Br distances in the published $[NdBr_3(THF)_4]$ (2.86(2) Å) [16] and $[SmBr_3(Pr^iOH)_4]$ (2.834(3) Å) [28]. A Sm–$Br_{terminal}$ bond distance in $[SmBr_2(DME)_2]_2$ (2.994(2) Å) [23] is longer due to larger Sm^{2+} ion. Ln–O bond lengths within each lanthanide compound differ significantly for **1**, **2** and **4** similar as in $[LnCl_3(DME)_2]$ [19]. One DME molecule is coordinated to lanthanide with two similar Ln–O bonds and the other with one short and one long Ln–O bond. The average Ln–O bond lengths are similar in the prepared complexes **2**–**4** (Table 4) as reported for $[LnCl_3(DME)_2]$ (Ln = Nd (2.52(1) Å), Sm (2.50(1) Å), Eu (2.48(1) Å)) [17,19]. Pr–O bonds in mononuclear complex **1** are shorter than in $[PrCl_3(DME)_2]_2$ (from 2.586(3) to 2.654(3) Å) [19] as expected for a lower coordination number of praseodymium in **1** than in the binuclear chloride.

3.3. Crystal structure of THF complexes 5–7

Crystallization of lanthanide bromide complexes from THF resulted in the compounds **5**–**7**. The com-

plexes **5** and **6** are isostructural to the previously described $[LnBr_3(THF)_4]$ (Ln = La [15], Nd [16]), while **7** is the first known ionic complex of lanthanides containing only bromo and THF ligands.

Three bromine atoms and four molecules of THF are coordinated to each praseodymium in **5** (Fig. 2) or samarium in **6** resembling a distorted pentagonal bipyramid. Two bromine atoms are in the apical *trans* and one

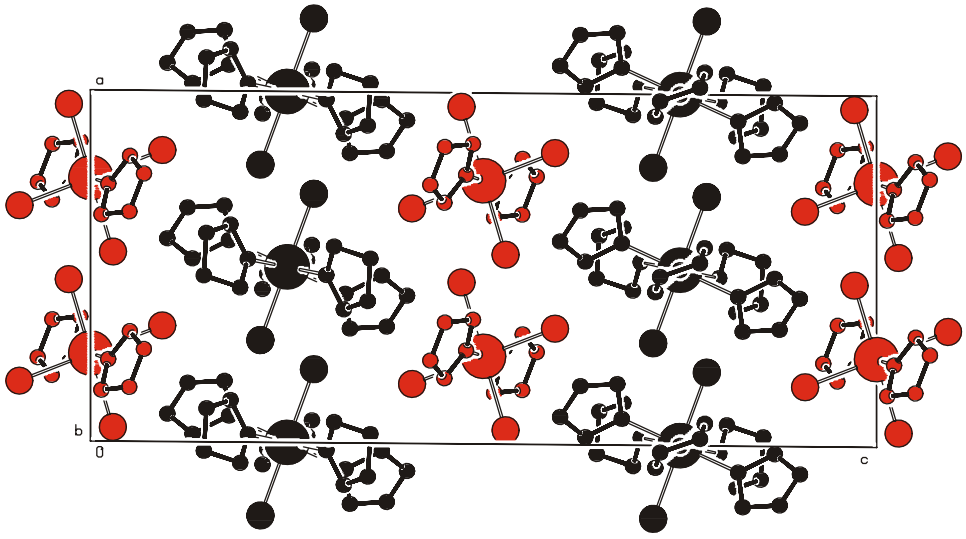

Fig. 4. Alternating layers of cations and anions in **7** along *c* axis. Hydrogen atoms are omitted for clarity.

bromine atom plus four oxygens of THF in equatorial positions. A comparison to the crystal structures of the known $[LnBr_3(THF)_4]$ (Ln = La [15], Nd [16]) shows an expected shortening of Ln–Br and Ln–O bonds and a reduction of unit cell volume in **5** and **6** [33]. The average Ln–Br bond lengths in **5** and **6** are similar as in **1**, **3** (Tables 4–6) and Ln–O as in $[PrCl_3(THF)_2]_n$ [1,2], $[PrI_3(THF)_4]$ [11] or $[SmCl_3(THF)_4]$ [6].

The ionic structure of **7** is presented in Fig. 3 and alternating layers of cations and anions lie along *c* axis in Fig. 4. The complex **7** is isostructural to analogous ionic lanthanide chloride (Gd–Yb) [3,6,9,10] and iodide (Nd–Yb) [6,11–13] complexes with THF. The two bromine atoms in the cation are in the *trans* positions and five oxygen atoms from THF in the equatorial plane of a rather undistorted pentagonal bipyramid. Only six ligands are octahedrally coordinated to europium in the centrosymmetric anion with two oxygens in *trans* positions. Despite lower coordination number in anion than in cation of **7**, the average Eu–Br bond lengths are similar in cation, anion (Table 7) and neutral complex **4** (Table 4). A higher negative partial charge on the europium centrum in the anion compensate a lower coordination number of the anion leading to elongation of Eu–Br bonds in the six-coordinated anion. The neutral ligands are expectedly less sensitive to ion charge and the average Eu–O distance in anion **7** is shorter than in the cation **7** (Table 7), complex **4** (Table 4) or $[EuCl_3(THF)_4]$ [7], which all poses the higher coordination number.

4. Conclusion

$[LnBr_3(DME)_2]$ (Ln = Pr, Nd, Sm, Eu), $[LnBr_3(THF)_4]$ (Ln = Pr, Sm) and $[EuBr_2(THF)_5]$ $[EuBr_4(THF)_2]$ were prepared following a new convenient synthetic route. Ln_2O_3 reacts with Me_3SiBr in the presence of DME and small amounts of water (n(Ln):n(H_2O) $\sim$ 5:1) at room temperature. The soluble products were crystallized from DME and THF in high yields.

A structural variety of different lanthanide halide complexes depends upon size and coordination mode of halide and neutral ligands. A transition from one to another type of crystal structure could be associated to a change of coordination number because of lanthanide contraction and/or coordination mode of halide, which is either a terminal or bridging one. A decrease of coordination number and associated transition to another structural type appears at lighter lanthanides, if larger halides are present in both, THF and DME complexes.

The complexes of lanthanide trichlorides or tribromides with DME crystallize as binuclear $[LnX_3(DME)_2]_2$ (CN = 8) or mononuclear $[LnX_3(DME)_2]$ (CN = 7). A polymeric structure was only proposed for $[LnCl_3(DME)]_n$ (Ln = La, Pr) [15,34]. A border between binuclear and mononuclear chlorides is set by neodymium complexes, which are known in both forms [10,17,19]. The X-ray crystal structures of **1** confirmed that the same change of coordination appears in bromide complexes of DME already for praseodymium, an earlier lanthanide than neodymium in chloride complexes. A crystal structure of analogous cerium complex should be determined to get undoubtedly the first lanthanide in the row, which forms mononuclear DME complexes of bromides.

Our results make possible to compare a transition between the mononuclear and ionic structures of different halide complexes with THF in the lanthanide row. The coordination number seven extends in $[LnBr_3(THF)_4]$ from lanthanum [15] to praseodymium in **5**, samarium in **6** and changes to the mixed, seven/six at europium in **7**. The same transition in crystal structures occurs in the analogous chloride at an later lanthanide, gadolinium, and in the analogous iodide complexes at an earlier lanthanide, neodymium. It would be interesting to determine the coordination numbers in THF complexes for lanthanide bromides from gadolinium to thulium to find the first complex with six-coordinated lanthanide. A mononuclear $[LnBr_3(THF)_3]$ could be expected for a lighter lanthanide than for the published ytterbium [15] according to the known crystal structures of lanthanide chloride and iodide complexes with THF.

Abstract

Reduction of 2-cyanopyridine in the presence of N(4)-ethylthiosemicarbazide produces 2-pyridineformamide N(4)-ethylthiosemicarbazone, HAm4E. Complexes with various zinc(II) and cadmium(II) salts have been prepared and characterized using physical and spectral methods. In addition, the crystal and molecular structure of $[Zn(Am4E)(OAc)]_2$ (**1**), $[Zn(HAm4E)I_2]$ (**4a**), $[Cd(Am4E)_2]$ (**5a**), $[Cd(HAm4E)Br_2] \cdot DMSO$ (**7a**) and $[Cd(HAm4E)I_2] \cdot DMSO$ (**8a**) have been obtained. Coordination is via the pyridyl nitrogen, imine nitrogen and thione or thiolato sulfur when coordinating as the neutral and anionic ligand, respectively. $[Zn(Am4E)(OAc)]_2$ is the first example of a binuclear complex with a 2-pyridineformamide thiosemicarbazonato ligand in which the two acetate bridging groups are equivalent resulting in a center of symmetry.

Keywords: Thiosemicarbazone; 2-pyridineformamide; Crystal structure; Zinc; Cadmium

1. Introduction

Thiosemicarbazones and their metal complexes have been subject of interest in numerous studies because of their chemical and biological activities [1,2], in as much as possess a wide range of beneficial medicinal properties [3,4] that are often attributed to their chelating ability with metals ions [5]. Really, an important number of thiosemicarbazones being NNS tridentate donors possess carcinostatic efficacy [6] and substantial in vivo activity against various human tumor lines [7,8] but structural variations on some thiosemicarbazones with regard to the chelating ability may be destroy or reduce its medicinal values [9].

Complexes of Group 12 metals, zinc and cadmium, can provide an interesting range of stoichiometries depending on the preparative salt. Although complexes with 2-formyl- and 2-acetylpyridine N(4)-substituted thiosemicarbazones [10–13] have been studied previously, thiosemicarbazones in which the thiosemicarbazone moiety is attached to an amide carbon rather than an aldehyde or ketone carbon have been less studied.

Previously, we have reported our studies of metal complexes of 2-pyridineformamide thiosemicarbazone [14,15], 2-pyridineformamide N(4)-methylthiosemicarbazone [16–18], 2-pyridineformamide N(4)-dimethylthiosemicarbazone [19–21] and 2-pyridine-formamide 3-piperidylthiosemicarbazone [22–24] and 3-hexamethyleneiminylthiosemicarbazone [25]. Fig. 1. Depiction of HAm4E showing the weak intramolecular N–H...N interactions.

report here our studies of the zinc(II) and cadmium(II) complexes of 2-pyridineformamide N(4)-ethylthiosemicarbazone, HAm4E (Fig. 1).

2. Experimental

HAm4E was prepared by reduction of 2-cyanopyridine [26] with sodium in the presence of N(4)-ethylthiosemicarbazide and is described elsewhere [27].

*Synthesis of [Zn(Am4E)(OAc)]$_2$ (**1**):* A solution of $Zn(OOCH_3)_2 \cdot 2H_2O$ (0.25 g, 1.12 mmol) in EtOH (30 ml) was mixed with a solution of HAm4E (0.25 g, 1.12 mmol) in EtOH (30 ml). The resultant solution is stirred at room temperature for 7 days and a yellow precipitate was filtered off. Recrystallization from DMSO gave yellow crystals of $[Zn(Am4E)(OAc)]_2$.

Yield: 0.29 g (74.5%). *Anal.* Calc. for $C_{22}H_{30}N_{10}O_4S_2Zn$: C, 38.4; H, 4.4; N, 20.2, S, 9.2. Found: C, 38.1; H, 4.4; N, 20.2; S, 9.3 %. FAB^+ MS *m/z* (assignment): 224.1 ($[H_2Am4E^+]$), 336.0 ($[Cd(Am4E)]^+$), 463.9 ($[Cd(HAm4E)I]^+$).

Recrystallization from DMSO gave colourless crystals of $[Cd(HAm4E)I_2] \cdot DMSO$ (**8a**).

Elemental analyses were performed with a Carlo Erba 1108 and Perkin–Elmer 240B microanalyser. NMR spectra were obtained as dmso solutions with a Brucker AMX300 spectrometer and chemical shifts are reported in parts per million downfield from Me_4Si. IR spectra were recorded as KBr disks (4000–400 cm^{-1}) or polyethylene-sandwiched Nujol mulls (500–100 cm^{-1}) with a Bruker IFS-66V spectrophotometer. Mass spectra were obtained in a Hewlett Packard HP598A. Yellow prismatic crystals of $[Zn(Am4E)(OAc)]_2$, $[Cd(Am4E)_2]$, $[Cd(HAm4E)Br_2] \cdot DMSO$, $[Cd(HAm4E)I_2] \cdot DMSO$ as well as a yellow plate crystal of $[Zn(HAm4E)I_2]$ were mounted on a glass fiber and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the range $5.81° < \theta < 10.21°$ for $[Zn(Am4E)(OAc)]_2$, $9.980° < \theta < 20.899°$ for $[Zn(HAm4E)I_2]$, $15.694° < \theta < 46.261°$ for $[Cd(HAm4E)Br_2] \cdot DMSO$, $18.631° < \theta < 45.792°$ for $[Cd(HAm4E)I_2] \cdot DMSO$ and $12.994° < \theta < 23.762°$ for $[Cd(Am4E)_2]$ with an Enraf-Nonius CAD4 or MACH3 automatic diffractometer. The structures were solved by direct methods [28], which revealed the position of all non-hydrogen atoms, and refined on F^2 by a full matrix least-squares procedure using anisotropic displacement parameters [29]. The H atoms were included in geometrically idealized positions employing appropriate riding models with isotropic displacement parameters constrained to $1.2U_{eq}$ of their carrier atoms. For $[Cd(HAm4E)Br_2] \cdot DMSO$ and $[Cd(HAm4E)I_2] \cdot DMSO$ the Flack x parameter (absolute structure parameter) was calculated to be 0.00(3) and 0.03(3) for the present structure and 1.04(3) and 0.97(3) for the inverted structure, respectively, thus providing strong evidence that the absolute structure has been assigned correctly [30]. Atomic scattering factors are from *International Tables for Crystallography* [31] and molecular graphics from PLATON [32]. A summary of the crystal data, experimental details and refinement results are listed in Table 1.

3. Results and discussion

The bond distances for the zinc(II) and cadmium(II) complexes are shown in Table 2 and their bond angles in Table 3. Table 4 lists the hydrogen bonding interactions and Table 5 the mean plane data and angles between planes.

3.1. Structural properties of [Zn(Am4E)(OAc)]$_2$ (1)

Previously, the crystal structures of acetate bridged zinc(II) complexes of 2-pyridineformamide N(4)-substituted thiosemicarbazones, as well as other heterocyclic thiosemicarbazones, have been reported. [Zn(Am4DH)(OAc)]$_2$, where Am4DH is the anion of 2-pyridineformamide thiosemicarbazone [33], [Zn(Ampip)OAc]$_2$, where Ampip is the anion of 2-pyridineformamide 3-piperidylthiosemicarbazone [16], and [Zn(Amhexim)(OAc)]$_2$, where Amhexim is the anion of 2-pyridineformamide 3-hexamethyleneiminylthiosemicarbazone [25] are all unsymmetrical with one acetate bridging with two oxygen atoms and the other with one oxygen; the second oxygen is weakly coordinated, at best, to one of the zinc centers. In addition, [Zn(Ac4E)(OAc)]$_2$, where Ac4E is the anion of 2-acetylpyridine N(4)-ethylthiosemicarbazone [34], is also bridged in an unsymmetrical manner by the two acetate ligands. However, [Zn(Am4M)(OAc)], where Am4M is the anion of 2-pyridineformamide N(4)-methylthiosemicarbazone [18], was found to be symmetrically bridged with a *syn–syn* arrangement of the two acetate ligands like the present [Zn(Am4E)(OAc)]$_2$ with a center symmetry (Fig. 2) in which the Zn–Zn distance is of 3.707(5) Å. The Am4E anion (i.e., loss of the hydrogen from N13) coordinates as a NNS tridentate ligand to give 5-coordinate zinc(II) centers. The bond distances for the coordinating atoms is Zn–N(im) < Zn–N(py) < Zn–S and the Zn–O distances which are different have the shortest bond distances to Zn(II). The anionic ligand has a longer C17–S1 bond (which formally becomes a single bond in [Zn(Am4E)(OAc)]$_2$), 1.759(19) Å, compared to an average of 1.696(3) Å for HAm4E [27], a shorter C16–N12 bond, 1.24(2) Å compared to an average of 1.292(3) Å and a shorter N13–C17 bond (which formally becomes a double bond), 1.31(2) Å compared to an average of 1.354(6) Å. The difference in the C–O bond distances, 1.270(19) and 1.18(2) Å, is caused by the difference in their coordination distances to Zn. Compared to [Zn(Am4M)(OAc)]$_2$ there are some differences in bond distances: Zn–S is longer in [Zn(Am4E)(OAc)]$_2$, 2.431(6) Å compared to 2.3697(9) Å and the C–O bond distances are closer to being the same in [Zn(Am4M)(OAc)]$_2$.

The identical ZnN_2O_2S chromophores in [Zn(Am4E)(OAc)]$_2$ have a N11–Zn1–S1 angle of 151.2(5)° compared to 156.58(6)° for [Zn(Am4M)(OAc)]$_2$. With

[a] Second number refers to S2 ligand.

N11–Zn–S1 assigned as β and N12–Zn1–O11 as α, $\tau = 0.43$ [35], compared to 0.56 for $[Zn(Am4M)(OAc)]_2$, indicates that the arrangement about Zn is not as close to a trigonal bipyramid (i.e., N11 and S11 apical and N12, O1a and O2 basal) than $[Zn(Am4M)(OAc)]_2$.

Intermolecular hydrogen bonding, Table 4, by N14H and $N15H_2$ is common to the 2-pyridineformamide thiosemicarbazone [14,15,32] and N-alkylthiosemicarbazones [16,17]. The distances and angles for the interactions with the coordinated thiol sulfur atoms are comparable to the N–H···S intermolecular interactions of N-2-pyridyl-N′-arylthioureas [36]. For $[Zn(Am4M)(OAc)]_2$ the N14–H14···S1 interaction was stronger based on H14···S1 and N14···S1 distances of 2.67 and 3.466(3) Å and the N15–H15···O11 interaction was also stronger, H15···O11 and N15···O11 distances of 2.20 and 2.973 Å. However, a N15–H15···S1 interaction, which is the stronger of the interactions with sulfur for $[Zn(Am4E)(OAc)]_2$, was not detected in $[Zn(Am4M)(OAc)]_2$.

As might be expected due to the greater bulkiness of the ethyl group compared to a methyl group, the thiosemicarbazone moiety has a mean plane deviation in $[Zn(Am4E)(OAc)]_2$, 0.0717, compared to $[Zn(Am4M)(OAc)]_2$, 0.0316. Also, the angle between the mean planes of the thiosemicarbazone moiety and the pyridine ring is considerably larger, 15.9(9)° compared to 3.8(2)°. However, because the stereochemistry about the Zn center in $[Zn(Am4M)(OAc)]_2$ is closer to a regular trigonal bipyramid, the thiosemicarbazone moiety makes an angle with the bridging acetate group's O11–C2–O12 of 87.3(1)° compared to 75.5(6)° for $[Zn(Am4E)(OAc)]_2$.

*3.2. Structural properties of [Zn(HAm4E)I$_2$] (**4a**)*

The molecular structure of the complex is represented in Fig. 3. The only other crystal structure reported for a 2-pyridineformamide thiosemicarbazone complex prepared with zinc(II) iodide, [Zn(HAm4DH)I$_2$] [13], crystallized in the monoclinic space group $P2_1/n$ while [Zn(HAm4E)I$_2$] is triclinic and $P\bar{1}$. The bond distances to Zn are in the expected order Zn–N(im) < Zn–N(py) < Zn–S with Zn–S and Zn–N(py) longer than for [Zn(Am4E)(OAc)]$_2$, with Zn–N(im) marginally shorter (Table 2). Compared to [Zn(HAm4DH)I$_2$] [13], Zn–S is longer, 2.502(3) Å compared to 2.436(3) Å, Zn–N(py) marginally longer and Zn(im) essentially the same. The Zn–I bond distances are all above 2.6 Å in the two complexes, but there is a difference of >0.06 Å between the Zn–I bonds of [Zn(HAm4DH)I$_2$]. Because the anionic form of the ligand is present in [Zn(Am4E)(OAc)]$_2$

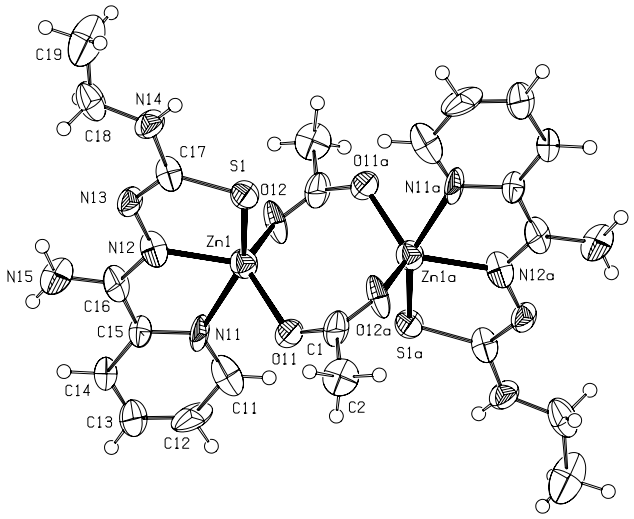

Fig. 2. A view of the molecular structure of $[Zn(Am4E)(OAc)]_2$ (**1**), showing the atom labeling scheme. The thermal motion ellipsoids are drawn at the 50% probability; (a: $-x+1, -y+1, -z+1$).

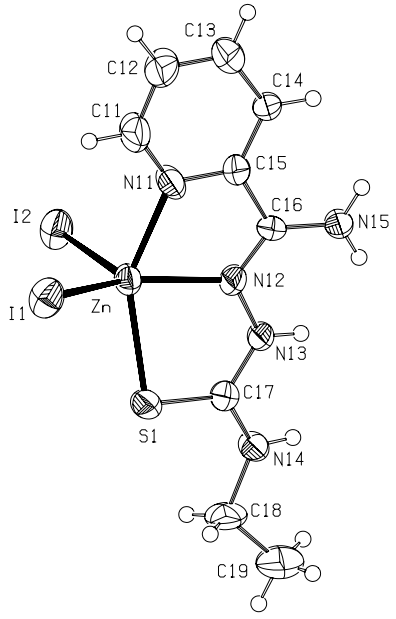

Fig. 3. Molecular structure of $[Zn(HAm4E)I_2]$ (**4a**).

and the neutral ligand in $[Zn(HAm4E)I_2]$, there are difference in the bond distances of the thiosemicarbazone moiety in the two complexes; the biggest difference in S1–C17, which has considerably more double bond character in $[Zn(HAm4E)I_2]$ and essentially the same as the average distance in HAm4E [27]. The bond distances throughout the thiosemicarbazone moiety in $[Zn(HAm4E)I_2]$ are comparable to those of $[Zn(HAm4DH)I_2]$ [14]. The bond angles involving the Zn center, as well as the thiosemicarbazone moiety, of the two complexes are also essentially the same. The parameter $\tau = 0.10$ for $[Zn(HAm4E)I_2]$ and indicates that it is closer to square planar than $[Zn(HAm4DH)I_2]$ ($\tau = 0.23$) [14]. The basal plane could involve either I1 or I2 with the thiosemicarbazone moiety, but because Zn–I1 is marginally shorter it can be designated as the apical donor.

There are a number of weak intermolecular interactions involving all of the hydrogens attached nitrogens in $[Zn(HAm4E)I_2]$, the distances and angles of these interactions are similar to those of $[Zn(HAm4DH)I_2]$ [14]. The angle between the best planes of the pyridine ring and the thiosemicarbazone moiety is smaller than 11.4(6)° found for $[Zn(HAm4DH)I_2]$; Zn is 0.489(8) Å from the mean plane of the thiosemicarbazone moiety.

3.3. Structural properties of $[Cd(Am4E)_2]$ (*5a*)

Fig. 4 shows the molecular structure of the compound along with the atom numbering scheme. $[Cd(Am4E)_2]$, like $[Cd(Ampip)_2]$ and $[Cd(Amhexim)_2]$, is 6-coordinate environment in which both ligands are coordinated in their deprotonated thiolate forms via the pyridine nitrogen, azomethine nitrogen and thiolate sulphur atoms. The two HAm4E are in a meridional position due to the planarity imposed by the conjugated system causing a distortion from octahedral symmetry due to the restricted bite angles for their chelation. One of the ligands HAm4E (S1) is disorder, so that we will consider only the ligand without disorder (S2).

The distances to the cadmium atom differ slightly from that found in $[Cd(HAm4E)Br_2] \cdot DMSO$ and $[Cd(HAm4E)I_2] \cdot DMSO$ and there are significant modifications in bond distances in the thiocarbamide group, C-S is longer than in the free ligand suggesting a degree

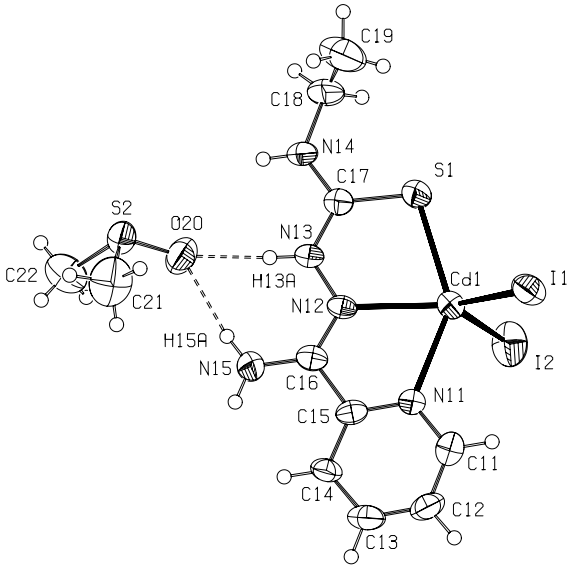

Fig. 4. Atomic displacement plot (50% probability level) of the molecular structure of $[Cd(Am4E)_2]$ (**5a**).

of thione to thiol change which also increase to bond order and shortens the bond length of C7–N3. The C6–N4 distance is longer in $[Cd(Am4E)_2]$ than in HAm4E probably because deprotonation of N(3) reduce the resonance contribution of the thiosemicarbazone chain. These changes in bond distances also differentiate from $[Cd(HAm4E)Br_2]\cdot\cdot$DMSO and $[Cd(HAm4E)I_2]\cdot$DMSO keeping with seems to be a general difference between complexes with neutral and deprotonated ligand.

The mean planes of the thiosemicarbazone moieties are at an angle of 85.3(2)°, similar to 86.5(2)° for $[Cd(Amhexim)_2]$ and 87.2(1)° for $[Cd(Ampip)_2]$, consistent with a nearly 90° octahedral angle.

3.4. Structural properties of $[Cd(HAm4E)Br_2]\cdot DMSO$ (*7a*)

$[Cd(HAm4E)Br_2]\cdot$DMSO (Fig. 5) is (configurationally) isotypic with $[Cd(HAm4E)I_2]\cdot$DMSO, both crystallizing as monoclinic in the space group *Cc* which allows a meaningful comparison of the differences caused by a change in the electronic and steric factor. Beside the difference in the Cd–X bond distances, the Cd–N11 bond is much shorter in $[Cd(HAm4E)Br_2]$ and also significantly shorter than the Cd–N12 bond, which is unusual for thiosemicarbazone complexes. However, a shorter Cd–N11 than Cd–N12 bond distance has also been found for $[Cd(HAc4M)Br_2]\cdot 2$DMSO [37], the only other example to our knowledge. There are no significant differences in the bond distances and angles of the thiosemicarbazone moieties of $[Cd(HAm4E)Br_2]$ and $[Cd(HAm4E)I_2]$. The bond angles involving Cd are also essentially the same for the two complexes and the value of τ, 0.25, for $[Cd(HAm4E)Br_2]$ is similar to the value for $[Cd(HAm4E)I_2]$.

The hydrogen bonding interactions with the oxygen of DMSO are essentially the same as for $[Cd(HAm4E)I_2]$, but the smaller and more electronegative Br allows for another weak interaction with a bromo ligand of a neighboring molecule, N15H15B...Br2. The planarity of the HAm4E ligand in the two cadmium complexes is essentially the same.

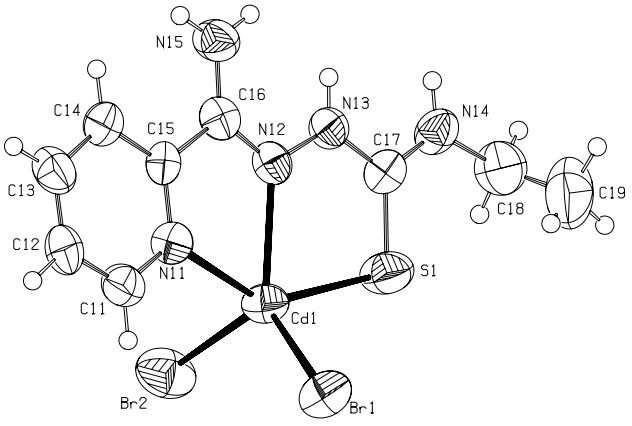

Fig. 5. Molecular structure of $[Cd(HAm4E)Br_2]\cdot$DMSO (**7a**). Solvent DMSO molecule is omitted for clarity.

3.5. Structural properties of $[Cd(HAm4E)I_2]\cdot DMSO$ (*8a*)

The structure of (**8a**) is shown in Fig. 6. The crystal structures of $[Cd(HAc4E)I_2]\cdot 2$DMSO (i.e, HAc4E represents 2-acetylpyridine N(4)-ethylthiosemicarbazone) [37], $[Cd(HAm4DH)I_2]$ [15], $[Cd(HAm4DM)I_2]$ (i.e., HAm4DM represents 2-pyridineformamide N(4)-dimethylthiosemicarbazone) [21], $[Cd(HAmpip)I_2]\cdot$DMSO (i.e., HAmpip represents 2-pyridineformamide 3-piperidylthiosemicarbazone) [23] and $[Cd(HAmhexim)I_2]\cdot$EtOH (i.e., HAmhexim represents 2-pyridineformamide 3-hexamethyleneiminyl thiosemicarbazone) [25] have been reported recently. This allows comparison of identical thiosemicarbazones of 2-acetylpyridine and 2-pyridineformamide, the electronic and steric effects of the N(4)-substituent of the thiosemicarbazone moiety, and the previously discussed $[Zn(HAm4E)I_2]$. As expected all bonds to Cd in $[Cd(HAm4E)I_2]$ are longer than in $Zn(HAm4E)I_2]$, but there are not significant differences between the bond distances of thiosemicarbazone moieties (Table 2). Similarly, there are not significant differences in the bond distances to cadmium in any of the complexes involving 2-pyridineformamide thiosemicarbazones except that in the previously reported structures

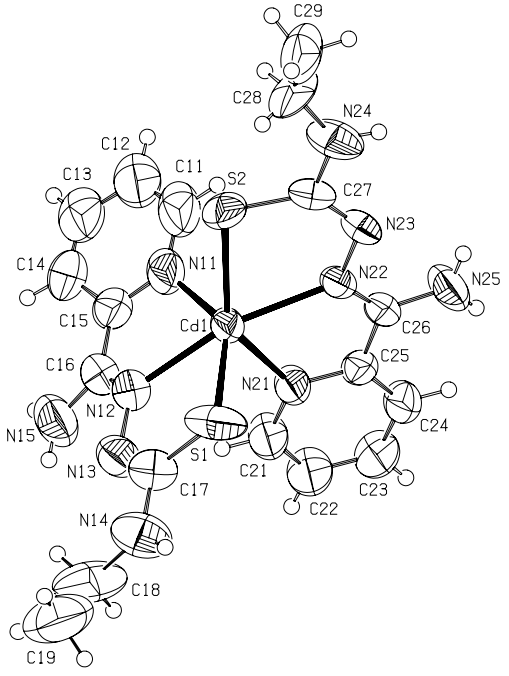

Fig. 6. Perspective view of the structure of $[Cd(HAm4E)I_2]\cdot$DMSO (**8a**). Hydrogen bonding interactions involving the solvent DMSO are also shown.

the Cd–N11 distance is longer than the Cd–N12 distance [15,19,23,25]. In contrast, in [Cd(HAc4E)I_2] the Cd–N12 is marginally longer, 2.398(9) Å compared to 2.362(10) Å, demonstrating the weaker inductive effect of a CH_3 group compared to NH_2 group and Cd–N12 is significantly longer than Cd–N11 in [Cd(HAc4E)I_2] [36], whereas they are the same in [Cd(HAm4E)I_2].

One measure of a steric effect among these complexes prepared with CdI_2 appears to be the τ parameter [35] which has a value of 0.23 for [Cd(HAm4E)I_2]. Other values of τ for related iodo complexes with tridentate neutral thiosemicarbazone ligands are [Cd(HAm4DH)I_2], 0.14 [15]; [Cd(HAm4DM)I_2], 0.21 [21]; [Cd(HAmpip)I_2], 0.10 [27]; [Cd(HAmhexim)I_2], 0.04 [25]; [Cd(HAc4M)I_2], 0.08 [38], [Cd(HAc4E)I_2], 0.05 [37] and [Cd(HAc4DM)I_2], 0.23 [39]. It appears that there is a steric effect which reaches a maximum with the N(4)-ethylthiosemicarbazone of the 2-pyridineformamide series; structures have not been solved for complexes with larger alkyl substituents in the 2-acetylpyridine series. Thus, more members of each series (i.e., Ac, Am), as well as more series (i.e., 2-formyl-, 2-benzoylpyridine etc.), are needed to establish where the actual maximum occurs. It should be noted that the N11–Cd–S1 angle ranges from 131.6(2)° for [Cd(HAm4DM)I_2] [19] to 142.3(3)° for [Cd(HAm4E)I_2], the two complexes with the largest values of τ and greatest distortion toward a trigonal bipyramid structure; the N12–Cd–X1 angle is larger than N11–Cd–S1 in [Cd(HAm4DM)I_2], which shows that these two complexes have very different structural details, despite similar values of τ. [Zn(HAm4E)I_2], $\tau = 0.10$, is closer to square planar than [Cd(HAm4E)I_2], as is [Cd(Ac4E)I_2] [37].

Stronger hydrogen bonding interactions occur for [Cd(HAm4E)I_2] · DMSO than for [Zn(HAm4E)I_2] due to interactions with the DMSO oxygen, Table 4. However, only one of the amide hydrogens, N15H15A, has a intermolecular interaction in contrast to [Zn(HAm4E)I_2] and [Cd(HAm4E)Br_2] · DMSO (vide infra). The larger cadmium atom in [Cd(HAm4E)I_2] places less of a demand on the ligand resulting in an angle between the best planes of the pyridine ring and thiosemicarbazone moiety of 3.9(6)°, substantially less than 8.9(4)° for [Zn(HAm4E)I_2].

3.6. Spectral and physical properties of [Zn(Am4E)(OAc)]$_2$, [Zn(HAm4E)Cl_2], [Zn(HAm4E)Br_2] and [Zn(HAm4E)$_2I_2$]

These zinc complexes have varying shades of yellow due to a $S \rightarrow Zn$ charge transfer band. Although [Zn(HAm4E)$_2I_2$] was isolated, crystals of [Zn(HAm4E)I_2] were obtained from solution. The mass spectra of these zinc complexes show an ion fragment centered at $m/z = 289$ assignable to {Zn(Am4E)$^+$} and the spectrum of [Zn(HAm4E)$_2I_2$] has an ion fragment at $m/z = 509$ which is likely {Zn(HAm4E)(Am4E)$^+$}. Compared to the IR spectrum of HAm4E, the spectra of [Zn(Am4E)(OAc)]$_2$, [Zn(HAm4E)Cl_2] and [Zn(HAm4E)Br_2] show a decrease in the energy of ν(CN), increase in ν(NN) and decrease in ν(CS) (i.e., the thioamide IV band which contains a significant contribution from ν(CS)), which along with bands assignable to ν(ZnN) and ν(ZnS), indicate coordination of the imine nitrogen and thione/thiolato sulfur. The ratio of ν_a(ZnBr)/ν_a(ZnCl) = 0.77 is consistent with [Zn(HAm4E)Cl_2] and [Zn(HAm4E)Br_2] having the same structure. Coordination of the anionic ligand in [Zn(Am4E)(OAc)]$_2$ causes a much larger decrease in the energy of the ν(CS) and bands at 1589 and 1406 cm^{-1} assignable to $\nu_a(CO_2)$ and $\nu_s(CO_2)$, respectively, are consistent with bridging acetate ligands in agreement with crystal structure. Based on IR, it appears that [Zn(HAm4E)$_2I_2$] is tetrahedral with coordination of the two iodo ligands and two thione sulfur atoms. The ^{1}H NMR spectra of these zinc complexes are not significantly different from spectrum of HAm4E except in the spectrum of [Zn(Am4E)(OAc)]$_2$ where the anionic ligand and coordination of the thiolato sulfur causes an upfield shift of N14H. This upfield was observed in [Zn(HAm4E)$_2I_2$] indicating the different structure of this complex respecting to the other halo zinc complexes. The CH_3 resonance of the bridging acetate ligands is at 1.76 ppm. In the ^{13}C spectra in the zinc halo complexes the C7 is the signal more deshield except in the [Zn(Am4E)(OAc)]$_2$ where the C(OAc) appears at 173.40 and the Me(OAc) appears at 23.02 ppm.

3.7. Spectral and physical properties of [Cd(Am4E)(OAc)]$_2$, [Cd(HAm4E)Cl_2], [Cd(HAm4E)Br_2] and [Cd(HAm4E)I_2]

The mass spectra of the cadmium complexes is less regular than the zinc complexes with only [Cd(Am4E)(OAc)]$_2$ and [Cd(HAm4E)I_2] having the ion fragment at $m/z = 336$ assignable to {Cd(HAm4E)$^+$}. Like the zinc complexes, however, the spectrum of [Cd(Am4E)(OAc)]$_2$ has a ion fragment at $m/z = 558$ consistent with {Cd(HAm4E)(Am4E)$^+$} and the spectrum of [Cd(HAm4E)I_2] and [Cd(HAm4E)Cl_2] at $m/z = 464$ and 371 consistent with {Cd(HAm4E)I$^+$} and {Cd(HAm4E)Cl$^+$}, respectively. In contrast to the zinc complexes ν(CS) in the cadmium complexes with neutral HAm4E is not shifted to lower energy due to back donation of electron density from the cadmium centers, which is consistetnt with ν(CdS) and ν(ZnS) being essentially the same. The ratios of ν_a(CdBr)/ν_a(CdCl) = 0.70 and ν_a(CdI)/ν_a(CdBr) = 0.89 are consistent with [Cd(HAm4E)Cl_2], [Cd(HAm4E)Br_2] and [Cd(HAm4E)I_2] being isostructural. Like [Zn(Am4E)(OAc)]$_2$ only the upfield shift of N14H in the spectrum of [Cd(A-

m4E)(OAc)]$_2$ compared to HAm4E is a significant difference on coordination and besides the disappearance of the proton N3 indicatives the deprotonation of the ligand. The ^{13}C NMR resonance assigned to the thione/thiolato carbon, C17, does shift upfield more for the cadmium complexes than the zinc complexes again indicating greater back donation of electron density from he cadmium centers. The resonances in ^{113}Cd NMR spectra for [Cd(Am4E)(OAc)]$_2$ are 254.8 and 415.1 ppm, which is compatible with a dinuclear complex and for [Cd(HAm4E)Cl$_2$], [Cd(HAm4E)Br$_2$] and [Cd(HAm4E)I$_2$] are 388.9, 294.6 and 366.6 ppm, respectively, where the progressive increase in shielding upon replacement of Cl by Br and Br by I is consistent with the decreasing electronegativity of the halide. The observed chemical shifts are in the range expected for 5-coordinate cadmium(II) complexes.

4. Supplementary data

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 236646–236650 for [Zn(Am4E)(OAc)]$_2$, [Zn(HAm4E)I$_2$], [Cd(Am4E)$_2$], [Cd(HAm4E)Br$_2$] · DMSO and [Cd(HAm4E)I$_2$] · DMSO, respectively. Syntheses and spectroscopy of diamine complexes of Zn(II) and Cd(II) ethylxanthates and the molecular structures of $[M(S_2COEt)_2TMEDA]$: formation of CdS nanoparticles from $[Cd(S_2COEt)_2]$ and $[Cd(S_2COEt)_2TMEDA]$

Abstract

The zinc and cadmium ethylxanthate complexes of *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (TMEDA), $[M(S_2COEt)_2TMEDA]$, were synthesized and characterized with infrared, ^1H and ^{13}C NMR spectroscopy, mass spectrometry and X-ray crystallography. Whereas the cadmium complex has a six-coordinate $\{CdS_4N_2\}$ centre with bidentate xanthate ligands, the zinc complex contains four coordinate $\{ZnS_2N_2\}$ zinc with two monodentate xanthate groups. The cadmium species $[Cd(S_2COEt)_2(diamine)]$ (where diamine = *N*,*N*-dimethylethylenediamine or *N*,*N*′-diisopropylethylenediamine) were also synthesized. The surfactant-assisted formation of nanoparticles from $[Cd(S_2COEt)_2]$ and $[Cd(S_2COEt)_2TMEDA]$ was studied with TEM, XRD and XRF techniques. From $[Cd(S_2COEt)_2]$, spherical nanoparticle aggregates 140–200 nm in diameter were obtained but from $[Cd(S_2COEt)_2TMEDA]$, single nanoparticles were produced with estimated diameters in the range of 4–7 nm and almost no aggregation.

Keywords: Xanthate; Diamine; Zinc; Cadmium; CdS; Nanoparticles

1. Introduction

Much attention has been given recently to the relatively new field of "quantum dot" nanoparticles [1,2] and their applications as optoelectronic materials [1,3]. The burgeoning interest in nanoparticles in general is due to their unique chemical and electronic properties, which have potential applications in non-linear optics, luminescence, electronics, catalysis and solar energy conversion [4–10] as well as optoelectronics. In order to make functioning devices, it will be necessary to synthesize nanomaterials which will have uniform size and properties. A major interest at the moment is in the development of single-source precursors of metal chalcogenides [11–15]. In the case of MX (M = Zn, Cd; X = S, Se) particular attention has been paid to dithiocarbamates and diselenocarbamates [16–19].

Suitable single-source precursors for MS (M = Zn or Cd) would contain direct metal–sulfur bonds. We have already shown the suitability of $[Zn(S_2COEt)_2]$ for the production of thin films of zinc sulphide [20]. However, relatively little use has been made of xanthates in the formation of nanoparticles [21]. We decided to investigate the synthesis of novel molecular precursors based on xanthates and to study their potential for the production of CdS nanoparticles.

Many methods have been devised for the preparation of nanoparticles and nanowires of metal sulphides. The most common methods for the synthesis of nanoparticles and nanowires involve reverse micelles [22,23], organic templates [24], inorganic templates, including mesoporous silica [25,26] and the thermal decomposition of precursors in the presence of capping ligands [27–29]. This last method has been especially successful with tri-*n*-octylphosphine oxide (TOPO) as the capping ligand [12–14,16]. With the exception of the thermal decomposition "TOPO method", only a small number of methods have employed single-source precursors. With this in mind it was decided to investigate the possibility of using a surfactant to enable the production of CdS nanoparticles from $[Cd(S_2COEt)_2]$ and $[Cd(S_2COEt)_2TMEDA]$ precursors. The method used was broadly based on that reported by Zhao et al. [30].

2. Experimental

All chemicals $[ZnCl_2 \cdot 4H_2O]$, $[CdCl_2 \cdot 2\frac{1}{2}H_2O]$, [K($S_2$COEt)], *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (TMEDA), *N*,*N*-dimethylethylenediamine (DMEDA), *N*,*N*′-diisopropylethylenediamine (DiPEDA), Brij 52 and solvents were supplied by Aldrich Chemical Co. and used as received. Microanalyses were recorded on an Exeter Analytical Inc. CE 444 CHN elemental analyzer at UCC. FT-IR spectra were recorded on a Perkin–Elmer Paragon 1000 spectrometer as KBr discs. NMR spectra (^{1}H and ^{13}C) were obtained in $CDCl_3$ solution at ambient temperature using a Bruker-Avance 300 spectrometer with TMS as an internal standard. Mass spectra were obtained on a KRATOS HV5 profile machine. XRD data was collected on a Philips PW3710 X'Pert diffractometer, equipped with a Cu Kα radiation source and accelerator detector at 40 kV/40 mA. X-ray fluorescence data were recorded on a Phillips Minipal PW4025, at 30 kV, 50 μA using an Al filter and a Kapton ray source. TEM was carried out on a JEOL 2000 microscope operating at 200 kV.

2.1. Synthesis and characterization of $[M(S_2COEt)_2]$ where M = Zn and Cd

2.1.1. General procedure

All reactions and workup procedures were carried out in air. The compounds $[Zn(S_2COEt)_2]$ [31] and $[Cd(S_2COEt)_2]$ [32] are well known and were prepared by methods based on the literature reports. Typically, an aqueous solution of K[S_2COEt] (13 mmol in 10 ml water) was added drop-wise to an aqueous solution of the metal chloride (6.5 mmol in 20 ml water) with continuous stirring. There was immediate formation of a cream coloured precipitate of $[M(S_2COEt)_2]$. The mixture was stirred for 20 min, the solid product filtered, washed with water and dried for 16 h at 60 °C.

2.1.1.1. $Cd(S_2COEt)_2$.

Elemental *Anal.* Calc. for $Cd(S_2COEt)_2$: C, 20.3; H, 2.8. Found: C, 20.3; H, 2.7%. IR (KBr): ν_{max} (cm^{-1}); 1198, 1122, 1031. ^{1}H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio, assignment: 4.53 (q, 2H, $S_2COCH_2CH_3$), 1.48 (t, 3H, $S_2COCH_2CH_3$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 231.64 ($S_2COCH_2CH_3$), 72.07 ($S_2COCH_2CH_3$), 14.12 ($S_2COCH_2CH_3$). Yield: 94.5%. M.p. (°C): 158–159 (dec.).

2.1.1.2. $Zn(S_2COEt)_2$.

Elemental *Anal.* Calc. for $Zn(S_2COEt)_2$: C, 23.4; H, 3.3. Found: C, 23.2; H, 3.2%. IR (KBr): ν_{max} (cm^{-1}); 1210, 1125, 1047, 1028. ^{1}H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio, assignment: 4.58 (q, 2H, $S_2COCH_2CH_3$), 1.49 (t, 3H, $S_2COCH_2CH_3$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 226.64 ($S_2COCH_2CH_3$), 70.70 ($S_2COCH_2CH_3$), 14.08 ($S_2COCH_2CH_3$). Yield: 85.5%. M.p. (°C): 139–140 (dec.).

2.2. Synthesis and characterization of $[M(S_2COEt)_2TMEDA]$ where M = Zn and Cd

TMEDA, equimolar to the $[M(S_2COEt)_2]$ used, was added drop-wise with stirring to a solution of $[M(S_2COEt)_2]$ in a minimum amount of methanol. The reaction mixture was stirred for 20 min, solid product filtered, washed with water and dried for 16 h at 60 °C.

2.2.1. $[Cd(S_2COEt)_2TMEDA]$

Elemental *Anal.* Calc. for $[Cd(S_2COEt)_2TMEDA]$: C, 30.6; H, 5.6; N, 5.95. Found: C, 30.4; H, 5.5; N, 5.6%. IR (KBr): ν_{max} (cm^{-1}); 1292, 1185, 1116, 1035, 1028. ^{1}H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio, assignment: 4.45 (q, 2H, $S_2COCH_2CH_3$), 2.64 (s, 2H, $(CH_3)_2N(CH_2)_2N(CH_3)_2$), 2.55 (s, 6H, $(CH_3)_2N(CH_2)_2N(CH_3)_2$) 1.42 (t, 3H, $S_2COCH_2CH_3$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 231.55 ($S_2COCH_2CH_3$), 73.46 ($S_2COCH_2CH_3$), 56.54 ($(CH_3)_2N(CH_2)_2N(CH_3)_2$), 46.00 ($(CH_3)_2N(CH_2)_2N(CH_3)_2$), 14.24 ($S_2COCH_2CH_3$). EI-MS: *m*/*z* 474 pmi ($[Cd(S_2COEt)_2TMEDA]$), 473 $[pmi - 1]^+$ ($[Cd(S_2COEt)_2TMEDA–H]^+$) for ^{116}Cd. Yield: 83.5%. M.p. (°C): 169 (dec.).

2.2.2. $[Zn(S_2COEt)_2TMEDA]$

Elemental *Anal.* Calc. for $[Zn(S_2COEt)_2TMEDA]$: C, 34.0; H, 6.2; N, 6.6. Found: C, 33.8; H, 6.2; N, 6.45%. IR (KBr): ν_{max} (cm^{-1}); 1290, 1176, 1122, 1047, 1026. ^{1}H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio, assignment: 4.47 (q, 2H, $S_2COCH_2CH_3$), 2.61 (s, 2H, $(CH_3)_2N(CH_2)_2N(CH_3)_2$),

2.53 (s, 6H, $(CH_3)_2N$–$(CH_2)_2N(CH_3)_2$) 1.40 (t, 3H, $S_2COCH_2CH_3$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 225.64 ($S_2COCH_2CH_3$), 71.00 ($S_2COCH_2CH_3$), 56.98 ($(CH_3)_2N(CH_2)_2N(CH_3)_2$), 46.85 ($(CH_3)_2N(CH_2)_2N(CH_3)_2$), 14.17 ($S_2COCH_2CH_3$). EI-MS: *m/z* 305 $[Zn(S_2COEt)_2–H]^+$. Yield: 85.5%. M.p. (°C): 129–130 (dec.).

2.3. Synthesis and characterization of $[Cd(S_2COEt)_2$ (diamine)] where diamine = N,N-dimethylethylenediamine (DMEDA) and N,N′-diisopropylethylenediamine (DiPEDA) in a 'one-pot' reaction

To an aqueous solution of $[CdCl_2 \cdot 2\frac{1}{2}H_2O]$ (4.5 mmol in 20 ml water) the diamine ligand was added drop-wise, with stirring. After 5 min, an aqueous solution of $K[S_2COEt]$ (9 mmol in 10 ml water) was added. The reaction mixture was stirred for 20 min, solid product filtered, washed with water and dried for 16 h at 40 °C.

2.3.1. $[Cd(S_2COEt)_2DMEDA]$

Elemental *Anal.* Calc. for $[Cd(S_2COEt)_2DMEDA]$: C, 27.1; H, 5.0; N, 6.1. Found: C, 27.15; H, 5.0; N, 6.1%. IR (KBr): ν_{max} (cm^{-1}); 1188, 1114, 1036, 1003. ^1H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio, assignment: 4.47 (q, 2H, $S_2COCH_2CH_3$), 3.06 (broad singlet, H, $(CH_3)_2NCH_2CH_2NH_2$), 2.64 (t, H, $(CH_3)_2NCH_2CH_2NH_2$), 2.54 (s, 3H $(CH_3)_2NCH_2CH_2NH_2$), 1.42 (t, 3H, $S_2COCH_2CH_3$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 231.24 ($S_2COCH_2CH_3$), 73.38 ($S_2COCH_2CH_3$), 59.65 ($(CH_3)_2NCH_2CH_2NH_2$), 45.85 ($(CH_3)_2NCH_2CH_2NH_2$), 37.34 ($(CH_3)_2NCH_2CH_2NH_2$), 14.24 ($S_2COCH_2CH_3$). Yield: 90%. M.p. (°C): 96–97.

2.3.2. $[Cd(S_2COEt)_2DiPEDA]$

Elemental *Anal.* Calc. for $[Cd(S_2COEt)_2DiPEDA]$: C, 33.7; H, 6.1; N, 5.6. Found: C, 33.5; H, 6.0; N, 5.5%. IR (KBr): ν_{max} (cm^{-1}); 1178, 1110, 1042. ^1H NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), multiplicity, relative ratio of H atoms, assignment: 4.46 (q, 2H, $S_2COCH_2CH_3$), 3.17 (septet, H, $(CH_3)_2CHN(CH_2)_2NCH(CH_3)_2$), 3.00 (s, 2H, $(CH_3)_2CHN(CH_2)_2NCH(CH_3)_2$), 1.42 (t, 3H, $S_2COCH_2CH_3$) 1.29 (d, 6H $(CH_3)_2CHN(CH_2)_2$ $NCH(CH_3)_2$). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K) ordered as δ (ppm), assignment: 229.65 ($S_2COCH_2CH_3$), 72.84 ($S_2COCH_2CH_3$), 50.02 ($(CH_3)_2CHN(CH_2)_2NCH(CH_3)_2$), 45.29 ($(CH_3)_2CHN(CH_2)_2NCH(CH_3)_2$), 22.44 ($(CH_3)_2CHN(CH_2)_2N$–$CH(CH_3)_2$), 14.21 ($S_2COCH_2CH_3$). Yield: 89%. M.p. (°C): 128.9–129.1 (dec.).

2.4. Preparation of CdS nanoparticles by a surfactant-assisted method using a single-source precursor

Brij 52 (5 g) in 10 ml water was stirred at 40 °C for 15 min. Five mmol of the precursor (0.18 g $[Cd(S_2COEt)_2]$, or 0.24 g of $[Cd(S_2COEt)_2TMEDA]$) was added. The mixture was heated at the reflux temperature for 8 h. The yellow precipitate was separated from the mixture by means of centrifugation. The precipitate was repeatedly washed with ethanol and ultrasonically dispersed in ethanol. A drop of the mixture was deposited on a copper grid and dried in air overnight for TEM analysis. The precipitate was also characterized by XRF and XRD.

2.5. X-ray crystallographic analyses of $[M(S_2COEt)_2TMEDA]$ where M = Zn (**1**) and Cd (**2**)

Crystals of crystallographic quality were obtained when $[Zn(S_2COEt)_2TMEDA]$ (**1**) and $[Cd(S_2COEt)_2$-TMEDA] (**2**) were synthesized in THF. Details of the crystals of complexes **1** and **2** are shown in Table 1. Data for **1** and **2** were measured with Mo Kα radiation using the MAR research Image Plate System. The crystals were positioned at 70 mm from the Image Plate. 100 frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [33]. The structure was solved using direct methods with the SHELX-86 program [34]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. Empirical absorption corrections were applied using the DIFABS program [35]. The structures were refined on F^2 using the SHELXL program [36].

3. Results and discussion

3.1. Syntheses

The success of the synthetic procedure was dependent on the choice of solvent and reagents. Thus, although a 'two-pot' method could be used with either methanol or THF as solvent to prepare the $[M(S_2COEt)_2TMEDA]$ complexes where M = Zn and Cd, it was not possible to obtain analytically pure samples of $[Cd(S_2COEt)_2$-(diamine)] with diamine = DMEDA or DiPEDA in these solvents. With water as solvent in a 'one-pot' reaction it was possible to obtain all three $[Cd(S_2COEt)_2$-(diamine)] complexes.

3.2. X-ray structural studies of $[M(S_2COEt)_2TMEDA]$ where M = Zn (1) and Cd (2)

The molecular structure of **1** which has a crystallographic twofold axis is shown in Fig. 1. The zinc atom is four-co-ordinate being bonded to two nitrogen atoms of the TMEDA ligand and to two xanthate ligands each via a single sulfur atom. The geometry of the coordination sphere is distorted tetrahedral. The chelating TMEDA ligand subtends an angle of 85.5(4)° at the metal while the S–Zn–S angle is 130.8(2)°, the remaining angles ranging from 105.9(2)° to 109.8(2)°. The Zn–N and Zn–S(2) bond lengths at 2.147(7) and 2.304(3) Å, respectively, are within the expected range of values for such bonds. The non-bonded sulfur atom, S(3), is 3.33 Å from the zinc atom and hence the molecules of **1** are essentially monomeric. In the $\{S_2C\}$ section of the xanthate ligands, the carbon to sulfur, S(2), distance is 1.729(9) Å which is typical of a single bond whereas the carbon to sulfur S(3) distance of 1.646(9) Å is typical of a carbon to sulfur double bond [37]. Indeed, the carbon to sulfur S(3) distance is shorter than the reported mean of C=S distances in $(X)_2$–C=S compounds (X = C, N, O or S) 1.671 Å and thioureas, 1.681 Å. The monomeric nature of **1** is in contrast to $[Zn(S_2COEt)_2]$ which has polymeric structure of xanthate-bridged zinc atoms [31].

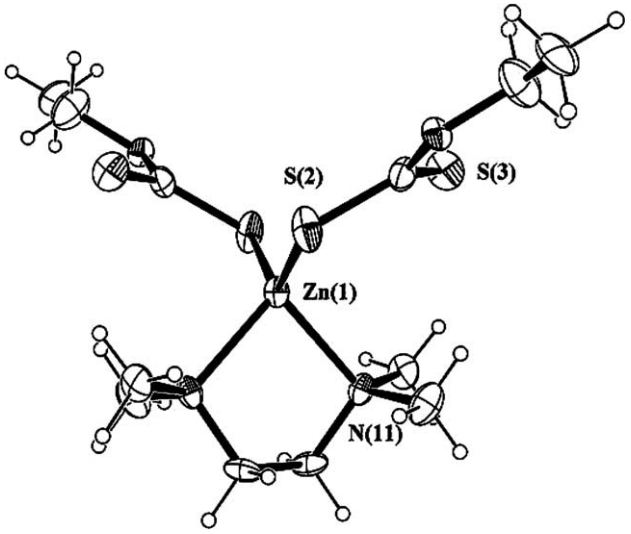

Fig. 1. The structure of $[Zn(Xan)_2TMEDA]$ which contains a crystallographic twofold axis, with ellipsoids at 30% probability. Unique bond lengths in the coordination sphere are Zn(1)–S(2) 2.304(3), Zn(1)–N(11) 2.147(6) Å. The Zn(1)–S(3) distance is 3.33 Å. The S–Zn–S angle is 130.8(2)°, N–Zn–N angle is 85.5(4)° and the remaining S–Zn–N angles are 105.88(18)° and 109.76(18)°. The C(4)–S(2) distance is 1.729(9) Å and the C(4)–S(3) distance is 1.649(9) Å.

In **2** the metal atom is bonded to two nitrogen atoms at 2.421(8), 2.420(9) Å and four sulfur atoms at distances in the range 2.680(5)–2.706(3) Å, values that are usual for cadmium. The distortions from octahedral geometry are primarily caused by the small S···S bite in the xanthate ligand that gives rise to S–Cd–S angles of 66.9(2)° and 67.2(11)° in the two ligands (see Fig. 2).

3.3. Spectroscopy

The ^1H NMR spectra of the zinc and cadmium TMEDA complexes are almost indistinguishable. However, the ^{13}C spectra show a significant difference between the compounds in the S_2COEt carbon signal region. The chemical shift moves 5.9 ppm downfield in the zinc complex with respect to the cadmium compound. This may be related to the coordination of the xanthate ligands in the structures of **1** and **2**. In general, the xanthate ligand is either a bidentate ligand on a single metal, as in **2**, or it bridges two metals [38]. The zinc complex **1** in the solid state has one sulfur atom from each xanthate bonded to the zinc and the other participating in what is essentially a C=S bond. The cadmium structure **2** is six-coordinate with bidentate xanthate ligands and partial C to S double bond character in both carbon–sulfur bonds. The difference is reflected in the downfield shift of the S_2COEt signal in the NMR spectra of complex **1** compared to **2** and also slightly affects the methylene carbon in the xanthate ligand.

The FT-IR spectra of all the complexes show three very strong bands in the region 1190–1035 cm^{-1} which are characteristic of xanthate compounds [39].

3.4. Preparation of CdS nanoparticles by the surfactant-assisted method using a single-source precursor

Both precursors, $[Cd(S_2COEt)_2]$ and $[Cd(S_2COEt)_2TMEDA]$ produced orange-yellow powders, after their ethanol solutions were allowed to evaporate in air. Initial characterization was by XRD and XRF analysis. The XRD analysis showed four major peaks at $2\theta = 26.5°$, 44, 52°, and 64°, corresponding to the (111), (220), (311) and (400) planes of cubic CdS (JCPRD card 10-0454), respectively. The XRD peaks are quite broad, for example, the peak corresponding

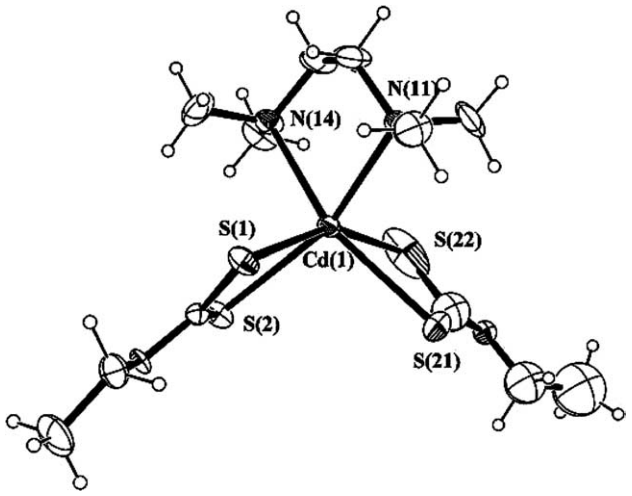

Fig. 2. The structure of $[Cd(Xan)_2TMEDA]$ with ellipsoids at 30% probability. Bond lengths (Å) in the metal coordination sphere are Cd(1)–S(1) 2.706(3), Cd(1)–S(2) 2.697(3), Cd(1)–S(21) 2.680(5), Cd(1)–S(22) 2.700(4), Cd(1)–N(11) 2.421(8), Cd(1)–N(14) 2.420(9). Bond angles (°) of note are: S(1)–Cd(1)–S(2) 67.2(1), S(1)–Cd(1)–S(21) 157.71(1), S(1)–Cd(1)–S(22) 97.83(16), S(2)–Cd(1)–S(21) 98.53(2), S(2)–Cd(1)–S(22) 100.38(13), S(22)–Cd(1)–S(21) 66.9(3), N(11)–Cd(1)–N(14) 76.0(3), N(11)–Cd(1)–S(1) 97.4(2), N(11)–Cd(1)–S(2) 159.4(2), N(11)–Cd(1)–S(22) 95.0(2), N(11)–Cd(1)–S(21) 100.0(3), N(14)–Cd(1)–S(1) 101.9(3), N(14)–Cd(1)–S(2) 93.4(2), N(14)–Cd(1)–S(22) 159.1(3), N(14)–Cd(1)–S(21) 95.7(3).

to the (3 1 1) reflection at 44° had a FWHM of 0.23. The XRF spectrum shows strong peaks for cadmium and sulfur.

Further characterization was by TEM. Fig. 3, shows pseudo-spherical nanoparticle aggregates produced from $[Cd(S_2COEt)_2]$. These aggregates are 140–200 nm in diameter. A small number of nanorods about 1.5 μm long and 100 nm wide in size was also observed. Heating the nanoparticle reaction mixture for 24 h instead of 8 h did not increase the relative number of nanorods or the size of either the nanoparticle aggregates or the nanorods.

In the work of Zhao et al. [30], who used Brij 58 surfactant and a mixture of $[Cd(NO_3)_2]$, thiourea and excess ethylenediamine, 8–15 nm nanorods of hexagonal CdS were reported and there was no mention of aggregated nanoparticles like those shown in Fig. 3. Spherical nanoparticles with a mean diameter of 4.2 ± 0.4 nm of hexagonal CdS were produced by Nair et al. [40] who used $[Cd(S_2COEt)_2]$ in the TOPO capping method. Although TEM analysis showed the particles grouping together in the work by Nair et al., there were no clearly defined aggregates. The difference between the nanoparticles produced by Nair et al. and the aggregates obtained in the present work is due presumably to the presence of the TOPO capping ligand which prevents aggregation of the CdS/TOPO nanoparticles.

It is noteworthy that, if the reaction leading to the nanoparticle aggregates was stopped after 6 h rather than 8 h, the aggregated nanoparticles had not fully formed, as can be seen in Fig. 4. Instead, a mixture of nanoparticles with an estimated diameter of between 4 and 7 nm and aggregates with diameters of ~20 nm were present.

Nanoparticle formation using the Brij surfactant and $[Cd(S_2COEt)_2TMEDA]$ as a single CdS source produced, after 8 h, nanoparticles with estimated diameters in the range of 4–7 nm. There was almost no aggregation. Clearly, the diamine in the cadmium reactant affects the final size of the CdS particles most probably by acting as an effective capping ligand.

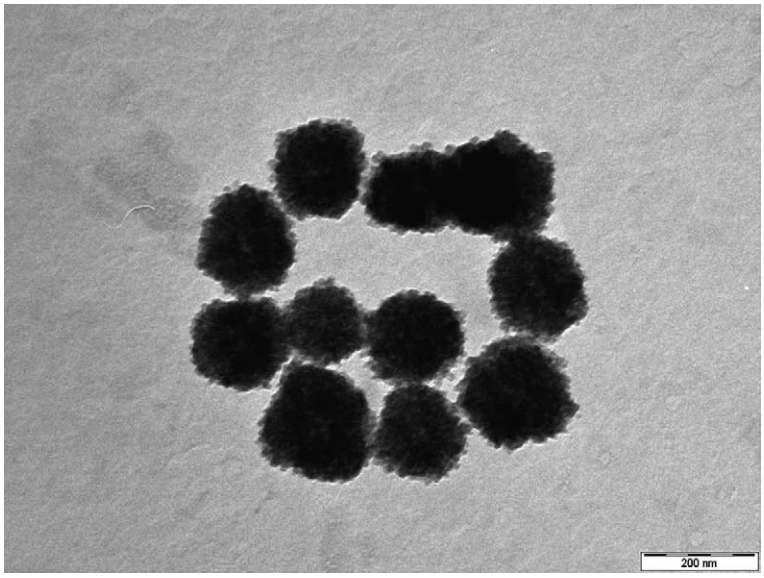

Fig. 3. CdS pseudo-spherical nanoparticle aggregates of 140–200 nm in diameter produced from $[Cd(S_2COEt)_2]$ single-source precursor via the Brij method after refluxing for 8 h.

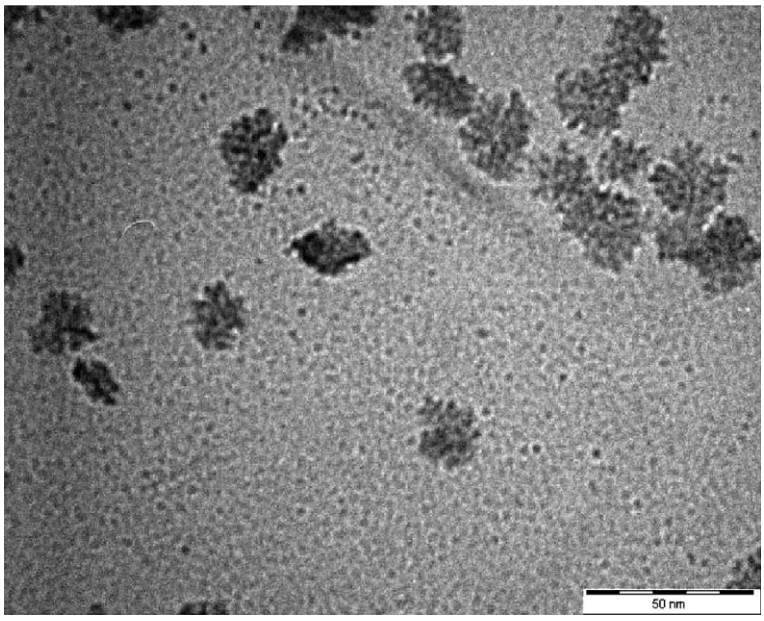

Fig. 4. TEM of nanoparticles produced via the Brij method from $[Cd(S_2COEt)_2]$ after refluxing for 6 h.

4. Supplementary material

Details in the CIF format of the two structures, $[Zn(S_2COEt)_2TMEDA]$ **1** and $[Cd(S_2COEt)_2TMEDA]$ **2**, have been deposited at the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk (Reference Nos. 239456 and 239457, respectively).

Abstract

Syntheses and structural studies for the two complexes dichloro-{2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine}Hg(II) (**1**) and dichloro-{2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine}Hg(II) (**2**) are reported. The solid-state structures of the complexes were determined by X-ray diffraction methods and in addition, the complexes were characterized in solution using ^{1}H, ^{13}C and ^{199}Hg NMR spectroscopy. The X-ray structures reveal that the complexes adopt surprisingly different structures. Complex **2** has an extended polymeric structure with 2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine behaving as a monodentate ligand via the pyridyl nitrogen, and all the chlorine atoms serving to bridge mercury atoms, whereas complex **1** has a dimeric structure with 2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine behaving as a bidentate ligand via the pyridyl nitrogen and one of the azo nitrogens, with a terminal chlorine on each Hg and a μ,μ′-dichloro bridge between the mercury atoms. But the coordination geometry around the mercury atom is similar in both complexes, each showing a distorted trigonal bipyramidal arrangement of the donor atoms. These complexes were characterized in solution by ^{1}H, ^{13}C, ^{199}Hg NMR spectroscopy.

Keywords: 2-[(*E*)-2-(aryl)-1-diazenyl]pyridine; Hg(II) complexes; NMR; Crystal structures

1. Introduction

The metal complexes of heterocyclic α-diimine ligands such as 2,2′-bipyridine and 1,10-phenanthroline have proven to be useful for studying such phenomena as luminescence and photo reduction/oxidation. It is for this reason that extensive studies with the 2-(arylazo)pyridine (hereafter named as 2-[(*E*)-2-(aryl)-1-diazenyl]pyridine, Fig. 1) system have been undertaken and a number of studies of metal complexes containing this type of ligand have been reported. These include investigations of complexes of Fe(II) [1,2], Ni(II) [2], Hg(II) [3,4], Os(II) [5,6], Ru(II) [7–19], Cr(0), Mo(0), W(0) [20,21], Cr(II) [22], Cu(I) [23], Rh(III) [24,25], Rh(I) [26], Ag(I) [27], Re(III) [28], Co(II) [29], Mo(IV) [15], Ru(III) [30], Sn(IV) [31] and organometallic complexes of Re(I) [32] and Sn(IV) [33–37]. In spite of such a wide-ranging series of studies on a variety of metal complexes involving these ligands, the structures of the mer-

(L^1: R = 4-CH_3 and L^2: R = 3-CH_3)

Fig. 1. Generic structure of the ligand.

cury complexes have remained uncertain [3,4]. A mercuration reaction was attempted with 2-[(*E*)-2-(phenyl)-1-diazenyl]pyridine but gave no detectable mercuration products, instead an addition product was isolated [3]. The same product (which was characterized by m.p. and microanalytical data) was again prepared by reacting mercuric chloride and 2-[(*E*)-2-(phenyl)-1-diazenyl]pyridine. Structures for the Hg(II) complexes of analogous ligands have been proposed on the basis of electronic, infrared and ^{1}H NMR spectra. However these studies cannot provide definitive conclusions concerning the co-ordination geometry of the complexes [4]. In this paper, X-ray diffraction results are reported for two mercury complexes in combination with their detailed ^{1}H, ^{13}C, ^{199}Hg NMR spectroscopic data. Consequently, we are able to be quite confident of our descriptions of the structures of these complexes at least in the solid state.

2. Experimental

2.1. Materials

$HgCl_2$ (Merck) was used without further purification. All the solvents used in the reactions were of AR grade and dried using standard literature procedures. The ligands, viz., 2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine and 2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine (abbreviated as L^1 and L^2, respectively) were prepared according to the literature methods [38,39]. The complexes, dichloro-{2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine}Hg(II); L^1HgCl_2 (**1**) and dichloro-{2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine}Hg(II); L^2HgCl_2 (**2**) were prepared by a method similar to that reported earlier with slight modifications [4]. A typical procedure is described below (see Section 2.3).

2.2. Physical measurements

Carbon, hydrogen and nitrogen analyses were performed with a Perkin–Elmer 2400 series II instrument. IR spectra in the range 4000–400 cm^{-1} were obtained on a Perkin Elmer 983 spectrophotometer with samples as KBr discs. For the ^{1}H (500.13 MHz) and ^{13}C (125.76 MHz) NMR spectra and two-dimensional experiments, the instrument used was a Bruker Avance 500 NMR spectrometer equipped with a triple (^{1}H/^{13}C/broadband) 5 mm inverse probe. The ^{1}H and ^{13}C chemical shifts were referred to internal TMS ($\delta = 0.00$). Samples were dissolved either in acetone-d_6 or DMSO-d_6. Two-dimensional experiments (gradient-selected (gs)-COSY, gs-HSQC and gs-HMBC) were performed using the manufacturer's software (XWINNMR version 3.1). The ^{199}Hg (64.50 MHz) NMR spectra were recorded on a Bruker AMX 360 NMR spectrometer equipped with a 5 mm tunable broadband probe. The ^{199}Hg chemical shifts were referred to $Hg(CH_3)_2$ ($\delta = 0.0$) by a calculation procedure using $\Xi(^{199}\text{Hg}) = 17\,910\,841$ Hz and $\Xi(^1\text{H}) = 100\,000\,000$ Hz for proton resonance in tetramethylsilane [40]. Positive values of chemical shifts denote shifts to higher frequencies.

2.3. Preparation of dichloro-{2-[(E)-2-(4-methylphenyl)-1-diazenyl]pyridine}Hg(II) (1)

$HgCl_2$ (0.345 g, 1.27 mmol) in 25 ml of acetone was added drop-wise to a stirred acetone solution (15 ml) containing L^1 (0.25 g, 1.26 mmol). The reaction mixture was stirred for 6 h at ambient temperature, and the solvent was removed using a rotary evaporator. The resulting dry mass was washed thoroughly with petroleum ether to remove any unreacted ligand, extracted into acetone (20 ml) and filtered. The red solution was allowed to evaporate slowly at ambient temperature until crystallization occurred. This yielded red crystals of **1** in 90 % yield; m.p.: 192–194 °C (180–181 °C) [4]. *Anal.* Calc. for $C_{12}H_{11}N_3HgCl_2$: C, 30.73; H, 2.35; N, 8.96. Found: C, 30.71; H, 2.38; N, 8.92%. (DMSO-d_6) δ: 160.89 (C-1), 151.72 (C-1′), 149.61 (C-3), 140.56 (C-5), 139.57 (C-3′), 133.99 (C-4′), 129.76 (C-5′), 126.89 (C-4), 123.42 (C-2′), 121.34 (C-6′), 116.44 (C-6), 20.08 (CH_3) ppm. ^{199}Hg NMR (acetone-d_6) δ: = −1349.8 and (DMSO-d_6) δ: = −1433.2 ppm.

2.5. X-ray crystallography

The intensity data for dark red block-shaped crystals of complexes **1** and **2** were measured on a Bruker P4S using Cu Kα radiation (λ = 1.54178 Å) and on a Bruker SMART 1K using Mo Kα radiation (λ = 0.71073 Å), respectively. Empirical corrections were made from psi-scan curves [41]. The structures were solved by direct methods. All hydrogen atoms were given calculated positions. Neutral atom scattering factors were taken from the literature [42]. All computations were performed using the SHELXTL programmes [43]. All refinements were performed by full-matrix least-squares on F^2. The data were corrected for Lorentz and polarization effects.

3. Results and discussion

3.1. Syntheses

The complexes dichloro-{2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine}Hg(II) (**1**) and dichloro-{2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine}Hg(II) (**2**) were prepared in good yield by stirring stoichiometric amounts of $HgCl_2$ and L^1 or L^2 in acetone. The complexes are stable and can be stored in the solid state at room temperature for months. Selected characterization data for the complexes are presented in the experimental section. The microanalytical data are in agreement with the calculated values and thus confirm the composition. They are highly soluble in acetone and DMSO but poorly soluble in common organic solvents.

3.2. NMR data

The ^1H and ^{13}C NMR spectra of the complexes display distinct signals for the ligand skeletons. The numbering scheme employed for the assignments of individual ^1H and ^{13}C signals are shown in Fig. 1. The efforts to use the NMR data in the elucidation of the coordination mode of the ligand and the geometries of the complexes were not successful since the solvents used for the spectra (DMSO-d_6 and acetone-d_6) could influence the nature of the coordination sphere.

3.3. X-ray diffraction analysis for complexes *1* and *2*

Pertinent crystallographic parameters are summarised in Table 1. The atomic numbering scheme and the coordination around the mercury atom for the complexes **1** and **2** are illustrated in Figs. 2 and 3, respectively. Selected bond lengths and bond angles are listed in Table 2 (for **1**) and 3 (for **2**). Considering the similarity of the ligands, the two complexes adopt surprisingly different structures. Complex **2** has an extended polymeric structure with 2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine behaving as a monodentate ligand via the pyridyl nitrogen, and all the chlorine atoms serving to bridge mercury atoms, whereas complex **1** has a dimeric structure with 2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine behaving as a bidentate ligand via the pyridyl nitrogen and one of the azo nitrogens, with a terminal chlorine on each Hg and a μ,μ′-dichloro bridge between the mercury atoms. But the coordination geometry around the mercury atom is similar in both complexes, each showing a distorted trigonal bipyramidal arrangement of the donor atoms.

3.3.1. Dichloro-{2-[(E)-2-(4-methylphenyl)-1- diazenyl]pyridine}Hg(II) (1)

This complex occurs as centro-symmetric dimers in the solid state with the ligand 2-[(*E*)-2-(4-methylphenyl)-1-diazenyl]pyridine behaving as a bidentate via the pyridyl nitrogen and one of the azo nitrogens, with one bridging and one terminal chlorine atom. The geometry around each mercury atom is probably best described as being that of a distorted trigonal bipyramid, with the terminal chlorine, one bridging chlorine and the pyridyl nitrogen forming the trigonal plane and the other bridging chlorine and one of the azo-nitrogen atoms taking the axial positions. The structure is very similar in many regards to that recently reported for dichloro-mercury(II)-2-(phenylazo)-pyrimidine [44]. The bond angles making up the trigonal plane in **1** are N(1)–Hg–Cl(2), 105.3(2)°; Cl(1)–Hg–Cl(2), 137.5(9)° and N(1)–Hg–Cl(1), 117.0(2)°, giving a total of 359.8°. The corresponding bond angles found for dichloro-mercury(II)-2-(phenylazo)-pyrimidine are 105.3(2)°, 137.53(9)° and 117.0(2)°, giving a total of 359.8°. The

ture of the structures of these two complexes is the occurrence of a dinuclear μ,μ-chloro bridged Hg_2Cl_2 fragment, of almost identical dimensions in both. The Hg–N distances in the two complexes are also comparable, being 2.541(8) Å (Hg–N(azo)) and 2.368(7) Å (Hg–N(pyridyl)) in **1** and 2.55 Å (Hg–N(azo)) and 2.41 Å (Hg–N(pyrimidyl)) in dichloro-mercury(II)-2-(phenylazo)-pyrimidine. The N–N distance for the azo groups of the respective coordinated ligand molecules are 1.26 Å in both instances. Despite the great difference in the overall structures of **1** and **2**, the two complexes still share several common structural features. The geometry around the Hg atoms in both is essentially that of a distorted trigonal bipyramid, but in **2**, the axial atoms are the pyridyl nitrogen and one of the bridging chlorines whilst the trigonal plane comprises the remaining three bridging chlorine atoms. Another similar compound, dichloro-mercury(II)-1-ethyl-2-(phenylazo)-imidazole [44] has the same dimeric structure reported here for **1** and dichloro-mercury(II)-2-(phenylazo)-pyrimidine. However, the presence of the five-membered imidazole ring in the ligand of this complex rather than the six-membered pyridine or pyrimidine rings in the other ligands results in some differences in individual bond distances. But the overall structural features are the same in all three complexes.

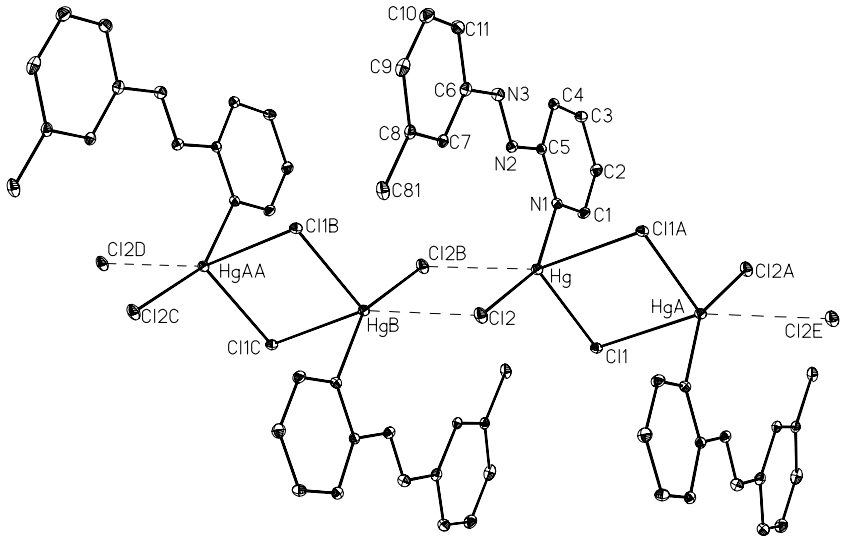

Fig. 4. Illustration of chlorine-bridging and polymeric structure of **2**.

*3.3.2. Dichloro-{2-[(E)-2-(3-methylphenyl)-1- diazenyl]pyridine}Hg(II) (**2**)*

Modifying the structure of the ligand by shifting the methyl group on the phenyl ring from the *para-* (in **1**) to the *meta-* (in **2**) position has a profound effect on the structure of the resulting complex. In contradistinction to **1** (as described above), compound **2** has an extended polymeric structure with 2-[(*E*)-2-(3-methylphenyl)-1-diazenyl]pyridine behaving as a monodentate ligand via the pyridyl nitrogen, and all the chlorine atoms serving to bridge mercury atoms. In this case, neither of the azo nitrogens is coordinated to mercury. A skewed repeating chain of Hg_2Cl_2 rhombohedra links the molecular units together, as shown in Fig. 4. Adjacent Hg_2Cl_2 units are staggered, whereas alternate ones lie in planes aligned parallel to one another. The coordinated ligand molecules are all aligned along planes parallel to each other, but in a third direction, roughly at right angles to the planes of each of the Hg_2Cl_2 rhombohedra. In addition to the chlorine bridges, which hold the units together in the polymeric structure, there are hydrogen-bonding interactions which provide some end-to-end cohesion between the monomeric units. These hydrogen bonds link the hydrogen atom on the carbon *para-* to the nitrogen in the pyridyl ring of each ligand with one of the bridging chlorines on an adjacent unit. The relevant bond distances are C(3)–H(3A) = 0.95 Å, H(3A)...Cl(1) = 2.80 Å and C(3)–Cl(1) = 3.49 Å and the angle C(3)–H(3A)...Cl(1) is 130.3°. These hydrogen-bonding interactions as well as the packing arrangements in the crystal and the chlorine bridges are shown in Fig. 5. The bond angles making up the trigonal plane in **2** are N(1)–Hg–Cl(1), 92.5(2)°; N(1)–Hg–Cl(2), 156.3(2)°; and Cl(1)–Hg–Cl(1A), 109.5(6)° giving a total of 358.3°. The angle between the two axial bonds in **2**, [Cl(1A)–Hg–Cl(2B)] is 161.3°. These values are comparable to those in **1**.

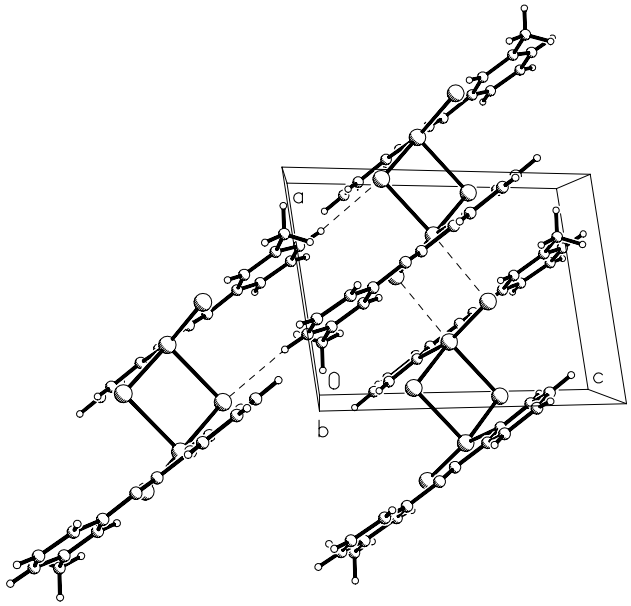

Fig. 5. Unit cell, chlorine bridging, and hydrogen bonding for **2**.

4. Supplementary material

Full tables of bond lengths and angles, tables of non-hydrogen and hydrogen atomic coordinates, anisotropic thermal parameters for non-hydrogen atoms have been deposited with Cambridge Crystallographic data center, CCDC No. 230005 and 230006 for L^1HgCl_2 (**1**) and L^2HgCl_2 (**2**), respectively. Abstract

Methods of preparation and far IR data are presented for various Cy_3SnX compounds. The synthesis of tris(cyclohexyl)tin hydroxide, Cy_3SnOH, is also described. Redeterminations of the crystal structures of tris(cyclohexyl)tin bromide and iodide, Cy_3SnBr and Cy_3SnI, confirm their molecular nature and improve considerably upon the results reported earlier [S. Calogero, P. Ganis, V. Peruzzo, G. Tagliavini, G. Valle, J. Organomet. Chem. 220 (1981) 11] providing, in both cases, lower R-factors and, in particular, a revised estimate of the Sn–I bond length, now 2.7463(6) Å.

Keywords: Tris(cyclohexyl)tin; Halostannanes; Crystal structure

1. Introduction

Halo- and pseudo-halostannanes of the general form $R_{4-n}SnX_n$, (R = an organic group, X = halide or pseudo halide and n =1–13), have received much attention. Of interest in compounds of this type, particularly for those with $n = 2$ and more especially those with $n = 1$, has been the investigation of the occurrence and nature of secondary Sn–X contacts to establish whether they contribute to the coordination of tin and change its nominal tetrahedral nature to one with a higher coordination number. Typical examples of this are the detailed report of the temperature dependent order–disorder transition in tris(cyclohexyl)tin chloride, **1** (X = Cl), [1, and references therein], and reports on the structures of **1** (X = F, Br and I) [2] and of various tris(2-methyl-2-phenyl-propyl)stannane derivatives $(Neo)_3SnX$, **2** (X = Cl, Br, I, N_3 and NCS) [3]. We now report the synthesis of **1** (X = Br, I, N_3 and NCS) and of tris(cyclohexyl)tin hydroxide, along with redeterminations of the structures of **1** (X = Br) and **1** (X = I). Far IR data are also presented for various Cy_3SnX compounds.

2. Experimental

Melting points were measured on Melt-Temp-II equipment. Far IR spectra were obtained using a Nicolet

Magna 760 FTIR instrument with samples suspended in Nujol between polythene plates. Cy_3SnCl was a recrystallised commercial sample, m.p. 127–129 °C.

Far IR: *v* 492, 439, 420, 327, 271, 252, 199 cm^{-1}.

2.1. Preparation of tris(cyclohexyl)tin iodide, **I** (X = I)

Solutions of Cy_3SnCl (2 mmol) in Me_2CO (15 ml) and NaI (5 mmol) in Me_2CO (15 ml) were mixed. After stirring at RT for 4 h the reaction mixture was filtered and the filtrate evaporated to leave a residue which was extracted into $CHCl_3$. The chloroform extract was evaporated and the solid residue was recrystallised from EtOH, m.p. 64–66 °C.

Far IR: *v*: 492, 439, 420, 324, 250(sh), 239, 212, 161 cm^{-1}.

2.2. Preparation of tris(cyclohexyl)tin hydroxide, **I** (X = OH)

A solution of Cy_3SnCl (2 mmol) in Et_2O (15 ml) was added to a solution of NaOH (5%) in H_2O (15 ml) and the mixture was stirred for 1 h, and then filtered. The ether layer in the filtrate was collected, dried and evaporated. The residue from the ether layer was added to the original solid collected by filtration and the combined solids were recrystallised from aqueous EtOH, m.p.174–179 °C. The wide m.p. range is attributed to the presence in trace amounts, and in situ formation, of bis[tris(cyclohexyl)tin] oxide, $(Cy_3Sn)_2O$, in accord with the previous report [4] that only with great difficulty can pure samples of either the oxide or the hydroxide be obtained, *v*(OH) 3623 cm^{-1}.

2.3. Preparation of tris(cyclohexyl)tin bromide, **I** (X = Br)

Concentrated HBr (2 ml) was added to a solution of Cy_3SnOH (0.5 mmol) in EtOH (20 ml). The mixture was stirred at room temperature for 2 h, the volatiles removed under vacuum and the solid product recrystallised from $CHCl_3$; m.p. 77–79 °C.

Far IR: *v*: 491, 438, 419, 322, 250(sh), 228(br), 203(sh) cm^{-1}.

2.4. Preparation of tris(cyclohexyl)tin azide, **I** ($X = N_3$)

A solution of Cy_3SnCl (2 mmol) in Me_2CO (15 ml) and a suspension of NaN_3 (5 mmol) in Me_2CO (15 ml) were mixed. After stirring at RT overnight, the reaction mixture was filtered. The filtrate was shaken with a further suspension of NaN_3 (5 mmol) in Me_2CO (15 ml) for 4 h, all volatiles removed by rotary evaporation and the residue extracted into $CHCl_3$. The chloroform extract was dried and rotary evaporated to leave a solid residue. $\nu(N_3)$ 2071 cm^{-1}: no *v*(OH)

2.5. Preparation of tris(cyclohexyl)tin isothiocyanate, **I** (X = NCS)

A solution of Cy_3SnCl (2 mmol) in Me_2CO (15 ml) and a suspension of NaNCS (5 mmol) in Me_2CO (15 ml) were mixed. After stirring at RT overnight, the reaction mixture was filtered and the filtrate collected. The filtrate was shaken with a further suspension of NaNCS (5 mmol) in Me_2CO (15 ml) for 4 h, all volatiles removed by rotary evaporation and the residue extracted into $CHCl_3$. The chloroform extract was dried and rotary evaporated to leave a solid residue which was recrystallised from CH_2Cl_2/hexane, m.p. 120–122 °C.

IR: *v*: 2071 cm^{-1}. Far IR: *v*: 570(br), 491, 439, 420, 326, 252, 220, 200 cm^{-1}

2.6. X-ray crystallography

2.6.1. Data collection

Intensity data for **1** (X = Br and I) were obtained with Mo Kα radiation, $\lambda = 0.71073$ Å, by means of the Enraf Nonius KappaCCD area diffractometer of the EPSRC's crystallography service at Southampton. For **1** (X = Br), for which the crystal shattered on cooling, the data were obtained at 298 K and at 120 K for **1** (X = I). The entire process of data collection, cell refinement and data reduction was accomplished by means of the programs DENZO [5] and COLLECT [6]. Correction for absorption by a semi-empirical method based upon the variation in intensity of equivalent reflections was achieved with the program SORTAV [7,8]. The transmission factors for each compound (Table 1) are not then on an absolute scale. Unfortunately both data sets have proved to be less than fully complete (see Table 1). This is especially true in the case of **1** (X = Br), where the available crystals were of particularly dubious quality, but is perceived to have no more deleterious effect than to limit the precision with which derived quantities such as bond lengths and bond angles are estimated.

2.6.2. Structure solution and refinement

In both cases initial solution of the structure was obtained by the heavy atom technique with the program SHELXS-86 [9] and completed and refined by full matrix least squares on F^2 with SHELXL-97 [10]. In the case of **1** (X = Br) the structure was finally re-refined with the atomic coordinates from the refinement of **1** (X = I) as starting parameters but with bromine substituted for iodine thus ensuring total equivalence between the labelling schemes of these two refinements. One reflection showing particularly poor agreement due to extinction was omitted from the refinement of **1** (X = Br). Despite a degree of disorder affecting the atoms of the cyclohexyl groups of **1** (X = Br), which was not modelled in detail, anisotropic thermal vibration parameters were refined for all non-H atoms. In all cases the residual electron

density features noted in Table 1 are in the vicinity (within 0.90 Å) of heavy atoms. In the final stages of refinement H atoms were introduced in calculated positions and refined with a riding model. The program ORTEP-3 for Windows [11] was used in the preparation of the Figures and SHELXL-97 and PLATON [12] for bond length and angle and other molecular geometry calculations. PLATON was used, in particular, for calculations based upon crystallographic data extracted from the Cambridge Structural Database [13]. It is noted here that in Table 4 for those compounds with more than one molecule in the asymmetric unit, e.g. all 2, the bond distances and bond angles and the associated estimated errors are average values. Further details of the data collection and structure refinement processes are available in Table 1.

3. Results and discussion

3.1. General features of the structures

All of the cyclohexyl rings are found to be in the chair conformation with C–C distances and internal C–C–C angles more or less as expected provided that due allowance is made for the disorder in **1** (X = Br) noted above. Apart from this the real significance of the structures presented here lies in the nature of the tin coordination which they reveal which is discussed below.

3.2. Crystal structures of *1* (*X = Br and I*)

The compounds **1** (X = Br) and **1** (X = I) are isomorphous and it is for this reason that both the drawing of the molecule (Fig. 1) and the layer of molecules shown in Fig. 2, although based on data for **1** (X = I), are applicable to both compounds. In these structures the tin and halogen atoms lie on a crystallographic mirror plane which also bisects one of the cyclohexyl groups and re-

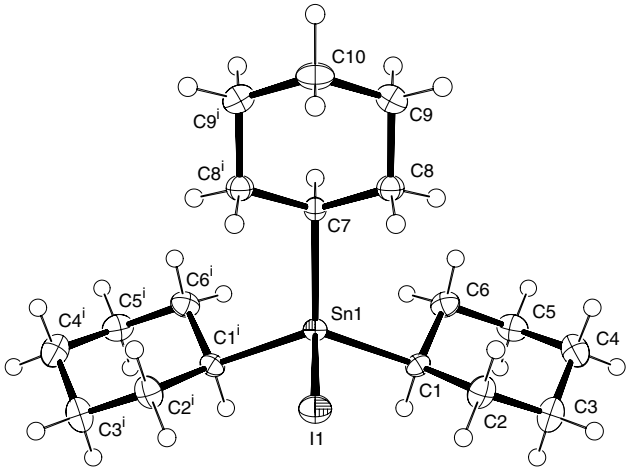

Fig. 1. The molecule of **1** (X = I) showing the labelling scheme. Non-H atoms are shown as 50% probability displacement ellipsoids and H atoms as small circles of arbitrary radius. Symmetry code (i) $x, 3/2 - y, z$.

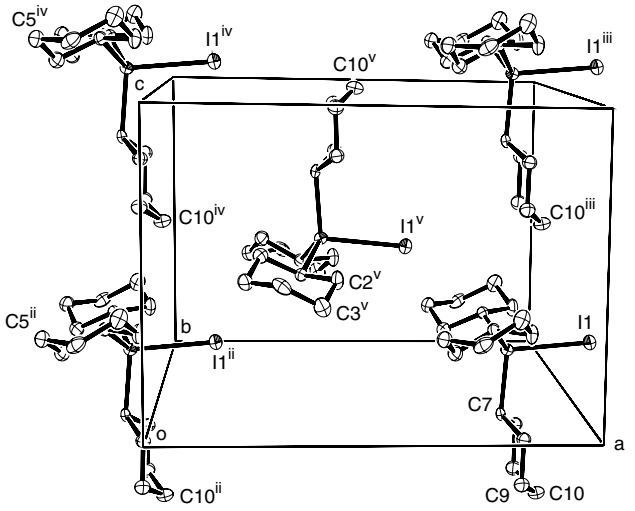

Fig. 2. A layer of molecules of **1** (X = I). Non-H atoms are shown as 50% probability displacement ellipsoids and H atoms have been omitted for clarity. Only selected atoms are labelled. Symmetry codes (ii) $x-1, y, z$; (iii) $x, y, 1+z$; (iv) $x-1, y, 1+z$; (v) $x-1/2, y, 1/2-z$.

lates the two remaining cyclohexyl groups by symmetry. Thus the asymmetric unit consists of one complete cyclohexyl group [C(1–6)], four atoms of another cyclohexyl group [C(7–10)] and the tin and halogen atoms (see Fig. 1). In both cases the bond length and bond angle data in Table 2 are consistent with tin in a tetrahedral environment distorted primarily in order to accommodate the steric requirements of the cyclohexyl groups. Particularly notable in this table is the Sn(1)–I(1) bond length of 2.7463(6) Å which is much more reasonable than the previous published value [2] of 2.54(1) Å. The molecules are found in layers on the crystallographic mirror planes as shown in Fig. 2 within which the next nearest neighbour Sn–X distances are 5.375(5) and 4.8013(7) Å for X = Br and X = I, respectively. The surprisingly shorter next nearest neighbour distance for X = I is attributed primarily to the different temperatures at which the intensity data were collected (see Table 1).

3.3. Structural trends in R_3SnX compounds with X = F, Cl, Br and I

The nature, polymeric or molecular, of the solid state structure of **1** (X = Cl) has been a matter of conjecture for many years. Initial X-ray structural results [14] were taken to be indicative of a molecular structure with four coordinate tin in contrast to earlier results from Mössbauer spectoscopy suggestive of a polymeric structure with five coordinate tin. Means were then found [2] to resolve this disparity in favour of the molecular structural model. Further support for this model was obtained, by comparison of ^{119}Sn chemical shifts in the solid state (CP/MAS) with those found for the compounds in solution, by Harris et al. [15]. The results of this study were considered to be compatible with **1** (X = Cl) existing as a molecular species in the solid state in the same manner as **1** (X = Br) and **3** (X = Cl). Most recently Asadi et al. [1] have investigated the X-ray crystal structure of **1** (X = Cl) over the temperature range 120–298 K. This study reveals, in addition to an order–disorder transition at about 248 K, an inverse and temperature dependent relationship between the nearest, Sn–Cl, and next nearest, Sn···Cl′, distances. These distances tend to equality with reducing temperature. Also present are essentially linear Cl–Sn···Cl′ and Sn–Cl···Sn′ groups (see Table 3). The findings of Asadi et al. support the earlier suggestion [4], based on NMR (solution) and Mössbauer spectroscopy, that **1** (X = Cl) is weakly polymeric in the solid state but

monomeric in solution. Thus in the context of compounds of the form R_3 SnCl (R = alkyl or aryl) **1** (X = Cl) is perceived as being polymeric but intermediate in this respect between, on the one hand, such as polymeric Me_3 SnCl and on the other, for example, molecular Ph_3 SnCl, **3** (X = Cl).

With the information now available the status of various **1** can be considered further in terms of the nature of X as well as R. Thus from the data in Table 3 **1** (X = F and Cl), with Sn···X′ distances much shorter than the sums of the contact radii of the relevant atoms (PLATON contact radii 2.26, 1.47, 1.75, 1.85 and 1.98 Å for Sn, F, Cl, Br and I, respectively) and essentially linear X–Sn···X′ groups, are clearly polymeric. The remainder, **1** (X = Br and I) with Sn···X′ distances greater than the relevant contact radii sums and non-linear X–Sn···X′ groups, are equally clearly molecular species. Table 4 shows Sn–X and Sn···X′ distances for compounds of the form R_3 SnX, R = Neo, **2**, and R = Ph, **3**, with, in both cases, X = Cl, Br and I. All of these compounds are molecular species as shown by the Sn···X′ distances, all much greater than the sums of the contact radii. For **2** this is largely because of the bulk of the non-halogen substituents. For **3** it comes about because the molecules occur in stacks in such a way as to permit large numbers of C–H–π intermolecular contacts. The Sn–X bonds of successive molecules in the stack are then directed in opposite directions away from the mid-line of the stack. In other words, in the case of **3** (X = Cl, Br and I), the stacking of the molecules favours interactions between the phenyl groups rather than Sn···X′ intermolecular contacts.

Three notable features arise from comparison of Tables 3 and 4. First, whereas in **3** (X = Cl), the only case for which the necessary data are available in Table 4, reduced temperature has virtually no effect on the Sn–Cl distance but shortens the Sn···Cl′ contact dramatically, in **1** (X = Cl) both types of distance are temperature dependent but in opposite senses. Second, the Sn–Cl distance is longer in polymeric **1** (X = Cl) than in either of the corresponding, but molecular, **2** and **3** in which last two this distance is very similar. Third, for all molecular **1**, **2** and **3** (X = Br and I) the Sn–X distances are much the same for any particular X. The implication of the above is that, at least for X = halogen, a polymeric compound of the form R_3Sn–X will display temperature dependency of the type noted above for **1** (X = Cl), more or less linear X–Sn···X′ groups and an Sn–X distance longer than that found in a molecular compound with the same X but, obviously, a different R. In general terms it appears that the formation of polymeric species with bridging X in R_3SnX (X = halogen) in the solid state is favoured for more electronegative and smaller X and disfavoured by large R. On the other hand, as in the case of **3** (X = Cl, Br and I), polymerisation with bridging X may be supplanted by other intermolecular interactions.

The structures for **1** (X = Br and I) presented here improve upon those previously reported [2] not only because they are better determined but also, in the case of **1** (X = I), because the data derived from the original structure determination are very similar to those obtained both here and previously for **1** (X = Br). Likewise the previously reported [2] structure of **1** (X = F) has been ignored in favour of that of Tudela et al. [16] because the data derived from the original determination closely resembled that of **1** (X = Cl). There is, therefore, doubt as to the authenticity of the samples used in the original structure determinations [2] of **1** (X = F and I).

4. Supplementary material

Supplementary data, including atomic coordinates, anisotropic thermal parameters and bond lengths and angles are available from the Cambridge Crystallographic Data Centre with reference codes CCDC 231208 and 231209 for **1** (X = I) and **1** (X = Br), respectively. Copies of this information may be obtained, free of charge, from the Director, CCDC, 12 Union Road,

Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk) or via http://www.ccdc.cam.ac.uk/conts/retrieving.html.

Abstract

Triethylenetetramine (L^4) and dipropylenetriamine (L^3) were used as blocking ligands (tetradentate and tridentate, respectively) that, after complexation with Ni(II), leave two or three sites ready for ligation with $N(CN)_2^-$ (dicyanamide, abbr. *dca*). The formed complexes are mononuclear, binuclear or polymeric. This was proven by the X-ray structure analysis for $[NiL^4(dca)_2]$ (mononuclear, **1**), $[(dca)L^3Ni(dca)_2NiL^3(dca)]$ (binuclear, **2**) and $[NiL^4(dca)](ClO_4)$ (polymeric, **3**). The magnetic susceptibility measurements for **1** confirm that the Curie law is obeyed at higher temperatures whereas the zero-field splitting is effective below 10 K ($D/hc = -4\ cm^{-1}$); **2** shows a weak antiferromagnetic coupling ($J/hc = -0.6\ cm^{-1}$); **3** exhibits a negligible exchange coupling ($J/hc \approx 0$).

1. Introduction

Halides and pseudohalides (both linear, CN^-, N_3^-, NCO^-, NCS^-, $NCSe^-$, CNO^-, and non-linear, $N(CN)_2^-$, $C(CN)_3^-$, $ONC(CN)_2^-$, etc.) represent versatile ligands which can form mononuclear, dinuclear, polynuclear and polymeric complexes. For instance, $[Ni(en)_2(NCS)_2]$ is a mononuclear complex [1], whereas $[(en)_2Ni(NCS)_2Ni(en)_2]I_2$ represents a typical dimer in which the thiocyanate bears a bridging functionality [2]; *en* = 1,2-diaminoethane (ethylenediamine), boldfaces visualise the donor atoms hereafter. Such dinuclear units are formed also in the $[(en)_2Ni(NCS)_2Ni(en)_2](ClO_4)_2$ complex [3] and an analogous coordination mode has been found in $[(en)_2NiCl_2Ni(en)_2]Cl_2$ [4] and $[(en)_2NiBr_2Ni(en)_2]Br_2$ [5]. A similar coordination mode is maintained when the tetradentate ligand *tren* is used for the complexation (*tren* = 2,2′,2″-triaminotriethylamine), as found in $[(tren)Ni(NCO)_2Ni(tren)](BPh_4)_2$ [6], and assumed also when NCO^- is substituted for NCS^- and $NCSe^-$ [7]. The dinuclear character has been assumed and later confirmed in $[(tren)Ni(N_3)_2Ni(tren)](BPh_4)_2$ [8,9]. The ligand–isomer of the latter complex, $[(teta)Ni(N_3)_2Ni(teta)](BPh_4)_2$, *teta* = triethylenetetramine, adopts a dinuclear structure, too [10]. Notice, the $[Ni(tren)(NCS)_2]$ complex again is mononuclear. A different dinuclear structure held only by a single $(N)_3^-$ bridge has been found in $[(N_3)(macro)Ni(N_3)Ni(macro)(N_3)]I$, *macro* = *N*-tetramethylcyclam where two $(N)_3^-$ ligands adopt a terminal functionality [11].

On changing the stoichiometry and nature of the *N*-donor neutral ligand, different structural types

doi:10.1016/j.poly.2004.06.022

occur. For example, $[Ni(L^2)_2(NO_2)]X$ complexes (L^2 = the bidentate ligand *en* or 1,3-diaminopropane; $X = (ClO)_4^-$ or $(I)_3^-$) adopt the single-chain structure with a $(NO)_2^-$ bridge; the modified complexes with tetradentate ligands L^4, i.e. $[NiL^4(NO_2)](ClO_4)$, behave analogously [12]. Chain structures are present, for instance, in $Ni(en)_2Ni(CN)_4$ and $Ni(dien)(mea)Ni(CN)_4$, *dien* = diethylenetriamine, *mea* = 2-aminoethanole [13,14]; here the diamagnetic square planar $[Ni(CN)_4]^{2-}$ ion bears the role of the bridging and charge-balancing agent.

The complex $[Ni(im)_2(NCS)_2]$, where *im* = imidazole, is a coordination polymer with the basal plane formed of $Ni(NCS)_4$-units showing a two-arm chain, and completed in the axial positions by two unidentate *im* ligands [15]; interesting is the ferromagnetic ordering below 5 K and the cobalt-analogue exhibits a ferromagnetic ordering with hysteresis too. A similar structural motif has been found in the $[Cu(ampym)_2(dca)_2]$ complex (*ampym* = 2-aminopyrimidine; *dca* = dicyanamide, $NCNCN^-$) [16]. Two reports on $(Ph_4P)_2$ $[Co(dca)_4]$ confirm a 1D two-arm chain held by the bidentate *dca* ligands, with the axial positions terminated by additional unidentate *dca* ligands [17,18]; at $T_c = 1.75$ K a ferromagnetic ordering starts to apply [17]. The complex $(Ph_4P)[Co(dca)_3]$ adopts a layered (2D) network structure where each *dca* ligand is bidentate [18]. Such a cation-templation into the $Mn(dca)_3^-$ polymer resulted in an analogous network [19]. The binary α-$M(dca)_2$ complexes possess a rutile-like structure and show either ferromagnetism (M = Co and Ni) or antiferromagnetism (M = Cr, Mn and Fe); the Cu-complex is a paramagnet. Just the interesting magnetic properties of these materials represent the driving force of the contemporary interest and a renaissance in research of the pseudohalide complexes [20]. Let us exemplify some recent investigations of magnetic properties of *dca* -containing complexes [21–28] and complexes of $C(CN)_3^-$ (tricyanomethanide, abbr. *tcm*) [29–33]. The coordination chemistry of *dca* and *tcm* ligands has been intensively studied in a systematic way for a longer period [34,35]. The magnetism of such a complexes has been reviewed elsewhere [36].

In the present communication we are focusing on the coordination mode of the *dca* ligand in Ni(II) complexes along with their associated magnetic properties. There exists a structural report on the mononuclear complex $[Ni(tren)(dca)_2]$ and its ligand–isomer $[Ni(teta)(dca)_2]$ at $T = 150$ K [37]; the synthesis and characterization of the complexes $[Ni(tren)(dca)](ClO_4)$ and $[Ni(teta)(dca)](ClO_4)$ are also reported but the structures of these complexes have not been determined by X-ray structure analysis. An analogous complex with the *tcm* ligand has been confirmed as binuclear, i.e. $[(teta)Ni(tcm)_2Ni(teta)](ClO_4)_2$, with a ferromagnetic ordering below 16 K [38,39].

We are reporting the synthesis, structure and magnetic properties of $[Ni(teta)(dca)_2]$, $[(dca)(dpt)Ni(dca)_2Ni(dpt)(dca)]$ and $[Ni(teta)(dca)](ClO_4)$ complexes, where *teta* is a tetradentate ligand and *dpt* = dipropylenetriamine is tridentate one.

2. Experimental

Caution: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of material should be prepared, and handled with caution.

The chemicals used were commercial products and were used without further purification. $NiSiF_6 \cdot 6H_2O$ was prepared with quantitative yield by combining a solution of hexafluorosilicic acid in water and an equimolar amount of basic nickel carbonate. For magnetic measurements pure macro crystalline materials were grounded into Agate mortar.

$[Ni(teta)(N(CN)_2)_2]$, **1.** $KN(CN)_2$ (10 mmol) in 10 cm^{-3} of water was added to a solution ($V = 20$ cm^3) obtained by mixing $Ni(NO_3)_2 \cdot 6H_2O$ (5 mmol), triethylenetetramine (5 mmol) and water. From the resulting blue solution a small quantity of nickel hydroxide was removed by filtration, and **1** was obtained by a slow evaporation of the filtrate (in one week) as blue-violet well-formed crystals suitable for the X-ray crystal structure analysis. Yield 26%. Complex **1** can also be prepared by the same procedure with $NiSiF_6 \cdot 6H_2O$. Found: C, 35.7; H, 5.55; N, 41.4; Ni, 16.9. Calc. for $C_{10}H_{18}N_{10}Ni$: C, 35.6; H, 5.38; N, 41.6; Ni, 17.4%. IR (cm^{-1}, KBr) 2282vs ($\nu_s + \nu_{as}$ C–N), 2224vs (ν_{as} NCN), 2159 vs, br (ν_s NCN), 1360s (ν_{as} C–N), 944m (ν_s C–N). UV–Vis (nm, MgO) 934, 559, 362.

$[Ni_2(dpt)_2(N(CN)_2)_4]$, **2.** A solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (2.5 mmol) containing dipropylenetriamine (2.5 mmol) in 15 cm^3 of water was combined with $KN(CN)_2$ (2.5 mmol) in 15 cm^3 of water. Nickel hydroxide was removed by filtration, and from the filtrate violet crystals of **2** were collected the next day. Yield 28%. Found: C, 37.2; H, 5.23; N, 38.9, Ni, 18.0. Calc. for $C_{10}H_{17}N_9Ni$: C, 37.3; H, 5.29; N, 39.2; Ni, 18.2%. IR (cm^{-1}, KBr) 2243m, 2211vs, 2185vs (ν CN). UV–Vis (nm, MgO) 894, 554, 358.

$[Ni(teta)(N(CN)_2)](ClO_4)$, **3.** The complex was synthesized from a dilute aqueous solution containing $KN(CN)_2$ (5 mmol), $Ni(ClO_4)_2 \cdot 6H_2O$ (5 mmol) and triethylenetetramine (5 mmol) in 50 cm^3 of water. Nickel hydroxide was removed by filtration and **3** was separated as violet crystals by slow evaporation of the filtrate. Yield 10%. Found: C, 25.9; H, 4.91; N, 25.7; Cl, 9.3; Ni, 14.9. Calc. for $C_8H_{18}N_7ClNiO_4$: C, 26.0; H, 4.86; N, 26.5; Cl, 9.57; Ni, 15.8%. IR (cm^{-1}, KBr) 2308s ($\nu_s + \nu_{as}$ C–N), 2230m (ν_{as} NCN), 2159vs (ν_s

NCN), 1267s (ν_{as} C–N), 990m (ν_s C–N). UV–Vis (nm, MgO) 972, 568, 362.

2.1. Spectra and magnetic measurements

Infrared spectra were recorded on a FTIR spectrometer MATTSON 5000 in the range of 400–4000 cm^{-1} as KBr pellets. Electronic spectra were monitored on an UV–Vis spectrometer Lambda 19 (Perkin–Elmer) between 200–2000 nm at room temperature.

Magnetic susceptibility data were taken with an alternating current susceptometer (LakeShore, model 7221); field parameters were $f = 222$ Hz, $H_{AC} = H_{DC} = 800$ A m^{-1}. Corrections to the underlying diamagnetism were estimated on the basis of Pascal constants. The magnetic susceptibility was converted to the effective magnetic moment $\mu_{eff}/\mu_B = 798(\chi'_{mol}T)^{1/2}$ (SI units are employed). The magnetisation measurements were done on a similar apparatus (LakeShore, model 7225) and a SQUID magnetometer (Quantum Design) until $B = 6$ T.

2.2. Structure analysis and refinement

Suitable single crystals of **1** and **2** were mounted on a STOE-STADI-IV diffractometer equipped with graphite monochromated Mo Kα radiation. Single crystals of 3 were mounted on a STOE-IPDS diffractometer. In all cases corrections to Lorentz and polarisation effects have been applied, and also for **1** an absorption correction.

Direct methods (SHELXS-97) and full least-squares refinement (SHELXL-97) with all non-H-atoms refined anisotropically have been applied [40,41]. Crystal data and refinement parameters are collected in Table 1. For the plots of the molecular structures, the program DIAMOND [42] was used.

3. Results and discussion

3.1. Crystal and molecular structure

The X-ray crystal structure analysis showed that complex **1**, [Ni(*teta*)(**N**CNCN)$_2$], is mononuclear (Fig. 1) with *cis* positioned $NCNCN^-$ ligands and with the terminal N atoms of the neutral ligand L^4 in *trans* positions. The $\{NiN_4N'_2\}$ chromophore is nearly octahedral. In fact this represents a room-temperature reinvestigation of the crystal structure already published elsewhere [37]. The former, low-temperature data (hereafter **1b**) show a compression of the unit cell on cooling to 150 K except the *a*-parameter; $a = 9.948$ (9.974), $b = 11.201$ (11.067), $c = 14.102$ (14.058), $V = 1481$ (1463) for $T = 293$ (150) K.

The bond lengths Ni−N in **1** vary scarcely and values were found between Ni−N(1) = 2.090(3) Å and Ni−N(9) = 2.118(3) Å (Table 2). For the angles N−Ni−N maximum deviations from 90° were found for N(7)−Ni−N(9) = 99.5(1)° and N(9)−Ni−N(10) = 81.3(1)°. A comparison with **1b** shows that on cooling not all Ni−N distances contract, and some of them expand. A new feature is the identification of close contacts typical for hydrogen bonds: 3.045, 3.101 and a longer pair of 3.314, 3.409 Å. These contacts form a complex network that can transmit an exchange interaction. These contacts contract on cooling to 150 K to 3.031, 3.096, 3.306, 3.380 Å.

Complex **2**, [(NCNCN)(*dpt*)Ni(NCNCN)$_2$Ni(*dpt*)-(NCNCN)], possesses isolated binuclear units (Fig. 2). The hexacoordinated nickel(II) atoms are capped by the tridentate polyamine with the terminal NH_2 groups in *trans* positions. Two *cis*-positioned vertices are occupied by *dca* anions that bear bridging-ligand functionality. The sixth site is occupied by a non-bridging, terminal ligand $NCNCN^-$. The interatomic distances Ni−N in the chromophore $\{NiN_3N'_2N''\}$ are almost equal and amount on average to 2.105(5) Å which cor-

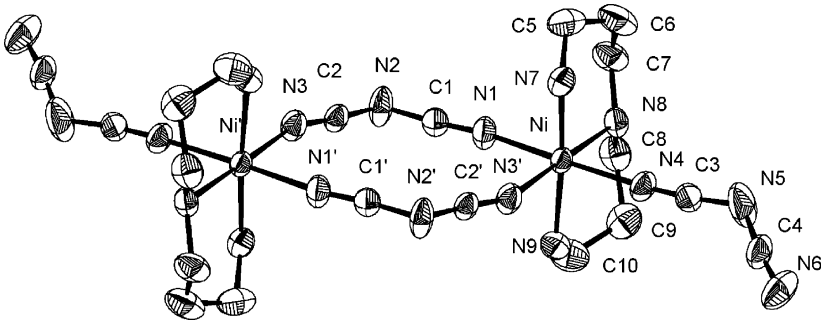

Fig. 2. Molecular structure of the complex **2** (hydrogen atoms are omitted for clarity); 50% probability thermal ellipsoids; [a] Symmetry code:^{i} $1-x$, $1-y$, $1-z$.

responds with the upper range for Ni–N (primary, secondary amines) bonds in octahedral complexes [43]. The almost planar *dca* utilizes two of three possible N-donors to coordinate which results in the formation of a twelve-membered, slightly puckered ring. The bond angle inside the ring, N(1)–Ni–N(3)^{i}, is 90.4(1)°. The intramolecular Ni–Ni separation is 7.328 Å. These molecules, formed in the *a*-direction, stack with parallel lying rings and a Ni···Ni distance of 8.415 Å. There are two other kinds of intermolecular Ni···Ni contacts: a very short one of 5.525 Å, and a long one of 9.332 Å.

Recently a structural report on **2** (hereafter **2b**) appeared [44]. Surprisingly, there are some different features for **2** (**2b**), of which the cell parameters $b = 70.8$ (79.8) and $V = 720$ (753) are the most significant. Thus, it is problematic to claim that our results on **2** represent a reinvestigation of **2b**. Different cell parameters reflect into significantly different Ni–N distances as seen from Table 2. Also the Ni···Ni separation differs for **2** and **2b**: 7.328 and 7.270 Å, respectively.

Complex **3**, [Ni(**NCNCN**)(*teta*)](ClO$_4$), adopts a polymeric (chain) structure along the *c*-axis where one *dca* ligand links two adjacent centres (Fig. 3). The coordination polyhedron of nickel is an octahedron with nitrogen atoms of the *dca* in *cis* positions and with terminal N atoms of the amine in *trans* positions. Within the 3σ criterion all Ni–N distances are equal [on average 2.13(1) Å] and the angles N–Ni–N vary between 82.1(1)° and 95.7(2)°. The intrachain Ni···Ni separation is 7.528 Å but interchain distances are 5.551 and 8.591 Å.

The structural data on *dca*-containing Ni(II) complexes, available from the CCDB, are collected in Table 3. The geometric parameters of *dca*-complexes **1–3** correspond well with those in a variety of other *dca*-complexes [55]. The comparison of the uni- (**1**) and bidentately (**2**, **3**) coordinated ligand shows scarcely significantly different parameters. The NCN arms are almost linear and the angles C–N–C lie between 121.2(5)° (**3**) and 123.4(3)° (**1**). The *dca* anions (**1–3**) are almost planar with maximum deviations from the plane formed by all five atoms of 0.009 Å for C(1) in complex **1**.

3.2. Magnetic data

The mononuclear Ni(II) complex **1** obeys the Curie law at temperature above 10 K because the effective magnetic moment stays almost temperature-independent (Fig. 4). Its value, $\mu_{\mathrm{eff}} = 2.76\ \mu_{\mathrm{B}}$ is a bit lower than the spin-only value of 2.83 μ_{B} for the $S = 1$ system. With temperature lowering the effective magnetic moment drops down as a consequence of the zero-field splitting. As the effective magnetic moment turns towards a constant value (not to zero), a negative zero-field splitting parameter D is expected with the Kramers doublet $|S,M_S\rangle = |1,\pm1\rangle$referring to the ground state [56].

The magnetic susceptibility data were fitted by assuming the usual form of the spin Hamiltonian

$$\hat{H} = D[S_z^2 - S(S+1)/3]\hbar^{-2} + g_a\mu_{\mathrm{B}}B\hat{S}_a\hbar^{-1} \qquad (1)$$

that accounts for an axial zero-field splitting parameter D and the anisotropic Zeeman term ($a = z$ or x). Within the spin Hamiltonian formalism the set of magnetic parameters is constrained through the relationship $D = (g_z - g_x)\lambda/2$, where $\lambda = \pm\xi^{\mathrm{so}}/2S$ and stands for the spin-orbit splitting parameter ($\lambda/hc = -315\ \mathrm{cm}^{-1}$ for Ni(II) complexes). The fitting procedure gave $g_z = 1.971$ and $g_x = 1.945$ whereas the constrained D-value was $D/hc = -4.00\ \mathrm{cm}^{-1}$. The quality of the fit is excellent: $R(\chi) = 0.0036$. The subnormal values of the *g*-parameters are assigned to a complex network (Fig. 1) that can transmit some exchange interaction.

The magnetisation data show some deviation from the Brillouin function at fields of about $B = 6$ T, which is a consequence of the zero-field splitting. The magnetisation data recovered by the above-mentioned set of magnetic parameters are also displayed in Fig. 4.

The magnetic properties of **2** are dominated by the exchange interaction between $S_{\mathrm{A}} = S_{\mathrm{B}} = 1$ local spins. The effective magnetic moment is temperature-independent down to 20 K and then drops down more abruptly (Fig. 5).

The magnetic susceptibility can be fitted using an isotropic exchange Hamiltonian of the type

$$\hat{H} = -J_{\mathrm{Ni-Ni}}\hbar^{-2}(\vec{S}_{\mathrm{A}}\cdot\vec{S}_{\mathrm{B}}) + \mu_{\mathrm{B}}\hbar^{-1}Bg_{\mathrm{Ni}}(\hat{S}_{\mathrm{A},z} + \hat{S}_{\mathrm{B},z}) - (zJ')\hbar^{-1}\langle S_z\rangle\hat{S}_z. \qquad (2)$$

For $S_{\mathrm{A}} = S_{\mathrm{B}} = 1$ one can handle an explicit formula for the magnetic susceptibility [57]. A fitting procedure gave the magnetic parameters $J_{\mathrm{Ni-Ni}}/hc = -1.00\ \mathrm{cm}^{-1}$ and $g_{\mathrm{Ni}} = 2.073$ (the discrepancy factor of the fit $R = 0.016$). A rather small value of the exchange-coupling constant of antiferromagnetic nature is consistent with an increasing magnetic susceptibility on cooling; its maximum will appear at a temperature T_{max} far below 4 K as the following equation holds true for the $S_{\mathrm{A}} = S_{\mathrm{B}} = 1$ system: $|J|/k = 0.976\ T_{\mathrm{max}}$ [57].

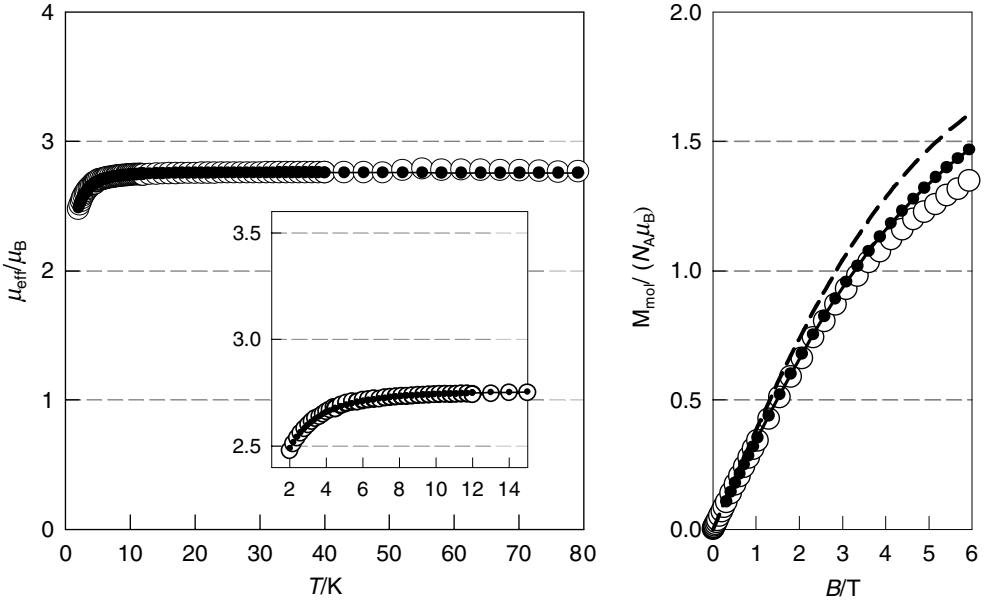

Fig. 4. Magnetic functions for **1**: temperature dependence of the effective magnetic moment (left) and field dependence of the magnetisation at $T = 4.60$ K (right); inset – enlarged low-temperature window; open circles – experimental data; full points and solid lines – the fitted data; dashed – the Brillouin function.

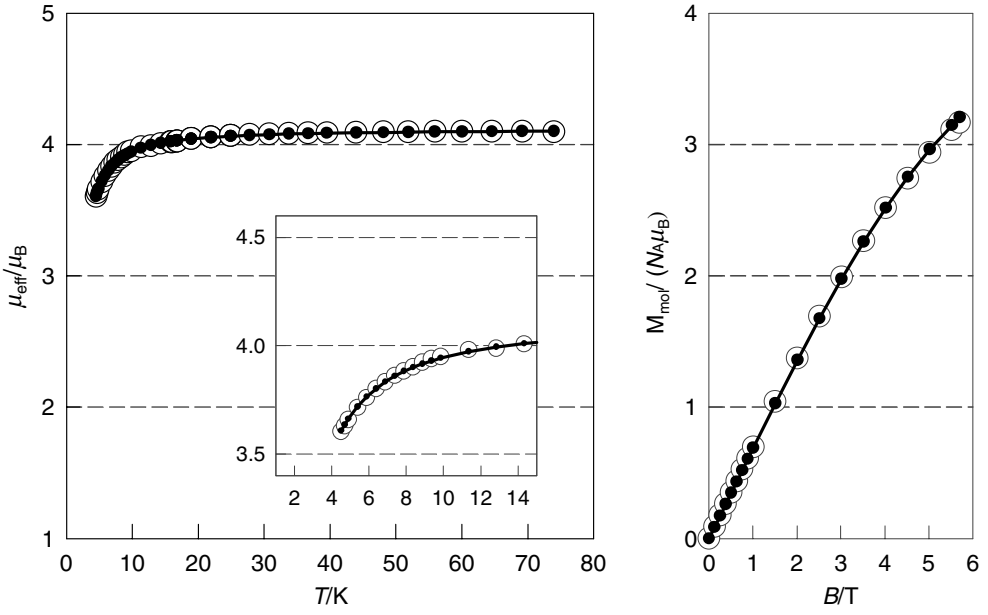

Fig. 5. Magnetic functions for **2** per dimer: temperature dependence of the effective magnetic moment (left) and field dependence of the magnetisation at $T = 4.40$ K (right); inset – enlarged low-temperature window; open circles – experimental data; full points and solid lines – the fitted data.

A slight antiferromagnetic nature of the exchange coupling constant in **2** results from a partial cancellation of the ferromagnetic and antiferromagnetic contributions. In the present case of an odd number of spacers (atoms) separating the metal centres the ferromagnetic portion becomes substantial and the spin-polarisation mechanism applies [58]. The counter parting antiferromagnetic portion, on the contrary, could be suppressed owing to a large intramolecular Ni···Ni separation (7.3 Å). Therefore the resulting value of the exchange coupling constant could be either slightly positive or slightly negative depending upon delicate balance between its ferromagnetic and antiferromagnetic portions.

Attempts to improve the fit of the experimental data by adding the molecular field correction with the molecular field parameter zJ' did not lead to the desired effect.

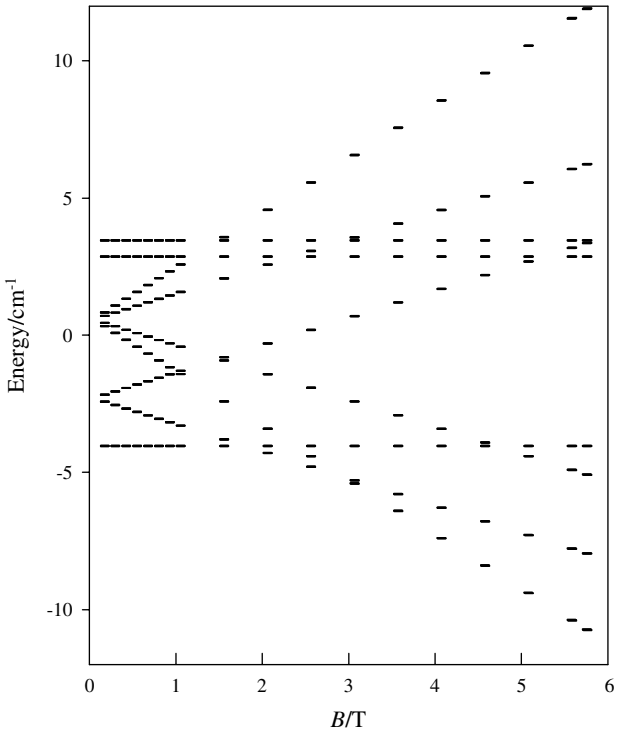

Fig. 6. Field dependence of the calculated energy levels for **2**.

Another extension is to consider the asymmetric exchange by considering an additional term to the Hamiltonian

$$\hat{H}_S^{(2)} = \hbar^{-2}(\vec{S}_A \cdot \bar{\bar{D}}_{AB} \cdot \vec{S}_B + \vec{S}_A \cdot \bar{\bar{D}}_A \cdot \vec{S}_A + \vec{S}_B \cdot \bar{\bar{D}}_B \cdot \vec{S}_B) = \hbar^{-2}(\vec{S} \cdot \bar{\bar{D}}_S \cdot \vec{S}). \quad (3)$$

The molecular-state D-tensor results from the combination of the local D_A- and D_B-tensors, and the pair-interaction D_{AB}-tensor. When the isotropic exchange coupling constant is large (positive, or negative, $|J| \gg |D|$), a contribution of D_S to the off-diagonal blocks of the exchange Hamiltonian would be ineffective: the energy levels are then dominated by the diagonal matrix elements only. In such a strong-exchange limit the asymmetric exchange results in the zero–field splitting: the situation would be analogous to the mononuclear case as the sublevels are separated by D_1 for $S = 1$, by D_2 and $3D_2$ for $S = 2$.

The strong-exchange limit is surely not a proper assumption in the present case so we are left with a need to construct and then to diagonalise the entire exchange Hamiltonian numerically. The easiest way is to skip the coupling process (as the coupling is only a unitary transformation that leaves the eigenvalues invariant) and to work in the basis set of uncoupled spin functions; the formulae for the matrix elements can be found elsewhere [57]. The fitting procedure enriched with the asymmetric exchange led to the following set of magnetic parameters for **2**: $J_{Ni-Ni}/hc = -0.577$ cm^{-1}, $g_{Ni} = 2.122$, $D_{Ni}/hc = +2.58$ cm^{-1} and $D_{Ni-Ni}/hc = -2.58$ cm^{-1}; the goodness of the fit is excellent ($R = 0.002$, both high-temperature and low-temperature data agree within ± 0.005 μ_B). As seen from Fig. 6, the energy levels no longer follow the usual strong-exchange picture.

The magnetisation measurements for **2** up to $B = 5.7$ T bring no evidence for a saturation at low temperature. The limiting value of magnetisation per particle, $M_{mol}/N_A = 4.0$ μ_B, will evidence the $S = 2$ ground state of

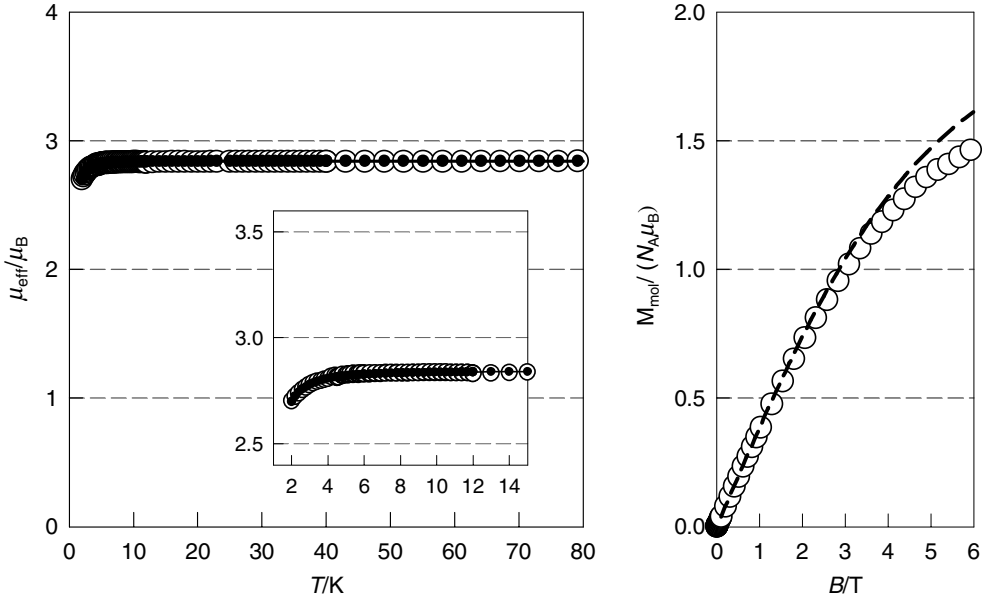

Fig. 7. Magnetic functions for **3**: temperature dependence of the effective magnetic moment (left) and field dependence of the magnetisation at $T = 4.60$ K (right); inset – enlarged low-temperature window; open circles – experimental data; full points and solid lines – the fitted data; dashed – the Brillouin function.

Table 4
Magnetic parameters (in cm^{-1}) for related mononuclear, binuclear and polymeric Ni(II) complexes

Complex[b]	Experimental	D/hc	g	zj/hc	J/hc[a]	Structure; magnetism
Mononuclear $[Ni(L^2)_2X_2]$ or $[NiL^4\ X_2]$						
trans-$[Ni(en)_2(NCS)_2]$	T = 0.3–20 K	+6.24;		E, 1.13		[1]; [60]

[a] The published exchange coupling constants have been re-adjusted to the definition of the exchange coupling Hamiltonian according to Eq. (2).

[b] Abbreviation for ligands: *BiIm* = biimidazolate; *dca* = $N(CN)_2^-$, dicyanamide; *dien* = diethylenetriamine; *dmpz* = 3,5-dimethypyrazolyl; *en* = $NH_2CH_2CH_2NH_2$, 1,2-diaminopropane (ethylenediamine); *im* = imidazole; *macro* = 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane; *mea* = 2-aminoethanole; *medpt* = *N*,*N*-bis(3-aminopropyl)methylamine; *mepn* = 1,2-diamino-2-methylpropane; *tcm* = $C(CN)_3^-$, tricyanomethanide; *terpy* = 2,2′:6′,2″-terpyridine; *teta* = $NH_2CH_2CH_2NHCH_2CH_2NHCH_2CH_2NH_2$, triethylenetetramine (abbr. also *tta*); *tren* = $N(CH_2CH_2NH_2)_3$, 2,2′,2″-triaminotriethylamine (abbr. also *taa*); *ter* = terephthalato; *am1* = *N*,*N*′ -bis(2-aminoethyl)propane-1,3-diamine; *am2* = *N*,*N*′ -bis(3-aminopropyl)ethane-1,2-diamine; *am3* = *N*,*N*′ -bis(3-aminopropyl)propane-1,3-diamine.

the complex (Fig. 5). The experimental data on magnetisation were perfectly reconstructed by using the thermodynamic partition function based upon the above mentioned magnetic parameters.

The magnetic properties of **3** show an almost constant effective magnetic moment of $\mu_{\mathrm{eff}} \approx 2.84\ \mu_{\mathrm{B}}$ (Fig. 7); this is a very typical feature of Ni(II) chains [59]. A fit to the equation suitable for an antiferromagnetic chain [59]

$$\bar{\chi}_{\mathrm{mol}} = \left(\frac{N_{\mathrm{A}}\mu_0\mu_{\mathrm{B}}^2}{k}\right)\frac{g_{\mathrm{Ni}}^2}{T}\,\frac{2 + 0.0194x + 0.777x^2}{3 + 4.346x + 3.232x^2 + 5.834x^3} \tag{4}$$

with $x = |J|/kT$ gave a negligible exchange coupling constant $J/hc = -0.07\ \mathrm{cm}^{-1}$ and $g_{\mathrm{Ni}} = 2.016$. This means that effectively a Curie-Weiss law holds true for isolated $S = 1$ centres. A fit with the simple Hamiltonian according to Eq. (1) gave $g_z = 2.002$, $g_x = 2.013$ and $D/hc = 1.81\ \mathrm{cm}^{-1}$.

The available magnetic data for related mononuclear, binuclear and polymeric Ni(II) complexes are collected in Table 4. (A more extensive tabulation can be found elsewhere [56]. Original literature sources can differ in definition of J and also D.) It can be seen that the local magnetogyric ratio falls into the interval $g_{\mathrm{Ni}} = 2.1$–2.4. The values of the local magnetic anisotropy ranges between moderate negative and positive values: $D_{\mathrm{Ni}}/hc = -12$ to $+7\ \mathrm{cm}^{-1}$ (with two exceptions). With small D-values the g-factor anisotropy is negligible and needs not to be accounted for. The only report that brings a value of the pair-wise magnetic anisotropy, $D_{\mathrm{Ni–Ni}}$ is the present communication. The isotropic exchange coupling constant in binuclear compounds varies between $J_{\mathrm{Ni–Ni}}/hc = -80$ to $+20\ \mathrm{cm}^{-1}$.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 168452 (**1**), 220110 (**2**), 168453 (**3**). Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-(1223)-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

The authors are thankful to the Grant agencies (VEGA, 1/9252/02; APVT, 20-009902, Slovakia), as well as the Fonds der Chemischen Industrie (Germany) for generous financial support. M.B. is thankful to Humboldt Stiftung (TU Darmstadt, Germany).

Abstract

Three new metal (II) complexes namely $[Mn(3\text{-ampy})_4(N_3)_2]$ (**1**), $[Cd(3\text{-ampy})(H_2O)_4]_n(SO_4)_n\cdot(H_2O)_n$ (**2**) and $[Cd(3\text{-ampy})(N_3)_2]_n$ (**3**) (3-ampy = 3-aminopyridine), have been synthesized and characterized by spectroscopic and crystallographic methods. The structure of **1** contains distorted octahedral Mn (II) atoms, monodentate 3-ampy and azide ligands. The structure of **2** consists of a packing of $[Cd(3\text{-ampy})(H_2O)_4]^{2+}$ cations and SO_4^{2-} anions and lattice water molecules. The Cd(1) center in the cation is coordinated by four O atoms from aqua molecules [Cd–O from 2.261(3) to 2.409(2) Å] and two N atoms; the hetero nitrogen atoms of 3-ampy [Cd–N 2.262(3) Å], whereas Cd(2) atom is surrounded by four aqua molecules and two nitrogen atoms of two amino groups of 3-ampy molecules [Cd–N 2.378(3) Å]. 3-Aminopyridine, therefore, acts as bidentate bridging ligands generating a 1D chain along $[0,1,-1]$. Different hydrogen bonds are formed extending the structure to a 3D network. Complex **3** contains dimeric units Cd_2N_2 through double μ-1,1 azide bridges, *N*,*N*′-3-ampy ligand and μ-1,3 azides generating a 3D network structure. There are hydrogen bonds of the type N–H···N between the NH_2 and azido groups consolidating the structure. The thermal properties of the three complexes have been recorded and discussed.

1. Introduction

The chemistry of coordination polymers has evolved rapidly in recent years and a variety of topologies has been constructed through ligand design and the use of different transition metal geometries. These polymers may have interesting properties and applications, e.g. adsorption, ion exchange, non-linear optical and magnetic materials [1–6]. On the other hand, thermal properties of metal azido complexes have received very little attention [7], due to their sensitivity to friction and heat. This explosive nature, however, is dependent on the mode of bonding of bridged azides [8]. Thermal properties of azido complexes are important for determination of the temperature at which the complex explodes, as well as its stability above room temperature, particularly when phase transitions are expected.

We have recently reported a number of cadmium(II) azido and thiocyanato coordination polymers with some pyridine derivative ligands containing different bridging modes and topologies of the $[Cd(N_3)_2]_n$ and $[Cd(NCS)_2]_n$ chains [9–13]. We now extend our work to include the reaction of cadmium(II) and manganese(II) ions with 3-aminopyridine (3-ampy) in presence of azide or thiocyanate ions. In case of the azide ion, manganese(II) forms a 1:4, $Mn(N_3)_2$: 3-ampy complex, whereas a 1:1

complex is obtained between $Cd(N_3)_2$ and 3-ampy. In case of the thiocyanate ion, however, our trials afforded a mixture of few good quality crystals of a polymeric ionic complex containing sulfate anion rather than the desired thiocyanate complex. In this paper we report the synthesis and structural characterization of the three complexes for which we isolated suitable crystals for X-ray measurements.

2. Experimental

2.1. Materials and instrumentation

Elemental analyses were carried out using a perkin-Elmer analysis. Infrared spectra were recorded on a Bruker IFS-125 model FT-IR spectrophotometer as KBr pellets. Other physical measurements have been done as described previously [10]. 3-Aminopyridine was purchased from Aldrich company and other chemicals were of analytical grade quality and used as received.

Caution! Metal azide complexes are potential explosives. Only a small amount of material should be prepared and handled with caution.

2.2. Synthesis

2.2.1. $[Mn(3\text{-ampy})_4(N_3)_2]$ (**1**)

The complex was prepared by combining 15 ml of an aqueous solution of NaN_3 (0.98 g, 15 mmol) saturated with hydrazoic azid [9] with an aqueous solution (20 ml) of $Mn(NO_3)_2\cdot 4H_2O$ (1.88 g, 7.5 mmol) and 3-aminopyridine (5.10 g, 54 mmol). After 1 day transparent brown crystals were separated from the clear solution at room temperature. Yield: 55%. *Anal.* Calc.: C, 46.6; H, 4.7; Mn, 10.7; N, 38.0. Found: C, 46.3; H, 4.9; Mn, 10.9; N, 37.9%. IR, KBr (cm^{-1}) (v, very; s, strong; m, medium; w, weak; br, broad): 3449 m, 3378 m, 3324 s, 3214 m (H-bonded NH_2), 2063 vs (ν_{as}-N_3), 1341 wm (ν_s-N_3), 1628 m (NH_2 sessors), 1589 m, 1579 s, 1485 m, 1443 ms, 1301 ms, 1263 m, 1192 wm, 1098 wm, 1019 w, 806 m, 706 ms, 640 m, 546 w, 5 (pyridine vibrations).

2.2.2. $[Cd(3\text{-ampy})(H_2O)_4]_n(SO_4)_n(H_2O)_n$ (**2**)

This complex was prepared by mixing $3CdSO_4\cdot 8H_2O$ (0.55 g, 1.99 mmol) in water (30 cm^3) with 3-aminopyridine hydrochloride (0.370 g, 4.0 mmol) in methanol (5 cm^3). An aqueous solution (5 cm^3) of NaNCS (0.32 g, 4 mmol) was added dropwise with continuous stirring. The final solution mixture was filtered off and then allowed to stand for several days in a refrigerator to yield colorless crystals of the complex, suitable for X-ray diffraction (20% yield) and a pale yellow microcrystalline powder of the thiocyanato complex. Analytical data for the colorless crystals of $C_5H_{16}N_2O_9CdS$: Calc.: C, 15.3; H, 4.1; N, 7.1; Cd, 28.6. Found: C, 15.5; H, 4.4; N, 7.0; Cd, 28.9%. IR, KBr (cm^{-1}): 3229 s, 3261 s, 1587 ms, 1488 s, 1266 m, 1251 ms, 1203 ms, 1119 vs, br (ν3-SO_4^{2-}), 1053 w, 967 m, 933 m, 809 ms, 699 s, 645 wm, 620 vs (ν4-SO_4^{2-}), 595 ms, 533 wm. Analytical data of the yellow thiocyanato complex: $C_{12}H_{12}N_6CdS_2$: Calc.: C, 34.6; H, 2.9; N, 20.2; Cd, 27.0. Found: C, 34.8; H, 3.0; N, 20.0; Cd, 26.9%.

2.2.3. $[Cd(3\text{-ampy})(N_3)_2]_n$ (**3**)

This complex was prepared by addition of a methanol solution(5 cm) of 3-aminopyridine hydrochloride (0.5 g, 3.8 mmol) to 30 cm^3 aqueous solution of $3CdSO_4\cdot 8H_2O$ (0.5 g, 2 mmol) followed by drop wise addition of (0.5 g, 7.6 mmol) NaN_3 in water (10 cm). Colorless crystals suitable for X-ray diffraction were obtained by allowing the final mixture to stand over several days in a refrigerator. Yield for $C_5H_6N_8Cd$: 62%. *Anal.* Calc.: C, 20.7; H, 2.1; N, 38.5; Cd, 38.7. Found: C, 20.9; H, 2.2; N, 38.1; Cd, 38.8%. IR, KBr (cm^{-1}): 3450 m, 3323 s, 3267 s, 3157 m (H-bonded NH_2), 2116 vs (ν_{as}-N_3), 2040 vs (ν_{as}-N_3), 1585 s, 1491 m, 1448 s, 1327 s (ν_s-N_3), 1286 m, 1263 s, 1201 wm, 1101 wm, 1055 vm, 954 m, 926 vm, 799 m, 703 s, 645 m, 558 m.

2.3. X-ray crystallography

Single crystal X-ray data were measured at 90(2) K on a modified STOE four circle diffractometer using graphite crystal-monochromatized Mo Kα radiation (λ = 0.71069 Å). The intensities were corrected for Lorentz-polarisation effects, intensity decay and for absorption. Crystallographic data and processing parameters are given in Table 1. The structures were solved by direct methods and subsequent Fourier analyses. The program DIFABS [14] and the SHELXTL/PC program package [15] were used for computations. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. Anisotropic displacement parameters were applied to non-hydrogen atoms in full-matrix least-squares refinements based on F^2. All hydrogen atoms were located from difference Fourier maps assigned with isotropic displacement factors and included in the final refinement cycles by use of geometrical restraints. Selected bond distances and bond angles are given in Tables 2–4, for complexes **1**, **2** and **3**, respectively.

3. Results and discussion

The reaction between manganese (II) ions and 3-ampy in presence of azide ion afforded a 1:4 complex (**1**), but in case of cadmium (II) ions a 1:2 complex (**3**) is obtained. In presence of the thiocyanate ions, however, cadmium (II) afforded few colorless crystals

of a sulfate ionic complex (**2**) and a pale yellow 1:2 thiocyanato complex. The stoichiometry of complex **1** is quite different from that of a polymeric complex of the same components: $[\{Mn_2(3\text{-ampy})_4(N_3)_4(H_2O)\cdot 4H_2O\}_n]$ [16]. This later complex was synthesized by different route. Complexes **1** and **2** are soluble in solvents like DMSO and DMF giving non-conducting solutions for **1** and 1:1 electrolytes for **2**. Although **3** is less soluble in these solvents it gives non-conducting solutions.

3.1. Structures

3.1.1. *[Mn(3-ampy)$_4$(N$_3$)$_2$] (**1**)*

Fig. 1 illustrates the principle structural features of complex **1**. The structure consists of isolated *trans* coordinated manganese(II) polyhedra, in which the manganese center is located at an inversion center (Fig. 2). Each metal atom is linked by a pair of *trans* azido ligands and the hetero nitrogen atom from the four 3-ampy ligands. The terminal azido ligands are linear

Symmetry codes: (A) $-x+1,-y+1,-z+2$; (B) $-x,-y+1,-z+2$; (C) $-x+1,-y+1,-z+1$; (D) $-x+1,-y+2,-z+1$; (E) $x+1,y,z$; (F) $-x+1,-y+2,-z+2$.

and asymmetric [N(11)–N(12) = 1.190(3), N(12)–N(13) = 1.165(3) Å, N(11)–N(12)–N(13) = 178.5(2)°]; as for other metal complexes with terminal azides, the shorter N–N bonds are more remote from the metal atom. The Mn–N(3-ampy) bond lengths are comparable with corresponding values found in the structure of [Mn(picolinate) $(N_3)(H_2O)]_n$ [2.278(3) Å] [17] and [Mn(4-acetylpyridine)$_2(N_3)_2]_n$ [2.291(3) Å] [18], but little longer than those reported in the structure of *trans*-[Mn(3-picoline)$(N_3)_2(H_2O)_2$] [2.252(27) Å] [19] and polymeric [Mn(pyridine)$_2(N_3)_2]_n$ [2.259(3) Å] [20]. The structure of **1** is consolidated by hydrogen bonds of the type N–H···N between the NH_2 group of 3-ampy and the uncoordinated nitrogen atom of terminal azides (Fig. 1).

The structure of **1** closely related to that of [Mn(pyrazole)$_4(N_3)_2$] [21] (**4**) with subtle differences. Although the pyrazole complex contains isolated coordinated

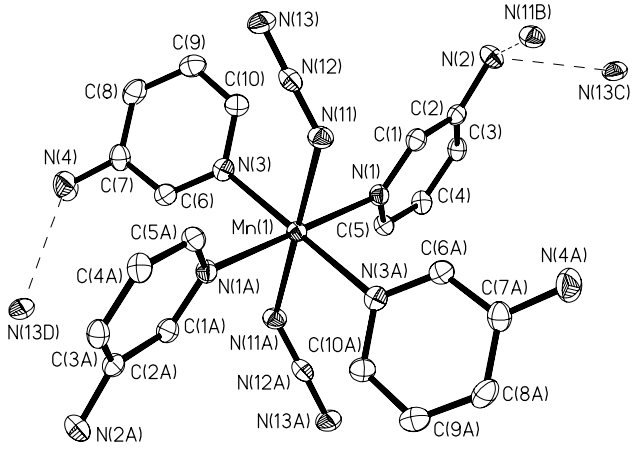

Fig. 1. Perspective view and atom labeling scheme of [Mn(3-ampy)$_4$(N$_3$)$_2$] (**1**). Broken lines indicate hydrogen bonds.

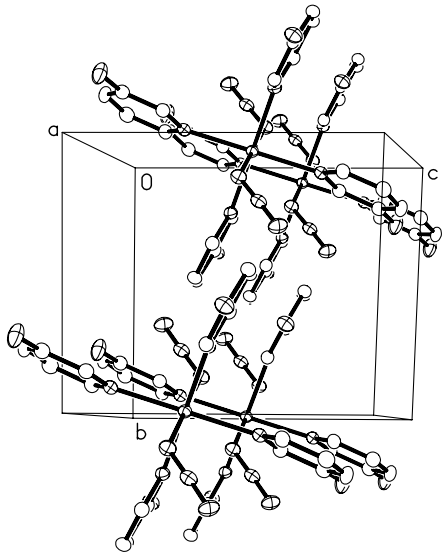

Fig. 2. Packing plot of [Mn(3-ampy)$_4$(N$_3$)$_2$] (**1**) along *a*-axis of unit cell.

manganese and contains N–H···N bonds between the NH of pyrazole and the uncoordinated nitrogen atom of terminal azides, its crystals are monoclinic with *C*2/*c* space group. The structural parameters for **4**, are : Mn(1)–N(11) = 2.182(4) Å, Mn–N(pyrazole) from 2.249(4) to 2.265(4) Å, N(12)–N(11)–Mn(1) = 38.0(4)°, N(11)–N(12) = 1.187(6) and N(12)–N(13) = 1.145(4) Å.

3.1.2. [Cd(3-ampy)(H$_2$O)$_4$]$_n$(SO$_4$)$_n$(H$_2$O)$_n$ (**2**)

The atom labeling scheme for complex **2** is shown in Fig. 3. The structure of **2** consists of a packing of [Cd(3-ampy)(H$_2$O)$_4$]$^{2+}$ cation, SO_4^{2-} anion and lattice water molecule. The cation contains two crystallographically different Cd centers. Cd(1) atom is *trans* coordinated by two hetero N atoms of 3-ampy ligands [Cd(1)–N(1) = 2.262(3) Å] whereas Cd(2) is *trans* coordinated by two amino N atoms of two 3-ampy molecules [Cd(2)–N(2) = 2.378(3) Å], in addition to four aqua molecules for each Cd center [Cd–O from 2.261(3) to 2.409(2) Å]. Thus 3-aminopyridine behaves as a *N*,*N*′-bidentate bridging ligand giving a 1D chain along [0, 1, −1] direction. Both Cd(II) centers are located at inversion centers. The intrachain Cd···Cd distance is 6.878(4) Å and the Cd(2)–N(2)–C(2) angle is 113.6(2)°. The interchain Cd···Cd distances are 6.864(4), 7.833(4) and 8.049(4) Å. Complex **2** contains different types of hydrogen bonds consolidating the structure: (a) O–H···O hydrogen bond between oxygen atoms of the SO_4^{2-} anion and oxygen atoms of aqua molecules and/or lattice water molecules, (b) O–H···O bond between oxygen atoms of aqua molecules and lattice water. These hydrogen bonds connect the 1D chains generating a supramolecular 3D network structure (Fig. 4).

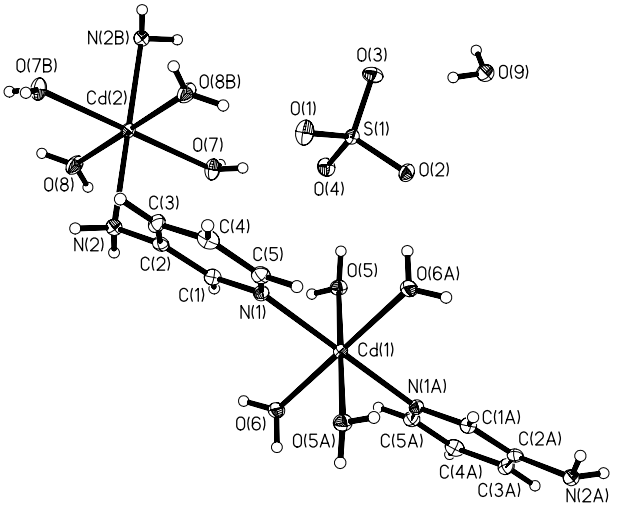

Fig. 3. [Cd(3-ampy)(H$_2$O)$_4$]$_n$(SO$_4$)$_n$(H$_2$O)$_n$ (**2**): perspective view with atom labeling scheme.

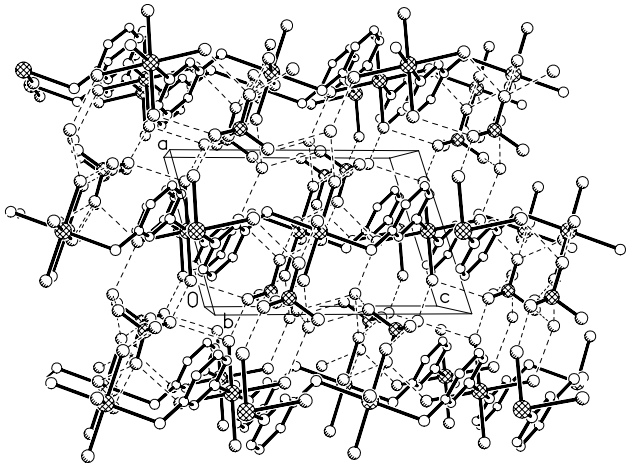

Fig. 4. [Cd(3-ampy)(H$_2$O)$_4$]$_n$(SO$_4$)$_n$(H$_2$O)$_n$ (**2**): packing view along the *b*-axis of the unit cell. Broken lines indicate hydrogen bonds.

3.1.3. $[Cd(3\text{-ampy})(N_3)_2]_n$ (3)

The principle structural features of complex **3** are illustrated in Fig. 5. In this structure each Cd(II) center is six-coordinated by four azido groups [Cd–N distances from 2.273(3) to 2.370(3) Å], a hetero N atom of 3-ampy [Cd–N = 2.319(3) Å] and the amino N atom of another 3-ampy ligand [Cd–N = 2.455(3) Å]. Two of the four azido groups act as μ(1,1) bridges [N(11)–N(12)–N(13)] linking two Cd(II) centers forming four-member Cd_2N_2 rings. The *N*,*N*′-bridging 3-ampy connect the Cd_2N_2 rings forming 1D subunits. These 1D subunits are connected via the other two μ(1,3) azide bridges (with their central nitrogen atoms N(22) and N(32) located at inversion centers) giving rise to a 3D network structure for **3** (Fig. 6). While the μ(1,1) azides are asymmetric the μ(1,3) bridges are symmetrical (Table 4), both types, however are linear [N–N–N angles 179.5(3)° and 180°]. The Cd···Cd distances are 3.655(2) Å in the four-member rings and 6.282(4)–6.661(4) Å in the other rings. The Cd–N_3 sublattice with *cis*-arrangement of 3-ampy ligands is similar to that of Mn(II) complex $[Mn(L)(N_3)_2]_n$ (L=4,4′-dimethyl-2,2′-bipyridine) [22]. The structure of **3** is further consolidated by two hydrogen bonds between the amino group and N atoms of a μ(1,1) and a μ(1,3) azide bridges [N···N distances are 3.125(4) and 3.090(4) Å] (Fig. 5).

At this point it is noteworthy to mention that although the metal center is octahedrally coordinated in the three complexes, 3-aminopyridine acts as a monodentate ligand in **1**, whereas it behaves as a *N*,*N*′-bidentate bridge in **2** and **3**. For complex **1** this is expected from ist chemical composition of 1:4 metal:3-ampy ratio, and is similar to that found in the structure of $[\{Mn_2(3\text{-ampy})_4(N_3)_4(H_2O)\}]_n$ [16] and $[\{Cu_2(3\text{-ampy})_4(N_3)_2(NO_3)_2\}(C_2H_5OH)]_n$ [23]. In case of **2**, this complex, which contains the sulfate counter ion, crystallizes with four aqua molecules, and as it contains only one 3-ampy, two of such molecules are expected to behave as *N*,*N*′-bidentate bridges to occupy the last two positions of each Cd center. In **3**, the $[Cd(N_3)_2]_n$ sublattice is similar to that of $[Mn(N_3)_2]_n$ found in the structures of many $[MnL_2(N_3)_2]_n$ complexes [24–26], in which the azides occupy four sites of the six positions around each metal center, and therefore the existing single 3-ampy per Cd is expected to act as *N*,*N*′-bridge, as in **2**, in order to complete the octahedral geometry. The *N*,*N*′-bridging mode of the 3-ampy ligand was observed in the dinuclear complex $[Ni(NCS)_2(3\text{-ampy})_2(H_2O)]_2\cdot 2H_2O$ [27]. To the best of our knowledge, in all other structurally characterized metal-(3-ampy) or related metal-(5,5′-diamino-2,2′-bipyridine) complexes, the aminopyridine ligand binds the metal center through the heterocyclic N atom and the amino group only functions as a hydrogen bond donor [28–35].

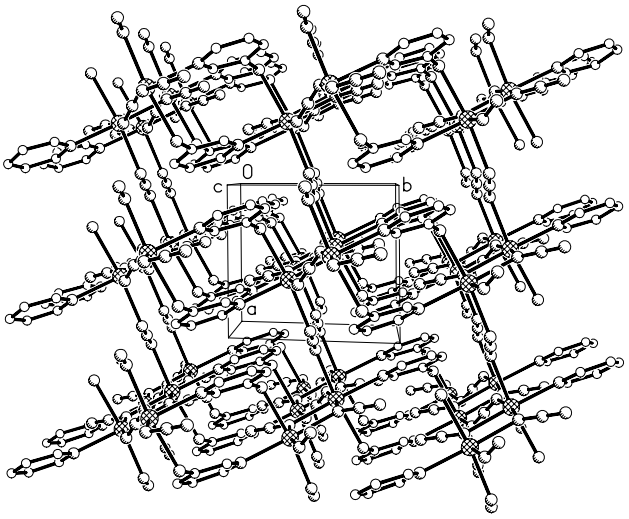

Fig. 6. Packing plot of $[Cd(3\text{-ampy})(N_3)_2]_n$ (**3**) viewed along the *c*-axis of the unit cell.

3.2. Spectra

The IR spectrum of **1** shows the vibrations of the hydrogen bonded NH_2 group as sharp bands at 3448

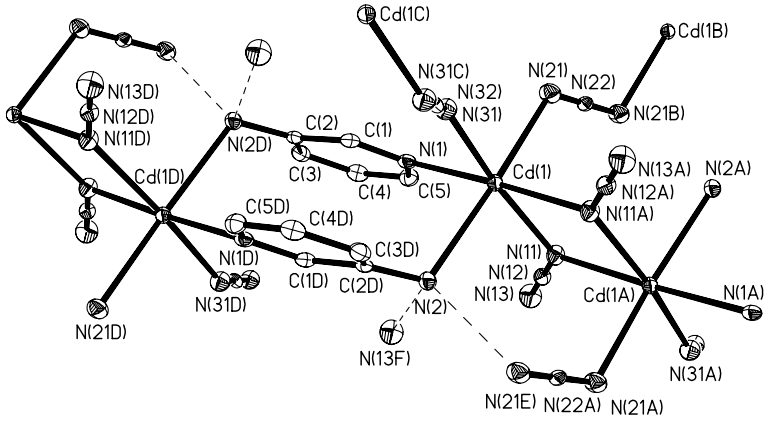

Fig. 5. Perspective view of $[Cd(3\text{-ampy})(N_3)_2]_n$ (**3**) with atom labeling scheme. Symmetry codes according to Table 4. Broken lines indicate hydrogen bonds.

ms, 3376 s, 3324 ms, 3214 ms, but the 1629 cm^{-1} (NH_2-sessors) band remains at the same position as in the spectrum of free 3-ampy, suggesting that the amino group is not involved in complexation. The position of the 2063 cm^{-1} (ν_{as}-N_3) falls within the absorption range of terminal azides in Mn(II) complexes [19,20], and the appearance of the ν_s-N_3 band at 1341 cm^{-1} indicates the asymmetric nature of the azide groups in **1**. The medium intensity broad band in the range 3500–3000 cm^{-1} with two strong peaks at 3329 and 3261 cm^{-1} in the IR spectrum of **2** is due to hydrogen bonded aqua and lattice molecules as well as NH_2 group. The disappearance of the 1629 cm^{-1} band from the IR spectrum of **2** suggests the participation of the NH_2 group in complex formation. The systematic blue shifts of the vibration bands due to pyridine moiety indicate that 3-ampy behaves as *N*,*N*′ bidentate bridging ligand in complex **2**. The ionic nature of the SO_4^{2-} group is indicated by the appearance of a very strong broad band centered around 1120 cm^{-1} (ν_3) and a sharp band at 620 cm^{-1} (ν_4) [36]. The IR spectrum of **3** is very similar to that of **2** for the NH_2 and pyridine ring vibrations, indicating that 3-ampy acts as a *N*,*N*′ bidentate bridging ligand and that NH_2 is H-bonded. Additionally, the spectrum exhibits two very strong bands at 2116 and 2040 cm^{-1} due to $\nu_{as}(N_3)$. The 2040 cm^{-1} band falls well within the range for μ(1,3) azide bridges [37], whereas the 2116 cm^{-1} is due to the μ(1,1) bridges [38].

The room temperature X-band ESR spectrum of polycrystalline samples of the manganese complex (**2**) have been recorded. The spectrum shows a broad intense isotropic signal centered at $g = 2.0$. In DMSO the spectrum of **1** shows a hyperfine structure due to Mn(II) ($I = 5/2$) with (A) of 92 G. These spectra of the solid as well as DMSO solution are very similar to those of hexa-coordinate manganese(II) complexes [39].

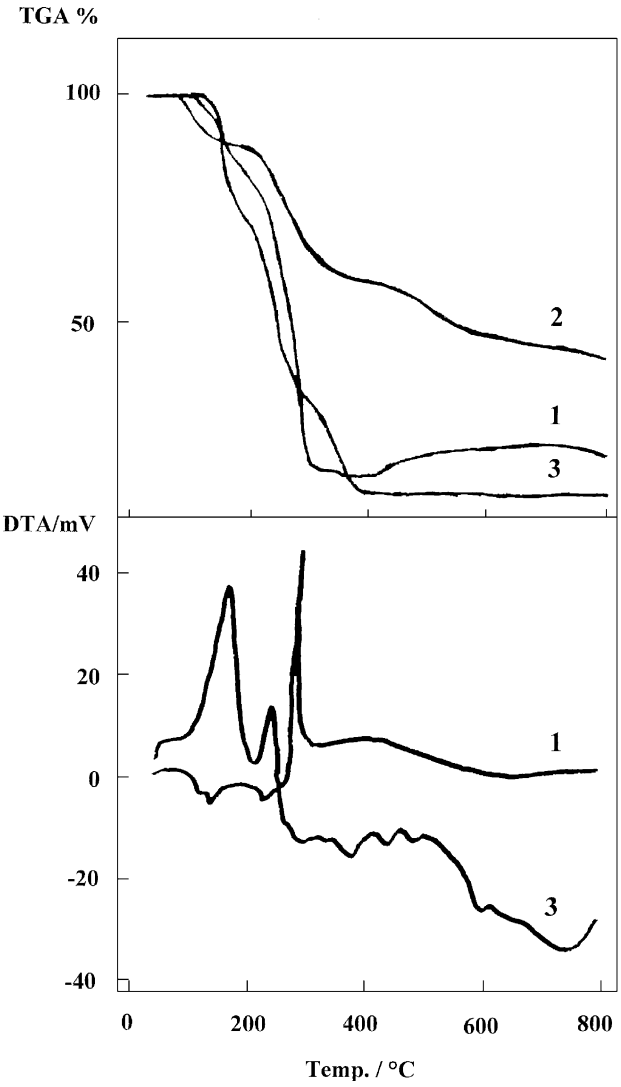

Fig. 7. Thermal behaviour of complexes **1**–**3**.

3.3. Thermal properties

The results of the thermal decomposition of complexes **1**, **2** and **3** are represented in Fig. 7. The first step of the thermal decomposition of **1** consists of a loss of one azide group and two amino groups from two 3-ampy ligands (loss of weight; exper. 13.9% and theor. 14.2%). The DTA shows two successive endothermic peaks with maxima at 125 and 150 °C. The residual polymeric complex is not stable and decomposes immediately with a weight loss of 33.2% which corresponds a loss of one py moiety and one 3-ampy. The theoretical loss in this step (160–254 °C) is 33.4%. In the third step the loss of 35.5%, is suggestive of the loss of 3-ampy, py and one nitrogen atom from the azide group (theor. loss 36.1%) with a residue of 17.4%. These two steps, however, are not well separated, suggesting that they are two stages of one step rather than two steps as seen from the TG curve. The DTA curve shows a weak endothermic peak at 260 °C followed by an exothermic peak at 335 °C. The weight of the final residue is a little higher than that corresponding to MnN_2 (16.1%). As the decomposition takes place under air, it is possible to suggest that the residue is MnO_2 (16.9%). The TG curve shows that the residual weight is about 15.5% just below 400 °C, increases again above 410 °C and reaches about 17%. The thermal decomposition of **1** differs from that of the corresponding $Mn(pyrazole)_4(N_3)_2$ [21].

The first step of decomposition of **2** starts at 80 °C with a weight loss of 9.6% which corresponds to the loss of two H_2O molecules (theor. loss 9.2%). In the second step (140–327 °C) the weight loss of 29.7% corresponds to the loss of 3-ampy and 1.25 water molecules (29.7%) leaving $CdSO_4 \cdot 1.75H_2O$, as a residue. In the third step which ends around 800 °C, the weight loss is 20%, which is less than that required for complete decomposition of the $CdSO_4 \cdot 1.75H_2O$, additionally the final residue weight is about 41%, which is much higher than that

assuming the final product to be CdO (32%). According to a previous study [40] the initial decomposition temperature of $CdSO_4$ is around 780 °C depending on the heating rate and the complete decomposition occurs around 950 °C. As a consequence the weight loss of 20% in this step is due to the loss of the water molecules and the decomposition of some $CdSO_4$.

Complex **3** loses an azide and N atom of the amino group of 3-ampy ligand with a weight loss of 18.8% (Theor. 19.3%). This step appears in the DTA curve as a strong exotherm at 168.6 °C. In the second step the weight loss of 30.1% is a little higher than the loss of 3-ampy ligand residue (27.6%) suggesting that the release of the second azide group starts before the third step, and this appears in the DTA curve as a weak exotherm at 241.9 °C. The DTA curve shows the last step as several weak endotherms, the first peak at 374 °C. The final residue of 34.5% is less than that calculated assuming only Cd (38.6%), suggesting that some explosion takes place.

4. Supplementary material

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), on request, quoting the deposition numbers: CCDC-233523–CCDC-233525 for **1**–**3**.

Hydrothermal synthesis and characterization of a new 3D iron phosphatooxalate templated by organo-amine

He Meng, Guang-Hua Li, Yan Xing, Yu-Lin Yang, Yan-Jie Cui, Li Liu, Hong Ding, Wen-Qin Pang *

State Key Laboratory of Inorganic Synthesis and Preparative Chemistry, College of Chemistry, Jilin University, Changchun 130012, P.R. China

Received 16 March 2004; accepted 7 July 2004
Available online 11 September 2004

Abstract

A new organically templated iron(II) phosphatooxalate, $(N_2C_4H_{12})[Fe_4(C_2O_4)_3(HPO_4)_2(H_2O)_2]$ **I**, has been synthesized under hydrothermal conditions and characterized by single-crystal X-ray diffraction. The structure possesses infinite chains made from Fe_2O_{10} dimers and PO_4 tetrahedra bridged by bidentate oxalate units and strong interlayer P–O–H-oxalate hydrogen bonds. The diprotonated piperazinium cations are located in the intersecting tunnels parallel to the [1 0 0] and [0 1 0] directions.

Keywords: Hydrothermal synthesis; Crystal structure; Iron phosphatooxalate; Template; Oxalate acid; Piperazine

1. Introduction

The study of framework materials continues to be of interest not only because of the wide variety of structures but also due to their potential applications in the areas of catalysis, sorption and separation processes [1]. Recent developments in the area of hybrid structures have placed special emphasis on metal phosphate chains or layers that are connected by oxalate moieties. Up to now, a few metal phosphatooxalates such as Al [2], V [3], Co [4], Mn [5], Zn [6] and Ga [7] have been reported in the literature. Most of the framework inorganic materials are normally synthesized under mild hydro/solvothermal conditions in the presence of a structure-directing agent. It has been shown recently that the oxalate units generally cross-link the inorganic parts and act as a bridge in the phosphatooxalates. In recent years, several iron phosphatooxalates [8] have also been expatiated, which exhibit interesting magnetic properties originating from the super-exchange interactions that are predominantly antiferromagnetic, involving the iron phosphates and the oxalate moieties. Here we report the synthesis, crystal structure, Mössbauer and magnetic behavior of a new iron phosphatooxalate $(N_2C_4H_{12})[Fe_4(C_2O_4)_3(HPO_4)_2(H_2O)_2]$ **I**, which was synthesized hydrothermally using piperazine as the template.

2. Experimental

Compound **I** was synthesized under hydrothermal conditions in a 15 ml Teflon-lined autoclave under autogenous pressure. The reagents used were deoxidized ferric powder (Beijing Chemical Plant, A.R.), phosphoric acid (Beijing Chemical Plant, 85%), oxalic acid dihydrate (Beijing Chemical Plant, A.R.), piperazine (PIP, Acros, 99%) and deionized water.

2.1. Synthesis and characterization

In a typical synthesis, a mixture of Fe:$2H_3PO_4$:1.6-PIP:$1.1H_2C_2O_4$:$155.6H_2O$ was stirred to form a homogeneous solution. The reaction was carried out in a Teflon-lined stainless-steel autoclave (70% filling rate) at 393 K for ca. 48 h. The product was cleaned by ultrasonication and filtration, washed with distilled water several times, and dried at room temperature. The final product consisted of pale green plates with a small amount of black solid.

The powder X-ray diffraction (XRD) pattern was recorded on a Siemens D5005 diffractometer with Cu Kα radiation ($\lambda = 1.5418$ Å). Element analyses were performed on a Perkin–Elmer 2400 element analyzer and the inductively coupled plasma (ICP) analysis on a Perkin–Elmer Optima 3300 DV ICP instrument. Thermogravimetric analysis (TGA) was conducted on a Netzsch STA 449C thermogravimetric analyzer with a heating rate of 10 °C min^{-1} in air. Magnetic susceptibility data were obtained on polycrystalline samples from 2 to ca. 300 K in a magnetic field of 5k Oe after zero-field cooling using a Quantum Design MPMS-7 SQUID magnetometer. The ^{57}Fe Mössbauer measurements were made on a XOFORD-500 instrument at room temperature. Isomer shifts are reported with respect to an iron foil standard at 300 K.

2.2. Determination of crystal structure

The intensity data were collected on a Siemens Smart CCD diffractometer equipped with a normal-focus, 2.4 kW sealed-tube X-ray source (graphite-monochromated Mo Kα radiation, λ(Mo Kα) = 0.71073 Å) operating at 50 kV and 40 mA. The structure was solved by direct methods and refined by full-matrix least-squares on F^2 using SHELXTL [10]. Version 5.1 [9]. It is noteworthy that the atoms (C5, C6, N1, N2) of piperazine are disordered over two positions with occupancy factors 0.5 in the crystal structure, and H atoms on the coordinated water molecules of Fe(2) in **I** were not located because of the large thermal parameter of $O(9)_w$. Further details of the X-ray structural analysis are given in Table 1.

3. Results and discussion

3.1. Characterization

The experimental and simulated powder X-ray diffraction patterns are in excellent agreement with each other, proving the phase purity of the sample.

The ICP analysis shows that compound **I** contains 28.85 wt% Fe and 7.69 wt% P, suggesting a molar ratio of Fe:P of 2:1, which is in good agreement with the value (28.87 wt% Fe and 7.71 wt% P) based on the single-crystal structure analysis. Elemental analysis indicates that the C, H and N contents are 14.89, 2.29 and 3.44 wt%, respectively, corresponding well to the values 14.93, 2.24 and 3.48 wt% on the basis of the structural formula.

The TGA studies for the title compound **I** carried out from 33–600 °C in air showed a sharp weight loss with a broad tail that begins at ca. 200 °C and is complete ca. 500 °C (the observed total weight loss is 43.6%). The DTA curve shows only one strong exothermic peak at ca. 323 °C. The weight loss is attributed to dehydration of hydrogen phosphate groups, decomposition of oxalate anions and release of organic components, giving $Fe_4(P_2O_7)_3$ and Fe_2O_3 as the final products. The observed total weight loss is close to the calculated value of 44.7% based on the empirical formula.

3.2. Description of the structure

The coordination geometry in compound **I** is shown in Fig. 1. Both distinct Fe^{II} atoms are in distorted octahedral environments (the Fe(1)–O bond lengths are in

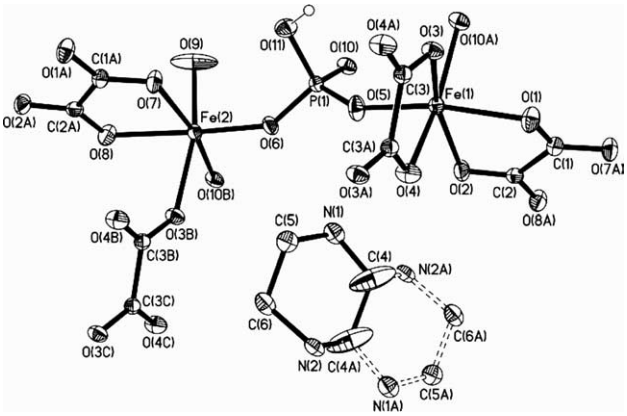

Fig. 1. ORTEP view of the structure of **I** showing the atom labelling scheme (50% thermal ellipsoids).

the range 1.980–2.244 Å, Fe(2)–O 1.985–2.202 Å. O–Fe(1)–O bond angles 75.53°–164.93°, O–Fe(2)–O 75.72°–168.20°). Fe(1) is coordinated by two bidentate oxalates and two phosphate units, while Fe(2) is coordinated by one bidentate oxalate, one monodentate oxalate, two phosphate units and one aqua ligand. The selected bond lengths and bond angles are listed in Table 2.

The $Fe(1)O_6$ and $Fe(2)O_6$ octahedra share corners to form a dimer $[Fe_2O_{10}]$ (Fig. 2(a)). The dimers and the phosphate groups are connected alternatively to form an infinite chain with four-membered rings (Fig. 2(b)). Such chains are further connected with each other via the oxalate bridges along [1 0 0] and [0 0 1], completing a three dimensional architecture (Fig. 2(c)). The connectivity between the chains and the oxalates creates an eight-membered (four $[Fe_2O_{10}]$ dimers, two phosphates and two oxalate units) one-dimensional (1-D) channel. The protonated piperazinium cation resides in the middle of the channel along the [0 1 0] direction. Along the [1 0 0] direction, the connectivity between these units also creates eight-membered one-dimensional channels, and also gives rise to a narrow elliptical 1-D channel formed by four $[Fe_2O_{10}]$ dimers and four oxalates (Fig. 3).

