The distances between the metal ion and the carbon atoms of these complexes are listed in Table 3. Compared with the bond lengths within this series of complexes, the bond distances of Ln–C(ring) almost follow a trend (going from La to Lu): the smaller the ionic radii, the shorter the average bond length, and the wider the bond length range. The bond lengths of complex **1** range from 2.797 to 2.883 Å (0.086 Å), and average 2.844 Å; while the bond lengths of complex **3** range from 2.565 to 2.809 Å (0.244 Å), and average 2.687 Å.

The size of the tetrahydrofurfurylindenyl ligand can be calculated as the difference between the mean bond length of Ln–C(ring) and ionic radius [9] (ionic radius vary in different coordination space). The changes of the rare earth ionic radii show little influence on the size of ligand (from 1.626 to 1.654 Å).

The distances between the metal ion and the centroid of the indenyl groups of these complexes show the same trend as the bond lengths of Ln–C(ring) (Fig. 2). This trend is also consistent with the lanthanide contraction. The difference between the bond lengths of Ln–Cent(1) and Ln–Cent(2) is small, ranging from 0.025 Å (Sm) to 0.002 Å (Lu).

The slip parameter ΔM–C [10], which quantifies the η^5–η^3 slippage within indenyl metal complexes, ranging from 0.0663 (0.0343) Å for complex **1** to 0.1763 (0.078) Å for complex **3**, is shown in Fig. 3. Although it is not a rectilinear trend, the slip distortion gradually increases with the decrease of the radii size of the central metals. Thereto, the pitch of ΔM–C(1) is higher than ΔM–C(2). It can also be described as follows: with the decrease of

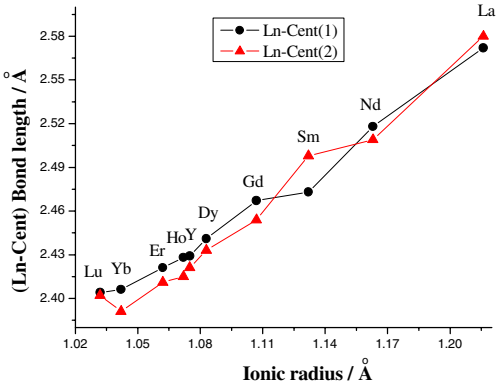

Fig. 2. Bond lengths of Ln–Cent.

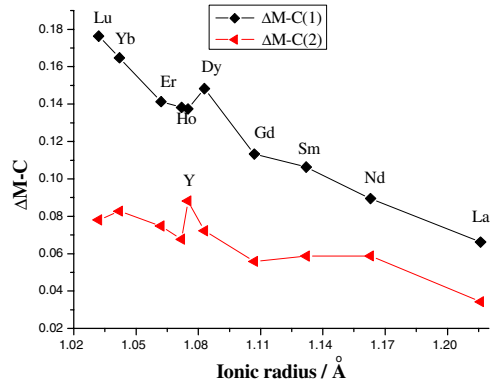

Fig. 3.

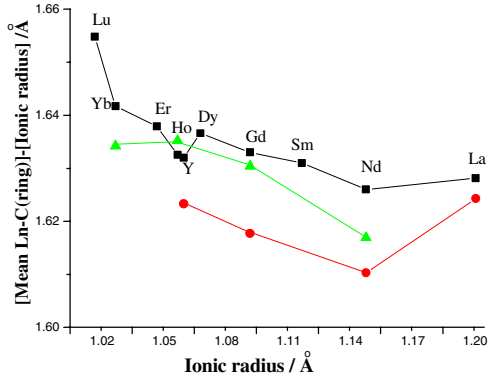

Fig. 4. Comparison between three ligands ■: $(C_4H_7OCH_2\ C_9H_6)_2$ LnCl; ●: $(CH_3OCH_2CH_2C_9H_6)_2LnCl$; ▲: $O(CH_2CH_2C_9H_6)_2LnCl$-THF.

the ionic radii, one indenyl plane almost keeps no slippage, and the other inclines gradually. In the Lu complex, it is noted that one indenyl ligand shows η^5-coordination to the Lu atom, while the another is almost bonded in η^3-mode.

The dihedral angle of indene planes ranging from 51.5° (Y, Ho) to 52.9° (La) and the RA angle [11] ranging from 152.11° (Yb) to 157.73° (Nd) show no obvious relation with ionic radii.

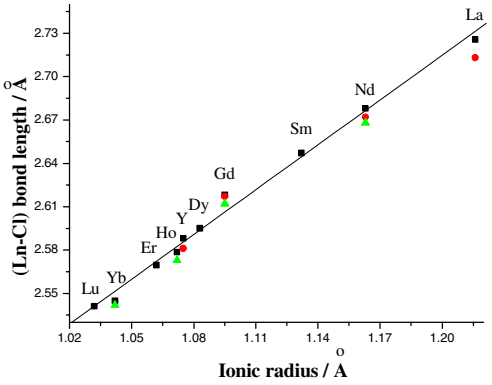

Fig. 5. Bond lengths of Ln–Cl ■: $(C_4H_7OCH_2C_9H_6)_2LnCl$; ●: $(CH_3OCH_2CH_2C_9H_6)_2LnCl$; ▲: $O(CH_2CH_2C_9H_6)_2LnCl \cdot THF$.

Compared with some other 9-coordinate lanthanocene chlorides of indenyl ligands bearing pendant O-donors, $(CH_3OCH_2CH_2C_9H_6)_2LnCl$ (Ln = La, Nd, Gd, Y [12] and $[O(CH_2CH_2C_9H_6)_2]$ LnCl · THF (Ln = Nd, Gd, Ho) [13] (Fig. 4), it is concluded that the space coordination environment of tetrahydrofurfurylindenyl is similar to the above two ligands. The distances between Ln–Cl of these three kinds of complexes are shown in Fig. 5 and their bond lengths are very close, and well accorded with the lanthanide contraction, which also support the above conclusion.

3. Conclusion

Ten stable lanthanocene chloride complexes (from La to Lu) with the tetrahydrofurfurylindenyl ligand have been synthesized and X-ray characterized. The investigation results indicate that they are isostructural, the side chain oxygen atoms displace THF to coordinate with the metal atom to form stable intramolecular bis-indenyl-type complexes. The changes of the bond length of Ln–C(ring), Ln–Cent, Ln–Cl, and ΔM–C are consistent with lanthanide contraction, while no obvious connections are found between the dihedral angles of indene planes and the RA angles with the rare earth radius.

4. Experiments

4.1. General procedures

All operations involving organometallic compounds were carried out under an inert atmosphere of argon using standard Schlenk techniques. Tetrahydrofuran, toluene and hexane were distilled under argon from sodium/potassium alloy with benzophenone ketyl prior to use. Anhydrous lanthanide chlorides [14], tetrahydrofurfurylindenyl lithium [7] were prepared according to

published procedures; the analysis of rare earth metals and chlorine were accomplished using direct complexometric titration with disodium EDTA and the Volhard method, respectively. Carbon and hydrogen analysis were carried out by the combustion method. IR spectra were recorded on a Bio-Rad FTS135 spectrometer in the form of KBr pellets. Mass spectra were recorded on a LGQ spectrometer.

4.2. Synthesis of bis(tetrahydrofurfurylindenyl) lanthanum chloride(*1*)

Tetrahydrofurfurylindenyl lithium (0.006 mol) in 15 mL of THF was added slowly to a suspension of $LaCl_3$ (0.7376 g, 0.003 mol in 20 mL THF) at low temperature (≈−60 °C). The reaction mixture was allowed to naturally warm to r.t and stirred for 24 h. After centrifugation the solvent was evaporated in vacuo. The residues were extracted with 30 mL toluene/THF (4:1) and kept at −10 °C. Colorless crystals were obtained in 35% yield. *Anal*. Calc. (%) for $C_{28}H_{30}O_2ClLa$: La, 24.33; Cl, 6.20; C, 58.65; H, 5.24. Found (%): La, 24.81; Cl, 6.82; C, 60.02; H, 5.61. 4.5. Crystal structure determination

A suitable crystal was sealed in thin-walled glass capillary under argon. Data were collected on a Rigaku Rapid Diffractometer with graphite-monochromated Mo-Kα ($\lambda = 0.071073$ Å) radiation using the $\omega - 2\theta$ technique at 293 K. Crystal data and experimental details are listed in Table 1, while selected bond lengths and bond angles are given in Table 2. The crystal structures were solved by direct methods and refined on F^2 by full-matrix least-squares methods, expanded using Fourier techniques [15]. All hydrogen atoms were added according to theoretical models with isotropic thermal parameters related to those of the supporting carbon atoms, but were not included in refinement. All calculations were performed using the SHELXS-97 crystallographic software package [16].

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 198715 and 198716 for compounds **1** and **3**. Abstract

Two polymeric Cu(II) complexes with *N*-(2-carboxyphenyl)iminodiaceticacid (H_3cpida) have been synthesized and characterized by elemental analysis, conductance, spectral, thermogravimetric, magnetic measurements and single-crystal X-ray diffraction. Green crystals of $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**) are obtained by digesting $Cu(OH)_2$ with hot aqueous solution of H_3cpida in 1:1 molar proportion. Blue crystals of $\{[Cu(Hcpida)(H_2O)]\cdot H_2O\}_n$ (**2**) are obtained by slow cooling of hot aqueous solution of **1**. Coordination environment of Cu(II) ion in the green compound **1** (λ_{max} 749, 365 nm) is five-coordinated distorted square pyramidal, which on hydration, is transformed to six-coordinated distorted octahedral blue compound **2** (λ_{max} 768, 315 nm). Single-crystal X-ray diffraction experiments indicate that the structures of both **1** and **2**, are made up of 1D polymeric Cu(II) units linked by carboxylato bridges in *syn–anti* bonding mode, stabilized via inter-chain hydrogen bonds and π–π stacking interactions of the phenyl rings. Crystal lattice of **2** contains channels that host the lattice water molecules. Variable temperature (2–300 K) magnetic measurements indicate that the Cu(II) ions in both **1** and **2** exist as magnetically quasi-isolated spin doublets ($g > 2$) involving weak ferromagnetic coupling among the Cu(II) ions through the carboxylato bridges resulting in J values of 3.60 cm^{-1} for **1** and 5.69 cm^{-1} for **2**.

Keywords: Copper(II); Aminopolycarboxylate; Ferromagnetic coupling; π–π stacking; Cylindrical channels

1. Introduction

Extended frameworks of coordination polymers, based on complexes of transition metals and multifunctional bridging ligands, are of great research interest due to their potential applications in the fields of catalysis, electrical conductivity, molecular magnetic materials and host–guest chemistry [1]. Construction of coordination polymers with multi-dimensional frameworks has focused on the use of directional interactions such as H-bonding and π–π stacking that control the aggregation of molecular species [2]. The carboxylato group is one of the most widely used bridging ligands for designing polynuclear complexes having novel structural features and interesting magnetic properties. Versatility of this group as a ligand is illustrated by the variety of its coordination modes when acting as a bridge [3], the most common being the *syn–syn* and *syn–anti* conformations that mediate large antiferromagnetic [4] and weak antiferromagnetic or ferromagnetic interactions [5]. Complexes containing the much less known *anti–anti* conformation show both antiferromagnetic and ferromagnetic couplings [5l]. Transition metal complexes with aminopolycarboxylates, functioning as chelating as well as bridging

doi:10.1016/j.poly.2004.01.009

ligands are well known. Extensive structural studies have been carried out on the metal chelates with simple aminopolycarboxylates, viz. iminodiacetate (ida) and N-substituted ida [6]. In contrast there are only a few reports of such studies on the complexes with tripodal quadridentate aminopolycarboxylate ligands like *N*-(2-carboxyphenyl)iminodiaceticacid (H_3cpida) [7]. In this paper, we report the synthesis, characterization, physicochemical studies, single-crystal X-ray diffraction and variable temperature magnetic measurements and magneto structural correlation of the two 1D coordination polymers $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**) and $\{[Cu(Hcpida)(H_2O)]\cdot H_2O\}_n$ (**2**), obtained as a hydration product of **1**. Compound **2** was found to be identical with the one reported by Shkolnikova et. al. [8], who synthesized the compound by a different procedure. Both the complexes **1** and **2** are made up of zigzag polymeric chains with carboxylato groups bridging the adjacent Cu(II) units in the *syn–anti* bonding mode. The interpenetrating chains are stabilized via inter-chain hydrogen bonds and π–π stacking interactions among the phenyl rings [2e]. Crystal lattice of **2** contains cylindrical channels that appear to host the lattice water molecules.

2. Experimental

2.1. Materials and measurements

All reagents were of A.R. grade obtained commercially and used without further purification. Elemental analyses (C, H and N) were done with a Perkin–Elmer 2400 CHNS/O analyzer and the copper (%) in the complexes were determined titrimetrically [9]. Molar conductance values of the complexes in aqueous solution were measured with a Systronics 304 digital conductivitymeter. The electronic spectra of the complexes in solid state and in aqueous solution were recorded on a Hitachi U-3501 spectrophotometer. IR spectra in KBr pellets were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Thermal analyses were carried out on a Metler Toledo TGA/SDTA 851 thermal analyzer in a dynamic atmosphere of dinitrogen (flow rate: 30 ml min^{-1}). Magnetic measurements were carried out on polycrystalline samples (0.03 g) with a Quantum Design MPMS XL-5 SQUID susceptometer operating at a magnetic field of 0.1 T between 2 and 300 K. The diamagnetic corrections were evaluated from Pascal's constants. Magnetization measurements were made in the same SQUID at 2 K.

2.2. Synthesis

2.2.1. N-(2-carboxyphenyl)iminodiacetic acid (H_3cpida)

The ligand H_3cpida was prepared by condensing anthranilic acid with monochloroacetic acid in presence of Na_2CO_3 following the reported procedure [10], m.p. 210 °C. *Anal*. Calc. for $C_{11}H_{11}NO_6$: C, 52.17; H, 4.34; N, 5.53. Found: C, 52.25; H, 4.29; N, 5.71%. IR (KBr disk, ν/cm^{-1}): ν(OH) 3671s; ν(CO) 1728vs; ν_{as}(COO) 1599s; ν(CN) 1553s; ν_s(COO) 1381s.

2.2.2. $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**)

To a suspension of freshly precipitated alkali free copper(II) hydroxide obtained from $CuSO_4\cdot 5H_2O$ (2.75 g, 11 mmol) in 40 ml water, H_3cpida (2.53 g, 10 mmol) was added with stirring and the mixture was digested at 60–70 °C for 1 h. Unreacted $Cu(OH)_2$ was filtered off and the resulting green solution was evaporated carefully at 60 °C to ~25 ml. Green prismatic crystals of **1**, suitable for X-ray diffraction were obtained on standing (yield: ca. 75%). *Anal*. Calc. for $C_{11}H_{11}CuNO_7$: C, 39.70; H, 3.31; N, 4.21; Cu, 19.09. Found: C, 39.55; H, 3.40; N, 4.16; Cu, 18.82%. λ_{max}/nm (solid state) 749, 365; λ_{max}/nm (H_2O) 759 (ε/mol^{-1} 1 cm^{-1}, 76). Molar conductivity (H_2O, S cm^2 mol^{-1}): 332.4. IR (KBr disk, ν/cm^{-1}):, ν(OH) 3618s, 3507s; ν(CO) 1713vs; ν_{as}(COO)1599s; ν(CN)1403s; ν_s(COO) 1360s. TG: found loss of 10.45% in the temperature range 90–165 °C, calc. for $2H_2O$: 10.27%, corresponding to the dehydration processes, $[Cu(Hcpida)(H_2O)]\cdot H_2O \rightarrow [Cu(Hcpida)]$.

2.3. Crystal structure determination

Table 1 summarizes the pertinent crystallographic data together with refinement details, for $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**) and $\{[Cu(Hcpida)(H_2O)]\cdot H_2O\}_n$ (**2**) and Table 2 lists some of the selected bond lengths and bond angles. The X-ray single-crystal diffraction data were collected at 293 K for complex **1** on a Bruker AXS Smart single-crystal diffractometer and for complex **2** an Enraf Nonius CAD4 single-crystal diffractometer was used. The data were corrected for Lorentz, polarization and absorption effects. The crystal structures of the complexes were solved by direct methods using SIR-97

[11] and SHELXS-97 [12] and refined by using SHELXL-97 [12]. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms in complexes **1** and **2** were refined using isotropic thermal parameters, except the carboxylic acid hydrogens (H13) in both the complexes, which were made to 'ride' on the atoms to which they were bonded (O13). Because of high thermal vibration, the hydrogen atoms of the water molecule in **1** could not be located. Neutral atom scattering factors were taken from Cromer and Weber [13] and anomalous dispersion effects were included in F_c [14]. The crystallographic illustrations were prepared using ORTEP-3 [15].

3. Results and discussion

Compound **1** obtained from the reaction of equimolar amounts of freshly precipitated alkali free $Cu(OH)_2$ with H_3cpida. In hot aqueous solution it is slowly transformed to compound **2**. Such transformation of **1** to **2** occurs with remarkable structural and spectral changes, as coordinately unsaturated square pyramidal Cu(II) ion in **1** becomes coordinately saturated distorted octahedral in complex **2** through hydration reaction (Scheme 1).

3.1. Physicochemical studies

Diffuse reflectance spectra of the green complex **1** (λ_{max} 749, 365 nm) and the blue complex **2** (λ_{max} 768, 315 nm) show significant differences. The d–d band ($^2B_{1g} \rightarrow {}^2B_{2g}$) shows a red shift of ~20 nm in going from **1** to **2** as a consequence of higher CFSE of Cu(II) (d^9) ion in a square pyramidal geometry in **1** than that in a distorted octahedral geometry in **2**. On the other hand, the LMCT band shows a blue shift of ~50 nm in going from **1** to **2** obviously due to stronger metal–ligand orbital overlap permitted in a distorted octahedral geometry than that in a square pyramidal geometry [16]. The IR bands in the range (3430–3618 cm^{-1}) confirm the presence of lattice water in both the compounds **1** and **2** [17]. This is further supported by the weight loss percent observed in the temperature range 90–165 °C. The asymmetric ν_{as}(COO) and the symmetric ν_s(COO) stretching bands of the Cu(II)-complexes fall in the region 1599–1647 and 1332–1366 cm^{-1}, respectively. The difference between ν_{as}(COO) and ν_s(COO) stretching frequencies suggests both terminal as well as bridging modes of coordination of the carboxylate groups [18,3a]. High molar conductance values of **1** and **2** in

$$\{[Cu(Hcpida)].H_2O\}_n \xrightarrow{nH_2O} \{[Cu(Hcpida)(H_2O)] \cdot H_2O\}_n$$

1, green **2**,blue

Scheme 1.

H_2O (332.5 and 305 S cm^2 mol^{-1}, respectively) indicate their electrolytic nature, obviously due to the presence of COOH groups coordinated to Cu(II) ions through their carbonyl oxygen atoms, as a result of which these coordinated COOH groups ionize almost completely in aqueous solution (pH∼3). Thus the complexes **1** and **2** in aqueous solution, possibly exist as complex acids, $\{H^+[Cu(cpida)]^-\}_n$ and $\{H^+[Cu(cpida)(H_2O)]^-\}_n$, respectively, similar to the Co(III)–dimethylglyoxime (H_2dmg) complex, $[Co(H_2dmg)(Hdmg)Cl_2]$ which exists as $H^+[Co(Hdmg)_2Cl_2]^-$ giving a molar conductance of 374 S cm^2 mol^{-1} in freshly prepared aqueous solution at room temperature [19]. In spite of different types of bonding of the two water molecules (one coordinated water and one lattice water) in compound **2**, both the water molecules are lost in an overlapping step in the temperature range 90–165 °C, possibly due to longer bond distance (Table 2) between Cu(II) and the coordinated water molecule [Cu–O2W = 2.651(5) Å] rendering the latter loosely bound.

3.2. Description of crystal structures

The crystal structure of **1** (Fig. 1) consists of asymmetric units containing Cu(II) ion in distorted square pyramidal environment (4 + 1 type) with O(9) and O(18) from two carboxylate groups, the amino-nitrogen N(15) and a carboxylate-oxygen O(10)^{i} of the carboxylate group attached to the phenyl ring (symmetry code $i = -x, y - 1/2, -z + 3/2$) occupying the four basal positions. The coordination at the apical position is completed by the carbonyl-oxygen O(11) of a carboxylate group of the ligand. The four closest donors [O(9), N(15), O(18), O(10)^{i}] define a mean equatorial plane (deviations from −0.253(3) to −0.260(3) Å for O(18) and O(9) to +0.147(2) and +0.249(3) Å for O(10)^{i} and N(15), respectively). The Cu(II) ion lies at +0.065(1) Å from this plane towards O(11). The percentage of distortion of this square pyramidal stereochemistry towards a hypothetical trigonal one is obtained from the value of $\tau = 21.01$ [5n]. The two glycinate like fragments of the ligand form five-membered puckered chelate rings at the Cu(II) ion. A mean plane drawn through one of the rings is almost coplanar with the basal plane (dihedral angle 13.28(9)°), while that through the other ring is nearly perpendicular to it (dihedral angle 104.30(7)°). The 'equatorial' ring, defined by the atoms Cu(1)–N(15)–C(16)–C(17)–O(18) (deviations from −0.202(3) to 0.282(3) Å from the mean plane) is less distorted than the 'perpendicular' one, consisting of the atoms Cu(1)–N(15)–C(14)–C(12)–O(11) (deviations from −0.264(3) to 0.322(4) Å). Both the rings have conformations intermediate between envelope and half-chair (q, ϕ values for 'equatorial' and 'perpendicular' rings are 0.337(3) Å, 313.8(5)° and 0.462(2) Å, 351.4(4)°, respectively) [20]. The phenyl ring is directed downward from the pyramid (i.e., on the opposite side of O(11)) and its mean plane makes a dihedral angle of 60.96(9)° with the basal plane.

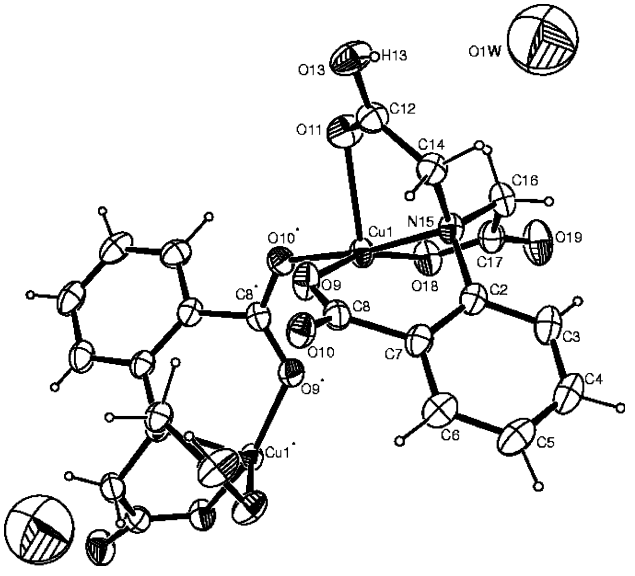

Fig. 1. ORTEP view of $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**) with atom labeling scheme. Thermal ellipsoids are shown at 50% probability.

Complex **1**, like other Cu(II)–(ida/substituted ida) complexes [6], crystallizes in the polymeric form with carboxylate moieties bridging the symmetry related Cu(II) ions in *syn–anti* bonding mode having Cu–Cu separation of 5.02 Å through this bridge. But the novelty of this complex is that the carboxylate group attached to the phenyl ring, rather than the carboxylate group of the glycinate like fragments, is responsible for the formation of polymeric chains along the *b*-axis. The torsion angle between the basal planes of the consecutive Cu(II) units is found to be 58.5(1)°. The carboxylic acid hydrogen atom (H13) reinforces the cohesion of the chains through H-bond formation with the O(18)^{ii} atom (symmetry code $ii = x, y + 1, z$) of the alternate Cu(Hcpida) units of the same chain (Table 3). Although the H atoms of the water molecule could not be located, there are some potential acceptors for water hydrogen atoms, which are possibly involved in H-bonding to link the two adjacent chains and thus contribute to crystal packing. The crystal packing is further reinforced by π–π stacking interactions [2e] between parallel phenyl rings ($\alpha = 0.03°$) of adjacent chains (related by symmetry code $iii = -x, -y, -z - 2$) with a shortest distance of 3.638(2) Å ($\beta = \gamma = 23.79°$) (Fig. 2).

Complex **2**, obtained as a hydration product of complex **1**, retains the similar polymeric nature as its parent. In this complex the atoms O(9), O(11) and O(18) from the three carboxylate groups, the amino nitrogen N(15), the carboxylate oxygen O(10)^{iv} of the carboxylate group attached to the phenyl ring (symmetry code $iv = -x + 1/2, -y, z + 1/2$) from an adjacent asymmetric unit and a water O(2W) atom define the asymmetrically

Table 3
Hydrogen bond distances (Å) and angles (°) for complexes **1** and **2**

elongated octahedral coordination of the Cu(II) ion (type 4 + 1 + 1) with unequally disposed *trans*-axial long Cu(1)–O(11) and Cu(1)–O(2W) bonds (Fig. 3). Both the Cu-glycinate like chelate rings are less distorted (deviations of 'equatorial' ring from −0.186(8) to 0.089(5) Å, and deviations of 'perpendicular' ring from −0.109(5) to 0.205(7) Å) compared to complex **1**. The conformation of the 'equatorial' ring has changed to envelope (*q*, ϕ values for 'equatorial' and 'perpendicular' rings are 0.186(5) Å, 147.3(16)° and 0.219(4) Å, 335.6(14)°, respectively) [20]. Dihedral angles between the basal plane and these two rings have changed to 4.51(13)° and 89.44(13)°. The plane of the phenyl ring has also rotated to make a dihedral angle of 35.73(13)° with the basal plane. Torsion angle between the basal planes of the consecutive Cu(II) units has been increased to 65.4(1)°.

The carboxylic acid hydrogen (H13) in complex **2** is involved in H-bonding with oxygen, $O(2W)^{v}$, of a $[Cu(Hcpida)(H_2O)]$ unit of the adjacent chain (related by symmetry code $v = -x-1/2, y-1/2, z$) and this closes a cylindrical channel along *b*-axis that hosts the lattice water molecule (Fig. 4). All the hydrogen atoms of both coordinated and uncoordinated water molecules take part in intra- and inter-chain H-bonding to reinforce the cohesion and contribute to crystal packing (Table 3). The conformational changes associated with the hydration reaction (Scheme 1) bring the copper atoms of the chains closer to each other with Cu–Cu separation of 4.87 Å through the bridge.

Although **2** is structurally similar to the compound described by Shkolnikova et al. [8], the bond lengths are slightly different, particularly the Cu–N(15) and the C12–O13 bonds, which are 2.078(4) and 1.304(6) Å, respectively, in **2** as compared to 2.058(5) and 1.325(7) Å in the other. Moreover, the novel feature of **2** is its

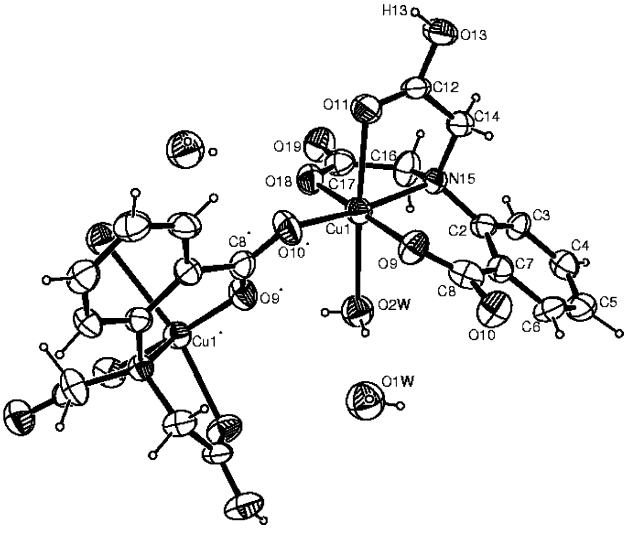

Fig. 3. ORTEP view of $\{[Cu(Hcpida)(H_2O)]\cdot H_2O\}_n$ (**2**) with atom labeling scheme. Thermal ellipsoids are shown at 50% probability.

ability to form cylindrical channels for hosting the H_2O molecules (Fig. 4).

3.3. Magnetic properties

The magnetic properties of complexes **1** and **2** are very similar, which seem logical taking into consideration the coincidence in the chemical pathway in their structures (carboxylato bridge in *syn–anti* equatorial–equatorial coordination mode). $\chi_M T$ versus T plot of **1** is shown in Fig. 5, that of **2** is quite similar. The values of $\chi_M T$ at 300 K are 0.45 $cm^3\ mol^{-1}$ K for **1** and 0.47 $cm^3\ mol^{-1}$ K for **2**, which are as expected for one magnetically quasi-isolated spin doublet ($g > 2.00$). Starting from the room temperature, $\chi_M T$ values smoothly increase up to 0.80 $cm^3\ mol^{-1}$ K for **1** and 0.96 $cm^3\ mol^{-1}$ K for **2** at 2 K. The shapes of these curves clearly indicate weak ferromagnetic coupling among the Cu(II) ions. The mathematical formula derived by Baker et al. [21] for ferromagnetic 1D systems with $S = 1/2$ is valid only for relatively high temperatures. Thus, when the ferromagnetic coupling is weak, this formula is not very accurate. For this reason the fit of the experimental data for complexes **1** and **2** was performed in numerical form from a full-matrix diagonalization of the Hamiltonian corresponding to a ring of 12 local $S = 1/2$ centers with the adequate J coupling parameters (through the carboxylato in *syn–anti* coordination mode) using the CLUMAG program [22]. With this program, the use of 12 cycled centers gives a good approximation for the system, which is actually infinite. The best J and g values are 3.6 and 2.18 cm^{-1} for **1** and 5.69 and 2.24 cm^{-1} for **2**. In the two cases R is 2.5×10^{-5} and 1.3×10^{-5}, respectively, where R is the agreement factor defined as $\sum_i[(\chi_M T)_{obs} - (\chi_M T)_{calc}]^2 / \sum_i[(\chi_M T)_{obs}]^2$. The reduced molar magnetization ($M/N\beta$) per Cu entity tends to $1N\beta$ (electron) (Fig. 5, inset) for both complexes **1** and **2**, but the shapes of the experimental curves are clearly above the theoretical ones for the Brillouin law. These features agree to the global ferromagnetic coupling within the copper(II) ions in **1** and **2**.

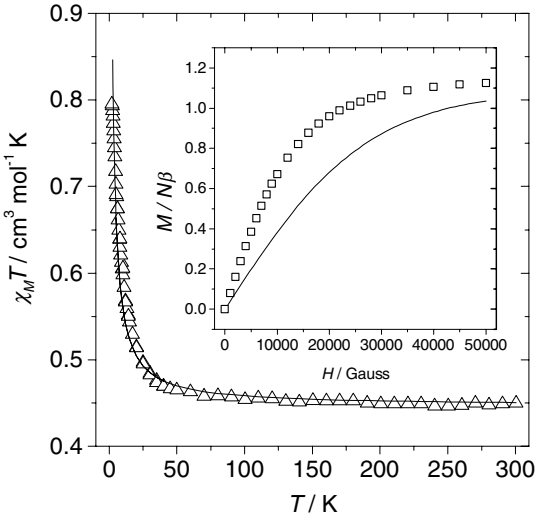

Fig. 5. Plot of the $\chi_M T$ vs. T of $\{[Cu(Hcpida)]\cdot H_2O\}_n$ (**1**). Solid line represents the best fit data. Inset: $M/N\beta$ vs. H. Solid line indicates the Brillouin curve with the calculated g value.

3.4. Magneto-structural correlations

From crystallographic analysis, it is evident that the Cu(II) ions in both the complexes **1** and **2**, are linked by carboxylato groups in *syn–anti* conformation with equatorial–equatorial coordination mode. For complex **1**, the Cu(II) center has almost perfectly square-pyramidal geometry while it is distorted octahedral for **2**. Small overlap between the magnetic orbitals ($d_{x^2-y^2}$) of the copper atoms for a planar Cu–O–C–O–Cu skeleton through the *syn–anti* carboxylato bridge account for the weak magnetic coupling observed. This overlap is significantly reduced for cases in which the Cu–O–C–O–Cu skeleton deviates from planarity (out-of-phase exchange pathway), which reduces the antiferromagnetic contribution, and as a result the ferromagnetic term becomes dominant (Scheme 2) [5d–5l]. This is true for both the complexes **1** and **2**. The higher J value for **2** can be explained by the greater dihedral angle between the two adjacent copper(II) planes of this complex compared to **1** (dihedral angles are 58.5(1)° and 65.4(1)° for complexes **1** and **2**, respectively). Theoretical DFT calculations corroborate these general features [5m]. Magneto structural data of some selected ferromagnetically coupled carboxylato bridged Cu(II) complexes along with those of **1** and **2** are presented in Table 4. From this table, it is easy to realize that the dihedral (or torsion) angle between the equatorial Cu(II) planes is important but not the exclusive factor that can influence J values. Dihedral angles for the complexes $\{[Cu(H_2O)_3][Cu(mal)_2(H_2O)]\}_n$ and **1** are very different, such as 85.95° (very close to the limit of 90°) and 58.5°, respectively (Table 4), but these two compounds have very similar J values (+3.0 and +3.6 cm^{-1}, respectively). Again, the

greatest *J* value (+12.4 cm^{-1}) does not correspond to the greatest dihedral angle (only 72.7°) (Table 4). Thus, other parameters, such as distances, other distortions, etc may be important and should be studied theoretically.

4. Conclusion

In this work, we report two 1D polymeric Cu(II) complexes, $\{[Cu(Hcpida)] \cdot H_2O\}_n$ (**1**) and $\{[Cu(Hcpida)(H_2O)] \cdot H_2O\}_n$ (**2**), derived from *N*-(2-carboxyphenyl)iminodiacetic acid (H_3cpida). Transformation of **1** to **2** through hydration is accompanied by remarkable structural (Cu(II)-square pyramidal to Cu(II)-distorted octahedral) and spectral changes. The carboxylato group attached to the phenyl ring of the coordinated $Hcpida^{2-}$ ion is responsible for the formation of the polymeric chain like structure in both **1** and **2**. Extensive H-bonding involving the H-atoms of water molecules and unionized carboxylic acid H-atom of the ligand reinforces the crystal packing, which is further reinforced by π–π stacking of the phenyl rings of the adjacent chains held parallel in the polymeric network. Such packing in **2** forms cylindrical channels that host the lattice water molecules. Both the complexes show ferromagnetic coupling between the Cu(II) ions through carboxylato bridge in *syn–anti* (equatorial–equatorial) coordination modes with Cu–Cu distances of 5.02 and 4.78 Å, respectively.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 206860, 206861 for complexes **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Di-protonated 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane tetra-*N*-oxide takes the *RSSR* configuration and is stabilized by a pair of charge-assisted intramolecular $[O–H\cdots O]^+$ hydrogen bonds; the di-cation induces the formation of lanthanide(III) complexes $[Ln(NO_3)_6]^{3-}$ (Ln = Ce, La, Nd), $[Er(NO_3)_3(H_2O)_3]$ and *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$, the latter being a novel linear coordination polymer constructed by a bridging nitrate ligand functioning in the $\mu\text{-}O, O, O', O''$ mode.

1. Introduction

Proton sponges [1] continue to attract much current interest due to their unusually high basicity, low nucleophilicity, slow deprotonation, and applications in modeling of low energetic enzymatic catalysis [2]. With mineral or organic acids, proton sponges of the diamine type form very stable ionic complexes consolidated by low-barrier intramolecular $[N–H\cdots N]^+$ hydrogen bonding, a primary example being 1,8-bis(dimethylamino) naphthalene [3]. Subsequent effort to explore other classes of *N*-donor proton sponges focused on cyclam-like macrocyclic tetramines [4] and, more recently, bowl and cage adamanzanes [5]. In this context, 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane (Me_4cyclam), which has been widely employed as a polydentate ligand to bind labile metal moieties [6], is readily protonated in acid solution [7]. Our recent studies on metal complexes with polydentate ligands [8] prompted us to synthesize 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane tetra-*N*-oxide ($Me_4cyclamO_4$) (**1**) as a potentially new type of proton sponge that features charge-assisted intramolecular $[N\rightarrow O–H\cdots O\leftarrow N]^+$ hydrogen bonding. Our attempt in using this tetra-*N*-oxide as a multidirectional linker for $[Ln(NO_3)_x]^{(x-3)-}$ nodes in coordination network construction was unsuccessful thus far, but rath- er yielded its diprotonated cation that led to the isolation of the crystalline complexes $[Me_4cyclam(OHO)_2]_2$ $[Ln(NO_3)_6](NO_3)\cdot H_2O$ (Ln = Ce **2**, La **3** and Nd **4**), $2[Me_4cyclam(OHO)_2](NO_3)_2\cdot[Er(NO_3)_3(H_2O)_3]\cdot 2H_2O\cdot CH_3OH$ **5** and $\{[Me_4cyclam(OHO)_2][Ce(NO_3)_4(\mu\text{-}NO_3)]\}_n$ **6**, the structures of which have been determined by X-ray crystallography.

2. Experimental

2.1. General procedures

IR spectra were recorded with a Nicolet Impact 420 FT-IR spectrometer using KBr pellets. Elemental analyses of C, H and N were performed by MEDAC LTD, Vrunel Science Centre, United Kingdom. 1,4,8,11-Tetramethyl-1,4,8,11-tetraazacyclotetradecane (Me_4cyclam) and the lanthanide salts were purchased from Aldrich and used in this work without further purification.

2.2. Synthesis of 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane-N-tetroxide ($Me_4cyclamO_4$) (**1**)

A mixture of 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane (Me_4cyclam, 2.0 g, 7.81 mmol), acetic acid (20 cm^3) and 35% hydrogen peroxide (10 cm^3) was heated at 80–85 °C for 1 h. Then hydrogen peroxide (7 cm^3) was added and the mixture kept at 80–85 °C for 1 h with stirring. An additional portion of hydrogen peroxide (7 cm^3) was introduced, and heating was continued for a further 9 h. The excess acetic acid and water were removed under vacuum, water (20 cm^3) was added twice, and each time the mixture was concentrated to dryness under vacuum. Acetone (100 cm^3) was then added to the remaining oil to yield a colorless precipitate, which was filtered off and washed with hot acetone to remove un-reacted Me_4cyclam. The solid mixtures were separated by LC on aluminum oxide 90 with MeOH-EtOAC (1:1 v/v) and then with MeOH to give $Me_4cyclamO_4$ as a powdery product. Colorless crystals of the hexahydrate $Me_4cyclamO_4 \cdot 6H_2O$ **1** (2.0 g, yield 60%) were grown by vapor diffusion of diethyl ether into a solution of the powder in MeOH-H_2O (4:1, v/v) at room temperature. *Anal.* Calc. for $C_{14}H_{32}N_4O_4 \cdot 6H_2O$: C, 39.25; H, 10.28; N, 13.08. Found: C, 38.94; H, 10.21; N, 13.30%. ^{1}H NMR (300 MHz, D_2O): δ 2.29 (4H, m, β-CH_2), 3.19 (12H, s, N–CH_3), 3.75 (16H, t, α-CH_2), 4.77 (w, H_2O); all shifted down field with reference to the parent Me_4cyclam [9]. IR (KBr, cm^{-1}): 3460*s*, 1649*s*, 1474*m*, 950*m*, 729*m*.

2.3. Synthesis of {[$Me_4cyclam(OHO)_2$]$_2$[$Ce(NO_3)_6$]-(NO_3)·(H_2O)} (**2**)

A solution of $Me_4cyclamO_4 \cdot 6H_2O$ **1** (85.6 mg, 0.20 mmol) in H_2O (1.5 cm^3, pH 4–5) and MeOH (6.5 cm^3) was carefully layered over a solution of Ce(NO_3)$_3 \cdot 6H_2O$ (43.4 mg, 0.10 mmol) in MeOH (3.0 cm^3) and CH_2Cl_2 (5.0 cm^3) in a test tube. Over a period of several days, colorless crystals were grown on the wall of the test tube and collected to give 55.0 mg of **2**. Yield: 44.5%. *Anal.* Calc. for $C_{28}H_{70}CeN_{15}O_{30}$: C, 27.18; H, 5.66; N, 16.99. Found: C, 26.98; H, 5.64; N, 16.77%. ^{1}H NMR (DMSO-d_6): δ 9.00 (O–H–O, w). Analogous ^{1}H spectra were also observed for complexes **3**–**6** at δ 9.00–10.00 ppm.

2.4. Synthesis of {[$Me_4cyclam(OHO)_2$]$_2$[$La(NO_3)_6$]-(NO_3)·(H_2O)} (**3**)

Colorless crystals of compound **3** were prepared in the same manner as **2**. Yield: 45.0%. *Anal.* Calc. for $C_{28}H_{70}LaN_{15}O_{30}$: C, 27.21; H, 5.67; N, 17.00. Found: C, 26.97; H, 5.70; N, 16.76%.

2.5. Synthesis of {[$Me_4cyclam(OHO)_2$]$_2$[$Nd(NO_3)_6$]-(NO_3)·(H_2O)} (**4**)

Pale pink crystals of compound **3** were prepared in the same manner as **2**. Yield: 44.0%. *Anal.* Calc. for $C_{28}H_{70}NdN_{15}O_{30}$: C, 27.09; H, 5.64; N, 16.93. Found: C, 26.91; H, 5.63; N, 16.67%.

2.6. Synthesis of 2[$Me_4cyclam(OHO)_2$](NO_3)$_2$·[Er(NO_3)$_3$(H_2O)$_3$]·2H_2O·CH_3OH (**5**)

Pale pink crystals of **5** were prepared in the same manner as **2**. Yield: 45.0%. *Anal.* Calc. for $C_{29}H_{82}ErN_{15}O_{35}$: C, 25.45; H, 5.99; N, 15.36. Found: C, 25.32; H, 5.95; N, 15.58%.

2.7. Synthesis of {[$Me_4cyclam(OHO)_2$][$Ce(NO_3)_4(\mu$-$NO_3)$]}$_n$ (**6**)

A solution of $Me_4cyclamO_4 \cdot 6H_2O$ **1** (85.6 mg, 0.20 mmol) in H_2O (1.5 cm^3, pH 6–7) and MeOH (6.5 cm^3) was carefully layered over a solution of Ce(NO_3)$_3 \cdot 6H_2O$ (43.4 mg, 0.10 mmol) in MeOH (3.0 cm^3) and CH_2Cl_2 (5.0 cm^3). Colorless crystals of **6** were obtained after several days. Yield: 46.0%. *Anal.* Calc. for $C_{14}H_{34}CeN_9O_{19}$: C, 21.76; H, 4.40; N, 16.32. Found: C, 21.93; H, 4.42; N, 16.60%.

2.8. X-ray crystallography

Selected single crystals of **1**–**5** sealed inside Lindemann glass capillaries were used for data collection on a Bruker SMART 1000 CCD diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. Intensity data was obtained in the range $1.5° < \theta < 28°$. An empirical absorption correction was applied using the SADABS program [10]. The data collection of compounds **6** was performed on a Rigaku AFC7R four-circle diffractometer in the variable ω-scan mode [11] using Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. Intensity data was recorded in the range $2.3° < \theta < 25°$, and an empirical absorption correction was applied using ψ-scan data for selected strong reflections. The structures were solved by direct methods

and refined by full-matrix least squares based on F^2 using the SHELXTL program package [12].

3. Results and discussion

3.1. Synthesis of 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane tetra-N-oxide and its lanthanide(III) complexes

The tetra-*N*-oxide was obtained by exhaustive oxidation of 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane (Me_4cyclam) with acetic acid and hydrogen peroxide. The workup procedure employing alumina and organic solvents ensured that the purified product was neutral $Me_4cyclamO_4$, rather than the acetate salt of its di-protonated form. Structural characterization of $Me_4cyclamO_4$ was performed by X-ray analysis of its crystalline hexahydrate $Me_4cyclamO_4 \cdot 6H_2O$ **1**.

Compound **2**–**6** were obtained by the reaction of $Ln(NO_3)_3$ (Ln = Ce **2**, **6**; La **3**; Nd **4**; Er **5**) with $Me_4cyclamO_4 \cdot 6H_2O$ **1** using a "diffusion solvent mixture" composed of the MeOH–H_2O and MeOH–H_2O–CH_2Cl_2 systems. The main function of dichloromethane is to slow down the rate of the reaction and facilitate crystal growth. The reaction of $Ce(NO_3)_3$ and $Me_4cyclamO_4$ in aqueous acidic solution (pH 4–5) yielded compound **2** containing the $[Ce(NO_3)_6]^{3-}$anion. In contrast, under weakly acidic or neutral condition (pH 6–7), compound **6** was obtained which features a novel *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$ chain bridged by μ-O,O,O',O'' nitrate ligands. This shows that formation of the lanthanide complexes can be controlled by changing the pH.

3.2. Crystal structures

The tetra-*N*-oxide molecule is located at a site of symmetry $\bar{1}$ and exhibits the *RSSR* configuration [13] (Fig. 1). The four nitrogen atoms are necessarily co-planar, with O1 and O2A pointing to one side, and O2 and O1A to the other, and the O···O distance is 4.676 Å. The plane of C6, N1 and O1 makes a dihedral angle of 94.9° with the plane of the four nitrogen atoms, and the plane of C7, N2 and O2 make a corresponding dihedral angle of 68.0°. The $Me_4cyclamO_4$ molecule forms acceptor O–H···O hydrogen bonds with water molecules O1W and O2W, generating a layer structure (Fig. 2). Such layers are further inter-connected through hydrogen bonds involving O3W, thus leading to a three-dimensional network (Fig. 3).

In $[Me_4cyclam(OHO)_2]_2[Ce(NO_3)_6](NO_3) \cdot H_2O$ **2**, the Ce(III) ion located at an inversion center is coordinated by six chelating nitrate ions (Ce–O, 2.617–2.669 Å), exhibiting an icosahedral coordination geometry similar to that found in $[(C_4H_9)_3NH]_3[La(NO_3)_6]$ [14] (Fig. 4(a)). The vertices of the coordination polyhedron constitute three co-planar sets: O11, O12, O11A, O12A and Ce1 (**I**); O21, O22, O21A, O22A and Ce1 (**II**), and O31, O32, O31A, O32A and Ce1 (**III**). These planes are almost orthogonal to one another, the dihedral angles being 92.8° between **I** and **II,** 90.5° between **II** and **III**, and 85.3° between **I** and **III** (Fig. 4(b)). Though the *N*-oxide group is known to be a good donor to coordinate the lanthanide(III) ion [15], each pair of contiguous *N*-oxide groups in $Me_4cyclamO_4$ sequestrates a proton from the solvent, forming a charge-assisted intramolecular

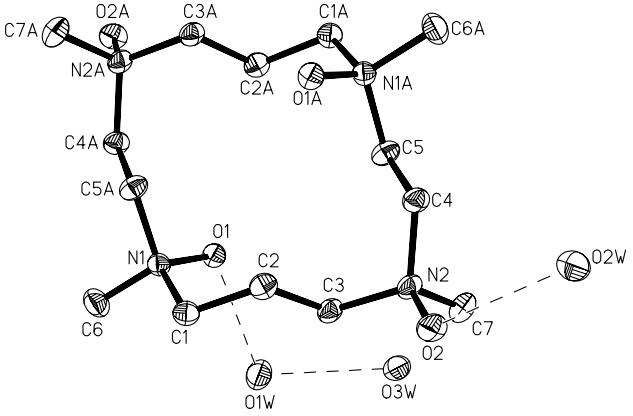

Fig. 1. The centrosymmetric 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane tetra-*N*-oxide molecule taking the *RSSR* configuration, and independent lattice water molecules involved in hydrogen bonding, in Me4cyclamO4 · $6H_2O$ **1**. Hydrogen atoms are omitted for clarity.

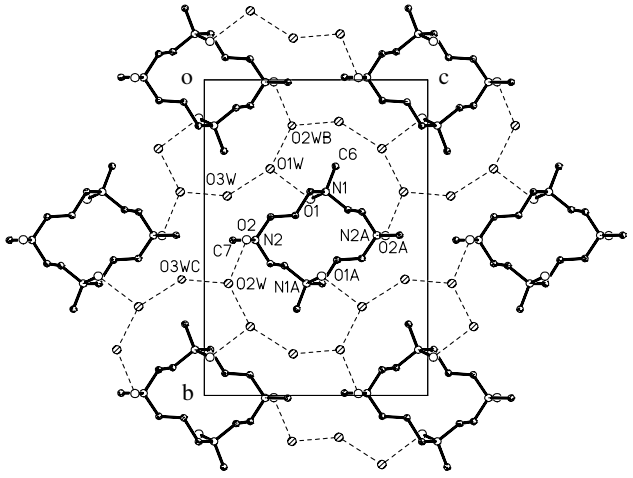

Fig. 2. Hydrogen-bonded layer structure of $Me_4cyclamO_4 \cdot 6H_2O$ **1** projected normal to the *a* axis. Hydrogen bonding: O1W–H···O1 177(3)°, O1W···O1 2.723(2) Å; O2W–H···O2 170(3)°, O2W···O2 2.708(2) Å; O3W–H···O1W 174(3)°, O3W···O1W 2.792(3) Å; O1W–H···O2WB 170(3)°, O1W···O2WB 2.712(2) Å; and O2W–H···O3WC 177(3)°, O2W···O3WC 2.758(2) Å (A: $-x+1,-y+1,-z+1$; B: $-x+1,y-1/2,-z+1/2$; C: $-x+1,-y+1,-z$).

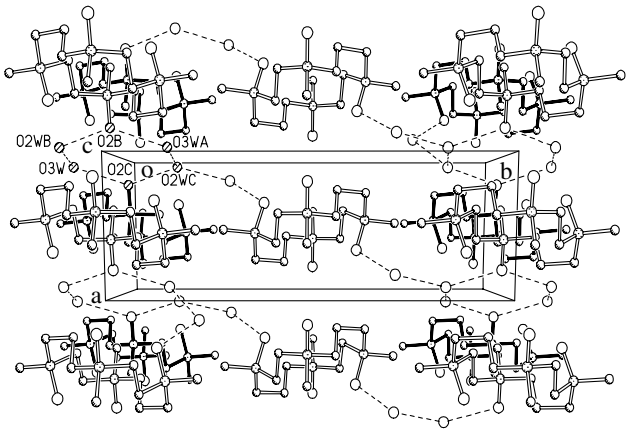

Fig. 3. Hydrogen-bonded three-dimensional framework of **1** viewed along the *c* axis.

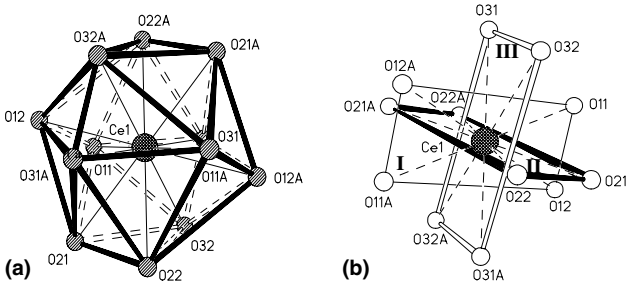

Fig. 4. (a) Icosahedral coordination polyhedron of the Ce(III) ion in **2**. (b) Ligand atoms arranged in three mutually perpendicular planes.

$[O–H\cdots O]^+$ hydrogen bond. The O···O distance between O1 and O1A is 2.538 Å, much shorter than that of 4.676 Å in **1**. The crystal structure of **2** consists of a packing of the $[Ce(NO_3)_6]^{3-}$ anion and two independent $[Me_4cyclam(OHO)_2]^{2+}$ ions (one of which is disordered), all three being located in sites of symmetry $\bar{1}$, together with a disordered discrete nitrate ion and a lattice water molecule.

Compounds **3** and **4** are isomorphous to **2** with Ce(III) replaced by La(III) in **3** and Nd(III) in **4**, respectively.

$2[Me_4cyclam(OHO)_2](NO_3)_2\cdot[Er(NO_3)_3(H_2O)_3]\cdot 2H_2O\cdot CH_3OH$ (**5**) can be considered as a double salt with co-crystallized water and methanol solvate molecules. The $[Er(NO_3)_3(H_2O)_3]$ molecule is located at a site of symmetry *m*, being coordinated by three chelating nitrate groups and three aqua ligands in a distorted tricapped trigonal prismatic environment (Fig. 5). The non-ligating nitrate ion, the lattice water molecule, and the disordered methanol molecule are connected to the uncharged $[Er(NO_3)_3(H_2O)_3]$ complex through hydrogen bonds to generate an infinite $\{[Er(NO_3)_3(H_2O)_3](NO_3)_3\cdot H_2O\cdot CH_3OH\}_n^{n-}$ chain, which is surrounded by $[Me_4cyclam(OHO)_2]^{2+}$ cations and discrete nitrate ions in the resulting crystal packing (Fig. 6).

In compound **6** SADABS $\{[Me_4cyclam(OHO)_2][Ce(NO_3)_4(\mu\text{-}NO_3)]\}_n$, the asymmetric unit contains three independent $[Me_4cyclam(OHO)_2]^{2+}$ cations (Fig. 7), two of which are located at inversion centers; all three have the same *RSSR* configuration consolidated by a pair of charge-supported asymmetric $[O–H\cdots O]^+$ hydrogen

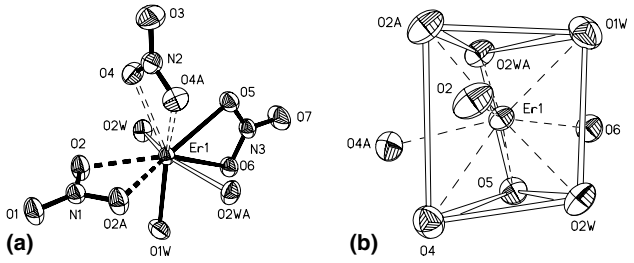

Fig. 5. (a) Molecular structure of $[Er(NO_3)_3(H_2O)_3]$ in **5**. The O1, N1, O3, N2, O5, O6, O7, N3, O1W and Er1 atoms are located on a mirror plane. (b) Tricapped trigonal prismatic coordination geometry of Er(III) in **5**.

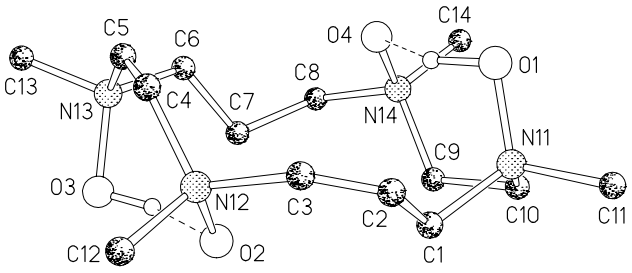

Fig. 8. $[Me_4cyclam(OHO)_2]^{2+}$ cation exhibiting the RSSR configuration and asymmetric $[O–H\cdots O]^+$ hydrogen bonds.

bonds (Fig. 8). Each of the two independent Ce(III) ions in the unit is surrounded by twelve oxygen atoms from six chelating nitrate ions, leading to an icosahedral coordination geometry analogous to that in **2**. Two of these nitrate groups act as consecutive μ-O, O, O', O'' linkers to bridge the Ce(III) ions (Fig. 9(a)), thus generating an unprecedented *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$ linear chain running parallel to the *a* axis (Fig. 9(b)). The literature contains several metal complexes in which the nitrate group functions in the μ-O, O, O', O'' mode to form binuclear [16], linear polymeric [17], and zeolite-like network [18] structures. However, in the reported nitrato-bridged binuclear and polymeric complexes, for example $[(dien)Pb(NO_3)_2]_n$ [17a], the coordination sphere about the metal center also comprises other types of ligands. To our knowledge, the $[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$ chain of compound **6** and the host framework of $C_{60}\{Ag(NO_3\}_5$ are the only polymeric structures that are constructed entirely with nitrate ligands.

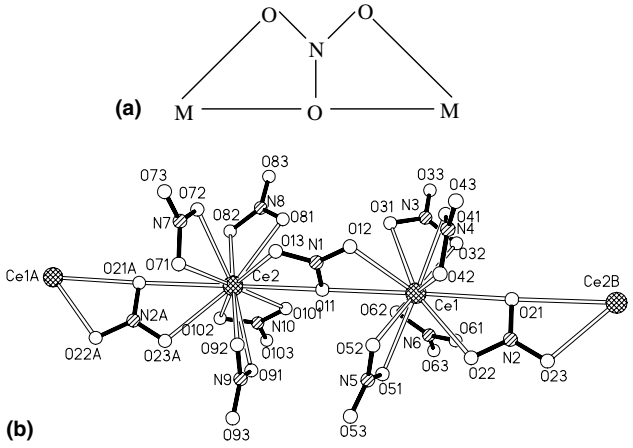

Fig. 9. (a) The nitrate ion acting in the μ-O, O, O', O'' mode to bridge two metal ions. (b) Polymeric chain *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$ running parallel to the *a* axis in **6**, successive pairs of lanthanide centers being bridged by a μ-O, O, O', O'' nitrate group.

4. Conclusions

Only a few compounds bearing multiple *N*-oxide groups have been reported in the literature, and they are generally derived from nitrogen heterocyclic systems. Known examples include the tri-*N*-oxides of pyrido[3,2-*f*]-quinoxaline [19] and benzo-*asym*-triazine [20], the tetra-*N*-oxide of hexamethylbipyrazine [21], and 1,2,3,4-tetrazino[5,6-*f*]benzo-1,2,3,4-tetrazine 1,3,7,9-tetra-*N*-oxides [22]. Another synthetic approach to tetra-*N*-oxides is based on the incorporation of a pair of 2,2′-bipyridine units into either an acyclic skeleton [23] or a macrocycle [24]. $Me_4cyclamO_4$ differs from all these in that it possesses two pairs of contiguous *N*-oxide groups.

Hydrophobic bulky organic cations such as PPh_4^+ [25], and $[Ph_3PNPPh_3]^+$ [26], $(Ph_3PCH{=}CHPPh_3)^{2+}$ [27], and $[Ph_3P(CH_2)_3PPh_3]^{2+}$[27] have been used to advantage to induce co-crystallization with a wide variety of inorganic and organometallic anionic species, most often in non-aqueous media. We envisage that the di-positive cation $[Me_4cyclam(OHO)_2]^{2+}$ may well play an analogous and complementary role in the stabilization of unusual mono- and poly-nuclear complexes in aqueous solution that leads to their isolation in the crystalline state, such as the *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$ linear chain in complex **6** (see Tables 1 and 2).

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 216202-216207 for compounds **1**–**6**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336033; deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Abstract

Dinuclear peroxo complexes of vanadium, $[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$ (**1**) and $[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$ (**2**) have been synthesized from the reaction of V_2O_5 with H_2O_2 and the respective amino acid ligand at pH ca. 2. Similar reactions conducted at pH ca. 5 afforded the monomeric complexes, $Na[VO(O_2)_2(asn)]\cdot H_2O$ (**3**) and $Na[VO(O_2)_2(gln)]\cdot H_2O$ (**4**). The compounds were characterized by elemental analysis and spectral studies. In complexes **1** and **2,** the two V(V) centres are bridged by a peroxo group and an amino acid ligand occurring as a zwitterion. The monomeric complexes **3** and **4** contain peroxo groups bonded in a side-on fashion and an amino acid co-ligand binding the V(V) centre through O (carboxylate) atoms. The complexes **1** and **2** rapidly degraded in solution with release of O_2 and formation of diperoxovanadate and decavanadate as shown by ^{51}V NMR spectra whereas complexes **3** and **4** remained stable in solution for over 24 h. Extent and rate of oxygen released from the two types of complexes under the effect of catalase action further evidenced the differences in their $V{:}O_2^{2-}$ content and mode of peroxide binding in these species. The μ-peroxovanadate complexes **1** and **2** instantaneously oxidized bromide to a bromination competent intermediate in phosphate buffer at physiological pH, and also efficiently mediated bromination of organic substrates in aqueous-organic media. Complexes **3** and **4** were inactive for bromination under analogous conditions. These findings make the dinuclear complexes **1** and **2** possible candidates of mimic in the action of vanadium in bromoperoxidase.

Keywords: Dinuclear peroxovanadate; Peroxo-bridged divanadate; Peroxidative bromination; Heteroligand peroxovanadate; Amino acid containing peroxovanadates

1. Introduction

Vanadium and its compounds are increasingly being recognized to have biological functions [1–4]. Potential usage of vanadium compounds as therapeutic anti-diabetic agents has been the subject of a number of recent reviews [5,6]. There has been a continuous upsurge in interest in the chemistry of vanadium peroxides mainly owing to their insulin-mimetic properties [5–7], their ability to oxidize organic and inorganic substrates [8] as well as their potential as models for understanding vanadium dependent biogenic systems [6]. Studies on synthetic peroxovanadate complexes as functional and structural models of bromoperoxidase [8–12], the enzyme involved in the biosynthesis of a variety of naturally occurring brominated products, have been immensely useful in helping to elucidate the details of the mechanism of the action of the enzyme and have provided diverse approaches to this area [8–14].

The majority of known synthetic hetero-ligand peroxovanadate(V) complexes represent anionic mono, di or tetraperoxo complexes containing the peroxo group bonded to vanadium in a side-on fashion [8]. Reports related to dinuclear peroxovanadium(V) compounds with a bridging peroxo group are limited [15–20] and it is an area needing exploration. Such peroxovanadate species have been implicated as intermediates in some biochemical processes [21,22]. The existence of a dimeric

species of the type, $(VO)_2(O_2)_3$ in an acidic solution and its being the possible critical oxidant of bromide has been reported [11] however, its exact identity in solution has yet to be ascertained. Thus the paucity of information on peroxo bridged divanadates and the current intensive search for bio-relevant vanadium complexes [5,6,9] prompted us to direct our efforts in establishing viable synthetic routes to new dimeric peroxovanadates in a biogenic ligand environment. We have recently achieved the synthesis of new members of peroxo bridged compounds of the type $[V_2O_2(O_2)_3(\text{dipeptide})_3]\cdot H_2O$ [18] and $[V_2O_2(O_2)_3(\text{tripeptide})_2]\cdot H_2O$ [19]. These triperoxo divanadate complexes distinguished themselves in terms of their spectral as well as solution properties from the known peroxovanadium complexes possessing exclusively terminally bound peroxo groups. The complexes exhibited unique redox properties and could act as a bromide oxidant with good activity at physiological pH [18,19], an essential requirement of a biomimetic model. Based on detailed investigations in solution, we have proposed that a μ-peroxo intermediate VOOV, is likely to be the active intermediate in such bromination reactions.

With an objective to provide further evidence to this proposal and in continuation of our work on peroxovanadates we have now synthesized additional members of dinuclear μ-peroxovanadate and monomeric peroxovanadate complexes stabilized by coordinatively versatile amino acids with polar side chains viz., glutamine and asparagine as heteroligands. It was considered imperative to investigate the possible similarities or differences in spectral, redox or solution properties which may exist between the μ-peroxovanadate and monomeric peroxovanadate complexes in analogous coligand environment.

In this paper, the synthesis and physicochemical characterization of complexes of the type $[V_2O_2(O_2)_3L_3]\cdot H_2O$ and $Na[VO(O_2)_2L]\cdot H_2O$, (L = asparagine and glutamine) are presented. The two types of complexes synthesized provided a means of undertaking a comparative study of their various properties.

2. Materials and methods

The chemicals used were all reagent grade products. Catalase was obtained from Sigma–Aldrich Chemical Company. The water used for solution preparation was deionised and distilled.

2.1. Synthesis of dimeric peroxovanadate complexes, $[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$ (1) and $[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$ (2)

In a typical reaction solid V_2O_5 (0.25 g, 1.37 mM) was mixed with amino acid in a 250 ml beaker maintaining the molar ratio of V:amino acid as 1:2, to which 15 ml of 30% H_2O_2 (132.3 mM) was added gradually with constant stirring. The reaction mixture was then stirred for ca.15 min in an ice bath keeping the temperature below 4 °C. During this period the solid dissolved yielding a clear reddish yellow solution. The pH of the solution was recorded to be 2.0. No attempt was made to adjust the pH of the reaction solution. On adding pre-cooled ethanol (ca. 50 ml) to the above solution under continuous stirring, an orange–yellow coloured pasty mass separated out. After allowing to stand for about 10 min in the ice bath, the supernatant liquid was decanted and the residue was treated repeatedly with an acetone:ethanol (3:1 v/v) mixture under scratching until it became a microcrystalline solid. The product was separated by centrifugation, washed with cold ethanol and dried in vacuo over concentrated sulfuric acid. In the solid state these complexes were found to be stable for several weeks stored dry at <20 °C but tended to be hygroscopic at ambient conditions and decomposed in a few days.

Anal. Calc. for $[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$: V, 15.82; O_2^{2-}, 14.91; C, 22.36; N, 13.00; H, 3.83. Found: V, 15.82; O_2^{2-}, 14.90; C, 22.59; N, 13.10; H, 4.01. Yield: approximately 50%.

Anal. Calc. for $[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$: V, 14.87; O_2^{2-}, 13.99; C, 26.24; N, 12.24; H, 4.37. Found: V, 14.80; O_2^{2-}, 14.10; C, 26.10; N, 12.30; H, 4.50. Yield: approximately 47%.

2.2. Synthesis of monomeric peroxovanadate complexes, $Na[VO(O_2)_2(asn)]\cdot H_2O$ (3) and $Na[VO(O_2)_2(gln)]\cdot H_2O$ (4)

The procedure adopted for the synthesis is common to both complexes. This consisted of gradual addition of 12 ml H_2O_2 (30% solution, 105.84 mM) to a mixture of V_2O_5 (0.25 g, 1.37 mM) and amino acid at a molar ratio of V:amino acid of 1:1 with continuous stirring. Keeping the temperature below 4 °C in an ice bath, the mixture was stirred for ca. 15 min until all solids dissolved. At this stage the pH of the solution was recorded to be ca. 2. Concentrated sodium hydroxide solution (conc. ca. 8 M) was added dropwise with constant stirring to raise the pH of the reaction medium to ca. 5. On adding precooled ethanol (about 50 ml) to this mixture under vigorous stirring a yellow coloured pasty mass separated out. After standing for about 15 min in the ice bath, the supernatant liquid was decanted, and the residue was treated repeatedly with acetone:ethanol (3:1 v/v) mixture under scratching until it became a microcrystalline solid. The product was separated by centrifugation, washed with cold ethanol and dried in vacuo over concentrated sulfuric acid. In the solid state these complexes were found to be stable for several months stored dry at <25 °C.

Anal. Calc. for $Na[VO(O_2)_2(asn)]\cdot H_2O$: Na, 7.56; V, 16.77; O_2^{2-}, 21.05; C, 15.79; N, 9.21; H, 2.30. Found: Na, 7.69; V, 16.89; O_2^{2-}, 20.90; C, 15.44; N, 9.15; H, 2.23. Yield: approximately 43%.

Anal. Calc. for $Na[VO(O_2)_2(gln)]\cdot H_2O$: Na, 7.23; V, 16.03; O_2^{2-}, 20.12; C,15.78; N, 9.21; H, 2.63. Found: Na, 7.32; V, 16.34, O_2^{2-}, 20.04; C, 15.62; N, 9.29; H, 2.49. Yield: approximately 40%.

2.3. Elemental analysis

The compounds were analyzed for C, H, N and Na at Regional Sophisticated Instruments Centre, North-Eastern Hill University, Shillong, India and at the Department of Organic Chemistry, Indian Institute of Science, Bangalore, India. Vanadium and peroxide were estimated by methods mentioned in earlier papers [23].

2.4. Spectroscopic measurements

Spectra in the visible and ultraviolet region were recorded in a Hitachi model 2001 recording spectrophotometer in 1 cm quartz cuvettes. The absorbance values are denoted as, e.g., A_{592}, A_{340}, at the wavelengths indicated. The infrared (IR) spectra were recorded with samples as KBr pellets in a Nicolet model Impact 410 FTIR spectrophotometer and also in a Perkin–Elmer Model 983 spectrophotometer. The spectra were recorded at ambient temperatures by making pressed pellets of the compounds. The ^{1}H NMR spectra were recorded in deuterated chloroform in a Varian EM–390 90 MHz spectrophotometer using TMS as the internal standard. The ^{51}V NMR spectra were recorded in a Brucker AMX 400 FT spectrometer at vanadium frequency 105.190 MHz with the samples in a 10 mm spinning tube with a sealed co-axial tube containing D_2O, which provided the lock signal. The chemical shift data are shown as negative values of ppm with reference to $VOCl_3$ at 293 K. HPLC analyses were performed using a Waters Tm 2487 dual λ detector and assayed at fixed wavelengths using a C_{18} column (Nova-Pak C_{18}, 3.9×150 mm, Waters).

2.5. Measurement of bromination activity in solution

The method of de Boer et al. [24] of introducing four bromine atoms into the molecule of phenol red (ε^{433}mM = 19.7) to form bromophenol blue (ε^{592}mM = 67.4) was used to measure bromination activity. Phenol red acts as an efficient trap of active bromine species without influencing the rate of reaction until it is exhausted. The reaction mixture contained phosphate buffer (50 mM, pH 5.5), KBr (2 M) and phenol red (20 μM). The redox activity was tested by adding a weighed amount of the solid compounds, and by monitoring the possible change in absorbance at 592 nm at 30 °C. The volume of the reaction mixture was kept at 25 ml to enable accurate weighing of small amounts of the solid samples of peroxovanadates added. Aliquots were transferred to the spectrophotometer immediately after mixing to record the jump in A_{592}. The added bridging-peroxo complexes acted directly as a bromide oxidant producing instant change in A_{592} and therefore represented as 'instant activity'. The steady rate of increase that followed due to residual peroxovanadate is referred to as 'secondary rate'.

2.6. Bromination of organic substrates and products analysis

In a representative procedure, organic substrate (0.5 mM) was added to a solution of acetonotrile:water (1:1) (3 ml) containing KBr (1.5 mM). A weighed amount of solid peroxovanadate complex **2** (0.25 mM) was then added to the reaction mixture at room temperature under continuous stirring. The stirring was continued for ca.1 h. Reaction products as well as unreacted organic substrates were then extracted with diethyl ether and dried over anhydrous Na_2SO_4. Products were then separated by TLC and HPLC. ^{1}H NMR spectroscopy and melting point determinations were made to interpret the products.

2.7. Stability of complexes in solution – measurement of oxygen release from the peroxovanadium complexes

A Gilson 5/6 H oxygraph fitted with a Clark oxygen electrode was used for measuring changes in the concentration of dissolved oxygen (0.224 mM at 30 °C) in the medium. The changes were recorded in units of μM of dissolved oxygen. The rate and total amount of oxygen released from a 0.2 mM solution of the compound in phosphate buffer (50 mM, pH 7.0) on adding catalase (0.08 mg protein/ml) were measured. In the middle of the chart paper the recorder pen was set for measuring the release of oxygen into the medium. The machine was standardized by the increases in dissolved oxygen obtained on adding catalase to buffered solutions containing known amounts of H_2O_2. Oxygen release from H_2O_2 was complete within 10 s under these conditions, but a maximum of only about 200 μM of O_2 can be measured before it comes out in the form of bubbles. This limits the concentration of the substrate to 0.2 mM in this method.

3. Results

3.1. Synthesis and characterization

The methodology for the successful synthesis of the orange coloured dinuclear peroxovanadate complexes **1**

and **2** was based on the reaction of $V_2O_5$with H_2O_2 and the respective amino acid in aqueous acidic solution. Since our primary aim was to isolate complexes with a $(VO)_2(O_2)_3$ moiety which has been reported to exist in acidic solution, the pH value of ca. 2 attained spontaneously during the reactions was not raised. In a solution of vanadate and excess H_2O_2 at a $pH > 5$, formation of diperoxoxvanadate (DPV) species is favoured [25,26]. Thus a comparatively higher pH of ca. 5 of the reaction medium is likely to be responsible for the formation of the yellow alkali oxodiperoxovanadate complexes **3** and **4**.

The compounds **1**–**4** were diamagnetic in nature as was evident from the magnetic susceptibility measurements, in conformity with the presence of vanadium(V) in each case.

From the elemental analysis data, the ratio of V:O_2^{2-} and V:amino acid was ascertained to be 2:3 for complexes **1** and **2** in agreement with their formulation as $[V_2O_2(O_2)_3L_3]\cdot H_2O$ and suggesting a dimeric nature for the complexes. The elemental analysis results for complexes **3** and **4** indicated the presence of two peroxide groups and one amino acid per vanadium centre which could be fitted with the formula $Na[VO(O_2)_2L]\cdot H_2O$.

Each of the amino acid containing triperoxodivanadates(V) and mononuclear diperoxovanadate complexes displayed characteristic spectral patterns in the infrared region involving absorptions due to ν(V=O), coordinated peroxide, amino acid ligands and lattice water. The strong absorption at ca. 960 cm^{-1} in the spectra of the complexes was consistent with the presence of a terminally bonded V=O group [26,27] in each case.

A triangularly bonded peroxo group exhibits a diagnostic IR pattern with ν(O–O) appearing at ca. 870 cm^{-1} and ν_2 and ν_3 which involve metal–oxygen stretches appearing in the region 500–600 cm^{-1} [27]. In the spectra of complexes **1** and **2** in addition to the strong ν(O–O) absorption appearing at ca. 870 cm^{-1}, an additional weak intensity but well resolved band has been observed at ca. 810 cm^{-1} which has been assigned to the ν(O–O) band of the bridging peroxo group [28,29]. The peroxo bands observed in the spectra of complexes **3** and **4** (Table 1) were in the range characteristic of triangularly bonded peroxide. Significantly, no band appeared in the 810 cm^{-1} region in the spectra of the monomeric complexes **3** and **4**. These results suggest the presence of two different types of peroxo groups, the terminal chelated and the bridging type in complexes **1** and **2**, and the presence of terminal bidentate peroxide in complexes **3** and **4** and thus support the original formulations. Similar observations were made earlier for compounds wherein the side-on bound and the bridging type of peroxo groups were encountered simultaneously [17–20,28,29]. Synthesis and structural characterization of a complex, $[F(O_2)\{VO(O_2)F\}_2]^{3-}$, was reported earlier by Schwendt et al. [15,16] having a bridging peroxo moiety bonded in a $\mu-\eta^2{:}\eta^2$ fashion. IR spectra of these complexes displayed the ν(O–O) stretch at a relatively higher frequency of ca. 900 and 870 cm^{-1} indicating that the mode of peroxide coordination is probably different in these complexes from that in dinuclear peroxovanadates reported here and in our earlier papers [18,19].

Existence of coordinated amino acids in the complexes **1**–**4** was evident from their IR spectra which showed characteristic differences between the spectral pattern originating from amino acids of the complexes and the spectra of the free amino acids [30,31]. The N–H stretching bands were observed in the 3300–3000 cm^{-1} region as expected from the $-N^+H_3$ group and the amino group of the amino acid side chains. The rocking modes of N^+H_3 occurred at ca. 1050 and 1160 cm^{-1}. A band appearing at 1660–1670 cm^{-1} has been assigned to the ν(C=O) mode of the amide group of the amino acid side chain. The band was observed to be slightly shifted from its free ligand value of ca. 1680 cm^{-1} probably owing to its participation in hydrogen bonding. The absorption attributable to ν_{as}(COO) of the coordinated carboxylate group appeared in the 1650–1640 cm^{-1} region in the spectra of the complexes [30]. The symmetric stretching vibration of the carboxylate group of uncoordinated asparagine and glutamine occur at 1411 and at 1430 cm^{-1}, respectively. The spectra of complexes **1** and **2** displayed a medium intensity band at ca. 1360 cm^{-1} which may be assigned to ν_s(COO). The shifting of this band to lower frequency with the difference

Table 1
Infrared and ultraviolet spectral data of the peroxovanadate complexes

Compound	IR peak (cm^{-1})				UV peak	
	ν_s(V–O_2)	ν_{as}(V–O_2)	ν(O–O)	ν(V=O)	nm	A (1 mM)
$[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$	562m	631m	859s 803m	954s	320	0.70
$[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$	562m	640m	870m 809m	955s	328	0.40
$Na[VO(O_2)_2(asn)]\cdot H_2O$	557m	640m	869s	949s	324	0.63
$Na[VO(O_2)_2(gln)]\cdot H_2O$	540m	660m	873s	953s	321	0.72
DPV	522m	602s	877s	935s	325	0.60

$v_{as} - v_s \approx 250$ cm^{-1} is characteristic of monodentate coordination of the carboxylate group via the O(carboxylate) atom [30]. The spectra of complexes **1** and **2** exhibited another distinct band at 1405 cm^{-1} in the case of complex **1** and at 1412 cm^{-1} in the case of complex **2**, attributable to a bridging carboxylate group ($v_{as} - v_s \approx 200$ cm^{-1}). The symmetric stretching frequencies of the coordinated carboxylate group of the amino acid ligands in complexes **3** and **4**, on the other hand, were found to be shifted to higher values of 1420 and 1435 cm^{-1}, respectively, compared to their free ligand values. The spectra of these complexes displayed the v_{as}(COO) in the 1635–1640 cm^{-1} region. The shift of the v_s(COO) band to a higher frequency and the decrease in Δ value [$\Delta \approx v_{as}$(COO) – v_s(COO)] is typical of an amino acid bonded in a bidentate fashion through the carboxylate group [30]. The presence of glutamine and asparagine as a zwitterion in these complexes with protonated N^+H_3 was ascertained from the spectrum as mentioned in the foregoing discussions. Presence of lattice water in each of the complexes, **1**–**4** was indicated by the strong ν(OH) absorptions displayed at 3500–3400 cm^{-1}. However, the bending mode of water could not be assigned with certainty as it occurred in the carbonyl frequency region. The IR spectral data thus suggest that in each of the complexes, **1**–**4** amino acid occurring as zwitterion binds the V(V) centers through O(carboxylate) atoms. Based on these observations a structure of the type shown in Fig. 1 has been proposed for complexes **1** and **2**, which is shown for the asparagine complex as a representative example. For complexes **3** and **4** a structure of the type shown in Fig. 2 has been envisaged.

3.2. Nature and stability of the complexes in solution

The stability of the monomeric diperoxovanadate complexes **3** and **4** in solution was observed to be much

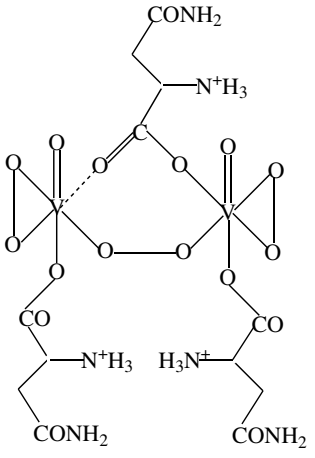

Fig. 1. Proposed structure of the dimeric peroxovanadate compounds shown with $[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$ as representative.

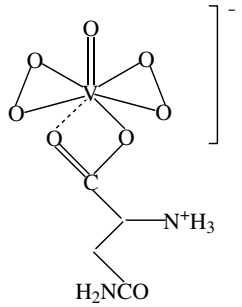

Fig. 2. Proposed structure of the monomeric peroxovanadate compounds shown with $Na[VO(O_2)_2(asn)]\cdot H_2O$ as representative.

higher as compared to that of dinuclear complexes **1** and **2**. Instability of the complexes **1** and **2** in water and degradative loss of the peroxide groups were evident from the oxygen evolution taking place from the complexes on adding the compounds to water. As a means of determining the stability of the complexes in solution, the rate of oxygen released from the complexes in solution was measured with an Oxygraph. Immediately on adding the compounds (ca. 2 mg/ml) to water the rate of oxygen release was exceedingly high, with a value of about 10 μM /min for a brief period of ca. 15 min.

In order to further investigate the nature of the species remaining in solution after oxygen evolution ceased to appear, we were interested to study their activity with the enzyme catalase. On addition of catalase to the solutions of **1** and **2** after the oxygen evolution ceased, further slow release of oxygen was recorded (Table 2) which revealed that the products in such solutions were indeed peroxovanadates. A maximum of 1.5 O_2 per mole of the compound would be released if all the three peroxides were retained. Lower values of 0.7 and 0.4 O_2 per mole of the compound were recorded since part of the peroxide was initially lost during the making of the solution in water. The subsequent secondary rates of oxygen release, calculated from the data, paralleled the residual peroxide concentrations.

The extent and rate of oxygen released under the effect of catalase action from complexes **3** and **4** (Table 2) were found to be comparable to that of the aquo oxodiperoxvanadate complex (DPV) [32] indicating their similarity with respect to number of peroxides and probably the pattern of their coordination to the V(V) centre. On incubation with catalase DPV was found to be degraded releasing half the molecular equivalent of oxygen at a rate of 36 μM/min from a solution of 0.2 mM [32]. The stability of the complexes **1**–**4** were also studied by estimating the peroxide content at different time intervals which revealed the variation in stability of the complexes. Whereas compounds **1** and **2** lost their peroxide rapidly, compounds **3** and **4** remained stable for a period of 24 h or more.

The electronic spectra of compounds **1**–**4** in aqueous solution exhibited a weak intensity broad LMCT band at

Table 2
Catalase dependent oxygen release from peroxovanadium compounds

Compound	Conc. (mM)	Oxygen release		ΔO_2/compound (mol. ratio)
		μM/min	Total (μM)	
$[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$	0.2	17.6	145	0.72
$[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$	0.2	11.2	87	0.44
$Na[VO(O_2)_2(asn)]\cdot H_2O$	0.2	32.2	185	0.92
DPV	0.2	36.0	192	0.96

310–320 nm (Table 1) originating from coordinated peroxide. Variations in absorbance values indicate partial loss of peroxide on making solutions of these compounds. In case of complexes **1** and **2** the intensity of this band was found to decrease with time, consistent with the loss of peroxide from these complexes and their unstable nature.

Further information regarding the nature of the complexes in solution was derived from ^{51}V NMR studies. Interaction of vanadium with amino acids and peptides is of considerable biological importance and has been studied extensively in solution [33–37]. The assignment of the peaks in the present study was on the basis of available data [33,38–40]. The solutions of **1** and **2** being acidic, it may be expected that free vanadate formed on depletion of its peroxide will oligomerize to the decameric form (V_{10}). The spectra of the complexes **1** and **2** displayed three peaks at −427, −509 and −527 ppm with an intensity ratio of 1:2:2 which have been assigned to V_{10}. The major signal at −694 ppm indicated the presence of diperoxovanadate as the predominant species. The small variations from the reported chemical shift values may be due to the presence of the coordinated ligands in some of the products and to variation of pH. The less intense peak observed at −545 ppm has been identified as monoperoxovanadate species. The two weak resonances appearing near −714 ppm were probably due to the presence of diperoxovanadate species containing an amino acid ligand coordinated through the carboxylate group [33,34]. Thus from the NMR spectral studies it was further evident that peroxo bridged dimeric complexes **1** and **2** undergo rapid degradation in water and hence provide no direct information regarding the nature of the original solid compound. The spectrum of complexes **3** and **4** displayed a predominant peak at −695 ppm characteristic of a diperoxovanadate species. Indication of the presence of traces of vanadates appeared in the spectra of the mononuclear complexes recorded 30 min after the preparation of the solutions.

3.3. Redox activity of the complexes in bromination reactions

3.3.1. Reaction with solid peroxovanadium compounds

The bromination of phenol red to bromophenol blue was employed to investigate the bromination activity of the complexes **1**–**4** in solution. Addition of a weighed amount of solid compound **1** or **2** to the standard reaction of bromide in phosphate buffer with phenol red as a trap for oxidized bromine resulted in instantaneous colour change of the solution from yellow to blue. The spectrum recorded showed a peak at A_{592} characteristic of the product bromophenol blue and a decrease in absorbance of the peak at A_{433} due to loss of phenol red (Fig. 3). After the initial very fast bromination activity referred as "instant" activity, a slow increase in A_{592} indicated a secondary rate of bromination (Fig. 4). The data in Table 3 show the instant and secondary bromination activities of dinuclear complexes **1** and **2**.

A similar reaction when carried out in the absence of phenol red displayed a peak at 262 nm with a shoulder at 237 nm on addition of compound **1** or **2**. Addition of phenol red to this solution resulted in the decrease in A_{262} nm and a peak at 592 nm appeared indicating the formation of bromophenol blue. The 262 nm peak, therefore, represents a bromination competent oxidized species of bromide, probably an equilibrium mixture of BrOH, Br_2 and Br_3^- as proposed earlier [1].

The results of the aforementioned experiments suggest the occurrence of two distinct types of bromination reaction. The fast bromination reaction which give a large increase in A_{592} indicates the presence of an active

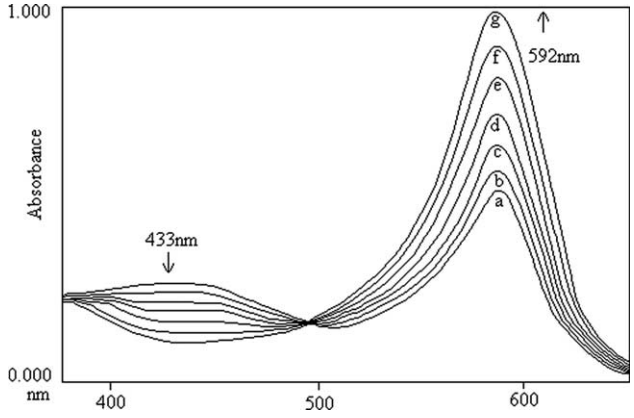

Fig. 3. Bromination activity with dinuclear peroxovanadate complex **2**. (a) The spectrum recorded immediately after adding the solid compound to the reaction mixture showing the "instant activity"; (b–g) spectral changes at 5 min intervals. The reaction mixture contained phosphate buffer (0.05 M, pH 5.5), KBr (2 M) and phenol red (0.02 mM).

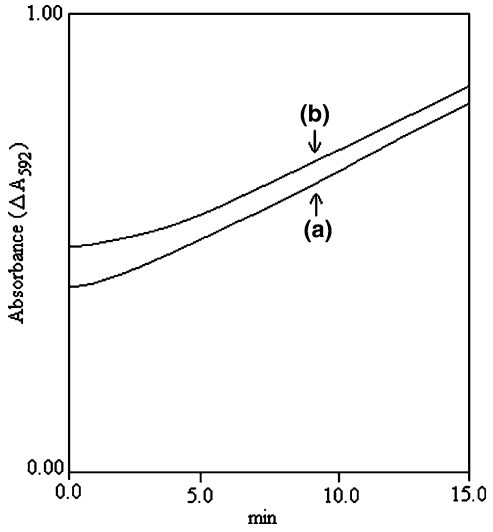

Fig. 4. The increase of A_{592} indicating the secondary rate of bromination: (a) with complex **1**; (b) with complex **2**. The reaction mixture contained phosphate buffer (0.05 M, pH 5.5), KBr (2 M) and phenol red (0.02 mM).

group in the peroxo bridged complexes that readily oxidizes bromide. It is evident that the degradation products of the compounds formed in solution are responsible for the slow secondary bromination reaction. The instant activity of 37–43% recorded, although small, substantiated the oxidant capacity of the original compounds in spite of their being highly unstable in solution.

Significantly, the monomeric diperoxovanadate compounds **3** and **4** were totally inactive in bromination under identical conditions. Under these conditions DPV (1 mM) was inactive on its own, however, in presence of vanadate showed the secondary rate but not the instant activity (Table 3).

3.3.2. Reaction with solutions of peroxovanadate compounds

Reactions conducted by addition of an aliquot of **1** or **2** from a freshly prepared solution, instead of the solid compound, to the standard reaction mixture gave a good rate of increase in A_{592}. The rate progressively decreased when equal aliquots were tested from this stock solution at 2–4 min intervals, followed by total loss of activity after about 2 h of making the solution. These experiments further confirmed that the vanadate products derived from the peroxo bridged complexes, responsible for the secondary slow bromination reaction, also undergo further inactivation.

These rapid inactivation processes constrained our studies on the kinetics of the reaction. Data collected by using a freshly prepared solution for each experiment indicated that increases in rates are nonlinear with increase in concentrations of complexes **1** or **2**. The rate showed a linear relationship when plotted against the square of the concentration of bromide indicating a second order dependence with respect to KBr (data not shown).

3.3.3. Effect of buffer

Omission of phosphate buffer from the reaction medium had no significant effect on the instant bromination activity of the complexes, although a small decrease of about 10% was observed in the secondary rate of bromination. This indicated that the presence of phosphate was not essential for such activity of dinuclear peroxovanadate complexes. This is in contrast to the requirement of phosphate with the vanadate–H_2O_2 system as bromide oxidant [41]. Vanadate is known to react with most of the compounds used in buffers including phosphate [42]. With respect to vanadates, Hepes is fairly inert and is the recommended buffer [42,43]. However, in the present study fast bromination activity was found to be suppressed when Hepes (pH 6.5) was used as the buffer indicating possible interaction between Hepes and the bimetallic peroxovanadate compounds. In investigations dealing with peroxovanadates, a near neutral phosphate buffer was found to be reasonably inert and its use proved to be satisfactory in several studies [18,19,43–45]. Instant bromination activity was realized with the compounds **1** and **2** in phosphate buffer at pH 7.0. The data in Table 3 were obtained at pH 5.5 in order to record the secondary activity.

3.3.4. Inhibition of bromination reaction

Inhibitor studies are valuable in giving clues on the involvement of reactive species. The effect of H_2O_2 and EDTA on the bromination reaction under standard assay conditions was tested. The initial fast bromination reaction was inhibited only to the extent of 5–10% with

Table 3
Bromination of phenol red with peroxovanadate complexes **1** and **2**

Compound	Conc.		Instant activity			Secondary rate (extrapolated to 1 mM compound) μM Br/min
	mg/ml	mM	ΔA_{592}	Bromine transfer		
				Total (μM)	μM/mM compound	
$[V_2O_2(O_2)_3(asn)_3]\cdot H_2O$	0.10	0.15	0.406	24.09	160.6	7.05
$[V_2O_2(O_2)_3(gln)_3]\cdot H_2O$	0.12	0.17	0.535	31.74	86.7	7.29

H_2O_2 (10 mM) and ca. 20% with EDTA (10 mM). After the initial jump in A_{592} the peak intensity remained unchanged with time in contrast to its slow increase in the absence of inhibitors, indicating complete inhibition of the secondary reaction. It is thus inferred that the peroxo bridged dimeric vanadate is probably the most proximate intermediate in bromide oxidation as it is only partly inhibited by H_2O_2 and EDTA which terminate the secondary bromination reaction carried out by degradation products of the dinuclear complex.

3.3.5. Substrate bromination in aqueous-organic media

The high bromination activity exhibited by the complexes in aqueous solution prompted us to explore the efficacy of complexes **1** and **2** in mediating bromination of organic substrates in the presence of inorganic bromide in aqueous-organic media. Reactions were carried out in the absence of buffer. Bromination of several activated aromatics into their corresponding bromo-organics were achieved in moderate yields in the presence of the dinuclear complex **1** or **2** (Table 4). Preferential bromination at either ortho or para positions of the aromatic ring leading to mono substitution indicate an electrophilic bromination mechanism. That the brominating species was 'Br^+' and not a Br· radical in these reactions was further evident from the ring substituted products obtained from the substrate, 2-methoxy toluene (Table 4). Bromination through radical reaction would have produced benzyl bromide instead of bromo-methoxy toluene [11]. Attempted bromination using complex **3** did not yield brominated products as anticipated.

4. Discussion

The reaction of vanadium with H_2O_2 is highly sensitive to pH and it is known that the number of peroxo groups per vanadium center increases with increasing pH of the reaction medium [25]. In the present study, it has been possible to isolate two types of peroxovanadates viz., molecular dimeric complexes $[V_2O_2(O_2)_3L_3]\cdot H_2O$ and anionic monomeric complexes $Na[VO(O_2)_2L]\cdot H_2O$, (L = asparagine or glutamine), by varying the pH of the reaction medium. The low pH apparently favoured the coordination of the amino acids in their zwitterionic form thereby stabilizing the $V_2O_2(O_2)_3$ moiety and leading to the synthesis of the desired molecular complexes **1** and **2**.

Bonding of more than one amino acid to the same metal center in different coordination modes as observed in the case of complexes **1** and **2** may appear unusual, however, it is not unprecedented [46]. Depending on the pH of the reaction solution and the nature of the metal, a tridentate amino acid of the glutamine and asparagine type provides several alternative coordination sites to the metal, viz., terminal amino and carboxylate groups as well as the amide groups of the side chain. Thus the chosen ligands can act as mono, bi or tridentate ligands with different combinations of donor atoms and can occur in complexes in either neutral zwitterionic form or the anionic form. In addition, they are known to form bridges between metal atoms leading to the formation of dinuclear or polynuclear structures [46]. Peroxovanadium compounds having a bridging peroxo moiety, bonded in a $\mu-\eta^1{:}\eta^1$ fashion, could so far be synthesized only in the presence of amino acids and peptides [17–20]. These ligands are likely to impart additional stability to the highly reactive 'VOOV' species by forming hydrogen bonds between their side chains.

The stabilization provided by the amino acid co-ligands to the μ-peroxovanadate moiety formed in solution, affording their isolation into solid state, would presumably be lost in aqueous solution resulting in the break up of the VOOV group with subsequent release of oxygen. The peroxo groups which are retained in the degradation products and are responsible for the further release of oxygen under the effect of catalase action, are the ones bonded in a side-on fashion as indicated by their ^{51}V NMR and electronic spectra. Since the diperoxovanadium complexes **3** and **4** contain side-on bound peroxo groups they appear to be relatively much more stable in solution and degrade steadily under the action of catalase releasing the amount of oxygen corresponding to two peroxo groups per molecule, consistent with their formulae.

The work of several groups on redox chemistry of vanadyl, vanadate and peroxovanadates are pertinent in explaining the reactions involved in the present study [21,47–50]. It has been known that oxidation of bromide by H_2O_2 to hypobromous acid, capable of transferring a bromine atom to an acceptor molecule, occurs at a pH < 3.0 but is ineffective in near neutral pH > 5.0. The reaction is catalyzed by vanadium compounds such as $VOSO_4$ [47] or V_2O_5 [12]. The most probable oxidants of bromide, monoperoxovanadate (MPV) and diperoxovanadate (DPV), are readily formed on adding excess H_2O_2 to vanadate solution [25,47,50], with DPV predominating at pH > 5.0. However, synthetic DPV or MPV, or compounds containing such moieties were catalytically incompetent in bromide oxidation at neutral pH [49]. A dimeric triperoxovanadate(V) intermediate presumed to be formed from a combination of MPV and DPV was then proposed to be the active oxidant [11]. However, this dimeric species was found only in highly acidic medium (pH < 5).

The observation that inactive DPV requires the presence of vanadyl or vanadate to gain oxidant activity at pH > 5, led to the proposal that the μ-peroxo bridged divanadate intermediate, $[OVOOV(O_2)]^{3+}$, formed by complexation between these two species is the proximate oxidant of bromide [41]. Support for such an interme-

diate came from our investigations on a series of synthetic compounds with a VOOV bridge which were found to be active in oxidative bromination at physiological pH [18,19]. Results of the present study lend further support to this contention.

A scheme of reactions, shown in Fig. 5, is proposed which is based on our results and work of some other laboratories [21,41,47–50]. The μ-peroxo group of the 'VOOV' moiety appears to be amenable for reductive cleavage by bromide which produces a bromination competent intermediate, –BrOVO(O_2), that can transfer the bromine atom to the substrate AH (reaction a and b in Fig. 5). On its dissolution the compound dissociates into MPV and DPV species (Fig. 5 reaction c) as identified by ^{51}V NMR with subsequent loss of instant bromination activity. These observations and the marginal effects of H_2O_2 and EDTA, which considerably inhibit vanadate dependent bromination activity, lend support to our earlier proposal that 'VOOV'' is the active group and is the likely primary oxidant of bromide at near neutral pH. The secondary bromination activity results from the formation of DPV and vanadate formed as

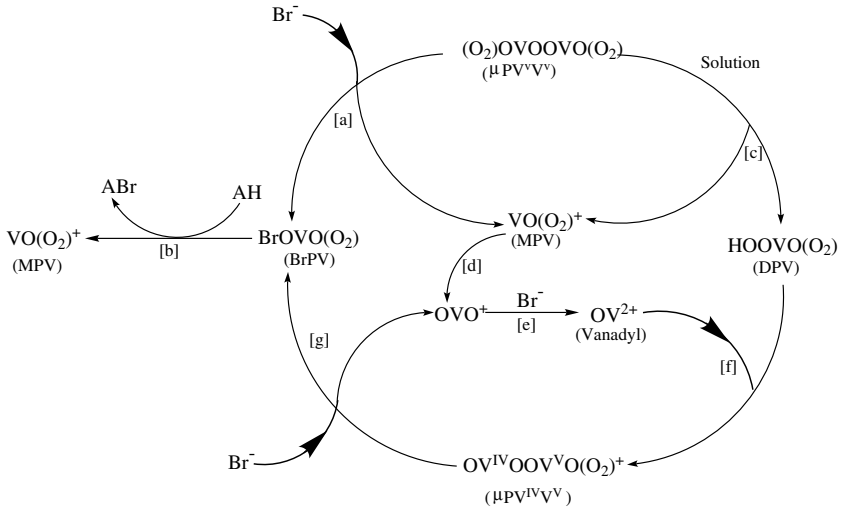

Fig. 5. Schematic representation of reactions occurring with peroxo bridged divanadate compounds: (a) formation of active bromine compound BrPV and MPV when solid is added to a bromide solution; (b) transfer of bromine to acceptor AH (phenol red); (c) dissociation of the dinuclear complex on dissolution in water into MPV and DPV (in absence of bromide) with concomitant loss of bromination activity; (d) reduction of MPV to vanadate; (e) reduction of vanadate to vanadyl by acid and bromide; (f) formation of μ-peroxo compound from DPV + vanadyl; (g) breakdown of μ-peroxo group and oxidation of bromide yielding BrPV. Amino acid ligands in the compounds are not shown. Valency state of reduced vanadium is shown as V^{IV} and all others are V^{V}. No attempt is made to show the exact stoichiometry of the reaction.

dissociation products of the dinuclear complex in solution (Fig. 5 reaction d). Dismutation of MPV generates vanadate which is then reduced to vanadyl by bromide (reaction d and e) as demonstrated experimentally in earlier work [41]. Vanadyl then complexes with DPV to form a μ-peroxovanadate dimer (reaction f) [48]. This complex can then oxidize bromide and produce a bromination competent intermediate that can be recycled till phenol red is completely consumed (reaction g). The striking feature of the essentiality of vanadyl V(IV) for converting DPV into an effective bromide oxidant was thus accommodated as V^{IV}–O–O–V^{V} in the reaction pathway in Fig. 5. Bromide is needed in two steps, in recycling vanadyl by reduction of vanadate and in interacting with the peroxo bridged intermediate, which explains the slow reaction being second order with respect to KBr concentration. Inhibition of the secondary reaction in the presence of excess H_2O_2 is evidently owing to the conversion of vanadate into DPV which is inactive in bromination. EDTA inhibits reaction g by complexing with V(V) and V(IV) centers of the μ-peroxovanadate intermediate as was demonstrated experimentally in earlier studies [51].

To summarize this investigation concerning the synthesis and some aspects of the chemistry of dinuclear and mononuclear peroxovanadate complexes, we would like to emphasize that the dimeric complexes with a μ-peroxovanadate moiety are distinctly different in nature, stability and reactivity from the monomeric anionic complexes possessing exclusively chelated bidentate peroxo groups. The heteroligand plays an important role in imparting stability to the VOOV group permitting its isolation in the solid state. Present experiments confirm the reactivity of the synthetic μ-peroxovanadate dimer in producing a bromination competent intermediate. The proposed reaction pathway confers the status of a selective bromide oxidant, at physiological pH, on the VOOV group. However, it is not completely clear as to why a peroxo bridged divanadate moiety is much more reactive in oxidative bromination than a peroxo group bonded to V(V) in a side-on fashion. Theoretical computations are expected to provide valuable insights into this aspect and such studies are being initiated. We are constrained in concluding that any of the above reactions are involved in the action of the enzymes in view of lack of direct evidence. However, since crystal structures of haloperoxidase proteins showed dimeric subunits with a vanadium per subunit [52], the possibility of the active site in the protein having a vanadium dimer cannot be ruled out.

Received 20 November 2003; accepted 11 December 2003

Abstract

An isonicotinic acid N-oxide Mn(II) compound was synthesized and characterized on the basis of elemental analysis and X-ray crystallography. In the complex, Mn(II) ions are coordinated by six water molecules, and the coordination number of the Mn(II) ion is six. FTIR spectra of the compound free isonicotinic acid N-oxide (INO) have been recorded in the range 4000–400 cm^{-1}. Cathodoluminescence (CL) spectra from the Mn(II) complex have been recorded. The luminescence data were interpreted in terms of the emission band at 480 nm. The green luminescence (~480 nm) arises from the Mn^{2+} transition $^4T_1$ (^4G) → $^6A_1$ (^6S). It shows weak vibronic structure, short lifetimes less than 250 μs, and indicates that Mn^{2+} is octahedrally coordinated, occupying sites with similar distortions. The lifetime and intensity of the signal is temperature dependent, and the parameters are reported for the 480 nm emission line.

1. Introduction

Lanthanide complexes of three isomers of pyridine carboxylic acid, namely nicotinic acid, isonicotinic acid and picolinic acid, have been extensively investigated [1–3]. Pyridine carboxylic acid N-oxides have an oxygen atom in place of the nitrogen donor site, but studies on ligand behavior toward lanthanides are limited, as so far only one dimeric lanthanium complex of 6-methylpicolinic acid N-oxide (6-mepicno) has been structurally examined [4,5]. N-oxide functionalization of nicotinic acid and isonicotinic acid should increase the flexibility of the resulting ligands in addition to enhancement of their capacities for coordination and or hydrogen bonding. Therefore their lanthanide complexes are expected to exhibit different characteristics as compared with the corresponding lanthanide nicotinates and isonicotinates. So far, only the molecular structure of monomeric $Mn[(SPPh_2)_2N]_2$ [6,7] and $Mn[(OPPh_2)_2N]_3$ [8], which exhibit tetrahedral MnS_4 and octahedral MnO_6, respectively, have been reported. By contrast, the Mn(II) acetylacetonate derivative is a trimer, with all manganese atoms exhibiting octahedral MnO_6 cores as a result of the bimetallic triconnective coordination of the ligands [9]. Recently the synthesis of $Mn[(XPR_2)(YPR'_2)N]_2$ (X, Y = 0, S; R, R′ = Me, Ph) complexes and the X-ray structure of monomeric $Mn[(OPPh_2)(SPPh_2)N]_2$ have been reported [10]. We wish to report here the molecular structure of a manganese (II) complex of INO and its luminescence properties. It has been known for many decades that some organic and inorganic materials emit light when bombarded by electrons (cathodoluminescence, CL), and that the nature of that emission in the complex could contain significant information. CL is a very sensitive technique to probe the surface state and changes in the crystal field resulting, for example, from pressure changes. The excitation density in this case is very high compared to X-ray irradiation, which enhances the light output. CL is an attractive option since, by varying the electron energy, it is possible to probe to successively deeper depths below the surface. The spectral

doi:10.1016/j.poly.2003.12.022

information aids identification of different types of defect but it is not an accurate quantitative route since the luminescence efficiency is strongly modified by the presence of defects, dislocations and surface states. Normally the emitted light level increases with higher incident energy, in part because there is luminescence quenching from the damage surface (i.e. dislocations) on the signal. CL is not a passive surface probe and it must be borne in mind that repeated measurements with energetic electron beams may contribute to surface modifications which range from the familiar degradation of halides, to relaxations giving improved crystallinity of $LiNbO_3$.

In order to understand the limitations and/or problems of the surface it is necessary to find surface sensitive techniques to assess the quality of some inorganic materials. These should be non-destructive, so methods such as transmission electron microscopy (TEM) are of minimal value in routine assessment. Whilst scanning electron microscopy (SEM) or atomic force microscopy (AFM) offer views of the outer surface and can include compositional data, they are of limited use for characterization of this kind of material. More appropriate measurements are optical absorption and luminescence. Note absorption and luminescence offer wavelength discrimination between different defect types. Numerous examples have been summarized for simple inorganic materials in a recent review [11] with particularly clear examples being seen for ammonium bromide, strontium titanate and potassium niobate. The approach has been effective not only for the simple inorganic materials but also for fullerenes and even superconductors. However, it has not been attempted previously with inorganic materials comprising of large molecular units. As far as we are concerned, there is no previous literature about luminescence of Mn(II) complexes. Therefore we believe that this is the first such work using luminescence.

2. Experimental

2.1. Synthesis

All chemicals were reagent grade (Aldrich) and were used without further purification. One millimole (0.35 g) $MnBr_2 \cdot 4H_2O$ was dissolved in absolute hot ethanol (10 ml). Two millimole (0.28 g) isonicotinic acid N-oxide was dissolved in hot ethanol and added to the solution. Workup as described above, single crystals were formed at the interface and also at the bottom of the solution at 2 °C.

2.2. Elemental analysis

The prepared complex was analyzed for C, H, N using a CHN (LECO, CHN-600) with the following results (found (%)/calculated (%));$[Mn(H_2O)_6]$ $[O–C_6H_4NO_2]_2$ C = 32.76/32.80, H = 4.53/4.58, N = 6.40/6.37.

2.3. Crystal structure determination

Data were collected at 173(2) K on an Enraf-Nonius CAD4 diffractometer at Sussex University using monochromated Mo Kα radiation (0.17073 Å) and corrected for Lorenz and polarization effects. The structures were determined by direct methods, with SHELXL 97 programs used for structure solution and refinement on F^2 using all reflections. In the ORTEP-3 plots the thermal ellipsoids are shown at the 50% probability level. All hydrogen atoms were located on a difference map and were refined.

2.4. Physical measurements

The IR spectra (KBr discs) of the free ligand and the compound $[Mn(H_2O)_6][O–C_6H_4NO_2]_2$ were recorded on a Mattson 1000 FTIR spectrometer in the range 4000–400 cm^{-1}, which was calibrated using polystyrene bands. The vibrational wavenumbers and proposed assignments of INO and Mn(INO) complex are discussed in Section 3.

CL time resolved spectroscopy was performed on an apparatus designed and built at the University of Sussex [12]. The acceleration potential was 10 kV and the current was 20 nA, corresponding to an incident power density of 0.8 mW cm^{-2}. The primary electron beam was pulsed using a Thandor TG501 5 MHz function generator as a sine function with a frequency of 90 Hz, except for the lifetime measurement. The CL response was gated using an EgandG Ortholoc-SC 9505 two-phase lock-in amplifier. Spectra were measured in the temperature range 40–300 K using an $f/4$ scanning monochromator and a cooled red-sensitive photomultiplier tube.

3. Results and discussion

The molecular geometry of INO and the Mn(II) compound was shown by an X-ray diffraction study to have the structure depicted in Fig. 1 (with the geometrical data shown in Table 2). If we assume the amido group (–COOH) has a single mass point all the molecules under consideration would belong the C_{2v} point group. This simplified model leads to 30 normal vibrations of which 21 are planar and nine are non-planar. In addition to these 30-ring vibrations there would be six vibrations due to the substituent carboxyl group. These vibrations cannot be classified as to their symmetry, with respect to the molecular plane as the carboxyl group makes the molecule non-planar.

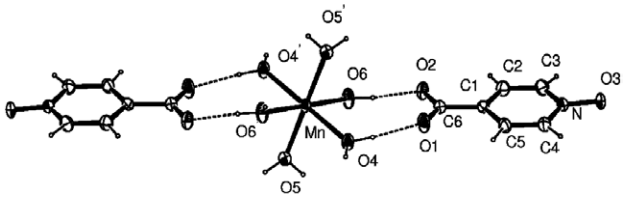

Fig. 1. Molecular structure of $[Mn(H_2O)_6][O–C_6H_4NO_2]_2$.

Information concerning crystallographic data and structure refinement of the Mn(II) complex is summarized in Table 1. Selected bond lengths and angles are presented Table 2.

The luminescence data were quite limited, but there have been room temperature structural characterizations of related rare earth complexes with nicotinic and isonicotinic acid N-oxides [13] that included data for erbium and europium site distortions from the changes of the photoluminescence and absorption of the rare-earth line spectra. Immediate initial effects of the isonicotinic acid N-oxide Mn(II) compound are seen in Fig. 2 for CL measurements. At a modulation frequency of just 9 Hz (i.e. effectively continuous ~ dc excitation) the main signal peaks near 480 nm in both cases, but there are poorly resolved additional features in the tails of the central region. The green luminescence of about 480–520 nm is generally attributed to the transition $^4T_1(^4G) \rightarrow {}^6A_1\ (^6S)$ between the lowest energy levels of Mn^{2+} in an octahedral coordination. Such a luminescence peak appears even at concentrations as low as 10 ppm [14]. It cannot be excluded, however, that some Mn^{2+} ions occupy very large (dodecahedral) sites which can also produce a small ligand field splitting Dq and green luminescence [15,16]. The remarkable similarity of the position and the shape of the Mn^{2+} green emission band (Fig. 2) strongly suggests that Mn^{2+} is octahedrally coordinated and occupies sites with similar ion–ligand interactions. At 40 K the position of the green luminescence peak in the sample remains practically the same. The independence of the band position on temperature might indicate that Mn^{2+} occupies sites with rigid Mn–O bonds which practically do not change with temperature.

The computer system used in the CL analysis records only the magnitude of the emission and not the sign and, therefore, the data are always a positive number. For cosine dependence, the data are always a positive number. For cosine dependence, data extend from positive to negative values, and hence we have converted sections of the data to negative values where they pass through zero. ϕ_c is related to the decay lifetime (τ) of the emission and frequency of the pulsed primary beam (f) for isolated luminescence bands by the expression $\tan\phi_c = 2\pi f\tau$. Unfortunately in the present CL system the maximum chopping frequency is only 100 kHz and this is slow compared with the luminescence lifetimes being considered. Nevertheless, attempts to estimate the

lifetime of the 480 nm emission gives a value near 215 μs at room temperature (RT), and near 235 μs at 40 K.

In this study time resolved luminescence spectra of the Mn complex have been measured. The following features can be deducted from the cathodoluminescence emission spectra. One type of emission spectra is observed and the decay of the green luminescence is non-exponential. Analysis of the luminescence spectra shows that Mn^{2+} occupies a similar and well defined octahedral site. The Mn^{2+}–water interactions are weak and affect the lifetime of the green band.

Isonicotinic acid N-oxides give two donor sites (a) carboxyl group and (b) pyridine N-oxides (N=O). In this kind of ligand the bonding may take place through the carboxyl oxygen or N=O.

The vibrational assignments for isonicotinamide and nicotinamide were made and structural characterization and spectroscopic features of their metal halogen compounds were investigated in previous works [17–20]. Also the vibrational assignments of isonicotinic acid for a few bands were made experimentally [21] and theoretically [22]. In this paper the vibrational wavenumbers and proposed assignments of INO for a few bands were made by comparing the results.

Significant absorption bands in the infrared spectrum of INO are observed at 3550(m), 1656(m) and 1606(m) cm^{-1}. They are assigned to ν(OH), ν(CO) and ν(RN=O). The absorption band in the infrared spectrum of $[Mn(H_2O)_6] \cdot [O - C_6H_4NO_2]_2$ at 1656 cm^{-1}, due to the carboxyl group (ν(CO)), is observed at 1639 cm^{-1}. Significant negative shift of the carboxyl group takes place because of the coordination through the carboxyl oxygen. This situation indicates that coordination of INO take place via the carboxyl oxygen to the metal ion (Mn).

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC no 222424. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax. +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www.http://ccdc.cam.ac.uk).

Acknowledgements

We would like to thank Prof. P.D. Townsend for giving kind permission to use his equipment in Sussex. Crystal structure determination was carried out at the Department of Chemistry, University of Sussex. The assistance of Peter B. Hitchcock is gratefully acknowledged.

Abstract

A dicopper complex of a Schiff's base, 2-[(4-methyl-pyridin-2-ylimino)-methyl]-phenol, with a bridging acetato ligand has been synthesized and characterized by single crystal XRD, EPR, magnetic susceptibility, IR, UV–Vis, CV and elemental analysis. The X-ray analysis indicates that the system belongs to the triclinic space group $P\bar{1}$. One of the copper atoms in the binuclear complex adopts a square-pyramidal geometry consisting of the tridentate *N*-salicylidimine dianions, the neutral monodentate pyridine ligand in the basal plane and the solvent molecule in the apical position, while the other copper assumes a square-planar geometry. A seven line pattern observed at half-field in the frozen solution EPR spectrum confirms the interaction between the two copper ions. The cyclic voltametric studies point to a two-step electron transfer indicating the reduction of the two copper ions to copper(I), i.e., Cu(II)Cu(II) ↔ Cu(II)Cu(I) ↔ Cu(I)Cu(I). The molar conductance for the complex measured in methanol solvent indicates that the complex is a 1:1 electrolyte.

1. Introduction

Polynuclear complexes with redox-active transition metal centers play an important role in biological processes because of facilitated electron transfer in redox reactions. Copper(II) complexes of tridentate Schiff base type, especially with dimeric units, are therefore suitable as bioinorganic model compounds. Numerous EPR spectroscopic studies, along with a few structural results of copper(II) complexes with tridentate Schiff base anions of the *N*-salicylideneamino acetate type have shown a variety of coordination geometries and cooperative ordering effects [1–4], which depend on Lewis basicity and the stereochemical properties of additional bidentate donor ligands. These ligands are essential for saturating the copper(II) coordination sphere of the tridentate Schiff base copper fragments. Also, the local distortion of the coordination polyhedra around the copper ion may vary from elongated square-pyramid to square-planar. However, in every case, it has been modified by an orthorhombic component, observable by spectroscopic means, such as EPR. The arrangement of the ligand molecules (monomer or dimer) in the crystal structure can be classified into three groups: the molecules appear as monomers [5]; can form phenoxy O-bridged dimeric units [6]; or may be connected to polymeric chains via an apically bound carboxylate oxygen atom of the respective neighbouring molecule [2,7]. In order to understand the nature of copper atoms in the complexes to see their viability as model compounds, a series of complexes have been prepared in our laboratory having dicopper with various bridging moieties [8–15]. The results are interesting, but the

doi:10.1016/j.poly.2004.01.016

interaction has not been confirmed by X-ray studies due to the failure of obtaining good single crystals. Hence, the present study has been undertaken, where we were able to obtain a good single crystal suitable for X-ray study. The results obtained with other techniques are also reported in this communication.

2. Experimental

2.1. Preparation of the ligand

The selected Schiff's base ligand [16] was synthesized by direct mixing of a 1:1 molar ratio of 4-methyl-2-aminopyridine (2.12 g) with salicylaldehyde (4 ml) under reflux for about 6 h in double distilled dry ethanol. Slow evaporation resulted in the formation of yellow diamond crystals. The ligand has been characterized by elemental analysis, IR, UV–Vis, NMR and mass techniques. The ligand, 2-[(4-methyl-pyridin-2-ylimino)-methyl]-phenol, is abbreviated as Hsalamp.

2.2. Preparation of the complex

To a methanolic solution of the ligand Hsalamp (2.12 g, 0.01 mol), a methanolic solution of copper acetate (0.998 g, 0.005 mol) was added, and the color of the solution changed from yellow to green. Further addition of a methanolic solution of lithium perchlorate (0.80 g 0.005 mol) turned the solution to dark green. The whole solution was then kept under reflux for 8 h at around 330 K. Slow evaporation of this solution resulted in the formation of a green colored powder, which when dissolved in methanol for crystallization by slow evaporation resulted in the formation of small crystals of shiny green color suitable for X-ray study. Fig. 1 gives the systematic procedure for the preparation of the copper complex, the structure of which has been confirmed by X-ray and EPR studies (vide infra). The analytical data for the complex is: molecular formula $Cu_2C_{29}H_{29}N_4O_9Cl$ Calculated (Found): %C = 47.0(44.6), %H = 3.9(3.6), %N = 7.5(6.8), %Cu = 17.2(17.0). The molar conductance for the complex measured in methanol solvent is $126\Lambda_m$ ($S\,cm^2\,mol^{-1}$), indicating that the complex is ionic and univalent in type.

2.3. Instrumentation

Infrared spectra were recorded on a Perkin–Elmer IR 598 spectrophotometer on KBr disks in the range of 4000–250 cm^{-1}. ^1H NMR (400 MHz) spectra were recorded using a model JEOL FX-400 FT NMR spectrometer in $CDCl_3$ solution using TMS as the internal

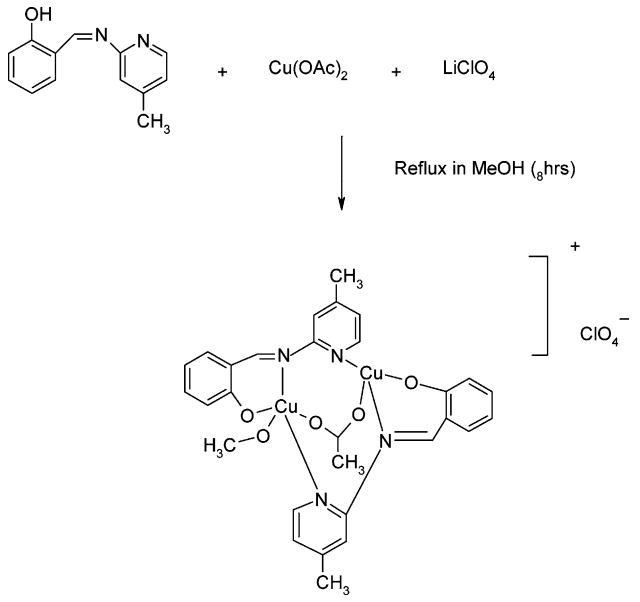

Fig. 1. Schematic representation of the preparation of the dimeric copper complex, $[Cu_2(Hsalamp)_2(OCOCH_3)(OCH_3)]ClO_4$.

standard. Elemental (C, H, N) analysis was performed with a Heraus rapid analyzer. Cu was estimated by AAS using a model 2380 Perkin–Elmer spectrophotometer. Electron impact (EI) mass spectra were recorded on a JEOL D-300 mass spectrometer. Fast atom bombardment (FAB) mass spectra were recorded on a JEOL SX 102/DA-6000 mass spectrometer using Ar/Xe (6 kV, 10 mA) as the FAB gas and m-nitrobenzyl alcohol as the matrix (NBA). Electronic spectral studies were conducted on an Ocean Optics SD1000 miniature fiber optics spectrometer using a 1 cm quartz cuvette in the wavelength range of 200–800 nm. Molar conductance (Λ_m) values were measured using a control dynamics conductivity meter in DMF solvent. The electro chemical measurements were performed at room temperature in DMF under O_2 free conditions using an Autolab PGSTAT 12 controlled by general purpose electrochemical system software (GPES). A three-electrode assembly comprising a Pt disc-working electrode, a Pt rod auxiliary electrode and a saturated calomel reference electrode (SCE) was used. The supporting electrolyte was tetra-*n*-butylammonium perchlorate (TBAP) 0.1 M, and all solutions were about 10^{-3} M in concentration. Magnetic susceptibility data of the powdered samples were measured in the 80–300 K range using a Princeton Applied Research Model 155 VSM instrument operating at 5000 G magnetic field. The instrument had been calibrated using metallic Ni. Diamagnetic corrections were evaluated by using Pascal's constants. ESR spectra were recorded with a JEOL TES 100 ESR spectrometer. Low temperature measurements were made at a liquid nitrogen temperature (77 K) using an insertion type Dewar.

3. Results and discussion

3.1. X-ray crystal structure of the complex

Crystals of suitable dimensions were selected for X-ray analysis. The intensity data were collected at room temperature using a Siemens SMART CCD area detector three-circle diffractometer [17] equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The data collection nominally covered over a full hemisphere of reciprocal space by a combination of three sets of exposures; each set had a different ϕ angle in the crystal and each exposure covered 0.3° in ω. The crystal-to-detector distance was 5.89 cm. Coverage of the unique set was over 86% complete to at least 25.6° in θ. The substantial redundancy in data allowed empirical absorption corrections [18] to be applied using multiple measurements of equivalent reflections. Depending on the intensity of the data, data frames were collected for 10–30 s/frames, giving an overall time for data collection of 7–18 h. The data frames were integrated using SAINT [19] and were merged to give a unique data set.

The structure was solved by automated Patterson methods and subsequent difference Fourier techniques using DIRDIF-98 [20] and was refined on F^2 using full-matrix least squares techniques using SHELXL-97 [21]. All hydrogen atoms were included at calculated positions using a riding model. The U_{iso} of H atoms of CH and CH_2 groups and the methyl group were taken as $1.2U_{eq}$ and $1.5U_{eq}$ of their carrier atoms, except for the water hydrogen atoms, which could not be identified. All non-hydrogen atoms were refined with anisotropic thermal parameters. The final R value was 0.064 for 4679 observed reflections with $I > 2\sigma(I)$ and 0.113 for all data (7401). The residual electron density of 0.84 e/Å^3 and the deepest hole of −0.66 e/Å^3 was close to the O8 and O6 atoms of the perchlorate solvent molecule. Anomalous dispersion effects for all atoms were included in the final calculation. The atomic scattering factor values were taken from the International Tables for X-ray Crystallography (1974). The crystal data, intensity data collection details and refinement parameters are summarized in Table 1. Fig. 2 shows the ZORTEP plot [22] of the molecule with the numbering scheme (thermal ellipsoids are drawn at the 50% probability level). Bond geometry calculations were performed using the software CIFTAB [25] and PARST [23]. Selected bond angles and bond distances are given in Table 2.

The copper ions in the complex take up two different coordination environments. Cu1 adopts a (4 + 1) square-pyramidal geometry defined by the bidentate *N*-salicylidimine dianions and the neutral monodentate pyridine ligand in the basal plane. The apical position is occupied by a solvent methanol molecule at a distance of 2.337(4) Å. In the polymeric structure of (3,5-dimethylpyridine)(*N*-salicylidimine copper(II)) [24], the apical distance is 2.386(2) Å. Both the copper ions are connected by an acetate bridge. The Cu–$O_{(acetate)}$ distances 1.965(4) and 1.957(4) Å are in agreement with those found in the related Cu(II) complex [25]. The Cu1 atom lies above the plane O1N2N4O3 by 0.133(1) Å and is displaced towards atom O5. The Cu–O [Cu1–O1 1.906(3) and Cu1–O3 1.965(4) Å] and Cu–N distances [Cu–N2 2.042(4) and Cu1–N4 2.012(4) Å] lie in the range reported in closely related structures [26,27]. Cu2 adopts a square-planar geometry and deviates from the base plane O1N2O3N4 by 0.019(1) Å. The Cu2–O2 distance is 1.877(4) Å, which is slightly shorter than Cu1–O1, due to solvent coordination, which may be involved in this slight weakening. The intramolecular distance between the two metal centers Cu1···Cu2 is 2.832(1) Å. The equatorial position is occupied by oxygen atoms from an adjacent chelate at an apical distance of [O3···O4] 2.236(5) Å. The pyridine ring (N2-C8) is inclined with respect to the basal plane (through O1N2N4O3) at an

angle of 79.6(2)°. The second pyridine ring (N3–C21) is twisted from the mean plane O2N1O4N3 through an angle of 86.3(1)°. These two pyridine rings are inclined to each other at an interplanar angle of 59.0(2)°. Both the six-membered rings (O1C14C19C20N4Cu1 and O2ClC6C7N1Cu2) involving metal ions adopt half-boat conformations. The ring puckering parameters are [28]: $q_2 = 0.282(4)$, $q_3 = 0.146(4)$, $Q_T = 0.317(4)$ Å, $\phi_2 = -62(1)°$ and $\theta_2 = 63(1)°$ for the ring involving Cu1, and $q_2 = 0.180(4)$, $q_3 = 0.100(4)$, $Q_T = 0.206(3)$ Å, $\phi_2 = -51(1)°$ and $\theta_2 = 61(1)°$ for the ring involving the Cu2 ion. Two eight-membered rings (including the metal ions) are formed by the donor atoms of the Schiff bases and the acetate bridges and both are in a twist-boat conformation. The ring puckering parameters are: $Q_T = 1.104(4)$, $q_2 = 1.085(4)$, $q_3 = 0.019(5)$, $q_4 = -0.201(4)$ Å, $\phi_2 = 176.8(2)°$, $\phi_3 = -75(11)°$, $\theta_2 = 89.0(3)°$ and $\theta_3 = 175(1)°$ for ring (N1Cu1N3C21N4-Cu1N2C8), and $Q_T = 2.015(3)$, $q_2 = 1.933(4)$, $q_3 = 0.164(4)$, $q_4 = 0.544(4)$ Å, $\phi_2 = 112.7(1)°$, $\phi_3 = 175(1)°$, $\theta_2 = 85.2(1)°$ and $\theta_3 = 16.8(4)°$ for ring (N1Cu2O4-C27O3Cu1N2C8). The packing of the molecular structure viewed down the a-axis is shown in Fig. 3.

The primary interactions between the molecules are Van der Waal's in nature. The perchlorate oxygen atoms O8 and O9 are the potential acceptors involved in two intermolecular hydrogen bonds with symmetry related molecules [C28–H28A···O8 and C29–H–29C···O9]. The layers lie parallel to the *xy* plane. In addition to the above, a few more C–H···O and O–H···O type of weak interactions are present to stabilize the molecular packing arrangement.

3.2. IR and UV–Vis studies

The IR spectra of the copper complex, recorded in KBr pellets and in polyethylene, show peaks in the region 1435–1465 cm^{-1}, assigned to the stretching vibrations of the aromatic skeleton of the salicylaldehyde portion. The one at 1094 cm^{-1} is due to the uncoordinated perchlorate ion [29]. The C=N stretching frequency is observed at 1612 cm^{-1}, showing a shift of about 15 cm^{-1}in relation to the free ligand. The phenolic C–O observed at 1299 cm^{-1}, further confirms the participation of the phenolic oxygen in the coordination with the metal ion [30]. It has been reported that if an

acetate bridge joins two copper centers, then the difference in the frequencies of ν_{asyCOO} and ν_{symCOO} should be less than 154 cm^{-1}. For a copper complex, if the difference is around 107 cm^{-1}, then the two copper ions in the complex are joined by a monoatomic acetate bridge [29,31]. In our case, the difference between the two frequencies is around 122 cm^{-1} as the asymmetric and symmetric values are 1557 and 1435 cm^{-1}. On similar lines mentioned in the literature, this value confirms the presence of mono acetate bridging in the copper complex. The deprotonation of the phenolic OH and subsequent coordination of oxygen with the copper metal ion has been confirmed by the reduction in the intensity of the peak in the region 2915–2935 cm^{-1}, compared to the corresponding band in the ligand. The bands at 360 and 301 cm^{-1} are assigned to the Cu–N and Cu–O modes, respectively [32].

The electronic spectrum of the complex, recorded in methanol solvent, shows three bands in the region 396, 288 and 235 nm. The calculated molar absorbtivity values are 5850, 16 160 and 22 280 (ε/l mol^{-1} cm^{-1}). When compared with the pure ligand spectrum, a shift in the bands is noticed, due to the formation of the complex. A peak or shoulder in the region 430–380 nm can be assigned to the nitrogen (pyridile/imino) to copper transitions [33]. The peak at 396 nm in the present system corresponds to the pyridile nitrogen to copper charge transition. The band at 288 nm corresponds to n-π^* and the one at 235 nm to π–π^* transitions. A broad band around 680 nm is assigned to a d–d transition in the metal complex. The redshift in the λ_{max} value is indicative of distortion in its coordination geometry.

3.3. EPR studies

As we were unable to get good single crystals suitable for EPR studies, only the solution and powder results are reported below. The sample was nicely powdered and the EPR spectrum was recorded both at RT and 77 K. The EPR spectra obtained at RT and 77 K are almost identical, except for a change in intensity of the resonance lines. The EPR spectrum obtained at RT is given in Fig. 4. It consists of a strong line at the center, a broad line at low field and two broad lines on either side of the strong line. This is a triplet spectrum, having appreciable zero-field splitting (D) [34–36]. When $S = 1$, it gives rise to two states $|\pm 1\rangle$ and $|0\rangle$, separated by D. The degenerate $|\pm 1\rangle$ state splits into $|+1\rangle$ and $|-1\rangle$ once an external magnetic field is applied. Now, two EPR lines are expected due to the allowed transitions of $|-1\rangle$ to $|0\rangle$ and $|0\rangle$ to $|+1\rangle$. The separation between these two lines is approximately equal to $2D$, to first-order. The deviation from axial symmetry in D values is estimated by a parameter known as E. In a few cases, the forbidden transition from $|-1\rangle$ to $|+1\rangle$ is also seen [34,35]. This is also known as half-field transition, since it occurs at approximately half the field at which the main allowed transitions are expected. As mentioned earlier, the intensity ratio of high field transition to low field transition is slightly decreased as the temperature is lowered from RT to 77 K. This suggests that the ground state is $|-1\rangle$. Further, as expected hyperfine resonance lines from copper nuclei are not seen, due to dipolar broadening. The solid state structure from X-ray analysis indicates that the two Cu(II) ions are out of plane (see X-ray data) thus showing a weaker ferromagnetic interaction. This spectrum can be divided into three parts: the first one, the resonance line at low field; the second one consisting of the strong central line and the third one corresponding to the two weak shoulders, like features on either side of the central strong line. The strong resonance at the center with a g value close to 2.1

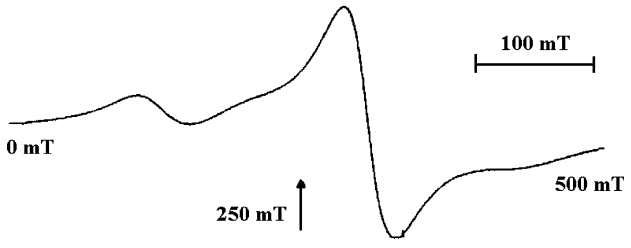

Fig. 4. EPR powder spectrum of the dimeric copper complex at 298 K. The presence of broad lines on either side of the strong line, indicate the zero-field splitting from $S = 1$. $\nu = 9.40041$ GHz.

is due to monomer impurity, as confirmed by the absence of hyperfine lines from the copper nucleus. On the other hand, the low field line is due to the half-field transition, arising from the coupling of the two copper ions and corresponds to the forbidden transition from $|-1\rangle$ to $|+1\rangle$. Here, one should expect seven hyperfine lines from the two interacting copper nuclei. This was not noticed here; however, it is clearly seen in the solution spectrum of the sample recorded at 77 K (see below). From the third part, two g and D values are calculated. Here, we want to mention that the broad nature of the central line is not only due to the unresolved hyperfine structure from the copper nucleus, but also from the small D value. This assumption has been made considering the 77 K solution spectrum (see below). The calculated spin Hamiltonian parameters obtained from RT and LNT EPR spectra are (the second D value is within the line width and hence is not calculated)

$$\text{RT}: \quad g_1 = 2.13, \quad g_2 = 2.23, \quad D_1 = 113(3)\ \text{mT},$$

$$\text{LNT}: \quad g_1 = 2.15, \quad g_2 = 2.25, \quad D_1 = 115(2)\ \text{mT}.$$

In order to understand and further confirm this dimeric phenomenon, a solution spectrum of the sample has been measured both at RT and 77 K. The copper sample is dissolved in dry ethanol and the EPR spectrum of the solution sample, recorded at RT, is shown in Fig. 5. This clearly indicates a four-line pattern due to the interaction of the single unpaired electron with a copper nucleus ($I = 3/2$). The broad nature of the first hyperfine line and the presence of two lines on the higher field of the strong line, indicates the presence of two Cu(II) ions, with different g and A values. In the solution EPR spectrum, due to isotropic exchange interaction, one expects an averaged spectrum, having isotropic spin Hamiltonian parameters. However, since the D tensor is traceless, it averages out to zero in solution samples and will not be shown in the EPR spectrum. The calculated isotropic g and A values for the two copper(II) centers are

$$\text{Center 1}: \quad g_{\text{iso}} = 2.166(4), \quad A_{\text{iso}} = 4.67\ \text{mT},$$

$$\text{Center 2}: \quad g_{\text{iso}} = 2.118(1), \quad A_{\text{iso}} = 6.25\ \text{mT}.$$

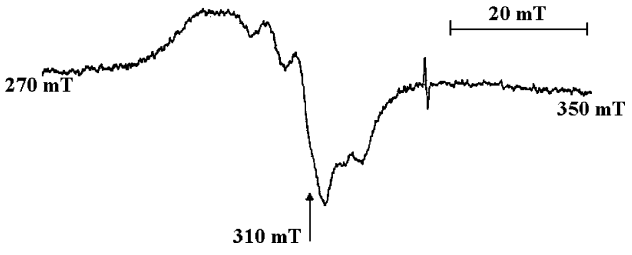

Fig. 5. EPR solution spectrum of the dimeric copper complex in ethanol solvent at 298 K. The sharp line in here and in other figures corresponds to DPPH. $\nu = 9.11610$ GHz.

The copper hyperfine structure, which is not seen in the powder spectrum due to dipolar–dipolar broadening, appeared in solution due to the very low concentration of the solution. At higher concentrations of the sample, the four copper hyperfine lines collapsed to a single broad line. The sample was then cooled to 77 K and the EPR spectrum recorded at 77 K in the magnetic field region of 210–410 mT is shown in Fig. 6. This clearly differs from the RT powder EPR spectrum. As mentioned earlier in the RT powder spectrum discussion, this also represents a clear triplet spectrum with an orthorhombic g tensor. As the line widths of the EPR spectrum are larger at RT compared to 77 K, the zero-field lines are not well resolved in the RT EPR spectrum. As the sample is cooled to 77 K, the two perpendicular components have split, resulting in orthorhombic symmetry for the copper complex. The calculated spin Hamiltonian parameters are

$$g_1 = 2.07, \quad g_2 = 2.13, \quad g_3 = 2.05,$$

$$D_1 = 77.5\ \text{mT}, \quad D_2 = 44.6\ \text{mT}, \quad D_3 = 1.6\ \text{mT}.$$

The g value obtained by taking the average of the three g values obtained in the solution spectrum at 77 K is 2.09. Alternatively, one can think of two g values only, with the central line at $g = 2.05$ arising from monomer impurity, whose concentration might have increased after dissolving the complex in the solvent. With this type of assumption, the calculated spin Hamiltonian parameters are

$$g_1 = 2.07, \quad g_2 = 2.13,$$

$$D_1 = 77.5\ \text{mT}, \quad D_2 = 44.6\ \text{mT}.$$

The average of these two g values obtained in the solution spectrum at 77 K is 2.11. The isotropic g value obtained from the solution spectrum at RT is 2.166. The latter assumption of two g values looks more appropriate. However, single crystal work at X-band and/or measurement at 77 K with Q-band will further help to confirm our hypothesis. As of now, these two could not be done. This difference in the g values could be due to a

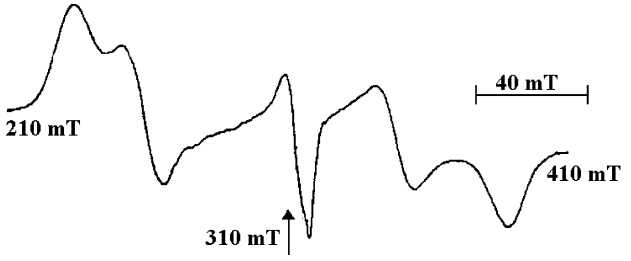

Fig. 6. EPR solution spectrum of the dimeric copper complex in ethanol solvent at 77 K in the range 210–410 mT. One can notice orthorhombic g and zero-field splitting from the two copper nuclei. $\nu = 9.04918$ GHz.

small structural change that might have occurred during dissolution in the solvent ethanol. However, when the EPR spectra are recorded in various solvents, the average g value is in the range 2.10–2.25. Hence, the indication of a small structural change has not been completely ruled out. The same type of observation was also noticed in some of our previous studies [8–15]. Although the X-ray data have suggested two types of copper ions, one in square-planar geometry and the other in square-pyramidal geometry, we did not notice two types of resonances from the two different copper ions. However, even if the resonances are present, they might not have appeared in powder samples due to the broadness of the resonance lines (line width around 10 mT). In addition, in the solution sample at RT, again due to rapid motion of ions, the resonances are averaged out. Even at 77 K, the resonance lines are still broad ruling out the possibility of observing two separate signals for the two copper ions.

An interesting observation of the present study is the presence of resonance lines at half-field transitions. This kind of result has been rarely reported in the EPR literature [34–37]. Here, we want to mention that even in the room temperature powder spectrum, the half-field line is noticed; however without any hyperfine splitting from the two copper nuclei. The EPR spectrum of the solution sample recorded at 77 K in the region 100–180 mT is shown in Fig. 7. One can clearly notice a seven line pattern with a rough intensity ratio of 1:2:3:4:3:2:1. The average hyperfine coupling constant is 6.1 mT. As discussed in the X-ray structural analysis, the distance between the two copper ions is 2.832 Å. It has been known that if the separation distance between the two metal centers is more than 3.5 Å, an interaction is not expected. In addition, the dihedral angle between the two copper atoms and the connecting ligand atoms also plays an important role in deciding the extent of the interaction. The half-field resonances are due to the transition between the $|-1\rangle$ and $|+1\rangle$ level in the triplet EPR spectrum [38]. However, it is forbidden, as the selection rule for this transition has been ± 2. The normal allowed transition is ± 1. Hence, it is not generally observed in most the EPR spectra, even though a small interaction is present between the two metal ions.

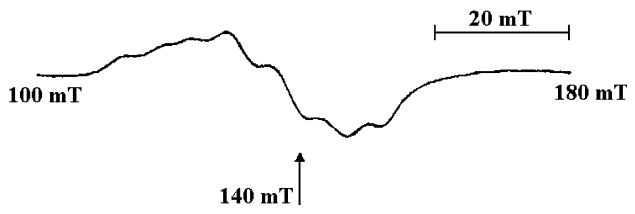

Fig. 7. EPR solution spectrum of the dimeric copper complex in ethanol solvent at 77 K in the region 100–180 mT, indicating hyperfine lines from two copper nuclei at half-field position. $\nu = 9.04918$ GHz.

The intensity pattern arises due to the two copper ions, having a total nuclear spin of 3. Hence, a seven-line pattern is expected and observed. Using the point dipole approximation and the measured D, the Cu–Cu separation (r) is calculated using the empirical formula [39]

$$r(\text{Å}) = [0.65 \times g_{\|}^2/D(\text{cm}^{-1})]^{1/3}.$$

By assuming a $g_{\|}$ value of 2.23 and D around 0.126 cm^{-1}, the calculated distance between the copper ions is 2.94 Å, and this value is close to that observed in the X-ray structural analysis (2.832 Å). However, the important observation is that the distance is sufficiently small to have an interaction between the two ions.

3.4. Magnetic study

The magnetic susceptibility of a powdered sample of the complex was measured in the temperature range 77–300 K using a vibrating sample magnetometer. Analysis has been carried out using the modified Bleaney–Bowers equation [40]

$$\chi_{\text{m}} = \{Ng^2\beta^2/KT\}[3 + \exp(-2J/KT)]^{-1}(1-p) + (Ng_{\text{i}}^2\beta^2/KT)p + N_{\alpha},$$

where χ_{m} is the paramagnetic susceptibility per molecule after the correction for diamagnetism, p is the paramagnetic impurities; g_{i} is the average g factor of the paramagnetic impurity. $-2J$ is the singlet–triplet energy separation, N_{α} is the TIP which is assumed to be 60×10^{-6} $\text{cm}^3\,\text{mol}^{-1}$ for Cu(II) dimers [41]. A best fit to the experimental value for the complex is summarized in Table 3. The observed J value is about 17.8 cm^{-1}. This suggests a weak ferromagnetic interaction between the two Cu(II) centers and also confirms the observation of EPR spectrum. The hydroxo bridged complexes exhibit a weak antiferromagnetic interaction when compared to nitrito and acetato bridged complexes, due to a π type overlap between the out of plane copper orbital and the non-bonding pair on oxygen (p_x). This will be more significant than the σ type overlap and hence gives rise to enhanced antiferromagnetism in the case of trigonal-planar oxygen and reduced antiferromagnetism in pyramidal oxygen [43,44]. Since the observed J value is made up of antiferromagnetic and ferromagnetic contributions, which in turn are influenced by a variety of structural and electronic factors, the detailed reasons for these variations in J can be quite complex. The ferromagnetic behaviour is generally due to the non-coplanarity of the two Cu chromophores. This "folding" feature is akin to the "roof shaped" geometry noted by Kahn [42] in various symmetrically bridged dihydroxo dimers. The consequent accidental orthogonality of the Cu $d_{x^2-y^2}$ magnetic orbitals postulated by Kahn to be responsible for reducing the $J_{\text{antiferro}}$ contribution relative

Table 3
Magnetic susceptibility data for the Complex $[Cu_2(Hsalamp)_2(OCOCH_3)(OCH_3)]ClO_4$

296	1.04	1.05	1.570	1.575

to J_{ferro} seems to broadly hold true in the case of asymmetrical species. The same compound also contains very tight Cu–O–Cu angles and short Cu–Cu distances within two coplanar *cis*-disposed square-pyramidal chromophores. However, in the present case, a ferromagnetic interaction is observed between the two copper ions, in relation to the previous studies. It has been reported that if the geometry around the copper ion is square-pyramidal, the magnetic orbital is $d_{x^2-y^2}$ and the lobes are pointed towards the ligands [45]. However, if the geometry is trigonal bipyramidal, the magnetic orbital is d_z^2 with lobes pointing towards the bonding ligands.

3.5. Cyclic voltammetric study

The cyclic voltammetric studies for the dimeric copper complex were performed in dried acetonitrile solvent. The most cathodic response is observed at an E_{pc} value of −0.88 V [44]. This has been assigned to a one-step two-electron reduction process, i.e., Cu(II)–Cu(II) → Cu(I)–Cu(I) redox process. The anodic scan following an initial cathodic scan is associated with a sharp feature at −0.08 V, which is characteristic of desorption of the electrogenarated copper(0) species. We observed a decrease in the intensities of the E_{pc} values in the multiple scan voltammogram performed at 50 mV/s, compared to the values obtained for 200, 100 and 50 mV/s. The $E_{1/2}$ value is found to be approximately at −1.00 V. It has been concluded from the differential pulse voltammogram that the initial process is the reduction of the two copper ions from +2 to +1 state and then +1 state to 0 state, as reported earlier [42]. This is achieved at the same $E_{1/2}$ value of about approximately −1.00 V, due to the broad feature observed in the differential pulse voltammogram. Further conformation of this reduction is obtained in a previous study, in which the two reductions were obtained at −0.54 and −0.86 V [46]. However, in the present case, due to the broad feature, we have observed both the reductions at −1.0 V.

4. Conclusions

The copper–copper dimer complex with the ligand Hsalamp has given very interesting results. Single crystal X-ray studies on this system have indicated that the two metal centers are in different geometries and the distance between them is appropriate for metal–metal interaction. The notable feature of the structure is that the Schiff base acts as a bidentate ligand (phenolic O– and imine –N=) with one of the copper ions and the hetero nitrogen atom coordinating with the other copper ion. The intramolecular distance between the two metal centers is 2.832(1) Å. The six-membered rings in the structure adopt a half-boat conformation, whereas the eight-membered rings assume a twist-boat conformation. The molecules are stabilized by C–H···O and O–H···O type weak hydrogen bond like interactions. The EPR results on this complex confirm the interaction between the two copper atoms and a well-resolved seven-line pattern is observed for the half-field transition, with a hyperfine value of 6.1 mT, nearly half of the value observed for a single electron on a copper nucleus. The assumption of axially symmetric or orthorhombic g needs confirmation from single crystal EPR studies at X-band or low temperature solution studies at Q-band. CV studies indicate a one-step two-electron reduction process, i.e., Cu(II)–Cu(II) → Cu(I)–Cu(I) redox process. Magnetic studies suggest a weak ferromagnetic interaction between the two Cu(II) centers and also confirms the observation of EPR spectrum.

5. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the Deposit No. 208446.

A novel potassium-centered highly symmetrically polynuclear zirconium complex: $K[\{(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3\}_4(NH_2)_5(NH_3)_7]$

Abstract

Treatment of $[Cp^*ZrCl_3]$ (**1**; $Cp^* = C_5Me_5$) with KH in liquid ammonia and toluene at −78 °C resulted in the complete removal of chloride and formation of the nitrogen-containing zirconium potassium complex $K[\{(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3\}_4(NH_2)_5(NH_3)_7]\cdot 6C_7H_8$ (**2**). X-ray structure analysis revealed this complex contains four $[(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3(NH_2)(NH_3)_2]$ building blocks where one of the protons is replaced by an interstitial potassium cation. Each of the four building blocks contains three Zr atoms forming a perfect equilateral triangular core, which is capped inside by a nitrido (N) and outside by an imido (NH) group, and furthermore symmetrically bridged by amido (NH_2) groups.

1. Introduction

Thin films of early transition metal nitrides have many applications as technologically important materials due to their unique properties [1–9]. In general, the nitrides have been prepared using chemical vapor deposition (CVD) techniques [10–15]. The development of synthesis in solution to yield solid-state materials via molecular precursors represents an intriguing challenge in the field of materials [16–19]. The interest in using transition metal nitrides has promoted studies on the intermediates with amido (NH_2), imido (NH) and nitrido (N) groups formed during the ammonolysis of transition metal compounds. Although some nitrogen-containing early transition metal compounds have been isolated and structurally characterized [20–28], polynuclear zirconium amide, imide and nitride species are very rare.

Wolczanski and co-worker [29] isolated the $[\{(t\text{Bu}_3\text{CO})\text{Zr}\}_5(\mu_5\text{-N})(\mu_3\text{-NH})_4(\mu\text{-NH}_2)_4]$ cluster from the ammonolysis of $[(t\text{Bu}_3\text{CO})\text{Zr}(\text{CH}_2\text{Ph})_3]$. Meanwhile, the pseudo-octahedral $[\{(t\text{Bu}_3\text{CO})\text{Zr}\}_6(\mu_6\text{-N})(\mu_3\text{-NH})_6(\mu\text{-NH}_2)_3]$ and the dodecaamido square pyramidal $[\{(t\text{Bu}_3\text{CO})\text{Zr}\}_5(\mu_5\text{-N})(\mu\text{-NH}_2)_{12}]$ compounds were obtained and characterized using ^{1}H, ^{13}C$\{^1$H$\}$, and ^{15}N NMR investigations. Our recent demonstration that the liquid ammonia/toluene two-phase system is highly effective for the ammonolysis and hydrolysis of transition metal compounds has led to the preparation of the amido, imido or nitrido group 4 complexes $[(\text{LTi})_6(\mu_3\text{-N})_2(\mu_3\text{-NH})_6\cdot 6(C_7H_8)]$ [30], $[\{(\text{MeC}_5\text{H}_4)\text{Zr}\}_5(\mu_5\text{-N})(\mu_3\text{-NH})_4(\mu\text{-NH}_2)_4]$ [31], and $[(\eta^3\text{-L})\text{Zr}(\mu\text{-NH})]_2$ ($\text{L} = (\text{PN}t\text{Bu})_2(t\text{BuN})_2$) [32], and related systems [33–40]. Herein we report the ammonolysis of a group 4 organometallic halide in a two-phase system, yielding a polynuclear zirconium anion.

2. Experimental

2.1. General data

All experimental manipulations were carried out under an atmosphere of purified nitrogen using standard Schlenk techniques. Samples prepared for spectral

measurements as well as for reactions were manipulated in a glove-box. Solvents were dried using conventional procedures, distilled under nitrogen and degassed prior to use. Deuterated NMR solvents were treated with K/Na alloy, distilled, and stored under nitrogen.

The NMR spectra were recorded on Bruker AM 250 spectrometer with $SiMe_4$ as external standard. Mass spectra were recorded on a Finnigan MAT 8230 mass spectrometer using the EI-MS method. The most intensive peak of an isotope distribution is tabulated. IR spectra are recorded on Bio-Rad FTS-7 spectrometer as nujol mulls between KBr plates. Elemental analyses were performed at the Analytical Laboratory of the Institute of Inorganic Chemistry, University of Göttingen.

2.2. Preparation of 2

Ammonia (50 ml) was condensed onto a suspension of **1** (1.37 g, 4.12 mmol) and KH (0.51 g, 12.76 mmol) in toluene (80 ml) at −78 °C under stirring. The stirring of the mixture was continued for 1 h at this temperature. Then the excess of ammonia was allowed to evaporate from the reaction mixture over a period of 4 h. During this time, the mixture was warmed slowly to room temperature. After filtration and subsequent concentration (to 15 ml) in vacuo, the resulting colorless solution was kept at −20 °C for two months to isolate colorless crystals of **2** (0.12 g). After isolating the crystals, and subsequent removal of the solvent, the colorless mother liquor was maintained at −20 °C for one week, from which additional crystals of **2** (0.15 g) were obtained. Total yield 0.27 g (21%); m.p. > 410 °C; IR (Nujol): $\tilde{\nu} = 3384, 1261, 1095, 1018, 801, 724, 666\ cm^{-1}$; ^1H NMR (300 MHz, C_6D_6): $\delta = 2.24$–1.62 (m, C_5Me_5), 2.05, 1.35, 1.18, 0.91, −0.12 (br, μ_3-N*H*, μ_2-NH_2, NH_2 and NH_3); EI-MS: *m/z* (%): 1498 (4) [M^+–2{(Cp*Zr)$_3$(μ_3-N)(μ_3-NH)(μ-NH$_2$)$_3$(NH$_2$)(NH$_3$)$_2$}–6C$_7$H$_8$–8NH$_3$–NH$_2$], 1364 (21) [M^+–2{(Cp*Zr)$_3$(μ_3-N)(μ_3-NH)(μ-NH$_2$)$_3$(NH$_2$)(NH$_3$)$_2$}–6C$_7$H$_8$–7NH$_3$–2NH$_2$–Cp*], 121 (100) [Cp*–CH$_2$]. Elemental *Anal.* Calc. for $C_{162}H_{287}KN_{32}Zr_{12}$ (3817.0): C, 51.0; H, 7.6; N, 11.7. Found: C, 51.0; H, 7.6; N, 10.7%.

2.3. Crystallographic measurement

Single crystals of **2** suitable for X-ray structural analysis were obtained from toluene by maintaining the reaction mixture at −20 °C for two months. Data for the structure were collected on a STOE IPDS II diffractometer. Intensity measurement was performed on a rapidly cooled crystal in an oil drop in the range $4.84° \leqslant 2\theta \leqslant 49.62°$. The structure was solved by direct methods (SHELXS-97) [41] and refined with all data by full-matrix least-squares on F^2 (SHELXL-97) (145 parameters) [42]. The hydrogen atoms of C–H bonds were added in idealized positions. $R_1 = 0.0471$ for $I > \sigma(I)$, $wR_2 = 0.1112$ for all data. The final difference Fourier synthesis gave a min/max residual electron density −0.521/+0.930 e Å^{-3}. Other details of the data collection, structure solution, and refinement are listed in Table 1.

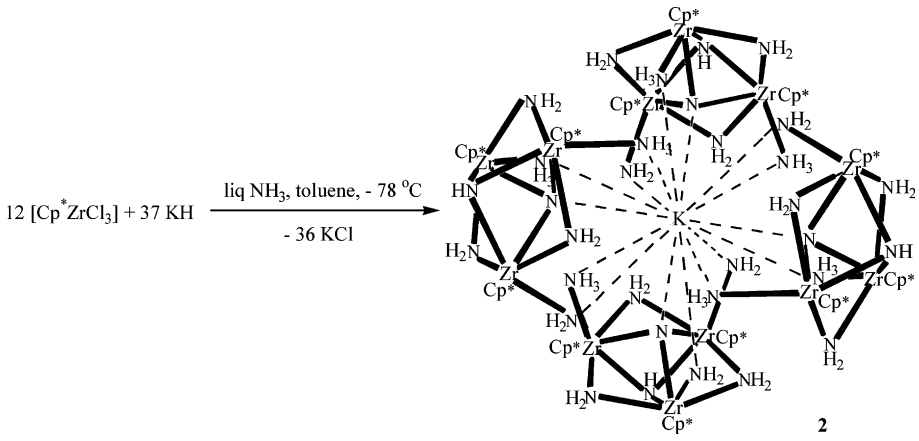
3. Results and discussion

Treatment of [Cp*ZrCl$_3$] (**1**) with KH (1:3 molar ratio) in liquid ammonia and toluene at −78 °C yields K[{(Cp*Zr)$_3$(μ_3-N)(μ_3-NH)(μ-NH$_2$)$_3$}$_4$(NH$_2$)$_5$(NH$_3$)$_7$]·6C$_7$H$_8$ (**2**; Scheme 1). Obviously, the hydride converts the ammonia to amide NH_2^- [43], and furthermore converts the resulting metal amide ($ZrNH_2$) to the corresponding imide (ZrNH) and nitride (ZrN) via inter-or intramolecular ammonia or hydrogen elimination.

Compound **2** is a colorless crystalline solid with unusual thermal stability. The melting point of **2** exceeds 410 °C (*no obvious decomposition was observed*). The IR spectrum of **2** shows a weak and broad absorption at 3384 cm^{-1}, assignable to the N–H stretching frequencies. Compound **2** exhibits the fragments [M^+-2{(Cp*Zr)$_3$(μ_3-N)(μ_3-NH)(μ-NH$_2$)$_3$(NH$_2$)(NH$_3$)$_2$}-6C$_7$H$_8$-8NH$_3$-NH$_2$] and [M^+–2{(Cp*Zr)$_3$(μ_3-N)(μ_3-NH)-(μ-NH$_2$)$_3$(NH$_2$)(NH$_3$)$_2$}–6C$_7$H$_8$–7NH$_3$–2NH$_2$–Cp*] at 1498 (4%) and 1364 (21%) in the EI mass spectrum of **2**, which indicates that two of the neutral building blocks



Scheme 1. Synthesis of **2**. Cp* = C_5Me_5.

of **2** are easily eliminated under EI-MS condition. The ^{1}H NMR spectral data of **2** show a series of resonances (from 2.24 to 1.62 ppm) for the protons of the Cp* groups and very broad resonances (2.05, 1.35, 1.18, 0.91 and −0.12 ppm) for the protons of the N–H moieties, indicative of the dissociation of **2** by dissolution.

Single crystals of **2** suitable for X-ray structural analysis were obtained from toluene by maintaining the reaction mixture at −20 °C for two months. Compound **2** crystallizes in the cubic space group *I*23. The molecular structure of **2** is shown in Fig. 1. In the crystal, **2** is a highly symmetrical complex, which consists of four $[(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3(NH_2)(NH_3)_2]$ building blocks where one of the protons is replaced by an interstitial potassium cation. Each of the four building blocks contains three Zr atoms forming a perfect equilateral triangular core, which is capped inside by a nitrido (N) and outside by an imido (NH) group, and

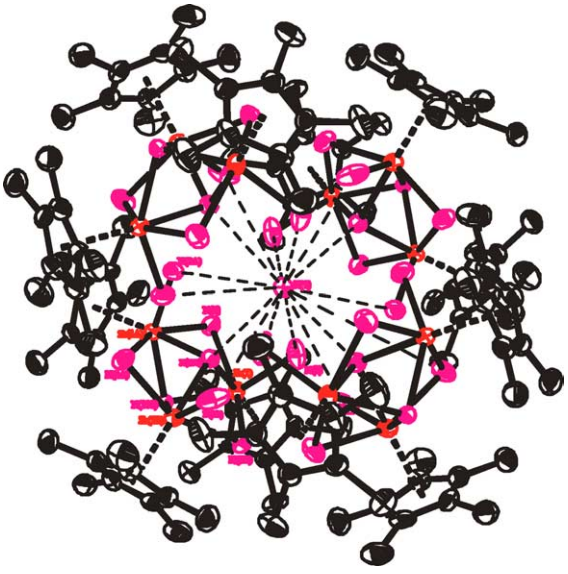


Fig. 1. The molecular structure of **2**. The hydrogen atoms and the toluene molecules are omitted for clarity.

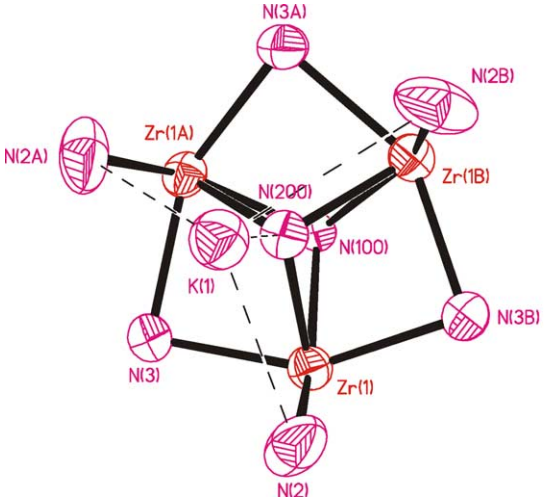

Fig. 2. The core structure of the building block $[(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3(NH_2)_2(NH_3)]$ with potassium.

furthermore symmetrically bridged by amido (NH_2) groups (Fig. 2 shows the core structure of one of the building blocks with potassium). The distorted octahedral coordination sphere of each zirconium is completed by a terminally bonded NH_3 or an amido NH_2 group oriented toward the inside of the cluster and a Cp* ligand tilted outside, leading to a geometry similar to that of trinuclear polyoxozirconium chloride $[\{(Cp^*ZrCl)(\mu\text{-}OH)\}_3(\mu_3\text{-}OH)(\mu_3\text{-}O)\cdot 2THF]$ [44].

The Zr(1)–N(100) (Zr–(μ_3-NH) 2.231(5) Å), Zr(1)–N(200) (Zr–(μ_3-N) 2.192(5) Å), Zr(1)–N(3) and Zr(1)–N(3B) (Zr–(μ-NH_2) 2.285(6) and 2.329(7) Å) bond lengths and the Zr···Zr (3.220(1) Å) distances are comparable to those found in $[\{(MeC_5H_4)Zr\}_5(\mu_5\text{-}N)(\mu_3\text{-}NH)_4(\mu\text{-}NH_2)_4]$ [1] and in $[\{(tBu_3CO)Zr\}_5(\mu_5\text{-}$

[1] Zr_a–(μ_3-NH) 2.253 Å, Zr_b–(μ_3-NH) 2.186 Å, Zr_a–(μ_5-N) 2.210 Å, Zr_b–(μ_5-N) 2.232 Å, Zr_b–(μ-NH_2) 2.296 Å, $Zr_a\cdots Zr_b$ 3.143 Å, $Zr_b\cdots Zr_b$ 3.1566 Å; Zr_a and Zr_b represent the one apical and the four basal zirconium atoms of the square pyramidal cluster, respectively [28].

Table 2
Selected bond lengths (Å) and bond angles (°) for $K[\{(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3\}_4(NH_2)_5(NH_3)_7]\cdot 6C_7H_8$ (**2**)

Bond lengths

$N)(\mu_3\text{-}NH)_4(\mu\text{-}NH_2)_4]$. [2] The bond lengths of Zr–(μ-NH_2) are longer than those of the Zr–(μ-NH) bonds in $[(\eta^3\text{-}L)Zr(\mu\text{-}NH)]_2$ (2.039(8) and 2.057(8) Å) [32]. The Zr···Zr distances are also similar with those exhibited by $[(\eta^3\text{-}L)Zr(\mu\text{-}NH)]_2$ (3.168(2) Å) and the polyoxozirconium cluster $[\{(EtMe_4C_5)Zr\}_6(\mu_6\text{-}O)(\mu_3\text{-}O)_8]\cdot(C_7H_8)$ (from 3.1542(9) to 3.1709(11) Å, av. 3.1635 Å) [33,34]. The Zr–NH_2 and Zr–NH_3 bond lengths (Zr(1)–N(2) 2.256(8) Å) are slightly shorter than those of Zr–(μ-NH_2) bonds, but a little bit longer than those of the Zr–(μ_3-NH) bonds (see Table 2).

The N···N distances N(3)···N(200) ((μ-NH_2)···μ_3-N) 2.715 Å), N(3)···N(2), N(3)···N(2A) ((μ-NH_2)···NH_2/NH_3 3.290 and 3.107 Å), and N(200)···N(2) ((μ_3-N)···NH_2/NH_3 2.830 Å), indicate the possibility of formation of hydrogen bonds (free NH_3 molecules may be involved) when the building blocks were formed. The K(1)–N(200) (K–(μ_3-N) 3.664 Å) and the K(1)–N(3) (K–NH_2/NH_3 3.815 Å) distances are significantly longer than those of the K–N bonds found in $[(\eta^1\text{-}LH)Zr(N\mathit{t}Bu)\{(N\mathit{t}Bu)_2PPN\mathit{t}Bu\}^-\{K(\eta^6\text{-}C_7H_8)\}^+\cdot 0.5C_7H_8]$ (2.859(3), 2.892(4), and 3.086(3) Å) [45] and in $[(tmp)_{12}K_6Mg_6(C_6H_5)_6]$ (tmp = 2,2,6,6-tetramethylpiperidide; (3.191(4) and 3.090(4) Å)) [46,47]. Obviously, potassium links the four blocks together to yield a highly symmetrical complex via sixteen weak K–N bonds. The argument that there are only weakly coordinating interactions between different blocks and potassium, suggests that **2** should easily dissociate in solution or under EI-MS condition, which is indeed supported by the ^1H NMR and EI-MS spectral data of **2**.

For the formation of **2** it seems likely that first the four trinuclear zirconium units are formed, of which one $[(Cp^*Zr)_3(\mu_3\text{-}N)(\mu_3\text{-}NH)(\mu\text{-}NH_2)_3(NH_2)(NH_3)_2]$ is deprotonated. In this case, three of the Cp* ligands should be in the *cis*-arrangement at the $(ZrNH_2)_3$ ring in the trinuclear zirconium precursor, because all of the Cp* ligands are oriented outside the ball resembled core of **2**. However, it has been demonstrated that two of the Cp* and one of the terminal chlorine atoms lie on the same side of the $(ZrOH)_3$ ring, while the remaining Cp* ligands and chlorine atoms are arranged in the opposite position in the trinuclear zirconium compound $[\{(Cp^*ZrCl)(\mu\text{-}OH)\}_3(\mu_3\text{-}OH)(\mu_3\text{-}O)\cdot 2THF]$ [44]. Furthermore, it should be difficult to convert the trimer from the *trans*- to the *cis*-position during the aggregation process. We assume liquid ammonia and potassium are important as well for generating the *cis*-building block as for the formation of **2**.

4. Conclusions

We have shown that the novel potassium-centered highly symmetrical polynuclear zirconium complex **2** has been prepared by the ammonolysis of the alkyl substituted cyclopentadienyl zirconium trichloride in the presence of KH in a two-phase system (NH_3/toluene). A potassium cation is surrounded by four trinuclear zirconium species in **2**. To the best of our knowledge, **2** represents the biggest nitrogen-containing zirconium cluster. So far, we were not able to obtain crystalline products using sodium cation. Further work is concentrated on other cations.

5. Supplementary materials

CCDC-202641 (**2**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ak/conts/retrieving.htm (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB21EZ, UK; (fax: +44-1223-336-033; or deposit@ccdc.cam.ac.uk).

Abstract

Several chiral copper(II) complexes of optically active Schiff bases (*R*,*R*)-**4a-c**, which have central seven-membered chelate rings, have been synthesized and characterized. X-ray single crystal analysis of a typical compound indicated that the complex is monomeric and the geometry around the metal atom is very distorted tetrahedral. All the complexes have been tested as catalysts for asymmetric oxidation of methyl phenyl sulfide. The mechanism of the catalytic reaction in the presence of these complexes has been tentatively elucidated.

Keywords: Asymmetric oxidation; Chiral copper(II) complexes; Schiff base; Sulfide; Seven-membered

1. Introduction

Metal complexes with Schiff base ligands, despite a vast literature, continue to be of current interest for their application in asymmetric catalysis [1–5]. So far, a large number of these kinds of complexes have resulted from the coordination reaction between transition metals and chiral salen-type Schiff base ligands derived from the condensation of salicylaldehyde derivatives and optically active diamines such as 1,2-diphenyl-ethylenediamine or 1,2-diaminocyclohexane. Generally, five-membered or six-membered metal chelate rings have been generated in the formation of the complexes with the above-mentioned ligands, and they play an important structural role when these complexes act as catalysts for asymmetric synthesis. Although Schiff base metal complexes with 1,4-diamines derivatives have been reported, much attention has been focused on their stereochemical aspects [6–11]. Chiral metal complexes of this type with seven-membered chelate rings, however, have been rarely involved in the area of asymmetric catalysis [12]. To explore the catalytic function of the category of complexes with this notable structural feature, we herein report the synthesis and crystal structure of a few of chiral copper(II) complexes together with an examination of their potential as asymmetric oxidation catalysts for the conversion of sulfides to sulfoxides.

2. Experimental

2.1. General remarks

All solvents were of analytical grade and dried with standard methods and distilled before use. 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde was prepared according to a literature method [13]. Elemental analyses were measured with a Perkin–Elmer 1400C analyzer. Infrared spectra (4000–400 cm^{-1}) were recorded on a Bruker Vector 22 FT-IR spectrophotometer. ^1H NMR spectra were obtained in a Bruker DRX 500 MHz spectrometer.

(*R,R*)-**3b**: Yield, 73%; m.p. 82–84 °C. $[\alpha]_D^{15} = +3.2$ ($c = 1$, $CHCl_3$). IR (KBr, cm^{-1}): 3424 br, w; 1634 s; 1473 m. ^1H NMR (500 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 13.50$ (br, 2H, OH), 8.50 (s, 1H, HC=N), 8.44 (s, 1H, HC=N), 7.50 (m, 2H, phenyl), 7.43 (s, 2H, phenyl), 7.36 (m, 3H, phenyl), 7.14 (s, 1H, phenyl), 7.09 (s, 1H, phenyl), 6.01 (s, 1H, CH), 4.48 (m, 2H, CH), 4.01–3.94 (m, 4H, CH_2), 1.49 (s, 18H, CH_3), 1.34 (s, 18H, CH_3). ESI-MS *m/z* (%): 641.3 (100) $[\mathbf{3b}+H]^+$. *Anal*. Calc. for $C_{41}H_{56}N_2O_4$: C, 76.84; H, 8.81; N, 4.37. Found: C, 76.88; H, 8.86; N, 4.44%.

(*R,R*)-**3c**: Yield, 70%; m.p. 122–124 °C. $[\alpha]_D^{15} = +49.5$ ($c = 1$, $CHCl_3$). IR (KBr, cm^{-1}): 3449 br, w; 1632 s; 1470 m. ^1H NMR (500 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 13.48$ (br, 2H, OH), 8.42 (s, 2H, HC=N), 7.39 (s, 2H, phenyl), 7.09 (s, 2H, phenyl), 4.21 (m, 2H, CH), 3.91 (m, 2H, CH_2), 3.84 (m, 2H, CH_2), 1.58 (s, 6H, CH_3), 1.44 (s, 18H, CH_3), 1.30 (s, 18H, CH_3). ESI-MS *m/z* (%): 593.4 (100) $[\mathbf{3c}+H]^+$. *Anal*. Calc. for $C_{37}H_{56}N_2O_4$: C, 74.96; H, 9.52; N, 4.73. Found: C, 74.92; H, 9.61; N, 4.82%.

2.4. Preparation of chiral copper(II) complexes (*R,R*)-*4a–c*

A general procedure is described here. To the solution of a salen ligand (0.1 mmol) in methanol was added $Cu(OAc)_2 \cdot H_2O$ (0.02 g, 0.1 mmol) and the reaction mixture was stirred under reflux for 2 h. The precipitated solids were filtered, washed with methanol and dried in vacuum.

(*R,R*)-**4a**: Yield, 73%. IR (KBr, cm^{-1}): 1609 s; 1530 m; 1462 m. ESI-MS *m/z* (%): 668.4 (100) $[\mathbf{4a}+H]^+$. *Anal*. Calc. for $C_{38}H_{56}CuN_2O_4$: C, 68.28; H, 8.44, N, 4.19. Found: C, 68.04; H, 8.55, N, 4.25%.

(*R,R*)-**4b**: Yield, 72%. IR (KBr, cm^{-1}): 1613 s; 1530 m; 1461 m. ESI-MS *m/z* (%) 702.3 (100) $[\mathbf{4b}+H]^+$. *Anal*. Calc. for $C_{41}H_{54}CuN_2O_4$: C, 70.11; H, 7.75; N, 3.99. Found: C, 70.42; H, 7.56, N, 4.18%.

(*R,R*)-**4c**: Yield, 57%. IR (KBr, cm^{-1}): 1605 s; 1531 m; 1461 m. ESI-MS *m/z* (%) 654.4 (100) $[\mathbf{4c}+H]^+$. *Anal*. Calc. for $C_{37}H_{54}CuN_2O_4$: C, 67.91; H, 8.32; N, 4.28. Found: C, 67.85; H, 8.39; N, 4.29%.

2.5. Asymmetric oxidation

General procedure for asymmetric oxidation: Thioanisole (1.00 mmol) and the catalyst (0.01 mmol) were dissolved in acetonitrile at room temperature. To the solution was added hydrogen peroxide (1.10 mmol) at the same temperature and the mixture was stirred for 24 h, and filtrated through a pad of Celite. No sulfone was detected by TLC analysis of the filtrate. The filtrate was concentrated and purified by thin layer chromatography on silica gel (petroleum:ethylacetate = 3:1) to yield methyl phenyl sulfoxide. The enantiomeric excess of the sulfoxide was determined by HPLC analysis Daicel Chiralcel OD (hexane:*i*-PrOH = 9:1).

2.6. Crystallographic data for (*R,R*)-*4c*

A single crystal of (*R,R*)-**4c** was measured on a Bruker CCD-4K diffractometer using graphite-monochromated MoKα ($\lambda = 0.71073$ Å) radiation at 293(2) K. The data were collected using SMART and reduced

by using the program SAINT [15]. Empirical absorption correction was done by using the SADABS program [16]. The structure was solved by direct methods and refined by least squares method on F^2_{obs} by using the SHELXTL-PC software package [17]. The anisotropic thermal parameters of all non-hydrogen atoms were refined by the full-matrix least-squares procedure and the hydrogen atom positions were geometrically fixed and allowed to ride on the attached atoms. The experimental details and refinement results for (*R*,*R*)-**4c** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and molecular structure of the copper(II) complexes

Following a modified literature procedure [13], condensation of optical 1,4-diamines (*R*,*R*)-**1a**–**c** with 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde **2** in ethanol at 80 °C yielded the corresponding Schiff base derivatives (*R*,*R*)-**3a**–**c**. Complexation of copper(II) acetate monohydrate by (*R*,*R*)-**3a**–**c** readily afforded complexes (*R*,*R*)-**4a**–**c** (Scheme 1).

Electrospray ionization mass spectra of these compounds revealed that all the copper(II) complexes were mononuclear. Slow evaporation of the acetonitrile solution of (*R*,*R*)-**4c** gave dark brown crystals suitable for X-ray analysis. The other two complexes (*R*,*R*)-**4a** and (*R*,*R*)-**4b** were consistently obtained as feathery needles unsuitable for crystallographic analysis. The molecular structure of (*R*,*R*)-**4c** is given in Fig. 1.

As shown, the presence of bulky substituents on the phenyl ring has made the two aromatic rings not co-planar. The copper(II) atom of (*R*,*R*)-**4c**, which is four-coordinate, has a geometry of very distorted tetrahedral. The dihedral angle between the Cu(1), N(2), C(22), C(16), C(17), O(2) plane and its counter-part is 48.7°, which is slightly larger than that [42.6(3)°] of the analogous (salen) Cu(II) complex reported by Nathan et al. [18]. This difference in dihedral angle can be explained by the steric repulsion of *tert*-butyl groups as well as the more flexible chain (four carbon atoms) of our salen-type ligand. The Cu–N distances and Cu–O distances are in the range 1.95–1.99 and 1.89–1.90 Å, respectively, comparable to the corresponding bond lengths found in the complex [Cu(sal-4)] reported earlier [18]. It is anticipated that the two imine-N atoms and its carbon chain form a seven-membered chelate ring with the metal atom in the complex. The chelate bite angle in the seven-membered ring is 101.3(3)°, and the C(32), C(33), O(4), C(35), O(3) atoms constitute a five-membered ring close to an ideal half-chair conformation in its neighbor.

3.2. Asymmetric oxidation of methyl phenyl sulfide

The oxidation of prochiral sulfides to sulfoxides has been catalyzed by a range of chiral vanadyl complexes [19], manganese complexes [20] and titanium complexes [21] of Schiff base ligands. Recently Cross and coworkers [22] have described the asymmetric oxidation of sulfide with copper(II) complexes. Using 10 mol % of the copper(II) complex as the catalyst and hydrogen peroxide as the oxygen source, they obtained enantioselectivity of only up to 14% e.e. However, to date there have been no reports of this reaction catalyzed by chiral Schiff base metal complexes with 1,4-diamines derivatives. To explore the effect of such a kind of metal complex as enantioselective catalysts, complexes (*R*,*R*)-**4a**–**c** were tested as catalysts for H_2O_2 oxidation of PhMeS (Scheme 2).

It is found that in acetonitrile catalysts (*R*,*R*)-**4a**–**c** were effective with good chemical yields (>80%), but only (*R*,*R*)-**4c** produced a reasonable enantiomeric excess (17%). To our knowledge, reaction at lower temperature may improve the enantioselectivity. In our further examination of the temperature effect on enantioselectivity, however, the reaction at 0 °C turned out to proceed very slowly. We also examined the oxidation of methyl phenyl sulfide in the presence of various solvents. Compared with acetonitrile, *n*-hexane

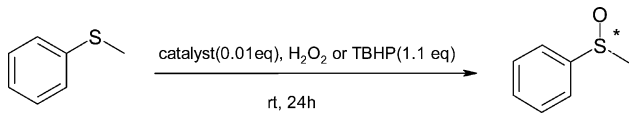
Selected bond lengths (Å) and angles (°) (standard deviations in parentheses): Cu(1)–O(1): 1.892(6); Cu(1)–O(2): 1.891(7); Cu(1)–N(1): 1.953(8); Cu(1)–N(2): 1.990(8). O(1)–Cu(1)–O(2): 89.2(3); N(1)–Cu(1)–N(2): 101.3(3); O(1)–Cu(1)–N(1): 92.5(3); O(2)–Cu(1)–N(2): 94.0(3); O(1)–Cu(1)–N(2): 149.6(3); N(1)–Cu(1)–O(2): 146.0(3).

slightly improved chemical yield but with negligible (<2%) e.e., while $CHCl_3$ and CH_2Cl_2 lower the chemical yield without generating significant enantiomeric excess. It is noted that the use of DMF as a solvent caused the decomposition of the catalysts. When Bu^{t}OOH was used as an oxidant instead of aqueous H_2O_2, the reac-



Scheme 2. Asymmetric oxidation of methyl phenyl sulfide catalyzed by (*R*,*R*)-**4a**–**c**.

tion proceeded smoothly but with lower e.e. (< 6%). In all cases of our reaction, no sulfone was observed.

The mechanism of the asymmetric oxidation of sulfide catalyzed by a chiral copper(II) complex with Schiff base ligands is still unclear at present. Recently Decinti and coworkers [23] have proposed that the mechanism of styrene epoxidation with iodosylbenzene in the presence of copper(II) Schiff base complexes involved the formation of copper–iodosylbenzene adducts as intermediates. We also performed the reaction of complex (*R*,*R*)-**4c** with hydrogen peroxide in the absence of substrate under the same conditions as a catalytic process in attempt to identify the reactive species. Spectrometric measurements in the UV-Vis region of metal complexes–hydrogen peroxide mixtures showed that the characteristic spectral bands of complex (*R*,*R*)-**4c** undergo a decrease in absorbance with increasing reaction time, which reflects a decrease in the concentration of the metal complex. Moreover it is observed that the rates of the spectral changes in different solvents are not the same (Fig. 2). We postulated that an analogous intermediate, copper–hydrogen peroxide adducts, may also be involved in our performed reaction. Differences in the observed rates of the spectral changes in different solvents may suggest that the stability of the copper–hydrogen peroxide adducts vary in the sequence $CH_3CN > n\text{-}C_6H_{14} > CHCl_3$. The instability of this adduct is also supported in the experiment by the observation of slow decomposition of the catalyst. It is known that the enantioselectivity of the reaction originates from the stereochemical communication between the substrate and catalytic species. The stability of the catalytic species is crucial for full stereochemical communication in the transition state. So the observation of relatively higher enatioselectivity in CH_3CN compared with other solvents may be interpreted on the basis of the above considerations. At 0 °C under the same conditions the absorbance of spectral bands of the copper(II) complex showed a slight change, perhaps indicative of no obvious interaction between (*R*,*R*)-**4c** and H_2O_2. It maybe suggested that at 0 °C no e.e. could be obtained in our catalytic system. Investigations are currently underway to improve the efficiency of the catalysts and to determine which copper species is responsible for the observed enantioselectivity.

The observation of lower enantioselectivity in the sulfide oxidation may also be interpreted on the basis of the molecular structure of the copper(II) complex (*R*,*R*)-**4c**. For the sake of comparison, we also performed

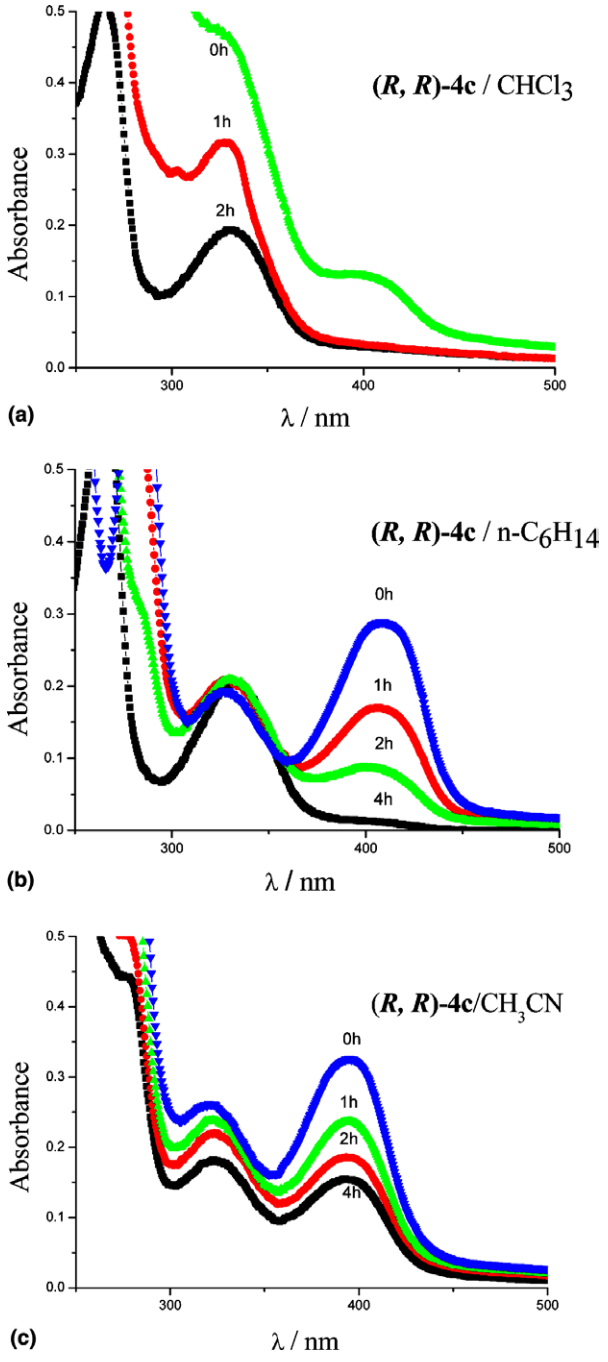


Fig. 2. Absorption spectra in the d–d band region of complex (*R*,*R*)-**4c** at room temperature in different solvents: in the absence of H_2O_2 ($t = 0$); in the presence of excess H_2O_2 at different time intervals ($t = 1$ h, $t = 2$ h, $t = 4$ h).

molecular mechanics (UFF) optimization calculations on copper(II) complexes (*R*,*R*)-**4a**–**b** with the GAUSSIAN 98 package [24]. The results revealed that the diol-protected groups in the complexes (*R*,*R*)-**4a**–**c** are far away from apical coordinating site of the central metal and exhibited no interaction with the oncoming sulfide approaching the metal along the orientations of two Cu–N bonds with similar ease (Fig. 3). Accordingly,

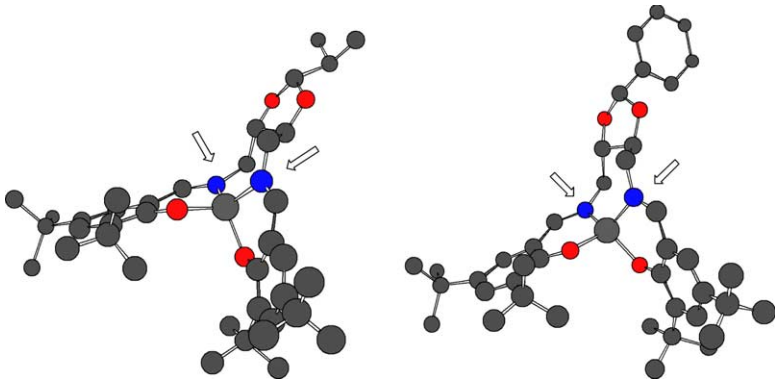

Fig. 3. Molecular structures of (*R*,*R*)-**4a** and (*R*,*R*)-**4b** optimized by molecular mechanics (UFF).

high asymmetric induction was not realized in the oxidation of sulfide with (*R*,*R*)-**4a**–**c**. On the other hand, it is not excluded that the accelerating non-catalytic oxidation reaction at room temperature may also contribute to low e.e.

4. Conclusion

Overall we have prepared three new chiral copper(II) complexes of an optically active schiff base (*R*,*R*)-**4a**–**c** with a central seven-membered ring. Although useful enantioselectivity has not yet been attained in sulfide oxidation with the system thus far, it is likely that significant improvements will result from further modification of the steric and electronic properties of these and related catalysts.

Preparation and crystal structure of (2,2′-bibenzimidazole)dihalobis(triphenylphospine)rhenium(III) halides

François Baril-Robert, André L. Beauchamp *

Département de chimie, Université de Montréal, C.P. 6128, Succursale Centre-ville, Montréal, QC, Canada H3C 3J7

Received 3 September 2003; accepted 18 January 2004

Abstract

The reaction of $ReOX_3(PPh_3)_2$ (where X = Cl, Br) with 2,2′-bibenzimidazole ($bibzimH_2$) in the presence of excess PPh_3 yields the rhenium(III) cationic complexes $[ReX_2(PPh_3)_2(bibzimH_2)]X$, in which the phosphines are *trans* to one another, whereas the plane perpendicular to this direction includes the chelating bidentate $bibzimH_2$ and two *cis* halogen ligands. The third halogen is a halide counter-ion, attached to the complex cation via a pair of $N–H\cdots X^-$ hydrogen bonds involving the two N–H groups of $bibzimH_2$. Crystallographic work on the chloro compound indicates that the departure from octahedral geometry is controlled by the bite of the $bibzimH_2$ ligand and that the presence of the phenylene groups does not introduce substantial steric hindrance. Despite the fact that the species is paramagnetic, the ^1H NMR spectra were fully assigned.

1. Introduction

In the recent years, our laboratory has become interested in the complexation of 2,2′-biimidazole ($biimH_2$, Scheme 1) to various metal centers. In the formally neutral form, two nitrogen donors in coplanar rings can adopt a *syn* orientation leading to chelates similar to those of bipyridine. However, $biimH_2$ differs from bipyridine by the presence of five-membered rings, which change the bite angle for chelate formation and allow for more conformational freedom about the connecting C2–C2′ bond, thereby leading to oligomeric or polymeric structures [1–3]. In both cases, the residual N–H bonds generate in the crystal particular hydrogen-bond patterns from which supramolecular assemblies can be constructed. Extra structural features appear when biimidazole coordinates in the monoanionic form, since one of the uncoordinated nitrogens is protonated and the other is not. Hydrogen bonding then takes place with donors, acceptors, or more interestingly, with units containing one of each, including monodeprotonated biimidazolate itself, which gives access to an enlarged variety of patterns for crystal engineering. This versatility is well illustrated by the series of compounds reported by Takodoro et al. [4–7]. Finally, fully deprotonated dianionic biimidazolate can behave as a bis-bidentate/chelating unit like the oxalate dianion and link two metal centers into larger building blocks [8–10] that could be considered in the development of molecular devices [11,12].

In our previous contributions [13,14], we reported that the Re(V) precursors $ReOX_3(PPh_3)_2$ and $ReO(OEt)X_2(PPh_3)_2$ are reduced cleanly by PPh_3 in the presence of $biimH_2$, giving good yields of the rhenium(III) cationic complexes *cis*,*trans*-$[ReX_2(PPh_3)_2(biimH_2)]X$ with X = Cl, Br and I. The residual N–H protons of coordinated $biimH_2$ were found to be moderately acidic and to participate in strong hydrogen-bonding interactions, leading to tight ion pairs with halide or carboxylate counter-ions. By using the smaller phosphine PMe_3, neutral complexes containing monodeprotonated

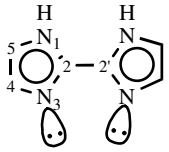
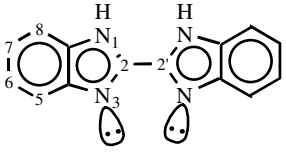


Scheme 1.



Scheme 2.

biimidazole could be isolated as dimers assembled by a pair of complementary N–H···N hydrogen bonds. This study is being extended here to 2,2-bibenzimidazole ($bibzimH_2$, Scheme 2), in which the presence of phenylene units opens a number of possibilities for ligand tuning via substitution on the ring. We wish to report the preparation and structural characterization of the compounds $[ReX_2(PPh_3)_2(bibzimH_2)]X$, which show that the extra phenylene rings do not introduce appreciable steric or other undesirable effects and that the chemistry of the Re(III)-$biimH_2$ systems is applicable to the bulkier $bibzimH_2$ system.

2. Experimental

2.1. Reactants and methods

$KReO_4$ and all other reactants were obtained from Aldrich and used without further purification. $ReOCl_3(PPh_3)_2$ [15] and $ReOBr_3(PPh_3)_2$ [16] were prepared by literature methods. Deuterated solvents were purchased from Aldrich or CDN Isotopes.

The NMR spectra were measured with Bruker ARX-400 or AMX-300 spectrometers. For the ^1H spectra, the residual solvent signals (DMSO-d_6, 2.50 ppm; $CDCl_3$, 7.26 ppm) were used as internal references and the chemical shifts are expressed in ppm versus $SiMe_4$. Electronic spectra were recorded as $CHCl_3$ solutions in quartz cells with a UV–Vis–NIR Cary 5E spectrometer. FAB^+ mass spectra in NBA were measured at the Centre de Spectrométrie de Masse de l'Université de Montréal. Elemental analyses were run at the Laboratoire d'Analyse Élémentaire de l'Université de Montréal.

2.2. Preparation of the ligand

2,2′-Bibenzimidazole was prepared as described by Fieselmann et al. [17]. In our hands, the purification by recrystallization from ethylene glycol was not totally efficient and an extra purification step was introduced. The yellow solid was dissolved in boiling NaOH, 0.25 M, and refluxed for 2 days. Some insoluble material was filtered off and the dark-brown solution was neutralized with concentrated HCl. The light-violet solid was filtered, transferred into water and refluxed for 1 h to remove any ionic form of the molecule. Finally, the solid was filtered, washed with water, ethanol and diethyl ether, and dried in air. Yield: 24%.

2.3. Preparation of $[ReX_2(PPh_3)_2(bibzimH_2)]X$

A suspension of PPh_3 (0.238 g; 0.91 mmol) and $bibzimiH_2$ (0.123 g; 0.52 mmol) in 40 mL $CHCl_3$ is heated to the boiling point, and $ReOCl_3(PPh_3)_2$ (0.354 g; 0.42 mmol) is added. The lime-green solution darkens quickly and the mixture is refluxed for 2.5 h. It is filtered hot and evaporation of the resulting dark-red solution yields a sticky dark-red material. Upon dropwise addition of diethyl ether, a red powder is obtained, which is filtered and washed with diethyl ether. Crystals of the solvent-free material are obtained by slow diffusion of diethyl ether into a CH_2Cl_2 solution.

2.3.1. $[ReCl_2(PPh_3)_2(bibzimH_2)]Cl$

Yield: 77%. ^1H NMR ($CDCl_3$): see text. MS FAB^+ (*m*/*z*): 1014 $[M]^+$, 752 $[M-PPh_3]^+$, 717 $[M-PPh_3-Cl]^+$. UV–Vis (λ (nm) (ε (M^{-1} cm^{-1}))): 558 (670), 522 (675), 469 (1350), 434 (1400), 404 (1200), 360 (8700), 341 (8750), 330 (6500). Composition was determined by X-ray diffraction on a crystal picked up in the morphologically homogeneous sample.

2.3.2. $[ReBr_2(PPh_3)_2(bibzimH_2)]Br$

Same as above, from $ReOBr_3(PPh_3)_2$. Yield: 72%. *Anal.* Calc. for $C_{50}H_{40}Br_3N_4P_2Re$: C, 50.69; H, 3.40; N, 4.73. Found: C, 50.94; H, 3.42; N, 4.72%. ^1H NMR ($CDCl_3$): see text. MS FAB^+ (*m*/*z*): 1102 $[M]^+$, 843 $[M-PPh_3]^+$, 762 $[M-PPh_3\text{-}Br]^+$.

2.4. X-ray diffraction study

To grow the crystals used for X-ray work, the powder was placed in a vial and covered with acetone, the vial was closed tightly and left at room temperature for a few days. The powder dissolved slowly and reprecipitated as less soluble red blocks of the solvate *cis*-$[ReCl_2(PPh_3)_2(bibzimH_2)]Cl\cdot 3(CH_3)_2CO$. The X-ray data were collected with a Bruker Smart 2K CCD diffractometer using the graphite-monochromatized Cu Kα radiation, as described elsewhere [18]. The data were interpreted with the SHELXTL software [19]. The XPREP procedure [20] was used to apply an absorption correction based on crystal morphology. The non-hydrogen atoms were generally refined anisotropically. The hydrogens were first placed at idealized positions and allowed to ride

$^* R = \sum \|F_o| - |F_c\| / \sum |F_o|$, $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2] / \sum w(F_o^2)^2\}^{1/2}$, $S = \{\sum[w(F_o^2 - F_c^2)^2] / (N_{obs} - N_{param})\}^{1/2}$.

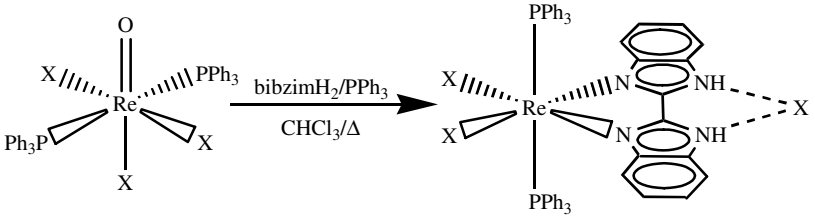
on the supporting atom. No disorder was detected in the $[ReCl_2(PPh_3)_2(bibzimH_2)]^+$ unit, but the chloride counter-ion and the three acetone molecules of the asymmetric unit were disordered. Each of these acetone sites was modeled with three different sets of positions. The FLAT option was used to keep the molecule planar, whereas constraints were applied on interatomic distances, based on the average data for solvate acetone in the Cambridge Crystallographic Database [21] [C=O, 1.21 Å; C–CH_3, 1.47 Å; O···CH_3, 2.33 Å; CH_3···CH_3, 2.51 Å]. A very small tolerance on the distances had to be applied to stabilize the refinement. The occupancies were first refined with a constraint applied to normalize their sum to unity, then they were rounded off to the nearest 0.05 and fixed (0.60/0.20/0.20) for the rest of the refinement. The chloride ion was described by means of two positions located on each side of the plane through $bibzimH_2$. These positions were initially refined separately, then simultaneously. The occupancies were refined as above and fixed (0.60/0.40) in the last least-squares cycles. The final R factor of 0.055 is considered to be satisfactory, considering the severe disorder present in the structure. The crystal data are collected in Table 1.

A data set was also collected on red plates of the solvent-free complex salt, grown by slow diffusion of diethyl ether into a saturated CH_2Cl_2 solution of the raw material. These crystals belong to space group *Pbca*, with $a = 11.199$, $b = 23.455$, $c = 34.567$ Å and $Z = 8$ molecules per cell. The complex showed the same structure as the Tris–acetone solvate, except for a two-fold orientation disorder around the Re–P bond for one of the PPh_3 ligands. Because of disorder and poor crystal quality, the R factor could not be reduced below of 0.12. No further efforts were devoted to this material, since better crystals of the solvate had become available in the meantime.

3. Results and discussion

Good yields of the bromo and chloro complexes $[ReX_2(PPh_3)_2(bibzimH_2)]X$ are obtained by heating $ReOX_3(PPh_3)_2$ and bibenzimidazole in $CHCl_3$ in the presence of excess PPh_3 (Scheme 3). Infrared spectra confirm the presence of PPh_3 and $bibzimH_2$ in the compounds. A definite proof for the structure is provided by the X-ray diffraction results discussed below. The presence of the $[ReX_2(PPh_3)_2(bibzimH_2)]^+$ ion in the solid is consistent with the FAB^+ spectra showing the parent-ion pattern with the expected isotopic distribution, together with fragments resulting from the loss of PPh_3 and X. The good solubility in solvents like CH_2Cl_2 and $CHCl_3$ agrees with the presence of tight ion pairs, as noted for the biimidazole complexes [13]. The compounds were fully characterized by ^1H NMR.

In the free ligand, the two benzimidazole units connected via the C2–C2′ bond are symmetry equivalent (Scheme 2). In addition, the N–H protons are involved in a fast tautomeric exchange between the ring N atoms, which renders the H_5/H_8 pair (and H_6/H_7 pair) chemically, but not magnetically, equivalent. Accordingly, only two signals are observed (AA′BB′ system, Fig. 1), but they are not first order. The chemical shifts and coupling constants (Table 2) were determined from the method described by Sohar [22].



Scheme 3.

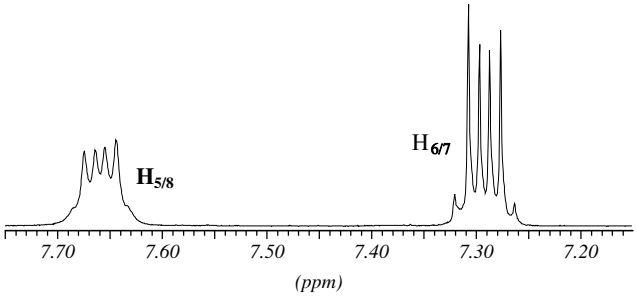


Fig. 1. ^{1}H NMR signals (DMSO-d_6) of the aromatic protons of free bibenzimidazole.

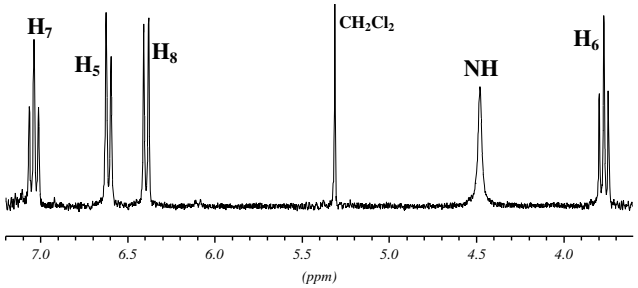

Fig. 2. Signals of the coordinated bibenzimidazole protons in the ^{1}H NMR spectrum ($CDCl_3$) of $[ReCl_2(PPh_3)_2(bibzimH_2)]Cl$. The CH_2Cl_2 signal results from residual traces of the recrystallization solvent.

Table 2
^{1}H NMR chemical shifts (ppm) and coupling constants (Hz) of bibzimH_2 (DMSO-d_6)

δ, $H_{5/8}$	7.66 ppm (m)
δ, $H_{6/7}$	7.29 ppm (m)
$^3J_{56} = {}^3J_{78}$	7.9 Hz
$^3J_{67}$	6.5 Hz
$^4J_{57} = {}^4J_{68}$	1.3 Hz
$^5J_{58}$	0.0 Hz

The low-spin d^4 center in rhenium(III) monomers is paramagnetic. Despite this fact, the ^{1}H NMR spectra are relatively clean, integrations are reliable and couplings are often observed. The data for the bibzimH_2 complexes are collected in Table 3. The PPh_3 signals appear at the same positions as for the related complexes of biimidazole [13] and they are readily identified from multiplicities and integrations. The *ortho* protons, close to the metal center, undergo a considerable shift (13.3 ppm) downfield from their normal position (7–8 ppm). Since the Re–N bonds are non-labile, bibzimH_2 gives four C–H signals between ~7 and ~3.7 ppm (Fig. 2). In contrast with those of PPh_3, they are shifted upfield by paramagnetism. The second-order effects noted for the free ligand have now disappeared, since the signals have been shifted considerably. H_5 and H_8 appear as doublets and can be distinguished from H_6 and H_7, which give pseudo-triplets because of couplings with two adjacent protons. One of the latter protons appears at much higher field (~4 ppm) than the other. Semi-empirical PM3 calculations [23] suggest that the orbitals containing the unpaired electrons are more concentrated on H_6 than on any other proton, whereas its neighbor H_7 is predicted to be the least affected by the unpaired electrons. Accordingly, the higher-field triplet (3.76 (Cl); 4.25 (Br) ppm) is assigned to H_6, whereas the other triplet (7.03 (Cl); 6.71 (Br) ppm) must correspond to H_7. A COSY 2D experiment for $[ReBr_2(PPh_3)_2(bibzimH_2)]Br$ indicates proximity for the protons appearing at 6.22 and 4.25 ppm, respectively. This allows us to assign the doublet at 6.22 ppm to H_5 and the other doublet at 6.01 ppm to H_8. The acidic N–H protons give a broad peak at 4.44 (Cl) or 4.89 (Br) ppm.

3.1. Crystal structures

The $[ReCl_2(PPh_3)_2(bibzimH_2)]Cl$ unit is shown in Fig. 3. The octahedral environment of rhenium(III) includes one non-deprotonated bidentate bibzimH_2 ligand, two phosphines *trans* to one another and two chlorines. The third chlorine is actually the counter ion forming two N–H···Cl^- hydrogen bonds with bibzimH_2. Selected interatomic distances and bond angles are compared with those of the biimidazole analog [13] in Table 4.

Most of the departure from octahedral coordination originates from the small bite angle (76.7(2)°) of bibzimH_2, which allows the opposite Re–Cl bonds to move away from each other (Cl(1)–Re–Cl(2) = 96.97(5)°). The Re–P bonds, perpendicular to the $ReCl_2N_2$ plane, are not exactly collinear (P(1)–Re–P(2) = 175.21(4)°), but

C(24)–N(23)–Re	140.8(3)	138.8(3)

the deviation is small. The Re–N and Re–Cl bond lengths compare well with those of the $biimH_2$ complex, but the Re–P bonds are ~0.02 longer here, probably because the extra phenylene rings leave less space for the phosphine phenyl rings.

The two benzimidazole halves of the coordinated ligand are coplanar (dihedral angle = 1.7(3)°). As depicted in Fig. 4, ring closure induces in-plane distortions to improve the overlap between the metal orbitals and the ligand σ lone pairs, leading to a large difference between the $N_3–C_2–C_2'$ and $N_1–C_2–C_2'$ angles. In the present $bibzimH_2$ complex, this difference is somewhat smaller (~117° versus ~130°) than for the $biimH_2$ complexes (~116° versus ~133°). Thus, the phenylene rings act as bulky α substituents counteracting ligand distortion, which explains that the Cl–Re–Cl angle is smaller here (~97°) than in the $biimH_2$ analog (~99°).

The N–H groups form hydrogen bonds with the chloride counter-ion (Fig. 3 and Table 5). The N···Cl distances of ~3.06 Å and the N–H···Cl angles (~154°) close to linearity correspond to moderately strong interactions [24]. The reduction of ligand distortion is a favorable factor, since it allows the N···Cl distance and the N–H···Cl angle to be greater than for the $biimH_2$ complexes (~3.16 Å and ~147°, respectively) [13].

The phosphines are related by an approximate mirror plane. Two phenyl groups of each phosphine are positioned above (or below) the $bibzimH_2$ ligand, whereas the third phenyl ring is roughly parallel to the Re–P bond and the ortho hydrogen is nested between the two chloro ligands. A similar conformation has been observed for $[ReCl_2(PPh_3)_2(biimH_2)]Cl$ [13]. However, in contrast with the latter case, there are no appreciable π interactions between the phosphine phenyl rings and those of the $bibzimH_2$, since these rings are not parallel (dihedral angle of 20.5° and 25.0°) and the inter-ring distances are relatively large (3.49 and 3.65 Å).

The ion pairs form columns along the unit cell *b* direction and the acetone solvent molecules occupy channels between these columns.

4. Conclusion

This work shows that the extra aromatic rings in bibzimH_2 do not preclude the formation of the [ReX_2(PPh_3)$_2$(LH_2)]X complexes observed with biimidazole and that they introduce only small structural differences due to steric effect. Therefore, this system, with the extra advantage of tunability by substitution on the phenylene unit, could provide a valuable starting point to prepare bimetallic compounds by coordination of an extra metallic center to the external N donors.

5. Supplementary material available

Crystallographic information as a CIF file has been deposited with the Cambridge Crystallographic Data Centre (CCDC No. 215000). Copies of the data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1233 336033; or e-mail: deposit@ccdc.cam.ca.uk.

A new octamolybdate: observation of the θ-isomer in $[Fe(tpyprz)_2]_2[Mo_8O_{26}] \cdot 3.7H_2O$ (tpyprz = tetra-2-pyridylpyrazine)

Damian G. Allis *, Eric Burkholder, Jon Zubieta *

Received 18 December 2003; accepted 18 January 2004

Abstract

The hydrothermal reaction of $Fe(CH_3CO_2)_2$, tetra-2-pyridylpyrazine (tpyprz) and $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ yields purple crystals of $[Fe(tpyprz)_2]_2[Mo_8O_{26}] \cdot 3.7H_2O$. The discrete octamolybdate anions represent a new isomeric form, θ-$[Mo_8O_{26}]^{4-}$. The cluster anion consists of four octahedra, two square pyramids, and two tetrahedra in an edge- and corner-sharing arrangement. A computational study of the isomer using both a single-point energy calculation of the crystallographic coordinates and a geometry optimization of the isomer at the Restricted Hartree–Fock level of theory illustrates the similarities of the θ-isomer and the low energy δ-isomer reported previously.

1. Introduction

The contemporary interest in inorganic oxides reflects their extensive compositional range, considerable structural diversity, and physical properties related to applications ranging from heavy construction to microelectronics [1–4]. In addition to a wealth of solid state materials [5], the polyoxometalates represent a subclass of molecular oxide species [6,7].

In the specific case of molybdenum polyoxoanions, these clusters have been extensively explored as analogues to oxide surfaces and as potential catalysts [8], as well as molecular building blocks in the synthesis of oxide solid phase materials [9]. A common example is the octamolybdate anion $[Mo_8O_{26}]^{4-}$, for which seven isomeric forms, α through η, have been reported. The α- and β-forms are selectively crystallized from aqueous solutions of molybdate acidified to pH 3–4, followed by addition of appropriate cations [10–14]. The γ-form has been prepared from aqueous solution by appropriate choice of cations [15]. The δ-isomer has been isolated by both conventional and hydrothermal methods [16]. All isomeric forms have been observed under hydrothermal conditions in the presence of secondary metal–ligand coordination cations. Thus, the α-isomer has been observed for $[\{Cu(bpe)\}_4Mo_8O_{26}]$ [17]; the β-form for $[\{Cu(Me\text{-}pyz)\}_4Mo_8O_{26}]$ [18], $[\{Cu(Me_2pyrm)\}_4Mo_8O_{26}]$ [18], $[\{Cu(pyr_2\text{-}S)\}_4Mo_8O_{26}]$ [19], $[\{Cu(dpa)\}_2Mo_8O_{26}]$ [20], $[\{Cu(pyr)\}_4Mo_8O_{26}]$ [21], and $[\{Cu(4,4'\text{-}bpy)(nic)(H_2O)\}_2Mo_8O_{26}$ [22]; the γ-isomer in $[\{Cu(en)_2Mo_8O_{26}]$ [23] and $[\{Cu(pyrd)\}_4\ H_4Mo_8O_{26}]$ [24]; and the δ-isomer for $[\{Cu(4,4'\text{-}bpy)\}_4Mo_8O_{26}]$ [25]. An ε-isomer has been reported for the Ni(II) species $[\{Ni(4,4'\text{-}bpy)_2(H_2O)_2\}_2Mo_8O_{26}]$ [25]. More recently, the η-isomer has been described for the structure of $[\{Cu(t\text{-}Bu_2bpy)\}_2Mo_8O_{26}]$ [26] and the ζ-form has been described in $[\{Cu_2(tpyprz)\}_2Mo_8O_{26}]$ [27].

As part of our continuing studies of the hydrothermal chemistry of polyoxomolybdates, we have prepared yet another isomeric form, the θ-type, in the structure of $[Fe(tpyprz)_2]_2[Mo_8O_{26}] \cdot 3.7H_2O$ (**1** $\cdot 3.7H_2O$).

2. Experimental methods

2.1. Synthesis and spectroscopy

Chemicals were used as obtained without further purification. Iron(II) acetate anhydrous, ammonium paramolybdate, and 1,2-ethylene diphosphonic acid were purchased from Alfa Aesar; tetra-2-pyridinylpyrazine (tpyprz) was purchased from Aldrich. The synthesis was carried out in 23 ml poly(tetrafluoroethylene) lined stainless steel containers under autogenous pressure. The reactants were stirred briefly and the initial pH measured before heating. Water was distilled in-house above 3 MΩ using a Barnstead Model 525 Biopure Distilled Water Center. The initial and final pH of the reaction was measured using Hydrion pH sticks. Syntheses were carried out in Parr acid digestion bombs with 23 ml poly(tetrafluoroethylene) liners. Infrared spectra were obtained on a Perkin–Elmer 1600 series FTIR spectrometer.

2.2. Synthesis of $[Fe(tpyryz)_2]_2[Mo_8O_{26}]\cdot 3.7H_2O$ ($\mathbf{1}\cdot 3.7H_2O$)

A mixture of $(NH_4)_6Mo_7O_{24}\cdot 4H_2O$ (0.197 g, 0.159 mmol), $Fe(II)(CH_3CO_2)_2$ (0.078 g, 0.45 mmol), tpyprz (0.086 g, 0.22 mmol), $H_2O_3P(CH_2)_2PO_3H_2$ (0.083 g, 0.44 mmol), and H_2O (10.053 g, 558 mmol) in the mole ratio 0.9:2.0:1.0:2.0:2500 was placed in a Parr acid digestion bomb. After heating at 150 °C for 96 h, purple crystals were isolated in 60% yield based on iron. Initial pH, 4.5; final pH, 4.0. Attempts to synthesize $\mathbf{1}\cdot 3.7H_2O$ in the absence of 1,2-ethylene-diphosphonic acid have proved unsuccessful. IR (KBr pellet, cm^{-1}): 3400 (m, br), 1380 (s), 910 (s, br), 850 (m), 810 (s).

2.3. X-ray crystallography

Crystallographic data for **1** were collected with a Bruker P4 diffractometer equipped with a SMART CCD system [28] and using Mo Kα radiation ($\lambda = 0.71073$ Å). The data were collected at 90 K and corrected for Lorentz and polarization effects [29]. Absorption corrections were made using SADABS [30]. The structure solution and refinement were carried out using the SHELXTL [31] crystallographic software package. The structures were solved using direct methods and all of the non-hydrogen atoms were located from the initial solution. After locating all of the non-hydrogen atoms in each structure, the model was refined against F^2, initially using isotropic then anisotropic thermal displacement parameters, until the final value of Δ/σ_{max} was less than 0.001. Crystal data for **1** are summarized in Table 1. Selected bond lengths and angles for compound **1** are collected in Table 2. CCDC reference number 225745.

2.4. Computational methods

The computational study of the θ-isomer consisted of both a single-point energy calculation of the crystallographic coordinates and a geometry optimization of the isomer at the Restricted Hartree–Fock (RHF) level of theory using the 6-31G* basis set for oxygen and the SBKJC effective core potential for molybdenum [32]. Calculations were performed using the PC-GAMESS version [33] of the GAMESS-US Quantum Chemistry package [34]. The single-point energy calculation was performed on the crystallographic coordinates in the absence of symmetry restrictions. As the isomer is of nearly C_i symmetry, the geometry optimization was performed on a position-averaged C_i symmetry structure with the same basis sets and convergence criteria employed previously for the complete octamolybdate isomer series [27]. A consequence of imposing symmetry in GAMESS, where the retention of the point group symmetry is enforced by the use of symmetry-unique input coordinates, is that the structure is never able to optimize to a lower symmetry minimum energy structure.

3. Results and discussion

3.1. Synthesis and structure

The bimetallic oxide of this study was prepared by conventional hydrothermal methods, which avoid thermal decomposition of the organic component while providing conditions which overcome the differential solubilities of the organic and inorganic components and which are optimal for crystal growth [35–37]. In this fashion, the reaction of $Fe(CH_3CO_2)_2$, $(NH_4)_6Mo_7O_{24}\cdot 4H_2O$, ethylenediphosphonic acid, and tetra-2-pyridylpyrazine yielded $[\{Fe_2(tpyprz)\}_2Mo_8O_{26}]\cdot$

Symmetry transformation used to generate equivalent positions: $\#1\ -x, -y+2, -z+2$.

$3.7H_2O$ ($\mathbf{1}\cdot 3.7H_2O$) in 60% yield as purple crystals. Curiously, a crystalline phase could be obtained only in the presence of the diphosphonate, suggesting the preformation of a molybdenum reservoir in the form of a molybdophosphonate cluster. The infrared spectrum of **1** exhibited strong bands in the 800–960 cm^{-1} range, attributed to υ (Mo=O) and υ (Mo–O–Mo). A group of peaks in the 1000–1500 cm^{-1} region is characteristic of the tpypyz ligand.

The structure of **1** consists of discrete $\{Fe(tpyprz)_2\}^{2+}$ cations and $\{\theta\text{-}Mo_8O_{26}\}^{4-}$ anions. The cations consist of distorted $\{FeN_6\}$ octahedra. The Fe(II) site coordinates to three nitrogen donors from each of two tpypyz ligands, with average distances of 1.870(4) and 1.960(4) Å to the pyrazine and pyridyl nitrogen donors, respectively. The nitrogen donors of each of the tpypyz ligands adopt a *meridional* arrangement about the metal center.

The structure of the $\{\theta\text{-}Mo_8O_{26}\}^{4-}$ anion is shown in Fig. 1. The cluster may be described as a ring of four $\{MoO_6\}$ octahedra and two $\{MoO_5\}$ square pyramids in an edge- and corner-sharing arrangement, capped on either face by tetrahedral $\{MoO_4\}$ subunits in a corner-

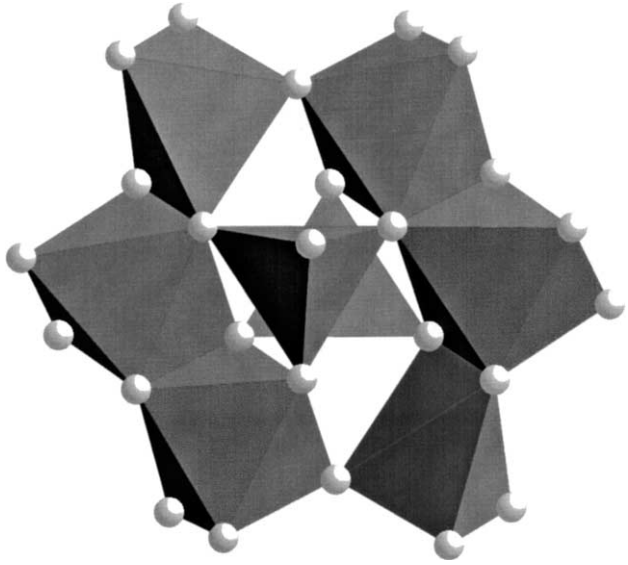

Fig. 1. A polyhedral representation of the structure of $\theta\text{-}[Mo_8O_{26}]^{4-}$.

Table 3
Polyhedral components and oxo-group types of the octamolybdate isomers

Isomer	Polyhedra	Oxo-group types
α-$Mo_8O_{26}^{4-}$	6 octahedra, 2 tetrahedra	14t, $6\mu^2$, $6\mu^3$
β-$Mo_8O_{26}^{4-}$	8 octahedra	14t, $6\mu^2$,$4\mu^3$, $2\mu^5$
γ-$Mo_8O_{26}^{4-}$	6 octahedra, 2 square pyramids (Type A)	14t, 10^2, $2\mu^3$
δ-$Mo_8O_{26}^{4-}$	4 octahedra, 4 tetrahedra	14t,$10\mu^2$, $2\mu^3$
ε-$Mo_8O_{26}^{4-}$	6 square pyramids, 2 octahedra	16t, $4\mu^2$, $6\mu^3$
ζ-$Mo_8O_{26}^{4-}$	4 octahedra, 4 square pyramids	14t, $6\mu^2$, $6\mu^3$
η-$Mo_8O_{26}^{4-}$	6 octahedra, 2 square pyramids (Type B)	14t, $4\mu^2$, $8\mu^3$
θ-$Mo_8O_{26}^{4-}$	4 octahedra, 2 square pyramids, 2 tetrahedra	14t, $8\mu^2$, $4\mu^3$

sharing mode. The ring is constructed of pairs of edge-sharing octahedra linked through the square pyramidal sites. Each square pyramid edge-shares with one binuclear unit of octahedra and corner-shares with the second. The tetrahedral sites share three oxo-groups with the equatorial ring and project a terminal oxo-group in a direction approximately normal to the ring plane. Each $\{MoO_4\}$ site contributes one oxo-group as a μ^3-bridge between the tetrahedral site and one octahedral and one square pyramidal center of the ring, a second μ^3-bridge between the tetrahedral site and a pair of octahedra and a μ^2-bridge to an octahedral site. Consequently, the structure exhibits 14 terminal, 8 doubly bridging and 4 triply bridging oxo-groups.

Seven isomeric forms of octamolybdate have been described previously, as noted in Table 3. The θ-form of this study is a unique example of an octamolybdate constructed from three polyhedral subunits. The structure of the θ-isomer is clearly related to that of the α- and δ-isomers by the breaking of two bonds and the making of two bonds, respectively, as shown in Fig. 2. Since the relative single-point energies of the seven previously reported isomers have been calculated, a computational study of the θ-isomer was undertaken.

3.2. Computational studies

Two views of the θ-isomer are shown in Fig. 3, including top-down and side view pairs from the crystallographic coordinates and the C_i symmetry structure obtained from the RHF geometry optimization. Within the ability of the RHF calculations to reproduce the actual form of the isolated octamolybdate, this comparison is meant to demonstrate the changes to the structure of the θ-isomer that occur in the absence of crystallographic forces. The major structural changes that occur in the RHF energy minimization are (1) a general expansion of the isomer (a change consistent with all previous RHF calculations of the octamolybdates, [27]), (2) a separation of the equatorial square pyramids (Mo3) away from the center of the isomer, resulting in an elongated Mo3–O11 bond, and (3) a small shift of the two apical tetrahedra away from a central plane composed of the two apical Mo4 centers and the two O4 atoms. The θ-isomer expands 0.021 Å along the axis composed of the two O4 atoms, 0.238 Å along the axis composed of the two Mo4 apical tetrahedral centers, and 0.928 Å along the axis composed of the two Mo3 square pyramids.

The symmetry-unique bond lengths of the crystallographic and calculated isomer are summarized in Table 4. While some of the overall changes in the larger structure are found to be significant during the optimization procedure, many of the Mo–O bonds are found to agree quite well between the crystallographic and calculated structures. The average difference between crystal and calculation is 0.074 Å, with sixteen of the symmetry-unique bonds within 0.05 Å of the crystallo-

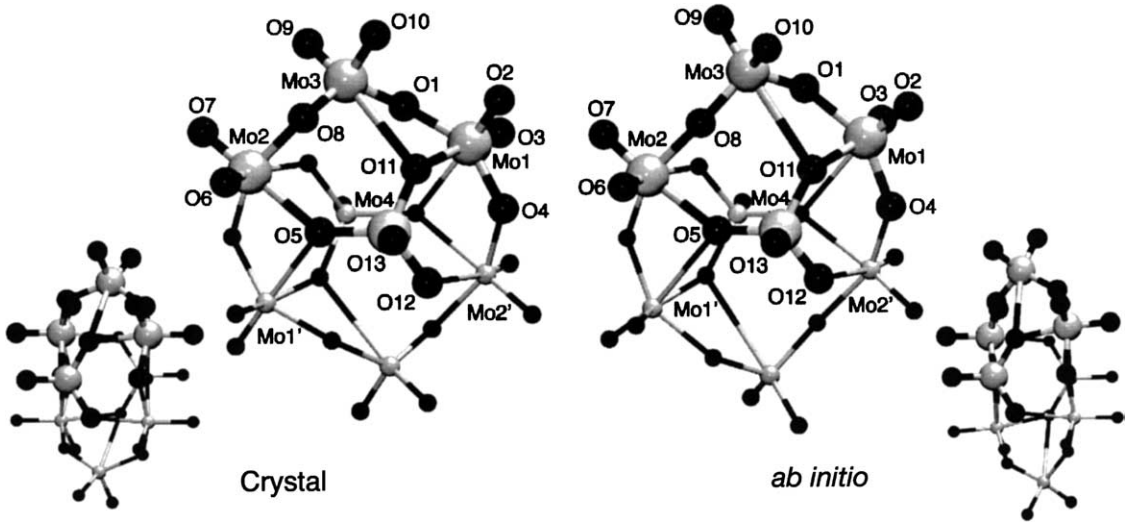

Fig. 3. Crystallographic (left) and calculated (right) structural comparison and labeling scheme for the new θ-isomer. Top-down and side view pairs are to scale with one another. Figures were generated with VMD [40].

Table 4
Mo–O bond lengths for the symmetry-unique atoms of the crystal and calculated θ-isomer

	Mo–O bond	Crystal (Å)	RHF (Å)		Mo–O bond (Å)	Crystal (Å)	RHF (Å)
Mo1 octahedral	Mo1–O1	1.982	2.021	Mo2 octahedral	Mo2–O5	2.355	2.320
	Mo1–O2	1.699	1.677		Mo2–O6	1.700	1.674
	Mo1–O3	1.699	1.679		Mo2–O7	1.693	1.677
	Mo1–O4	1.902	1.901		Mo2–O8	1.939	2.016
	Mo1–O11	2.280	2.167		Mo2′–O4	1.904	1.935
	Mo1′–O5	2.365	2.867		Mo2′–O12	2.328	2.331
Mo3 square pyramidal	Mo3–O1	1.858	1.832	Mo4 tetrahedral	Mo4–O5	1.810	1.793
	Mo3–O8	1.856	1.823		Mo4–O11	1.791	1.793
	Mo3–O9	1.702	1.695		Mo4–O12	1.752	1.747
	Mo3–O10	1.708	1.695		Mo4–O13	1.698	1.694
	Mo3–O11	2.522	3.076				

See Fig. 3 for the atom labels. Crystallographic values represent the average Mo–O bond length where differences exist.

graphic bond lengths. Three metal–oxygen bonds are found to change by more than 0.1 Å and, together, are the changes responsible for the major differences between theory and experiment. The bond Mo1–O11 decreases in the calculated structure by 0.113 Å while the bond Mo3–O11 increases by 0.554 Å. In this pair, the μ^3-O11 atom increases bonding character in one shorter (Mo1–O11, 2.280 Å) crystallographic bond at the expense of lost bonding character in one longer (Mo3–O11, 2.522 Å) metal–oxygen bond. This weakening of the Mo3–O11 bond and enhancement of the Mo1–O11 bond permits both the elongation that occurs between the Mo3 and Mo3′ atoms and the pull of each apical tetrahedron (Mo4) towards one of the octahedral Mo1 centers. This pull between one pair of Mo1 and Mo4 atoms through O11 also leads to an elongation of the Mo1–O5 bond formed in the crystal between, as shown in Fig. 3, Mo1′ and O5 (the symmetry-related Mo1 center in the C_i symmetry structure). The Mo–O bonds in the apical tetrahedra change little from the crystallographic values upon energy minimization and these tetrahedra are found to shift as complete units in the direction of Mo1. The most pronounced bond length changes occur in the longest Mo–O bonds in the structure. These longer Mo–O interactions are, by their length, weaker than the majority of the bonds in the θ-isomer and are expected to be the most susceptible to shifting during a structural rearrangement.

The single point and geometry-optimized energies of the θ-isomer are compared with the seven previously examined isomers in Table 5. Both the crystal coordinates and minimum energy θ-structures are found to agree best in their respective calculations with the δ-isomer. Apparent from the comparison of the δ- and θ-isomers in Fig. 4 are the similarities of the two forms and a straightforward rearrangement pathway between two mirror image forms of the θ-isomer by way of a δ-isomer intermediate. The mirror plane in the "transition structure" through which the mirror image forms are related is, in fact, the mirror plane of the D_{2h}

Table 5
Relative energies (in kJ/mol) of the eight octamolybdate isomers as calculated from their crystallographic coordinates (left) and RHF energy minimizations (right)

	Crystal structures			RHF calculations	
	6-31G* $\Delta E_{relative}$	6-31G* $\Delta E_{neighbor}$		6-31G* $\Delta E_{relative}$	6-31G* $\Delta E_{neighbor}$
θ	0.00	0.00	θ	0.00	0.00
δ	3.78	3.78	δ	0.97	0.97
α	26.78	23.00	α, η[a], ε[a], ζ[a]	25.30	24.33
ε	69.78	43.01	γ(ζ)[b]	36.19	10.88
ζ	86.82	17.04	β	150.19	113.97
γ	101.74	14.92			
η	162.44	60.70			
β	196.98	34.54			

Both the energy differences relative to the lowest-energy form (relative) and the energy difference between neighboring isomers (neighbor) are provided. Isomer energies for α–η are taken from [27].

[a] The η-, ε-, ζ-isomers were found to optimize to the D_{3d}-symmetry α-isomer. See [27].

[b] The ζ-isomer optimizes to the γ-isomer or the α-isomer depending on the starting coordinates. See [27].

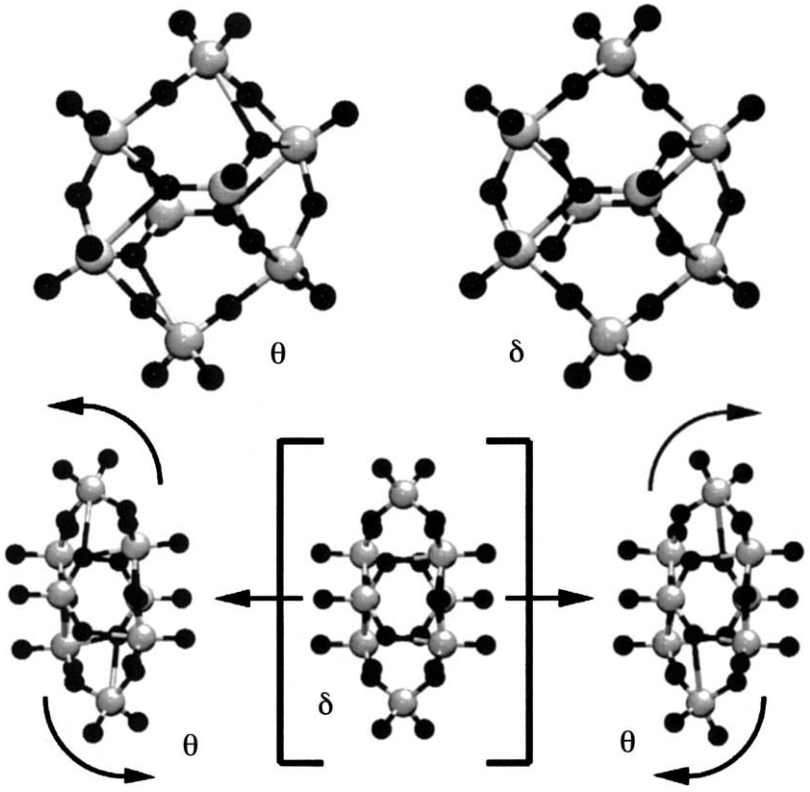

Fig. 4. RHF structure comparison (to scale) of the θ-isomer (left) and δ-isomer (right), and the rearrangement pathway between mirror image forms of the θ-isomer through a higher-symmetry δ-isomer intermediate (bottom). Figures were generated with VMD [40].

δ-isomer. The single-point energy analysis places the θ-isomer 3.78 kJ/mol more stable in energy than the δ-isomer, making it the new lowest energy form at the RHF/6-31G* level of theory and with the selected basis set and effective core potential combination. Geometry optimization changes this relative energy difference to 0.97 kJ/mol, a remarkably small value given the large perceived difference in structure. The δ-isomer was recalculated with imposed C_i symmetry in an effort to determine if the D_{2h} symmetry constraints prevented it from falling to a lower energy θ-isomer structure. With no geometry change calculated at this lower symmetry, it is predicted that the δ-isomer is a stable local minimum. While higher-level calculations are required to more accurately determine the energy difference between these two structures, the RHF re-

sults show with reasonable accuracy that these two structures are far closer to one another in energy that either is to the remaining isomers of the octamolybdate series.

It is important to acknowledge at the end of the crystal/calculated analysis of this isomer, and the known octamolybdate series in general, that each of these data sets provides information about the isolated isomers in limited ways. Both RHF and DFT calculations [38] have been used in the analysis of these isomers, and agree in the general ordering of isomer energies, indicating that this ordering is reasonably accurate for the isolated forms. The calculations are obviously limited by their lack of treatment of the crystal environment into which these various isomers have been isolated. The calculated energies are, within the limited sampling size of available crystal forms, in contradiction with the relative abundances of the isomers in their crystals. The β-isomer is seen by all computational methods as a very high-energy octamolybdate form, yet it is most prevalent from among the available crystal structures. Its existence in solution, however, is found most prominently only under very acidic conditions [39] that presumably mimic the charge features of their crystal environments through either direct contact or surrounding effects. The importance of environment, then, cannot be understated in performing comparisons of energy and structure between the isomers.

4. Conclusions

Hydrothermal synthesis has been exploited in the isolation of yet another isomeric form of octamolybdate. The θ-isomer is unique in containing three polyhedral building blocks, four octahedra, two square pyramids and two tetrahedra.

Single point and geometry-optimized energies of the θ-isomer reveal its similarities to the δ-isomer and suggest a rearrangement pathway between the two minor images of the θ-isomer through a δ-intermediate. While the calculations suggest that the θ-isomer is the new lowest energy structure, the previously lowest energy δ-isomer appears to be a stable local minimum.

5. Supplementary material

The supplementary materials, including atomic positional parameters, hydrogen atom positions, anisotropic thermal parameters and full tables of bond lengths and angles have been deposited with the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 IEZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), as supplementary material CCDC 225745 and can be obtained by contacting the CCDC, quoting the article details and the corresponding SUP number.

Abstract

Potassium *N*-*R*-sulfonyldithiocarbimates, $K_2(RSO_2N{=}CS_2)$, react with $K_2[PtCl_4]$ in water/methanol to yield complex anions bis(*N*-*R*-sulfonyldithiocarbimato)platinate(II), $[Pt(RSO_2N{=}CS_2)_2]^{2-}$, (R = C_6H_5 (**1**) and 4-BrC_6H_4 (**2**)) which were isolated as their *n*-Bu_4N^+ salts.The single crystal X-ray analysis showed that $(Bu_4N)_2[Pt(C_6H_5SO_2N{=}CS_2)_2]$ crystallizes in the triclinic space group $P\bar{1}$, and $(Bu_4N)_2[Pt(4\text{-}BrC_6H_4SO_2N{=}CS_2)_2]$ crystallizes in the monoclinic space group $P2_1/c$ with disorder in the two chains of the two univalent Bu_4N^+ cation and 4-BrC_6H_4 groups of the anion. All complexes present a similarly distorted square-planar configuration due to the asymmetric bidentate chelation by two sulfur atoms. In both compounds the Pt atoms are in the crystallographic center of symmetry. Elemental analyses, IR spectra and electronic spectra were also consistent with the formation of platinum–sulfur diamagnetic square planar complexes. The ^{1}H NMR, ^{13}C NMR and ^{195}Pt NMR spectra showed the expected signals for the *n*-Bu_4N^+ cation and the anionic complexes.

1. Introduction

Dithiocarbamate salts and dithiocarbamate complexes are well known compounds, their wide range of applications being described in the literature. For example, dithiocarbamate and their derivatives are very active accelerators in vulcanization [1]. Many dithiocarbamates, anions and complexes, show biological activity and are used as fungicides [2,3]. The interest in platinum(II) complexes containing S donors has increased in recent years, with the aim of synthesizing anti-tumor drugs having reduced toxicity with respect to *cis*platin [4].

We became interested in the synthesis and characterization of dithiocarbimate metal complexes because they are similar to dithiocarbamates and have been less studied. The platinum(II) bisdithiocarbimate complexes are necessarily anionic species. Thus, the use of active counter ions could improve their biological activity and different cations should also allow a variation in the solubility of these platinum–sulfur compounds.

Here, we describe the synthesis of two bis(*N*-*R*-sulfonyldithiocarbimato)platinate(II) tetra-*n*-butylammonium salts. The anionic complexes are the first examples of platinum complexes with dithiocarbimates derived from sulfonamides. These compounds were characterized by IR, electronic spectra, ^{1}H, ^{13}C and ^{195}Pt NMR spectra, elemental analyses for C, H, N, Pt and by single X-ray diffraction techniques.

2. Experimental

2.1. Materials and methods

Solvents (acetonitrile, dichloromethane, dimethylformamide, ethanol and methanol) were purchased from

Merck and were used as supplied. Benzenesulfonamide, 4-bromobenzenesulfonyl chloride, potassium tetrachloroplatinate(II) and tetra-*n*-butylammonium bromide were purchased from Aldrich. The 4-bromobenzenesulfonamide was prepared from the 4-bromobenzenesulfonyl chloride as described elsewhere [5]. Potassium *N*-phenylsulfonyldithiocarbimate and potassium *N*-4-bromophenylsulfonyldithiocarbimate were prepared from sulfonamides using procedures described in the literature for analogous compounds [6,7]. These salts, which are soluble in H_2O and insoluble in most organic solvents, were recrystallized from hot ethanol/water mixtures. KOH and CS_2 were purchased from Vetec. IR spectra were recorded with a Perkin–Elmer 1000 FT-IR spectrophotometer using CsI pellets. The electronic spectra were recorded with a Beckman DU 640 spectrometer. The NMR spectra were recorded with a Bruker DRX-400 spectrophotometer in $CDCl_3$ with TMS or $K_2[PtCl_4]$ (for the ^{195}Pt NMR) as internal standards. Microanalyses for C, H and N were obtained from a Perkin–Elmer 2400 CHN elemental analyzer. Platinum was analyzed by atomic absorption on a Hitachi Z-8200 atomic absorption spectrophotometer. Uncorrected melting points were measured with a Mettles FP5 melting point apparatus.

2.2. Syntheses

The syntheses of the platinum complexes were performed according to Scheme 1. Potassium tetrachloroplatinate(II) (0.415 g; 1.0 mmol) and tetra-*n*-butylammonium bromide (0.647 g; 2.0 mmol) were added to a solution of potassium *N*-*R*-sulfonyldithiocarbimate dihydrate (2.0 mmol) in methanol/water 1:1 (10 mL). The reaction mixture was stirred for 3 h at room temperature. The yellow solid obtained was filtered, washed with distilled water and dried under reduced pressure for one day, yielding $(Bu_4N)_2[Pt(RSO_2N{=}CS_2)_2]$ (ca. 70% based on the $K_2[PtCl_2]$). Suitable crystals for X-ray structure analyses were obtained after slow evaporation of solutions of the compounds in methanol/water 4:1.

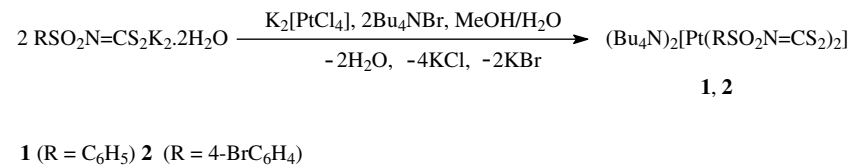
2.3. X-ray diffraction experiments

Intensity data of the compounds **1** and **2** were collected on an Enraf-Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å), provided with a cryogenic device operating at 120 K. Data collection were made using the COLLECT program [8] up to 55° in 2θ with a redundancy of 4 in both cases. The final lattice parameters were based on all reflections. Integration and scaling of the reflections, correction for Lorentz and polarization effects were performed with the HKL Denzo-Scalepack system of programs [9]. The face-indexed numerical absorption was calculated by the method Gaussian using the PLATON program [10].

The structures were solved by direct methods with SHELXS 97 [11] and refined on F^2 by full-matrix least-squares using SHELXL 97 [12]. All non-hydrogen atoms were modelled anisotropically, while hydrogen atoms were stereochemically positioned and refined with the riding model [12]. Hydrogen atoms of the aromatic rings and CH_2 were set isotropic with isotropic thermal parameters of $1.2U_{eq}$ of the carbon atoms joined directly to



Scheme 1.

the hydrogen atoms and CH_3 group with isotropic parameters of $1.5U_{eq}$ of the methyl carbon atom.

Data collection and experimental details for compounds **1** and **2** are summarized in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

The compounds **1** and **2** are yellow crystalline solids stable at the ambient conditions. They are soluble in most of organic solvents and insoluble in water.

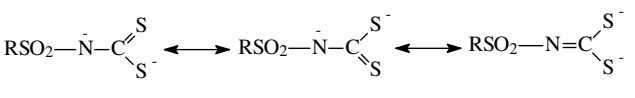
Their electronic spectra in ethanol showed three bands for **1** and four bands for **2**. The band around 400 nm was assigned to the charge transfer transition. This band is also observed in the spectra of other diamagnetic planar platinum(II)–bisdithiocarbimato complexes [13]. The other bands were assigned to the internal transitions of the ligands. The $\pi \rightarrow \pi^*$ (NCS) band in the spectrum of **1** was obscured by the very intense band assigned to $\pi \rightarrow \pi^*$ (SCS).

There are no strong or medium bands in the 1450–1550 cm^{-1} region in the IR spectra of the potassium dithiocarbimates related to the complexes here prepared, the ν(CN) band being observed at 1267 and 1258 cm^{-1}

for $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$ and 4-$BrC_6H_4SO_2N{=}CS_2K_2\cdot 2H_2O$, respectively. A strong band observed around 1390 cm^{-1} in the spectra of the compounds **1** and **2** was assigned to the ν(CN). These bands are in higher wavenumbers when compared with the spectra of $(Bu_4N)_2[Ni(C_6H_5SO_2N{=}CS_2)_2]$ and $(Bu_4N)_2[Ni(4\text{-}BrC_6H_4SO_2N{=}CS_2)_2]$ [14]. In the case of the dithiocarbimates here studied, the CN bond is formally a double bond. However, because of the SO_2 neighbor group, the canonical forms (a) and (b) (Scheme 2) contribute appreciably to the resonance hybrid. This fact explains the low values for de ν(CN) band wavenumbers. The spectra of the complexes $[Pt(C_6H_5N{=}CS_2)_2]^{2-}$ [13] and $[Pt(N\text{-}4\text{-}NH_2C_6H_2N{=}CS_2)_2]^{2-}$ [15] that does not have the SO_2 group, show the ν(CN) band at 1520 cm^{-1} and 1501 cm^{-1}, respectively. The $\nu(CS_{2ass})$ were observed at higher frequencies in the spectra of the potassium salts of dithiocarbimates (971 and 973 cm^{-1} for $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$ and 4-$BrC_6H_4SO_2N{=}CS_2K_2\cdot 2H_2O$, respectively) than in the spectra of the compounds **1** and **2** ($\sim$930 cm^{-1}). The shifts observed in the $\nu(CS_{2ass})$ and ν(CN) bands of the complexes when compared to the spectra of the free ligands, are consistent with the increased importance of the canonical form (c) after complexation (Scheme 2). The spectra of the compounds **1** and **2** also show the expected medium/strong band in the 300–400 cm^{-1} range assigned to the ν(PtS).

The NMR spectra were typical for diamagnetic species and were consistent with the proposed structures. The integration curves on the ^{1}H NMR spectra were consistent with a 2:1 proportion between the tetra-*n*-butylammonium cation and the complex anion. In the ^{13}C NMR spectra of the compounds **1** and **2** the signal of the quaternary carbon of the dithiocarbimate moiety is shifted upfield when compared to the correspondent signal in the potassium dithiocarbimate spectra. Although the spectra were obtained in different solvents (the potassium *N*-*R*-dithiocarbimate were only soluble in water), this fact is also consistent with the increase in the contribution of canonical form (c) after the complexation (Scheme 2). The ^{195}Pt NMR spectra show a singlet at $\delta = -3857$ and $\delta = -3872$ for **1** and **2**, respectively. These values are close to those observed for compounds containing the PtS_4 chromophore, such as $[Pt(Et_2CNS_2)_2]$ (−3835), $[Pt(^iPr_2CNS_2)_2]$ (−3779) and $[Pt(^nBu_2CNS_2)_2]$ (−3843) [16].

The crystal structure of the anions of the compounds **1** and **2** are illustrated in Figs. 1 and 2, respectively. The



Scheme 2.

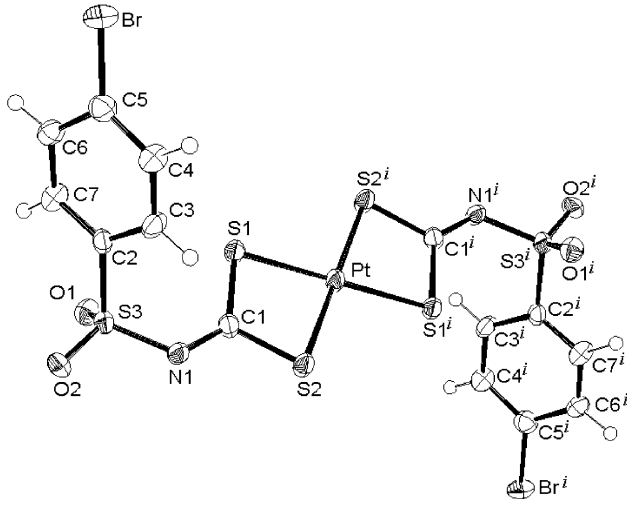

Fig. 2. ORTEP 3 [18] view of the anion of compound **2**, showing displacement ellipsoids at 50% probability level. Symmetry code (i) $-x+1, -y+1, -z$.

$[Pt(RSO_2N{=}CS_2)_2]^{2-}$ anions and two univalent *n*-Bu_4N^+ cations are related by an inversion centre at Pt. In the compound **2**, two of the chains of the *n*-Bu_4N^+ cation and 4-BrC_6H_4 groups were found to be disordered.

In both complex anions, the platinum(II) is coordinated by the four sulfur atoms of the two *N*-*R*-sulfonyldithiocarbimate ligands into a distorted square planar configuration. The S(1)–Pt–S(2) angle is smaller than 90° due to the asymmetric bidentate chelation.

The $N{=}CS_2$ fragments of the complexes show interesting features. In the compounds **1** and **2**, the CS bond lengths are nearly equal and are slightly shorter than typical C–S single bond lengths (ca. 1.81 Å) due to the partial π-delocalization in the S–C–S group (Scheme 2). However, in the $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$ they are quite different [7] (Table 3). Their differences can be

[b] Crystallographic data from [17], spectroscopic data from [14].
[c] Ref. [14].

explained by the greater repulsive interaction between S(2) and the lone-pair located on the nitrogen [7] than the repulsion between S(1) and the RSO_2 group. When the complexation occurs two factors must be considered. First, the S(1)–C(1)–S(2) angle decreases. This fact weakens the interaction between S(2) and the nitrogen lone-pair shortening the difference between the C(1)–S(1) and the C(1)–S(2) bond lengths (Table 3). Another interesting point to consider is the greater C–S bond lengths in the Pt complexes when compared to the Ni analogous. This fact is probably due to the fact that the platinum(II) is a softer acid than nickel(II) which favors the M–S linkage and the canonical form (c) (Scheme 2). The increase on the importance of the canonical form (c) reflects on the CN bond length. This bond in **1** and **2** have approximately the same lengths and are shorter than the CN bonds in $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$ (Table 4). Besides, the CN bonds in the anionic complexes **1** and **2** are shorter than those on the analogous nickel(II) complexes [14,17].

4. Conclusion

Two novel platinum(II) dithiocarbimates complexes were described. Their tetra-*n*-butylammonium salts were obtained in crystalline form and were characterized by X-ray diffraction techniques. There is an interesting relationship between the spectroscopic data and the X-ray experiments results (Table 4) that pointed to an increase of the contribution of the canonical form (c) to the resonance hybrid from the ligands to the complexes, and from nickel(II) complexes to platinum(II) complexes, with a consequent increase of the CN double bond character. Thus, in the IR spectra the wavenumbers of the ν(CN) are smaller for the ligands than for the complexes, the ^{13}C NMR spectra show that the carbon atoms of the dithiocarbimate moiety are more shielded in the complexes than in $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$, and the crystallographic data show that the CN bond are shorter in the complexes than in $C_6H_5SO_2N{=}CS_2K_2\cdot 2H_2O$.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 219805 and 219806 for **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Platinum(II) and palladium(II) complexes containing a mixed donor 'P_2N' multidentate ligand

Eric W. Ainscough *, Andrew M. Brodie *, Anthony K. Burrell [1], Andreas Derwahl, Geoffrey B. Jameson, Steven K. Taylor

Chemistry, Institute of Fundamental Sciences, Massey University, Private Bag 11 222, Palmerston North, New Zealand

Received 10 December 2003; accepted 22 January 2004

Abstract

The 'P_2N' mixed donor ligand 2-(diphenylphosphino)-*N*-[2-(diphenylphosphino)benzylidene]benzeneamine (PNCHP) reacts with [MCl_2(1,5-cyclooctadiene)] and [$M(CH_3)Cl$(1,5-cyclooctadiene)] to give the complexes [M(PNCHP-κ^3P,N,P)Cl]Cl (M = Pt or Pd) and [Pd(PNCHP-κ^3P,N,P)(CH_3)]Cl, respectively. The ionic chloride can be exchanged with BF_4^- by reaction with $AgBF_4$. Abstraction of the covalent chloride with $AgBF_4$ in the presence of acetonitrile yields [Pt(PNCHP-κ^3P,N,P)(CH_3CN)]$^{2+}$. The acetonitrile ligand of this dication can be substituted with a variety of ligands to afford complexes of the type, [Pt(PNCHP-κ^3P,N,P)L]$^{2+}$ (L = the monodentate ligands: triphenylphosphine, 2-picoline, 3-picoline or the chelate ligands: 1,10-phenanthroline, 2,2′-bipyridine, bis(diphenylphosphino)ethane, 2,2′:6′,2″-terpyridine). The latter ligands all bind in a bidentate fashion to give five-coordinate complexes. The compounds have been characterised by spectroscopic and analytical means. The single crystal structures of the four-coordinate complexes, [Pt(PNCHP-κ^3P,N,P)Cl]Cl and [Pt(PNCHP-κ^3P,N,P)(PPh_3)]$(BF_4)_2$, and the five-coordinate complexes, [Pt(PNCHP-κ^3P,N,P)L]$(BF_4)_2$ (L = 1,10-phenanthroline and 2,2′:6′,2″-terpyridine), have been determined.

1. Introduction

Interest in the chemistry of the platinum group metals with mixed-donor, multidentate ligands [1] tends to be driven by interest in these systems as potential catalysts [1a,2]. To date, studies which involve ligands containing mixed phosphorus and nitrogen donor atoms have generally focussed on bidentate ligands [1,2c,3]. In contrast, mixed donor terdentate ligands, such as the 'P_2N' ligand, 2-(diphenylphosphino)-*N*-[2-(diphenylphosphino)benzylidene]benzeneamine (PNCHP), have received considerably less attention. PNCHP contains two inequivalent 'soft' phosphorus donor atoms and a 'borderline' nitrogen donor atom [4] (see Scheme 1). Therefore, with respect to the Hard and Soft Acid and Base (HSAB) principle, the ligand should be well suited to binding to platinum(II) and palladium(II). The favourable 'soft'–'soft' interactions of the phosphorus donor atoms of the PNCHP ligand with the low valent metal atom of concern are expected to anchor the ligand to the platinum(II) or palladium(II) metal centre. On one hand, the 'borderline'-'soft' nitrogen–metal atom interaction will have the potential for facile dissociation, and consequently the metal–PNCHP complex could exhibit interesting reactivity patterns [5]. For example, ring-opening, which is considered to be an important step in the mechanism of successful CO insertions 'into' metal–methyl bonds involving other terdentate ligands, allows an incoming CO ligand to bind to a coordination site in the square plane *cis* to the methyl group [6]. On the other hand, PNCHP has shown preference for terdentate coordination, occupying three sites of a square plane and has shown no previous signs of ring-opening [7]. Therefore, in this study we have concen-

PNCHP

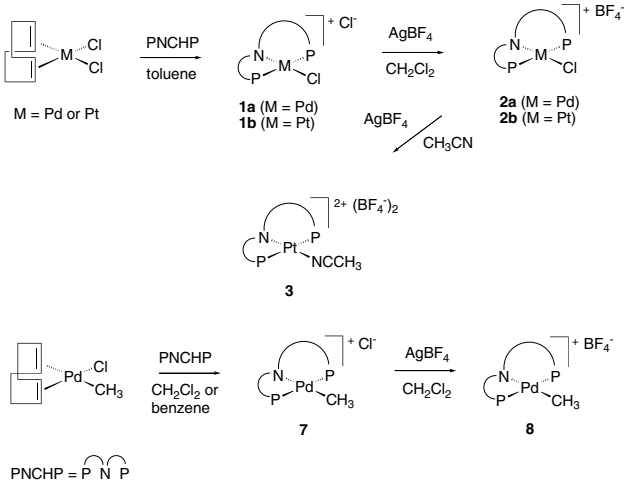
Scheme 1.

trated on the replacement of the chloride group with 'strong' bidentate ligands, such as 1,10-phenanthroline (phen), 2,2′-bipyridine (bipy) and bis(diphenylphosphino)ethane (diphos) as well as the terdentate, 2,2′:6′,2″-terpyridine (terpy) and report that these additional ligands are forced to bind to the fifth coordination site of the metal to give five-coordinate d^8 metal complexes.

2. Results and discussion

2.1. Synthesis of [Pt(PNCHP-κ³P,N,P)(MeCN)](BF₄)₂ (3) and related compounds

The syntheses of [M(PNCHP-κ^3P,N,P)Cl]Cl (M = Pd **1a** or Pt **1b**) and [Pd(PNCHP-κ^3P,N,P)-(CH_3)]Cl (**7**) are depicted in Scheme 2. PNCHP coordinates to platinum(II) and palladium(II) in a terdentate fashion by displacing 1,5-cyclooctadiene (COD) and one chloride from [M(COD)Cl_2] to yield complexes of the type [M(PNCHP-κ^3P,N,P)Cl]Cl (M = Pd **1a** and M = Pt **1b**). Attempts to isolate [M(PNCHP-κ^2P,P)Cl_2] were unsuccessful. However, several intermediates, which were suggestive of mono- and bidentate PNCHP species, were observed when monitoring the synthesis of [M(PNCHP-κ^3P,N,P)Cl]Cl by ^{31}P NMR. PNCHP



Scheme 2.

displaces COD and the chloro group from [Pd(COD)(-CH_3)Cl] yielding the compound [Pd(PNCHP-κ^3P,N,P)(CH_3)]Cl (**7**).

The ionic chloride of both **1a** and **1b** can be exchanged for a BF_4^- ion to give [M(PNCHP-κ^3P,N,P)Cl]BF_4 (M = Pd **2a** and M = Pt **2b**). In the presence of acetonitrile (MeCN) a second chloride of **1b** can be abstracted with $AgBF_4$ to give [Pt(PNCHP-κ^3P,N,P)(MeCN)]-(BF_4)$_2$ **3**. The chloride of **7** is easily exchanged for BF_4^- by a metathetical reaction of **7** with $AgBF_4$, affording the compound [Pd(PNCHP-κ^3P,N,P)(CH_3)]BF_4 **8**. When compound **8** was subjected to CO (7 atm) at room temperature there was no evidence for the formation of a CO adduct or for an insertion reaction. This is in contrast to palladium complexes with terdentate nitrogen ligands [6a], where insertion likely occurs via a mechanism involving dissociation of one of the distal nitrogen atoms to from a four-coordinate intermediate. In **8** the PNCHP ligand cannot dissociate a distal phosphorus atom [6a].

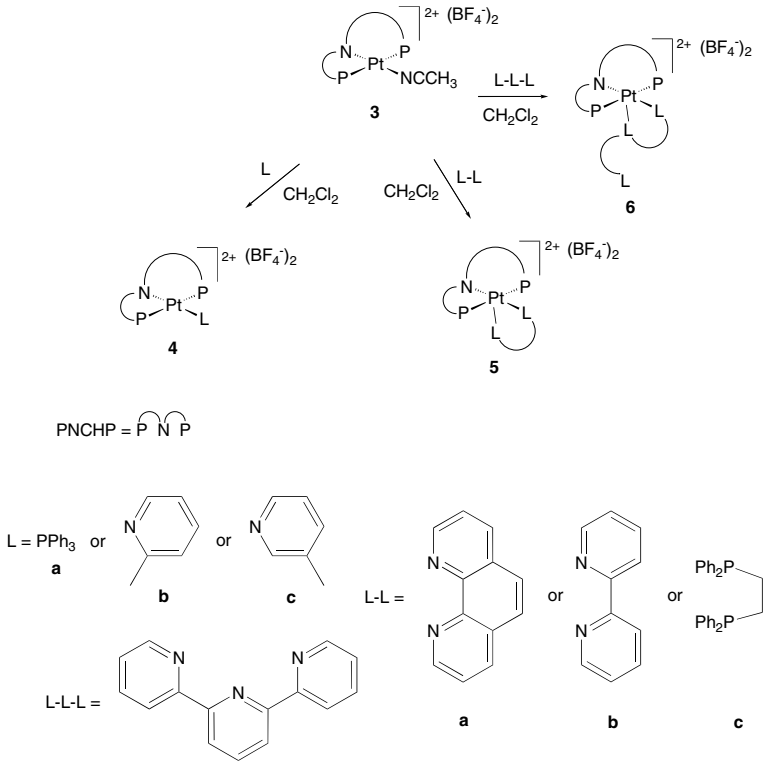
The reaction of **3** with monodentate ligands, L (L = 2-picoline, 3-picoline or triphenylphosphine) results in the substitution of the coordinated acetonitrile to give four-coordinate, dicationic complexes of the type [Pt(PNCHP-κ^3P,N,P)(L-κ^1)]$^{2+}$ (**4**) (Scheme 3). Analogous substitution reactions with the bidentate ligands (L–L), 2,2′-bipyridine (bipy), 1,10-phenanthroline (phen) or bis(diphenylphosphino)ethane (diphos)] gave complexes of the type [Pt(PNCHP-κ^3P,N,P)(L–L-κ^2)]$^{2+}$ (**5**), where the metal is now considered to be five-coordinate. Reaction of **3** with the potentially terdentate ligand 2,2′:6′,2″-terpyridine (terpy) also gives rise to a five-coordinate complex, [Pt(PNCHP-κ^3P,N,P)(terpy-κ^2N,N)]$^{2+}$ (**6**).

2.2. Single crystal X-ray diffraction studies

The X-ray determined crystal structures of **1b, 4a, 5a**, and **6** are shown as ORTEP plots of the cations in Figs. 1–4, respectively, and selected bond lengths and angles are given in Table 2.

2.2.1. Crystal structure of [Pt(PNCHP-κ³P,N,P)Cl]-Cl·2CH₂Cl₂ (1b)

The structure of the cation [Pt(PNCHP-κ^3P,N,P)Cl]$^+$ of **1b** (Fig. 1) contains a four-coordinate platinum atom with the two phosphorus atoms [P(1) and P(2)] and the imine nitrogen atom (N′ or N″) of PNCHP and one chloride [Cl(1)] atom making up the four donor atoms. A second chloride (ionic) and two molecules of dichloromethane are also present but omitted from Fig. 1 for clarity. The coordination geometry around the platinum atom is slightly distorted square planar which can be attributed to the steric requirements of the coordinated PNCHP ligand. The mean C(1)=N imine bond length at 1.272 Å is similar to the value found for the free ligand (1.266 Å) [4] as well



Scheme 3.

as for the related compounds, **4a**, **5a** and **6** [1.290(6)–1.297(15) Å] reported in this study.

*2.2.2. Crystal structure of [Pt(PNCHP-κ³P,N,P)-(PPh₃)](BF₄)₂ (**4a**)*

The structure of the dication, [Pt(PNCHP-κ^3P,N,P)(PPh_3)]$^{2+}$ **4a** (Fig. 2), shows the two phosphorus atoms [P(1) and P(2)] and nitrogen atom (N) of PNCHP and the phosphorus atom of a triphenylphosphine [P(3)] coordinated to a central platinum atom (Pt). As for **1b**, the coordination geometry of the platinum is slightly distorted square planar. Calculation of a plane involving the platinum atom and the four donor atoms, N, P(1), P(2) and P(3), shows a significant deviation from coplanarity of 0.146 Å, much greater than in the structure discussed above (0.095 for molecule A and 0.024 Å for molecule B). The Pt–P bond lengths to PNCHP [Pt–P(1), 2.3151(12) Å and Pt–P(2), 2.3247(12) Å] are similar

[2.332(2)–2.347(2) Å] to other square planar d^8 complexes of platinum for compounds with two phosphines *trans* to each other [8] Pt–P and Pt–N bond lengths are similar to those found in the complexes *cis*-$[Pt(PNH_2)]^{2+}$ and *trans*-$[Pt(PNH_2)]^{2+}$ ($PNH_2 = o$-aminophenyldiphenylphosphine) [9]. However, the bond lengths Pt–P(1) and Pt–P(2) are significantly longer (by 0.0215 and 0.0390 Å, respectively) than those found for [Pt(PNCHP-κ^3P,N,P)Cl]$^+$ (**1b**), which is consistent with the greater steric requirement of the mutually *cis* coordinated triphenylphosphine ligand – effectively there are three bulky triphenylphosphino moieties in close proximity.

2.2.3. Crystal structure of [Pt(PNCHP-κ^3P,N,P)-(phen–κ^2N,N)](BF$_4$)$_2\cdot$CH$_2$Cl$_2$ (**5a**)

For the dication, [Pt(PNCHP-κ^3P,N,P)(phen–κ^2N,N)]$^{2+}$ of **5a** (Fig. 3), the platinum atom is five-coordinate with a slightly distorted square-pyramidal geometry. The PNCHP ligand occupies three sites of the basal plane, coordinating through the two phosphorus atoms [P(1) and P(2)] and the nitrogen atom (N). The remaining coordination site of the basal plane is filled by one of the nitrogen atoms [N(1)] of the 1,10-phenanthroline (phen) ligand. The second nitrogen atom [N(2)] of the 1,10-phenanthroline is located at the apex of the square pyramid. There is no significant difference between the Pt–N(imine) [2.038(2) Å] and Pt–N(1)(phen) [2.043(2) Å] bond lengths, which are *trans* to one another in the basal plane. The axial phen–N(2)–Pt distance of 2.526(2) Å is considerably greater than the equatorial N(1)–Pt distance of 2.043(2) Å, the latter being typical for platinum(II)-1,10-phenanthroline species [10]. Due to the rigid structure of 1,10-phenanthroline, the second nitrogen atom is forced to be in the vicinity of the metal, making it difficult to decide whether or not the axial nitrogen atom-to-metal distance N(2)–Pt corresponds to a weak bond. However, in **5a** the phen is considered to be bidentate for the following reasons: (i) The platinum atom is displaced from the basal plane by 0.1052(8) Å towards the N(2) atom. (ii) The ratio of the axial/equatorial phen–N–Pt bond lengths at 1.24 is close to values for accepted five coordinate species [11]. For example, ratios of 1.17 are found for the five coordinate species $[Ni(CN)_5]^{2-}$ and 1.14 for the five coordinate $[PtI_2(CO)(dmphen)]$ (dmphen = 2,9-dimethyl-1,10-phenanthroline), where the phenanthroline ligand is bound in an axial-to-equatorial bidentate mode. By contrast, in $[PtCl(phen)(PEt_3)_2]^+$, where the phen ligand is considered monodentate, the ratio is 1.33 [12]. (iii) The N(1)–Pt–N(2) angle of 74.54(8)° lies close to the average phen N–M–N angle of 79.5° when the ligand is clearly bidentate [11]. For comparison, the equivalent angles in $[Pt(CN)(phen)_2]^+$ and $[PtCl(phen)(PEt_3)_2]^+$, where the phen ligand is monodentate, are 69.7(2)° and 68.2°, respectively [13,14]. (iv) The difference between the Pt–N(1)–C(105) and Pt–N(1)–C(101) angles of only −2.7°, is indicative of a phenanthroline ligand bound to both the basal plane and the apical site of the metal atom [15]. (v) Lastly, the axial phen–N–Pt distance [2.526(2) Å] in **5a** is considerably shorter than the analogous distances in $[Pt(CN)(phen)_2]^+$ and $[PtCl(phen)(PEt_3)_2]^+$ [2.761(5) and 2.843(20) Å, respectively], which are considered to be too long for a bonding interaction.

2.2.4. Crystal structure of [Pt(PNCHP-κ^3P,N,P)(terpy-κ^2N,N)](BF$_4$)$_2$ (**6**)

The geometry around the metal in [Pt(PNCHP-κ^3P,N,P)(terpy-κ^2N,N)]$^{2+}$ **6** (Fig. 4) is similar to that

found in [Pt(PNCHP-κ^3P,N,P)(phen)]$^{2+}$. Again, the platinum atom is square pyramidal with the two phosphorus atoms [P(1) and P(2)] and one nitrogen atom (N) of PNCHP occupying three equatorial sites, with the fourth site occupied by one of the terminal nitrogen atoms [N(1)] of the 2,2′,6′2″-terpyridine ligand. The central nitrogen atom [N(2)] of the terpy occupies the axial site with the axial Pt–N(2) distance at 2.625(7) Å being longer than the equatorial Pt–N(1) distance of 2.061(7) Å. The Pt–N(2) distance is considered to cor-

respond to a bonding interaction since the same arguments put forth to describe the nature of the axial Pt–N(2) bond in [Pt(PNCHP)(phen–$\kappa^2 N,N$)]$^{2+}$ (**5a**) also hold for **6**, although the interaction is weaker: the platinum atom is displaced from the basal donor atom plane by only 0.0349(8) Å towards the N(2) atom, the axial/equatorial ratio is slightly larger at 1.27 and difference between the M–N(1)–C(105) and M–N(1)–C(101) angles is also slightly larger at +5.0°. In addition, unlike the phen ligand in **5a**, the pyridyl ring containing the axial bound nitrogen atom is free to rotate around the C(105)–C(106) axis and therefore is not required to orientate itself for bonding with the metal, as it does. The two rings containing the N(1) and N(2) atoms lie in one plane. In contrast, the mean plane of the pyridyl ring containing the non-bonding nitrogen atom N(3) is tilted 47.7° relative to the mean plane of the middle pyridyl ring.

2.3. NMR spectroscopy

The ^{31}P NMR data for selected compounds are collected in Table 3. All the platinum(II) compounds displayed similar spectra, showing two doublets with platinum-195 satellites which are assigned to the two phosphorus atoms of the PNCHP ligand with ^2J(P,P) coupling between the two inequivalent phosphorus nuclei and ^1J(Pt,P) coupling due to the spin 1/2 nucleus ^{195}Pt, found in 33% abundance. In general, for all the platinum(II) compounds discussed here, one of the phosphorus atoms gives rise to a high frequency resonance (δ 45.9–28.7) and the other to a low frequency resonance (δ 19.5–12.3). The former resonances can reasonably assigned to the phosphorus atoms involved in the five-membered ring, due to the ring contribution (ΔR) effect [16,17]. The ^2J(P,P) coupling constants ranged from 306 to 422 Hz which is indicative of a *trans* arrangement of inequivalent phosphorus atoms [18]. Coupling constants of larger magnitude were exhibited by the monocationic complexes, whilst those of smaller magnitude were displayed by the dicationic complexes. ^1J(P,Pt) coupling constants ranged from 2353 to 2789 Hz and were typical of *trans*-platinum(II) complexes [18]. The ^1J(P,Pt) coupling constants associated with the higher frequency resonances, i.e. those from δ 45.9–28.7, were on average 30 Hz higher than their lower frequency counterparts at δ 19.5–12.3, further supporting the assignment of the signals at high frequency to the phosphorus atoms involved in the five-membered ring, again due to the ring contribution (ΔR) effect [18].

The spectra of the two complexes, [Pt(PNCHP-$\kappa^3 P,N,P$)(PPh$_3$)](BF$_4$)$_2$ (**4a**) and [Pt(PNCHP-$\kappa^3 P,N,P$)-(diphos)](BF$_4$)$_2$ (**5c**) contain additional phosphorus signals due to their phosphine co-ligands. For **4a**, where the ancillary ligand is triphenylphosphine, an additional resonance at δ 5.1, with ^2J(P,P) coupling constants of 18 and 21 Hz and a ^1J(P,Pt) of 3397 Hz, was observed. The relatively large ^1J(P,Pt) coupling constant for the triphenylphosphine ligand, relative to those observed for PNCHP, is due to the poorer *trans* influence of the ni-

[k] Not resolved.

trogen when compared to the phosphorus atom. The chemical shift is similar to other triphenylphosphine platinum(II) compounds [19] with the ^2J(P,P) coupling constant being typical of phosphorus atoms in a *cis* arrangement [18]. Free diphos contains equivalent phosphorus atoms but on coordination in **5c**, these become inequivalent, exhibiting one resonance at 42.6 and the other at δ 38.3, values which support both diphos phosphorus atoms being coordinated to the platinum atom. The ^1J(P,Pt) coupling constant of 3088 Hz is typical of diphos coordinated in square planar platinum(II) complexes [20,21] and consistent with P *trans* to N. The expected second ^1J(P,Pt) coupling constant could not be resolved.

The phosphorus-31 NMR spectra of the palladium complexes are similar to those of the platinum compounds, but with the expected absence of phosphorus-to-metal coupling. All spectra displayed two doublet signals, which are assigned to the inequivalent phosphorus atoms of PNCHP. As for the platinum compounds, chemical shifts are indicative of phosphorus-transition metal coordination. The ^2J(P,P) coupling constants were typical of the PNCHP ligand bound to palladium(II) with its two phosphorus atoms *trans* to one another. As previously reported [18], chemical shifts and coupling constants for the palladium complexes were significantly larger than those for their platinum analogues.

All the compounds listed in Table 3 displayed a signal in the range δ 10.9–8.6 which can be assigned to the imine proton of coordinated PNCHP with coupling to ^{195}Pt (60 – 110 Hz) being observed for the platinum complexes. As the ancillary ligand is changed from a halogen to a nitrogen to a phosphorus donor ligand, the chemical shift of the imine proton moves to lower frequency and the ^3J(H,Pt) coupling constant decreases. The shift to lower frequency can be explained using the relative *trans* influence of the donor atom of the ancillary ligand. For example, when the ancillary donor atom is phosphorus (high in the *trans* influence series), as it is in [Pt(PNCHP-κ^3P,N,P)(PPh_3)]$(BF_4)_2$ (**4a**) and [Pt(PNCHP-κ^3P,N,P)(diphos)]$(BF_4)_2$ (**5c**), the imine proton exhibits its lowest frequency shifts.

3. Conclusions

For the d^8 metals, platinum(II) and palladium(II), the PNCHP ligand coordinates to three sites of the square-plane, using the two phosphorus atoms and the imino-nitrogen atom. In the compound [Pt(PNCHP-κ^3P,N,P)(MeCN)]$(BF_4)_2$ (**3**), the acetonitrile ancillary ligand, which occupies the fourth site of the square-plane, can be substituted with monodentate ligands, such as 2- and 3-picoline and triphenylphosphine. Reaction of **3** with the bidentate ligands 2,2′-bipyridine, 1,10-phenanthroline and bis(diphenylphosphino)ethane, does not result in any observable competition with the PNCHP ligand for coordination sites. Instead, these ligands act in a bidentate fashion, with one of their donor atoms occupying the fourth site of the square-plane, and the second donor atom the apical site of a square pyramid to give five-coordinate dicationic complexes. The potentially tridentate ligand, 2,2′,6′,2″-terpyridine, also behaves as a bidentate, forming the five-coordinate complex [Pt(PNCHP-κ^3P,N,P)(terpy-κ^2N,N)]$^{2+}$ (**6**).

4. Experimental

4.1. Materials and instrumentation

Spectral measurements were performed as previously described [7]. Microanalyses were performed by the Campbell Microanalytical Laboratory, University of Otago. Many of the compounds contained solvated CH_2Cl_2 which was readily lost and the analytical data reflect this. The PNCHP ligand [4], [Pt(COD)Cl_2], [Pd(COD)Cl_2] and [Pd(COD)(Me)Cl] [22] were prepared according to literature preparations. All reactions were carried out under an inert atmosphere. Solvents were dried by standard procedures [23].

4.2. Preparation of the complexes

4.2.1. [Pd(PNCHP-κ^3P,N,P)Cl]Cl (**1a**)

A mixture of [Pd(COD)Cl_2] (0.100 g, 0.350 mmol) and PNCHP (0.193 g, 0.351 mmol) in benzene (12 mL) was heated to reflux for 1 h. The resulting yellow precipitate was isolated by filtration, washed with *N*-pentane and air dried to yield **1a** (0.235 g, 86.9%) as a yellow powder. *Anal.* Calc. for $C_{37}H_{29}Cl_2NP_2Pd \cdot 0.5\ CH_2Cl_2$: C, 58.54; H, 3.93; N, 1.82. Found: C, 58.41; H, 3.99; N, 1.78%.

4.2.2. [Pt(PNCHP-κ^3P,N,P)Cl]Cl (**1b**)

A mixture of [Pt(COD)Cl_2] (0.100 g, 0.267 mmol) and PNCHP (0.147g, 0.267 mmol) in benzene (12 mL) was stirred at room temperature for 40 min, giving a yellow precipitate. The mixture was heated to reflux for 30 min and allowed to cool. The resulting yellow precipitate was isolated by filtration, washed with diethylether and air dried to yield **1b** (0.146 g, 60.7%) as a yellow powder. The compound can be crystallised from dichloromethane/*N*-hexane. M.p: 294-296 °C (dec). *Anal.* Calc. for $C_{37}H_{29}Cl_2NP_2Pt \cdot 1.5CH_2Cl_2$: C, 49.04; H, 3.42; N, 1.49. Found: C, 48.78; H, 2.75; N, 1.52%.

4.2.3. [Pd(PNCHP-κ^3P,N,P)Cl]BF_4 (**2a**)

A mixture of **1a** (0.202 g, 0.263 mmol) and $AgBF_4$ (0.054 g, 0.277 mmol) in dichloromethane (12 mL) was

exposed to ultrasound for 1 h resulting in yellow and white precipitates. This mixture was filtered through kieselguhr and the trapped yellow precipitate dissolved and washed through into the filtrate with acetonitrile, leaving the insoluble white precipitate behind. The filtrate was taken to dryness in vacuo and the resulting yellow residue crystallised from dichloromethane/*n*-hexane. Compound **2a** (0.169 g, 82.6%) was isolated as large yellow crystals, washed with a dichloromethane/*N*-pentane mixture and air-dried. *Anal.* Calc. for $C_{37}H_{29}BClF_4NP_2Pd$: C, 57.10; H, 3.76; N, 1.80. Found: C, 56.68; H, 3.70; N, 1.90%.

4.2.4. [Pt(PNCHP-κ^3P,N,P)Cl]BF_4 (**2b**)

A mixture of **1b** (0.300 g, 0.333 mmol) and $AgBF_4$ (0.071 g, 365 mmol) in dichloromethane (12 mL) was exposed to ultrasound for 1 h, resulting in yellow and white precipitates. The mixture was filtered through kieselguhr and the trapped yellow precipitate dissolved and washed through into the filtrate using acetonitrile, leaving the insoluble white precipitate behind. The filtrate was taken to dryness in vacuo and the resulting yellow residue crystallised from dichloromethane/*N*-hexane overnight. Compound **2b** (0.248 g, 79.9%) was isolated as orange crystals, washed with a dichloromethane/*N*-pentane mixture and air-dried. M.p. 198–200 °C. *Anal.* Calc. for $C_{37}H_{29}BClF_4NP_2Pt \cdot 0.75CH_2Cl_2$: C, 48.72; H, 3.30; N, 1.51. Found: C, 48.55; H, 3.29; N, 1.56%.

4.2.5. [Pt(PNCHP-κ^3P,N,P)(MeCN)]$(BF_4)_2$ (**3**)

A mixture of **2b** (0.401 g, 0.431 mmol) and $AgBF_4$ (0.0899 g, 401 mmol) in acetonitrile (c.a. 15 mL) was heated to reflux for 27 h, giving a dark-orange solution. The solvent was removed in vacuo and the resulting orange residue crystallised from dichloromethane/*N*-hexane to yield **3** (0.369 g, 96.0%). *Anal.* Calc. for $C_{39}H_{32}B_2F_8N_2P_2Pt \cdot 0.5CH_2Cl_2$: C, 47.36; H, 3.32; N, 2.80. Found: C, 47.89; H, 3.45; N, 2.81%.

4.2.6. [Pt(PNCHP-κ^3P,N,P)(PPh_3)]$(BF_4)_2$ (**4a**)

A mixture **2b** (0.101 g, 0.108 mmol) and $AgBF_4$ (0.0226 g, 0.116 mmol) in acetonitrile (12 mL) was heated to reflux for ca. 25 min, giving a white precipitate. PPh_3 (0.0306 g, 0.117 mmol) was added to the reaction mixture and refluxing continued for a further 30 min. This mixture was filtered through kieselguhr and the trapped yellow precipitate dissolved and washed through into the filtrate with dichloromethane, leaving the original white precipitate behind. The filtrate solvent was evaporated in vacuo and the resulting yellow residue precipitated from dichloromethane/*N*-hexane overnight. Compound **4a** (0.103 g, 80.8%) was isolated as a very pale yellow powder, washed with *N*-pentane and air-dried. The powder can be recrystallised from a CH_2Cl_2/*N*-hexane vapour diffusion to yield colourless crystals. *Anal.* Calc. for $C_{55}H_{44}B_2F_8NP_3Pt \cdot CH_2Cl_2$: C, 53.15; H, 3.66; N, 1.11. Found: C, 53.36; H, 3.80; N, 1.18%.

4.2.7. [Pt(PNCHP-κ^3P,N,P)(2-pico)]$(BF_4)_2$ (**4b**)

A mixture of **2b** (0.162 g, 0.174 mmol) and $AgBF_4$ (0.0360 g, 0.185 mmol) in acetonitrile (12 mL) was heated to reflux for 30 min, giving a white precipitate. 2-Picoline (2-pico) (0.0183 mL, 0.185 mmol) was added to the reaction mixture and refluxing continued for a further 30 min. The white precipitate was removed by filtration through kieselguhr and the filtrate taken to dryness in vacuo. The resulting yellow residue converted to a white and brown mixture over two days. The white product was separated from the insoluble brown product by dissolving in dichloromethane, followed by filtration. Crystallisation was initiated by addition of *N*-hexane to the filtrate. Compound **4b** (0.1354 g, 72.4%) was isolated as white microcrystals, washed with diethylether and dried in vacuo. *Anal.* Calc. for $C_{43}H_{36}B_2F_8N_2P_2Pt$: C, 51.06; H, 3.59; N, 2.78. Found: C, 51.04; H, 3.48; N, 2.79%.

4.2.8. [Pt(PNCHP-κ^3P,N,P)(3-pico)]$(BF_4)_2$ (**4c**)

A mixture of **2b** (0.154 g, 0.165 mmol) and $AgBF_4$ (0.0343 g, 0.176 mmol) in acetonitrile (12 mL) was heated to reflux for ca. 25 min, giving a white precipitate. 3-Picoline (3-pico) (0.016 mL, 0.18 mmol) was added to the reaction mixture and refluxing continued for a further 30 min. The white precipitate was removed by filtration through kieselguhr and the filtrate taken to dryness in vacuo. The resulting yellow residue was taken into solution with acetonitrile, followed by addition of diethylether to precipitate out the desired product. Compound **4c** (0.101 g, 56.5%) was isolated as a very pale yellow powder, washed with diethylether and air-dried. *Anal.* Calc. for $C_{43}H_{36}B_2F_8N_2P_2Pt \cdot CH_2Cl_2$: C, 48.20; H, 3.49; N, 2.56. Found: C, 47.88; H, 3.31; N, 3.05%.

4.2.9. [Pt(PNCHP-κ^3P,N,P)(phen)]$(BF_4)_2$ (**5a**)

A mixture of **3** (0.114 g, 0.119 mmol) and 1,10-phenanthroline (phen) (0.024 g, 0.133 mmol) in benzene (15 mL) was heated to reflux for 1 h, giving an orange toffee-like solid. The solvent was removed in vacuo and the resulting orange residue taken up into dichloromethane and heated to reflux overnight. The orange solution was subject to vapour diffusion using *N*-hexane giving **5a** (0.126 g, 96.4%) as chunky orange crystals. *Anal.* Calc. for $C_{49}H_{37}B_2F_8N_3P_2Pt \cdot CH_2Cl_2$: C, 50.75; H, 3.32; N, 3.55. Found: C, 51.05; H, 2.95; N, 3.52%.

4.2.10. [Pt(PNCHP-κ^3P,N,P)(bipy)]$(BF_4)_2$ (**5b**)

A yellow solution of **2b** (0.194 g, 0.209 mmol) and $AgBF_4$ (0.0436 g, 0.224 mmol) in acetonitrile (12 mL) was heated to reflux for 20 h. The resulting orange solution was filtered through kieselguhr. 2,2′-Bipyridine

(bipy) (0.033 g, 0.21 mmol), dissolved in acetonitrile, was added to the filtrate and refluxing continued for a further 1 h, giving an intense orange solution. The solution was allowed to cool, followed by solvent removal in vacuo. Additional white precipitate was removed by filtration through kieselguhr and washed with acetonitrile, and the filtrate plus washings were taken to dryness in vacuo. The resulting yellow residue was recrystallised from dichloromethane/*N*-hexane. Compound **5b** (0.141 g, 62.7%) was isolated as orange crystals, washed with *N*-pentane and air-dried. M.p: 259-260 °C. *Anal.* Calc. for $C_{47}H_{37}B_2F_8N_3P_2Pt \cdot 0.5CH_2Cl_2$: C, 51.08; H, 3.43; N, 3.76. Found: C, 51.22; H, 3.26; N, 3.85%.

4.2.11. [Pt(PNCHP-κ^3P,N,P)(diphos)]$(BF_4)_2$ (**5c**)

Compound **3** (0.100 g, 0.104 mmol) and bis(diphenylphosphino)ethane (diphos) (0.0420 g, 0.105 mmol) were dissolved together in dichloromethane (12 mL) and heated to reflux for 3 h. A small amount of the by-product $[Pt(diphos)_2](BF_4)_2$ (0.015 g, 24.5%), as a yellow precipitate, was removed by filtration and the filtrate set up for vapour diffusion with *N*-hexane. Compound **5c** was isolated as a yellow powder which on exposure to air, slowly turns green. *Anal.* Calc. for $C_{63}H_{53}B_2F_8NP_4Pt \cdot 2CH_2Cl_2$: C, 52.52; H, 3.86; N, 0.94. Found: C, 52.60; H, 3.79; N, 0.58%.

4.2.12. [Pt(PNCHP-κ^3P,N,P)(terpy)]$(BF_4)_2$ (**6**)

Compound **3** (0.100 g, 0.105 mmol) and 2,2′,6′,2″-terpyridine (terpy) (0.0244 g, 0.105 mmol) were dissolved together in dichloromethane (c.a. 12 mL) and heated to reflux for ca. 3 h. The reaction mixture was filtered and set up for vapour diffusion in *N*-hexane. Compound **6** (0.0919 g, 76.9%) was isolated as orange crystals, washed with *N*-pentane and air dried. *Anal.* Calc. for $C_{52}H_{40}B_2F_8N_3P_2Pt$: C, 54.24; H, 3.50; N, 4.87. Found: C, 53.97; H, 3.50; N, 4.85%

4.2.13. [Pd(PNCHP-κ^3P,N,P)(CH_3)]Cl (**7**)

A mixture of [Pd(COD)(CH_3)Cl] (0.101 g, 0.381 mmol) and PNCHP (0.208 g, 0.378 mmol) in dichloromethane (12 mL) was stirred at room temperature for 1 h, giving a yellow solution. *N*-Hexane was added until a slight cloudiness was observed. Very pale yellow microcrystals resulted after standing overnight. These were isolated by filtration, washed with *N*-pentane and air dried to yield **7** (0.239 g, 89.4%). *Anal.* Calc. for $C_{38}H_{32}ClNP_2Pd$: C, 64.60; H, 4.57; N, 1.98. Found: C, 64.30; H, 4.64; N, 2.01%.

4.2.14. [Pd(PNCHP-κ^3P,N,P)(CH_3)]BF_4 (**8**)

Compound **7** (164 g, 0.232 mmol) and $AgBF_4$ (0.0447 g, 0.230 mmol) were combined in dichloromethane (ca. 12 mL) and heated to reflux for 1 h. The reaction mixture was filtered through kieselguhr. *N*-Pentane was vapour diffused into the filtrate over a weekend. Compound **8** (0.114 g, 61.9%) was isolated as pale yellow microcrystals, washed with *N*-pentane and dried in vacuo. *Anal.* Calc. for $C_{38}H_{32}BF_4NP_2Pd \cdot 0.5CH_2Cl_2$: C, 57.78; H, 4.16; N, 1.75. Found: C, 58.15; H, 4.18; N, 1.83%.

4.3. Crystallography

Single crystals of the compounds, **1b**, **4a**, **5a** and **6**, were grown as described under their respective syntheses and attached to the ends of glass fibres with cyanoacrylate glue. Data collection and refinement were performed as previously described [24]. Table 1 lists the crystal data for the compounds. For **1b**, the imine bond of the PNCHP ligand and contiguous phenyl rings are disordered over two sites, A and B, and were refined with a free variable giving the occupancy of these as 0.67 and 0.33, respectively. In the case of **6**, the platinum atom and the two pyridyl rings of the terpy ligand lie on a mirror plane and were refined with special position constraints. The PNCHP ligand is disordered about this mirror plane and the two single phenyl rings and the phosphorus are assigned with occupancies of 1. When the imine link between the two phosphorus atoms was refined with an occupancy of 0.5 (as this was indicated by the large temperature factors in this part of the molecule in the initial refinement) with the N constrained to lie on the mirror plane, unreasonable C=N bond distances resulted. Removing the special position constraint allowed the imine nitrogen, N, and carbon, C(1), to take their respective disordered positions slightly above and below the mirror plane, hence giving bond distances in the usual range.

5. Supplementary material

CCDC 213469 (**1b**), 213470 (**5a**), 213471 (**4a**) and 213472 (**6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336033; or data_request@ccdc.cam.ac.uk).

Received 5 November 2003; accepted 24 January 2004

Abstract

An unprecedented tetranuclear complex bridged by 3,5-pyridinedicarboxylate (abbreviated as 3,5-PDC) with an empirical formula $[Cu_2(2,2'\text{-bpy})_3(3,5\text{-PDC})]_2(ClO_4)_4 \cdot 2(H_2O)$, has been synthesized and spectrally characterized. X-ray structural analysis reveals that there are two types of copper(II) centers, one is penta-coordinate with a distorted pyramidal geometry, while the other is tetra-coordinate with a distorted square planar geometry. 3,5-PDC serves as a tridentate ligand linking three adjacent metals with its one nitrogen and two monodentate carboxylic donors.

1. Introduction

In recent years, supramolecular frameworks, including transitional metal polynuclear complexes, have been extensively studied for generating new materials with expected structures, prescribed functions and interesting magnetic properties [1]. Among those complexes certain tetranuclear examples that have been well characterized structurally and magnetically have attracted much attention for designing metal clusters with heterocubane cores [2]. Tetranuclear copper(II) species are of interest in bioinorganic modeling, multi-electron transfer processes, catalysis and magneto-structure research. Of the many known Cu_4 species, the most common strategy to obtain these compounds is metal self-association induced by bridging ligands like hydroxo [3], imidazolate [4], oximate [5], diazine [6] and carboxylate [7]. On the other hand, coordination polymers of multi-carboxylate ligands such as 1,3-benzenedicarboxylate and 1,3,5-benzene-tricarboxylate anions possessing high symmetry have been widely investigated [8,9].

The high symmetry 3,5-$PDCH_2$ molecule is a potential rigid multidentate ligand containing a pyridine ring and two carboxylic groups, which can be used as a terminal ligand or a bridging ligand with different coordination numbers when coordinated with various metal ions. In addition to its versatile coordinating modes, 3,5-PDC may take part in hydrogen bonding interactions and π–π interactions with its N, O donors and pyridine ring. So far, only three papers involving mononuclear Ni(II), Co(II) and Pd(II) complexes with 3,5-PDC have been postulated [10], but there are a few examples to elucidate the feature of 3,5-PDC as a bridging ligand connecting two or more metals. In this report, we describe a novel tetranuclear copper(II) complex, by self-assembly utilizing 3,5-PDC as the multifunctional bridge and 2,2′-bipyridine as a metal protecting block, whose crystal structure has been explored. To our knowledge, this represents the first tetranuclear copper(II) complex involving 2,2-bpy protecting metal

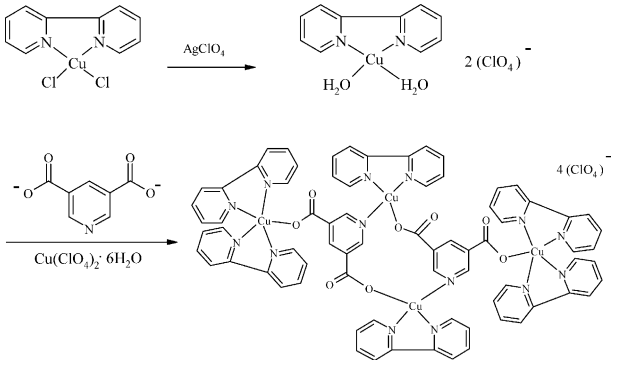
blocks and four Cu(II) centers that are bridged by two tridentate 3,5-PDC ligands.

2. Experimental

2.1. Materials and measurements

Cu(2,2′-bpy)Cl_2 was prepared by the literature method [11], other reagents were commercially available and used as received. Microanalysis was carried out on a Perkin–Elmer 1400C element analyzer. Metal contents were measured by a Jarrell-Ash 1100 + 2000 type quantometer. Infrared spectra (4000–400 cm^{-1}) were recorded using a Nicolet FT-IR 170X spectrophotometer on KBr disks. Electrospray ionization mass spectra (ESMS) were recorded on a Finnigan MAT SSQ 710 mass spectrometer in a scan range of 200–1500 amu.

2.2. Preparation of the tetranuclear Cu(II) complex



Treatment of Cu(2,2′-bpy)Cl_2 (0.29 g, 1 mmol) dissolved in ethanol (20 cm^{-3}) and water (10 cm^{-3}) with stoichiometric $AgClO_4$ aqueous solution (5 cm^{-3}) formed a solution of Cu(2,2′-bpy)$\cdot(ClO_4)_2$, then 20 cm^{-3} of ethanol containing $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol) was added at 50 °C. After 2 h, the above-mentioned blue solution was added to 3,5-PDCNa_2 (0.21 g, 1 mmol) in a mixed solution of ethanol/water (20 cm^{-3}/10 cm^{-3}). The final blending solution was stirred for another 18 h at 50 °C, the deep blue filtrate was allowed to stand for self-evaporation in the atmosphere at room temperature. After 5 days, blue block-shaped single crystals were obtained that were suitable for X-ray structure analysis. Yield: 64%. *Anal.* Calc. for $Cu_4C_{74}H_{58}Cl_4N_{14}O_{26}$: C, 45.46; H, 2.99; N, 10.03. Found: C, 45.17; H, 2.96; N, 10.01%. Metal contents calc. for $Cu_4C_{74}H_{58}Cl_4N_{14}O_{26}$: Cu, 13.00. Found: 12.6%. IR (KBr disk, cm^{-1}): 3416 (b), 3141 (s), 2945 (m), 2864 (m), 1638 (s), 1619 (s), 1569 (m), 1515 (w), 1458 (m), 1407 (w), 1363 (w), 1287 (w), 1232 (w), 1163 (m), 1086 (m), 833 (w), 758 (m) and 626 (m). ES-MS: m/z 385 [Cu(2,2′-bpy)(3,5-PDCH)]$^+$.

2.3. Crystallographic data for $[Cu_2(2,2'\text{-bpy})_3(3,5\text{-PDC})]_2(ClO_4)_4 \cdot 2(H_2O)$

A blue single crystal with approximate dimensions of $0.20 \times 0.30 \times 0.40$ mm was measured on a Bruker CCD-4K diffractometer using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at 293 K. The data were collected using SMART and reduced by using the program SAINT [12]. Empirical absorption correction was done by using the SADABS program [13]. The structure was solved by direct methods and refined by the least squares method on F^2_{obs} by using the SHELXTL PC software package [14]. The anisotropic thermal parameters of all non-hydrogen atoms were refined by the full-matrix least-squares procedure and the hydrogen atom positions were geometrically fixed and allowed to ride on the attached atoms. The summary of the crystal data, experimental details and refinement results for the title complex is listed in Table 1, while selected bond distances and bond angles are given in Table 2.

3. Results and discussion

Four copper ions in our tetranuclear complex are confirmed more by the ICP analysis than by the X-ray determination. The asymmetric and symmetric vibrations of the carboxylate moiety in the infrared spectrum of the title compound were observed at ν_{as}(COO): 1638, 1619cm^{-1} and ν_s(COO): 1407, 1363 cm^{-1}, respectively. The Δ values of 212 and 275 cm^{-1} frequencies between the ν_{as}(COO) and the ν_s(COO) are indicative of the existence of monodentate carboxylic groups. Meanwhile, the typical stretching bands of perchlorate ions were observed at 1086 and 626 cm^{-1}, and a broad peak at 3416 cm^{-1} revealed the presence of weakly coordinating water molecules. Though the molecular ion peak of $[Cu_2(2,2'\text{-bpy})_3(3,5\text{- PDC})]_2(ClO_4)_4$ has not been found, the electro-spray ionization mass spectra demonstrates that a mono-charged peak corresponding to $[Cu(2',2\text{-bpy})(3'5\text{-PDCH})]^+$ is present. The structure of the compound has been further confirmed by X-ray diffraction determination.

The crystal structure of $[Cu_2(2,2'\text{-bpy})_3(3,5\text{- PDC})]_2(ClO_4)_4 \cdot 2(H_2O)$ is revealed by an X-ray diffraction study of a suitable blue single crystal. An ORTEP drawing of the compound with the atom numbering scheme is shown in Fig. 1. In the unit cell, there are two kinds of crystallographically independent copper(II) atoms with different coordination geometries that are bridged by two 3,5-PDC ligands. The Cu_4 core is composed of two kinds of Cu(II) atoms [namely, Cu(1) and Cu(2)]. The four copper ions, which lie on a plane, form a parallelogram array which is similar to the $[Cu_4O_4]^{4+}$ macrocyclic complex we reported previously [15]. The inter-atomic distances between the crystallographically independent Cu(II) atoms, Cu(1)···Cu(2) and Cu(1)···Cu(2A), which compose the long and the short sides of the parallelogram, are 9.664 and 6.914 Å, respectively. The two diagonals of the parallelogram, Cu(1)···Cu(1A) and Cu(2)···Cu(2A), are 15.099 and 7.378 Å in length, respectively.

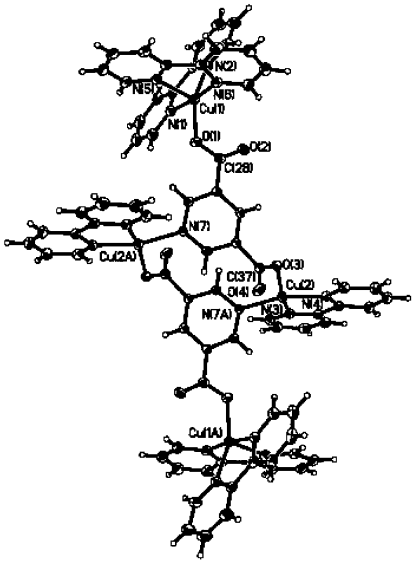

Fig. 1. ORTEP drawing of the complex cation species (30% thermal probability) with the atom-numbering scheme. Lattice water molecules, hydrogen atoms and perchlorate anions are omitted for clarity.

The Cu(1) atom is in a five-coordinate distorted pyramidal environment composed of one oxygen atom from

Table 3

C(35)–H(35)A...O(1W)	0.930	2.520	2.840(6)	101.00	$1-x,1-y,1-z$
C(36)–H(36)A...O(17)	0.930	2.520	3.143(6)	125.00	$x,y,-1+z$

one carboxylate of one 3,5-PDC ligand and four nitrogen atoms from two terminal 2, 2′-bpy molecules. The equatorial plane consists of N(1), N(2), N(6) and O(1) atoms with bond distances of Cu–N: 1.973(4)–2.056(3) Å and Cu(1)–O(1): 1.955(3) Å and bond angles of 80.60(15)–94.94(15)°. The apical site of the copper square plane is occupied by N(5) from one 2, 2′-bpy molecule with a relatively longer Cu(1)–N(5) bond distance of 2.168(4) Å. The corresponding bond angles between N(5) and those atoms in the basal plane are in the range 79.00(15)–105.61(13)°.

The geometry of the other metal atom may be described as a tetra-coordinate distorted square plane. Cu(2) is coordinated by one 2, 2′-bpy molecule, one nitrogen atom of a 3,5-PDC ligand and one carboxylate nitrogen atom of another neighboring 3,5-PDC ligand. The coordination plane around the Cu(2) atom is composed of N(3), N(4), O(3), N(7A) atoms with the normal Cu–N distances of 1.975(3)–2.005(4) Å and the bond angles of 81.29(16)°–95.30(16)°. The bond distance of Cu(2)–O(3) is 1.971(3) Å and the four bond angles of the square plane are in the range 81.29(16)°–95.69(14)°. It is noted that O(1)–C(28) and O(3)–C(37) are 1.276(5) and 1.274(5) Å long, respectively, which appear to be somewhat longer than the O(2)–C(28) and O(4)–C(37) distances of 1.227(5) and 1.221(5) Å, indicating the presence of some double-bond character in the O(2)–C(28) and O(4)–C(37) bonds. The water molecule and one perchlorate anion, with rather longer Cu(1)···O(1W) and Cu(2)···O(17A) distances of 2.522(4) and 2.724(4) Å, respectively, are positioned above and below the Cu(2) coordination plane, which may arise from the Jahn–Teller effect. In this sense, the coordination environment around Cu(2) may be described as a six-coordinate elongated octahedron.

It is worthy to note that 3,5-PDC functions as a bridging tridentate ligand connecting three adjacent copper(II) ions via its one nitrogen and two monodentate carboxylate donors, and two bridging 3,5-PDC ligands and two symmetry related copper(II) ions form a 12-membered supramolecular chelating ring. In addition, six 5-membered rings consist of 2,2′-bpy and copper(II) centers in the tetranuclear copper(II) complex. The Cu···Cu separations are 6.914 Å [Cu(1)···Cu(2)], 7.378 Å [Cu(2)···Cu(2A)], and 15.099 Å [Cu(1)···Cu(1A)].

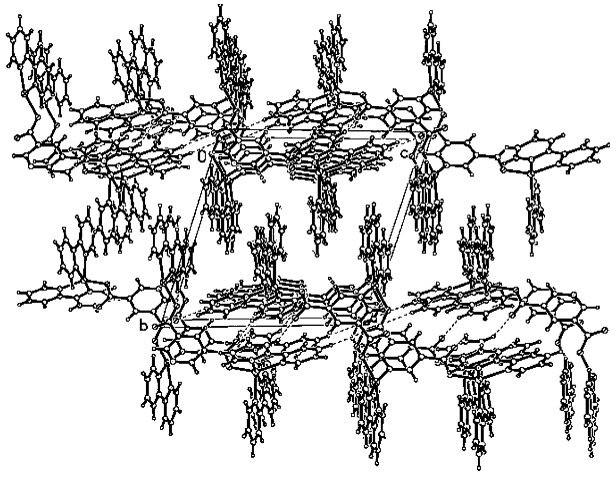

Fig. 2. View of the 3D network depicting the connection via non-classic hydrogen bonds down the *a*-axis. For clarity, crystal water molecules and percholate anions are omitted.

The dihedral angles between the pyridine ring and three 5-membered rings are 100.2°, 70.8° and 6.2°. It is found that there exists a small cavity of ca. 4.24×4.05 Å^2 from the 12-membered ring. Furthermore, the tetranuclear copper(II) centers form an absolutely coplanar structure exhibiting centrosymmetry.

Another interesting structural feature of the compound is the formation of a 3D hydrogen bond network. The corresponding data of H-bonds are listed in Table 3 and illustrated in Fig. 2. Two kinds of O–H···O intramolecular hydrogen bonds are observed between the same water molecule O(1W) and the uncoordinated carboxylic oxygen atom O(4) and perchlorate oxygen atom O(12), respectively. Intermolecular and intramolecular C–H···O hydrogen bonding interactions are common in this compounds with the donor–acceptor bond distances and the donor–H–acceptor bond angles varying from 2.840(6)–3.481(6) Å and 101.00°–178.00°, respectively.

4. Conclusion

One of the research aims of our group is to obtain dinuclear or multinuclear complexes [16] instead of infinite

networks. As we know, coordination polymers are often yielded when pyridine-based carboxylate derivatives are treated directly with metal ions. Using certain capped groups is a good strategy to prevent polymerization and interpenetration. But it does not always works. On the one hand, only certain organic compounds with suitable size and geometry are qualified for this purpose. On the other hand, only certain metal centers with flexible coordinating numbers or weakly coordinated groups (such as an aqua ligand which can be easily replaced) can serve as templating ions to direct the further assembly. In view of these we have used 2,2′-bipyridine protected copper(II) species as a building unit to react with 3,5-PDC bridging ligands in order to cap the ends of a potentially polymeric system. As a result, we have prepared successfully the first tetranuclear copper(II) complex partly capped by 2,2-bpy with four Cu(II) centers that are bridged by two tridentate 3,5-PDC ligands. In our case, the geometries of two metal centers have changed from tetra-coordinate square planar to penta-coordinate pyramidal. The other two metal ions have maintained their original geometries, but their coordinating water molecules have been replaced by ligands possessing higher coordinating abilities, namely the nitrogen atoms of pyridines as well as the oxygen atoms of carboxylic groups.

5. Supplementary materials

Crystallographic data (excluding structural factors) for the structure of **1** have been deposited with the Cambridge Crystallographic Data Center with the CCDC number 200969. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk for www: http://www.ccdc.cam.ac.uk).

Abstract

Examples of mononuclear (Ni(II)), dinuclear (Ni(II), Co(III)) and trinuclear (Ni(II)) complexes of the ligand 1,4-di-2′-pyridyl-aminophthalazine (pap) are reported. In the dinuclear complexes two metal ions are bridged by phthalazine (N–N) groups and two water molecules (Ni(II)), and two hydroxide ions (Co(III)). A novel $Ni_3(\mu_3\text{-}OH)_2$ central core exists in the trinuclear example, with additional phthalazine (N–N) bridges linking the Ni(II) centers. The polynuclear nickel complexes exhibit antiferromagnetic exchange through combinations of diazine (N–N) and water and hydroxide bridges ($J(Ni_2) = -4.9, -5.25\ cm^{-1}$; $J(Ni_3) = -15.7\ cm^{-1}$). The Co(III) complex is diamagnetic.

1. Introduction

The ligand 1,4-di-2′-pyridyl-aminophthalazine (pap) has been studied in detail, and has produced numerous dinuclear copper(II) complexes involving combinations of diazine (N–N) and other bridges (X) (e.g. $X = OH^-$, N_3^-, Cl^-, Br^-, IO_3^-) [1–17]. These examples have formed the basis for a detailed understanding of magnetic exchange interactions in this type of complex, and magneto-structural correlations within related series of complexes have provided fundamental insights into the geometrical and electronic properties of the bridge group (X), particularly N_3^- and OH^-, as it pertains to modern theoretical interpretations of exchange mechanisms. Complexes with other metals are less well characterized, and full structural details are not well documented. Some early reports highlighted complexes of Ni(II), Co(II) and Co(III) with pap and its alkyl substituted congeners, with evidence for dinuclear and mononuclear systems, based largely on elemental and spectroscopic evidence [18,19]. However, a lack of structural and magnetic details left the broad picture of these systems largely unexplored, despite some preliminary structural details reported for $[Co_2(pap)_3(OH)_2]Br_4 \cdot 9H_2O$ and $[Ni_2(pap)_3(H_2O)_2]Br_4 \cdot 6H_2O$ [19]. These structures were not reported fully at the time, but revealed dinuclear Co(III) and Ni(II) structures, respectively, with $\{\mu_2\text{-}N\text{–}N(\mu_2\text{-}O)_2\}$ triple bridges between metal centers ($O{=}OH^-$ (Co), H_2O (Ni)). Complex formation with these ligands was found to be pH dependent, and in acidic aqueous solvents protonated ligand complexes were produced as well, with a structurally characterized mononuclear example with Cu(II) ($[Cu(papH)_2(H_2O)_2](BF_4)_4$) [2].

We have revisited these systems in part to document the structural details of the Ni(II) and Co(III) complexes of the ligand pap in more detail, which were largely unavailable before, but also to examine the variable temperature magnetic properties. In this report, we describe the molecular structures of the complexes $[Ni(papH)_2(H_2O)_2](BF_4)_4 \cdot 4H_2O$ (**1**), $[Ni_2(pap)_3(H_2O)_2](NO_4)_4 \cdot 5H_2O$ (**2**), $[Ni_3(pap)_3(OH)_2](BF_4)_3F \cdot xH_2O$ (**5**),

doi:10.1016/j.poly.2004.01.022

which has a novel, and previously unobserved trinuclear structural motif, and $[Co_2(pap)_3(OH)_2](NO_4)_4 \cdot 9.5H_2O$ (**4**). Variable temperature magnetic properties for **2**, **5**, and the previously reported dinuclear complex $[Ni_2(pap)_3(H_2O)_2]Br_4 \cdot 3.5H_2O$ (**3**) [19] are also reported, all of which exhibit intramolecular antiferromagnetic exchange coupling.

2. Experimental

2.1. Physical measurements

Infrared spectra were recorded as Nujol mulls using a Mattson Polaris FTIR instrument. UV–Vis spectra were obtained as Nujol mulls with a Cary 5E spectrometer. C, H, N analyses on vacuum dried samples were performed by the Canadian Microanalytical Service, Delta, BC, Canada. Variable temperature magnetic data were obtained with a Quantum Design MPMS5S SQUID magnetometer operating at 0.1 T in DC mode (2–300 K), and with an Oxford Instruments Faraday magnetometer operating at 1.0 T with a field gradient of 10 T m^{-1} (5–300 K). Calibrations were carried out using a palladium standard cylinder, and $HgCo(NCS)_4$. Diamagnetic corrections for the sample holders and diamagnetic components of the complexes were applied.

2.2. Synthesis of the complexes

2.2.1. $[Ni(papH)_2(H_2O)_2](BF_4)_4$ (**1**)

Pap [1] (0.75 g, 2.4 mmol) was added to a solution of $Ni(BF_4)_2 \cdot 6H_2O$ (0.85 g, 2.5 mmol) in water (75 ml), and the mixture refluxed for 2 h. A small amount of pale green precipitate was filtered off and discarded, and the green solution concentrated until a green crystalline product formed (Yield: 0.56 g). Recrystallization from a water/methanol mixture gave pale green crystals suitable for structural analysis. These were kept under mother liquor prior to structural analysis because they desolvate on exposure to air. Elemental analysis (dried sample): *Anal*. Calc. for $(C_{18}H_{15}N_6)_2Ni(H_2O)_2(BF_4)_4$: C, 40.30; H, 3.17; N, 15.70. Found: C, 40.32; H, 3.27; N, 15.75%.

2.2.2. $[Ni_2(pap)_3(H_2O)_2](NO_3)_4 \cdot 5H_2O$ (**2**), $[Ni_2(pap)_3(H_2O)_2]Br_4 \cdot 3.5H_2O$ (**3**)

Pap (0.314 g, 1.00 mmol) was added to a solution of $Ni(NO_3)_2 \cdot 6H_2O$ (0.300 g, 1.00 mmol) in water/methanol (15/2 ml), and the mixture warmed. The ligand dissolved to form a purple solution, which produced turquoise green crystals on standing (Yield: 0.30 g). Crystals for structural analysis were kept under mother liquor because of instability on exposure to air. **3** was prepared in a similar manner [19]. Elemental analysis: *Anal*. Calc. for $(C_{18}H_{14}N_6)_3Ni_2(H_2O)_7(NO_3)_4$: C, 45.21; H, 3.90; N, 21.48. Found (**2**): C, 45.67; H, 3.63; N, 21.48%. Elemental analysis: *Anal*. Calc. for $(C_{18}H_{14}N_6)_3Ni_2(H_2O)_{5.5}Br_4$: C, 43.85; H, 3.61; N, 17.05. Found (**3**): C, 43.80; H, 3.42; N, 16.93%.

2.2.3. $[Co_2(pap)_3(OH)_2](NO_3)_4 \cdot 9.5H_2O$ (**4**)

Pap (0.314 g, 1.00 mmol) was added to a solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.290 g, 1.00 mmol) in water (25 ml) and the mixture warmed with stirring in air becoming dark brown in color after 24 h. The solution was filtered and allowed to stand. Dark brown crystals suitable for structural analysis formed after several days (Yield: 0.25 g). Elemental analysis: *Anal*. Calc. for $(C_{18}H_{14}N_6)_3Co_2(OH)_2(H_2O)_{9.5}(NO_3)_4$: C, 42.83; H, 4.16; N, 20.35. Found: C, 42.92; H, 3.98; N, 20.30%.

2.2.4. $[Ni_3(pap)_3(OH)_2](BF_4)_3F \cdot 9H_2O$ (**5**)

$Ni(BF_4)_2 \cdot 6H_2O$ (1.6 g, 4.7 mmol) was dissolved in water (45 ml) and the pH adjusted to 5.5 by addition of NaF. Pap (1.0 g, 2.9 mmol) was added, and the mixture heated forming a deep blue solution. The solution was filtered and reduced in volume with the formation a turquoise green crystalline product (Yield: 1.2 g), which contained some white crystals, presumed to be NaF. The combined product was recrystallized from methanol, to give turquoise green crystals, which were filtered off and air dried. They were observed to desolvate on exposure to air. A final recrystallization of a portion of this product from water gave turquoise crystals that were kept under mother liquor for structural analysis. This sample was used for magnetic analysis. Elemental analysis: *Anal*. Calc. for $(C_{18}H_{14}N_6)_3Ni_3(OH)_2(H_2O)_9F(BF_4)_3$: C, 40.70; H, 3.89; N, 15.82. Found: C, 40.62; H, 3.17; N, 15.91%.

2.2.5. Synthesis of $Ni(BF_4)_2$ complexes

The synthetic procedures for compounds **1** and **5** were based on those outlined in [18]. Structural data have now correctly identified **1**, but **5** has turned out to be a trinuclear complex, rather than the dinuclear complex proposed previously on the basis of elemental and spectroscopic data.

2.3. X-ray crystallography

The diffraction intensities of a green crystal of **1** were collected with graphite-monochromatized Mo-Kα X-radiation (rotating anode generator) using a Bruker P4/CCD diffractometer at 193(1) K to a maximum 2θ value of 52.8°. The data were corrected for Lorentz and polarization effects. The structure was solved by direct methods [20,21]. All atoms except hydrogens were refined anisotropically. Hydrogen atoms were placed in calculated positions with isotropic thermal parameters set to 20% greater than their bonded partners, and were not refined. Neutral atom scattering factors [22] and anomalous-dispersion terms [23,24] were taken from the

usual sources. All other calculations were performed with the teXsan [1] crystallographic software package using a PC computer. One tetrafluoroborate anion was found to have rotational disorder, and occupancy factors were set to averages of the refined values. The three fluorine atoms (occupancy 0.3) were refined isotropically, and all other non-hydrogen atoms were refined anisotropically. All aromatic hydrogen atoms were found and placed at ideal positions with riding thermal parameters. Hydrogen atoms on nitrogen atoms and those on water molecules were found and refined with riding positional and thermal parameters. Abbreviated crystal data are given in Table 1. **2** and **5** were treated in similar manner and crystal data are given in Table 1. For **2** hydrogen atoms (amino and hydroxyl) were introduced in calculated or difference map positions with isotropic thermal parameters set 20% greater than those of their bonding partners at the time of their inclusion. They were not refined. Of the four nitrates in the model two (N22, N23) are present at half occupancy and disordered. Nitrate N23 is also paired with a half occupancy disordered water molecule, and was fixed for the final round of refinement. For **5** hydrogen atoms were introduced in calculated or difference map positions, with isotropic thermal parameters set 20% greater than those of their bonding partners at time of their inclusion. Amine hydrogen atoms were placed in difference map positions and optimized by positional refinement, but fixed for the final round of refinement. Other hydrogen atoms were not refined. One BF_4^- ion is disordered over two sites, with what has been modeled as a partial occupancy water in close proximity. These atoms were fixed for the final round of refinement. A charge imbalance occurs in the expanded model, effectively associated with a missing fluoride ion. However, the acidic conditions used in the preparation of **5**, the neutral nature of the ligands, and the sensible elemental analysis suggests that an additional fluoride ion is present.

The diffraction intensities of a dark red-brown single crystal of **4** were collected with graphite-monochromated Mo Kα X-radiation using a Rigaku AFC6S diffractometer at 299(1) K and the ω–2θ scan technique to a 2θ value of 55.1°. The data were corrected for Lorentz and polarization effects. The structure was solved by direct methods and expanded using Fourier techniques [20,21]. Some non-hydrogen atoms were refined anisotropically, while the rest were refined isotropically. Hydrogen atoms were included but not refined. The final cycle of full-matrix least-squares refinement on F was based on 5722 observed reflections ($I > 2.00\sigma(I)$) and 797 variable parameters and converged (largest parameter shift was 0.01 times its esd) with unweighted and weighted agreement factors of: $R = 0.116$, and $R_w = 0.118$. The standard deviation of an observation of unit weight was 3.04. The weighting scheme was based on counting statistics and included a factor ($p = 0.007$) to downweight the intense reflections. The maximum and minimum peaks on the final difference Fourier map corresponded to 1.35 and −2.44 e$^-$/Å^3, respectively. Neutral atom scattering factors [22] and anomalous-dispersion terms [23,24] were taken from the usual sources. All calculations were performed with the teXsan [1] crystallographic software package using a PC computer. Hydrogen atoms were introduced in calculated or difference map positions with isotropic thermal parameters set 20% greater than those of their bonded partners at the time of their inclusion. They were not

[1] teXsan for Windows: Crystal Structure Analysis Package, Molecular Structure Corporation (1997).

refined. Hydrogen atoms have not been included on the lattice water molecules and one ligand amino group. Two nitrate anions were found to be loose and were fixed for the final round of refinement. The crystal studied diffracted weakly, with a low percentage of observed data. However, the essential features of the structure are clearly revealed. Abbreviated structural details for **4** are listed in Table 1.

3. Results and discussion

3.1. Structure of $[Ni(papH)_2(H_2O)_2](BF_4)_4$ (**1**)

The structure of the cation in **1** is shown in Fig. 1, and selected bond distances and angles are listed in Table 2. Two bidentate, protonated ligands are bound to an octahedral Ni(II) center, coordinating via adjacent pyridine and phthalazine nitrogen atoms. Two *cis*-water molecules fill the two remaining coordination sites. Ni–N and Ni–O distances (Ni–L 2.064–2.085 Å) are typical for Ni(II) complexes of this sort, and bond angles around the metal ion indicate only slight distortion from regular octahedral geometry. Proton H(61) located on the uncoordinated pyridine nitrogen N(6) appears to form an internal hydrogen bond to phthalazine nitrogen N(4) (H(61)–N(4) 1.833 Å; N(6)–H(61)–N(4) 139.1°), thus preventing metal ion coordination at this ligand site. The uncoordinated pyridine rings (e.g. N(6)) are close to coordinated pyridine rings (e.g. N(1_4), with an N–N separation of 3.855 Å, and equivalent C–C distances in the range 3.77–4.42 Å). They are not parallel, but their proximity, and the possible π interactions between the aromatic rings, may contribute to the stability of the unusual structural arrangement.

3.2. Structure of $[Ni_2(pap)_3(H_2O)_2](NO_3)_4 \cdot 5H_2O$ (**2**)

The structure of the dinuclear cation in **2** is shown in Fig. 2, and selected bond lengths and angles are listed in Table 3. Three neutral ligands are bound to two pseudo-octahedral *cis*-N_4O_2 nickel(II) ions, with one ligand coordinating in a tetradentate manner through two external pyridine nitrogen atoms, and the phthalazine N–N, which acts as a bridge between the metal centers. This ligand spans the dinuclear center with the pyridine rings arranged in a *trans* conformation relative to the two Ni(II) atoms. The other two ligands are bidentate

with one pyridine and one phthalazine nitrogen filling *cis* coordination positions at each nickel center. Two water molecules complete the triple bridging arrangement between the nickel atoms. Ni–N distances are in the range 2.043–2.083 Å, typical for systems of this sort. The Ni–O(H_2O) distances are much longer (2.109–2.139 Å), as expected for bond connections to neutral water molecules. The Ni(1)–Ni(2) distance is 3.126 Å, and Ni–O–Ni angles are 94.5° and 94.8° (O(2), O(1)). The presence of four nitrate groups in the lattice, and normal bonding distances within the ligands, confirms the assignment of O(1) and O(2) as water molecules, assuming that the nickel ions are Ni(II) (vide infra). This dinuclear $[(pap)_3Ni_2(H_2O)_2]^{4+}$ structural arrangement has been observed before in the complex $[Ni_2(pap)_3(H_2O)_2]Br_4 \cdot 3.5H_2O$ (**3**), which has been published in a preliminary form [19]. Ni–N and Ni–O distances are very slightly longer, with a Ni–Ni distance of 3.151(3) Å, and Ni–O–Ni angles of 94.3(4)° and 94.5(4)°.

The unusual dinuclear structure raises the question of why two ligands are bidentate, which is untypical of this class of compounds. Clearly, there are too many potential nitrogen donors (12) to be accommodated in a simple dinuclear structure and it begs the question as to whether a third metal can be accommodated (vide infra). However, some interesting structural features appear to have a stabilizing effect on the structure of **2**. Fig. 3 shows an alternate view with the superposition of some aromatic rings not fully involved in coordination. Very close cross ring contacts are observed between the phthalazine ring (N(3)–N(4)) and phthalazine ring N(15)–N(16) (N(4)–N(16) 3.020 Å, C(13)–C(49) 3.385 Å, C(6)–N(18) 3.360 Å, C(7)–C(50) 3.523 Å, C(12)–N(17) 3.555 Å), indicating significant π interactions between the rings, perhaps contributing to the stability of the structure.

3.3. Structure of $[Co_2(pap)_3(OH)_2](NO_3)_4 \cdot xH_2O$ (**4**)

The molecular structure of the cation in **4** is shown in Fig. 4, and selected bond distances and angles are listed in Table 4. The structure of the cation is similar to that of $[Co_2(pap)_3(OH)_2]Br_4 \cdot 9H_2O$ reported in an earlier publication in preliminary form [19]. Two Co(III) centers are bridged by two hydroxide ions, and the N–N fragment of a tetradentate pap ligand. Each Co(III) ion has a CoN_4O_2 coordination environment, with two bidentate ligands completing the coordination sphere. Co–L distances are quite short (1.89–1.96 Å) consistent with the Co(III) oxidation state. The Co(1)–Co(2) distance is consistently short (2.777(3) Å), with Co–O–Co angles of 93.3(5)° and 94.2(5)° (O(1), O(2), respectively). The 2:3 (metal:ligand) stoichiometry is the same as in **2**

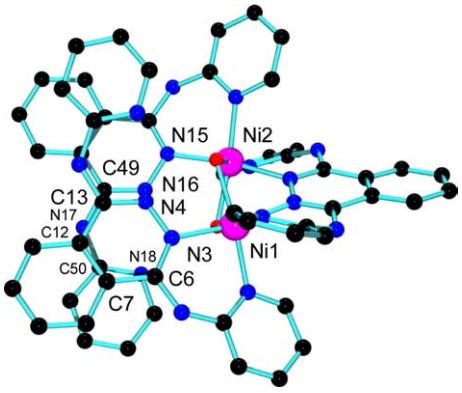

Fig. 3. Structural representation of the cation in **2** showing overlapping aromatic rings.

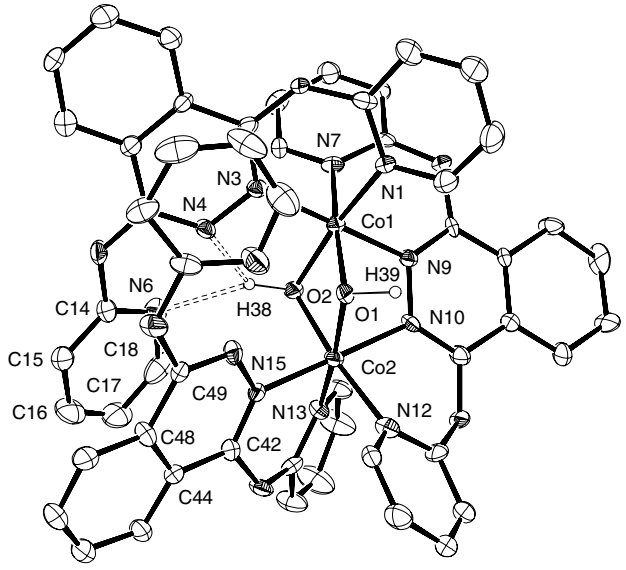

Fig. 4. Structural representation of the cation in **4** (40% thermal ellipsoids).

and **3**, with an almost identical structural arrangement. Structural features that stabilize the arrangement of ligands are similar to those in **2** and **3**. Proton H(38), bound to bridging oxygen O(2), is close to nitrogen atoms N(4) and N(6) on one bidentate ligand (H–N distances 1.832, 2.198 Å, respectively), and may provide a significant hydrogen bonding contact, and be partly responsible for stabilizing the structure. Overlapping aromatic ring components again appear to play an important structural role. Close contacts between phthalazine ring atoms N(15)–N(16) and the adjacent pyridine ring (N(6)) fall in the range 3.37–3.68 Å, clearly indicating significant π contacts across the rings, which contribute to the stability of the structure. A similar situation exists with the corresponding pair of rings in the other half of the molecule.

3.4. Structure of $[Ni_3(pap)_3(OH)_2](BF_4)_3F\cdot xH_2O$ (5)

The structure of the cation in **5** is shown in Fig. 5, and selected bond distances and angles are listed in Table 5. Three tetradentate ligands are bound to a triangular, trinuclear Ni(II) center, with the three nickel ions bridged externally by three phthalazine N–N diazine groups, and internally by two μ_3-OH groups. Three BF_4^- ions show up in the lattice, and given the neutral nature of the ligands (vide infra), and the fact that F^- ion was added in the reaction mixture to synthesize **5**, it is reasonable to assume that one of the residual peaks in the lattice can be assigned to fluoride, and that the bridging oxygen atoms are hydroxides. The cation has twofold symmetry through Ni(1), with Ni(1)–Ni(2) and Ni(2)–Ni(2′) distances of 3.027 and 2.998 Å, respectively. The Ni–N distances fall in the range 2.043–2.129 Å, slightly longer than in **2**, with Ni–O distances in the range 2.093–2.116 Å, shorter than in **2** and consistent with the presence of OH bridges. There are no unusually short Ni–N contacts, which would indicate any coordinated anionic sites due to proton loss from the ligands, and C–N distances to the exocyclic ligand nitrogen atoms are typical for C–N single bonds, thus indicating the neutral nature of the ligands.

The triangular core structure is shown in Fig. 6, highlighting the three N–N, and two μ_3-OH bridges. The three Ni(II) centers form a roughly planar triangle and the Ni–N–N-Ni torsional angles (19.8°, 22.4°) indicate that the $Ni_3(\mu_2\text{-N–N})_3$ ring is only slightly dis-

torted from a plane. The oxygen bridging atoms are displaced from this pseudo-plane, by virtue of the octahedral geometry at each nickel center, and the Ni(1)–O(1)–Ni(2), Ni(1)–O(1)–Ni(2′) and Ni(2)–O(1)–Ni(2′) angles (91.96°, 91.85°, and 91.34°, respectively) indicate significant pyramidal distortion at each oxygen bridge (solid angle 275.15°).

3.5. Magnetic properties

The mononuclear complex **1** has a room temperature moment of 3.13 μ_B, which drops slightly on cooling to 3.00 μ_B at 30 K, followed by a more pronounced drop to 2.37 μ_B at 2 K. This is typical behavior for a mononuclear Ni(II) complex with the low temperature drop associated with zero field splitting. Compound **4** has a magnetic moment of <1 μ_B in this temperature range, indicating the presence of low spin Co(III) centers, as expected based on the structural results. The variable temperature magnetic data for **2** are presented in Fig. 7 as χ_{mol}, and the sharp rise in χ as temperature is lowered to a maximum at 8 K signifies the presence of weak intra-molecular anti-ferromagnetic exchange between the Ni(II) centers. The data were fitted to an isotropic exchange expression based on the exchange Hamiltonian $H = -JS_1 \cdot S_2$ (Eq. (1)) within the software package MAGMUN4.0. [2] The spin state combinations and their

[2] MAGMUN4.0 is available free of charge from http://www.ucs.mun.ca/~lthomp/index.html. It has been developed by Dr. Zhiqiang Xu (Memorial University), in conjunction with Dr. O. Waldmann (waldmann@mps.ohio-state.edu). We do not distribute the source codes. The programs may be used only for scientific purposes, and economic utilization is not allowed. If the routine is used to obtain scientific results, which are published, the origin of the programs should be quoted.

$$H = -JS_1 \cdot S_2, \tag{1}$$

$$\chi_{M'} = \frac{N\beta^2 g^2}{3k(T-\theta)} \frac{\sum S'(S'+1)(2S'+1)\,e^{-E(S')/kT}}{\sum (2S'+1)\,e^{-E(S')/kT}}, \tag{2}$$

$$\chi_M = \chi_{M'}(1-\rho) + \frac{4S(S+1)N\beta^2 g^2 \rho}{3kT} + \mathrm{TIP}, \tag{3}$$

energies were permuted using normal vector summation methods [25] within the software and substituted into the van Vleck equation (2). Corrections were applied for paramagnetic impurity fraction (ρ), Weiss-like temperature factor (θ) and temperature independent paramagnetism (TIP) (Eqs. (2) and (3)). An excellent data fit

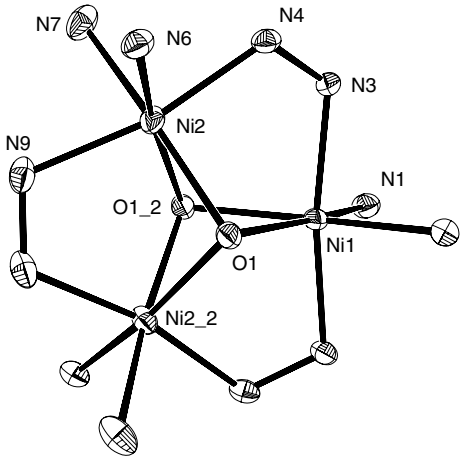

Fig. 6. Structural representation of the trinuclear core in **5** (30% thermal ellipsoids).

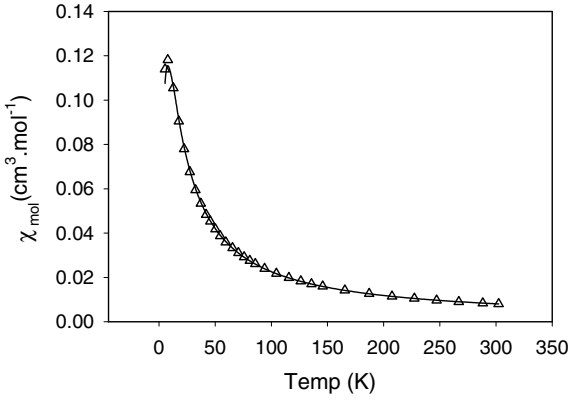

Fig. 7. Magnetic data for **2**. The solid line represents the best to Eq. (3), with $g = 2.169(3)$, $J = -5.25(9)$ cm^{-1}, $\rho = 0.014$, TIP $= 395\times10^{-6}$ cm^3 mol^{-1}, $\theta = -1$ K.

was obtained for $g = 2.169(3)$, $J = -5.25(9)$ cm^{-1}, $\rho = 0.014$, and TIP $= 395\times10^{-6}$ cm^3 mol^{-1} ($10^2R = 0.71$; $R = [\sum(\chi_{obs} - \chi_{calc})^2/\sum\chi^2_{obs}]^{1/2}$). The solid line in Fig. 7 was calculated with these values. The experimental susceptibility data for **3** are shown in Fig. 8, and correspond closely, as expected, with **2**. A similar data treatment for **3** gave $g = 2.206(1)$, $J = -4.88(2)$ cm^{-1}, $\rho = 0.008$, and TIP $= 440\times10^{-6}$ cm^3 mol^{-1} ($10^2R = 0.30$). Comparable J values are obtained, in agreement with the similarities in structure. Inclusion of zero field splitting terms in these analyses gave inferior data fittings, and so the magnetic data appear to be dominated mainly by exchange effects.

Magnetic data for **5**, plotted as μ_{mol}/temperature, are shown in Fig. 9, and the smooth drop in moment as temperature is lowered is indicative of quite strong antiferromagnetic exchange. The data were fitted using MAGMUN4.0 to an isotropic exchange expression based on the exchange Hamiltonian (Eq. (4)) for three $S = 1$ spin centers arranged in an equilateral triangle

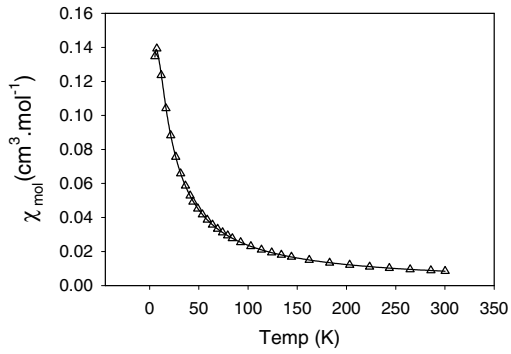

Fig. 8. Magnetic data for **3**. The solid line represents the best to Eq. (3), with $g = 2.206(1)$, $J = -4.88(2)$ cm^{-1}, $\rho = 0.008$, TIP $= 440\times10^{-6}$ cm^3 mol^{-1}, $\theta = 0$ K.

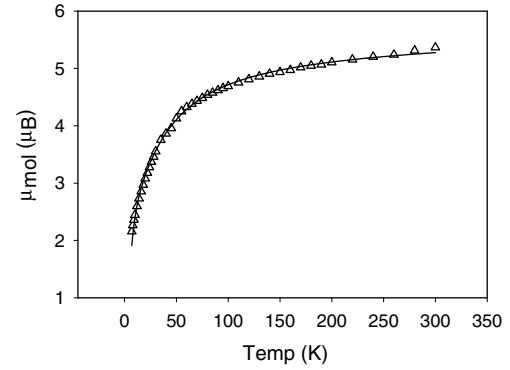

Fig. 9. Magnetic data for **5**. The solid line represents the best to Eq. (4), with $g = 2.214(6)$, $J = -15.7(4)$ cm^{-1}, $\rho = 0.05$, TIP $= 500\times10^{-6}$ cm^3 mol^{-1}, $\theta = -1$ K.

with a single J value. This combines the effects of the two different bridges which connect adjacent pairs of nickel centers. A good fit gave $g = 2.214(6)$, $J = -15.7$ cm^{-1}, $\rho = 0.05$, TIP $= 500\times10^{-1}$ cm^3 mol^{-1}, $\theta = -1$ K, $10^2R = 1.8$. The solid line in Fig. 9 was calculated with these parameters

$$H = -J\{S_{12} + S_{23} + S_{13}\}. \quad (4)$$

The magnetic properties of **2**, **3** and **4** are the result of the combination of the exchange effects of two different bridging groups connecting the Ni(II) centers. Since it is not possible to differentiate the contributions of two groups in the overall exchange process the J values obtained are the resultants of these combined effects. The exchange effects of phthalazine bridges have been studied widely in polynuclear copper(II) complexes, and it is generally accepted that coupling is always antiferromagnetic, with moderate $-2J$ values, e.g. 100–200 cm^{-1} [26]. In nickel chemistry there are few examples of systems with just phthalazine bridges, and a study by Ball and Blake on $[Ni_2(DHPH)_2(H_2O)_4]X_4$ (X = Cl, Br, I; DHPH = 1,4-dihydrazino-phthalazine) involving a double bridged $Ni_2(\mu\text{-N–N})_2$ dinuclear center, led to $-J$

values in the range 20–25 cm^{-1} ($H = -2JS_1 \cdot S_2$) [27]. For an analogous di-copper(II) system $[Cu_2(DHPH)(H_2O)_2(ClO_4)_2](ClO_4)_2$ a much larger exchange integral was observed ($-2J = 489\ cm^{-1}$) [28].

Hydroxide bridges are renowned for their ability to propagate exchange coupling between metal ions, e.g. copper(II), with an exchange dependence on bridge angle between the active metal magnetic orbitals, and magneto-structural correlations on a range of related complexes have shown that for Cu–O–Cu angles >97.5° anti-ferromagnetic coupling is observed, while ferromagnetic exchange occurs at smaller angles [29,30]. Magneto-structural correlations for H_2O bridged systems appear not to have been studied. The small Ni–O–Ni angles in **2** and **3** (94.3°–94.8°) might suggest that the water bridges could be responsible for a ferromagnetic exchange component in comparison with hydroxide. However, the phthalazine bridge is likely to have a dominant anti-ferromagnetic effect, and so the small $-J$ values observed for **2** and **3** (4.88, 5.25 cm^{-1}) could well be the resultant of two antagonistic exchange effects. The Ni–OH–Ni bridge angles in **5** are even smaller (91°–92°), and might again be candidates for a ferromagnetic exchange contribution. However, the larger exchange coupling in **5** indicates that efficient N–N phthalazine bridging must again dominate the exchange situation.

4. Conclusions

The ligand pap shows considerable versatility in its coordination chemistry with Ni(II) and Co(III), with examples of mononuclear, dinuclear and trinuclear complexes. The dinuclear and trinuclear Ni(II) complexes are bridged by combinations of N–N (phthalazine) and water and hydroxide bridges, respectively, with magnetic properties that result from a combination of two bridging interactions. All examples are anti-ferromagnetically coupled.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 232257–232260. Copies of this information may be obtained free of charge from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk; www: http://www.ccdc.cam.ac.uk).

Abstract

Crystal structures of organosulfur donor 2-(5′,6′-dihydro[1,3]dithiolo[4,5-b][1,4]-dithiin-2′-ylidene)-6,7-di-hydro-5H-[1,3]dithiolo[4,5-b][1,4]dithiepine-6,6-dimethanol (**D**) and its conducting salt $\mathbf{D}_2\mathrm{I}_3$ are described. Conductivity properties of $\mathbf{D}_2\mathrm{I}_3$ are also discussed.

Keywords: Radical salts; Bis(ethylenedithio)tetrathiafulvalene (ET); Crystal structures; Electrical conductivity

1. Introduction

The radical cation salts based on bis(ethylenedithio)tetrathiafulvalence (ET) are the major class of organic quasi-two-dimensional metals and superconductors [1]. Their conductive properties are highly sensitive to chemical modifications of the ET framework, and considerable efforts have been devoted to the search for molecular superconductors presenting higher critical temperatures (T_c) by the synthetic chemistry methods [2–4]. Most of these chemical modifications were aimed to increase the dimensionality of these materials which can suppress the Peierls distortions at low temperature by favoring the intermolecular interaction among electron donors and acceptors (or counter anions). To introduce the possibility of strong hydrogen bonding some ET derivatives with hydroxy groups have been synthesised [5–9].

We report here the crystal structures of the title donor **D** (Fig. 1) and its conducting salt $\mathbf{D}_2\mathrm{I}_3$.

2. Experimental

2.1. Materials and equipment

Unless stated otherwise, all reagents were purchased from commercial sources and used without additional purification. Organosulfur donor (**D**) and the supporting electrolyte n-$\mathrm{Bu_4NI_3}$ were prepared according to literature procedures [6,10]. Conductivity was measured by the four-probe technique on a compressed pellet.

2.2. Synthesis of $\boldsymbol{D_2I_3}$

The conducting salt $\mathbf{D}_2\mathrm{I}_3$ was obtained by electrocrystallization. Single crystals were grown on a platinum wire anode as brown thin plates by anodic oxidation of **D** in the presence of n-$\mathrm{Bu_4NI_3}$ at constant low-current density (1 $\mu\mathrm{A\,cm^{-2}}$) in $\mathrm{CH_3CN}$.

2.3. Crystallography

Intensity measurements were collected on a Stoe Image Plate Diffraction System [11] for donor **D** and a Stoe Mark II-Image Plate Diffraction System [12] for its salt $\mathbf{D}_2\mathrm{I}_3$, equipped with graphite monochromated Mo

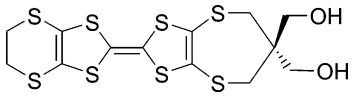

Fig. 1. Organosulfur donor **D**.

Kα radiation ($\lambda = 0.71073$ Å) using the $\omega - 2\theta$ scan technique. The structures were solved by Direct methods using the programme SHELXS 97 [13]. The refinement and all further calculations were carried out using SHELXL 97 [14].

For donor **D**, the H-atoms were either located from Fourier difference maps and refined isotropically or included in calculated positions and treated as riding atoms using SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. The crystal diffracted weakly and only 1/3 of the reflections can be considered to be observed [$I > 2\sigma(I)$]. Owing to the extremely long *b*-axis, a certain fraction of the reflections (ca. 12%) was overlapped and eliminated from the *hkl* file. The molecule is structurally disordered, with the terminal $-C_2H_4$ group having two conformations.

For its salt $\mathbf{D}_2I_3$, the hydrogen atoms were included in calculated positions and treated as riding atoms using SHELXL 97 default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. An absorption correction was applied using DIFABS [15] ($T_{min} = 0.325$, $T_{max} = 0.755$).

3. Results and discussion

3.1. Structure of *D*

Organosulfur donor **D** was recrystallised from THF/CH_3CN to afford single crystals. The X-ray crystal analysis revealed that in the crystal lattice, the molecules are linked by a 1D polymer arrangement of some conventional O–H···O hydrogen bonds (Table 3), so forming zig-zag chains along the *b*-axis (Fig. 2). The donor molecules are quasi-parallel caused by asymmetric hydrogen-bonds and mutually shifted with interplanar distances of 4.17 Å and stacked along the *c*-axis. There are intermolecular S···S contacts in the range of 3.29–3.60 Å.

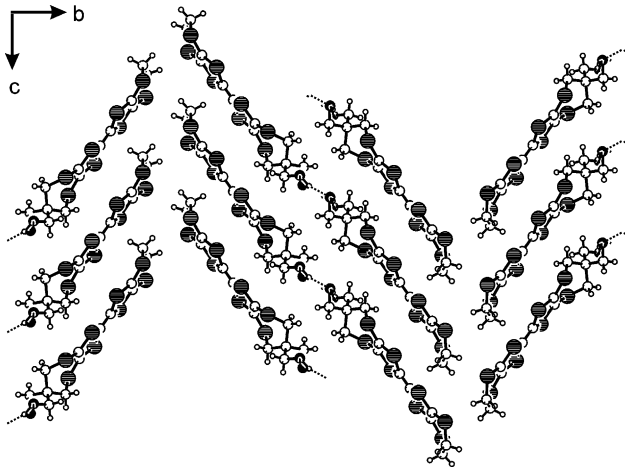

Fig. 2. Crystal packing of the neutral donor **D** showing hydrogen bonding (dashed lines) between stacks.

3.2. Synthesis, conductivity properties and structure of D_2I_3

In order to obtain the conducting salts of **D**, standard electrocrystallizations were examined in the presence of various tetrabutylammonium (TBA) salts as the electrolyte: these included linear (I_3^-), tetrahedral (ClO_4^-), and octahedral (PF_6^-) anions. However, only the electrocrystallization at a constant current (1.0 μA) in CH_3CN with TBA· I_3 gave crystalline salts as brown thin plates. The room-temperature conductivity measured by a four-probe technique on a compressed pellet showed a relatively high conductivity ($\sigma_{rt} = 2.95$ S cm^{-1}). The temperature dependence of the resistivity is shown in Fig. 3. From room temperature to about 240 K, its electrical resistance varies very little. But when the temperature is lowered further, the electrical resistance increases strongly, showing semiconducting behaviour with the activation energy being about 0.35 eV.

Table 3
Hydrogen bonds (Å, °) for donor **D**

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	D–H···A (°)
O(2)–H(2)···O(1)^{i}	1.05(11)	1.85(11)	2.884(10)	170(11)
O(1)–H(1)···O(2)^{ii}	1.00(13)	1.76(13)	2.719(11)	159(12)

Symmetry transformations used to generate equivalent atoms: (i) $1x-1,\ y,\ z$; (ii) $-x+2,\ -y,\ -z+1$.

The X-ray analyses showed that the charge-transfer complex D_2I_3 crystallises with two positively charged donor molecules A and B and one disordered I_3^- anion per asymmetric unit (Fig. 4). The molecular structures of the two donor units (A and B) are only slightly different. For both units A and B in the salt, the central TTF units are coplanar with deviations from the least-squares plane being less than 0.047 Å. Apparently, in the oxidation state the TTF units show less deviations from planarity

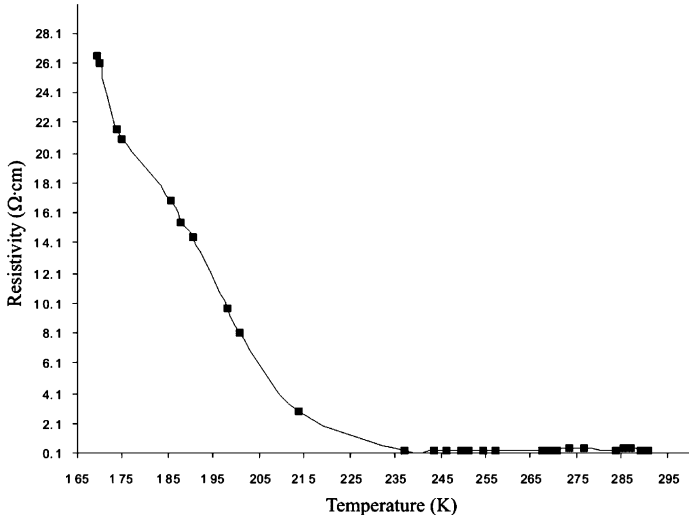

Fig. 3. Temperature dependence of the resistivity for D_2I_3.

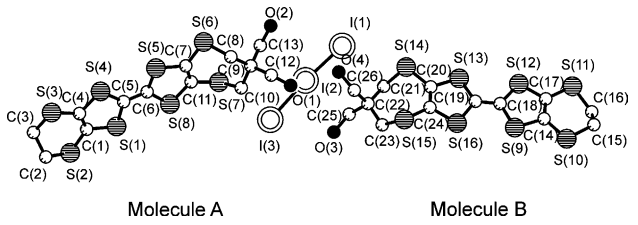

Fig. 4. Crystal structure of the conducting salt $\mathbf{D}_2\mathrm{I}_3$. Hydrogen atoms are omitted for clarity.

than those in the neutral state (largest deviation is 0.064 Å). The bond lengths of the central C=C [C(5)–C(6); C(18)–C(19)] bonds are 1.416 and 1.370 Å, respectively, in the salt (Table 2). As compared to that of the neutral donor **D** (1.325 Å), it can be inferred that the TTF units in salt $\mathbf{D}_2\mathrm{I}_3$ are partially oxidised according to the correlation between the oxidation states of TTF derivatives and bond lengths of the central C=C bonds [16]. As depicted in Fig. 5, the donor molecules are dimerised in 'head-to-head' manner, which might increase the effective overlap area of the molecules and stabilise the electronic state with van der Waals attractive force [17]. Dimers are orthogonally arranged to each other along the *b*-axis. The dihedral angles between the molecules are 84.6° and 72.3° for pairs A–A and B–B, respectively. The donor array of the present salt is classified as the so-called κ-type. There are S···S contacts (3.46–3.62 Å, sum of van der Waals radii 3.70 Å) and weak hydrogen bonds (C–H···S = 3.49–3.76 Å and C–H···O = 2.84–2.91 Å) between neighboring dimers. Whereas between A and B stacks, some conventional O–H···O hydrogen bonds with 1D polymer arrangement (Table 4 and Fig. 5), a short S···I contact (3.63 Å) and weak hydrogen bonds C–H···I (3.74–3.95 Å) are observed.

In both **D** and $\mathbf{D}_2\mathrm{I}_3$, no intramolecular hydrogen bonds are observed which can be explained by strong competition of bimolecular ring motifs [18]. The hydrogen bond pattern in these two compounds is different, as shown by the graph-set analysis following the accepted proposition of Etter et al. [19]. In donor **D**, one kind of hydrogen bond gives rise to chains and two other different kinds of hydrogen bond give rise to rings, which form a higher-order network. Therefore, the graph-set for **D** is $C(6)\ R_4^4(8)\ R_2^2(12)\ R_4^4(16)$. Whereas in its salt, $\mathbf{D}_2\mathrm{I}_3$, one kind of hydrogen bond gives rise to chains and another kind of hydrogen bond gives rise to a ring, two of which make up a higher-order network. Thus, the graph-set for $\mathbf{D}_2\mathrm{I}_3$ is $C(6)\ R_3^3(10)\ R_4^4(16)$.

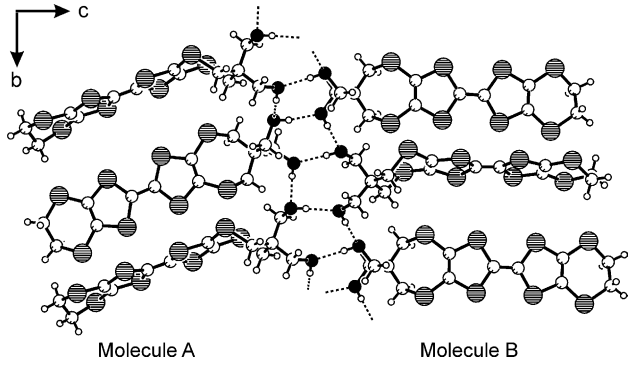

Fig. 5. Crystal packing of the conducting salt $\mathbf{D}_2\mathrm{I}_3$ showing hydrogen bonding (dashed lines). I_3^- anions are omitted for clarity.

4. Conclusions

In conclusion, the title donor has yielded a conducting salt $\mathbf{D}_2\mathrm{I}_3$ and shows a unique crystal structure. Thus, compound **D** can be expected to be a suitable donor for exploring organic metals in the future.

5. Supplementary material

Crystallographic data for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 218114–218115 for compounds **D** and $\mathbf{D}_2\mathrm{I}_3$. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Reaction of 2,6-bis(phenylhydrazone)pyridine with $Ln(NO_3)_3 \cdot 6H_2O$ nitrate (Ln = Y, Pr, Sm and Er) produces mononuclear complexes. The crystal structures of $[Ln(C_{23}H_{19}N_5O_2)(H_2O)(NO_3)]$ (Ln = Y or Er) and $\{[Ln(C_{23}H_{19}N_5O_2)(C_{23}H_{20}N_5O_2)](H_2O)_2((CH_3)_2SO)\}$ (Ln = Pr or Sm) were determined. Coordination of the dianionic and the monoanionic ligands in the complexes is via the pyridyl nitrogen, hydrazino nitrogen and iminol oxygen. The crystal structures were determined.

In the isostructural complexes (Ln = Y, Er) the lanthanide ion have exactly the same coordination, being an irregular polyhedron with coordination number of eight.

In the isostructural complexes (Ln = Pr, Sm) the lanthanide ion assumes a ten co-ordinated geometry for both metal ions. The coordination polyhedron around each lanthanide atom in both complexes is best described as a distorted bicapped square antiprism.

1. Introduction

Owing to the ramifying applications of the lanthanides macrocyclic complexes in applied and fundamental sciences, this field continues to receive much attention. They are used as catalysts [1] in transesterification, as radiopharmaceuticals [2] and as fluoroimmuno assay reagents [3,4]. Certain Eu(III) and Nd(III) complexes have been reported to have laser property [5].

Our research interest in the synthesis and the study of the physicochemical properties of lanthanides(III) complexes derived from macroacyclic ligand molecules with N_5O_2 inners. We have recently reported the synthesis of lanthanides complexes of a N_3O_2 ligand [6].

The lanthanide in their trivalent state, complexes with strongly chelating species containing highly electronegative donors atoms [7,8]. 2,6-diacetylpyridine and benzoylhydrazide possesses potential nitrogen and oxygen donors. They can interact together to form 2,6-diacetylpyridine-bis-(benzoylhydrazone) which can acts with metal ion to form stable complexes [9,10].

In view of these facts, reaction of some lanthanides nitrates and 2,6-diacetylpyridine-bis-(benzoylhydrazone) has been carried out and structures of the resulting complexes were investigated using spectroscopic techniques and X-ray diffraction. The results of this study are reported in this present paper.

2. Experimental

2.1. Reagents materials

All chemicals and solvents used were of reagent grade. All metal(III) salts were used as nitrates. NMR spectrum was recorded on a Bruker 400 spectrometer, infrared spectra were recorded on a Nicolet 5SXC FT-IR spectrophotometer using KBr pellets or Nujol mulls. Elemental analysis of C, H and N was performed by the analytical laboratory of the Department of Inorganic Chemistry (University of Padua, Italy). Molar conductance measurement was made using a WTW LF-330 conductivity meter with a WTW conductivity cell on about 1 mmol dm^{-3} dimethylformamide solution at room temperature. Room temperature magnetic susceptibility measurements were made on solid complexes using a Johnson Mattey balance with $Hg[Co(SCN)_4]$ as the calibrator. Melting point were recorded on a Büchi apparatus and are uncorrected.

2.2. Preparation of the Schiff base (H_2L)

To a solution of 2,6-diacetylpyridine (1.63 g, 10 mmol) in 60 ml of methanol was added a solution of benzoylhydrazine (2.72 g, 20 mmol) in 10 ml of the same solvent. Two drops of glacial acetic acid were added and the resulting mixture was refluxed under stirring for 2 h. On cooling the white precipitate, which appeared, was filtered off, washed with 2×10 ml of methanol and 2×20 ml of ether before dried under vacuum. The yield is 93%, m.p. 224 °C. *Anal.* Calc. for $C_{23}H_{21}N_5O_2 \cdot 1/2H_2O$. C, 67.63; H, 5.43; N, 17.15. Found: C, 67.49; H, 5.65; N, 17.26%. Mass spectrum (EI): $m/z = 408$ ($[C_{23}H_{21}N_5O_2 \cdot 0.5H_2O]^+$). IR ($cm^{-1}$, Nujol mulls) $\nu_{C=N}$ 1667; ν_{N-N} 1018. ^1H NMR ($(CD_3)_2SO$, 400 MHz): 2.55 (s, 6H), 7.7 (m, 13 H), 10.9 (s, 2H) ppm. ^{13}C NMR ($(CD_3)_2SO$, 75 MHz): 12.54, 120.58, 128.35, 131.65, 134.10, 137.24, 154.30.

2.3. Preparation of [Y(L) (H_2O)(NO_3)] (1)

To a suspension of H_2L (2 mmol) in absolute ethanol (20 ml) was added $Y(NO_3)_3 \cdot 6H_2O$ (2 mmol) in 10 ml of absolute ethanol. The white suspension turns to yellow immediately. After 20 min under stirring a solution of LiOH (4 mmol) in 5 ml of absolute ethanol was added. The yellow precipitate disappears and the solution was refluxed for two hours. On cooling the deep yellow precipitate, which was formed, was filtered off, washed with 2×10 ml of absolute ethanol and dried under vacuum (yield, 78%). Crystals suitable for X-ray analysis were grown by dissolving 0.5 g of this compound in minimum amount of dimethylsulfoxide (4–5 cm^3) to yield a saturated solution. The resulting solution was allowed to evaporate slowly at room temperature for several days to yield fine crystals. *Anal.* Calc. for $YC_{23}H_{21}N_6O_6$ C, 48.78 (48.73), H, 3.74 (3.73), N, 14.84 (14.82)%. IR (cm^{-1}, Nujol mulls) ν(C=N) 1645, ν(N–N) 1018, $\nu(NO_3^-)$ 1453, 1307, 1032, $\Delta\nu$ 146, $\nu(H_2O)$ 3225. Λ_M (S cm^2 mol^{-1}), 23 (dmf solution).

2.4. Preparation of [Er(L)(H_2O)(NO_3)] (2)

Complex **2** was prepared in the form of yellow powder as described for **1**. Crystallization from dimethylsulfoxide solution gave crystal suitable for X-ray analyses. The yield is 79%. *Anal.* Calc. for $ErC_{23}H_{21}N_6O_6$ C, 42.85; H, 3.28; N, 13.03. Found: C, 42.82; H, 3.25; N, 13.01%. IR (cm^{-1}, Nujol mulls) ν(C=N) 1639, ν(N–N) 1018, $\nu(NO_3^-)$ 1450, 1303, 1032, $\Delta\nu$ 147, $\nu(H_2O)$ 3225 ; $\mu_{eff} = 9.72$ μ_B; $\Lambda_M = 72$ S cm^2 mol^{-1}.

2.5. Preparation of {[Pr(HL)(L)](H_2O)$_2$($(CH_3)_2SO$)} (3)

To a solution of H_2L (2 mmol) in absolute ethanol (20 ml) was added $Pr(NO_3)_3 \cdot 6H_2O$ (1 mmol) in 10 ml of absolute ethanol. The white suspension turns to yellow immediately. After 20 min under stirring a solution of LiOH (3 mmol) in 5 ml of absolute ethanol was added. The yellow precipitate disappears and the solution was refluxed for two hours. On cooling no precipitate was observed. A yellow solid was obtained after slow evaporation. Crystallization from dimethylsulfoxide solution gave crystal suitable for X-ray analyses. The yield is 70%. *Anal.* Calc. for $PrC_{48}H_{49}N_{10}O_7S$ C, 54.86; H, 4.70; N, 13.33; S, 3.05. Found: C, 54.83; H, 4.68; N, 13.29; S, 3.08%. IR (cm^{-1}, Nujol mulls) $\nu_{C=N}$ 1645; ν_{N-N} 1018 ; $\mu_{eff} = 3.20$ μ_B; $\Lambda_M = 34.3$ S cm^2 mol^{-1}.

2.6. Preparation of {[Sm(HL)(L)](H_2O)$_2$($(CH_3)_2SO$)} (4)

Complex **4** was prepared in the form of yellow powder as described for **3**. Crystallization from dimethylsulfoxide solution gave crystal suitable for X-ray analyses. The yield is 72%. *Anal.* Calc. for $SmC_{48}H_{49}N_{10}O_7S$ C, 54.37; H, 4.66; N, 13.21; S, 3.02. Found: C, 54.34; H, 4.63; N, 13.17; S, 3.04%. IR (cm^{-1}, Nujol mulls) $\nu_{C=N}$ 1637; ν_{N-N} 1018; $\mu_{eff} = 1.67$ μ_B; $\Lambda_M = 25.4$ S cm^2 mol^{-1} (see Table 1).

2.7. X-ray data collection and reduction

Yellow crystals of [Y(L)(H_2O)(NO_3)], [Er(L)(H_2O)-(NO_3)], {[Pr(HL)(L)](H_2O)$_2$($(CH_3)_2SO$)} and {[Sm(HL)-(L)](H_2O)$_2$($(CH_3)_2SO$)} obtained by slow evaporation of dimethylsulfoxide were mounted on glass fibers and used for data collection. Data were collected on CAD 4 diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å).

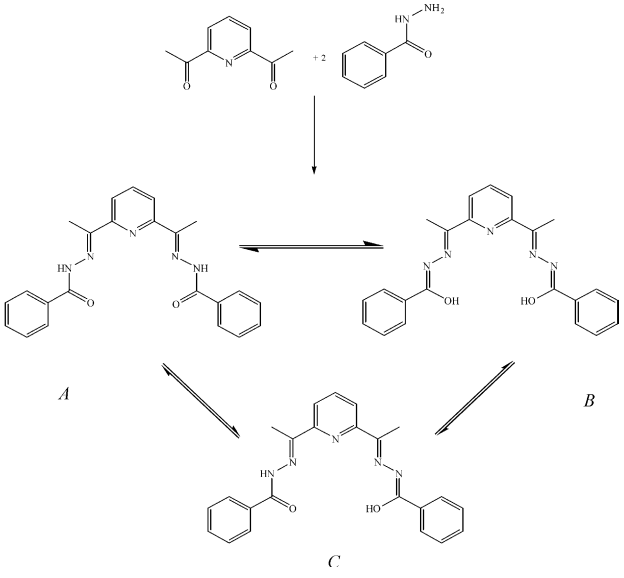
The structure were solved by direct methods which revealed the positions of all non-hydrogen atoms, and refined on F^2 by full-matrix least-square procedure using anisotropic displacement parameters. Molecular graphics are from PLATON or ORTEP.

3. Results and discussion

3.1. Formation of the Schiff base

H_2L (2,6-diacetylpyridine-bis-(benzoylhydrazone)) was prepared according to the Scheme 1. N_3O_2 Schiff base was obtained from the condensation of 2,6-diacetylpyridine and two equivalent of benzoylhydrazide. The resulting compound is insoluble in ethanol and methanol. The ^{1}H and ^{13}C NMR data for the Schiff base, the analytical and spectral data are consistent with the proposed structure. Infrared spectra of the compound show the appearance of some bands in the region 1700–1600 cm^{-1} characteristic of the amide (N–C=O) and the imine (C=N) bonds in the Schiff base and a band at 1018 cm^{-1} characteristic of N–N vibrations. The ^{1}H NMR data show the appearance of **H**O–C(=N)–Ph hydrogen resonance at 10.9 ppm which suggested the transformation of the amide groups in iminol groups in solution (Scheme 1). This is confirmed by the infrared data. No band characteristic of HO bending vibrations was observed in the solid state.



Scheme 1. The three isomeric forms in solution of the ligand H_2L.

3.2. Characterization and spectroscopic studies

The mononuclear Ln(III) complexes were prepared by mixing equimolecular amount of penta or hexahydrated lanthanide nitrate salts and 2,6-diacetylpyridine-bis-(benzoylhydrazone) (H_2L) in absolute ethanol at reflux. H_2L results from the 1/1 Schiff base condensation of 2,6-diacetylpyridine with benzoylhydrazide in ethanol. The immediate color change of the H_2L solution upon addition of the $Ln(NO_3)_3$ and LiOH indicated instant occurrence of the formation of the complex. For Er^{3+} and Y^{3+} most of the compound precipitated out during refluxing and stirring. Unlike the lanthanide complexes of Sm^{3+} and Pr^{3+} had considerable solubility in hot ethanol. The yields are quite high for the lanthanide complexes (70–85%). The elemental analyses of the complexes were consistent with the composition of $[Ln(L)(H_2O)(NO_3)]$ for Y and Er and $\{[Ln(L)(HL)](H_2O)_2((CH_3)_2SO)\}$ for Pr and Sm where HL denotes a monodeprotonated ligand and L a dideprotonated ligand molecules. All the complexes are characterized by elemental analysis, infrared study, molar conductance, magnetic measurements and X-ray crystallography.

All complexes show a strong IR band in the region 1650–1630 cm^{-1} assigned to the ν(C=N) vibration. In the spectra of **1** and **2** the bands at ca. 3225 and 820 cm^{-1} are characteristic of co-ordinated water molecules [11]. In the spectra of **3** and **4** the broad band of medium intensity occurring in the range 3450–3380 cm^{-1} is due to the stretching vibration of the HO of the lattice water molecules. All the spectra show band at 1580 cm^{-1} as expected for the highest-energy pyridine ring vibration. The weak band of moderate intensity at 1018 cm^{-1} is due to the N–N vibrations [12]. Comparison to the literature values of IR data gives information regarding to the possible bonding modes of the nitrate anion. The bands in the range 1420–1460 cm^{-1} (ν5), at ca. 1305 cm^{-1} (ν1) and at ca. 1032 cm^{-1} (ν2) clearly identify the nitrates as co-coordinated species in the complexes **1** and **2** [13]. The molar electrical conductivity was measured in dimethylformamide for freshly prepared solution and after standing for two weeks. The values are quite constant for all the complexes. No replacement of a co-coordinated site by dmf molecules was observed. The Λ_M values of the complexes **3** is higher than the expected value for a 2:1 electrolyte and those of complexes **1**, **2** and **4** are consistent with the expected value for a 1:1 electrolyte [14]. The μ_{eff} of the lanthanide complexes show that these are paramagnetic except for the complex **1** which is diamagnetic in nature. This paramagnetic behaviour is consistent with the presence of unpaired 4f electrons. The observed μ_{eff} values are close proximity of the values for the free metal ions reported by Van Vleck and Frank [15]. These observations suggest that the 4f electrons of the lanthanide(III) do not take part in bond formation in these species.

3.3. Crystal structures of $[Y(L)(H_2O)(NO_3)]$ and $[Er(L)(H_2O)(NO_3)]$

In the reaction of 2,6-diacetylpyridine-bis-(phenylhydrazone) with yttrium(III) or erbium(III) nitrate, the two iminol protons are exchanged. The coordination of the hydrazone to lanthanide(III) results in the formation of five membered (two LnOCNN and two LnNCCN) chelating rings in which the lanthanide ion is eight coordinated. The complexes **1** and **2** crystallized in monoclinic space group $P2_1/n$. Each unit cell contains four molecules. ORTEP drawing with the atoms numbering scheme for $[Y(L)(HL)(H_2O)(NO_3)]$ and $\{[Er(L)(HL)(H_2O)(NO_3)]$ are shown in Figs. 1 and 2. Relevant interatomic distances and angles are given in Table 2. The coordination polyhedron is described by one nitrate group coordinated as bidentate, five donors atoms (two iminolic oxygen and three nitrogen) of the ligand and one coordinated water molecule. The five angles involving adjacent equatorial atoms namely O1–Y–O2, O2–Y–N2, O1–Y–N4, N1–Y–N2 and N1–Y–N4 are not differ notably, being 100.94(14)°, 165.59(15)°,

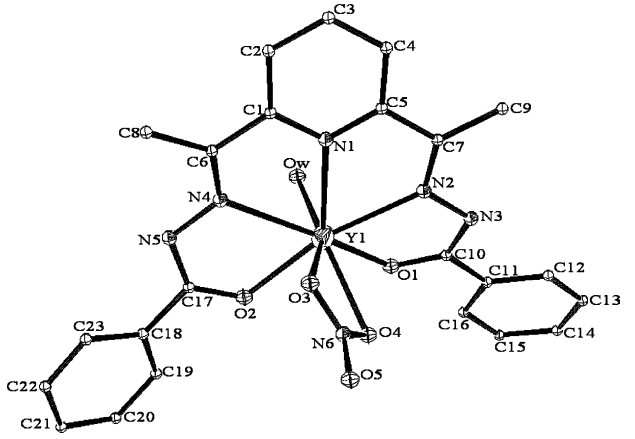


Fig. 1. ORTEP drawing of $[Y(L)(NO_3)(H_2O)]$ with atom numbering scheme.

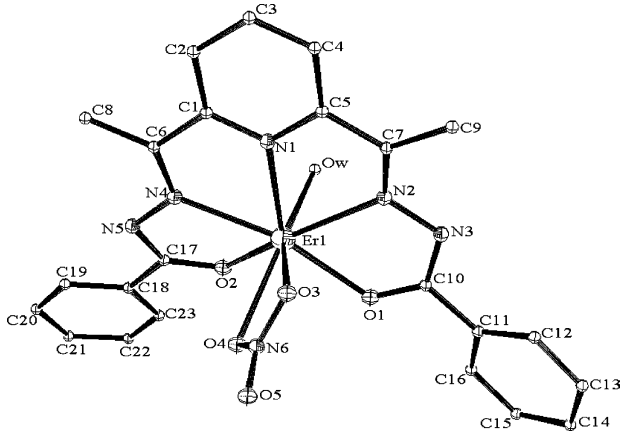

Fig. 2. ORTEP drawing of $[Er(L)(NO_3)(H_2O)]$ with atom numbering scheme.

Table 2
Selected bond distances (Å) and angles (°) for complexes **1** and **2**

Bond	Ln = Y	Ln = Er	Angle	Ln = Y	Ln = Er
O1–C10	1.286(7)	1.282(12)	O2–Ln–N2	165.59(15)	155.6(2)
O2–C17	1.290(7)	1.296(11)	O3–Ln–O4	51.80(14)	52.0(2)
N2–C7	1.297(7)	1.286(12)	O2–Ln–N4	65.58(15)	66.1(2)
N3–C10	1.321(7)	1.332(13)	N2–Ln–N4	128.83(16)	129.5(3)
N4–C6	1.297(8)	1.283(12)	O1–Ln–N1	126.61(15)	130.9(3)
N5–C17	1.335(8)	1.327(12)	O2–Ln–N1	130.11(15)	127.2(3)
O3–N6	1.278(6)	1.270(10)			
O4–N6	1.258(6)	1.258(10)			
O5–N6	1.229(6)	1.228(10)			

156.69(15)°, 64.28(16)° and 64.60(15)°, respectively, (O1–Er–O2, O2–Er–N2, O1–Er–N4, N4–Er–N3 and N2–Er–N3 are 99.5(2)°, 155.6(2)°, 164.5(3)°, 65.0(3)° and 64.5(3)°, respectively). Four types of Ln-ligand interatomic distances have been found: Y–O (hydrazonic) 2.265(4) and 2.268(4) Å, (Er–O (hydrazonic) 2.252(7) and 2.267(7) Å), Y–N (hydrazonic) 2.429(5) and 2.468(5) Å (Er–N (hydrazonic) 2.418(8) and 2.450(8) Å), Y–O (nitrate) 2.449(4) and 2.463(4) Å (Er–O (nitrate) 2.447(7) and 2.449(8) Å) and Y–O (H_2O) 2.330(4) Å (Er–O (H_2O) 2.318(7) Å). As found in the infrared study the nitrate acts as bidentate in both complexes [3].