The structure-directing amine molecules are located within the channels of **I**, interacting with the framework via multipoint hydrogen bonding. Such multipoint hydrogen bonding is known to be associated with the formation as well as structural stability of various open-framework materials [10]. The hydrogen bond interactions in **I** between the framework and the protonated piperazinium cation are quite strong. The terminal –OH group of the HPO_4 unit and terminal H_2O of a $Fe(2)O_6$ unit participate in intra- as well as inter-framework hydrogen bonding. A complete list of hydrogen bond interactions is listed in Table 3.

(b) The infinite chain-like structure is formed by the dimers connecting with PO_4 tetrahedra alternatively. (c) The structure of compound **I** viewed along the [0 1 0] direction.

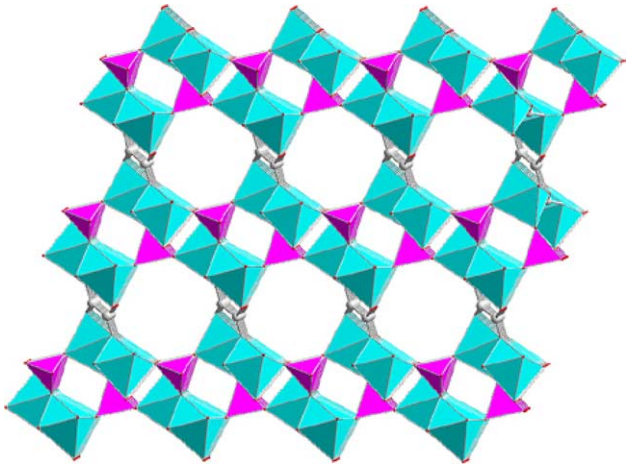

Fig. 3. The structure of compound **I** viewed along the [1 0 0] direction.

The magnetic behavior of a powdered sample of compound **I** was measured in the temperature range 2–300 K. The temperature dependence of χ_m and χ_m^{-1} curves, where χ_m is the molar magnetic susceptibility, are shown in Fig. 4. The maximum around 23 K suggests the presence of an antiferromagnetic coupling, the thermal variation of the molar susceptibility follows a Curie–Weiss law ($1/\chi_m = (T-\theta)/C_m$) with values of the Curie–Weiss constants of $C_m = 13.74\ \mathrm{cm^3\,K\,mol^{-1}}$ and $\theta = -17.97$ K. Although the computed curve does not match the χ_m^{-1} curve very well, the values of the magnetic interactions obtained are correct in sign and the magnitude is physically reasonable. The mismatch between the calculated curve and the experimental data may be due to the orbital contribution of the distorted octahedral high spin iron(II) ion, because of the Jahn–Teller compres-

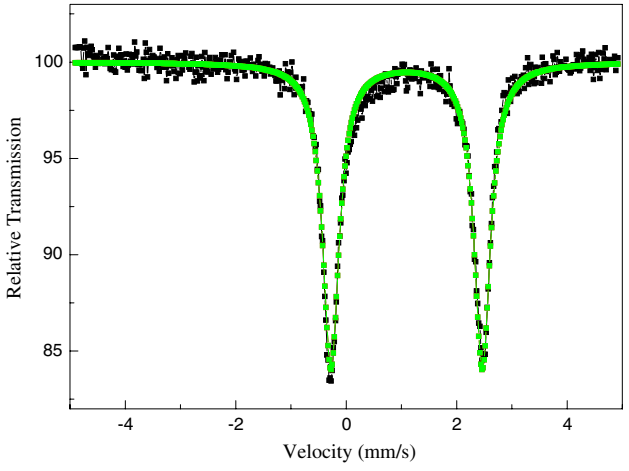

Fig. 5. Mössbauer spectroscopy of compound **I** at 300 K.

sion. Furthermore, the magnetic interaction could be due to super-exchange coupling between Fe(1) and Fe(2) via O(3) and O(10) within the dimeric units. Similar interactions have been reported in some iron phosphates [11] and oxalates [12].

The room temperature ^{57}Fe Mössbauer spectrum of **I** was least-squares fitted by one doublet (Fig. 5). The obtained parameters are δ (isomer shift) = 1.21 mm s^{-1}, ΔE_Q (quadrupole splitting) = 2.74 mm s^{-1}, and Γ (full-width at half-height) = 0.18 mm s^{-1}. The large quadrupole splitting corresponds to a large octahedral distortion. According to Menil, the isomer shift is characterisitic of high-spin Fe^{II} [13]. Therefore, the valence of the iron atoms in **I** is confirmed by Mössbauer spectroscopy.

It is instructive to compare the structural features of **I** with those of others metal phosphate-oxalates. Since we completed the present study, we also noticed two papers on Fe(II) oxalate-phophates by K.H. Lii [10a] and C.N.R. Rao [10b] which have an analogous structural formula to **I** and have comparable structural features. In the reported structures, FeO_6 and FeO_5 share their edges forming a dimeric unit [Fe_2O_9], the dimers are linked to each other via the phosphate, with the oxalate units forming the framework structures. In most of the oxalate-phosphates based open-framework structures iron is present in either five or six coordination, forming trigonal bipyramidal FeO_5 or octahedral FeO_6 as the building units. Here in the reported compound **I**, both Fe(II) centres have six coordination. According Choudhury and Natarajan [8e], this is because the average charge per oxygen on the oxalate (0.5) is less than that on the phosphate (0.75), such that more oxalate oxygens are needed to satisfy the valence of iron.

4. Conclusion

In conclusion, a new open-framework iron phosphatooxlate has been synthesized hydrothermally in the presence of a structure-directing amine. The 3-D architecture of the title compound **I** contains Fe_2O_{10} dimers and PO_4 moieties connected with each other to form infinite chains, which are linked via oxalate units to form a 3-D structure. Such a dual role of the oxalate unit is noteworthy. The magnetic behavior indicates the presence of antiferromagnetic interactions. It would be worthwhile to explore the possibility of introducing other magnetic components into the iron phosphatooxalate framework, in order to obtain materials with novel magnetic properties.

Abstract

Density functional calculations for the $[ReBr_3(NO)(PPh_3)_2]$ (**1**) and $[ReBr_3(NO)(OPPh_3)_2]$ (**2**) complexes have been carried out using the DFT method with the B3LYP functional. The experimentally characterised molecular structures of **1** and **2** have been properly reproduced by the B3LYP method. The UV–Vis spectra of both complexes have been interpreted on the basis of the electronic transitions calculated with the time-dependent DFT method (TDDFT) for **1** and **2**.

1. Introduction

For many years nitrosyl compounds of transition metals have been the centre of interest for scientists both engaged in basic research and trying to employ these complexes as catalysts of polymerisation, oligomerisation, metathesis, epoxidation, oxidation and reduction [1–7].

One of the most important aspects of metal nitrosyl complexes is the bonding nature of the nitric oxide to the metal centre. Historically, the bonding of the M–NO unit has been described by assigning formal oxidation states to the metal centre and the nitrosyl ligand. In such an assignment, the linear M–NO unit is deemed to possess a bound NO^+ ligand, and conversely, a bent M–NO core is deemed to possess a bound NO^- ligand. However, the bonding in the $M(NO)_x$ moieties of metal nitrosyl complexes is largely of a covalent nature, and the electron distribution in the M–NO unit is more or less evenly distributed in this group. Enemark and Feltham have proposed the $\{M(NO)_x\}^n$ formalism for metal nitrosyls in which n is taken as the total number of electrons associated with the metal d and π*(NO) [5].

Studies of the electronic structure and electronic spectroscopy of nitrosyl complexes of transition metals are dominated by investigations of the nitroprusside ion $[Fe(CN)_5(NO)]^{2-}$ [8,9] and ruthenium nitrosyls [10–13]. To our knowledge, only the model $[Re(NO)_2(PH_3)_2L]$ nitrosyl complexes (L = H^-, CO, $CNCH_3$, PH_3, CN^-, $NCCH_3$, Cl^-) have been the subject of quantum chemical calculations based on density functional theory (DFT) [14].

The papers [15–19] present the preparation, structural and some spectroscopic characterisation of rhenium nitrosyl complexes of the general formula $[ReX_3(NO)L_2]$, where X = Cl or Br and L = PPh_3, $AsPh_3$, $OPPh_3$ or $OAsPh_3$.

This study presents a comparison of the electronic structure and bonding nature of $[ReBr_3(NO)(PPh_3)_2]$ (**1**) and $[ReBr_3(NO)(OPPh_3)_2]$ (**2**), based on the results of DFT calculations. The paper also includes calculations of electronic transitions with the time-dependent

DFT method (TDDFT) for **1** and **2**, and discussion of their UV–Vis spectra on the basis of the TDDFT calculations.

Calculations with the TDDFT method for open-shell organic, inorganic and organometallic molecules are still limited, but a few studies have already appeared and support the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [20–23]. There are also several works performed with this method for 5d-metals (including rhenium complexes) in which good correlations between experimental and calculated results have been confirmed [24–30].

2. Experimental

$[ReBr_3(NO)(PPh_3)_2]$ (**1**) and $[ReBr_3(NO)(OPPh_3)_2]$ (**2**) complexes were prepared according to the literature methods [16,17].

Electronic spectra of **1** and **2** were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 800–220 nm in deoxygenated dichloromethane solution.

3. Computational details

The GAUSSIAN 03 program [31] was used in the calculations. The geometry optimisation was carried out with the DFT method with the use of the B3LYP functional [32,33]. The LANL2DZ basis set [34] was used on the rhenium and bromine atoms, 6-31G(d) on the nitrogen and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations.

4. Results and discussion

4.1. Molecular geometries

The geometries of **1** and **2** were optimised in the doublet state by the DFT method with the B3LYP functional. Table 1 shows the possible electronic configurations and spin multiplicities of the $[ReBr_3(NO)L_2]$ (L = PPh_3 or $OPPh_3$) complexes. The doublet state agrees well with the experimental values of the effective magnetic moment for **1** and **2**, they are both equal, ~1.8 BM, and correspond to one unpaired electron.

The structures and atomic numbering schemes of the examined complexes are shown in Figs. 1 and 2. Complex **1** has pseudooctahedral geometry with *trans* phosphine molecules, *meridional* bromo ligands and a linear nitrosyl group. The rhenium atom of **2** is also in a distorted octahedral environment with three bromine ligands in *meridional* geometry, but the linear N–O group is *trans* to one of $OPPh_3$ ligands, and the two $OPPh_3$ molecules are mutually *cis*. The geometric parameters of **1** and **2** optimised by the DFT method are gathered in Table 2. For comparison, the experimental bonds and bond angles are also included. Two polymorphs, orthorhombic with all atoms in general positions and monoclinic with the rhenium atom on the special position *e* of the space group *C*2/*c* with multiplicity 4 and site symmetry 2, were isolated for complex **2** [17,19]. Table 1 shows only the X-ray crystal structure data for orthorhombic polymorph [19]. The optimised geometries are in good agreement with the experimental ones, the largest differences are found for the Re–Br bond distances. A similar elongation of the rhenium–halogen bond lengths in the B3LYP with different basis sets has been found in other rhenium complexes [35]. In the X-ray structure of **1**, the

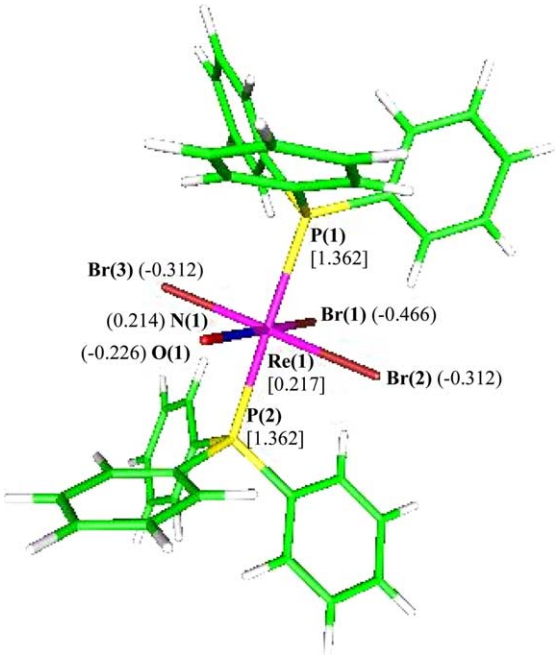

Fig. 1. Structure of **1** and atomic charges from the Natural Population (NP) analysis.

Table 1
Possible oxidation numbers and spin multiplicities of Re and NO in $[ReBr_3(NO)L_2]$ complexes (L = PPh_3 or $OPPh_3$)

Re	Spin of Re	NO	Spin of NO	Total spin	Spin multiplicity
Re(II)	5/2, 3/2, 1/2	$NO^+(\pi_1^*)^0(\pi_2^*)^0$	0	5/2, 3/2, 1/2	6, 4, 2
Re(III)	2, 1, 0	$NO(\pi_1^*)^1(\pi_2^*)^0$	1/2	5/2, 3/2, 1/2	6, 4, 2
Re(IV)	3/2, 1/2	$NO^-(\pi_1^*)^1(\pi_2^*)^1$	1	5/2, 3/2, 1/2	6, 4, 2

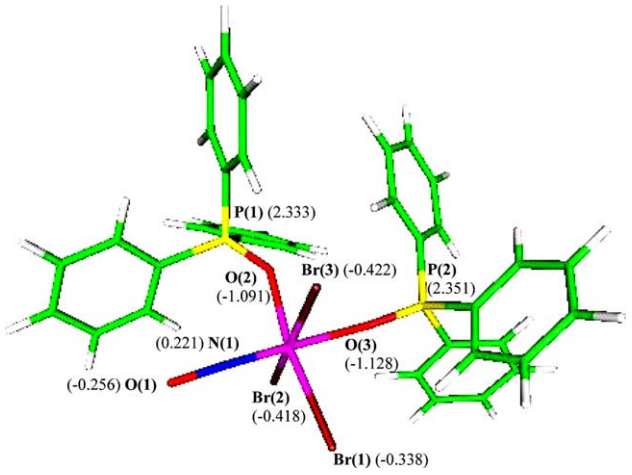

Fig. 2. Structure of **2** and atomic charges from the Natural Population (NP) analysis.

rhenium, NO and bromine species are sited on a crystallographic twofold axis, so the N–O–Re–Br unit is perfectly linear. In the optimised structure, the N–Re–Br and N–O angles are almost linear. There is no significant difference in the calculated Re–N and N–O bond lengths for **1** and **2**. The shortening of the experimental N–O bond length in **2** may be a consequence of crystal packing. In monoclinic polymorph of *mer-cis*-[$ReBr_3(NO)(OPPh_3)_2$] the N–O distance is equal 1.26(1) Å [19], in *mer-cis*-[$ReCl_3(NO)(OPPh_3)_2$] – 1.21(3) Å [15] and in *mer-cis*-[$ReBr_3(NO)(OAsPh_3)_2$] – 1.156(6) Å [18]. A similar shortening of the N–O bond as a result of steric requirements or some disorders is observed in [NEt_4][$ReBr_4(NO)(MeCN)$] – 0.99(2) Å [36] and *mer*-[$RuCl_3(NO)\{PPh_2(CH_2)_3PPh_2$] – 0.907(7) Å [37]. The general trends observed in the experimental data are well reproduced in the calculations, e.g., the significant shortening of the Re–Br bond length in the *trans* position to the $OPPh_3$ molecule in **2**, the notable differences in O–P–Re angle values and O–P bond lengths in **2**, and the lengthening of the Re–Br bond length in the *trans* position to NO in **1**.

4.2. Charge distribution and spin densities

Figs. 1 and 2 present the atomic charges from the Natural Population (NP) analysis [38] for **1** and **2**, respectively. For both complexes **1** and **2**, the charges on the nitrogen atoms of the nitrosyl groups are positive, whereas the oxygen atoms are negatively charged. The total charges on the NO groups of these complexes are close to zero, −0.012 and −0.035 for **1** and 2, respectively. The more negative total charge of the NO ligand in **2** indicates the stronger electron acceptor ability of the NO group in this complex. The calculated charge on the rhenium atom of **1** is far from the formal charge +2. It results from charge donation from the bromine

ions and triphenylphosphine ligands, which act as σ-donors. There are large positive charges on the phosphorus atoms, and the charges on the bromine ligands are significantly smaller than −1. There is a noticeable difference between the calculated charge on the bromine ion in the *trans* position to the NO group and the charges on two mutually *trans* bromine ligands. The second ones are less negative. The positive charge on the rhenium atom of **2** is higher in comparison with 1, but it is also considerable smaller than the formal +2 charge. It results mainly from strong charge donation from bromine ions, the charges on the bromine ligands are significantly smaller than −1. A visible difference between the calculated charge on the bromine ion in the *trans* position to the $OPPh_3$ molecule and charges on two mutually *trans* bromine ligands is also noticed for complex **2**. A smaller negative charge is observed on the bromine ion in the *trans* position to the $OPPh_3$ molecule. The oxygen atoms of $OPPh_3$ ligands are negatively charged, whereas the phosphorous atoms are positively charged.

For both complexes, there are positive spin densities on the rhenium atoms of about **1** (0.988 for **1** and 1.072 for **2**) and small negative spin densities of about −0.1 on the nitrogen and oxygen atoms of the nitrosyl ligands. The spin densities on the bromine ligands and phosphorous atoms of PPh_3 ligands for complex **1** are as follows: Br(1), −0.003; Br(2/3), −0.131; P(1/2), −0.034. The spin densities on the phosphorous and oxygen atoms of $OPPh_3$ ligands and the bromine ligands for complex **2** are also close to zero and they are: Br(1), −0.068; Br(2/3), −0.029; P(1), −0.002, P(2)/O(2), 0.000 and O(1), 0.014.

4.3. Electronic structure

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of **1** and **2** are presented in Table 3. The selected HOMO and LUMO of **1** and **2** with α spin are depicted in Figs. 3 and 4, respectively. Most of the MOs of **1** and **2** have complicated characters. The percent participation of atomic orbitals in the selected HOMO and LUMOs of **1** and **2** is given in Table 3.

4.3.1. $[ReBr_3(NO)(PPh_3)_2]$ (**1**)

Among the MOs of **1** there are no orbitals of pure π_{Re-NO} character. The π_{ReNO} bonding interaction makes the largest contribution into HOMO − 22 and HOMO − 19 with α-spin, and HOMO − 21 and HOMO − 19 with β-spin. A substantial contribution of π_{Re-NO} orbitals is also shown in HOMO − 2 with α spin and HOMO − 1 with β spin, but the π bromine orbitals are the main components of these MOs (see Table 3). The bonding π_{Re-NO} orbitals with and β spin are localised mainly on the rhenium d orbitals and they are mixed with π_{Br} and π_{Ph} orbitals. LUMO + 1 and LUMO + 2 with α-spin and β-spin are of π^*_{Re-NO} antibonding character. They have prevalent NO character. On the basis of the molecular orbital composition and the small charge on the NO group, the NO^+ character of the nitrosyl in this complex can be confirmed.

The HOMO with α-spin and HOMO with β-spin are mainly localised on the bromine ligands, but they have a substantial contribution from the free electron pairs on the phosphorus atom. They present an interaction between the free phosphorus electron pairs and rhenium d_{yz} orbitals, which explains the strong donation of electron density from the phosphorous atoms to the rhenium atom. HOMO − 23 is of σ_{Re-P} character.

The d_{xy} rhenium orbital and π orbitals of bromine ligands in an anti-bonding arrangement make the main contributions into HOMO − 1 with α-spin and the LUMO with β-spin. The LUMO with α-spin and LUMO + 3 with β-spin are of $d_{x^2-y^2} - \sigma_{Br}$ character. LUMO + 3 with α-spin and LUMO + 7 with β-spin are mainly localised on the rhenium d_{x^2} orbital. LUMO + 4, LUMO + 5 with α-spin and LUMO + 5, LUMO + 6 with β-spin present a π interaction of the phosphorous orbitals with the π* orbitals of the phenyl groups.

4.3.2. $[ReBr_3(NO)(OPPh_3)_2]$ (**2**)

The largest participation of the bonding π_{Re-NO} orbitals are shown in HOMO − 12, HOMO − 7, HOMO − 2 and HOMO − 1 with α-spin and HOMO − 6, HOMO − 2, HOMO − 1 and HOMO with β spin. Similar to **1**, they are mixed with π_{Br} and π_{Ph} orbitals. However, the contribution of π_{Br} and π_{Ph} orbitals is significantly larger in comparison with the corresponding orbitals of **1**. The percent participation of the rhenium d orbitals and π^*_{NO} orbitals in the bonding π_{Re-NO} orbitals are very similar. LUMO + 6, LUMO + 7, LOMO + 8 and LUMO + 9 with α-spin and LUMO + 7, LUMO + 9, LUMO + 11 and LUMO + 11 with β-spin present a π-antibonding interaction between d_{yz} and d_{xz} metal orbitals and π^*_{NO} orbitals. For complex **2**, the number of unoccupied MOs with significant contribution of π^*_{Re-NO} orbitals is larger in comparison with compound **1**. It is a consequence of the *trans* position of the nitrosyl group to $OPPh_3$ ligand. All the π^*_{Re-NO} orbitals are mixed with π^*_{Ph} orbitals. Moreover, the percent participation of the rhenium d orbitals and π^*_{NO} orbitals in the antibonding π^*_{Re-NO} orbitals are very similar. Nevertheless, the character of the nitrosyl ligand in **2** may be described as NO^+.

The LUMO, LUMO + 2 and LUMO + 3 with α-spin and LUMO + 1, LUMO + 2 and LUMO + 3 with β-spin present the π interaction of phosphorous orbitals with π* orbitals of the phenyl groups. The HOMO with α-spin and LUMO with β-spin consist of the rhenium d_{xy} orbital and π orbitals of bromine ligands in an anti-bonding phase.

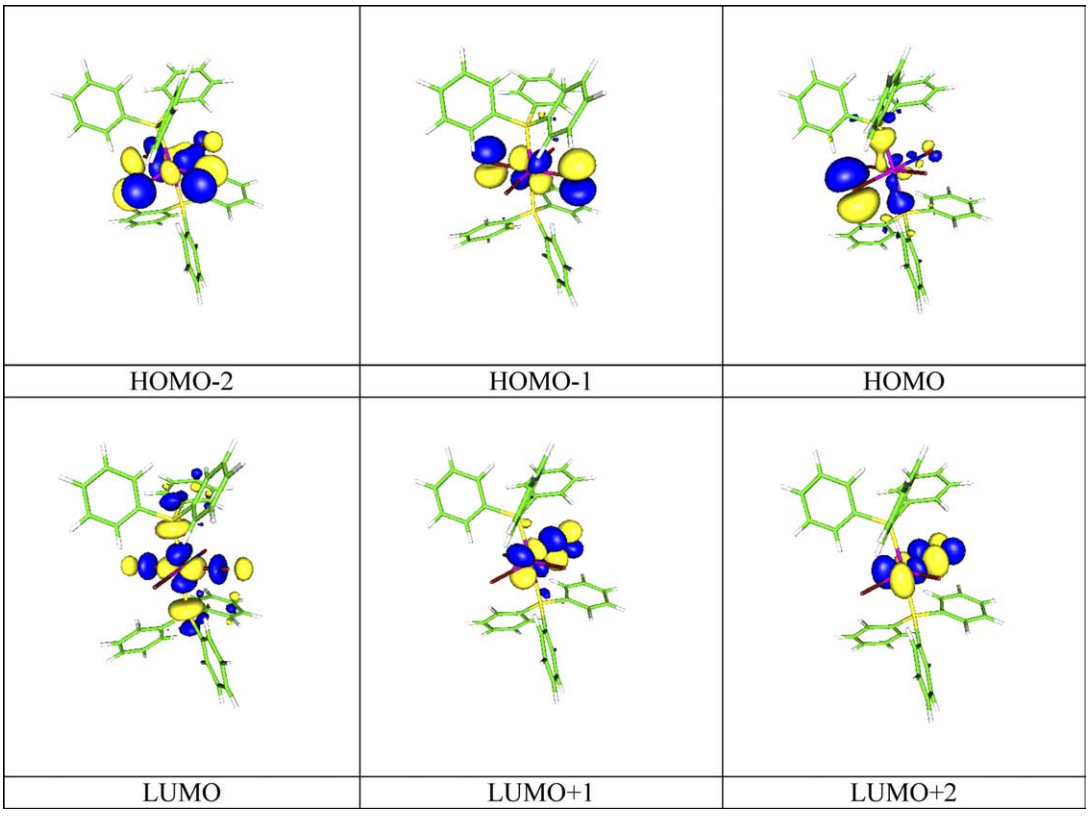

Fig. 3. Selected HOMO and LUMO orbitals with α spin for **1**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

4.4. Electronic spectra

The investigated molecules are of large size, the numbers of basis functions are equal to 674 and 702 for **1** and **2**, respectively. For both complexes, 80 electron transitions were calculated by the TDDFT method. However, the calculated transitions do not comprise all the experimental absorption bands, and some of the experimental bands (of the highest energy) are not assigned to the calculated transitions.

It is known that commonly used functionals, including B3LYP have incorrect asymptotic properties. However, the transitions of energies smaller than the energy of the HOMO orbital are well reproduced by this method [39–41]. In the present calculations the highest calculated transitions are of energy 4.44 and 4.23 eV for **1** and **2**, respectively. This is much smaller than the energy of the HOMO orbitals for **1** and **2** (Table 3).

Table 4 presents the energy and molar absorption coefficients of experimental absorption bands and the spin-allowed doublet–doublet electronic transitions calculated with the TDDFT method for **1** and **2**. The calculations result in many transitions with very small oscillator strengths. Except for the electronic transition of $d \rightarrow \pi^*_{NO}$ character and the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.0050 and 0.0020 are listed for **1** and **2**, respectively. The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions the main components of the molecular orbital are used. The bonding π_{Re-NO} orbitals are described as d orbitals, and the antibonding π^*_{Re-NO} as π^*_{NO}.

*4.4.1. [$ReBr_3(NO)(PPh_3)_2$] (**1**)*

The longest wavelength experimental band at 645 nm is low in intensity and it may be attributed to the transition of $\pi_{Br}/n(P) \rightarrow d$ character with a small oscillator strength calculated at 885.4 nm.

The next experimental band at 571.0 nm is much more intense and it is assigned to the calculated transition at 648.5 nm. The transition is of $\pi_{Br} \rightarrow d$ origin and its oscillator strength is large.

The absorption band at 456.0 nm is ascribed to the calculated transitions in the range 545–475 nm. These transitions have $\pi_{Ph} \rightarrow d$ (LMCT) character and they are mediated by phosphorus orbitals.

The experimental band at 420 nm can be attributed to two calculated transitions at 419.4 and 409.6 nm. The first one is a $d \rightarrow d$ transition, and the second has $\pi_{Br} \rightarrow d$ character.

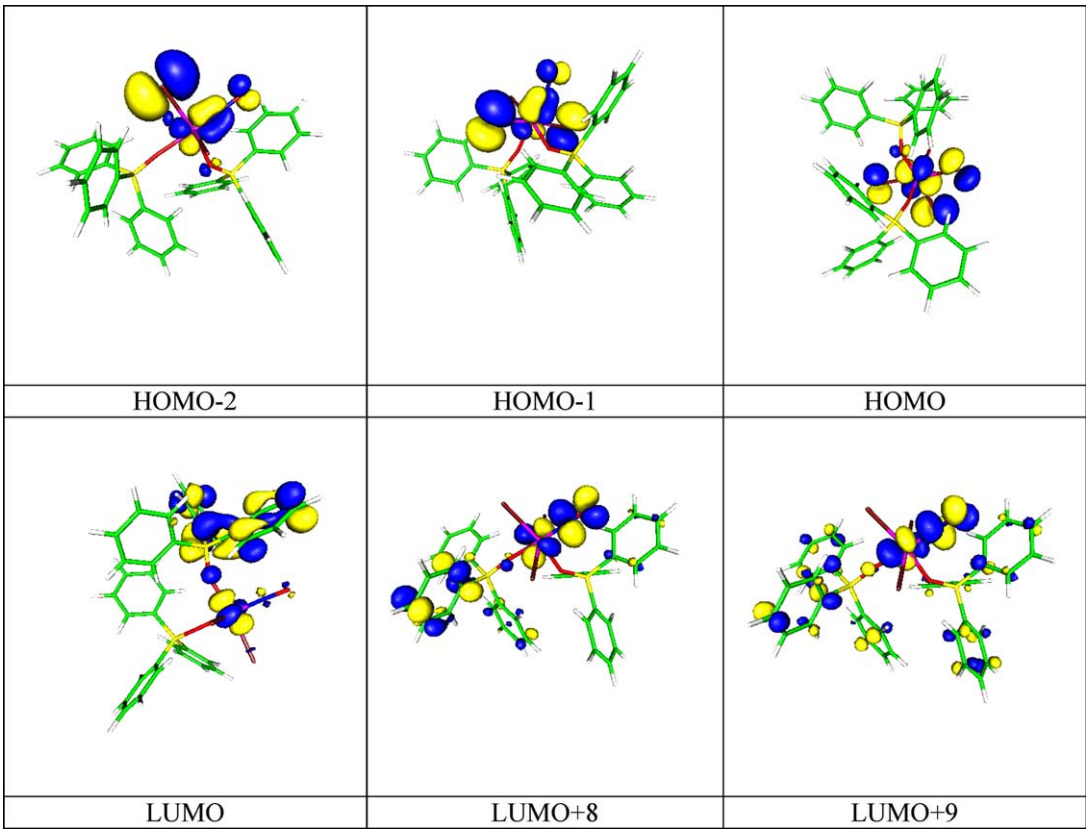

Fig. 4. Selected HOMO and LUMO orbitals with α spin for **2**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The intense absorption band at 307 nm is assigned to two electronic transitions with large oscillator strengths calculated at 329.3 and 297.1 nm, respectively. Both the transitions are of LMCT ($\pi_{Br}/n(P) \rightarrow d$) character.

The shortest wavelength experimental band at 241.8 nm is attributed to the calculated transitions of LLCT character, but this assignment is not completed. The UV–Vis spectrum of **1** was calculated only to 277 nm and additional intraligand and interligand transitions are expected to be found in the calculation at higher energies. The solution spectra of PPh_3 exhibit an intense absorption band at 263.2 nm, which can support this assignment.

The electronic transition from the rhenium d orbitals to the π* orbitals of the nitrosyl group are calculated at 529.4, 366.0 and 363.0 nm. Considering the large contribution of π bromine orbitals in HOMO − 2 with α spin and HOMO − 1 with β spin, the transition at 529.4 nm is of mixed character $d_{xz}/\pi(Br) \rightarrow \pi^*(NO)$. The transitions at 366.0 and 363.0 nm are of $d_{xy} \rightarrow \pi^*(NO)$ origin. Owing to the small oscillator strengths, none of the transitions contribute significantly to the overall shape of the spectrum. In the experimental spectrum they are hidden under the more intense transitions of LMCT ($\pi_{Br} \rightarrow d$ and $\pi_{Ph} \rightarrow d$) character. Such small values of the oscillator strengths seem to be typical of the $d \rightarrow \pi^*_{NO}$ transitions, and they have been supported by the calculations for other metal nitrosyls [10,11].

4.4.2. *[$ReBr_3(NO)(OPPh_3)_2$] (**2**)*

The TDDFT calculations for complex **2** resulted in many transitions with oscillator strengths close to zero. Similarly as for complex **1**, the spectrum of **2** was calculated only to 290 nm, and the experimental absorption bands recorded below 290 nm were not assigned to the calculated transitions. Considering our previous calculations [42], it can be assumed that the transitions in the high energy part of the spectrum correspond mainly to intraligand $\pi \rightarrow \pi^*$ transitions in the phosphine ligands and interligand transitions. However, the calculations in the range 700–290 nm enable the comparison of the $d \rightarrow \pi^*_{NO}$ transition energy for complexes **1** and **2**.

The longest wavelength experimental bands at 689.2 and 647.4 nm are of low intensity and they are attributed to the transitions of $\pi_{Br}/d_{yz} \rightarrow d$ character with small oscillator strengths calculated at 697.7 and 677.8 nm, respectively.

					274.0 (4.52) 6859
					268.0 (4.63) 7624
					261.9 (4.73) 7029
					236.8 (5.54) 11841

The next experimental band at 429.9 nm is much more intense and it is assigned to the calculated transitions of $\pi_{Br}/d_{yz} \rightarrow d$ (at 539.3 nm) and $\pi_{Br} \rightarrow d$ (at 454.4 and 449.1 nm) character with large oscillator strengths.

The absorption band at 368.3 nm is attributed to the transitions of $\pi_{Br}/\pi_O \rightarrow d_{yz}$ character calculated at 413.8, 387.0 and 347.0 nm.

The experimental band at 321.0 nm is assigned to the calculated transitions of $\pi(Br)/d_{yz} \rightarrow \pi^*$(Ph) character (at 328.5 and 293.2 nm) and π(Br → π*(Ph) origin (at 294.4 nm).

The electronic transition from the rhenium d orbitals to the π* orbitals of the nitrosyl ligand are calculated at 327.7, 326.5, 317.4, 295.6 and 293.6 nm. The larger number of $d \rightarrow \pi^*_{NO}$ transitions for complex **2** compared to complex **1** results from the larger number of molecular orbitals with substantial contribution of the bonding and antibonding π_{Re-NO} orbitals. In the case of **2**, the π-bonding π_{Re-NO} orbitals are mixed with π bromine orbitals, and the π-antibonding π_{Re-NO} orbitals with π* orbitals of the phenyl groups. Consequently, the transitions at 327.7 and 326.6 nm are of d_{xz}/π(Br → π*(NO)/π*(Ph) origin, and the other ones have

$d_{xy} \rightarrow \pi^*(NO)/\pi^*(Ph)$ character. All the $d \rightarrow \pi^*(NO)$ transitions of complex **2** are shifted towards higher energy in comparison with **1**. The replacement of the triphenylphosphine (strong σ-donor and π-acceptor) by the triphenylphosphine oxide (weak σ-donor and strong π-donor) [43] causes an increase in the energy of the π^*_{Re-NO} orbitals of **2**, whereas the energies of the molecular orbitals of d(Re) character are similar for both **1** and **2**. Similar to complex **1**, the oscillator strengths of the $d_{xy} \rightarrow \pi^*(NO)$ transitions are very small and all the transitions are hidden under the more intense transitions of LMCT ($\pi_{Br} \rightarrow d$, $n(P) \rightarrow d$ and $\pi_O \rightarrow d$) character.

Abstract

This article describes the synthesis, spectroscopic characterization and single crystal X-ray structure of several Pd(II) dinuclear complexes with the ligand 4,5-dihydro-1,2,4-triazolo[1,5-a]pyrimidine-5-one (5HtpO) in its anionic form ($5tpO^-$). The synthesis and characterization of the related mononuclear compound $[PdCl_2(5HtpO)_2]$ is also included. This compound is transformed into the dinuclear $[Pd_2(5tpO)_4] \cdot 4H_2O$ by raising the pH, the structure of which indicates a head–tail–head–tail disposition of the heterocycles (D_{2d} symmetry) as a difference with the analogous Cu(II) and Pt(II) clusters. Using the auxiliary ligands bipyridine (bpy), phenanthroline (phen) and *trans*-1,2-diaminocyclohexane (*t*-dach, racemic mixture), dinuclear compounds with the general formula $[Pd_2(5tpO)_2(a–a)_2](NO_3)_2 \cdot nH_2O$ are obtained. The crystal structure of those with a–a = phen and a–a = *t*-dach have been solved showing a head–tail disposition of the organic ligands, in contrast with the NMR data for a–a = bpy, which point to a head–head disposition.

1. Introduction

The coordination chemistry of 1,2,4-triazolo[1,5-a] pyrimidine derivatives is a research field that has yielded a considerable number of new compounds with interesting structural features [1], which may be considered as model systems for some naturally occurring metal coordination compounds with isomeric purine derivatives. The binding modes of triazolopyrimidines are rather variable and, among these, the bidentante mode through the nitrogen atoms at positions 3 and 4 (corresponding to positions 9 and 3 of purines in the biochemical numbering scheme) is interesting, since it usually gives rise to the formation of dinuclear compounds including one or more eight-member $M_2N_2C_4$ rings. Such compounds have been described for Cu(I) [2], Cu(II) [3], Ag(I) [4], Pd(II) [5] and Pt(II) [6], and there are also examples of heteronuclear Pt–Ag [7] and Pt–Pd complexes [8].

The distance between both metal atoms in the core is forced to be rather short, which makes it possible for a direct metal–metal interaction to take place. In the case of Cu(II), this interaction is observed as a strong antiferromagnetic coupling [3]. Theoretical studies have been performed in order to obtain information about the nature of this interaction and the topological analysis of the calculated charge density (AIM theory [9]) revealed the existence of a bond critical point between the metal atoms for Ag(I) [10], Cu(II) [3] and Pt(II) [6]. The relative disposition of the bridging heterocycles (head–head, head–tail) is also an interesting subject and it has shown to relay more in the kinetic path that leads to the formation of the compound or in the interactions with neighbouring species than in intrinsic electronic reasons [11].

doi:10.1016/j.poly.2004.07.024

Following this research line, we present in this paper the synthesis, characterization and crystal structures of a number of dinuclear Pd(II) complexes with the anionic form of 4,5-dihydro-1,2,4-triazolo[1,5-a]pyrimidine-5-one (5HtpO), including the mononuclear precursor of one of them. The goal of the study is to extend the results previously obtained for this kind of compound, trying to relate the structural features of the dinuclear clusters with the nature of the metal atoms (Cu, Pd or Pt), the substituents in the bridging ligand and the presence of auxiliary ligands.

2. Experimental

2.1. Synthesis of the complexes

The compound 5HtpO was prepared according to the published method from 3-amino-1,2,4-triazole and ethyl 3,3-diethoxypropionate in NaOEt/EtOH [12]. Other reagents were obtained from commercial sources.

$[PdCl_2(5HtpO)_2]$ (**1**) was obtained by mixing two solutions, 10 mL each, one containing 2 mmol of $K_2[PdCl_4]$ and the other 4 mmol of 5HtpO, both in 1 M HCl. A yellow precipitate immediately appeared, which was filtered, washed with water and ethanol, and dried with ether. Elemental *Anal*. Calc. for $C_{10}Cl_2H_8N_8O_2Pd$: C, 26.7; H, 1.8; N, 24.9. Found: C, 26.9; H, 1.8; N, 24.1%.

$[Pd_2(5tpO)_4] \cdot 4H_2O$ (**2**): 2 mmol of **1** were suspended in 40 ml of water and the pH was raised up to 6.4 by dropwise addition of 0.1 M NaOH. The solid was completely dissolved after this and an orange solution was obtained. After several minutes, an orange precipitate appeared which was filtered and washed with water and ethanol, and then recrystallized in an acetonitrile:ethanol:water 2:2:1 mixture, yielding X-ray suitable orange crystals. Elemental *Anal*. Calc. for $C_{20}H_{20}N_{16}O_8Pd_2$: C, 29.1; H, 2.4; N, 27.1. Found: C, 28.7; H, 2.5; N, 26.7%.

$[Pd_2(5tpO)_2(bpy)_2](NO_3)_2 \cdot 2H_2O$ (**3**), $[Pd_2(5tpO)_2(phen)_2](NO_3)_2 \cdot 4H_2O$ (**4**) and $[Pd_2(5tpO)_2(t\text{-dach})_2](NO_3)_2 \cdot 4H_2O$ (**5**) (where bpy = bipyridine, phen = phenanthroline and *t*-dach = *trans*-diaminocyclohexane): Firstly, the compounds $[PdCl_2(a–a)]$ (a–a = bpy, phen or *t*-dach) were obtained using the procedure previously described for $[PdCl_2(en)]$ [13], changing the ethylenediamine by the appropriate diamine. 2 mmol of $[PdCl_2(a–a)]$ and 4 mmol of $AgNO_3$ were dissolved in 40 ml of water and kept in the dark at 45 °C for an hour. The resulting AgCl was filtered off and the solution was treated with 4 mmol of 5HtpO and kept at 60 °C for 4 h. After this, it was left to stand at room temperature, crystalline solids appearing after several days. The crystals of compound **5** were found to be suitable for X-ray work. **3** and **4** were recrystallized in an acetonitrile:ethanol:water 2:2:1 mixture and the crystals obtained for **4** were also suitable for X-ray work. Elemental analysis data:

Compound **3**: *Anal*. Calc. for $C_{30}H_{26}N_{14}O_{10}Pd_2$: C, 37.7; H, 2.7; N, 20.5. Found: C, 37.8; H, 2.5; N, 20.8%.

Compound **4**: *Anal*. Calc. for $C_{34}H_{30}N_{14}O_{12}Pd_2$: C, 39.3; H, 2.9; N, 18.9. Found: C, 39.0; H, 2.9; N, 19.0%.

Compound **5**: *Anal*. Calc. for $C_{22}H_{42}N_{14}O_{12}Pd_2$: C, 29.1; H, 4.7; N, 21.6. Found: C, 29.0; H, 4.4; N, 21.3%.

2.2. Instrumentation

Microanalysis of C, H and N were performed in a Fisons Instruments EA-1008 analyser. Thermal behaviour was studied under an air flow in Shimadzu TGA-50 and Shimadzu DSC-50 equipment. ^1H and ^{13}C NMR spectra were recorded for dmso-d_6 solutions of the compounds on a Bruker AM-300 spectrometer (all this equipment is sited at the Centre of Scientific Instrumentation of the University of Granada). IR spectra were obtained using a FT MIDAC Prospect 1 spectrophotometer with samples dispersed in KBr pellets.

2.3. Crystallography

Data were collected at room temperature for compounds **2**, **4** and **5** in a Siemens P4 diffractometer with Mo Kα radiation ($\lambda = 0.7107$ Å). The crystals were covered with a drop of paraffin oil to prevent their decomposition. Data were corrected for absorption only for **2** (ψ-scans, transmission range, 0.4251–0.6778). Structures were solved by the heavy atom method and refined in F^2 using SHELXL-97 [14]. The nitrate ion in **4** was disordered into two positions with half occupancy and refined with restrained geometry. Four carbon atoms of each *t*-dach moiety (those in α and γ positions respect to the to N atoms) in **5** are also disordered into two positions, which correspond to the two enantiomers of the auxiliary ligand. Several water molecules in the three structures have been introduced with partial occupancy. Atoms with partial occupancy have been refined isotropically and remaining non-H atoms anisotropically. Hydrogen atoms of the heterocycles were placed in ideal positions and those of water molecules were not introduced. Isotropic thermal parameters of all H atoms were fixed to 1.2 times the equivalent isotropic thermal parameter of their parent atoms. Crystal data for the three structures have been listed in Table 1.

3. Results and discussion

3.1. X-ray structural studies

The main structural blocks of the crystal structures of compounds **2**, **4** and **5** are dinuclear clusters in which

both palladium atoms are linked by 5tpO$^-$ moieties, 5tpO$^-$ representing the anionic form of 4,5-dihydro-1,2,4-triazolo[1,5-a]pyrimidine-5-one, which are linked to the metal atoms through the nitrogen atoms at positions 3 and 4. Several examples of this coordination mode have been described for 1,2,4-triazolo[1,5-a]pyrimidine derivatives which lead to dinuclear (or polynuclear, if other bridges are present) compounds of Cu(I), Ag(I), Cu(II), Pd(II) and Pt(II) (see Section 1). The crystal structures are completed by interstitial water molecules and, in the structures of **4** and **5**, by nitrate counteranions balancing the charge of the cationic clusters. Bond distances and angles around the palladium atoms are listed in Table 2.

Four 5tpO$^-$ bridges are present in the molecular structure of compound **2**, building in this way neutral $[Pd_2(5tpO)_4]$ species. Each Pd atom in these species is surrounded in a square-planar fashion by two N3 and two N4 atoms in a *trans* disposition, thus defining the head–tail–head–tail isomer with molecular D_{2d} symmetry. Two crystallographically different but chemically identical $[Pd_2(5tpO)_4]$ molecules are present (Fig. 1), in both cases a crystallographic binary axis runs across the molecule, relating the two equivalent halves of it. In one case (Pd1) the crystal binary axis in the b direction is perpendicular to the Pd–Pd line (C_2' axis of the D_{2d} point group) where in the other (Pd2–Pd3) the crystal binary axis in the a direction crosses through the metal atoms (main axis of D_{2d}).

This kind of cluster with triazolopyrimidine ligands has been previously described for Cu(II) [3] and for Pt(II) [6], but in these two cases the head–head–tail–tail isomer (C_{2h}) was found. For steric reasons, it is expected that the D_{2d} isomer is thermodynamically more stable than the C_{2h} isomer, but the synthetic procedure and the slower Pt(II) kinetics and the presence of a water molecule in the apical position of the Cu(II) compound would explain the presence of the C_{2h} isomer in these

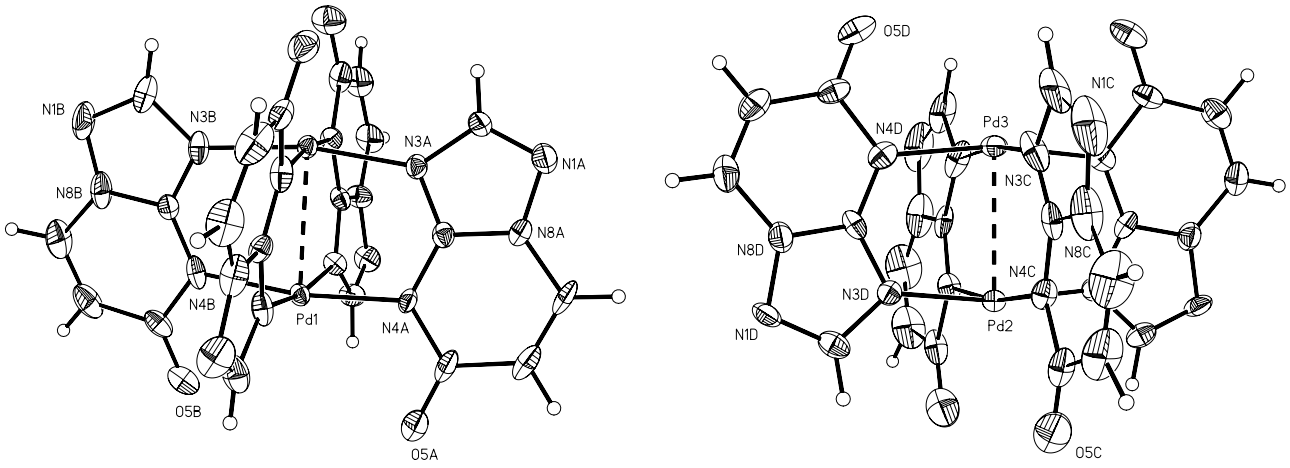

Fig. 1. Crystallographically independent clusters of compound **2** as deduced from X-ray diffraction data. There is a crystallographic binary axis perpendicular to the Pd–Pd line in the cluster on the left side and another one through the metal atoms in the cluster on the right. Non-hydrogen atoms are represented by ellipsoids at the 30% probability level.

cases. None of these reasons are applicable to **2**, so the D_{2d} isomer is obtained.

The N_4 planes are perfectly parallel for the Pd2–Pd3 dimer (imposed by the crystallographic symmetry) and almost so for the Pd1 dimer (interplanar angle, 0.4(3)°). The metal atoms are deviated from these planes by 0.172(2) (Pd1), 0.179(1) (Pd2) and 0.178(1) Å (Pd3), in all cases away from the other Pd atom, as it happens in the above mentioned Cu and Pt compounds. The Pt–Pt distance in the later is almost identical to the Pd–Pd distances in **2**.

We have found only three structures in the literature comprising a $Pd_2N_8C_4$ core, two of them with flexible ligands [15,16] with a Pd–Pd distance shorter than in **2**, these compounds being oxidizable to Pd(II)–Pd(III) species. The only example we have found with the N atoms belonging to a rigid bicyclic heterocycle is a Pd(III) compound [17] with a very short (2.391(2) Å) intermetallic distance.

On the other hand, there are only two bridging 5tpO$^-$ ligands in the dinuclear entities in the crystal structures of **4** and **5**. Each metal atom in these is linked by the N3 atom of one ligand and the N4 atom of the other thus defining the head–tail isomer. The other two coordination sites are occupied by the nitrogen atoms of the bidentate phenanthroline (**4**) or *trans*-diaminocyclohexane (**5**). Figs. 2 and 3 display the structures of these dinuclear cations. Both halves of the cluster in **4** are related by a crystallographic binary axis. Four carbon atoms of each auxiliary ligand in **5** are disordered between two positions, which is clearly due to the presence of both enantiomers (RR and SS) of *t*-dach, randomly distributed across the crystal.

As it happens with structurally analogous compounds [5], the interaction between the auxiliary ligands influences the geometry of the cluster, as indicated by the intermetallic distance (Table 2) and the angle between the N_4 planes (19.2(2)° and 36.5(2)° for **4** and **5** respectively). Stacking takes place between the phen planes, with an angle between them of 1.6(2)° and average interplanar distance of 3.47 Å. The optimization of such an interaction produces the relative rotation of both PdN_4 planes (torsional angles N–Pd–Pd–N, 10.4(3)° and 13.6(3)°) as was observed for the analogous compound with the 7-oxo isomer of the ligand [11].

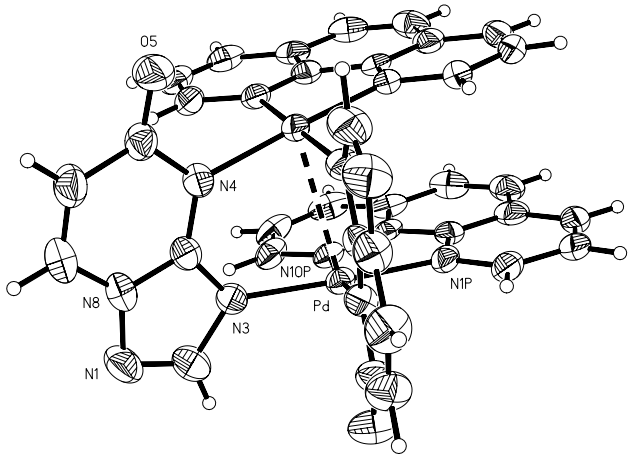

Fig. 2. Structure of the dinuclear cation in **4** according to X-ray analysis. A crystallographic binary axis runs perpendicular to the Pd–Pd line. Non-hydrogen atoms are represented by ellipsoids at the 30% probability level.

3.2. Infrared and thermal studies

The thermal behaviour of these compounds in air has been studied from their TG and DSC plots. Dehydration appears as a well defined weight loss accompanied by the corresponding endothermic effect only for compound **2**, for which a dehydration enthalpy of 49 kJ per mole of water can be calculated. For the remaining

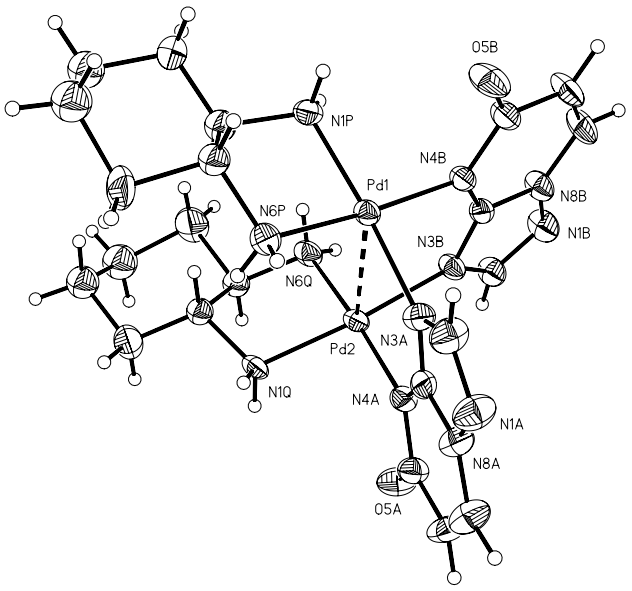

Fig. 3. Structure of the dinuclear cation in **5** according to X-ray analysis. Non-hydrogen atoms are represented by ellipsoids at the 30% probability level.

compounds these effects are poorly defined, showing a loose attachment of water to the structure, which also explain a certain lack of reproducibility of water content in the analysis and partial occupancy of water in the crystal structures. Dehalogenation of **1** is clearly seen from the corresponding weight loss and endothermic effects (peak at 310 °C) which overlap with the beginning of the pyrolysis. The final residue of the pyrolysis is PdO in all cases.

The infrared spectra are not very informative. Those including the anionic form of the ligand show the expected bathochromic effect for the ν(C=O) band that appears between 1645 and 1650 cm^{-1}. The spectrum of **1** displays an acute band at 342 cm^{-1}, assignable to ν(Pd–Cl): the presence of a single band may indicate a *trans* geometry. Most compounds with the $PdCl_2N_2$ chromophore included in the Cambridge Structural Database [18] (excluding of course those with both N atoms belonging to the same ligand) display *trans* geometry (159 *trans* vs. only 3 *cis*), but one of the few with a *cis* geometry include a triazolopyrimidine derivative as a ligand [19].

3.3. NMR studies

^1H and ^{13}C NMR spectra have been recorded for dmso-d_6 solutions of compounds **1**, **2**, **3** and **5**. **4** was found to be insoluble in this solvent. DEPT spectra were also recorded to help in ^{13}C assignments. Both spectra of **1** display two sets of signals, the most intense ones being clearly attributable to free 5HtpO [12], which indicates that **1** extensively decomposes when dissolved in dmso, this decomposition quickly reaches equilibrium since the spectra do not appreciably change with time. The other species (with a concentration of about one third of free 5HtpO), possibly a complex of the type $[PdCl_2(5HtpO)L]$ (L = H_2O or dmso), exhibits the resonances listed in Table 3. Downfield shifts with respect to the free ligand are observed for H2, C5 and C6, and upfield shifts for the remaining signals.

Table 3
^1H and ^{13}C assignments (δ in ppm) for 5HtpO and 5tpO$^-$ moieties

	5HtpO	**1**[a]	**2**	**3**	**5**
H2	8.11	8.32	8.03	8.50	8.14–8.21
H6	6.16	6.11	5.97	6.18	6.04–6.11

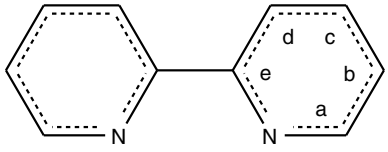
C5	161.0	166.2	165.7	165.5	166.4–166.6
C6	108.0	108.7	108.6	109.6	108.5–109.0
C7	136.9	135.3	135.0	135.9	134.9–135.2

[a] Data refer to the minor species: see text.
[b] Not observed.

In both ^1H and ^{13}C spectra of **2**, all organic moieties appear equivalent, indicating that a single species is present, so we may infer that the solid state molecular structure is retained in solution. Nevertheless, the possibility of complete and quick isomerisation to the C_{2h} (head–head–tail–tail) isomer cannot be ruled out, since for compound **3** (see below) the head–tail isomer seems to be more stable in solution and the reasons for stabilizing the HT isomer of **3** could also apply the stabilization of the C_{2h} isomer of **2**.

For **3**, there is clearly a major species in solution, with a single set of resonances for the 5tpO$^-$ moiety (listed in Table 3), which indicates that one of the two possible isomers (head–head, HH or head-tail, HT) is much more stable in solution than the other. Two sets of signals appear for bipyridine, either both bpy are equivalent but the two halves of each molecule are not (HT) or there are two different bpy moieties with equivalent halves (HH). In a previous work with the isomeric 7-oxo derivative as a bridging ligand [11], the position of the signals assigned to Hb protons (see Scheme 1 for the labelling of bpy used in this section) is regarded as diagnostic to distinguish between HH and HT isomers. In compound **3**, the Hb triplets are centred at 7.31 and 7.35 ppm,



Scheme 1.

overlapping to build an ill-shaped quintet, so it is deduced that they belong to the HH isomer: two well separated triplets would be expected for the HT isomer, as happens with the analogous compound with the 5-methyl-7-oxo derivative [5], for which the HT isomer is much more stable due to the steric repulsion between the methyl groups for the HH isomer. Other ^{1}H resonances of the auxiliary ligand are 7.83 and 8.03 (Ha), 8.08 and 8.17 (Hc) and 8.24 and 8.31 ppm (Hd) with J(Ha-Hb) = 5.6, J(Hb-Hc) = 7.8 and J(Hc-Hd) = 8.1 Hz. ^{13}C resonances of bpy (assigned by comparison with free bpy [20]) appear at 151.3 and 151.5 (Ca), 128.1 and 128.3 (Cb), 141.9 and 142.4 (Cc), 123.8 and 123.9 (Cd) and 154.7 and 154.8 ppm (Ce). Apart from this, we can also see in the ^{1}H spectrum a number of very weak signals attributable to a very small proportion of the HT isomer: in particular, Hb triplets are visible at 7.24 and 7.44 ppm, well separated as expected. Other visible signals for this species are 8.51 (H2), 6.24 (H6), 8.62 (H7) and 7.87 ppm (one of the Ha), the rest being obscured by the intense HH isomer signals.

It is noteworthy that we find that the HH isomer of **3** is much more stable in solution than the HT isomer, a difference from the analogous compound with the 7-oxo isomer as the bridging ligand [11], for which both isomers display analogous stability. This could be explained by the possible presence of a water molecule simultaneously hydrogen-bonded to both carbonyl oxygen atoms keeping in this way the ''heads'' together. There is also a noticeable difference between the molecular structure of **3** in solution and the solid state structure of **4**, which is HT (see above), possibly favoured by crystal packing considerations. Unfortunately, comparisons cannot be done for these compounds since no good single crystals of **3** could be grown and **4** is insoluble in dmso. The coupling pattern of the resonances of the H atoms of phen belonging to the external (benzene) ring would let us unequivocally distinguish between HH and HT isomers [11].

Finally, the spectra of **5** are very complex, due to the presence of both enantiomers (RR and SS) of *trans*-diaminocyclohexane. The existence of four different 5tpO^{-} species can be deduced since there are four signals in the region of the H2 singlet and four signals can also be seen for each carbon of this ligand (the δ ranges are listed in Table 3). At least seven signals (possibly eight), easily assignable (with the aid of the DEPT spectrum) to the CH next to the amino groups of *t*-dach, are visible. If we think that only HH species are present, the presence of four non-equivalent triazolopyrimidine moieties can be explained by the existence of RRRR (and enantiomeric SSSS) and RRSS diasteromers since the symmetry plane that would make the two ''heads'' equivalent is eliminated by the chiral auxiliary ligands. Also, if only HT species are present, four 5tpO^{-} sets are expected, two for asymmetric RRSS and another two for RRRR (+SSSS), for which the two bridging ligands are related by a binary axis but with two non-equivalent possibilities for the disposition of the ligands. Therefore, the spectra are compatible with a major presence of either only HH or only HT species.

4. Supplementary data

The supplementary crystallographic data for this paper have been deposited in the CCDC (Deposition numbers CCDC 234810, CCDC 234811 and CCDC 234812 respectively for **2**, **4** and **5**). These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

The deep-blue compound $Na_{48}[H_xMo_{368}O_{1032}(H_2O)_{240}(SO_4)_{48}] \cdot$ ca. $1000H_2O \equiv Na_{48}$ **1a** $\cdot$ ca. $1000H_2O$ (**1**) exhibiting an unusual nanosized hedgehog-type cluster anion, could now be obtained in good yield – allowing now several materials science studies – in the presence of a high concentration of an electrolyte destroying the hydration shell, in only two days. **1** was characterized by elemental analysis (including redox titrations to determine the (formal) number of Mo^V centers), thermogravimetry and spectroscopic methods (IR, resonance Raman, Vis/NIR). Information about unusual aspects of the formation is reported together with additional spectroscopic details as well as a new crystal structure determination of the very complex system while confirming the earlier one.

1. Introduction

Aesthetically beautiful giant polyoxomolybdates of the type $\{Mo_{11}\}_n$ which are either sphere- ($n = 12$) or wheel-shaped ($n = 14$) can now be obtained by undergraduates in facile syntheses [1,2]. Following our related work other research groups have also reported comparable syntheses of the cluster species [3] and used them e.g., for materials science studies (see below). The mentioned cluster anions, in spite of their completely different overall structure, have formally similar building blocks resulting in the remarkable mentioned equivalent stoichiometry [2e] which is also of importance for the cluster reported here. The related molybdate building units abundant in a unique 'dynamic library' can form – via a type of 'split and/or link process' – a versatility of molecular architectures upon slight variation of the boundary conditions under reduced conditions. This is especially the case for Mo-blue-type solutions [2] from which the above mentioned wheel-type species can be obtained. From this 'library' an even larger and highly reduced cluster anion containing 368 Mo atoms can – under very special conditions – be obtained [4] which shows much more structural complexity than the wheel-type cluster species. As the related earlier published synthetic method requires a rather long time – crystallization occurs only after 2 weeks according to the high solubility – we report here (1) a facile synthesis allowing now several types of studies together with some detailed spectroscopic information for an easy identification of the cluster, (2) a second (crystal) structure

determination for the extremely complex inorganic cluster confirming the earlier published one and (3) further details about the related cluster-formation problem which seems to be interesting.

2. Experimental

The chemicals were purchased from commercial sources and all manipulations were performed using materials as received.

2.1. $Na_{48}[H_xMo_{368}O_{1032}(H_2O)_{240}(SO_4)_{48}] \cdot ca.\ 1000\ H_2O,\ x \approx 16$

To a solution of 6 g $Na_2MoO_4 \cdot 2H_2O$ (24.8 mmol) in 25 ml of water acidified with 100 ml 0.5 M H_2SO_4, 0.18 g $N_2H_6SO_4$ (1.38 mmol) as reducing agent is added under stirring. After stirring for 30 min 1.50 g NaCl (25.6 mmol) is added. The solution is then stored in a closed flask for 2 days and the precipitated deep-blue crystals of **1** are filtered off. Yield: 1.2 g (23% based on Mo). Characteristic IR bands (KBr pellet, cm^{-1}): ν = 1620m ($\delta(H_2O)$), 1199w, 1101w, 1060 (all $\nu_{as}(SO_4)$), 981/958s (ν(Mo=O)), 765s, ≈700sh, 628w, 557m, 462w; characteristic resonance Raman bands (solid/KBr dilution, λ_e = 1064 nm, cm^{-1}): ν = 810m, 681w, 456 m; Vis spectrum (in H_2O, nm): λ = 785(very broad) ($\epsilon = 2.4 \times 10^5$ $mol^{-1}\ dm^3\ cm^{-1}$). *Elemental Anal.* Calc.: Na, 1.39; S, 1.92. Found: Na, 1.5; S, 2.2% (cerimetric titration ≈110 Mo^V centers).

Vibrational spectra were recorded on a Bruker FTIR IFS 66 with a Raman FRA 106 unit spectrophotometer (λ_e = 1064 nm). The Vis spectrum was measured using a Shimadzu UV-3101PC instrument.

3. Results and discussion

By reducing an aqueous molybdate solution acidified with sulfuric acid – the important reagent in the present case, corresponding to [4] – the deep-blue giant mixed-valence cluster anion **1a** (Fig. 1) with the size of hemoglobin is formed and can be crystallized as Na salt. In order to improve the yield of the synthesis and decrease the crystallization time we changed the reaction conditions leading to a decrease of the solubility of **1** due to the presence of a rather high concentration of an electrolyte, which destroys the hydration shell of the giant cluster anion (see Section 2). The presence of the hydration shell caused by the abundance of a large number of H_2O ligands – which are responsible for the high solubility of molybdenum blue type species – prevented the isolation of crystalline Mo-blue type materials for more than 200 years since the times of Scheele and Berzelius [2], see also [5–7].

Compound **1,** which was now obtained with a facile synthesis by decreasing the solubility drastically, was characterized by elemental analysis (including redox titrations to determine the (formal) number of Mo^V centers), thermogravimetry (to determine the actual crystal water content which is important for the analyses), and spectroscopic methods (IR, resonance Raman, Vis/NIR). The data obtained for the new synthesized compound agree with those of the earlier reported substance including the results of the thermogravimetry [4].

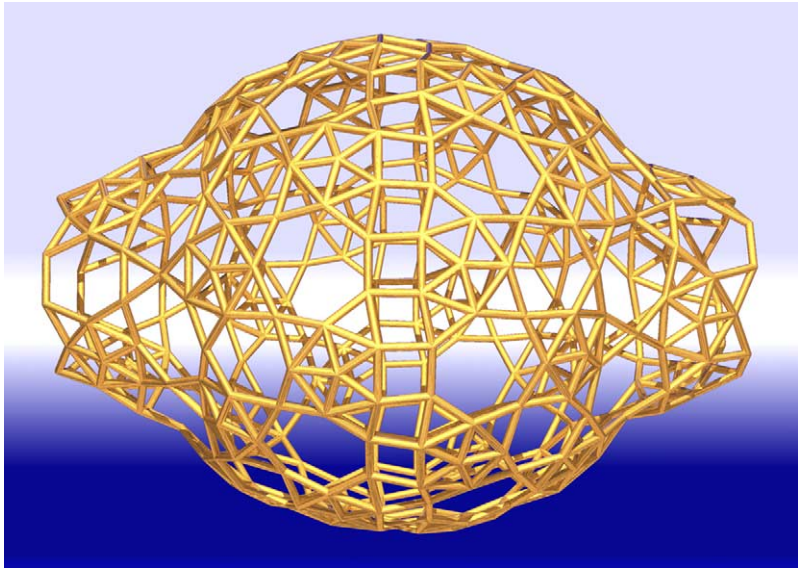

Fig. 1. $\{Mo_{368}\}$ metal atom framework of **1a** in wire-frame representation showing nicely the change from positive via negative to positive curvature at the surface.

$Na_{48}[H_xMo_{368}O_{1032}(H_2O)_{240}(SO_4)_{48}] \cdot$ ca. $1000H_2O \equiv Na_{48}$ **1a** $\cdot$ ca. $1000H_2O$ (**1**). **1a** $\equiv [H_x\{(Mo)Mo_5\}'_8\{(Mo)Mo_5\}''_{32}\{Mo_2\}'_{16}\{Mo_2\}''_8\{Mo_2\}'''_8\{Mo_1\}_{64}]^{48-}$ ($x \approx 16$ corresponding to ≈112 Mo^V-type centers).

Definitions: $\{(Mo)Mo_5\}' \equiv \{Mo_6O_{21}(H_2O)_6\}$; $\{(Mo)Mo_5\}'' \equiv \{Mo_6O_{21}(H_2O)_3(SO_4)\}$; $\{Mo_2\}' \equiv \{Mo_2O_3(H_2O)_2\}$; $\{Mo_2\}'' \equiv \{Mo_2O(t)_2O(br)_3(SO_4)\}$; $\{Mo_2\}''' \equiv \{Mo_2O(t)_4O(br)(SO_4)\}$; $\{Mo_1\} \equiv \{MoO(H_2O)\}$.

Compound **1** crystallizes in the space group *I4mm* and contains in the unit cell two giant hedgehog-like cluster anions **1a** with a central spheroid-shaped fragment $\{Mo_{288}O_{784}(H_2O)_{192}(SO_4)_{32}\}$ = B and two capping units $\{Mo_{40}O_{124}(H_2O)_{24}(SO_4)_8\}$ = C (*note:* the second structure analysis which confirmed the earlier published one was performed with crystals obtained with the earlier reported synthesis [4]). Remarkably, there are three rather large areas, i.e. 2 C + B, with different local symmetries: D_{8d} in the central B part and C_{4v} in the two capping areas C. There is a small error limit for the correlated number of protonations and Mo^V centers.

The comparably large number of different building units of **1a** can be identified from the above given formulae. The two $\{(Mo)Mo_5\}$-type units differ with respect to the abundance of the SO_4^{2-} ligands (32 occur with SO_4^{2-} ligands, and 8 without, located in the C_{4v} areas; the two numbers were erroneously referred to in [4]). The dinuclear units $\{Mo_2\}$ do not only differ with respect to the abundance of bidentate SO_4^{2-} ligands (see formulae): those at the ends of both C caps, i.e., the borderlines, have contrary to the other type two terminal O atoms at both Mo centers, a situation characteristic for stopping growth. The $\{Mo_1\}$ units are of the 'classical' type $\{OMo^V(H_2O)\}^{3+}$ and contribute correspondingly to the highly reduced state of **1a**; the remaining predominantly Mo^V-type centers are distributed over several parts of the large cluster areas and cause a widespread delocalization of Mo (4d) electrons while the capping units C are less reduced (corresponding the size of the cluster and the resolution obtained there are of course limits with respect to the interpretation of the bond valence sum values). This again causes broad peaks in the resonance Raman and electron absorption spectra of **1**. The structure of the cluster anion can be formally considered as a hybrid between the $\{Mo_{176}\}/\{Mo_{154}\}$-type giant molecular wheels and the $\{Mo_{102}\}/\{Mo_{132}\}$-type spherical clusters mentioned above (for details see [4]).

The high reduction state (ca. 112 Mo^V/256 Mo^{VI}), which is much higher than that in the above mentioned Mo-blue type wheel systems (i.e. 28 Mo^V/126 Mo^{VI} for $n = 14$ [2a]), refers to the fact that strong reducing conditions favour cluster growth (see [4]). The largest cluster existing in acidified molybdate solution is – in absence of a reducing agent – the 'rather small' $\{Mo_{36}\}$ anion [2,8,9] which 'starts growing' upon reduction [2a].

Due to the rather short crystallization time of the new synthesis method no suitable crystals for single crystal X-ray diffraction analysis were obtained. Important in this context is that in case of less symmetrical giant species like **1a** nucleus formation is less favoured than in case of more symmetrical and smaller ones (see [10]). A crystal obtained according to the earlier reported synthetic method was again used for a new crystal structure determination. As even the crystals of the latter method are normally obtained in small size, data were collected with an instrument equipped with a rotating anode and an X-ray mirror (see Acknowledgements). The structure analysis confirmed the earlier reported one. [1] Compound **1**, obtained with the new method, could be identified clearly by comparison of the spectroscopic (Figs. 2 and 3) and analytical data with those of the earlier reported compound obtained with the synthesis leading to larger crystals [4]. Especially the IR spectrum of **1** (Fig. 2) is very characteristic and, e.g., different from the compounds containing the other Mo-blue-type species, i.e., the wheel-shaped clusters [1b], and can therefore be easily used for the simple identification. The presence of the bidentate SO_4^{2-} ligands is proven by the IR bands at 1199, 1101, 1060 cm^{-1} originating from the $\nu_3(F_2)$ vibration of discrete SO_4^{2-}.

Some important additional experiments have to be mentioned. If K^+ ions are present in the reaction mixture not the hedgehog-type species is formed but a derivative of the $\{Mo_{176}\}$ wheel-type cluster in which a novel $\{KSO_4\}_{16}$ ring has been integrated [11]. The related unusual species was reported recently in a paper [11] entitled 'Synergetic activation of 'silent receptor' sites leading to a new type of inclusion complex: integration of a 64-membered ring comprising K^+ and SO_4^{2-} ions into a molybdenum oxide-based nanoobject'. The unusual inclusion species $[Mo^{VI}_{114}Mo^{V}_{32}O_{429}(H_2O)_{50}(KSO_4)_{16}]^{30-}$ shows the remarkable 64-membered $\{K(SO_4)\}_{16}$ ring integrated into a wheel-shaped nanocluster host. It is formed by a novel unprecedented reaction type, based on synergetically induced functional complementarity [11]. Furthermore it represents a text-book example of a very complex non-biological material. The K^+ ions have in presence of SO_4^{2-} a direct influence on the activation of the ring-type cluster's silent receptor sites and prevent formation of the $\{Mo_{368}\}$-type cluster having much smaller formation tendency than the more

[1] The structure of **1** was redetermined using crystals prepared according to the earlier reported method [4]. The lattice constants were determined as $a = 43.257(2)$, $c = 68.999(5)$ Å, $V = 129111(13)$ Å^3. The structure could be nicely refined in space group *I4mm* as done in [4], though the situation showed that the partial 'disorder' of a part of the anion could be removed by refining the structure in space group *I*4 assuming that the crystal is merohedrally twinned. The special twin problem will be considered separately at a later date.

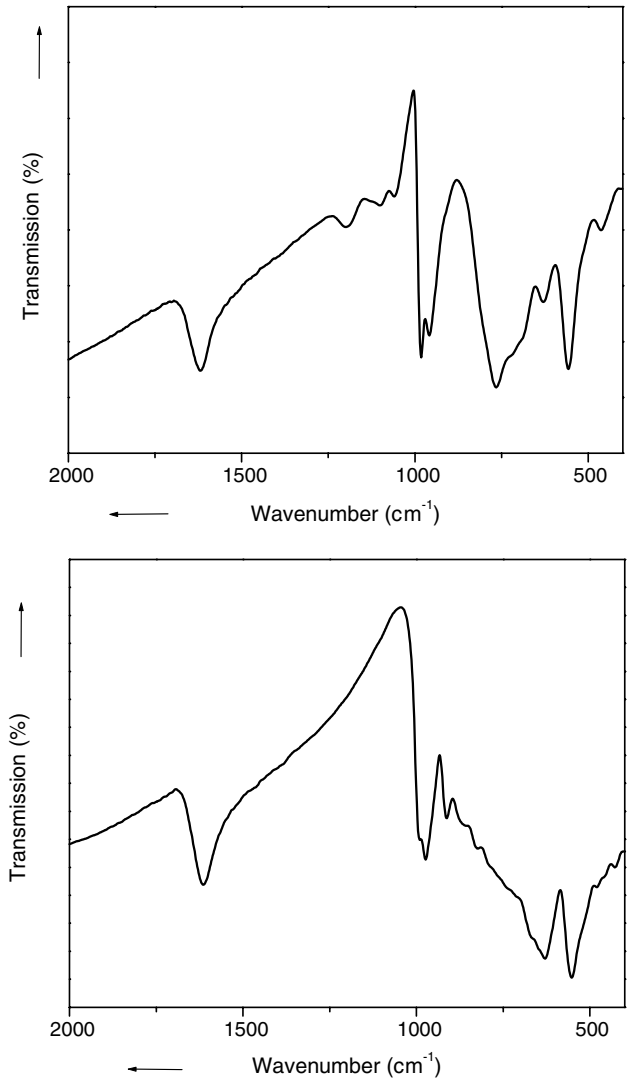

Fig. 2. IR-spectra of **1** (KBr pellets; top) and of the typical wheel-shaped Mo-blue cluster $\{Mo_{154}\}$ (bottom, see [1b], too). (See Section 2 for details.)

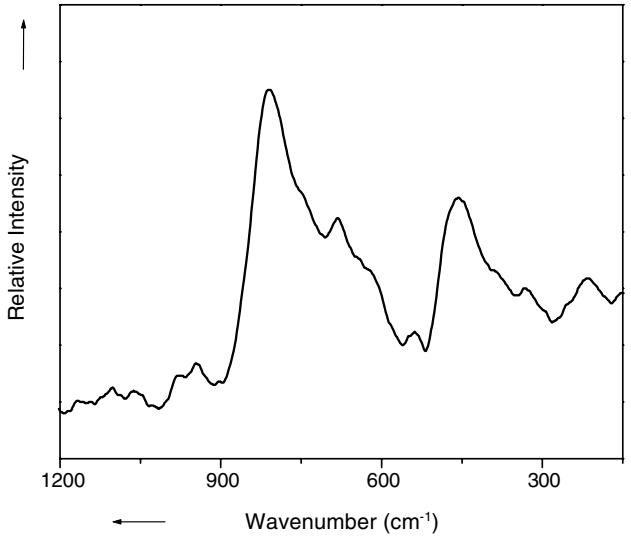

Fig. 3. Solid state resonance-Raman spectrum of **1**. The missing intense lines due to ν(Mo=O) vibrations proves that the corresponding terminal bonds are not involved in the Mo 4d electron delocalization as compared to the $\{Mo_{154}\}$ wheel-type species, where in each of the 14 $\{Mo_5O_6\}$ units two 4d electrons are delocalized (see [2a]). (See Section 2 for experimental details.)

symmetrical one. On the other hand in the presence of Li^+ cations in the reaction mixture also not the hedgehog-type species is formed but the neutral spherical $\{Mo_{102}\}$ ball-type cluster species [12]. The results can be understood, as the wheel- and ball-shaped species have a much higher formation tendency while the formation of the very complex $\{Mo_{368}\}$ cluster, showing in case of the synthesis of **1** an unprecedented symmetry breaking of the surface, really only occurs under very special limited conditions. Note: the role of the Na^+ cations is not understood until now.

The knowledge of the cluster **1a** will probably be the starting point for the syntheses of related other clusters of comparable size. This should be possible in case of the abundance of ligands like 'the medium-ligand-strength' SO_4^{2-} ions generating a large number of building units (for details see [4]) and may be a starting point of an interesting route in nanochemistry. This includes also the option of handling the giant clusters as intact units for instance for the preparation of composites, e.g., with silica or cationic surfactants, which is possible with these types of anionic clusters as was shown before in case of the above mentioned giant ball- and wheel-type species with the generation of micelles, films, monolayers and even liquid crystals [13]. A further option for the future is to study the vesicle formation of the giant cluster which follows unprecedented principles (see [14]).

An important result of the present paper is the formation of an extreme complex structure, showing symmetry breaking at the surface which is very much dependent on the special synthesis conditions in contrary to cases of higher symmetrical species (see [15]).

Abstract

In this study an unusual dinuclear bis-chloride bridged Mn(II) compound, $[Mn(\mu\text{-}Cl)(biz)_2]_2Cl_2$ (in which biz = 2,2′-bi-imidazoline), has been described and characterised. Also the magnetic susceptibility and EPR investigations are made. The distorted octahedral geometry around the Mn(II) ion is formed by four nitrogen atoms of two dichelating biz ligands and two bridging chloride atoms. The lattice is further stabilised by hydrogen bonds between uncoordinating N atoms of the ligand and the coordinating and uncoordinating chloride atoms. Magnetic susceptibility measurements reveal a weak ferromagnetic interaction between the two high-spin Mn(II) ions of $J = 0.33$ cm^{-1}.

Keywords: Crystal structure; Manganese; Hydrogen bond; Magnetism; EPR

1. Introduction

The organic ligand 2,2′-bi-imidazoline (abbreviated as biz, see Scheme 1) is an interesting and flexible bifunctional ligand. This heterocyclic didentate ring ligand is of special interest as it deviates from the more "flat" molecules, like bisimidazole, bipyridine or bipyrimidine, due to the fact that the steric effects at the rear side of the molecule are influenced by two acidic hydrogen atoms. These two N–H donor groups can form polymeric aggregates by hydrogen bonding [1,2].

So far X-ray structures with biz and transition metals have only been reported for a few Fe(II), Fe(III) and Co(II), Co(III) compounds [3,4], in which neutral and mono-deprotonated biz are present. Recently, X-ray structures of Cu(II), Ni(II) and Co(II) as transition metal ions with this ligand and the anion dicyanamide and a copper(II) azide compound have been reported by us [1,2]. Furthermore, the ligand is capable to hydrolyse in-situ with a metal ion to form different organic ligands [5,6].

The coordination chemistry of manganese ions with N and/or O containing ligands has been receiving a great deal of attention, because of the variable structures of manganese complexes and the importance of manganese

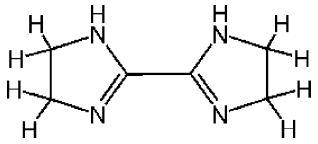

Scheme 1. 2,2′-bi-imidazoline.

enzyme models, the possibility of magnetic coupling interactions, and the application of manganese compounds in industrial catalysis [7,8].

The behaviour of these manganese complexes is mainly dependent on the structure and coordination mode of the ligands in addition to the oxidation number of manganese. Dinuclear chloro-bridged Mn(II) compounds with N/O donor ligands are relatively rare and only a few six-coordinated Mn(II) compounds have been structurally investigated [8–12]. Of these compounds only two have also been magnetically investigated [8,12].

In this study the molecular and X-ray structure of an unusual dinuclear chloro-bridged Mn(II) compound with the formula $[Mn(\mu\text{-}Cl)(biz)_2]_2Cl_2$ is reported along with its EPR and magnetic susceptibility properties.

2. Experimental

2.1. Syntheses

The ligand, 2,2′-bi-imidazoline (biz), was prepared by the method reported in the literature [13]. The title compound was prepared according to the following procedure: 0.24 g (1.2 mmol) of Mn(II) chloride tetrahydrate and 0.33 g (2.4 mmol) ligand were each dissolved in 10 ml of ethanol. The ligand solution was then added slowly to the metal-salt solution and filtered to remove any undissolved material. After a few weeks, the product separated as a crystalline product, which was isolated by filtration and dried in air, and characterised by elemental analysis and spectroscopic methods. Yield 64%. Elemental analysis: found (calc) for $C_{24}H_{40}Cl_4$ Mn_2N_{16} (M_w 804.40): 35.7 (35.8) %C; 4.8 (5.0) %H; 27.6 (27.9) %N.

2.2. Physical measurements

C,H,N determinations were performed on a Perkin Elmer 2400 Series II analyser. Ligand-field spectra were obtained on a Perkin-Elmer Lambda900 spectrophotometer using the diffuse-reflectance technique, with MgO as a reference. X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer, using DPPH ($g = 2.0036$) as a standard and measured at 4 mW.

Magnetic susceptibility measurement (5–200 K) were carried out using a Quantum Design MPMS-5 5T SQUID magnetometer (measurements carried out at 1 T). Data were corrected for magnetisation of the sample holder and for diamagnetic contributions, which were estimated from Pascal constants.

2.3. Crystal structure determination and refinement of the structures

The reflection intensities were measured on a four-circle Enraf-Nonius CAD-4 diffractometer using graphite-monochromated Cu Kα radiation ($\lambda = 1.54184$ Å). The cell dimensions were determined using 25 independent reflections. Intensity data were corrected for Lorentz and polarization effects. Absorption correction was not applied. The positions of the heavy atoms were determined from a Patterson map (DIRDIF) [14]. The atomic scattering factors were taken from the International tables for X-ray crystallography [15]. The remainder of the non-H atoms were located in subsequent difference Fourier syntheses. Hydrogen atoms were placed at calculated positions (at 0.95 Å) from their parent atoms. Full-matrix least-squares refinement on F using the XTAL3.4 set of programs [16] with the function minimized being $\sum w(|F_o| - |F_c|)^2$ with $w = 1/\sigma^2(F)$. Positional refinement of all non-H atoms, anisotropic for the nonhydrogen atoms, fixed isotropic thermal parameters for the hydrogens. Geometric calculations and molecular graphics were performed with the PLATON package [17] (see Table 1).

3. Results and discussion

3.1. Description of the crystal structure of $[Mn(\mu\text{-}Cl)(biz)_2]_2Cl_2$ (1)

The structure of the dinuclear unit is depicted in Fig. 1. Relevant bond length and bond angle information is given in Table 2. The molecular structure consists of two centro-symmetrically related Mn(II) centres, bridged almost symmetrically by two chloride ions.

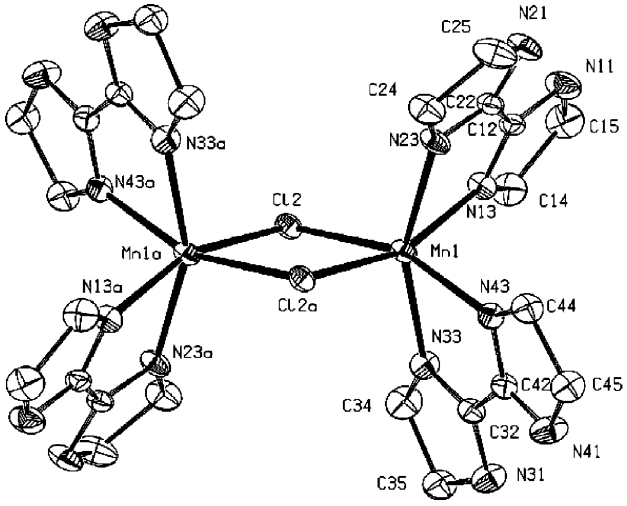

Fig. 1. Thermal ellipsoid plot [17] at 50% probability of $[Mn(\mu\text{-}Cl)(biz)_2]_2Cl_2$ with atom-labelling scheme. Hydrogen atoms are omitted for clarity. Atoms marked with an "a" are generated by an inversion centre.

The octahedral coordination around each Mn atom is formed by four nitrogen atoms of two dichelating biz ligands (with distances which vary from 2.232(4) to 2.262(3) Å) and two bridging chloride atoms with distances of 2.5578(13) and 2.5754(13) Å. The two other chloride atoms are not coordinating. The Mn–Mn distance is 3.740 Å and the Mn–Cl–Mn bridging angle is 93.53(4)°.

The lattice is stabilised through hydrogen bonds between the uncoordinated nitrogen atoms of the biz ligand at the rear side of the molecule and both the uncoordinated and coordinated chloride anions with distances which vary from 3.184(5) to 3.271(5) Å (see Fig. 2 and details of the H-bonding in Table 2). The lattice is further stabilised by ring–ring contacts of imidazoline units (closest ring–ring contacts of 3.960 Å).

3.2. EPR and magnetic properties

The X-band EPR recorded on the powdered solid reveals a spectrum with a broad band around $g \approx 2$ (RT and 77 K give the same spectrum) typical for Mn(II) in a distorted octahedral environment [18] (Fig. 3(a)). The broad signals above and below $g = 2$ are due to the $S = 5/2$ zero-field splitting, as has been reported for distorted mononuclear Mn(II) complexes [19–21], but the same type of spectra are also reported for dinuclear Mn(II) compounds [7,12,22].

The compound measured as a frozen solution in DMF/MeOH (1:1) exhibits a well-resolved six-line signal ($A \sim 90$ G) centred near $g = 2$, consistent with the

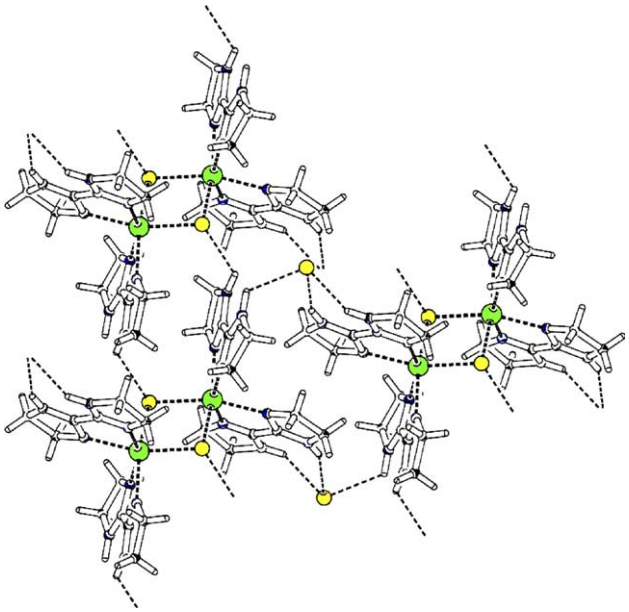

Fig. 2. Hydrogen bonding and packing in the title compound.

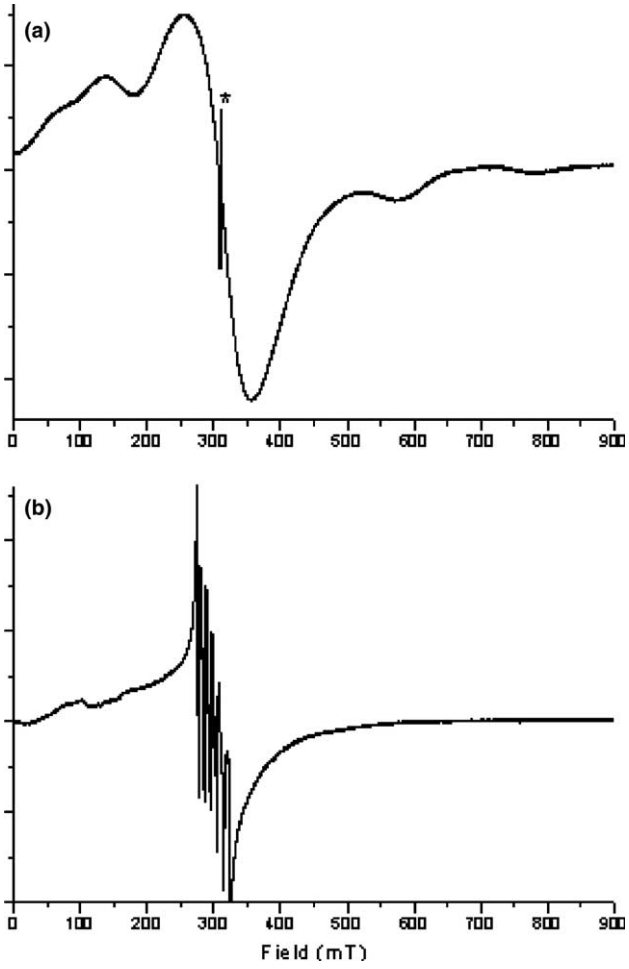

Fig. 3. X-band EPR spectrum of the powdered solid (a; * = dpph reference) and frozen solution (b) in DMF/MeOH in the range from 0–900 mT.

hyperfine splitting due to the coupling of the electron spin with $I = 5/2$ of the ^{55}Mn(II) nucleus [19]. Also the broad signals, albeit weaker, are visible below and above $g = 2$, which are also observed in other Mn(II) dinuclear [8,22] and mononuclear compounds [20] (Fig. 3(b)). So from the point of view of an EPR study alone, it is hard to prove whether a Mn(II) compound is mononuclear or dinuclear [8], as also in most cases a mononuclear impurity is present in dinuclear species (vide infra).

To gain more insight in the magnetic behaviour of the dinuclear compound, magnetic susceptibility measurements were undertaken from 5 to 200 K. The result is depicted in Fig. 4 in the form of X_mT versus T. The X_mT value of the title compound is about 8.5 $cm^3\,K\,mol^{-1}$ (μ_{eff} 8.4 μ_B) per dinuclear unity at 200 K, a value close to the spin-only value for two independent high-spin Mn(II) ions (8.7 μ_B). This value stays almost constant till around 80 K and then increases with decreasing temperature, typical for a ferromagnetic interaction between the pair of high-spin Mn(II) ions. The equation for the magnetic susceptibility per Mn(II) for the dinuclear Mn(II) system based on the isotropic Heisenberg model $\boldsymbol{H} = -J\boldsymbol{S}_1 \cdot \boldsymbol{S}_2$ ($\boldsymbol{S}_1 = \boldsymbol{S}_2 = 5/2$) is given as follows [8,23,24]:

$$\chi_M = \frac{Ng^2\beta^2}{kT} \cdot \frac{x^{28} + 5x^{24} + 14x^{18} + 30x^{10} + 55}{x^{30} + 3x^{28} + 5x^{24} + 7x^{18} + 9x^{10} + 11} + N\alpha \quad (1)$$

where $x = \exp(-J/kT)$, $N\alpha$ = paramagnetic impurity and the other symbols have their usual meanings. No zero-field splitting parameter was needed to obtain a good fit. The magnetic parameters $g = 2.00$, $J = 0.33(1)$ cm^{-1} and $N\alpha = 0.07$ cm^3/mol are obtained from a fit of the experimental data, with $R = 4 \times 10^{-4}$.

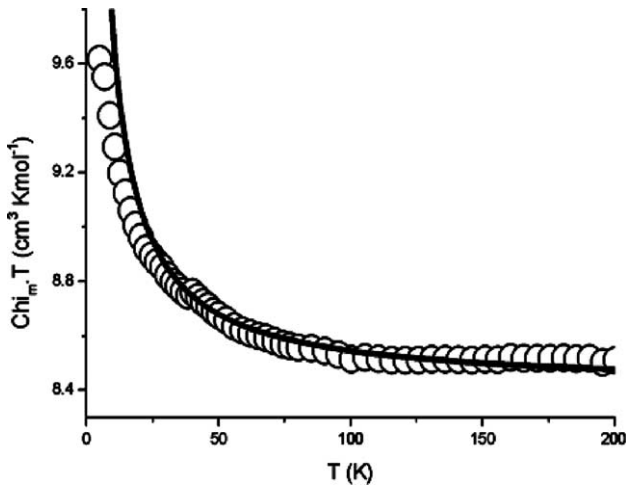

Fig. 4. Temperature dependence of $\chi_M T$ versus T per dinuclear unity. The solid lines is the best fit with $J = 0.33(1)$ cm^{-1}, $g = 2.00$ (see text).

[a] *Abbreviations*: biz = 2,2-bi-imidazoline; mpbpa = *N*-(3-methoxypropyl)-*N*,*N*-bis(pyridin-2-ylmethyl)amine; bpea = *N*,*N*-bis(2-pyridyl methyl)ethylamine.

4. Conclusions

In this study investigations by X-ray, EPR and magnetic susceptibility of a novel dinuclear chloro-bridged Mn(II) compound are reported. The small ferromagnetic exchange interaction of $J = 0.33(1)$ cm^{-1} between the pair of Mn(II) ions is similar in strength to that found for the (few) analogous compounds with the same chromophore, $[MnCl(\mu\text{-}Cl)(bpea)]_2$ and $[MnCl(\mu\text{-}Cl)(mpbpa)]_2$ (see Table 3).

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-242535. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) +44(1223)336-033, e-mail: deposit@ccdc.cam.ac.uk, or www at http://www.ccdc.cam.ac.uk].

Abstract

The coordination of the aluminium(III) cation to 2,3-dihydroxybenzoic acid (2,3-dhba), 5-nitrosalicylic acid (5-nsa), 4-nitrocatechol (4-ncat) and 3,5-dinitrocatechol (3,5-dncat) was studied by pH-potentiometry and by spectroscopic techniques. The stoichiometry of the complexes and their formation constants were determined. NMR spectroscopy allowed us to obtain thermodynamical, dynamical and structural information about the complexes formed in solution. The complexing power of these molecules was compared to that of catechol and salicylic acid. Additionally, the proton exchange rate constant between the phenolic and the phenolate forms of 5-nsa was determined by NMR line-shape analysis. This proton exchange that is usually very fast is considerably slowed down by the formation of an intramolecular hydrogen bond between the carboxylate and the phenolic groups.

1. Introduction

Many trades are evolving in application domains which resort to the complexation properties of metals by organic molecules. For instance, the surface treatment of metals in electronics, galvanoplasty and electroplating allows to improve the performances, to decorate or to protect against oxidation, respectively. The treatment of water used in heat exchangers or in the detergency domain, is also included in these areas; a large variety (and amount) of complexing molecules is involved in this activity.

There is an important class of compounds: the salicylate and catecholate derivatives, the complexing properties of which are recognised. These compounds are industrially produced in a great quantity. They are not always employed for their complexing ability and could be valorised in fields where this property is required (galvanoplasty, electroplating for instance). Aluminium(III) is concerned by this kind of use.

The study of the complexation of Al(III) by salicylate and catecholate derivatives is also important to understand the phytotoxicity of this element when it is released from the mineral matter and solubilized under acidic conditions [1,2]. The availability of Al in the soils depends on its state: free or in organic complexes. Humic acids are able to complex the aluminium(III) cation and have an influence on its speciation in soils. The complexing parts of these organic macromolecules are constituted by salicylate and catecholate functions. The knowledge of the complexes that are formed in aqueous solution with the Al(III) ion is crucial to evaluate the

doi:10.1016/j.poly.2004.07.017

competition with the other organic ligands and to reach the concentration of the different species.

This paper reports the study of the complexation of the Al(III) ion with four ligands: 2,3-dihydroxybenzoic acid (2,3-dhba), 5-nitrosalicylic acid (5-nsa), 4-nitrocatechol (4-ncat) and 3,5-dinitrocatechol (3,5-dncat) in aqueous solutions as a function of pH. The first compound was chosen because of the possible competition between the salicylate and the catecholate coordination modes. The three other compounds have one or two nitro substituants on the aromatic ring that enhance the acidity of the salicylic and catechol functions and consequently induce a modulation of the complexing power of the molecules.

Besides the pH-potentiometric study that allowed us to propose a set of complexes for each Al(III)/ligand system, an extensive spectroscopic investigation was made (IR, UV–visible and especially ^{1}H and ^{13}C NMR) to confirm the potentiometric results and to obtain information on the structure and the dynamics of the complexes. Additionally, the proton exchange kinetics between the OH function and the phenolate form of 5-nsa could be studied; the formation of an intramolecular hydrogen bond, inducing the slowing down of the proton exchange rate, leads to unusual line broadenings in the NMR spectra.

2. Experimental

2.1. Materials

Aluminium(III) chloride (Fluka $\geqslant$99%) was used with no further purification. The concentration of aluminium(III) solutions was determined by a standard procedure using EDTA (Merck).

2,3-Dihydroxybenzoic acid ($\geqslant$99%), 2,4-dihydroxybenzoic acid ($\geqslant$97%), 5-nitrosalicylic acid ($\geqslant$99%) and 4-nitrocatechol ($\geqslant$97%) were purchased from Aldrich without further purification. 3,5-Dinitrocatechol was a Rhodia product.

The ionic strength was adjusted by potassium chloride (BDH AnalaR 99.5%).

pH-metric titration were performed with sodium hydroxide from Prolabo (0.100 mol L^{-1} Titrinorm).

The pH of the solutions was adjusted with hydrochloric acid and sodium hydroxide from Prolabo (1.00 mol L^{-1} Titrinorm).

2.2. pH-potentiometric measurements

The pH-potentiometric titrations were performed in aqueous solutions to investigate the protonation and coordination equilibria of the ligands at $T = 298.0 \pm 0.1$ K and for an ionic strength $I = 0.1$ mol L^{-1} (KCl) under an argon atmosphere. They were recorded using an automatic titration set, including a Metrohm Dosimat 716 DMS Titrino titrator and an Orion 9103SC type combined glass electrode.

The different equilibria were characterised by the following equation:

$$pM + qL + rH = M_pL_qH_r$$

and the corresponding constants are given by:

$$\beta_{pqr} = \frac{[M_pL_qH_r]}{[M]^p \cdot [L]^q \cdot [H]^r},$$

where M denotes the aluminium(III) cation, L the non-protonated ligand and H the proton. For simplicity, charges are omitted in most cases. However, they can be calculated knowing the fully protonated ligand is LH_2, leading to the LH^- and L^{2-} anions by successive deprotonations. A detailed description of the experimental procedure and data evaluation (from the PSEQUAD computer program [3]) was reported earlier [4,5].

The protonation and complex formation constants were determined from 6 to 8 independent titrations (between 30 and 70 data points per titration). The ligand to metal ratios varied from 1/1 to 10/1. The ligand concentration was 0.01 mol L^{-1}, except in the case of 5-nsa (0.004 mol L^{-1}) that is sparingly soluble. The pH-metric data between pH 2 and 11.3 were used for the evaluation, unless precipitation occured.

For the analysis of the titration curves, the formation of the hydroxo complexes MH_{-1}, M_2H_{-2}, M_3H_{-4}, $M_{13}H_{-32}$ and MH_{-4} were taken in account, with the following formation constant values [6]: $\log\beta_{10-1} = -5.52$, $\log\beta_{20-2} = -7.70$, $\log\beta_{30-4} = -13.57$, $\log\beta_{130-32} = -109.1$ and $\log\beta_{10-4} = -23.46$.

2.3. NMR spectroscopy

The ^{1}H and a part of ^{13}C NMR spectra were recorded on a Bruker DRX 400 apparatus at 400 and 100.6 MHz, respectively. The same apparatus was used for recording HMQC ^{13}C-^{1}H correlation maps. Another part of the ^{13}C spectra were recorded on a Bruker AC 200 apparatus at 50.3 MHz. The solutions were mainly prepared in D_2O/H_2O (20/80 v/v) mixtures. The chemical shifts were referenced to dioxane and converted to the TMS scale, knowing that $\delta_{dioxane}(^{13}C) = 67.40$ ppm and $\delta_{dioxane}(^{1}H) = 3.700$ ppm. In the case of the exchange rate measurements, an external capillary tube, filled up with D_2O and dioxane, was used.

The concentration of the ligand varied from 0.1 to 0.001 mol L^{-1}.

2.4. IR spectroscopy

The IR spectra were recorded on a Perkin–Elmer Spectrum One apparatus with an ATR accessory.

The spectra were analysed after the subtraction of the solvent (water) spectrum. The concentration of 2,3-dhba was 0.05 mol L^{-1} and the ligand to metal ratio varied from 1/1 to 5/1. According to ligand spectra, the 1390 and 1232 cm^{-1} vibration bands were attributed to COO^- and to COOH functions, respectively.

3. Results

3.1. pH-potentiometry

The values of the protonation and complexation constants deduced from the pH-potentiometric studies are shown in Table 1.

The acidity constant values are in agreement with those proposed in the literature for 2,3-dihydroxybenzoic acid (2,3-dhba) [7,8], 5-nitrosalicylic acid (5-nsa) [9–11], 4-nitrocatechol (4-ncat) [12,13] and 3,5-dinitrocatechol (3,5-dncat) [14,15] at 25 °C and for a 0.1 mol L^{-1} ionic strength. All the ligands are noted LH_2 with two ionizable functions. The third potential acidity constant of 2,3-dhba could not be determined indicating a pK_a value higher than 12.

The set of complexes for the Al(III)–2,3-dhba system determined in this work is less large than that found by Kiss et al. [7] (25 °C and 0.2 mol L^{-1} KCl) or S. Desroches et al. [8] (37 °C, 0.15 mol L^{-1} NaCl), but the species ML, ML_2, ML_2H_{-1} and $M_2L_2H_{-3}$ are common for all the systems. The additional complexes are ML_2H_{-2} and $M_2L_2H_{-2}$ for the first reference and MLH, M_2L and $M_2L_2H_{-2}$ for the second reference. The comparison of the literature results [7] to our data, both obtained at 25 °C, indicates that the $\log\beta_{pqr}$ values determined in this work are slightly higher, probably because of the presence of less species in our system. For this ligand, the problem of the complexation mode: catecholate or salicylate, arises and will be discussed in the discussion part with the help of the NMR results.

For 5-nsa, the complexes formed with Al(III) are ML, ML_2, ML_3. The formation constants of these complexes are very close to those reported in the literature [9–11]. The structure of these complexes and the existence of different isomers for the ML_2 and ML_3 species have been analysed by NMR spectroscopy and discussed below.

The 4-ncat ligand also leads to the formation of ML, ML_2 and ML_3 complexes with the Al(III) cation. The formation constant for the ML species is comparable to that reported in the literature [12,13] and those for ML_2 and ML_3 are slightly higher.

There is no previous study on the complexation of Al(III) with 3,5-dncat to the best of our knowledge. The pH-potentiometric study shows that ML_2 and ML_3 complexes are formed with $\log\beta$ values equal to 21.80 and 31.68, respectively. Beyond pH = 5, another species appears; it was not possible to determine its stoichiometry.

The distribution curves deduced from the pH-potentiometric measurements are plotted in Fig. 1.

3.2. NMR spectroscopy

The ^1H NMR chemical shifts of all the systems described below are summarised in Table 2.

3.2.1. 2,3-dhba

^1H NMR spectroscopy allowed us to follow the formation of the four complexes detected by pH-potentiometry. Besides the signal due to the free ligand (doublets for the H_4 and H_6, a doublet of doublets for H_5) the signals due to the different complexes successively appear when the pH is increased. For a ligand to metal ratio L/M equal to 5/1, the proportion of ML and ML_2 can be easily quantified by integrating the corresponding NMR signals. The ML_2H_{-1} complex exhibits many peaks that overlap the other signals; its concentration cannot be determined.

For L/M = 3/1 or 1.1/1, the different complexes can be distinguished but the overlapping of the numerous signals is very important preventing the determination of their concentrations.

ML and ML_2 present very similar spectra that are slightly shifted to higher field relatively to the free ligand.

$M_2L_2H_{-3}$ appears in the NMR spectra for low L/M ratio such as 1.1/1. The spectrum presents two patterns similar to that of the free ligand. They are more shifted relatively to the free ligand than those of the ML and ML_2 complexes. The spectrum corresponding to ML_2H_{-1} is composed of many peaks due probably to inequivalences in the complex and/or different isomeric species.

A ^{13}C NMR study was also performed in order to determine the complexation mode with 2,3-dhba. The chemical shifts of all the carbons (the carboxylate carbon is noted C_7) for the LH_2, LH and L forms are summarised in Table 3. A shift amplitude from 4 to 9 ppm is measured from the LH_2 to the L species. When Al(III) is added to the solution, new peaks appear in the spectra corresponding to the formation of the complexes (Table 3). The chemical shifts of these signals do not depend on pH. For the spectra recorded between pH 2.0 and 6.5, two series of "bound" peaks are successively observed.

3.2.2. 5-nsa

As for 2,3-dhba, the chemical shifts of the H_3, H_4 and H_6 aromatic protons depend on the pH. They were measured as a function of pH and the chemical shifts of the species L, LH and LH_2 deduced from these measurements. As mentioned above, the peaks are broad for a pH value around the pK_{a2} value.

Table 1
Protonation constants of the 2,3-dhba, 5-nsa, 4-ncat and 3,5-dncat molecules and complex formation constants with Al(III) at 298 K and for $I = 0.1$ mol L^{-1} compared to those of catechol and salicylic acid ligands

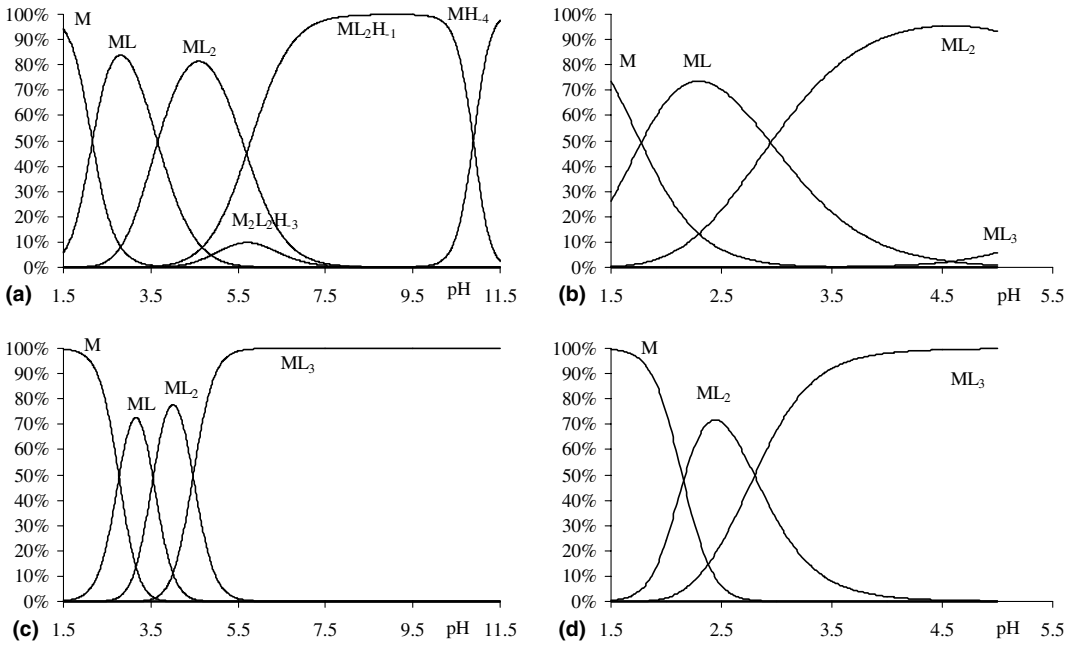

Fig. 1. Distribution diagrams of the complexes formed at 25 °C between aluminium(III) and 2,3-dhba (a), 5-nsa (b), 4-ncat (c), 3,5-dncat (d) as a function of the pH; [ligand] = 0.01 mol L^{-1}, ligand to metal ratio 5/1.

When aluminium(III) is present in solution, new peaks corresponding to the Al-bound ligand molecule merge in the spectra. These different ''bound'' signals are observed when pH is increased and correspond to the formation of the ML, ML_2, and ML_3 complexes. The chemical shift of the ML complex signals is only shifted of a few hundredth ppm. The spectrum of ML_2 is not well resolved at room temperature. At 5 °C, there are two series of signals with similar intensities for this complex.

The fine structure of ML_3 is visible at room temperature and corresponds to four sets of signals with nearly equal intensities (Fig. 2).

3.2.3. 4-ncat

The signals of the free ligand shift according to the pH of the solutions and the knowledge of the chemical shifts for the species LH_2, LH and L are needed to discriminate them from those of the bound ligand molecules. The successive apparition of the complexes is seen when pH is increased. The structures of the patterns corresponding to the bound ligand are similar to that of the free ligand and are shifted to a higher field. H_5 is not very perturbed by the complexation of the ligand to the Al(III) cation. The shift of H_3 is more pronounced and almost corresponds to that of the deprotonated ligand L. H_6 also undergoes an important shift and the shift of the complexes is near to that of the free deprotonated ligand L. For ML_2, the peaks are broadened contrary to those of the ML_3 complex for which only one set of signal is observed.

3.2.4. 3,5-dncat

There are only two aromatic protons in the molecule. H_4 and H_6 give two doublets in the NMR spectra ($J \approx 2.8$ Hz). The chemical shift of these doublets depends on the pH. The pH effect is weak for H_4 (LH_2: $\delta = 8.56$ ppm; LH: $\delta = 8.56$ ppm; L: $\delta = 8.41$ ppm) and much stronger for H_6 (LH_2: $\delta = 7.91$ ppm; LH: $\delta = 7.53$ ppm; L: $\delta = 7.27$ ppm).

For pH $\leqslant$ 5, two species are detected. The determination of their concentrations from NMR spectra and the comparison to those obtained from the potentiometric results allow us to assign the peaks to the ML_2 and ML_3 complexes. The chemical shifts of ML_2 and ML_3 are similar for H_4 whereas those for H_6 are different: 7.42 and 7.58 ppm, respectively. The peaks corresponding to ML_3 are broadened when these two species are present together whereas those of ML_2 remain sharp.

Beyond pH 5, a new complex is detected in the NMR spectra in agreement with the potentiometric results. It gives rise to many peaks (two doublets and a triplet for H_6, for instance) but its structure could not be determined.

3.3. Infrared spectroscopy

In order to study the complexation mode of the 2,3-dhba ligand (salicylate or catecholate), IR spectra were recorded. COO^- and COOH bands can be easily distinguished [17]. The peak at 1390 cm^{-1} corresponds to the carboxylate in an aqueous phase. Another peak at 1232 cm^{-1} is characteristic of the COOH function. Their

variations in intensity can be correlated to the proportion of COO^- group compared to that of COOH groups in the solution. The intensity of the peak at 1390 cm^{-1} (COO^-) is proportional to the sum of LH, ML and ML_2 concentrations in solution and not to the alone LH concentration.

4. Discussion

4.1. 2,3-dhba

The ^{1}H NMR study allowed us to confirm the potentiometric results. Four different complexes were

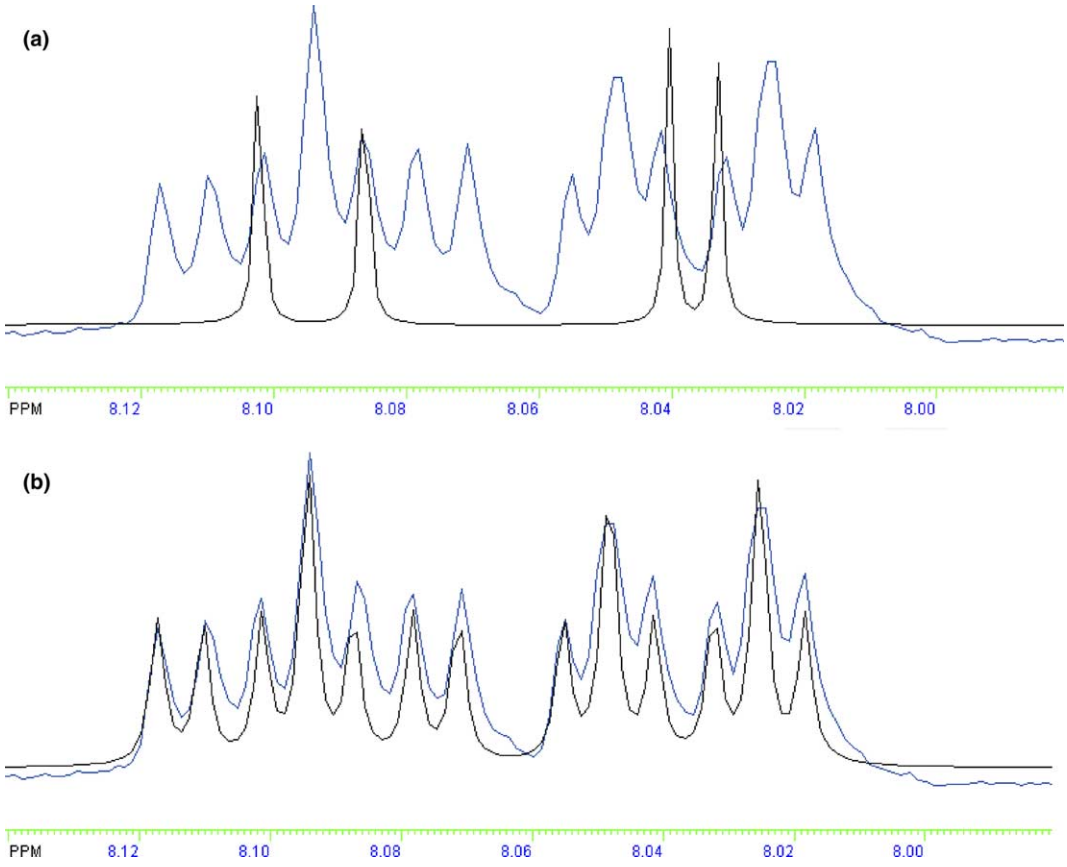

Fig. 2. Simulation (dark lines) of H_4 NMR pattern for $Al(5\text{-nsa})_3$ complex; spectrum (light lines) recorded at 400 MHz: [5-nsa] = 4×10^{-3} mol L^{-1}, [Al(III)] = 1.33×10^{-3} mol L^{-1}, pH 9.7; $T = 278$ K; a: simulation in the absence of coupling (chemical shifts of the four species: 8.103, 8.087, 8.041 and 8.034 ppm); b: simulation with coupling (2.8 Hz with H_6 and 9.2 Hz with H_3).

detected. For L/M = 5/1, we could determine the concentrations of two of them. The values correspond to those deduced from potentiometric results for the ML and ML_2 complexes. The ML_2H_{-1} species gives rise to many peaks that overlap the other NMR signals. For this reason, it was not possible to quantify its concentration. For L/M = 1/1, $M_2L_2H_{-3}$ is the major complex. From the integrals of the NMR spectra, the logβ values could be evaluated: 10.96 and 10.97 at pH 3.0 and 4.0, respectively, for ML; 19.55 and 19.39 at pH 3.0 and 4.0, respectively, for ML_2 and 10.49 at pH 4.0 for $M_2L_2H_{-3}$. These values are similar to those found by pH-potentiometry: 10.62, 19.20 and 10.30 for ML, ML_2 and $M_2L_2H_{-3}$, respectively.

Once the stoichiometry of the species known, the question of the structure and of the coordination mode of the ligand arises. It is well recognised that catecholate

leads to stronger complexes than salicylate. 2,3-dhba can act as both of these ligands. The salicylate complexation mode implies that the less acidic OH function must be deprotonated. The catecholate complexation implies that the carboxylic function be not ionised in the ML and ML_2 complexes in which only two (OH) deprotonations occur. A ^{13}C NMR study was performed to solve this question. Up to pH 3.5, the C_7 carbon gives one signal. From pH 4.5, two signals are observed: one at 176.4 ppm for the free carboxylate and another one at 174.6 ppm for the complex ML_2. This latter value approximately corresponds to the chemical shift of the free COOH ligand. The shifts of the C_2 and C_3 carbons are more important: nearly 3.0 ppm and 4.0 ppm at lowfield for C_2 in ML and ML_2, respectively, and nearly 3.1 ppm and 3.4 ppm at lowfield for C_3 in ML and in ML_2, respectively. These raw results are in favour of a catecholate complexation for which the carboxylic function remains protonated. Nevertheless this observation is inconsistent with the fact that the logβ values for 2,3-dhba are similar to the corresponding one for 5-nsa (Table 1) which is a salicylate-type ligand and very different from the values found for 4-ncat which is a catecholate-type ligand.

This difficulty was solved by an IR study that showed that the intensity of the COO^- band corresponds to the sum of the concentrations of the free ligand, LH, and of the ML and ML_2 complexes, and not to the concentration of LH. Thus, the carboxylate function is deprotonated in the complex: this result proves a salicylate complexation.

This conclusion was reinforced by the ^{13}C NMR study of 2,4-dhba for which the complexation can only be of the salicylate type. The shift of the C_7 carbon of the free 2,4-dhba and that of the C_7 carbon in the complex ML_2 at pH 5.2 are identical to the corresponding ones for 2,3-dhba.

For all these reasons it can be concluded that the complexation of 2,3-dhba with Al(III) occurs through the carboxylate and the deprotonated α-OH function in the ML and ML_2 complexes as for the salicylate ligand.

The stoichiometry of the $M_2L_2H_{-3}$ species supposes that at less one hydroxide ion participates to the coordination of Al(III). The ^1H NMR spectrum of this species shows two sets of peaks with an equal intensity indicating that there is either one complex with two inequivalent ligands or two isomeric forms in which rapid intramolecular ligand exchange occurs.

The ligand can be coordinated to the Al^{3+} in a catecholate manner, so the complex can be more properly written $M_2(LH_{-1})_2(OH)$ in this case.

Mixed catecholate/salicylate coordination modes with two OH^- ions, as already reported in the literature [7], or only salicylate coordination with three OH^- ion can also be evoked.

4.2. 5-nsa (see NMR spectra on Fig. 3)

4.2.1. Kinetics study of the phenolic proton exchange

The NMR study of the ligand leads to the exceptional direct observation of the slow exchange of the OH proton in the LH species between the ligand and the bulk. Indeed, the ^1H and ^{13}C NMR signals are broadened around pH 9.90 (Fig. 3), whereas they are sharp for pH $\leqslant$ pK_{a2} − 1 and for pH $\geqslant$ pK_{a2} + 1. This broadening is due to the observation of an averaged signal between the LH and the L species: the full coalescence is not achieved because of the slow exchange of the OH proton relatively to the NMR time scale. It is effectively known that the intermolecular exchange of this proton between the protonated form of the ligand and a base present in the solution can be slowed down because of the intramolecular hydrogen bond between the carboxylate group and the OH function [18–22]. The NMR study allows the determination of the rate constants for the exchange of the phenolic OH proton between LH^- and L^{2-} or OH^- [23]

$$LH^- + L^{2-} \underset{k}{\overset{k}{\rightleftarrows}} L^{2-} + LH^-$$

$$LH^- + OH^- \underset{k^-}{\overset{k^+}{\rightleftarrows}} L^{2-} + H_2O$$

The exchange rate is the sum of the rates corresponding to these two mechanisms, leading to:

$$k_{NMR} = k[L^{2-}] + k^+[OH^-]$$

For pH = pK_a, the concentration of L^{2-} and LH^- species are equal and it can be written that:

$$k[L^{2-}] + k^+[OH^-] = k[LH^-] + k^-[H_2O].$$

In this case: $k^+[OH^-] = k^-[H_2O] = k'$, since the water concentration is constant. k, k^+ and k^- can be calculated from the measurement of the NMR linewidths for different ligand concentrations.

^{13}C NMR was preferred to ^1H NMR because the chemical shift differences $\Delta\delta$ between the signals corresponding to the acidic and basic forms of the ligand are higher. The chemical shifts for the different carbon atoms in the LH^- and L^{2-} species are summarised in Table 4. $\Delta\delta$ values are particularly important for C_1, C_2 and C_5 carbons (10.7, 7.8 and 6.4 ppm, respectively).

Beyond the coalescence of the LH^- and the L^{2-} signals, at pH = pK_a = 9.90, and consequently for $[LH^-] = [L^{2-}]$, the exchange rate k_{NMR} is given by the formula [23]:

$$(\Delta\nu_{1/2})_{obs} - (\Delta\nu_{1/2})_0 = \frac{\pi(\nu_{LH^-} - \nu_{L^{2-}})^2}{2k_{NMR}}$$

where $(\Delta\nu_{1/2})_{obs}$ is the observed linewidth at half height, $(\Delta\nu_{1/2})_0$, that of the signals not submitted to the exchange and ν, the chemical shift in Hz.

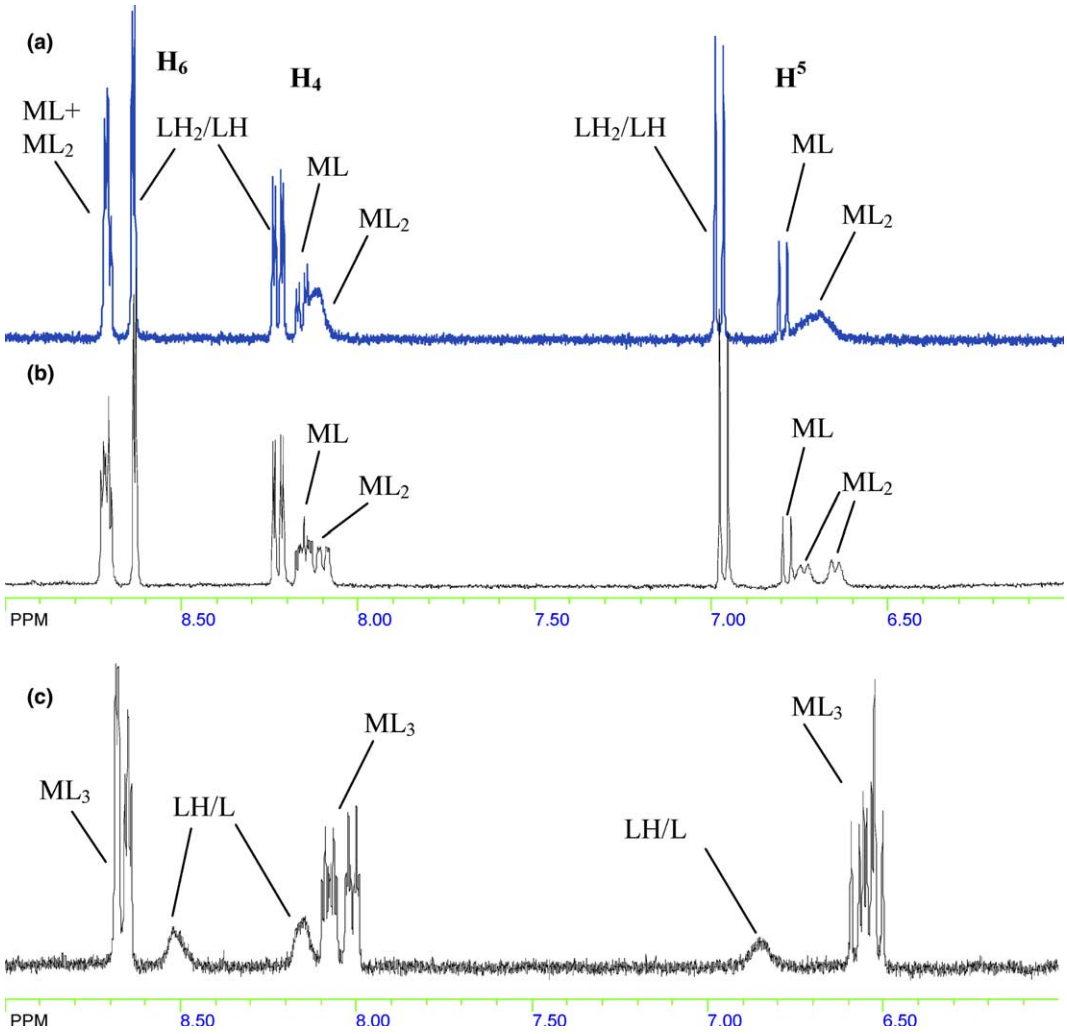

Fig. 3. ^{1}H NMR spectra of aluminium(III)–5-nsa (4×10^{-3} mol L^{-1}) solutions for a ligand to metal ratio 3/1, recorded at 400 MHz in D_2O/H_2O (20/80 v/v); a: $T = 298$ K, pH 3.92, b: $T = 278$ K, pH 4.08 and c: $T = 298$ K, pH 9.80, the peaks corresponding to the LH/L species are broad; this is due to the relatively slow exchange of the phenolic proton.

Table 4
^{13}C chemical shifts (δ) in ppm for 5-nsa, linewidth at half-height of ^{13}C peaks ($(\Delta\nu_{1/2})_0$) in Hz for the LH species; linewidth at half-height of ^{13}C peaks ($(\Delta\nu_{1/2})_{obs}$) in Hz for LH/L mixtures (50/50 mol/mol) at pH = pK_a = 9.9 and for different concentrations

	δ		$(\Delta\nu_{1/2})_0$	$(\Delta\nu_{1/2})_{obs}$

The spectra were recorded at 50 MHz; $T = 298$ K.
[a] Peak too broad to be detected.

k_{NMR} was found to be dependent on [LH$^-$] or [L^{2-}]. For these different concentration values, a straight line was obtained when k_{NMR} is plotted versus [L^{2-}] (Fig. 4). The slope of this line gave a k value equal to 5.7×10^5 L mol^{-1} s^{-1} and $k' = 4.5 \times 10^3$ s^{-1} ($k^+ = 5.7 \times 10^7$ L mol^{-1} s^{-1} and $k^- = 80$ L mol^{-1} s^{-1}).

The k value found in this work with 5-nsa is in the same order of magnitude as the value reported by

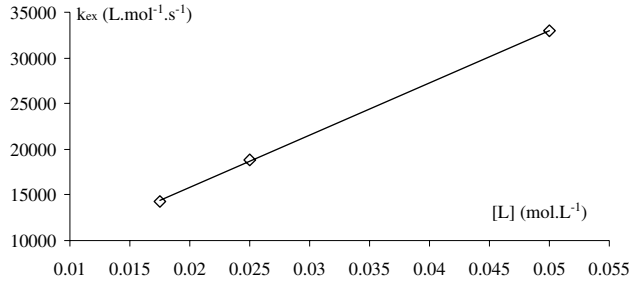

Fig. 4. Exchange constant (k_{ex}) of the phenolic proton in 5-nsa measured by ^{13}C NMR as a function of ligand concentration; $T = 298$ K; pH 9.9.

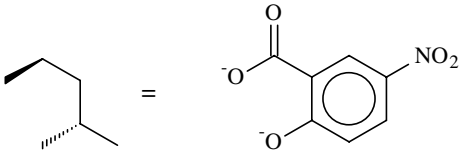
Diebler et al. [19] for the exchange rate constant corresponding to the exchange of the dinitrosalicylic anion with the NH_3 base. ($k = 1.9 \times 10^6$ L mol^{-1} s^{-1}). The k^+ value is higher than the value obtained for alizarine yellow S [22] ($k^+ = 1.4 \times 10^7$ L mol^{-1} s^{-1}) and comparable to that obtained for the exchange of thiosalicylic acid with OH^- (4.4×10^8 L mol^{-1} s^{-1} [19] or 5.3×10^7 L mol^{-1} s^{-1} at 12 °C [21]). The literature values were obtained from *T*-jump experiments.

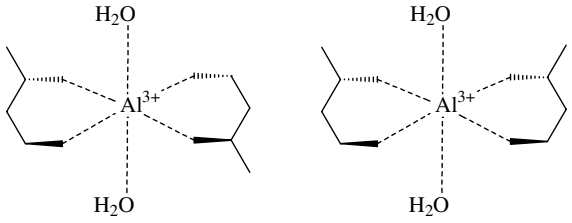
4.2.2. Complexation study

^1H NMR spectroscopy confirms the formation of three different complexes when pH is varied. Separate signals from those of the free ligand are observed for each complex. The integration of these signals allows the determination of the logβ values for the ML and ML_2 complexes. Because of the broadness of the free ligand peaks around pH 10.0 (see above) the determination of the logβ values for ML_3 is not possible. The logβ values calculated for ML and ML_2 from NMR spectra at 3 different pH values are close to the values deduced from the potentiometry experiments (11.3 against 10.65 for ML and 20.35 against 19.61 for ML_2).

The NMR spectrum of the ML species is similar to that of the free ligand, but slightly shifted.

The signals of ML_2 are broad at room temperature. By cooling down the solution to 5 °C, two sets of signals with equal intensities are observed for this complex (Fig. 3). This can be due to the non-equivalence of the two ligand molecules in the complex or to two different isomeric forms of equivalent stability. If we consider a cis-complexation of the two salicylate ligands with the hexa-coordinated Al^{3+} cation with two axial water molecules, there are two possible isomers in which the ligands are equivalent (probabilities 1/2–1/2).



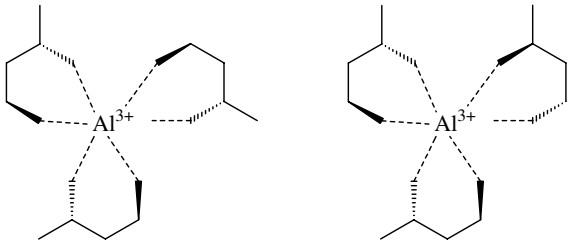


isomers of the cis-ML_2 species

An intramolecular exchange can convert an isomer into another and leads to the partial coalescence of the signals at room temperature.

The signals of the ML_3 complex are sharp at room temperature and present four different patterns of equal intensities (Fig. 2).

The hexa-coordination of Al(III) with the three unsymmetrical chelating ligands leads to the formation of two isomers. In the fully symmetrical isomer, all the three ligands are equivalent. In the other isomer, the hydrogen atoms of each ligand are inequivalent. It can be considered that the stability of the two isomers are close together. Moreover, if the steric effects are weak, the population for the symmetrical and for the other isomer must be 1/4 and 3/4. This leads to four patterns of equal intensities as observed.



isomers of the ML_3 species

4.3. 4-ncat

^1H NMR allows to follow the formation of three successive complexes. The signals of the first and third species are sharp whereas those of the second complex are broad. When the second species is present, the peaks of the free ligand are also broadened. At 5 °C, these signals become sharper. The integration of the free and bound signals allows the determination of the percentages of all the species present in solution. On the basis of the formation of the ML, ML_2 and ML_3 complexes, the proportions determined by NMR are fully consistent with the results of the potentiometric study. It can be

concluded that the three species which are detected in the ^{1}H NMR spectra are effectively ML, ML_2 and ML_3.

The $\log\beta_{110}$ and $\log\beta_{120}$ for the ML and ML_2 complexes were determined from the ^{1}H NMR spectra. The values found at pH 2.0 and 3.0 (13.96 for ML and 25.62 for ML_2) are very close to that determined from the potentiometric study (13.89 for ML and 26.33 for ML_2). The $\log\beta$ values for ML_3 could not be evaluated because of the quantitative complexation which occurs for the pH range where this species is formed.

It must be mentioned that, from pH 8, additional peaks due to the formation of other species are detected in the ^{1}H NMR spectra but their total concentration do not exceed 4% of the total complex concentration.

The broadening of the ligand and ML_2 signals when the ML_2 complex is formed can be due to the exchange of the LH_2 molecules with the bound L^{2-} ligands:

$$ML_2^- + L^*H_2 = MLL^{*-} + LH_2$$

where the asterisk is only a typographical distinction.

This kind of exchange is not observed for the ML^+ and $ML_3{}^{3-}$ species at the NMR time scale level.

4.4. 3,5-dncat

The NMR results are consistent with the potentiometric results. For pH $\leqslant$ 5.0, the ML_2 and ML_3 complexes are formed in solution. The determination of the formation constants from the NMR experiments is difficult because the poor solubility of the ligand leads to the use of low concentrations. Nevertheless, the average values obtained from six different experiments (two different ligand to metal ratios at three different pH values for each) are 21.2 and 31.7 for $\log\beta_{120}$ and $\log\beta_{130}$, respectively. The values are close to those obtained from the potentiometric experiments: $\log\beta_{120} = 21.80$ and $\log\beta_{130} = 31.68$.

It must be mentioned that these $\log\beta$ values are lower than those obtained for 4-ncat: $\log\beta_{120} = 26.33$ and $\log\beta_{130} = 37.08$. It might be due to the presence of one nitro-substituent in an *ortho*-position relatively to one OH function in the 3,5-dncat ligand leading to a decrease of the negative charge on the phenolate oxygen atom owing to mesomeric effects.

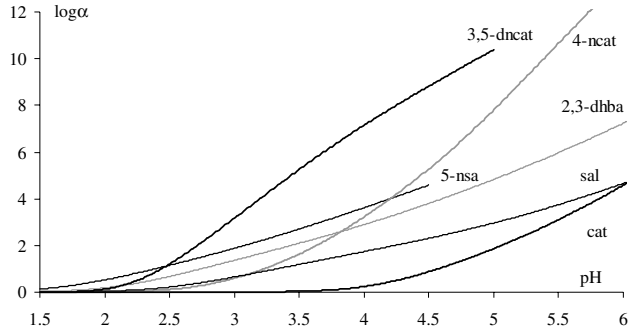


Fig. 5. logα as a function of pH for 2,3-dhba, 4-ncat, 5-nsa, 3,5-dncat, catechol (cat) and salicylic acid (sal); α is the ratio of the total aluminium(III) concentration to that of free aluminium(III); [ligand] = 0.01 mol L^{-1}, ligand to metal ratio 5/1, $I = 0.1$ mol L^{-1}, $T = 298$ K.

5. Conclusion

The spectroscopic investigation of some salicylate or catecholate/aluminium(III) systems allowed us to obtain dynamical, thermodynamical and structural information on the ligands and the complexes formed in aqueous solutions. These results prove that the studied ligands are good complexing agents for the Al(III) cation. This complexing ability can be easily shown by considering the plot of logα versus pH, where α is the ratio of the total cation concentration to that of free cation. A high α value is characteristic of a strong complexation. It can be seen on Fig. 5 that 3,5-dncat is the best ligand from pH $\approx$ 2.5 up to pH $\approx$ 5. 5-nsa and 2,3-dhba have a similar complexing ability. The complexing power of 4-ncat which is the lowest up to pH 3.5, strongly increases from pH 3.5 and becomes comparable to that of 3,5-dncat at pH $\approx$ 5.0. The $\log\beta_{1n0}$ values for the formation of the ML_n complexes are higher for catecholate derivatives than for salicylate compounds but, at low pH values, the complexing ability of salicylate ligand is nevertheless good, owing to low pK_{a1} values. The $\log\beta_{1n0}$ values are lower for 3,5-dncat and 4-ncat, but they are offset by a low pK_{a1} value leading to a very good complexing power.

For systems that do not lead to precipitate formation (4-ncat and 2,3-dhba) beyond pH $\approx$ 5.0, the complexation is challenged by the formation of the aluminate species $Al(OH)_4{}^-$ from pH $\approx$ 6.0.

The $\log\beta_{1n0}$ formation constants for 5-nsa are lower than those for salicylic acid ($\log\beta_{110} = 13.2$, $\log\beta_{120} = 23.7$ for salicylic acid [7]). Similarly, these values for 4-ncat are lower than those for catechol ($\log\beta_{110} = 16.2$, $\log\beta_{120} = 29.3$ and $\log\beta_{130} = 37.95$ [7]). The presence of one nitro-substituant on the aromatic ring decreases the negative charge borne by the phenolate oxygen atoms owing to mesomeric effects. When a second NO_2-substituent is present in an *ortho*-position relatively to the OH function, this effect is enhanced, leading to lower values for the formation constant as noted for 3,5-dncat and 4-ncat. This is true if the interactions between the Al^{3+} cation and the ligand are essentially electrostatic. Theoretical calculations on these systems might allow to precise these points.

Abstract

New tin(IV) complexes of empirical formula, Sn(NNS)I_3 (NNS = anionic forms of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate) have been prepared and characterized by a variety of physico-chemical techniques. In the solid state, the Schiff bases exist as the thione tautomer but in solution and in the presence of tin(IV) iodide they convert to the thiol tautomer and coordinate to the tin atom in their deprotonated thiolate forms. The structures of the free ligand, Hqaldsbz and its triiodotin(IV) complex, [Sn(qaldsbz)I_3] have been determined by X-ray diffraction. The complex, [Sn(qaldsbz)I_3] has a distorted octahedral structure with the Schiff base coordinated to the tin atom as a uninegatively charged tridentate chelating agent via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. The three iodo ligands are coordinated meridionally to the tin atom. The distortion from an ideal octahedral geometry of [Sn(qaldsbz)I_3] is attributed to the restricted bite size of the tridentate Schiff base ligand.

Keywords: Tin(IV) complexes; Dithiocarbazates; 2-Quinolinecarboxaldehyde Schiff bases of *S*-alkyl/aryl dithiocarbazates

1. Introduction

Interest in metal complexes of Schiff bases derived from *S*-alkyl- and *S*-aryl esters of dithiocarbazic acid [1–10] has been stimulated by their interesting physico-chemical properties [3–5] and potentially useful biological activities [6–10]. However, in the past, most work on dithiocarbazates involved their complexes with transition metal ions. Complexes of these ligands with non-transition metal ions such as tin have not received as much attention. In view of the importance of tin compounds in medicinal chemistry and biotechnology [11] and as part of our ongoing work on metal-dithiocarbazates, we report here two new tin(IV) complexes of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyl esters of dithiocarbazic acid together with the

X-ray crystal structures of the Schiff base, Hqaldsbz and its tin(IV) complex, [Sn(qaldsbz)I_3].

2. Experimental

2.1. Reagents

All chemicals were of analytical reagent grades and used without any further purification. 2-Quinolinecarboxaldehyde was purchased from the Aldrich Chemical Company and tin(IV) iodide was prepared according to the published procedure [17]. Microanalyses for C, H and N were performed by the Elemental Analysis Laboratory, National University of Singapore, Singapore. Molar conductances of ca. 10^{-3} M solutions of the complexes in either DMSO or CH_2Cl_2 were measured by means of a Jenway 4310 conductivity meter. The IR spectra in KBr discs and the electronic spectra either as Nujol mulls or in solution were recorded on a Perkin–Elmer 2000 FT IR spectrometer and a Shimadzu MPC-3100 spectrophotometer, respectively. The ^1H and ^{13}C NMR spectra of the Schiff bases were run in DMSO-d_6 on a Bruker Advance DPX 300K FT NMR spectrometer whereas the ^1H NMR spectra of the tin(IV) complexes were run in $CDCl_3$ on a Bruker DPX 300 MHz spectrometer using TMS as an internal standard.

2.2. Preparation of the ligands

2-Quinolinecarboxaldehyde (0.79 g; 0.01 mol) was dissolved in boiling ethanol (30 ml) and the solution mixed with a solution of the appropriate *S*-alkyldithiocarbazate (0.01 mol; 1.22 g of *S*-methyldithiocarbazate or 1.74 g of *S*-benzyldithiocarbazate) in methanol (35 ml). The mixture was heated on a water bath for ca. 30 min and then left to stand overnight. The yellow product that had formed was filtered off, washed with cold ethanol, dried in a desiccator over silica gel and then recrystallized from chloroform. Yield: Hqaldsbz: 54.3%; m.p. 184–186 °C. Calc. for $C_{18}H_{15}N_3S_2$: C, 64.07; H, 4.48; N, 12.45. Found: C, 64.20; H, 5.11, N, 12.33%. Hqaldsme: Yield: 85.6%; m.p. 194–195 °C. Calc. for $C_{12}H_{11}N_3S_2$: C, 55.15; H, 4.24; N, 16.08. Found: C, 55.20, H, 4.61; N, 16.70%.

2.3. Preparation of the complexes

Tin(IV) iodide (1 mmol; 0.626 g) dissolved in boiling abs. ethanol (20 ml) was mixed with a hot solution of the appropriate Schiff base (1 mmol; 0.337 g of *S*-benzyldithiocarbazate or 0.261 g of *S*-methyldithiocarbazate) in the same solvent (30 ml) and the mixture was then refluxed for one hour. On cooling to room temperature, crystals of the tin complexes were obtained which were filtered off, washed with cold ethanol and dried in a desiccator over silica gel. Yield: 50–60%. Crystals of [Sn(qaldsbz)I_3] suitable for X-ray analysis were obtained during preparation of the complex: [Sn(qaldsbz)I_3]: Calc. for $C_{18}H_{14}N_3S_2SnI_3$: C, 25.87; H, 1.69; N, 5.03. Found: C, 25.73; H, 2.01; N, 5.22%. [Sn(qaldsme)I_3]: Calc. for $C_{12}H_{10}N_3S_2SnI_3$: C, 19.00; H, 1.33; N, 5.53. Found: C, 18.89; H, 1.25; N, 5.38%.

2.4. Crystallography

Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf–Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $2 < 2\theta < 50°$. Empirical absorption correction (ψ scans) and data reduction were performed with the WINGX [18] suite of programmes. The structures were solved by direct methods with SHELX86 and refined by full-matrix least-squares analysis with SHELXL97 [19]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions. Despite absorption correction, significant electron density remained close to the I and Sn atoms in the structure of [Sn(qaldsbz)I_3]. Drawings of each molecule were produced with ORTEP3 [20] or PLUTON [21]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1 and selected bond lengths appear in Tables 4 and 5.

3. Results and discussion

Like thiosemicarbazones and all other Schiff bases derived from *S*-alkyl/aryldithiocarbazates, the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate (Fig. 1(a); R = –SCH_3, *S*-$CH_2C_6H_5$) are also capable of exhibiting thione (**1a**)- thiol (**1b**) tautomerism since they contain the thioamide, -NH–C(=S)S functional group.

However, their IR spectra (Table 2) exhibit broad and weak bands in the 3087–2784 cm^{-1} range attributable to the *sec* NH group of the thione form. The spectra do not show any band at ca. 2700 cm^{-1} that can be assigned to $\bar{\nu}_{SH}$ indicating that, in the solid state, they remain solely as the thione tautomer. However, in solution, they could exist as an equilibrium mixture of both the thione and thiol tautomers. The ^1H NMR spectra of the Schiff bases in DMSO-d_6 (Table 3) show a broad signal at ca. 13.60 ppm attributable to the resonance of the *sec* N(1)H proton. The appearance of the –NH– signal at ~13 ppm and the absence of any signal at ca. 4.00 ppm due to the -SH proton, indicate that in DMSO, both the Schiff bases remain in their thione

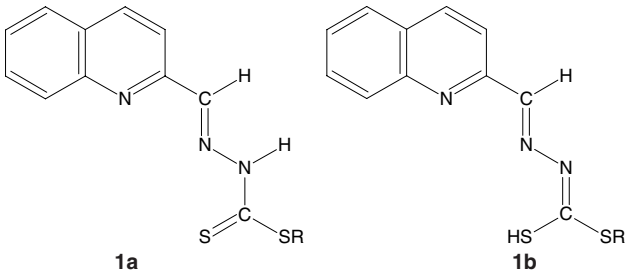

Fig. 1. The thione and thiol forms of the ligands (**1a** – R = CH_3, $CH_2C_6H_5$; thione form), (**1b** – R = CH_3, $CH_2C_6H_5$; thiol form).

forms. The presence of the N(H) signal at ca. 13.60 ppm in the ^{1}H NMR spectra of the Schiff bases also indicates that both Schiff bases remain as the Z isomer with the hydrogen atom on N(1) being intramolecularly H-bonded with the quinoline nitrogen atom similar to that observed in the related 1-quinolinecarboxaldehydethiosemicarbazone [22]. In ethanolic solutions and in the presence of tin(IV) iodide, the ligands quickly convert to the thiol forms with the concomitant formation of tin(IV) complexes of their deprotonated thiolate forms. The ready conversion of a thione tautomer to a thiol form in the presence of a metal ion has been found to be a common property of most Schiff bases derived from *S*-alkyl- and *S*-aryldithiocarbazates [1–10]. Thiosemicarbazones, which are structurally similar to Schiff bases derived from *S*-alkyl- and *S*-aryldithiocarbazates, on the other hand, do not always deprotonate in the presence of metal ions and consequently, complexes of both protonated [18] and deprotonated [19] forms of these ligands have been prepared in neutral media. There are also interesting examples of metal complexes in which both protonated and deprotonated forms of a thiosemicarbazone ligand have been found to be present in the same complex [29]. In contrast with thiosemicarbazones, Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid, almost invariably coordinate in their deprotonated forms even in the presence of mineral acids.

When tin(IV) iodide was allowed to react with the Schiff bases in boiling abs. ethanol, crystalline tin(IV) complexes of empirical formula, [Sn(NNS)I_3] (NNS = anionic form of the Schiff bases) were readily obtained. These compounds are quite stable at ambient temperature. They are sparingly soluble in weak-donor solvents such as acetonitrile, chloroform and dichloromethane but dissolve readily in donor solvents like DMSO. The molar conductance of Sn(qaldsme)I_3 in dichloromethane is 0.80 Ω^{-1} cm^2 mol^{-1} indicating that it is essentially a non-electrolyte in this solvent [30]. The [Sn(qaldsbz)I_3]

[a] Because of insufficient solubilities of [Sn(qaldsme)I_3] and [Sn(qaldsbz)I_3] in $CDCl_3$, their ^{13}C NMR spectra could not be recorded in this solvent.

complex was not sufficiently soluble in dichloromethane and so its conductance in this solvent could not be measured. The very low conductance of [Sn(qaldsme)I_3] in dichloromethane is strong evidence that the Schiff base is coordinated to the tin atom as a uninegatively charged ligand and that the three iodo ligands are also coordinated to the tin ion. The complexes, [Sn(qaldsme)I_3] and [Sn(qaldsbz)I_3] however, exhibit molar conductance values 100.5 and 101.0 $\Omega^{-1}\,cm^2\,mol^{-1}$, respectively, in DMSO indicating that there is extensive dissociation of these complexes in DMSO [30]. The high conductances of these complexes in DMSO lend further support to the NMR results (see later) that extensive solvolysis of the complexes occurs in this solvent.

Relevant IR spectral bands of the ligands and their tin complexes together with their assignments are given in Table 2. A comparison of the IR spectra of the ligands with those of their tin complexes indicate that the $\bar{\nu}_{NH}$ bands of the free ligands are absent in the spectra of the complexes supporting deprotonation of the ligand during coordination with the tin ion. The $\bar{\nu}_{C=N}$ bands of the free ligands at 1617 cm^{-1} are shifted to lower wavenumbers (1600–1585 cm^{-1}) in the spectra of the complexes indicating coordination of the ligand to the tin ion via the azomethine nitrogen atoms. Additional support in favor of coordination of the azomethine nitrogen atom to tin is provided by the shift of the $\bar{\nu}_{N-N}$ bands of the free ligands at 1050–1047 cm^{-1} to higher frequency (1089–1085 cm^{-1}) in the spectra of the complexes [31]. The positive shift of the $\bar{\nu}_{N-N}$ band upon coordination with the tin ion is a consequence of the reduction of repulsion between lone pairs of electrons on the nitrogen atoms. The splitting of the $\bar{\nu}_{aCSS}$ band of the ligand at ca. 900 cm^{-1} in the spectra of the complexes indicates coordination of the ligands to the tin ion via one of the sulfur atoms [32].

The electronic spectral data of the Schiff bases and their tin(IV) complexes in dichloromethane are shown in Table 2. The spectra of the ligands exhibit five bands at ~390, 360, 345, 297 and 252 nm of which the band at ca. 390 nm of the free ligands shows a bathochromic shift in the spectra of the complexes and those at ca. 360 and 346 nm disappear in the spectra of the complexes. The electronic spectra of the present tin complexes do not exhibit any band which can be attributed to ligand-to-metal charge transfer transitions. Electronic spectra of metal complexes of Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid and thiosemicarbazones, invariably exhibit a ligand-to-metal charge transfer (S → M) band [24]. The absence of such a band in the electronic spectra of the present tin(IV) complexes suggests that the metal center is not easily

reduced, i.e. the metal centered orbitals are not accessible by the electrons on the sulfur atom of the ligands.

The ^{1}H and ^{13}C NMR spectral data for the ligands in DMSO-d_6, together with the assignments of the relevant signals, are compiled in Table 3. Because of extensive dissociation of the [Sn(qaldsme)I_3] and [Sn(qaldsbz)I_3] complexes in DMSO, as indicated by the conductance results discussed above, the NMR spepctra of these complexes were recorded in $CDCl_3$. The ^{1}H NMR spectra of the complexes do not contain the signals due to the -NH- protons of the free ligands lending further support to the IR and conductivity results that the ligands are coordinated to the tin atoms in their deprotonated forms. The ^{1}H NMR spectra of the complexes also exhibit downfield shift of the azomethine protons because of the coordination of the ligands via the azomethine nitrogen atom. The quinoline ring protons also exhibit shifts in the complexes relative to that in the free ligands as a result of coordination via the quinoline ring nitrogen atom.

3.1. The crystal structure of Hqaldsbz

A view of the free ligand Hqaldsbz is shown in Fig. 2. The dithiocarbazate moiety shows *E* configurations about the C(1)–N(1), N(1)–N(2) and C(2)–N(2) bonds similar to that exhibited by most semicarbazones [36–38] and thiosemicarbazones [39–41]. The compound contains two planar fragments viz. the quinoline and dithiocarbazate moiety. The planarity in the dithiocarbazate chain is revealed by all dihedral angles along the S(2)–C(1)–N(1)–N(2)–C(2)–C(3) chain being within 2° of 180° (or 0°). All atoms in the quinoline group and those along the S(2)–C(1)–N(1)–N(2)–C(2) chain lie within 0.05 Å of the least-squares plane. The only significant deviations in the dihedral angles from planarity involve the phenyl-methylene bond viz. S(2)–C(12)–C(13)–C(18) 79.8(9)°, which orients the phenyl ring almost orthogonally relative to the best plane defined by the remaining atoms in the molecule.

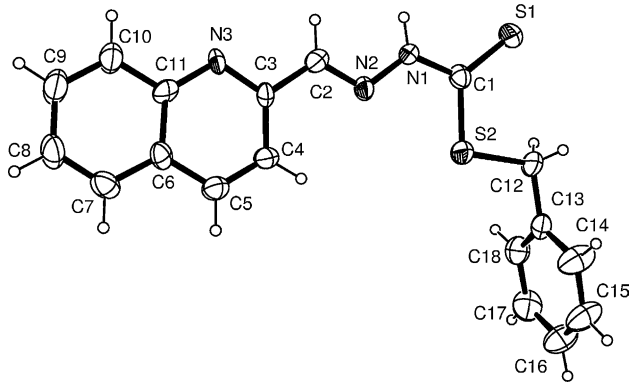

Fig. 2. ORTEP drawing of Hqaldsbz (30% probability ellipsoids).

The bond lengths in the dithiocarbazate chain [NNCSSCH$_2$Ph] (Table 4) are similar to those observed in free dithiocarbazates [31] except that the C(1)–S(1) bond length [1.622(7) Å] (Table 4) in this compound is by far the shortest value observed in this class of ligands indicating that the C–S bond is very close to a double bond and that there is minimal electron delocalization in the C–S bond compared to those in related ligands. However, the C–S bond length still has an intermediate value between 1.82 Å for a single bond and 1.56 Å for a C=S double bond [45]. The C(2)–N(2) distance [1.287(8) Å] corresponds to a double bond whereas the C(1)–N(1) distance [1.352(8) Å] indicates some double bond character. A comparison of the N–N distance [1.372(7) Å] with that in *S*-benzyldithiocarbazate [46] shows that the bond is shorter than a single N–N bond [1.44 Å] indicating that a significant π-charge delocalization occurs along the CNNC moiety. In contrast with *S*-benzyldithiocarbazate, Hqaldsbz has an extensively delocalized group attached to the imino nitrogen atom N(2). The inclusion of resonance forms including the quinoline ring in the ligand would account for the shortening of the N–N distance through extensive electron delocalization.

As is usual in free unsubstituted thiosemicarbazides and *S*-alkyldithiocarbazates, the S atom in Hqaldsbz is *trans* to the azomethine nitrogen atom. The quinoline nitrogen atom and the azomethine nitrogen atoms are also *trans* to each other. Therefore, the configuration of the ligand as observed in the solid state is ill-suited for its coordination with a metal ion as an NNS

Table 4

C(12)–C(13)–C(18)	122.1(9)

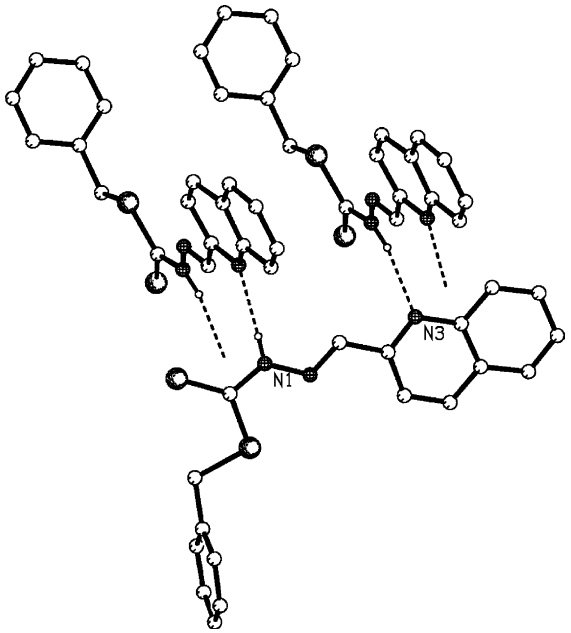

Fig. 3. PLUTON drawing of Hqaldsbz showing the H-bonded chain (amide H-atom shown only).

tridentate chelating agent. However, rotation of the S(2)C(1)S(1) fragment by 180° about the C(1)–N(1) bond and a simultaneous rotation of the quinoline ring by 180° about the C(2)–C(3) bond can place the S(1) atom, the N(2) atom and the quinoline N(3) atom all in the same side thus enabling the ligand to function as an NNS tridentate chelating agent as found for other tridentate thiosemicarbazones [47] and Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid [35].

A notable feature of the crystal structure of Hqaldsbz is the formation of an intermolecular, H-bonded chain linked through the quinoline nitrogen and the amide NH of an adjacent ligand (N(1)–H(1)···N(3)′ 2.17 Å, 169°, symmetry operation $x + 1/2, -y + 3/2, -z + 1$) (Fig. 3).

3.2. The crystal structure of [Sn(qaldsbz)I_3]

The structure of the [Sn(qaldsbz)I_3] complex, together with atom numbering scheme adopted is depicted in Fig. 4 and selected bond lengths and angles are compiled in Table 5. The structure shows that the complex is

a monomer in which the tin atom adopts a six-coordinate geometry being ligated to three iodide ions, two nitrogen atoms and one sulfur atom. The Schiff base is coordinated to the tin atom as a uninegatively charged chelating agent in its deprotonated thiolate form via the thiolate sulfur atom, the azomethine nitrogen atom and the quinoline nitrogen atom.

There is an extensive delocalization of the negative charge, which is generated upon deprotonation of the ligand, in the C–N–N–C chain as indicated by the intermediate C(2)–N(2) [1.30(3) Å], N(1)–N(2) [1.38(2) Å] and N(1)–C (1) [1.28(3) Å] bond distances. The two Sn–N distances are close to the sum of the non-polar covalent radii 2.15 Å [50] indicating strong tin-nitrogen interaction. However, as found in other tin(IV) complexes of related tridentate thiosemicarbazone ligands [51], the Sn–N_{azom} bond distance [2.198(17) Å] in the present complex is shorter than the Sn–$N_{quinoline}$ distance [2.377(18) Å]. The stronger coordination of the tin atom to the azomethine nitrogen compared with the quinoline nitrogen atom is consistent with the higher basicity of the azomethine nitrogen atom, and also a consequence of the atom being shared by adjacent five-membered chelate rings. The Sn–S distance is longer than the sum of the covalent radii (2.42 Å) but is considerably shorter than the van der Waals radii (4.0 Å) [52]. A comparison of the Sn–S, Sn–$N_{quinoline}$ and Sn–$N_{azom.}$

distances with those for [Sn(pytsc)Cl_3] [51] which also has a distorted octahedral geometry, shows that the lengths of these bonds compare well with those in [Sn(pytsc)Cl_3] although the Sn–S bond in the present complex is slightly weaker than that in [Sn(pytsc)Cl_3] [51]. In the present tin complex, the Schiff base shows an *E* configuration about both the C(2)–N(2) and C(1)–N(1) bonds similar to those in other complexes of related ligands [51]. The C–S bond distance [1.71(2) Å] is slightly longer than that in the free ligand, but caution should be exercised in drawing comparisons due to the poorer precision of this structure compared with that of the free ligand. However, the apparent lengthening of the C–S bond in the complex is consistent with the ene-thiolate resonance form of the ligand being the major contributor.

An examination of the bond angle data for [Sn(qaldsbz)I_3] (Table 5) indicates that the complex has a distorted octahedral structure in which the iodide ions are meridionally coordinated to the tin(IV) ion. The two *trans*-disposed iodo ligands exhibit slightly longer bonds to tin than the remaining iodo ligand, which is *trans* to the azomethine nitrogen atom. A similar difference in the Sn–Cl bond lengths has also been observed in the related six-coordinate tin(IV) complex [$SnCl_3$(pytsc)] whose structure has been determined by X-ray diffraction [51]. The distortion of [Sn(qaldsbz)I_3] from an ideal octahedral geometry is reflected in all the twelve bond angles subtended at the tin atom which show substantial deviation from that required for an ideal octahedral geometry. The largest deviation from ideal values are observed for the angles S(1)–Sn(1)–N(3) [149.1(5)° versus 180°], N(2)–Sn(1)–S(1) [77.1(4)° versus 90°], N(2)–Sn(1)–N(3) [72.0(6)° versus 90°]. The deviation from octahderal geometry is due to the restricted bite size of the ligand.

4. Conclusions

The 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazates, like most other Schiff bases derived from *S*-alkyl esters of dithiocarbazic acid, remain as the thione tautomer in the solid state, and remain predominantly in this form in solution but, in the presence of tin(IV) iodide they convert to the iminothiol form, deprotonate and coordinate with the tin atom as uninegatively charged NNS tridentate chelating agents with the elimination of HI. The complexes adopt a distorted octahedral geometry as a result of the strain imposed by the five-membered chelate rings, Sn1–N3–C3–C2–N2 and Sn1–N2–N1–C1–S1. They appear stable in the solid state and in solutions of non-donor solvents such as chloroform and dichloromethane but they are extensively dissociated in donor solvents such as DMSO.

5. Supplementary material

Full crystallographic data (CCDC 239922 for Hqaldsbz and CCDC 239923 for [Sn(qaldsbz)I_3] have been deposited at the Cambridge Crystallographic Data Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The isomeric flexible double betaines 1,4-bis(2-picolyloxyl)benzene-*N*,*N*′-diacetate (L^1), 1,4-bis(3-picolyloxyl)benzene-*N*,*N*′-diacetate (L^2) and 1,4-bis(4-picolyloxyl)benzene-*N*,*N*′-diacetate (L^3) were used to react with $AgNO_3$, affording coordination polymeric complexes $\{[Ag_2L^1](NO_3)_2 \cdot 3.5H_2O\}_n$ (**1**), $\{[Ag_2L^1](NO_3)_2 \cdot 6H_2O\}_n$ (**2**) and $\{[Ag_3L^3](NO_3)_3 \cdot 3H_2O\}_n$ (**3**). The crystal structures of the betaine hydrates $L^1 \cdot 8H_2O$, $L^2 \cdot 6H_2O$, $L^3 \cdot 5H_2O$ and the silver(I) complexes have been determined. $L^1 \cdot 8H_2O$ consists of a hydrogen-bonded three-dimensional network, whereas both $L^2 \cdot 6H_2O$ and $L^3 \cdot 5H_2O$ feature hydrogen bonded two-dimensional frameworks. In complex **1**, the Ag(I) ions in the dimeric unit have different coordination environments; through the linkage of L^1 ligands and nitrates, the dimeric units are extended into a polymeric double chain. In complex **2**, each Ag(I) ion of the centrosymmetric dimeric unit adopts a severely distorted tetrahedral coordination geometry; the dimeric subunits are connected by the L^2 ligands, giving an infinite one-dimensional chain, and the chains are further connected through hydrogen bonding to generate an infinite three-dimensional network. In complex **3**, three Ag(I) ions constitute an isosceles triangle consolidated by weak Ag···Ag interactions, and such trinuclear subunits are further connected by the L^3 ligands, nitrate ions and water molecules through coordination and hydrogen bonding, yielding a three-dimensional network.

1. Introduction

Supramolecular assembly has been employed as a powerful tool in the design of metallo-organic based complex molecular architectures [1]. Furthermore, strong, selective and directional hydrogen bonding and π–π interactions have been fully exploited for the generation of metal-organic complexes, and molecular recognition associated with biological activity and the crystal engineering of molecular solids have attracted much recent attention [2]. For some time we have been engaged in the investigation of inorganic polymeric structures using various double betaine ligands each comprising two carboxylate betaine moieties [3]. Recent studies have shown that the variation of double betaine ligands regarding the type of bridging units, the flexibility of the molecular backbone, conformational preference, as well as the metal ions and counter ions employed, has a profound influence on the polymeric structures obtained [4]. In the present work, we report three isomeric double betaine ligands: 1,4-bis(2-picolyloxyl)benzene-*N*,*N*′-diacetate (L^1) [5], 1,4-bis(3-picolyloxyl)benzene-*N*,*N*′-diacetate (L^2) [6] and 1,4-bis(4-picolyloxyl)benzene-*N*,*N*′-diacetate (L^3) (Scheme 1) and determined the structures of their crystalline hydrates $L^1 \cdot 8H_2O$,

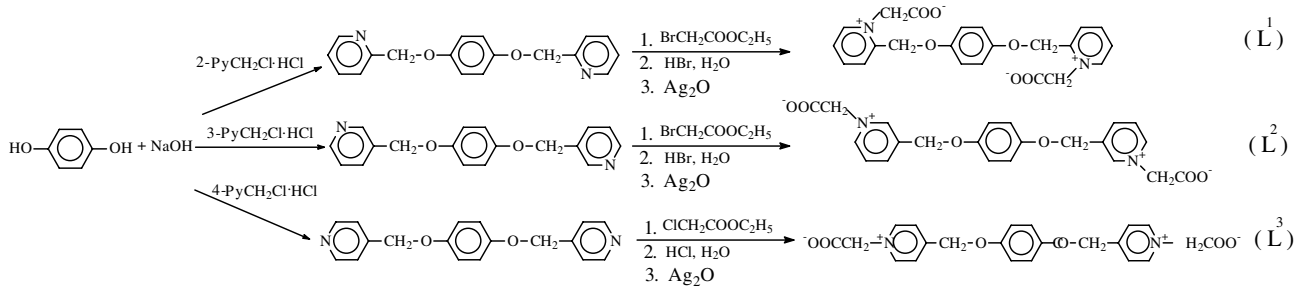

Scheme 1. Synthesis procedure for isomeric ligands.

$L^2 \cdot 6H_2O$ and $L^3 \cdot 5H_2O$ by single crystal X-ray analysis. As Ag(I) is known to exhibit flexible coordination geometries (linear, bent, trigonal planar, T-shaped, tetrahedral, trigonal pyramidal) in its complexes with polydentate ligands [7], we decided to study the coordination behavior of the isomeric double betaine ligands through the synthesis and structural characterization of their silver(I) complexes $\{[Ag_2L^1](NO_3)_2 \cdot 3.5H_2O\}_n$ (**1**), $\{[Ag_2L^2](NO_3)_2 \cdot 6H_2O\}_n$ (**2**) and $\{[Ag_3L^3](NO_3)_3 \cdot 3H_2O\}_n$ (**3**).

Although complex **2** and **3** were synthesized by the same procedure as that for complex **1**, the products differ in regard to their silver(I) coordination modes and overall structures, which may be attributed to the different positions of the betaine moieties in the relevant ligands. Complex **1** and **2** are both binuclear polymers, which are bridged by the carboxylate group in the common *syn–syn* bidentate mode [8]. However complex **3** is trinuclear, being bridged by the carboxylate group in the tridentate μ-*O*,*O*′$_{syn}$-μ-*O*,*O* mode [8].

2. Experimental

2.1. General

All chemicals were obtained commercially (Aldrich) and used without further purification. Elemental analyses of C, H and N were performed by the MEDAC LTD Vrunel Science Centre, United Kingdom. IR spectra were recorded with a Nicolet Impact 420 FT-IR spectrometer using KBr pellets. ^{1}H NMR spectra were taken at 300 Hz with a Bruker-300 spectrometer using D_2O as solvent.

2.2. Synthesis of the hydrate of 1,4-bis(2-picolyloxyl)benzene-N,N′-diacetate ($L^1 \cdot 8H_2O$)

We have reported the synthesis of 1,4-bis(2-picolyloxyl)benzene-*N*,*N*′-diacetate (L^1) previously (Scheme 1) [5]. The light yellow hydrate $L^1 \cdot 8H_2O$ is obtained by re-crystallization of the dehydrated solid of L^1 in water. *Anal.* Calc. for $C_{22}H_{20}N_2O_6 \cdot 8H_2O$: C, 47.82; H, 6.57; N, 5.07. Found: C, 47.69; H, 6.37; N, 5.13%. IR (KBr, cm^{-1}): 3472 brs, 3074 w, 1635 s, 1512 s, 1444 s, 1372 s, 1239 s, 1211 m, 1072 m, 818 m, 775 w, 718 w. ^{1}H NMR (300 Hz, D_2O): δ 5.20 (s, 4H), 5.42 (s, 4H), 7.01 (s, 4H), 8.02 (t, 2H), 8.18 (d, 2H), 8.52 (t, 2H), 8.79 (d, 2H) (Table 1).

2.3. Synthesis of the hydrate of 1,4-bis(3-picolyloxyl)benzene-N,N′-diacetate ($L^2 \cdot 6H_2O$)

1,4-Bis(3-picolyloxyl)benzene-*N*,*N*′-diacetate (L^2) [6] was recrystallized in water to obtain $L^2 \cdot 6H_2O$. *Anal.* Calc. for $C_{22}H_{20}N_2O_6 \cdot 6H_2O$: C, 51.16; H, 6.24; N, 5.42. Found: C, 51.19; H, 6.71; N, 5.44%. IR (KBr, cm^{-1}) 3399 brs, 3073 w, 1639 s, 1508 m, 1451 w, 1373 s, 1231 s, 1059 m, 917 w, 809 w, 769 w, 711 w. ^{1}H NMR (300 Hz, D_2O): δ 5.18 (s, 4H), 5.32 (s, 4H), 7.01 (s, 4H), 8.03 (dd, 2H), 8.56 (d, 2H), 8.68 (d, 2H), 8.83 (s, 2H) (Table 1).

2.4. Synthesis of the hydrate of 1,4-bis(4-picolyloxyl)benzene-N,N′-diacetate ($L^3 \cdot 5H_2O$)

This compound was synthesized in the same way as $L^1 \cdot 8H_2O$, but ethyl chloroacetate was used instead of ethyl bromoacetate and 4-picolylchloride hydrochloride

Table 1
^{1}H NMR spectroscopic data for the series of double betaines L^1, L^2 and L^3

Compound	$\delta_{1,3\text{-H}}$	$\delta_{4\text{-CH}_2\text{–}}$	$\delta_{11\text{-CH}_2\text{–}}$	$\delta_{6\text{-H}}$	$\delta_{7\text{-H}}$	$\delta_{8\text{-H}}$	$\delta_{9\text{-H}}$	$\delta_{10\text{-H}}$
L^1	7.01	5.42	5.20		8.79	8.52	8.02	8.18
L^2	7.01	5.32	5.18	8.83		8.68	8.03	8.56
L^3	7.01	5.43	5.15	8.06	8.66		8.66	8.06

instead of 2-picolylchloride hydrochloride. *Anal.* Calc. for $C_{22}H_{20}N_2O_6 \cdot 5H_2O$: C, 53.01; H, 6.07; N, 5.62. Found: C, 52.80; H, 5.76; N, 5.64%. IR (KBr, cm^{-1}) 3419 brs, 3073 w, 1641 s, 1512 m, 1441 w, 1373 s, 1228 m, 1062 m, 897 w, 829 w, 729 w. ^{1}HNMR (300Hz, D_2O): δ 5.15 (s, 4H), 5.43 (s, 4H), 7.01 (s, 4H), 8.06 (d, 4H), 8.66 (d, 4H) (Table 1).

2.5. Synthesis of $\{[Ag_2L^1](NO_3)_2 \cdot 3.5H_2O\}_n$ (1)

Aqueous solutions of L^1 (dehydrated) (6 ml; 0.08 g, 0.2 mmol) and $AgNO_3$ (4 ml; 0.17 g, 1 mmol) were mixed together and heated at 70 °C for 10 min with continuous stirring, and then filtered. Upon slow evaporation of the filtrate at room temperature, light yellow needle-shaped crystals of **1** were obtained after several weeks (ca. 46% yield based on L^1). *Anal.* Calc. for $C_{22}H_{27}Ag_2N_4O_{15.5}$: C, 32.57; H, 3.35; N, 6.91. Found: C, 32.69; H, 3.51; N, 6.73%. IR (KBr, cm^{-1}): 3429 brs, 3066 w, 1624 s, 1509 m, 1380 s, 1232 m, 1078 w, 910 w, 823 w, 776 w, 715 w, 614 w.

2.6. Synthesis of $\{[Ag_2L^2](NO_3)_2 \cdot 6H_2O\}_n$ (2)

This complex was prepared as colorless needle-like crystals by the procedure described for **1** using L^2 instead of L^1 (ca. 63% yield based on L^2). *Anal.* Calc. for $C_{22}H_{32}Ag_2N_4O_{18}$: C, 30.86; H, 3.77; N, 6.54. Found: C, 30.41; H, 3.46; N, 6.40%. IR (KBr, cm^{-1}): 3432 brs, 3066 w, 1638 s, 1506 m, 1380 s, 1228 m, 1058 w, 910 w, 829 w, 715 w, 628 w.

2.7. Synthesis of $\{[Ag_3L^3](NO_3)_3 \cdot 3H_2O\}_n$ (3)

This complex was prepared as colorless block-like crystals by the procedure described for **1** using L^3 instead of L^1 (ca. 37% yield based on L^3). *Anal.* Calc. for $C_{22}H_{20}Ag_3N_5O_{15}$ (thoroughly dried sample): C, 28.78; H, 2.20; N, 7.63. Found: C, 28.42; H, 2.18; N, 7.34%. IR (KBr, cm^{-1}): 3441 brs, 3046 w, 1633 s, 1508 m, 1381 s, 1232 m, 1058 w, 923 w, 823 w, 715 w, 588 w.

2.8. X-ray crystallography

Intensity data of all compounds were collected on a Bruker SMART 1000 CCD diffractometer with graphite-monochromatized Mo K radiation ($\lambda = 0.71073$ Å) at 293 K [9]. The structures were solved by direct methods and refined by full-matrix least squares based on F^2 using the SHELXTL program package [10]. All the non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were generated geometrically except for those of the water molecules, which were located from the ΔF maps. Complex **3** belongs to non-centric space group $P1$, and the structure is refined as a racemic twin. The crystallographic data of the hydrated ligands and complexes **1**–**3** are summarized in Table 2, and

selected bond distances and angles for **1**–**3** are given in Table 3.

3. Results and discussion

3.1. Supramolecular structures of three isomeric double betaines hydrates

Betaine compounds are good proton acceptors, so they readily form stoichiometric hydrates upon crystallization in water [11].

The crystal structure of $L^1 \cdot 8H_2O$ exhibits a hydrogen-bonded three-dimensional network. There are two independent double betaine molecules (labeled **A** and **B**) each located at an inversion center, and intermolecular π–π overlap occurs between the phenylene ring of one and a pyridyl ring of the other in the "T" fashion, with a separation of 3.846 Å between the ring centers and a dihedral angle of 6.3° (Fig. 1). The two parallel pyridyl rings of each molecule are twisted with respect to the phenylene ring; the dihedral angle is 6.4° for molecule **A** and 5.1° for molecule **B**. The torsion angle C(9)–O(3)–C(8)–C(3) in molecule **A** is 174.2(2)°, and in molecule **B** the torsion angle C(20)–O(6)–C(19)–C(14) is 176.5(2)°. Both carboxymethyl groups of each double betaine molecule lie on opposite sides of the pair of pyridine rings. The oxygen atoms of the carboxylate group are not equidistant to the positively charged nitrogen atom [N(1)···O(1) 2.72, N(1)···O(2) 3.62 Å; N(2)···O(4) 2.72, N(2)···O(5) 3.62 Å], and the C–O bonds are different in length [C(1)–O(1) 1.239(4), C(1)–O(2) 1.246(4) Å; C(12)–O(4) 1.226(3), C(12)–O(5) 1.242(3) Å]. The close proximity of O(1) to N(1) and O(4) to N(2) facilitate internal charge neutralization. The torsion angles O(1)–C(1)–C(2)-N(1) and O(2)–C(1)–C(2)-N(1) are −2.4(4)° and 177.0(3)°, respectively. For molecule **B**, the torsion angles O(4)–C(12)–C(13)–N(2) and O(5)–C(12)–C(13)–N(2) are −5.9(4)° and 174.3(2)°, respectively. In molecule **A**, the plane of the carboxylate group is nearly perpendicular to the pyridine plane (dihedral angle 88.8°), but in molecule **B** the dihedral angle is about 94.0°. The water molecules are joined together by strong O—H···O hydrogen bonds and occupy the hydrophilic region between double betaine molecules. In particular, a pair of independent water molecules O1W and O2W, together with their centrosymmetrically-related partners, connects two centrosymmetrically-related carboxylate oxygen atoms of betaine molecules **A** and **C** by strong O—H···O$^-$ hydrogen bonds to generate a chair-like six-member ring of the type O1W···O2WB···O4B···O1WB···O2W···O(4). This six-member ring is further linked by two pairs of bridging water molecules derived from O3W and O8W to fuse with another pair of non-planar six-member

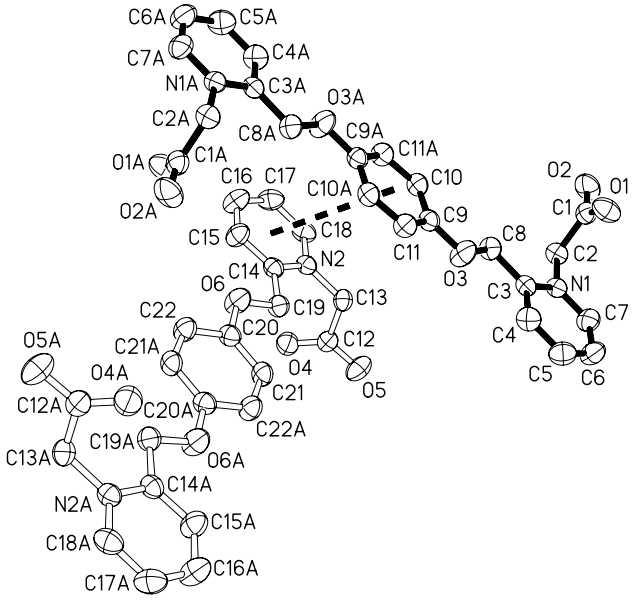

Fig. 1. π–π Interaction between two betaine molecules in the "T" fashion of $L^1 \cdot 8H_2O$. Hydrogen atoms and water molecules are omitted for clarity. Displacement ellipsoids are plotted at the 30% probability level. Symmetry transformations: (A) $-x$, $-y+1$, $-z+1$; (B) $-x+1$, $-y+2$, $-z+1$.

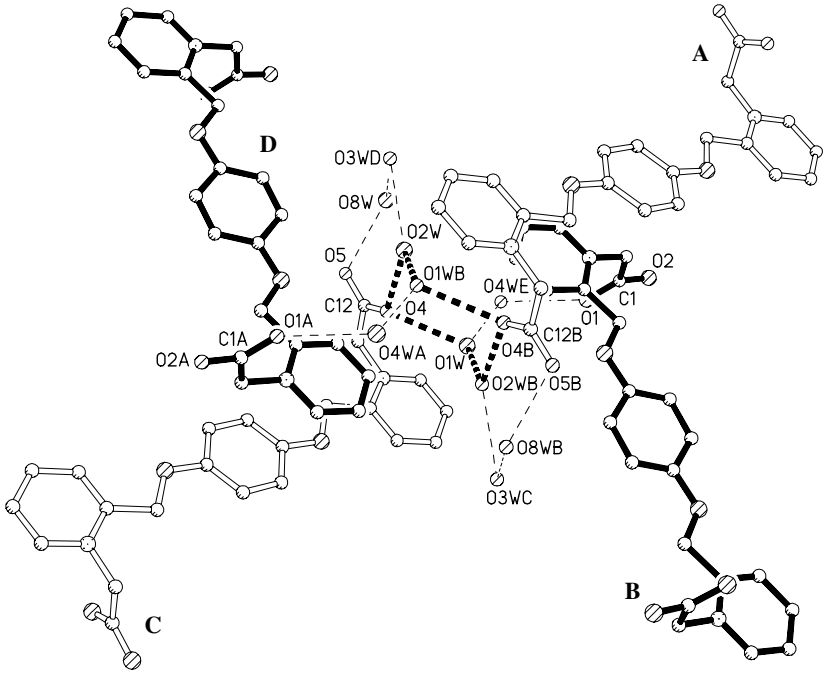

Fig. 2. Scheme of hydrogen bonding in $L^1 \cdot 8H_2O$. Two types of symmetry-related molecules are drawn in different bond types, and the centrosymmetric chair-like six-member ring is highlighted by bold dotted lines. Hydrogen atoms are omitted for clarity. Symmetry transformations: (A) $-x + 1, -y + 1, -z + 1$; (B) $-x + 1, -y + 1, -z + 2$; (C) $-x, -y + 1, -z + 2$ and (D) $x + 1, y, z$.

rings O2W···O(4)—C(12)—O(5)···O8W···O3WD and O2WB···O4B—C12B—O5B···O8WB···O3WC. Another pair of symmetry-related betaine molecules **B** and **D** are joined to this hydrogen-bonded ring system through a pair of bridging water molecules derived from O4W with strong O—H···O^- hydrogen bonds of the type O2W···O4W···O(1) (Fig. 2). In this way, the betaine molecules are alternately bridged by water molecules to produce an infinite three-dimensional network (Fig. 3). Details of the hydrogen bonding scheme are shown in Table 4.