According to the infrared and NMR data of the 2,6-diacetylpyridine-bis-(benzoylhydrazone) the imine group (O=C–NH) is transformed in iminol group in solution (**HO**–C(=N)). In solution the ligand acts with the lanthanide ion in his iminol form. In both complexes the C10–N3 and C17–N5 distances are consistent with a double bond while the C10–O1 and C17–O2 distances are consistent with a single bond.

3.4. Crystal structures of {[Pr(HL)(L)](H₂O)₂((CH₃)₂SO)} and {[Sm(HL)(L)](H₂O)₂((CH₃)₂SO)}

In both complexes, the lanthanide(III) ion has a coordination number of ten binding the two imines nitrogen, the pyridine nitrogen and the two anionic oxygen of one ligand molecule and the two imines nitrogen, the pyridine nitrogen, the one anionic oxygen and the one neutral oxygen of the other ligand molecule.

The complexes **3** and **4** crystallized in orthorhombic space group $Pn2_1a$. Each unit cell contains four molecules. ORTEP drawing with the atoms numbering scheme for {[Pr(L)(HL)](H_2O)$_2$((CH_3)$_2$SO)} and {[Sm(L)(HL)](H_2O)$_2$((CH_3)$_2$SO)} are shown in Figs. 2 and 3. Relevant interatomic distances and angles are given in Table 3. The lanthanides ions are ten-coordination in the complexes. In addition to the three anionic oxygen, Ln(III) complete their coordination spheres with six neutral nitrogen from the ligand molecules and one neutral oxygen. The dmso and the water molecules was not linked to the metal ion. The coordination of the hydrazone to Ln results in the formation of five membered (two LnOCNN and two LnNCCN) chelating rings. In the two complexes the Ln–N(pyridine) bonds are the largest metal-ligand distances (Pr–N1 is 2.715(10) and Pr–N6 is 2.733(11) Å) while Sm–N1 and Sm–N6 are 2.697(16) and 2.707(16) Å, respectively. The Ln–N bonds involving the hydrazone's nitrogen are essentially equal (2.595(10), 2.661(10), 2.667(10) and 2.673(12) Å for {[Pr(L)(HL)](H_2O)$_2$((CH_3)$_2$SO)}; 2.562(16), 2.629(15), 2.645(19) and 2.650(2) Å for {[Sm(L)(HL)](H_2O)$_2$((CH_3)$_2$SO)}. The Ln–O bonds involving the hydrazonic oxygen are in the range (2.376–2.680 Å) and are comparable in the two complexes.

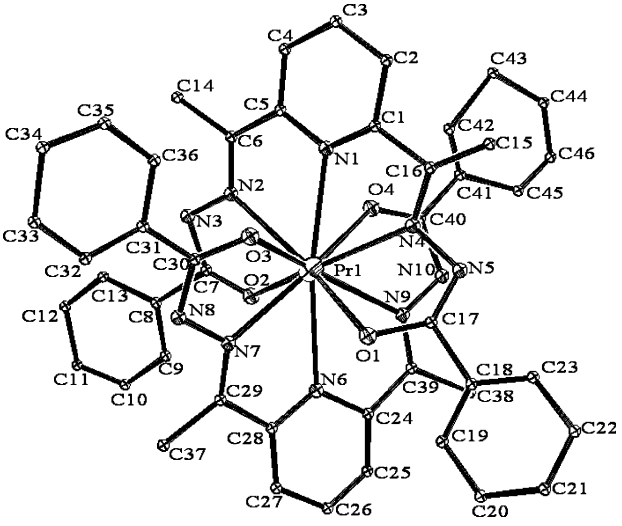

Fig. 3. ORTEP drawing of [Pr(L)(HL)] with atom numbering scheme, H_2O and (CH_3)$_2$SO) are omitted for clarity.

In praseodymium complex one ligand molecule have two ionic oxygen while the other one have one neutral oxygen and one ionic oxygen. The C7–O2, C17–O1 and C30–O3 distances are consistent with a single bond while the C7–N3, C17–N5 and C30–N8 distances are consistent with a double. The remaining bond distances of the hydrazone moiety, as well as C40–N10 and C40–O4 are consistent with a single and a double bond, respectively. In the case of the samarium complex the C17–O1 distance appears to be consistent with a double bond; both ligand molecules present one neutral oxygen and one ionic oxygen.

Table 3
Selected bond distances (Å) and angles (°) for complexes **3** and **4**

Bond	Ln = Pr	Ln = Sm	Angle	Ln = Pr	Ln = Sm
Ln–O1	2.503(9)	2.477(15)	O2–Ln–O1	130.8(3)	129.3(5)
Ln–O2	2.462(10)	2.402(14)	O1–Ln–N2	159.5(3)	159.1(5)
Ln–O3	2.411(11)	2.376(16)	O2–Ln–N4	156.2(4)	155.4(6)
Ln–O4	2.680(12)	2.668(17)	N2–Ln–N4	119.1(3)	121.2(5)
N3–C7	1.319(17)	1.30(3)	O3–Ln–N9	160.5(4)	159.3(6)
N5–C17	1.317(18)	1.32(3)	N7–Ln–N9	118.7(4)	119.9(6)
N8–C30	1.331(18)	1.34(3)	O3–Ln–O4	130.5(3)	130.2(5)
N10–C40	1.39(2)	1.34(3)	N7–Ln–O4	156.8(5)	155.4(7)
O2–C7	1.315(16)	1.29(2)	O2–Ln–N1	117.2(3)	117.7(5)
O1–C17	1.285(16)	1.23(3)	O1–Ln–N1	112.0(3)	113.0(5)
O3–C30	1.293(17)	1.30(3)			
O4–C40	1.234(19)	1.21(3)			

The bond angles (Table 3) of the two ligands, which involve the Ln(III) ions, are similar in both complexes. In particular the angles involving donor atoms (O, N) within the same ligand are very close proximity. The greatest difference occurs in comparing analogous angles between the two ligands; for example in the {[Pr(L)(HL)](H$_2$O)$_2$((CH$_3$)$_2$SO)} complex, O2–Pr–N2 is 60.2(3)°, but O3–Pr–N7 is 61.3(4)°. The difference is even smaller in {[Sm(L)(HL)](H$_2$O)$_2$((CH$_3$)$_2$SO)}, O1–Sm–N4 is 58.8(5)°, but O4–Sm–N9 is 57.7(6)°). As would be expected due to the comparable sizes of praseodymium(III) and samarium(III) the bond angles involving the metals ions in both complexes are not notably different (see Fig. 4).

Two possible coordination polyhedra with ten vertexes are known. The coordination polyhedron around each lanthanide atom in both complexes is better described as a distorted bicapped square antiprism in which N1 and N6 are the caps as shown in Fig. 5. In fact, considering those to be a bicapped dodahedron, severe distortions have to be take in account.

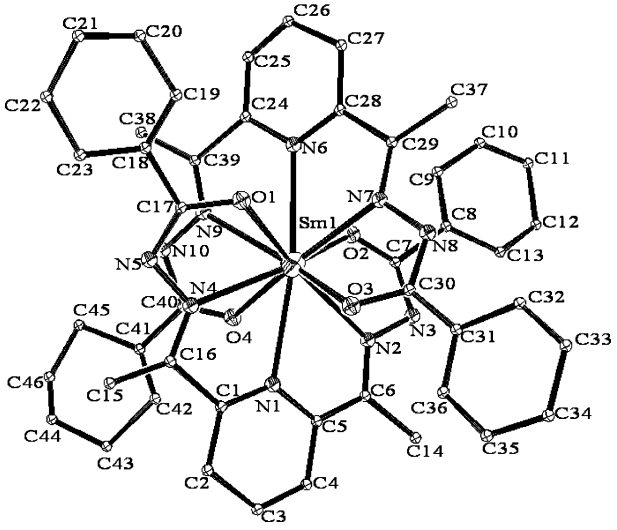

Fig. 4. ORTEP drawing of [Sm(L)(HL)] with atom numbering scheme, H$_2$O and (CH$_3$)$_2$SO) are omitted for clarity.

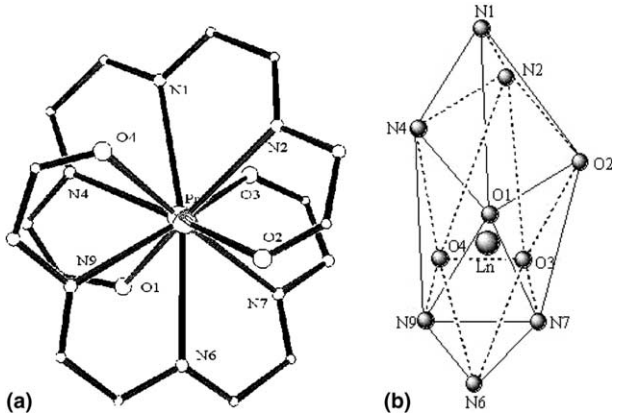

Fig. 5. (a) Coordination polyhedron around the lanthanide ion (e.g., Pr); (b) coordination polyhedron around the lanthanide ion described as a distorted bicapped square antiprism.

4. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC 206711 for [Y(L)(H$_2$O)(NO$_3$)], CCDC-224955 for [Er(L)(H$_2$O)(NO$_3$)], CCDC-208792 for {[Pr(L)(HL)](H$_2$O)$_2$((CH$_3$)$_2$SO)} and CCDC-208834 for [Sm(L)(HL)](H$_2$O)$_2$((CH$_3$)$_2$SO)}. Received 11 December 2003; accepted 29 January 2004

Abstract

Laser ablation of elemental phosphorus, sulfur, their mixtures or some phosphorus sulfides in connection with Time-Of-Flight (TOF) mass spectrometry was studied. Laser ablation of pure red phosphorus leads to formation of singly charged P_n^+ ($n = 1$–189) and P_n^- ($n = 1$–225) clusters. Much higher n values than those known in the literature were proved. Similarly, laser ablation of elemental sulfur produces S_m^+ ($m = 1$–11) and S_m^- ($m = 1$–15) species. Via laser ablation of P_4S_3 and P_4S_{10} compounds, the formation of several clusters with different P:S ratio was observed. Their stoichiometry was estimated from the mass spectra and natural abundance of sulfur isotopes. Similarly to laser ablation of red phosphorus, the amounts of P_nS_m clusters generated from P_4S_3 and P_4S_{10} with an odd number of phosphorus atoms were much higher than those with an even number. Generation of various mixed P–S clusters was also reached via direct laser ablation of a mixture of the elements. Higher yield of the mixed clusters was obtained when the mixture was first homogenized using ultrasound. Partially, some reactions were also initiated by ultrasound itself.

Totally, at least 68 new P_nS_m clusters were formed and detected. The laser ablation synthesis either from phosphorus sulfides or from elemental mixtures represents a new possibility of forming and studying mixed clusters of these elements.

1. Introduction

Phosphorus and sulfur exist in several allotropic modifications. Atoms of these elements can be connected in many ways, usually to polymeric non-linear chains or rings [1]. Concerning the mixed 15/16 group elements clusters, some of them are known for a long time. Alchemists were attracted by bright golden yellow color of realgar (As_4S_4) and orpiment (As_2S_3) mixtures with cheaper metals such as lead to form "gold" [2]. In modern chemistry wide scale of phosphorus sulfides has been synthesized and characterized. From the literature compounds P_4S_m ($m = 2$–7, 9, 10) [1,3] are known, usually synthesized by heating elements at the temperature higher than the melting point of sulfur, or adding sulfur to P_4S_3 or P_4S_7. These phosphorus sulfides, mostly P_4S_{10} and P_4S_3, have wide range of technological applications in the organic synthesis, respectively, for "strike anywhere" matches manufacturing [1] and therefore studying their properties is a scope of several papers. Infrared and Raman spectra of P_4S_3, P_4S_7, P_4S_{10} were studied in [4,5]. The intramolecular bonding in crystalline tetraphosphorus trisulfide was studied by Raman spectroscopy in [6]. ^{31}P NMR has been successfully applied in studies of P_4S_3 [7,8], P_4S_9 and P_4S_{10} [9]. Tattershall et al. [10–12] by NMR provided the evidence for phosphorus-rich phosphorus sulfide cage compounds derivatived from P_4S_3.

Laser ablation of red phosphorus leads to the formation of several homo-atomic poly-anions and cations with single charge [13,14]. Phosphorus clusters P_n^- (up to $n = 40$) and their cations P_n^+ (up to $n = 91$) were

doi:10.1016/j.poly.2004.01.018

synthesized in the gas phase by laser ablation of crystalline red phosphorus. The neutral P_n clusters are found to be even-numbered with the local abundance maxima at $n = 8$, 10, 14, and 40. On the contrary, the cationic clusters are preferentially odd-numbered with P_{21}^+ being the most abundant ion.

It is suggested that dodecahedral fullerene-like P_{20}, stabilized with an additional phosphorus ion in the laser plasma can be significantly stable [13]. A theoretical study of the isomers of neutral, cationic and anionic phosphorus clusters P_5, P_7, P_9, P_8 and P_9 was performed using the B3LYP, DFT method to predict the most stable isomers of these compounds present in the spectra [15–17].

Time-Of-Flight (TOF) mass spectrometric observations of gaseous phosphorus sulfides and oxysulfides were made in [18]. Bews and Glidewell [19] studied structures and energies of mass spectral fragments for P_4S_3 and its molecular ion $P_4S_3^+$ and for further spectral fragment pairs. Electronic structures of P_4S_n ($n = 5$, 6) were investigated using ab initio methods [20]. Electronic structures of phosphorus sulfide P_4S_{10} and P_4S_7 and phosphorus oxide P_4O_{10} are discussed in [21].

Recently, we have shown a new approach to the synthesis using laser ablation of a mixture of the elements. New tellurium–sulfide clusters were formed by a laser while simultaneous chemical analysis of the products formed by TOF mass spectrometry was done [22]. The aim of this work is to continue development and evaluation of this new perspective synthetic approach of inorganic chemistry and to study systematically possibilities of laser ablation as a method for generation of new phosphorus–sulfide clusters and to characterize the fragments or mixed P_nS_m clusters formed by TOF mass spectrometry.

2. Experimental

2.1. Chemicals and reagents

Elemental red phosphorus was purchased from R. de Haën (Hannover, Germany) and elemental sulfur was from Spolek pro chemickou a hutní výrobu (Ústí n/L, Czech Republic). Benzene was from Lachema a.s. (Brno, Czech Republic). Bradykinin, α-cyano-4-hydroxycinnamic acid, guanosine-5′-monophosphate and harmane were all purchased from Sigma (Steinheim, Germany). P_4S_{10} was purchased from Sigma (Steinheim, Germany) and P_4S_3 from Fluka AG (Buchs, Switzerland). All these chemicals were of analytical grade purity, except bradykinin, the purity of which was 98%.

2.2. Apparatus

Mass spectra measurements were carried out on AXIMA CFR (Kratos Analytical, Manchester, United Kingdom) mass spectrometer equipped with a nitrogen laser wavelength of 337 nm from Laser Science Inc. (Franklin, MA, USA). For the calibration of positive mode, molecular ions $[M+H]^+$ of α-cyano-4-hydroxycinnamic acid and bradykinin were used. In case of negative mode, $[M-H]^-$ ions of harmane and guanosine-5′-monophosphate were applied. Each mass spectrometric analysis was performed using at least 100 shots and the obtained data were accumulated. The ultrasound UC 006 DM1 bath was from Tesla (Rožnov pod Radhoštěm, Czech Republic).

2.3. Procedure of synthesis

Synthetic procedure by means of laser ablation used in this work is similar to that one described earlier [22]. A suspension of either fine powdered sulfur or red phosphorus, eventually a suspension of sulfur-phosphorus powder mixture in benzene in volume of 1 μl (suspension containing 1 mg ml^{-1}) was pipetted on a sample plate and dried at room temperature in an air stream. Synthesis was then initiated by laser pulses and mass spectrometric analyses of the products formed were carried out with pulsed extraction in negative and positive modes, either in linear or reflectron arrangement.

3. Results and discussion

The first part of the paper focuses on the mass spectra obtained using LDI–TOF MS with the aim to follow similarities or differences between modes and laser energies. Even if the formation of sulfur species [14] and phosphorus clusters [13,14] is described in the literature, in the first stage we studied carefully the formation of pure elemental clusters under the laser energy conditions used later on in this work for synthesis of P_nS_m clusters.

3.1. Phosphorus P_n^+ and P_n^- clusters

Phosphorus clusters were synthesized by laser pulses from elemental red phosphorus and the products were analyzed by TOF mass spectrometry, both in positive and negative modes. Applying the laser power of 2.2 mW results in formation of charged phosphorus clusters up to P_{65}^+ and P_{57}^-. In agreement with the literature [13], we also observed that clusters containing an even number of phosphorus atoms are less abundant than odd ones. All these compounds are stable enough, as they can be detected also in the reflectron mode prolonging ion flight time. Exceeding the laser power of 2.6 mW results in the formation of higher cluster ions. Due to lower stability of these higher clusters the signals were not observed in the reflectron modes. An example of mass spectra concerning laser ablation of red phospho-

rus using high laser power is given in Fig. 1. It is evident that negatively charged clusters consisting of up to 225 atoms are produced with maximum abundance for P_{27}^- of the low mass region and P_{103}^- for the high mass region. In the literature [13] only clusters up to P_{91}^+ and P_{40}^- have been described. Almost no clusters with an even number of atoms are observed in the negative mode. In the mass spectra obtained in the positive mode (Fig. 2),

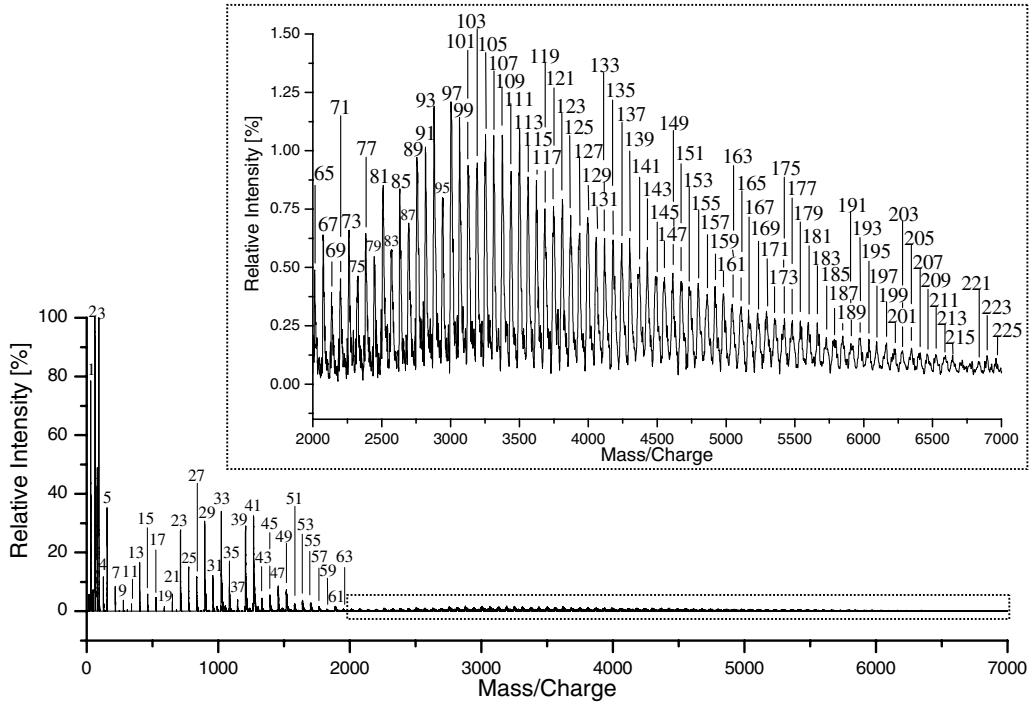

Fig. 1. Mass spectra of negatively charged phosphorus clusters produced during laser ablation of red phosphorus powder. Linear negative mode with pulsed extraction, laser power of 2.67 mW.

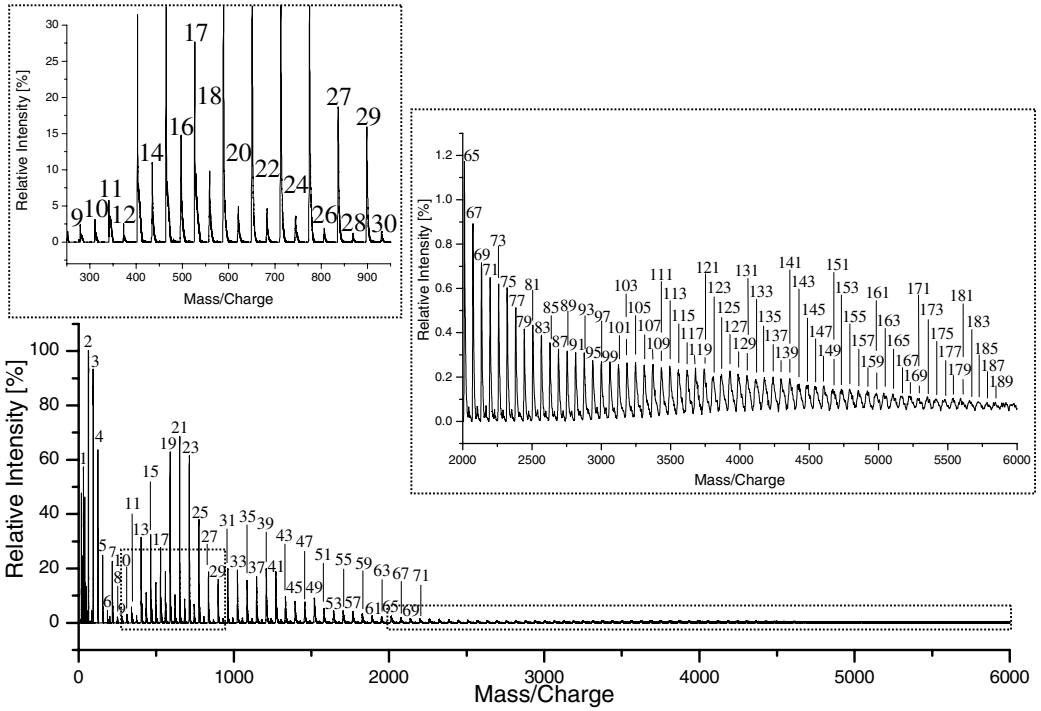

Fig. 2. Mass spectra of positively charged phosphorus clusters produced during laser ablation of red phosphorus powder. Linear positive mode with pulsed extraction, laser power of 2.67 mW.

the highest observed cluster P_n^+ contains 189 phosphorus atoms. Similarly to the negative mode, clusters with an odd number of atoms dominate in the spectra. On the other hand, several signals corresponding to an even number of phosphorus atoms present in the clusters with local intensity maximum around P_{18}^+ are formed.

Concerning the structure of P_n clusters there is some discussion in the literature. For example Chen et al. [16] did a theoretical study for the possible structure of the isomers of neutral, cationic and anionic phosphorus clusters P_5, P_7, P_9. In another study [15] about the structure of P_{20} cluster it is suggested that the smallest fullerene cage (dodecahedron with I_h symmetry) is the most stable. A positively charged P_{20}^+ cluster was observed here but not a negatively charged one. Although P_4 tetrahedron is the basic structural unit for several phosphorus compounds, LDI TOF mass spectra show dominant abundance of P_n clusters with an odd number of atoms. However, only clusters that are charged can be detected by the instrumentation and therefore, there is a probability that various uncharged, even more stable structures formed during the laser ablation process can be formed, but these neutral molecules are not observed in the mass spectra.

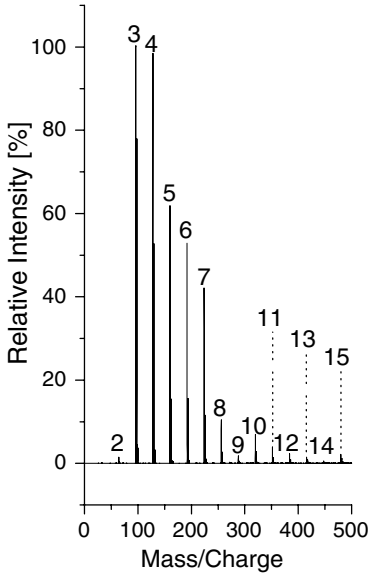

Fig. 3. Mass spectra of negatively charged sulfur species produced during laser ablation of fine sulfur powder. Linear negative mode with pulsed extraction, laser power of 3.17 mW.

3.2. Sulfur S_n^+ and S_n^- species

Sulfur species synthesized via laser ablation were observed both in the positive and the negative modes. An example of mass spectra concerning laser ablation of elemental sulfur is given in Fig. 3, where S_n^- anions up to S_{15}^- can be seen, while in the positive mode S_n^+ ($n = 1$–11) cations are observed. On the contrary to phosphorus, there is not any significant difference between intensities of the signals of even and odd species. The results concerning sulfur LDI–TOF MS are in agreement with the literature [14].

3.3. Synthesis of mixed P_nS_m clusters from a mixture of the elements

Red phosphorus is highly polymeric and insoluble in any solvent. Therefore, its suspension with sulfur in

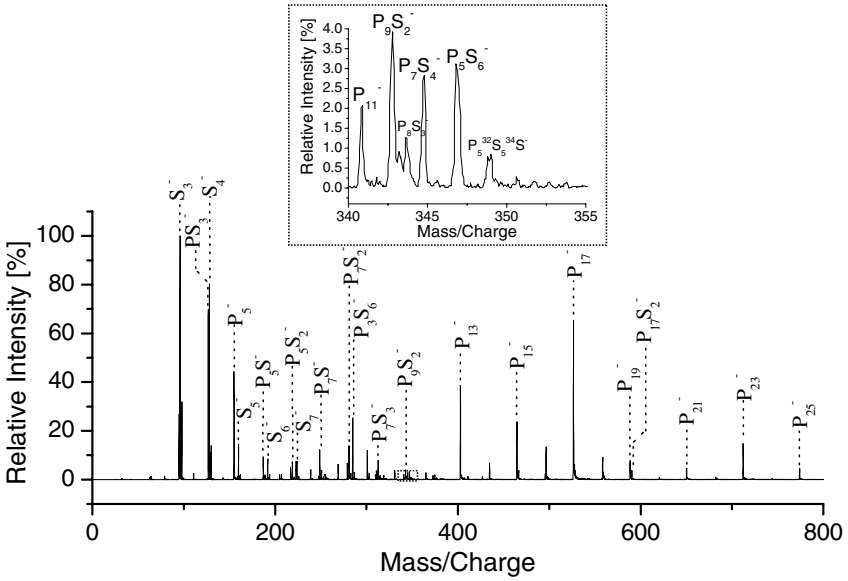

Fig. 4. Mass spectra obtained from laser ablation of a mixture of red phosphorus and sulfur (in molar ratio 1:1). Linear negative mode with pulsed extraction, laser power of 2.67 mW. Detailed view on section 340–355 Da with dominant component formulas added.

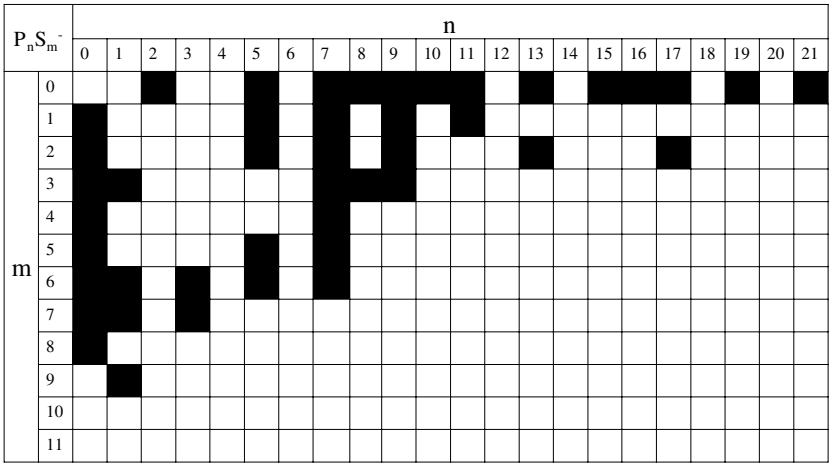
benzene was used for the synthesis. An excess of one of the components causes problems as the ablation of pure elements is too intensive and interferes with the observation of mixed clusters. When the suspension of elements (1:1, w/w) was mixed by stirring only with a glass stick, the generation of P_nS_m compounds was observed only from a few "sweet spots" and quite high laser power was needed for the mixed clusters generation. An example of mass spectra obtained from laser ablation of such P:S mixture is given in Fig. 4. A section of the spectrum containing P_{11}^-, $P_9S_2^-$, $P_8S_3^-$, $P_7S_4^-$ and $P_5S_6^-$ clusters is magnified. It follows from this figure that the resolution of the signals allows distinguishing isotopic patterns of the cluster signals, allowing the use of the isotopic pattern modeling for unambiguous identification of the species. The dominant peak in the magnified section corresponds to $P_9{}^{32}S_2^-$. However, $P_9S_2^-$ cluster ion is also induced in isotopic forms of $P_9{}^{32}S^{34}S^-$ and several other less abundant species. According to the natural distribution of sulfur isotopes, the peak of $P_9{}^{32}S^{34}S^-$ which cannot be under given conditions separated from the $P_7S_4^-$ signal, should possess $\approx 8\%$ of $P_9{}^{32}S_2^-$ intensity. Therefore, it is clear that the $P_7S_4^-$ cluster signal is also present in the mass spectra. All peaks from the mass spectra were analyzed in a similar way. The review of the compounds identified from mass spectra is given in Table 1.

For better homogenization of the mixture we used the ultrasound as well. An example of the mass spectrum obtained from the ultrasound homogenized mixture

Table 1
Review of $P_nS_m^-$ clusters stoichiometry identified in the mass spectra of a mixture of red phosphorus and sulfur (displayed in Fig. 4)



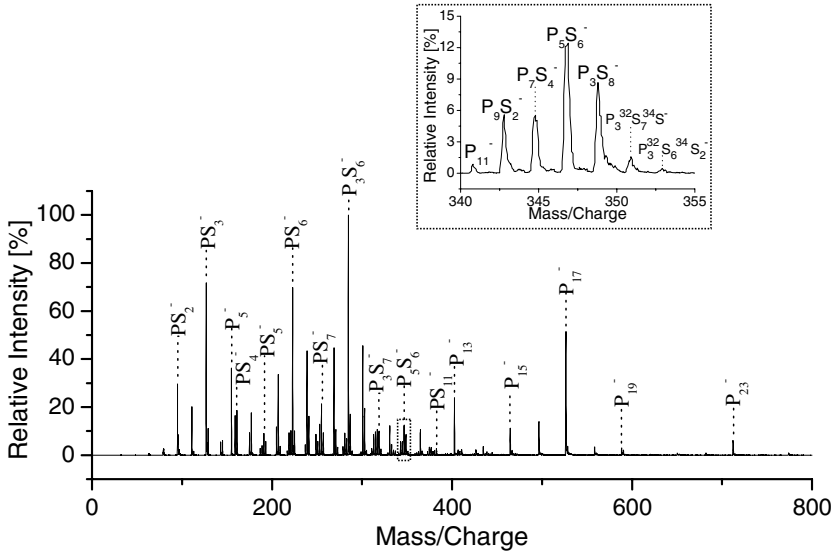


Fig. 5. Mass spectra obtained from laser ablation of the mixture of red phosphorus and sulfur (in the molar ratio 1:1) homogenized by the ultrasound. Linear negative mode with pulsed extraction, laser power of 1.67 mW. Detailed view on section 340–355 Da with dominant component formulas added.

(1:1, w/w) is given in Fig. 5. Complete review of mixed P_nS_m clusters identified from mass spectra is given in Table 2. It is possible to see that the ultrasound application leads to significant increase in the number of the mixed P_nS_m clusters. Mostly, the number of sulfur atoms in the clusters is higher compared to previous results obtained without the ultrasound homogenization. This effect can be related to reactions initiated by the ultrasound itself. After the homogenization we noticed that the suspension produced a sulfane-like odor. However, the increase of the number of species might be related to the improved contact between the two elements during the laser ablation process caused by enhanced homogeneity of the mixture. The ultrasound can initiate several reactions, radicals are formed and thus the reactivity of the components is increased.

3.4. Formation of clusters from P_4S_3 and P_4S_{10}

The compounds P_4S_3 and P_4S_{10} are well characterized as stable compounds built of phosphorus and sulfur atoms which are derived from different structural models. Ablating these sulfides we wanted to study their fragmentation and to compare structure of clusters formed with those generated from phosphorus and sulfur mixture ablation. Eventually, the idea was to use these two compounds as precursors for the synthesis of new P_nS_m clusters.

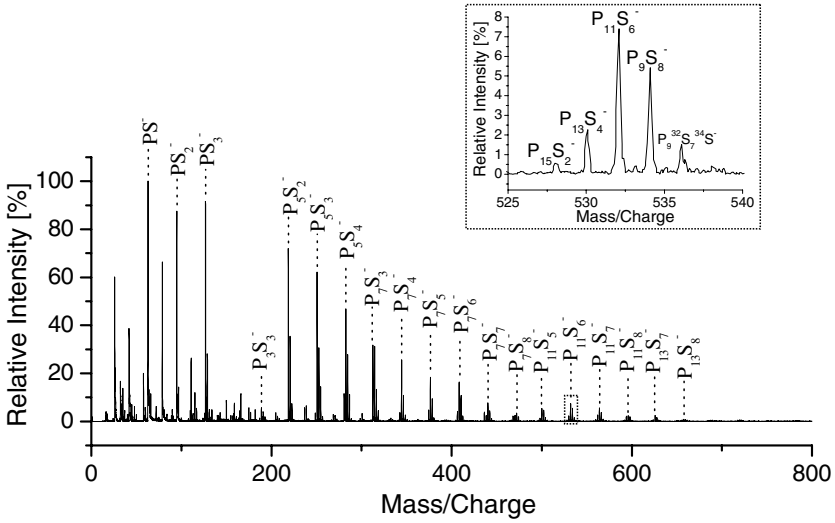

Fig. 6. Mass spectra of the mixed phosphorus–sulfur clusters produced during laser ablation of fine powder of pure P_4S_3. Linear negative mode with pulsed extraction, laser power of 3.33 mW. Detailed view on section 525–540 Da with dominant component formulas added.

Mass spectra obtained from ionization of P_4S_3 measured in the negative mode, which are shown in Fig. 6, are similar to those obtained from phosphorus and sulfur mixtures. There are only few clusters containing an odd number of phosphorus atoms. The number of sulfur atoms in observed clusters is rather high. Stoichiometries of the clusters identified from the mass spectra are summarized in Table 3. In the positive mode of the mass spectra measurement, formation of low molecular weight clusters was observed.

Although P_4S_{10} molecule contains more sulfur atoms, laser ablation from P_4S_{10} produces lower number of mixed clusters. An example of mass spectra concerning P_nS_m clusters obtained via laser ablation of P_4S_{10} is displayed in Fig. 6 and the stoichiometries of the clusters formed are reviewed in Table 4. Both studied phosphorus sulfides are not ionized in a form of a molecular ion. Mass spectra obtained in the positive mode are similar to those measured in the negative one, where only signals of $P_5S_8^+$, $P_5S_9^+$ and $P_5S_{10}^+$ were additionally observed.

From the comparison of the mass spectra between all mixed P_nS_m clusters spectra (Figs. 4–7) several similarities can be observed. Clusters with an odd number of phosphorus atoms are preferably formed in all cases, not depending on the original nature of the P–S system ionized (elemental mixture or phosphorus sulfides). That means that application of laser pulses results in cleavage of bonds in the phosphorus sulfides and the atoms or ions in the plasma plume are then reorganized always in a similar way forming similar mixed clusters.

4. Conclusions

Via laser ablation of red phosphorus, the formation of singly charged P_n^+ ($n = 1$–189) and P_n^- ($n = 1$–225) clusters was observed. Much higher values of cluster molecular weights than those reported earlier in the literature were found. Laser ablation of elemental sulfur produces S_m^+ ($m = 1$–11) and S_m^- ($m = 1$–15) species. Laser ablation of phosphorus and sulfur mixture leads to formation of a wide range of P_nS_m clusters with various P:S ratio. Clusters P_1S_m ($m = 1$–8, 11), P_3S_m ($m = 2$–11), P_5S_m ($m = 1$–8), P_7S_m ($m = 1$–6), P_9S_m ($m = 1$–6), $P_{11}S_m$ ($m = 1$–3), $P_{13}S_m$ ($m = 1$–2), $P_{15}S_m$ ($m = 1$–2), $P_{17}S_m$ ($m = 1$–2) and $P_{19}S_m$ ($m = 1$–2) were detected. The number of mixed P_nS_m clusters formed can be enhanced when the ultrasound is used for homogenization of the elemental mixture. Species similar to those ionized from the phosphorus–sulfur mixture can be generated by laser ablation of P_4S_3 and P_4S_{10} phosphorus sulfides. The stoichiometry of new clusters not described in the literature before was determined.

Abstract

Six diorganotin(IV) compounds with dicyanoethylene-1,2-dithiolate (mnt) of the type $[R_2Sn(mnt)Cl_nL]\cdot Y$ (when $n = 0$, L = 0: R = CH_3, Y = 0, **1**; R = *n*-Bu, Y = 0, **2**; R = C_6H_6, Y = 0.5C_6H_6, **3**; R = CH_3, Y = 1.5(4,4′-Bipy), **4**; when $n = 1$, L = 0, R = CH_3, Y = 4,4′-Bipy, **5**; when $n = 0$, L = Phen, R = CH_3, Y = 0, **6**; 4,4′-Bipy = 4,4′-bipyridyl; Phen = 1,10-phenanthroline) are synthesized by the reaction of diorganotin dichloride and disodium maleonitriledithiolate (Na_2mnt) in the presence of 4,4′-Bipy or Phen. All the compounds **1**–**6** are characterized by elemental, IR, ^{1}H NMR spectroscopy and X-ray crystallography analyses. The X-ray data showed the geometries of all the tin atoms in compounds **1**–**4** are tetrahedral, and those in **5** and **6** are trigonal bipyramidal and distorted octahedral, respectively. Co-crystallization is found in crystals of compounds **3** and **4**. The co-crystallized solvents are benzene and 4,4′-Bipy, respectively. Compound **5** is a stannate with a five-coordinated tin(IV) atom. Compound **6** is a six-coordinated dimethyltin(IV) derivative from mixed ligands of mnt and Phen.

1. Introduction

The environmental and biological chemistry of organotin(IV) complexes have been subjects of interest for some time due to their wide use [1,2]. In particular, organotin(IV) 1,2-dithiolate complexes have been studied extensively due to the diversity of their commercial application and the richness of their structural chemistry [3–5]. A uniform view has been formed in previous reports that the tin center in neutral diorganotin(IV) dicyanoethylene-1,2-dithiolate compounds is clearly unsaturated and will coordinate, at least in the solid state, beyond four if steric effects allow. Consequently, it is possible to synthesize some diorganotin(IV) dicyanoethylene-1,2-dithiolate compounds of mixed ligands such as 4,4′-Bipy or Phen (4,4′-Bipy = 4,4′-bipyridyl; Phen = 1,10-phenanthroline).

Out of the above consideration, we designed a series of experiments of diorganotin dichloride and Na_2mnt in the presence of 4,4′-Bipy or Phen. To our surprise, we obtained six compounds of the type $[R_2Sn(mnt)Cl_nL]\cdot Y$ [when $n = 0$, L = 0: R = CH_3, Y = 0 (**1**); R = *n*-Bu, Y = 0 (**2**); R = C_6H_6, Y = 0.5C_6H_6 (**3**); R = CH_3, Y = 1.5(4,4′-Bipy) (**4**); when $n = 1$, L = 0: R = CH_3, Y = 4,4′-Bipy (**5**); when $n = 0$, L = Phen, R = CH_3, Y = 0 (**6**)]. Determinations by elemental, IR, ^{1}H NMR spectroscopy and X-ray crystallography analyses of all the compounds **1**–**6** are given, among which only IR and NMR data of compounds **1** and **2** have been reported previously [6,7]. The X-ray data show the geometries of all the tin atoms in compounds **1**–**4** are tetrahedral, and those in **5** and **6** are trigonal bipyramidal and distorted octahedral, respectively.

2. Experimental

2.1. Materials and measurements

Dimethyltin dichloride, di-*n*-butyltin dichloride, diphenyltin dichloride, 4,4′-bipyridyl and 1,10-phenanthroline are commercially available and they were used without further purification. Na_2mnt was prepared by a standard method as reported in the literature [8]. The melting points were obtained with Kofler micro melting point apparatus and are uncorrected. Infrared-spectra were recorded on a Nicole-460 spectrophotometer using KBr discs and sodium chloride optics. ^1H NMR spectra were recorded on a FX-90Q Spectrometer. The chemical shifts are given in ppm relative to Me_4Si in $CDCl_3$ solvent. Elemental analyses were performed with a PE-2400II apparatus.

2.2. Synthesis of the compounds **1**–**6**

2.2.1. $[(CH_3)_2Sn(mnt)]$ (**1**)

The reaction was carried out under nitrogen atmosphere. Na_2mnt (0.372 g, 2 mmol) and dimethyltin dichloride (0.439 g, 2 mmol) were added to a solution of absolute ethanol (20 ml) in a Schlenk flask. The mixture was stirred for 12 h at 40 °C and then filtered. The filtrate was gradually removed by evaporation under vacuum until a solid product was obtained. The solid was then recrystallized from benzene. Buff crystal compound **1** was formed. Yield: 81%; m.p. >250 °C. *Anal*. Calc. for $C_6H_6N_2S_2Sn$: C, 24.94; H, 2.09; N, 9.70. Found: C, 24.88; H, 2.16; N, 9.58%. IR (KBr, cm^{-1}): ν(Sn–S), 288 and 351; ν_{as}(Sn–C), 555; ν_s(Sn–C), 450; ν(C–S), 1200 and 1234; ν(C≡N), 2208; ν(C=C), 1490. ^1H NMR ($CDCl_3$, ppm): 1.22 [s, $^2J(^{119}Sn–^1H)$, 74.7 Hz, Me].

2.2.2. $[(n\text{-}Bu)_2Sn(mnt)]$ (**2**)

Compound **2** was prepared in the same way as compound **1**, by adding di-*n*-butyltin dichloride (0.607 g, 2 mmol) instead of dimethyltin dichloride. Yield: 80%; m.p. 176–178 °C. *Anal*. Calc. for $C_{12}H_{18}N_2S_2Sn$: C, 38.63; H, 4.86; N, 7.51. Found: C, 38.51; H, 4.78; N, 7.53%. IR (KBr,cm^{-1}): ν(Sn–S), 290 and 355; ν_{as}(Sn–C), 575; ν_s(Sn–C), 457; ν(C–S), 1190 and 1220; ν(C≡N), 2217; ν(C=C), 1474. ^1H NMR ($CDCl_3$, ppm): 1.15 (t, 6H, CH_3), 1.56–1.78 (m, 12H, $CH_2CH_2CH_2$).

2.2.3. $[Ph_2Sn(mnt)]\cdot 0.5C_6H_6$ (**3**)

The compound **3** is prepared in the same way as that of compound **1**, by adding diphenyltin dichloride (0.687 g, 2 mmol) instead of dimethyltin dichloride. Yield: 85%; m.p. 200–202 °C. *Anal*. Calc. for $C_{19}H_{13}N_2S_2Sn$: C, 50.47; H, 2.90; N, 6.19. Found: C, 50.22; H, 3.01; N, 6.10%. IR (KBr,cm^{-1}): ν(Sn–S), 291 and 358; ν_{as}(Sn–C), 585; ν_s(Sn–C), 460; ν(C–S), 1182 and 1150; ν(C≡N), 2190; ν(C=C), 1464. ^1H NMR ($CDCl_3$, ppm): 7.39–7.85 (m, 26H, $2C_6H_5 + C_6H_6$).

2.2.4. $[(CH_3)_2Sn(mnt)]\cdot 1.5(4,4'\text{-}Bipy)$ (**4**)

The reaction was carried out under nitrogen atmosphere. Na_2mnt (0.372 g, 2 mmol) and dimethyltin dichloride (0.439 g, 2 mmol) were added to a solution of absolute ethanol (20 ml) in a Schlenk flask and stirred. After 4,4′-Bipy (0.468 g, 3 mmol) was added to the flask, the mixture was stirred for 12 h at 40 °C and then was filtered. The filtrate was gradually removed by evaporation under vacuum until solid product was obtained. The solid was then recrystallized from benzene. Buff crystal compound **4** was formed. Yield: 78%; m.p. 246–248 °C. *Anal*. Calc. for $C_{21}H_{18}N_5S_2Sn$: C, 48.21; H, 3.47; N, 13.39. Found: C, 48.33; H, 3.59; N, 13.18%. IR (KBr,cm^{-1}): ν(Sn–S), 262 and 276; ν_{as}(Sn–C), 551; ν_s(Sn–C), 455; ν(C–S), 1190 and 1210; ν(C≡N), 2207; ν(C=C), 1480; ν(C=N), 1178. ^1H NMR ($CDCl_3$, ppm): 1.20 [s, $^2J(^{119}Sn–^1H)$, 75.1 Hz, Me], 7.68 (d, 6H, $C_{10}H_8N_2$), 8.51 (d, 6H, $C_{10}H_8N_2$).

2.2.5. $[4,4'\text{-}BipyH]^+[(CH_3)_2SnCl(mnt)]^-$ (**5**)

The reaction was carried out under nitrogen atmosphere. Na_2mnt (0.372 g, 2 mmol) and 4,4′-Bipy (0.468 g, 3 mmol) were added to a solution of absolute ethanol (20 ml) in a Schlenk flask and stirred. After dimethyltin dichloride (0.439 g, 2 mmol) was added to the flask, the mixture was stirred for 12 h at 40 °C and then was filtered. The solid was then recrystallized from benzene. Yield: 83%; m.p. 208–210 °C. *Anal*. Calc. for $C_{16}H_{15}ClN_4S_2Sn$: C, 39.91; H, 3.14; N, 11.63. Found: C, 39.78; H, 3.03; N, 11.88%. IR (KBr,cm^{-1}): ν(Sn–S), 260 and 278; ν_{as}(Sn–C), 557; ν_s(Sn–C), 451; ν(Sn–Cl), 280; ν(C–S),1186 and 1198; ν(C≡N), 2199; ν(C=C), 1490; ν(C=N), 1201, ν(N–H), 3418. ^1H NMR ($CDCl_3$, ppm): 1.16 [s, $^2J(^{119}Sn–^1H)$, 78.2 Hz, Me], 7.75 (d, 4H, $C_{10}H_8N_2$), 8.43 (d, 4H, $C_{10}H_8N_2$).

2.2.6. $[(CH_3)_2Sn(mnt)(Phen)]$ (**6**)

Compound **6** was prepared in the same way as compound **5**, by using Phen (0.360 g, 2 mmol) instead of 4,4′-Bipy. Yield: 76%; m.p. 192–194 °C. *Anal*. Calc. for $C_{18}H_{14}N_4S_2Sn$: C, 46.08; H, 3.01; N, 11.94. Found: C, 46.10; H, 3.24; N, 11.71%. IR (KBr,cm^{-1}): ν(Sn–S), 258 and 275; ν_{as}(Sn–C), 558; ν_s(Sn–C), 453; ν(Sn–N), 420 and 457; ν(C–S), 1180 and 1206; ν(C≡N), 2197; ν(C=C), 1450; ν(C=N), 1180. ^1H NMR ($CDCl_3$, ppm): 1.17 [s, $^2J(^{119}Sn–^1H)$, 65 Hz, Me], 7.26–7.81 (m, 8H, $C_{12}H_8N_2$).

2.3. X-ray crystallography

All X-ray crystallographic data were collected on a Bruker Smart CCD 1000 diffractometer. Criterion of

observability was used for the solution and refinement. The structure was solved by direct methods and refined by a full-matrix least-squares procedure based on F^2 using the SHELXL 97 program system. All data were collected at 298(2) K using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and corrected for Lorentz and polarization effects for absorption. The positions of partly hydrogen atoms are retained, and their contributions in structural factor calculations are included. Table 1 lists the crystal data and structure refinement parameters for compounds **1–6**.

3. Results and discussion

3.1. Synthesis of compounds *1–6*

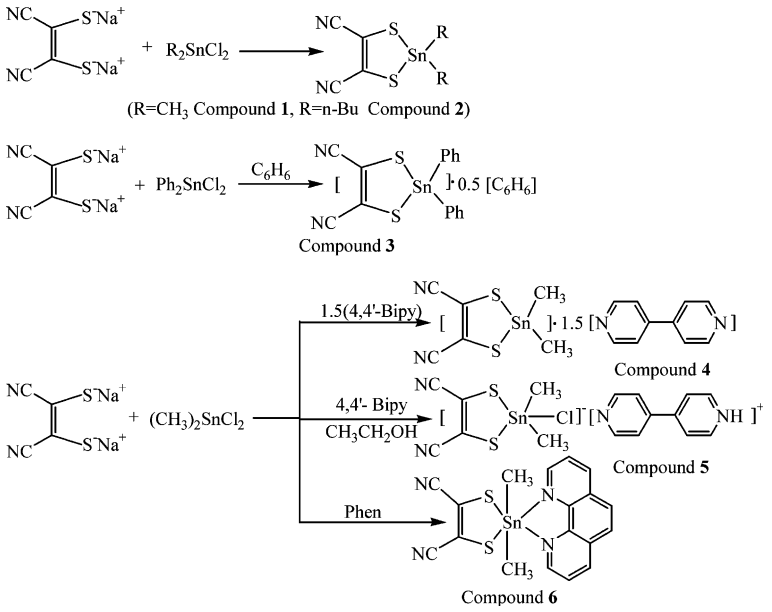
The synthesis procedures are shown in Scheme 1.

3.2. Spectroscopic studies

3.2.1. IR spectroscopic studies of compounds *1–6*

The assignment of IR bands of these compounds has been made by comparison with IR spectra of their related precursors. The spectra of all six compounds **1–6** show some common characters. The frequencies appearing in the region 258–280 cm^{-1} are assigned to the Sn–S stretching mode of vibration, all of which are consistent with those detected in a number of organotin(IV)–sulfur complexes [9–11]. IR bands at about 2000, 1460 and 1200 cm^{-1} have been assigned to ν(C≡N), ν(C=C) and ν(C–S), respectively, among which those related to the C=C and C–S stretching modes show a genuine positive shift [6].

Some obvious differences among the spectra of the six compounds **1–6** are also observed. For compound **5**, new vibrations appear at 280 and 3418 cm^{-1}, which can



Scheme 1.

be assigned to the vibrations of ν(Sn–Cl) and ν(N–H), respectively, indicating the nature of a one-substituted compound. For compound **6**, new vibrations appearing at about 420 and 457 cm^{-1}, attributed to Sn–N bonds between the tin atom and two nitrogen atoms of Phen, further testify the coordinated format of compound **6**. These formations are consistent with the following X-ray structure analyses.

3.2.2. ^1H NMR spectroscopic studies of compounds 1–6

^1H NMR spectra shows that the chemical shifts of the methyl groups, 1.16–1.27 ppm in compound **1** and compounds **4**–**6**, the butyl group in compound **2**, 1.56–1.78 ppm, and the phenyl group in compound **3**, 7.34–7.67 ppm, are all shifted upfield as compared with their corresponding precursors, similar to those appearing in the literature [12,13]. In addition, the resonances appearing at 7.68–8.51 ppm for compounds **4** and **5** are attributed to the protons of 4,4′-Bipy and the resonance at 7.26–7.81 ppm for compound **6** is assigned to the protons of Phen [14,15].

Moreover, the $^2J(^{119}Sn–^1H)$ of dimethyltin derivatives **1** and **4** have values of 74.7 and 75.1 Hz respectively, typical of tetra-coordinated tin species. While complexes **5** and **6** have values of 78.2 and 65 Hz, respectively, consistent with those of five- or *cis*-six-coordinated tin species, respectively. On the basis of Lockarts's Eq. [16], the Me–Sn–Me angle are estimated to be approximately 124.6° for compound **1**, 125.1° for compound **4**, 128.7° for compound **5** and 115.6° for compound **6**, which are all in agreement with those values found in the crystal structures.

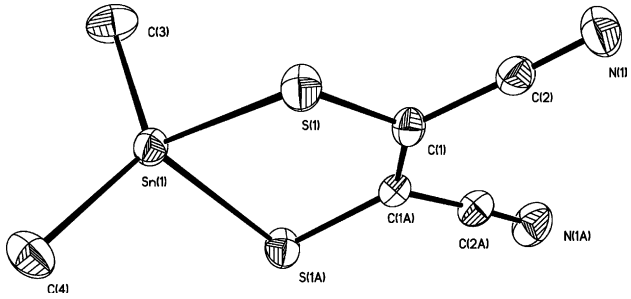


Fig. 1. Molecular structure of compound **1**.

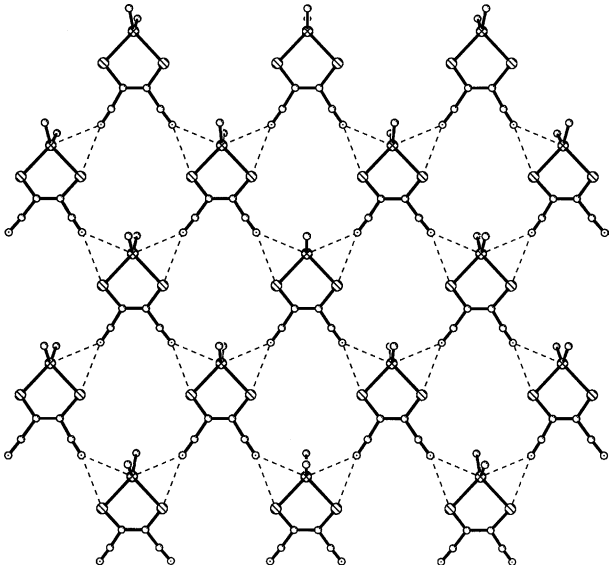

Fig. 2. A network of compound **1**.

3.3. X-ray studies

From X-ray crystal structure analysis, we note that the geometries of all the tin atoms in compounds **1**–**4** are tetrahedral, and those in **5** and **6** are trigonal bipyramidal and distorted octahedral, respectively. Co-crystallization is found in crystals of compounds **3** and **4**. The co-crystallized solvents are benzene and 4,4′-Bipy, respectively. Compound **5** is a stannate with a five-coordinated tin atom. Compound **6** is a six-coordinated dimethyltin(IV) derivative from mixed ligands of mnt and Phen. Detailed analysis on all the compounds **1–6** follows.

3.3.1. Crystal structures of $(CH_3)_2Sn(mnt)$ (1), $(n\text{-}Bu)_2Sn(mnt)$ (2) and $[Ph_2Sn(mnt)]\cdot 0.5C_6H_6$ (3)

The crystal structure and unit cell of compounds **1**, **2** and **3** are shown in Figs. 1–6, respectively, and selected bond lengths and bond angles are listed in Table 2. For compounds **1**, **2** and **3**, the geometry of the tin atoms is distorted tetrahedral and the tin atom forms four primary bonds: two to the methyl (butyl or phenyl) groups and two to sulfur atoms. Two weak intermolecular Sn···N and S···N interactions are recognized. The former exists between the Sn atom and two nitrogen atoms from two adjacent molecules. The latter exists between two sulfur atoms of the same molecule and two nitrogen atoms from two adjacent molecules. The corresponding intermolecular Sn···N and S···N distances are 3.068 and 3.174 Å for compound **1**, 2.828 and 3.060 Å for compound **2**, 2.867 and 3.222 Å for compound **3**, respectively. These Sn···N bond distances are similar to the values recorded in the Cambridge Crystallographic Database [17], and are much shorter than the sum of the van der Waal's radii of Sn and N (3.75 Å) [18,19]. Thus by the two weak intermolecular Sn···N and S···N

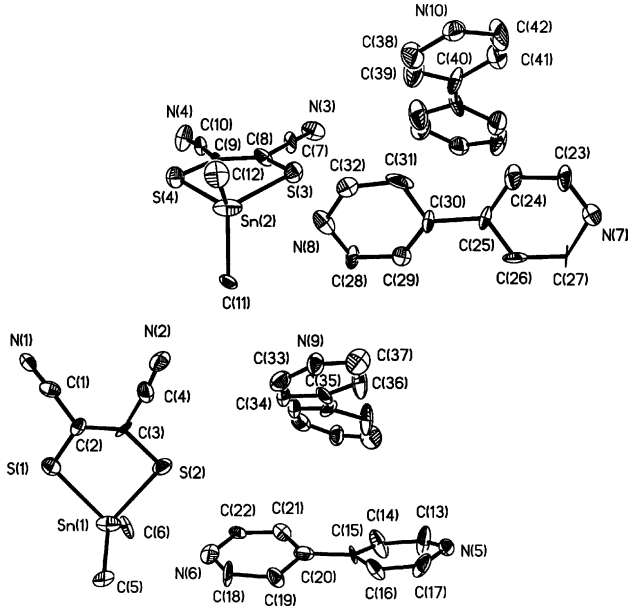

Fig. 7. Molecular structure of compound **4**.

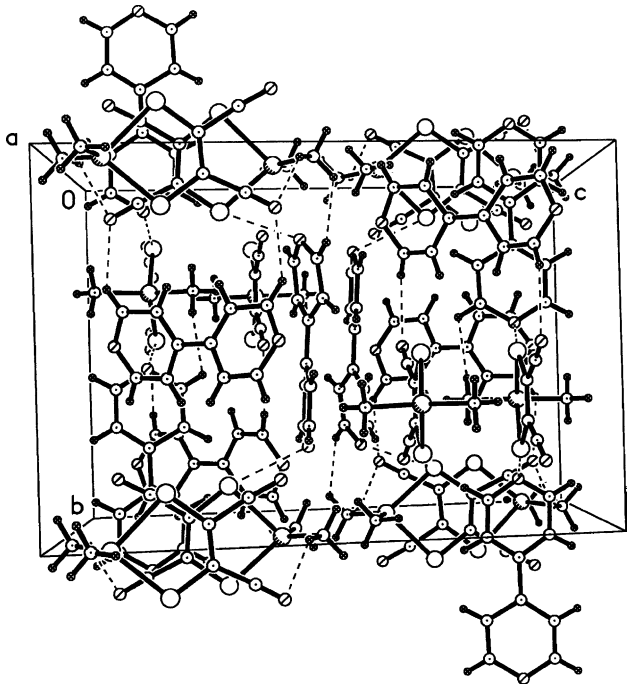

Fig. 8. Unit cell of compound **4**.

interactions, a similar network structure is constructed in all the crystals of **1**–**3**.

For compound **3**, co-crystallization is found in the crystals and the co-crystallized solvent is benzene, with a molar ratio of $Ph_2Sn(mnt)$: C_6H_6 of 2:1. For the main component, $Ph_2Sn(mnt)$, there exist two monomers in the asymmetric unit which are almost the same with regard to the conformation, but are different from a crystallographic point of view, with small differences in bond lengths and bond angles.

3.3.2. Structure of $[(CH_3)_2Sn(mnt)]\cdot 1.5(4,4'\text{-Bipy})$ (**4**)

The crystal structure and unit cell of compound **4** are shown in Figs. 7 and 8, respectively, and selected bond lengths and bond angles are listed in Table 3. For compound **4**, similar to compound **3**, co-crystallization is found but the co-crystallized solvent is 4,4′-Bipy with a molar ratio of $(CH_3)_2Sn(mnt)$: 4,4′-Bipy of 2:3. Two monomers of the main component, $(CH_3)_2Sn(mnt)$, exist in the asymmetric unit which are almost the same with regard to the conformation, but with small differences in bond lengths and bond angles. The geometry of the tin atoms involved is a distorted tetrahedron. Distortion from strict tetrahedral coordination is partly because of the variation of the sulfur bonding, and the sulfur atoms occupying *cis* positions [S(1)–Sn(1)–S(2)] 84.69(10)° and [S(4)–Sn(2)–S(3)] 85.09(11)°,. There also exist two intermolecular Sn···N and S···N interactions but the function atoms involved differ. The weak Sn···N interactions exist between the Sn atom and two nitrogen atoms from two adjacent 4,4′-Bipy molecules while the S···N interactions exist between two sulfur atoms of the same molecule and two nitrogen atoms from two adja-

C(17)–Sn(1)–S(1)	96.7(4)		

cent 4,4′-Bipy molecules. The corresponding intermolecular Sn···N and S···N distances are 2.708 and 2.935 Å, respectively. Compared with that in complex **1**, the Sn···N bond distances are much shorter. Meanwhile, hydrogen bonding is formed between 4,4′-Bipy and nitrogen atoms from an adjacent $(CH_3)_2Sn(mnt)$ (H(37)···N(1) 2.409, H(33)···N(2) 2.726 and H(28)···N(9) 2.712 Å). Thus by all three weak interactions, a network is constructed.

3.3.3. Structure of $[4,4'\text{-BipyH}]^+[(CH_3)_2SnCl(mnt)]^-$ (**5**)

The crystal structure and unit cell of compound **5** are shown in Figs. 9 and 10, respectively, and selected bond lengths and bond angles in Table 3. X-ray crystal structure analysis revealed compound **5** is a ionic stannate and contains a penta-coordinated tin atom. The geometry of the tin atom of the anion $[(CH_3)_2SnCl(mnt)]^-$ is distorted trigonal bipyramidal with Cl(1) and S(2) occupying the axial sites and the S(2)–Sn–Cl(1) is 166.72(7)°. The Sn–Cl bond lengths are in the region usually found in those bipyramidal complexes [20] while those Sn–S bond lengths (2.449(2) and 2.644(2) Å) are appreciably less than those for the trigonal bipyramidal neutral compound $[Me_2ClSnS_2\text{-}CNMe_2]$ (Sn–S(*ax*) 2.79(1) and Sn–S(*eq*) 2.48(2) Å), indicating the strong coordination at these sites [21].

The weak hydrogen bonds of N···H between cations help the construction of one dimension infinite chain. The N(3)H(3)···N(4) is 2.678 Å. Furthermore, weak CH···Cl (H(16)···Cl(1), 4.005 Å) and CH···N (H(7)···N(2), H(11)···N(2) 3.762 Å) hydrogen bonds between anion and cation are recognized, which link two component into a layer.

3.3.4. Structure of $[(CH_3)_2Sn(mnt)(Phen)]$ (**6**)

The crystal structure and unit cell of compound **6** are shown in Figs. 11 and 12, respectively, selected bond lengths and bond angles are listed in Table 3. Compound **6** contains a hexa-coordinated tin atom and has a distorted octahedral environment. Two carbons of methyl and two sulfur atoms of mnt are covalently linked to the tin atom. The valence extension is performed via two nitrogen atoms of Phen. The carbons are situated in

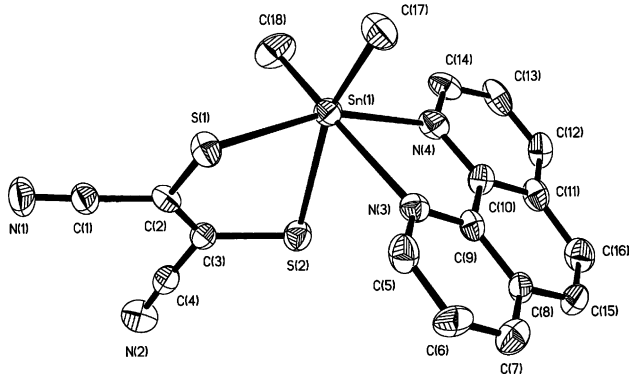

Fig. 11. Molecular structure of compound **6**.

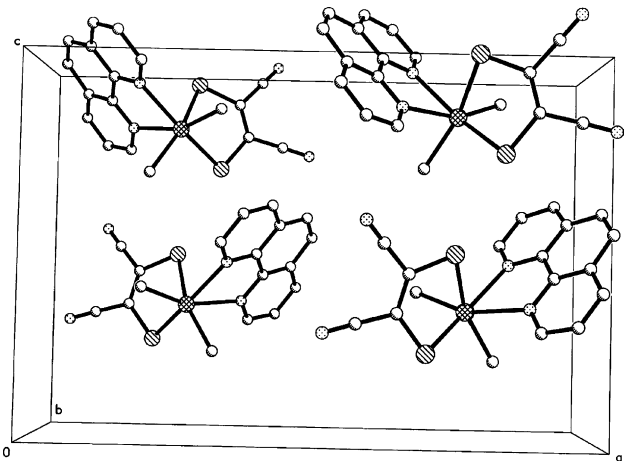

Fig. 12. Unit cell of compound **6**.

Table 4
Sn–S bond lengths (Å) and S–Sn–S bond angles (°) for all compounds **1**–**6**

Compound	Sn–S	Bond lengths	S–Sn–S	Angles (°)
1	Sn(1)–S(1)	2.4604(11)	S(1)–Sn(1)–S(1)#1	87.09(5)
	Sn(1)–S(1)#1	2.4604(11)		
4	Sn(1)–S(1)	2.455(3)	S(1)–Sn (1)–S(2)	84.69(10)
	Sn(1)–S(2)	2.555(3)	S(3)–Sn(2)– S(4)	85.09(11)
	Sn(2)–S(3)	2.496(3)		
	Sn(2)–S(4)	2.498(3)		
5	Sn(1)–S(1)	2.449(2)	S(1)–Sn(1)–S(2)	83.23(6)
	Sn(1)–S(2)	2.644(2)		
6	Sn(1)–S(1)	2.550(3)	S(1)–Sn(1)–S(2)	81.29(10)
	Sn(1)–S(2)	2.637(3)		

a *cis* position to each other (C(17)–Sn(1)–C(18) = 109.7(5)). One Sn(1)–C(17) is trans to the sulfur atom S(2) of mnt and the other Sn(1)–C(18) is trans to a nitrogen N(3) of Phen. Sn(1), N(3), N(4), C(18) and S(1) are almost coplanar with the tin atom deviating from the best plane by 0.2892 Å. Distortion from strict octahedral coordination is partly because of the variation of the sulfur bonding, and the sulfur atoms occupying *cis* positions (S(1)–Sn(1)–S(2), 81.29(10)°).

Sn–S bond lengths and S–Sn–S bond angles are shown in Table 4. Comparing Sn–S bond lengths of compounds **1**, **4**, **5** and **6**, which belong to dimethyltin(IV) derivatives from mnt, we find that when these dimethyltin(IV) derivatives are four-coordinated (**1** and **4**), two Sn–S bond are symmetric and lie in the range 2.45–2.56 Å. However, when the tin atom coordination number is greater than four, as in the case of compounds **5** and **6**, the Sn–S bond lengths are asymmetric with the longer at about 2.64(3) Å and the shorter at about 2.55 Å. Meanwhile, we find that S–Sn–S bond angles lessen when the coordination number of the tin atom increases. The above differences in Sn–S bond lengths and S–Sn–S angles among compounds **1**, **4**, **5** and **6** are attributed to the distinction of the coordination numbers of the central tin atoms.

It is noted that despite using a 1:1:1 molar ratio of Na_2mnt:(n-Bu)$_2SnCl_2$ (or Ph_2SnCl_2): Phen(or 4,4′-Bipy), we did not obtain the product with mixed ligands. The result suggested that the spatial resistances from two butyl (two phenyl) groups are strong enough to prevent another ligand chelating to the central tin atom.

4. Supplementary material

Received 15 December 2003; accepted 2 February 2004

Abstract

Three metal complexes with the 5-(4-pyridyl)tetrazolate anion, $(4\text{-PTZ})^-$, as ligand were obtained by the reaction of 4-cyanopyridine with corresponding metal azides in aqueous solution. Isomorphic complexes of composition $[M(4\text{-PTZ})_2(H_2O)_4]\cdot 2H_2O$ with M = Mn(II) (**1**) and Cd(II) (**2**) were obtained, whereas $[Ca_{1.5}((4\text{-PTZ})_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$ (**3**) was separated from calcium azide solutions. The IR spectra and the thermal behaviour of the complexes are measured and discussed. The single crystal X-ray diffraction revealed that the isomorphous structures of **1** and **2** consist of octahedrally coordinated metal centers, where two 4-PTZ anions act as monodentate ligands via their pyridine-N atoms in *trans*-positions. The structures also contain six water molecules, four act as monodentate ligands and the remaining two as lattice water molecules. Hydrogen bonds of the types O–H...O and O–H...N connect the mononuclear units to a three-dimensional network structure. The chain structure of complex **3** features octahedrally coordinated Ca(1); dinuclear subunits of pentagonal-bipyramidal Ca(2) centers; azide groups acting in end-on and end-to-end bridging mode; a $(4\text{-PTZ})_2H$ ligand in its zwitter ionic form coordinated via N(1) atom of the tetrazole ring to Ca(2), as well as lattice and ligand water molecules. Again, a complicated hydrogen bond system connects the chains of polyhedra to form a 3-D network structure.

1. Introduction

Tetrazole as functional group plays an increasingly important role in coordination chemistry as ligand [1], in medical chemistry as a metabolically stable surrogate for a carboxylic acid group [2] and in various materials science applications, including special explosives [3]. Also of great potential are the many useful transformations that make tetrazoles versatile intermediates for substituted tetrazoles, in particular of other 5-ring heterocycles via the Huisgen rearrangement [4]. Sharpless and Demko [5] have recently reported an environmentally friendly, relatively simple synthetic approach for generating 5-substituted 1H-tetrazoles. In the general [2+3] cycloaddition reaction, the tetrazoles are prepared by the addition of azide to nitriles in water with the aid of Zn^{2+} as Lewis acid; and for the reaction of PhCN with $ZnBr_2$ and NaN_3 $Zn(PhCN_4)_2$ has been postulated as solid intermediate. Subsequent density functional theory calculations result a reduction of the energy barrier of the zinc catalyzed reaction by 5–6 kcal/mol [6]. Very recently, Xue et al. [7] reported two novel Cd(II) coordination polymers employing the 5-(4-pyridyl)tetrazolate anion $(4\text{-PTZ})^-$ as a bridging ligand. The reaction of $CdCl_2$ with 4-cyanopyridine in the presence of NaN_3 and water under hydrothermal conditions yielded

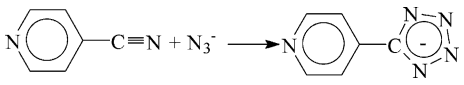
$Cd_3(OH)_2Cl_2(4\text{-PTZ})_2$ while $Cd(4\text{-PTZ})_2(H_2O)_2$ was obtained by the treatment of 4-H-PTZ with $CdCl_2$ and H_2O under similar experimental conditions. The structure of the latter complex consists of sheets of *trans*-coordinated Cd(II) octahedra, with the 4-PTZ anions acting as bidentate bridging N-donor ligands (via pyridine and tetrazole N atoms). The 2D system of the first complex is more complicated with the 4-PTZ anions acting as tridentate ligands, thus demonstrating the bridging abilities of the 4-PZT anions. Bidentate bridging 4-PTZ anions were also found in the 2D layered network (4-PTZ)Zn(OH)(H_2O), also reported by this group [8].

In the course of our systematic investigations of molecular magnets based on metal azido complexes containing pyridine derivative ligands [9–13] we observed that the intermediate reaction of 4-cyanopyridine with azide ion



takes place at even milder experimental conditions and we separated three metal complexes with 4-PZT anions as ligand.

2. Experimental

2.1. Materials and instrumentation

Infrared spectra were recorded by a Bruker IFS-125 model FT-IR spectrophotometer as KBr pellets [14]. 4-Cyanopyridine has been purchased from Aldrich Company and other chemicals were of analytical grade quality and used without further purification. C,H,N analyses were carried out using a Perkin–Elmer analyzer [15], metal analyses by complexometric titration [16].

Caution: Metal azide complexes are potential explosives. Only a small amount of material should be prepared and handled with caution.

2.2. Synthesis

2.2.1. $[Mn(4\text{-PTZ})_2(H_2O)_4](H_2O)_2$ (**1**)

The complex was prepared by combining 8 ml of an aqueous solution of NaN_3 (0.32 g, 5.0 mmol) saturated with hydrazoic acid [16], with an aqueous solution (20 ml) of $Mn(NO_3)_2 \cdot 4H_2O$ (1.00 g, 0.4 mmol) and 4-cyanopyridine (0.1 g, 0.96 mmol), followed by subsequent heating of the reaction solution to 80 °C for 6–8 h to complete the tetrazol reaction. The final clear solution was cooled to room temperature and prism shaped, colorless crystals of the complex were separated within several days. Yield: 75%. *Anal*. Calc.: C, 31.7; H, 4.4; N, 30.8; Mn, 12.1. Found: C, 31.5; H, 4.2; N, 30.6; Mn, 12.3%. IR, KBr (cm^{-1}) (v very, s strong, m medium, w weak, br broad): 3205 vs, br, 1623 s, 1445 m, 1431 s, 1378 m, 1219 ms, 1156 wm, 1071 mw, 1043 w, 1014 ms, 877 w, 836 m, 750 m, 728 m, 712 s, 528 m, 446 mw.

2.2.2. $[Cd(4\text{-PTZ})_2(H_2O)_4](H_2O)_2$ (**2**)

A similar procedure as for **1** was used for synthesis. The complex was prepared by combining 31 ml of an aqueous solution of NaN_3 (0.32 g, 5.0 mmol) saturated with hydrazoic acid [16], with an aqueous solution (20 ml) of $3CdSO_4 \cdot 8H_2O$ (0.50 g, 1.95 mmol Cd) and 4-cyanopyridine (0.20 g, 1.9 mmol), followed by subsequent heating of the reaction mixture to 75 °C for 10 h to obtain the tetrazol. The clear solution was slowly cooled to room temperature and the first undefined precipitate filtered. From the mother liquor needle shaped, colorless crystals of the complex were separated within several days. Yield: 80%. *Anal*. Calc.: C, 28.1; H, 3.9; N, 27.3; Cd, 21.9. Found: C, 27.9; H, 3.7; N, 27.5; Cd, 21.8%. IR, KBr(cm^{-1}): 3200 vs, br, 1622 s, 1446 m, 1432 s, 1375 m, 1219 ms, 1156 wm, 1073 mw, 1045 w, 1019 s, 874 w, 834 m, 750 m, 728 m, 713 s, 527 m, 454 mw.

2.2.3. $[Ca_{1.5}((4\text{-PTZ})_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$ (**3**)

Compound **3** was synthesized by adding 4-cyanopyridine (0.11 g, 1.0 mmol) to 10 ml of an aqueous solution of $Ca(N_3)_2$ (4.97 g, 40 mmol Ca), saturated with HN_3 (pH 5.5–6.0) [16] and subsequent heating of the mixture to 80 °C for 6 h. After slow cooling of the final clear solution to room temperature irregular shaped, colorless and transparent crystals of **3** were separated within a few days. Yield: 70%. *Anal*. Calc: C, 27.0; H, 3.7; N, 42.1; Ca, 11.3. Found: C, 27.2; H, 3.9; N, 42.0; Ca, 11.2%. IR KBr (cm^{-1}): 3260 vs, br, 2056 s, 2037 s, 1664 ms, 1622 s, 1523 w, 1445 ms, 1431 s, 1409 m, 1151 m, 1039 w, 1008 m, 874 m, 843 ms, 754 ms, 710 s, 641 m, 527 m, 456 m.

2.3. X-ray crystallography

Single crystal X-ray data were measured at 90(2) K on a modified STOE four circle diffractometer using graphite crystal-monochromatized Mo Kα radiation ($\lambda = 0.71069$ Å). The intensities were corrected for Lorentz-polarisation effects and for absorption [range of normalized transmission factors: 1.000–0.638; 1.000–0.491 and 1.000–0.526, for **1**–**3**, respectively]. Crystallographic data and processing parameters are given in Table 1. The structures were solved by direct methods and subsequent Fourier analyses. The program DIFABS [17] and SHELXTL/PC program package [18] were used for computations. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. Anisotropic displacement parameters were applied to non-hydrogen

atoms in full-matrix least-squares refinements based on F^2. All hydrogen atoms were located from difference Fourier maps assigned with isotropic displacement factors and included in the final refinement cycles as follows: (a) pyridine hydrogen atoms bonded to carbon by geometrical restraints using the HFIX utility of SHELXTL/PC package; (b) disordered H(7) and H(8) of **3** with HFIX utility and split occupancy of 0.50; (c) water hydrogens by use of O–H distance restraints. The occupancy of disordered lattice water molecule O(6) of **3** was refined to 0.296(6) and finally fixed to 0.30. Selected bond distances and bond angles are given in Tables 2–4, for complexes **1**–**3**, respectively.

2.4. Thermogravimetry, differential thermal analysis, and mass spectroscopy

All experiments were performed in simultaneous TG/DTA/MS mode. TG/DTA data were obtained using a symmetric thermobalance (Setaram, model TAG 2416) compensating the buoyancy effect. The samples were heated in Al_2O_3 crucibles from 20 to 260 °C with a ramp rate of 5 °C/min. Ar (5.0) was used as carrier gas with flow rates of 1 l/h. The thermobalance was coupled to a quadrupole mass spectrometer (Pfeiffer Vacuum, model ThermoStar GSD 301 T1, max. 100 amu). MS data were recorded in multiple ion detection mode.

3. Results and discussion

The reaction of 4-cyanopyridine with aqueous solutions of their divalent metal azides at temperatures of 60–80 °C formed $[M(4\text{-PTZ})_2(H_2O)_4]\cdot 2H_2O$, [M = Mn, Cd; (4-PTZ = 5-(4-pyridyl)tetrazolate)] and $[Ca_{1.5}((4\text{-PTZ})_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$. In the calcium compound the tetrazolate ligands are observed in their protonated zwitter ionic form. The [2+3] cycloaddition reaction was not observed with 3-cyanopyridine and similar experimental conditions; instead the 2D system $[Cd(3\text{-CNpy})(N_3)_2]_n$ [19] was obtained. The $[Mn(4\text{-CNpy})_2(N_3)_2]_n$ 2-D system was formed at lower reaction temperatures [20]. However, under hydrothermal conditions (105 °C), the monomeric $[Zn(2\text{-PTZ})_2(H_2O)_2]$ and the 3D diamondoid-like network $[Zn(3\text{-PTZ})_2]_n$ were obtained by the [2+3] cycloaddition reaction with 2- and 3-cyanopyridine, respectively [8].

3.1. Structures

The single crystal X-ray diffraction revealed that the isomorphous structures of **1** and **2** consist of octahedrally coordinated metal centers, where two 4-PTZ anions act as monodentate ligands via their pyridine-N atoms in *trans*-positions [Mn(1)–N(1) 2.301(2); Cd(1)–N(1) 2.329(2) Å]. The structures also contain six water molecules, four act as monodentate ligands [Mn–O 2.163(2), 2.164(2) Å; Cd–O 2.282(3), 2.290(3) Å] and the remaining two as lattice water molecules. Selected bond parameters are listed in Tables 2 and 3, respectively; the principle structural features of complex **1** are shown in Fig. 1. Hydrogen bonds of type O–H...O and O–H...N connect the mononuclear units to a three-dimensional network structure (Fig. 2). The four N-donor atoms of the tetrazolato group are not coordinated to metal centers, but act as acceptor of the O–H...N hydrogen bonds. The six-membered pyridine ring and the five-membered tetrazolate ring of the 4-PTZ ligands are both planar and their mean planes have acute angles of 12.67(10)° and 12.47(15)°, for **1** and **2**, respectively. Adjacent mononuclear units show alternate stacking of their 4-PTZ ligands along the *a*-axis of the triclinic unit cell. The shortest separation of tetrazole ring centers from pyridine ring centers is 3.571(2) and 3.602(3) Å, for **1** and **2**, respectively.

A perspective view of compound **3** is given in Fig. 3, selected bond parameters are summarized in Table 4. The chain structure (Fig. 4) of compound **3** features octahedrally coordinated Ca(1); dinuclear subunits of pentagonal-bipyramidal Ca(2) centers; azide groups acting in end-on and end-to-end bridging mode; a $(4\text{-PTZ})_2H$ ligand in its zwitter ionic form coordinated via N(1) atom of the tetrazole ring to Ca(2); lattice and ligand water molecules. Again, a complicated hydrogen bond system connects the chains of polyhedra to form a 3-D network structure. Ca(1) centers are located at inversion centers. Their *trans*-coordinated octahedra are formed by oxygen atoms of four water molecules and the nitrogen atoms of two end-to-end azido bridges [Ca(1)–O(1) 2.320(2), Ca(1)–O(2) 2.377(2), Ca(1)–N(11) 2.460(2) Å]. The basal positions of the pentagonal bipyramids of Ca(2) centers are occupied by nitrogen atoms N(13), N(21) and N(21B) of azido groups [Ca(2)–N(13) 2.454(2), Ca(2)–N(21) 2.599(2), Ca(2)–N(21B) 2.597(2) Å] and oxygen atoms O(4) and O(5) of two water molecules [Ca(2)–O(4) 2.517(2), Ca(2)–O(5) 2.381(2) Å], which deviate −0.76 and +0.69 Å, respectively, from the mean basal plane. The apical positions are occupied by O(3) of water molecule and N(1) of monodentate tetrazolate ligand [Ca(2)–O(3) 2.301(2), Ca(2)–N(1) 2.581(2) Å, O(3)–Ca(2)–N(1) 168.64(5)°]. Two centrosymmetrically related polyhedra of Ca(2) have common basal edges via N(21) and N(21B) of end-on bridging azido groups. The Ca(2)...Ca(2B) separation is 4.318(2) Å, the Ca(2)–N(21)–Ca(2B) bridge angle is 112.42(6)°. Pentagonal bipyramidal Ca polyhedra also connected by two common end-on azido bridges to dinuclear subunits have been observed in the crystal structures of $CsCa(N_3)_3 \cdot H_2O$ [21], $Cs_5Ca_2(N_3)_9 \cdot 2H_2O$ [22], and $Cs_7Ca_4(N_3)_{15}$ [23]. The octahedra of Ca(1) are linked by end-to-end bridging azido groups with the dinuclear subunits of Ca(2) centers to form a 1D chain

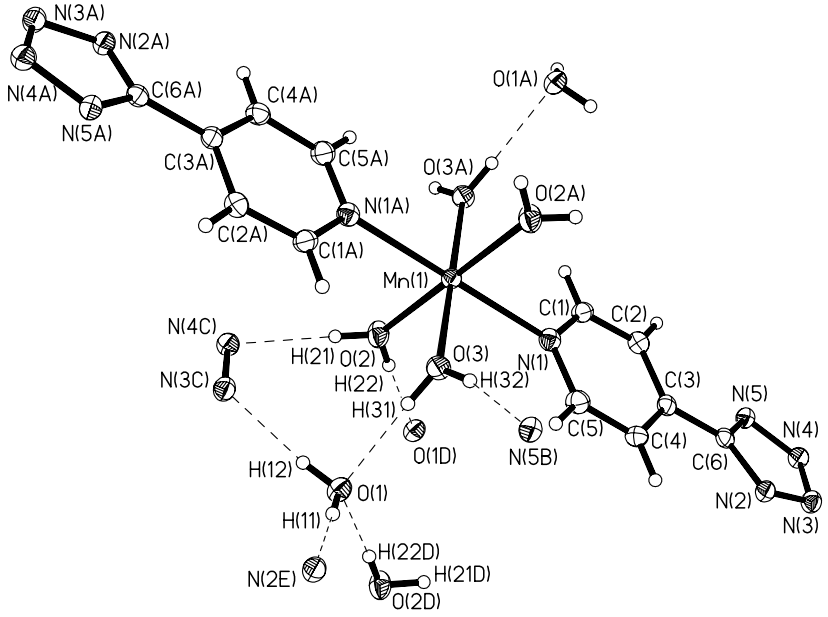

Fig. 1. Perspective view and atom labeling scheme of $[Mn(4\text{-PTZ})_2(H_2O)_4] \cdot 2H_2O$ (**1**). Broken lines indicate hydrogen bonds . Symmetry codes according to Table 2.

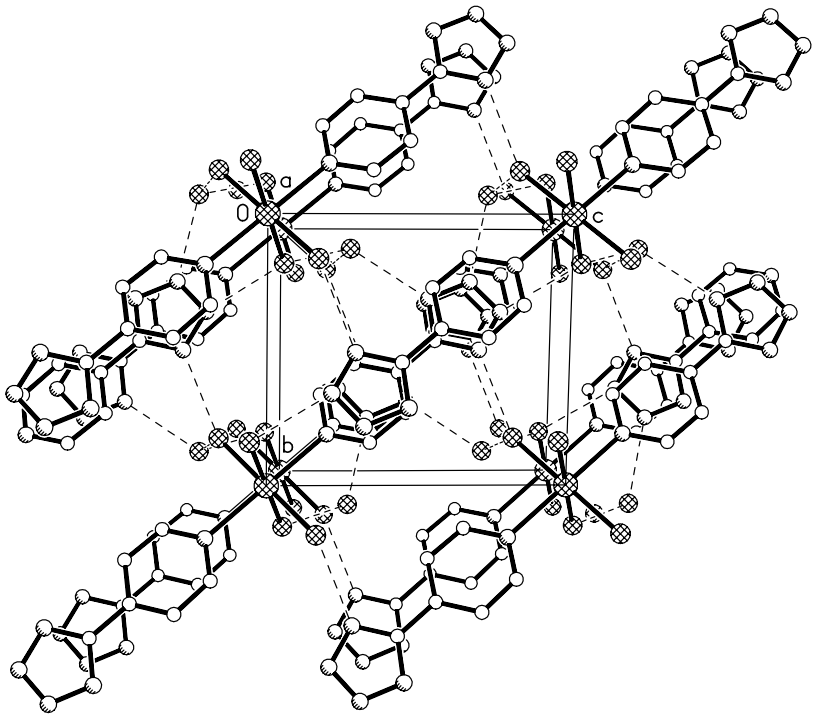

Fig. 2. Packing plot of $[Mn(4\text{-}PTZ)_2(H_2O)_4]\cdot 2H_2O$ (**1**) along *a*-axis of unit cell. Hydrogen bonds are indicated by broken lines.

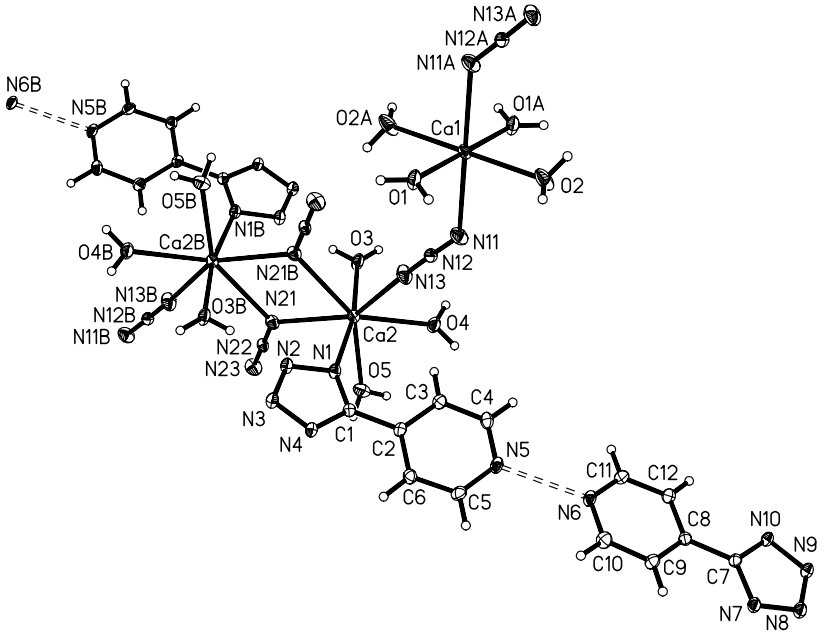

Fig. 3. Perspective view of $[Ca_{1.5}((4\text{-}PTZ)_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$ (**3**) with atom labeling scheme. Disordered atoms are omitted for clarity. Symmetry codes according to Table 4.

systems along [0 1 −1] direction (Fig. 4). The Ca(1)...Ca(2) centers are separated by 6.811(2) Å. The Ca(2)–N(13)–N(12) bond angle is almost linear [177.2(2)°], whereas Ca(1)–N(11)–N(12) is 134.78(14)°. The Ca(1)–N(11)...N(13)–Ca(2) torsion angle is 176.6(4)°.

In contrast to complexes **1** and **2** the monodentate 4-PTZ ligand is not coordinated via its pyridine nitrogen

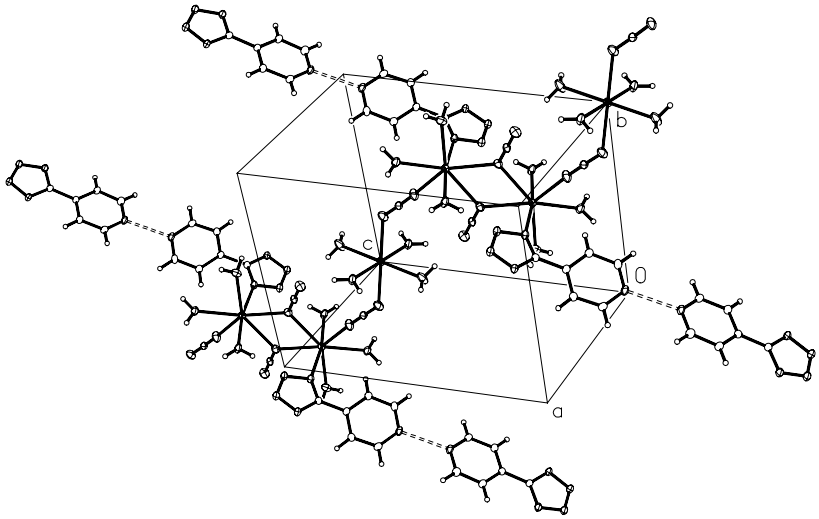

Fig. 4. Propagation of the chain structure of $[Ca_{1.5}((4\text{-}PTZ)_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$ (**3**) along the [0 1 −1] direction of the unit cell.

atom to the metal center. Instead, a zwitter ion pair is formed with a second, non-coordinated 4-PTZ anion, with a N(5)...N(6) separation of 2.631(3) Å. The four aromatic rings of the zwitter ion are not coplanar. The tetrazole rings form acute angles of 14.92(9)° and 5.22(11)° with their pyridine rings, respectively, whereas the acute angle between central pyridine rings is 17.00(8)°. Except N(1), which is coordinated to Ca(2), all tetrazolate N-donor atoms are involved in hydrogen bonds of type N...H–O. The 1D chains of Ca-polyhedra form layers extended parallel to the *bc*-planes of the triclinic unit cell. Along the *a*-axis these layers are separated by sheets of alternate stacked $(4\text{-}PTZ)_2H^+$ zwitter ions. The shortest separations between adjacent ring centers are 3.577(2) and 3.688(2) Å.

Bond lengths and bond angles of the tetrazolate groups of the $(4\text{-}PTZ)_2H^+$ zwitter ion of **3** and of the 4-PTZ ligands of **1** and **2** agree well with values reported in a series of bis-tetrazolate-dianions [24]. The N2–N3 bond opposite to C in position 5 is significantly shorter [1.319(4)–1.323(2) Å] than other interatomic distances within the heterocycle despite of the aromatic nature of the five-membered ring. In case of 5-phenyl tetrazolate anion (5-PhTZ) the deprotonation had also led to a noticeable elongation of the N2–N3 bond from 1.247 to 1.307(3) Å, in excellent agreement with ab initio calculations [25].

3.2. IR spectra

The dominating feature in the IR spectra of compounds **1**–**3** is the strong and very broad band in the region 3550–3000 cm^{-1} originating from the extensive hydrogen bonded water molecules. The IR spectra of isomorphic complexes **1** and **2** are practically identical in shape and positions of their vibrational bands. The absence of any bands in 2200–1700 cm^{-1} region confirms ring formation to the tetrazolate ligand by [2+3] cycloaddition. Neither vibrations associated with ν(CN) of 4-CNpy (expected weak to medium bands centered around 2240 cm^{-1}) nor strong bands associated with $\nu_{as}(N_3)$ in the 2150–2000 cm^{-1} region are present [26]. In agreement with the crystal structure, the IR spectrum of **3** shows two additional very strong bands at 2056 and 2037 cm^{-1}, due to $\nu_{as}(N_3)$. The former band at 2056 cm^{-1} may be assigned to the μ-1,1 azide bridge, and the latter one to the μ-1,3 azide bridge [27,28].

3.3. Thermoanalytic investigations

The thermal decomposition of the three compounds was studied by thermogravimetry with simultaneous differential thermal analysis and mass spectrometry. Onset of dehydration of the Cd compound (**2**) is observed at 61 °C. Mass spectrometry confirms that the mass loss is due to emission of H_2O ($m/z = 18$). The TG signal indicates that the departure of water can be described as a two-step process. Correspondingly, DTG, DTA, and MS signals show two partly overlapping peaks. From the TG signal a loss of 5.8 mol H_2O can be calculated which is somewhat smaller than the theoretically expected loss of 6 mol H_2O. The third step of weight loss, with onset temperature at about 200 °C, can be assigned to the decomposition of tetrazole rings by release of N_2 ($m/z = 28$). The calculated amount of 2.5 mol N_2 is larger than the theoretically expected loss of 2 mol N_2. However, as the MS signal indicates an overlap in the emission of H_2O and N_2 separation of these two effects is difficult.

The Mn compound (**1**) shows a thermal behavior which is analogous to (**2**). Dehydration starts at 66 °C and is characterized by two superimposed peaks which

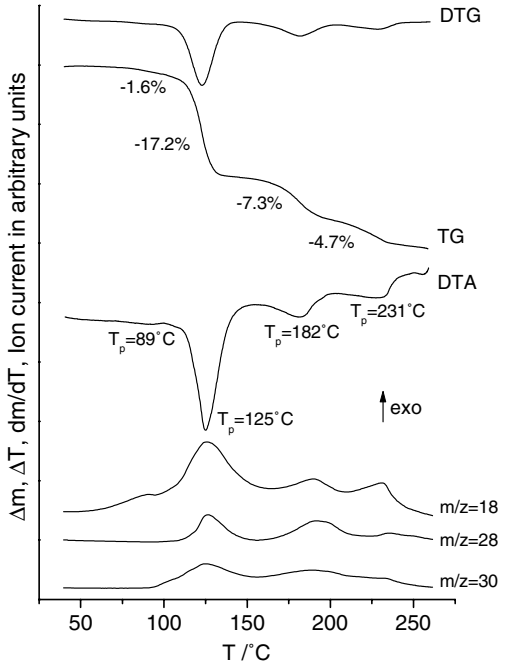

Fig. 5. TG, DTG, DTA, and MS curves for compound (**3**) (simultaneous measurement); powder weight: 10.66 mg; heating rate: 5 °C/min; dynamic argon atmosphere; flow rate: 1 l/h; $m/z = 18$ (H_2O); $m/z = 28$ (N_2); $m/z = 30$ (NO).

correspond to the removal of all water molecules (calculated amount: 5.9 mol H_2O; theoretically expected amount: 6 mol H_2O). Further decomposition of the sample, with onset temperature at 225 °C, is due to departure of N_2 (calculated amount: 2.3 mol N_2; theoretically expected amount: 2 mol N_2).

Compared with (**1**) and (**2**) the behavior of the Ca compound (**3**) is more complex (Fig. 5). Onset of mass loss upon heating occurs at approximately 55 °C. Four overlapping peaks in DTA and DTG signals as well as mass spectrometer signal ($m/z = 18$) indicate that dehydration takes place in four steps. Additionally, the simultaneous departure of N_2 ($m/z = 28$) and NO ($m/z = 30$) with H_2O is detected by mass spectrometry which makes a quantitative separation of the effects difficult. However, the experimentally observed total mass loss of 30.7% is in agreement with a theoretically expected mass loss of 28.4% associated with release of 5.30 mol H_2O and 2 mol N_2 (from tetrazole).

4. Supplementary material

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers: CCDC-225740 to CCDC-225742 for **1**–**3**, respectively.

Abstract

An interesting series of three Ni(II) complexes with the general formula $[NiLX]\cdot\frac{1}{2}H_2O$ (X = Cl, N_3 and NCS) were synthesized using di-2-pyridyl ketone N^4,N^4-(butane-1,4-diyl) thiosemicarbazone (HL). The structures of the compounds NiLCl (**1**) and $NiL(N_3)$ (**2**) have been solved by single crystal X-ray crystallography with $P\bar{1}$ and *Pbca* space groups, respectively. Electronic spectral data suggests a square planar geometry around nickel(II) in all the complexes. X-ray diffraction studies reveal that the thiosemicarbazone is bonded to the nickel(II) centre as an NNS donor ligand coordinating through one of the pyridine nitrogens, azomethine nitrogen and thiolate sulfur. Magnetic susceptibility measurements at room temperature indicate the diamagnetic nature of all the complexes. ^{1}H NMR, UV/Vis and IR spectroscopic data are consistent with the structures of compounds **1** and **2** derived from the crystallographic results and the spectral data for compound NiL(NCS) (**3**) suggest a structure similar to the chloro and azido derivatives.

1. Introduction

Metal complexes of thiosemicarbazones possess significant biological activity and are nowadays widely used as potential drugs [1]. It has been shown that metal complexes derived from substituted thiosemicarbazones from 2-acetylpyridine exhibit antimalarial activity. There are also some reports on the anticancer activity of some of the transition metal complexes of thiosemicarbazones [2]. The biological activity of thiosemicarbazones is related to its chelating ability with transition metal ions, bonding through nitrogen, nitrogen and sulfur [3] or oxygen, nitrogen and sulfur [4]. In the case of α-N heterocyclic carbaldehyde thiosemicarbazones, the biological activity depends on the parent aldehyde or ketone [5,6]. Compared to the extensive studies on 2-acetylpyridine thiosemicarbazones [7–9], there are only few reports on the metal complexes of thiosemicarbazones derived from di-2-pyridyl ketone [10]. We have recently reported the synthesis, spectral characterization and structural studies of the present thiosemicarbazone with the aim to correlate the structural features and chelating ability [11]. Di-2-pyridyl ketone N^4,N^4-(butane-1,4,diyl) thiosemicarbazone resonates into thione and thiol forms and as a result a small negative charge resides on the nitrogen atom of the pyridine ring, which enhances its biological activity [12,13]. This paper deals with the synthesis, spectral and structural studies of Ni(II) complexes of the potential tetradentate ligand, di-2-pyridyl ketone N^4,N^4-(butane-1,4-diyl) thiosemicarbazone (Fig. 1). An interesting aspect of the present study is that the quadridentate HL behaves as a tridentate ligand in all the complexes under study, since only one of the pyridyl nitrogens is coordinated to the metal. The Ni(II) complexes are square planar in

geometry with the fourth coordination site occupied by Cl, N_3 or NCS in compounds **1**, **2** and **3**, respectively.

2. Experimental

2.1. Synthesis of ligand

Di-2-pyridyl ketone N^4,N^4-(butane-1,4-diyl) thiosemicarbazone was prepared by the earlier reported method [11].

2.2. Synthesis of complexes

2.2.1. Synthesis of $[NiLCl]\cdot\frac{1}{2}H_2O$

A solution of the ligand HL (0.311 g, 1 mmol) in 20 ml of hot ethanol was treated with an ethanolic solution of $NiCl_2\cdot 6H_2O$ (0.237 g, 1 mmol). The solution was heated under reflux for 2 h. The resulting solution was allowed to stand at room temperature and after slow evaporation, dark brown crystals of compound **1** separated out, which were collected, washed with water, followed by ether and dried over P_4O_{10} in vacuo.

2.2.2. Synthesis of $[NiL(N_3)]\cdot\frac{1}{2}H_2O$

A solution of the ligand HL (0.311 g, 1 mmol) in 20 ml of hot ethanol was treated with an ethanolic solution of $Ni(OAc)_2\cdot 4H_2O$ (0.248 g, 1 mmol). The solution was heated under reflux and sodium azide (0.065 g, 1 mmol) was added in portions to the solution and further refluxed for 2 h. The resulting solution was allowed to stand at room temperature for few days and upon slow evaporation gave dark brown crystals of compound **2**. The crystals separated out were collected, washed with water, followed by ether and dried over P_4O_{10} in vacuo.

2.2.3. Synthesis of $[NiL(NCS)]\cdot\frac{1}{2}H_2O$

A solution of the ligand HL (0.311 g, 1 mmol) in 20 ml of hot ethanol was treated with an ethanolic solution of $Ni(OAc)_2\cdot 4H_2O$ (0.248 g, 1 mmol). The solution was heated under reflux and an ethanolic solution of potassium thiocyanate (0.097 g, 1 mmol) was added to the solution and further refluxed for 2 h. The resulting solution was allowed to stand at room temperature and after slow evaporation, dark brown crystals of compound **3** separated out, which were collected, washed with water, followed by ether and dried over P_4O_{10} in vacuo.

2.3. Physical measurements

Elemental analyses were carried out using a Heraeus Elemental Analyzer at the Regional Sophisticated Instrumentation Center, Central Drug Research Institute, Lucknow, India. Molar conductance measurements of the complexes were carried out in DMF solvent at 28 ± 2 °C on a Centuary CC-601 digital conductivity meter with dip type cell and platinum electrode. Approximately 10^{-3} M solutions were used. The magnetic susceptibility measurements were made using a simple Gouy balance at room temperature using mercury tetrathiocyanatocobaltate(II), $Hg[Co(NCS)_4]$ as calibrant. Infrared spectra were recorded on a Shimadzu DR 8001 series FTIR instrument as KBr pellets for spectra run from 4000 to 400 cm^{-1}, and using polyethylene for the range 500–100 cm^{-1} in a Nicolet Magna 550 FTIR instrument. Solid state reflectance spectra in the 200–900 nm range were recorded on an Ocean Optics SD 2000 Fibre Optic Spectrometer. ^1H NMR spectra were recorded in an AMX 400 MHz FT-NMR Spectrometer using $CDCl_3$ as a solvent and TMS as an internal standard at the Sophisticated Instruments Facility, Indian Institute of Science, Bangalore, India.

2.4. X-ray crystallography

Single crystals of compound **1** for X-ray analysis were grown by slow evaporation of the complex in methanol. A dark brown crystal of [NiLCl] (**1**) was mounted on a glass fiber using epoxy cement. The X-ray diffraction data were measured in frames with increasing ω (width of 0.3°/frame) at room temperature (293 K) using a Bruker SMART APEX CCD diffractometer, equipped with a fine focus sealed tube X-ray source. Selected crystal data and data collection parameters are given in Table 2. SMART software was used for data acquisition and SAINT software for data extraction [14]. Empirical absorption corrections were made on the intensity data [15]. The structure was solved by the heavy atom method and refined by full-matrix least squares using the SHELX system of programs [16] and the graphics tool was PLATON for windows [17]. All non-hydrogen atoms of the complex cations were refined anisotropically. Some hydrogen atoms were located from the difference Fourier map, and the rest were generated, assigned isotropic thermal parameters, and refined using a riding model. The hydrogen atoms were used for structure factor calculation only. A dark brown crystal of the compound $[NiLN_3]$ (**2**) was analyzed in a similar way and the crystallographic data along with the structural refinements are also given in Table 2.

3. Results and discussion

3.1. Synthesis of complexes

Colours, elemental analyses and stoichiometries of the ligand (HL) and its nickel(II) complexes are presented in Table 1. Elemental data for all the complexes are consistent with the 1:1:1 ratio of the metal:thiosemicarbazone:gegenion. All the complexes are found to be brown in colour, which is common to complexes involving thiosemicarbazone coordination, resulting from the sulfur to metal charge transfer bands [18,19]. Conductivity measurements in 10^{-3} DMF solution indicate that all complexes are non-electrolytes in this solution [20]. The non-electrolytic nature of complexes indicates that the ligand, which behaves as a uninegative ion, coordinates to Ni(II) along with the chloride, azide or thiocyanate ions giving the formula [NiLX] $\cdot\frac{1}{2}H_2O$ (where X = Cl, N_3 and NCS). The square planar geometry around Ni(II) in the complexes is also evident from their magnetic moment measurements.

3.2. Crystal structures of [NiLCl] and [NiL(N_3)]

The molecular structures of [NiLCl] (**1**) and [NiL(N_3)] (**2**) along with the atomic labelling are shown in Figs. 2 and 3, and selected bond lengths and bond angles are summarized in Table 3. The ligand behaves as

NNS tridentate, coordinating via its pyridine nitrogen, azomethine nitrogen and the thiolate sulfur atom giving a distorted square planar geometry around the nickel atom. The configuration of the thiosemicarbazone chain about the C(6)–N(3) bond changes *Z* to facilitate the coordination of the thiolate sulfur to Ni(1) in both complexes. The Ni(II) coordination is almost square planar in compound **1**, with a maximum value for the mean deviation of the pyridine N(1), imino N(3), thiosemicarbazone S(1) and chloride Cl(1) atoms from their own plane of 0.0447 Å. Compared to this, greater distortion from square planar configuration is observed in **2** as evident from the maximum mean deviation value of 0.2042 Å for the plane constituted by N(1), N(3), S(1) and N(6). The bond angles, S(1)–Ni(1)–N(3) (87.07°) and Cl(1)–Ni(1)–N(1) (96.99°) of [NiLCl] (**1**) and N(3)–Ni(1)–N(1) (83.54°) and S(1)–Ni(1)–N(6) (95.40°) of [$NiL(N_3)$] (**2**) also reveal the distortion of the square planes comprising of Ni(1), Cl(1), N(1), N(3) and S(1) atoms in compound **1** and Ni(1), N(1), N(3), N(6) and S(1) in compound **2**, respectively. The bond angles Ni(1)–N(3)–C(6) (116.68°) and Ni(1)–N(1)–C(5) (112.16°) in compound **1** and Ni(1)–N(3)–C(6) (117.11°) and Ni(1)–N(1)–C(5) (112.9°) in compound **2** are almost identical. Similarly, the bond angles N(1)–Ni(1)–Cl(1) (96.99°); N(3)–Ni(1)–S(1) (87.07°) in compound **1** and N(2)–Ni(1)–N(6) (93.84°); N(3)–Ni(1)–S(1) (87.32°) in compound **2** are also analogous, as expected on the basis of the similar square planar nature for both complexes. The dihedral angles formed by the least square planes Cg(1) and Cg(2) are 2.29° and 42.14° respectively for **1** and **2**. This strongly supports the distorted square planar conformation of both the molecules where greater distortion is observed for compound **2**. The C(6)–N(3)

N(6)–Ni(1)–S(1)			95.41(5)
N(7)–N(6)–Ni(1)			124.25(14)
N(8)–N(7)–N(6)			175.9(2)

bond distances in the complexes are observed to be 1.293(3) and 1.308(2) Å in compounds **1** and **2** respectively and compared to the corresponding C(6)–N(3) bond distance in the ligand, this bond length is much shorter in **1**. This indicates stronger coordination of the azomethine nitrogen in compound **1** compared to compound **2**. Also, this implies a partial double bond character for the C(6)–N(3) bond in compound **1** [21]. The delocalisation of electron density from the coordinating nitrogen onto the central metal atom gives rise to an elongated N(3)–N(4) bond compared to the uncomplexed thiosemicarbazone in both complexes. The loss of the proton bound to N(4) in HL produces a negative charge, which is delocalised on the N(3)–N(4)–C(12) system. This is indicated by the lengthening of the bond S(1)–C(12), 1.741 Å in **1** and 1.7422 Å in **2**, compared to the value of 1.671 Å in the ligand. The decrease in the bond length of C(12)–N(4), 1.331 Å in compound **1** and 1.329 Å in compound **2**, from the value of 1.384 Å of the thiosemicarbazone also supports thiolate formation. Ring puckering analyses and least-square plane calculations show that the Cg(3) ring comprising of N5, C13, C14, C15 and C16 adopts an envelope conformation on C(15) in both complexes **1** and **2**. These observations are consistent with the work on nickel(II) complexes of di-2-pyridyl ketone N(4) substituted thiosemicarbazones by West et al. [22,23].

The molecules of [NiLCl] are packed in a 'face to face' manner within the unit cell (Fig. 4). However, the molecules of [NiL(N_3)] adopt a 'zig-zag' arrangement as is evident from Fig. 5. The unit cell is viewed down the *a* axis and 2 and 8 molecules of compound **1** and **2** respectively are arranged in their unit volume cell. The assemblage of molecules in the respective manner in the unit cell is resulted by the diverse π–π stacking, CH–π and ring–metal interactions depicted in Tables 4 and 5. The metal chelate rings Cg(1) and Cg(2) are involved in π–π interactions with the pyridyl ring of the neighbouring unit at average distances of 3.7897 and 3.7733 Å in compounds **1** and **2**, respectively. In addition to the π–π stacking, the CH–π interactions of the pyridyl hydrogens with the metal chelate rings of the neighbouring molecules contribute to the stability of the unit cell packing. Short ring–metal interaction of the chelate ring Cg(4) is observed at a distance of 3.586 Å from the Ni centre in compound **1**, while they are perceived at 3.788 Å for Cg(5) from the metal in the packed molecules of compound **2**. The crystal structure of **1** is further stabilized by the two CH–π interactions, viz. C(3)–H(3)–Cg(5) and C(13)–H(132)–Cg(1) while stability is enhanced by the C(2)–H(2)–Cg(1) and C(16)–H(162)–Cg(2) interactions in compound **2**. These π–π, CH–π and ring–metal interactions point out the possibility for metalloaromaticity – a classic concept recently reviewed by Masui [24].

3.3. Infrared spectra

Selected IR bands are listed in Table 6. The assignments of IR bands are observed to be in good agreement with the X-ray structural data. The spectrum of the ligand exhibits a medium band at 3049 cm^{-1}, which is assigned to *ν*(NH) vibration. The absence of *ν*(NH) in the spectra of the complexes provides strong evidence for the ligand coordination around the Ni(II) ion in its deprotonated form. The spectra of the complexes exhibit a systematic shift in the position of the bands in the region 1600–1350 cm^{-1} due to *ν*(C=C) and *ν*(C=N) vibrational modes, and their mixing patterns are different from those present in the ligand spectrum. As a result of coordination, the band corresponding to azomethine nitrogen, *ν*(C=N) shifts to higher wavenumbers by ca. 10 cm^{-1} in the complexes [25–28]. The band at 810 cm^{-1}, which is assigned to *ν*(C=S) in the free ligand, is shifted to lower wavenumbers in the complexes suggesting the change of bond order and strong electron-delocalisation upon

[a] Hydrate waters are omitted for convenience.

chelation [29]. The appearance of a new peak at ca. 1540 cm^{-1} in the complex is due to the asymmetric stretching vibration of the newly formed C(12)=N(4) bond. A medium band around 470 cm^{-1} further supports azomethine nitrogen coordination. The spectrum of the chloro complex exhibits bands at 351 and 304 cm^{-1} corresponding to ν(Ni–S) and ν(Ni–Cl), respectively.

The azido complex (compound **2**) exhibits a strong band at 2037 cm^{-1} corresponding to the ν_a(NNN) stretching vibration [30] of the coordinating azido group. The broad bands at 575 and 440 cm^{-1}, assigned to δ(NNN) and ν(Ni–N), respectively [31], are not prominent, suggesting that Ni–N–N–N is not linear. Compound **3** shows a sharp band at 2101 cm^{-1}, which is assigned to ν(C–N) of the thiocyanato group, indicating coordination through the thiocyanate sulfur [32]. A weak band at 700 cm^{-1} and several weak bands near 420 cm^{-1} corresponding to ν(C–S) and δ(NCS) of the thiocyanato group further supports sulfur coordination of the thiocyanate anion with the nickel centre [33–36].

3.4. Electronic spectra

Solid state electronic spectra of compounds **1**, **2** and **3** were determined in the region 200–900 nm. The data are given in Table 7. The ligand (HL) has absorption maxima at 36,240 and 35,100 cm^{-1} due to the $\pi \rightarrow \pi^*$ transition of the pyridyl ring and the imine function of thiosemicarbazone moiety, respectively. There are two bands at 30,880 and 29,150 cm^{-1} corresponding to the $n \rightarrow \pi^*$ transition of the pyridyl nitrogen and thioamide function, respectively. These bands suffer marginal shifts on complexation. The broad band at 31,150 cm^{-1} in [NiLCl] is assigned for both $n \rightarrow \pi^*$ transitions and Cl $\rightarrow$ Ni(II) charge transfer transitions [37]. The shift of the $\pi \rightarrow \pi^*$ bands to the longer wavelength region is the result of the C=S bond being weakened and conjugation system being enhanced after the formation of the complex [38]. The absence of bands below 10,000 cm^{-1} confirms the planar nature of the complexes. The $d \rightarrow d$ spectral transitions can be assigned to $^1A_{1g} \rightarrow {}^1E_g$, $^1A_{1g} \rightarrow {}^1A_{2g}$ and $^1A_{1g} \rightarrow {}^1B_{1g}$ in the order of decreasing energy [39]. The d–d bands appearing as weak shoulders centered around the 20,000 cm^{-1} region are typical of square planar monoligated Ni(II) complexes [40]. The presence of intense $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions cause the lower energy d–d bands and LMCT bands to appear as weak shoulders, bringing about difficulty in the assignment of bands.

3.5. ^1H NMR spectra

^1H NMR spectral measurements are assigned as previously reported on di-2-pyridyl ketone N(4)-methyl and N(4)-dimethyl thiosemicarbazone and its metal complexes [23]. Table 8 shows that the N4H resonance is obtained at 15.0 ppm in HL. The large downfield shift of this proton indicates its involvement in hydrogen

bonding with the pyridyl nitrogen atom. This disappears in the spectra of complexes, which supports the enolisation and coordination of sulfur to Ni(II) in the thiolate form after deprotonation. The signals corresponding to aromatic protons are shifted downfield by 0.2–0.4 ppm on complexation. This is due to the electron withdrawal from the aromatic ring during the coordination of pyridyl nitrogen with the metal. The protons corresponding to the two pyridyl rings of di-2-pyridyl ketone appear as separate signals in the complexes, indicating its loss of equivalence due to imposition of a rigid geometry around the metal ion after complexation. This observation is consistent with the resonance of HL protons with C(1)H and C(11)H at $\delta = 8.71$ ppm (2H, doublet), C(2)H and C(10)H at $\delta = 7.34$ ppm (2H, triplet), C(4)H and C(8)H at $\delta = 7.00$ ppm (2H, doublet), C(3)H and C(9)H at $\delta = 6.8$ ppm (2H, triplet), which on complexation resonate at different fields. Due to the hydrogen bonding and CH–π interactions, the resonance absorptions of protons of the pyridyl ring are shifted downfield, which is further supported by X-ray crystallography.

4. Supplementary data

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Center, CCDC 216757 for compound NiLCl (**1**) and CCDC 216756 for compound NiL(N_3) (**2**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The synthesis and single-crystal X-ray structure of an ion-pair complex, [4,4′-H_2bpy][Cu(mnt)$_2$] (**1**), is described. In the crystal structure, the interactions between anions and cations via bifurcated (bpyN)–H···(NC–mnt)$_2$ hydrogen bonds give rise to a three-dimensional supramolecular network having well-defined channels. Complex **1** exhibits two redox waves at +0.44 and −0.36 V (versus SCE) in dimethylformamide corresponding to the Cu(mnt)$_2]^{1-}$/Cu(mnt)$_2]^{2-}$ and [4,4′-H_2bpy]$^{2+}$/[4,4′-H_2bpy]$^{1+}$ couples, respectively. The near-IR absorption at 1225 nm in the solid state has been attributed to the charge transfer from the copper dithiolate anion, [Cu(mnt)$_2]^{2-}$, to the bipyridinium cation, [4,4′-H_2bpy]$^{2+}$.

Keywords: Ion pair complex; Hydrogen bonding network; Non-covalent interaction; Charge transfer; Near-IR absorption

1. Introduction

The supramolecular construction of specific architectures from well-defined molecular building blocks has been an active area of chemical research over the past few years because such molecular assemblies may have new exciting properties and thereby can be used as functional materials [1,2]. The basis of supramolecular assembly is the reliable and meaningful connections between molecular structures based on non-covalent intermolecular interactions such as H-bonding. The use of metal–(bis)dithiolene complexes as building units in the construction of such molecule based framework materials has received considerable attention due to their potential applications in the areas of near-infrared (near-IR) dyes [3], conducting [4], magnetic [5] and non-linear optical materials [6]. The near-IR absorption is of special interest among these properties. There is a practical need for obtaining materials that give rise to a strong absorption in the near-IR region for the application in Q-switching infrared lasers [3]. The origin of such low energy absorption from metal (bis)dithiolene complexes may be discussed under two headings: (i) The HOMO and LUMO are delocalized over both dithiolene ligands, and the electronic transition between these orbitals gives rise to a strong absorption in the near-IR region. Donor substituents in the parent dithiolene raise the energy of the HOMO more than that of LUMO resulting in a shift of the low energy band to lower frequencies. (ii) Ion-pair charge transfer (IPCT) complexes $\{A^{2+}[ML_2]^{2-}\}$, M = Ni, Pd, Pt and Cu, between bipyridinium acceptors and (dithiolene)metalate donors exhibit IPCT bands in the near-IR region [7]. IPCT complexes of the type [M(Me$_2$-pipdt)$_2$][M(mnt)$_2$] (M = Pd, Pt) have recently been reported with near-IR absorption properties [8]. The present work deals with an IPCT complex. Although this ion-pair charge-transfer has been described as a supramolecular electronic interaction between the components, any supramolecular network based on such an ion pair is not yet known.

This is because bipyridinium derivatives have always been used, the parent dication $[4,4'\text{-}H_2bpy]^{2+}$ (simply protonated) has not been previously utilized as a redox active acceptor. Taking advantage of the ability of protons on bipyridine-nitrogen donors to form bifurcated H-bonding with cyano-nitrogens of the mnt ligand, we wish to report here that the $[Cu(mnt)_2]^{2-}$ anion undergoes N–H$\cdots$ N linking with the $[4,4'\text{-}H_2bpy]^{2+}$ cation to form a new type of 3D supramolecular network in $[4,4'\text{-}H_2bpy]_n[Cu(mnt)_2]_n$ (**1**).

2. Experimental

2.1. General methods

Elemental analyses were performed using a Perkin–Elmer 240C analytical instrument. Infrared (IR) spectra were recorded on KBr pellets with a JASCO FT/IR-5300 spectrometer in the region of 400–4000 cm^{-1}. Electronic spectra were obtained on a UV-3101PC/UV–VIS–NIR spectrophotometer (Shimadzu), equipped with a diffuse reflectance accessory (reflectance spectra were recorded on KBr pellets). The diffuse reflectance spectra obtained were then Kubelka-Munk corrected. The ESR spectra were recorded on a (JEOL) JES-FA200 ESR Spectrometer. A Cypress model CS-1090/CS-1087 electroanalytical system was used for cyclic voltammetric experiments. The electrochemical experiments were measured in DMF containing $[Bu_4N][ClO_4]$ as a supporting electrolyte, using a conventional cell consisting of two platinum wires as working and counter electrodes, and a saturated calomel electrode (SCE) as reference. The potentials reported here are uncorrected for junction contributions. Electrical resistivities of compacted pellets were checked by the conventional two-probe technique. Powder X-ray diffraction data were collected on a Phillips PW 3710 diffractometer.

2.2. Materials

Disodium maleonitriledithiolate (Na_2mnt) was prepared using a synthetic procedure described in the literature [9]. $[Bu_4N]_2[Cu(mnt)_2]$ was prepared following a method as reported by Davison and Holm [10]. 4,4′-Bipyridine was purchased from Merck and used as received. Solvents were purified by standard methods. The preparations and measurements were carried out in diffuse light since dithiolene complexes are known to be light sensitive.

2.3. Synthesis of $[4,4'\text{-}H_2bpy][Cu(mnt)_2]$ (**1**)

2.3.1. Method 1

To a solution of 4,4′-bipyridine (0.31 g, 2.0 mmol) in CH_3CN (25 ml) kept in an oil bath, was added a solution of $CuCl_2\cdot 2H_2O$ (0.17 g, 1 mmol) in water (10 ml). A solution of $[Bu_4N]_2[Cu(mnt)_2]$ (0.83 g, 1 mmol) in CH_3CN (10 ml) was subsequently added to the resulting dark red reaction mixture, which was then refluxed with stirring for 2 h. The insoluble material, formed during this time, was removed by filtration and the filtrate was allowed to stand for three days at room temperature. This resulted in the formation of deep-red, prismatic crystals, which were filtered off and washed with *i*PrOH/Et_2O and then air-dried at room temperature. Yield: 0.090 g (9%, based on 4,4′-bipyridine). Elemental *Anal.* Calc. for $C_{18}H_{10}CuN_6S_4$: C, 43.06; H, 2.01; N, 16.74. Found: C, 43.12; H, 1.98; N, 16.68%. IR (cm^{-1}): 3200m (ν_{N-H}), 3132m (ν_{N-H}), 3090w (ν_{N-H}), 3070w (ν_{N-H}), 2205vs (ν_{CN}), 1471m ($\nu_{C=C}$), 862w (ν_{C-S}). The compound was additionally characterized by UV–Vis and ESR spectroscopy, cyclic voltammetry and single-crystal X-ray structural analysis.

2.3.2. Method 2

To a solution of 4,4′-bpy (0.10 g, 0.64 mmol) in methanol (5 ml), HCl (0.2 ml, 36%) was added slowly, resulting in the precipitation of $[4,4'\text{-}H_2bpy]Cl_2$ as colorless crystalline compound. It was filtered, washed with methanol-diethylether and dried in vacuum. Yield: 0.127 g (86% based on 4,4′-bipyridine used). Elemental *Anal.* Calc. for $C_{10}H_{10}N_2Cl_2$: C, 52.42; H, 4.40; N, 12.23. Found: C, 53.01; H, 4.31; N, 12.02%. IR (cm^{-1}): 3054m (ν_{N-H}), 2733br, 1630m, 1593s, 1481s, 1232m, 1194m, 787s.

An aqueous solution (5 ml) of $[4,4'\text{-}H_2bpy]Cl_2$(0.12 g, 0.52 mmol) was slowly added to an acetone solution (15 ml) of $[Bu_4N]_2[Cu(mnt)_2]$ (0.48 g, 0.58 mmol) and the reaction mixture was stirred for 10 min at room temperature. Subsequently, it was heated on a water bath for 5 min resulting in the formation of a dark red microcrystalline solid. The solid was filtered off, washed with acetone and dried under vaccum. This compound was recrystallized by slow diffusion of diethylether into its DMF solution at 10 °C for 48 h. The dark red plate-shaped crystals, appearing during this time, were filtered, washed with diethylether and dried in vacuum. Yield: 0.192 g (65%, based on $[Bu_4N]_2[Cu(mnt)_2]$). This compound was identified as **1**. Elemental *Anal.* Calc. for $C_{18}H_{10}CuN_6S_4$: C, 43.06; H, 2.01; N, 16.74. Found: C, 42.98; H, 1.95; N, 16.65%. The compound exhibited identical IR spectrum, X-ray powder diffraction pattern, cyclic voltammograms, electronic and ESR spectra as shown by compound **1**, obtained in method 1. Crystals, suitable for single-crystal X-ray diffraction study, were grown in a λ-shaped diffusion glass-tube set-up by dissolving $[Bu_4N]_2[Cu(mnt)_2]$ (0.22 g, 27 mmol) in acetone in one arm and $[4,4'\text{-}H_2bpy]Cl_2$ in water in the other arm of the λ-shaped set-up. The remaining gap, inside the tubes, was carefully filled up with acetone and the set-up was kept at room temperature for 20 days. Deep-red

prismatic crystals, precipitated inside the tubes, were identified as **1** using the above-mentioned routine techniques and gave identical unit cell parameters ($a = 12.742(1)$ Å, $b = 7.462(9)$ Å, $c = 21.041(5)$ Å, orthorhombic, $V = 2000(3)$ Å^3) as shown by the crystals obtained in method 1.

2.4. X-ray crystallography

A deep-red prismatic crystal of size $0.68 \times 0.68 \times 0.52$ mm^3 was mounted on an Enraf-Nonius CAD4 diffractometer and the data were collected at 20 °C temperature using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. An empirical absorption correction based on a series of ψ scans was applied. The structure was solved by the direct method (SHELXS-97) [11a] and refined by the full-matrix least-squares on F^2 method (SHELXL-97) [11b]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were introduced at calculated positions and included in the refinement riding on their respective parent atoms. The crystallographic data and the parameters of structure refinement are summarized in Table 1.

2.5. X-ray powder diffraction studies

The X-ray powder diffraction pattern of the crystals, synthesized by method 2, and the computer simulated [12] pattern obtained from the single-crystal X-ray data of the crystal, isolated in method 1, were practically identical (see Supplementary information).

3. Results and discussion

3.1. Synthesis

Compound **1** has been synthesized (in method 1) by heating a ~3:1 acetonitrile/water solution of $[Bu_4N]_2[Cu(mnt)_2]$, $CuCl_2 \cdot 2H_2O$ and 4,4′-bipyridine. The dissolution of $CuCl_2$ lowers the pH of the reaction mixture by generating HCl acid, whereby 4,4′-bipyridine gets protonated with the formation of the $[4,4'\text{-}H_2bpy]^+$ cation. However, the yield in method 1 is very poor. **1** can easily be obtained in a high yield synthesis (method 2) simply by using $[4,4'\text{-}H_2bpy]Cl_2$ and $[Bu_4N]_2[Cu(mnt)_2]$ as shown in the following reaction:

$$[4,4'\text{-}H_2bpy]Cl_2 + [Bu_4N]_2[Cu(mnt)_2] \rightarrow [4,4'\text{-}H_2bpy][Cu(mnt)_2] + 2Bu_4NCl \quad (1)$$

3.2. Description of the structure

1 crystallizes in the orthorhombic space group $Pca2_1$. A thermal ellipsoidal plot of **1** with non-hydrogen atom labelling is presented in Fig. 1. This shows the abundance of $[4,4'\text{-}H_2bpy]^{2+}$ and $[Cu(mnt)_2]^{2-}$ as an ion-pair. The crystallographic details are summarized in Table 1 and relevant bond lengths and angles for the complex are described in Table 2. In the anion, the geometry around the copper atom, which is coordinated by four sulfur atoms from two mnt ligands, is considerably distorted, with a dihedral angle of 30.28° between the mnt planes. The two pyridine rings of the $[4,4'\text{-}H_2bpy]^{2+}$ cation also exhibit non-coplanar geometry with a dihedral angle of 37.84° between the least-square planes of the two rings (Table 3). The non-planarity around the metal ion, which is not very common in bis-dithiolene complexes, is generally caused by dimerization via metal sulfur interactions as observed in complexes, $Co_2[S_2C_2(CF_3)_2]_4$ [13], $[Bu_4N]_2[Co_2(S_2C_6Cl_4)_4]$ [14], $[Bu_4N_2[Fe_2(mnt)_4]$ [15], $[Bu_4N]_2[Fe_2(edt)_4]$ [16] and $[Et_4N]_2[Mn_2(edt)_4]$ [17,18]. Deviations from planarity were also found in copper bis-dithiolene complexes $[epy]_2[Cu(dmit)_2]$ [19], $[NMe_4]_2[Cu(mnt)_2]$ [20] and $[methyleneblue]_2[Cu(mnt)_2] \cdot Me_2CO$ [21] with dihedral angles of 57.3°, 41° and 47.4°, respectively. These deviations are ascribed to a close H···S distance of 2.9 Å, the presence of several short contacts between the atoms of the anion and cations, and the introduction of stacked, large methylene blue molecules, respectively. Non-planarity between two mnt ligands in the present ion pair complex **1** seems to be caused by the supramolecular interactions between the cation and anion through all possible hydrogen bonding sites of both components as described in the following section.

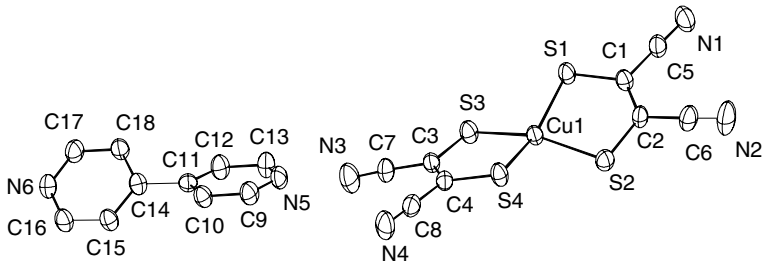

Fig. 1. Thermal ellipsoid plot of **1** (50% probability).

There are two H-bonding donors for the [4,4′-H_2bpy]$^{2+}$ dication and four H-bonding acceptors for the Cu(mnt)$_2$]$^{2-}$ dianion. Supramolecular interactions are thus expected between the cations and anions via bifurcated H-bonds. This is indeed the case as depicted in Fig. 2. The bifurcated hydrogen bonding, which is observed in other bipyridinium containing compounds, involves the interactions between the N–H groups of bipyridinium cations and the CN groups of mnt ligands. In the crystal structure, each bipyridinium dication interacts with four complex anions and each complex anion communicates with four bipyridinium dications (Fig. 2). The hydrogen bonding interactions between non-planar components (cation and anion) of the ion pair complex **1** gives rise to a three-dimensional supramolecular network having well-defined channels as shown in Fig. 3. Whereas one type of channel is found in the views along the crystallographic *a*- and *c*-axes (see Supplementary information), two types of channels (20 and 30 membered rings) are clearly shown in Fig. 3, viewed along cystallographic *b*-axis. There are four types of N–H···N hydrogen bonds through out this supramolecular network of **1**. The relevant distances and angles of hydrogen bonding contacts are summarized in Table 4.

3.3. IR spectroscopy

Compound [Bu_4N]$_2$[Cu(mnt)$_2$] exhibits a ν(CN) band at 2190 cm^{-1} in the IR spectrum. Upon (bpyN)–H···(NC–mnt)$_2$ hydrogen-bond formation (Fig. 2) in **1**, the ν(CN) shifts to a higher frequency (2205 cm^{-1}). The cyanide group acts as a donor by donating electrons to the proton of the [4,4′-H_2bpy]$^{2+}$ cation from an orbital which is weakly antibonding in nature [22]. Thus the ν(CN) of the hydrogen bonded-complex **1** is higher than the value obtained in [Bu_4N]$_2$[Cu(mnt)$_2$]. The ν(NH) vibrations appear at 3054 cm^{-1} in the IR spectrum of [4,4′-H_2bpy]Cl_2. Four weak features are observed at 3200, 3132, 3090 and 3070 cm^{-1} for ν(NH) vibrations in the IR spectrum of **1**. This shifting of ν(NH) bands to higher frequencies in **1** is not unexpected because strong N–H···Cl hydrogen bonding is anticipated in [4,4′-H_2bpy]Cl_2.

3.4. Electrochemistry

The cyclic voltammogram of **1** in DMF exhibits two quasi-reversible redox waves at $E_{1/2} = -0.36$ V versus SCE ($\Delta E_p = 98$ mV) and 0.44 V versus SCE ($\Delta E_p = 79$ mV). Both electrochemical responses, displayed by the complex, are quasi-reversible processes. The first response at 0.44 V is assigned to the Cu(mnt)$_2$]$^{1-}$/Cu(mnt)$_2$]$^{2-}$ couple. This data agrees well with that reported for the [Bu_4N]$_2$[Cu(mnt)$_2$] complex [23]. The second reductive response at −0.36 V can be described as the [4,4′-H_2bpy]$^{2+}$ + e ⇌ [4,4′-H_2bpy]$^{1+}$ process.

3.5. Electronic spectra

The UV–Vis solution spectra of **1**, [Bu_4N]$_2$[Cu(mnt)$_2$] and [4,4′-H_2bpy]Cl_2 are displayed in Fig. 4. The ab-

sorption bands at 325 and 375 nm are due to L(π)–L(π*) transitions and bands in the 490 nm region are assigned to MLCT absorptions for the metal dithiolene parts [7e]. In solution, the bipyridinium cation does not absorb above 300 nm. As compared to the tetrabutylammonium salt, the band positions remain unchanged in 4,4′-bipyridinium salt **1**. The broad and weak absorption bands appear at ~1200 nm (Fig. 4(b)). The intensity of this near-IR band of **1** ($\varepsilon = 110$ M^{-1} cm^{-1}) is higher than that of $[Bu_4N]_2[Cu(mnt)_2]$ ($\varepsilon = 70$ M^{-1} cm^{-1}).

In the solid state, compound **1** exhibits a band at 1225 nm (in the near-IR region) of much higher intensity and a sharp band at 760 nm in its diffuse reflectance spectrum; the complex $[Bu_4N]_2[Cu(mnt)_2]$ does not show any intense band in the near-IR region, but shows a moderate absorption at 810 nm in the solid state as shown in Fig. 5. Whereas the peak at ~1200 nm is predominant in the diffuse reflectance spectrum of **1**, this peak is weaker but recognisable in the solid state electronic spectrum of $[Bu_4N]_2[Cu(mnt)_2]$ (Fig. 5). The molar extinction coefficient of this peak (~1200 nm) in the solution absorption spectrum of $[Bu_4N]_2[Cu(mnt)_2]$ is 70 M^{-1} cm^{-1}. We, therefore, tentatively assign this 1225 nm band in the solid state electronic spectrum of **1** to a d–d absorption overlapped by an IPCT-band. The absorptions at 760 and 810 nm of compounds **1** and $[Bu_4N]_2[Cu(mnt)_2]$, respectively, in their solid states (Fig. 5) are not visible in the corresponding solution absorption spectra (Fig. 4). These solid state bands are tentatively assigned to an anion–cation type intermolecular interaction in their corresponding solid states. The diffuse reflectance spectrum of $[4,4'\text{-}H_2bpy]Cl_2$ shows a broad band in the region of 450–700 nm (Fig. 5). A similar broad feature (with little shift) is observed in the solid state electronic spectrum of $[4,4'\text{-}H_2bpy](BF_4)_2$. However, in the absence of further studies, mainly theoretical calculations, the assignment of these bands is difficult.

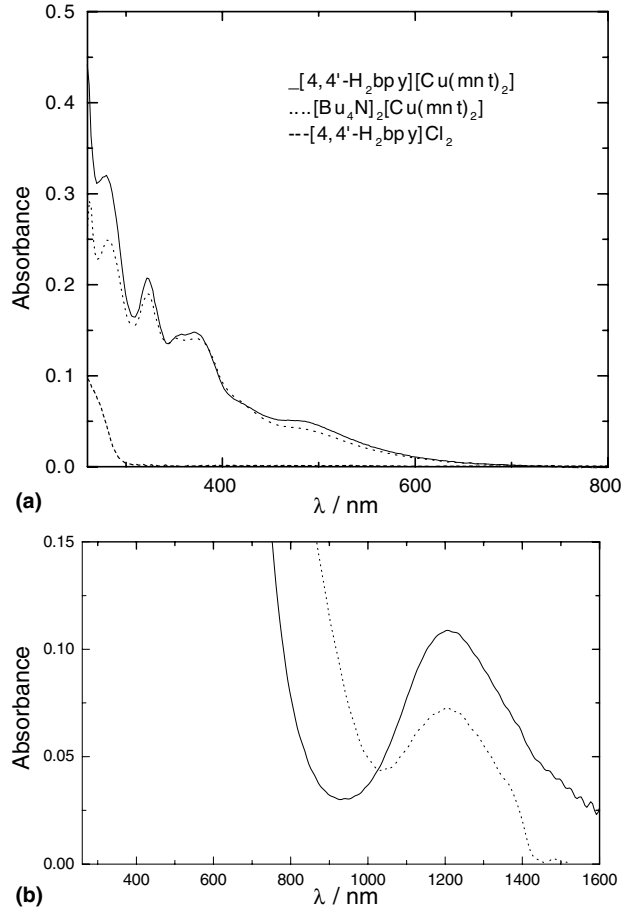

Fig. 4. (a) UV–Vis spectra in DMF (1×10^{-5} M). (b) 1×10^{-3} M in DMF, —, $[4,4'\text{-}H_2bpy][Cu(mnt)_2]$; ···, $[Bu_4N]_2[Cu(mnt)_2]$.

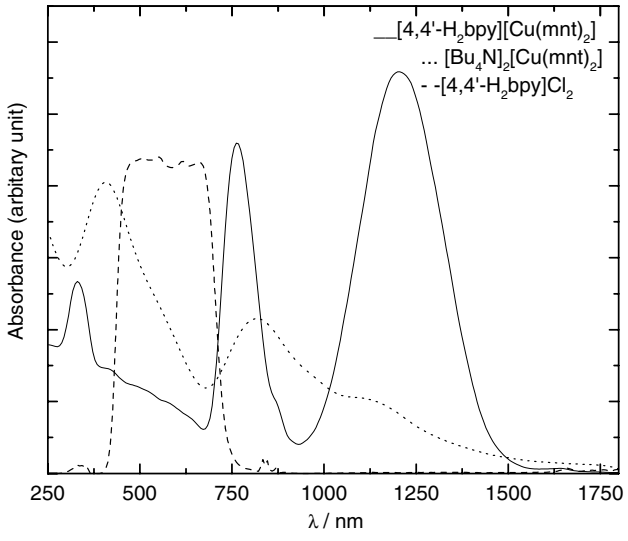

Fig. 5. The diffuse refletance spectra of $[4,4'\text{-}H_2bpy][Cu(mnt)_2]$ (**1**), $[NBu_4]_2[Cu(mnt)_2]$ and $[4,4'\text{-}H_2bpy]Cl_2$.

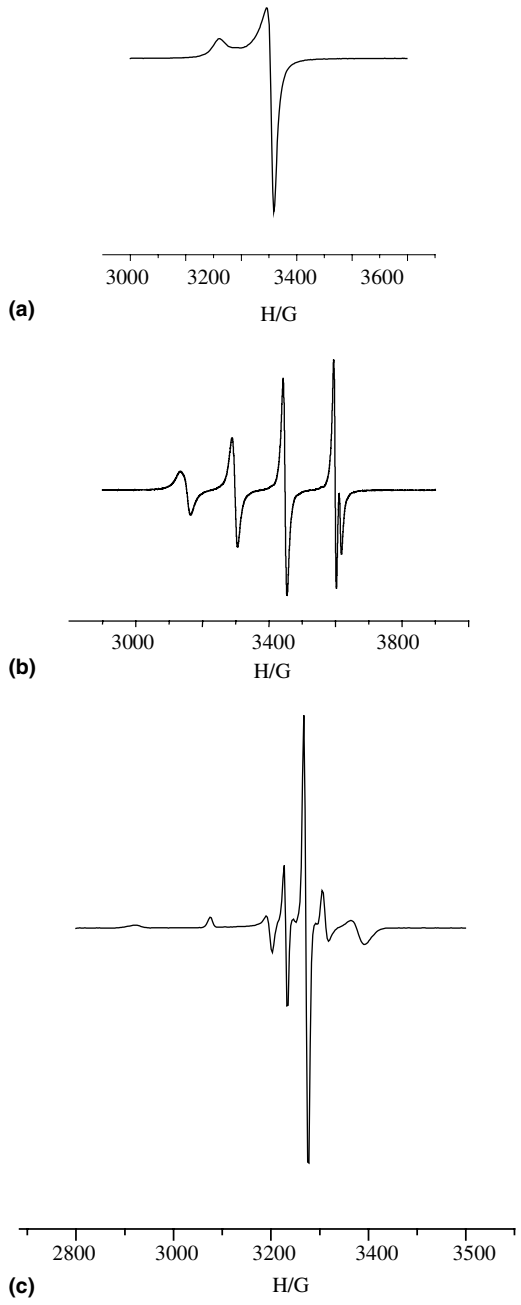

Fig. 6. The ESR spectra of [4,4′-H_2bpy][Cu(mnt)$_2$] (**1**) at room temperature: (a) in the solid state, (b) in DMF. (c) The ESR spectrum of [4,4′-H_2bpy][Cu(mnt)$_2$] (**1**) in the solid state at liquid nitrogen temperature.

3.6. ESR spectroscopy

Fig. 6 illustrates the ESR spectra of **1** in the solid-state and in solution at room temperature. The g values ($g_{\|} = 2.08$, $g_{\perp} = 2.03$) observed in the room temperature solid-state ESR spectrum (Fig. 6(a)) are very close to those ($g_{\|} = 2.090$, $g_{\perp} = 2.024$ and $g_{\|} = 2.092$, $g_{\perp} = 2.026$) of the non-planar Cu(II)–dithiolene complexes, [mb]$_2$[Cu(mnt)$_2$]·Me_2CO (mb = methylene blue) [20] and [epy]$_2$[Cu(dmit)$_2$] (epy = N-ethylpyridinium, H_2dmit = 4,5-dimercapto-1,3-dithiole-2-thione) [19], respectively. These g values are also close to those ($g_1 = 2.023$, $g_2 = 2.026$, $g_3 (= g_{\|}) = 2.086$) of the planar Cu-mnt complex, [Bu_4N]$_2$[Cu(mnt)$_2$] [24]. The isotropic ^{63,65}Cu hyperfine structure is observed ($g_0 = 2.052$, $|A_0| = 7.648$ mT) in the solution spectrum of **1** (Fig. 6(b)). The solid-state ESR spectrum of **1** at liquid nitrogen temperature exhibits hyperfine structure due to ^{63,65}Cu nuclei as shown in Fig. 6(c). Interestingly, both $g_{\|}$ and $g_{\perp}$ features get resolved due to ^{63,65}Cu hyperfine coupling, which is very rarely observed in metal–dithiolene complexes. The average value of the hyperfine coupling parameters (determined from $|A_{\|}| = 15.28$ mT and $|A_{\perp}| = 4.39$ mT) is 8.02 mT, which is close to that (7.648 mT) of the solution ESR spectrum at room temperature.

4. Conclusions

A series of ion-pair charge-transfer (IPCT) complexes {$A^{2+}[ML_2]^{2-}$}, M = Ni, Pd, Pt, and Cu, between bipyridinium acceptors and (dithiolene)metalate donors, that exhibit IPCT bands in the near-IR region, has been reported in literature. In these complexes, the acceptors are always bipyridinium derivatives, not the parent bipyridinium (protonated) cation. The results, presented herein, show that the protonated bipyridnium dication, not only forms an ion pair charge transfer complex with a metal dithiolate dianion showing a sharp absorption in the near-IR region, but also it undergoes hydrogen bonding interactions with cyano ligands of the mnt complex constructing a three-dimensional supramolecular network in the crystal of **1**.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 204645 for compound **1**. Received 4 December 2003; accepted 3 February 2004

Abstract

Two new copper(II) azide complexes $Cu_2(pn)_2(N_3)_4$ (**1**) and $Cu_3(dien)_2(N_3)_6$ (**2**) (pn = 1,3-diaminopropane and dien = diethylenetriamine) have been synthesized and characterized by single crystal X-ray diffraction. In complex **1** each copper(II) atom is coordinated to six nitrogen atoms from four azide anions and one 1,3-diaminopropane molecule in a distorted octahedral geometry. Successive pairs of copper(II) atoms are linked by two end-on azide bridges to form a polymeric chain. In centrosymmetric complex **2** the central copper(II) is coordinated by two monodentate azide anions and linked to two terminal copper atoms by double end-on azide bridges to give a linear trinuclear unit. The coordination geometry around each of the terminal copper atoms is square pyramidal, being surrounded by two nitrogen atoms of the bridging azide anions and three nitrogen atoms of the diethylenetriamine ligand. Magnetic susceptibility measurement of complex **2** in the range 2–300 K showed weak antiferromagnetic exchange between the copper(II) ions ($J = -2.09(8)$ cm^{-1}) through the double end-on azide bridges.

1. Introduction

Great efforts have been devoted to the study of transition metal azide complexes because of their diverse structural types and fascinating magnetic properties [1–4]. To clarify the magneto-structural correlation of azide-bridged complexes, diverse co-ligands were introduced and the structures as well as magnetic properties of the adjusted complexes have been systematically investigated. Numerous complexes including dinuclear [5,6], trinuclear [7,8] and tetranuclear [9–11] species, together with one- [12,13], two- [14–16] and three-dimensional [17] coordination polymers have been well documented. On the other hand, the investigation results indicate that the introduction of polyamine co-ligands to the copper(II) azide complex system may bring about some interesting structures and magnetic properties due to the coordination functionality of various nitrogen donor atoms of the co-ligands [18–26]. To better understand the influence of the polyamine co-ligands on the structures and properties of the copper(II) azide complexes, we herein report the synthesis and characterization of two new copper(II) azide complexes $Cu_2(pn)_2(N_3)_4$ (**1**) and $Cu_3(dien)_2(N_3)_6$ (**2**).

2. Experimental

2.1. Materials and physical measurements

All reagents were commercial grade and were used as received. Elemental analyses for C, H, N were carried

out on an Elementar Vario EL-III analyzer, metal was determined by the ICP method. Magnetic measurement was performed on an Oxford Maglab2000 system in the temperature range of 2–300 K under a 30 kOe field. Diamagnetic corrections were made with Pascal's constants for all constituent atoms and magnetic moments were calculated by the equation $\mu_{\text{eff}} = 2.828(\chi_M T)^{1/2}$.

2.2. Preparation of the complexes

2.2.1. $Cu_2(pn)_2(N_3)_4$ (1)

A 2 ml ethanol solution of 1,3-diaminopropane (44 mg, 0.60 mmol) was added dropwise to a 3 ml ethanol solution of $CuCl_2 \cdot 2H_2O$ (51 mg, 0.30 mmol) under stirring. A 2 ml aqueous solution of NaN_3 (78 mg, 1.20 mmol) was added to a 3 ml ethanol solution of $MnCl_2 \cdot 4H_2O$ (59 mg, 0.30 mmol) and the mixture was stirred for another 5 min. Then the above two solutions were mixed, and a deep blue solution was formed and filtered, the filtrate evaporated slowly in air. After two weeks, deep blue block crystals of $Cu_2(pn)_2(N_3)_4$ (**1**) were obtained in 22% yield. *Anal.* Found: C, 15.71; H, 5.14; N, 50.27; Cu, 27.13. Calc. for $C_6H_{20}Cu_2N_{16}$: C, 16.25; H, 4.55; N, 50.54; Cu, 28.66%.

2.2.2. $Cu_3(det)_2(N_3)_6$ (2)

A 4 ml ethanol solution of diethylenetriamine (31 mg, 0.30 mmol) and a 4 ml ethanol solution of copper acetate (60 mg, 0.30 mmol) were mixed and stirred for 5 min. To the resulting deep-blue mixture was added dropwise a 2 ml aqueous solution of sodium azide (20 mg, 0.30 mmol). After stirring for another 5 min, the solution was filtered and the filtrate evaporated slowly in air. After one month, deep blue block crystals of $Cu_3(dien)_2(N_3)_6$ (**2**) were separated in 17% yield. *Anal.* Found: C, 14.53; H, 4.45; N, 52.33. Calc. for $C_8H_{26}Cu_3N_{24}$: C, 14.80; H, 4.04; N, 51.79%.

2.3. X-ray crystallography

Data collection for **1** and **2** was carried out on a Bruker Smart APEX CCD diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å) at 298 K. Intensities were corrected for empirical absorption based on SADABS scan technique [27]. Both structures were solved by direct methods and refined by full-matrix least-squares on F^2 [28]. All non-H atoms were refined anisotropically, the H atoms attached to C atoms were added at calculated positions and the H atoms linked to N atoms were located from the difference Fourier map and refined freely with N–H distances 0.71(3)–0.87(5) Å. Table 1 gives crystallographic data of the two complexes. Tables 2 and 3 list the selected bond parameters and hydrogen bond parameters of complex **1**. Tables 4 and 5 show the selected bond parameters and hydrogen bond parameters of complex **2**.

3. Results and discussion

3.1. Description of the structures

The copper(II) coordination environment of complex **1** is depicted in Fig. 1. Each Cu(1) atom is surrounded by one terminal azide N atom (N(4)), one bridging azide N atom (N(1A)) and two N atoms (N(7), N(8)) of one 1,3-diaminopropane molecule in the basal plane, along with two bridging azide N atoms (N(1), N(3B)) in the apical sites to form a distorted octahedral geometry. Two copper(II) atoms are connected by two end-on azide bridges to define a centrosymmetric dimeric unit, and each dimeric units is linked together to form a chain

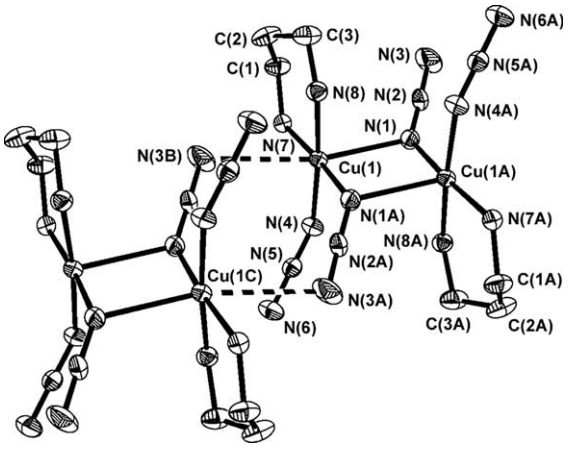

Fig. 1. The copper(II) coordination environment of complex **1**. Thermal ellipsoids are at 50% probability level.

structure via weak interactions ($Cu\cdots N = 2.856(5)$ Å). Finally, these chains are crosslinked via hydrogen bonds involving the terminal azide N atoms and the amino H atoms of the pn group ($N\cdots N = 3.068(5)$–$3.194(5)$ Å, $H\cdots N = 2.29(5)$–$2.40(5)$ Å and $N–H\cdots N = 159(4)°$–$164(4)°$), thus forming a two dimensional network structure (Fig. 2). In complex **1** the bridging azide anions exhibit two types of coordination modes: end-on fashion within the dimeric unit and end-to-end fashion between neighboring dimeric units. The $Cu\cdots Cu$ distance within the dimer is 3.3088(9) Å, and that between two dimers is 6.835(2) Å.

The molecular structure of the trinuclear complex **2** is depicted in Fig. 3. The central copper(II) atom adopts a *cis*-octahedral geometry, being linked to four basal nitrogen atoms (N(4), N(4A), N(10) and N(10A)) and two apical nitrogen atoms (N(7), N(7A)) from end-on bridging azide groups. Each of the two terminal copper(II) atoms adopts a square pyramidal geometry, with the azide nitrogen atom N(7) and three nitrogen atoms (N(1), N(2) and N(3)) from one diethylenetriamine ligand in the basal plane, along with azide nitrogen atom N(4) in the apical site. The distances between two adjacent copper(II) atoms is 3.3509(8) Å. Complex **2** is the first trinuclear copper(II) azide complex with polyamine co-ligands [18–26]. Intermolecular hydrogen-bonding interactions between the N atoms of the azide groups and the amino H atoms of the dien group ($N\cdots N$ 3.057(5)–3.157(5) Å, $H\cdots N$ 2.37(3)–2.58(4) Å and $N–H\cdots N$ 130(3)°–161(4)°) lead to the construction of a three-dimensional network structure (Fig. 4).

In complex **1** and **2** the $Cu–N_{basal}$ distances show no significant difference. The $Cu–N_{pn}$ distances in complex **1** (1.994(3)–2.006(3) Å) are almost equal to the $Cu–N_{dien}$ distances in complex **2** (1.994(4)–1.996(4) Å), and are consistent with the corresponding distances in aliphatic amine-copper complexes [29,30]. In complex **1** the axial $Cu–N_{azide}$ distances (2.461(3)–2.856(5) Å) are markedly

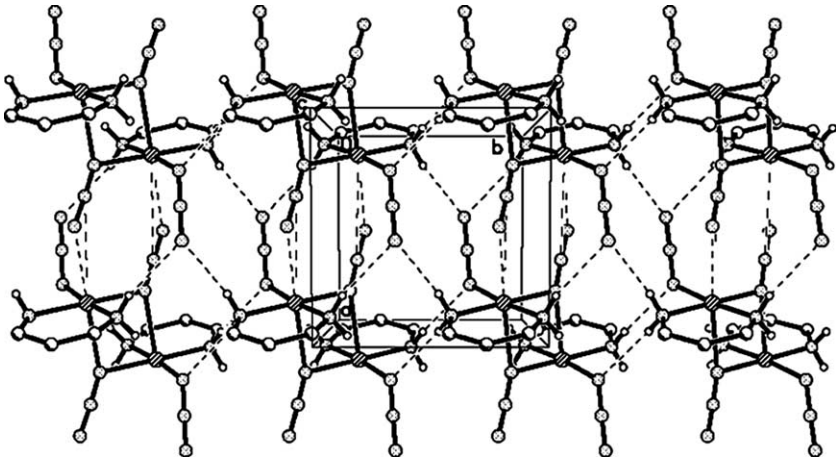

Fig. 2. The two-dimensional network structure of complex **1** form by hydrogen-bonding interactions (dashed lines).

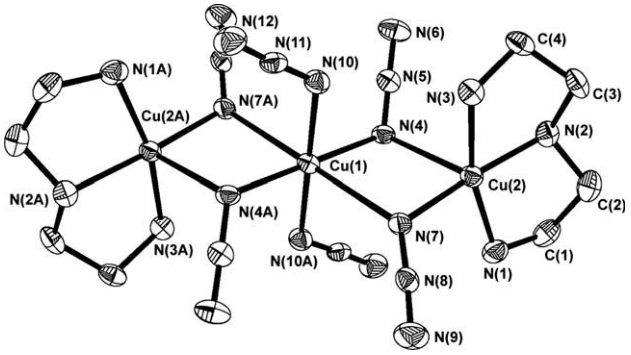

Fig. 3. The molecular structure of complex **2**. Thermal ellipsoids are at 50% probability level.

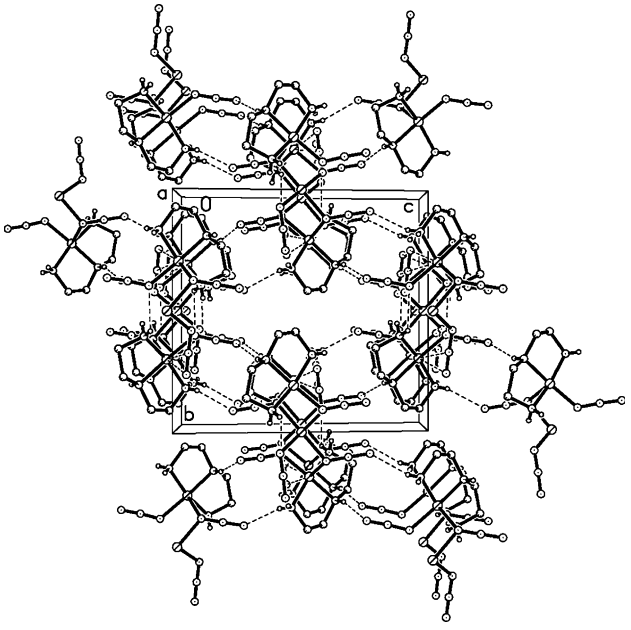

Fig. 4. The three-dimensional network structure of complex **2** formed by hydrogen-bonding interactions (dashed lines).

longer than the basal Cu–N_{azide} distance (2.006(3) Å); a similar situation is also observed in complex **2** and this axial elongation could be attributed to the Jahn–Teller distortion of copper(II) ions. The Cu–N_{azide} distances of the two complexes are respectively comparable to the corresponding distances in other copper(II) azide complexes [8,25,31]. In **2** the N_{basal}–Cu–N_{basal} (two neighboring basal N atoms) and N_{apical}–Cu–N_{basal} angles for the central copper(II) atom are in the ranges 89.8(1)°–90.2(1)° and 81.6(1)°–98.4(1)°, respectively, while the corresponding values for the terminal copper(II) atoms are 84.3(2)°–95.4(2)° and 84.6(1)°–101.7(1)°, indicating that the geometry of the terminal copper(II) atoms are more distorted than that for the central one. Further comparison also reveals that the geometry of complex **1** is more distorted than that of complex **2**.

It is interesting to note that the replacement of pn by dien results in the change of the coordination mode of the copper(II) atom with polyamine ligands from octahedral for **1** to square pyramidal for **2**. Obviously, this may be attributed to the larger steric effect of dien, which prohibits other azide groups from further coordination to the terminal copper, therefore favoring formation of trinuclear complex **2**. The steric effect of two aliphatic amines is also reflected by the relatively larger N(4)–Cu(2)–N(2) angle (101.7(1)°) in complex **2** as compared to the N(7)–Cu(1)–N(1) angle (94.7(1)°) in complex **1**.

3.2. Magnetic properties

The magnetic susceptibilities of complex **2** have been measured in the temperature range of 2–300 K at 30 kOe, and the plots of $\chi_M T$ and ${\chi_M}^{-1}$ vs T are shown in Fig. 5. The magnetic susceptibility above 20 K obeys the Curie–Weiss law with the Weiss constant $\theta = -0.5$ K, and a Curie constant $C = 1.14$ cm^3 mol^{-1} K. The C value is very close to the value (1.13 cm^3 mol^{-1} K) of three non-interacting Cu^{II} ions with $g = 2.0$. With the

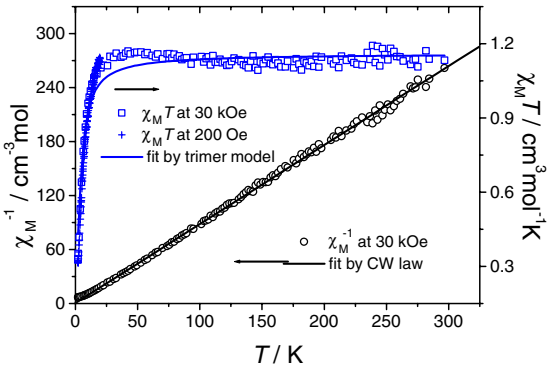

Fig. 5. Plot of $\chi_M T$ at 30 kOe (open square), $\chi_M T$ at 200 Oe (cross) and χ_M^{-1} (open circle) vs. T for complex **2**; the solid line shows the best fit theoretical curves for complex **2**.

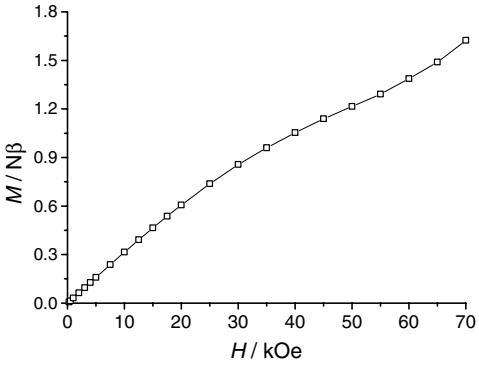

Fig. 6. Magnetization (open square) for complex **2** at 1.86 K as a function of the applied magnetic field (0–70 kOe).

decrease of the temperature, $\chi_M T$ remains almost constant to ca. 20 K, and then decreases rapidly, reaching a minimum of 0.33 cm^3 mol^{-1} K at 2.2 K. The $\chi_M T$ measured at low field (200 Oe) below 20 K also shows a decrease, suggesting the occurrence of antiferromagnetic interactions between adjacent Cu(II) ions. These may be attributed to magnetic coupling in end-on azide-bridging copper(II) complexes in which large Cu–N (EO azide nitrogen) distances above 2.05 Å often promote antiferromagnetic coupling between adjacent copper(II) atoms [32]. In complex **2** the Cu(1)–N(7) and Cu(2)–N(4) distances are 2.531(3) and 2.448(3) Å, respectively, leading to antiferromagnetic coupling within the trinuclear unit.

The magnetic data of the complex **2** were fitted using a trinuclear Cu^{II} model [33].

$$\chi_M = \frac{Ng^2\beta^2}{4kT}\,\frac{1+\exp\left(\frac{-2J}{kT}\right)+10\exp\left(\frac{J}{kT}\right)}{1+\exp\left(\frac{-2J}{kT}\right)+2\exp\left(\frac{J}{kT}\right)}. \qquad (1)$$

In Eq. (1), N, β, and g have their usual meaning and J is the exchange coupling constant describing the magnetic interaction between two adjacent copper(II) ions within the trinuclear unit. The fitted values are in good agreement with the experimental data and the parameters $J = -2.09(8)$ cm^{-1}, $g = 2.031(3)$ and $R = 1 \times 10^{-3}$ ($R = \Sigma[(\chi_M)\text{obs} - (\chi_M)\text{calc}]^2/\Sigma[(\chi_M)\text{obs}^2$ further confirm antiferromagnetic exchange coupling within the trimers. It is interesting to compare the magnetic properties of complex **2** with [Cu(4-Etpy)(N$_3$)$_2$]$_2$ [6]. Both complexes are homo-azide end-on bridged copper(II) complexes; the former shows weak antiferromagnetic coupling while the latter displays ferromagnetic coupling between adjacent copper(II) ions. The ferromagnetic properties for the latter complex originate from the fact that the Cu–N (EO azide nitrogen) distances of [Cu(4-Etpy)(N$_3$)$_2$]$_2$ are in the normal range (1.970(10)–1.979(9) Å) and the Cu–N–Cu bond angles within each dimeric unit is 103.0(5)°, which is slightly less than 104°. These bond parameters are known to lead to ferromagnetic interaction between the two nearest-neighbouring spin doublets in homo-azide end-on bridged copper(II) complexes [32].

The field dependence of the magnetization (0–70 kOe) measured at 1.86 K is shown in Fig. 6, where M, N, β and H are magnetization, Avogadro's number, electron Bohr magneton and applied magnetic field, respectively. The magnetization increases with the increase of magnetic field, reaching ca. 1.2 $N\beta$ per Cu$_3$ unit around 50 kOe, being consistent with the expected value of $1N\beta$ for an anti-parallel linear alignment of three Cu^{II} magnetic moments with $S_T = 1/2$. Above 50 kOe, the magnetization increases further, indicating that the spins deviate from antiferromagnetic coupling and align with the applied field.

In conclusion, the interaction between double end-on azide bridges of complex **2** is weak antiferromagnetic.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 222993 and 222994 for complexes **1** and **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (+44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Abstract

Five Ag(I) complexes containing the ligands bis(imidazol-2-yl)methane (2-BIM) and its derivatives were prepared and $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$ and $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$ were characterised using X-ray crystallography. In each dimer the two Ag(I) ions are two-coordinate and there are small but definite argentophilic Ag–Ag (d^{10}–d^{10}) interactions. All of the complexes display anti-fungal activity when tested in vitro against the fungal pathogen *Candida albicans*.

1. Introduction

In our efforts to develop new metal complexes that would greatly inhibit the growth of the human fungal pathogen *Candida albicans* [1–4] we have found that, to date, the most active drug tested in aqueous media is the Ag(I) complex $[Ag(phendio)_2]ClO_4$ (phendio = 1,10-phenanthroline-5,6-dione) [5]. As part of these ongoing studies into the synthesis and in vitro testing of new metal-based anti-fungal drugs we report here the preparation of five Ag(I) complexes containing bis(imidazole) ligands. Bis(imidazol-2-yl)methane (2-BIM) and its derivatives (Fig. 1), in which the two imidazole rings are linked via a single tetrahedral carbon atom, can be viewed as primitive models for multi-histidine coordination in biological systems. Such bis(imidazole) ligands have been shown to form stable six-membered chelate rings with a variety of transition metals [6–12], and the Pt(II) complex $[Pt(2\text{-}BIM(Me)OH)Cl_2]$ (2-BIM(Me)OH = bis(*N*-methylimidazol-2-yl)carbinol) [10] has been reported to exhibit notable antitumor activity.

2. Results and discussion

In the current study, $AgClO_4$ was reacted at room temperature with methanolic solutions of the five bis(imidazole) ligands shown in Fig. 1 to give the respective Ag(I) complex in moderate to good yield. The complexes were soluble in hot acetonitrile and DMSO and insoluble in water. The X-ray crystal structure of $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$ (Fig. 2 and Table 1) showed the complex to be centrosymmetric, containing two $Ag(2\text{-}BIM)^+$ units. The two metal ions are two-coordinate and have identical atoms in the plane of the chelating ligand. Using its two imine N atoms each 2-BIM ligand bridges the pair of Ag(I) ions. All four N atoms (N1, N4A, N4, N1A) are coplanar and the two imidazole groups in each 2-BIM ligand have an interplanar angle of 75.52(8)°. The two Ag(I) ions are only weakly interacting, the distance separating them being 3.2612(4) Å. The binding of the two 2-BIM ligands is similar to that

2-BIM(ClBz)	Cl_2PhCH_2	H

Fig. 1. Ligand symbols and structures.

observed for the $Biim^{2-}$ ligand ($Biim^{2-}$ = 2,2′-biimidazolate) in the heteropolynuclear complex, $[\{Ru(pap)_2(Biim)\}_2Ag_2](ClO_4)_2 \cdot H_2O$ (pap = 2-(phenylazo)pyridine) [13]. The shorter Ag–Ag separation in the latter species is (2.8899 Å) is mainly a consequence of the smaller size of the $Biim^{2-}$ ligand compared to 2-BIM (no methylene bridge between the two imidazole rings in $Biim^{2-}$). The formula unit of $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$ is completed by two lattice perchlorate, which are involved in hydrogen bonding to the hydrogen atoms of the imidazole nitrogen atoms (N2 and N3, and N2A and N3A, respectively). The lattice perchlorate anions show unsymmetric bridging interactions with Ag(I) ions of neighbouring cations ($AgOClO_3$ 2.965(2) and 3.264(2) Å). There are hydrogen bonding interactions along the *a* and *b* directions which link the units together in the lattice, forming sheets. However, there are no hydrogen bonds in the *c* direction, that is to say, between the sheets. There are some intermolecular π–π interactions involving the imidazole rings on adjacent dimer molecules and there is also evidence of some interdimer C–H···π interactions between neighbouring imidazole functions. A perspective view of the cell packing is shown in Fig. 3.

The X-ray crystal structure of $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$ (Fig. 4 and Table 2) shows the asymmetric unit containing one $[Ag_2(2\text{-}BIM(Bz)OH)_2]^{2+}$ unit, two perchlorate anions and a solvate ethanol. The two Ag(I) ions are again bridged by the two ligands and each metal is approximately linearly coordinated to a pair of imine nitrogens. There are additional longer interactions with the perchlorate anions. The metal-metal distance of 3.018(4) Å is considerably shorter than in $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$. Within the $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$ complex molecule there appears to be some degree of intramolecular π–π interaction between the imidazole and phenyl rings of the opposing two 2-BIM(Bz)OH ligands in the dimer. Interestingly, the angles N(1A)–Ag(1)–Ag(2) and N(4B)–Ag(1)–Ag(2) are very different to one another (168.30(12)° and 68.35(8)°, respectively). One of the perchlorate anions in the complex is disordered and was modeled with two alternative sets of oxygen atom positions (50% occupancy each). The ethanol solvate is also disordered and was modeled as 50% occupancy of two alternative positions. Hydrogen atoms attached to carbon were inserted at calculated positions, whilst those attached to the 2-BIM(Bz)OH alcohol groups were located from difference maps and not further refined, those bonded to the disordered oxygen atom of the ethanol solvate were not located or included in the model. One view of the packing in the crystal is illustrated in Fig. 5.

Repeated attempts to grow crystals of $[Ag_2\{2\text{-}BIM(Me)\}_2](ClO_4)_2$, $[Ag_2\{2\text{-}BIM(CN)\}_2](ClO_4)_2$ and $[Ag_2\{2\text{-}BIM(BzCl)\}_2](ClO_4)_2$ suitable for X-ray structural anal-

ysis were unsuccessful. However, given the close similarities in the core structures of all five bis(imidazole) ligands the latter three silver complexes are thought to be essentially isostructural with $[Ag_2(2\text{-}BIM)_2]$ $(ClO_4)_2$ and $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$ and are thus also formulated as dimers. For $[Ag_2\{2\text{-}BIM(CN)\}_2](ClO_4)_2$ there is also the possibility of the pendant cyano groups participating in the bonding to the metal since Ag(I) has a high affinity for organonitrile donors.

2.1. In vitro anti-Candida studies

All of the metal-free bis(imidazole) ligands and the Ag(I) complexes were screened for their ability to inhibit the growth of *C. albicans*. The minimum inhibitory concentration (MIC) is the concentration of drug (expressed as μg of complex per 1 cm^3 of aqueous growth medium solution) required to totally inhibit the growth of the fungal cells at 37 °C. As the complexes and the

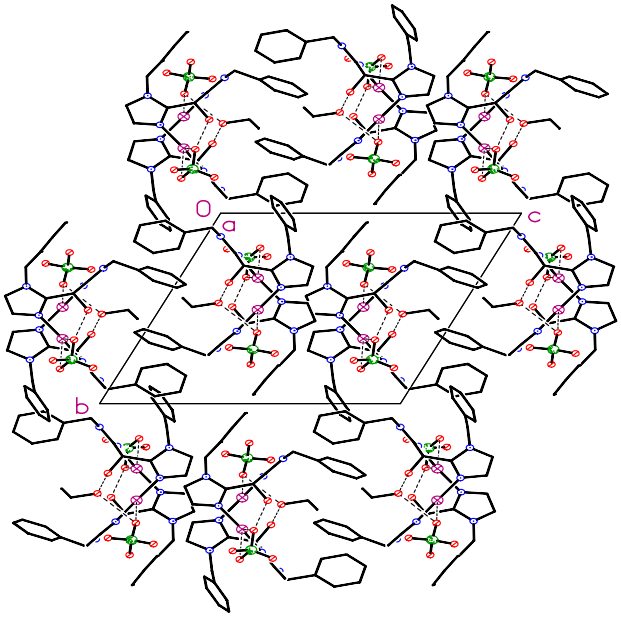

Fig. 5. Packing diagram for $[Ag_2(2\text{-BIM(Bz)OH})_2](ClO_4)_2 \cdot EtOH$.

ligands were essentially water insoluble the tests were carried out as suspensions of the complexes in the aqueous growth medium. In addition, because the complexes were soluble in DMSO a series of anti-fungal tests were also conducted using DMSO/water solutions of the complexes (see Section 3). In all cases, the activity of the complexes were compared to that of a control system in which the cells were grown in the absence of any added complex or free ligand (under these conditions the fungal cell replication was rapid). In addition, under the present biological test conditions an aqueous suspension of the anti-*Candida* prescription drug ketoconazole had an MIC value of ca. 2.5 $\mu g\,cm^{-3}$.

All of the metal-free ligands were found to be inactive against the fungal cells. As aqueous suspensions, the silver complexes were moderately active with MIC value ranges indicated in brackets: $[Ag_2(2\text{-BIM})_2](ClO_4)_2$ (10–20 $\mu g\,cm^{-3}$); $[Ag_2(2\text{-BIM(Bz)OH})_2](ClO_4)_2 \cdot EtOH$ (50–100 $\mu g\,cm^{-3}$); $[Ag_2\{2\text{-BIM(Me)}\}_2](ClO_4)_2$ (20–50 $\mu g\,cm^{-3}$); $[Ag_2\{2\text{-BIM(CN)}\}_2](ClO_4)_2$ (20–50 $\mu g\,cm^{-3}$). A considerable improvement in anti-fungal activity was observed upon administering the complexes as DMSO/water solutions as opposed to aqueous suspensions: $[Ag_2(2\text{-BIM})_2](ClO_4)_2$ (5–10 $\mu g\,cm^{-3}$); $[Ag_2(2\text{-BIM(Bz)-OH})_2](ClO_4)_2 \cdot EtOH$ (2.5–5 $\mu g\,cm^{-3}$); $[Ag_2\{2\text{-BIM(Me)}\}_2](ClO_4)_2$ (2.5–5 $\mu g\,cm^{-3}$); $[Ag_2\{2\text{-BIM(CN)}\}_2](ClO_4)_2$ (5–10 $\mu g\,cm^{-3}$); $[Ag_2\{2\text{-BIM(BzCl)}\}_2](ClO_4)_2$ (5–10 $\mu g\,cm^{-3}$). Besides greatly increasing the solubility of the complexes the DMSO is also thought to make the cells more permeable to the complexes so that they can enter the cells and exert their effects on the organism. In comparison, as an aqueous suspension $[Ag(phen\text{-}dio)_2]ClO_4$ has an MIC value of 0.3 $\mu g\,cm^{-3}$ [5].

3. Experimental

Chemicals were purchased from commercial sources and, unless specified, were used without further purification. Literature methods were used to prepare 2-BIM [14,15], 2-BIM(Me) [7,16] and 2-BIM(OH)Bz [17]. The preparation of the silver complexes was conducted in the absence of light and the samples were stored in the dark. Infrared spectra of solids (in a KBr matrix) were recorded in the region 4000–400 cm^{-1} on a Nicolet FT-IR Impact 400D infrared spectrometer and ^1H NMR spectra were run on a Bruker Avance 300 MHz instrument. Microanalytical data were provided by the Microanalytical Laboratory, National University of Ireland, Cork, Ireland.

3.1. 2-BIM(CN)

Acrylonitrile (3.6 g, 67 mmol) was added to a mixture of 2-BIM (5.0 g, 34 mmol), and triethylamine (6.8 g, 67 mmol) in acetonitrile (150 cm^3). The reaction mixture was refluxed with stirring for 5 h. The solvent was removed under reduced pressure giving a white solid, which was recrystallised from acetone. Yield: 4.7 g (55%). Mp 170 °C. *Anal.* Calc. C, 61.40; H, 5.50; N,

IR: 3125, 2932, 2264, 1485, 1447, 1383, 1287, 1166, 1134, 1089, 926, 722, 743, 705 cm^{-1}. Mass spec.: m/z: 254 (M^+, 4%), 200 (4), 173 (8), 161 (6), 148 (10), 134 (11), 120 (14), 107 (14), 94 (28), 82 (84), 66 (20), 54 (100).

3.2. 2-BIM(BzCl)

2,6-Dichlorobenzyl chloride (0.53 g, 2.7 mmol) was added to a stirred mixture of 2-BIM (0.2 g, 1.3 mmol) and sodium hydride (0.06 g, 2.5 mmol) in dry DMF (15 cm^3). The mixture was stirred overnight at room temperature and the solvent removed under reduced pressure. Water (20 cm^3) was added and the product extracted with dichloromethane, and the dichloromethane solution was then dried over magnesium sulphate. After filtration the solvent was removed under reduced pressure. The resulting brown oily residue was digested in cyclohexane and the white product precipitated upon cooling. Yield: 0.34 g (54%). Mp 93 °C. *Anal*. Calc. C, 54.10; H, 3.43; N, 12.02. Found: C, 54.09; H, 3.58; N, 11.73%. ^{1}H NMR ($CDCl_3$): 7.4 (2H, d, $J = 2$ Hz), 7.1 (2H, dd, $J = 8.3$ Hz), 6.9 (2H, d, $J = 1.3$ Hz), 6.7 (2H, d, $J = 1.3$ Hz), 6.5 (2H, d, $J = 8.3$ Hz), 5.2 (4H, s), 4.2 (2H, s). ^{13}C NMR ($CDCl_3$): 143, 134.5, 133.6, 132.7, 129.5, 129.1, 128.1, 127.5, 120.5, 47, 27 ppm. 3.3. $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$

Silver perchlorate (0.70 g, 3.37 mmol) was added to a stirred solution of 2-BIM (0.5 g, 3.37 mmol) in methanol (15 cm^3) and the mixture stirred for 1 h at room temperature. The precipitated white was filtered off, washed with methanol and air-dried. Yield: 1.00 g (83%). *Anal*. Calc. C, 23.64; H, 2.25; N, 15.76. Found: C, 23.58; H, 2.13; N, 15.78%. IR: 3344, 3151, 1293, 1095, 759, 624 cm^{-1}. ^{1}H NMR (ppm DMSO): 6.8 (8H, s), 4 (4H, s). The complex was soluble in hot acetonitrile and DMSO, and crystals suitable for X-ray analysis were obtained by recrystallising from acetonitrile.

3.4. $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$

This white complex was prepared and recrystallised in a similar way to $[Ag_2(2\text{-BIM})_2](ClO_4)_2$ using silver perchlorate (0.06 g, 0.17 mmol) and 2-BIM(Bz)OH (0.1 g, 0.29 mmol). Yield: 0.11 g (68%). *Anal*. Calc. C, 43.87; H, 3.48; N, 9.70. Found: C, 44.21; H, 3.45; N, 9.69%. The complex was soluble in hot acetonitrile, hot acetone and DMSO.

3.5. $[Ag_2\{2\text{-}BIM(Me)\}_2](ClO_4)_2$

To a solution of silver perchlorate (0.10 g, 0.48 mmol) in methanol (3 cm^3) was added a solution of 2-BIM(Me) (0.10 g, 0.56 mmol) in methanol (3 cm^3). A white precipitate formed immediately and the reaction mixture was stirred for 20 min at room temperature. The white product was filtered off, washed with methanol and then dried in air. Yield: 0.13 g (62%). *Anal*. Calc. C, 28.10; H, 3.13; N, 14.60. Found: C, 27.5; H, 3.00; N, 14.13%. IR: 3485, 3138, 2971, 1497, 1414, 1293, 1102, 772, 627 cm^{-1}. ^{1}H NMR (ppm DMSO): 3.5 (12H, s), 4.36 (4H, s), 6.8 (4H, s), 7.2 (4H, s). The complex was soluble in hot acetonitrile, hot acetone and DMSO.

3.6. $[Ag_2\{2\text{-}BIM(CN)\}_2](ClO_4)_2$

This white complex was prepared in a similar way to $[Ag_2\{2\text{-BIM(Me)}\}_2](ClO_4)_2$ using silver perchlorate (0.10 g, 0.48 mmol) and 2-BIM(CN) (0.20 g, 0.78 mmol). Yield: 0.32 g (89%). *Anal*. Calc. C, 33.81; H, 3.03; N, 18.20. Found: C, 33.46; H, 2.92; N, 18.20%. IR: 3511, 3138, 2984, 2264, 1497, 1427, 1287, 1102, 756, 627 cm^{-1}. ^{1}H NMR (ppm DMSO): 7.3 (4H, s), 6.8 (4H, s), 4.4 (4H, s), 4.2 (8H, t), 2.9 (8H, t). The complex was soluble in hot acetonitrile, hot acetone and DMSO.

3.7. $[Ag_2\{2\text{-}BIM(BzCl)\}_2](ClO_4)_2$

This white complex was prepared in a similar way to $[Ag_2\{2\text{-BIM(Me)}\}_2](ClO_4)_2$ using silver perchlorate (0.08 g, 0.38 mmol) in 3 ml methanol was added to 2-BIM(BzCl) (0.20 g, 0.43 mmol). Yield: 0.16 g (57%). *Anal*. Calc. C, 37.43; H, 2.37; N, 8.31. Found: C, 37.03; H, 2.41; N, 8.04%. IR: 3511, 3138, 1593, 1491, 1395, 1274, 1102, 836, 749, 628 cm^{-1}. ^{1}H NMR (ppm DMSO): 7.9 (4H, d), 7.56 (4H, dd), 7.5 (4H, d),7.25 (4H, d) 6.8 (4H, d), 5.5 (8H, s), 4.8 (4H, s). The complex was soluble in hot acetonitrile, hot acetone and DMSO.