In the crystal structure of $L^2 \cdot 6H_2O$ (Fig. 4), L^2 is located at an inversion center, and each pyridyl ring is twisted by 8.6° with respect to the phenylene ring. The torsion angle C(9)–O(3)–C(8)–C(4) is −172.8(2)°. The oxygen atoms of the carboxylate group are not equidistant to the positively charged nitrogen atom [N(1)···O(1) 2.71, N(1)···O(2) 3.61 Å], and the close proximity of O(1) to N(1) also facilitates internal charge neutralization. The torsion angle O(1)–C(1)–C(2)–N(1) is 6.7(3)°. The plane of the carboxylate group makes a dihedral angle of 77.6° with the pyridine plane. The L^2 betaine molecules are stacked along the *a*-axis and interlinked by strong O—H···O^- hydrogen bonds with water molecules derived from O1W to form an infinite chain (Fig. 5). The remaining two independent water molecules O2W and O3W together with their symmetry-related partners generate a pleated ladder characterized by an alternating arrangement of $R_4^2(8)$ and $R_4^4(8)$ hydrogen bonding motifs (Fig. 6a) running parallel to the *a*-axis. This functions as a wide bridging ribbon to connect adjacent chains of water-bridged double betaines by strong O—H···O^- hydrogen bonds to form a

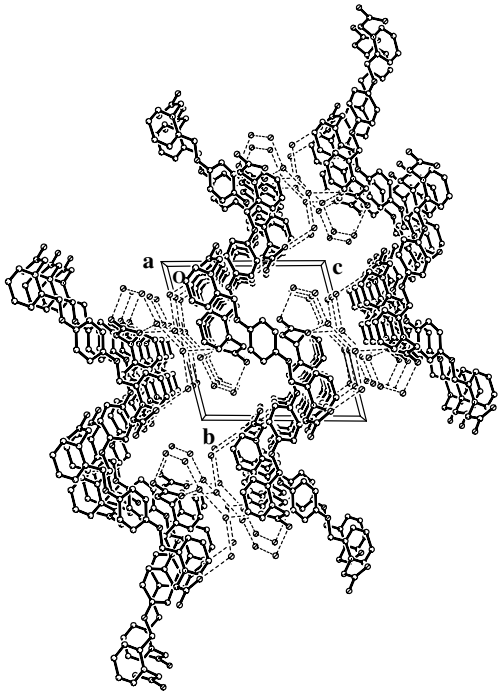

Fig. 3. Three-dimensional framework connected by hydrogen bonds in $L^1 \cdot 8H_2O$. Hydrogen atoms are omitted for clarity. Displacement ellipsoids are plotted at the 30% probability level.

Symmetry codes. For $L^1 \cdot 8H_2O$: (i) $-x+1, -y+1, -z+2$; (ii) $x+1, y, z$; (iii) $-x, -y, -z+1$; (iv) $x, y, z+1$; (v) $x, y, z-1$; (vi) $-x, -y, -z$. For $L^2 \cdot 6H_2O$: (i) $x+1, y, z$; (ii) $x-1, y, -z$; (iii) $-x+1, -y+1, -z+1$. For $L^3 \cdot 5H_2O$: (i) $x, -y+1, z+1/2$; (ii) $-x, -y+1, -z$; (iii) $-x+1/2, -y+1/2-z$. For compound **1**: (i) $-x+1, -y, -z$; (ii) $-x+1, -y, -z+1$; (iii) $x-1, y+1, z-1$. For Compound **2**: (i) $x-1, y, z$; (ii) $-x, y+1/2, -z+3/2$; (iii) $x+1, y, z$. For compound **3**: (i) $x+1, y, z$; (ii) $x, y-1, z$.

[a] d(D–H) is set to 0.92 Å for all compounds.

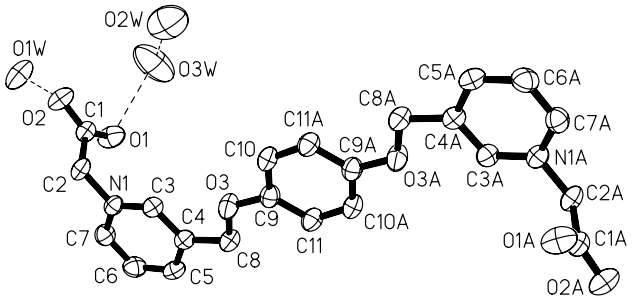

Fig. 4. Asymmetric unit with atom labeling in $L^2 \cdot 6H_2O$. Hydrogen atoms are omitted for clarity.

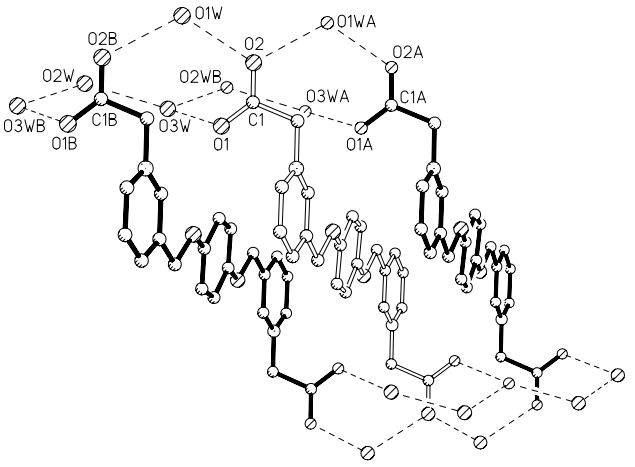

Fig. 5. Perspective diagram showing the hydrogen-bonding interactions between the double betaine and the water molecules in $L^2 \cdot 6H_2O$. Hydrogen atoms are omitted for clarity. Symmetry transformations: (A) $x-1, y, z$ and (B) $x+1, y, z$.

corrugated layer (Fig. 6b) featuring a ten-member ring motif of the type O(1)—C(1)—O(2)···O1W···O2B—C1B—O1B···O3WB···O2W···O3W (Fig. 5). There is no distinct π–π interaction in this structure, and the hydrogen bonds are shown in Table 4.

$L^3 \cdot 5H_2O$ shows the hydrogen bonded two-dimensional network. The molecular backbone of the double betaine L^3 has a twofold axis passing through the mid points of the C(10)–C(10A), C(11)–C(11A) bonds, being different from those of L^1 and L^2 (Fig. 7). The two pyridyl rings are not parallel to each other but make a dihedral angle of 5.3°, and each is twisted by 3.7° with respect to the phenylene ring. The torsion angle C(5)–C(8)–O(3)–C(9) is −178.6(2)°. Both carboxymethyl groups also lie on opposite sides of the two pyridine rings. The two oxygen atoms of the carboxylate group are not equidistant to the positively charged nitrogen atom [N(1)···O(1) 2.73, N(1)···O(2) 3.60 Å], facilitating internal charge neutralization. The torsion angles O(1)–C(1)–C(2)–N(1) and O(2)–C(1)–C(2)–N(1) are 8.8(4)° and −173.0(2)°, respectively. The carboxylate group makes a dihedral angle of 99.4° with the pyridine plane. Water molecules derived from O1W bridge two adjacent

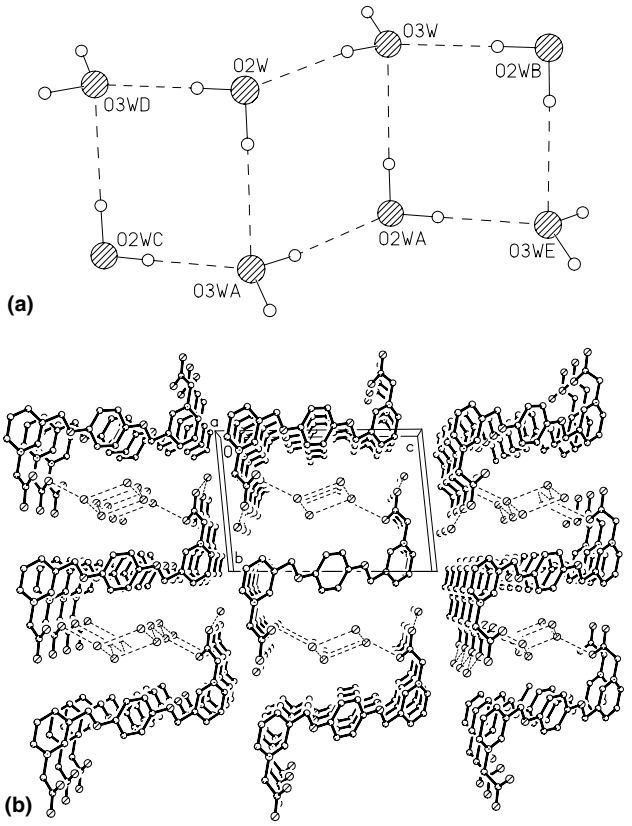

Fig. 6. (a) Water molecules are connected by strong O—H···O hydrogen bonds and form a "water-ladder" running along the *a*-axis in $L^2 \cdot 6H_2O$. Symmetry transformations: (A) $-x+1, -y+1, -z+1$; (B) $x+1, y, z$; (C) $-x, -y+1, -z+1$; (D) $x-1, y, z$ and (E) $-x+2, -y+1, -z+1$. (b) Perspective view of the crystal structure of $L^2 \cdot 6H_2O$ along the *a*-axis showing highly pleated sheets composed of "water-ladders" and double betaine molecules. The sheets are further consolidated by the terminal water molecules.

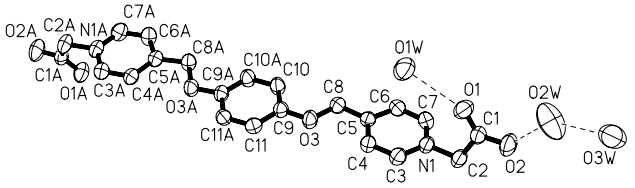

Fig. 7. Asymmetric unit with atom labeling in $L^3 \cdot 5H_2O$. Displacement ellipsoids are plotted at the 30% probability level.

L^3 molecules by pairs of strong O—H···O^- hydrogen bonds. The other two independent water molecules O2W and O3W together with their symmetry-related partners form a zigzag water chain running along the *c*-axis. This zigzag water chain interlinks two neighboring sets of betaines further by strong O—H···O^- hydrogen bonds to generate an infinite two-dimensional network (Fig. 8). The betaine molecules are associated through π–π interactions between the pyridyl and phenylene rings of adjacent molecules with a separation of 3.57 Å between ring centers and a twist angle of 3.7° between the planes. The metric parameters of the hydrogen bonds are shown in Table 4.

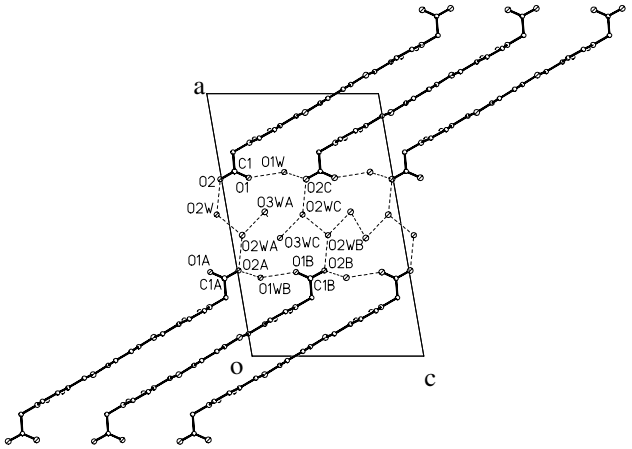

Fig. 8. Two-dimensional network connected by hydrogen bonds in $L^3 \cdot 5H_2O$. Symmetry transformations: (A) $-x$, $-y+1$, $-z$; (B) $-x+1/2$, $-y+1/2$, $-z$; (C) x, $-y+1$, $z+1/2$.

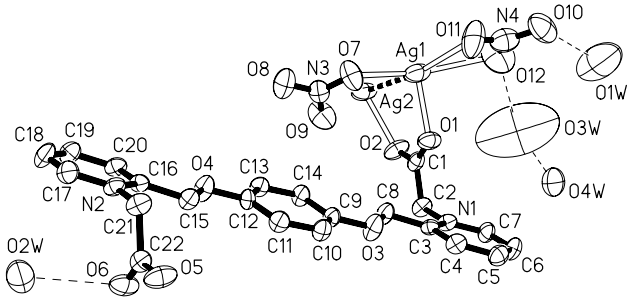

Fig. 9. Asymmetric unit and atom labeling in compound **1** with thermal ellipsoids represented at the 30% probability level. All hydrogen atoms are omitted for clarity.

3.2. Supramolecular structures of Ag(I) complexes of three isomeric double betaines

Molar ratio 5:1 was chosen to carry out the reaction between $AgNO_3$ and the three isomeric double betaine ligands L^1, L^2 and L^3. Excess $AgNO_3$ was used to prevent the deposit of the hydrated ligands. Complexes **1**, **2** and **3** exhibit different polymeric molecular structures, being bridged by the carboxylate groups in bidentate and/or tridentate mode, which may be attributed to the different positions of the betaine moieties in the relevant ligands.

The structure of $\{[Ag_2L^1](NO_3)_2 \cdot 3.5H_2O\}_n$ **1** is a one-dimensional double-chain network containing dimeric subunits (Fig. 9). The Ag···Ag separation (2.873(1)Å) in the dimeric subunit is close to that in metallic silver, indicating a comparable d^{10}–d^{10} closed-shell [12] attractive argentophilic interaction [13]. The two independent silver ions have different coordination environments. The coordination geometry around Ag(1) can be described as a distorted trigonal bipyramid surrounded by two μ_2-carboxylate groups and two nitrate ligands. The Ag(1)–O distances for the μ_2-carboxylate groups are Ag(1)–O(1), 2.224(5) Å and Ag(1)–O(5a), 2.234(5) Å, (a: x, $y+1$, $z-1$). Each Ag(1) atom also makes two intermediate contacts (Ag(1)–O(11), 2.608(7) and Ag(1)–O(12), 2.688(8) Å) with the oxygen atoms of a bidentate chelating nitrate and one bond (Ag(1)–O(7), 2.646(5) Å) to a tridentate nitrate. The Ag(2) atom is coordinated by two oxygen atoms from two different carboxylate groups (Ag(2)–O(2), 2.256(5) Å and Ag(2)–O(6a) 2.253(5) Å) and two oxygen atoms from a tridentate chelating nitrate (Ag(2)–O(8b), 2.2660(7) and Ag(2)–O(9b), 2.698(6) Å; b: $-x+1$, $-y+1$, $-z$), giving a distorted tetragonal pyramidal coordination geometry. The dimeric subunits are extended into an infinite chain in the [0 1 1] direction through the linkage of double betaine ligands L^1. In this compound, the two pyridyl rings of L^1 ligand are not parallel to each other as in its hydrate crystals, but twist 3.7° to bridge the Ag(I) ions. Two adjacent chains are further connected through tridentate nitrate ions (Ag(1)–O(7), Ag(2b)–O(8), Ag(2b)–O(9), generating an infinite double-chain structure, which contains cavities of size 12×6 Å. These double chains are further

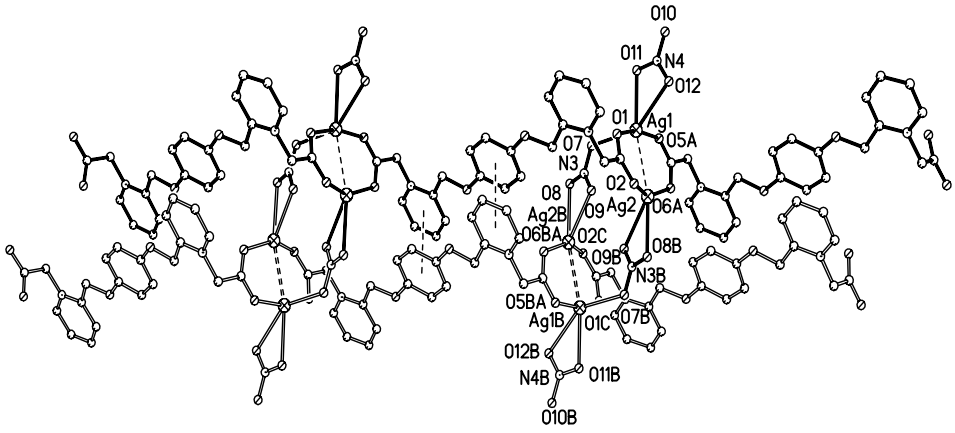

Fig. 10. Double-chain polymeric structure of compound **1**, showing the π–π interactions formed between the ligands and Ag···Ag interactions. Lattice water molecules and all hydrogen atoms are omitted for clarity.

consolidated through π–π stacking interactions between adjacent phenylene rings and pyridyl rings, with centroid-to-centroid distance 3.879 Å and dihedral angle 7.8° (Fig. 10). The lattice water molecules O1W, O2W, O3W and O4W (disorder, with half occupation) are accommodated in the cavities and the space between the double-chain structures, connecting to the chain through hydrogen bonds (Table 4).

Complex **2**, $\{[Ag_2L^2](NO_3)_2 \cdot 6H_2O\}_n$, is also a dimeric complex but different from complex **1**. The asymmetric unit of **2** only contains a silver ion, one half of a centrosymmetric L^2 double betaine ligand, a nitrate ion and three water molecules. The Ag1 ion is tetrahedrally coordinated by two oxygen atoms from two L^2 ligands (Ag(1)–O(1), 2.228(5) Å; Ag(1)–O(2a), 2.251(4) Å; a: $-x$, $-y+1$, $-z+1$) and two aqua ligands (Ag(1)–O1W, 2.378(5) Å; Ag(1)–O2W, 2.590(6) Å). The other Ag1a ion of the dimeric center is generated by the symmetry operator $-x$, $-y+1$, $-z+1$ at a separation of 2.826(1) Å from Ag(1), close to that in metallic silver as in complex **1**. Similarly, the other half of the L^2 ligand is obtained through the symmetry operator ($-x-1$, $-y+2$, $-z+1$) (Fig. 11). The pyridyl ring of ligand L^2 is twisted by 8.8° with respect to the phenylene ring. The combined effect of these connections is to render a series of one-dimensional zigzag chains in the crystal lattice. These chains are further connected by the hydrogen bond O2W–H2WA···O(1b), 170.6°; O2W···O(1b), 2.791(8)Å (b: $x-1$, y, z) (Table 4), generating an infinite two-dimensional layer structure parallel to the *ab*-plane (Fig. 12). The π–π stacking interactions are also found between the pyridyl rings and the phenylene rings of adjacent L^2 ligands in this plane, with an inter-ring distance of 3.92 Å and dihedral angle 8.8°. The layers are extended into a three-dimensional network through the connection of the hydrogen bonds (Table 4, Fig. 13).

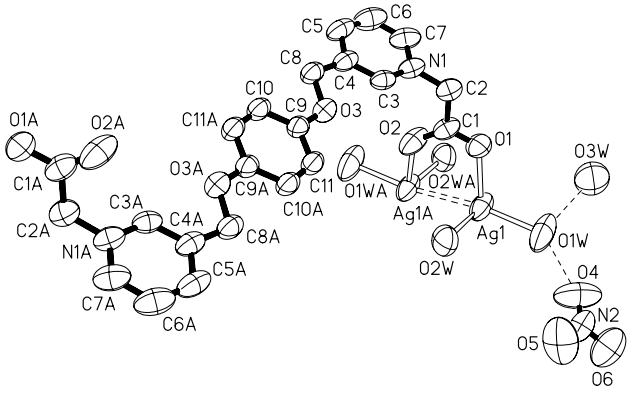

Fig. 11. Asymmetric unit and atom labeling in compound **2** with thermal ellipsoids represented at the 30% probability level. All hydrogen atoms are omitted for clarity.

The asymmetric unit of complex **3**, $\{[Ag_3L^2](NO_3)_3 \cdot 3H_2O\}_n$, consists of three silver atoms at the apices of an isosceles triangle, a L^3 ligand, three nitrate ions, two coordinated and two halves lattice water molecules (Fig. 14). In this compound, the molecular back-

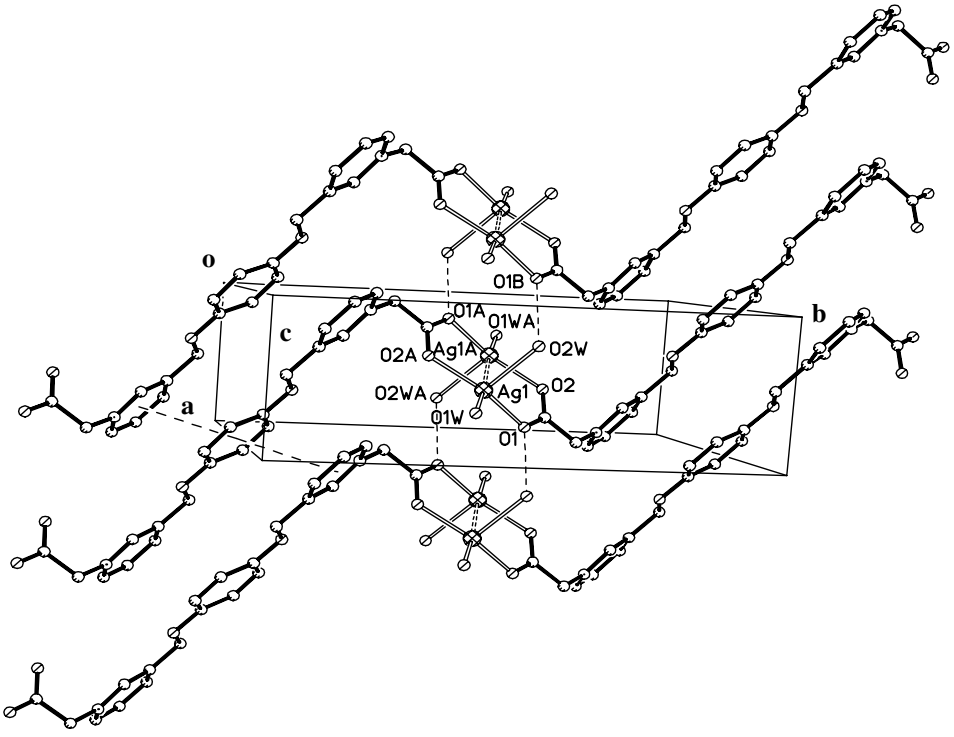

Fig. 12. View of the two-dimensional layer structure in compound **2**, in which the chains are connected through hydrogen bonding and π–π interactions. Lattice water molecules, hydrogen atoms, and all other atoms, which make no contribution to this connection, are omitted for clarity.

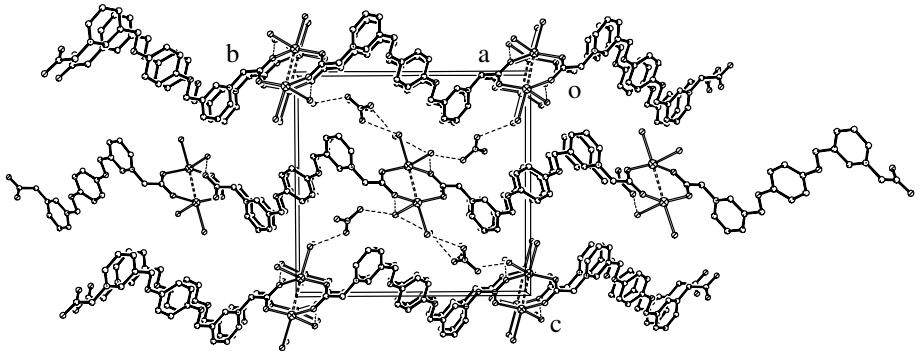

Fig. 13. Three-dimensional network of **2**, which are connected by hydrogen bonds through the nitrate ions.

bone of the double betaine L^3 does not possess C_2 symmetry as in its hydrate, and the two pyridyl rings of ligand L^3 are not parallel to each other, but twisted by 3.1° to link the Ag(I) ions. The triangular Ag(I) cluster is found in this compound with silver–silver distances of 3.057(1), 3.090(1) and 3.360(2) Å, suggesting weak d^{10}–d^{10} interactions. It is notable that the three silver ions have different coordination environment (Fig. 15). Ag(1) exhibits trigonal pyramidal coordination geometry, being coordinated by an aqua ligand (Ag1–O1W, 2.71(2) Å), a nitrate (Ag1–O7, 2.45(1) Å), and a L^3 ligand (Ag1–O1, 2.398(9) Å). Although also coordinated by three oxygen atoms belonging to three different L^3 ligands (Ag(2)–O(2), 2.189(8) Å; Ag(2)–O(6), 2.206(9) Å; Ag(2)–O(1a), 2.417(8) Å; a: $x-1$, y, z), Ag(2) shows a T-shaped coordination geometry. Ag(3) is coordinated by four oxygen atoms, which are provided by an aqua ligand (Ag(3)–O2W, 2.27(1) Å), a nitrate ion (Ag(3)–O(12), 2.69(1) Å) and two L^3 ligands (Ag(3)–O(5), 2.370(9) Å; Ag(3)–O(6b), 2.505(9) Å; b: $x+1$, y, z) in a distorted tetrahedral environment. The carboxyl oxygen atoms of the L^3 ligand coordinate to four different silver ions, linking the triangular silver clusters to generate an infinite two-dimensional network with large cavities (18 × 5 Å) (Fig. 16). The layer structures are further linked through hydrogen bonds (O1W–H1WA···O(10d), 170.2°; O1W···O(10d), 2.98(2) Å; d: x, $y-1$, z) (Table 4), extending to a more complex three-dimensional network (Fig. 17). The remaining nitrate ion,

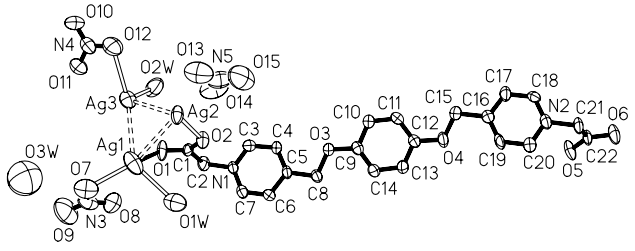

Fig. 14. Asymmetric unit and atom labeling in compound **3** with thermal ellipsoids represented at the 30% probability level. All hydrogen atoms are omitted for clarity.

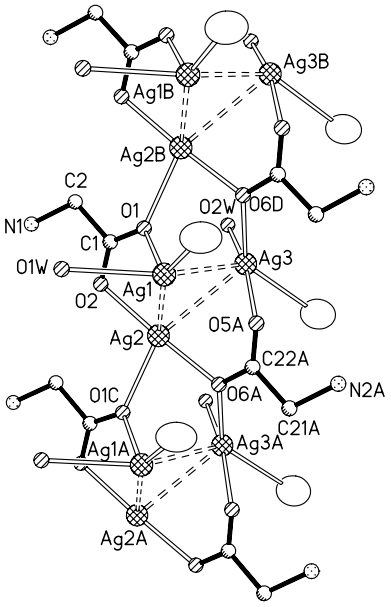

Fig. 15. A section of the polymeric structure of **3**, showing the interactions between the silver atoms of the trinuclear unit and the oxygen atoms of carboxylate, nitrate and aqua ligand. Large open circle represents terminal nitrate group for clarity.

which is not coordinated to silver ions directly, is connected to the network through hydrogen bonds O2W–H2WB···O(13) (Table 4). The lattice water molecules O3W and O4W are accommodated between the layers, and no distinguishable π–π interaction is found in the crystal structure.

4. Concluding remarks

In the crystal structures of the hydrated ligands and silver(I) complexes **1**–**3**, the –CH_2–py–CH_2–O–C_6H_4–O–CH_2–py–CH_2– backbone of the isomeric betaine molecules is nearly planar, the largest dihedral angle between the pyridyl rings being 5.3° in $L^3 \cdot 5H_2O$. Intermolecular π–π interaction between the central phenylene ring and the pyridyl ring of a neighboring betaine molecule exists in $L^1 \cdot 8H_2O$ and $L^3 \cdot 5H_2O$,

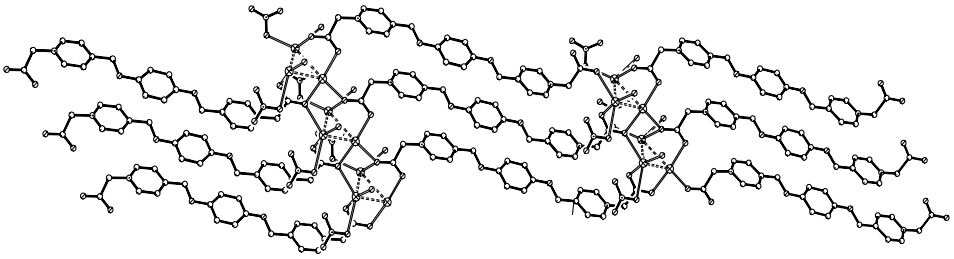

Fig. 16. Layer structure of **3** exhibiting the connection between the trinuclear silver clusters and the L^3 ligands. The parallelogram-like cross-section between the Ag centers and betaine ligands is about 18 Å × 5 Å.

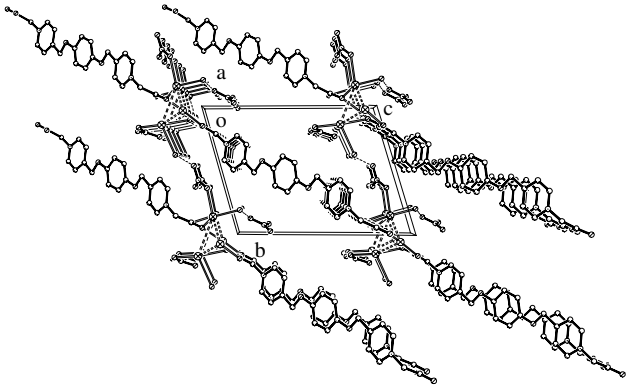

Fig. 17. Three-dimensional network of **3** linked by hydrogen bonding.

as well as in complex **1** and **2**. The dinuclear building block in **1** and **2**, with close Ag···Ag contact comparable to that in metallic silver, exhibits significant argentophilic interaction, whereas in **3** the Ag···Ag distances in the trinuclear unit are longer, suggesting much weaker d^{10}–d^{10} attraction. The structure of **3** is comparable with that of $[Ag_2(O_2C(CH_2)_2CO_2)]$, in which four silver atoms are connected by the more flexible and shorter succinate ligand to give a planar tetrasilver cluster that also exhibits weaker d^{10}–d^{10} attraction [14].

The flexible double betaines L^1 and L^2 are versatile ligands for the generation of novel coordination networks in lanthanum complexes. They can act in the bidentate, tridentate and tetradentate modes to bridge La(III) centers, forming 2D or 3D network with the aid of complementary hydrogen bonding involving coexisting aqua ligands and/or lattice water molecules [6]. Ligand L^1 can also display two principal types of bridging modes (*anti* and *syn*) leading to different metal–metal separations in complexes $[Cu(\mu\text{-}L)Cl_2]_n$ and $\{[Zn(\mu\text{-}L)Cl_2]\cdot 2H_2O\}_n$ [5]. In contrast to L^1 and L^2, as L^3 has its pair of carboxylate groups fully extended to the limit and accordingly possesses a less bulky backbone, it is expected to be best suited to the generation of porous coordination networks.

Abstract

Lead(II) complexes with the 4,4′-bipyridine (4,4′-bipy) ligand have been synthesized and characterized by CHN elemental analysis, IR, ^{1}H NMR, ^{13}C NMR and ^{207}Pb NMR spectroscopy. The structures of the compounds $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$, $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$ and $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$ have been determined by X-ray crystallography. The single crystal X-ray data shows the $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ complex to be polymeric and the Pb atom has a 10 coordinate geometry, and the $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$ complex to be polymeric and the Pb atom has an eight coordinate geometry. The single-crystal X-ray data of the compound $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$ shows the complex to be two dimensional polymeric and the Pb atom has an eight coordinate geometry. The lone pair of electrons on lead(II) is active in the complexes $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ and $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$, and inactive in the complex $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$.

1. Introduction

The 4,4′-bipyridine (4,4′-bipy) ligand is widely used for the synthesis of polynuclear complexes with extended structures. In relation to work on different metal ions (Cd^{2+}, Zn^{2+}, Cu^{2+}, Co^{2+}, Ni^{2+}, Fe^{2+}) [1–8] and Pb^{2+} [9] complexes containing the 4,4′-bipyridine bridge ligand described in earlier papers, it is interesting to find further examples of these complexes with the Pb^{2+} ion. The lead(II) complexes are interesting and frequently discussed when considering the coordination and stereo-activity of heavy metals, that is the "stereo-chemical activity" of the valence shell electron lone pairs [10–15]. Extensive recent structural studies on lead (II) compounds [16] in particular have provided a basis for a rather detailed analysis for the evidence of coordination sphere distortions as a consequence of the presence of such lone-pairs. It appears that in complexes of lead(II) (and probably in those of related species such as Tl^{I} [17–19] and Bi^{III} [20–24]), the nature and form of the coordination sphere is generally determined by a number of factors, possibly lone-pair bond-pair repulsions of comparable influence, so that seemingly minor differences in ligands or in the crystal array can have quite marked effects upon the coordination stereochemistry. Since the presence of a lone pair is not directly detected but recognized on the basis of the spatial distribution of the atoms assumed to be donors to the central ion, the identification of these donor atoms is fundamental to the analysis of any particular system. Interestingly, this is not a straightforward process. Building new molecular species and modifying their architectures in order to control their physical properties, has been a topic for many research groups. Different ligands have been used to study the lead(II) complexes. The ligand

doi:10.1016/j.poly.2004.08.014

4,4′-bipyridine, because of its ability to form polynuclear complexes, is a very good candidate for the investigation of the ''stereo-chemical activity'' of valence shell electron lone pairs in polymeric and supramolecular compounds.

2. Experimental

2.1. Physical measurements

IR spectra were recorded as Nujol mulls using Perkin-Elmer 597 and Nicolet 510P spectrophotometers. Microanalyses were carried out using Heraeus CHN-O-RAPID. The ^{207}Pb solution NMR spectra were recorded on a Bruker DRX-500 AVANCE spectrometer at 104.6 MHz using a 5-mm broadband probe. Lead chemical shifts are reported (ppm) downfield from tetramethyllead using $Pbph_4$ ($\delta_{Pb} = -178.0$ ppm, saturated in $CDCl_3$) as an external standard. Each lead spectrum was acquired over 3–10 h.

2.2. Preparation of $[Pb_2(4,4'\text{-bipy})(NO_3)_4]$

4,4′-Bipyridine (4,4′-bipy) (0.156 g, 1 mmol) was placed in one arm of a branched tube and lead (II) nitrate (0.331 g, 1 mmol) in the other. Methanol was carefully added to fill both arms, the tube sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature. After 15 days, white crystals had deposited in the cooler arm which were filtered off, washed with acetone and ether, and air dried (0.288 g, yield 60%), m.p. > 320 °C. Calc. for $C_8H_8N_6O_{12}Pb_2$: C, 11.70; H, 1.66; N, 10.24. Found C, 10.87; H, 0.97; N, 11.12%. IR (cm^{-1}) selected bands: 740(s), 1010(s), 1380(vs), 1528(s), 1618(s), 3038(w). ^{1}H NMR (DMSO, δ): 7.80 (m, 2H), 8.70 (m, 2H). ^{13}C–{^{1}H} NMR (DMSO; δ): 124.30, 139.30, 144.50, 149.30. ^{207}Pb NMR (DMSO; δ) −2590.00.

2.3. Preparation of $[Pb(4,4'\text{-bipy})Cl_2]$

4,4′-Bipyridine (4,4′-bipy) (0.156 g, 1 mmol) was placed in one arm of a branched tube and lead (II) chloride (0.28 g,1 mmol) in the other. Methanol was carefully added to fill both arms, then the tube was sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature (Fig. 1). After 30 days, yellow-white crystals had deposited in the cooler arm, which were filtered off, washed with acetone and ether, and air dried (0.177 g yield 40%), m.p. > 320 °C. Calc. for $C_{10}H_8N_2Cl_2Pb$: C, 27.52; H, 1.83; N, 6.42. Found C, 27.32; H, 1.75; N, 6.55%. IR (cm^{-1}) selected bands: 612(vs), 797(vs), 1209(s), 1396(s), 1583(s), 3015(w). ^{1}H NMR (DMSO, δ): 7.75 (m, 2H), 8.80 (m, 2H). ^{13}C–{^{1}H} NMR (DMSO; δ): 124.30, 139.30, 144.50, 149.30. ^{207}Pb NMR (DMSO; δ) −2556.78.

2.4. Preparation of $[Pb(4,4'\text{-bipy})(CH_3COO)_2]$

4,4′-Bipyridine (4,4′-bipy) (0.156 g, 1 mmol) was placed in one arm of a branched tube and lead (II) acetate (0.36 g,1 mmol) in the other. Methanol was carefully added to fill both arms, then the tube was sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature (Fig. 1). After 15 days, white crystals had deposited in the cooler arm, which were filtered off, washed with acetone and ether, and air dried (0.240 g yield 50%), m.p. > 320 °C. Calc. for $C_{14}H_{14}N_2O_4Pb$: C, 34.85; H, 2.90; N, 5.80. Found C, 34.61; H, 2.18; N, 5.33%. IR (cm^{-1}) selected bands: 740(s), 1010(s), 1398(vs), 1557(vs), 1618(s), 3040(w). ^{1}H NMR (DMSO, δ): 1.70 (s, 3H), 7.8 (m, 2H), 8.75 (m, 2H). ^{13}C–{^{1}H} NMR (DMSO; δ): 27.30 ($^{13}CH_3$-COO), 124.30, 139.30, 144.50, 149.30, 178.58 (CH_3-^{13}COO). ^{207}Pb NMR (DMSO; δ) −2556.78.

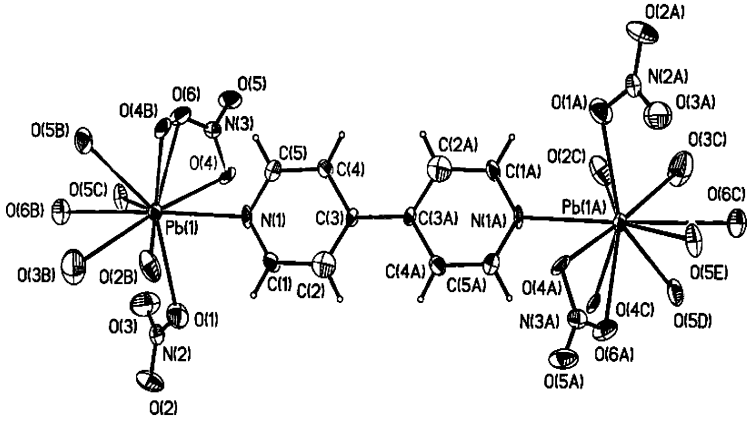

Fig. 1. ORTEP drawing of compound $[Pb_2(4,4'\text{-bipy})(NO_3)_4]$.

2.5. Preparation of $[Pb_2(4,4'\text{-bipy})(SCN)_4]$

4,4′-Bipyridine (4,4′-bipy) (0.156 g, 1 mmol) was placed in one arm of a branched tube and a mixture of lead (II) acetate (0.36 g, 1 mmol) and potassium thiocyanate (1.96 g, 2 mmol) in the other. Methanol was carefully added to fill both arms, then the tube was sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature. After 10 days, white crystals, m.p. > 320 °C had deposited in the cooler arm, which were filtered off, washed with acetone and ether, and air dried (0.40 g, yield 60%). Calc. for $C_{14}H_8N_6S_4Pb_2$: C, 20.92; H, 0.99; N, 10.46. Found C, 20.41; H, 1.08; N, 10.73%. IR (cm^{-1}) selected bands: 740(s), 1010(s), 1255(s), 1557(s), 1618(s), 2025(vs), 3040(w). ^1H NMR (DMSO, δ): 7.80 (m, 2H), 8.70 (m, 2H). ^{13}C–{^1H} NMR (DMSO; δ): 123.20 ($S^{13}CN$), 124.50, 139.40, 144.50, 149.30. ^{207}Pb NMR (DMSO; δ) −2856.78.

2.6. Preparation of $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$

4,4′-Bipy (0.156 g, 1 mmol) was placed in one arm of a branched tube and mixture of lead(II) nitrate (0.331 g, 1 mmol) and potassium thiocyanate (0.097 g, 1 mmol) in the other. Methanol was carefully added to fill both arms, the tube sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature. After 10 days, white crystals (m.p. = 220 °C) had deposited in the cooler arm which were filtered off, washed with acetone and ether, and air dried (0.242 g, yield 50%). Calc. for $C_{11}H_8N_4O_3PbS$ C, 27.30; H,1.65; N,11.58. found C, 27.87; H, 1.29; N, 11.25%. IR (cm^{-1}) selected bands: 718(s), 800(s), 1060(m), 1365(vs), 1585(s), 2040(s), 3035(w). ^1H NMR (DMSO, δ): 7.8 (m, 2H), 8.75 (m, 2H). ^{13}C–{^1H}NMR (DMSO, δ): 123.20 ($S^{13}CN$), 124.30, 139.30, 144.50, 149.30. ^{207}Pb NMR (DMSO; δ) −2369.44.

3. Results and discussion

3.1. Synthesis

Reaction between 4,4′-bpy ligand with lead(II) thiocyanate, lead(II) nitrate, lead(II) chlorate, lead(II) acetate and mixture of lead(II) nitrate and potassium thiocyanate provided crystalline materials analyzing as $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$, $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$, $[Pb(4,4'\text{-bipy})(CH_3COO)_2]$, $[Pb(4,4'\text{-bipy})Cl_2]$ and $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$, respectively. Attempts to isolate the 1:1 adduct of lead(II) thiocyanate and lead(II) nitrate with 4,4′-bpy ligand, {$[Pb(4,4'\text{-bipy})(NCS)_2]$ and $[Pb(4,4'\text{-bipy})(NO_3)_2]$}, were not successful and each time the 1:2 (L:M) adduct was isolated.

3.2. Crystal structure of $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$

The crystal structure of $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ consists of polymeric units of $[Pb_2(4,4'\text{-bipy})(NO_3)_4]$. The nitrogen atoms of the 4,4′-bipyridine ligand link each lead atom with a Pb–N distance of 2.578(9) Å. The oxygens of two nitrate anions are coordinated with distances of Pb(1)–O(1) = 2.672(11) Å, Pb(1)–O(4) = 2.910(10) Å and Pb(1)–O(6) = 2.731(11) Å, and also six oxygen atoms of neighboring nitrate anions with distances of about 2.6–3.035(11) Å. The coordination number in this complex is 10 (one from the '4,4′-bipy' ligand, nine from nitrate anions) (Fig. 1). The interaction of lead(II) with oxygen atoms of an adjacent molecule produce polymer units in the solid state (Fig. 2). The two lead atoms are bridged by the 4,4′-bipy ligand. Since the inversion center is located at the middle of the C(3)–C(3A) bond, the aromatic rings of the 4,4′-bipy ligand are coplanar. In conclusion, the structure reported here reveals a new type of interpenetration and a rarely observed 2D framework type.

3.3. Crystal structure of $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$

The crystal structure of $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$ consists of polymeric units of $[Pb_2(4,4'\text{-bipy})(NCS)_4]$. Each lead atom is linked by the nitrogen atoms of 4,4′-bpy ligand and with a Pb–N distance of 2.675 Å and thiocyanate anions with Pb–N distances of 2.543(8) and 2.590(9) Å. The lead atom also has weak links to one nitrogen atom and four sulfur atoms of neighboring thiocyanate anions. So the coordination number in this complex is three (one from the '4,4′-bpy' ligand and two from thiocyanate ligands) (Fig. 3) and the weak interaction of lead(II) with nitrogen and sulfur atoms of an adjacent molecule produces polymeric units in solid state (Fig. 4). In fact each Pb atom in this structure, along with three normal bonds, forms five "weak" Pb···N and Pb···S bonds and the exact distances are Pb(1)–N(3)#1 = 2.829(9), Pb(1)–S(2)#2 = 3.174(3), Pb(1)–S(1)#3 = 3.192(3), Pb(1)–S(2)#4 = 3.203(3) and Pb(1)–S(1)#5 = 3.376(3) Å (Table 4).

The presence of a lone pair on the lead atom is apparently the reason that the bridging interactions cannot come closer together. If the stereochemically active lone pair was not present, there might be more of an interaction between the bridging atoms of lead (II) with the neighboring sulfur atoms of the thiocyanate ligand, and this phenomenon could lead to more symmetry. The coordination number in this complex would be eight (one from the '4,4′-bpy' ligand, seven from thiocyanate anions) and indeed, interaction of lead (II) with nitrogen and sulfur atoms of an adjacent molecule

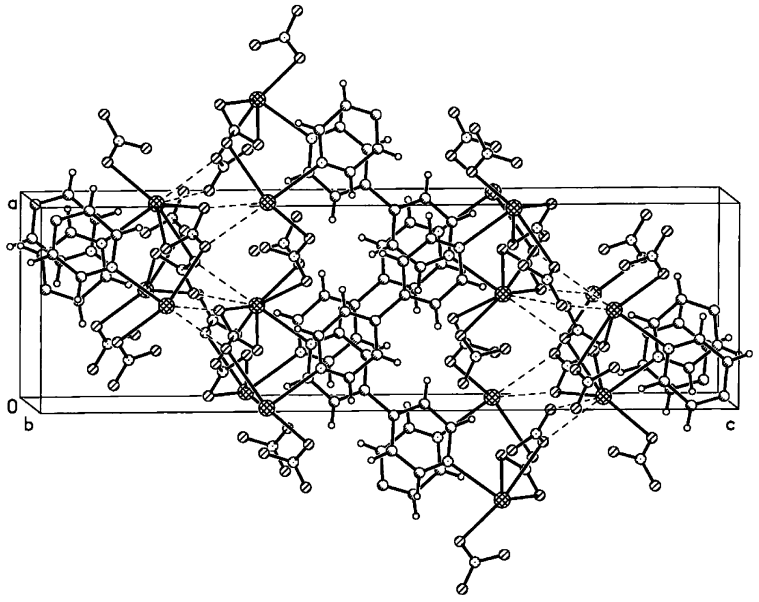

Fig. 2. The unit cell showing the π–π stacking interaction (charge-transfer arrays) between the parallel aromatic rings belonging to adjacent chains in $[Pb_2(4,4'\text{-bipy})(NO_3)_4]$.

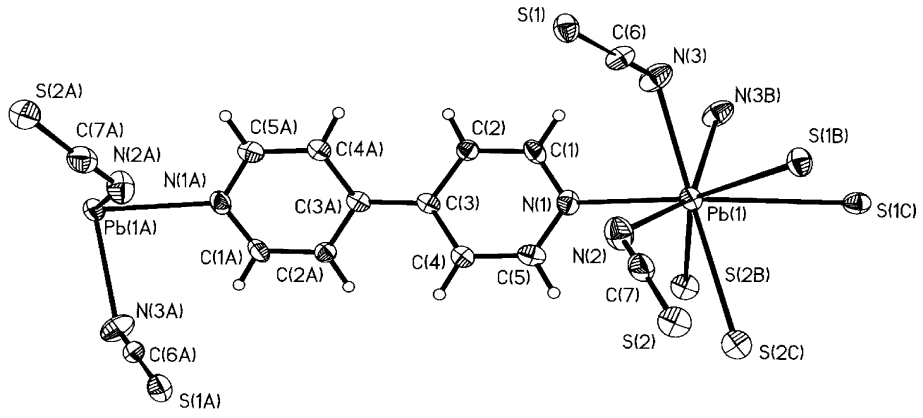

Fig. 3. ORTEP drawing of compound $[Pb_2(4,4'\text{-bipy})(SCN)_4]$.

produces polymer units in solid state. 4,4′-Bipyridine bridges the two lead atoms. Since the inversion center is located at the middle of the C(3)–C(3A) bond, the aromatic rings of 4,4′-bipyridine are coplanar. In conclusion, the structure reported here, analogously to $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$, reveals a new type of interpenetration and rarely observed 2D framework type.

3.4. Crystal structure of $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$

The crystal structure of $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$ consists of two dimensional polymeric units of $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]$. The nitrogen atoms of the 4,4′-bipy ligand and the oxygen atoms of the nitrate anion are linked to different lead atoms and the sulfur and nitrogen atoms of the thiocyanate anion are bridged to two lead atoms. Each lead atom is linked by the nitrogen atoms of the 4,4′-bipy ligand with Pb–N distances of 2.664(5) and 2.702(5) Å, the oxygens of nitrate anions with Pb–O distances of 2.724(6), 2.802(6), 2.815(6) and 2.842(6) Å, the nitrogen of the thiocyanate anion with a Pb–N distance of 2.461(6) Å and also the sulfur atom of the thiocyanate anion with a Pb–S distance of 2.909(2) Å. The coordination number in this complex is eight (two from 4,4′-bipy ligands, four from nitrate anions, two from thiocynate anions) (Fig. 5) and the lead atoms are bridged by 4,4′-bipy, nitrate and thiocyanate ligands and produce polymer units in the solid state (Fig. 6). Since the inversion center is not located at the middle of the C(3)–C(3′) bond, the aromatic rings of 4,4′-bipyridine are not coplanar. The two 4,4′-bipyridine ligands are trans and the N(1)–Pb(1)–N(1′A) angle is 162.4(2)°. The thiocyanate and also the nitrate ligands are *cis*. The nitrate anion could be bidentate chelated

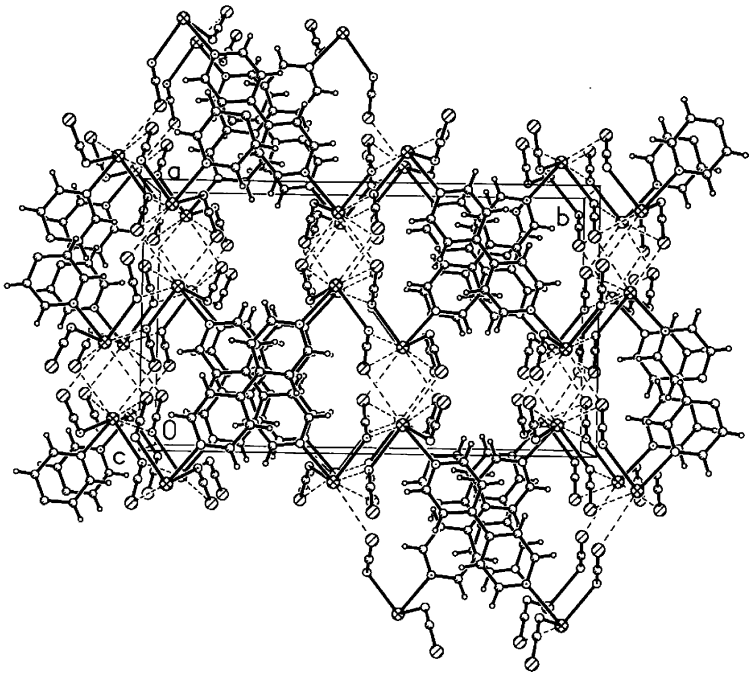

Fig. 4. The unit cell showing the π–π stacking interaction (charge-transfer arrays) between the parallel aromatic rings belonging to adjacent chains in $[Pb_2(4,4'\text{-bipy})(SCN)_4]$.

and also could be bridged, and indeed one of oxygen atoms of this anion is linked to two difference lead atoms (Chart 1).

It is very interesting that the bond lengths of the three N–O bonds and also the three bond angles for the nitrate anion in this complex are different, [N(3)–O(1) = 1.256(8), N(3)–O(2) = 1.232(8) and N(3)–O(3) = 1.231(8) Å; O(2)–N(3)–O(3) = 122.6(6)°, O(2)–N(3)–O(1) = 118.8(6)° and O(1)–N(3)–O(3) = 118.6(6)°]. This point shows that the nitrate anion has been distorted in forming a bridge between the two lead atoms and in producing the polymeric structure, and the result of this phenomena causes the variety of bond lengths and bond angles of the nitrate anion in this complex (Table 5).

The structure of the $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$ compound is interesting in several aspects. The above-mentioned compound is a new rarely observed 2D framework type and a new mixed-ligand complex containing three ligands that have simultaneously been bridged in its crystal structure and also the lone pair in this complex is inactive. The lone pair in most lead (II) complexes is active, and structures with inactive lone pairs are rarely observed [16].

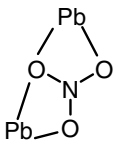

Chart 1.

The arrangement of 4,4′-bipy and nitrate anions do not suggests a gap or hole in the coordination geometry around the metal, indicating the lone pair of electrons on lead (II) is probably inactive in this complex.

The possible stereochemical activity of the lone pair in divalent lead compounds has recently been discussed by Shimoni-Livny et al. [16] based on a thorough review of crystal data available in the Cambridge Structural Database (CSD). They classify lead complex coordination as holodirected which refers to complexes in which the bonds to ligand atoms are placed throughout the surface of the encompassing sphere, while hemidirected refers to those cases in which the bond to ligand atoms are directed to particular parts of the coordination sphere, leaving a gap in the distribution of bonds to ligands. The latter holds for all lead (II) complexes with coordination number 2 to 5, is quite common for coordination numbers 6, 7 and 8, and does not exist in lead complexes with higher coordination numbers where holodirected geometry is the rule (Chart 2).

For the three structures described here, the coordination around the lead atoms is holodirected. It is becoming increasingly clear, however, that it is not necessarily true that one of the effects of the lone pair activity in Pb(II) compounds is to cause a void in the coordination geometry; in fact this geometry can take various forms [25]. Some authors [26] have also suggested that in the holodirected Pb(II) complexes there may be some adjacent short Pb^{II}–X bonds and some other long Pb–X bonds. Such a specific pattern of difference in bond lengths of holodirected complexes has been attributed

by various authors to repulsion involving a stereochemically active lone pair [27]. In two of the reported complexes {1:2 (L:M) adducts, $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$ and $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$}, the bond lengths of the coordination sphere are very difference {2.578–3.035 Å for $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ and 2.543–3.376 Å for $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$}. This point shows that in the $[Pb_2(4,4'\text{-bipy})(NCS)_4]_n$ and $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ complexes the coordination geometry is holodirected and there is a relatively large difference between the Pb–L distances in the two axial directions so possibly the lone pair is active. In contrast, in the $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$ complex, the coordination geometry is holodirected and the difference between the Pb–L distances is relatively small and the lone pair is likely to be inactive.

The striking similar feature of the three reported complexes here and $[Pb(4,4'\text{-bipy})I_2]$ [9] is that there is

a π–π stacking [28,29] interaction between the parallel aromatic rings that belong to an adjacent chain in the lead(II) polymer complex, as shown in Figs. 2, 4 and 6. As planar species in which the mean molecular planes are close to parallel and are separated by a distance of ~3.5 Å, they have a close resemblance to the planes in graphite.

The parallel arrays of the planes of the aromatic moieties indicate that these interactions in $[Pb_2(4,4'\text{-bipy})(SCN)_4]_n$, $[Pb(4,4'\text{-bipy})I_2]$ and $[Pb(4,4'\text{-bipy})(NO_3)(NCS)]$ are of the "π-stacking" type, rather than "edge-to-face" or "vertex-to-face" types [30–33]. Projection of the structure perpendicular to the ring plane shows the overall form of "slipped" stacking [30–34],

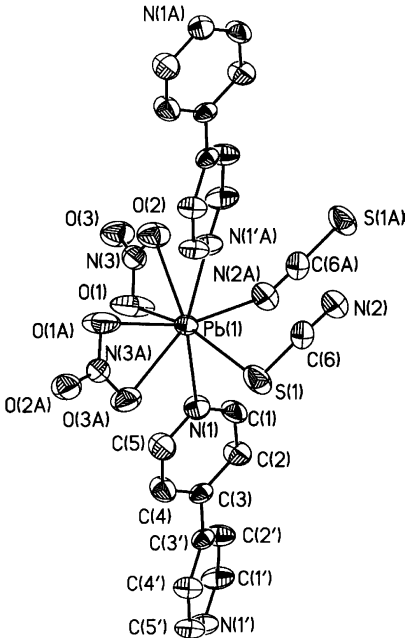

Fig. 5. ORTEP drawing of compound $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$.

which can be rationalized qualitatively in terms of optimizing the attraction between atoms of opposite charges [35]. In the $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ complex the parallel arrays interactions are of the ''edge-to-face'' type.

A simple model to describe the nature of π–π interactions has been developed by Hunter et al. [35]. This model predicts that face-to-face π-stacked interactions will be disfavored due to the dominance of π–π repulsion. However, in offset π-stacked, and edge-on or T-shaped geometries, favourable π–σ attractions dominate. The polarization of aromatic systems through the introduction of heteroatoms, electron-withdrawing groups or electron-donating groups, alters the nature of any π–π interactions. For example, although it is well known that neither benzene [36] nor hexafluorobenzene tend to form stacked arrangements, the adduct between these two molecules adopts a structure comprising of inclined stacks of alternating molecules [37]. Here the hexafluorobenzene π-system is electron-deficient with respect to benzene and this reduces the π–π repulsion, making the formation of offset π-stacked molecules more favorable. The introduction of heteroatoms can lead to a similar perturbation of aromatic interactions [32], specifically nitrogen atoms have been shown to remove electron density from the π-system, and hence have a similar effect to electron-withdrawing groups. It has been shown that electron-deficient aromatic groups interact most strongly with electron-rich aromatic groups. Hence, since the molecules of these complexes include equally or almost equally electron-deficient, or indeed electron-rich, rings, it can be expected that within $[Pb_2(4,4'\text{-bipy})(SCN)_4]_n$, $[Pb(4,4'\text{-bipy})I_2]_n$ and [Pb(4,4′-

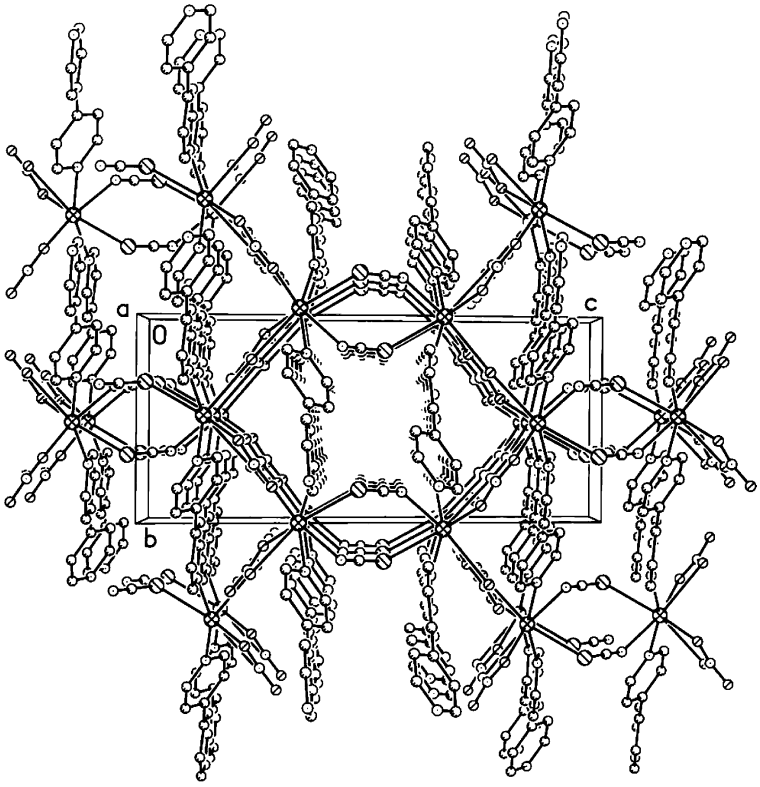

Fig. 6. The unit cell showing the π–π stacking interaction (charge-transfer arrays) between the parallel aromatic rings belonging to adjacent chains in $[Pb(4,4'\text{-bipy})(NO_3)(SCN)]_n$.

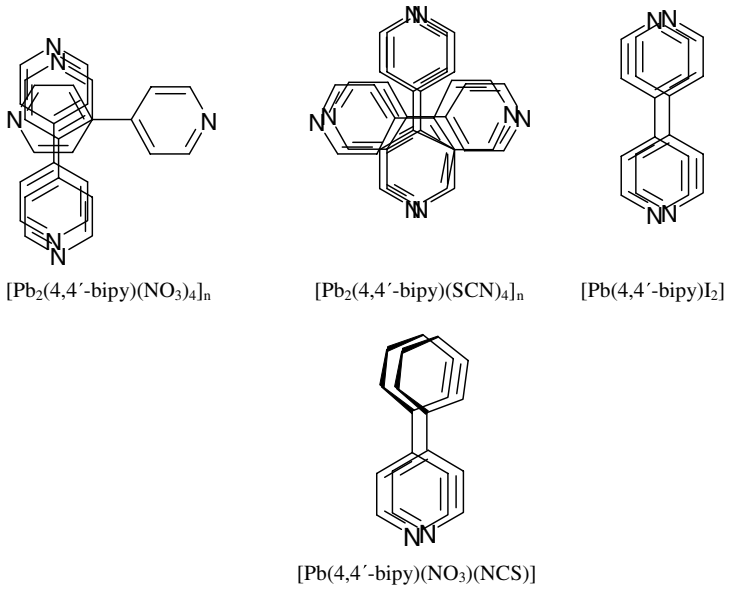

Fig. 7. Projection of nearest neighbour pairs in the π–π stacks of heteroaromatic bases in Pb(II) complexes containing the 4,4′-bipy ligand.

bipy)$(NO_3)(NCS)]_n$ complexes, model face-to-face π-stacked interactions must be disfavored due to the dominance of π–π repulsion and within $[Pb_2(4,4'\text{-bipy})(NO_3)_4]_n$ the edge-to-face model must be favor. This point suggests that the lone pair activity is the most important factor and it may be more important than the π–π repulsion that is formed (Fig. 7).

Thus two factors, lone pair activity and π–π stacking, may control the coordination sphere of this complex. The obvious question then is whether the lone pair activity has stretched coordinate bonds to result in ligand stacking or whether it is the stacking interaction, which has imposed a positioning of the donor atoms for forming gap in the coordination sphere. Since the model face-to-face π-stacked interactions must be disfavored due to the dominance of π–π repulsion, this possibly suggests that lone pair activity may be the most important factor and results in the formation of π–π stacking. Indeed, it is now realized that lone pair activity can also play a significant and predictable structure-determining role in the polymeric structures.

Crystallographic data, selected bond lengths and angles are given in Tables 1–3. Atomic coordinates, anisotropic thermal parameters, observed and calculated structure factors; full lists of bond distances, band angles and torsion angles are given in the supplementary material. A perspective view of ORTEP diagrams and the packing in the unit cells are shown in Figs. 1–6.

4. Supplementary material

Complete bond lengths and angles, co-rdinates and displacement parameters have been deposited at the Cambridge Crystallography Data Centre. Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number 195034 for $[Pb_2(4,4'\text{-bipy})(NO_3)_2]$, 208614 for $[Pb_2(4,4'\text{-bipy})(SCN)_2]$ and 208613 for [Pb(4,4′-bipy)$(NO_3)(NCS)$].

Abstract

Reaction of $LaX_3(THF)_n$ (X = Cl, I) with two equiv. of K(Tp^{Me2}) gave good yields of the bis-Tp complexes [La(Tp^{Me2})$_2$X] (X = Cl (**1**); I (**3**)). However, the formation of **1** and **3** is always accompanied by significant amounts of La(Tp^{Me2})$_2$(κ^2-pz^{Me2}) ([pz^{Me2}]$^-$ = 3,5-dimethyl-pyrazolato) (**2**). The pyrazolato complex **2**, which presumably arises from decomposition of the [Tp^{Me2}]$^-$ moiety during salt metathesis, was independently prepared in good yield from **1** and in situ generated [pz^{Me2}]$^-$. The solid-state structures of **1** and **2** were determined by single-crystal X-ray diffraction studies. Subsequent reactions of halogeno-Tp^{Me2} complexes **1** and **3** with various alkali metal salts MR (M = Li, R = CH_2SiMe_3, Ph, $N(SiMe_3)_2$; M = K, R = OAr) gave M(Tp^{Me2}) as the major product. Alternatively, the mono-Tp bis(aryloxide) derivatives [Ln(Tp^{Me2})(OC_6H_2-2,6-^{t}Bu-4-Me)$_2$] (Ln = La (**4**); Nd (**5**)) were obtained in high yields by salt metathesis of [Ln(OC_6H_2-2,6-^{t}Bu-4-Me)$_3$] with one equiv. of K(Tp^{Me2}).

Keywords: Tris(pyrazolyl)hydroborate (Tp) ligands; Lanthanum; Neodymium; Salt metathesis; Aryloxide derivatives

1. Introduction

First introduced by Trofimenko [1], tris(pyrazolyl)hydroborate (Tp) ligands is an attractive class of sterically demanding ancillaries for a wide variety of ionic metal centers [2]. Of particular interest is the case of lanthanides and analogous group 3 metals [3], due to their predominant ionic character. Indeed, one of the most attractive features of the Tp ligands is their steric tunability. This is a crucial point in lanthanide chemistry, which is recognized to be largely affected by steric factors [4]. Also, albeit ubiquitous cyclopentadienyl-type ligands are excellent for lanthanides, recent years have witnessed a considerable interest in developing related organolanthanide complexes involving other supporting ligands [5]. This quest for alternative ancillaries originates in large part from the permanent search for new-generation olefin polymerization catalysts, which is a very topical application field of early transition organometallic chemistry [6]. In this regard, the first use of Tp ligands for

doi:10.1016/j.poly.2004.08.013

lanthanide-mediated ethylene polymerization was claimed with yttrium complexes $[Y(Tp^{Me2})R_2(THF)_x]$ (R = CH_2SiMe_3, C_6H_5) and analogous complexes with variously substituted $Tp^{R,R'}$ ligands [1] and lanthanide metal centers [7,8]. Despite the quite poor catalytic activity, the results suggested potentiality for improvement via specific catalyst design [7].

Potential precursors for this purpose include half-sandwich trivalent lanthanide dihalides $[Ln(Tp^R)X_2]$, and the more sterically crowded sandwich monohalides $[Ln(Tp^R)_2X]$ [3]. Relevant examples of such complexes derived from the ubiquitous Tp^{Me2} ligand are the mono-solvated complexes $[Ln(Tp^{Me2})Cl_2(THF)]$ (Ln = Yb [9], Nd [10], Lu [11], Y [10], Sc [12]) and the non-solvated complexes $[Nd(Tp^{Me2})_2X]$ (X = Cl, NPh_2, dpm, OAr, β-dike, H_2BEt_2) [13] and $[Sm(Tp^{Me2})_2X]$ (X = Cl, Br, I) [14]. However, at this early stage, one shall face a first synthetic problem, that is the preparation of these complexes is often hampered by the propensity of the Tp^R ligand, especially Tp^{Me2}, to decompose [15]. A number of degradation products that likely arise from hydrolysis by adventitious water during purification or crystallization, e.g., pyrazole adducts $[Ln(Tp^{Me2})Cl(\mu\text{-}Cl)(Hpz^{Me2})]$ (Ln = Nd, Pr; Hpz^{Me2} = 3,5-dimethylpyrazole) [9] and $[Ln(Tp^{Me2})X_2(Hpz^{Me2})]$ (Ln = La, Y) [10], and dimers $[Ln(Tp^{Me2})(\mu\text{-}BOp^{Me2})]_2$ (Ln = La, Ce, Sm; $BOp^{Me2} = (HBO(pz^{Me2})_2)^{2-}$) [16], have been isolated. Beside those, significant amounts of other products are formed directly from the salt metathesis reactions between LnX_3 and the Tp^R salt, of which the identity remains to be established [16]. Further complications arise for the preparation of potentially active polymerization complexes from the halide lanthanide precursors. For instance, attempts at derivatization of $[Sm(Tp^{Me2})Cl_2(L)]$ (L = coordinating molecule) using such groups as RO^-, Et_2N^-, or R^- failed due to ligand redistribution [17].

This work reports on the synthesis and characterization of new trivalent lanthanum mono-halide complexes incorporating the Tp^{Me2} ligand, and the identification of side-products that originate directly for the salt metathesis reactions. In addition, reactions of these halide precursors with alkoxides, amides and alkyl reagents have been investigated and shown to give mainly undesired products. An alternative synthesis toward diaryloxide lanthanide complexes $[Ln(Tp^{Me2})(OAr)_2]$ (Ln = La, Nd) is proposed.

[1] The abbreviation used for the ligands is that proposed by Trofimenko [2g]: Tp stands for tris(pyrazolyl)borate; R and R′ are substituents at the 3 and 5 positions of the pyrazolyl group, respectively, and a 4-substituent is denoted by the superscript 4R.

2. Experimental

2.1. General procedures

All manipulations were performed under a purified argon atmosphere using standard high vacuum Schlenk techniques or in a glovebox. Solvents were distilled from Na/benzophenone (THF) and Na/K alloy (toluene, pentane and cyclohexane) under nitrogen and degassed thoroughly prior to use. Deuterated solvents (>99.5% D, Eurisotop) were vacuum-transferred from drying agents (benzene-d_6, toluene-d_8, THF-d_8: Na/K; $CDCl_3$: CaH_2). $LaCl_3(THF)_{1.5}$ was obtained after repeated extraction of anhydrous $LaCl_3$ (Strem) from THF. $NdCl_3(THF)_2$ was generously provided by Rhodia. $K(Tp^{Me2})$ [1b], $LaI_3(THF)_n$ [18], $Ln(OC_6H_2\text{-}2,6\text{-}{}^tBu_2\text{-}4\text{-}Me)_3$ (Ln = La, Nd) [19], and $Nd(Tp^{Me2})_2Cl$ [13] were prepared according to literature procedures. $LiCH_2SiMe_3$ (1.0 M solution in pentane, Aldrich), PhLi (1.9 M solution in THF, Aldrich) and *n*-BuLi (1.6 M solution in hexane, Acros) were used as received. NMR spectra were recorded on Bruker DPX-200 and AC-300 spectrometers in Teflon-valved NMR tubes at 20 °C unless otherwise indicated. ^1H and ^{13}C chemical shifts are reported versus $SiMe_4$ and were determined by reference to the residual solvent peaks. Assignment of signals was made from ^1H–^1H COSY, ^1H–^{13}C HMQC and HMBC NMR experiments. Coupling constants are given in Hertz. Elemental analyses (C, H, N) were performed by the Microanalytical Laboratory at the Institute of Chemistry of Rennes and are the average of two independent determinations. IR spectroscopy was carried out on a Nicolet 510 FTIR spectrophotometer and is expressed by wave number (cm^{-1}).

2.2. Synthesis of lanthanide complexes

2.2.1. Salt elimination reaction of $LaCl_3$ and $K(Tp^{Me2})$: synthesis of $[La(Tp^{Me2})_2Cl]$ (1) and $[La(Tp^{Me2})_2(\kappa^2\text{-}pz^{Me2})]$ (2)

$LaCl_3$ (0.900 g, 3.68 mmol) was introduced in a Schlenk flask and THF (70 mL) was added. The suspension was stirred for 12 h at room temperature and $K(Tp^{Me2})$ (2.47 g, 7.35 mmol) was added. The mixture was stirred at 20 °C for 7 days, period over which the amount of insoluble material decreased. Volatiles were removed under vacuum and the residue was extracted with toluene (2 × 40 mL). The colorless filtrate was evaporated under vacuum and the residue washed with pentane (3 × 25 mL) to afford **1** as a white powder (1.88 g, 65%). Crystals of **1** suitable for X-ray diffraction were grown from a 1:2 toluene/pentane solution at −34 °C.

Elemental *Anal.* Calc. for $C_{30}H_{44}B_2ClN_{12}La$ (MW 768.32): C, 46.87; H, 5.77; N, 21.86. Found: C, 47.18; H, 5.93; N, 21.79%.

^{1}H NMR (200 MHz, toluene-d_8): δ 5.60 (s, 6H, 4-H), 2.22 (s, 18H), 2.03 (s, 18H) (3-CH_3 and 5-CH_3).

^{13}C{^{1}H} NMR (50 MHz, toluene-d_8): δ 151.1 (3-C), 145.5 (5-C), 106.9 (4-C), 14.0, 13.6 (3-CH_3 and 5-CH_3).

Evaporation of the final pentane washings (vide supra) left **2** as a white powder (0.49 g, 16%). Crystals of **2** suitable for X-ray diffraction were grown from a toluene/cyclohexane solution at −34 °C.

Elemental *Anal.* Calc. for $C_{35}H_{51}B_2N_{14}La$ (MW 828.01): C, 50.75; H, 6.21; N, 23.67. Found: C, 50.25; H, 6.31; N, 22.66%.

^{1}H NMR (200 MHz, toluene-d_8): δ 5.95 (s br, 1H, 4-H pyrazolato), 5.60 (s, 6H, 4-H pyrazolyl), 2.28 (s, 18H, CH_3 Tp^{Me2}), 1.93 (s br, 6H, 3,5-CH_3 pyrazolylato), 1.75 (s, 18H, CH_3 Tp^{Me2}).

^{13}C{^{1}H} NMR (50 MHz, toluene-d_8): δ 150.4 (3-C), 145.5 (3,5-C pyrazolato), 144.9 (5-C), 106.9 (4-C pyrazolato), 106.4 (4-C Tp^{Me2}), 14.0 (3,5-CH_3 pyrazolato), 13.7, 12.7 (3-CH_3 and 5-CH_3).

2.2.2. Synthesis of $[La(Tp^{Me2})_2Cl]$ (1) and $[La(Tp^{Me2})_2(\kappa^2\text{-}pz^{Me2})]$ (2) from $LaCl_3(THF)_{1.5}$

$LaCl_3(THF)_{1.5}$ (0.560 g, 1.78 mmol) and K(Tp^{Me2}) (1.31 g, 3.56 mmol) were introduced in a Schlenk flask and THF (50 mL) was added. The mixture was stirred at 20 °C for 7 days, period over which the amount of insoluble material decreased. Volatiles were removed under vacuum and the residue was extracted with toluene (2 × 40 mL). The colorless filtrate was evaporated under vacuum and the residue washed with pentane (3 × 25 mL) to afford **1** as a white powder (0.66 g, 48%). Evaporation of the final pentane washings left **2** as a white powder (0.49 g, 33%).

2.2.3. Conversion of $[La(Tp^{Me2})_2Cl]$ (1) to $[La(Tp^{Me2})_2(\kappa^2\text{-}pz^{Me2})]$ (2)

The reaction was performed using a procedure similar to that described by Winter et al. [20]. Complex **1** (0.210 g, 0.275 mmol) and 3,5-dimethylpyrazole (0.080 g, 0.825 mmol) were introduced in a Schlenk flask, with some toluene (15 mL). Under magnetic stirring, NEt_3 (0.12 mL, 0.825 mmol) was added dropwise to the solution by syringe. The solution became immediately turbid. The mixture was stirred for 5 days at 20 °C. After this period, volatiles were removed under vacuum and the residue was analyzed by ^{1}H NMR (C_6D_6), which showed the presence of **1** (36%) and **2** (64%).

2.2.4. $La(Tp^{Me2})_2I]$ (3)

This reaction was performed as described above for **1** starting from $LaI_3(THF)_{0.63}$ (1.76 g, 3.13 mmol) and K(Tp^{Me2}) (2.10 g, 6.26 mmol), with a reaction time of 3 days at 20 °C. Usual workup afforded **2** (0.31 g, 12%) from the final pentane washings and **3** as a white powder insoluble in pentane (1.82 g, 67%).

Elemental *Anal.* Calc. for $C_{30}H_{44}B_2IN_{12}La$: (MW 859.84): C, 41.89; H, 5.16; N, 19.54. Found: C, 41.88; H, 5.45; N, 19.80%.

^{1}H NMR (200 MHz, $CDCl_3$): δ 5.73 (s, 6H, 4-H), 2.38 (s, 18H, CH_3 Tp^{Me2}), 1.88 (s, 18H, CH_3 Tp^{Me2}).

^{13}C{^{1}H}NMR (50 MHz, $CDCl_3$): δ 151.3 (3-C), 146.8 (5-C), 107.0 (4-C), 14.5, 13.8 (3-CH_3 and 5-CH_3).

2.2.5. $La(Tp^{Me2})(OC_6H_2\text{-}2,6\text{-}^tBu_2\text{-}4\text{-}Me)_2]$ (4)

$La(OC_6H_2\text{-}2,6\text{-}^tBu_2\text{-}4\text{-}Me)_3$ (0.560 g, 0.725 mmol) and K(Tp^{Me2}) (0.240 g, 0.725 mmol) were introduced in a Schlenk flask, and toluene (10 mL) was added. The mixture was stirred at 60 °C for 12 h, period over which a white solid precipitated. Pentane (10 mL) was added and the solid was filtered out. Volatiles were removed under vacuum and the residue was heated at 60 °C under ca. 0.1 mm Hg to remove the phenol 2,6-^{t}Bu$_2$-4-Me- C_6H_2OH formed in the reaction, leaving **4** as a pale brown solid (0.514 g, 81%).

Elemental *Anal.* Calc. for $C_{45}H_{68}N_6O_2BLa$: (MW 874.22): C, 61.79; H, 7.84; N, 9.61. Found: C, 62.23; H, 7.52; N, 9.86%.

^{1}H NMR (200 MHz, C_6D_6): δ 7.16 (s, 4H, C_6H_2), 5.48 (s, 3H, 4-H Tp^{Me2}), 2.31 (s, 6H, 4-CH_3 Ar), 2.27 (s, 9H, CH_3 Tp^{Me2}), 2.12 (s, 9H, CH_3 Tp^{Me2}), 1.56 (s, 36H, 2,6-^{t}Bu Ar).

^{13}C{^{1}H} NMR (50 MHz, C_6D_6): δ 150.0, 146.4 (3-C and 5-C pyrazolyl), 136.2 (*ipso*-C Ar), 128.4 (*o*-C Ar), 126.4 (*m*-C Ar), 125.0 (*p*-C Ar), 106.6 (4-C pyrazolyl), 35.3 (C ^{t}Bu), 32.6 ($CH_3{}^t$Bu), 21.7 (4-CH_3 Ar), 14.6, 13.4 (3-CH_3 and 5-CH_3).

2.2.6. $Nd(Tp^{Me2})(OC_6H_2\text{-}2,6\text{-}^tBu\text{-}4\text{-}Me)_2]$ (5)

This complex was synthesized using the same procedure as that described above, starting from $Nd(OC_6H_2\text{-}2,6\text{-}^tBu\text{-}4\text{-}Me)_3$ (0.300 g, 0.376 mmol) and K(Tp^{Me2}) (0.130 g, 0.376 mmol), to afford **5** as a clear blue solid (0.204 g, 88%).

Elemental *Anal.* Calc. for $C_{45}H_{68}N_6O_2BNd$ (MW 879.56): C, 61.41; H, 7.79; N, 9.55. Found: C, 62.14; H, 7.79; N, 9.61%.

2.3. Crystal structure determination of complexes 1 and 2

Suitable single crystals of all investigated compounds were mounted onto glass fibers using the "oil-drop" method. All diffraction data were collected at 120 K using a NONIUS Kappa CCD diffractometer with graphite monochromatized Mo Kα radiation (λ = 0.71073 Å). A combination of ω- and φ-scans was carried out to obtain at least a unique data set. Crystal structures were solved by means of the Patterson method, remaining atoms were located from difference Fourier synthesis, followed by full-matrix least-squares refinement based on F^2 (programs SHELXS-97 and SHELXL-97) [21]. Many hydrogen atoms could be found

from the Fourier Difference. Carbon-bound and boron-bound hydrogen atoms were placed at calculated positions and forced to ride on the attached carbon and boron atoms. The hydrogen atom contributions were calculated but not refined. All non-hydrogen atoms were refined with anisotropic displacement parameters. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities were of no chemical significance. The cell of **2** was found to contain half a molecule of crystallization cyclohexane. Crystal data and details of data collection and structure refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis and characterization of [La(Tp^{Me2})$_2$X] compounds (X = Cl, I)

The procedure we used to prepare [La(Tp^{Me2})$_2$X] (X = Cl, I) compounds involves the common salt metathesis (elimination) reaction of LaX_3 or the appropriate THF adduct complex $LaX_3(THF)_n$ (X = Cl, n = 1.5; X = I, n = 0.63) with two equiv. of K(Tp^{Me2}) in THF at room temperature. Thus, $LaCl_3$ reacts with K(Tp^{Me2}), over a time period ranging from 3 to 7 days, to give reproducibly a mixture of the lanthanum complexes [La(Tp^{Me2})$_2$Cl] (**1**) and La(Tp^{Me2})$_2$(κ^2-pz^{Me2}) ([pz^{Me2}]$^-$ = 3,5-dimethylpyrazolato) (**2**) (Eq. (1)). The desired chloro complex **1** is easily separated from this mixture due to its insolubility in pentane, in contrast to the pyrazolato complex **2** which is highly soluble in aliphatic hydrocarbons. Compounds **1** and **2** were obtained after workup as white powders in 65% and 16% yields, respectively. It is important to note that the use of different experimental conditions, i.e., temperature, reaction time, and lanthanide precursor, did not avoid the formation of the side-product **2**. [2] For instance, the use of $LaCl_3(THF)_{1.5}$ instead of $LaCl_3$ led reproducibly to a mixture of complexes, from which **1** and **2** were isolated in 48% and 33% yields, respectively. The analogous iodine derivative [La(Tp^{Me2})$_2$I] (**3**) was prepared readily in 67% yield using the same procedure as for **1**. However, the use of the iodide precursor $LaI_3(THF)_{0.63}$ instead of chloride ones did not avoid the formation of complex **2**, which was isolated in 12% yield (Eq. (1)).

$$\begin{aligned} &LaX_3(THF)_n + 2K(Tp^{Me2}) \\ &\xrightarrow[-2KCl]{THF,20^\circ C} [La(Tp^{Me2})_2X]\ (X = Cl, \mathbf{1};\ X = I, \mathbf{3}) \\ &\quad + [La(Tp^{Me2})_2(\kappa^2\text{-}pz^{Me2})]\ \mathbf{2} \end{aligned} \tag{1}$$

The identity of compounds **1**–**3** was established on the basis of elemental analysis, ^{1}H and ^{13}C NMR spectroscopy, and by single-crystal X-ray diffraction studies for **1** and **2**. A noteworthy feature of these complexes, which reflects the steric size of the Tp^{Me2} ligand, is the lack of coordinated THF molecule.

The ^{1}H NMR spectra of complexes **1** and **3** in toluene-d_8 are quite similar, featuring a singlet corresponding to the H-4 of the pyrazolyl ring ($\delta_{H\text{-}4}$ **1**, 5.60; **3**, 5.73 ppm), and two singlets assigned to the both methyl groups at the 3/5-positions of the pyrazolyl ring ($\delta_{Me3,5}$ **1**, 2.22 and 2.03; **3**, 2.38 and 1.88 ppm). The equivalence between the 3/5-methyl groups of the three pyrazolyl rings (one resonance for each) can be attributed to a rapid reorganization of the coordination sphere on the NMR timescale.

The ^{1}H NMR spectrum of **2** in toluene-d_8 contains a set of pyrazolyl resonances ($\delta_{H\text{-}4}$ 5.60; $\delta_{Me3,5}$ 2.28 and 1.75 ppm) similar to those observed for **1** and **3**. The equivalence between the signals relative to the methyl groups of the pyrazolyl rings indicates the ability of the lanthanum atom, thanks to its large ionic radius [22], to accommodate all the ligands in its coordination sphere, without occurrence of important steric hindrance. In addition to those signals, two relatively broad

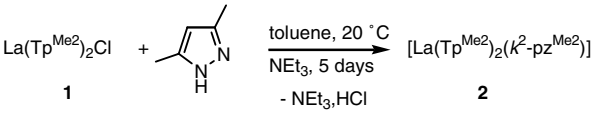
[2] On the other hand, consistent with Sellas's recent report [13], we observed that the reaction of $NdCl_3(THF)_2$ with 2 equiv. of K(Tp^{Me2}) in THF solution at 20 °C for 4 days is selective for the formation of [Nd(Tp^{Me2})$_2$Cl] (84% isolated yield); no pyrazolato complex was observed in this case, as during the syntheses of the analogous Eu and Sm complexes [14]. Introduction of two Tp^{Me2} ligands appear therefore problematic for large metal centers (La) and small metal centers (Y) where only the half-sandwich complex can be prepared. There appears therefore to be a trade-off between excessive crowding and a bite-angle mismatch.

signals are observed for the H-4 (δ 5.95 ppm) and the methyl groups ($\delta_{Me3,5}$ 1.93 ppm) of the pyrazolato ring.

3.2. Possible pathways for the formation of the pyrazolato complex 2

The relatively low yields obtained in the syntheses of **1** and **3** (up to 65% and 67%, respectively), as compared to Nd, Sm, and Eu analogues, [2] can be rationalized in terms of partial decomposition of the [Tp^{Me2}] moiety to the benefit of the pyrazolato complex **2**. Two pathways are usually proposed to account for decomposition processes involving Tp-lanthanide compounds [16,23]. The first one is related to ligand rearrangements involving either 1,2-borotropic or 1,2-metallotropic shifts; the second one is based on partial or complete decomposition of the Tp ligand within the coordination sphere of the metal centers, in the presence of adventitious protic sources, generating most often free pyrazole which can coordinate to the metal center in the neutral form [9,10]. The latter process is frequently observed for Tp^{Me2} complexes, presumably due to the high steric crowding induced by the presence of the methyl group at 5-position of the pyrazolyl ring.

Only one example of a lanthanide compound containing two Tp ligands and one pyrazolato ligand, i.e., the samarium counterpart of **2**, is reported in the literature [24,25]. The latter was prepared from the chloro precursor and 3,5-dimethylpyrazole in the presence of the strong base $KC_6H_4CH_2NMe_2$. In a separate experiment, we also observed that the chloro complex **1** is selectively converted to the pyrazolato complex **2** by treatment with 3 equiv. of 3,5-dimethylpyrazole in the presence of NEt_3, albeit the reaction proceeds slowly with this weak base (64% conversion after 5 days) (Eq. (2)) [20]. These results give evidence, as simply expected from the formulae, that complex **2** can arise from the substitution of the chloride in **1** by a pyrazolato moiety. In principle, the latter can be generated in situ during the salt metathesis of $LaX_3(THF)_n$ (X = Cl, I) with K(Tp^{Me2}) in two different ways: (i) either as achieved in Eq. (2), from free 3,5-dimethylpyrazole (Hpz^{Me2}) arising from preliminary hydrolysis and acting as both the pyrazolato source and base, or (ii) directly as a transient [pz^{Me2}]$^-$ moiety. The former hypothesis: (i) is unlikely in our case considering the stringent precautions to avoid adventitious protic sources, and the fact that no free Hpz^{Me2} nor adducts of the type [$La(Tp^{Me2})_2Cl(Hpz^{Me2})$] could be detected (NMR) during the reaction course [26]. Rather, we assume that the lanthanum center in $LaX_3(THF)_n$ and/or **1** promotes cleavage of a B–N bond, possibly in K(Tp^{Me2}) or in **1** which features elongated and therefore probably weakened bonds due to twisting of the pyrazolyl rings about the B–N bond (vide infra).



(2)

3.3. Solid-state structures of [$La(Tp^{Me2})_2Cl$] (1) and [$La(Tp^{Me2})_2(\kappa^2\text{-}pz^{Me2})$] (2)

Crystal data for **1** and **2** are summarized in Table 1, refinement details are discussed in Section 2, and selected bond distances and angles are listed in Tables 2 and 3, respectively. Both compounds are very similar to their samarium and neodymium counterparts [13,14,24] and show comparable metrical parameters, allowing for the difference in ionic radius of the metal [22]. We will therefore discuss them briefly.

The molecular structure of **1** features a seven-coordinate monomeric species with a distorted pentagonal bipyramidal geometry (Fig. 1). The average La–N values (2.6485(5) Å) are comparable to those found in similar Tp-lanthanum compounds such as [La(Tp^{Me2})-(μ-BOp^{Me2})]$_2$ (average La–N = 2.6366(1) Å) [16]. The Tp^{Me2} ligands show the typical twisting of the

Table 2

N(3)–La(1)–N(5)	73.31(10)	N(13)–La(1)–N(14)	32.13(11)
N(7)–La(1)–N(9)	77.62(10)		

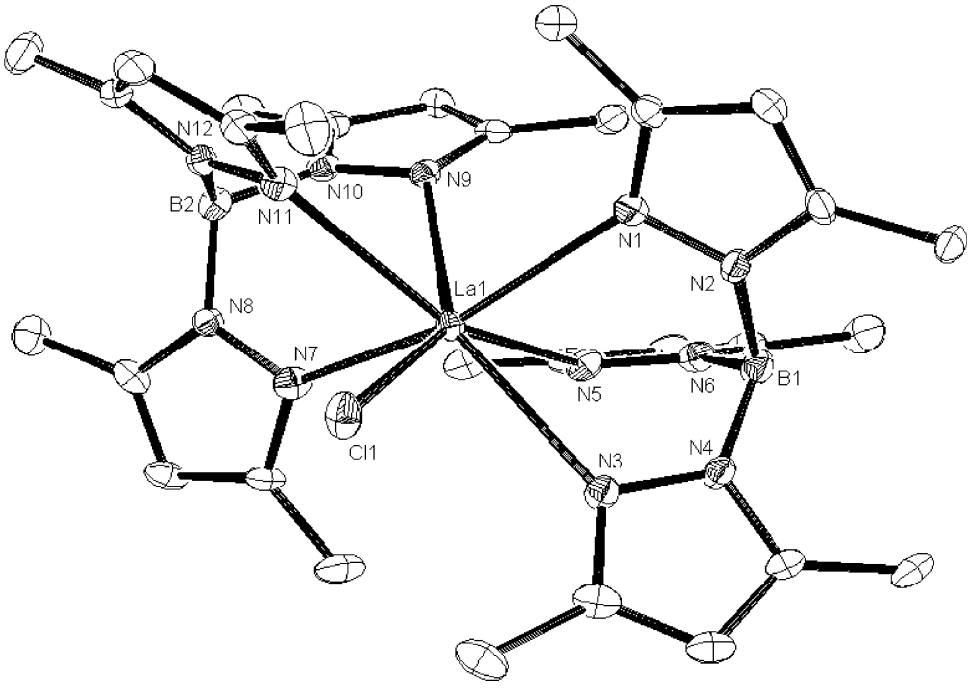

Fig. 1. Molecular structure of compound **1** drawn at the 30% probability level (hydrogen atoms omitted for clarity).

pyrazolyl rings about the B–N bond in consequence of the presence of bulky groups at 3- and 5-positions [16,27]. The extent of this twisting is different for the two Tp ligands of a given $[La(Tp^{Me2})_2X]$ complex, which accounts for the ca. 10° difference between the B–La–Cl angles. The largest B–N–N–La torsion angles is found for B(1)–N(2)–N(1)–La (33.5(6)°). [3] The B–N bond distance associated to the twisted pyrazolyl rings (N(2)–B = 1.557(11) Å) is slightly longer than the other B–N distances (average 1.539(9) Å).

The lanthanum atom in complex **2** is eight-coordinate in a pentagonal bipyramidal geometry, with N(3) and N(9) occupying the apical sites (N(3)–La–N(9) = 157.83(10)°) and considering the center of the N–N bond in the $[pz^{Me2}]^-$ moiety as a monodentate ligand (Fig. 2). The nitrogen atoms of the Tp^{Me2} ligands are bent back with a bond angle B–La–B of 137.4(8)° significantly lower than the one observed in the samarium analogue (146.0 (2)°) [24]. Also, one pyrazolyl group is 35.6° twisted around the B(1)–N(4) bond, a distortion which is slightly larger than the one found in **1** and that can be associated to the increased steric interactions between the pyrazolyl group of the Tp^{Me2} ligands and the pz^{Me2} group. The $[pz^{Me2}]^-$ ligand is bonded to lanthanum in a slightly asymmetric fashion with a difference in La–N bond distance of 0.047 Å.

[3] Additional torsion angles (deg) for 1: La(1)–N(3)–N(4)–B(1) = −1.1(8), La(1)–N(5)–N(6)–B(1) = 23.8(7), La(1)–N(7)–N(8)–B(2) = 20.1(7), La(1)–N(9)–N(10)–B(2) = 23.7(7), La(1)–N(11)–N(12)–B(2) = −4.6(7).

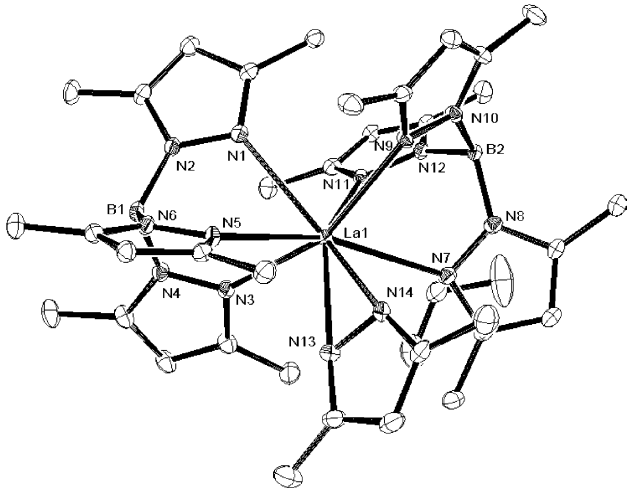

Fig. 2. Molecular structure of compound **2** drawn at the 30% probability level (hydrogen atoms omitted for clarity).

The N–N bond distance (1.379(5) Å) and the bite angle (N(13)–La–N(14) = 32.13(11)°) associated with the $[pz^{Me2}]^-$ ligand are similar to the values found in related group 3 pyrazolato complexes [25].

3.4. Metathesis reactions of $[La(Tp^{Me2})_2X]$ (X = Cl, I) with alkali metal salts

Neutral group 3 metal complexes having a reactive Ln–R bond (R = hydrocarbyl, aryl, amide, aryloxide) have increasingly attracted attention in recent years, in particular to act as single-component initiators for

polymerization of polar and non-polar monomers [5]. We have therefore investigated the possibility to access some $[La(Tp^{Me2})_2R(L)_n]$ (L = coordinating solvent; $n = 0$, 1) derivatives via salt metathesis reactions of the prepared halides **1** and **3** with appropriate alkali metal reagents. This strategy is analogous to that claimed by Bianconi et al. to prepare the yttrium complexes $[Y(Tp^{Me2})(CH_2SiMe_3)_2(THF)]$ and $[Y(Tp^{Me2})Ph_2(THF)]$ from $[Y(Tp^{Me2})Cl_2(THF)]$ [7]. However, we have not been able to reproduce the latter results and found that treatment of $[Ln(Tp^{Me2})_2X]$ (Ln = La, Nd; X = Cl, I) and $[Y(Tp^{Me2})Cl_2(THF)]$ with $LiCH_2SiMe_3$, LiPh, $LiN(SiMe_3)_2$, or $K(OC_6H_2$-2,6-^{t}Bu-4-Me) [4] under a variety of conditions led essentially to the formation of $M(Tp^{Me2})$ (M = Li, K) in 33–90% yield (depending on the starting compound and the alkali metal reagent). Similar displacement of the Tp ligand from chloro-scandium complexes by lithiated reagents has been reported by Piers et al. [12]. In any case, the expected complexes $[Ln(Tp^{Me2})_{3-x}R_x(L)_n]$ could be identified in no more than 10% NMR yield in the crude reaction mixtures. Clearly, other routes to $[Ln(Tp^{Me2})_{3-x}R_x(L)_n]$ complexes are necessary.

3.5. Synthesis of $[Ln(Tp^{Me2})(OC_6H_2$-26-^{t}Bu-4-Me$)_2]$ compounds (Ln = La (**4**), Nd (**5**))

An alternative preparation of Ln-Tp-aryloxide derivatives was developed. The salt metathesis reaction of $[Ln(OC_6H_2$-2,6-^{t}Bu-4-Me$)_3]$ (Ln = La, Nd) with one equiv. of $K(Tp^{Me2})$ in toluene at 60 °C affords the mono-substituted $[Ln(Tp^{Me2})(OC_6H_2$-2,6-^{t}Bu-4-Me$)_2]$ compounds (Ln = La (**4**); Ln = Nd (**5**)) as pale brown and blue solids in 81% and 88% yield, respectively

$$Ln(OC_6H_2\text{-}2,6\text{-}^t\text{Bu-4-Me})_3 + K(Tp^{Me2}) \xrightarrow[60^\circ C,12h\text{-}KOAr]{\text{toluene}} Ln(Tp^{Me2})(OC_6H_2\text{-}2,6\text{-}^t\text{Bu-4-Me})_2] \quad (Ln = La, (\mathbf{4}); Ln = Nd, (\mathbf{5})) \qquad (3)$$

The structures of **4** and **5** were assigned on the basis of elemental analysis, and multinuclear (^{1}H, ^{13}C) NMR for the diamagnetic complex **4**. The ^{1}H NMR spectrum of **4** in benzene-d_6 contains a set of resonances for two equivalent aryloxide groups and one set of resonances for the pyrazolyl moiety (one doublet for 4-H pz and two singlets for the methyl groups) indicating a fluxional behavior that is fast on the NMR time scale.

Complexes **4** and **5** are sensitive to air and moisture, decomposing in solution or in the solid state when exposed to air at room temperature within two days to give the corresponding phenol (2,6-^{t}Bu$_2$-4-Me-C_6H_2OH) and unidentified solid materials. It is noteworthy to mention that the reactions carried out using two equiv. of $K(Tp^{Me2})$ afford only the mono-substituted Tp-Ln complexes **4** and **5**, presumably because of the steric effects between the ^{t}Bu groups at 2- and 6-positions of the bulky aryloxide ligand and the methyl groups of the Tp ligand. This may account, at least in part, for the impossibility to introduce the aryloxide group into $[Ln(Tp^{Me2})_2X]$ (vide supra) [4].

[4] The preparation and structural characterization of Sm-$(Tp^{Me2})_2(OC_6H_2$-2,6-^{t}Bu-4-Me) via a slightly different salt metathesis procedure has been reported; see Ref. [24].

4. Conclusions

The synthesis and characterization of bis-Tp^{Me2}-lanthanum complexes have been described. Besides obtaining of the desired Tp^{Me2}-halogeno-lanthanum complexes, decomposition processes generating a free pyrazole group and a κ^2-pyrazolato group have been evidenced. In general, $[Ln(Tp^{Me2})_{3-x}X_x]$ ($x = 1$, 2) complexes appear to be poor precursors to synthesize via salt metathesis reactions $[Ln(Tp^{Me2})_{3-x}R_x(L)_n]$ (L = coordinating solvent) derivatives with a potentially Ln–R reactive moiety. Alternative efficient syntheses are still required to provide an easy entry to a broad range of such derivatives and thus enable to investigate their true potentialities in (polymerization) catalysis.

5. Supplementary data

Crystallographic data for the structures reported in this paper (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 237701 for compound **1**, CCDC No. 237702 for **2**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Reaction of copper(II) salts with 3,5-dinitrosalicylic acid yields to the complex formation of the composition $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$ ($3,5\text{-}(NO_2)_2sal^{x-}$ = 3,5-dinitrosalicylate anion). The complex was characterized, by elemental microanalysis, electronic, IR and EPR spectra and magnetic susceptibility measurements. The crystal structure of the complex has been determined and refined to $R = 0.0482$, and $wR = 0.1206$ for 2980 reflections with $I > 2\sigma(I)$ ($R = 0.0724$, and $wR = 0.1283$ for all 4124 reflections. The complex crystallizes in monoclinic system, space group $P2_1/c$, $a = 10.873(2)$, $b = 14.726(3)$, and $c = 13.167(3)$ Å, $\beta = 94.11(3)°$, $V = 2102.8(8)$ Å^3, and $Z = 4$. Structure of the complex comprises of the centrosymmetric $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]$ molecules and the water molecules which are held together by system of different types of hydrogen bonds and van der Waals interactions. The Cu(1) atom is centrosymmetrically coordinated by two 3,5-dinitrosalicylato dianions, thus forming the square planar CuO_4 chromophore. Each of the satellite Cu(2) atoms are coordinated by one oxygen atom of bridging 3,5-dinitrosalicylato dianion, two oxygen atoms of chelating 3,5-dinitrosalicylato monoanion (in the phenolato form), and by two water oxygen atoms in the square pyramidal coordination polyhedron. Variable-temperature magnetic susceptibility measurements (1.9–300 K) show occurrence of significant ferromagnetic interactions caused by *syn–anti* conformation of carboxylato bridges within the trimer ($J_{12} = 4.31$, $J_{13} = 0$ cm^{-1}). Bellow 3 K, antiferromagnetic intermolecular interaction between trimeric molecules in the crystal lattice was observed ($zJ' = -0.29$ cm^{-1}). The EPR spectroscopy is in agreement with the molecular structure of the complex and magnetic properties, indicates superposition spectra of copper centres ($S = 1/2$) with square-planar and square pyramidal coordination polyhedrons ($g_\parallel = 2.32$, $g_\perp = 2.05$).

1. Introduction

The chemistry of copper compounds has been extensively investigated and the relationship between the structure and reactivity, ranging from industrial catalysis to biomedical activity, is of major importance. The ability of salicylic acid to act as an oxygen donor and to form complexes with different metal atoms is well known [1]. Nitro-derivatives of salicylic acids as a donor in solid state coordination compounds has been studied only sporadically [2] and study of metal complexes with 3,5-dinitrosalicylic acid in solid state is also

rare [3–5]. Published data concerning copper(II) 3,5-dinitrosalicylates are not consistent, e.g., the EPR study of frozen solutions [4] and/or microcrystalline samples [3] using only stoichiometric metal/anion formulae (e.g., $Cu(2NO_2–SA)_2$) or proposing dimeric structure formula [5] $[Cu(Hdns)_2(H_2O)_2]\cdot 10H_2O$ for substance showing the effective magnetic moment $\mu_{eff} = 2.12$ BM per copper ion at 298 K. In addition to that only the study of stability constants of some nitrosalicylic acids complexes with different metal ions have been done [6–8].

On the other hand, the 3,5-dinitrosalicylato moiety could be relatively frequently found in the CCDC System, mostly as ionic salts with different organic cations (e.g., including *N*-protonized aminobenzoic acids) [9–20] and as the structure of free acid solvates. A logical explanation of that could be related to the pK_a values of 3,5-dinitrosalicylic acid [21] ($pK_1 = 0.45$, and $pK_2 = 7.6$). Very interesting structural feature of 3,5-dinitrosalicylate anion in mentioned structures [9–20] is an existence of all three possible types that in solid state. The phenolato anions (figure (b) of Scheme 1) is more frequent [9–12,16–18] than existence of carboxylato anion [9,13–16,19,20] (figure (a) of Scheme 1). Presence of 3,5-dinitrosalicylato dianions (figure (c) of Scheme 1) were found in the cases of ethylenediamonium 3,5-dinitrosalicylate monohydrate [9]. The 3,5-dinitrosalicylic acid molecules were found in structures [22–24] in spite of the presence of protonizable nitrogen atoms of urea [22], diethylurea [23] and phenazine [24]. This, together with controversial data in the literature, is the aim of the study of the donor properties of the 3,5-dinitrosalicylic acid to the copper(II) atom and our preliminary communication [25] is the first structural example of a 3,5-dinitrosalicylatometal complex. The compound of the composition $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$ was prepared and characterized by elemental analysis, spectral and magnetic properties. The crystal and molecular structure of the complex was also studied and analyzed in relation to spectral and magnetic properties.

Caution. Metal complexes of 3,5-dinitrosalicylic acid are potentially explosive. Only a small amount of material should be prepared and handled with caution.

2. Experimental

2.1. Synthesis of $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2\text{-}sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$

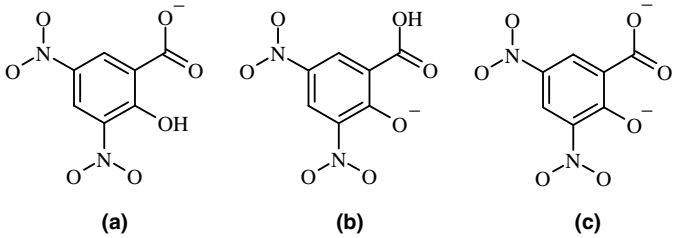
Procedure 1. Crystals suitable for X-ray crystal structure analysis were obtained by slow crystallization of the yellow-green reaction mixture containing copper(II) sulphate (0.0926 g $CuSO_4\cdot 5H_2O$, 0.37 mmol), 3,5-dinitrosalicylic acid (0.2811 g, 0.74 mmol) and nicotinamide (0.186 g, 1.52 mmol) in water solution (50 mL), in an Erlenmayer flask at ambient temperature for a few weeks. Mixture of dark green and yellow-orange crystals were collected by filtration, washed with a small amount of water and dried in air. The dark green crystals of title compound and yellow-orange plates of 1*H*-nicotinamidium 3,5-dinitrosalicylate [20] were separated mechanically and used for X-ray structure determination.

Procedure 2. The water solution of copper(II) sulphate (17 mL, $c(CuSO_4) = 0.281$ mol L^{-1}) was under stirring added to water solution of 3,5-dinitrosalicylic acid (2.3532 g, 9.56 mmol in 150 mL) and reaction mixture was left for slow crystallization at ambient temperature in an Erlemayer flask. Crystals were filtered off, washed with water and dried at room temperature. Yields of crystals were found between 30% and 60% (depending on the time of crystalization). *Anal*. Calc. for $C_{28}H_{26}N_8O_{36}Cu_3$: C, 27.10; H, 2.11; N, 9.03, Cu, 15.36. Found: C, 27.5; H, 2.3; N, 9.2; Cu, 15.5%.

2.2. Spectral studies

Electronic spectrum of the complex was measured in Nujol suspension in the region of 190–1100 nm with a SPECORD 200 (Carl Zeiss Jena) spectrophotometer. Infrared spectrum in the region of 4000–100 cm^{-1} was measured with a Nicolet MAGNA 750 IR spectrometer using both KBr pellet and Nujol suspension technics for 4000–400 cm^{-1} region and PE pellet for 400–100 cm^{-1}.

EPR spectra of powdered sample were recorded at room temperature, 77 and 4.5 K, on the spectrometer Bruker ESP 300, operating at X-band equipped with an ER 035M Bruker NMR gaussmeter and a HP 5350B Hewlett–Packard microwave frequency counter.



Scheme 1.

The EPR measurements at 4.3 K were performed on a conventional X–band reflection spectrometer equipped with an Oxford Instruments ESR-900 helium flow cryostat.

2.3. Magnetic measurements

Magnetic susceptibility measurements in the temperature range of 1.9–300 K were carried out on powdered samples of complex, at the magnetic field 5 kG, using a Quantum Design SQUID Magnetometer (type MPMS-XL5). Corrections for diamagnetism of the constituting atoms were calculated using the Pascal constants [26], the value of 60×10^{-6} cm^3 mol^{-1} was used as the temperature-independent paramagnetism of copper(II) ion.

2.4. X-ray measurement

Data collection and cell refinement of the complex were carried out using Kuma KM4CCD κ-axis diffractometer (graphite monochromated Mo Kα radiation, $\lambda = 0.71073$ Å) [27]. Crystal was positioned at 65 mm distance from CCD camera; 312 frames were measured at 0.75° intervals with a counting time of 20 s. Accurate cell parameters were determined and refined by the least-squares fit of 6000–7000 of the strongest reflections. Intensity data were corrected for Lorenz and polarization factors. Absorption correction based on least-squares fit to $|F_c| - |F_o|$ differences was also applied [28]. Data reduction and analysis were carried out with the Oxford Diffraction Poland (formerly Kuma Diffraction Wroclaw, Poland) programs. The structure was solved by the heavy atom method with SHELX86 [29], and subsequent Fourier synthesis using SHELXS93 [30]. Geometrical analysis was performed using SHELXL97 [31] (see Table 1) and the structure was drawn using ORTEP-3 for Windows program [32].

3. Results and discussion

3.1. Complex preparation

The title compound was for the first time prepared by the reaction of copper(II) sulphate with 3,5-dinitrosalicylic acid in presence of nicotinamide in our effort to study the preparation and properties of new copper(II) complexes containing nicotinamide as biologicaly active ligand (see procedure 1 in Section 2). This procedure gave us the mixture of dark green and yellow-orange crystals. The yellow-orange crystals were found as 1*H*-nicotinamidium 3,5-dinitrosalicylate [20]. The preliminary structural parameters of the dark green complex were already published [25]. Later both products were prepared separately. The 1*H*-nicotinamidium 3,5-dinitrosalicylate [20] was obtained by the direct reaction of nicotinamide with 3,5-dinitrosalicylic acid. The reaction of different copper(II) salts with 3,5-dinitrosalicylic acid (e.g., procedure 2) resulted in obtaining the dark green crystals of title compound. Those experiments could be taken as confirmation of two independent chemical reactions were proceeding within the experiment described as procedure 1. Unusual stoichiometry and properties of dark green product could be explained only on the base of the X-ray crystal structure determination.

3.2. Crystal and molecular structure

The atom numbering of $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$ complex and the structure of complex molecule are illustrated in Fig. 1 and the selected bond distances and angles are listed in Table 2. The complex molecule is centrosymmetric and Cu(1) atom is in the centre of symmetry. The 3,5-dinitrosalicylate dianions are forming with Cu(1) two six-membered metallocyclic rings with the angle O(22)–Cu(1)–O(23) of 90.7(1)°. The carboxylato oxygen atom O(22) and the O(23) phenolato oxygen atom exhibit the Cu(1)–O distances of 1.937(3) and 1.916(3) Å, respectively. The other carboxylato oxygen atom of this dianion O(21) is bonded to the terminal Cu(2) atom with little bit

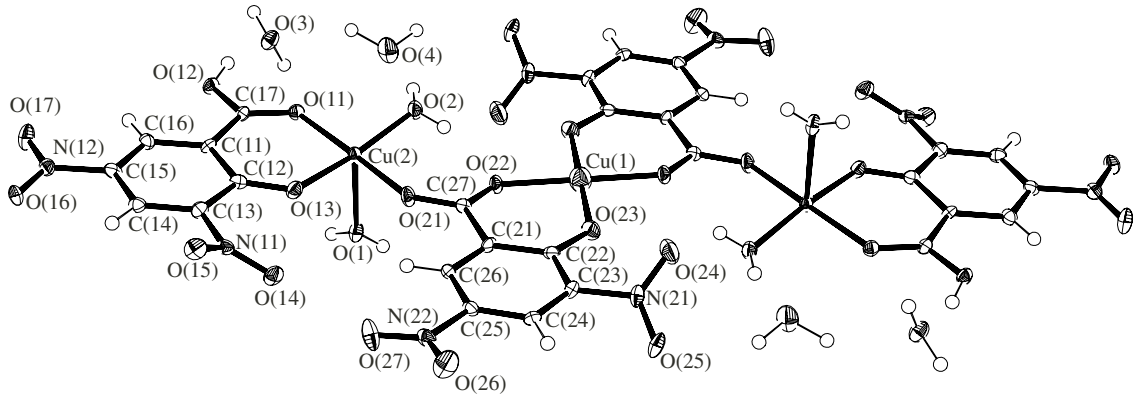

Fig. 1. An ORTEP drawing of the $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$ with the numbering scheme.

(i) $-x, -y, -z$.

longer Cu(2)–O(21) distance of 2.000(3) Å, thus forming the bridging *syn–anti* bonding mode of the carboxylato group. The terminal Cu(2) atom exhibits square pyramidal coordination polyhedron formed by the O(21) oxygen atom of the bridging 3,5-dinitrosalicylate dianion, by two oxygen atoms O(11) and O(13) of the terminal chelating 3,5-dinitrosalicylate monoanion, and by two O(2) and O(1) oxygen atoms of the water molecules. The terminal chelating salicylato anion exhibit slightly longer both Cu(2)–O distances (1.990(3) and 1.942(3) Å, respectively) in comparison to those ones of the Cu(1) atom. This elongation is in good relation to the anion charge. The equatorial water molecule exhibit the Cu(2)–O(2) distance 1.953(3) Å, and the apical Cu(2)–O(1) distance is longer (2.382(3) Å).

The terminal 3,5-dinitrosalicylato anion is rather unique from the transition metal coordination chemistry point of view. This is the first example of presence of phenolato monoanion of the salicylic acid bonded as chelate to the 3d transition metal atom. There are only five examples of structures containing this type of salicylato anion – four of them are tungsten complexes $[W(Cl)_2(sal^{1-})]\cdot THF$, $[W_2(\mu_2\text{-}O)(O)_2(sal^{1-})_2(sal^{2-})_2]\cdot CH_2Cl_2$ (where THF = tetrahydrofuran) [33] $[W(Cl)_3(5Cl\text{-}sal^{1-})(\eta^2\text{-dpe})]$, $[W(Cl)_3(sal^{1-})(\eta^2\text{-dpe})]\cdot$18-crown-6 (where dpe = diphenylethenyl anion, 18-crown-6 = $C_{12}H_{24}O_6$ crown ether) [34] and one of them is a molybdenum complex $[pyH]^+[Mo(O)_2(sal^{1-})(sal^{2-})]^-$ [35].

Another structural feature of the trimeric complex under study is the presence of mono- and di-anions of 3,5-dinitrosalicylic acid within one complex molecule [25]. Such complexes were up to now found only for unsubstituted salicylato complexes, the simpliest one is the dimeric $[Bi_2(sal^{1-})_2(sal^{2-})_2(phen)_2]\cdot CH_3Ph$ (where sal^{x-} = salicylato anion, phen = phenantroline, and CH_3Ph = toluene), that has been published recently [36]. The others are higher oligomeric substances, as mixed metal complexes $[Ti_3Bi_2(sal^{1-})_2(sal^{2-})_8]\cdot CH_2Cl_2$, $[Ti_4Bi_2(sal^{1-})_1(sal^{2-})_{10}(i\text{PrO})_1]\cdot i\text{PrOH}\cdot H_2O$, $[Nb_2Bi_2(sal^{1-})_4(sal^{2-})_4(i\text{PrO})_4]$, and $[Ta_2Bi_2(sal^{1-})_4(sal^{2-})_4(i\text{PrO})_4]$ (where $i\text{PrO}^-$ = izopropanoloato anion) [37] and/or nonamanganese complexes $[Mn_9(O)_4(sal^{1-})_2(sal^{2-})_4(PhCO_2)_8(py)_4]\cdot CH_2Cl_2$ (where py = pyridine, $PhCO_2$ = benzoate anion) [38], $[Mn_9(O)_4(sal^{1-})_2(sal^{2-})_4(PhCO_2)_8(py)_4]\cdot xH_2O$ [39] or decazirconium complex $[Zr_{10}(O)_6(OH)_4(sal^{1-})_8(sal^{2-})_8]\cdot$PrOH [40].

A planarity of the complex molecule, with exception of apical O(1) atom and the oxygen atoms (O(14), O(15), O(16), O(17), O(24), O(25), O(26), and O(27), respectively) is another structural feature of studied complex that allows stepwise stacking molecules in solid state. The deviations of the oxygen atoms of nitro-groups from the mentioned plane is due to rotation of nitro-groups along the C–N bond and could be characterized by the angle between the nitro-group plane and the least square plane mentioned above. Those angles are 31.8°, 2.0°, 33.8° and 11.5° for nitro-groups containing the N(11), N(12), N(21) and N(22) atoms, respec-

tively. The difference in rotational position of the individual nitro-groups is in connection with another feature of this structure and this is a system of hydrogen bonds.

Three types of hydrogen bonds – intramolecular, and two types of intermolecular ones – could found in this structure. The intramolecular hydrogen bonds system (Fig. 2) involving the O(12)–H(12)–O(3)–H(42)–O(4)–H(21)–O(2)–H(22)–O(22) might be together with the additional intermolecular hydrogen bonds (Table 3 and text below) a reason of the larger deviation (of 0.150 Å) of the O(22) from the complex molecule plane. The planar trimeric molecules are within the structure coplanar (Fig. 2) each to other and water molecules containing the O(1), O(3) and O(4) atoms are involved in extending intermolecular hydrogen bonds between the neigbouring trimeric molecules (Table 3). The O(4) oxygen atom containing water molecules form intermolecular hydrogen bonds only within the individual plane (Fig. 2), while the O(3) and O(1) water molecules form hydrogen bonds between the planes (Fig. 3). The O(1) water molecules are with oxygen atom and both hydrogen atoms involved in the strong hydrogen bonds only within the neigbouring planes (Figs. 3 and 4) and the relatively short distance Cu(2)–O(1) of 2.382(3) Å consequently gives the relatively short distance between the neigbouring planes, 3.108 Å. The mutual position of neigbouring interplanar molecules is shown in Fig. 4 with Cu(2)–Cu($2^{iv,i}$) distance of 3.718 Å (the O(1)–Cu(2)–Cu($2^{iv,i}$) angle is 155.0°), the distance is shorter than the intramolecular Cu(1)–Cu(2) distance 5.201 Å. This shorter interplanar distance together with the mutual position of trimeric molecules is probably the reason that there is not enough space for another ligands to be bonded to copper atoms and thus increasing the coordination number of copper atoms.

The coordination ability of 3,5-dinotrosalicylato anion firstly proved in this paper allow us to compare coordination Cu–O bond distances of this ligand with those ones for other salicylato complexes of copper (II) and because of uniqueness of terminal salicylato monoanion only comparation for dianion [41–46] could be done. The Cu–O_p (O_p = phenolato oxygen) distances and the Cu–O_c (O_c = carboxylato oxygen) distances of salicylato dianion are in all found examples shorter those ones for the complex under study in this work (Table 4 and text above).

Searching for above structural data brings interesting result in the case of some dimeric copper(II) complexes with ligands containing salicylato-group moiety. When salicylic acid contains another coordinationable substituent, mostly Schiff base fragment, next to hydroxo-group dimeric phenolato bridged complexes could be formed. There are four examples [47–50] of dimeric species containing salicylato-group moiety that exhibit two different coordination polyhedra within each molecule (Scheme 2) and two examples [51,52] containing salicylato-group moiety (Scheme 3) showing the same coordination polyhedra for both copper(II) atoms. There are two main structural differences between those two groups of complexes. The first group of complexes (Scheme 2) shows "planar" organization of the most part of complex molecule with exception of apical water molecule ligand and the "cis" organization of donor atoms sets. In the case of the second group of complexes (Scheme 3) there are longer side arms that are nonplanar

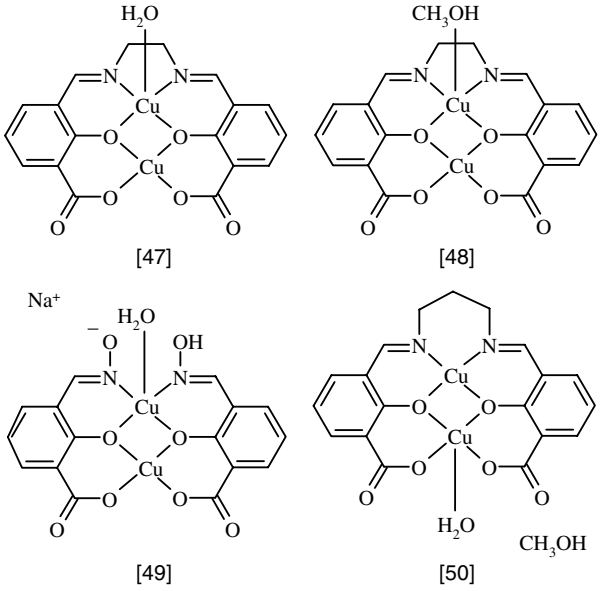
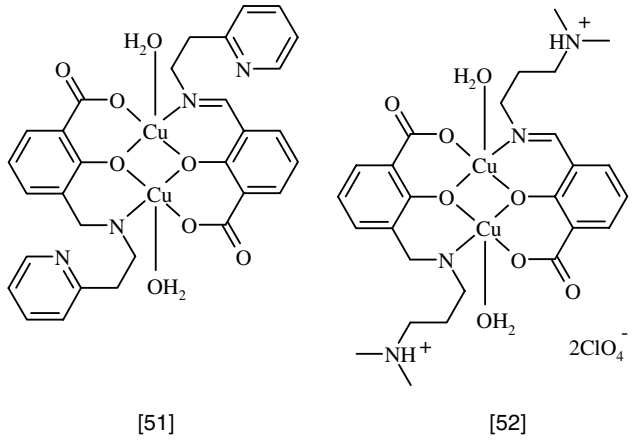


Scheme 2.

with the nearest surrounding of both central atoms and "trans" of donor atoms set is preferred thus both central atoms shows the same coordination atom polyhedra including the apical water molecule. It is interesting that within the first group of complexes (Scheme 2) the complexes containing water molecule as apical ligand show similar organisation of crystal structure packing as it was found in trimeric complex studying – stacking complex molecules one over the other, water molecules involving in hydrogen bond system within neighbouring plane of molecules and some sterical hindrance of the



Scheme 3.

square planar coordination polyhedra of copper atom by neighbouring complex molecules.

3.3. Magnetic susceptibility and EPR measurements

Magnetic susceptibility measurements on a polycrystalline sample of the complex between 1.9 and 300 K shows a dependence on the temperature (Fig. 5). Magnetic moment value of 1.80 BM at the 300 K increases with the lowering temperature to 2.13 BM at 3 K. The graphic functions χ_M versus T and $\chi_M T$ versus T, are shown on Fig. 5. The $\chi_M T$ value is 0.406 cm^3 mol^{-1} K at 300 K (it corresponds to non coupled copper(II) atoms, $S = 1/2$ spin-only value). This value increases with the lowering temperature to a maximum 0.568

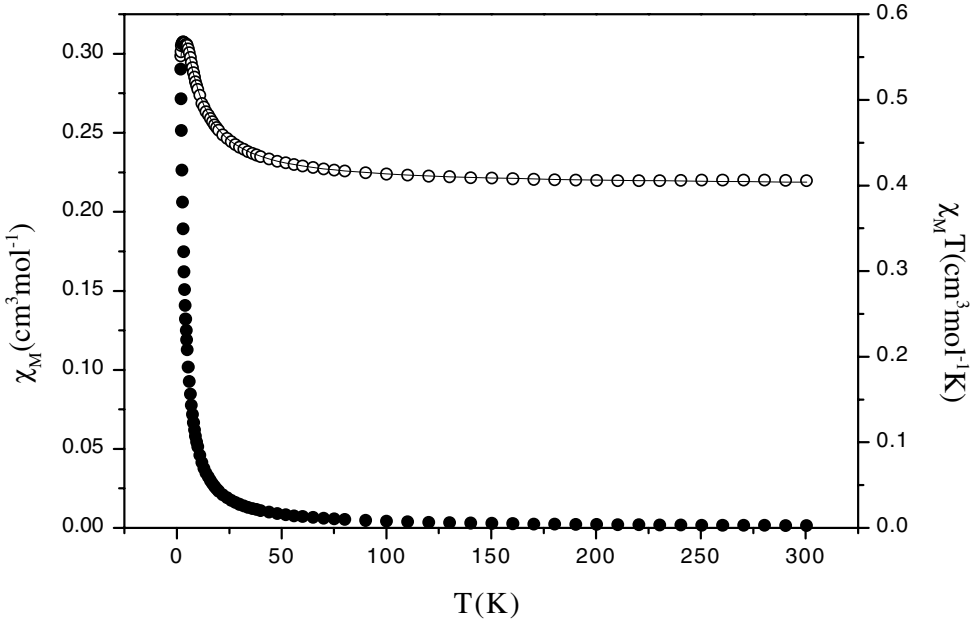


Fig. 5. The plot of the χ_M and $\chi_M T$ product vs. temperature (χ_M – the molar magnetic susceptibility calculated per one copper(II) centre). The solid line was generated from the best-fit magnetic parameters.

$cm^3\ mol^{-1}$ K at about 3 K and decreases upon further cooling. This behavior indicates a weak ferromagnetic interaction between copper(II) atoms. In keeping with the structure, the experimental magnetic susceptibility data were analyzed with Eq. (1)

$$\chi_M = \frac{Ng^2\beta^2}{12kT} \times \frac{10\exp(J_{12}/kT)+\exp(-2J_{12}/kT)+\exp(-2J_{13}/kT)}{2\exp(J_{12}/kT)+\exp(-2J_{12}/kT)+\exp(-2J_{13}/kT)} \quad (1)$$

where χ_M denotes the magnetic susceptibility per mole of copper(II) [53]. The spin Hamiltonian appropriate to describe the exchange interaction in a linear symmetric copper(II) trimmer, based on the isotropic HDvV model may be written

$$H = -2J_{12}(S_1S_2 + S_2S_3) - 2J_{13}S_1S_3. \quad (2)$$

The exchange integral J_{12} refers to two adjacent centres and J_{13} to the interaction between the terminal centres. Linear trimmers with ferromagnetic ground states have been reported and some authors have proposed to negligible interaction between the terminal centres. and accept $J_{13} = 0$ [54–59]. To take into account, the decrease of the $\chi_M T$ value at low temperatures (intertrimer exchange interactions) a molecular field correction term is added to Eq. (1). The equation for the susceptibility then has the form

$$\chi_M = \frac{\chi_C}{1 - (2zJ'/Ng^2\beta^2)\chi_C}, \quad (3)$$

where χ_C is the susceptibility calculated from Eq. (1), J' is the intertrimer exchange parameter and the z is the number of interacting nearest neighbours. The best fitting for the experimental data gives the following parameters: $J_{12} = 3.75\ cm^{-1}$, $J_{13} = 0.56\ cm^{-1}$, $zJ' = -0.32\ cm^{-1}$, and $g = 2.063$. As was shown earlier [59], $J_{13} \neq 0$ gives better agreement between experimental and calculated susceptibility data ($R = 8.866 \times 10^{-4}$) than obtained with constant $J_{13} = 0$: $J_{12} = 4.31\ cm^{-1}$, $zJ' = -0.29\ cm^{-1}$, and $g = 2.061$ ($R = 1.552 \times 10^{-3}$). The agreement factor is defined as

$$R = \frac{\sum_{i=1}^{n}(\chi_i^{exp}T_i - \chi_i^{calc}T_i)^2}{\sum_{i=1}^{n}(\chi_i^{exp}T_i)^2}. \quad (4)$$

The obtained exchange parameters are comparable to those found in other linear trimeric and polymeric *syn–anti* carboxylate copper(II) compounds [54–63].

To understand the ferromagnetic exchange interaction it is necessary to know the factors leading to orthogonal magnetic orbitals on Cu(1) and Cu(2) atoms. This compound represents the first structurally characterized linear trinuclear copper(II) complex containing 3,5-dinitrosalicylate bridges and showing weak ferromagnetic interaction between adjacent copper(II) atoms. Ferromagnetic coupling in the compound is consistent with the nature of the magnetic orbitals (built up from d-orbitals of the metals and the symmetry adapted linear contribution of the ligands orbitals) on Cu(1) and Cu(2) atoms, and the geometrical features of the Cu–O–C–O–Cu bridges. Central Cu(1) atom is, as it was shown above, joined to the other two satelite Cu(2) atoms by two bridging carboxylate groups of 3,5-dinitrosalicylates in a *syn–anti* conformation, resulting in a Cu…Cu separation between the nearest neighbours of 5.201(7) Å. The complex molecule is planar. The plane is formed by: Cu(1), Cu(2), bridging salicylato–dianion (except O atoms of nitro–groups) and terminal salicylato monoanion (except of nitro–groups O atoms) shows average deviation from the plane of 0.0513 Å. The O(22) atom (bridging COO group) exceeds deviation from the respective plane of 0.132(2) Å.

The coordination arrangement of the central Cu(1) atom is nearly square planar – CuO_4 and the two satelite Cu(2) atoms show nearly square-pyramidal coordination – CuO_5 with a tetragonality parameter $\tau \approx 0$ [64]. The magnetic d-orbitals on Cu(1), Cu(2) and Cu(2^i) atoms are delocalized toward the 2p oxygen orbitals of the both COO bridges and then the exchange coupling through the carboxylate groups may be operative [60]. According to Kahn's model [65], the exchange coupling constant J, can be expressed as a sum of both ferromagnetic (J_F) and antiferromagnetic (J_{AF}) contributions $J = J_F + J_{AF}$.

The ferromagnetic contribution is weak when the metal ions are bridged by polyatomic extended ligands whereas the magnitude of the antiferromagnetic one is proportional to the square of the overlap integral between magnetic orbitals centred on nearest-neighbour metal atoms. So, the sign and magnitude of J are primarily governed by the overlap [66]. For the well characterized copper(II) complexes with bridging *syn–anti* carboxylate groups, the magnitudes of the exchange coupling constants are rather small [60] (from −8.5 to 6.5 cm^{-1}). To generalize which factors determine the sign of the exchange coupling many examples are needed. In the present complex the *syn–anti* conformation and the small deviation of bridging O(22) carboxylate atom from the plane would cause the unfavourably orientation of magnetic orbitals centred on Cu(1) and Cu(2), reduce the antiferromagnetic contribution, so the ferromagnetic one would become predominant. Our results confirm suggestion that intramolecular ferromagnetic interaction (positive J constant) is observed when the *syn–anti* bridging mode of the Cu–O–C–O–Cu skeleton deviates from planarity [63]. Structural factors such as Cu–O lengths and Cu…Cu distances seem not to be determining the sign of the exchange coupling [61].

Decreasing of $\chi_M T$, observed below 3 K (Fig. 5) suggests antiferromagnetic intermolecular interaction

[59,65]. Planar molecules of trimers are stacked in the crystal lattice, interplanar distance of neighbouring planes is 3.31 Å and intramolecular hydrogen bond system exists (Figs. 2–4 and text above). Antiferromagnetic component obtained from fitting procedure confirm weak antiferromagnetic intermolecular interaction $zJ' = -0.32\ cm^{-1}$.

The EPR spectra of solid state of this complex, independent of the temperature (293, 77 and 4.5 K) display a pattern consistent with an axially distorted Cu^{II} centre with $g_{\|} = 2.32$, $g_{\perp} = 2.05$ and $g_{av} = 2.14$.

It is in agreement with the molecular structure of the trimer, square-planar and square pyramidal coordination polyhedrons of Cu^{II} [67,68]. The small differences between g values: $g = 2.06$ obtained from the fitting procedure and $g_{av} = 2.14$ from the EPR spectra is often observed and can be attributed to the unresolved axial anisotropy of the EPR spectra and the fact that the g value obtained from the magnetic data are only refined isotropically [69].

3.4. Spectral study

The electronic spectrum of the complex shows a wide asymmetric band at about 1.37 μm^{-1} (730 nm) and a shoulder at about 2.90 μm^{-1} (345 nm). The band at about 1.37 μm^{-1} is due to d–d transitions. Wideness and asymmetry of this d–d band is in connection with known structure showing two types of coordination polyhedra of the copper atoms. The other band may be assigned as a charge-transfer.

All the features of the IR spectrum of the compound are clearly compatible with the structural characteristics of the $[Cu_3\{3,5\text{-}(NO_2)_2sal^{2-}\}_2\{3,5\text{-}(NO_2)_2sal^{1-}\}_2(H_2O)_4]\cdot 4H_2O$. The IR spectrum of the compound shows strong and broad absorption band in the area 3620–3300 cm^{-1} with three maxima around 3095, 3460 and 1577 cm^{-1}, belonging O–H vibrations of water molecules and O–H of protonized carboxylic group. Carboxylate stretching frequencies were found as dublets $\nu_{as}(COO^-)$ at 1624 and 1605 cm^{-1}, and $\nu_s(COO^-)$ at 1448, and 1431 cm^{-1}. The difference between the asymmetric and symmetric stretching vibrations ($\Delta\nu = \nu_{as}(COO^-) - \nu_s(COO^-)$) of 176 and 174 cm^{-1} indicates [70] that the 3,5-dinitrosalicylate anions coordinated as a bidentate chelating, or bridging carboxylic group (see the crystal structure). The nitro-group stretching frequencies were found, $\nu_{as}(NO_2)$ at 1524 cm^{-1}, and $\nu_s(NO_2)$ at 1343 cm^{-1} as wider and unresolved probably triplets.

4. Supplementary material

CCDC-223041 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at http://www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; [fax: +44 (0) 1223/336033; e-mail: deposit@ccdc.cam.ac.uk].

Abstract

Copper(II) complexes of a series of new tetradentate NSNO ligands were synthesized and characterized spectroscopically. The ligands were also characterized by elemental analyses, IR, ^{1}H NMR, FAB-MS and UV–Vis spectroscopy. The solid-state structures of two complexes **2a** and **4a** were established by X-ray crystallography. The geometry about the copper ion of the complexes is dependent on the counter anion of the copper salt used. The five-coordinated copper ion is distorted square pyramidal when SCN^- or Cl^- ligate with the copper(II) ion, occupying the equatorial position, whereas the geometry about the four-coordinated copper ion is square planar when the counter anion is perchlorate. The electronic spectra of **2** and **3** in methanol show that the distortion of square pyramidal towards trigonal bipyramidal geometry about the copper ion of the complexes in solution is dependent on the presence of the electron withdrawing group. All the complexes exhibit a band for $S(\sigma) \rightarrow Cu(II)$ charge transfer (LMCT) in the range of 380–394 nm. The EPR spectra of complexes **2** and **3** are consistent with the fact that the unpaired electron is predominantly in the $d_{x^2-y^2}$ orbital as $g_{II} > g_I$. The redox behavior of all the complexes in methanol was studied by CV using TBAP as the supporting electrolyte.

1. Introduction

The coordination chemistry of transition metal complexes involving nitrogen and sulfur donor ligands has been the cynosure among chemists during recent years due to the application of these chelates in modelling of biomolecules, in the field of chemical and biological reactivity and nuclear medicine. The potential role played by copper ions, being present in the active sites of a large number of metalloproteins having the CuN_2S_2 chromophore [1], has stimulated efforts to design new ligand frames having nitrogen–sulfur donor sets and characterize copper complexes as models for providing a better understanding of the biological system [2]. It has been found that copper(II) chelates, especially of nitrogen–sulfur ligand frames, have antineoplastic activities and interactions with biological systems [3]. Considerable attention has been directed towards the synthesis of copper(II) chelates, especially of nitrogen–sulfur containing ligands, in search of nuclear medicine [4] and anticancer agents present in the hypoxic cell [5]. Again, current research shows that the involvement of both the

doi:10.1016/j.poly.2004.07.023

sulfur-to-copper charge transfer (LMCT) and the copper d–d band in the photosensitization process lead to an efficient DNA cleavage [6].

Herein, we have synthesized three sets of copper(II) complexes of a series of new tetradentate NSNO ligands using different copper(II) salts. In this paper, we present an account on copper(II) complexes of pyridylthioazophenol ligands. The present contribution aims to study the structural chemistry of the copper(II) complexes of the new ligands and the change of the geometry about the copper ion due to the presence of the anions (Cl^-, SCN^- and ClO_4^-) in the copper salts. The complexes **2** and **3** are five-coordinated inner metallic complexes where the fifth coordination number is satisfied by NCS^- or Cl^- being present in the equatorial position and the borderline base pyridine-N of the tetradentate (NSNO) ligands are in the axial site of the distorted square pyramidal geometry. In the cationic copper(II) pyridylthioazophenol complexes (**4**), the counteranion is perchlorate and the geometry about the copper ion is square planar.

2. Experimental

2.1. Materials

All the reagents were obtained from commercial sources and used without further purification. Copper(II) thiocyanate was obtained by adding a saturated solution of potassium thiocyanate to a solution of copper(II) chloride in methanol, followed by removing the precipitate of KCl by filtration. Tetra-*n*-butylammoniumperchlorate was prepared by the addition of sodium perchlorate to a hot solution of tetra-*n*-butylammonium bromide (Aldrich). The product was recrystallized from aqueous ethanol and tested for the absence of bromide. Solvents were distilled from an appropriate drying agent [7].

2.2. Physical measurements

The ^1H NMR spectra were obtained on a Bruker AC300 spectrometer with chemical shifts reported in δ values relative to the residual solvent resonance of $CDCl_3$. IR spectra were obtained on a JASCO FT-IR model 420 spectrometer using KBr disks, UV–Vis on a JASCO UV–Vis/NIR model V-570 spectrometer and mass spectra on a VG system, model 70-250S spectrometer. Microanalyses were performed with the use of a Perkin–Elmer 2400 CHN elemental analyzer and copper analysis was carried out by the iodometric titration method [8]. Molar conductance (Λ_M) were measured in a systronics conductivity meter 304 model using $\sim 10^{-3}$ M solutions in MeOH. Magnetic moments (μ, BM) were obtained from vibrating sample magnetometer PAR 155 model. X-band EPR spectra were taken on a Brucker spectrometer with a variable temperature liquid nitrogen cryostat at NTHU, Hsinchu, Taiwan. The values g_{II} and A_{II} were measured at 77 K. Electrochemical measurements were made with a computer controlled EG&G PAR model 270 VERSTAT electrochemical instrument using Ag/AgCl electrodes. All measurements were made at 298 K in dry MeOH with $[Bu_4N]ClO_4$ as the supporting electrolyte. The experimental solutions were deoxygenated by bubbling with research grade dinitrogen. The reported potentials are uncorrected for junction potential.

2.3. Syntheses of the ligands (HL)

The syntheses of the ligands were carried out following the common procedure of coupling different *para*-substituted phenols with the diazotized 2-(2-pyridylmethylthio)-aniline (Scheme 1). The procedure for the synthesis of 2-hydroxy-4-methyl-2′-(2-picolyl-thio)azobenzene (HL1) is as follows.

At first 2-(2-pyridylmethylthio)-aniline was synthesized following the reported procedure [9]. Then the preparation of 2-(2-pyridylmethylthio)-phenylazo-(4-methyl)-phenolate was carried out. The details are given as follows for **1a**. To an alkaline solution of *p*-cresol (1.0 g, 9.3 mmol) at 5 °C was added a diazotized solution of 2-(2-pyridylmethyl-thio)-aniline (2.0 g, 9.3 mmol) dropwise with continuous stirring. The temperature was controlled at ice-cold conditions. The resulting solution was acidified and the pH was controlled between 6 and 7. The red colored compound so precipitated was filtered and washed with water. Finally the pure recrystallized compound was obtained from ethanol-water. The yield was 65%. The yield of the other ligands varied from 50% to 68% following a similar method. *Anal*. Calc. for **1a**: C, 68.06; H, 5.07; N, 12.53. Found: C, 68.83; H, 4.96; N, 12.74%. Scheme 1. Synthetic procedure for the ligands.

2.4. Syntheses of Cu(II) complexes of the ligands (HL)

The preparation follows a common procedure. To a methanolic solution (15 mL) of **1a** (0.335 g, 1.0 mmol) the corresponding copper salt (1.0 mmol) solution was added dropwise and the resulting solution stirred for a period of 3 h for **2a**, 2 h for **3a** and 4 h for **4a**. The solution was dried at ambient temperature. The product was collected by washing with cold MeOH–H_2O and dried. The pure reddish-violet colored crystallized product was obtained from dichloromethane. Yield: 80–85%. *Anal*. Calc. for **2a**: C, 52.66; H, 3.69; N, 9.70; Cu, 14.67. 2.5. X-ray crystal structure analysis

Single crystals suitable for X-ray work of **2a** were grown by slow evaporation of a solution of the complex **2a** in methanolic:toluene (1:2) at ambient temperature while **4a** was grown by slow diffusion of hexane into a benzene solution of the complex at 298 K. A suitable single crystal of the complex **2a** was mounted on a Bruker SMART CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was also employed using the SAINT program. A total of 10601 [unique data = 4107; $R_{int} = 0.032$] reflections were measured and 2876 reflections were assumed observed the applying the condition $I > 2\sigma(I)$. The structure was solved by Patterson syntheses, followed by successive Fourier and difference Fourier syntheses. Full matrix least squares refinements on F^2 were carried out using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms in all cases. Hydrogen atoms were constrained to ride on the respective carbon atoms with an isotropic displacement parameter equal to 1.2 times the equivalent isotropic displacement parameter of their parent atom. The refinement converged to residual indices $R = 0.0390$; $wR_2 = 0.0927$ with $I > 2\sigma(I)$. The final difference Fourier map showed the maximum and minimum peak heights at 0.43 and -0.27 e Å^{-3}, respectively, having no chemical significance. Complex neutral atom scattering factors [10a] were used throughout. All calculations were carried

out using SHELXS-93 [10b], SHELXL-97 [10c], PLATON-99 [10d] and ORTEP3 [10e] programs. Data of **4a** were measured with Mo Kα radiation using the MARresearch Image Plate System. The crystal was positioned at 70 mm from the Image Plate. 100 frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [11a] to provide 2593 independent reflections. The structure was solved using direct methods with the SHELX-86 program [11b]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. An empirical absorption correction was applied using DIFABS [11c]. The structure was refined on F^2 using SHELXL [11d] with $I > 2\sigma(I)$.

3. Result and discussions

3.1. Synthesis

The ligands 2-(2-pyridylmethylthio)-phenylazo-(4-methyl)phenolates (**1**) were prepared by coupling 4-substituted-phenols with the diazonium ion obtained from 2-(2-pyridylmethylthio)-aniline, which was synthesized from 2-aminothiophenol by reacting it with 2-picolylchloride in presence of a base at the first step. This series of organic moieties act as tetradentate NSNO ligands which are interesting chelators due to the presence of hard donor azo-N and phenolate-O, borderline base pyridine-N and soft thioether S donor centres. The ligands have been spectroscopically characterized. The copper(II) complexes of these ligands were obtained by their reaction with equimolar amounts of the appropriate copper salts in methanol. All the complexes are soluble in common organic solvents.

3.2. Structures of the Cu(II) complexes (*2a* and *4a*)

The ORTEP views of **2a** and **4a** are illustrated in Figs. 1 and 2, respectively, with the atom numbering schemes shown. The selected bond distances and angles are listed in Tables 1 and 2, respectively. The crystal of **2a** is of the monoclinic system with the space group $P2_1/n$. In this monomeric complex **2a**, the copper center is bonded to a tetradentate monobasic NSNO donor pyridylthioazophenolate organic moiety (L1) and a monodentate chloride ligand. The coordination geometry is distorted square pyramidal with two nitrogen, one oxygen and chlorine donor atoms occupying the basal plane. The pyridinic N(1) shows the axial contact at a long distance of 2.2194 (18) Å. The axial Cu–N(1) bond distance (2.2194 (18) Å) is longer than the equatorial Cu–N(2) (1.980 (2) Å) due the geometric position as

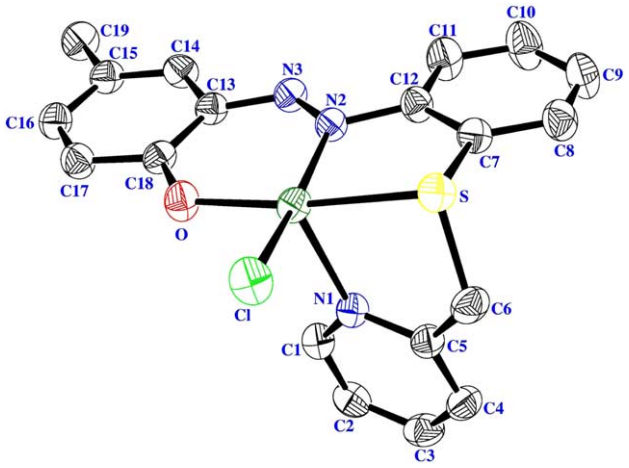

Fig. 1. Solid-state structure of [Cu(L1)Cl] (**2a**) showing the atom labelling scheme.

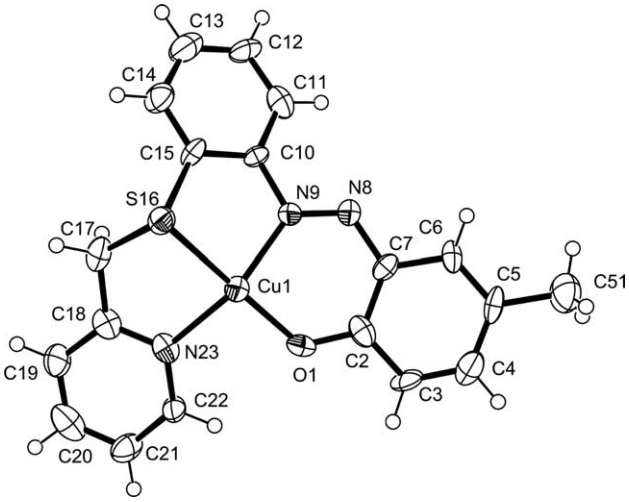

Fig. 2. An ORTEP view of the cation of the complex **4a** with thermal ellipsoids at the 50% probability level and the atom numbering scheme.

usual. The Cu–Cl bond distance is 2.2973(9) Å. The thioether sulfur S is strongly coordinated with copper, being present in the basal plane, and the Cu–S bond distance of 2.3360(8) Å is shorter than axial [12] and moderate in comparison to the usually observed basal Cu–S bond distances in pentacoordinated copper complexes [13]. The structure of **2a** is almost regular square pyramidal as seen from the trigonality index [14] τ of only 0.116 [$\tau = (\beta - \alpha)/60$ where β = O–Cu–S = 172.95(6)° and α = N2–Cu–Cl = 165.99(7)°].

In the complex cation of $[Cu(L1)]ClO_4$ (**4a**), Cu(II) is located in the centre of a square planar environment and the metal atom is bonded to four atoms of the ligand. Here, both coordinating N atoms are at equivalent distances whereas this fact is different in the case of **2a**. The distortion from square planar geometry to tetrahedral geometry is also observed as distances from the donor atoms to the square plane are −0.29, 0.29, −0.27, 0.28

Å for O(1), N(9), S(16) and N(23), respectively, the copper atom being −0.07 Å from this plane. The perchlorate ion has no close contact to the copper atom.

Both complexes are monomeric but all the corresponding Cu–O, Cu–N and Cu–S distances of **4a** are significantly shorter than those of **2a**. It may be due to the increase in formal charge on **2a** by coordination of chloride and the difference in geometry of the complexes. The Cu–N(pyridinic) distance in **4a** is shorter than that of **2a** by ca. 0.24 Å. This Cu–N bond in **2a** is axial and not in the same plane as the other donor atoms of the ligand, which is different from that in **4a**. This difference in bond lengths for the same ligand frame is due to the flexibility of the Cu(II) coordination geometry.

3.3. Spectral properties

The ligands **1** exhibit medium intense IR bands at ~3300 cm^{-1} (O–H of H bonded phenolic OH) [15] which is absent in all the complexes. This indicates coordination of oxygen to the metal centre [16]. The $\nu_{N=N}$ mode of the free ligand (1495–1505 cm^{-1}) is shifted to lower to wave numbers ($\Delta \sim 20$–30 cm^{-1}) in the complexes, suggesting coordination of the metal ions to the azo function [17]. The $\nu_{N=N}$ band is observed at 1465–1478 cm^{-1} for all the complexes. In addition to this ν_{C-S} at 790 cm^{-1} for the ligands shifts to 760 cm^{-1} for the complexes. Thiocyanato complexes **3** show a characteristic band in the range of 2050–2060 cm^{-1} indicating the presence of N-bonded NCS groups [18]. Infrared spectra of the complexes **4** exhibit an intense band at approximately 1090 cm^{-1} along with a weak band at 625 cm^{-1} which have been assigned to $\nu_{(ClO_4^-)}$. The conductivity measurements of complexes **2** and **3** in methanolic solution show the conductance in the range of 9–20 Λ_0 mol^{-1} cm^{-1} and those of **4** in MeOH are 89–102 Λ_0 mol^{-1} cm^{-1}. The values suggest that the complexes **2** and **3** exist as non-electrolytes and **4** as having 1:1 electrolytic nature in the solution state. Magnetic susceptibility data reveal spin-only values for all the copper complexes as the values are very close to 1.73 BM (in the range of 1.72–1.92 BM).

3.3.1. Electronic spectra

The electronic absorption spectra of the azo ligands and their complexes were recorded at room temperature using MeOH as the solvent, and the results are shown in Table 3. The spectra of the free ligands and the complexes exhibit transitions at lower than 400 nm corresponding to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions [19]. In the case of the complexes, a band around 390 nm is assignable to the $S(\sigma) \rightarrow Cu(II)$ charge transfer (LMCT) transition [6,20]. The copper(II) complexes are characterized by a rather broad d–d absorption band in their solution electronic spectra; often a low- or high-energy shoulder is also present or, occasionally, two distinct absorption maxima are observed. In many cases it has been shown that the presence of a single d–d band with a high energy shoulder

is typical of a trigonal bipyramidal stereochemistry for copper, whereas an absorption with a low energy shoulder indicates a square pyramidal geometry [21].

On the basis of the above criterion, the observed data of **2** and **3** suggest that the distortion of square pyramidal towards trigonal bipyramidal about the copper ion of the complexes in solution is maximum in case of the complexes **2d** and **3d**. Here, complexes **2d** and **3d** in methanol exhibit two bands of nearly equal intensity between 730 and 824 nm, this pattern suggests that the geometry about the copper ion in solution is between square pyramidal and trigonal bipyramidal. In the case of the complexes **4**, only one broad d–d absorption band around 705 nm and an intense band at 528 nm demon-

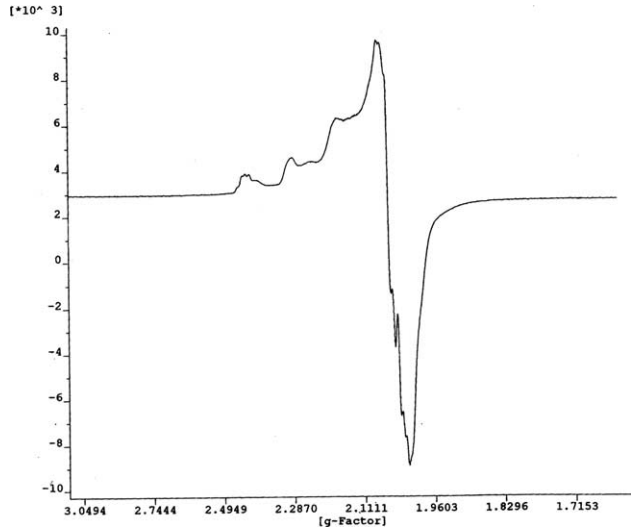

Fig. 3. EPR spectra of [Cu(L1)Cl] (**2a**) in MeOH at 77 K.

strates the square planar geometry around the copper ion.

3.3.2. EPR spectra

EPR spectra of the cupric complexes **2** and **3** have been recorded in MeOH at 300 and 77 K. The data are tabulated in Table 3 and one representative spectra of **2a** is shown in Fig. 3. However, the complexes in the frozen state at 77 K show well-resolved peaks of low intensities in the low-field region and an intense peak in the high field region. No band corresponding to the $M_s = +2$ transition was observed in the spectra, ruling out any Cu–Cu interaction. The complexes **2** and **3** appear to exhibit axial spectra of square pyramidal species with g_{II} varying from 2.217 to 2.238 and A_{II} having a range from 154×10^{-4} to 173×10^{-4} cm^{-1}. The result are in general agreement with the solution electronic spectra, which also suggest the existence of distorted square pyramidal geometries with more distortions in the complexes **2d** and **3d**. From the observed g-tensor values of the Cu(II) complexes it is clear that $g_{II} > g_I$ which dictate that in complexes **2** and **3** the unpaired electron is predominantly in the $d_{x^2-y^2}$ orbital [22] giving $^2B_{1g}$ as the ground state.

3.4. Electrochemistry

Redox properties of the complexes were examined by cyclic voltametry using a Pt-disk working electrode and a Pt-wire auxiliary electrode in dry MeOH and in the presence of [*n*-Bu$_4$N]ClO$_4$ as the supporting electrolyte. The potentials (Table 3, Fig. 4) are expressed with reference to Ag/AgCl electrodes. In solution all compounds displayed a quasi-reversible voltammogram having $i_{pc}/i_{pa} \approx 1$ in the range from −65 to 177 mV with $\Delta E = 96$–210 mV. The influence of the substituents in the ligands is apparent from the data.

Abstract

A series of novel bidentate ligands have been synthesized by the condensation of 4-acetyl-2,4-dihydro-5-methyl-2-(4′-methylphenyl)-3H-pyrazol-3-one and various aromatic amines. All of these ligands have been characterized on the basis of elemental analysis, IR, ^{1}H and $^{13}C\{^{1}H\}$ NMR data. The molecular geometries of five of these ligands have been determined by single crystal X-ray study. Crystallographic study reveals that these ligands exist in the amine-one tautomeric form in the solid state. NMR study also suggests the existence of the amine-one form in solution at room temperature. The reaction of these ligands with copper(II) resulted in the formation of mononuclear octahedral complexes of the general formulae $[CuL_2(H_2O)_2]$, with water molecules at the axial positions. These complexes were characterized on the basis of analytical and spectroscopic data. Thermal analyses of these complexes were also carried out. Magnetic moment measurements of these complexes at room temperature correspond to one unpaired electron. An ESR study of all these complexes in solution at room temperature, and also under frozen conditions at liquid nitrogen temperature, is consistent with the distorted octahedral geometry of the metal ion in these complexes. Semi-empirical quantum mechanical calculations (PM3) have been performed on the ligands to get charges over the coordinating atoms. A fairly good linear relation was found between the charges over the coordinating atoms of the ligands and the ligand field transition energies.

1. Introduction

The chemistry of pyrazolone derivatives has attracted much attention because of their interesting structural properties and applications in diverse areas [1–10]. They are useful reagents for the extraction and separation of various metal ions [11–15]. They can also be used in laser materials, as ^{1}H NMR shift reagents, in chromatographic study and in the petrochemical industry [16–20]. Recently, photochromism of pyrazolone derivatives have also been reported [21]. Many of these ligands exhibit keto enol tautomerism, and because of this they show interesting structural and spectroscopic properties which have been the subject matter of many reports [22,23]. Among these ligands, acyl pyrazolones have been studied extensively owing to their effective properties with respect to extracting metal ions [24,25]. On the other hand pyrazolone-based Schiff base chemistry is less extensive. Our laboratory has been exploring the chemistry of this class of ligand for quite some time [26–30]. Some other groups have also reported lantha-

nide complexes of this class of ligand along with their luminescence properties [31–33].

We were interested to synthesis a new series of pyrazolone-based Schiff base ligands, which can form stable neutral complexes with transition metal ions and may find some application in solvent extraction chemistry. With this view we have synthesized a series of ligands by condensation of acyl pyrazolone with substituted aromatic amines. These ligands are shown in Fig. 1 with the H-numbering scheme (for interpretation of ^1H NMR spectra). Many of these ligands have been characterized crystallographically. We report here synthesis and characterization of these ligands and their Cu(II) complexes. Spectroscopic, magnetic and EPR studies of all the complexes have also been reported.

2. Experimental

2.1. Materials

The compound 3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one was obtained from Shree Sidhdhanath Industries, Sachin, India. All of the amines were obtained from Sisco-Chem. Pvt. Ltd., India. The liquid amines were purified by distillation and the solid amines were recrystallised from hot ethanol before use. Dioxane was obtained from E. Merck (India) Ltd., and used after purification following a standard procedure [34]. Absolute alcohol was obtained from Baroda Chem. Industry Ltd. and was used after distillation. Calcium hydroxide and acetyl chloride were obtained from Samir Tech. Chem. Pvt. Ltd. Sodium acetate was obtained from Spectrochem Pvt. Ltd., India. All the chemicals used were of AR grade. Solvents used in this study were purified following the standard procedures.

2.2. Physical measurements

Elemental analyses (C, H, N) were performed on a model 2400 Perkin–Elmer elemental analyzer. Copper was estimated by the titrimetric method using EDTA [35]. FAB mass spectra were recorded on a JEOL SX 102/DA-6000 mass spectrometer using xenon (6 kV, 10 mA) as the FAB gas. The accelerating voltage was 10 kV and the spectra were recorded at room temperature using *m*-nitrobenzyl alcohol as the matrix. Infrared (IR) spectra were recorded on a Nicolet-400D spectrometer as KBr pellets. NMR spectra were recorded on a model DPX 200 Bruker FT-NMR instrument. The electronic spectra were recorded on a model UV160A Shimadzu spectrophotometer. Specific conductivity of the complexes was measured on a model 305 Systronic conductivity bridge. Magnetic moments were measured on a model 7304 Lake Shore Cryotronics vibrating sample magnetometer. The ESR spectra were recorded on a Varian E112 ESR spectrometer.

2.3. Synthesis of ligands

2.3.1. Preparation of 4-acetyl-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (AMMP)

3-Methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (20.1 g, 0.1mol) was dissolved in hot dioxane (80 cm^3) in a flask equipped with a stirrer, separating funnel and reflux condenser. Calcium hydroxide (14.81 g, 0.2 mol) was added to this solution, followed by acetyl chloride (7.85 g, 0.1 mol) added dropwise with precaution, as this reaction was exothermic. During this addition the whole mass was converted into a thick paste. After the complete addition, the reaction mixture was refluxed for half an hour and then it was poured into dilute hydrochloric acid (200 cm^3, 2 M). The colored crystals (AMMP) thus obtained were separated by filtration and recrystallized from an acidified methanol–water mixture (HCl:MeOH:H_2O = 1:80:19). Yield: 20.2 g (88%). Melting point (mp): 192 °C. *Anal.* Calc. for $C_{13}H_{14}N_2O_2$: C, 66.06; H, 6.42; N, 12.84. Found: C, 65.78; H, 6.40; N, 12.67%.

2.3.2. General method for the preparation of the ligands

- 4-[{(Phenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^1).
- 4-[{(2-Methylphenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^2).
- 4-[{(3-Methylphenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^3).
- 4-[{(4-Methylphenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^4).

- 4-[{(2-Chlorophenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^5).
- 4-[{(3-Chlorophenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^6).
- 4-[{(4-Chlorophenyl)imino}ethyl]-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (HL^7).

The compound 4-acetyl-3-methyl-1-(4′-methylphenyl)-2-pyrazolin-5-one (AMMP, 2.30 g, 0.01 mol) was dissolved in ethanol (20 cm^3) and the appropriate amine (0.01 mol, aniline for HL^1, *ortho*-, *meta*- and *para*-toluidine for HL^2–HL^4, respectively, and *ortho*-, *meta*- and *para*-chloroaniline for HL^5–L^7, respectively) was added to this solution. The reaction mixture was refluxed for 2 h. During the reflux a microcrystalline compound was separated, which was isolated by filtration, washed with ethanol and dried in air. Suitable crystals for single crystal X-ray study were grown from acetonitrile.

2.3.3. General method for the preparation of the Copper(II) complexes $[Cu(L)_2(H_2O)_2]$, ($L = L^1$, L^2, L^3, L^4, L^5, L^6 and L^7)

The appropriate ligand (0.01 mol) dissolved in hot DMF (20 cm^3) was added dropwise into an aqueous solution (20 cm^3) of copper(II) nitrate (0.01 mol, 2.41 g) with stirring. After the complete addition, 2.0 g of sodium acetate was added to the solution and the reaction mixture was refluxed for 2 h. The solution thus obtained was concentrated to half of its original volume by evaporation using a hot plate and allowed to cool to room temperature. During this period, a brownish microcrystalline solid was separated, which was isolated by filtration, washed with hot water followed by ethanol and dried in air. Yield: 50–60%.

2.3.4. Single crystal X-ray structure determination of the ligands

Crystallographic data for five of the ligands are summarized in Table 1. The data collections were carried out on a Bruker Mart Apex CCD diffractometer using graphite monochromated Mo Kα (λ = 71073 Å) radiation at 293 K. An absorption correction based on SADABS [36] was also applied. The structures were solved by direct methods (SHELXTL) and refined by least squares methods with atomic anisotropic thermal parameters for all non-hydrogen atoms [37,38]. All hydrogen atoms were either generated geometrically or obtained from the fourier difference map, and were assigned fixed isotropic thermal parameters in the structure factor calculations.

3. Results and discussion

3.1. Characterization of the ligands

All seven ligands, HL^1–HL^7, gave satisfactory elemental analysis (Table 2). A representative FAB mass spectrum, obtained for HL^1, exhibits the largest *m*/*z* isotropic peak at 306, which is in excellent agreement with the calculated value of 305.37 (based on the most common isotope for each element). The molecular structures of these ligands are such that they can exist in three tau-

Table 2
Melting point, elemental analysis (C, H and N)[a] and yield of the ligands

Ligand	Melting point (°C)	%C	%H	%N	Yield %
HL^1	193	75.04 (74.73)	6.26 (6.27)	13.83 (13.76)	75
HL^2	170	75.10 (75.20)	6.60 (6.62)	12.28 (12.38)	70
HL^3	180	67.12 (67.15)	5.32 (5.34)	12.47 (12.37)	60

HL^5	195	67.10 (67.15)	5.24 (5.34)	12.60 (12.37)	55
HL^6	197	75.10 (75.20)	6.13 (6.62)	12.40 (12.38)	60
HL^7	210	67.13 (67.15)	5.20 (5.34)	12.38 (12.37)	62

[a] Calculated values are given in the parentheses.

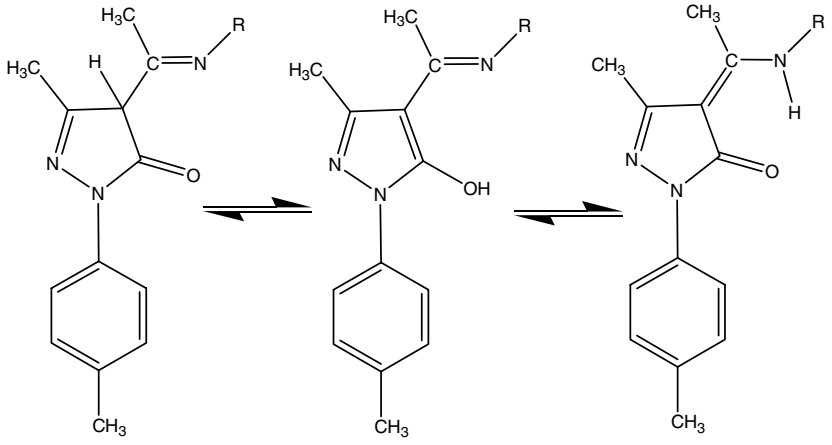

Fig. 2. Tautomeric forms of the ligands.

tomeric forms as shown in Fig. 2. Detailed solution and solid-state studies of these ligands were carried out to establish their geometry. The IR spectra of these ligands exhibit two characteristic bands in the ranges 3228–3241 and 1620–1637 cm^{-1}, which can either be assigned to $\nu_{(O-H)}$ and $\nu_{(C=N)}$, respectively, for the tautomeric imine-ol form (Fig. 2, II) or $\nu_{(N-H)}$ and $\nu_{(C=O)}$ respectively for the amine-one form (Fig. 2, III) of the ligand. We assigned these two peaks to $\nu_{(N-H)}$ and $\nu_{(C=O)}$, respectively for the later form based on the information obtained from crystallographic studies (discussed later).

The ^1H and $^{13}C\{^1H\}$ NMR spectra of all the ligands were recorded in $CDCl_3$ at room temperature and the data are presented in Tables 3 and 4. The signals due to methyl protons (three CH_3 for HL^1 and HL^5–HL^7; and four CH_3 for HL^2–HL^4) appear as singlets in the region δ 2.23–2.41. In some cases signals of two CH_3 groups are overlapped and all of these signals are so closely spaced that it is difficult to assign each signal to a particular methyl group unambiguously. Moreover, such an assignment would not contribute to the establishment of the geometry of the ligands, therefore, no attempt has been made for such an assignment. In the aromatic region, a few doublets and in a few cases some overlapping doublets/multiplets are observed. The appearance of multiplets is mainly because of the different substituents at the *ortho*-, *meta*- and *para*-positions of one of the two benzene rings. The protons marked as 'a' and 'b' (Fig. 1) are common to all ligands and appeared as doublets. The most deshielded doublet in the region δ 7.89–7.91 is assigned to the 'b' protons and the doublet at δ 7.17/7.18 (in a few cases it is overlapped with other signals) is due to 'a' protons. This assignment is on the basis of the substituents in the benzene ring, CH_3 being an electron-donating group is expected to shield the protons attached to the carbon atoms adjacent to it. For the other benzene ring, the spectra are simpler for the ligands with *para*-substituents (HL^4 and HL^7). For HL^4, the 'd' protons appear as a doublet at the same position (δ 7.18) as found for the 'a' protons, this is because of the same substituent at the *para*-position. The 'c' proton for HL^4 appears as a doublet at δ

Table 3
^{1}H NMR spectral data for the ligands recorded in $CDCl_3$

Ligand	CH_3	*a*-H (*J*, Hz)[a]	*b*-H (*J*, Hz)	*c*-H (*J*, Hz)	*d*-H (*J*, Hz)	NH
HL^1	2.32 s, 2.38 s,	7.17 d, $J = 7.4$	7.91 d, $J = 7.8$	7.17 d, $J = 7.4$	7.25–7.43 m (3H)[b]	13.10 s
HL^2	2.23 s, 2.32 s, 2.39 s	7.09–7.26 m	7.91 d, $J = 8.2$	7.09–7.26 m (4H)[c]		12.96 s
HL^3	2.32 s, 2.35 s, 2.38 s	7.08–7.31 m	7.91 d, $J = 7.4$	6.97 d, ($J = 7.8$, 1H), 7.08–7.31 m (3H)[c]		13.06 s
HL^4	2.32 s, 2.36 s, 2.38 s	7.18 d, $J = 6.8$	7.90 d, $J = 7.6$	7.06 d, $J = 7.2$	7.18 d, $J = 6.8$	13.02 s
HL^5	2.30 s, 2.34 s, 2.41 s	7.19 d, $J = 8.4$	7.89 d, $J = 8.4$	7.29–7.36 m (3H), 7.50 (m, 1H)[c]		13.01s
HL^6	2.34 s, 2.35 s, 2.39 s	7.07–7.39 m	7.89 d, $J = 7.4$	7.07–7.39 (m, 4H)[c]		13.12 s
HL^7	2.32 s, 2.38 s	7.18 d, $J = 8.0$	7.89 d, $J = 7.6$	7.11 d, $J = 8.4$	7.37 d, $J = 7.4$	13.05 s

[a] See Fig. 1 for numbering scheme.
[b] The proton at the para position of the ring is overlapped with 'd' protons.
[c] The protons of the benzene ring attached to the imine nitrogen are overlapped and 'c' and 'd' numbering is not applicable to them.

Table 4
$^{13}C\{^1H\}$ NMR spectral data (δ) for the ligands recorded in $CDCl_3$

Ligand	CH_3	>C–N–	Aromatic	>C=N–	>C=O
HL^1	17.3, 17.9, 21.4	100.9	119.5, 125.9, 127.7, 129.7, 129.9, 134.2, 137.1, 147.5	163.5	165.8

HL^3	17.4, 17.9, 21.4, 21.7	100.7	119.5, 122.9, 126.5, 128.5, 129.6, 134.2, 137.1, 137.3, 140.0, 147.5	163.4	165.8
HL^4	17.3, 18.0, 21.4	100.6	119.6, 125.8, 129.6, 130.5, 134.2, 137.5, 137.1, 137.8, 147.4	163.6	165.8
HL^5	17.2, 17.9, 21.4	101.5	119.7, 128.0, 128.5, 129.3, 129.7, 130.9, 131.7, 134.3, 134.9, 137.0, 147.5	163.7	166.0
HL^6	17.3, 17.9, 21.3	101.5	119.6, 124.0, 126.0, 127.8, 129.7, 130.9, 134.4, 135.5, 136.9, 138.5, 147.4	162.7	165.8
HL^7	17.2, 17.9, 21.3	101.2	119.6, 127.1, 129.7, 130.1, 133.4, 134.3, 135.9, 136.8, 147.4	163.1	165.8

7.06. In the case of HL^7 the 'c' and 'd' protons appear at δ 7.11 and 7.37, respectively. For the other five ligands the aromatic protons of the later benzene moiety are overlapped and appear as multiplets in the range δ 7.07–7.43. Another singlet corresponding to one proton for all compounds is observed in the range δ 12.96–13.12. This signal disappeared when a D_2O exchange experiment was carried out. It can be assigned either to OH or NH, in either case it is strongly deshielded because of hydrogen bonding with the other atom (N/O). It may be noted that the integration of this signal perfectly matches with one proton and there is no other fragment(s) of this signal, which suggests that only one tautomeric form of the ligands exist in solution under the experimental conditions. We have not done any temperature dependent experiments. Comparing with the solid state study, we prefer to assign this signal to NH, however, assignment of this peak to OH cannot be ruled out provided solid state structural evidence is not considered.

In the $^{13}C\{^1H\}$ NMR spectra the carbon atoms of the methyl groups appear in the range δ 17.2–21.7 (Table 4). The carbon atoms of the two benzene rings exhibit signals in the range δ 119.5–140.0 and the number of signals varies from seven to ten. Eight signals were observed for HL^4 and HL^7, as expected for the *p*-substituted benzene rings because of symmetry. However, HL^1 shows seven signals, so some of the signals might be overlapped as indicated by the intensity of a few signals. All other ligands, where one of the benzene rings is *ortho*- or *para*-substituted, show ten signals, as expected because of the loss of symmetry. In the low field region, three signals were observed around δ 147.5, 163.5 and 165.8, which are associated with the carbon atoms of the heterocyclic ring. The most deshielded signal (δ 147.5) can be assigned to >C=O and the next signal ($\sim\delta$ 163.5) could be due to >C=N of the heterocyclic ring. The singlet appearing for all compounds in the range δ 100.6–101.5 is assigned to the carbon atom of the >C N- moiety, the significant upfield shift is due to the electron-donating methyl group attached to it.

3.2. Molecular structures of the ligands

The molecular structures of five ligands (HL^1–HL^5) were determined from single crystal X-ray studies. ORTEP diagrams of compounds HL^1 to HL^5 with the atom numbering schemes are shown in Fig. 3. Important bond lengths and angles for all the compounds are listed in Table 5. These structure determinations are quite significant in view of the existence of these compounds in the solid state in different tautomeric forms. An analysis of the structural data shows that the C(10)–O(1) distances in the pyrazol moiety of all the compounds are in the range 1.245–1.261 Å, which are significantly shorter than the distance found for >C–OH in some pyrazolone derivatives, 1.341, 1.346 Å [39] and 1.331 Å [40], however, they are close to the distances found for

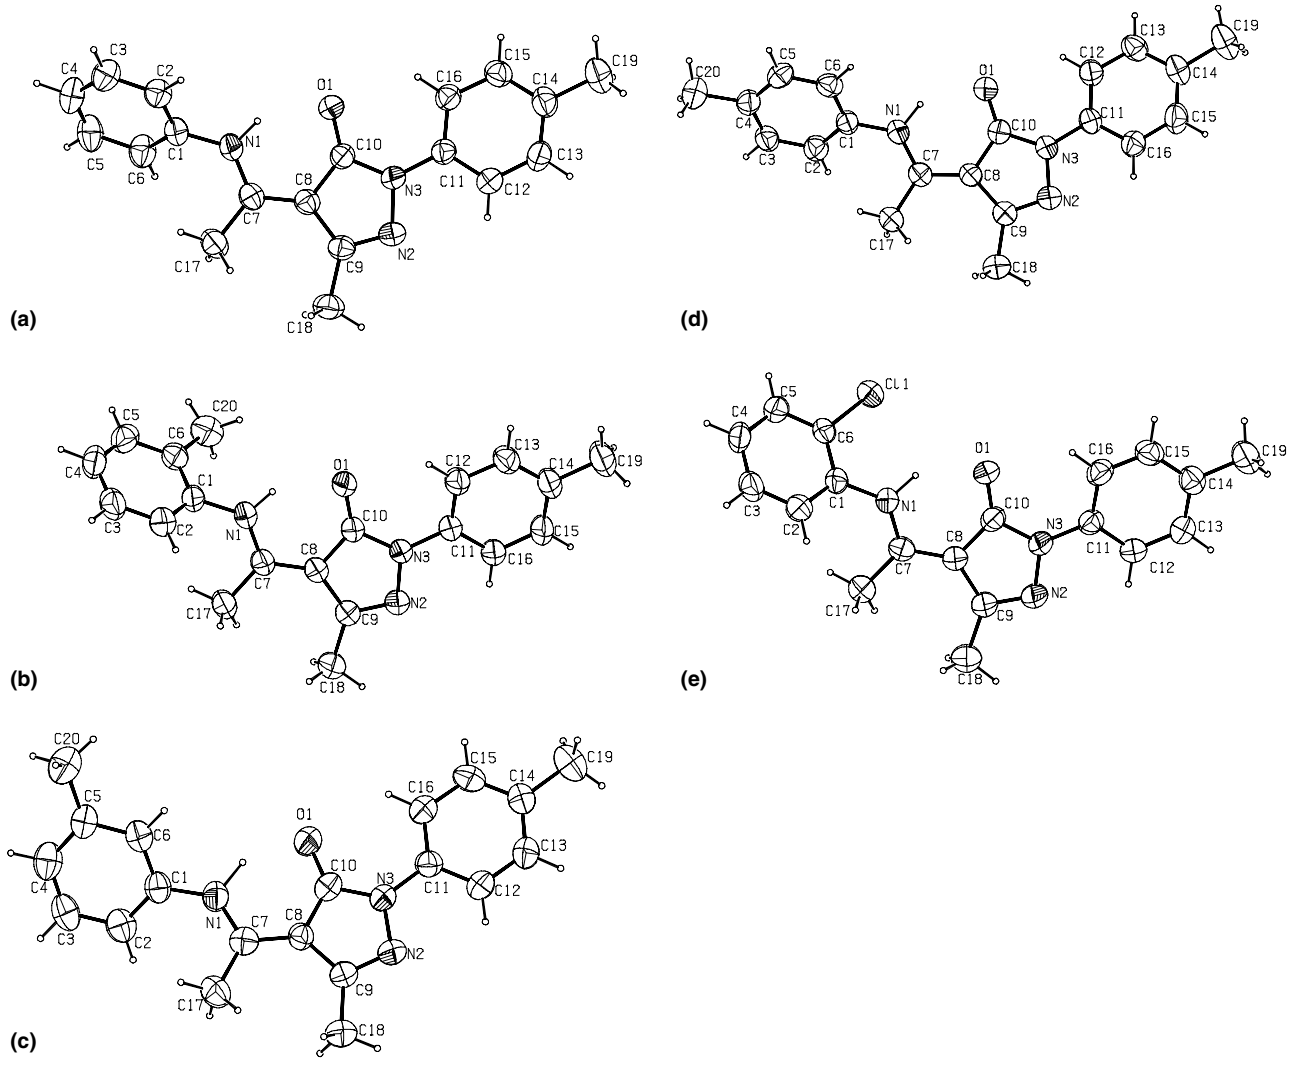

Fig. 3. ORTEP diagram of HL^1 (a), HL^2 (b), HL^3 (c), HL^4 (d) and HL^5 (e).

>C=O in similar compounds, 1.262 Å [39] and 1.254 Å [10]. The C(7)–N(1) distances of the imine moiety are in the range 1.327–1.338 Å, which are significantly longer than that found for C=N in pyrazolone compounds, 1.298 Å [21] and 1.292 Å [10], but similar to that found for >C–N (1.339 Å) [41]. It may be also noted that the proton associated with N(1) is located from the Fourier difference map in all of the five compounds. These three observations clearly establish that these compounds exist in the keto-form in the solid state. However, the N–H proton is strongly hydrogen bonded with the O(1) atom, the N(1)···O(1) distances are in the range 2.664–2.709 Å and ∠N(1)–H(1)···O(1) are in the range 140.35°–145.61° (Table 6). The possibility of the attachment of H(1) with C(8) (imine-one form) is ruled out on the basis of the angles around C(8), the summation of the three angles, ∠C(7)–C(8)–C(10) + ∠C(10)–C(8)–C(9) + C(9)–C(8)–C(7) are in the range 357.00°–360.78°, which is close to the ideal value of 360°, expected from the coplanar C(7), C(8), C(9) and C(10) atoms. Thus, the crystal structure study conclusively proves the existence of these compounds in amine-one form.

The ligand HL^1 crystallizes in the $P\bar{1}$ space group with two molecules in the asymmetric unit. The packing diagram of this compound is shown in Fig. 4. The molecules are associated in pairs by strong C–H···π interactions between the methyl hydrogen atoms and the phenyl rings, and also offset face-to-face π···π interactions between the phenyl rings. The phenyl ring of the first molecule, C(1)–C(6), exhibits strong π···π stacking with the phenyl ring of the second molecule, C(20)–C(25) in the asymmetric unit, forming a layered architecture along the *a*-axis. The various C–H···π interactions of HL^1 are deposited (Table S1) as supplementary material. The ligands HL^2, HL^3 and HL^4, which have *ortho*-, *meta*- and *para*-substituted methyl groups, also exhibit strong intermolecular C–H···π and offset face-to-face π···π stacking interactions forming a novel

supramolecular architecture. In addition to the stacking interactions of phenyl rings in HL^5, a moderate C–H···Cl interaction is also observed (C(3)–H(3)···Cl(1); C(3)–H(3) = 0.930; H(3)···Cl(1) = 2.804; C(3)–Cl(1) = 3.550 Å; ∠C(3)–H(3)···Cl(1) = 137.88°). The packing diagram of HL^5 showing hydrogen bonding interactions is deposited (Fig. S1) as supplementary material.

3.3. Characterization of the metal complexes

Cu(II) complexes of all the seven ligands have been synthesized by the reaction of $Cu(NO_3)_2$ and the respective ligands in water–DMF (1:1) under reflux conditions in the presence of sodium acetate. The metal and C, H and N analyses of these complexes (Table 7) suggest a molecular formula of the composition $[Cu(L)_2(H_2O)_2]$, where L = deprotonated HL^1, HL^2, HL^3, HL^4, HL^5, HL^6 and HL^7. The IR spectra of the metal complexes exhibit no band for $\nu_{(N-H)}$ (3228 cm^{-1}) of the ligands, indicating deprotonation of the N–H group in metal complexes. The molar conductivity measurements show Λ_M values (Table 7), which are much lower than those expected for 1:1 electrolytes, confirming the non-electrolytic nature of the complexes. The magnetic moment measurements of the complexes show μ_{eff} values of 1.72–1.95 μ_B (Table 7), which corresponds to one unpaired electron and is expected from mononuclear Cu(II) complexes (d^9) with some orbital contribution. On the basis of all these data, the molecular geometry assigned to the metal complexes is shown in Fig. 5. Attempts have been made to grow X-ray quality single crystals of these complexes, however, this has been unsuccessful so far. A FAB mass spectrum of a representative complex $[Cu(L^1)_2(H_2O)_2]$ was recorded and the largest *m/z* isotropic peak appeared at 673, which corresponds to the composition $[Cu(L)_2]$ (672.27, molecular mass – $2H_2O$). Fragmentation of a weakly coordinated molecule/ion in the FAB mass spectrum is not unlikely. To confirm the presence of weakly coordinat-

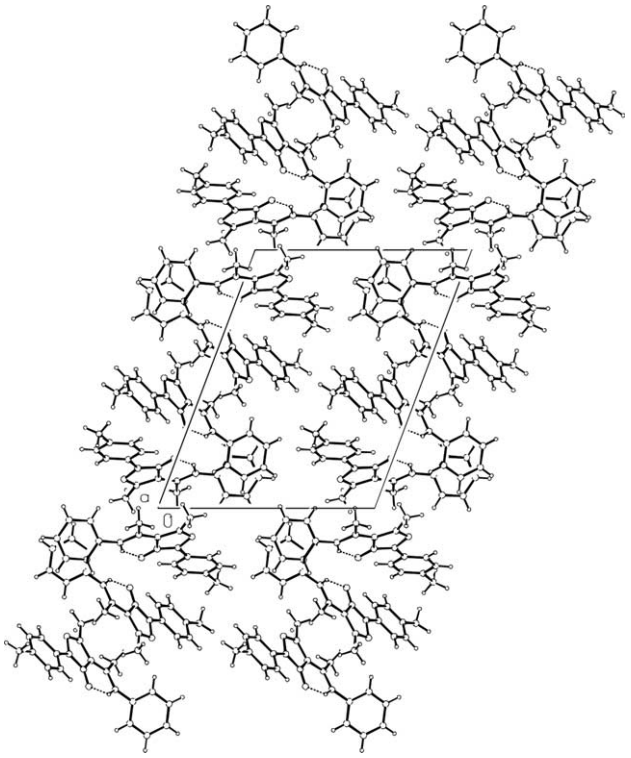

Fig. 4. Packing diagram of HL^1 down the *a*-axis.

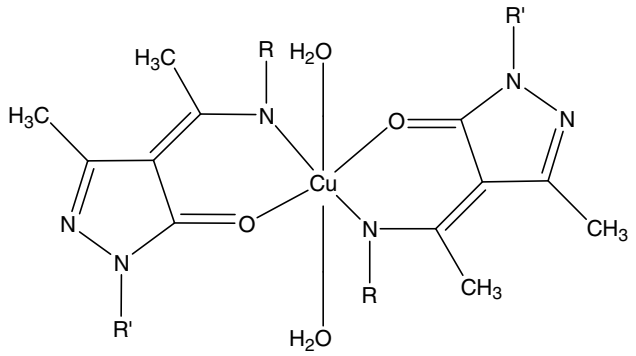

Fig. 5. Structural drawing of the Cu(II) complexes.

ing H_2O molecules in the complex we carried out thermogravimetric analyses of all the complexes. This study shows loss of weight corresponding to two water molecules in the temperature range 130–170 °C, indicating that the water molecules in these complexes are weakly coordinated to the metal ion. The presence of a H_2O molecule in the complexes is also indicated by IR spectra, which show a broad band centered around 3400 cm^{-1} and two sharp bands at 710 and 420 cm^{-1}, the later two can be assigned to the wagging and rocking modes of vibration of the water molecule, respectively [42]. The octahedral geometry of the metal ion in these complexes is also evident from electronic spectra and an EPR study, discussed below.

3.4. Electronic spectra of the metal complexes

The electronic spectra of all the complexes were recorded in DMF and the data are presented in Table 8. All of these complexes exhibit a broad band in the region 659–690 nm and another strong absorption in the region 454–504 nm. In an octahedral geometry, the ^2D state of the free Cu(II) ion (d^9) splits into a lower energy doublet ^2E_g state and a higher energy triplet $^2T_{2g}$ state, from which a $^2T_{2g} \leftarrow {}^2E_g$ d–d transition in the visible re-

Table 8

gion is expected. However, a complex with the d^9 configuration of the metal ion is expected to experience Jahn–Teller distortion, which leads to further splitting of the ^2E_g and $^2T_{2g}$ levels into $^2B_{1g}$, $^2A_{1g}$ and $^2B_{2g}$, ^2E_g levels, respectively. With this splitting three possible transitions are $^2A_{1g} \leftarrow {}^2B_{1g}$ (ν_1), $^2B_{2g} \leftarrow {}^2B_{1g}$ (ν_2) and $^2E_g \leftarrow {}^2B_{1g}$ (ν_3). The energy difference between these levels depends on the extent of the Jahn–Teller distortion. If the energy difference is not large, then all these three transitions are expected to be close in energy and in this situation these bands may not resolve and may appear as a broad band. Therefore, the broad band in the region 659–690 nm could be due to the combination of these three transitions. The strong absorption found for all complexes in the range 454–504 nm is due to a ligand to copper(II) charge transfer transition.

3.5. Semi empirical calculation of atomic charges and its correlation with the d–d band

The absorption maxima (λ_{max}) of d–d transitions for metal complexes are related to the net atomic charges on the coordinating atoms of the ligands. We were interested to find the correlation between the average atomic charge of the coordinating atoms of the ligands and λ_{max} of the d–d transition. The net atomic charges on the coordinating O and N atoms of the ligands have been calculated using the semi-empirical PM3 Hamiltonian in the MOPAC package [43] and the charges thus obtained have been averaged (Table 8) and plotted against the experimentally obtained λ_{max} of the d–d transition of the complexes (Fig. 6). The plot shows a linear correlation between the net atomic charge and λ_{max}, as the average negative charge of the coordinating atoms increases the absorption maxima shifts towards lower energy. Using the correlation parameters thus obtained (Fig. 6) one can predict the λ_{max} for a similar type of complex by calculating the net atomic charges by semi empirical PM3 on the atoms bound to the metal ion. This method (PM3) is simple compared to the more elaborate calculations (high level ab initio) using quantum mechanical methods and this simple method is quite useful for predicting the absorption maxima of the d–d band for similar classes of metal complexes.

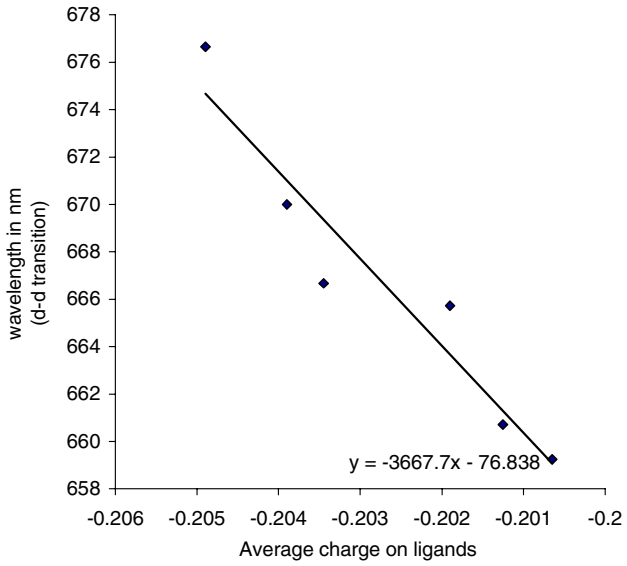

Fig. 6. Plot of the wavelength of d–d transitions vs average charge on the coordinating atoms of the ligands calculated by semi-empirical calculations (PM3 Hamiltonian).

3.6. Electron spin resonance

EPR spectra of all the complexes were recorded in DMF at room temperature (25 °C) and also under frozen conditions at liquid nitrogen temperature. At room temperature all the complexes show four line (equally spaced) spectra, characteristic for mononuclear copper(II) complexes. In frozen solution some hyperfine splitting was observed in the parallel region, however, no such splitting was noted in the perpendicular line. The relevant data are summarized in Table 9. Analysis of these data show that in all cases $g_{II} > g_{\perp}$, which suggest a $d_{x^2-y^2}$ ground state for the Cu(II) ion in these complexes. The axial spectrum with $g_{II} > g_{\perp} > 2.03$ is consistent with a distorted octahedral geometry around the copper(II) ion.

Table 9

Abstract

The *meso* form of $(RMeSiOH)_2$ [R = $Si(SiMe_3)_3$] (**2**) was synthesized exclusively by hydrolysis of a diastereomeric mixture of $(RMeSiCl)_2$ (**1**). The novel cyclic metal disiloxides (*E*)-$(RMeSiO)_2Ti(OEt)_2$ (**3**) and $[(Z)\text{-}(RMeSiO)_2]_2Zr \cdot HNEt_2$(**4**) are readily prepared from the reaction of *meso*-**2** with $Ti(OEt)_4$ and $Zr(NEt_2)_4$, respectively. The results of X-ray structure analyses reveal complexes **3** and **4** to be strained five-membered ring compounds forming a dimeric structure and an adduct with diethylamine.

1. Introduction

The ability of siloxide ligands [1] to act as effective σ- and π-donors enables electronic stabilization of highly electrophilic metal centers, which have found applications in the catalysis of processes such as olefin polymerization [2], olefin metathesis [3] and oxidations [4]. Moreover, siloxide ligands bearing sterically demanding substituents can probably protect the coordination sphere of the metal complexes, thus enforcing coordinative unsaturation and stabilizing reduced early TM centers [5]. Among the various substituted disiloxane-1,3-diols, incompletely condensed polyhedral silsesquioxanes and related compounds mainly consisting of Si–O–Si backbones [6], there are only a few diols that have both an oligosilane backbone and asymmetric silicon centers [7]. These diols might be of interest for the synthesis of stereoregular cyclic metal siloxide complexes. Recently, we reported the preparation of silanols of the general formula $(RMeSiOH)_2$ [R = $Si(SiMe_3)_3$, $Si(SiMe_3)_2Ph$] and we have shown that these derivatives can act as supporting ligands for Cp_2Ti fragments [8]. Herein we report on the first highly diastereoselective formation of a *meso*-disilane-1,2-diol and its utilization for the straightforward synthesis of cyclic titanium and zirconium siloxides in high yields.

2. Results and discussion

The starting point of our investigations was the dichlorohexasilane **1**, which could be synthesized according to the procedure outlined in Scheme 1 [8]. In fact, the reaction of two equiv. of $(Me_3Si)_3Si\text{–}K \cdot 3THF$ with $Cl_2MeSi\text{–}SiMeCl_2$ in pentane at −78 °C gave **1** as a diastereomeric mixture (*rac* and *meso*) in high yield. However, initial efforts to produce one of the two possible diastereomers of diol **2** exclusively by hydrolysis of **1** in the presence of several bases failed. Under the conditions applied only mixtures of both dia-

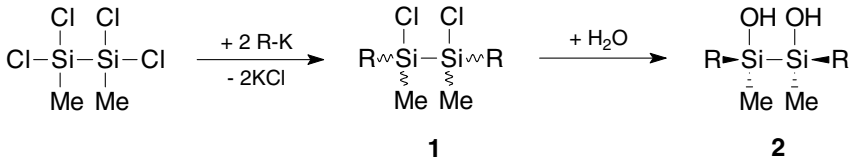

Scheme 1. Synthesis of **2** [R = $Si(SiMe_3)_3$].

stereomers (*rac* and *meso*) were obtained, which had to be separated by column chromatography, limiting the potential application of these ligands in coordination chemistry.

Surprisingly, a very simple hydrolysis of **1** without a base in a two-phase system consisting of water and ether gave the diastereomerically pure *meso*-diol **2** as a colorless crystalline material in 79% yield (Scheme 1). To our knowledge this is the first example of a highly diastereoselective hydrolytic reaction from a diastereomeric mixture of a dichlorodisilane. Compound **2** can be synthesized on a large scale, up to 50 g, and handled in air for months without decomposition; it is stable towards self-condensation and isomerization into the racemic form of **2** [9].

Although the origin of the diastereoselectivity is still unclear, it is reasonable to assume an S_N1 mechanism for the nucleophilic substitution at the silicon centre, since otherwise a diastereomeric mixture would be expected. The fact that the intermediate silylium ion can be sufficiently stabilized by hyperconjugation or σ-conjugation of the oligosilane backbone supports this view.

With the intent to investigate the ability of **2** to act as a supporting dianionic ligand for early transition metals, we extended our studies to the synthesis of novel Ti and Zr siloxide complexes. A suitable entry into the coordination chemistry of Ti and Zr is the use of the corresponding amides and alkoxides as starting materials (Scheme 2).

When $Ti(OEt)_4$ was reacted with one equiv. of **2** in heptane for three hours, a yellow microcrystalline material of what was thought to be the titanium complex **3** could be isolated in a yield of 85%. In contrast, the reaction of **2** with $Zr(NEt_2)_4$ in heptane led to the formation of a colorless solid which could be identified as spirocyclic zirconium complex **4** in a yield of 64%. Whereas **4** is highly moisture sensitive in solution and even in the solid state, **3** is reasonable stable in the solid phase and was unaffected by atmospheric moisture. The proposed structures of the complexes **3** and **4** were confirmed by NMR data and elemental analysis.

Single crystals obtained by slow crystallization from heptane solutions were analyzed by X-ray diffraction. In the case of the titanium compound **3** (Fig. 1, Table 1), the results reveal a dimeric structure in which two titanium diethoxide fragments are linked by two ethoxide groups forming a planar four-membered ring. Distances from the titanium atom to the non-equivalent bridging oxygen centers [2.030(3), 1.984(3) Å], are strongly elongated from the Ti1–O3 distance [1.755(4) Å] indicating only weak interactions in this dimeric structure. The Ti-O distances [1.833(3), 1.820(3) Å] within the ring are comparable to those found in related compounds containing Si–O–Ti units. The coordination geometry around the titanium centers can be regarded as distorted square pyramidal, with the O3 atom and the remaining atoms O1, O2, O4, O4A occupying axial and basal positions, respectively.

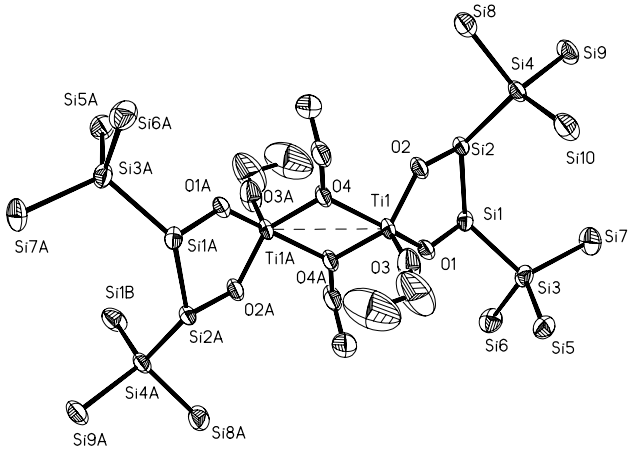

Fig. 1. Thermal ellipsoid plot (30% probability) of **3**. All methyl groups at silicon and one disordered tris(trimethylsilyl)silyl group are omitted for clarity.

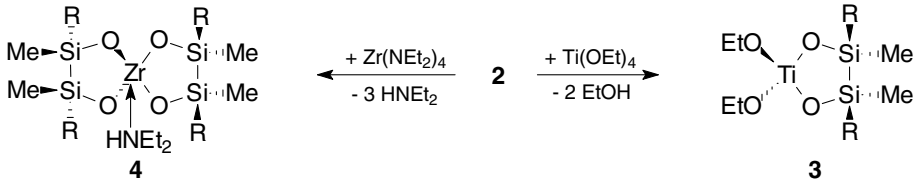

Scheme 2. Synthesis of **3** and **4** [R = $Si(SiMe_3)_3$].

Table 1
Selected bond lengths (Å) and bond angles (°) for **3** and **4**

	3 (M = Ti)	**4** (M = Zr)
Bond lengths		
M–O	1.833(3), 1.820(3)	2.020(2), 1.960(2)
Ti(1)–O(3)	1.755(4)	
Ti–$O_{bridging}$	2.030(3), 1.984(3)	
Zr–N		2.346(6)
Si–O	1.666(3), 1.652(3)	1.674(2), 1.658(2)
Si(1)–Si(2)	2.4368(17)	2.4381(13)
Bond angles		
O–M–O	91.06(12)	88.95 (9)
Si–O–M	131.57(16), 131.23(16)	129.67(12), 123.51(13)
O(1)–Si(1)–Si(2)	92.16(11)	94.16(9)
O(2)–Si(2)–Si(1)	93.70(11)	97.43(9)
Si(3)–Si(1)–Si(2)	136.54(7)	133.95(5)
Si(4)–Si(2)–Si(1)	138.00(7)	137.46(5)

The results of the X-ray analysis of **4** (Fig. 2, Table 1) confirm the expected extensive shielding of the zirconium atom by the two sterically demanding ligands and the diethylamine in which the ethyl groups are disordered. The geometry around the zirconium atom is described best as distorted trigonal bipyramidal with the O2, O2A atoms and the N, O1, O1A atoms occupying axial and apical positions, respectively. Typically, the length of the apical Zr–O1 bond [1.960(2) Å] is somewhat shorter than that of the axial Zr–O2 bond [2.020(2) Å].

Although the geometry and coordination environment around the metal centers are completely different, the structural features of the ligand backbone in **4** are quite similar to those in the titanium complex **3**. The central metal atoms are bonded in a chelate fashion [**3** O–Ti–O 91.06(12)°; **4** O–Zr–O 88.95s(9)°] to both siloxide groups of the ligand, giving a nearly planar five-membered ring. Most of the Si–Si bonds lie unremarkably within the range of 2.34–2.38 Å. But the spatial demand of the two extended hemispherical $(Me_3Si)_3Si$ groups which adopt a (*Z*) position, leads to a significant elongation of the central Si1–Si2 bond in both compounds [**3**; 2.4368(17) Å; **4**; 2.4318(13) Å] and an extreme widening of the central Si–Si–Si angles to values within the range of 134°–138°. Only the Si–O–Ti angles [131.57(16)°, 131.23(16)°] of **3** are somewhat larger than those found in **4** [129.67(12)°, 123.51(13)°] probably due to the fact that the ionic radius of zirconium is larger than that of titanium. In comparison to other cyclic complexes mainly consisting of Si–O–Si backbones the M–O–Si angles and chelate angles of **3** and **4** are remarkably smaller reflecting the exceptionally spatial requirements in these five-membered ring structures. Consequently, it is reasonable to assume that ring strain in both compounds causes only weak oxygen p_π–d_π donation of the siloxide ligand towards the metal center, which makes the metal electrophilic. The fact that **3** adopts a dimeric structure and **4** forms a thermally stable donor adduct with diethylamine can be understood best as a result of coordinative unsaturation of both metals.

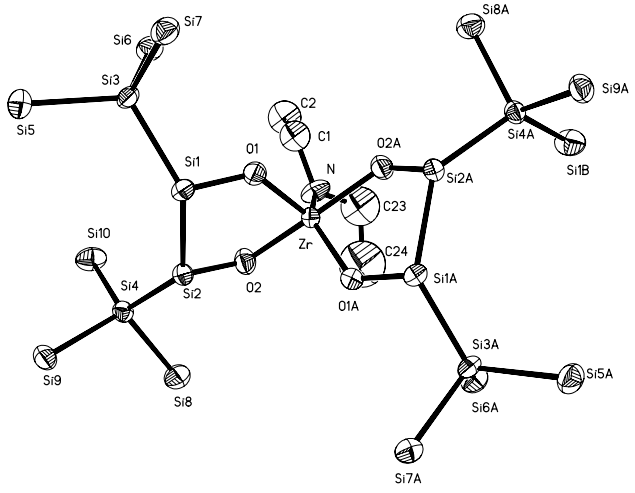

Fig. 2. Thermal ellipsoid plot (50% probability) of **4**. All methyl groups at silicon and one disordered amine ligand are omitted for clarity.

3. Conclusion

In conclusion, *meso*-$(RMeSiOH)_2$ [R = $Si(SiMe_3)_3$] (**2**) was synthesized exclusively by simple hydrolysis of $(RMeSiCl)_2$ (**1**). It has been shown that diol **2** is a supporting dianionic ligand for Ti and Zr fragments, which yields the disiloxides (*E*)-$(RMeSiO)_2Ti(OEt)_2$ (**3**) and [(*Z*)-$(RMeSiO)_2]_2Zr \cdot HNEt_2$(**4**) from the reaction of **2** with $Ti(OEt)_4$ and $Zr(NEt_2)_4$. The results of X-ray analyses reveal disiloxides **3** and **4** to be strained five-membered ring compounds that form a dimeric structure or an adduct with diethylamine, respectively. Studies are underway to examine the electrophilic properties of these disiloxides and their ability to be acceptors towards neutral and anionic donors.

4. Experimental

All manipulations of air- and/or moisture-sensitive compounds were carried out under an atmosphere of argon using standard Schlenk techniques. Solvents were dried using standard procedures. Compound **1** was prepared as previously described [8].

4.1. (meso)-3,4-Dihydroxy-1,1,1,3,4,6,6,6-octamethyl-2,2,5,5- tetrakis(trimethylsilyl)-hexasilane (2)

A mixture of **1** (10 g, 15.3 mmol), 400 ml of ether and 400 ml of water was vigorously stirred at room temperature for one day. The organic phase was separated,

dried with $MgSO_4$, and the solvent was evaporated. The solid residue was recrystallized from heptane at −40 °C to yield crystals of **2** (7.45 g, 79%). The analytical data obtained were in full agreement with those reported [8].

4.2. *Bis-{(Z)-1,2-dimethyl-1,2-bis[tris(trimethylsilyl)-silyl]-η^2-disilanediolato-η^2-diethoxo-η^1-diethoxo-titanium} (**3**)*

Freshly distilled $Ti(OEt)_4$ (0.45 ml, 2.13 mmol) was added to a solution of (*meso*)-2 (1.255 g, 2.04 mmol) in 10 ml heptane at room temperature. After 1 h, a yellow crystalline material started to precipitate from the solution. The mixture was allowed to stand at room temperature for one day and at −40 °C for another day. The resulting yellow crystalline solid 3 (1.15 g) was isolated by filtration, washing with cold heptane, and drying under vacuum. Crystallization from the mother liqueur gave another 0.15 g of 3 (1.3 g, 85%), m.p. 209 °C (decomp.); ^{1}H NMR (500 MHz, C_6D_6): δ 4.77, 4.50 (2m, CH_2CH_3, 2×2H), 1.52, 1.26 (2m, CH_2CH_3, 2×3H), 1.02 (s, OSiMe, 6 H), 0.46 (s, $SiMe_3$, 54H); ^{13}C NMR (125 MHz, C_6D_6): δ 73.6, 71.6 (CH_2CH_3), 18.9, 19.1 (CH_2CH_3), 10.5 (OSiMe), 3.8 ($SiMe_3$); ^{29}Si NMR (60 MHz, C_6D_6): δ −121.1 [*Si*($SiMe_3$)$_3$], −9.7 ($SiMe_3$), 49.0 (OSiMe). *Anal*. Calc. for $C_{24}H_{70}O_4Si_{10}Ti$ (751.53) C, 38.36; H, 9.39. Found: C, 38.63; H, 9.55%.

4.3. *Bis-{(Z)-1,2-dimethyl-1,2-bis[tris(trimethylsilyl)-silyl]-η^2-disilanediolato}-η^1-diethyl-amino-zirconium (**4**)*

$Zr(NEt_2)_4$ (0.3 ml, 1.65 mmol) was added to a stirred solution of (*meso*)-2 (1 g, 1.62 mmol) in 30 ml heptane at room temperature. After stirring for 30 min, a microcrystalline material started to precipitate from the solution and the reaction mixture was refluxed for additional 1 h. The solution was concentrated to a volume of ca. 10 ml and slowly cooled to −40 °C for 2 days to yield colorless crystals of 4 (0.72 g, 64%), m.p. 206 °C (decomp.); ^{1}H NMR (250 MHz, C_6D_6): δ 0.43 (s, 54H, $SiMe_3$), 1.04 (s, 6H, OSiMe); ^{13}C NMR (125 MHz, C_6D_6): δ 4.0 (s, $SiMe_3$), 11.7 (s, OSiMe); ^{29}Si NMR (100 MHz, C_6D_6): δ −122.5 [*Si*($SiMe_3$)$_3$], − 10.1 ($SiMe_3$), −11.7 (OSiMe).

5. X-ray crystallography

Structure determination and refinement of **3** and **4**. The data collections were done on a STOE IPDS (laser scanned imaging plate) equipped with a molybdenum fine focus X-ray tube and graphite monochromator. The structures were solved by direct methods (Bruker SHELXTL software package). The refinement calculations were performed by the full matrix least-squares method of Bruker SHELXTL [10]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were put into theoretical positions and refined according to the riding model (see Table 2).

6. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 236559 (3) and CCDC 236560 (4). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ UK (fax: Int. code +44(1223) 336-033; e-mail: deposit@ccdc.cam.ac.uk or on the web: http://www.ccdc.cam.ac.uk).

Acknowledgements

We thank Prof. Dr. H. Oehme for his generous support and we gratefully acknowledge the support of our research by the Fonds der Chemischen Industrie. We thank Prof. M. Michalik for recording the NMR spectra.

Abstract

Four zinc(II) (**6**, **8**, **10** and **12**) and four cobalt(II) (**5**, **7**, **9** and **11**) compounds derived from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester (**1**) (**5** and **6**), 1-benzothiazol-2-ylid-3-methyl-thiourea (**2**) (**7** and **8**), 1-benzothiazol-2-yl-2,3-dimethyl-*iso* thiourea (**3**) (**9** and **10**) and *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithio-carboimine (**4**) (**11** and **12**) are reported. The complexes were characterized in the solid state by UV–Vis–NIR diffuse reflectance, IR, mass spectrometry and compounds **5**, **9**–**12** by X-ray single crystal diffraction analyses. In all cases two ligand molecules are bonded to a tetracoordinated metal atom. In compounds **5**–**10** the ligand is anionic and bidentate with the metal atom in the center of spirocyclic structures formed by two planar unsaturated six membered rings. In compounds **7**–**10** the metal atom is linked to four nitrogen atoms and in **5** and **6** to two sulfur and two nitrogen atoms. In compounds **11** and **12** the ligand is neutral and monodentate and the metal ion remains coordinated to the chlorine atoms.

Keywords: Zinc(II) cobalt(II) compounds from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester; 1-Benzothiazol-2-ylid-3-methyl-thiourea; 1-Benzothiazol-2-yl-2,3-dimethyl-*iso*thiourea; *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithio-carboimine

1. Introduction

Functionalized benzazoles have many applications as fertilizers, antimicotics, antibiotics, pesticides and neuroprotectors [1–11]. We are interested in unsaturated and planar benzazoles having a framework with alternating sp^2 carbon and heteroatoms such as nitrogen, oxygen and sulfur, and their use as ligands [12–15]. One of our aims is the preparation of benzazoles with coordinative arms in order to give coordination compounds forming planar six membered rings in which the metal atom is included in the electronic unsaturated system. With this idea, we have synthesized metal derivatives of 2-guanidino- and 2-uroylbenzimidazole [7–10]. The molecular structure of the diphenylboron compound derived from 2-guanidinobenzimidazole is particularly remarkable [9], because it does not have the expected structure in which a B–N covalent bond is present for one of the nitrogen atoms and a coordinative bond for the other. The solid state data show that the tetracoordinated boron atom has two similar B–N bond lengths (≈1.56 Å), which could be considered to be between a covalent and a coordinative bond, indicative of a resonance hybrid with a partial negative charge at boron and the positive charge delocalized between the C–N bonds of the ring, Scheme 1. A similar behavior is expected for other Lewis acids and it was found that zinc and nickel compounds derived from 2-guanidinobenzimidazole are

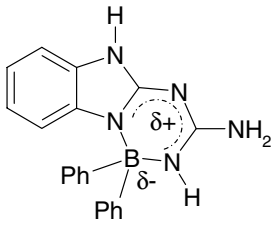
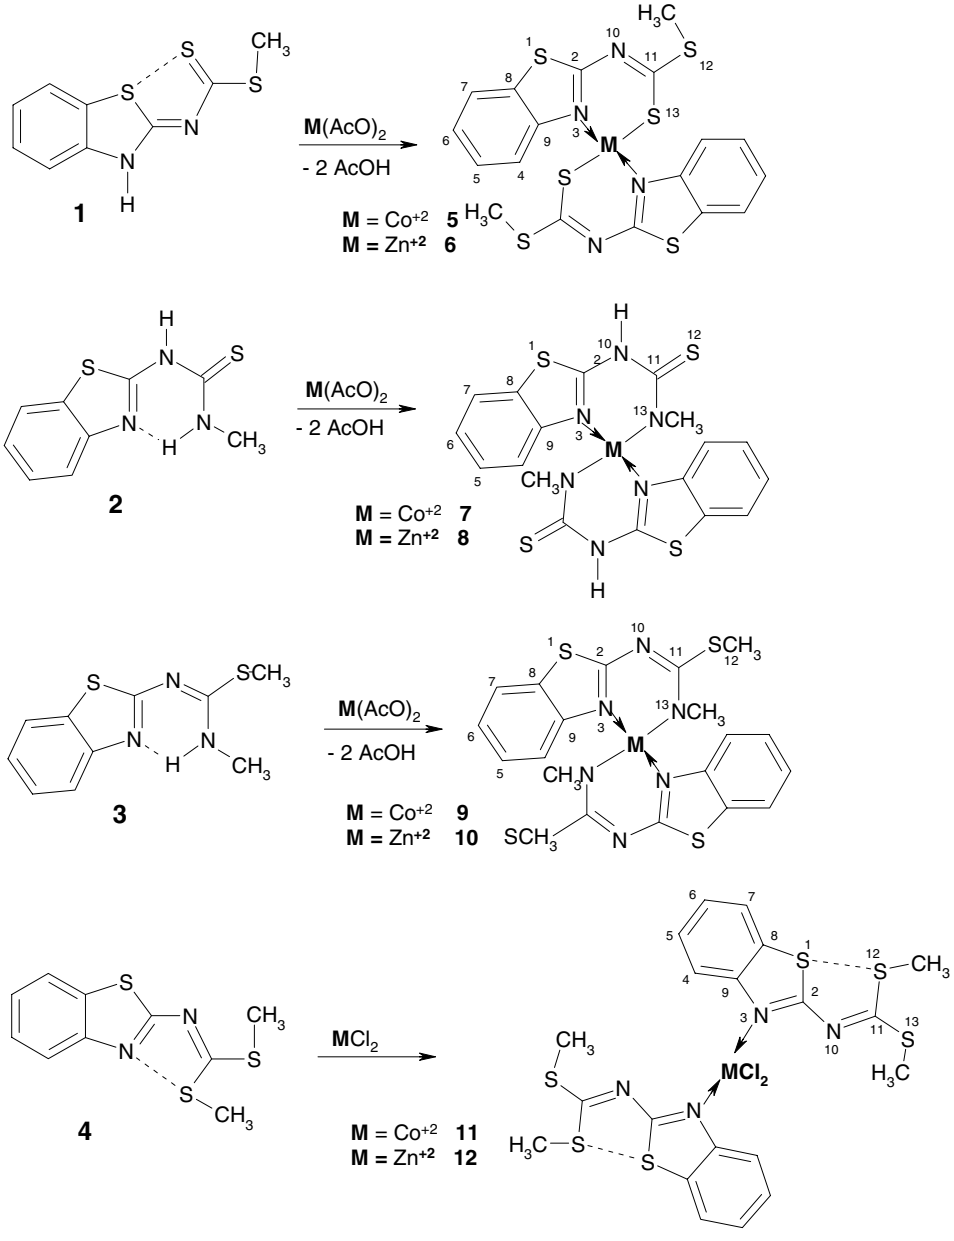


Scheme 1.

some examples in which the ligand is coordinated to the metal with two similar N–M bond lengths [Zn–N 1.996(4); 1.942(4) and Ni–N 1.893(2); 1.867(3) Å] [7].

In this context, we have prepared four compounds derived from 2-aminobenzothiazole with functionalized arms bearing sulfur atoms [15] that could act as ligands: *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester (**1**), 1-benzothiazol-2-ylid-3-methyl-thiourea (**2**), 1-benzothiazol-2-yl-2,3-dimethyl-*iso*thiourea (**3**) and *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithiocarboimine (**4**), Scheme 2. Syntheses of **1** and **4** have been reported by Merchán et al. [16]. The ligands **1**–**4** are complex molecules that can be depicted by several conformers and tautomers, therefore their behavior towards coordination with transition metals is not straightforward. To better understand their reactivity, we have achieved



Scheme 2. Reported metal coordination compounds.

a detailed investigation in order to establish their preferred tautomers and conformers [15], and they are depicted in Scheme 2.

The aim of this research was to study the ability of these planar and delocalized ligands towards metal coordination in order to know if they can form the less stable six membered metallocycles in which the metal participates in the delocalization of the π system. Also it is interesting to evaluate the role of the nitrogen and sulfur atoms in the metallic coordination and the preferred arrangement of the ligands.

2. Experimental

2.1. Materials

The metal salts $Co(OAc)_2 \cdot H_2O$, $Zn(OAc)_2 \cdot H_2O$, $CoCl_2 \cdot 6H_2O$ and $ZnCl_2$, methanol (J.T. Baker) and 2-aminobenzothiazole (Aldrich) were used without further purification. Ligands **1**–**4** were prepared as previously described [15,16].

2.2. Synthesis of complexes: general procedure

All coordination compounds were synthesized as described for compound **5**.

2.2.1. Compound **5** *[Co(**1**)$_2$]*

Compound **1** (240 mg, 1 mmol) was dissolved in 40 ml of hot methanol and added to a solution of $Co(OAc)_2 \cdot H_2O$ (98 mg, 0.5 mmol), in 10 ml of methanol. The solution was heated and stirred for 2 h. A light brown precipitate was formed which was filtered and recrystallized from acetone. Single crystals were suitable for diffraction analysis. Yield: 205 mg, 40%, m.p. 210 °C. *Anal*. Calc. for $C_{18}H_{14}N_4S_6Co$: C, 40.21; H, 2.62; N, 10.42. Found: C, 40.23; H, 2.59; N, 10.40%. IR (cm^{-1}): 1464, 1448, 1391. UV–Vis–NIR (cm^{-1}): CT 23427, 17092, 8847. MS: *m/z* 239.

2.2.2. Compound **6**, *[Zn(**1**)$_2$]*

A pale yellow powder was obtained. Yield: 156 mg, 30%, m.p. 218 °C. *Anal*. Calc. for $C_{18}H_{14}N_4S_6Zn$: C, 39.73; H, 2.59; N, 10.30. Found: C, 40.24; H, 2.65; N, 10.37%. IR (cm^{-1}): 1469, 1450, 1407. UV–Vis–NIR (cm^{-1}): CT 24190. MS: *m/z* 239.

2.2.3. Compound 7, *[Co(**2**)$_2$]*

Green powder. Yield: 176 mg, 35%, m.p. 239 °C. *Anal*. Calc. for $C_{18}H_{16}N_6S_4Co$: C, 42.93; H, 3.20; N, 16.69. Found: C, 43.33; H, 3.32; N, 16.67%. IR (cm^{-1}): 1481, 1448, 1387. UV–Vis–NIR (cm^{-1}): CT 24408, 17080, 8684. MS: *m/z* 503 [M^+].

2.2.4. Compound **8**, *[Zn(**2**)$_2$]*

Colorless powder. Yield: 193 mg, 38%, m.p. 130 °C. *Anal*. Calc. for $C_{18}H_{16}N_6S_4Zn$: C, 42.39; H, 3.16; N, 16.48. Found: C, 42.57; H, 3.23; N, 16.48%. IR (cm^{-1}): 1483, 1450, 1386. UV–Vis–NIR (cm^{-1}): CT 26618. MS: *m/z* 508 [M^+].

2.2.5. Compound **9**, *[Co(**3**)$_2$] · 1/2H$_2$O*

Orange powder, recrystallized from DMSO. Crystals were suitable for X-ray diffraction analysis. Yield: 318 mg, 60%, m.p. 192 °C. *Anal*. Calc. for $C_{20}H_{20}N_6S_4Co \cdot 1/2H_2O$: C, 44.41; H, 3.91; N, 15.55. Found: C, 44.42; H, 3.59; N, 15.04%. IR (cm^{-1}): 1463, 1386. UV–Vis–NIR (cm^{-1}): TC 22818, 11663. MS: *m/z* 531 [M^+].

2.2.6. Compound **10**, *[Zn(**3**)$_2$]*

Colorless crystals. Yield: 350 mg, 66%, m.p. 169 °C. *Anal*. Calc. for $C_{20}H_{20}N_6S_4Zn$: C, 44.64; H, 3.75; N, 15.62. Found: C, 44.55; H, 3.70; N, 15.68%. IR (cm^{-1}): 1503, 1469, 1453, 1392. UV–Vis–NIR (cm^{-1}): TC 25158. MS: *m/z* 536 [M^+].

2.2.7. Compound **11**, *[Co(**4**)$_2$Cl$_2$] 1/6C$_6$H$_6$*

Compound **11** was prepared from $CoCl_2 \cdot 6H_2O$ at r.t. for 1 h. A green precipitate was obtained, which was crystallized by liquid–liquid diffusion in methanol–benzene (5:1). Crystals were suitable for X-ray diffraction. Yield: 511 mg, 80%, m.p. 240 °C. *Anal*. Calc. for $C_{20}H_{20}N_4S_6Cl_2Co \cdot 1/6C_6H_6$: C, 38.68; H, 3.25; N, 8.60. Found: C, 38.53; H, 3.13; N, 8.79%. IR (cm^{-1}): 1588, 1514, 1465, 1431. UV–Vis–NIR(cm^{-1}): CT 24318, 16348, 7498. MS: *m/z* 254.

2.2.8. Compound **12** *[Zn(**4**)$_2$Cl$_2$] 1/2C$_3$H$_6$O*

Compound **12** was prepared from $ZnCl_2$ at r.t. for 1 h. Yellow crystals were obtained after several days from the reaction mixture. Yield: 529 mg, 82%, m.p. 238 °C. *Anal*. Calc. for $C_{20}H_{20}N_4S_6Cl_2Zn \cdot 1/2C_3H_6O$: C, 38.28; H, 3.41; N, 8.31. Found: C, 38.06; H, 3.11; N, 8.65%. IR (cm^{-1}): 1516, 1467, 1455, 1432. UV–Vis–NIR (cm^{-1}): CT 25178. MS: *m/z* 254.

2.3. Physical measurements

FT IR spectra were recorded with a (Perkin–Elmer 1600) spectrophotometer using KBr pellets (4000–400 cm^{-1}). The UV–Vis–NIR spectra (diffuse reflectance, 40000–4000 cm^{-1}) were recorded on a Cary-5E (Varian) spectrophotometer. The MS spectra were obtained by direct insertion at 20 eV in an HP 5989 spectrometer. Elemental analyses were carried out with a Fisons EA 1180 analyzer.

2.4. X-ray crystallographic study

Suitable single crystals of compounds **5**, **9**–**12** were mounted on a glass fiber in a small amount of perfluoro ether oil. Data were collected at 293 K. Crystal data and information about the data collection and structure refinement details are given in Tables 1–4. X-ray diffraction studies were performed with ENRAF-Nonius CAD4 and KAPPA-CCD diffractometers. The WINGX [17] software was used. The crystal structures were determined and refined with the SHELXTL-97 [*x*,*y*] system [18]. H atoms were systematically placed in idealized positions and refined with a riding model.

3. Results and discussion

The synthesis of compounds **5**–**12** was carried out from a molar ratio 2:1 ligand:metal salt. Compounds **5**–**10** were obtained by reaction of **1**–**3** with cobalt(II) and zinc(II) acetates, respectively, whereas **11** and **12** were obtained from ligand **4** and cobalt(II) and zinc(II) chlorides, respectively, Scheme 2. Complexes were characterized in the solid state by UV–Vis–NIR diffuse reflectance, IR and mass spectrometry, and compounds **5**, **9**–**12** by X-ray single crystal diffraction analyses (Tables 1–4).

Compounds **5**–**12** are not ionic, **5**–**10** have spirocyclic structures with two deprotonated bidentate ligands for each metal atom, the ligands maintain their planar structure and the metal is included in the six membered unsaturated rings.

From the mass spectra, IR and elemental analyses it is assumed that compounds **5** and **6** have the same structure. Cobalt(II) compound **5** has a light brown color, its magnetic moment μ_{eff} (4.8 BM) is characteristic of a tetrahedral cobalt(II) atom [19], and its electronic spectrum presents two transitions ν_2 8847 cm^{-1} and ν_3 17092 cm^{-1}, and a charge transfer band at 23427 cm^{-1}. The zinc(II) compound **6** is pale yellow, the charge transfer band is found at 24190 cm^{-1}. The experimental data correspond to a distorted geometry and the effect of the planar unsaturated and delocalized ligand.

From the X-ray diffraction study of **5** (Fig. 1), it is known that the metal atom is bonded to the ligands through the sulfur atom of the thione group and is coordinated by the nitrogen atom of the thiazole. This arrangement is different from the preferred structure of the free ligand (**1**, Scheme 2), where the thione group is close to the endocyclic sulfur atom with a stabilizing

lengths N3–C2 1.323(3), N10–C2 1.357(3) and N10–C11 1.297(3) Å show that the latter has a stronger double character. The two different orientations for the S–CH_3 groups, one pointing to N10, another to S13A, could be explained by the intermolecular tricentric interaction of the sulfur atom S12A with H7B (2.884 Å)

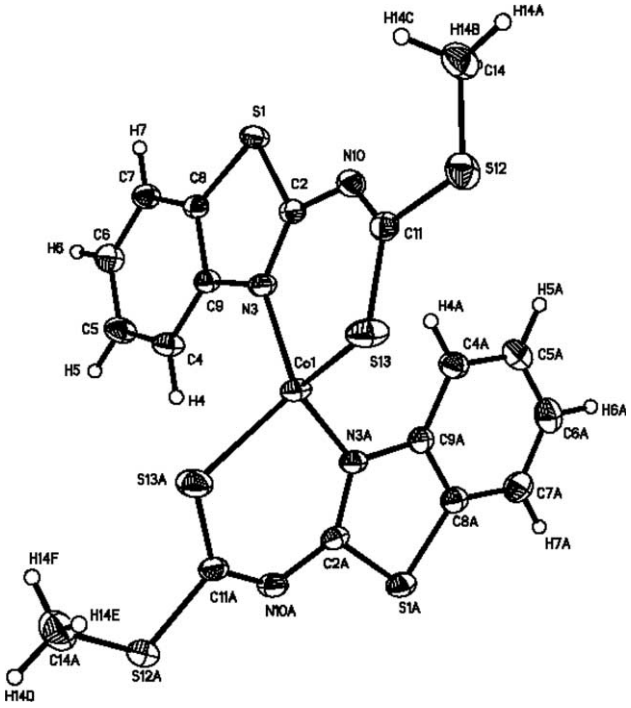

Fig. 1. Molecular structure of compound **5**.

and S1B [3.451 Å] [20]. The ligands are not completely orthogonal, the angle between the planes described by atoms N3–Co1–S13 and N3A–Co1–S13A is 83.54°, Fig. 2.

Compounds **7**–**10** were prepared from **2** and **3**, both ligands have in common a hydrogen bond between two nitrogen atoms forming a six membered ring [15] as it is known from their X-ray diffraction structures and is depicted in Scheme 2. The difference between the two ligands is that **2** has two N–H groups and in **3** one proton is substituted by a methyl group placed at S-12. The mass spectra of compounds **7**–**10** present the molecular ion which indicates the correct formula and the high stability of the compounds.

Compound **7** has a green color with a magnetic moment μ_{eff} of 4.9 BM and UV–Vis–NIR spectrum bands at 8684 and 17080 cm^{-1}, both data indicate a distorted geometry for **7**. The charge transfer band from the metal to the ligand was observed at 24408 cm^{-1} for **7** and at 26618 cm^{-1} for **8**. In compound **9**, the UV–Vis–NIR transitions correspond to distorted cobalt geometry [$^4A_2(F) \rightarrow {}^4T_1(F)$ and $^4A_2(F) \rightarrow {}^4T_1(P)$]. For compounds **9** and **10**, the charge transfer bands are 22818 and 25158 cm^{-1}, respectively.

The X-ray diffraction analyses for compounds **9** and **10**, Figs. 3 and 4, show that the two ligands are bonded to the metal ion by nitrogen atoms which have similar bond lengths in the range of 1.96–1.97 Å for Co–N and 1.93–2.0 Å for Zn–N.

The distorted geometry of the metal atoms is confirmed by the bite angles which for the cobalt compound are 93.8(2)° and 92.5(1)°, while for zinc they are 94.4(3)° and 92.8(2)°; these angles are far from the ideal tetrahedral values of 109° and from the value of 120° for a planar and unsaturated six membered ring. The bond lengths N3–C2, C2–N10, N10–C11, C11–N13 have an average value of 1.33 Å, indicating delocalized π-bonds through the six membered ring. It is noteworthy the unusual orange color of the tetrahedral compound **9** that is in contrast with the green color of compound **7**.

Compounds **11** and **12** were obtained from the reactions of ligand **4** with the cobalt and zinc chlorides, respectively. The metal ions are bonded to two chlorine atoms and to two ligands through the nitrogen atom of the thiazole. They have a C_2 symmetry. The

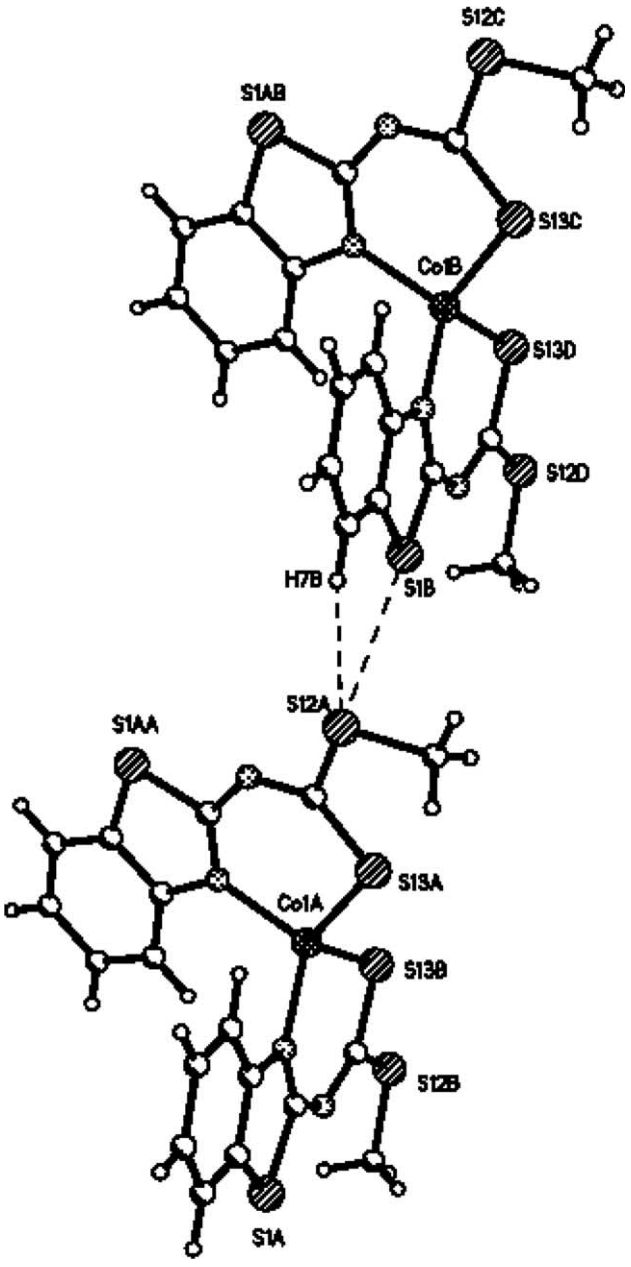

Fig. 2. Intermolecular interactions in compound **5**.

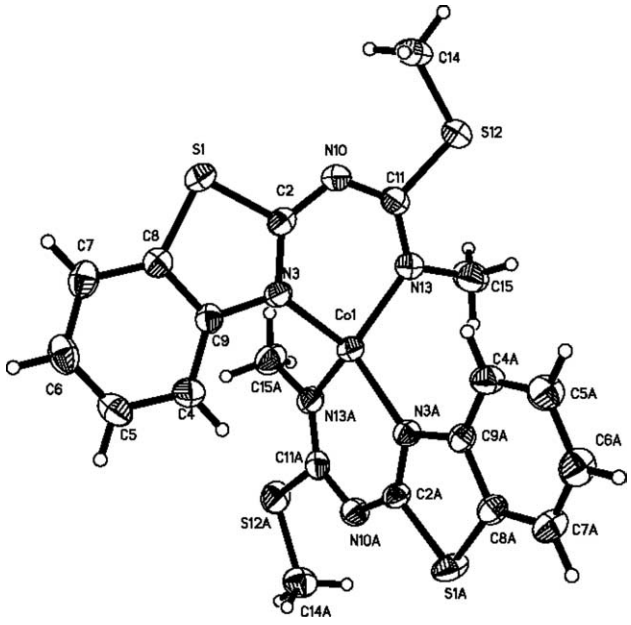

Fig. 3. Molecular structure of compound **9**.

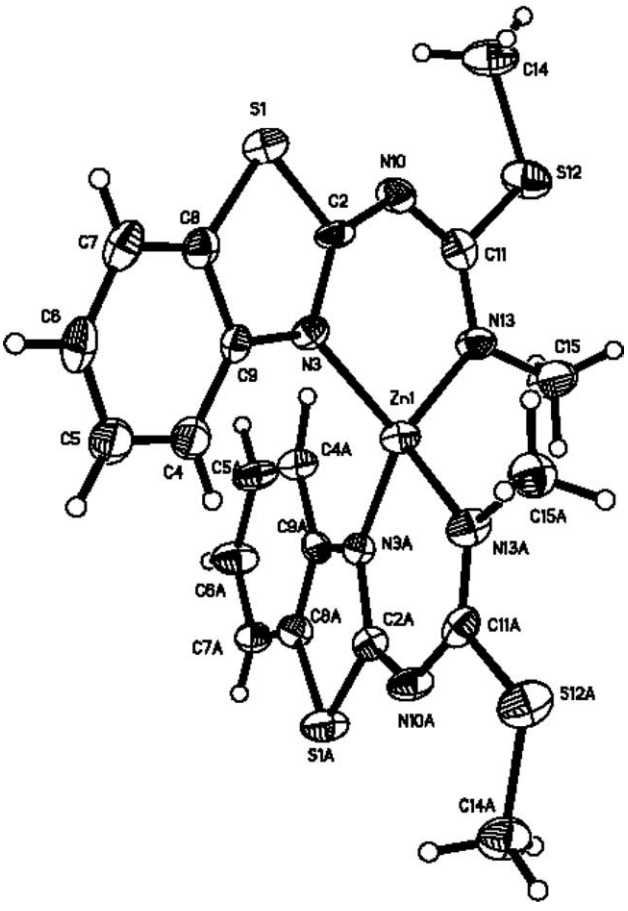

Fig. 4. Molecular structure of compound **10**.

UV–Vis–NIR spectrum bands for **11** are ν_2 7293 cm^{-1} [$^4A_2(F) \rightarrow {}^4T_1(F)$] and ν_3 16313 cm^{-1} [$^4A_2(F) \rightarrow {}^4T_1(P)$] and the value of the magnetic moment is $\mu_{eff} = 4.6$ BM. For **11** and **12**, the bands at 24271 and 25178 cm^{-1} are associated to the metal to ligand charge transfer for cobalt and zinc, respectively. Data are borderline between values for tetrahedral and octahedral geometries and are attributed to the distorted tetrahedral geometry and to the effect of the unsaturated six membered ring. The IR band for the vibration of the C=N bond of the thiazolic ring appears at ν 1514 cm^{-1}, a higher energy value with respect to the free ligand **4** (1510 cm^{-1}) [15], confirms the coordination.

X-ray diffraction analyses of compounds **11** and **12** show that they present the same structure, Figs. 5 and 6. The ligands are coordinated to the metal atom by the nitrogen of the thiazolic ring. It is interesting to observe that the preferred conformation of the free ligand with a short contact between one exocyclic sulfur and N-3 has changed in the complex, where one exocyclic sulfur is pointing to the sulfur of the ring. The ligands are in an *anti* arrangement and their arms are 34.7° (**11**) and 35.6° (**12**) out of the heterocycle plane. This fact indicates that electronic delocalization does not occur, and it is in agreement with the short bond lengths of C2–N3 and

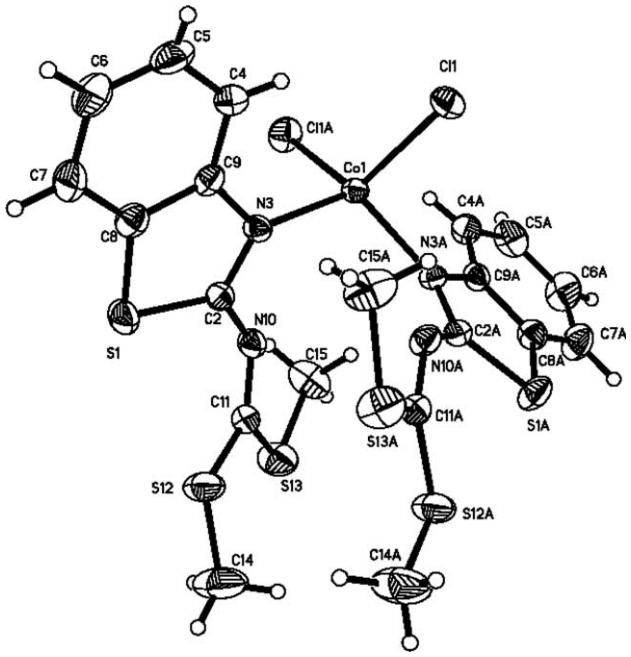

Fig. 5. Molecular structure of compound **11**.

C11–N10 which suggest a stronger double bond character (~1.28–1.32 Å) than those of C2–N10 (~1.37 Å).

Intramolecular interactions occur between H4 and Cl1, and H4a and Cl1A (2.977 Å). Each molecule has two intermolecular π-bonds between two S–CH protons and the double bond N3–C8 (H15B···N3 2.64; H15B···C8 2.63 Å for **11** and H15B···N3 2.58; H15B···C8 2.61 Å for **12**), Fig. 7.

Tricentric intermolecular short contacts are found between S1 and Cl (3.293 Å) and S1 and H7 (2.950 Å),

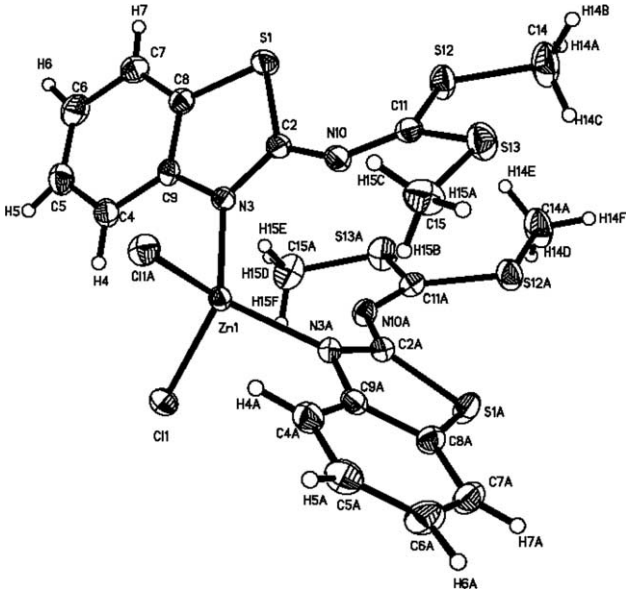

Fig. 6. Molecular structure of compound **12**.

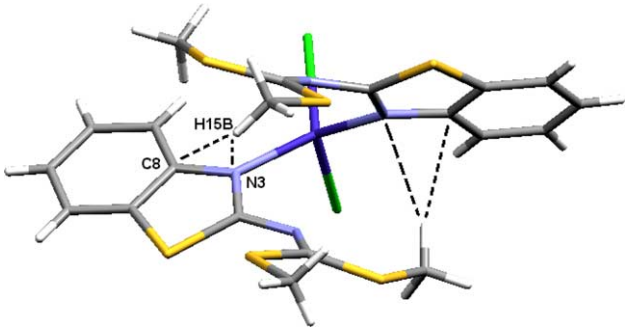

Fig. 7. H···π intramolecular contacts in compound **11**.

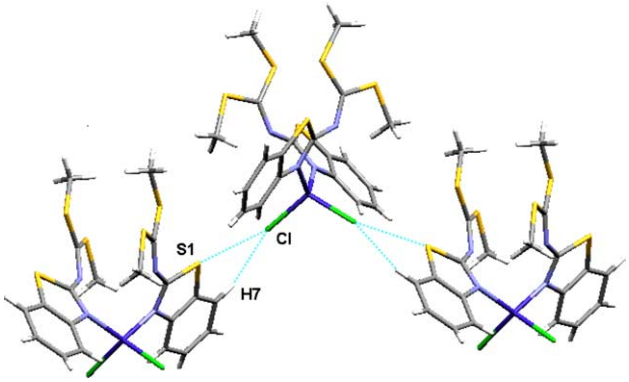

Fig. 8. Tricentric intermolecular short contacts between Cl and S1 and H7, in compound **11**.

Fig. 8. A similar structure was reported for a cobalt derivative of 2-uroylbenzimidazole [10].

4. Summary

New aromatic planar molecules bearing coordinative arms were investigated as ligands. These complex molecules are in equilibrium between different conformers and tautomers, and several coordinative sites of sulfur and nitrogen are possible. It was found that deprotonation of compounds **1**–**3** with the metallic acetate afforded metal spirocyclic molecules. The metal coordination gave planar tricyclic chelates, where the metal is part of six-membered rings. In two compounds sulfur metal covalent bonds were found together with nitrogen coordination. It was found that the cobalt is bonded to the ligands through four similar N–Co bonds indicating a resonance phenomenon which includes the ligand. The six membered rings have four similar C–N bonds for a delocalized unsaturated system. In compounds **5**–**10** the metal atom is tetracoordinated, but with a distorted geometry due to the rigidity of the planar ligands. Compound **4** behaves as a monodentate ligand through N3 and the conformation of the ligand changed in the coordination compound giving S···S intramolecular interactions.

Abstract

New mixed-ligand complexes of general empirical formula, [Cu(NNS)(sac)(H_2O)] (NNS′ = *S*-methyl-β-*N*-(6-methylpyrid-2-yl)methylenedithiocarbazate, NNS″ = *S*-methyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate and NNS‴ = *S*-methyl-β-*N*-(2-benzoylpyrid-2-yl) methylenedithiocarbazate, sac = the saccharinate anion) have been synthesized by reacting $[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ with the appropriate ligands in water–ethanol mixtures and characterized by elemental analysis and conductance, magnetic, IR and electronic spectroscopic measurements. Magnetic and spectral evidence support a five-coordinate geometry for the complexes in which the Schiff bases coordinate as NNS tridentate ligands and the saccharinate anion coordinates as a unidentate N-donor ligand. An X-ray crystallographic structural analysis of [Cu(NNS′)(sac)(H_2O)] shows that the complex has a distorted square-pyramidal structure in which the Schiff base is coordinated to the copper ion as a tridentate NNS chelating agent via the pyridine nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom, the fourth and fifth coordination positions of the five-coordinate Cu(II) ion being occupied by the imino nitrogen of the saccharinate anion and oxygen atom of the aqua ligand. The complexes have been evaluated for their biological activities against eight pathogenic microbials and human T-lymphoblastic leukemia cell lines. The complexes exhibit marked cytotoxicity against leukemic cell lines and display moderate activity against pathogenic bacteria and fungi.

1. Introduction

Saccharin (also known as *o*-sulfobenzoimide) is a polyfunctional ligand [1]. It has a low solubility in most organic solvents but its sodium salt is soluble in these solvents [2]. The sodium salt of saccharin is a synthetic sweetening agent and is commonly used as a sugar substitute in order to reduce caloric intake in the diet and this is of significant use in industry today due to the increased demand of dietary products [3,4]. The chemistry of saccharin had attracted attention in years past as

doi:10.1016/j.poly.2004.08.005

preliminary studies showed that saccharin implanted into the bladders of mice caused urinary bladder carcinomas [5]. The ban that was consequently imposed on saccharin was lifted by the FDA in 1991 when further studies failed to form any conclusive evidence that it was a carcinogen [6].

Reports on the ability of saccharin to act as an inhibitor for certain enzyme reactions have been published [6]. Saccharin complexes have also been reported to have superoxide dismutase-like behaviour (SOD) and the SOD activity of the saccharinate complexes of manganese, iron, cobalt, nickel, copper and zinc have been investigated [7,8].

The structural formula of the saccharinate anion and some of its modes of coordination with metal ions are given in Fig. 1. The saccharinate anion may coordinate to metals through the N, the carbonyl O or both, as shown below [9].

Coordination by N is most commonly observed in complexes of general formula, $[M(C_7H_4SO_3N)_2(H_2O)_4]\cdot 2H_2O$, where M is a first-row transition metal. In these complexes, the saccharinate anions adopt a centrosymmetric arrangement in an octahedral environment [9].

In an attempt to better understand the anticancer properties of Cu(II) complexes of 2-formylpyridinthiosemicarbazone (HL), two saccharin complexes of formula, $[CuL\text{-}(sac)(H_2O)]\cdot 0.5H_2O$ and $[CuL(bipy)(sac)]\cdot 2H_2O$ were synthesized by Ainscough et al. [10]. X-ray crystallographic structure determinations showed that the coordination geometries around the Cu(II) ion varied significantly where the saccharinate anion was coordinated to the central metal ion in one case and not in the other.

As part of our ongoing study of metal complexes of dithiocarbazate derivatives, we report herein the synthesis, characterization and bioactivity of some mixed-ligand ternary Cu(II) complexes of three NNS donor ligands formed by condensation of *S*-methyldithiocarbazate (SMDTC) with 2-acetylpyridine, 2-benzoylpyridine and 6-methyl pyridine-2-aldehyde with the saccharinate anion and water as co-ligands. Since very little work has been reported on metal-saccharinate complexes, the present work is expected to shed some light on the coordination properties of this industrially important sweetener.

2. Experimental

All chemicals and solvents were of analytical grade and were used as received.

2.1. Preparation of the Schiff bases

These were prepared following published procedures [11–13].

2.2. General method of synthesis of $[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$

$[Cu(CH_3COO)_2]\cdot H_2O$ (2.01 g, 0.01 mol) dissolved in boiling water (25 ml) was mixed with a solution of sodium saccharinate monohydrate (4.46 g; 0.02 mol) in water (25 ml) and the mixture heated for 15 minutes to reduce the volume to ca. 30 ml. On standing overnight, the resulting blue solution yielded blue crystals of the $[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ complex which were filtered off, washed with cold ethanol and dried in a desiccator over anhydrous silica gel. Yield: ca. 90%.

2.3. General method of synthesis of the complexes

$[Cu(sac)_2(H_2O)_4]\cdot 2H_2O$ [2] (0.536 g, 0.001 mol) dissolved in boiling water (25 ml) was mixed with a solution of the appropriate Schiff base (0.001 mol) in ethanol (40 ml) and the resulting mixture was heated on a water bath for 30 minutes. On standing overnight, the mixture yielded crystalline complexes which were filtered off, washed with ethanol and dried in a desiccator over anhydrous silica gel, overnight. Yield: ca. 75%. Crystals of $[Cu(NNS')(sac)(H_2O)]$ suitable for X-ray diffraction analysis were obtained from acetonitrile solution. Some analytical, physical and spectral data on the complexes can be found in Tables 1 and 2.

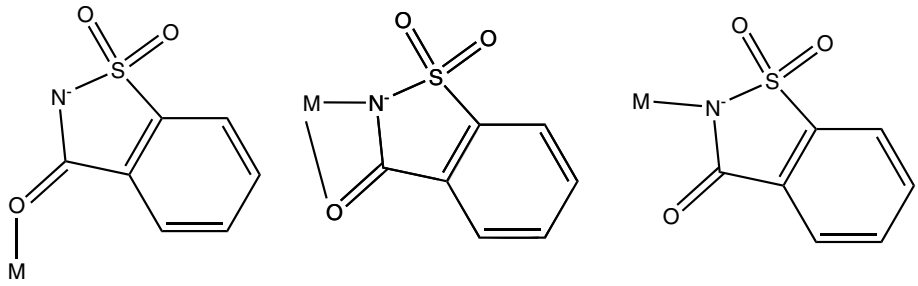

Fig. 1. Different coordination modes of the saccharinate anion.

Table 1
Analytical data and physical properties of the Cu(II) complexes

2.4. Physical measurements

The analyses for carbon, hydrogen, nitrogen and sulfur were carried out using a LECO CHNS-932 instrument. The IR spectra in KBr pellets were recorded on a Perkin–Elmer FT IR 1750X spectrophotometer (4000–400 cm^{-1}). Metal determinations were carried out using a Perkin–Elmer Plasma 1000 Emission Spectrometer. The molar conductance of 10^{-3} M solutions of the metal complexes in DMSO were measured at 29 °C using a Jenway 4310 conductivity meter and a dip-type cell with a platinized electrode. Magnetic susceptibilities at room temperature were measured using a Sherwood Scientific MSB-AUTO magnetic susceptibility balance. The UV–Vis spectra were run on a Shimadzu UV- 2501 PC Recording Spectrophotometer (1000–200 nm).

2.5. X-ray structure determination of [Cu(NNS′)(sac)(H_2O)]

Beautiful dark green crystals of the metal complex were formed after the acetonitrile solution was allowed to slowly evaporate over a few weeks. A dark-green platy single crystal was selected and mounted on a glass fibre using perfluropolyether oil and cooled rapidly to 150 K in a stream of cold N_2 using Oxford Cryosystems CROSTREAM unit. Diffraction data were measured using an Enraf–Nonius Kappa CCD diffractometer (graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$Å). Intensity data were processed using the DENZO-SMN package [14]. The crystal was found to be monoclinic with $a = 14.2347(2)$ Å, $b = 10.7154(2)$ Å, $c = 14.2428(2)$ Å and $\beta = 119.14(1)°$. The structure was solved in the space group $P2_1/n$ using the direct-methods program SIR92 [14] which located all non-hydrogen atoms. Subsequent full-matrix least-squares refinement on F was carried out using CRYSTALS Program Suite [15]. Coordinates and anisotropic thermal parameters of all non-hydrogen atoms were refined. Hydrogen atoms were positioned geometrically after each cycle of refinement. A five-term Chebychev polynomial weighting scheme was applied. Refinement converged satisfactorily to give $R = 0.036$ and $R_w = 0.033$ with residual electron density minimum and maxima of −0.47 and 1.26

e Å^{-3}. Further crystallographic and refinement details are shown in Table 1.

2.6. Bioactivity

2.6.1. Target microorganisms

Eight pathogenic microbials were used to test the biological potential of the complexes. They were Methicillin resistant *staphylococcus* (MRSA), *Bacillus subtilis* wild type (B29), *Subtilis mutant* (mutant defective DNA repair, B28), *Pseudomonas aeruginosa* (60690), *Candida albicans* (C.A.), *Aspergillus ochraceous* (398), *Saccaromyces ceciricaee* (20341) and *Candida lypolytica* (2075).The source of microbes and culture maintenance were as previously described [19].

2.6.2. Qualitative antimicrobial assay

Antimicrobial activity of each sample was qualitatively determined by a modified disc diffusion method [16] as previously detailed [17]. A lawn of microorganisms was prepared by pipetting and evenly spreading inoculum (10^{-4} cm^{-3}), adjusted turbidometrically to 10^5–10^6 cfu cm^{-3} (cfu: colony forming units) on to agar set in Petri dishes, using Nutrient agar (NA) for the bacteria and potato dextrose agar (PDA) for fungi. Whatman No. 1 filter paper discs of 6 mm diameter were impregnated with stock solution of the compound (100 mg cm^{-3}) and dried under sterile conditions. The dried discs were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 30 °C for bacteria and 37 °C for fungi. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs. Commercially available streptomycin (Sigma, USA) was used for the antibacterial control while nystatin (Sigma, USA) was used as the antifungal control.

2.6.3. Quantitative antimicrobial assay

Compounds that showed positive (diameter > 15 mm) anti-microbial inhibition with the disc diffusion assay were subjected to the broth dilution method for the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [18]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg, cm^{-3}). Streptomycin and nystatin were used as controls for bacteria and fungi, respectively.

2.6.4. Cytotoxic assay

The HL-60 (human T-lymphoblastic leukemia) cell line was obtained from the National Cancer Institute, U.S.A. The cells were cultured in RPMI-1640 (Sigma) medium supplemented with 10% fetal calf serum, Cytotoxicity was determined using the microtitration of 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay (Sigma, USA) as reported by Mosmann [19]. Controls that contained only cells were included for each sample. Cytotoxicity was expressed as CD_{50}, i.e. the concentration that reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin and Tamoxifen were used as standard cytotoxins.

3. Results and discussion

The physical and analytical data for the Cu(II) complexes are shown in Table 1. The analytical data agree well with the proposed formulations of the complexes. The complexes are soluble in most organic solvents and appear stable in air. The physical and analytical data for the three Schiff bases used in this work have previously been reported by Akbar Ali et al. [12] and Hossain et al. [13].

3.1. Magnetic and conductivity data

The complexes exhibit room temperature magnetic moments in the 1.6–1.7 B.M. range. Although these values are slightly lower than that expected for a $3d^9$ metal ion (Table 1) [20], they, nevertheless, indicate that the complexes contain the Cu(II) ions. The molar conductance values of the complexes in DMSO (Table 1) fall in the range of 0.45–15 Ω^{-1} cm^2 mol^{-1} indicating that they are essentially non-electrolytes in DMSO. Although some dissociation of the complexes seems to occur, the conductance values are much lower than that expected for a 1:1 electrolytes in this solvent. The conductivity data, therefore, indicate that both the saccharinate anion and the Schiff bases are coordinated to the Cu(II) ion as uninegatively charged ligands [21].

3.2. Electronic and Infrared spectra

The electronic spectra of the complexes in DMSO (Table 2) exhibit an intra-ligand $n \rightarrow \pi^*$ band in the 336–326 nm range, a S → Cu(II) charge transfer band in the 420–450 nm range and a d–d band in the 640–690 nm range. The presence of a S → Cu(II) LMCT band at ca. 420 nm in the spectra of the metal complexes is indicative of the coordination of the Schiff base to the Cu(II) ion via the thiolate sulfur atom [22]. Such LMCT bands are common in the electronic spectra of five-coordinate Cu(II) complexes of related tridentate NNS thiosemicarbazone ligands [23,24]. The presence of a d-d band at ca. 640 nm is consistent with a five-coordinate geometry since such a band has also been observed in the electronic spectrum of the related five-coordinate [Cu(Ap-SBz)NO_3] complex (Ap-SBz is the anionic form of the 2-acetylpyridine Schiff base of S-benzyl-

dithiocarbazate), the structure of which has been established by X-ray diffraction [25].

The IR spectra of the ligands (Table 2) exhibit the ν(C=N), ν(N–N) and (CS) bands at ca. 1580, 1050–1100 and 800–900 cm^{-1}, respectively, which are shifted in the spectra of the complexes, indicating coordination of the ligands to the metal ions via the azomethine nitrogen and the thiolate sulfur atoms. The coordination of the azomethine nitrogen to the Cu(II) ion is indicated by the shift of the ν(C=N) band to lower frequencies along with the occurrence of the ν(N–N) band at higher frequencies. The lowering of the ν(C=N) band is due to the lowering of the C=N bond order as a result of the M–N bond formation. The ν(N–N) bands of all the free ligands were shifted to higher wavenumbers on complexation as a result of a reduction in the repulsion between the lone pairs of electrons on the nitrogen atoms due to coordination via the azomethine nitrogen atom [26]. The splitting of the ν(CSS) band of the free ligands at ca. 950 cm^{-1} in the spectra of the Cu(II) complexes indicates coordination through one of the sulfur atoms. The pyridine ring deformation modes of the free ligands at ca. 600 cm^{-1} are lowered in the spectra of the complexes indicating coordination of the pyridine ring nitrogen atom to the Cu (II) ion. The spectra of the complexes do not exhibit the ν(NH) bands of the free ligands indicating deprotonation of the ligands during coordination to the Cu(II) ion. The IR spectra of the complexes also show the $\nu(SO_2)$ symmetric, $\nu(SO_2)$ asymmetric and ν(C=O) bands of the sac anion at ca. 1150, 1290 and 1640 cm^{-1} [27–29], respectively, confiming the presence of the saccharinate anion in the complexes [17].

3.3. X-ray crystal structure of the Cu(NNS′)(sac)(H_2O)] complex

The ORTEP diagram of the [Cu(NNS′)(sac)(H_2O)] molecule, with the atom numbering scheme is shown in Fig. 2. Selected bond lengths and bond angles are given in Tables 3 and 4. The complex crystallizes as a five-coordinate monomeric species. The structure shows that the complex has a water molecule bonded to the central Cu(II) atom. As inferred by the physicochemical results, the Cu(II) ion has a five-coordinate geometry with the donor atoms of the Schiff base being the pyridyl nitrogen atom, the azomethine nitrogen atom and the mercapto-sulfur atom. The nitrogen from the saccharinate anion and oxygen from the water molecule occupy the fourth and fifth coordination positions of the five-coordinate Cu(II) ion. The Schiff base is coordinated to the Cu(II) ion in its deprotonated iminothiolate form. This form results in delocalisation of the negative charge caused by the deprotonation of the NH proton. The delocalisation is observed in the C–*N*–*N*–C chain as is evident in the interatomic bond distances, C108–N109 [1.290(4) Å], N109–N110 [1.376(3) Å] and C111– N110 [1.318(4) Å]. The C111–S112 bond retains its partial double bond character as its length [1.713(3) Å] is between that of a C–S single bond [1.82 Å] and a C=S double bond [1.62 Å]. It is, however, longer than that found in free methylpyruvate Schiff base of *S*-methyldithiocarbazate [1.652(6) Å] [30] and pyridine-2-carboxaldehydethiosemicarbazone [1.698(3) Å] [31]. The lengthening of the C111–S112 bond in the complex is attributed to the enethiolisation process that occurs when the Schiff base coordinates to the Cu(II) ion. The C–S bond length in the present complex is however close to that found in the [Cu(pysme)(sac)(MeOH)] complex (pysme = *S*-methyl-β-*N*-(pyridine-2-yl)methylenedithiocarbazate) [21]. Other bond lengths, Cu–S [2.3043(8) Å], Cu–N (azomethine) [1.973(2) Å] and Cu–N (py) [2.113(2) Å], are similar to those observed in analogous five-coordinate square-pyramidal Cu(II) complexes (Table 5). Also apparent from the data given in Table 5 is the variation in Cu–N (sac) bond distances of different geometries around the central Cu(II)ion.

Since the Cu(II) ion in [Cu(NNS′)(sac)(H_2O)] is five-coordinate, it can adopt either a square-pyramidal or a trigonal-bipyramidal structure. To determine the more likely structure, the formula of Addison et al.

$\tau = (\beta - \alpha)/60 * 100\%$, where β is the larger of the two largest angles subtended at the copper atom, was used [32]. An ideal square pyramid will have $\beta = 180°$ and $\alpha = 180°$ and therefore $\tau = 0\%$, but an ideal trigonal-bipyramidal structure will have $\beta = 180°$ and $\alpha = 120°$ and therefore $\tau = 100\%$. In the current case, the calculated τ of 10.3% is close to that expected for the square-pyramidal structure. However, an examination of the bond angles given in Table 4 leads us to expect a distorted geometry since there is deviation from the ideal values, with the exception of the values for the N101–Cu1–O301 and N201–Cu1–S112 angles. Distor-

[b] MIC (μg ml^{-3}) = minimum inhibitory concentration, i.e the lowest concentration to completely inhibit microbial growth.

tion from the ideal square-pyramidal geometry can be attributed to the restricted bite angles of the deprotonated tridentate Schiff base ligand.

3.4. Biological activity

3.4.1. Antimicrobial activities

The three Cu(II) complexes are moderately active (inhibitory zones > 15 mm) against all eight bacteria and fungi assayed (Table 6). The values are, however, lower than those observed for both *S*-methyldithiocarbazate and S-benzyldithiocarbazate [33]. The [Cu(NNS″)(sac)(H_2O)] complex shows a higher activity towards the bacteria and fungi than the other two complexes. [Cu(NNS′)(sac)(H_2O)] was completely inactive towards all fungi assayed as compared to the other two complexes. The quantitative assays gave MIC values in the region 3125–25 000 μg ml^{-3} (Table 7).

3.4.2. Cytotoxic activities

When tested against the HL60 cell line (human T-lymphoblastic leukemic cells), all the three Cu(II) complexes exhibited marked activity with CD_{50}(μg cm^{-3}) value of 0.25. This is in contrast with S-benzyldithiocarbazate from which these Schiff bases are derived [34] and also the free salt $CuCl_2 \cdot 2H_2O$ which are inactive. CD_{50} is the cytotoxic dose at 50%, i.e. the concentration required to reduce growth of cancer cells by 50%. CD_{50} values <5.0 μg cm^{-3} indicate that the complex is strongly active whereas CD_{50} values of 5.0–10.0, 10.0–25.0 and >25.0 μg cm^{-3} indicate that the complex is moderately active, weakly active and inactive, respectively. The CD_{50} values for the standards, Doxorubicin and Tamoxifen were 0.1 and 36.0 μg cm^{-3}, respectively.

4. Conclusion

The reaction of $Cu(sac)_2(H_2O)_4] \cdot 2H_2O$ with the tridentate Schiff bases derived from *S*-methyldithiocarbazate and heterocyclic ketones in a methanol–water mixture produces crystalline green complexes in high yields. These were found to be mixed-ligand ternary Cu(II) complexes containing the saccharinate anion, the tridentate NNS^- Schiff base and water as ligands. The complexes display strong cytotoxic activity against the leukemic HL60 cell lines. An X-ray crystal structure determination of [Cu(NNS′)(sac)(H_2O)] shows that it has a five coordinate distorted square pyramidal geometry. In view of the similarity of the IR and electronic spectra of [Cu(NNS″)(sac)(H_2O)] and [Cu(NNS‴)(sac)(H_2O)] with that of [Cu(NNS′)(sac)(H_2O)] it is indeed most expected that the former two complexes also have a distorted square-pyramidal geometry.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 237550. A copy of this

information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, Cb2 1EZ, UK (fax: +44 1223 336033; email: deposit@ccdc.cam.ac.uk or http://www.ccdc.ac.uk).

Abstract

Reaction of $Ph_2P(O)_2CH_2$ with one equivalent of RLi (R = Me, Bu) leads to monodeprotonation of the methylene bridge and formation of a Horner–Wittig type reagent. The crystal structure of the resulting lithium complex $[\{\{Ph_2P(O)\}_2CHLi \cdot (THF)\}_2 \cdot THF]$, **1**, reveals a dimeric aggregate, where each lithium is tetracoordinate through bonding to two bridging and one terminally chelating phosphoryl unit, and to a THF molecule. Upon exposing complex **1** to molecular oxygen, an unexpected mixed-anionic species was formed, $[\{\{Ph_2P(O)\}_2CHLi\}_4 \cdot \{Ph_2P(O)_2Li\}_2 \cdot 8C_6H_6]$ **2**. Complex **2** was identified by X-ray crystallography and found to exist in two polymorphic forms that differ only slightly in their metrical parameters. The structure of **2** is an unusual hexalithium cage aggregate containing four Horner–Wittig anions and two diphenyl phosphinate anions. In both complexes **1** and **2** the β-diphosphine oxide anions were found to contain localized P=O double bonds and the negative charge was partially delocalized over the P–C–P fragments. Neither complex displays direct metal–C (anion) contacts but the relative planarity of the individual carbanions show significant variation.

1. Introduction

The use of α-stabilized carbanions as synthons in carbon–carbon bond forming reactions continues to be a central feature of modern organic synthesis [1–3]. The synthetic utility of the lithiated derivatives in particular, has led to detailed studies regarding their structure, reactivity and bonding behavior [4]. Our interest in this area has been directed towards a specialized class of these ligands, α,α′-stabilized carbanions, where a methylene group bridges a pair of electron withdrawing groups, e.g., nitriles, phosphonates, sulfonyls [5–8]. During our studies regarding the alkali metal complexes of several unsymmetrical monometallated ligands we have uncovered new structural patterns which contrast with those established for the simple mono-stabilized carbanions [4–8]. This led us to investigate the use of bis(diphenylphosphino)methane dioxide, $\{Ph_2P(O)\}_2CH_2$, as a potentially symmetrically chelating ligand in lithiation reactions. Furthermore, although β-diphosphine oxide Horner–Wittig anionic reagents of the type $\{R_2P(O)\}_2CH^-$ have found widespread use as versatile synthetic units [9–12] the structural elucidation of the metallated intermediates involved has received very limited attention [13]. This deficit is even more surprising considering that these ligands are close analogues to the ubiquitious β-diketonates [14], and the more recently

studied β-diketiminates [15] and β-diphosphiniminates [16] (Fig. 1). In comparison, there have been numerous studies of the neutral β-diphosphine oxides as ligands for various transition metal, lanthanide and main group elements [17–27].

Herein, we outline the structural characterization of $[\{\{Ph_2P(O)\}_2CHLi\cdot(THF)\}_2\cdot THF]$, **1**, a lithiated bis(phosphoryl)-stabilized carbanion. In addition, we have identified the unexpected complex $[\{\{Ph_2P(O)\}_2CHLi\}_4\cdot\{Ph_2P(O)_2Li\}_2\cdot 8C_6H_6]$, **2**, which is formed as an intermediate in the oxidation of **1** by dioxygen.

2. Results and discussion

Reaction of $\{Ph_2P(O)\}_2CH_2$ with one equiv. of either BuLi or MeLi in THF solution, followed by recrystallization from *n*-hexane at −45 °C yielded colorless crystalline cubes that were isolated and identified by NMR spectroscopic and X-ray crystallographic studies as **1** (Fig. 2).

The solid-state structure of **1** was found to be a centrosymmetric Li_2O_2 dimer where the metals are tetracoordinate, each binding to a pair of bridging phosphoryl units, a terminally chelating phosphoryl unit and a THF molecule. Two independent dimers are present within the crystalline lattice, however, their core bonding arrangements are similar with the main differences between the structures being in the orientations of the attached phenyl rings (Table 1). THF molecules of crystallization are also present within the lattice but they have no close contacts to the lithiated complex.

The central Li_2O_2 dimeric core within **1** is in accordance with the structures of related mono(phosphoryl)-stabilized carbanions [28,29]. Also, the absence of any direct interactions between the carbanionic carbons and the metals is expected due to the highly electrostatic nature of the bonding present [30]. We have previously observed a similar chelated core arrangement in $[\{LiCl\cdot\{(Pr^iO)_2P(O)\}_2CH_2\}_2]$, [31], where a neutral β-diphosphonate acts as a Lewis base to monomeric LiCl fragments. A distinction in **1** from previously characterized α-phosphoryl carbanions is the position adopted by the hydrogen attached to the carbanion. Usually the carbanionic hydrogen lies in a synperiplanar orientation with respect to the α-phosphoryl group, i.e., the O=P–C–H torsion angles lie close to 0° [28a,c,29a–g,32]. In **1** the O=P–C–H torsion angles are 108.9°, 115.2°, 137.6° and 145.8°, which are closer to antiperiplanar arrangements. This unusual orientation is a consequence of chelation of the ligand to lithium, in turn restricting the flexibility of the P–C(H)–P backbone. This geometry also appears to be retained in solution. The ^1H NMR of **1** in pyridine shows a $^2J_{HP}$ coupling constant for the carbanionic ($P–CH^-$) proton of 4.5 Hz, which is indicative of O=P–C–H torsion angles in the approximate range 120°–180° [33]. The carbanionic carbons in **1** show a significant degree of pyramidalization as can be assessed from: (i) the sum of the angles around the carbanionic C (355.6° and 353.4°), the deviation, Δ_1, of the carbanionic C from the P–H–P plane (0.160 and 0.202 Å); (ii) the pyramidalization angle, χ_1, which is defined as 180° minus the improper P–C–P–H torsion angle (mean for each dimer is 24.2° and 31.0°). Also, the mean P–C distance of 1.714 Å (range 1.708(2)–1.718(3) Å) within the anionic backbone shows significant shorten-

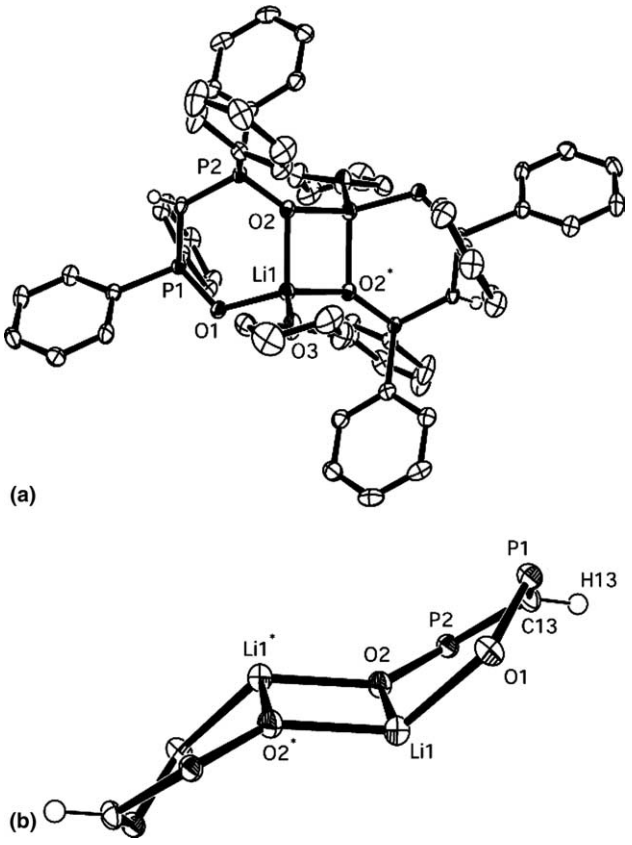

Fig. 2. Molecular structure of one of the two independent dimers of **1** showing: (a) the view perpendicular to the central Li_2O_2 ring; (b) an alternative view of the twisted three fused ring systems. The hydrogens (except those of the carbanions) and the non-bonded THF molecule of crystallization are omitted for clarity.

Parameters are given for both of the independent dimers present.

ing compared with the free ligand (mean 1.819 Å) [34]. The carbanions can therefore be considered as intermediately hybridized between sp^2 and sp^3. The P═O distances lie in the narrow range 1.508–1.517 Å (mean 1.514 Å) and are only slightly elongated compared to those of the free ligand (mean 1.492 Å). In combination these values indicate relatively localized double bonding in the P═O units and delocalized partial multiple bonding over the P–C–P segment.

A final point of note within the structure of **1** are the highly asymmetrical Li–O distances within the Li_2O_2 central ring. The Li–O bonds resulting from association between non-chelating units are substantially shorter than those of the chelated unit, e.g., Li(1)–O(2*) is 1.931(4), whereas Li(1)–O(2) is 1.996(4). Such asymmetrical bridging of the neutral ligand has previously been observed in $[\{LiCl \cdot \{(Pr^iO)_2P(O)\}_2CH_2\}_2]$ [31] and can be assigned to the limited flexibility of the ligand resulting in relatively long Li–O bonds for the chelated portions.

During our NMR studies of **1** in d_6-benzene, crystals were found to slowly form on the walls of a NMR tube. X-ray crystallographic analysis revealed the formation of the unexpected product $[\{\{Ph_2P(O)\}_2CHLi\}_4 \cdot \{Ph_2P(O)_2Li\}_2 \cdot 8C_6D_6]$, **2**. After a systematic study it was established that complex **2** could be prepared by exposing benzene solutions of **1** to dry air or O_2, followed by recrystallization (Scheme 1).

Several crystalline samples were prepared but these invariably co-precipitated with various unidentified side products (most likely further oxidation products) rendering the purification of **2** problematic. Also, attempts at preparing **2** rationally by the combination of the separately prepared components $[\{Ph_2P(O)\}_2CHLi]$ and $[Ph_2P(O)_2Li]$ or alternatively by the lithiation of a mixture of the neutral ligands were unsuccessful. Aqueous quenching studies of samples of **1** exposed to O_2 did, however, confirm the presence of both the β-diphosphine oxide ligand and diphenylphosphinic acid. It is therefore likely that the formation of **2** is related to its method of preparation, i.e., it is a kinetically stable intermediate formed during the oxidation of a lithiated β-diphosphine oxide. Unfortunately, this limited the unambiguous characterization of **2** to crystallographic analysis. Nevertheless, an interesting outcome of these studies was the identification of a polymorphic variant of **2**, **2a** (the C_6D_6 is replaced by C_6H_6 in this case). Such solid-state polymorphism is notable since it is rarely encountered for lithiated species [35]. The polymorphs **2** and **2a** crystallize in different space groups (triclinic $P\bar{1}$ and monoclinic $P2(1)/n$) and they also contain minor variations in their metrical parameters (Tables 2 and 3). For brevity, only details of complex **2** will be discussed and its molecular structure is depicted in Fig. 3.

Complex **2** is a centrosymmetric, hexalithium aggregate containing four $[\{Ph_2P(O)\}_2CHLi]$ units, similar to those in **1**, and a pair of $[Ph_2P(O)_2Li]$ fragments. Formation of the lithiated diphenylphosphinate group was determined to be via exposure of **1** to molecular oxygen, resulting in P–C bond cleavage. Such P–C bond fission through the oxidation of simple α-stabilized

Horner–Wittig reagents has significant precedent and has been assigned to the formation of a peroxide intermediate [36,37]. However, the reaction pathway has generally been interpreted by analysis of products found upon aqueous quenching, as opposed to directly analyzing the organometallic intermediates involved. Furthermore, the identification of such complex mixed-anion intermediates is particularly relevant when considering factors that influence their selectivity in organic synthesis. The benzene solvent of inclusion in **2** and **2a** displays no close contacts with the cage structure. Although incorporation of solvent of crystallization is commonplace the amount present, six benzene molecules per cage, is somewhat unusual.

Viewing the structure of **2** in detail, it can be seen that although each metal is tetracoordinate, there are three distinct lithium environments, Li(1), Li(2) and Li(3). The core of the framework is an atypical tetrametallic cage arrangement (Fig. 3(b)), where a pair of Li_2O_2 rings, Li(1)O(5*)Li(2*)O(6) and Li(1*)O(5)Li(2)O(6*), are connected by two phosphorous centers, P(5) and P(5*), and two phosphoryl groups, O(2) and O(2*). Overall, the cage is composed of two four-membered Li_2O_2 rings and four six-membered LiOLiOPO rings. The framework is then completed by incorporation of a terminal lithium center, Li(3) and Li(3*), at each side of the central cage which, in turn, creates another pair of Li_2O_2 rings, Li(3)O(3)Li(2)O(5) and Li(3)O(1*)-

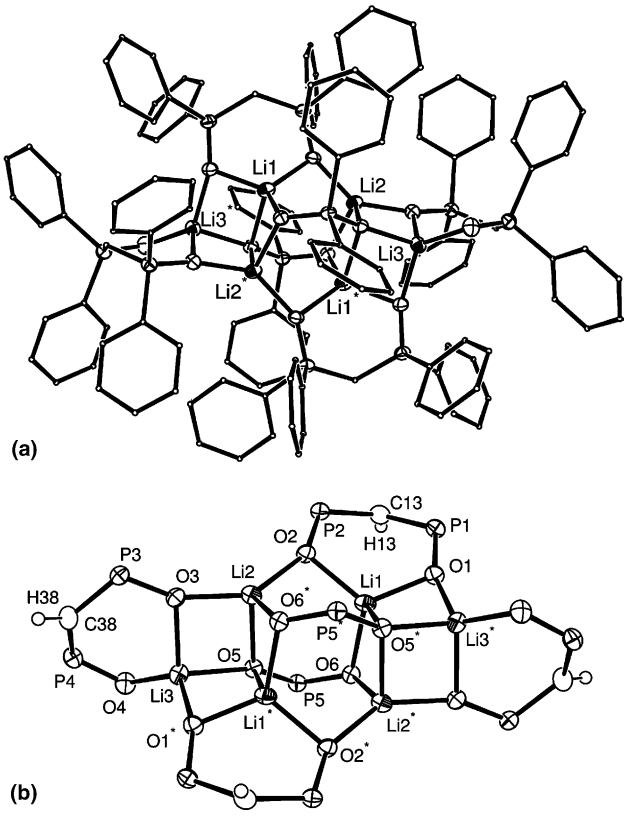

Fig. 3. Molecular structure of **2** showing (a) the complete molecule, and (b) the core framework. Hydrogens, except those of the carbanions in (b), and benzene molecules of solvation are omitted for clarity.

Li(1*)O(5), (and their symmetry equivalents) on each side of the central cage. Although the structure of **2** is somewhat unusual, we were intrigued to find significant similarities with our recently reported structure of the hexasodium β-diphosphonate complex $[\{\{(EtO)_2P(O)\}_2CHNa\}_6]$, **3** [38]. Whereas **2** is a mixed-anion species complex **3** is homoleptic. Nevertheless, the connectivities within the two hexametallic complexes are remarkably similar, with the main difference being the absence of the Li(2)–O(6) and Li(2*)–O(6*) interactions in **2** (Fig. 4).

These additional metal–O interactions in **3** result in a six Na–O rung ladder framework, as opposed to the more open cage core found within **2**. This structural variance is likely due to replacement of the central β-diphosphonate ligands in **3** by the less flexible and smaller phosphinates in **2**. Additionally, the larger sodium cations in **3** can accommodate higher coordination numbers than the lithium centers in **2**, as is required for the six-rung structure.

Turning to the geometric parameters in **2**, the bonding within the β-diphosphine oxide anions is found to follow a similar pattern to those in **1**. The phosphoryl units display relatively localized P=O double bonds (mean P–O 1.522 Å, range 1.516 (2)–1.527 (2) Å) with delocalization over the P–C–P fragment (mean P–C 1.718 Å, range 1.714(3)–1.721(3) Å). Regarding the planarity of the carbanions in **2**, a significant difference is found between the two independent β-diphosphine oxide anions, where the central P(1)–C(13)–P(2) ligand is substantially more pyramidalized compared with the almost planar terminal P(3)–C(38)–P(4) ligand. The sum of the angles around the carbanionic carbons are 350.2° and 360.0°, Δ_1 is 0.225 and 0.007 Å, and χ_1 is 36.3° and 1.2° for these units, respectively. These results clearly indicate that the carbanions in the P–C–P backbone are not necessarily pyramidalized as a consequence of either chelation or due to the presence of localized charge. It is likely that the arrangement adopted at the anionic carbon is dictated by the minimization of torsional strain in the molecule and that its position is a relatively minor effect in energetic terms. Finally, the P–O bond lengths within the phosphinate are essentially identical (1.510(2) and 1.515(2) Å) indicating delocalization over the O–P–O unit [39].

3. Experimental

3.1. X-ray crystallography

Table 4 contains information on the data collection. In all cases (**1**, **2** and **2a**), the crystalline samples were placed in inert oil, mounted on a glass pin and transferred to the cold gas stream of the diffractometer. Crystal data were collected and integrated using a Bruker Apex system, with graphite monochromated Mo Kα (λ = 0.71073 Å) radiation at 100 K. The structure was

solved by direct methods using SHELXS-97 and refined using SHELXL-97 (Sheldrick, G.M., University of Göttingen). Non-hydrogen atoms were refined anisotropically and the carbanionic hydrogens were located from difference Fourier maps and were refined isotropically. The remaining hydrogen atoms were placed at calculated positions and were refined isotropically.

3.2. General synthetic procedures

All experiments were carried out under a dry dinitrogen atmosphere and scrupulously anhydrous conditions using standard Schlenk techniques [40]. The phosphine oxide ligand $\{Ph_2P(O)\}_2CH_2$ was prepared by the oxidation of $(Ph_2P)_2CH_2$ (Aldrich) using H_2O_2. The solvents (except anhydrous benzene that was used as supplied by Aldrich) were purified by passage through copper-based catalyst and molecular sieve columns (Innovative Technology). The *n*-butyl lithium and methyl lithium were supplied by Aldrich as 1.6 M solutions in hexane and diethylether, respectively, and standardized by titration with salicylaldehyde phenylhydrazone directly before use [41]. The NMR experiments were recorded on Varian-300 and -500 spectrometers. ^{1}H and ^{13}C NMR spectra were referenced internally to the protonated portions of the deuterated solvents, whereas ^{31}P NMR spectra were referenced externally to 85% *o*-phosphoric acid. Mass spectra were recorded on 'GCmate' GC–MS instrument and 'Micromass' Triple Quadrupole LC–MS–MS systems. Elemental analyses were performed by the Canadian Microanalytical Service Ltd.

3.2.1. $[\{\{Ph_2P(O)\}_2CHLi\cdot(THF)\}_2\cdot THF]$ (**1**)

The parent phosphine oxide (0.5 mmol) was dissolved in 5 mL of THF and the solution cooled to 0 °C. A solution of alkyllithium reagent (MeLi of BuLi, 0.5 mmol) was added to the reaction mixture via a syringe over several minutes, and the resulting solution was slowly warmed to room temperature. The solvent was then evaporated and 2 ml hexanes were added to dissolve the resultant white solid and the solution stored at −45 °C. After one day, small colorless blocks of **1** precipitated from solution. Yield 85%, m.p. 134 °C, ^{1}H NMR (300 MHz, pyridine-d_5, 25 °C): δ = 1.66 (m, 4H, THF), 2.37 (bt, $^2J_{H,P}$ = 4.5 Hz, 1H, CH^-), 3.69 (m, 4H, THF), 7.28 (m, 3H, *meta* and *para*-Ph), 8.13 (m, 2H, *ortho*-Ph). ^{31}P–{^{1}H} NMR (300 MHz, pyridine-d_5, 25 °C): δ = 37.2 (bs). ^{13}C–{^{1}H} NMR (300 MHz, pyridine-d_5, 25 °C): δ = 131.9, 130.1, 128.4 (Ar–H), 68.3 (OCH_2, THF), 26.3 (CH_2, THF). The ^{1}H NMR spectra indicated loss of the THF of crystallization on isolation. No signal for the carbanionic carbon could be located even after increasing the sample concentration and running extended scans. Elemental *Anal.* for $C_{58}H_{58}Li_2O_6P_4$ (MW 989 based on the integration values obtained from the ^{1}H NMR spectra): Calc. C, 70.45; H, 5.91; N, 0.00. Found: C, 69.96; H, 6.06; N < 0.3%.

3.2.2. $[\{\{Ph_2P(O)\}_2CHLi\}_4\cdot\{Ph_2P(O)_2Li\}_2\cdot 8C_6H_6]$, **2** and polymorph **2a**

The parent phosphine oxide (0.5 mmol) was dissolved in 5 mL of THF and the solution cooled to 0 °C. MeLi in diethyl ether (0.5 mmol) was added to the reaction

mixture via a syringe over several minutes, and the resulting solution was slowly warmed to room temperature. The solution was stirred for three days at room temperature and air was allowed to enter the flask through a $CaCl_2$ tube (or alternatively O_2 from a cylinder). The solvent was then removed in vacuo and benzene (benzene/1 mmol TMEDA mixture in the case of the second polymorph **2a**) was added to dissolve the resultant white solid. After storing the solution at 5 °C for one day, small colorless blocks of **2** (or **2a**) precipitated out of the solution. Unfortunately, **2** and **2a** co-precipitated with other unidentified products, most likely further oxidation species. This resulted in the unambiguous characterization of **2** and **2a** being limited to the solid-state analysis. NMR data proved to be of little value giving broad, ill-defined signals that could be complicated by dynamic processes occurring in solution.

The quenching studies were performed using deionized water, the organic components were extracted into ether and dried over anhydrous $MgSO_4$. The products were identified by ^1H NMR and mass spectroscopy and compared with authentic samples.

3.2.2.1. $Ph_2P(O)CH_2P(O)Ph_2$, L_1. ^1H NMR (300 MHz, pyridine-d_5, 25 °C): $\delta = 4.26$ (t, $^2J_{H-P} = 14.08$ Hz, CH_2), 7.39 (m, 6H, *meta* and *para*-H, Ph), 8.17 (m, 4H, *ortho*-H, Ph). $^{31}P-\{^1H\}$ NMR (300 MHz, pyridine-d_5, 25 °C): $\delta = 24.0$ (s). $^{13}C-\{^1H\}$ NMR (300 MHz, pyridine-d_5, 25 °C): $\delta = 134.9, 132.2, 132.0, 129.1$ (Ar–C, Ph.), 34.4 (t, $^1J_{C,P} = 59.1$ Hz, CH_2). MS (FAB+) $m/z = 417$ $[\mathbf{L_1} + H]^+$, 339 $[\mathbf{L_1} - Ph]^+$. When using ES/MSMS the larger aggregate was observed: $m/z = 839$ $[2\mathbf{L_1} + Li]^+$ and its daughter 423 $[\mathbf{L_1} + Li]^+$.

3.2.2.2. $Ph_2P(O)(OH)$,L_2. ^1H NMR (300 MHz, pyridine-d_5, 25 °C) $\delta = 7.34$ (m, *meta* and *para*-Ar · H), 8.47 (m, *ortho*-Ar · H). $^{31}P-\{^1H\}$ NMR (300 MHz, pyridine-d_5, 25 °C): $\delta = 17.8$ (s). $^{13}C-\{^1H\}$ NMR (300 MHz, pyridine-d_5, 25 °C): $\delta = 132.0$ (d, $J = 10.4$ Hz, Ph), 130.8 (s, Ph), 130.4 (d, $J = 12.2$ Hz) [40]. GC/EI + $m/z = 218.04988$ $[\mathbf{L_2}]^+$ (calculated: 218.04967). ES/MSMS $m/z = 641$ $[\mathbf{L_1} + \mathbf{L_2} + Li]^+$ and its daughter 423 $[\mathbf{L_1} + Li]^+$.

Abstract

The kinetics of the oxidation of 4-hydroxycoumarin (HDC) by permanganate in aqueous alkaline medium at a constant ionic strength of 0.40 mol dm^{-3} was studied spectrophotometrically using a rapid kinetic accessory. The reaction between permanganate and HDC in alkaline medium exhibits 6:1 stoichiometry (permanganate:HDC). The reaction is of first order in [permanganate ion] and has less than unit order in both [HDC] and [alkali]. A decrease in the dielectric constant of the medium increases the rate of reaction. The effect of added products and ionic strength of the reaction medium have been investigated. The oxidation reaction in alkaline medium has been shown to proceed via a permanganate–HDC complex, which decomposes slowly in a rate determining step followed by a fast reaction between a free radical of HDC and five molecules of permanganate species to give the products. The main products were identified by spot test, IR and NMR. A suitable mechanism is proposed. The reaction constants involved in the different steps of the mechanism are calculated. The activation parameters with respect to the slow step of the mechanism are computed and discussed and thermodynamic quantities are determined.

Keywords: Kinetics; Permanganate; Oxidation; 4-Hydroxycoumarin

1. Introduction

The permanganate ion (MnO_4^-) oxidises a great variety of substrates and it finds extensive applications in organic synthesis [1,2], especially after the advent of phase transfer catalysis [3,4] which permits the use of solvents such as methylene chloride and benzene. Kinetic studies constitute an important source of mechanistic information on the reaction, as demonstrated by results referring to unsaturated acids in both aqueous [1,3] and non-aqueous media [5].

During oxidation by permanganate, it is evident that the Mn(VII) in permanganate is reduced to various oxidation states in acidic, alkaline and neutral media. Furthermore, the mechanism by which this multivalent oxidant oxidises a substrate depends not only on the substrate but also on the medium [6] used for the study. In strongly alkaline medium, the stable reduction product [7] is the manganate ion, MnO_4^{2-}. It is interesting that the oxidant species (MnO_4^-) requires a pH range 12–13, below which the system becomes disturbed and the reaction will proceed further to give a reduced product of the oxidant as Mn(IV), which slowly develops yellow turbidity. Hence, it becomes apparent that in carrying out this reaction the role of pH in a reaction medium is crucial. No mechanistic information is available to distinguish between a direct one-electron reduction to

Mn(VI) and a mechanism in which a hypomanganate is formed in a two-electron step followed by a rapid reaction [7].

The biological importance of coumarin derivatives as anticoagulants, aflatoxins, mycotoxins and antibiotics has led to a considerable amount of synthetic work in the field of coumarin for their pharmacological evaluation. 4-Hydroxycoumarin (4-hydroxy-2H-1-benzopyran-2-one) is used in the synthesis of pharmaceuticals especially for anticoagulants. It is used in manufacturing fluorescent dyes and rodenticides. Ichikawa et al. [8], reported that 4-hydroxy-3-sulfonamidocoumarins are used as antibacterial and antitubercular agents [9].

A literature survey reveals that there are no reports on the oxidative mechanism of 4-hydroxycoumarin by any oxidant. In view of the medicinal value, the present study deals with the title reaction to investigate the redox chemistry of permanganate in such media and to arrive at a plausible mechanism of the reaction based on kinetic and spectral results.

2. Experimental

2.1. Materials

All chemicals used were of reagent grade. A solution of 4-hydroxycoumarin (M/s. S.S. Antibiotics Pvt. Ltd., Aurangabad, India) was prepared by dissolving an appropriate amount of recrystallised sample in double distilled water. The purity of the sample was checked by TLC and its m.p. 212–214 °C. The preparation of other stock solutions are as given in an earlier paper [7].

2.2. Kinetic measurements

Since the initial reaction was too fast to be monitored by the usual methods, kinetic measurements were performed on a Peltier Accessory (Temperature Control) attached Varian CARY 50 Bio UV–Vis Spectrophotometer connected to a rapid kinetic accessory (HI-TECH SFA-12). All kinetic experiments followed are as given in the previous paper [7].

In the course of measurements, the solution changed from violet to blue and then to green. The spectrum of the green solution was identical to that of MnO_4^{2-}. It is probable that the blue colour originated from the violet of permanganate and the green from the manganate, excluding the accumulation of hypomanganate. The formation of Mn(VI) was also evidenced by a decreasing absorbance of Mn(VII) at 526 nm and an increasing absorbance of Mn(VI) at 608 nm during the course of the reaction (Fig. 1). The effect of dissolved oxygen, added carbonate and surface of the reaction vessel on the kinetics are studied as in the earlier paper [7].

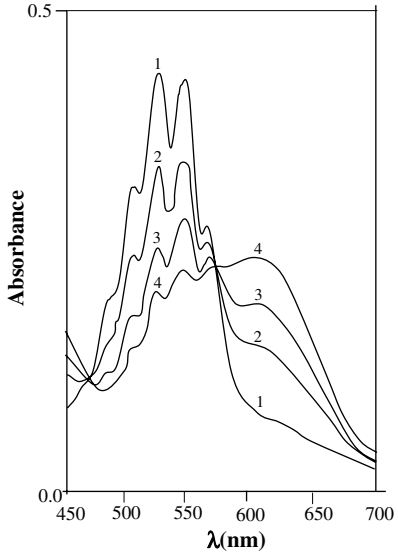

Fig. 1. Spectroscopic changes occurring oxidation of 4-hydroxycoumarin by permanganate with 10^3 [HDC] = 1.0, 10^4 [MnO_4^-] = 1.0, [OH^-] = 0.06 and I = 0.40 mol dm^{-3} at 25 °C, Scanning time interval = 60 s.

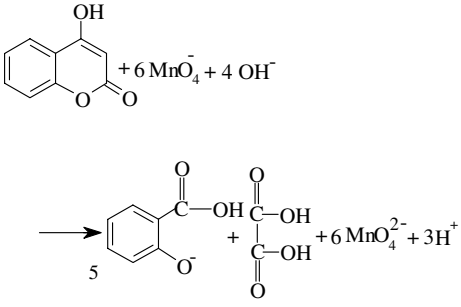
3. Results and discussion

3.1. Stoichiometry and product analysis

The reaction mixtures containing an excess of permanganate concentration over 4-hydroxycoumarin, constant 0.06 mol dm^{-3} NaOH and adjusted to an ionic strength of 0.40 mol dm^{-3} were allowed to react for 2 h at 25 ± 0.1 °C. The remaining permanganate was then analysed spectrophotometrically. The results indicated that 6.0 ± 0.2 mol of MnO_4^- were consumed by 1 mol of 4-hydroxy coumarin as given by the following equation:



(1)

For identification of products, the reaction mixture containing an excess of 4-hydroxycoumarin was kept for completion of the reaction. The reaction product, salicylic acid, was extracted with ether and recrystallised from aqueous alcohol and the purity was checked by HPLC. This was identified as salicylic acid by its IR spectrum (KBr), which showed a band at (ν) 1701 cm^{-1} due to C=O stretching of the acid, a broad band at 2920 cm^{-1} due to O–H stretching of the acid and

3392 cm^{-1} due to phenolic OH. Salicylic acid was further characterised by its ^1H NMR spectrum ($CDCl_3$ + DMSO-d_6/TMS)δ, 5.74 (s, 1H, phenolic OH, disappeared on D_2O exchange), 7.27–7.82 (m, 4H, 4 aromatic protons), 11.5 (s, 1H, acidic OH, vanished on D_2O exchange). The product Mn(VI) was identified by its visible spectrum showing an absorbance maxima at 608 nm. Oxalic acid, which is highly soluble in water, was identified by a spot test [10]. It was observed that the salicylic acid and oxalic acid did not undergo further oxidation under the present kinetic conditions.

3.2. Reaction orders

The reaction orders were determined from the slopes of log k_{obs} versus log (concentration) plots by varying the concentration of the reductant and alkali in turn while keeping other conditions constant.

The potassium permanganate concentration was varied in the range of 4.0×10^{-5} to 4.0×10^{-4} mol dm^{-3}, and the linearity of plots of log absorbance versus time ($r \geqslant 0.9996$, $S \leqslant 0.0142$) up to 85% completion of the reaction, Fig. 2, indicated a reaction order of unity in [MnO_4^-]. This was also confirmed by variation of [MnO_4^-], which did not result in any change in the pseudo-first order rate constants, k_{obs} (Table 1). The substrate 4-hydroxycoumarin concentration was varied in the range 4.0×10^{-4} to 4.0×10^{-3} mol dm^{-3} at 25 °C while keeping all other reactant concentrations and conditions constant. The k_{obs} values increased with the increase in concentration of 4-hydroxycoumarin indicating an apparent less than unit order dependence on [4-hydroxycoumarin] (Table 1). The effect of alkali on the reaction has been studied at constant concentrations of 4-hydroxycoumarin, potassium permanganate, and a constant ionic strength of 0.40 mol dm^{-3}. The rate constants increased with increasing [alkali] and the order was found to be less than unity (Table 1).

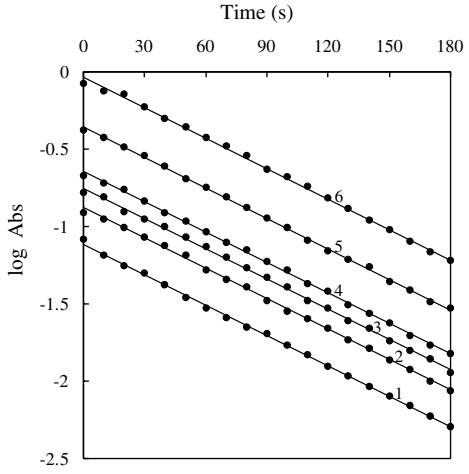


Fig. 2. First-order plots of oxidation of 4-hydroxycoumarin by permanganate aqueous alkaline medium at 25 °C. 10^4 [MnO_4^-] (mol dm^{-3}); (1) 0.4; (2) 0.6; (3) 0.8; (4) 1.0; (5) 2.0; (6) 4.0 (10^3 [HDC] = 1.0, [OH^-] = 0.06 and I = 0.40 mol dm^3).

3.3. Effect of ionic strength and relative permittivity

The effect of ionic strength was studied by variation of the $NaClO_4$ concentration in the reaction medium. The ionic strength was varied from 0.04 to 0.4 mol dm^{-3} at constant concentrations of permanganate, 4-hydroxycoumarin and alkali. It was found that the rate constants increased with increasing concentration of $NaClO_4$. The plot of log k_{obs} versus $I^{1/2}$ was linear with a positive slope (Fig. 3) ($r \geqslant 0.9995$, $S \leqslant 0.0144$).

The effect of relative permittivity (ε_T) on the rate constant has been studied by varying the t-butanol–water content in the reaction mixture with all other conditions being maintained constant. Attempts to measure the relative permittivities were not successful. However, they were computed from the values of pure liquids [11]. No reaction of the solvent with the oxidant occurred under the experimental conditions employed. The rate constant, k_{obs} increased with decreasing relative permittivity of the medium. The plot of log k_{obs} versus $1/\varepsilon_T$ was linear with a positive slope (Fig. 3) ($r \geqslant 0.9994$, $S \leqslant 0.0128$).

3.4. Effect of initially added products

The initially added products, such as manganate, salicylic acid and oxalic acid did not have any significant effect on the rate of the reaction.

3.5. Test for free radicals

The intervention of free radicals in the reaction was examined as follows. The reaction mixture to which a known quantity of acrylonitrile scavenger had been added initially was kept for one hour in an inert atmosphere. On diluting the reaction mixture with methanol, a precipitate resulted, suggesting the possibility of free radical intervention. The blank experiments of either MnO_4^- or 4-hydroxycoumarin with acrylonitrile alone did not induce polymerization under the same conditions as those induced with reaction mixture. Initially added acrylonitrile decreases the rate indicating the free radical intervention, which is the case in earlier work [12].

3.6. Effect of temperature

The rate of reaction was measured at different temperatures under varying 4-hydroxycoumarin concentrations. The rate of reaction increased with the increase of temperature. The rate constants, k of the slow step of Scheme 1 were obtained from intercepts of the plot

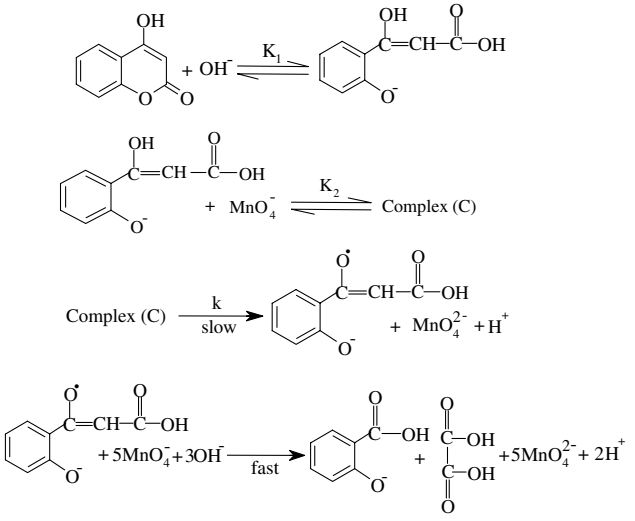

Scheme 1.

of $1/k_{obs}$ versus 1/[4-hydroxycoumarin] ($r \geqslant 0.9993$, $S \leqslant 0.0122$) and were used to calculate the activation parameters. The values of k (s^{-1}) are given in Table 2. The activation parameters corresponding to these constants were evaluated from the plot of log k versus $1/T$ ($r \geqslant 0.9998$, $S \leqslant 0.0134$) and are tabulated in Table 2.

The permanganate ion, MnO_4^-, is a powerful oxidant in an aqueous alkaline medium. As it exhibits many oxidation states, the stoichiometric results and pH of the reaction media play an important role. Under the prevailing experimental conditions at pH > 12, the reduction product of Mn(VII), i.e., Mn(VI), is stable and further reduction of Mn(VI) might be stopped [7]. Diode array rapid scan spectrophotometric (DARSS) studies have shown that at pH > 12, the product of Mn(VII) is Mn(VI) and no further reduction was observed as reported by Simandi et al. [13]. However, on prolonged standing, the green Mn(VI) is reduced to Mn(IV) under our experimental conditions.

The reaction between permanganate and 4-hydroxycoumarin in alkaline medium has a stoichiometry of

Table 2
Thermodynamic activation parameters for the oxidation of 4-hydroxycoumarin by permanganate in alkaline medium with respect to the slow step of Scheme 1

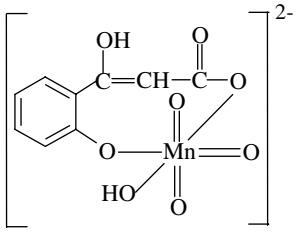
6:1 with a first order dependence on the [MnO_4^-] and less than unit order dependence on both the [alkali] and [4-hydroxycoumarin]. No effect of added products was observed. Based on the experimental results, a mechanism can be proposed for which all the observed orders with respect to each constituent such as oxidant, reductant and OH^- may be well accommodated. Here, the 4-hydroxycoumarin reacts with alkali in a prior-equilibrium step to form an anionic form of (2Z)-3-hydroxy-3-(2-hydroxyphenyl)acrylic acid which reacts with one molecule of permanganate species to form a complex (C). This complex (C) decomposes in a slow step to liberate a free radical derived from (2Z)-3-hydroxy-3-(2-hydroxyphenyl)acrylic acid, and the product MnO_4^{2-}. K_2 is the equilibrium constant comprising the equilibrium to bind (2Z)-3-hydroxy-3-(2-hydroxyphenyl)acrylic acid to Mn. This radical in turn reacts with five more molecules of permanganate species in a fast step to yield the products as given in Scheme 1.

Probable structure of the complex (C) is given by



Spectroscopic evidence for the complex formation between oxidant and substrate was obtained from UV–Vis spectra of 4-hydroxycoumarin (1.0×10^{-3} mol dm^{-3}), permanganate (1.0×10^{-4}, [OH^-] = 0.06 mol dm^{-3}) and a mixture of both. A bathochromic shift of about 7 nm from 327 to 334 nm in the spectra of permanganate was observed and hyperchromicity was observed at 334 nm. This was also evident from the Michaelis–Menten plot, $1/k_{obs}$ versus 1/[HDC], (Fig. 4) and such complex formation between substrate and oxidant have also been observed in other studies [14]. Since Scheme 1 is in accordance with the generally well-accepted principle of non-complementary oxidations taking place in sequences of one-electron steps, the reaction between a substrate and oxidant would afford a radical intermediate. A free radical scavenging experiment revealed such a possibility (vide infra). This type of radical intermediate has also been observed in earlier work on the permanganate oxidation of various organic substrates in alkaline medium [15].

Scheme 1 leads to the rate law (5),

$$\text{Rate} = \frac{kK_1K_2[\text{HDC}][\text{MnO}_4^-][\text{OH}^-]}{(1+K_1[\text{OH}^-]+K_1K_2[\text{MnO}_4^-][\text{OH}^-])(1+K_1K_2[\text{HDC}][\text{OH}^-])} \quad (2)$$

In view of the low concentration of [MnO_4^-] used $1 + K_1[OH^-] + K_1K_2[MnO_4^-] \approx 1 + K_1[OH^-]$

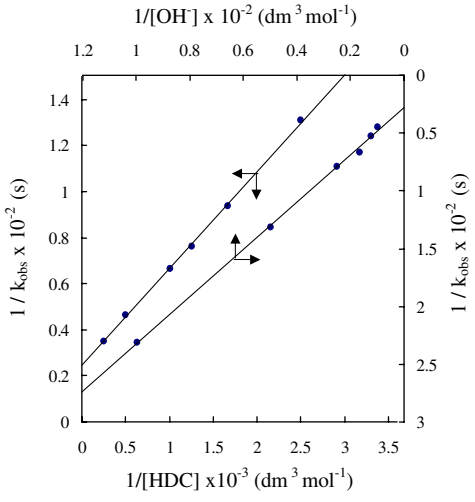


Fig. 4. Verification of rate law (5) in the form of (6) for the permanganate oxidation of 4-hydroxycoumarin in aqueous alkaline medium.

$$\text{Rate} = \frac{kK_1K_2[\text{HDC}][\text{MnO}_4^-][\text{OH}^-]}{(1+K_1[\text{OH}^-])(1+K_1K_2[\text{HDC}][\text{OH}^-])} \quad (3)$$

$$\text{Rate} = \frac{kK_1K_2[\text{HDC}][\text{MnO}_4^-][\text{OH}^-]}{1+K_1K_2[\text{HDC}][\text{OH}^-]+K_1^2K_2[\text{HDC}][\text{OH}^-]^2} \quad (4)$$

Neglecting the square terms in view of the low value compared to unity in the denominator,

$$\frac{\text{Rate}}{[\text{MnO}_4^-]} = k_{\text{obs}} = \frac{kK_1K_2[\text{HDC}][\text{OH}^-]}{1+K_1[\text{OH}^-]+K_1K_2[\text{HDC}][\text{OH}^-]} \quad (5)$$

Eq. (5) can be rearranged to Eq. (6), which is suitable for verification,

$$\frac{1}{k_{\text{obs}}} = \frac{1}{kK_1K_2[\text{HDC}][\text{OH}^-]} + \frac{1}{kK_2[\text{HDC}]} + \frac{1}{k} \quad (6)$$

According to Eq. (6), the plots of $1/k_{\text{obs}}$ versus 1/[4-hydroxycoumarin] ($r \geqslant 0.9993$, $S \leqslant 0.0122$) and $1/k_{\text{obs}}$ versus $1/[\text{OH}^-]$ ($r \geqslant 0.9996$, $S \leqslant 0.0212$) should be linear which is verified in Fig. 4. The slopes and intercepts of such plots lead to the values of K_1, K_2 and k at 25 °C of 1.64 ± 0.06 dm^3 mol^{-1}, $(7.34 \pm 0.45) \times 10^3$ dm^3 mol^{-1} and $(4.06 \pm 0.12) \times 10^{-2}$ s^{-1}, respectively. Using these values, the rate constants under different experimental conditions were calculated and compared with experimental data (Table 1). Experimental and calculated values agree reasonably well, which supplements Scheme 1.

The effect of ionic strength and solvent polarity on the rate of reaction in the present case is entirely different from that of earlier studies. In the case of the L-asparagine–$KMnO_4$ reaction [16], there was no effect of ionic strength and relative permittivity on the rate of reaction. In the case of L-phenylalanine [17] also the rate was independent of ionic strength. But in our present study the effect of increasing ionic strength on the rate explains qualitatively the reaction between two negatively charged ions, as seen in Scheme 1. The effect of solvent on the reaction rate has been described in detail in the literature [18]. Increasing the content of *t*-butanol in the reaction medium leads to an increase in the rate of reaction, which seems to be contrary to the expected interaction between neutral and anionic species in media of lower relative permittivity. However, an increase in the rate of reaction with decreasing relative permittivity may be due to stabilization of the complex (C) at low relative permittivity, which is less solvated than MnO_4^- at higher relative permittivity because of its larger size.

The thermodynamic quantities for the first equilibrium step in Scheme 1 can be evaluated as follows. The 4-hydroxycoumarin and hydroxide ion concentrations (as in Table 1) were varied at different temperatures. The plots of $1/k_{\text{obs}}$ versus 1/[HDC] ($r \geqslant 0.9993$, $S \leqslant 0.0122$) and $1/k_{\text{obs}}$ versus $1/[\text{OH}^-]$ ($r \geqslant 0.9996$, $S \leqslant 0.0212$) should be linear as shown in Fig. 4. From the slopes and intercepts, the values of K_1 are calculated at different temperatures and these values are given in Table 2. A van 't Hoff plot was made for the variation of K_1 with temperature [i.e., log K_1 versus $1/T$ ($r \geqslant 0.9997$, $S \leqslant 0.0201$)] and the values of the enthalpy of reaction ΔH, entropy of reaction ΔS and free energy of reaction ΔG, were calculated. These values are also given in Table 2. A comparison of the latter values with those obtained for the slow step of the reaction shows that these values mainly refer to the rate limiting step, supporting the fact that the reaction before the rate determining step is fairly slow and involves a high activation energy [19].

The negative value of $\Delta S^{\#}$ suggests that the intermediate complex is more ordered than the reactants [20]. The observed modest enthalpy of activation and a higher rate constant for the slow step indicates that the oxidation presumably occurs via an inner-sphere mechanism. This conclusion is supported by earlier observations [21,22]. The existence of two isobestic points as shown in the UV–Vis spectrum (Fig. 1) indicates [23] the presence of two equilibrium steps before the slow step of the mechanism (Scheme 1).

Appendix A

According to Scheme 1

$$\text{Rate} = k[\text{C}] = kK_1K_2[\text{HDC}]_f[\text{MnO}_4^-][\text{OH}^-]_f \quad (\text{I})$$

$$\begin{aligned}[\text{HDC}]_T &= [\text{HDC}]_f + [\text{HDC}^-] + [\text{C}] \\ &= [\text{HDC}]_f + K_1[\text{HDC}][\text{OH}^-] \\ &\quad + K_2[\text{HDC}^-][\text{MnO}_4^-] \\ &= [\text{HDC}]_f(1 + K_1[\text{OH}^-] + K_1K_2[\text{MnO}_4^-][\text{OH}^-])\end{aligned}$$

$$[\text{HDC}]_f = \frac{[\text{HDC}]_T}{1+K_1[\text{OH}^-]+K_1K_2[\text{MnO}_4^-][\text{OH}^-]} \quad (\text{II})$$

$$\begin{aligned}[\text{OH}^-]_T &= [\text{OH}^-]_f + [\text{HDC}^-] + \text{C} \\ &= [\text{OH}^-]_f(1 + K_1[\text{HDC}] + K_1K_2[\text{HDC}][\text{MnO}_4^-])\end{aligned}$$

$$[\text{OH}^-]_f = \frac{[\text{OH}^-]_T}{1+K_1[\text{HDC}]+K_1K_2[\text{HDC}][\text{MnO}_4^-]}$$

In view of the low concentration of $[\text{MnO}_4^-]$ and [HDC] used,

$$[\text{OH}^-]_f = [\text{OH}^-]_T \quad (\text{III})$$

$$\begin{aligned}[\text{MnO}_4^-]_T &= [\text{MnO}_4^-] + [\text{C}] \\ &= [\text{MnO}_4^-] + K_1K_2[\text{HDC}][\text{MnO}_4^-][\text{OH}^-] \\ &= [\text{MnO}_4^-]_f(1 + K_1K_2[\text{HDC}][\text{OH}^-])\end{aligned}$$

$$[MnO_4^-]_f = \frac{[MnO_4^-]_T}{1 + K_1K_2[HDC][OH^-]} \quad \text{(IV)}$$

Substituting Eqs. (II),(III) and (IV) in Eq. (I) (Subscripts T and f stand for total and free)

$$\text{Rate} = (kK_1K_2[HDC]_T[MnO_4^-]_T[OH^-]_T) / ((1 + K_1[OH^-] + K_1K_2[MnO_4^-][OH^-]) \times (1 + K_1K_2[HDC][OH^-]))$$

Abstract

The compounds [Cu(Salmeen)(Im)(H_2O)](ClO_4) (**1**) and [Cu(Cl–Salmeen)(Im)(ClO_4)] (**2**), where Salmeen = *N*,*N*-dimethyethylenesalicylidenamine, were synthesized and characterized. The Copper(II) metal in both complexes [Cu(Salmeen)Im(H_2O)](ClO_4) (**1**) and [Cu(Cl–Salmeen)(Im)(ClO_4)] (**2**) possesses square pyramidal geometry, fulfilling the four corners of the square base with the Salmeen moiety and imidazole ligand, while the water and perchlorate anions occupy the axial position of the respective complexes. The weak inter and intra-dimeric H-bonding interactions mediated through heterocyclic nitrogens of imidazole, perchlorate anions and π–π stacking interactions between the aromatic rings and imidazole rings form an interesting supramolecular association. The electronic spectral studies indicate that the existence of weak apical coordination by water and perchlorate ions found in the solid state, is replaced by strong coordinating solvents such as DMSO in solution and thereby the opening of an active site for catalytic reaction is demonstrated with the reduction by the ascorbate dianion (Asc^{2-}) as a model for type-2 Cu(II) ascorbate oxidase. The self-assembled molecular association that favors the electron transfer redox process is demonstrated using UV–Vis electronic spectral studies.

Keywords: Copper(II) complex; Ascorbic oxidation; Crystal structure; Imidazole

1. Introduction

Sacconi et al. [1] originally synthesized the Salmeen ligand in 1966. In continuation a number of substituted and modified Cu(II)–Salmeen schiff base complexes were synthesized and investigated for various research interests, due to their interesting geometrical [2], solvatochromic [3] and magnetic properties [2–4]. Monomeric, dimeric and multi-metallic complexes have also been synthesized and investigated for various applications. Szalda et al. [5] have made considerable effort to generalize the determination of the binding site and stereochemistry of the chelate metal system based on the stereo-selective metal ligand and ligand–ligand interactions by keeping the tridentate Salmeen ligand constant and varying purine [5], pyrimidine [6], cytosyine [6], adinine [7], etc. The various intra and intermolecular interactions originating from N-terminus of dimethylamine of ethylenediamine and phenolate oxygen of salicylaldehyde of these complexes were extensively studied [5–7]. In this continuing interest, the present report explores the molecular association in the solid state, the effect

doi:10.1016/j.poly.2004.08.020

of substitution on the salicylaldehyde ring and consequent geometrical change in the Cu(II) environment in addition to its synthesis, electronic spectral studies and its reactivity, using ascorbic acid. The existence of weak intra and inter-pair molecular associations of both the complexes in the solid state are explored to favor the catalytic process. The Cu(II) being an ubiquitous bio-element, the present complexes **1** and **2**, possessing $[Cu(Salmeen)Im]^+$ as a common moiety together with square pyramidal geometry (4 + 1) with labile water and perchlorate apical coordination, inspired us to investigate their oxygen transfer process with ascorbic acid. In particular, oxidation of ascorbic acid using Cu(II) and oxygen deserves significant enzymatic importance in bioinorganic chemistry of ascorbic oxidase. Interestingly the ascorbate ion, a two electron donor, readily reduces both the Cu(II) complexes into their Cu(I) counterparts. Ascorbic oxidase has three types of copper centers in which the type-2 site belongs to the functional trinuclear copper cluster [8]. The Cu(II) in AO is coordinated to two histidine molecules and a water molecule. The primary role of the type-2 copper center is electron transfer, in which ascorbate under physiological reaction conditions acts as an electron donor. The reduced Cu(I) sites activate dioxygen and convert it to water involving four electrons and four protons in AO. The present mononuclear square pyramidal Cu(II) complexes possessing labile binding sites are of great importance for modeling the type-2 site of copper oxidases [9].

2. Experimental

Microanalyses of the complexes were done using a Perkin–Elemer PE 2400 series II CHNS/O elemental analyzer. Electronic spectra were recorded in several solvents using a UV–Vis spectrometer (HP Diode array spectrometer model 8452A).

2.1. Materials

The chemicals for the syntheses, ascorbic acid, *N*,*N*-dimethylethylenediamine and salicyladihyde, were received from Sigma–Aldrich and were used without further purification. All solvents were dried and distilled by standard methods prior to use [10].

CAUTION! Perchlorate salts of metal complexes are potentially explosive and should be handled in small quantity with care.

2.2. Preparation of the complexes

2.2.1. [Cu(N,N–Salmeen)(Im)(H_2O)](ClO_4) (**1**)

A schiff base condensation product was obtained by mixing equimolar ethanolic solutions of salicylaldehyde and *N*,*N*-dimethylethylenediamine, followed by constant stirring with gentle heating in a water bath. To this yellow colored oily schiff base product, an equivalent amount of an alcoholic solution of $CuSO_4 \cdot 5H_2O$ (0.5 mmol) was added gradually. An aqueous solution of 0.5 mmol $NaClO_4 \cdot H_2O$ and an ethanolic solution of 0.5 mmol imidazole were added successively. The change in color from yellow to blue and then dark green upon addition of imidazole was observed. *Anal.* Calc. for $CuC_{14}H_{22}N_4O_7Cl$: C, 36.5; H, 4.9; N, 12.8. Found: C, 36.80; H, 4.81; N, 12.26%. UV–Vis [CH_3CN, λ_{max}, nm, (ε, M^{-1}, cm^{-1})], 308(3030), 374(2840), 600(180).

2.2.2. [Cu(Chloro-N,N–Salmeen)(Im)(ClO_4)] (**2**)

The above procedure was repeated except with the addition of 5-Chlorosalicylaldehyde in place of salicylaldehyde. *Anal.* Calc. for $C_{14}H_{18}N_4Cl_2O_5Cu$: C, 36.92; H, 3.95; N, 12.3. Found: C, 36.91; H, 4.14; N, 12.17%. UV–Vis [CH_3CN, λ_{max}, nm, (ε, M^{-1}, cm^{-1})], 306(2700), 384(2600), 602(200).

2.3. X-ray crystallographic analysis

Data collection for both crystals were carried out on an Enraf–Nonius CAD-4 diffractometer with graphite monochromatised Mo Kα radiation (λ = 0.7107 Å). Cell constants and the orientation matrix for data collections for both crystals were obtained from least squares refinement using 25 high angle reflections within the θ range 8–12°. The $\omega - 2\theta$ scan mode, with a maximum θ value being 24.93° and 22.42°, were used to collect the intensity data for complex **1** and complex **2**, respectively. Preliminary data, cell refinement and intensity data collection were carried out using the program CAD4-PC [11] and the data reduction using NRCVAX [12]. The data were corrected for Lorentz Polarization effects but not for absorption. The structure solution was carried out using direct methods with full-matrix least-squares refinement on F^2 using SHELXL-97 [13]. Scattering factors and anomalous dispersion were taken from the International Tables for X-ray Crystallography [14]. Hydrogen atoms were located either from the difference Fourier map or kept fixed using the riding model using the program SHELXL-97.

3. Results and discussion

3.1. Crystal structure and molecular association

ORTEP views along with an atom-numbering scheme for **1** and **2** are shown in Figs. 1 and 2. A summary of the crystallographic data, selected bond lengths and angles for complex **1** and **2** are given in Tables 1 and 2, respectively. The Schiff base ligand obtained by condensation of salicylaldehyde and *N*,*N*-dimethylethylenedi-

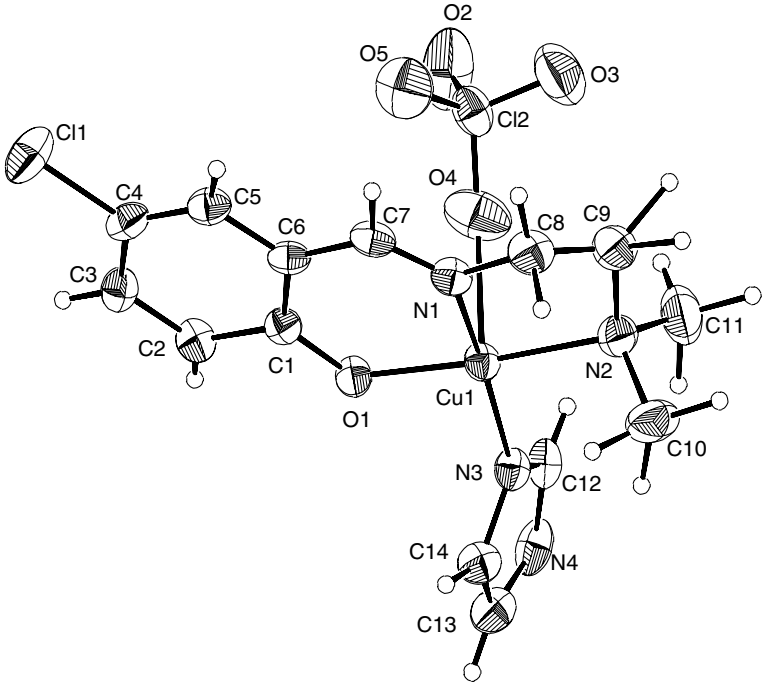

Fig. 2. ORTEP diagram (50% probability for thermal ellipsoids) of complex **2** with the atom numbering scheme.

amine, is basically a mono-anionic tridentate ligand. The metal ion in complexes **1** and **2** forms a square pyramidal geometry and the square base is occupied by the Salmeen and Cl–Salmeen moiety along with imidazole. The longer water coordination in complex **1** (Cu1–O1w = 2.469(5) Å) and perchlorate anion (Cu1–O4 = 2.618 Å) in complex **2** occupies the apical position and completes the N3O2 square pyramidal geometry of the Cu1 atom. The average Cu–N distance (1.991 Å) and Cu–O1 distance (1.936(3) Å) of the square base

coordination for complex **2** is well within the range of reported [Cu(salen)] complexes [15,16]. In complex **1**, the metal center is displaced by 0.057 Å, with a considerable deviation of the coordinated atoms from the N3O plane towards the apically coordinated perchlorate oxygen O4 and the "Sal" unit makes an angle of 7.71(2)° with respect to the N3O2 plane. Both the *trans* atoms, i.e., the atoms from the "Salmeen" moiety N2 and O1 (N2 = 0.100 Å and O1 = 0.150 Å) and imidazole N3 and "Salmeen" N1 (N3 = −0.135 Å and N1 = −0.126 Å) are displaced in the same direction. The degree of distortion on the Cu(II) geometry (τ) in both these square pyramidal complexes can be easily measured by the approach of Addison and coworkers [17], using the distortion parameter (τ). According to Addison and coworkers [17] perfect square pyramidal and trigonal bipyramidal geometries should have τ values ($=\beta - \alpha/60$ where β and α are the *trans* angles, i.e., ∠N(3)–Cu(1)–N(1) = 173.48°; and N(2)–Cu(1)–O(1) = 176.15°) of zero and unity, respectively. The τ values in the present case, calculated as 0.0428 and 0.1177 for **1** and **2**, respectively, indicates that the distortion in the former is negligible, when compared to the perfect square pyramid, resembling the recently reported square pyramidal complexes [Cu(salphe)(bpy)] ($\tau = 0.09$) [18] and $Cu(Salmeen)_2$ ($\tau = 0.098$) [19], while the later compound resembles $Cu(salala)(bpy)\cdot 4H_2O$ ($\tau = 0.10$) [18]. The torsion angle of the ethylenediamine collar of the ligand moiety (torsion angle N1–C8–C9–N2 = −50.14°) shows buckled conformation with displacement of C8 (−0.249 Å) and C9 (+0.250) carbon atoms in the opposite direction from the CuN1N2 plane. The average Cu–N distance is 1.999 Å in complex **1** is similar to that in complex **2,** whereas the Cu1–O1 distance (1.960(5) Å) is longer by 0.024 Å, which may be due to the more numerous and stronger H-bonding interactions of O1 in **2**. The Cu1 atom in **1** is displaced by 0.065 Å from the N3O plane towards the apical coordinated water molecule. The *trans* atoms of the basal plane, O1 and N2 of the "Cl–Salmeen" moiety, are displaced by 0.042 and 0.041 , where as N1 and N3 are displaced by −0.044 and −0.040 Å, respectively, in the opposite direction. The ethylenediamine collar makes a five membered chelate ring with the metal center in a buckled conformation (torsion angle N1–C8–C9–N2 = −47.98°), as observed in **1**, with the C8 and C9 atoms displaced by 0.260 and −0.260 Å, respectively, from the CuN1N2 plane.

The packing diagram for complex **1** viewed down the *a*-axis is shown in Fig. 3. Pairs of the cationic part of the molecules are associated via stacking of the imidazole ring and are arranged along the *b*-axis. The cationic part of the molecules are packed along the *a*-axis with O–H···O and N–H···O H-bonding interactions between O1w, O1 and N4, O1 from adjacent molecules, extending a H-bonded linear chain along the *a*-axis. The perchlorate anions are arranged between the adjacent cationic layers, and the O3 and the O4 perchlorate oxygen atoms act as acceptors in the O–H···O and C–H···O interactions with the cationic moiety to stabilize the molecule in the crystal lattice and connect the adjacent layers along the *c*-axis to form a two dimensional H-bonded network. The nearest Cu···Cu distance between the molecules within the H-bonded linear chain along the *a*-axis is 5.685(2) Å. In addition to the H-bonding interactions, there is a C–H···π interaction of the imidazole hydrogen with the aromatic ring between the neighboring molecule within the layer (C14–

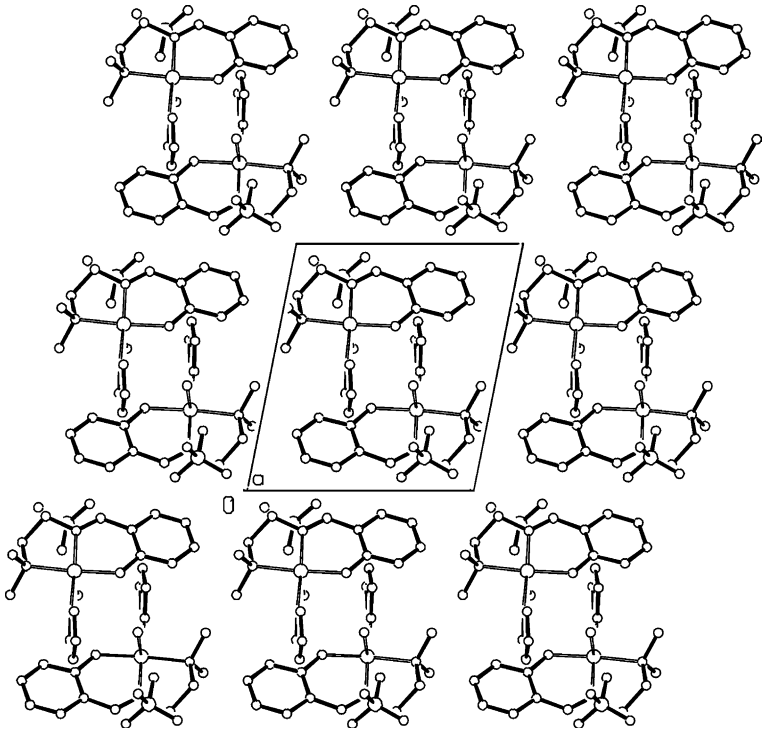

Fig. 3. Packing diagram of complex **1** viewed down the *a*-axis showing the molecular association.

H14···Cg, H14···Cg = 2.768 Å and ∠C14–H14···Cg = 146.63°, where Cg is the center of gravity of the C1–C6 ring). The intra-pair imidazole rings make a significant offset π–π interaction between the C12 carbons (C12–C12 = 3.12 Å) and N3–N4 nitrogens (N3···N4 = 3.648 Å).

The $[Cu(Cl–Salmeen)(Im)]^{+1}$ moiety is associated in pairs due to the intermolecular N–H···O hydrogen bonding interaction between the imidazole nitrogen and the phenolate oxygen (N4···O1 = 2.84(2) Å; ∠N4–H1N4···O1 = 152.9(1)°). Due to this strong H-bonding interaction the imidazole rings make an effective intra pair stacking and the centroid (Cg1)···centroid (Cg1) distance of the stacked imidazole rings is 3.39(2) Å. In addition to the N–H···O H-bonding within the pairs, the pyrrole proton H14 of imidazole is oriented in such a way to make a good C–H···π interaction (H1N4···Cg1 = 3.018 Å; ∠N4–H1N4···Cg1 = 91.2° where C1g is the centroid of the imidazole ring N3 to C14). The Cu···Cu distance within this pair is 7.31 Å. The phenyl rings of the Cl–sal ligand of the hydrogen-bonded pair are involved in π···π offset stacking from either side with the adjacent associated molecules (C2g···C2g = 3.78 Å, where C2g is the centroid of the phenyl ring C1 to C6), extending the pairs to form a one-dimensional corrugated chain along the *b*-axis. These corrugated chains are cross linked along the *c*-axis through C–H···O H-bonding from the perchlorate oxygens O2 and O5 and C–H···Cl interactions with the neighboring chains to form an extended two-dimensional corrugated sheet-like architecture. The various H-bonding interactions with their symmetry codes for compounds **1** and **2** are given in Table 3.

3.2. Electronic spectra

Both these compounds are green in color and are soluble in almost all solvents. The electronic spectral data recorded in various solvents are very similar for compounds **1** and **2** and are shown in Table 4. The characteristic UV peak obtained approximately at 370 nm (ε = 2800–3000) and 600 nm (ε = 120–200) corresponds to the Cu(II) → phenolate MLCT band [20,19] and d–d transition respectively. The peak appearing around 300 nm (ε = 2800–3000) can be attributed to the $\sigma(N) \rightarrow Cu(II)$ LMCT band. The electronic spectra recorded for complexes **1** and **2** in various solvents indicate the effect of solvent with significant red shift in their d–d transition. The bathochromic shift observed for their d–d band follows the Gutmann Donor [21] capacity of the solvent in the ascending order, acetonitrile ⩽ acetone < DMF < water < methanol < DMSO (Table 4). The broad symmetric and metal centered d–d transition appeared approximately at 600 nm in acetonitrile and acetone matches well with the reported UV–Vis values for the square planar geometry [22]. But the existence of square pyramidal geometry in strong coordinating solvents such as DMSO for both the complexes, by replacing the weak water and perchlorate coordination and accommodating the solvent mol-

ecule in its apical position, is evident from the shift of the d–d band from 600 to 636 nm.

The fifth coordination being so labile in strong coordinating solvents such as DMSO has inspired us to investigate their catalytic capability using ascorbic acid.

3.3. Ascorbic oxidase

Ascorbic acid, a common reducing agent such as 3,5-di-*tert*-butyl catechol (DTBC), is an efficient two-electron transfer system. Complexes **1** and **2** are readily reduced to Cu(I) in an aqueous methanolic solution at pH 8.4 by ascorbic acid and form a partially unstable brown Cu(I) species. The complete disappearance of the d–d band as shown in Fig. 4 (complex **1**) and Fig. 5 (complex **2**) upon addition of a methanolic solution of ascorbic acid indicates the stepwise reduction of the vacant d^9 Cu(II) system, becoming a filled d^{10} Cu(I) species. But the partial reappearance of the d–d band after a given time gap indicates that the Cu(I) species, when

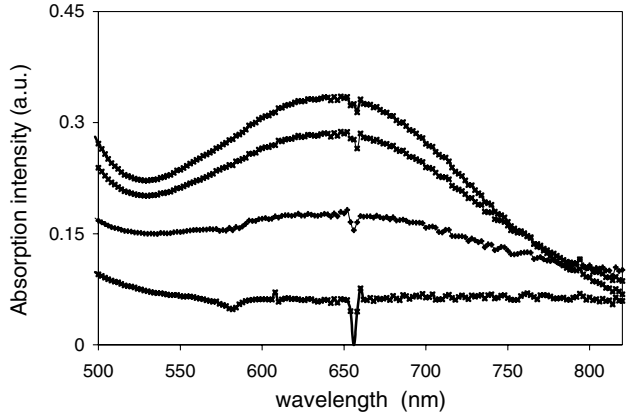

Fig. 4. Electronic spectra for **1** showing the stepwise reduction of Cu(II) to Cu(I) upon addition of ascorbic acid.

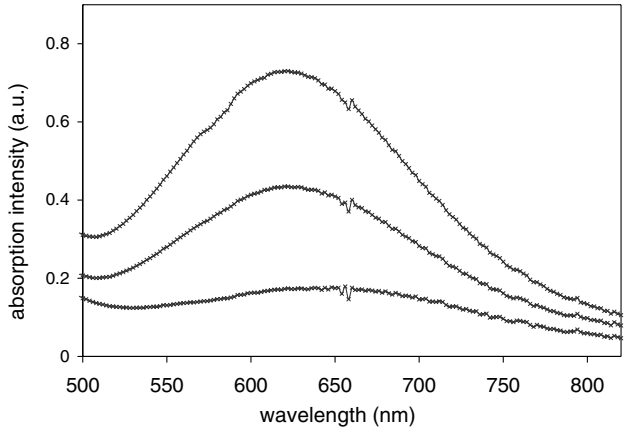

Fig. 5. Electronic spectra for **2** showing the stepwise reduction of Cu(II) to Cu(I) upon addition of ascorbic acid.

exposed to air, takes oxygen and converts into a Cu(II) species as shown below:

$$2[Cu(Salmeen)(Im)(H_2O)](ClO_4) + H_2A \rightarrow 2[Cu(I)(Salmeen)(Im)](ClO_4) + A\cdots \quad (1)$$

$$2[Cu(I)(Salmeen)(Im)](ClO_4) + O_2 + 2H^+ \rightarrow 2[Cu(Salmeen)(Im)(H_2O)](ClO_4) + 2H_2O\cdots \quad (2)$$

The self assembled Cu(II) pairs, as observed in the crystal structure, dissociate into monomeric species and are involved in the electron transfer process. The present complexes **1** and **2** effectively catalyze the ascorbic acid to oxalic acid at a [H_2A]:[complex] mole ratio of 51:1 and 48:1, respectively. The catalytic capability based on the mole ratio of [H_2A]:[complex] indicates that the present compounds are good oxidation catalysts for the oxidation of ascorbic acid compared to the Cu(II) thiosemicarbazone [23] compounds reported by Chakravarty et al, which show a [H_2A]:[complex] mole ratio of 120:1, but a little less effective with respect to [Cu(salgly)(bpy) · $4H_2O$], [Cu(salphe)(bpy)] and [Cu(salala)(bpy) · $4H_2O$] [18] which exhibit ratios of 25:1, 30:1 and 35:1, respectively.

By looking at the molecular association of the solid state, it is obvious that the intra-dimeric H-bonded pairs are dissociated into monomeric species in solution. Ascorbic acid replaces the weak water and perchlorate axial contacts in complexes **1** and **2** in a similar manner to DMSO as indicated in the UV–Vis spectral study (Table 4). Due to the coordination of the imidazole group between the Cu centers in the intra-pair H-bonded association, the intra-pair Cu–Cu distance exceeds more than 7 Å in compound **2** and are not suitable for the binding of the ascorbate as it exceeds the reported optimum distance [24a]. The perpendicular conformational arrangements of the phenyl and imidazole ring and the longer Cu–Cu intra-pair distance jointly forces the ascorbic acid to coordinate with Cu(II) through the inter-pair space available between the phenyl rings by replacing the weak water/perchlorate contacts and thereby facilitate the electron transfer.

3.4. Molecular association and reactivity correlation

The plane of the aromatic benzene ring and the imidazole heterocyclic rings are aligned perpendicular to each other in both complexes. In addition to various other intermolecular interactions, the H-bond connecting the pyrrole nitrogen of the imidazole and phenolate oxygen of the 'Sal' group coordinated to the Cu(II) metal center plays a significant role towards bringing them close, to approximately 2.8 Å *via* ImN(4)–H(1)–O(1)(phenolate). The existence of a π···π stacking interaction between the imidazole rings plays an important role for the formation of intra-pair assembly in both complexes. While an aromatic π–π interaction between the benzene rings stabilize the inter-pair molecular association; the imidazole rings stabilize the intra-pair association through their strong H-bonding network routed through (Im)N–H···O(phenolate). The intra-pair stacking interaction between the imidazole rings ($d_{\pi-\pi}$ = 3.39(2) Å) is found to be more tightly arranged than the inter-pair stacking of the phenyl rings ($d_{\pi-\pi}$ = 3.78(3) Å).

The weak inter-pair π–π stacking association between the benzene rings ($d_{\pi-\pi}$ = 3.78(3) Å) and the intra-pair imidazole rings (d_{Im-Im} = 3.39 Å) play an important role for this novel molecular assembly and facilitates the two-electron transfer catalytic reaction. The Cu–Cu separation calculated through the self-assembled imidazole H-bond spacer exceeds more than 7 Å, while the inter-pair distance between the benzene ring is 3.78 Å.

A detailed analysis carried out by Kao et al. [24a] and other reports [24a–d], show a fine correlation between the optimum geometrical Cu–Cu distance and the catalytic activity of DTBC and ascorbic acid. The dinuclear copper complexes with a Cu–Cu distance between 2.9 and 3.0 Å apparently show higher activity. The approximate Cu–Cu distance of about 3 Å is considered to be the basic criteria for an efficient electron transfer process in ascorbic oxidation and catechol oxidase to take place.

It may be tentatively proposed that the ascorbic acid may approach between the inter-pair stacked phenyl rings assembled by the π–π interaction, thereby replacing the apically coordinated water/perchlorate molecules, and bind the two copper (II) centers to facilitate electron transfer.

4. Conclusion

Compounds **1** and **2** containing *N*,*N*-dimethylethylenesalicyladimine and *N*,*N*-dimethylethylene-chlorosalicyladimine ligands were synthesized and characterized. The self assembled weak intra and inter-pair association, mediated by imidazole and aromatic benzene rings, play a significant role in their catalytic processes upon reduction of ascorbic acid and control the coordination site for catalytic reaction. The intra-pair distance mediated by the imidazole ring, being more than 7 Å, and the perpendicular conformation of the benzene ring and imidazole ring with in the molecule cooperatively adopt the ascorbic acid to coordinate to the Cu(II) centres. However the intra-pair dicopper distance is very close to the expected theoretical value for the binding of ascorbic acid, so it is concluded that the intra-pair assembly is dissociated but the inter-pair association is retained due to the binding of the ascorbic acid in solution, which favors the electron transfer process from ascorbic acid to the Cu(II) active site. The study of the

oxidation of catechol and substituted catechols, such as 3,5-DTBC, to the corresponding quinone is under progress.

5. Supporting information available

CCDC 237638 and 237639 contains the supplementary crystallographic data for these complexes. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrievel.html or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; Fax (internet.). +44-1223/336-033. e-mail: deposit@ccdc.ac.uk.

Abstract

The reaction of the $[ReBr_3(NO)(AsPh_3)_2]$ complex with pyrazole (pzH) has been examined and a new rhenium nitrosyl – $[ReBr_3(NO)(AsPh_3)(pzH)]$ – has been obtained. The crystal, molecular and electronic structure of the $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex has been determined. The geometric parameters of $[ReBr_3(NO)(AsPh_3)(pzH)]$ have been examined using the density functional theory (DFT) method. The UV–Vis spectrum of the complex has been interpreted on the basis of the electronic transitions of $[ReBr_3(NO)(AsPh_3)(pzH)]$ calculated with the time-dependent DFT method.

Keywords: Rhenium nitrosyl complexes; Pyrazole; Arsine ligands; X–ray structure; Density functional theory calculations

1. Introduction

For many years much attention has been focused on the synthesis and study of a variety of nitrosyl transition metal complexes, due to their catalytic abilities and uses in the production of organonitrogen compounds or in pollutant control [1–11].

Considering the relation between the coordination mode of the NO group and the reactivity patterns of the MNO unit, the most important aspect of the research on nitrosyl complexes is determination of the bonding nature of nitric oxide to metal centers. Terminal NO ligands may adopt either linear or bent geometries. Historically, the bonding of the M–NO unit has been described by assigning formal oxidation states to the metal centre and the nitrosyl ligand. In such an assignment, a linear M–NO unit is deemed to possess a bound NO^+ ligand, and conversely, a bent M–NO core is deemed to possess a bound NO^- ligand. However, the bonding in the $M(NO)_x$ moieties of metal nitrosyl complexes is largely of covalent nature, and the electron distribution in the M–NO unit is more or less evenly distributed. Enemark and Feltham [1,3,9,11] have proposed the $\{M(NO)_x\}^n$ formalism for metal nitrosyls in which n is taken as the total number of electrons associated with the metal d and π^*(NO).

The chemistry of nitrosyl rhenium complexes arouses particular interest among these compounds, which is connected with the favourable nuclear properties of ^{186}Re and ^{188}Re nuclides, which make the radioisotopes useful for diagnostic nuclear medicine and applications in radioimmunotheraphy [12,13].

Previously, we investigated the reactivity of $[ReOX_3L_2]$ compounds (X = Cl and Br, L = PPh_3 and $AsPh_3$) towards gaseous nitric oxide and we examined the reactions

doi:10.1016/j.poly.2004.08.021

of $[NBu_4]_2[ReX_5(NO)]$ with an excess of triphenylphosphine and triphenylarsine [14–22]. Dependent on the reaction conditions, various products were isolated: $[ReX_3(NO)(OPPh_3)_2]$, $[ReX_3(NO)(PPh_3)_2]$, $[ReX_2(NO)_2(PPh_3)_2]$, $[ReBr_3(NO)(MeCN)(PPh_3)]$, $[ReCl_3(NO)(PPh_3)(OPPh_3)]$, $[ReCl_4(PPh_3)_2]$, $[ReBr_3(NO)(dppe)]$ $[ReBr_4(dppe)]$, $[ReX_3(NO)(OAsPh_3)_2]$, $[ReCl_4(OAsPh_3)_2]$, $[ReCl_3(NO)(AsPh_3)_2][ReCl_4(AsPh_3)_2]$, $[ReBr_3(NO)(AsPh_3)_2]$ and $[ReCl_3(NO)(AsPh_3)_2][ReCl_4(AsPh_3)_2]$.

Here, we present the synthesis, crystal, molecular and electronic structure of a new rhenium nitrosyl with pyrazole (pzH) in the coordination sphere – $[ReBr_3(NO)(AsPh_3)(pzH)]$. The electronic structure of $[ReBr_3(NO)(AsPh_3)(pzH)]$ has been determined based on the results of density functional theory (DFT) calculations. The spin-allowed doublet–doublet electronic transitions of $[ReBr_3(NO)(AsPh_3)(pzH)]$ have been calculated with the time-dependent DFT method (TDDFT), and the UV–Vis spectrum of the title complex has been discussed on this basis.

The calculations with the TDDFT method for open-shell organic, inorganic and organometallic molecules have supported the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [23–26]. There are also several works performed with this method for 5d-metals (including rhenium complexes) in which good correlations between experimental and calculated results have been confirmed [27–33].

2. Experimental

2.1. General procedure

The reaction was carried out under argon atmosphere. All the reagents used in the synthesis of the complex are commercially available and were used without further purification. The $[ReBr_3(NO)(AsPh_3)_2]$ complex was prepared according to the literature method [22].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 800–220 nm in deoxygenated dichloromethane solution. Magnetic susceptibilities were measured at 296 K by the Faraday method. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReBr_3(NO)(AsPh_3)(pzH)]$

$[ReBr_3(NO)(AsPh_3)_2]$ (1 g, 0.9 mmol) and pzH (0.54 g, 8 mmol) in chloroform (100 cm^3) were refluxed for 5 h. The volume was condensed to 20 cm^3 and a dark red microcrystalline solid was formed on the addition of 100 cm^3 of diethyl ether. The product was washed with EtOH and cold ether, and dried in vacuo. Crystals suitable for X-ray investigation were obtained by recrystallisation from $CHCl_3$–EtOH. Yield: 70%. IR (KBr, cm^{-1}) 3347 (m), 3137 (w), 3055 (w), 1754 (vs), 1579 (w), 1518 (w), 1482 (s), 1433 (s), 1408 (m), 1351 (m), 1310 (w), 1269 (w), 1182 (w), 1136 (s), 1070 (m), 1051 (s), 1023 (w), 997 (m), 910 (w), 764 (s), 746 (vs), 697 (s), 669 (m), 589 (w), 559 (m), 476(s), 453 (m). Calc. for $C_{21}H_{19}N_3Br_3OAsRe$: C, 30.38; H, 2.31; N, 5.06. Found: C, 30.46; H, 2.40; N, 5.15%.

2.3. Crystal structure determination and refinement

The X-ray intensity data of $[ReBr_3(NO)(AsPh_3)(pzH)]$ was collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector, 30 s exposure time were used and a half of the Ewald sphere was collected. The unit cell parameters were determined from least-squares refinement of the setting angles of 6510 strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarisation and numerical absorption corrections [34] were applied. The structure was solved by means of the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as ''riding'' on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent carbon atom. SHELXS 97 [35], SHELXL 97 [36] and SHELXTL [37] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.4. Computational details

The GAUSSIAN03 program [38] was used in the calculations. The geometry optimisation was carried out with the DFT method with the use of the B3LYP functional [39,40]. The electronic spectrum was calculated with the TDDFT method [41].

The LANL2DZ basis set [42] was used on the rhenium, arsenic and bromine atoms, 6-31G(d) on the nitrogen and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations. The arsenic basis set LANL2DZ was used with additional p ($\alpha = 1.0$) and d ($\alpha = 1.0$) functions.

3. Results and discussion

3.1. Preparation

The $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex has been obtained in high yield in the reaction of $[ReBr_3(NO)(AsPh_3)_2]$ with pyrazole.

$$[ReBr_3(NO)(AsPh_3)_2] + pzH \rightarrow [Re(NO)Br_3(pzH)(AsPh_3)] + AsPh_3$$

The excess of pzH used in the reaction ensures a maximum yield of the product.

3.2. Crystal structure

The complex $[ReBr_3(NO)(AsPh_3)(pzH)]$ crystallises in the monoclinic space group $P2_1/n$ and its structure consists of discrete and well-separated monomers. A thermal ellipsoid plot of $[ReBr_3(NO)(AsPh_3)(pzH)]$ is shown in Fig. 1. The rhenium atom is in a distorted octahedral environment with the bromine ligands in *meridional* geometry and the linear N–O group *trans* to the pyrazole molecule and *cis* to the $AsPh_3$ ligand. The nitrosyl group of the starting complex occupies the *trans* position to one of the bromine ligands. Two intramolecular hydrogen bonds [43–45] linking N(3)–H(3A) ··· Br(1) (D ··· A distance 3.214(8) Å and D–H ··· A angle 115.4°) and C(21)–H(21) ··· Br(3) (D ··· A distance 3.279(9) Å and D–H ··· A angle 114.6°) provide additional stabilisation of the $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex. Except those mentioned above, no other short contacts that can be classified as intra- or intermolecular hydrogen bonds can be found. Table 1 presents the crystal data and structural refinement for $[ReBr_3(NO)(AsPh_3)(pzH)]$. The most important experimental bond lengths and angles for $[ReBr_3(NO)(AsPh_3)(pzH)]$ are reported in Table 2. The Re–NO and N–O bond lengths and the value of the Re–N–O angle confirm the linear coordination of the nitrosyl group and they are compared with values previously found [1,14–22]. In comparison with the starting $[ReBr_3(NO)(AsPh_3)_2]$ complex [Re–N = 1.740(11) and N–O = 1.117(13) Å] [22], the elongation of Re–N and N–O bond lengths is observed in $[ReBr_3(NO)(AsPh_3)(pzH)]$. The Re–As distance [2.5879(9)] is slightly shorter than those found for $[ReBr_3(NO)(AsPh_3)_2]$ [2.5946(9) Å], $[ReCl_4(AsPh_3)_2]$ [2.6023(10) Å] and $[ReCl_3(NO)(AsPh_3)_2]$ [2.6060(11) and 2.6186(11) Å][22]. A *trans* position of the pyrazole ligand to the nitrosyl group explains a significant elongation of the Re–N_{pzH} bond length [2.198(6)] in comparison with $[ReOBr_3(pzH)(OAsPh_3)]$ – 2.089(18) Å [46], but it is comparable with values found for $[Re(CO)_3(pzH)_2Br]$ with a *trans* arrangement of the pyrazole ligands to the carbonyl groups – 2.187(6) and 2.211(3) Å [47].

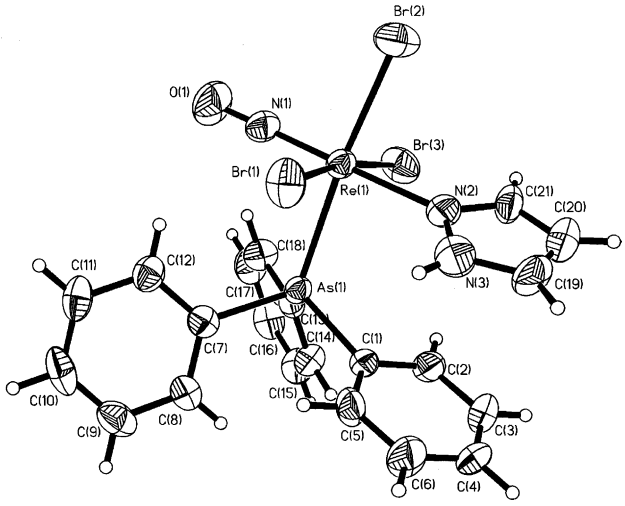

Fig. 1. Thermal ellipsoid plot of $[ReBr_3(NO)(AsPh_3)(pzH)]$ showing the atom numbering scheme (50% probability ellipsoids).

The bond valences were computed as $v_{ij} = \exp[(R_{ij} - d_{ij})/B]$ [48–50], where R_{ij} is the bond-valence parameter (in the formal sense R_{ij} is the single-bond length between i and j atoms [51]). The R_{Re-N}, R_{Re-As}, R_{Re-Br}values were taken as 2.06, 2.54 and 2.45 [48], respectively, and the value of B was taken as 0.37 [49]. The computed bond valences of the rhenium are $v_{Re(1)-N(1)} = 2.28$, $v_{Re(1)-N(2)} = 0.69$, $v_{Re(1)-As(1)} = 0.88$ and $v_{Re(1)-Br(1)} = 0.89$, 0.83, 0.84 v.u. (valence units), thus the NO moiety is bonded more than two times stronger than the rest of the substituents, and the Re–N(1) bond can be formally considered as a double bond.

Table 2
The experimental and optimised bond lengths [Å] and angles [°] for $[ReBr_3(NO)(AsPh_3)(pzH)]$

Bond lengths			Bond angles		
	Experimental	Optimised		Experimental	Optimised

N(1)–O(1)	1.149(8)	1.171	N(1)–Re(1)–Br(2)	94.1(2)	93.2
			N(2)–Re(1)–Br(2)	84.90(18)	84.1
			Br(1)–Re(1)–Br(2)	93.04(4)	91.4
			Br(3)–Re(1)–Br(2)	91.76(4)	94.0
			N(1)–Re(1)–As(1)	91.4(2)	93.4
			N(2)–Re(1)–As(1)	89.64(18)	89.4
			Br(1)–Re(1)–As(1)	87.74(3)	83.7
			Br(3)–Re(1)–As(1)	86.66(3)	90.11
			Br(2)–Re(1)–As(1)	174.40(3)	172.1
			O(1)–N(1)–Re(1)	178.5(7)	178.0

The triphenylarsine and bromide ligands are bounded with comparable strength, and the pyrazole ligand is bounded distinctly weaker.

3.3. Infrared data and magnetochemical measurements

The IR spectrum of $[ReBr_3(NO)(AsPh_3)(pzH)]$ exhibits a strong band at 1754 cm^{-1} assignable to ν (NO). The value of ν(NO) corresponds to the linear NO range of Haymore and Ibers [52] [ν(NO) above 1620–1610 cm^{-1} were assigned to linear M–N–O systems, while ν(NO) below 1610 cm^{-1} were assigned to bent M–N–O systems]. The considerable lowering of the ν_{NO} of $[ReBr_3(NO)(AsPh_3)(pzH)]$ in comparison with the starting $[ReBr_3(NO)(AsPh_3)_2]$ nitrosyl (1773 cm^{-1}) is consistent with the elongation of the N–O bond length in $[ReBr_3(NO)(AsPh_3)(pzH)]$.

The band (3347cm^{-1}) in the range assignable to N–H vibrations confirms the coordination of the pyrazole in a neutral monodentate form. The characteristic bands of the C=C and C=N stretching modes, observed at 1640 and 1558 cm^{-1}in uncomplexed pyrazole, are shifted to considerable lower frequencies 1579 and 1518 cm^{-1}, respectively. It is consistent with the somewhat longer C=C and C=N bonds in the title complex in comparison with the same distances in the uncomplexed ligand [53].

$[ReBr_3(NO)(AsPh_3)(pzH)]$ is a paramagnetic compound with a room temperature magnetic moment of 1.7 BM, corresponding to one unpaired electron.

3.4. Optimised geometry

The geometry of $[ReBr_3(NO)(AsPh_3)(pzH)]$ was optimised in a doublet state by the DFT method with the B3LYP functional. Table 3 shows the possible electronic configurations and spin multiplicities of the $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex. The doublet state agrees well with the experimental value of the effective magnetic moment for $[ReBr_3(NO)(AsPh_3)(pzH)]$. The optimised geometry is in good agreement with the experimental one, the largest differences are found for the Re–Br bond distances. A similar elongation of the rhenium–halogen bond lengths in the B3LYP with different basis sets has been found in other rhenium complexes [54]. The significant elongation of the calculated Re–Br(1) bond length in comparison with the experimental one can be explained by contribution of Br(1) in the N(3)–H(3A)$\cdots$Br(1) hydrogen bond. The formation of the hydrogen bond causes local deficiency of electron density on the bromine atom and consequently the Br(1) ligand is closer to the rhenium atom in the experimental structure.

3.5. Charge distribution and spin densities

Table 4 presents the atomic charges from the natural population analysis (NPA) and spin densities for $[ReBr_3(NO)(AsPh_3)(pzH)]$. The calculated charge on the nitrogen atom of the nitrosyl group is positive, whereas the oxygen atom is negatively charged. The total charge on the NO group of the title complex is positive, 0.015. The calculated charge on the rhenium atom of $[ReBr_3(NO)(AsPh_3)(pzH)]$ is far from the formal charge +2. It results from charge donation from the bromine ions and triphenylarsine ligand, which act as σ-donors. There is large positive charge on the As atom, and the charges on the bromine ions are significantly smaller than −1. The charge on the

Table 3
The possible oxidation numbers and spin multiplicities of Re and NO in $[ReBr_3(NO)(AsPh_3)(pzH)]$

N(3)	−0.312	0.000

pyrazole nitrogen atom bonded with the rhenium is negative – the pyrazole and nitrosyl ligands act as electron acceptors.

In the title complex, there is positive spin density of about 1 on the rhenium atom and small negative spin densities of about −0.1 on the nitrogen and oxygen atoms of the nitrosyl ligand.

3.6. Electronic structure

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals with α- and β-spin for $[ReBr_3(NO)(AsPh_3)(pzH)]$ are presented in Table 5. The selected HOMO and LUMO orbitals of $[ReBr_3(NO)(AsPh_3)(pzH)]$ with α-spin are depicted in Fig. 2. Most of the MOs of $[ReBr_3(NO)(AsPh_3)(pzH)]$ have complicated character. The percent participations of the ligand atomic orbitals in the selected HOMO and LUMO orbitals of mixed character are shown in Table 5.

Table 5

The percent participation of the atomic orbitals is given in round brackets.

The bonding of NO to the rhenium center involves a synergic interaction between the nitrosyl ligand orbitals and the metal orbitals. The Re–NO bond consists of two components (i) a donation of electron density from a σ-type orbital on NO to the metal orbital and (ii) a donation of electron density from the occupied metal d-orbitals into the π* anti-bonding orbitals of the NO ligand. The occupied d_{yz} and d_{xz} rhenium orbitals participate in the back-donation from the central ion to the NO ligand and in the $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex. The π_{Re-NO} bonding interaction makes the largest contribution into HOMO − 16 and HOMO − 15 with α- and β-spin. A substantial contribution of π_{Re-NO} orbitals are also shown in HOMO − 3 and HOMO − 1 with α-spin and HOMO − 2 and HOMO − 1 with β-spin, but the bromine orbitals are the main components of these orbitals (see Table 5). The bonding π_{Re-NO} orbitals with α- and β-spin are localised mainly on the rhenium d orbitals. The LUMO + 1 and LUMO + 2 orbitals with α- and β-spin are of π^*_{Re-NO} anti-bonding character, and they have prevalent NO character. Considering the molecular orbital composition and positive total charge on the NO group, the character of the nitrosyl ligand in $[ReBr_3(NO)(AsPh_3)(pzH)]$ may be described as NO^+.

HOMO − 4 with α-spin and HOMO − 3 with β-spin are mainly localised on the bromine ligands, but they have a substantial contribution from the free electron pair on the arsenic atom of $AsPh_3$ molecule.

The d_{xy} rhenium orbital and π orbitals of bromine ligands in an anti-bonding arrangement make the main contribution into the HOMO with α-spin and LUMO with β-spin. The HOMO with β-spin is mainly localised on the bromine ligands.

The LUMO with α-spin and LUMO + 3 with β-spin are of $d_{x^2-y^2}-\sigma_{Br}-\sigma_{As}$ character. The LUMO + 3 with α-spin and LUMO + 4 with β-spin are mainly localised on the d_{z^2} rhenium orbital. LUMO + 3, LUMO + 4, LUMO + 5 with α-spin and LUMO + 4, LUMO + 5, LUMO + 6 with β-spin present a π interaction of the arsenic orbitals with the π* orbitals of the phenyl groups.

3.7. Electronic spectra

The experimental and calculated electronic spectra of $[ReBr_3(NO)(AsPh_3)(pzH)]$ are presented in Fig. 3. Each calculated transition in Fig. 3(b) was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.06.

Table 6 shows the spin-allowed doublet–doublet electronic transitions calculated with the TDDFT method for $[ReBr_3(NO)(AsPh_3)(pzH)]$.