3.8. Anti-Candida testing

Candida albicans ATCC 10231 was obtained from the American Type Culture Collection (Manasas, VA, USA). Cultures were grown on Sabouraud dextrose agar (SDA) plates at 37 °C and maintained at 4 °C for short-term storage. Minimum inhibitory concentrations (MICs) were determined as follows. RPMI-1640 broth medium was used for the anti-*Candida* susceptibility testing. RPMI (5.15 g) was dissolved in cold distilled water (425 cm^3) in a 1-l Duran bottle and the pH

adjusted to 4.0 using a few drops of HCl (ca. 2 M). The resulting solution was autoclaved and then allowed to cool to approximately 50 °C. Morpholinepropanesulfonic acid (MOPS) (17.3 g) and L-glutamate (0.15 g) were dissolved together with stirring in distilled water (50 cm^3) and the resulting solution filter sterilized. The MOPS and L-glutamate solution was added to the warm RPMI and the pH of the mixture adjusted to 7.0 using sterile NaOH (6 M). Prior to MIC testing, cells were grown on SDA at 37 °C for 24 h. Cell suspensions were prepared in sterile phosphate buffered saline (PBS, pH 7.2) and cells were counted microscopically following dilution with PBS. A microtitre plate was inoculated with cells at a density of 5×10^5 cells cm^{-3}. Test suspensions (in water) and solutions (in aqueous DMSO) of the silver complexes were each prepared as follows. *Suspensions in water*: the complex (0.02 g) was suspended in distilled water (10 cm^3) to yield a stock suspension of concentration 2000 $\mu g\,cm^{-3}$. Doubling dilutions of the stock suspension were made to yield a series of test suspensions ranging in complex concentration from 20 to 1.25 $\mu g\,cm^{-3}$. *Solutions in DMSO*: the complex (0.02 g) was dissolved in DMSO (10 cm^3) to yield a stock solution of concentration 2000 $\mu g\,cm^{-3}$. Doubling dilutions of the stock solution were made using distilled water to yield a series of test solutions ranging in complex concentration from 20 to 1.25 $\mu g\,cm^{-3}$. The DMSO concentration (% v/v) in the test solutions ranged from 1.0% to 0.06% (note that a 2% DMSO aqueous solution, without added complex, does not inhibit the growth of the microorganism whereas a 3% DMSO aqueous solution will arrest cell growth totally). For the aqueous test suspensions and the aqueous-DMSO test solutions the complex/cell mixtures were incubated at 37 °C for 24 h with continuous shaking and the assays were performed in triplicate. Plates were read using a Labsystems iEMS Reader MF (absorbance at $\lambda = 540$ nm) and data were statistically analysed.

3.9. X-ray crystallography

All of the data were collected at 150 K on a Bruker SMART 1000 diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using all the reflections. One of the prechlorate anions in $[Ag_2(2\text{-BIM(Bz)OH})_2](ClO_4)_2 \cdot EtOH$ is disordered and was modeled with two alternative sets of oxygen atom positions (50% occupancy each). The ethanol solvate is also disordered and was modeled as 50% occupancy of two alternative positions. All non-hydrogen atoms were refined with anisotropic atomic displacement parameters and hydrogen atoms bonded to carbon were inserted at calculated positions. Hydrogen atoms bonded to nitrogen ($[Ag_2(2\text{-BIM})_2](ClO_4)_2$) or the ligand alcohol group ($[Ag_2(2\text{-BIM(Bz)OH})_2](ClO_4)_2 \cdot EtOH$) were located from difference maps and not further refined; those bonded to the disordered oxygen of the ethanol solvate in $[Ag_2(2\text{-BIM(Bz)OH})_2](ClO_4)_2 \cdot EtOH$ were not included in the model. All programmes used in the structure solution and refinement are included in the SHELXTL package [18] and data collection and refinement details are summarised in Table 3.

Table 3

Abstract

Two coordination polymers, $[M(NDA)(4,4'\text{-bpy})(H_2O)_2]\cdot nH_2O$ (M = Co, $n = 1$ (**1**); M = Ni, $n = 0.5$ (**2**), NDA = 1,4-naphthalenedicarboxylate, 4,4′-bpy = 4,4′-bipyridine) have been synthesized by the hydrothermal reaction of $MCl_2\cdot 6H_2O$, NDA and 4,4′-bpy. Single-crystal X-ray diffraction analysis shows that they are isostructural and represent the first examples of a square grid metal-organic framework constructed by a transition metal, dicarboxylate and 4,4′-bpy with each edge formed by one ligand. The layers are assembled together through hydrogen bonding, resulting in a 3-D supramolecular architecture. Magnetic susceptibility studies reveal that there is a weak antiferromagnetic exchange interaction between the Co(II) ions in the 2-D square grid network of **1**, and a weak ferromagnetic exchange interaction between the Ni(II) ions in **2**.

1. Introduction

In recent years, great attention has been paid to the design and synthesis of functional metal-organic frameworks (MOFs) for their potential application as porous materials [1–7], as well as magnetic materials [8,9]. In constructing MOFs, polycarboxylates, especially dicarboxylates, are usually selected because they may act as both counteranions and bridging ligands to extend the architecture to 1-D chain [10], 2-D layer [11] and 3-D network [12]. The coordination of the metal with NDA is less investigated [1,13,14]. In this paper, NDA is utilized to build coordination networks for two reasons. On one hand, they can furnish the directional conformation of structures via coordination interactions with versatile bonding modes as well as via non-covalent bonding interactions such as hydrogen bonding and π–π stacking interactions. On the other hand, it can construct MOFs with channels because of its linear structure. 4,4′-Bpy is also a neutral linear bifunctional ligand that is widely used as an excellent spacer in the construction of supramolecular architectures [5,15–20]. Both ligands are of length ca. 7.0 Å, which is favorable for the formation of a square grid or cubic framework. The reported structures of MOFs constructed by carboxylates and 4,4′-bpy are 1-D chains [20–23], 2-D grids (square grids [19,25] or others [24]) and 2-D sheet pillared by 4,4′-bpy to form a 3-D network [16–18]. Each edge of the square grid is mostly built by the linkage of two ligands. Here, we report the first square grid metal-organic framework constructed by a transition metal, dicarboxylate and 4,4′-bpy, with each ligand constituting one edge.

2. Experimental

All chemicals and reagents were used as received.

2.1. Measurements

Elemental analyses were performed with an Elementar Vario EL analyzer. The IR spectrum was recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique. Thermogravimetric analysis was performed with a ZRY-2P Thermal Analyzer. The magnetic susceptibility measurements were performed in the range of 2–300 K on crystal sample using an oxford MagLab System 2000 magnetometer. The experimental susceptibilities were corrected for the sample holder and the diamagnetism contributions estimated from Pascal's constants. Effective magnetic moments were calculated using the equation $\mu_{\text{eff}} = 2.828(\chi_{\text{M}}T)^{1/2}$, where χ_{M} is the molar magnetic susceptibility.

2.2. Preparation of the title complexes

2.2.1. [Ni(NDA)(4,4′-bpy)(H$_2$O)$_2$]·0.5H$_2$O

A mixture of $NiCl_2 \cdot 6H_2O$ (0.024 g, 0.1 mmol), 1,4-naphthalenedicarboxylic acid (0.033 g, 0.15 mmol), 4,4′-bpy·2H$_2$O (0.02 g, 0.1 mmol), NaAc·3H$_2$O (0.04 g, 0.3 mmol), H$_2$O (12 ml) and aqueous NaOH (0.4 ml, 0.26 mmol) was sealed in a 25-ml stainless steel reactor with a Teflon liner and slowly heated to 150 °C for 96 h, then cooled to room temperature. Green crystals were obtained and washed with ethanol (yield: 0.025 g, 52.7%). *Anal.* Calc. for $C_{22}H_{19}N_2NiO_{6.5}$: C, 55.74; H, 4.04; N, 5.91. Found: C, 55.75; H, 3.49; N, 5.86. FT-IR data (cm^{-1}): 3562s, 3425s, 3255s, 1607s, 1557s, 1510m, 1464m, 1414s, 1361s, 814m, 632m.

2.2.2. [Co(NDA)(4,4′-bpy)(H$_2$O)$_2$]·H$_2$O

A mixture of $CoCl_2 \cdot 6H_2O$ (0.024 g, 0.1 mmol), 1,4-naphthalenedicarboxylic acid (0.022 g, 0.10 mmol), 4,4′-bpy·2H$_2$O (0.02 g, 0.1 mmol), NaAc·3H$_2$O (0.04 g, 0.3 mmol), H$_2$O (12 ml) and a drop of aqueous NaOH solution (0.65 mol L^{-1}) was sealed in a 25-ml stainless steel reactor with a Teflon liner and slowly heated to 120 °C for 96 h, then cooled to room temperature. Pink crystals were obtained and washed with ethanol (yield: 0.002 g, 4.2%). *Anal.* Calc. for $C_{22}H_{20}CoN_2O_7$: C, 54.67; H, 4.17; N, 5.80. Found: C, 55.18; H, 3.72; N, 5.76%. FT-IR data (cm^{-1}): 3565s, 3430s, 1606s, 1557s, 1415s, 1363s, 1219m, 1084m, 812m, 630m.

2.3. X-ray crystallographic analyses

The single-crystal X-ray data collection for the title complexes was performed with a Bruker Smart 1000 CCD diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Semi-empirical absorption corrections were applied using the SADABS program. The structure was solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXTL 97 program [26]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms on water molecules were located by difference Fourier synthesis and refined isotropically, while the other hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained refinement. The crystal data for **1** and **2** are summarized in Table 1. Selected bond distances and bond angles for **1** and **2** are listed in Table 2.

3. Results and discussion

3.1. Crystal structures

Complex **1** is isostructural to complex **2**. Therefore, only the structure of complex **2** will be discussed in detail. The coordination environment around the Ni^{2+} ion is shown in Fig. 1. The Ni^{2+} ion is located in a slightly distorted octahedral surrounding with two oxygen atoms from two water molecules and two oxygen atoms from two carboxylate groups of two NDA anions [Ni(1)–O(1) = Ni(1)–O(1A) 2.066(2); Ni(1)–O(3) = Ni(1)–O(3A) 2.069(2) Å] building the equatorial plane, and two nitrogen atoms from two 4,4′-bpy molecules [Ni(1)–N(1) 2.166(3); Ni(1)–N(2A) 2.115(3) Å] in the axial positions. The two aromatic rings of 4,4′-bpy make a dihedral angle of 46.8°. Each 4,4′-bpy molecule acts as an *N*,*N*′-bis(monodentate) ligand, bridging the Ni^{2+} ions in the [0 1 0] direction, whereas each carboxylate group of each NDA anion adopts the monodentate coordination mode, making the ligand NDA bridge the Ni^{2+} ions in the [1 0 1] direction. The dihedral angle of the two carboxylate groups of a NDA ligand is 60.8° and they are not in the plane of the naphthalene ring. Based on the bridging of 4,4′-bpy and NDA, a square grid coordination polymer is constructed (Fig. 2) with dimensions of 11.25×11.38Å and the adjacent edges are represented by 4,4′-bpy and NDA, respectively.

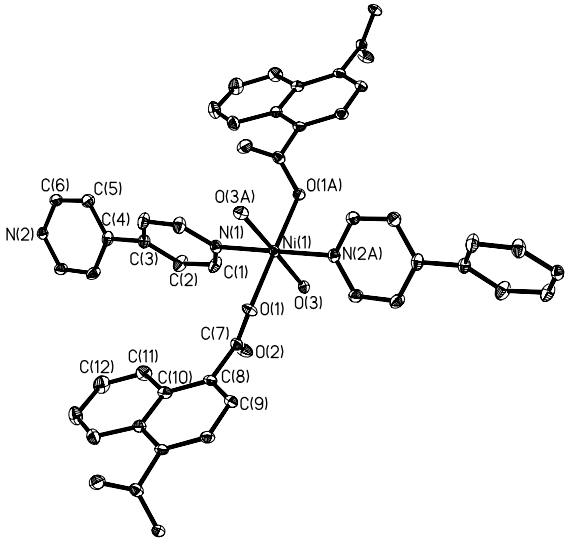

Fig. 1. Coordination environment of complex **2**. The asymmetric unit and the related coordinated atoms are labelled. The lattice water molecule (O4) and all hydrogen atoms are omitted for clarity. Thermal ellipsoids are shown at 30% probability.

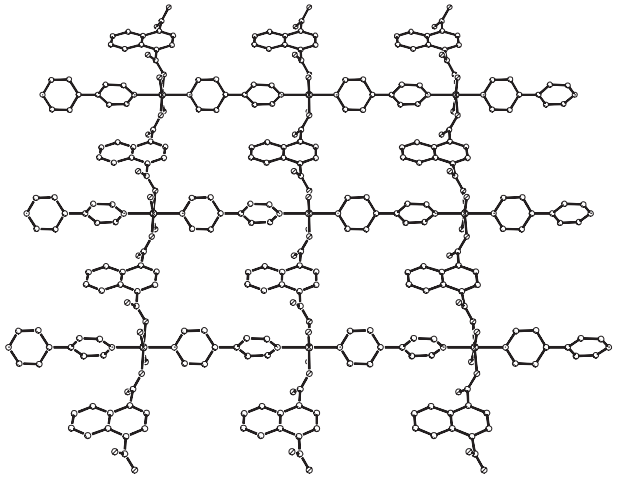

Fig. 2. Perspective view of the 2-D square grid structure of complex **2** viewed along the *c*-axis.

There are abundant hydrogen bonds in the crystal of complex **2** (Table 3). The coordinated water molecules are involved in both an intramolecular hydrogen bond with the uncoordinated carboxylate oxygen atom of NDA from the same asymmetrical unit and an intermolecular hydrogen bond with the coordinated carboxylate oxygen atom of NDA from the adjacent layer. The lattice water molecule is located in the layer of the square grid. As a bridging center, it is simultaneously hydrogen bonded to two uncoordinated carboxylate oxygen atoms of two NDA ligands from its neighboring two layers. Thus, every two adjacent layers are organized by hydrogen bonds between coordinated water molecules and coordinated carboxylate oxygen atoms of NDA, whereas every two separate layers are assembled together through the hydrogen bond between the lattice water and uncoordinated oxygen atoms of NDA (Fig. 3). Interestingly, the adjacent two square grids are stacked parallel but in a staggered manner on each other along the [1 0 $\bar{1}$] direction, with an interlayer separation of 3.98 Å and an interlayer Ni···Ni separation of 5.22 Å, which are much shorter than the intralayer Ni···Ni separations (11.38 and 11.25 Å). The arrangement of layers in such a staggered manner leads to cavities with small dimensions as shown in Fig. 4. Every square grid

Table 3
Hydrogen bonds geometry (Å and °) in complex **2**

D–H	*d*(D–H)	*d*(H···A)	∠DHA	*d*(D···A)	A
O3–H3A	0.804	1.954	153.86	2.699	O2
O3–H3B	0.781	1.994	168.65	2.765	O1 $[x, -y+2, z-1/2]$
O4–H4A	0.851	1.915	171.24	2.759	O2 $[x-1, y, z]$
O4–H4B	0.852	1.894	177.25	2.745	O2 $[-x+1, y, -z+1/2]$

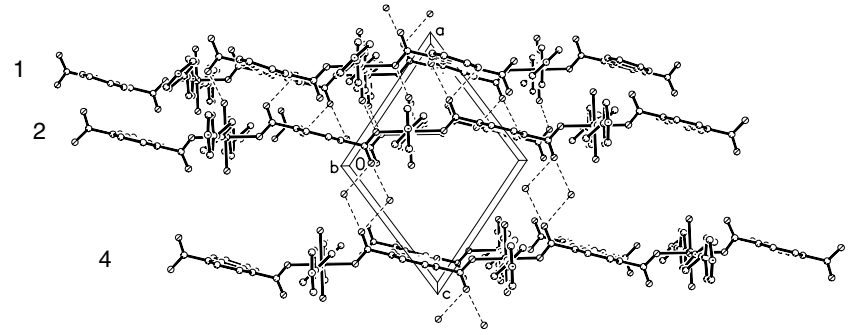

Fig. 3. The hydrogen-bonding interactions between the neighboring layers and two separate layers of complex **2**. For the interest of clarity, the third layer and all the hydrogen atoms are omitted.

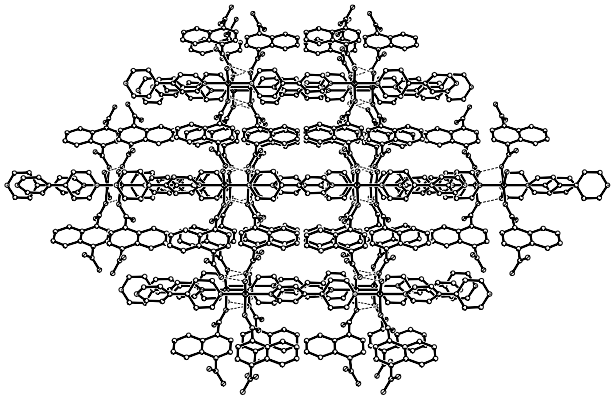

Fig. 4. Packing diagram of complex **2**, showing the cavities viewed along the *c*-axis. For the interest of clarity, all hydrogen atoms and lattice water molecules are omitted.

is divided into two parts by two naphthalene rings, and the dimension of every cavity is 9.5×3.0 Å. The 4,4′-bpy rings in the neighboring layers are not parallel to each other, whereas the NDA rings in the neighboring layers are parallel to each other, but not overlapped. Therefore, no π–π stacking interactions were observed in the crystal.

3.2. Magnetic properties

The variable temperature magnetic susceptibility data of the title complexes were measured in the range of 2–300 K under a magnetic field of 1 T. The plots of χ_M and effective magnetic moment μ_{eff} versus T for **1** and **2** are shown in Figs. 5(a) and (b), respectively. It can be seen from Fig. 5(a) that the μ_{eff} value decreases gradually upon cooling and the μ_{eff} value at 300 K is 4.69 μ_B, which is much larger than that expected for the spin-only case of Co ($\mu_{eff}^{so} = 3.87\mu_B$), indicating that an important orbital contribution is involved.

Complex **1** can be regarded as 1-D chains built by NDA and Co(II) ions, and the magnetic interactions transferred by 4,4′-bpy and hydrogen bonds should be very weak. The antiferromagnetic chain model ($S = 3/2$) was applied to **1** and the expression of the magnetic susceptibility is given below: $\chi_M = (Ng^2\beta^2/kT)[A + Bx^2][1 + Cx + Dx^3]^{-1}$, with $x = |J|/kT$ and $A = 1.2500$, $B = 17.041$, $C = 6.7360$ and $D = 238.47$ [27]. Considering the weak magnetic coupling transferred by 4,4′-bpy and hydrogen bonds, the mean field approximation, zJ' was introduced [28]. The total magnetic susceptibility is $\chi_{total} = \chi_M/[1 - \chi_M(2zJ'/Ng^2\beta^2)]$. The best fit (line in Fig. 5(a)) for the magnetic data (2–300 K) leads to $g = 2.49$, $J = -0.12$ cm^{-1}, $zJ' = -0.03$ cm^{-1},

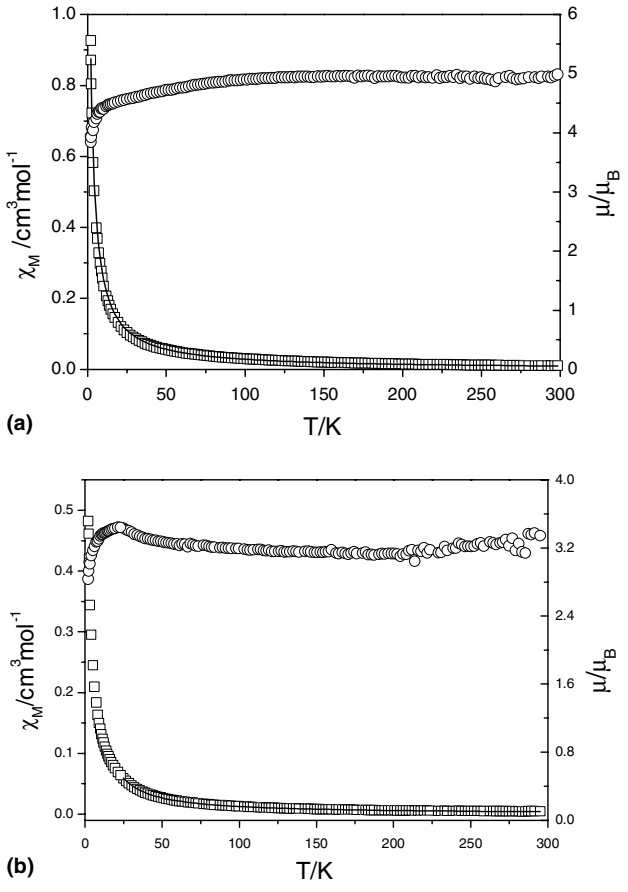

Fig. 5. Plot of the temperature dependence of χ_M (□) and μ_{eff} (○) for complex **1** (a) and **2** (b).

$R = 1.76 \times 10^{-3}$ (the value R is defined as $\sum[(\chi_M)_{obs} - (\chi_M)_{calc}]^2 / \sum[(\chi_M)_{obs}]^2$). The fitting results show that the exchange coupling between the Co(II) ions through the NDA bridge is weakly antiferromagnetic. The antiferromagnetic interactions transferred by 4,4′-bpy and hydrogen bonds are much weaker.

For complex **2**, upon cooling, the μ_{eff} value increases up to a maximum value of $3.43\mu_B$ around 25 K. Below 25 K, the μ_{eff} value abruptly decreases to $2.83\mu_B$ at 2 K. The magnetic behavior of **2** indicates a weak ferromagnetic exchange interaction between the Ni(II) ions in the 2-D square grid network. The structure of **2** was treated with the same method as **1** and the magnetic data of **2** have been fitted at 25 K by means of a 1-D ($S = 1$) ferromagnetic chain model [29]. [1] The expression of the magnetic susceptibility is $\chi_M = (2/3)(Ng^2\beta^2/kT)(AX^3 + BX^2 + CX + 1)/(DX^2 + EX + 1)$, with $X = J/kT$ and for $\alpha = 1$, $A = 0.14709$, $B = -0.788967$, $C = 0.866426$, $D = 0.096573$ and $E = -0.624929$. The best fit (line in Fig. 5(b)) for the magnetic data leads to $g = 2.17$, $J = 2.92\ cm^{-1}$, $R = 1.85 \times 10^{-4}$, indicating a weak ferromagnetic interaction between Ni(II) ions transferred through NDA. The abrupt decrease in the μ_{eff} versus T plot below 25 K may result from a possible zero-field splitting effect of Ni(II) ions in axially elongated octahedral surroundings [30], and antiferromagnetic interactions transferred by 4,4′-bpy and hydrogen bonds. However, the zero-field splitting of Ni(II) will be effective since the antiferromagnetic interactions transferred by 4,4′-bpy and hydrogen bonds are very weak as shown in complex **1**.

In the title complexes, weak ferro- or antiferromagnetic interactions between metal ions via NDA ligand were observed. Thus, the NDA ligand will be useful for the design of a range of magnetically interesting molecule materials.

3.3. Thermogravimetric analysis

Thermogravimetric analysis of complex **2** was carried out to examine its thermal stability. The TGA curve shows that the first weight loss of 9.6%, which occurs between 103.5 and 186 °C, corresponds to the loss of two coordinated water molecules and half an uncoordinated water molecule (calculated: 9.5%). Further decomposition begins at 308 °C and ends at 695.7 °C with residue NiO being obtained in 17.4% yield (calculated: 15.8%).

[1] The model is 1-D chain ($S = 1$) with alternating ferro-ferromagnetic coupling and when α is equal to 1, the model can be applied for ferromagnetic 1-D chain ($S = 1$).

4. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Center as supplementary publication: CCDC Nos. 223356 and 205533 for **1** and **2**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The phosphino molybdenocene complex $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ **(1)** (Cp = η^5-C_5H_5) was prepared by reaction of Cp_2MoI_2 with PPh_2H and excess of $TlBF_4$ in NCMe. The monocation $[Cp_2MoI(PPh_2H)]^+$ (**2**) as the BF_4^- or I^- salt was synthesised by treatment of $Cp_2MoI(SPh)$ with HBF_4 followed by addition of PPh_2H, or by reaction of Cp_2MoI_2 with PPh_2H, respectively. The indenyl phosphine complex $[IndMo(CO)_2(PPh_2H)_2]BF_4$ (**3**) (Ind = η^5-C_9H_7) was prepared by reaction of $IndMo(CO)_2(\eta^3$-$C_3H_5)$ with HBF_4 followed by addition of PPh_2H. Deprotonation of **1** with *dabco* led to the formation of the phosphinophosphido molybdenocene $[Cp_2Mo(PPh_2)(PPh_2H)][BF_4]$ (**4**). Treatment of **1** with two equivalents of LiBu in thf at −30 °C formed a thermally unstable complex (**5**) which could not be isolated. ^{31}P NMR and protonation to reform **1** support its formulation as $CpMo(PPh_2)_2$. The molecular structures of $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ and $[Cp_2MoI(PPh_2H)]^+$ have been determined by single-crystal X-ray diffraction.

1. Introduction

Following the pioneering studies of Green and co-workers on the synthesis of polynuclear complexes derived from organometallic ligands, namely of type $Cp_2M(\mu$-$SR)_2M'L_n$ (M = Mo, W, Nb; $M'L_n$ several transition metal fragments) [1], the related bis-phosphido derivatives $Cp_2M(\mu$-$PR_2)_2M'L_n$ (M = Zr, Hf) were first reported simultaneously by three groups in 1985 [2–4].

Extension of this work to the metallocenes of group 5 led to the synthesis of $Cp_2ML(PPh_2)$ (M = Nb, Ta; L = CO, PMe_2Ph, $P(OMe)_3$) and its PPh_2 bridged adduct with $Cr(CO)_5$ [5]. The corresponding Mo and W complexes of formula $Cp_2MH(PPh_2)$ and their adducts with $CpMn(CO)_2$ were reported in 1990 [6]. Both these groups **5** and **6** complexes are obtained by deprotonation of $Cp_2ML(PPh_2H)]^+$ (M = Nb, Ta) or $[Cp_2MH(PPh_2H)]^+$ (M = Mo, W). In turn, the PPh_2H cations were obtained by reaction of PPh_2Cl with Cp_2MLH (M = Nb, Ta) [7] and Cp_2MH_2 (M = Mo, W) [6] respectively. The search for bis-phosphido derivatives of the Cp_2Nb fragment was carried out by reaction of $Cp'_2NbH(PPh_2H)$ with PR_2Cl (R = Me, [8] Ph [9]) that leads to the cations $[Cp'_2Nb(PPh_2H)_2]^+$ (Cp′ = MeCp) [9] and $[Cp_2Nb(PPh_2H)PMe_2H)]^+$ [8]. Deprotonation of these cations forms $Cp_2Nb(PPh_2)(PMe_2H)$ [8], $Cp'_2Nb(PPh_2H)(PPh_2)$ and $[Cp'_2Nb(PPh_2)_2]M'$ (M′ = Li, Na) [9]. The latter product is more stable as the Na salt the Li salt decomposing readily at room temperature.

The co-ordination chemistry of $Cp_2Nb(PPh_2)(PMe_2H)$ was briefly examined [10].

The recent report on the synthesis and the crystal structure of $Cp_2Nb(PPh_2H)(PPh_2)$ includes a large literature coverage of this topic [11].

In the present work we report our findings on the synthesis and chemistry of molybdenocene derivatives of PPh_2H and our attempts to prepare the corresponding phosphido indenyl analogues.

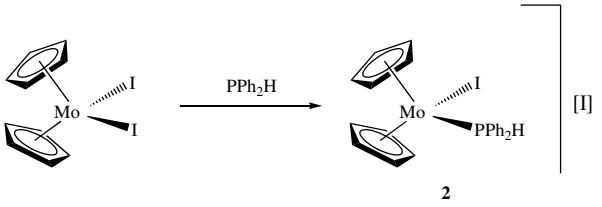
2. Results and discussion

2.1. Synthesis of cationic complexes containing the phosphine ligand PPh_2H

Refluxing a solution of Cp_2MoI_2 with PPh_2H in NCMe in the presence of excess $TlBF_4$, followed by filtration of TlI and recrystallisation of the remaining residue from NCMe/Et_2O, gave orange–yellow crystals of $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ (**1**) in ≈72% yield (see Scheme 3). The ^{31}P NMR spectrum of **1** shows only one doublet at δ 20.45 ppm (J_{P-H} = 396.0 Hz, P–H). Its ^1H NMR spectrum shows a doublet at δ 7.60 ppm (J_{P-H} = 396.0 Hz, P–H) assigned to the P–H proton of the phosphine ligands. The resonance of the Cp protons appears in the region usually observed for other dications of type $[Cp_2Mo(PR_3)_2]^{2+}$ [12], a triplet at δ 5.99 ppm. The coupling of the Cp protons with the two equivalent P atoms is very small, 2 Hz.

In the absence of $TlBF_4$ the above reaction mixture produced a modest yield (24%) of the red complex $[Cp_2MoI(PPh_2H)]I$ (**2, I**) (see Scheme 1). This compound was best prepared as the BF_4 salt by reaction of PPh_2H with the reaction mixture obtained by treatment of $Cp_2MoI(SPh)$ [13] with 1 equivalent of HBF_4 in Et_2O (see Scheme 2). Under these conditions a good yield of $[Cp_2MoI(PPh_2H)]BF_4$ (**2, BF_4**) was obtained. The ^{31}P NMR spectra of both salts of **2** in dichloromethane show one doublet slightly shielded compared to that of **1**, with slightly different chemical shifts for each anion. As expected, the resonance of the Cp protons in the ^1H NMR spectrum reveals a higher shielding (≈0.5 ppm) as compared to that of **1**. The crystal structure of the BF_4^- salt of **2** was also solved by X-ray diffraction (see below).

Starting from $IndCpMoX_2$ (X = Cl, I), we were unable to prepare any of the indenyl containing analogues of both **1** and **2**. Highly coloured dichroic products containing both PPh_2H and indenyl were observed by ^1H and ^{31}P NMR but the syntheses were totally irreproducible. This is a surprising and unexplained result



2

Scheme 2. Synthesis of $[Cp_2MoI(PPh_2H)][BF_4]$.

having in mind the similar chemistry of both Cp_2Mo and IndCpMo fragments [16]. On the other hand, reaction of PPh_2H with the species formed in situ by addition of one equivalent of HBF_4 on $IndMo(CO)_2(\eta^3\text{-}C_3H_5)$, gave a moderate yield of a yellow compound formulated as $[IndMo(CO)_2(PPh_2H)_2]BF_4$ (**3**) by means of IR and NMR spectroscopy. The ^1H NMR spectrum of **3** is consistent with the presence of a pentahapto indenyl ring as observed in similar examples with other phosphines. The P–H protons appear at δ 7.27 ppm (J_{P-H} = 392.7 Hz) in the ^1H NMR spectrum. Accordingly, the ^{31}P NMR spectrum shows only one doublet at δ 34.55 ppm (J_{P-H} = 393.6 Hz). The IR spectrum shows the two strong vibrations of the *cis*-CO ligands in the region expected for a Mo(II) complex with this charge and structure. In spite of the lack of X-ray diffraction data, the spectroscopic data are consistent with the given formulation that corresponds to a very wide variety of indenyl containing piano stool complexes.

2.2. Crystallography studies

The molecular structures of **1** and **2** have been determined by X-ray diffraction. Their cationic moieties are shown in Figs. 1 and 2, respectively. Bond lengths and bond angles are listed in Table 1. A search in the Cambridge Structural Database revealed five Mo^{IV} compounds in addition with the same Mo-core geome-

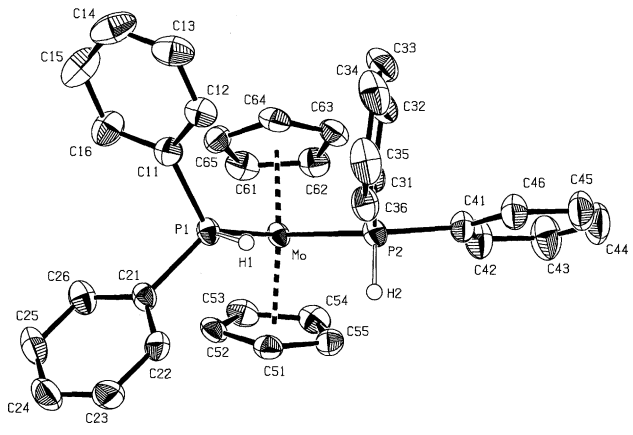

Fig. 1. ORTEP style plot of the di-cationic part of **1** in the solid state. Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms are omitted for clarity.

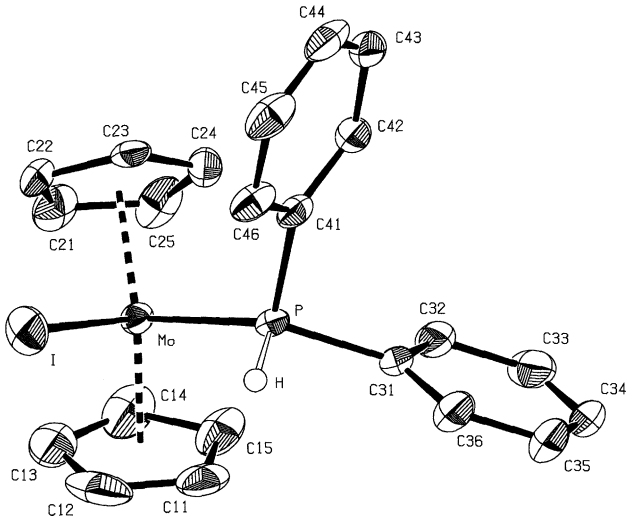

Fig. 2. ORTEP style plot of the mono-cationic part of **2** in the solid state. Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms are omitted for clarity.

try $Mo(\eta^5\text{-}C_5H_4R)_2E_2$ with R = H, ^{t}but and one E = PR'_3 [14]. The results are given in Table 1, too. As expected from the NMR and IR data all three Mo-cations are monomeric. The cyclopentadienyl ligands are bound to molybdenum in a typical η^5 manner. No ring slippage is observed in the planar rings. The values of the Cp–Mo–Cp bent angles of 135.41°, 136.20°, and 134.79° in comparison to the other five compounds (Table 1) indicates that they are relatively insensitive to the nature of the E ligand and its steric demands. More pronounced, and caused by the steric repulsion, are the observed differences in the E–Mo–E angle (≈74–92°). All other intramolecular distances and angles lie in the typical ranges and need no further discussion.

2.3. Reactivity studies on the PPh_2H complexes 1–3

The cationic nature of the complexes **1**–**3** suggests facile deprotonation of the PPh_2H ligands with formation of phosphido complexes, much in the same way as has been reported for the Nb complexes mentioned above. Indeed, treatment of a suspension of **1** in CH_2Cl_2 with excess NEt_3 gives a bright orange solution. Concentration and addition of Et_2O gives an orange crystalline product formulated as $[Cp_2Mo(PPh_2)(PPh_2H)]BF_4$ (**4**). The same product is, however, best prepared using *dabco* (1,4-diazabicyclo[2.2.2]octane) instead of NEt_3 since the protonated form of *dabco* precipitates out and allows an easier purification of the product (see Scheme 3). Treatment of a CH_2Cl_2 solution of **4** with HBF_4 in Et_2O immediately precipitates the yellow dication **1,** as ascertained by ^{31}P and ^1H NMR. The ^1H NMR of **4** in CD_2Cl_2 at room temperature shows a set of signals between δ 7.60 and 7.10 ppm and one signal at δ 4.96 ppm assigned to the Cp protons. The ^{31}P NMR in the same solvent shows two resonances: a doublet at δ 41.1 ppm (J_{P-H} = 364 Hz) and a singlet at δ −11.9 ppm. The former signal is assigned to the Ph_2PH ligand and the latter to the PPh_2 ligand. A similar upfield resonance of the P atom was found in $Cp_2MoH(PPh_2)$ at δ −10.3 ppm [2]. In the isoelectronic Nb complex, $Cp_2Nb(PPh_2)(HPPh_2)$ two P resonances are found at δ 66.2 and 5.9 ppm [11]. The proton resonance of the Ph_2P–H ligand is certainly hidden under the other aromatic signals, like in $Cp_2Nb(PPh_2)(HPPh_2)$. A value of δ 7.60 ppm is given for the complex $[Cp_2Nb(PPh_2H)(PMe_2H)]Cl$ [8]. The ^1H NMR spectrum remains essentially unchanged on lowering the temperature down to 185 K.

Although air sensitive in solution, **4** is clearly much more thermally stable than its isoelectronic Nb congener

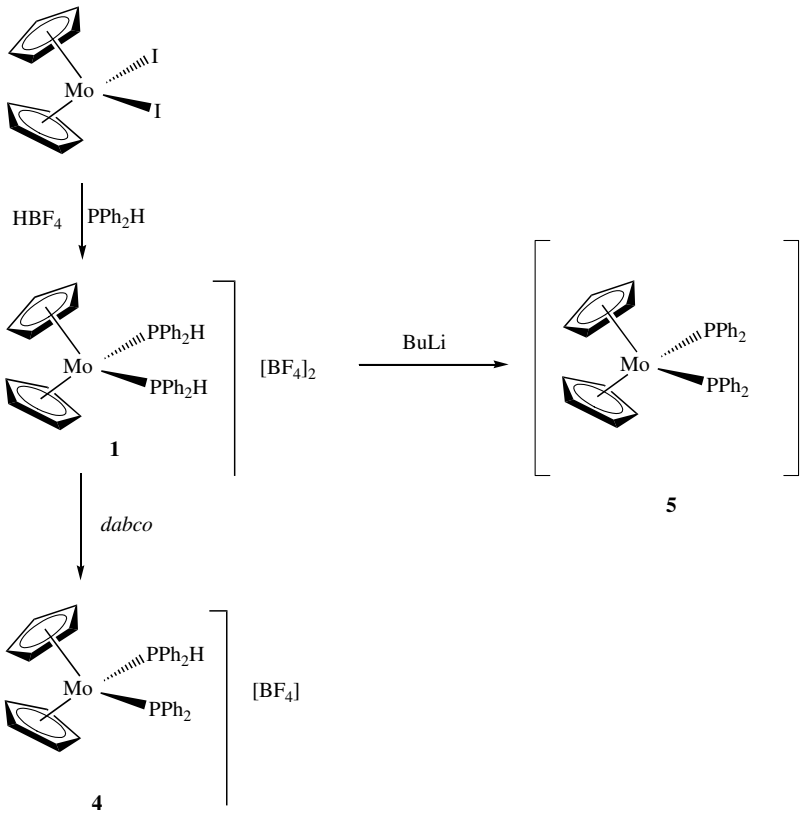

Scheme 3. Synthesis of the molybdenum derivatives **1**, **4** and **5**.

$Cp_2Nb(PPh_2H)(PPh_2)$ which decomposes readily to the ortho-metallated species [$Cp_2Nb(PHPh–C_6H_4–)$] [11].

Further deprotonation was attempted in order to obtain the neutral bis-phosphido complex $Cp_2Mo(PPh_2)_2$, isoelectronic with the well known thiolato ligands $Cp_2Mo(SR)_2$ and $[Cp'_2Nb(PPh_2)_2]^-$. Reaction of **1**, suspended in thf, with LiOMe, $LiNEt_2$, HNa, LiBu, always at a temperature below −30 °C affords a red solution (see Scheme 3). This fact suggests that deprotonation has occurred since the cations **1** and **4** are insoluble in thf and $Cp_2Mo(PPh_2)_2$ (**5**) is expected to be freely soluble in this solvent. However, the solution is very unstable and decomposes above −30 °C giving a brown intractable residue. Similar behavior is observed in a MeOH/LiOMe system. In order to attempt the characterization of **5** in situ the reaction of **1** with BuLi was carried out in a NMR tube at −50 °C. The ^{31}P NMR spectrum of the red solution in thf-d_8 at −40 °C shows *only one* singlet resonance at δ −24.7 ppm revealing the presence of only one product, the equivalence of the two P atoms, and the absence of a PPh_2H ligand that should give a doublet resonance. The integrity of the Cp_2Mo fragment was ascertained by the fact that treatment of the red solution of **5** with $HBF_4 \cdot Et_2O$ led to the precipitation of **1** in essentially quantitative yield. These observations strongly support the formulation of **5** as the bis-phosphido complex $Cp_2Mo(PPh_2)_2$ (**5**).

The instability of $Cp_2Mo(PPh_2)_2$ is not unexpected. The crystal structure of $Cp_2Zr(PPh_2)_2$ clearly showed that the Zr–P bonds are unequal, one of them exhibiting a clear shortening due to P to Zr backdonation which results in a partial double bond character [15]. Of course, in the Cp_2Mo (IV) fragment the corresponding metallocene a1 frontier orbital is filled, thereby preventing this stabilisation and actually creating a destabilising interaction between both P lone pairs and the filled a1 orbital. One might envisage a possibility of avoiding this repulsion either by a ring-slippage mechanism capable of lowering the electronic density at the Mo atom or by a rotation of the lone pairs of the P atoms away from the a1 orbital. The latter possibility should also exist in the isoelectronic Nb(III) complexes [$Cp'_2Nb(PPh_2)_2$]- and $Cp_2Nb(PPh_2)(PMe_2H)$. However, both of them are rather unstable in contrast to the formally 16 electron $Cp_2Zr(PPh_2)_2$, suggesting that this rotation is not enough to stabilise the complexes. The fact that indenyl slippage would be more favourable for the indenyl than for the Cp ring, justified our attempts to synthesize the analogous compounds for the IndCpMo fragment. Unfortunately, we were unable to obtain any of the necessary precursors, namely [$IndCpMo(PPh_2H)_2]^{2+}$.

The cation $[IndMo(CO)_2(PPh_2H)_2]BF_4$ (**3**) also undergoes deprotonation by addition of NEt_3 or NaH, but

the solutions obtained are unstable and no products could be clearly identified.

One alternative possibility of stabilizing the structure of **5** would be its coordination to electrophilic species capable of coordinating the P donor atoms. This was attempted by reacting the solution of **5** at −30 °C with electrophilic, unsaturated metal fragments or precursors like $CoBr_2(thf)_2$, $NiBr_2(thf)_2$, $(NBD)Mo(CO)_4$, $Mo(\eta^3\text{-}C_3H_5)(CO)_2(NCMe)_2Cl$. In no case was there possible to isolate some compound corresponding to the adducts of general type $Cp_2Mo(\mu\text{-}PPh_2)_2M'Ln$. Instead, successive color changes and or mixtures of products were obtained. The reaction of **1** with Cp_2ZrMe_2 expected to liberate CH_4 and form $[Cp_2Mo(\mu\text{-}PPh_2)_2ZrCp_2]^{2+}$ was also unsuccessful. Clearly, the reactivity of $Cp_2Mo(PPh_2)_2$ (**5**) seems to be rather complex and simple adduct formation with other metal centers is not the main reaction pathway.

3. Conclusions

Several diphenylphospine derivatives of molybdenocene were prepared, two of them characterised by X-ray diffraction. The dication $[Cp_2Mo(PPh_2H)_2]^{2+}$ (**1**) can be deprotonated to the mono-phosphido complex $[Cp_2Mo(PPh_2)(PPh_2H)][BF_4]$ (**4**) by Et_3N or dabco. In thf, deprotonation with LiBu at −40 °C forms the bis-phosphido complex $Cp_2Mo(PPh_2)_2$ (**5**). Due to its thermal instability **5** was only characterised by its ^{31}P NMR spectrum, showing a singlet at δ −24.7 ppm, and by its reaction with HBF_4 to give **1**. Disappointingly, the high reactivity of $Cp_2Mo(PPh_2)_2$ seems to limit its use as an organometallic ligand in contrast to the isostructural $Cp_2Zr(PPh_2)_2$ and the isoelectronic $Cp_2Mo(SR)_2$ both of which have a rich chemistry in this regard.

4. Experimental

All operations were carried out under an atmosphere of dinitrogen with standar Schlenk line and glove-box techniques. Solvents were purified by conventional methods and distilled under nitrogen prior to use. ^1H and ^{31}P NMR spectra were measured on a Bruker CXP 300 spectrometer (H, 300 MHz, ^{31}P, 121.49 MHz), referenced internally to $SiMe_4$ and externally to 85% H_3PO_4, respectively. IR spectra were measured on an Unicam Mattson model 7000 FTIR spectrometer. Elemental analyses were performed by Maria Conceição Almeida in the Elemental Analysis Service of ITQB.

All common chemicals and solvents were purchased from commercial suppliers. The synthesis of $[CpMo(\eta^5\text{-}C_5H_6)(CO)_2][BF_4]$ [16], $[IndMo(\eta^5\text{-}C_5H_6)(CO)_2][BF_4]$ [16], Cp_2MoI_2 [16], Cp_2MoCl_2 [12], was done according to literature procedures.

4.1. Preparation of $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ (**1**)

A suspension of Cp_2MoI_2 (0.3 g, 0.62 mmol) in NCMe (20 ml) was treated with PPh_2H (0.36 ml, 1.49 mmol) and the reaction mixture was stirred overnight under reflux in the absence of light. To the resulting greyish solution was added an excess of $TlBF_4$ and the mixture was left under reflux for another 2 h, in the absence of light. The solution was filtered through celite to separate the TlI, the filtrate was taken to dryness and the residue washed with Et_2O and dried under vacuum to yield the title compound **1** as a yellow powder. Recrystallisation from NCMe/Et_2O affords orange–yellow crystals. When Cp_2MoCl_2 or the corresponding dibromide was used as a starting material, under the same conditions, similar results were obtained. Yield: 0.34 g (72.5%). Selected IR (KBr, cm^{-1}): 2211, broad, ν(PH), 1085, vs, ν(BF). *Anal.* Calc. for $C_{34}H_{32}B_2F_8MoP_2$: C, 52.89; H, 4.18. Found: C, 52.78; H, 4.07%. ^1H NMR (Me_2CO-d^6, δ ppm): 7.60–7.53 (m, 20H, Ph), 7.60 (d, 2H, J_{P-H} = 405 Hz, P–H), 5.99 (t, 10H, J_{P-H} = 2 Hz, Cp). ^{31}P NMR (CD_2Cl_2/NCMe-d^3, δ ppm): 20.45 (d, J_{P-H} = 396.0 Hz, P–H).

4.2. Preparation of $[Cp_2MoI(PPh_2H)]^+$

4.2.1. Preparation of $[Cp_2MoI(PPh_2H)][BF_4]$ (**2**, BF_4)

A solution of $Cp_2MoI(SPh)$ (0.88 g, 1.91 mmol) in CH_2Cl_2 (50 ml) was treated with a slight excess of $HBF_4 \cdot Et_2O$ giving a dark green solution, which was stirred for 15 min. Then, in the absence of light, a slight excess of PPh_2H (0.4 ml) was added and the solution was stirred for another 30 min giving a brownish solution. The volume was reduced to a fifth and the solution was filtered. The resulting precipitate was washed twice with Et_2O, further washed with CH_2Cl_2 and hexane and dried under vacuum. Recrystallisation from a mixture of Me_2CO, EtOH and Et_2O at 4 °C gave red single crystals of $[Cp_2MoI(PPh_2H)][BF_4]$ suitable for X-ray analysis. Yield: 0.63 g (53%). Selected IR (KBr, cm^{-1}): 2295, w, ν(PH), 1084, vs, ν(BF). *Anal.* Calc. for $C_{22}H_{21}BF_4IMoP$: C, 42.21; H, 3.38. Found: C, 42.35; H, 3.41%. ^1H NMR (NCMe-d^3, δ ppm): 7.67–7.51 (m, 10H, Ph); 7.82 (d, 1H, J_{P-H} = 404.0 Hz, P–H); 5.47 (s, 10H, Cp). ^{31}P NMR (CD_2Cl_2/NCMe-d^3, δ ppm): 27.53 (d, J_{P-H} = 405.8 Hz, P–H).

4.2.2. Preparation of $[Cp_2MoI(PPh_2H)]I$ (**2**,**I**)

A suspension of Cp_2MoI_2 (0.3 g, 0.63 mmol) in NCMe (20 ml) was treated with 2 equivalents of PPh_2H. The reaction mixture was stirred overnight under reflux, in the absence of light. The resulting purple solution was filtered and the filtrate was concentrated to yield $[Cp_2MoI(PPh_2H)]I$ as a bordeaux solid. Yield: 0.19 g (24%). Selected IR (KBr, cm^{-1}): 2309, w, ν(PH), 1099, vs, ν(BF). *Anal.* Calc. for $C_{22}H_{21}I_2MoP$: C, 39.67; H,

3.18. Found: C, 39.88; H, 3.31%. ^{1}H NMR (CD_2Cl_2/NCMe-d^3, δ ppm): 7.78–7.19 (m, 10H, Ph); 7.11 (d, 1H, J_{P-H} = 402.0 Hz, P–H); 5.54 (s, 10H, Cp). ^{31}P NMR (CD_2Cl_2/NCMe-d^3, δ ppm): 24.58 (d, J_{P-H} = 403.4 Hz, P–H).

4.3. Preparation of $[IndMo(CO)_2(PPh_2H)_2][BF_4]$ (3)

A solution of $IndMo(\eta^3\text{-}C_3H_5)(CO)_2$ (0.34 g, 1.10 mmol) in CH_2Cl_2 (15 ml) was treated with 1 equiv of $HBF_4 \cdot Et_2O$. After 5 min stirring at room temperature, the deep red solution was cooled in an ice bath and was treated with 2 equiv of PPh_2H in the absence of light. The solution was allowed to warm up to room temperature and after stirring for 1 h, the volume was reduced to half and Et_2O (30 ml) was added to precipitate a red powder. The solid was further washed with Et_2O and the product was recrystallised from a mixture of Me_2CO, EtOH and Et_2O at room temperature to afford yellow crystals of the title compound **3**. Yield: 0.33 g (42%). *Anal*. Calc. for $C_{35}H_{29}BF_4MoP_2$: C, 60.55; H, 4.21. Found: C, 60.68; H, 4.22%. Selected IR (KBr, cm^{-1}): 2068, w, ν(PH), 1977, vs, ν(CO), 1898, vs, ν(CO), 1081, vs, ν(BF). ^{1}H NMR (Me_2CO-d^6, δ ppm): 7.69–7.53 (m, 20H, Ph); 7.39–7.35 (m, 2H, H$^{5-8}$); 7.28–7.15 (m, 2H, H$^{5-8}$); 7.27 (d, 2H, J_{P-H} = 392.7 Hz, P–H); 6.08 (d, 2H, H$^{1/3}$); 6.02 (t, 1H, H^2). ^{31}P NMR (Me_2CO-d^6, δ ppm): 34.55 (d, J_{P-H} = 393.6 Hz, P–H).

4.4. Preparation of $[Cp_2Mo(PPh_2)(PPh_2H)][BF_4]$ (4)

A slight excess of *dabco* (0.12 g, 1.07 mmol) was added to a solution of $[Cp_2Mo(PPh_2H)_2][BF_2]_2$ (0.4 g, 0.56 mmol) in dichloromethane (30 ml). The solution immediately changed from the initial yellow colour to an orange solution with a white precipitate. The mixture was stirred for 1 h and the solution was filtered. The filtrate was concentrated to dryness and the residue was washed with ether to yield the title compound **4** as an orange solid. Yield: 0.35 g (92%). Selected IR (KBr, cm^{-1}): 1084, vs, ν(BF). *Anal*. Calc. for $C_{34}H_{31}BF_4MoP_2$: C, 59.68; H, 4.57. Found: C, 59. 86; H, 4.62%. ^{1}H NMR (Me_2CO-d^6, δ ppm): 7.80–7.20 (m, 20H, Ph); 5.34 (t, 10H, Cp). ^{31}P NMR (Me_2CO-d^6, δ ppm): 41.1 (d, J_{P-H} = 393.6 Hz, $\underline{P}Ph_2H$); −11.9 (s, $\underline{P}Ph_2$).

4.5. Reaction of $[Cp_2Mo(PPh_2H)_2][BF_4]_2$(1) with BuLi

A suspension of **1** in thf-d^8 was prepared in a NMR tube and cooled to −50 °C. Solution of BuLi in hexanes (1.6 M) was added dropwise. The yellow suspension instantaneously changed to a deep red solution. The ^{31}P NMR spectra was recorded at −40 °C showing a singlet resonance at −24.7 ppm. ^{31}P NMR (thf-d^8, δ ppm): −24.7 (s, $\underline{P}Ph_2$).

4.6. Single crystal X-ray structure determination experiments

4.6.1. Structure determination of compound 1

Details of the X-ray experiment, data reduction, and final structure refinement calculation are summarized in Table 2. Crystals of complex **1** suitable for an X-ray structure determination were grown from a saturated solution of **1** in a NCMe/Et_2O. A clear orange–yellow fragment ($0.20 \times 0.40 \times 0.50$ mm) was stored under perfluorinated ether, transferred in a Lindemann capillary, fixed and sealed. Preliminary examination and data collection were carried out on a four-circle diffractometer (NONIUS CAD4) at the window of a sealed tube (NONIUS FR590; 50 kV; 30 mA; 1.5 kW) and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were obtained by full-matrix least-squares refinement of 24 high angle reflections. Data collection was performed at 193 K within a Θ-range of $1.52° < \Theta < 24.97°$ and an exposing time of maximum 90 s per scan (omega scans; scan width $(1.00 + 0.25 \tan \Theta)° \pm 25\%$ at each side of the reflection to determine the background). A total of 6295 intensities were collected [17a]. Raw data were corrected for Lorentz and polarization effects. Corrections for absorption effects (based

on psi-scans) were applied [17b]. No decay was observed during the measurement. After merging ($R_{int} = 0.0125$) and rejecting of the systematically absent intensities a sum of 5820 (all data), 4739 ($I > \sigma(I)$), respectively, remained and all were used in the further calculations. The structure was solved by Patterson methods [17c] and difference Fourier syntheses [17d]. All non-hydrogen atoms of the asymmetric unit were refined with anisotropic thermal displacement parameters. All hydrogen atoms were found and refined with individual isotropic displacement parameters. Full-matrix least-squares refinements with 580 parameters were carried out by minimizing $\sum w(F_o^2 - F_c^2)^2$ with SHELXL-97 weighting scheme and stopped at shift/err <0.001. In compound **1** a disorder 0.556(6):0.444(6) of three fluorine atoms of one BF_4 anion could be resolved clearly. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from INTERNATIONAL TABLES FOR CRYSTALLOGRAPHY [17e]. All calculations were performed on a DEC 3000 AXP workstation and an Intel Pentium II PC, with the STRUX-V system [17f], including the programs PLATON [17g], MOLEN [17b], and SHELXL-97 [17d].

4.6.2. Structure determination of compound ***2****,* ***BF_4***

Crystal data and details of the structure determination are presented in Table 2. Suitable single crystals for the X-ray diffraction study were grown from a mixture of Me_2CO, EtOH and Et_2O at 4 °C. A red colored fragment ($0.18 \times 0.23 \times 0.38$ mm) was stored under perfluorinated ether, transferred in a Lindemann capillary, fixed and sealed. Preliminary examination and data collection were carried out on an area detecting system (NONIUS KAPPACCD) at the window of a rotating anode (NONIUS FR951) and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were obtained by full-matrix least-squares refinement of 11,993 reflections. Data collection were performed at 123 K within a Θ-range of $2.06° < \Theta < 26.40°$; two sets with 206 films were measured in rotation modus with $\Delta\varphi/\Delta\Omega = 1.0°$. A total of 10,037 intensities were integrated [17h]. Raw data were corrected for Lorentz, polarization, decay and absorption effects [17i]. After merging ($R_{int} = 0.025$) a sum of 4448 (all data), 4143 ($I > \sigma(I)$), respectively, remained and were used for all calculations. The structure was solved by a combination of direct methods [17j] and difference Fourier syntheses [17d]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms could be located and were allowed to refine with individual isotropic displacement parameters freely. Full-matrix least-squares refinements with 374 parameters were carried out by minimizing $\sum w(F_o^2 - F_c^2)^2$ with SHELXL-97 weighting scheme and stopped at shift/err <0.001. A disorder 0.52(4):0.48(4) of two fluorine atoms of the BF_4 anion could be resolved clearly. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from INTERNATIONAL TABLES FOR CRYSTALLOGRAPHY [17e]. All calculations were performed on a DEC 3000 AXP workstation and an Intel Pentium II PC, with the STRUX-V system [17f], including the programs PLATON [17g], SIR92 [17j], and SHELXL-97 [17d].

5. Supporting information available

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-211212 (**1**) and CCDC-211213 (**2**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

2,2′-Bipyrimidine (bpym) in iron(III) carboxylate chemistry: preparation and characterization of $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$, and the influence of weak interactions in the formation of metal clusters

Received 14 November 2003; accepted 17 February 2004

Abstract

The full investigation of the synthetic possibilities in the $Fe(ClO_4)_3 \cdot 6H_2O/NaO_2CMe/bpym$ reaction system, where bpym is 2,2′-bipyrimidine, in MeCN has provided access to only one product. This is the dinuclear complex $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2 \cdot H_2O \cdot 2MeCN$ (**3** $\cdot H_2O \cdot 2MeCN$). Its cation contains the (μ-oxo)bis(μ-carboxylato)diiron(III) core, while a chelating bpym molecule and one aquo ligand complete a distorted octahedral coordination at each metal ion. The complex cations participate in intercationic hydrogen bonds creating chains along the *b* axis, which form pairs due to π–π interactions between bpym rings of adjacent chains. The complex has been characterized by IR spectroscopy; characteristic bands are discussed in terms of the known structure and the coordination modes of the ligands. The room-temperature effective magnetic moment of **3** is 1.81 BM, a value indicating the presence of relatively strong antiferromagnetic interaction. The $Fe^{III}/ClO_4^-/MeCO_2^-$/bpym chemistry is compared to the already well-developed $Fe^{III}/ClO_4^-/MeCO_2^-$/bpy (bpy = 2,2′-bipyridine) chemistry.

1. Introduction

Dinuclear and polynuclear iron(III) carboxylate complexes have been much investigated in recent years owing to their relevance as models for the active sites of various non-heme iron proteins [1,2], and the interesting magnetic properties that some of them possess [3,4]. The continuing development of these areas requires the discovery of new examples on a regular basis, and several groups have thus been investigating new synthetic procedures capable of allowing access to new structural types. One approach has been the use of appropriately chosen chelating ligands to encourage aggregation while ensuring discrete products that are soluble and can be purified, crystallized and studied in solution. Restricting further discussion to 2,2′-bipyridine (bpy) or its derivatives, the up to now structurally characterized members of this family are $[Fe_2O(O_2CMe)_2Cl_2(bpy)_2]$ [5], $[Fe_2O(O_2CCH_2Cl)_2(bpy)_2(H_2O)_2](NO_3)_2$ [6], $[Fe_4O_2(O_2CMe)_7(bpy)_2]X$ (X = ClO_4 (**1**) [7], Cl [8]), $[Fe_4O_2(O_2CEt)_7(bpy)_2]X$ (X = ClO_4 [9], PF_6 [10]), $[Fe_4O_2Cl_2(O_2CMe)_6(bpy)_2]$ [11], $[Fe_4(OHO)(OH)_2(O_2CMe)_4(bpy)_4](ClO_4)_3$ (**2**) [12], $[Fe_6O_3(OEt)_2(O_2CMe)_9(bpy)_2](ClO_4)$ [13] and $[Fe_2O(O_2CCF_3)_2(Me_2bpy)_4](ClO_4)_2$ [14], where Me_2bpy is 4,4′-dimethyl-2,2′-bipyridine. In

doi:10.1016/j.poly.2004.02.008

all cases, the metal ions are held together by O-based monatomic bridges such as O^{2-}, OH^- and OR^-.

More recently we have decided to extend the above studies by using bis(chelating) aromatic N-donors to investigate to what extent such ligands might affect the identity of products obtained compared to normal bpy and to what extent this might thus prove a route to new cluster types. Our hope was that such ligands could provide access to new types of clusters involving repeating cluster units (available as discrete species with bpy) rather than repeating mononuclear centres, although isolation of coordination polymers could not a priori be ruled out. Christou's group has introduced and successfully developed this approach by using the bis(bipyridine) ligand 1,2-bis(2,2′-bipyridyl-6-yl)ethane (L) and isolating complexes with novel 3d-metal cluster types such as the face-sharing triple cubane core of $[Co_8O_4(OH)_4(O_2CMe)_6L_2]^{2+}$ [15], the "dimer-of-dimers" topology of $[Mn_4O_2(O_2CMe)_4L_2]^{2+}$ [16], the "four-rung ladder" cores of $[Fe_6O_4Cl_4(O_2CPh)_4L_2]^{2+}$ [17] and $[Mn_4O_2(OMe)_3(O_2CPh)_2L_2(MeOH)]^{2+}$ [16], and the "six-rung ladder" motif of $[Fe_6O_6(O_2CPh)_3\ L_3(H_2O)_2]^{3+}$ [18]. In addition, and irrespective of the identities of possible products, we wanted to thoroughly examine the elementary underlying chemistry of this general reaction system, by fully exploring its "parameter space" through subtle changes in reaction parameters, such as the nature of the aromatic N-donors.

Our first choice was 2,2′-bipyrimidine (bpym). Although strictly speaking this molecule is not a bis(2,2′-bipyridine) ligand, it can adopt the bis(chelating) bridging coordination mode [19] (Fig. 1) seen in normal bis(bpy) ligands. Of particular interest is the ability of bridging bpym to transmit antiferromagnetic coupling between paramagnetic 3d-metal ions separated by more than 5 Å [20]. In contrast to the great number of studies devoted to Mn(II), Fe(II), Co(II), Ni(II) and Cu(II) complexes of bpym [19–26], practically nothing is known for the coordination chemistry of bpym with iron(III). Only two iron(III)-bpym complexes have been structurally characterized [27]. These are the mononuclear complex $[FeCl_3(bpym)(H_2O)]$ in which bpym acts as a bidentate terminal(chelating) ligand (Fig. 1) and the dinuclear complex $[Fe_2(bpym)Cl_6(H_2O)_2]$ in which bpym behaves as a bis(chelating) bridging ligand (Fig. 1).

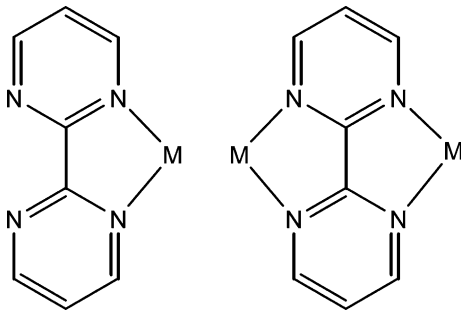

Fig. 1. The chelating (left) and bis(chelating) bridging (right) coordination modes of 2,2′-bipyrimidine (bpym).

The synthetic investigation of the reaction system $Fe(ClO_4)_3\cdot 6H_2O/NaO_2CMe/bpym$ in MeCN is herein reported. The *analogous* reaction system with bpy gave complexes **1** [7] and **2** [12], see Eqs. (1) and (2), respectively, depending on the Fe^{III}:bpy reaction ratio. Complex **1** has a bent ("butterfly") disposition of four Fe^{III} atoms with the pyramidal μ_3-O^{2-} groups on the same side of the fused Fe_3 planes, whereas **2** contains the novel rectangular $[Fe_4(\mu_4\text{-}OHO)\ (\mu\text{-}OH)_2]^{7+}$ core:

$$4Fe(ClO_4)_3\cdot 6H_2O + 7NaO_2CMe\cdot 3H_2O + 2bpy \xrightarrow{MeCN} [Fe_4O_2(O_2CMe)_7(bpy)_2](ClO_4) + 7NaClO_4 + 4HClO_4 + 43H_2O \quad (1)$$

$$4Fe(ClO_4)_3\cdot 6H_2O + 4NaO_2CMe\cdot 3H_2O + 4bpy \xrightarrow{MeCN} [Fe_4(OHO)(OH)_2(O_2CMe)_4(bpy)_4](ClO_4)_3 + 4NaClO_4 + 5HClO_4 + 32H_2O \quad (2)$$

We wondered whether bpym would have the ability to assemble new cluster types with Fe^{III} not available with bpy. Not surprisingly for 3d-metal cluster chemistry, our efforts resulted in the isolation of a dinuclear compound, whose X-ray structure and characterization are herein described. This work can be regarded as a step in a broad programme [28–36] concerned with developing synthetic routes and strategies to polynuclear complexes of middle- and late-3d metals at intermediate oxidation states.

2. Experimental

2.1. Materials

All reagents and solvents were of analytical grade and used as received. The synthesis was carried out under aerobic conditions. *Warning*: Although no such tendency was observed during the present work, perchlorate salts are potentially explosive and should be handled with caution "and" in small quantities.

2.2. Synthesis of $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$ (3)

To a solution of $Fe(ClO_4)_3\cdot 6H_2O$ (0.234 g, 0.51 mmol) and $NaO_2CMe\cdot 3H_2O$ (0.124 g, 0.89 mmol) in MeCN (6 ml) was added a solution of bpym (0.080 g, 0.51 mmol) in the same solvent (7 ml). The color of the solution changed from deep red to dark green. The solution was left undisturbed in a closed flask and after ca 1 week dark green prismatic crystals of $\mathbf{3}\cdot H_2O\cdot 2MeCN$ formed, along with a few colorless prisms, which were

identified as $NaClO_4$ by their IR spectra. The dark green crystals were manually separated, washed with MeCN and dried in vacuo. Typical yields are in the range 50–55%. The dried sample analysed as solvent-free. *Anal.* Calc. for $C_{20}H_{22}Cl_2Fe_2N_8O_{15}$: C, 30.13; H, 2.79; N, 14.06. Found: C, 30.05; H, 2.59; N, 13.54%. IR data (KBr, cm^{-1}): 3374m, 3096m, 1578s, 1562s, 1534s, 1442s, 1406s, 1358w, 1334w, 1302w, 1270w, 1246w, 1216w, 1146s, 1118sb, 1032s, 1020s, 988w, 916m, 820w, 758s, 692m, 660s, 620m, 556m.

2.3. Measurements

Microanalyses (C, H, N) were performed by the Microanalytical Laboratory of the Laboratoire de Chimie de Coordination at Toulouse (France). Infrared spectra (4000–500 cm^{-1}) were recorded as KBr disks on a Perkin–Elmer 16PC spectrometer with samples prepared as KBr pellets. Magnetic susceptibility measurements at ambient temperature were carried out on a Faraday balance equipped with a SARTORIUS micro-electrobalance and a DRUSH electromagnet; diamagnetic corrections were estimated from Pascal's constants.

2.4. X-ray crystallography

A crystal of $\mathbf{3}\cdot H_2O\cdot 2MeCN$, with approximate dimensions of $0.05\times0.25\times0.50$ mm, was mounted in a capillary. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo radiation. Crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the range $11° < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan to $2\theta_{max} = 50°$ with scan speed $3.0°\,min^{-1}$ and scan range 2.0° plus $\alpha_1\alpha_2$ separation. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and Ψ-scan absorption corrections were applied using Crystal Logic software.

The structure was solved by direct methods using SHELXS-86 [37] and refined by full-matrix least squares techniques on F^2 with SHELXL-97 [38]. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms, except those on the water molecules which were located by difference maps and were refined isotropically. All non-hydrogen atoms were refined using anisotropic thermal parameters.

3. Results and discussion

3.1. Synthetic comments

The reaction that leads to **3** – which contains terminal bpym ligands (vide infra) – can be summarized in balanced Eq. (3), based on the reasonable assumption that H_2O from the starting materials and/or the solvent is the source of the O^{2-} ion:

$$2Fe(ClO_4)_3\cdot 6H_2O + 2NaO_2CMe\cdot 3H_2O + 2bpym \xrightarrow[20°C]{MeCN} [Fe_2O(O_2CMe)_2(bpm)_2(H_2O)_2](ClO_4)_2 + 2NaClO_4 + 2HClO_4 + 15H_2O \quad (3)$$

The Fe^{III}:$MeCO_2^-$:bpym ratio initially employed in the reaction mixture was the same that led to the isolation of complex **2**, i.e., 1:1.75:1 (see Section 2.2). This ratio was chosen in order to allow for a direct comparison of the chemistry of bpym and bpy in the present system. With the identity of **3** established by X-ray crystallography, our next goal was either to try to "force" a percentage of bpym to act as a bis(chelating) bridging ligand (thus favoring aggregates based on the tetranuclear cluster unit $[Fe_4(OHO)(OH_2)(O_2CMe)_4(bpym)_4]^{3+}$, i.e. the bpym analogue of discrete **2**), or to prepare the bpym analogue of **1**, i.e., $[Fe_4O_2(O_2CMe)_7(bpym)_2](ClO_4)$. It seemed logical to us that one (or both) of the above goals would be realized by increasing the Fe^{III}:bpym molar ratio. Unfortunately, we could not confirm this synthetic expectation. Use of the same reaction system in MeCN but employing the 2:*x*:1 Fe^{III}:$MeCO_2^-$:bpym ratios ($x = 1.0, 1.2, 1.4, 1.6, 1.8, 2.0$) and a variety of crystallization conditions, led repeatedly

to the isolation of pure **3** in various yields. The facts that in all cases the bpym-based yields are lower than 60% and the final filtrates are intensely coloured probably indicate additional bpym-containing iron(III) species in solution. Also, directed attempts to obtain the above-mentioned desired polynuclear complexes, or even a tetranuclear cluster that would be the bpym analogue of **2**, from reactions of the pre-isolated **1** or **2** with bpym resulted always in the isolation of **3**.

It is clear that the potential of the bis(chelating) bridging coordination mode for bpym is not realized in the $Fe(ClO_4)_3 \cdot 6H_2O/NaO_2CMe$/bpym reaction system in MeCN. It should be reminded at this point that bpym does have the ability to bridge Fe^{III} atoms [27]. A preliminary examination of the above-described experimental adventures is not informative about the reasons that lead to the isolation of the dinuclear complex **3** instead of higher nuclearity species. However, a careful examination of the molecular and crystal structure of **3** helps us to understand its exclusive isolation (vide infra).

3.2. Description of structure

The cation of complex $\mathbf{3} \cdot H_2O \cdot 2MeCN$ is shown in Fig. 2. Selected interatomic distances and bond angles are presented in Table 2.

Complex **3** crystallizes in the triclinic space group $P\bar{1}$. Its structure consists of the dinuclear $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2]^{2+}$ cation, two ClO_4^- anions, and solvate H_2O and MeCN molecules; the latter three will not be further discussed. The complex cation contains two Fe^{III} atoms bridged by one μ-O^{2-} group and two $\eta^1{:}\eta^1{:}\mu_2$-$MeCO_2^-$ ligands, forming a $\{Fe_2(\mu\text{-}O)(\mu\text{-}O_2CMe)_2\}^{2+}$ core. The distorted octahedral geometry at each Fe^{III} is completed with one chelating bpym molecule and one aquo ligand. The Fe(1)–N(4) bond *trans* to the oxo bridge is longer (2.234(3) Å) than its counterpart in the *cis* position (Fe(1)–N(1) = 2.181(3) Å) as a result of the powerful *trans* influence of the short Fe(μ-O^{2-}) bond [6,39]. A similar trend is seen in the Fe(2)–O(W2) bond which is *trans* to the oxo bridge; this bond is longer (2.127(3) Å) than the Fe(1)–O(W1) bond (2.063(4) Å) which is *cis* to the oxo bridge.

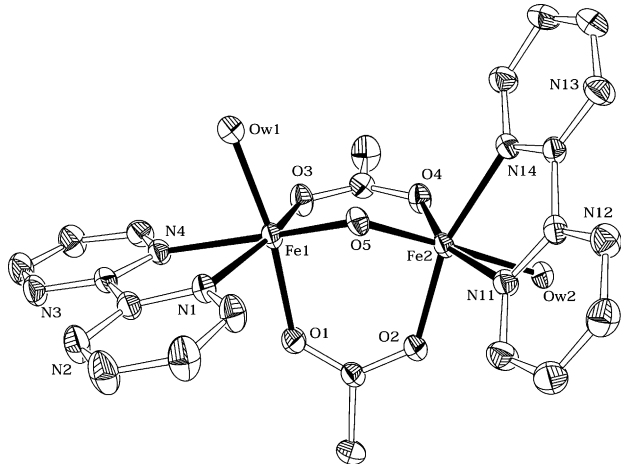

Fig. 2. Partially labelled ORTEP plot of the cation of complex $\mathbf{3} \cdot H_2O \cdot 2MeCN$ at the 30% probability level. Hydrogen atoms have been omitted for clarity.

Table 2
Selected interatomic distances (Å) and bond angles (°) for complex $\mathbf{3} \cdot H_2O \cdot 2MeCN$

Interatomic distances			
Fe(1)–O(1)	2.045(3)	Fe(2)–O(2)	1.995(3)
Fe(1)–O(3)	2.022(3)	Fe(2)–O(4)	2.021(3)
Fe(1)–O(5)	1.783(2)	Fe(2)–O(5)	1.787(3)

Bond angles			
O(1)–Fe(1)–O(W1)	169.7(1)	O(2)–Fe(2)–N(14)	163.0(1)
O(3)–Fe(1)–N(1)	162.0(1)	O(4)–Fe(2)–N(11)	162.9(1)
O(5)–Fe(1)–N(4)	169.8(1)	O(5)–Fe(2)–O(W2)	178.1(1)
N(1)–Fe(1)–N(4)	73.4(1)	N(11)–Fe(2)–N(14)	75.1(1)
Fe(1)···Fe(2)	3.098(1)	Fe(1)–O(5)–Fe(2)	120.4(1)

Complex **3** joins a family of structurally characterized dinuclear complexes containing the (μ-oxo)bis(μ-carboxylato)diiron(III) core [39]. Close precedents to **3** are complexes $[Fe_2O(O_2CMe)_2Cl_2(bpy)_2]$ [5] and $[Fe_2O(O_2CCH_2Cl)_2(bpy)_2(H_2O)_2](NO_3)_2$ [6]. In Table 3 are compared selected structural parameters for the three complexes. A comparison of these structural parameters for **1** and the other two complexes reveals a general similarity. The slightly smaller Fe–O–Fe angle in **3** is associated with a slightly shorter Fe···Fe separation. However, there are also some slight structural differences. In the bpy complexes, both donor atoms *trans* to the oxo group are nitrogen atoms. Thus, the two monodentate terminal ligands are positioned *cis* to the bridging oxo group and are in an *anti* arrangement with respect to the Fe–O–Fe plane. In the bpym-containing complex **3**, only one nitrogen atom [N(4)] is *trans* to the bridging oxo group, the other *trans* donor atom being a water oxygen [O(W2)]. Thus, only one monodentate terminal ligand [O(W1)] is positioned *cis* to the oxo group. The two terminal aqua ligands are neither in an *anti* nor in a *syn* arrangement with respect to the Fe–O–Fe plane; O(W1) is 1.520(4) Å above this plane, while O(W2) is practically on the plane (it lies only 0.064(4) Å below the Fe–O–Fe plane).

The crystal structure is stabilized by a network of strong intermolecular hydrogen bonds. Details of the hydrogen bonds are provided in Table 4. A partial crystal packing diagram of $\mathbf{3} \cdot H_2O \cdot 2MeCN$ is shown in Fig. 3. Of particular interest is an intercationic hydrogen bond of medium strength with the coordinated H_2O oxygen O(W2) as donor and the "free" (uncoordinated)

Table 3
Comparison of selected structural parameters (Å, °) for complexes $[Fe_2O(O_2CMe)_2Cl_2(bpy)_2]$, $[Fe_2O(O_2CCH_2Cl)_2(bpy)_2(H_2O)_2](NO_3)_2$ and $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$ (**3**)

Complex	Fe···Fe	Fe-(μ-O^{2-})[a]	Fe–N_{cis} [a,b]	Fe–N_{trans} [a,b]	Fe–O–Fe
$[Fe_2O(O_2CMe)_2Cl_2(bpy)_2]$	3.151(1)	1.785(4)	2.151(5)	2.208(5)	123.9(2)
$[Fe_2O(O_2CCH_2Cl)_2(bpy)_2(H_2O)_2](NO_3)_2$	3.111(1)	1.784(2)	2.121(2)	2.183(2)	121.5(1)
3	3.098(1)	1.785(3)	2.174(3)	2.234(3)	120.4(1)

[a] Average values except the Fe–N_{trans} bond length for **3** which represents a single value.
[b] Fe–$N_{cis/trans}$ describes iron-nitrogen bonds *cis* or *trans* to the bridging oxo ligand.

Table 4
Hydrogen bonding details[a] for complex $\mathbf{3}\cdot H_2O\cdot 2MeCN$

D–H···A	D···A (Å)	H···A (Å)	D–H···A (°)	Symmetry equivalence of A
O(W1)–HA(OW1)···O(7)	2.847	2.143	173.3	x, y, z
O(W1)–HB(OW1)···O(W3)	2.599	1.869	175.7	x, y, z
O(W2)–HA(OW2)···N(31)	2.819	2.012	172.2	$1+x, y, z$
O(W2)–HB(OW2)···N(3)	2.851	2.142	167.5	$x, -1+y, z$
O(W3)–HA(OW3)···O(6)	2.861	1.997	154.5	$-x, -y, -z$
O(W3)–HB(OW3)···O(11)	2.806	1.793	151.6	$x, 1+y, z$

A, acceptor; D, donor.
[a] Atoms O(6), O(7) and O(11) belong to ClO_4^- counteranions.

bpym nitrogen N(3) of an adjacent cation as acceptor. This ligand–ligand hydrogen bond connects the dinuclear cations and creates one-dimensional (1D) assemblies (chains) parallel to the crystallographic *b* axis. There are also π–π interactions [40] between bpym rings that belong to different chains connecting them into pairs. These π–π interactions are shown as a single line in Fig. 3, joining the centre of the C(14)–C(15) bond between the two symmetrically related bpym ligands.

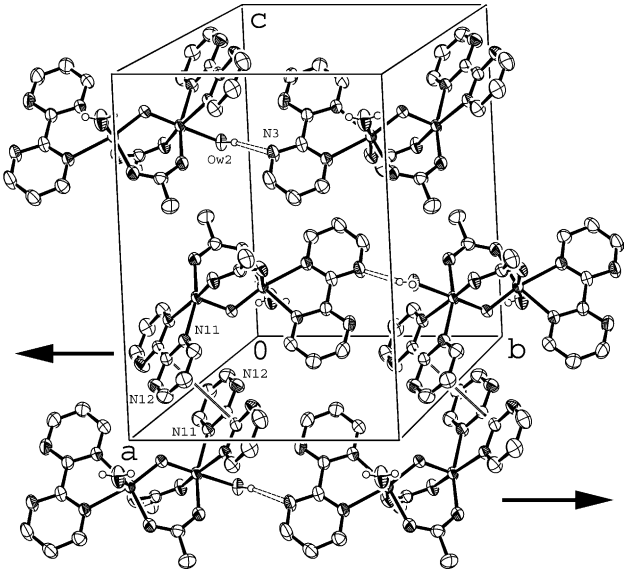

Fig. 3. Crystal packing diagram of complex **3**. Hydrogen bonds (dotted lines) connect the dinuclear cations forming 1D chains along the *b* axis, while π–π interactions (single lines) between the bpym aromatic rings form pairs of such chains. Counteranions, solvate molecules and hydrogen atoms (except those of the aqua ligands) have been omitted for clarity. The arrows indicate the directions of the H-bonds' donor–acceptor vectors (O–H···N) of each chain.

The average distance between the best mean planes of the two symmetrically related bpym ligands (the symmetry code is $1-x, -y, -z$) is 3.48 Å. The complex cations that share π–π interactions are symmetry related to each other by an inversion centre between them and, thus, the π–π interacting chains run the crystal lattice in antiparallel to each other, as can be seen by the opposite orientations of the H-bond donor–acceptor vectors (N···H–O and O–H···N).

The existence of the above described interactions stabilizes the obtained product and therefore it accelerates its precipitation, in contrast with complexes **1** and **2**, where such interactions do not operate in an analogous manner. It is obvious from the labile nature of these systems, confirmed by ^1H NMR experiments in previous studies [34], that many species coexist in solution and that a combination of stability and solubility factors determines which species will precipitate. This example illustrates how secondary interactions (hydrogen bonds, π–π stackings) can have an effect on the identity of the product isolated from a complicated reaction mixture.

3.3. IR spectroscopy

In the $\nu(OH)_{water}$ region, the spectrum of dried **3** shows one medium band at 3374 cm^{-1}, assignable to coordinated water [41]. The spectrum of **3** presents two strong bands at 1534 and 1406 cm^{-1}, attributed to the antisymmetric and symmetric stretching vibrations of the carboxylate group, respectively [42,43]. The difference $\Delta = \nu_{as}(COO) - \nu_s(COO)$ is equal to 128 cm^{-1}, lower than that of NaO_2CMe (164 cm^{-1}), as expected for the crystallographically established bidentate bridging mode of the acetate ligation [43].

The ν(C⎓C) and ν(C⎓N) stretching vibrations of free 2,2′-bipyrimidine at 1565, 1556, 1432 and 1404 cm^{-1} shift to slightly higher frequencies upon complexation and appear at 1577, 1561 and 1405 cm^{-1} in **3**, with the band at 1432 cm^{-1} being masked by the carboxylate symmetric stretch. This appearance of two bands (in the form of a quasi –symmetric doublet) at 1580–1560 cm^{-1} is in accordance with the terminal coordination of bpym [26,44,45]; the lower frequency band does not appear when bpym is bridging(bis-chelating) [23]. The γ(CH) vibration of free bpym (830 and 820 cm^{-1}) appears as a single medium intensity band at 820 cm^{-1} [44]. The Fe–O–Fe antisymmetric stretch, ν_{as}(Fe–O–Fe), is located at 758 cm^{-1} [39,46]. Finally the strong and broad band around 1100 cm^{-1} and the medium band at 620 cm^{-1} are attributed to the $\nu_3(F_2)$ and $\nu_4(F_2)$ modes of the uncoordinated T_d perchlorate anions [42]. The broad character and signs of splitting of the band at ~1100 cm^{-1} both indicate the involvement of the ClO_4^- ions in hydrogen bonding [47].

3.4. Magnetic susceptibility at room temperature

For complex **3** the effective magnetic moment (μ_{eff}) value per Fe_2 is 1.81 BM at 300 K. This value is considerably less than the 8.37 BM value expected for a dinuclear species containing non-interacting Fe^{III} ($S = 5/2$) ions, suggesting the presence of a relatively strong antiferromagnetic interaction in the complex [18]. However, since the magnetic properties of similar dinuclear complexes containing the $\{Fe_2(\mu\text{-}O)(\mu\text{-}O_2CR)_2\}^{2+}$ core have been exhaustively studied [5,6,18,48], no variable-temperature studies were further pursued.

4. Conclusions

In this study, the chemistry of the $Fe^{III}/MeCO_2^-$/L–L systems previously explored with L–L = bpy, was expanded to include 2,2′-bipyrimidine (bpym), in an attempt to obtain different and – if possible – larger clusters, but also in order to examine the basic chemistry of this general system. The use of the bpym ligand in Fe^{III} acetate chemistry has provided access to one dinuclear complex containing the (μ-oxo)bis(μ-carboxylato)diiron(III) core and exhibiting an interesting supramolecular structure. Although one of the goals of this study, i.e., the preparation of larger molecular aggregates, was not attained, we managed to further elucidate some of the factors governing the formation of metal clusters in the above general system. Consideration of synthetic parameters, in combination with careful analysis of the crystal structure of the complex, allowed us to reach some conclusions regarding the reasons that led to the complex obtained. A rational extension of the work reported here is to study the $Fe^{III}/PhCO_2^-$/bpym system in order to investigate the different electronic and steric nature, and the π–π capability of the benzoate ligand. Our results will be reported in due course.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 220156. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Electrochemical, spectroelectrochemical, and pyridine binding properties of tetrathia macrocycle-bridged dimeric cobalt phthalocyanine

Ismail Yilmaz *, Makbule Burkut Koçak

Department of Chemistry, Technical University of Istanbul, Maslak, Istanbul 34469, Turkey

Received 31 December 2003; accepted 17 February 2004

Abstract

Tetrathia macrocycle-bridged dimeric cobalt phthalocyanine, $[(RS)_6CoPc]_2CR$ where $R = C_6H_{13}$, CR = [1,4,7,10-tetrathia-(12-crown-4)], was investigated electrochemically and spectroelectrochemically. Pyridine binding properties of the complex were also investigated by spectrophotometric technique in the solution of dichloromethane. The neutral complex undergoes two quasi-reversible two-electron-oxidations and two quasi-reversible two-electron-reductions in CH_2Cl_2 containing 0.1 M tetra-*n*-butylammonium perchlorate (TBAP). The half-wave potentials for oxidation of the hexylthio substituted complex are located at $E_{1/2} = 0.65$ and 1.28 V, while the two reductions are located at $E_{1/2} = -0.38$ and −1.37 V vs. SCE. These potentials of the complex show little or no difference compared to those of unsubstituted CoPc and other SR substituted phthalocyanines under the same experimental condition, thus suggesting the weak electron-donating properties of the peripheral hexylthio substituents on the phthalocyanine rings. Evaluation of the well-defined UV–Vis spectra of the neutral complex and its electrochemically oxidized and reduced, $\{[(RS)_6Co(2+)Pc(-)]_2CR\}^{2+}$, $\{[(RS)_6Co(+)Pc(2-)]_2CR\}^{2-}$, and $\{[(RS)_8Co(+)Pc(3-)]_2CR\}^{4-}$, species obtained with applied potentials in thin layer cell showed that neutral and mono-oxidized species remained its highly aggregation properties while mono- and doubly reduced complexes behave as monomeric form in the solution as a result of a weak coupling effect. The complex was also investigated as to pyridine-binding ability in dichloromethane/pyridine mixtures. Spectroscopic changes were monitored by UV–Vis spectrophotometry where the Q band of the neutral complex resulted in an increase in intensity, which was associated with the formation of pyridine mono-adduct for binuclear cobalt phthalocyanine complex, $[(RS)_6CoPc]_2CR$.

1. Introduction

Metallophthalocyanines (MPc) are well studied as molecular electronics [1,2], non-linear optics [3], liquid crystals [4,5], gas sensors [6], photosensitizers [7], catalysts [8–13], semiconductive materials [14], photovoltaic cells [15], and electrochromic displays [16,17] over the last few years. Especially, the cobalt phthalocyanine (CoPc) and its derivatives are shown to catalyze reactions like the reduction of oxygen, CO_2, formic acid, formaldehyde, trichloro acetic acid, and cysteine-containing proteins. The catalytic behavior of CoPc complexes is associated with the redox activity of the central metal which undergoes oxidation and reduction related with Co(3+)/Co(2+) and Co(2+)/Co(I) in electrochemical reaction [8–13]. The values of the oxidation or reduction potentials of the central metal in CoPc thus strongly influence the catalytic behavior of the complexes which are essential for the design of more efficient catalysts. The spectroelectrochemical studies of the phthalocyanines facilitate the understanding of the nature of the redox processes which may occur at either the central metal atom or the phthalocyanine ring, but this cannot usually be distinguished by using electrochemistry alone. The spectroelectrochemical studies of the phthalocyanines are also important with regard to their

doi:10.1016/j.poly.2004.02.009

possible use as electrochromic materials where display several colors depend on applied potential on the electrode surface [18–20].

In these respects, the synthesis [21–23], the electrochemical [24–26], spectroelectrochemical [24,26–28] and electrocatalytic behavior [8–13] of cobalt phthalocyanines derivatives have been extensively investigated under different experimental conditions. In particular, multinuclear cobalt phthalocyanines having various kinds of linkage have been the subject of interest in electrocatalysis for the reduction of oxygen at fuel cell cathode because the electrocatalyst can participate in a concerted fashion with the multielectron reduction which makes effective oxygen reduction catalysts to hydrogen peroxide [26].

The present paper reports the electrochemical and spectroelectrochemical characterization and pyridine binding properties of tetrathia macrocycle-bridged dimeric cobalt phthalocyanine, $[(RS)_6CoPc]_2CR$ where R = C_6H_{13}, CR = [1,4,7,10-tetrathia-(12-crown-4)] (Chart 1) in CH_2Cl_2.

No detailed study on the spectroelectrochemistry of macrocycle-bridged dimeric cobalt phthalocyanines has been carried out with the exception of a few reports [24,26]. The synthesis of $[(RS)_6CoPc]_2CR$ was afforded with the reaction of $[(RS)_6H_2Pc]_2CR$ (metal-free phthalocyanines) and cobalt chloride in quinoline. Long-alkyl chains substituted on the peripheral position of phthalocyanine units in the molecule provide high solubility in non-coordinating solvents (e.g., dichloromethane, chloroform, diethylether, *n*-hexane) such as has been observed for long-alkyl chains or bulky-groups substituted mono, unsymmetrical, double-decker phthalocyanines and quinoxaline or some oxime complexes [29–32].

The purpose of this work was to understand the redox behavior of neutral and electrogenerated tetrathia macrocycle-bridged dimeric cobalt phthalocyanine $[(RS)_6CoPc]_2CR$ using electrochemical and spectroelectrochemical techniques, as well as to determine aggregation behaviour and the number of pyridine adduct for the axially ligation of the complex in CH_2Cl_2. The pyridine binding experiment also provides the first example on axially ligation for the binuclear cobalt phthalocyanines in CH_2Cl_2 although there have been some experiments on ligation with pyridine for monophthalocyanines in DMSO [33].

2. Experimental

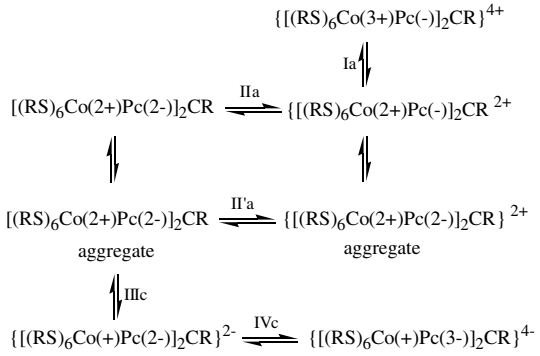
2.1. Chemicals and reagents

Dichloromethane (CH_2Cl_2) was three times treated with H_2SO_4 and distilled over P_2O_5 and CaH_2 prior to use. Dimethylsulfoxide (DMSO) was freshly distilled after drying over alumina. Tetra-*n*-butylammonium perchlorate (TBAP, Fluka Chemical Co.) was recrystallized from ethyl alcohol and dried in a vacuum oven at 40 °C for at least 1 week prior to use. Ferrocene was recrystallized from ethyl alcohol, before use. The target molecule in this work is tetrathia macrocycle-bridged dimeric cobalt phthalocyanine bearing hexylthio substituents on the periphery, which was accomplished by the reaction of $[(RS)_6H_2Pc]_2CR$ (metal-free phthalocyanine) [34] and cobalt chloride in quinoline. The synthesis of $[(RS)_6CoPc]_2CR$ was adopted from a procedure similar to that used for the synthesis of the zinc phthalocyanine complex $[(RS)_6ZnPc]_2CR$ [34]. Purification was achieved by column chromatography over silica gel using CH_2Cl_2 as eluent. The compound was highly soluble in dichloromethane, chloroform, carbon tetrachloride, diethlyether, and *n*-hexane due to the introduction of long-hexylthio chains on the peripheral position of two phthalocyanine cores.

2.2. Instrumention

Cyclic voltammograms (CV) was carried out using CV measurements with a Princeton Applied Research Model 273 potentiostat controlled by an external PC. Current–voltage curves were recorded using an X–Y recorder (RE 0091). A three electrode system was used for CV measurements in CH_2Cl_2 and consisted of a glassy carbon working electrode, a platinum wire counter electrode and a saturated calomel reference electrode (SCE). The reference electrode was separated from the bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard but all potentials in the paper are referenced to the SCE. Solutions containing $[(RS)_6CoPc]_2CR$ were deoxygenated by a stream of high purity nitrogen for at least 5 min. prior to running the experiment and the solution was protected from air by a blanket of nitrogen during the experiment. Controlled potential electrolysis (CPE) was performed with the Princeton Applied Research Model 273 potentiostat/Galvanostat. An "H" type cell with a fritted glass to separate the cathodic and

anodic portions of the cell was used for bulk electrolysis. The working and counter electrodes were platinum and the reference electrode was an SCE. The sample and solvent were transferred into the electrolysis cell under nitrogen. UV–Vis spectroelectrochemical experiments were performed with a home-built thin-layer cell that utilized a light transparent platinum gauze working electrode. Potentials were applied and monitored with an Princeton Applied Research Model 273 potentiostat. Time-resolved UV–Vis spectra and spectrophotometric titration experiments were recorded with a Unicam UV2 Model spectrophotometer.



Scheme 1.

3. Results and discussion

3.1. Electrochemistry

The electrochemistry of CoPc is classified into two sections, that referring to donor solvents and non-donor solvents. Whether the metal or the ring is oxidized first depending on the nature of solvent is the principal difference for the redox couples of CoPc. Doner solvents such as dimethylsulfoxide, dimethylformamide, and acetonitrile or coordinating counter anions in non-donor solvents such as dichlorobenzene and dichloromethane are known to strongly favour Co(3+)Pc species. But, the ring oxidized is seen first in non-donor solvents in the absence of coordinating counter anions [25,26].

Fig. 1 shows a typical cyclic voltammogram of the investigated compound, in that $[(RS)_6CoPc]_2CR$ undergoes a two quasi-reversible two-electron-oxidations and two quasi-reversible two-electron-reductions in CH_2Cl_2 containing 0.1 M TBAP. These reactions are schematically illustrated in Scheme 1 where the oxidations are labeled as reactions I and II and the reductions as reactions III and IV.

The half-wave potentials for the reduction of $[(RS)_6CoPc]_2CR$ in CH_2Cl_2, 0.1 M TBAP are located at

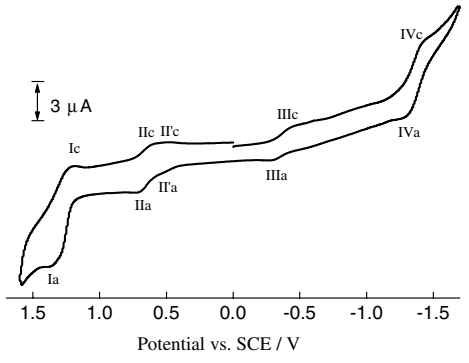


Fig. 1. Cyclic voltammograms of $[(RS)_6CoPc]_2CR$ in CH_2Cl_2 solution containing 0.1 M TBAP. Scan rate = 0.02 V/s.

$E_{1/2} = -0.38$ and -1.37 V, while the two oxidations are located at $E_{1/2} = 0.65$ and 1.28 V vs. SCE. The half-wave potentials of $[(RS)_6CoPc]_2CR$ and some selected mono and dimeric cobalt phthalocyanines are given in Table 1.

Introduction of electron–donating substituents to the phthalocyanine cores should lead to an increase in the electron density of the central metal atom ion thereby making the MPc complex more easily oxidized and less easily reduced [35,36]. However, the investigated compound here and available reports on alkylthio substituted cobalt phthalocyanines show little or no difference in their reduction potentials compared to the unsubstituted CoPc [37]. For example, the first reduction potential ($E_{1/2}$) for the CoPc in dimethylformamide is −0.37 V vs. SCE, while it is −0.38 and −0.34 V vs. SCE for the $[(RS)_6CoPc]_2CR$ and $CoPc(SC_2H_4OH)_8$ [38] in CH_2Cl_2 and DMSO, respectively. These data indicate the weak electron-donating influence of the alkylthio substituents on the average electron density of the metal phthalocyanines. It is also seen that there is little difference between the reduction potentials of $[(RS)_6CoPc]_2CR$, monomeric CoTNPc [25], and dimeric Et-MeO(5)[CoTrNPc] [34] (TN = tetraneopentoxy substituent, electron-donation influence of which is almost similar to that of the alkylthio substituents). We also observed the same weak electron-donating influence of the alkylthio-substituents for previously investigated $[(C_6H_{13}S)_8Pc]_2Lu$, $[(C_{12}H_{25}S)_4Pc]_2Lu$ complexes under the same experimental conditions [18–20].

The redox processes of $[(RS)_6CoPc]_2CR$ were examined as a function of potential scan rate in order to ascertain the mode of mass transport. The cathodic and anodic currents for the oxidation and reduction couples in CH_2Cl_2 each increased in direct proportion to the square root of scan rate between 0.02 and 0.25 V/s, thus suggesting the redox reactions in solution are controlled by diffusion [39].

The investigated compound, $[(RS)_6CoPc]_2CR$, is a relatively planar binuclear molecule which can be regarded as having low flexibility in the plane connecting

Table 1

Solvent/condition	Compound	Ox_2(**I**)	Ox_1 (**II**)	Red_1 (**III**)	Red_2(**IV**)	Reference
CH_2Cl_2	$[(RS)_6CoPc]_2CR$	1.28 (0.10)	0.65 (0.08)	−0.38 (0.09)	−1.37 (0.01)	tw
DMF	CoPc		0.54	−0.37	−1.40	[37]
DMSO	$CoPc(SC_2H_4OH)_8$			−0.34	−1.22	[38]
DCB	CoTNPc	1.10	0.54	−0.40	−1.56	[24,37]
DCB	EtMeO(5)[CoTrNPc]$_2$		0.56	−0.42	−1.56	[24,37]

Values of $\Delta E_p (= E_{pa} - E_{pc})$ for $[(RS)_6CoPc]_2CR$ are given in parenthesis. tw: this work.

two phthalocyanines units. That is to say, two phthalocyanines units do not rotate from the standpoint of constrains of tetrathia macrocycle-bridges between two phthalocyanines units. Thus, no splitting of the redox peaks could be expected for binuclear cobalt complex, $[(RS)_6CoPc]_2CR$, such as has been observed for the Co(2+)/Co(+) couple of a clamshell cobalt porphyrin and the Co(2+)/Co(+) and Co(2+)/Co(+) couples of face-to-face cobalt porphyrins [40,41] due to interactions between the two cobalt atoms, which are held in close proximity by the ligand geometry. But intermolecular interaction between phthalocyanine molecules should result in aggregation which is expected to show an additional wave (II'a) corresponding to the reduction of aggregated species as observed in Fig. 1, if there is an equilibrium between the aggregated and non-aggregated species where the equilibrium is slow relative to the electrochemical timescale [42]. Therefore, II'a and IIa in Fig. 1 should be assigned to the oxidation of aggregated and non-aggregated $[(RS)_6CoPc]_2CR$ species as shown in Scheme 1. Aggregation appears to be influenced by the net charge on the phthalocyanine units, being more important with positively charged than with negatively charged species. The results were also confirmed with spectroscopic date obtained from spectroelectrochemical measurement of the $[(RS)_6CoPc]_2CR$ in a thin layer cell. In the case of the binuclear cobalt phthalocyanine $[(RS)_6CoPc]_2CR$ studied here, the two phthalocyanine units of each molecule oxidize and reduce simultaneously although some mixed-valence species were seen for the binuclear phthalocyanines in the literature [24]. The controlled potential coulometric (CPC) study indicated that the number of electrons transferred for electrochemical reactions of the complex is two for each oxidation and reduction processes. The redox potentials of $[(RS)_6CoPc]_2CR$ measured in this work are consistent with those of binuclear cobalt phthalocyanines reported in the literature [25].

3.2. UV–Vis spectra of electrooxidized and electroreduced complexes

Typical absorption spectra for neutral $[(RS)_6CoPc]_2CR$ and its electrochemically generated species, $\{[(RS)_6Co(2+)Pc(-)]_2CR\}^{2+}$, $\{[(RS)_6Co(+)Pc(2-)]_2CR\}^{2-}$, and $\{[(RS)_8Co(+)Pc(3-)]_2CR\}^{4-}$, are shown in Figs. 2 and 3(a)–(c). Spectroscopic data for neutral and electrochemically generated species are also given in Table 2.

The typical UV–Visible spectra of neutral $[(RS)_6CoPc]_2CR$ exhibited characteristic Q and B bands, one in the visible region at 700 nm (Q-band) attributed to the $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc(-2) ring, and the other in the UV region at 321 nm (B-band) arising from the deeper π-levels $\rightarrow$ LUMO transition. Neutral $[(RS)_6CoPc]_2CR$ shows an additional band centered at ca. 50 nm to the blue of the normal Q band as a result of aggregation through exciton coupling of phthalocyanine units [26].

The intensity of Q band relative to B is also low (Fig. 2, as shown solid line). These results are similar to those previously observed for binuclear cobalt phthalocyanines [25]. Both B and Q bands of $[(RS)_6CoPc]_2CR$ are slightly shifted to longer wavelengths compared to unsubstituted CoPc. Such a red shift is an indication that the energy gap between the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) of the complex are narrower than those of the CoPc, thereby increasing the electroconductivity of the molecule [19].

$[(RS)_6CoPc]_2CR$ was stepwise oxidized or reduced in a thin-layer cell and the resulting UV–Vis spectra were

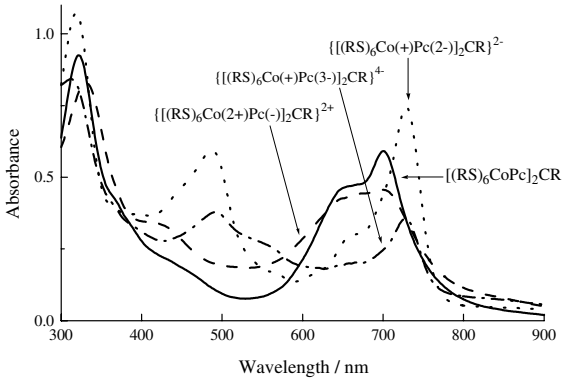

Fig. 2. UV–Vis spectra of $[(RS)_6CoPc]_2CR$ (solid line), $\{[(RS)_6Co(+)Pc(2-)]_2CR\}^{2-}$ (dot line), $\{[(RS)_8Co(+)Pc(3-)]_2CR\}^{4-}$ (dash dot line), and $\{[(RS)_6Co(2+)Pc(-)]_2CR\}^{2+}$ (dash line) in CH_2Cl_2 containing 0.2 M TBAP.

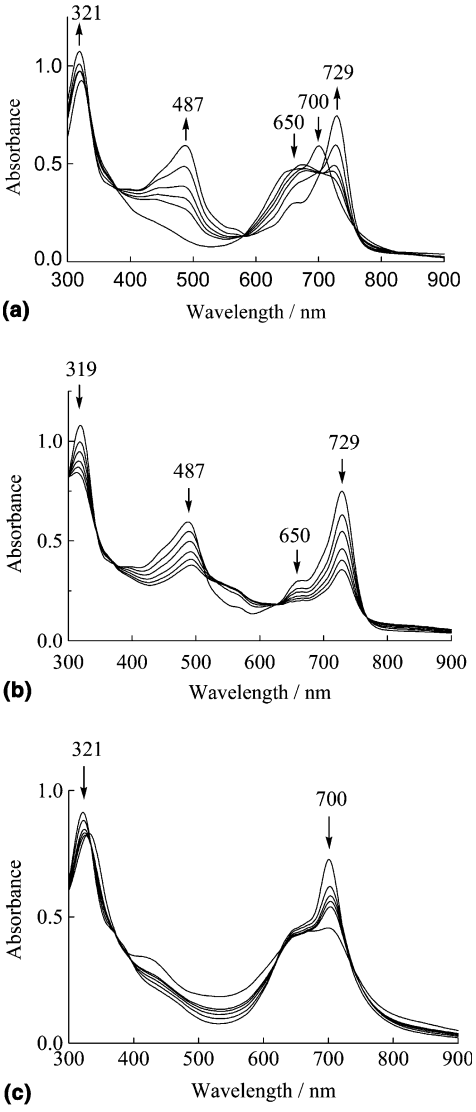

Fig. 3. Time-resolved UV–Vis spectral changes of $[(RS)_6CoPc]_2CR$ (a) during the first reduction at $E_{app} = -0.7$ V, (b) during the second reduction at $E_{app} = -1.5$ V (c) during the first oxidation at $E_{app} = 0.9$ V in CH_2Cl_2 solution containing 0.2 M TBAP.

measured as a function of time. Examples of the time-resolved spectra are shown in Fig. 3(a)–(c) and summary of the spectroscopic data is given in Table 2.

The evolution of the UV–Vis spectral changes upon the first reduction of $[(RS)_6CoPc]_2CR$ results in the spectroscopic changes are shown in Fig. 3(a) and Fig. 2 (dot line) for the final spectrum of $\{[(RS)_6Co(+)Pc(2-)]_2CR\}^{2-}$ and accompanies with a change of color from green to yellow. Isobesting points are observed at 334, 377, 581, 766 nm. The spectrum is typical of a Co(+)Pc(−2) species, characterized by the appearance of strong band at 487 nm, assigned as a metal-to-ligand charge transfer from Co(+)Pc(2−) $[d(xz, yz)] \rightarrow \pi$ (1b1u) Pc(2−), a red shift, and an increase in intensity of the Q band centered at 729 nm [25,26,43]. The Co(I) species is expected to be much less intermolecularly coupled than the Co(2+) species as a result of the negative charge on the cobalt atoms giving rise to weak coupling effect. Thus, the intensity of the band at 650 nm decreases as seen in Figs. 2 and 3(a). An equilibrium between aggregated and non-aggregated products could not be expected following the first reduction process of $[(RS)_6CoPc]_2CR$ based on the metal centered, which is consistent with CV of $[(RS)_6CoPc]_2CR$. This shows that the reduced species of the complex $\{[(RS)_6Co(+)Pc(2-)]_2CR\}^{2-}$ behaves as a monomeric form in the solution, which could be expected for common MPc molecules in their solution state of electrochemistry. The electron transfer reaction was reversible on the spectroelectrochemical timescale and the original spectrum (and color) of the compounds was obtained upon re-oxidation. Thus, the reduced phthalocyanine remained fully stable throughout the experiment. The well-defined UV–Vis spectral changes during the second reduction of $[(RS)_6CoPc]_2CR$ are shown in Fig. 3(b) and Fig. 2 (dash dot line) for the final spectrum of $\{[(RS)_8Co(+)Pc(3-)]_2CR\}^{4-}$. The reduction product results in a color change from yellow to pink. Isobesting points are observed at 342, 372, 627, 766 nm. The observed small red shift of the MLCT band and decrease in intensity of the Q and B bands relative to that of the first reduction product are similar to those mentioned for monomeric [44] and dimeric [25] cobalt phthalocyanines in literature. Re-oxidation of ring-reduced species at a positive potential generates the starting material with the same Q band intensity.

UV–Vis spectral changes upon the first oxidation of $[(RS)_6CoPc]_2CR$ in CH_2Cl_2 are shown in Fig. 3(c) and Fig. 2 (dash line) for the final spectrum of $\{[(RS)_6Co(2+)Pc(-)]_2CR\}^{2+}$. Isobesting points are observed at 333, 394, 622, 734 nm. The decreases in the intensity of the Q and B bands with small red shift are observed but no drastic color change was seen as previously

Table 2
UV–Vis spectral data of $\{[(RS)_8CoPc]_2CR\}^n$ in CH_2Cl_2 containing 0.2 M TBAP

Charge, n	Species	λ (nm) (log ε)			
0	$[(RS)_6CoPc]_2CR$	321 (5.62)		650 (5.32)	700 (5.43)
−2	$[(RS)_6CoPc]_2CR$	319 (5.70)	487 (5.43)	650 (5.08)	729 (5.54)
−4	$[(RS)_6CoPc]_2CR$	313 (5.58)	493 (5.23)	650 (4.9)	729 (5.21)
+2	$[(RS)_6CoPc]_2CR$	331 (5.57)		650 (5.29)	700 (5.31)

mentioned [25]. The broad, low-intensity spectrum is very similar in appearance to those reported for the ring oxidations of phthalocyanines [25,45] and metalloporphyrins [46] to form the phthalocyanine and porphyrin cation radical species.

Re-reduction at a negative potential of ring-oxidized species generates the starting material with the same Q band intensity which means the oxidized product remains stable during the spectroelectrochemical process. The aggregation band corresponding to the first oxidizided species is centered at 650 nm which is similar to that of neutral molecule with the exception of the almost same height of bands as shown Fig. 3(c). This aggregation effect could be also observed in CV of $[(RS)_6CoPc]_2CR$ corresponding to the equilibrium between aggregation and non-aggregation species (Fig. 1 and Scheme 1).

3.3. Formation of mono-pyridine adduct and equilibrium measurement

The binding of pyridine to $[(RS)_6CoPc]_2Cr$ was carried out at 296 K in dichloromethane and the reaction was monitored by UV–Vis spectroscopy. The absorbance data can be fitted to the Hill equation (1) [47]

$$\log[(A_i - A_o)/(A_f - A_i)] = \log K + p\log[py], \quad (1)$$

where A_i is the absorbance at a specific concentration of pyridine; A_o the initial absorbance, where $[py] = 0$, and A_f the final absorbance, where the fully ligated $[(RS)_6CoPc]_2CR$ is the only species present. The value for log K was obtained from the intercept of the regression line $\log[(A_i - A_o)/(A_f - A_i)]$ vs. log [py]. The slope, p, should be equal to the number of axially coordinated ligands. The concentration of the $[(RS)_6CoPc]_2CR$ for the measurement was $\sim 10^{-5}$ M and that of pyridine was in the range of 10^{-5} to 0.5 M. The binuclear cobalt complex, $[(RS)_6CoPc]_2CR$ was investigated as to pyridine binding ability in dichloromethane/pyridine mixtures. The addition of pyridine to dichloromethane solution of $[(RS)_6CoPc]_2CR$ leads to an increase in intensity for the Q band of the neutral complex. The new spectra are formed with isobesting points at 661, 715 nm for the measurement of dichloromethane solution. Further addition of pyridine had no effect on the position of maxima.

The first axial ligand in MPc complexes generally occurs at a fast rate causing very minor spectroscopic changes that are difficult to observe [33,48]. The spectral changes are associated with pyridine adduct for $[(RS)_6CoPc]_2CR$ as shown in Eq. (2) for the $[(RS)_6CoPc]_2CR$, whose spectrum in dichloromethane and neat pyridine is illustrated in Fig. 4(a) and (b).

$$[(RS)_6Co(2+)Pc(2-)]_2CR + 2py \rightleftharpoons [(RS)_6Co(3+)Pc(2-)(py)_2]_2CR \quad (2)$$

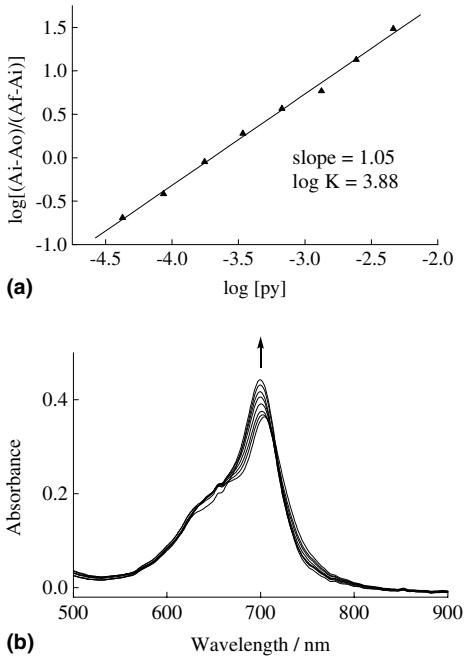

Fig. 4. (a) Plots of $\log[(A_i - A_o)/(A_f - A_i)]$ vs. log [py] for the formation of $[(RS)_6Co(3+)Pc(2-)(py)_2]_2CR$ in CH_2Cl_2 and (b) Absorbtion spectral changes of $[(RS)_6CoPc]_2CR$ on addition of pyridine in CH_2Cl_2.

The spectral changes associated with the conversion of $[(RS)_6CoPc]_2CR$ to its pyridine adducts are shown in Fig. 4(b) and, when analyzed by the Hill plot of $\log[(A_i - A_o)/(A_f - A_i)]$ vs. log [py] shown as Fig. 4(a), give a slope of 1.05, consistent with the binding of one pyridine molecule per cobalt atom in the two phthalocyanine units to form $[(RS)_6Co(III)Pc(-2)(py)_2]_2CR$. The value of log K for the axially ligation of pyridine in $CH_2Cl_2$is 3.88 as shown in Fig. 4(a), which is higher than that of CoPc in DMSO where axial ligand exchange reaction with pyridine in $CoPc(DMSO)_2$ was reported [33].

Dedicated to Professor Milan Sikirica on the occasion of his 70th birthday

Abstract

A series of novel complexes, dihalo-bis(*N*-benzyl-2-oxo-1-naphthylideneamine-*O*)zinc(II), $ZnX_2(bznapH)_2$ (**1**–**3**), dihalo-bis(*N*-*p*-tolyl-2-oxo-1-naphthylideneamine-*O*)zinc(II), $ZnX_2(tolnapH)_2$ (**4**–**6**), of the general formula $[ZnX_2(LH)_2]$ X = Cl, Br, I, have been prepared. The crystal structures of four compounds (**1**–**4**) reveal four coordinated zinc centres by two halogen and two oxygen atoms from the Schiff-base in the form of distorted tetrahedra. Complex **4** crystallizes as the one-to-one solvate with ethanol.

The tetrahedral distortion is most pronounced in the structure of $ZnI_2(bznapH)_2$ complex. X-ray structural data showed that the Schiff-base ligand in the naphthylideneamine tautomeric form is weakly bound to Zn atom in **1**–**4** (being in the range from 1.952(3) Å in **2** to 2.002(3) Å in **4**). The molecular structures of **1**–**4** are governed by the type of halide and the corresponding Schiff-base. Although the structure comparison of $ZnX_2(bznapH)_2$ vs. $ZnX_2(tolnapH)_2$ leads to the conclusion that ligand spatial accomodation (non-planar bznapH with aliphatic interruption vs. aromatic tolnapH) is the dominating factor in the crystal structures. The crystal structures of **2**–**4** are dominated by van der Waals forces. There is a weak intermolecular hydrogen bond of the C–H···Cl type in **1** (3.710(5) Å joining molecules into endless chains. The UV–Vis and ^{1}H NMR spectra, obtained in ethanolic and acetone solution indicate that the complexes do not exist in the solutions.

Keywords: Zinc complexes; Schiff-bases; Crystal structures; IR; UV and NMR spectroscopy; Thermal analysis

1. Introduction

In the context of our investigation of mercury(II) compounds with Schiff-bases [1], we undertook the investigation of the analogous zinc(II) compounds in order to make more complete the coordination chemistry of the group 12 metals. It is well known that zinc and Schiff-bases play important roles in biological systems; zinc mainly as a part of metalloenzymes [2] and Schiff-bases as the intermediates in aminoacid metabolism [3,4].

This paper reports the synthesis, IR, NMR and UV characterization as well as thermal studies of a series of 1:2 complexes of zinc(II) halides with *N*-benzyl-, *N*-*p*-tolyl-2-oxo-1-naphthylideneamine. The crystal structures of the complexes **1**–**4** have been determined by crystal X-ray diffractometry.

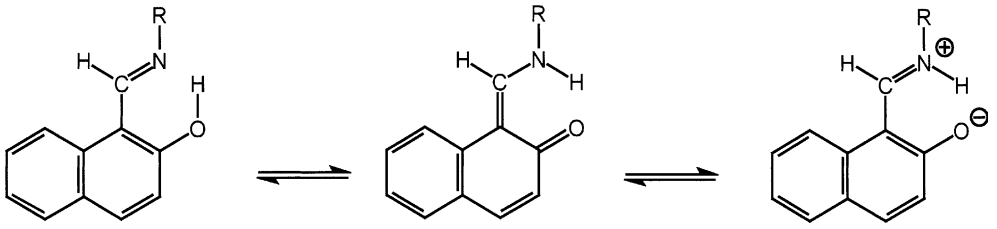

Scheme 1.

Schiff-bases derived from *O*-hydroxy aromatic aldehydes such as salicylaldehyde and 2-hydroxy-1-naphthaldehyde with the *N*,*O*-donor set react with the zinc ion to yield two different types of compounds, i.e. metal chelates and adducts of general formulas ZnL_2 and $ZnX_2 \cdot 2LH$, respectively, both containing a four-coordinated zinc metal centre [5]. The chelate zinc complexes of the ZnL_2 type where L = salicylaldiminato ligand are well known, but according to the Cambridge Structural Database [6a,6b] there are only two zinc(II) complexes with the Schiff-bases derived from 2-hydroxy-1-naphthaldehyde that are structurally characterized. One of them (refcode: POGJAW) [7] contains a five-coordinated zinc atom (three nitrogen atoms, one oxygen atom and one bromine atom) and the other has a tetrahedrally coordinated zinc atom (refcode: SUQWOK) [8]. According to our best knowledge, there is only one more zinc(II) complex with a Schiff-base derived from 2-hydroxy-1-naphthaldehyde and that has only been characterized spectroscopically [9]. There is no structural characterization of zinc adducts with the naphthaldimine type of Schiff-bases.

The crystal structures of these non-coordinated ligands have not been determined up until now. The tautomeric equilibrium of the Schiff-bases derived from 2-hydroxy-1-naphthaldehyde and amines (1:1 molar ratio), in the solid state [10–12] as well as in solution [3], is usually shifted toward the keto-amine tautomeric form (Scheme 1). There are also examples of the structures of this Schiff-base type that in the solid state exist in the enol-imine tautomeric form [13].

2. Experimental

All reagents used were purchased from Aldrich, solvents from Kemika-Zagreb and were used without further purification. C, H and N analysis was provided by the Analytical Services Laboratory of the Ruđer Bošković Institute. The IR spectra of all mentioned compounds were recorded in a Perkin–Elmer Fourier Transform 1600 spectrometer in the range of 4000–450 cm^{-1} as KBr discs. The UV–Vis spectra were recorded using a Varian Cary 300 operating in the range 190–900 nm. The ^1H NMR spectra were recorded in a Varian Gemini 300 spectrometer, at 20 °C. All chemical shifts, in parts per million (ppm), are referred to TMS. Digital resolution was 0.32 Hz per point. The thermal measurements were performed using a simultaneous TGA–DTA analyser (TA Instruments, SDT Model 2960 coupled with MS). The samples were placed in small alumina sample pans. The TGA and DTA curves were obtained by placing the samples of about 2 mg in mass, in open sample pans, with a heating rate of 10 °C min^{-1} and argon (purity above 99.996%) flowing at the rate of 50 ml min^{-1}. The SDT was calibrated with indium.

2.1. Preparation of the ligands and basic analytical data

The Schiff-bases *N*-benzyl-2-oxo-1-naphthylideneamine (bznapH) [14] and *N*-*p*-tolyl-2-oxo-1-naphthylideneamine (tolnapH) were prepared by the conventional condensation method.

[bznapH]. Chemical analysis: found (required for $C_{18}H_{15}NO$) C, 82.73 (82.89); H, 6.18 (5.79); N, 5.66 (5.36). Melting point: 98.5 °C. Selected IR-max (KBr disc, cm^{-1}): 1629vs (C=O), 1542s and 1209m-s (C–N). Selected UV–Vis absorptions (EtOH): λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}) 231 (45370), 307 (10920) and 420 (11010). ^1H NMR peaks (d_6-acetone): 14.98 (s, 1H, –O*H*), 9.36 (s, 1H, *H*C=N), 8.14-6.92 (m, 11H, Ar–*H*), 4.91 (s, 2H, –CH_2–).

[tolnapH]. Chemical analysis: found (required for $C_{18}H_{15}NO$) C, 82.05 (82.89); H, 5.77 (5.79); N, 5.46 (5.36). Melting point: 131 °C. Selected IR-max (KBr disc, cm^{-1}): 1619vs (C=O), 1543s and 1211m-s (C–N). Selected UV–Vis absorptions (EtOH): λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}) 233 (47420), 318 (13810) and 440 (16370). ^1H NMR peaks (d_6-acetone): 15.73 (s, 1H, –O*H*), 9.68 (s, 1H, *H*C=N), 8.44-7.06 (m, 10H, Ar–*H*), 2.36 (s, 3H, –CH_3).

2.2. Preparation of the complexes and basic analytical data

2.2.1. General procedure

Ethanolic solutions of the corresponding zinc(II) salts and the appropriate Schiff-base in a 1:2 molar ratio were refluxed for several hours. The reaction mixture was then left to stand for two days. The compounds were filtered off, washed with ethanol and dried in vacuo. After standing for a few days, the filtrates **1**–**4**

2.3. X-ray single crystal analyses of the compounds *1, 2, 3 and 4*

Relevant data on the summary of intensity data collection for the structures **1**–**4** are given in Table 1. Data collection for **1** and **4** were controlled by the STADI4 program [15]. Lattice constants were obtained by the least-squares refinement from the settings of 46 reflections ($10° \leqslant \theta \leqslant 16°$) for **1** and 21 reflections ($8° \leqslant \theta \leqslant 15°$) for **4**. 7383 reflections with $1° \leqslant \theta \leqslant 28°$ and 3409 reflections with $1° \leqslant \theta \leqslant 28°$ were used for unit cell refinement for structures **2** and **3**, respectively. Two sets of 311 frames and one of 167 frames were collected at the crystal-detector distance of 70 mm, 0.6° scans, 12 s per frame for structure **2** and two sets of 187 and 62 frames at the crystal-detector distance of 45 mm, 1.0° scans, 30 s per frame for structure **3**.

Reference reflections were monitored periodically showing no significant intensity decay for all four structures. The data were corrected for Lorentz-polarization by the X-RED [16] program for **1** and **4** and by DENZO-SMN [17] for **2** and **3**. The Gaussian absorption correction based on the crystal dimensions by the X-RED [16] program was performed for **1**, but for **2** and **3** only scaling based on all symmetrically dependent reflections were applied.

The structures were solved by direct methods implemented in the SHELXS [18] program. The applied refinement procedure based on the F^2 values against all reflections included the anisotropic model for all non-H atoms using the SHELXL [19] program. The hydrogen atoms were generated at ideal geometrical positions [Csp^2–H 0.93, Csp^3–H 0.97 Å, Csp^3–H 0.96 Å for phenyl, methylene and methyl carbon atoms with $U_{iso}(H) = 1.2$ or 1.5 $U_{eq}(C)$] and refined applying the riding model. In the structure of compound **1** the hydrogen atoms belonging to the nitrogen atoms of the C=N group were found, but finally refined at idealized stereochemical positions (N–H 0.86 Å) by the riding model procedure. Structurally identical hydrogen atoms in **2** and **3** were found in the electron density difference Fourier maps and refined freely [N1–H1N 0.74(4) Å and N2–H2N 0.83(4) Å in **2** and N1–H1N 0.64(4) Å in **3**].

In the structure of compound **4**, due to the poorer quality X-ray diffraction data (data-to-parameter ratio is less than 4.5), the positional disorder of the atoms C1, C2 and O3 of the ethanol molecule could not be refined, thus hydrogen atoms belonging to C1, C2 and O3 were not modelled. The hydrogen atom which belongs to the N2 atom is found in the electron density difference Fourier map and is refined freely, but the hydrogen atom which belongs to N1 atom could not be found and it was generated at an ideal position and refined by the riding model procedure (N–H 0.86 Å). The standard deviations of the molecular geometry of **4** are significantly larger than in **1**, **2** and **3** making the comparison of its geometry to the other ones impossible. Only the main stereochemical features of the solid state structure of **4** could be obtained, but not the fine structural details. Graphical work has been performed by the program PLATON-98 [20].

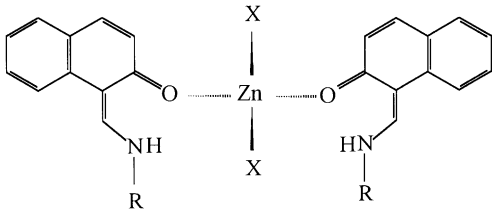
3. Results and discussion

3.1. General aspects

The reactions of zinc(II) halides with *N*-benzyl-2-oxo-1-naphthylideneamine and *N*-*p*-tolyl-2-oxo-1-naphthylideneamine in ethanolic solution, give complexes of the general formula [ZnX$_2$(HL)$_2$] (X = Cl, Br, I) (Scheme 2). The isolated compounds are stable in air at room temperature, but do not exist in DMSO, DMF, pyridine, chloroform, acetone or ethanol solutions, i.e. they undergo decomposition, which is revealed by ^{1}H NMR and UV spectra. Compound **4** crystallizes as an ethanolic solvate, but its crystals, losing the ethanol, slowly decompose into the unsolvated compound at room temperature.

$$ZnX_2 + 2LH \underset{\text{reflux}}{\overset{\text{EtOH}}{\rightleftharpoons}} ZnX_2(LH)_2$$

LH = *N*-benzyl-2-oxo-1-naphthylideneamine (bznapH)
N-*p*-tolyl-2-oxo-1-naphthylideneamine (tolnapH)



$ZnX_2(bznapH)_2$ [X = Cl (**1**), Br (**2**), I (**3**)]
$ZnX_2(tolnapH)_2$ [X = Cl (**4**), Br (**5**), I (**6**)]

Scheme 2.

3.2. Spectroscopic studies

The IR spectra of the free Schiff-bases and compounds **1**–**6** are quite similar in the "finger print" region. The common feature of all these spectra is a very weak and broad stretching band in the 3000–1800 cm^{-1} region that can be assigned as the ν(NH) stretching band. The very strong absorption band in the region of 1630–1610 cm^{-1}, is due to the C=O stretching vibrations and indicates the presence of the keto-amine tautomeric form of the Schiff-base, both in the free ligand and in the complexes. Furthermore, the strong absorption bands in the region of 1550–1540 cm^{-1} that can be assigned to the C=C stretching accompanied with that in the region of 1220–1210 cm^{-1} that suggests C=N stretching, confirm the existence of the keto-amine tautomeric form of the Schiff-base [21–23], suggesting metal-to-ligand coordination via the carbonyl oxygen atom.

The UV–Vis absorption spectra measured for the absolute ethanolic solution of the zinc complexes (**1**–**6**) suggest that they decompose when dissolved. Such a conclusion can be drawn because of the similarity of the spectra of the free ligands with those measured for the solution of the complexes. Moreover, that is quite consistent with the our previous results obtained for the mercury(II) halide adducts with the same ligand [1]. The spectra reveal a predominance of the keto-amine tautomeric form of both ligands [24,25].

We also measured the ^{1}H NMR spectra in acetone. The NMR measurements show that complexes **1**–**6** are not stable in acetone either. This conclusion was drawn from the fact that there are no significant changes in the ^{1}H NMR chemical shifts of the dissolved compounds in comparison with those of the free ligands. In the ^{1}H NMR spectrum of bznapH the signals of azomethine and hydroxyl protons appear at 9.36 and 14.98 ppm, while in tolnapH they appear at 9.68 and 15.73 ppm, respectively. The signals corresponding to Ar–*H* appear in the region 6.9–8.2 ppm and 7.0–8.5 ppm for bznapH and tolnapH, respectively. At 4.91 ppm the signal corresponding to the two methylene protons for bznapH have been observed and that at 2.36 ppm corresponds to the three methyl protons for tolnapH [8,26,27].

3.3. X-ray structural studies

The structural study of the four zinc complexes **1**–**4** was undertaken in order to establish the general mode of ligating of this type of Schiff-base, dependence of the zinc coordination sphere geometry on the type of zinc halide (chloride, bromide and iodide) and to compare results with the 1:1 mercury halide adducts of the same Schiff-base which have been previously structurally characterized by us [1].

In the $ZnX_2 \cdot 2LH$ adducts or in the $[ZnX_2(LH)_2]$ complexes zinc retains X^- ions in the coordination sphere and thus neutral LH Schiff-base completes the coordination sphere bonding monodentately by either oxygen or nitrogen ligating centre, but not with both donor atoms. Contrary to the ZnL_2 complexes where the Schiff-base is bound in an anionic form, the intramolecular hydrogen bond of the O–H···N or N–H···O type is preserved in the adducts or in the $[ZnX_2(LH)_2]$ type of complexes. Usually, the type of intramolecular hydrogen bond found in the adduct or in the $[ZnX_2(LH)_2]$ complexes and non-coordinated Schiff-base is different, thus leading to the change of the tautomeric form of the Schiff-base ligand upon complexation [5]. Adducts of the type $ZnX_2 \cdot 2LH$ are only known for salicylaldimine Schiff-bases and according to the Cambridge Structural Database [6a,6b] there are three such adducts: *N*-isopropylsalicylaldimine with ZnI_2 (refcode: VATROX) [28], dichloro-bis(2-(*o*-tolyliminomethyl)phenolato-O)-zinc(II) (refcode: XAXVIB) [29] and bis(1-anilinomethylidene-2-oxo-1H,2H-naphthalene-chloro)-zinc (refcode: VIRVUN) [30]. The common feature of these three adducts is stronger Zn–X bonds (2.564(1)–2.587(1) Å range for the Zn–I bond in VATROX, 2.2401(7) Å for the Zn–Cl bond in XAXVIB and 2.203(7), 2.226(7), 2.201(7) and 2.217(8) Å for the Zn–Cl bonds in VIRVUN) and weaker Zn–O bonds being in the range from 1.955 Å (mean value) in VATROX to 2.00(1) Å in VIRVUN. These Zn–O bond distances are longer than in the chelate ZnL_2 complexes (the average Zn–O bond distance value in the ZnL_2 complexes with salicylaldimine Schiff bases is 1.926 Å). This elongation is the consequence of the Schiff-base ligation in the neutral form in the adducts and the participation of N,O-donor atoms in the intramolecular hydrogen bond formation. The length of the N–H···O intramolecular hydrogen bond varies from 2.499 Å in VIRVUN to 2.636 Å in VATROX.

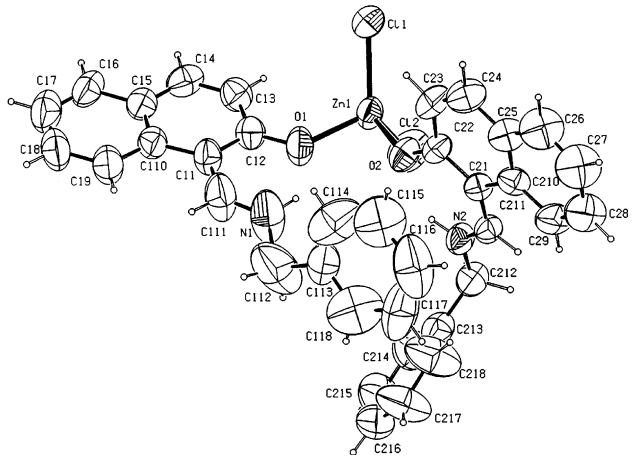


Fig. 1. ORTEP drawing of $ZnCl_2(bznapH)_2$ (**1**) with the atom numbering scheme. The thermal ellipsoids are at the 50% probability level.

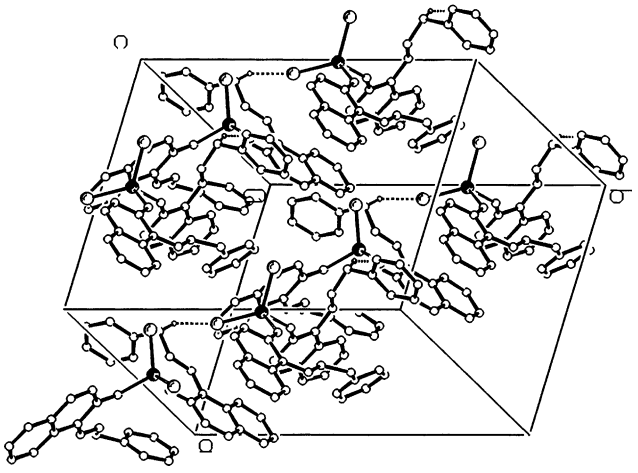

Fig. 2. The crystal packing of $ZnCl_2(bznapH)_2$ (**1**) showing the intermolecular C212–H21A···Cl1 hydrogen bonds by dashed lines that link molecules into endless chains parallel to the *y*-axis. The other hydrogen atoms are omitted for clarity.

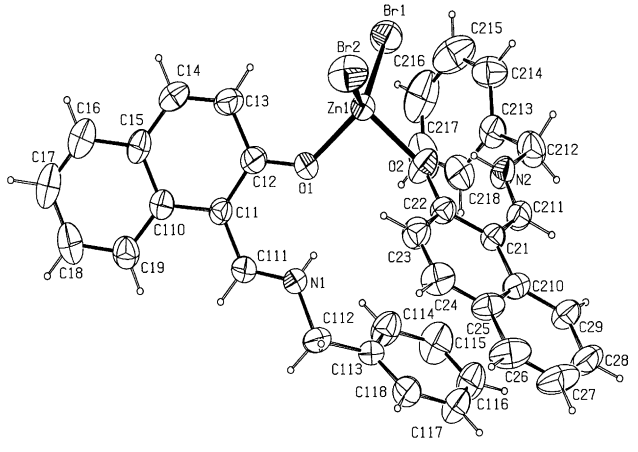

Fig. 3. ORTEP drawing of $ZnBr_2(bznapH)_2$ (**2**) with atom the numbering scheme. The thermal ellipsoids are at the 50% probability level. There are two crystallographically independent molecules within the asymmetric unit. Only one is shown for clarity.

The crystal structures of the two isostructural adducts, $HgX_2(bznapH)$ (X = Cl, Br) revealed dimers formed by bridging halogen atoms and generated a 2 + 2 effective coordination sphere of the mercury atoms [1]. The dimers are joined only by the van der Waals contacts.

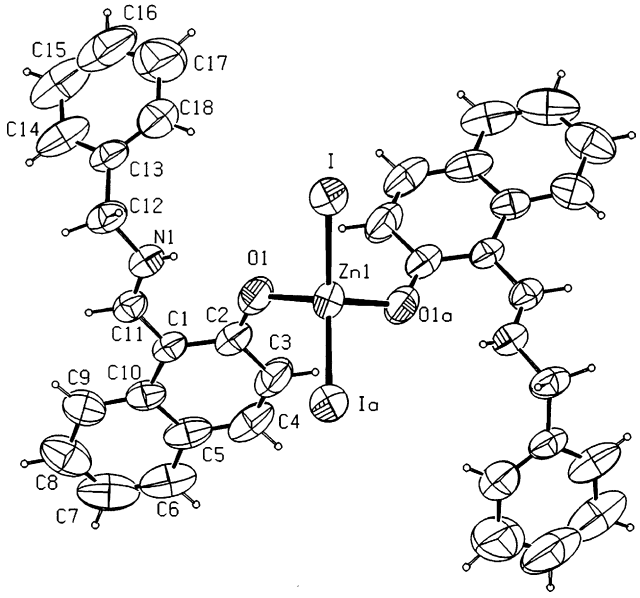

Fig. 4. ORTEP drawing of $ZnI_2(bznapH)_2$ (**3**) with the atom numbering scheme. The thermal ellipsoids are at the 50% probability level. Symmetry code: (a): $1-x, y, 3/2-z$.

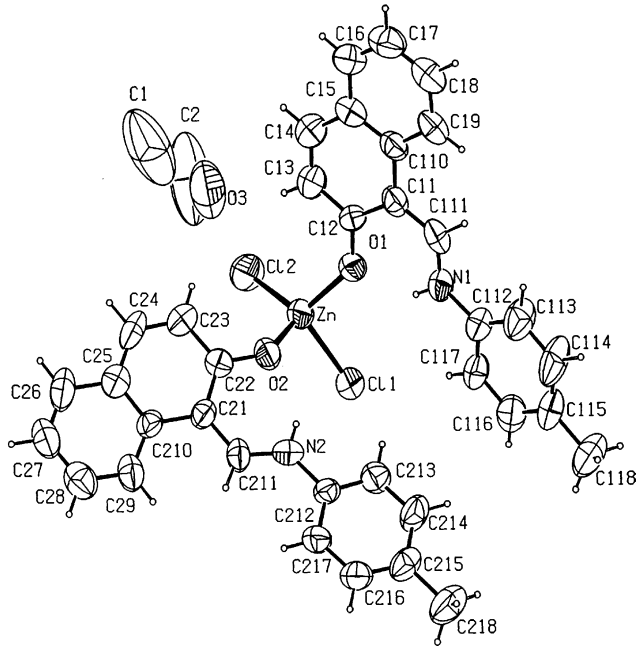

Fig. 5. ORTEP drawing of $ZnCl_2(tolnapH)_2 \cdot EtOH$ (**4**) with the atom numbering scheme. The thermal ellipsoids are at the 50% probability level.

In the zinc complexes **1**–**4** the common feature is the distorted tetrahedral coordination sphere of the zinc atom formed by two halogen atoms [Zn1–Cl1 2.215(2) and Zn1–Cl2 2.229(2) Å in **1**; Zn1–Br1 2.344(1), Zn1–Br2 2.356(1), Zn2–Br3 2.371(1) and Zn2–Br4 2.355(1) Å in **2** and Zn1–I1 2.564(1) Å in **3**, Zn–Cl1 2.255 (2) and Zn–Cl2 2.204 (2) in **4**] and two oxygen atoms from two neutral monodentate Schiff bases [Zn1–O1 1.968(4) and Zn1–O2 1.982(3) Å in **1**, Zn1–O1 1.960(3), Zn1–O2 1.975(3), Zn2-O3 1.957(3) and Zn2–O4 1.952(3) Å in **2**, Zn1–O1 1.968(4) Å in **3**, Zn–O1 1.976(3) and Zn–O2 2.002(3) Å in **4**] (Figs. 1, 3, 4 5). The Zn–O bond distance values are comparable with those found in zinc complexes with salicylaldimines (VATROX, XAXVIB, VIRVUN) and are longer than in the chelate complexes.

In the structures of complexes **1**–**4** the X1–Zn–X2 bond angles are the most deformed from ideal tetrahedral geometry. The degree of deformation is most pronounced in the iodo derivative [X1–Zn–X2 bond angles values are 118.81(7)° in **1**, 119.49(3)° in **2**, 123.49(4)° in **3** and 120.94(7)° in **4**].

The dihedral angles between planes of the naphthalene rings and phenyl rings of the *N*-substituents (Table 3) indicate non-planarity of the ligands in the **1**–**3** complexes, while in **4** the corresponding dihedral angles are remarkably smaller, but still the molecules are not planar [20.3(2)° and 22.2(3)° in **4** vs. the range from 56.2(5)° to 81.7(2)° for **1**, **2** and **3**]. The tendency of a stacking arrangement of planar tolnapH molecules is observed in the structure of $HgCl_2$(tolnapH) [1] causing the needle-shaped crystal morphology.

In **2**, the rings 1 and 2 are oriented to each other by approx. 70°, while other rings (3–8) do not deviate significantly from planarity (Table 3).

The molecules are mutually connected only by van der Waals interactions, except in **1** where weak intermolecular hydrogen bonds of the C–H···Cl type link molecules into endless chains parallel to the *y*-axis.

8	C413–C418	
*Compound **3***		
1	C1–C10	1,2 70.5(4)
2	C13–C18	
*Compound **4***		
1	C11–C110	1,2 20.3(2)
2	C112–C116	
3	C21–C210	3,4 22.2(3)
4	C212–C216	

(Table 4, Fig. 2.) [31,32]. This hydrogen bond does not influence the Zn–Cl1 bond distance since it is comparable with the Zn–Cl2 bond distance (atom Cl2 does not participate in hydrogen bond formation) [Zn1–Cl1 2.215(2) and Zn1–Cl2 2.229(2) Å in **1**].

The significant difference of the Zn–Cl1 and Zn–Cl2 bond distances in **4** (Table 2) can indicate the participation of the Cl1 atom in the O–H···Cl intermolecular hydrogen bond formation with the O3 atom of an ethanol molecule (Cl1···O3 distance is 3.266(7) Å).

So, the conclusion is that the geometry of the zinc coordination sphere in the three complexes **1**–**3** is not affected by the crystal packing forces (i.e. intermolecular hydrogen bonds). Therefore, the bond distances and angles values within the coordination sphere are mutually comparable.

3.4. Description of the ligands

The bznapH and tolnapH Schiff-bases exist in the keto-amine tautomeric form in all four complexes (**1**–**4**) revealing the N–H···O resonance assisted intramolecular hydrogen bond (RAHB) [range for the N···O distance is 2.565(5)–2.599(5) Å] (Table 4). The same tautomeric form is found in the crystal structures of the analogous 1:1 adducts with mercury(II) halides [1].

The C=N bond distance values are in the range from 1.280(6) Å in **3** to 1.299(5) Å in **1**. The C–O bond distance values (1.283(6)–1.301(5) Å) are shortened in relation to the Csp^2–OH bond distance value in phenols (1.36 Å) [33]. These two bonds, C=N and Csp–O, are the most sensitive indicators of the proton location, on the oxygen or nitrogen site, i.e. on the type of the tautomer. In the mercury analogues the intramolecular hydrogen bond N–H···O is 2.58(1) Å in the chloro derivative and 2.59(1) Å in the bromo derivative.

The geometry of the ligands in the complexes **1**–**4** are comparable with the similar non-coordinated naphthaldimines in the keto-amine form, indicating the labile bounding of the ligands with the zinc centre.

3.5. Thermal analysis

The samples of the free ligands, bznapH and tolnapH, as well as the zinc complexes **1**–**6** were heated from room temperature up to 700 °C.

Table 4

The DTA curves of the complexes **1**–**3** were dominated by the typical endothermic minima, which correspond to the melting points (Table 5). Degradation of bznapH (ca. 88%) was observed in the range of 200–400 °C and was characterized by the endothermic peak in the DTA-curve. On heating the samples **1**–**3** up to 600 °C elimination of halogen occurred which was determined by an exothermic peak but still ca. 20% of the initial mass of the samples was left as a mixture of carbonated residue and zinc.

Thermal analysis of the complexes **4**–**6** showed that only the zinc chloride complex **4** melts, while **5** and **6** initially underwent degradation over two consecutive endothermic processes. Elimination of halogen was represented by the exothermic peak. As for **1**–**3**, there was also ca. 25% of the initial mass left in the sample pan.

4. Supplementary material

Atomic coordinates and equivalent isotropic displacement parameters, calculated hydrogen atom parameters, anisotropic thermal parameters and bond lengths and angles have been deposited and allocated deposition numbers at the Cambridge Crystallographic Data Centre (CCDC Nos. 198366–198369 for structures **1**, **2**, **3** and **4**, respectively). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; email: deposit@ccdc.caom.ac.uk or www.ccdc.com.ac.uk). All structural factor tables are available from the authors upon request.

Abstract

The synthesis, characterization and structure of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$ are reported. The structure is centrosymmetric and the copper(II) atom has a square–pyramidal coordination by four oxygen atoms of carboxylate groups with a mean Cu–O distance of 1.964(1) Å which creates a plane, and the apical position is occupied by a water molecule at a Cu–OH_2 bond distance of 2.111(1) Å.

The electronic and infrared spectra exhibit typical features consistent with the observed structure. The EPR spectrum of a microcrystalline sample is consistent with a dimeric structure with the Hamiltonian parameters $g_\perp = 2.018$, $g_\parallel = 2.315$, $D = 0.343$ and $E = 0.003$ cm^{-1}. The magnetic susceptibility measurements of a polycrystalline sample proved the dimeric structure and gives at 300 K an effective magnetic moment of 1.33 BM and at 70 K $\mu_{eff} \cong 0.04$ BM. The magnetic susceptibility data best fitting to a Bleaney–Bowers equation gives $2J = -332$ cm^{-1}.

1. Introduction

Copper(II) carboxylates including copper(II) benzoates have been extensively studied from different points of view because the carboxylato anions exhibit different bonding modes that are related to their properties, e.g. basicity of the anion, position of substituent on the aromatic ring [1–3]. A bulky benzene ring substituent in an *ortho* position to the carboxylato group is believed to prefer the dimeric copper(II) benzoate structure [4] and that was the reason of their wider structural study [5–21]. In general, copper(II) carboxylates exhibit a dimeric paddle-wheel cage structure. Some 250 X-ray crystal structures containing the $Cu_2(OOCR)_4$ core can be found in the Cambridge Structural Database, of which about 200 are of the type $[Cu_2(OOCR)_4L_2]$, where L is an apical ligand with an oxygen or a nitrogen donor atom [3].

In this paper we present our results on the structural, spectroscopic and magnetic properties of the dimeric $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$ (2-NO_2bz = 2-nitrobenzoate anion). These studies are important to establish the structure of the active components of pharmaceutical preparations.

2. Experimental

2.1. Preparation of the complex

Green crystals of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$ were prepared by the reaction of an aqueous solution of copper(II) acetate (1 mmol) with 2-nitrobenzoic acid (2 mmol). The blue–green solution obtained after the

doi:10.1016/j.poly.2003.12.025

reaction was left for crystallization at room temperature (about 20 days) and green crystals were filtered off. *Anal.* Calc. for $C_{14}H_{10}N_2O_9Cu$: Cu, 14.71; C, 38.94; H, 2.80; N, 6.49. Found: Cu, 14.38; C, 39.57; H, 2.76; N, 6.40%.

2.2. Spectral analysis

The electronic spectrum (190–1100 nm) of the complex was measured in Nujol suspension with a SPECORD 200 (Carl Zeiss Jena) spectrophotometer, and the infrared spectrum in the region of 4000–100 cm^{-1} was measured with a Nicolet MAGNA 750 IR spectrometer using both KBr pellet and Nujol suspension techniques for the 4000–400 cm^{-1} region and a polyethylene pellet for 400–100 cm^{-1}.

An EPR spectrum of a powdered sample was obtained using an EPR Bruker ER 200E-SRC at room temperature.

2.3. Magnetic susceptibility measurements

Magnetic susceptibility measurements in the temperature range of 1.9–300 K were carried out on powdered samples of the complex, at the magnetic field 5 kG, using a Quantum Design SQUID Magnetometer (type MPMS-XL5). Corrections for diamagnetism of the constituting atoms were calculated using Pascal constants [1,2] and the value of 60×10^{-6} $cm^3\,mol^{-1}$ was used as the temperature-independent paramagnetism of the copper(II) ion. The effective magnetic moments were calculated from the expression

$$\mu_{\text{eff}} = 2.83\sqrt{\chi_{\text{M}}^{\text{corr}} \cdot T}\ (\text{BM}).$$

2.4. Analytical methods

The copper content was determined by electrolysis of a water solution obtained by the sample mineralization with a mixture of sulfuric acid and potassium peroxodisulfate. Carbon, hydrogen and nitrogen analysis were performed on a Carlo Erba instrument.

2.5. X-ray measurement

Data collection and cell refinement of presented complex were carried out using a Kuma KM4 CCD diffractometer [22]. Intensity data were corrected for Lorenz and polarization factors. The structure was solved by the heavy atom method with SHELX 86 [23], and subsequent Fourier synthesis using SHELXL 93 [24]. Geometrical analysis was performed using SHELXL 97 [25] and the structure was drawn using the ORTEP-3 for Windows program [26]. Final crystal data and structure refinement parameters are given in Table 1.

3. Results and discussion

3.1. Spectroscopic properties

All the typical features of the IR spectrum of the compound are clearly compatible with the structural characteristics of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$. The IR spectrum of the title compound shows a strong and broad absorption band in the area 3620–3300 cm^{-1}, and the deformation band at 1637 cm^{-1} belongs to water in the crystal structure. Carboxylate stretching frequencies were found, with $\nu_{as}(COO^-)$ at 1626 cm^{-1} and $\nu_s(COO^-)$ at 1413 cm^{-1}. The difference between the symmetric and asymmetric stretching vibrations of 213 cm^{-1} is about 24 cm^{-1} larger than that in 2-nitrobenzoic acid (189 cm^{-1}) and 20 cm^{-1} larger than in sodium 2-nitrobenzoate (193 cm^{-1}) which indicates [27] that the 2-nitrobenzoate anion is coordinated as a ligand with a bidentate bridging carboxylic group (see Section 3.2).

The solid state electronic spectrum of the complex shows a broad band (band I) at 14,164 cm^{-1} which could assigned to a $d_{xz}, d_{yz} \rightarrow d_{x^2-y^2}$ transition [28]. Moreover, the spectrum displays a shoulder at 33,000 cm^{-1} (band II). Band II has been assigned to a charge-transfer LMCT absorption [29] and is believed to be indicative of a dimer complex [30]. Finally, the complex displays bands I and II in the usual range for copper(II)

complexes with a square–pyramidal CuO_4O' environment [31].

The EPR spectrum of the powdered sample of the complex was made at room temperature (Fig. 1). The spectrum exhibits features typical of those for dimeric carboxylatocopper(II) complexes [1,2], absorptions at low and high field ($H_{z1} \approx 300$ and $H_{z2} \approx 6000$ G, respectively) and line $H_{\perp 2} \approx 4700$ G. The EPR spectrum was interpreted by using the effective spin Hamiltonian [32] for a randomly oriented triplet state $S = 1$

$$\hat{H} = g\beta H\hat{S} + D\hat{S}_{z^2} + E(\hat{S}_{z^2} - \hat{S}_{z^2}) - 2/3D,$$

where D and E are the axial and rhombic zero-field splitting parameters, and x, y, z are the principal axes of the coordinate system fixed with respect to the Cu–Cu axes. The calculated spin Hamiltonian parameters are $g_\perp = 2.018$, $g_\parallel = 2.315$, $D = 0.343$ and $E = 0.003$ cm^{-1}. These parameters are "classical" for dimeric copper(II) carboxylate complexes [1,2].

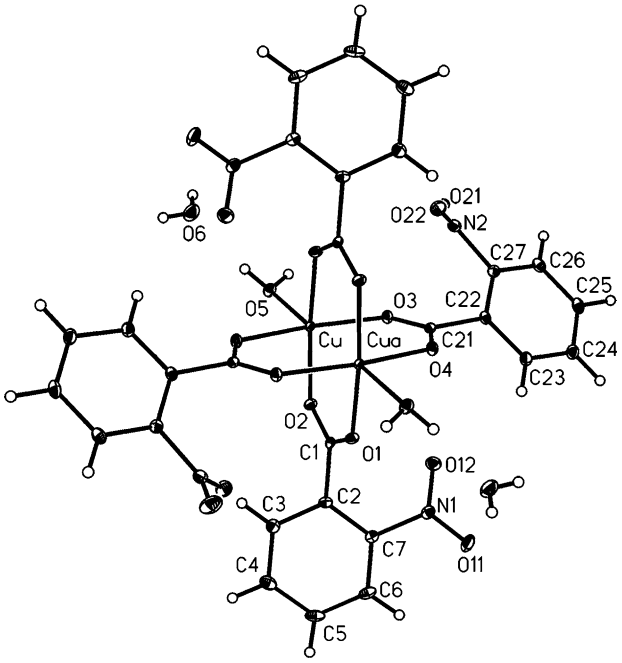

Fig. 1. The molecular structure and atom numbering of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2] \cdot 2H_2O$.

3.2. Crystal structure

The molecular structure and atomic numbering scheme are shown in Fig. 2. The structure consists of the centrosymmetric dimer molecule $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]$ in which two copper(II) atoms are bridged via four carboxylato anions thus forming a square base of four oxygen atoms (Table 2) around each copper (average Cu–O distance 1.964(1) Å). The apical position of the square pyramidal coordination polyhedron is occupied by the oxygen atom O5 of a water molecule (Cu–O5 distance 2.111(1) Å). The copper atoms are displaced from the respective basal planes towards the apical oxygen atoms by 0.184(1) Å, and the Cu–Cu separation within the dimer was found to be 2.5954(6) Å. The

O4–Cu–O5	90.89(5)	O4–C21–O3	126.66(15)
O1–Cu–O5	91.64(5)		

crystal structure of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$ is completed by a crystalline water molecule that is hydrogen bonded (Table 3) to the water molecule that is coordinated to the copper atom (O5–H51–O6 with a O6–H51 distance of 1.914 Å) and to the nitro-group oxygen atom of neighbouring dimeric units (O6–H61–O1 with a O1–H61 distance of 2.154 Å and O6–H62–O22 with a O22–H62 distance of 2.639 Å).

X-ray analysis of the similar $[Cu_2(2\text{-}NO_2bz)_4(DMSO)_2]$ shows [19] significantly longer Cu–O distances both in the equatorial positions (average Cu–O distance 1.984 Å) and in the apical position 2.138 Å. The analysis of dimeric structures of composition $[Cu_2(2\text{-}Xbz)_4(H_2O)_2]$ (where X = benzoyl [6], methoxy [15], Cl [20] and NO [3]) shows that in the 2-NO_2bz complex the Cu–O(apical) distance is the shortest, together with the smallest displacement of the copper atom from the basal plane towards the apical ligand. Further analysis of the Cu–O(apical) and Cu–(basal plane) distances within the group of known structures [5–21] showed that only within the group of $[Cu_2(2\text{-}Xbz)_4(H_2O)_2]$ (where X = benzoyl [6], methoxy [15], Cl [20] and NO [3]) could the linear correlation between the Cu–O(apical) and Cu–(basal plane) distances be found (Fig. 3). In addition to that the smallest displacement of the copper atom from the basal plane in our 2-NO_2bz complex results in the shortest Cu–Cu distance 2.5954(6) Å in comparison to those for the benzoyl [6] (2.638 Å), methoxy [15] (2.613 Å) and Cl [20] (2.599 Å) derivatives. These structural features were the base for further study of the magnetic properties of the title compound.

3.3. Magnetic properties

The magnetic susceptibility of the complex has been measured in the temperature range 70–300 K. Fig. 4 shows the plots of χ_M and/or $\chi_M \times T$ versus T. The value of $\chi_M \times T$ continuously decreases with the lowering of the temperature. At 300 K the observed value of $\chi_M \times T$ is 0.22 ($cm^3\,K\,mol^{-1}$) and the effective magnetic moment is equal to 1.33 BM. At the temperature 70 K $\chi_M \times T \cong 0$ and $\mu_{eff} \cong 0.04$ BM. At temperatures lower than 70 K diamagnetic properties of the dimer are observed. This trends indicates an antiferromagnetic exchange interaction between the two copper(II) magnetic centers of the dimeric unit and depopulation of the excited triplet ($S = 1$) state [33]. The magnetic data of the complex were fitted to a susceptibility equation derived from a spin Hamiltonian

$$H = -2JS_1S_2,$$

with a Bleaney–Bowers equation [34]

$$\chi_M = \frac{N\beta^2 g^2}{3kT}\left[1 + \frac{1}{3}\exp\left(\frac{-2J}{kT}\right)\right]^{-1} + N\alpha,$$

where N is the Avogadro's number, g is the spectroscopic splitting factor, β is the Bohr magneton, k is the Boltzmann's constant and J is the exchange parameter.

The best fitting parameters are $J = -166$ cm^{-1} and $g = 2.17_2$ obtained with a good agreement factor $R = 3.382 \times 10^{-8}$, where

$$R = \frac{\sum_{i=1}^{n}\left(T_i\chi_i^{exp} - T_i\chi_i^{calc}\right)^2}{\sum_{i=1}^{n}\left(T_i\chi_i^{exp}\right)^2}.$$

In spite of the shortest Cu–Cu distance found in the structure of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$, the energy separation between the triplet state and singlet ground state, the $-2J$ value, exhibits a "normal" value in the range 300–350 cm^{-1}. The "normal" $-2J$ value for the complex under study could be taken as a proof of mutual relation between the $-2J$ value and the structure of the Cu–O–C–O′–Cu′ bridges which can be described by the ϕ_{bend} angle that is defined [35] as the angle between

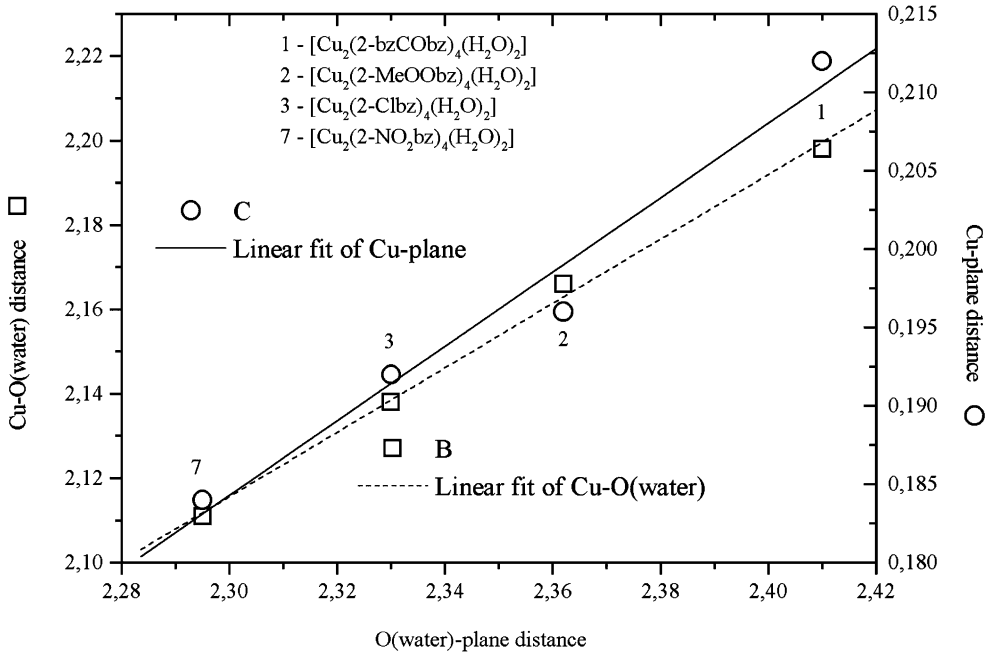

Fig. 3. Plot of the Cu–O(apical) distance and/or Cu–basal plane displacement versus the O(apical) to basal plane distance together with the linear fit of the data used.

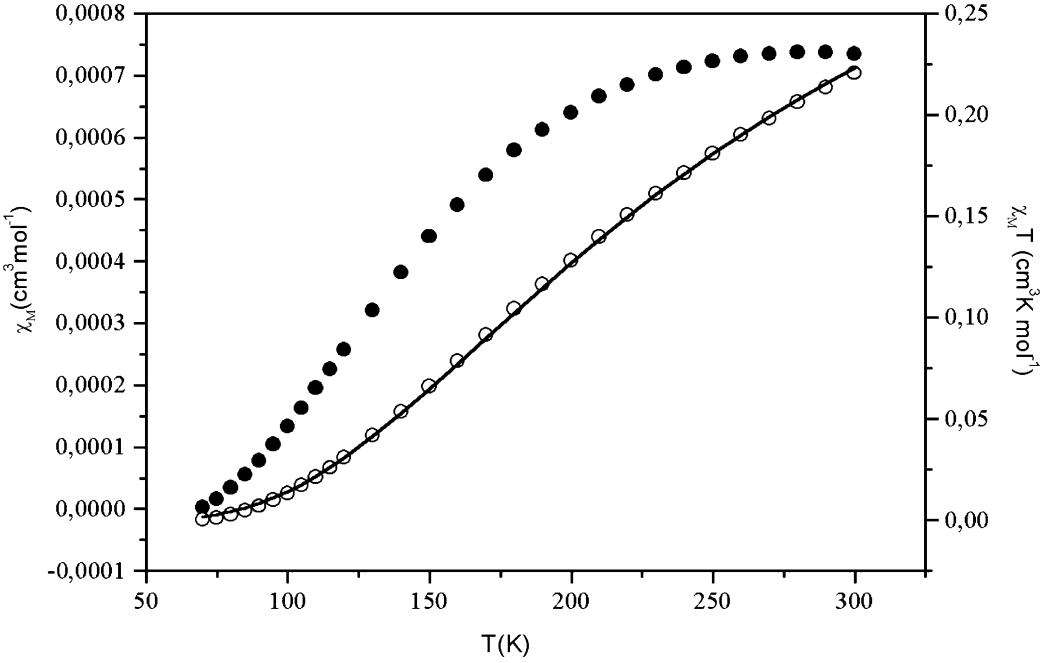

Fig. 4. Plots of the magnetic data versus temperature; $\chi_M^{exptl.}$ (•), $\chi_M^{exptl.} \times T$ (○) and $\chi_M^{calcd.} \times T$ (full line) vs. T using calculated results from the Bleaney–Bowers equation.

CuOO′Cu′ and OCO′ planes. Both structurally independent bridges are nearly planar and exhibit small values of the ϕ_{bend} angle, 1.28(14)° and 1.94(17)°. The orientation of the benzene rings with respect to the carboxylato bridge probably has no influence on the magnetic interaction between the copper centres.

4. Supplementary material

Supplementary material including all atomic coordinates ($\times 10^4$), anisotropic displacement parameters for non-hydrogen atoms and all interatomic distances and bond angles have been deposited with the Cambridge

Crystallographic Centre, CCDC No. 220840 for the compound $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Reaction of 1-hydroxymethyl-3,5-dimethylpyrazole (LOH) with copper(II) salts yields new dinuclear $[CuLLONO_3]_2$ (**1**) or mononuclear $CuL_3(NO_3)_2$ (**2**) co-ordination compounds, where L – (3,5-dimethylpyrazole), LO – (1-methoxy-3,5-dimethylpyrazole). The type of the obtained complex strongly depends on the solvent used during the preparation (propan-2-ol,T = 298K for **1** and a mixture of solvents: methanol, propan-2-ol, trimethyl orthoformate, $T = 333K$ for **2**). The crystal and molecular structure for both of the compounds were determined by single-crystal X-ray diffraction. The structure **1** consists of a dicopper complex with two bridging methoxide groups with a Cu–Cu separation of 2.958 (1) Å. Each copper atom is in a N_2O_3 donor set. The coordination geometry of the copper centres is described as distorted square-pyramidal with one of the oxygen atoms of the NO_3^- anion at the apex. The structure of **1** is compared with those observed previously for two similar $[CuL(LO)X]_2$ complexes where $X = BF_4^-$ (**3**) or ClO_4^- (**4**) instead of NO_3^- (**1**). Variable-temperature EPR spectra (77–295 K) and magnetic susceptibility measurements (1.9–300 K) indicate the antiferromagnetic exchange interaction is dependent on the compensating ligand; it is apparently smaller for the complex with $X = NO_3^-$ than for those with $X = BF_4^-$ and ClO_4^-, in agreement with the same order of increase of the Cu(II)–Cu(II) distances and bond angles of the bridging atoms. The structure of **2** is very close to regular square-pyramidal a with CuN_3O_2 chromophore formed by three L and one NO_3^- ligand, giving a trigonal distortion parameter (τ) of 0.094. The results of spectroscopic studies, IR, UV–Vis and EPR, of the compounds **1** and **2** appear to be in a good accord with the molecular structure determined by single-crystal X-ray analysis.

1. Introduction

The occurrence of a pair of Cu–Cu or Cu–Zn ions at the active site of metalloenzymes, which are all involved in the redox chemistry in cellular life, has stimulated much interest in modelling the active-site structure to the research of the physicochemical properties of such metalloenzymes. The use of chelating ligands incorporating pyrazole derivatives has drawn strong interest in modelling such biological systems [1–3]. Driessen et al. [4,5] discussed coordination properties of 1-(2-hydroxyethyl)-3,5-dimethylpyrazole (N-hed) towards several first-row transition metal ions. They concluded that N-hed in the complexes with Cu(II) was in the neutral form $[Cu(HL)_2X_2]$ (X = Cl, NCS or NO_3), or in the dehydrogenated form $[Cu_2L_2X_2]$ (X = Cl, Br and NO_3) or in both the neutral and the dehydrogenated forms $[Cu_2(HL)_2L_2(ClO_4)_2$. Additionally, the pyrazole has been extensively employed in pyrazolylborates to stabilize a variety of organometallic and coordination compounds [6]. Our studies on the coordination chemistry of Cu(II) complexes with diazoles containing the hydrox-

doi:10.1016/j.poly.2004.01.024

ymethyl substituent situated in position 2 of the imidazole ring led us to the conclusion that in aqueous solution [7–9] and in the solid state [10,11], the oxygen atom of the substituent interacts with the Cu(II) ion, participating in a five-membered chelate ring together with the imidazole nitrogen.

In light of our previous results we extended the investigations to 1-hydroxymethyl-3,5-dimethylpyrazole (LOH), providing the same hydroxymethyl substituent in the α position of the pyridine-like nitrogen atom of the pyrazole ring. The protonation constants ($pK_a = 3.48$) of LOH and the equilibrium stability constants of the complexes with the copper(II) ion, determined by the pH potentiometric technique at 298 K [$I = 0.5$ mol/dm^3 (KNO_3)] ($\log\beta_1 = -6.10$, $\log\beta_2 = 2.68 \pm 0.02$), clearly indicate that the donor properties of the ligand depend on electron density located on the pyridine-like nitrogen atom of the pyrazole ring. The 1-hydroxymethyl-3,5-dimethylpyrazole forms very weak complexes in water solution because the H_2O molecules efficiently compete as ligands with the pyrazole derivatives in Cu(II) coordination [12]. Now continuing the studies on the synthesis and characterization of copper(II) complexes as simply models of the active-site of metalloenzymes, we attempted to obtain dinuclear Cu(II) complexes in the solid state using 1-hydroxymethyl-3,5-dimethylpyrazole as a starting ligand in the reaction with the Cu(II) ion. Special attention was paid by us not only to the conditions of the complex preparation but also to the structural effect of the compensative anions: NO_3^-, BF_4^- and ClO_4^-, acting as the apical monodentate ligands, on the magnetic exchange between the coupled copper centers in terms of the change of metal–metal separation, bond angles at the bridging atoms, dihedral angles between the planes containing the copper(II) ions and other details of the metal ion stereochemistry of the particular dimers. Thus, determination of the crystal structure (**1** and **2**), measurements of magnetic susceptibility as a function of temperature (**1**, **3** and **4**) and spectroscopic (EPR IR, UV–Vis) studies of all these complexes have been undertaken by us.

2. Experimental

2.1. Materials and methods

Copper(II) nitrate trihydrate, copper(II) perchlorate hexahydrate, copper(II) tetrafluoroborate hydrate and 1-hydroxymethyl-3,5-dimethylpyrazole (Aldrich Chemical Company) were reagent grade and were used without further purification.

Magnetic measurements in the temperature range 1.72–300 K were determined using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The SQUID magnetometer was calibrated with a palladium rod sample (Materials Research Corporation, measured purity 99.9985%) for which the gram magnetic susceptibility was taken as 5.30×10^{-6} cm^3 g^{-1} at 293 K (National Bureau of Standards, USA) [13]. All susceptibility measurements were made at a field of 5 kG. The corrections for diamagnetism of the constituent atoms were calculated from the Pascal constants [14]. Electron paramagnetic resonance (EPR) spectra were performed at 77 K on a Bruker ESP 300E spectrometer at the X-band frequency (about 9.45 GHz) and equipped with a Bruker NMR gaussmeter ER 035M and a Hewlett-Packard microwave frequency counter HP 5350B. The spectra were analysed by a computer simulation program based on resonance fields calculated according to the method of Sakaguchi et al. [15,16]. Elemental analyses were run on a Model 240 Perkin–Elmer CHN Analyser. FAB mass spectra were obtained on an AMD 604 mass spectrometer.

The infrared spectra (4000–400 cm^{-1}) in KBr and FIR spectra (400–30 cm^{-1}) in Nujol with specimens applied as a suspension of the complexes in Nujol onto a polyethylene window, were recorded on a Perkin–Elmer 180 spectrophotometer.

The absorption spectra were recorded using a Specord M-40 (Carl Zeiss Jena). The reflectance spectra were measured on a Cary 5 UV–Vis–near IR spectrometer.

2.2. Synthesis of the coordination compounds

2.2.1. $[CuLLONO_3]_2$ (**1**)

The sea green dinuclear Cu(II) complex (L = 3,5DMePz, LO = 1-CH_2O-3,5-DMePz) was prepared in the open air using propan-2-ol as the solvent and the molar ratio Cu:L was 1:4. A solution of 1-CH_2OH-3,5-DMePz (0.5046 g, 4 mmol) in 20 cm^3 of propan-2-ol was added dropwise to a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.2416 g, 1 mmol) dissolved in 20 cm^3 of propan-2-ol. The reaction was carried out at room temperature for 25 min, all the time stirring. The solution was filtered and the filtrate was left to stand at room temperature for about three weeks and the resulting sea green crystals were filtered and washed with cold Et_2O. After that, the crystals were dried for three days in a vacuum box.

Yield: 0.1476 g, 42.6%. (Found: C, 38.2; H, 4.9; N, 20.1%. $C_{22}H_{34}N_{10}O_8Cu_2$ requires: C, 38.1; H, 5.0; N, 20.2).

Positive ion FAB mass spectrum; $m/z = 504$ [$Cu_2Pz(PzCH_2O)_2(NO_3)_2$]$^+$; 440 [$Cu_2(PzCH_2O)_2(NO_3)_2$]$^+$; 379 [$Cu_2(PzCH_2O)_2NO_3$]$^+$; 317 [$Cu(PzCH_2O)_2NO_3$]$^+$; 255 [$Cu(PzCH_2O)_2$]$^+$; 223 [$CuPz(PzCH_2O)$]$^+$; 159 [$CuPzCH_2O$]$^+$; 107 [$CuNCH_2O$]$^+$, where (Pz = pyrazole).

The other $[CuL(LO)X]_2$ complexes containing $X = BF_4^-$ (**3**) [17] and ClO_4^- (**4**) anions were prepared by a method similar to that used for complex **1**. Sat-

isfactory elemental analysis results were obtained in all cases.

Caution! Perchlorate salts are potentially explosive. Although no detonation tendencies have been observed with $[CuL(LO)ClO_4]_2$, caution is advised and handling of only small quantities is recommended.

2.2.2. $CuL_3(NO_3)_2$ (2)

The ligand 1-hydroxymethyl-3,5-dimethyl pyrazole (1-CH_2OH-3,5-DMePz), 0.2523 g, 2 mmol was dissolved in 20 cm^3 of the mixture (1:1) methanol and propan-2-ol and added dropwise to the solution which contained the salt of $Cu(NO_3)_2 \cdot 3H_2O$ (0.1208 g, 0.5 mmol) dissolved in 20 cm^3 of the mixture of trimethyl orthoformate and methanol, while stirring. The synthesis was carried out at 333 K or at room temperature. The solution was filtered and the filtrate was left to stand at room temperature for 2–3 weeks and the resulting blue crystals were filtered and washed with cold Et_2O. Crystals which were more suitable for X-ray diffraction study were obtained by recrystallizing the product from after boiling the mixture of methanol and propan-2-ol. After that, the obtained complex was formulated as $[CuL_3(NO_3)_2]$, where L = 3,5DMePz (yield 36%). (Found: C, 37.9; H, 5.0; N, 23.3%. $C_{15}H_{24}N_8O_6Cu$ requires: C, 37.9; H, 5.1; N, 23.5).

Positive-ion FAB mass spectrum; $m/z = 413$ $[CuL_3NO_3]^+$; 317 $[CuL_2NO_3]^+$; 255 $[CuL_2]^+$; 159 $[CuL]^+$; 106 $[Cu–N–C–CH_3]^+$.

2.3. Single crystal structure determinations

For (**1**) and (**2**) respectively, sea green and blue prisms with dimensions of $0.15 \times 0.18 \times 0.20$ and $0.12 \times 0.10 \times 0.07$ mm were measured on a KUMA KM4 (**1**) and KM-4CCD (**2**) diffractometer with graphite monochromator and Cu Kα (**1**), Mo Kα (**2**) radiation. The crystallographic data and the refinement procedure details are given in Table 1. The structures were solved by direct methods using the SHELXS97 [18] program system and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [19] program. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms for (**1**) were included from the difference maps and were refined with isotropic thermal parameters; for (**2**) were included in calculated positions from the geometry of molecules. The absorption corrections were applied for (**1**) empirically [20] and for (**2**) from indexed faces [21].

3. Results and discussion

The type of coordination compounds which have been obtained in the reaction of 1-hydroxymethyl-3,5-dimethylpyrazole with the copper(II) ion strongly depends on the kind of solvent which has been used during the preparation. It is one of the factors affecting the redox potential of the Cu(II) ion. Preparing the mixture of the solvent (trimethyl orthoformate, methanol and propan-2-ol), for the molar ratio Cu:L of 1:2 or 1:4 only one type of mononuclear Cu(II) complex, $[CuL_3(NO_3)_2]$, has been obtained. For all stoichiometries used the ligand decomposed to HCOH and 3,5-dimethylpyrazole (L) according to Scheme 1.

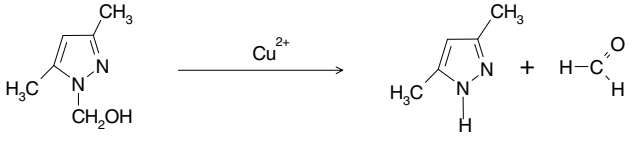
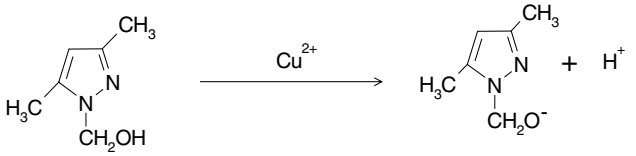
Carrying out the coordination reaction using only propan-2-ol as the solvent and with the Cu:L molar ratio of 1:4, in the open air, a new type of dinuclear complex with mixed ligands, $[CuL(LO)X]_2$ (X = NO_3, BF_4, ClO_4) has been obtained. During the coordination process half of the stoichiometrically used ligand decomposes to HCOH and 3,5-dimethylpyrazole (L) (Scheme 1) and another part undergoes dehydronation giving 1-methoxy-3,5-dimethylpyrazole (LO) according to Scheme 2.



Scheme 1. The ligand reaction during the formation of the monodentate Cu(II) complex.



Scheme 2. The process of dehydronation during the formation of $[CuL(LO)X]_2$ complexes.

A similar dinuclear complex with the ClO_4^- anion was obtained by Oki et al. [22] but in a different way using as a starting ligand not only 1-hydroxymethyl-3,5-dimethylpyrazole but also 3,5- dimethylpyrazole.

3.1. Description of the structures

3.1.1. Crystal structure of $[CuLLONO_3]_2$ (1)

A perspective view of complex **1** is depicted in Fig. 1 along with the atomic numbering scheme. Selected interatomic distances and angles are given in Table 2. The crystal structure reveals that the dimeric Cu(II) complex contains three kinds of ligands: 3,5-dimethylpyrazole (L), 1-methoxy-3,5-dimethylpyrazole (LO), which are received during the coordination process, and the NO_3^- anion. The molecular structure consists of a dicopper complex with two bridging methoxide groups with a Cu–Cu separation of 2.958 (1) Å and Cu–O(11)–Cu_a bond angle of 99.21(9)°. Each copper atom is in a N_2O_3 donor set. A description of the geometry of the five-coordinated centres can be obtained by determining the structural index τ defined by Addison et al. [23]. The application of this method yields values τ of 0.39. The coordination geometry of the copper centres is therefore best described as a distorted square pyramidal with one of the oxygen atom of the NO_3^- anion at the apex. The Cu–O(1) bond distance is 2.256(2) Å. The four basal positions are comprised of one nitrogen atom (N21) of the pyrazole ring from the L the nitrogen (N11) and two bridging methoxide oxygen atoms (O11 and $O11_a$) from LO. The latter ligand acts as a bidentate ligand, forming a five-membered chelate ring with the central ion. The chelation is rather symmetric because Cu–N(11) (1.983(3)) Å and Cu–O(11) (1.936(2)) Å have a similar length. The overall stability of this complex in the solid state depends on the contribution of the extensive intramolecular hydrogen bonding between the pyrazole NH and the oxygen atoms of the nitrate ions, with a N(22)–H(22)$\cdots$O(1)$(-x, -y+1, -z)$ distance of 2.34 Å. By comparison of the structural data of compound **1**

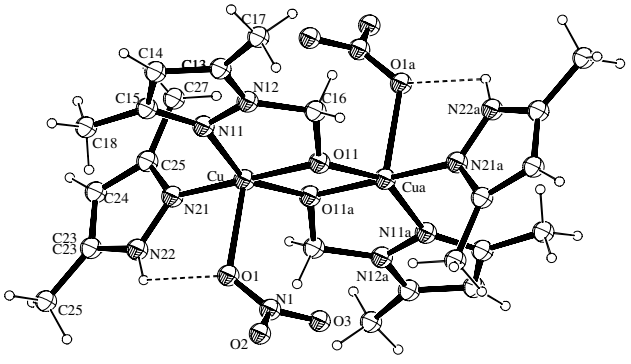


Fig. 1. Molecular structure of dinuclear $[CuLLONO_3]_2$ (**1**) showing the atom numbering scheme. Fifty percent probability amplitude displacement ellipsoids are shown.

Symmetry transformations used to generate equivalent atoms: (a) $-x, -y+1, -z$.

with those determined previously for similar $[CuL(LO)X]_2$ complexes in which instead of $X = NO_3$ (**1**), the apical site is occupied by $X = BF_4^-$ (**3**) [17] or ClO_4^- (**4**) [22] anions, some differences in the bond lengths and bond angles are observed. The Cu–Cu separation being 3.0031(8) Å and 3.022(1) Å for **3** and **4**, respectively, is considerably longer than that of **1**. This fact changes drastically the Cu–O–Cu bond angles of 102.91(9)° and 103.(1)° for **3** and **4**, respectively. The similar ligand, 1-(2-hydroxyethyl-3,5-dimethylpyrazole (N-hed), which is different from LOH only in the length of the substituent in position 1, behaves quite differently during the coordination process with the Cu(II) ion. Driessen et al. [4] reported that the geometry of three dinuclear compounds $[Cu(N\text{-}oed)X]_2$ ($X = Cl$, Br, NO_3, N-oed – the dehydronated form of the N-hed) corresponds to square planar coordination with e.g. the Cu–Cu distance of 3.042(4) Å for $[Cu(N\text{-}oed)Br]_2$ being longer than those observed by us for $[CuL(LO)X]_2$ complexes. The greatest metal–metal distance of 3.07(6) Å was determined for the compound $[Cu(HL)L]_2(ClO_4)_2$ [5], containing the ligand (N-hed) both in the neutral form (HL) and in the dehydronated form (L)

with two Cu(II) ions bridged by the oxygen atoms of two L ligands.

3.1.2. Crystal structure of $CuL_3(NO_3)_2$ (2)

Complex **2** was characterized by single-crystal X-ray crystallography. Selected bond lengths and angles are given in Table 2. A perspective view of the molecule is shown in Fig. 2. Complex **2** has a binary structure consisting of 3,5-dimethylpyrazole, which has been obtained in the reaction of 1-hydroxymethyl-3,5-dimethylpyrazole with the Cu(II) ion and NO_3^- anions. While the basal plane is occupied by three nitrogen atoms of the pyrazole rings and the oxygen atom (O1) of the NO_3^- anion, the oxygen atom (O4) of the second nitrate anion is involved in axial bonding in the 4+1 coordination geometry of the CuN_3O_2 chromophore. The axial Cu–O(4) bond length of 2.324(3) Å is longer than that of **1**. The structure of **2** is very close to regular square pyramidal, giving a trigonal distortion parameter (τ) value of 0.094 [23]. The crystal structure of **2** is stabilized by a network of hydrogen bonds (Table 3). Additionally, the hydrogen atoms of the pyrazole N–H(22) and N–H(32) are engaged in hydrogen bonding with the next molecule of **2** (Fig. 3).