The investigated complex is of large size, the number of basis functions is equal to 450. Eighty electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectrum of $[ReBr_3(NO)(AsPh_3)(pzH)]$ was calculated only to 265 nm, so the shortest wavelength experimental band cannot be assigned completely to the calculated transitions. Considering that the solution spectra of $AsPh_3$ and pyrazole exhibit intense

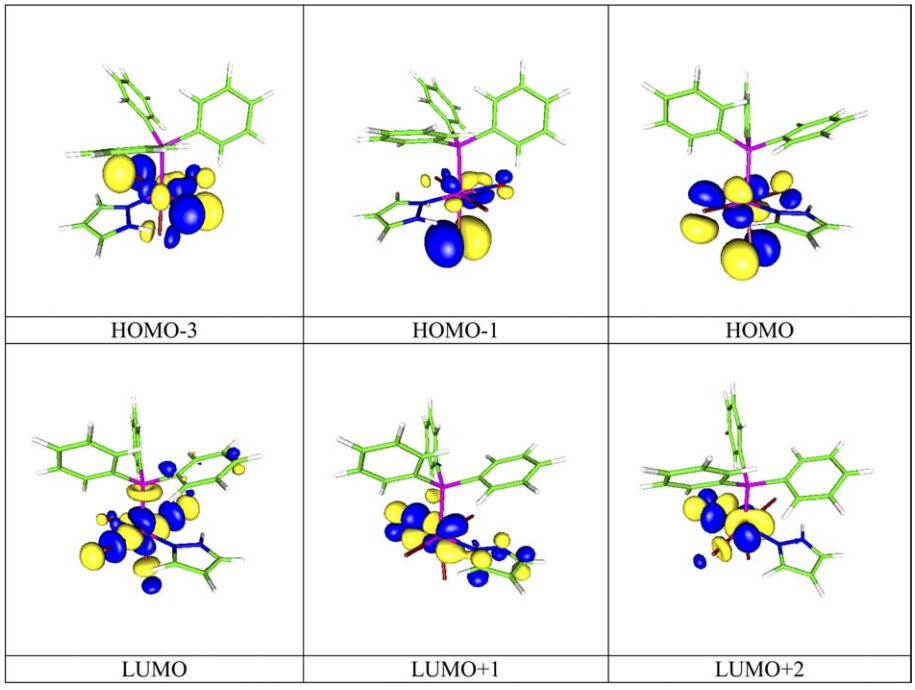

Fig. 2. The selected HOMO and LUMO orbitals with α-spin for $[ReBr_3(NO)(AsPh_3)(pzH)]$. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

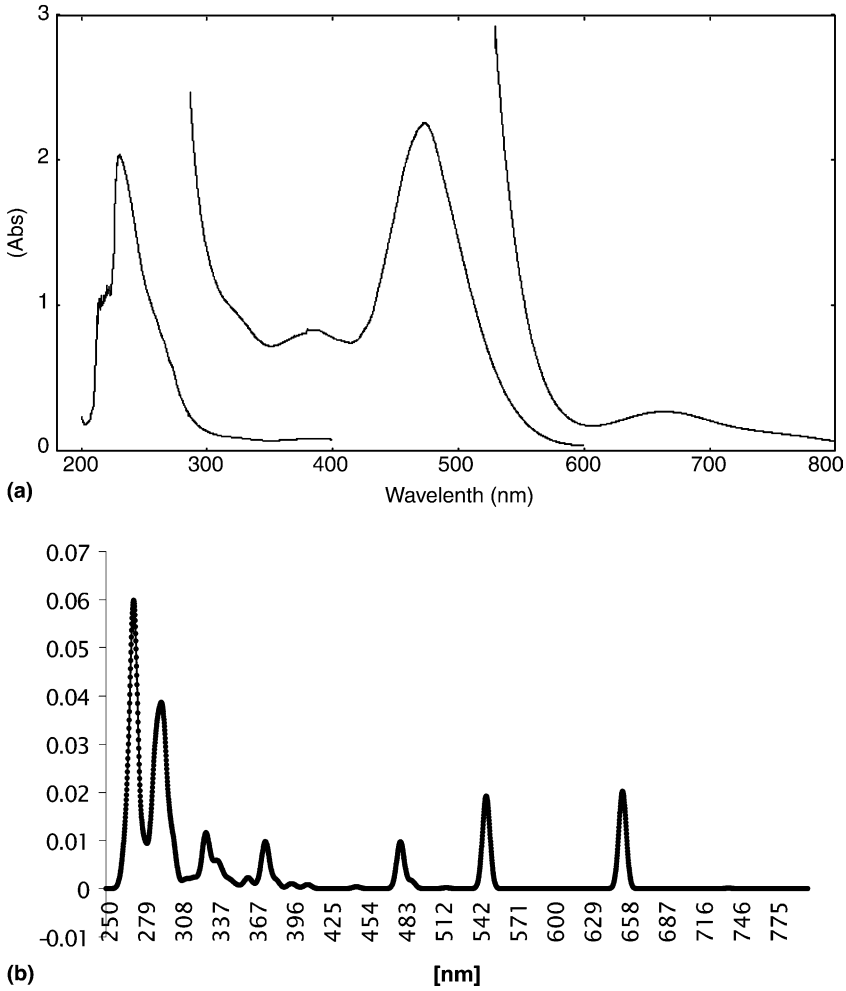

Fig. 3. The experimental (a) and calculated (b) electronic absorption spectrum of $[ReBr_3(NO)(AsPh_3)(pzH)]$.

absorption bands in the 250–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculation.

The calculations result in many transitions with very small oscillator strengths. Except for the electronic transition of $d \rightarrow \pi^*_{NO}$ character and the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.0050 are listed in Table 6.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions the main components of the molecular orbital are used. The bonding π_{Re-NO} orbitals are described as d orbitals, and the anti-bonding π^*_{Re-NO} orbitals – as π^*_{NO}.

The longest wavelength experimental band of $[ReBr_3(NO)(AsPh_3)(pzH)]$ (at 765.0 nm) may be attributed to the transitions of $\pi(Br)/d_{xz} \rightarrow d$ character with small oscillator strength, calculated at 737.9 nm.

The next experimental band can be assigned to the calculated transition at 654.8. The transition is of LMCT ($\pi_{Br} \rightarrow d$) character.

The broad experimental band at 476 nm is assigned to the transitions calculated between 548 and 439 nm. Among these electronic transitions are transitions of $d \rightarrow d$ character and transitions of LMCT ($\pi_{Br} \rightarrow d$, $n_{As} \rightarrow d$ and $\pi_{Ph} \rightarrow d$) origin. Considering the large contribution of π bromine orbitals in HOMO – 3 with α-spin and HOMO – 2 with β-spin, character of the transition at 516.7 nm is determined as $d_{xz}/\pi(Br) \rightarrow \pi^*(NO)$.

The next experimental absorption band at 390 nm is attributed to the transitions of LMCT ($\pi_{Br} \rightarrow d$, $\pi_{pzH} \rightarrow d$ and $\pi_{Ph} \rightarrow d$) and MLCT ($d \rightarrow \pi^*_{NO}$) character, calculated between 410 and 345 nm. The electronic transitions from the rhenium d_{xy} orbitals onto π* orbitals of the nitrosyl group are calculated at 408.4 and 405.2 nm. The calculated transitions at 375.1, 358.7, 350.9 and 346.2 nm are of mixed character $d_{xz}/\pi(Br) \rightarrow \pi^*(NO)$. All the transitions from the rhenium d orbitals onto π* orbitals of the nitrosyl group have

small oscillator strengths and they do not contribute significantly to the overall shape of the band. They are hidden under the more intense transitions of LMCT ($\pi_{Br} \rightarrow d$ and $\pi_{Ph} \rightarrow d$) character. Such small values of the oscillator strengths seem to be typical of $d \rightarrow \pi^*_{NO}$ transitions, and they have been supported by the calculations for other metal nitrosyls [55,56].

The experimental band at 330.8 nm is assigned to the calculated transition of $\pi_{Br} \rightarrow d$ type (at 328.2 nm) and some transitions ($303 \div 288$ nm) of LLCT character. The LLCT transitions occur from the bromine, phenyl and pyrazole orbitals to the π^*_{NO} or π^*_{Ph} orbitals.

The shortest wavelength experimental band of $[ReBr_3(NO)(AsPh_3)(pzH)]$ (at 230.6 nm) corresponds to the electronic transitions that are of LLCT ($\pi_{Br} \rightarrow \pi^*_{Ph}$ and $\pi_{Ph} \rightarrow \pi^*_{NO}$) character.

4. Supplementary data

Supplementary data for $C_{21}H_{19}AsBr_3N_3ORe$ are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.ac.uk or www:http://www.ccdc.cam.ac.uk) on request, quoting the Deposition No. 243039.

Abstract

Thallium derivatives of the sterically demanding methyl tris(pyrazolyl)borate ligands $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]^-$ and $[MeB(3\text{-}(Mes)Pz)_3]^-$ have been synthesized using the corresponding pyrazole, $Li[MeBH_3]$ and thallium(I) acetate. Product formation could be followed by ^1H and ^{11}B NMR spectroscopy. $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ and $[MeB(3\text{-}(Mes)Pz)_3]Tl$ display monomeric structures. The thallium sites adopt a pyramidal geometry. The crystal structure of 3-(Mes)PzH is also reported. It forms planar, hydrogen bonded tetramers in the solid state.

1. Introduction

Tris(pyrazolyl)borates constitute one of the most widely used group of ligands in chemistry [1,2]. In fact, complexes of tris(pyrazolyl)borates are now known for most of the elements in the periodic table [2]. The vast majority of these involve the use of ligands with a hydride group on the boron atom (e.g., $[HB(Pz)_3]^-$, $[HB(3,5\text{-}(Me)_2Pz)_3]^-$, $[HB(3\text{-}(Mes)Pz)_3]^-$ (**1**), $[HB(3\text{-}(t\text{-}Bu)Pz)_3]^-$). Relatively, few tris(pyrazolyl)borate systems featuring B-alkyl or B-aryl substituents have also been isolated [1]. Most of these ligands, however, are based on the parent pyrazole (e.g., $[PhB(Pz)_3]^-$ (**2**), $[(\eta^5\text{-}C_5H_5)Fe\{\eta^5\text{-}C_5H_4B(Pz)_3\}]^-$).

B-hydride free ligands that also contain sterically demanding substituents at the pyrazolyl moiety 3-position (e.g., $[t\text{-}BuB(3\text{-}(t\text{-}Bu)Pz)_3]^-$ (**3**) and $[PhB(3\text{-}(t\text{-}Bu)Pz)_3]^-$ (**4**)) are rare [3–5]. Such ligands are very attractive because they not only lack the reactive and sometimes problematic B–H functionality, but they also provide excellent protection for labile or reactive metal adducts. In this paper, we describe the synthesis of two methyl tris(pyrazolyl)borate ligands featuring sterically demanding pyrazolyl moieties. X-ray crystal structures of the thallium adducts $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ and $[MeB(3\text{-}(Mes)Pz)_3]Tl$ are also reported. Thallium adducts like these serve as excellent ligand transfer agents [6–8].

2. Experimental

2.1. General procedures

All manipulations were carried out under an atmosphere of purified nitrogen using standard Schlenk techniques. NMR spectra were recorded at 25 °C on a JEOL Eclipse 500 spectrometer (^{1}H, 500.16 MHz, ^{13}C, 125.78 MHz, ^{11}B, 160.47 MHz). Proton and carbon chemical shifts are reported in ppm versus Me_4Si. ^{11}B NMR spectra were referenced to external $BF_3 \cdot Et_2O$. Melting points were obtained on a Mel-Temp II apparatus and were not corrected. 3-*tert*-Butylpyrazole [9] and 3-mesitylpyrazole [10] were prepared using published methods. TlOAc was purchased from commercial sources.

2.2. Synthesis of Li[MeBH$_3$]

It was synthesized as described using $MeB(OH)_2$ and $LiAlH_4$ in Et_2O, and purified using a slightly modified procedure [11]. A 50-mL Schlenk tube containing a magnetic stirring bar was fitted with a rubber septum and charged with 2,2′-biquinoline (0.002 g) and $LiAlH_4$ (10 mL of a 1.0 M solution in diethylether). The solution became deep blue after stirring for a few minutes. A solution of methylboronic acid (0.395 g, 6.6 mmol) in diethylether (15 mL) was slowly added at 25 °C. After stirring for 1 h, the mixture was filtered, and the filtrate was collected. The solid precipitate was washed with diethylether (3×10 mL), and the washings were combined with the filtrate. Evaporating the solvent from the filtrate under reduced pressure gave Li[$MeBH_3$] as a colorless, oily product. To this, hexane (15 mL) was added and the solution stirred for 10 min. Then the volatile materials were removed under reduced pressure. After repeating this process three times, Li[$MeBH_3$] was obtained as a white powdery product, 0.210 g, 89% yield. ^{11}B NMR (DMSO-d_6): δ −30.7 (qq, $^1J(^{11}B–^1H) = 78.5$ Hz, $^2J(^{11}B–^1H) = 4.8$ Hz). ^{1}H NMR (DMSO-d_6): δ 0.33 (BH_3, quartet of quartets superimposed on a heptet of quartets, $^1J(^{11}B–^1H) = 78.5$ Hz, $^1J(^{10}B–^1H) = 26.5$ Hz, $^3J(^1H–^1H) = 6.5$ Hz); −0.64 (m, BCH_3). See supplementary material for K[BH_4] spectra taken under similar conditions as well as for ^{1}H NMR signals corresponding to BCH_3 protons.

2.3. Synthesis of [MeB(3-(t-Bu)Pz)$_3$]Tl

A mixture of Li[$MeBH_3$] (0.107 g, 3.00 mmol) and 3-*tert*-butylpyrazole (1.127 g, 9.07 mmol) was heated at ca. 220 °C under N_2 for one hour. The product was allowed to cool to room temperature. It was suspended in THF (8 mL), then solid thallium(I) acetate (1.225 g, 4.65 mmol) was added at room temperature and the mixture was stirred overnight. The resulting mixture was filtered and the volatile components were removed from the filtrate by a rotary evaporator giving crude [MeB(3-(*t*-Bu)-Pz)$_3$]Tl as an off-white solid. Pure [MeB(3-(*t*-Bu)Pz)$_3$]Tl was obtained as colorless crystals by crystallization from hexane at −25 °C. Yield: 65%; m.p.: 142–143 °C. ^{1}H NMR ($CDCl_3$): δ 0.95 (s, 3H, BCH_3), 1.36 (s, 27H, $C(CH_3)_3$), 6.05 (d, 3H, $J = 2.0$ Hz, Pz–H) 7.61 (d, 3H, $J = 2.0$ Hz, Pz–H). ^{11}B NMR ($CDCl_3$): δ−0.3 (s). ^{13}C{^{1}H} NMR ($CDCl_3$): δ 31.84 (br), 32.27, 101.28, 133.62, 163.20 (the *C*H_3B-signal could not be clearly detected in the ^{13}C NMR spectrum). *Anal.* Calc. for $C_{22}H_{36}N_6BTl$: C, 44.06; H, 6.05; N, 14.01. Found: C, 43.74; H, 5.88; N, 13.74%.

2.4. Synthesis of [MeB(3-(Mes)Pz)$_3$]Tl

Freshly sublimed 3-mesitylpyrazole (1.690 g, 9.07 mmol) and Li[$MeBH_3$] (0.1074 g, 3.00 mmol) were added into a Schlenk tube containing mesitylene (5 mL). This mixture was stirred for about 5 h at room temperature until the gas evolution ceased. Then it was heated for 48 h at 180 °C. Removal of the solvent by distillation gave the crude product [MeB(3-(Mes)Pz)$_3$]Li. The crude [MeB(3-(Mes)Pz)$_3$]Li and thallium(I) acetate (1.185 g, 4.5 mmol) were mixed in THF (20 mL), and the resulting mixture was stirred overnight at room temperature. The solution was filtered over Celite and the filtrate was collected. Removal of solvent from the filtrate afforded crude [MeB(3-(Mes)Pz)$_3$]Tl. It was washed with methanol to obtain analytically pure [MeB(3-(Mes)Pz)$_3$]Tl (1.766 g). Yield: 75%; m.p.: 245–247 °C; ^{1}H NMR ($CDCl_3$): δ 1.16 (s, 3H), 1.91 (s,

18H), 2.27 (s, 9H), 6.06 (d, 3H, ^3J(H,H) = 1.5Hz), 6.84 (s, 6H), 7.85 (d, 3H, ^3J(H,H) = 1.5Hz); $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 20.44 (br d, $J = 47$ Hz), 21.19, 104.62, 128.00, 131.11, 133.36, 137.42, 137.54, 150.06 (the CH_3B-signal could not be clearly assigned in the ^{13}C NMR spectrum). ^{11}B NMR ($CDCl_3$): δ 0.0 (s). *Anal.* Calc. for $C_{37}H_{42}N_6BTl$: C, 56.54; H, 5.39; N, 10.69. Found: C, 56.55; H, 5.19; N, 10.62%.

2.5. X-ray structure determinations

X-ray quality crystals of [MeB(3-(*t*-Bu)Pz)$_3$]Tl and [MeB(3-(Mes)Pz)$_3$]Tl were obtained from hexane and THF–hexane solutions at −15 °C, respectively. A suitable crystal of the thallium compound covered with a layer of hydrocarbon oil was selected and mounted with paratone–N oil in (or on) a cryo-loop, and immediately placed in a low-temperature nitrogen stream. The X-ray intensity data were measured at 100(2) K on a Bruker SMART APEX CCD area detector system equipped with a Oxford Cryosystems 700 Series cooler, a graphite monochromator and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å). The detector was placed at a distance of 5.995 cm from the crystal. The data frames were integrated with the Bruker SAINT-PLUS software package. Data were corrected for absorption effects using the multi-scan technique (SADABS). Structures were solved and refined using the Bruker SHELXTL (Version 6.14) software package. [MeB(3-(*t*-Bu)Pz)$_3$]Tl and [MeB(3-(Mes)Pz)$_3$]Tl crystallize in the *Pnma* and *Cc* space groups, respectively. We have considered the potential ambiguities of the *Cc* space group (e.g., centrosymmetric option) for [MeB(3-(Mes)Pz)$_3$]Tl, but remain confident of the assignment. Some details of the data collection and refinement of [MeB(3-(*t*-Bu)Pz)$_3$]Tl and [MeB(3-(Mes)Pz)$_3$]Tl are given in Table 1. Selected bond distances and angles are presented in Tables 2 and 3. The

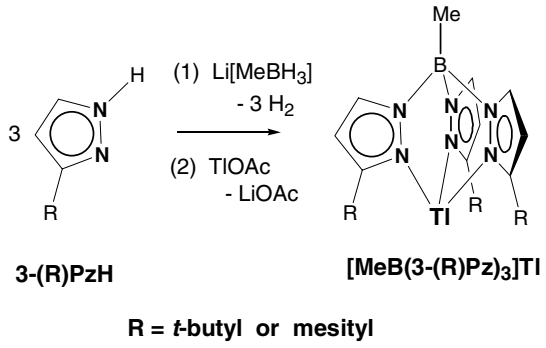
X-ray crystal structure of 3-(Mes)PzH was also determined as the solid-state structures of pyrazoles are of interest [12]. Further details and the X-ray crystallographic data for 3-(Mes)PzH are in the cif files.

3. Results and discussion

The thallium derivative of the methyl substituted tris(pyrazolyl)borate $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]^-$ can be synthesized by treating the lithium adduct $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Li$ (which was obtained from a reaction between $Li[MeBH_3]$ and 3-*tert*-butylpyrazole) with thallium(I) acetate.



The formation of the final product and the consumption of $Li[MeBH_3]$ could be followed using ^{11}B and ^{1}H NMR spectroscopy. For example, the ^{11}B NMR spectrum of $Li[MeBH_3]$ in d_6-DMSO reveals a quartet of quartets (Fig. 1). The ^{11}B NMR spectrum of the thallium adduct $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ shows only a broad singlet. The ^{1}H NMR spectra are also very informative. For example, the BH_3 protons of $Li[MeBH_3]$ appear as a heptet of quartets superimposed on a quartet of quartets (Fig. 2). The heptet (signals show equal intensity as expected) of quartets arises from the coupling between protons of the BH_3 unit with the ^{10}B isotope ($I = 3$, abundance = 19.9%) and methyl protons [13]. The superimposed quartet (peaks have equal intensity) of quartets can be attributed to the splitting caused by the ^{11}B isotope ($I = 3/2$, abundance = 80.1%) and methyl protons. The $^{1}J(^{1}H\text{–}^{11}B/^{1}H\text{–}^{10}B)$ ratio is consistent with the $^{11}B/^{10}B$ nuclear magnetogyric ratio of 2.986 (see supplementary material for $K[BH_4]$ spectra taken under similar conditions) [13]. Protons of the methyl group appear as a complex multiplet (see supplementary material). The ^{1}H NMR spectrum of $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$, in contrast, shows the presence of signals corresponding to the pyrazolyl units, a broad singlet for B–Me protons and the disappearance of BH_3 related resonances. We did not observe the Tl–H coupling in the ^{1}H NMR (500 MHz) spectrum. However, Tl–H coupling has been observed in the ^{1}H NMR (300 MHz) spectrum of the hydroborato analog, $[HB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ [14,15]. This somewhat surprising Tl–H (also true for Tl–C) coupling related observation has been attributed to thallium relaxation via chemical shift anisotropy, which is strongly dependent on the external magnetic field strength [15].

The X-ray crystal structure of $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ is illustrated in Fig. 3. It contains a crystallographically imposed mirror plane involving Tl, B and one of the pyrazolyl groups. $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ exhibits the common symmetric, tridentate coordination of the tris(pyrazolyl)borate ligand. Interestingly, $[HB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ crystallizes in the same space group and has a very similar structure [14]. The Tl–N (2.582(6), 2.587(9) Å) distances of $[HB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ are not significantly different from the Tl–N bond lengths of $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ (2.5306(17), 2.5496(14) Å). The molecular structure of the B-phenyl analog, however, is very different [4]. The tris(pyrazolyl)borate ligand in $[PhB(3\text{-}(t\text{-}Bu)Pz)_3]Tl$ coordinates to thallium primarily in a bidentate fashion. The third pyrazolyl group, which is rotated by about 90°, shows a contact to thallium, via the nitrogen atom directly bonded to the boron.

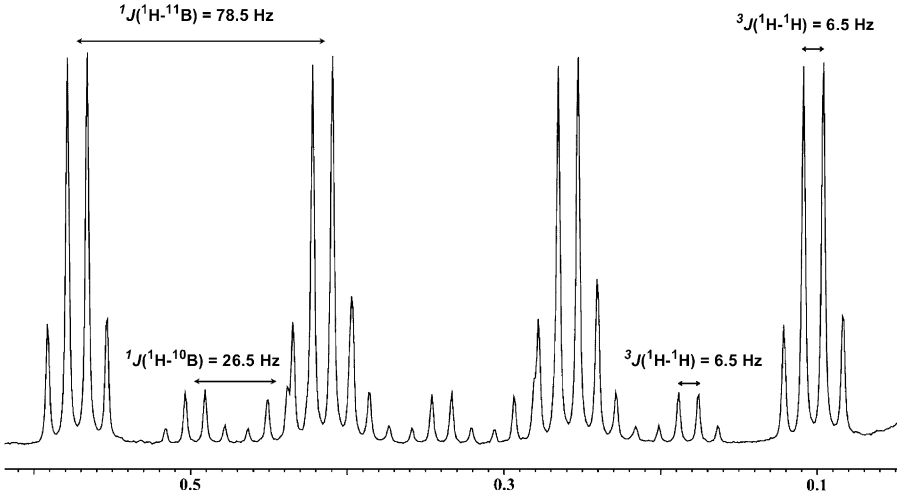

Fig. 2. ^{1}H NMR (500 MHz, d_6-DMSO, 25 °C) spectrum of Li[MeBH$_3$] showing the BH_3-related resonances.

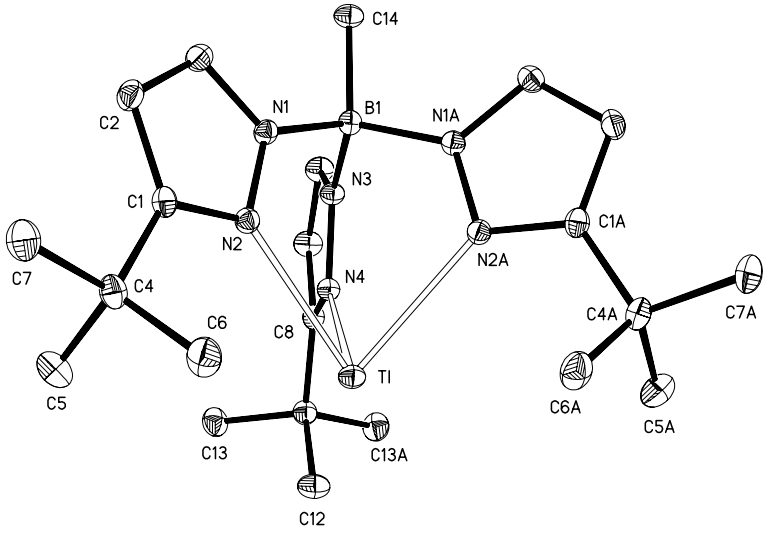

Fig. 3. Crystal structure of [MeB(3-(*t*-Bu)Pz)$_3$]Tl (H-atoms have been omitted for clarity).

The synthesis of [MeB(3-(Mes)Pz)$_3$]Tl was accomplished by using 3-(Mes)PzH, Li[MeBH$_3$] and TlOAc. It was isolated in 75% yield as the only product. Interestingly, the reaction between KBH$_4$ and 3-(Mes)PzH leads to a mixture of isomers [10]. [HB(3-(Mes)Pz)$_3$]Tl, which is closely related to the B–Me analog [MeB(3-(Mes)Pz)$_3$]Tl, was obtained as the minor product whereas the asymmetric species [HB(5-(Mes)Pz)(3-(Mes)Pz)$_2$]Tl is the major product. The X-ray crystal structure of [MeB(3-(Mes)Pz)$_3$]Tl is illustrated in Fig. 4. It crystallizes with two chemically similar but crystallographically different molecules in the asymmetric unit. X-ray data confirm the formation of the isomer with mesityl groups at the pyrazolyl ring 3-positions. The thallium center adopts a pyramidal geometry. The Tl–N distances of 2.530–2.564 Å are in the typical range [6,7].

We have also obtained the X-ray crystal structure of 3-mesitylpyrazole (Fig. 5). It features an interesting planar, tetrameric structure in the solid state due to N–H $\cdots$ N hydrogen bonding [16]. Solid-state structures of pyrazoles are of current interest [12,16–21]. *N*-Unsubstituted pyrazoles display structures ranging from dimers, trimers and tetramers, to polymeric chains. Among these, the tetrameric form is the least common. 3,5-(CF$_3$)$_2$PzH, 3,5-(Ph)$_2$PzH, 3-(CF$_3$),5-(Ph)PzH and 3(5)-phenyl-5(3)-methylpyrazole are some examples of pyrazoles that adopt the tetrameric form in the solid state [16–21].

Overall, we have described the isolation of sterically demanding tris(pyrazolyl)borates with B-methyl groups. Such ligands are rare. The related hydroborato analogs have received significant attention in recent years.

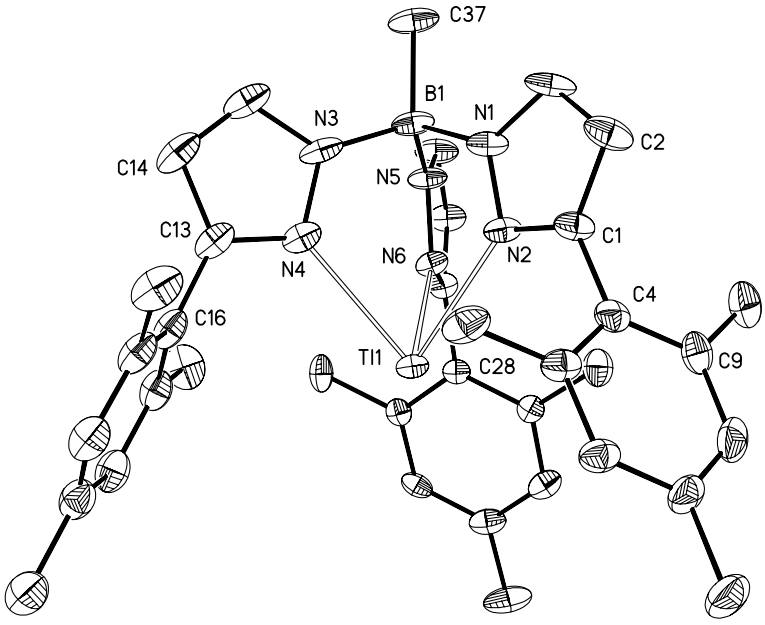

Fig. 4. Crystal structure of $[MeB(3\text{-}(Mes)Pz)_3]Tl$ (only one of the two molecules in the asymmetric unit is shown. H-atoms have been omitted for clarity).

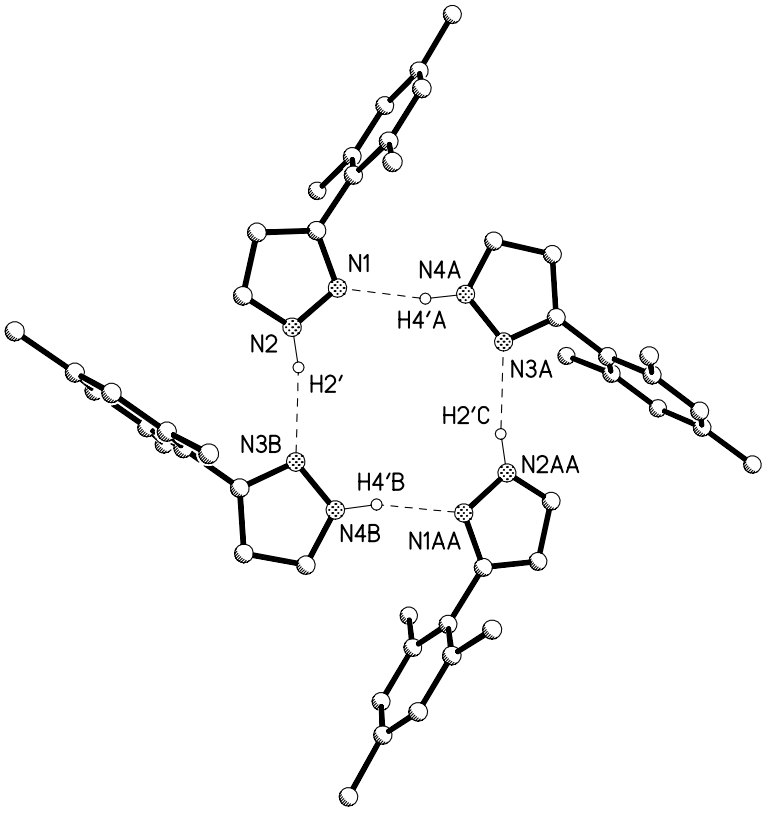

Fig. 5. The structure of 3-(Mes)PzH showing the tetramer (all the hydrogens except those on nitrogen atoms have been omitted for clarity).

[9,10,15,22–34] $[MeB(3\text{-}(t\text{-}Bu)Pz)_3]^-$ and $[MeB(3\text{-}(Mes)Pz)_3]^-$ would be particularly useful for investigating chemistry where B–H units typically create problems. Due to the presence of the B-methyl group, these ligands may also have a somewhat reduced tendency to isomerize (e.g., from the 3,3,3 isomer to the 3,3,5 form) during

reactions [2]. We are currently investigating the coordination chemistry of these B-protected ligand systems. Thallium derivatives are useful in this regard because they serve as good ligand transfer agents [2,6–8]. Preliminary results show that we can synthesize a variety of metal adducts including those involving copper(I). A comparison of IR data of $[MeB(3\text{-}(Mes)Pz)_3]CuCO$ ($\nu_{CO} = 2074$ cm^{-1}) [35] to $[HB(3\text{-}(Mes)Pz)_3]CuCO$ ($\nu_{CO} = 2079$ cm^{-1}) [33] shows that there is no notable electronic effect on the copper(I) center as a result of replacing the hydride on boron with a methyl group [17].

Abstract

Supramolecular $[Cu(II)(ONQ)_2(H_2O)_2]_n$ (**1**) a complex of the 2-hydroxy-1,4-naphthoquinone ligand (2HNQ), has been synthesized using $CuCl_2 \cdot 2H_2O$. ONQ is the deprotonated oxidized form of the ligand (viz. 2-oxido-1,4-naphthoquinone). The complex has been characterised by X-ray crystallography, variable temperature magnetic susceptibility measurements (SQUID), EPR and CV studies. The crystal structure of **1** has been solved at 295 and 161 K. The cell volume decreases from 435.3(6) $Å^3$ at 295 K to 427.9(6) $Å^3$ at 161 K. The monomeric units of **1** are linked by three types of intermolecular hydrogen bondings through coordinated ONQ ligands and water molecules, which results in a supramolecular three dimensional hydrogen bonding network. The magnetic susceptibility data of **1** were best fitted with the Bonner Fisher equation with the coupling parameter $J = -3.2\ cm^{-1}$, indicating a weak antiferromagnetic interaction along the chain.

1. Introduction

The syntheses and characterization of supramolecular assemblies have been of great interest in recent years due to their potential applications in the crystal engineering of non-linear optical, conducting and molecular ferromagnetic materials [1,2]. They can also be used to build polynuclear assemblies to synthesize bioactive materials having relevance, as chemical models, mimicking biological processes. Intermolecular hydrogen-bonding networks play an important role in the formation of supramolecular structures from smaller molecular units [3]. Such a hydrogen bonding network can also mediate interesting magnetic interactions among the spin centers of assembled molecular materials if they possess unpaired electrons [4,5].

Due to their complicated redox properties, quinone complexes have been of considerable interest for many years [6,7]. Quinones can bind potentially to metal ions in three different oxidation states, viz. (i) quinone, (ii) its one electron reduced form, semiquinone, and (iii) its two electron reduced form, catechol. Coordination complexes of quinones with different oxidation states reflect differences in their structural, magnetic and electrochemical properties [7].

I) Quinone Form (ONQ) **R = H = Lawsone** II) Semi-quinone Form (ONSQ) III) Catechol Form (CAT)

Scheme 1. Various redox forms of 2-hydroxy-1,4-naphthoquinone and its derivatives.

The binding ability of quinones in different oxidation states allows them to play an important role in biological systems. Copper containing oxidases, such as amine oxidase which catalyses the oxidative deamination of primary amines to aldehydes, contain quinone as an active cofactor [8,9]. Another copper containing oxidase enzyme, galactose oxidase, involves the formation of a free radical which is antiferromagnetically coupled with the copper ions. There have been many efforts in recent years to understand the metal–quinone interactions and to mimic the structural and functional models for these enzymes [10,11]. Because of the biological significance of complexes of derivatized hydroxy naphthoquinones [12–14], in this present report we have used 2-hydroxy-1,4-naphthoquinone, viz. 2HNQ or lawsone, for complex **1** to investigate its spectroscopic and magnetic properties. The ligand, 2HNQ, can coordinate (in its deprotonated ONQ form) to metal ions in three different oxidation states, viz. quinone; I, semiquinone; II and catechol; III (Scheme 1).

We report here magnetostructural properties of a synthesized copper complex $[Cu(II)(ONQ)_2(H_2O)_2]_n$ with 2HNQ. We also report the crystal structures at 161 and 295 K. The three-dimensional intermolecular hydrogen-bonding network existing in the structure leads to a weak antiferromagnetic coupling among the copper centers along the *a*-axis.

2. Experimental

2.1. Materials and measurements

All the reagents used in the synthesis were obtained from Aldrich Chemical Co. and are used without further purification. 2-Hydroxy-1,4-naphthoquinone was obtained from Fluka. The polycrystalline EPR spectra were recorded on a Varian E-112 spectrometer using 100 kHz field modulation at X-band (9.5 GHz) and Q-band (35 GHz) frequencies. The magnetization curves are recorded using a SQUID magnetometer (Quantum Design MPMS5) operating in the alternative mode at the Laboratoire de Magnétisme et d'Optique, CNRS/Université de Versailles (UMR 8634) France. The experimental molar magnetic susceptibilities were corrected for the underlying diamagnetic susceptibility using Pascal constants and temperature independent paramagnetism (-60×10^{-6}) cgs units/copper atom [15,16]. The molar magnetic susceptibility data were fitted using a non-linear simplex fitting routine [17]. The function minimized was [18]

$$F=\sum_t \frac{(\chi_t^{\mathrm{obsd}}-\chi_t^{\mathrm{calcd}})^2}{(\chi_t^{\mathrm{obsd}})^2}.$$

Cyclic voltammetry (CV) measurements were performed on BAS-CV-27 assembly in conjunction with an *X–Y* recorder using the three electrode system with direct correction of the uncompensated cell resistance (iR drop). The three-electrode cell includes a glassy carbon working electrode (area 0.23 mm^2) referenced with an Ag|AgCl electrode and platinum wire as an auxiliary electrode. The glassy carbon working electrode was activated according to a procedure by Thorp et al [19]. The solvents used in CV studies were purified according to the literature procedure [20] and were always de-gassed for 10 min before the experiment. 0.1 M tetraethyl ammonium perchlorate (TEAP) in CH_3CN was used as the supporting electrolyte. Before each CV run, the solution in the cell was carefully deareated with purified N_2.

2.2. Synthesis of compound $[Cu(ONQ)_2(H_2O)_2]_n$ (1)

To a solution of $CuCl_2\cdot 2H_2O$ (1 mM) in 15 ml of water, a solution of 2HNQ (1 mM) in 50 ml of methanol, was mixed with constant stirring. This mixture was stirred for 15 min; to this solution solid sodium carbonate (0.5 mM) was added. An orange coloured precipitate was obtained after stirring for 15–20 min; stirring was continued for another 2 h in air for complete precipitation of the orange residue. The yield of this orange precipitate was 20%, and this orange coloured solid was characterised by elemental analysis, infrared spectral studies, thermal and magnetic studies [21] as $[Cu_2(ONQ)_4(\mu\text{-}CO_3)]$ *Anal.* Calc. for $C_{41}H_{20}Cu_2O_{15}$: C, 55.85; H, 2.52; Cu, 14.41. Found : C, 55.64.10; H, 3.28; Cu, 14.10%. The orange precipitate was filtered. Brown crystals of **1** were obtained in a 40% yield from the filtrate after 4 days. *Anal.* Calc. for $C_{20}H_{14}CuO_8$: C, 53.83; H, 3.16; Cu, 14.25. Found: C, 54.10; H, 3.46; Cu, 13.6%. X-ray structures at 295K and 161 K, EPR and magnetic studies were performed on these crystals.

The brown crystals of **1** were also obtained when anhydrous $CuCl_2$ was used as the metal source and the $CuCl_2$:2HNQ ratio was kept as 1:2 at pH 5–6. The X-ray crystal structure of those crystals solved at 300 K [22] using an Enraf-Nonius CAD 4 single crystal X-ray diffractometer showed the same cell parameters as those shown in Table 1.

Weighting scheme of the form $w = w'[1 - ((\|F_o\| - \|F_c\|)/6\sigma(F_o))^2]^2$ with $w' = 1/\sum_r A_r T_r(X)$, with coefficients 3.37, 0.94 and 2.27 for a Chebychev series for which $X = F_c/F_c(\max)$ at 295 K.
Weighting scheme of the form $w = w'[1 - ((\|F_o\| - \|F_c\|)/6\sigma(F_o))^2]^2$ with $w' = 1/\sum_r A_r T_r(X)$, with coefficients 2.37, 0.681 and 1.53 for a Chebychev series for which $X = F_c/F_c(\max)$ at 161 K.

2.3. Crystallography

The low temperature and the room temperature crystal structures were solved for the crystals of **1** at the Centre de Resolution de Structures, Université Pierre et Marie Curie, Paris France. Crystals of $[Cu(ONQ)_2(H_2O)_2]$ belong to the triclinic system with space group $P\bar{1}$. The selected crystal was a brown parallel piped of approximate dimensions: $0.15 \times 0.25 \times 0.40$ mm. The crystal was mounted on a glass fiber and data were collected on an Enraf-Nonius CAD4 diffractometer. Cell constants were obtained from a least-squares fit of 25 reflections. Crystal and intensity collection data are summarized in Table 1. A total of 1715 (1693) reflections were recorded to a 2θ (Mo) maximum of 50°. Intensity standards, recorded periodically, showed no significant variations during measurements. Reflections were corrected for Lorentz and polarization effects. 1455 (1416) of the reflections with $I > 3\sigma$ were used in subsequent calculations. Difabs absorption corrections were made.

The structure was solved by direct methods using the SHELXS [23] program and for all other calculations the CRYSTALS [24] program was used. Atomic scattering factors and anomalous dispersion terms were taken from the International Tables for X-ray Crystallography [25]. Full-matrix, least-squares refinement based on $|F|$, and a Chebychev weighting scheme [26] were performed. All non-hydrogen atoms were anisotropically refined. Hydrogen atoms on water molecules were found by difference Fourier techniques. Other hydrogen atoms were introduced in calculated positions. All hydrogen atoms were allocated one overall refinable isotropic thermal parameter. The final refinement minimizing converged to $R = 0.0497$ (0.0431) and $Rw = 0.0577$ (0.0501). The goodness of fit was $S = 1.013$ (1.063) with 1455 (1416) observations and 135 variables.

3. Result and discussion

3.1. Crystal structure of $[Cu(ONQ)_2(H_2O)_2]_n$ (1)

The crystal structure of the complex **1** has been solved at two different temperatures, viz. 161 and 295 K and the cell parameters are given in Table 1. The ORTEP view of complex **1** as a monomeric unit is depicted in Fig. 1, where one half of the molecule generates the other half to give a monomeric unit with the Cu(II) ion lying on the center of inversion. The copper(II) ion is hexa-coordinated with two bidentate ONQ ligands and two water molecules. The basal plane of the complex is occupied by the quinone carbonyl oxygen atoms, O(1) and O(1a) and the phenoxy oxygens O(2) and

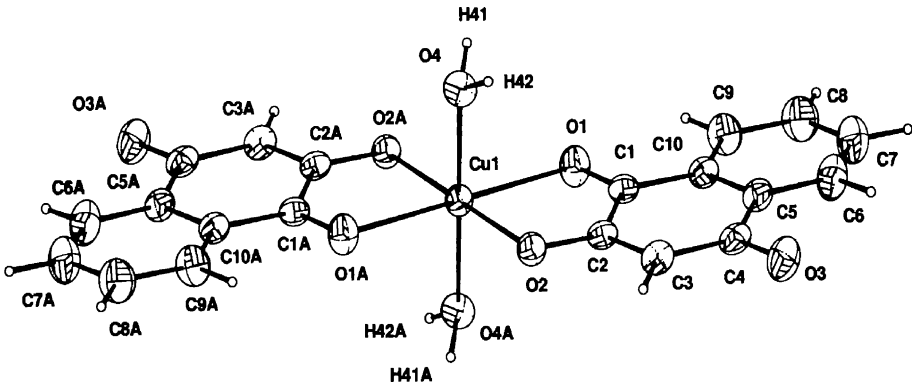

Fig. 1. ORTEP view of monomeric $[Cu(Lw)_2(H_2O)_2]$ at room temperature (showing 50% probability thermal ellipsoids).

O(2a) of ONQ at 2.336(2) Å and 1.954(3) Å, respectively. The apical positions are occupied by the two oxygen atoms of water, viz. O(4) and O(4a) at a distance 2.007(3) Å. The biting angle of the ligand, O(1)–Cu–O(2) is acute (77.05(11)°) while the bond angle between the two biting ligands is 102.95(11)°. The bond angles between the coordinating atoms (O(1) and O(2)) of the ligand ONQ and the oxygen atoms of the coordinating water molecules are nearly at right angles: O(1)–Cu–O(4) = 90.24(13)°, O(1)–Cu(1)–O(4a) = 89.76(13)°, O(2)–Cu(1)–O(4) = 89.04(14)° and O(2)–Cu(1)–O(4a) = 90.96(14)°. Thus, the geometry of the complex can be best described as an axially elongated octahedron. Selected bond distances and angles are given in Table 2. The C(1)–O(1) bond distance (1.216(4) Å) of the coordinating ligand is less than that of chelating semiquinone anions (1.27–1.30 Å) or catecholate (1.34–1.36 Å) [27–30], implying that the ligand 2HNQ is in its fully oxidized deprotonated ONQ form coordinating to a copper(II) ion. The other bond lengths of the coordinated quinone molecule are found to be normal and similar to that of reported metal complexes with the ONQ ligand [31]. The C(2)–O(2) phenoxy distance is similar to that of the phenoxy distance found in iron [31] and manganese[32] complexes with the ONQ form of the ligand.

Table 2
Selected bond distances and angles for $[Cu(Lw)_2(H_2O)_2]$

	295 K	161 K
Bond distances (Å)		
Cu(1)–O(1)	2.336(2)	2.328(2)
Cu(1)–O(2)	1.954(3)	1.953(2)
Cu(1)–O(4)	2.007(3)	1.995(2)
O(1)–C(1)	1.216(4)	1.227(4)
(O2)–C(2)	1.297(4)	1.295(4)

O(1)–Cu(1)–O(2a)	102.95(11)	102.96(8)
O(1)–Cu(1)–O(4)	90.24(13)	90.12(8)
O(1)–Cu(1)–O(4a)	89.76(13)	89.88(8)
O(2)–Cu(1)–O(4)	89.04(14)	89.12(8)
O(2)–Cu(1)–O(4a)	90.96(14)	90.88(8)

a, Symmetry: $1-x, 1-y, 1-z$; b, symmetry: $1+x, y, z$; c, symmetry: $x, y-1, z$.

Formation of supramolecular assemblies via H-bonding is an interesting part of the molecular structure of **1** (Fig. 2). Three types of intermolecular hydrogen bonds exist: (i) between one of the hydrogens of water and the phenoxy oxygen, O(2), of a nearby molecule (symmetry: $-x, 1-y, 1-z$) along the *a*-axis; (ii) between the second hydrogen of water and an oxygen of the uncoordinated carbonyl group of a quinone ring of the next molecule (symmetry: $x, 1+y, z$) along the *c*-axis and (iii) between the uncoordinated quinone oxygen atoms and the H atom at the C3 position of a ONQ quinone group of nearby molecules. Thus, these three types of hydrogen bonding networks with the crystallographic symmetry form an interesting supramolecular hydrogen bonding network assembly. The possible hydrogen bonding distances and angles between the acceptor and donor atoms are summarized in Table 3 and they are in the acceptable range [33]. The nearest Cu–Cu distances are 5.03 and 9.54 Å.

Due to the interesting intermolecular hydrogen bonding networks, we were curious to see the structure of compound **1** at a low temperature. The crystal structure was solved at 161 K and the structure is found to be similar to that of the RT structure (Fig. 1) with some changes in the bond distances and angles. The crystallographic parameters, selected bond distances, angles and

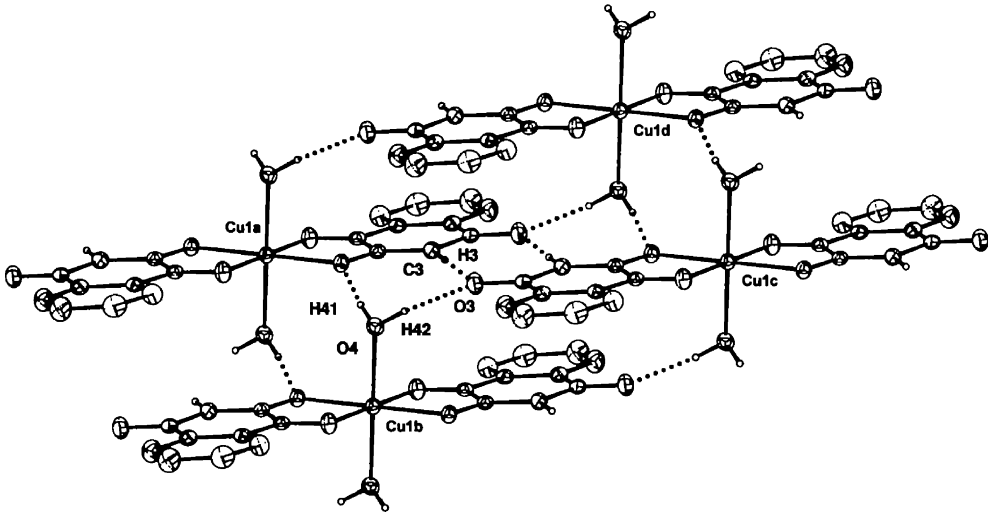

Fig. 2. ORTEP view of the molecular packing of $[Cu(Lw)_2(H_2O)_2]$ showing the possible inter molecular H-bonding networks (showing 30% probability thermal ellipsoids).

Table 3
Possible hydrogen bonding interactions in $[Cu(Lw)_2(H_2O)_2]$ (distances in (Å) and bond angles in (°))

Symmetry (a): $-x$, $1-y$, $1-z$; (b) x, $y+1$, z; (c) $-x$, $-y$, $1-z$.

possible hydrogen bond distances are given in Tables 1–3, respectively, along with the room temperature results for a comparison purpose. There is shrinkage in unit cell length and the volume (see Table 1) due to contraction at the low temperature. As can be seen in Table 2, the bonding parameters are within the estimated error except for the copper ion and the oxygen of the coordinating water molecule, which is 0.01 Å shorter at lower temperature. Similarly, the Cu–Cu distance is ~0.04 Å shorter at lower temperature along the *a*-axis, though there is no difference along the other crystallographic directions. The donor–acceptor distances are also smaller at lower temperatures as indicated in Table 3.

3.2. EPR spectroscopy

X-band polycrystalline EPR spectra recorded at RT and 77 K and Q-band EPR spectra at RT of the present complex are given in Fig. 3. The room temperature X-band EPR spectrum shows a highly anisotropic rhombic pattern where the perpendicular component is not fully resolved, though the unsymmetrical shape is evident. The g_1 (g_z) value appears rather high, indicating the weak ligand field strength. There is no visible signal in the half-field region, indicating absence of a forbidden $\Delta M_s = \pm 2$ transition. At 77 K the features are almost the same except that there is a reduction in the linewidth especially at the $g_\perp$ region. The room temperature Q-band EPR spectrum exhibits a rhombic pattern where the (g_y) and (g_x) signals are resolved. The resolution of $g_\parallel$ and $g_\perp$ into a four line feature results in g_1 to g_4 as 2.399, 2.25, 2.109, 2.0601. Similar features are observed in $[Cu(Lw)_2(H_2O)]_2$ [14b]. This characteristic is in accordance with aggregation of monomeric molecules as seen in the X-ray structure.

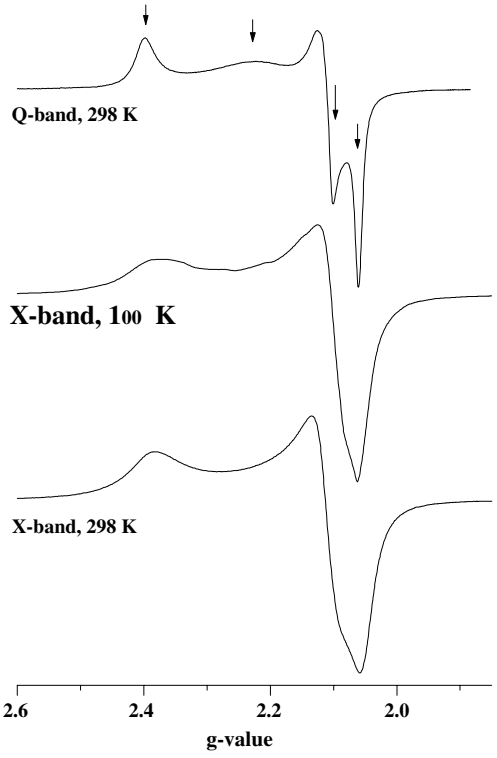

Fig. 3. X-band EPR spectra at 100 and 298 K and Q-band EPR spectrum at 298 K.

3.3. Magnetic properties

Variable temperature magnetic susceptibility measurements (SQUID) for complex **1** were performed on polycrystalline samples in the range 5–300 K. The experimental values of χ_{mol} and μ_{eff} per copper ion are plotted in Fig. 4. At room temperature (300 K) the experimental μ_{eff} value is 1.62 μB, which is less than the spin only value expected for mononuclear copper(II) complexes,

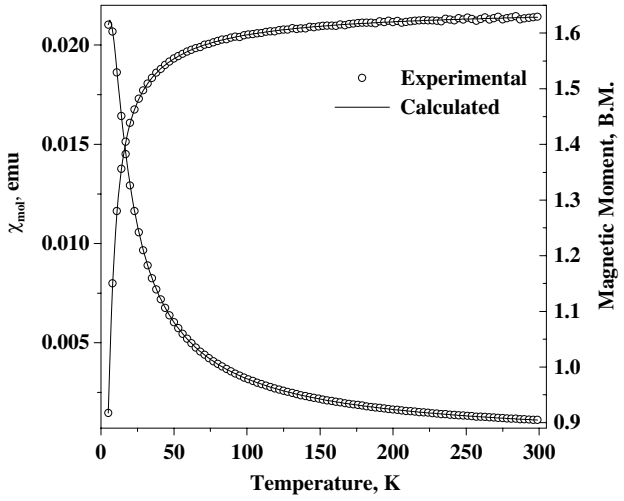

Fig. 4. Experimental and theoretical molar magnetic susceptibility and magnetic moment per copper ion of $[Cu(Lw)_2(H_2O)_2]$. (○○○○, experiment; —-, theoretical). The fit was obtained using Eqs. (1) and (2).

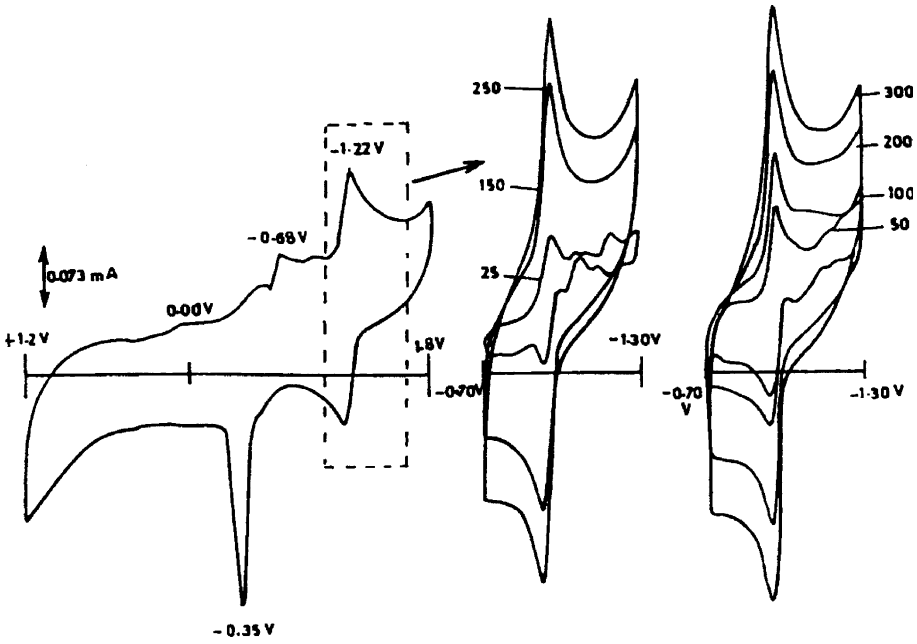

Fig. 5. Cyclic voltammogram of **1** in 0.1 M TEAP in CH_3CN. The dotted line represents the scan rate variations.

and this decreases gradually and steadily with temperature down to 50 K. Below this temperature, the magnetic moment decreases steeply on decreasing the temperature and drops down to 0.9 μB at 5 K. The current magnetic moment behaviour with temperature probably indicates an antiferromagnetic coupling among the copper ion centers. Looking at the structure of compound **1**, there is no direct bonding interaction between the copper ions. So the observed antiferromagnetic behaviour among the copper centers should arise through the intermolecular hydrogen-bondings. It should also be noted that this hydrogen-bonding network brought the copper–copper distance to 4.99 Å along the *a*-axis while the shortest Cu–Cu distance along the other axes is 9.53 Å. The experimental magnetic susceptibility data were best fitted with the Bonner Fisher equation (Eq. (1)) [34] which accounts for the magnetic interaction along the chain and also interactions between chains.

$$\chi_m = Ng^2\beta^2/kT[(0.25 + 0.074975x + 0.07523x^2) /(1.0 + 0.9931x + 0.172135x^2 + 0.757825x^3)], \quad (1)$$

where $x = |J/kT|$, J is the antiferromagnetic coupling parameter, k is the Boltzmann's constant and T is the temperature, g is the gyromagnetic ratio, β is the Bohr-magneton value. The inter-chain exchange (zJ') was estimated following a mean field correction Eq. (2) [16]

$$\chi_m^{corr} = \chi_m/(1 - 2zJ'\chi_m/Ng^2\beta^2). \quad (2)$$

The experimental data were best fitted with the following parameters: $J = -3.26\ cm^{-1}$, $g = 1.9$, $zJ' = 0.01$ and the least-square error: 2.7×10^{-7}.

3.4. Cyclic voltammetric studies

Fig. 5 shows a cyclic voltammogram of **1** and the reactions ascertained with the respective cathodic as well as anodic peak potentials are shown in the following equations.

$$\text{Ligand ONQ} : \text{ONQ} \xrightarrow[1e^-]{-0.51\ V} \text{ONSQ} \underset{1e^-}{\overset{-1.19\ V}{\rightleftharpoons}} \text{CAT}$$

$$\mathbf{1} : \text{ONQ} \xrightarrow[1e^-]{-0.68\ V} \text{ONSQ} \underset{1e^-}{\overset{-1.22\ V}{\rightleftharpoons}} \text{CAT}$$

$$\text{Cu(II)(ONQ)(ONSQ)} \underset{1e^-}{\overset{-0.00\ V}{\rightleftharpoons}} \text{Cu(O)} + 2\text{ONQ}$$

The ligand based peaks in **1** were shifted towards negative potentials compared to the ligand, which suggest weak intramolecular metal–ligand interactions, however the ligand mediated Cu–Cu interaction is observed at 0.00 V [35].

4. Conclusion

Three types of intermolecular H-bondings found in the crystal structure of **1** complex lead to three dimensional network assemblies of $[Cu(ONQ)_2(H_2O)_2]$ units. The magnetic chain of Cu(II) ions in **1** via H-bondings

results in antiferromagnetism with numerical fittings of χ_m with the Bonner and Fisher model.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication Nos. 212886 and 212887. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44 1223/336 033; E-mail: deposit@ccdc.cam.ac.uk, or http://www.ccdc.cam.ac.uk].

Received 10 August 2004; accepted 2 September 2004
Available online 13 October 2004

Abstract

Seven new copper(II) complexes of 2-hydroxyacetophenone *N*(4)-substituted thiosemicarbazones (H_2L) and bidentate polypyridyl compounds 2,2′-bipyridine and 1,10-phenanthroline (B) were prepared and characterized. The thiosemicarbazones bind to the metal as dianionic ONS donors (L^{2-}) and yield compounds of the stochiometry [MLB]. The structure of the compound [Cu(L^4)(2,2′-bipy)] (**6**) was investigated by single-crystal X-ray diffraction method. Spin Hamiltonian and bonding parameters of the compounds calculated from the EPR spectra suggest square pyramidal (SPY) structure for the compounds. The *g* values predict geometry of C_{4v} symmetry with B_{1g} ground state. The bonding parameters show significant in-plane π-bonding. The cyclic voltammetric study of the complexes shows irreversible redox peaks corresponding to Cu(II/I) couple and quasi-reversible redox peaks corresponding to copper(II/III) oxidation. The thiosemicarbazones and their copper complexes show significant growth inhibitory activity against bacteria *Escherichia coli*, *Staphylococcus aureus*, and fungi *Candida albicans* and *Aspergillus flavus*.

1. Introduction

Thiosemicarbazones constitute an important class of nitrogen sulfur donor ligands, because of the highly interesting chemical, biological and medicinal properties [1,2]. Studies of 2-acetylpyridine *N*(4)-substituted thiosemicarbazones and their copper(II) complexes [3,4] have shown interesting electronic structure and bonding characteristics. Recently, there have been reports of copper(II) complexes of thiosemicarbazones with potential therapeutic properties [5,6]. The coordination chemistry of ONS donor ligands has been of considerable interest due to their remarkable structural and biological properties [7–10]. Interactions between aromatic rings are very important in proteins and protein–DNA systems for protein stabilization and various regulatory processes [11–14]. There has been considerable interest in

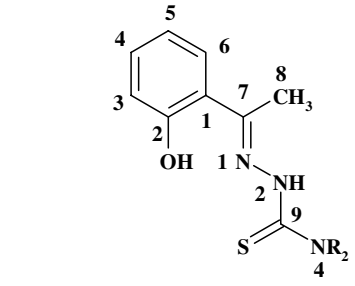
the compounds containing bidentate heterocyclic bases such as phenanthroline and bipyridine because of their versatile self-assembling properties [15]. Multidentate ligands with nitrogen containing heterocycles in general figure prominently as building blocks in the design of metal-ligand networks [16,17]. However, transition metal polypyridyl base adducts containing thiosemicarbazones have not been much investigated. Therefore, in continuation with our studies of polypyridyl adducts of copper(II) [18–20] thiosemicarbazones, we report the synthesis and spectral characterization of a series copper(II) complexes of 2-hydroxyacetophenone *N*(4)-substituted thiosemicarbazones, along with the crystal structure of compound [Cu(L^4)2,2′-bipy] (**6**). Their inhibitory activity against the growth of *Escherichia coli*, *Staphylococcus aureus*, *Candida albicans* and *Aspergillus flavus* was also determined. Primary ligands chosen in this study (Fig. 1) are *N*(4)-substituted thiosemicarbazones of 2-hydroxyacetophenone. 2,2′-bipyridyl (2,2′-bipy) and 1,10-phenanthroline (1,10-phen) were used as co-ligands for coordination with copper metal.



N(4)-substituents

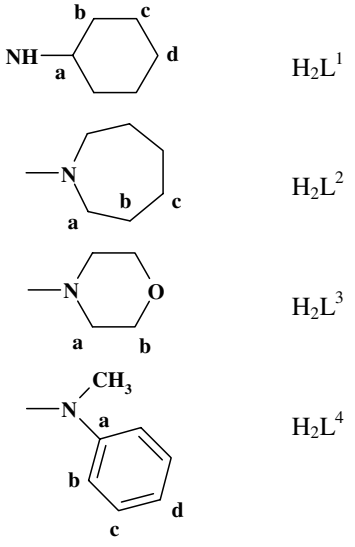


Fig. 1. Formulae of thiosemicarbazone ligands.

2. Experimental

2.1. Materials

All compounds used for the synthesis of thiosemicarbazone ligands and their complexes were purified by standard methods and solvents were purified by distillation. 1,10-Phenanthroline (Merck) and 2,2′-bipyridine (Merck) were used as received. Tetrabutylammonium tetrafluroborate (TBAB) was purchased from Aldrich Chemical Co. Solvents used for cyclic voltammetry were of spectroscopic grade and were used after drying over 4A molecular sieves.

2.2. Synthesis of ligands and their metal complexes

Synthesis of the thiosemicarbazone ligands (except H_2L^4) was carried out as per a modification of the procedure reported by Scovill [21,22]. 4-Methyl-4-phenyl thiosemicarbazone (1 mmol), 2-hydroxyacetophenone (1 mmol) and the respective amines cyclohexylamine/morpholine/hexamethyleneimine (1 mmol) were refluxed in methanol or acetonitrile (20 mL) for 15–60 min. The solution was allowed to cool; the crystalline product formed was filtered, washed with methanol and then with ether and dried over P_4O_{10} in vacuo. For the ligand H_2L^4, 4-methyl-4-phenyl thiosemicarbazone (1 mmol) and 2-hydroxyacetophenone (1 mmol) were refluxed in the presence of a small amount of cyclohexylamine in methanol for 10 min. The crystalline product formed was filtered washed with methanol, ether and then dried over P_4O_{10} in vacuo.

*Synthesis of complexes**1–7***. To a hot solution (20 mL) of the thiosemicarbazone ligand (0.5 mmol) in ethanol is added a 10 mL methanolic solution of the base, bipyridine or phenanthroline (0.5 mmol) while stirring. This is followed by a drop wise addition of about 10 mL of a methanolic solution of copper(II) acetate monohydrate (0.5 mmol). The solution is refluxed for about 2–3 h, allowed to cool, when microcrystals of the respective compounds in decent yield crystallized out. The compounds were filtered off, washed with ethanol, water followed by ether and dried in vacuo over P_4O_{10}.

2.3. Physical methods

Elemental analyses were performed on a Heraeus Elemental analyzer. The metal contents were estimated in a Perkin–Elmer AAnalyst 700 Atomic Absorption spectrometer, after decomposing the compounds in conc. HNO_3. Magnetic measurements were performed in the polycrystalline state on a Gouy magnetic balance using $Hg[Co(SCN)_4]$ as a calibrant. Diamagnetic corrections for various atoms and structural units were computed from Pascal's constants. The effective magnetic moments were calculated from the corrected molar susceptibilities of the complexes using Curie's relation. The FT-IR spectra were recorded on a Shimadzu DR 8001 series FTIR spectrometer as KBr pellets and the UV–Vis spectra were recorded on a Shimadzu 160A UV–visible spectrophotometer in DCM solvent. The EPR spectra were recorded on a Varian E-112 Spectrometer using TCNE as the standard. Cyclic voltammetry and chronoamperometry measurements were performed on a BAS Epsilon Electrochemical Workstation equipped with a three-electrode system consisted of a glassy carbon (working), platinum wire (auxiliary) and a silver–silverchloride (reference) electrode on a C3 cell stand. The cyclic voltammetric (CV) measurements were made after degassing (Argon bubbling for 15 min) a dichloromethane solution (10^{-3}M) containing 0.1 M *n*-Bu_4NBF_4 (TEAB) as the supporting electrolyte. A blanket of argon gas was maintained throughout the measurement. The Ag–AgCl reference electrode was standardized for the ferricinium/ferrocene redox couple located at $E_{1/2} = +0.400$ V ($\Delta E_p = 60$ mV). The working electrode was polished fresh before each experiment with an alumina solution. Molar conductance of the complexes was measured in a Century CC-601 Digital Conductivity meter using 10^{-3} M DMF solution.

2.4. X-ray crystallography

A dark brown crystal [3] of the compound **6** having approximate dimensions $0.44 \times 0.38 \times 0.16$ mm was sealed in a glass capillary and intensity data were measured at room temperature (293 K). Accurate unit cell parameters and orientation matrices were obtained by a least-squares fit of several high angle reflections on a Siemens SMART CCD area detector using ω scan mode. Cell refinement and data reduction were carried out using SAINT (Siemens, 1996) [23,24]. A total of 31 541 reflections were collected, resulting in 5886 independent reflections of which 3874 had $I = 2\sigma(I)$ and these were considered as observed. An absorption correction was applied to the data with the maximum and minimum effective transmission factors of 0.867 and 0.510, respectively. Averaging the symmetry equivalent reflections resulted in an R_{int} value of 0.069. The structure was solved by direct methods and the full-matrix least-squares refinement using SHELX97 [25,26] package. The positions of all the non-hydrogen atoms were included in the full-matrix least-squares refinement using SHELXL97 [25,26] program. The final refinement cycle was based on all 5886 reflections and 307 variables, the $R_1 = 0.070$ and $wR_2 = 0.112$. For the subset of data with $I = 2\sigma(I)$ the R_1 value is 0.039 and the wR_2 is 0.098 for 3874 reflections. The maximum and minimum values of the electron densities in the final electron density map were 0.378, −0.671.

3. Results and discussion

3.1. Synthesis of the ligands and complexes

The complexes are readily formed by refluxing a methanolic/ethanolic solutions of the ligand and copper(II) acetate monohydrate. The polypyridyl base 1,10-phen 2,2′-bipy was added as the co-ligand, that also promotes the enolization of the principal thiosemicarbazone ligand and provides the basicity for the medium. Thiosemicarbazones coordinate as a tridentate ligand in the thiolate form (L^{2-}) – as is evident from IR spectra – after double deprotonation. The elemental analyses of the complexes are in agreement with the general formula [MLB]. An X-ray quality single crystal of compound **6** was obtained by slow evaporation of a DMF solution over a period of 8 days.

Since the thiosemicarbazones bind to the metal as a doubly deprotonated anion, it neutralizes +2 oxidation state of the copper(II) ion. The magnetic moment values

[3] The crystal data: Black, slab crystal; dimensions, $0.44 \times 0.38 \times 0.16$ mm; empirical formula, $C_{26}H_{23}CuN_5OS$; orthorhombic, space group Pbca, $a = 21.285(3)$ Å, $b = 9.8755(8)$ Å, $c = 22.609(2)$ Å, $\alpha = \beta = \gamma = 90.0°$, $V = 4752.5(8)$ Å^3, $Z = 8$, $d_{calculated} = 1.445$ g cm^{-3}. θ-range 1.80°–28.32°, completeness 99.4%.

of the complexes are in agreement with the values expected for mononuclear d^9 copper(II) complexes.

3.2. X-ray diffraction studies

An ORTEP plot of the compound **6** along with atom labeling is given in Fig. 2. Selected bond length and bond angles are summarized in Table 1. The copper in the mononuclear complex is five coordinated and is having an approximate square pyramidal (SPY) geometry. The basal coordination positions are occupied by the phenolato oxygen, O(1), azomethine nitrogen, N(1), and thiolate sulfur, S(1), of the thiosemicarbazone and the pyridine nitrogen, N(5), of the base 2,2′-bipy. While the Cu—O bond length is 1.9116 Å the Cu–N equatorial bond length varies between 1.9606 Å (azomethine) to 2.0474 Å (bipyridine). The apical position is occupied by second nitrogen of the base 2,2′-bipy, N(5), with a Cu–N(4) bond length of 2.2278 Å. The shorter Cu–$N_{(azomethine)}$ bond than Cu–$N_{(bipy)}$ bond indicates that the thiosemicarbazone moiety dominates equatorial bonding. The difference in bond lengths can be attributed to the difference in the extent of π-back bonding between the 2,2′-bipyridine and thiosemicarbazone moiety. However, the large bond distance of the axial Cu–N(4) supports the lack of significant out-of-plane π-bonding. This fact is in accordance with the EPR analysis.

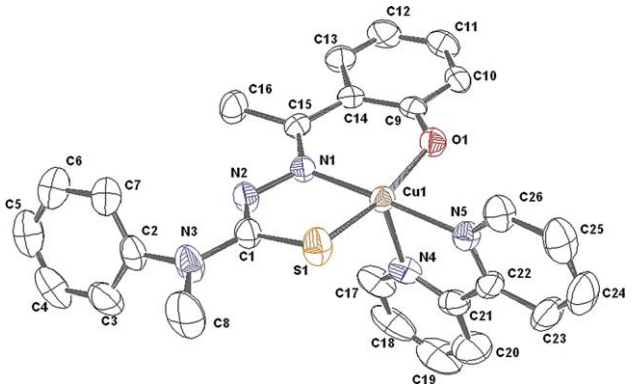

Fig. 2. ORTEP drawing and atomic labelings for compound [Cu(L^4)(2,2′-bipy)] (**6**) with thermal ellipsoids given at 50% probability. Hydrogen atoms are omitted for clarity.

Table 1
Selected bond lengths (Å) and angles (°) of compound [Cu (L^4)(2,2′-bipy)] (**6**)

Atoms	Bond distance	Atoms	Angles
Cu(1)–O(1)	1.9116(15)	O(1)–Cu(1)–N(1)	93.63(6)
Cu(1)–N(1)	1.9606(16)	O(1)–Cu(1)–N(5)	89.40(6)
Cu(1)–N(5)	2.0474(16)	N(1)–Cu(1)–N(5)	176.94(6)
Cu(1)–N(4)	2.2278(18)	O(1)–Cu(1)–N(4)	95.52(7)
Cu(1)–S(1)	2.2729(7)	N(1)–Cu(1)–N(4)	102.39(7)
S(1)–C(1)	1.740(2)	N(5)–Cu(1)–N(4)	76.86(7)
O(1)–C(9)	1.308(2)	O(1)–Cu(1)–S(1)	161.32(5)
N(1)–C(15)	1.307(2)	N(1)–Cu(1)–S(1)	85.91(5)
N(1)–N(2)	1.392(2)	N(5)–Cu(1)–S(1)	91.36(5)
N(2)–C(1)	1.302(2)	*N*(4)–Cu(1)–S(1)	102.83(5)

The four basal atoms are coplanar showing a slight but significant tetrahedral distortion. The central copper atom is slightly displaced from the basal plane in the direction of the axial nitrogen, which is evident from the bond angles of N(1)–Cu–N(5) 176.94°, and O(1)–Cu-S(1) 161.32°. The O(1)–Cu–N(4) bond angle, 95.52°, and S(1)–Cu–N(4) bond angle, 102.83°, indicate a slight tilting of the axial Cu–N(4) bond in the direction of the O(1)–Cu bond and away from S(1)–Cu bond. The small variations in the O(1)–Cu–N(1) (93.63°), O(1)–Cu–N(5) (89.40°), N(1)–Cu-S(1) (85.91°) and S(1)–Cu–N(5) (91.36°) base plane angles from the expected (90°) also contribute to distortion in the SPY geometry. One of the reason for the deviation from an ideal stereochemistry is the restricted bite angle imposed by both the $(L^4)^{2-}$ and 2,2′-bipy ligands. In other complexes involving HL or L coordinated to copper [27], the bite angles around the metal viz., N(1)–Cu–O(1) and N(1)–Cu-S(1) are limited to 80°–85°. Similarly, the bite angle created by the heterocyclic base N(5)–Cu–N(4) of 76.86° (76.2° for compound **3a**) may be considered normal, when compared with an average value of 77° cited in the literature [28–30].

The Cu–N bond lengths of the heterocyclic base are longer than those reported for mononuclear copper(II) complexes [31,32] indicating a weaker binding of the base compared to the thiosemicarbazone. The comparison of the thiosemicarbazone moiety bond distances of the compound **6** to those of the uncoordinated thiosemicarbazone [33–35] shows that coordination lengthen the $^7C{=}^1N$ bond slightly [1.297–1.307 Å] and the $^9C{=}S$ bond length substantially [1.692–1.740 Å], as would be expected on coordination of the azomethine nitrogen and thiolate sulfur.

3.3. IR and electronic spectra

The infrared spectral data of the complexes **1**–**7** are presented in Table 2 with their tentative assignments. The new band found at ca. 1595 cm^{-1} is due to $^2N{=}^9C$ bond resulting from enolization of the principal thiosemicarbazone ligand and the one at ca. 1605 cm^{-1} is due to $C{=}^1N$ of the thiosemicarbazone moiety that shifts to ca. 1560 cm^{-1} upon complexation. Bands in the range 420–470 cm^{-1} are assignable to $\nu_{(Cu-N)}$frequencies [36]. The decrease in the stretching frequency of C–S bond from ca. 830 cm^{-1} in thiosemicarbazones by 60–80 cm_{-1} upon complexation indicates coordination via its thiolate sulfur.

The electronic absorptions of the complexes are presented in Table 3. Two charge transfer (CT) bands are found at ca. 27000 cm^{-1} and 21000–23000 cm^{-1}. In accordance with studies of previous copper(II) complexes the higher energy bands are assignable to $S \rightarrow Cu^{II}$ LMCT transitions, [37,38] tailing into the vis-

ible region, and the band in 21000–23000 cm^{-1} are assignable to phenolate $O \rightarrow Cu^{II}$ LMCT transitions [39]. The d–d bands of copper(II) complexes are at ca. 14000 and 17000 cm^{-1}, the later being seen as a very weak shoulder in the tail of the CT bands and are similar to copper(II) complexes of S–N donor ligands having a square pyramidal geometry [40,41].

3.4. EPR spectra

The EPR spectra of compounds **1**–**7** in the polycrystalline state at 298 K display different type of geometrical species. Compounds **1** and **6** show typical axial spectra with well-defined $g_\parallel$ and $g_\perp$ features. Compounds **2**, **5** and **7** give signals corresponding to axial symmetry with diffused $g_\parallel$ features. All the above compounds have their g values (Table 4) in conformity with that of a copper(II) species (d^9 system) with a $d_{x^2-y^2}$ ground state. Compounds **3** (Fig. 3) and **5** give three g values viz., g_1, g_2, g_3 indicating slight rhombic distortions in their geometry. The geometric parameter G (R for compounds **3** and **5**) obtained are in the range of 3.5–5.0 (Table 5), indicating that the g values obtained in the polycrystalline samples are near to the molecular g

values and hence the unit cell of the compounds contain magnetically equivalent sites [42–45].

The solution spectra of complexes at 298 K in DMF show four hyperfine lines. The signal corresponding $M_I = +3/2$ splits into three with a hyperfine coupling constant $A_N \approx 18$ G which indicates that the azomethine nitrogen dominates the bonding in solution. The EPR spectra of the compounds in frozen DMF (77 K) (Figs. 4(a) and (b)) show four hyperfine lines and $g_\parallel$

f[b] (cm)	125.98	124.51	125.86	125.98	124.73	128.48	123.58

[a] Expressed in units of cm^{-1} multiplied by a factor of 10^{-4}.
[b] Parameter $f = g_\parallel/A_\parallel$.
[c] Parameter $R = (g_2 - g_1)/(g_3 - g_2)$.

($\sim$2.19) > $g_\perp$ ($\sim$2.06) values corresponding to monomeric copper(II) species with a square pyramidal geometry. Five superhyperfine (shf) lines in the $g_\parallel$ features ($M_I = -3/2$, or $M_I = -1/2$) of compounds **2**, **3**, **4**, **5**, and **7** evidence the coordination of two coplanar nitrogen atoms [46]. Simulated best-fits [4] of the spectra at 77 K in DMF were used to determine magnetic parameters $g_\parallel$, $g_\perp$, g_{av}, $A_\parallel$ (Cu), $A_\perp$ (Cu) and energies of d–d transitions were used to evaluate the bonding parameters α^2, β^2, γ^2 regarded as measures of covalency of the in-plane σ bonds, in-plane π bonds and out-of-plane π bonds, respectively [47]. The $g_\parallel$ values <2.3 indicate significant covalency in bonding [48,49]. The variation in g_{av} values can be attributed to the variation in the overall geometry and resulting change in the covalency of the bonds, which decreases with increase in covalency.

In all the compounds $g_\parallel > g_\perp > 2.00$ and $G = (g_\parallel - 2)/(g_\perp - 2)$ values are less than 4.4 that are consistent with a copper(II) center in $d_{x^2-y^2}$ ground state having small exchange coupling [50]. The value of in-plane π bonding parameter α^2 was estimated following Maki and McGarvey. All the compounds have $K_\parallel < K_\perp$, which suggests stronger in-plane π bonding [51–53]. The values of the bonding parameters α^2 ($\sim$0.74), β^2 ($\sim$0.89) and γ^2 ($\sim$0.94) < 1.0 (value of 1.0 for 100% ionic character) indicate significant in-plane π-bonding and in-plane σ bonding while the axial bond is more polar in nature. The Fermi contact hyperfine interaction term $K = A_{iso}/P\beta^2 + (g_{av}\text{-}2.0023)/\beta^2$ – a measure of the contribution of the 's' electrons to the hyperfine interaction - is found to be $\sim$0.3 in agreement with general observation. The empirical factor $f = g_\parallel/A_\parallel$ (cm), an index of tetrahedral distortion, is $\sim$126 cm corresponding to a copper(II) center with medium distortion.

3.5. Cyclic voltammetry

Investigations of redox behavior of copper complexes of ONS donor ligands are limited [54] and therefore the mechanistic aspects of redox behavior of most of the copper(II) thiosemicarbazone complexes still remains largely uncovered. Though a few extensive studies were reported most of them are on four-coordinate copper(II) complexes [55,56] where the mechanistic behavior is tractable. Generally, the redox behavior of the complexes depend on a number of factors such as the chelate ring size, axial ligation, degree and distribution of unsaturation and substitution pattern in the chelate ring [57–60]. In our attempt to develop an understanding of the redox behavior of five-coordinate copper(II) complexes of thiosemicarbazones, cyclic voltammetric measurements of compounds **1**–**7** were carried out. Since the complex and products of redox process are susceptible to coordination by coordinating solvents, dichloromethane was chosen as the preferred solvent for cyclic voltammetric studies.

The complexes were scanned at different scan rates ranging from 10 to 2000 mV/s in the potential range of +1000 to −1300 mV. All the cyclic voltammograms are more or less similar with minor variation in the position and appearance of some peaks (Fig. 5). Table 6 shows details of redox couples at 100 mV/s. The irreversible peak ca. −675 mV can be attributed to Cu(II/I) reduction, which is consistent with a previous report of five coordinate O_2N_2S and O_2N_3 copper(II) complexes of dianionic ligands [61]. The subsequent peak ca. −985 mV could be arising out of the ligand conjugate reduction [62]. The three-electron reduction was confirmed by a chronoamperometry experiment.

To confirm the ligand conjugate reduction three of the respective ligands were scanned in the range +1400 to −1300 mV at different scan rates of 50 to 1000 mV/s. During the cathodic sweep except ligand H_2L^4 all others gave two consecutive reduction waves ca. −850 and −1030 mV. These two reduction signals could be inferred as a two-step two-electron reduction process corresponding to the ligand conjugation. However, in the case of ligand H_2L^4 only one signal at −1034 mV was observed. During the anodic sweep a signal of lower intensity was observed for all the ligands at a higher positive potential which gradually increases from H_2L^1 to H_2L^4. This signal was assigned to the re-oxidation of the ligand conjugation.

While complexes containing 2,2′-bipyridine gives rise to an irreversible couple at ca. −675 mV, 1,10′-phenanthroline containing complexes does not give a clear couple. This could be due to the fact that the Cu(II/I) redox couple may be lying close to the conjugate reduction peak ca. −986 mV of the thiosemicarbazone moiety and hence can be buried under it. The irreversible nature of the peaks can be attributed to the formation of a new tetrahedral four coordinate copper(I) complex. Since the addition of the new electron is likely to be occurring in the half-filled $d_{x^2-y^2}$ orbital the bonds in the equatorial region is likely to be destabilized resulting in the weakening and consequent cleavage of one of them. The copper(II/I) reduction peak is followed by the ligand conjugate reduction peak at −986 mV that is shifted to a lower potential compared to the ligand, since the azomethine nitrogen involved in conjugation is bound to copper. The reduction of the ligand conjugation helps flexing of the planar thiosemicarbazone moiety and there by facilitating the formation of a four coordinated pseudo-tetrahedral species. This four coordinate copper(I) species is stabilized in the given condition, which accounts for a high positive irreversible Cu(I/II) re-oxidation signal ca. +485 mV during the reverse anodic sweep. This stability of the resulting copper(I) species

[4] The authors thanks Professor M. V. Rajasekharan, School of Chemistry, Hyderabad Central University for EPR simulation package.

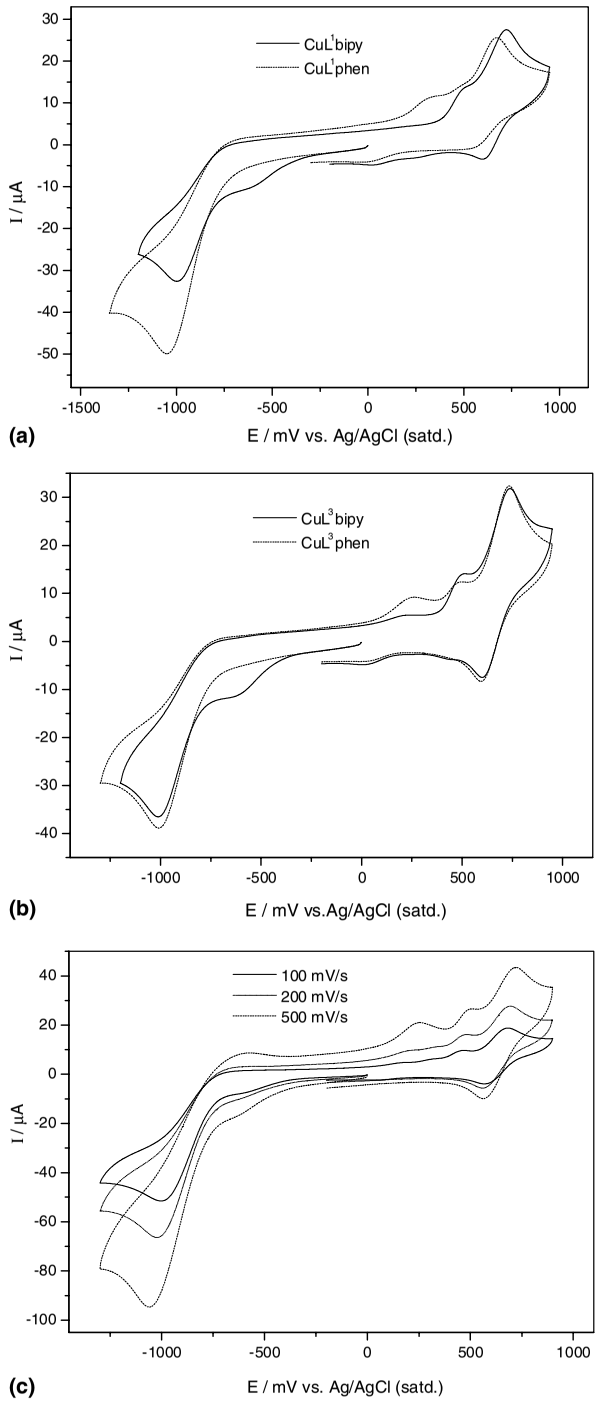

Fig. 5. Cyclic voltammogram of: (a) compound **1** and **2** at 200 mV/s scan rate, (b) compound **4** and **5** at 200 mV/s, (c) compound **6** at different scan rates.

can be attributed to the π-acceptor ability of the coordinated pyridyl groups and stabilization by sulfur donor atoms [63]. A rather diffused peak appears around +360 mV which can be arising out of the re-oxidation of the ligand conjugation. The broad peak cannot be clearly deciphered in the case of compounds **1**, **3**, **3a**, **4** at 100 mV/s, while its gains in intensity at higher scan

[c] quasi reversible.
[d] $E_{1/2} = (E_{pc} + E_{pa})/2$.
[e] Reported elsewhere.

rates viz, 500, 1000 mV/s (see Fig. 5(a) and (b)). In the case of compound **6** two broad peaks can be clearly seen at 100 and 200 mV/s scan rates that corresponds to a two electron re-oxidation of ligand conjugation, but merges at higher scan rates to give a single signal (Fig. 5(c)).

The quasi-reversible signal that appears at ca. +715 mV immediate to the copper(I/II) re-oxidation signal was assigned to a copper(II/III) couple. This value is also in conformity with other reports of four- or five-membered copper(II) complexes of ONS type donor ligands [64]. A scanning from a more positive potential of +900 mV gives an anodic current flow which is indicative of oxidation of copper(II) at potentials higher than +715 mV [65]. This is consistent with our assignment of the couple at E_{pa} = +715 mV arising from copper(II/III) redox process. Conversely, a scanning from a negative potential of −1300 mV gives a cathodic current which is indicative of a reduced species at the potential.

On initial anodic scanning only peak corresponding copper(II/III) oxidation couple is observed at the same potential. This is a further confirmation that the preceding peaks have their origin in post-reduction processes.

The ratio ($I_p/\upsilon^{1/2}$) is practically constant for all the compounds which indicate that the redox process is diffusion controlled. The ΔE_p ($=E_{pc} - E_{pa}$) values vary in the range of 104–118 mV at a scan rate of 100 mV/s, while for individual complexes the variation is between 100 and 237 mV in the scan range 100–1000 mV/s. Except in the case of compound **2** for all other complexes the couple corresponding to Cu(II/III) redox process can be inferred as quasi-reversible one-electron processes on the basis of the above observation. A small intensity peak that appears at a low positive potential is likely to be an unstable species formed during the oxidation couple.

3.6. Antimicrobial studies

All copper complexes (**1**–**7**) along with their parent thiosemicarbazone ligands were screened against two bacterial cultures viz., *E. coli* and *S. aureus*, and two fungal cultures viz., *C. albicans* and *A. flavus*. The 'hole plate diffusion method' [66] was adopted for the activity measurements. The bacterial strains were grown in Nutrient agar slants and fungal strains were grown in Sabouraud dextrose agar slants. The viable bacterial cells were swabbed onto Nutrient agar plates and fungal spores onto Sabouraud dextrose agar plates. The compounds were dissolved in dimethylsulfoxide to a final concentration of 0.1%. A 0.5 cm diameter well was cut in a medium inoculated with the respective cultures, and the solutions of the compounds in different concentrations (5 and 1 μg for bacterial cultures and 50 and 20 μg for fungal cultures) were allowed to stay in the wells. The petri-plates were incubated for 36 h for bacterial cultures and 76 h for the fungal cultures. All the compounds were screened against a standard reference viz., flucanazole for fungal cultures and gentamycin for bacterial cultures, in their standard concentration (200 μg/well). The activity of the compounds was counted by measuring diameter of the inhibition zone around the respective wells. The results are presented in Table 7.

All the copper(II) complexes were found to be more active than uncomplexed thiosemicarbazones at the measured concentrations. The compounds are having potential inhibitory activity to a concentration as low as 1 μg/well for bacterial cultures and 20 μg/well for fungal cultures. The 2-hydroxyacetophenone morpholine-3-thiosemicarbazone (H_2L^3) and its copper-phenanthroline base adduct (compound **5**) are found to be more active against *E. coli*, followed by compound

[a] All measurements are in mm diameter of the inhibition zone (9.0 mm indicates no inhibition).
[b] Commercially available anti-microbial agents.

5, **4**, **3**, **2**, respectively. There are reports that phenathroline and bipyridyl base adducts of copper are less toxic in biological systems [67] than the free ligand. The role of such complicating factors cannot be ruled out which may be responsible for the variation of inhibitory activity in some cases. However, compounds **2**, **4** and **6** are more active against bacteria *S. aureus* among complexes, while H_2L^3 shows better activity among uncomplexed thiosemicarbazones. The inhibitory action of the complexes can be due to their inhibition of the replication of DNA by interacting with enzyme prosthetic group.

Though the complexes are less effective against the fungal culture *A. flavus* compounds **3**, **4** and **5** are found to have better growth inhibitory activity. Compound **2** shows potential growth inhibitory activity against culture *C. albicans*, followed by compounds **5** and **6**. The complexes are found to be more active due to their better membrane penetrating ability. However, the reduced activity of the compounds against fungal cultures can be attributed to their inability to form hydrogen bonds with the cell constituents.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data centre, CCDC 187884 for compound CuL^4bipy. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2, IEZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk)

Abstract

Complexes of the bisphosphine dioxide ethers, bis[(2-diphenylphosphino)phenyl]ether dioxide (**I**) and 4,5-bis(diphenylphosphino)-9,9-dimethylxanthane dioxide (**II**) with lanthanide chlorides, bromides and nitrates have been synthesised, giving $LnX_3(\mathbf{I})_2(H_2O)_n$ and $LnX_3(\mathbf{II})_2(H_2O)_n$ X = NO_3, Cl, Br. The structures of the complexes of $PrCl_3$ and $NdCl_3$ with (**I**) and $LaCl_3$ and $LaBr_3$ with (**II**) are reported. These complexes are ionic $[LnX_2(\mathbf{I})_2]^+X^-$, $[LnX_2(\mathbf{II})_2]^+X^-$ and show the effect of flexibility in the ligand structure with (**I**) able to coordinate through one of its ether oxygen atoms, whilst (**II**) bonds through the phosphoryl oxygens only. The infrared spectra of the nitrates indicate that $Ln(NO_3)_3(\mathbf{I})_2$ contain monodentate nitrate whilst in $Ln(NO_3)_3(\mathbf{II})_2$ the nitrates are bidentate.

1. Introduction

Multidentate phosphine oxide donors to lanthanides have been previously studied with the aim of developing selective extractants [1] and many complexes with f-block metals have been structurally characterised. Ligands in which two phosphine oxide donors flank a third donor atom have recently been extensively reported. Complexes where the third donor is a phenolic OH [2], pyridine [3] and, in particular, pyridine oxide [1,4–8] have received considerable attention and a number of coordination complexes with both lanthanides and actinides have been structurally characterised.

We chose to examine the coordination behaviour of two related ligands (**I**) and (**II**) in which the PO groups surround an ether oxygen donor. Here the potential formation of a six membered O–P–C2–O–Ln chelate ring might be expected to result in tridentate binding of the ligand to the metal. The secondary structure linking the donor sites varies significantly between the two ligands, being more flexible for (**I**), and we felt it of interest to examine the structures of related complexes with a view to assessing the structural effects of ligand backbone rigidity.

2. Results and discussion

2.1. Synthesis

Reaction of lanthanide nitrates and halides with the ligands (**I**) and (**II**) was carried out in hot ethanol or methanol solutions as described in Section 4. Generally all complexes formed with stoichiometries $LnX_3L_2(H_2O)_n$ with the exception of the $Eu(NO_3)_3$ complex of (**II**) for which compositional analysis suggests the formation of a 2:3 complex. This is probably based on an ionic structure $[Eu(NO_3)_2(\mathbf{II})_2][Eu(NO_3)_4(\mathbf{II})]$ which is formed as a result of the slightly higher metal to ligand ratio used in its preparation. We have previously obtained similar complexes with $[Ph_2P(O)]_2CH_2$ [9].

2.2. Solid state structures

Complexes of both ligands could be obtained in a form suitable for X-ray crystallography only with difficulty. Details of crystallisations are given in Section 4. Complexes of (**I**) and (**II**) form with lanthanide nitrates, but to date, we have been unable to obtain crystals of satisfactory quality for structural work. The complexes formed between the ligands and lanthanide chlorides and bromides gave better results and structures of several complexes have been obtained. The structures of $[PrCl_2(\mathbf{I})_2]^+Cl^-$, $[NdCl_2(\mathbf{I})_2]_+[Cl]^-$, $[LaCl_2(\mathbf{II})_2(H_2O)_2]^+ \cdot [Cl]^-$ and $[LaBr_2(\mathbf{II})_2(H_2O)_2]^+ \cdot [Br]^-$ are discussed below. Details of the data collection and refinement are given in Table 1 and selected bond lengths and angles in Table 2.

The structures adopted by the complexes of (**I**) and (**II**) differ significantly and reflect the flexibility of the backbone of the ligand. The structure of $[NdCl_2(\mathbf{I})_2]^+$ is shown in Fig. 1 and that of $[LaBr_2(\mathbf{II})_2(H_2O)_2]^+$ in Fig. 2. Complexes of (**I**) can accommodate, in addition to the two phosphine oxides, the coordination of one of the ether oxygen atoms to give seven coordinate structures based on the cations $[LnCl_2(\kappa^2L)(\kappa^3L)]^+$. The non bonded O(ether)···Ln distances are greater than 4 Å for both the complexes. The coordination geometry about the metal in both complexes of (**I**) can be visualised as a rather distorted pentagonal bipyramid with the chlorine atoms occupying the axial positions. The O–Ln–O angles in the "equatorial plane" are on average 73.7° ± 6.5°, the Cl–Ln–Cl angle is 161.75°

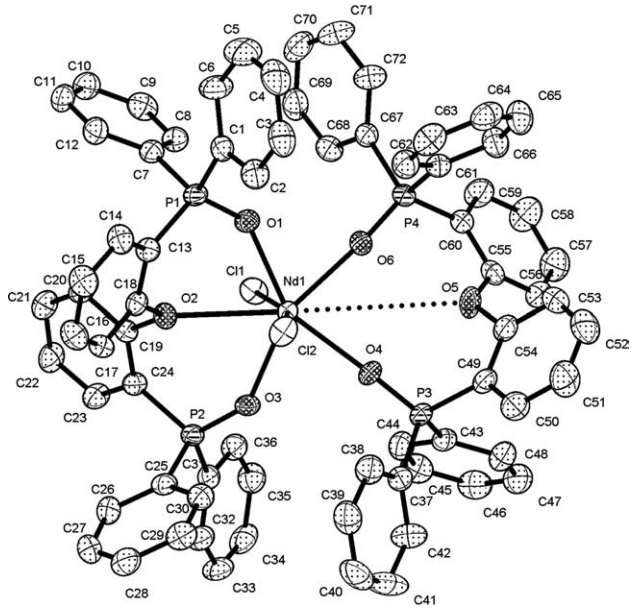

Fig. 1. The structure of $[NdCl_2(\mathbf{I})_2]^+$ showing the atom label scheme and 50% displacement ellipsoids. H atoms and lattice solvent molecules have been omitted for clarity. The dashed distance is 4.156 Å.

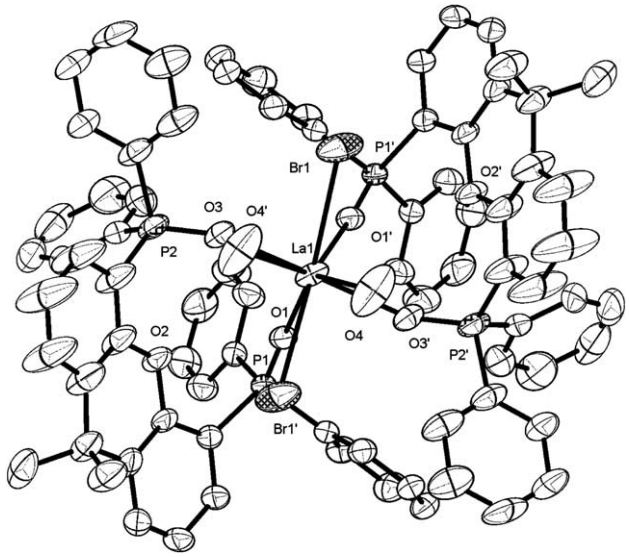

Fig. 2. The full structure of $[LaBr_2(\mathbf{II})_2(H_2O)_2]^+$. The La atom is located on a 2-fold axis and the molecule/ion is completed by symmetry $(1 - x, y, 0.5 - z)$. The Br- is disordered across two sites. Br^-, H atoms and lattice solvent molecules have been omitted for clarity.

and the Cl–Ln–O angles range from 80.45° to 111.81°. The ligand geometry changes depending on whether coordination via the ether oxygen occurs. The main effect is the twisting of the backbone aromatic rings, which increases when the ether oxygen coordinates to the metal from 74.8° to 87.9° (Pr) and from 75.2° to 90.1° (Nd). As expected the C–O distances increase slightly, by up to 0.04 Å, for the tridentate ligand compared to the bidentate. Chelating as a tridentate ligand also forces a narrowing of the C–O–C angle from 123.3(3)° to 114.2(3)° (Pr) and from 122.9(4)° to 114.2(3)° (Nd).

The Ln–O–P angle is strongly dependant on whether the ligand acts as a bidentate or tridentate ligand. In the bidentate chelate the angle approaches linearity which might be expected for unrestrained phosphine oxide donors due to a strong contribution from P^+–O^-, with larger angles reducing repulsion between the positively charged Ln and P centres and seen, for example, in yttrium halide [10] and scandium and lanthanide triflate [11] complexes of Ph_3PO. For the tridentate ligand the angle reduces considerably to around 142° and this in turn increases the Ln–O distances slightly.

The co-planarity of the phenyl rings imposed by the structure of (**II**) restricts the twisting of the ligand around the ether oxygen thus preventing tridentate coordination to the metal. Here the lanthanum ions are eight coordinate bonded to the 4PO, 2Cl (2Br) and $2H_2O$. The complexes of (**II**) both have a distorted square antiprismatic coordination geometry about the metal with the square faces formed by the phosphine oxide oxygen atoms, the halogen and the water oxygen. The angles within each square face range from 84.39° to 97.79° (Cl) and from 86.55° to 97.59° (Br).

Despite the inability of (**II**) to coordinate via the ether oxygen atoms its complexes have higher coordination numbers than those of (**I**). This is probably linked to the relative arrangement of the chelate rings. The angle between the $(P)O_2La$ planes in complexes of (**II**) is around 75°; in comparison the corresponding planes in the Pr and Nd complexes of (**I**) are twisted by only 28.0° (Pr) and 27.6° (Nd). This juxtaposition of the ligands creates a relatively open face of the complex which allows the coordination of additional water molecules. This arrangement is further stabilised by additional hydrogen bonding to non coordinated water and halide ion.

2.3. Infrared spectroscopy

The infrared spectra of the halide complexes show the expected shift in the PO stretching frequency. The two bands at 1197 and 1186 cm^{-1} in (**I**) and 1204 and 1190 cm^{-1} in (**II**) shift to give two bands at around 1160 cm^{-1} in both series of complexes. Similar features are seen in the spectra of the nitrate complexes with additional information from the nitrate absorptions. The spectra of $Ln(NO_3)_3(\mathbf{I})_2$ show two bands assigned to the N–O stretches between 1200 and 1500 cm^{-1}. These occur as a relatively weak band between ~1370 and 1380 cm^{-1} and a stronger absorption between 1295 and 1307 cm^{-1}, the frequencies increasing with the atomic weight of Ln. The splitting of these bands at ~70–80 cm^{-1} is very much smaller than normal range for bidentate nitrates [12]. The small splitting implies that the nitrates are bound as monodentate ligands. Unfortunately this assignment relies only on the infrared data as we have been unable to grow crystals suitable for X-ray diffraction studies. The complexes of (**II**) give spectra which fall into two different classes differing principally in the appearance of the N–O stretches. For the lighter lanthanides (La to Dy), in addition to bands due to (**II**), two intense broad bands between 1464–1485 cm^{-1} and 1290 cm^{-1} can be assigned to nitrate. Here the splitting in the region of 170–190 cm^{-1} is as expected for bidentate nitrates. The spectrum of $[Eu(NO_3)_2(\mathbf{II})_2][Eu(NO_3)_4(\mathbf{II})](H_2O)_4$ is essentially identical to those described above, a similar effect being found for the previously reported complexes with $[Ph_2P(O)]_2CH_2$ [9]. For the heavier lanthanides (Er to

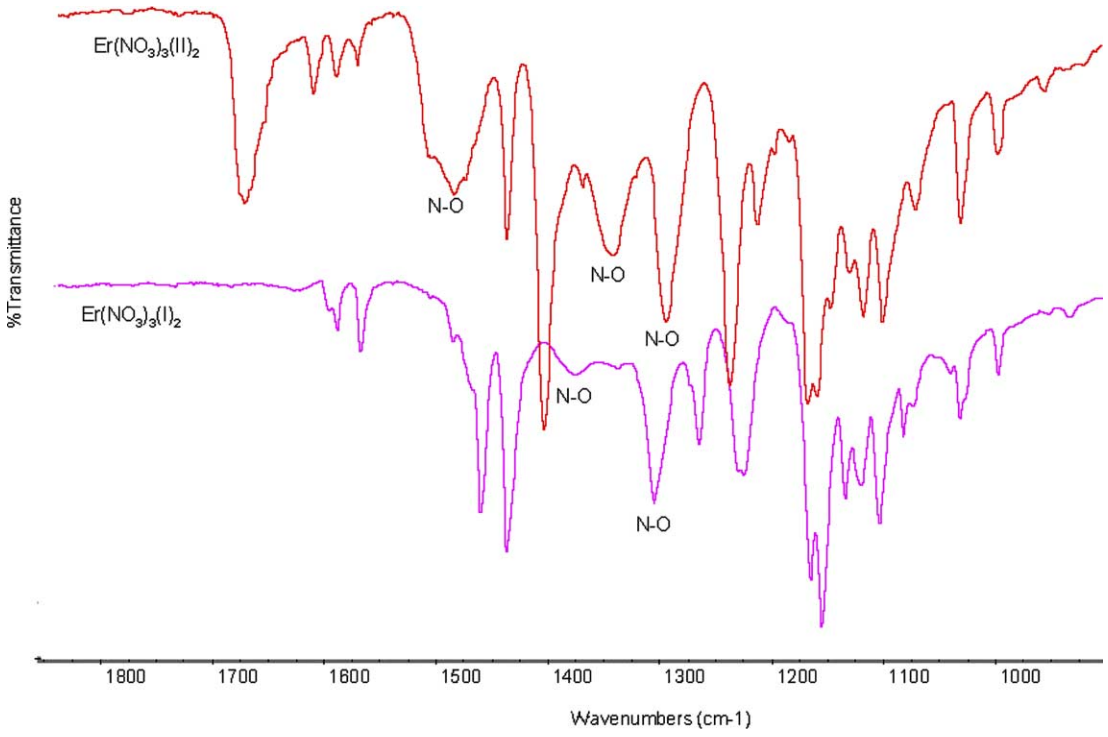

Fig. 3. Infrared spectra of $Er(NO_3)_3$ complexes of (**I**) and (**II**).

Lu) an additional splitting of the lower frequency band occurs $\Delta\nu \sim 50\ cm^{-1}$. This implies some changes to the nitrate coordination as a result of the lanthanide contraction, but in the absence of crystallographic data it is not possible to explain these differences. Fig. 3 shows the spectra of the $Er(NO_3)_3$ complexes of (**I**) and (**II**) with the bands due to nitrate indicated. Other bands are readily assigned to the ligand or water associated with the complex.

The difference in the nitrate coordination mode between the two series of complexes could arise from the ability of (**I**) to act as a tridentate ligand, thus forcing the nitrate to adopt a monodentate coordination mode. As (**II**) is unable to bond with its ether oxygen further coordination sites are available for the nitrates to adopt the bidentate mode.

2.4. Electrospray mass spectra

Mass spectra were obtained on representative complexes in methanol solution. The results are shown in Table 3. The spectra are dominated by strong signals from (**I**) and (**II**) due to $[L + H]^+$ at $m/z = 571$ (**I**) and 611 (**II**), respectively.

Ions produced by ligand redistribution are abundant in most of the spectra with $[LnL_3]^{3+}$ giving rise to the base peak for complexes of both (**I**) and (**II**). Some dependence of abundance on the size of the lanthanide ion is apparent with less sterically congested ions such as $[LnL_2]^{3+}$, $[LnXL_2]^{2+}$ and $[LnX_2L_2]^+$ being favoured over $[LnL_3]^{3+}$ for the heavier lanthanides.

Table 3
Electrospray mass spectra for LnX_3(**I**)$_2$ and LnX_3(**II**)$_2$ in methanol

Values of m/z are quoted for the most intense peak in the isotope profile and are within 1 Da of the theoretical values. The relative intensities of the signals are given in parenthesis.

3. Conclusions

The structures of the halide complexes show that with the flexible backbone structure of (**I**) chelation via the ether oxygen becomes possible. A further consequence of this flexibility appears to be the influence on the mode of coordination of the nitrate which from spectroscopic evidence is monodentate in the $Ln(NO_3)_3$ complexes of (**I**), although this remains a tentative conclusion in the absence of crystallographic characterisation.

4. Experimental

4.1. Crystallography

Data for the complexes were measured on a Bruker SMART diffractometer with a 2K CCD area detector. All data were collected using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Semi-empirical absorption corrections, based on comparison of Laue equivalents, were applied to the data sets. The structures were solved by Patterson methods and refined by full-matrix least squares cycles on F^2 for all data, using SHELXTL [13]. All non hydrogen atoms were refined with anisotropic displacement parameters and all hydrogen atoms were included in refinement cycles riding on bonded atoms. For both the Pr and Nd complexes the refinement of the metal complexes was straightforward, however peaks in the residual Fourier map satisfactorily modelled as disordered C_2H_5OH and H_2O were not stable to anisotropic refinement. The Pr complex was modelled using the SQUEEZE option of PLATON [14] with disordered atoms excluded. This indicated the presence of 4 symmetry related voids of 886 $Å^3$ at 0, 1/4, 0 and an estimate of 935 electrons/cell due to disordered solvent. The final refinement employed the modified reflection file with the estimated solvent contribution eliminated from the data. The final formula is assumed to include 2EtOH and $3H_2O$ as indicated by the Fourier map, this accounts for 656e of the 935e estimate from the SQUEEZE calculation.

4.2. Mass spectrometry

Electrospray mass spectrometry was carried out on either a Waters 2695 separation module spectra were take on a Micromass/Waters LCT at Sheffield University or at the EPSRC National mass spectrometry service at Swansea University as described previously [15].

4.3. Preparative work

4.3.1. Bis[(diphenylphosphino)phenyl]ether dioxide (**I**)

5.00 g of Bis[(diphenylphosphino)phenyl]ether was suspended in 70 ml acetone and 2.34 g 30% H_2O_2 was added. A thick white precipitate formed during the addition. The mixture was stirred for 30 min at room temperature and heated briefly to boiling and allowed to evaporate to 50 ml at room temperature. The mixture was filtered, washed with diethyl ether and dried at the pump to give 4.94 g (93%) of white solid. Electrospray mass spectrum (methanol) m/z = 571 (100%) $[(\mathbf{I}) + H]^+$, m/z = 593 (60%) $[(\mathbf{I}) + Na]^+$. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1184(s).

4.3.2. 4,5-Bis(diphenylphosphino)-9,9-dimethylxanthane dioxide (**II**)

4,5-Bis(diphenylphosphino)-9,9-dimethylxanthane 5.12 g was suspended in 30 ml acetone and 2.23 g 30% H_2O_2 was added in small portions, giving an exothermic reaction on each addition. The mixture was heated to boiling for 1 h, cooled to room temperature and allowed to stand for 16 h. The suspension was filtered and the solid washed with diethyl ether and dried at the pump to give 4.62 g (86%) white powder. Electrospray mass spectrum (methanol) m/z 611 (100%) $[(\mathbf{II}) + H]^+$. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1197(s), 1186(s).

4.3.3. $LaBr_3(\mathbf{I})_2(H_2O)_2$

Hot methanolic solutions of hydrated lanthanum bromide (0.10 g, 0.20 mmol) in 3 ml and (**I**) (0.23 g, 0.40 mmol) in 6 ml were mixed. The mixture was evaporated to dryness and the residue recrystallised from ethanol to give 0.23 g (74%) white solid. *Anal.* required: C, 55.59; H, 3.89. Found: C, 55.65; H, 4.19%. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1144(s).

4.3.4. $La(NO_3)_3(\mathbf{I})_2(H_2O)_4$

Hot ethanolic solutions of hydrated lanthanum nitrate (0.11 g, 0.25 mmol) in 2 ml was and (**I**) (0.26 g, 0.47 mmol) in 6 ml were mixed. On continued warming a white powder precipitated. The mixture was cooled and the solid filtered and dried at the pump to give 0.28 g (76%). *Anal.* required: C, 56.22; H, 4.19; N, 2.73. Found: C, 55.92; H, 4.08; N, 2.69%. Principle infrared bands (cm^{-1}) ν_{NO} 1373(w), 1295(m) $\nu_{P=O}$ 1149(s).

4.3.5. $Nd(NO_3)_3(\mathbf{I})_2(H_2O)_4$

Solutions of hydrated neodymium nitrate (0.10 g, 0.23 mmol) in 2 ml and (**I**) (0.26 g, 0.47 mmol) in 15 ml ethanol were reacted as for the La complex and gave 0.29 g (85%) of lilac solid. *Anal.* required: C, 56.03; H, 4.18; N, 2.72. Found: C, 55.42; H, 4.16; N, 2.55%. Principle infrared bands (cm^{-1}) ν_{NO} 1373(w), 1295(m), $\nu_{P=O}$ 1147(s).

4.3.6. $Yb(NO_3)_3(\mathbf{I})_2(H_2O)_3$

Hot solutions of hydrated ytterbium nitrate (0.11 g, 0.25 mmol) in 2 ml and (**I**) (0.26 g, 0.47 mmol) in 6 ml ethanol were mixed and led to the immediate formation of a white precipitate. The mixture was heated to boiling, cooled and the solid filtered, washed with ethanol and dried at the pump to give 0.23 g (60%) white solid. *Anal.* required: C, 55.64; H, 4.02; N, 2.70. Found: C, 55.58; H, 4.17; N, 2.53%. Principle infrared bands (cm^{-1}) ν_{NO} 1377(w), 1307(m), $\nu_{P=O}$ 1163(s), 1155(s).

4.3.7. $LaCl_3(\mathbf{II})_2(H_2O)_4$

$LaCl_3 6H_2O$ (0.11 g, 0.31 mmol) in 2.5 ml MeOH was mixed with a solution of (**II**) (0.37 g, 0.61 mmol) in 4 ml MeOH. The mixture was heated to boiling and cooled to room temperature. The solution was evaporated to dryness and the residue recrystallised from MeCN to give 0.25 g (52%) of colourless crystals suitable for X-ray diffraction. *Anal.* required for $LaCl_3(\mathbf{II})_2(H_2O)_4$: C, 60.89; H, 4.72; Cl, 6.91. Found: C, 60.73; H, 4.62; Cl, 6.95%. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1172(s), 1165(s).

4.3.8. $LuCl_3(\mathbf{II})_2(H_2O)_3$

$LuCl_3 6H_2O$ (0.10 g, 0.26 mmol) in 1.5 ml MeOH was mixed with a solution of (**II**) (0.34 g, 0.56 mmol) in 6 ml MeOH. The mixture was heated to boiling and cooled to room temperature when a thick suspension formed. This was evaporated to dryness and the resulting solid recrystallised from CH_3CN to give 0.39 g (96%) of colourless crystals. *Anal.* required for $LuCl_3(\mathbf{II})_2(H_2O)_3$: C, 60.18; H, 4.53; Cl, 6.83. Found: C, 60.14; H, 4.30; Cl, 7.13%. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1158(s), 1146(s).

4.3.9. $LaBr_3(\mathbf{II})_2(H_2O)_3$

$LaBr_3 6H_2O$ (0.15 g, 0.31 mmol) in 3 ml MeOH was added to a solution of (**II**) (0.38 g, 0.62 mmol) in 7 ml MeOH). After heating to boiling and cooling the solution was evaporated to dryness. The solid residue was recrystallised from MeCN giving very small crystals. A sample suitable for X-ray diffraction was obtained by recrystallising the bulk from MeCN/toluene to give 0.27 g (53%). *Anal.* required for $LaBr_3(\mathbf{II})_2(H_2O)_3{=}C_{78}H_{70}Br_3LaO_9P_4$: C, 56.64; H, 4.27; Br, 14.49. Found: C, 56.40; H, 4.16; Br, 14.97%. Principle infrared bands (cm^{-1}) $\nu_{P=O}$ 1162(s), 1148(s).

4.3.10. $[Eu(NO_3)_3]_2(\mathbf{II})_3(H_2O)_4$

Hot ethanolic solutions of hydrated europium nitrate (0.12 g, 0.27 mmol) in 5 ml and (**II**) (0.26 g, 0.42 mmol) in 5 ml were mixed. On standing at room temperature for 16 h a white precipitate formed. This was filtered, washed with ethanol and dried at the pump to give 0.25 g (72%). *Anal.* required: C, 54.47; H, 4.06; N, 3.26. Found: C, 54.66; H, 3.77; N, 3.26%. Principle

infrared bands (cm^{-1}) ν_{NO} 1464(s), 1297(s), $\nu_{P=O}$ 1155(s).

4.3.11. $Dy(NO_3)_3(\mathbf{II})_2(H_2O)_2$

Hot ethanolic solutions of hydrated dysprosium nitrate (0.11 g, 0.24 mmol) in 5 ml and (**II**) (0.28 g, 0.46 mmol) in 5 ml were mixed. No solid was deposited on standing and the solution was evaporated to dryness and the residue recrystallised from ethanol/toluene to give 0.30 g (78%) colourless powder. *Anal.* required: C, 58.34; H, 4.27; N, 2.62. Found: C, 58.40; H, 4.33; N, 2.62%. Principle infrared bands (cm^{-1}) ν_{NO} 1508(m), 1483(m), $\nu_{P=O}$ 1158(s), 1144(s).

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 237032–237035 for $LaBr_3(\mathbf{II})_2$, $LaCl_3(\mathbf{II})_2$, $NdCl_2(\mathbf{I})_2$ and $PrCl_2(\mathbf{I})_2$ complexes, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk; http://www.ccdc.cam.ac.uk).

Preparation and coordination chemistry of *p*-(xylylenediaminodiphenyl) phosphine

Alexandra M.Z. Slawin, Joanne Wheatley, J. Derek Woollins *

School of Chemistry, University of St. Andrews, St. Andrews, Fife KY16 9ST, UK

Received 17 June 2004; revised 10 September 2004; accepted 20 September 2004

Abstract

Reaction of *p*-xylene diamine with two equivalents of Ph_2PCl in the presence of NEt_3, proceeds in thf to give *p*-(xylylenediaminodiphenyl) phosphine **1** in good yield. **1** was derivatised as the dichalcogenides $Ph_2P(O)NHCH_2(C_6H_4)CH_2NHP(O)Ph_2$, $Ph_2P(S)NHCH_2(C_6H_4)CH_2NHP(S)Ph_2$ and $Ph_2P(Se)NHCH_2(C_6H_4)CH_2NHP(Se)Ph_2$ and the structures of the latter two compounds determined crystallographically. The binuclear compounds $[\{(PEt_3)PtCl_2(Ph_2PNHCH_2)\}_2C_6H_4]$ (**5**), $[\{(PPhMe_2)PtCl_2(Ph_2PNHCH_2)\}_2C_6H_4]$ (**6**), $[\{IrCl_2(\eta^5\text{-}C_5Me_5)(Ph_2PNHCH_2)\}_2C_6H_4]$ (**7**) $[\{RhCl_2(\eta^5\text{-}C_5Me_5)(Ph_2PNHCH_2)\}_2C_6H_4]$ (**8**), $[\{RuCl_2(\eta^6\text{-}p\text{-}MeC_6H_4{}^iPr)(Ph_2PNHCH_2)\}_2C_6H_4]$ (**9**), $[\{Pd(\eta^3\text{-}C_3H_5)Cl(Ph_2PNHCH_2)\}_2C_6H_4]$ (**10**), $[\{RhCl(C_8H_{12})(Ph_2PNHCH_2)\}_2C_6H_4]$ (**11**), $[\{AuCl(Ph_2PNHCH_2)\}_2C_4H_6]$ (**12**) have been prepared and characterised spectroscopically.

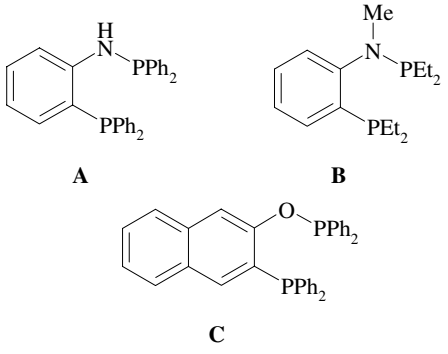
Keywords: Ligand; Bidentate; Bridging; X-ray; Phosphine

1. Introduction

Bridging ligands are of interest as they can form a number of bi-, tri- and tetra-nuclear species. There are a variety of different ligands that can have bridging properties and these include *o*-, *m*- and *p*-derivatives of benzene or pyridine. For example, $Ph_2PNHC_6H_4PPh_2$ [1,2], (**A**), ($Et_2PN(Me)C_6H_4PEt_2$) [3], (**B**), and 1-(diphenylphosphany)naphtha-2-oxydiphenylphosphane [4], (**C**)



whilst 2,6-bis(diphenylphosphino)pyridine, ($\{Ph_2P\}_2py$), an *o*-bidentate pyridine, has the potential to act as a tridentate PNP ligand [5,6] and was shown to react with a variety of platinum and palladium starting materials to give four different complexes. Gaw et al. [7] recently reported the preparation of the tetradentate (phosphine)amine 1,4-$\{(Ph_2P)_2NCH_2\}_2C_6H_4$. They used this

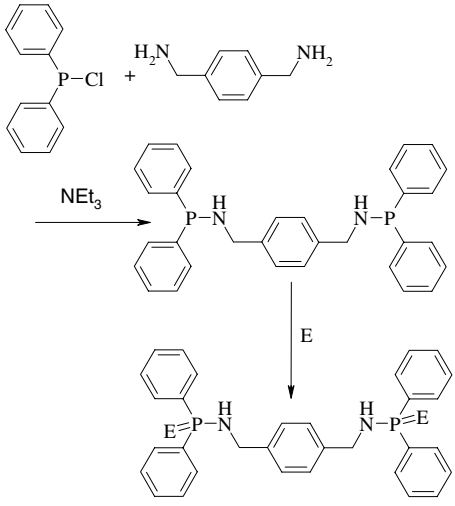
ligand to form a binuclear complex containing two *cis*-$[Mo(CO)_4]$ metal fragments.

Here, we report the preparation of a new phosphine *p*-(xylylenediamonodiphenyl)phosphine which has the potential to act as a bidentate bridging ligand. Illustrative coordination complexes have been prepared.

2. Results and discussion

Reaction of *p*-xylene diamine with two equivalents of Ph_2PCl in the presence of NEt_3, proceeds in thf to give **1** (Eq. (1)) in very good yield (89%) with δ_P 43.3 ppm. The IR spectrum has bands at 3303, 1432 and 997 cm^{-1} that are assigned to ν_{NH}, ν_{PPh} and ν_{PN}, respectively, (ν_{PPh} represents the ν_{CC} of the phosphine aromatic rings). The mass spectrum gave the expected parent ion and fragmentation pattern and microanalysis gave good results.



(1)

The oxide (**2**) $Ph_2P(O)NHCH_2(C_6H_4)CH_2NHP(O)Ph_2$ was easily prepared by addition of excess aqueous hydrogen peroxide to **1** in thf whilst the sulfur (**3**) and selenide (**4**) analogues were prepared by the addition of elemental S or Se to **1** in toluene. The EI^+ mass spectral data obtained for these chalcogenides gave the expected parent ions and fragmentation patterns. $^{31}P\{^1H\}$ NMR showed single resonances ($CDCl_3$) at δ_P 24.5 and 60.5 ppm for the oxide and sulfide and at δ_P 58.6 ppm with selenium satellites $^1J(^{31}P–^{77}Se)$ 756 Hz for **4** which is typical for a P=Se group [8].

In the solid state the sulfur and selenide analogues, although not isomorphous, are isostructural, (Fig. 1, Table 1) both have a centre of symmetry; in **3** P(1)–S(1) = 1.9523(11) and P(1)–N(2) = 1.654(3) Å and in **4** P(1)–N(2) = 1.654(5) Å and the P(1)–Se(1) = 2.1198(10) Å which are in the range for previously reported bond lengths [8].

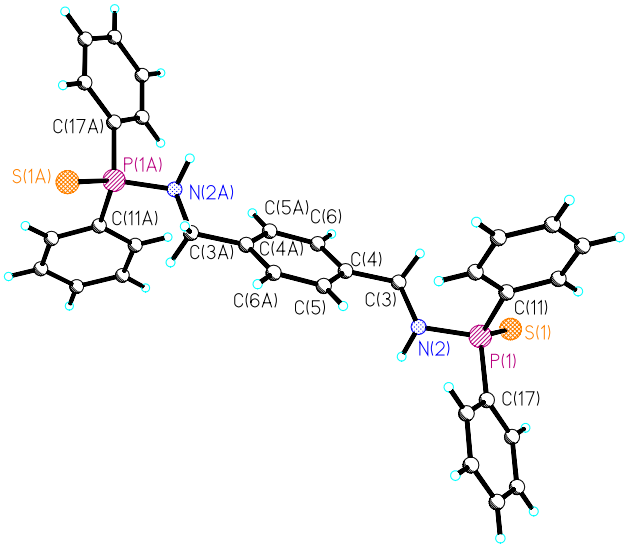


Fig. 1. X-ray structure of *p*-$Ph_2P(S)NHCH_2(C_6H_4)CH_2NHP(S)Ph_2$ (**3**).

Table 1
Selected bond lengths (Å) and angles (°) for *p*-$Ph_2P(S)NHCH_2(C_6H_4)$-$CH_2NHP(S)Ph_2$ (**3**) and *p*-$Ph_2P(Se)NHCH_2(C_6H_4)CH_2NHP(Se)Ph_2$ (**4**). The values in square brackets are for the second independent molecule in **3**

A range of binuclear compounds were synthesised (Eq. (2)); thus reaction of $[\{PtCl(\mu\text{-}Cl)(PEt_3)\}_2]$ with **1** gives $[\{(PEt_3)PtCl_2(Ph_2PNHCH_2)\}_2C_6H_4]$ (**5**). The EI^+ mass spectrum of (**5**) contains the expected parent ion and fragmentation pattern and the complex displays resonances with platinum satellites in the $^{31}P\{^1H\}$ NMR spectrum (δ_{PA} 34.0 ppm, $^1J\{^{31}P_A–^{195}Pt\}$ 1984 Hz, δ_{PX} 7.5 ppm, $^1J\{^{31}P_X–^{195}Pt\}$ 1715 Hz $^2J\{^{31}P_A–^{31}P_X\}$ 18 Hz). The IR spectrum has ν_{NH} at 3289 cm^{-1}, ν_{PPh} and ν_{PN} at 1435 and 997 cm^{-1}, respectively, and two ν_{PtCl} (symmetric and antisymmetric) bands at 340 and 310 cm^{-1} suggesting a *cis* geometry at the metal. (**6**–**9**) were prepared in a similar way and have comparable spectroscopic properties to **5** (Table 2) see Fig. 2.

[$(Pd(\eta^3\text{-}C_3H_5)Cl(Ph_2PNHCH_2))_2C_6H_4$] (**10**) was prepared (68%) from [{$Pd(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)$}$_2$] and **1** in dichloromethane. The microanalysis obtained was satisfactory for the suggested structure and EI^+ mass spectral data gave the expected parent ion and fragmentation pattern. The IR spectrum has bands at 3246, 1433, 998, 276 cm^{-1} that correspond to the ν_{NH}, ν_{PPh}, ν_{PN} and ν_{PdCl} vibrations. The ^{31}P NMR ($CDCl_3$) is a single peak at δ_P 58.1 ppm. Similarly, complex (**11**) was prepared by reaction of [{$Rh(\mu\text{-}Cl)(cod)$}$_2$] and **1** (Eq. (3)).

We also prepared a simple bimetallic gold complex **12**. It is clear from the above observations that **1** is readily prepared and able to function as a bridging ligand, but there is no evidence for **1** behaving as a bidentate *trans* ligand (see Table 3).

3. Experimental

Unless otherwise stated, all reactions were carried out under an oxygen-free nitrogen atmosphere using standard Schlenk techniques. Diethyl ether and thf were purified by reflux over sodium-benzophenone and distillation under nitrogen. Dichloromethane was heated to reflux over calcium hydride and distilled under nitrogen. Toluene and hexane were heated to reflux over sodium and distilled under nitrogen. The complexes [AuCl(tht)] (tht = tetrahydrothiophene)[9], $[MCl_2(cod)]$ (M = Pt or Pd; cod = cycloocta-1,5-diene)[10,11], $[\{RuCl(\mu\text{-}Cl)(\eta^6\text{-}p\text{-}MeC_6H_4{}^iPr)\}_2]$[12], $[\{Rh(\mu\text{-}Cl)(cod)\}_2]$[13], $[\{Pd(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)\}_2]$ $[\{MCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (M = Rh or Ir) [14] $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$[15] and $[\{PtCl(\mu\text{-}Cl)(PEt_3)\}_2]$ [16] were prepared using the literature procedures. Chlorodiphenylphopshine was distilled prior to use. NEt_3 (99% purity), ^{t}BuOK (95% purity), H_2O_2 (30 wt% in H_2O), *p*-xylylene diamine and reagent grade KBr were used without further purification. Infra-red spectra were recorded as KBr discs in the range 4000–200 cm^{-1} on a Perkin–Elmer 2000 FTIR/RAMAN spectrometer. ^{31}P and ^1H NMR spectra were recorded on a Gemini 2000 spectrometer (operating at 121.4 MHz for ^{31}P and 300 MHz for ^1H) or a JEOL DELTA 270 and are referenced to 85% H_3PO_4 and tetramethylsilane, respectively. Microanalyses were performed by the St. Andrews University service and mass spectra by the Swansea Mass Spectrometer Service.

3.1. $Ph_2PNHCH_2C_6H_4CH_2NHPPh_2$ (1)

To a stirring solution of triethylamine (2.26 g, 22.29 mmol) in thf (100 cm^3) at room temperature was added a thf (50 cm^3) solution of chlorodiphenylphosphine (4.92 g, 22.29 mmol) over 2 h and simultaneously a thf solution of *p*-xylylene diamine (1.52 g, 11.14 mmol) over 2 h. The stirring was continued for a further hour before removing the colourless precipitate that had formed by filtration and the solvent removed to yield a colourless solid which was recrystallised from dichloromethane and hexane to give the desired product as a fine colourless solid that was collected by suction filtration and dried in vacuo. Yield 4.99 g, 89%. ^1H ($CDCl_3$) δ 1.4 (m, 4H, CH_2), 4.1 (br s, 2H, NH), 7.3–7.9 (m, 24H, aromatics). MS: *m/z* 504 $[M]^+$.

3.2. $Ph_2P(O)NHCH_2C_6H_4CH_2NHP(O)Ph_2$ (2)

AqueousHydrogen peroxide (30% w/w, 0.1 cm^3, 0.9 mmol) was added drop wise to a suspension of $Ph_2PNHCH_2C_6H_4CH_2NHPPh_2$ (223 mg, 0.4 mmol) in thf (10 cm^3) and the mixture was stirred for 30 min. The solution was filtered through Celite to remove a small amount of insoluble material and the solvent was removed in vacuo to give viscous oil, which was dissolved in dichloromethane (0.5 cm^3) before precipitating a colourless solid upon addition of diethyl ether (6 cm^3). The product was collected by suction filtration and dried in vacuo. Yield 188 mg, 79%. ^1H NMR ($CDCl_3$): δ 1.4 (m, 4H, CH_2), 4.1 (br s, 2H, NH), 7.3–7.9 (m, 24H, aromatics) ppm. MS: *m/z* 559 $[M + Na]^+$.

3.3. $Ph_2P(S)NHCH_2C_6H_4CH_2NHP(S)Ph_2$ (3)

$Ph_2PNHCH_2C_6H_4CH_2NHPPh_2$ (214 mg, 0.4 mmol) and sulfur (27 mg, 0.8 mmol) were heated to reflux in toluene (15 cm^3) for 4 h. The reaction mixture was filtered through Celite to remove any insoluble material remaining befpre reducing the solvent to yield an off-white solid that was washed with $CHCl_3$ (5 cm^3) and dried in vacuo. Yield 106 mg, 44%. ^1H NMR ($CDCl_3$): δ 1.4 (m, 4H, CH_2), 4.1 (d, 2H, ^2J (^{31}P–^1H) 8 Hz, NH), 7.2–8.0 (m, 24H, aromatics) ppm. MS: *m/z* 591 $[M + Na]^+$.

3.4. $Ph_2P(Se)NHCH_2C_6H_4CH_2NHP(Se)Ph_2$ (4)

$Ph_2PNHCH_2C_6H_4CH_2NHPPh_2$ (198 mg, 0.4 mmol) and grey selenium (62 mg, 0.8 mmol) were heated to reflux in toluene (10 cm^3) for 5 h. The solvent was removed in vacuo and the crude product was taken up in CH_2Cl_2 (5 cm^3) and filtered through Celite to remove a trace of unreacted selenium. The filtrate was evaporated to dryness to yield an off-white solid, which was dried in vacuo overnight. Yield 189 mg, 73%. ^1H NMR ($CDCl_3$): δ 1.4 (m, 4H, CH_2), 4.1 (d, 2H, ^2J (^{31}P–^1H) 8 Hz, NH), 7.2–8.0 (m, 24H, aromatics) ppm. MS: *m/z* 681 $[M + Na]^+$.

3.5. $[\{(PEt_3)PtCl_2(Ph_2PNHCH_2)\}_2C_6H_4]$ (5)

$[\{PtCl(\mu\text{-}Cl)(PEt_3)\}_2]$(39 mg, 0.05 mmol) and ligand (26 mg, 0.05 mmol) were dissolved in dichloromethane (5 cm^3) and stirred overnight. The reaction mixture was filtered through Celite to remove any insoluble material and then reduced to 0.5 cm^3 before addition of diethyl ether (10 cm^3) to precipitate a colourless solid that was isolated by filtration and dried in vacuo. Yield 45 mg, 69%. ^1H ($CDCl_3$) δ 1.0 (m, 18H, CH_3), 1.2 (m, 12H, CH_2), 1.4 (m, 4H, CH_2N), 4.1 (d, 2H, ^2J(^{31}P–^1H) 8 Hz, NH), 7.2–8.0 (m, 24H, aromatics) ppm. MS: *m/z* 1293 $[M + Na]^+$, 1235 $[M - Cl]^+$, 1200 $[M - 2Cl]^+$.

3.6. [{(PPhMe$_2$)PtCl$_2$(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$] (**6**)

[{PtCl(μ-Cl)(PMe$_2$Ph)}$_2$](41 mg, 0.05 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (26 mg, 0.05 mmol) were dissolved in dry CH_2Cl_2 (5 cm^3) and stirred overnight. The pale yellow solution formed was filtered through Celite to remove any inorganic impurities before reducing the solvent volume to 0.5 cm^3 and addition of diethyl ether (10 cm^3) to precipitate a colourless solid that was isolated by suction filtration and dried in vacuo. Yield 40 mg, 60%. ^{1}H ($CDCl_3$) δ 1.2 (m, 12H, CH_3), 1.4 (m, 4H, CH_2N), 4.1 (d, 2H, ^2J(^{31}P–^{1}H) 8 Hz, NH), 7.2–8.0 (m, 34H, aromatics) ppm. MS: *m/z* 1333 [M + Na]$^+$, 1275 [M − Cl]$^+$, 1239 [M − 2Cl]$^+$.

3.7. [{(IrCl$_2$η^5-C$_5$Me$_5$)(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$] (**7**)

[{IrCl(μ-Cl)(^{5}-ηC$_5$Me$_5$)}$_2$](50 mg, 0.06 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (32 mg, 0.06 mmol) were dissolved in dry CH_2Cl_2 (5 cm^3) and stirred for 2 h. The orange solution was filtered through Celite to remove a small amount of insoluble material before reducing the volume to 0.5 cm^3 and addition of diethyl ether (20 cm^3) to precipitate an orange solid that was isolated by filtration and dried in vacuo. Yield 60 mg, 73%. ^{1}H ($CDCl_3$) δ 1.3 (s, 30H, CH_3), 1.5 (m, 4H, CH_2N), 4.1 (d, 2H, ^2J (^{31}P–^{1}H) 8 Hz, NH), 7.2–8.0 (m, 24 H, aromatics) ppm MS: *m/z* 1323 [M + Na]$^+$, 1158 [M − 4Cl]$^+$.

3.8. [{RhCl$_2$(η^5-C$_5$Me$_5$)(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$] (**8**)

[{RhCl(μ-Cl)(η^5-C$_5$Me$_5$)}$_2$](48 mg, 0.08 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (39 mg, 0.08 mmol) were dissolved in dry CH_2Cl_2 (5 cm^3) and stirred for 2 h. The orange solution was filtered through Celite to remove a small amount of insoluble material before reducing the volume to 0.5 cm^3 and addition of diethyl ether (10 cm^3) to precipitate an orange solid that was isolated by filtration and dried in vacuo. Yield 68 mg, 78%. ^{1}H ($CDCl_3$) δ 1.3 (s, 30H, CH_3), 1.5 (m, 4H, CH_2N), 4.1 (d, 2H, ^2J(^{31}P–^{1}H) 8 Hz, NH), 7.2–8.0 (m, 24 H, aromatics) ppm. MS: *m/z* 1145 [M + Na]$^+$, 1087 [M − Cl]$^+$, 1049 [M − 2Cl]$^+$.

3.9. [{RuCl$_2$(η^6-*p*-MeC$_6$H$_4$^{i}Pr)(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$] (**9**)

[{RuCl(μ-Cl)(η^6-*p*-MeC$_6$H$_4$^{i}Pr)}$_2$] (47 mg, 0.08 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (39 mg, 0.08 mmol) were dissolved in dry CH_2Cl_2 (5 cm^3) and stirred for 1 h. The orange solution was filtered through Celite to remove a small amount of insoluble material before reducing the volume to 0.5 cm^3 and addition of diethyl ether (10 cm^3) to precipitate an orange solid that was isolated by filtration and dried in vacuo. Yield 62 mg, 72%. ^{1}H ($CDCl_3$) δ 0.8 (m, 12H, CH_3), 1.2 (6H, CH_3), 1.9 (m, 4H, CH_2N), 2.5 (m, 2H, CH), 4.1 (d, 2H, ^2J (^{31}P–^{1}H) 8 Hz, NH), 7.2–8.0 (m, 28H, aromatics) ppm. MS: *m/z* 1139 [M + Na]$^+$.

3.10. [{Pd(η^3-C$_3$H$_5$)Cl(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$]. (**10**)

[{Pd(μ-Cl)(η^3-C$_3$H$_5$)}$_2$](61 mg, 0.2 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (84 mg, 0.2 mmol) were dissolved in dry CH_2Cl_2 (5 cm^3) and stirred overnight. The reaction mixture was filtered through Celite to remove any insoluble inorganic material before reducing the solvent to 0.5 cm^3 and addition of diethyl ether (10 cm^3) to precipitate a yellow microcrystalline solid that was isolated by suction filtration. Yield 98 mg, 68%. ^{1}H ($CDCl_3$) δ 1.3 (m, 8H, CH_2), 1.9 (m, 4H, CH_2N), 2.5 (m, 2H, CH), 4.1 (d, 2H, ^2J (^{31}P–^{1}H) 8 Hz, NH), 7.2–8.0 (m, 24H, aromatics) ppm. MS: *m/z* 835 [M − Cl]$^+$.

3.11. [{RhCl(C$_8$H$_{12}$)(Ph$_2$PNHCH$_2$)}$_2$C$_6$H$_4$] (**11**)

[{Rh(cod)Cl}$_2$](49 mg, 0.1 mmol) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (50 mg, 0.1 mmol) were dissolved in dry toluene (5 cm^3) and stirred for 2 h. The solution was filtered through Celite to remove a small amount of insoluble material before reducing the volume to 0.5 cm^3 and addition of hexane (20 cm^3) to precipitate a yellow solid that was isolated by filtration and dried in vacuo. Recryst from CH_2Cl_2/hexane. Yield 56 mg, 57%. ^{1}H ($CDCl_3$) δ 1.8 (m, 24H, C_8H_{12}), 1.9 (m, 4H, CH_2N), 4.1 (d, 2H, ^2J(^{31}P–^{1}H) 8dz, NH), 7.2–8.0 (m, 24H, aromatics) ppm MS: *m/z* 961 [M − Cl]$^+$.

3.12. [{AuCl(Ph$_2$PNHCH$_2$)}$_2$C$_4$H$_6$] (**12**)

[AuCl(tht)] (116 mg, 0.4 mmol) was dissolved in dry CH_2Cl_2 (5 cm^3) and Ph$_2$PNHCH$_2$C$_6$H$_4$CH$_2$NHPPh$_2$ (91 mg, 0.2 mmol) was added in one portion before stirring for 30 min. The colourless solution was filtered through Celite to remove a small amount of insoluble material before reducing the volume to 2 cm^3 precipitate a colourless solid that was isolated by suction filtration and dried in vacuo. Yield 88 mg, 43%. ^{1}H ($CDCl_3$) δ 1.6 (s, 4H, CH_2N), 4.2 (d, 2H, ^2J(^{31}P–^{1}H) 10 Hz, NH), 7.2–8.0 (m, 24H, aromatics) ppm MS: *m/z* 991 [M + Na]$^+$, 933 [M − Cl]$^+$.

4. Crystallography

X-ray diffraction studies were performed at 125 K using a Bruker SMART diffractometer with graphite-monochromated Mo Kα radiation. The structures were solved by direct methods, non-hydrogen atoms were refined with anisotropic displacement parameters;

hydrogen atoms bound to carbon were idealised, the NH protons were located by a ΔF map. Structural refinements were by the full-matrix least-squares method on F^2 using SHELXTL [17].

Full lists of structure refinement data, atomic coordinates, bond lengths and angles, anisotropic displacement parameters and hydrogen atom parameters have been deposited as supplementary material, CCDC Nos. 239833 and 239834 at the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk, or http://www.ccdc.cam.ac.uk].

Synthesis and coordination of 2-diphenylphosphinothiophenocarboxamide and bis(2,5-diphenylphosphinepicolinamide)

Heather L. Milton, Matthew V. Wheatley, Alexandra M.Z. Slawin, J. Derek Woollins *

School of Chemistry, University of St. Andrews, St. Andrews, Fife KY16 9NB, UK

Received 29 June 2004; accepted 20 September 2004

Abstract

2-Diphenylphosphinothiophenocarboxamide (dpptc) and bis(2,5-diphenylphosphinepicolinamide) (bdpppa) have been prepared and complexed with a variety of metals. Bdpptc behaves as a monodentate P donor ligand and can become bidentate by making use of the C=O site. Bdpppa behaves as a P donor bridging ligand. In many cases, the X-ray structures reveal that the ligand backbone geometry is strongly influenced by intramolecular H-bonding.

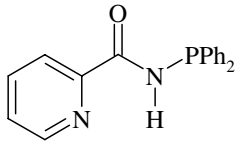
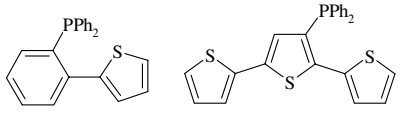
1. Introduction

Hemilabile phosphorus–nitrogen ligands are of great interest and we have recently described the synthesis and coordination of 2-diphenylphosphinopicolinamide (dpppa) and other P–N-based ligands [1,2].



dpppa

There are few known examples of phosphino-thiophenes, and even fewer that act as bidentate phosphino-thiophene ligands. Clot et al. described the major examples in 2000 [3]; 2-(2′-{diphenylphosphino}phenyl)thiophene (dpppth) (**A**) and 3′-diphenylphosphino-2,2′:5′,2″-terthiophene (dppterth) (**B**).



A **B**

These ligands were both shown to bind with a bidentate motif on reaction with $[RuCl_2(PPh_3)_3]$.

Early bridging diphosphines include 2,6-bis(diphenylphosphino)pyridine ($(Ph_2P)_2py$) (**C**), 2,6-(diphenylphosphinomethyl)pyridine (**D**) and *N*,*N*′-bis(diphenylphosphino)-2,6-diaminopyridine (**E**) [4]. These ligands are commonly found as bridging ligands and bidentate ligands with a variety of transition metals.

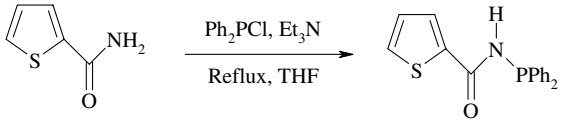
Here, we describe two new hemilabile ligands: 2-diphenylphosphinothiophenocarboxamide (dpptc) and bis(2,5-diphenylphosphinepicolinamide) (bdpppa). The coordination properties are compared with dpppa.

2. Results and discussion

The synthesis of dpptc (**1**) is analogous to that of dpppa (Eq. (1)).



(1)

1

The ligand is readily soluble in chlorinated solvents, acetone, tetrahydrofuran, somewhat less so in toluene, methanol and diethylether. A singlet is observed in the ^{31}P spectrum of dpptc at δ(P) 25.9 ppm; comparable with the value for dpppa. The ^{1}H NMR spectrum does not show the presence of an amide proton, as this resonance is obscured by the main body of the aromatic protons. The IR spectra shows the expected peaks, a weak ν(N–H) band is present at 3265 cm^{-1} together with bands attributable to ν(thCS) and ν(P–N) at 1096 and 996 cm^{-1} respectively, with ν(C–N) coming at 1522 cm^{-1}. The expected ν(C=O) signature is visible at 1624 cm^{-1}.

Only the sulfide of dpptc was synthesised (by reaction of dpptc with elemental sulfur in toluene, dpptc-S (**3**), δ(P) 57.2 ppm) as a representative example of the P(V) form. However, a crystal of the oxide derivative was obtained via air oxidation of the free ligand in a $CDCl_3$ solution (Fig. 1). In the solid state, the molecules adopt a chain line structure as a consequence of hydrogen bonding.

Dpptc reacts with [$PtCl_2$(cod)] in dichloromethane to give *cis*-[$PtCl_2$(dpptc-*P*)$_2$] (**4**), no *trans*-bis(dpptc) or mono-(dpptc) binding was observed. The ^{31}P NMR of **4** is a singlet at δ(P) 27.9 ppm with the expected platinum satellites, $^{1}J_{Pt-P}$ = 3870 Hz, consistent with phosphorus *trans* to chloride. The ^{1}H NMR spectrum

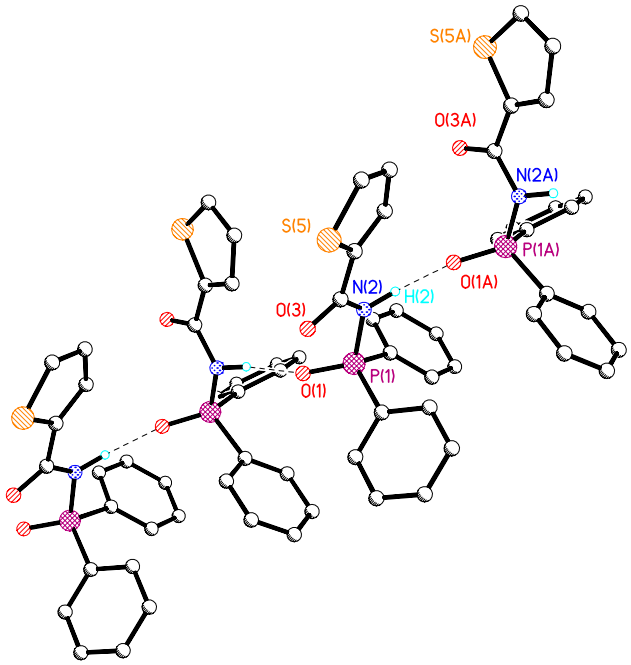


Fig. 1. Crystal structure of dpptc-*O*, **2**, selected bond lengths (Å) and angles (°): P(1)–O(1) 1.456(3), P(1)–N(2) 1.692(3), O(3)–C(3) 1.229(4), N(2)–C(3) 1.373(5), C(3)–C(4) 1.463(5), S(5)–C(4) 1.725(4), C(4)–C(8) 1.365(5), N(2)–O(1) 2.80, N(2)–P(1)–O(1) 115.10(16), C(17)–P(1)–O(1) 112.61(16), N(2)–H(2)···O(1) 171.

displays the anticipated changes from the free ligand. The amine proton is shifted to δ(H) 9.7 ppm, also the coupling constant has increased to $^{2}J_{P-H}$ = 11 Hz. The ν(N–H) vibration in the IR spectrum has shifted to a lower wave number (3214 cm^{-1}), suggesting the possibility of intermolecular hydrogen bonding interactions within the complex. The ν(C=O) also shifts considerably to 1672 cm^{-1} Two Pt-Cl stretches are visible in the spectrum (304 and 273 cm^{-1}), another indication of a *cis*-conformation in **4**.

Reaction of dpptc with [{Pd(μ-Cl)(η^3-C_3H_5)}$_2$] gives the expected monodentate dpptc complex [PdCl(η^3-C_3H_5)(dpptc-*P*)] (**5**), δ(P) 54.3 ppm. The X-ray structure of **5** (Fig. 2) confirms the *P* coordination and displays hydrogen bonding, [N(7)–H(7)···Cl(1) 3.166 Å, with a N(7)–H(7)···Cl(1) 131°], there is no evidence of sulfur coordination.

The mixed phosphine complex [$PtCl_2$($PPhMe_2$)-(dpptc-*P*)] (**6**) was synthesised from [{PtCl(μ-Cl)-($PPhMe_2$)}$_2$] and dpptc in dichloromethane. The ^{31}P NMR of **6** showed two doublets with the appropriate platinum satellites [δ(P) 29.7 ppm, $^{2}J_{P-P}$ = 18.8 Hz, $^{1}J_{Pt-P}$ = 3890 Hz, δ(P) −15.6 ppm, $^{2}J_{P-P}$ = 18.8 Hz, $^{1}J_{Pt-P}$ = 3500 Hz], which are consistent with two phosphorus *cis*- to each other and *trans*- to a chloride (see Fig. 3).

Further monodentate complexes were synthesised (Scheme 1) and these all exhibited the expected spectroscopic properties.

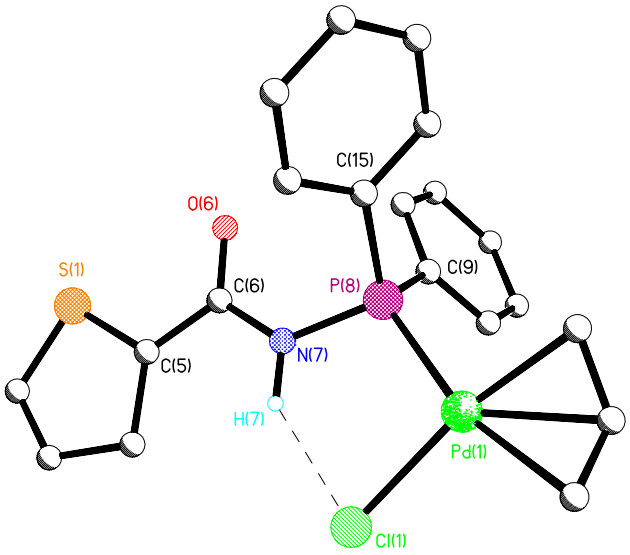

Fig. 2. Crystal structure of [PdCl(η^3-C_3H_5)(dpptc-P)] (**5**), selected bond lengths (Å) and angles (°): P(8)–Pd(1) 2.2937(14), Pd(1)–Cl(1) 2.3780(13), P(8)–N(7) 1.706(4), N(7)–C(6) 1.377(6), O(6)–C(6) 1.227(6) C(6)–C(5) 1.455(8), S(1)–C(5), 1.712(6), N(7)···Cl(1) 3.166(4), P(8)–Pd(1)–Cl(1) 97.18(4), C(15)–P(8)–Pd(1) 116.93(15), N(7)–P(8)–Pd(1) 106.26(14), C(9)–P(8)–Pd(1) 114.06(16), N(7)–H(7)···Cl(1) 131(4).

The X-ray structure of **8** is in space group $P2_12_12_1$ Flack parameter 0.01(3) but we have no evidence there is only one isomer in solution. In **8** there is an interaction between the amide proton and both chlorides attached to the metal and it is worthy of note that there is no interaction involving the oxygen or the sulfur heteroatom in the ring. This could be due to the fact that the sulfur is less likely to form a hydrogen bond, or that the geometry of the five-membered ring as opposed to that of the six-membered ring is less favourable for an N(2)–H(2)···S(5) interaction. These issues and the easy availability of the chlorides account for the chosen motif in this molecule. In the X-ray structure of **9** (Fig. 4), the two hydrogen bonds present are almost identical, showing the favourable motif that can be produced by *trans*-coordination. **10** also has (Fig. 5) H-bond interactions with a N(2)–H(2)···Cl(1) hydrogen bond controlling the ligands geometry, forming a pseudo five-membered ring, similar to the ones we have seen previously; again the sulfur has no part in the bonding motif.

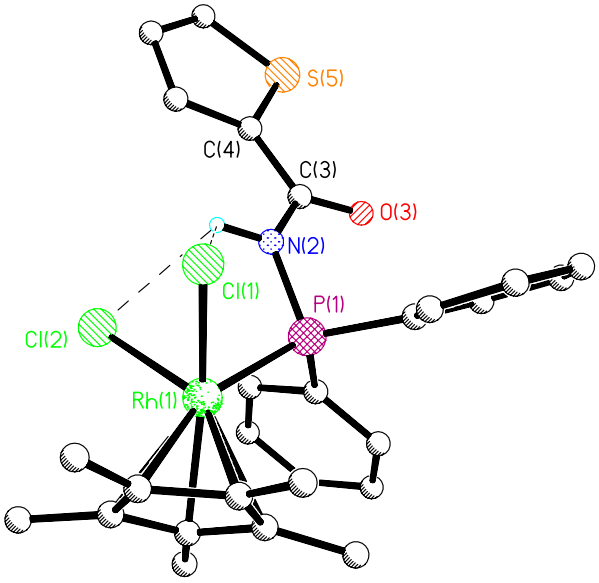

Fig. 3. Crystal structure of [$RhCl_2$(η^5-C_5Me_5)(dpptc-P)] (**8**), selected bond lengths (Å) and angles (°): P(1)–Rh(1) 2.3077(10), Rh(1)–Cl(1) 2.3998(9), Rh(1)–Cl(2) 2.4163(9), P(1)–N(2) 1.695(3), O(3)–C(3) 1.218(4) N(2)–C(3) 1.387(4), N(2)···Cl(1) 3.379(3), N(2)···Cl(2) 3.113(3), P(1)–Rh(1)–Cl(1) 89.44(3), P(1)–Rh(1)–Cl(2) 89.19(3), Rh(1)–P(1)–N(2) 106.88(10), Cl(1)–Rh(1)–Cl(2) 87.96(3), N(2)–H(2)···Cl(1) 112(3), N(2)–H(2)···Cl(2) 121(3).

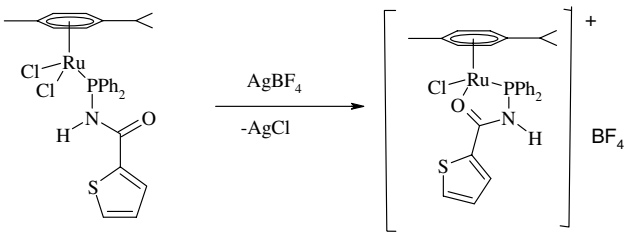
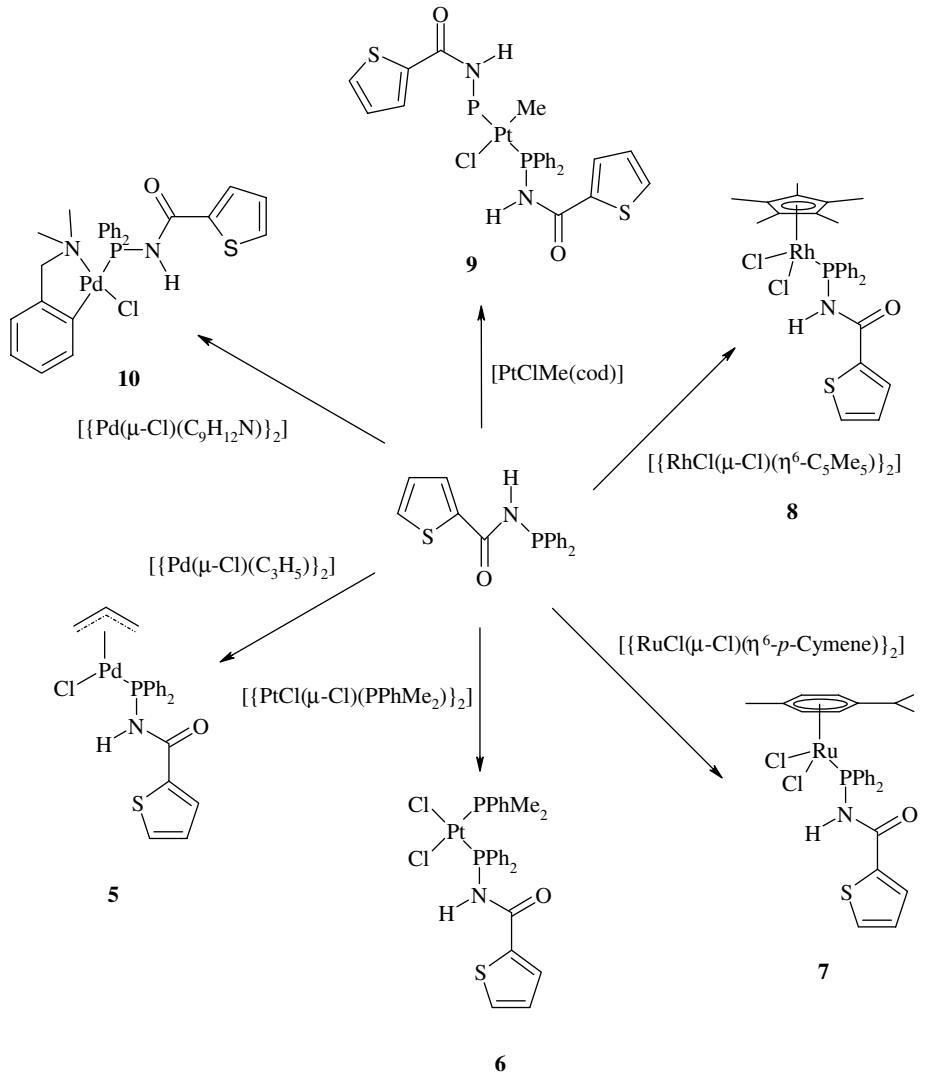
Dpptc also exhibits bidentate chemistry, though there are significant differences between the chemistry of dpppa and dpptc. Reaction of a halide abstraction reagent with monodentate dpppa complexes gives the *P*,*N* bidentate species. In the case of dpptc, when the same reaction is undertaken one might expect the binding of the thiophene sulfur atom or chelation via the C=O group since thiophene is not an especially good ligand. The coordination mode can be investigated by IR spectroscopy, the frequency of the ν(C=O) vibration indicating chelation through the oxygen. The example investigated was reaction of [$RuCl_2$(*p*-cymene)(dpptc-*P*)] with $AgBF_4$ in CH_2Cl_2, the silver salt was removed by filtration and the product [RuCl(*p*-Cy)(dpptc-*P*,*O*)]BF_4 (**11**) precipitated with diethylether. The ^{31}P NMR displays the expected downfield shift in the spectrum, the peak moves from δ(P) 59.9–100.0 ppm, again the chelate ring effect is responsible for this. The proton spectrum shows some interesting aspects, as the amine proton moves from δ(H) 7.9 ppm in the monodentate complex to δ(H) 10.1 ppm in the bidentate complex and changes from a doublet to a broad singlet, this is typical of extensive hydrogen-bonding being present. The ν(NH) is unchanged in comparison with the monodentate complex at 3216 cm^{-1}. The important IR data is the ν(C=O) – chelation would cause a high frequency shift and this is observed with the band moving to 1561 cm^{-1}, a shift of 104 cm^{-1} from the monodentate complex, typical of C=O bound, bidentate ligand, as described by Braunstein [5]. We also observed the $[BF_4]^-$ counterion in the IR spectrum.

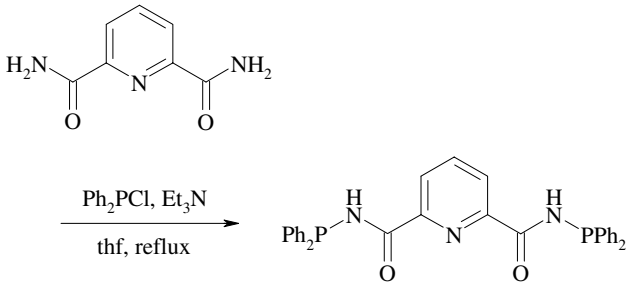


(2)



Scheme 1. Formation of monodentate complexes of dpptc.

The synthesis of bdpppa (**12**) is very similar to that of dpppa (Eq. (3)).



(3)

The expected singlet in the ^{31}P NMR is observed at δ(P) 21.9 ppm. This is extremely close to the value for dpppa (22.0 ppm). We see the same similarities in the proton spectra, the N–H peak appears again as a doublet with a more or less identical shift to dpppa at δ(H) 8.4 ppm, however the coupling constant is significantly larger for bdpppa, being 8 Hz as compared to 4 Hz for dpppa. When one examines the IR spectra for bdpppa we see some significant deviation in the characteristics of bdpppa compared to dpppa. In bdpppa ν(N–H) vibrations are visible at 3345 and 3262 cm^{-1}, this trend continues into the ν(C=O) vibrations – again two are visible at 1665 and 1646 cm^{-1}, the ν(C=N) stretches are also twinned at 1588 and 1571 cm^{-1}. However there is only one ν(P–N) vibration observed at 999 cm^{-1}; from this we could surmise that there is a slight difference in the to 'arms' of the molecule present in the solid state.

The presence of two P^{III} atoms in this molecule provides an opportunity for a variety of oxidation products to be synthesised. Bis(2,6-diphenylphosphino)picolinamide disulfide (**13**) and the diselenide (**14**) were prepared by refluxing bdpppa in toluene with a stoichiometric amount of sulfur or selenium for 1 h, the disulfide has

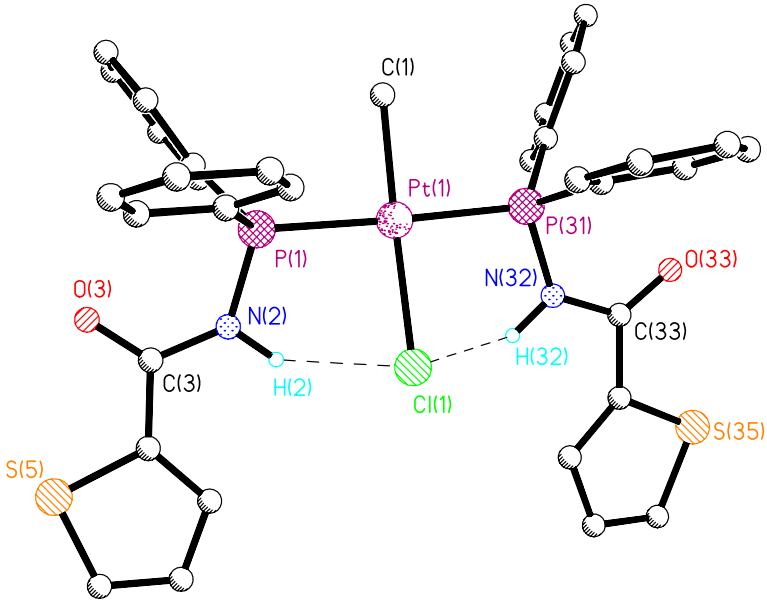


Fig. 4. Crystal structure of [PtMeCl(dpptc-P)$_2$] (**9**), selected bond lengths (Å) and angles (°): P(1)–Pt(1) 2.2902(15), P(31)–Pt(1) 2.2902(15), P(1)–N(2) 1.702(5), P(31)–N(32) 1.700(5), N(2)–C(3) 1.371(8), N(32)–C(33) 1.365(7), C(3)–O(3) 1.227(7), C(33)–O(33) 1.227(7), Pt(1)–Cl(1) 2.4343(16), Pt(1)–C(1) 2.074(6) N(2)···Cl(1) 3.085(6), N(32)···Cl(1) 3.045(5), P(1)–Pt(1)–Cl(1) 91.72(5), P(31)–Pt(1)–Cl(1) 90.34(5), P(1)–Pt(1)–C(1) 89.79(18), N(2)–P(1)–Pt(1) 106.14(18), N(32)–P(31)–Pt(1) 106.14(18), N(2)–H(2)···Cl(1) 139(4), N(32)–H(32)···Cl(1) 139(5).

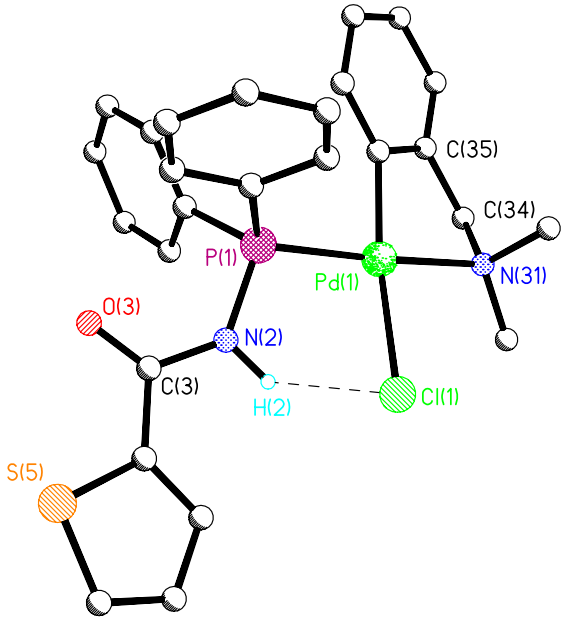

Fig. 5. Crystal structure of [PdCl($C_9H_{12}N$)(dpptc-P)] (**10**), Selected bond lengths (Å) and angles (°): P(1)–Pd(1) 2.2479(12), Pd(1)–N(31) 2.143(4), Pd(1)–Cl(1) 2.4249(12), C(3)–O(3) 1.219(5), N(2)–C(3) 1.382(5), C(4)–S(5) 1.713(4), N(2)···Cl(1) 3.027(4), P(1)–Pd(1)–Cl(1) 93.58(4), P(1)–Pd(1)–N(31) 173.10(10), Cl(1)–Pd(1)–N(31) 91.83(10), N(2)–H(2)···Cl(1) 141(4).

δ(P) 55.1 ppm and the diselenide δ(P) 49.7 ppm with $^1J_{P=Se}$ = 795 Hz. The amide protons in **13** and **14** are shifted to δ(H) 8.9 and 8.8 ppm, respectively, and are both doublets with $^2J_{P-H}$ = 9 Hz, these values are similar to the values observed for the unoxidized ligand. The IR data shows no real variation from the dpppa equivalents, for **13** the ν(N–H) is observed at 3360 cm^{-1} as a sharp peak, however the ν(C=O) is observed at 1697 cm^{-1} with significant line broadening, the ν(P–N) peak remains constant at 999 cm^{-1}. A similar pattern is observed for **14**, with ν(N–H), ν(C=O) and ν(P–N) coming at 3256, 1698 and 998 cm^{-1}, respectively, although the slightly lower value for the ν(N–H) may suggest more extensive hydrogen-bonding in **14** compared to both the disulfide and the free ligand. In the solid state (Fig. 6) **14** adopts a pseudo five-membered ring formed by an interaction of the amide hydrogen's with the pyridyl nitrogen (see Scheme 2).

By making use of the mild conditions involved in synthesis of the sulfur species one can isolate the mono-sulfur derivative of bdpppa, bdpppa-S (**15**). This generates a compound where only one sulfur is bound to phosphorus, leaving one free for further chemistry. The ^{31}P spectrum clearly shows this motif with two singlets being present at δ(P) 56.0 (P=S), and 21.7 ppm (P^{III}). The IR data shows the two now different arms of the molecule clearly, two ν(N–H) vibrations are observed, one at 3345 cm^{-1} which is consistent with bdpppa, and the other at 3262 cm^{-1}, similar to dpppa-S and bdpppa-diS. The same pattern is seen in the ν(C=O), a peak at 1697 cm^{-1} representing the sulfide arm, and a peak at 1665 cm^{-1} represents the P^{III} arm.

As we speculated the mono-oxidised form of bdpppa can use it is unoxidised phosphorus to react further, and reaction with one equivalent of selenium in toluene generates the unsymmetrical bdpppa-S,Se (**16**), δ(P) 55.0

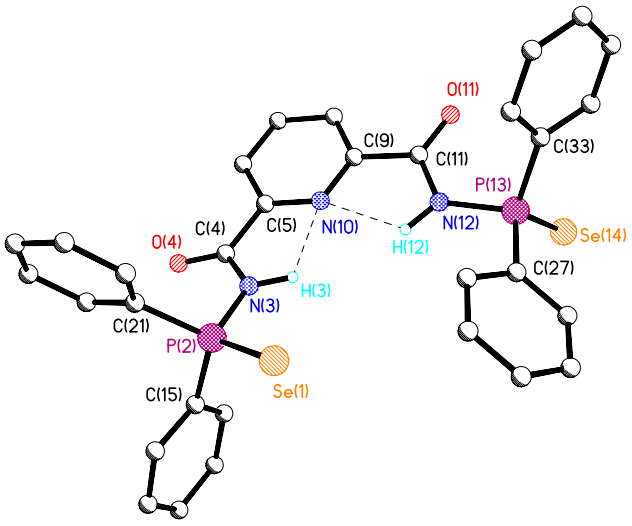

Fig. 6. Crystal structure of bdpppa-diSe (**14**), selected bond lengths (Å) and angles (°): P(2)–Se(1) 2.0974(14), P(13)–Se(14) 2.1014(15), P(2)–N(3) 1.687(4), P(13)–N(12) 1.698(4), N(3)–C(4) 1.374(6), N(12)–C(11) 1.373(6), C(4)–O(4) 1.209(6), C(11)–O(11) 1.207(6), C(4)–C(5) 1.513(6), C(11)–C(9) 1.510(7), C(5)–N(10) 1.334(6), C(9)–N(10) 1.334(16), N(3)···Cl(3) 3.050, N(12)···Cl(3) 3.368, N(3)···N(10) 2.684(5) N(12)···N(10) 2.721(5), Se(1)–P(2)–N(3) 107.68(16), Se(14)–P(13)–N(12) 114.97(16), P(2)–N(3)–H(3) 120(5), N(3)–H(3)···N(10) 113(5), N(12)–H(12)···N(10) 113(5).

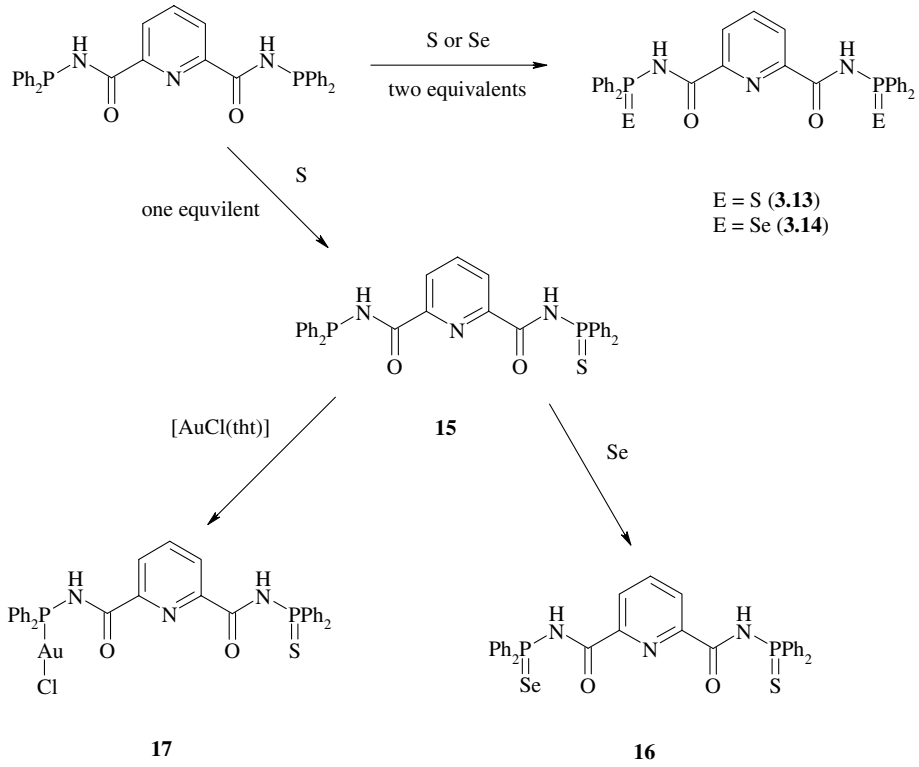
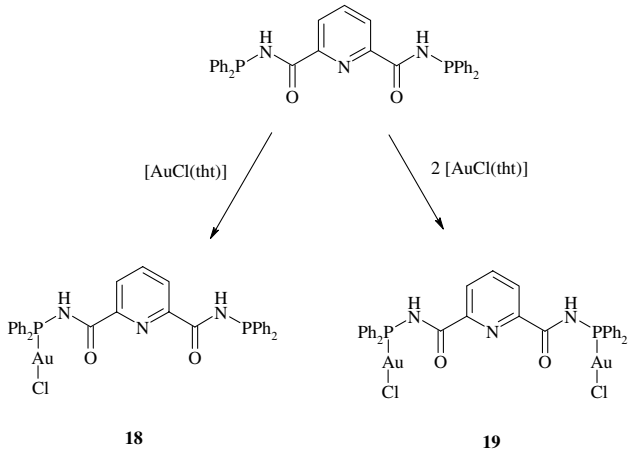
ppm (consistent with P=S), δ(P) 49.7 ppm $^{1}J_{P=Se}$ of 795 Hz.. Compound **15** can also be reacted with one equivalent of [AuCl(tht)] in dichloromethane to generate [AuCl(bdpppa-S-*P*)] **17**, δ(P) 55.0 (P=S) and δ(P) 50.2 (P–Au). Reaction of bdpppa with [AuCl(tht)] in dichloromethane gives two products dependant on the stoichiometry of the reaction. One equivalent of [AuCl(tht)] generates the expected product with one phosphorus bound to gold and one remaining unbound (**18**). With two equivalents of [AuCl(tht)] both phosphorus atoms are coordinated (Scheme 3) to give (**19**). In the case of this digold complex, we see the expected singlet in the ^{31}P NMR at 50.0 ppm, this agrees well with the one previous gold complex of dpppa, and the peak seen in **17**. The proton spectrum also displays the characteristics of its dpppa analogue, the amide peak is clearly seen at δ(H) 10.3 ppm with a $^{2}J_{P-H}$ = 16 Hz and the aromatics are all found in the 8.2–7.2 region. The ν(N–H) stretch in the IR spectrum is a broad peak at 3261 cm^{-1}, also the ν(C=O) band is broad, located at 1698 cm^{-1}, both these values correlate well with [AuCl(dpppa-*P*)] (3288 and 1698 cm^{-1}, respectively).

However, when one considers the mono-gold complex it, unlike **15**, does not display two separate peaks in the ^{31}P NMR for P–Au and P^{III}, it displays a singlet at δ(P) 64.3 ppm, at significantly higher chemical shift than anything we have seen earlier, and does not correlate with the shift observed in the mono-sulfide/gold complex. Inspection of the IR data provides further evidence for a single phosphorus environment, with only single peaks being displayed for ν(N–H) and ν(C=O) (3054 and 1698 cm^{-1}, respectively). Also the ^{1}H NMR



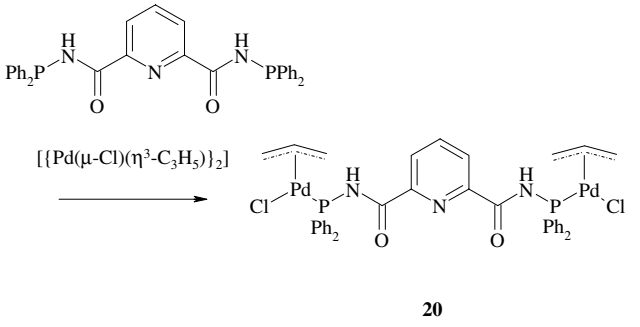
Scheme 2. Reactions of bdpppa and its mono-oxidized derivatives.



Scheme 3. Reaction of bdpppa with [AuCl(tht)].

data shows a single resonance for the amide proton, a broad singlet at δ(H) 11.0 ppm. The most plausible explanation for these data is for **18** to exist as a dimer, this is not a unique conformation as a similar system has been reported for dppap [13].

Reaction of bdpppa with a range of Pt and Pd dimers generates complexes where the bdpppa ligand bridges two metal atoms. Treatment of bdpppa with one equivalent of $[\{Pd(\mu\text{-}Cl)(\eta\text{-}C_3H_5)\}_2]$, generating $[Pd_2Cl_2(\eta\text{-}C_3H_5)_2$(bdpppa-*P*,*P*)] (**20**). The ^{31}P NMR shows a singlet at δ(P) 55.1 ppm, consistent with the complexes structure when compared to dpppa and dpptc.



(4)

The analogous reaction with $[\{Pt(\mu\text{-}Cl)(\eta\text{-}C_3H_5)\}_2]$ generated a similar product, $[Pt_2Cl_2(\eta\text{-}C_3H_5)_2$(bdpppa-*P*,*P*)] (**21**), δ(P) 51.7 ppm, $^1J_{Pt-P} = 4730$ Hz. A crystal of **21** was prepared for crystallographic analysis by vapour diffusion of diethylether into a concentrated solution of **21** in $CDCl_3$. Given our conclusions based on **20**, we could imagine the two compounds would be almost analogous in the solid state.

The X-rays structure of **21** (Fig. 7) shows it has an arrangement much like that of **14**, with the amide protons interacting with the pyridyl nitrogen, and if one considers the chlorides to be analogous to the selenium atoms, then we can see that again one is 'in' and one is 'out', of the hole in the centre of the complex. Similar

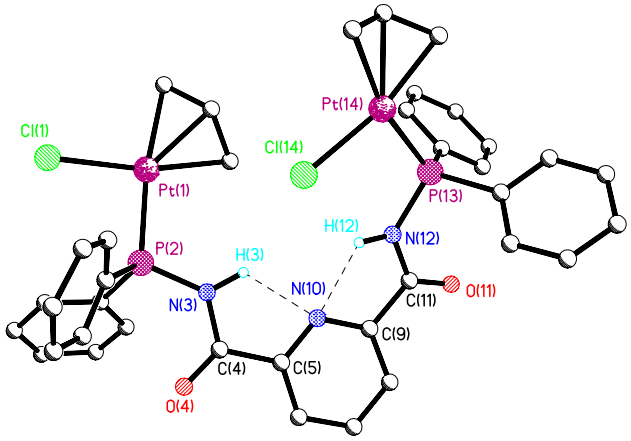


Fig. 7. Crystal structure of $[Pt_2Cl_2(\eta\text{-}C_3H_5)_2$(bdpppa-P,P)] (**21**), selected bond lengths (Å) and angles (°): P(2)–Pt(1) 2.249(2), P(13)–Pt(14) 2.250(2), P(2)–N(3) 1.699(7), P(13)–N(12) 1.720(7), N(3)···N(10) 2.689(10), N(12)···Cl(14) 3.167(7), N(12)···N(10) 2.674(9), Pt(1)–P(2)–N(3) 110.4(2), Pt(14)–P(13)–N(12) 109.9(3), N(3)–H(3)···N(10) 119(7), N(12)–H(12)···N(10) 110(6).

to **14** one can imagine in this scenario that there is probably too much steric bulk involved for both of the chlorides to occupy the 'in' slot as was the case with the selenium atoms.