3.2. Spectroscopic properties

In the infrared spectra of the free LOH ligand, which is used as a starting ligand for the synthesis, the OH-stretching band lies at 3152 cm^{-1} and is very broad due to the strong inter- and intramolecular hydrogen bond $\nu(O\cdots H\cdots N)$ vibrations. This band disappears in the infrared spectra of Cu(II) complexes, $[CuL(LO)NO_3]_2$ (**1**), $CuL_3(NO_3)_2$ (**2**) or $[CuL(LO)BF_4]_2$ (**3**). This fact

and new absorption bands at 3288, 3304 and 3352 cm^{-1} for **1**, **2** and **3**, respectively, which can be assigned to ν(N–H), confirmed that the complexes contain new ligands, L and LO, received during the coordination reaction with the Cu(II) ion. The broadness and rather low position of the N–H band of (**1**) are indicative of a strong intramolecular hydrogen bonding between the NH of L and the oxygen atoms of the nitrate ions in accord with the crystal structure (Fig. 1). Dinuclear (**1**, **3**) and mononuclear (**2**) Cu(II) complexes show new bands, compared to the ligand spectra, at 352, 353 and 257 cm^{-1}, respectively, which arise from ν(Cu–N) stretches as well as at 408, 414 and 350 cm^{-1}, respectively, due to the Cu–oxygen bonds vibrations.

The reflectance spectra of **1** and **3** (solid state) show the bands at 14 200 and 15 600 cm^{-1}, respectively, characteristic of a d → d transition for compounds with a square pyramidal geometry of the individual copper(II) ions with a $d_{x^2-y^2}$ ground state [24]. At the highest energy the spectra exhibit a very broad intense absorption with poorly marked maxima between ca. 21 000 and 50 000 cm^{-1}. It contains most likely several

transitions associated with the ligand to copper charge transfer transitions which correspond to the peak position established by means of the Gaussian distribution at 26 700, 26 500 [$O \rightarrow Cu(II)$], 34 200, 33 200 [$\pi_{2(pirazol)} \rightarrow \sigma^*(Cu(II)$] and 49 200, 48 000 $cm^{-1}(\pi \rightarrow \pi^*$, $\sigma_{(N)} \rightarrow \sigma^*$, respectively. The transition in the 25 000–33 000 cm^{-1} region is usually used as a good evidence of the formation of alkoxo bridged complexes [25–28].

The reflectance spectrum of mononuclear complex **2** displays bands at 11 000 and 16 900 cm^{-1} which correlates with a square pyramidal environment of copper(II) ions. Additionally, using the Gaussian distribution of the absorption in the highest-energy the following peak positions are established: 27 500 [$\pi_{1(pirazol)} \rightarrow \sigma^*(Cu(II)$], 34 100 [$\pi_{2(pirazol)} \rightarrow \sigma^*(Cu(II)$] 47 900 cm^{-1} ($\pi \rightarrow \pi^*$). The proposed assignments are in agreement with the data reported for the Cu(II) complexes with 3.5-dimethylpyrazole [29].

3.3. EPR spectroscopy

The EPR spectra of the polycrystalline dimers are presented in Fig. 4. Only in the case of the dimer with $X = NO_3^-$ does the spectrum exhibit two signals – a stronger one at 550 mT and a weak, broad one at about 200 mT, which are associated with the transitions within $S = 1$ levels. The spectrum was simulated using the following Spin Hamiltonian parameters: $D = 0.59\ cm^{-1}$, $E = 0.01\ cm^{-1}$, $g_{\|} = 2.20$, $g_{\perp} = 2.06$. The smallest gap between $S = 1$ and $S = 0$ levels for the complex with $X = NO_3^-$ is most likely the reason of its exceptional EPR properties as compared to those when $X = ClO_4^-$ and BF_4^- and for other alkoxo bridged dimers derived from 1-(hydroxyethyl)-3,5-dimethylpyrazole[4,5] which exhibit stronger antiferromagnetic interactions and are EPR-silent.

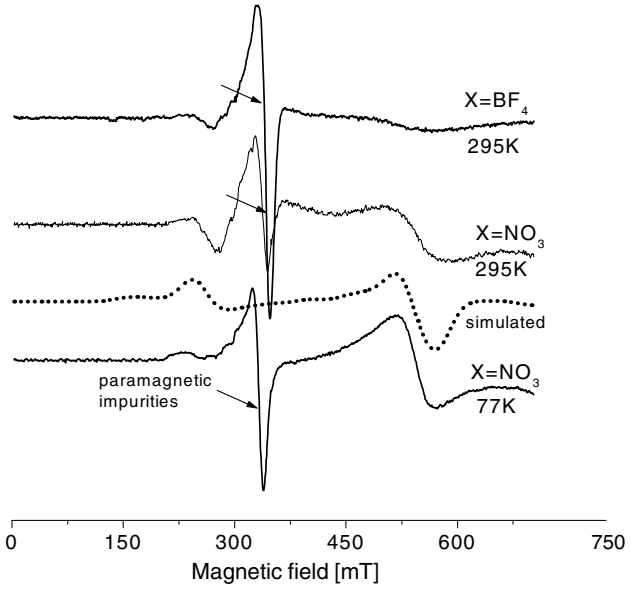

Fig. 4. EPR spectra of polycrystalline [CuLLOHX] at 295 K, the arrows indicate the signal due to paramagnetic impurities.

The EPR spectra of polycrystalline complex **2** at 295 and 77 K are resolved in the parallel region due to hyperfine interaction with the copper nuclei. The spectral parameters, $g_{\|} = 2.270$, $g_{\perp} = 2.055$ and $A_{\|} = 180 \times 10^{-4}$ cm^{-1}, are characteristic of axial symmetry of the Cu(II) coordination sphere. The parameters values are in a good correspondence with the N_3O donor set in the Cu(II) *xy* plane evidenced by the crystal structure analysis.

3.4. Magnetic properties

The magnetic properties of complexes **1**, **3** and **4** under the form of $\chi_M T$ versus T and χ_M versus T (χ_M being the molar magnetic susceptibility) are shown in Figs. 5–7, respectively.

$\chi_M T$ at room temperature for **1** is close to 0.66 $cm^3\,mol^{-1}\,K$ and is smaller than the spin-only value of 0.75 $cm^3\,mol^{-1}\,K$ expected for an uncoupled dicopper(II) system. It decreases slightly up to 120 K, then rapidly and finally reaches a plateau below approxi-

mately 25 K with a value of 0.35×10^{-2} cm^3 mol^{-1} K. This behavior indicates an antiferromagnetic interaction between the two Cu(II) centers [30]. Upon cooling from room temperature the χ_M increases and achieves a maximum value of 4.09×10^{-3} cm^3 mol^{-1} at ca. 120 K. At this temperature a structural phase transition of the first order is observed. The systematic studies of the order–disorder and thermodynamic characteristics of this phase transition by X-ray diffraction and calorimeter methods are in progress and will be published elsewhere. When the temperature is lowered below 120 K, one can observe that the χ_M decreases, reaches a minimum at 19 K and increases rapidly between 19 and 1.90 K. This increase indicates the presence of a paramagnetic impurity. The impurity accounts for the plateau value of χ_MT in the low temperature region. In the case of complexes **3** and **4** the values of χ_MT are at room temperature close to 0.211 cm^3 mol^{-1} K and 0.19 cm^3 mol^{-1}, respectively, which are significantly below the spin-only value suggesting the presence of stronger antiferromagnetic intramolecular interactions than for **1**. Both χ_M and $\chi_M T$ decrease as the temperature is lowered from room temperature to 110 K. At lower temperatures a rapid increase in the magnetic susceptibility, preceded by a plateau for **4**, is next observed as a result of a small amount of monomeric Cu(II) ion.

The temperature dependence of the magnetic susceptibility measured between 1.9 and 300 K was analysed on the basis of the isotropic Heisenberg model, $\hat{H} = -2J(\hat{S}_1 \cdot \hat{S}_2)$, using the modified Bleaney–Bowers equation [31]:

$$\chi_M = \frac{Ng_{dim}^2\beta^2}{3kT}\left[1 + \frac{1}{3}\exp\left(\frac{-2J}{kT}\right)\right]^{-1}(1-x) + \left(\frac{Ng_{mon}\beta^2}{4kT}\right)x, \quad (1)$$

where x is the proportion of the paramagnetic impurity (presumably non-coupled monomeric copper(II) complex), $2J$ is the interaction parameter between two spin carriers and the other symbols have their usual meaning.

The best least-squares fitting of the experimental data through this expression leads to $2J = -58$ cm^{-1} $g_{dim} = 2.11$, $g_{mon} = 2.13$, $x = 0.5\%$ (in the temperature range 1.9–110 K) and $2J = -45$ cm^{-1}, $g_{dim} = 2.11$, $g_{mon} = 2.13$, $x = 0.5\%$ (in the temperature range 120–300 K) for complex **1**, $2J = -269$ cm^{-1}, $g_{dim} = 2.25$, $g_{mon} = 2.06$, $x = 1.20\%$ for complex **3**, $2J = -288$ cm^{-1}, $g_{dim} = 2.18$, $g_{mon} = 2.20$, $x = 0.14\%$ for complex **4**. The agreement factor R, defined as $[R = \sum(\chi_{exp}T - \chi_{calc}T)^2/\sum(\chi_{exp}T)^2]$, is 4.93×10^{-4} for **1** (1.9–110 K), 3.34×10^{-4} for **1** (120–300 K), 6.97×10^{-4} for **3**, 1.28×10^{-3} for **4**. The large negative $2J$ values in the cases confirm a very strong antiferromagnetic interaction between the two Cu(II) centers. This interaction can be understood in term of the non-zero overlap between the copper(II) magnetic $d_{x^2-y^2}$ orbitals, depending on the coordination geometry around the metal ions [32–35].

In such dimeric copper(II) complexes these magnetic interactions occur via the double oxygen bridge. For the studied complexes the antiferromagnetic exchange interaction tends to increase according to the series of compensative ligands: $NO_3^- \ll BF_4^- < ClO_4^-$. Replacement of NO_3^- by BF_4^- or ClO_4^- anions results in the increase of the Cu(II)–Cu(II) distance and consequently substantially increases the bond angles of the bridging atoms. With increasing bond angles the magnetic orbitals of both Cu(II) ions are favorably oriented and delocalized towards the bridging network, which leads to a very large overlap and hence to a very strong antiferromagnetic interaction [35]. It is well know [36] that for the hydroxide-bridged dimers the way of exchange interaction characteristically depends on the bridge angle implying a crossover from antiferromagnetic to ferromagnetic coupling at about 97.6°. The studies of a chlorine-bridged dimeric system [37] (Cu–Cl–Cu) have shown that the crossover-bridging angle is at 95.1°. A similar relation between Cu–O–Cu bridge angles (99.21(9)° for 1, 102.91(9)° for **3** and 103(1)° for **4**) and the exchange coupling, antiferromagnetic in nature, is observed by us for the new dinuclear complexes. The ferromagnetic coupling for **4** was postulated erroneously in the previous work [22] as a too rash interpretation of the solution paramagnetic susceptibility measured by ^{1}H shift in the NMR spectra only at room temperature.

3.5. Conclusion

By carrying out the synthesis in a special way and using only 1-hydroxymethyl-3,5-dimethylpyrazole as the starting ligand in the presence of copper(II) salts, new dinuclear Cu(II) complexes of [CuL(LO)X]$_2$ or mononuclear [CuL$_3$(NO$_3$)](NO$_3$) where L – (3,5-dimethylpyrazole), LO – (1-methoxy-3,5-dimethylpyrazole), X = NO_3^-, BF_4^-, ClO_4^-) have been obtained. In particular, the kind of solvent used plays an important role in the synthesis of the complexes. Moreover, in the three

examples of Cu(II) dimers characterized in this paper, the coordinating anions significantly contribute to the magnetic behaviour. With the increase of the volume of the anions, parallel to the change in Cu(II)–Cu(II) bond length and bond angle, the spin super-exchange interaction measured by the energy gap between the singlet and triplet states increases. So it is interesting to point out that the antiferromagnetic exchange interaction tends to increase according to the series of compensative ligands: $NO_3^- \ll BF_4^- < ClO_4^-$.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 218201 (**1**) and 218200 (**2**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Abstract

The macrocycle L, prepared by template condensation of bis-6,6″-(α-methylhidrazino)-4′-phenyl-2,2′:6″,2′-terpyridine with glyoxal, forms a stable crystalline complex of copper(II) $[Cu(L)(H_2O)_2][PF_6]_2$ which has been used as a starting material to prepare, for electrochemical studies, a series of seven coordinate copper(II) complexes $[Cu(L)X_2][PF_6]_2$ (X = pyridine, 4-cyanopyridine, 4-aminopyridine, 4-dimethylaminopyridine, pyrazine, imidazole, 1-methylimidazole, 2-methylimidazole, and trimethylphosphite). Cyclic voltammetry of the aquo complex in DMSO show one reversible reduction wave at −0.36 V versus $Ag/AgBF_4$ reference electrode and controlled potential electrolysis in the presence of trimethylphosphite affords a diamagnetic species which has been assigned as a mononuclear d^{10} Cu(I) species. The crystal and molecular structure of $[Cu(L)(imidazole)_2][PF_6]_2$ shows the metal to be in a pentagonal bipyramidal N_7 environment.

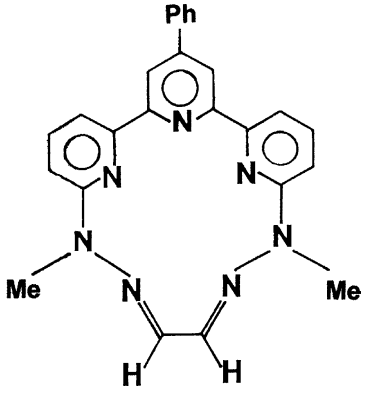
1. Introduction

Earlier studies [1,2] reported the electrochemical investigation of the redox behaviour in acetonitrile solution of the copper(II) complexes with 14-membered saturated tetraaza macrocycles. It was found that controlled potential electrolysis performed both in oxidation and reduction did not produce the corresponding copper(III) and copper(I) complexes, in contrast to the nickel analogues. However, cyclic voltammetry performed at high potential scan rate showed both in oxidation and in reduction a reversible one electron redox process, ascribed to the formation of copper(III) and copper(I) complex cations, respectively.

The reduction of transition metal complexes of potential π-acceptor macrocyclic ligands such as **L** is of interest because of the possibility of forming either metal reduced species or metal-stabilized ligand radical species in which the electron resides mainly on the macrocyclic ligand.



As previously shown [3–15], these redox properties may be highly dependent on the axial ligation. Continuing with early studies [16–24] we have studied the redox chemistry of copper(II) complexes of **L** in the presence of a series of axial ligands in order to determine whether variations in redox properties are observed.

2. Experimental

2.1. Physical measurements

IR spectra were recorded on a Perkin–Elmer Model 983 spectrophotometer using KBr pellets. The spectra were calibrated against the 1603 cm^{-1} band of polystyrene. Conductance measurements were made using a Wayne Kerr Universal Bridge. The conductivity cell was calibrated with aqueous KCl. Microanalyses were performed on a Leco 932 CHNS elemental analyzer. Electrochemical measurements were recorded on a Model 170 Electrochemistry System (Princeton Applied Research). All readings were taken using a three electrode potentiostatic system in MeCN with 0.1 mol dm^{-3} (n-Bu)$_4$NBF$_4$ as supporting electrolyte. The potentials are referenced against a saturated calomel electrode (SCE). CV studies were carried out using Pt wires as auxilliary and working electrodes and a Ag–AgBF$_4$ reference electrode with sample concentrations of 10^{-3}–10^{-4} mol dm^{-3}. EPR spectra were measured at 77 K on a Varian E109 spectrophotometer (X band) and calibrated with diphenylpicrylhydrazyl (dpph; $g = 2.0037$). Magnetic susceptibilities were measured on a Johnson Matthey susceptibility balance at room temperature using HgCo(NCS)$_4$ as calibrant.

2.2. Materials

Published methods were used to prepare H$_2$L[PF$_6$]$_2$ by the template condensation of bis-6,6″-(α-methylhidrazino)-4′-phenyl-2,2′:6″,2′-terpyridine with glyoxal about Cr^{3+} or $SnMe_2Cl_2$ [16–19]. Solvents were distilled over appropriate drying agents prior to use. All other chemicals were commercial materials of analytical grade. Unless otherwise stated the reactions were carried out under dry N_2.

2.3. Preparation of [Cu(L)(H$_2$O)$_2$][PF$_6$]$_2$

The free macrocycle H$_2$L[PF$_6$]$_2$ (0.029 g, 0.04 mmol) and Cu(O$_2$CMe)$_2\cdot$4H$_2$O (0.025 g, 0.1 mmol) in of dry MeOH (50 cm^3) were boiled under reflux, until a clear solution was obtained. A solution of [NH$_4$][PF$_6$] (0.033 g, 0.2 mmol) in MeOH was added to the hot solution, which was allowed to cool slowly. Copper(II) complex was obtained as a brown precipitate.

2.4. Preparation of [Cu(L)(X)$_2$][PF$_6$]$_2$ (X = pyridine (Py), 4-cyanopyridine (4-NCPy), 4-aminopyridine (4-H$_2$NPy), 4-dimethylaminopyridine (4-Me$_2$NPy), pyrazine, imidazole (Im), 1-methylimidazole (1-MeIm), 2-methylimidazole (2-MeIm) and trimethylphosphite (P(OMe)$_3$))

The complex [Cu(L)(H$_2$O)$_2$][PF$_6$]$_2$ (0.090 g. 0.11 mmol) was dissolved in boiling methanol (50 cm^3), excess of X ligand was added, and the reaction mixture was refluxed for 25 min. Addition of a concentrated methanolic solution of ammonium hexafluorophosphate to the hot solution gave a precipitate of the pure product, which was collected, washed copiously with diethyl ether and dried in vacuo. The yield was quantitative. Completion of reaction could be determined by the absence of the two water ν(O–H) resonances in the infrared spectrum near 3500 cm^{-1}.

2.5. X-ray crystallography: structure of [Cu(L)(Im)$_2$][PF$_6$]$_2$

Green prismatic crystals were obtained by recrystallization of the complex from acetone and diethyl ether. For X-ray structural determination a single crystal with approximate dimensions $0.35\times0.28\times0.20$ mm was selected. Data were collected on a Brucker SMART APEX diffractometer equipped with an Oxford Cryosystem low temperature device at 150 K. The initial unit cell was indexed using a least-squares analysis of a random set of reflections collected from three series of 0.3° wide ω-scans, 10 s per frame and 25 frames per series that were well distributed in reciprocal space. Data frames were collected [Mo Kα ($\lambda = 0.71073$ Å)] with 0.3° wide ω-scans, 10 s per frame and 600 frames per series. Four complete series were collected at varying ϕ angles ($\phi = 0°$, 90°, 180° and 240°). The crystal to detector distance was 6.0 cm, this providing a set of $3.48° \leqslant 2\theta \leqslant 52.80°$. A total of 15 601 reflections were collected and performed using SAINT [25], while absorption correction was applied using SADABS [26] with 7928 unique [$R_{int} = 0.0297$]. System symmetry, systematic absences and intensity statistics indicated the unique triclinic space group $P\bar{1}$. The structure was determined by direct methods with the location of the nearly all non-hydrogen atoms using the program SHELXS [27] and refined by full-matrix least-squares on F^2 using SHELXL [28]. All non-hydrogen atoms were refined anisotropically, while hydrogen atoms were placed in calculated positions, constrained to ride on their carbon atoms with group U_{iso} values assigned ($U_{iso}(H) = 1.20U_{iso}$ for aromatic carbons and $1.50U_{iso}$ for methyl atoms).

3. Results and discussion

Although complexes of 6,6″-bis(α-methylhydrazino)-4′-phenyl-2,2′:6″,2′-terpyridine have been prepared with a wide range of transition metal and main group metal ions, the condensation with glyoxal only proceeded in a satisfactory way with nickel(II) or manganese(II) as the template. However, the metal-free macrocycle L may be obtained as its dication from condensations in which the transient template ions Cr^{3+} or $[SnMe_2]^{2+}$ are used [18].

The elemental analyses and some physical properties of $H_2(L)[PF_6]_2$ and the substituted complexes $[Cu(L)(X)_2][PF_6]_2$ are given in Table 1. The molar conductivities of 10^{-3} mol dm^{-3} solutions in $MeNO_2$, MeCN or DMSO fall in the range expected for 1:2 electrolytes [29]. This is supported by the IR spectrum where two bands at 842 and 558 cm^{-1} characteristic of the non-coordinated hexafluorophosphate anion are present.

The spectrum of L itself is devoid of any evidence for the presence of either a ketonic carbonyl (1700 cm^{-1}) or primary amine groups (3300, 3200 cm^{-1}). This and the presence of a strong C=N stretching band in the range 1580–1620 cm^{-1} provide assurance that the required Schiff base linkages have formed. The spectra of the complexes show similarities to one another and include absorptions characteristic for L. The bands assigned to the pyridine ring vibrations are shifted to lower frequencies, which is a good indication of the coordination of the heterocyclic nitrogen atoms. The shifting of the ν(C=N) band to lower wavenumbers relative to the free ligand results from a decrease in the C=N double bond character upon coordination. In all the compounds the band assigned to the monosubstituted benzene falls in the range 740–730 cm^{-1}. The spectrum of the aquo complex showed in addition to the O–H stretching vibration at 3500–3400 cm^{-1} a broad band of moderate intensity at 605 cm^{-1}, which is usually assigned to wagging or rocking modes of coordinated water [30].

The UV–Vis spectrum of $[Cu(L)(H_2O)_2]^{2+}$ macrocyclic complex presents a broad band of low intensity at very low energy (6993 cm^{-1} in DMSO and 8547 cm^{-1} in acetonitrile) which parallel the spectral band at 7400 cm^{-1} observed in pentagonal bipyramidal complexes of copper(II) and assigned to the transition $^2A_1' \rightarrow {}^2E_2'$ in D_{5h} symmetry [31]. Pentagonal bipyramidal complexes of copper(II) present another band at 11 900 cm^{-1} assigned to the transition $^2A_1' \rightarrow {}^2E_1''$ which could not be detected in the present work. The high energy band observed at 20 800 cm^{-1} in nitromethane solvent appears to be too far red-shifted to tentatively assign to the aforementioned transition.

The room temperature magnetic moment of the compound $[Cu(L)(H_2O)_2][PF_6]_2$ is 1.75 μ_B, which is characteristic of high spin d^9 systems with one unpaired electron. The X-band EPR spectrum of the complex in acetonitrile glass at 77 K shows a typical pattern of magnetically dilute $S = 1/2$ centres with spectral characteristics ($g_\parallel = 2.26$, $g_\perp = 2.06$ and $A_\parallel = 170$ G) resembling those of copper(II) in other six and seven coordinate geometries. The EPR hyperfine structure (four lines) is due to interaction of the unpaired electron with the ^{63}Cu and ^{65}Cu nuclei which have the same nuclear spin $I = 3/2$.

3.1. Electrochemical studies

Cyclic voltammetry measurements on the axially substituted copper(II) complexes were made in DMSO solution where an equilibrium between the solvated species $[Cu(L)(DMSO)_n]^{2+}$ and the species incorporating the axial X substituent $[Cu(L)(X)_2]^{2+}$ should be expected. Therefore, in order to force the equilibrium in favour of the axially substituted adducts, an excess of the neutral substituent was added into the electrochemical cell. Electrolyte concentrations of 0.1 M were used in all electrochemical experiments and all solutions were degassed with argon prior to use. A well resolved reduction wave was observed for the copper(II) aquo complex at −0.36 V (less than free macrocycle $E_{1/2} = -0.94$ V) which is assigned to the Cu(II)/Cu(I) reduction.

Further electrochemical studies of axially substituted derivatives were carried out and Table 2 shows the $E_{1/2}$ values of the different reversible waves detected in our experiments. In general, the shift in $E_{1/2}$ compared with the value for the aquo species reflects a relative stabilization of the divalent metal ion. The most contrasting

[a] All potentials are relative to a Ag/Ag^+ reference electrode at room temperature in DMSO solution. Scan rate: 100 mV s^{-1}.

behaviour can be appreciated when imidazole or 1-methylimidazole (π donor properties) and the triphenylphosphine (π acceptor properties) are separately added to the electrochemical cell.

The bis-(1-MeIm) adduct of the copper(II) macrocycle displays a shift in the half wave potential from −0.36 V (aquo ligand) to −0.54 V which is consistent with the strong σ/π donor effects of 1-MeImidazole. The more difficult reduction of the axial 1-MeImidazole species in comparison with the aquo complex reflects the relative stabilization of the Cu(II) oxidation state towards reduction. On the other hand, the more easy reduction of the axial trimethylphosphite species (−0.10 V) in relation with the aquo complex reflects the stabilization of the copper(I) oxidation state.

Controlled potential electrolysis of $[Cu(II)(L)(P(OMe)_3)_2][PF_6]_2$ in DMSO in the presence of excess of trimethylphosphite at −0.06 V under a constant stream of argon gas led to the reduction of the copper(II) species with change of colour from dark orange to green. On completion of reduction the reaction mixture was transferred by syringe to a Schlenk tube and the copper(I) species was isolated as a green precipitate of $[Cu(L)(H_2O)_2][BF_4]$ by the addition of dry, oxygen-free diethyl ether. To confirm that the green colour is due to the formation of a copper(I) complex the compound $[Cu(L)(H_2O)_2][BF_4]_2$ was also prepared and shows the same orange colour than the starting material $[Cu(L)(H_2O)_2][PF_6]_2$. The infrared spectrum for the copper(I) complex shows similarities with the spectrum of the copper(II) complex but the PF_6 group was changed for BF_4 group from the supporting electrolyte. The B–F stretching frequency is quite broad, centred around 1084 cm^{-1} and is typical of complexes having tetrafluoroborate counter ions. The electrical conductance value in acetonitrile, nitromethane and DMSO solutions fall in the range expected for 1:1 electrolytes and the elemental analysis (Table 1) agrees well with the proposed formulae. A 400-MHz ^1H NMR spectrum of a $(CD_3)_2SO$ solution was consistent with the formulation and the mass spectrum of the salt showed a peak at m/z 417 which corresponds to the parent ion of the free macrocycle. The reduction was also followed by EPR spectroscopy, which showed the gradual loss of signal assigned to high spin d^9 copper(II), and on completion of the reduction no EPR signal could be observed at 77 K as DMSO glass. The EPR spectrum of the isolated green material exhibited no signals at all. This was consistent with the formation of a low spin d^{10} copper(I) species and confirming the process as a metal centred reduction following Nelson's criteria [32].

The electrochemical results described above are analogous to the redox properties observed for $[Co(L)(H_2O)_2]^{2+}$ $E_{1/2} = -1.35$ V [21] in which reduction occurs also at the metal centre. This is in contrast to the redox properties of Ni(II) [24], Mn(II) [23] and Fe(II) [22] complexes of L which on addition of $P(OMe)_3$ to their solutions in the electrochemical cell showed essentially no shifts in the value of $E_{1/2}$ for the above reduction process. No metal(I) species could be detected in the quantitative reductions of such solutions. These are ligand centred processes.

The CV of $[Cu(L)(H_2O)_2]^{2+}$, $[Cu(L)(1\text{-}MeIm)_2]^{2+}$ and $[Cu(L)(P(OMe)_3)_2]^{2+}$ in DMSO is shown in Fig. 1. Finally, the cyclic voltammetry in most cases showed peak separation ($E_{pa} - E_{pc}$) near 80 mV suggesting that the electrode reactions approached Nernstian behaviour. All the attempts to crystallize reduced species were not successful.

3.2. Structure of $[Cu(L)(Im)_2][PF_6]_2$

X-ray crystallographic study revealed that the structure comprises a cationic macrocyclic coppert(II) complex (see Fig. 2), two PF_6^- counter anions and a

Available online 10 April 2004

Abstract

Six new square-planar nickel(II) complexes of 18-membered decaaza macrocyclic ligands 5,6,14,15-tetramethyl-1,3,4,7,8,10,12,13,16,17-decaazacyclooctadecane $[Ni(Me_4[18]aneN_{10})](ClO_4)_2$ (**1**); 1,10-dimethyl-$[Ni(Me_2Me_4[18]aneN_{10})](ClO_4)_2$ (**2**); 1,10-diethyl-$[Ni(Et_2Me_4[18]aneN_{10})](ClO_4)_2$ (**3**); 1,10-dipropyl-$[Ni(Pr_2Me_4[18]aneN_{10})](ClO_4)_2$ (**4**); 1,10-dibutyl^{iso}-$[Ni(Bu_2Me_4[18]aneN_{10})](ClO_4)_2$ (**5**); 1,10-dibenzyl-5,6,14,15-tetramethyl-1,3,4,7,8,10,12,13,16,17-decaazacyclooctadecane $[Ni((Benzyl)_2Me_4[18]aneN_{10})](ClO_4)_2$ (**6**); $[Ni(Me_4[18]aneN_{10})](PF_6)_2$ (**7**); $[Ni(Me_2Me_4[18]aneN_{10})](PF_6)_2$ (**8**); $[Ni(Me_4Me_4[18]aneN_{10})](PF_6)_2$ (**9**); $[Ni(Pr_2Me_4[18]aneN_{10})](PF)_2$ (**10**); $[Ni(Bu_2Me_4[18]aneN_{10})](PF_6)_2$ (**11**); $[Ni((Benzyl)_2Me_4[18]aneN_{10})](PF_6)_2$ (**12**); $[Ni(Me_4[18]aneN_{10})(NCS)_2]$ (**13**); $[Ni(Me_2Me_4[18]aneN_{10})(NCS)_2]$ (**14**); $[Ni(Et_2Me_4[18]aneN_{10})(NCS)_2]$ (**15**); $[Ni(Pr_2Me_4[18]aneN_{10})(NCS)_2]$ (**16**); $[Ni(Bu_2Me_4[18]aneN_{10})(NCS)_2]$ (**17**) and $[Ni((Benzyl)_2Me_4[18]aneN_{10})(NCS)_2]$ (**18**) have been prepared from the one-pot template condensation reaction of formaldehyde, 2,3-butanedihydrazone with alkyl and benzyl amine in the presence of the nickel(II) ion. Elemental analyses, IR, UV–Vis spectroscopy, conductometric and magnetic measurements have been used to characterize the nickel(II) complexes of these decaaza macrocycles. The spectra of $[Ni(R_2Me_4[18]aneN_{10})](ClO_4)_2$ shows that the four nitrogen (α-diimine) atoms are coordinated to the nickel(II) ion. The hydrazones of the (α-diimine) function have the *anti–anti* configuration yielding a macrocyclic species with D_{2h} symmetry. The nickel(II) complexes are diamagnetic and four coordinate, exhibiting only weak interactions with different solvents. The physical and chemical properties of the complexes are compared with other closely related complexes.

1. Introduction

Metal template syntheses often provide selective routes toward products that are not obtainable in the absence of metal ions. Especially, template reactions involving formaldehyde and amines facilitate the preparation of saturated polyaza multidenatate, macrocyclic and macropolycyclic complexes [1–6]. The reactions are simple "one-pot reactions", cheap and high yielding. Metal template condensation reactions involving amines and formaldehyde have been employed in the preparation of various saturated polyazamacrocyclic complexes [7–13].

A wide variety of amines, both "free" and coordinated, are known to react with aldehydes to form a more complicated amine ligand. The products of these reactions can be of many different types, although the innumerable Schiff-base ligands represent the largest class of these ligands. Related types of reactions include the well-known reaction of ammonia with formaldehyde to yield hexamethylenetetramine (I) [14]. More recent examples of polydentate and macrocyclic ligand syntheses from the reaction of amines with formaldehyde (II, III) are illustrated [13,15,16].

The octaazamacrocyclic complexes,(VII), obtained by the metal template condensation of 2,3-butanedihydrazone with aldehydes have uncoordinated secondary nitrogen atoms which are capable of under-

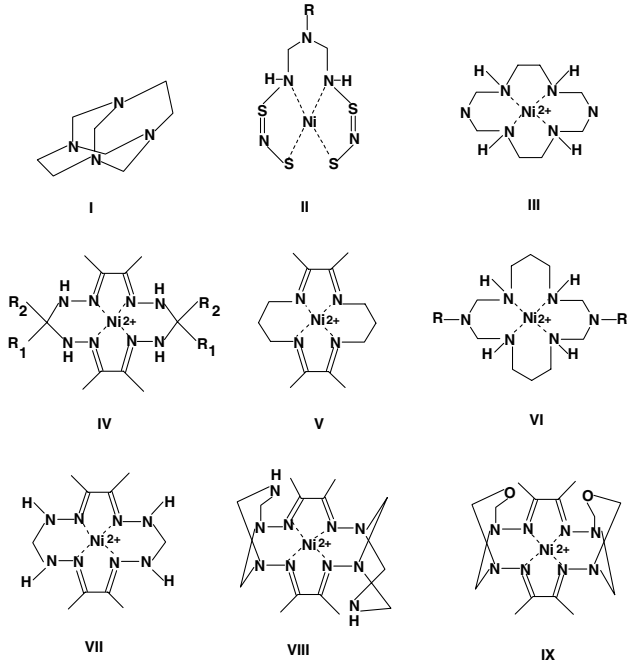
Scheme 1.

going further reactions with aldehydes [17]. It was therefore expected that (VII) might undergo a further condensation reaction with formaldehyde and ammonia to yield a tricyclic macro ring ligand (VIII) in which two triazacyclohexan rings were fused to the original 14-membered macrocyclic ring. The products obtained in all cases were of type (IX) that formally results from the condensation of four molecules of formaldehyde with the macrocyclic complexes of type (VII) [18].



In this paper, we report the synthesis, characterization and properties of the new square planar nickel(II) complexes of 5,6,14,15-tetramethyl-1,3,4,7,8,10,12,13,16,17-decaazacyclooctadecane $[Ni(Me_4[18]aneN_{10})](ClO_4)_2$ (**1**), 1,10-dimethyl-$[Ni(Me_2Me_4[18]aneN_{10})](ClO_4)_2$ (**2**), 1,10-diethyl-$[Ni(Et_2Me_4[18]aneN_{10})](ClO_4)_2$ (**3**), 1,10-dipropyl-$[Ni(Pr_2Me_4[18]aneN_{10})](ClO_4)_2$ (**4**), 1,10-dibutyl^{iso}-$[Ni(Bu_2Me_4[18]aneN_{10})](ClO_4)_2$ (**5**), 1,10-dibenzyl-5,6,14,15-tetramethyl-1,3,4,7,8,10,12,13,16,17-decaazacylooctadecane $[Ni((Benzyl)_2Me_4[18]aneN_{10})](ClO_4)_2$ (**6**), $[Ni(Me_4[18]aneN_{10})](PF_6)_2$ (**7**), $[Ni(Me_2Me_4$ [18]aneN$_{10}$)$](PF_6)_2$ (**8**), $[Ni(Me_4Me_4[18]aneN_{10})](PF_6)_2$ (**9**), $[Ni(Pr_2Me_4[18]aneN_{10})](PF)_2$ (**10**), $[Ni(Bu_2Me_4[18]$ aneN$_{10}$)$](PF_6)_2$ (**11**), $[Ni((Benzyl)_2Me_4[18]aneN_{10})](PF_6)_2$ (**12**), $[Ni(Me_4[18]aneN_{10})(NCS)_2]$ (**13**), $[Ni(Me_2Me_4[18]$ aneN$_{10}$)$(NCS)_2]$ (**14**), $[Ni(Et_2Me_4[18]aneN_{10})(NCS)_2]$ (**15**), $[Ni(Pr_2Me_4[18]aneN_{10})(NCS)_2]$ (**16**), $[Ni(Bu_2Me_4$ [18]aneN$_{10}$)$(NCS)_2]$ (**17**) and $[Ni((Benzyl)_2Me_4[18]aneN_{10})(NCS)_2]$ (**18**), which are given in Scheme 1.

2. Experimental

2.1. Materials and measurements

Safety note. Perchlorate salts of transition metal complexes with organic ligands are often explosive and should be handled with caution. All chemicals and solvents used in the syntheses were of reagent grade and were used without further purification. For the spectroscopic measurements, water was distilled and organic solvents were purified according to the literature method [19]. Electronic absorption spectra were obtained with a Shimadzu UV–Vis scanning spectrophotometer (Model 2101 PC), FTIR spectra with a Shimadzu Varian 4300 spectrophotometer, ^{1}H NMR spectra with a Bruker AC 80 (in CH_3NO_2-d_3 as solvent), and conductance measurements with a Metrohm Herisau conductometer E 518. The elemental analyses (carbon, hydrogen and ni-

trogen) of the complexes were obtained from a Carlo ERBA Model EA 1108 analyser. Magnetic moments were calculated from magnetic susceptibility data obtained using a Johnson Matthey MK-1 magnetic susceptibility balance. Atomic Absorption Spectra (AAS) were recorded on a Perkin–Elmer 4100-1319 spectrophotometer.

2.2. Preparation of 2,3-butanedihydrazone

2,3-butanedihydrazone was prepared by the method of Bush and Bailar [20].

2.3. Preparation of [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**2**)

To a stirred methanol solution (500 ml) of $NiCl_2 \cdot 6H_2O$ (10.00 g, 42.07 mmol) were slowly added 2,3-butanedihydrazone (9.61 g, 84.20 mmol), 36% formaldehyde (13 ml) and 36% methylamine (10.47 ml, 84.20 mmol). One drop of concentrated perchloric acid was added to catalyse the condensation reaction. The mixture was heated at reflux for 24 h until a dark red solution resulted. The solution was cooled to room temperature and filtered to remove nickel hydroxide. Excess percholoric acid or lithium perchlorate dissolved in methanol was added to the filtrate, and the mixture was kept in the refrigerator until a red-brown solid formed. The red-brown solid was filtered, washed with diethyl ether, and air-dried. The product was crystallized from hot water. Yield: ~48%. *Anal*. Calc. for (**2**); Ni, 9.85; C, 28.21; H, 5.07; N, 23.50. Found Ni, 9.76; C, 28.11; H, 5.01; N, 23.61%.

2.4. Preparation of [Ni(Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**1**)

The procedure followed was similar to that for [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$, except that 25% ammonia (6.3 ml, 84.20 mmol) was used instead of methylamine. Yield: ~41%. *Anal*. Calc. for (**1**): Ni, 10.33; C, 25.37; H, 4.61; N, 24.66%. Found: Ni, 10.24; C, 25.27; H, 4.50; N, 24.72%.

2.5. Preparation of [Ni(Et_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**3**)

This complex was prepared by a method similar to that for [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$, except 50% ethylamine (8.72 ml, 84.20 mmol) was used instead of methylamine. Yield: ~38%. *Anal*. Calc. for (**3**): Ni, 9.40; C, 30.79; H, 5.49; N, 22.22. Found: Ni, 9.28; C, 30.68; H, 5.41; N, 22.51%.

2.6. Preparation of [Ni(Pr_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**4**)

The procedure followed was similar to that for [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$, except that propylamine (6.91 ml, 84.2 mmol) was used instead of methylamine. Yield: ~39%. *Anal*. Calc. for (**4**): Ni, 8.99; C, 33.15; H, 5.87; N, 21.48. Found: Ni, 8.81; C, 33.04; H, 5.78; N, 21.56%.

2.7. Preparation of [Ni($Bu^{iso}_2Me_4$[18]$aneN_{10}$)]$(ClO_4)_2$ (**5**)

This complex was prepared by a method similar to that for [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$, except *iso*-butylamine (8.36 ml, 84.20 mmol) was used instead of methylamine. Yield: ~42%. *Anal*. Calc. for (**5**): Ni, 8.63; C, 35.31; H, 6.22; N, 20.59. Found: Ni, 8.54; C, 35.22; H, 6.09; N, 20.64%.

2.8. Preparation of [Ni($(Benzyl)_2Me_4$[18]$aneN_{10}$)]$(ClO_4)_2$ (**6**)

This complex was prepared by a method similar to that for [Ni(Me_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$, except benzyl amine (9.2 ml, 84.20 mmol) was used instead of methylamine. Yield: ~52%. *Anal*. Calc. for (**6**): Ni, 7.84; C, 41.74; H, 5.12; N, 18.72. Found: Ni, 7.76; C, 41.69; H, 5.01; N, 18.93%.

2.9. Preparation of [Ni(R_2Me_4[18]$aneN_{10}$)](PF_6) (**7**)–(**12**)

A solution of 3.1 mmol NH_4PF_6 in 5 ml of H_2O was added to a solution of 1.2 mmol [Ni(R_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**1**)–(**6**) in 10 ml of H_2O. The brown-orange product that precipitated was filtered, washed with H_2O and dried in air. *Anal*. Calc. for (**7**) (Yield: ~70%): Ni, 8.90; C, 21.86; H, 3.98; N, 21.25. Found: Ni, 8.74; C, 21.74; H, 3.89; N, 21.32%. *Anal*. Calc. for (**8**) (Yield: ~71%): Ni, 8.54; C, 24.47; H, 4.40; N, 20.38. Found: Ni, 8.42; C, 24.31; H, 4.36; N, 20.42%. *Anal*. Calc. for (**9**) (Yield: ~73%): Ni, 8.21; C, 26.87; H, 4.79; N, 19.58. Found: Ni, 8.13; C, 26.80; H, 4.68; N, 19.71%. *Anal*. Calc. for (**10**) (Yield: ~75%): Ni, 7.95; C, 29.29; H, 4.61; N, 18.95. Found: Ni, 7.86; C, 29.21; H, 4.51; N, 19.05%. *Anal*. Calc. for (**11**) (Yield: ~76%): Ni, 7.66; C, 31.33; H, 4.96; N, 18.26. Found: Ni, 7.58; C, 31.23; H, 4.83; N, 18.32%. *Anal*. Calc. for (**12**) (Yield: ~78%): Ni, 7.03; C, 37.41; H, 4.07; N, 16.77. Found: Ni, 6.91; C, 37.33; H, 3.92; N, 16.85%.

2.10. Preparation of [Ni(R_2Me_4[18]$aneN_{10}$)][$(NCS)_2$] (**13**)–(**18**)

A saturated solution of NaNCS in 10 ml of CH_3CN was added to a solution containing 0.2 g of [Ni(R_2Me_4[18]$aneN_{10}$)]$(ClO_4)_2$ (**1**)–(**6**) in 20 ml of CH_3CN. The solution was allowed to stand at room temperature and then the pink precipitate that formed was filtered, washed with acetonitrile, and dried in vacuum. *Anal*. Calc. for (**13**) (Yield: ~52%): Ni, 12.09;

C, 34.65; H, 5.40; N, 34.64. Found: Ni, 11.86; C, 34.49; H, 5.31; N, 34.78%. *Anal.* Calc. for (**14**) (Yield: ~53%): Ni, 11.43; C, 37.44; H, 5.89; N, 32.75. Found: Ni, 11.30; C, 37.29; H, 5.76; N, 32.89%. *Anal.* Calc. for (**15**) (Yield: ~55%): Ni, 10.84; C, 39.94; H, 6.33; N, 31.05. Found: Ni, 10.71; C, 9.78; H,. 22; N, 31.21%. *Anal.* Calc. for (**16**) (Yield: ~56%): Ni, 10.31; C, 42.19; H, 6.73; N, 29.52. Found: Ni, 10.20; C, 42.01; H, 6.59; N, 29.66%. *Anal.* Calc. for (**17**): (Yield: ~57%): Ni, 9.82; C, 44.22; H, 7.09; N, 28.13%. Found: Ni, 9.71; C, 44.11; H, 6.89; N, 28.28%. *Anal.* Calc. for (**18**): (Yield: ~59%): Ni, 8.82; C, 50.53; H, 5.76; N, 25.26. Found: Ni, 8.69; C, 50.41; H, 5.61; N, 25.34%.

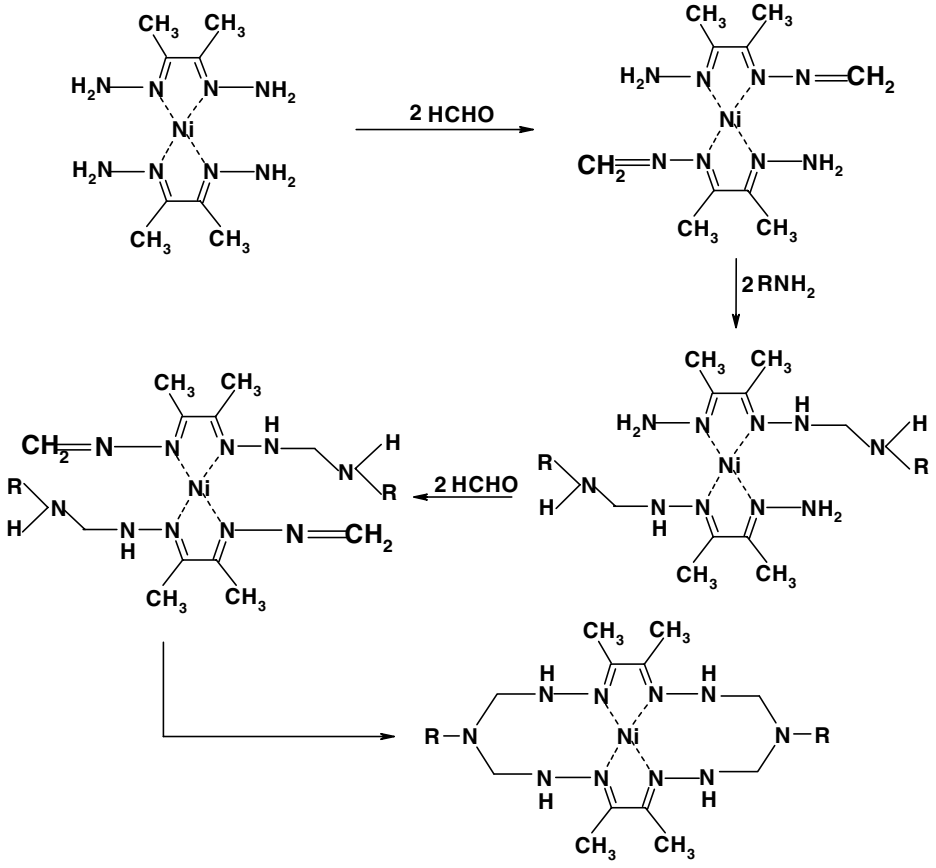
2.11. Preparation of [Ni($C_{14}H_{28}N_{10}$)] (*XII*)

Triethylamine (0.5ml) was added to a deaerated solution of 200 mg of (**2**) in 15 ml of CH_3CN. The red-brown solution changed to an intense dark red colour upon mixing the reagents. The air-sensitive product, which began precipitating within minutes, was filtered after 0.5 h under a nitrogen atmosphere, washed with anhydrous ethanol, and dried in vacuum. IR (KBr, cm^{-1}): 1598 ($\nu_{C=N}$). *Anal.* Calc. for [Ni($C_{14}H_{28}N_{10}$)]: Ni, 14.84; C, 42.58; H, 7.09; N, 35.45. Found: Ni, 14.77; C, 14.77; H, 6.91; N, 35.53%.

3. Results and discussion

Decaaza bis (α-diimine) macrocyclic nickel(II) complexes were prepared by reacting 2 equivalents of 2,3-butanedihydrazone, 4 equivalents of formaldehyde with 2 equivalents of the appropriate amine in the presence of the nickel(II) ion (Schemes 1, 2). It was observed that the 18-membered decaaza macrocyclic product obtained from the reaction was largely affected by the molar ratio of the reactants. The cyclization process is acid catalysed, but large excesses of acid destroy the complexes. The crude product often contained a small amount of the octaazabis (α-diimine) macrocyclic (VII) complex as a by-product. However, the mononuclear complex can be readily isolated by fractional recrystallization of the product from ca. 0.05 M $HClO_4$ aqueous solutions.

The free amino groups of coordinated 2,3-butanedihydrazone are ideally oriented for ring closure by reaction with carbonyl functions to give six-membered chelated rings and ultimately octaaza-14-membered ring macrocyclic complexes, with the 2,3,9,10-tetramethyl-1,4,5,7,8,11,12,14-octaazacyclotetradeca-1,3,8,10-tetraene ligand (IV). This type of reaction closely parallels that reported by Kerwin and Melson [21] in which tetradentate ligands were formed by the condensation of benzil monohydrazone in the presence of Ni(II). In the

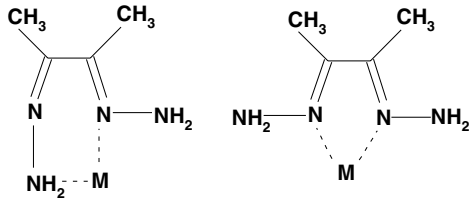


Scheme 2.

absence of added carbonyls, the 2,3-butanedihydrazone complexes described by Stouffer and Busch [22] are formed.

The complexes in this paper (Scheme 1) were expected to have physical properties very similar to those of the metal complexes of 2,3,9,10-tetramethyl-1,4,8,11-tetraazacyclotetradeca-1,3,8, 10-tetraene(V) [23,24], but to be much more chemically reactive for a number of reasons. The 18-membered decaazamacrocycle contains hydrazone linkages, which are more reactive than the 1,3-diaminopropane ring (V) complexes. In addition, C–N linkages are easier to oxidize than C–C single bonds. Other possible reactions include (a) reduction of the C=N double bonds (the resulting completely saturated complexes should have no particularly unusual physical properties, however, reoxidation of the ligand should occur at the N–N linkages in the 18-membered decaaza macrocycle yielding a new type of chelate ring), (b) nucleophilic attack on C=N double bonds, (c) deprotonation of hydrazine protons, (d) further condensation reaction which can occur at the secondary N–H centers. The decaazabis(α-diimine) macrocyclic ligands are strong-field ligands and promote spin pairing whenever possible. The magnetic moments (−0.10 to $-0.51\mu_B$) of the nickel(II) complexes measured in the solid state correspond to the square-planar coordination geometry of the complexes.

The possibility of *syn–anti* and *anti–anti* isomerization among the free dihydrazone ligands and their decaaza complexes were considered. Both isomers of 2,3-butanedihydrazone are capable of forming metal chelates with the *syn–anti* configuration forming six-membered chelate rings, while the *anti–anti* configuration yield five-membered α-diimine chelate rings.



X XI

The *syn–anti* configuration of a number of cyclic 1,2-dihydrazones was observed by Baldwin et al. [25]. However, the NMR spectrum of 2,3-butanedihydrazone indicates the *anti–anti* configuration. The π-acceptor property of the α-diimine moieties enhances their chelating tendency with metals of significant π-donor tendency. Therefore the cyclization products of XI obtained from condensation of 2,3-butanedihydrazone with formaldehyde and amine are expected to yield products having the symmetrical *anti–anti* structure of 18-membered decaaza macrocycle nickel(II) complexes.

$[Ni(R_2Me_4[18]aneN_{10})]^{2+}$ react with excess NaNCS in aqueous solution to form tetragonal complexes $[Ni(R_2Me_4[18]aneN_{10})(NCS)_2]$, whose IR spectra (Table 1) show that the nitrogen atoms of the NCS^- ligands are coordinated to the Ni(II) ion [26]. Pink complexes of thiocyanate are not soluble in most solvents such as CH_3CN, EtOH, DMF and in H_2O.

The infrared spectra of the complexes, $[Ni(R_2Me_4[18]aneN_{10})](ClO_4)_2$, are all very similar to one another

[a] In nitromethane solution unless other wise specified.

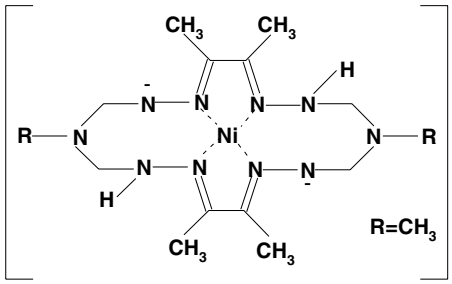
and support the ligand structure proposed in Scheme 1. The most diagnostic absorption bands are the N–H and C=N stretching modes, as well as those attributable to free perchlorate anions. Some of the representative N–H and C=N stretching frequencies are tabulated in Table 1. There were no other absorption bands present which could be assigned to uncondensed functional groups, e.g., such as $-NH_2$ or C=O, of the starting materials.

A comparison of the spectra of the 18-membered decaaza macrocycles $[Ni(R_2Me_4[18]aneN_{10})](ClO_4)_2$ with those of the closely related divalent metal complexes of $Me_4[14]1,3,8,10$-tetraeneN_4 (V) and $Me_4[14]$-1,3,8,10-tetraeneN_8 (VII) reveals some differences in the C=N stretching frequency region of the spectra [23,24]. The intensity and position of the C=N stretching frequency of our 18-membered decaaza macrocycle complexes are strong and sharp and are one indication of the difference in dipole strength of the hydrazone's C=N as compared to the α-diimine C=N bond.

The electronic spectra (Table 1) of the Ni(II) complexes are comparable to those of square-planar Ni(II) complexes with tetraaza macrocycles, V, VII, IV, indicating that the decaaza ligands of this study do not differ significantly from the tetraaza ligands with respect to the ligand field strength [23,24]. The UV–Vis spectra of these intensely coloured complexes are dominated by intense charge-transfer absorptions in the visible and UV portions of the spectra. The spectra are tabulated for identification purpose only; no detailed assignment will be made due to the overlap of ligand field and charge-transfer absorptions. Generally, the lowest energy bands of the spectra for Ni(II) complexes are $d \rightarrow \pi^*$ charge-transfer bands which have been extensively studied and characterized in other α-diimine complexes [27].

The 18-membered decaaza macrocyclic nickel(II) complexes undergo intense colour changes due to deprotonation of the macrocyclic ligand in the presence of amine bases such as pyridine and triethylamine. Similar N–H deprotonation reactions have been observed with other metal complexes containing hydrazones linkages [28,29]. For the Ni(II) complex, triethylamine is sufficiently basic for the formation of the molecular complex. The C=N stretching frequency of this compound [Ni ($C_{14}H_{28}N_{10}$)], 1598 cm^{-1}, is reduced significantly from its dicationic precursor, $[Ni(C_{14}H_{30}N_{10})](ClO_4)_2$, 1606 cm^{-1}. The C=N stretching frequencies, together with the change in the electronic bands (lowering of the energy of charge-transfer bands and increased intensity) indicate that the loss of these protons is accompanied by increased delocalization which includes the deporotonated hydrazine linkage.

The deprotonated macrocyclic complexes are very susceptible to ligand dehydrogenation reactions with dioxygen, double bonds being introduced into the six-membered chelate rings [28–35].



XII

The ^1H NMR spectrum of $[Ni(Me_2Me_4[18]aneN_{10})](PF_6)_2$ in nitromethane showed the methyl resonance of the 2,3-butanedihydrazone linkage occurring in the vicinity of 2.0–3.0 ppm (δ) and appearing as a singlet, confirming the symmetrical D_{2h} structure of Scheme 1. There was no observable coupling between the protons of these methyl groups and the N–H protons of the six-membered rings. The $-CH_2$ groups of $[Ni(Me_2Me_4[18]aneN_{10})](ClO_4)_2$ exhibit a triplet in the vicinity of 4.85 ppm due to the coupling with the hydrogen atoms of the adjacent nitrogen atoms. The N–H resonance appears as a broad band near 6.7 ppm, the broad nature of absorption being attributable to the combined effects of the quadrupole moment of nitrogen, rapid exchange of N–H protons, and motion of these protons (resulting from configuration inversion about the nitrogen atom) in the anisotropic magnetic field created by the square-planar coordination environment of the metal ions. The methylene resonances of the amine linkage in $[Ni(Me_2Me_4[18]aneN_{10})](ClO_4)_2$ are also broader than usual and attributable to rapid equilibrium between the conformers depicted below and to the anisotropic nature of the magnetic field of a low spin d^8 system.

4. Conclusions

New square planar decaaza bis (α-diimine) macrocyclic nickel(II) complexes, $[Ni(R_2Me_2[18]aneN_{10})]^{2+}$, can be prepared by the simple metal template condensation of 2 moles of 2,3-butanedihydrazone, 4 moles of CH_2O with 2 moles of amine. The spectra of the complexes show that the four nitrogen (α-diimine) atoms are coordinated to the nickel(II) ion.

Abstract

Mononuclear $(LH_2)[Fe\{HB(pz)_3\}(CN)_3]_2 \cdot 2H_2O \cdot 2MeOH$ (**2**) (L = C-*meso*-3,14-dimethyl-2,6,13, 17-tetraazatricyclo[16.4.0.0^{7,12}] docosane) and two cyano-bridged bimetallic complexes $[\{Fe\{HB(pz)_3\}(CN)_3\}_2Mn(MeOH)_4] \cdot 2MeOH$ (**3**) and $[Mn_2Fe_2\{HB(pz)_3\}_2(CN)_6(4,4'\text{-bipyridine})_2](ClO_4)_2 \cdot 4MeCN$ (**4**) have been prepared and their structures and magnetic properties studied. A crystal structure analysis of complex **2** revealed a hydrogen bonded dimeric structure of two $[Fe\{HB(pz)_3\}(CN)_3]^-$ anions and two water molecules. The structure of **3** consists of a neutral Fe^{III}–Mn^{II}–Fe^{III} molecule and two crystal methanol molecules. The manganese ion is coordinated by two $[Fe\{HB(pz)_3\}(CN)_3]^-$ moieties through cyanide bridging ligands with *trans* geometry, resulting in a linear trinuclear structure. Reaction of the 2,2′-bipyridine ligand with complex **3** resulted in the formation of complex **4**. The crystal structure of **4** consists of a discrete tetranuclear square Fe_2Mn_2 complex, two perchlorate anions and four acetonitrile solvent molecules. The manganese ions are surrounded by two 2.2′-bipyridine ligands and bridged by two $[Fe(tbp)(CN)_3]^-$ moieties through cyanide bridging ligands to form a cyclic tetranuclear structure. The magnetic properties of **3** and **4** are found to be dominated by a weak antiferromagnetic interaction of low-spin Fe^{III} ($S = 1/2$) and high-spin Mn^{II} ($S = 5/2$). The Fe^{III}–Mn^{II} coupling constant J was determined to be −5.90(9) or −7.6(2) cm^{-1} for **3** and −2.29(3) cm^{-1} for **4**.

1. Introduction

Hexacyanide complexes of the first transition metal elements have been used as useful building blocks to synthesize molecular based magnets possessing the Prussian blue structure type [1–5]. Several cyano-bridged three dimensional molecular magnets display their Curie temperature (T_c) above room temperature and may find application in many areas, including memory storage and magneto-optic devices [6–10]. To understand the correlation between crystal structure and molecular magnetism of cyano-bridged molecular magnets, various heterobimetallic systems with different dimensionalities have been extensively investigated by using $[M(CN)_6]^{3-}$ (M = Cr, Mn, Fe), $[Mo(CN)_7]^{4-}$ and $[Mo(CN)_8]^{3-}$ molecular building blocks [11–14]. Furthermore, many research efforts of cyano-bridged clusters has focused on exploring new single-molecule magnets, which possess an energy barrier for magnetic moment reversal due to high spin (S) and negative magnetic anisotropy (D), and exhibit new physical phenomena of magnetic quantum tunneling. Various cyano-bridged polynuclear complexes were prepared by using molecular building blocks such as $[M(CN)_6]^{3-}$ (M = Cr, Fe), $[Mo(CN)]^{3-}$ and *fac*-$[M(L_3)(CN)_3]$ [15–22]. The cyanide-bridged cluster having the highest ground-state spin value ($S = 51/2$) is known to be a $Mn_9^{II}Mo_6^{V}$ cluster which does not exhibit molecular

doi:10.1016/j.poly.2004.02.026

hysteresis and slow relaxation of the magnetization [18], whereas the $Mn_9^{II}W_6^{V}$ cluster ($S = 39/2$) shows some indication of slow relaxation [19]. The well-characterized cyano-bridged single-molecule magnet is the trigonal prismatic cluster $[(Me_3tacn)_2MnCr_6(CN)_{18}]^{2+}$ (Me_3tacn = 1,4,7-trimethyltriazacyclononane), showing temperature dependence in out-of-phase ac susceptibility [23]. In order to expand such a molecular chemistry for magnetic materials, we utilized a new molecular building block, [*fac*-Fe{HB(pz)$_3$}(CN)$_3$]$^-$ {HB(pz)$_3$ = hydrotris(1-pyrazolyl)borate}, and successfully synthesized the trinuclear cyano-bridged complex, $[MnFe_2\{HB(pz)_3\}_2(CN)_6(CH_3OH)_4]$ and the tetranuclear square complex, $[Mn_2Fe_2\{HB(pz)_3\}_2(CN)_6(4,4'\text{-bipyridine})_2](ClO_4)_2$. All the complexes were characterized by X-ray crystallographic analyses and magnetic measurements.

2. Experimental

2.1. Materials and measurements

$(LH_2)Cl_2$ was prepared as described previously [24]. The chemicals were purchased from Aldrich and used without further purification.

Infrared spectra (400–4000 cm^{-1}) were recorded from KBr pellets on a Perkin–Elmer FT-IR spectrometer. Elemental analyses were performed at the Korea Basic Science Institute, Seoul, Korea. Variable temperature (2.0–300 K) magnetic susceptibility measurements were carried out with a Quantum Design MPMS-XL SQUID magnetometer under an applied magnetic field of 1000 Oe. Magnetic data were corrected for diamagnetic contribution of diamagnetic moieties according to Pascal tables.

2.2. Synthesis of K[Fe{HB(pz)$_3$}(CN)$_3$] (1)

The synthetic method used for complex 1 is a modification of a known method [25]. K{HB(pz)$_3$} (126 mg, 0.5 mmol) and KCN (160 mg, 2.5 mmol) in 20 cm^3 of H_2O was added into a solution of $FeCl_3 \cdot 4H_2O$ (100 mg, 0.5 mmol) in 20 cm^3 of methanol. The solution color changed immediately to dark red and a red brown powder was precipitated. After heating at 70 °C for 2 h, the solution was filtered to remove insoluble KCl. An orange powder was collected by filtration from the concentrated solution and recrystallization from methanol–diethyl ether solution gave orange crystals of **1**. Yield: 53%. IR (KBr, cm^{-1}): ν_{CN}, 2129.

2.3. Synthesis of (LH_2)[Fe{HB(pz)$_3$}(CN)$_3$]$_2 \cdot 2H_2O \cdot$ 2MeOH (2)

To a solution of $(LH_2)Cl_2$ (L = C-*meso*-3,14-dimethyl-2,6,13,17-tetraazatricyclo[16.4.0.0^{7,12}]docosane) (50 mg, 0.1 mmol) in 10 cm^3 of water, was added K[Fe{HB(pz)$_3$}(CN)$_3$] (85 mg, 0.2 mmol) in 20 cm^3 of water–methanol mixed solvents. An orange solid was formed immediately. The reaction mixture was stirred for 1 h at ambient temperature. The orange solid was collected by filtration and recrystallized from MeOH–Et_2O solution. Analytically pure crystals were obtained by slow diffusion of diethyl ether into a methanol solution. Yield: 60%. *Anal.* Calc. for $C_{46}H_{72}B_2Fe_2N_{22}O_4$: C, 48.9; H, 6.4; N, 27.3. Found: C, 48.4; H, 6.6; N, 27.6%. IR (KBr, cm^{-1}): ν_{CN}, 2122.

2.4. Synthesis of {Fe{HB(pz)$_3$}(CN)$_3$}$_2$Mn(MeOH)$_4$] · 2MeOH (3)

To a slurry of $MnBr_2 \cdot 4H_2O$ (130 mg, 0.45 mmol) and $KClO_4$ (104 mg, 0.75 mmol) in 10 cm^3 of water, was added K[Fe{HB(pz)$_3$}(CN)$_3$] (60 mg, 0.15 mmol). The reaction mixture was stirred for 30 min at ambient temperature. A dark red crystalline powder was collected by filtration and dissolved in a small amount of methanol solvent. Analytically pure red crystals were obtained by slow diffusion of diethyl ether into methanol solution. Yield: 78%. *Anal.* Calc. for $C_{30}H_{44}B_2Fe_2MnN_{18}O_6$: C, 38.3; H, 4.7; N, 26.8. Found: C, 38.1; H, 4.7; N, 26.4%. IR (KBr, cm^{-1}): ν_{CN}, 2128, 2151.

2.5. Synthesis of [Mn$_2$Fe$_2${HB(pz)$_3$}$_2$(CN)$_6$ (4,4′-bipyridine)$_2$](ClO$_4$)$_2$ · 4MeCN (4)

To a solution of [{Fe{HB(pz)$_3$}(CN)$_3$}$_2$Mn(HOMe)$_4$] (**3**) (220 mg, 0.2 mmol) in 100 cm^3 of MeOH, was added $[Mn(2,2'\text{-bipy})_2(H_2O)_2](ClO_4)_2$ (240 mg, 0.4 mmol) in 20 cm^3 of MeOH. The resulting deep red solution was stirred for 1 h and treated with Et_2O to result in precipitation. Analytically pure dark red crystals were obtained after recrystallization from MeCN–Et_2O solution. Yield: 34%. *Anal.* Calc. for $C_{64}H_{52}B_2Cl_2Fe_2Mn_2N_{26}O_8$: C, 47.2; H, 3.2; N, 22.4. Found: C, 47.4; H, 3.3; N, 22.7%. IR (KBr, cm^{-1}): ν_{CN}, 2148.

2.6. Crystallography

The data collections were performed on an Enraf-Nonius CAD4 diffractometer (complexes **2** and **3**) and a Bruker SMART CCD diffractometer (complex **4**) with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The structures of the compounds were solved by direct methods and refined by the full-matrix least-squares method on all F^2 data using SHELX-97 [26]. The anisotropic thermal parameters for all non-hydrogen atoms were included in the refinements. All hydrogen atoms bonded to carbon atoms were included in calculated positions. The C–H bond distances were fixed and the U values were assigned based approxi-

mately on the U value of the attached atom. The crystal and refinement data are summarized in Table 1.

3. Results and discussion

The cyanide stretching frequency of **2** is slightly shifted to lower energy compared to that of **1** because of hydrogen bonding interactions between the cyanides and water molecules. For **3** and **4**, a CN stretching band is shifted to a higher wavenumber, suggesting formation of CN^- bridges, as observed in other cyanide bridged transition metal complexes.

3.1. Description of the structures

The crystal structure of **2** consists of one LH_2^{2+} cation, two $[Fe\{HB(pz)_3\}(CN)_3]^-$ anions, two water molecules and two methanol molecules. Two $[Fe\{HB(pz)_3\}(CN)_3]^-$ anions are linked by hydrogen bonds between cyanide ligands and water molecules, as displayed in Fig. 1. The geometry of the $[Fe\{HB(pz)_3\}(CN)_3]^-$ anion is not quite the same as the structure analyzed for the PPh_4^+ salt of the $[Fe\{HB(pz)_3\}(CN)_3]^-$ anion [25]. The Fe^{III} ion of the $[Fe\{HB(pz)_3\}(CN)_3]^-$ anion is coordinated by one $HB(pz)_3^-$ anion and three cyanide anions with octahedral geometry. The values of the three Fe–C distances are in the very narrow range of 1.923(3)–1.930(3) Å, and these values are somewhat longer than those found in $(PPh_4)[Fe\{HB(pz)_3\}(CN)_3]$ [1.910(6)–1.929(6) Å] [25] and $(PPh_4)[Fe(bipy)(CN)_4]$ [1.87(2)–1.91(2) Å] [27] which have a low spin Fe^{III} ($S = 1/2$) ion. The Fe-N distances are also in a very narrow range of 1.977(2)–1.981(2) Å. The Fe···Fe distance of the hydrogen bonded dimeric unit is 9.172 Å, while the shortest Fe···Fe distance is 7.841 Å. The hydrogen bonded N···O distances are 2.885(4) and 2.905(4) Å and N···H–O angles are 162.1° and 169.1° (see Table 2).

The structure of complex **3** consists of the neutral $[\{Fe\{HB(pz)_3\}(CN)_3\}_2Mn(MeOH)_4]$ molecule and two methanol molecules. The manganese ion is placed in a crystallographic inversion center and coordinated by two $[Fe(tbp)(CN)_3]^-$ moieties through cyanide bridging

ligands with *trans* geometry. The four residual coordination sites of Mn^{II} are occupied by methanol molecules. The arrangement of the trinuclear unit is shown in Fig. 2. The Fe^{III}–C and Fe^{III}–N bond distances are 1.918(3)–1.934(3) and 1.968(2)–1.985(2) Å, respectively, while Mn^{II}–N and Mn^{II}–O bond distances are 2.179(2) and 2.191(2) Å, respectively. The Mn–N–C–Fe structural unit is almost linear with Fe–C–N and Mn–N–C angles of 176.9(3)° and 167.3(2)°, respectively. The Fe···Mn distance is 5.1931(5) Å, which is comparable to the values found in other Fe^{III}–CN–Mn^{II} connectivities [28] (see Table 3).

The crystal structure of **4** consists of a discrete tetranuclear mixed metal complex, two perchlorate anions and four acetonitrile solvent molecules. An ORTEP diagram of complex of **4** is displayed in Fig. 3. The overall structure of the cationic complex can be best described as a tetranuclear square composed of low-spin Fe^{III} ions and high-spin Mn^{II} ions. The $[Fe\{HB(pz)_3\}(CN)_3]^-$ ion coordinates to two adjacent Mn ions with its two linear cyano bridges [C10–N7–Mn1, 161.1(2)°; C11–N8–Mn1 172.0(2)°]. The Mn^{II} ion has a slightly distorted octahedral geometry. The Fe^{III}–C and Fe^{III}–N bond distances are 1.912(3)–1.927(3) and 1.965(2)–1.981(2) Å, respectively, while Mn^{II}–N bond distances are 2.180(3) and 2.291(3) Å. The intramolecular Fe···Mn distances are 5.174(1) and 5.220(1) Å. The intramolecular Fe···Fe and Mn···Mn distances are 7.310(1) and 7.389(1) Å, respectively (see Table 4).

3.2. Magnetic properties

Magnetic susceptibilities for **3** and **4** were measured down to 2.0 K. The resulting plot of $\chi_m T$ versus T for **3** is given in Fig. 4. As shown in the figure, the $\chi_m T$ value is 6.29 cm^3 K mol^{-1} at room temperature and it decreases gradually with lowering temperature to reach 1.3 cm^3 K mol^{-1} at $T = 2$ K. The $\chi_m T = 6.29$ cm^3 K mol^{-1} at 300 K is close to but somewhat larger than the spin-only value of $\chi_m T = 5.13$ cm^3 K mol^{-1} for the uncorrelated three-spin system consisting of two low-spin Fe^{III} ($S = 1/2$) and one high-spin Mn^{II} ($S = 5/2$) with

Symmetry transformations used to generate equivalent atoms (*): $-x+1, -y+1, -z$.

$g = 2.00$. Since the temperature dependence of $\chi_m T$ indicates that Fe^{III} and Mn^{II} ions are coupled antiferromagnetically through cyanide bridges, we expect, within the linear three-spin model [29], the $S_{total} = 3/2$ ground-state spin of the molecule and $\chi_m T \cong 1.9$ cm^3 K mol^{-1} for $g = 2.0$ at $T = 2$ K, which is in good agreement with the experimental result $\chi_m T \cong 1.3$ cm^3 K mol^{-1} at $T = 2$ K. Thus, we include the exchange interactions in the spin Hamiltonian as $H = -2J(S_{Fe1} \cdot S_{Mn} + S_{Fe2} \cdot S_{Mn})$ and fit the magnetization data of **3**. The solid and dashed curves in Fig. 4 are the fitting results using the model Hamiltonian and the following two parameter sets: $J = -5.90(9)$ cm^{-1}, $g_{Fe} = 2.83(3)$, $g_{Mn} = 2.12(1)$ (solid line in Fig. 4) or $J = -7.6(2)$ cm^{-1} and $g_{Fe} = g_{Mn} = 2.22(1)$ (dashed line in Fig. 4). Both curves agree with the experimental results reasonably well.

Shown in Fig. 5 is the plot of $\chi_m T$ versus T for **4**. Overall, the temperature dependence of $\chi_m T$ is similar to that of **3**, whereby $\chi_m T$ gradually decreases with lowering temperature and reaches 3.23 cm^3 K mol^{-1} at $T = 2$ K. This similar behavior is rather surprising, in particular due to the small value of $\chi_m T$ at low temperatures. Suppose, as we did for **3**, that Fe^{III} is in the low-spin state ($S = 1/2$) and Mn^{II} is in the high-spin state ($S = 5/2$) for **4**. Then the $\chi_m T = 10.61$ cm^3 K mol^{-1} at 300 K is reasonably close to the spin-only

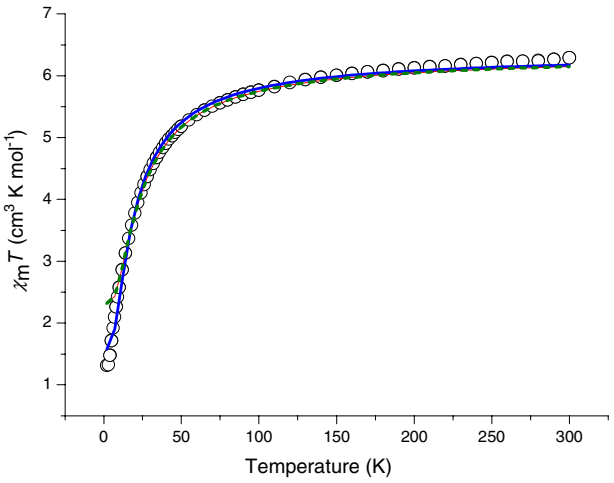

Fig. 4. The plot of $\chi_m T$ vs. T for **3**. The solid line and dashed line represent the best fit of the data. The dashed line is not visible clearly since it almost overlaps with the solid line.

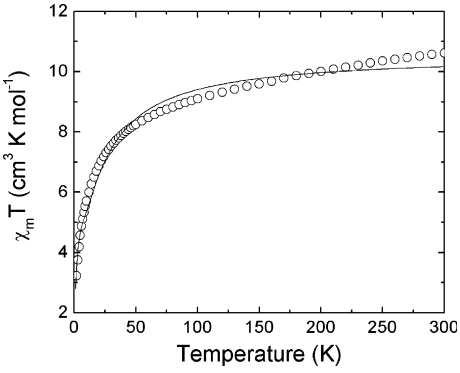

Fig. 5. The plot of $\chi_m T$ vs. T for **4**. The solid line represents the best fit of the data.

value $\chi_m T = 9.50$ cm^3 K mol^{-1} for uncorrelated two low-spin Fe^{III} ($S = 1/2$) and two high-spin Mn^{II} ($S = 5/2$) with $g = 2.00$. However, if only the antiferromagnetic interactions between Fe^{III} and Mn^{II} ions are considered, the ground-state spin is $S_{total} = 4$ and $\chi_m T \cong 10$ cm^3 K mol^{-1} for $g = 2.0$ at $T = 2$ K, which is much larger than the experimental value $\chi_m T \cong 3.23$ cm^3 K mol^{-1} at $T = 2$ K. Thus, in order to find a reasonable model to fit the magnetization data of **4**, we include the exchange interactions between the same kind of ions as well as between different kinds of ions in the spin Hamiltonian, as $H = -2J_1(S_{Fe1} \cdot S_{Mn1} + S_{Fe1} \cdot S_{Mn2} + S_{Fe2} \cdot S_{Mn1} + S_{Fe2} \cdot S_{Mn2}) - 2J_2 S_{Mn1} \cdot S_{Mn2} - 2J_3 S_{Fe1} \cdot S_{Fe2}$. The solid curve in Fig. 5 is the fitting result using the model Hamiltonian and the parameters: $J_1 = -2.29(3)$ cm^{-1}, $J_2 = -0.76(1)$ cm^{-1}, $|J_3| < 10^{-4}$ cm^{-1}, $g_{Fe} = g_{Mn} = 2.10(1)$. Although the model Hamiltonian fits the experimental results reasonably, no strong argument on the antiferromagnetic interaction between Mn^{II} and Mn^{II} ions can be attached at the moment. However, it should be noted that the low-spin state of Fe^{III} and the high-spin state of Mn^{II} are still valid for **4** since, as it has been mentioned previously, the $\chi_m T$ value at room temperature is reasonably close to the spin-only value for uncorrelated two low-spin Fe^{III} ($S = 1/2$) and two high-spin Mn^{II} ($S = 5/2$) with $g = 2.00$.

4. Supplementary material

X-ray crystallographic files, in CIF format, for the structure determination of **2**, **3** and **4** are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 210062, 210061 and 210060, respectively.

The origin of optical activity in complexes of the type [Co(diimine)$_2$carbohydrate]$^{2+}$

José Parada *, Guillermo Larrazábal

Departamento de Química Inorgánica y Analítica, Facultad de Ciencias Químicas y Farmacéutica, Universidad de Chile, Casilla 233, Santiago, Chile

Abstract

Complexes of the type Δ- and Λ-[Co(diimine)$_2$carbohydrate]$^{2+}$ were synthesized with the diimines: 1,10-phenanthroline and 2,2′-bipyridine and with the carbohydrates: aminosugars, hexoses, pentoses and sucrose, with the aim of finding out which are the determining factors of the resultant chirality in these compounds. The optical characteristics of the complexes obtained were determined through measurement of their absorption and circular dichroism spectra. All the complexes synthesized exhibited an excitonic effect in the UV spectral region. Assignment of the circular dichroism bands in the visible could be performed by applying ligand field theory treatment and assuming a D_2 local symmetry to the optically active bands in the region of the d–d* absorption bands corresponding to the $^1A_1 \rightarrow {}^1B_2$ and $^1A_1 \rightarrow {}^1B_3$ transitions. Rotatory strength of these bands can be ascribed to coupling of the magnetic moments of the d–d* bands with the electric moments of the $\pi \rightarrow \pi^*$ transitions, polarized along the short axis of the diimine molecules, which turned out to be almost parallel in the Δ- and Λ-[Co(diimine)$_2$carbohydrate]$^{2+}$ complexes.

1. Introduction

Carbohydrates, such as aminosugars: D-glucosamine, D-galactosamine, D-mannosamine; hexoses: D-glucose, D-galactose, D-mannose; pentoses: D- and L-arabinose, D- and L-xylose, D-ribose and sucrose (Scheme 1), react stereoselectively with the species Δ-, Λ-[Co(phen)$_2$Cl$_2$]$^+$ with the exception of D-glucose (Table 1) [1–6]. The products thus obtained are of the type Δ- and Λ-[Co(phen)$_2$carbohydrate]$^{2+}$, where the carbohydrate behaves as a bidentate ligand and is monodeprotonated. The chiral preference in the formation of these compounds may be caused by different structural factors, such as: interatomic distances, bonding angles, etc., leading to differences in the steric interactions of the diastereomers as a result of bigger or smaller distances of the carbohydrate to the phenanthroline molecules in the coordination sphere (Fig. 1) [1–6]. The degree of stereoselectivity, though, does not change on replacing the phenanthroline ligands bipyridine (Scheme 2), in order to obtain compounds of the type Δ- and Λ-[Co(bipy)$_2$carbohydrate]$^{2+}$. Results appearing in Table 2 [1] show that the higher degree of flexibility of the bipyridine molecule, compared to that of the phenanthroline, has no influence on the chiral preference in the process of formation of these complexes.

The monosaccharides, which adopt mainly the anomeric forms α or β, coordinate to the metallic ion through the ligand groups O^--1 and NH_2 or OH-2, adopting an axial, equatorial disposition or viceversa (Fig. 1) [1–5]. The coordinated anomer has one of the chair conformations: $^4C_1$ or $^1C_4$, slightly distorted, [7–9] compared to that of the free monosaccharide in water solution. On the other hand, coordination of the anomer (α or β) is independent of the nature of the aromatic diimine, thus coinciding with the independence of stereoselectivity with the nature of these ligands. Sucrose coordinates as a bidentate ligand,

through the O^--2 fragment of glucopyranose and through OH-1 of fructofuranose [6]. Conformation of coordinated sucrose does not change significantly compared to that of this ligand in its crystalline form [6].

The higher coordinating power of the amino group in the aminosugars [10] does not exert influence on the chiral preference nor on the degree of stereoselectivity of the resulting complexes [1]. In relation with this point, the complexes with aminosugars, as well as those with hexoses reach a higher degree of product with absolute configuration Δ during the synthetic process (Table 1). Besides, when the CH_2OH group in the position 5 of the hexopyranoses and of the aminohexopyranoses (Scheme 1) is replaced by an hydrogen atom, thus turning into a pentopyranose (Scheme 1), this last confers higher flexibility and higher entropy to the coordinated carbohydrate on both diastereomers [7–9], and the degree of chiral preference lowers (Table 1).

In complexes of the same type with the aminoalcohol "ephedrine", which shows a higher degree of flexibility than the carbohydrates, the products obtained do not show chiral preference [11]. Considering the evidence previously mentioned it is possible to correlate the "rigidity" [7–9] of the ligand with the degree of chiral preference in the systems here studied. Additionally, a direct relationship is observed between the size of the carbohydrate (Scheme 1) and the chiral preference. In this way,

sucrose, which has a bigger size than the remaining carbohydrates here studied, can enter into the coordination sphere of the complexes Δ- and Λ-[Co(phen)$_2$Cl$_2$]$^+$ with a minimum steric hindrance for the diastereomer of Δ configuration, which is formed exclusively [7]. From the previously mentioned evidence, it is possible to correlate the degree of stereoselectivity in the process of formation of the complexes Δ- and Λ-[Co(phen)$_2$carbohydrate]$^{2+}$ with both the rigidity of the ligand molecule and their relative size, according to the sequence [1]

sucrose > aminosugars ≈ hexopyranoses

> pentopyranoses.

This work covers also the study of the absorption and circular dichroism spectra of the complexes in terms of the "ligand-field" [12,13] and "perturbation" theories [14] in order to discover the origin of the optical activity in the visible spectral region.

2. Experimental

2.1. Synthesis of the bis-(diimine)(carbohydrate) Co(III) complexes

All the reagents and solvents used were p.a. and were used without further purification.

The complexes here synthesized, of the type bis-(diimine)(carbohydrate) cobalt(III), were prepared from complex salts of the general formula *cis*-[Co(diimine)$_2$Cl$_2$]Cl which, in turn, were obtained by the technique described by Ablov [15], to obtain *cis*-[Co(phen)$_2$Cl$_2$]Cl. This last compound, in our case, is the "precursor" complex. The same method was applied to obtain the precursor complex with 2,2′-bipyridine.

The compounds formed by Co(III), a carbohydrate molecule, and the previously mentioned diimines were obtained according to the following general procedure: 1 mmol of [Co(diimine)$_2$Cl$_2$]Cl and 2 mmol of a carbohydrate were mixed in 40 ml of water and the pH of the solution was adjusted to 8, with 0.1 M NaOH. The total volume was completed to 50 ml in a volumetric flask that was then sealed and introduced into a thermoregulated Haake K-F3 Model bath, where it was kept for one week at 25 °C. During that period the pH of the solution and its optical activity were controlled at intervals of 2 h in a Jobin Yvon CD-6 spectropolarimeter.

Once the maximum value of the optical activity was reached, the solution was transferred to an SP-Sephadex C25 chromatographic column (1 m long and 2 cm diameter) maintaining a speed of elution of 3 ml/min. The eluant used was NaCl in water in a gradient of 0.05–0.1 M concentrations. The fractions were gathered in an automatic collector (Advance SF-2120) and their circular dichroism and absorption spectra were recorded both in the visible as in the ultraviolet regions. The fractions showing the same sequence of optical activity signals were mixed in order to know the amount of complex through the concentration of cobalt. The fractions corresponding to the complexes of general formula Δ- and Λ-[Co(diimine)$_2$carbohydrate]$^{2+}$ showed a brownish colour in the case of the aminosugars and a red colour in the complexes formed by the hexoses, pentoses and sucrose. In all these cases, yellow coloured products remained at the top of the column. They could be eluted with an NaCl 0.5 M solution. They corresponded to a racemic product, the complex [Co(diimine)$_3$]$^{3+}$ [16].

The complexes of Δ and Λ configuration, once isolated chromatographically, were precipitated with 0.1 M KI_3 as complex salts of this anion.

The solid products obtained were suspended in water and sonnicated, so as to remove the NaCl salt, that coprecipitated with the complex in the presence of the triiodide anion. The composition of the salts obtained was known through elemental analysis (Table 3). The compounds which do not appear in the table were only studied in solution.

2.2. Spectral measurements

Optical rotation measurements were performed in a Perkin–Elmer 141 spectropolarimeter, at 475 and 550 nm wavelength, at 25 °C in cells of 1 and 5 cm width.

The circular dichroism spectra were obtained in a Jobin Yvon CD-6 spectropolarimeter with 10^{-3}–10^{-4} M solutions of the complexes in the visible and 10^{-5}–10^{-6} M solutions in the ultraviolet spectral region, in quartz cells 0.1, 0.5 and 1 cm widths, in such a way as to have a maximum absorbance not greater than 0.8 absorbance units. Measurements of the absorption spectra were carried out in the same way as was described for the measurement of the circular dichroism, in the Jobin Yvon CD-6 and Unicam UV3 spectrophotometers, both in the visible and in the ultraviolet regions.

The cobalt content of the complexes in the solutions as in the solid compounds was found out by atomic absorption spectroscopy, with a Perkin–Elmer 1100B spectrophotometer.

Elemental analysis of C, H and N on the compounds synthesized were performed on a Fisons-Carlo Erba EA 1108 micro-analyzer.

3. Results and discussion

All of the Co(III) compounds formed by two molecules of an aromatic diimine and a carbohydrate, be it an aminosugar, an aldose (hexoses, pentoses) or sucrose, exhibit only one absorption band in the visible region (Fig. 2 and Tables 4–6) [1–6]. It is located in the region of 480–519 nm, corresponding to the $^1T_{1g}$ state in octahedral symmetry. This spectral range of absorption coincides with the expected one, according to the average field rule of the ligands [12,13,17,18], indicating, thus, that coordination of the aminosugar occurs through the NH_2 and OH groups. The remaining carbohydrates coordinate through two OH groups. On comparing the location of the $^1T_{1g}$ state of the complexes with aminosugars with that of complexes formed by the corresponding carbohydrates, it can be observed that the positions of the absorption band maxima are shifted ~30 nm towards shorter wavelength (Fig. 2).

The energy level scheme included is a qualitative one and shows the sequence for octahedral (O_h) complexes of Co(III) and the resulting levels produced by rhombic distortion, assuming that they turn out to be orthoaxial, with holohedrized symmetry D_2 [16,24] (see Scheme 3). In regular octahedral complexes the Cartesian orbitals are split by symmetry in the e_g "class" that gives origin to σ bonds and the t_{2g} "class"

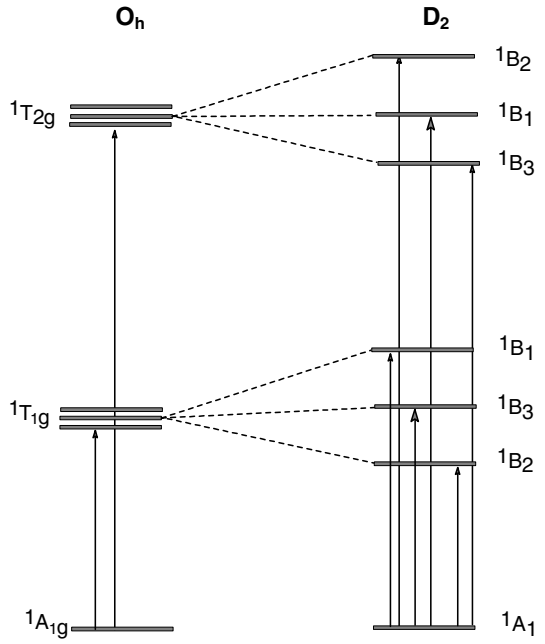
[a] The carbohydrates are: D-galactose, D-mannose, D-, L-arabinose, L-xylose and D-ribose.

that forms π bonds. This classification can be applied to a Cartesian system of coordinates whose origin is placed at the nucleus of the central ion, in such a way that the axis addresses through the nuclei of the ligands. The chromophores that belong to this class are named orthoaxial. Holohedrized symmetry has been applied to such a structure where any interaction that takes place along the x, y and z axes is divided in halfs: one half addresses through $-x, -y, -z$, while the other half does it through x, y and z [16a,24]. On lowering the symmetry, three energy levels: $^1B_1$, $^1B_2$ and $^1B_3$ are expected for each singlet state of Co(III). Table 7 shows the three energy levels originating from the $^1T_{1g}$ and $^1T_{2g}$ octahedral levels on applying crystal field calculations [12,13]. The energy differences between these levels are small and the observed spectral absorption band covers the three separate bands. The circular dichroism spectra, though, show two bands in this region.

Calculations of the rotatory strength based on the perturbation theory and considering D_2 symmetry show that only two out of the three transitions are optically active and of opposite signs. These last correspond to transitions between the fundamental, $^1A_1$ state to the $^1B_2$ and $^1B_3$ excited states.

These results coincide with the experimental evidence showing two circular dichroism signs in the region of the $^1T_{1g}$ state for each one of the complexes studied (Fig. 3).

Optical activity of the d–d transitions in the complexes Δ- and Λ-[Co(diimine)$_2$carbohydrate]$^{2+}$ may rise



Scheme 3.

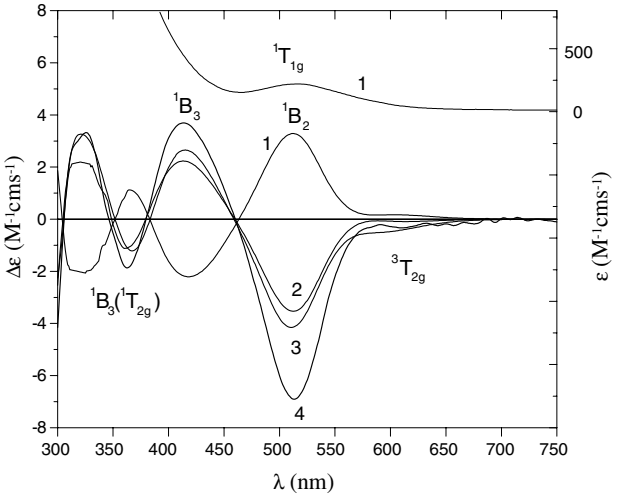


Fig. 3. Absorption and circular dichroism spectra in the visible region of complexes Δ- and Λ-[Co(phen)$_2$carbohydrate]$^{2+}$: (1) Λ-[Co(phen)$_2$D-arabinose]$^{2+}$, (2) Δ-[Co(phen)$_2$D-galactose]$^{2+}$, (3) Δ-[Co(phen)$_2$D-arabinose]$^{2+}$, (4) Δ-[Co(phen)$_2$sucrose]$^{2+}$.

as the result of coupling of the magnetic moments in these transitions (m^*_{dd}) with the electric moments of the π–π* transitions of the diimines (α band), that are polarized along the short axis of the diimine molecule ($\mu^*_{\pi\pi}$), both of which turn out to be parallel in all of the obtained compounds [14,19,20] and their rotatory strengths are of opposite signs.

Calculations of the energy levels of the complexes [Co(diimine)$_2$carbohydrate]$^{2+}$ having origin in the $^1T_{1g}$ state once split by rhombic distortion (D_2) (Table 7) give an average value of $Dq^{O^-} = 2033$ cm^{-1}, corresponding to the splitting of the energy levels produced by the alcoxide group.

The calculated value for Dq^{O^-} is similar to that of other Co(III) complexes, where the donor group is also O^-, as is the case for the oxalate or carbonate ions [17,21–24].

Regarding the absorption and circular dichroism bands in the zone of the d–d* transitions, the calculated energy level values for the Dq^{OH} parameter show an average of 2118 cm^{-1} for the complexes [Co(diimine)$_2$carbohydrate]$^{2+}$, (carbohydrate: hexoses, pentoses and sucrose). This value is also similar to those obtained for other Co(III) complexes with ligands coordinated through O^- and OH, as is the case with H_2O [17,21–24]. Results indicate that the carbohydrates as ligands coordinate through the O^- bonded to the carbon atoms 1 or 3 and through the NH_2 group bonded to the carbon atom 2 in the complexes with aminosugars. In complexes with sugars coordination is established through two OH groups, one of which is deprotonated.

Values obtained for B (Racah parameter) of d–d* transitions related to interelectronic repulsions (Table 8) are placed in the range of ~500 cm^{-1}. This value is in the order of magnitude of those calculated for other [CoN_5O_1] and [CoN_4O_2] systems [12,13]. It is generally

Table 7
Energies of transitions from the fundamental state $^1A_1$ to the excited state $^1B_1$, $^1B_2$ and $^1B_3$ (rhombic symmetry, D_2) for both $^1T_{1g}$ and $^1T_{2g}$ states

[Co(diimine)$_2$carbohydrate]$^{2+d}$	16584	19432	27950	532	3552

[a] The energy values, cm^{-1}, correspond to the average of the experimental values, both for complexes with aminosugars as for those with sugars, standard deviation: 110 cm^{-1}.
[b] Diimines corresponds to 1,10-phenanthroline and 2,2′-bipyridine.
[c] Aminosugars are: D-glucosamine, D-galactosamine and D-mannosamine.
[d] Carbohydrates are: D-glucose, D-galactose, D-mannose, D-, L-arabinose, D-, L-xylose, D-ribose and sucrose.

considered that the Racah parameter C (Table 8) reflects the radial expansion of the d orbitals in complexes [12,13]. Values of 3866 cm^{-1} were obtained for complexes with aminosugars and of: 3673, 3689 and 3682 cm^{-1} for complexes with hexoses, pentoses and sucrose, respectively.

Comparison of the values 3873 cm^{-1} for $[Co(NH_3)_4C_2O_4]^+$ and 3720 cm^{-1} for $[Co(NH_3)_4CO_3]^+$ [12,13,25] shows that expansion by delocalization towards the ligands via π system is relatively unimportant in these cases.

In the present work the absolute configurations Δ and Λ of complexes [Co(diimine)$_2$carbohydrate]$^{2+}$ were identified by their circular dichroism spectra, according to the sign sequence of the "excitonic" effect [18] of the $\pi \rightarrow \pi^*$ transition at ~270 nm for compounds with phenanthroline and of ~300 nm for complexes with 2,2′-bipyridine (p band) [16], in the complexes having two diimine molecules as ligands (Fig. 4, Tables 4–6). The "excitonic" effect [18] consists of the presence of two

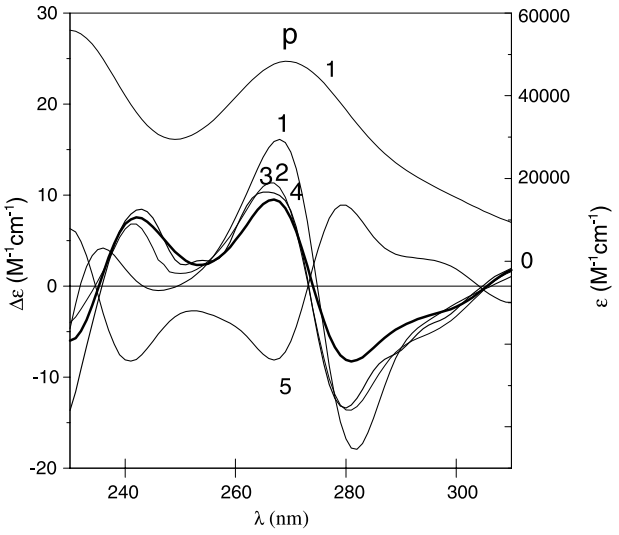

Fig. 4. Absorption and circular dichroism spectra in the UV region of complexes Δ-[Co(phen)$_2$carbohydrate]$^{2+}$: (1) D-mannosamine, (2) sucrose [6], (3) D-galactose [5], (4) D-arabinose [5] and (5) Λ-[Co(phen)$_2$D-arabinose]$^{2+}$ [5].

circular dichroism bands of opposite signs under the p absorption band, as a result of electrostatic coupling of the dipolar moments of the electric transitions in the individual diimine ligand molecules in these type of complexes. Besides the previously mentioned signals, a circular dichroism band is observed in the UV region, localized in the range of 241–243 nm (β band), that should correspond to a transition polarized along the major axis of the diimine molecule and calculated by self consistent field [13] to be at 260 nm. The corresponding absorption band is generally masked. The band of phenanthroline appears as a shoulder at ~320 nm in the absorption spectrum and gives a neat circular dichroism band at this wavelength (Fig. 3).

This last band is overlapped by the "p" band in the absorption spectra of the complexes [Co(bipy)$_2$carbohydrate]$^{2+}$. In the circular dichroism spectra, though, it can be observed at ~340 nm (Tables 4–6).

Correlation among the circular dichroism spectra in the visible region and configuration around Co(III) in the *tris*-chelate complexes is based on the location of the $^1A_2$ and ^1E states in D_3 symmetry (or $^1B_1$, $^1B_2$ and $^1B_3$ in the systems of D_2 symmetry), corresponding to the first excited state [14,19]. It has been found that the transition of ^1E symmetry shows a positive circular dichroism signal, whereas, in that of $^1A_2$ symmetry, the signal is negative when the complex has a Λ configuration (the signs will be the apposite ones for a complex of Δ configuration). It has to be born in mind also that the signal corresponding to the ^1E transition is always more intense than that of the $^1A_2$ transition, making it possible to identify them in the corresponding spectrum [17,21–24]. In the complexes of the type [Co(diimine)$_2$AB], where AB is a bidentate ligand, one of the components of the first excited state, the one deriving from the ^1E state in D_3 symmetry ($^1B_2$ under D_2 symmetry), dominates the circular dichroism spectrum. This is the one responsible for the positive or negative Cotton effect in the circular dichroism curve in the visible region, and is correlated with the absolute configuration of the *tris*-chelate Co(III) complex [1,18,21–24].

In all of the circular dichroism spectra examined, whose configuration has been known through the exci-

tonic effect, it can be seen that the first signal in the visible spectra is located at 502–513 nm. This is the band showing higher rotatory strength (higher $\Delta\varepsilon$) and has a negative sign in the complexes of Δ configuration and a positive sign for those of Λ configuration (Fig. 3 and Tables 4–6). This band corresponds to the $^1A_1 \rightarrow {}^1B_2$ transition under D_2 symmetry, according to the calculated rotatory strength for the complexes [14,19,20]. The band located at 410–415 nm has a lower $\Delta\varepsilon$ value, is of opposite sign to that of the previously mentioned one and it should correspond to the $^1B_3$ state under D_2 symmetry. It was assigned, as it was previously described [14,19,20]. In all of these complexes the states $^1B_3$ and $^1B_2$ in D_2 symmetry (region of the $^1T_{1g}$ state in O_h symmetry) are those that coincide with the sign sequence of the excitonic effect and, consequently, with the absolute configuration of the complexes [13,21]. Under the first absorption band in the visible region, corresponding to the $^1T_{1g}$ state there are two circular dichroism signals of opposite signs (Fig. 3 and Tables 4–6) under the first absorption band in the visible region, corresponding to the $^1T_{1g}$ state. The two circular dichroism signals arise from the partition of the $^1T_{1g}$ state of Co(III) under rhombic distortion, as a result of coordination of two molecules of an aromatic diimine plus one molecule of a carbohydrate around the metallic ion (Table 7) [12,13].

The p and α bands of the aromatic diimine overlap part of the absorption spectrum of Co(III) in all the Δ- and Λ-[Co(diimine)$_2$carbohydrate]$^{2+}$ complexes. Nevertheless, the corresponding circular dichroism spectra reveal a clear signal at ~364 nm. (Fig. 3 and Tables 4–6), that can be assigned to the $^1T_{2g}$ state in octahedral symmetry and, under D_2 symmetry, it would correspond to the transition from the fundamental $^1A_1$ state to the $^1B_3$ excited state [14,19,20]. The transition from the $^1A_1$ to the $^1B_2$ state in this region is expected to show optical activity of opposite sign to that of the $^1B_3$ state. This point could not be checked experimentally, since in the complexes Δ-, Λ-[Co(phen)$_2$carbohydrate]$^{2+}$ (Fig. 3, Tables 6–8) the circular dichroism spectra of these bands are overlapped by the α band, whereas in the complexes Δ- and Λ-[Co(bipyridine)$_2$carbohydrate]$^{2+}$ they are overlapped by the p and α bands (Table 6).

It could be observed also that the $^1A_1 \rightarrow {}^1B_1$ transition is not optically active in these complexes [14,19,20]. This result is in agreement with the number of signals of these compounds in the region of the $^1T_{2g}$ state [1–6].

In the circular dichroism spectra of the Δ and Λ isomers examined, a weak signal appears at the lower energy side of the $^1T_{1g}$ state band, that can be isolated by gaussian analysis: its location and $\Delta\varepsilon$ value lead to associate it to the $^3T_{2g}$ state of Co(III) in the complexes (Fig. 3 and Tables 4–6). Location of this spectral signal coincides with that of spin-forbbiden bands in Co(III) complexes with a similar coordination sphere [17,21].

Summarizing, it is worthwhile to remark the following features for the type of complexes here studied.

The circular dichroism spectra of the complexes show remarkable regularity in the number of spectral bands, sign sequence and intensity of the signals, independently of the nature of the carbohydrate ligands, number of asymmetric centers present in the chiral ligands; distribution of the asymmetric centers (*R* or *S*) of the C atoms bonded to N or O atoms that establish coordination, nor the conformation of the ring around the metallic ion. The same can be said about the different aromatic diimines 1,10-phenanthroline and 2,2′-bipyridine.

The spectra of the complexes here studied make it possible to spot the circular dichroism bands corresponding to singlet–triplet electronic transitions, which are rarely observed.

It is also worthwhile remarking that the carbohydrates as ligands, when bonded to Co(III) and form *tris*-quelate complexes with a particular configuration, make it possible to observe, as few other ligands do, the majority of the electronic transitions of this ion.

Abstract

As an effort to explore new complexes of the 2,3-dicyano-5,6-dimercaptopyrazyne (dcdmp) ligand with different transition metals, different salts containing both the Au(dcdmp)$_2^-$ complex and the new species 2,3,7,8-tetracyano-1,4,6,9-tetraazothianthrene (tctata), were obtained and characterized. *n*-Bu$_4$N Au(dcdmp)$_2$ crystallises in monoclinic space group $C2/c$, $Z = 8$ with unit cell parameters $a = 35.147(4)$, $b = 9.527(1)$, $c = 21.792(2)$ Å and $\beta = 109.626(8)°$. Its crystal structure consist of almost regular columns of [Au(dcdmp)$_2$]$^-$, stacked along b, surrounded by *n*-Bu$_4$N$^+$ cations. *n*-Bu$_4$N AuBr$_2$ (tctata) crystallises in triclinic space group $P\bar{1}$, $Z = 2$, with unit cell parameters $a = 10.986(1)$, $b = 13.230(2)$, $c = 13.791(1)$ Å, $\alpha = 79.150(9)°$, $\beta = 69.663(6)°$, $\gamma = 70.254(9)°$. The crystal packing is made by zig-zag chains of tctata separated by layers of cations, with AuBr$_2$ anions located in alternated cavities between the tctata chains and the cation layers. At last, *n*-Bu$_4$N[Au(dcdmp)$_2$] (tctata) crystallises in monoclinic space group $P2_1/n$, $Z = 4$, with unit cell parameters $a = 10.693(2)$, $b = 40.308(7)$, $c = 10.870(1)$ Å, $\beta = 92.16(1)°$. Its crystal structure can be seen has a mix of those of the two preceding compounds. It consists of bidimensional layers composed of out of registry parallel zig-zag chains of alternating tctata and [Au(dcdmp)$_2$]$^-$ units. The adjacent layers are separated by layers of [*n*Bu$_4$N]$^+$. In the last two compounds the tctata appears as a planar molecule.

1. Introduction

Transition metal bisdithiolene complexes have, since their earlier studies during the sixties, attracted a great interest due to a rich variety of coordination geometry, and vivid redox behaviour [1]. These characteristics made them as choice building blocks for molecular materials displaying unconventional electrical and magnetic properties [2]. One of the key aspects in the versatility of these complexes, making them so attractive in the design of magnetic properties of molecular materials, is that both by change in the transition metal and in the oxidation state they can display different magnetic moments.

Square planar coordination geometry with these ligands is frequently observed in the anionic form with metals of Ni and Cu groups and such complexes have been used as counterions in charge transfer solids with a variety of donors. This planar geometry often favours solid state structures presenting more or less regular staking of the planar units providing chains of extended interactions in the solid, which can give rise to interesting properties such as ferromagnetism [3], metallic conductivity [4] or even superconductivity [5,6].

In these type of complexes both the accessibility to different oxidation states and the magnitude of the solid state interactions is expected to be favoured by ligands with more extended π-systems. While sulfur rich ligands have been extensively explored significantly less effort has been devoted to the study of other extended dithiolene π-ligands containing different heteroatoms like

N and O. These heteroatoms are expected to act also as an extra coordinating site which may provide an additional degree of freedom in crystal engineering of these solids, as recently demonstrated for pyrazinediselenate [7] and pyrazinedithiolate [8] Cu complexes. With the 2,3-dicyano-5,6-dimercaptopyrazyne (dcdmp) ligand the only reported complexes previously to our work are with nickel in the monoanionic form, $Ni(dcdmp)_2^-$ [9] and with it a few charge transfer salts with TTF and other related donors have been also described.

Preliminary data on charge transfer salts of $Au(dcdmp)_2^-$ with TTF type donors were previously reported by us [10]. In this paper we report the synthesis and characterization of the $Au(dcdmp)_2^-$ complex, and we describe two salts containing the new species 2,3,7,8-tetracyano-1,4,6,9-tetraazothianthrene (tctata) obtained as the product of a side reaction between the ligand with its precursor.

2. Experimental

2.1. Synthesis

To a suspension of sodium sulfate monohydrated in acetone (241 mg, 1×10^{-3} mol) was added, under stirring, an acetone solution of 2,3-dichloro-5,6-dicianopyrazine (100 mg, 5.02×10^{-4} mol). The formed red solution was filtered and added to a solution (2 ml) of potassium tetrachloroaurate (95 mg, 2.51×10^{-4} mol) in acetone, turning to a brown mixture. The inorganic precipitate was removed and the liquor added to 1 ml of a solution of tetrabutylammonium bromide (81 mg, 2.51×10^{-4} mol) in acetone, giving rise to an orange-gold solution. The stirring was maintained, in all steps, until no visible modification was observed. This solution was then filtered and allowed to a slow evaporation of the solvent in inert atmosphere. The orange solid obtained was filtered and recrystallised in acetone-diethyl ether, to afford needle shape crystals with three different colours. There are red (**3**) and yellow (**4**) crystals dominating the sample, but some green (**5**) crystals can be found also. In all cases, the crystals were suitable for X-ray diffraction measurements, revealing three different compositions. Visual separation of the crystals afforded the following characterisation data.

3: Tetrabutylammonium salt of gold(III)-bis-5,6-dicyano-2,3-dithiopyrazine, *n*-Bu_4N $Au(dcdmp)_2$, m.p. 258.3–260.5 °C (followed by decomposition). IR (KBr): $\widetilde{V} = 434$ (w, Au–S), 735 (m, CH_2–S–CH_2), 1172 (S, C–N), 1266 (m), 1301 (S), 1455 (m), 1481 (w, C=N–C), 2233 (m, C≡N), 2879–2966 (m, C–H alifat) cm^{-1}. UV–Vis (CH_3CN): $\lambda_{max} = 1413$, 1721, 1911, 2275, 2496 nm. *Anal.* Calc. for CHNS ($C_{28}H_{36}N_9S_4Au$): C, 40.82; H, 4.40; N, 15.30; S, 15.56. Found: C, 42.38; H, 3.70; N, 15.64; S, 15.71%. MS: *m*/*z* (%) 580.9 [M^-] (100) [$C_{12}N_8S_2Au$], 242.3 [M^+] (100) [$C_{16}H_{36}N$].

4: Tetrabutylammonium salt of gold dibromide with 2,3,7,8-tetracyano-1,4,6,9-tetraazothianthrene, *n*-Bu_4N $AuBr_2$ (tctata), m.p. 189.2–191.3 °C (followed by decomposition). IR (KBr): $\widetilde{V} = 428$ (S, Au–Br), 742 (m, CH_2–S–CH_2), 884 (m), 1170 (S, C–N), 1235 (m), 1325 (S), 1381 (m), 1485 (m, C=N–C), 1507 (m), 2240 (w, C≡N), 28877–2966 (m, C–H alifat) cm^{-1}. UV–Vis (CH_3CN): $\lambda_{max} = 1413$, 1721, 1911, 2275, 2496 nm. *Anal.* Calc. for CHNS ($C_{28}H_{36}N_9S_2AuBr_2$): C, 36.57; H, 3.94; N, 13.71; S, 6.97. Found: C, 38.54; H, 3.61; N, 14.04; S, 6.68%. MS: *m*/*z* (%) 288.0 (100) [$C_{12}N_8S^-$], 250.0 (39) [$C_{12}N_7S^-$], 356.8 (28) [$AuBr_2^-$], 197.0 (100) [Au^+], 242.3 (78) [$C_{16}H_{36}N^+$].

5: Tetrabutylammonium salt of gold(III)-bis-5,6-dicyano-2,3-dithiopirazine with 2,3,7,8-tetracyano-1,4,6,9-tetraazothianthrene, *n*-$Bu_4N[Au(dcdmp)_2]$ (tctata): the isolated amount of this compound was not enough to any characterization further than its structure determined by X-ray diffraction.

2.2. X-ray structure determination

The data collection was performed on two different Enraf-Nonius CAD4 diffractometer, one equipped with a graphite monochromatised Mo Kα radiation ($\lambda = 0.71069$ Å) and the other equipped with a graphite monochromatised Cu Kα radiation ($\lambda = 1.54150$ Å), in the $\omega - 2\theta$ scan mode. The structures were solved by direct methods using SIR97 [11] and refined by full-matrix least-squares methods using the program SHELXL97 [12] and the WINGX software package[13]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in idealised positions and allowed to refine riding on the parent C atom. Molecular graphics were prepared using ORTEP3 [14] and SCHAKAL-97 [15]. Crystal data and structure refinement of are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

The synthesis of the gold complex **3** was performed following a standard procedure for the preparation of dithiolates from dichlorides, (Scheme 1) also used to prepare the Ni analogue [9]. The dithiolate ligand (**2**) in solution was obtained from the corresponding chloride salt (**1**) by treatment with Na_2S, in acetone. This ligand, without intermediate isolation was successively reacted with potassium tetrachloroaurate and *n*-Bu_4NBr, also in acetone solutions, followed by slow evaporation of the solvent in inert atmosphere, to give the gold(III) complex that was obtained as a red needle

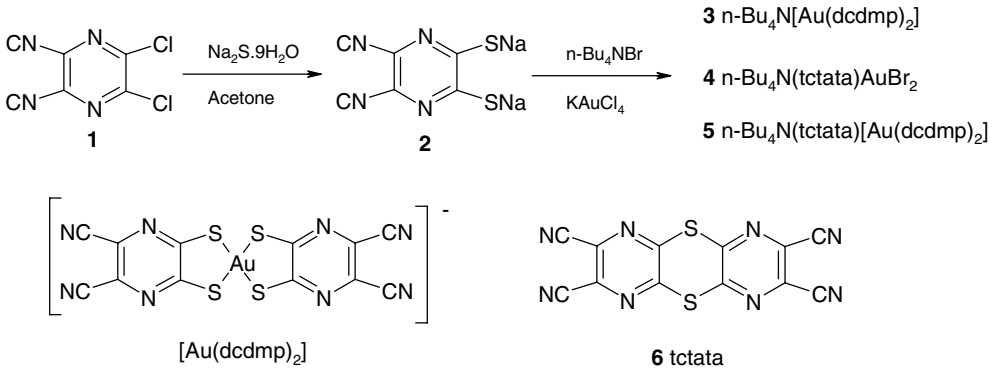
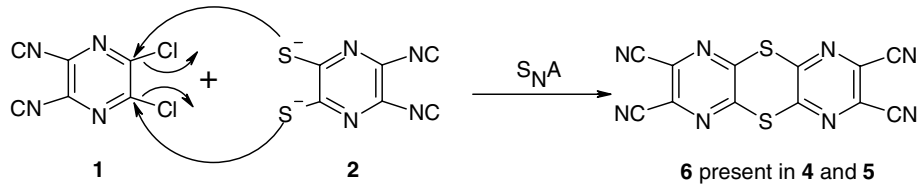


Scheme 1.

shaped crystals. The elemental analysis is consistent with a 1:1 stoichiometry, as confirmed by the X-ray crystal structure determination. Unexpectedly two other different kind of complexes were obtained, *n*-$Bu_4N[Au(dcdmp)_2]$ (tcdpdt) (**4**), as yellow needles and *n*-Bu_4NAuBr_2(tcdpdt) (**5**) as green needle shaped crystals, both containing the new species (tctata) (**6**). The structures of **3**, **4** and **5** were solved by single crystal X-ray diffraction (Scheme 1).

The unprecedented formation of the tetracyanotetraazathianthrene **6** incorporated in the structure of **4** and **5**, can be explained by a side reaction, taking place between the starting dichloride **1** and the dithiolate ligand **2**. The dithiolate acts as a nucleophilic agent, and substitutes the chlorine atoms in the pyrazine ring through an aromatic nucleophilic substitution mechanism which is activated by the cyano groups and further helped by the presence of the nitrogen atoms in the aromatic ring. Both the cyano groups and the nitrogen atoms are electroattractors, enhancing an electronic deficiency on the carbon atoms linked to chlorine (Scheme 2).

This explanation is supported by the fact that the above proposed reaction is similar to that previously



Scheme 2.

used to prepare other thiantrenes [16,18], but wewere not successful in isolating **6** as a pure compound.

Cyclic voltammetry of *n*-$Bu_4NAu(dcdmp)_2$ (**3**) in acetonitrile (Fig. 1, full line) shows a pair of symmetric reversible redox waves at $E_{1/2} = -0.629$ V vs Ag/AgCl ascribed to the couple $Au(dcdmp)_2^{2-}/Au(dcdmp)_2^{-}$. The cyclic voltammetry of **4** in the same conditions (Fig. 1, dashed line) shows three irreversible waves at −0.604, −0.349 and +0.732 V. The last wave is close to the values reported for the reaction $AuBr_2^- \leftrightarrow Au+2Br^-$ [17] but the two first waves are ascribed to tctata.

3.2. Structural characterisation

The crystal quality made possible to solve the crystal structure of compounds **3**, **4** and **5**. The geometry of the $Au(dcdmp)_2^-$ complex in **3** and **5** is identical, with average Au–S bond lengths of 2.307(3) and 2.320(3) Å, respectively (see Table 2). These values are in the upper side of the range of values reported for other gold(III) dithiolates that extend from 2.29 to 2.34 Å, with an average value of 2.305 Å. In both cases the complex is almost planar, with significant non planar deviations

observed only in the terminal cyano groups, which are displaced towards opposite directions giving rise to a very small chair type distortion (Figs. 2 and 3). In both complexes the dcdmp ligands are identical within experimental uncertainty and with a geometry close to that found in the corresponding Ni analogue [9].

The new tetracyanothianthrene tctata species, present in complexes **4** and **5**, has bond lengths and angles identical to the corresponding ones in the dcdmp ligand in the dithiolates and an almost planar geometry in good agreement with that found in the unsubstituted analogue tetraazothiaantrene [18] (Figs. 3 and 4, Table 3). The two tctata molecules in **4**, are identical with an almost planar geometry, with a small twist of the terminal cyano groups, in opposite directions. The angles of the central ring range from 126.1° to 127.9°, in the case of the C=C–S angles, and show the values of 105.6° and 105.9° for the C–S–C angle. In the crystal structure of **5**, the tctata molecule shows a slight deviation from pla-

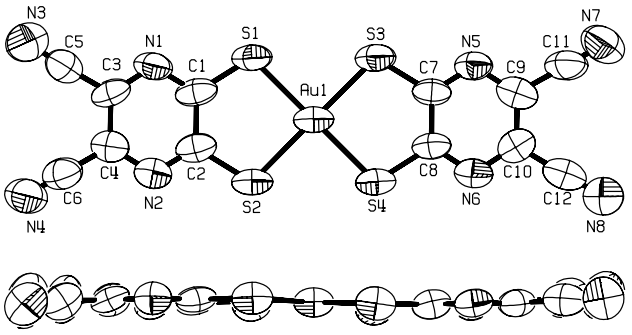

Fig. 2. ORTEP views and atomic numbering scheme of $Au(dcdmp)^{2-}$, in **3**, with thermal ellipsoids at 40% probability.

narity. There is a significant deviation of the sulphur atom, relatively to the average plane of the molecule and therefore the dihedral angle between the two half of the molecule is 174°. The non planarity is also denoted by the central ring bond angles that in the case of C=C–S bonds range from 125.5° to 126.6° while those of the C–S–C bonds are 107.7° and 106.3°. The deviation of the S atoms from the average molecular plane is certainly due to short contacts between these atoms and gold and carbon atoms in neighbouring ditiolate species (see Table 6).

To the best of our knowledge tctata, together with bis(quinoxaline)-2,2′,3,3′-disulfide [19] and 1,4,6,9-tetraazathianthrene [18], are the only azathiaantrenes displaying an essentially planar geometry, while all others present significant molecular dihedral angles ranging from 132° to 143°.

The tetrabutylammonium salt **3**, crystallises in the monoclinic system, space group $C2/c$, $Z = 8$. The unit cell contains one independent $[Au(dcdmp)_2]^-$complex and one independent tetrabutylammonium cation in general positions. The crystal structure consists of columns of $[Au(dcdmp)_2]^-$pairs, stacked along b (Fig. 5). The normal to complex plane makes an angle of 51.6° with this axis. There are two different overlap modes between complexes characterised by a different displacement along their long axis. The distance between the average plane of $[Au(dcdmp)_2]^-$ complexes are almost identical, being 3.49 and 3.47 Å, between and within the pairs of dithiolates, respectively. The stacks of the complexes are completely surrounded by $[n\text{-}Bu_4N]^+$ cations which prevent any contact between neighbouring stacks (Fig. 6).

The adopted overlap mode between stacked complexes at such a short distance corresponds to the existence of several short interatomic contacts (see Table 4),

Au···N6	3.960		1.04
Au···C4	3.965		1.02

Σr_{vdw} = van der Waals radii sum

some clearly below the sum of van der Waals radii (dotted lines in Fig. 5), the shortest one being Au···S1 (3.71 Å). Other interactions are noticed slightly above the sum of van der Waals radii, as Au···Au exceeding by 1% that sum (dashed line in Fig. 5).

The interactions between the dithiolate complexes and the tetrabuthylamonium cations are established though several hydrogen bonds (Fig. 7, Table 4), only one through a pyrazinic nitrogen atom. Clearly the crystal structure of **3** is determined by the short complex interactions through both Au–S and Au–Au contacts and π–π interactions between ligands.

Compound **4** crystallises in the triclinic system, space group $P\bar{1}$, $Z = 2$. The unit cell has two independent units of tctata located at inversion centres, one independent tetrabutylamonium cation and one independent $AuBr_2$ anion. The crystal packing is made by zig-zag chains of tctata, separated by layers of the tetrabutylammonium cations parallel to the *b*, *a*–*c* plane (Fig. 8). The tctata units along the chains are connected by short S···S

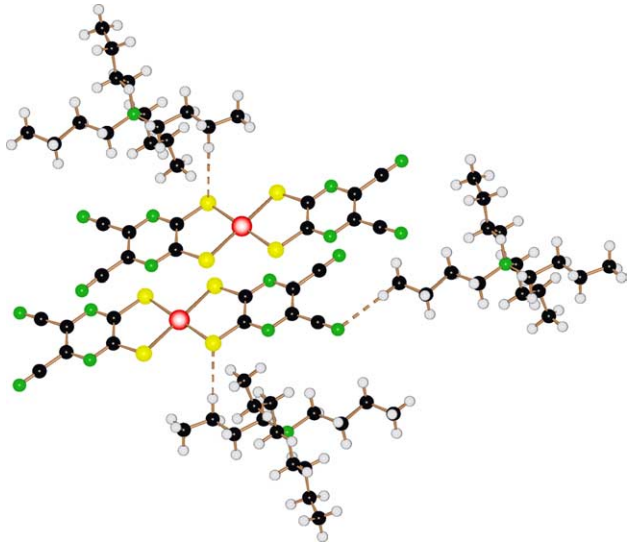

Fig. 7. Hydrogen bonds between the dithiolate anions and neighbouring cations, in the crystal structure of **3**.

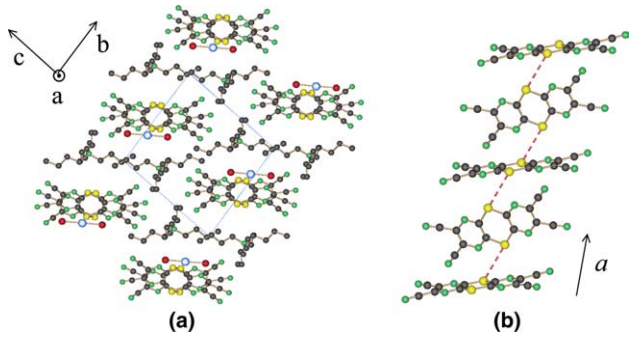

Fig. 8. (a) View of the crystal structure of **4** along *b*. (b) Partial view of the tctata zig-zag chains emphasising the S···S short contact, along the chain.

contacts at 3.586 Å and the angle between the average planes of these species is 76.1°. The $AuBr_2$units, with a linear geometry typical of monoanionic state, are located in alternated cavities between the tctata chains and cationic planes (Fig. 9). There are several short contacts (≈4 Å) between the gold atom and the sulphur atoms of the tctata unit and hydrogen bonds between the Au atom and the surrounding tetrabuthylamonium cations (see Table 5). The interactions between the tctata units and the tetrabuthylamonium cation are made through several hydrogen bonds (Table 5, Fig. 9), none of them involving the pyrazinic nitrogen atoms.

The last salt, **5**, crystallises in the monoclinic system, space group $P2_1/n$, $Z = 4$. The unit cell contains one independent molecule of tctata, one independent tetrabutylamonium cation and one independent $[Au(dcdmp)_2]^-$ complex all located in general in general positions. Its crystal structure can be seen as a combination of those of the two preceding compounds. It consists of bidimensional layers, in the *a*, *c* plane, composed of out of registry parallel zig-zag chains of alternating tctata and $[Au(dcdmp)_2]^-$ units (Fig. 11). The adjacent layers are separated by cation layers $[nBu_4N]^+$, along *b*, (Fig. 10). Several short contacts, within layer, can be noticed. With exception of the S3···S3 interaction between the anions in neighbouring

chains, all short contacts are between different species and involve the sulphur atom of the neutral complex and the carbon atom of the pyrazine ring in the anion. The short contacts along the chain are of the Au···S type and the angle between the units is 62.7° (Fig. 11, Table 6). The neutral tctata and the $Au(dcdmp)_2^-$ anions in the layer are connected with the tetrabutylammonium through C–H···N hydrogen bonds. The nitrogen atoms involved in this interaction, are available both from the anion and the neutral specie (Fig. 12, Table 6), only one trough the pyrazinic N6 atom. The crystal structure of this compound is dominated by strong interactions between tctata and $Au(dcdmp)_2^-$ involving S–S and S–Au contacts as in **3** which determine the formation of layers.

4. Conclusion

In conclusion the $Au(dcdmp)_2$ complex was prepared and the structure of two salts described in detail. Although tetracyanotetraazothianthrene could no be isolated as a pure compound, two salts containing this new thianthrene derivative were obtained. In both cases this thianthrene derivative presents an almost planar geometry.

At variance with other pyrazinediselenate [7] or pyrazinedithiolate [8] salts where the N heteroatom acted as a new coordination centre in these compounds with the dicyanopyrazine ligand no such role is observed. However the pyrazinic ring contributes to electron delocalisation and allows π–π interactions between ligands of different complexes.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited in the Cambridge Crystallographic Data Centre. The deposition numbers are CCDC 222525, CCDC 222526 and CCDC 222527 for compounds **3**, **4** and **5** respectively. Copies of the data can be obtained free of charge upon application to the director of CCDC, 12 Union Road, GB, Cambridge CB12 1EZ. Abstract

We wish to report the synthesis, crystal structures, spectroscopic and electrochemical properties of new Pt(II) heteroleptic complexes with two diimines (2,2′-bipyridine, 4,4′-dimethyl-2,2′-bipyridine), and the crown trithioether 9S3 (1,4,7-trithiacyclononane). In addition, we report the synthesis and spectroscopic properties of three related 9S3/diimine (4,4′-di-*t*-butyl-2,2′-bipyridine, 4,4′-dinonyl-2,2′-bipyridine, 3,4,7,8-tetramethyl-1,10-phenanthroline) complexes as well as an examination of the spectroscopic and electrochemical properties of the reported [Pt(9S3)(1,10-phenanthroline)]$(PF_6)_2$. All complexes have the general formula [Pt(9S3)(N_2)](PF_6) (N_2 = diimine) and form similar structures in which the Pt(II) center is surrounded by a *cis* arrangement of the two N donors from the diimine chelate and two sulfur atoms from the 9S3 ligand. The ^{195}Pt NMR chemical shifts for all six complexes show a value near −3290 ppm, consistent with a *cis*-PtS_2N_2 coordination sphere. The third sulfur in each structure forms a longer interaction with the platinum resulting in an elongated square pyramidal structure. These distances, however, are approximately 0.2 Å longer than with the analogous diphosphine complexes, demonstrating that better π acids, in fact, do not result in shorter Pt–S axial distances as has previously been proposed.

Keywords: Thioether complexes; Platinum complexes; Trithiacyclononane; Platinum nuclear magnetic resonance; Diimine complexes; Crown thioethers

1. Introduction

Over the past 10 years several research groups have examined the coordination chemistry of crown thioether ligands, such as 1,4,7-trithiacyclononane (9S3), in a number of areas including transition metal complexes, main group compounds, and organometallic complexes [1–6]. A key metal ion in thiacrown coordination chemistry is platinum(II) due to the high stability of Pt–S bonds, the relevance of this type of bond in catalysis, and the physicochemical properties exhibited by complexes with platinum group metals [7–11]. An interesting and unusual structural feature in 9S3/Pt(II) complexes is the presence of longer distance Pt–S interactions between the metal and axial sulfur atoms in the coordinated thioether macrocycle. Two equatorial Pt–S bonds in the coordinated 9S3 are observed close to the expected range of 2.2–2.4 Å, but there are longer axial

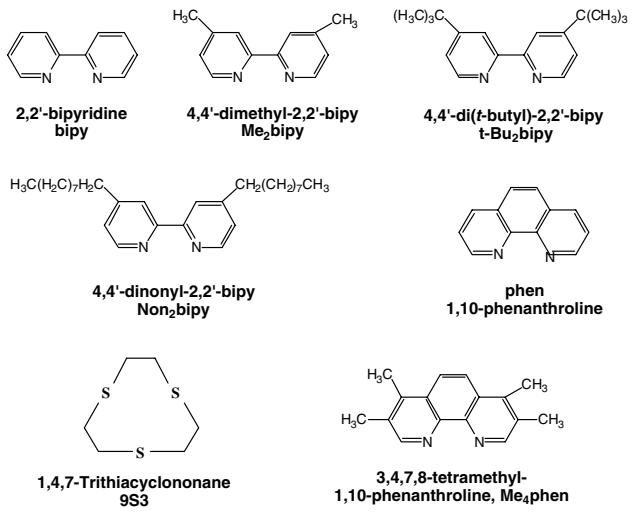
doi:10.1016/j.poly.2004.02.023

interactions present which show a great variation in distance, ranging anywhere between 2.6 and 3.3 Å. The long distance interactions result in Pt(II) structures best described as elongated square pyramids [$S_4 + S_1$ coordination] [7] or elongated octahedra [$S_4 + S_2$ coordination] [9,11]. The Pt–S axial interactions alter the electrochemical and spectroscopic properties of the platinum(II) ion and are of theoretical interest as they possibly contain a weak attractive component [12]. Indeed, all of the observed Pt–S axial distances fall between the covalent bond distance and the sum of the Van der Waals radii for a platinum(II)–sulfur interaction [13]. [2] The anomalous behavior of crown thioether complexes of Pt(II) and related metal ions results from their unusual long distance interactions [14].

There is current interest in platinum(II) complexes involving long distance interactions such as these because they can serve as models for transition states of associative substitution reactions involving d^8 metal ions [15]. Recent reports by our group and others have extended work to include heteroleptic 9S3 platinum(II) complexes ($[Pt(9S3)(L)]^{2+}$), and it is observed that the Pt–S axial interaction is highly dependent upon the nature of the ancillary ligand (L) [16–24]. When the initial observations of the phenomena were made, it was proposed that the platinum–axial sulfur distance was controlled by the π-acceptor ability of the ancillary ligand [15,16]. The hypothesis was that the Pt d_{xz} and d_{yz} orbitals would function as donor orbitals, and electron density would be transferred via back bonding into the π^* orbitals on the ancillary ligand. Accordingly, the increasing positive charge on the metal would then draw the axial sulfur closer to it through electrostatic interactions. In order to examine this hypothesis more fully, we undertook the current study of a series of complexes with diimine ligands such as 2,2-bipyridine (bipy), a class of ligands well known to be excellent π acceptors. We have reported a recent series of papers involving 9S3/Pt(II) complexes with a variety of diphosphine ligands as the ancillary ligand [21–24]. There have also been previous reports describing heteroleptic complexes with Pt(II) and 9S3 containing halides [20] and both σ and π carbon donors [17,25] as the second ligand, but previous work with diimine ligands was limited to one compound, 1,10-phenanthroline (phen) [15]. Another key factor in diimine/Pt(II) chemistry is the importance of these complexes in the development of molecular photochemical devices, and a review of the photochemistry of Pt(II) complexes with diimines has recently appeared [26]. A listing for the different diimine structures used in our study is given in Scheme 1, and we wish to report the syntheses and spectroscopic properties for



Scheme 1. Ligands discussed in this report.

five new Pt(II) heteroleptic complexes containing a series of diimine ligands. The complexes all have the general formula $[Pt(9S3)(N_2)](PF_6)_2$ where N_2 is a diimine ligand [N_2 = 2,2-bipyridine (bipy), 4,4′-dimethyl-2,2-bipyridine (Me_2bipy), 4,4′-di-*t*-butyl-2,2-bipyridine (t-Bu_2bipy), 4,4′-di-nonyl-2,2-bipyridine (Non_2bipy), and 3,4,7,8-tetramethyl-1,10-phenanthroline (Me_4phen)]. Additionally, full spectroscopic and electrochemical data for the analogous and previously reported with 1,10-phenanthroline (phen) [15] is given. Platinum-195 NMR serves as an excellent tool to probe these complexes, and we also include the study of the six thioether–diimine complexes employing this technique [27].

2. Experimental

2.1. Materials and measurements

All solvents and reagents were purchased from Aldrich Chemical Company and used as received. The starting complex $[Pt(9S3)Cl_2]$ was prepared by the published method [20]. Elemental analyses were performed by Atlantic Microlab, Inc., of Atlanta, GA. Fourier transform infrared spectra were obtained using a Galaxy FT-IR 5000 spectrophotometer and ultraviolet-visible spectra were obtained on a Varian DMS 200 UV–Vis spectrophotometer. Carbon-13 and proton NMR spectra were recorded on a Varian Gemini 300 NMR spectrometer using CD_3NO_2 for both the deuterium lock and reference. Carbon connectivity was confirmed via distortionless enhancement by polarization transfer (DEPT) experiments. Platinum-195 NMR spectra were recorded at 20 °C and 64.270 MHz using aqueous solutions of $[PtCl_6]^{2-}$ (0 ppm) as an external reference and delay time of 0.01 s. Referencing was verified versus authentic samples of $[PtCl_4]^{2-}$ which was

[2] The sum of the van der Waals radii for platinum and sulfur is 3.50 Å.

found to have a chemical shift at −1626 ppm, in agreement with the reported value of −1624 ppm. [27]. A Biological Analytical Systems CV50W Analyzer was used for all electrochemical measurements. The supporting electrolyte was 0.1 M $(Bu)_4NBF_4$ in CH_3CN, and sample concentrations were approximately 3 mM. All voltammograms were recorded at a scan rate of 100 mV/s. The standard three-electrode configuration was as follows: Pt-disk working electrode, Pt-wire auxiliary electrode, and Ag/0.01 M Ag(I) pseudo-reference electrode. All reported potentials were referenced against Fc/Fc^+ couple.

2.2. Preparation of the 9S3/bipy complexes

2.2.1. Preparation of [Pt(9S3)(bipy)](PF6)2

A mixture of [Pt(9S3)Cl_2] (100 mg, 0.224 mmol) and 2,2′-bipyridine (34.9 mg, 0.224 mmol) was refluxed in 50 mL of nitromethane for 3 h. A mass of NH_4PF_6 (73.0 mg, 0.448 mmol) was added, and the mixture refluxed an additional 30 min. The solution was filtered whilst hot, and then concentrated to 2/3 its original volume. Ether was then diffused overnight into the nitromethane solution. A yellow-orange precipitate formed which is filtered, washed with ethanol (3 × 15 mL), ether (3 × 15 mL), and then recrystallized by ether diffusion into a nitromethane to yield dark brown crystals (113 mg, 61.5%) of [Pt(9S3)(bipy)]$(PF_6)_2$ suitable for X-ray diffraction studies. The electronic absorption spectrum measured in acetonitrile showed three λ_{max}'s at 396 nm ($\varepsilon = 1750$), 329 nm ($\varepsilon = 1960$), and 308 nm ($\varepsilon = 8500$). FT-IR (KBr, cm^{-1}): 3141, 2952, 2825, 1642, 1588, 1425, 1410, 1248, 1149, 1079, 849 (s, PF_6^-), 763, 649 (C–S), 563. *Anal*. Calc. for $C_{16}F_{12}H_{20}N_2P_2PtS_3$: C, 23.39; H, 2.45; N, 3.41; S, 11.71. Found: C, 23.54; H, 2.55; N, 3.45; S, 11.76%. ^{1}H NMR (CD_3NO_2): δ (ppm), 9.04 (m, $^3J_{Pt-H} = 36$ Hz, $^3J_{H-H} = 5.7$ Hz, *bipy*, 2H), 8.60 (m, *bipy*, 2H), 8.52 (m, *bipy*, 2H), 7.90 (m, *bipy*, 2H), 3.36 (m, broad, *9S3*, 12H) ppm. $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ (ppm), 157.5 (s, *bipy*, 2C), 151.5 (s, *bipy*, 2C), 144.0 (s, *bipy*, 2C), 130.6 (s, *bipy*, 2C), 126.5 (s, *bipy*, 2C), 34.5 (s, *9S3*, 6C). $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($v_{1/2}$): singlet at −3261 ppm (726 Hz). The complex showed an irreversible oxidation at +0.94 V and an irreversible reduction at −1.22 V.

2.2.2. Preparation of [Pt(9S3)(Me2bipy)](PF6)2·2.5 CH3NO2

A mixture of [Pt(9S3)Cl_2] (100 mg, 0.224 mmol) and 4,4-dimethyl-2,2′-bipyridine (Me_2bipy) (41.3 mg, 0.224 mmol) was refluxed in 50 mL of CH_3NO_2 for 3 h. A mass of NH_4PF_6 (73.0 mg, 0.448 mmol) was added, and the mixture refluxed an additional 30 min. The solution was filtered whilst hot, and then concentrated to 2/3 its original volume. Ether was then diffused overnight into the nitromethane concentrate. Yellow-orange crystals had formed which were filtered, washed with ethanol (3 × 15 mL), ether (3 × 15 mL). The yield was 124 mg (64.7%) of [Pt(9S3)(Me_2bipy)]$(PF_6)_2 \cdot 2.5\ CH_3NO_2$. Recrystallization using ether diffusion into a nitromethane yielded crystals suitable for X-ray diffraction studies. The electronic absorption spectrum measured in acetonitrile showed two λ_{max}'s at 382 nm ($\varepsilon = 2720$) and 277 nm ($\varepsilon = 17\,500$) and shoulders at 319 ($\varepsilon = 11\,800$) and 308 ($\varepsilon = 12\,000$). FT-IR (KBr, cm^{-1}): 3090, 2978, 1698, 1616, 1439, 1400, 1215, 1038, 848 (s, PF_6^-), 662 (C–S), 555, 422. *Anal*. Calc. for $C_{20.50}H_{31.50}F_{12}N_{4.50}O_5P_2PtS_3$: C, 24.57; H, 3.11; S, 9.60; N, 6.29. Found: C, 24.77; H, 3.05; S, 9.61; N, 6.49%. ^{1}H NMR (CD_3NO_2): δ (ppm), 8.83 (m, $^3J_{Pt-H} = 36$ Hz, $^3J_{H-H} = 5.6$ Hz, *bipy*, 2H), 8.41 (s, *bipy*, 2H), 7.68 (m, $^3J_{H-H} = 5.6$ Hz, *bipy*, 2H), 3.36 (m, broad, *9S3*, 12H, 2.67 (s, –C*H*$_3$, 6H). $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ (ppm) 157.7 (s, *bipy*, 2C), 157.0 (s, *bipy*, 2C), 150.5 (s, *bipy*, 2C), 130.9 (s, *bipy*, 2C), 127.0 (s, *bipy*, 2C), 34.4 (s, *9S3*, 6C), 21.9 (s, –*C*H$_3$, 2C) ppm. $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($v_{1/2}$): singlet at −3279 ppm (678 Hz). The complex showed an irreversible oxidation at +0.97 V and an irreversible reduction at −1.48 V.

2.2.3. Preparation of [Pt(9S3)(t-Bu2bipy)](PF6)2

A mixture of [Pt(9S3)Cl_2] (50.0 mg, 0.112 mmol) and $AgPF_6$ (56.6 mg, 0.224 mmol) was stirred in the dark in 10 mL of CH_3CN for 24 h. The white precipitate of AgCl was then filtered and a mass of 4,4′-di-tertiary-butyl-2,2′-bipyridyl (*t*-Bu_2bipy), (30.1 mg, 0.112 mmol) was added. The solution was then stirred for an additional 48 h. The solution was concentrated to 1/3 its original volume, and ether was then diffused overnight into the acetonitrile concentrate to form yellow crystals. The crystals were filtered, washed with ethanol (3 × 15 mL), ether (3 × 15 mL) to yield 84.2 mg (80.5%) of [Pt(9S3)(t-Bu_2bipy)]$(PF_6)_2$. The electronic absorption spectrum measured in acetonitrile showed two λ_{max}'s at 386 nm ($\varepsilon = 2230$) and 309 nm ($\varepsilon = 13\,200$) and a shoulder at 319 ($\varepsilon = 11\,100$). FT-IR (KBr, cm^{-1}): 3004, 2957, 2901, 2866, 1616, 1543, 1482, 1418, 1254, 1073, 836 (s, PF_6^-), 740, 663 (C–S), 555. *Anal*. Calc. for $C_{24}H_{36}F_{12}N_2P_2PtS_3$: C, 30.87; H, 3.89; N, 3.00; S, 10.30. Found: C, 30.77; H, 3.85; N, 3.24; S, 10.19%. ^{1}H NMR (CD_3NO_2): δ (ppm), 8.88 (m, $^3J_{Pt-H} = 36$ Hz, $^3J_{H-H} = 5.6$ Hz, *bipy*, 2H), 8.55 (d, $^4J_{H-H} = 2.4$ Hz, *bipy*, 2H), 7.87 (d of d, $^3J_{H-H} = 5.6$ Hz, $^4J_{H-H} = 2.4$ Hz, *bipy*, 2H), 3.41 (m, broad, *9S3*, 12H), 1.47 (s, –C(C*H*$_3$)$_3$, 18H). $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ (ppm) 169.4 (s, *bipy*, 2C), 157.2 (s, *bipy*, 2C), 150.9 (s, *bipy*, 2C), 127.7 (s, *bipy*, 2C), 123.5 (s, *bipy*, 2C), 37.4 (s, –*C*(CH$_3$)$_3$, 2C), 34.5 (s, *9S3*, 6C), 30.3 (s, –C(*C*H$_3$)$_3$, 6C). $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($v_{1/2}$): singlet at −3289 ppm (539 Hz).

2.2.4. Preparation of [Pt(9S3)(Non2bipy)](PF6)2

A mixture of [Pt(9S3)Cl_2] (50.0 mg, 0.112 mmol) and $AgPF_6$ (56.6 mg, 0.224 mmol) was stirred in the dark in

10 mL of CH_3CN for 24 h. The white precipitate of AgCl was then filtered and a mass of 4,4′-di-nonyl-2,2′-bipyridyl (Non_2bipy), (45.7 mg, 0.112 mmol) was added. The solution was then stirred for an additional 48 h. The solution was concentrated to 1/3 its original volume, and ether was then diffused overnight into the acetonitrile concentrate to form yellow crystals. The crystals were filtered, washed with ethanol (3 × 15 mL), ether (3 × 15 mL) to yield 95.1 mg (79.1%) of [Pt(9S3)(Non_2bipy)]$(PF_6)_2$. The electronic absorption spectrum measured in acetonitrile showed two λ_{max}'s at 386 nm ($\varepsilon = 2530$) and 319 nm ($\varepsilon = 11\,400$) and a shoulder at 308 ($\varepsilon = 10\,400$). FT-IR (KBr, cm^{-1}): 3090, 2922, 2849, 1616, 1555, 1491, 1422, 1284, 1137, 1038, 835 (s, PF_6^-), 654 (C–S), 555. *Anal*. Calc. for $C_{34}H_{56}F_{12}N_2P_2PtS_3$: C, 37.95; H, 5.43; N, 2.61; S, 8.94. Found: C, 38.05; H, 5.30; N, 2.75; S, 9.07%. ^1H NMR (CD_3NO_2): δ (ppm), 8.84 (m, $^3J_{Pt-H} = 36$ Hz, $^3J_{H-H} = 5.8$ Hz, *bipy*, 2H), 8.44 (s, *bipy*, 2H), 7.70 (m, $^3J_{H-H} = 5.8$ Hz, *bipy*, 2H), 3.28 (m, *9S3*, 12H), 2.95 (t, $^3J_{H-H} = 7.4$ Hz, $-CH_2(CH_2)_7CH_3$, 4H), 1.79 (q, $^3J_{H-H} = 6.9$ Hz, $-CH_2CH_2CH_2(CH_2)_5CH_3$, 4H), 1.39 (b, m, $-CH_2CH_2(CH_2)_2(CH_2)_4CH_3$, 8H), 1.29 (b, m, $-CH_2CH_2(CH_2)_2(CH_2)_4CH_3$, 16H), 0.87 (t, $^3J_{H-H} = 6.6$ Hz, $-CH_2CH_2(CH_2)_2(CH_2)_4CH_3$, 6H). $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ (ppm), 162.0 (s, *bipy*, 2C), 157.2 (s, *bipy*, 2C), 150.8 (s, *bipy*, 2C), 130.3 (s, *bipy*, 2C), 126.4 (s, *bipy*, 2C), 34.5 (s, *9S3*, 6C), 36.7 (s, $-C_9H_{19}$, 2C), 33.0 (s, $-C_9H_{19}$, 2C), 31.1 (s, $-C_9H_{19}$, 2C), 30.6 (s, $-C_9H_{19}$, 2C), 30.4 (s, $-C_9H_{19}$, 2C), 30.3 (s, $-C_9H_{19}$, 2C), 30.2 (s, $-C_9H_{19}$, 2C), 23.7 (s, $-C_9H_{19}$, 2C), 14.5 (s, $-C_9H_{19}$, 2C) ppm. $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($\nu_{1/2}$): singlet at −3284 ppm (353 Hz).

2.3. Preparation of the 9S3/phen complexes

2.3.1. Preparation of [Pt(9S3)(phen)](PF6)2

The synthesis of this compound has been previously reported using a different route [15]. We include the new synthesis as well as additional spectroscopic and electrochemical data. A mixture of [Pt(9S3)Cl_2] (100 mg, 0.224 mmol) and 1,10-phenanthroline (phen) (40.4 mg, 0.224 mmol) was refluxed in 50 mL of CH_3NO_2 for 3 h. The resulting solution was cooled slightly before a mass of NH_4PF_6 (73.0 mg, 0.448 mmol) was added, and the mixture refluxed an additional 30 min. The solution is filtered whilst hot and concentrated to 2/3 of its original volume. Ether was then diffused overnight into the nitromethane solution. A yellow-orange precipitate formed which is filtered, washed with ethanol (3 × 15 mL), ether (3 × 15 mL), and then recrystallized by ether diffusion into a nitromethane to yield dark brown crystals (143 mg, 75.4%) of [Pt(9S3)(phen)]$(PF_6)_2$. The electronic absorption spectrum measured in acetonitrile showed two λ_{max}'s at 393 nm ($\varepsilon = 2780$) and 275 nm ($\varepsilon = 31\,700$). ^1H NMR (CD_3NO_2): δ, 9.37 (m, $^3J_{Pt-H} = 37$ Hz, $^3J_{H-H} = 5.8$ Hz, *phen*, 2H), 9.08 (m, $^3J_{H-H} = 7.9$ Hz, *phen*, 2H), 8.36 (s, *phen*, 2H), 8.21 (m, $^3J_{H-H} = 7.2$ Hz, *phen*, 2H), 3.40 (m, broad, *9S3*, 12H) ppm. $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ, 152.1 (s, *phen*, 2C), 148.1 (s, *phen*, 2C), 143.2(s, *phen*, 2C), 133.5 (s, *phen*, 2C), 130.0 (s, *phen*, 2C), 128.5 (s, *phen*, 2C), 34.6 (s, *9S3*, 6C) ppm. $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($\nu_{1/2}$): singlet at −3292 ppm (754 Hz). The complex showed no oxidative electrochemistry and an irreversible reduction at −1.18 V.

2.3.2. Preparation of [Pt(9S3)(Me4phen)](PF6)2

A mixture of [Pt(9S3)Cl_2] (88.0 mg, 0.197 mmol) and 3,4,7,8-tetramethyl-1,10- phenanthroline (Me_4phen) (21.1 mg, 0.0892 mmol) was refluxed in 50 mL of CH_3NO_2 for 3 h. The resulting solution was cooled slightly before a mass of NH_4PF_6 (64.2 mg, 0.394 mmol) was added, and the mixture refluxed an additional 30 min. The solution is filtered whilst hot and concentrated to 2/3 of its original volume. Ether was then diffused overnight into the nitromethane solution to form brown crystals. These were washed with washed with ethanol (3 × 15 mL), ether (3 × 15 mL), and then recrystallized by ether diffusion into a nitromethane to yield dark brown crystals (96.0 mg, 54.1%) of [Pt(9S3)(Me_4phen)]$(PF_6)_2$. The electronic absorption spectrum measured in acetonitrile showed three λ_{max}'s at 377 nm ($\varepsilon = 3780$), at 336 nm ($\varepsilon = 4290$), and 276 nm ($\varepsilon = 62\,000$). FT-IR (KBr, cm^{-1}): 3055, 2970, 1615 1555, 1439, 1417, 1283, 1098, 840 (s, PF_6^-), 654 (C–S), 555. *Anal*. Calc. for $C_{22}F_{12}H_{28}N_2P_2PtS_3$: C, 29.30; H, 3.13; N, 3.11; S, 10.67. Found: C, 29.20; H, 3.16; N, 3.34; S, 10.67%. ^1H NMR (CD_3NO_2): δ, 8.99 (m, $^3J_{Pt-H} = 36$ Hz, *phen*, 2H), 8.44 (s, *phen*, 2H), 3.48 (m, broad, *9S3*, 12H) 2.93 (s, $-CH_3$, 6H), 2.69 (s, $-CH_3$, 6H) ppm. $^{13}C\{^1H\}$ NMR (CD_3NO_2): δ, 152.4 (s, *phen*, 2C), 151.6 (s, *phen*, 2C), 151.6 (s, *phen*, 2C), 137.9 (s, *phen*, 2C), 131.7(s, *phen*, 2C), 125.9 (s, *phen*, 2C), 34.4 (s, *9S3*, 6C), 18.0 (s, $-CH_3$, 2C), 15.8 (s, $-CH_3$, 2C) ppm. $^{195}Pt\{^1H\}$ NMR(CD_3NO_2), δ ($\nu_{1/2}$): singlet at −3313 ppm (822 Hz).

Data collection and processing. Suitable crystals of all complexes were grown by slow diffusion of ether into a nitromethane solution, and summary of key crystallographic details for the structures is presented in Table 1. For all structures, intensity data were collected on a Siemens SMART 1K CCD diffractometer [28,29], and the structures were solved using direct methods [28]. For the bipy complex, the *h*, *k*, *l* ranges used during its structure solution and refinement were −13/11, −13/13, −13/12. For 10 346 measured reflections 5023 were unique. The merging *R*-values on intensities were 0.0366. The structure was refined by a full-matrix least squares on F^2 using 5023 unique reflections and 340 parameters. The residuals were as follows: for reflections having $I > 2\sigma(I)$ $R = 0.0329$, $R_w = 0.0730$ and GoF = 1.054; for all reflections $R = 0.0396$, $R_w = 0.0754$. The secondary extinction coefficient was 0.0088(18) μm. For the Me_2bipy complex, the *h*, *k*, *l* ranges used during its structure solution and refinement were −32/33, −24/22,

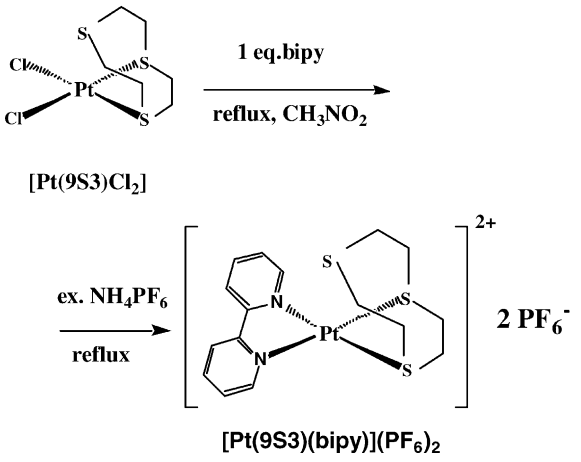
−17/21. For 10 255 measured reflections 9691 were unique. The merging R-values on intensities were 0.0503. The structure was refined by a full-matrix least squares on F^2 using 9691 unique reflections and 897 parameters. The residuals were as follows: for reflections having $I > 2\sigma(I)$ $R = 0.0527$, $R_w = 0.1281$ and GoF = 1.035; for all reflections $R = 0.0561$, $R_w = 0.1314$.

3. Results and discussion

3.1. Synthesis, spectra, and electrochemistry

All of complexes are readily prepared by the reaction of $[Pt(9S3)Cl_2]$ with one equivalent of diimine ligand which replaces the two chloride donors. In four cases, this is accomplished by the refluxing of the reaction mixture in nitromethane followed by metathesis to the hexafluorophosphate salt as shown below. We would like to note that this reaction proceeds more cleanly and in better yield than starting with the $[Pt(diimine)Cl_2]$ complex as previously described [15]. For the cases involving the more sterically hindered *t*-butyl and nonyl disubstituted bipy ligands, the procedure either did not work or gave poor yields. Therefore, we successfully employed an alternative preparation whereby $[Pt(9S3)Cl_2]$ was dechlorinated with silver ion in acetonitrile, followed by the addition of the diimine ligand at room temperature. Lastly, we would note that we have been unable to obtain the analogous diimine complexes when electron-withdrawing groups are present on the diimine ring. Similar reactions with dibromo and dicarboxylic acid substituted bipyridines did not give the desired products, probably due to electron-withdrawing effects on their substituent groups.



The composition of the new complexes is confirmed using a variety of spectroscopic techniques and elemental analysis. The proton NMR spectra of the six complexes show resonances for all protons in the appropriate ratios and splittings. The 12 protons of the 9S3 appear as a broad, complex ABCD pattern, in contrast to the characteristic $AA'BB'$ pattern commonly observed for 9S3 in phosphine and halide complexes [20–24]. The hydrogen *ortho* to the nitrogen of the pyridine rings for the six ligands exhibits a distinctive $^3J_{(Pt-H)}$ coupling at 36 Hz. In addition, ^{13}C DEPT experiments confirm carbon connectivity in all complexes. As expected, the 9S3 ligand is fluxional in solution resulting in a single ^{13}C NMR resonance for the thioether ligand, showing all six carbon atoms to be equivalent. The fluxionality has been proposed to occur via rapid intramolecular exchanges of sulfur atoms (1,4-metallotropic shift) [15,30] and has been observed in the presence of a variety of ancillary ligands. All six complexes show this feature in their carbon NMR spectra. For the Non_2bipy complex, even at −90 °C, we have not been able to observe a slow exchange of 9S3 in the carbon-13 NMR spectrum, suggesting a very low barrier to rotation. [3]

[3] The Non_2bipy complex has excellent acetone solubility so we had hoped to observe a slow ligand exchange in its ^{13}C NMR spectrum. Although the 9S3 resonance appears as a singlet at 20 °C, cooling down sequentially to −90 °C results first in broadening, then a collapse of this peak into the baseline. The slow exchange of 9S3 is not observed even at this temperature. [15] does report decoalescence of the 9S3 resonances in the proton NMR spectrum of the phen complex at −80 °C.

Table 2
Solid state structures of platinum(II) crown thioether complexes, [Pt(9S3)L], and their ^{195}Pt NMR chemical shifts

Complex	Geometry	^{195}Pt NMR δ (ppm)

[d] Ref. [21–24].

A summary of the ^{195}Pt NMR chemical shifts for all six complexes appears in Table 2. All are shifted downfield compared to other 9S3 Pt(II) complexes and average −3286 ppm. It is interesting to note that this chemical shift lies intermediate between the values for $[Pt(9S3)Cl_2]$/$[Pt(bipy)Cl_2]$ and $[Pt(9S3)Br_2]$/$[Pt(bipy)Br_2]$, illustrating how the platinum chemical shift is sensitive to the average ligand environment [31]. [4] One surprising aspect of our data is how little variation there is in the chemical shifts of the different diimine complexes. For example, as also seen in Table 2, a comparable set of six diphosphine complexes exhibit ^{195}Pt NMR chemical shifts that vary by almost 700 ppm while the six diimines complexes vary by only about 50 ppm.

Both the bipy and Me_2bipy complexes show similar electrochemical behavior with an irreversible oxidation close to +0.95 V and an irreversible reduction between −1.22 and −1.48 V, respectively. In contrast, the phen complex shows no oxidation waves, but does exhibit a reduction at a similar value of −1.18 V. The lack of an oxidation wave of the phen complex may reflect enhanced π backbonding for that complex. Electrochemical measurements on the Pd(II) 9S3 analogs of the bipy and phen complexes show reversible one-electron reductions, but no oxidation waves [16]. It has been proposed that the Pt dπ orbital is involved in the oxidation process while the π* orbital on the diimine is involved in the reduction process, a hypothesis supported by our data on these compounds [32].

[4] The compound $[Pt(bipy)Cl_2]$ shows a ^{195}Pt NMR resonance at −2315 ppm. The resonances for the bromo analog are shifted upfield to −2544 ppm.

3.2. Structures

Crystallographic data for the two complexes are presented in Table 1, selected bond distances and angles appear in Table 3, and thermal ellipsoid plots of the two structures are presented in Fig. 1, 2. Both complexes show an elongated square pyramidal structure which is common for heteroleptic crown trithioether complexes of Pt(II) and Pd(II) [4,21–24]. The square plane is comprised of a *cis* arrangement of the two nitrogen donors of the diimine and two sulfur donors from the 9S3. The third 9S3 sulfur shows a long distance axial interaction to complete the elongated square pyramidal structure. In the bipy complex, the Pt(II) ion is raised slightly (by 0.1008(14) Å) above the mean square equatorial plane and directed towards the axial sulfur donor, and the four atoms in the equatorial plane have an average displacement of 0.0425 Å. The Me_2bipy complex crystallizes with two independent but similar cations in the asymmetric unit. For both structures the Pt(II) is raised slightly less than in the bipy structure, 0.0747(0.0037) and 0.0860(0.0036) Å from the equatorial plane which has an average displacement of 0.0297 and 0.0303 Å, respectively. There are several contrasts between the two complexes resulting from the presence of the two methyl groups in *para* positions of the Me_2bipy ligand. Its Pt(II)/9S3 complex shows a larger N–Pt–N chelate angle, shorter Pt–N distances, and also shorter Pt–S equatorial distances.

The two pyridine rings in both the bipy and Me_2bipy structures are inclined towards each other (3–4°) and away from the axial sulfur. This bow deformation of the diimine ligand is also seen in the crystal structures of the related Pd(II) complexes, [Pd(9S3)(bipy)]$(PF_6)_2$ and [Pd(9S3)(phen)]$(PF_6)_2$, which show a similar degree of tilting of their rings [16]. In order to accommodate complexation of the platinum by the thiacrown, the diimine ligand distorts from a planar structure via this inward bowing. The bowing of the bipy rings is especially seen in the C–N–N–C dihedral angles which measure, 24.2° (C10–N1–N2–C19) and 26.8° (C20–N21–N10–C11), respectively, for the two Pt(II) complexes. It is interesting to note that this bowing distortion is also observed in the analogous [Pt(9S3)(phen)]$(PF_6)_2$ structure [15]. However, the bowing for the phen ligand is even more pronounced and noticeably larger, by almost a factor of two, compared to what is observed for the two bipy structures. One would have anticipated that the more rigid phen ligand would distort less, not more, and the distortion suggests an enhanced π interaction with the metal center, as supported by our electrochemical data.

One particular structural feature of interest is the distance between the axial sulfur donor and the platinum center since this distance is quite sensitive to the nature of the ancillary ligand. Table 4 summarizes the Pt–S equatorial and axial distances for a series of heteroleptic 9S3 complexes. [5] When the axial distances in the diimine complexes are compared to phosphines, the axial distances are significantly longer. Initial observations of the sulfur axial interactions in heteroleptic Pt(II) and Pd(II) complexes of 9S3 led to the proposal that better π acids, such as bipy and phen, would result in shorter M–S axial distances through π backbonding between the metal d_{yz} and d_{xz} orbitals and the π^* orbitals of the diimine [15,16]. Similarly, better σ donating ligands would result in longer M–S axial distances. However, as our data demonstrates, this is, in fact, not the case. Rather, better π acceptors like bipy and phen and their methyl-substituted derivatives, have longer Pt–S axial distances than do any of the phosphines donors. [6] Phosphines are both stronger σ donor and weaker π acceptor ligands than are diimines. According to the original hypothesis, they should show longer, not shorter, Pt–S axial interactions since their Pt centers would have less positive charge.

We have noticed a general trend in the structural data presented in Table 4. Ligands, which have the shorter equatorial Pt–S distances, generally have longer axial distances and vice versa. Pi donor ligands such as halides have the shortest equatorial and longest axial distances. Phosphine ligands which are better σ donors show the longest equatorial, but the shortest axial distances. Based upon this collection of data, we would like to propose an alternative hypothesis concerning the metal–axial sulfur interaction in the approximately fifty Pt(II) and Pd(II) complexes of trithiacrowns. The role of the ancillary ligand is certainly very important, but it is predominately one for controlling the equatorial M–S distances and not increasing the positive charge on the metal. We would note that the Pt–N distances are longer in the 9S3 complexes with diimines than in the dichloro complexes for bipy (average: 2.008(10) versus 2.053(3) Å) [33]. This suggests that the presence of the 9S3 ligand weakens the Pt–diimine interaction compared to a chloride donor. The balance of the electron density at

[5] The sum of the two equatorial Pt–S bonds and the axial Pt–S distance is surprisingly constant, averaging 7.40 (±0.19) Å for the full set of diimine, thioether, and phosphine complexes.

[6] We have attempted to solve the structure for [Pt(9S3)(Me_4phen)]$(PF_6)_2$ but the *R* value remains fairly high at 10%. However, the axial/equatorial Pt–S distances are very similar to the values given in Table 4 with Pt–S equatorial distances of 2.26 Å and axial distances of 2.88 Å.

[e] Ref. [35], we have recently determined the structures for $[Pt(9S3)_2](PF_6)_2$, CCDC 219803 and $[Pt(9S3)_2](BF_4)_2$, CCDC 219804, BF_4^- and PF_6^- salts, respectively.

[f] Refs. [21–24].

the metal center by the σ and π interactions involving the ancillary ligand influences the positioning of the axial sulfur donor. Depending upon the donor/acceptor characteristics of the ancillary ligand, the equatorial sulfur atoms are pushed or pulled towards the metal in the equatorial plane by the lengthening or shortening of the metal–sulfur bonds. Due to the rigidity of the 9S3, however, the third sulfur donor will approach the metal more closely if the equatorial sulfurs are pushed back or it will move away if they are pulled towards the metal. We feel that the original hypothesis proposing that σ donor ligands will exhibit longer axial interactions while π acceptor ligands will show shorter ones no longer fits the structural data that has now been accumulated for this series of compounds [34]. [7]

[7] In their study of 9S3-phen fused ligands, Lippolis and co-workers noted that the metal–axial sulfur distances did not fit the increased positive charge hypothesis. We note that their data fits this hypothesis regarding longer axial distances being seen with shorter equatorial ones.

4. Conclusions

One equivalent of a variety of diimines readily reacts with $[Pt(9S3)Cl_2]$ forming heteroleptic thioether–diimine complexes of the formula $[Pt(9S3)(N_2)](PF_6)$ (N_2 = diimine) with elongated square pyramidal structures $[S_2N_2 + S_1]$ in the solid state. The presence of a *cis*-PtS_2N_2 coordination sphere for the six complexes is supported by ^{195}Pt NMR chemical shifts. The third sulfur in each structure forms a longer interaction with the platinum resulting in an elongated square pyramidal structure. These distances, however, are approximately 0.2 Å longer than with the analogous diphosphine complexes, demonstrating that better π acids, in fact, do not result in a shorter Pt–S axial distance compared to better σ donor ligands as has previously been proposed.

5. Supplementary material

Crystallographic data for the two structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as 223510 and 223511. Copies of the data can be obtained free of charge upon application to CCDC, 12 Union Road, Cambridge, CB2 1 EZ UK (fax: +44-1223-336-033); email: deposit@ccdc.cam.ac.uk or on the web: http://www.ccdc.cam.ac.uk.

Oxidatively induced one-electron reductive elimination of pentafluorophenyl from $[Mo(C_6F_5)(CO)_5]^-$

Jungsook Kim, Stephen L. Gipson *

Department of Chemistry, Baylor University, Waco, TX 76798, USA

Received 11 December 2003; accepted 15 February 2004
Available online 12 April 2004

Abstract

The anionic molybdenum(0) complex $[Mo(C_6F_5)(CO)_5]^-$ displays a one-electron oxidation by cyclic voltammetry that is only partially chemically reversible. The partial chemical reversibility is caused by a slow chemical reaction following oxidation. This reaction has been shown to be cleavage of the $Mo–C_6F_5$ bond in a one-electron reductive elimination process. Chemical oxidation by ferrocenium in the presence of nucleophiles yields known $Mo(CO)_5L$ (L = Py, PPh_3) complexes, while oxidation with tropylium traps the C_6F_5 radical as $C_7H_7C_6F_5$. NMR and mass spectrometry were used to identify the oxidation products. Simulated cyclic voltammograms have been used to estimate the rate constant for cleavage of the $Mo–C_6F_5$ bond in the presence of pyridine as approximately 700 $M^{-1}\,s^{-1}$.

1. Introduction

For some years now we have been studying the redox-induced chemistry of pentafluorophenylmolybdenum carbonyl complexes. We have shown that the cycloheptatrienyl derivative $Mo(C_6F_5)(CO)_2(\eta\text{-}C_7H_7)$ undergoes an inefficient oxidatively induced CO insertion [1], while upon reduction it dimerizes by coupling of the cycloheptatrienyl rings to give the ditropyl complex $[\{Mo(C_6F_5)(CO)_2\}_2(\eta^6{:}\eta'^6\text{-}C_{14}H_{14})]^{2-}$ [2]. Displacement of the ditropyl ligand from the dimeric dianion by $P(OMe)_3$ yields *cis-mer*-$[Mo(C_6F_5)(CO)_2\{P(OMe)_3\}_3]^-$ [3], which undergoes other substitution reactions and an oxidatively induced isomerization [4]. In an effort to find a more convenient entry into related Mo(0) chemistry, we developed a synthesis of the $[Mo(C_6F_5)(CO)_5]^-$ anion [5]. We have now concluded an investigation of the oxidative chemistry of this complex, in which it was demonstrated that oxidation is followed by relatively slow one-electron, homolytic reductive elimination via cleavage of the $Mo–C_6F_5$ bond to yield the 16-electron $Mo(CO)_5$ fragment and a pentafluorophenyl radical.

While the possibility of one-electron reductive elimination from transition metal organometallic compounds has long been discussed, the literature contains relatively few reported examples. The chemical oxidation of R_4Pb (R = Me, Et), $Me_2Pt(PPh_3)_2$ and $Et_2Pt(PMe_2Ph)_2$ by $IrCl_6^{2-}$ is believed to be followed by metal–carbon bond cleavage to yield alkyl radicals which subsequently react with additional $IrCl_6^{2-}$ to yield RCl as the organic product of one-electron reductive elimination [6,7]. Similarly, chemical or electrochemical oxidation of tetramethylaurate [8] and dimethylcobalt macrocyclic chelates [9] produces methyl radicals. One-electron oxidation of several group 4 dicyclopentadienyl complexes Cp_2MR_2 (M = Ti, Zr; R = Me, Ph, Bz) produces organic radicals which subsequently dimerize [10–12]. Chemical or electrochemical oxidation of $Cp^*Ir(DMSO)Me_2$ in DMSO as solvent yields CH_4 through $Ir–CH_3$ bond cleavage followed by hydrogen abstraction from adventitious water, while oxidation of the rhodium analog yields instead the two-

doi:10.1016/j.poly.2004.02.022

electron reductive elimination product ethane [13]. Oxidation of Cp^*RuL_2R ($L = PMe_3$, PMe_2Ph, $R = Me$; $L = PMe_3$, $R = CH_2CMe_3$) and $CpRu(PPh_3)_2Me$ yield RH via Ru–C bond cleavage followed by H-atom abstraction from one of the other ligands [14]. In a similar study of the oxidations of $CpRu(CO)(PR_3)Me$ ($R = Cy$, Ph), it was concluded that coordination of solvent to the $17e^-$ cation precedes Ru–Me bond cleavage [15]. The only reported example of one-electron reductive elimination from group 6 compounds is that of Cp_2MX_2 ($M = Mo$, W; $X =$ halide, thiolate) [16]. We report here the first oxidatively induced metal–carbon bond cleavage (one-electron reductive elimination) in a molybdenum complex, $[Mo(C_6F_5)(CO)_5]^-$, which also has the distinction of not having any hydrogen-containing ligands.

2. Experimental

2.1. Reagents

All reactions were carried out under argon using Schlenk techniques or in a nitrogen-atmosphere glovebox. All solvents were distilled from appropriate drying agents and stored under nitrogen. The compounds $PPN[Mo(C_6F_5)(CO)_5]$ [5] (PPN = bis(triphenylphosphoranylidene)ammonium) and Cp_2FeBF_4 [17] were prepared by published methods. All other reagents were obtained commercially and were used as received.

2.2. Instrumentation

IR spectra were obtained using a Mattson Instruments Genesis II FTIR and a cell with CaF_2 windows separated by a 0.1 mm spacer. ^1H, ^{31}P, and ^{19}F NMR spectra were obtained on a Bruker DPX 300 MHz NMR spectrometer. NMR chemical shifts were referenced to residual protons in the solvent (for ^1H), 85% H_3PO_4 external standard (for ^{31}P), or $CFCl_3$ external standard (for ^{19}F). Mass spectra were obtained on a VG/Fisons Prospec 3000 double focusing spectrometer using EI ionization. Peaks in the mass spectrum were referenced to perfluorokerosene.

Cyclic voltammetry was performed using a Bioanalytical Systems BAS 100B/W electrochemical analyzer. Solutions contained approximately 0.1 M $[Bu_4N]PF_6$ supporting electrolyte. Electrodes consisted of a 0.5 mm Pt disk working electrode, Pt wire auxiliary electrode, and Ag/AgCl reference electrode. Potentials were referenced to the formal potential of the decamethylferrocenium–decamethylferrocene couple ($Cp^*_2Fe^+/Cp^*_2Fe$), which we measure as approximately −0.1 V vs. Ag/AgCl. Simulations of the cyclic voltammetry were run using Bioanalytical Systems DigiSim 3.0 software.

3. Results and discussion

3.1. Cyclic voltammetry of $PPN[Mo(C_6F_5)(CO)_5]$

The cyclic voltammetry of $PPN[Mo(C_6F_5)(CO)_5]$ in CH_2Cl_2 displays a partially chemically reversible one-electron oxidation at +0.66 V vs. $Cp^*_2Fe^+/Cp^*_2Fe$. The ratio of the cathodic to the anodic peak currents for this couple ranges from near zero at scan rates below 20 mV/s to near unity at scan rates above 5 V/s. This change in chemical reversibility suggests that the presumed product of the oxidation, the neutral 17-electron complex $Mo(C_6F_5)(CO)_5$, undergoes a relatively slow chemical reaction. In THF and MeCN solvents the chemical reversibility is even lower, with the peak current ratio for a given scan rate decreasing in the order $CH_2Cl_2 >$ THF > MeCN. Given that this is the same order as the coordinating ability of the solvents, these results suggest that the decomposition of the 17-electron species involves nucleophilic attack by solvent.

The participation of nucleophiles in the chemical reaction following oxidation of $[Mo(C_6F_5)(CO)_5]^-$ is further supported by the observation that the addition of ligands such as pyridine and triphenylphosphine to CH_2Cl_2 solutions of $PPN[Mo(C_6F_5)(CO)_5]$ causes a decrease in chemical reversibility of the oxidation. At a scan rate of 0.2 V/s, the peak current ratio for a 1.0 mM solution of $PPN[Mo(C_6F_5)(CO)_5]$ in CH_2Cl_2 decreases from 0.72 in the absence of pyridine to essentially zero with 5.0 mM added pyridine. All of these observations are consistent with an EC mechanism for the oxidation of $[Mo(C_6F_5)(CO)_5]^-$.

3.2. Chemical oxidation of $PPN[Mo(C_6F_5)(CO)_5]$ by ferrocenium and tropylium

In order to identify the products of the reaction of $Mo(C_6F_5)(CO)_5$ with nucleophiles, $PPN[Mo(C_6F_5)(CO)_5]$ was treated with the mild oxidants Cp_2FeBF_4 and $C_7H_7BF_4$. The oxidations with ferrocenium (1 equiv.) were conducted in the presence of pyridine or triphenylphosphine (2 equiv.) in $CDCl_3$ as solvent. NMR spectroscopy of the resulting solutions identified the products as $Mo(CO)_5L$ (by ^1H and ^{31}P, L = Py or PPh_3), C_6F_5H (by ^1H and ^{19}F), and Cp_2Fe (by ^1H). Thus, the 16-electron $Mo(CO)_5$ fragment produced by the Mo–C_6F_5 bond cleavage was trapped as a stable 18-electron complex by the added ligand, while the C_6F_5 radical most likely abstracted a hydrogen atom from adventitious water to yield the pentafluorobenzene.

The reaction of $PPN[Mo(C_6F_5)(CO)_5]$ with $C_7H_7BF_4$ could not be performed in the presence of nucleophiles since the tropylium reacted more rapidly with the nucleophiles than with the Mo complex. Nevertheless, a slow reaction between $PPN[Mo(C_6F_5)(CO)_5]$ and $C_7H_7BF_4$ did occur in the absence of added nucleophile

in $CDCl_3$ and the NMR spectra of the product solution were consistent with $C_7H_7C_6F_5$ being the pentafluorophenyl-containing product. Isolation of this species by preparative TLC followed by mass spectral analysis gave a parent ion at *m/z* 258.11 ($C_7H_7C_6F_5$) and fragments at 167.03 (C_6F_5) and 91.08 (C_7H_7). Thus the oxidation of $[Mo(C_6F_5)(CO)_5]^-$ by $C_7H_7BF_4$ is believed to involve the following sequence of reactions:

$$[Mo(C_6F_5)(CO)_5]^- + C_7H_7^+ \rightarrow Mo(C_6F_5)(CO)_5 + C_7H_7^{\cdot}$$

$$Mo(C_6F_5)(CO)_5 + S \rightarrow Mo(CO)_5S + C_6F_5^{\cdot}$$

$$C_7H_7^{\cdot} + C_6F_5^{\cdot} \rightarrow C_7H_7C_6F_5$$

where S in the above reactions could be solvent, the BF_4^- anion, or adventitious water.

3.3. Simulation of cyclic voltammetry

In order to understand more about the mechanism of the apparent one-electron reductive elimination of C_6F_5 from $Mo(C_6F_5)(CO)_5$, we have simulated the cyclic voltammetry of PPN[$Mo(C_6F_5)(CO)_5$] in CH_2Cl_2 in the presence of pyridine using the reactions in Scheme 1.

At reasonably fast scan rates in the absence of pyridine, the electron transfer reaction appears chemically and electrochemically reversible and can be simulated using a slightly slow electron transfer with a rate constant of 0.06 cm/s and a transfer coefficient of 0.5. Fig. 1 shows the effect of pyridine concentration on the apparent chemical reversibility of experimental and simulated cyclic voltammograms of 1.0 mM PPN[$Mo(C_6F_5)(CO)_5$] at a scan rate of 0.2 V/s. In the absence of pyridine, simulations gave an optimum fit using a first-order rate constant for reaction (1) of 0.22 s^{-1}. This reaction almost certainly involves some nucleophile, but since this species can be neither conclusively identified nor quantitated, the reaction was modeled as a first-order process.

With all other parameters held constant at values given in Table 1, simulations were then run to obtain the second-order rate constant, k_2, for the reaction of pyridine with $Mo(C_6F_5)(CO)_5$, reaction (2). Optimum fits were obtained with k_2 values ranging from 646 to 1041 $M^{-1}\,s^{-1}$. Fig. 2 illustrates the effect of scan rate on the apparent chemical reversibility of experimental and simulated cyclic voltammograms of 1.0 mM PPN[$Mo(C_6F_5)(CO)_5$] in the presence of 5.0 mM pyridine. Using the same values for other parameters as in

$$[Mo(C_6F_5)(CO)_5]^- \rightleftharpoons Mo(C_6F_5)(CO)_5 + e^- \quad (E)$$

$$Mo(C_6F_5)(CO)_5 \rightarrow Mo(CO)_5S + C_6F_5 \quad (1)$$

$$Mo(C_6F_5)(CO)_5 + Py \rightarrow Mo(CO)_5Py + C_6F_5 \quad (2)$$

Scheme 1.

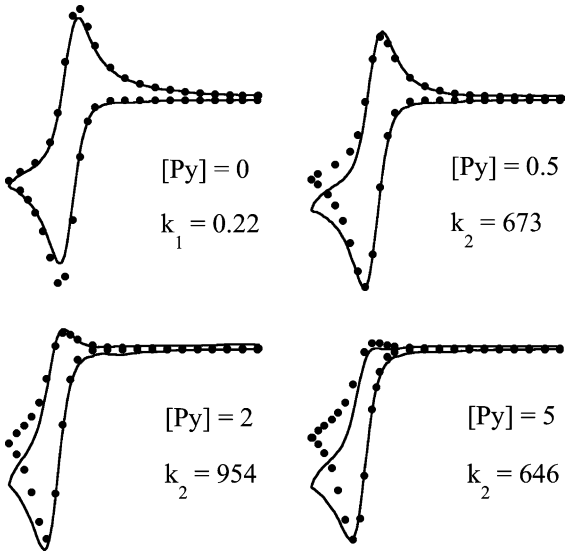

Fig. 1. Experimental (solid lines) and simulated (circles) cyclic voltammograms of 1.0 mM PPN[$Mo(C_6F_5)(CO)_5$] + pyridine in CH_2Cl_2/0.1 M $[Bu_4N]PF_6$ at a 0.5 mm diameter Pt disk electrode at 0.2 V/s. Concentrations of pyridine labeled in mM. Optimized rate constant for k_1 labeled in s^{-1} and for k_2 in $M^{-1}\,s^{-1}$.

Fig. 1, optimization of k_2 gave values ranging from 482 to 823 $M^{-1}\,s^{-1}$. Generally excellent agreement between experimental and simulated results was thus achieved using the parameters shown in Table 1 and an average value for k_2 of approximately 700 $M^{-1}\,s^{-1}$. This corresponds to a relatively slow reaction, much slower than the elimination of methyl radical from dimethylcobalt(IV) macrocycles [9], though significantly faster than the reaction of $CpRu(CO)(PR_3)CH_3$ with CH_3CN [15].

The mechanism of the oxidatively induced one-electron reductive elimination is proposed to involve nucleophilic attack (association) of the incoming ligand at the Mo, followed by extrusion of the C_6F_5 radical. Essentially identical results could be obtained by modeling the reaction with pyridine as either a rate-limiting pre-equilibrium between $Mo(C_6F_5)(CO)_5$ and pyridine followed rapid extrusion of C_6F_5 or a rapid pre-equilibrium followed by a rate-determining homolysis of the Mo–C_6F_5 bond. Therefore, the combination of nucleo-

α, transfer coefficient; k_E, standard heterogeneous rate constant for electron transfer; k_1, first-order rate constant for reaction in absence of nucleophile; K_{eq}, equilibrium constants for reactions (1) and (2) (see Scheme 1).

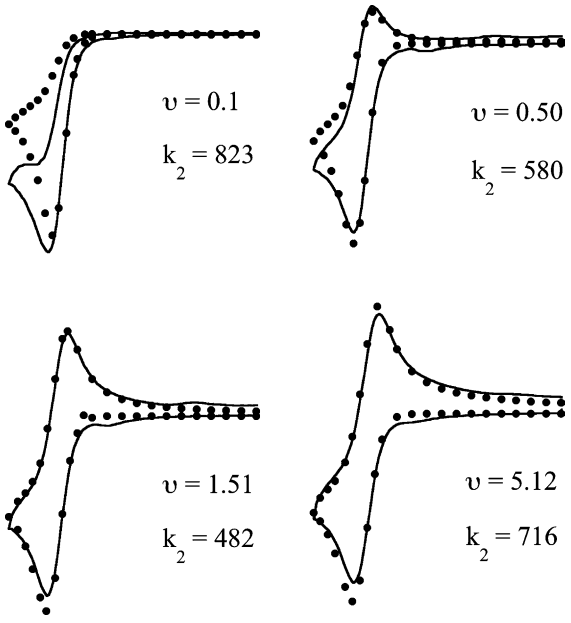

Fig. 2. Experimental (solid lines) and simulated (circles) cyclic voltammograms of 1.0 mM PPN[$Mo(C_6F_5)(CO)_5$] + 5.0 mM pyridine in CH_2Cl_2/0.1 M $[Bu_4N]PF_6$ at a 0.5 mm diameter Pt disk electrode. Scan rates labeled in V/s. Optimized rate constants labeled in $M^{-1}\,s^{-1}$.

philic attack and bond homolysis were modeled as the single second-order reaction shown in Scheme 1. Consistent with qualitative observations of the cyclic voltammetry, the reductive elimination in the presence of added nucleophile is significantly more rapid than in pure solvent. This observation lends support to the proposed associative nature of the overall reaction.

4. Conclusions

On the basis of experimentally observed cyclic voltammetry, simulations of this cyclic voltammetry, and products observed from chemical oxidation, a mechanism for the oxidatively induced one-electron reductive elimination of C_6F_5 from PPN[$Mo(C_6F_5)(CO)_5$] has been proposed. An initial one-electron oxidation produces the 17-electron species $Mo(C_6F_5)(CO)_5$. In agreement with previously published results for other systems [15], further reaction of this species is believed to involve prior association of the incoming ligand. The resulting 19-electron species then undergoes cleavage of the metal–carbon bond, effecting a one-electron reductive elimination reaction. The products of the reaction have all been identified by a combination of IR, NMR, and mass spectrometries.