3. Experimental

All manipulations were carried out in a atmosphere of nitrogen, unless stated otherwise. All solvents were either freshly distilled from an appropriate drying agent (thf, Et_2O, dcm) or obtained as anhydrous grade from Aldrich. ^{1}H and ^{31}P NMR spectra were recorded using a Jeol Delta FT (270 MHz) spectrometer. IR spectra were recorded as KBr discs (prepared in air) on a Perkin–Elmer 2000 FTIR/RAMAN spectrometer. All significant peaks (>800 cm^{-1}) are quoted to serve as a fingerprint. Silver salts, 2-thiophenecarboxamide, 2,6-pyridinedicarboxamide (Aldrich Chemical Co.) and BuLi (2.5 M, Lancaster) were purchased and used as received. Triethylamine and chlorodiphenylphosphine were distilled prior to use. Dimethylaminopyridine (DMAP) was sublimed before use. The various metal starting materials were made by the appropriate literature methods; [AuCl(tht)] [5], $[MCl_2(cod)]$ (M = Pt or Pd; cod = cycloocta-1,5-diene) [6,7], [PtMeCl(cod)] [8], $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$ [9], $[\{MCl(\mu\text{-}Cl)(Cp^*)\}_2]$ (M = Rh or Ir) [10], $[\{RuCl(\mu\text{-}Cl)(\eta^6\text{-}p\text{-}MeC_6H_4{}^iPr)\}_2]$ [11], $[\{PdCl(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)\}_2]$ [12–14].

*3.1. 2-(Diphenylphosphino)thiophenecarboxamide (Dpptc) (**1**)*

Chlorodiphenylphosphine (3.53 ml, 20 mmol) was added to a solution of 2-thiophenecarboxamide (2.5 g,

20 mmol), triethylamine (2.88 ml, 20.6 mmol) and DMAP (240 mg, 2 mmol) in THF (100 cm^3) and refluxed overnight. The reaction mixture was filtered to remove a white solid (Et_3NHCl) and washed with THF (50 cm^3). The solvent was removed in vacuo leaving a pale yellow solid. This solid was recrystallised by cooling a concentrated methanol solution in a fridge overnight (yield: 3.28 g, 10.5 mmol, 54%). *Anal.* Calc. $C_{17}H_{14}NOSP$ requires: C, 65.5; H, 4.53; N, 4.50. Found: C, 63.8; H, 4.09; N, 4.70%. ν_{max}/cm^{-1}: 3265, 1624, 1522, 1442, 1270, 1096, 996. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 25.9. ^1H NMR (270 MHz, $CDCl_3$), 7.6 (2H, m, aromatic), 7.5–7.3 (10H, m, aromatic), 7.1 (2H, m, aromatic).

3.2. 2-(Diphenylphosphino)thiophenecarboxamide sulfide (**3**)

Sulfur (77 mg, 2.4 mmol) was added to a solution of 2-(diphenylphosphino)thiophenecarboxamide (750 mg, 2.4 mmol) in toluene (20 cm^3) and refluxed overnight. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystallised by cooling a concentrated toluene solution at 4 °C overnight (yield: 1.39 g, 93%). *Anal.* Calc. $C_{17}H_{14}NOPS_2$ requires: C, 59.5; H, 4.11; N, 4.08. Found: C, 59.2; H, 3.70; N, 4.48%. ν_{max}/cm^{-1}: 3167, 1624, 1436, 1000. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 57.2 ppm. ^1H NMR ($CDCl_3$), δ 8.0 (3H, m, aromatic), 7.7–7.3 (6H, m, aromatic), 7.3–7.1 (4H, m, aromatic), 7.0 (1H, d, N–H).

3.3. [$PtCl_2$(dpptc-P)$_2$] (**4**)

Dpptc (166 mg, 0.534 mmol) and [$PtCl_2$(cod)] (100 mg, 0.267 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 170 mg, 72%). *Anal.* Calc. $C_{34.5}H_{29}N_2O_2P_2S_2Cl_3Pt$ requires: C, 44.5; H, 3.14; N, 3.01. Found: C, 44.0; H, 3.89; N, 2.95%. ν_{max}/cm^{-1}: 3214, 1672, 1424, 1398, 1042, 304, 273. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 27.9 ($J_{P–Pt}$ = 3870 Hz). ^1H NMR (270 MHZ, $CDCl_3$), 9.7 (2H, d, J = 11 Hz, N–H), 7.8–6.9 (26H, m, aromatic).

3.4. [PdCl(η^3-C_3H_6)(dpptc-P)] (**5**)

Dpptc (170 mg, 0.54 mmol) and [{Pd(μ -Cl)(η^3-C_3H_5)}$_2$] (100 mg, 0.27mmol) were weighed into a Shlenk type flask and DCM (5 ml) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 117 mg, 87%). *Anal.* Calc. $C_{20}H_{20}NOSPClPd$ requires: C, 48.5; H, 4.07; N, 2.83. Found: C, 48.3; H, 2.35; N, 2.82%. ν_{max}/cm^{-1}: 3208, 1671, 1435, 1394, 1010, 277. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 54.3. ^1H NMR (270 MHz, $CDCl_3$), 9.4 (1H, d, J = 19 Hz, N–H), 7.7 (1H, d, J = 1 Hz, thC[5**]H), 7.7–7.6 (4H, m, aromatic), 7.5–7.3 (7H, m, aromatic) 7.1 (1H, dd, J = 3, 6 Hz, thC[4**]) 5.5 (1H, m, allyl), 4.8 (1H, t, J = 6 Hz, allyl), 3.7 (1H, dd, J = 10, 13 Hz, allyl), 3.3 (1H, obscured, allyl), 2.6 (1H, d, J = 13 Hz, allyl).

3.5. [$PtCl_2$($PPhMe_2$)(dpptc-P)] (**6**)

Dpptc (58 mg, 0.18 mmol) and [{PtCl(μ-Cl)(Me_2PhP)}$_2$] (75 mg, 0.0927 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A yellow solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 66 mg, 50%). *Anal.* Calc. $C_{25}H_{25}NOSP_2Cl_2Pt$ requires: C, 39.7; H, 4.20; N, 2.01. Found: C, 40.0; H, 3.31; N, 1.72%. ν_{max}/cm^{-1}: 3226, 1671, 1435, 948, 316, 281. ^{31}P NMR (109.3 MHz, $CDCl_3$) δ 29.7 (d, $J_{P–P}$ = 18.78 Hz, $J_{P–Pt}$ = 3890 Hz), -15.6 (d, $J_{P–P}$ = 18.78 Hz, $J_{P–Pt}$ = 3500 Hz). ^1H NMR (270 MHz, $CDCl_3$) δ 11.4 (1H, d, J = 16 Hz, N–H), 8.6 (1H, d, J = 7 Hz, pyC[6]H), 8.2 (4H, m, aromatic), 7.9–7.4 (9H, m, aromatic), 1.6–1.4 (9H, m, Me–H) 1.0–0.8 (6H, m, –CH_2–).

3.6. [$RuCl_2$(p-Cymene)(dpptc-P)] (**7**)

Dpptc (102 mg, 0.326 mmol) and [{RuCl(μ-Cl)(*p*-Cymene)}$_2$] (100 mg, 0.0163 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A red solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 155 mg, 77%). *Anal.* Calc. $C_{27}H_{28}NOPCl_2Ru$ requires: C, 52.5; H, 4.57; N, 2.27. Found: C, 52.1; H, 3.48; N, 2.19%. ν_{max}/cm^{-1}: 3312, 1665, 1435, 1404, 1091, 288. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 59.9. ^1H NMR (270 MHZ, $CDCl_3$), 8.0 (5H, m, aromatic) 7.9 (1H, d, J = 14 Hz, N–H), 7.6 (1H, dd, J = 1, 4 Hz), 7.5–7.3 (10H, m, Aromatic), 5.3–5.2 (4H, m, *p*-Cy), 2.5 (1H, m, C–H), 1.9 (3H, s, Me–H), 0.8 (6H, d, J = 7Hz, ^{1}Pr–H).

3.7. [$RhCl_2$(η^5-C_5Me_5)(dpptc-P)] (**8**)

Dpptc (101 mg, 0.326 mmol) and [{RhCl(μ-Cl)(η^5-C_5Me_5)}$_2$] (100 mg,. 0161 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A red solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 159 mg, 80%). $C_{27.5}H_{30}NSOPCl_3Rh$ requires: C, 49.8; H, 4.56; N, 2.11. Found: C, 50.7; H,

4.17; N, 2.27%. ν_{max}/cm^{-1}: 3299, 1669, 1435, 1097, 246, 231. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 63.5 ($^1J_{Rh-P}$ = 148 Hz).. ^1H NMR (270 MHZ, $CDCl_3$), 8.2 (1H, d, J = 14 Hz, N–H) 8.1–8.0 (4H, m, aromatic) 7.7 (1H, d, J = 4 Hz, N–H), 7.5–7.3 (7H, m, aromatic), 7.0 (1H, t, J = 8 Hz, aromatic), 1.4 (15H, d, Cp*Me–H).

3.8. [PtClMe(dpptc-P)$_2$] (**9**)

Dpptc (39 mg, 0.12 mmol) and [PtClMe(cod)] (22 mg, 0.06 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A yellow solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 34 mg, 65%). *Anal.* Calc. $C_{35}H_{31}N_2S_2O_2P_2ClPt$ requires: C, 48.4; H, 3.60; N, 3.23. Found: C, 48.4; H, 3.40; N, 3.17%. ν_{max}/cm^{-1}: 3209, 1671, 1435, 1094. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 49.1 (J_{P-Pt} = 3220 Hz). ^1H NMR (270 MHZ, $CDCl_3$), 9.7 (2H, t, J_{Pt-H} = 19 Hz, N–H), 7.9 (10H, m, aromatic), 7.6–7.3 (14H, m, aromatic), 7.1 (2H, d, J = 3 Hz, thiophene), 1.5 (3H, s, Me).

3.9. [PdCl($C_9H_{12}N$)(dpptc-P)] (**10**)

Dpptc (79 mg, 0.25 mmol) and [Pd(μ-Cl)($C_9H_{12}N$)]$_2$ (70 mg, 0.13 mmol) were weighed into a Schlenk type flask and DCM (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A yellow solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 82 mg, 55%). *Anal.* Calc. $C_{26}H_{26}N_2SOPClPd$ requires: C, 53.0; H, 4.63; N, 4.76. Found: C, 52.3; H, 4.52; N, 4.53%. ν_{max}/cm^{-1}: 3171, 1672, 1438, 1259, 1101, 286. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 62.4ppm. ^1H NMR (270 MHZ, $CDCl_3$), 10.1 (1 H, bs, N–H) 8.2 (4 H, m, aromatic) 7.2–7.7 (10H, m, aromatic), 7.1 (1H, dd, J = 1, 4 Hz, aromatic) 7.0 (1H, d, J = 6 Hz, aromatic), 6.8 (1H, t, J = 15 Hz, aromatic) 6.4 (2H, m, aromatic) 2.9 (6H, s, N–Me).

3.10. [RuCl(p-Cy)(dpptc-P,O)]BF_4 (**11**)

$AgBF_4$ (22 mg, 0.11 mmol) was added under dark conditions to a solution of [$RuCl_2$(*p*-Cy)(dpptc-*P*)] (70 mg, 0.11 mmol) in DCM (5 cm^3). The solution was stirred overnight and filtered through a celite bed. The majority of the solvent was removed in vacuo. An orange solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 45 mg, 70%). *Anal.* Calc. $C_{27}H_{28}NRuClOSPBF_4$ requires: C, 48.48; H, 4.21; N, 2.09. Found: C, 48.0; H, 4.07; N, 2.02%. ν_{max}/cm^{-1}: 3216, 1561, 1460, 1433, 1084, 1060, 764. ^{31}P NMR (109.3 MHz, $CDCl_3$) δ 100.0. ^1H NMR (270 MHz, $CDCl_3$) δ 10.1 (1H, s, N–H), 8.3 (1H, d, J = 3Hz, thC[5]H), 8.0 (2H, m, aromatic), 7.7–7.1 (11H, m, aromatic), 5.9 (1H, dd, J = 7 Hz, *p*-Cy-H), 5.6 (1H, dd, J = 6 Hz, *p*-Cy-H), 5.3 (1H, m, *p*-Cy), 5.0 (1H, d, J = 6 Hz, *p*-Cy), 2.6 (1H, m, C–H), 2.1 (3H, s, Me–H), 1.3 (6H, m, Pr^i–H).

3.11. Bis(2,6-diphenylphosphino)picolinamide (bdpppa) (**12**)

Chlorodiphenylphosphine (5.44 cm^3, 30.3 mmol) was added to a solution of 2,6-pyridinedicarboxamide (2.5 g, 30.3 mmol), triethylamine (4.44 cm^3, 32 mmol) and DMAP (370 mg, 3.0 mmol) in thf (100 cm^3) and refluxed overnight. The reaction mixture was filtered to remove a white solid (Et_3NHCl) and washed with thf (50 cm^3). The solvent was removed in vacuo leaving a pale yellow solid. This solid was recrystallised by cooling a concentrated methanol solution at 4 °C overnight (yield: 4.89 g, 61%). *Anal.* Calc. $C_{31.5}H_{26}N_3O_2P_2Cl$ requires: C, 66.0; H, 4.50; N, 7.22. Found: C, 65.7; H, 4.41; N, 7.40%. ν_{max}/cm^{-1}: 3345, 3262, 1665, 1646,, 1588, 1571, 1408, 999. ^{31}P NMR ($CDCl_3$) 21.9. ^1H NMR ($CDCl_3$), 8.42 (2H, d, J = 8 Hz, N–H), 8.00 (3H, m, py), 7.5–7.1 (21H, m, aromatic).

3.12. Bis(2,6-diphenylphosphino)picolinamide disulfide (**13**)

Sulfur (120 mg, 3.7 mmol) was added to a solution of bis(2,6-diphenylphosphino)picolinamide (1 g, 3.7 mmol) in toluene (20 cm^3) and refluxed for 10 min. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystillised by cooling a concentrated toluene solution at 4 °C overnight (yield: 876 mg, 78%). *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2S_2$ requires: C, 63.8; H, 4.32; N, 4.80. Found: C, 64.1; H, 4.46; N, 4.50%. ν_{max}/cm^{-1}: 3360, 1697, 1424, 999. ^{31}P NMR ($CDCl_3$) 55.1 ppm. ^1H NMR ($CDCl_3$), δ 8.9 (2H, d, J = 9 Hz, N–H), 8.3 (2H, d, J = 8 Hz, pyC[3,5]H), 8.1–7.9 (8H, m, aromatic), 7.6–7.4 (10H, m, aromatic), 7.1–7.3 (3H, m, aromatic).

3.13. 2,5-bis(Diphenylphosphino)picolinamide diselenide (**14**)

Selenium (74 mg, 0.9 mmol) was added to a solution of 2,5-bis(Diphenylphosphino)picolinamde (250 mg, 0.47 mmol) in toluene (20 cm^3) and refluxed for 10 min. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystillised by cooling a concentrated toluene solution in a fridge overnight (yield: 263 mg, 81%). *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2Se_2$ requires: C, 53.9; H, 3.64; N, 6.08. Found: C, 53.7; H, 3.24; N, 6.17%. ν_{max}/cm^{-1}: 3256, 1698, 1421, 998. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 49.6 ($^1J_{P=Se}$ = 795 Hz). ^1H NMR (270 MHz, $CDCl_3$), δ 8.8 (2H, d, J = 9Hz, N–H), 8.3 (1H, d, J = 8Hz, pyC[6]H), 8.0 (8H, m, aromatic), 7.5 (13H, m, aromatic).

3.14. Bis(2,6-diphenylphosphino)picolinamide monosul-fide (**15**)

Sulfur (36 mg, 0.37 mmol) was added to a solution of bis(2,6-diphenylphosphino)picolinamide (600 mg, 0.37 mmol) in toluene (20 cm^3) and refluxed for 10 min. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystallised by cooling a concentrated toluene solution at 4 °C overnight (yield: 415 mg, 65%). *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2S$ requires: C, 65.7; H, 4.46; N, 7.43. Found: C, 67.4; H, 4.47; N, 7.20%. ν_{max}/cm^{-1}: 3345, 3262, 1697, 1665, 1646, 1432, 999. ^{31}P NMR ($CDCl_3$) 56.0 (s, P═S), 21.7 (s, P^{III}). ^1H NMR ($CDCl_3$), δ 8.8 (2H, d, $J = 9$ Hz, N–H), 8.4 (4H, m aromatic), 7.8–8.1 (5H, m, aromatic), 7.0–7.6 (14H, m, aromatic).

3.15. Bis(2,6-diphenylphosphino)picolinamide monosulfide monoselenide (**16**)

Selenium (22 mg, 0.26 mmol) was added to a solution of bis(2,6-diphenylphosphino)picolinamide monosulfide (150 mg, 0.26 mmol) in toluene (10 cm^3) and refluxed for 10 min. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystillised by cooling a concentrated toluene solution at 4 °C overnight (yield: 120 mg, 71%). *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2SSe$ requires: C, 57.7; H, 3.91; N, 6.52. Found: C, 58.8; H, 3.68; N, 6.30%. ν_{max}/cm^{-1}: 3449, 1697, 1421, 997. ^{31}P NMR ($CDCl_3$) 55.0 (s, P═S), 49.7 (s, P═Se, $^1J_{P-Se} = 789$ Hz). ^1H NMR ($CDCl_3$), δ 8.8 (2H, d, $J = 8$ Hz, N–H), 8.3 (2H, dd, $J = 8$, 1 Hz, pyC[3,5]H), 7.9-8.1 (7H, m, aromatic), 7.6–7.4 (14H, m, aromatic).

3.16. [{AuCl}(bdpppa-S)] (**17**)

[AuCl(tht)] (57 mg, 0.17 mmol) and Bis(2,6-diphenylphosphino)picolinamide (100 mg, 0.17 mmol) were added to a round bottomed flask and DCM (5 cm^3) added. The solvent volume was reduced to ~1 cm^3 and the product precipitated with *n*-hexane (20 cm^3). Yield 93 mg, 66%. *Anal.* Calc. $C_{32}H_{26}N_3O_2P_2SAuCl_3$ requires: C, 41.9; H, 2.80; N, 4.58. Found: C, 41.7; H, 2.74; N, 4.69%. ν_{max}/cm^{-1}: 3256, 1697, 1437, 999. ^{31}P NMR ($CDCl_3$) δ(P) 55.0 (s, P═S), 50.2 (s, P–Au). ^1H NMR ($CDCl_3$) δ (H) 10.2 (2H, bs, N–H), 7.0–8.0 (23H, m, aromatic).

3.17. [{AuCl} (bdpppa)] (**18**)

A solution of [AuCl(tht)] (120 mg, 0.37mmol) in DCM (10 cm^3) was dropped into a solution of bis(2,6-diphenylphosphino)picolinamide (200 mg, 0.37 mmol) in DCM (15 cm^3). The solvent volume was reduced to ~1cm^3 and the product precipitated with *n*-hexane (20cm^3). Yield 240 mg, 83%. *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2AuCl$ requires: C, 48.6; H, 3.29; N, 5.49. Found: C, 48.2; H, 2.91; N, 5.48%. ν_{max}/cm^{-1}: 3054, 1698, 1436, 999. ^{31}P NMR ($CDCl_3$) δ(P) 64.3. ^1H NMR ($CDCl_3$) δ(H) 11.0 (2H, bs, N–H), 9.0 (2H, m, aromatic), 7.1–8.1 (21H, m, aromatic).

3.18. [{AuCl}$_2$(bdpppa)] (**19**)

[AuCl(tht)] (84 mg, 0.26 mmol) and bis(2,6-diphenylphosphino)picolinamide (70 mg, 0.13 mmol) were added to a round bottomed flask and DCM (5 cm^3) added. The solvent volume was reduced to ~1 cm^3 and the product precipitated with *n*-hexane (20 cm^3). Yield 125 mg, 95%. *Anal.* Calc. $C_{31}H_{25}N_3O_2P_2Au_2Cl_2$ requires: C, 37.3; H, 2.52; N, 4.21. Found: C, 37.16; H, 2.37; N, 4.12%. ν_{max}/cm^{-1}: 3261, 1697, 1436, 999. ^{31}P NMR ($CDCl_3$) δ(P) 50.0. ^1H NMR ($CDCl_3$) δ(H) 10.2 (2H, d, $J_{H-H} = 16$ Hz, N–H), 8.1 (2H, m, aromatic), 7.9–7.6 (8H, m, aromatic), 7.6–7.1 (13H, m, aromatic).

3.19. [Pd$_2$Cl$_2$(allyl)$_2$(bdpppa-P,P)] (**20**)

Bdpppa (397 mg, 0.7.45 mmol) and [{Pd(μ-Cl)(η^3-C_3H_5)}$_2$] (272 mg, 0.373 mmol) were weighed into a Schlenk type flask and DCM (10 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 671 mg, 91%). *Anal.* Calc. $C_{37}H_{37}N_3O_2P_2Cl_2Pd_2$ requires: C, 49.3; H, 4.13; N, 4.66. Found: C, 49.23; H, 3.68; N, 4.57%. ν_{max}/cm^{-1}: 3351, 3209, 1698, 1434, 1385, 999. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 55.1. ^1H NMR (270 MHZ, $CDCl_3$), 10.2 (2H, d, $J = 18$ Hz, N–H), 8.2 (2H, d, $J = 8$ Hz, –pyC[6]H), 8.0–7.8 (10H, m, aromatic), 7.6–7.4 (10H, m, aromatic), 5.5 (4H, quin, $J = 10$ Hz, allyl), 4.7 (4H, t, $J = 7$Hz, allyl), 3.7 (2H, t, $J = 10$ Hz, allyl).

3.20. [Pt$_2$Cl$_2$(allyl)$_2$(bdpppa-P,P)] (**21**)

Bdpppa (59 mg, 0.092 mmol) and [{Pt(μ-Cl)(η^3-C_3H_5)}$_2$] (60 mg, 0.046 mmol) were weighed into a Schlenk type flask and THF (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was isolated after addition of Et_2O then filtered and washed with further ether (yield: 43 mg, 43%). *Anal.* Calc. $C_{37}H_{37}N_3O_2P_2Cl_2Pt_2$ requires: C, 41.1; H, 3.46; N, 3.90. Found: C, 40.3; H, 3.59; N, 3.86%. ν_{max}/cm^{-1}: 3360, 3231, 1700, 1434, 1000. ^{31}P NMR (109.3 MHz, $CDCl_3$), δ 51.7 ($^1J_{Pt-P} = 4730$Hz). ^1H NMR (270 MHz, $CDCl_3$), 10.2 (2H, d, $J = 10$ Hz, N–H), 8.2 (2H, d, $J = 8$Hz, pyC[**6]H), 8.0–7.8 (10H, m, aromatic), 7.7–7.3 (12H, m, aromatic), 5.3 (2H, m, allyl), 5.0 (2H, m, allyl), 4.3 (2H, m, allyl), 3.2 (2H, m, allyl), 3.0 (2H, m, allyl), 2.2 (2H, m, allyl).

4. Crystallography

Details of the structure determination are given in Table 1. X-ray diffraction measurements were made with graphite-monochromated Mo Kα X-radiation using a Bruker SMART diffractometer. Intensity data were collected using ω/ϕ steps accumulating area detector frames spanning a hemisphere of reciprocal space for all structures. All data were corrected for Lorentz, polarisation and long-term intensity fluctuations. Absorption effects were corrected on the basis of multiple equivalent reflections or by semi-empirical methods. Structures were solved by direct methods and refined by full-matrix least-squares against F^2 (SHELXTL). Hydrogen atoms were assigned isotropic displacement parameters and were constrained to idealised geometries. **8** gave a Flack parameter of 0.01(3). Refinements converged to residuals given in Table 1. All calculations were made with SHELXTL [15].

5. Supplementary material

Atomic coordinates, thermal parameters and bond lengths and angles have been deposited at the Cambridge Crystallographic Data Centre (CCDC Nos. 243091–243097). Any request to CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk; http://www.ccdc.cam.ac.uk) for this material should quote the full literature citation and the reference number.

Abstract

$[Cd(phen)_2(CA)]_n$ (**I**, where phen is 1,10-phenanthroline and CA^{2-} is the dianion of 3,6-dichloro-2,5-dihydroxy-1,4-benzoquinone) has been synthesized and its crystal structure has been determined by single-crystal X-ray diffraction at room temperature. The crystal of **I** is built from infinite chains of chloranilate-bridged cadmium(II) leading to a zig-zag structure, with the phenanthroline ligands being stacked between the chains. These interactions assist the formation of a closely packed 3D structure. The coordination environment of cadmium(II) – very scarce in its chemistry – is square antiprismatic. The polymer was also characterized with spectroscopic (IR, Raman, DRS) and thermogravimetric (TG, DTA) techniques.

1. Introduction

The synthesis of coordination polymers is one of the most essential elements in advancing materials chemistry. In general, it remains more of an art than a science, since most new compounds have been synthesized through self-assembly routes and not from controlled synthesis. Research on that area is directed towards the utilization of ligands that maintain their structure in solution and possess more than one well-known coordination sites [1]. Building metal complex – based polymers is an important step to create not only a system to perform optical, electronic and magnetic functions, but also an intercalation system for ion- or molecule-exchange, absorption and catalytic properties (see for example [2,3]).

Substituted dihydroxy benzoquinones, and especially chloranilic acid (CA), hold an important place in the family of bridging ligands [4–15]. This is due to their two allyl systems connected by C–C single bonds, with four partially negatively charged oxygen atoms [16] (Scheme 1). Thus, the chelating effect in addition to the bridging capability of the chloranilate dianion allows the formation of robust frameworks. In addition, the polyoxocarbon molecules have frontier orbitals with energies comparable to those of the transition metal ions and the nature of the reduced and oxidized species depends on the metal ions and the coordination environment [12]. The delocalized π system associated with its planar geometry can provide [9,13] interesting and possibly useful electronic communication between suitable metal centers.

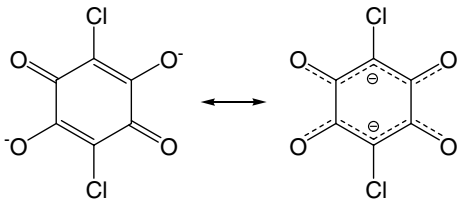

Scheme 1.

Our continuous interest in chloranilate chemistry is stimulated by both its analytical applications and coordination properties. Chloranilic acid can be used for the determination of Mg(II) with FAAS [17], for the construction of electrode membranes [18], and the kinetic determinations of formaldehyde [19] and Mn(II) [20]. Our involvement in the coordination chemistry of the chloranilates have produced several monomeric [21–23] and polymeric [11,24] coordination compounds with interesting structural features. For example, in the case of hydrated sodium chloranilate [11], the ligand can bind four sodium cations using all of its oxygen atoms and one of the organic chlorine atoms, while the number of sodium cations bound to CA is reduced to three when 1,10-phenanthroline is used to block sodium coordination sites.

In the present paper, we present the synthesis, the crystal structure and the spectroscopic and thermal characterization of the chain compound $[Cd(phen)_2(CA)]_n$. The structure is based on rare square antiprismatic CdN_4O_4 polyhedra connected through bis-chelating chloranilato bridges. Stacking interactions provide a 3D supramolecular architecture.

2. Experimental

2.1. Materials

All manipulations were carried out under aerobic conditions. $Cd(CH_3COO)_2 \cdot 2H_2O$ was purchased from Merck, sodium silicate solution, KBr, $BaSO_4$ and organic reagents were purchased from Aldrich. Solvents were of analytical grade and purchased from Lab-Scan Chemical Co.

2.2. Instrumentation

C, H and N analyses were conducted by the University of Ioannina, Greece, Microanalytical Service. IR (4000–370 cm^{-1}) and far-IR (600–30 cm^{-1}) spectra were recorded on a Perkin–Elmer Spectrum GX FT IR System with samples prepared as KBr and polyethylene pellets, respectively. The Raman spectrum was recorded on a SPEX Model 1403 0.85 m double spectrometer, equipped with a Spectra Physics Model 2020 argon ion laser; a spinning cell sample holder was used to avoid thermal degradation of the compound. The excitation was provided by the 514.5 nm line with a laser power of 100 mW, at a resolution of 2 cm^{-1} and signal recording was done using photon counting with an integration time of 1 s. UV/Vis diffuse reflectance spectra were recorded on a Shimadzu UV-2401 PC spectrophotometer with a Shimadzu integration sphere. Thermal studies were carried out on a Shimadzu DTG-60 simultaneous DTA-TG apparatus, under N_2 or forced air flow (50 cm^3 min^{-1}) with a heating rate of 5 °C min^{-1}. Sample sizes were about 5 mg. X-ray powder diffraction patterns were recorded on a Siemens (now Bruker) D8 ADVANCE diffractometer.

2.3. Preparation of the compound

$Cd(CH_3COO)_2 \cdot 2H_2O$ (0.50 g, 1.88 mmol) was dissolved in H_2O (20 cm^3). To this, a solution of 1,10-phenanthroline (0.676 g, 3.75 mmol) in ethanol (10 cm^3) was added. A white solid precipitated readily and dissolved after the addition of 2 cm^3 of glacial acetic acid. Separately, chloranilic acid (0.393 g, 1.88 mmol) was dissolved in water and the pH was adjusted to 7 with an aqueous solution (ca. 0.5 g in 20 cm^3 H_2O) of tris(hydroxymethyl)amino methane. The resulting solution was added to the metal solution to give a dark purple mixture. The mixture was refluxed for 2 h. The dark purple solid which separated upon cooling was filtered, washed with ethanol (3×10 cm^3) and diethylether (3×10 cm^3) and dried under vacuum over silica gel. Yield: 0.97 g (76% based on cadmium).

Slow reaction of an aqueous cadmium acetate solution (0.1 M) with an aqueous solution containing sodium chloranilate (0.05 M) and 1,10-phenanthroline (0.05 M) through a sodium silicate gel (formed after titration of 2 M HNO_3 with a ca. 2 M sodium silicate up to pH $\approx$ 5.3) in a U tube led to large purple crystals suitable for X-ray structural studies.

Anal. Calc. for $C_{30}H_{16}CdCl_2N_4O_4$: C, 53.00; H, 2.38; N, 8.24. Found: C, 52.71; H, 2.63; N, 8.39%. Selected IR (KBr pellet) and far-IR (polyethylene pellet) data (cm^{-1}): 3077w, 3065w, 1624w, 1513vs, 1424ms, 1374m, 1275m, 1207w, 1099w, 1047w, 988w, 841ms, 770w, 728m, 634w, 589w, 573m, 434m, 417m, 377w, 272m, 230s, 215msh, 178w, 156s, 145s, 127s. Selected Raman data (cm^{-1}): 3076w, 1615w, 1521m, 1460s, 1427m, 1346s, 1305s, 1051m, 725s, 586s, 566w, 423m, 312w, 123m. Electronic spectrum (DRS, $BaSO_4$ solution) (nm): 520, 325.

2.4. X-ray crystallography

A suitable single crystal of **I** was selected under a polarizing microscope, cleaned from the gel residues

and glued to a thin glass fibre with cyanoacrylate (super glue) adhesive. X-ray diffraction intensities were collected at room temperature on a Siemens P4 diffractometer employing graphite monochromated Mo Kα radiation, $\lambda = 0.71073$ Å. The WINGX environment was used for the solution and refinement of the structure [25]. The structure was solved by direct methods (SIR-97) [26] and refined by full-matrix least-squares techniques on F^2 (SHELXL-97) [27]. All non-hydrogen atoms were refined anisotropically. All H atoms were located in a difference Fourier map but were introduced in idealized positions and treated as riding on the parent hydrogen atoms. Sources of atomic scattering factors were as in SHELXL-97. Simulated XRPD patterns were produced with PLATON [28].

The details of the final refinements are given in Table 1. Selected bond distances and angles for **I** are given in Table 2.

3. Results and discussion

3.1. Synthesis of the compound

The title compound was initially synthesized in the form of single crystals from slow reaction, through silica gel, of a solution of cadmium(II) acetate with a solution of sodium chloranilate and 1,10-phenanthroline (phen).

The preparation of the compound in larger quantities was proved to be difficult.

When we attempted to prepare the polymer by the direct reaction of its components in various molar ratios and different addition sequences, we systematically isolated solids, which had similar IR spectra with the above mentioned crystals but their XRPD patterns revealed contamination with a second, unknown phase (different from that calculated from the single crystal data). Microanalyses showed that the molar ratio of Cd(II):phen:CA was neither 1:1:1 nor 1:2:1 but, depending on the synthesis, between 1:1.3:1 and 1:1.8:1. Several attempts to synthesize the polymer were made, including use of different counter ions, reaction solvents, temperature, and molar ratios, but reasonably pure products (i.e. having IR spectrum, X-ray powder pattern and stoichiometry with formula $[Cd(CA)(phen)_2]_n$) were isolated only in the case described in Section 2. The XRPD patterns [simulated (for the single crystal) and

experimental (for the separately prepared bulk sample)] are presented in Fig. 1.

We believe that this behavior can be explained in terms of the kinetic and thermodynamic stability of the two products, $[Cd(CA)(phen)]_n$ and $[Cd(CA)(phen)_2]_n$, probably involved in the reaction mixture. Bearing in mind that chloranilate will act as bis-chelating bridging ligand, when in lower concentration than the metal, the 1D polymer $[Cd(CA)(phen)]_n$ would be the initial product, according to Eq. (I). This product must be kinetically stable.

$$n\mathrm{Cd}^{2+} + n\mathrm{CA}^{2-} + n\mathrm{phen} \rightarrow [\mathrm{Cd(CA)(phen)}]_n \qquad \text{(I)}$$

The next, most obvious, step in a successive addition scenario is the addition of the second phen molecule to the coordination sphere of cadmium, which should begin almost simultaneously, and lead to the formation of the thermodynamically stable product as shown in the following equation.

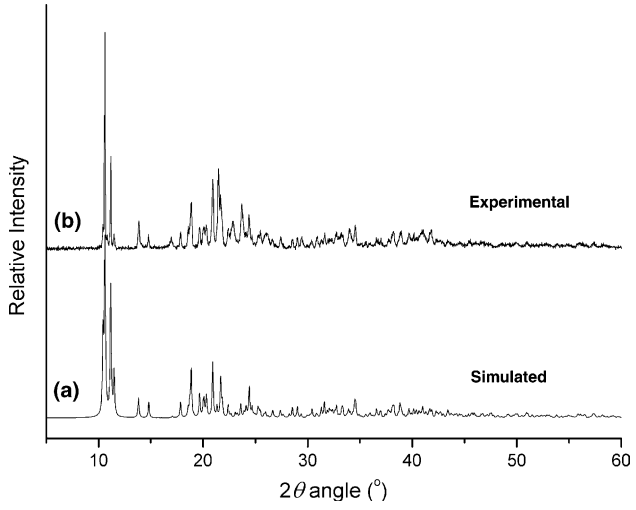

Fig. 1. Experimental (b) and simulated (a) powder XRD patterns for **I**.

$$[Cd(CA)(phen)]_n + n\mathrm{phen} \rightarrow [Cd(CA)(phen)_2]_n \qquad \text{(II)}$$

Though speculative, the mechanism above is supported by two experimental observations: (a) the microanalyses of the insoluble products suggested formulations $[Cd(CA)(phen)_x]$, where $1 < x < 2$ and (b) only after extended heating of the reaction mixture was the desired product isolated.

3.2. Description of the structure

An ORTEP drawing of the asymmetric unit of $[Cd(CA)(phen)_2]_n$ is presented in Fig. 2(a). Selected bond distances (Å) and angles (°) with their standard deviations are presented in Table 2.

The crystal structure of the polymer is built from zigzag chains (type I chain structure), extended along the $[-1, 1, 1]$ direction, accompanied by by stacking interactions (Fig. 3).

The asymmetric unit consists of one cadmium atom, two 1,10-phenanthroline molecules and halves of two different chloranilato ligands (Fig. 2(a)). The coordination sphere of the metal is formed by four nitrogen atoms belonging to two chelating phen ligands, and four oxygen atoms belonging to two different bis-chelating bridging chloranilato ligands.

There are several examples of eight-coordinate cadmium complexes in the literature. They can be separated in two different groups. Those with multidentate ligands (see for example [30–32]) and those with bidentate chelating ligands with small bite angles (see for example [33–35]). To the best of our knowledge the only examples of eight-coordinated Cd(II) complexes with four five-membered chelate rings belong to the family of the oxalate polymers [36–39].

The geometry about Cd(II) can be described as distorted square antiprismatic. As indicated by Drew [40], the values of φ angles, which assess the planarity of the two trapezoids formed in an eight-coordination

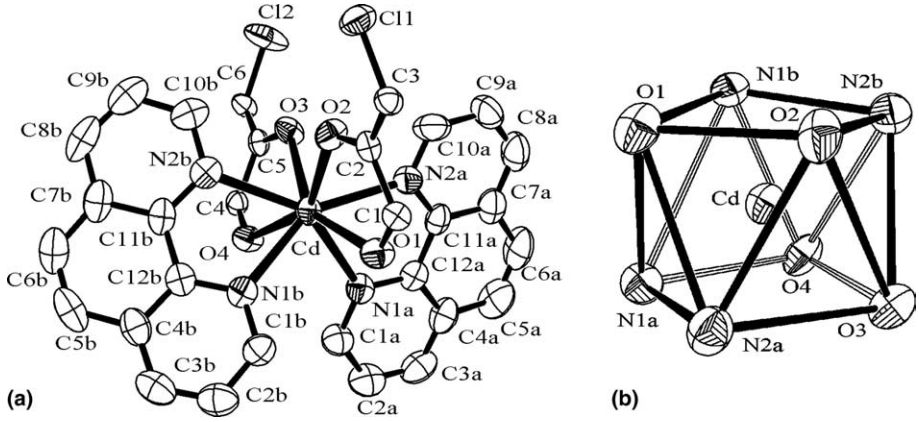

Fig. 2. (a) ORTEP [29] plot of the asymmetric unit of $[Cd(CA)(phen)_2]_n$ (**I**) including the labelling scheme. Hydrogen atoms have been omitted for clarity. (b) The coordination polyhedron about Cd, defined as square antiprism.

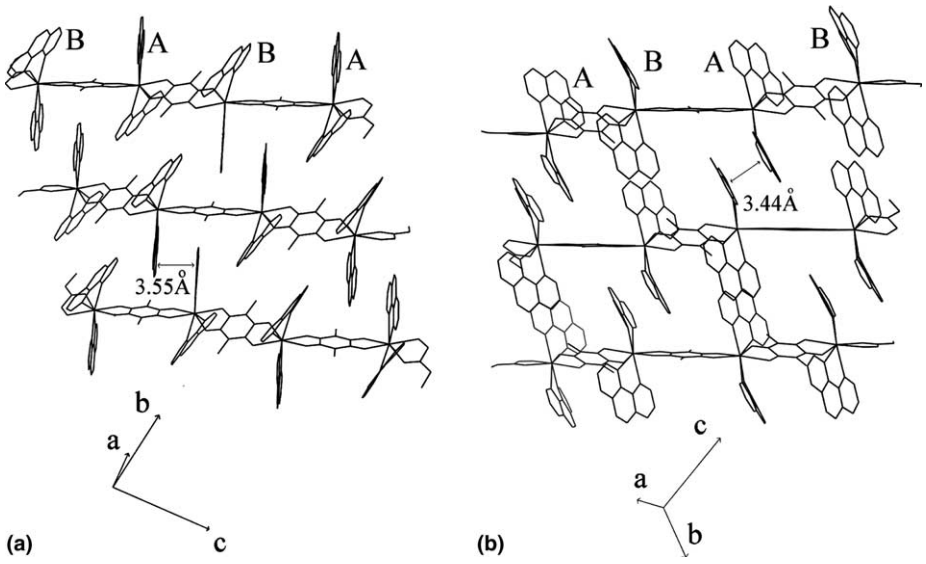

Fig. 3. A part of the 2D sheet (a) formed by stacking interactions of phenanthroline (phen A) molecules. The second phenanthroline (B) forms stacking interactions with the corresponding phen of a neighboring sheet. By this interaction a second sheet intersecting the previous is formed (b). As a result a 3D structure is obtained.

environment, are a good test for the determination of the shape of the coordination polyhedron. The φ angles, calculated by using the hard sphere model (HSM) shape characteristics, are 0.0° and 24.5° for the ideal dodecahedron and the ideal square antiprism, respectively. In our case, the φ values are 26.78° and 29.53°, which indicates that the coordination polyhedron is best described as a distorted square antiprism. The coordination polyhedron is presented in Fig. 2(b). The centroids of the CA moieties are located on inversion centres.

The Cd–N bond distances span the range 2.470(4)–2.481(4) Å and they can be considered long, related to other Cd–phen complexes. A survey of the Cambridge Structural Database shows that there are ca. 40 crystal structures of Cd–phen complexes. None of them has eight-coordinated cadmium, probably due to steric effects. Phen is too large and two of them cannot be easily accommodated in an eight-coordination environment unless other stabilizing interactions (π–π stacking for example) are involved, as well. The coordination number itself can explain the long length of the Cd–N bonds.

The two CA ligands, in the coordination sphere of Cd, are bonded in a slightly different fashion. There are four different Cd–O bond distances in the range 2.350(3)–2.443(3) Å. These distances are well in the range observed in the literature [41,42]. This asymmetry, in addition to the square antiprismatic geometry of course, leads to the formation of the zig-zag chain. As far as the C–O distances are concerned, both of the chloranilates chelate Cd symmetrically (C(1)–O(1), C(2)–O(2), 1.246(5) Å, C(4)–O(4), 1.244(5) Å, C(5)–O(3), 1.256(5) Å). The differences are very small compared with the associated su's. The C–O bond characteristics are similar to those reported for the free chloranilate dianion [43]. The similarity between the C–O bonds is reflected to the C–C bond lengths, connecting the two parts of the chloranilato ligand, as shown in Scheme 1(b). In both chloranilates the distances of the C–C bonds connecting the negatively charged sites are longer than the rest C–C distances (mean values; 1.542, 1.394 Å, respectively). These differences are systematic and suggest extended conjugation between halves of the CA ligands.

Both phen moieties are involved in stacking interactions (Fig. 3) which lead to a 3D supramolecular architecture. Phen A (Fig. 3(a)) utilizes the central ring for π–π interaction with the same ring of a parallel chain. The distance between the least square planes is 3.55 Å, and the offset of the centroids is 0.50 Å. That zipper-like interaction leads to the formation of 2D sheets, which interact with each other through the stacking of the B phen molecule (Fig. 3(b)). Two rings, the central and one external, are involved in this interaction. The distance of the least square planes is 3.44 Å, and the offset of the two ring centroids is 1.36 Å.

3.3. Thermal stability and spectroscopic characterization

The polymer is stable up to 315 °C, when heated in nitrogen atmosphere. A rather complicated decomposition process begins after that temperature, which involves at least four different exothermic steps as shown by the DTA curve. The decomposition proceeds up to 800 °C, where no residue remains. This is probably due to the reduction of Cd(II), from the organic fragments produced by the complex decomposition, and

its subsequent sublimation. When a sample is heated under forced air, the decomposition begins at 275 °C. The decomposition is rather fast, the final plateau is reached at 345 °C and corresponds good to CdO (found 17.5%, calculated 18.9%).

The bands present below 1600 cm^{-1} in the vibrational spectra of the polymer (IR: 1514, 1374; Raman: 1521, 1346 cm^{-1}) are characteristic of symmetry close to D_{2h} for the CA^{2-} ligand, since any other bands above 1600 cm^{-1} are very weak. This is in agreement with its structure. The bands at 434 and 417 cm^{-1} in the far-IR spectrum are assignable to the Cd–O stretches while the Cd–N stretching vibrations appear at 230 and 215 cm^{-1}.

The electronic spectrum of the complex is dominated by two broad bands centered at 520 and 325 nm. These bands are most likely associated with π–π* transitions and their position is in agreement with delocalization of the negative charge over the allyl system. The band at higher energy probably overlaps with phen absorption [44].

4. Concluding remarks

In this work, we have synthesized and characterized a new zig-zag polymer using as bridging ligand the CA^{2-} dianion. In our case CA^{2-} is planar and the charge is delocalized over the two allyl systems presented in Scheme 1(b). Phen forms pairwise offset face-to-face stacking motifs that lead to a 3D supramolecular architecture. We have also described physicochemical and spectroscopic characteristics.

Synthetic attempts to prepare and characterize cadmium(II) chloranilate adducts with Lewis bases other than 1,10-phenanthroline are in progress.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC 235812. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk, or on the web: http://www.ccdc.cam.ac.uk).

Acknowledgments

The authors thank the Horizontal Laboratory Network of the University of Ioannina for the X-ray (powder and single crystal) measurements. One of the referees is also acknowledged for his helpful comments.

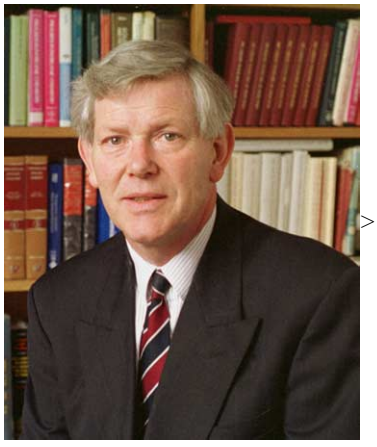
Preface



This issue of *Polyhedron* is dedicated to Professor Malcolm L.H. Green on the occasion of becoming an Emeritus Professor at Oxford University, where he was formerly Professor and Head of the Inorganic Chemistry Laboratory.

Malcolm was born in Eastleigh, Hampshire, on the 16th of April, 1936. He received his B.Sc. (Hons) in 1956 from the University of London (Acton Technical College) and his Ph.D. in 1959 from Imperial College of Science and Technology, where he studied under Professor Sir Geoffrey Wilkinson. Following Imperial College, Malcolm moved to Cambridge University in 1960, and finally to Oxford University in 1963, where he was appointed Septcentenary Fellow of Inorganic Chemistry at Balliol College. He was married to Jennifer Green (née Bilham) on the 2nd of January 1965. In 1985 Malcolm was elected to Fellow of the Royal Society and was appointed Professor and Head of the Inorganic Chemistry Laboratory and fellow of St. Catherine's College, Oxford, in 1989. He became a research active Emeritus Professor on the 1st of October 2003, with a current group of 13 researchers.

Malcolm has made numerous outstanding contributions to the field of organometallic chemistry, beginning with his first publication in 1958 on "*Bis*-cyclopentadienylrhenium hydride", resulting from his Ph.D. thesis, entitled "A study of some transition metal hydrides and olefin complexes". To date, he has published more than 600 papers and patents describing synthetic, structural, and mechanistic aspects of the chemistry of virtually every transition element. In view of the great breadth and success of Malcolm's research, it is difficult to single out a specific accomplishment that deserves highlighting over others. Nevertheless, some of the topics that immediately come to mind when prompted by the name Malcolm Green include: (i) the now infamous molybdenocene and tungstenocene systems, (ii) his fundamental studies on α- and β-hydrogen migratory insertion, carbon–hydrogen bond activation, and agostic interactions, and (iii) his development of multigram-scale metal vapor synthesis techniques. Malcolm never stands still and is constantly moving into new and exciting areas: e.g., organometallic intercalation compounds, organometallic chemistry of fullerenes and, most recently, the chemistry of metal complexes in carbon nanotubes. Moreover, his new approach to the formal classification of covalent compounds of the elements (the "MLX scheme") alleviates the problems and pitfalls often associated with oxidation state formalisms,

doi:10.1016/j.poly.2004.09.016

thereby enabling the student (and also researcher!) to understand better the nature of a specific compound.

Without a doubt, Malcolm's enthusiasm and passion has contributed greatly to the excitement that the field of organometallic chemistry has enjoyed over the years and his research has been widely recognized by numerous awards, some of which include: The Royal Society of Chemistry Corday-Morgan Medal and Prize in Inorganic Chemistry (1974); the Chemistry Society Medal in Transition Metal Chemistry (1978); the Royal Society of Chemistry Tilden Lectureship and Prize (1982); The J.C. Bailar Lecture and Medal, University of Illinois (1983); the American Chemical Society Award in Inorganic Chemistry (1984); the Royal Society of Chemistry Medal in Organometallic Chemistry (1986); the Royal Society of Chemistry Sir Edward Frankland Prize (1989); The Karl-Ziegler Prize of the Gesellschaft Deutscher Chemiker (1992); the Davy medal of the Royal Society (1995) ; American Chemical Society award in Organometallic Chemistry (1997) and The Royal Society of Chemistry Sir Geoffrey Wilkinson Medal and Prize (2000). Other recognitions of his work include: University of Western Ontario, Visiting Professor (1971); Ecole de Chimie and Institute des Substances Naturalles, Paris, Visiting Professor (1972); Harvard University, A.P. Sloan Visiting Professor (1973); Pacific West Coast Lecturer in Inorganic Chemistry (1977); Sherman Fairchild Visiting Scholar at the California Institute of Technology (1981); Karl Ziegler Gastprofessor, Max Plank Institute, Mulheim (1983); Hutchinson Lectureship, University of Rochester (1983); The University Lecturer in Chemistry, University of Western Ontario (1984); Debye Lecturer, Cornell University (1985); Wuhan University, PRC, Visiting Professor (1985); Julius Stieglitz Lecturer, University of Chicago (1986); Frontiers of Science Lecturer, Texas A&M University (1987); The DuPont Lecturer, Indiana University (1989/90); The Ida Beam Lecturer, University of Iowa (1990); The Glenn T. Seaborg Lecturer in Inorganic Chemistry at the University of California, Berkeley (1991); The South-East Lecturer in Inorganic Chemistry, USA (1991); The Walter Heiber Gastprofessor, University of Munich (1991); The Pacific Coast Lecturer (1994); The Rayson Huang Visiting Lecturer, Hong Kong (1995); The A.D. Little Lecturer, Massachusetts Institute of Technology (1995); The Stauffer Lecturer, University of Southern California (1996); the Dow Lecturer at the University of Ottowa (1996); and the James Walker Memorial Lecture, University of Edinburgh (1996); Doutor Honoris Causa, University of Lisbon, Portugal (1997); The Frank Dyer Medal, University of New South Wales (1997); The Fred Basolo Medal and Lecture., Northwestern University (1998); Ernest H. Swift Lectureship, California Institute of Technology (1998); Lewis Lecture, Cambridge UK (2001); FMC Lecturer, Princeton (2001); Distinguished Visiting Professor, Hong Kong University (2002); Eastman Company Distinguished Lecturer in Inorganic Chemistry, University of North Carolina (2002); 34th Canille and Henry Dreyfus Lecturer, Dartmouth College (2002); Raymond Siedle Lecturer, Indiana University (2004); Burt Vallee Visiting Professor at Harvard University (2004).

To date, Malcolm has supervised 118 Ph.D. graduate students and about 50 of his alumni now hold academic posts throughout the world. Many of his former students and visiting scientists convened in Oxford on the 20th September 2003 to participate in a symposium to celebrate his career. This special issue of Polyhedron includes contributions from those who have had the privilege of working in his laboratory and from many other colleagues in the organometallic community who hold him in equally high regard.

Dedicated to Professor Malcolm L.H. Green on the occasion of his retirement

Abstract

Three ferrocene derivatives, $Li[FcBH_3]$, $Li_2[1,1'\text{-}fc(BMe_3)_2]$ and $Li_2[1,1'\text{-}fc(BMe_2pz)_2]$ [$Fc = (C_5H_5)Fe(C_5H_4)$, $fc = (C_5H_4)_2Fe$, pz = pyrazolyl], have been synthesized and structurally characterized to investigate the interaction of the negatively charged sandwich complex with its Li^+ counterion(s) in the solid state. Single crystals of $Li[FcBH_3]\cdot$(12-crown-4), obtained from a THF solution after addition of 12-crown-4, contain hexacoordinated Li^+ ions, which are bonded to one molecule of crown ether and to two hydrogen atoms of the BH_3 fragment. The compound $Li_2[1,1'\text{-}fc(BMe_3)_2]$ crystallized from THF as solvent-separated ion pairs with each Li^+ being encapsulated by four THF molecules. Single crystals of $Li_2[1,1'\text{-}fc(BMe_2pz)_2]$ were grown from diethyl ether. In this compound, the lithium ions are coordinated by two solvent molecules, the pyrazolyl side-arm and the cyclopentadienyl ring. Thus, $Li_2[1,1'\text{-}fc(BMe_2pz)_2]$ can be regarded as a trinuclear segment of the polymeric structure $[-(C_5H_4R)Li(C_5H_4R)Fe-]_\infty$ with $R = BMe_2pz$.

Keywords: Multiple-decker sandwich complex; Ferrocene; Boron; Lithium; Crystal structure

1. Introduction

For more than 30 years, multiple-decker sandwich complexes have been in the focus of attention due to their promising potential as building blocks for nanoscale applications (e.g., one-dimensional wires and spin-chains) [1]. A most remarkable representative of this class of compounds was reported in 1985 by Siebert [2,3], who succeeded in the synthesis of extended columnar structures from Ni ions and η^5,μ-2,3-dihydro-1,3-diborolyl ligands. Later, this one-dimensional system was shown to possess semiconducting properties in the solid state [4–6]. For practical reasons, it would, however, be desirable to substitute simple cyclopentadienyl ligands for the sophisticated boron heterocycle. Numerous triple-decker sandwich complexes of the permethylated cyclopentadienyl derivative $[C_5Me_5]^-$ have already been isolated and structurally characterized [1]. In contrast, the number of known examples featuring exclusively the unsubstituted $[C_5H_5]^-$ ligand is still rather small (e.g., $[Ni_2(C_5H_5)_3]^+$ [7,8], $[Tl_2(C_5H_5)_3]^-$ [9]). Even though Schildcrout [10] reported as early as 1973 the detection of $[Fe_2(C_5H_5)_3]^+$ in the high-pressure electron-impact mass spectrum of ferrocene, this compound has not been isolated yet. However, clusters of the general formula $V_n[Fe(C_5H_5)_2]_{n+1}$ ($n = 1$–3) have recently been generated by two-laser vaporization of vanadium and ferrocene targets. Time-of-flight mass spectra measured with and without the addition of NH_3 gas indicate that these species possess multiple-decker sandwich structures rather than consisting of a central core of vanadium atoms capped by ferrocene molecules [11].

doi:10.1016/j.poly.2004.05.017

Our group has published the synthesis and X-ray crystal structure analysis of compound **I** (Fig. 1), in which an array of alternating Ga(I) and Fe(II) ions is connected by η^5,μ-$[C_5H_5]^-$ moieties [12]. According to density functional (DFT) calculations, the binding energy of two ferrocenes to Ga^+ is about 80 kJ mol^{-1} higher than that for the formation of $[Ga(C_6H_6)_2]^+$ from Ga^+ and two benzene molecules. Fragment analysis of $\{[Fe(C_5H_5)_2]_2Ga\}^+$ indicated a transfer of 0.4 electrons into the gallium 4p orbitals compared with a zero occupancy for the isolated ion. More detailed insight into the gas phase basicity of ferrocene toward metal cations is provided by a recent DFT study on the ferrocene–Li^+ complex [13]. Two minima have been located on the energy surface: in the lower energy structure, the lithium cation is coordinated on top of one of the cyclopentadienyl rings (cf. **II**; Fig. 1), whereas the second minimum structure **III**, being 33 kJ mol^{-1} higher in energy, has the Li^+ ion bonded laterally to the iron atom. We found a similar structural motif as predicted for the hypothetical aggregate **III** in the [1.1]diborataferrocenophane **IV**, which crystallizes with one lithium cation inside its molecular cavity [d(Fe···Li): 2.4 Å (**III**); 2.706(5), 2.720(6) Å (**IV**)] [14,15]. ^{7}Li NMR spectroscopy shows this ferrocenophane–Li^+ complex to be stable in THF solution even in the presence of excess 12-crown-4.

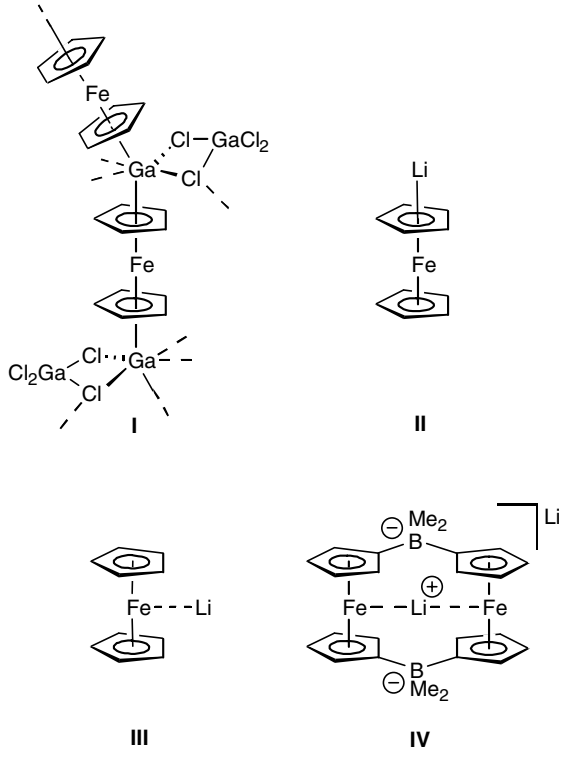

Fig. 1. The Ga^+–ferrocene multiple-decker sandwich complex **I**, the two calculated minimum structures **II** and **III** of the $Li^+\cdots$ferrocene complex in the gas phase, and the lithium [1.1]diborataferrocenophane **IV**.

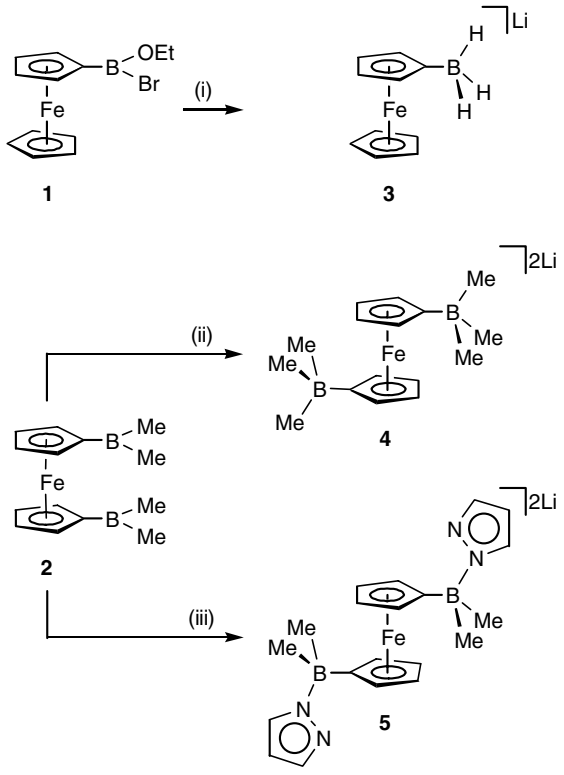
The purpose of this paper is to describe the synthesis and structural characterization of type-**II** ferrocene–Li^+ adducts, which appears to be a realistic goal given the fact that the ferrocene–Ga^+ fragments in **I** already resemble the geometry of our target structure. It has, however, to be borne in mind that the synthesis protocol leading to **I** is quite unique in that we are starting from the covalent molecule $GaCl_3$ which is readily soluble in non-coordinating solvents. Consequently, there is no competition between the ferrocene donor and Lewis basic solvent molecules for the Ga(I) ion formed in situ in the course of the reaction. Moreover, in the calculated gas phase structure **II** any possible perturbations of the molecular geometry caused by the presence of solvent molecules are necessarily neglected. For a more general approach to ferrocene–metal multiple-decker sandwich complexes, however, we will have to use transition metal salts as starting materials which usually require strongly coordinating solvents as the reaction media. It therefore seemed reasonable to employ ferrocene derivatives equipped with suitable functional groups able to assist the cyclopentadienyl ring in metal ion binding. Such auxiliary substituents will greatly enhance the stability of the ferrocene–metal aggregate but still allow for those metal···Cp interactions that have been theoretically predicted and experimentally proven to exist in the solid state (cf. the unsupported multiple-decker complex **I**).

2. Results and discussion

To bring about close contacts between a lithium cation and the ferrocene cyclopentadienyl ring, we decided to introduce substituents into the ferrocene core that (i) increase the electron density on the organometallic moiety and (ii) bear a negative charge able to attract Li^+ electrostatically. It is important to know in this context, that the Fe(II)/Fe(III) redox potentials of ferrocenylborane-amine adducts have a pronounced shift to cathodic values with respect to the parent ferrocene [cf. $FcBMe_2$–picoline: $E^{0\prime} = -0.33$ V, 1,1′-fc(BMe_2–picoline)$_2$: $E^{0\prime} = -0.56$ V; in CH_2Cl_2 vs. FcH/FcH^+, $Fc = (C_5H_5)Fe(C_5H_4)$, $fc = (C_5H_4)_2Fe$] [16,17]. This effect becomes even stronger when the amine base is replaced by a negatively charged organyl group [14,15]. Thus, tetra-coordinated boryl substituents appear to be particularly well-suited to meet the two requirements outlined above. Starting from the well-known ferrocenylboranes FcB(Br)OEt (**1**) [18] and 1,1′-fc(BMe_2)$_2$ (**2**) [19], three derivatives of ferrocenylborates were chosen for our further investigations (Scheme 1): Li[$FcBH_3$] (**3**), Li_2[1,1′-fc(BMe_3)$_2$] (**4**) and Li_2[1,1′-fc(BMe_2pz)$_2$] (**5**; pz = pyrazolyl), in which the aimed-for Li···Cp coordination may be stabilized by a chelating pyrazolyl side-arm.



Scheme 1. Syntheses of the lithium ferrocenylborates **3**, **4** and **5**: (i) +Li[AlH_4], Et_2O/C_5H_{12}, 0 °C; (ii) +2LiMe, Et_2O, −78 °C; (ii) +2Lipz, Et_2O, −78 °C.

2.1. Syntheses and NMR spectroscopic characterization

FcB(OEt)Br (**1**) and 1 equiv. of Li[AlH_4] in ether/pentane gave lithium ferrocenylborohydride **3** in excellent yield (Scheme 1). Details of the synthesis procedure and NMR data of **3** have been published elsewhere [20]. Single crystals of Li[$FcBH_3$]·(12-crown-4) were grown by gas phase diffusion of diethyl ether onto a THF solution of **3**, to which a small amount of 12-crown-4 had been added. In the absence of the crown ether, no single crystalline material could be obtained. Reaction of 1,1′-fc(BMe_2)$_2$ (**2**) with either 2 equiv. of LiMe or 2 equiv. of Lipz in diethyl ether at −78 °C gave Li_2[1,1′-fc(BMe_3)$_2$] (**4**) and Li_2[1,1′-fc(BMe_2pz)$_2$] (**5**). The ^{11}B NMR spectra of **4** and **5** show resonances at $\delta = -21.8$ and −9.0, respectively, which agree nicely with those of Li[BMe_4] [$\delta(^{11}B) = -20.2$] [21] on one hand and Na[$B(NH_2)Et_3$] [$\delta(^{11}B) = -9.8$] [22] on the other. The ^{11}B NMR signal of **4** possesses a narrow linewidth ($h_{1/2} = 25$ Hz) testifying to a high local symmetry at the boron atom. In contrast, the less symmetrical boron coordination sphere in **5** results in a significantly broader ^{11}B NMR resonance ($h_{1/2} = 300$ Hz). In the ^{1}H NMR spectrum of **4**, three signals appear at −0.47, 3.55 and 3.75 ppm (integral ratio = 9:2:2), which are assigned to the methyl protons and the two types of magnetically non-equivalent ferrocene hydrogen atoms. In the ^{1}H NMR spectrum of

5, the corresponding signals are visible at 0.11, 4.05 and 4.19 ppm. This time, an integral ratio of 6:2:2 reveals the presence of only two methyl substituents at each boron atom. Moreover, the electronegative pyrazolyl groups lead to a downfield shift of the methyl and ferrocenyl resonances of **5** compared to **4** and to a pattern of three signals in the aromatic region of the proton spectrum [$\delta(^1H) = 5.95$, 7.01, 7.48]. In the ^{13}C NMR spectrum of **4**, a 1:1:1:1 quadruplet for the methyl groups is observed [$\delta(^{13}C) = 16.4$, $^1J_{BC} = 40$ Hz] as a result of ^{11}B ($I = 3/2$) coupling. The methyl resonance of the less symmetrically substituted derivative **5** [$\delta(^{13}C) = 12.8$] is severely broadened and its multiplet structure was not resolved, which was attributed to the quadrupolar relaxation of the adjacent boron nucleus [22].

2.2. X-ray crystal structure determinations

Selected crystallographic data are summarized in Table 1. Lithium ferrocenylborohydride **3** crystallizes together with 1 equiv. of 12-crown-4 in the orthorhombic space group *Pnma* (Fig. 2). Each Li^+ ion is complexed by four oxygen atoms of a crown ether molecule and establishes close contacts to two hydrogen atoms of the BH_3 fragment [Li(1)–H(1A) = 1.97(2) Å]. The Li···H distance to the third hydrogen atom is almost 1 Å longer [Li(1)···H(1B) = 2.94(2) Å]. Thus, $[FcBH_3]^-$ acts as a bidentate ligand toward the lithium cation. In metal borohydrides, this is the most common binding mode [23]. The coordination geometry of Li^+ in **3** · (12-crown-4) is reminiscent of the structure determined for $Li[BH_4] \cdot 2DME$ in the solid state (DME = dimethoxyethane) [23]. Here, the hexacoordinated Li ion is surrounded by four oxygen atoms of two DME molecules and two hydrogen atoms from a μ_2-$[BH_4]^-$ group. Consequently, the Li–H bond lengths {**3** · (12-crown-4): 1.97(2) Å; $Li[BH_4] \cdot 2DME$: 2.02(2) Å}, as well as the Li–H–B bond angles {**3** · (12-crown-4): 96.4(12)°; $Li[BH_4] \cdot 2DME$: 98.1(9)°} are rather similar in both compounds. A significantly shorter B···Li distance is found in **3** · (12-crown-4) [2.382(4) Å] compared to $Li[BH_4] \cdot 2DME$ [2.470(4) Å]. Using Edelstein's correlation of metal–boron distances as a measure of the denticity of borohydride groups [24], values of 1.6 ± 0.1 and 1.36 ± 0.06 Å are estimated for the ionic radii of bidentate and tridentate borohydride ligands, respectively. Thus, B···Li distances of about 2.50 and 2.26 Å are to be expected for Li-μ_2-BH_3R and Li-μ_3-BH_3R coordination modes [ionic radius of hexacoordinated $Li^+ = 0.90$ Å [25]]. It may therefore be concluded, that the $[BH_4]^-$ ion in $Li[BH_4] \cdot 2DME$ represents the ideal Li-μ_2-BH_3R arrangement, whereas the BH_3 fragment in **3** · (12-crown-4) is slightly tilted in the direction of a Li-μ_3-BH_3R coordination {cf. the distance between Li^+ and the non-coordinating H atom(s) is shorter in **3** · (12-crown-4) than in $Li[BH_4] \cdot 2DME$ with values of 2.94(2) and 3.27(2) Å, respectively}. This effect is most likely caused by steric repulsion between the crown ether ligand and the bulky ferrocenyl substituent in **3** · (12-crown-4).

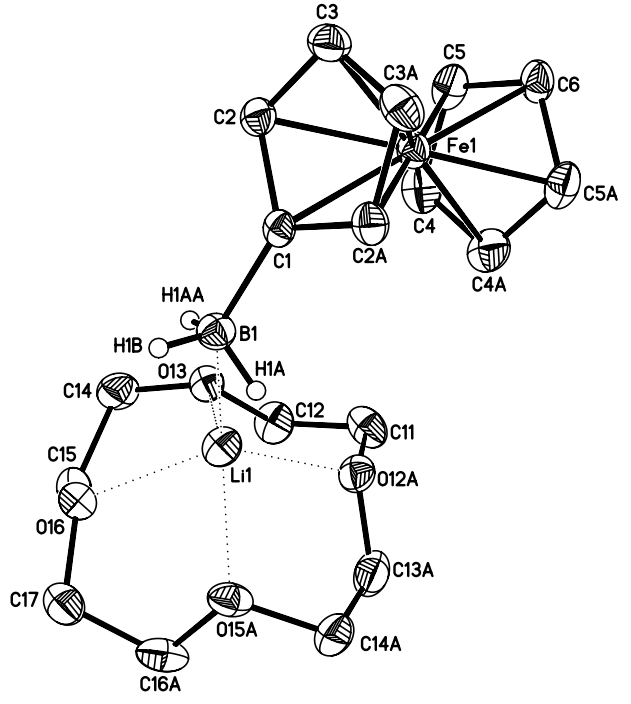

Fig. 2. Molecular structure of compound **3** · (12-crown-4); thermal ellipsoids are shown at the 50% probability level. Selected bond lengths (Å), atom···atom distances (Å), angles (°), torsion angles (°) and dihedral angles (°): B(1)–C(1) = 1.600(4), B(1)···Li(1) = 2.382(4), B(1)–H(1A) = 1.14(2), B(1)–H(1B) = 1.15(3), Li(1)–H(1A) = 1.97(2), Li(1)···H(1B) = 2.94(2); C(2)–C(1)–C(2A) = 104.2(2), C(2)–C(1)–B(1) = 127.8(1), C(1)–B(1)···Li(1) = 141.3(2), C(1)–B(1)–H(1A) = 112.6(10), C(1)–B(1)–H(1B) = 111.6(14), H(1A)–B(1)–H(1B) = 105.1(12), Li(1)–H(1A)–B(1) = 96.4(12); COG–C(1)–B(1) = 176.5; C(2)–C(1)–B(1)···Li(1) = 92.4(2), C(2)–C(1)–B(1)–H(1B) = −87.6(2), C(1)–COG–COG′–C(4A) = −36.1; C(1)C(2)C(3)C(3A)C(2A)//C(4)C(5)C(6)C(5A)C(4A) = 0.2. COG: centre of gravity of a C_5H_4 ring. Symmetry transformation used to generate equivalent atoms: $x, -y + 3/2, z$.

The molecular structure of **3** · (12-crown-4) indicates coordination of Li^+ to the BH_3 group via two hydride bridges to be preferred over $Li^+ \cdots \eta^5$-ferrocene bonding. The system was therefore developed further by replacing the hydrogen substituents with methyl groups, which can be expected to interact less strongly with lithium cations. Moreover, two borate substituents were introduced into the ferrocene core in order to increase the electrostatic attraction of Li^+ ions. Single crystals of the resulting compound **4** were obtained from THF [**4** · $(THF)_8$: orthorhombic, $Pca2_1$; Fig. 3]; addition of 12-crown-4 was not required. The crystal lattice of **4** · $(THF)_8$ consists of solvent-separated ions with each Li^+ being coordinated to four THF molecules in a tetrahedral fashion. The $[1,1'\text{-fc}(BMe_3)_2]^{2-}$ ion adopts a conformation in which the BMe_3 substituents are pointing away from each other [C(11)–COG–COG′–C(21) = 154.1°; COG: centre of gravity of a cyclopentadienyl ring].

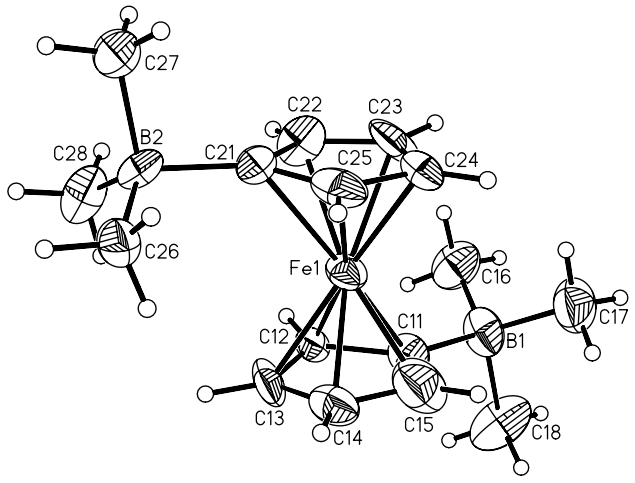

Fig. 3. Molecular structure of the anionic part of compound $\mathbf{4}\cdot(\mathrm{THF})_8$; thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å), angles (°), torsion angles (°) and dihedral angles (°): B(1)–C(11) = 1.734(16), B(2)–C(21) = 1.634(16); C(12)–C(11)–C(15) = 102.7(11), C(12)–C(11)–B(1) = 127.6(10), C(15)–C(11)–B(1) = 129.7(13), C(22)–C(21)–C(25) = 101.7(10), C(22)–C(21)–B(2) = 126.4(11), C(25)–C(21)–B(2) = 131.9(11), COG–C(11)–B(1) = 174.9, COG–C(21)–B(2) = 177.7; C(12)–C(11)–B(1)–C(18) = −94.3(14), C(22)–C(21)–B(2)–C(27) = −88.5(13), C(11)–COG–COG′–C(21) = 154.1; C(11)C(12)C(13)C(14)C(15)// C(21)C(22)C(23)C(24)C(25) = 2.2.

Since the desired Li–ferrocene interaction could not be achieved just by increasing the number of negatively charged side-chains, each of the borate groups was equipped with a Lewis-basic pyrazolyl substituent in order to anchor the Li^+ ion via a Li–N adduct bond. The lithium pyrazolylborate **5** crystallizes from diethyl ether together with four solvent molecules in the triclinic space group $P\bar{1}$ [$\mathbf{5}\cdot(Et_2O)_4$; Fig. 4]. This time, each Li^+ ion is bonded to two ether molecules and to the nitrogen lone-pair of the pyrazolyl side-arm [Li(1)–N(32) = 1.998(5), Li(2)–N(42) = 1.999(6) Å], which places it on top of the cyclopentadienyl ring [C(12)–C(11)–B(1)–N(31) = 97.7(3)°, C(22)–C(21)–B(2)–N(41) = −81.3(3)°]. As a consequence, three lithium–carbon contacts [Li(1)–C(11) = 2.646(5), Li(1)–C(12) = 2.395(5), Li(1)–C(13) = 2.910(6), Li(2)–C(21) = 2.475(5), Li(2)–C(22) = 2.496(5), Li(2)–C(25) = 2.730(6) Å] are established by Li(1) as well as Li(2). As the internal angles of the C(Cp)–B–N–N–Li chains do not depart appreciably from the ideal values of 109° [C(11)–B(1)–N(31) = 105.3(2)°, C(21)–B(2)–N(41) = 106.6(2)°] and 120° [B(1)–N(31)–N(32) = 121.9(2)°, N(31)–N(32)–Li(1) = 124.0(2)°, B(2)–N(41)–N(42) = 124.2(2)°, N(41)–N(42)–Li(2) = 122.3(2)°], the molecular framework of the heterotrimetallic aggregate is apparently free of ring strain. Compound **5** is related to the ferrocene-based tris(1-pyrazolyl)borates **V** [26] (Fig. 5), of which several metal complexes [27,28] (including one Li^+ salt) [29] have been synthesized and structurally characterized. In all these cases, the tris(1-pyrazolyl)borate units act as di- or trihapto ligand toward the metal centre, which in turn was never found to interact with the ferrocene backbone. Thus, as is to be expected, Li^+–ferrocene bonding appears to be less favourable than lithium-pyrazolyl adduct formation. Some key structural features of $\mathbf{5}\cdot(Et_2O)_4$ resemble Laguna's coordination polymer **VI** [30] (Fig. 5), consisting of 1,1′-ferrocenediyl bis(dialkyldithiocarbamate) ligands [31] and Ag(I) ions. Here, each silver ion is not only bonded to two sulfur atoms of different ferrocene moieties but also to two cyclopentadienyl rings in an η^2 fashion. In 1998, **VI** represented the first example where an η^5-cyclopentadienyl ring of ferrocene was shared with another metal atom via the π-system.

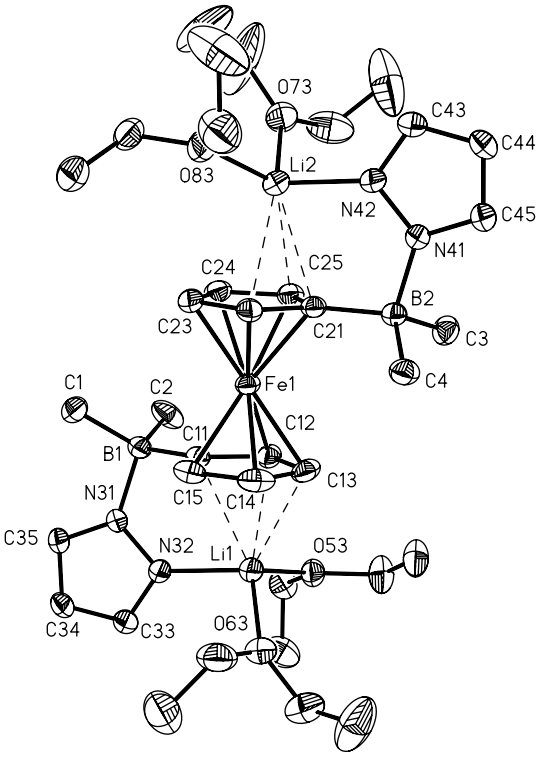

Fig. 4. Molecular structure of compound $\mathbf{5}\cdot(Et_2O)_4$; thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å), angles (°), torsion angles (°) and dihedral angles (°): B(1)–C(11) = 1.617(4), B(1)–N(31) = 1.611(3), B(2)–C(21) = 1.621(4), B(2)–N(41) = 1.610(3), Li(1)–N(32) = 1.998(5), Li(1)–C(11) = 2.646(5), Li(1)–C(12) = 2.395(5), Li(1)–C(13) = 2.910(6), Li(2)–N(42) = 1.999(6), Li(2)–C(21) = 2.475(5), Li(2)–C(22) = 2.496(5), Li(2)–C(25) = 2.730(6); C(12)–C(11)–C(15) = 104.5(2), C(12)–C(11)–B(1) = 128.8(2), C(15)–C(11)–B(1) = 126.7(2), C(22)–C(21)–C(25) = 104.9(2), C(22)–C(21)–B(2) = 127.0(2), C(25)–C(21)–B(2) = 128.1(2), C(11)–B(1)–N(31) = 105.3(2), B(1)–N(31)–N(32) = 121.9(2), N(31)–N(32)–Li(1) = 124.0(2), C(21)–B(2)–N(41) = 106.6(2), B(2)–N(41)–N(42) = 124.2(2), N(41)–N(42)–Li(2) = 122.3(2), N(32)–Li(1)–O(53) = 109.0(3), N(32)–Li(1)–O(63) = 106.3(3), O(53)–Li(1)–O(63) = 111.2(2), N(42)–Li(2)–O(73) = 105.4(3), N(42)–Li(2)–O(83) = 109.4(3), O(73)–Li(2)–O(83) = 107.1(2), COG–C(11)–B(1) = 177.5, COG–C(21)–B(2) = 179.3; C(12)–C(11)–B(1)–N(31) = 97.7(3), C(11)–B(1)–N(31)–N(32) = −35.4(3), B(1)–N(31)–N(32)–Li(1) = 14.2(4), C(22)–C(21)–B(2)–N(41) = −81.3(3), C(21)–B(2)–N(41)–N(42) = 4.0(3), B(2)–N(41)–N(42)–Li(2) = −9.2(4), C(11)–COG–COG′–C(21) = −157.9; C(11)C(12)C(13)C(14)C(15)// C(21)C(22)C(23)C(24)C(25) = 1.0.

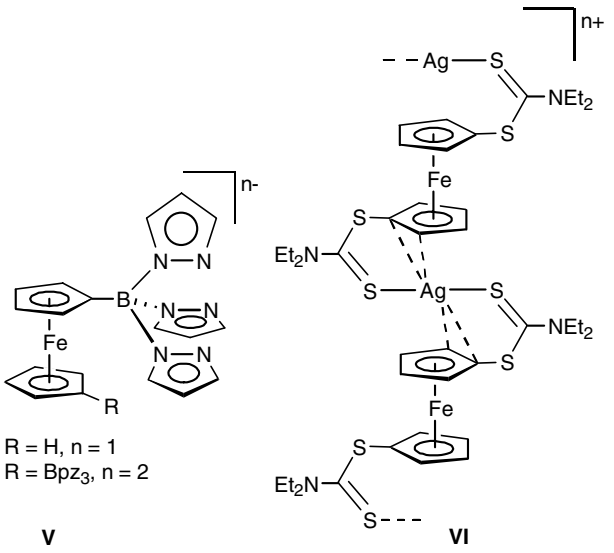

Fig. 5. Ferrocene-based tris(1-pyrazolyl)borate derivatives **V** and a double sandwich silver(I)–ferrocene polymer **VI**.

3. Conclusions

Inspired by a DFT study on the ferrocene–Li^+ complex in the gas phase [13], we synthesized three ferrocene derivatives, $Li[FcBH_3]$, $Li_2[1,1'\text{-fc}(BMe_3)_2]$ and $Li_2[1,1'\text{-fc}(BMe_2pz)_2]$ [Fc = $(C_5H_5)Fe(C_5H_4)$, fc = $(C_5H_4)_2Fe$, pz = pyrazolyl], in order to establish the structural motif of a Li^+ cation located on top of a ferrocene–Cp ring. Our rationale was to stabilize a potential interaction between both components by introducing negatively charged substituents into the ferrocene core. Initially, it appeared to be of prime importance to use anionic side-chains that do *not* possess electron lone pairs able to compete with the cyclopentadienyl π-system for Li^+ coordination. Thus, borate substituents were chosen for all further investigations. A crystal structure analysis of $Li[FcBH_3]\cdot$(12-crown-4), obtained from a THF solution after addition of 12-crown-4, revealed hexacoordinated Li^+ ions bonded to one molecule of crown ether and two hydrogen atoms of the BH_3 fragment. Even a hydridoborate fragment is thus preferred over the Cp π-system for Li^+ coordination. Attempts to block this coordination site by substitution of methyl groups for the hydrogen atoms failed, since the related methylborate crystallized from THF as solvent-separated ion pairs $\{[Li(THF)_4]^+\}_2[1,1'\text{-fc}(BMe_3)_2]^{2-}$. Single crystals of this compound from less strongly coordinating solvents (e.g., diethyl ether) could not be obtained up to now. Contrary to our a priori assumptions, we thus came to the conclusion that a Lewis-basic functionality might be required to stabilize the aimed-for Li^+–ferrocene complex, provided the electron lone pair is part of a side-arm designed to put the Li^+ ion on the cyclopentadienyl ring. From molecular modelling studies, the rigid pyrazolyl ring appeared to be well-suited for this purpose. Single crystals of $Li_2[1,1'\text{-fc}(BMe_2pz)_2]$ were grown from diethyl ether. In this compound, the lithium ions are coordinated by two solvent molecules, the pyrazolyl side-arm and the cyclopentadienyl ring. Thus, $Li_2[1,1'\text{-fc}(BMe_2pz)_2]$ can be regarded as a trinuclear segment of the polymeric structure $[-(C_5H_4R)\text{-}Li(C_5H_4R)Fe-]_\infty$ with R = BMe_2pz. In the future, we are planning to employ the $[1,1'\text{-fc}(BMe_2pz)_2]^{2-}$ ligand in combination with metals other than Li^+ for the synthesis of ferrocene-based multiple-decker complexes.

4. Experimental section

4.1. General remarks

All reactions and manipulations of air-sensitive compounds were carried out in dry, oxygen-free argon using standard Schlenk ware. Solvents were freshly distilled under N_2 from Na–benzophenone (diethyl ether, THF) prior to use. NMR: Bruker DPX 400, Bruker DPX 250. ^{11}B NMR spectra are reported relative to external $BF_3\cdot Et_2O$. Unless stated otherwise, all NMR spectra were run at ambient temperature; abbreviations: s, singlet, d, doublet, vtr, virtual triplet, q, quadruplet, n.r., multiplet expected in the ^1H NMR spectrum but not resolved, n.o., signal not observed. Compounds **1** [18] and **2** [19] were synthesized according to the literature procedures.

4.2. Preparation of *3*

For the synthesis of compound **3** see [20]. Single crystals of **3**·(12-crown-4) were grown by gas phase diffusion of diethyl ether onto a THF solution of **3** to which a small amount of 12-crown-4 had been added. Compound **3** is sensitive to air and moisture. *Anal.* Calc. for $C_{18}H_{28}BFeLiO_4$ [382.00]: C, 56.60; H, 7.39. Found: C, 56.33; H, 7.12%.

4.3. Preparation of *4*

LiMe (1.6 M, 4.42 mL, 7.07 mmol) in Et_2O was added dropwise with stirring at −78 °C to **2** (0.94 g, 3.54 mmol) in Et_2O (20 mL). The mixture was slowly warmed to room temperature and the solvent removed under reduced pressure. The remaining highly viscous oily residue was dissolved in THF (20 ml) and the solution stored at 5 °C overnight, whereupon dark red X-ray quality crystals of **4**·$(THF)_8$ formed. Yield: 2.79 g (89%). ^{11}B NMR (128.4 MHz, d_8-THF): δ −21.8 ($h_{1/2} = 25$ Hz). ^1H NMR (400.1 MHz, d_8-THF): δ −0.47 (s, 18H, CH_3), 3.55, 3.75 (2 × n.r., 2 × 4H, C_5H_4). ^{13}C NMR (100.6 MHz, d_8-THF): δ 16.4 (q, $^1J_{BC} = 40$ Hz, CH_3), 67.8, 70.7 (C_5H_4), n.o. C_5H_4-C_{ipso}. The com-

pound is extremely sensitive to air and the crystals lose THF rapidly when isolated at ambient temperature; a decent elemental analysis was therefore not obtained.

4.4. Preparation of 5

Lipz (0.34 g, 4.60 mmol) in Et_2O (15 mL) was added dropwise with stirring at −78 °C to **2** (0.61 g, 2.30 mmol) in Et_2O (15 mL). The mixture was slowly warmed to room temperature, filtered and the clear yellow filtrate stored at 5 °C overnight, whereupon yellow–orange X-ray quality crystals of $\mathbf{5}\cdot(Et_2O)_4$ formed. Yield: 1.52 g (93%). ^{11}B NMR (128.4 MHz, d_8-THF): δ −9.0 ($h_{1/2}$ = 300 Hz). ^{1}H NMR (400.1 MHz, d_8-THF): δ 0.11 (s, 12H, CH_3), 4.05, 4.19 (2 × vtr, 2 × 4H, $^3J_{HH} = {}^4J_{HH} = 1.6$ Hz, C_5H_4), 5.95 (vtr, 2H, $^3J_{HH} = 1.9$ Hz, pz–H4), 7.01, 7.48 (2 × d, 2 × 2H, $^3J_{HH} = 1.7$, 2.0 Hz, pz–H3,5). ^{13}C NMR (100.6 MHz, d_8-THF): δ 12.8 (n.r., CH_3), 71.0, 72.2 (C_5H_4), 102.8 (pz–C4), 131.9, 135.4 (pz–C3,5), n.o. C_5H_4-C_{ipso}. The compound is sensitive to air and the crystals lose diethyl ether rapidly when isolated at ambient temperature; a decent elemental analysis was therefore not obtained.

4.5. X-ray crystal structure analyses

The crystals of $\mathbf{3}\cdot$(12-crown-4), $\mathbf{4}\cdot(THF)_8$ and $\mathbf{5}\cdot(Et_2O)_4$ were measured on a STOE IPDS II two-circle diffractometer with graphite-monochromated Mo Kα radiation. An empirical absorption correction was performed using the MULABS [32] option in the program PLATON [33]. The structures were solved by direct methods using the program SHELXS [34] and refined against F^2 with full-matrix least-squares techniques using the program SHELXL [35]. The crown ether ring in $\mathbf{3}\cdot$(12-crown-4) is located on a crystallographic mirror plane and therefore disordered over two equally occupied sites. $\mathbf{4}\cdot(THF)_8$ is a racemic twin composed of two domains with an occupancy ratio of 0.70(6)/0.30(6). All non-H atoms of $\mathbf{3}\cdot$(12-crown-4), $\mathbf{4}\cdot(THF)_8$ and $\mathbf{5}\cdot(Et_2O)_4$ were refined with anisotropic displacement parameters. The BH_3 hydrogen atoms of $\mathbf{3}\cdot$(12-crown-4) could be located in the difference Fourier map and were freely refined. All other H atoms were refined using a riding model.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC reference numbers: 230425 [$\mathbf{3}\cdot$(12-crown-4)], 230426 [$\mathbf{4}\cdot(THF)_8$], 230427 [$\mathbf{5}\cdot(Et_2O)_4$]. Dedicated to M.L.H. Green in recognition of his outstanding contribution to inorganic chemistry

Abstract

Acidic aqueous solutions of the $[Cp^*MoO_2(H_2O)_x]^+$ ion yield single crystals of the novel organometallic polyoxomolybdate $Cp^*_2Mo_6O_{17}$ via a slow protonolysis of the Mo–Cp* bond. This compound has subsequently been obtained selectively and in good yields from the combination of $Cp^*_2Mo_2O_5$ and four equivalents of MoO_4^{2-} under acidic conditions. The X-ray structure of $Cp^*_2Mo_6O_{17}$ is analogous to other hexanuclear polyoxometallate ions but is the most distorted so far reported according to the continuous symmetry measure, the inner $(\mu_6\text{-O})Mo_6$ core featuring a large displacement of the central oxygen atom toward the organometallic moieties and away from the inorganic ones.

1. Introduction

We have recently initiated a research program aimed at exploiting the chemistry of high oxidation state organometallic compounds in water. Aqueous organometallic chemistry is attracting growing interest because of its ''green'' impact [1–3] and because of its promise in catalytic [4,5] and biomedical applications [6]. Its development, however, has so far been restricted for the most part to low-valent systems to which hydrophilic functionalities are added on the ligand periphery [7–9], in order to make the systems compatible with an aqueous environment. High oxidation organometallics are now a well established family of compounds [10,11], mostly supported by oxo ligands. Pioneering work in this area was carried out by Cousins and Green [12,13], with the now 40-year old synthesis and subsequent investigations of $Cp_2Mo_2O_5$. Some of these high oxidation state organometallic compounds exhibit interesting catalytic applications [14]. Nonetheless, their investigation has so far mostly involved the use of organic solvents and very little is known about their behaviour in water. The investigation of these materials in water, especially for electroactive metals, offers opportunities for the development of new catalytic and electrocatalytic processes [15]. Our first studies have focused on the speciation [16] and on the electrochemical [17,18] and chemical [19,20] reduction behavior of the Cp^*Mo^{VI} moiety. In particular, we have established that the Cp^*Mo^{VI} species is stable in air and in the entire pH range in a mostly aqueous medium (80% H_2O, 20% MeOH), at least for the time necessary to carry out the speciation studies (several hours at room temperature). While the species is stable in the form of the previously known [21–23] $Cp^*MoO_3^-$ complex at high pH,

doi:10.1016/j.poly.2004.06.025

its nature changes to the hitherto unknown cationic complex $Cp^*MoO_2(H_2O)_x^-$ at very low pH (ca. <2) [16]. For the latter species, the hydration status (e.g., whether it contains a coordinated water molecule or not) could not be determined from its spectroscopic characteristics (UV–Vis) nor from its reactivity (kinetics of proton transfer processes). We have therefore attempted to obtain this information from a single crystal X-ray study. The outcome of these attempts have led to the chemistry which is described herein.

2. Experimental

2.1. General part

The compound $Cp^*_2Mo_2O_5$ was prepared as described previously [24]. The infrared spectra were recorded on a Brucker Vector 22 instrument equipped with a Globar (MIR) source. The powder X-ray diffraction spectrum was recorded with a Seifert XRD3000 $\theta/2\theta$ diffractometer using Cu radiation at 40 kV and 30 mA, and equipped with a graphite monochromator. The elemental analysis was carried out by the analytical services of LSEO with Fisons EA 1108 instruments.

2.2. Procedure leading to single crystals of $Cp^*_2Mo_6O_{17}$

To a MeOH solution (2 mL) of $Cp^*_2Mo_2O_5$ (37 mg) was added 2 mL of aqueous HNO_3 (0.2 M) in air. This solution was transferred into a 50 mL Schlenk tube and the oxygen was removed by argon bubbling. The solution was subsequently left undisturbed on the bench. Brown crystals were obtained over a 2.5 month period. One of these crystals was used for the X-ray diffraction analysis.

2.3. Synthesis of $Cp^*_2Mo_6O_{17}$

$Cp^*_2Mo_2O_5$ (54 mg, 0.1 mmole) was dissolved in 2.5 mL of MeOH. Separately, $Na_2MoO_4 \cdot 2H_2O$ (96.8 mg, 0.4 mmol) was dissolved in 2.5 mL of water. The two solutions were mixed with no apparent change. 1 mL of HNO_3 0.1 M was slowly added, forcing the immediate precipitation of an orange solid. The solid was filtered, washed with H_2O, then with MeOH, and finally dried at 70 °C. (Yield 86.5 mg, 77.4%). *Anal.* Calc. for $C_{20}H_{30}Mo_6O_{17}$: C, 21.48; H, 2.70. Found: C, 21.46; H, 2.91%. IR (Nujol mull, cm^{-1}): 978 w, 966 s, ca. 820 sh, 792 s, ca. 770 sh.

2.4. Single crystal X-ray diffraction study

Intensities were collected on an Enraf-Nonius KappaCCD diffractometer at 110 K using Mo Kα radiation. The structure was solved via a Patterson search program [25] and refined with full-matrix least-squares methods [26] based on $|F^2|$ with the aid of the WINGX program [27]. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were included with a riding model with isotropic temperature factors fixed to 1.5 times those of the corresponding parent atoms. The essential crystallographic parameters are listed in Table 1 and selected bond distances and angles are collected in Table 2.

3. Results

According to our recent investigation [16], adjusting the pH of a 4:1 H_2O–MeOH solution of $Cp^*_2Mo_2O_5$ to <2 selectively generates the new oxo cation $Cp^*MoO_2(H_2O)_x^+$, where the most likely values of x are 0 and 1. In order to verify the presence of coordinated water in this complex, an acidic aqueous solution of $Cp^*MoO_2(H_2O)_x^+$ was set out for a long term crystal-

lization, as described in Section 2. Salts of various anions such as PF_6^- or BPh_4^- were used, but the procedure typically led to the recovery of crystals of the neutral starting complex, $Cp^*_2Mo_2O_5$. A longer scale crystallization attempt, carried out without added salt, slowly yielded single crystals of a new compound. This turned out to correspond to the title organometallic polyoxometallate.

The title compound is a new member of the family of organometallic polyoxometallates [28]. Once the chemical nature of this compound was revealed by a single crystal X-ray diffraction study (vide infra), a more logical, selective and high yield synthesis was conceived, as illustrated in Eq. (1). Mixing a methanolic solution of the organometallic reagent with an aqueous solution of the inorganic reagents in the appropriate stoichiometry yields a clear solution, from which the desired product rapidly precipitates upon acidification in an analytically pure form. The compound is sparingly soluble in water and only slightly soluble in organic solvents. Unlike the previously reported $[Cp^*Mo_6O_{18}]^-$ analogue [29,30], its solubility in MeCN or DMSO at temperatures up to 80 °C was not sufficient to allow the recording of ^{95}Mo or ^{17}O solution NMR spectra. However, the identity of the bulk sample as obtained from reaction (1) was established by the excellent match of its experimental powder X-ray diffraction pattern with the pattern calculated from the single crystal X-ray data, see Fig. 1 and Table 3

$$Cp^*_2Mo_2O_5 + 4MoO_4^{2-} + 8H^+ \rightarrow Cp^*_2Mo_6O_{17} + 4H_2O \quad (1)$$

The single crystal X-ray analysis shows that the molecule is hexanuclear with the six Mo atoms placed at the vertices of an octahedron, see Fig. 2. Each of the 12 octahedron edges is bridged by an oxygen atom. Four more oxygen atoms are placed on as many Mo atoms in the terminal coordination mode, while the remaining two *cis*-Mo atoms are η^5-bonded to Cp* ligands. The structure is completed by an additional oxygen atom, placed near the center of the octahedron. The molecule sits on

a crystallographic twofold axis, which contains the central O(1) and the edge-bridging O(5) and O(8) atoms. The molecular geometry is identical with that of the previously published tungsten analogue, $Cp^*_2W_6O_{17}$, including the relative *cis*-arrangement of the two Cp*-substituted metal atoms [31]. The geometry can also be related to those of the $[Mo_6O_{19}]^{2-}$ and $[Cp^*Mo_6O_{18}]^-$ complexes [29,30,32–34], with which it can be considered isoelectronic and isostructural in light of the isolobal analogy between the terminal Cp^{*-} and O^{2-} ligands.

Selected bond distances and angles are listed in Table 2. The terminal Mo–O distances average 1.685(3) Å,

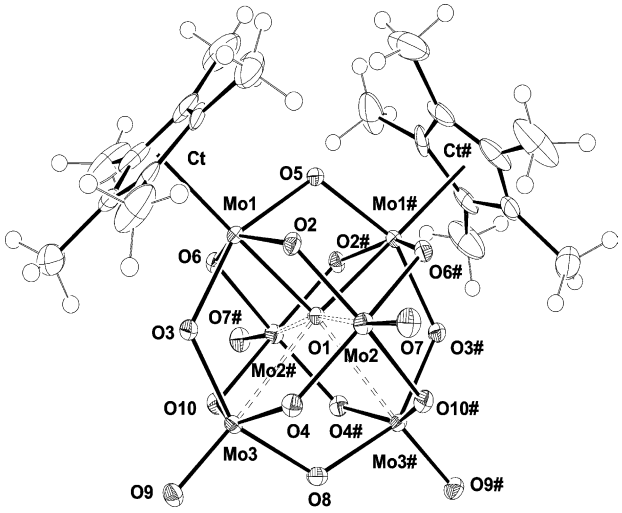

Fig. 2. An ORTEP view of the $Cp^*_2Mo_6O_{17}$ molecule.

which compares with 1.681(8) Å for $[Mo_6O_{19}]^{2-}$ (average over 14 different structures containing this ion available in the CCDC) and with 1.686(11) or 1.66(3) Å in the two different salts of $[Cp^*Mo_6O_{18}]^-$ [29,30]. The edge-bridging Mo–O distances are longer and spread in a rather wide range between 1.855(3) and 2.029(3) Å, showing a certain degree of asymmetry for the octahedral framework, similar to what is commonly found for other polyoxometallate ions [29,35]. Their overall average is 1.93(6) Å, whereas the same average over the 14 different structures of the $[Mo_6O_{19}]^{2-}$ ion in the CCDC is 1.93(3) Å. There is no clear trend depending on the nature of the Mo atom (i.e., inorganic or organometallic). For instance, atoms O(2) and O(3) are closer to the inorganic Mo atom [1.855(3) and 1.883(3) Å] than to the organometallic Mo atom [2.029(3) and 1.955(3) Å], whereas the reverse is true for atom O(6) [1.980(3) versus 1.890(3) Å]. The O atoms bridging two Mo(=O) units [O(4), O(8) and O(10)] also show distances in a relatively wide range [from 1.861(3) to 2.006(3) Å]. The highest degree of asymmetry, however, is exhibited for the μ_6-O atom. The distances are shorter for the

Mo(1) atom, 2.145(2) Å, intermediate for the Mo(2) atom [i.e., *cis* to Mo(1)], 2.3674(5) Å, and longer from the Mo(3) atom [i.e., *trans* to Mo(1)], 2.542(3) Å. A similar, though slightly less pronounced asymmetry was noted for the $[Cp^*Mo_6O_{18}]^-$ ion, where the Mo-(μ_6-O) distances in the two independently determined structures [29,30] are 2.134(9) or 2.14(1) Å to the Cp*Mo atom, 2.343(9) or 2.33(2) Å to the *cis*-Mo atoms, and 2.498(9) or 2.48(1) Å to the *trans*-Mo atom. By comparison, the central oxygen is placed symmetrically in the $[Mo_6O_{19}]^{2-}$ ion, the average over the 14 structures available in the CCDC being 2.318(7) Å. The use of the quantitative ''octahedral symmetry measure'', as defined by Avnir and coworkers [36,37], for the title compound and for the related Cp*-containing polyoxometallates shows that the distortion of the (μ_6-O)M_6 core is systematically and significantly larger than the distortion of the M_6 core and that it is larger for compounds with two Cp* substituents than for those with one. The distortion parameter for the (μ_6-O)M_6 core is by far the largest (0.172) for the title compound (cf. 0.099 for $Cp^*_2W_6O_{17}$, 0.073 and 0.066 for the two salts of $[Cp^*Mo_6O_{18}]^-$ and 0.030 for $[Cp^*TiMo_5O_{18}]^{3-}$). The displacement of the oxygen atom from the octahedron center was previously interpreted in terms of a stronger *trans* influence by the terminal oxo ligand relative to the terminal Cp* ligand. It is possible, however, to provide an alternative rationalization in terms of the greater donor power of the terminal O^{2-} ligand with respect to the terminal Cp^{*-} ligand. Thus, the hypothetical $Cp^*_2Mo_6O_{16}^+$ moiety that is obtained by removal of the central O^{2-} ion would feature a lower electron density for the organometallic Mo atoms. The internal O atom is consequently attracted to a greater extent by these atoms. The metal distance from the Cp* ring centroid, 2.109(4) Å, compares with 2.091(15) Å in the $[Cp^*Mo_6O_{18}]^-$ structure.

4. Discussion

The result of the previous aqueous speciation study of the Cp^*Mo^{VI} moiety seemed to suggest that the Cp*–Mo^{VI} bond is stable in an aqueous environment and in air in the entire pH range. Attempts to grow crystals of salts of the sought acidic $Cp^*MoO_2(H_2O)_x^+$ species, and the consequent formation of the organometallic polyoxomolybdate compound $Cp^*_2Mo_6O_{17}$, show that this is not quite so true. It should be remarked, however, that the crystals were formed over an extended period of time (over 2 months), at pH 1 and in direct summertime sunlight. This proves that the hydrolytic sensitivity of the Cp*–Mo^{VI} bond is not a marked one. Therefore, the possible use the Cp^*Mo^{VI} species for catalytic applications in an aqueous environment at low pH remains promising.

Several other attempts to crystallize salts of the $Cp^*MoO_2(H_2O)_x^+$ ion at low pH over a shorter time scale have systematically resulted in the formation of $Cp^*_2Mo_2O_5$. Our strategy consisted in the diffusion of a liquid (e.g., methanol) perceived as having poor solvent properties with respect to salts, into a solution containing the $Cp^*MoO_2(H_2O)_x^+$ ion and a suitable counterion. However, the solubility product of compound $Cp^*_2Mo_2O_5$ (as a weak electrolyte generating $Cp^*MoO_2(H_2O)_x^+$ and $Cp^*MoO_3^-$) must be very low and the very low concentration of $Cp^*MoO_3^-$ in equilibrium with the cation at pH 1 (the pK_a of $Cp^*MoO_2(OH)$ is 3.65) is sufficient to precipitate the molecular compound. Future efforts at experimentally determining the number of coordinated water ligands in $Cp^*MoO_2(H_2O)_x^+$ will focus on NMR spectroscopy.

5. Conclusions

Our systematic investigation of the aqueous chemistry of Cp^*Mo^{VI} has led to the serendipitous discovery and then to a simple, selective and high-yield synthesis of the organometallic polyoxomolybdate $Cp^*_2Mo_6O_{17}$. This compound is a new member of a relatively small class of cyclopentadienyl containing polyoxometallates, which includes $[CpTiM_5O_{18}]^{3-}$ (M = Mo, W) [35], $[Cp^*Mo_6O_{18}]^-$[29,30] and $Cp^*_2W_2O_{17}$ [31]. The synthetic method shown in Eq. (1) can probably be extended to the synthesis of a wide range of organometallic homo- and heteronuclear polyoxometallates.

6. Supplementary material

Crystallographic data (atomic coordinates, thermal parameters, full lists of bond distances and angles) have been deposited at the Cambridge Crystallographic Data Centre, CCDC No. 231765. Copies of the data can be obtained free of charge from CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.com.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

An isomeric pair of the title compounds have been prepared and characterized by NMR spectroscopy and X-ray crystallography. The major isomer contains three dimethylphenylphoshine ligands coordinated to rhenium atoms in the direction of the μ_3-S atom in the starting trinuclear rhenium cluster complex, whereas the minor isomer has a dimethylphenylphosphine ligand in the opposite direction. The temperature of the preparative reactions controls the orientation of the phosphine ligands.

Keywords: Rhenium cluster

1. Introduction

Recent development of the chemistry of sulfide and selenide cluster compounds of rhenium has been limited mostly to hexanuclear compounds [1,2]. Only a few trinuclear and tetranuclear rhenium chalcogenide cluster compounds are known [3,4] and mixed metal clusters are even rarer, a single example being a rhenium–nickel complex $[Re_3NiS_4Cl_6(PEt_3)_4]$ [5]. Rhenium is a group 7 metal and its cations are isoelectronic with those of group 6 molybdenum or tungsten in one-electron lower oxidation states [3]. Since there are a number of mixed-metal sulfide clusters of Mo(IV) or W(IV) [6–8], it is anticipated that similar rhenium derivatives can be prepared using Re(V). The starting compounds to prepare rhenium cluster sulfide complexes are rare and $Re_3S_7Cl_7$ [9], isoelectronic with $Mo_3S_7Cl_4$ [10], is useful as a starting compound to lead to either trinuclear [11–13] or higher nuclear mixed-metal cluster compounds [5]. The present paper, describes the preparation of the first tetranuclear rhenium–cobalt mixed metal sulfide cluster complexes coordinated by dimethylphenylphosphine.

2. Experimental

2.1. Materials and methods

All experiments were performed under dinitrogen atmosphere. Solvents were dried and distilled by the reported methods. Electronic spectra were recorded on a JASCO Ubest-570 UV–Vis spectrometer. ^1H and ^{31}P NMR spectra were measured in $CDCl_3$ with a JEOL GX-400 spectrometer.

Rhenium metal, PMe_2Ph and $(PPh_3)_2NCl$ were purchased from Aldrich, while $CoCl_2$ was from WAKO chemicals. These materials were used without further purification. $Re_3S_7Cl_7$ was prepared according to a literature method [9].

2.1.1. $[Re_3CoS_4Cl_6(PMe_2Ph)_4]\cdot(C_2H_5)_2O$, **1**

$[(PPh_3)_2N][Re_3S_4Cl_6(PMe_2Ph)_3]\cdot 3CH_2Cl_2$ [14]: $Re_3S_7Cl_7$ (1.03 g, 0.99 mmol) and PMe_2Ph (0.97 g, 7.02 mmol) in dichloromethane (30 mL) were reacted for 3

days at room temperature. The mixture was filtered and the solvent was removed by evaporation. The residue was washed twice with diethylether and dried. The product was dissolved in dichloromethane (10 mL), and $(PPh_3)_2NCl$ (0.70 g, 1.21 mmol) was added to the solution. The dichloromethane solution was layered with diethylether (30 mL) and then left to stand for 3 days. The crystalline product was obtained by filtration.

A solution of $[(PP_3)_2N][Re_3S_4Cl_6(PMe_2{}^-Ph)_3]\cdot 3CH_2Cl_2$ (0.35 g, 0.16 mmol) in dichloromethane (20 mL) was treated with $CoCl_2$ (0.045 g, 0.34 mmol) and PMe_2Ph (0.1 g, 0.72 mmol) and stirred for 7 days at room temperature and then refluxed for 90 min. The solution was filtered, the solvent was evaporated and the residue was washed with diethylether. The product was dissolved in dichloromethane (10 mL), and diethylether (30 mL) was layered on the solution which was left for 7 days. A black crystalline compound was obtained in 38% yield. *Anal*. Calc. for $C_{32}H_{44}CoCl_6P_4Re_3S_4\cdot 0.4C_4H_{10}O$: C, 25.95; H, 3.16. Found: C, 26.06; H, 3.29%. UV–Vis (CH_2Cl_2): 522 nm (ε 1123 $M^{-1}\,cm^{-1}$), 771 nm (ε 456 $M^{-1}\,cm^{-1}$). ^1H NMR (δ, $CDCl_3$): 1.71 (d, Re–P(CH_3)$_2$(C_6H_5)), 2.10 (dd, Co–P(CH_3)$_2$(C_6H_5)), 2.28 (d, Re–P(CH_3)$_2$(C_6H_5)), 7.22–7.87 (m, P(CH_3)$_2$(C_6H_5)). ^{31}P NMR (δ, $CDCl_3$, 15% H_3PO_4): −24.69 (Re–*P*(CH_3)$_2$(C_6H_5)), 38.77 (Co–*P*(CH_3)$_2$(C_6H_5).

2.1.2. $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$ 2

A solution of $[(PPh_3)_2N][Re_3S_4Cl_6(PMe_2Ph)_3]\cdot 3CH_2Cl_2$ (0.52 g, 0.24 mmol) in dichloromethane (20 mL) was stirred with $CoCl_2$ (0.067 g, 0.56 mmol) for 4 days, following which PMe_2Ph (0.072 g, 0.53 mmol) was added and the mixture was stirred for 3 days at room temperature. The solution was filtered, the solvent was evaporated and the residue was washed with diethylether. The product was dissolved in dichloromethane (10 mL) and chromatographed on a silica gel column with dichloromethane and acetone as eluents. Crystals obtained from the dichloromethane eluate were identical with the cluster **1** and those from the acetone eluate were crystallized from dichloromethane/diethylether to give black crystals **2** in 19% yield. *Anal*. Calc. for $C_{32}H_{44}CoCl_6P_4Re_3S_4$: C, 25.43; H, 2.93. Found: C, 25.36; H, 2.95%. UV–Vis (CH_2Cl_2): 520 nm (ε 1259 $M^{-1}\,cm^{-1}$), 768 nm (ε 452 $M^{-1}\,cm^{-1}$). ^1H NMR (δ, $CDCl_3$): 1.85, 1.87, 2.37 (d, Re–P(CH_3)$_2$(C_6H_5)), 1.92 (d, Co–P(CH_3)$_2$(C_6H_5)), 7.34–8.06 (m, P(CH_3)$_2$(C_6H_5)). ^{31}P NMR (δ, $CDCl_3$, 15% H_3PO_4): −24.80, −26.89, −30.92 (Re–*P*(CH_3)$_2$(C_6H_5)), 33.10 (Co–*P*(CH_3)$_2$(C_6H_5)).

2.1.3. Crystal structures of 1 and 2

Crystals suitable for X-ray crystallography were obtained by recrystallization of the products from dichloromethane and diethylether over a week. Data were collected on a Bruker Smart APEX CCD system with a sealed molybdenum source and graphite monochromator. Crystals were transferred to the goniostat where they were cooled to −100 °C for data collection. The data were collected using 15 s frames with an omega scan of 0.30° and corrected for Lorentz and polarization effects. Data were treated by the Bruker SAINT software and the structures were solved using SHELXTL [15] and Fourier techniques. All hydrogen atoms were placed in calculated positions and included in the final cycles of refinement. Four solvent $(C_2H_5)_2O$ molecules were found in a unit cell of **1**. The final $R_1(wR_2)$ indices for **1** are 0.0345(0.0859) using 12,778 independent reflections. The final $R_1(wR_2)$ indices for **2** are 0.0505(0.0790) using 10,854 independent reflections. Crystallographic data are given in Table 1.

3. Results and discussion

3.1. Synthesis

Treatment of $[(PPh_3)_2N][Re_3(\mu_3\text{-}S)(\mu\text{-}S)_3Cl_6(PMe_2Ph)_3]$ with anhydrous cobalt(II) chloride in dichloromethane in the presence of dimethylphenylphosphine formed isomeric rhenium–cobalt mixed metal cluster complexes, $[Re_3Co(\mu_3\text{-}S)_4Cl_6(PMe_2Ph)_4]$ **1** and **2**. ^1H

and ^{31}P NMR spectra showed the presence of two types of cluster compounds in the products obtained from the reaction at room temperature which were isolated by silica-gel column chromatography using dichloromethane (compound **1**) and acetone (compound **2**) as eluents. Only the isomer **1** was obtained from the reaction at room temperature followed by reflux. Single crystals were obtained by slow diffusion of diethyl ether onto the dichloromethane solutions. Although coordination of three bridging sulfurs in the trinuclear rhenium complex to a hetero metal seems to be a facile reaction, only nickel [5] and copper [16] derivatives have been prepared and the present synthesis of the cobalt derivatives gives some clue to the difficulty of the preparation.

3.2. Structures

3.2.1. NMR spectra

^{1}H NMR spectra of **1** show methyl bands at 1.71 (d, Re–P(CH_3)$_2$(C$_6$H$_5$)), 2.10 (dd, Co–P(CH_3)$_2$(C$_6$H$_5$)) and 2.28 (d, Re–P(CH_3)$_2$(C$_6$H$_5$)) ppm with the intensity ratio of 3:2:3. The dimethylphenylphosphine coordinated to three rhenium atoms gives two kinds of methyl signals due to different conformations of the groups. The double doublet signals are assigned to the two methyl groups of dimethylphenylphosphine coordinated to a cobalt atom with slight difference of conformation. ^{31}P NMR spectra of **1** show a band at −24.69 ppm assignable to dimethylphenylphosphine coordinated to rhenium and at 38.77 ppm assignable to the one coordinated to cobalt. ^{1}H NMR spectra of **2** show methyl bands at 1.85 (d, Re–P(CH_3)$_2$(C$_6$H$_5$)), 1.95 (dd, Re–P(CH_3)$_2$(C$_6$H$_5$)), 2.00 (d, Co–P(CH_3)$_2$(C$_6$H$_5$)) and 2.45 (d, Re–P(CH_3)$_2$(C$_6$H$_5$)) with the intensity ratio of 1:1:1:1. ^{31}P NMR spectra of **2** show three bands at −30.92, −26.89 and −24.80 ppm assignable to dimethylphenylphosphine coordinated to rhenium and a band at 33.10 ppm assignable to the one coordinated to cobalt. ^{1}H and ^{31}P NMR spectra indicate the different conformations of the methyl groups of the dimethylphenylphosphine ligands with respect to the Re$_3$ plane and μ_3-S atom. The structures (vide infra) of the isomers indicate that the major isomer has three phosphines directed opposite to μ_3-S and the minor isomer contains a dimethylphenylphosphine in the direction of μ_3-S.

3.2.2. X-ray structures

The crystal of **1** contains a diethylether molecule as a solvate molecule. Both the major product (compound **1**) and minor product (compound **2**) have tetranuclear metal frameworks with three rhenium and one cobalt atom bonded together by four μ_3-S atoms (Figs. 1 and 2).

The Re–Re, Re–Co, Re–S and Co–S interatomic distances in the two isomers are not appreciably different (Table 2).

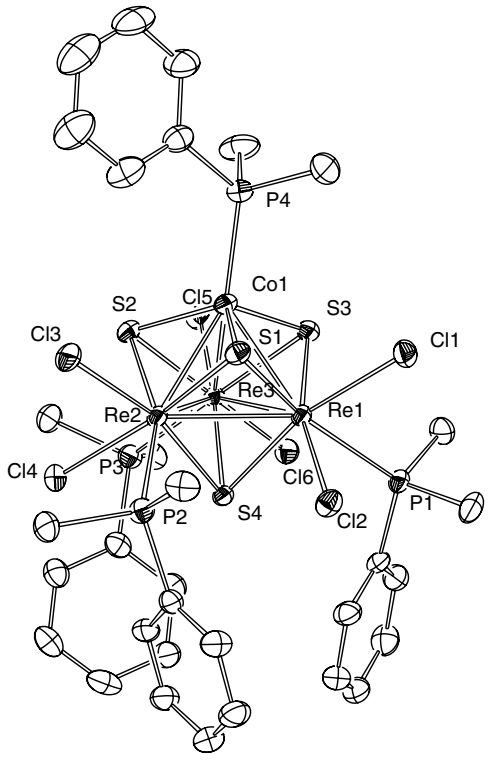

Fig. 1. ORTEP representation of [Re$_3$CoS$_4$Cl$_6$(PMe$_2$Ph)$_4$] **1** at the 50% probability level.

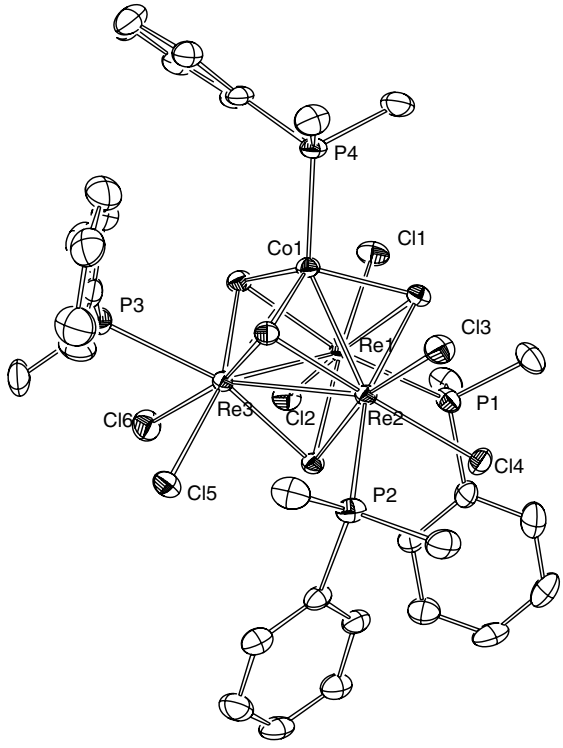

Fig. 2. ORTEP representation of [Re$_3$CoS$_4$Cl$_6$(PMe$_2$Ph)$_4$] **2** at the 50% probability level.

As the Re–Re distances are larger than Re–Co distances, the shapes of the cluster frameworks are flattened tetrahedra. The tetranuclear cluster compounds

1 and **2** have 60 valence electrons counted on the basis of neutral atoms (Re7, Co9, S4, Cl1, P2) and the number is common among tetrahedral cluster compounds [17]. The average Re–Re (2.769 Å) and Re–Co (2.599 Å) distances are close enough to invoke Re–Re and Re–Co metal–metal bonding interactions. They are a little shorter than Re–Re (2.806 Å) and Re–Ni (2.710 Å) interatomic distances in $[Re_3NiS_4Cl_6(PEt_3)_4]$, which has 61 valence electrons [5]. The smaller total number of valence electrons (60 vs. 61 e) seems to have a slight influence upon shortening of the metal–metal distances in spite of the fact that different phosphines are coordinated. Each rhenium atom is coordinated by two chlorine atoms and one dimethylphenylphosphine ligand. Compound **1** has three dimethylphenylphosphine ligands in the direction of the original μ_3-S atom in the starting trinuclear cluster, but compound **2** has one dimethylphenylphosphine ligand in the opposite direction. The steric influence of dimethylphenylphosphine ligands upon the capture of the cobalt atom seems to make formation of isomers with two or three dimethylphenylphosphine ligands in the direction opposite to the original μ_3-S atom in the trinuclear cluster less favorable. The cobalt atom is coordinated by a dimethylphenylphosphine ligand. Thus the rhenium atoms are hexa-coordinate and cobalt tetra-coordinate if metal-metal bonds are not taken into account.

The present synthesis of mixed metal Re_3Co sulfide cluster complexes indicates that the conformation of coordinated phosphines in the trinuclear rhenium cluster complex is important to facilitate coordination of μ-S atoms to a hetero atom like cobalt. The fact that the major product **1** contains three dimethylphenylphosphines in the opposite orientation to that in the starting cluster compound necessitates the change of the conformation of chlorine and phosphine ligands during the reaction. It is conceivable that **1**, obtained under reflux, is thermodynamically more stable than **2**.

4. Supplementary material

All the crystallographic data of **1** and **2** have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication Nos. CCDC 232748 and 232749 for **1** and **2**, respectively. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html, by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336-033.

Abstract

The steady-state fluorescence, fluorescence excitation spectra and fluorescence lifetime of pentacoordinate [8-(dimethylamino-κ*N*)-1-naphthalenyl-κ*C*]diethynylmethylsilicon as a function of excitation and emission wavelengths were investigated in solvents of various polarities at room temperature. Inhomogeneous spectral broadening and biexponential decay-times ($\tau_1 \sim 1$ ns and $\tau_2 \sim 15$ ns) were associated with the existence of two types of electronic states created as a result of the interaction of the amino group with the π-conjugated system and the $CH_3Si(C{\equiv}CH)_2$ group. The crystal structure of the silicon monomer shows a monocapped tetrahedral geometry in which the N atom is opposite one of the acetylene groups. An interaction between the N and Si atoms is evident, the N–Si distance being less than the sum of the van der Waals radii of the 2 atoms. The crystal structure of the analogous hypercoordinate acetylene phosphorus compound [8-(dimethylamino- κ*N*)-1-naphthalenyl-κ*C*]diphenylethynylphosphorus is similar, the short P–N distance and only slight distortion of the naphthalene ring reflecting the P–N interaction. Oxidation of the phosphorus compound to the corresponding oxide readily occurs on treatment with hydrogen peroxide.

1. Introduction

The physical–chemical and optical properties of organic polymers are widely investigated due to their potential use in optoelectronics in optical switching, photorefractive and photovoltaic devices. Several conditions have to be fulfilled simultaneously in order to create solid-state organopolymer systems for practical use including polymer films of high optical quality, solubility in organic solvents and molecular structures providing effective intra- and intermolecular charge transfer between donor and acceptor fragments of the organopolymer. From this point of view, silicon-containing organopolymers are very promising compounds giving rise to films of good optical quality by the sol–gel method and with long π-conjugated polymeric chains. The nonlinear optical properties of conjugated silicon-containing polymers have been investigated [1] and it was shown that polymers including pentacoordinate silicon in the main chain exhibit particularly high values of

doi:10.1016/j.poly.2004.06.026

third-order nonlinear susceptibility. Indeed, hypercoordinate silicon [2] and phosphorus [3–5] compounds exhibit very different chemical and electronic behaviour from the tetracoordinate analogues. The spectroscopic characteristics of the molecule with silicon pentacoordination, [8-(dimethylamino-κ*N*)-1-naphthalenyl-κ*C*]diethynylmethylsilicon (**1**), are presented here. Its crystal structure is reported and compared to that of an analogous hypercoordinated acetylene phosphorus compound, [8-(dimethylamino-κ*N*)-1-naphthalenyl-κ*C*]-diphenylethynylphosphorus (**2**). Both molecules contain the 1-(8-dimethylamino)naphthyl ligand, which is known to give stable hypercoordinate species [6].

2. Experimental

All reactions were performed using standard Schlenk-tube techniques under an atmosphere of dry argon. Solvents were distilled from appropriate drying agents and degassed before use. NMR spectra were obtained using a Bruker Avance DPX-200 spectrometer operating at 200 MHz (^{1}H), 50.327 MHz (^{13}C) or 39.763 MHz (^{29}Si), except ^{31}P NMR spectra which were obtained on a Bruker 250 AC spectrometer at 101.202 MHz. ^{1}H, ^{13}C and ^{29}Si NMR chemical shifts are reported relative to Me_4Si, and ^{31}P chemical shifts relative to H_3PO_4. Infrared spectra were obtained in the region 500–4000 cm^1 with a Perkin–Elmer 1600 FT spectrophotometer. Elemental analyses were carried out by the Service Central de Microanalyse du CNRS. [8-(Dimethylamino)-1-naphthalenyl]phosphonous dichloride was prepared as previously described [7].

2.1. Preparation of **1** [8]

Monoacetylene Grignard reagent was prepared by bubbling acetylene through a solution of the Grignard reagent prepared from magnesium (4.4 g, 181.0 mmol) and bromoethane (19.78 g, 181.5 mmol) in THF (350 ml). A solution of [8-(dimethylamino-κ*N*)-1-naphthalenyl-κ*C*]dichloromethylsilicon [9] (17.72 g; 62.3 mmol) in THF (200 ml) was added rapidly to the monoacetylene Grignard reagent at −78 °C. The mixture was allowed to warm to r.t. overnight with stirring. The reaction mixture was pumped to dryness and the residue taken up in diethylether to give a solution which was washed successively with aqueous acetic acid (10%), aqueous sodium bicarbonate and water. The organic layer was dried over $MgSO_4$ and evaporated to give the crude solid product, which was recrystallised from *n*-hexane affording beige crystals (12.5 g; m.p. 102.4–104.3 °C) in 76% yield. IR [nujol, $\bar{\nu}$/cm^{-1}]: 3259vs [ν(≡C–H)], 2036s [ν(C≡C)], 2021s [ν(C≡C)], 1943vw, 1890vw, 1839vw, 1611w, 1588w, 1566m, 1331s, 1284m, 1252s, 1208m, 1164m, 1147w, 1092m, 1072s, 1037m, 1020s, 951s, 882s, 836s, 780s, 742s, 725vs, 714vs, 703vs, 682vs, 672vs, 631vs, 607s, 591vs. ^{1}H NMR ($CDCl_3$): δ 7.4–8.6 (m, 6H, arom.), 2.72 (s, 6H, NCH_3), 2.63 (s, 2H, C≡CH), 0.65 (s, 3H, $SiCH_3$). ^{13}C NMR ($CDCl_3$): δ 152.18, 139.05, 134.69, 134.38, 131.08, 127.91, 126.46, 126.07, 117.33, 93.00 (SiC≡*C*H), 91.34 (Si*C*≡CH), 48.30, 2.47. ^{29}Si NMR ($CDCl_3$): δ −56.65. *Anal.* Calc. for $C_{17}H_{17}NSi$: C, 77.52; H, 6.50; Si, 10.66. Found: C, 77.60; H, 6.18; Si, 10.20%.

2.2. Preparation of **2**

A solution of phenylethynyllithium, prepared from *n*-BuLi in *n*-hexane and phenylacetylene (4.5 ml, 41.0 mmol) in diethylether at −50 °C, was added rapidly to a stirred suspension of [8-(dimethylamino)-1-naphthalenyl]phosphonous dichloride (5.59 g, 20.54 mmol) in diethylether (100 ml) at −50 °C. The mixture was allowed to warm to r.t. and was hydrolysed after being stirred for 20 h. The aqueous phase was extracted with diethylether and the combined organic phase was washed with water. After drying over $MgSO_4$, evaporation afforded a brown oil (8.4 g). Crystallisation from *n*-heptane gave yellow crystals (3 g; m.p. 107.1–107.6 °C) in 36% yield. IR [nujol, $\bar{\nu}$/cm^{-1}]: 3054m, 2177w, 2157s [ν(C≡C)], 1964w, 1894w, 1819w, 1681w, 1592m, 1567m, 1331m, 1290w, 1219m, 1204m, 1182m, 1156w, 1087m, 1072m, 1038m, 1024m, 999w, 970w, 950m, 920m, 875w, 826vs, 801w, 790w, 774vs, 760vs, 743m, 690vs, 668m, 631s, 610s, 602s, 538vs. ^{1}H NMR ($CDCl_3$): δ 7.3–8.8 (m, 16H, arom.), 2.9 (s, 6H, NCH_3). ^{13}C NMR ($CDCl_3$): δ 152–120 (arom.), 103.95 (d, $^2J_{^{31}P^{13}C}$ = 2 Hz, PC≡*C*), 89.20 (d, $^1J_{^{31}P^{13}C}$ = 16.36 Hz, P*C*≡C), 47.55 (CH_3), 47.39 (CH_3). ^{31}P NMR ($CDCl_3$): δ −61.88. *Anal.* Calc. for $C_{28}H_{22}NP$: C, 83.36; H, 5.50; N, 3.47; P, 7.68. Found: C, 83.29; H, 5.79; N, 3.47; P, 7.54%.

2.3. Preparation of [8-(dimethylamino-κN)-1-naphthalenyl-κC]diphenylethynylphosphorus oxide (**3**)

Aqueous hydrogen peroxide (15% w/w, 20 ml, 88 mmol) was added to a solution of **2** (2.00 g, 4.96 mmol) in dichloromethane (20 ml). After the mixture had been stirred at r.t. for 3 h, the aqueous phase was separated and extracted with dichloromethane. The combined organic phases were washed with water and dried over magnesium sulfate. Evaporation afforded a yellow solid (1.82 g, 87%). IR [nujol, $\bar{\nu}$/cm^{-1}]: 2178s [ν(C≡C)], 1610w, 1591m, 1566m, 1335m, 1293w, 1224s, 1199vs, 1182s, 1153s, 1087m, 1082s, 1072m, 1043m, 1026s, 957sw, 916w, 884m, 846vs, 836vs, 790m, 771s, 752vs, 688vs, 653vs, 633s, 604s, 512vs. ^{1}H NMR ($CDCl_3$): δ 7.3–9.0 (m, 16H, arom.), 2.8 (s, 6H, NCH_3). ^{13}C NMR ($CDCl_3$): δ 152–120 (arom.), 101.40 (d, $^2J_{^{31}P^{13}C}$ =

36.64 Hz, PC≡*C*), 87.69 (d, $^2J_{^{31}P^{13}C} = 207.6$ Hz, P*C*≡C), 48.20 (CH_3). ^{31}P NMR ($CDCl_3$): δ −20.29. *Anal.* Calc. for $C_{28}H_{22}NOP$: C, 80.18; H, 5.29; N, 3.34; O, 3.81; P, 7.38. Found: C, 79.98; H, 5.36; N, 3.56; O, 3.83; P, 7.27%.

2.4. Spectroscopic measurements

Spectroscopic-grade solvents (Merck) were used for all investigations. The absorption spectra of the solutions were recorded by using a Cary-500 spectrophotometer. The fluorescence and fluorescence excitation spectra measurements were performed on an SLM-4800 spectrofluorimeter (spectral width of excitation and registration slits were 8 and 4 nm, respectively). The fluorescence decay times were recorded by the single-photon counting method using a thyratron-controlled flash lamp as the excitation source. The instrumental resolution of the device was $\Delta\tau = 0.5$ ns at 400 nm. Fluorescence decay times were obtained from double-exponential decay analysis:

$$I_f(t) = B + A_1 \exp(t/\tau_1) + A_2 \exp(t/\tau_2).$$

The fractional contribution (f_i) of each decay-time was estimated according to:

$$f_i = \frac{A_i\tau_i}{\sum_{j=1}^{2} A_i\tau_i}.$$

All specroscopic measurements were performed at room temperature and a molecular concentration of 1×10^{-5} M.

2.5. Crystal structure determinations

The crystals of **1** and **2** used were found to produce only moderate diffraction intensities. Owing to the small number of observed data, only the silicon, phosphorus and nitrogen atoms were refined anisotropically.

In the case of **1**, the systematic absences revealed either space group $Pca2_1$ or *Pbcm*. Direct methods (SHELXS-86 [10]) solved the structure with space group $Pca2_1$ (No. 29). All the atomic positions appeared in the E-map excepted for atoms C(6) and C(7). A difference Fourier map gave the positions of the remaining atoms. The calculated hydrogen atoms [11] were included in the last stages of the refinement. Convergence occurred for the R_1 value of 0.0480 ($wR_2 = 0.0818$).

In the case of **2**, direct methods [10] solved the structure with the monoclinic space group *C*2/*c* (No. 15). Three carbon atoms [C(34), C(35) and C(36)] were missing but their positions were revealed in a subsequent difference-Fourier synthesis. The hydrogen atoms were positioned by calculation [11] and taken into account in the next refinements. The final R_1 and wR_2 values were 0.0680 and 0.1884, respectively.

3. Results and discussion

3.1. Preparation of complexes

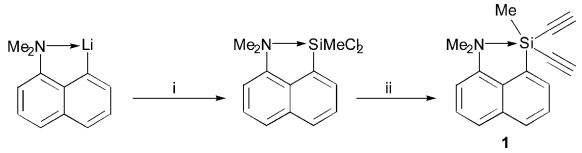
The pentacoordinate silicon-containing monomer **1** (which can be considered as being (4+1) coordinate [12]) was prepared in 76% yield by treating the previously characterised [9] pentacoordinate dichlorosilane with monoethynyl Grignard reagent (Scheme 1). The ^{29}Si NMR spectrum of **1** shows a signal at δ −56.65 whereas that for the hexacoordinate analogue occurs at δ −63.8 [13], and for the tetracoordinate compound $Ph_2Si(C{\equiv}CH)_2$ at δ −48.2 [14]. The IR spectrum exhibits a ν(C≡C) absorbance at 2036 cm^1, between those for the hexacoordinate analogue (2026 cm^{-1}) [13] and $Ph_2Si(C{\equiv}CH)_2$ (2044 cm^{-1}) [15].

The hypercoordinate phosphorus-containing compound **2** was prepared by treatment of [8-(dimethylamino)-1-naphthalenyl]phosphonous dichloride [7] with phenylethynyllithium (Scheme 2). The ^{31}P NMR spectrum of **2** shows a signal at δ −61.88 and the IR spectrum exhibits a ν(C≡C) absorbance at 2157 cm^1. The relative magnitudes of the ^{31}P–^{13}C coupling constants were used to assign the acetylene ^{13}C NMR resonances, δ 103.95 (PC≡*C*) and δ 89.20 (P*C*≡C). As previously observed for such hypercoordinate phosphorus compounds [16], the room temperature solution ^1H NMR spectrum for **2** shows a singlet for the NMe_2 protons, the ^{13}C NMR spectrum exhibiting two signals for the NMe_2 methyls.

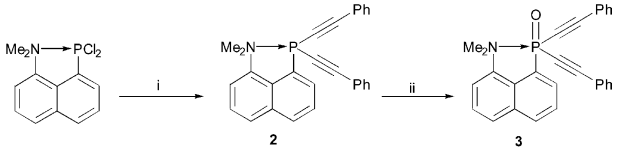
Complex **2** is readily transformed into the oxide **3** in 87% yield on treatment of a dichloromethane solution with hydrogen peroxide (Scheme 2). The IR ν(C≡C) absorbance for **3** occurs at higher energy (2178 cm^{-1}) than that for **2** (2157 cm^{-1}), and both acetylene ^{13}C NMR resonances are shifted to higher field.

3.2. Spectroscopic investigations of *1*

In Fig. 1, the absorption (a) and fluorescence (b) spectra of **1** in cyclohexane and dimethylformamide



Scheme 1. Reagents and conditions: (i) excess $MeSiCl_3$, Et_2O, room temp., 5 h and (ii) HC≡CMgBr, THF, −78 °C to room temp.



Scheme 2. Reagents and conditions: (i) PhC≡CLi, Et_2O, −50 °C to room temp., 20 h and (ii) H_2O_2, CH_2Cl_2, room temp., 3 h.

(DMF) are displayed. Table 1 shows the spectral characteristics obtained in the set of different polarity solvents. The fluorescence spectra were recorded at excitation into the absorption band maximum. The fluorescence excitation spectra measured with excitation at the fluorescence band maxima correspond well to the absorption spectra regarding both shape and maxima position. As can be seen from the data presented in Table 1, the molecules examined exhibit the following spectral peculiarities: (i) large Stokes shifts between the absorption and fluorescence spectra maxima increasing up to 11 000 cm^{-1} in solvents of high polarity, (ii) the maximum position of the absorption spectrum depends weakly on the solvent polarity and shifts to shorter wavelengths with polarity increase, (iii) the increase in solvent polarity leads to an essentially long wavelength shift of the fluorescence spectrum maximum, (iv) the full width at half maximum (f.w.h.m.) of the fluorescence spectrum depends on the solvent polarity.

The spectral data presented afford evidence of an essential increase of the molecule dipole moment in the excited electronic state (μ_e) with respect to the dipole moment in the ground state (μ_g). It is known that the formation of a charge transfer emitting state includes intramolecular charge transfer during the absorption process and subsequent stabilization of the created electron density distribution by the polar environment [17].

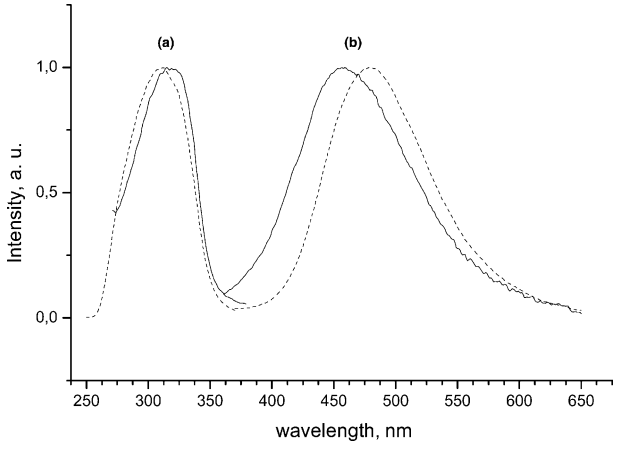


Fig. 1. Absorption (a) and fluorescence (b) spectra of **1** in cyclohexane (bold line) and DMF (dotted line).

To estimate $\Delta\mu = \mu_e - \mu_g$ we used the Bakhshiev equation [18]:

$$hca^3\Delta\nu = 2(\mu_g^2 + \mu_e^2 - 2\mu_g\mu_e\cos\alpha)F(\varepsilon,n)F^2(n), \quad (1)$$

where

$$F(\varepsilon,n) = (\varepsilon-1)/(\varepsilon+2) - (n^2-1)/(n^2+2);$$
$$F^2(n) = (2n^2+1)/(n^2+2)^2,$$

$\Delta\nu = (\nu_a^{max} - \nu_{fl}^{max})$, α is the angle between μ_e and μ_g, ε is the solvent dielectric constant, n is the refractive index (at the sodium d line), c is the velocity of light, a is the Onsager cavity radius. We assume a cavity radius of 3.5 Å, a little higher than that of dimethylaminonaphthalene [19] in view of the presence of the accepting $CH_3Si(C{\equiv}CH)_2$ group in the molecule. The least squares fit analysis of the data based on Eq. (1) is shown in Fig. 2. The slope of the line yields a change of dipole moment of 2.9 D.

To further investigate the nature of the excited electronic state of the molecule, we studied in detail the dependence of the fluorescence spectrum on excitation wavelength. As can be seen from the above results, the maximum position and shape of the fluorescence spectrum do not depend on the excitation wavelength when the excitation is within the region of the first absorption band from 280 to 330 nm in all the solvents used. However, under excitation at the red edge of the absorption spectrum in highly polar solvents a short-wavelength shift of the fluorescence band maximum and an increase of its f.w.h.m. are observed. The fluorescence band spectral characteristics of the DMF solution as a function of excitation wavelength are shown in Table 2. It can be clearly seen from these data that red edge excitation causes the essential transformation of the fluorescence band. The fluorescence excitation spectra measured at various registration wavelengths are depicted in Fig. 3. It follows from these results that the fluorescence excitation spectrum of the molecules forming the short-wavelength part of the fluorescence spectrum shifts to the red side with respect to the absorption spectrum maximum. The set of spectral dependencies obtained gives evidence of essential inhomogeneous broadening of the absorption and fluorescence spectra revealed in high polar solvents at room temperature. The inhomogeneous broadening cannot be caused by

the fluctuations of the solvent reactive field or the dynamics of dipole–dipole interactions between solute and solvent molecules because the Debye relaxation time of the solvent used at room temperature is too fast (of the order of picoseconds). On the other hand, electronic spectra inhomogeneous broadening can be of an intramolecular nature as a result of the presence of centres with different electronic state structure in the solution.

Valuable additional information concerning the nature of the emitting state can be obtained from the analysis of time-resolved fluorescence data. These results are presented in Table 3. When a dimethyformamide solution is excited at the short (λ_{ex} = 290 nm) and long wavelength (λ_{ex} = 330 nm) parts of the first absorption band,

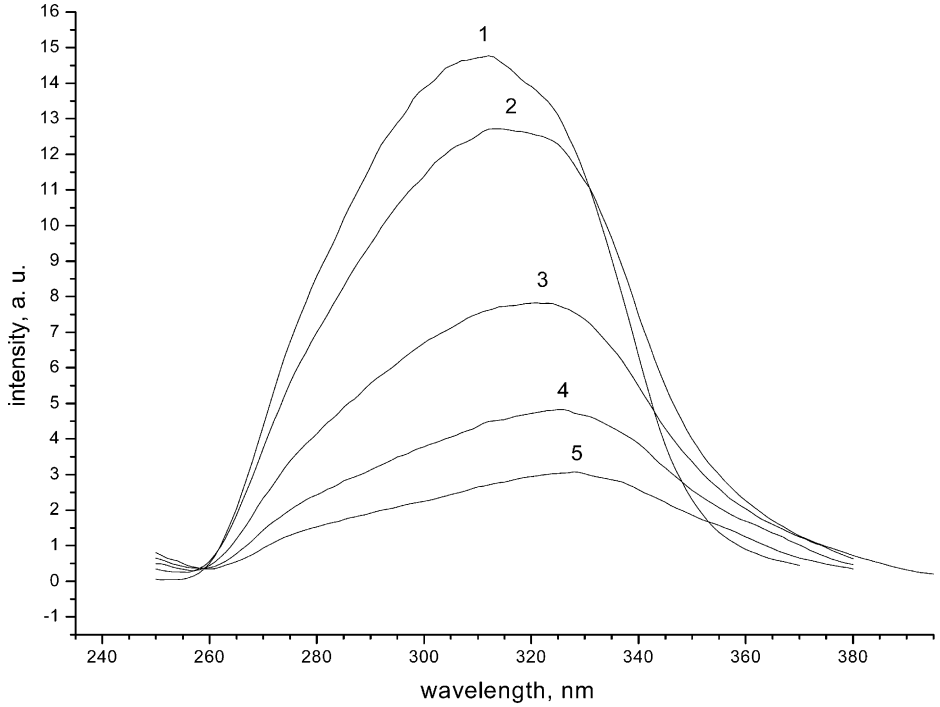

Fig. 3. Fluorescence excitation spectra of **1** in DMF at various recorded wavelengths (1–480, 2–430, 3–420, 4–410 and 5–400 nm).

the fluorescence decay curves are sufficiently well described by two exponents with essentially different decay times ($\tau_1 \sim 1$ ns and $\tau_2 \sim 15$ ns). It should be noted that at red edge excitation the weight contribution of the component with higher decay time increases. The ethanol solution possesses the same spectral and temporal features but both decay times are shorter and the long component weight is essentially higher. Thus, summarizing the above presented frequency dependencies of the fluorescence, fluorescence excitation spectra and biexponential fluorescence decay times one can suggest the existence of two types of electronic transitions in the absorption and fluorescence spectra resulting from the molecular structure. The proposed scheme of electronic levels and the transitions between them are shown in Fig. 4. The absorption spectrum consists of the short wavelength (I) and long wavelength (II) transitions that are separated (Fig. 3) by a sufficiently narrow energy gap ($\sim$3000 cm^{-1}). Intramolecular (non-radiative transition between two excited electronic states) and intermolecular (the interactions between the doped centre and surrounding solvent molecules) processes form two equilibrated excited electronic states S_I^{eq} and S_{II}^{eq}. Both states possess essential charge transfer character due to the large Stokes shift and have different fluorescence lifetimes.

As regards the mechanisms of the excited states formation, we propose the following hypothesis. The crystal structure determination (see below) shows an essentially trigonal bipyramidal geometry at silicon with the amino group lone pair of electrons opposite one of the acetylene groups, both groups lying in the axial positions. The photophysical characteristics of conjugated π-electronic systems containing the electron-donor amino group substituent (including aminonaphthalenes) and the mechanisms of excited state formation have been widely studied [20–22]. It was shown that sp^3-hybridization of the amino group nitrogen and rotation of its hybrid non-shared electron pair with respect to the π-electrons of the ring gave rise to the formation of a charge transfer emitting state. The latter is stabilized by polar solvent molecules. In our case, the presence of the bulky $CH_3Si(C{\equiv}CH)_2$ substituent can cause two additional effects: (i) A change in the orientation of the nitrogen hybrid non-shared electron pair due to additional steric hindrance. This effect results in an alteration of the electronic charge transfer degree from the dimethylamino group into the ring. (ii) The chemistry of silicon is very dependent on coordination number and valency state, and in the case of hypercoordination arising from the 8-dimethylaminonaphthyl group there is extensive evidence of intramolecular coordination of the nitrogen lone pair to the silicon [2]. Quantum-chemical calculations of the electronic charge distribution in tetracoordinated silicon (for silylacetylenes in particular) show the essential decrease of the negative charge at silicon in such structures [23]. This makes for an enhancement of the acceptor properties of silicon in **1**. Thus, the amino group lone pair can interact both with the π-system of the naphthalene ring and with the $CH_3Si(C{\equiv}CH)_2$ group. These interactions can cause inhomogeneous broadening of the absorption spectrum and lead to the possibility of the formation of different excited states. In the case of strong coupling between the nitrogen lone pair and the naphthalene ring π-system, an S_I excited state is formed that corresponds to the dimethylaminonaphthalene local excitation since all the spectral characteristics in various solvents and the decay time value of dimethylaminonaphthalene [19] agree well with the measured features of the S_I state. A decrease of this interaction due to either steric hindrance or direct donor–acceptor interactions between the dimethylamino group nitrogen and silicon leads to the S_{II} state formation. It is seen from the spectral data presented in Table 1 that the importance of the S_{II} state is higher in non-polar cyclohexane, the absorption spectrum maximum shifting towards the red and the fluorescence spectrum f.w.h.m. being larger than that in polar solvents. In the case of polar ethanol solution, one can envisage that the alcohol OH-group provides specific interactions between the nitrogen lone pair and hydrogen on the one hand and between oxygen and silicon

on the other. These interactions increase the weighting of the S_{II} state as can be seen from the data shown in Table 3, resulting in a large f.w.h.m. of the fluorescence spectrum in this solvent. Bearing in mind that both ethanol and DMF exhibit electron donor properties and only ethanol interacts with the nitrogen lone pair through H-bonding, one can assume that the orientation of the latter with respect to the ring π-system plays a crucial role in S_{II} state formation.

3.3. Crystal structures

The X-ray crystal structures of **1** (Fig. 5) and **2** (Fig. 6) show a monocapped tetrahedral geometry (including the lone pair in the case of **2**) in which the N atom is opposite one of the acetylene groups, the C(11)–Si–N angle in **1** being 172.3° and the C(11)–P–N angle in **2** being 168.6° (see Table 4 for selected bond lengths and

angles and Table 5 for a summary of crystal data, intensity measurements and refinement). The distances in **1** between the Si and the nearest acetylene carbons (Si–C(11) and Si–C(13)) are similar to those for the analogous hexacoordinate compound, being slightly greater than for alkynylsilanes containing tetracoordinate silicon [13]. The distance between the nitrogen and the silicon atoms (2.73 Å) in **1** is less than the sum of the van der Waals radii of the 2 atoms (3.65 Å [24]), thus showing that they interact. Likewise, the distance between the nitrogen and the phosphorus atom (2.59 Å) in **2** is less than the sum of the van der Waals radii of the 2 atoms (3.35 Å [24]), consistent with an interaction [5]. Indeed, the P–N distance is even less than the N–N distance (2.79 Å) in 1,8-bis(dimethylamino)naphthalene [25] despite phosphorus being much larger than nitrogen. Moreover, it should be noted that the naphthalene ring in **2** is distorted out of the plane by only ca. 7° (dihedral

angle between the P–C(1)–C(9)–C(2) and N–C(7)–C(8)–C(9) mean planes) whereas for 1,8-bis(dimethylamino)naphthalene [25] the corresponding angle can be evaluated at 28°. In the case of **1**, the distortion angle is ca. 25° (dihedral angle between the Si–C(1)–C(9)–C(2) and N–C(7)–C(8)–C(9) mean planes). The presence of the lone pair in **2** gives rise to a much smaller angle C(1)–P–C(13) (102.4°) with respect to C(1)–Si–C(13) in **1** (123.0°).

4. Conclusions

1. The crystal structure determinations of compounds **1** and **2** show that both compounds are hypercoordinate with an interaction between the ligand N atom and the Si or P, respectively.
2. The steady-state fluorescence, fluorescence excitation spectra and fluorescence lifetime investigations of **1** as a function of excitation and emission wavelengths in solvents of different polarity at room temperature are consistent with the existence of two types of electronic states created as a result of the interaction of the amino group with the π-conjugated system and the $CH_3Si(C{\equiv}CH)_2$ group.

5. Supplementary data

The crystal structure data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-224849 (**1**) and CCDC-224850 (**2**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, G.B. [Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk].

Abstract

The reaction between $[TaMe_3Cl_2]$ and the potassium salt of the silylated pentalene dianion $[K_2\{C_8H_4(1,4\text{-}Si^iPr_3)_2\}]$ gives the η^8-pentalene complex $[Ta\{\eta^8\text{-}C_8H_4(1,4\text{-}Si^iPr_3)_2\}(CH_3)_3]$ (**1**). Sequential protonolysis of **1** with $[Et_3NH]Cl$ affords $[Ta\{\eta^8\text{-}C_8H_4(1,4\text{-}Si^iPr_3)_2\}(CH_3)_2Cl]$ (**2**), $[Ta\{\eta^8\text{-}C_8H_4(1,4\text{-}Si^iPr_3)_2\}(CH_3)Cl_2]$ (**3**) and $[Ta\{\eta^8\text{-}C_8H_4(1,4\text{-}Si^iPr_3)_2\}Cl_3]$ (**4**). An alternative and cleaner route to **4** involves treatment of **1** with BCl_3; in an analogous fashion, the reaction of **1** with BI_3 gives $[Ta\{\eta^8\text{-}C_8H_4(1,4\text{-}Si^iPr_3)_2\}I_3]$ (**5**). The X-ray crystal structures of **1**, **2**, **3** and **5** are reported.

1. Introduction

Until recently, the organometallic chemistry of the aromatic pentalene dianion, $[C_8H_6]^{2-}$, had only been sporadically studied since the original report of $[C_8H_6]^{2-}$ in 1962 by Katz and Rosenberger [1]. Early work in this area described binuclear transition metal systems which contain the planar pentalene dianion, e.g. $[M_2(\eta^5,\eta^5\text{-}C_8H_6)_2]$ (M = Co, Ni) [2,3], $[(\eta^3\text{-}C_3H_5)\text{-}Ni(\eta^5,\eta^5\text{-}C_8H_6)Ni(\eta^3\text{-}C_3H_5)]$ [4] and $[(\eta^5\text{-}C_5Me_5)\text{-}M(\eta^5,\eta^5\text{-}C_8H_6)M(\eta^5\text{-}C_5Me_5)]$ (M = Fe, Co, Ni) [5], in which the two metal fragments bind to the adjacent 5-membered rings of the pentalene ligand in a *trans* disposition. Binding of two transition metal fragments on the same face of a pentalene ligand was first reported in 1975 by Stone et al., e.g. $[\{Ru(MMe_3)(CO)_2\}_2(\eta^5,\eta^5\text{-}C_8H_6)]$ (M = Si, Ge), $[Ru_3(CO)_8(\eta^5,\eta^5\text{-}C_8H_6)]$ and $[Ru_3(CO)_8(\eta^5,\eta^5\text{-}C_8H_4\{SiMe_3\text{-}1,4\},2)]$ [6]; very recently the binuclear vanadium complex $[\{V(\eta^5\text{-}C_5H_5)\}_2(\eta^5,\eta^5\text{-}C_8H_6)]$ of this general class has also been reported [7]. In addition, we have reported the dimolybdenum bis-pentalene sandwich complex $[Mo\{C_8H_4(1,4\text{-}Si^iPr_3)_2\}]_2$ [8]. In 1997 our group and that of Jonas described the first complexes in which a pentalene ligand binds to a *single* metal centre in an η^8-fashion, viz. $[Ta\{\eta^8\text{-}C_8H_4(1,5\text{-}SiMe_3)_2\}Cl_3]$ [9], $[V(\eta^8\text{-}C_8H_6)(\eta^5\text{-}Cp')]$

($Cp' = C_5Me_5$, C_5H_4Me), [V{η^8-C_8H_5(2-Me)}(η^5-C_5H_5)] and [V(η^8-C_8H_6)(η^5-C_9H_7)] [10], [Ti(η^8-C_8H_6)(η^5-C_5H_5)], [M(η^8-C_8H_6)(η^5-C_5H_5)X] (M = Ti, Zr; X = Cl, Br) and [Zr(η^8-C_8H_6)Cl_2(THF)$_2$] [11], and subsequently [Th{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$_2$] [12] and [U(η^5-C_5Me_5){η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$_2$] [13]. Of particular interest to us was the formation of the pentalene complex, [Ta{η^8-C_8H_4(1,5-SiMe$_3$)$_2$}Cl_3], from a cyclooctatetraene complex [Ta{η^8-C_8H_6(1,4-SiMe$_3$)$_2$}$(CH_3)_3$] via protonolysis with [Et(^{i}Pr)$_2$NH]Cl and sublimation at 140 °C/10^{-5} mbar [8]. In the light of this unexpected and low yield (ca. 10%) synthesis of [Ta{η^8-C_8H_4(1,5-SiMe$_3$)$_2$}Cl_3], we decided to develop a rational and higher yielding route to Ta(V) pentalene complexes. Here we extend our studies with the Si^{i}Pr$_3$-substituted pentalene ligand [C_8H_4(1,4-Si^{i}Pr$_3$)$_2$]$^{2-}$, and report the synthesis of a trimethyl tantalum pentalene complex, [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$(CH_3)_3$], and its conversion to the mixed alkyl-halide [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$(CH_3)_{3-n}Cl_n$] ($n = 1$ and 2) and trihalide [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}X_3] (X = Cl, I) complexes.

2. Results and discussion

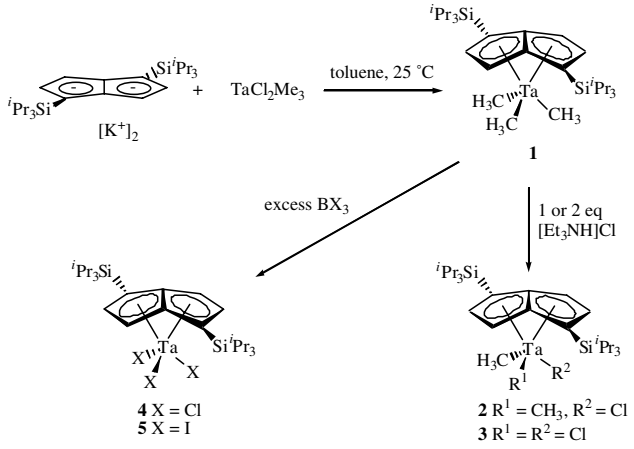
2.1. Synthetic studies

The cyclooctatetraene tantalum complexes [Ta(η^8-C_8H_8)Me$_3$] and [Ta{η^8-C_8H_6(1,4-SiMe$_3$)$_2$}$(CH_3)_3$] have been previously prepared by treatment of [$TaMe_3Cl_2$] with the appropriate dilithium cyclooctatetraenide salt [14,8]. In an analogous manner, the η^8-pentalene complex [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$(CH_3)_3$] (**1**) was prepared in high yield via a direct salt metathesis reaction between the dipotassium salt of the ligand, [K_2{C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}] [15], and [Ta$(CH_3)_3Cl_2$] in toluene (see Scheme 1).

NMR spectra for **1** are typical of complexes containing the η^8-C_8H_6(1,4-SiMe$_3$)$_2$ ligand, in particular the diastereotopic nature of the isopropyl groups of the silyl substituents on the pentalene ring resulting from the facially enantiotopic η^8-bonding mode of the latter. Singlets at δ 0.91 (^{1}H) and δ 50.1 (^{13}C{^{1}H}) ppm can be assigned to the Ta–Me groups.

1 provides a suitable precursor for the synthesis of the mixed alkyl/chloride complexes via the protonolysis of one, two or three of the methyl groups and their replacement by chloride (see Scheme 1). Initially the reaction between [Et_3NH]Cl and **1** in 1:1 and 2:1 ratios in benzene at room temperature gave [Ta {η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}$(CH_3)_2Cl$] (**2**) and [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}-$(CH_3)Cl_2$] (**3**), respectively. These compounds can be prepared on multigram scales by heating a mixture of the reactants in toluene at ca. 90 °C, and are readily obtained from saturated pentane solutions as yellow crystalline solids. NMR data for **2** and **3** were in accord with the proposed structures. In particular, the ^{1}H NMR of **2** shows the two expected resonances for the Me groups in the prochiral $TaMe_2Cl$ unit bound to the facially enantiotopic pentalene ring. The associated carbons were not readily discernible in the ^{13}C{^{1}H}spectrum, presumably due to quadrupolar broadening by ^{181}Ta (100%, $I = 7/2$). [1]

If three or more equivalents of [Et_3NH]Cl are allowed to react with the trimethyl compound **1** at a higher temperature, instead of the intense yellow solution observed during the synthesis of **2** and **3**, a deep red colour is observed. Workup as per before resulted in a complex mixture of products, by ^{1}H NMR, although the mass spectrum showed the trichloride [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}Cl_3] (**4**) to be one component of the mixture. Sublimation of the mixture at high temperature (160 °C/10^{-6} mbar) gave a pure sample of **4**, but in very low yield. Accordingly, **1** was treated with a slight excess of BCl_3, which resulted in a smooth reaction and facile isolation of **4** in high (82%) yield, as a red-purple crystalline solid. The dark purple tri-iodide analogue [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}I_3] (**5**) was similarly prepared from **1** and boron triiodide.



Scheme 1. Synthesis of tantalum η^8-pentalene complexes.

2.2. Structural studies

Although problems with disorder frustrated attempts to determine the X-ray structure of **4**, the molecular structures of **1**, **2**, **3** and **5** have been determined and are shown in Figs. 1–4 respectively, together with selected bond lengths and angles.

All four molecules display the expected three-legged, piano stool structure. An important structural parameter in η^8-mononuclear pentalene complexes is the penta-

[1] Quadrupolar broadening of attached carbons by Ta (100% $I = 9/2$) is rare, but its extent would obviously depend on the electric field gradient at the Ta centre in turn dependent on the symmetry of the molecule (thus it is absent in **1** and **3**).

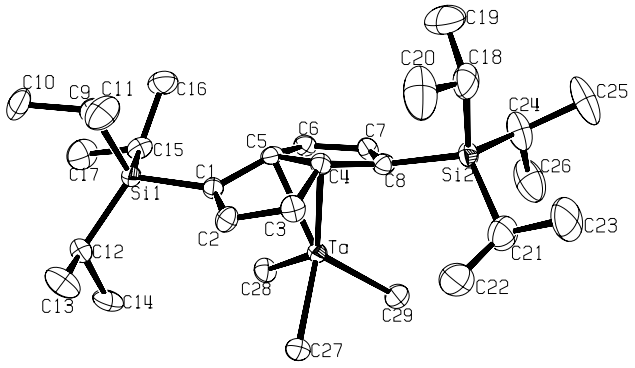


Fig. 1. The molecular structure of **1**. lene fold angle about the bridge head C–C vector, i.e. the angle between the two 5-membered ring planes. Mononuclear transition metal compounds containing an η^8-pentalene ligand typically have fold angles ranging from 33° to 43° [9–11], inversely related, to a large extent, to the size of the metal. The only previously reported tantalum pentalene complex, [Ta{η^8-C_8H_4(1,4-$SiMe_3$)$_2$}Cl_3], has a fold angle of 33.0° [9]; in **1**, **2** and **3** the fold angles are 29.2°, 31.2° and 32.5°, respectively. Thus there is a small, but discernible increase in fold angle (29.2–33.0°) with increasing chloride substitution (ignoring any effects caused by differing silyl group substitution of the ring). This may be a consequence of sequential substitution of an electron withdrawing chlorine for one of the methyl groups resulting in increasing electron deficiency at the tantalum centre. The tantalum-bridge head carbon distances remain essentially constant (within e.s.d.s.) in **1**, **2** and **3** and [Ta{η^8-C_8H_4(1,4-$SiMe_3$)$_2$}Cl_3] [9] (respectively: 2.192(3), 2.269(3); 2.186(6), 2.237(6); 2.187(3), 2.227(3); 2.182(13), 2.217(12) Å); thus, it appears that, rather than donating electron density from the bridge head C–C bond, the anionic pentalene ligand bends about the bridge head carbons to relieve this electron deficiency. The C–C bond lengths within the pentalene ring system are unexceptional in all three compounds and comparable to those found in [Ta{η^8-C_8H_4(1,4-$SiMe_3$)$_2$}Cl_3] [9].

The tantalum–methyl bond lengths in **1**, **2** and **3** (respectively: 2.203(3), 2.187(3), 2.200(3); 2.199(6), 2.326(3); [2] 2.208(3) Å) are all very similar and are comparable to those found in e.g. [Ta(TBM)$(CH_3)_2$Cl] (TBM = tribenzylidenemethane), which has a tantalum–

[2] In **2** the Cl atom is disordered 0.65:0.35 between the sites labelled Cl(1) and C(28). Therefore bonds and angles involving these two atoms are unreliable.

methyl bond length of 2.149(6) [16]. The tantalum–chlorine bond lengths in **2** and **3** are 2.355(2) Å, [2] and 2.3771(9) and 2.3810(9) Å, respectively; in comparison, Ta–Cl bonds in [{η^8-C_8H_4(1,4-$SiMe_3$)$_2$}$TaCl_3$] lie in the range 2.362(3) to 2.386(3) Å [9].

The triiodide **5** crystallises with two slightly different molecules in the unit cell with fold angles of 31.2 (molecule 1) and 31.6° (molecule 2); the discussion pertains to molecule 1. The Ta-bridge head carbon distances in **5** are 2.220(4) and 2.167(4) Å, very similar to those in **1**, **2** and **3**, and the fold angle of 31.2° fits well with the electron deficiency argument (vide supra), given the relative electronegativities of chlorine and iodine. The average ring C–C distance of 1.435 Å is essentially identical to those in **1**, **2** and **3**.

The tantalum–iodine distances in **5** range from 2.7126(4) to 2.7965(4) Å, slightly shorter than that in the more sterically congested Ta(V) complex [Ta(η^5-C_5H_5)$_2$(η^1-$CHCH_3$)I] (2.8840(7) Å) [17].

3. Experimental

All manipulations were carried out using a combination of standard Schlenk, high vacuum and glovebox techniques. All solvents were distilled from appropriate drying agents and degassed prior to use. K_2[C_8H_4(1,4-Si^iPr_3)$_2$] [15] and [$Ta(CH_3)_3Cl_2$] [18] were prepared according to literature methods. Boron trichloride and boron triiodide were purchased from Aldrich as a 1.0M solution in heptane, and as the solid respectively. NMR spectra were recorded on a Bruker 300DPX Spectrometer operating at 75.475 MHz for ^{13}C and 300.132 MHz for ^{1}H, and at a probe temperature of 295K unless otherwise stated; chemical shifts were referenced to internal solvent resonances. Mass spectra were recorded on a VG Autospec instrument operating in EI mode. Carbon and hydrogen elemental analyses were performed by Mikroanalytisches Labor Pascher (Germany).

3.1. Synthesis of [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_3$] (1)

Toluene (ca. 30 mL) was added to a stirred mixture of K_2[C_8H_4(1,4-Si^iPr_3)$_2$] (1.80 g, 3.65 mmol) and $Ta(CH_3)_3Cl_2$ (1.08 g, 3.64 mmol) at room temperature and the resulting yellow-brown mixture was stirred for ca. 3 h at room temperature. The solvent was removed under reduced pressure, the residue extracted into pentane (ca. 100 mL) and filtered through a bed of Celite supported on a glass frit producing a clear yellow filtrate. The filtrate was concentrated under reduced pressure to a volume of ca. 10 mL and stored overnight at ca. −50 °C. The resulting crop of yellow crystals were isolated by filtration and dried under reduced pressure giving [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_3$] as a yellow solid (1.10 g, 47%). *Anal.* Calc. for $C_{29}H_{54}Si_2Ta$: C, 54.35; H, 8.65. Found: C, 54.46; H, 8.63%. Mass spectrum: m/z = 640 (M^+).

^{1}H NMR (300.132 MHz, C_6D_6): δ 0.91 {Ta(CH_3)$_3$, 9H, s},1.09 {CH(CH_3)$_2$, 18H, d, J_{H-H} = 7.4}, 1.12 {CH(CH_3)$_2$, 18H, d, J_{H-H} = 7.4}, 1.24 {CH(CH_3)$_2$, 6H, sept, J_{H-H} = 7.4}, 5.39 {CH, 2H, d, J_{H-H} = 3.2}, 6.55 {CH, 2H, d, J_{H-H} = 3.2}; ^{13}C NMR (75.475 MHz, C_6D_6): δ 50.1 {Ta(CH_3)$_3$, q, J_{C-H} = 118}, 12.3 {CH(CH_3)$_2$, d, J_{C-H} = 121}, 19.3 {CH(CH_3)$_2$, q, J_{C-H} = 125}, 19.5 {CH(CH_3)$_2$, q, J_{C-H} = 125}, 105.8 {CH, d, J_{C-H} = 171}, 106.5 {C,s},125.5 {C,s}, 130.2 {CH, d, J_{C-H} = 172}.

3.2. Synthesis of [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_2Cl$] (2)

Toluene (ca. 30 mL) was added to a stirred mixture of [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_3$] (0.50 g, 0.78 mmol) and [Et_3NH]Cl (0.10 g, 0.73 mmol) at room temperature and the resulting suspension was stirred for ca. 15 h at ca. 90 °C in a sealed (Teflon stopcock) ampoule. The solvent was removed under reduced pressure, the residue extracted into pentane (ca. 50 mL) and filtered through a bed of Celite supported on a glass frit. The filtrate was concentrated under reduced pressure to a volume of ca. 3 mL giving a crop of yellow crystals which were isolated by filtration and dried under reduced pressure giving [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_2$Cl] as a yellow solid (0.13 g, 27%, based on [Et_3NH]Cl). *Anal.* Calc. for $C_{28}H_{51}Si_2TaCl$: C, 50.86; H, 7.93. Found: C, 50.82; H, 7.84%. Mass spectrum: m/z = 645 ([M − CH_3]$^+$).

^{1}H NMR (300.132 MHz, C_6D_6): δ 0.93 {Ta(CH_3), 3H, s}, 0.94 {Ta(CH_3), 3H, s}, 1.07 {CH(CH_3)$_2$, 18H, d, J_{H-H} = 7.1}, 1.11 {CH(CH_3)$_2$, 18H, d, J_{H-H} = 7.1}, 1.22 {CH(CH_3)$_2$, 6H, sept, J_{H-H} = 7.1}, 5.46 {CH, 2H, d, J_{H-H} = 3.3}, 6.50 {CH, 2H, d, J_{H-H} = 3.3}; ^{13}C NMR (75.475 MHz, C_6D_6): δ 32.6 {Ta(CH_3), br}, 48.4 {Ta(CH_3), br}, 12.2 {CH(CH_3)$_2$, d, J_{C-H} = 124}, 19.3 {CH(CH_3)$_2$, q, J_{C-H} = 121}, 19.5 {CH(CH_3)$_2$, q, J_{C-H} = 121}, 106.4 {CH, d, J_{C-H} = 178}, 108.8 {C,s}, 124.8 {C,s}, 131.2 {CH, d, J_{C-H} = 169}.

3.3. Synthesis of [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)Cl_2$] (3)

Toluene (ca. 30 mL) was added to a mixture of [Ta{η^8-C_8H_4(1,4-Si^iPr_3)$_2$}$(CH_3)_3$] (1.00 g, 1.56 mmol) and [Et_3NH]Cl (0.64 g, 4.65 mmol) at room temperature and the resulting suspension was stirred for ca. 20 h at ca. 90 °C in a sealed (Teflon stopcock) ampoule. The solvent was removed under reduced pressure, the residue extracted into pentane (ca. 150 mL) and filtered through a bed of Celite supported on a glass frit producing a clear orange yellow filtrate. The filtrate was concentrated under reduced pressure to a volume of ca. 10

mL resulting in the formation of a crop of yellow crystals which were isolated by filtration and dried under reduced pressure giving [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}-$(CH_3)Cl_2$] as a yellow solid (0.78 g, 73%). *Anal.* Calc. for $C_{27}H_{49}Cl_2Si_2Ta$: C, 47.57; H, 7.24. Found: C, 47.64; H, 7.26%. Mass spectrum: $m/z = 665$ ($[M - CH_3]^+$).

^{1}H NMR (300.132 MHz, C_6D_6): δ 1.28 {Ta(CH_3), 3H, s}, 1.06 {CH(CH_3)$_2$, 18H, d, $J_{H-H} = 7.2$},1.10 {CH(CH_3)$_2$, 18H, d, $J_{H-H} = 7.2$}, 1.27 {CH(CH$_3$)$_2$, 6H, sept, $J_{H-H} = 7.2$}, 5.42 {CH, 2H, d, $J_{H-H} = 3.3$}, 6.42 {CH, 2H, d, $J_{H-H} = 3.3$}; ^{13}C NMR (75.475 MHz, C_6D_6): δ 12.2 {Ta(CH$_3$), q, $J_{C-H} = 128$}, 12.5 {CH(CH$_3$)$_2$, d, $J_{C-H} = 121$}, 19.3 {CH(CH$_3$)$_2$, q, $J_{C-H} = 125$}, 19.4 {CH(CH$_3$)$_2$, q, $J_{C-H} = 125$}, 107.4 {CH, d, $J_{C-H} = 181$}, 111.0 {C,s}, 124.7 {C,s}, 132.6 {CH, d, $J_{C-H} = 174$}.

3.4. Synthesis of [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}Cl_3] (**4**)

Boron trichloride (2.0 mL of a 1.0 M solution in heptane) was added to a yellow solution of [C_8H_4(1,4-Si^{i}Pr$_3$)$_2$]Ta(CH$_3$)$_3$ (0.50 g, 0.78 mmol) in benzene (ca. 5 mL) at room temperature. The resulting red-purple mixture was stirred for ca. 20 min at room temperature and the solvent was removed under reduced pressure. The red purple solid was washed with pentane (ca. 5 mL) giving [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}Cl$_3$] (0.45 g, 82%). *Anal.* Calc. for $C_{26}H_{46}Si_2TaCl_3$: C, 44.48; H, 6.60. Found: C, 44.80; H, 6.78%. Mass spectrum: $m/z = 702$ (M^+).

^{1}H NMR (300.132 MHz, C_6D_6): δ 1.01 {CH(CH_3)$_2$, 18H, d, $J_{H-H} = 7.3$}, 1.12 {CH(CH_3)$_2$, 18H, d, $J_{H-H} = 7.3$}, 1.27 {CH(CH$_3$)$_2$, 6H, sept, $J_{H-H} = 7.3$}, 5.31 {CH, 2H, d, $J_{H-H} = 3.3$}, 6.75 {CH, 2H, d, $J_{H-H} = 3.3$}; ^{13}C NMR (75.475 MHz, C_6D_6): δ 12.1 {CH(CH$_3$)$_2$, d, $J_{C-H} = 113$}, 19.2 {CH(CH$_3$)$_2$, q, $J_{C-H} = 126$}, 19.4 {CH(CH$_3$)$_2$, q, $J_{C-H} = 126$}, 115.2 {CH, d, $J_{C-H} = 183$}, 122.4 {C,s}, 131.8 {C,s}, 136.2 {CH, d, $J_{C-H} = 177$}.

3.5. Synthesis of [Ta{η^8-C_8H_4(1,4-Si^{i}Pr$_3$)$_2$}I_3] (**5**)

Boron triiodide (0.95 g, 2.42 mmol) was added to [C_8H_4(1,4-Si^{i}Pr$_3$)$_2$]TaMe$_3$ in an ampoule, and 15 ml toluene added quickly, resulting in an immediate colour change from orange to deep red. The reaction mixture was stirred at room temperature for 2 h, before removal of the solvent in vacuo. The solid residue was pumped on for 2 h before being redissolved in toluene, and filtered through flame dried Celite on a glass frit. The

Abstract

The use of an ozone/oxygen mixture for the preparation of pyridinecarboxylate complexes of silver(II), $[AgL_2]$, (L = 2-, 3- and 4-pyridinecarboxylate; 2,3-, 2,4-, 2,5- and 3,5-pyridinedicarboxylate), Mn^{III}(picolinate)$_3$, and the heteropolyanion $[Co^{III}W_{12}O_{40}]^{5-}$ are reported. It is shown that previous literature work on oxidation of alcohols with O_3/O_2 using $Co(OAc)_2$ are erroneous in that the latter has no catalytic effect. In the course of this work the title complex was made and its X-ray crystal structure determined.

Keywords: Ozone; X-ray crystal structure; Silver(II) complexes; Manganese(III) complexes; Cobalt(III) complexes

1. Introduction

We have shown previously that an ozone/oxygen (O_3/O_2) mixture, produced from dioxygen by a commercial silent electric-discharge ozoniser running from a domestic 13-amp supply, provides a safe and convenient method of producing high oxidation state complexes of iron, ruthenium, osmium, palladium, platinum, gold and cerium under ambient conditions [1,2]. Here we extend this work to show that complexes of silver(II), manganese(III) and cobalt(III) can equally simply be prepared using a similar method. We also report for the first time the single crystal X-ray structure of the new compound $Co(py)_2(OAc)_2(H_2O)_2$ which resulted unexpectedly as a by-product during ozonolysis of a cobalt(II) acetate/pyridine mixture.

In many of the oxidations reported in our earlier work [1] we found that an O_3/O_2 mixture effected oxidations normally carried out with persulfate, unsurprisingly since the oxidation potentials in acid of ozone (+2.07 v.) and persulfate (+2.01 v.) are very close [2]. Ozonolysis is often more convenient since the only by-product is oxygen, giving easier workup, and no heating is required.

2. Experimental

2.1. Materials

Silver nitrate, manganese(II) chloride, cobalt(II) acetate and the pyridinecarboxylic acids were obtained

from Aldrich and used without further purification. The pyridine monocarboxylic acids, HL ($L = C_5H_4N\text{-}COO^-$), were 2-pyridinecarboxylate (pic), 3-pyridinecarboxylate (nic) and 4-pyridinecarboxylate (isonic). The pyridinedicarboxylic acids, H_2L ($L = C_5H_3N\text{-}(COO)_2^{2-}$), were 2,3-pyridinedicarboxylate (quin), 2,4-pyridinedicarboxylate (lut), 2,5-pyridinedicarboxylate (isocinc), 3,4-pyridinedicarboxylate (cinc) and 3,5-pyridinedicarboxylate (dinic).

2.2. Syntheses of compounds

2.2.1. Ozonolysis

This was effected, as in our earlier work [1], with a Tri-Ox model TOG AI ozoniser using 0.02 g of O_3 in 2 dm^3 of O_2 per minute; the O_3 content was determined for various gas flows of O_2 and applied potentials by titration with thiosulfate of iodine released from standard iodide solutions [3].

2.2.2. Silver(II) complexes

The preparation of $Ag(pic)_2$ is typical. To a solution of silver nitrate (0.5 g, 4 mmol, in 25 cm^3 water) was added a solution of picolinic acid (0.72 g, 8 mmol, in 25 cm^3 water). The resultant colourless, gel-like solution was stirred and an O_3/O_2 stream passed through it for 3 h. After 15 min an orange-brown precipitate appeared which was filtered off, washed with 20 cm^3 of water and dried in a vacuum desiccator.

Similar methods were used for the preparation and isolation of $Ag(nic)_2$, $Ag(isonic)_2 \cdot H_2O$, $Ag(quinH)_2 \cdot 2H_2O$, $Ag(lutH)_2 \cdot 3H_2O$, $Ag(isocincH)_2$, $Ag(cincH)_2 \cdot H_2O$ and $Ag(dinicH)_2 \cdot 4H_2O$.

2.2.3. Manganese(III) species

$Mn(pic)_3 \cdot 0.5H_2O$. An aqueous solution of $MnCl_2 \cdot 4H_2O$ (0.5 g, 2.5 mmol) was added to an aqueous solution of picolinic acid (1 g, 8 mmol). An ozone/oxygen stream was passed through the resultant colourless solution, which turned clear red within 2 min. Ozone was passed through the solution for a total of 15 min, during which time the solution darkened in colour as crystals were deposited. Further ozonolysis results in over-oxidation and formation of a green precipitate.

Anal. Calc. for $C_{18}H_{13}N_3O_{6.5}$: C, 50.2; H, 2.9; N, 9.8. Found: C, 50.2; H, 2.8; N, 9.7%. IR (cm^{-1}): 3540s, 3449s, 1749vs, 1688vs, 1600s, 1568m, 1472s, 1446s, 1349s, 1253vs, 1230m, 1164m, 1135vs, 1095w, 1042m, 1017m, 862s, 759m, 693m, 642m, 539w, 480s. Raman (cm^{-1}): 1588(7), 1562(3), 1474(2), 1387(2), 1439(2), 1387(2), 1306(2), 1234w, 1142(1), 1087(1), 1043(3), 1010(10), 986(3), 842(3), 698(2), 632(2).

2.2.4. Cobalt(III) and cobalt(II) species

$[Co^{III}W_{12}O_{40}]^{5-}$. Through a solution of $[Co^{II}W_{12}O_{40}]^{6-}$, made as in [4,5], O_3/O_2 was passed for 3 h, during which time the solution turned green and then golden yellow. The Raman spectrum was identical to that of a solution of the authentic sample made as in [4,5].

$Co(py)_2(OAc)_2(H_2O)_2$. This was first made by dissolving $Co(OAc)_2 \cdot 4H_2O$ (1.5 g, 6 mmol) in methanol,

to which pyridine (2 g, 25 mmol) was added, and O_3 passed through for 3 h. Orange crystals of the product were deposited. It was then made non-ozonolytically by reaction of $Co(OAc)_2 \cdot 4H_2O$ (1 g, 4 mmol) dissolved in 95% acetic acid/5% water (total 150 cm^3) and stirred for 30 min. The solvent was then removed and the residue suspended in methanol. Pyridine (0.1 cm^3) was then added and the mixture cooled to 4°C. After two days pale orange crystals were deposited.

$Co(py)_2(OAc)_2(H_2O)_2 \cdot H_2O$. *Anal.* Calc. for $C_{14}H_{22}N_2O_7$: C, 42.7; H, 5.6; N, 7.1. Found: C, 42.9; H, 5.9; N, 7.0%. IR (cm^{-1}): 3315vs, 3080vs, 1698w, 1606s, 1546s, 1418vs, 1321w, 1240w, 1078m, 1042m, 1012m, 934w, 848m, 762s, 698vs, 655m, 631m.

2.2.5. Oxidations of menthol with O_3/O_2

The method of Odinokov et al. [6] was used in an attempt to catalyse the oxidation of menthol to menthone using cobalt(II) acetate as a catalyst. Menthol (1.0 g, 6.4 mmol) and powdered $Co(OAc)_2 \cdot 4H_2O$ (5 mg, 0.02 mmol) were added to ethyl acetate (10 cm^3), and O_3/O_2 passed for 1 h at 0.3 $dm^3\ min^{-1}$, after which a stream of O_2 was continued for 5 min to purge the system of O_3. A solution of sodium thiosulfate was added to the mixture, the organic layer separated and washed with first ether and then with aqueous sodium bicarbonate and sodium chloride solutions, dried and concentrated to give the product mixture which was analysed by gas chromatography. The experiment was repeated in the same way but without cobalt acetate. In both cases the yield of menthone was ca. 33%. A similar lack of catalytic activity was found when dichloromethane was substituted for ethyl acetate.

2.3. Instrumentation

Magnetic moments were measured on a Johnson Matthey Evans magnetic susceptibility balance [7]. FAB measurements in 3-nitrobenzyl alcohol with a primary Cs^+ 25 keV ion beam were recorded using an AutoSpec-Q Micromass FAB+ instrument. Raman spectra were measured on a Dilor LabRam Infinity instrument with 632.8 nm He–Ne excitation of 8 mW at the powdered sample, and IR spectra on a Perkin–Elmer RX-1 spectrometer as discs in KBr (4000–500 cm^{-1}).

2.4. Crystal data for *1*

$C_{14}H_{20}CoN_2O_6$, $M = 371.25$, orthorhombic, *Pbca* (No. 61), $a = 12.5908(10)$, $b = 8.9461(10)$, $c = 15.0180(15)$ Å, $V = 1691.6(3)$ $Å^3$, $Z = 4$ (C_i symmetry), $D_c = 1.458$ g cm^{-3}, μ(Cu Kα) = 8.239 mm^{-1}, $T = 203$ K, pale orange prisms; 1348 independent measured reflections, F^2 refinement, $R_1 = 0.040$, $wR_2 = 0.087$, 926 independent observed absorption corrected reflections [$|F_o| > 4\sigma(|F_o|)$, $2\theta_{max} = 126°$], 116 parameters.

3. Results and discussion

3.1. Silver(II) complexes

A number of such complexes are known, normally made by oxidation of the corresponding silver(I) species with persulfate, but ozonolysis has occasionally been used. Thus the 2,2′-bipyridyl complex $[Ag^{II}(bpy)(NO_3)_2]$ [8] has been so made as have salts of $[Ag(bpy)_2]^{2+}$ [9] and $[Ag(phen)_2]^{2+}$ [10].

We find that ozonolysis at room temperature of a mixture of silver nitrate with the pyridinecarboxylic acids given in Section 2 in a metal:ligand ratio of 1:2 gives good yields of $[Ag^{II}L_2] \cdot nH_2O$. To our knowledge ozonolysis has not been used for such preparations before, most of these silver(II) species having been prepared by reactions involving heating silver nitrate, the ligand and persulfate [11,12]. In our procedure, by contrast, the preparations are simple and are carried out at room temperature.

There are two X-ray structures of such complexes: $Ag(quinH)_2 \cdot 2H_2O$ shows a slightly distorted square planar coordination [13], whilst the silver(II) dipicolinate complex is octahedral with coordination from two tridentate ligands, one neutral and the other dianionic, i.e., $[Ag^{II}(dipic)(dipicH_2)]$ [14,15].

It is clear that all of our AgL_2 complexes contain silver(II) since they are paramagnetic at room temperature with a magnetic moment close to the expected value of 1.73 B.M. Fast-atom bombardment (FAB) studies on $Ag(pic)_2$, $Ag(isonic)_2 \cdot H_2O$, $Ag(quinH)_2 \cdot 2H_2O$ and $Ag(lutH)_2 \cdot 3H_2O$ all show the expected isotope patterns (^{107}Ag 51.8%, ^{109}Ag 48.2%) for the parent ions $[\{AgL_2H\}]^+$, $[\{AgLH\}]^+$ and $[LH]^+$. Their IR spectra are listed in Section 2 and, for the case of $Ag(cincH)_2 \cdot H_2O$, the Raman spectrum; the colours of the other silver(II) complexes precluded recording of Raman spectra. IR spectra for only some of these complexes have been reported previously, and only in the range 1500–1800 cm^{-1} [16].

For pyridine carboxylic acids the simple formula AgL_2 (L = pic, isonic) with square-planar coordination seems likely; $Ag(nic)_2$ was also made but analyses were unsatisfactory. In the cases of the pyridinedicarboxylate ligands, coordination may occur as the dianion (e.g., $quin^{2-}$), the mono-anion (e.g., $quinH^-$) or as the neutral species (e.g., $quinH_2$). We formulate ours as $Ag(LH)_2$ (L = quinH, lutH, isocincH, cincH, dinicH) since the published X-ray crystal structure of $Ag(quinH)_2 \cdot 2H_2O$ [13] shows the anion to be centrosymmetric with coordination from two *trans* $[C_5H_3N(COOH)(COO)]^-$ ligands. The fact that we observe few IR–Raman coincidences

for $Ag(cincH)_2 \cdot H_2O$ also suggests a centrosymmetric structure for this complex.

3.2. Manganese(III) complexes

We have already reported the use of ozone in forming $Mn^{III}(OAc)_3 \cdot 2H_2O$ by ozonolysis of $Mn(OAc)_2$, and in the preparations of the manganese(IV) polyoxometalates $K_6[Mn^{IV}Mo_9O_{32}] \cdot 10H_2O$, $K_8[Mn^{IV}W_6O_{24}] \cdot 6H_2O$ and $(NH_4)_6[Mn^{IV}Mo_6H_6O_{32}] \cdot 10H_2O$; ozonolysis was much more effective in producing these species than was the use of persulfate [1].

We find that reaction of manganese(II) chloride with picolinic acid under an O_3/O_2 stream gave $Mn(pic)_3$ (which has also been made by conventional procedures [11,12]), but our other pyridinecarboxylate complexes, though containing $Mn^{III}L_3$ species, were impure.

3.3. Cobalt(III) and (II) complexes

Salts of $[Co^{III}W_{12}O_{40}]^{5-}$ are normally made by oxidation of $[Co^{II}W_{12}O_{40}]^{6-}$ with persulfate [4,5]. The procedure is tedious; we find that an O_3/O_2 mixture will effect the oxidation of $[CoW_{12}O_{40}]^{6-}$ at room temperature, whilst the persulfate procedure requires heating. Our ozonolytic procedure gave a sample which had an identical Raman spectrum with that of the product made by the procedure of [4,5]. A number of applications of $[Co^{III}W_{12}O_{40}]^{5-}$ as an oxidation catalyst have been described, the most recent of which are its use in the catalytic acetylation and formylation of alcohols [17] and deprotonation of dioxolanes [18].

3.3.1. Oxidation of alcohols by ozone catalysed by $Co(OAc)_2$

We have shown that an O_3/O_2 mixture will epoxidise alkenes to epoxides catalysed by iron(II) porphyrin complexes [19], and we are currently studying other transition-metal catalysed ozonolytic reactions. In 1998 it was claimed that $Co(OAc)_2$ catalysed the ozonolytic oxidation of menthol to menthone, in dichloromethane or ethyl acetate solvents [6] although it has long been known that non-catalysed ozonolysis of alcohols to carbonyl products occurs [20].

We found that, although menthol was indeed oxidised by ozonolysis to menthone in good yield, the presence or absence of $Co(OAc)_2$ had no effect on the yield.

3.3.2. $Co(py)_2(OAc)_2(H_2O)_2$ (1)

In connection with the above oxidation experiments we studied the effect of ozonolysis on solutions of the cobalt(II) acetate with pyridine; there are several reports of the formation of polymeric oxo-centred cobalt(III) species from such a reaction [21,22]. We found that, although some cobalt(III)-containing materials were formed, an orange material $Co(py)_2(OAc)_2(H_2O)_2$ was also present. We subsequently found that this complex could be made without ozone, by direct reaction of cobalt(II) acetate with acetic acid and pyridine. Surprisingly this material seems not to have been reported before, although there is a brief reference to $Co(OAc)_2(py)_2$ [23].

3.3.3. X-ray crystal structure of 1

A single crystal X-ray analysis of **1** showed the complex (Fig. 1) to have crystallographic inversion symmetry and to be isomorphous with its nickel analogue [24]. The pyridine rings are inclined by ca. 61° to the $\{Co,N_2,(OH_2)_2\}$ plane, and the acetate group is rotated by ca. 15° about the Co–O(7) bond, out of the CoO_4 plane. There is an intramolecular O–H···O hydrogen bond between one of the aqua hydrogen atoms and the acetate oxygen atom O(9A), and an intermolecular O–H···O hydrogen bond between the other aqua hydrogen atom and this same oxygen atom in a glide related molecule. These interactions combine to form hydrogen bonded sheets that extend throughout the {0 0 1} plane (Fig. 2). The geometry at cobalt is only slightly distorted octahedral with *cis* angles in the range 87.31(10)°–92.69(10)°. The Co-aqua, –pyridine and –acetate bond lengths (Table 1) all lie within the ranges of values observed in the closely related complexes catena-bis(μ_2-terephthalato-O,O′)-tetra-aqua-tetrapyridine-di-cobalt(II) [25] and catena-(μ_2-4,4′-biphenyldicarboxylato)-diaqua-dipyridine-cobalt(II) [26]. Interestingly, these two literature polymers also have intramolecular aqua···carboxylate hydrogen bonds directly analogous to those observed in **1**.

3.4. Possible mechanism of these oxidations by ozonolysis

We have not carried out any mechanistic studies on the oxidations. However, it seems likely that oxygen-atom transfer is involved, as proposed in our work on

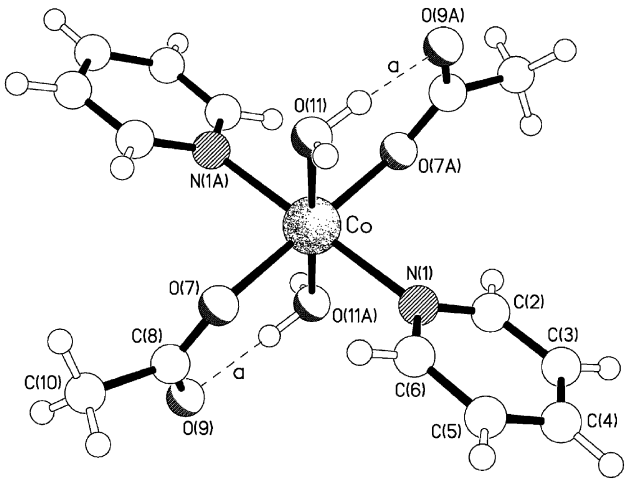

Fig. 1. The molecular structure of **1**.

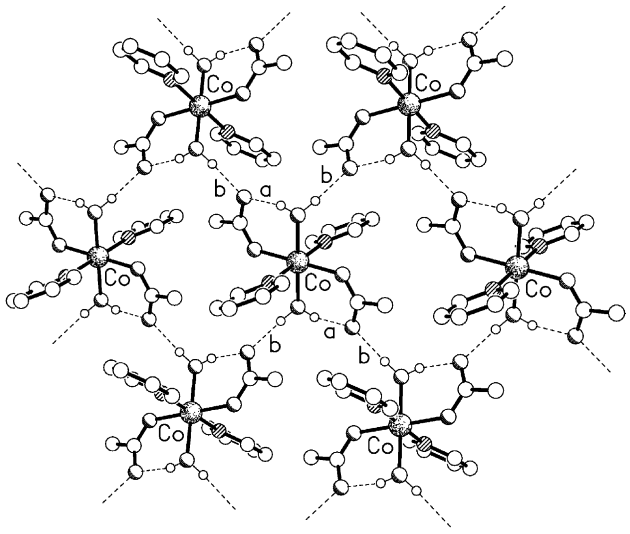

Fig. 2. Part of one of the hydrogen bonded sheets of molecules in the structure of **1**. The hydrogen bonding geometries are: [O···O], [H···O] Å, [O–H···O]°, (a) 2.717(3), 1.84, 165; (b) 2.775(3), 1.88, 172.

the epoxidation of alkenes by an O_3/O_2 mixture catalysed by iron(II) porphyrins [19]. Such a mechanism has also been proposed for other ozonolytic reactions, notably the reaction of iron(II) species with an O_3/O_2 mixture [2,27].

4. Conclusions

We have shown that simple ozonolysis can be used to prepare complexes of silver(II), manganese(III) and cobalt(III) under ambient conditions, oxidations which can be less conveniently carried out with persulfate. This successful use of ozonolysis in place of more conventional chemical methods as a route to high oxidation state complexes opens up the possibility of preparing other such species by this simple and environmentally friendly technique. It is thought likely that these oxidations involve oxygen atom transfer from the ozone to the metal centre.

During this work, the new complex $Co(py)_2(OAc)_2(H_2O)_2$ was prepared and its X-ray crystal structure determined.

5. Supplementary material

Crystallographic data for complex **1** has been deposited with the Cambridge Crystallographic data centre, CCDC No. 235093. Copies of this data may be obtained free of charge from The Director CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44-1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The synthesis and structural characterization of the complex $Ru_2(CN)(\mu\text{-DPhF})_4$ (**1**) (DPhF = *N*,*N*′-diphenylformamidinate) is reported. The reactivity of the axial position of $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ is studied and the crystal structures of $Ru_2(N_3)(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ (**2**) and $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ (**3**) are described. The isolation of $Ru_2Cl(\mu\text{-}N_3Ph_2)_4$ (**4**) and $Ru_2Cl_2(\mu\text{-}N_3Ph_2)_4$ (**5**), and the crystal structure determination of complex **4**, which constitutes the first example of a chlorotriazenido derivative, are also reported. Each complex forms discrete dinuclear molecules in the solid state, having (each diruthenium unit) one free axial position. The shortest Ru–Ru distance [2.286(2) Å] is observed in the cyano derivative (**1**) and the longest [2.4747(11) Å] is found in the triazenido complex (**4**). The azido (**2**) and isothiocyanato (**3**) derivatives show similar Ru–Ru distances of 2.3182(11) and 2.3159(4) Å, respectively. Complexes **2** and **4** display magnetic moments at room temperature corresponding to three unpaired electrons in agreement with the $\sigma^2\pi^4\delta^2(\pi^*\delta^*)^3$ ground-state configuration, whereas compounds **1** and **3** are low spin complexes with only one unpaired electron. Only very few examples of low spin diruthenium(II,III) species have been previously characterized. The diruthenium(III) compound **5** is diamagnetic.

Keywords: Diruthenium compounds; Metal–metal bonds; Triazenido complexes; Formamidinato complexes; Multiple bonds; Low spin complexes

1. Introduction

Diruthenium complexes form a well known class of compounds in which a pair of ruthenium atoms are bridged by four ligands giving a ''paddlewheel'' structure [1–3]. Numerous tetracarboxylatodiruthenium(II,III) and diruthenium(II) complexes are known [3], whereas the analogous diruthenium(III) derivatives have not been isolated [4], although the formation of the cationic complex $[Ru_2(\mu\text{-}O_2CMe)_4(PCy_3)_2]^{2+}$, containing a Ru_2^{6+} unit [5], has been reversibly generated by a cyclic voltammetry technique.

In contrast, with N,N-donor bridging ligands such as formamidinate or aminopyridinate, in addition to the formation of diruthenium(II,III) [1,2,6] and diruthenium(II) complexes [1,2,7], numerous stable diruthenium(III) complexes have been reported [8]. Thus, the reaction of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ with molten formamidines leads to the diruthenium(II,III) derivatives [6b,6c] of the type $Ru_2Cl(\mu\text{-DRF})_4$ (DRF = dialkyl- or diarylformamidinate). We have shown very recently [9] that the similar reaction with *N*,*N*′-diphenylformamidine

(HDPhF) in refluxing thf leads to the trisubstituted complex $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$, and we have explored its use as a starting material in substitution reactions of the acetato ligand by other carboxylate groups. An analogous behaviour has been observed with the *N*,*N*′-di-*p*-anisylformamidinate ligand (DAniF) [10].

However, the diruthenium chemistry employing triazenide ligands has been little explored [11–14]. Thus, only the preparation and crystal structure determination of two diruthenium(II) complexes of the type $Ru_2(\mu\text{-}N_3R_2)_4$ (R = Ph, C_6H_4-*p*-Me) have been described [12,13]. Some mono- and bis-adducts of these diruthenium(II) complexes such as $Ru_2(\mu\text{-}N_3Ph_2)_4(Bu^tNC)$ or $Ru_2(\mu\text{-}N_3Ph_2)_4(CO)_2$ are also known [11]. These diruthenium(II) complexes can be oxidized with silver salts to diruthenium(II,III) complexes as in the examples $\{Ru_2[\mu\text{-}N_3(C_6H_4\text{-}p\text{-}Me)_2]_4(MeCN)\}BF_4$ [13] and $Ru_2(\mu\text{-}N_3Ph_2)_4(OPF_4)$ [14]. In addition, the chlorotris(triazenido) complex $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}N_3Ph_2)_3$ has been proposed as an intermediate in the synthesis of $[Ru_2(\mu\text{-}O_2CMe)(\mu\text{-}N_3Ph_2)_3(MeCN)_2]BF_4$, but has not been isolated [15]. To our knowledge there is no example reported of any chloro(triazenido) complex of diruthenium.

In this work we describe the preparation and characterization of some new complexes containing diphenylformamidinate or diphenyltriazenide as bridging ligands. The reactivity of the axial position of $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ is studied and the crystal structures of $Ru_2(CN)(\mu\text{-}DPhF)_4$, $Ru_2(N_3)(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$, $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ and $Ru_2Cl(\mu\text{-}N_3Ph_2)_4$ are also reported.

2. Results and discussion

2.1. Synthesis and characterization of the complexes

The reaction of $Ru_2Cl(\mu\text{-}DPhF)_4$ with NaCN in thf in air leads to the formation of the diruthenium(III) complex $Ru_2(CN)_2(\mu\text{-}DPhF)_4$ as described previously [6b]. The formation of this complex must occur through the intermediate $Ru_2(CN)(\mu\text{-}DPhF)_4$ which accepts a new CN ligand at the free axial position providing the diruthenium(II,III) anion $[Ru_2(CN)_2(\mu\text{-}DPhF)_4]^-$. This anion is easily oxidized to give the corresponding stable diruthenium(III) complex. Since there was no example of a cyanodiruthenium(II,III) complex well characterized, we undertook the isolation of the intermediate $Ru_2(CN)(\mu\text{-}DPhF)_4$ (**1**).

In a previous paper, we have demonstrated that the substitution of the acetate ligand in $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ by other carboxylate groups is facile [9]. The axial chloride ligand of this complex can also be removed in thf employing a silver salt such as $AgBF_4$. The addition of NaN_3 to the solution gives the discrete complex $Ru_2(N_3)(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ (**2**) where the azide ligand is bonded to the axial position. The reaction of $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ with AgSCN leads directly to $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ (**3**).

Cotton and co-workers [15] have described that the reaction of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ in melted HN_3Ph_2 followed by the removal of the axial chloride ion with $AgBF_4$ gives $[Ru_2(\mu\text{-}O_2CMe)(\mu\text{-}N_3Ph_2)_3(MeCN)_2]BF_4$. We have carried out this reaction in refluxing 2-methoxyethanol without $AgBF_4$ in order to obtain the tetrasubstituted complex. This solvent has proved to be useful for the complete substitution of the acetate groups in $Ru_2Cl(\mu\text{-}O_2CMe)_4$ by amides [16]. However, we have obtained crystals of $Ru_2Cl(\mu\text{-}N_3Ph_2)_4$ (**4**) in low yield (12%). The diruthenium(III) complex $Ru_2Cl_2(\mu\text{-}N_3Ph_2)_4$ (**5**) could be isolated after purifying the mixture by column chromatography.

Complexes **1**–**5** exhibit characteristic bands of the diphenylformamidinate and diphenyltriazenide ligands. The spectrum of **1** shows a sharp and intense band at 2096 cm^{-1} while the azide asymmetric stretching absorption in complex **2** appears as an intense band at 2031 cm^{-1}. Similar values have been found for the diruthenium(III) compounds $Ru_2(DMBA)_4X_2$ (DMBA = *N*,*N*′-dimethylbenzamidinate) where X is a CN or N_3 terminal axial ligand [8b]. Complex **3** presents at 2060 cm^{-1} the absorption corresponding to the SCN group bonded to the ruthenium atom. The shifting of this band with respect to the free SCN group suggests that this ligand is N-bonded to the ruthenium atom, which is corroborated by the crystal structure determination described below.

2.2. Magnetic properties

Complexes **1**–**4** are paramagnetic whereas complex **5** is diamagnetic. Complexes **2** and **4** display magnetic moments at room temperature corresponding to three unpaired electrons in agreement with the $\sigma^2\pi^4\delta^2(\pi^*\delta^*)^3$ ground-state configuration proposed by Norman and co-workers [17] for carboxylatodiruthenium(II,III) complexes. The magnetic moment of complex **2** (4.1 B.M.) is comparable to the parent chloro derivative $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ (4.0 B.M.), its analogous $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-}DAniF)_3$ (3.8 B.M.) [10] and the rare example $[Ru_2(\mu\text{-}O_2CMe)(\mu\text{-}N,N'\text{-}o\text{-}MeOForm)(\mu\text{-}N,N'\text{-}\eta^2\text{-}N,O\text{-}o\text{-}OMeForm)(\mu\text{-}N,N'\text{-}\eta^2\text{-}N,O\text{-}o\text{-}OMeForm')]$ (3.8 B.M.), where *o*-MeOForm is di(*o*-methoxyphenyl)formamidinate and *o*-MeOForm' is the *o*-demethylation derivative of *o*-MeOForm [18]. Similar magnetic moments are also observed in the chlorotetrakis(formamidinato)diruthenium(II,III) derivatives [6b,6c,19] and in all tetracarboxylatodiruthenium(II,III) derivatives described in the literature [1,3]. As it has been proved, the π^* and δ^* energy levels of the electronic structure of the diruthenium(II,III) units are dependent

on the nature of the bridging and axial ligands [1,3]. Thus, when in diruthenium complexes both bridging acetate and chlore axial ligands are replaced by triazenide groups and MeCN ligands, respectively, the δ^* energy level moves above the π^* level, and their electronic structures become $\sigma^2\pi^4\delta^2\pi^{*3}\delta^{*0}$ [13,15]. As a consequence, a low spin complex is formed as observed in $\{Ru_2[\mu\text{-}N_3(C_6H_4\text{-}p\text{-}Me)_2]_4(MeCN)\}BF_4$ (1.9 B.M.) [13] and $[Ru_2(\mu\text{-}O_2CMe)(\mu\text{-}N_3Ph_2)_3(MeCN)_2]BF_4$ (1.5 B.M.) [15]. These observations are corroborated in the magnetic behaviour of $Ru_2(CN)(\mu\text{-}DPhF)_4$ (**1**) and $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{-}DPhF)_3$ (**3**), which have at the axial position π-acceptor ligands, showing a magnetic moment of 1.6 and 1.7 B.M., respectively, corresponding to the presence of only one unpaired electron.

On the other hand, the magnetic moment obtained for the first chlorotetrakis(triazenido)diruthenium-(II,III) complex **4** (4.1 B.M.) indicates that the substitution of the carboxylate groups by triazenide ligands is not sufficient to give a low spin complex. Therefore, the substitution of the chloride axial ligand by a good π-acceptor ligand is also needed.

The presence of a high or low spin electronic configuration in diruthenium species is also strongly dependent on the oxidation state of the diruthenium unit. Thus, the chlorotetrakis(formamidinato)diruthenium(II,III) compounds are paramagnetic with a high spin configuration, whereas the analogous diruthenium(II) compounds are diamagnetic [20]. The tetrakis(triazenido)diruthenium(II) complexes [12–14] and many diruthenium(III) compounds, such as complex **5**, are also diamagnetic [8]. According to this diamagnetic behaviour, complex **5** displays a well resolved ^1H NMR spectrum.

2.3. Crystal structures

The structures of complexes **1**–**4** have been determined by X-ray crystallography. Table 1 lists relevant crystallographic data, and selected distances and angles are given in Table 2.

Fig. 1 shows the molecular structure of $Ru_2(CN)(\mu\text{-}DPhF)_4\cdot C_6H_{14}$ (**1** · $\mathbf{C_6H_{14}}$). In this molecule, one axial position is occupied by a CN ligand while the other one remains free. Thus, the first Ru atom has a pseudo-octahedral environment and the second has a square pyramidal geometry. Four bridging diphenylformamidinate ligands form the equatorial planes.

The Ru–Ru distance in **1** · $\mathbf{C_6H_{14}}$ is 2.4747(11) Å, which is significantly longer than in other diruthenium(II,III) complexes, including the parent compound $Ru_2Cl(\mu\text{-}DPhF)_4$ (2.339 Å) [6b] or $Ru_2Cl(\mu\text{-}DtolF)_4$ (DtolF = di-*p*-tolylformamifinate) (2.370(2) Å) [6c], but similar to the value found in $Ru_2(CN)_2(\mu\text{-}DMBA)_4$ (DMBA = *N*,*N*′-dimethylbenzamidinate) (2.4508(9) Å) [8b]. The metal-metal bond distance is even longer (2.539(1) Å) [6b] for the dicyano derivative of diruthenium(III) $Ru_2(CN)_2(\mu\text{-}DPhF)_4$ [6b]. Thus, the Ru–Ru distance in complex **1** · $\mathbf{C_6H_{14}}$ with a theoretical bond order of 2.5, is shorter than that observed in $Ru_2(CN)_2(\mu\text{-}DPhF)_4$, which has a theoretical triple bond order. The shorter Ru–Ru distance in

diruthenium(II,III) derivatives than in the diruthenium(III) complexes, has been observed previously [6b].

The Ru–C bond length (2.112(11) Å) is longer than the average Ru–C bond distance of 1.971 Å found in $Ru_2(CN)_2(\mu\text{-DPhF})_4$[6b], in accord with the shorter C-N bond distance for **1 · C$_6$H$_{14}$** (1.111(14) Å) in comparison with the dicyano complex (1.148(13) and 1.179(14) Å). The molecule is rotated around the Ru–Ru axis with a N–Ru–Ru–N torsion angle of 14.22(16)°. This torsion angle is analogous to that observed in $Ru_2Cl(\mu\text{-DPhF})_4$ (14.6°) [6b]. The phenyl rings of each ligand are twisted out of the bridging ligand plane (C2–N3–C9–C10 = 36.6(8)° and C2–N2–C3–C8 = 69.9(7)°), similar to $Ru_2Cl(\mu\text{-DPhF})_4$ [6b]. Ru–Ru–C and Ru–C–N are strictly linear.

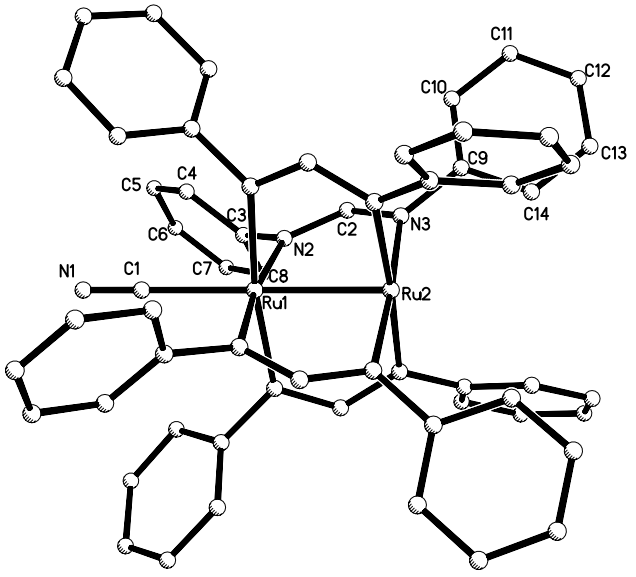

Fig. 1. PLUTO view of **1 · C$_6$H$_{14}$**. Crystallization molecule and hydrogen atoms are omitted for clarity.

Figs. 2 and 3 show a PLUTO view of the structures of $Ru_2(N_3)(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ (**2**) and $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{- DPhF})_3$ (**3**), respectively. The asymmetric unit of crystal **2** contains two independent molecules (**2a** and **2b**). The differences in the metric parameters of the first coordination spheres of the Ru_2 cores are insignificant except in the torsion angles which are slightly different. Consequently, the metric parameters listed in Table 2 for this complex correspond to one of the two molecules.

The molecular structures of both complexes **2** and **3** are alike. In these derivatives the diruthenium atoms are bridged by three formamidinate ligands and one carboxylate group giving a paddle wheel structure with low values in the torsion angles. The Ru–Ru distances are very similar for **2** and **3**: 2.3182(11) and 2.3159(4) Å, respectively. These distances are comparable to those found in the parent compound $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ [9] and in other trisformamidinato complexes

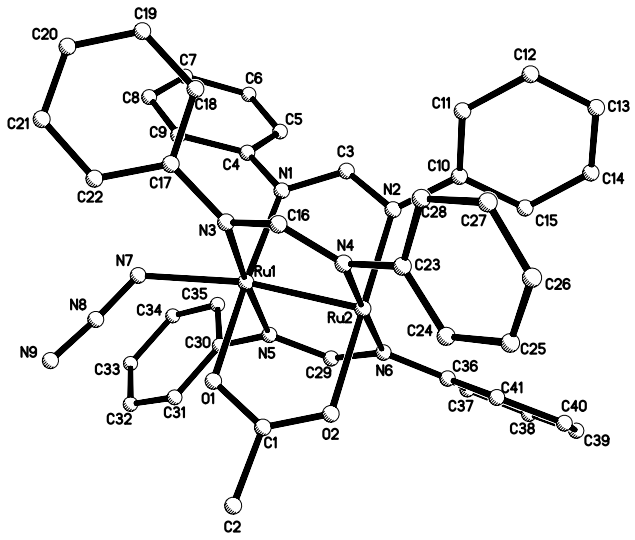

Fig. 2. PLUTO view of **2a**. Hydrogen atoms are omitted for clarity.

[9,10,18]. The Ru–N_{axial} distances are 2.116(8) and 2.103(3) Å for **2** and **3**, respectively, reflecting a similar donor nature for the N_3 and NCS ligands. In the azide ligand the N7–N8 bond length is longer (1.173(9) Å) than the distance N8–N9 (1.144(10) Å). In the NCS ligand the C–N distance is 1.146(4) Å, whereas the C–S distance is 1.612(4) Å. The N_{axial}–Ru–Ru angle in **2** (170.4(2)°) is more acute than the corresponding angle in **3** (178.16(8)°). The azide ligand (N–N–N angle: 175.8(11)°) and the isothiocyanate ligand (N–C–S angle: 179.1(4)°) are both almost linear. However, the N–N–Ru and C–N–Ru angles are very different, being 120.5(7) and 167.7(3)° for **2** and **3**, respectively.

Despite the Ru–Ru bond distance in **2** being very close to that observed in $Ru_2(DMBA)_4(N_3)_2$ (2.3166(7) Å) [8b], the structural parameters of the azide ligands are very different, especially the Ru–N_1 and N_1–N_2

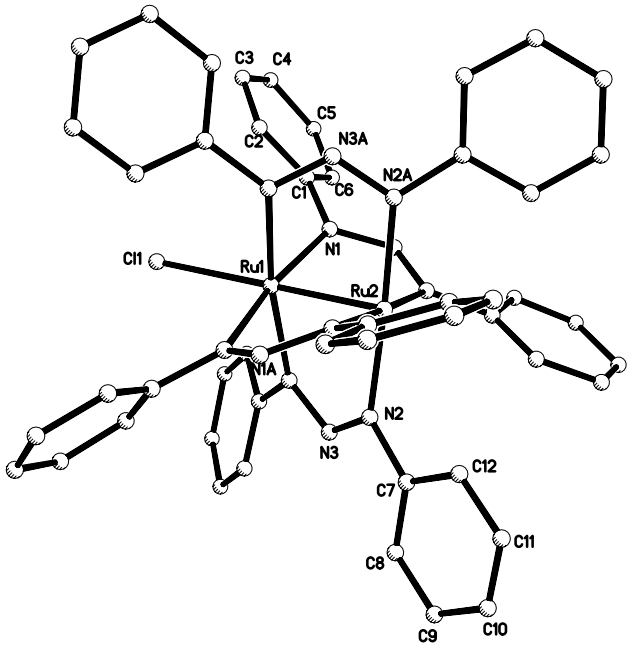

Fig. 4. PLUTO view of $\mathbf{4 \cdot 2H_2O}$. Water molecules and hydrogen atoms are omitted for clarity.

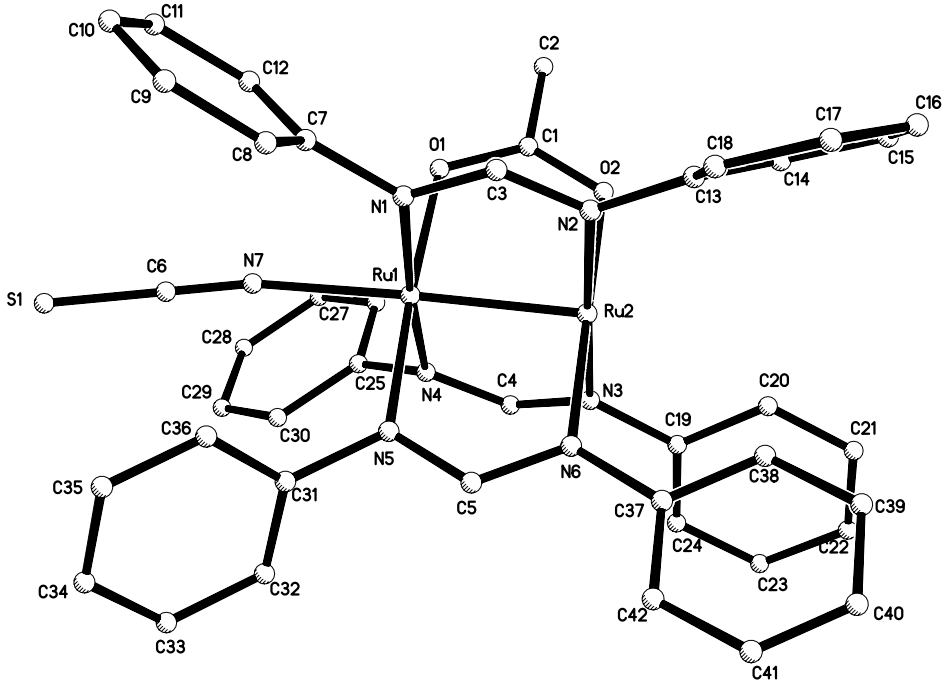

Fig. 3. PLUTO view of **3**. Hydrogen atoms are omitted for clarity.

distances (2.246(4) and 1.036(5) Å) and the Ru–N_1–N_2 angle (153.6(5)°).

The molecular structure of $\mathbf{4 \cdot 2H_2O}$ is shown in Fig. 4. The coordination about Ru1 and Ru2 is essentially octahedral and square pyramidal, respectively, with the four triazenide ligands occupying the equatorial planes. Similarly to compound $\mathbf{1 \cdot C_6H_{14}}$, this complex has elevated torsion angles (23.08°).

The Ru–Ru distance in $\mathbf{4 \cdot 2H_2O}$ (2.286(2) Å) is comparable to tetracarboxylatodiruthenium(II,III) complexes [**1**–**3**], but surprisingly short in comparison with other triazenido or formamidinato complexes: $Ru_2(\mu\text{-}N_3Ph_2)_4(OPF_4)$ (2.385(2) Å) [14], $\{Ru_2[\mu\text{-}N_3(C_6H_4\text{-}p\text{-}Me)_2]_4(MeCN)\}BF_4$ (2.373(2) Å) [13], $[Ru_2(\mu\text{-}O_2CMe)(\mu\text{-}N_3Ph_2)_3(MeCN)_2]BF_4$ (2.3822(8) Å) [15], $Ru_2Cl(\mu\text{-DPhF})_4$ (2.339(1) Å) [6b] and $Ru_2Cl(\mu\text{-DtolF})_4$ (2.370(2) Å) [6c].

3. Conclusions

The preparation of $Ru_2(CN)(\mu\text{-DPhF})_4$ confirms that diruthenium(II,III) complexes with strong π acceptor ligands are stable with suitable bridging ligands. Low spin configurations seem to be preferred for diruthenium(II,III) compounds with this kind of axial ligand. The facile substitution of the axial chloro ligand in $Ru_2Cl(\mu\text{-}O_2CCH_3)(\mu\text{-DPhF})_3$, in addition to the replacement of the carboxylate group, makes this complex very versatile as a starting material to build supramolecular structures.

4. Experimental

Unless otherwise stated, all reactions were routinely carried out under an atmosphere of dry oxygen-free nitrogen. $Ru_2Cl(\mu\text{-}O_2CMe)_4$, $Ru_2Cl(\mu\text{-DPhF})_4$ and $Ru_2Cl(\mu\text{-}O_2CCH_3)(\mu\text{-DPhF})_3$ were prepared as previously reported [21,6b,9]. Other chemicals and solvents were obtained from commercial sources and used without further purification.

Elemental analyses were done by the Microanalytical Service of the Complutense University of Madrid. IR spectra were recorded on a FT ThermoNicolet IR200 spectrometer using KBr pellets. Mass spectra were performed on a Bruker Esquire-LC with electrospray ionization (ESI) using chloroform. The ^1H NMR spectrum was recorded with a Bruker Avance DPX300 using acetone-d_6 as solvent. The magnetic susceptibility data were measured on a Quantum Design MPMS*XL* SQUID (Superconducting Quantum Interference Device) susceptometer. All data were corrected for the diamagnetic contribution of both the sample holder and the compound to the susceptibility. The molar diamagnetic corrections for the complexes were calculated on the basis of Pascal's constants.

4.1. Synthesis of $Ru_2(CN)(\mu\text{-DPhF})_4$ (**1**)

To a violet solution of 0.220 g (0.22 mmol) $Ru_2Cl(\mu\text{-DPhF})_4$ in 20 mL thf was added 0.100 g (2.04 mmol) NaCN with 40 ml thf. The mixture was stirred for 3 days and pumped to dryness to give a solid, which was treated with a mixture of toluene and dichloromethane and stirred overnight. The solid was filtered and 0.060 g (0.06 mmol, 27%) **1** was extracted as the monohydrate with dichloromethane from the residue. *Anal.* Calc. for $Ru_2ON_9C_{53}H_{46}$ ($\mathbf{1 \cdot H_2O}$): C, 61.98; H, 4.51; N, 12.27. Found: C, 61.73; H, 4.50; N, 12.67%. IR (KBr, cm^{-1}): 3435 (m), 3058 (w), 3030 (vw), 2943 (vw), 2096 (w), 1637 (w), 1592 (m), 1533 (s), 1487 (vs), 1450 (w), 1331 (m), 1214 (vs), 1077 (vw), 1027 (w), 933 (m), 779 (m), 760 (s), 696 (vs). MS (ESI^+): *m/z* 984, [**1**-CN]. $\mu_{eff.} = 1.6$ B.M. Crystals of $\mathbf{1 \cdot C_6H_{14}}$ were obtained by layering hexane over a dichloromethane solution of the compound.

4.2. Synthesis of $Ru_2(N_3)(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ (**2**)

To a solution containing 0.200 g (0.23 mmol) $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ in 20 mL thf was added 0.044 g (0.23 mmol) $AgBF_4$. The mixture was stirred overnight and the solid was filtered off using celite. The solution was evaporated to dryness and the residue was dissolved in 10 mL methanol. The addition of 0.015 g (0.23 mmol) NaN_3 to this solution was followed by an immediate precipitation which left the solution almost colourless. After stirring the mixture for half an hour, the solid was filtered, washed with methanol (3 x 4 mL), and dried under vacuum. Yield: 0.170 g (84%). *Anal.* Calc. for $Ru_2O_2N_9C_{41}H_{36}$: C, 55.40; H, 4.08; N, 14.18. Found: C, 55.00; H, 4.09; N, 14.05%. IR (KBr, cm^{-1}): 3060 (vw), 3030 (vw), 2959 (vw), 2031 (vs), 1592 (m), 1537 (vs), 1488 (vs), 1435 (m), 1322 (s), 1219 (s), 1122 (sh), 1080 (w), 1027 (w), 940 (w), 776 (m), 758 (m). MS (ESI^+): *m/z* 878 [MH_2–2N]; 848 [M–N_3]; 834 [M–N_3–CH_2]. $\mu_{eff.} = 4.1$ B.M. Crystals of **2** suitable for X-ray analysis were obtained by layering hexane on a solution of the compound in dichloromethane.

4.3. Synthesis of $Ru_2(NCS)(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$ (**3**)

A mixture of 0.200 g (0.23 mmol) $Ru_2Cl(\mu\text{-}O_2CMe)(\mu\text{-DPhF})_3$, 0.039 g (0.24 mmol) AgSCN, and 20 mL thf was stirred overnight. The solid was removed filtering through celite and the solution was evaporated to dryness. The residue was washed with diethyl ether (4×5 mL) and dried under vacuum. Yield: 0.150 g (73%). *Anal.* Calc. for $Ru_2O_2SN_7C_{42}H_{36}$: C, 55.74; H, 4.01; N, 10.83; S, 3.54. Found: C, 55.81; H, 4.09; N, 10.75; S, 3.56%. IR (KBr, cm^{-1}): 3058 (w), 3032 (vw),

2964 (vw), 2060 (vs), 1593 (m), 1533 (vs), 1487 (vs), 1435 (m), 1319 (s), 1219 (s), 1077 (w), 1027 (w), 940 (w), 773 (m), 758 (s), 695 (s). MS (ESI^+): *m/z* 848 [M–NCS] together with *m/z* 847 [M–O_2CMe]. $\mu_{eff.} = 1.7$ B.M. Crystals of **3** were collected after a slow diffusion of hexane into a solution of the complex in thf.

4.4. Synthesis of $Ru_2Cl(\mu\text{-}N_3Ph_2)_4$ (**4**)

A mixture containing 0.200 g (0.42 mmol) $Ru_2Cl(\mu\text{-}O_2CMe)_4$, 0.500 g (2.53 mmol) 1,3-diphenyltriazene, 0.120 g (2.84 mmol) LiCl, 0.4 mL (2.84 mmol) Et_3N and 20 mL 2-methoxyethanol was refluxed for 24 h, giving a dark violet solution. This solution was treated again with fresh 1,3-diphenyltriazene (0.500 g, 2.53 mmol) and Et_3N (0.4 mL, 2.84 mmol) under the same conditions to complete the replacement of the acetate ligands. The solution was evaporated to dryness under vacuum and the dark violet solid obtained was extracted three times with 30 mL toluene. The solvent was removed and the solid left was washed twice with 20 mL petroleum ether (40–60 °C). Yield: 0.052g (12%). *Anal.* Calc. for $Ru_2ClN_{12}C_{48}H_{40}$: C, 56.38; H, 3.94; N, 16.44. Found: C, 56.20; H, 3.89; N, 16.23%. IR (KBr, cm^{-1}): 3065 (w), 2965 (w), 2852 (w), 1590(m), 1483 (vs), 1454 (m), 1409 (w), 1329 (s), 1306 (vs), 1287 (vs), 1220 (m), 1165 (m), 1069(m), 1026 (m), 901 (w), 756 (vs), 688 (vs), 664 (m), 528 (m), 511 (m). MS (ESI^+): *m/z* 988, [M–Cl]. $\mu_{eff.} = 4.1$ B.M. A thf solution of this complex was layered with hexane to give violet single crystals of $Ru_2Cl(\mu\text{-}N_3Ph_2)_4 \cdot 2H_2O$ (**4 · 2H$_2$O**).

4.5. Synthesis of $Ru_2Cl_2(\mu\text{-}N_3Ph_2)_4$ (**5**)

The synthetic procedure is similar to that described for **4**, but the solid obtained was dissolved in toluene and passed through a silica gel chromatographic column and eluted with toluene. Three bands, violet, green and brown, were obtained. The violet one was collected and the spectroscopic characterization revealed that this first band corresponds to $Ru_2Cl_2(\mu\text{-}N_3Ph_2)_4$. Yield: 0.089 g (20%). *Anal.* Calc. for $Ru_2Cl_2N_{12}C_{48}H_{40}$: C, 54.49; H, 3.81; N, 15.89. Found: C, 54.32; H, 3.71; N, 15.73%. IR (KBr, cm^{-1}): 3062 (w), 3034 (w), 1961(w), 1591 (m), 1484 (vs), 1454 (w), 1305 (s), 1290 (s), 1208 (m), 1166 (w), 1073 (w), 1025 (w), 759 (s), 697 (s), 689 (s), 664 (m), 551 (w), 516 (w). MS (ESI^+): *m/z* 988, [M–2Cl]. NMR (acetone-d_6, δ, ppm): 7.75 (m), 7.27 (m), 6.67 (m).

4.6. X-ray crystallography

Single crystals of compounds **1**–**4** were obtained as described above. Details for data collection and crystal structure refinement for these compounds are summarized in Table 1. Representative crystals were mounted on a Bruker Smart-CCD diffractometer with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. In each case data were collected, at 293(2) K, over a hemisphere of the reciprocal space by a combination of three exposures sets. The cell parameters were determined and refined by a least-squares fit of all reflections collected. The structures were solved by direct methods and refined by the full-matrix least-squares method against F^2 of all data. Calculations were performed with the aid of the SHELXS and SHELXL programs [22,23]. The final mixed refinement was undertaken with anisotropic thermal parameters for the non-hydrogen atoms, except for the hexane and water molecules. For **1 · C$_6$H$_{14}$** a massively disordered area of electron density was found, which is presumed to be hexane. The solvent molecule did not refine freely and was refined to convergence with the carbon-carbon bond length restraint in SHELX-76. Similar compounds with the same space group and disordered solvent molecules have been found previously [6b,6c]. For **4 · 2H$_2$O** due to the low quality of the crystal only the good reflections (max. $2\theta = 44°$) have been used in the refinement. In the last cycles of this refinement disordered solvent was found. The best R factor was obtained with two water solvent molecules. It has not been possible to locate the hydrogen atoms in the Fourier synthesis.

5. Supplementary material

Crystallographic data for **1**–**4** have been deposited at the Cambridge Crystallographic Data Centre as a supplementary publication (CCDC Nos. 235127–235130). These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: + 44-1223/336-033; e-mail: deposit@ccdc.cam.ac.uk].

Dedicated to Professor Malcolm Green, in honour of his numerous inspiring contributions to Organometallic Chemistry

Abstract

The acetylacetonato complexes [Rh(κ^2-O-O)(C_2H_4)(P*i*Pr$_3$)] (O-O = acac **5**, acac-f$_3$ **6**, acac-f$_6$ **7**) and [Rh(κ^2-O-O)(P*i*Pr$_3$)$_2$] (O-O = acac **10**, acac-f$_6$ **11**) were prepared from either [Rh(κ^2-O-O)(C_2H_4)$_2$] (**2–4**), [Rh(η^3-C_3H_5)(P*i*Pr$_3$)$_2$] (**8**) or [RhCl(P*i*Pr$_3$)$_2$]$_2$ (**9**) as the starting materials. While attempts to obtain the diazoalkane derivatives [Rh(κ^2-O-O)(N_2CR_2)(P*i*Pr$_3$)] (R = Ph, *p*-Tol) failed, treatment of **5–7** with $N_2CC_4Cl_4$ gave the corresponding substitution products [Rh(κ^2-O-O)($N_2CC_4Cl_4$)(P*i*Pr$_3$)] (**12–14**) in good yields. The reaction of **8** with C_6Cl_5OH afforded the square-planar complex [Rh(κ^2-OC_6Cl_5)(P*i*Pr$_3$)$_2$] (**15**), in which the pentachlorophenolato ligand is coordinated in a chelating fashion. From **15** and C_2H_4, O_2 and N_2CPh_2 the 1:1 adducts *trans*-[Rh(κ^1-OC_6Cl_5)(L)(P*i*Pr$_3$)$_2$] (**16–18**) were prepared. Compound **15** catalyzes the reaction of ethene with diaryldiazomethanes to give, instead of 1,1-diarylcyclopropanes, the isomeric olefins $R_2C{=}CHCH_3$ (R = C_6H_5 **1b**, *p*-C_6H_4Me **19**, *p*-C_6H_4Cl **20**) as the main products. The carboxylato complexes [Rh(κ^2-O_2CMe)(P*i*Pr$_3$)$_2$] (**21**) and [Rh(κ^2-O_2CCF_3)(P*i*Pr$_3$)$_2$] (**25**) react with N_2CRR' (R = R′ = C_4Cl_4; R = R′ = Ph; R = H, Ph, R′ = C(O)Ph) by opening the chelate bond to give the four-coordinate 1:1 adducts *trans*-[Rh(κ^1-O_2CMe)(N_2CRR')(P*i*Pr$_3$)$_2$] (**22–24**) and *trans*-[Rh(κ^1-O_2CCF_3)(N_2CRR')(P*i*Pr$_3$)$_2$](**26–28**), respectively. Treatment of **25** with $PhCHN_2$ produced the dinitrogen complex *trans*-[Rh(κ^1-O_2CCF_3)(N_2)(P*i*Pr$_3$)$_2$] (**29**). In contrast to the trifluoracetato compound **25**, which catalyzes the reaction of ethene and diaryldiazomethanes N_2CRR' to give mainly the trisubstituted olefins $R'RC{=}CHCH_3$, the corresponding reaction of C_2H_4 and N_2CRR' with acetato complex **21** as the catalyst affords the isomeric ethene derivatives $CH_2{=}CHCHRR'$ as the major products. A mechanism for this unexpected C–C coupling reaction is discussed.

1. Introduction

In the context of our studies on the preparation and reactivity of carbenerhodium(I) complexes of the general composition *trans*-[RhCl(=CRR′)(L)$_2$] with L = PR_3, AsR_3 and SbR_3 [1], we observed that upon treatment of [RhCl(C_2H_4)$_2$]$_2$, [Rh(κ^2-acac-f$_6$)(C_2H_4)$_2$] or [RhCl-(P*i*Pr$_3$)$_2$]$_2$ with an excess of ethene and diphenyldiazomethane a catalytic reaction occurred and the trisubstituted olefin 1,1-diphenylpropene (**1b**) was generated as the dominating product [2,3]. The formation of this olefin can be considered, in a formal sense, as the coupling of two carbene fragments :CPh_2 and :CHMe, of which the

1a **1b**

[Kat^1] : [$Rh_2(O_2CCH_3)_4$], [$Rh_6(CO)_{16}$], [Rh(κ^2-acac)$(C_2H_4)_2$]

[Kat^2] : [$RhCl(C_2H_4)_2]_2$, [$RhCl(PiPr_3)_2]_2$, [Rh(κ^2-acac-f_6)$(C_2H_4)_2$]

Scheme 1.

latter derives from the isomeric ethene. Besides **1b**, only traces of the isomeric disubstituted cyclopropane **1a** could be detected which was surprising insofar as it was well known that dinuclear bis(carboxylato)rhodium(II) compounds such as $[Rh_2(O_2CMe)_4]$ and derivatives thereof [4], some carbonylrhodium(0) clusters [5] and the chelated rhodium(I) complex [Rh(κ^2-acac)$(C_2H_4)_2$] [6] are effective catalysts for the synthesis of cyclopropanes from olefins and diazoalkanes (Scheme 1).

By taking the difference in reactivity of [Rh(κ^2-acac)$(C_2H_4)_2$] on one hand and of $[RhCl(C_2H_4)_2]_2$ and [Rh(κ^2-acac-f_6)$(C_2H_4)_2$] on the other into consideration, it became quite obvious that the anionic ligand of the corresponding rhodium complex has a significant influence on the course of the reaction of ethene and diphenyldiazomethane. Therefore, we set out to prepare some relatives of the above-mentioned chelated rhodium(I) compounds and to study their reactivity, in particular the directing role of the ligands in the C–C coupling reaction. For comparison, we also included in our investigations the mononuclear carboxylato derivatives [Rh(κ^2-O_2CR)$(PiPr_3)_2$] (R = CH_3, CF_3, *p*-C_6H_4OMe, *p*-$C_6H_4NO_2$), the preparation of which was recently reported by our group [7]. Some preliminary results of the present work have already been communicated [8].

2. Results and discussion

The synthetic routes leading to the mono(phosphine) and bis(phosphine) acetylacetonato complexes **5**–**7** and **10**, **11** are outlined in Scheme 2. The preparation of **5** and **7** by ligand exchange from **2** and **4** with an equimolar amount of $PiPr_3$ has previously been described and the spectroscopic data have been reported [9]. Compound **6** with acac-f_3 as an unsymmetrical chelating ligand, was isolated as a mixture of two isomers showing slightly different NMR signals (see Scheme 3). Since the isomers are formed in a ratio of *cis*-**6**:*trans*-**6** = 15:1, the corresponding signals can be easily assigned. The bis(phosphine) compound **11** was initially prepared from **4** and two equivalents of $PiPr_3$ in a modest yield [9]. The preferred pathway is the reaction of **8** with hexafluoroacetylacetone, which gives **11** in 76% yield by elimination of propene.

Quite surprisingly, the acac complex **10** is not accessible either from **2** and excess $PiPr_3$ or from **8** and acacH. However, it can be obtained by salt metathesis

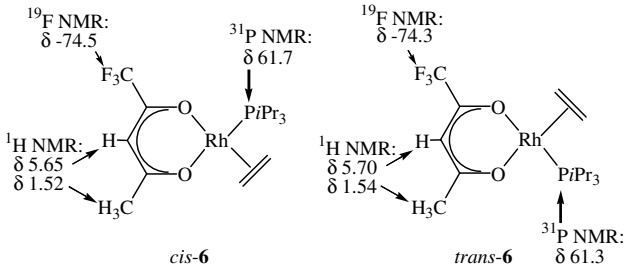


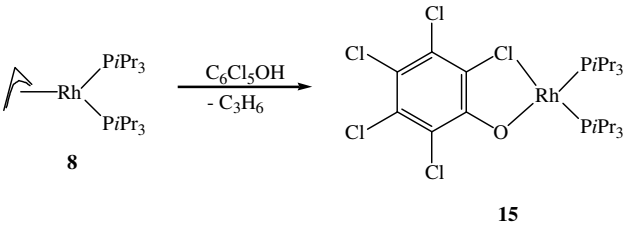
Scheme 3.

from **9** and Na(acac) in a slurry of diethylether. Both **10** and **11** are moderately air-sensitive solids, which are readily soluble in aromatic and chlorinated solvents but almost insoluble in pentane and diethylether. The IR as well as the ^{1}H and ^{13}C NMR data of **10** are similar to those of the bis(tricyclohexylphosphine) compound $[Rh(\kappa^2\text{-acac})(PCy_3)_2]$, the molecular structure of which was determined by X-ray crystallography [10].

While the ethene ligand in the chlororhodium(I) complex *trans*-$[RhCl(C_2H_4)(PiPr_3)_2]$ can be smoothly displaced by diphenyldiazomethane [2], attempts to substitute the olefin in compounds **5**–**7** by N_2CPh_2 failed. Although the formation of a 2:3 mixture of **1a** and **1b** could be detected by GC–MS, the composition of the organometallic product remained obscure.

However, the starting materials **5**–**7** react with $N_2CC_4Cl_4$ in pentane at low temperatures to afford the diazocyclopentadiene complexes **12**–**14** in 58–79% yields (Scheme 4). The greenish air-stable solids were characterized by elemental analysis and mass spectra. Even if they were stored in solution at 20 °C for several days, no conversion to a corresponding carbene derivative occurred by elimination of N_2. The IR spectra of **12**–**14** display the N–N stretching mode at around 1950 cm^{-1}, which is shifted by ca. 150 cm^{-1} to lower frequency compared with uncoordinated $N_2CC_4Cl_4$. Since the signals for the N_2C carbon atom appear in the ^{13}C NMR spectra of **12**–**14** at about the same chemical shift as that of *trans*-$[RhCl(N_2CC_4Cl_4)(SbiPr_3)_2]$ (which was characterized crystallographically) [11], we assume that the $N_2CC_4Cl_4$ ligands in **12**–**14** are bonded end-on to the metal center. In the presence of ethene, compounds **12**–**14** are inert and even upon heating do not undergo a C–C coupling reaction.

The preferred preparative route to obtain the pentachlorophenolato complex **15** is similar to that used for the related compound **11**. Treatment of **8** with an equimolar amount of C_6Cl_5OH in toluene gave **15** (Scheme 5) as a red microcrystalline solid, which is exceedingly air-sensitive and slowly decomposes in solution. The ^{1}H NMR spectrum of **15** shows at room temperature a single resonance for the methyl protons of the isopropyl groups indicating that under these conditions the two



8 **15**

Scheme 5.

$PiPr_3$ ligands are equivalent on the NMR timescale. Accordingly, the ^{31}P NMR spectrum of **15** displays at 295 K one doublet at δ 61.2, which at 213 K splits into two doublets of doublets at δ 60.4 and 59.2. On the basis of these observations, we assume that at room temperature compound **15** is fluxional in solution and that the two identical chelates are transformed into each other via a three-coordinate species as an intermediate (Scheme 6). From the coalescence temperature (228 K in toluene-d_8) and the difference in the chemical shift of the two signals at 213 K in the ^{31}P NMR spectrum, a $\Delta G^{\neq}$ value of 37 kJ/mol can be calculated. We note that the chelating capability of the pentachlorophenolate anion is not unexpected and has also been illustrated in gold(I) [12,13] as well as in ruthenium(II) and osmium(II) chemistry [14].

In agreement with the rather weak interaction between Rh and Cl, compound **15** reacts readily at room temperature with ethene in pentane to give the non-chelate complex **16** in good yield (Scheme 7). The olefinic ligand is only weakly coordinated and thus, during attempts to dry **16** in vacuo, the starting material **15** was regenerated. Under argon at 295 K, or in solution at 223 K in the presence of excess ethene, **16** can be stored without decomposition. The ^{31}P NMR spectrum of **16** in toluene-d_8 shows at 223 K a doublet resonance with a ^{31}P–^{103}Rh coupling constant of 125.0 Hz, which is typical for a *trans*-disposed $PiPr_3$–Rh–$PiPr_3$ moiety [11,15].

More readily than with ethene, compound **15** reacts with O_2 in pentane to form the 1:1 adduct **17**. The brownish compound, the composition of which has been substantiated by elemental analysis, is moderately air-sensitive and decomposes slowly both in solution and

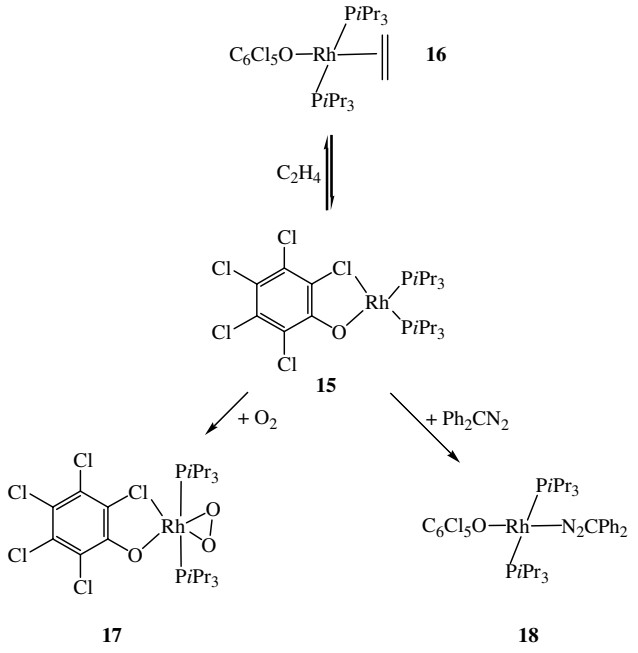


Scheme 7.

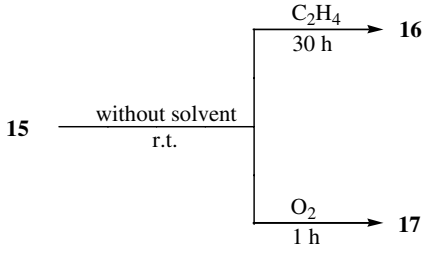
as a solid. Among the decomposition products, $OPiPr_3$ could be detected. The increased reactivity of **15** towards O_2 compared with C_2H_4 is illustrated by the fact that the solid–gas reaction with oxygen to give **17** is finished after 1 h at room temperature whereas the analogous reaction with ethene to afford **16** takes 30 h under the same conditions (Scheme 8). In either case, the product is formed in quantitative yield.

Treatment of **15** with diphenyldiazomethane also leads to partial opening of the chelate bond and to the formation of compound **18** (see Scheme 7). Similarly to the chlororhodium(I) derivative *trans*-[RhCl(N_2CPh_2)($PiPr_3$)$_2$], the phenolato complex **18** is a green air-sensitive solid that has been characterized by elemental analysis and spectroscopic techniques. With respect to the bonding mode, the position of the N–N stretching vibration at 2024 cm^{-1} in the IR spectrum suggests an end-on coordination of the N_2CPh_2 unit [16]. In the ^{13}C NMR spectrum, the resonance for the N_2C carbon atom appears at δ 87.1 as a broad singlet, the broadening probably being due to the quadrupole moment of the nitrogen atoms. The ^1H NMR spectrum of **18** displays one doublet of virtual triplets for the PCHCH_3 protons, which indicates that the two phosphine ligands are in a *trans* disposition [15,17].

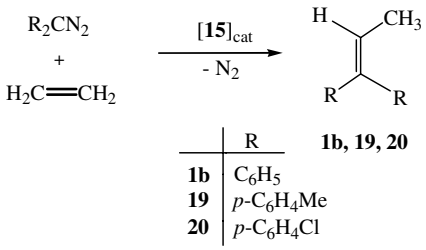
Although the diazoalkane complex **18** reacts with a saturated solution of ethene in benzene at 40 °C rather slowly to give the olefin **1b**, the precursor **15** catalyzes not only the reaction of C_2H_4 with N_2CPh_2 but also that of ethene with $N_2C(C_6H_4Me\text{-}p)_2$ and $N_2C(C_6H_4Cl\text{-}p)$, respectively (Scheme 9). By monitoring the corresponding reactions by NMR, the exclusive formation of the C–C coupling products **1b**, **19** and **20** has been observed. The turnover number (TON) is ca. 10 and thus is much lower than with [RhCl($PiPr_3$)$_2$]$_2$ or [RhCl(C_2H_4)$_2$]$_2$ as the catalyst [2,3].

To compare the reactivity of **15** with that of the related bis(triisopropylphosphine) analogues [Rh(κ^2-O_2CR)($PiPr_3$)$_2$], the reactions of the previously prepared carboxylato complexes **21** and **25** with various diazoalkanes have been investigated. The results are summarized in Schemes 10 and 11. While the acetato complex **21** reacts with $N_2CC_4Cl_4$ almost instantaneously to give the 1:1 adduct **22** in nearly quantitative yield, the corresponding reactions of **21** with N_2CPh_2 and $N_2C(Ph)C(O)Ph$ lead to equilibria between the starting material and compounds **23**, **24** which could not be completely shifted to the side of the products. Since attempts to separate **21** from **23** or **24** by fractional crystallization or column chromatography failed, the diazoalkane complexes **23** and **24** could only be characterized by IR and NMR spectroscopy. In contrast, the diazocyclopentadiene derivative **22** was isolated as a pale-green solid for which a correct elemental analysis was obtained. The spectroscopic data of **22**–**24** are in agreement with a square-planar arrangement of the four monodentate ligands around the rhodium(I) center and deserve no further comments.

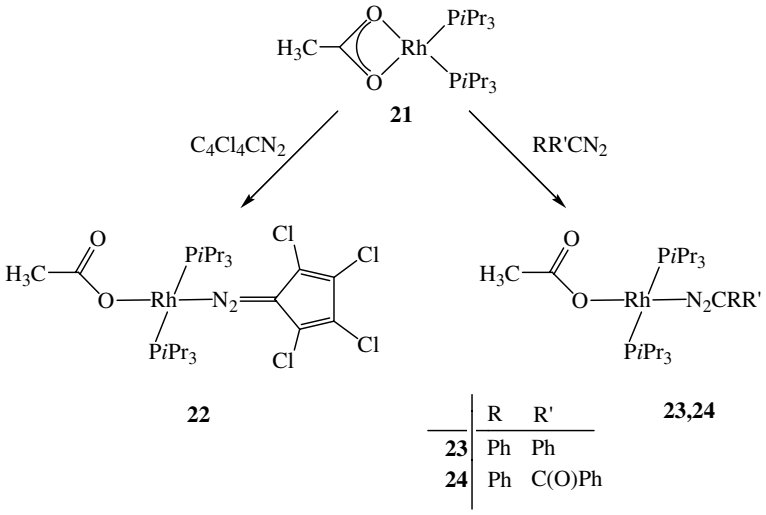
The trifluoracetato compound **25** is significantly more reactive toward diazoalkanes than the counterpart **21** and upon treatment with N_2CPh_2, $N_2CC_4Cl_4$ and $N_2CHC(O)Ph$ in pentane affords the expected 1:1 adducts **26**–**28** in good to excellent yields (Scheme 11). The IR spectra of the green (**26**, **27**) or yellow (**28**) solids display a band for the asymmetric OCO stretching mode



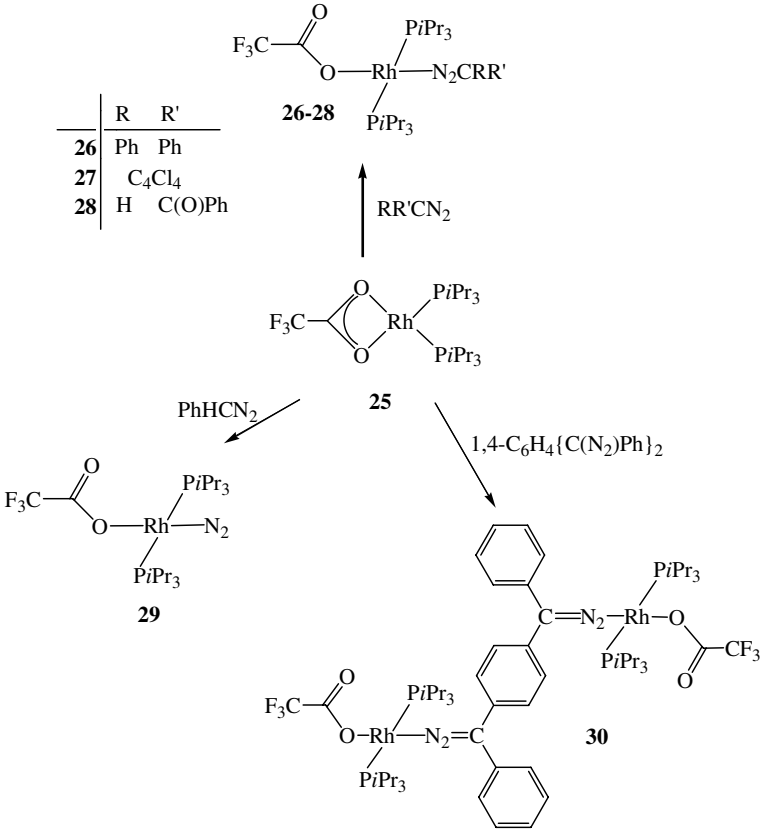
Scheme 8.



Scheme 9.



Scheme 10.



Scheme 11.

at around 1640–1700 cm^{-1}, which is consistent with the monodentate coordination of the trifluoracetato ligand [18]. The bis(diazoalkane) derivative 1,4-C_6H_4-$\{C(N_2)Ph\}_2$ behaves similarly to N_2CPh_2 and reacts with the starting material **25** in diethylether to give the dinuclear complex **30**. The ^{31}P NMR spectrum of **30** shows a doublet at δ 41.9, the chemical shift and the ^{31}P–^{103}Rh coupling constant of which are nearly identical to those of the corresponding signal for **26**.

In contrast to N_2CPh_2, phenyldiazomethane reacts with **25** in pentane to give, instead of *trans*-[Rh(κ^1-O_2CCF_3)(N_2CHPh)($PiPr_3$)$_2$], the dinitrogen complex **29** in 59% yield. Thus, the trifluoracetato compound behaves similarly to [RhCl($PiPr_3$)$_2$]$_2$ which upon treatment

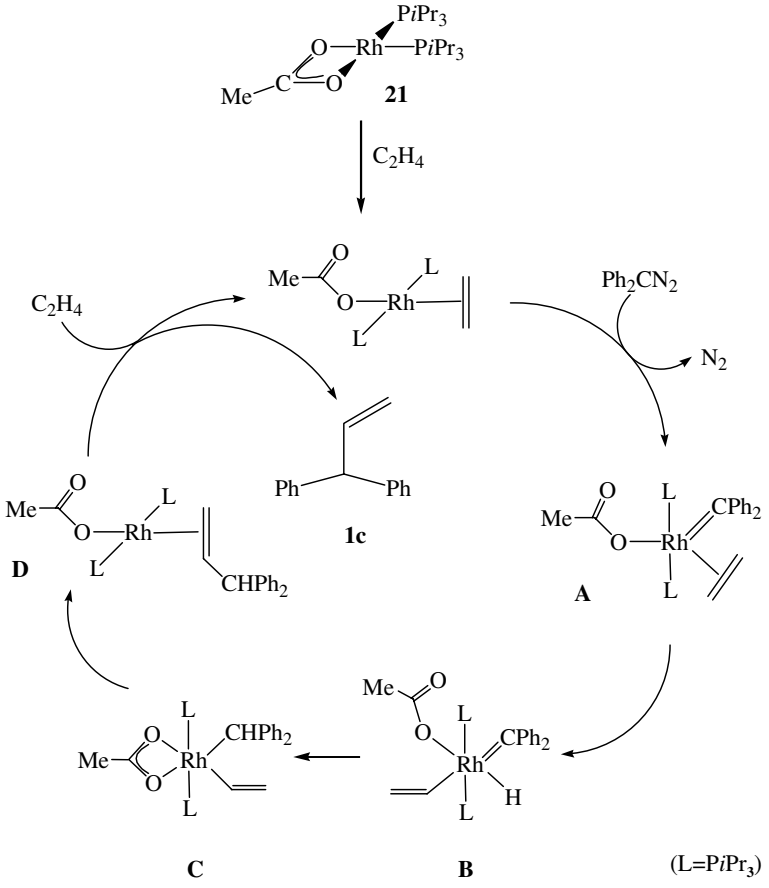

Scheme 12.

with N_2CHPh affords *trans*-[RhCl(N_2)(P*i*Pr$_3$)$_2$] [19,20]. Diagnostic for the coordination of the N_2 ligand in **29** is the $\nu(N_2)$ stretch at 2098 cm^{-1} in the IR spectrum, which is shifted by ca. 160 cm^{-1} to higher frequency compared with the N_2CPh_2 derivative **26**. In solution, compound **29** is less stable than the counterparts **26** and **28** and decomposes slowly to give **25** as the dominating species.

Both the acetato and the trifluoracetato complexes **21** and **25** are also catalysts for the C–C coupling reaction of ethene and diaryldiazomethanes. However, while the catalytic activity is comparable to that of the pentachlorophenolato analogue **15** (see Scheme 9), the substituent of the carboxylato unit has a significant influence on the composition of the coupling product. With **25** as the catalyst, the reaction of C_2H_4 with $N_2C(C_6H_4X)_2$ (X = H, *p*-Me, *p*-Cl) leads almost exclusively to the formation of the trisubstituted olefins **1b**, **19** and **20** with turnover numbers (in toluene at 40 °C) of 33 (X = H), 18 (X = *p*-Me) and 12 (X = *p*-Cl), respectively. At the beginning

of the catalytic processes, the formation of the diazoalkane complexes *trans*-[Rh(κ^1-O_2CCF_3)(N_2CR_2)(P*i*Pr$_3$)$_2$] could be detected by ^{1}H and ^{31}P NMR spectroscopy.

With catalytic amounts of the acetate **21**, the reaction of ethene and diaryldiazomethanes N_2CRR' takes a different course. In this case, the coupling product is neither the disubstituted cyclopropane nor the trisubstituted olefin $CH_3CH{=}CRR'$ but, quite remarkably, the isomeric monosubstituted ethene derivative $CH_2{=}CHCHRR'$. Thus, formally an insertion of the carbene :CRR′ into one of the C—H bonds of ethene occurs. The TON values lie between 6 and 13 (see Table 1) and depend only slightly on the substituents R and R′. If instead of ethene, propene is treated with N_2CPh_2 in the presence of **21** as the catalyst, no reaction occurs under the same conditions. The coupling products $CH_2{=}CHCHRR'$, of which as far as we know those with R = Ph, R′ = *o*-C_6H_4Me, *p*-C_6H_4Me and R = R′ = *p*-C_6H_4(OMe), *p*-C_6H_4Cl have not been described in the literature, were characterized by GC–MS and ^{1}H NMR spectroscopy.

The mechanism of the reaction of ethene and diaryldiazomethanes with **21** as the catalyst to give predominantly the monosubstituted ethene derivative is not clear as yet. As shown in Scheme 12 with N_2CPh_2 as the substrate, we assume that in the initial step, in the presence of a large excess of ethene, the intermediate *trans*-[Rh(κ^1-O_2CCH_3)(C_2H_4)(P*i*Pr$_3$)$_2$] is formed and reacts with diphenyldiazomethane to generate the five-coordinate carbene(olefin) compound **A**. While we have postulated that on this stage, for chloride instead of acetate as the anionic ligand, ring closure occurs to give a metallacyclobutane, alternatively an intramolecular C—H activation could take place to afford the six-coordinate intermediate **B**. Migration of the hydride ligand from the metal to the carbene moiety with concomitant formation of a chelate ring would then give the alkyl(vinyl)rhodium(III) derivative **C**, that rearranges via intramolecular C–C coupling to generate **D**. With excess C_2H_4, the olefinic ligand of **D** could be replaced to produce **1c** (the isomer of **1a** and **1b**) and the ethene compound *trans*-[Rh(κ^1-O_2CCH_3)(C_2H_4)(P*i*Pr$_3$)$_2$], which can start a new catalytic cycle. To explain the rather low TON value for **1c** and the analogous C–C coupling products, we assume that in the course of the reaction either the initially formed ethene complex or one of the postulated intermediates decomposes to give free P*i*Pr$_3$ which reacts with the diazoalkane to form the corresponding phosphorus yield. With regard to the C—H activation step from **A** to **B**, it is worth mentioning that we recently observed, in the presence of L (pyridine or P*i*Pr$_3$), the formation of the hydrido(vinyl)iridium(III) complexes [IrH($CH{=}CH_2$)(κ^2-acac)(L)(P*i*Pr$_3$)] from the etheneiridium(I) precursor [Ir(κ^2-acac)(C_2H_4)(P*i*Pr$_3$)] under either photochemical or thermal conditions [21]. Moreover, in a control experiment we found that upon irradiation of a solution of **21** in C_6D_6, saturated with ethene, a hydridorhodium(III) intermediate is generated that displays in the ^{1}H NMR spectrum a high-field resonance at δ – 20.6, i.e., at a similar chemical shift as for [RhH(κ^1-O_2CCF_3)(κ^2-O_2CCF_3)(P*i*Pr$_3$)$_2$] (δ – 19.0) [22].

In summarizing, the present work extended the series of chelate rhodium(I) complexes with Rh(P*i*Pr$_3$)$_2$ as the core unit. These complexes not only react with ethene but also with diazoalkanes, in particular with N_2CPh_2 and $N_2CC_4Cl_4$, by opening of the chelate bond and formation of four-coordinate rhodium(I) derivatives with the two phosphine ligands in a *trans* disposition. In the presence of excess C_2H_4, compounds such as **15**, **21** and **25** catalyze the reaction of ethene and diaryldiazomethanes N_2CRR' to give, instead of the anticipated 1,1-disubstituted cyclopropane, either $CH_3CH{=}CRR'$ or the isomer $CH_2{=}CHCHRR'$ as the main product. The postulated mechanism for the formation of the terminal olefin, with the acetato complex **21** as the catalyst, involves a stepwise opening and closing of the chelating Rh(κ^2-O_2CCH_3) bond that allows the metal to maintain the preferred coordination number of four for rhodium(I) and six for rhodium(III). The question whether instead of compounds such as **15** and **25** the isolated carbene complexes *trans*-[Rh(OPh)($=CPh_2$)(P*i*Pr$_3$)$_2$] [16] and *trans*-[Rh(κ^1-O_2CCF_3)($=CPh_2$)(P*i*Pr$_3$)$_2$] [23] equally catalyze the reaction of ethene with diphenyldiazomethane to give either **1a**, **1b** or **1c** is currently being investigated in our laboratory.

3. Experimental

3.1. General considerations

All experiments were carried out under an atmosphere of argon by Schlenk techniques. Solvents were purified and degassed by standard procedures. The starting materials **2**–**4** [24], **8** [7], **9** [25], **21** and **25** [7] were prepared as described in the literature. P*i*Pr$_3$ was a commercial product from Strem. IR spectra were recorded on a Perkin–Elmer 1420 infrared spectrometer and NMR spectra were recorded (if not otherwise mentioned) at room temperature (r.t.) on Bruker WH 90, Bruker AC 200 and Bruker AMX 400 instruments. Abbreviations used: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; br, broadened signal; vt, virtual triplet; $N = {}^3J(PH) + {}^5J(PH)$ or $^1J(PC) + {}^3J(PC)$. Melting points were determined by Differential Thermal Analysis (DTA). The mass spectra were measured on a Finnigan 90 MAT instrument.

3.2. Preparation of [Rh(κ^2-acac)(C_2H_4)(P*i*Pr$_3$)] (5)

A solution of **2** (60 mg, 0.23 mmol) in 4 ml of pentane was treated with P*i*Pr$_3$ (42 μl, 0.23 mmol) and stirred for

15 min at r.t. The solvent was evaporated in vacuo and the orange residue was recrystallized from 1 ml of acetone at −78 °C: yield 70 mg (81%). The product was characterized spectroscopically by comparison with reference data [9].

3.3. Preparation of [Rh(κ²-acac-f_3)(C_2H_4)($PiPr_3$)] (*cis*- and *trans*-**6**)

This compound was prepared as described for **5**, with 100 mg (0.32 mmol) of **3** and 62 μl (0.32 mmol) of P*i*Pr_3 as starting materials. Orange solid, yield 130 mg (91%), m.p. 86 °C. *Anal*. Calc. for $C_{16}H_{29}F_3O_2PRh$: C, 43.23; H, 6.58. Found: C, 42.89; H, 6.71%. Spectroscopic data for *cis*-**6**: ^{1}H NMR (C_6D_6, 200 MHz): δ 5.65 [s, 1H, CHC(O)], 3.34, 2.76 (both br s, 4H, CH_2), 1.77 (m, 3H, PC*H* CH_3), 1.52 [s, 3H, $CH_3C(O)$], 1.08 [dd, ^3J(PH) = 13.0, ^3J(HH) = 7.2, 18H, PCHC*H*$_3$]. ^{19}F NMR (C_6D_6, 188.2 MHz): δ −74.5 (s, CF_3). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 61.7 [d, ^1J(RhP) = 179.8]. Spectroscopic data for *trans*-**6**: ^{1}H NMR (C_6D_6, 200 MHz): δ 5.70 [s, 1H, CHC(O)], 3.34, 2.76 (both br s, 4H, CH_2), 1.77 (m, 3H, PC*H*CH_3), 1.54 [s, 3H, $CH_3C(O)$], 1.08 [dd, ^3J(PH) = 13.0, ^3J(HH) = 7.2, 18H, PCHC*H*$_3$]. ^{19}F NMR (C_6D_6, 188.2 MHz): δ −74.3 (s, CF_3). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 61.3 [d, ^1J(RhP) = 180.9]. Ratio of *cis*-**6**:*trans*-**6** = 15:1.

3.4. Preparation of [Rh(κ²-acac-f_6)(C_2H_4)($PiPr_3$)] (**7**)

This compound was prepared as described for **5**, with 100 mg (0.27 mmol) of **4** and 64 μl (0.33 mmol) of P*i*Pr_3 as starting materials. Orange solid, yield 118 mg (91%). The product was characterized spectroscopically by comparison with reference data [9].

3.5. Preparation of [Rh(κ²-acac)($PiPr_3$)$_2$] (**10**)

A solution of **9** (241 mg, 0.26 mmol) in 10 ml of diethylether was treated with Na(acac) (150 mg, 1.23 mmol) and stirred for 2 h at r.t. After 30 ml of diethylether were added, the suspension was filtered and the filtrate was brought to dryness in vacuo. The residue was dissolved in 3 ml of boiling acetone and the solution was slowly cooled at −78 °C. Yellow crystals precipitated which were separated from the mother liquor and washed twice with small amounts of pentane: yield 192 mg (70%), m.p. 77 °C (dec.). *Anal*. Calc. for $C_{23}H_{49}O_2P_2Rh$: C, 52.85; H, 9.46; Rh, 19.71. Found: C, 52.39; H, 9.12; Rh, 19.36%. MS (70 eV): *m*/*z* 522 (M^+). IR (KBr): *ν*(N_2) 1958, *ν*(CO) 1579, 1510 cm^{-1}. ^{1}H NMR (C_6D_6, 400 MHz): δ 5.35 [s, 1H, CHC(O)], 2.18 (m, 6H, PC*H*CH_3), 1.74 [s, 6H, $CH_3C(O)$], 1.36 [dd, ^3J(PH) = 12.0, ^3J(HH) = 7.3, 36 H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 100.6 MHz): δ 183.3 (s, CO), 99.8 [s, *C*HC(O)], 27.1 [s, *C*$H_3C(O)$], 24.6 (vt, *N* = 19.1 Hz, P*C*HCH_3), 20.7 (s, PCH*C*H_3). ^{31}P NMR (C_6D_6, 162.0 MHz): δ 59.4 [d, ^1J(RhP) = 192.1].

3.6. Preparation of [Rh(κ²-acac-f_6)($PiPr_3$)$_2$] (**11**)

A solution of **8** (74 mg, 0.16 mmol) in 10 ml of diethylether was treated with hexafluoroacetylacetone (23 μl, 0.16 mmol) and stirred for 20 min at r.t. The solvent was evaporated in vacuo and the residue was dissolved in 4 ml of acetone. After the solution was slowly cooled at −78 °C, orange crystals precipitated which were separated from the mother liquor and washed twice with small amounts of pentane: yield 77 mg (76%), m.p. 88 °C (dec.). *Anal*. Calc. for $C_{23}H_{43}F_6O_2P_2Rh$: C, 43.82; H, 6.87; Rh, 16.32. Found: C, 43.55; H, 6.69; Rh, 15.31%. MS (70 eV): *m*/*z* 630 (M^+). IR (hexane): *ν*(CO) 1541, 1508 cm^{-1}. ^{1}H NMR (C_6D_6, 200 MHz): δ 6.27 [s, 1H, CHC(O)], 2.04 (m, 6H, PC*H*CH_3), 1.22 [dd, ^3J(PH) = 12.8, ^3J(HH) = 7.3, 36H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 100.6 MHz): δ 170.0 [q, ^2J(FC) = 33.2, CO], 119.8 [q, ^1J(FC) = 280.1, CF_3], 91.8 [s, *C*HC(O)], 24.6 (vt, *N* = 21.1 Hz, P*C*HCH_3), 20.3 (s, PCH*C*H_3). ^{19}F NMR (C_6D_6, 188.2 MHz): δ −75.3 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 55.7 [d, ^1J(RhP) = 191.8].

3.7. Preparation of [Rh(κ²-acac)($N_2CC_4Cl_4$)($PiPr_3$)] (**12**)

A solution of **5** (86 mg, 0.22 mmol) in 15 ml of pentane was treated at −78 °C with $N_2CC_4Cl_4$ (101 mg, 0.44 mmol). After the solution was slowly warmed to 0 °C, it was stirred for 10 min. The solvent was evaporated in vacuo, the greenish residue was washed three times with 10 ml portions of pentane (−78 °C) and dried: yield 87 mg (67%), m.p. 61 °C (dec.). *Anal*. Calc. for $C_{19}H_{28}Cl_4N_2O_2PRh$: C, 38.54; H, 4.77; N, 4.73. Found: C, 38.26; H, 4.75; N, 4.47%. IR (hexane): *ν*(N_2) 1958, *ν*(CO) 1579, 1510 cm^{-1}. ^{1}H NMR (C_6D_6, 200 MHz): δ 5.15 [s, 1H, CHC(O)], 2.55 (m, 3H, PC*H*CH_3), 1.92, 1.54 [both s, 3H each, $CH_3C(O)$], 1.20 [dd, ^3J(PH) = 14.2, ^3J(HH) = 7.2, 18H, PCHC*H*$_3$]. ^{13}C NMR ($C_6D_5CD_3$, 50.3 MHz, 233 K): δ 192.0, 182.5 (both s, CO), 109.8, 104.4 (both s, C_4Cl_4), 101.7 [s, *C*HC(O)], 81.7 (br s, N_2C), 27.9, 26.8 [both s, *C*$H_3C(O)$], 23.9 [d, ^1J(PC) = 24.6 Hz, P*C*HCH_3], 19.7 (s, PCH*C*H_3). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 64.0 [d, ^1J(RhP) = 164.7].

3.8. Preparation of [Rh(κ²-acac-f_3)($N_2CC_4Cl_4$)($PiPr_3$)] (*cis*- and *trans*-**13**)

This compound was prepared as described for **12**, with **6** (42 mg, 0.09 mmol) and $N_2CC_4Cl_4$ (43 mg, 0.19 mmol) in 5 ml of pentane as starting materials. Greenish solid; yield 48 mg (79%), m.p. 61 °C (dec.). *Anal*. Calc. for $C_{19}H_{25}Cl_4F_3N_2O_2PRh$: C, 35.32; H, 3.90; N, 4.34. Found: C, 35.25; H, 3.99; N, 4.19%. IR (diethylether):

$\nu(N_2)$ 1950 cm^{-1}. Spectroscopic data for *cis*-**13**: ^1H NMR ($C_6D_5CD_3$, 200 MHz): δ 5.79 [s, 1H, CHC(O)], 2.12 (m, 3H, PC*H*CH_3), 1.87 [s, 3H, $CH_3C(O)$], 1.15 [dd, $^3J(PH) = 14.2$, $^3J(HH) = 6.9$, 18H, PCHC*H*$_3$]. ^{13}C NMR ($C_6D_5CD_3$, 50.3 MHz, 223 K): δ 197.3 [s, $CH_3C(O)$], 162.8 [q, $^2J(FC) = 33.3$, $CF_3C(O)$], 118.1 [q, $^1J(FC) = 283.1$, CF_3], 110.4, 104.6 (both s, C_4Cl_4), 97.7 [s, *C*HC(O)], 84.6 (br s, N_2C), 28.8 [s, *C*$H_3C(O)$], 23.4 [d, $^1J(PC) = 25.0$ Hz, P*C*HCH$_3$], 19.6 (s, PCH*C*H$_3$). ^{31}P NMR ($C_6D_5CD_3$, 81.0 MHz): δ 66.6 [d, $^1J(RhP) = 164.3$]. Selected spectroscopic data for *trans*-**13**: ^1H NMR ($C_6D_5CD_3$, 200 MHz): δ 5.83 [s, 1H, CHC(O)]. ^{31}P NMR ($C_6D_5CD_3$, 81.0 MHz): δ 65.8 [d, $^1J(RhP) = 165.2$].

3.9. Preparation of [Rh(κ^2-acac-f_6)($N_2CC_4Cl_4$)(*PiPr*$_3$)] (**14**)

This compound was prepared as described for **12**, with **7** (144 mg, 0.29 mmol) and $N_2CC_4Cl_4$ (133 mg, 0.58 mmol) in 15 ml of pentane as starting materials. Greenish solid; yield 118 mg (58%), m.p. 67 °C (dec.). *Anal*. Calc. for $C_{19}H_{22}Cl_4F_6N_2O_2PRh$: C, 32.00; H, 3.17; N, 4.00. Found: C, 31.82; H, 3.06; N, 4.03%. MS (70 eV): *m*/*z* 700 (M^+). IR (KBr): $\nu(N_2)$ 1955 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 6.15 [s, 1H, CHC(O)], 1.77 (m, 3H, PC*H*CH_3), 0.91 [dd, $^3J(PH) = 14.7$, $^3J(HH) = 7.2$, 18H, PCHC*H*$_3$]. ^{13}C NMR ($C_6D_5CD_3$, 100.6 MHz, 223 K): δ 176.5 [q, $^2J(FC) = 35.2$, $CF_3C(O)$], 117.7 [q, $^1J(FC) = 273.6$, CF_3], 111.7, 105.5 (both s, C_4Cl_4), 91.7 [s, *C*HC(O)], 87.6 (br s, N_2C), 23.1 [d, $^1J(PC) = 25.7$, P*C*HCH$_3$], 19.0 (s, PCH*C*H$_3$). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 68.0 [d, $^1J(RhP) = 164.6$].

3.10. Preparation of [Rh(κ^2-OC_6Cl_5)(*PiPr*$_3$)$_2$] (**15**)

A solution of **8** (166 mg, 0.36 mmol) in 10 ml of toluene was treated with a solution of pentachlorophenol (95 mg, 0.36 mmol) in 5 ml of toluene and stirred for 30 min at r.t. The solvent was evaporated in vacuo and the residue was extracted with 20 ml of pentane. The extract was brought to dryness in vacuo and the residue was recrystallized from acetone at −78 °C to give a red microcrystalline solid: yield 179 mg (73%), m.p. 124 °C (dec.). *Anal*. Calc. for $C_{24}H_{42}Cl_5OP_2Rh$: C, 41.85; H, 6.15. 3.11. Preparation of trans-[Rh(κ^1-OC_6Cl_5)(C_2H_4)(*PiPr*$_3$)$_2$] (**16**)

A slow stream of ethene was passed for 1 min through a solution of **15** (98 mg, 0.14 mmol) in 5 ml of pentane at r.t. A change of colour from red to yellow occurred. After the solution was cooled at −78 °C, light yellow crystals precipitated which were separated from the mother liquor, washed twice with small amounts of pentane (−78 °C) and dried in a stream of argon: yield 72 mg (71%), m.p. 38 °C (dec.). *Anal*. Calc. for $C_{26}H_{46}Cl_5OP_2Rh$: C, 43.57; H, 6.47. Found: C, 43.46; H, 6.39%. ^1H NMR (C_6D_6, 200 MHz, 295 K): δ 2.34 (br s, 4H, C_2H_4), 1.71 (m, 6H, PC*H*CH_3), 1.07 [d, $^3J(HH) = 7.3$, 36H, PCHC*H*$_3$]. ^1H NMR ($C_6D_5CD_3$, 400 MHz, 223 K): δ 2.50 (br s, 4H, C_2H_4), 2.11 (br s, 6H, PC*H*CH_3), 1.25 (br s, 36H, PCHC*H*$_3$). ^{13}C NMR ($C_6D_5CD_3$, 100.6 MHz, 223 K): δ 160.4 (s, CO), 131.7, 123.2, 114.6 (all s, C_5Cl_5), 23.3 (vt, $N = 15.3$, P*C*HCH$_3$), 20.1 (s, PCH*C*H$_3$), signal for C_2H_4 not exactly located. ^{31}P NMR ($C_6D_5CD_3$, 162.0 MHz, 223 K): δ 24.9 [d, $^1J(RhP) = 125.0$]. Compound **16** had alternatively been prepared by storing the starting material **15** in a Schlenk tube under an atmosphere of ethene for 30 h at r.t.; the yield was quantitative.

3.12. Preparation of [Rh(κ^2-OC_6Cl_5)(O_2)(*PiPr*$_3$)$_2$] (**17**)

A slow stream of O_2 was passed for 1 min through a solution of **15** (72 mg, 0.10 mmol) in 6 ml of pentane at r.t. The solution was concentrated to ca. 3 ml in vacuo and then stored at −78 °C for 12 h. A dark brown microcrystalline solid precipitated which was separated from the mother liquor, washed twice with small amounts of pentane (−20 °C) and dried: yield 59 mg (82%), m.p. 48 °C (dec.). *Anal*. Calc. for $C_{24}H_{42}Cl_5O_3P_2Rh$: C, 40.00; H, 5.87. Found: C, 39.73; H, 6.02%. IR (CH_2Cl_2): $\nu(O_2)$ 890 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 2.50 (m, 6H, PC*H*CH_3), 1.21 [dvt, $N = 13.1$, $^3J(HH) = 7.3$, 18H, PCHC*H*$_3$], 1.13 [dvt, $N = 14.2$, $^3J(HH) = 6.9$, 18H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 162.9 (s, CO), 133.5, 131.7, 131.1, 128.3, 123.0 (all s, C_5Cl_5), 22.3 (vt, $N = 19.4$, P*C*HCH$_3$), 19.6, 19.3 (both s, PCH*C*H$_3$). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 32.9 [d, $^1J(RhP) = 98.8$]. Compound **16** had alternatively been prepared by storing the starting material **15** in a Schlenk tube under an atmosphere of oxygen for 1 h at r.t.; the yield was quantitative.

3.13. Preparation of trans-[Rh(κ^1-OC_6Cl_5)(N_2CPh_2)(*PiPr*$_3$)$_2$] (**18**)

A solution of **15** (76 mg, 0.11 mmol) in 10 ml of pentane was treated dropwise at −78 °C with a solution of

diphenyldiazomethane (22 mg, 0.11 mmol) in 2 ml of pentane. While the solution was warmed to r.t., a change of colour first from red to dark brown and then to green occurred. The solution was stirred for 5 min at r.t. and then concentrated to ca. 2 ml in vacuo. After it was stored at −78 °C for 12 h, dark green crystals precipitated which were separated from the mother liquor, washed twice with small amounts of pentane (−20 °C) and dried: yield 70 mg (72%), m.p. 43 °C (dec.). *Anal.* Calc. for $C_{37}H_{52}Cl_5N_2OP_2Rh$: C, 50.33; H, 5.94; N, 3.17. Found: C, 49.97; H, 5.90; N, 2.82.%. IR (hexane): $\nu(N_2)$ 2043 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 7.30 (m, 4H, C_6H_5), 7.14–6.97 (br m, 6H, C_6H_5), 1.97 (m, 6H, PC*H*CH_3), 1.18 [dvt, $N = 13.2$, $^3J(HH) = 6.2$, 36 H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 161.8 (s, CO), 139.8, 132.0, 130.2, 129.7, 129.1, 128.9, 126.7 (all s, C_6H_5 and C_5Cl_5), 87.1 (br s, N_2C), 23.3 (vt, $N = 17.6$, P*C*HCH$_3$), 19.4 (s, PCH*C*H$_3$). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 37.8 [d, $^1J(RhP) = 130.8$].

3.14. Catalytic reaction of ethene with diaryldiazomethanes with compound **15** as a catalyst

In an NMR tube, a slow stream of ethene was passed for 30 s through a solution of **15** (25 mg, 0.03 mmol) and N_2CR_2 (0.10 mmol) (R = Ph, *p*-C_6H_4Me, *p*-C_6H_4Cl) in 0.5 ml of C_6D_6 at r.t. After the solution was warmed to 40 °C, the formation of the olefins **1b** [26], **19** [27], **20** [28] was detected by ^1H NMR spectroscopy. After 30 min, the catalyst decomposed and no Rh-containing product could be characterized.

3.15. Preparation of *trans*-[Rh(κ^1-O_2CCH_3)(N_2C-C_4Cl_4)($PiPr_3$)$_2$] (**22**)

A solution of **21** (38 mg, 0.08 mmol) in 10 ml of pentane was treated at −78 °C with $N_2CC_4Cl_4$ (18 mg, 0.08 mmol). After the solution was slowly warmed to r.t., it was stirred for 10 min. The solvent was evaporated in vacuo and the greenish residue was recrystallized from pentane at −78 °C: yield 45 mg (80%), m.p. 85 °C (dec.). *Anal.* Calc. for $C_{25}H_{45}Cl_4N_2O_2P_2Rh$: C, 47.16; H, 6.37; N, 3.93. Found: C, 48.02; H, 6.67; N, 3.27%. IR (KBr): $\nu(N_2)$ 1930, $\nu(CO_2)$ 1625 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 2.00 (m, 6H, PC*H*CH_3), 1.73 (s, 3H, CH_3CO_2), 1.13 [dvt, $N = 13.9$, $^3J(HH) = 7.1$, 36H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 174.4 (s, CO_2), 102.0, 109.3 (both s, C_4Cl_4), 85.1 (br s, N_2C), 24.4 (vt, $N = 19.0$ Hz, P*C*HCH$_3$), 22.7 (s, *C*H_3CO_2), 19.7 (s, PCH*C*H$_3$). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 46.0 [d, $^1J(RhP) = 117.7$].

3.16. Generation of *trans*-[Rh(κ^1-O_2CCH_3)(N_2CPh_2)-($PiPr_3$)$_2$] (**23**)

A solution of **21** (80 mg, 0.18 mmol) in 30 ml of diethylether was treated at −30 °C with a solution of diphenyldiazomethane (71 mg, 0.36 mmol) in 4 ml of diethylether. A change of colour from red to green occurred. The solution was warmed to r.t., stirred for 10 min, and the solvent was evaporated in vacuo. The residue was dissolved in 10 ml of pentane and the solution was stored at −78 °C for 6 h. A greenish-brown solid precipitated which was separated from the mother liquor, washed with small amounts of pentane (0 °C) and dried. The NMR spectra revealed that a mixture of **21** and **23** in the ratio of 1:2 was isolated. Attempts to separate the two compounds by fractional crystallization or chromatographic techniques failed. If the reaction was repeated by using a 10-fold excess of N_2CPh_2, a mixture of **21** and **23** in the approximate ratio of 1:3 was isolated. Spectroscopic data for **23**: IR (KBr): (N_2) 1950, $\nu(CO_2)$ 1635, 1495 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 7.40–6.83 (br m, 10H, C_6H_5), 2.06 (m, 6H, PC*H*CH_3), 2.00 (s, 3H, CH_3CO_2), 1.28 [dvt, $N = 13.5$, $^3J(HH) = 6.6$, 36H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 174.1 (s, CO_2), 79.4 (br s, N_2C), 24.0 (vt, $N = 17.3$ Hz, P*C*HCH$_3$), 20.6 (s, *C*H_3CO_2), 20.0 (s, PCH*C*H$_3$), signals for phenyl protons were partly covered by the solvent signal. ^{31}P NMR (C_6D_6, 81.0 MHz): δ 42.5 [d, $^1J(RhP) = 130.8$].

3.17. Generation of *trans*-[Rh(κ^1-O_2CCH_3){$N_2C(Ph)$-$C(O)Ph$}($PiPr_3$)$_2$] (**24**)

The reaction of **21** (63 mg, 0.13 mmol) with $N_2C(Ph)C(O)Ph$ (29 mg, 0.13 mmol) in diethylether was carried out as described above with N_2CPh_2 as the substrate. No change of colour occurred. A red solid was isolated which, owing to the NMR spectra, consisted of a mixture of **21** and **24** in the ratio of 1:4. Attempts to separate the two compounds failed. Spectroscopic data for **24**: IR (KBr): $\nu(N_2)$ 1920 cm^{-1}. ^1H NMR (C_6D_6, 400 MHz): δ 7.96, 7.86 (both m, 2H each, C_6H_5), 7.20–6.77 (br m, 6H, C_6H_5), 2.43 (m, 6H, PC*H*CH_3), 1.67 (s, 3H, CH_3CO_2), 1.28, 1.27 [both dvt, $N = 13.4$, $^3J(HH) = 7.0$, 18H each, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 100.6 MHz): δ 181.4 (s, CO_2), 158.1 (s, C═O), 108.8 (br s, N_2C), 23.4 (vt, $N = 17.3$ Hz, P*C*HCH$_3$), 20.5 (s, *C*H_3CO_2), 19.9, 19.8 (both s, PCH*C*H$_3$), signals for phenyl protons were partly covered by the solvent signal. ^{31}P NMR (C_6D_6, 162.0 MHz): δ 29.9 [d, $^1J(RhP) = 113.4$].

3.18. Preparation of *trans*-[Rh(κ^1-O_2CCF_3)(N_2CPh_2)-($PiPr_3$)$_2$] (**26**)

A solution of **25** (44 mg, 0.08 mmol) in 10 ml of pentane was treated at −78 °C with a solution of diphenyldiazomethane (18 mg, 0.08 mmol) in 2 ml of pentane. A change of colour from red to green occurred. The solution was warmed to r.t., stirred for 10 min, and the solvent was evaporated in vacuo. The

residue was recrystallized from pentane at −78 °C to give a green microcrystalline solid. This was separated from the mother liquor, washed with small amounts of pentane (−20 °C) and dried: yield 44 mg (73%), m.p. 52 °C (dec.). *Anal*. Calc. for $C_{33}H_{52}F_3N_2O_2P_2Rh$: C, 54.25; H, 7.17; N, 3.83. Found: C, 53.94; H, 7.09; N, 3.50%. IR (KBr): $\nu(N_2)$ 1936, $\nu(CO_2)$ 1640 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 7.70–6.84 (br m, 10H, C_6H_5), 1.97 (m, 6H, PC*H*CH_3), 1.20 [dvt, $N = 13.5$, $^3J(HH) = 6.9$, 36H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 160.6 [q, $^2J(CF) = 35.6$, CO_2], 129.0, 128.8, 125.4, 125.1 (all s, C_6H_5), 120.4 [q, $^1J(CF) = 277.2$, CF_3], 81.0 (br s, N_2C), 23.7 (vt, $N = 17.6$, P*C*HCH$_3$), 19.8 (s, PCH*C*H$_3$). ^{19}F NMR (C_6D_6, 188.3 MHz): δ −74.6 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 42.2 [d, $^1J(RhP) = 126.4$].

3.19. Preparation of trans-[Rh(κ¹-O₂CCF₃)(N₂CC₄Cl₄)(PiPr₃)₂] (27)

This compound was prepared as described for **26**, with **25** (64 mg, 0.12 mmol) and $N_2CC_4Cl_4$ (27 mg, 0.12 mmol) as starting materials. Greenish microcrystalline solid; yield 83 mg (92%), m.p. 111 °C (dec.). *Anal*. Calc. for $C_{25}H_{42}Cl_4F_3N_2O_2P_2Rh$: C, 39.18; H, 5.52; N, 3.65. Found: C, 38.87; H, 5.36; N, 3.38%. IR (KBr): $\nu(N_2)$ 1940, $\nu(CO_2)$ 1700 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 1.93 (m, 6H, PC*H*CH_3), 1.10 [dvt, $N = 14.1$, $^3J(HH) = 7.1$, 36H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 159.6 [q, $^2J(FC) = 36.1$, CO_2], 119.5 [q, $^1J(FC) = 278.3$, CF_3], 110.2, 102.8 (both s, C_4Cl_4), 86.6 (br s, N_2C), 24.1 (vt, $N = 19.4$, P*C*HCH$_3$), 19.8 (s, PCH*C*H$_3$). ^{19}F NMR (C_6D_6, 188.3 MHz): δ −74.4 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 46.5 [d, $^1J(RhP) = 114.8$].

3.20. Preparation of trans-[Rh(κ¹-O₂CCF₃){N₂CH-C(O)Ph}(PiPr₃)₂] (28)

This compound was prepared as described for **26**, with **25** (54 mg, 0.10 mmol) and $N_2CC_4Cl_4$ (27 mg, 0.12 mmol) as starting materials. Yellow microcrystalline solid; yield 62 mg (90%), m.p. 56 °C (dec.). *Anal*. Calc. for $C_{28}H_{50}F_3N_2O_3P_2Rh$: C, 49.27; H, 7.09; N, 4.10. Found: C, 49.48; H, 7.31; N, 3.87%. IR (KBr): $\nu(N_2)$ 1940, ν (CO_2) 1685, ν(C═O) 1625 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 8.28–7.14 (br m, 5H, C_6H_5), 2.20 (m, 6H, PC*H*CH_3), 1.42 (s, 1H, N_2CH), 1.20 [dvt, $N = 14.6$, $^3J(HH) = 7.6$, 36 H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 163.2 [q, $^2J(FC) = 34.7$, CO_2], 150.1 (s, C═O), 136.1, 128.8, 128.1, 126.6 (all s, C_6H_5), 122.6 [q, $^1J(FC) = 287.8$, CF_3], 83.5 (br s, N_2C), 24.0 (vt, $N = 17.8$, P*C*HCH$_3$), 19.6, 19.4 (both s, PCH*C*H$_3$). ^{19}F NMR (C_6D_6, 188.3 MHz): δ −74.1 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 31.5 [d, $^1J(RhP) = 117.1$].

3.21. Preparation of trans-[Rh(κ¹-O₂CCF₃)(N₂)(PiPr₃)₂] (29)

A solution of **25** (59 mg, 0.12 mmol) in 5 ml of pentane was treated at −50 °C with a solution of phenyldiazomethane (13 mg, 0.12 mmol) in 1 ml of pentane. While the solution was warmed to r.t., a brown solid precipitated. The suspension was stirred for 5 min, concentrated to ca. 2 ml in vacuo and then stored for 6 h at −78 °C. A brown microcrystalline solid was obtained, which was separated from the mother liquor, washed with small amounts of pentane (−20 °C) and dried: yield 40 mg (59%), m.p. 91 °C (dec.). *Anal*. Calc. for $C_{20}H_{42}F_3N_2O_2P_2Rh$: C, 42.56; H, 7.50; N, 4.96. Found: C, 43.02; H, 7.21; N, 5.36%. IR (KBr): $\nu(N_2)$ 2098, $\nu(CO_2)$ 1650 cm^{-1}. ^1H NMR (C_6D_6, 200 MHz): δ 2.03 (m, 6H, PC*H*CH_3), 1.22 [dvt, $N = 13.5$, $^3J(HH) = 7.3$, 36 H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 50.3 MHz): δ 159.7 [q, $^2J(CF) = 35.7$, CO_2], 116.5 [q, $^1J(CF) = 255.1$, CF_3], 23.3 (vt, $N = 19.1$, P*C*HCH$_3$), 19.7 (s, PCH*C*H$_3$). ^{19}F NMR (C_6D_6, 188.3 MHz): δ −74.6 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 43.3 [d, $^1J(RhP) = 126.3$].

3.22. Preparation of trans,trans-[{Rh(κ¹-O₂CCF₃)(PiPr₃)₂}{μ-1.4-C₆H₄(C(Ph)N₂)₂}] (30)

A solution of **25** (74 mg, 0.14 mmol) in 5 ml of diethylether was treated dropwise at −78 °C with a solution of 1.4-$C_6H_4(C(Ph)N_2)_2$ (26 mg, 0.08 mmol) in 3 ml of diethylether. A change of colour from red to green occurred. The work-up procedure was the same as described for **26**. A dark green microcrystalline solid was obtained: yield 65 mg (68%), m.p. 46 °C (dec.). *Anal*. Calc. for $C_{60}H_{92}F_6N_4O_4P_4Rh_2$: C, 52.10; H, 7.14; N, 4.05. Found: C, 52.67; H, 7.41; N, 3.91%. IR (KBr): $\nu(N_2)$ 1930, $\nu(CO_2)$ 1630 cm^{-1}. ^1H NMR (C_6D_6, 400 MHz): δ 7.88–6.89 (br m, 14H, C_6H_4 and C_6H_5), 2.00 (m, 12H, PC*H*CH_3), 1.24 [dvt, $N = 13.6$, $^3J(HH) = 6.8$, 72 H, PCHC*H*$_3$]. ^{13}C NMR (C_6D_6, 100.6 MHz): δ 160.3 [q, $^2J(CF) = 35.1$, CO_2], 129.1, 127.9, 125.6, 125.5, 125.3, 124.5 (all s, C_6H_4 and C_6H_5), 122.4 [q, $^1J(CF) = 262.6$, CF_3], 81.2 (br s, N_2C), 23.8 (vt, $N = 17.5$, P*C*HCH$_3$), 19.9 (s, PCH*C*H$_3$). ^{19}F NMR (C_6D_6, 376.5 MHz): δ −74.8 (s). ^{31}P NMR (C_6D_6, 81.0 MHz): δ 42.21.9 [d, $^1J(RhP) = 126.3$].

3.23. Catalytic reaction of ethene with diaryldiazomethanes with compound 21 or 25 as a catalyst

In a typical experiment, a solution of the catalyst (20–30 mg, ca. 0.05 mmol) in 6 ml of toluene was treated dropwise (ca. 10 ml/h) at 40 °C with a 0.1 M solution of N_2CRR' in toluene. While adding the substrate, a slow stream of ethene was passed through the solution. The catalytic reaction was finished when the violet colour of the diazoalkane solution did not disappear on further

addition to the reaction mixture. The solvent was evaporated in vacuo and the oily residue was dissolved in 3 ml of hexane. In order to destroy the excess of N_2CRR' and separate the catalyst, the mixture was filtered through Al_2O_3 (neutral, activity grade III, height of column 4 cm). After removal of the solvent, a colorless oil was isolated from the eluate. The product was analyzed by GC–MS and the dominating olefin (see Table 1) characterized by ^1H NMR spectroscopy. The data for **1b** [26], **1c** [29], **19** [27], **20** [28] and **33** [30] were already reported. ^1H NMR data for N_2CRR' (C_6D_6, 200 MHz): **31**: δ 7.83, 7.77 [both d, $^3J(HH) = 8.2$, 2 H each, C_6H_4], 7.62–7.12 (br m, 5H, C_6H_5), 6.31 [ddd, $^3J(HH)_{trans} = 17.2$, $^3J(HH)_{cis} = 10.2$, $^3J(HH) = 7.3$, 1 H, C*H*=CH_2], 5.22 [ddd, $^3J(HH)_{cis} = 10.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.1$, 1 H, one H of =CH_2 *trans* to CH], 5.01 [ddd, $^3J(HH)_{trans} = 17.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.8$, 1 H, one H of =CH_2 *cis* to CH], 4.72 [br d, $^3J(HH) = 7.3$, 1H, C*H*RR′], 2.39 (s, 3H, $C_6H_4CH_3$). **32**: δ 7.31–6.82 (br m, 9H, C_6H_4 and C_6H_5), 6.18 [ddd, $^3J(HH)_{trans} = 16.8$, $^3J(HH)_{cis} = 10.2$, $^3J(HH) = 6.6$, 1H, C*H*=CH_2], 5.12 [ddd, $^3J(HH)_{cis} = 10.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.5$, 1H, one H of =CH_2 *trans* to CH], 4.81 [br d, $^3J(HH) = 6.6$, 1H, C*H*RR′], 4.75 [ddd, $^3J(HH)_{trans} = 17.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.8$, 1H, one H of =CH_2 *cis* to CH], 2.18 (s, 3H, $C_6H_4CH_3$). **34**: δ 7.28 [d, $^3J(HH) = 8.4$, 4H, C_6H_4], 7.02 [d, $^3J(HH) = 8.8$, 4H, C_6H_4], 6.44 [ddd, $^3J(HH)_{trans} = 17.2$, $^3J(HH)_{cis} = 10.2$, $^3J(HH) = 6.5$, 1H, C*H*=CH_2], 5.36 [br d, $^3J(HH)_{cis} = 10.2$, 1H, one H of =CH_2 *trans* to CH], 5.14 [ddd, $^3J(HH)_{trans} = 17.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.4$, 1H, one H of =CH_2 *cis* to CH], 4.82 [br d, $^3J(HH) = 7.3$, 1H, C*H*RR′], 2.94 (s, 3H, OCH_3). **35**: δ 7.90 [d, $^3J(HH) = 8.4$, 4H, C_6H_4], 7.40 (m, 4H, C_6H_4), 6.38 [ddd, $^3J(HH)_{trans} = 17.2$, $^3J(HH)_{cis} = 10.2$, $^3J(HH) = 6.9$, 1H, C*H*=CH_2], 5.42 [ddd, $^3J(HH)_{cis} = 10.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.2$, 1H, one H of =CH_2 *trans* to CH], 5.14 [ddd, $^3J(HH)_{trans} = 17.2$, $^2J(HH) = 1.5$, $^4J(HH) = 1.2$, 1H, one H of =CH_2 *cis* to CH], 4.85 [br d, $^3J(HH) = 7.3$, 1H, C*H*RR′].

Acknowledgements

Financial support from the Fonds der Chemischen Industrie and BASF AG, Ludwigshafen, is gratefully acknowledged. We also thank Mrs. R. Schedl and Mr. C.P. Kneis for elemental analyses and DTA measurements, Dr. G. Lange and Mr. F. Dadrich for the mass spectrum, and Dr. J. Wolf for valuable advice.

Dedicated to Prof. Malcolm Green FRS for his guidance and inspiration

Abstract

Cationic iridium(III) complexes of bifunctional $\eta^5,\kappa P$-Cp–P and trifunctional $\eta^5,\kappa P,\kappa L$-Cp–PL ligands may be conveniently prepared by intramolecular dehydrofluorinative carbon–carbon coupling. The iridium(III) complex $[(\eta^5\text{-}C_5Me_5)IrCl(dfppe)]BF_4$ (dfppe = $(C_6F_5)_2PCH_2CH_2P(C_6F_5)_2$) undergoes rapid dehydrofluorinative coupling on addition of proton sponge to produce $[\{\eta^5,\kappa P,\kappa P\text{-}C_5Me_3[CH_2C_6F_4\text{-}2\text{-}P(C_6F_5)CH_2]_2\text{-}1,3\}IrCl]BF_4$. The reaction requires less than the stoichiometric quantity of proton sponge and also occurs on addition of Bu^n_4NF. The cationic phosphine–thioether complex $[(\eta^5\text{-}C_5Me_5)IrCl\{\kappa P,\kappa S\text{-}(C_6F_5)_2PC_6H_4SMe\text{-}2\}]BF_4$ undergoes rapid dehydrofluorinative coupling to $[\{\eta^5,\kappa P,\kappa S\text{-}C_5Me_4CH_2C_6F_4\text{-}2\text{-}P(C_6F_5)C_6H_4SMe\text{-}2\}IrCl]BF_4$ on treatment with proton sponge. NMR studies indicate that on treatment with proton sponge the cations $[(\eta^5\text{-}C_5Me_5)IrCl(CNR)\{PPh_2(C_6F_5)\}]^+$ (R = Ph or ^{t}Bu) undergo coupling to give $[(\eta^5,\kappa P\text{-}C_5Me_4CH_2C_6F_4\text{-}2\text{-}PPh_2)IrCl(CNR)]^+$, but at a much slower rate and less cleanly than for the cations containing chelating ligands. The neutral compound $[(\eta^5\text{-}C_5Me_5)IrCl_2\{PPh_2(C_6F_5)\}]$ does not undergo coupling, indicating that a positive charge is necessary for the reaction. The results are analogous to those for rhodium complexes.

1. Introduction

Transition metal complexes of chelating bifunctional $\eta^5,\kappa P$-cyclopentadienyl–phosphine (Cp–P) or trifunctional $\eta^5,\kappa P,\kappa L$-cyclopentadienyl–phosphine-donor (Cp–PL) ligands can possess benefits over the analogous complexes of the unlinked ligands. Enhancement of stability [1–4], reactivity [5,6] and regio and stereo-selectivity in their reactions [7] has been reported, and configurational stability is expected for chiral-at-metal complexes of Cp–PL ligands [8]. Despite the benefits relatively few complexes of Cp–P ligands, and even fewer of Cp–PL ligands, have been reported, primarily due to the lack of convenient synthetic routes [9,10]. Nonetheless a number of rhodium complexes of Cp–P and Cp–PL ligands have been reported [4–6,9,11–14]. In contrast the number of complexes of iridium is limited to those of the Cp–P ligands **1** [15,16] and **2** [17], and **3** [18].

We have demonstrated that intramolecular dehydrofluorinative carbon–carbon coupling provides a convenient route to cationic rhodium complexes of Cp–P and Cp–PL ligands [12]. The coupling of the pentamethylcyclopentadienyl and fluorophenylphoshphines of cationic complexes of the formula $[(\eta^5\text{-}C_5Me_5)\ RhXL\{PR_2(C_6F_5)\}]^+$ (X = Cl or Br, L = 2-electron donor ligand) may be performed by addition of less than one equivalent of 1,8-bis(dimethylamino)naphthalene (proton sponge) or fluoride ions. The reaction is rapid and quantitative for complexes in which the phosphine is part of a chelating ligand, as in a diphosphine or a phosphine-thioether, but considerably slower for complexes of monodentate phosphines. Alternatively, for cations containing chelating phosphines, heating a solution of the salt in an appropriate solvent yields the coupled product, although not always cleanly [18,19]. The preparation of the complexes of trifunctional cyclopentadienyl–diphosphine ligands containing two linkages has also been accomplished by heating a slurry of a 2:1 mixture of the diphosphine and $[(\eta^5\text{-}C_5Me_5)RhCl(\mu\text{-}Cl)]_2$ in benzene or ethanol [18,20]. The last method has also been found to yield **3** from $[(\eta^5\text{-}C_5Me_5)IrCl(\mu\text{-}Cl)]_2$ and $(C_6F_5)_2PCH_2CH_2P(C_6F_5)_2$ (dfppe) [18]. A mechanism involving formation of an η^4-fulvene by loss of a proton from the pentamethylcyclopentadienyl ligand and intramolecular nucleophilic attack of the methylene carbon on an *ortho* C–F bond has been proposed for cationic rhodium(III) and cobalt(III) complexes [12,21]. The similarity of the chemistry of analogous rhodium(III) and iridium(III) pentamethylcyclopentadienyl complexes suggests that intramolecular dehydrofluorinative carbon–carbon coupling would also provide a convenient route to Cp–P and Cp–PL complexes of iridium. In support η^4-fulvene complexes of iridium have been proposed as nucleophilic intermediates in a number of reactions [22–26] and $[(\eta^4\text{-}C_5Me_4CH_2)IrMe(dppe)]$ has been structurally characterized [27]. However, some differences in reactivity between analogous complexes of iridium and rhodium have been observed. One apposite example is provided by the reactions between $[(\eta^5\text{-}C_5Me_5)MCl(\mu\text{-}Cl)]_2$ and $(C_6H_3\ F_2\text{-}2,6)_2PCH_2CH_2P(C_6H_3F_2\text{-}2,6)$, which yielded the coupled product **4** and the uncoupled bimetallic compound **5** [19]. Therefore, we set out to examine whether the coupling reactions that occur for the cationic rhodium complexes also occur for the analogous complexes of iridium. Here, the results of our study are reported.

2. Experimental

2.1. Physical measurements

The ^1H, ^{19}F and ^{31}P NMR spectra were recorded using a Bruker DPX300 spectrometer. ^1H (300.01 MHz) were referenced internally using the residual protio solvent resonance relative to $SiMe_4$ (δ 0), ^{19}F (282.26 MHz) externally to $CFCl_3$ (δ 0) and ^{31}P (121.45 MHz) externally to 85% H_3PO_4 (δ 0). All spectra were recorded in $CDCl_3$ at 300 K. Data are given as chemical shifts (δ) using the high frequency positive convention, [relative intensity, multiplicity, *J*/Hz, assignment], s, singlet; d, doublet; t, triplet; m, multiplet; br, broad. The IR spectra were recorded on a Perkin–Elmer RX I Fourier transform spectrometer. Mass spectra were recorded on a VG Autospec X series mass spectrometer. Elemental analyses were carried out by A.S.E.P., The School of Chemistry, Queen's University Belfast.

2.2. Materials

The compounds $[(\eta^5\text{-}C_5Me_5)IrCl(\mu\text{-}Cl)]_2$, sodium tetrafluoroborate and proton sponge (Aldrich) were used as supplied. The salt $[(\eta^5\text{-}C_5Me_5)IrCl(dfppe)]BF_4$ [18] and phenylisonitrile [28] were prepared as described. The phosphines $P(C_6F_5)_3$ and $PPh_2(C_6F_5)$ [29] were prepared from PCl_3 and Ph_2PCl as described for similar compounds [30].

2.3. $(C_6F_5)_2PC_6H_4SMe$-2 (**6**)

A solution of Bu^nLi in hexane (3.0 cm^3, 1.6 M) was added to $MeSC_6H_4Br$-2 (1.10 g, 5.4 mmol) in diethyl ether at 0 °C. After stirring for 1 h the solution was added over 10 min to $P(C_6F_5)_3$ (3.12 g, 5.8 mmol) in diethyl ether (100 cm^3) at 0 °C to give a black solution. After stirring for a further 5 min water (100 cm^3) was added. The organic layer was washed with water (100 cm^3). The aqueous layer and washings were extracted with 1:2 ethyl acetate/chloroform (200 cm^3). The combined organic extracts were dried over magnesium sulfate. Filtration and removal of the solvent by rotary evaporation yielded a brown oil comprising $P(C_6F_5)_3$, (**6**) and $(C_6F_5)P(C_6H_4SMe\text{-}2)_2$. Compound **6** was obtained by distillation by kugelrohr at 130–140 °C and 0.03 mm Hg. Yield 0.120 g (4.2%).

2.4. $[(\eta^5\text{-}C_5Me_5)IrCl\{\kappa P,\ \kappa S\text{-}(C_6F_5)_2PC_6H_4SMe\text{-}2\}]BF_4$ (**7**)

Sodium tetrafluoroborate (0.164 g, 1.5 mmol) was added to $[(\eta^5\text{-}C_5Me_5)IrCl(\mu\text{-}Cl)]_2$ (0.175 g, 0.22 mmol) and **6** (0.216 g, 0.44 mmol) in dichloromethane (30 cm^3) and methanol (30 cm^3), and the mixture stirred for 90 min. The solvent was removed by rotary evaporation

and the product extracted into dichloromethane. The extract was filtered and the solvent removed by rotary evaporation to give the product as a yellow solid. Yield 0.351 g (87%). *Anal.* Calc. for $C_{29}H_{22}BClF_{14}PIrS$ (**7**): C, 37.0; H, 2.4. Found: C, 36.9; H, 2.2%. ^{1}H NMR: δ 8.55 (1H, m, C_6H_4), 8.10 (2H, m, C_6H_4), 7.98 (1H, m, C_6H_4), 3.14 (3H, s, SMe), 1.78 (15H, s, Me). ^{19}F NMR: −122.50 (1F, br s, F_o), −127.32 (1F, br s, F_o), −127.55 (1F, br s, F_o), −131.76 (1F, br s, F_o), −141.99 (1F, br s, F_p), −144.65 (1F, br s, F_p), −153.59 (0.8F, s, $^{10}BF_4^-$), −153.64 (3.2F, s, $^{11}BF_4^-$), −155.14 (1F, br s, F_m), −157.24 (1F, br s, F_m), −158.41 (1F, br s, F_m), −160.61 (1F, br s, F_m). $^{31}P\{^1H\}$ NMR: 5.4 (s).

2.5. [{η^5,κP,κS-$C_5Me_4CH_2C_6F_4$-2-P(C_6F_5)C_6H_4SMe-2}IrCl]BF_4 (**8**)

Proton sponge (0.041 g, 0.19 mmol) was added to **7** (0.129 g, 0.14 mmol) in dichloromethane (40 cm^3) and the solution left at ambient temperature for 48 h. The solution was washed with water (50 cm^3), dilute hydrochloric acid (50 cm^3) and water (50 cm^3), and dried over magnesium sulfate. Filtration and removal of the solvent by rotary evaporation gave the product as a yellow solid, which was dried in vacuo. Yield 0.084 g (66.5%). *Anal.* Calc. for $C_{29}H_{21}BClF_{13}PIrS$ (**8**): C, 37.9; H, 2.3. Found: C, 40.05; H, 2.6%. Repeated washing and drying in vacuo failed to give satisfactory analysis ($N < 0.1$%). LSIMS: 831 ($[M-BF_4]^+$) [Found: 831.02980 $C_{29}H_{21}ClF_9^{193}IrPS$ requires 831.02759]. ^{1}H NMR: δ 8.14 (1H, m, C_6H_4), 7.97 (1H, m, C_6H_4), 7.74 (1H, m, C_6H_4), 7.66 (1H, m, C_6H_4), 4.58 [1H, dd, ^2J(HH) 17.9, ^4J(PH) 7.6, CH_2], 3.05 [1H, d, ^2J(HH) 17.9, CH_2], 2.65 (3H, s, SMe), 2.34 [3H, d, ^4J(PH) 6.5, CH_3], 1.87 [3H, d, ^4J(PH) 2.2, CH_3], 1.82 [3H, d, ^4J(PH) 2.9, CH_3], 1.69 (3H, s, CH_3). ^{19}F NMR: δ −119.47 (1F, m), −128.81 (1F, m), −133.22 (1F, m), −133.52 (1F, m), −142.81 (1F, m), −146.05 [1F, t ^3J(FF) 20.7], 151.97 [1F, t ^3J(FF) 22.0, F_p], −153.77 (0.8F, s, $^{10}BF_4^-$), −153.83 (3.2F, s, $^{11}BF_4^-$), −158.85 (2H, m). $^{31}P\{^1H\}$ NMR: δ 31.9 (s).

2.6. [(η^5-C_5Me_5)$IrCl_2${PPh_2(C_6F_5)}] (**9**)

A mixture of [(η^5-C_5Me_5)IrCl(μ-Cl)]$_2$ (0.112 g, 0.14 mmol) and $Ph_2P(C_6F_5)$ (0.099 g, 0.28 mmol) in dichloromethane/methanol (50 cm^3) was left at ambient temperature for 2 h. The solvent was removed by rotary evaporation affording the product as an orange solid, which was recrystallized from dichloromethane. Yield 0.160 g (76.1%). *Anal.* Calc. for $C_{28}H_{27}Cl_2F_5PIr$ (**9**): C, 44.8; H, 3.4. Found: C, 44.5; H, 3.1%. ^{1}H NMR: δ 7.81 (4H, m, C_6H_5), 7.41 (6H, m, C_6H_5), 1.44 [15H, d, ^4J(PH) 2.5, Me]. ^{19}F NMR: δ −120.06 (2F, m, F_o), −148.52 [1F, t, $^3J(F_mF_p)$ 19.8, F_p], −160.22 (2F, m, F_m). $^{31}P\{^1H\}$ NMR: −1.7 (s).

2.7. [(η^5-C_5Me_5)IrCl(CNPh){PPh_2(C_6F_5)}]BF_4 (**10a**)

Sodium tetrafluoroborate (0.110 g, 1.00 mmol) in methanol (30 cm^3) was added to **9** (0.100 g, 0.13 mmol) and phenylisonitrile (0.108 g, 1.05 mmol) in dichloromethane/methanol (30 cm^3), and the mixture stirred for 2 h. The solvent was removed by rotary evaporation and the product extracted into dichloromethane. Concentration by rotary evaporation and addition of hexane precipitated the product as a yellow solid. Yield 0.070 g (59.1%). *Anal.* Calc. for $C_{35}H_{30}BClF_9IrNP.0.5CH_2Cl_2$ (**10a**): C, 44.7; H, 3.9; N, 1.5. Found: C, 45.15; H, 3.15; N, 1.75%. ν(N≡C) 2181 cm^{-1}. ^{1}H NMR: δ 7.85 (2H, m), 7.33 – 7.54 (11H, m), 6.86 (2H, m), 5.30 (1H, s, CH_2Cl_2), 1.80 [15H, d, ^4J(PH) 2.7, Me]. ^{19}F NMR: δ −124.67 (2F, m, F_o), −143.55 (1H, br s, F_p), −153.68 (0.8F, s, $^{10}BF_4^-$), −153.74 (3.2F, s, $^{11}BF_4^-$), −156.93 (2F, br s, F_m). $^{31}P\{^1H\}$ NMR: δ 9.4 (s).

2.8. [(η^5-C_5Me_5)IrCl($CNBu^t$){PPh_2(C_6F_5)}]BF_4 (**10b**)

Compound **9** (0.060 g, 0.08 mmol), ^{t}butylisonitrile (0.009 cm^3, 0.08 mmol) and sodium tetrafluoroborate (0.109 g, 1.00 mmol) were treated as for **10a**. Yield 0.045 g (63.6%). *Anal.* Calc. for $C_{33}H_{34}BClF_9IrNP$ (**10b**): C, 44.8; H, 3.9; N, 1.6. Found: C, 44.5; H, 3.9; N, 1.75%. LSIMS: 798 ($[M-BF_4]^+$), 763 ($[M-BF_4-Cl]^+$) [Found: 798.16367 $C_{33}H_{34}BClF_9^{193}IrNP$ requires 798.16670]. ν(N≡C) 2199 cm^{-1}. ^{1}H NMR: δ 7.79 (2H, m), 7.37 −7.63 (8H, m), 1.72 [15H, d, ^4J(PH) 2.6, Me], 1.29 (9H, s, ^{t}Bu). ^{19}F NMR: δ −124.71 (2F, m, F_o), −144.04 (1H, br s, F_p), −153.87 (0.8F, s, $^{10}BF_4^-$), −153.96 (3.2F, s, $^{11}BF_4^-$), −157.22 (2F, br s, F_m). $^{31}P\{^1H\}$ NMR: δ −9.0 (s).

2.9. [(η^5,κP-$C_5Me_4CH_2C_6F_4$-2-PPh_2)IrCl(CNPh)]BF_4 (**11a**)

Proton sponge (0.005 g, 0.023 mmol) was added to **10a** (0.057 g, 0.063 mmol) in dichloromethane (15 cm^3). After 7 days dichloromethane (85 cm^3) was added and the solution washed with water (3 × 50 cm^3) and dried over magnesium sulfate. Filtration and removal of the solvent by rotary evaporation gave an oily brown solid, which was washed with diethyl ether (10 cm^3) and dried in vacuo. Yield 0.045 g (80.7%). *Anal.* Calc. for $C_{35}H_{29}BClF_8IrNP$ (**11a**): C, 47.5; H, 3.3; N, 1.6. Found: C, 49.4; H, 3.9; N, 1.9%. Repeated washing and drying in vacuo failed to give satisfactory analysis. LSIMS: 798 ($[M-BF_4]^+$), 763 ($[M-BF_4-Cl]^+$) [Found: 798.12522 $C_{35}H_{29}ClF_4^{193}$ IrNP requires 798.12917]. ν(N≡C) 2180 cm^{-1}. ^{1}H NMR: δ 7.05–7.82 (15H, m, C_6H_5), 3.85 [1H, dd, ^2J(HH) 16.9, ^4J(PH) 4.8, CH_2], 3.64 [1H, dd, ^2J(HH) 16.9, ^4J(PH) 4.8, CH_2], 2.30 [3H, d, ^4J(PH) 4.0, CH_3], 1.90 [3H, d, ^4J(PH) 4.3, CH_3], 1.73 [3H, d, ^4J(PH) 4.4, CH_3], 1.51

(3H, s, CH_3). ^{19}F NMR: δ −118.64 (1F, m), −136.29 (1F, m), −145.78 (1F, m), −152.30 (1F, m), −153.05 (0.8F, s, $^{10}BF_4^-$), −153.11 (3.2F, s, $^{11}BF_4^-$). $^{31}P\{^1H\}$ NMR: δ 5.6 (s).

2.10. *[(η^5,κP-$C_5Me_4CH_2C_6F_4$-2-PPh_2)IrCl(CNBu^t)]BF_4 (**11b**)*

A sample was obtained from the reaction between **10b** and proton sponge in an NMR tube. There was insufficient sample for elemental analysis. LSIMS: 778 ($[M-BF_4]^+$), 743 ($[M-BF_4-Cl]^+$) [Found: 778.16394 $C_{33}H_{33}ClF_4^{193}IrNP$ requires 778.160471]. ν(N≡C) 2197 cm^{-1}. ^{19}F NMR: δ −120.71 (1F, m), −136.76 (1F, m), −146.35 (1F, m), −152.45 (1F, m), −153.20 (0.8F, s, $^{10}BF_4^-$), 153.25 (3.2F, s, $^{11}BF_4^-$). $^{31}P\{^1H\}$ NMR: δ 5.1 (s). Important ^1H NMR resonances are given in Section 3 (vide infra).

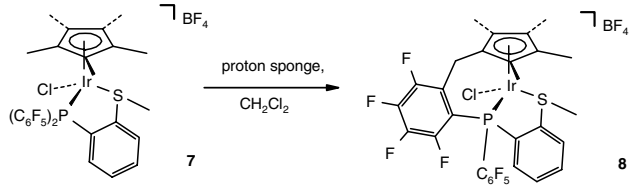
3. Results and discussion

An in situ NMR experiment in $CDCl_3$ revealed that the salt [($\eta^5C_5Me_5$)IrCl(dfppe)]BF_4 underwent rapid intramolecular dehydrofluorinative carbon–carbon coupling in the presence of less than one equivalent of proton sponge to give **3** [18]. As for the rhodium analogue, the fluoride generated as the by-product acted as a base. An in situ NMR experiment confirmed that the coupling occurred rapidly on addition of tetrabutylammonium fluoride to [(η^5-C_5Me_5)IrCl(dfppe)]BF_4 in acetone. In contrast [(η^5-C_5Me_5)IrCl{κP,κP-[($C_6H_3F_2$-2,6)$_2PCH_2$]$_2$}]BF_4 [20] did not undergo any reaction in the presence of proton sponge in $CDCl_3$ at ambient temperature over 24 h. This observation is consistent with the lack of a coupling reaction of this salt in refluxing ethanol and also when [(η^5-C_5Me_5)IrCl(μ-Cl)]$_2$ and ($C_6H_3F_2$-2,6)$_2PCH_2CH_2P$($C_6H_3F_2$-2,6) are heated in benzene. The rhodium analogue [(η^5-C_5Me_5)RhCl{κP,κP-[($C_6H_3F_2$-2,6)$_2PCH_2$]$_2$}]BF_4 also did not undergo a reaction with proton sponge. This salt also underwent no reaction in refluxing ethanol, but dehydrofluorinative carbon–carbon coupling was observed in the reaction between [(η^5-C_5Me_5)RhCl(μ-Cl)]$_2$ and ($C_6H_3F_2$-2,6)$_2PCH_2CH_2P$($C_6H_3F_2$-2,6) in benzene [20].

We wished to attempt the coupling reaction with an iridium complex of the phosphine-thioether (C_6F_5)$_2$ PC_6H_4SMe-2, (**6**), which possesses only one phosphine functionality. Compound **6** has been prepared by the reaction between $MeSC_6H_4Li$ and (C_6F_5)$_2PBr$ [12], but following the observation that when a mixture of (C_6F_5)PPhCl and (C_6F_5)PPhBr was treated with an excess of $MeSC_6H_4Li$-2 the phosphine $PhP(C_6H_4SMe2)_2$ was formed, consistent with previous reports of P–C_6F_5 bond cleavage by Grignard reagents [31], it was decided to investigate whether **6** could be prepared from $P(C_6F_5)_3$. Addition of one equivalent of $MeSC_6H_4Li$-2 to $P(C_6F_5)_3$ in diethyl ether at 0 °C gave a black solution, consistent with the formation of C_6F_5Li. Following hydrolysis a brown oil was isolated which was shown by NMR spectroscopy to contain $P(C_6F_5)_3$, (**6**) and $(C_6F_5)P(C_6H_4SMe\text{-}2)_2$ in roughly equal amounts. Although the result confirms that the P–C_6F_5 bond can be readily cleaved by organolithium reagents, the reaction is not selective. Further, separating these phosphines proved difficult, although slightly impure **6** was obtained in ca. 4% yield by distillation by kugelrohr at 130–140 °C and 0.03 mm Hg. Thus this method of preparing **6** is inferior to that we have reported previously [12].

Treatment of [(η^5-C_5Me_5)IrCl(μ-Cl)]$_2$ with **6** in the presence of an excess of sodium tetrafluoroborate yielded the salt [(η^5-C_5Me_5)IrCl{κP,κS-(C_6F_5)$_2PC_6H_4SMe$-2}]BF_4, **7**. The ^1H and ^{19}F NMR spectra of **7** are similar to those of the rhodium analogue [11,12]. The ^{19}F NMR spectrum exhibits 10 resonances in addition to those of tetrafluoroborate. Each fluorine atom of the cation is unique due to hindered rotation about the P–C_6F_5 bonds. The $^{31}P\{^1H\}$ spectrum exhibits a singlet at δ 5.4, which is to a lower frequency of the doublet resonance of the rhodium analogue (δ 30.2). This difference is consistent with differences observed between rhodium and iridium analogues of similar compounds [18,20]. There are two stereogenic centres in the cation: the iridium and sulfur atoms. However only one set of resonances is seen in the NMR spectra, in particular there is only one thiomethyl hydrogen resonance, at δ 3.14, strongly suggesting that only one pair of enantiomers are present in solution. It is expected that the $R_{Ir}R_S$ and $S_{Ir}S_S$ pair, in which the methyl group is *trans* to the pentamethylcyclopentadienyl ligand would be the thermodynamically and kinetically preferred products for steric reasons. It is not known whether the exclusive existence of one pair of enantiomers is as a result of kinetics of coordination of the thioether or whether the other stereoisomers are formed and isomerize rapidly. This process can occur by dissociation and re-coordination of the labile thioether or by inversion at coordinated sulfur, which is presumed to have a low activation barrier. In support of the latter, the pyramidal inversion at the sulfur of $PPh(C_6H_4SMe\text{-}2)_2$, κP,κS-coordinated to palladium, has a free energy of activation, $\Delta G^{\ddagger}$, of 40–60 kJ mol^{-1} [32].

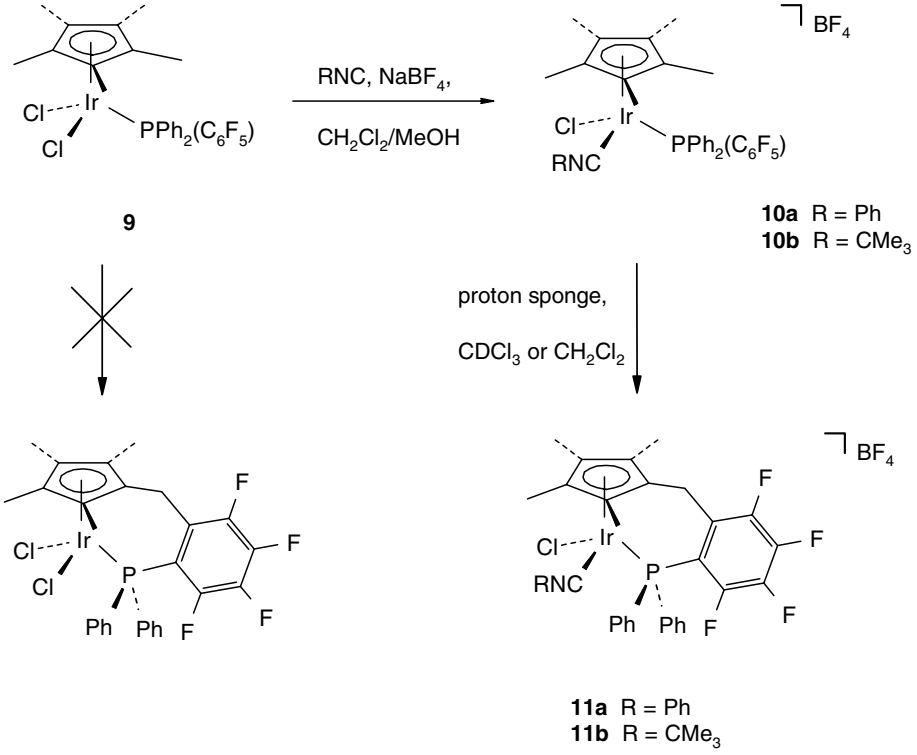
An in situ NMR spectroscopic study revealed that on treatment with proton sponge **7** underwent rapid intramolecular dehydrofluorinative coupling to give salt **8** (Scheme 1), which was isolated in 67% yield from a preparative scale reaction. The ^1H and ^{19}F NMR spectra of **8** are similar to those of the rhodium analogue [11,12] and the $^{31}P\{^1H\}$ spectrum exhibits a singlet at δ 31.9. The shift of the phosphorus resonance to higher frequency on coupling of the phosphine to the pen-



Scheme 1.

tamethylcyclopentadienyl ligand is consistent with previous observations [12,18,20]. The ^{1}H spectroscopic studies show NOE correlation between the thiomethyl hydogen atoms and one aromatic hydrogen, but not between the thiomethyl and pentamethylcyclopentadienyl hydrogen atoms, suggesting that the thiomethyl group is *trans* to the cyclopentadienyl ring, as for the rhodium analogue [11,12]. The cation of **8** contains three stereogenic centres: the iridium, sulfur and phosphorus atoms. In rhodium complexes of Cp–PL ligands the configurations at the metal and phosphorus are fixed relative to each other by the ligand's geometry such that the non-ligating substituent of the phosphine and the halide are on the same side of the plane defined by the metal and phosphorus atoms and the cyclopentadienyl centroid [12]. Presumably the same argument is valid for **8**. This, together with the exclusively *trans* disposition of the thiomethyl and pentamethylcyclopentadienyl groups, leads to the existence of only the $R_{Ir}R_{S}S_{P}$ and $S_{Ir}S_{S}R_{P}$ pair of enantiomers.

Treatment of $[(\eta^5\text{-}C_5Me_5)IrCl(\mu\text{-}Cl)]_2$ with $PPh_2(C_6F_5)$ yielded the neutral complex $[(\eta^5\text{-}C_5Me_5)IrCl_2\{PPh_2(C_6F_5)\}]$ (**9**). Consistent with the rhodium analogue, compound **9** underwent no reaction with proton sponge. The cationic iridium complexes $[(\eta^5\text{-}C_5Me_5)IrCl(CNR)\{PPh_2(C_6F_5)\}]BF_4$ (**10a** R = phenyl; **10b** R = *t*-butyl) were prepared by treatment of **9** with the appropriate isonitrile in the presence of an excess of sodium tetrafluoroborate (Scheme 2). The ^{1}H and ^{19}F NMR spectra of **10a** are similar to those of the rhodium analogue [12] and the $^{31}P\{^{1}H\}$ NMR spectrum exhibits a singlet at δ −9.1. The ^{19}F and $^{31}P\{^{1}H\}$ NMR spectral properties of **10b** are similar to those of **10a**. In situ NMR studies indicate **10a** and **10b** undergo slow reactions in the presence of proton sponge. The NMR data are fully consistent with intramolecular dehydrofluorinative coupling to give **11a** and **11b**. In particular, the ^{19}F NMR spectra show four resonances in addition to those of tetrafluoroborate with values of δ similar to those of the rhodium analogue (−119.22, −136.07, −145.54 and −152.01 [12]). Both $^{31}P\{^{1}H\}$ NMR spectra exhibit a singlet resonance at ca. δ 5. The shift of ca. 15 ppm to higher frequency on coupling is similar to that of 18.3 ppm observed in the rhodium analogue of **11a** [12]. The ^{1}H NMR spectrum of **11a** exhibits the two expected methylene resonances at δ 3.85 (dd) and 3.64 (dd), and four methyl resonances at δ 2.30 (d), 1.90 (d), 1.73 (d) and 1.51 (s), which are at similar chemical shifts to those of the rhodium analogue (δ 2.08, 1.82, 1.71 and 1.52).



Scheme 2.

Although methylene resonances at δ 3.75 (m) and 3.46 (m), and two methyl resonances at δ 2.18 (d) and 1.85 (d) are evident in the ^{1}H NMR spectrum of **11b**, the other resonances are obscured by other products and the proton sponge resonances. The reaction of **10a** is reasonably clean, but that of **10b** is not and **11b** is produced in ca. 50% yield. The identities of **11a** and **11b** were confirmed by mass spectrometry. The values of ν(N≡C) for **11a** and **11b** were identical within experimental error to those of **10a** and **10b** respectively. The coupling reaction of **10a** was also performed on a preparative scale giving **11a** as a yellow–brown solid in 81% yield.

4. Conclusion

The intramolecular dehydrofluorinative coupling of pentamethylcyclopentadienyl and pentafluorophenylphosphine ligands can be accomplished in cationic iridium complexes by treatment with less than one equivalent of proton sponge. The fluoride generated as the byproduct is sufficient to facilitate the reaction. The reaction occurs slowly for complexes of monophosphines to give bifunctional η^5,κP-Cp–P ligands, but is more successful for complexes of chelating phosphine ligands, which give trifunctional η^5,κP,κL-Cp–PL ligands rapidly. The reported reactions are identical to those of the rhodium analogues.

Abstract

The formation of products derived from competing reactions in Rh-catalyzed alkene hydroborations prompted us to study in situ interactions of several hydroborating reagents with unsaturated phosphinorhodium complexes. The reaction of $[Rh(\mu\text{-}H)(DiPPE)]_2$ (**1**) with borane–dimethylsulfide gave several rhodium–boron containing products including the structurally characterized metallaborane $[RhH(DiPPE)]_2B_3H_7$ (**2**) [DiPPE = 1,2-bis(diisopropylphosphino)ethane]. Addition of thexylborane and 9-H-BBN dimers, containing alkyl groups, to **1** gave the corresponding mononuclear substituted borohydride complexes $Rh(\eta^2\text{-}H_2BRR')(DiPPE)$ (**4**: R = H, R′ = $C(CH_3)_2CH(CH_3)_2$; **5**: R,R′ = bicyclo-[3.3.1]-nonane [C_8H_{14}]). The analogous monodentate phosphine complex $Rh(\eta^2\text{-}H_2BC_8H_{14})(PPr^i_3)_2$ (**6**) was isolated and structurally characterized. Addition of catecholborane (HBcat; cat = 1,2-$O_2C_6H_4$) to **1** gave the unusual dinuclear species $Rh(DiPPE)(\mu\text{-}H)_2(\mu\text{-}Bcat)RhH(DiPPE)$ (**7**) containing a semi-bridging Bcat group, confirmed by single-crystal X-ray diffraction, and zwitterionic $Rh(\eta^6\text{-}catBcat)(DiPPE)$ (**8**). Implications for rhodium-catalyzed hydroborations are addressed.

1. Introduction

Metal-catalyzed hydroboration of alkenes using dialkoxyboranes, such as catecholborane, HBcat (cat = 1,2-$O_2C_6H_4$), has recently found utility in organic synthesis [1–3]. Organolanthanide-catalyzed alkene hydroborations have been proposed to proceed via a

'σ-bond metathesis' pathway involving a four-centered transition state between the M–C and B–H bonds [4]. Theoretical calculations suggest that the rate determining step is elimination of the alkylboronate ester product from the metal center to regenerate the metal hydride catalyst [5]. While similar reactions using early transition metal catalysts [6–11] may also proceed by this mechanism, Muhoro and Hartwig [11] have suggested that titanocene-catalyzed alkene hydroborations may employ a catecholborane 'σ complex' as the species that initially interacts with the alkene substrate. The vast majority of metal-catalyzed hydroborations, however, employ late transition metals such as rhodium and have been postulated to proceed via initial oxidative addition of HBcat to the metal center [12] with subsequent insertion of an alkene into either the Rh–H [13,14] or Rh–B bond [15–19]. Reductive elimination of the B–C or C–H bond then affords the alkylboronate ester, whereas β-hydrogen elimination from the Rh–B insertion product can give a vinylboronate ester and a rhodium dihydride which may subsequently afford the alkane. Initial theoretical studies of rhodium phosphine complex-catalyzed alkene hydroboration examined two pathways based on B–H oxidative addition, but the details for the insertion step are incomplete [20] as the two studies employed different boranes [BH_3 versus $HB(OH)_2$] and catalysts [$RhCl(PH_3)$ versus $RhCl(PH_3)_2$] [14,17]. A more recent study showed that both associative and dissociative reaction pathways are energetically accessible and that the associative pathway shows little preference for insertion into the M–H versus the M–B bond [21]. Further theoretical studies are therefore needed to address both the origins of regioselection and the *cis*-bis(phosphine)rhodium model catalyst, as related precursors often generate the most active and selective catalysts for alkene hydroborations. To gain additional insight into the role played by the metal in these transformations, we have examined the stoichiometric reactivity of several common hydroborating agents with bis(phosphine)rhodium hydride complexes and present our findings herein.

2. Experimental

2.1. General procedures

NMR spectra were recorded on General Electric QM-300 (^{1}H at 300 MHz, ^{13}C at 75.4 MHz, ^{31}P at 121 MHz) and Nicolet NMC-300 (^{11}B at 96 MHz) spectrometers in toluene-d_8 unless stated otherwise. ^{1}H NMR chemical shifts are reported in ppm relative to external TMS and were referenced to residual protons in toluene-d_8; coupling constants are in Hz. Multiplicities are reported as (s) singlet, (d) doublet, (t) triplet, (q) quartet, (sext) sextet, (m) multiplet, (br) broad and (ov) overlapping. ^{11}B and ^{31}P chemical shifts are reported in ppm relative to external standards $F_3B\cdot OEt_2$ and 85% H_3PO_4, respectively. THF and toluene were freshly distilled from sodium benzophenone ketyl. Catecholborane (Aldrich Chemical Co.) was distilled under reduced pressure. 1,2-Bis(diisopropylphosphino)ethane (DiPPE) [22] was prepared via literature methods. Reagent purity was ascertained by ^{1}H NMR spectroscopy. $[Rh(\mu\text{-}H)(DiPPE)]_2$ (**1**) [23] and $RhH(N_2)(PPr^i_3)_2$ [24] were prepared by established methods.

2.2. Synthesis

2.2.1. Reaction of $[Rh(\mu\text{-}H)(DiPPE)]_2$ (1) with $H_3B\cdot SMe_2$

To a solution of 73 mg (0.1 mmol) $[Rh(\mu\text{-}H)(DiPPE)]_2$ (**1**) in 1 ml of THF-d_8 in a 5 mm NMR tube was added dropwise 15 mg (0.2 mmol) of $BH_3\cdot SMe_2$. Analysis of the solution by multinuclear NMR spectroscopy indicated a mixture of complexes. Subsequent addition of two 7 mg portions of $BH_3\cdot SMe_2$ was monitored by NMR and eventually gave a mixture of complexes, including **2**. From this solution was obtained an amber crystal of **2** for the X-ray diffraction study. Selected NMR data for complex **2**: (THF-d_8) $^{31}P\{^1H\}$ 106.5, 98.8 (br d), at −80 °C: 106.5 (d d, $J_{PRh} = 169$ Hz, $^2J_{PP} = 29$ Hz), 98.4 (d d, 194, 29 Hz); $^{11}B\{^1H\}$ −26.7; ^{11}B −26.7 (d quint, $J_{BH} = 63$, 62.5 Hz); ^{1}H δ −2.7 (br, 4H, Rh–H–B and terminal B–H), −10.0 (t t t, Rh–H–Rh).

2.2.2. Reaction of $[Rh(\mu\text{-}H)(DiPPE)]_2$ (1) with thexylborane

A solution of thexylborane dimer (10 mg, 0.05 mmol) in 10 ml of toluene was added dropwise to a solution of **1** (73 mg, 0.1 mmol) in 10 ml of toluene. After stirring for 0.5 h, the solution was concentrated in vacuo to 5 ml and cooled at −30 °C for 48 h. The resulting red crystals were filtered, washed with cold pentane and dried in vacuo to yield (**3**), 57 mg (69%). NMR spectroscopic data for **3** (in toluene-d_8): $^{31}P\{^1H\}$ 100.8 (br d, $J_{PRh} = 170$ Hz), at −40 °C, 104.2 (d d, $J_{PRh} = 178$, $^2J_{PP} = 26$ Hz), 97.0 (d d, $J_{PRh} = 169$, $^2J_{PP} = 26$ Hz); $^{11}B\{^1H\}$ 35.9 (br); $^1H\{^{11}B\}$ δ at −40 °C (in THF-d_8) −9.72 (t quint, $J_{HRh} = {}^2J_{HP} = 20$ Hz, 1H, Rh–H–Rh), −3.91 (br, 3H, Rh–H–B and B–H), 0.87 (d, $^3J = 7$ Hz, 6H, $BC(CH_3)_2CH(CH_3)_2$), 0.98 (s, 6H, $BC(CH_3)_2CH(CH_3)_2$), 1.07 (d d, $^3J = 7$, $^3J_{HP} = 12$ Hz, 24H, $PCHCH_3$), 1.17 (d d, $^3J = 7$, $^3J_{HP} = 15$ Hz, 24H, $PCHCH_3$), 1.52 (ov m, 8H, PCH_2CH_2P), 1.88 (sept, $^2J = 7$ Hz, 1H, $BC(CH_3)_2CH(CH_3)_2$), 2.17 (d sept, $^3J = {}^2J_{HP} = 7$ Hz, 8H, $PCHCH_3$). In another experiment, a solution of thexylborane dimer (30 mg, 0.15 mmol) in 1 ml of toluene-d_8 was added dropwise to a solution of **1** (73 mg, 0.1 mmol) in 1 ml of toluene-d_8. The resulting solution was stirred for 1 h and then an-

alyzed by high-field NMR spectroscopy. NMR spectroscopic data for **4** (in toluene-d_8): $^{31}P\{^1H\}$ 112.9 (d, $J_{PRh} = 163$ Hz); $^{11}B\{^1H\}$ 1.7 (br); ^1H δ −80 °C (in THF-d_8) −2.27 (br, 3H, Rh–H–B and B–H), 0.86–0.95 (ov m, 18H, CH_3), 1.21 (ov m, 18H, CH_3), 1.41 (br ov m, 4H, PCH_2CH_2P), 1.55 (m, 1H, $BC(CH_3)_2CH(CH_3)_2$), 1.81 (m, 4H, $PCHCH_3$); $^1H\{^{11}B\}$ −1.53 (d t, $J_{HRh} = 23$, $^2J_{HP} = 15$ Hz). Selected FT-IR data (nujol): 1825, 2515 cm^{-1}.

2.2.3. Reaction of [Rh(μ-H)(DiPPE)]$_2$ (1) with 9-H-BBN

A solution of 9-H-BBN dimer (36 mg, 0.15 mmol) in 1 ml of toluene-d_8 was added dropwise to a solution of **1** (73 mg, 0.1 mmol) in 1 ml of toluene-d_8. The resulting solution was stirred for 1 h and then analyzed by high-field NMR spectroscopy. Selected NMR spectroscopic data for **5** (in toluene-d_8): $^{31}P\{^1H\}$ 111.7 (d, $J_{PRh} = 161$ Hz); $^{11}B\{^1H\}$ 49.6 (br); ^1H δ −4.6 (br, Rh–H–B).

2.2.4. Reaction of trans-RhH(N$_2$)(PPr$^i_3$)$_2$ with 9-H-BBN

A solution of 9-H-BBN dimer (73 mg, 0.3 mmol) in 10 ml of toluene was added dropwise to a solution of *trans*-$RhH(N_2)(PPr^i_3)_2$ (78 mg, 0.2 mmol) in 10 ml of toluene. After stirring for 0.5 h, the solution was concentrated in vacuo to 5 ml and cooled at −30 °C for 48 h. The resulting orange crystals were collected by filtration, washed with cold pentane and dried in vacuo to yield 55 mg of **6** (57%). Selected NMR spectroscopic data for **6** (in toluene-d_8): $^{31}P\{^1H\}$ 71.3 (d, $J_{PRh} = 161$ Hz); $^{11}B\{^1H\}$ 58.5 (br); ^1H δ −7.83 (br, Rh–H–B).

2.2.5. Reaction of [Rh(μ-H)(DiPPE)]$_2$ (1) with HBcat

A solution of HBcat (36 mg, 0.3 mmol) in 1 ml of toluene-d_8 was added dropwise to a solution of **1** (73 mg, 0.1 mmol) in 1 ml of toluene-d_8. The resulting solution was stirred for 1 h and then analyzed by high-field NMR spectroscopy. Selected NMR spectroscopic data (in toluene-d_8): $^{31}P\{^1H\}$ 102.1 (br, major, **7**), 106.9 (d, $J_{PRh} = 209$ Hz, **8**), at −80 °C (in THF-d_8) 114.4 (br, $J_{PRh} = 102$ Hz, **7**); $^{11}B\{^1H\}$ 15.0 (s, **8**), 35.0 (br, **7**); ^1H δ −9.8 (br, Rh–H), 0.93–1.42 (ov m), 1.95 (br), 2.38 (d sept, $^3J = {}^3J_{HP} = 7$ Hz, $CHMe_2$), 4.97 (br), 6.15 (br), 6.6–6.8 (ov m), 7.82 (br d, $J_{HP} = 97$ Hz, **7**), −8.69 (br, **7**), −17.9 (br, **7**).

2.3. Crystallography

Crystals of **2** and **7** suitable for X-ray diffraction studies were obtained by recrystallization from toluene solutions at −30 °C and crystals of **6** from a pentane solution at −30 °C. Diffraction data were collected at low temperatures on an Enraf-Nonius CAD4 diffractometer for **7**, on a Siemens R3m/v diffractometer for **2** using graphite-filtered Mo Kα radiation ($\lambda = 0.71073$ Å) and the ω scan method, and on a Bruker SMART 1K CCD-equipped diffractometer for **6** (see Table 1). Data were reduced in the usual fashion for Lorentz and

polarization effects, and corrected for 6% (**6**) decay in intensity versus the standard reflections. When required, data sets were corrected for absorption using azimuthal ψ scan measurements. Heavy atom positions were obtained via automated Patterson analysis (PHASE, **2** and **7**) or direct methods (**6**) and used to phase the reflections for the remaining light atoms via Fourier synthesis. The solution and refinement of the structures were performed on a VAX/IBM cluster system using a local program set or on a Microvax cluster using SHELX. Structures were solved by direct methods (SHELXS and MULTAN) [25]. All refinements were performed using full-matrix least-squares on *F*, with anisotropic thermal parameters for all non-hydrogen atoms, and included anomalous dispersion terms [26] for Rh and P, as well as idealized hydrogen coordinates as fixed atom contributors. The atomic scattering factors were taken from the tabulations of Cromer and Waber [27]. Full details of the structures are given in the Section Supplementary material.

2.4. Computations

Geometry optimization was performed at the Becke3LYP (B3LYP) level [28]. The effective core potentials (ECPs) of Hay and Wadt [29] with a double-ξ valence basis set (LanL2DZ) were used to describe the Pt, Rh and P atoms, while the 6-31G basis set was used for all other atoms [30]. Polarization functions have been added for the P ($\xi_d = 0.340$) atoms [31].

All calculations were performed with the use of the GAUSSIAN-98 package [32] on PC Pentium IV computers. The electron density analysis was carried out with MOPLOT 2.4 [33] and the molecular orbitals obtained from B3LYP calculations were plotted using the MOLDEN 3.7 program [34].

3. Results and discussion

Reactions of 9-H-BBN [$(HBC_8H_{14})_2$] and thexylborane [$(BH_2CMe_2CHMe_2)_2$] with saturated iridium hydride $IrH(PMe_3)_4$ proceed via initial loss of phosphine as the corresponding phosphine–borane adducts ($RR'HB \cdot PMe_3$), followed by oxidative addition of the organoborane B–H bond to the metal center to give the dihydridoiridium boryl complexes *fac*-$IrH_2(BRR')(PMe_3)_3$ [35]. Unfortunately, the analogous chemistry with $RhH(PMe_3)_4$ is more complicated, affording a complex mixture of rhodium complexes containing only one or two phosphines. In order to avoid complications arising from loss of phosphine, we then investigated the reactivity of unsaturated rhodium hydride [Rh(μ-H)(DiPPE)]$_2$ (**1**) [23] with several hydroborating agents.

As one of the most common mechanisms for HBcat degradation during metal-catalyzed hydroborations involves the formation of B_2cat_3 and diborane, or its ligand adducts ($L \cdot BH_3$) [36], it is therefore important to examine what deleterious effects liberated borane would have on the catalyst. We have found that reactions of **1** with $H_3B \cdot SMe_2$ gave a mixture of phosphinorhodium products (as ascertained by multinuclear NMR spectroscopy) in varying yields depending on the B:Rh stoichiometry employed (Scheme 1). Using three equivalents of $H_3B \cdot SMe_2$ per Rh dimer, we generated metallaborane [RhH(DiPPE)]$_2B_3H_7$ (**2**) in good yield (by NMR) and isolated amber crystals suitable for X-ray diffraction studies. The structure of **2** (Fig. 1) is a distorted square-pyramidal cluster analog of pentaborane(9), which is similar to that of [(η^5-C_5Me_5)Rh]$_2B_3H_6Cl$ which was obtained recently by Fehlner and co-workers from the reaction of [(η^5-C_5Me_5)RhCl]$_2$ with $H_3B \cdot THF$ [37]. While the bond distances are somewhat longer in **2** [Rh–Rh = 2.8544(6) Å in **2** versus 2.848(1) Å in the Fehlner cluster, Rh–B_{apical} = 2.166(5), 2.177(5) Å versus 2.07(1), 2.08(1) Å, Rh–B_{eq} = 2.247(6), 2.253(6) Å versus 2.20(1), 2.20(1) Å], the biggest distinction between the two complexes is the lack of symmetry in **2** (see Table 2). Indeed, the two terminal hydrides are on the same side of the equatorial Rh_2B_2 plane, but the bis(phosphine) ligands are on opposite sides.

Owing to the propensity of diborane derivatives to form stable high nuclearity clusters [38], metallaborane **2** arises presumably from a dehydrooligomerization reaction. Thus, addition of three equivalents of borane to **1** affords the *nido*-metallaborane [RhH(DiPPE)]$_2B_3H_7$ (**2**) with loss of dihydrogen. The structure of **2** is in accord with Wade's electron counting rules [39] where each RhH(DiPPE) fragment is isolobal with a B–H vertex, contributing two electrons to cluster bonding. Com-

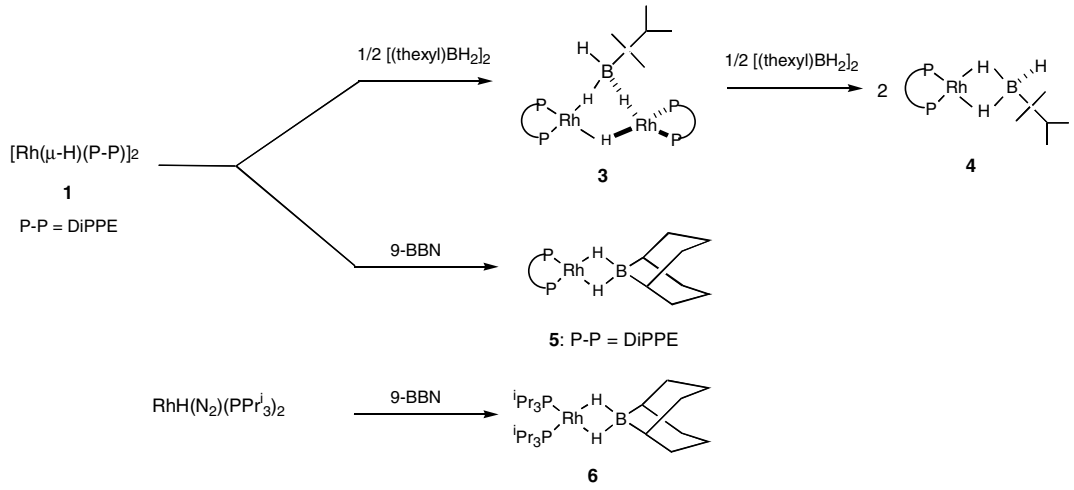
pound **2** has a $2n + 4 = 14$ skeletal electron count and is derived from *nido*-B_5H_9 by replacement of two basal BH groups by P_2RhH vertices. The fluxional process observed by NMR spectroscopy for **2** (effective C_s symmetry at 25 °C) may involve a pairwise trigonal twist by the adjacent $RhHP_2$ vertices as more complicated schemes involving terminal and bridging hydrogen exchange can be ruled out. Formation of **2** presumably proceeds via initial insertion of B–H into a Rh–H–Rh bond, analogous to reactions with thexylborane. Oxidative addition of B–H bonds to the metal center during the synthesis of **2** may provide a pathway for the liberation of one equivalent of H_2.

Similar cluster formation was not observed for the reactions of **1** with alkylboranes. We reported previously [40] that addition of 0.5 equivalents of thexylborane to **1** affords red crystals of the dinuclear complex $[Rh(DiPPE)]_2(\mu\text{-}H)\{\eta^2\text{-}H_2BH(thexyl)\}$ (**3**) as the only new phosphinorhodium complex. Further addition of thexylborane gives orange crystals of mononuclear $Rh[\eta^2\text{-}H_2BH(thexyl)](DiPPE)$ (**4**) (Scheme 2). The molecular structure of **3** consists of two distorted 16 electron square-planar Rh(I) centers bridged by hydride and thexylborohydride ligands. The Rh–Rh distance of 2.912 Å is significantly longer than that observed for **1** (2.628(1) Å) [41]. The two square planes are twisted with respect to one another (dihedral angle of 54.8°) to accommodate the disparate bridges. Similar effects have been observed in related structures with bridging $[BH_4]^-$ ligands [42–44].

Complex **3** is fluxional in solution with inequivalent P atoms of the DiPPE ligands, which at −60 °C constitute the A_2A_2' portion of a complicated 10 spin system. These are averaged at 25 °C giving rise to one doublet ^{31}P



Scheme 2. Reaction of unsaturated phosphinorhodium hydrides with thexylborane and 9-H-BBN dimers.

NMR resonance ($J_{PRh} = 170$ Hz). In the ^{1}H NMR spectrum of **3**, the inequivalent Rh–H–B bridges and the terminal B–H of the thexylborohydride ligand undergo rapid exchange; a single broad resonance at δ −4.0 is observed, even at −100 °C. Slow exchange of the thexylborohydride B–Hs with the Rh–H–Rh bridge was demonstrated qualitatively by proton magnetization transfer experiments at 80 °C. At 25 °C, the Rh–H–Rh bridge is observed as a triplet of quintets at δ −9.63 ($J_{HRh} = {}^2J_{HP} = 20$ Hz).

The ^{1}H NMR spectrum of **4** contains a broad resonance at δ −1.53, which gives rise to a doublet of triplets upon ^{11}B decoupling ($J_{HRh} = 23$, $^2J_{HP} = 15$ Hz). This is assigned to rapidly exchanging terminal and bridging H's of the η^2-thexylborohydride ligand, a significant feature that occurs in almost all covalent metal borohydride complexes [45]. Assignment of the bidentate coordination mode (versus tridentate) of the thexylborohydride ligand is based on the observation of a terminal B–H stretch at 2515 cm^{-1} in the IR spectrum of **4** (versus 1825 cm^{-1} for the Rh–H–B stretch).

Addition of one equivalent of 9-H-BBN to **1** gives the substituted borohydride Rh(η^2-$H_2BC_8H_{14}$)(DiPPE) (**5**) in nearly quantitative yield. A dinuclear intermediate was not detected by multinuclear NMR spectroscopy even at low temperatures (−80 °C). The ^{1}H NMR spectrum of **5** contains a broad resonance at −4.6 ppm attributed to the bridging H's of the η^2-$H_2BC_8H_{14}$ unit. Although we were unable to obtain suitable crystals of **5** for X-ray diffraction studies, addition of 0.5 equivalents of 9-BBN to RhH(N_2)(PPr^i_3)$_2$ [24] gave orange crystals of the analogous complex Rh(η^2-$H_2BC_8H_{14}$)(PPr^i_3)$_2$ (**6**) in 57% yield. The molecular structure of **6** (Fig. 2) consists of a 16 electron square-planar Rh(I) center with the disubstituted borohydride ligand bound to the metal center in an η^2-fashion. The largest deviation from the plane through Rh, both phosphine ligands and B is only 0.007 Å. Similar ruthenium 9-BBN and related exopolyhedral rhodium carborane structures have been reported [46–48] (see Table 3).

Unlike many of the parent tetrahydroborate complexes [45], these alkyl-substituted borohydride compounds are indefinitely stable in solution at room temperature. It is possible that these borohydride complexes may play a vital role in certain metal-catalyzed hydroborations. For example, catalyzed reactions of sterically demanding substrates often results in the degradation of HBcat into B_2cat_3 and 'BH_3' [36], where the latter rapidly hydroborates the organic substrate to give a complicated mixture of alkylboranes. While also severely affecting regioselectivities, the in situ generation of borane and organoboranes may be responsible, in part, for catalyst deactivation. Indeed, no reaction was

observed by multinuclear NMR spectroscopy when complex **5** was treated with an excess of 1-octene.

The reactivity of catecholborane with phosphinorhodium hydrides is of singular interest due to the ubiquity of this borane in metal-catalyzed alkene hydroborations. In contrast to reactions with alkylboranes, or recent studies using early transition metal complexes [49], substituted borohydride complexes are not generated from the addition of HBcat to **1**. The room temperature ^{31}P NMR spectrum of the reaction of **1** with two equivalents of HBcat consists of a broad resonance at 102.1 ppm for the novel mixed oxidation state dimer Rh(DiPPE)(μ-H)$_2$(μ-Bcat)RhH(DiPPE) (**7**), which eventually decomposes (24 h) to give a number of unidentified products, along with a sharp doublet at 106.9 ppm assigned to zwitterionic Rh(η^6-catBcat)(DiPPE) (**8**) (Scheme 3).

The ^{31}P NMR spectrum of **7** in THF-d$_8$ at −80 °C contains only a broad doublet-like resonance at 114.4 ppm indicating the overlap of various phosphine signals. The low temperature ^{1}H NMR spectrum, however, consists of three broad resonances at δ −7.82 (br d, J_{HP} = ca. 97 Hz), −8.69, and −17.9, with the latter presumably being a terminal Rh–H. All three resonances broadened considerably upon warming to room temperature, as expected if rapid exchange of the bridging and terminal hydrides is occurring. It is clear from our DFT calculations, vide infra, that other structures are close in energy to the one observed in the solid state.

The molecular structure of **7**, as determined by X-ray diffraction, consists of one Rh(I) center coordinated to a DiPPE group and two bridging hydrides in a square-planar arrangement (Fig. 3). The Rh(III) center is octahedrally coordinated with two bridging hydrides, a terminal hydride, a DiPPE and a σ-bound Bcat ligand. The trigonal-planar boron shows a weak interaction with an apical site on the Rh(I) center, in which the Rh–B distance is 2.444(9) Å. The Rh(III)–B bond distance of 2.057(8) Å is slightly elongated when compared to a length of 1.961(7) Å found in RhHCl(Bcat)(PPr$^i_3$)$_2$ [50]. The strong *trans*-directing effect of the boryl ligand leads to a longer Rh(1′)–P(1′) bond distance (2.324(2) Å) as compared to that with P *trans* to the bridging hydride (Rh(1′)–P(2′) = 2.232(2) Å). The Rh–Rh bonding distance in **7** (2.574(1) Å) is significantly shorter than that observed for **1** [41] (see Table 4). Dinuclear **7** is a rare example of a compound containing a bridging boryl group that has been characterized by both high-field NMR spectroscopy and X-ray diffraction.

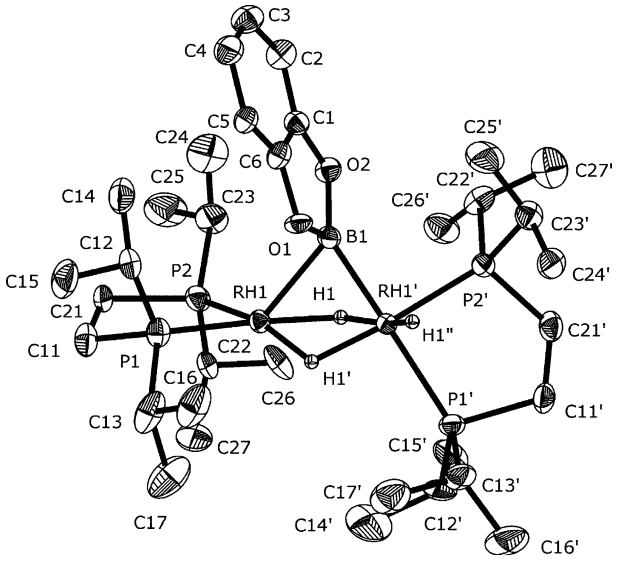

Fig. 3. Molecular structure of Rh(DiPPE)(μ-H)$_2$(μ-Bcat)RhH(DiPPE) (**7**) with hydrogen atoms on the DiPPE and Bcat ligands omitted for clarity.

The only previous structurally characterized examples are the two platinum dimers isolated by Norman and co-workers [51], namely, [Pt$_2$(PPh$_3$)(μ-dppm)$_2$(Bcat)(μ-Bcat)] (**9**) and the analogous compound in which a monodentate, κ^1-dppm ligand replaces the PPh$_3$ group. Another pair of rhodium dimers has also been observed in solution by Brown and co-workers [52]

and structures containing bridging boryl units were proposed on the basis of ^{1}H and ^{31}P NMR data; as the exact nature of these latter compounds are not known, they will be addressed only briefly. With the aid of DFT calculations, we have examined the bonding nature of M1–(μ-B)–M2 and the structural features of the structurally characterized rhodium (**7**) and platinum (**9**) dimers.

In analyzing [Rh(DiPPE)(μ-H)$_2$(μ-Bcat)RhH(DiPPE)], we employed a simplified model complex, [Rh(H$_2$PCH$_2$-PH$_2$)(μ-H)$_2${μ-B(O$_2$C$_2$H$_2$)}RhH(H$_2$PCH$_2$- PH$_2$)]. Selected structural parameters for the calculated model complex, together with the experimental values in parentheses, illustrated in Fig. 4, show that the optimized structure is in good agreement with the observed one. It can be described as two Rh centers bridged by two μ-hydrides and a semi-bridging boryl group. The coordination sphere of Rh1 can be viewed as square planar, as expected for d^8-Rh(I), if the Rh1-B interaction is ignored, whereas Rh2 adopts a distorted octahedral structure, as expected for d^6-Rh(III).

For a square planar 16-electron Rh1 fragment, ignoring initially the interaction with (μ-B) and Rh2, the filled t_{2g} and d_{z^2} orbitals are approximately non-bonding whereas the octahedral 18-electron Rh2 moiety has a filled t_{2g} set of non-bonding orbitals. As the two Rh centers are electronically saturated, their approach (Rh–Rh = 2.574 Å) is a result of two bridging hydrogen atoms rather than direct Rh–Rh attraction.

The Rh1–(μ-B) interaction can be viewed as σ-donation to the vacant p-orbital of the semi-bridging boron from the filled d_{z^2} orbital of Rh1. This is similar to the structurally characterized square pyramidal complex [(PPh$_3$)$_2$Rh(CO)(Cl)(SO$_2$)] in which the bent, apical SO$_2$ moiety is indicative of it functioning as a Lewis acid coordinated to the filled d_{z^2} orbital of Rh rather than as a Lewis base [53]. The relevant MO for the semi-bridging interaction in (**7**) from our B3LYP DFT calculations is illustrated in Fig. 5.