Abstract

The title compound, *cis*-$[PtCl_2(p\text{-}TPPTP(H)_7)_2]Cl_2 \cdot 4H_2O \cdot (CH_3CH(OH)CH_3)$ (TPPTP = triphenylphosphine triphosphonate), is formed via crystallization from a water-isopropanol solution of *cis*-$[PtCl_2(TPPTP(H_6))_2]$. The coordination geometry around platinum is distorted square planar with two coordinated chloride ligands, and two free chloride ions in the crystal lattice. Two of the phosphonic acid groups are protonated $-PO_3H_3^+$ and the complex contains extensive intra- and inter-molecular hydrogen bonding.

Keywords: Phosphine; Phosphonic acid; Platinum

1. Introduction

Phosphonic acid functionalized complexes of transition metals are currently being explored as water-soluble homogeneous catalysts, photo-catalysts and supported catalysts. The $-PO_3H_2$ functional group has a number of desirable attributes which can be exploited: (1) due to the dianionic nature of the $[PO_3]^{2-}$ group, both functionalized organic and inorganic species are expected to be highly water-soluble and highly organophobic, two characteristics which are important for the design of biphasic/aqueous phase homogeneous catalysts [1]; (2) organophosphonic acids are known to form two- and three-dimensional supramolecular arrays stabilized by hydrogen bonding. This property has piqued the interest of crystal engineers who can make use of the wide variety of H-bonding motifs for the design of new functional solids [2]; (3) the phosphonate group forms strong covalent bonds with inorganic oxides such as SiO_2, Al_2O_3 and TiO_2 and thus provides a suitable tether for anchoring the molecular species for the purposes of heterogenizing organometallic and coordination complexes. Bujoli and co-workers [3] have recently prepared a titanium phosphonate supported rhodium/2,2′-bipyridine complex for hydrogenation of ketones and carbon–carbon multiple bonds. We have demonstrated the utility of a phosphine–phosphonic acid complex of palladium, anchored to silica, for catalytic carbon–phosphorus bond formation [4]. Our research has mainly focused on the synthesis of phosphonic acid and phosphonate functionalized phosphine complexes of late transition metals. In 1996, we reported the synthesis and use of *m*-TPPMP (triphenylphosphine monophosphonate disodium salt) in aqueous phase palladium catalyzed carbonylation [5]. More recently, we described the use of a *p*-$TPPTP(H)_6$ (TPPTP = triphenylphosphine triphosphonate) [6,7] derivative of molybde-

num(0) for monolayer functionalization of aluminum, and a *p*-TPPTP complex of palladium for the aqueous phase phosphonylation of phenyl triflate [4].

2. Experimental

Reagents and solvents were obtained from commercial sources and used as received. *Cis*-[$PtCl_2$(*p*-TPPTP$(H)_6)_2$] was prepared according to the literature procedure [4]. Yellow crystals of **1**·$4H_2O$·($CH_3CH(OH)CH_3$) suitable for X-ray diffraction were isolated from H_2O/2-propanol (slow diffusion at room temperature).

3. Crystal data structure and refinement

Crystal data and details of structure determination for **1** are given in Table 1. Single-crystal X-ray diffraction measurements were carried out using Mo Kα radiation ($\lambda = 0.71073$ Å) at 198 K. The structure was solved by direct methods using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms attached to O, O(3A), O(2E), O(3E), and O(2F) were first located in difference Fourier maps and were then idealized with the X–O–H tetrahedral angle. The hydrogen atoms attached to water oxygens were located in difference Fourier maps and then idealized by fixing the O–H distance at 0.85 Å and refining the H···H distance for all water hydrogen atoms as a variable. The final value (1.36517 Å) corresponds to a H–O–H angle of 106.8°. All hydrogen atoms attached to carbons were idealized using SHELXL default values for each type of carbon. Data collection and cell refinement were performed using SMART [12]. SAINT and XPREP [13,14] were used for data reduction, and SHELX-97 programs [13] were used to refine the structure.

4. Results and discussion

The reaction of 1.6 equivalents of *p*-TPPTP$(H)_6$ with K_2PtCl_4 in water, followed by precipitation with ethanol, gives *cis*-[$PtCl_2$(*p*-TPPTP$(H)_6)_2$] as a cream powder. When an aqueous solution of *cis*-[$PtCl_2$(*p*-TPPTP$(H)_6)_2$] is layered with 2-propanol, yellow crystals of *cis*-

1

Here, we report the crystal structure of **1** which shows extensive inter-molecular hydrogen bonding as well as a novel intra-molecular hydrogen bonded interaction. The ORTEP representation of **1** is shown in Fig. 1 and selected bond lengths and angles are listed in Table 2. Only three crystal structures containing the subunit *cis*-$[PtCl_2L_2]$ (L = triarylphosphine) were found in the Cambridge Crystallographic Database for comparison of geometric parameters and **1** shows some interesting differences with these structures. Compound **1** crystallizes in space group $P\bar{1}$ and with two discreet molecules in the unit cell. The geometry around the central platinum atom is best described as distorted square planar with two phosphorus atoms of the phosphine ligands coordinated in a *cis* fashion, and two chloride ligands similarly disposed. Deviation of atoms from the least squares plane for the central platinum and the four coordinated atoms are: Pt, 0.006 Å; P(1), −0.085 Å; P(2), 0.106 Å; Cl(1), −0.143 Å; Cl(2), 0.115 Å. These deviations from the plane are much greater than those found for the complex *cis*-$[PtCl_2(PPh_3)_2]$ [8] in which the maximum deviation of any atom from the least square planes is only 0.006 Å, possibly reflecting the distortion imposed by hydrogen bonding in **1**. The Pt–Cl bond distances in **1** are 2.355(3) and 2.328(3) Å for Pt–Cl(1) and PtCl(2), respectively. This asymmetry in Pt–Cl bond lengths was noted in a report of the structure of *cis*-$[PtCl_2(PPh_3)_2]$ in which the longest Pt–Cl bond was *trans* to the shortest Pt–P bond and vice versa. This is not the case in complex **1** in which the longest Pt–Cl is in fact *trans* to the longest Pt–P bond (Pt–P(1)). The sum of *trans* Pt–Cl and Pt–P bonds are thus quite different and this suggests that other factors, in addition to electronic properties of the ligands, are affecting the *trans*-influences of Cl and phosphine ligands in **1**. It is not surprising that the P(1)–Pt–P(2) angle (98.30(10)°) is significantly larger than ideal (90°) presumably to overcome steric crowding of the phosphine ligands. This angle is larger than any previously reported for the structures of *cis*-$[PtCl_2L_2]$ (L = triarylphosphine) complexes: $L = PPh_3$, [97.8°] [8]; $L = P(C_6H_4C_6F_{13}\text{-}4)_3$ [97.73(9)°] [9]; $L = P(C_6H_5)_2(C_6H_4COOH\text{-}3)$ [96.18(16)°] [10]. Similarly, the Cl(1)–Pt–Cl(2) angle is compressed in **1** (88.04(10)°).

One of the more interesting features of compound **1** is the presence of both intra- and inter-molecular hydrogen bonding. The phosphonic acid group can act both as hydrogen acceptor (P=O) and hydrogen donor (P–OH) and the presence of water molecules and a 2-propanol molecule results in an extended three-dimensional hydrogen bonded network. The intra-molecular hydrogen bonding occurs between *para*-substituted phenyl phosphonic acid groups on adjacent phenyl rings on one of the triarylphosphine ligands. This is illustrated in Fig. 2.

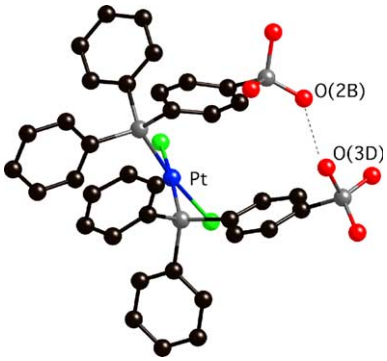

Fig. 2. Portion of **1** showing intra-molecular hydrogen bonding. Hydrogen atoms, solvate molecules and non-intra-molecular H-bonded phosphonic acid groups omitted for clarity.

A hydrogen bond is located between O(2B) and O(3D)–H (D···A = 2.600 Å). Inter-molecular phosphonic acid hydrogen bonding occurs between O(3A)–H and O(2D) (D···A = 2.448(11) Å), O(3E)–H and O(3F) (D···A = 2.509(11) Å) and O(2F)–H and O(3F) (D···A = 2.643(10) Å). Four water molecules are also hydrogen bonded to the phosphonate groups and chloride anions forming an extended 3D array.

A second interesting feature is the presence of two acidic protons located between phosphonate oxygen atoms on each ligand, and two water molecules. The P–O bond lengths are consistent with a structure intermediate between a protonated phosphonic acid group and a hydronium ion [11]. The presence of two extra protons per molecule gives an overall charge of 2+ on the molecule that is balanced by the presence of two free chloride anions in the crystal lattice.

Abstract

Two binuclear compounds $[Ni_2(pmdtn)_2(tp)(H_2O)_2](ClO_4)_2(H_2O)_4$ (**1**) and $[Ni_2(pmdtn)_2(tp)(N_3)_2](H_2O)_4$ (**2**) have been prepared by using the multibinding terephthalate (= tp) dianion and the tridentate capping ligand *N*,*N*,*N*′,*N*′,*N*″-pentamethyldiethyltriamine (= pmdtn) and have been characterized by X-ray crystallography and magnetic measurements. The crystal structures of both complexes show distorted octahedral geometries around the Ni(II) centers linked by the tp bridges in a bisbidentate fashion. The dihedral angles between the benzene rings and carboxylate groups correspond to 14.2° for **1** and 21.5° for **2**. The intradimer distance of Ni···Ni through the tp ligand for **1** and **2** are 10.731 and 10.800 Å, respectively. The magnetic data reveal weak antiferromagnetic interactions transmitted by the tp bridge with $J = -0.18$ cm^{-1} (**1**) and -0.02 cm^{-1} (**2**), which is explained by the structural parameters.

Keywords: Nickel(II) compounds; Crystal structures; Terephthalate ligand; Binuclear complexes; Magnetic properties

1. Introduction

There has been considerable interest in molecule-based magnets due to possible applications to magnetic devices [1,2]. It is essential to gain an intimate understanding of the magnetic exchange phenomena between paramagnetic metal ions, which helps to design magnetic systems with desirable properties. Bridging ligands that can mediate magnetic interactions between spin carriers become one of crucial ingredients to achieve coordination materials exhibiting intriguing magnetic behaviors. The basic question related to the current subject is how far the magnetic exchange couplings can propagate. To test this matter it is appropriate to utilize the tp ligand that connects paramagnetic metal ions within 10–11 Å, along with a variety of binding modes, generating compounds ranging from discrete molecules to 1D, 2D and to 3D networks [3–7]. To probe the underlying magnetic interaction mechanism especially in tp-linked magnetic systems, we have studied nickel compounds with the tp ligand, due to the fact that examples of such Ni(II) compounds are limited to date [8–10]. Herein, we report the syntheses, structures and magnetic behaviors of two new binuclear compounds $[Ni_2(pmdtn)_2(tp)(H_2O)_2](ClO_4)_2(H_2O)_4$ (**1**) and $[Ni_2(pmdtn)_2(tp)(N_3)_2](H_2O)_4$ (**2**) (tp = terephthalate, pmdtn = *N*,*N*,*N*′,*N*′,*N*″-pentamethyldiethyltriamine). The tp unit in both compounds acts as bisbidentate and communicates weak antiferromagnetic interactions depending on structural parameters.

2. Experimental

2.1. Materials

All chemicals and solvents were purchased from commercial sources and used without further purification. Potassium tp was readily prepared by reacting terephthalic acid with a stoichiometric amount of KOH in water.

2.2. Preparation of $[Ni_2(pmdtn)_2(tp)(H_2O)_2](ClO_4)_2\cdot(H_2O)_4$ (1)

To a 10 ml aqueous solution of nickel(II) perchlorate hexahydrate (2.0 mmol) was added an aqueous solution (10 ml) of pmdtn (2.0 mmol) and potassium tp (1.0 mmol) with stirring. Green precipitates were immediately formed and redissolved by adding methanol (10 ml). The resulting deep green solution was filtered and left undisturbed, giving green crystals of **1** in a yield of 70% based on Ni. *Anal*. Calc. for $C_{26}H_{62}N_6O_{18}Cl_2Ni_2$: C, 33.4; H, 6.68; N, 8.99. Found: C, 33.1; H, 6.62; N, 9.11%. Selected IR data (cm^{-1}, KBr pellet): 3618 (m), 3536 (m), 3470 (m), 3352 (m), 3019 (m), 2887 (m), 2904 (m), 2904 (m), 2815 (w), 1698, 1647 (m, HOH bendings), 1553 (vs, tp $\nu_a(CO_2^-)$), 1513 (m), 1477 (s), 1450 (s), 1411 (vs, tp $\nu_s(CO_2^-)$), 1306 (m), 1285 (w), 1244 (w), 1127, 1079 (vs, Cl–O stretchings), 1019 (m), 988 (m), 936 (m), 889 (w), 855 (m), 801 (w), 755 (m), 623 (m), 520 (m). UV–Vis (MeOH) [λ_{max}, nm (M^{-1} cm^{-1})]: 238 (5510), 388 (114), 636 (47), 1056 (22).

2.3. Preparation of $[Ni_2(pmdtn)_2(tp)(N_3)_2](H_2O)_4$ (2)

To a 10 ml aqueous solution of nickel(II) nitrate hexahydrate (2.0 mmol) was added an aqueous solution (10 ml) of pmdtn (2.0 mmol) and potassium tp (1.0 mmol) with stirring. Green precipitates immediately formed which were redissolved by adding methanol (10 ml) and then treated with sodium azide (1.0 mmol). The filtrate of the resulting solution was allowed to stand for several days, providing green crystals of **2** in a yield of 60% based on Ni. *Anal*. Calc. for $C_{26}H_{58}N_{12}O_8Ni_2$: C, 39.8; H, 7.45; N, 21.4. Found: C, 39.3; H, 7.31; N, 21.0%. Selected IR data (cm^{-1}, KBr pellet): 3500 (m), 3452 (m), 2980 (w), 2890 (w), 2846 (w), 2041 (vs, $\nu_a(N_3^-)$), 1645, 1620 (w, HOH bendings), 1550 (s, tp $\nu_a(CO_2^-)$), 1516 (w), 1465 (m), 1414 (s, tp $\nu_s(CO_2^-)$), 1292 (w), 1248 (w), 1177 (w), 1154 (w), 1130 (w), 1102 (w), 1044 (w), 1026 (m), 990 (w), 943 (w), 900 (w), 882 (w), 851 (m), 802 (m), 781 (w), 751 (m), 510 (m), 391 (w). UV–Vis (MeOH) [λ_{max}, nm (M^{-1} cm^{-1})]: 234 (2080), 384 (151), 640 (51), 1068 (24). The reaction of **1** with one or two equiv of sodium azide in water-methanol (1:1 v/v) solvent yielded an identical product to **2**.

2.4. Physical measurements

Elemental analyses for C, H and N were performed at the Elemental Analysis Service Center of the Korea Basic Science Institute. Infrared spectra were obtained from KBr pellets with an EQUINOX 55 spectrometer. Electronic spectra were obtained and manipulated by using a Shimadzu UV-3100S spectrophotometer. Magnetic susceptibilities for **1** and **2** were carried out using a Quantum Design MPMS-7 SQUID susceptometer. Diamagnetic corrections were estimated from Pascal's tables.

2.5. Crystallographic data collection and structure determination

Data were collected at 293 K using an Enraf-Nonius CAD4TSB diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) in the $\omega/2\theta$ scan mode. The unit cell parameters were calculated by least-squares refinement of 25 well-centered reflections. All data were corrected for Lorentz polarization effects. A total of 3501 (**1**) and 2731 (**2**) reflections with the maximum 2θ of 49.94° (**1** and **2**) were measured, and 2361 (**1**) and 2024 (**2**) reflections were assumed to be observed applying the condition $F_o > 4\sigma(F_o)$. Crystallographic data and details of data collection are listed in Table 1.

The structures were solved with the SIR-92 program and refined by least-squares analysis using anisotropic thermal parameters for non-hydrogen atoms with the SHELXL-93 program [11,12]. H atoms were calculated at idealized positions ($d_{CH} = 0.970$ Å for methylene, 0.960 Å for methyl and 0.930 Å for phenyl) and refined riding on the corresponding carbon atoms with isotropic thermal parameters [$U = 1.2U(C_{methylene})$, $1.5U(C_{methyl})$ and $1.2U(C_{phenyl})$]. The goodness-of-fit for all observed reflections was 1.178 (**1**) and 1.092 (**2**). Maximum and minimum peaks in the final difference synthesis were

3. Results and discussion

3.1. Syntheses and characterization

Compound **1** was prepared by the reaction of the Ni(II) ion with a mixture of pmdtn as a capping ligand and dicarboxylate dianion as a bridging ligand. In the IR spectrum of **1**, the most interesting features are the COO stretching bands occurring at 1563 and 1411 cm^{-1}. The binding modes of carboxylate ligands can be assessed on the basis of the difference (Δ) between asymmetric stretching $\nu_a(CO_2^-)$ and symmetric stretching $\nu_s(CO_2^-)$. Accordingly, the calculated Δ value of 152 cm^{-1}, which is compared with the value ($\Delta = 170$ cm^{-1}) of potassium tp, allows one to assume the bridging mode of the tp ligand as bidentate [13]. It appears that the broad bands in the O–H region show the presence of hydrogen bonds. In the UV–Vis spectrum, the strong absorption at 238 nm ($\varepsilon = 5510$ M^{-1} cm^{-1}) can be assigned to the charge transfer transition. The other three bands are associated with the spin-allowed transitions from the $^3A_{2g}$ ground state to the excited triplet states: $^3A_{2g}$ (F) $\rightarrow$ $^3T_{1g}$ (P) for 388 nm ($\varepsilon = 114$ M^{-1} cm^{-1}), $^3A_{2g}$ (F) $\rightarrow$ $^3T_{1g}$ (F) for 636 nm ($\varepsilon = 47$ M^{-1} cm^{-1}), and $^3A_{2g}$ (F) $\rightarrow$ $^3T_{2g}$ (P) for 1056 nm ($\varepsilon = 22$ M^{-1} cm^{-1}). The magnitude of the absorptions in the d-d transitions is stronger than that of $Ni(H_2O)_6^{2+}$, indicating that the geometry about the nickel center can be described as a distorted octahedron [14]. From the Tanabe-Sugano diagram, values of 10 Dq and B (Racah parameter) are estimated to be 9820 and 727 cm^{-1}, respectively. The β value, defined as $\beta = B_{complex}/B_{gaseous}$, demonstrates that there is a reduction to 70% of the free ion value for interelectronic repulsion, due to some degree of covalency of the metal-ligand bond.

The further reaction of **1** with one or two equiv of sodium azide produced the binuclear compound **2** where the coordinated water molecules are replaced by the azide ligands. It is evident that **2** is very stable since **2** is exclusively formed regardless of the amount of sodium azide used. In situ generated **1** also leads to the formation of **2** in the presence of sodium azide. The IR spectrum of **2** is distinguished from that of **1** due to the existence of the stretching frequency of the azide ligand instead of the perchlorate anion. In addition, the disappearance of the peak occurring at 3618 cm^{-1} that can be assigned to the coordinated water molecules implies the coordination of the azide ligands to the nickel centers. The UV–Vis spectrum of **2** is analogous to that of **1**. The assignment of each band is as follows: the charge transfer transition for 234 ($\varepsilon = 2080$ M^{-1} cm^{-1}), $^3A_{2g}$ (F) $\rightarrow$ $^3T_{1g}$ (P) for 384 nm ($\varepsilon = 151$ M^{-1} cm^{-1}), $^3A_{2g}$ (F) $\rightarrow$ $^3T_{1g}$ (F) for 640 nm ($\varepsilon = 51$ M^{-1} cm^{-1}), and $^3A_{2g}$ (F) $\rightarrow$ $^3T_{2g}$ (P) for 1068 nm ($\varepsilon = 24$ M^{-1} cm^{-1}). The estimated 10 Dq value of 10 600 cm^{-1} designates that the effect of the ligand field on the complex formation in **2** is stronger than that of **1**. The β value of 85% can be derived from a B value of 881 cm^{-1}.

3.2. Description of the structures

A perspective view of **1** with the atom-numbering scheme is shown in Fig. 1. Selected bond distances and angles are reported in Table 2. The Ni1 atom is in a distorted octahedral arrangement comprising three nitrogen atoms of the pmdtn ligand [Ni1–N1 = 2.141(4) Å, Ni1–N2 = 2.132(4) Å, and Ni1–N3 = 2.143(4) Å], two oxygen atoms of the tp bridge [Ni1–O2 = 2.113(3) Å and Ni1–O3 = 2.178(4) Å] and one oxygen atom of a water

O3–C10–Ni1	61.8(3)	C11–C10–Ni1	174.3(4)

molecule [Ni1–O1w = 2.074(4) Å]. The O2, O3, N1 and N3 atoms constitute the equatorial plane in which the small bite angle of the carboxylate group [O2–Ni1–O3 = 61.29(13)°] gives the main distortion on the octahedral geometry, while the axial positions are filled by the O1w and N2 atoms. The bite angle in **1** is slightly more acute than that (61.9(1)°) reported for $[Ni_2(tp)(bpy)_4](ClO_4)_2$ (bpy = 2,2′-bipyridine), indicating that the octahedron around the Ni atom in **1** is rather more distorted [10]. The tp ligand behaves as a bidentate ligand as expected from the IR data. The dihedral angle between the carboxylate group and the benzene ring of the tp ligand is 14.2°. The intradimer Ni···Ni distance is 10.713 Å.

Hydrogen bonds make the binuclear entity extend toward a higher dimensional system. In **1**, the coordinated water molecule (O1w) undergoes hydrogen bonding to the perchlorate oxygen atom (O6a; a = $1-x, 0.5+y, 0.5-z$) with a distance of 2.850 Å and then the other oxygen atom (O5b; b = $1-x$, $-0.5+y, 0.5-z$) of the anion forms a hydrogen bond to the lattice water oxygen atom (O9w) [O5b··· O9w = 2.902 Å]. The O9w atom is additionally hydrogen-bonded to the carboxylate oxygen atom (O3) [O9w···O3 = 2.768 Å]. The resulting structural overview can be described as a ladder-like array running along the *b*-axis as illustrated in Fig. 2(a). Linkage between the 1D arrays is formed by taking into account that the O1w atom has another hydrogen bond to the lattice water atom (O8w) [O1w···O8w = 2.692 Å] that is close to the other lattice water oxygen (O9wc; c = $-x, -y, -z$) with a distance of 2.749 Å. Consequently, these hydrogen bonds fabricate a 2D network as shown in Fig. 2(b) in the *ca*-plane. The shortest intermolecular distance of Ni···Ni is 8.155 Å.

The molecular structure of **2** resembles that of **1** except the absence of the perchlorate anions and the coordinated water molecules are replaced by the azido groups (Fig. 3). Selected bond distances and angles are reported in Table 3. Each nickel atom adopts a distorted octahedral coordination sphere. The equatorial plane is composed of two oxygen atoms of the tp ligand [Ni1–O1 = 2.187(4) Å and Ni1–O2 = 2.186(3) Å] with a small bite angle of 60.23(13)° and two nitrogen atoms of the pmdtn ligand [Ni1–N1 = 2.135(4) Å and Ni1–N3 = 2.145(5) Å]. The dihedral angle between the carboxylate group and benzene ring of the tp bridge is 21.5°, larger than that of **1**. The intradimer distance of Ni···Ni is 10.800 Å, slightly longer than that of **1**.

As found in **1**, there are plenty of hydrogen bonds in the lattice of **2**. The oxygen atom (O1a; a = $-0.5+x, 0.5-y, 0.5+z$) of the carboxylate group of the tp bridge is connected via a hydrogen bond to the oxygen atom (O4w) of the lattice water molecule [O1a···O4w = 2.892 Å] that is also linked to the other lattice water oxygen atom (O3w) [O3w···O4wb = 2.830 Å; b = $0.5-x, 0.5+y, 1.5-z$]. This lattice water (O3w) is connected to the carboxylate oxygen atom (O2) of the other binuclear entity [O3w···O2b = 2.868 Å] and the nitrogen atom (N4) of another binuclear unit [O3w···N4c = 2.934 Å; c = $-x, 1-y, 1-z$]. In this way, these hydrogen bonds construct a 3D network system as seen in Fig. 4. The shortest intermolecular distance of Ni···Ni is 7.707 Å, shorter than that of **1**.

3.3. Magnetic results

The variable temperature magnetic susceptibility data were measured for **1** in the temperature range 5–300 K. Plots of χ_m and the $\chi_m T$ product versus temperature are presented in Fig. 5. At 300 K, the value of $\chi_m T$ is 2.38 cm^3 K mol^{-1}, which falls in the normal range of two non-coupled Ni(II) ions. On cooling, the $\chi_m T$ value decreases continuously, finally reaching a value of 2.06

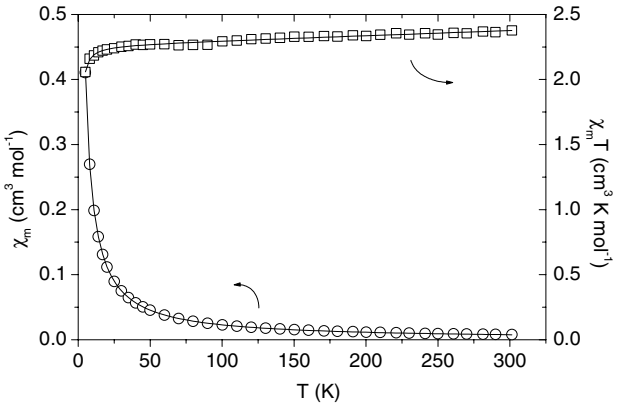

Fig. 5. Plots of χ_m and $\chi_m T$ vs. T for **1**. The solid line shows the best theoretical fit.

m^3 K mol^{-1} at 5 K, suggesting the presence of an antiferromagnetic interaction. A quantitative analysis can be performed on the basis of a spin Hamiltonian $H = -JS_1 \cdot S_2 - D(S_{1z}^2 + S_{2z}^2)$, where D is the zero-field parameter [15]. The experimental data were fitted including the temperature-independent paramagnetism (TIP). Least-squares fitting of the magnetic data gives parameters of $g = 2.12$, $J = -0.18$ cm^{-1}, $D = -2.4$ cm^{-1} and TIP = 0.00039 cm^3 mol^{-1}. The measure of the goodness-of-fit R, defined as $R = [\Phi/(n-k)]^{1/2}$ where n is the number of data points, k is the number of parameters, and $\Phi = \sum[(\chi_m T)_i^{obs} - (\chi_m T)_i^{calc}]^2$, is equal to 7.0×10^{-5}. The J value consistent with the reported value ($J = -0.6$ cm^{-1}) for the nickel dimer bridged by the tp ligand indicates the presence of a weak antiferromagnetic interaction, which is operating via the extended tp ligand [16]. As seen in Fig. 6, the $\chi_m T$ plot of **2** is similar to that of **1**. Magnetic data were fitted using the same equation as **1**, affording magnetic parameters of $g = 2.18$, $J = -0.02$ cm^{-1}, $D = -2.4$ cm^{-1} and TIP = 0.00041 cm^3 mol^{-1} with $R = 2.7 \times 10^{-4}$. The tp ligand in **2** mediates a weaker antiferromagnetic coupling than that in **1**.

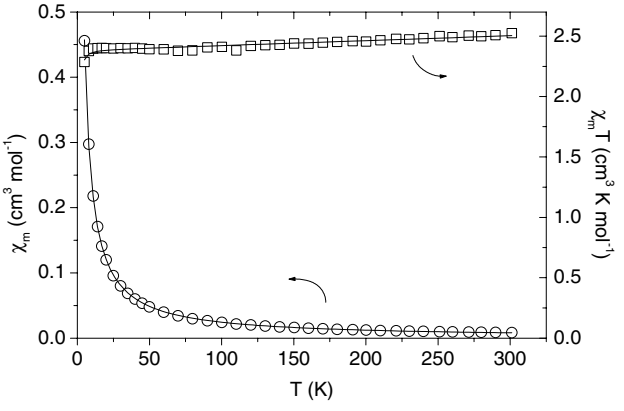

Fig. 6. Plots of χ_m and $\chi_m T$ vs. T for **2**. The solid line presents the best theoretical fit.

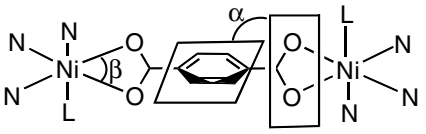

Scheme 1.

Table 4
Magnetic and structural parameters for tp-bridged Ni(II) binuclear complexes

Compound	α (°)	β (°)	d_{Ni-Ni} (Å)	J (cm^{-1})
1	14.2	61.29	10.731	−0.18
2	21.5	60.23	10.800	−0.02
$[Ni_2(bpy)_4(tp)](ClO_4)_2$[a]	5.2	61.9	9.449	−0.6

[a] Refs. [10,16].

It is worth comparing the magnetic properties of **1** and **2**. The magnetic orbitals on the nickel(II) centers that are parallel to the basal plane can be propagated through the tp unit. The magnitude of the magnetic exchange for **1** and **2** likely depends on three factors observed in the structure (Scheme 1): the bite angle (β), the dihedral angle (α), and the intramolecular distance between Ni···Ni (d_{Ni-Ni}). The first factor (β) is related to the orientation of the magnetic orbitals that are delocalized more effectively over the oxygen atoms of the tp ligand when the bite angle is closer to 90°. It is known that the greater the dihedral angle (α) and metal–metal separation (d_{Ni-Ni}) are, the weaker the magnetic interaction between metal centers would be [16]. From the structural parameters, **1** has the larger β, the smaller α, and the shorter d_{Ni-Ni} than **2**. On these criteria, as summarized in Table 4, it is reasonably understood that the magnetic interaction of **1** is stronger than that of **2**.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 229699 and 229700 for complexes **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; email: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Condensation of SMDTC with 2-furyl-methylketone and 5-methyl-2-furaldehyde gave isomeric Schiff bases, (NS) and (NS′). The metal complexes of these uninegatively charged bidentate Schiff base ligands with cadmium, tin, iron, lead and cobalt have been prepared. The complexes have been characterized by a variety of physico-chemical techniques. X-ray crystallographic analysis shows that the Cd(II) complex, bis[*S*-methyl-β-*N*-(2-furylmethylketone)dithiocarbazato]cadmium(II), consists of two molecules with distorted octahedral structure. The Co(II) complexes are paramagnetic with a square-planar stereochemistry. The diamagnetic Sn(II), Fe(III) and Pb(II) complexes also have square-planar structures while the diamagnetic $[Cd(NS')_2]\cdot 3H_2O$ complex is tetrahedral. The $[Cd(NS')_2]\cdot 3H_2O$, $[Sn(NS)_2]$ and $[Co(NS)_2]$ showed clear inhibition of almost all bacteria and fungi tested However, $[Cd(NS)_2]$, $[Fe(NS)]Cl_2$, $[Pb(NS)_2]$ and $[Pb(NS')_2]$ were inactive against all bacteria assayed while $[Cd(NS)_2]$, $[Fe(NS)]Cl_2$ and $[Pb(NS)_2]$ showed clear inhibition of some fungi. The $[Cd(NS)_2]$, $[Cd(NS')_2]\cdot 3H_2O$ and $[Co(NS)_2]$ were found to be very active against Human cell T-lymphoblastic leukemia (CEM-SS) and cervical cancer cells (HELA) with CD_{50} values between 1.8 and 3.6 $\mu l\,cm^{-3}$.

Keywords: *S*-methyldithiocarbazate (SMDTC); NS Schiff base; Crystal structure of Cd(II) complex; Dithiocarbazate derivatives

1. Introduction

Dithiocarbazate, $NH_2NHCS_2^-$, and its substituted derivatives have been synthesized and investigated over the past few decades [1–12]. Dithiocarbazic acid and the Schiff bases derived from its *S*-alkyl and aryl esters form an interesting series of ligands and metal complexes. Researchers in this area have been continuing the syntheses of new nitrogen–sulfur donor ligands through Schiff base condensation with various aldehydes and ketones. The number of ligands synthesized continues to increase because of the intriguing observation that different ligands show different biological properties, although they may differ only slightly in their molecular structures [1,4]. Indeed, carcinostatic activities have already been found for some metal complexes of dithiocarbazic acid and some Schiff bases derived from its *S*-methyl ester [3]. As part of our ongoing study of Schiff bases derived from dithiocarbazate, we report herein the

coordination chemistry and bioactivity of some transition and non-transition metal complexes containing nitrogen–sulfur donor SMDTC derivatives.

2. Experimental

2.1. Preparation of S-methyldithiocarbazate (SMDTC)

This compound was synthesized as previously reported [10]. Potassium hydroxide (22.8 g, 0.4 mol) was dissolved completely in 90% ethanol (140 ml) and the mixture was cooled in ice. To the mixture, hydrazine hydrate (20 g, 0.4 mol) was added slowly with stirring. Carbon disulfide (30.4 g, 0.4 mol) was then added dropwise with vigorous stirring. The temperature of the reaction mixture was not allowed to rise above 6 °C during the period of addition of carbon disulfide. The resulting yellow oil was separated by means of a separatory funnel and dissolved in 40% ethanol (40 ml) and the solution was cooled in ice. Methyl iodide (58 g, 0.4 mol) was added slowly with vigorous stirring. The white product was separated by filtration, washed with water and dried in air. The crude product was recrystallized from ethanol. Yield, 20 g (40%). The melting point was 81 °C (Lit. 81–82 °C) [10].

2.2. General method for preparation of the Schiff bases

The Schiff bases were synthesized as previously reported [11]. SMDTC (0.2 mol) was dissolved in absolute ethanol (35 ml). To this solution was added an aldehyde or ketone, also in absolute ethanol (30 ml). The mixture was heated while being stirred for 15 min and later allowed to stand for 20 min. The precipitate was filtered and dried over silica gel. Crude products were recrystallized from ethanol.

2.3. General method for preparation of the metal complexes

Schiff base (0.2 mol) in 40 ml of absolute ethanol was added to a solution containing a stoichiometric amount of metal salt in absolute ethanol (40 ml). The mixture was heated while being stirred. The precipitate was filtered, washed with ice-cold alcohol and dried over silica gel. The yield and melting point of each product was determined. The metal salts used were $Cd(CH_3COO)_2 \cdot 2H_2O$, $SnCl_2$, $FeCl_3$, $Pb(CH_3COO)_2 \cdot 3H_2O$ and $CoCl_2 \cdot 6H_2O$.

2.4. Physical measurements

Carbon, hydrogen, nitrogen and sulfur analyses were carried out using a LECO CHNS-932 instrument. The IR spectra were recorded as KBr pellets, in the 4000–400 cm^{-1} region, on a Perkin–Elmer 1750X FTIR spectrometer. Metal determinations were carried out using a Perkin–Elmer Plasma 1000 Emission Spectrometer. The molar conductances of 10^{-3} M solutions of the metal complexes in DMSO were measured at 30 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinized electrode. The UV–Vis spectra were run on a Shimadzu UV-2501 PC spectrophotometer (900–200 nm). Melting points were determined using an Electrothermal digital melting point apparatus. Magnetic susceptibility measurements were carried out using a Sherwood Scientific MSB-AUTO magnetic susceptibility balance at 298 K.

2.5. X-ray structure determination

Beautiful yellow crystals of the Cd(II) complex formed when the dimethylsulfoxide (DMSO) solution was allowed to slowly evaporate for a couple of weeks. The selected crystal of the Cd(II) complex was mounted on a SMART CCD diffractometer at the X-ray Crystallography Unit, School of Physics, University of Science Malaysia (USM). Reflection data were measured at 20 °C using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation with a detector distance of 4 cm and a swing angle of −35°. The data collected were reduced using a program SAINT [13] and a multi-scan absorption correction was carried out using SADABS [14]. The structure was solved using direct methods and refined using the full-matrix least-squares methods on F^2_{obs} using the SHELXTL [15] software package. The non-H atoms were anisotropically refined. The hydrogen atoms were located by difference syntheses and later were fixed geometrically and allowed to ride on their parent C atoms, with C–H = 0.93–0.96 Å. The molecular graphics were created using SHELXTL. Atomic scattering factors and anomalous dispersion correction were taken from the International Table for X-ray crystallography [16].

2.6. Bioactivity

2.6.1. Qualitative antimicrobial assay

Eight pathogenic microbials were used to test the biological potential of the compounds: (i) Methicillin resistant *staphylococcus* (MRSA), (ii) *Bacillus subtilis* wild type (B29), (iii) *Bacillus subtilis* mutant defective DNA repair (B28), (iv) *Pseudomonas aeruginosa* (60690), (v) *Candida albicans* (CA), (vi) *Aspergillus ochraceous* (398), (vii) *Saccharomyces cerevisiae* (20341) and (viii) *Candida lypolytica* (2075). The sources of microbes and culture maintenance were as previously described [17]. The antimicrobial activity of each compound was determined qualitatively through the modified disc diffusion method [18]. A lawn of microorganisms was prepared by pipetting and evenly spreading 10 μl of inoculum (adjusted turbidometrically to 10^5–10^6 CFU/cm^3; CFU, colony forming units) onto agar set in petri

dishes. Nutrient agar (NA) was used for bacteria while potato dextrose agar (PDA) was used for fungi. Filter paper discs (Whatman No. 1) measuring 6mm in diameter were impregnated with dimethylsulfoxide (DMSO) stock solution of the compounds (100 mg/cm^3) and dried under sterile conditions. The dried discs were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 37 °C for the bacteria and 30 °C for the fungi. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs.

2.6.2. Quantitative antimicrobial assay

Compounds that showed positive antimicrobial activity with the disc diffusion assay were subjected to the broth dilution method for the qualitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [19]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg/ml). Streptomycin and nystatin (Sigma, USA) were used as positive controls for bacteria and fungi, respectively.

2.6.3. Cytotoxic assay

Two types of cell line were used, CEM-SS (Human cell T-lymphoblastic leukemia) and HELA (cervical cancer cells). The CEM-SS and HELA cell lines were obtained from the National Cancer Institute, USA. Cytotoxicity was evaluated using MTT (3-[4,5-dimethylthiazo-2-yl]-2,5-diphenyltetrazolium bromide) (Sigma, USA) assay following Mosmann's method [17] as previously reported [12]. Cytotoxicity is shown as the minimum concentration required to reduce the absorbance of treated cells by 50% with reference to the untreated cells (CD_{50}). Doxorubicin and tamoxifen were used as cytotoxic standards.

3. Results and discussion

Condensation of SMDTC with 2-furyl-methylketone (NS) and 5-methyl-2-furaldehyde (NS′) gave the isomeric uninegatively charged bidentate Schiff bases. These coordinated with metal ions through the thiolo sulfur and the azomethine nitrogen as reported previously [11].

Analytical data and yields for the Schiff bases and their metal complexes are given in Table 1. Significant IR bands of the Schiff bases and their metal complexes are given in Table 2. The absence of ν(S–H) absorbance at ca. 2570 cm^{-1} in the spectrum of the Schiff bases indicates that in the solid state, they exist primarily in the thione form. These thione groups are relatively unstable in the monomeric form and tend to convert to the more stable thiolo forms by enethiolization in solution [2]. The ^{1}H NMR spectra of the Schiff bases in DMSO

$[Co(NS')_2]$		1572		1028	

showed a peak at ca. δ 4.00 ppm attributed to the S–H proton [11], indicating that the thiolo tautomer was present in solution. The ν(C=S) bands at 1064 and 1094 cm^{-1} observed in the free ligands were not observed in the spectra of the metal complexes, thus supporting the suggestion that coordination was through the thione sulfur. The disappearance of ν(N–H) bands in the IR spectra of the metal complexes suggest that the ligand lost one proton on complexation, thus acting as a uninegative ligand. The lowering in frequency of the azomethine (C=N) band is evidence that the Schiff bases are bonded to the metal ions as bidentate NS chelating agents. Consequently the ν(C–S) mode is observed in the spectra of the complexes confirming that complexation occurred. There is no important displacement of the frequency of the ring breathing, ν(C–O–C) vibration at 1250 cm^{-1} [20] and there was also no absorption observed at ca. 450 cm^{-1} that can be assigned to metal–oxygen bond stretching. This confirms that there was no coordination of furyl ring oxygen to central metal atom except for complex (**3**), in which case it has been proven by X-ray crystallography that there is long distance contact between furyl ring oxygen and the central Cd ion. This can be further proved by the IR spectrum of complex (**3**) where complex (**3**) has the significant displacement of the frequency of the ring breathing, ν(C–O–C) vibration at 1230 cm^{-1} and absorption was observed at 449 cm^{-1} which can be attributed to metal–oxygen bond stretching.

The molar conductance data (Table 3) showed that complexes (**4**), (**5**), (**6**), (**9**), (**10**), (**11**) and (**12**) were non-electrolytes, indicating that the ligand is coordinated to the metal ions as a uninegatively charged bidentate species. Complexes (**7**) and (**8**) exhibit the behavior of 1:2 electrolytes in DMSO [21]. Presumably these complexes undergo solvation to release chloride ions as has been proposed for similar complexes under the same conditions [12].

The magnetic susceptibility measurements (Table 3) showed that complexes (**11**) and (**12**) were paramagnetic at room temperature with magnetic moments of 1.98 and 1.92 B.M., respectively, characteristic of a square-planar structure. The diamagnetic complexes (**5**), (**6**), (**7**), (**8**), (**9**) and (**10**) have square-planar structures whereas complex (**4**) is expected to be tetrahedral [22]. The electronic spectra of the Schiff bases display two

[b] Ref. [11].

bands in the 356–349 and 298–297 nm ranges which can be assigned to the $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions of the azomethine group, respectively. The spectra of metal complexes display two absorptions at 363–324 and 297–289 nm which can be assigned to the intra-ligand transitions of the azomethine group in each case [23]. The bands at 462–452 and 392–387 nm may be assigned as combination of the $^1A_{1g} \rightarrow {}^1E_g$ (d–d) and $S \rightarrow M$ (charge-transfer) transitions. LMCT bands of the type $S \rightarrow M$ are quite common in metal complexes of thiosemicarbazone ligands [24,25] and therefore are not unexpected in the complexes under study here.

3.1. The structure of $Cd(NS)_2$

The molecular structure of the complex with its atom numbering scheme is depicted in Fig. 1. The crystal data and refinement are given in Table 4. The asymmetric unit consists of 2 molecules.

The geometry of the central Cd1A (Table 5) atom is distorted octahedral with atoms O1A and S2A in the axial positions. The O1A–Cd1A–S2A bond angle is 140.10(10)°. The O2A, N1A, S3A and N3A atoms occupy the equatorial positions with bond angles between 64.10(16)° and 118.20(13)° about the central Cd1A ion (Table 5). The Cd1A···O1A and Cd1A···O2A bond lengths of 2.710(4) and 2.654(6) Å, respectively, are slightly longer than normal [26] but bonds of this length have been observed in compounds such as $[Cd\{C_2(COO)_2\}(H_2O)_3]\cdot H_2O$ [27] and $[Cd_2(NO_3)_2(C_6H_{12}N_4)_2](NO_3)_2$ [28].

In the second molecule, the octahedral geometry about Cd1B is severely distorted with long range Cd1B···O2B and Cd1B···O1B bond lengths of 2.850(6) and 2.763(5) Å, respectively. Such a long Cd–O bond length has been previously reported in Λ-$[Cd(C_{20}H_{44}N_4O_4)](C_6H_2N_3O_7)_2\cdot CH_3CN$ for Cd···O(H) (2.845(2) Å) [29]. The lengthening of this Cd1B···O2B bond may be due to interaction in the packing of the molecules. The furyl ring O2B–C9B–C10B–C11B–C12B and Cd1B are planar with maximum deviation for Cd1B of only 0.032(1) Å from the mean plane. However, the central atom, Cd1B is deviated by −0.610(1) Å from the opposite furyl ring, O1B–C1B–C2B–C3B–C4B. The two furyl fragments are almost perpendicular to one another (83.5(5)°). In the first molecule, the central atom, Cd1A, is deviated from both furyl rings O1A–C1A–C2A–C3A–C4A and O2A–C9A–C10A–C11A–C12A by −0.938(1) and −0.641(1) Å, respectively, with dihedral angle between the furyl rings of 66.2(5)°. Both Cd central atoms chelated to the thiolo sulfur, β-azomethine nitrogen and furyl oxygen in a tridentate manner.

In the second molecule, the O1B and S2B atoms occupy the axial position with O1B–Cd1B–S2B bond angle of 138.17(12)°. The O2B, N1B, S3B and N3B atoms occupy the equatorial positions with angles between 61.68(18)° and 138.29(13)°. The bond lengths and angles in the Schiff bases are typical of dithiocarbazate Schiff bases [11]. However the elongation of the S1B–C8B bond to 1.819(9) Å in comparison to the other S–C(Me) bonds (1.767(8)–1.793(8) Å) is possibly the result of vibration.

The chelated fragments Cd1A–N1A–N2A–C7A–S2A (maximum deviation 0.034(6) Å for N1A) and Cd1A–N3A–N4A–C15A–S3A (maximum deviation 0.0014(5) Å for N3A) in the first molecule are planar. The angle between the two fragments is 82.76(19)°. In the second molecule, the chelated fragments Cd1B–N1B–N2B–C7B–S2B and Cd1B–N3B–N4B–C15B–S3B are less planar with maximum deviations of 0.151(6) and 0.182(5) Å for N1B and N3B atoms, respectively, with dihedral angle of 68.2(2)°.

Table 4
Crystal data, data collection and structure refinement parameters for the $[Cd(C_8H_9N_2S_2O_1)_2]$ complex

Compound	$[Cd(C_8H_9N_2O_1S_2)_2]$

Bacillus subtilis (mutant-defective DNA repair) (B28), *Pseudomonas aeruginosa* (60690, Methicillin resistant *Staphylococcus* (MRSA), *Bacillus subtilis*-wild type (B29), *Saccharomyces cerevisiae* (20341), *Candida albicans* (C.A.), *Candida lypolytica* (2075), *Aspergillus ochraceous* (398).

[a] MIC ($\mu g\,ml^{-3}$), minimum inhibitory concentration, i.e. the lowest concentration to completely inhibit microbial growth. Complexes (**4**), (**5**), (**6**) and (**11**) indicate that they are less active than the standard drug, streptomycin.

clear inhibition of *Candida lypolytica* (2075) and *Aspergillus ochraceous* (398), respectively. Complex (**6**) showed activity against three bacteria [*Pseudomonas aeruginosa* (60690), Methicillin resistant *Staphylococcus* (MRSA) and *Bacillus subtilis*-wild type (B29)] and two fungi [*Candida lypolytica* (2075) and *Aspergillus ochraceous* (398)]. Complexes (**8**), (**10**) and (**12**) were inactive toward all bacteria and fungi. Qualitative antimicrobial results are shown in Table 6. Compounds that showed clear inhibition zones of 15 mm and above were considered active and attempts were made to determine the minimum inhibitory concentration (MIC) (Table 7). The MIC values against bacteria ($=390$–$12\,500\ \mu g\,cm^{-3}$) for complexes (**4**), (**5**), (**6**) and (**11**) indicate that they are less active than the standard drug, streptomycin. The MIC values for complexes (**4**) and (**11**) against *Candida lypolytica* (2075) and *Aspergillus ochraceous* (398) were higher than the standard drug, nystatin; however, complexes (**3**) and (**7**) were less active than nystatin toward *Saccharomyces cerevisiae* (20341) and *Candida lypolytica* (2075), respectively, while complexes (**6**) and (**9**) were less active against *Aspergillus ochraceous* (398) than nystatin. The activities of the remainder were comparable to nystatin.

Table 8
Cytotoxic activity

Compound	CD_{50} (μg/ml)	
	T-lymphoblastic leukemic cells (CEM-SS)	Cervical cancer cells (HELA)
NS	>25	>25
NS′	>25	>25
$[Cd(NS)_2]$	1.8	1.8
$[Cd(NS')_2]\cdot 3H_2O$	2.0	1.8
$[Sn(NS)_2]$	>25	na
$[Sn(NS')_2]\cdot 3H_2O$	>25	na
$[Fe(NS)]\cdot Cl_2$	>25	na
$Fe(NS')]\cdot Cl_2$	>25	>25
$[Pb(NS)_2]$	>25	na
$[Pb(NS')_2]$	>25	na
$[Co(NS)_2]$	2.1	3.6
$[Co(NS')_2]$	>25	>25
$CdBr_2\cdot 4H_2O$	14.0	na
$SnCl_2\cdot 2H_2O$	>25	na
$FeCl_2$	>25	na
$PbNO_3$	>25	na
$CoCl_2\cdot 6H_2O$	12.0	na
Doxorubicin (standard)	0.10	11.0
Tamoxifen (standard)	36.0	7.0

Note. na, not available; CD_{50}, <5.0 μg/ml – strongly active; CD_{50}, 5.0 to <10.0 μg/ml – moderately active; CD_{50}, 10.0–25.0 μg/ml – weakly active; CD_{50}, >25.0 μg/ml – not active.

3.2.2. Cytotoxic activity

Complexes $[Cd(NS)_2]$ (**3**); $[Cd(NS')_2]\cdot 3H_2O$ (**4**) and $[Co(NS)_2]$ (**11**) (where NS and NS′ are the 2-furylmethylketone and 5-methyl-2-furaldehyde Schiff bases of SMDTC) were found to be very active against T-lymphoblastic leukemic cells (CEM-SS) and cervical cancer cells (HELA) with CD_{50} values between 1.8 and 3.6 $\mu l\,cm^{-3}$. While both Schiff bases utilized in this work had been shown to be inactive [11] in their uncomplexed state, Tarafder et al. [22] reported that the 5-methyl-2-furaldehyde Schiff base of the closely related S-benzyldithiocarbazate (SBDTC) exhibited strong activity against CEM-SS. It is of note that the inactive 2-furylmethylketone Schiff base of SMDTC became active on complexation with Cd(II) (**3**) while for the SBDTC derivative, the opposite was the case, the Cd(II) complex was found [22] to be inactive against CEM-SS. Interestingly, the Cd(II) complexes of 5-methyl-2-furaldehyde Schiff bases of both SBDTC and SMDTC (**4**) showed good activity towards CEM-SS. However, Pb(II) complexation of the 5-methyl-2-furaldehyde Schiff bases of both SBDTC [22] and SMDTC (**10**) did not alter their activity towards CEM-SS. Complexes (**8**) and (**12**) were found to be inactive toward both cell lines. Complexes (**5**), (**6**), (**7**), (**9**) and (**10**) were tested against only CEM-SS and were found to be inactive (Table 8). In all cases the simple inorganic metal salts were no more than weakly active at the maximum concentrations used in the assay of the complexes. It is clear that more

comparative data must be collected for Schiff bases containing different functional groups and complexed to different metal ions before a pattern of activity can be determined.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 215299. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Li[(C_5H_4)CMe_2PHPh] reacted with [$CrCl_3(THF)_3$] with formation of a mixture of products, among which only [{(η^5-C_5H_4)CMe_2PPh}$CrCl]_2$ (**1**) could be isolated. However, when [$CrCl_3(PMe_2Ph)_3$] was treated with Li[(C_5H_4)CMe_2PHR], the complexes [{(η^5-C_5H_4)CMe_2PHR}$CrCl_2(PMe_2Ph)$] (R = Ph (**2**), ^{t}Bu (**3**)) were obtained in moderate yield. Complexes **1** and **2** were characterised by X-ray crystallography, **1–3** by IR spectroscopy. In the solid state, a phosphanido-bridged dimer is observed for **1**, while **2** and **3** are monomeric complexes without coordination of the phosphanyl group of the cyclopentadienyl ring. **2** and **3** were also characterised by mass spectrometry and NMR and UV–Vis spectroscopy, and their magnetic moments were determined. **2** and **3** were studied in the catalytic polymerisation of ethylene with methylalumoxane (MAO) as cocatalyst.

Keywords: Phosphanylalkylcyclopentadienyl ligands; Chromium complexes; Polymerisation studies

1. Introduction

After the discovery of α-olefin polymerisation [1], numerous metallocene and monocyclopentadienyl derivatives with different steric and electronic properties were synthesised and employed as catalysts in polymerisation reactions. *Ansa*-metallocene dichlorides of Ti, Zr, and Hf (especially chiral ones) are important catalysts for the methylalumoxane-promoted isotactic polymerisation of olefins. Therefore, intensive research is being carried out towards the synthesis of improved catalysts [2–5]. Recently, monocyclopentadienyl derivatives in which the cyclopentadienyl ring has a heteroatom-functionalised side chain were prepared and employed in the polymerisation and copolymerisation of olefins [6]. These studies were also extended to phospholyl ligands [7].

While numerous cyclopentadienyl ligands with *O*- and *N*-functionalised side chains are known, the number of cyclopentadienes with a *P*-functionalised alkyl or silyl side chain is still small [8], and it was only in 1994 that Heidemann and Jutzi [9] reported the first compound in which the P atom bears a reactive P–H bond. We extended this class of compounds to other derivatives in 1999 [10,11]. The lithium salts [Li(TMEDA)]$_2$[(C_5H_4)-CMe_2PPh] [12] and [Li(TMEDA)][(C_5H_4)CMe_2PR_2] (R = Ph, Me) [13], 1-$SiMe_2PHMes^*C_5Me_4H$ and its dimeric dipotassium salt [$K(THF)_2]_2$[(C_5Me_4)$SiMe_2$-PMes*] (Mes* = 2,4,6-$^t Bu_3C_6H_2$) [14] have been structurally characterised. Such compounds should be useful precursors for dianionic bifunctional ligands in transition metal chemistry. In addition, the presence of a P-containing group is advantageous for reactivity studies by ^{31}P NMR spectroscopy.

We previously reported the synthesis of the PH-functionalised ferrocene derivatives *rac*-[Fe{(η^5-C_5H_4)CMe_2PHR}$_2$] [R = Ph, 2,4,6-$Me_3C_6H_2$ (Mes)] [15] the monosubstituted phosphanylalkylcyclopentadienyl

complexes of group 4 metals, [{(η^5-C_5H_4)$SiMe_2PHR$}-$ZrCl_3$] (R = Ph, Cy) and [{(η^5-C_5H_4)CMe_2PH^tBu}-MCl_3] (M = Ti, Zr) [16] and of the metallocene derivatives [{(η^5-C_5H_4)CMe_2PHR}$_2ZrCl_2$] and [{(η^5-C_5H_4)CMe_2PHR}$_2$TiCl] (R = Ph, ^{t}Bu). The last-named slowly decompose on recrystallisation from THF, Et_2O or toluene with formation of [{(η^5-C_5H_4)$_2CMe_2$}MCl_2] (M = Zr, Ti) and $(PR)_n$ (R = Ph, n = 4–6, R = ^{t}Bu, n = 4) and PH_2R [17]. Recently, Erker and coworkers [18] reported the synthesis and catalytic properties in the polymerisation of olefins of the constrained-geometry catalysts [{(C_5H_4)CMe_2PCy}$M(NR_2)_2$] (M = Ti, R = Me, M = Zr, R = Et). Hou and coworkers [14] reported the synthesis of [{(η^5-C_5Me_4)$SiMe_2PMes$*}-$Ln(L)_n$] (Ln = Sm: L = THF, n = 1 or 3; L = $MeOCH_2$-CH_2OMe, n = 2; L = $PO(NMe_2)_3$, n = 2; Ln = Yb, L = THF, n = 3) and the polymerisation of ethene, ε-caprolactone and 1,3-butadiene with the Sm^{II} mono-THF complex.

We now report the synthesis and catalytic properties of the first PH-functionalised phosphanylalkylcyclopentadienyl complexes of chromium(III), [{(η^5-C_5H_4)CMe_2PHR}$CrCl_2$(PMe_2Ph)] (R = Ph (**2**), ^{t}Bu (**3**)), and the first constrained-geometry chromium complex with a phosphanidoalkylcyclopentadienyl ligand, [{(η^5-C_5H_4)CMe_2PPh}CrCl]$_2$ (**1**).

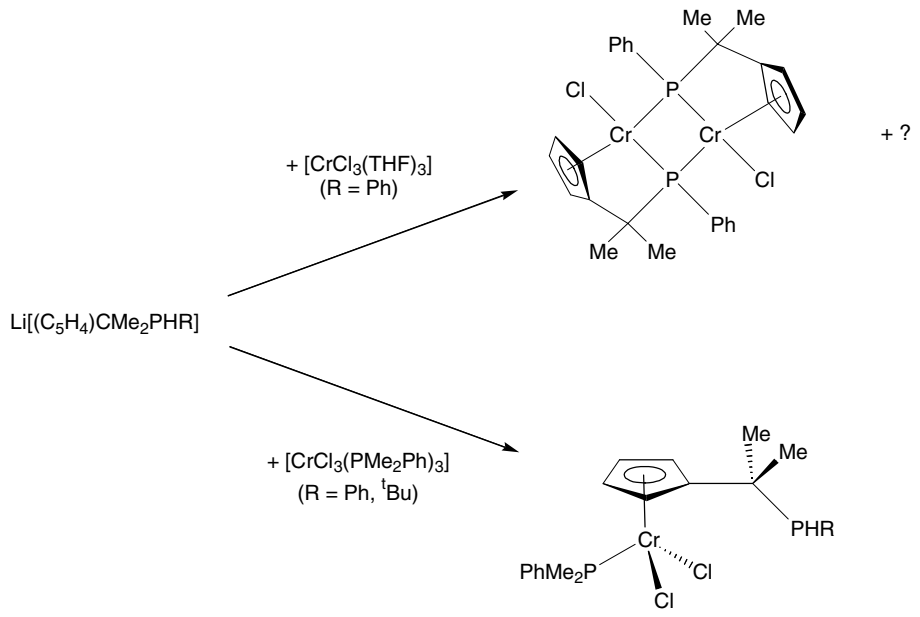
Only a limited number of chromium complexes with chelating tertiary phosphanylalkylcyclopentadienyl ligands is known [19]. [{(η^5-C_5H_4)$CH_2CH_2PR_2$}$CrCl_2$] (R = Me, Et, Pr, ^{i}Pr, ^{i}Bu, ^{t}Bu, neopentyl, hexyl, Cy, Ph, *o*-tolyl, 1-naphthyl) are accessible from the corresponding lithium cyclopentadienide and [$CrCl_3(THF)_3$] [19]; reaction with MeLi and R′MgCl gave the corresponding dimethyl and dialkyl derivatives (R′ = Me, Pr, Cy, ^{t}Bu). The dichloride complex can be used with methyl alumoxane (Al:Cr = 100:1) as a catalyst for the polymerisation of ethene [20].

2. Results and discussion

The lithium reagents Li[(C_5H_4)CMe_2PHR] (R = Ph [10], ^{t}Bu [17]) are readily accessible by reaction of LiPHR with 6,6-dimethylfulvene. The reaction of Li[(C_5H_4)CMe_2PHPh] with [$CrCl_3(THF)_3$] yielded a pale blue powder, from which a small amount of blue crystals of [{(η^5-C_5H_4)CMe_2PPh}CrCl]$_2$ (**1**) was obtained on recrystallisation from toluene/hexane (Eq. (1)). Attempts to synthesise **1** in better yield (a) by heating to reflux after addition of Li[(C_5H_4)CMe_2PHPh] to [$CrCl_3(THF)_3$]; (b) by reaction of [{(η^5-C_5H_4)CMe_2-$PHPh$}$CrCl_2$(PMe_2Ph)] with DBU (DBU = 1,8-diazabicyclo[5.4.0]undec-7-ene); or (c) by reaction of Li[(C_5H_4)CMe_2PHPh] with [$CrCl_3(THF)_3$] in the presence of DBU failed. The molecular structure (vide infra) shows a phosphanido-bridged dimer. However, the presence of a PH band at 2289 cm^{-1} in the IR spectrum of the pale blue powder indicates that a mixture of products was obtained. The other product(s) could, however, not be obtained in pure form by fractional crystallisation, extraction or thin-layer chromatography. The formation of 6,6-dimethylfulvene in the reaction mixture, shown by ^{1}H NMR spectroscopy, indicated decomposition of the phosphanylalkylcyclopentadienyl ligand. Similarly, decomposition of Li[(C_5H_4)C-Me_2PHPh] was observed on protonation with HCl gas in diethyl ether (formation of PH_2Ph, LiCl and 6,6-dimethylfulvene) and in reactions with $AlCl_3$, for which elimination of HCl is proposed as the first reaction step [21]. A similar reaction is proposed here, with attack of $CrCl_3$ on the cyclopentadienyl ring (with elimination of LiCl) and/or at the phosphanyl group (with elimination of HCl).

Activation of the PH proton and elimination of HCl can be avoided if [$CrCl_3(PMe_2Ph)_3$] is employed as starting material, as this prevents attack at the phosphanyl group, as well as subsequent reactions after formation of the cyclopentadienyl complexes, because coordination of the phosphanyl group to chromium is prevented. Dark green [$CrCl_3(PMe_2Ph)_3$] is readily obtained from the reaction of $CrCl_3$ with three equivalents of PMe_2Ph in refluxing THF/toluene (if less PMe_2Ph is employed, unconsumed insoluble $CrCl_3$ remains) [22]. After filtration, the solution of the phosphine complex was treated in situ with a solution of Li[(C_5H_4)C-Me_2PHR] in THF at −50 °C, and the blue chromium(III) complexes [{(η^5-C_5H_4)CMe_2PHR}$CrCl_2$(PMe_2Ph)] (R = Ph (**2**), ^{t}Bu (**3**)) were obtained in high yield (Eq. (1)).

Crystals of **2** and **3** are only slowly oxidised in air, while a blue solution of **3** in THF, toluene or CH_2Cl_2 slowly turns green on prolonged exposure to air. In the IR spectra, complexes **2** and **3** exhibit a sharp PH absorption at 2278 (**2**) and 2276 cm^{-1} (**3**). The $^{31}P\{^1H\}$ NMR spectra (CH_2Cl_2/C_6D_6) show very broad signals ($v_{1/2}$ ca. 900 Hz) at 92 (**2**) and 111 ppm (**3**) (cf. Li[(C_5H_4)CMe_2PHR]: −1.2 ppm (R = Ph) [10]), 26.0 ppm (R = ^{t}Bu) [17]. Typical of half-sandwich Cr^{III} complexes, the ^{1}H NMR spectra of **2** and **3** (C_6D_6) show several broad and isotropically shifted resonances ranging in chemical shift approximately from +11 to −30 ppm. Consistent with the structural similarity of **2** and **3**, both spectra feature a series of very similar peaks, namely, those at 10.5, 5.0, ca 0.0 and ca. −28 ppm. These are likely associated with the PMe_2Ph ligand and the geminal methyl groups of the cyclopentadienyl substituent, although the greater signal intensity at 0.0 ppm in **3** suggests accidental coincidence with the resonance of the *tert*-butyl group. The spectrum of **2** exhibits a few minor additional peaks, which are attributed to the P-bound phenyl ring. In summary, the ^{1}H NMR spectra of paramagnetic organometallics can rarely be unambi-



(1)

R = Ph (**2**), ^{t}Bu (**3**)

gously assigned. However, the spectra of **2** and **3** clearly show them to be closely related and are entirely consistent with the crystal structures. The cyclopentadienyl protons are probably too far shifted and broadened to be readily detectable.

In the UV–Vis spectra the blue complexes **2** and **3** show absorptions at $\lambda = 661$ ($\log(\varepsilon/\mathrm{cm}^2\ \mathrm{mol}^{-1}) = 4.69$) and 667 nm ($\log(\varepsilon/\mathrm{cm}^2\ \mathrm{mol}^{-1}) = 4.72$), respectively.

No meaningful mass spectrum was obtained for **2**, while for **3**, a molecular ion peak as well as fragmentation products thereof were observed in the FAB mass spectrum.

2.1. Molecular structures of *1* and *2*

Crystals of **2** suitable for X-ray crystallography were obtained from a concentrated solution in diethyl ether at −30 °C. Compound **3** crystallises in very thin plates regardless of the solvent used for crystallisation. Therefore, only a poor data set was obtained, but it was sufficient to elucidate the structural motif, which is similar to that of **2**.

Compounds **1** and **3** crystallise in the monoclinic space group $P2_1/c$ with 2 and 8 formula units in the unit cell, respectively; **2** crystallises in the triclinic space group $P\bar{1}$ with 4 formula units in the unit cell.

In **1**, the centre of the Cr_2P_2 ring coincides with a crystallographic centre of inversion. The Cr_2P_2 ring forms a parallelogram with a Cr···Cr distance of 2.9383(1) Å and a P–Cr–P bond angle of 102.75(2)° (Table 1). The cyclopentadienyl ring and the Cr_2P_2 ring form an angle of 32.4(1)°; the cyclopentadienyl and phenyl rings form an angle of 35.8°. The chromium atom, C1 of the cyclopentadienyl ring, C12 of the methylene bridge and P1 form a planar four-membered ring; this plane forms an angle of 54.8(1)° with the Cr_2P_2 ring (see Fig. 1).

There are two independent molecules in the asymmetric unit of **2**, which differ mainly in the configuration of the chiral P atoms, P1 and P3. One has *R*, and the other *S* configuration (see Fig. 2).

In **1**, the Cr–P bond is 0.09 Å shorter than the coordinative Cr–P(PMe$_2$Ph) bond in **2** (2.439(1) and 2.447(1) Å). Similar Cr–P bond lengths are observed in the phosphanido-bridged complexes [{(η^5-C_5Me_5)Cr}$_2$(μ-

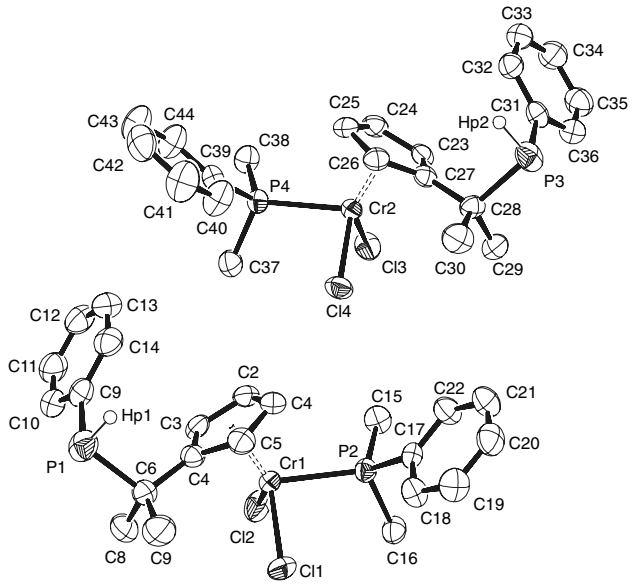

Fig. 2. Molecular structure of $[\{(\eta^5\text{-}C_5H_4)CMe_2PHPh\}CrCl_2(PMe_2Ph)]$ (**2**) showing the atom-numbering scheme employed (ORTEP plot, 50% probability, SHELXTL PLUS; XP [26]). Hydrogen atoms (other than PH) are omitted for clarity. There are two independent molecules in the unit cell.

$PPh_2)_n(\mu\text{-}Cl)_{3-n}]^+$ ($n = 1$, 2; Cr–P 2.385(2)–2.404(4) Å) [23] and the phosphine complexes $[\{(\eta^5\text{-}C_5H_4)CH_2\text{-}CH_2PR_2\}CrCl_2]$ (2.459(1) (R = Cy), 2.447(1) Å (R = Ph)) [19]. The different environment of Cr in **1** and **2** has only minor influence on the Cr–C (cyclopentadienyl ring) and Cr–Cl distances (see Table 1).

2.2. Ethylene polymerisation catalysis

Cyclopentadienyl chromium(III) complexes are known to catalyse the polymerization of ethylene, and in view of the structural novelty of the complexes described above their catalytic activity was evaluated. 10 mg of chromium compound and 100 equivalents of methylalumoxane (MAO) were dissolved in 50 ml toluene ([Cr] $\approx 10^{-6}$ M) and exposed to 1.4 MPa of ethylene for 1 h at room temperature. Under these conditions both **2** and **3** produced moderate amounts of polyethylene (**2**, 0.54 g; **3**, 1.38 g). Characterisation of the resulting polymers by ^{13}C NMR spectroscopy showed them to be highly linear polyethylene with negligible branching (**2**, 0.9 branches per 1000 backbone C atoms; **3**, 1.9 branches per 1000 backbone C atoms). However, molecular weight determination by gel permeation chromatography (GPC) revealed a surprising difference between the two samples. Polyethylene obtained with **3** had a very narrow molecular weight distribution ($M_n = 2220$, $M_w = 4710$, $M_w/M_n = 2.12$), consistent with a homogeneous single-site catalyst. In contrast, the polymer produced by **2** was at least trimodal and accordingly had a much higher

polydispersity ($M_n = 4830, M_w = 617000, M_w/M_n = 127.8$). The reasons for this disparity are not clear, given the subtle structural differences between the two catalyst precursors.

3. Experimental

3.1. General

All experiments were carried out under purified dry nitrogen. Solvents were dried and freshly distilled under argon. The NMR spectra were recorded with an AVANCE DRX 400 spectrometer (Bruker): ^{1}H NMR (400.13 MHz): internal standard solvent, external standard TMS; ^{31}P NMR (161.9 MHz): external standard 85% H_3PO_4. The IR spectra were recorded on an FT-IR spectrometer Perkin–Elmer System 2000 (KBr) in the range 350–4000 cm^{-1}. UV–Vis spectra were recorded with a LAMBDA 900 (Perkin–Elmer). The magnetic moments were determined with a magnetic susceptibility balance of Johnson Mathey Alfa Products. EI MS: MAT 212 (Varian); FAB: ZAB-HSQ-VG Analytical Manchester. The melting points were determined in sealed capillaries under nitrogen and are uncorrected (Boetius). Li[$(C_5H_4)CMe_2PHPh$] [10] Li[$(C_5H_4)CMe_2PH^tBu$] [17] and [$CrCl_3(PMe_2Ph)_3$] [24] were prepared according to the literature procedures. $CrCl_3$ is commercially available (Merck).

3.2. Synthesis of [{(η-C_5H_4)CMe_2PPh}$CrCl$]$_2$ (1)

At ca. −50 °C a solution of Li[$(C_5H_4)CMe_2PHPh$] (1.7 g, 7.7 mmol) in THF (10 ml) was slowly added to a suspension of [$CrCl_3(THF)_3$] (2.9 g, 7.7 mmol) in THF (25 ml). During the addition, [$CrCl_3(THF)_3$] slowly dissolved, and the initially colorless solution turned dark green after addition of several drops of the solution of the Li salt. The solution was stirred for 24 h at r.t., after which it had turned blue. Then the solvent was evaporated in vacuum and the slimy blue residue was washed with *n*-hexane to give 2.0 g of a blue powder after drying in vacuo. The blue powder was dissolved in toluene (15 ml) and layered with *n*-hexane. A blue powder was obtained and a small amount of blue crystals of **1** suitable for X-ray structure determination formed at the interface between the two solvents.

3.3. Synthesis of [{(η^5-C_5H_4)CMe_2PHPh}$CrCl_2$-(PMe_2Ph)] (2)

$CrCl_3$ (1.2 g, 7.6 mmol) was suspended in toluene (25 ml), and THF (25 ml) and PMe_2Ph (3.3 ml, 22.8 mmol) were added quickly. The mixture slowly turned green and was refluxed for ca. 2 h, after which the reaction was complete. The solution was filtered and the filtrate cooled to −50 °C. A solution of Li[$(C_5H_4)CMe_2PHPh$] (1.7 g, 7.6 mmol) in THF (25 ml) was slowly added to this solution. During the addition, the initially green solution turned blue. The solution was stirred for 12 h at r.t. Then the solvent was evaporated in vacuo and the blue residue dissolved in CH_2Cl_2 (25 ml). LiCl was separated from the blue solution by filtration and extracted twice with CH_2Cl_2 (10 ml). The CH_2Cl_2 fractions were combined and the solvent was evaporated in vacuum. The blue residue was washed with hexane (2×20 ml) and extracted repeatedly with Et_2O (70 ml) to give 1.8 g (50%) of **2**; m.p. 114–117 °C. Blue crystals were obtained from a concentrated Et_2O solution at −30 °C.

^{1}H NMR (C_6D_6): $\delta = -28.3$ (br s), 0.3 (s), 4.5 (sh), 5.0 (s), 5.8 (s), 10.5 (s). ^{31}P NMR (CH_2Cl_2/C_6D_6): $\delta = 92$ ppm. IR: 3076 (w, CH, C_5H_4), 3054 (w, CH, Ph), 2964, 2910 (m, CH, CH_3 (CMe)), 2866 (w, CH, CH_3 (PMe)), 2278 (m, PH), 1476, 1365 (m-st, CH_3 (CMe)), 1435 (st, CH_3 (PMe)), 1282, 1106 (w-m, PC (PMe_2Ph), 955, 924, 829, 913 (st, CH, CH_3 (PMe)) 745, 694 (st, CH, Ph) 485 (m, PC (PMe_2Ph)) cm^{-1}. UV–Vis: log(ε/cm^2 mol^{-1}) = 4.69 ($\lambda = 661$ nm). $\mu_{eff} = 4.0$ B.M. ($\mu_{calc} = 3.8$). *Anal*. Calc. for $C_{22}H_{27}Cl_2CrP_2$ (476.3): C, 55.5; H, 5.7. Found: C 53.9, H 5.3%.

3.4. Synthesis of [{(η^5-C_5H_4)CMe_2PH^tBu}$CrCl_2$-(PMe_2Ph)] (3)

$CrCl_3$ (1.3 g, 8.2 mmol) was suspended in toluene (25 ml), and THF (25 ml) and PMe_2Ph (3.5 ml, 24.2 mmol) were added quickly. The mixture slowly turned green and was refluxed for ca. 2 h, after which the reaction was complete. The solution was filtered and the filtrate cooled to −50 °C. A solution of Li[$(C_5H_4)CMe_2PH^tBu$] (1.65 g, 8.2 mmol) in THF (10 ml) was slowly added to this solution. During the addition, the initially green solution turned blue. The solution was stirred at r.t. for 2 h and then refluxed for 1 h. Then the solvent was evaporated in vacuum and the blue residue dissolved in CH_2Cl_2 (25 ml). LiCl was separated from the blue solution by filtration and extracted twice with CH_2Cl_2 (10 ml). The CH_2Cl_2 fractions were combined and the solvent was evaporated in vacuum. The blue residue was washed with hexane (2×25 ml) and extracted repeatedly with Et_2O (50 ml) to give 1.9 g (51%) of **3** as blue crystals; m.p. 143 °C.

^{1}H NMR (C_6D_6): $\delta = -28.3$ (br s), 0.0 (s), 5.0 (s), 8.9 (br s), 10.5 (s). ^{31}P NMR (CH_2Cl_2/C_6D_6): $\delta = 111$ ppm. IR: 3080 (w, CH, C_5H_4), 3054 (w, CH, Ph), 2953, 2892 (m-st, CH, CH_3 (CMe)), 2859 (m-st, CH, CH_3 (PMe)), 2295, 2276 (m, PH), 1474, 1365 (m-st, CH_3 (CMe)), 1436 (m-st, CH_3 (PMe)), 1411 (m-st, CH_3 (^{t}Bu)) 1280, 1107 (m, PC (PMe_2Ph)), 955, 924, 829, 913 (st, CH, CH_3 (PMe)) 744, 694 (st, CH, Ph) 485 (m, PC (PMe_2Ph)), 408

3.5. Data collection and structural refinement of **1** and **2**

Data (λ(Mo Kα) = 0.71073 Å) were collected with a Siemens CCD (SMART) diffractometer. All observed reflections were used for refinement (SAINT) of the unit-cell parameters. Empirical absorption correction with SADABS [25]. The structures were solved by direct methods (SHELXTL PLUS) [26]. For **1** and **2**, Cr, P, Cl, and C atoms were refined anisotropically; H atoms were located by difference maps and refined isotropically (see Table 2).

4. Supplementary material

CCDC-221773 (**1**) and -221774 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44)-1223-336-033; or deposit@ccdc.cam.uk).

Abstract

A combination of host guest and coordination chemistry in the design of a spectroscopic sensor for lanthanide and aluminium ions is described. Nickel(II) and copper(II) complexes with a N_2O Schiff base ligand and bearing two benzo-15-crown-5 moieties as flexible arms have been prepared and characterised by FAB-MS, UV–Vis and FTIR spectroscopies and, depending on the transition metal, by ^1H NMR or EPR. Recognition studies of alkaline, alkaline-earth, aluminium and lanthanide ions have been attempted in dmf by UV–Vis spectroscopy. Charge transfer and intraligand electronic bands of the Ni(II) and Cu(II) complexes show significant changes only in the presence of the M^{3+} ions used, lanthanides (Er^{3+}, Gd^{3+} and Pr^{3+}) and Al^{3+}. Spectral changes induced by increasing M^{3+} concentrations have allowed the calculation of stability constants associated with the coordination of one trivalent ion in each crown ether moiety, corresponding to the formation of 1:2 adducts (metal complex:M^{3+}), with values of $\log \beta_{21}$ in the range 8.2–9.5. No apparent correlation is perceptible between $\log \beta_{21}$ values and the transition metal, but a cavity effect was detected for each metal complex since $\log \beta_{21}$ values increased as lanthanide radii increased.

1. Introduction

Molecular recognition is the first step in the design of molecular sensors for detection of ions or neutral species in organic or aqueous media. In the presence of the target species, the molecular sensor is designed to exhibit a physical response which must be easily detected.

The traditional approach of host–guest chemistry has focused primarily on systems, such as crown ethers, calixarenes and cryptands, which have shown to act as selective hosts for ions and neutral species [1–3]. Upon specific functionalisation they can act as excellent platforms to append several sensing moieties, allowing the preparation of panoply of molecular sensors which will detect the target species by using specific physicochemical properties of the attached sensing block.

There has been an increasing interest in the preparation of the referred host groups with appended transition metal complexes, and examples of this work include as signalling moieties ferrocene and other organometallic compounds [4–7], Schiff base complexes [7–9], metalloporphyrins and phthalocyanines [7,10–12]. These systems, owing to intrinsic properties of transition metals, constitute versatile spectroscopic and electrochemical responsive receptors for charged and neutral guests.

We have been interested in the preparation of Schiff base complexes functionalised with crown ether and pseudo-crown ether moieties for ion recognition, both in solution and as polymeric films deposited onto Pt and ITO electrodes. We have grafted dibenzo18-crown-6- and benzo-15-crown-5-ether onto N_2O_2 Schiff base ligands [13] and explored their properties to sense representative and lanthanide cations, both in solution [14] and as-deposited polymeric films [15]. Currently, we are pursuing the synthesis of Schiff base ligands

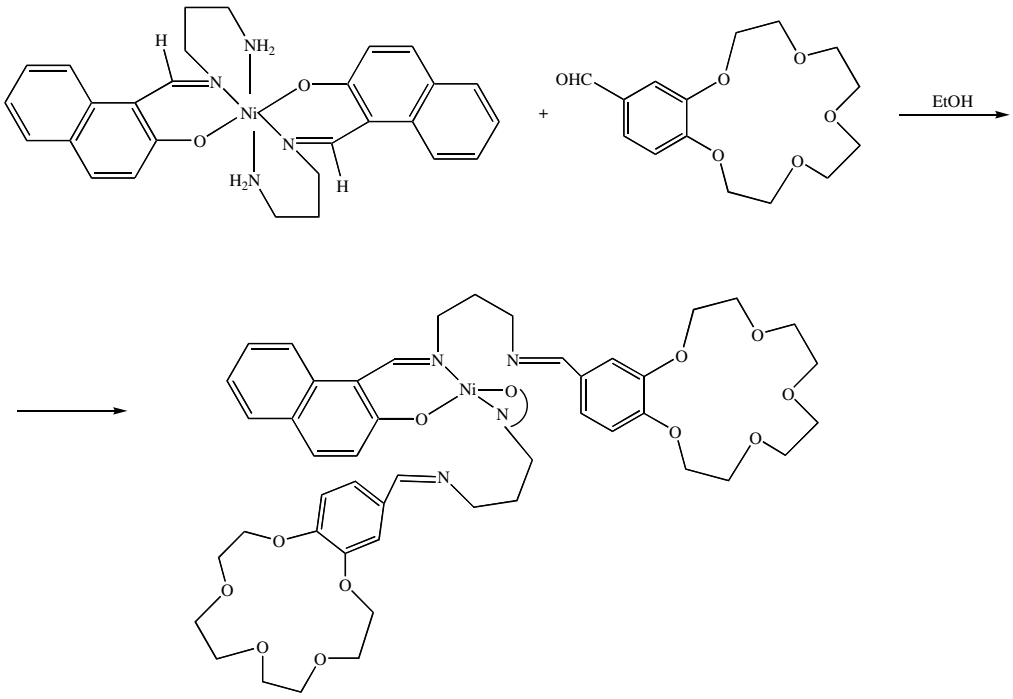

Scheme 1. Reaction steps used in the preparation of $[Ni(nlpb15)_2]$.

functionalised with the same motif, but including the crown ether moiety as flexible appended arms.

In a preceding paper we have reported the synthesis of nickel(II) complexes of general formula NiL_2, where L is an asymmetric N_2O tridentate ligand obtained by Schiff condensation of propane-1,3-diamine with salicylaldehyde or a derivative [16]. The nickel(II) complexes have amine groups that can react with formyl groups of crown-ether derivatives yielding Schiff base nickel(II) and copper(II) complexes with two appended flexible crown ether arms, as depicted in Scheme 1. The introduction of a transition metal complex moiety into the crown ether framework allows the exploitation of its spectroscopic and electrochemical properties to sense s-block, aluminium and lanthanide ions.

2. Experimental

2.1. Reagents and solvents

All reagents and solvents were used as received. Solvents for syntheses were of reagent grade and those for electrochemical and UV–Vis studies of analytical grade. Nickel acetate tetrahydrate, copper acetate monohydrate, dimethylglyoxime, potassium perchlorate, sodium perchlorate hydrate and calcium nitrate tetrahydrate were from Merck; strontium nitrate, barium perchlorate and magnesium perchlorate from Fluka; lithium perchlorate, rubidium chloride, cesium fluoride, erbium perchlorate (40 wt% solution in water) and gadolinium trifluoromethanesulfonate from Aldrich; praseodymium nitrate from Alfa Aesar; and aluminium nitrate nonohydrate from J.T. Baker. Tetraethylammonium perchlorate (TEAP) was from Fluka and was kept in an oven at 60 °C prior to use.

Caution! perchlorates are hazards may explode.

2.2. Synthesis

The compound 4′-formylbenzo-15-crown-5 was prepared by a procedure described in literature [17], by reacting 3,4-dihydroxybenzaldehyde with 1,11-dichloro-3,6,9-trioxaundecane. The parent nickel complex, $[Ni(nlp)_2]$, was synthesised by the procedure described in [16].

2.2.1. Preparation of bis[o-(3-(benzo-15-crown-5-formimidoyil)propylformimidoyil)naphtholate-O,N]nickel [Ni(nlpb15)$_2$]

A solution of 4′-formylbenzo-15-crown-5 (0.85 g; 2.9 mmol) in EtOH was added to an ethanolic solution of $[Ni(nlp)_2]$ (0.62 g; 1.2 mmol) and the mixture was refluxed for 6 h. A light-green solid was collected, washed with EtOH and dried over vacuum. Yield 0.65 g (51%).

MS (FAB), m/z: 1069 $[M+H]^+$ (5%), 1092 $[M+Na+H]^+$ (27); high resolution: 1069. Calc. for $NiC_{58}H_{67}N_4O_{12}$: 1069.410896. Found: 1069.412454. ^{1}HNMR $CDCl_3$: $\delta = 9.08$ (s; 2H; –CHN), 8.52 (s; 2H; –CHN), 7.80–7.77 (d; 2H; –H arom), 7.66–7.64 (d; 2H; –H arom), 7.51–7.48 (d; 2H; –H arom), 7.42–7.35 (t; 4H; –H arom), 7.22–7.17 (t; 2H; –H arom), 7.05–7.03 (d; 2H;

–H arom), 6.84–6.78 (t; 4H; –H arom), 4.15–4.13 (m; 8H; $-CH_2$), 3.94–3.76 (m; 32H; $-CH_2$); 2.36 (s; 4H; $-CH_2$); 1.71 (s; 2H; $-H_2O$). IR(KBr) (ν/cm^{-1}): 3457, 2931, 2853, 1643, 1619, 1602, 1562, 1540, 1516, 1460, 1435, 1401, 1370, 1345, 1326, 1270, 1239, 1208, 1177, 1131, 1087, 1053, 1016, 975, 923, 860, 830, 777, 752, 687, 662, 640, 620, 535, 473, 429. UV–Vis λ_{max} (dmf)/nm ($\varepsilon \times 10^3$/dm^3 mol^{-1} cm^{-1}): 345 (15.5), 403 sh (6.52), 423 (8.0), 445 sh (4.8).

2.2.2. Preparation of bis[o-(3-(benzo-15-crown-5-formimidoyil)propylformimidoyil)naphtholate-O, N]copper [Cu(nlpb15)$_2$]

A solution of [Ni(nlpb15)$_2$] (0.11 g; 0.10 mmol) in $CHCl_3$was added to a solution of dimethylglyoxime (H_2dmg) (0.024 g; 0.21 mmol) in EtOH and the mixture was stirred for 14 h at room temperature. The red nickel complex, [Ni(dmg)$_2$], was filtered off and rejected. An ethanolic solution of copper(II) acetate (0.021 g; 0.10 mmol) was added to the filtrate and the mixture was stirred for 6 h. A light-brown solid was collected, washed with diethyl ether and dried over vacuum. Yield 0.016 g (15%).

MS (FAB), m/z: 1074 $[M+H]^+$ (5%), 1097 $[M+Na+H]^+$ (15); high resolution: 1074. Calc. for $CuC_{58}H_{67}N_4O_{12}$: 1074.405149. Found: 1074.409683. IR(KBr) (ν/cm^{-1}): 2915, 2867, 1641, 1615, 1606, 1560, 1541, 1512, 1461, 1438, 1414, 1400, 1365, 1344, 1323, 1270, 1238, 1208, 1179, 1129, 1103, 1052, 1017, 984, 938, 888, 858, 829, 779, 749, 666, 649, 602, 519, 502, 473, 417. UV–Vis λ_{max} (dmf)/nm ($\varepsilon \times 10^3$/dm^3 mol^{-1} cm^{-1}): 382 (3.4), 396 (33.9), 422 sh (13.8).

No accurate elemental analysis could be obtained for the functionalised complexes due to the high capacity of crown ether cavities for solvation; for this reason purity of the complexes were checked by high resolution mass spectra.

2.3. Physical measurements

Mass spectra were obtained at 'Departamento de Química da Universidade de Aveiro' (Portugal). ^{1}H NMR spectra were recorded with a Bruker AC 200 in $CDCl_3$ and the chemical shifts are reported relative to Me_4Si, used as an internal standard. Infrared spectra (KBr pellets) were recorded in the range 4000–400 cm^{-1} using a BioRad FTS 155 spectrometer. EPR spectra were obtained at 120 K with a Bruker ESP 300 (X-band); the magnetic field was calibrated by using Mn^{2+} in MgO, and diphenylpicrylhydrazyl was used as internal reference (dpph; $g = 2.0037$).

Cyclic voltammetry was performed using an Autolab PGSTAT20 potentiostat/galvanostat. A Pt disk electrode with an area of 0.0314 cm^2 was used as the working electrode, a Pt electrode as the counter electrode and an Ag/AgCl (1 mol dm^{-3} NaCl) as the reference electrode. Prior to use, the Pt working electrode was polished with an aqueous suspension of 0.05 μm alumina (Beuhler) on a Master-Tex (Beuhler) polishing pad, then rinsed with water and dried. All solutions were deareated by a stream of argon.

Room temperature electronic spectra of the complexes in dmf and $CHCl_3$ were recorded with a Unicam UV 2 spectrophotometer in the range 335–1100 nm, using standard 1-cm quartz cells; complex concentrations were 1×10^{-3} mol dm^{-3} (d–d bands) and 1×10^{-5} mol dm^{-3} (CT and intra ligand bands). Spectrophotometric titrations were carried out at 25.0 ± 0.1 °C in dmf and the spectra recorded in the wavelength range 335–550 nm, using a slit width of 2 nm. To a series of solutions of [M(nlpb15)$_2$], M = Ni(II) or Cu(II), with concentrations in the range 1×10^{-5}–2×10^{-4} mol dm^{-3} were added increasing concentrations of ions of representative metals (Al^{3+}, Li^+, Na^+, K^+, Rb^+, Cs^+, Mg^{2+}, Ca^{2+}, Sr^{2+} and Ba^{2+}) or of lanthanides (Er^{3+}, Pr^{3+} and Gd^{3+}), spanning the range 1.0×10^{-6}–1.0×10^{-4} mol dm^{-3} and the respective spectra recorded. The Beer–Lambert law was obeyed for solutions of the complex at the experimental conditions used (5.0×10^{-6}–2.5×10^{-4} mol dm^{-3}); solutions of lanthanide ions ($< 1 \times 10^{-4}$ mol dm^{-3}) did not absorb in the wavelength range used. The stability constants (β_{21}), the equilibrium concentrations of the species in solution and the extinction coefficients at selected wavelengths were determined using the programme SQUAD [18].

Stock solutions of the representative metal ions (Li^+, Na^+, K^+, Rb^+, Cs^+, Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+} and Al^{3+}) and of the lanthanides ions (Er^{3+}, Pr^{3+} and Gd^{3+}) (0.01 mol dm^{-3}) were prepared in dmf.

3. Results and discussion

3.1. Complex preparation and characterisation

The four-coordinate functionalised complex [Ni(nlpb15)$_2$] was prepared by Schiff condensation of the coordinated amine groups of [Ni(nlp)$_2$] [16] with the formyl group of formylbenzo-15-crown-5 (Scheme 1). The homologous Cu complex, [Cu(nlpb15)$_2$], was prepared by demetalation of [Ni(nlpb15)$_2$] with dimethylglyoxime and addition of copper acetate, as it was not possible to prepare the parent copper compound, [Cu(nlp)$_2$].

The FAB mass spectrum of [Ni(nlpb15)$_2$] shows peaks at $m/z = 1069$ and 1092, which correspond to $[M+H]^+$ and $[M+Na+H]^+$, respectively. That of the copper(II) complex shows not only fragments with $m/z = 1074$ and 1097, values associated with $[M+H]^+$ and $[M+Na+H]^+$, but also a peak at $m/z = 1139$ which corresponds to protonated binuclear species $[Cu_2(nlpb15)_2+H]^+$; formation of protonated binuclear

species have also been observed in the FAB mass spectrum of [Ni(nlp)$_2$] [16].

Solutions of [Ni(nlpb15)$_2$] in $CDCl_3$ exhibit ^{1}H NMR spectra with chemical shifts typical of a diamagnetic Ni(II) compound, what provides a first indication that upon reaction of the transition metal complex amine groups with crown ether formyl functionalities, the nitrogen atoms of the newly formed imine bonds are not bound to the metal centre, with the implication that the novel complex exhibits an almost N_2O_2 square planar geometry. In the ^{1}H NMR spectrum of [Ni(nlpb15)$_2$] the two resolved singlets at $\delta = 9.08$ and 8.52 ppm are assigned to the two C(H)=N protons, that of the ether and the aldehyde moieties, respectively. The observation of these two singlets provides confirmation of Schiff base reaction between amine groups of the complex and formylbenzo-15-crown-5.

The signals of the aromatic protons appear at 7.80 and 6.78 pm, the multiplet at 4.15 ppm is assigned to crown ether methylene groups, and that at 3.76 pm to terminal CH_2 of the imine bridge and the protons of the central CH_2 in this bridge appear at 2.36 pm.

The EPR spectrum of [Cu(nlpb15)$_2$] in frozen dmf solution is similar to those of copper(II) complexes with tetradentate Schiff base ligands [19–21]; it is of apparent axial symmetry and exhibits in all magnetic regions well-resolved hyperfine couplings with copper (^{63}Cu/^{65}Cu, $I = 3/2$), although no superhyperfine splitting with ligand nitrogen atoms could be observed in any of the g regions, probably due to the large bandwidth associated with the spectrum in dmf. The similarity between this spectrum, and those observed for other four-coordinate copper Schiff base complexes, allows for the same orientation scheme for the g tensor: $g_1 = g_z$, $g_2 = g_x$, $g_3 = g_y$, where g_1 and g_3 refer to the lowest and highest magnetic fields g values (obviously, $|A_1| = |A_z|$, $|A_2| = |A_x|$ and $|A_3| = |A_y|$ [19–21]. Simulation of the spectrum using a rhombic spin Hamiltonian yields: $g_z = 2.312$, $g_x = 2.139$, $g_y = 2.131$, $A_z(\mathrm{Cu}) = 180$ G, $A_x(\mathrm{Cu}) = A_y(\mathrm{Cu}) = 25$ G; $a_z(\mathrm{N}) = 20$ and $a_x(\mathrm{N}) = a_y(\mathrm{N}) = 10$ G. The value of the copper hyperfine coupling in the z region is typical of almost square planar complexes (or with incipient axial coordination), which combined with the fact that $g_z > g_x, g_y$ indicates that the complex has a $d_{x^2-y^2}$ ground state and an almost square planar geometry.

The IR spectra of [Ni(nlpb15)$_2$] and [Cu(nlpb15)$_2$] are very similar, a consequence of their expected structural similarity. The most sticking difference between the spectrum of Ni(nlpb15)$_2$] and that of the parent complex [Ni(nlp)$_2$] [16] is the disappearance of two sharp bands at 3345 and 3276 cm^{-1}, assigned to the symmetric and anti-symmetric stretchings of –NH_2 in the six-coordinate complex, thus providing further indication that condensation between NH_2 groups of [Ni(nlp)$_2$] and formylbenzo-15-crown-5 has occurred; no comparison between the spectra of [Cu(nlp)$_2$] and [Cu(nlpb15)$_2$] was possible, as the latter was prepared by demetalation of the corresponding nickel complex. The C=N stretching vibration is observed at 1619 cm^{-1} for [Ni(nlpb15)$_2$] and at 1615 cm^{-1} for [Cu(nlpb15)$_2$] [16,22,23], the shift to lower energies on going from nickel to copper reflects the increase in the system reduced mass. Moreover, the bands due to Ar–O–C (crown ether) and to C–O–C (crown ether) vibrations [24,25] are detected in the ranges: 1270–1131 cm^{-1} for [Ni(nlpb15)$_2$] and 1270–1103 cm^{-1} for [Cu(nlpb15)$_2$].

Electronic spectra of the two complexes are very similar, either in dmf and $CHCl_3$, although the bands of the copper complex are shifted to higher energies. They are typical of square planar complexes, as they show one broad medium intensity band at $\lambda \approx 600$ nm ($\varepsilon = 130$–140 dm^3 mol^{-1} cm^{-1}) due to several d–d transitions of similar energies: $d_{x^2-y^2} \leftarrow (d_{z^2}; d_{xy}; d_{xz}; d_{xy})$; as example, the electronic spectra for nickel complex are depicted in Fig. 1 [26]. These observations further confirm that the complexes have similar structures, and that after crown ether functionalisation the imine nitrogens are not bound to the metal. The profile of the d–d bands contrasts with that of the nickel precursor complex, which shows d–d bands in the NIR–Vis region (λ in the range 500–1100 nm), a consequence of its octahedral geometry [16]. In the region of $\lambda < 460$ nm, both nickel and copper complexes show several high intensity CT and intra-ligand bands.

Both compounds show, in the potential range 0–1.3 V, an irreversible oxidation process, whereas their reductive electrochemical behaviour is more complex. The cyclic voltammogram of [Ni(nlpb15)$_2$] shows in the potential range −0.30 to −1.90 V (0.50 V s^{-1}), one cathodic wave at −1.57 V and three anodic waves at −1.43, −1.06 and −0.58 V. Similarly, [Cu(nlpb15)$_2$] shows in the potential range −0.3 to −1.8 V (0.020 V s^{-1}), two cathodic waves at −0.99 and −1.59 V and two low intensity anodic waves at −0.73 and 0.06 V. As these results suggest that charge transfer in both complexes is associated with chemical reactions involving the metal and the ligand [27], no further characterisation of their electrochemical behaviour was pursed.

3.2. Metal ion recognition studies

Metal ion recognition was performed by monitoring the CT and $\pi \rightarrow \pi^*$ band region (from $\lambda = 335$ to 550 nm) of the nickel and copper complexes upon incremental addition of dmf solutions of the target metal ions.

Addition of alkaline (Li^+, Na^+, K^+, Rb^+ and Cs^+) and alkaline-earth (Mg^{2+}, Ca^{2+}, Sr^{2+} and Ba^{2+}) ions causes no significant changes in the energy of the CT and $\pi \rightarrow \pi^*$ bands of any of the complexes. However, incremental additions of aluminium and of lanthanide

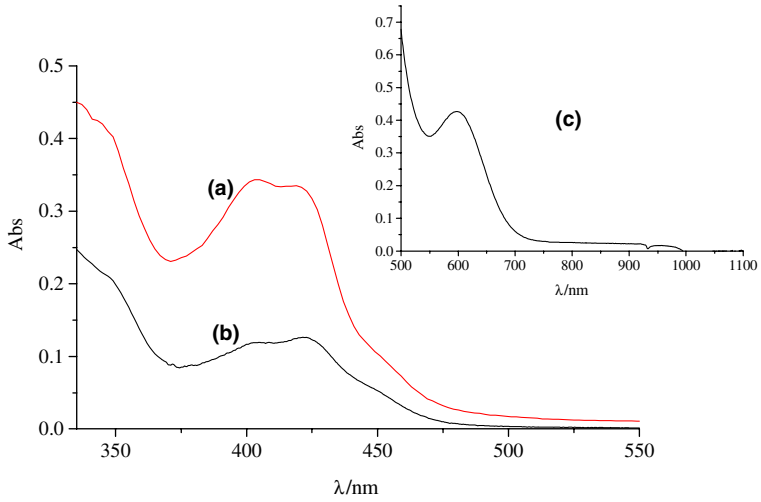

Fig. 1. UV–Vis spectra of $[Ni(nlpb15)_2]$: (a) in dmf $\lambda = 335$–550 nm; (b) in $CHCl_3$ $\lambda = 335$–550 nm; (c) in $CHCl_3$ $\lambda = 550$–1000 nm.

ions (Er^{3+}, Gd^{3+} and Pr^{3+}) induce large changes in the electronic band profile, and that are similar for both complexes (typical responses are depicted in Fig. 2). For solutions of $[Ni(nlpb15)_2]$ and upon aluminium and lanthanide additions the absorbance of the electronic band at 345 nm decreases until practically zero, and the band at 400 increases in intensity and exhibits a small hypsochromic shift; for the corresponding copper(II) complex the band at 381 practically vanishes and the band at 421 not only increases in intensity but is slightly shifted to lower energies. Moreover, for the nickel complex, the shoulder at 455 nm also decreases in intensity.

The changes in absorbance as a function of added ion concentration give rise to sharp isosbestic points at $\lambda = 363$ and 435 nm for the nickel complex, and at $\lambda = 350$, 395 and 441 nm for the copper complex, thus providing a strong indication of the presence of two absorbing species in solution [28–30]: the original transition metal complexes and their Ln^{3+} or Al^{3+} adducts.

The spectral change induced by Ln^{3+} and Al^{3+} ions is a consequence of adduct formation between the metal complexes and the added metal cations. Based on the structure of the nickel precursor complex, $[Ni(nlp)_2]$ [16], we propose that the bidentate ligands in the functionalised complexes are in *trans* conformation. This conformation prevents electrostatic interactions between phenolic oxygen atoms bound to the transition metal centre and the added cations, a behaviour that has been observed for nickel and copper complexes with *cis*-N_2O_2-type tetradentate Schiff base ligands [31–33]. Consequently, for these crown ether functionalised complexes the coordination sites for extrinsic cations are the two crown ethers moieties.

Two types of adduct formation mechanism can be proposed (Scheme 2): (i) complexation of one cation to one of the two crown ethers, 1:1 adduct formation (Eq.

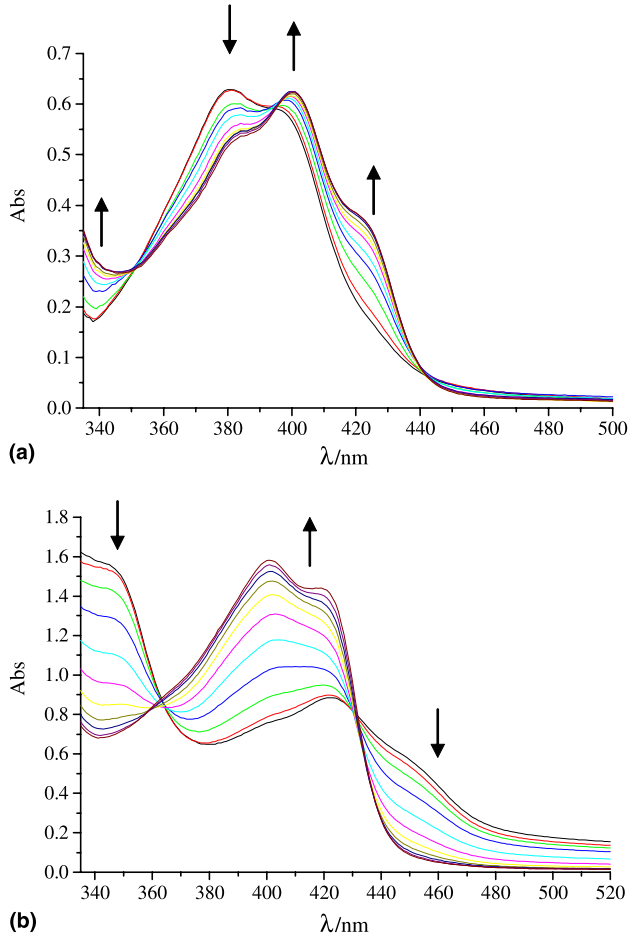

Fig. 2. (a) UV–Vis spectra of $[Cu(nlpb15)_2]$ ($C_{complex} = 5.002 \times 10^{-5}$ mol dm^{-3}, dmf) after addition of increasing quantities of Er^{3+}; $[Cu(nlpb15)_2]$:Er^{3+}molar ratio from 1:0.2 to 1:1.2. (b) UV–Vis spectra of $[Ni(nlpb15)_2]$ ($C_{complex} = 1.669 \times 10^{-4}$ mol dm^{-3}, dmf) after addition of increasing quantities of Al^{3+}; $[Ni(nlpb15)_2]$:Al^{3+}molar ratio from 1:0.2 to 1:1.2.

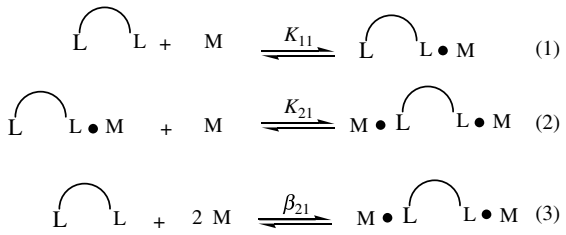

Scheme 2. Solution equilibria for metal complex adduct formation.

(1)), followed by coordination of a second metal ion to the free crown ether moiety, 1:2 adduct (Eq. (2)) or (ii) simultaneously coordination of *two* metal ions to the crown ether cavities, 1:2 adduct (Eq. (3)).

Preliminary information on the adduct formation mechanism can be gathered by considering the system, upon addition of the metal ions, a 1:1 adduct, and apply linear functions, as the double reciprocal and Scatchard plots, to absorbance and metal ion concentration [34]. As the plots obtained with these functions, for all the systems studied, were non-linear it is possible to conclude that the nickel and copper complexes must form adducts with a stoichiometry higher than 1:1. Furthermore, the use of graphical methods [34] to determine the number of species in solution permit to conclude that, upon metal cation addition, there are only two absorbing species in solution. The coupling of these results suggests a model for adduct formation that comprises concomitant coordination of *two* metal ions to each metal complex, one in each crown ether cavity as depicted in (Eq. (3)), Scheme 2.

Taking into account the proposed adduct formation mechanism, we have used the program SQUAD to quantify the interaction between the nickel and copper complexes and the added cations (β_{21} in (Eq. (3)), Scheme 2) using the UV–Vis spectral changes, and the results obtained are summarised in Table 1. Further confirmation for the absence of 1:1 adducts was obtained by the impossibility to determine stability constants associated with coordination of only one cation to the transition metal complexes, although data in the range where these species could exist were used ($C_{\text{complex}} \gg C_{\text{M}}^{n+}$).

Table 1
$\log \beta_{21}$ values for $\{[Ni(nlpb15)_2]\cdot 2M^{3+}\}$ and $\{[Cu(nlpb15)_2]\cdot 2M^{3+}\}^{+}$ adducts in dmf at 25 °C

Complex	M^{3+}	$\log \beta_{21}$
$[Ni(nlpb15)_2]$	Al^{3+}	8.60 ± 0.12
	Er^{3+}	8.28 ± 0.05
	Gd^{3+}	8.70 ± 0.08
	Pr^{3+}	9.01 ± 0.10
$[Cu(nlpb15)_2]$	Al^{3+}	9.08 ± 0.10
	Er^{3+}	7.99 ± 0.05
	Gd^{3+}	8.21 ± 0.10
	Pr^{3+}	9.45 ± 0.15

The agreement between the experimental and calculated spectra (using data from SQUAD) supports the model proposed for adduct formation by simultaneous coordination of *two* metal ions to each transition metal centre, one in each crown ether cavity. In Fig. 3 are depicted the calculated and experimental spectra of $\{[Ni(nlpb15)_2]\cdot 2M^{3+}\}$ and $\{[Cu(nlpb15)_2]\cdot 2M^{3+}\}$ ($M = Ln^{3+}$, Al^{3+}).

As no crystals with diffractometric quality could be obtained for any of the adducts, no definitive information on the coordination number of the lanthanide ions upon complexation into the crown cavities was gathered; nevertheless, we assume that a high coordination number must occur and thus water or solvent molecules must also be bonded to the lanthanide cations.

The absence of any spectral changes upon addition of alkaline and earth-alkaline ions prevented the determination of stability constants using this technique. But this negative result can not exclude the existence of interactions between the representative ions and the crown ether groups.

Our data suggest that ion charge density is determinant in the recognition process using the spectroscopic properties of the metal complexes, as significant changes on the electronic spectra could only be observed after

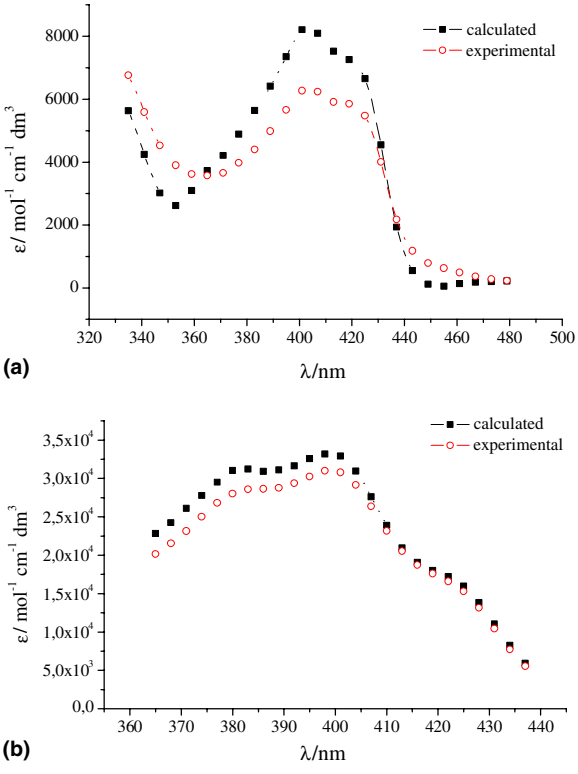

Fig. 3. Calculated and experimental spectra of: (a) $[Ni(nlpb15)_2]\cdot 2Al^{3+}$ and (b) $[Cu(nlpb15)_2]\cdot 2Pr^{3+}$.

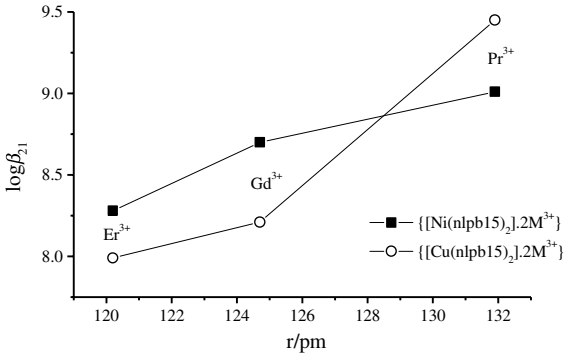

Fig. 4. Plots of $\log \beta_{21}$ vs. M^{3+} radii: [Cu(nlpb15)$_2$] and [Ni(nlpb15)$_2$]. M^{3+} radii (coordination number 9) from [38].

addition of trivalent cations. The spectral bands used in this study are associated with charge transfer and intraligand naphthaldehyde derivative) transitions and thus spectroscopic recognition has occurred mainly through chemical bonds. The energy of the electronic states involved in the transitions was found to be influenced only when cations with charge density higher than 0.025 pm^{-1} (coordination number 6) are bound to the crown ether groups, a consequence of the length of the spacer between naphthaldehyde fragment and the crown ether group.

No correlation was detected between $\log \beta_{21}$ values and the transition metal complex used, although the nickel complex tends to exhibit larger $\log \beta_{21}$ values. However, for each complex there is a rough linear correlation between the $\log \beta_{21}$ values and the lanthanide ionic radii, as depicted in Fig. 4: the larger the lanthanide ionic radii the higher the $\log \beta_{21}$. These results indicate the existence of the cavity effect, as the lanthanide cation with the larger radii, which is closer to that of Na^+, that is known to provide a better fit to the 15-crown-5 cavity [35–37], is the one that exhibits the larger stability constant.

4. Concluding remarks

Nickel and copper complexes functionalised with flexible crown ether moieties were shown to behave as spectroscopic probes for Al^{3+} and lanthanide cations in organic media, by making use of spectral changes in the charge transfer and naphthaldehyde intraligand based bands. It was possible to calculate the stability constants for 1:2 adducts (metal complex:cation), and for each complex there is a linear correlation between the $\log \beta_{21}$ values and the lanthanide ionic radii, what indicates the existence of a cavity effect, an important property for the design of selective chemosensors.

However, no detectable changes were observed in the UV–Vis spectra of the nickel(II) and copper(II) complexes upon addition of alkaline and alkaline earth ions, what was taken as an indication that ion recognition occurs mainly via chemical bonds and that space effects are not relevant, although the ligand has been designed to have flexible arms to allow for such type of molecular sensing mechanism.

Abstract

Several new Mn^{II} compounds with X-phenylcyanamido (Xpcyd) and 1,10-phenantroline (phen) ligands of formula [Mn(3-Clpcyd)(H_2O)(phen)$_2$]$(NO_3)\cdot H_2O$ (**1**), [{Mn(3-Fpcyd)(MeOH)(phen)}$_2$(μ-3-Fpcyd)$_2$] (**2**), [{Mn(3-Fpcyd)(EtOH)(phen)}$_2$(μ-3-Fpcyd)$_2$] (**3**), [{Mn(3-Clpcyd)(MeOH)(phen)}$_2$(μ-3-Clpcyd)$_2$] (**4**) and [{Mn(4-Clpcyd)(EtOH)(phen)}$_2$(μ-4-Clpcyd)$_2$] (**5**) have been synthesised and characterised. Mononuclear compound **1** crystallises in the monoclinic system, $P2_1/c$ space group, dinuclear compounds **2**–**5** crystallise in the monoclinic system, $C2/c$ space group **2**, triclinic system, $P\bar{1}$ space group **3**–**4** and in the monoclinic system, $P2_1/a$ space group **5**. These compounds contain the unusual end-to-end R-cyanamide bridge and give supramolecular one-dimensional networks by means of H-bonds involving the N-amide atoms of the phenylcyanamide ligands. Susceptibility measurements on compounds **2**–**5** reveal moderate AF coupling in all cases. Coupling constants related to the phenylcyanamido bridges are compared with the superexchange model recently proposed for ligands of this kind.

1. Introduction

Phenylcyanamide ligands (Pcyd) are interesting and practically unexplored ligands from the synthetic and magnetic point of view. Very recently, we have reported the first magnetic measurements on systems with different dimensionality containing the Mn^{II}–$(NCN)_2$–Mn^{II} unit [1,2], the cyanamido group (NCN) being coordinated in the end-to-end mode. In these preliminary works, we demonstrate the ability of this kind of bridge to transmit moderate antiferromagnetic coupling. We propose, on the basis of MO calculations, that the $\mu_{1,3}$-NCN pcyd ligands have an intermediate place between azido and dicyanamido as superexchange mediators [1].

From the synthetic point of view, pcyd ligands offer a wide range of possibilities based on the use of different X-pcyd derivatives which can modify the solubility and crystallinity of the resulting compounds and in the different coordination properties of the two nitrogen atoms: one N-nitrile, (which coordinates preferently) and one N-amide atom, with characteristic bond parameters in each case. Also remarkable is the strong tendency to participate in H-bonded extended networks of X-pcyd ligands by means of the N-amide atom. Exploration of the coordination properties of these kinds of ligands is still a challenge, because most of the work performed with Xpcyd derivatives has been done with Ru^{III} (mainly mononuclear systems) and only a few dinuclear systems derived from other cations such as Ag^{I}, Cu^{I} or Cu^{II} have been reported [3]. The evident relationship with other pseudohalide ligands which in the last few years have provided a great variety of structural topologies and magnetic properties, including ferro, antiferro, (homogeneous or alternating) or in some few cases, ferrimagnetic systems [4–7], encourages us to explore the magnetic properties of pcyd derivatives.

Following our work with this family of ligands, we now report five new Mn^{II}/Xpcyd compounds (using

3-fluoro, 3-chloro or 4-chlorophenylcyanamide, 3-Fpcyd, 3-Clpcyd or 4-Cl-pcyd, respectively) in combination with the blocking 1,10-phenantroline ligand (phen). The new systems, one mononuclear and four dinuclear molecular derivatives, shows newly how the H-bonds play a central role in generating one-dimensional supramolecular arrangements. Measurement of their magnetic properties adds new data to check the recently proposed coupling model [1].

2. Experimental

2.1. Physical measurements

Magnetic susceptibility measurements were carried out on polycrystalline samples with a DSM8 pendulum susceptometer working in the range 4–300 K, under magnetic fields of approximately 1 T or in a SQUID instrument in the range 2–300 K under an external field of 0.1 T at the Magnetochemistry Service of the University of Barcelona. Diamagnetic corrections were estimated from Pascal Tables. The infrared spectra (4000–400 cm^{-1}) were recorded from KBr pellets on a Nicolet 520 FTIR spectrophotometer. EPR spectra were recorded with a Bruker ES200 spectrometer at X-band frequency. Thermogravimetric measurements were carried out in a Mettler TG 50 instrument at a heating rate of 10 °C min^{-1}.

2.2. Synthesis

Neutral 3-fluoro-, 3-chloro and 4-chlorophenylcyanamide (XpcydH) were prepared in all cases by desulphurization of the corresponding X-phenylthiourea with lead acetate, following the general synthetic procedure described for the haloderivatives of phenylcyanamide [8].

The five compounds were prepared following a common procedure: reaction of a solution of manganese nitrate hexahydrate (1 mmol) and phenantroline (2 mmol for **1** and 1 mmol for **2**–**5**) in 50 mL of methanol (for **1**, **2** or **4**) or ethanol (for **3** and **5**) with a solution of the corresponding XpcydH (2 mmol) in 6 mL of NaOH 0.2 M to deprotonate the ligand, produce yellowish solutions. After filtration of possible impurities, the resulting clear solutions were allowed to evaporate, giving yellowish-orange crystalline compounds suitable for X-ray measurements in one week. Yield for the five compounds around 40%. Elemental *Anal.* Calc. for **1** as $C_{31}H_{24}ClMnN_7O_5$ (665): C, 56.0; H, 3.6; N, 14.7. Found: C, 55.9; H, 3.4; N, 14.7%. (μ-3-Fpcyd)$_2$] (**3**), [{Mn(3-Clpcyd)(MeOH)(phen)}$_2$(μ-3-Clpcyd)$_2$] (**4**) and [{Mn(4-Clpcyd)(EtOH)(phen)}$_2$(μ-4-Clpcyd)$_2$] (**5**) were collected on a modified STOE four-circle diffractometer. The crystallographic data, conditions retained for the intensity data collection, and some features of the structure refinement are listed in Table 1. Graphite-monochromatized MoKα radiation ($\lambda = 0.71069$ Å) with the ω-scan technique was used to collect the data sets. Corrections were applied for Lorentz-polarisation effects and intensity decay. The structures were solved by direct methods using the SHELX-86 computer program [9], and refined by full-matrix least-squares methods on F^2, using the SHELXS-93 program [10] incorporated in the SHELXTL/PC package [11] and PLUTON-92 [12] program. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms bonded to C-atoms were located on calculated positions by use of the HFIX utility of the SHELXS-93 program whereas the remaining hydrogen atoms were located from difference Fourier maps and included in the final refinement cycles by use of O–H distance restraints. For compounds **1** and **3** the occupancy of disordered atoms Cl(1)/Cl(2) and F(2)/F(12) was refined as 0.564(2)/0.436(2) and 0.827(5)/0.173(5), respectively. IR Xpcyd main absorptions: 2136 cm^{-1} **1**, 2170, 2143 cm^{-1} **2** and **3**, 2170, 2140 cm^{-1} **4** and 2149 cm^{-1} **5b**.

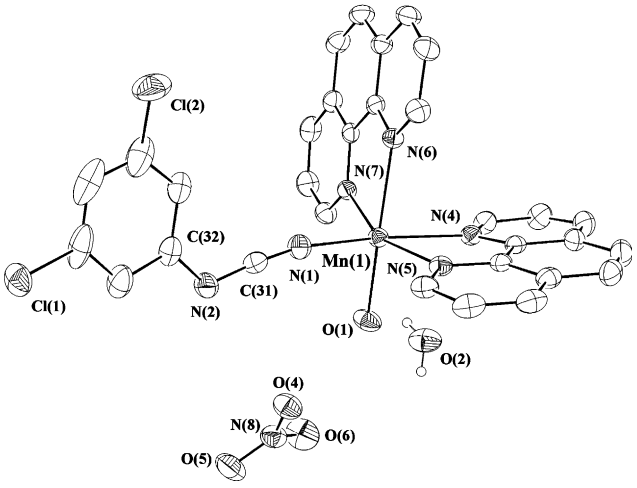

Fig. 1. ORTEP labelled plot (probability 30%) for compound **1**. For the sake of clarity, only the labels for the coordination sphere of the Mn^{II} cations and the NCN groups are shown. Cl(1)/Cl(2) atoms correspond to the disordered Cl atom of the 3-Clpcyd ligand.

3. Results and discussion

3.1. Description of the structures

3.1.1. Crystal structure of [Mn(3-Clpcyd)(H$_2$O)(phen)$_2$](NO$_3$)·H$_2$O (1)

The structure consists of mononuclear [Mn(3-Clpcyd)(H$_2$O)(phen)$_2$]$^+$ units and nitrate counterions. Hexacoordination of the Mn^{II} atoms is completed by two phenantroline ligands and one N-nitrile atom from the 3-Clpcyd$^-$ ligand and one water molecule, Fig. 1. Selected bond parameters are listed in Table 2.

The coordination polyhedron is strongly distorted as result of placement of the phen ligands, which impose two N–Mn–N bond angles around 72°, and consequently several bond angles are strongly deviated from the regular 90° value. Bond distances are also asymmetric, with two short distances Mn(1)–O(1) and Mn(1)–N(1) of 2.149(3) and 2.119(3) Å, respectively, whereas the four Mn–N(phen) bond distances are larger than 2.300 Å. Coordination of the 3-Clpcyd ligand is close to linearity with a Mn(1)–N(1)–C(31) bond angle of 168.3(2)°.

Mononuclear units form a supramolecular structure by means of H-bonds involving the N-amide (3-Clpcyd), the coordinated water molecule, the nitrate counterion and the crystallization water molecule, giving a one-dimensional double chain arrangement along *b* crystallographic axis, Fig. 2. Shorter Mn···Mn distance is 8.465(1) Å.

*3.1.2. Common remarks on crystal structure of the dinuclear compounds **2**–**5***

The four structures show common features that permit a general description. In all cases the system consists of dinuclear centrosymmetric entities, with double Xpcyd bridge. In addition to the N-amide and N-nitrile atoms from the bridging ligands, coordination polyhedron around Mn^{II} atoms is completed with one bidentate phenantroline ligand, one terminal Xpcyd ligand and one solvent (MeOH or EtOH) molecule in *trans* position with respect to the N-amide atom of the bridging Xpcyd.

Also, for all of them, coordination polyhedra are strongly distorted as a consequence of the coordination of phen ligands that gives N–Mn–N bond angles close to 72°. Bond distances in the bridging region show as common features large Mn–N(amide) bond distances, greater than 2.300 Å, short Mn–N-nitrile bond distances around 2.150 Å and intermediate Mn–O(solvent) bond distances around 2.200 Å.

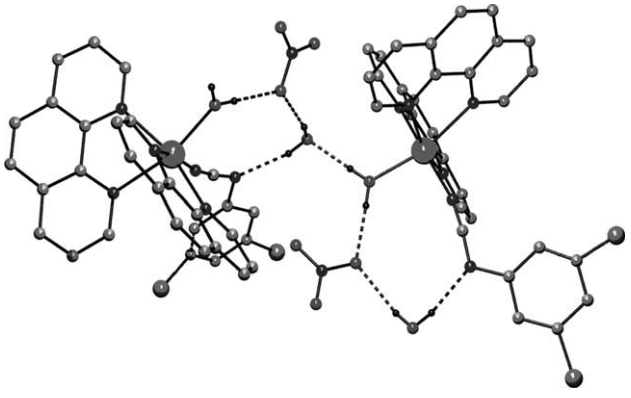

Fig. 2. One-dimensional H-bond network for compound **1**. H-bonds (dashed lines) involve the N-amide atoms of terminal 3-Clpcyd ligands, the coordinated water molecule, the O(4) atom from nitrate anion and the crystallization water molecule present in the structure. The two positions for the disordered Cl atom of the 3-Clpcyd ligand are shown in the plot.

In a similar fashion to previously reported dinuclear systems with similar arrangement [1,2], the R–OH coordinated solvent forms H-bonds with the N-amide atom of the neighbouring terminal X-pcyd ligand, giving double H-bond bridges and a one-dimensional arrangement of the dinuclear units, in which the intramolecular Mn···Mn distance is always 1–2 Å shorter than the intermolecular Mn···Mn. As example, Fig. 3 show one of these H-bond one-dimensional arrays.

Description of relevant details of the bond parameters of the bridging ligands will be set out separately below.

*3.1.3. Crystal structure of [{Mn(3-Fpcyd)(MeOH)(phen)}$_2$(μ-3-Fpcyd)$_2$] (**2**)*

Selected bond parameters are given in Table 3 and a labelled ORTEP plot of the dinuclear unit is shown in Fig. 4.

Bond angles in the bridging region follow the general trends of this kind of bridges, that is to say, a large Mn(1A)–N(1)–C(1) (nitrile) bond angle of 157.7(3)° and a closed Mn(1)–N(2)–C(1) (amide) bond angle of 114.4(2)°. Mn–$(NCN)_2$–Mn ring shows a chair distortion which may be evaluated from the dihedral angle (named δ) between the $(NCN)_2$ plane and the N(1)–Mn(1)–N(2A) plane as 12.6(1)°. The bridging 3-Fpcyd ligand is practically coplanar with the main $(NCN)_2$ plane, the angle between the direction C(2)–N(2) and this plane being only 4.8(2)°. Intramolecular Mn···Mn distance is 5.498(1) Å whereas the intermolecular Mn···Mn distance trough the H-bonds direction is 6.690 Å.

*3.1.4. Crystal structure of [{Mn(3-Fpcyd)(EtOH)(phen)}$_2$(μ-3-Fpcyd)$_2$] (**3**)*

Selected bond parameters are given in Table 4 and a labelled ORTEP plot of the dinuclear unit is shown in Fig. 5.

This compound is analogous to **2** with EtOH instead the coordinated MeOH. Therefore, this minor variation in the coordinated solvent introduce important differ-

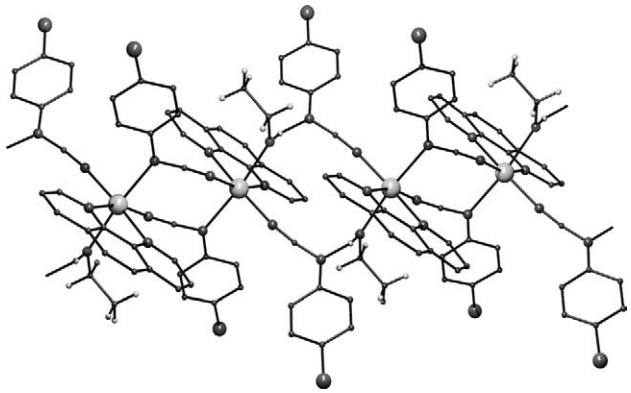

Fig. 3. H-bonds involving the N-amide and the –OH group of the coordinated solvent that allow to one-dimensional extended arrays for **2**–**5**. As example, in the figure is shown compound **4**.

ences in the bond parameters of the compound. Mn(1)–N(1A)–C(1A) (nitrile) bond angle is only of 140.8(2)° and also Mn(1)–N(2)–C(1) (amide) bond angle reduces to 110.6(2)°. Mn–$(NCN)_2$–Mn ring show a greater chair distortion, being the dihedral angle δ between the $(NCN)_2$ plane and the N(1A)–Mn(1)–N(2) plane 37.6(1)°.

In this case, the 3-Fpcyd ligand is not coplanar with the main $(NCN)_2$ plane, being the angle of the C(2)–N(2) vector with this plane of 22.9(1)°. Intramolecular Mn···Mn distance is 5.233(1) Å and the intermolecular Mn···Mn distance trough the H-bonds direction is 7.115(1) Å.

*3.1.5. Crystal structure of [{Mn(3-Clpcyd)(MeOH)(phen)}$_2$(μ-3-Clpcyd)$_2$] (**4**)*

Selected bond parameters are given in Table 5 and a labelled ORTEP plot of the dinuclear unit is shown in Fig. 6.

Mn(1)–N(1A)–C(1A) (nitrile) bond angle is only of 154.0(2)° and Mn(1)–N(2)–C(1) (amide) bond angle is 111.7(2)°. Mn–$(NCN)_2$–Mn ring shows an intermediate chair distortion, being the dihedral angle δ between the $(NCN)_2$ plane and the N(1A)–Mn(1)–N(2) plane 17.2(1)°.

In this case, the 3-Clpcyd ligands are strongly deviated from planarity with the main $(NCN)_2$ plane, the angle of the C(2)–N(2) vector with this plane being 34.5(1)°. Intramolecular Mn···Mn distance is 5.430(1) Å and the intermolecular Mn···Mn distance trough the H-bonds direction is 6.517(1) Å.

*3.1.6. Crystal structure of [{Mn(4-Clpcyd)(EtOH)(phen)}$_2$(μ-4-Clpcyd)$_2$] (**5**)*

Selected bond parameters are given in Table 6 and a labelled ORTEP plot of the dinuclear unit is shown in Fig. 7.

Mn(1A)–N(1)–C(1) (nitrile) bond angle is only of 148.4(4)° and Mn(1)–N(2)–C(1) (amide) bond angle is 110.5(3)°. Mn–(NCN)$_2$–Mn ring shows a strong chair distortion, the dihedral angle δ between the (NCN)$_2$ plane and the N(1A)–Mn(1)–N(2) plane being 26.6(1)°.

The 4-Clpcyd ligands are close to co-planarity with the main (NCN)$_2$ plane, the angle of the C(2)–N(2) vector with this plane being 5.8(3)°. Intramolecular Mn···Mn distance is 5.319(1) Å and the intermolecular Mn···Mn distance trough the H-bonds direction is 6.258(1) Å.

3.2. Thermal behaviour

Crystals of dinuclear compounds **2**–**5** degraded more or less slowly if they are maintained in open air, due to the loss of coordinated solvent. Structural determination was performed at low temperature on crystals just extracted from the mother solutions. In order to characterise the reason for this behaviour, thermogravimetric measurements on fresh crystals or freshly powdered crystalline samples.

For compounds **2**–**4** the measurements reveal a reasonable stability, with loss of coordinated solvent at

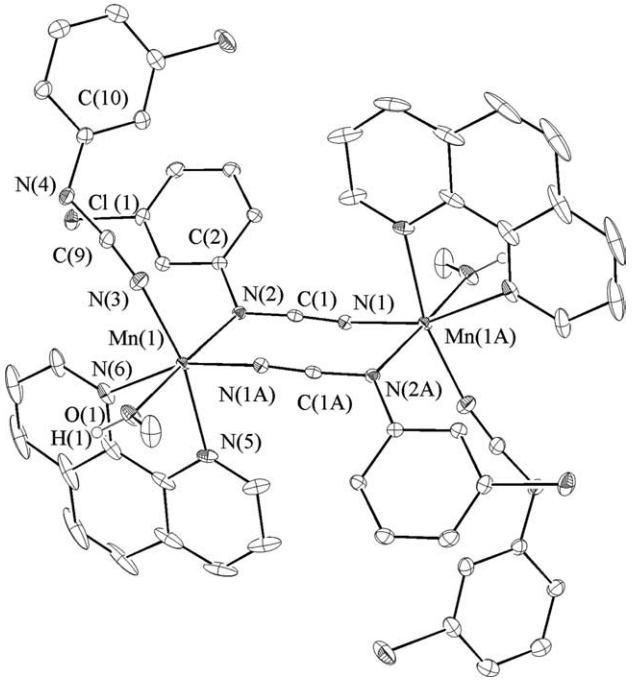

Fig. 6. ORTEP labelled plot (probability 30%) for compound **4**.

similar temperatures (120, 130, and 135 °C). The three compounds start to decompose at temperatures greater than 250 °C. The loss of weight agrees with the alcohol molecules present in the structure, 5.6% for **2** (theoretical 5.95%) and 6.6% for **3** (theoretical 8.3%) and 5.6% for **4** (theoretical 5.62%). In contrast, compound **5** does not show relevant loss of weight until 250 °C, corresponding to the decomposition of the complex. For **5**, the loss of coordinated ethanol is very fast and becomes practically total in the time of preparation of the sample under a dry nitrogen atmosphere. On the basis of these data, compounds **2**–**4** can be studied magnetically as the dinuclear entities structurally characterized. But compound **5** should be assumed to be a homogeneous chain with double 4-Clpcyd bridge with formula $[Mn(phen)(\mu\text{-}4\text{-}Clpcyd)_2]_n$ (**5b**). This assumption is reasonable on the basis of the arrangement of the H-bonds and the vicinity of the N-amide atoms of the terminal 4-Clpcyd ligands to the corresponding Mn^{II} atom of the neighbour dinuclear molecule and agree with the analytical data and the single IR absorption in the nitrile region at 2149 cm^{-1}. As corroborated by the EPR and susceptibility measurements, as is shown in the next section, $[Mn(phen)(\mu\text{-}4\text{-}Clpcyd)_2]_n$ (**5b**) formulation should be assumed for the solvent-free powdered compound.

3.3. Susceptibility measurements and powder EPR spectrum

Susceptibility measurements performed on freshly powdered samples for the four **2**–**5** compounds reveals

more or less weak antiferromagnetic coupling. In all cases, the $\chi_M T$ value at room temperature is slightly lower than the 4.375 $cm^3\,K\,mol^{-1}$ value by Mn^{II} atom, corresponding to the isolated isotropic Mn^{II} ions. On cooling, $\chi_M T$ decreases, tending to zero at low temperature. $\chi_M T$ versus T plots, Fig. 8, show susceptibility maxima at 11 K (**2**), 15.2 K (**4**) and 15 K for **5b**. In contrast, compound **3** does not reach maximum in the susceptibility plot, indicating a much less weak AF coupling. As explained above, due to the fast loss of coordinated solvent for **5**, this compound was assumed as the homogeneous $[Mn(phen)(\mu\text{-}4\text{-}Clpcyd)_2]_n$ one-dimensional **5b** system and compounds **2**–**4** as dinuclear entities. Then, the susceptibility data were fitted to the expression derived from the Hamiltonian $H = -JS_1S_2$ for an isotropic $S = 5/2$ dinuclear system and in the case of compound **5** with the expression derived from $H = \Sigma - JS_iS_{i+1}$ for an isotropic $S = 5/2$ uniform one-dimensional chain [13]. The best fit parameters obtained for the reported compounds were $J = -3.34$ cm^{-1}, $g = 2.01$ for **2**, $J = -0.41$ cm^{-1}, $g = 2.01$ for **3**, $-2.89\,cm^{-1}$ $g = 2.01$ for **4** and $-2.60\,cm^{-1}$ $g = 2.00$ for the one-dimensional system **5**.

Powder EPR spectra also confirm the dimensionality of the above compounds. In all cases, the spectra at room temperature consist of an isotropic absorption centred at $g = 2.00$; on cooling, weak half field signals may be observed, but the main $g = 2.00$ absorption remains constant. Peak-to-peak linewidth for the dinuclear systems **2**–**4** are 282, 303 and 255 G. In contrast, compound **5** exhibits a sharp isotropic signal centred at $g = 2.00$ with a linewidth of only 66 G in good agreement with similar one-dimensional pseudohalide or X-pcyd systems [1,14], giving a complementary confirmation of the $[Mn(phen)(\mu\text{-}4\text{-}Clpcyd)_2]_n$ (**5b**) formula for the powdered **5** compound.

X-Pcyd ligands introduce a large number of variable parameters in the coordination sphere of the metallic ion and in the bridging region. Structural parameters for compound **5** cannot be used for the solvent-free 5b; thus, useful magneto-structural data is only available for **2**–**4**. Previous MO calculations show that the factors favouring the greatest AF coupling are mainly related to the distortions in the Mn–$(NCN)_2$–Mn region: greater AF coupling is expected for systems in which the bridging region is not chair-distorted or in which the NCN-pcyd mean plane lies coplanar to the $(NCN)_2$ plane [1]. As a minor effect, for similar distortions, the ligands with the X-atom in *para* position (4-Xpcyd) should be more AF than pcyd or 3-Xpcyd ligands. In our case, compounds **2**–**4**, with 3-Xpcyd (X = F, Cl) and the same phen terminal ligand permit a good comparison of the general rules for these kinds of compounds. Compound **2** shows the minor distortion in all parameters, with a δ chair distortion of only 12.6° and shows the 3-Fpcyd ligands

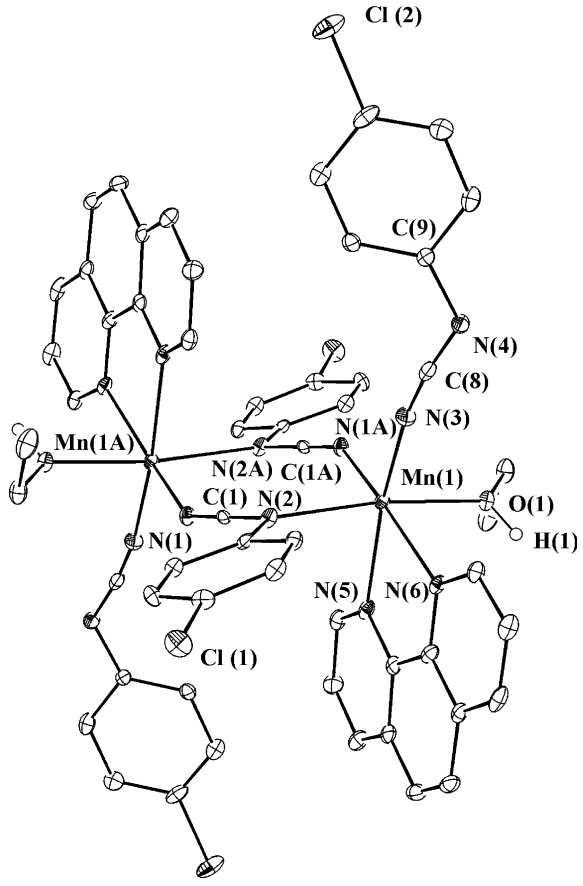

Fig. 7. ORTEP labelled plot (probability 30%) for compound **5**.

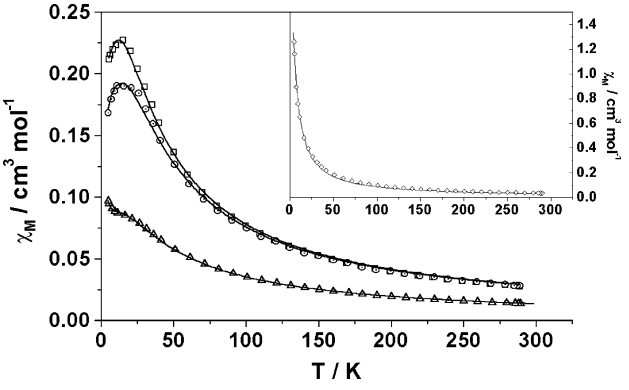

Fig. 8. Susceptibility data for compounds **2** (○), **3** (inset), **4** (□) and **5** (△). Solid lines correspond to the best fit indicated in the text.

practically coplanar with the main Mn–$(NCN)_2$–Mn plane, exhibits greater AF coupling. On the other hand, the highly distorted compound **3** (δ of 37.6° and phenyl rings 22.9° out of the mean Mn–$(NCN)_2$–Mn plane) shows a very weak AF coupling. In good accordance with the general rules, compound **4**, with chair distortion closer to **2** and greater out-of-plane deviation of the phenyl rings, shows a J value closer to **2**.

Therefore, it should be taken into account that correlations for ligands of this kind are multiparameter and only the extreme data, between comparable compounds, is reliable.

4. Supplementary material

Crystallographic data in CIF format have been deposited at the Cambridge Crystallographic data centre with CCDC reference numbers CCDC 216085–216089 for **1**–**5**, respectively. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The crystal structure and Mössbauer spectrum of the dinuclear complex $[(ox)(BMPA)Fe^{III}(\mu\text{-}O)Fe^{III}(BMPA)(ox)]\cdot 5H_2O$ (**4**), isolated from the reactions between $[(BMPA)FeCl_3]$ and $(HOCH_2)_3CNHCO(CH_2)_nCONHC(CH_2OH)_3$, (**1**: $n = 0$) or HO_2CCO_2H in basic media, are reported: BMPA = bis-(2-pyridylmethyl)amine; ox = oxalato. Each iron centre in **4** is coordinated to all three nitrogen atoms of a BMPA ligand, to two oxygen atoms from a chelating oxalato ligand and to a bridging oxide linking the two metals. The central Fe–O–Fe bond in centrosymmetric **4** is linear. The Fe(III) centres have distorted octahedral geometries with the three oxygen donor centers *trans* to nitrogen centres. Molecules of **4** are linked mainly via the water solvate molecules into a supramolecular network by an extensive array of hydrogen bonds, involving both strong O–H···O interactions as well as weaker C–H···O interactions. The amido NH group only takes part in an intramolecular interaction with a carbonyl oxygen of the oxalate ligand. Reactions of $(HOCH_2)_3CNHCO(CH_2)_nCONHC(CH_2OH)_3$, (**2**: $n = 1$: **3**: $n = 2$) with BMPA led to no identifiable products. The crystal structure and supramolecular arrangement in **3** are reported and are compared with those of **1** and **2**. Compounds, **1**–**3**, have elaborate, but different, H-bonding networks.

1. Introduction

Polyhydroxy-organic compounds attract attention for various reasons. The major interests, especially of carbohydrate derivatives, are their biological activities. However, considerable attention has also been paid to other aspects such as interactions with inorganic and organometallic species [1,2].

Our work with polyhydroxy compounds, such as the hexahydroxydiamido compounds, $(HOCH_2)_3CNHCO(CH_2)_nCONHC(CH_2OH)_3$, (**I**), [3–6] is concerned with interactions with inorganic/organometallic compounds, supramolecular arrangements in the solid state and uses

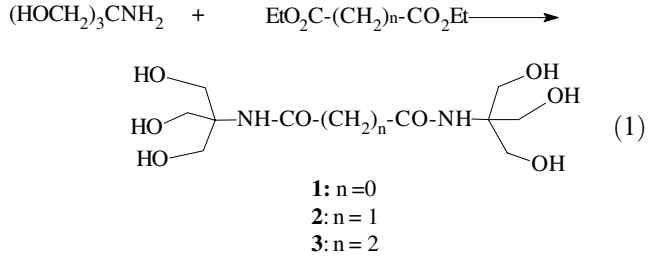
doi:10.1016/j.poly.2004.02.027

as dendrimer precursors. We have previously reported the crystal structures and supramolecular arrangements of *N*,*N*′-bis[tris(hydroxymethyl)methyl]ethanediamide **1** [3] and *N*,*N*′-bis[tris(hydroxymethyl)methyl]malonamide, **2** [4], formed from $(HOCH_2)_3CNH_2$ with EtO_2CCO_2Et [7] and $EtO_2CCH_2CO_2Et$, respectively, as well as the formation of derivatives of **1**, including organotin and mercury derivatives [5,6].



(1)

We now wish to report the synthesis and crystal structure of a further member of the series **I**, namely *N*,*N*′-bis[tris(hydroxymethyl)methyl]succinamide, **3**, as well as reactions of **1**–**3** with [Fe(BMPA)Cl_3] [BMPA = bis-(2-pyridylmethyl)amine]. Unexpectedly, one of the products isolated from the reaction with **1** was (μ- oxo)bis{(oxalato){[bis(pyridylmethyl)amine] iron(III)}, **4**. (μ-Oxo)di-iron complexes [8–11] are of interest due to the presence of complexes with (μ-oxo) diiron cores in metalloproteins, such as hemerythrin [12,13], ribonucleotide reductase [14,15] and methane mono-oxygenase [16,17].

2. Experimental

2.1. General information

Aminotris(hydroxymethyl)methane, $(HOCH_2)_3CNH_2$ (TRIS), dimethyl oxalate, diethyl malonate and diethyl succinate were purchased from Aldrich Chemical Co. and were used as received. Compounds, bis(2-pyridylmethyl)amine [18] and [{bis(2-pyridylmethyl)amino}trichloroiron(III)], [Fe(BMPA) Cl_3] [19] were synthesized according to literature procedures. Elemental (C, H, N) analyses were performed on a Perkin–Elmer 2400 CHN analyzer. Infrared spectra were recorded in KBr or CsI disks or polyethylene films on a Nicolet-Magna IR 760 instrument. Mössbauer spectra were obtained at 298 and 115 K using a Wissel instrument in the constant acceleration mode with transmission geometry where the WEB Research 20 mCi ^{57}Co/Rh source was maintained at room temperature. The resultant spectra where least square fitted to Lorentzian-shaped lines using the NORMOS software (Wissel company). Metallic iron was used for energy calibration and also as a reference for the isomer shift (δ) scale.

2.2. Synthesis of *1*, *2* and *3*

N,*N*′-bis[tris(hydroxymethyl)methyl]ethanediamide (**1**) [3,7] and *N*,*N*′-bis[tris(hydroxymethyl)methyl]malonamide (**2**) [4] were prepared according to published procedures.

2.2.1. Compound *1*

IR(KBr, cm^{-1}): 3700–2500br (max at 3412, 3338, 3223, 2956, 2916, 2878) 1667(CO), 1515(CN). ^1H (NMR (Me_2SO-d_6): δ: 3.51(d, 12H, CH_2OH), 4.76(t, 6H, OH), 7.78(s, 2H, NH). ^{13}C (NMR (Me_2SO-d_6): δ: 60.0(CH_2OH), 62.2(C_{quart}), 160.0(CO).

2.2.2. Compound *2*

IR(KBr, cm^{-1}): 3700–2500br (max at 3361, 3308, 3218, 2953, 2883, 2740), 1650(CO), 1561(CN). ^1H (NMR (Me_2SO-d_6): δ: 3.15(s, 2H, CH_2C)), 3.54(d, 12H, CH_2OH), 4.63(t, 6H, OH), 7.55(s, 2H, NH). ^{13}C (NMR (Me_2SO-d_6): δ: 44.4(CH_2CH_2), 60.6(CH_2OH), 62.9(C_{quart}), 168.8(CO).

2.2.3. Synthesis of *N,N′-bis[tris(hydroxymethyl)methyl]succinamide (3)*

A mixture of diethyl succinate (0.0226 mol) and $(HOCH_2)_3CNH_2$ (0.0451 mol) in methanol (40 ml) was refluxed for 5 h. On cooling, colorless crystals of **3** slowly formed, yield 90%, m.p. 224–225 °C. The product was recrystallised from EtOH for the X-ray diffraction study. IR(KBr, cm^{-1}): 3700–2500br (max at 3515, 3264, 3099, 2964, 2942, 2887), 1633(CO), 1574(CN). ^1H (NMR (Me_2SO-d_6): δ: 2.36(s, 4H, CH_2CH_2), 3.52(d, 12H, CH_2OH), 4.64(t, 6H, OH), 7.15(s, 2H, NH).

^{13}C (NMR (Me_2SO-d_6): δ: 31.6(CH_2CH_2), 60.4(CH_2OH), 62.2(C_{quart}), 172.9(CO).

2.3. General reactions between *[Fe(BMPA)Cl3]* and *1*–*3*

Reactions of the hexahydroxydiamides, **1**–**3** (ca. 1.0 mmol), with [Fe(BMPA)Cl_3] (ca. 2.1 mmol) were carried out in the presence of Et_3N in refluxing methanol. Interactions in all cases were evident from the formation of deep red-colored solutions. However, it was only possible to characterize products from the reaction with **1**.

2.4. Reaction between *[Fe(BMPA)Cl3]* and formation of *4* and *5*

Solutions of [Fe(BMPA)Cl_3] (750 mg, 2.08 mmol) in methanol (20 cm^3) and **1** (280 mg, 0.9 mmol) in methanol (50 cm^3) were mixed and Et_3N was added until pH 6. The reaction mixture was refluxed for 4 h and then left at room temperature. Dark-red crystals of $[(ox)(BMPA)Fe^{III}(\mu\text{-}O)Fe^{III}(BMPA)(ox)]\cdot 5H_2O$ (**4**) slowly formed. The crystals were collected after one week, yield: 35%. *Anal.* Calc. for $C_{28}H_{32}Fe_2N_6O_{14}$: C,

44.47; H, 4.26; N, 11.11. Found: C, 44.34; H, 4.23; N, 11.15%. IR (KBr, CsI or polyethylene, cm^{-1}): *v*: 3500–2500br (max at 3508, 3431, 3214, 3111, 3076, 3034, 2946, 2916), 1708, 1678 and 1642(all C=O), 1606, 1572, 1487, 1439, 1397, 1362, 1288, 1264, 1225, 1167, 1101, 1056, 1023, 1009, 984, 930, 897, 832, 810, 783, 724, 649, 631, 571, 519, 485, 418, 341, 310, 292, 265, 237. The bands in the OH region were relatively much less intense than those observed for **1**.

The filtrate yielded on concentration and further standing a deep brown solid, **5**. *Anal*. Calc. for $C_{22}H_{35}FeN_5O_9Cl_3$: C, 39.10; H, 5.22; N, 10.36. Found: C, 39.05; H, 5.34; N, 10.44%. IR(KBr, cm^{-1}) *v* 3500–2000br (max at 3103, 3080, 3038, 2899), 1632 (C=O), 1597, 1566, 1475, 1464, 1362, 1291, 1262, 1245, 1171, 1154, 1114, 1094, 1047, 1025, 987, 900, 855, 831, 794, 769, 738, 692, 673, 692, 673, 649, 625, 581, 542, 443, 334, 312, 287, 271, 241, 229.

2.5. Direct synthesis of *4*

Solutions of [Fe(BMPA)Cl_3] (360 mg, 1.00 mmol) in methanol (20 mL) and oxalic acid (90 mg, 1.0 mmol) in methanol (20 mL) were mixed and Et_3N was added until pH 6. The reaction mixture was refluxed for 5 h and then left at room temperature. Dark-red crystals of **4** slowly formed and were collected after one week, yield: 55%. Physical and spectral properties were identical with the product formed from **1**.

2.6. Crystal structure determination and refinement

Intensity data were collected on a Nonius Kappa CCD area detector by the EPSRC X-ray crystallographic service at the University of Southampton, UK. The entire processes of data collection, cell refinement and data reduction were accomplished by means of the programs, DENZO [20] and COLLECT [21]. Correction for absorption was achieved by a semi-empirical method based upon the variation in intensity of equivalent reflections with the program SORTAV [22,23]. The structure was solved by direct methods in SHELXS 97 [24] within the OSCAIL suite of programs [25] and refined in SHELXL 97 [26]. In the final stages of refinement H atoms were placed in calculated positions and refined with a riding model. PLATON was used for the analysis of the hydrogen bonding [27]. The program ORTEP-3 for windows [28] was used to obtain the figures. Crystal data and structure refinement for **3** and **4** are shown in Table 1.

Table 1

R indices (all data)	$R_1 = 0.0996$, $wR_2 = 0.2599$	$R_1 = 0.1216$, $wR_2 = 0.1909$
Largest difference peak and hole ($Å^3$)	0.663 and −0.470	0.462 and −0.570

Data collection for **4** was hampered by the quality of the crystals, as evidenced by the high R_{int}, low completeness (83%) and poor ellipsoidal shapes; however, of data collections from several crystals, this represents the best possible, and results were consistent between crystals. Therefore, we believe that this is a good representation of the crystal structure within the limits of the available material.

3. Results and discussion

3.1. Compound 3

Compound **3** was obtained as a crystalline colorless solid from reactions of TRIS with $EtO_2C(CH_2)_2CO_2Et$ in refluxing methanol, by a similar reaction used to prepare **1** and **2**, Eq. (1).

3.2. Crystal structure of 3

Selected bond lengths and angles are listed in Table 2. An extensive array of H-bonds is present in the crystal, see Fig. 1 and Table 3. The molecule of **3**, which lies across an inversion plane, see Fig. 1(a), are linked into dimers and an $R_2^2(10)$ motif, via N(1)–H(1)···O(13)^{ii} H-bonds [ii $= -x, 1-y, -z$], Fig. 1(b). The supramolecular arrangements are completed by (a) H-bonds, O(12)–H(12)···O(1)^{iii}, which provide C(7) chains along *a* and by (b) H-bonds, O(13)–H(13)···O(12)^{iv}, which lead to C(6) chains along *b*. For the graph set notations, $R_m^n(X)$, C(*Y*) and S(*Z*), see [29]. These H-bonds combine to give $R_4^4(22)$ rings, [iii $= 1+x, y, z$; iv $= x, 1+y, z$], see

(a) Atom arrangements and numbering scheme for a molecule of **3**: symmetry operation: i, $-x-1, -y, -z$; (b) Formation of dimers and $R_2^2(10)$ rings, generated by N(1)–H1···O13^{ii}: symmetry operation: ii, $-x, 1-y, -z$; (c) sheets, and $R_4^4(22)$ rings, formed from further O–H···O hydrogen bonds: O12–H12···O1^{iii} [leading to C(7) chains along *a*] and O13–H13···O12^{iv} [leading to C(6) chains along *b*]: only the symmetry related half of each molecule is omitted for clarity: symmetry operations: iii, $1+x, y, z$; and iv $= x, 1+y, z$. Ellipsoids drawn at the 50% level.

Table 3
Parameters (Å) and (°) for hydrogen bonds in **3**

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	D–H···A (°)
N(1)–H(1)···O(13)^{ii}	0.88	2.03	2.886(4)	162.6
O(12)–H(12)···O(1)^{iii}	0.84	1.89	2.725(4)	171.3
O(13)–H(13)···O(12)^{iv}	0.84	1.82	2.653(4)	170.2
C(11)–H(11B)···O(1)	0.99	2.49	3.033(5)	114.5
C(13)–H(13B)···O(12)	0.99	2.55	2.930(5)	102.5

i, $-x-1,-y,-z$; ii, $-x,-y+1,-z$; iii, $x+1,y,z$; iv, $x,y+1,z$.

Fig. 1(b) and (c), in which only half of each molecule is shown for purposes of clarity. Altogether, the H-bonds form a sheet in (1 1 0), i.e., perpendicular to (0 0 1). The dimers have the effect of doubling the thickness of this sheet.

The different number of methylene groups in **1**–**3** results in significant differences between the structures. All three compounds have elaborate, but different, H-bonding networks. Molecules of near centro-symmetric **1** are linked into a two-dimensional structure, made up of distinct ring motifs: S(7), $R_3^3(10)$ and $R_2^2(22)$. Molecules of **2** lie about a twofold axis and are linked into a three-dimensional framework, formed from C(5) C(7) and C(12) chains, and $R_2^2(18)$, $R_2^2(12)$, $R_4^4(8)$, $R_2^2(8)$ and $R_2^2(13)$ rings.

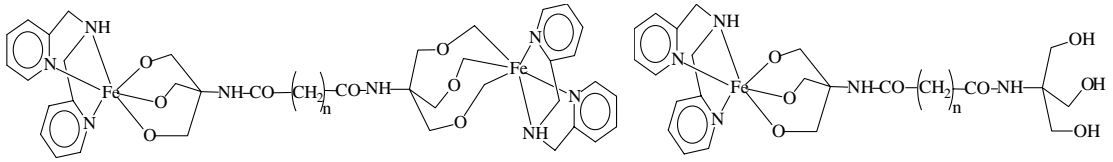
As in **3**, the amido NH groups in **2** form intermolecular H-bonds with HO groups in adjacent molecules, but in contrast, the amido NH units in **1** take no part in the supramolecular aggregation, and are only involved in intramolecular bonding with the adjacent carbonyl atoms.

3.3. Spectra of *1*–*3*

There are some significant spectral shifts for the amido group in going from **1** to **3**. For example, the sequences of values for: (i) ν(CO) in the IR spectra in KBr disks are 1667, 1647 and 1633 cm^{-1}, for (ii) δ ^{1}H (NH) values in the ^{1}H NMR spectra are 7.78, 7.55 and 7.15 ppm and (iii): δ^{13}C (CO) values in the ^{13}C NMR spectra are 160.0, 168.8 and 172.9 ppm, all for **1**–**3**.

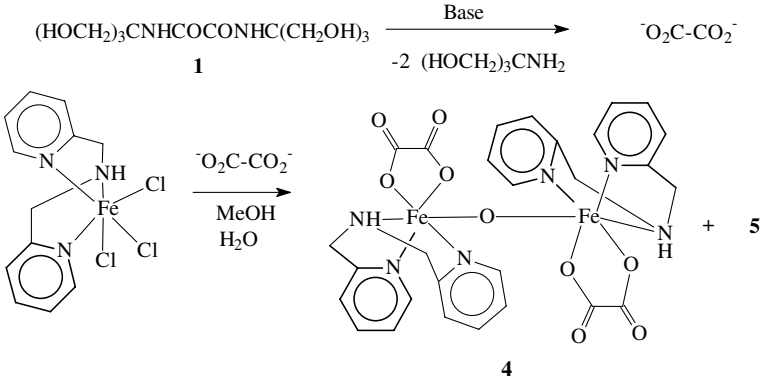
3.4. Reactions of *1*–*3* with *[Fe(BMPA)Cl$_3$]*

The reactions between **1**–**3** and [Fe(BMPA)Cl$_3$] were carried out with the expectation of obtaining mono- and bis-metallated complexes, such as **6** and **7**, see Fig. 2. However, in no case were there any indications that such complexes were formed. Moreover, while some reactions occurred between **1** and **3** with [Fe(BMPA)Cl$_3$], as shown by the color change of the solutions, solid products were only characterized from the reaction with



6 **7**

Fig. 2. Target products of reaction between **1**–**3** and [Fe(BMPA)Cl$_3$.



4

Scheme 1. Reaction of **1** with [Fe(BMPA)Cl$_3$].

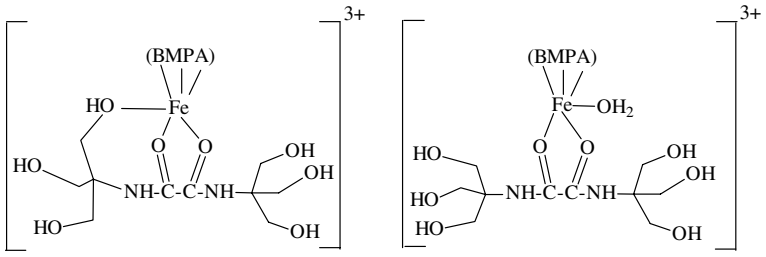


Fig. 3. Possible structures of the cation of **5**.

1. The residues extracted from reactions with **2** and **3** were inseparable oily-solid mixtures of compounds.

As indicated in Section 2, two products were obtained from reaction of **1** and [Fe(BMPA)Cl_3]: a crystalline material, **4**, which was confirmed by X-ray crystallography to be {[(ox)(BMPA)Fe(μ-O)Fe(BMPA)(ox)]·$5H_2O$}, and an amorphous material, **5**, see Scheme 1.

The formation of **4** proceeded via the base hydrolysis of the bis-amide, **1**, to the oxalato dianion, which then underwent reaction with [Fe(BMPA)Cl_3], Scheme 1. Base hydrolysis of an ester to a carboxylate anion and an alcohol is a well-known process. From subsequent study, **4** was obtained directly from [Fe(BMPA)Cl_3] and oxalic acid in basic medium.

3.5. Compound 5

Suitable crystals of **5** could not be grown and its structure remains uncertain. However, a combination of C,H,N analysis, IR and Mössbauer spectra indicated possible structures, such as [(BMPA)(**1**)Fe(OH_2)]Cl_3 or [(BMPA)(**1**)Fe]$Cl_3 \cdot H_2O$, in which an intact ligand, **1**, is chelated to Fe(III) via the carbonyl groups, with the hexacoordination of Fe(III) completed by the tridentate BMPA and an aqua ligand or a hydroxyl group, see Fig. 3. The broad and intense absorptions in the IR spectrum of **5** in the 2000–3500 cm^{-1} region pointed to the presence of several hydroxyl groups, while (CO) = 1632 and the combined NH deformation + C–N stretching band at 1597 cm^{-1} (compared to the values of 1660 and 1515 cm^{-1} in free **1**) indicated complexation had occurred with the amido groups. Relatively strong bands in the far IR were observed at 443 and 334 cm^{-1}. The Mössbauer spectral data for **5**, $\delta = 0.34$ and $\Delta E_Q = 0.84$ mm/s, at 298 K, were as expected for a distorted octahedral Fe(III) complex with 3N and 3O donor atoms [30]. Some changes in the Mössbauer spectral parameters occurred on cooling to 115 K, the values at the lower temperature being $\delta = 0.44$ and $\Delta E_Q = 0.66$ mm/s. The ΔE_Q values exclude the possibility of **5** being a (μ-oxo)di-iron species as such compounds are known to have ΔE_Q values near 1.5 mm/s [31,32].

3.6. Compound 4

X-ray crystallography revealed **4** to be a penta-hydrated centrosymmetric dinuclear complex, in which each iron centre is coordinated to all three nitrogen at-

Symmetry transformations used to generate equivalent atoms: i, $-x+2, -y, -z+1$.

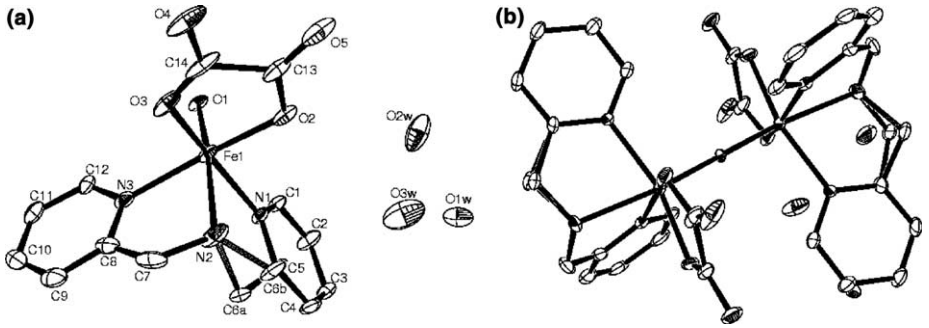

Fig. 4. (a) Atom arrangements and numbering scheme for the asymmetric unit of $[(Ox)(BMPA)Fe(\mu\text{-}O)Fe(BMPA)(Ox)]\cdot 5H_2O$ **4**. (b) Molecular structure of **4**. Hydrogen atoms have been omitted for clarity. Ellipsoids drawn at the 30% level.

oms of a BMPA ligand, to two oxygen atoms from a chelating oxalate ligand, ox, and to a bridging oxide linking the two metals. Selected bond lengths and angles are listed in Table 4. The asymmetric unit is made up of a [(ox)(BMPA)Fe] moiety, two and half water solvate molecules and half the bridging O, see Fig. 4(a). The complete molecule is shown in Fig. 4(b). Atom C(6) was best modeled by disordering the atom over two sites, as shown in Fig. 4(a). The $Fe\text{–}O_{bridge}$ bond length, 1.7885(7)Å, is in the region normally found for other oxygen bridged di-iron compounds [33]: all other Fe–O and the Fe–N bond lengths are also in the expected regions. All three oxygen donor centers are *trans* to nitrogen centres in **4**: the bridging oxide, O1, is *trans* to the aliphatic amine, N(2) [O(1)–Fe(1)–N(2) = 169.30(18)°] and oxalato O *trans* to pyridinyl N [N(3)–Fe(1)–O(2) = 160.81(17)° and O(3)–Fe(1)–N(1) = 161.89(16)°]. The bite angles of the bidentate oxalato ligands [O(3)–Fe(1)–O(2) = 79.3(3)°] and two of the three bite angles of the tridentate bis(2-pyridylmethyl)amine [N(1)–Fe(1)–N(2) = 76.57(17)° and N(2)–Fe(1)–N(3) = 76.0(2)°] are considerable less than the ideal *cis* 90° angles. The third bite angle of the BMPA ligand, N(3)–Fe(1)–N(1), is much larger at 96.58(17)°. The BMPA ligand is a very flexible tridentate ligand as shown by the variation in its bite angles in different iron complexes. For example, the bite angles in two independent molecules of $[(BMPA)Fe(\mu\text{-}O)(\mu\text{-}O_2CCH_3)_2Fe(BMPA)][ClO_4]_2\cdot 0.9Me_2CO$ (**8**) [34], are 77.1(2)°, 77.2(2)° and 83.8(2)°, and 76.7(2)°, 77.3(2)° and 89.4(2)°], while in orthorhombic $[(BMPA)FeCl_3]$, all three BMPA bite angles are between 75.8(2)° and 79.9(2)° [19b].

The crystallographic symmetry imposes an 180° angle on the Fe(1)–O(1)–Fe(1)^{i} bond $(i: -x+2, -y, -z+1)$ and consequently a Fe(1)···Fe(1)^{i} separation of twice the $Fe\text{–}O_{bridge}$ bond length of 1.7885(7) Å. A wide range of Fe–O–Fe bond angles (from ca. 115° to 180°) have been reported for (μ-O)di-iron species [33]. A 180° angle is also present, for example, in $[(H_2O)_2(Cl\text{-}pdc)Fe(\mu\text{-}O)Fe(Cl\text{-}pdc)(H_2O)_2]$ [35]: Cl-pdc = 2,6-($^{-}O_2C$)$_2$-4-Cl-pyridine), while in **8**, the Fe–O–Fe angle is one of the smallest reported at 116.2(2)° [34]. A further difference between **4** and **8** was found with the bonding modes of the carboxylate ligands: in **4**, the dicarboxylato ligands are chelating while in **8** the mono-carboxylate groups are bridging [34].

The molecules of **4** are linked mainly via the water solvate molecules into a supramolecular network by an extensive array of hydrogen bonds, involving both

C(12)–H(12)···O(2)^{i}	0.95	2.37	3.314(8)	174.6

Symmetry transformations used to generate equivalent atoms: i, $-x+2, -y, -z+1$; ii, $-x+3/2, -y+1/2, -z+1$; iii, $-x+1, y, -z+1/2$; iv, $x+1/2, y+1/2, z$; v, $-x+5/2, -y+1/2, -z+1$.

strong O–H···O interactions as well as weaker C–H···O interactions. The amido NH group only takes part in an intramolecular interaction with a carbonyl oxygen of the oxalato ligand (see Table 5).

3.7. Spectra of **4**

Selected IR frequencies associated with the chelating oxalate groups in $K_3[Fe(oxalato)_3]\cdot 3H_2O$ have been reported to be 1712, 1688 and 1647 [ν(C=O)], 1390, 1270 and 1255 [ν(C–O)], 892 [ν(C–C)], 803 and 790 [δ(O–C–O)], 580 and 532 [ν(Fe–O)] [36]. Corresponding frequencies in **4** are considered to be 1708, 1678 and 1642 [ν(C=O)], 1397, 1288 and 1264[ν(C–O)], 810 and 783 [ν(C–C)], and 571 and 518[ν(Fe–O)]. Sanders-Loehr et al. [33] reported a correlation between the Fe–O–Fe bond angle and values of IR active ν_{as}(Fe–O–Fe) and Raman active ν_s(Fe–O–Fe) in various oxo-bridged dinuclear iron species. For a Fe–O–Fe bond angle of 180°, as in **4**, ν_{as}(Fe–O–Fe) is expected to be near 885 cm^{-1}. The IR spectrum of **4** in fact contained a weak band at 897 cm^{-1}.

The Mössbauer parameters at 298 K for **4** were $\delta = 0.25$ and $\Delta E_Q = 1.47$ mm/s, which are in the regions consistent with a substantial distorted octahedral high-spin Fe(III) compound, with a (μ-O)di-iron core [31,32].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC 212024 and 212025, for **3** and **4**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Available online 12 April 2004

Abstract

An improved method for the synthesis of the polypyridyl ligand [2,3-a:3′,2′-c]dipyridophenazine (ppb) is reported. In addition, the syntheses of the new ppb-based ligands L (L = [2,3-a:3′,2′-c]dipyridophenazine, [2,3-a:3′,2′-c]dipyrido-6,7-dimethylphenazine, [2,3-a:3′,2′-c]dipyrido-6,7-dichlorophenazine, [2,3-a:3′,2′-c]dipyrido[1,2-e]benzophenazine, [2,3-a:3′,2′-c:3″,2″-e]tripyridoquinoxaline and [2,3-a:3′,2′-c]dipyrido-5-methylphenazine) are detailed. The complexes $[Os(ppb)(bpy)_2]^{2+}$ and $[Os(L)(bpy)_2]^{2+}$ have been synthesised and their electrochemical, electronic absorption and UV–Vis spectrochemical properties measured. Syntheses of the rhenium(I) complexes *fac*-$[Re(L'')(CO)_3Cl]$ (L″ = [2,3-a:3′,2′-c]dipyridophenazine, [2,3-a:3′,2′-c]dipyrido-6,7-dimethylphenazine, [2,3-a:3′,2′-c]dipyrido-6,7-dichlorophenazine, [2,3-a:3′,2′-c]dipyrido[1,2-e]benzophenazine) are also reported. The osmium(II) complexes $[Os(L')(bpy)_2]^{2+}$ (L′ = 2,3-di-(2-pyridyl)quinoxaline, 6,7-dimethyl-2,3-di-(2-pyridyl)quinoxaline, 6,7-chloro-2,3-di-(2-pyridyl)quinoxaline, 2,3-di-(2-pyridyl)benzo[g]quinoxaline, 4-methyl-di-(2-pyridyl)quinoxaline) have also been prepared and studied. The electronic spectra of the Os and Re complexes are dominated by strong MLCT transitions. The lowest energy MLCT transitions correlate linearly with the first reduction potential for the $[Os(L)(bpy)_2]^{2+}$ series. Electrochemical oxidation of the $[Os(L)(bpy)_2]^{2+}$ and $[Os(L')(bpy)_2]^{2+}$ complexes results in the appearance of LMCT transitions in the visible region while reduction of the $[Os(L)(bpy)_2]^{2+}$ complexes produces complex electronic spectra. Comparison with the reduced *fac*-$[Re(L'')(CO)_3Cl]$ complexes allows assignment of $L''^{\cdot-}$ $\pi \rightarrow \pi^*$ transitions in the NIR (1200–1000 nm) and red (850–700 nm) regions. The nonsymmetrical ligands [2,3-a:3′,2′-c:3″,2″-e]tripyridoquinoxaline and [2,3-a:3′,2′-c]dipyrido-5-methylphenazine both coordinate to the $[Os(bpy)_2]^{2+}$ unit in a stereospecific manner to give a single geometric isomer. The crystal structure of $[Re(CO)_3(ppb)Cl]$ is reported, in which the polypyridyl ligand deviates significantly from planarity.

1. Introduction

There has been a considerable amount of research into the use of polypyridyl ligands that can act as bridging units in the formation of supramolecular arrays and grids [1–5] and large multinuclear complexes [6–9]. Such complexes may be used in photocatalysis [10], CO_2 remediation [11], solar energy systems [12–14], molecular electronics [6–8,15] and light-emitting diodes [16–24]. In this paper we report the syntheses and electronic properties of mononuclear Os(II) and Re(I) complexes containing a series of rigid ligands L based on the potential bridging ligand [2,3-a:3′,2′-c]dipyridophenazine (ppb, **21**, Fig. 1) and these are compared to analogous complexes containing the more flexible ligands L′ (**11-14**, **16**, Fig. 1) [25–29]. We also report a synthesis of **21** which utilises less forcing conditions than the previously

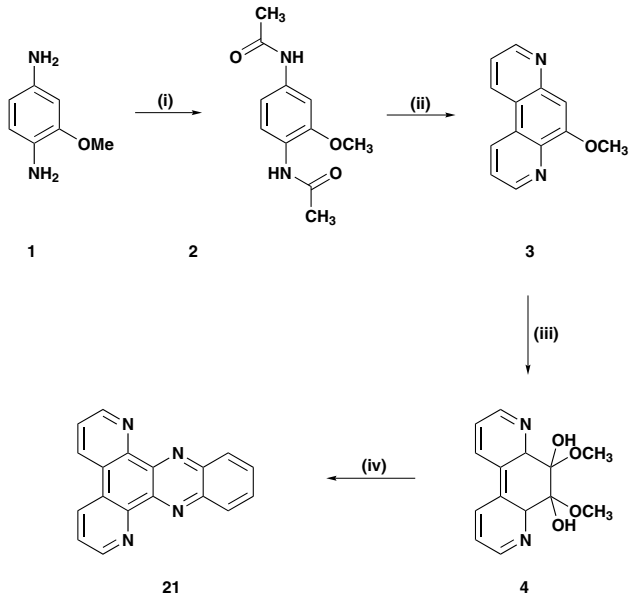
reported method [30] and which was adapted to prepare the series of ligands L (**22–26**). The metal-containing moieties $[Os(bpy)_2]^{2+}$, $[Os(phen)_2]^{2+}$ and *fac*-$[Re(CO)_3Cl]$ were chosen in order to influence the electronic properties of the ligand [31]. Complexation of polypyridyl ligands to the *fac*-$[Re(CO)_3Cl]$ moiety simplifies the electronic absorption properties of the resulting compounds by removing the chromophores associated with the 2,2′-bipyridine or 1,10-phenanthroline ancillary ligands from the coordination sphere, thus allowing easier assignment of the observed absorptions [32,33].

2. Results and discussion

2.1. Ligand synthesis

The ligands **21**–**26** were synthesised in a four step process modified from that used previously for ppb [30] (Scheme 1). Acetylation of 2-methoxyphenylene-1,4-diamine (**1**) using pyridine/acetic anhydride gave **2** in reasonable yield. **2** was found to react less vigorously than **1** in the subsequent exothermic Skraup reaction and gave a good yield of product. Addition of acetic acid also helped to moderate this reaction.

The published synthesis of **3** requires two separate Skraup reactions, an additional step involving the reduction of the nitro-substituted starting material to an amine, and the use of As_2O_5 as an oxidant to lower the amount of reduction during the first Skraup reaction [30]. The synthesis reported herein produces **3** under milder conditions, in a higher overall yield and in fewer steps than the published procedure. The attempted oxidation of **3** to 4,7-phenanthroline-5,6-dione was carried out following the published procedure [30] by use of a mixture of fuming nitric acid and concentrated sulfuric acid. However, the product isolated was the bis-methyl hemiacetal **4**, and not the free diketone as reported [30]. However, Schiff-base condensation [34] of **4** with the appropriately substituted phenylenediamine in slightly



Scheme 1. The synthesis of [2,3-a:3′,2′-c]dipyridophenazine (ppb). Ligands **22**–**26** were prepared in analogous fashions by the use of the appropriate diamine in step (iv): (i) acetic anhydride, pyridine; (ii) ethylene glycol, conc. H_2SO_4, acetic acid, $Fe_2(SO_4)_3$; 120 °C 1 h, 140 °C 1 h; (iii) fuming HNO_3, conc. H_2SO_4; 120 °C, 2 h; (iv) phenylene-1,2-diamine, methanol, dilute HCl; reflux 30 min.

acidic methanol gave the series of ligands L outlined in Fig. 1.

2.2. Synthesis of metal complexes

The Os(II) complexes were prepared by refluxing $[Os(bpy)_2Cl_2]$ or $[Os(phen)_2Cl_2]$ with a 2-fold excess of the appropriate ligand in ethylene glycol. Purification was achieved by column chromatography on Sephadex SP-C25 resin using sodium *p*-tolylsulfonate as eluent [35] and the complexes were isolated as PF_6^- salts following addition of NH_4PF_6. The Re(I) complexes were prepared by heating $[Re(CO)_5Cl]$ with a slight excess of ligand under reflux in methanol under argon. Chromatography on silica separated the desired mononuclear species from some binuclear impurities. Satisfactory elemental analyses were obtained for all metal complexes reported herein.

Bidentate coordination of the asymmetric ligands **16**, **25** and **26** to a single metal centre can result in the formation of geometric isomers having the metal disposed either *syn* or *anti* with respect to the nitrogen atom or methyl substituent of the terminal phenazine ring (Fig. 2).

The ^1H (2.35 ppm) and ^{13}C NMR (17.7 ppm) spectra of $[Os(bpy)_2(\mathbf{26})](PF_6)_2$ both show only one methyl resonance. This can be compared to the corresponding dimethyl complex $[Os(bpy)_2(\mathbf{22})](PF_6)_2$ which displays two ^1H peaks (2.36 and 1.98 ppm) and two ^{13}C peaks (19.8 and 18.9 ppm) in the methyl region. The complex

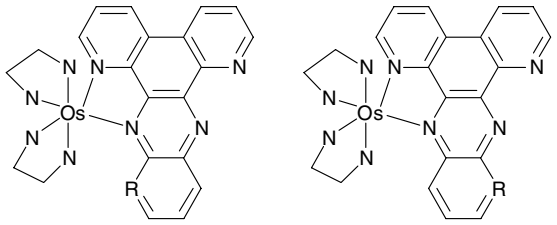


Fig. 2. The two geometric isomers of $[Os(bpy)_2L]^{2+}$ (L = **25** (R = N) and **26** (R = C–CH_3)).

$[Os(bpy)_2(\mathbf{16})](PF_6)_2$ also displays only one methyl resonance in both the ^1H (3.17 ppm) and ^{13}C NMR (16.6 ppm) spectra. These observations are consistent with the formation of only one isomer, which we assign as that in which the sterically demanding methyl group points away from the metal centre. Despite the fact that ligand **25** is sterically only slightly different from **21**, neither the ^1H nor ^{13}C NMR spectra of $[Os(bpy)_2(\mathbf{25})](PF_6)_2$ show any evidence of an isomeric mixture. Likewise, the COSY spectrum of $[Os(bpy)_2(\mathbf{25})](PF_6)_2$ showed no evidence of any ''hidden'' proton signals attributable to a second isomer. Nuclear Overhauser effect (nOe) experiments were carried out to allow complete assignment of the ^1H spectrum of $[Os(bpy)_2(\mathbf{25})](PF_6)_2$. Linked pyridine rings of the bpy ligands were identified through interactions between the 3 and 3′ protons. Irradiation of the 6 and 6′ protons of the 2,2′-bipyridine ligand was used to determine the orientation of ligand **25** with respect to the bpy ligands. No interaction between any of the 6 or 6′ protons and the proton on **25** *para* to the terminal ring nitrogen was observed, and this suggests that the nitrogen of the terminal ring is *syn* to the osmium centre.

The formation of only a single isomer in both cases is surprising. There is a possibility that the other isomer was lost during workup, either through irreversible binding to the Sephadex SP-C25 resin or through differences in solubility during the precipitation process, but we believe any such losses to be small. In the case of $[Os(bpy)_2(\mathbf{25})]^{2+}$, the observed selectivity may possibly be due to the decreased steric requirements of **25** as compared to ppb; the absence of a proton attached to the nitrogen in the terminal ring of **25** may result in reduced steric interactions with the *cis* bpy ligand. The positioning of the terminal ring nitrogen atom *syn* to the metal ion may also assist in pre-organisation of the metal–ligand assembly, resulting in the observed stereochemistry.

2.3. Crystallography

Selected bond lengths and angles for *fac*-[Re(**21**)$(CO)_3Cl$] are given in Table 1, and ORTEP diagrams of the complex are given in Fig. 3.

Table 1

The structure consists of a rhenium(I) ion coordinated to the carbon atoms of three facially disposed carbonyl ligands, a chloride ligand and two nitrogen atoms of the chelating ppb ligand. The Re–Cl, Re–C and Re–N bond distances are comparable to those previously found in *fac*-[Re(L)$(CO)_3$Cl] complexes containing bidentate polypyridyl ligands [33,36–39]. The severely distorted octahedral geometry of the metal ion results from the small bite angle of the ppb ligand, with the angle N1–Re1–N2 being 75.27(14)°. The distorted environment of the metal ion is further evidenced by the fact that Re(1) lies 0.0917 Å above the least-squares plane of the four equatorial ligand donor atoms N1, N2, C22 and C23. The ppb ligand is extremely distorted and exhibits remarkable curvature in the complex, with both C9 and C10 lying ~2.8 Å below the C22–Re1–C23 plane and C16 1.21 Å above it. Similar but less pronounced distortions have been observed previously in *fac*-[Re(L)$(CO)_3$Cl] complexes [36–39], and may possibly be due, in part, to a destabilising steric interaction between the equatorial carbonyl groups and the protons *ortho* to the nitrogen donor atoms. In this case, there is an additional destabilising steric interaction between the carbonyl carbon C22 and H17A, which lie only 2.425 Å apart, and which would be significantly closer if the ligand was coplanar with the carbonyl ligands. This argument is supported by the observation that the dichloro ppb ligand in $[(PPh_3)_2Cu(\mathbf{23})Cu(PPh_3)_2](BF_4)_2 \cdot 4H_2O \cdot CH_2Cl_2$ [40], the only other structurally characterised ppb complex, is planar; the tetrahedral geometry about the Cu(I) ions means that there are no potentially destabilising interactions between the PPh_3 ligands and protons of the ppb ligand [40].

2.4. Electrochemistry

The electrochemistry of the ligands **11–14**, **16** and **21–26** and of the complexes of these ligands was investigated using cyclic voltammetry (Table 2). Ligands **21–26** display a reversible single electron reduction over the range −0.95 to −1.31 V versus SHE. The reduction potentials are more anodic than those found for the corresponding **11–14** and **16** species due to the comparatively extended conjugation of the π systems of **21–26**. The ligands display shifts in their reduction potential commensurate with the electron donating or withdrawing character of the substituent [7,41] and the substituent effects for **21–26** are maintained upon coordination to the $[Os(bpy)_2]^{2+}$, $[Os(phen)_2]^{2+}$ or *fac*-[Re$(CO)_3$Cl] moieties.

In addition to the ligand-based reduction process, an oxidation at a potential typical of the Os(II)/(III) couple

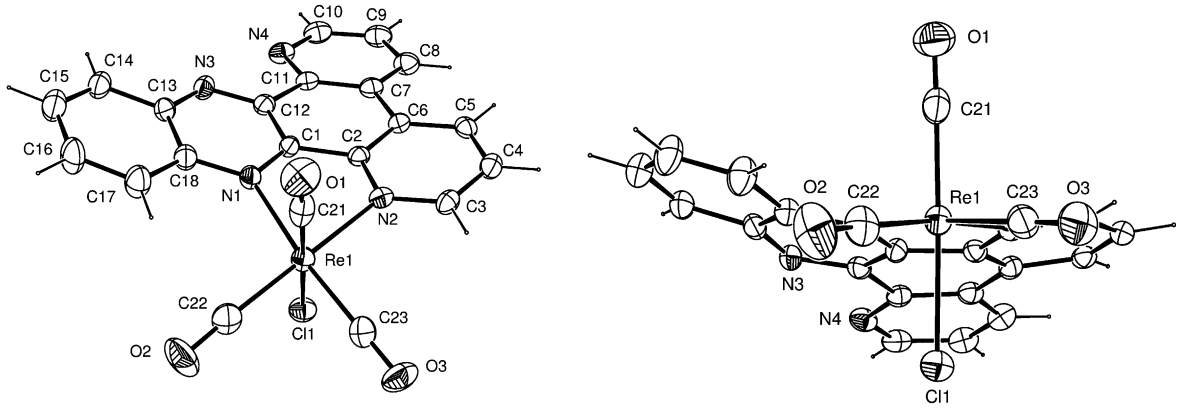

Fig. 3. ORTEP diagrams of *fac*-[Re$(CO)_3$(**21**)Cl]. The right-hand diagram emphasises the distortion of the ligand **21**.

Conditions used for the cyclic voltammograms: **11**–**16** (Pt w.e., MeCN, SCE); **21**–**26** (Pt w.e., 200 $mV\,s^1$, CH_2Cl_2, Fc internal calibrant); Os(II) complexes (Pt w.e., 200 $mV\,s^{-1}$, MeCN, Fc internal calibrant); Re(I) complexes (Pt w.e., 200 $mV\,s^{-1}$, CH_2Cl_2, Fc internal calibrant); qr = quasi-reversible.

[29] is also observed for the Os(II) complexes. Little variation in the oxidation potential is observed as the ligand is changed, supporting the Os(II)/(III) assignment. The modest variation that is observed may be attributed to the ability of the ligand to tune the metal orbital energies.

2.5. Electronic absorption

The electronic absorption spectra of ligands **21–23** are similar, with three absorption bands observed in the UV region (Table 3). These bands are ligand-centred (LC) with band maxima at ~385, 310 and 270 nm, respectively, and are assigned as $\pi \rightarrow \pi^*$ electronic transitions.

The spectral profiles of the four *fac*-$[Re(L'')(CO)_3Cl]$ complexes are similar. Four absorption bands are present, three in the UV and one in the visible region. The UV bands are correlated to the LC transitions of the free ligands and are similarly assigned as $\pi \rightarrow \pi^*$ transitions. The LC features show little change upon complexation. The lowest energy transition at ~ 470 nm ($\varepsilon \sim 4000\ M^{-1}\,cm^{-1}$) is responsible for the red colour of the mononuclear complexes. This electronic absorption band is assigned to a $Re(d\pi) \rightarrow L''(\pi^*)$ MLCT transition by comparison with assignments made for similar complexes, and exhibits band shifts that correlate with the electron-donating/withdrawing nature of the ligand substituents.

The electronic absorption spectra of the Os(II) complexes are summarised in Table 3. LC $\pi \rightarrow \pi^*$ transitions are observed for the $[Os(bpy)_2(L)]^{2+}$ and $[Os(bpy)_2(L')]^{2+}$ complexes in the UV region. These have been assigned in the literature [31] as corresponding to two bpy $\pi \rightarrow \pi^*$ transitions (250 and 280 nm) and a π–π^* transition (350 nm for L′ and 360 nm for L). Substitution on the ligand L or L′ has little effect on the energy of either bpy transition. The UV–Vis spectra of $[Os(bpy)_2(\mathbf{21})]^{2+}$ and $[Os(phen)_2(\mathbf{21})]^{2+}$ support these assignments as the transition attributed to **21** at 360 nm is common to both complexes.

The energies of the lowest energy MLCT transitions for $Os(II) \rightarrow L$ and $Os(II) \rightarrow L'$ can be related to the nature of the acceptor ligand and the electrochemical properties of the complexes. In the case of the Os(II) complexes a plot of ΔE_{red-ox}, the thermodynamic energy gap ($\Delta E_{red-ox} = E_{first\ oxidation} - E_{first\ reduction}$), versus the transition energy, ΔE_{op} (eV), is linear (Fig. 4) [31]. This holds for the energies of both the ^{1}MLCT and ^{3}MLCT transitions in the Os(II) complexes.

2.6. Electronic absorption spectroelectrochemistry

Spectroelectrochemical data for the oxidation and reduction processes of the Os and Re complexes are summarised in Tables 4 and 5, respectively.

Upon oxidation of the Os(II) complexes the MLCT features in the visible region are bleached, leaving two weak transitions in the visible region. The low intensity of the new transitions is consistent with oxidation of the metal as the resulting LMCT transitions have generally lower oscillator strengths than their MLCT counterparts [42]. The variation in wavelength and extinction coefficient observed for the LMCT transitions suggests that they are associated with the non-ancillary ligands, i.e. L,L′ or L″.

The UV region shows bpy features characteristic of a Os(III)-bpy complex [21], supporting the assignment of the first oxidation as being metal-based; the intense $\pi \rightarrow \pi^*$ transition of the Os(II) complexes at 285 nm is split into two bands at 305 and 315 nm, as is also found for $[Os(bpy)_3]^{3+}$.

Electrochemical reduction of the *fac*-$[Re(L'')(CO)_3Cl]$ and $[Os(L)(bpy)_2]^{2+}$ complexes gives spectral changes throughout the visible and NIR regions (Table 5). The UV–Vis spectra corresponding to the first reduction process associated with the *fac*-$[Re(L'')(CO)_3Cl]$ complexes show a bleach of the ground state features and the

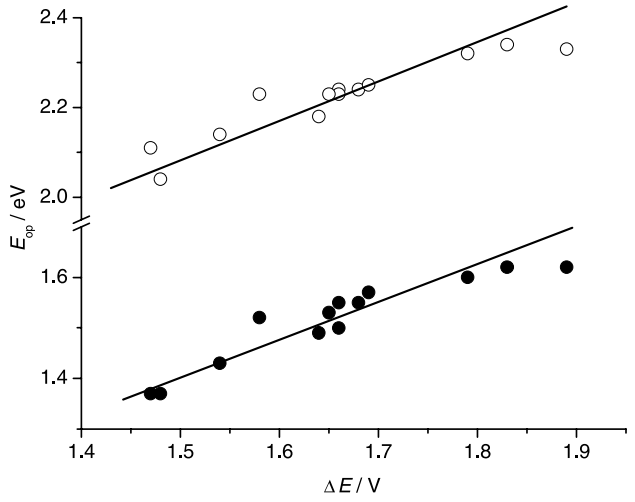

Fig. 4. Plot of the energy of the two lowest energy electronic absorptions vs. the electrochemical difference between the oxidation and the reduction potentials for the $[Os(bpy)_2(L'')]^{2+}$ and $[Os(bpy)_2(L)]^{2+}$ complexes. Open circles denote transitions assigned as ^{1}MLCT. Closed circles denote transitions assigned as ^{3}MLCT. The relationship for the ^{1}MLCT transition energies follows: $E_{op} = 0.66 \times \Delta E + 1.12$, $R^2 = 0.88$; for the ^{3}MLCT transitions the relationship is: $E_{op} = 0.62 \times \Delta E + 0.86$, $R^2 = 0.89$.

concomitant growth of new features of lower intensity at longer wavelengths. These spectra are consistent with the formation of the ligand radical anion species *fac*-$[Re(L'')(CO)_3Cl]^{\cdot -}$ with four features present at ~1100, 530, 400 and 330 nm (Table 5).

In the $[Os(bpy)_2(L')]^{2+}$ series the new features displayed upon reduction are assigned as π^*–π^* transitions of the radical anion $L'^{\cdot -}$. Similar bands are seen in the electronic absorption spectrum of the radical anions of **11–14** and **16** and of Re(I) complexes with similar ligands [43]. The spectra of the electrochemically reduced $[Os(bpy)_2(L)]^+$ complexes display bands in the visible region that are associated with the radical anion $L^{\cdot -}$. The reduced forms of the *fac*-$[Re(CO)_3(L'')Cl]$ complexes show similar transitions.

The MLCT (Os(II) → bpy) bands of the reduced Os(II) species are slightly red-shifted with respect to the parent complexes. This is consistent with the electron being localised mainly on the ligand moiety. The red-shift is caused by electron donation from the ligand π^* orbital to the metal dπ orbital which is thus destabilised.

3. Conclusions

We have developed a method for the synthesis of rigid polypyridyl bridging ligands based on ppb. The electrochemical properties of the ppb-ligands (**21–26**) are consistent with the electron withdrawing and donating effects of the substituents, and the electrochemical and electronic absorption properties of the complexes mirror these substituent effects.

The Os(II) complexes have strong MLCT transitions in the visible region that are singlet and triplet in nature. For these complexes the ^{1}MLCT and ^{3}MLCT bands show a linear correlation with the electrochemical properties of the complexes. This strengthens the assignment of these bands as involving the non-ancillary ligands.

Spectroelectrochemical studies reveal that the first oxidation for the Os(II) complexes is metal-based, with the strong MLCT bands being bleached and weaker LMCT transitions growing in. Electrochemical reduction is based on the non-ancillary ligands, as evidenced by the spectroelectrochemical behaviour of the Re(I) complexes.

The present study provides a method for the synthesis of a new group of complexes containing polypyridyl ligands based on ppb. These have already been shown to possess very interesting photophysical properties and

Data recorded from 1 mM solutions with 0.1 M $TBAPF_6$ supporting electrolyte for Os(II) complexes (CH_3CN) and Re(I) complexes (CH_2Cl_2).

rich electronic spectral properties. The utility of these materials as photosensitisers in solar cells [44] and as electroluminescent emitting materials [45] is currently underway in our laboratory.

4. Experimental

Synthetic reagents were LR or AR grade and were used without further purification unless otherwise specified. All solvents used for spectroscopic and electrochemical measurements were Aldrich spectroscopic or HPLC grade and were used without further purification. [Os(bpy)$_2$Cl$_2$] was prepared by literature methods [29]. [Re(CO)$_5$Cl] was prepared from [Re$_2$(CO)$_{10}$] (Aldrich) according to literature methods [46]. DMF (HPLC grade) was dried by stirring over CaH_2 with subsequent vacuum distillation. Tetrabutylammonium hexafluorophosphate (TBAPF) was metathesised from tetrabutylammonium hydroxide (TBAH) and hexafluorophosphoric acid, recrystallised twice from dry methanol and stored in a vacuum desiccator. NaI solutions used as eluents were prepared as required due to the air oxidation of I^- to I_2. 1 M solutions of sodium *p*-tolylsulfonate were prepared by the basification of a *p*-tolylsulfonic acid solution with an equimolar amount of solid NaOH. The resulting solution was filtered to remove a brown impurity and diluted as required.

4.1. Instrumentation

Electronic absorption spectra were recorded on a Perkin–Elmer Lambda-19 UV–Vis–NIR spectrophotometer using Perkin–Elmer UVDM software. Extinction coefficients were calculated by linear regression of the absorbance of a number of parallel-diluted solutions ($\varepsilon \pm 10\%$). Solid-state IR spectra were recorded as KBr discs using a Perkin–Elmer BX FTIR spectrometer and Perkin–Elmer Spectrum v2.00 software. Solution IR spectra were collected on the same instrument in a 0.50 mm path-length solution cell with NaCl windows, against a background of the pure solvent. Post-acquisition data treatment was performed using Galactic Grams/32 version 5.05. Cyclic voltammograms and square-wave voltammograms were recorded on an EG&G PAR Model 273A Potentiostat with Model 270 software. Typically the samples were at 1 mM concentration with 0.1 M TBAPF electrolyte. The scans were recorded at 200 mV s^{-1} and referenced to silver wire, which was itself referenced to the ferrocene/ferrocenium couple (0.40V versus NHE). The reversibility of a process was defined by comparison of the peak separation in the cyclic voltammogram to an internal ferrocene reference (typically $\Delta E_p \approx 0.100$ V for the cell used).

4.2. X-ray crystallography

Single crystals of *fac*-[Re(CO)$_3$(**21**)Cl] were grown by slow diffusion of diethyl ether into a dichloromethane solution of the complex. Single crystal data were collected using a Bruker SMART CCD system (Mo Kα radiation, 0.71073 A). The structure was solved by direct methods using SHELXS-97 [47] running within the WinGX [48] package and weighted full-matrix refinement on F^2 was carried out using SHELXL-97 [49], with all non-hydrogen atoms being refined anisotropically.

Hydrogen atoms were included in calculated positions and were refined as riding atoms with individual isotropic displacement parameters. The maximum and minimum peaks on the final difference Fourier maps corresponded to 1.650 and −1.214 e Å^{-3}.

4.3. Ligand precursor synthesis

4.3.1. N,N′-Diacetyl-2-methoxy-1,4-phenylenediamine (2)

2-Methoxyphenylene-1,4-diamine (25 g) was suspended in pyridine (75 ml) and stirred vigorously. Acetic anhydride (100 ml) was added slowly. No attempt was made to control the temperature of the strongly exothermic reaction. The solution was cooled, poured onto ice, and the crude product collected by filtration. The crude product was purified by recrystallisation from ethanol. A second crop of product was collected by concentration of the combined filtrates followed by recrystallisation from ethanol. Yield (18.52 g, 46%). Found: C, 59.34; H, 6.45; N, 12.76%. $C_{11}H_{14}N_2O_3$ requires: C, 59.45; H, 6.35; N, 12.60. δ_H (200 MHz, $CDCl_3$) 8.24 (1H, d, $J^d = 8.5$ Hz), 7.65 (2H, d, $J^d = 2.0$ Hz), 7.20 (1H, br s) 6.63 (1H, dd, $J^{d1} = 8.5$ Hz, $J^{d2} = 2.0$ Hz), 3.80 (3H, s), 2.19 (3H, s), 2.17 (3H, s). δ_C (50 MHz, $CDCl_3$) 143.8, 137.5, 136.9, 119.8, 111.7, 111.3, 103.1, 103.1, 55.9, 24.9, 24.7.

4.3.2. 5-Methoxy-4,7-phenanthroline (3)

N,*N*′-Diacetyl-2-methoxy-1,4-phenylenediamine (5 g), glacial acetic acid (100 ml) and conc. H_2SO_4 (30 ml) were added to a suspension of $Fe_2(SO_4)_3 \cdot xH_2O$ (45 g) in conc. H_2SO_4 (37 ml). Glycerol (10 g) was added and the reaction heated to 120 °C for 2 h in an open round bottomed flask, before being raised to 140 °C for a further 2 h. On cooling, the reaction mixture was carefully poured onto ice and the pH adjusted to ≈10 with 10 M KOH. The resulting black/brown solid was removed by filtration with the aid of celite and retained. The filtrate was extracted 3 times with $CHCl_3$ (200 ml) and discarded. The solid/celite mixture was boiled three times with $CHCl_3$ (500 ml), each time being filtered through additional celite. The combined $CHCl_3$ extracts were concentrated and purified by column chromatography on neutral alumina ($CHCl_3$ eluant). Yield (4.40 g, 93%). Found: C, 74.47; H, 4.96; N, 13.05%. $C_{13}H_{10}N_2O$ requires: C, 74.27; H, 4.79; N, 13.32. δ_H (200 MHz, $CDCl_3$) 8.95 (1H, d, $J^d = 3.0$ Hz), 8.79 (1H, d, $J^d = 4.0$ Hz), 8.69 (1H, d, $J^d = 7.5$ Hz), 8.59 (1H, d, $J^d = 8.5$ Hz), 7.56 (1H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.0$ Hz), 7.38 (1H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.5$ Hz), 7.33 (1H, s), 4.15 (3H, s). δ_C (50 MHz, $CDCl_3$) 155.8, 149.6, 149.1, 147.9, 140.6, 130.5, 130.1, 124.7, 122.1, 119.2, 119.8, 106.2, 55.6.

4.3.3. 5,6-Dimethoxy-5,6-dihydro-[4,7]phenanthroline-5,6-diol (4)

To a solution of 5-methoxy-4,7-phenanthroline (4.70 g) in conc. H_2SO_4 (25.0 ml) at −10 °C (ice/NaCl bath) was slowly added fuming nitric acid (15.0 ml, $d = 1.51$). The mixture was then heated to 120 °C for 2 h in a dry reflux apparatus. On cooling, the reaction mixture was poured carefully onto ice and was adjusted to pH 7 with 10 M NaOH, care being taken to not let the solution change from yellow to blue/black (at pH >7). After standing for 2 h at 4 °C, the crude precipitate was collected by filtration. The pure product was collected by filtration following recrystallisation from methanol. Yield (2.48 g, 40%). Found: C, 61.09; H, 5.19; N, 10.21%. $C_{14}H_{14}N_2O_4$ requires: C, 61.31; H, 5.15; N, 10.21. δ_H (200 MHz, $CDCl_3$) 8.54 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 5.0$ Hz), 8.08 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 8.0$ Hz), 7.45 (2H, dd, $J^{d1} = 5.0$ Hz, $J^{d2} = 8.0$ Hz), 6.09 (2H, s) 3.04 (6H, s). δ_C (50 MHz, $CDCl_3$) 153.5, 147.3, 131.9, 125.9, 124.6, 95.5, 50.0.

4.4. Synthesis of ligands 21–26

5,6-Dimethoxy-5,6-dihydro-[4,7]phenanthroline-5,6-diol (300 mg, 1.0 mmol) and an equimolar amount of the appropriate diamine were gently heated in 50 ml of methanol until all of the solids dissolved. Two drops of 2 M HCl were added and the mixture rapidly heated to reflux. After 30 min, 50 ml of water was added to the solution and the crude products were collected by filtration and washed with ice cold methanol and copious amounts of ether. The individual products were purified by chromatography on a short (3 cm) plug of silica gel with $CHCl_3$ as eluent. The products crystallised on evaporation of the $CHCl_3$ solution.

4.4.1. [2,3-a:3′,2′-c]dipyridophenazine (21)

Yield (271 mg, 90%). Found: C, 76.86; H, 3.81; N, 19.69%. $C_{18}H_{10}N_4$ requires: C, 76.58; H, 3.57; N, 19.85. δ_H (200 MHz, $CDCl_3$) 9.30 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 4.5$ Hz), 8.91 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 8.5$ Hz), 8.69 (2H, dd, $J^{d1} = 6$ Hz, $J^{d2} = 3$ Hz), 8.00 (2H, AA′BB′, $J = 3.5$ Hz), 7.82 (2H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.5$ Hz). δ_C (50 MHz, $CDCl_3$) 151.5, 146.1, 143.4, 143.2, 131.5, 131.4, 127.9, 126.6, 124.8.

4.4.2. [2,3-a:3′,2′-c]dipyrido-6, 7-dimethylphenazine (22)

Yield (327 mg, 74%). Found: C, 69.23; H, 5.03; N, 16.14%. $C_{20}H_{14}N_4 \cdot 2H_2O$ requires: C, 69.34; H, 5.24; N, 16.18. δ_H (200 MHz, $CDCl_3$) 9.27 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 4.5$ Hz), 8.88 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 8.5$ Hz), 8.40 (2H, s), 7.78 (2H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.0$ Hz), 2.62 (6H, s). δ_C (50 MHz, $CDCl_3$) 151.3, 146.2, 142.7, 142.5, 142.4, 131.3, 129.0, 125.1, 124.4, 20.9.

*4.4.3. [2,3-a:3′,2′-c]dipyrido-6,7- dichlorophenazine (**23**)*

Yield (466 mg, 93%). Found: C, 55.68; H, 2.75; N, 14.55%. $C_{18}H_8N_4Cl_2 \cdot 2H_2O$ requires: C, 55.83; H, 3.12; N, 14.47%. δ_H (200 MHz, $CDCl_3$) 9.28 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 4.5$ Hz), 8.90 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 8.5$ Hz), 8.79 (2H, s), 7.84 (2H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.5$ Hz). δ_C (50 MHz, $CDCl_3$) 151.6, 145.5, 143.9, 141.8, 136.5, 131.5, 130.7, 126.9, 125.3.

*4.4.4. [2,3-a:3′,2′-c]dipyrido[1,2-e]benzophenazine (**24**)*

Yield (394 mg, 83%). Found: C, 74.07; H, 3.88; N, 15.64%. $C_{22}H_{12}N_4 \cdot 1.5H_2O$ requires: C, 74.45; H, 4.12; N, 15.80. δ_H (200 MHz, $CDCl_3$) 9.30 (2H, s), 9.29 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 4.5$ Hz), 8.86 (2H, dd, $J^{d1} = 1.5$ Hz, $J^{d2} = 8.0$ Hz), 8.24 (2H, AA′BB′, $J = 3.5$ Hz), 7.81 (2H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 8.5$ Hz), 7.64 (2H, AA′BB′, $J = 3.0$ Hz). δ_C (50 MHz, $CDCl_3$) 151.5, 150.4, 143.4, 142.7, 139.4, 134.9, 131.4, 129.0, 128.9, 127.4, 125.0.

*4.4.5. [2,3-a:3′,2′-c:2″, 3″-e]tripyridoquinoxaline (**25**)*

Yield (252 mg, 86%). Found: C, 72.21; H, 3.35; N, 24.92%. $C_{17}H_9N_4$ requires: C, 72.08; H, 3.20; N, 24.78. δ_H (200 MHz, $CDCl_3$) 9.47 (1H, dd, $J^{d1} = 2.0$ Hz, $J^{d2} = 4.0$ Hz), 9.31 (2H, m), 9.01 (1H, dd, $J^{d1} = 2.0$ Hz, $J^{d2} = 8.5$ Hz), 8.92 (2H, m), 7.92 (1H, dd, $J^{d1} = 4.0$ Hz, $J^{d2} = 8.5$ Hz), 7.84 (2H, m). δ_C (50 MHz, $CDCl_3$) 156.6, 153.4, 151.5, 151.4, 145.4, 145.3, 143.9, 140.3, 139.0, 131.5, 131.2, 128.5, 126.9 (2C), 126.3, 125.3, 125.2.

*4.4.6. [2,3-a:3′,2′-c]dipyrido-5-methylphenazine (**26**)*

Yield (327 mg, 77%). δ_H (200 MHz, $CDCl_3$) 9.25 (2H, m), 8.86 (2H, d, $J^d = 7.0$ Hz), 8.49 (1H, d, $J^d = 8.0$ Hz), 7.9-7.7 (4H, m), 3.17 (3H, s). δ_C (50 MHz, $CDCl_3$) 151.3, 151.2, 146.2, 146.0, 143.4, 142.6 (2C), 141.9, 138.6, 131.3 (2C), 131.1, 128.3, 128.1, 126.4, 126.3, 124.5, 124.4, 17.8.

4.5. Synthesis of Os(II) complexes

$[Os(bpy)_2Cl_2]$ (100 mg) or $[Os(phen)_2Cl_2]$ (110 mg) and a 2-fold excess of the appropriate ligand were gently heated in ethylene glycol (50 ml) until completely dissolved. The solution was then heated to reflux for 2 h. On cooling, dichloromethane (100 ml) and water (200 ml) were added. The organic layer was separated and discarded and the aqueous layer again extracted with dichloromethane (100 ml). The water layer was diluted and loaded on to a Sephadex SP-C25 column (10 cm × 2 cm diameter) and washed well with water and 0.05 M sodium *p*-tolylsulfonate to remove uncharged species. The mononuclear complex was eluted with 0.1–0.2 M sodium *p*-tolylsulfonate and was separated from the eluent by precipitation with solid NH_4PF_6 (1 g) followed by extraction with 5 × 100 ml of dichloromethane. The resulting intensely coloured organic solution was reduced to dryness (rotavap), dissolved in a minimum volume of acetonitrile and reprecipitated by addition to an aqueous solution of NH_4PF_6. The solid was collected by filtration, dissolved in acetonitrile and reprecipitated by addition to ether.

*4.5.1. [Os(bpy)$_2$(**21**)](PF$_6$)$_2$*

Yield (140 mg, 70%) Found: C, 41.10; H, 2.83; N, 9.89%. $C_{38}H_{26}N_8OsP_2F_{12} \cdot 2H_2O$ requires: C, 41.09; H, 2.72; N, 10.09. δ_H (200 MHz, d_3-MeCN) 9.14 (2H, m), 8.94 (1H, dd, $J^{d1} = 8.5$ Hz, $J^{d2} = 1.5$ Hz), 8.64 (1H, d, $J^d = 8.0$ Hz), 8.57 (1H, d, $J^d = 8.0$ Hz), 8.36 (1H, dd, $J^{d1} = 8.5$ Hz, $J^{d2} = 1.0$ Hz), 8.00 (4H, m), 7.88 (2H, m), 7.77 (5H, m), 7.49 (6H, m), 7.09 (3H, m). *m/z* 931 ({M-PF_6}$^+$).

*4.5.2. [Os(bpy)$_2$(**22**)](PF$_6$)$_2$*

Yield (90 mg, 45%). Yield (125 mg, 66%). Found: C, 42.59; H, 2.66; N, 10.52%. $C_{38}H_{28}N_8OsP_2F_{12}$ requires: C, 42.39; H, 2.62; N, 10.40. δ_H (200 MHz, d_3-MeCN) 8.69 (3H, m), 8.26 (2H, m), 8.19 (1H, dd, $J^{d1} = 7.5$ Hz, $J^{d2} = 1.5$ Hz), 8.08 (2H, m), 7.90 (2H, d, $J^{d} = 6.5$ Hz), 7.81 (5H, m), 7.66 (1H, ddd, $J^{d1} = 5.0$ Hz, $J^{d2} = 4.5$ Hz, $J^{d3} = 1.5$ Hz), 7.58 (2H, m), 7.48 (4H, m), 7.39 (4H, m), 7.26 (1H, ddd, $J^{d1} = 6.5$ Hz, $J^{d2} = 6.0$ Hz, $J^{d3} = 1.5$ Hz), 7.13 (1H, ddd, $J^{d1} = 7.5$ Hz, $J^{d2} = 6.0$ Hz, $J^{d3} = 1.5$ Hz).

4.5.9. [Os(bpy)$_2$(**12**)](PF$_6$)$_2$

Yield (156 mg, 81%). Found: C, 42.36; H, 3.22; N, 9.92%. $C_{40}H_{32}N_8OsP_2F_{12} \cdot 2H_2O$ requires: C, 42.11; H, 3.18; N, 9.82. δ_H (200 MHz, d_3-MeCN) 8.67 (2H, m), 8.33 (1H, d, $J^{d} = 8.5$ Hz), 8.23 (1H, d, $J^{d} = 8.0$ Hz), 8.17 (2H, m), 8.00 (3H, m), 7.85 (5H, m), 7.61 (2H, m), 7.49 (3H, m), 7.4-7.1 (7H, m), 2.42 (3H, s), 2.01 (3H, s).

4.5.10. [Os(bpy)$_2$(**13**)](PF$_6$)$_2$

Yield (118 mg, 59%). Found: C, 39.00; H, 2.24; N, 9.53%. $C_{38}H_{26}N_8OsP_2F_{12}Cl_2 \cdot H_2O$ requires: C, 39.22; H, 2.43; N, 9.62%. δ_H (200 MHz, d_3-MeCN) 8.70 (3H, m), 8.38 (1H, d, $J^{d} = 7.5$ Hz), 8.30 (1H, s), 8.28 (1H, d, $J^{d} = 9.0$ Hz), 8.19 (2H, m), 8.03 (2H, m), 7.91 (4H, m), 7.68 (2H, m), 7.53 (5H, m), 7.49 (1H, s), 7.37 (2H, m), 7.26 (1H, ddd, $J^{d1} = 7.5$ Hz, $J^{d2} = 6.0$ Hz, $J^{d3} = 1.5$ Hz), 7.15 (1H, ddd, $J^{d1} = 7.5$ Hz, $J^{d2} = 6.0$ Hz, $J^{d3} = 1.5$ Hz).

4.5.11. [Os(bpy)$_2$(**14**)](PF$_6$)$_2$

Yield (100 mg, 50%). Found: C, 43.62; H, 3.06; N, 9.71%. $C_{42}H_{30}N_8OsP_2F_{12} \cdot 2H_2O$ requires: C, 43.37; H, 2.96; N, 9.62. δ_H (200 MHz, d_3-MeCN) 8.72 (4H, m), 8.22 (2H, m), 8.15 (2H, m), 8.00 (4H, m), 7.91 (1H, s), 7.84 (2H, m), 7.75 (1H, dd, $J^{d1} = 6.0$ Hz, $J^{d2} = 1.5$ Hz), 7.69-7.35 (12H, m), 7.18 (1H, ddd, $J^{d1} = 9.5$ Hz, $J^{d2} = 6.0$ Hz, $J^{d3} = 1.5$ Hz), 7.14 (1H, ddd, $J^{d1} = 9.5$ Hz, $J^{d2} = 6.5$ Hz, $J^{d3} = 1.5$ Hz).

4.5.12. [Os(bpy)$_2$(**16**)](PF$_6$)$_2$

Yield (185 mg, 93%). Found: C, 42.05; H, 3.11; N, 10.23%. $C_{38}H_{30}N_8OsP_2F_{12}$ requires: C, 42.30; H, 2.80; N, 10.39. δ_H (200 MHz, d_3-MeCN) 9.26 (1H, dd, $J^{d1} = 6.5$ Hz, $J^{d2} = 1.0$ Hz), 9.16 (1H, d, $J^{d} = 4.5$ Hz), 8.94 (1H, dd, $J^{d1} = 8.0$ Hz, $J^{d2} = 1.0$ Hz), 8.69 (2H, m), 8.63 (1H, d, $J^{d} = 7.0$ Hz), 8.57 (1H, d, $J^{d} = 8.0$ Hz), 8.36 (1H, dd, $J^{d1} = 8.5$ Hz, $J^{d2} = 1.0$ Hz), 8.11 (6H, m), 7.94 (4H, m), 7.49 (7H, m), 7.28 (2H, m), 2.30 (3H, s).

4.5.13. [Os(phen)$_2$(**11**)](PF$_6$)$_2$

Yield (130 mg, 65%). Found: C, 43.97; H, 2.27; N, 10.13%. $C_{42}H_{28}N_8OsP_2F_{12} \cdot H_2O$ requires: C, 44.14; H, 2.64; N, 9.80. δ_H (200 MHz, d_3-MeCN) 9.19 (2H, m), 8.81 (1H, dd, $J^{d1} = 8.0$ Hz, $J^{d2} = 1.0$ Hz), 8.75 (1H, d, $J^{d} = 7.0$ Hz), 8.51(2H, m), 8.05 (3H, m), 7.98 (3H, m), 7.76 (3H, m), 7.64 (5H, m), 7.49 (5H, m), 7.09 (2H, m), 6.97 (1H, dd, $J^{d1} = 7.0$ Hz, $J^{d2} = 6.5$ Hz).

4.6. Synthesis of Re(I) complexes

[$Re(CO)_5Cl$] (149 mg) and a 1.5-fold excess of the appropriate ligand were refluxed in methanol (50 ml) under an argon atmosphere for 2.5 h, to give a dark red solution. This was left to cool and the resulting precipitate was collected by filtration. The crude solid was washed with methanol, diethyl ether and finally pentane, then dissolved in dichloromethane (~1000 ml) and any remaining solid removed by filtration. The dilute solution was loaded onto a partially deactivated (10% v/v H_2O) silica gel column (25 cm × 5 cm diameter, 200–400 mesh, 0.040–0.063 mm) and a 4:1 ratio of dichloromethane:ethyl acetate eluted the purple binuclear complex. The desired mononuclear complex eluted as an orange band using a 1:4 dichloromethane:ethyl acetate mixture. Removal of solvent (rotavap) afforded the pure complex.

4.6.1. fac-[Re(CO)$_3$(**21**)Cl]

Yield (126 mg, 52%). Found: C, 42.71; H, 1.41; N, 9.24%. $C_{21}H_{10}N_4O_3ClRe$ requires: C, 42.89; H, 1.71; N,

9.53. δ_H (300 MHz, $CDCl_3$) 9.56 (1H, dd, $J^{d1} = 4.8$ Hz, $J^{d2} = 0.9$ Hz), 9.43(1H, dd, $J^{d1} = 4.2$ Hz, $J^{d2} = 1.5$ Hz), 9.14 (two overlapping doublets, 2H, $J = 8.1$ Hz), 8.97 (1H, dd, $J^{d1} = 8.1$ Hz, $J^{d2} = 1.5$ Hz), 8.84 (1H, dd, $J^{d1} = 8.7$ Hz, $J^{d2} = 1.2$ Hz), 8.30-8.19 (2H, m), 8.04 (1H, dd, $J^{d1} = 7.8$ Hz, $J^{d2} = 5.4$ Hz), 7.96 (1H, dd, $J^{d1} = 7.8$ Hz, $J^{d2} = 4.5$ Hz). *m/z* 589 ($\{MH\}^+$), 553 ($\{MH\text{-}HCl\}^+$).

4.6.2. *fac*-[Re(CO)$_3$(**22**)Cl]

Yield (151 mg, 60%). Found: C, 44.93; H, 2.25; N, 9.11%. $C_{23}H_{14}N_4O_3ClRe$ requires: C, 44.84; H, 2.29; N, 9.09. δ_H (300 MHz, $CDCl_3$) 9.54 (1H, dd, $J^{d1} = 5.3$ Hz, $J^{d2} = 1.4$ Hz), 9.41 (1H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 1.5$ Hz), 9.12 (dd, 1H, $J^{d1} = 8.9$ Hz, $J^{d2} = 1.4$ Hz), 8.95 (1H, dd, $J^{d1} = 8.7$ Hz, $J^{d2} = 1.5$ Hz), 8.92 (1H, s), 8.57 (1H, s), 8.07 (1H, dd, $J^{d1} = 8.4$ Hz, $J^{d2} = 5.1$ Hz), 7.92 (1H, dd, $J^{d1} = 8.3$ Hz, $J^{d2} = 4.4$ Hz), 2.77 (3H, s), 2.70 (3H, s). *m/z* 617 ($\{MH\}^+$), 589 ($\{MH\text{-}CO\}^+$), 581 ($\{MH\text{-}HCl\}^+$), 560 ($\{MH\text{-}HC_2O_2\}^+$).

4.6.3. *fac*-[Re(CO)$_3$(**23**)Cl]·0.5CH_2Cl_2

Yield (202 mg, 70%). Found: C, 36.75; H, 1.27; N, 7.91%. $C_{21.5}H_9N_4O_3Cl_4Re$ requires: C, 36.87; H, 1.30; N, 8.00. δ_H (300 MHz, $CDCl_3$) 9.55 (1H, dd, $J^{d1} = 5.1$ Hz, $J^{d2} = 1.2$ Hz), 9.42 (1H, dd, $J^{d1} = 4.5$ Hz, $J^{d2} = 1.5$ Hz), 9.29 (s, 1H), 9.15 (1H, dd, $J^{d1} = 8.4$ Hz, $J^{d2} = 1.2$ Hz), 8.97 (1H, dd, $J^{d1} = 8.3$ Hz, $J^{d2} = 1.4$ Hz), 8.97 (1H, s), 8.07 (1H, dd, $J^{d1} = 8.1$ Hz, $J^{d2} = 5.4$ Hz), 7.98 (1H, dd, $J^{d1} = 8.3$ Hz, $J^{d2} = 4.4$ Hz). *m/z* 657 ($\{MH\}^+$), 621 ($\{MH\text{-}HCl\}^+$).

5. Supplementary material

$C_{21}H_{10}ClN_4O_3Re$, $M = 587.98$, monoclinic, $a = 15.3346(2)$, $b = 9.42610(10)$, $c = 13.02640(10)$ Å, $\beta = 92.7560(10)°$, $U = 1880.73(3)$ Å^3, $T = 203(2)$ K, space group $P2_1/c$ (no. 14), $Z = 4$, μ(Mo Kα) = 6.636 mm^{-1}, 11 223 reflections measured, 4151 unique ($R_{int} = 0.0292$) which were used in all calculations. The final $wR(F^2)$ was 0.0782 (all data).

Crystallographic data for *fac*-[Re(CO)$_3$(**21**)Cl] (CCDC 226823) have been deposited with the Cambridge Crystallographic Data Centre. A copy of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-3360333; e-mail: deposit@ccdc.cam.ac.uk; www: http://www.ccdc.cam.ac.uk).

Abstract

$[(\eta^5\text{-}C_5H_5)Fe(CO)_2](Fp)$-complexes of the parabanic acid mono- and dianion have been synthesised in a photochemical reaction of FpI with parabanic acid and diisopropylamine in benzene. The former contains a reactive *N(3)*–H bond and can be readily thallated with TlOEt. Reaction of the thallated complex with Ph_3PAuCl, benzyl chloride and ethyl bromoacetate in DMF gave *N(3)*-aurated, *N(3)*-benzyl and *N(3)*-carboethoxymethyl complex, respectively. The structures of these complexes were confirmed by X-ray diffraction. The ester function in the *N(3)*-carboethoxymethyl complex was hydrolysed to afford air-stable, water-soluble acid, a potential metallocarbonyl labelling reagents for proteins.

Keywords: Parabanic acid; Iron; Cyclopentadienyl; Carbonyl; Thallium; Gold (I) complex; Alkylation

1. Introduction

The $[(\eta^5\text{-}C_5H_5)Fe(CO)_2](Fp)$-moiety forms neutral and cationic complexes with a variety of nitrogen ligands [1–5]. In this laboratory, we have elaborated a way to Fp-complexes of anions of N–H acids by the photochemical substitution of iodide in FpI (Eq. (1)), where X and/or Y are electron-withdrawing groups and dipa stands for diisopropylamine [6–14]:

$$\mathrm{FpI} + \mathrm{HN(X)(Y)} + \mathrm{dipa} \xrightarrow{h\nu} \mathrm{FpN(X)(Y)} + \mathrm{dipaH^+I^-} \quad (1)$$

We have synthesised using this approach Fp-complexes of anions of a variety of NH acids, e.g., pyrroles, indoles, cyclic imides, sulfonamides, sulfamates, hydantoins and barbiturates. Some of these compounds proved useful metallocarbonyl labelling reagents of biomolecules [12–15].

In this paper, we report on synthesis of the Fp-complexes derived from parabanic acid **1** (Scheme 1). It is a dibasic acid forming mono- and bis-anion. Therefore, one can expect formation of its mono- and bis-Fp complexes. The former will contain a reactive imide N(3)–H bond, providing a possibility of further fuctionalisation. We thought that it would be of interest to check if it is possible to alkylate or metallate N(3) without affecting rather labile Fp group because this would open a way to substituted or binuclear complexes.

2. Results and discussion

All reactions described in this work are presented in Schemes 1 and 2.

Photolysis of FpI with **1** in benzene containing diisopropylamine yielded a mixture of mono-Fp and bis-Fp complexes (**2** and **3**, respectively).

Previous experiments have shown that the best solvent for photochemical reactions of FpI with NH-acids and diisopropylamine is benzene. Unfortunately, **1** is

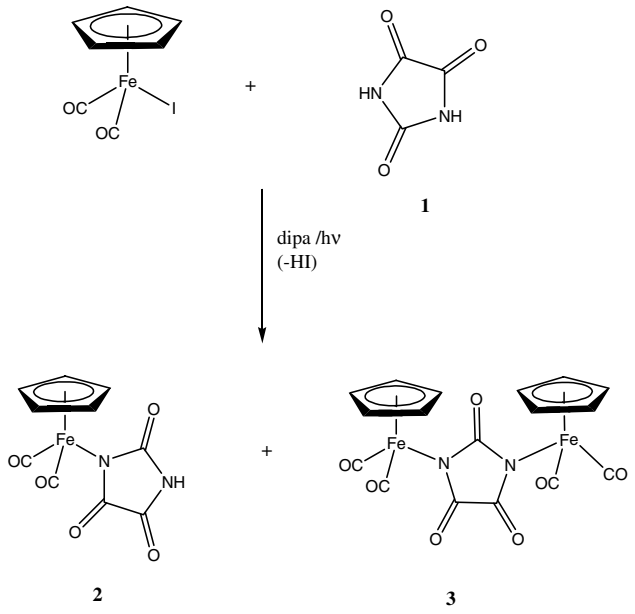
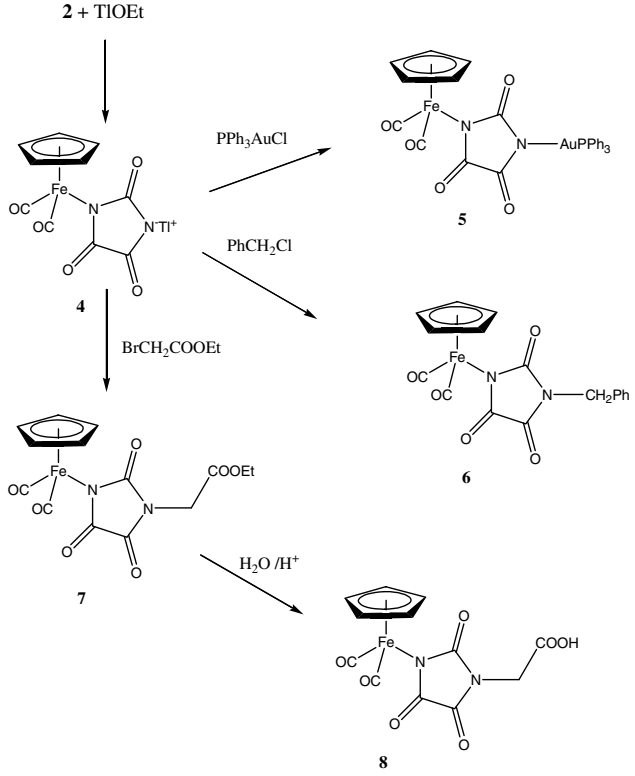


Scheme 1.



Scheme 2.

only scarcely soluble in this solvent and we had to photolyse solutions of FpI in benzene containing diisopropylamine and suspended **1**. However, hopefully, it has been found that a small solubility of **1** in benzene is sufficient for a substitution of iodide in FpI by the anion of **1** to take place quite efficiently. Regardless of the ratio FpI to **1**, both mono-Fp (**2**) and bis-Fp (**3**) products were formed. They were separated by column chromatography and their structure confirmed by spectral and analytical data as well as by X-ray diffraction (vide infra). At the molar ratio of FpI to **1** equals 0.25, the isolated yields of **2** and **3** were 40% and 17%, respectively, whereas at the FpI to **1** ratio equals 2.3, these yields were 5% and 27%, respectively. The bis-Fp product **3** was therefore formed even when an excess of **1** was used. This may be explained by the fact that **2** is much better soluble in benzene than **1** and therefore efficiently competes with this compound in the photoreaction with FpI. Another interesting fact is also worth noting. It has been found that irradiation with visible light of **3** in the presence of **1** and diisopropylamine leads to the formation of **2** (via Fp^+ dissociation?).

Compound **2** contains an imide N–H bond, offering a possibility of N-alkylation or N-metallation of the heterocyclic ligand. However, since it has been found that Fp-complexes with *N*-imidato ligands decompose in alkaline media [15] we wanted to avoid generation of alkaline metal *N*-anions. We have decided to try to transform **2** into thallium(I) salt **4** (Scheme 2), which was expected to react under mild conditions with reactive organic halides or compounds having metal–halogen bonds with formation of nitrogen–carbon or nitrogen–metal bonds, respectively.

In fact, it is known that pyrrylthallium(I) reacts with alkyl halides to afford 1-alkylpyrroles [16], and reaction of succinimidylthallium(I) with $Mn(CO)_5Br$ leads to $Mn(CO)_5$ (η^1-*N*-succinimidato) [17].

The treatment of **2** with thallium(I) ethoxide in ethanol at 0–5 °C brings about precipitation of a rather unstable pale-yellow solid, for which we suggest the structure **4** (Scheme 2). This material has been filtered off, dried and used without additional purification or analyses in further syntheses. It has been found that reaction of **4** Ph_3PAuCl in DMF at r.t. leads to the heterobinuclear complex **5** isolated in 50% yield. The coordinated triphenylphosphane ligand in this compound gives the ^{31}P NMR signal at 31.7 ppm, which is close to the value reported for the PPh_3-Au bound to the *N*-anion of hydantoin, 32.7 ppm [18].

Reaction of **4** with benzyl chloride and ethyl bromoacetate proceeded smoothly in DMF at r.t. to afford the *N*-alkylated complexes **6** and **7** in 53% and 88% yield, respectively. The structures of these compounds have been confirmed by spectral and analytical data and for **5** and **6** also by X-ray diffraction (vide infra). A careful acid hydrolysis of **7** in 0.1 M aqueous HCl at 50 °C gave acid **8** in 55% yield. This complex is air-stable, water-soluble, yellow crystalline solid. It can be regarded as a metallocarbonyl derivative of the simplest aminoacid, glycine. Its stability and solubility in water make it interesting for bioorganometallic applications (e.g., as an IR-detectable marker for biomolecules).

The aforementioned reactions demonstrate that chemical modification of the parabanic acid ligand in **2** using its Tl(I) salt **4** is feasible and can proceed with formation of either N–C or N–metal bond. This opens a new entry to complexes of *N*-substituted parabanic acids and to bimetallic complexes.

The infrared data for synthesised compounds provide an evidence that the electronic properties of the Fp-moiety bound to N(1) are influenced by the substitution at N(3) (Table 1).

It is seen that replacement of the N–H nitrogen in **2** by a metal centre results in diminution of the $\nu_{(C\equiv O)}$ frequencies of the Fp moieties. This means that there is stronger backbonding from nitrogen to iron caused by the second electron-donating metal centre. On the other hand benzylation of N(3) practically does not influence these frequencies.

3. X-ray crystal structures of 2, 3, 5, 6

The structures of compounds **2**, **3**, **5**, **6** were determined by single-crystal X-ray diffraction (Table 2 and Figs. 1–4).

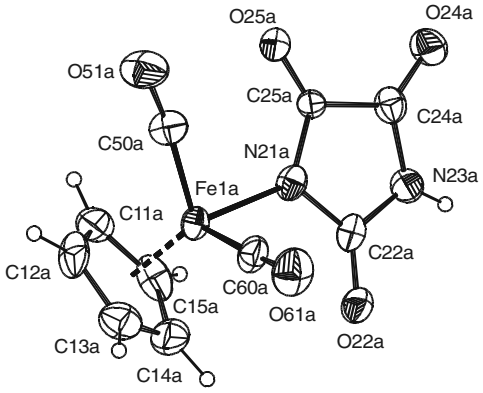

Fig. 1. Molecular drawing of compound **2** (molecule **a**). Displacement ellipsoids are shown at 30% probability level. The Fe–N distances: 1.955 (6) Å (**2a**) and 1.976 (6) Å (**2b**).

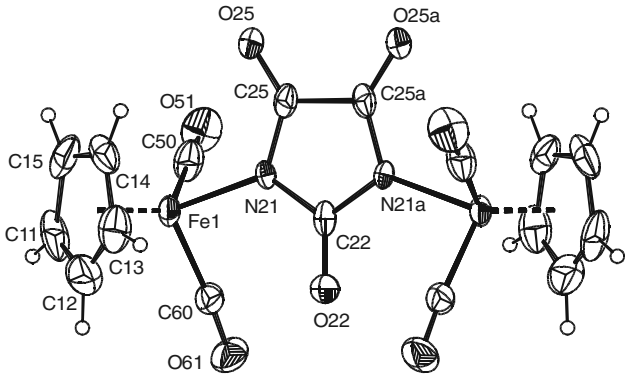

Fig. 2. Molecular drawing of compound **3**. Displacement ellipsoids are shown at 30% probability level. The Fe–N distance 1.959 (6) Å.

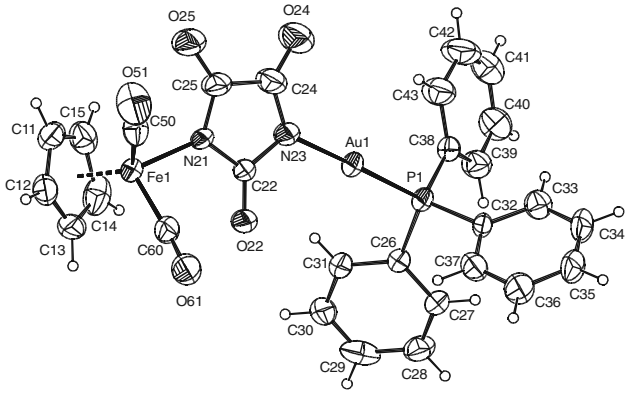

Fig. 3. Molecular drawing of compound **5**. Displacement ellipsoids are shown at 30% probability level. The Fe–N distance 1.961 (6) Å.

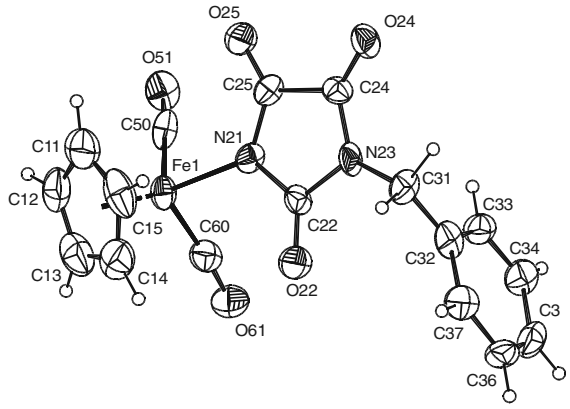

Fig. 4. Molecular drawing of compound **6**. Displacement ellipsoids are shown at 30% probability level. The Fe–N distance 1.958 (6) Å.

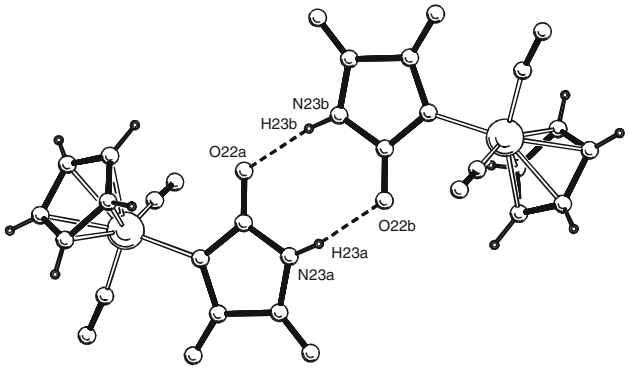

Fig. 5. Scheme of hydrogen bonding in crystal structure of **2**.

Table 3
Geometry of hydrogen bonding in dimers of **2**

	D–H (Å)	H···A (Å)	D···A (Å)	D–H···A (°)
N23a–H23a···O22b[a]	0.86	1.984	2.833(4)	169
N23b–H23b···O22a[b]	0.86	1.987	2.840(4)	171

[a] symmetry codes: $x-1, y, z$.
[b] symmetry codes: $x+1, y, z$.

They confirm in all the cases the η^1-*N*-coordination. In the solid state compound, **2** forms dimers through intermolecular N–H···O bonds (Fig. 5 and Table 3).

The Fe–N bonding distances in the investigated complexes are the same within experimental error (~1.962(8) Å) and similar to that found in 1-Fp-5,5-diphenylhydantoin, 1.949(3) Å [12]. Therefore, the length of this bond does not seem to be sensitive to electronic or steric factors in the heterocyclic ligand.

4. Conclusion

We have synthesised Fp-complexes of parabanic acid mono- and dianion. The mono-Fp complex has proven

useful staring material in syntheses of N(3)-substituted and metallated complexes.

5. Experimental

All reactions were carried our under argon. Benzene was distilled over sodium-benzophenone. Other solvents and reagents were reagent grade and were used without prior purification. Chromatographic separations were carried out using silica gel 60 (Merck, 230–400 mesh ASTM). NMR spectra were recorded in $CDCl_3$ on a Varian Gemini 200BB (200 MHz for ^1H) spectrometer. IR spectra were recorded in $CHCl_3$ on a Biorad 175C apparatus.

5.1. Synthesis of 2 and 3

A magnetically stirred solution of FpI (151 mg, 0.5 mmol) in benzene (15 ml) and diisopropylamine (1 ml), containing suspended parabanic acid (112 mg, 2 mmol) was photolysed (4×150 W tungsten lamp and external cooling with ice-water) for 2 h. The solid residue was filtered off and washed with benzene. The solvent was evaporated from the filtrate and the residue dissolved in chloroform–methanol (25:1) and chromatographed using the same solvent mixture as eluent. Two yellow fractions were collected: the first one containing **3** and the second containing **2**. Analytical samples were prepared by crystallisation from chloroform–hexane. Yields: **3**: 20 mg (17%); **2**: 56 mg (40%).

3. ^1H NMR (δ, ppm): 5.08 (s, Cp) IR (cm^{-1}): 2056, 2011, 1651, 1633. Elemental *Anal.* Calc. for $C_{17}H_{10}O_7FeN_2$: C, 43.82; H, 2.16; N, 6.01. Found: C, 43.94; H, 2.30; N, 6.07%.

2. ^1H NMR (δ, ppm): 7.97 (bs, 1H, NH), 5.15 (s, 5H,Cp). IR (cm^{-1}): 2062, 2015, 1701, 1682. Elemental *Anal*. Calc. for $C_{10}H_6O_5FeN_2$: C, 41.42; H, 2.09; N, 9.66. Found: C, 41.80; H, 2.14; N, 9.60%.

5.2. Synthesis of 4

Thallium(I) ethoxide (45 μl, 0.63 mmol) was added to a stirred solution of **2** (98 mg, 0.33 mmol) in ethanol (12 ml) at 0–5 °C. After 30 min strirring at this temperature the pale yellow solid was filtered off, washed with ethanol and dried under vacuum. Yield: 170 mg (100%).

5.3. Synthesis of 5

$(PPh_3)AuCl$ (198 mg, 0.40 mmol) was added to the solution of **4** (190 mg, 0.38 mmol) in DMF (15 ml) at r.t. After 1.5 stirring the colorless precipitate of TlCl was filtered off and the solvent evaporated under vacuum. Column chromatography (eluent-chloroform) afforded **5** as a yellow crystalline solid. Yield: 130 mg (48%).

^1H NMR (δ, ppm): 7.5 (m, 15H, Ph), 5.11 (s, 5H, Cp). ^{31}P NMR (δ, ppm): 31.7. IR (cm^{-1}): 2056, 2009, 1657, 1635. Elemental *Anal.* Calc. for $C_{28}H_{22}AuFeN_2PO_6$ (monohydrate): C, 43.89; H, 2.89; N, 3.66. Found: C, 43.60; H, 2.66; N, 3.59%.

5.4. Synthesis of 6

Benzyl chloride (43 μl, 0.37 mmol) was added to the solution of **4** (77 mg, 0.15 mmol) in DMF (10 ml) at r.t. After 30 min stirring the colourless precipitate of TlCl was filtered off and the solvent evaporated under vacuum. Column chromatography (eluent-chloroform) afforded **6** as a yellow crystalline solid. Analytical sample was recrystallized from chloroform–hexane. Yield: 30 mg (53%).

^1H NMR (δ, ppm): 7.26–7.36 (m, 5H, Ph), 5.11 (s, 5H, Cp), 4.69 (s, 2H, CH_2). IR ($CHCl_3$, cm^{-1}): 2061, 2014, 1658, 1637. Elemental *Anal.* Calc. for $C_{17}H_{12}FeN_2O_5$: C, 53.71; H, 3.18; N, 7.37. Found: C, 53.40; H, 3.00; N, 7.34%.

5.5. Synthesis of 7

Ethyl bromoacetate (113 μl, 1 mmol) was added to the solution of **4** (254 mg, 0.5 mmol) in DMF (15 ml) at r.t. After 30 min stirring the colourless precipitate of TlBr was filtered off and the solvent evaporated under vacuum. Column chromatography (eluent-chloroform) afforded **7** as an yellow oil. Yield: 165 mg (88%).

^1H NMR (δ, ppm): 5.21 (s, 5H, Cp), 4.26 (s, 2H, CH_2), 4.18 (t, $J = 8$ Hz, 2H, CH_2 in Et), 1.25 (t, $J = 8$ Hz, 3H, CH_3 in Et). IR (cm^{-1}): 2062, 2015, 1749, 1657, 1637. Elemental *Anal.* Calc. for $C_{14}H_{12}FeN_2O_7$: C, 44.71; H, 3.22; N, 7.45. Found: C, 44.77; H, 3.31; N, 7.40%.

5.6. Synthesis of 8

Compound **7** (169 mg, 0.44 mmol) was dissolved in 50 ml of 0.1 M aq. HCl and heated to 50 °C for 5 h. Extraction with CH_2Cl_2 and chromatography (SiO_2, $CHCl_3$–methanol 10:3 v/v) afforded **8** as an yellow solid. Yield: 93 mg (55%).

^1H NMR (δ, ppm): 5.21 (s, 5H, Cp), 4.01 (s, 2H, CH_2). IR (cm^{-1}): 3424, 2051, 2001, 1742, 1683, 1617. Elemental *Anal.* Calc. for $C_{12}H_8FeN_2O_7 \cdot 2H_2O$: C, 37.50; H, 3.15; N, 7.29. Found: C, 37.25; H, 3.19; N, 7.01%.

6. X-ray structure determinations

X-ray data were collected on Rigaku AFC5S difractometer [19] using Cu Kα X-ray source and graphite monochromator. For all the crystals procedure of

measurement, structure solution and refinemnt was the same. The unit cell dimensions were obtained from least-squares fit to setting angles of 25 reflections. Monitoring of three standard reflections during data collections show no significant change of intensities under X-ray radiation. Reflection intensities were corrected for Lorentz and polarization effects and analytical absorption corrections were applied [20]. A summary of X-ray details is given in Table 2. The crystal structures were solved using SHELXS86 [21] program and refined using full-matrix least squares calculation using SHELXL97 [22]. In the final step of refinement procedure, all non-hydrogen atoms were refined with anisotropic themal displacement parametrs. Hydrogen atoms were included in calculated positions with ideal geometry using rigid body model. They were given isotropic displacement parametrs equal to 1.2 (for aromatic C parent atoms) or 1.5 (in the other cases) of the equivalent displacement parameters of the atoms to which they are attached. The molecular geometry was calculated by SHELXL and the plots were made by PLATON [23].

There are two independent molecules (molecule **a** and molecule **b**) in the asymmetric unit for compound **2**. As no significant differences in their geometry are observed these molecules were refined using SAME instruction with default parameters. Molecules of compound **5** were found to cocrystalize with one water molecule. In the molecular drawing of this compound the water molecule is omitted for clarity.

7. Supplementary material

Full crystallographic data (CCDC No. 207091 for compound **2**, CCDC No. 207092 for compound **3**, CCDC No. 207093 for compound **5** and CCDC No. 207094 for compound **6**) have been deposited at the Cambridge Crystallographic Data Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; Email:deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Two complexes of 4,5-bis(methylthio)-1,3-dithiole-2-thione ($C_5H_6S_5$), $C_5H_6S_5CuI$ (**1**) and $(C_5H_6S_5)_2PdI_2$ (**2**), have been synthesized and characterized crystallographically. They are assembled into ribbon structures by coordination bonds and S···S contacts. There are very short S···S contacts (3.268 Å) between the ribbons of complex **1**. The contacts are arranged parallel to the heterocycle plane with one C–S···S–C grouping close to linear. The results of the synthetic reactions and crystal structures indicate that the planar coordination of the thiocarbonyl sulfur with Pd(II) is more efficient than the tetrahedral coordination of Cu(I) and the preferential coordination site to Cu(I) and Pd(II) is the S in thiocarbonyl group not the methylthio group.

1. Introduction

In order to achieve the goals of developing advanced materials, for chemists, the past 10 years have brought a blossoming of a large field of supramolecular chemistry [1,2]. Intermolecular interactions such as hydrogen bonds, S···S contacts and π···π stacking are efficient organizing forces in supramolecular architecture and design of new solid-state materials for applications. Many research groups have succeeded in the strategy to control organic molecular aggregation by hydrogen bonding [3,4], and to synthesize organic conductors assembled by π···π stacking [5–7] or S···S contacts [8–12]. The unique physical properties of these compounds not only depend on the specific properties of the individual components, but also are strongly influenced by the arrangement of molecules within the crystal lattice. In sulfur-rich compounds, such as tetrathiafulvalene (TTF) and its derivatives [13–15], and 4,5-disulfanyl-1,3-dithio-2-thionate (dmit) complexes $[M(C_3S_5)_2]^{n-}$ [11,12], short S···S contacts were found to play an important role in their electric conductivity.

We have reported a series of complexes of 4,5-ethylenedithio-1,3-dithiole-2-thione ($C_5H_4S_5$). $C_5H_4S_5$ is a derivative of dmit and has a structure similar to half of BEDT-TTF. Up to now, three silver(I) [16,17], one copper(I) [18] and one mercury(II) [19] complex of $C_5H_4S_5$ have been synthesized and crystallographically characterized. They display a variety of one- to three-dimensional frameworks based on the coordination bonds as well as intermolecular S···S contacts. Our recent interest is still focused on the construction of this kind of supramolecular frameworks. The ligand used in this work is 4,5-bismethylthiol-1,3-dithiole-2-thione ($C_5H_6S_5$), a derivative of dmit. It is also an electron donor and shows some common features to $C_5H_4S_5$, but the 4,5-ethylenedithio group is replaced by 4,5-bis(methylthio) groups. In this paper, we report the synthesis and new structures of the copper(I) and

palladium(II) complexes of $C_5H_6S_5$ with short S···S contacts.

2. Experimental

2.1. General comments

$C_5H_6S_5$ was prepared using a literature method [20] and characterized. Acetonitrile was dried and distilled by a standard method before use. All other chemicals were obtained from commercial sources and used without further purification. Infrared spectra were measured as KBr discs on a Nicolet Magna 550 FT-IR Spectrometer and elemental analysis was recorded on an EA-1110 analytical instrument.

2.2. Preparation of the complexes of $C_5H_6S_5$

2.2.1. $C_5H_6S_5CuI$ (1)

A solution of CuI (38.0 mg, 0.2 mmol) in acetonitrile (4 ml) was added to a solution of $C_5H_6S_5$ (22.6 mg, 0.1 mmol) in acetonitrile (4 ml) at room temperature under argon atmosphere. An orange precipitate was formed immediately and the mixture was stirred for 30 min. The precipitate was filtered, washed with acetonitrile and dried in argon (yield: 73%). Orange crystals for X-ray measurement were obtained by slow evaporation of the filtrate. *Anal.* Calc.: C, 14.41; H, 1.45. Found: C, 14.11; H, 1.42%. IR (cm^{-1}), 2905vw, 1451m, 1420w, 1034vs, 968w, 538w, 463w.

2.2.2. $(C_5H_6S_5)_2PdI_2$ (2)

A solution of $Pd(CH_3CN)_2Cl_2$ (22 mg, 0.086 mmol) in dichloromethane (50 ml) was added to a solution of $C_5H_6S_5CuI$ (36 mg, 0.086 mmol) in acetonitrile (50 ml) at room temperature. The solution was stirred for 30 min and then it was filtered. Dark-red crystals for X-ray measurement were obtained by slow evaporation of the red filtrate (yield: 51%). *Anal.* Calc.: C, 14.77; H, 1.49. Found: C, 14.53; H, 1.39%. IR (cm^{-1}), 2904vw, 1467m, 1424w, 1035vs, 967w, 538w, 464w.

2.3. X-ray crystallography

X-ray diffraction experiments were made on a Rigaku Mercury CCD area detector with graphite monochromated Mo Kα radiation. The data were collected at a temperature of -80 ± 1 °C to a maximum 2θ value of 55.0° by using the ω-scan method. For complex **1**, a total of 4254 reflections were collected, in which 2411 were unique; for complex **2**, a total of 4520 reflections were collected, in which 2409 were unique. An empirical absorption correction was applied for both **1** and **2**, which resulted in transmission factors ranging from 0.64 to 1.00. The data were corrected for Lorentz and polarization effects.

The structures were solved by direct methods [21] and expanded using Fourier techniques [22]. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. All calculations were performed using the Crystal Structure [23,24] crystallographic software package.

3. Results and discussion

3.1. Crystal structure of $[C_5H_6S_5CuI]_\infty$ (1)

An ORTEP view of the unit of $[C_5H_6S_5CuI]_\infty$ (**1**) with selected atom labelling is shown in Fig. 1. The crystallographic data are listed in Table 1 and the selected bond distances and angles are listed in Table 2. The geometry around the copper atom is a distorted tetrahedron with three bridging iodide ions and a thiocarbonyl sulfur atom from the ligand. This is different from the structure of $[Cu_4I_4(C_5H_4S_5)_4]$ [18], although the difference for $C_5H_6S_5$ and $C_5H_4S_5$ is only the replacement of an ethylenedithio group by a bis(methylthio) group at sites 4 and 5. In the $C_5H_4S_5$ case, the ligand displays a bidentate coordination mode through the sulfur atoms of both the thioether and the thiocarbonyl groups. The Cu–S (thiocarbonyl sulfur) distance of 2.284(1) Å and the S(1)=C(1) distance of 1.667(3) Å for **1** are close to those for $[Cu_4I_4(C_5H_4S_5)_4]$ [18]. The Cu–I distances are within the expected values for these kinds of sulfur-rich ligands.

The most striking feature of complex **1** is that the $C_5H_6S_5CuI$ unit forms a poly structure in the solid state. The central part of this structure is a zig-zag ladder-like ribbon (or chain, Fig. 2), which is formed by the Cu and

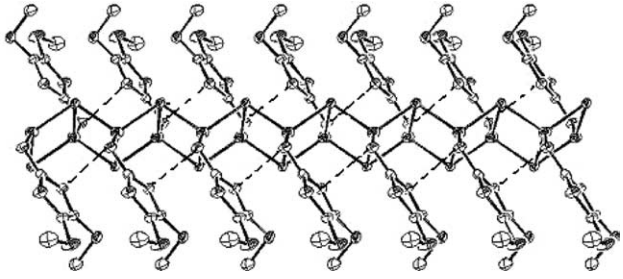

Fig. 2. Part of a zig-zag ladder-like ribbon in which the intrachain S···S contacts are showed by dashed lines.

I atoms and propagated in the direction of the a-axis. A similar structure has been reported in $[Cu(C_6H_4OS_5)I]_\infty$ ($C_6H_4OS_5$ = 2-thioxo-5H-1,3-dithiolo[4,5-b][1,4]di-thiepin-6(7H)-one) [25]. The Cu···Cu separation of 2.929 Å in the complex is longer than that in $[Cu_4I_4(C_5H_4S_5)_4]$ (2.789 Å) [18]. The short intra-ribbon S···S contacts occurs between S(1) and S(3′) (3.578 Å), which is smaller than the sum of the van der Waals radii of two S atoms (3.70 Å). The shortest inter-ribbon contacts of 3.268 Å between S(4) and S(4′) indicate that there are strong interactions between two neighboring polymeric units. This gives rise to a novel two-dimensional network. Fig. 3 shows the molecular packing and the intermolecular S···S contacts.

S···S contacts with distances below 3.30 Å are rarely found in the crystals of sulfur-rich compounds and in general the contacts are in the range 3.35–3.70 Å. An example having an unusually short contact is $[Cu_4I_4(C_5H_4S_5)_4]$ [18], in which the S···S contact (3.257 Å) is between thioether and thiocarbonyl sulfur atoms (head to tail), but in the present case, the contacts are between two thioether sulfur atoms (tail to tail). Another example of an unusually short contact, with a S···S distance of 3.251 Å, is an organic compound [26]. The arrangement of the unusual S···S contact of **1** is shown in Fig. 3(b), which is similar to the case reported in [26]. The contacts are arranged parallel to the heterocycle plane with a center inversion. It is known that the contacts where one C–S···S–C grouping is close to linear are shorter than those where the S···S vector is perpendicular to the plane of the sulfides [26,27].

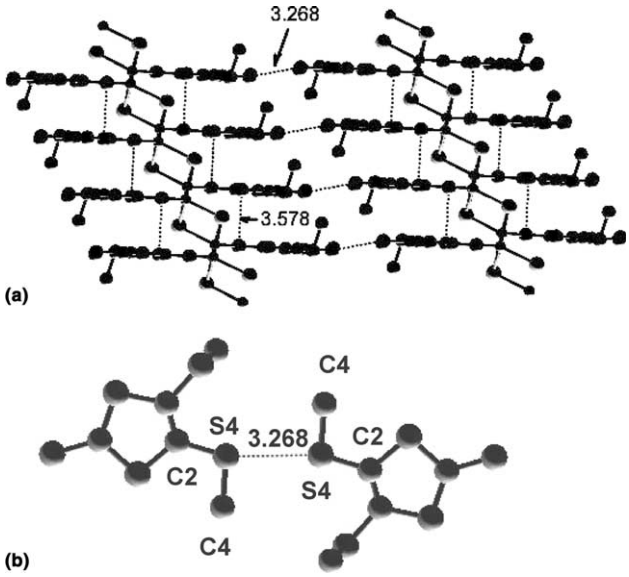

Fig. 3. The molecular packing and the two-dimensional assembly (a) and the unusually short intermolecular S···S contact (b).

3.2. Crystal structure of $(C_5H_6S_5)_2PdI_2$ (2)

An ORTEP view of complex **2** together with the atomic labelling scheme is given in Fig. 4. The selected bond lengths and angles are given in Table 3. The palladium atom is four-coordinated with two iodide atoms and two thiocarbonyl sulfur atoms. The geometry around Pd(II) is square planar. The Pd(II) ion and the two ligands, except the methyl groups, are basically coplanar. The Pd–S and Pd–I distances are 2.330 and 2.602 Å, respectively. The C(1)═S(1) distance of 1.676 Å is similar to that in the CuI complex (1.667 Å), in accordance with the results of the IR measurements. The C═S IR stretching frequencies of **1** and **2** are essentially same, 1034 cm^{-1} for **1** and 1035 cm^{-1} for **2** (1057 cm^{-1} for the free ligand). The complexes are further self-assemble to a one-dimensional network by short contacts of 3.539 Å between S(1) and S(2′). The ribbon structure is shown in Fig. 5.

It is notable that there is a significant difference between the bond lengths of C(1)–S(3) and C(1)–S(2) for both compounds **1** and **2** (see Tables 2 and 3). The former bond is shorter in both cases and *cis* to the S–metal bond. It is unclear for this phenomena, but we found it might be related to the torsion angles of M–S(1)–C(1)–S(3). The torsion angles of **1** and **2** are 0.91° and 0.79°, in other words, the M–S(1) bond is within the plane defined by S(1)–S(3) and C(1)–C(3). The bond lengths of C(1)–S(3) and C(1)–S(2) tend to equivalence when the torsion angle is increased [17,19].

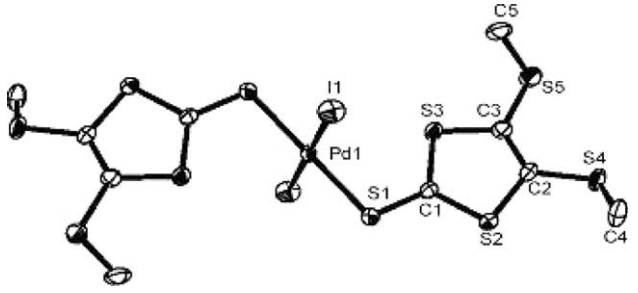

Fig. 4. ORTEP view of $(C_5H_6S_5)_2PdI_2$ (**2**) showing the atom labelling scheme. Non-H atoms are shown as 50% probability displacement ellipsoids.

S(5)–C(3)–C(2)	125.1(5)		

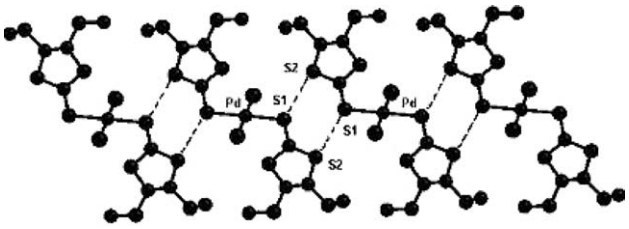

Fig. 5. Part of the band-like structure of **2**, the intermolecular S···S contacts are showed by dashed lines.

The complex **2** is an unexpected product. The goal for the synthesis is a hetero nuclear polymer. Because the bis(methylthio)-ethylene moiety is a well-known chelate for soft metals, such as Ag(I), Cu(I) and Pd(II) [8,28–30], and a palladium complex with tetrakis(methylthio)-ethylene $[Pd(TMTE)Cl_2]$ has been prepared recently by our group [30], it seems reasonable to prepare a hetero-nuclear coordination compound by introducing Pd(II) to complex **1**. However, the result is that the Cu(I) of **1** is completely replaced by Pd(II) in the reaction

$$2[(C_5H_6S_5)CuI] + PdCl_2 \xrightarrow{\text{inacetonitrile}} [PdI_2(C_5H_6S_5)_2] + 2CuCI \quad (1)$$

It reveals that the planar coordination of the thiocarbonyl sulfur with Pd(II) is more efficient than the tetrahedral coordination of Cu(I), although the bond strengths of M–S(1) in **1** and **2** are similar. On the other hand, the coordination ability of the thioether sulfur (methylthio group) is weaker than that of the thiocarbonyl group, thus the preferential coordination site is the S of the C═S group not the methylthio group.

4. Conclusion

As sequential work in the study of the structures of a series of complexes of 4,5-ethylthiol-1,3-dithiole-2-thione, $C_5H_4S_5$, we have now succeeded in the synthesis and characterization of two new complexes of 4,5-bis(methylthio)-1,3-dithiole-2-thione, $C_5H_6S_5$. With the co-operation of coordination bonds and S···S contacts, the complexes are assembled to form two- and one-dimensional supermolecules. The unusual shortest S···S contacts 3.268 Å found for **1** indicates that the molecular assembly of organic donors with coordination linkage in metal complexes can be expected to enhance the intra- or inter-molecular interactions, which may be an important strategy in the search for new materials in crystal engineering.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC reference numbers 226839 and 226840. Abstract

We have carried out the study of the interaction of cobalt(II) and nickel(II) chloride salts with 2-(2-pyridyl)iminotetrahydro-1,3-thiazine hydrochloride · water (1/2) (PyTzHCl · $2H_2O$) in order to determine what complex species can be formed, with the aim of evaluating the different behaviour of the complexes with respect to the free ligand. The compounds carbonato-κ^2O,O'-bis[2-(2-pyridyl-κN)amino-5,6-dihydro-4H-1,3-thiazine-κN]cobalt(III) chloride · water (1/6.6), $[Co(CO_3)(PyTz)_2]Cl \cdot 6.6H_2O$, and diaqua-bis[2-(2-pyridyl-κN)amino-5,6-dihydro-4H-1,3-thiazine-κN]nickel(II) chloride · water (1/6), $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$, have been isolated and their crystal and molecular structure determined by X-ray diffraction. Both complex cations show a distorted octahedral geometry. The solid phases were also characterized through elemental analysis, magnetic susceptibility, UV–Vis–NIR (UV–Visible–Near IR) diffuse reflectance and infrared spectroscopy. Likewise, the equilibria study of PyTzHCl · $2H_2O$ with Co(II) and Ni(II) at 298 K and 0.1 M ionic strength in aqueous solution was performed by means of potentiometric titration.

Keywords: Crystal structure; Thiazine; Cobalt(III) complex; Nickel(II) complex; Pyridine

1. Introduction

In recent years, the investigation on thiazine derivatives coordination chemistry has undergone a considerable increase, due to the potential pharmacological and medical applications of these compounds.

Siderophore analogues constitute a clear example of this development, since they are prototypes for the synthesis of chelating agents employed for clinical use [1]. The research on this area will lead to the design of new clinical drugs for certain metal detoxification [2]. There have been characterized siderophores containing thiazine or thiazoline rings, as the desferrithiocin analogue DL-2-(3-hydroxipyridin-2-yl))-4H-5,6-dihydro-1,3-thiazine-4-carboxilic acid [3].

Taking into account the aforementioned, as well as their interest as potential antibiotic and anti-tumour agents [4], during last years we have carried out a systematic investigation on the coordination chemistry of thiazine derivatives with ions from the transition elements [5]. As a continuation of this research, we report here the study of the interactions between PyTzHCl · $2H_2O$ and the metal ions cobalt(II) and nickel(II).

The reactions between PyTz and the metal ions Co(II) and Ni(II) have afforded the complexes $[Co(CO_3)(PyTz)_2]Cl \cdot 6.6H_2O$ and $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$, respectively. During the reaction of the first complex, the cobalt(II) ion has been oxidized to cobalt(III). The coordination behaviour of PyTz in these complexes is analogous to that exhibited towards copper(II) [5], as was to be expected, acting in both cases as didentate ligand. The solid phases obtained by these reactions were isolated and characterized through elemental analyses, UV–Vis–NIR (UV–Visible–Near IR) diffuse reflectance, infrared spectroscopy, magnetic susceptibility measurement and X-ray diffraction. Likewise, the equilibria study of $PyTzHCl \cdot 2H_2O$ with Co(II) and Ni(II) was performed in aqueous solution at 298 K and 0.1 M ionic strength in $NaClO_4$, yielding several complex species different from those obtained as solid phases.

2. Experimental

2.1. Reagents

Nickel(II) and cobalt(II) stock solutions were prepared in doubly distilled freshly boiled water from its chloride and their concentrations were determined by titration against NaOH. The ionic strength of the solutions was adjusted to a perchlorate concentration of 0.1 M by the addition of sodium perchlorate. Sodium hydroxide stock solutions were prepared by dilution of a concentrated solution of sodium hydroxide, according to Kolthoff et al. [6]. These solutions were kept under a CO_2-free atmosphere and standardized by titration against potassium hydrogen phthalate.

2.2. Preparation of $[Co(CO_3)(PyTz)_2]Cl \cdot 6.6H_2O$

The cobalt(III) complex was isolated from a freshly prepared aqueous solution of cobalt(II) chloride (106.4 mg, 0.447 mmol) that was added to an aqueous solution of $PyTzHCl \cdot 2H_2O$ (106.3 mg, 0.400 mmol). The pH of the whole solution was adjusted by dropwise addition of NaOH, to an appropriate pH according to the titration curves (pH 8). The solution was allowed to evaporate slowly at room temperature and after a few days, red crystals were isolated from the solution (68%, 100 mg). During the course of the reaction, the cobalt ion has been oxidized from its starting 2+ to state 3+ in the complex. *Anal.* Calc. for $C_{19}H_{35}ClCoN_6O_{9.6}S_2$: C, 34.59; H, 5.38; N, 12.73; S, 9.72. Found: C, 34.54; H, 5.26; N, 12.66; S, 9.11%.

2.3. Preparation of $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$

The nickel(II) complex was obtained by addition of a freshly prepared aqueous solution of nickel(II) chloride (58.4 mg, 0.246 mmol) to an aqueous solution of $PyTzHCl \cdot 2H_2O$ (115.1 mg, 0.433 mmol) and adjusting the pH of the mixture, by dropwise addition of NaOH, to an appropriate value according to the potentiometric titration curves (pH 8). The solution was allowed to evaporate slowly at room temperature for a few days, being isolated blue crystals (83%, 121 mg). *Anal.* Calc. for $C_{18}H_{38}Cl_2NiN_6O_8S_2$: C, 32.74; H, 5.80; N, 12.72; S, 9.71. Found: C, 32.87; H, 5.64; N, 12.85; S, 8.51%.

2.4. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen and sulfur were performed by means of microanalytical methods using a Leco CHNS-932 microanalyser. A UV–Vis–NIR reflectance spectrum of each complex in the 200–1000 nm range was obtained from a pellet of the sample, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Magnetic susceptibility measurements were performed on powdered samples in the temperature range 2–290 K using a magnetometer with pendulum MANICS DSM8, equipped with helium continuous-flow cryostat and a electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature-independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants.

Potentiometric measurements were carried out with a Metrohm 702 SM Titrino equipped with a combined pH glass electrode. The electrode system was calibrated in terms of hydrogen ion concentration by performing strong acid versus strong base titrations [7]. The ligand concentration of the samples was always 2×10^{-3} M, and metal complex formation curves were obtained at different ligand-to-metal ratios from 1:1 to 3:1. Sample solutions were titrated in a double-walled vessel maintained at 298 ± 0.1 K by circulating water and stirred magnetically under a continuous flow of nitrogen. The ionic strength was fixed to 0.1 M by addition of appropriate amount of $NaClO_4 \cdot H_2O$. The numerical analysis of all the experimental e.m.f. data was carried out with the computer program SUPERQUAD [8]. All calculations were performed on a PC.

2.5. Crystal structure determinations

Crystal data, data collection and refinement details for $[Co(CO_3)(PyTz)_2]Cl \cdot 6.6H_2O$ and $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$ are given in Table 1. The first 50 frames were recollected at the end of data collection to monitor for decay.

All intensity data were corrected for Lorentz and polarization effects. Moreover, data were also corrected for absorption effects using an empirical method based on azimuthal scan data. The structures were solved by direct methods and subsequent Fourier differences using the WINGX package [9] and refined by full-matrix least-squares. The H-atoms were located from a differential Fourier synthesis and included in the calculation with estimated isotropic displacement parameters without refinement (riding model).

3. Results and discussion

3.1. Potentiometric studies

As we described in a previous paper [5], the analysis of $PyTzHCl \cdot 2H_2O$ potentiometric titration curves by SUPERQUAD [8] computer method led to the establishment of the ligand ionization constant, whose value is essential for the later determination of possible complex stability constants.

In the present report, the titration curves for the $PyTzHCl \cdot 2H_2O$/Ni(II) and $PyTzHCl \cdot 2H_2O$/Co(II) systems were obtained for duplicate in the 5–11 pH range. They are studied using SUPERQUAD program in order to determine what complex species are formed and their stability constants, designed as β_{pqrs}, where the subscripts p, q, r, s make reference to the complex stoichiometry in the metal, ligand, hydrogen ion, chloride order.

The more probable complex species, together with formation constants and statistical parameters σ and χ^2, are reported in Table 2.

Metal hydroxides and cobalt chlorocomplexes formation constants are considered in calculations, but not the presence of nickel chlorocomplexes in accordance with the bibliography related with the formation of these species [10,11].

Table 2
Formation constants ($\log\beta$) at 298 K and $I = 0.1$ M ($NaClO_4$)

System	Species	$\log\beta$	χ^2	σ
$PyTzH^+/Co^{2+}$ (1/1)	$[Co(PyTz)]^{2+}$	13.80(0)	11.04	2.46
$PyTzH^+/Co^{2+}$ (2/1)	$[Co(PyTz)]^{2+}$	13.76(1)	3.33	2.00
	$[Co(PyTz)_2]^{2+}$	17.77(1)		
$PyTzH^+/Co^{2+}$ (3/1)	$[Co(PyTz)]^{2+}$	13.73(3)	3.87	1.24
	$[Co(PyTz)_2]^{2+}$	17.11(13)		
$PyTzH^+/Ni^{2+}$ (1/1)	$[Ni(PyTz)]^{2+}$	17.80(1)	5.00	2.96
$PyTzH^+/Ni^{2+}$ (2/1)	$[Ni(PyTz)]^{2+}$	18.32(6)	2.21	2.47
	$[Ni(PyTz)_2]^{2+}$	23.81(10)		
$PyTzH^+/Ni^{2+}$ (3/1)	$[Ni(PyTz)]^{2+}$	17.46(2)	4.37	3.32
	$[Ni(PyTz)_3]^{2+}$	26.05(7)		

As it can be observed, in the case of a 1:1 ligand/metal ratio, a complex specie was detected for $PyTzHCl \cdot 2H_2O$/Ni(II) system, and the best fit between experimental and theoretical potentiometric titration curves was found for the model considering the specie ML. Likewise, in the titration curve with 2:1 ligand/metal ratio it was found that the species ML and ML_2 satisfied the experimental data, while in the titration curve with a 3:1 ligand/metal ratio, a new model formed by the combination of complex ML and ML_3 resulted in a satisfactory numerical and graphical fit.

With regard to $PyTzHCl \cdot 2H_2O$/Co(II) system, the 1:1 ligand/metal ratio titration curves study provided the specie ML, whereas for 2:1 and 3:1 ligand/metal proportions, the model that gave a satisfactory fit to the experimental data was that which considers the species ML and ML_2 in both cases.

In an analogous way to its behaviour towards copper [5], the ligand acts as unprotonated form in all detected species.

Every proposed hydroxide and chlorinated complexes have been rejected by SUPERQUAD species selection [8], generating a new model that did not include them.

Finally, it can be said that the reported global formation constants are reproducible and the statistical parameters acceptable.

3.2. Description of the structures

The structure of the red cobalt(III) complex is built up by $[Co(CO_3)(PyTz)_2]^+$ cations, chloride anions and water molecules of crystallization. Fig. 1 shows the molecular structure of the complex cation. Selected bond lengths, angles and hydrogen-bond parameters are listed in Table 3.

The environment around the cobalt(III) atom may be described as a distorted octahedral geometry with the ligand–metal–ligand bite angles varying between 68.9(1)° [O(1)–Co–O(2)] and 98.9(1)° [O(1)–Co–N(3)], and the metallic atom coordinated to two carbonato

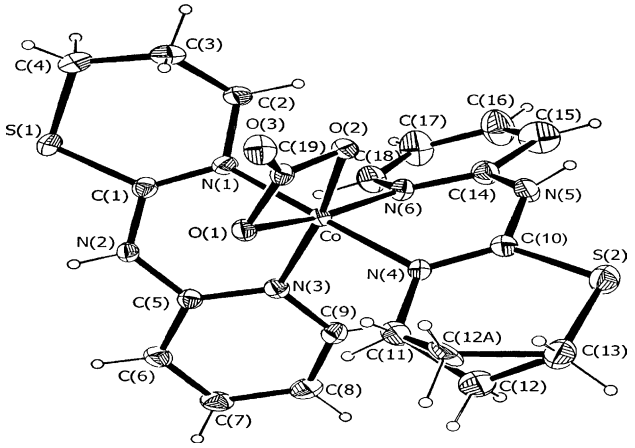

Fig. 1. Molecular structure of the $[Co(CO_3)(PyTz)_2]^+$ cation, showing the atom-numbering scheme. The thermal ellipsoids are drawn at a 50% level.

oxygen atoms [av. Co–O = 1.913 Å], two thiazine nitrogen atoms [av. Co–N = 1.933 Å] and two pyridine nitrogen atoms [av. Co–N = 1.936 Å]. This compound is the first structurally characterized compound having a 1,3-thiazine link to cobalt(III). The whole molecule exhibits pseudo-C_2 symmetry with the C_2 axis passing through the C(19)–O(3) bond.

The Co–O bond lengths are similar and comparable to the calculated average value [1.913(16) Å] for 35 octahedral cobalt(III) carbonato complexes with a chromophore group CoN_4O_2 obtained from the Cambridge Structural Database (CSD) [12]. Likewise, the Co^{III}–$N_{(pyridine)}$ distances are in good agreement with the mean value [1.946(33) Å] calculated using the data of 19 six-coordinate cobalt(III) complexes obtained from CSD.

The two six-membered chelate rings show an intermediate form between boat and half-boat conformations with the atoms Co and N(2) [or N(5)] deviating ~ 0.80 and ~0.25 Å, respectively, above the plane formed by N(1), C(1), N(3), C(5) [or N(4), C(10), N(6), C(14)]. These geometries are proved by the puckering parameters [$Q = 0.587$ Å; $\phi = 179.1°$; $\theta = 110.1°$] for the chelate ring Co–N(1)–C(1)–N(2)–C(5)–N(3) and [$Q = 0.607$ Å; $\phi = 177.1°$; $\theta = 108.8°$] for the chelate ring Co–N(4)–C(10)–N(5)–C(14)–N(6), both of them calculated according to Cremer and Pople [13].

The chelate ring Co–O(1)–C(19)–O(2) is essentially planar with maximum mean plane deviation for O(3) (0.003 Å).

In a similar way to that observed in the previously reported copper(II) complex [5], the analysis of bond lengths and angles shows that the organic ligands present an amino-5,6-dihydro-4H-1,3-thiazine form instead the imino-tetrahydro-1,3-thiazine form, detected for PyTz as free ligand.

The thiazine ring S(1)–C(1)–N(1)–C(2)–C(3)–C(4) presents an intermediate form between half-boat conformation with the apex at C(2) and twist boat confor-

mation with S(1) and C(2) above and C(1) and C(3) below the atoms N(1) and C(4). This geometry is proved by the puckering parameters [$Q = 0.596$ Å; $\phi = 26.4°$; $\theta = 112.1°$], calculated according to Cremer and Pople [13].

The other thiazine ring shows a dynamic disorder affecting C(12) and C(12A) atoms, each one with a 50% of occupancy, which give rise to two extreme conformations. One of them shows an intermediate form between half-chair and half-boat, with the C(12) and C(13) atoms deviating −0.578 and 0.106 Å, respectively, from the plane formed by S(2), C(10), N(4) and C(11) [$Q = 0.480$ Å; $\phi = 251.8°$; $\theta = 50.7°$]. On the contrary, the second conformation is near to half-boat, with the apex at C(12A). This atom is 0.385 Å out of the plane formed by S(2), C(10), N(4), C(11) and C(13) [$Q = 0.292$ Å; $\phi = 51.3°$; $\theta = 122.9°$].

Moreover, the crystal structure shows static disorder that involves some of the crystallization water molecules. Specifically, it is observed a partial substitution of a pair H_2 (O6W1)···H_2 (O6W3) for a molecule H_2 (O6W2) that is located on a halfway position between both members of the pair, in such a way that the occupation degree for the first pair component is ~55%, while for the second one is ~45%.

Likewise, the crystal structure presents an extensive hydrogen-bond network, in which atoms O(1) and O(2)

and chloride anions act as acceptors of hydrogen, amino nitrogen atoms act as donors and crystallization water molecules act on both ways.

The X-ray study of the nickel(II) complex revealed that the crystals are made up of monoclinic unit cells, each one containing four $[Ni(PyTz)_2(H_2O)_2]^{2+}$ cations, eight chloride anions and 24 crystallization water molecules. Therefore, the complex salt may be formulated as $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$. A diagram of the molecular structure of the complex cation is shown in Fig. 2, and selected bond lengths, angles and hydrogen-bond parameters are given in Table 4.

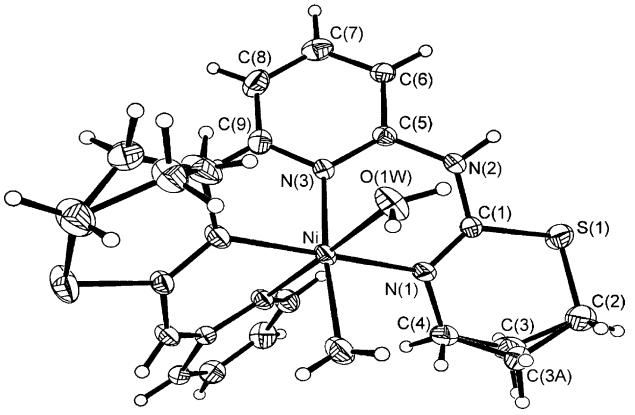

Fig. 2. Molecular structure of the $[Ni(PyTz)_2(H_2O)_2]^{2+}$ cation, showing the atom-numbering scheme. The thermal ellipsoids are drawn at a 50% level.

The complex cation possesses a crystallographic C_2 symmetry, with the twofold axis being coincident with the bisector of the angle formed by the two oxygen atoms and the central cation.

The environment around the nickel(II) atom may be described as a distorted octahedral geometry with the metal coordinated to two water molecules [Ni–O(1W) = 2.119(2) Å], two thiazine nitrogen atoms [Ni–N(1) = 2.075(2) Å] and two pyridine nitrogen atoms [Ni–N(3) = 2.082(2) Å]. The ligand–metal–ligand bite angles differ from the ideal value of 90°, varying between 86.0(1)° and 94.2(1)°. Likewise, this compound is the first structurally characterized compound having a 1,3-thiazine link to nickel(II).

In this complex, the bond length Ni–O(1W) is similar to the average value [2.120(64) Å] calculated using 104 octahedral Ni(II) aquacomplexes with a chromophore group NiN_4O_2 collected in CSD. The $Ni–N_{pyridine}$ bond distance is comparable with the mean value [2.104(33) Å] calculated from the data of 19 octahedral Ni(II)

diaquacomplexes with a chromophore group NiN_4O_2 using CSD.

The chelate ring [$Q = 0.594$ Å; $\phi = 0.6°$; $\theta = 69.0°$] shows an intermediate conformation between half-boat and boat, with the atoms Ni and N(2) deviating 0.832 and 0.234 Å, respectively, above the plane formed by N(1)–C(1)–C(5)–N(3).

The organic moiety shows an amino-5,6-dihydro-4H-1,3-thiazine form, like in the cobalt(III) complex. Likewise, the thiazine ring also shows a dynamic disorder affecting C(3) atom, which give rise to two extreme conformations. One of them is near to half-boat [$Q = 0.499$ Å; $\phi = 297.5°$; $\theta = 57.5°$], with C(4) deviating 0.637 Å from the plane formed by S(1)–C(1)–N(1)–C(2)–C(3). The second conformation is intermediate between half-boat [$Q = 0.505$ Å; $\phi = 17.6°$; $\theta = 109.1°$] with the apex at C(2), and twist boat with S(1) and S(2) above and C(1) and C(3) below the atoms N(1) and C(4).

There are two kinds of chloride anions in the crystal structure, named as Cl(1) and Cl(2). The Cl(1) ions are located on the twofold axis of symmetry, as the nickel atom. However, the Cl(2) ions are situated in a general position, which lead to a Cl(2) occupation degree of 50%, in order to reach neutrality. Because of this, a static disorder takes place in the structure in such a way that the holes left by the Cl(2) ions are occupied by two water molecules: $H_2O(3)$ and $H_2O(4)$, each one with an occupation degree of 50%.

The crystal structure is stabilized by a wide network of hydrogen-bonds, in which the coordination water molecules and the exocyclic nitrogen atoms act as hydrogen donors, the chloride ions act as acceptors and the crystallization water molecules act on both ways.

3.3. Magnetic studies

The observed molar magnetic susceptibility for $[Ni(PyTz)_2(H_2O)]Cl_2 \cdot 6H_2O$ was corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature ($\mu = 3.23$ MB). This value is consistent with the octahedral environment around nickel(II) [14].

3.4. Spectroscopic studies

The electronic spectrum of the isolated cobalt(III) complex in the Vis–near UV region exhibits the presence of only two absorption bands due to the d–d transitions in the octahedral CoN_4O_2 crystal field. The higher energy band at 395 nm (25 320 cm^{-1}) is found as a shoulder covered by the charge transfer transition. This d–d absorption is assigned to the $^1A_{1g}(I) \rightarrow {}^1T_{2g}(I)$ transition. Therefore, a Gaussian-shaped band is found at 532 nm (18 800 cm^{-1}), which can be assigned to the $^1A_{1g}(I) \rightarrow {}^1T_{1g}(I)$ transition. This shape and its intensity suggest that the compound has a *cis* octahedral geometry, which is supported by the X-ray structural determination for this carbonato complex.

The bands of more intensity at 305 nm (32 800 cm^{-1}) and 239 nm (41 300 cm^{-1}) can be assigned to the $\pi \rightarrow \pi^*$ transitions of the organic ligand, whereas the band at 328 nm (30 500 cm^{-1}) is assigned to charge transfer absorption involving the imine function.

Using the frequencies of the d–d transitions, we have calculated the values of 10 Dq and the Racah interelectronic repulsion parameters B and C by means of the Tanabe–Sugano diagram and the equations proposed by Lever [15]:

$$E[^1A_{1g}(I) \rightarrow {}^1T_{1g}(I)] = 10\ Dq - C$$

$$E[^1A_{1g}(I) \rightarrow {}^1T_{2g}(I)] = 10\ Dq + 16B - C$$

The calculated values of the ligand field parameters 10 Dq = 19 700 cm^{-1}, $B = 408$ cm^{-1} and $C = 880$ cm^{-1} are consistent with the presence of the chromophore group $[Co^{III}N_4O_2]$ in several carbonato complexes [16].

In the nickel(II) complex, the electronic spectrum shows two intense bands at 296 nm (33 780 cm^{-1}) and 246 nm (40 630 cm^{-1}), which are assigned to the $\pi \rightarrow \pi^*$ transitions of the organic ligand. Moreover, the spectrum exhibits absorption bands at 948 nm (10 550 cm^{-1}) and 587 nm (17 030 cm^{-1}), both of low intensity. These bands may be assigned to: $^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)$ (10 550 cm^{-1}) and $^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$ (17 030 cm^{-1}) transitions in an idealized O_h symmetry. The position of the observed d–d transitions permits to calculate the ligand field parameters 10 Dq and B, using the following known relationships:

$$E[^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)] = 10\ Dq$$

$$E[^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)] = (1/2)(15B + 30\ Dq) - (1/2)[(15B - 10\ Dq)^2 + 12B.10\ Dq]^{1/2}$$

The calculated values of the ligand field parameters 10 Dq = 10 550 cm^{-1} and $B = 900$ cm^{-1} are consistent with the presence of the chromophore group $[Ni^{II}N_4O_2]$ [17].

The IR spectrum of both complexes in the 4000–370 cm^{-1} region shows the presence of bands due to the in plane thiazine ring vibrations at 1636, 954, 856, 790, 776, 630 and 602 cm^{-1} for the cobalt(III) complex, and at 1630, 944, 876, 778, 700, 626 and 595 cm^{-1} for the nickel(II) complex, whereas the out of plane thiazine ring vibrations are detected at 530 and 435 cm^{-1} for the former and at 524 and 430 cm^{-1} for the latter.

Likewise, characteristic bands of pyridine ring vibrations are registered at 1601(8a), 1530(8b), 1485(19a), 1428(19b), 653(4) and 417(16b) cm^{-1} for the cobalt(III) complex and at 1603(8a), 1520(8b), 1485(19a), 1423(19b), 1015(1), 638(6b) and 653(4) cm^{-1} for the nickel(II) complex.

The spectra exhibit other relevant bands at 3269, 3242, 3195, 3177 and 3137 cm^{-1}, corresponding to the bridging amino group stretching vibrations [18], 1293 cm^{-1} [ν(C–N)] and 3410 cm^{-1} [$\nu(H_2O)$] for the cobalt(III) complex and at 3192 and 3148 cm^{-1} [ν(N–H)] [16], 1291 cm^{-1} [ν(C–N)] and 3392 cm^{-1} [$\nu(H_2O)$] [19] for the nickel(II) complex.

Due to the presence of the carbonato group, the cobalt(III) complex spectrum shows several bands at 2052, 1658, 1267, 987, 842 and 733 cm^{-1}, that are in accord with the available bidentate carbonato ligands bibliography [20–24].

In the far infrared region, the C_2 symmetry of both complex cations predicts the existence of six bands [20,25] in the $[Co(CO_3)(PyTz)_2]Cl \cdot 6.6H_2O$ and $[Ni(PyTz)_2(H_2O)_2]Cl_2 \cdot 6H_2O$ spectra, which takes place for the first complex, but not for the second one.

Thus, the Co(III) spectrum shows six bands at 486, 464 cm^{-1} [$\nu(Co–OCO_2)$] [19,20], 376, 337 cm^{-1} [$\nu(Co–N_{pyridine})$] [20], 293 and 249 cm^{-1} [$\nu(Co–N_{thiazine})$] [26], whereas for Ni(II) complex, only two bands are detected at 370 cm^{-1}, corresponding to a $\nu(Ni–OH_2)$ vibration [19,27], and at 280 cm^{-1}, which could be assigned to a $\nu(Ni–N_{thiazine})$ vibration, registered at 270 cm^{-1} for $[Ni(btz)_3](ClO_4)_2$ [26], or to a $\nu(Ni–N_{pyridine})$ vibration, according to the consulted bibliography for several octaedrical nickel(II) complexes [20,21,28,29].

Abstract

The reaction of tetrasodium *p*-sulfonatothiacalix[4]arene and transition metal ions (Co^{2+}, Ni^{2+} and Cu^{2+}) in the presence of 4,13-diaza-18-crown-6 gives two types of crystalline complex: (4,13-diaza-18-crown-6)$_2$[$M(H_2O)_6^{2+}$]{(4,13-diprotodiaza-18-crown-6) $\subset$ [$M(H_2O)_3^{2+}$(*p*-sulfonatothiacalix[4]arene)$^{4-}$]$_2$} $\cdot$ nH_2O ($M^{2+} = Co^{2+}$, Ni^{2+}, $n = 12$ for Co^{2+} and 14 for Ni^{2+}) (**1**) and (4,13-diprotodiaza-18-crown-6)$_2$[$Cu(H_2O)_6^{2+}$] [$Cu(H_2O)_2^{2+}$(*p*-sulfonatothiacalix[4]arene-H^+)$^{5-}$]$_2$ $\cdot$ $12H_2O$ (**2**). Both complexes feature slipped capsule assemblies with the diprotonated diaza-18-crown-6 shrouded by two head-to-head thiacalixarenes to form a bi-layer structure in which an exo-capsule diaza-18-crown-6 traverses the hydrophobic layer of the thiacalixarenes and a hexa-aqua metal ion occupies the hydrophilic layer. In complex **1**, each thiacalixarene coordinates to a metal ion through two deprotonated phenolic groups and a bridging sulfur atom, and an exo-capsule crown ether is located in the hydrophilic equator. However, in complex **2**, a coordination dimer is formed with the metal ion bound to a sulfonato group of one thiacalixarene as well as a deprotonated phenolic group and a bridging sulfur atom of an adjacent thiacalixarene.

1. Introduction

Certain rigid, non-planar molecules with curved or bowl-shaped micro-environments have the extraordinary ability to assemble into capsules or cage molecules or ions [1–7]. These species may form nano-structures of relevance to materials and biological science, and their encapsulation of guest molecules has implications for drug delivery and catalysis [8]. The hydrophobic, bowl-shaped motif of calixarenes and related resorcinarenes make them inherently versatile building blocks for the construction of ionic or molecular capsules. Capsules based on two *p*-sulfonatocalix[*n*]arenes shrouding other molecules including crown ethers [9–11], tetra-protonated cyclam [12], di-protonated [2,2,2] cryptand ($n = 4$) [13] and H_2SO_4 ($n = 5$) [14] have recently been established. The use of the large water soluble, highly charged sulfonated calix[*n*]arenes to gain access to novel capsules relies on a combination of supramolecular interactions, notably coordination, hydrogen bonding, electrostatic and van der Waals, where there is size, shape and electronic complementarity between the molecular components [9].

In 1997, soon after the discovery of the practical method for the synthesis of *p*-tert-butylthiacalix[4]arene [15], thiacalix[4]arene tetrasulfonate, a new water-soluble host molecule, was obtained [16]. Similar to *p*-sulfonatocalixarenes, Na_4[thiacalix[4]arene tetrasulfonate] $\cdot$ ethanol $\cdot$ $8H_2O$ also shows a bi-layer structure in the solid state [17] in which the thiacalixarene unit adopts the cone configuration. Herein, we report the formation of new ionic capsules, where the di-protonated 4,13-diaza-18-crown-6 is shrouded by two *p*-sulfonatothiacalix[4]arenes in the presence of transition metal ions, and a new type of intercalation within the thiacalixarene bi-layer system showing that amphiphilic macrocyclic compounds without aromatic rings, in this case

diaza-crown ethers or di-protonated diaza-crown ether cations, can span the hydrophobic layers.

2. Experimental

2.1. Materials and methods

4,13-Diaza-18-crown-6 [18] and tetrasodium *p*-sulfonatothiacalix[4]arene [17] were synthesized by literature methods. All other reagents were commercially available and used without further purification.

Elemental analyses were performed with an Elementar Vario EL analyser. The IR spectra were recorded on a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique in the 400–4000 cm^{-1} region.

2.2. Synthesis of (4,13-diaza-18-crown-6)$_2$[M(H$_2$O)$_6^{2+}$] {(4,13-diaza-18-crown-6+2H$^+$) ⊂ [M(H$_2$O)$_3^{2+}$(p-sulfonatothiacalix[4]arene)$^{4-}$]$_2$ · nH$_2$O} ($M^{2+} = Co^{2+}$, Ni^{2+}, $n = 12$ for Co^{2+} and 14 for Ni^{2+}), (**1**)

4,13-Diaza-18-crown-6 (39 mg, 0.15 mmol) and tetrasodium *p*-sulfonatothiacalix[4]arene (90 mg, 0.1 mmol) were dissolved in deionized water (5 mL). The solution was adjusted to pH ≈ 2 with perchloric acid and 0.15 mmol of the corresponding M^{2+} nitrate ($M^{2+} = Co^{2+}$, Ni^{2+}) was added. After several days, large crystals suitable for X-ray diffraction analysis were formed, yield = 32 mg (21%, for the Co^{2+} complex) and 40 mg (26%, for the Ni^{2+} complex). The crystals quickly cracked when removed from the mother liquor. IR: sulfonate absorptions: $v = 1222$, 1181, 1146, 1037 cm^{-1} (for the Co^{2+} complex), $v = 1220$, 1174, 1141, 1034 cm^{-1} (for the Ni^{2+} complex). Elemental analysis (%): *Anal.* Calc. for $C_{42}H_{76}Co_{1.5}N_3O_{34}S_8$: C, 33.36; H, 5.08; N, 2.78. Found: C, 33.21; H, 4.78; N, 2.61%; *Anal.* Calc. for $C_{42}H_{76}N_3Ni_{1.5}O_{34}S_8$: C, 33.36; H, 5.08; N, 2.78. Found: C, 33.13; H, 4.71; N, 2.64% (the analytical data is only for samples having lost one water molecules during transport).

2.3. Synthesis of (4,13-diaza-18-crown-6+2H$^+$)$_2$[Cu(H$_2$O)$_6^{2+}$] [Cu(H$_2$O)$_2^{2+}$(p-sulfonatothiacalix[4]arene-H$^+$)$^{5-}$]$_2$ · 12H$_2$O, (**2**)

4,13-Diaza-18-crown-6 (26 mg, 0.1 mmol) and tetrasodium *p*-sulfonatothiacalix[4]arene (90 mg, 0.1 mmol) were dissolved in deionized water (5 mL). The solution was adjusted to pH ≈ 2 with perchloric acid and 0.15 mmol of Cu^{2+} nitrate was added. Yellow green crystals formed after several days, yield = 80 mg (29%). The crystals quickly cracked if removed from the mother liquor. IR: sulfonate absorptions: $v = 1220$, 1183, 1145, 1036 cm^{-1}, Elemental analysis (%): *Anal.* Calc. for $C_{72}H_{108}Cu_3N_4O_{55}S_{16}$: C, 33.09; H, 4.17; N, 2.14. Found: C, 32.79; H, 3.89; N, 2.01% (the analytical data is only for samples having lost seven water molecules during transport).

2.4. X-ray crystallography

X-ray data were collected at 293 (2) K on a Bruker SMART 1000 CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). The crystals were mounted in a glass capillary with a drop of mother liquor in order to

prevent deterioration of the crystal owing to solvent loss. The structures were solved by direct methods and refined by full-matrix least-square techniques on F^2 using the SHELXL 97 program. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms on the crown ether and the thiacalixarene were placed at their calculated positions and assigned with isotropic displacement parameters. The hydrogen atoms of the water molecules could not be located. A number of lattice water molecules were disordered and given partial occupancies. Experimental details for X-ray data collection of the complexes are presented in Table 1.

3. Results and discussion

The complexes were prepared by mixing the corresponding transition metal ion (II) nitrates, 4,13-diaza-18-crown-6 and tetrasodium *p*-sulfonatothiacalix[4]arene in an aqueous solution, with the pH adjusted to 2 (see Scheme 1).

The structure of complex **1**, as shown in Fig. 1, consists of several structural components: the superanion capsule {(4,13-diprotodiaza-18-crown-6) ⊂ $[M(H_2O)_3{}^{2+}$ (*p*-sulfonatothiacalix[4]arene)$^{4-}]_2$}, one hexa-aqua metal ion(II) and two types of exo-capsule diaza-crown ethers.

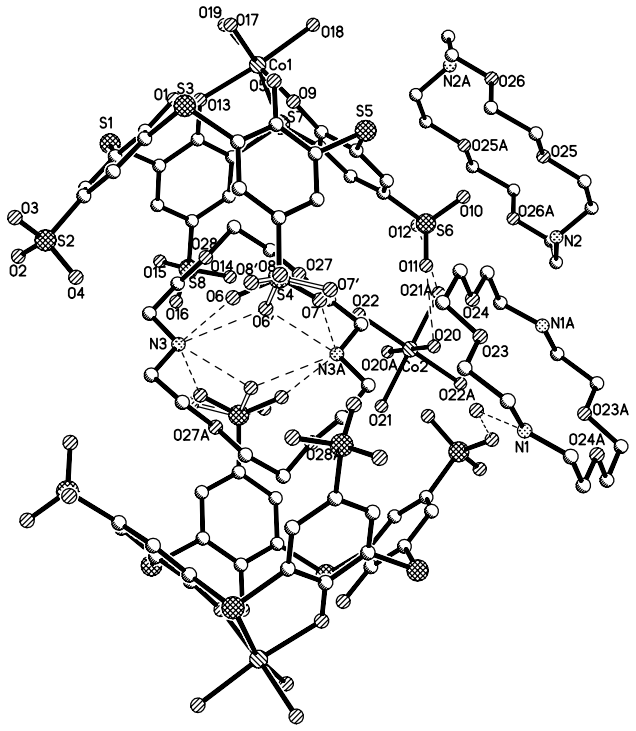

Fig. 1. An 'ionic capsule' in complex **1**, M = Co^{2+}, dashed lines indicate hydrogen bonds (hydrogen atoms and crystal water molecules have been omitted for clarity).

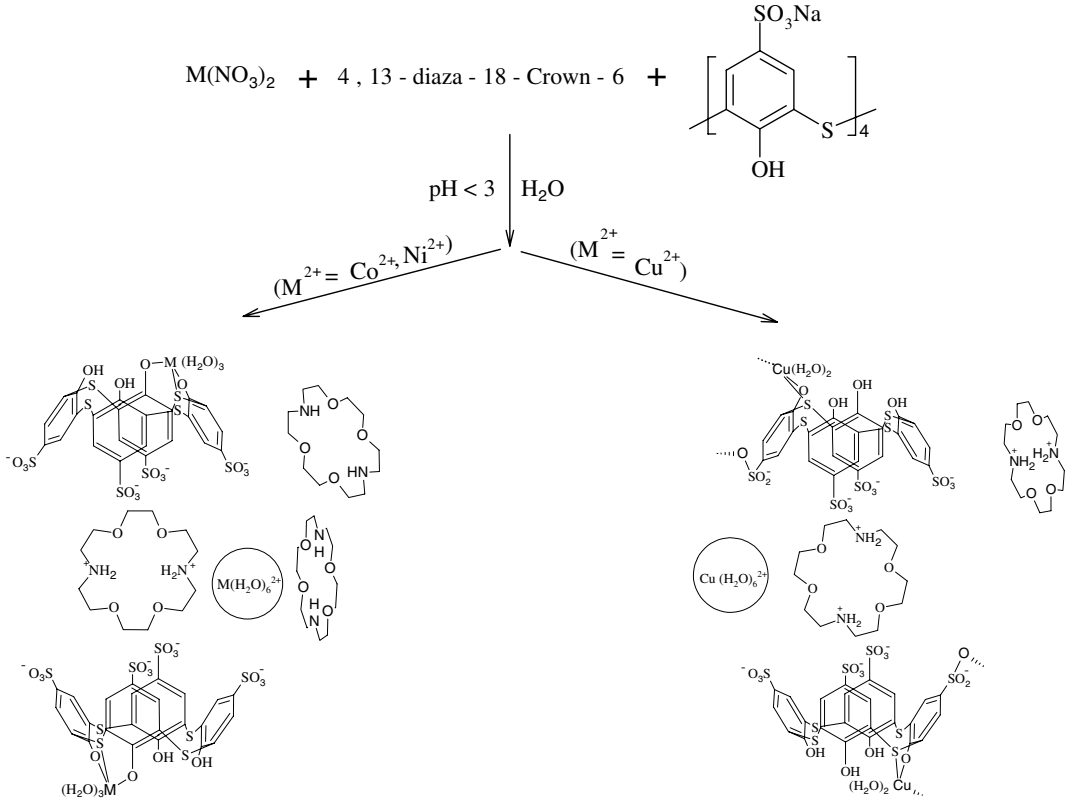

Scheme 1.

There are also several lattice water molecules and some of them are disordered and given partial occupancies.

A di-protonated diaza-crown ether is sandwiched by two thiacalixarenes in an 'up–down' fashion to create a capsule. Two phenolic groups of each thiacalixarene are deprotonated and coordinate to a M^{2+} at the base of the thiacalixarene. A bridging sulfur atom of this thiacalixarene and three aqua ligands also coordinate to M^{2+}, which is ligated in a distorted octahedral manner with average M–O (phenolic) bond distances of 2.019 Å (Ni^{2+}), 2.040 Å (Co^{2+}), M–OH_2 of 2.078 Å (Ni^{2+}), 2.139 Å (Co^{2+}) and M–S of 2.427 Å (Ni^{2+}), 2.502 Å (Co^{2+}). Two of the four sulfonato groups of each thiacalixarene are necessarily protonated to achieve overall charge balance. These protons were not found crystallographically and the hydrogen bonding network is implied through the numerous close N···O contacts. Some sulfonato groups are disordered (three for the Ni^{2+} complex and one for the Co^{2+} complex). The di-protonated nitrogen atoms of the crown ether are hydrogen-bonded to the sulfonato groups of the two thiacalixarenes in the 'ionic capsule' with N···O distances from 2.821 to 3.021 Å. There are also hydrogen bonds from the lattice water molecules to the sulfonato groups of these two thiacalixarenes with O···O distances from 2.741 to 2.986 Å. In addition to the H-bonding interactions, the crown ether cation interacts with the two thiacalixarenes through a non-classical H-bond (C–H···aromatic ring; a methylene hydrogen atom points to the centre of one of the aromatic rings of each thiacalixarene, with a C···ring centroid distance 3.621 Å (for the Ni^{2+} complex) or 3.596 Å (for the Co^{2+} complex)). The capsule is an example of a slipped capsule, with the two bowl thiacalixarene cavities offset relative to each other. Similar capsules have been observed in [{cyclamH_4^{4+}} ⊂ {(*p*-O_3S- calix[4]arene)$_2$}]$^{4-}$ [12]. Complementarity of curvature of the crown ether with that of the thiacalixarene is achieved by the splaying of two opposite phenol rings. The dihedral angles between the two aromatic rings and the plane of the four phenolic oxygens are 140° and 135.8°. The dihedral angles between other two aromatic rings and the plane of the four phenolic oxygens are 103.9° and 122.2°. The conformation of the thiacalixarene is less symmetrical than that of the 'classical' calixarene in the ionic capsules[11]. This may be due to the coordination of two phenolic groups to one M^{2+} ion.

In addition to the M^{2+} ion coordinated by the thiacalixarene, there is another type of M^{2+} ion, which is not coordinated by the thiacalixarene but exists simply as a hexa-aqua cation [M $(H_2O)_6^{2+}$] in the hydrophilic layer and forms part of the second coordination sphere through hydrogen bonding of the aqua ligands to the sulfonato groups of two thiacalixarenes which belong to different capsules.

There are two types of non-protonated crown ethers, which are not involved in the capsules. One crown ether molecule is located at the hydrophilic equator of the superanion through lattice water molecules bridging the nitrogen atoms and sulfonato groups, with N···OH_2 and H_2O···OS distances ranging from 2.754 to 2.790 Å. The other crown ether is intercalated into the hydrophobic layer. The nitrogen atoms of the crown ether are weakly hydrogen-bonded to the sulfonato groups of two adjacent 'up' and 'down' thiacalixarenes, with N···OS distances from 3.069 to 3.155 Å. The crown ether is seen to traverse the hydrophobic layer with one NH group directed towards the sulfonato groups of the 'up' thiacalixarene and the other NH group directed towards the sulfonato groups of the 'down' one.

A particular bi-layer structure forms in the present structure because exo-capsule crown ethers are interspersed between columns of 'up'/'down' thiacalixarenes (see Fig. 2). An 'up' thiacalixarene is surrounded by three 'down' thiacalixarenes. The 'up' thiacalixarene interacts with only one of these 'down' thiacalixarenes through aromatic ring π-stacking (the distances between two adjacent parallel aromatic ring planes are 3.525 Å (for the Co^{2+} complex) and 3.573 Å (for the Ni^{2+} complex)), but is staggered to the other two 'down' thiacalixarenes and linked to them through H-bonds between sulfonato groups and the ligated water molecules of the M^{2+} ions, or H-bonds between sulfonato groups and lattice water molecules. It also links an exo-capsule crown ether which traverses the hydrophobic layer.

The structure of complex **2** (Fig. 3) consists of several structural components: the superanion capsule, the coordination dimer $[Cu(H_2O)_2^{2+}$(*p*-sulfonatothiacalix[4]arene – $H^+)^{5-}]_2$, one hexa-aqua copper ion(II) and one exo-capsule diprotonated diaza-crown ether. There are also several lattice water molecules and some of them are disordered and given partial occupancies.

Each copper ion (Cu2 and Cu2A) in the dimer is coordinated by four oxygen and one sulfur donor forming a distorted square pyramid: two coordinated water molecules occur at an average Cu–O bond distance of 1.983 Å, a sulfonato group of one thiacalixarene at a distance of Cu–OSO_2 2.297 Å as well as a deprotonated phenolic group and a bridging sulfur atom of an adjacent thiacalixarene *cis* to the sulfonato group at a Cu–O distance of 1.937 Å and at a Cu–S distance of 2.451 Å.

This is another example of slipped ionic capsules in which a di-protonated diaza-18-crown-6 is at the core. The supramolecular assembly is primarily stabilized by van der Waals forces associated with complementary curvature. The dihedral angles between the two splaying aromatic rings and the plane of the four phenolic oxygens are 147° and 122.7°. The dihedral angles between the other two aromatic rings and the plane of the four phenolic oxygens are 107.1° and 116.8°. The nitrogen atoms of the crown ether in the cavity are surrounded by

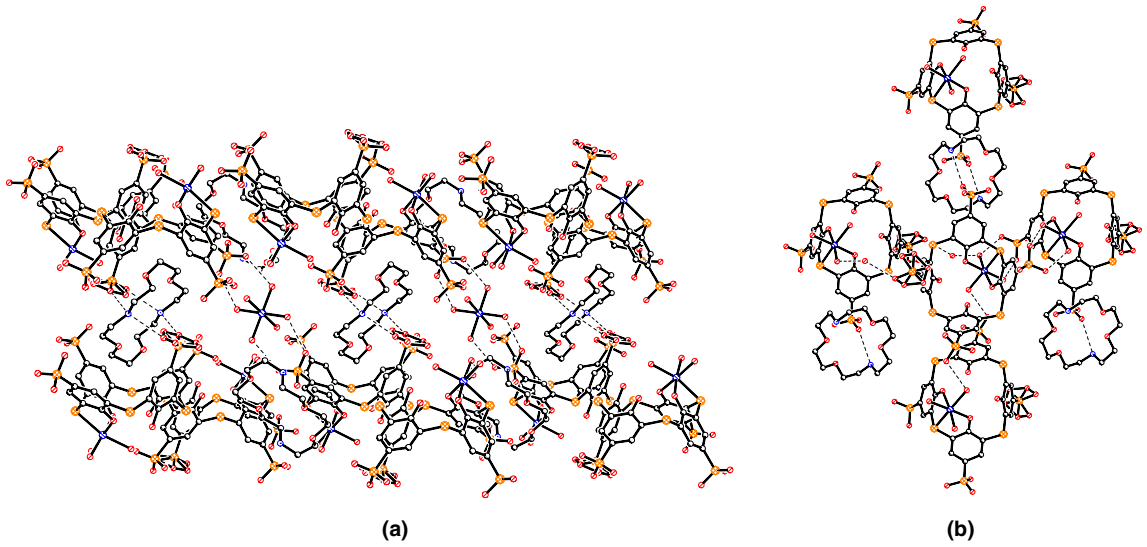

Fig. 2. Projection of the structure of complex **1**, M = Co^{2+}: (a) showing the bi-layer arrangement in which the crown ether molecules span the hydrophobic layer (the exo-capsules crown ethers in the hydrophilic layer have been omitted for clarity) and (b) the interactions of the adjacent thiacalixarenes and the crown ether in the hydrophobic layer.

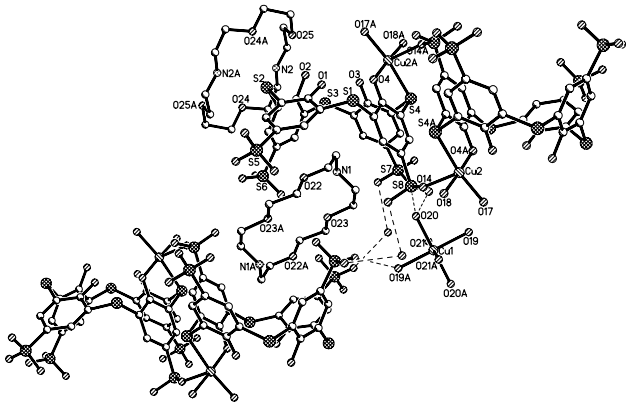

Fig. 3. The 'ionic capsule' in complex **2**, showing the coordination spheres of coordination dimer and the interactions around the 'ionic capsule'; dashed lines indicate hydrogen bonds (hydrogen atoms and crystal water molecules have been omitted for clarity).

the sulfonato groups of the two thiacalixarenes. This presumably maximizes the electrostatic interaction between the sulfonato and the NH_2^+ groups. There are also hydrogen bonds from the lattice water molecules to the sulfonato groups of these two thiacalixarenes with O···O distances from 2.877 to 3.030 Å.

There is also a $[M(H_2O)_6^{2+}]$ moiety in the hydrophilic layer. The hexa-aqua copper(II) ion takes the shape of a flattened octahedron. In addition, there are extensive hydrogen bonds from two aqua ligands to the sulfonato groups of the two thiacalixarenes that form the shell of the 'ionic capsule' with MO···OS distances ranging from 2.826 to 2.923 Å. Other aqua ligands are also hydrogen-bonded to the sulfonato groups of thiacalixarenes from neighbouring capsule with similar MO···OS distances.

A particular bi-layer structure similar to that in complex **1** also forms, in which the exo-capsule diprotonated

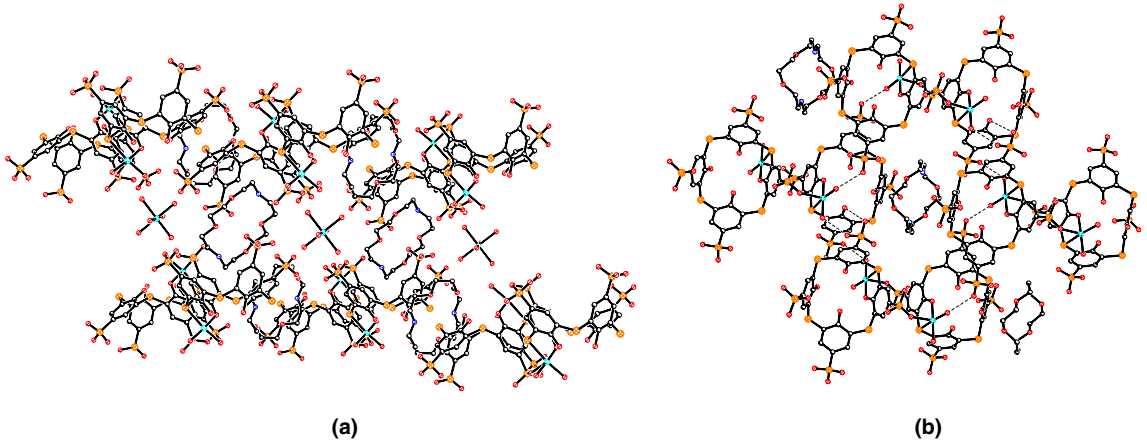

Fig. 4. Projection of the structure of complex **2**: (a) showing the bi-layer arrangement in which the crown ether cations span the hydrophobic layer and (b) the interactions of the adjacent thiacalixarenes and the crown ether in the hydrophobic layer.

diaza-crown ethers intersperse into hydrophobic layers (see Fig. 4). An 'up' thiacalixarene is also surrounded by three 'down' thiacalixarenes, but the interactions with adjacent thiacalixarenes are different from those of complex **1**. In this structure, the adjacent thiacalixarenes are interconnected through π-stacking (the distances between two adjacent parallel aromatic ring planes are in the range 3.380–3.561 Å). H-bonds between sulfonato groups and the aqua ligands of the M^{2+} ions coordinated by the adjacent thiacalixarene (with MO···OS distances ranging from 2.779 to 2.854 Å) and H-bonds between sulfonato groups and the phenolic groups of the adjacent thiacalixarene (with a HO···OS distance of 2.930 Å) should also exist. This 'up' thiacalixarene also links an exo-capsule crown ether cation not through H-bonds but through shape complementarity. The crown ether spans the hydrophobic layer with NH_2^+ groups located in the middle section.

4. Conclusion

In complexes **1** and **2**, 4,13-diaza-18-crown-6 is shrouded by two thiacalixarenes in the presence of transition metal ions and forms an ionic capsule. The thiacalixarene coordinates to the transition metal ion through phenolic hydroxyl groups and a bridging sulfur atom at the base. This may be attributed to the fact that the bridging sulfur atom tends to bind the transition metal ions. Due to the Jahn–Teller effect, the copper(II) ion has a flexible coordination manner. So in complex **2**, the copper ion can be coordinated by the sulfonato group of the adjacent thiacalixarene forming a coordination dimer. In addition to forming 'ionic capsules', the diaza-crown ethers can also insert into the hydrophobic layers and the hydrophilic layers via a variety of supramolecular interactions (hydrogen bonding, shape complementarity).

5. Supplementary data

CCDC-218691 (Co complex), CCDC-218692 (Ni complex) and CCDC-218693 (complex **2**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge, CB2 1EZ, UK [fax: (internat.) +44-1223/336-033; e-mail: deposit@ccdc.cam.ac.uk].

Received 2 February 2004; accepted 4 March 2004
Available online 13 April 2004

Abstract

Cerium(IV) oxazoline derivatives $Ce(Me_2oxaz)_4$ (**1**) [Me_2oxazH = 2-(2′-hydroxyphenyl)-4-dimethyl)oxazoline] and $Ce(Pr^iHoxaz)_4$ (**2**) [$Pr^iHoxazH$ = 2-(2′-hydroxyphenyl)-4-isopropyl)oxazoline] were prepared in high yields by ligand exchange reactions between $Ce_2(OPr^i)_8(Pr^iOH)_2$ and the corresponding 2-(2′-hydroxyphenyl)-2-oxazolines. Characterisation was achieved by elemental analysis, FT-IR, ^1H NMR and mass spectroscopy (MS). **2** was also characterized by polarimetric measurement. Their thermal decomposition pathways under nitrogen were studied by TGA and coupled TGA-CG/MS experiments.

1. Introduction

Cerium dioxide films find use in numerous applications such as corrosion protection coating alternative to chromate films, electrode in solid oxide fuel cell (SOFC), photocatalysts and buffer layers for superconducting electronics [1,2]. Indeed, ceria displays a relative lattice misfit to $YBa_2Cu_3O_{7-x}$ of only 0.6% and ceria or ceria doped with Gd_2O_3 has thus been, with YSZ (yttrium stabilized zirconia) films, one of the most investigated buffer layers for high T_c superconductors [3]. Films of CeO_2 have been deposited by physical or chemical techniques such as sputtering, sol–gel methods [4], metal–organic deposition (MOD) [3] or metal–organic chemical vapour deposition (MOCVD) [5,6]. MOCVD offers a number of advantages including easy scale-up, conformational deposition on a variety of complex substrates, access to multilayer architectures, rapid growth rates, epitaxial layers. If deposition can be achieved in the absence of an oxygen atmosphere, deposition on substrates sensitive to oxidation such as silicon becomes possible. MOCVD relies on the availability of appropriate volatile precursors [7,8]. Easy to handle, fluorine free precursors allowing deposition of CeO_2 at low temperature are desirable. Fluorinated and non-fluorinated-diketonates have been the most investigated [9–12] although fluorinated alkoxide complexes [13] or β-ketoiminates [14,15] have also been used as CVD sources and volatile Ce(IV) β-ketoesterates have been developed [16].

The use of oxazoline type ligands as chirality-transfer auxiliaries has been largely developed in the recent years for a broad range of catalytic reactions based on a variety of metals [17–19]. The oxazoline fragment is easily accessible by reaction between commercially available starting materials namely aminoalcohols and nitriles and the nature of the substituents can thus be modified for a fine tuning of the properties. Such chelating N,O ligands were attractive to us for MOCVD applications. 2-(2′-hydroxyphenyl)-2-oxazoline related ligands for instance should favor monomeric structures due to the rigidity of the ligand (the two cycles are in a same plane), a favorable feature for volatility and for kinetically inert complexes. Hydrolytic stability is also of interest either for conventional MOCVD or for MOCVD by liquid

injection (PI-MOCVD) where precursors might be mixed in an unique reactor for access to multimetallic materials.

We wish to report herein the synthesis, the characterisation of cerium(IV) hydroxyphenyl oxazoline derivatives and how a small modifications of the ligand can generate different thermal behaviours.

2. Experimental

All reactions were achieved under inert atmosphere using Schlenk tube techniques. Solvents were dried and purified by distillation by standard methods. $Ce_2(OPr^i)_8(Pr^iOH)_2$ [20], Me_2oxazH and (S)-Pr^iHoxazH were obtained according to the literature.[21,22] ^{1}H NMR and FT-IR spectra were run on Bruker AC-200 and IR-FTS 45 spectrometers, respectively. IR spectra were obtained as Nujol mulls. Polarimetric measurements were carried out on a Ameria AA-10 apparatus (26 °C, 589 nm). Analyses were obtained from the Centre de Microanalyses du CNRS. Mass spectrometry (Electronic Impact) experiments were achieved on a Thermofinnigan MAT95XL spectrometer. TGA and TGA-CG/MS analyses were carried out on a Mettler-Toledo TGA 851^e thermobalance coupled with an GC(6890)/MS(5973) Agilent Technologies system using a temperature ramp of 10 °C/mn.

2.1. Synthesis of $Ce(Me_2oxaz)_4$ (1) and $Ce(Pr^iHoxaz)_4$ (2)

6.92 mmol of hydroxyphenyloxazoline in 5 ml of THF was added to a solution of 0.75 g of $Ce_2(OPr^i)_8(Pr^iOH)_2$ (0.86 mmol) in 30 ml of THF. The colour of the solution turned immediatly from yellow to dark red. Crystallisation yielded dark red crystals of $Ce(Me_2oxaz)_4$ (**1**) and $Ce(Pr^iHoxaz)_4$ (**2**) (1.40 g, 90% and 1.56 g, 95%, respectively). **1** and **2** were volatile (195–200 °C and 175–180 °C, respectively, under 4×10^{-4} Torr) and soluble in chloroform, toluene, THF and diglyme.

2 could also be obtained from $(NH_4)_2Ce(NO_3)_6$; 2.73 mmol of Pr^iHoxazH and Et_2NH in 5 ml of THF were added to 0.37g of $(NH_4)_2Ce(NO_3)_6$ (0.68 mmol) in 10 ml of THF. The colour of the solution changed from yellow to dark red. The solvent was evaporated after 19 h and the solid obtained was dissolved in toluene. After filtration, crystallisation yielded **2** (0.58 g, 90%).

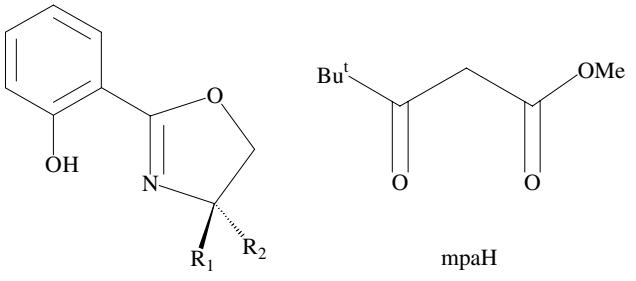
3. Results and discussion

3.1. Syntheses and characterisation

Two 2-(2′-hydroxyphenyl)-2-oxazoline ligands were selected in view of their easy synthesis and purification as well as simplicity of their NMR pattern. These were based on R_1 and R_2 substituents with $R_1 = R_2 = Me$ and $R_1 = H$, $R_2 = {}^i$Pr and abbreviated as Me_2oxazH and Pr^iHoxazH respectively. Methylpivaloylacetate (mpaH) [16] was also used as a ligand for Ce(IV) in similar conditions [17–19] and the data compared with those obtained with the hydroxyphenyl oxazolines.



The reactions between $Ce_2(OPr^i)_8(Pr^iOH)_2$ and Me_2oxazH or Pr^iHoxazH in THF (1:8 stoichiometry) at r.t. afforded dark red microcrystals of $Ce(Me_2oxaz)_4$ (**1**) and $Ce(Pr^iHoxaz)_4$ (**2**) which were isolated with yields higher that 90%. These compounds are air stable as solids and were characterized by elemental analyses, FT-IR, NMR and MS. Their diamagnetic character confirms oxidation state IV for cerium and thus that the four 2-(2′-hydroxyphenyl)-2-oxazoline acts as anionic ligands. FT-IR spectra show the absence of υOH and δOH absorption bands. These spectra display essentially the absorption bands due to the C=N stretching vibrations between 1643 and 1550 cm^{-1} and those of the C–O bonds around 1230–1000 cm^{-1}. Absorption bands between 600 and 400 cm^{-1} account for the Ce–O and Ce–N vibrations.

Despite numerous attempts, no single crystals suitable for X-ray studies could be grown for either **1** nor **2**. Structural information was thus gained by ^{1}H NMR. All ligands are magnetically equivalent for **2** but the diastereotopy of the methyl of the isopropyl groups is enhanced by complexation and they appear as two doublets at 0.79 and 0.40 ppm, respectively. The compound is chiral with an optical activity of $[\alpha]_{589}^{26}$ in chloroform (concentration 2×10^{-2} moll^{-1}). **1** and **2** are likely to be monomeric (as shown by MS) and cerium is thus octacoordinated (Fig. 1). Such a coordination number was observed for instance for $Ce(thd)_4$ [9–12] or $Ce(salphen)_2$ [salphen = *N*,*N*′-1,2-diphenylethylene-bis(salicyldeimine)] [23] whose structures were determined by X-ray diffraction. In contrast, the ^{1}H NMR spectrum of **1** at r.t. shows two types of magnetically non-equivalent ligands in a 1:1 ratio. The two types of ligands are differentiated by their methyl groups as well as by two hydrogens of the aromatic ring which are quite deshielded (8.10 ppm). These observations suggest that the coordination sphere of **1** is more distorted than that of **2** with two types of Ce–O and Ce–N bond distances. Molecular modelling (Hyperchem V) confirms this hypothesis since the steric interactions between the ligands are best released (lowest energy) with a structure in which the Ce–O distances have values of 2.27 and 2.29 Å. A first set of two ligands would form a square with the ligands in trans position in order to minimize steric hindrance [as observed for the solid state structure of $Cu(\eta^2\text{-}Me_2oxaz)_2$ [16,24] and could account for the resonances at 1.61 ppm (four equivalent Me groups) and at 8.1 ppm (two aromatic protons in ortho position). For the two other ligands, the methyl groups are non-equivalent (1.41 and 1.10 ppm) and the H in ortho position are less deshielded (7.71 ppm).

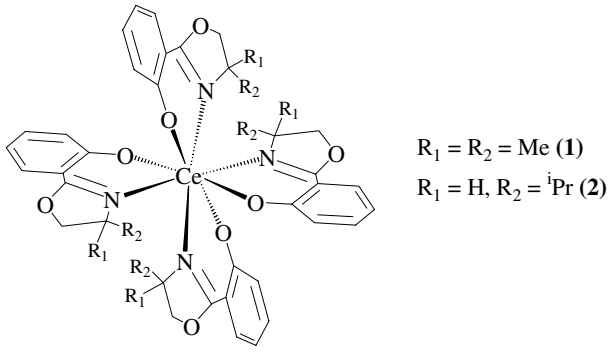


Fig. 1. Proposed structure of complexes **1** and **2**.

3.2. Physicochemical properties

Liquid injection MOCVD is a promising alternative to conventional MOCVD especially for metal oxide thin films whose sources are mostly solids, thus generating a number of problems such as modification of the surface properties, and thus of transport properties over time. Solubility, stability in solution, clean deposition are important requirements for control of the material properties [7,8]. Both novel cerium compounds as well as $Ce(mpa)_4$ are air stable as solids. However, the structural differences between **1** and **2** in solution as shown by ^{1}H NMR result in a difference in stability toward hydrolysis. By contrast to **2**, **1** is hydrolysed after two days in a solution open to air. This difference in hydrolytic susceptibility explains why **1**, by contrast with **2**, could not be prepared by starting from ammonium cerium(IV) nitrate. **1** and **2** are both volatile but less than $Ce(thd)_4$, $Ce(mpa)_4$ or the adducts of the fluoroisopropoxides such as $Ce(hfip)_4$(diglyme) (hfip = $OCH(CF_3)_2$ despite the fact that they have similar molecular weight (Table 1). The lower volatility of the oxazoline compounds is probably due to some intermolecular π interactions due to the phenyl substituent. Such effect has been pointed out to reduce the volatility of copper β-diketonates $Cu(bac)_2$ (bacH = 1-phenyl propane-1,3-dione) and $Cu(dbzm)_2$

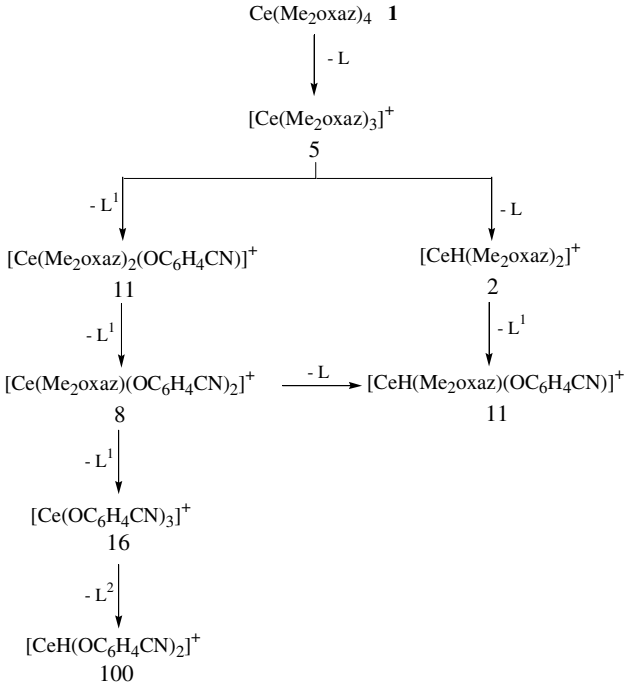
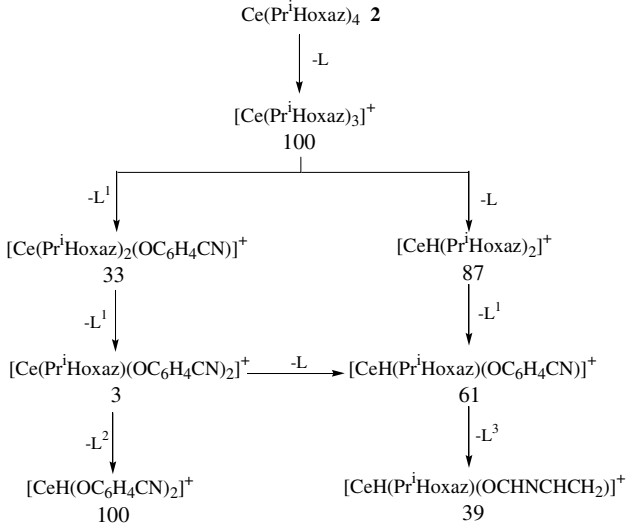
(dbzmH = 1,3-diphenyl propane-1,3-dione) compared to $Cu(acac)_2$ [25,26].

MOCVD liquid delivery techniques are a way to overcome problems related to limited volatility and/or stability of solid precursors. However, since reasonable growth rates are required for applications, high solubility properties in a solvent appropriate for injection or aerosol assisted techniques are needed in order to minimize the influence of the volatiles issued from solvent decomposition. The solubility of **1** and of **2** was compared to that of $Ce(thd)_4$ which remains the precursor commonly used for access to CeO_2 by MOCVD techniques. They are slightly more soluble in diglyme than thd analogs but much less than $Ce(mpa)_4$ (Table 1). No complexation was observed in diglyme for **1** or **2** as indicated by UV–Vis spectroscopy. Hydrocarbons such as hexane or octane are better solvents than diglyme for the isopropoxide adducts and for $Ce(thd)_4$.

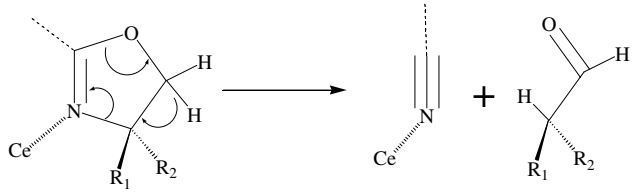
The thermal behaviour of **1** and **2** was investigated under dinitrogen (1 atm) by TGA up to 700 °C (Fig. 2). Although the general patterns are similar, they are drastically dependent on the R_1 and R_2 substituents since the Pr^i derivative **2** decomposes into ceria whereas decomposition remains partial for the Me derivative. **2** starts also to decompose 100 °C lower than **1**. Its first weight loss (100–200 °C) corresponds to a partial decomposition (−8%) of the oxazoline ligand and the second one (200–380 °C) to a weight loss of 68%. The last thermal event (−4%) between 380 and 450 °C leads to cerium oxide. In the case of $Ce(Me_2oxaz)_4$, only three hydroxyphenyloxazoline ligands are removed totally between 200–450 °C. Decomposition of the last one remains incomplete leading thus to a black residue (≃36%)



Scheme 1. Fragmentation pathway of **1** (with relative intensities) [L = Me_2oxaz, $L^1 = R_1R_2CHCHO$, $L^2 = OC_6H_4CN$].



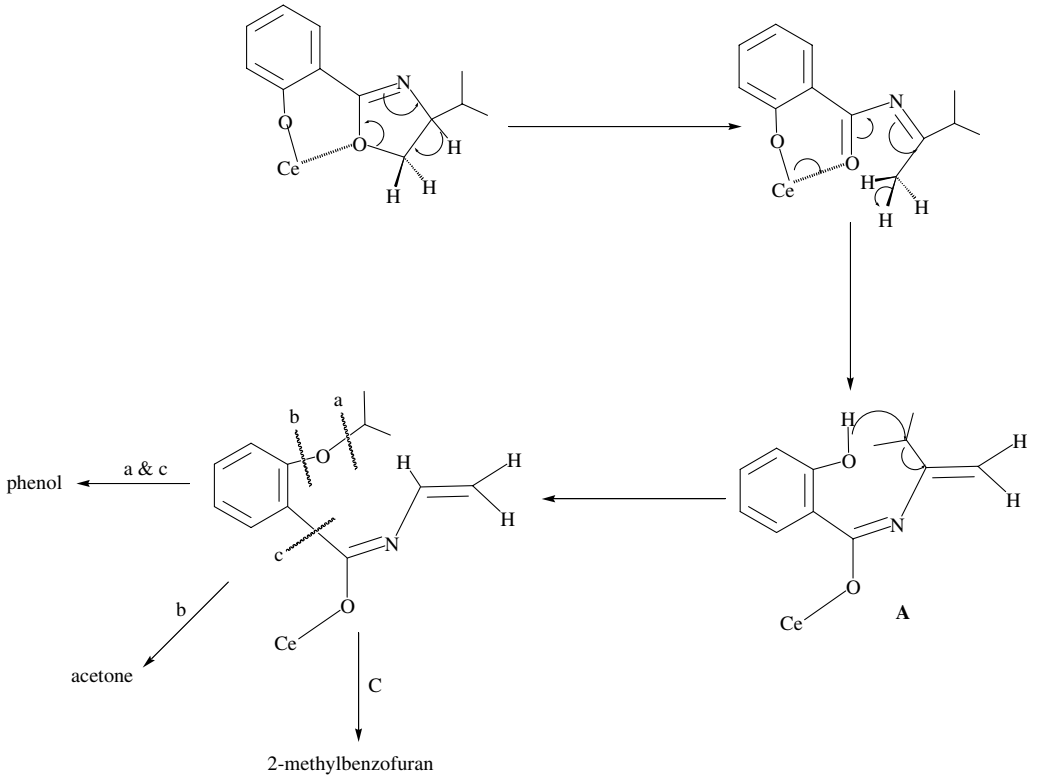
Scheme 2. Fragmentation pathway of **2** (with relative intensities) [L = Pr^iHoxaz, $L^1 = R_1R_2CHCHO$, $L^2 = OC_6H_4CN$, L^3 = 2-methylbenzofuran].



Scheme 3. Proposed degradation pathway of the oxazoline moiety of **1** and **2** mediated by cerium.

containing organics (as evidenced by FT-IR) and no CeO_2 is obtained up to 1000 °C under dinitrogen.

Mass spectrometry (IE) and coupled TGA-GC/MS experiments were carried out in order to get insight into the decomposition pathways of **1** and **2** (analyses of the volatiles by FT-IR or ^{1}H NMR was uninformative due to the presence of large amounts of oxazoline). Those are summarised in Schemes 1 and 2, respectively. For both compounds, the first fragment corresponds to $[CeL_3]^+$ (L = Me_2oxaz or Pr^iHoxaz) and the most intense one (m/z 376) corresponds to $[CeH(OC_6H_4CN)_2]^+$ (OC_6H_4CN = cyanophenoxo). These results indicate that steric hindrance favours the loss of one of the hydroxyphenyloxazoline ligand and that oxazoline moieties are easily degraded (Scheme 3). Indeed, fragments at m/z 638 and 666, for **1** and **2**, respectively, confirm the decomposition of the oxazoline ligands giving $[CeL_2(OC_6H_4CN)]^+$. The same process is repeated giving successively the $[CeHL_2]^+$ and $[CeHL(OC_6H_4CN)]^+$ fragments for both **1** and **2**. This was also confirmed by analysing the volatiles by TGA-GC/MS. Between 200 and 350 °C, 2-methyl 1-propene was detected for **1** whereas 2-methylpropanal and 2-methyl 2-propenal were obtained for **2**. At higher temperature, ≈400 °C, acetone and aromatics such as phenol and 2-methylbenzofuran were detected for **2** while only C4 and C5 alkenes and ketones could be found for **1**. Two main differences are observed in the mass spectra: (i) the very low intensity for all fragments derived from **1** except that at m/z 376 and (ii) the presence for **2** of the fragment m/z 418 resulting from the degradation of the phenoxo moiety. Loss of 2-methylbenzofuran explains the fragments at m/z 418 and 134 for **2**. The overall data suggest that the degradation of **1** is mainly directed by the decomposition of the oxazoline moiety giving a stable $[CeH(OC_6H_4CN)_2]^+$ species. By contrast, the phenoxo moiety can be significantly degraded for **2**. Hence, in order to get CeO_2, the last phenoxo group has to be removed but oxygen atoms are also needed. This can be afforded for **2** since the lower steric hindrance might permit the rotation around the phenoxo-oxazoline bond to link the oxygen of the oxazoline moiety with cerium. The opening of the oxazoline moiety leads to compound **A** stabilised by electronic delocalisation and subsequent cleavage reactions can give the expected organics (Scheme 4). Indeed decomposition of **1** under



Scheme 4. Proposed degradation pathway of **2**.

air afforded CeO_2 at 450 °C, thus at a temperature similar to that observed for **2** or $Ce(mpa)_4$, which both can be converted into ceria in the absence of additional oxygen.

These results show how small modifications at the ligand can affect decomposition pathways. Ligands containing phenyl substituents favour monomers, improve stability toward moisture but might lead to high sublimation temperatures due to a higher MW as well as high decomposition temperatures especially under inert atmosphere. **2** can be a potential precursor for CeO_2 deposits on oxidation sensitive substrates, thus under inert atmosphere, whereas **1** is an unsuitable precursor in non-oxidative conditions.

Abstract

The reaction of (1-Et-Ind)Li (1-Et-Ind = 1-ethylindenyl) with 1.81 equivalent of $Ni(PPh_3)_2Cl_2$ in ether, followed by crystallization from CH_2Cl_2/hexane, affords (1-Et-Ind)$Ni(PPh_3)Cl$ (**1**) in 58% yield. Similar reaction of (1-Et-Ind)Li with 1.81 equivalent of $Ni(PPh_3)_2Br_2$ in 1,2-dimethoxyethane (DME) affords (1-Et-Ind)$Ni(PPh_3)Br$ (**2**) in 60% yield. The reaction of complex **1** with KI in THF/acetone affords (1-Et-Ind)$Ni(PPh_3)I$ (**3**) quantitatively. Crystal structure analysis revealed that **2** and **3** are isomorphous. The hapticities of the indenyl ligand in these complexes are very similar and significantly distorted from an idealized η^5 mode to an unsymmetrical η^3 mode. The complexes are inert toward the insertion of styrene, but are able to catalyze the polymerization of styrene effectively in the presence of PPh_3 and $NaBPh_4$.

1. Introduction

In recent years, the use of Ind (Ind = indenyl anion and its substituted derivatives) as supporting ligand systems in transition metal coordination chemistry has attracted considerable attention [1–5]. In comparison to their Cp analogues (Cp = cyclopentadienyl anion and its substituted derivatives), many transition metal Ind complexes possess greater reactivity owing to the so-called "indenyl effect". The Ind ligands can be tuned spontaneously to coordinated to the center metal from η^1 to η^5 via relatively facile "ring slippage", thus leading to better stabilization of transition states or reaction intermediates. However, their application in regard to group 10 metal complexes remains relatively poorly explored [6–9]. Recently, Zargarian reported that (Ind)$(PR_3)Ni$–X (Ind = indenyl anion and its substituted derivatives; R = Ph, Me, Cy, Bu; X = halide, alkyl, alkynyl, imidate, thiolate) [10] could act as effective pre-catalysts in a number of reactions, such as the oligomerization or polymerization of ethylene [11–15], styrene [16] and phenylacetylene [17]. Preliminary studies have implied that the in situ generated cationic species $[Ind(PPh_3)Ni]^+$ might be the active centers for these reactions, which is in evidence by styrene reactions catalyzed by in situ generated cations from (η^3, η^0-Ind–$CH_2CH_2NMe_2$)$(PPh_3)Ni$–Cl [16]. However, detailed knowledge about the structure–activity relationships of indenyl nickel complexes seems still insufficient.

Recently, we have found that simple alkyl-substituted indenylnickel complexes [(1-R-Ind)$Ni(PPh_3)Cl$, R = cyclopentyl, and benzyl] can efficiently initiate the polymerization of styrene in the presence of PPh_3 and $NaBPh_4$, and the alkyl substituent has a manifest effect on the catalytic activity of these complexes [18]. As an extension, we report herein the synthesis and characterization of a series of indenylnickel complexes containing different halogen atom with the general formula (1-Et-Ind)$Ni(PPh_3)X$ [1-Et-Ind = 1-ethylindenyl; X = Cl (**1**), Br (**2**) and I (**3**)], together with the initial

investigation of their catalytic activities in the polymerization of styrene.

2. Results and discussion

2.1. Synthesis

The indenylnickel complexes **1** and **2** were synthesized by the reaction of the corresponding $Ni(PPh_3)_2Cl_2$ or $Ni(PPh_3)_2Br_2$ with (1-Et-Ind)Li (1-Et-Ind = 1-ethylindenyl), respectively (Scheme 1). Because the reaction of 1-Et-Ind with an equimolar amount of *n*-BuLi in Et_2O gave a quantitative yield of (1-Et-Ind)Li, so freshly prepared solution of indenyl lithium was directly used in the following metathesis reaction. Thus, 1-Et-Ind reacted with *n*-BuLi in Et_2O for half an hour at 0 °C, and the resultant solution was added dropwise into a stirring suspension of $Ni(PPh_3)_2Cl_2$ in Et_2O, or a solution of $Ni(PPh_3)_2Br_2$ in 1,2-dimethoxyethane (DME), in 1:1.8 molar ratio at 0 °C. After workup, the expected complexes (1-Et-Ind)$Ni(PPh_3)X$ [X = Cl (**1**), Br (**2**)] were isolated as dark red crystals in 58% (**1**) or 60% (**2**) yield, as substantiated by elemental analysis and ^1H NMR spectroscopy. Suitable crystals of **1** and **2** for X-ray diffraction studies were grown from Et_2O/hexane at 0 °C. It is noteworthy that the reaction conditions, such as concentration, temperature, and especially the rate of the addition of (1-Et-Ind)Li, have an obvious effect on the formation of indenylnickel complexes. It is of benefit to prepare these complexes by the dropwise addition of a dilute solution of (1-Et-Ind)Li to a dilute suspension of $Ni(PPh_3)_2Cl_2$ in Et_2O, or a dilute solution of $Ni(PPh_3)_2Br_2$ in DME, at 0 °C, since such conditions could efficiently suppress the formation of the byproducts, i.e., the Ni(I) species and 1,1′-biindene [19].

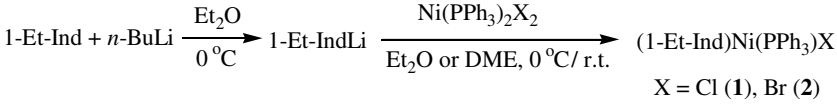
The reaction of complex **1** with KI in THF/acetone at 50 °C afforded the product (1-Et-Ind)$Ni(PPh_3)I$ (**3**) quantitatively. After workup, the red microcrystals were obtained in high yield as identified by elemental analysis and ^1H NMR spectroscopy. Suitable crystals of **3** for X-ray diffraction studies were grown from Et_2O/hexane at 0 °C.

Complexes **1**, **2**, and **3** are soluble in dichloromethane, toluene, DME, THF and diethyl ether. However, complex **1** is completely insoluble in hexane, while complex **2** and **3** have a little solubility in hexane. Due to their good solubility in CH_2Cl_2 or Et_2O and sparing solubility in hexane, they can be crystallized from CH_2Cl_2/hexane (or Et_2O/hexane) in high yield. Notably, their solubility in organic solvents is evidently better than that of bis(triphenylphosphine)halides, e.g., $Ni(PPh_3)_2Cl_2$.

As expected, among these complexes, **1** has the best thermal stability, while **3** has the relatively lower thermal stability. For example, the color of complex **1** remains unchanged at 301–302 °C (its melt point); however, the decomposition of complex **3** is observed at 165–167 °C. Furthermore, complex **1** is slightly sensitive to air and moisture, while both **2** and **3** are sensitive, especially the later one, and can be kept for only a few minutes in open air. However, all of them are relatively more sensitive to air and moisture as compared to the corresponding bis(triphenylphosphine)halides.

2.2. Crystal structures of (1-Et-Ind)$Ni(PPh_3)X$ [X = Cl (**1**), Br (**2**) and I (**3**)]

Since structural data for indenylnickel halides (1-R-Ind)$Ni(PPh_3)X$ have seldom been reported [10], the crystal structures of **1**, **2** and **3** were determined in order to assess the influence of the halogen on the structures of these complexes. Complex **2** and **3** are isomorphous, and the molecular structures of **1** and **2** are presented in Figs. 1 and 2, respectively. The crystallographic data and selected bond lengths and angles for **1**, **2** and **3** are listed in Tables 1 and 2, respectively. The coordination geometries around nickel atoms in **1**, **2** and **3** are similar, i.e., each Ni in these complexes is bound to X, P, C1, C2, and C9 based on the bond distances of Ni to these atoms, while the bond distances of the other two carbon atoms of the five-membered ring, i.e., C3 and C8, to Ni are significantly longer. Inspection of the C–C and Ni–C bond distances for these complexes revealed that the geometry of these complexes around Ni can be described as a distorted square planar with C1=C9 occupying a single coordination site (reflected by a shorter C1–C9 bond relative to C1–C2 bond) (Table 2). In all of these structures, the Ind ligand is significantly distorted away from an idealized η^5 mode toward a fairly unsymmetric η^3 coordination, which is common in this family of complexes [10]. Such distortions can be mainly attributed to the tendency of Ni(II) to avoid forming an 18-electron configuration and the unequal trans influences of the PPh_3 and X (Cl, Br and I) groups [20]. Somewhat to our surprise, except for the Ni–X bond distance, the halogen atom has little effect on the structures of these complexes. For instance, almost the same Ni–Ind interaction occurred in present case. According to the literature [20], the Ni–Ind interaction can be compared



Scheme 1.

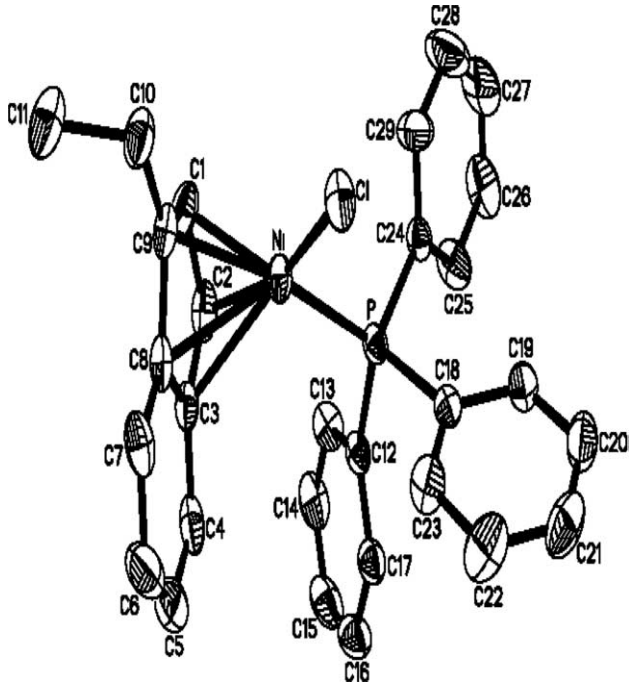


Fig. 1. Molecular structure of complex **1**.

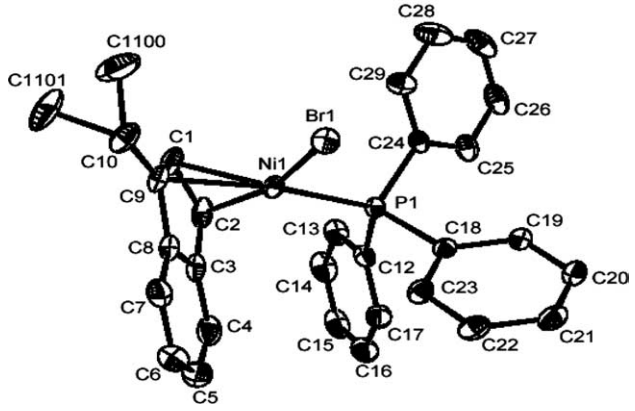

Fig. 2. Molecular structure of complex **2**.

quantitatively by calculating geometrical parameters such as the slip value (ΔM–C) = [M–C_{av} (for C_1, C_5)] – [M–C_{av} (for C_2, C_4)]. In **1**, ΔM–C = 0.256, meanwhile the values of **2** and **3** are 0.250 and 0.246, respectively (Table 2), indicating almost the same slip-fold distortion of the Ind ligand in these complexes. Furthermore, as the observed values of the C1–C9, C1–C2, Ni–C2 and Ni–C9 bond lengths reflect the delocalization of the allyl moiety of Ind ligand, so the local symmetry in the coordination of the allyl moiety are also very similar in **1**, **2** and **3**, and indicate an unsymmetrical η^3 mode Ni–Ind interaction in these complexes. Additionally, the difference among the Ni–P bond distance in these complexes is rather small, and just a bit longer bond distance is observed in **3** [2.1805(9)] as compared to that of in **1** [2.179(1)] or **2** [2.178(1)]. Thus, both Ni–Ind interaction and Ni–P interaction are very similar among these complexes, indicating that the halogen atom play a slight role on these interactions in the indenylnickel halide, which is quite different from the role of the alkyl substituent on indenyl ring [18]. On the other hand, as expected, apparent difference among the Ni–X bond distance in these complexes is observed, i.e., Ni–I > Ni–Br > Ni–Cl (Table 2).

Since the nature of the Ni–Ind interaction in solution is believed to be able to influence substantially the reactivity of Ind complexes, it is important to understand Ind hapticity in solution. Zargarian's group [20] had reported that, for (1-Me-Ind)Ni(PPh_3)Cl (**4**) and its methyl derivative, the ^{1}H NMR resonances for the symmetry-related pairs of protons (H2/H9, H4/H7, and H5/H6) could be used as a convenient indicator of Ind hapticity. Accordingly, they concluded that the solid state structures of these complexes were maintained in the solution. Herein, the same conclusion could also be reached from the paired comparisons of the ^{1}H NMR spectra of these complexes (i.e., **1/4**, **2/4**, and **3/4**), as their ^{1}H NMR spectra are very similar in pairs. For example, the H2 resonance in **1** (3.37 ppm) or in **2** (3.61 ppm) is very close to the corresponding resonance for **4** (3.37 ppm).

*2.3. The catalysis of (1-Et-Ind)Ni(PPh_3)X [X = Cl (**1**), Br (**2**) and I (**3**)] in styrene polymerization*

To the best of our knowledge, the catalytic activity of indenyl nickel complexes for styrene reactions has been reported only by Zargarian's group, a chelating amino-indenyl cationic nickel complex in situ generated from the reaction of (η^3, η^0-Ind–$CH_2CH_2NMe_2$)Ni(PPh_3)Cl and $AgBPh_4$ (or $AgBF_4$) for styrene polymerization or a [(1-Me-Ind)Ni(PPh_3)Cl/$AgBF_4$ system for oligomerization of styrene[16]. Recently, we have found that simple alkyl-substituted indenylnickel complexes [(1-R-Ind)Ni(PPh_3)Cl, R = cyclopentyl and benzyl] could also efficiently initiate the polymerization of styrene in the presence of PPh_3 and $NaBPh_4$, and the alkyl substituent has a manifest effect on the catalytic activity of these complexes [18]. The purpose of $NaBPh_4$ is to abstract the Cl^- ligand from these complexes and facilitate the formation of cationic species [16], while the addition of moderate PPh_3 is of benefit to suppress the decomposition of the cationic species [18]. In the present case, the catalytic activity of (1-Et-Ind)Ni(PPh_3)X [X = Cl (**1**), Br (**2**), I(**3**)] in styrene polymerization has been preliminarily investigated. It is observed that complex **1** or **2** or **3** without $NaBPh_4$ is inert toward the insertion of styrene, however, together with $NaBPh_4$ and PPh_3, they show highly catalytic activity for the polymerization of styrene, and the halogen atom of (1-R-Ind)Ni(PPh_3)X possess an significantly effect on their catalytic activity. For example, when styrene polymerization was carried

out in toluene at 80 °C with $NaBPh_4$/**1**/PPh_3 = 7:1:4 (mole ratio), [styrene]/[**1**] = 300 (mole ratio), the polymer yield could reached 100% after 24 h, but only 84% for **2** and 41% for **3** under the same conditions. The obtained polystyrene is soluble in THF with $M_n = 18\,000$ ($M_w/M_n = 2.1$) for **1**, $M_n = 12\,000$ ($M_w/M_n = 2.6$) for **2**, and $M_n = 9000$ ($M_w/M_n = 1.8$) for **3**. The differences among their catalytic activities are probably due to the different Ni–X distance together with the different thermal stability of these complexes at the polymerization temperature. By the way, some experimental results are in the negative of a radical pathway. Careful experiments showed that the addition of varying amounts of 2,2,6,6-tetramethyl-1-piperidinyloxy (TEMPO), a strong and efficient radical scavenger, only partly reduced the speed of the present styrene polymerization. For instance, when 1% or 2% (referred to monomer weight) amounts of TEMPO were added into $NaBPh_4$/**1**/PPh_3 (in large excess to 1 mol) at the beginning of the polymerization, the polymer yield still remained at 75% (no adding TEMPO, yield is 100%). Meanwhile, styrene polymerization initiated by azobis(isobutyronitrile) (AIBN; conditions are the same as **1**), which is a classical radical initiator, was completely hindered by adding the same amount of TEMPO. Thus, combination with the reported results [16,18] indicate that the present styrene polymerization mainly also be catalyzed by the in situ generated cationic species [1-Et-Ind(PPh_3)Ni(PPh_3)]$^+$, which produced from the reaction of (1-Et-Ind)Ni(PPh_3)X and $NaBPh_4$ in the presence of PPh_3. Further investigations focusing on the detailed structure–activity relationships and mechanistic aspects of the polymerization using these complexes are now in progress.

3. Experimental

All manipulations were performed under pure argon with rigorous exclusion of air and moisture using standard Schlenk techniques. Solvents were distilled from Na/benzophenone ketyl prior to use. 2,2,6,6-Tetramethyl-1-piperidinyloxy (TEMPO) (Aldrich) was used as received. Azobis(isobutyronitrile) (AIBN) were recrystallized from 95% ethanol. Indene (Fluka) (dried over 4 Å molecular sieves) and styrene (dried over CaH_2) were distilled before use. $(PPh_3)_2NiCl_2$ [21] and $(PPh_3)_2NiBr_2$ [22] were prepared by published methods. 1-Ethylindene was prepared according to the literature method [23]. Melting points were determined in sealed Ar-filled capillaries and are uncorrected. Carbon and hydrogen analyses were performed by direct combustion on a Carlo Erba-1110 instrument; quoted data are the average of at least two independent determinations. ^1H NMR (C_6D_6) spectra were measured on a Unity Inova-400 spectrometer. Molecular weight and molecular weight distributions were determined against polystyrene standard by gel permeation chromatography (GPC) on a Waters 1515 apparatus with three HR columns (HR-1, HR-3 and HR-4); THF was used as an eluent at 30 °C.

3.1. Synthesis of (1-Et-Ind)Ni(PPh_3)Cl (1)

A Schlenk flask was charged with 1-Et-Ind (0.43 g, 3 mmol), Et_2O (30 ml) and a stir bar. To this solution was added a solution of *n*-BuLi in hexane (2.3 ml, 3 mmol) dropwise via syringe at 0 °C. The solution was stirred for 30 min and then added slowly to a stirring suspension of $Ni(PPh_3)_2Cl_2$ (3.53 g, 5.4 mmol) in Et_2O (60 ml) at 0 °C. The color of the solution immediately changed to red. The resultant solution was then stirred for another 40 min at room temperature, filtered, and evaporated to dryness. The residue was washed with hexane (3× ca. 20 ml) to remove PPh_3 and other byproducts and recrystalized from CH_2Cl_2/hexane at −30 °C to give the product as a dark red needle crystals (869 mg, 58%) suitable for elemental analysis, m.p. 301–302 °C. *Anal.* Calc. for $C_{29}H_{26}$ ClNiP: C, 69.74; H, 5.21. Found: C, 69.65; H, 5.25%. ^1H NMR (400 MHz, C_6D_6): 7.80 (t, 1H, H6), 7.69 (m, 5H, P*Ph*$_3$), 7.40 (m, 1H, H7), 7.02 (m, 10H, P*Ph*$_3$), 6.89 (t, 1H, H5), 6.42 (br s, 1H, H2), 6.16 (d, 1H, H4), 3.37 (br s, 1H, H1), 1.80 (m, 2H, *CH*$_2$), 1.39 (d, 3H, *CH*$_3$). Crystals suitable for X-ray diffraction studies were obtained by recrystallization from Et_2O/hexane at 0 °C.

3.2. Synthesis of (1-Et-Ind)Ni(PPh_3)Br (2)

The synthesis of compound **2** was carried out as described for **1**, but a solution of $Ni(PPh_3)_2Br_2$ (4.01 g, 5.4 mmol) in DME (60 ml) was used in place of the solution of $Ni(PPh_3)_2Cl_2$ (3.53 g, 5.4 mmol) in Et_2O. The dark red product was obtained by recrystallization from CH_2Cl_2/hexane at −30 °C (979 mg, 60%), m.p. 285–287 °C. *Anal.* Calc. for $C_{29}H_{26}BrNiP$: C, 63.31; H, 4.68. Found: C, 64.02; H, 4.82%. ^1H NMR (400 MHz, C_6D_6): 7.68 (m, 5H, P*Ph*$_3$), 7.40 (t, 1H, H6), 7.14 (m, 1H, H7), 7.02 (m, 10H, P*Ph*$_3$), 6.90 (t, 1H, H5), 6.35 (br s 1H, H2), 6.17 (d, 1H, H4), 3.61 (br s, 1H, H1), 2.01 (m, 1H, *CH*$_2$), 2.47 (m, 1H, *CH*$_2$), 1.37(t, 3H, *CH*$_3$). Crystals suitable for X-ray diffraction studies were obtained by recrystallization from Et_2O/hexane at 0 °C.

3.3. Synthesis of (Et-Ind)Ni(PPh_3)I (3)

A Schlenk flask was charged with a solution of **1** (499 mg, 1 mmol) in THF (20 ml) and a stir bar. To this solution, a solution of KI (200 mg, 1.2 mmol) in acetone (10 ml) was added. The resultant mixture was stirred for 12 h at 50 °C, evaporated to dryness and extracted with Et_2O. The product was obtained by evaporization of the solvent as a red solid (ca. quantitative yield), m.p. 165–167 °C (dec.). *Anal.* Calc. for $C_{29}H_{26}INiP$: C, 58.92; H, 4.43. Found: C, 58.54; H, 4.53%. ^1H NMR(400 MHz, C_6D_6): 7.66 (m, 5H, P*Ph*$_3$), 7.41 (t, 1H, H6), 7.14 (m, 1H, H7), 7.03 (m, 10H, P*Ph*$_3$), 6.94 (t, 1H, H5), 6.35 (br s 1H, H2), 6.17 (d, 1H, H4), 3.93 (br s, 1H, H1), 2.87 (m, 1H, CH_2), 2.46 (m, 1H, *CH*$_2$), 1.37 (t, 3H, *CH*$_3$). Crystals suitable for X-ray diffraction studies were obtained by recrystallization from Et_2O/hexane at 0 °C.

3.4. A typical procedure for polymerization of styrene

A typical polymerization reaction is as follows. Under dry argon, the solid initiator **1** (10 mg, 0.02 mmol), PPh_3 (21 mg, 0.08 mmol), $NaBPh_4$ (48 mg, 0.14 mmol), toluene (0.2 ml) and styrene (1.2 ml, 0.01 mol) were added into a dry glass ampule in turn. Then, the sealed ampule was placed in a water bath held at 80 °C. After a definite reaction time, the polymerization was stopped by adding 1 ml of 5% HCl/ethanol. After evaporation of solvent and unreacted monomer, the resulted polymer was dissolved in THF, followed by precipitation in 95% ethanol. After filtration, the white polymer was dried in vacuum at room temperature overnight. The polymer yield was determined gravimetrically.

3.5. X-ray structural determination of 1, 2 and 3

Suitable single crystals of complex **1**, **2** and **3** were each sealed in a thin-walled glass capillary for X-ray structural analysis. Diffraction data were collected on a Siemens SMART CCD area detector using theta scans for **1**, or a Rigaku Mercury CCD area detector using omega scans for **2** and **3**. The crystal structures of **1** and **3** were solved by direct methods using the SHELXS-97 program, and the crystal structures of **2** was solved by

Patterson methods using the CRYSTALSTRUCTURE program. All the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were treated as idealized contributions.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge crystallographic data Center, CCDC Nos. 225155, 223964 and 227411 for complexes **1**, **2** and **3**, respectively. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 20 February 2004; accepted 1 April 2004

Abstract

This review based on 169 references gives an actual overview on group 1 and 2 clusters with oxygen donor ligands. A first part deals with alkali metal compounds of which synthesis and the most important structurally characterized examples a presented in detail. Homo- and heterometallic aggregates of group 1 metals as well as mixed group 1 and 2 compounds are classified with respect to the ligand type. Finally, alkaline earth metal clusters are treated, starting with Mg-compounds, then pursuing with the heavier homologues. This chapter also contains a brief description of CVD and sol-gel methods.

Keywords: Alkoxides; Enolates; β-Diketonates; Carboxylates; Alkali metals; Alkaline earth metals; Cluster compounds

1. Introduction

During the past years, two major tendencies are found for the motivations of doing research in s-block chemistry. The first one is based on the formation of polymetallic complexes with alkali and/or alkaline earth metals mainly based on organic oxygen or nitrogen donor ligands. These organo-heterometallic compounds are of interest due to their enhanced reactivity compared to their homometallic homologues. This higher reactivity induces an important role in synthetic chemistry, especially based on the superbasic character of such species. The second motivation is related to the application of alkali and alkaline earth metals in materials. The oxides and halides of s-block elements occupy an especially important place. They can act as material themselves with a proper functionality or else as precursor for more complicated materials such as superconductors. The high temperature synthesis of such oxide materials is generally more complicated for s-block elements due to the ionic character of their oxides, the hygroscopy of the compounds, and the reactivity of s-block metal oxides towards carbon dioxide in order to form carbonates. This is why an alternative had to be found for the controlled elaboration of these compounds during the past 15 years. So in parallel, a molecular route was tested, compared to the traditional solid-state synthesis, evidencing more flexible synthetic methods such as metal-organic chemical vapor deposition (MO-CVD) or sol–gel techniques.

This review will deal with the recent developments of ''organo-metallic'' compounds of s-block elements, with a focus on the synthesis and characterization of polymetallic compounds with mainly M–O bonds. It is meant to give an overview on the most significant clusters containing O-donor ligands such as alkoxides/aryloxides, enolates, β-diketonates or carboxylates. The compounds are regrouped by the type of ligands, first the pure group 1 metals, then mixed alkali and alkaline earth metal compounds, and finally group 2 metals. They are chosen for their originality and variety in structure and synthesis. The recent results in this field,

doi:10.1016/j.poly.2004.04.014

presented in this review, give rise to high expectations as to new compounds and structural varieties, which are yet to be discovered.

The polymetallated compounds that are dealt with in this review will be called "clusters" in the sense of aggregates of two or more metal atoms with bridging ligands, not necessarily implying that metal–metal bonds are present (which is a more strict definition of the term "cluster" in transition metal chemistry).

2. Alkali metal clusters

2.1. General introduction

Historically, a great number of alkali metal clusters was merely discovered by serendipity as secondary products using superbases [1] or metallation agents [2] in organic synthesis. However, many of the structures as well as the formation mechanisms for these species remain to be investigated. The so far characterized clusters possess very interesting structures, such as tetramers, hexamers, nonamers or decamers, which might explain their reactivity. Indeed, larger aggregates seem to exhibit an enhanced reactivity compared to more simple compounds.

Organo-lithium compounds show some typical properties known for covalent species: solubility in non-polar solvents and volatility. Thus, the lithium clusters were among the first discovered ones, as unexpected intermediates or secondary products during metallation reactions. Some of them are now used as reagents in organic synthesis and possess fascinating structures. They are known for their formation of aggregates in solution, the gas phase, and the solid state [3]. Small alkali metal cations have been found to form cage structures, whereas clusters of the heavier homologues are almost unknown [4].

The reactivity of organometallic compounds MR in general can be increased considerably by addition of Lewis bases, such as amines or alkoxides M′OR′. This important effect is based on the formation of mixed aggregates of for instance [(MR)(M′OR′)], yielding a "superbase". A better solubility in organic solvents is observed, which is reflected in higher reactivity as well.

Since many of these compounds are air and/or moisture sensitive, the single crystal structure resolution is usually delicate. However, the great interest in alkoxides and enolates of alkali metals pushed forward the investigations of these compounds.

2.2. Homo-ligand homo-metallic clusters

2.2.1. Alkoxides

The use of alkoxides as reagents or building blocks in organometallic synthesis often depends on their solubility, a property derived from their structure [5]. The regain in interest of alkali alkoxides also resides in the discovery of high-temperature superconducting compounds which has generated a great interest in the formation of oxide materials and other ceramics. Soluble alkoxides can thus serve as valuable precursors for making metal oxides under rather mild conditions as encountered by sol–gel methods or chemical vapor deposition (CVD) [6,7].

2.2.1.1. General synthesis of $M(OR)_x$ for cluster formation. Compounds of the type $M(OR)_n$ and $L_xM(OR)_y$ (R = alkyl or aryl, L_x = other neutral or anionic ligands, n, y = integers) are accessible via several synthetic procedures of which the most relevant are listed below. The methods of preparation are often chosen as a function of the electronegativity of the metal [8].

Alkoxides and phenoxides can be obtained by direct reactions of the crude metal which is dissolved in the corresponding alcohol, following the reaction:

$$M + ROH \rightarrow MOR + 1/2\,H_2 \quad (1)$$

The interest in this reaction clearly relies on the fact that the secondary product, hydrogen, is volatile, allowing easy purification of the product. This method is limited to the more electropositive metals (group 1) due to the high pK_a values of the most common alcohols and phenols. For the less electropositive metals, a catalyst is necessary to start the reaction, in general I_2 or HgX_2.

Alkali metal alkoxides and phenoxides can also be prepared by a reaction of the metal hydroxide with the alcohol:

$$MOH + ROH \rightarrow MOR + H_2O \quad (2)$$

The water formed during this reaction has to be eliminated by azeotropic distillation, for instance with NaOH dissolved in a mixture ethanol/benzene under reflux. The more acidic phenols allow formation of the group 1 phenoxides more readily by simple heating of the hydroxide in dried ethanol, followed by recrystallization. Magnesium phenoxide is obtained commercially by a reaction of MgO with phenol.

Finally, beryllium and magnesium form mixed compounds of the type RMOR′ which are obtained by reaction of an organometallic compound MR_2 (R = alkyl or H) with the alcohol R′OH. The carbanion or the hydride reacts then with R′OH to give R′OM in good yield. The secondary product is usually volatile (hydrogen or alkane) [9,10].

2.2.1.2. Physical and spectroscopic properties. Given the strong electronegative character of oxygen, mainly ionic character for the metal–oxygen bond can be expected. However, most of the alkoxides present properties such as solubility in non-polar solvents and volatility due to their hydrophobic envelope formed by more or less

sterically demanding alkyl chains. Many alkali metal monoalkoxides are neither volatile nor soluble and decompose when heated. They possess a very ionic character and form polymers. Li*O*t*Bu* is an exception to this rule as it can be sublimed at 110 °C and a pressure of 1.1 torr and is soluble in most organic solvents, such as cyclohexanes and benzene.