To elucidate further the Rh1–(μ-B)–Rh2 interaction, we have analyzed the Laplacian [54] plot of the electron density ($-\nabla^2\rho$) on the plane defined by [Rh1–(μ-B)–Rh2], shown in Fig. 6. In the contour plot, solid lines represent local electron density concentration ($\nabla^2\rho < 0$) and dashed lines represent local electron density depletion ($\nabla^2\rho > 0$). There are higher electron density concentrations along the (μ-B)–Rh2 direction, with some distorted concentrations around the semi-bridging boron atom in the direction of Rh1. This electron density distortion shows that there is an interaction between Rh1 and (μ-B). The natural bond order (NBO) analyses show that the Wiberg bond indices of Rh1–(μ-B) and Rh2–(μ-B) are 0.3275 and 0.5190, respectively.

The Rh$_2$(μ-H)$_2$ core exhibits a butterfly geometry, as shown in Fig. 4. The importance of the Rh1–(μ-B) interaction in directing the structure is illustrated by our calculations on an isomeric model complex with the μ-boryl group in the equatorial plane and the terminal hydride on Rh2 in an axial position (i.e., interchanging the positions of the μ-boryl and terminal hydride ligands with respect to those found in the X-ray structure). This model would not be expected to exhibit any interaction between the μ-boryl group and Rh1. The calculation indeed yields a planar structure, with the two Rh metal centers and two bridging hydrides in the same plane and an energy which is 1.08 kcal/mol higher than that for the complex with the Rh1–(μ-B) interaction.

We expected to find a related M1–(μ-boryl) interaction in the di-platinum complex (**9**). The bonding in the Pt$_1$-(μ-boryl) system has thus been investigated by DFT calculations on the model complex [Pt$_2$(PH$_3$)(H$_2$-PCH$_2$CH$_2$PH$_2$)$_2$(BO$_2$C$_2$H$_2$)(μ-BO$_2$C$_2$H$_2$)]. The optimized geometry for this model gave a terminal boryl unit which lies approximately orthogonal to the one in the experimental structure which emphasizes the weak π-

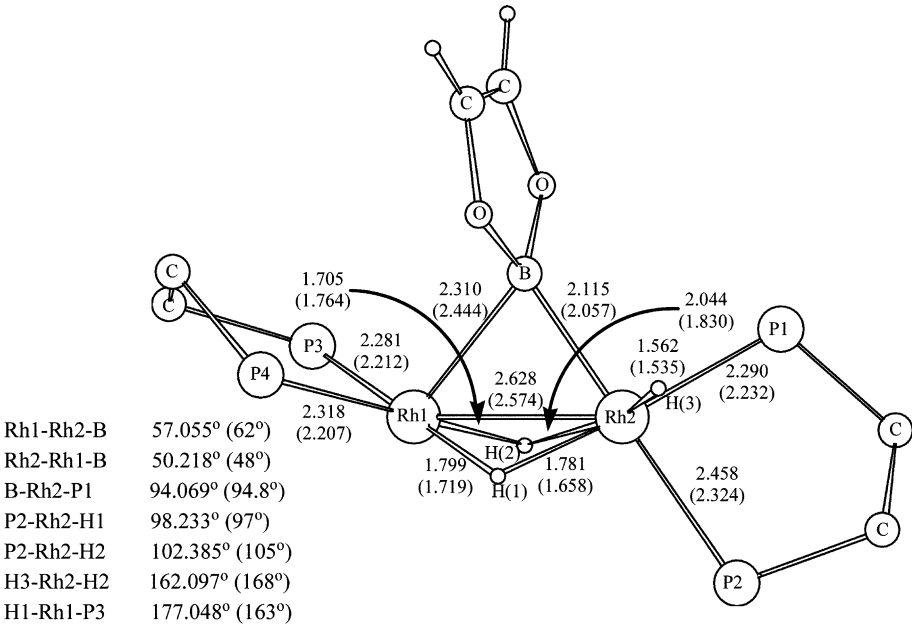

Fig. 4. Selected calculated structural parameters (bond lengths in Å and bond angles in °) for the model complex [Rh($H_2PCH_2CH_2PH_2$)(μ-H)$_2${μ-B($O_2C_2H_2$)}RhH($H_2PCH_2CH_2PH_2$)] together with the experimental structural parameters for [Rh(DiPPE)(μ-H)$_2$(μ-Bcat)RhH(DiPPE)] shown in parentheses. For the purpose of clarity, hydrogen atoms on simplified DiPPE are omitted.

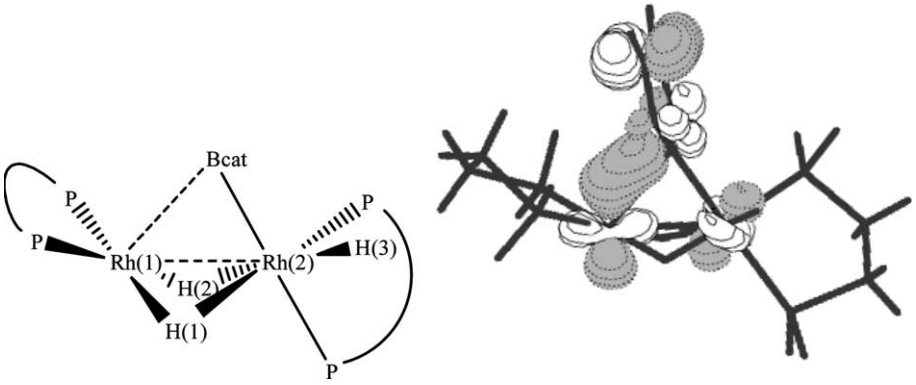

Fig. 5. Spatial plots of the metal–boryl bonding MO for [Rh($H_2PCH_2CH_2PH_2$)(μ-H)$_2${μ-B($O_2C_2H_2$)}RhH($H_2PCH_2CH_2PH_2$)]. The molecular orbital was obtained from the B3LYP calculations.

backbonding to this ligand. This is a known problem with boryl complexes wherein the steric interactions of the experimental ligand set are critical in obtaining the correct orientation for the terminal boryl moiety [50,55]. The di-platinum complex can be described as being composed of a distorted tetrahedral 18-electron, Pt(0) d^{10}-ML_3(boryl) anion coordinated to a T-shaped 14-electron d^8-ML_2(boryl) cation fragment via a donor–acceptor Pt–Pt bond. The spatial plot of the calculated MO corresponding to the Pt-(μ-boryl) interaction between the empty p-orbital on the semi-bridging boryl group and d_{xz} on the Pt1 metal center is illustrated in Fig. 7.

It is interesting that the metal d-orbitals involved in the M1–(μ-B) interaction are different for the Pt and Rh complexes, being d_{xz} for Pt1 and d_{z^2} for Rh1. It is clear that the d-orbital which is utilized depends on the metal–metal bond distance, with d_{xz} preferred for the longer Pt1–Pt2 bond and d_{z^2} preferred for the shorter Rh1–Rh2 bond (Scheme 4). Indeed, the M1–M2–(μ-B) angles (θ) are almost the same in the di-rhodium and di-platinum [1] complexes, being 62.5° and 59.4°, respectively.

The vacant p-orbital on the semi-bridging boryl group can interact not only with a d-orbital on M1 (σ-

[1] We note that some of the angles quoted in Table 2 of [37] are, unfortunately, typographically incorrect, and the experimental ones referred to herein were obtained from the Cambridge Structural Database. N.C. Norman, personal communication.

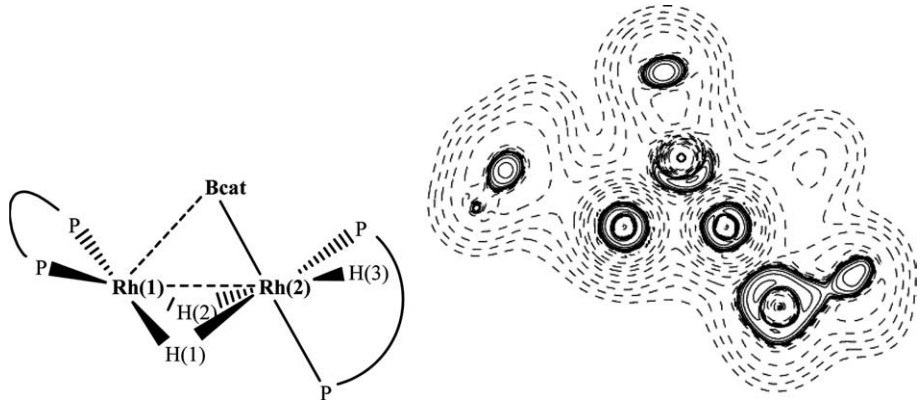

Fig. 6. Plot of the Laplacian of electron density for $[Rh(H_2PCH_2CH_2PH_2)(\mu\text{-}H)_2\{\mu\text{-}B(O_2C_2H_2)\}RhH(H_2PCH_2CH_2PH_2)]$ in a plane defined by the two metal centers and the boron atoms of the bridging boryl ligands.

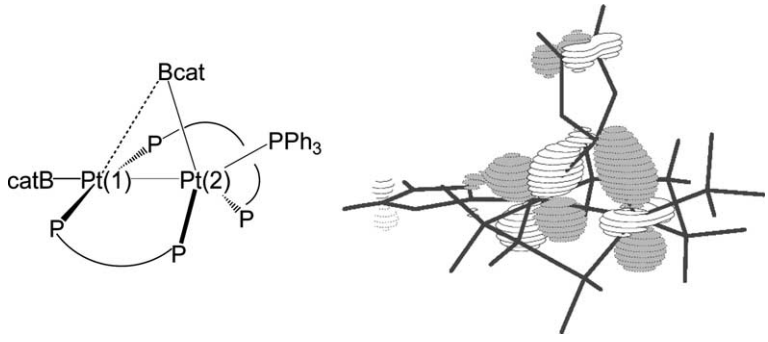

Fig. 7. Spatial plots of the metal–boryl bonding MO for $[Pt_2(PH_3)(\mu\text{-}H_2PCH_2PH_2)_2\{B(O_2C_2H_2)\}\{\mu\text{-}B(O_2C_2H_2)\}]$. The molecular orbital was obtained from the B3LYP calculations.

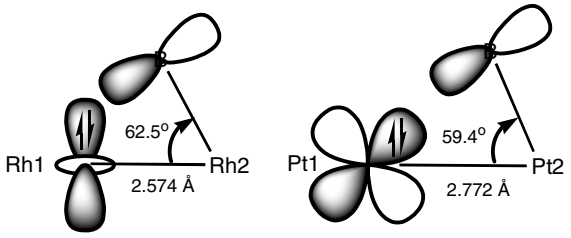

Scheme 4.

donation), but also with a d-orbital on M2 (π-backbonding). The π-accepting property of the boryl group is still controversial but in general, they are believed to be weak π-acceptors at best [49,56]. Here, however, the strong M1–(μ-B)-type interaction shows that the potential electron accepting ability of the B(p-orbital) is strong but that the strength of the interaction depends on the type of interaction (σ or π) [57]. In the present case, we can clearly view the semi-bridging boryl as acting as a Lewis acid to the second metal center.

Finally, it is worth considering the two proposed bridging boryl complexes of Brown and co-workers [52] as illustrated in Fig. 8. Electron counting arguments, along with the details of the above analysis suggest that the two compounds are probably neutral and not dicationic, and that the proposed structures would be unlikely as they are electron deficient. Alternatively, a bridging structure in which the boryl group is terminal to one Rh and O-bound to the other one would satisfy electron counting arguments and would represent yet another type of bridging boryl interaction. Clearly, further synthetic and structural efforts are required to provide additional information on the nature of such novel interactions.

The formation of **7** from dihydride **1** can be rationalized by oxidative addition of one molecule of HBcat to one of the rhodium atoms. Further addition of HBcat eventually affords the novel zwitterion **8**, which has been shown to be a remarkably active and selective catalyst precursor for the hydroboration of a wide variety of alkenes [19]; 'BH_3' production is required for mass balance. Unfortunately, if borane is being liberated in the corresponding catalyzed reactions, this degradation product could compete with HBcat and rapidly hydroborate any unsaturated substrate in solution. As a result, product selectivities could be greatly altered depending upon the amount of borane liberated. Thus, it is useful for catalysis to preform the zwitterionic compounds or to use an alternate mode of generating them in situ [18b,58].

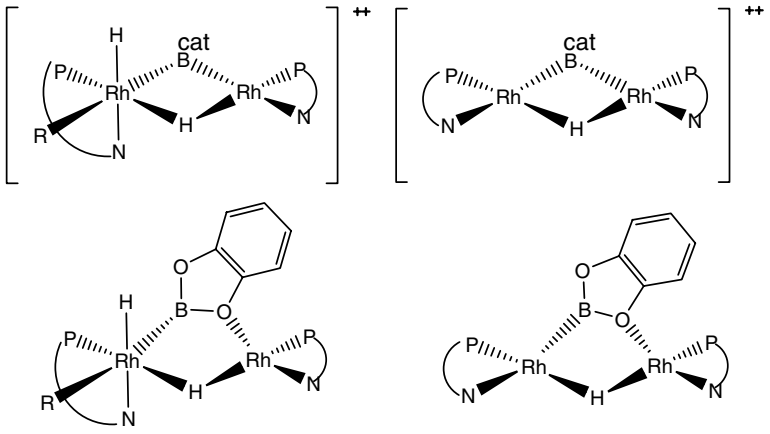

Fig. 8. The two structures at the top were proposed by Brown and co-workers [52] and the ones at the bottom are possible alternatives, which are more consistent with electron counting arguments.

The molecular structure of **8** [59] consists of a chelated bis(phosphine)rhodium cation unsymmetrically coordinated to one of the arene rings of the $[Bcat_2]^-$ anion. There are two unique molecules in the crystallographic asymmetric unit which differ in the rotational orientation and slippage of the P_2Rh moiety with respect to the π-bound arene ring. For instance, the Rh–C bonds (C α to O) in molecule 1 are 2.516(6) and 2.372(6) Å and those for molecule 2 are 2.458(6) and 2.426(7) Å. The potential surfaces for such distortions appears to be quite shallow. Structures and theoretical studies of related zwitterions will be described elsewhere [60]. Significant differences in the Rh–arene carbon bond distances were also observed in the molecular structure of $[Rh\{P(OMe_3)_3\}_2(\eta^6\text{-PhBPh}_3)]$ [61]. The J_{PRh} coupling constant for **8** of 209 Hz is consistent with a P_2Rh fragment π-bound to an arene ring [62]. The formation of **8** involves the redistribution of catecholato groups, which has been observed previously in reactions of HBcat with $NaBH_4$ [63] and tertiary phosphines [36].

4. Conclusions

The nature of the rhodium-containing products observed here demonstrates major reactivity differences between the hydroborating agents employed. Unlike reactions with phosphinoiridium complexes, which give oxidative addition products, addition of borane and alkylboranes to unsaturated rhodium hydride **1** proceeds via initial insertion of B–H into a Rh–H bond to afford stable borohydride complexes. Alkylboranes derived from BH_3 formation (degradation of HBcat) during hydroborations of sterically demanding substrates could result, therefore, in removal of active Rh–H species from the catalytic cycle. The formation of borane in such catalytic reactions also has severe ramifications for product selectivities and for catalyst stability and lifetime due to the formation of metallaborane clusters of undefined activity. Reactions with HBcat are unique, however, in that boron-substituent redistribution products are formed. Addition of HBcat to rhodium hydride **1** gave the novel dinuclear complex $Rh(DiPPE)(\mu\text{-H})_2(\mu\text{-Bcat})RhH(DiPPE)$ (**7**) and, subsequently, zwitterion $Rh(\eta^6\text{-catBcat})(DiPPE)$ (**8**). A single-crystal X-ray diffraction study on **7** shows that the Bcat ligand asymmetrically bridges the two rhodium atoms.

5. Supplementary material

Complete X-ray data collection parameters, bond distances, bond angles, anisotropic thermal parameters, and hydrogen atom coordinates and isotropic thermal parameters for complexes **2**, **6**, and **7**, quoting the deposition numbers CCDC 249353–249355, are available free of charge on request from CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.ac.uk or www: http://www.ccdc.cam.ac.uk).

Dedicated to Prof. M.L.H. Green on the occasion of his retirement from the position of Head of the Inorganic Chemistry Department at Oxford University

Abstract

The ionic liquids 1-butyl-3-methyl-imidazolium tetrafluoroborate ([bmim][BF_4]), 1-butyl-3-methyl-imidazolium hexafluorophosphate ([bmim][PF_6]) and 1,2-dimethyl-3-butyl-imidazolium hexafluorophospate ([bdmim][PF_6]) were investigated as potential media for hydroformylation catalysis in a liquid–liquid biphase reaction environment. The study used the known rhodium/tppti* (tppti* = tri(*m*-sulfonyl) triphenyl phosphine 1,2-dimethyl-3-butyl-imidazolium salt) system as the catalyst and hexene-1 as the substrate, which enabled the produced heptanal to be conveniently isolated from the ionic liquid by phase separation. All catalyst evaluations were carried out in high-purity ionic liquids to avoid any decomposition of the catalyst, substrate and/or ionic liquid. The activity of the biphasic ionic liquid system containing the Rh/tppti* catalyst was approximately one order of magnitude lower than that observed for the conventional Rh/PPh_3 catalyst in toluene. The Rh/tppti* catalyst system showed a decrease of activity in the semicontinuous hydroformylation of hexene-1 due to catalyst deactivation and/or metal loss. The *n*/*i* ratio of the produced heptanal only slightly increased after changing the Rh/P ratio from 1:3 to 1:100 in [bmim][PF_6]. The loss of rhodium metal from the ionic liquid phases appears to be correlated to the solubility characteristics of the ionic liquid and the concentration of the aldehyde in the organic phase. In support of this theory, the ionic liquid [bmim][PF_6] gave the best results due to its very low miscibility with polar substances. A high-pressure NMR (HP-NMR) study revealed that the solution structure of HRh(^{13}CO)(tppts)$_3$ (tppts = tri(*m*-sulfonyl)triphenyl phosphine sodium salt) in [bmim][BF_4] was similar to that of HRh(^{13}CO)(PPh_3)$_3$ in toluene-d^8. The HP-NMR investigation at elevated syngas pressures showed that HRh(^{13}CO)(tppts)$_3$ lies in equilibrium with HRh(^{13}CO)$_2$(tppts)$_2$.

1. Introduction

The separation of homogeneous hydroformylation catalysts from reaction mixtures has been a tremendous challenge and continues to be the focus of intense research [1]. Over the last three decades, several elegant approaches have been explored to overcome this limitation including aqueous [2] and fluorous biphase catalysis [3], reactions in supercritical media [4] and catalyst immobilization onto solid support materials [5]. Although some of these novel concepts have successfully been developed into commercial processes, like the Ruhr Chemie Rhône Poulenc Process used in the production of butyraldehyde [2], catalyst recovery continues to be one of the key issues of homogeneous catalysis.

More recently, ionic liquids have been used as alternative reaction media for homogeneous catalysis [6]. Based on their highly charged nature, ionic liquids are

well suited for biphasic reactions with organic substrates. While the first hydroformylation reaction in an ionic liquid (at that time referred to as a molten salt) was performed by Parshall [7] as earlier as 1972, it was not until 1995 that Chauvin et. al. [8] used water-soluble phosphine ligands like the tri(*m*-sulfonyl)triphenyl phosphine sodium salt (tppts) [9] to retain active rhodium complexes in the ionic liquid phases and used them successfully in biphasic hydroformylation catalysis. Since then, a variety of different metal complexes have been investigated for liquid–liquid biphasic hydroformylation reactions in ionic liquid media [10].

As the production of aldehyde is one of the largest volume processes [11] in the chemical industry we have recently attempted to ascertain the viability of ionic liquids for hydroformylation reactions [12]. In this paper, we report our findings on the biphasic hydroformylation catalysis using conventional rhodium catalysts in ionic liquid media, which was encouraged by the initial report of Chauvin et. al. [8]. In this study we have investigated the reactivity of the hydroformylation catalyst $HRh(CO)(P)_3$ (P = phosphine ligand) in imidazolium based ionic liquid derivatives of tetrafluoroborate and hexafluorophosphate. In addition, we have complimented our investigation with a high-pressure NMR (HP-NMR) study of the reaction mixture containing the active rhodium species.

2. Experimental

2.1. General experimental details and materials

All operations were performed in a Vacuum Atmospheres or MBraun dry box under purified nitrogen or using Schlenk techniques under a nitrogen atmosphere. The following chemicals have been purchased from Aldrich and have been used as received: anhydrous heptane, anhydrous toluene, dichloromethane, hexene-1, 1-chlorobutane, 1-methyl-imidazol, 1,2-dimethyl-imidazol, Celite, alumina, activated carbon, sodium tetrafluoroborate, sodium hexafluorophosphate and potassium hexafluorophosphate. The following compounds have been purchased from Strem and have been used as received: tris(*m*-sulfonylphenyl)phosphine sodium salt (tppts) and $Rh(CO)_2(acac)$ (acac = acetylacetonate). The gases CO/H_2 (1:1, UHP grade) and ^{13}CO (UHP grade) were purchased from BOC and MG industries, respectively. NMR spectra were recorded on a Varian Unity 400 spectrometer. Chemical shifts (ppm) were referenced to either an internal standard (e.g. tetramethylsilane) or an external standard (e.g. triphenylphoshite). HP-NMR experiments were performed using single-crystal sapphire NMR tubes [13]. Toluene-d_8 was purchased from Cambridge Isotopes and was degassed and dried over potassium metal. Gas chromatography samples were analyzed using a HP-5890 gas chromatograph with a 30 m Spb-1 capillary column, 0.25 mm i.d. and 0.25 mm film thickness and a HP-6890 GC/MS equipped with a 30 m HP-1 capillary column, 0.25 mm i.d. and 0.25 mm film thickness. Rhodium analyses were performed on an inductively coupled plasma–atomic emission spectrometer (ICP/AES), Jarrell-Ash Model 1100, with argon gas flow and torch alignment. The ICP/AES instrument was calibrated with 10 ppm rhodium solution. Elemental analyses were performed by the Galbraith Laboratory.

2.2. Preparation of the ionic liquids

2.2.1. 1-Butyl-3-methyl-imidazolium tetrafluoroborate – [bmim][BF_4]

A 500 ml round bottom flask was charged under N_2 with 95 g (0.54 mol) 1-butyl-3-methyl-imidazolium chloride [14] and 63 g (0.57 mol) sodium tetrafluoroborate in 250 ml of degassed water. After the reaction was stirred for 15 h at room temperature, the mixture was extracted with dichloromethane (3× 100 ml). The combined organic phases were dried over magnesium sulfate and filtered through a bed of activated carbon and alumina. After the removal of the volatile components under reduced pressure the ionic liquid [bmim][BF_4] was obtained as a colorless liquid in 73% yield. Elemental analysis (%) calculated for $C_8H_{15}N_2BF_4$: C, 42.51; H, 6.69; N, 12.39. Found: C, 42.66; H, 7.12; N, 12.49%.

2.2.2. 1-Butyl-3-methyl-imidazolium hexafluorophosphate – [bmim][PF_6]

A 1000 ml round bottom flask was charged under N_2 with 175 g (1.0 mol) 1-butyl-3-methyl-imidazolium chloride and 190 g (1.03 mol) potassium hexafluorophosphate in 400 ml degassed water. After the reaction was stirred for 15 h at room temperature, the mixture was extracted with dichloromethane (3× 200 ml). The combined organic phases were dried over magnesium sulfate and filtered through a bed of activated carbon and alumina. After the removal of the volatile components under reduced pressure the ionic liquid [bmim][PF_6] was obtained as a colorless liquid in 80% yield. Elemental analysis (%) calculated for $C_8H_{15}N_2PF_6$: C, 33.81; H, 5.32; N, 9.86. Found: C, 33.92; H, 5.64; N, 9.72%.

2.2.3. 1,2-Dimethyl-3-butyl-imidazolium hexafluorophosphate – [bdmim][PF_6]

A 500 ml round bottom flask was charged under N_2 with 56.6 g (0.3 mol) 1,2-dimethyl-3-butyl-imidazolium chloride and 55.4 g (0.33 mol) sodium hexafluorophosphate in 250 ml of degassed water. After the reaction was stirred for 15 h at 40 °C, the mixture was extracted with dichloromethane (3× 100 ml). The combined organic phases were dried over magnesium sulfate and filtered through a bed of activated carbon and alumina.

After the removal of the volatile components under reduced pressure the ionic liquid [bdmim][PF_6] was obtained as a yellow-colored viscous liquid in 70% yield. Elemental analysis (%) calculated for $C_9H_{17}N_2PF_6$: C, 36.25; H, 5.75; N, 9.39. Found: C, 36.27; H, 5.83; N, 9.36%.

2.3. HP-NMR investigation

A solution of 3 mg (0.013 mmol) $Rh(CO)_2(acac)$ and 43 mg (0.075 mmol) tppts in 2 ml of [bmim][BF_4] containing 5 wt% of D_2O was prepared under N_2 and charged into a sapphire NMR tube. The tube was placed into a safety shield container and pressurized to 60 psi with $^{13}CO/H_2$ (1:1). To ensure the formation of $HRh(CO)(tppts)_3$ (**1a**), the tube was shaken at 60 °C for 1 h. After the pressure was released the $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectra were recorded under 15 psi of $^{13}CO/H_2$ (1:1), confirming the presence of **1a**. During the course of the HP-NMR investigation the tube was pressurize up to 2000 psi with $^{13}CO/H_2$ (1:1) and further monitored by NMR spectroscopy.

2.4. Catalyst evaluation

2.4.1. General experimental details for hydroformylation reactions

In a typical experiment carried out in a 300 ml autoclave, catalyst solution was prepared from the ionic liquid, the rhodium precursor $Rh(CO)_2(acac)$ and the phosphine (tppti*) stock solution. The mixture was charged into the reactor under nitrogen and the volatile components removed under reduced pressure (10^{-2} Torr). The reactor was then flushed and pressurized with CO/H_2 (1:1) to ca. 150 psi. The run olefin was charged in a glovebox into a 100 ml injection bomb, which was then mounted into the feed line of the reactor. After the reactor was heated to the run temperature, the reaction was initiated by injecting the olefin into the reactor and the pressure adjusted up to 600 psi CO/H_2 (1:1). The pressure in the reactor was maintained constant by making up the consumed CO/H_2 (1:1) from the PVT tank. The conversion was followed by recording the pressure drop in the PVT tank.

The apparent turnover frequency (TOF) used in the kinetic analysis is defined as the rate of olefin conversion by 1 mol of rhodium and is expressed as the moles of olefin converted to aldehyde per moles of rhodium per minute: $TOF = \{(dn_{olefin}/dt)_t\}/n_{Rh}$. The rate of olefin conversion is calculated from the PVT pressure versus time data. The values for the TOF were determined during the initial 30 min of the gas consumption which corresponds to an approximate olefin conversion of between 10% and 20%.

For the semicontinuous hydroformylation of hexene-1, the autoclave was fitted with a dip leg that reached ca. 5 mm above the heavier ionic liquid phase. At the end of each run, the reactor was cooled to 15 °C, the stirrer was then stopped and the supernatant product phase was removed from the reactor. For metal balance, the concentration of Rh in each product was determined by ICP-AES. For each consecutive run, the catalyst phase was rapidly heated to the reaction temperature and a fresh charge of hexene-1 was injected to initiate the reaction.

For the rhodium analysis, aliquots of the product were ashed with 1 ml of concentrated H_2SO_4 and left in a furnace at 530 °C for at least 8 h. The remaining residue was fused with 0.5 g $K_2S_2O_7$. The resulting mixture was solubilized in a 20% H_2SO_4 solution. The rhodium analysis was performed using ICP/AES instrumentation with matrix-matched standards (3.35 RSD).

2.4.2. Preparation of the tri(m-sulfonyl)triphenylphosphine 1,2-dimethyl-3-butyl-imidazolium salt (tppti*)

A 50 ml round bottom flask was charged under N_2 with 10.1 g (0.017 mol) tri(*m*-sulfonyl)triphenyl phosphine sodium salt (tppts) and 10.0 g (0.053 mol) 1,2-dimethyl-3-butyl-imidazolium chloride in acetonitrile (25 ml). After the reaction was stirred for 3 days at room temperature, the mixture was filtered through a bed of Celite. The filter aid was further washed with acetonitrile (30 ml). The resulting filtrates were combined and used as a stock solution for the tppti* ligand.

2.4.3. Biphasic Hydroformylation using $Rh(CO)_2(acac)$/tppti* in [bmim][BF_4] (Table 2/Entries 1–10)

A mixture of 26 mg (0.1 mmol) $Rh(CO)_2(acac)$ and 3.2 ml (1.0 mmol) tppti* (stock solution) in 60 ml [bmim][BF_4] was stirred at room temperature. After 1 h the yellow solution was charged into a 300 ml autoclave and the volatile components removed under reduced pressure (10^{-2} Torr). The reactor was pressurized with CO/H_2 (1:1) to ca. 150 psi. After the reactor was heated to 100 °C, the reaction was initiated by injecting 61 g (720 mmol) hexene-1 with 300 psi of CO/H_2 (1:1) into the reactor. Due to the extended induction period after the first recycle run the reactor pressure was increased to 600 psi. All further runs were conducted at this run pressure.

2.4.4. Reaction of $Rh(CO)_2(acac)$/tppti* in [bmim][PF_6] (Table 2/Entries 11–20)

A mixture of 26 mg (0.1 mmol) $Rh(CO)_2(acac)$ and 3.2 ml (1.0 mmol) tppti* stock solution in 60 ml [bmim][PF_6] was stirred at room temperature. After 1 h the yellow solution was charged into a 300 ml autoclave and the volatile components removed under reduced pressure (10^{-2} Torr). The reactor was pressurized with CO/H_2 (1:1) to ca. 300 psi. After the reactor was heated to 100 °C, the reaction was initiated by injecting 26 g (307 mmol) hexene-1 in 38 ml of heptane with 600 psi of CO/H_2 (1:1) into the reactor. The

autoclave studies using Rh/P ratios of 1:3 and 1:100 (Table 1/Entries 28, 29) were carried out under the identical conditions.

2.4.5. Reaction of $Rh(CO)_2(acac)$/tppti* in [bdmim][PF_6] (Table 2/Entries 21–27)

A mixture of 26 mg (0.1 mmol) $Rh(CO)_2(acac)$ and 3.2 ml (1.0 mmol) tppti* stock solution in 60 ml [bdmim][PF_6] was stirred at room temperature. After 1 h the yellow solution was charged into a 300 ml autoclave and the volatile components removed under reduced pressure (10^{-2} Torr). The reactor was pressurized with CO/H_2 (1:1) to ca. 300 psi. After the reactor was heated to 100 °C, the reaction was initiated by injecting 25 g (295 mmol) hexene-1 in 38 ml of heptane with 600 psi of CO/H_2 (1:1) into the reactor.

2.4.6. Reaction of $Rh(CO)_2(acac)/PPh_3$ in toluene (Table 2/Entries 30)

A mixture of 6.5 mg (0.025 mmol) $Rh(CO)_2(acac)$ and 66 mg (0.25 mmol) PPh_3 was dissolved in 60 ml toluene and stirred at room temperature. The yellow solution was charged into a 300 ml autoclave and pressurized with CO/H_2 (1:1) to ca. 300 psi. After the reactor was heated to 100 °C, the reaction was initiated by injecting 61 g (720 mmol) hexene-1 at 600 psi of CO/H_2 (1:1) into the reactor.

3. Results and discussion

3.1. Catalyst screening in HP-NMR tubes

We started our study by investigating hydroformylation reactions in ionic liquids under different reaction environments. This initial study was conveniently carried out in sapphire NMR tubes which enabled us to visually follow phase separations and determine solubility limitations. In this investigation the well-established catalyst precursor $Rh(CO)_2(acac)$ (acac = acetylacetonate) was dissolved in the ionic liquid [bmim][PF_6] with (a) no phosphine, (b) triphenylphoshine (PPh_3) and (c) the tri(*m*-sulfonyl)triphenyl phosphine 1,2-dimethyl-3-butyl-imidazolium salt (tppti*). The resulting solutions were loaded into HP-NMR tubes and treated with the substrate hexene-1. The organic phases showed a lower density and therefore generated the top layers while the ionic liquids were confirmed as the bottom phases. After the reaction mixtures were pressurized with CO/H_2 (1:1) to 600 psi the tubes were shaken at 100 °C. The reaction was stopped after 3 h and the tubes were cooled to room temperature. During this time the organic components separated from the ionic liquid phases. While the reaction without a ligand and with the ligand tppti* gave colorless organic phases (upper layer), the experiment using the ligand PPh_3 showed a strong yellow coloration of the organic phase. As the complex $HRh(CO)(PPh_3)_3$ has a yellow coloration in solution, it is a good indication that a substantial amount of the catalyst migrated during the reaction from the ionic liquid into the organic layer. After the pressure was released from the sapphire NMR tubes the organic products were analyzed for their composition and rhodium metal content. In all three cases a significant amount of aldehyde was produced. Concerning the issue of metal leaching, only the reaction mixture using tppti* exhibited a negligible amount of rhodium loss from the ionic liquid, while the other ionic liquid phases suffered from a significant amount of metal loss. On the basis of these initial experiments, the approach of using highly charged ligands like for example tppti* seemed to be a viable method for retaining a rhodium catalyst in an ionic liquid.

One interesting result was that although the organic phase in the reaction using no ligand was colorless, a large amount of rhodium metal was found in this phase. Furthermore, a significant amount of aldehyde was produced in this reaction which indicates that species other than $HRh(CO)(PPh_3)_3$ are active for the hydroformylation of the olefin. Most likely the aldehyde was produced by rhodium-hydrido-carbonyl complexes which tend to form under hydroformylation reaction conditions in the absence of suitable ligands and have been observed in other areas of oxo-catalysis [15]. For this reason, all of our produced aldehyde samples were analyzed for their rhodium content.

Another potentially complicating factor in the evaluation of these ionic liquid media for hydroformylation catalysis are the solubility limitations of the highly charged phosphine ligand. In an early HP-NMR study

Table 1
Selected $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR data for the Rh/P catalyst system (P = PPh_3, tppts) in [bmim][BF_4], toluene-d^8 and water under varying pressure conditions

Solvent	Pressure[a] (psi)	Complex	$\delta(^{13}CO)$ (ppm)	J_{C-Rh} (Hz)	$\delta(^{31}PR_3)$ (ppm)	J_{P-Rh} (Hz)

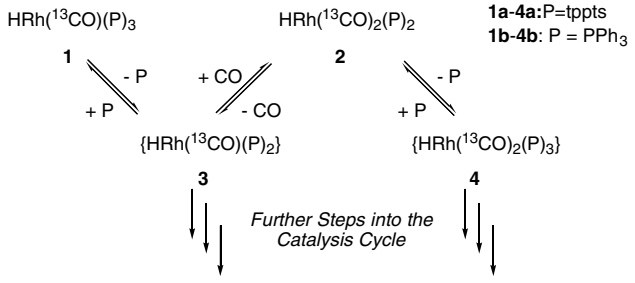
[a] Syngas $^{13}CO/H_2$ (1:1).

we realized that not all the water-soluble phosphine ligands like the tri(*m*-sulfonyl)triphenyl phosphine sodium salt (tppts) are also automatically soluble in ionic liquid phases. Although the ligand showed excellent solubility in water, it only dissolved in [bmim][BF_4] after the addition of small amounts of water. Even more surprising was the fact that it has negligible solubility in [bmim][PF_6]. To verify this low solubility we charged [bmim][PF_6] together with $Rh(CO)_2$(acac) and tppts (Rh/P ratio 1:10) into a HP-NMR tube. The resulting mixture was stepwise pressurized with CO/H_2 (1:1) to 2000 psi and heated up to 150 °C. During this process we recorded the $^{31}P\{^1H\}$ NMR spectra of the solution and were unable to detect neither coordinated nor free tppts. On the basis of this investigation we synthesized a more soluble derivative of the phoshine ligand. After exchanging the sodium cation of tppts with 1,2-dimethyl-3-butyl-imidazolium we prepared the tri(*m*-sulfonyl)triphenyl phosphine 1,2-dimethyl-3-butyl-imidazolium salt (tppti*) which showed good solubility characteristics in [bmim][PF_6] and was used in all the following catalyst evaluations.



Scheme 1. Initial steps of the hydroformylation mechanism.

3.2. In situ investigation of the rhodium catalyst in ionic liquids

Despite the fact that the mechanism for hydroformylation catalysis is well established in organic [16] and aqueous [17] solvents, we wanted to study the active rhodium species in an ionic liquid environment (Scheme 1). To build upon a recent study focused on the in situ investigation of the rhodium-sulfoxantphos hydroformylation catalyst [18] in ionic liquids, we set out to investigate the rhodium-tppts catalyst system using HP-NMR techniques. In these experiments a mixture consisting of $Rh(CO)_2$(acac), tppts (Rh/P ratio 1:6) and [bmim][BF_4] was pressurized with 60 psi of $^{13}CO/H_2$ (1:1) in a sapphire NMR tube. To ensure the formation of the catalyst species $HRh(^{13}CO)(tppts)_3$ (**1a**) the solution was shaken at 60 °C for 1 h. After the pressure was released the $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectra were recorded (Fig. 1). The $^{31}P\{^1H\}$ NMR spectrum of the catalyst solution showed a doublet at 32.2 ppm for the rhodium bound tppts ligand and a minor resonance at 29.1 ppm for the uncoordinated phosphine oxide species tri(*m*-sulfonyl)triphenylphosphine oxide trisodium (tppts-oxide) (Table 1). A strong signal at −3.7 ppm was apparent for uncoordinated tppts. The corresponding $^{13}C\{^1H\}$ NMR spectrum of the catalyst solution showed a doublet at 195.2 ppm for the metal coordinated carbon monoxide. For a better comparison we also investigated $HRh(^{13}CO)(PPh_3)_3$ **1b** in toluene-d^8 under $^{13}CO/H_2$ (1:1) pressure. Furthermore, we used the HP-NMR study by Horváth et. al. [17] for hydroformylation catalysis in aqueous phases as a reference. Thus, similar to the results of our catalyst investigation in [bmim][BF_4], the $^{31}P\{^1H\}$ NMR spectrum of **1b** in tolu-

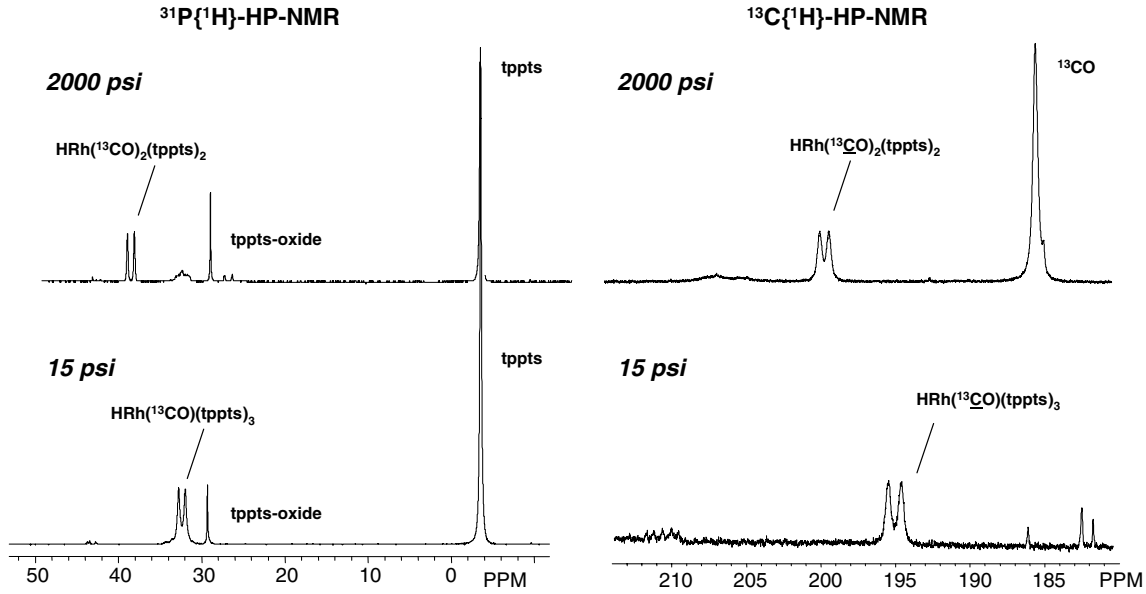


Fig. 1. High-pressure NMR investigation of a rhodium hydroformylation catalyst in the ionic liquid [bmim][BF_4] at 15 and 2000 psi $^{13}CO/H_2$ (1:1).

ene-d^8 showed a doublet at 37.8 ppm for the rhodium bound PPh_3 (Table 1). The corresponding $^{13}C\{^1H\}$ NMR spectrum of the solution exhibited a doublet at 206.6 ppm for the coordinated carbon monoxide ligand. On the basis of these spectroscopic results it can be assumed that the structure of $HRh(^{13}CO)(tppts)_3$ in [bmim][BF_4] is very similar to that of $HRh(^{13}CO)(PPh_3)_3$ in toluene-d^8.

Following this we studied the rhodium catalyst in ionic liquids under elevated syngas pressure. Mechanistic studies [16] of $HRh(^{13}CO)(PPh_3)_3$ (**1b**) and $HRh(^{13}CO)_2(PPh_3)_2$ (**2b**) in toluene have suggested the presence of two coordinatively unsaturated catalyst intermediates $\{HRh(^{13}CO)(PPh_3)_2\}$ (**3b**) and $\{HRh(^{13}CO)_2(PPh_3)\}$ (**4b**). While both of these species are responsible for the production of aldehyde, it is believed that the normal to iso ratio (*n*/*i*) of the aldehyde is largely controlled by the competitive reactions of the olefin with the species **3b** and **4b** resulting in high or low *n*/*i* ratios, respectively. Although we are not able to record the NMR spectra of the reactive intermediates **3b** and **4b**, we can observe the resting state of the catalyst in form of complexes **1b** and **2b**. As the equilibrium between these two complexes is strongly pressure dependent, complex **1b** can readily be converted into complex **2b** at a $^{13}CO/H_2$ (1:1) pressure of less than 300 psi in a toluene-d^8 solution. In contrast, the investigation of $HRh(^{13}CO)(tppts)_3$ **1a** in an aqueous solution showed that applied pressures of $^{13}CO/H_2$ (1:1) as high as 3000 psi did not lead to the formation of $HRh(^{13}CO)_2(tppts)_2$ (**2a**) [17]. Based on this information, we pressurised the complex **1a** in [bmim][BF_4] stepwise with $^{13}CO/H_2$ and recorded the corresponding NMR spectra. The increasing pressure resulted in the formation of new doublets in both the $^{31}P\{^1H\}$ NMR spectrum (39.1 ppm) and the $^{13}C\{^1H\}$ NMR spectrum (199.2 ppm). By going to higher syngas pressures, the intensities of the NMR resonances for **1a** continued to decrease. Finally, at a $^{13}CO/H_2$ pressure of 2000 psi the NMR signals for **1a** disappeared. We believe that the newly formed species in [bmim][BF_4] has the solution structure of $HRh(^{13}CO)_2(tppts)_2$ (**2a**) and corresponds to **2b** which has been observed in toluene-d^8 under elevated pressure. After the ionic liquid sample was depressurized the NMR resonances of **1a** were detected again. It is interesting to note that the NMR signal of the high-pressure species **2a** in [bmim][BF_4] exhibited a down field shift, while the related complex **2b** in toluene-d^8 showed an upfield shift for the corresponding resonances. Although the ionic liquid and toluene samples showed the formation of the high-pressure rhodium species **2a** and **2b**, the chemical environment on the metal center in [bmim][BF_4] seems to be different to that in the toluene-d^8. Finally, it should be noted that the in situ formation of **1a** in [bmim][BF_4] can be accompanied by a series of side reactions. Although it was possible to suppress most of the side reactions through the use of high-purity ionic liquids, we did sometimes observe the formation of unknown species during the investigation of **1a** in ionic liquids.

3.3. Preparation of high-purity ionic liquids

In addition to being important for catalyst lifetime, we also discovered that the purity of the ionic liquid is critical for the stability of the ionic liquid phase itself. In several biphasic hydroformylation experiments we observed the partial decomposition of [bmim][BF_4] and [bmim][PF_6]. After carefully analyzing the purity of these ionic liquids we found that trace amounts of acid were responsible for their decomposition. For this reason, we have used a synthesis procedure which produces high-purity ionic liquids [14]. In our synthesis 1-butyl-3-methyl-imidazolium chloride and 1,2-dimethyl-3-butyl-imidazolium chloride were either treated with $NaBF_4$ or KPF_6 giving [bmim][BF_4], [bmim][PF_6] and [bdmim][PF_6], respectively. The reactions were carried out in water followed by extraction with dichloromethane. The work-up procedure involved the filtration of the extract through a bed of activated carbon and alumina which produced high-purity ionic liquids after the removal of the solvent. The ionic liquids prepared via this route showed a neutral pH value and did not suffer from any substantial decomposition during hydroformylation reactions.

3.4. Evaluation of biphasic hydroformylation catalysis using ionic liquid phases

As a control experiment in the beginning of our study we investigated the reactivity of $Rh(CO)_2(acac)$ in [bmim][PF_6] without a ligand for the hydroformylation of hexene-1. The formed catalyst species produced C_7-aldehyde with a TOF between 21 and 2 min^{-1} and showed an *n*/*i* ratio for the aldehyde of 0.5–1.5 in the five respective runs. The low *n*/*i* ratio between 0.5 and 1.0 for the produced aldehyde is typically observed for rhodium catalysts in the absence of any coordinating ligand [15]. Typically under these reaction conditions, as mentioned earlier, rhodium forms an active rhodium-hydrido-carbonyl complex which readily converts olefin to aldehyde. The active species has no charge and dissolves preferentially in the organic phase. As a result, a substantial amount of the rhodium metal leaches from the ionic liquid into the organic layer. The loss of metal in our control experiment was also confirmed by rhodium metal analysis of the isolated product phases. After the first catalyst run an amount of 119 ppm of rhodium metal was found in the product phase. This amount corresponded to almost 75% of the initial rhodium charge to the reactor. Further runs showed continuous leaching of the metal until >90% of the initial rhodium charge was

removed with the product phase. Corresponding to the loss of active metal species, the conversion of olefin was significantly reduced after every consecutive run. It is therefore not viable to run hydroformylation reactions in ionic liquids with rhodium catalysts which cannot be sufficiently retained in the ionic layer.

Our next investigation focused on the evaluation of $Rh(CO)_2(acac)$ with tppti* in [bmim][BF_4] (Fig. 2/Table 2/Entries 1–10). The initial two runs (Entries 1 and 2) were carried out at a CO/H_2 (1:1) pressure of 300 psi. After we observed an extended induction period of 450 minutes in the first recycle we increased the reactor pressure to 600 psi CO/H_2 (1:1) for all of the consecutive runs. The activity of the catalyst decreased in the following eight runs (Entries 3–10) with their TOF values decreasing from 14 to 4 min^{-1}. The *n*/*i* ratio of the aldehyde remained between 2.6 and 2.1. This ratio is typically observed for a rhodium based hydroformylation catalyst in the presence of a coordinating phosphine ligand (Rh/P ratio 1:10). The analysis of the resulting organic products revealed the presence of low amounts of soluble rhodium species. During the 10 runs almost 10% of the total rhodium charged was removed from the reactor with the product phase. Although the rhodium leaching contributed towards the drop in activity, other catalyst deactivation processes like the formation of rhodium carbonyl clusters are most likely the reason

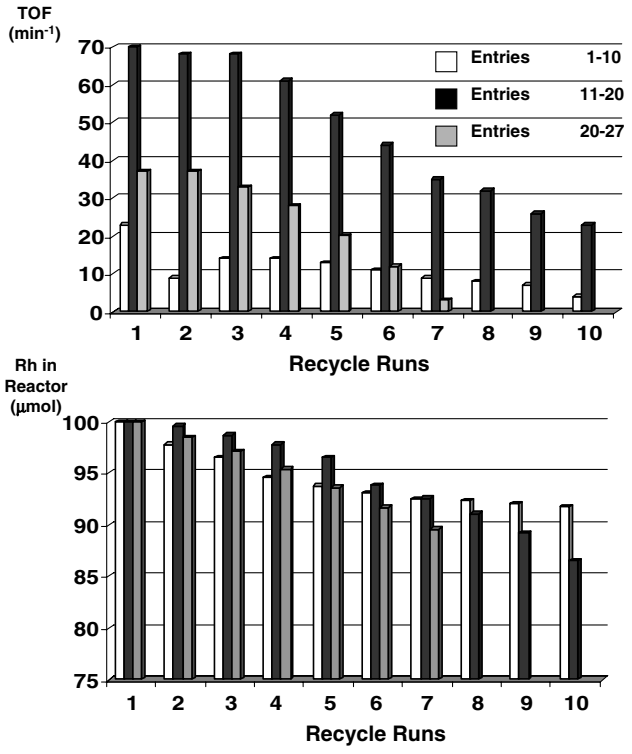

Fig. 2. TOF for biphasic hydroformylation reactions in different ionic liquid phases and rhodium metal content in the reactor during recycle runs.

for the loss in activity. The rhodium leaching from the ionic liquid phase into the organic layer may be associated with the solubility characteristics of [bmim][BF_4]. The ionic liquid has the ability to readily dissolve in water and other polar solvents. Depending on the aldehyde content in the product phase, small amounts of ionic liquid and rhodium complex can become soluble and leach into the organic layer. In one of our investigations (Entry 3) 2.7 ppm rhodium metal was detected in the organic phase at an aldehyde content of 61%. However, when the aldehyde level in the product phase was only 21% the amount of rhodium leaching was reduced to only 0.3 ppm (Entry 10). This trend indicated that the increasing polarity of the organic phase is partially responsible for the metal loss from the ionic liquid phase.

The next investigation focused on the evaluation of [bmim][PF_6]. All reactions were carried out at 600 psi CO/H_2 (1:1) and 100 °C using $Rh(CO)_2(acac)$ and tppti* (Rh/P ratio of 1:10) (Entries 11–20). The TOF values of the catalyst system decreased over the course of the investigation from 70 to 23 min^{-1}. Again the *n*/*i* ratios of the produced aldehydes were observed from 2.6 to 1.8, supporting a phosphine-stabilized rhodium center as the catalytically active species. Although the initial rhodium retention was better than in [bmim][BF_4], after the 6th recycle run the metal leaching became more prominent and surpassed the values obtained for the [bmim][BF_4] system.

To investigate the impact of a changing metal to phosphine ratio we also investigated the [bmim][PF_6] ionic liquid system with a Rh/P ratio of 1:3 and 1:100. As expected the TOF for the reaction carried out with a lower amount of phosphine ligand (1:3) was slightly increased to 75 min^{-1} (Entry 28), while the TOF for the catalysis with the higher loading (1:100) was reduced to 30 min^{-1} (Entry 29). Under both sets of reaction conditions the *n*/*i* ratios remained unchanged at 2.5 and 2.6. However, the higher amount of phosphine ligand helped to better retain the rhodium catalyst and reduced the metal loss to levels below the detection limit.

To broaden the scope of the studied ionic liquids we also investigated [bdmim][PF_6] (Entries 21–27). Although the TOF values were slightly higher than those obtained for [bmim][BF_4], ranging from 37 to 3 min^{-1}, the rhodium leaching was significantly increased. This may indicate that the less polar cation is partially responsible for the higher rhodium loss. Furthermore, the catalyst system showed a drastically reduced activity after the 5th recycle run and we concluded the campaign after the 7th run due to low activity.

In our final study we investigated the conventional homogeneous rhodium catalyst under similar reaction conditions. The reaction was carried out in toluene using $Rh(CO)_2(acac)$ together with PPh_3 (Rh/P ratio of 1:10). The homogeneous catalyst in a monophasic system

exhibited a significantly higher TOF value of 400 min^{-1} with an *n*/*i* ratio of 2.6 for the produced aldehyde. For comparison the best TOF values obtained for any of the biphasic hydroformylation runs in ionic liquids ranged between 70 and 75 min^{-1} under comparable reaction conditions. Finally the homogeneous catalyst system showed a significantly higher reactivity, however, the biphasic ionic liquid catalyst systems offer the possibility of convenient product separation and easy catalyst recovery.

4. Conclusion

The ionic liquids [bmim][BF_4], [bmim][PF_6] and [bdmim][PF_6] were successfully used for the immobilization of rhodium based hydroformylation catalysts and have been evaluated for the production of aldehyde in a liquid–liquid biphase environment. The purity of the ionic liquids was strictly monitored to avoid any decomposition of the catalyst, substrate and/or ionic liquid. A complimentary HP-NMR study confirmed that the solution structure of $HRh(^{13}CO)(tppts)_3$ (**1a**) in [bmim][BF_4] is similar to that of $HRh(^{13}CO)(PPh_3)_3$ (**1b**) in toluene-d^8. Furthermore, the NMR investigation at elevated syngas pressures showed that **1a** lies in equilibrium with the high-pressure species $HRh(^{13}CO)_2(tppts)_2$ (**2a**). As expected the activity of the biphasic ionic liquid system containing the Rh/tppti* catalyst is approximately one order of magnitude lower than the conventional Rh/PPh_3 catalyst in toluene. The Rh/tppti* catalyst system showed a decrease of activity in the semicontinuous hydroformylation of hexene-1 due to catalyst deactivation and/or metal loss. The *n*/*i* ratio of the produced heptanal only slightly increased after changing the Rh/P ratio from 1:3 to 1:100 in [bmim][PF_6]. The loss of rhodium metal from the ionic liquid phases seemed to be dependent on the solubility characteristics of the ionic liquid and on the concentration of the aldehyde in the organic phase. In this respect, the ionic liquid [bmim][PF_6] was preferred due to its very low miscibility with polar substances. Although ionic liquids offer tremendous opportunities for the development of novel separation technologies, further progress will be necessary to fully establish their potential as a large-volume reaction medium.

Dedicated to Professor Malcolm Green, whose inspiring appetite for discovery has given us such an amazing breadth of new inorganic and organometallic chemistry

Abstract

Oxidation of the sterically crowded complex $(C_5Me_5)_3U$ provides access to two classes of uranium compounds that previously were unknown, a U(III) oxide and a U(IV) carbene, $[(C_5Me_5)_2U]_2(\mu\text{-}O)$ (**1**) and $(C_5Me_5)_2U(O)[C(NMeCMe)_2]$ (**2**), respectively. The structure of **1** allows a direct actinide versus lanthanide comparison within the $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ class. The uranium carbene complex (**2**), represents a rare example of a monometallic uranium mono-oxo-compound. Complex **1** has a 2.094(14) Å U(1)–O(1) bond distance and a 171.5(6)° U(1)–O(1)–U(2) bond angle while the U(1)–O(1) and U(1)–C(21)[C(NMeCMe)$_2$] bond distances in complex **2** are 1.917(6) and 2.673(7) Å, respectively.

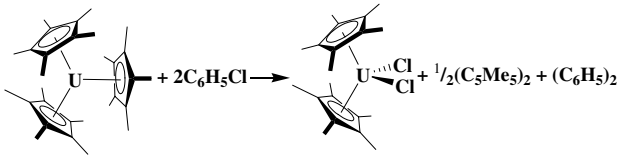
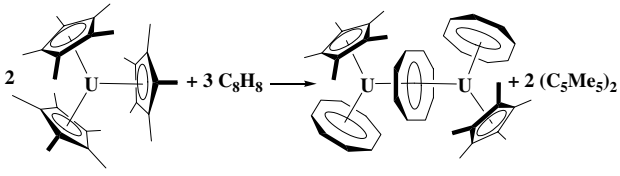
1. Introduction

Recent studies of the chemistry of the sterically crowded trivalent uranium complex, $(C_5Me_5)_3U$ [1,2], have shown that it can function as a two or three electron reductant depending on the substrate available, as shown in Eqs. (1) and (2), respectively [3,4].



(1)



(2)

The reductive reactivity arises not only from the conventional metal-based U(III)/U(IV) redox couple, as is typical for trivalent uranium complexes, but also from $C_5Me_5^{1-}/C_5Me_5$ ligand-based reductions arising from the steric crowding in the system. Since the reductive chemistry of the normally inert $C_5Me_5^{1-}$ ligand appears to be activated by the steric crowding, it has been called sterically induced reduction (SIR) [4].

One reaction common to any type of reductant is oxidation to form oxide products. With organometallic complexes of electropositive metals, this is usually avoided by using rigorously purified inert atmospheres,

doi:10.1016/j.poly.2004.08.007

solvents, reagents, and in some cases even silylated glassware [5]. Nevertheless, oxide products occasionally arise despite the best efforts to avoid extraneous oxidants [6–10].

When highly reactive organometallic complexes react with oxygen, insoluble oxide products often form that are difficult to characterize. Hence, little is known about the preliminary stages of this common reaction. Only in the occasional cases in which fully characterizable organometallic oxide complexes are obtained as byproducts can such information be obtained [11–15]. In organometallic uranium chemistry, only U(IV), U(V), and U(VI) oxides are familiar. Oxide complexes of uranium in the trivalent state are not generally accessible since oxidation of the metal is likely and this usually results in formation of tetra-, penta-, or hexavalent uranium oxides [16–20].

We report here on two new organometallic uranium oxide products formed from the $(C_5Me_5)_3U$ reduction system. One is unusual in that it is an organometallic U(III) oxide. To our knowledge, this is the first molecular trivalent uranium oxide reported. This complex provides the first opportunity to make direct structural comparisons between $5f^3$ and $4f^3$oxides, a comparison that is of interest in regard to the separation of lanthanide contaminants from highly reactive actinide components in spent nuclear fuel [21–23]. The other compound represents a rare example of a uranium terminal monooxide. Generally uranium oxo-compounds contain the dioxo $(O{=}U{=}O)^{2+}$ unit and few examples of terminal mono-oxides have been reported. Furthermore, this second compound constitutes the first U(IV) *N*-heterocyclic carbene in the literature. The unusual structural aspects of both complexes are discussed.

2. Experimental

2.1. $[(C_5Me_5)_2U]_2(\mu\text{-}O)$ (1)

In an argon-filled glovebox free of coordinating solvents, X-ray quality crystals of **1** were obtained unexpectedly from an NMR sample of a reaction between $(C_5Me_5)_3U$ [1,2] and potassium graphite in toluene. A large blackberry-colored crystal of approximate dimensions $0.20 \times 0.33 \times 0.78$ mm was mounted on a glass fiber and transferred to a Bruker CCD platform diffractometer. The SMART [24] program package was used to determine the unit cell parameters and for data collection (25 s/frame scan time for a sphere of diffraction data). The raw frame data was processed using SAINT [25] and SADABS [26] to yield the reflection data file. Subsequent calculations were carried out using the SHELXTL [27] program. There were no systematic absences. The noncentrosymmetric triclinic space group $P\bar{1}$ was assigned and later determined to be correct ($Z = 1$). The structural parameters for **1** are summarized in Table 1.

The structure was solved by direct methods and refined on F^2 by full-matrix least-squares techniques. The analytical scattering factors [28] for neutral atoms were used throughout the analysis. Hydrogen atoms were included using a riding model. One molecule of toluene solvent was present per formula unit. Attempts to solve the structure using the centrosymmetric space group $P\bar{1}$ were unsuccessful. At convergence, $wR_2 = 0.0859$ and Gof = 1.103 for 452 variables refined against 7845 data (0.80 Å). As a comparison for refinement on F, $R_1 = 0.0351$ for those 7673 data with $I > 2.0\sigma(I)$. The structure was refined using the TWIN and BASF (0.26) instructions [27]. Selected bond distances and angles for **1** and **2** are given in Table 2.

2.2. $(C_5Me_5)_2U(O)[C(NMeCMe)_2]$ (2)

In an argon-filled glovebox free of coordinating solvents, X-ray quality crystals of **2** were obtained from an NMR sample of a reaction between $(C_5Me_5)_3U$ [1,2] and the carbene $C(NMeCMe)_2$ [29] in toluene. A red/brown crystal of approximate dimensions $0.17 \times 0.20 \times 0.22$ mm was mounted on a glass fiber and transferred to a Bruker CCD platform diffractometer. The SMART [24] program package was used to determine the unit cell parameters and for data collection (40 s/frame scan time for a sphere of diffraction data). The raw frame data was processed using SAINT [25] and SADABS [26] to yield the reflection data file. Subsequent calculations were carried out using the SHELXTL [27] program. The diffraction symmetry was 2/*m* and the systematic absences were consistent with the centrosym-

As a comparison for refinement on F, $R_1 = 0.0457$ for those 3299 data with $I > 2.0\sigma(I)$ [27].

3. Results and discussion

3.1. $[(C_5Me_5)_2U]_2(\mu\text{-}O)$ (1)

Complex **1** was isolated from a reaction of $(C_5Me_5)_3U$ with KC_8 in toluene. Formation of **1** in this system is unusual for several reasons. First, the oxide is obtained in a reducing environment. Second, formation of oxides from U(III) organometallic complexes generally gives products in at least the U(IV) oxidation state. For example, stoichiometric addition of oxygen to the less crowded trivalent $(C_5H_5)_3U$ generated the tetravalent product, $[(C_5H_5)_3U]_3(\mu\text{-}O)$ [17]. Similarly, a tetravalent uranium oxide, $\{[C_5H_3(SiMe_3)_2]_2U\}(\mu\text{-}O)_2$, is isolated from hydrolysis of $[C_5H_3(SiMe_3)_2]_3U$ with one equivalent of H_2O, a reaction that goes through a trivalent bridging hydroxide intermediate, $\{[C_5H_3(SiMe_3)_2]_2U\}_2(\mu\text{-}OH)_2$ [20]. In addition, trivalent uranium complexes generally react with oxide delivery agents, such as R_3NO, by the U(III)/U(IV) redox couple [18,19].

Finally, if the oxide is formed by oxidation of a $C_5Me_5^{1-}$ ligand, it would be the first reaction identified in which the SIR involving the $C_5Me_5^{1-}$ reduction precedes the U(III) electron transfer. For example, the reaction of $(C_5Me_5)_3U$ with aryl halides (Eq. (1)) proceeds by reduction with U(III) followed by the $C_5Me_5^{1-}$ based sterically induced reduction [3]. Hence, regardless of the oxygen source, be it O_2, H_2O, or some other oxide delivery agent, a U(IV) product might be expected instead of the U(III) complex isolated here.

Since complex **1** was isolated from the reaction of $(C_5Me_5)_3U$ and KC_8 in toluene, an alternative possibility involves initial reductive cleavage of a $C_5Me_5^{1-}$ ring by KC_8 to form a $[(C_5Me_5)_2U]_2(MeC_6H_5)$ intermediate which subsequently reacts with the oxygen impurity [30–32]. However, attempts to make **1** directly along these lines have been unsuccessful.

The structure of $[(C_5Me_5)_2U]_2(\mu\text{-}O)$, Fig. 1, provides an interesting addition to uranium oxides, Table 2, as well as to the series of $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ oxides previously identified for several trivalent lanthanides (M = La [9], Nd [33], Sm [11], and Y[34]), Table 3. Direct comparisons of analogous lanthanide and actinide complexes and identification of the subtle differences between these elements could provide the basis for effective actinide/lanthanide separation methods [21–23,35–38]. Although several classes of actinide and lanthanide complexes have been compared [39–42], no studies have been published on trivalent organometallic metal oxides since synthetic routes to the U(III) oxide complexes were not available. The structure of **1** allows a direct comparison of U(III) with the trivalent lanthanides and an evaluation of 5f/4f similarities and differences.

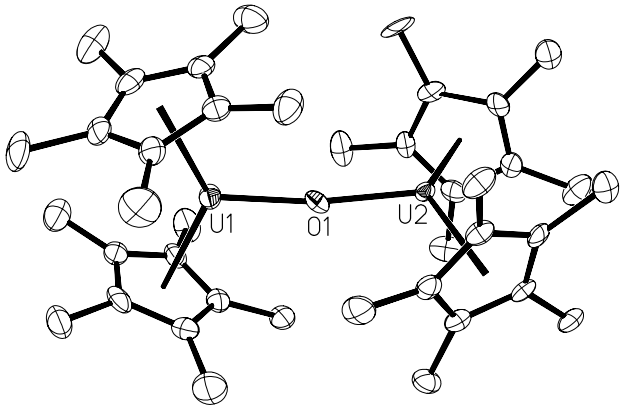

Fig. 1. A thermal ellipsoid plot of **1**, $[(C_5Me_5)_2U]_2(\mu\text{-}O)$, with thermal ellipsoids drawn to 50% probability. The molecule of toluene has been omitted for clarity.

Table 3
Bond distances and ionic radii [44] of $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ (M = U, La [9], Nd [34], Sm [11], Y [35]) complexes

Compound	Ionic radius (Å)	M–O distance (Å)	M–O–M angle (°)	M–C(C_5Me_5) (Å)	M-ring centroid (Å)
$[(C_5Me_5)_2La]_2(\mu\text{-}O)$	1.10	2.1443(3)	180	2.811(3)–2.852(3)	2.561
$[(C_5Me_5)_2U]_2(\mu\text{-}O)$	1.075	2.125(13) 2.094(14)	171.5(6)	2.676(9)–2.823(9)	2.455–2.487
$[(C_5Me_5)_2Nd]_2(\mu\text{-}O)$	1.046	2.101	180	2.739–2.796	2.496
$[(C_5Me_5)_2Sm]_2(\mu\text{-}O)$	1.02	2.094(1)	180	2.72(1)–2.77(1)	2.470
$[(C_5Me_5)_2Y]_2(\mu\text{-}O)$	0.96	2.0525(10)	180	2.656(5)–2.710(5)	2.396

No error limits were available for the Nd structure.

The four structurally characterized lanthanide analogs of **1**, $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ (M = La [9], Nd [33], Sm [11], and Y [34]), display a direct correlation between the M–O bond distances and the ionic radius of the metal. This is as expected for an isomorphous series of complexes in which the bonding is predominantly ionic. Each of these complexes also has a 180° M–O–M angle. This can be rationalized on the basis of steric interactions between the two bulky $[(C_5Me_5)_2M]^+$ units which collectively have the sterically preferred tetrahedral arrangement of the four $C_5Me_5^{1-}$ rings. Alternatively, the linear M–O–M angle could be attributed to multiple bonding between the oxygen and the metals.

Complex **1** is not isomorphous with the other members of the $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ (M = La, Nd, Sm, Y) oxide family and it crystallizes with a molecule of toluene in the cell. The closest approach of the planar toluene molecule to U(1) is 6.73 Å.

On the basis only of ionic radii and extrapolating from the bond distances of the $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ complexes (La, Nd, Sm, and Y [9]), a U–O bond of 2.126 Å would be expected. The 2.094(14) Å U(1)–O(1) and 2.125(13) Å U(2)–O(1) distances in complex **1** are equivalent to this prediction within the experimental error. Hence, an ionic estimation of the U–O bond length based on Shannon radii is close to the observed values [43]. Related to this, Ephritikhine and co-workers [41]have recently observed that U–O distances in the $\{UI_2[OP(C_6H_5)_3]_3\}$ {I} complex can also be predicted based on ionic radii.

Although the U–O distance in **1** is consistent with those of the $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ complexes, the geometry differs slightly in that the U–O–U angle is 171.5(6)° rather than the usual 180°. As shown in the end-on view of Fig. 2, the four $C_5Me_5^{1-}$ ring centroids are still nearly tetrahedral. The (ring centroid)–U(1)–(ring centroid) plane makes a 91.2° angle with the (ring centroid)–U(2)–(ring centroid) plane. In the lanthanide structures, this value is exactly 90° by the crystallographic symmetry.

Associated with this structural distortion, the coordination environments around U(1) and U(2) are not rigorously trigonal planar as in the lanthanide structures. U(1) and U(2) are displaced from the plane defined by their two ring centroids and the oxide by 0.13 and 0.25 Å, respectively. The structure of **1** also differs from the previously characterized $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ complexes in that each uranium atom has one ring in which all of the U–C(C_5Me_5) bond distances are similar, 2.716(9)–2.749(10) Å for U(1)–C(1–5)(C_5Me_5), and one ring that has a wide range of U–C(C_5Me_5) bond distances, 2.676(9)–2.823(9) Å for U(1)–C(11–15)(C_5Me_5). The longest U–C(C_5Me_5) distances are found for the carbons most distant from the oxide and the interior of the structure. In comparison, the values for $[(C_5Me_5)_2Sm]_2(\mu\text{-}O)$ are 2.72(1)–2.77(1) Å for both rings. In both **1** and the lanthanide structures, the rings on each metal are closer to eclipsed than staggered, which is consistent with a sterically crowded environment [44].

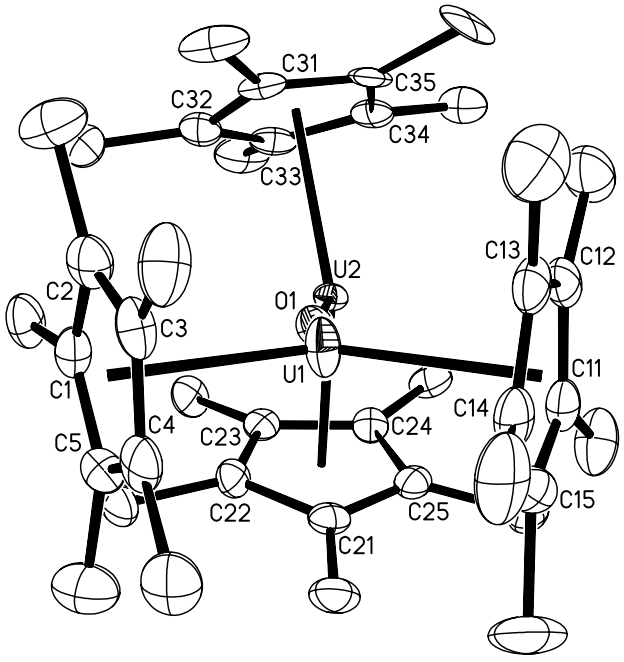

Fig. 2. A thermal ellipsoid plot of **1**, $[(C_5Me_5)_2U]_2(\mu\text{-}O)$, with thermal ellipsoids drawn to 50% probability. The molecule of toluene has been omitted for clarity.

The structure of **1** is unusual in that a more covalent 5f $[(C_5Me_5)_2M]_2(\mu\text{-}O)$ complex might be expected to have more M–O multiple bonding which would generate a shorter M–O distance and a rigorously linear M–O–M

angle. Neither of these structural features are observed in **1**. It is interesting to compare the 2.094(14) and 2.125(13) Å U–O distances as well as the 171.5(6)° U–O–U angle in **1** to those in related organouranium oxide and sulfide structures. The tetravalent uranium oxide complexes $[(C_5H_5)_3U]_2(\mu\text{-O})$ [17] and $[(C_5H_4SiMe_3)_3U]_2(\mu\text{-O})$ [16] both have 180° U–O–U angles and similar 2.0881(4) and 2.1053(2) Å U–O distances, respectively. The sulfur bridged complex, $[(C_5H_4Me)_2U]_2(\mu\text{-S})$, has longer 2.60(1) Å U–S distances that separate the metallocene units to a greater extent than in the oxide and a 164.9(4)° angle is observed [45]. The slightly bent structure of **1** differs from all of these prior examples.

3.2. $(C_5Me_5)_2U(O)[C(NMeCMe)_2]$ (2)

Complex **2** was isolated from a reaction between $(C_5Me_5)_3U$ and the strong sigma bonding N-heterocyclic carbene (NHC) ligand, $C(NMeCMe)_2$ [46–48]. Although a carbene complex was isolated, this was accompanied by unexpected oxidation and complex **2** represents not only the first U(IV) carbene complex, Fig. 3, but also a rare example of a uranium mono-oxide. Although the $[UO_2]^{2+}$ unit is common in uranium chemistry [49–52], only a few reports of uranium terminal mono-oxides are in the literature [18,19,53]. To our knowledge this is the first such example in organometallic U(IV) chemistry.

Complex **2** is assigned a U(IV) oxide structure rather than a U(III)–OH structure on the basis of the short 1.916(6) Å U–O bond length, Table 2. The U–O distance in **2** is shorter than (a) the corresponding distance in bridging U(IV) oxides, i.e. the 2.0881(4) Å in $[(C_5H_5)_3U]_2(\mu\text{-O})$ [17], (b) the 2.145(6) Å U–O(OH) distance in the U(IV) terminal hydroxide complex $U(NN'_3)(OH)(CH_2PMe_3)$ [8], and (c) the 2.44(2) Å U–$O(OH_2)$ distance in the U(VI) terminal H_2O complex $[C_{20}H_{36}O_6][(UO_2)_2(H_2O)_6](ClO_4)_2$ [50]. The U–O bond length in **2** is longer than those in higher valent uranium organometallic terminal mono-oxide complexes: 1.859(6) Å in $(C_5Me_5)_2U^{(V)}(OAr)(O)$ [18], 1.844(4) Å in $(C_5Me_5)_2U^{(VI)}(NAr)(O)$ [19], and 1.76(1) Å in $U^{(VI)}OCl_5^{1-}$ [53]. U–O distances of 1.70–1.76 Å are typical in $U^{VI}O_2$ uranyl compounds [49–52].

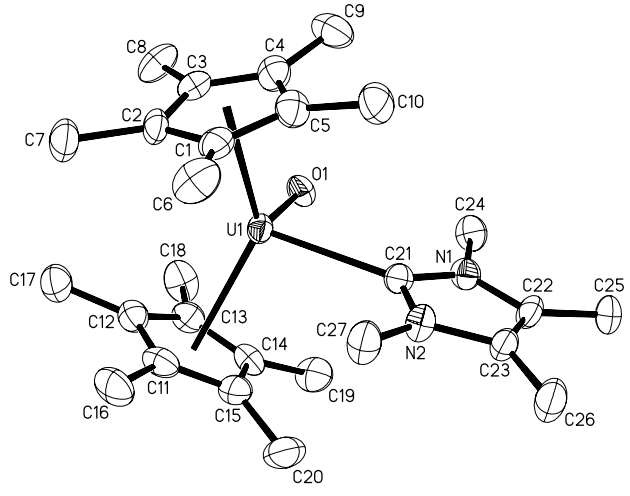

Fig. 3. A thermal ellipsoid plot of **2**, $(C_5Me_5)_2U(O)[C(NMeCMe)_2]$, with thermal ellipsoids drawn to 50% probability.

Recently, NHC ligands have been shown to function as effective sigma bonding ligands in the hexavalent uranium dioxide complexes, $UO_2Cl_2[C(NArCH)_2]_2$ (**3**) and $UO_2Cl_2[C(NArCCl)_2]_2$ (Ar = 2,4,6-$Me_3C_6H_2$) (**4**) [46]. Trivalent uranium carbenes are also known in $[(Me_3Si)_2N]_3U[C(NMeCMe)_2]$ (**5**) and $[(^{Ad}ArO)_3tacn]U[C(NMeCMe)_2]$ (**6**) [55]. The 2.636(9) Å U–C(NHC) distance in tetravalent **2** is indistinguishable from those in hexavalent **3**, 2.626(7) Å, and **4**, 2.609(4) Å [46]. In contrast, the U–C(NHC) distances in trivalent **5** and **6** are 2.672(5) and 2.789(14) Å, respectively [54].

The carbene and oxide donor atoms are not located symmetrically with respect to the $(C_5Me_5)_2U^{2+}$ metallocene unit. The $C_5Me_5^{1-}$ rings are tipped toward the oxide side of the metallocene and away from the sterically bulky carbene. As a result the U–C(C_5Me_5) distances for C(3), C(4), C(13), and C(14) are significantly shorter than the others. These are in the 2.72(1)–2.75(1) Å range, whereas C(2), C(5), C(12), and C(15) range from 2.82(1)–2.83(1) Å. The longest U–C(C_5Me_5) distances are 2.871(9) and 2.858(9) Å for C(1) and C(11), the carbon atoms furthest from the oxide ligand. The 136.3° (ring centroid)–U–(ring centroid) angle is normal and is not in the range of the 120° angle found for the sterically crowded $(C_5Me_5)_3M$ complexes [55].

4. Conclusion

The special reactivity of the sterically crowded $(C_5Me_5)_3U$ has provided synthetic access to the first examples of a U(III) oxide and a U(IV) terminal oxide and carbene complex, compounds that have not been accessible by traditional reactions pathways. The full synthetic utility of the sterically crowded $(C_5Me_5)_3M$ complexes for formation of such compounds remains to be determined. Although additional examples will be required to determine the generality of the structural features of these complexes, they provide the first data for comparison with related analogs.

5. Supporting material

Details on data collection and refinement, fractional atomic coordinates, anisotropic displacement parameters and full list of bond lengths and angles in CIF format has been deposited at the Cambridge Crystallographic

Data Centre, CCDC No. 235982 for compound **1** and CCDC No. 235983 for compounds **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac. uk).

Synthesis and characterisation of $[(\eta^6\text{-cymene})Ru(L)X_2]$ compounds: single crystal X-ray structure of $[(\eta^6\text{-cymene})Ru(P\{OPh\}_3)Cl_2]$ at 203 K

Dedicated to Malcolm Green on his retirement; thank you for teaching me that chemistry should be fun and that the "suck it and see" approach is the most fun of all

Abstract

Treatment of the chloro bridged dimer $\{[(\eta^6\text{-cymene})RuCl]_2(\mu\text{-}Cl)_2\}$ (**1**) with the donor molecules $P(OPh)_3$, $P(OMe)_3$, PPh_3, PMe_3, CO, SMe_2, CN^tBu and CNTos in hot hexane causes bridge splitting reactions that produce the monomeric compounds $[(\eta^6\text{-cymene})Ru(L)Cl_2]$, (**4**)–(**11**), respectively. Use of the chiral isonitrile *S*(−)-α-methylbenzylisonitrile produced the corresponding complex **12**. The diiodo analogues, **13**–**15**, were prepared similarly from $\{[(\eta^6\text{-cymene})RuI]_2(\mu\text{-}I)_2\}$ (**3**) for $P(OPh)_3$, $P(OMe)_3$ and PPh_3, respectively. Insertion of tin(II) chloride into both metal–chlorine bonds was observed for $[(\eta^6\text{-cymene})Ru(P\{OMe\}_3)Cl_2]$ (**5**), while only monosubstitution was observed for $[(\eta^6\text{-cymene})Ru(PPh_3)Cl_2]$ (**6**). Halide abstraction in the presence of a substrate reaction has been used to prepare some selected cationic compounds which contain an asymmetric ligand environment. Reaction of $\{[(\eta^6\text{-cymene})RuCl]_2(\mu\text{-}Cl)_2\}$ with 1,2-bis(diphenylphosphino)-ethane under ionising conditions produced the cation $[(\eta^6\text{-cymene})Ru(dppe)Cl]PF_6$ (**20**). Selected compounds have been examined by $\{^{13}C\text{–}^1H\}$ heteronuclear correlation and $\{^1H\text{–}^1H\}$ COSY and NOESY experiments. The structure of $[(\eta^6\text{-cymene})Ru(P\{OPh\}_3)Cl_2]\cdot CH_2Cl_2$ (**4**) has been determined at −70 °C.

Keywords: Cymene; Ruthenium; X-ray

1. Introduction

The chemistry of $(\eta^6$-arene)ruthenium half-sandwich systems has been explored to a lesser extent than that of the isoelectronic $(\eta^5$-cyclopentadienyl)ruthenium systems. This is probably due to the requirement for 1,3- or 1,4-cyclohexadienes as ligand precursors; these are normally obtained by Birch reduction of the appropriate arene. However the diene precursor to $(\eta^6$-cymene)ruthenium compounds, (*R*)-α-Phellandrene, (5-isopropyl-2-methyl-1,3-cyclo-hexadiene) is commercially available and thus the bulk of the reported chemistry to date is of complexes of this arene ligand [1,2]. Other arene ligands such as mesitylene and hexamethylbenzene have generally been introduced by high temperature ligand exchange using the cymene dimer **1** and the free arene.

We have a developing interest in metal complexes which contain chiral at metal centres and/or chiral ligands. The present work describes the development of reaction chemistry designed to generate racemic $(\eta^6$-cymene)ruthenium complexes with an asymmetric ligand environment. These complexes have been examined

doi:10.1016/j.poly.2004.06.016

by NMR spectroscopy in order to investigate the chemical shift differentiation of the arene ring substituents.

Some of the compounds prepared have been reported previously; **4** and **6** [3–5], **5** and **7** [6], and **10** and **11** [7]. We have improved yields in some cases and provided fuller spectroscopic data in all these cases.

2. Results and discussion

Treatment of a suspension of red {[(η^6-cymene)RuCl]$_2$(μ-Cl)$_2$} (**1**) in hexane with triphenylphosphite, trimethylphosphite, triphenylphosphine or trimethylphosphine under reflux for several hours gave orange or red-orange suspensions of the monomeric compounds [(η^6-cymene)Ru(L)Cl$_2$], (**4**) to (**7**), respectively. The salmon-pink carbonyl compound **8** was prepared from the dimer starting material by stirring the hexane suspension under carbon monoxide (150 psig) for 2 h at 50 °C. An increase in the reaction time to 12 h resulted in the isolation of a small quantity of bright yellow crystals which contained two sharp infrared absorptions at 2080 and 2023 cm^{-1}. This is probably [(η^6-cymene)Ru(CO)$_2$Cl]Cl and was not investigated further. Similarly reactions with dimethylsulfide (SMe$_2$), *tert*-butylisonitrile (CN^{t}Bu) and *p*-toluenesulfonylmethylisonitrile (CNTos), gave the hexane insoluble compounds **9** to **11**, respectively (see Scheme 1).

Subsequent crystallisation of the precipitated products in each case from dichloromethane/petroleum ether provided crystalline products which were used for spectroscopic characterisation. The infrared spectra of **8**, **10** and **11** contain inter alia sharp absorptions at 2042 (ν_{CO}), 2133 (ν_{CN}) and 2162 cm^{-1} (ν_{CN}), indicating only a small degree of π-backbonding from the metal centre to the ligand π^* orbitals in the isonitrile complexes; the free ligand stretching frequencies being 2143, 2131 and 2150 cm^{-1}, respectively.

Scheme 1.

The diiodo complexes **12**, **13** and **14** were prepared similarly from {[(η^6-cymene)RuI]$_2$(μ-I)$_2$} (**3**) and the ligands in hot heptane solution (see Scheme 2). Treatment of the red dichloro complex **6** with an excess of sodium iodide in moist acetone also produced the purple diiodo complex **14** in 80% yield.

Reaction of anhydrous stannous chloride with **5** in tetrahydrofuran under reflux led to insertion into both ruthenium–chlorine bonds producing orange [(η^6-cymene)Ru(P{OMe}$_3$)(SnCl$_3$)$_2$)] (**15**). The poor solubility of this compound required long acquisition times to obtain NMR spectra and did not allow observation of tin satellites in the ^{31}P{^{1}H} spectrum. The ring protons on the cymene ligand of these complexes formally constitute an AA′BB′ spin system, but in all of the complexes **4**–**15** and the dimer starting materials **1**–**3** they appear as the more simple [AB]$_2$ spin system with J_{AB} being approximately 6 Hz. This is an expected result of both a very small value of $^5J_{HH}$ and rapid ring rotation relative to the [MX$_2$L] fragment; adoption of a static structure like that found in the solid state for [(η^6-cymene)Ru(P{OPh}$_3$)Cl$_2$] (**4**) (vide infra) must lead to two isolated [AB] spin systems. The ring substituent chemical shifts are collected in Table 1, and they do not suggest any correlation with ligand (L) donor or acceptor properties. The ring proton chemical shift differentiation ($\Delta\delta$) is largest for compounds **4**, **11** and **14**, zero for complex **7**, and similar to that of the dimer precursor for the other complexes. The nature of the three ligands is such that the ring protons are differentiated in all rotational conformations but it is likely that there may be some shielding process involving the ring current from a spatially close pendant phenyl ring. A complete assignment of the cymene ring protons in **6** and **12** was made possible by obtaining both COSY and NOESY spectra and demonstrates that the protons *ortho* to the isopropyl substituent (H$_{2,6}$,) are to low-field of those *ortho* to the methyl substituent (H$_{3,5}$). The assignments made in Table 1 assume that this is generally the case for these compounds.

Heteronuclear correlation spectra (^{13}C–^{1}H) were obtained for selected compounds to establish if there was a pattern which would facilitate assignment of the cymene ring chemical shifts for future compounds. Table 2 is a compilation of these data. It is clear from the values of $\Delta(\delta^{13}C)$ that the relative assignment of ^{13}C NMR chemical shifts for the ring methine groups is not predictable; in the free *p*-cymene ligand the chemical shifts are δ 126.3 and δ 129.0 for C$_{2,6}$ and C$_{3,5}$, respectively, while the ^{1}H NMR chemical shifts are isochronous at δ 7.32 [8].

Replacement of one of the two chloro ligands in the symmetrical compounds **4** to **11** would produce compounds which contain an asymmetric centre rendering

Scheme 2.

all the cymene ring protons inequivalent and also differentiating the isopropyl methyl groups. Such a product would be obtained as a racemic mixture under most reaction conditions and in the Schemes 3–5 only one enantiomer is drawn for clarity.

A valuable synthetic target would be to prepare neutral molecules of the type [(η^6-cymene)Ru(L)(Cl)X] where X is a different halogen; differing metal–halogen bond strengths in subsequent reactions could be exploited. All efforts to replace one chloro ligand with a bromo, cyano or iodo ligand using sodium or potassium salts failed, variation of stoichiometry, solvent, reaction time and temperature gave only mixtures of the symmetrical product, starting material and trace amounts of the required product. Later work with analogues containing more heavily substituted arene ligands has proved more successful [9]. Reaction of [(η^6-cymene)Ru(PPh_3)Cl_2] (**6**) with stannous chloride in tetrahydrofuran gave the orange complex [(η^6-cymene)Ru(PPh_3)($SnCl_3$)(Cl)] (**16**) (see Scheme 2), whose ^{1}H NMR spectrum contained an [AB] system (δ_A 6.11, δ_B 6.01) and two doublets (δ 5.29, 4.95) for the cymene ring protons. The isopropyl group methyl resonances occur as two doublets at δ 1.21, 1.14. The nature of the three ligands is such that the ring protons are differentiated in all rotational conformations but it is likely that the major conformation is one which has a pair of protons in a similar environment and the other pair more strongly differentiated, such as in Fig. 1.

In contrast to **15**, the greater solubility of **16** allowed the observation of the tin satellites in the $^{31}P\{^1H\}$ NMR spectrum; the values of $^2J(^{119}Sn–^{31}P)$ and $^2J(^{117}Sn–^{31}P)$ being 704 and 671 Hz, respectively.

Treatment of the dimer **1** with the chiral isonitrile ligand *S*(−)-α-methylbenzylisonitrile under the conditions used for compounds **10** and **11** gave red microcrystalline **17** (see Scheme 3). The cymene ring protons are all differentiated in the ^{1}H NMR spectrum of **17** as expected when a chiral centre is introduced. The remoteness of

the chiral centre from the cymene ring protons induces an equivalence of only 0.02 ppm between the positionally related pairs. The heteronuclear correlation spectrum (^{13}C–^{1}H) established the ((δ_H, δ_C) pairings (5.56, 87.9), (5.54, 87.5), (5.40, 87.6) and (5.38, 87.4) establishing the effect of the remote chiral centre on the cymene ring carbon atoms.

Halide abstraction in the presence of a substrate can also be used to generate asymmetric metal centres; thus the reaction of **4** with dimethylsulfoxide in hot methanol

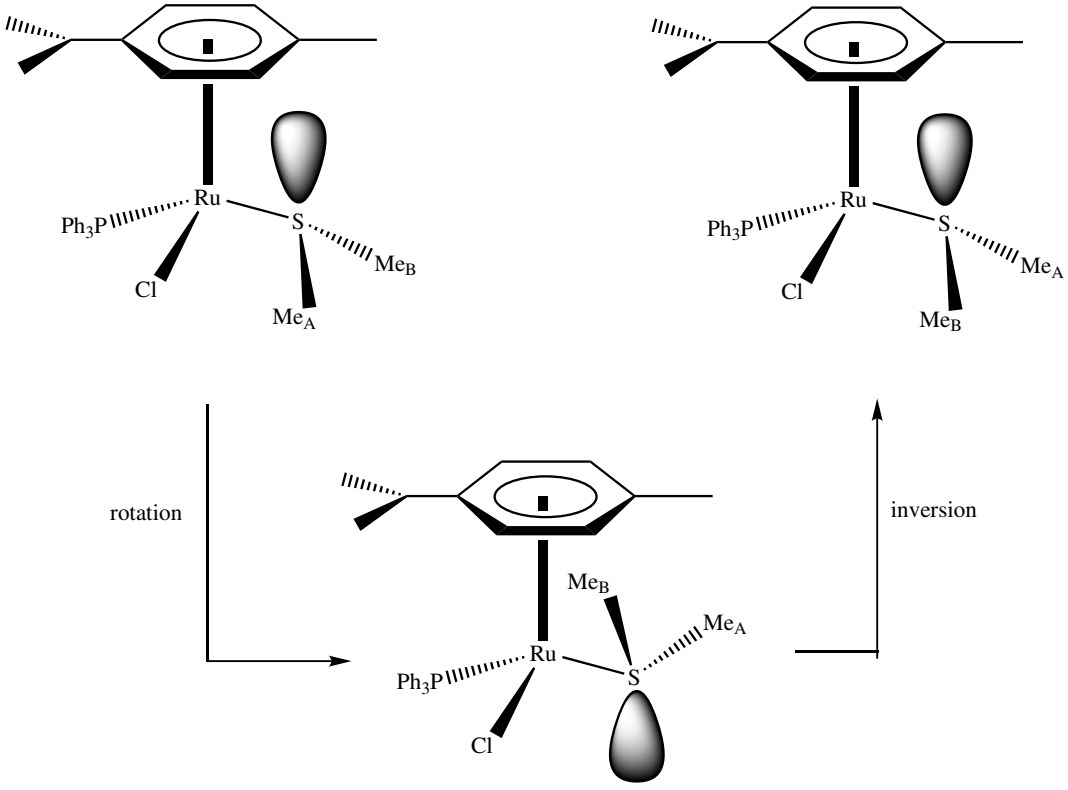
CNTos (**22**)
quinoline (**23**)

Scheme 4.



Scheme 5. Rotation–inversion process for the SMe_2 group in **20**.

solutions containing ammonium hexafluorophosphate produced bright yellow [(η^6-cymene)Ru(P{OPh}$_3$)(S{O}Me_2)(Cl)]PF_6 (**18**).

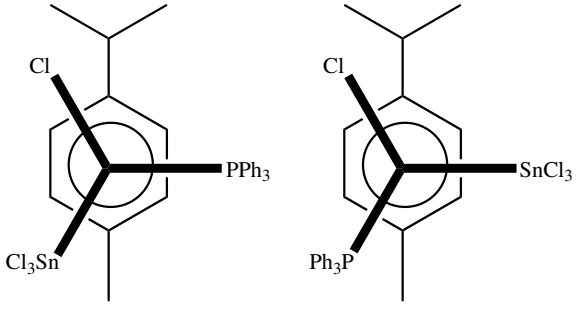


Fig. 1. Possible preferred conformations of **16**.

Similarly compound **5** could be transformed into the cation [(η^6-cymene)Ru(P{OMe}$_3$)(S{O}Me_2)(Cl)]PF_6 (**19**). The infrared spectra of **18** and **19** contained a weak band at 1124 and 1129 cm^{-1}, respectively, indicative of sulfur rather than oxygen coordination. Treatment of **6** with dimethylsulfide, *tert*-butylisonitrile, *p*-toluenesulfonylmethylisonitrile, or quinoline gave the requisite cationic compounds **20** to **23**, respectively, (*see* Scheme 4). The partial ^{1}H NMR chemical shift data for compounds **18** to **23** showing the cymene ring and isopropyl ligand methyl group resonances are collected in Table 3. The assignment of the ring protons is given such that H_A and H_B are mutually coupled and H_C and H_D form the other coupled pair. It seems reasonable to conclude that H_A and H_C are the $H_{2,6}$ pair while H_B and H_D are the $H_{3,5}$ ring protons. The appearance of "AB-roofing"

in the 300 MHz ^{1}H NMR spectra of these compounds has been used to aid this assignment.

These compounds all show inequivalence of the diastereotopic methyl groups of the isopropyl fragment and of the four ring protons. The relative shieldings for some particular complexes, such as **21** and **22**, indicate some preferred conformations leading to differential proximity shielding arising from the π-system of the isonitrile group. The dimethylsulfide group of compound **20** exhibited a broad singlet resonance (δ 2.40) at 294 K which changed into the expected pair of singlets on cooling (δ 2.49, 2.22); the barrier (ΔG_{245}) to this rotation-inversion process was 49.1 kJ mol^{-1} at coalescence (see Scheme 5).

In compounds **18** and **19** where this exchange process is not possible the methyl groups of the dimethylsulfoxide ligands were anisochronous (δ 3.55, 3.37) and (δ 3.55, 3.27), respectively, as required by the lack of molecular mirror planes.

The reaction of the dimer **1** with bis-1,2-(diphenylphosphino)ethane (dppe) and ammonium hexafluorophosphate in 1,2-dichloroethane under reflux produced the symmetrical cation [(η^6-cymene)Ru(dppe)(Cl)]PF_6 (**24**). The conductivity of a dilute nitromethane solution (ca. 5 mM) of this salt was 57.3 Ω^{-1} cm^2 mol^{-1} while that of the very weakly ionized **8** and **9** was 2.0 and 1.3 Ω^{-1} cm^2 mol^{-1}, respectively.

The X-ray single crystal structure of **4** was determined at 203K in order to confirm the disposition of the three metal σ-bound ligands relative to the cymene ligand. The ruthenium–phosphorus bond Ru(1)–P(1) bisects one edge of the cymene ligand, C(5)–C(6), the arrangement expected for minimization of intramolecular repulsions. Selected bond lengths and angles are given in Table 4. The general structure is similar to that

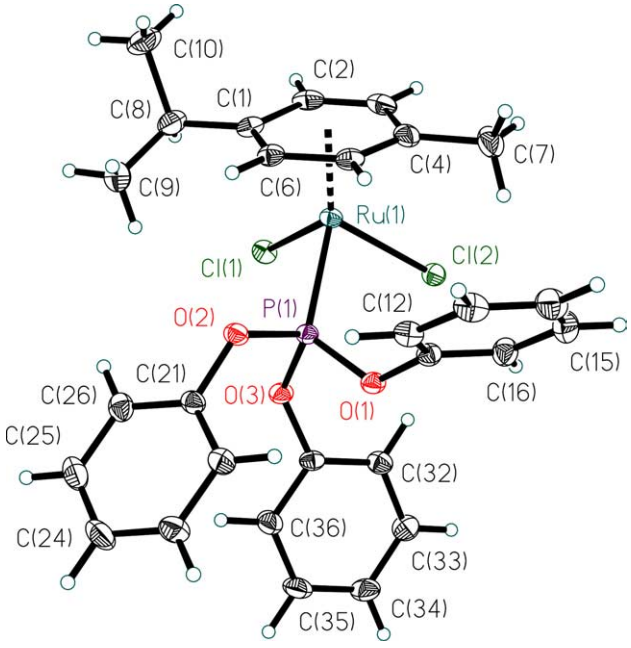

Fig. 2. Structure of the ruthenium containing fragment in **4** showing 25% probability ellipsoids.

found for other [(η^6-cymene)Ru(L)($Cl)_2$] compounds, for example L = PCy_3 [10], L = P(*m*-tolyl)$_3$ [10] and L = $PPh_2{}^tBu$ [11].

Fig. 2 shows the structure obtained of the ruthenium containing fragment and omits the dichloromethane solvent molecule which is also present in the unit cell. The solution structure of **4**, as evidenced by the ^{1}H NMR spectrum, shows that there is free rotation of the cymene ligand about the ruthenium centre and this is consistent with the general disposition of the phenyl rings in the triphenylphosphite ligand.

3. Conclusions

The methine protons of the cymene ligand in these complexes are a sensitive reporter of the auxiliary ligand environment in ^{1}H NMR spectroscopy. Even the presence of a very remote chiral centre in the complex **17** differentiates these ring protons. There does not appear to be a straightforward predictive method of absolutely assigning $\delta(C_{2,6})$ and $\delta(C_{3,5})$ in the ^{13}C NMR spectra of these complexes, the relative ordering being variable unlike the ordering in their ^{1}H NMR spectra. We will report subsequently our results with related compounds possessing planar chiral arene ligands where the asymmetry of the arene ligand facilitates absolute assignment, and also our results concerning the absence of a barrier to rotation of the cymene ring in the compounds [(η^6-cymene)Ru(L)Cl_2] in the range 170–350 K [12].

4. Experimental

All reactions and preparations were carried out on a vacuum/nitrogen line using standard Schlenk-tube techniques. Diethylether was dried over sodium wire. Dichloromethane, hexane, heptane, petroleum ether (40–60 °C) and Analar grade acetone were used as supplied. All solvents were degassed prior to use. All products isolated were dried under reduced pressure, in a hot water bath for at least one hour. Infrared spectra were recorded on a Perkin–Elmer 1710 FTIR instrument, calibrated against polystyrene film; only significant absorption bands are reported. Nuclear magnetic resonance spectra were recorded on Bruker AC300 (300.13 MHz, ^{1}H; 75.47 MHz, ^{13}C; 121.49 MHz ^{31}P) and Bruker Avance 400 (400.13 MHz, ^{1}H; 100.62 MHz, ^{13}C; 161.98 MHz ^{31}P) spectrometers. All ^{1}H and ^{13}C NMR chemical shifts are expressed in ppm relative to $SiMe_4$ (0.00 ppm) and ^{31}P NMR chemical shifts relative to $P(OPh)_3$ (126.5 ppm). All NMR and infrared spectra were measured at room temperature. Standard Bruker microprograms were used for the acquisition of HETCORR, NOESY and COSY-45 spectra. Elemental analyses were obtained at Butterworth Laboratories, London and Manchester University laboratories. Fast Atom Bombardment (FAB) mass spectra were obtained on a Kratos Concept S1 spectrometer. *R*(−)-α-Phellandrene (technical grade) was used as received from Fluka. *Tert*-butylisonitrile and *S*(−)-α-methylbenzylisonitrile were prepared from the respective amines by the phase-transfer Hofmann carbylamine reaction. Compounds **2** and **3** were prepared from **1** by a literature procedure [13].

4.1. Preparation of {[(η^6-cymene)RuCl]$_2$(μ-Cl)$_2$} (*1*)

Hydrated ruthenium trichloride (0.74g, 2.83 mmol) in ethanol (40 ml) was heated under reflux overnight with α-phellandrene (2 ml, 16.4 mmol). The orange precipitate was filtered off, washed with methanol and dried under reduced pressure, yield 0.55 g, 63.5%. ^{1}H NMR [$CDCl_3$]: δa 5.44, δb 5.30 (dd, *J*(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 2.90 (sept, *J*(HH) ~ 7 Hz, H, *CH*(Me)$_2$), 2.12 (s, 3H, CH_3{ring}), 1.24 (d, *J*(HH) ~ 7.0 Hz, 6H, CH(*Me*)$_2$); ^{13}C{^{1}H} NMR [$CDCl_3$]: δ 101.1 (s, $C1_{(quat)}$), 96.7 (s, $C4_{(quat)}$), 81.2 (s, C2,6-H{ring}), 80.5 (s, C3,5-H{ring}), 30.6 (s, *CH*(Me)$_2$), 22.1 (s, CH(*Me*)$_2$), 18.9 (s, Me{ring}).

4.2. Preparation of [(η^6-cymene)Ru(P{OPh}$_3$)Cl_2] (*4*)

A mixture of **1** (0.30 g, 0.49 mmol) and triphenylphosphite (1 ml) in hexane (30 ml) was heated under reflux for 8 h. The reaction mixture yielded a red microcrystalline solid which was filtered warm. The product was washed with light petroleum ether (2 × 10 ml). The crude product was crystallised from dichloromethane and light petroleum ether to give bright red crystals, yield 0.38 g, 62%. ^{1}H NMR [$CDCl_3$]: δ 7.22 (m, 15H, Ph_3), δa 5.39, δb 5.07 (dd, *J*(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 2.70 (sept, *J*(HH) ~ 7.0 Hz, H, *CH*(Me)$_2$), 1.8 (s, 3H, CH_3{ring}), 1.16 (d, *J*(HH) ~ 7.0 Hz, 6H, CH(*Me*)$_2$)); ^{13}C{^{1}H}NMR [$CDCl_3$]: δ 151.44 (d, *J*(PC) ~ 11.0 Hz, C_{ipso}, P{OPh}$_3$), 129.42 (s, C_{ortho}, P{OPh}$_3$), 125.06 (s, C_{para}, P{OPh}$_3$), 121.74 (d, *J*(PC) ~ 4.0 Hz, C_{meta}, P{OPh}$_3$) 109.37 (s, $C1_{(quat)}$), 103.07 (s, $C4_{(quat)}$), 88.92 (d, *J*(PC) ~ 7.0 Hz, C3,5-H{ring}), 88.60 (d, *J*(PC) ~ 6.0 Hz, C2,6-H{ring}), 30.55 (s, *CH*(Me)$_2$), 22.11 (s, CH(*Me*)$_2$), 17.96 (s, Me{ring}); ^{31}P{^{1}H} NMR [$CDCl_3$]: δ 104.2 (s, P{OPh}$_3$).

4.3. Preparation of [(η^6-cymene)Ru(P{OMe}$_3$)Cl_2] (*5*)

A suspension of **1** (0.1 g, 0.16 mmol) and trimethylphosphite (0.1 ml) in hexane (30 ml) was heated under reflux for 4 h. After solvent removal under reduced pres-

sure, fine orange crystals were obtained by crystallising the orange residue at −30 °C from dichloromethane and light petroleum ether overnight, yield 0.14 g, 99.6%. Calc. for $C_{13}H_{23}Cl_2O_3PRu$: C, 36.27; H, 5.34. Found: C, 36.24; H, 5.19%. IR (nujol): ν_{max} 1042 s, 839 w cm^{-1} (PO). ^1H NMR [$CDCl_3$]: δa 5.52, δb 5.38 (dd, J(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 3.77 (d, J(PH) ~ 10.8 Hz, 9H, P{OMe}$_3$), 2.90 (sept, J(HH) ~ 7.0 Hz, H, CH(Me)$_2$), 2.15 (s, 3H, CH_3{ring}), 1.22 (d, J(HH) ~ 7.0 Hz, 6H, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$CDCl_3$]: δ 109.9 (s, $C1_{(quat)}$), 101.9 (s, $C4_{(quat)}$), 89.1 (d, J(PC) ~ 6.0 Hz, C2,6-H{ring}), 88.8 (d, J(PC) ~ 6.0 Hz, C3,5-H{ring}), 54.3 (d, J(PC) ~ 6.0 Hz, P(OMe)$_3$), 30.4 (s, CH(Me)$_2$), 22.0 (s, CH(Me)$_2$) 18.3 (s, Me{ring}); $^{31}P\{^1H\}$ NMR [$CDCl_3$]: δ 115.9 (s, P{OMe}$_3$). M.S.[FAB]: m/z 432 {M^+}.

4.4. Preparation of [(η^6-cymene)Ru(PPh_3)Cl_2] (6)

A suspension of **1** (0.4 g, 0.32 mmol) and triphenylphosphine (0.4 g, 1.52 mmol) in hexane (30 ml) was heated under reflux for 5 h. After solvent removal under reduced pressure, bright red crystals were obtained by crystallising the red residue at −30 °C from dichloromethane and light petroleum ether overnight, yield 0.59 g, 80%. ^1H NMR [$CDCl_3$]: δ 7.84−7.24 (m, 15H, PPh_3), δa 5.17, δb 4.97 (2d, 4H, J(HH) ~ 6.0 Hz, C-H{ring}), 2.83 (sept, H, J(HH) ~ 7.0 Hz, CH(Me)$_2$), 1.84 (s, 3H, CH_3{ring}), 1.07 (d, 6H, J(HH) ~ 7.0 Hz, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$CDCl_3$]: δ 134.3 (d, J(PC) ~ 10.0 Hz, C_{ortho}, PPh_3), 128.0 (s, C_{para}, PPh_3), 128.0 (d, J(PC) ~ 10.0 Hz, C_{meta}, PPh_3), 111.2 (s, $C1_{(quat)}$), 96.0 (s, $C4_{(quat)}$), 89.0 (s, C2,6-H{ring}), 87.2 (s, C3,5-H{ring}), 30.2 (s, CH(Me)$_2$), 21.9 (s, CH(Me)$_2$), 17.7 (s, Me{ring}); $^{31}P\{^1H\}$ NMR [$CDCl_3$]: δ 23.1 (s, PPh_3). M.S.[FAB]: m/z 568 {M^+}.

4.5. Preparation of [(η^6-cymene)Ru(PMe_3)Cl_2] (7)

A suspension of **1** (0.2 g, 0.32 mmol) and trimethylphosphine (0.15 ml) in hexane (30 ml) was heated under reflux for 4 h. After solvent removal under reduced pressure, fine orange crystals were obtained by crystallising the orange residue at −30 °C from dichloromethane and light petroleum ether overnight, yield 0.22 g, 88%. ^1H NMR [$CDCl_3$]: δ 5.39 (d, 4H, J(HH) ~ 6.0 Hz, C-H{ring}), 2.81 (sept, H, J(HH) ~ 7.0 Hz, CH(Me)$_2$), 2.02 (s, 3H, CH_3{ring}), 1.57 (d, 9H, J(PH) ~ 11.0 Hz, PMe_3), 1.18 (d, 6H, J(HH) ~ 7.0 Hz, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$CDCl_3$]: δ 106.8 (s, $C1_{(quat)}$), 93.4 (s, $C4_{(quat)}$), 89.2 (d, J(PC) ~ 3.5 Hz, C-H{ring}), 84.7 (d, J(PC) ~ 5.5 Hz, C-H{ring}), 30.5 (s, CH(Me)$_2$), 21.9 (s, CH(Me)$_2$), 18.2 (s, Me{ring}), 16.3 (d, J(PC) ~ 33.5 Hz, PMe_3); $^{31}P\{^1H\}$ NMR [$CDCl_3$]: δ 3.08 (s, PMe_3). M.S.[FAB]: m/z 382 {M^+}.

4.6. Preparation of [(η^6-cymene)Ru(CO)Cl_2] (8)

A suspension of **1** (0.18 g, 0.29 mmol) in hexane (30ml) was pressurised with carbon monoxide (150 psig.) in a Fischer–Porter bottle and stirred at 50 °C for 2 h. Evaporation of the solvent under reduced pressure produced a salmon pink solid, which upon crystallisation from dichloromethane and petroleum ether afforded bright red microcrystals, yield 0.12 g, 56.0%. Calc. for $C_{11}H_{14}Cl_2ORu$: C, 39.51; H, 4.19. Found: C, 38.34; H, 4.06%. IR (nujol): ν_{max} 2042 s, cm^{-1} (CO); ^1H NMR [$CDCl_3$]: δa 5.94, δb 5.79 (dd, J(HH) ~ 6.5 Hz, 4H, C2,3,5,6-H{ring}), 2.87 (sept, J(HH) ~ 7.0 Hz, H, CH(Me)$_2$), 2.35 (s, 3H, CH_3{ring}), 1.30 (d, J(HH) ~ 7.0 Hz, 6H, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$CDCl_3$]: δ 189.7 (s, CO), 114.8 (s, $C1_{(quat)}$), 113.5 (s, $C4_{(quat)}$), 93.4 (s, C2,6-H{ring}), 93.0 (s, C3,5-H{ring}), 31.4 (s, CH(Me)$_2$), 22.5 (s, CH(Me)$_2$) 19.1 (s, Me{ring}).

4.7. Preparation of [(η^6-cymene)Ru(SMe_2)Cl_2] (9)

A suspension of **1** (0.2 g, 0.33 mmol) and dimethylsulfide (0.3 ml) in hexane (30 ml) was heated under reflux in an oil bath overnight. The solvent was removed under reduced pressure. Dissolution in dichloromethane (30 ml), and slow addition of light petroleum ether yielded bright red crystals on storage at −30 °C overnight, yield 0.18 g, 74.8%. Calc. for $C_{12}H_{20}Cl_2SRu$: C, 39.12; H, 5.43. Found: C, 39.09; H, 5.45%. ^1H NMR [$(CD_3)_2$ CO]: δa 5.61, δb 5.43 (dd, J(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 2.92 (sept, J(HH) ~ 7.0 Hz, H, CH(Me)$_2$), 2.29 (s, 6H, SMe_2), 2.18 (s, 3H, CH_3{ring}), 1.31 (d, J(HH) ~ 7.0 Hz, 6H, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$(CD_3)_2$ CO]: δ 104.6 (s, $C1_{(quat)}$), 99.4 (s, $C4_{(quat)}$), 84.2 (s, C2,6-H{ring}), 83.8 (s, C3,5-H{ring}), 31.4 (s, CH(Me)$_2$), 22.6 (s, SMe_2), 22.3 (s, CH(Me)$_2$), 18.3 (s, Me{ring}). M.S.[FAB]: m/z 577 {$C_{20}H_{28}Cl_3Ru_2^+$}, 368 {M^+}.

4.8. Preparation of [(η^6-cymene)Ru(CN^tBu)Cl_2] (10)

Tert-butylisonitrile (0.2 ml) was added to a suspension of **1** (0.15 g, 0.25 mmol) in hexane (30 ml) and heated under reflux in an oil bath overnight. Filtration and evaporation under reduced pressure produced an orange residue. Dissolution in dichloromethane and slow addition of light petroleum ether afforded a bright orange microcrystalline solid **10**, yield 0.12 g, 61.5%. Calc. for $C_{15}H_{23}Cl_2NRu$: C, 46.26; H, 5.91. Found: C, 45.95; H, 5.91%. IR (nujol): ν_{max} 2194 s, cm^{-1} (CN). ^1H NMR [$CDCl_3$]: δa 5.53, δb 5.37 (dd, J(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 2.80 (sept, J(HH) ~ 7.0 Hz, H, CH(Me)$_2$), 2.26 (s, 3H, CH_3{ring}), 1.58 (s, CNC(CH_3)$_3$), 1.27 (d, J(HH) ~ 7.0 Hz, 6H, CH(Me)$_2$); *$^{13}C\{^1H\}$ NMR [$CDCl_3$]:* δ 137.0 (s, $CNC(CH_3)_3$), 107.6 (s, $C1_{(quat)}$), 106.3 (s, $C4_{(quat)}$), 87.4 (s, C2,6-H{ring}),

87.2 (s, C3,5-H{ring}), 58.5 (s, CN*C*(CH_3)$_3$), 31.3 (s, *CH*(Me)$_2$), 30.6 (s, CNC(CH_3)$_3$), 22.5 (s, CH(*Me*)$_2$), 18.7 (s, Me{ring}).

4.9. Preparation of [(η^6-cymene)Ru($CNCH_2SO_2C_6H_4Me$)Cl_2] (**11**)

A mixture of **1** (0.15 g, 0.25 mmol) and *p*-toluenesulfonylmethylisocyanide (0.18 g, 0.92 mmol) was suspended in hexane and heated under reflux for 12 h. The product was filtered, washed with petroleum ether and dried under reduced pressure. Dissolution in dichloromethane followed by slow addition of light petroleum ether afforded an orange microcrystalline solid, characterised as **11**, yield 0.15 g, 61.1%. Calc. for $C_{19}H_{23}O_2Cl_2NSRu$: C, 45.50; H, 4.59. Found: C, 43.84; H, 4.61%. IR (nujol): ν_{max} 2162 s, cm^{-1} (CN). ^{1}H NMR [$CDCl_3$]: δa 7.87, δb 7.41 (dd, J(HH) ~ 8.0 Hz, 4H, Me(*C_6H_4*)SO_2CH_2CN), δa 5.72, δb 5.40 (dd, J(HH) ~ 5.5 Hz, 4H, C2,3,5,6-H{ring}), 4.96 (s, 2H, Me(C_6H_4)SO_2CH_2CN), 2.92 (sept, J(HH) ~ 7.0 Hz, H, *CH*(Me)$_2$), 2.43 (s, 3H, Me(C_6H_4)SO_2CH_2CN), 2.30 (s, 3H, Me{ring}), 1.29 (d, J(HH) ~ 7.0 Hz, 6H, CH(*Me*)$_2$)). ^{13}C{^{1}H} NMR [$CDCl_3$]: δ 147.1 (s, $C_{(quat)}$, Me(*C_6H_4*)SO_2CH_2CN), 132.5 (s, $C_{(quat)}$, Me(*C_6H_4*)SO_2CH_2CN), 130.8 (s, Me(*C_6H_4*)SO_2CH_2CN), 129.1 (s, Me(*C_6H_4*)SO_2CH_2CN), 109.9 (s, $C1_{(quat)}$), 108.5 (s, $C4_{(quat)}$), 89.5 (s, C2,6-H{ring}), 89.4 (s, C3,5-H{ring}), 63.6 (s, Me(C_6H_4)SO_2*CH_2*CN), 31.2 (s, *CH*(Me)$_2$), 22.4 (s, CH(*Me*)$_2$) 21.8 (s, *Me*(C_6H_4)SO_2CH_2CN) 18.9 (s, Me{ring}). M.S.[FAB]: *m*/*z* 501 {M^+}.

4.10. Preparation of [(η^6-cymene)Ru(P{*OPh*}$_3$)I_2] (**12**)

A mixture of **3** (0.30 g, 0.49 mmol) and triphenylphosphite (1 ml) in heptane (30 ml) was heated under reflux for 6 h. The reaction mixture yielded a purple microcrystalline solid which was filtered warm. The product was washed with light petroleum ether (2 × 10 ml). The crude product was crystallised from dichloromethane and light petroleum ether to give light purple crystals, yield 0.6 g, 85%. Calc. for $C_{28}H_{29}O_3PI_2Ru$: C, 42.00; H, 3.63. Found: C, 41.88; H, 3.85%. ^{1}H NMR [$CDCl_3$]: δ 7.41 (m, 15H, Ph_3), δa 5.32, δb 5.17 (dd, J(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 3.07 (sept, J(HH) ~ 7.0 Hz, H, *CH*(Me)$_2$), 2.11 (s, 3H, CH_3){ring}), 1.13 (d, J(HH) ~ 7.0 Hz, 6H, CH(*Me*)$_2$)); ^{13}C{^{1}H} NMR [$CDCl_3$]: δ 152.03 (d, J(PC) ~ 12.0 Hz, C_{ipso}, P{OPh}$_3$), 129.48 (s, C_{ortho}, P{OPh}$_3$), 125.00 (s, C_{para}, P{OPh}$_3$), 121.86 (d, J(PC) ~ 4.0 Hz, C_{meta}, P{OPh}$_3$) 114.17 (s, $C1_{(quat)}$), 102.84 (s, $C4_{(quat)}$), 87.85 (d, J(PC) ~ 7.0 Hz, C2,6-H{ring}), 90.33 (d, J(PC) ~ 6.0 Hz, C3,5-H{ring}), 31.69 (s, *CH*(Me)$_2$), 22.49 (s, CH(*Me*)$_2$), 19.93 (s, Me{ring}); ^{31}P{^{1}H} NMR [$CDCl_3$]: δ 105.7 (s, P{OPh}$_3$).

4.11. Preparation of [(η^6-cymene)Ru(P{*OMe*}$_3$)I_2] (**13**)

A suspension of **3** (0.2 g, 0.32 mmol) and trimethylphosphite (0.2 ml) in heptane (30 ml) was heated under reflux for 5 h. Dissolution into dichloromethane, filtration, concentration and slow addition of light petroleum ether yielded deep red/purple crystals on storage at −30 °C, overnight, yield 0.21 g, 80%. Calc. for $C_{13}H_{23}O_3PI_2Ru$: C, 25.41; H, 3.75. Found: C, 25.24; H, 3.69%). ^{1}H NMR [$CDCl_3$]: δa 5.56 δb 5.38 (2d, 2H, J(HH) ~ 6.0 Hz, C-H{ring}), 3.73 (d, 9H, J(PH) ~ 11.0 Hz, P{OMe}$_3$), 3.22 (sept, H, J(HH) ~ 7.0 Hz, *CH*(Me)$_2$), 2.39, (s, 3H, CH_3){ring}), 1.23 (d, 6H, J(HH) ~ 7.0 Hz, CH(*Me*)$_2$); ^{13}C{^{1}H} NMR [$CDCl_3$]: δ 113.31 (d, J(PC) ~ 5.0 Hz, $C1_{(quat)}$), 103.38 (d, J(PC) ~ 3.0 Hz, $C4_{(quat)}$), 89.31 (d, J(PC) ~ 4.0 Hz, C2,6-H{ring}), 89.31 (d, J(PC) ~ 4.0 Hz, C3,5-H{ring}), 55.30 (d, J(PC) ~ 7.0 Hz, P(OMe)$_3$), 31.55 (s, *CH*(Me)$_2$), 22.56 (s, CH(*Me*)$_2$) 20.06 (s, Me{ring}); ^{31}P{^{1}H} NMR [$CDCl_3$]: δ 118.7 (s, P{OMe}$_3$). M.S.[FAB]: *m*/*z* 613 {M^+}.

4.12. Preparation of [(η^6-cymene)Ru(PPh_3)I_2] (**14**)

An acetone solution of **6** (0.22 g) and a large excess of NaI (0.5 g, 3.34 mmol) was heated to 50 °C for 4 h. The solvent was removed under reduced pressure. Dissolution into dichloromethane, filtration, concentration and slow addition of light petroleum ether yielded deep red/purple crystals on storage at −30 °C, overnight, yield 0.20 g, 80%. Calc. for $C_{28}H_{29}PI_2Ru$: C, 44.68; H, 3.89. Found: C, 44.78; H, 4.09%. ^{1}H NMR [$CDCl_3$]: δ 7.77−7.34 (m, 15H, PPh_3), δa 5.42, δb 4.90 (2d, 4H, J(HH) ~ 6.0 Hz, C-H{ring}), 3.42 (sept, H, J(HH) ~ 7.0 Hz, *CH*(Me)$_2$), 1.94 (s, 3H, CH_3){ring}), 1.06 (d, 3H, J(HH) ~ 7.0 Hz, CH(*Me*)$_2$); ^{13}C{^{1}H} NMR [$CDCl_3$]: δ 135.6 (d, J(PC) ~ 47.0 Hz, C_{ipso}, PPh_3), 135.0 (d, J(PC) ~ 8.5 Hz, C_{ortho}, PPh_3), 130.2 (s, C_{para}, PPh_3), 127.6 (d, J(PC) ~ 9.5 Hz, C_{meta}, PPh_3), 112.71 (br.s, $C1_{(quat)}$), 99.5 (s, $C4_{(quat)}$), 88.7, 88.6 (2s, C-H{ring}), 32.0 (s, *CH*(Me)$_2$), 18.9 (s, CH(*Me*)$_2$), 18.1 (s, Me{ring}); ^{31}P{^{1}H} NMR [$CDCl_3$]: δ 21.4 (s, PPh_3).

4.13. Preparation of [(η^6-cymene)Ru(P{*OMe*}$_3$)($SnCl_3$)$_2$] (**15**)

Prior to use $SnCl_2 \cdot 2H_2O$ was dehydrated by stirring vigorously in acetic anhydride (120 g salt for 100 g anhydride) for 1 h. The salt was filtered, washed with dry ether (2 × 50 ml) and dried under reduced pressure. Dehydrated stannous chloride (0.07 g, 0.39 mmol) was then added to a solution of **5** (0.1 g, 0.23 mmol) in THF and heated under refluxing conditions for 4 h. A yellow precipitate formed, concentration and filtration

gave **12** as a yellow solid. Evaporation of the filtrate gave a small amount of a crystalline yellow-orange solid identified as **15** by ^{1}H NMR spectroscopy. Yield 0.12 g, 65%. Calc. for $C_{13}H_{23}PO_3Cl_6Sn_2Ru$: C, 19.27; H, 2.84. Found: C, 20.08; H, 3.20%. ^{1}H NMR [CD_2Cl_2]: δa 6.18 δb 6.02 (2d, 4H, J(HH) ~ 6.5 Hz, C-H{ring}), 3.83 (d, 9H, J(PH) ~ 12.0 Hz, P{OMe}$_3$), 2.99 (sept, H, J(HH) ~ 7.0 Hz, *CH*(Me)$_2$), 2.47 (d, 3H, J(PH) ~ 1.5 Hz, CH_3{ring}), 1.30 (d, 6H, J(HH) ~ 7.0 Hz, CH(*Me*)$_2$); ^{13}C{^{1}H} NMR [CD_2Cl_2]: δ 121.0 (s, C1$_{(quat)}$), 113.8 (br.s, C4$_{(quat)}$), 92.0, 91.8, (2s, C-H{ring}), 56.0 (d, J(PC) ~ 9.5 Hz, P{OMe}$_3$), 31.6 (s, *CH*(Me)$_2$), 23.2 (s, CH(*Me*)$_2$), 20.0 (s, Me{ring}); ^{31}P{^{1}H} NMR [CD_2Cl_2]: δ 127.8 (s, PMe_3). M.S.[FAB]: *m*/*z* 773 {M^+}.

4.14. Preparation of [(η^6-cymene)Ru(PPh$_3$)Cl(SnCl$_3$)] (**16**)

Freshly dehydrated stannous chloride (0.03 g, 0.16 mmol) was added to a solution of **6** (0.1 g, 0.12 mmol) in dry THF (30 ml) and heated under refluxing conditions for 4 h. The solution changed from red to orange. Removal of the solvent under reduced pressure produced an orange solid, which was crystallised from dichloromethane and diethylether. Yield 0.10 g, 71%. Calc. for $C_{28}H_{29}PCl_4SnRu$: C, 44.34; H, 3.83. Found: C, 44.38; H, 3.74%). ^{1}H NMR [CD_2Cl_2]: δ 7.71−7.32 (m, 15H, Ph), δa 6.11 δb 6.01 (2d, 2H, J(HH) ~ 6.0 Hz, C-H{ring}), 5.29 (d, H, J(HH) ~ 6.0 Hz, C-H{ring}), 4.95 (d, H, J(HH) ~ 6.0 Hz, C-H{ring}), 2.45 (sept, H, J(HH) ~ 7.0 Hz, *CH*(Me)$_2$), 1.84 (s, 3H, CH_3{ring}), 1.21, 1.14 (2d, 6H, J(HH) ~ 7.0 Hz, CH(Me)$_2$); ^{13}C{^{1}H} NMR [CD_2Cl_2]: δ 134.9 (s, C$_{ipso}$, PPh_3), 134.2 (d, J(PC) ~ 9.5 Hz, C$_{ortho}$, PPh_3), 131.3 (s, C$_{para}$, PPh_3), 129.0 (d, J(PC) ~ 10.0 Hz, C$_{meta}$, PPh_3), 116.5 (s, C1$_{(quat)}$), 102.8 (s, C4$_{(quat)}$), 92.3, 90.9, 89.3 (3s, C-H{ring}), 89.0 (d, J(PC) ~ 5.0 Hz, C-H{ring}), 30.5 (s, *CH*(Me)$_2$), 22.6, 22.4 (2s, CH(*Me*)(Me′)), 18.1 (s, Me{ring}); ^{31}P{^{1}H} NMR [CD_2Cl_2]: δ 27.7 (s, Sn satellites, ^2J(^{119}Sn–^{31}P) ~ 704 Hz, ^2J(^{117}Sn–^{31}P) ~ 671 Hz, PPh_3). M.S.[FAB]: *m*/*z* 534 {M^+}.

4.15. Preparation of [(η^6-cymene)Ru(CN-(*S*)-CH(Me)(Ph))Cl$_2$] (**17**)

S(−)-α-Methylbenzylisonitrile (0.2 ml) was added to a suspension of **1** (0.15 g, 0.49 mmol) in hexane and heated at 70 °C for 12 h. Filtration and evaporation under reduced pressure produced a red residue. Crystallisation from dichloromethane and petroleum ether (40–60 °C) afforded microcystalline **17**. Yield 0.19 g, 89%. Calc. for $C_{19}H_{23}NCl_2Ru$: C, 52.17; H, 5.26; N, 3.20. Found: C, 52.36; H, 5.46; N, 3.05%. IR (nujol): ν_{max} 2186 (CN) cm^{-1}. ^{1}H NMR [CD_2Cl_2]: δ 7.40–7.24 (m, 5H, Ph), δa 5.56, δb 5.54 (dd, 2H, J(HH) ~ 6.0 Hz, C-H{ring}), δa 5.40, δb 5.38 (2d, 2H, J(HH) ~ 6.0 Hz, C-H{ring}), 5.18 (q, H, J(HH) ~ 7.0 Hz, CHMeNC), 2.72 (sept, J(HH) ~ 7.0 Hz, H, CH(Me)$_2$), 2.22 (s, 3H, CH_3{ring}), 1.72 (d, 3H, J(HH) ~ 7.0 Hz, CHMeNC), 1.19, 1.18 (2d, 6H, J(HH) ~ 7.0 Hz, CH(Me)$_2$); ^{13}C{^{1}H} NMR [CD_2Cl_2]: δ 140.9 ('t', J(NC) ~ 15.0 Hz, CHMeNC), 137.9 (s, C$_{ipso}$, Ph), 129.0 (s, C$_{ortho}$, Ph), 128.5 (s, C$_{para}$, Ph), 125.5 (s, C$_{meta}$, Ph), 107.4 (s, C1$_{(quat)}$), 106.9 (s, C4$_{(quat)}$), 87.9, 87.6, 87.5, 87.4 (4s, C-H{ring}), 53.8 (s, CHMeNC), 31.1 (s, CH(Me)2), 24.8 (s, CHMeNC), 22.3, 22.2 (2s, CH(Me)$_2$), 18.7 (s, Me{ring}). M.S.[FAB]: *m*/*z* 437 {M^+}.

4.16. Preparation of [(η^6-cymene)Ru(P{OPh}$_3$)(SOMe$_2$)Cl]PF$_6$ (**18**)

Dimethylsulfoxide (1 ml) was added to a solution of **4** (0.15 g, 0.24 mmol) and ammonium hexafluorophosphate (0.2 g, 1.22 mmol) in methanol (30 ml) and stirred at 50 °C for 6 h. The solution turned progressively paler. The solvent was removed under reduced pressure to give a bright orange oil. A mixture of dichloromethane (20 ml) and water (5 ml) was added and shaken, the dichloromethane layer was separated and dried with calcium chloride. Filtration and addition of diethylether afforded bright yellow microcrystals, identified as **18**. Yield 0.10 g, 50%. Calc. for $C_{30}H_{35}ClF_6O_4P_2SRu$: C, 41.59; H, 4.04. Found: C, 41.90; H, 4.12%. IR (nujol): ν_{max} 1124, 1054 br, 845 s (PF_6^-) cm^{-1}. ^{1}H NMR [CD_2Cl_2]: δ 7.40−6.89 (m, 15H, Ph), 6.23 (d, 2H, J(HH) ~ 6.5 Hz, C-H{ring}), 5.78, 5.01 (2d, H$_c$, H$_d$, J(HH) ~ 6.5 Hz, C-H{ring}), 3.55, 3.37 (2s, 6H, SO*Me*$_2$), 2.65 (sept, J(HH) ~ 7.0 Hz, H, *CH*(Me)$_2$), 2.07 (s, 3H, CH_3{ring}), 1.25, 1.12 (2d, 6H, J(HH) ~ 7.0 Hz, CH(*Me*)$_2$); ^{13}C{^{1}H} NMR [CD_2Cl_2]: δ 151.0 (d, J(PC) ~ 14.0 Hz, C$_{ipso}$, P{OPh}$_3$), 130.7 (s, C$_{ortho}$, P{OPh}$_3$), 126.9 (s, C$_{para}$, P{OPh}$_3$), 121.4 (d, J(PC) ~ 3.0 Hz, C$_{meta}$, P{OPh}$_3$), 126.1 (s, C1$_{(quat)}$), 108.7 (s, C4$_{(quat)}$), 98.9 (s, C-H{ring}), 97.6 (d, J(PC) ~ 5.0 Hz, C-H{ring}), 93.8 (d, J(PC) ~ 10.0 Hz, C-H{ring}), 89.8 (s, C-H{ring}), 51.6, 51.2 (2s, SO*Me*$_2$) 31.7 (s, *CH*(Me)$_2$), 21.7, 21.6 (2s, CH(*Me*)$_2$), 18.4 (s, Me{ring}); ^{31}P{^{1}H} NMR [CD_2Cl_2]: δ 109.0 (s, P{OPh}$_3$). M.S.[FAB]: *m*/*z* 721 {M^+}.

4.17. Preparation of [(η^6-cymene)Ru(P{OMe}$_3$)(SOMe$_2$)Cl]PF$_6$ (**19**)

NH_4PF_6 (80 mg, 0.49 mmol) was added to a solution of complex **5** (0.15 g, 0.35 mmol) and dimethylsulfoxide (0.2 ml) in methanol (30 ml) and stirred at room temperature for 48 h. The solvent was removed under reduced pressure and the orange residue extracted with dichloromethane. Concentration and slow addition of diethylether afforded bright yellow crystals

on storage in a refrigerator (−30 °C, overnight), yield 0.14 g, 64%. Calc. for $C_{15}H_{29}ClF_6O_4P_2SRu$: C, 29.15; H, 4.70. Found: C, 28.71; H, 4.80%). M.S.[FAB]: m/z 728 {M^+}.

4.21. Preparation of [(η^6-cymene)Ru(PPh_3)(C_9H_7N)-Cl]PF_6 (**23**)

A red solution of **6** (0.10 g, 0.18 mmol) and KPF_6 in methanol (30 ml) was treated with quinoline (1 ml) and stirred at room temperature for 24 h. A bright yellow solid precipitated out on concentration. The solution was filtered and the yellow solid washed with diethylether. Crystallisation from dichloromethane and diethylether afforded microcrystalline **23**. Yield 0.09 g, 62%. Calc. for $C_{37}H_{36}ClF_6NP_2Ru$: C, 55.05; H, 4.46; N, 1.74; recalc. for 0.5 mol CH_2Cl_2: C, 53.00; H, 4.36; N, 1.65. Found: C, 53.58; H, 4.44; N, 1.63%. IR (nujol): ν_{max} 837 s (PF_6) cm^{-1}. ^1H NMR [$CDCl_3$]: δ 9.41 (s, H, C_9H_7N), 8.67 (d, H, J(HH) ~ 6.5 Hz, C_9H_7N), 7.87–7.47 (m, 22H, Ph, C_9H_7N), 6.01, 5.97, 5.52, 5.33 (4d, 4H, J(HH) ~ 6.0 Hz, C-H{ring}), 2.17 (sept, H, J(HH) ~ 7.0 Hz, CH(Me)$_2$), 1.65 (s, 3H, CH_3{ring}), 1.06, 1.03 (2d, 6H, J(HH) ~ 7.0 Hz, CH(Me)$_2$); $^{13}C\{^1H\}$ NMR [$CDCl_3$]: δ 159.4 (s, C_9H_7N), 147.8 (s, C_9H_7N), 134.0 (s, C_{ortho}, PPh_3), 133.0 (s, C_9H_7N), 131.0 (s, C_{para}, PPh_3), 128.6 (d, J(PC) ~ 8.5 Hz, C_{meta}, PPh_3), 128.6, 128.5 (s, C_9H_7N), 128.2 (s, C_9H_7N), 126.0 (s, C_9H_7N), 123.0 (s, C_9H_7N), 114.1 (d, J(PC) ~ 8.0 Hz, $C1_{(quat)}$), 103.5 (s, $C4_{(quat)}$), 94.7 (d, J(PC) ~ 6.0 Hz, C-H{ring}), 90.2, 88.7, 84.0 (3s, C-H{ring}), 30.8 (s, CH(Me)$_2$), 23.1, 20.9 (2s, CH(Me)$_2$), 18.1 (s, Me{ring}); $^{31}P\{^1H\}$ NMR [$CDCl_3$]: δ 36.6 (s, PPh_3). M.S.[FAB]: m/z 662 {M^+}.

4.22. Preparation of [(η^6-cymene)Ru(dppe)Cl]PF_6 (**24**)

A Schlenk tube was charged with a solution of **1** (0.2 g, 0.33 mmol) in 1,2 dichloroethane (25 ml), NH_4PF_6 (0.3 g, 1.84 mmol), dppe (0.52 g, 1.31 mmol) and a magnetic stirrer bar. The orange solution was stirred under reflux conditions for 16 h. After solvent removal under reduced pressure the yellow residue was extracted in dichloromethane (2 × 15 ml). Concentration followed by addition of light petroleum ether produced yellow microcrystals on storage at −30 °C overnight, yield 0.32 g, 60.2%. H NMR [acetone-d_6]: δ 7.97–7.36 (m, 20H, Ph) δa 6.38, δb 6.24 (dd, J(HH) ~ 6.0 Hz, 4H, C2,3,5,6-H{ring}), 3.12-2.92 (m, 4H, $PPh_2(CH_2)_2PPh_2$) 2.24 (sept, J(HH) ~ 7 Hz, H,$CH(CH_3)_2$), 1.21 (s, 3H, CH_3{ring}), 0.87 (d, J(HH) ~ 7 Hz, 6H, $CH(CH_3)_2$); $^{13}C\{^1H\}$ NMR [acetone-d_6]: δ 136.3 ('t', J(PC) ~ 46.5 Hz, C_{ipso}), 134.7, 133.1 (2s, C_{ortho}, PPh_3), 132.2, 131.9 (2s, C_{para}, PPh_3), 130.0, 129.2 (2'st', J(PC) ~ 10.0 Hz, C_{meta}, PPh_3), 123.5 (s, $C1_{(quat)}$), 101.3 (s, $C4_{(quat)}$), 96.2 (s, C2,6-H{ring}), 92.3 (s, C3,5-H{ring}), 31.1 (s, CH(Me)$_2$), 26.8 (t, J(PC) ~ 22 Hz, $PPh_2(CH_2)_2PPh_2$) 21.4 (s, CH(Me)$_2$) 15.8 (s, Me{ring}). $^{31}P\{^1H\}$ NMR [acetone-d_6]: δ 72.7 (s, $PPh_2(CH_2)_2PPh_2$), 144.1 (sept, PF_6^-). M.S.[FAB]: m/z 669 {M^+}.

4.23. X-ray structure of (**4**)

Well-shaped red cubes were obtained by crystallisation from a dichloromethane/diethylether mixture on cooling to −30 °C. A suitable crystal specimen was mounted on a glass fibre with epoxy resin and cooled on the goniometer head by means of nitrogen gas to 203 K. Precession photographs and intensity data were collected on a Siemens R3m/V diffractometer using graphite monochromatised Mo Kα X-rays.

Crystal data. $C_{28}H_{29}Cl_2O_3PRu\cdot CH_2Cl_2$, M = 701.4, monoclinic, space group $P2_1/n$, a = 12.936(2), b = 16.809(3), c = 13.979(2) Å, β = 98.06(1)°, U = 3009.6(8) Å^3, D_c = 1.548 g cm^{-3} for Z = 4, F(0 0 0) = 1424, μ(Mo Kα) = 9.59 cm^{-1}, T = -70 °C, crystal size 0.45 × 0.45 × 0.50 mm^3. Cell dimensions were obtained from 50 centred reflections with 2θ values from 22.5° to 32.1°. Intensity data in the range 3.5° < 2θ < 58.0° were collected using a 2θ–θ scan technique. The intensities of three reflections measured periodically showed a decrease of less than 1% over the data collection. An empirical absorption correction was applied using azimuthal scan data for twelve selected reflections. A total of 8285 reflections were collected of which 7966 were independent and 6992, for which $I > 2\sigma(I)$, were used in the refinement. The structure was solved by standard heavy atom routines and refined by full matrix least squares methods. All non-hydrogen atoms were given anisotropic temperature factors. Hydrogen atoms were placed in the model at calculated positions and allowed to ride on their respective carbon atoms. The highest peaks in the final difference map were <1.6 e Å^3, at convergence R_1 = 4.55% and wR_2 = 12.73%, $w = [\sigma^2 (F_o) + 0.0822P^2 + 2.0235P]^{-1}$ where $P = (F_o^2 + 2F_o^2)/3$, S = 1.10 for a data/parameter ratio 20.4:1.

5. Supplementary material

CCDC-236210 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via ccdc.cam.ac.uk/data_request/cif, by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK; fax +44 1223 336033.

Dedicated with affection and gratitude to Malcolm Green on the occasion of his 'retirement'. It's nice being Green

Abstract

The reaction of nitric oxide with the divalent lanthanide complex $[Ln(Tp^{Me2})_2]$ and $[Ln(Tp^{Me2,4\text{-}Et})_2]$ (Ln = Sm, Eu, Yb) gives the corresponding seven-coordinate nitrites $[Ln(Tp^{Me2,X})_2NO_2]$ in a smooth reaction. A possible mechanism is proposed for this NO disproportionation. A single crystal X-ray diffraction study of $[Sm(Tp^{Me2,Et})_2NO_2]$ reveals a dodecahedral metal centre. However, as is customary for these species, the complex is fluxional in solution by NMR even at the lowest accessible temperatures.

1. Introduction

Over the past 20 years nitric oxide has come to be seen as a critically important molecule from both an environmental and biological [1] standpoint. While the binding of nitric oxide to transition metals has been explored for many years [2], transition metal-mediated transformations of nitric oxide, disproportionations in particular, have received renewed impetus with the recent discovery of systems capable of stepwise NO conversion [3]. By contrast, we are aware of very few reports of its reactions of the lanthanides [4].

The chemistry of the divalent lanthanides has provided a wealth of reactivity as a result of their unusual combination of reducing power and electrophilicity [5–7]. Much of the work exploring this chemistry has been carried out using cyclopentadienyl ligands as ancillaries, but increasingly other spectator ligands have come to be used [8]. The tris-pyrazolylborate ligand has found increasing application in p-block, transition metal [9,10] and lanthanide [11,12] chemistry because of the range of steric control which can be achieved by varying the substituents on the pyrazolyl groups. The activation of small molecules by the lanthanides continues to generate surprises. Because of the absence of back-bonding, classical complexes of CO are rare [13–16], and complexes of NO [4] and ethylene unknown so far [17,18]. However, an example of σ-only binding of alkyne has been reported [19] and a growing number of examples of side-on binding of dinitrogen to pairs of lanthanide centres have come to light recently [20–27]. The report of the reduction of O_2 by $[Sm(Tp^{Me2})_2]$ [28,29] to yield a thermally stable superoxide complex $[Sm(Tp^{Me2})_2(O_2)]$ [30], in which the O_2^- is enclosed in a steric "pocket" prompted us to examine the corresponding reaction of NO in the hopes of isolating an analogous product.

2. Results

Stirring a suspension of [Sm(Tp^{Me2})$_2$] (**1a**) or a solution of the more soluble [Sm($Tp^{Me2,4-Et}$)$_2$] (**1b**) in THF under 1 atm of NO and warming from −78 °C to room temperature resulted in a bleaching of the purple colour of the starting materials consistent with an oxidative reaction of the metal centre. The resulting white solid could be recrystallized to yield analytically pure [Sm(Tp^{Me2})$_2$NO$_2$] (**2a**) and [Sm($Tp^{Me2,4-Et}$)$_2$NO$_2$] (**2b**), respectively.

The infrared spectrum of **2** is virtually superimposable with that of **1** apart from the appearance of two new bands at 1200 and 1297 cm^{-1}, assigned to the symmetric and antisymmetric stretching vibrations of a chelating O-bound nitrito group [31], and the splitting of many of the peaks in the fingerprint region, consistent with the reduction in symmetry expected with the addition of a new ligand. The frequency difference between the symmetric and antisymmetric stretching bands in the IR spectra of nitrito complexes has been shown to be a good indicator of the difference in N–O bond lengths in the chelate, with values less than 100 cm^{-1} indicating symmetrical binding [32]. The ^{1}H NMR spectrum of **2a** and **2b**, though broadened and shifted by the paramagnetic Sm(III) centre, shows a single set of resonances for the pyrazolyl groups, consistent with a structure containing two equivalent, fluxional $Tp^{Me2-4-Et}$ groups. The B–H protons were visible as a very broad lump in the baseline in the region around δ4. Thus the spectra display none of the complexity of those observed for other eight-coordinate species with symmetrical bidentate ligands such as [Sm(Tp^{Me2})$_2$(S_2CNR_2)] (R = Me, Et) and [Sm(Tp^{Me2})$_2$(S-2-pyr)] [33], and [Sm(Tp^{Me2})$_2$(PhNNPh)] [28] – these display distinct environments for each pyrazole group implying a C_2-symmetric, static coordination sphere. Instead, in **2a** and **2b**, a fast fluxional process occurs which makes all of the pyrazolyl groups equivalent on the NMR timescale. Attempts to slow down these dynamic processes were not successful – the ^{1}H NMR spectra broadened and shifted as the temperature was lowered to −95 °C in toluene-d_8 but the slow exchange limit was not reached. In this respect **2a** and **2b** more closely resemble seven coordinate species.

The synthesis of **2a** by metathesis of [Sm(Tp^{Me2})$_2$Cl] with sodium nitrite

$$[Sm(Tp^{Me2})_2Cl] + NaNO_2 \rightarrow [Sm(Tp^{Me2})_2(NO_2)] + NaCl$$

was also attempted. However the product could not be obtained entirely pure, with evidence of contamination by decomposition products arising from fragmentation of the ligand, which varied in quantity from one prep to another, a credible indicator of adventitious moisture. This is likely due to our failure to obtain sodium nitrate in an entirely anhydrous form in spite of repeated attempts. Lanthanide Tp^{Me2} complexes are notoriously sensitive to hydrolysis, a problem which has dogged this area [34].

The reaction of [Eu($Tp^{Me2-4-Et}$)$_2$] and [Yb($Tp^{Me2-4-Et}$)$_2$] proceeded similarly to give colourless products **3** and **4**, respectively. Complex **3** was NMR silent as expected for a f^6 trivalent europium complex. The ^{1}H NMR spectrum of **4** consisted of four highly shifted peaks with the correct integration ratio, though specific assignment was not possible. The infrared spectra of both compounds were virtually superimposable with those of **2b** although the nitrito bands of **4** were shifted to higher energy. We presume therefore that **3** and **4** are structurally analogous to **2** and that the shift is simply the result of the higher charge to radius ratio of the ytterbium centre.

In order to verify the nature of these complexes, and since we are only aware of one other structure of a lanthanide nitrite in the literature [35], crystals of **2b** suitable for X-ray diffraction were grown by slow evaporation of a solution of **2b** in toluene.

3. X-ray crystallographic study of 2b

Complex **2b** crystallized from toluene in the space group *C2/c*. The structure consists of well-separated discrete molecules of [Sm($Tp^{Me2,4-Et}$)$_2$(κ^2-NO$_2$)] rather similar to the structure of the previously reported [La(Tp^{Me2})$_2$(κ^2-NO$_3$)] [36]. A view of the molecule and the atomic numbering scheme is shown in Fig. 1. The metal centre is eight coordinate with the metal centre and the nitrogen atom of the nitrito group lying on

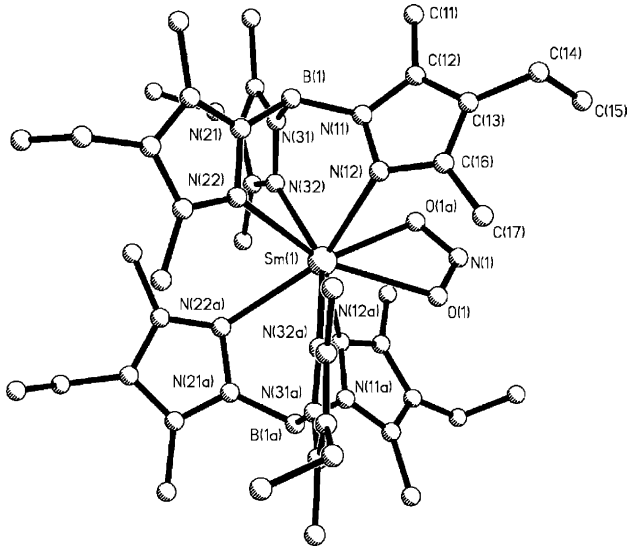

Fig. 1. The molecular structure of **2b** (hydrogen atoms are omitted for clarity). Selected bond angles (Å) and distances (°): Sm(1)–N(12) 2.551(4), Sm(1)–N(22) 2.565(4), Sm(1)–N(32) 2.495(4), Sm(1)–O(1) 2.486(4), Sm(1)–N(1) 2.953(3), O(1)–N(1) 1.263(5), O(1)–N(1)–O(1A) 112.7(6), O(1)–Sm(1)–O(1A) 50.0(2). Symmetry transformations used to generate equivalent atoms: $-x+1, y, -z+\frac{1}{2}$.

the crystallographic C_2 axis, making half of the molecule unique. On the basis of polytopal analysis, the coordination around the metal is best described as being dodecahedral, as shown in Fig. 2, similar to most other eight-coordinate bis-Tp^{Me2} complexes [28,33,36,37]. The two crystallographically planar trapezoids, defined by N12, N22, N12A, N22A and O1, N32, O1A, N32A, intersect at 94°. Thus the polyhedron around the metal is significantly closer to ideality than that observed in $[La(Tp^{Me2})_2(NO_3)]$ where significant distortion towards a bicapped trigonal prismatic arrangement was observed [36].

The two tridentate $Tp^{Me2,4\text{-}Et}$ ligands are mutually staggered and bent back away from the bidentate nitrito group (B1–Sm–B2 = 159.0°). This angle is the largest thus far observed for the Tp^{Me2} type complexes, and presumably reflects the small size of the NO_2 group and its ability to nestle in the gap between the two pyrazolyl groups from opposite ligands. We note however that in $[(SmTp^{Me2})_2(\eta^2\text{-}O_2)]$ the corresponding angle is 144° [30]. However, although the molecule appears analogous to a metallocene, the nitrito group does not lie in the "equatorial plane", but rather is twisted by 45.2° relative to the plane defined by the metal centre and the boron atoms. It therefore lies in the N32–Sm–N32A plane. The $Tp^{Me2,4\text{-}Et}$ ligands deviate significantly from the expected C_3 symmetry. In particular ring 1 shows marked twisting around the B–N bond (51.8° cf. ring 2, 2.7°; ring 3, 14.2°). Thus N11 is drawn in somewhat closer to the samarium (Sm–N11 = 3.166(6) Å cf. Sm–N(21,31) = 3.386(4), 3.336(4) Å) and as a result the pyrazolyl groups lies almost parallel to the orientation of the NO_2 group. The twisting of the ligand serves to enhance the steric protection afforded by the pocket around the nitrito group, pointing to the possibility of the availability of considerable steric control in these systems. But in addition it allows the two Tp ligands to be squeezed together allowing the B–Sm–B angle to increase, as discussed earlier. The distortion may also be thought of as an intermediate structure between normal coordination and the "side-bound" behaviour observed by Takats in $[U(Tp^{Me2})_2I]$ [38], and $[Sm(Tp^{tBu,Me})(\eta\text{-}C_5H_4SiMe_3)]$ [39], by Parkin in $[Tp^{tBu,Me}Tl]$ [40], and by us in $[Sm(Tp^{Me2})_2(SeC_6H_4\text{-}4\text{-}R)]$ (R = H, CH_3) [41]. We note that in $[La(Tp^{Me2})_2(NO_3)]$, which differs effectively only in the ionic radius of the metal (and hence its Lewis acidity), the twisting is much less pronounced. In addition, the distortion results in a Sm–B distance of 3.421 Å, which is much shorter (after correction for ionic radius [42]) than that in $[La(Tp^{Me2})_2(NO_3)]$ (3.681 Å) [36]. Nevertheless, the distortion hardly alters the Sm–N distances which range from 2.495(4) to 2.565(4) Å, very similar to the distances seen in other crystallographically characterized eight-coordinate complexes with this ancillary, $[Sm(Tp^{Me2})_2(\eta^2\text{-}O_2)]$ [30] $[Sm(Tp^{Me2})_2(2\text{-}SC_6H_4N)]$ $[Sm(Tp^{Me2})_2(S_2CNEt_2)]$ [33] and $[Sm(Tp^{Me2})_2(PhNNPh)]$ [28].

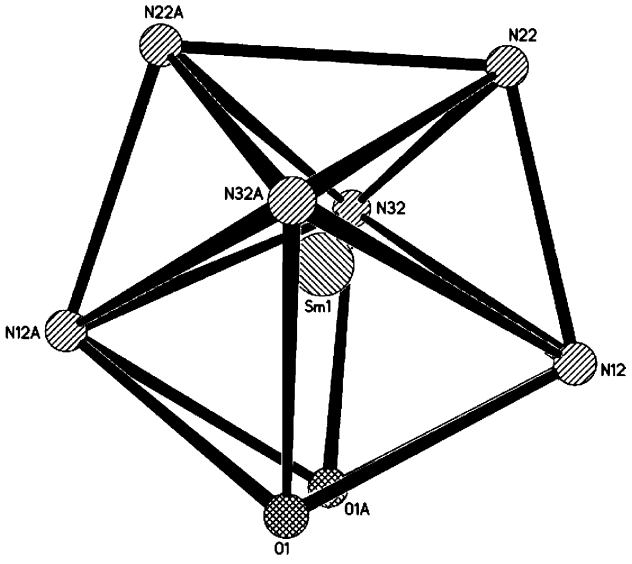

Fig. 2. A view of the dodecahedral coordination polyhedron around the samarium atom in **2b**.

The nitrite group is O-bonded and bidentate, as expected from the infrared spectra. After correcting for ionic radius, the Sm–O distance, 2.487(4) Å, is very similar to that observed in the nitrate $[La(Tp^{Me2})_2(NO_3)]$ but slightly longer than $[YbCp_2(NO_2)(THF)]$ [35]. This difference may reflect the greater steric demand of the pyrazolylborate ligand set compared with the metallocene. Indeed, evidence from related chalcogenolate chemistry suggests that the steric demand of the $(Tp^{Me2})_2Ln$ fragment is similar to that of the more substituted Cp^*_2LnL (L = unidentate ligand) [43]. The N–O distance of 1.263(5) Å is somewhat longer than that observed in $NaNO_2$ (1.24 Å) [35], but is very similar to the binding of nitrito group in transition metal complexes such as $[TpCu(\eta^2\text{-}ONO)]$, for which angles of about 110° and N–O distances of 1.24 Å are typical [44]. The N–O distance observed in **2** is in sharp contrast to those reported for $[YbCp_2(NO_2)(THF)]$ (average 1.10 Å) [35]. The bond length in the latter complex is surprisingly short, being of the order of those observed for the nitronium ion, NO_2^+ (1.123 Å) [45]. This distance, which the authors ascribed to particularly effective π-donation from the antibonding orbital of the nitrito group to the electrophilic lanthanide centre, is not reflected by the vibrational data. Although the electrophilicity increases somewhat on moving from samarium to ytterbium, the shortness of the N–O bond length is surprising. We note that the dataset for $[YbCp_2(NO_2)(THF)]$ appears to have been collected on a particularly poorly diffracting crystal, was refined with a low data:parameters ratio with most atoms in the structure refined isotropically. In addition the authors refer to the possibility of an "un-

resolved disorder'' of the nitrito group. Thus the structure of [$YbCp_2(NO_2)(THF)$] should probably be treated with circumspection.

4. Discussion

Complexes **1a/1b** react with NO to give **2a/2b**, with the more soluble **2b** being isolated in a better yield. This behaviour is in contrast to Evans' report of the behaviour of [$Sm(\eta^5\text{-}C_5Me_5)_2$], which reacts rapidly with NO to give the trivalent μ-oxo complex, [$(Sm(\eta^5\text{-}C_5Me_5)_2)_2(\mu\text{-}O)$], together with several other products [4]. The selectivity in the case of **1** highlights the extent of steric crowding in such systems which restricts the pathways available to the reaction.

No mechanism was proposed for the formation of the samarocene oxo complex. A related zirconium oxo-bridged species, $[Cp_2ZrO]_n$ has been reported to form from the reaction of $[Cp_2Zr(PMe_3)_2]$ with NO. This very fast reaction is accompanied by the formation of N_2 and involves the intermediate formation of N_2O [46]. Hence the samarocene system may also be a stoichiometric reagent for the conversion of NO to N_2. One can envisage a scheme whereby rapid electron transfer to NO yields a transient species ''Cp^*_2SmNO'', in which the NO is presumably side-bound. Dimerization followed by coupling yields a binuclear complex with a bridging $(NO)_2^{2-}$ ligand – Karlin has proposed the intermediacy of a bis-nitrosyl species to account for the conversion of NO to N_2O and oxide in a binuclear copper system [47]. In the case of samarium, the driving force associated with the formation of the bridging oxo ligand can be expected to be considerably larger than for copper, hence the elimination N_2O may be much more favoured. Evans showed that N_2O also reacts rapidly with Cp^*_2Sm to generate the oxo dimer, thereby releasing N_2 and completing the reaction.

The mechanism of the reaction of **1a/1b** with NO is instead presumed to involve a metal-mediated redistribution, as has been reported for a number of transition metal system [3,48–51], and which we presume has the following stoichiometry:

$$[Sm(Tp^{Me2})_2] + 3NO \rightarrow [Sm(Tp^{Me2})_2(NO_2)] + N_2O$$

However, our attempts to identify N_2O in the headspace gas were inconclusive because of the small volumes involved and the difficulty of obtaining NO which we could convince ourselves was entirely free of nitrous oxide as a contaminant.

We presume that NO does bind to the samarium, a process which is accompanied or driven by rapid electron transfer. This may account for the initial yellow colour observed at low temperature. Unfortunately even at these low temperatures it did not prove possible to observe IR or NMR bands consistent with the formation of the adduct [52]. It cannot be surprising that the NO^- ligand, not stabilized by significant covalent interactions, is highly reactive and is presumably attacked rapidly by two further molecules of NO to give **2a/2b** and nitrous oxide. In a similar reaction, Tolman has been able to isolate a terminal nitrosyl species, TpCu(-NO), which, stabilized by back-bonding from the copper centre, subsequently rearranges to give a coordinated nitrito species [3,53]. It is interesting that we have not observed the formation an μ-oxo species, {[$Sm(Tp^{Me2,4\text{-}Et})_2]_2(\mu\text{-}O)$}, analogous to that isolated by Evans. Several attempts have been made to prepare monoatomic bridged species of this type by other routes without success [52,54,55]. These failures may reflect the steric interactions between the ancillary ligands which prevent a close approach in such a dimer, as well as the fragility of the pyrazolyborate which provides several alternative decomposition pathways [34].

5. Conclusions

Nitric oxide appears to be too reactive to bind to low valent lanthanide centres since it undergoes rapid electron transfer followed by disproportionation. Nevertheless it may be possible to form simple adducts of NO to trivalent metal centres with vacant coordination sites and detect this binding by infrared spectroscopy.

6. Experimental

All preparations and manipulations were carried out using standard Schlenk line and dry box techniques in an atmosphere of dinitrogen [56]. Oxygen-free nitrogen was purified by passage over columns containing 3 Å molecular sieves and MnO [57]. All solvents were predried over 5 Å molecular sieves or sodium wire and distilled under nitrogen from the appropriate drying agents {Na (toluene), Na/K alloy (petroleum ether b.p. 30–40 °C, diethyl ether)}, before use.

[$Ln(Tp^{Me2})_2$] and [$Ln(Tp^{Me2,4\text{-}Et})_2$] were prepared by reaction of LnI_2 (Ln = Sm, Yb) with two equivalents of the appropriate KTp reagent, or in the case of Eu by Na/Hg reduction of $[Eu(Tp)_2Cl]$ as previously described [29]. Nitric oxide was either taken from cylinders or was prepared by the action of 7.5 M HNO_3 on copper turnings, and purified by passage through water and then through a trap at −78 °C. Nitric oxide free from N_2O was prepared by the action of HCl on $NaNO_2$ in the presence of $FeSO_4$ [58].

Infrared spectra were recorded as KBr pellets on a Nicolet 205 FTIR spectrometer. NMR spectra were recorded in solution using Varian XL-200 and VXR-400 spectrometers operating at 200 (^1H), 400 (^1H) and 100.6 (^{13}C) MHz. Spectra were calibrated using residual

proton (^{1}H) and solvent resonances (^{13}C), and are reported relative to tetramethylsilane. Elemental analyses were determined by Mr. Alan Stones of the UCL Analytical Services.

6.1. Preparation of $Sm(Tp^{Me2})_2NO_2$ (**2a**)

$Sm(Tp^{Me2})_2$ (0.205 g, 0.275 mmol) was placed in a Schlenk flask. 30/40 petrol (20 cm^3) was added and the solution cooled to −78 °C in a dry ice/acetone bath before being evacuated and then refilled with NO to a pressure of 760 mm Hg (1 atm). No reaction was observed at −78 °C but as the mixture was allowed to warm to room temperature the purple suspension decolourized and a yellow solid was formed. As the solvent was removed under reduced pressure the solid became white. The crude product was extracted into toluene (50 cm^3), filtered and then the solvent removed to yield a white solid.

Yield: 30 mg (14%). *Anal.* Calc. for $C_{30}H_{44}N_{13}B_2O_2Sm$: C, 45.6; H, 5.6; N, 23.0. Found: C, 44.8; H, 5.3; N, 23.8%. ^{1}H NMR (C_6D_6, 298K): 0.35 (s, 18H, Me); 2.41 (s, 18H, Me); 5.50 (s, 6H, 4-CH). IR (KBr pellet, cm^{-1}): ν_{B-H} 2528, ν_{N-O}(a/sym) 1300 (w), ν_{N-O}(sym) 1200 (s).

6.2. Preparation of $Sm(Tp^{Me2-4-Et})_2NO_2$ (**2b**)

$Sm(Tp^{Me2-4-Et})_2$ (0.135 g, 0.148 mmol) was placed in a Schlenk flask. 30/40 petrol (20 cm^3) was added and the solvent frozen in liquid nitrogen. The flask was evacuated and allowed to warm to −78 °C in a dry ice/acetone bath before being filled with NO to a pressure of 760 mm Hg (1 atm). No reaction was observed at −78 °C but as the mixture was allowed to warm to room temperature the purple suspension decolourized and a yellow solid was formed. As the solvent was removed under reduced pressure the solid became white. The crude product was extracted into diethyl ether (50 cm^3), filtered and then the volume reduced by one half. Cooling to −25 °C gave a white microcrystalline solid.

Yield: 50 mg (35%). *Anal.* Calc. for $C_{42}H_{68}N_{13}B_2O_2Sm$: C, 52.6; H, 7.15; N, 18.99. Found: C, 53.3; H, 7.15; N, 18.68%. ^{1}H NMR (C_6D_6, 298K): 1.03 (t, 18H, Me); 1.07 (s, 18H, Me); 2.16 (s, 18H, Me); 2.20 (q, 12H, CH_2); 4.70 (br s, 2H, BH). ^{11}B NMR (C_6D_6, 298K): −9.3. ^{13}C NMR (C_6D_6, 298K): 11.5 (q, 3 or 5 Me); 12.1 (q, 5 or 3 Me); 15.5 (q, 4-Me); 16.9 (6, 4 CH_2); 117.5 (s, 4 C); 141.5 (s, 3 or 5 C); 148.1 (s, 5 or 3 C). IR (KBr pellet, cm^{-1}): ν_{B-H} 2522, ν_{N-O}(a/sym) 1297 (w), ν_{N-O}(sym) 1200 (s).

6.3. Preparation of $Eu(Tp^{Me2-4-Et})_2NO_2$ (**3**)

Complex **3** was prepared by analogy with that of **2**. *Anal.* Calc. for $C_{42}H_{68}N_{13}B_2O_2Eu$: H, 7.13; B, 2.25; C, 52.51; N, 18.95. IR (KBr pellet, cm^{-1}): ν_{B-H} 2522, ν_{N-O}(a/sym) 1298(w), ν_{N-O}(sym) 1202 (s). The compound was NMR silent.

6.4. Preparation of $Yb(Tp^{Me2-4-Et})_2NO_2$ (**4**)

Complex **4** was prepared by analogy with that of **2**. *Anal.* Calc. for $C_{42}H_{68}N_{13}B_2O_2Yb$: H, 6.98; B, 2.2; C, 51.38; N, 18.55. ^{1}H NMR (C_6D_6, 298 K): −6.80 (br s, 18H, Me); −2.2 (t, 18H, Me); 1.04 (q, 18H, CH_2); 14.20 (s, 18H, Me). IR (KBr pellet, cm^{-1}): ν_{B-H} 2522, ν_{N-O}(a/sym) 1303(w), ν_{N-O}(sym) 1210(s).

7. X-ray crystallography

All measurements were made on a Nicolet R3mV four circle diffractometer using Mo Kα ($\lambda = 0.71073$ Å) radiation. Crystallographic calculations were carried out with the SHELX-93 suite of programs on a Pentium computer.

A colourless block of **2**, grown by slow crystallization from toluene, was mounted in a Lindemann capillary under nitrogen in a glove box. The orientation matrix of the crystal and the unit cell determined using 26 reflections chosen from a rotation photograph with 2θ in the range of 11.90–26.95°. Unit cell dimensions were confirmed by axial photographs. Data were collected by ω-2θ scans in a range $5° \leqslant 2\theta \leqslant 50°$. The intensities of three standard reflections monitored every 100 reflections showed no sign of crystal decay. Corrections for Lorentz, polarization and an empirical correction for absorption (using ψ-scans) were applied. The structure of **2** was solved by Patterson methods and developed by alternating cycles of difference Fourier syntheses and full matrix least-squares procedures. Anisotropic thermal parameters were used in the final model for all non-hydrogen atoms. Hydrogen atoms were not located but placed in idealized positions d(C–H) = d(B–H) 0.96 Å and assigned a common isotropic thermal parameter ($U = 0.08$ Å^2).

8. Supplementary material

Details of the experimental conditions appear in Table 1. Final atomic coordinates, thermal parameters, and bond lengths and angles have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Any request to the CCDC for this material should quote the full literature citation and the reference number CCDC 236295.

Acknowledgements

We are grateful to the Royal Society and the University of London Central Research Fund for support, to the EPSRC for a studentship to G.H.M. (GR/H31943)

and for provision of the X-ray diffractometer. We are grateful to Prof. Josef Takats and Dr. Noemia Marques for helpful discussions and to Dr. Derek Tocher for assistance with the X-ray determination.

Abstract

The reaction between the binuclear dicationic compound $[(PPh_3)_2Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)_2][PF_6]_2$ (**1**) and either 2 or 4 equivalents of isocyanides leads to the substitution of a single PPh_3 ligand per nickel atom. The new binuclear compounds $[(CNR)(PPh_3)Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)(CNR)][PF_6]_2$ (R = *S*-(−)-CH(Ph)Me (**2**), cyclohexyl (**3**), *tert*-butyl (**4**) and mesityl (**5**)) were prepared in almost quantitative yields and were fully characterised by elemental analysis, FT-IR and NMR spectroscopies. In the X-ray crystal structure of **4** two crystallographically inequivalent $CpNi(PPh_3)(CN^tBu)$ moieties are observed, where the $Ni(PPh_3)(CN^tBu)$ fragments are positioned on the C_5H_4 faces of the bridging ligand to minimise inter-ring repulsions. Addition of an excess of *S*-(−)-CNCH(Ph)Me to **1** results in the catalytic polymerisation of the isocyanide, yielding polymers of increasing molecular weights when the ratio $[CNR]_o/[Ni]_o$ is increased, consistent with non-living polymerisation. The molecular weights of the poly(*S*-(−)-1-phenylethyl isocyanide) (**6**) obtained with complex **1** are higher than those obtained with the related mononuclear complex $[Ni(\eta\text{-}C_5H_5)(PPh_3)_2]PF_6$ (**8**), which suggests an initiation step involving migratory insertion of isocyanide into the Ni–cyclopentadienyl bonds. An EPR spectrum of the reaction mixture acquired at 77 K, after 10 min of polymerisation at 20 °C, reveals the existence of two pentacoordinated Ni(I) $3d^9$ chain propagating species with trigonal bipyramidal geometry (d_{z^2} ground state). One of the Ni species contains two PPh_3 ligands occupying both axial positions of an axially distorted trigonal bipyramid, whereas the other species contains an axially coordinated PPh_3 and either a PPh_3 coordinated in the equatorial plane or dissociated from the nickel atom.

1. Introduction

Despite the great number of NiCp (Cp = η-C_5H_5) compounds reported in the literature, those containing isocyanide ligands (C≡NR) are scarce. In the 1960s,

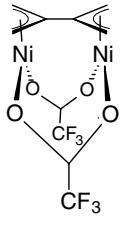
Yamamoto et al. [1,2] described the stoichiometric reaction of neutral [Ni(η-C_5H_5)(PPh_3)R′] (R′ = alkyl, aryl) with alkyl isocyanides to yield iminoacyl derivatives of the type [Ni(η-C_5H_5)(CNR){C(=NR)R′}], which were formed by insertion of a coordinated isocyanide into a Ni–R′ bond. According to these authors, the reaction between CN^{t}Bu and [Ni(η-C_5H_5)LX] (L = $P(OPh)_3$, $AsPh_3$; X = Br, I) does not give insertion products, but leads to the formation of cationic compounds of the type [Ni(η-C_5H_5)(CN^{t}Bu)$_2$]$^+X^-$ (X = I, Br). Using analogous compounds [Ni(η-C_5H_5)LX], (L = PPh_3, PEt_3 and X = I) the monosubstituted complexes [Ni(η-C_5H_5)(CNR)L]$^+I^-$ (R = ^{t}Bu, Cy), could be obtained, demonstrating that the selectivity of the cationic products is sensitive to the co-ligands in the coordination sphere.

More recently, Takahashi and co-workers [3] found that the neutral alkynyl derivative [Ni(η-C_5H_5)(PPh_3)(C≡CPh)] is an effective catalyst for the polymerisation of isocyanides [4] and managed to isolate and characterise a PPh_3 free iminoacyl NiCp complex resulting from double insertion, with a proposed structure incorporating a four-membered ring [Ni(η-C_5H_5){C(=N=R)C(=NR)C≡CPh}], which is the first intermediate of multiple insertion reactions. Previous studies on the polymerisation of isocyanides catalysed by nickel complexes comprises the highly active systems based on $Ni(CO)_4$ [5] and $NiCl_2$ [4b,6], and the controlled synthesis of well-defined poly(isocyanides) achieved by Deming and Novak [7]. These authors employed the neutral allyl nickel complex [Ni(η-CH_2CHCH_2)(μ-$OOCF_3$)]$_2$, in which the allyl ligand plays a key role in the rapid initiation of the polymerisation reaction facilitating fast insertion of coordinated isocyanide molecules under living polymerisation conditions. This method enabled the synthesis of elastomeric diblock butadiene–isocyanide [8] and triblock butadiene–isocyanide–butadiene [9] copolymers, the latter being prepared with the bifunctional allyl nickel initiator [(μ-CF_3COO)-Ni{μ-(η-$(CH_2)_2C$)-$(C(CH_2)_2$-η)}Ni(μ-$OOCCF_3$)] (**7**).



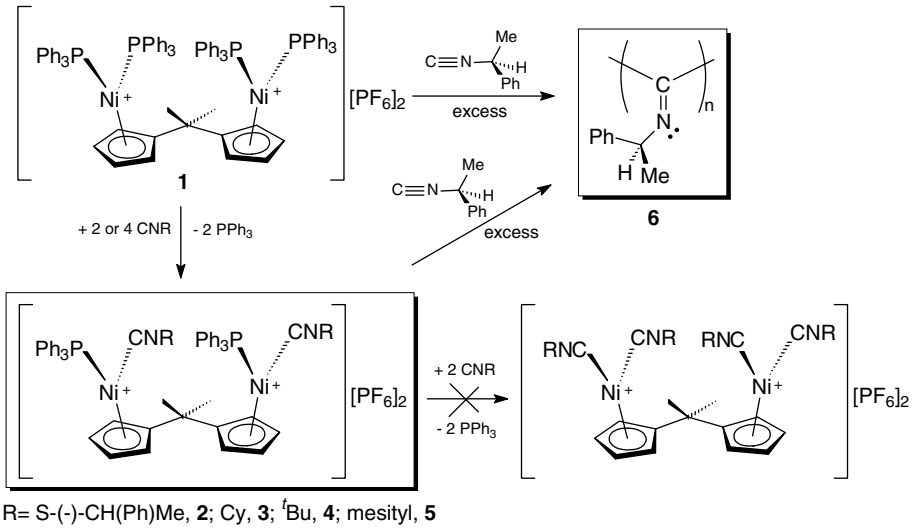
7

We have recently reported the living polymerisation of isocyanides using the cationic allyl nickel complex [Ni(η-$CH_2C(CH_3)CH_2$)(COD)]PF_6 (COD = 1,5-cyclooctadiene) [10]. We demonstrated that indenyl and cyclopentadienyl ligands bound to Ni can also play an important role in the initiation of the isocyanide polymerisation since the cationic allyl, indenyl and cyclopentadienyl nickel derivatives [Ni(η-$CH_2C(Me)CH_2$)(PPh_3)$_2$]PF_6, [Ni(η-C_9H_7)(PPh_3)$_2$]PF_6 and [Ni(η-C_5H_5)(PPh_3)$_2$]PF_6 (**8**) are effective catalysts for this reaction, although in a non-living fashion. Furthermore we have also studied the synthesis and characterisation of ring-coupled cyclopentadienyl and indenyl homobimetallic nickel compounds, including the complex [(PPh_3)$_2$Ni{μ-(η-C_5H_4)CMe_2(η-C_5H_4)}Ni(PPh_3)$_2$][PF_6]$_2$ (**1**) [11]. In this paper, we report the stoichiometric and catalytic reactions between isocyanides and the dicationic binuclear compound **1**.

2. Results and discussion

The reaction between the binuclear compound [(PPh_3)$_2$Ni{μ-(η-C_5H_4)CMe_2(η-C_5H_4)}Ni(PPh_3)$_2$][PF_6]$_2$ (**1**) [11] and stoichiometric amounts of isocyanides (C≡N—R) in *o*-dichlorobenzene at room temperature gives exclusively compounds **2**–**5** [(CNR)(PPh_3)Ni{μ-(η-C_5H_4)CMe_2(η-C_5H_4)}Ni(PPh_3)(CNR)][PF_6]$_2$, where R = *S*-(−)-1-phenylethyl (**2**), cyclohexyl (**3**), *tert*-butyl (**4**) and mesityl (**5**) (Scheme 1). Irrespective of the electronic or stereochemical properties of the isocyanide used and the stoichiometry (2 or 4 equivalents), only the product of a nucleophilic monosubstitution of PPh_3 by CNR at each Ni atom is obtained. These new dicationic binuclear Ni compounds were obtained in almost quantitative yields as green microcrystals (**3**), green lamellar crystals (**4**) or green amorphous powders (**2** and **5**) and all are relatively stable in air. Attempts to synthesise the bis-isocyanide derivative [(CNR)$_2$Ni{μ-(η-C_5H_4)YMe_2(η-C_5H_4)}Ni(CNR)$_2$][PF_6]$_2$ (Y = C or Si) by using an analogous synthetic route to that used for the synthesis of compound **1** [11], from the reaction between [$NiBr_2${*S*-(−)-CNCH(Ph)Me}$_2$] and Li_2[$CMe_2(C_5H_4)_2$] or Li_2[$SiMe_2(C_5H_4)_2$], failed.

Recrystallisation of **4** from CH_2Cl_2–Et_2O gave crystals suitable for a single crystal X-ray diffraction study. The molecular structure of the dication is shown in Fig. 1, and selected distances and angles are listed in Table 1. Unlike the parent compound **1** [11], the molecular structure reveals that dication **4** contains two crystallographically inequivalent CpNi(PPh_3)(CN^{t}Bu) moieties. The Ni(PPh_3)(CN^{t}Bu) fragments are positioned on the C_5H_4 faces of the bridging ligand to minimise inter-ring repulsions. As a consequence there is a long interatomic separation Ni(1)···Ni(2) of 6.659(10) Å, which is, however, shorter than that observed in **1** (6.750(1) Å) [11]. The plane defined by the bridging carbon atoms C(1)—C(6)—C(7) bisects the Cp ring bound to Ni(2) (dihedral angle of 89.4(5)°), whereas the Cp ring connected to Ni(1) shows a 4.9° clockwise rotation in rela-



Scheme 1. Reactions between **1** and isocyanides: synthesis of compounds **2**–**5** and polymerisation of *S*-(−)-1-phenylethyl isocyanide catalysed by **1**.

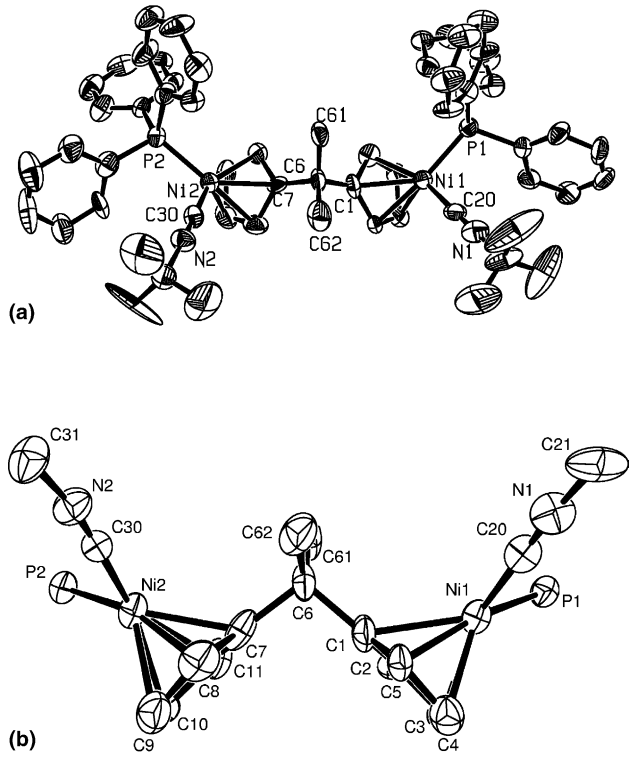


Fig. 1. ORTEPIII diagram of dication **4**, using 30% probability level ellipsoids. (a) Global view. (b) Side view (the hydrogens, the phenyl groups of PPh_3 and the methyl groups of CN^tBu have been omitted for clarity).

tion to the same plane. Geometries at both nickel atoms are trigonal planar (sum of bond angles using Cp ring centroids are 359.6(4)° and 359.5(4)°, respectively, at Ni(1) and Ni(2)), but the Cp planes are deviated slightly from the perpendicular to the corresponding P—Ni—$C_{isocyanide}$ planes (dihedral angles of 83.7(3)° and 84.3(4)°, respectively, for Ni(1) and Ni(2)). This is also observed in the reported structure of binuclear **1** [11] and in other known X-ray structures of monosubstituted nickel cyclopentadienyl complexes [12–14]. The Ni—C_{Cp} distances are within the range of values observed for **1** [11], but the Ni—P distances are shorter than in **1** (2.211(2) and 2.214(2) Å) and similar to the value found in the related indenyl analogue [Ni(η-1-^{i}Pr-C_9H_6)(PPh_3)(CN^tBu)][OSO_2CF_3] (2.1838(9) Å) [15]. This is a consequence of lower steric crowding around the Ni atoms in compound **4**, which have less bulky ligands than **1** (CN^tBu instead of a second PPh_3). The isocyanide ligands are bound to the Ni in a terminal fashion and are essentially linear: Ni(1)—C(20)—N(1) and C(20)—N(1)—C(21) are 179.1(11)° and 175.0(13)°, respectively, while Ni(2)—C(30)—N(2) and N(2)—C(30)—Ni(2) are 176.8(10)° and 175.0(13)°, respectively. These values together with those of Ni(1)—C(20) and Ni(2)—C(30), 1.877(11) and 1.810(10) Å, and C(20)—N(1) and C(30)—N(2), 1.123(13) and 1.124(11) Å, respectively, are within the range of values found for other Ni compounds containing CN^tBu ligands [12,16,17]. The low quality of the crystals precluded a standard refinement, not allowing a reliable discussion of the distortions of the Cp rings according to the classification introduced by Andersen and co-workers [18].

In solution, all the new compounds **2**–**5** exhibit C_{2v} symmetry, which implies the existence of unrestricted rotation of the Ni(PPh_3)(CNR) groups around each Cp—Ni bond. In fact, the ^{1}H NMR spectra of **2**–**5** show single resonances in the range δ 1.53–1.73 for both bridging methyl protons and only two resonances in the ranges δ 5.41–5.49 and 4.91–5.19 for the Cp ring protons, assigned by NOE experiments to the equivalent proximal (H2/H5 – closer to the bridge) and distal (H3′/H4′) protons, respectively. The separation between their chemical shifts ($\Delta = \delta$(H2/H5) – δ(H3/H4) = 0.24–0.50)