2.2.1.3. Structural varieties. (a) *Non-solvated pure alkoxides.* The progress made during the last 15 years in the techniques of single crystal data acquisition allowed the screening of the structures of a large number of organometallic group 1 and magnesium compounds. They show a variety of possible structure types, such as cycles, hetero-cubanes, chains, layers, etc.) (Fig. 1). These structural types can be applied to carbanions as well as amides, imides, halides, and oxygen-donor ligands such as alkoxides, phenoxides, and enolates. The first monographies by Bradley in 1978 and Malhotra in 1982 show, however, that the investigations of alkoxide and phenoxide compounds are more recent than the ones on organometallic compounds [11,12].

The geometry of the structures depends very much on the steric demand of the group R. Since the classical synthesis is carried out in organic solvents, uncoordinating solvents will lead to solvent-free structures, whereas coordinating solvents may lead to the formation of other structures.

The unsolvated group 1 methoxides of type MOMe (M = Li–Cs) and some iso-propanolates M*O*^{i}*Pr* (M = K–Cs) form sheet-like infinite structures [13–19]. So do some of the methoxides of the alkaline earths Ca, Sr, and Ba [20–22]. The alkoxide groups of these structures are oriented toward the outside of the layers, whereas the cations are distributed inside the structure on one (Li, Na, Ca, Sr, and Ba) or two different sites (K, Rb, and Cs), depending on their charge and radius. Due to their polymer arrangement in layers, these compounds are neither volatile nor soluble in organic compounds.

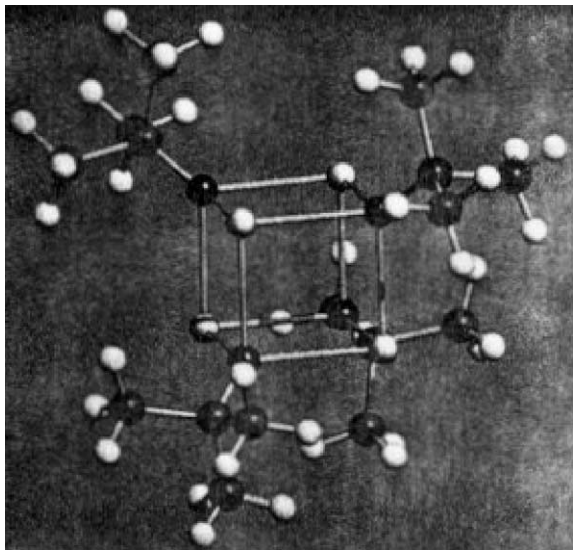

Fig. 2. The cubane structure of (KO*t*Bu)$_4$. Isotypic structures include [MO*t*Bu]$_4$ (M = Rb, Cs) and [MOSiMe$_3$]$_4$ (M = K, Rb, Cs) [23–26].

The formation of layers is not possible any more with sterically more demanding groups R. Then, spherical or cyclic structures are built and molecular compounds are obtained. This is the case for *tert*-butoxides. The first ones to be discovered, (MO^{t}*Bu*)$_4$, M = K, Rb, Cs [23–26], are all tetrameric and build cubane structures (Fig. 2).

The metal and the oxygen atoms sit on alternating corners of a distorted cube. The compounds are soluble and volatile due to their structures where the shell of the

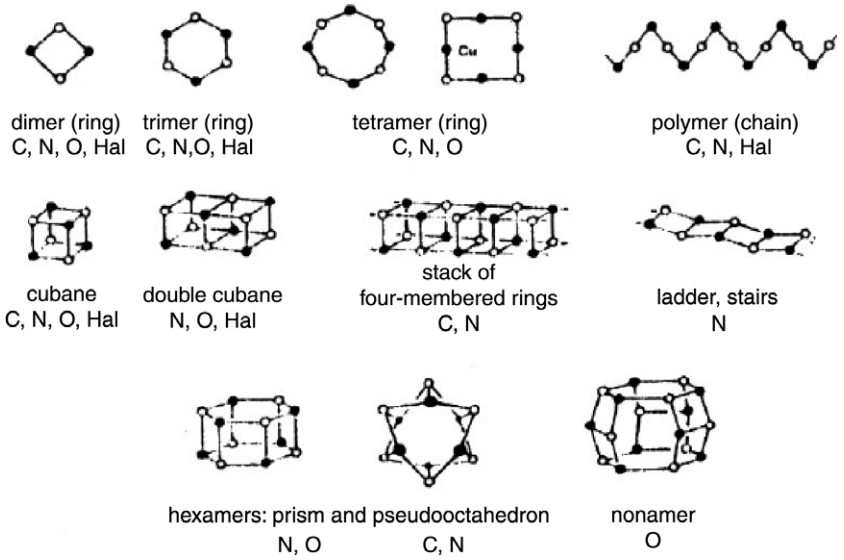

Fig. 1. Important idealized coordination types for ion aggregates of the alkali metals (•) with C, N, O, and halogen anions (○) [11,12].

structure exhibits a highly hydrophobic character. The determination of molar masses in solution by colligative methods and in aprotic solvents usually indicates a similar state of aggregation as in the solid state [27]. The structures are also maintained in the gas phase as can be deduced from the mass spectrum of $(KO^tBu)_4$ [28,29].

The structure of the lighter homologue, sodium, is particularly interesting as in the unit cell, two types of aggregates coexist. Hexamers $(NaO^tBu)_6$ and nonamers $(NaO^tBu)_9$ are found in the solid state (Figs. 3(a) and (b)) [23–26]. Whereas the cubane structure can be interpreted as a stacking of two dimers M_2O_2 to give a ring, the trigonal prismatic structure of the hexamer can be seen as stacking of three entities M_2O_2 arranged to a ring. The nonamer can then be interpreted as fusion of three deformed cycles of M_3O_3.

For many years, several attempts have been made to solve the crystal structure of Li*O*t*Bu*. The structure has been confirmed to be hexameric in the gas phase as well as in solution [28–30]. Only recently, in 1998, a non-solvated hexamer was described from an octane solution [31]. Very recently has the crystal structure been obtained by the authors' group as well as by Olbrich and co-workers [32,33]. As for the sodium homologue, two independent molecules are found in the unit cell. In contrast to the sodium compound, both are hexamers. They are different insofar as they possess different symmetry. The oxygen atoms of the O*t*Bu groups form a regular octahedron. The six lithium atoms are then delocalized over the eight equivalent triangular faces of the octahedron. This is why disorder is so great in this structure and structure solution was problematic (Fig. 4).

This type of coordination is also found in the copper compound $[Li_7(OtBu)_6][Cu_2(Si(SiMe_3)_3)_3]$ in which the hexagonal prism of $(LiOtBu)_6$ is capped on one side by a Li^+ (Fig. 5) [34].

(b) *Superbasic compounds of type [(RM)(MOR′)] (R, R′ = alkyl)*. The lithiated compound $[(n\text{BuLi})(LiOtBu)]_4$ is an example for a superbasic compound with a tetrameric structure containing a core Li_8O_4 which builds a structure of three stacked hetero-cubanes as shown in Fig. 6 [35]. The four central lithium ions are

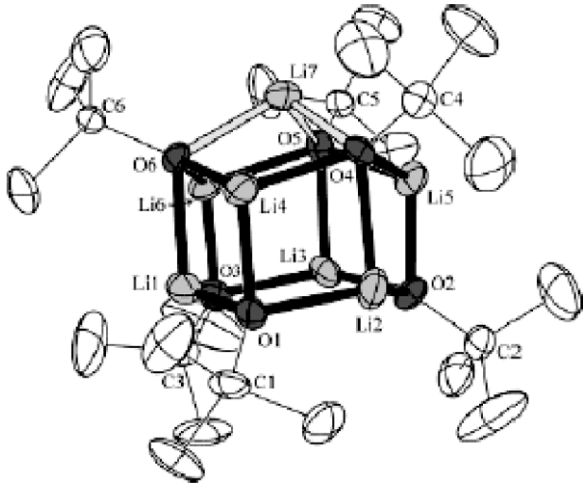

Fig. 5. ORTEP structure of the cationic species $[Li_7(OtBu)_6]^+$ [34].

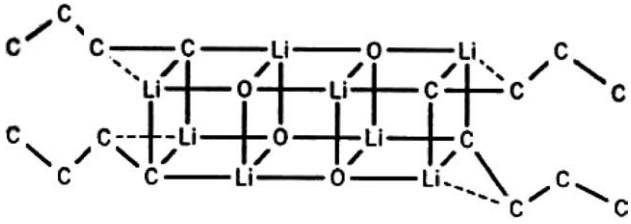

Fig. 6. Schematic drawing of $[(LinBu)(LiOtBu)]_4$ [35].

coordinated by one carbon atom of the *n*Bu groups and three oxygen atoms of the anions O*t*Bu. The four outer lithium cations are linked to one oxygen atom, two α-

carbon atoms, and one β-carbon of *n*Bu groups. This compound is soluble in apolar and aprotic solvents as benzene.

(c) *Superbasic compounds of type [(ROM)(MOH)].* The alkoxide LiO*t*Bu can also be built into a larger aggregate structure, as can be seen from the following example of a mixed anion compound, which can be written as $(LiOtBu)_{10}(LiOH)_6$ and was described in 1995 [36]. This compound was simply obtained by partial hydrolysis in air of a solution of LiO*t*Bu, as described by the following reaction scheme:

$$16LiOtBu + 6H_2O \rightarrow (LiOR)_{10}(LiOH)_6 + 6HOR \quad (3)$$

Complete hydrolysis leads to the formation of the alcohol and precipitation of LiOH. The single crystal structure of the above compound can be described as a centrosymmetric dimer of hexagonal prismatic moieties of $Li_6(OtBu)_5(OH)$, which themselves are linked by a crossed ladder-type arrangement of LiOH-units (Fig. 7). The latter structural motif is also often found in lithium amide chemistry for $LiNR_2$-compounds.

(d) *Solvated compounds.* The larger the organic ligand R is, and the more sterically hindering it is, the smaller the clusters which are formed. Thus, compounds with an extremely low coordination number for the metal ions can be realized. This is the case for the dimer $[Li(OCtBu_3)]_2$ which was characterized in solution as well as in the solid state. The crystals are obtained at −25 °C after a room temperature reaction of *n*BuLi with the corresponding alcohol [37]. A solvated form of this compound was isolated as $[\{Li(OCtBu_3)(thf)_2\}]$ where two THF-molecules complete the coordination spheres of the lithium ions which reach a coordination number of 3 [38]. The Li–O distances are therefore also longer than in the non-solvated compound (1.83–1.85 Å). The sterical hindering of the ligand is so important that dimerisation is impossible, avoiding therefore the formation of the typical and more often encountered heterocubane structure, even though the coordination numbers of the metal atoms are rather low.

(e) *Compounds of type $[(ROM)_x(HOR)_y]$.* The alkoxides which are solvated by their parent alcohol are mostly known for the first elements of a series of the periodic table of elements, and only few structures are described, i.e. $[(KOtBu)(tBuOH)]$ [39–42]. For $x = 1$ and $y = 2$, $[Li(OMe)(MeOH)_2]$ can be found as an example; it possesses a tetramer unit of $[Li_4(\mu\text{-}OMe)_4(\mu\text{-}MeOH)_2(MeOH)_4]\cdot 2MeOH$. The structure can be described as two distorted squares of $[Li_2(OMe)(MeOH)]$ linked by bridging methoxy ligands and hydrogen bonds (Fig. 8) [43]. This compound easily looses the solvating molecules of alcohol to give the polymeric structure of LiOMe described before.

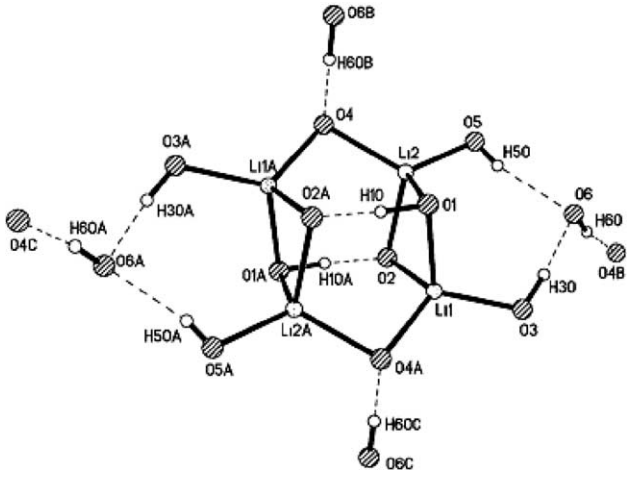

Fig. 8. Structure of $[Li_4(\mu\text{-}OMe)_4(\mu\text{-}MeOH)_2(MeOH)_4]\cdot 2MeOH$ [43].

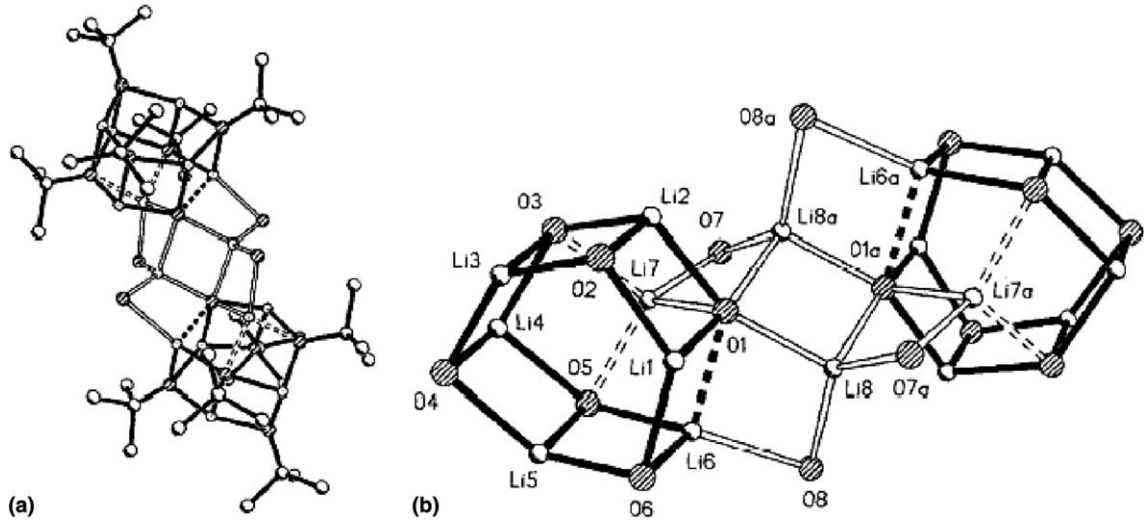

Fig. 7. Structural arrangement in $(LiOtBu)_{10}(LiOH)_6$: (a) of the molecule, (b) of the core [36].

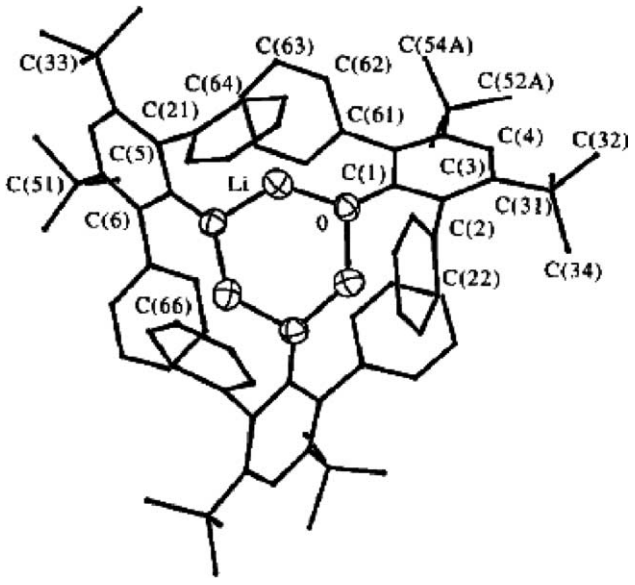

Fig. 10. ORTEP structure of [{Li(μ-OAr)}$_3$](2,6-diphenyl-3,5-di-*tert*-butylphenoxide = OAr) [45].

2.2.2. Aryloxides

The lithium aryloxides can be prepared similar to the methods encountered before for the alkoxides. The degree of aggregation depends also on the steric demand of the phenoxide and on the presence or absence of a Lewis base. Thus, the simple lithium phenoxide forms a hexameric structure of $[Li(\mu_3\text{-}OPh)(thf)]_6$ at the solid state as well as in solution (Fig. 9) [44], whereas the sterically more demanding ortho-substituted lithium 2,6-di-*tert*-butylphenoxide builds dimers of composition $[Li(\mu\text{-}OC_6H_3{}^tBu\text{-}2,6)(thf)]_2$.

In the case of aryloxides, substitution in meta-positions reduces the tendency to form cyclic anti-prismatic aggregates. Thus, the sterically important alcohol 2,6-diphenyl-3,5-di-*tert*-butylphenoxide (HOAr) reacts with *n*BuLi in toluene to give a lithiated trinuclear species [{Li(μ-OAr)}$_3$][45]. A six-membered ring is formed, alternating Li and O, with the phenyl groups of the ligand pointing alternatingly up and down of the ring plane. Due to this bulk, fusion of two rings to yield the hexagonal anti-prism is inhibited (Fig. 10).

Basic adducts of alkoxides and phenoxides are formed from alkoxides as well as organometallic compounds. Those with alkoxides are rare. Apart from alkali metal enolates, two examples found in the literature are the dimers of phenoxides, $[Li(p\text{-}OC_6H_4Br)(tmeda)]_2$ and $[Na(OPh)(pmdeta)]_2$ [46,47]. The lithium has a coordination number of 4, sodium of 5, and in both structures dimers of M_2O_2 are found [46,47]. Only a few more substituted phenoxides possess cyclic structures as well, such as $[Li(OC_6H_3\text{-}tBu_2\text{-}2,6)(OEt_2)]_2$ and $[Li(OC_6H_2Me\text{-}4\text{-}tBu_2\text{-}2,6)(OEt_2)]_2$ [48], and $[Na(OC_6H_2(CF_3)_3\text{-}2,4,6)(thf)_2]_2$ [49], which are also arranged in dimers M_2O_2. The compound $[Li\{OC_6H_2\text{-}2,6\text{-}(CH_2NMe_2)_2\text{-}4\text{-}Me\}]_3$ is a special case where a cyclic trimer $(LiOR)_3$ is formed by internal solvation by the two amino substituents [50]. In these compounds, lithium usually has the coordination number of 4.

With bulky ligands as in $[Li(OC_6H_2Me\text{-}4\text{-}tBu_2\text{-}2,6)(OEt_2)]_2$ [48], the lithium ion adopts a coordination number of three, the overall compound possessing an almost spherical structure with the alkyl groups pointing

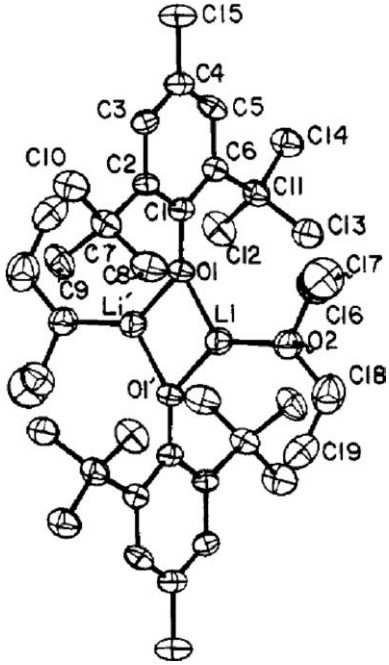

Fig. 11. ORTEP structure of $[Li(OC_6H_2Me\text{-}4\text{-}tBu_2\text{-}2,6)(OEt_2)]_2$ [48].

to the surface of the sphere. Hence, it possesses unexpectedly good solubility in hydrocarbons (Fig. 11).

$$2n\mathrm{BuLi} + 2\mathrm{ArOH} \overset{\mathrm{OEt_2}}{\rightarrow} (\mathrm{LiOAr} \cdot \mathrm{OEt_2})_2 + 2\mathrm{C_4H_{10}} \qquad (4)$$

2.2.3. Enolates

The enolate anions are other widely used ligands in the construction of clusters. An enolate is a nucleophilic reagent through the carbon as well as the oxygen atom and is very useful in organic synthesis.

Seebach [51] has shown that the chemistry of lithium enolates is well developed. The aggregates generally form dimers, tetramers or hexamers. The cited examples show that the degree of aggregation depends less on the structure of the enolate but on the otherwise present complexing agents [52]. Thus, dimers are more readily formed in the presence of polydentate ligands, i.e., ethylene diamine and its derivatives, whereas tetramers are obtained with ether ligands such as THF [51,53]. In solution, aggregates are formed as well, as for instance the lithiated derivative of isobutyrophenone which exists as a tetramer with a heterocubane structure, oxygen and lithium alternating on the corners of the cube [54,55].

In 1981, reports of two lithium enolates derived from pinacolone and cyclopentanone were published. Already identified in solution, they also form tetramers in the solid state, their structure being based on the heterocubane Li_4O_4 moiety, with the lithium atoms also solvated by one THF each [56]. In 1985, Williard and Carpenter [57] described the structure of the unsolvated lithiated pinacolone, which forms a hexamer. With sodium and potassium, the corresponding pinacolones

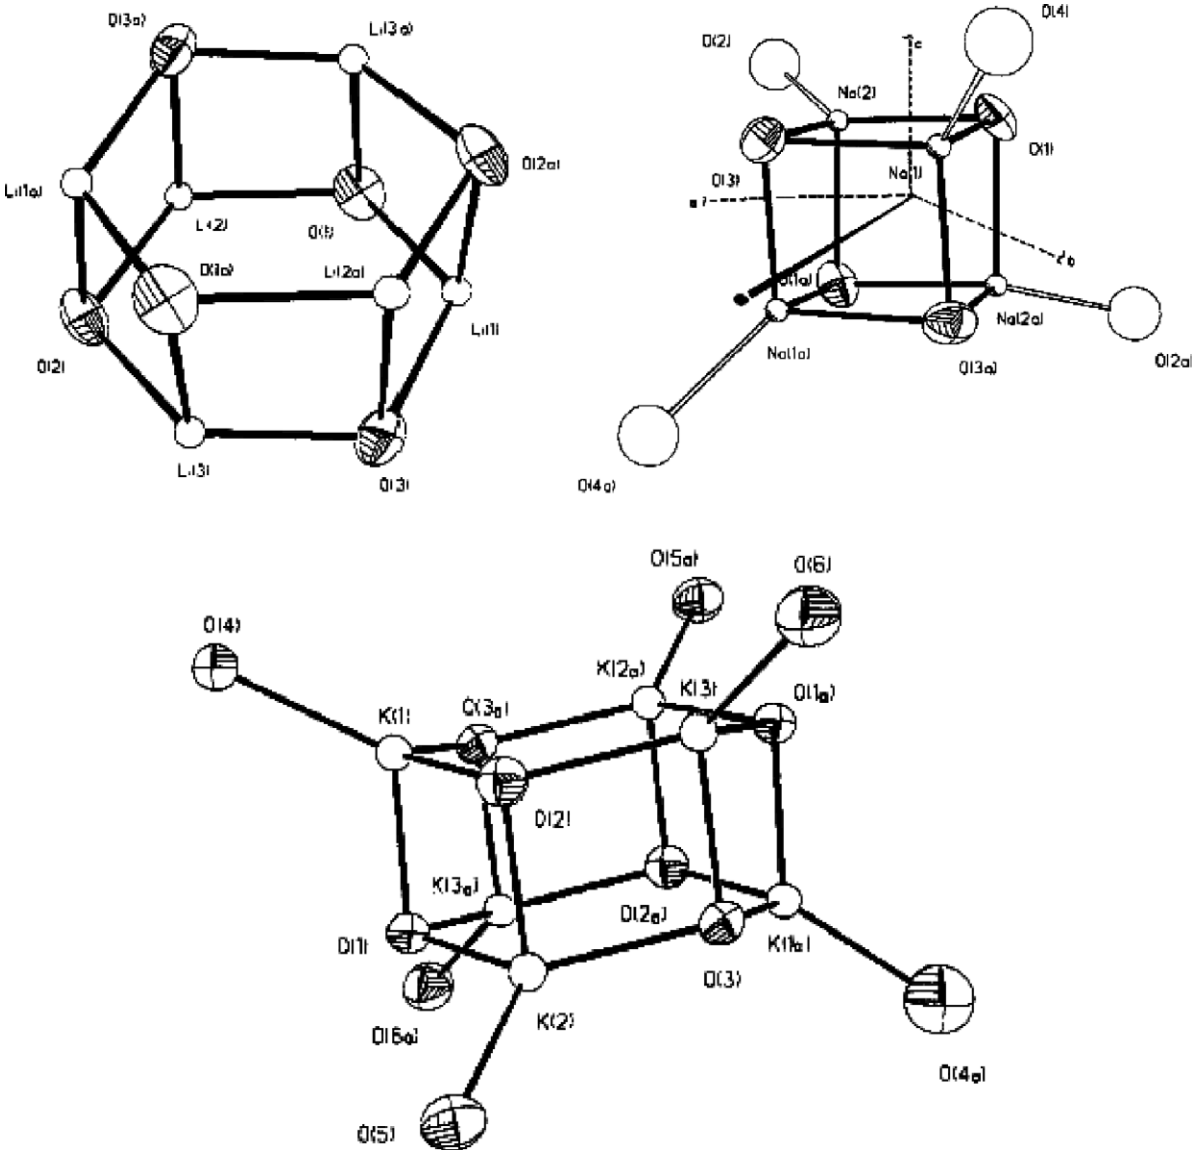

Fig. 12. ORTEP structure comparison for metallated pinacolone with Li, Na, and K, solvated and un-solvated structures [57,58].

were also obtained by reaction of the metal amide with pinacolone [58]. This allows comparison of the structures as a function of the cation size (Fig. 12). Thus, the tetrameric enolate of sodium, solvated by pinacolone, $[NaOC(=CH_2)(t\text{Bu})\{O=C(Me)(t\text{Bu})\}]_4$ presents similarities with the cubane structure of the lithiated compound solvated by THF, $[LiOC(=CH_2)(t\text{Bu})(thf)]_4$. The non-solvated lithiated pinacolone $[LiOC(=CH_2)(t\text{Bu})]_6$ forms a hexamer in which the presence of π interactions of the $=CH_2$ groups and the lithium cations inhibits the stacking of the Li_3O_3 cycles [58]. For the potassium compound, the stacking is inhibited by solvating THF molecules, so that a hexamer, $[KOC(=CH_2)(t\text{Bu})(thf)]_6$, is obtained [57].

This solvated potassium structure can be compared to the tetrameric sodium compound described earlier. The size of the aggregate has been found to apparently augment with the size of the cation, which is the inverse tendency, observed for non-solvated M*O*t*Bu*. The unsolvated lithium derivative has the same structure as the solvated higher homologues, so that solvation generally leads to smaller clusters and inhibits aggregation. Comparing the hexameric structures reveals that the larger potassium ion is displaced out of the hexameric prism, whereas the lithium resides more inside of the prism. The differences in structure are also probably responsible for the differences in reactivity. With a sterically more important Lewis base, the lithium pinacolone forms dimeric units, $[LiOC(=CH_2)(t\text{Bu})(tmeda)]_2$, [59] with the typical M_2O_2 rings and a coordination number of four for the lithium ions.

2.3. Homo-metallic hetero-ligand clusters

In 1995, Williard et al. described a homo-metallic dimer which was obtained from a mixture of anionic ligands, one alkoxide and one amide. $[\{Pr_2NLi\}\{(Me_2NCH_2)_2CHOLi\}]_2$ was obtained by reaction of *n*BuLi on di-isopropylamine and 1,3-bis(dimethylamino)-2-propanol in hexanes [60]. The structure consists of two four-membered cycles [LiNLiO], which are linked together via a $[LiO]_2$ unit in order to give a ladder-like motif (Fig. 13). This structure has been confirmed by ^{6}Li NMR in solution.

With sodium, homo-metallic hetero-ligand clusters exist as well. Thus, Bock et al. [61] have recently described a cluster with 14 sodium ions, $[(Na_8O)Na_6(bpy)_6(tmeda)_6]$, which compares well to the general structure that transition metal clusters adopt with the metal atoms in the cluster core, protected by bulky ligands. Two types of ligands act as protecting ligands: one with oxygen and the other with nitrogen donor atoms (Fig. 14).

2.4. Hetero-metallic hetero-ligand clusters

As described above, the organo-lithiated compounds MR, (alkyls, amides or enolates) with alkali metal alkoxides M′OR′ (M = Na, K, Rb, Cs; R′ = O*t*Bu), for instance BuLi/KO *t*Bu, are known as superbases. These reagents with enhanced reactivity are capable of chemo-, region- or stereo-selective reactions compared to the all-lithiated compounds [1]. The increase in reactivity of the obtained mixtures of RLi/MOR′ seems to be due to metal ion exchange, yielding RM/LiOR′. Electrostatically, the interaction of the small and hard cation Li^+

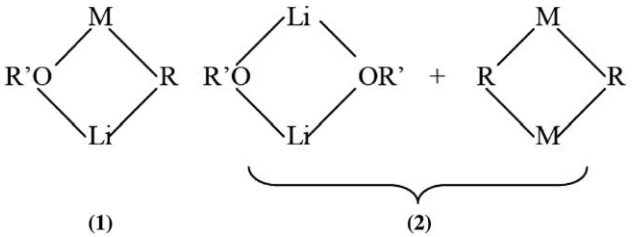

Scheme 1. Formation of superbases.

with the hard oxygen anion is favorable. In addition to this, these compounds form aggregates in solution as well as in the solid state [62–64]. The aggregates can exist either as mixed aggregates of monomers RM and R′OM (1) or as separate aggregates RM and R′OLi (2), as shown in Scheme 1.

The crystallization of such clusters is extremely difficult, as generally a simple mixture of compounds leads to the precipitation of homo-metallic species. This does however not exclude the existence of the mixed metal compounds in solution, as these precipitates simply correspond to the less well soluble species [65,66].

Mixed-metal hetero-ligand compounds were, for instance, obtained by heating to reflux an equimolar mixture of sodium 2,4,6-trimethyl-phenoxide with *n*BuLi in hexanes under an inert atmosphere [67]. The single crystal structure of the obtained compound can be described as a tetrameric aggregate of the composition $[Li(OC_6H_2\text{-}4,6\text{-}Me_2\text{-}2\text{-}CH_2Na)(tmeda)]_4$, and it is the very first example of a mixed aggregate between an organo-sodium compounds and a lithium alkoxide. The ligand plays the role of both R and R′ (Fig. 15).

In 1989, the group of Williard et al. co-crystallized at low temperature the *tert*-butoxides of lithium or potassium with the pinacolates of lithium or potassium in THF. They obtained the first hetero-metal (Li/K) hetero-ligand (alkoxide/enolate) compound $[Li_4\{OC(=CH_2)(t\text{Bu})\}_4K_4(O t\text{Bu})_4(KOH)(thf)_5]$ [68]. The cations and oxygen atoms form a dome (Fig. 16), protected by the diverse ligands.

The same group has also described the first example of a hetero-metallic enolate which contains a protic ligand, a secondary amide, in its structure. Thus, the deprotonation reaction of pinacolone with LDA/NDA leads to the formation of a cluster with six metal ions, $[Li_2Na_4\{C(=CH_2)(t\text{Bu})\}_6(HNiPr_2)_2]$ [69]. It has an open hetero-cubane structure, where two $[LiNa_3O_4]$ cubes with one open edge are fused together via a $[Na_2O_2]$ face. It can also be described as partially open ring-stacking structure where two $[LiO_2Na]$ rings sandwich a $[Na_2O_2]$ ring (Fig. 17).

Two of the sodium ions are pushed slightly out of the cubanes due to their larger size compared to lithium and their interaction with the di-isopropylamine molecules.

Following this result, sodium was introduced in many other organo-lithium compounds in order to obtain more basic and nucleophilic reagents which are more performing than the simple lithiated homologues. With the same aim to increase reactivity and selectivity, the first trimetallic alkali metal clusters were synthesized, following the reaction below [70]

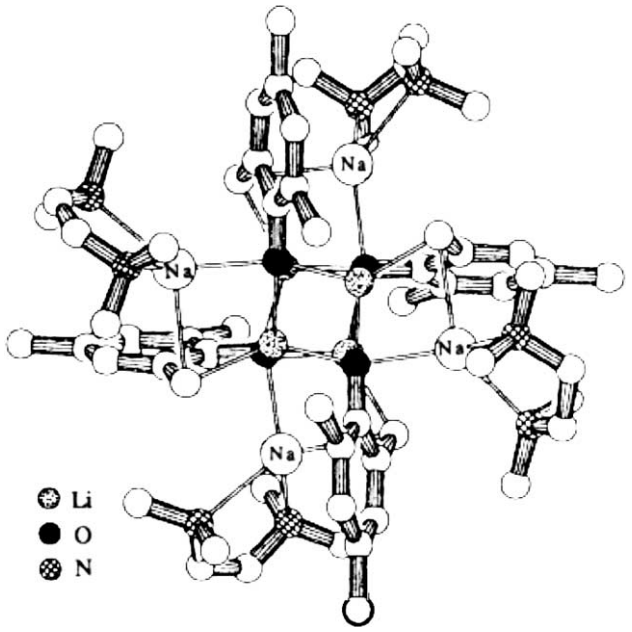

Fig. 15. Structure of $[Li(OC_6H_2\text{-}4,6\text{-}Me_2\text{-}2\text{-}CH_2Na)(tmeda)]_4$ [67].

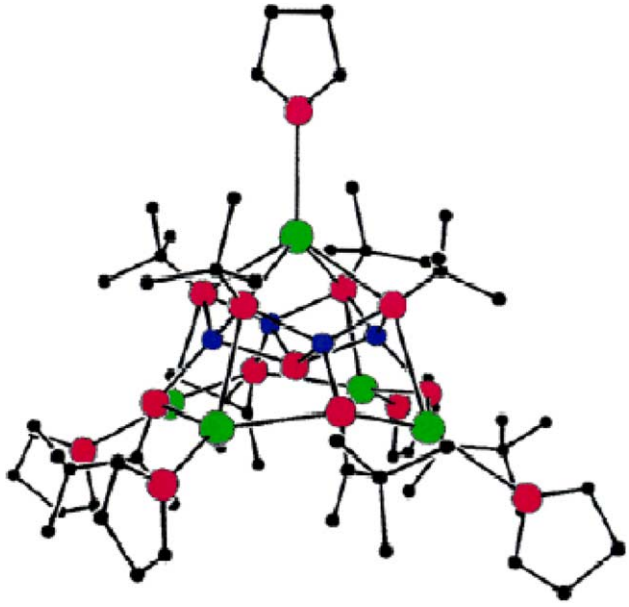

Fig. 16. Structure of $[Li_4\{OC(=CH_2)(t\text{Bu})\}_4K_4(O t\text{Bu})_4(KOH)(thf)_5]$ [68].

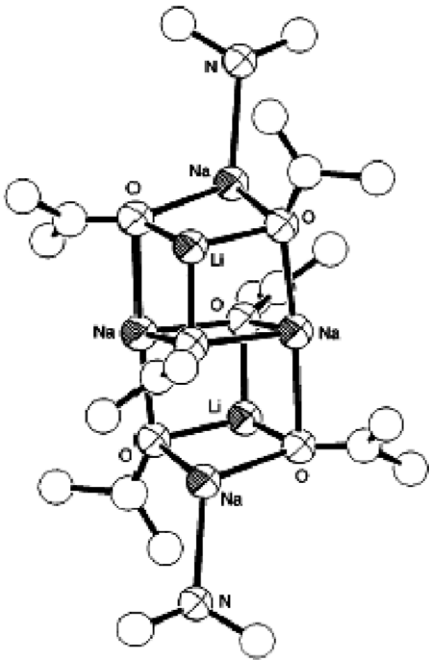

Fig. 17. ORTEP structure of $[Li_2Na_4\{OC(=CH_2)(t\text{Bu})\}_6(HNiPr_2)_2]$ [69].

$$2RN(H)Li + {}^{t}BuONa + {}^{t}BuOK + 2tmeda \xrightarrow{\text{hexane}} 1/2(\{[RN(H)]_2({}^{t}BuO)LiNaK(tmeda)_2\}) \quad (R = Ph \text{ or } p\text{-}CH_3C_6H_4\}) \quad (5)$$

These clusters, derived from the parent (*n*BuLi) (*t*BuOK), contain a mixture of alkali metal ions as well as anions, alkoxides, and amides. The two compounds presented here, which are formed from *p*-toluidine and lithiated anilide, are isostructural [71]. The compound $[\{[PhN(H)]_2(t\text{BuO})LiNaK(tmeda)_2\}_2]$ is one of the first examples combining two distinct anions, amide and alkoxide. It is obtained from a reaction containing lithium anilide, NaO*t*Bu and KO*t*Bu in the presence of tmeda in hexanes. The cluster crystallizes in a centrosymmetric space group, where four out of the six cations, two Li and two Na, possess a distorted tetrahedral coordination, and the larger potassium ions have a coordination number of six resulting from a distorted octahedral environment. Whereas the sodium ions are only linked to nitrogen atoms of the amide or tmeda, Li^+ and K^+ interact with nitrogen and oxygen donor atoms of the ligands (Fig. 18). This cluster can also be described as assembly of two hetero-metallic cycles of [NaNLiN] with the homometallic cycle K_2O_2, linked perpendicularly (Scheme 2).

Considering this structure as a model for superbases as far as their reactivity is concerned, it is probable that the amides, which are responsible for deprotonation of the protic substrate, probably form a σ-bond to the lithium cation and two more elongated, and therefore less strong bonds, to the sodium and potassium ions.

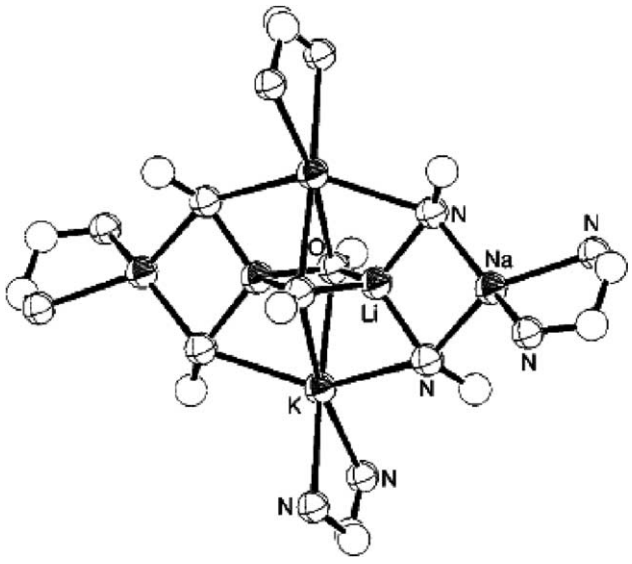

Fig. 18. ORTEP structure of $[\{[PhN(H)]_2(t\text{BuO})LiNaK(tmeda)_2\}_2]$ [71].

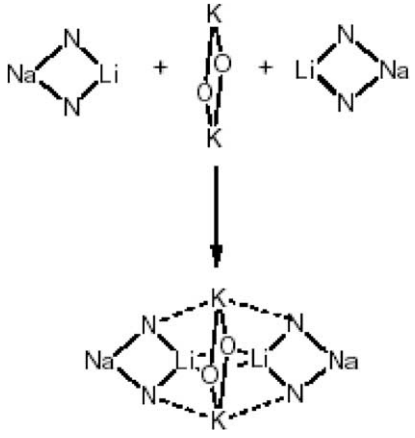

Scheme 2. Possible formation of $[\{[PhN(H)]_2(t\text{BuO})LiNaK(tmeda)_2\}_2]$ [71].

This could render the amides more cleavable and, therefore, more reactive than if they were linked to the same metal ion, as it is the case in the lithium amides where ladder-type, polymeric structures are observed.

2.5. Homo- and hetero-metallic clusters with diverse ligands

Other anions can intervene as well in the constructions of clusters, such as hydrides, oxo, peroxo, and hydroxyl-groups and they can be considered as models for superbases as well. Thus, the largest lithium cluster ever registered so far contains 33 lithium ions and is based on *tert*-butoxide and hydride, $[Li_{33}H_{17}(Ot\text{Bu})_{16}]$ [72]. It has been obtained by photolysis of a 7:3 mixture of *t*BuOLi/*t*BuLi, a synthetic method which has not been explored very much so far. The structure consists of

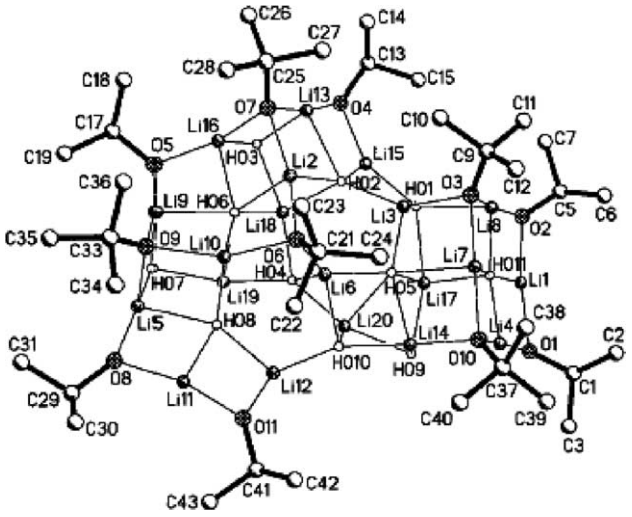

Fig. 19. Structure of $[Li_{33}H_{17}(OtBu)_{16}]$ [72].

several fused cubes of lithium hydride whose expansion into infinity is limited by the presence of bulky O*t*Bu groups at the periphery of the cluster. The latter are also responsible for the good solubility of the cluster in non-polar solvents (Fig. 19).

Homo- and hetero-alkali metal clusters with amino-alkoxide anions, $[Me_2N(CH_2)_2OLi]_8$ and $[\{Me_2N(CH_2)_2O\}_2Li_8K_6]O$, have been obtained only recently [73]. They are obtained from the reaction of *n*BuLi, respectively, *n*BuLi/*n*BuK on DMAEH ($=N,N'$-dimethyl amino ethanol), and their structures are shown below (Fig. 20).

Both form cage-type structures. The lithium compound is reminiscent of a trimer $(LiO)_3$ in form of a hexagonal anti-prism to which a dimer $(LiO)_2$ has been fused. The hetero-metallic cluster is comprised of a quasi spherical structure, incorporating an oxo-anion in the center of the structure, the remainder of traces of water during the reaction.

A decanuclear compound, $[Li_8K_2(O)(OtBu)_8(tmeda)_2]$, was also characterized in the solid state. It forms a polyhedron with 16 vertices (Li_8O_8) which are constructed around a central oxo-anion. This polyhedron can also be described as superposition of two $(LiO)_4$ rings. The potassium ions are then linked at the outside of the polyhedron and chelated by the tmeda molecules (Fig. 21) [74]. Again, the product is obtained by serendipity in the presence of traces of water during the reaction of *t*BuNHLi with KO*t*Bu in the presence of tmeda.

The heterometallic compound $[\{tBuOLi)_5(tBuORb)_4(Li_2O_2)(tmeda)_2\}_\infty$ [75] has oxo, alkoxide, and N-donor ligands and possesses a cage-like structure with 11 metal ions. The clusters are linked via the tmeda molecules, leading to a polymeric chain of clusters (Fig. 22).

In order to synthesize a compound similar to the previous one but without oxo-anions, Mulvey et al. obtained the mixed-metal cluster $[Li_4K_4(OtBu)_8]$ from a toluene solution of the two starting products in equimolar proportions. An empty cage structure is built (Fig. 23) [76]. The cluster is formed of fused M_2O_2 rings.

Another octanuclear compound is obtained with a mixture of anions when KO*t*Bu is reacted with

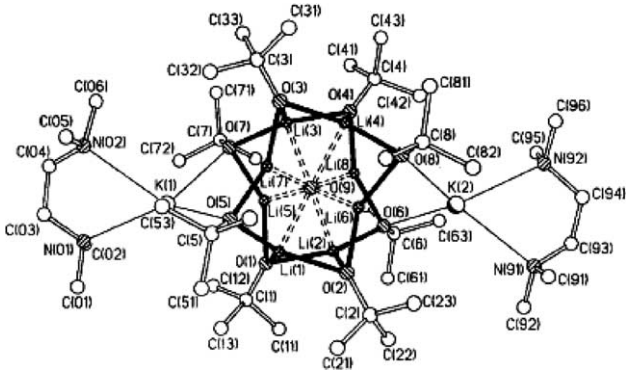

Fig. 21. Structure of $[Li_8K_2(O)(OtBu)_8(tmeda)_2]$ [74].

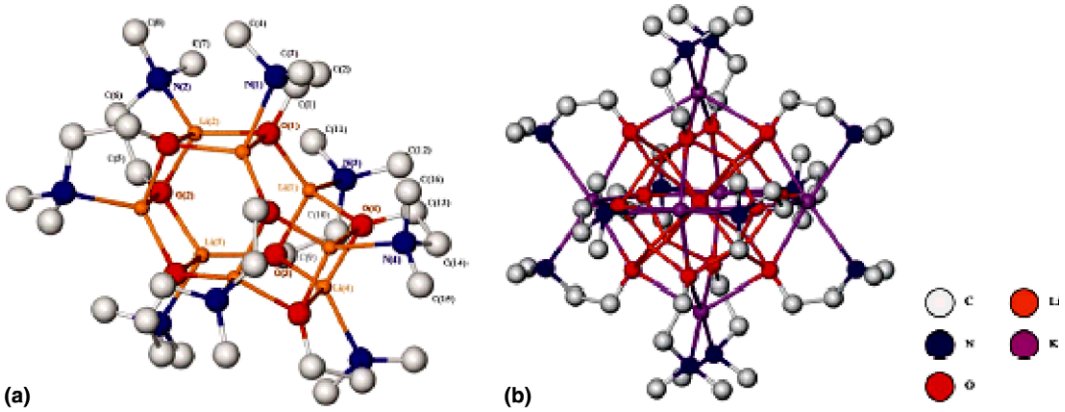

Fig. 20. Structures of $[Me_2N(CH_2)_2OLi]_8$ (a) and $[\{Me_2N(CH_2)_2O\}_{12}Li_8K_6]O$ (b) have been obtained only recently [73].

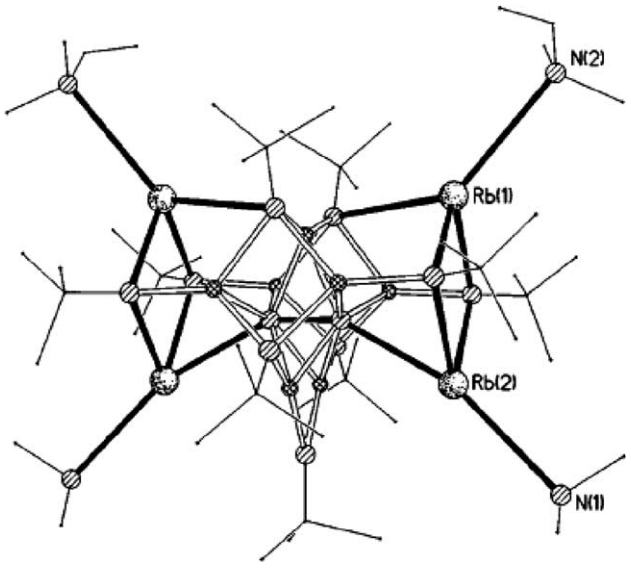

Fig. 22. Structure of $[\{t\text{BuOLi})_5(t\text{BuORb})_4(Li_2O_2)(tmeda)_2\}_\infty]$ [75].

*t*BuNHLi in benzene [77]. Again, the structure is formed of rings, (M-heteroatom)$_2$, this time two (Li_2N_2) and two (K_2O_2) rings are oriented quasi-perpendicular to each other. The rings are attached to each other via rather short Li–O contacts (1.872 Å) compared to the ones in Li*O*t*Bu (1.96 Å) [78]. Identical rings are parallel to each other. Benzene molecules act as η^6 and η^3-ligands toward potassium ions, linking the clusters to infinite chains by this type of π-interaction (Fig. 24).

Nonanuclear compounds of group I metals have recently been obtained, based on alkoxides, amides, and hydroxide. The compound $[Li_4Na_4(t\text{BuO})_4\{PhN(H)\}_4(NaOH)(4\text{-Me-py})_4]$ was obtained either by reaction of lithium anilide with Na*O*t*Bu or vice versa from the sodium anilide with Li*O*t*Bu, both in the presence of the substituted pyridine ring [79].

The structure is composed of a dome-like arrangement with 17 summits, based on a tetrameric ring (Na–N)$_4$. Above this ring, another ring of (Li–O)$_4$ is placed which is capped by a fifth sodium ion in apical position. The OH group is found in the centre of the dome (Fig. 25a).

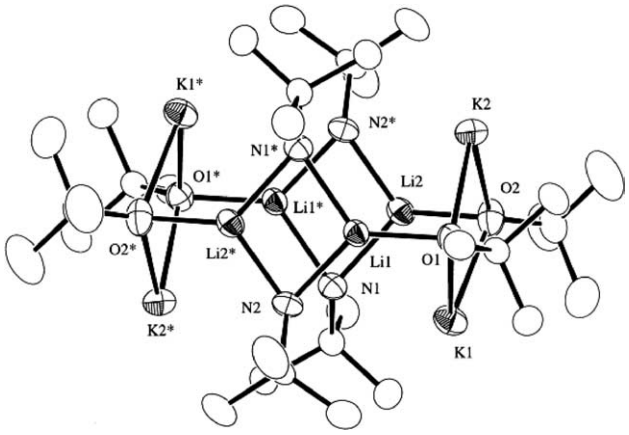

Fig. 24. ORTEP structure of $[LiK(Ot\text{Bu})(NHt\text{Bu})]_4$ [77].

This structure resembles very much the one obtained for the mixed metal cluster obtained by Williard and MacEwan [68] $[Li_4K_4(t\text{Bu})_4(C_6H_{11}O)_4(KOH)(thf)_5]$ (Fig. 25b). It was the first compound combining alkoxide ligands and enolates within such a cluster structure. The enolates form with the potassium ions the lower rim of the cluster, followed in the layer above by the tetrameric LiOR-unit in one plane, which is finally capped by one potassium ion. The latter carries additionally one THF-ligand. The encapsulation of hydroxide is explained by traces of water being present during the reaction.

2.6. Hetero-metallic compounds of group I and II with diverse ligands

The two structures described above possess OH groups in their structure derived from NaOH and KOH.

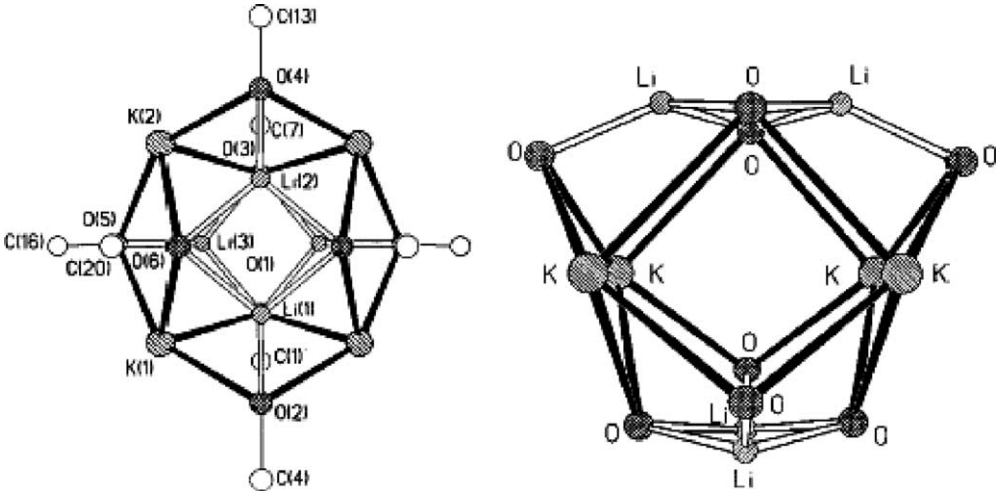

Fig. 23. Structure and core of $[Li_4K_4(Ot\text{Bu})_8]$ [76].

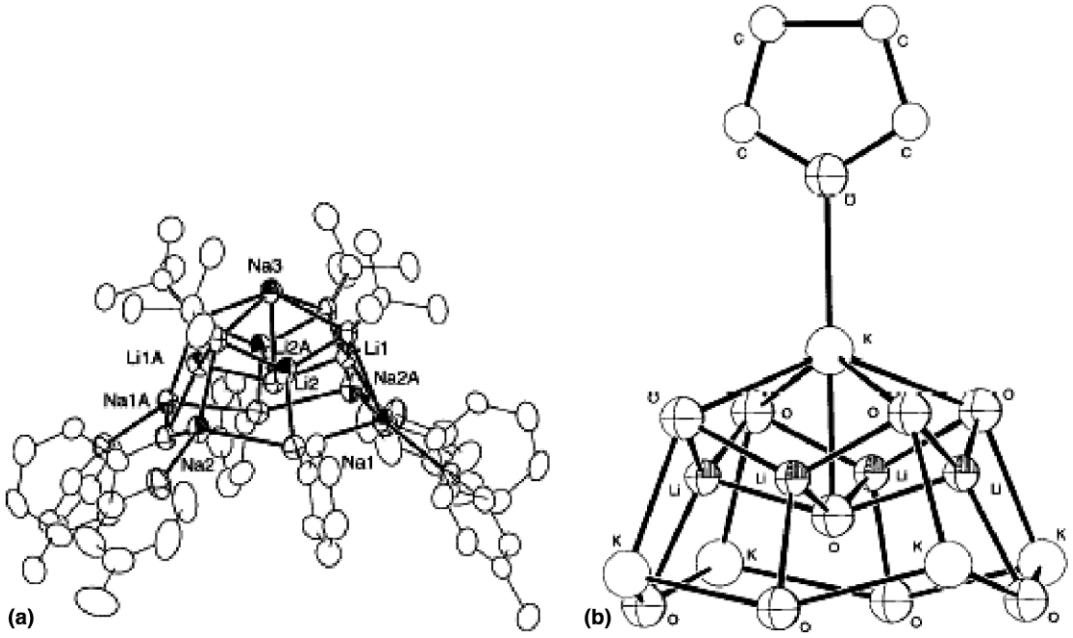

Fig. 25. ORTEP structure of $[Li_4Na_4(t\text{BuO})_4\{PhN(H)\}_4(NaOH)(4\text{-Me-py})_4]$ (a) [79] and $[Li_4K_4(t\text{Bu})_4(C_6H_{11}O)_4(KOH)(thf)_5]$ (b) [68].

Very recently, penta nuclear clusters with group I and group II metals as well as mixed ligands of type $[IM(\text{-LiO}t\text{Bu})_4(OH)(thf)_4]$, M = Sr, Ba, have been reported by the authors' group (Fig. 26) [32,33,80]. The structure resembles the former two compounds and is to our knowledge the first one incorporating a IM(OH) entity. Similar to the other two structures described above, the structure contains a square anti-prismatic arrangement of lithium and oxygen atoms of a $(\text{LiO}t\text{Bu})_4$ tetramer. Instead of a capping alkali metal, Na^+ or K^+, this has been replaced by an isoelectronic fragment, $(MI)^+$, M = Sr, Ba. Furthermore the lower rim of the dome, consisting either of $(NR)_4$- or $(KO)_4$-units, has been removed. However, adding such a reagent to the reaction mixture in order to obtain a much larger group I/II mixed metal cluster should be possible.

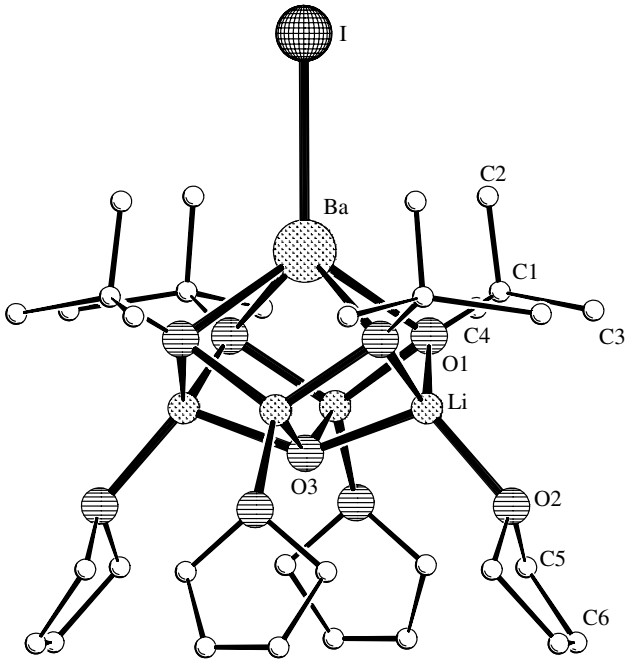

Fig. 26. Structure of $[IM(\text{LiO}t\text{Bu})_4(OH)(thf)_4]$, M = Sr, Ba, H-atoms omitted [32,33,80].

Mixed-anion group I/II metal clusters as described above are rather rare. One example is the $[Ba_6Li_3O_2(Ot\text{Bu})_{11}(thf)_3]$ [81]. The synthesis is successful when using metallic barium which reacts with *tert*-butanol in the presence of *n*BuLi in hexanes. The structure of the $Ba_6Li_3O_2$-core of the cluster contains two oxo-anions, one of which is surrounded by six barium cations in form of an octahedron and the other by a prism of three barium and three lithium ions. Both structural features are fused via the triangular Ba_3-face of both polyhedra. The cluster core is charged 11+, which is neutralized by the O*t*Bu groups, which form a lipophilic mantle around the core assuring the kinetic stability of the compound (Fig. 27).

The following series of compounds give an example of how a central anion such as the oxo or peroxo ion can be integrated under controlled conditions, not only by serendipity. Metallation of the N-donor ligand 2,2,6,6-tetramethylpiperidine $Me_2C(CH_2)_3CMe_2NH$ yields the homometallated lithiated compound $[\{Me_2C(CH_2)_3CMe_2NLi\}_4]$, which adopts a cyclic structure (Fig. 28) [82].

Two of the lithium ions can then be substituted by two Mg^{2+}, which possess a similar size to give a 2+ charged complex. The additional charge will then be

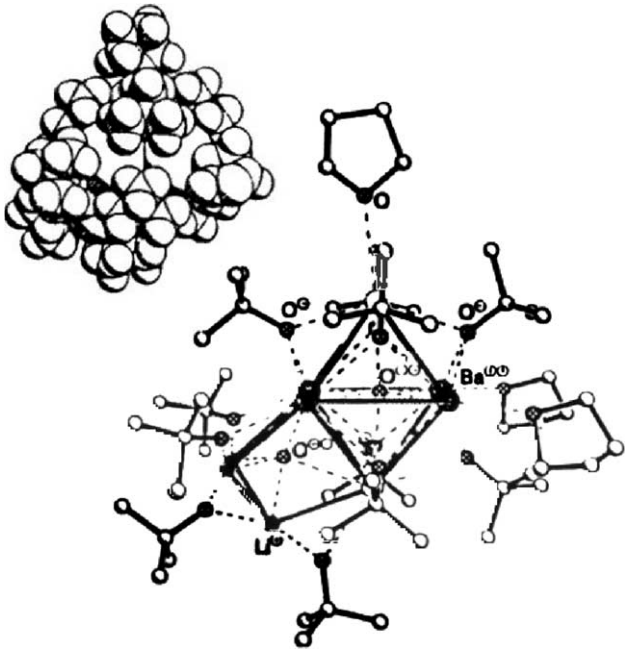

Fig. 27. Structure of $[Ba_6Li_3O_2(OtBu)_{11}(thf)_3]$ [81].

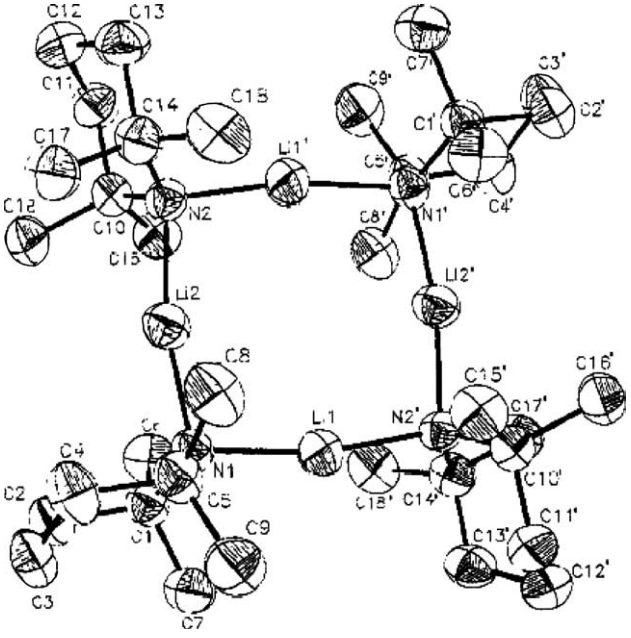

Fig. 28. ORTEP structure of $[\{Me_2C(CH_2)_3CMe_2NLi\}_4]$ [82].

compensated by introducing an oxo anion in the centre of the structure (Scheme 3) [71].

Similarly, the compound $[\{(Me_3Si)_2N\}_4Li_2Mg_2(O_2)]$ was obtained, and this time the resulting compound possesses a central peroxo-anion (Fig. 29) [83].

This type of compound can be classified as a molecular oxide as well as an intermetallic amide, and their possible applications in the synthesis of new materials or in organic synthesis remain promising and need to be studied. Thus, the performances of such compounds can be improved when certain alkali metal amides are paired with the corresponding magnesium bis-amides [84]. The obtained basicity can then be useful to polymetallate a metallocene [85]. Therefore, this chemistry has been developed recently and mixed metal lithium–sodium–magnesium alkoxides/di-idopropyl-amides, $[\{MMg(NiPr_2)_2OR\}_2]$, M = Li, Na; R = *n*Bu or *n*Oct, have been obtained by reaction of a mixture of the amides with the appropriated alcohol [86]. The characterized structures of these compounds can be attributed to the ones called "inverse crowns" due to their inversed topology compared to the classical crown ethers. Thus, the cations are found in the host part of the structure

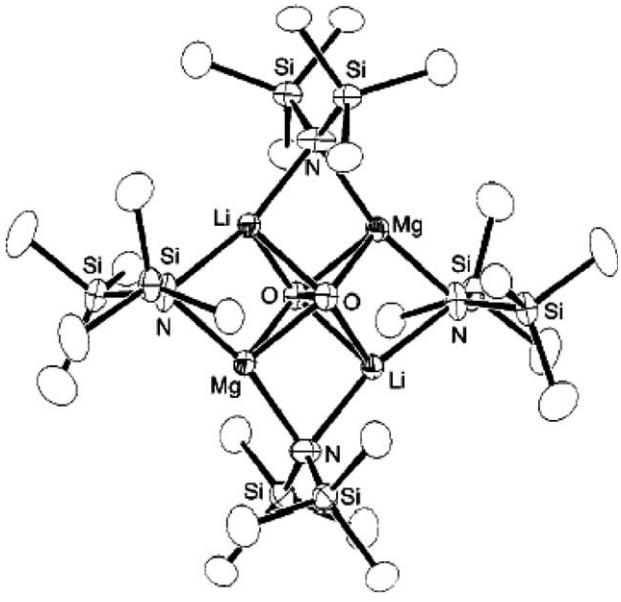

Fig. 29. ORTEP structure of $[\{(Me_3Si)_2N\}_4Li_2Mg_2(O_2)]$ [83].

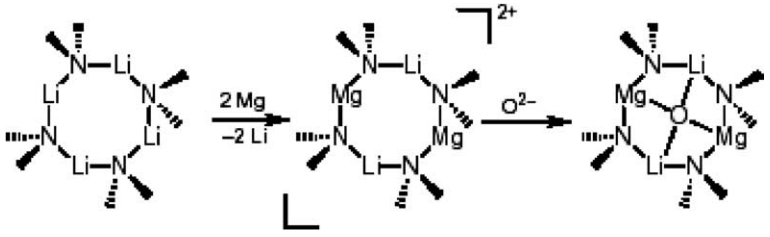

Scheme 3. Formal substitution of two Li^+ by $(Mg_2O)^{2+}$ [71].

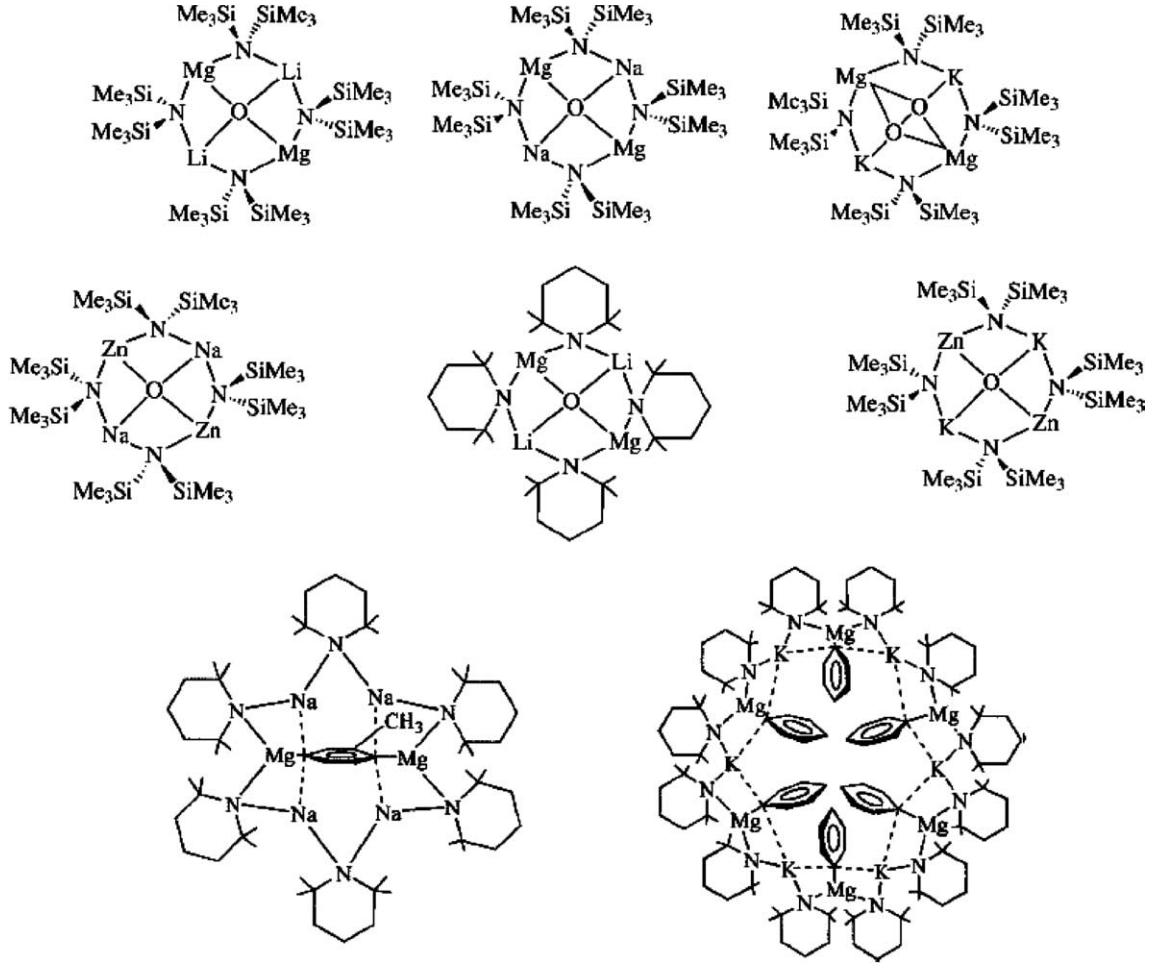
whereas the oxo or peroxo anion is considered as guest (Fig. 30).

Some examples of inverse crown ethers are given in Scheme 4. The larger ones do, however, not contain



Scheme 4. Examples of inverse crown ethers.

oxygen atoms in their center and will, therefore, not be further discussed in this review.

One of the largest aggregates of this type containing oxygen is to our knowledge the hexameric $[\{NaMg(NiPr)(O)(thf)\}_6]$ with 12 metal ions in total [87]. Six magnesium ions combine with six oxo anions to form a hexagonal prism, which is capped by three sodium ions on either rim (Fig. 31).

3. Clusters of alkaline earth metals

3.1. Introduction and properties of alkaline earth metals

Some alkaline earth metal compounds were already encountered in the previous section when discussing group I/II heterometallic clusters of the superbasic type. Pure alkaline earth metal compounds are often also used as precursors for metal oxides with a view to applications in CVD [88] or for sol–gel processes [6,7], and the compounds of the heavier homologues have especially regained in interest in this context [89].

The utilization of sterically important ligands allows the heavier alkaline earth metal compounds to get out of the shadow of the beforehand studied compounds of magnesium, i.e., the well-studied Grignard reagents. As for the alkali metals, the number of examples of alkoxides is smaller than the better studied carbanionic species.

Concerning coordination, except for Mg^{2+}, the heavier group 2 ions have a non-saturated coordination sphere with medium sized ligands, such as ethyl, methoxy or Cp. In order to compensate for their higher coordination numbers (8–12, growing in the order Ca < Sr < Ba), irreversible formation of oligomers/polymers in the solid state or decomposition of the species occurs. The polarizability of the cations grows toward the heavier homologues, which renders the organic groups of these simple ligands more nucleophilic.

Monovalent species can be stabilized in gas matrices and at low temperatures. The radical species of organometallics have been shown to exist in the gas phase, i.e., $CpCa^{\cdot}$, $CH_3Ca^{\cdot}$, $HCCSr^{\cdot}$, etc. [90]. Apart from these examples, the alkaline earth metal ions have their oxidation state of 2^+. No redox chemistry is known as for transition metals. Usually, they form species like MLL′ or ML″, where the ligands are negatively charged, 1- or 2-, respectively. Anionic complexes with alkaline earth metal ions are quite rare, such as $K_2[(C_8H_8)_2Ca(dme)_2]$ [91] and $Li[Cp_2{*}BaR(thf)_2]$ [92]. The missing valence electrons lead to a kinetic lability of the ligands which are therefore generally easily split off.

As far as their relation between charge and size is concerned, the alkaline earth metal ions are similar to the alkali metal ions. They are rather hard and weakly polarizable [93,94]. The M–C bonds are usually polar and sensitive to humidity and oxygen. The alkaline earth metal compounds are in general ionic and soluble in water and polar solvents such as DMSO, ethers or amines. Organobarium compounds often exist as ion pairs, even in THF and pyridine. Coordinating solvents will generally lead to solvated ion pairs [95,96].

The influence of the ligand on the compound will be to avoid oligomerisation in the solid state as well as in solution, and to stabilize the Lewis base/acid adducts.

3.2. Magnesium compounds

3.2.1. Grignard-type reagents

Before describing the magnesium clusters obtained with alkoxides and aryloxides, one has to mention the Grignard reagents of the type RMgX, (R = Alkyl, X = halide), which were discovered in the early 20th century. Their use in organic synthesis is so important that they can be considered among the most important organometallic compounds. The Grignard reagents are generally synthesized by the reaction of a lithium organyl with a magnesium halide salt, following the equation:

$$LiR + MgX_2 \rightarrow RMgX + LiX \quad (6)$$

Even though they are mainly prepared and directly used in solution, the knowledge of their structure is important because it gives hints about possible coordination numbers and geometries, aggregates that might be formed in solution, as well as basic information for theoretical investigations of the compounds. In solution, the Schlenk equilibrium can be observed:

$$2RMgX(solvent)_x \rightleftarrows MgR_2(solvent)_y + MgX_2(solvent)_z \quad (7)$$

In ethers and other Lewis basic solvents, the compounds probably have similar coordination numbers than in the solid state.

3.2.2. Organomagnesium alkoxides, aryloxides, and carboxylates

The first synthesis of magnesium alkoxides dates back to the beginning of the 20th century [97–99], but only for the past 15–20 years have they found an application in organic chemistry, either as reagents or precursors for catalytic reactions [100–102]. Meanwhile, a few of the alkoxides could be isolated and characterized. For instance, the magnesium methoxide $[Mg(OMe)_2(MeOH)_{3.5}]$ possesses a molecular formula which can be written as $[Mg_4(\mu_3\text{-}OMe)_4(OMe)_4(MeOH)_8]$ (Fig. 32). Other examples are the tetrameric aggregates $[Mg_4(OCH_2CH(CH_2)_3O)_6Cl_2]$ and $[Mg(OCH(CH_3)CH_2OCH_3)_2]_4$ [40,103].

These compounds have been described as intermediates for the synthesis of polymerization catalysts for

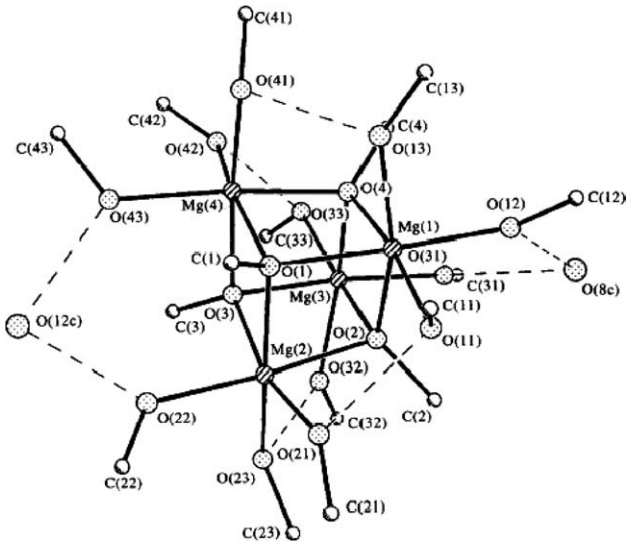


Fig. 32. Structure of $[Mg_4(\mu_3\text{-}OMe)_4(OMe)_4(MeOH)_8]$ [40,103].

alkenes. Based on the idea to have polymers of a certain form, one can build pro-catalysts of the same form with a good productivity and selectivity. Knowing that the compound $[Mg_4(OMe)_6(MeOH)_{10}]$ already exists [104], one can aim to synthesize a new cluster of Mg incorporating alcoxo species such as the bidentate 2-tetrahydro furfuroxo [105]. Such a compound would then be a good starting material for the preparation of polyalkene catalysts. This is the case with $[Mg_4\{OCH_2CH(CH_2)_3O\}_6Cl_2]$ (Fig. 33), which was obtained from the reaction of $Mg(OCH_2CH(CH_2)_3O]_2$ with $MgCl_2$ in CH_2Cl_2.

The structure consists of an almost regular rhombus of four Mg ions, with bridging oxygen atoms. Two types of Mg-ions are present: one of which is coordinated by six oxygen atoms quasi octahedrally and the other in a trigonal bipyramid of MgO_4Cl with a coordination number of 5.

With aryloxide ligands, dimers such as $[Mg(OAr)_2]_2$, ($OAr = OC_6H_2(CMe_3)_2Me = BHT$, and $OC_6H_3(CMe_3)_2 = BHB$), prepared by Ittel and coworkers [106], or the fluorinated species, $[Mg\{OC_6H_2(CF_3)_3\}_2(thf)_3]$ have been described [107]. Recently, a number of new compounds were obtained by reacting $MgBu_2$ with several derivatives of bulky phenols, such as 2,6-dimethyl-, 2,6-diisopropyl-, and 2,4,6-trichlorophenol, Hdmp, Hdip, and Htcp, respectively [108]. These ligands were chosen as they can increase the solubility of the product and are easily deprotonated. Depending on the Lewis bases present, monomeric compounds of type $[MgL_2(solvent)_3]$ with a trigonal bipyramidal arrangement around the metal ion are obtained. In the absence of a Lewis basic solvent, trimeric species are isolated in which the metal ions are arranged linearly with a coordination number of 4 for the central metal ions and 3 for the outer ones (Fig. 34). These structures have been determined spectroscopically.

With carboxylates, carbamato, and carbonato ligands, a large variety of Mg-clusters could be obtained, mainly hexameric ones in which the six magnesium ions adopt ring-like structures in boat or chair conformations, or rather build cage-like clusters as soon as an oxo-anion is incorporated (Fig. 35) [109].

3.2.3. Magnesium enolates

The enolates were generally obtained by reaction of an organometallic base, such as lithium amide or magnesium amide, on the ketone. In 1998, a new synthetic route was discovered, using halogenated bases such as R_2NMgX (Hauser bases), iPr_2NMgCl or iPr_2NMgBr, which allows the preparation of aggregates of magnesium enolates [110].

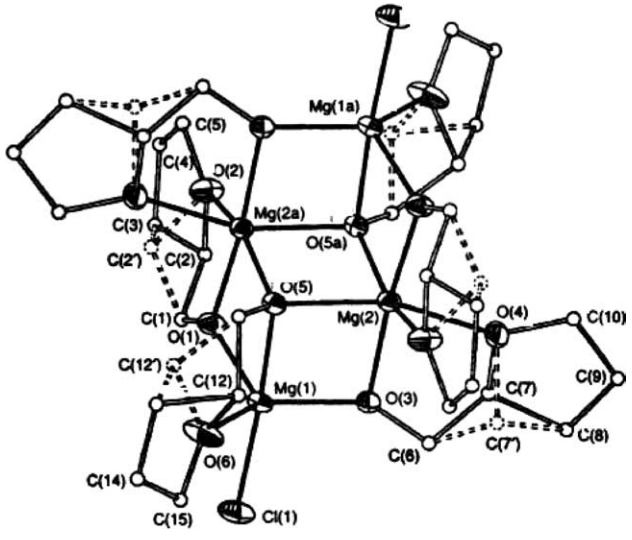

Fig. 33. ORTEP structure of $[Mg_4\{OCH_2CH(CH_2)_3O\}_6Cl_2]$ [105].

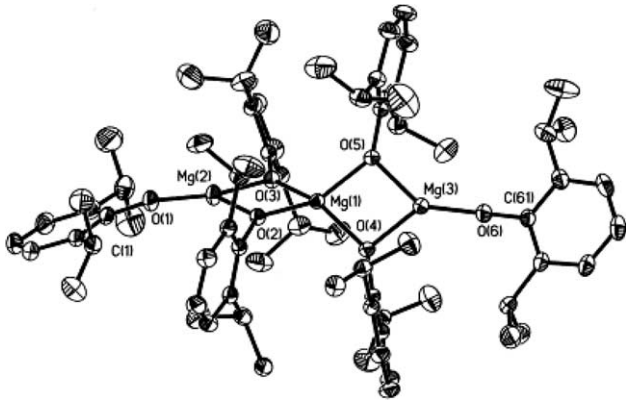

Fig. 34. ORTEP structure of $[MgL_2(solvent)_3]$ for L = 2,6-dimethylphenol [108].

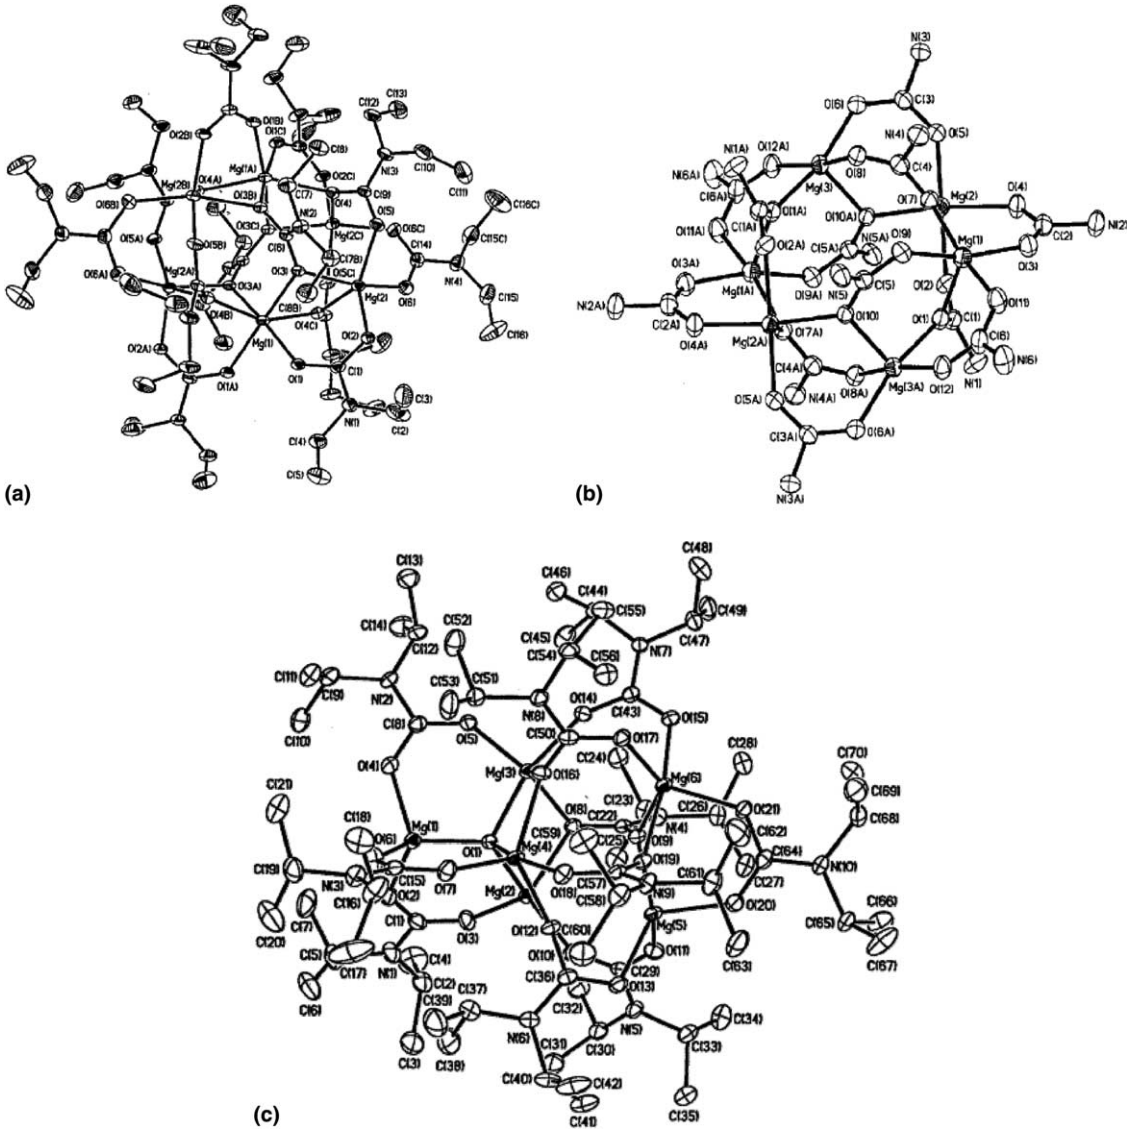

Fig. 35. ORTEP structure of: (a) $[Mg_6(O_2CNEt_2)_{12}]$, (b) $[Mg_6(O_2CNPh_2)_{12}]$, and (c) $[Mg_6(\mu_4\text{-}O)(O_2CN\mathit{i}Pr_2)_{10}]$ [109].

$$R_2NH + EtMgX \rightarrow R_2NMgX + EtH \quad (8)$$

$$R_2NMgX + R'CH_2C(=O)R'' \rightarrow R''(R'CH=)COMgX + R_2NH \quad (9)$$

Thus, the two compounds $[\{t\text{BuC}(=CH_2)\text{OMgBr(hmpa)}\}_2]$ and $[Me_2CHC(=CMe_2)O\text{-MgBr(hmpa)}]$ have been obtained from pinacolone, respectively, from di-isopropylketone, in ether. In both cases, the cations possess a coordination number of 4. Only the first one forms a dimeric structure (Fig. 36), whereas the ligand of the second compound is too bulky to allow oligomerization.

Non-solvated enolates exist also as trimers, as for instance in $[Mg_3(acac)_6]$ or its derivative $[Mg_3\{(Et_2O)_2P(O)CHC(O)Me\}_6]$ [52]. As the dications usually prefer an octahedral coordination sphere, MO_6-units with

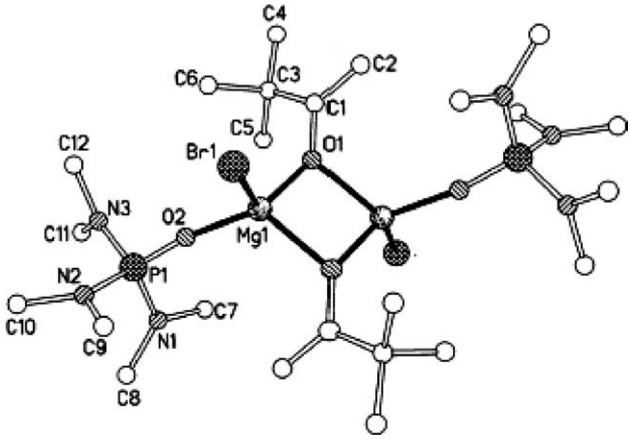

Fig. 36. Structure of $[\{t\text{BuC}(=CH_2)\text{OMgBr(hmpa)}\}_2]$ [110].

common faces similar to the ones found in transition metal enolates such as $[Zn_3(acac)_6]$ or $[Ni_3(acac)_6]$ are present in the structures [111,112]. Recently, the dimeric $[\{HC(C(Me)=N\text{-}2,6\text{-}iPr_2C_6H_3)_2\}Mg(\mu\text{-}OC(=CH_2)\text{-}2,4,6\text{-}Me_3C_6H_2)]_2$ was described. It forms an eight-membered ring MgOCCMgOCC and is an excellent catalyst for the syndioselective polymerization of methyl methacrylate [113].

3.3. Compounds of the heavier alkaline earth metals

Recently after the discovery of Grignard compounds in 1900, their heavier homologues appeared in the literature [114]. Even though they were intensely studied by Gilman et al. [115,116], these compounds could not be used in a similar fashion to the Grignards, because of the difficult synthesis of RMX, their thermal instability, and their insolubility in organic solvents compared to their magnesium homologues.

Only the synthesis of high temperature superconductors containing alkaline earth metal oxide has revived the interest in group II compounds [117–120]. They could be molecular precursors [11,121] for compounds such as $YBa_2Cu_3O_7$ [122–124] or for the deposition in thin films of catalysts, for instance ABO_3, A = Ca, Sr, Ba and B = Ti, Zr, Ce [125,126].

3.3.1. Principles of CVD and sol–gel methods

The technique of CVD in general is based on the decomposition/thermolysis of organometallic volatile precursors. The precursors must be volatile at low temperatures, easy to synthesize and handle, and void of impurities which might influence the epitaxy of the deposits as thin layers or powders [127,128]. In order to make superconductors as described above [122–124], several precursors are generally processed together in order to obtain a mixture of oxides, which is then annealed. As single molecule precursors are unknown for this type of mixed metal compounds, usually the alkoxides or β-diketonates of the metals are used. Whereas the ones for transition metals are well studied and suitable for CVD, many alkaline earth metal precursors of this type show a tendency to decompose or oligomerize under the physical conditions of CVD. This makes a quantitative deposition of the group II compounds more difficult.

The disadvantages of CVD are the great technological requirements such as high vacuum, so other techniques have been developed based on sol–gels. As ceramics generally require high temperatures for annealing in order to obtain a superconducting material [87], they can be made by the sol–gel process as well. The sol–gel synthesis is based on compounds with hydrolysable metal–ligand bonds in order to control the stoichiometries as well as the size of the formed particles [129]. Hydrolysis then leads to polycondensation of the molecules to yield a sol or a gel of a mixture of compounds. By gentle thermal treatment, the volatile building blocks are eliminated to give the (mixed) oxide in the end. Barium amides, such as $[\{BaNP(NMe_2)_2NP(NMe_2)_2NSiMe_3\}_4]$ which is based on a hetero-cubane structure, for instance have been shown to lead to a gel of composition $Ba(OH)_2(H_2O)_x$ [130]. Research has of course also focused on oxygen donor ligands as described below.

3.3.2. Alkoxides and aryloxides

Whereas many precursors have been studied for copper [131] and lanthanides [132] as common ingredients for oxide materials, relatively few results are known for alkoxides of alkaline earth metals, probably due to their low solubility, as for instance for $Sr(OMe)_2$ (which is polymeric) [20–22].

Recently, two strontium compounds, $[Sr(\mu\text{-}ONc)_2(HONc)_4]_2$ and $[Sr_5(\mu_4\text{-}O)(\mu_3\text{-}ONep)_4(\mu\text{-}ONep)_4(HONep)(solvent)_4]$, ONc = $O_2CCH_2CMe_3$; Nep = neopentyl; solvent = THF or 1-methyl-imidazole) have been synthesized [133]. They are more soluble than the commercially available precursors $Sr(Oac)_2$ and $Sr(OiPr)_2$, which are used in solution to synthesize thin films of ceramics such as $SrBi_2Ta_2O_9$ or $Ba_{1-x}Sr_xTiO_3$ [134].

The first isolated alkoxides of Ca, Sr, and Ba were obtained by desolvation of $M(OR)_2 \cdot 4ROH$ and contain compact groups such as OMe, OEt, etc. They form oligomers or polymers of type $[M(OR)_2]_n$ with a three-dimensional structure of the CdI_2-type. They are neither volatile nor soluble in organic solvents [11,12]. However, in aprotic solvents, alkaline earth metal alkoxides may form molecular aggregates, as shown by Turova et al. They have described a cluster $[Ca_6(O)_2(OEt)_8](OEt_2)_{14}$, which was obtained after refluxing $Ca(OEt)_2$ in ethanol [39–42]. The structure consists of two hetero-cubanes $[Ca_4O_4]$ fused via a $[Ca_2O_2]$-face containing the oxo groups.

Among the pure alkoxide compounds, $[Ca_9(OCH_2CH_2OMe)_{18}(HOC_2H_4OMe)_2]$ is with its nine metal atoms the largest calcium cluster so far described and build an excerpt of a sheet structure (Fig. 37) [135]. The central core adopts also the CdI_2-type structure, but the bidentate ligands reduce the tendency to polymerize and allow formation of a molecular structure.

Whereas the preceding example has a sheet-like arrangement, more spherical clusters can also be obtained with smaller oxygen donor ligands such as OH. Thus, in the author's group, the aggregate $Li[\{Ca_7(\mu_3\text{-}OH)_8I_6(thf)_{12}\}_2(\mu\text{-}I)](thf)_3$ has been synthesized [136]. It consists of a dumb bell arrangement of two Ca_7-units which are built by two $[Ca_4O_4]$-hetero-cubanes linked via one calcium ion (Fig. 38).

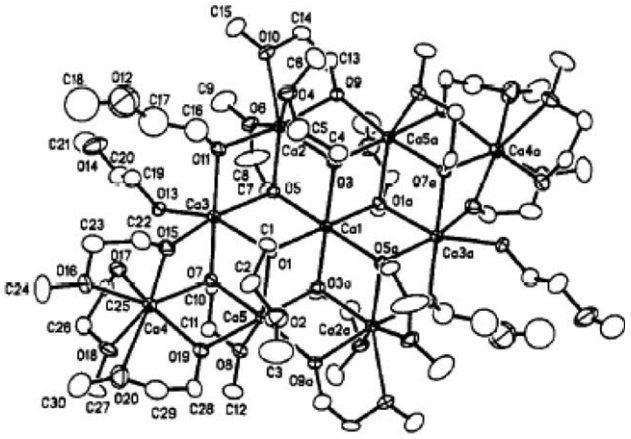

Fig. 37. ORTEP structure of $[Ca_9(OCH_2CH_2OMe)_{18}(HOC_2H_4OMe)_2]$, the largest calcium cluster so far described [135].

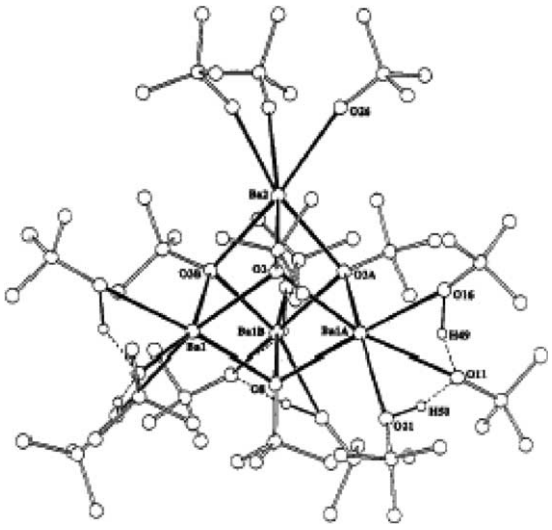

Fig. 39. Structure of $[Ba(\mu_3\text{-}OtBu)(OtBu)(HOtBu)_2]_4$ consisting of a distorted heterocubane $[Ba_4O_4]$ [42].

A similar structural motif is found in the cluster $[Ba(\mu_3\text{-}OtBu)(OtBu)(HOtBu)_2]_4$ which consists of a distorted heterocubane $[Ba_4O_4]$ (Fig. 39) [42].

This compound is the first homoleptic alkoxide of barium with this structural motif and it is obtained upon alcoholysis of $[Ba\{N(SiMe_3)_2\}_2]_2(thf)_2$.

Controlling the structure of an alkoxide is possible by introducing sterically important groups such as BHT (OC_6H_2-tBu_2-2,6-Me-4) and clox ($OC(Ph)_2CH_2C_6H_4$-Cl-4), with which lipophilic species such as $[M(BHT)_2(thf)_n]$ ($M = Ca$, $n = 3$; Ba, $n = 4$) or $[\{Ca(m\text{-clox})(clox)(thf)\}_2]$. They possess trigonal or tetragonal bipyramidal arrangements [137,138]. The monomeric compounds $[M(OAr)_2(thf)_3]$ ($OAr = BHT$ or clox) are isostructural. Other monomers, solvated or not, are also formed with other bulky ligands, such as $[Sr(OC_6H_2(tBu)_3)_2(thf)_3]$ [139], $[Ca\{OC_6H_3\text{-}(NO_2)_2\text{-}2,4\}_2]$ and $[Ba\{OC_6H_2\text{-}(NO_2)_3\text{-}2,4,6\}_2]$ [140,141], $[Ba(2,6\text{-}tBu_2C_6H_3O)_2(HOCH_2CH_2NMe_2)_4]$ which is bonded by hydrogen bonds, [117–120] and the alkoxides $[Ba\{(OC_2H_4)[N(C_2H_4OH)_2]\}_2(EtOH)_2]$, and $[Ba_2(OCPh_3)_4(thf)_3]$ [146–148].

In the compound $[Sr_4(OPh)_8(PhOH)_2(thf)_6]$ [142], the simple combination of the solvent with the metal ion and phenol is enough to produce a soluble molecular aggregate in which the cation possesses a pseudo-octahedral environment. The THF present in the structure is on one hand responsible for avoiding polymerization and on the other hand labile enough to yield a volatile species.

As barium is present in many superconducting cuprates [143,144], some authors have chosen to use simple aryloxides in the presence of bulky ligands, i.e., hmpa ($= [NMe_2]_3PO$). A homo-metallic species, $[H_2Ba_8(\mu_5\text{-}O)_2(OPh)_{14}(hmpa)_6]$ and a mixed-metal cluster with Sr and Ba are obtained [145]. Thus, a first intermediate $[Sr_3(OPh)_6(hmpa)_5]$ has been characterized before reaction with barium metal and phenol to yield $[H_2Sr_6Ba_2(\mu_5\text{-}O)_2(OPh)_{14}(hmpa)_6]$. Both structures

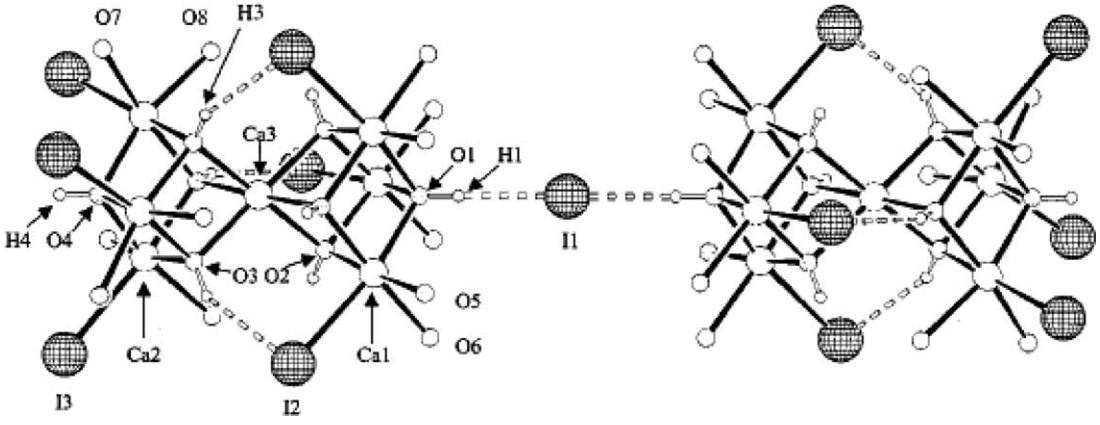

Fig. 38. Structure of $Li[\{Ca_7(\mu_3\text{-}OH)_8I_6(thf)_{12}\}_2(\mu\text{-}I)(thf)_3]$ [136].

consist of two edge-fused square pyramids with the oxo-anions in the center of the square plane of metal atoms (Fig. 40).

Oxo-free derivatives of silyloxides, alkoxides, and aryloxides have been described before [146–148], but they seldom have more than three metal atoms, except for $[Ba_6(OPh)_{12}(tmeda)_4]$. The presence of oxo-anions introduced upon hydrolysis by traces of humidity augments the nuclearity, as shown for instance in $[H_4Ba_6(O)(OCH_2CH_2OCH_3)_{14}]$ and $[Ba_6(O)(OCH_2CH_2OMe)_{10}(HOCH_2CH_2OMe)_4]$ [117–120], $[H_3Ba_6(O)(O\mathit{t}Bu)_{11}(OCEt_2CH_2O)(thf)_3]$ and $[Ba_4(O)(\mu_2\text{-}OC_6H_2(CH_2NMe_2)_3\text{-}2,4,6)_6]$ [146–148], $[HBa_5(O)(OPh)_9(thf)_8]$ and $[H_2Ba_8(O)_2(OPh)_{14}(hmpa)_6]$ [145]. In general, the higher the nuclearity of the cluster, the lower the volatility, and the less they are useful as precursors in CVD.

3.3.3. β-Diketonates

The β-diketonates of metals in general and more precisely alkaline earth metals are among the best studied systems [149]. The coordination modes are very flexible. The metallacycles are six-membered and therefore rather stable when coordinating in the anionic enol form [150,151]. Not only the structure, but also the physical properties depend strongly on the ligand type. For main group and transition metals, the volatility is good when alkoxides are used [152,153], whereas for group II metal ions, the β-diketonates are the best ligands so far as volatility and stability are concerned. The barium derivatives have been extensively studied. The volatility depends on the degree of oligomerization, and the latter depends on the ligand size. 2,2,6,6-Tetramethylheptane-3,5-dionate (thd) has turned out to be

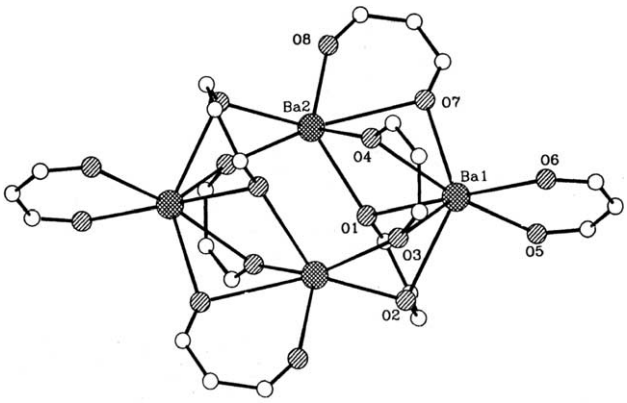

Fig. 41. Structure of $[Ba_4(thd)_8]$ [154,155].

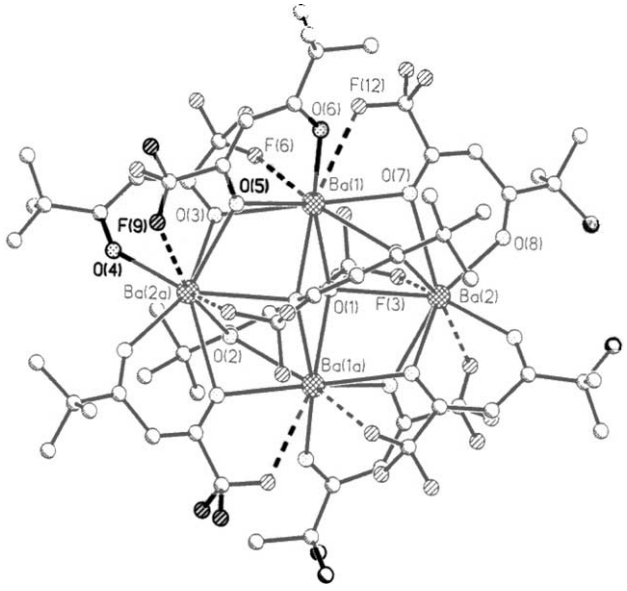

Fig. 42. Structure of $[Ba_4(pta)_8]$ [159].

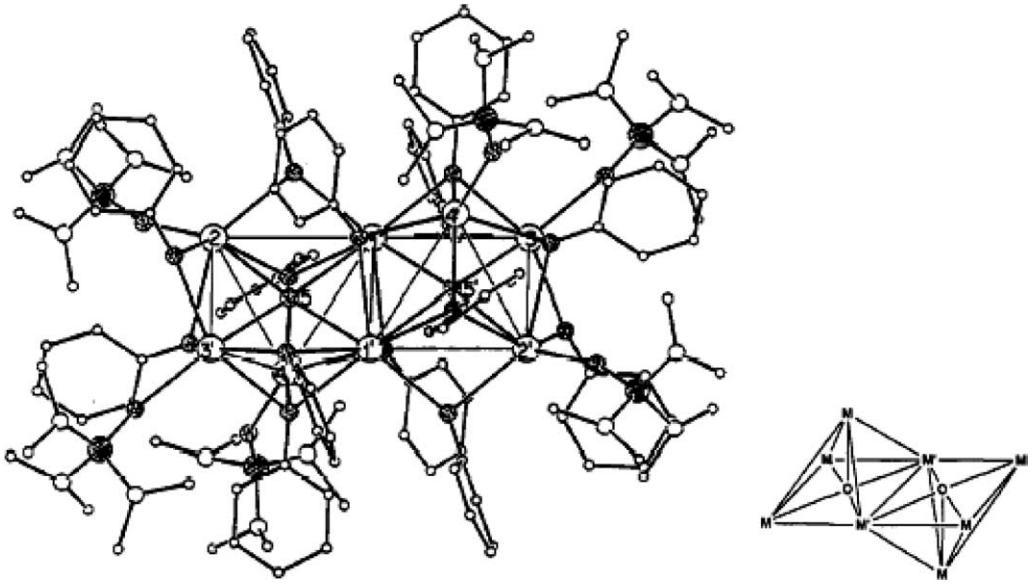

Fig. 40. Structure of $[H_2Sr_6Ba_2(\mu_5\text{-}O)_2(OPh)_{14}(hmpa)_6]$ [145].

a suitable ligand and forms the tetrameric compound $[Ba_4(thd)_8]$ with barium (Fig. 41) [154,155].

More volatility was expected by introducing the fluorinated ligand 1,1,1,5,5,5-hexafluoropentane-2,4-dionate (hfa), which forms however a polymer Ba-compound $[Ba(hfa)_2]$. The latter is therefore less volatile, whereas the tetramer sublimes under mild conditions [156,157].

Upon hydrolysis of $[Ba_4(thd)_8]$ in air, the compound $[Ba_6(thf)_{10}(O_2)(H_2O)]$ is obtained [158]. It consists of a hexanuclear octahedral Ba_6-cluster surrounding a peroxo anion. Such systems have also been studied with the ligand pivaloyltrifluoro acetone (Hpta), containing *t*Bu groups as well as terminal trifluoromethane units [159]. The compound $[Ba(pta)_2(H_2O)]$, which is obtained from a mixture of water and methanol, can be heated gently to give $[Ba_4(pta)_8]$ upon sublimation. Whereas the precursor forms infinite chains, the final product is made of tetrameric units (Fig. 42).

Even though $[Ba_4(thd)_8]$ is frequently used as CVD-precursor for the preparation of oxide materials, the research for more volatile species continues. The ligand 2-methoxy-2,6,6-trimethylheptane-3,5-dionate (HL) gives with metallic barium the compound $[Ba_2L_4(H_2O)_{1.81}]$ [160]. In this dinuclear product, the distance Ba–Ba is the shortest ever observed so far with 3.910(1) Å.

The alkaline earth metal ethoxides $[\{M(OEt)_2(EtOH)_4\}_n]$ react with β-diketonates such as 2,2,6,6-tetramethylheptane-3,5-dione (Htmhd) to give volatile complexes of the type $[Sr_3(tmhd)_6(Htmhd)]$ or $[Ba_4(tmhd)_8]$, following the general reaction scheme [161]:

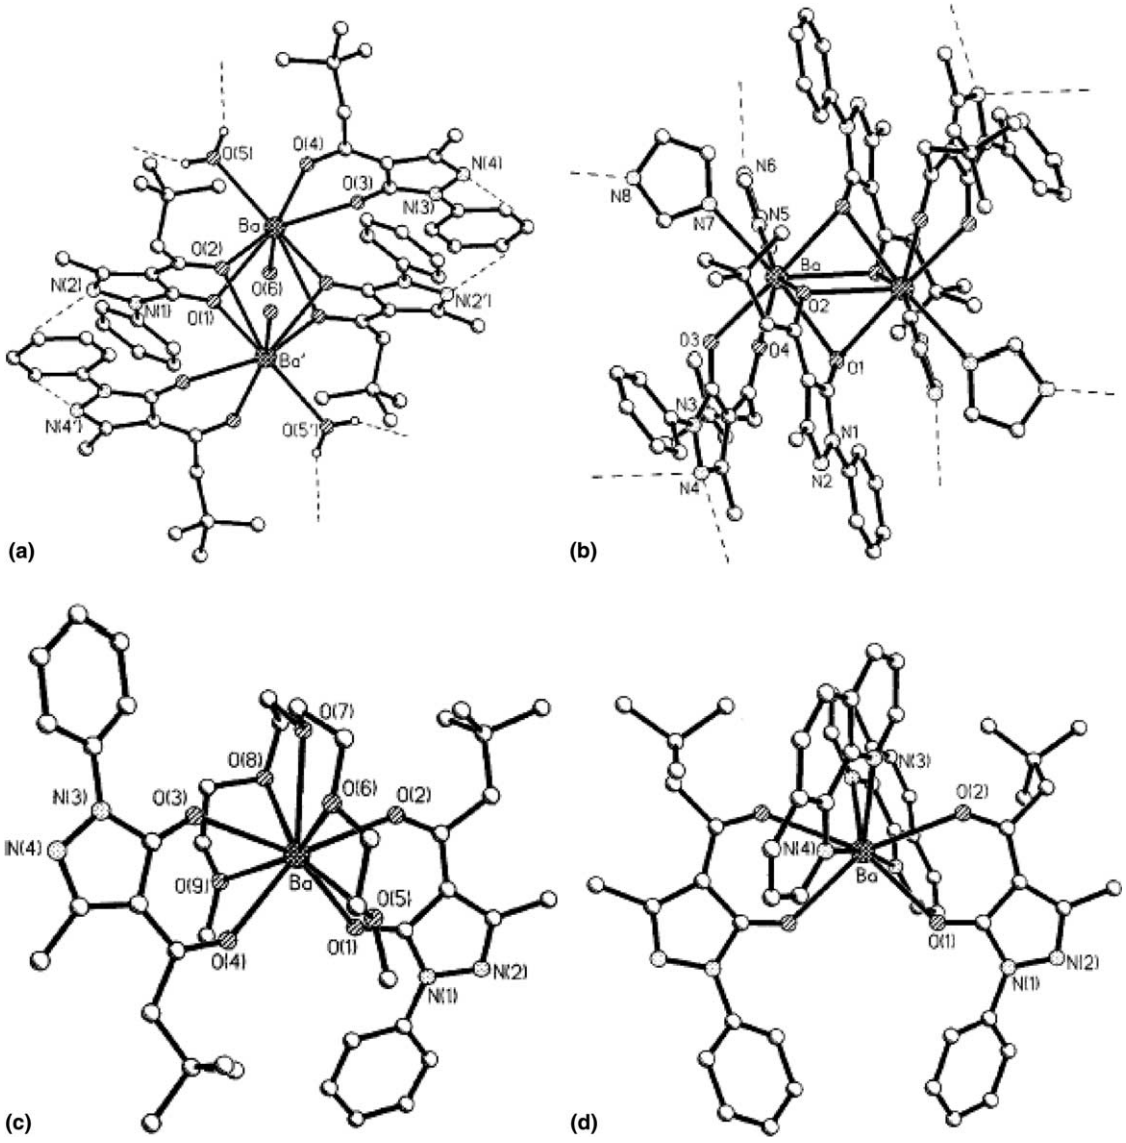

Fig. 43. Structures of $[\{BaQ_2(H_2O)_2\}_2]$, $[Ba_2Q_4(Him)_4]$, $[BaQ_2(tetraglyme)$, and $[BaQ_2(phen)_2]$ (Q = 4-*tert*-butylacetyl-3-methyl-1-phenylpyrazol-5-onate) [164].

$$[M(OEt)_2(EtOH)_4] + 2Htmhd \rightarrow [\{M(tmhd)_2\}_n] + 6EtOH \quad (10)$$

Some difficulties remain when it comes to synthesizing homoleptic β-diketonates of Sr and Ba with Htmhd or Hhfa, $[M(L)_2]$, due to their tendency to decompose and their sensitivity toward humidity and O_2 as well as the facile incorporation of coordinating solvent molecules. With the aim to make new single source precursors for CVD, mixed-ligand mixed-metal compounds were studied and were obtained for the combinations Ba/Cu and Ba/Y with β-diketonates and alkoxides as well as Lewis base solvent molecules as ligands [162,163].

Parallel to this, the chemistry of hetero-cyclic β-diketonates has only been poorly developed [164]. However, they generally possess a good solubility in organic solvents. The anionic ligand 4-*tert*-butylacetyl-3-methyl-1-phenylpyrazol-5-onate (Q^-) was used to obtain different products, depending on the coordinating solvent used. These are $[\{BaQ_2(H_2O)_2\}_2]$, $[Ba_2Q_4(Him)_4]$, $[BaQ_2(tetraglyme)]$, and $[BaQ_2(phen)_2]$ (Fig. 43).

Even though the interest is great in alkaline earth metal β-diketonates, little effort has been made to correlate their structure to the volatility [89]. Many solid state structures of compounds used in CVD are unknown, and the composition of them can vary from case to case depending on the preparation. For instance, traces of humidity can transform the compound $[Ba(tmhd)_2]$ [165] into the cluster compound $[Ba_5(tmhd)_9(H_2O)_3(OH)]$ [166].

The sublimation temperatures of a series of alkoxides and fluoroalkoxides have been monitored as a function of their molecular weight. The more bulky the ligand is, the less it forms oligomers, and the lower its sublimation temperature.

3.3.4. Carboxylates

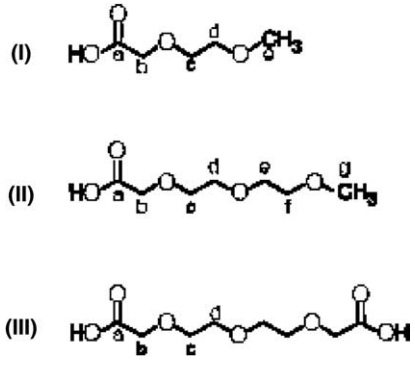
For several years now the carboxylates have taken a place as possible precursors in CVD. Even though the preparation is similar to the alkoxides, few examples of polyether carboxylates (Scheme 5) with electron poor metal ions are known to date. The most efficient procedure is reaction of the metal hydroxide with the acid in water. After elimination of water, the carboxylates can be isolated generally in high yields, following the reaction

$$M(OH)_2 + (2/n)R(COOH)_n \rightarrow M(OOCR)_{2/n}(H_2O)_m + 2H_2O \quad (11)$$

(M = Ca, Sr, Ba; R = see Scheme 5).

Some calcium-containing compounds have been isolated as structural models for intermediates in biological systems, such as $[Ca_2\{2\text{-}OCO\text{-}3\text{-}CH_3C_6H_3NHCO)_2\text{-}C(CH_3)_2\}_2(CH_3OH)_6]$ (Fig. 44) [168].

The structure of this compound is stabilized by the presence of four hydrogen bonding interactions between the amide groups and the oxygen of a carboxylate anion (NH···O) [169,167]. Polymeric structures can thus be obtained by bridging oxygen atoms.



Scheme 5. Polyether carboxylates.

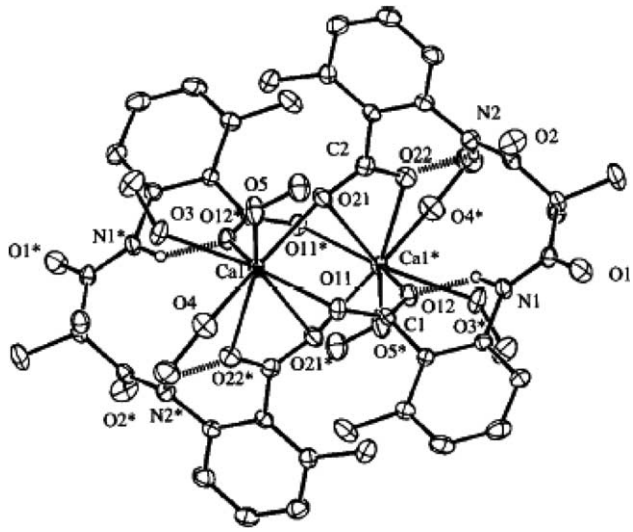


Fig. 44. ORTEP structure of $[Ca_2\{2\text{-}OCO\text{-}3\text{-}CH_3C_6H_3NHCO)_2C(CH_3)_2\}_2(CH_3OH)_6]$ [168].

4. Conclusions

In the chemistry of alkali and alkaline earth metal compounds, the pure organo-metallic compounds with metal–C bonds have dominated for a long time, and a number of review articles report on the importance of these compounds in synthesis and catalysis. Only recently have the compounds with metal–O bonds been investigated, as analogues to the organo-metallics, and several papers review either one group of metals or one single family of oxygen donating ligands. The purpose of this review was to regroup some of these results. The compounds described herein were chosen for their original structures and are presented also as examples of

synthesis. Their structures reflect the huge variety of geometric arrangements possible for alkali and alkaline earth metal aggregates, of which tetramers and hexamers with hetero-cubane, respectively, hexagonal prismatic structures are among the most common so far. Recent results, however, suggest that many structural varieties remain to be discovered in this field. Therefore, with the revival of research in this area, the improved techniques of controlled synthesis in non-aqueous solvents, and the routine single crystal analysis available today, many more advances are to be expected.

Abstract

Nine mononuclear metal complexes of monoanionic α-hydroxycarboxylates (HL′) with imidazole as a co-ligand have been synthesised and structurally characterized by X-ray diffraction. The nickel(II) complexes can be described by two formulae: $[Ni(HL')_2(Im)_2]$, HL′ = 2-methyllactate (HmL) (**1**) or mandelate (HM) (**2**), and $[Ni(HB)_2(Im)_3]$, HB = benzylate (**3**). In these compounds the nickel atom is in a distorted octahedral environment. The copper(II) complexes of the general formula $[Cu(HL')_2(Im)]$, HL′ = glycolate (HG) (**4**), lactate (HL) (**5**) or 2-methyllactate (HmL) (**6**) presents a square pyramidal coordination geometry with a distortion evaluated in terms of the τ parameter. The zinc(II) complexes have the general formula $[Zn(HL')_2(Im)_2]\cdot xH_2O$, HL′ = lactate (HL) and $x = 1/2$ (**7**), 2-methyllactate (HmL) and $x = 0$ (**8**) and display a distorted octahedral geometry. However, the reaction with H_2B afforded the imidazole complex $[Zn(Im)_6](HB)_2$, HB = benzylate (**9**), which has two uncoordinated benzylate units. In most of the complexes the α-hydroxycarboxylato ligands behave as bidentate monoanionic systems, apart from in **3**, where one ligand is monodentate. All of the complexes are extended into 2D or 3D frameworks through hydrogen bonding. The complexes were also characterized by elemental analysis, FT-IR and UV/Vis spectroscopy. The nickel and copper compounds were also studied by room temperature magnetic susceptibility and room temperature ESR spectra were obtained for the copper compounds. Finally, the thermal behaviour of all the compounds was investigated.

1. Introduction

An important group of biogenic ligands is represented by the anions of α-hydroxycarboxylic acids. These anions take part in many fundamental biochemical processes, e.g., in the Krebs cycle (malate, citrate, isocitrate), Cory cycle (lactate), photorespiration (glycolate) and others. Elsewhere, α-hydroxycarboxylates, by virtue of their hydroxy and carboxylate functionalities, may also mimic more complex biogenic ligands, e.g., sugars. The imidazole ring, as a histidine moiety, is also present as a ligand toward transition metal ions in a variety of biologically important molecules including non-heme systems and several metalloproteins. These two ligands can simultaneously coordinate metal ions and provide potential intermolecular interactions that allow the formation of supramolecular arrays. Together with the use of these ligands, a selection of individual metal ions with different coordination properties can be a useful tool to generate networks of different dimensionality.

Scheme 1.

The present paper includes a detailed structural study on the solid state of nickel(II), copper(II) and zinc(II) mixed-ligand complexes with biologically relevant ligands such as α-hydroxycarboxylates and imidazole. For this study, five α-hydroxycarboxylic acids with different levels of bulkiness (Scheme 1) were selected: Glycolic (H_2G), Lactic (H_2L), 2-methyllactic (H_2mL), Mandelic (H_2M) and Benzylic (H_2B) acids.

Previous work in this field has been undertaken by our group and involved the study of mixed-ligand complexes of copper(II) with *N*,*N*-chelating aromatic amines such as 1,10-phenanthroline [1,2] and 2,2′-bipyridine [3,4]. In most of these complexes a pentacoordinated copper(II) ion in a distorted square pyramidal environment is present, but there are also some complexes with an octahedral coordination geometry. The behaviour of the α-hydroxycarboxylic acids in these complexes is very diverse and includes: bidentate monoanion, bidentate dianion, bidentate bridging by the hydroxyl oxygen, monodentate monoanion, monoanionic counterion and also as a neutral molecule in the outer coordination sphere. However, structural studies of first-row transition metal complexes of α-hydroxycarboxylates with monodentate N-donor ligands are not common. To the best of our knowledge the only structural reports in this area concern the glycolate ligand and NH_3 or pyridine as monodentate N-donor ligands: $[Ni(HG)_2(py)_2]\cdot 2H_2O$ [5], $[Cu(HG)_2(NH_3)_2]$ and $[Cu(HG)_2(py)_2]$ [6] contain bidentate monoanionic ligands and the dinuclear copper compound $[Cu_2G_2(py)_2]$ ethane-1,2-diol solvate [7], which contains a bridging bidentate dianionic glycolate ligand.

2. Results and discussion

Reaction of the α-hydroxycarboxylic acids and imidazole in EtOH and/or H_2O with $Ni(AcO)_2\cdot 4H_2O$, $CuCO_3\cdot Cu(OH)_2\cdot 1/2H_2O$ and $ZnCO_3$ led to the isolation of the crystalline products **1**–**9** after slow evaporation of the mother liquors (compounds **2**, **4** and **9**) or after the redissolution of oils or powders obtained in the reactions in MeOH/*i*PrOH (compounds **1**, **3**, **5**, **6** and **8**) or in MeOH/acetone (compound **7**). The yields are high for **1** and **2**, around 50% for **4**–**7** and low for **3**, **8** and **9**. The complexes are air-stable, with melting or decomposition points above 250 °C (**1, 2**), around 200 °C (**4**–**6**) and slightly above 100 °C for the zinc compounds. The complexes are soluble in water, methanol, ethanol and slightly soluble in chlorinated solvents.

2.1. Crystal structures

Metal–ligand bond distances and angles are listed in Table 1. Figs. 1–7 show drawings of the molecular structures together with the atom-numbering schemes used.

The Ni(II) compounds **1** and **2** (Fig. 1 shows compound **2**) and the Zn(II) compounds **7** (Fig. 2) and **8** (Fig. 3) have structures based on neutral complexes $[M(HL')_2(Im)_2]$, where HL′ is a monoanionic *O*,*O*′-bidentate α-hydroxycarboxylato ligand (2-methyllactato for **1** and **8**, lactato for **7** and mandelato for **2**) that chelates the M^{2+} ion through the carboxylato and the hydroxyl oxygen atoms to form a five-membered chelate ring. In this chelate ring the two imidazole ligands are *cis* to each other and *trans* to the hydroxyl oxygen atoms when the metal ion is nickel, but *trans* to the carboxylato oxygen atom in the zinc compound **8**. In compounds **1** and **2** the hydroxyl groups of the two ligands are mutually *cis*, but in **8** they are mutually *trans* in a similar way to the aqua-complex $[Zn(HmL)_2(H_2O)_2]$ [8]. In compound **7** an *all cis* configuration is found. The structure of the nickel compound **3** (Fig. 4) corresponds to neutral molecules $[Ni(HB)_2(Im)_3]$ with a *fac*-disposition of the ligands. In this arrangement one HB ligand acts as a monoanionic *O*,*O*′-bidentate chelating system but the other HB ligand is monoanionic unidentate, so the coordination of the hydroxyl group of one HB ligand is replaced by the coordination of a third imidazole molecule. It therefore appears that the steric requirements of this ligand favour the coordination of a small monodentate ligand like imidazole over the stabilization provided by chelate formation. In all of these complexes, the coordination polyhedra are distorted octahedral with the main deviations from regularity affecting the chelating angles $O_{hydroxyl}$–M–$O_{carboxy}$ [in the range 76.37°–77.95° for the nickel compounds and 74.68°–76.85° for **7** and **8**]. The Ni–N bond lengths are in the range 2.031–2.077 Å, which is only slightly shorter than that found in the pyridine complex $[Ni(HG)_2(py)_2]\cdot 2H_2O$ [5]. The Ni–$O_{hydroxyl}$ distances (Table 1) increase slightly on going from **1** (containing the less bulky hydroxycarboxylato ligand) to **3** (with the more bulky ligand) and are longer than those in the nickel(II) pyridine compound with the glycolato ligand [5]. The Ni–$O_{carboxy}$ distances are in the range 2.027–2.0466 Å

[*] $i = -x, y, -z + 1/2$.
[**] $I = -y + 1, -x + 1, -z + 1/2$.
[***] $i = -x + 1, -y + 1, -z$.

when the α-hydroxycarboxylato ligand is a bidentate chelate but in **3**, where one HB ligand acts in a monodentate manner, this bond length has a larger value (2.155 Å). In the nickel compounds, however, when the anionic ligand acts as a chelating system, the Ni–$O_{hydroxyl}$ bonds are longer than the Ni–$O_{carboxy}$ bonds. In **7** and **8** the Zn–N bond lengths are shorter than those observed in hexakis-substituted imidazole complexes (compound **9** in this work and [9]) but slightly longer than those found in other bis-substituted systems [10–12]. The Zn–$O_{hydroxyl}$ and Zn–$O_{carboxy}$ distances are longer than the corresponding distances observed in $[Zn(HmL)_2(H_2O)_2]$ [8].

In compounds **4**–**6** the asymmetric unit is composed of the neutral complex $[Cu(HL')_2(Im)]$ where HL′ = HG (**4**), L = HL (**5**) and L = HmL (**6**). In these three compounds the copper atom is pentacoordinated and the α-hydroxycarboxylato ligands acts as monoanionic *O*,*O*′-bidentate chelate systems. The resulting coordination polyhedra are square pyramids, which are almost perfect for **4** and **5** (Fig. 5 shows compound **5**) but with a slight deviation towards a trigonal bipyramid in **6** (Fig. 6) (Addison's τ value [13] is 0.04 in **4**, 0.03 in **5** and 0.29 in **6**). The hydroxyl group (O13) of one of the anionic ligands is located at the apex of the square pyramid and there is a correlation between this apical Cu–O distance (Table 2) and the value of the tetragonality parameter *T* (ratio between the mean of the four shortest and largest distances: 0.82 for **4**, 0.85 for **5** and 0.87 for **6**). In the basal plane of **4** and **5** the carboxylato oxygen atoms are mutually *trans* but in **6**, where the ligand is 2-methyllactato, they are mutually *cis*. The chelate angles $O_{carboxy}$–Cu–$O_{hydroxyl}$ (range 76.14°–77.09°) have similar values to those observed in the nickel complexes. The Cu–N bond lengths agree with those reported for other copper(II) complexes with imidazole [14,15]. Both the apical and the basal Cu–$O_{hydroxyl}$ distances decrease on going from **4** to **6** and as usual in square pyramidal copper complexes, the Cu–apex distance Cu–O13 is longer than the bond lengths in the base. The apical Cu–$O_{hydroxyl}$ distances are similar to the Cu–$O_{hydroxyl}$ distances found in hexacoordinated copper(II) α-hydroxycarboxylato complexes with 4,4′-bipyridine [16] or 2,2′-bipyridine [3]. In **6** the basal

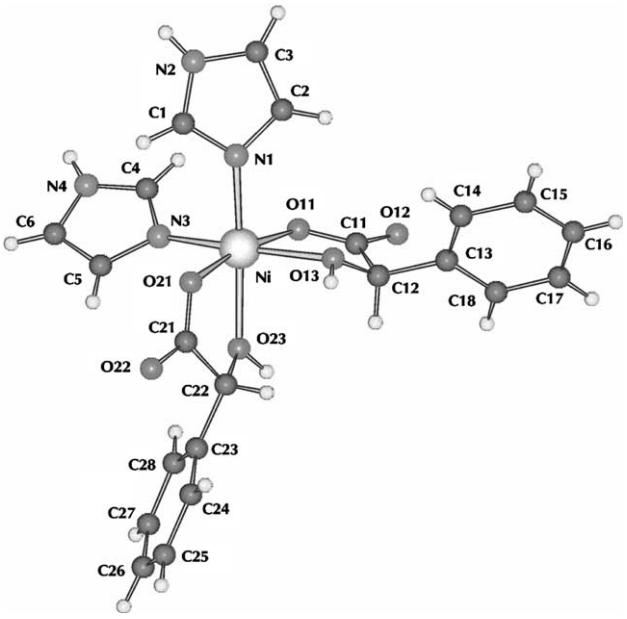

Fig. 1. Molecular structure of $[Ni(HM)_2(Im)_2]$ (**2**), showing the atom numbering scheme.

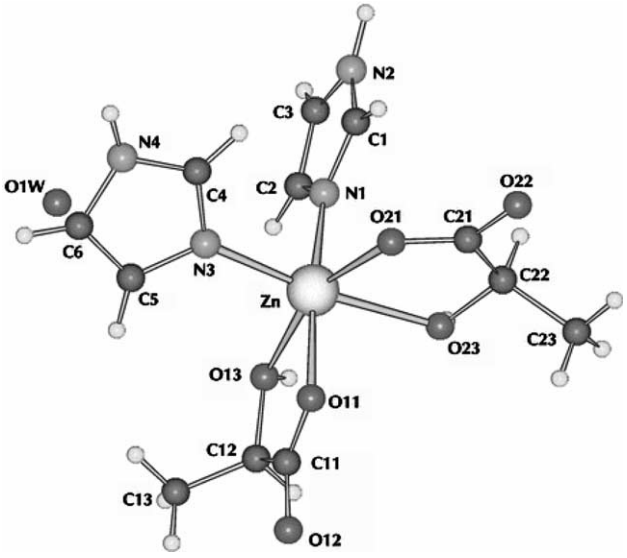

Fig. 2. Molecular structure of *all cis*-$[Zn(HL)_2(Im)_2] \cdot 1/2H_2O$ (**7**).

$Cu–O_{hydroxyl}$ distance is slightly shorter than the $Cu–O_{carboxy}$ distance (belonging the two oxygen atoms of the same ligand). The $Cu–O_{carboxy}$ distances fall within the range usually observed in other copper(II) α-hydroxycarboxylato complexes with N-donor ligands [1–4,16].

The structure of compound **9** is shown in Fig. 7. The zinc ion (located on an inversion centre, d position in the Wyckoff notation) is coordinated to six imidazole ligands and the α-hydroxycarboxylato (benzylato) is present as a monoanionic counterion. Numerous structural reports have been published on octahedral hexakis(imidazole) complexes with first-row transition metals such as Mn(II), Ni(II), Co(II) and Cu(II) but, to the best of our knowledge, only one structure has been reported for a hexakis-substituted complex with Zn(II): $[Zn(Im)_6]Cl_2 \cdot 4H_2O$ [9]. As required by symmetry, the imidazole rings in a *trans* arrangement are coplanar and the metal ion also lies in this plane. The Zn–N distances (Table 1) are similar to those found in $[Zn(Im)_6]Cl_2 \cdot 4H_2O$ [9].

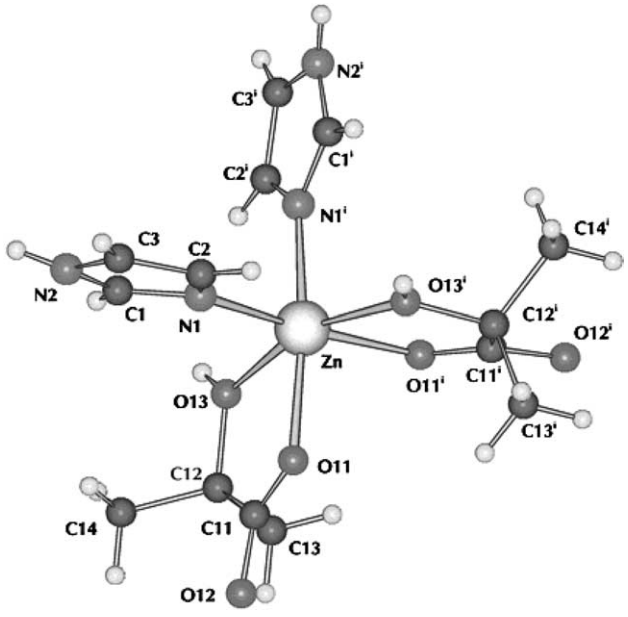

Fig. 3. Molecular structure of $[Zn(HmL)_2(Im)_2]$ (**8**).

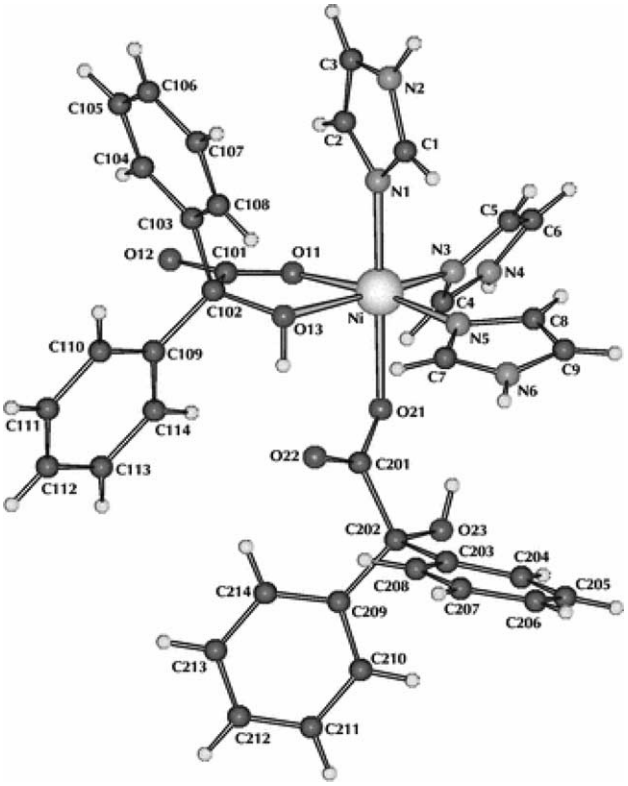

Fig. 4. Molecular structure of *fac*-$[Ni(HB)_2(Im)_3]$ (**3**).

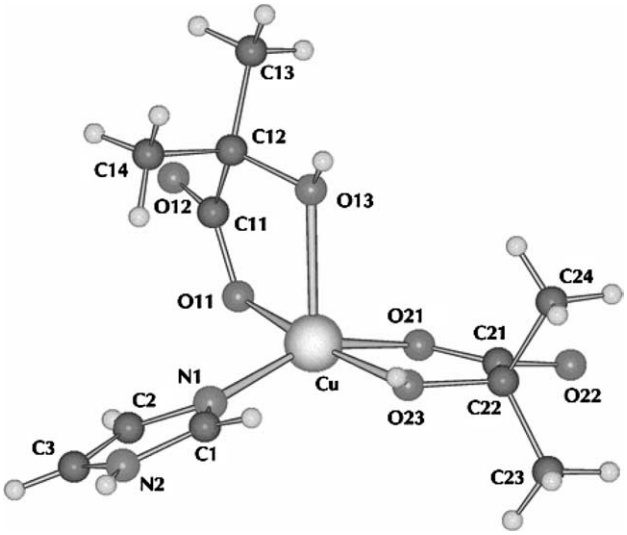

Fig. 6. Molecular structure of $[Cu(HmL)_2(Im)]$ (**6**).

The nature of the imidazole and α-hydroxycarboxylato ligands allows the formation of supramolecular architectures based on hydrogen bonding (Table 2). In most cases, an infinite two-dimensional network is obtained and the 2D structure for **5** is shown in Fig. 8. In complex **3** (Fig. 9), the presence of three imidazole ligands in a *fac*-disposition gives rise to a 3D structure. In all compounds the shortest and most linear intermolecular hydrogen bonds are those between the hydroxyl groups and/or the –NH groups as donors and the uncoordinated oxygen atoms of the carboxylato groups of adjacent molecules as acceptors (O...O range 2.50–2.76 Å and N...O range 2.72–2.95 Å). In addition, other types of intermolecular hydrogen bonds are present in some complexes, where the coordinated $O_{carboxy}$ atom acts as an acceptor and the donors are the –NH groups of the imidazoles (nickel compounds **1** and **3**, N...O distances = 3.004 and 3.191 Å; zinc compound **7**, N...O = distance: 2.799 Å) or the –OH group (copper complexes **5** and **6**, O...O distances = 2.827 and 3.226 Å; zinc compound **7**, O...O distance = 2.785 Å). An interaction between the –NH group and the –OH group acting as an acceptor is also observed in the nickel compound **3** (N...O distance = 2.814 Å) and the zinc compound **9,** where HB acts as a counterion (N...O distance = 3.218 Å). In **4** and **8** there are also C–H...O bonds, which involve imidazole carbons and uncoordinated $O_{carboxy}$ atoms. The values of C...O distances (3.215 and 3.346 Å) and C–H...O angles (152.3° and 161.2°) provide evidence for a significant interaction [17]. This latter bond leads to the formation of 3D networks in **4** (Fig. 10 shows the 2D sheets linked by C–H...O bonds) and in **8** (Fig. 11). In **9** each imidazole ligand participates

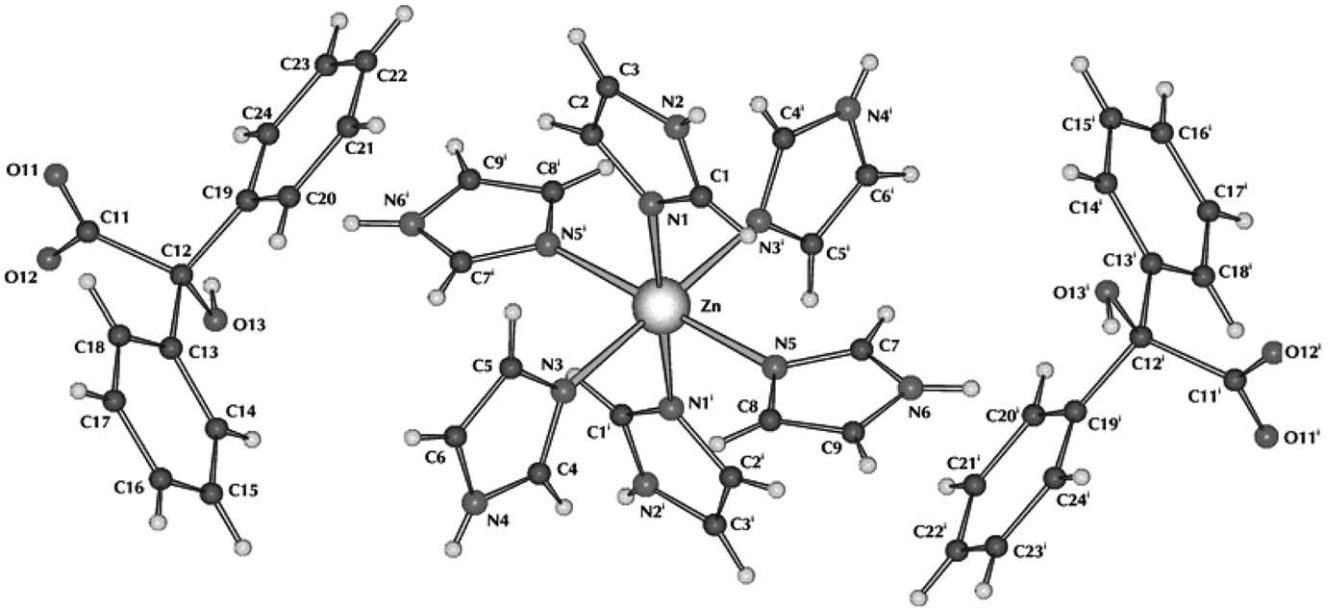

Fig. 7. Molecular structure of $[Zn(Im)_6](HB)_2$ (**9**).

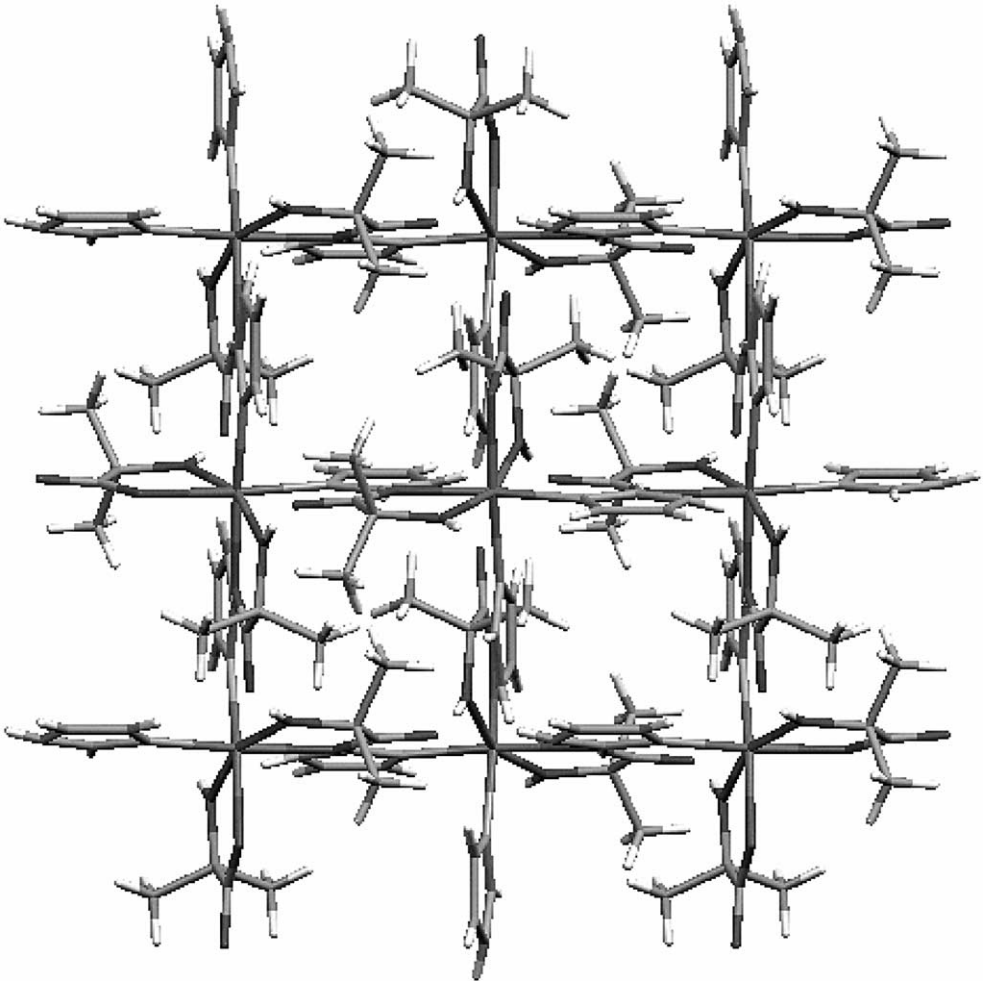

Fig. 11. View of the 3D crystal packing in $[Zn(HmL)_2(Im)_2]$ (**8**) in the ab plane.

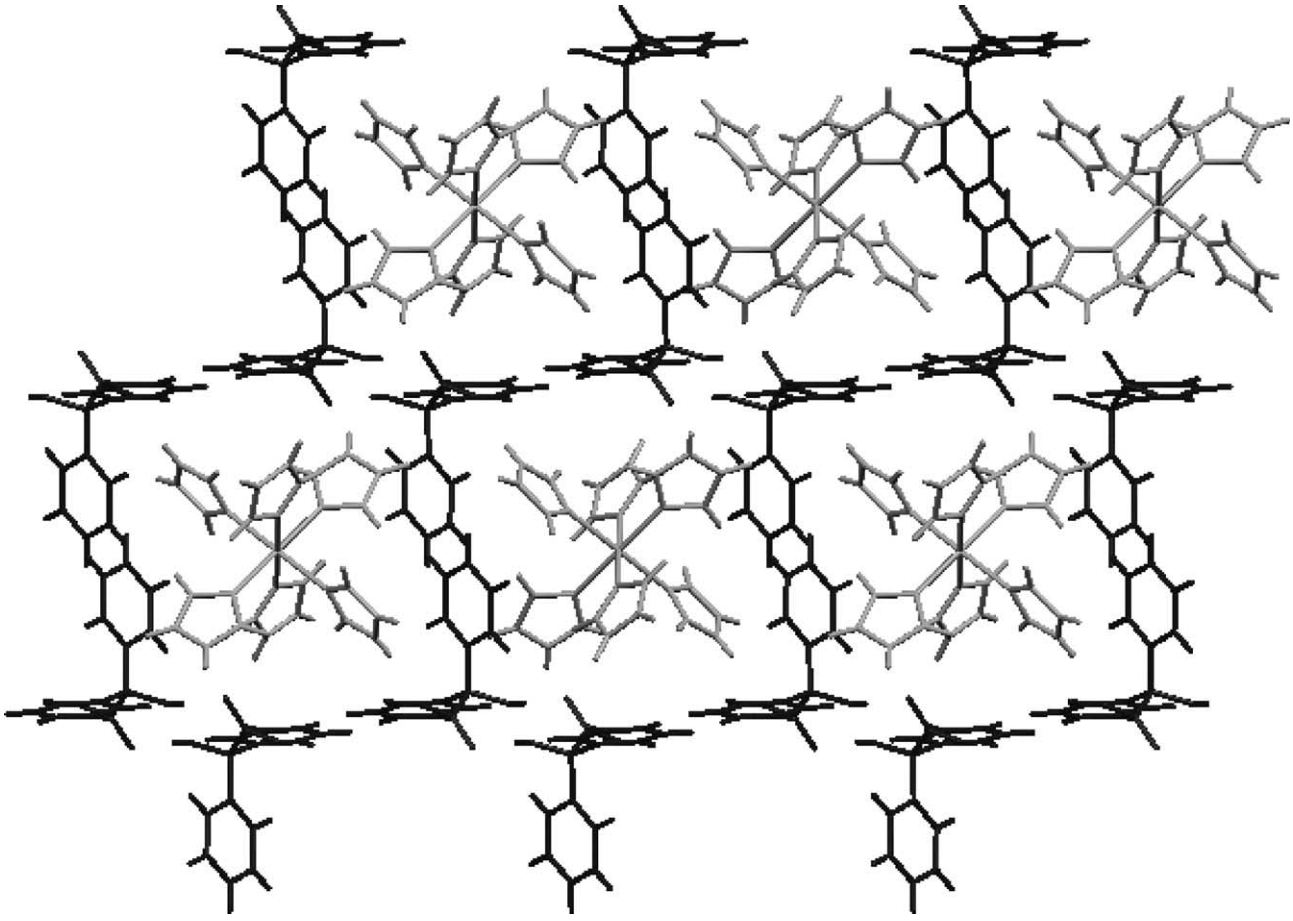

Fig. 12. A fragment of the infinite 3D network through hydrogen bonds of $[Zn(Im)_6](HB)_2$ (**9**) showing the close-packing in the plane *ac*.

in hydrogen bonds with HB molecules, meaning that each cation $[Zn(Im)_6]^{2+}$ is surrounded by six HB molecules and each HB molecule interacts with three cationic species to generate a 3D network (Fig. 12).

All compounds crystallize without solvent molecules in their structures apart from **7**, which contains one water molecule located on a twofold axis (Wyckoff position 4c). This water molecule is not involved in hydrogen bonding.

There are also a number of stacking interactions that involve the imidazole rings. The shortest centroid-to-centroid distances are observed in compounds **4** and **5** (3.581 and 3.571 Å, respectively) with an interplanar dihedral angle α of 0.00° (indicating Im/Im parallelism) and slipping angles β and γ of approximately 24°, revealing a moderate slipping of the stacked rings [18]. Edge-to-face C–H$\ldots\pi$ interactions are also observed in some cases. The main interactions are found in **9** [with an intramolecular C–H(Im)...imidazole centroid of 3.59 Å] and intermolecular interactions in **2** [C–H(Im)... phenyl centroid, 3.52 Å], **4** [C–H(methyl group)... imidazole centroid, 3.49 Å], **5** [C–H(Im)...imidazole centroid, 3.30 Å], **6** [C–H(methyl group)...imidazole centroid,3.67 Å] and **7** [C–H(Im)...imidazole centroid, 3.49 Å].

2.2. Thermal behaviour

Thermogravimetric analysis (TGA) was performed to investigate the thermal stability of compounds **1**–**9**. A summary of the results is given in Table 3. The species were investigated by monitoring the evolved gases by IR spectroscopy. The thermal behaviour of most of the compounds is very similar and generally shows two steps, with the exception of **2** and **9** (three steps) and **7**, which contains water of crystallization (four steps). The nickel and copper compounds are stable up to 170–200 °C and the zinc compounds to 120–150 °C. In **7** the first step corresponds to the loss of the non-coordinated water (75–150 °C). In most of the compounds, however, the first mass loss corresponds to pyrolysis of the α-hydroxycarboxylato ligands followed, in a second step, by the loss of imidazole. Finally, the complexes give residues of NiO at 375–500 °C (nickel compounds), CuO at 425–450 °C (copper compounds) and ZnO or $Zn(OH)_2$ at 475–550 °C (zinc compounds).

2.3. Infrared spectra

The IR spectra of most of the complexes (Table 3) show sharp bands in the 3100–3200 cm^{-1} region, which are assigned to the NH stretching frequency. Complexes **1** and **8** show broad bands in the 3100–3200 cm^{-1} region including ν(OH) and ν(NH) and the remaining complexes show broad bands in the 3200–3400 cm^{-1} region, which correspond to ν(OH). The intense bands appearing around 1600 cm^{-1}, which in most cases overlap with bands associated with the imidazole I band, are assigned to the asymmetric COO^- vibration. The bands found between 1360 and 1400 cm^{-1} are assigned to ν_s(COO). The estimated values around 200 cm^{-1} for $\Delta\nu = \nu_{as}(OCO) - \nu_s(OCO)$ are typical of monodentate carboxylato groups [19]. In compounds **1**–**8** a band is observed in the 420–450 cm^{-1} region and this is attributed to ν(MO) [20].

2.4. Electronic spectra

The reflectance spectra of the nickel and copper complexes in the solid state were recorded in the range 250–1500 nm. The spectra of compounds **1**–**3** (Table 3) are typical of Ni(II) [ground state $^3A_{2g}(F)$] octahedral complexes. The band found between 9090 and 9900 cm^{-1} can be assigned to the $^3T_{2g}(F) \leftarrow {}^3A_{2g}(F)$ (ν_1) transition, that observed around 15 000 cm^{-1} to the $^3T_{1g}(F) \leftarrow {}^3A_{2g}(F)$ (ν_2) transition and the band close to 26 000 cm^{-1} to the $^3T_{1g}(P) \leftarrow {}^3A_{2g}(F)$ (ν_3) transition. The spectra of the copper(II) complexes **4**–**6** all exhibits a broad band, centred at around 13 500 cm^{-1} for **4** and **5** and at 12 300 cm^{-1} for **6**. These bands are characteristic of a copper(II) d–d transition [21] in a tetragonal field in which the copper(II) atom is in a distorted square-based pyramidal coordination environment.

2.5. Magnetic properties

For the nickel complexes (**1**–**3**) the magnitude of the effective magnetic moments between 2.96 and 3.36 BM at room temperature are as one would expect for octahedral symmetry but larger than the spin-only value (2.83 BM) expected for the two unpaired electrons of the Ni(II) cation with a d^8 configuration [22]. For the copper complexes (**4**–**6**), μ_{eff} at room temperature varies from 1.75 to 2.25 BM and these values lie in the range expected for pentacoordinated complexes of copper(II) [23] and are also larger than the spin-only value for an uncoupled Cu(II) ion (1.73 BM).The ESR spectra at room temperature are of the axial type for compounds **4** and **5** ($g_{\|} = 2.31 > g_{|} = 2.06$–$2.05$) and quasi-isotropic or near isotropic ($g_{av} \sim 2.13$) for **6**. These spectra are in accordance with a $d_{x^2-y^2}$ ground state for copper(II), as one would expect for an elongated square-based pyramidal coordination polyhedron.

3. Experimental

3.1. Materials and physical measurements

All reagents and solvents were obtained commercially and were used as supplied.

Microanalyses (C, H, N) were carried out with a FISONS EA-1108 elemental analyser. Melting points (m.p.) were measured with a Gallenkamp MBF-595 apparatus. FT-IR spectra in the 4000–400 cm^{-1}region were recorded from KBr pellets on a Bruker VECTOR 22 spectrophotometer. A Shimadzu UV-3101PC spectrophotometer was used to obtain the electronic spectra in the region 250–1500 nm. ESR spectra of polycrystalline samples were recorded without magnetic dilution using a Bruker ESP 300E spectrophotometer (X band) at room temperature. Magnetic susceptibility measurements were performed at 25 °C using a Johnson Matthey Alfa MSB-MKI Gouy balance. TG/DTG analysis profiles (pyrolysis, 300–1000 K, with IR and MS investigation of evolved gases) were recorded under a 100 mL min^{-1} air flow using a Shimadzu TGA-DTG-50H Thermobalance coupled to a Nicolet Magma 550 FT-IR apparatus and a Fisons Thermolab mass spectrometer.

3.2. Synthesis and crystallisation of the complexes

3.2.1. Nickel(II) Compounds

Compounds **1** and **2** were synthesised by reacting $Ni(AcO)_2 \cdot 4H_2O$ (1 mmol) with 2-methyllactic acid (H_2mL) and mandelic acid (H_2M) (2 mmol), respectively, and Im (2 mmol) in EtOH (30 mL). The mixture was refluxed for 2 h and was then left to cool to room temperature, after which stirring was maintained for 7 days. The light blue powders of **1** and **2** were filtered off. When the reactions were carried out in the molar ratio 1:2:1, the resulting products were respectively: $[Ni(HmL)_2(OH_2)_2]$ (~50%) and **1** (~50%); $[Ni(HM)_2(OH_2)_2]$. H_2O (~50%) and **2** (~50%).

*3.2.1.1. [Ni(HmL)$_2$(Im)$_2$] (**1**).* Yield: 81%; m.p. >250 °C. *Anal.* Calc. for $C_{14}H_{22}N_4O_6Ni$ (401.07): C, 41.9; H, 5.1; N, 13.1. Found: C, 41.1; H, 6.1; N, 12.4%. IR (ν cm^{-1}): 3140 vs b, 2975 vs, 1640 vs, 1579 vs, 1491 s, 1401 s, 1175 s, 1073 s, 966 m, 925 s, 824 m, 730 s, 623 m, 432 m.

Recrystallisation from MeOH/*i*PrOH (1:1) of the light blue oil resulting from the slow evaporation of the mother liquor yielded single crystals of **1**.

*3.2.1.2. [Ni(HM)$_2$(Im)$_2$] (**2**).* Yield: 73%; m.p.> 250 °C. *Anal.* Calc. for $C_{22}H_{22}N_4O_6Ni$ (497.15): C, 53.2; H, 4.5; N, 11.3. Found: C, 53.0; H, 4.0; N, 11.0%. IR (ν cm^{-1}): 3240 s, 3139 s, 2956 s, 1597 vs, 1419 s, 1379 s, 1066 s, 944 m, 802 s, 741 s, 698 s, 576 s, 444 m.

Single crystals of **2** were obtained by slow evaporation at room temperature of the filtrate.

*3.2.1.3. [Ni(HB)$_2$(Im)$_3$] (**3**).* Compound **3** was obtained by a similar procedure, but in this case only when the molar ratio 1:2:1 was used was it possible to identify the resulting products. Firstly, a green powder of formula $[Ni(HB)_2(OH_2)_2]$ was isolated from the resulting suspension. Secondly, recrystallisation from MeOH/*i*PrOH (1:1) of the green oil obtained after the slow evaporation of the mother liquor allowed the isolation of single crystals of **3**.

Data for *[Ni(HB)$_2$(OH$_2$)$_2$]*: m.p.>250 °C. *Anal.* Calc. for $C_{28}H_{24}O_8Ni$ (547.18): C, 61.2; H, 4.8. Found: C, 62.1; H, 5.1%. IR (ν cm^{-1}): 3421 s, 1652 s, 1375 m, 1051 m. UV–Vis (ν, cm^{-1}): 23 480, 13 120, 8010.

*[Ni(HB)$_2$(Im)$_3$] (**3**).* Yield: 25%; m.p. 243 °C. *Anal.* Calc. for $C_{37}H_{34}N_6O_6Ni$ (717.41): C, 61.9; H, 4.8; N, 11.7. Found: C, 61.5; H, 4.8; N, 11.5%. IR (ν cm^{-1}): 3400 m b, 3178 s b, 2967 m, 1620 vs, 1599 vs, 1362 s, 1173 m, 1069 s, 942 m, 831 m, 747 s, 699 s, 598 m, 424 w.

3.2.2. Copper(II) compounds

A mixture of $CuCO_3 \cdot Cu(OH)_2 \cdot 1/2H_2O$ (0.5 mmol) and glycolic acid (H_2G) (**4**), lactic acid (H_2L) (**5**) or 2-methyllactic acid (H_2mL) (**6**) (2 mmol) and Im (1 mmol) in H_2O (30 mL) for **4** and in EtOH (30 mL) for **5** and **6** was refluxed for 2 h and then left to cool to room temperature, after which stirring was maintained for several days. The resulting blue solids **4**–**6** were filtered off and dried over $CaCl_2$.

When a molar metal:imidazole ratio of 1:2 was used the same compounds were obtained.

*3.2.2.1. [Cu(HG)$_2$(Im)] (**4**).* Yield: 50%; m.p. 219 °C. Anal. Found: C, 29.7; H, 3.9; N, 9.7. Calcd. for $C_7H_{10}N_2O_6Cu$ (281.71): C, 29.8; H, 3.6; 9.9%. IR (ν cm^{-1}): 3230 m, 3137 m, 2942 m, 1597 vs, 1377 m, 1075 m, 931 w, 841 w, 771 w, 698 w, 550 w, 451 vw.

Single crystals of **4** were obtained by slow concentration of the mother liquor at room temperature.

*3.2.2.2. [Cu(HL)$_2$(Im)] (**5**).* Yield: 56%; m.p. 190 °C. *Anal.* Calc. for $C_9H_{14}N_2O_6Cu$ (309.76): C, 34.9; H, 4.6; N, 9.0. Found: C, 35.1; H, 5.1; N, 9.6%. IR (ν cm^{-1}): 3399 m, 3169 m, 2980 m, 1610 vs, 1380 s, 1102 m, 1077 m, 959 w, 865 m, 769 m, 654 m, 556 m, 425 w.

The recrystallisation of **5** from a 1:1 mixture of MeOH/*i*PrOH yielded blue single crystals.

*3.2.2.3. [Cu(HmL)$_2$(Im)] (**6**).* Yield: 46%; m.p. 200 °C. *Anal.* Calc. for $C_{11}H_{18}N_2O_6Cu$ (337.81): C, 39.1; H, 5.4; N, 8.3. Found: C, 39.1; H, 5.8; N, 8.3%. IR (ν cm^{-1}): 3279 m b, 3142 s, 2978 s, 1643 vs, 1571 s, 1548 s, 1379 s, 1349 s, 1174 s, 1076 m, 960 m, 817 s, 777 m, 622 m, 527 w, 434 w.

Recrystallisation from MeOH/*i*PrOH (1:1) of the blue oil resulting from the slow evaporation of the mother liquor yielded single crystals.

3.2.3. Zinc(II) compounds

A solution of lactic acid (H_2L) (**7**), 2-methyllactic acid (H_2mL) (**8**) or benzylic acid (H_2B) (**9**) (2 mmol) in ethanol (10 mL) and a solution of Im (2 mmol) in EtOH (10 mL) were added to a suspension of $ZnCO_3$ (1 mmol) in EtOH (10 mL). The mixture was refluxed for 2 h and the resulting white suspension was stirred for several days. The resulting white solids were filtered off and dried. Identification of the solid proved impossible in the reaction with 2-methyllactic acid, but with benzylic acid the solid corresponds to a compound of the formula $[Zn(HB)_2(OH_2)_2]$ and that obtained with lactic acid is consistent with the formula $[Zn(HL)_2(Im)_2]\cdot 1/2H_2O$.

Slow evaporation of the mother liquors of **7** and **8** gave colourless oils, which were dissolved in MeOH/acetone (1:1) for **7** and MeOH/*i*PrOH (1:1) for **8**. Slow solvent evaporation led to the isolation of single crystals of **7** and **8**.

*3.2.3.1. [Zn(HL)$_2$(Im)$_2$]·1/2H$_2$O (**7**).* Yield: 42%; m.p. 104 °C. *Anal.* Calc. for $C_{12}H_{19}N_4O_{6.5}Zn$ (388.68): C, 37.1; H, 4.9; N, 14.4. Found: C, 36.3; H, 4.8; N, 14.1%. IR (ν cm^{-1}): 3388 s b, 3149 s, 2934 m, 1597 vs, 1456 m, 1388 s, 1118 s, 1074 s, 948 m, 831 m, 769 m, 661 s, 557 m, 444 m. ^{1}H NMR (400 MHz, D_2O, ppm): imidazole, 8.15 (s, 1H), 7.32 (s, 2H); lactate, 4.20 (q, 1H), 1.38 (d, 3H).

*3.2.3.2. [Zn(HmL)$_2$(Im)$_2$] (**8**).* Yield: 15%; m.p. 164 °C. *Anal.* Calc. for $C_{14}H_{22}N_4O_6Zn$ (407.73): C, 41.2; H, 5.4; N, 13.7. Found: C, 41.2; H, 5.4; N, 14.1%. IR (ν cm^{-1}): 3400 sh, 3118 vs, 2971 vs, 1589 vs b, 1489 vs, 1362 vs, 1176 vs, 1074 vs, 943 s, 861 s, 731 s, 663 s, 562 m, 432 m. ^{1}H NMR (400 MHz, D_2O, ppm): imidazole, 8.10 (s, 1H), 7.29 (s, 2H); 2-methyllactate, 1.42 (s, 6H).

*3.2.3.3. [Zn(Im)$_6$](HB)$_2$ (**9**).* Yield: 35%; m.p. 130 °C. *Anal.* Calc. for $C_{46}H_{46}N_{12}O_6Zn$ (928.32): C, 59.5; H, 5.0; N, 18.1. Found: C, 59.4; H, 5.0; N, 18.2%. IR (ν cm^{-1}): 3391 s, 3216 s, 3133 s, 2933 s, 1598 vs, 1367 vs, 1146 m, 1098 m, 936 s, 831 s, 773 s, 616 s, 582 m. ^{1}H NMR (400 MHz, D_2O, ppm): imidazole, 7.98 (s, 3H), 7.25 (s, 6H); benzylate, 7.45 (s, 10H).

Slow evaporation of the mother liquor from the reaction with benzylic acid afforded colourless single crystals of **9**.

3.3. X-ray structure determination

Crystallographic data were collected on a Bruker Smart CCD diffractometer at 293 K using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data were corrected for absorption using the program SADABS [24]. The structures were solved by direct methods using the program SHELXS-97 [25]. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F^2 using the program SHELXL-97 [26]. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters, except for those of the hydroxyl groups and of the nitrogen atom in imidazole, which were generally located using a Fourier difference map and refined isotropically. For **8**, which crystallized in the chiral space group $P4_32_12$, the absolute structure parameter of 0.47(3) indicated a twinning by inversion [27] of the crystals. Disorder was observed in some carbon atoms of the phenyl groups in **3** and, consequently, the agreement factors R_1 and wR_2 have unusually high values. Drawings were produced with SCHAKAL [28]. Special computations for the crystal structure discussions were carried out with PLATON for Linux [29]. Crystal data and structure refinement parameters are listed in Table 4.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 224575–224583. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The geometrical structure and bonding in $[Mo_6S_8(CN)_{12}]^{6-}$, $[Re_6S_8(CN)_6]^{4-}$ and $Rh_6(CO)_{16}$ clusters were studied on the basis of quantum chemical calculations. The main attention was paid to the study of electron density distribution and polarizabilities for these compounds. There is noticeable electron density in the inner part of the M_6 octahedrons as well as on the edges and faces of the M_6S_8 polyhedrons. These observations lead to a model of the electronic structure of the clusters with octahedral cores, in which the mobile electrons are moving in a potential well of spherical symmetry. The resulting one electron states are classified according to the orbital quantum number l (1s, 1p, 1d, 1f and so on). Subsequent crystal field splitting leads to a calculated succession of one electron states of O_h point group symmetry. The high values of the calculated polarizabilities of the compounds under consideration are in accord with the suggested model.

1. Introduction

The nature of the bonding in transition metal clusters is of great importance to understand their physical and chemical properties, including stability, reactivity and reaction mechanisms [1–3]. In recent years, special attention has been paid to the study of hexanuclear halcogenide clusters of rhenium and molybdenum of the type $[M_6(\mu_3\text{-}X)_8L_6]^q$ (M = Re, Mo, X = S, Se, L = Cl, Br, I, PR_3, CN^-) [3,4]. The early studies on the electronic structure of such compounds by EHT [5–7] and X_α [8] methods led to the understanding of their molecular orbital energy schemes. The general patterns of these MO schemes were confirmed in recent publications in which more sophisticated quantum chemical methods were used [9–12]. The bonding in these compounds with octahedral metal cores was discussed in terms of the local bonds formed between the ML_4 fragments by the d-orbitals of the metal atoms [3,11].

Electron density distribution is an important manifestation of the nature of the bonding in clusters. The electron density in polyhedral clusters M_n is always significant along the M–M edges; it corresponds to the axial symmetrical M–M σ-bonds. On the other hand, the electron density distribution on the faces and in the cavity of the cluster polyhedron M_n does not directly arise from any characteristics of $M_nX_xY_y$, but can be obtained in the course of special investigations.

Simultaneous information about the electron density distribution on the faces and in the cavity of the cluster polyhedron M_n is important for the theoretical aspect, namely for the comparisons of the main parameters of the electronic structures of $M_nX_xY_y$ with analogous characteristics of the core and polyhedral hydrocarbons C_nH_m and boranes B_nH_m and their numerous derivatives [13]. The quantum chemical study of the geometrical and electronic structure of $[Mo_6S_8(CN)_6]^{6-}$ [12] showed that there is noticeable, almost uniform, electron density in

doi:10.1016/j.poly.2004.03.013

the inner cavity of the Mo_6 octahedron. It was suggested that this effect is to be taken into account in the construction of an appropriate model of the bonding in this compound. This model is based on an assumption that the movement of the electrons takes place in the spherically symmetrical potential with the subsequent splitting of the one-electron energy levels due to the lowering of the symmetry according to the O_h structure of the cluster. The calculated MO levels succession and their symmetry are in accord with this assumption.

In this work, we investigated the relevancy of this model for other transition metal clusters with octahedral metal cores. For this study we have chosen compounds with different metal–ligand bonding: the clusters $[Mo_6S_8(CN)_6]^{6-}$ and $[Re_6S_8(CN)_6]^{4-}$ (with donor ligands but different valence electron counts) and the rhodium $Rh_6(CO)_{16}$ cluster (with π-acid ligands). The electron density distribution over all the complex volume including its inner part suggests the high polarizability of the compounds under consideration. To examine this suggestion, the electron density distribution and polarizability for the clusters of Mo, Re and Rh with octahedral metal cores were calculated and a comparison of these parameters of the three clusters was performed.

2. Method

Quantum chemical calculations were performed by the ab initio SCF method with the 6-31G basis sets for C, N and S atoms. For Mo, Re and Rh atoms, we used SBK (Steven–Bash–Krauss–Jasien) effective core potentials [14] and the corresponding basis sets. Molecular polarizability was calculated with the finite electric field

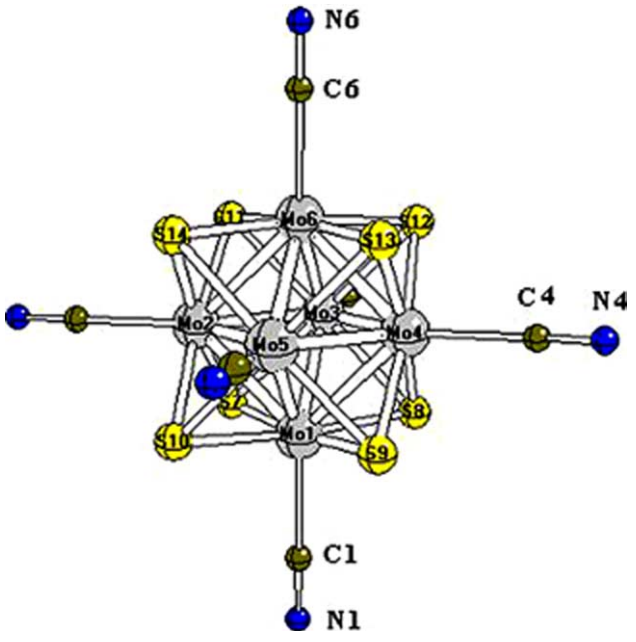

Fig. 1. Molecular structure of the $[Mo_6S_8(CN)_6]^{6-}$ cluster.

Table 1
Average bond lengths for $[M_6S_8(CN)_6]^{n-}$ clusters

Cluster	R(Mo–Mo) (Å)	R(Mo–S) (Å)	R(Mo–C) (Å)
$[Mo_6S_8(CN)_6]^{6-}$	2.725	2.491	2.280
$[Re_6S_8(CN)_6]^{7-}$	2.620	2.400	2.100

method. The bond lengths for the molybdenum cluster were optimized assuming O_h symmetry of this molecule (Fig. 1 and Table 1). For $[Re_6S_8(CN)_6]^{4-}$ and $Rh_6(CO)_{16}$ clusters we used the experimental geometry [4b,15]. The Re complex's bond lengths were obtained by averaging over the data for a number of compounds which contained the $[Re_6S_8(CN)_6]$ fragment, using restrictions imposed according to the symmetry considerations. For the Mo_6S_8 molecule we also performed geometry optimization calculations with a basis which included polarization functions (f-functions for Mo and d-functions for S). All calculations, including electronic density and finite field calculations, were performed with the GAMESS program package [16].

3. One-electron energy levels

The calculated one-electron energy levels diagrams for $[Mo_6S_8(CN)_6]^{6-}$ and $[Re_6S_8(CN)_6]^{4-}$ are shown in Table 2 and for Mo_6S_8 is shown in Table 3. The lowest groups of energy levels (82 in the case of $[M_6S_8(CN)_6]^{6-}$ and 72 in the case of Mo_6S_8) correspond to the molecular orbitals formed by the inner shell atomic orbitals (3d, 4s, 4p for Mo, 1s–2s, 2p and 3s for S and 1s for N and C) and CN molecular orbitals 1σ and 2σ. These molecular orbitals are symmetry adapted linear combinations of the corresponding atomic or CN group molecular orbitals and can be regarded as forming (with the atomic nuclei) the frame for the movement of the remaining valence electrons. Molecular orbitals, corresponding to the upper energy levels (9 t_{2g}–5 t_{2u}), are composed almost totally of the metal and S atomic orbitals. The molecular orbitals that belong to the next large group of MOs (11 a_{1g}–4 t_{2u}) have considerable contributions (up to 83%) from the atomic orbitals of the CN ligand's atoms. In [12], we compare the results of SCF and DFT (B3LYP) calculations of the MO schemes for the $[Mo_6S_8(CN)_6]^{6-}$ cluster. For the upper group of MOs there is good agreement between the results of these calculations. Comparison with the corresponding data for $[Mo_6S_8(CN)_6]^{7-}$ [10] and $Mo_6S_8(PH_3)_6$ [11], obtained in the course of the DV-X_α calculations, shows that in this case there is also general agreement concerning the nature of the nine MOs of the upper group. According to [11], the orbitals of the lower group can be divide into two groups: those composed almost totally of the Mo and S atomic orbitals and those composed by the CN group orbitals. In our case there is substantial mixing of the orbitals of these cluster fragments. The possible reason for such a

RHF calculations with the basis set SBK (M)/6-31G (other atoms). The molecular orbitals, which are regarded as mainly localized on the CN groups, are shown in italic.

difference is in the nature of the methods of the calculations used in this work (SCF) and [12] (DFT/B3LYP), on the one hand, and in [10,11] (DV-X_α method), on the other hand. However, even in our case it is possible to distinguish molecular orbitals with negligible contribution from the AO of Mo and S atoms and those with the noticeable CN component.

In the case of the rhodium $Rh_6(CO)_{16}$ cluster there are 88 core and 75 valent orbitals. The molecular orbitals 89–136 are composed mainly of CO atomic orbitals with moderate contribution from the Rh atoms. The upper 27 MOs are mainly the metal core orbitals with a CO orbital contribution of about 10–35%.

4. Electron density distribution

The Mulliken atomic populations are as follows: $[Mo_6S_8(CN)_6]^{6-}$: Mo, −0.13; S, −0.19; C, +0.08 and N, −0.71.

$[Re_6S_8(CN)_6]^{4-}$: Re, −0.55; S, +0.24; C, +0.18 and N, −0.61.

In the rhodium $Rh_6(CO)_{16}$ cluster the effective Rh atoms charges are −0.035 (equatorial atoms) and +0.055 (apex atoms).

In all clusters studied in this work, there are molecular orbitals of a_{1g} symmetry with electron density mainly concentrated inside the metal atoms octahedron (Fig. 2).

The 12 a_{1g} MO is formed mainly by metal s-AOs (with essential contributions from p- and d-AOs) and its density is localized on the edges of the metal octahedron, but it also has a considerable contribution to the density in the inner part of this polyhedron. The next MO of this symmetry, 13 a_{1g}, is constructed from the metal d-orbitals and corresponds to the a_{1g} orbital scheme proposed in [11] (Fig. 8 in [11]). The calculations of the electron density distribution in the clusters under consideration along the edges and planes of the polyhedron showed that the main features are the same for all

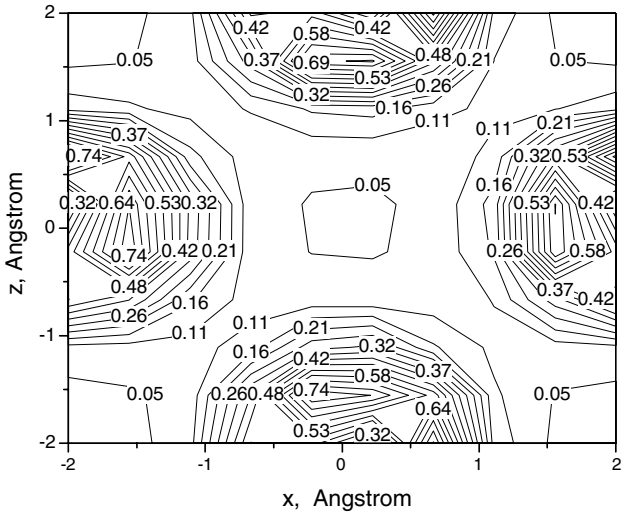

Fig. 3. The electron density distribution in the Re_4 vertical plane (e/a.u.^{3}).

compounds. The electron density distributions in the planes Mo(3)–Mo(4)–Mo(5)–Mo(6), Mo(1)–S–Mo(2), Mo(1)–Mo(3)–Mo(4) are shown in Figs. 3–6 of [12] and on the Re(1)–Re(2)–Re(6)–Re(4) plane – in Fig. 3 of this work. In all cases there is considerable electron density along the edges of the polyhedron; it is never less than 0.08 e/a.u.^{3}. Along the line, connecting the sulfur atom with the center of the metal polyhedrons, there is a small, but distinct maximum near the intersection of this line with the Mo_3 (Re_3) plane. In the central metal octahedral region the density is almost uniform, its value is about 0.04–0.06 e/a.u.^{3} (Fig. 3 of this work and Fig. 5 in [12]). This region can be approximately represented as a sphere with a radius equal to 2 a.u. The effective number of electrons in this volume can be estimated as $0.06 \times \frac{4}{3}\pi R^3 \approx 2$. Besides the electron density from the MOs, mentioned above, some of the density in the center of octahedron comes from the overlap between the other atomic orbitals of the metal atoms.

5. Polarizability calculations

Non-zero electron density inside the M_6S_8 and Rh_6 octahedrons allows to suppose that the polarizability of the cluster compounds under consideration is large. We began the study of this effect from the calculations of the polarizability of the Mo_6S_8 cluster core. To study the influence of the choice of the basis set on the results of polarizability calculations, we performed several RHF calculations for this molecule (Table 4). As can be seen from Table 4, the polarizability of the Mo_6S_8 cluster, calculated in the RHF approximation, increases only by 4% when the basis set is changed from SBK/3-21G (relatively small basis without any polarization and diffuse functions) to the rather extended SBK(f)/6-31+G* basis set. Such a small basis effect on the calcu-

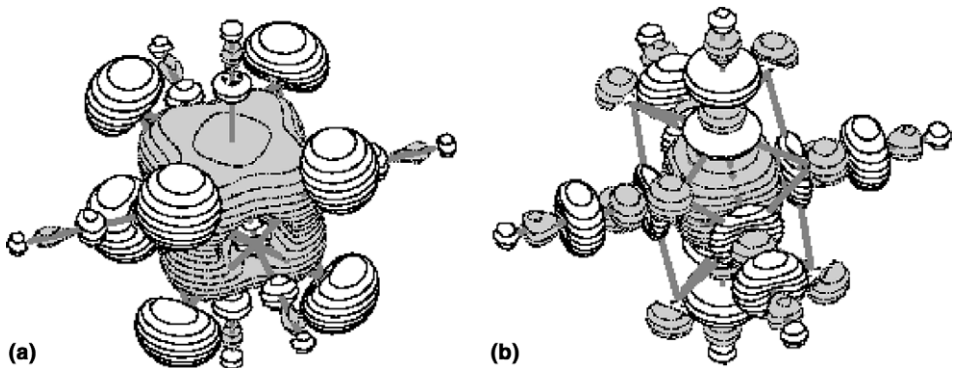

Fig. 2. Molecular orbitals 12 a_{1g} (a) and 13 a_{1g} (b) of the $[Mo_6S_8(CN)_6]^{6-}$ cluster.

Table 4
Results of the RHF polarizability calculations for Mo_6S_8

Basis set Mo/S	Polarizability (Å^3)	
	From energy	From dipole moment
3-21G/3-21G	45.5	45.6
SBK/6-31G*	46.6	46.7
SBK(f)/6-31G*	46.7	46.8
SBK(f)/6-31+G*	47.3	47.4

Geometry optimized with SBK(f)/6-31G* basis set (R(Mo–Mo) = 2.6157 Å, R(Mo–S) = 2.4550 Å).

lated polarizability shows that in the electric field there is electron density displacement through the whole inside volume of the octahedron rather than along chemical bonds and inner atomic spaces.

As in the case of the Mo_6S_8 core, the basis set dependence of the calculated polarizabilities of the clusters is small (Table 5). It is also worth mentioning that in all cases the difference between polarizabilities, calculated from the energy change and from the dipole moment change, is practically negligible. The polarizability of $[Mo_6S_8(CN)_6]^{6-}$ was also calculated according to the additive scheme

$$\alpha_{\parallel}([Mo_6S_8(CN)_6]^{6-}) = \alpha_{\parallel}(Mo_6S_8) + 2\alpha_{\parallel}(CN^-) + 4\alpha_{\perp}(CN^-)$$

with the use of the data for the CN^- group (see Table 5). The results of such an estimation (approximately 56 Å^3) are in good agreement with the results of the straightforward calculations. So the polarization of the CN^- ligands takes place independently (or almost independently) from the main effect – polarization of the inner Mo_6S_8 core.

To examine the electric field effect in more details we performed calculations of the electronic density distribution in the cluster with an electric field (0.01 a.u.) directed along the Mo1–Mo6 axes (Tables 6 and 7). In Fig. 4, the plot of the changes in the electron density distribution due to the inclusion of the electric field is presented. The general trend is a shift of the electronic density in the direction opposite to the direction of the electric field. In accordance with the additivity model, the main effects occur inside the Mo_6S_8 polyhedron. In addition to the main effect there are some more subtle but important effects which do not correspond to the global uniform density shift in the direction opposite to the electric field vector (Fig. 4). In particular, there is a noticeable increase of the electronic density in the outer regions near the Mo6–Mo(equatorial) edges and a pronounced decrease of the electron density in the regions of the Mo1–Mo(equatorial) bonds. This leads to the increase of the Mo6–Mo(equatorial) bond orders and to a decrease of the Mo1–Mo(equatorial) bond orders. There are also

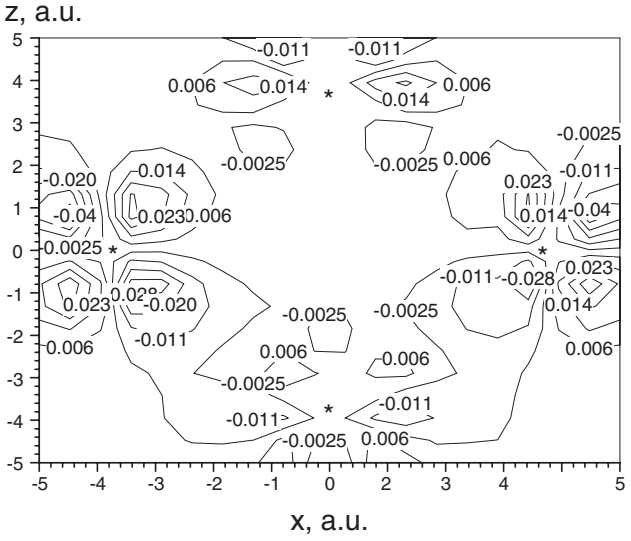

Fig. 4. The changes in electron density distribution in the Re_4 vertical plane due to the electric field effect (e/a.u.^{3}).

analogous changes in the bond orders between the other atoms (Table 7). It is reasonable to expect that such changes in the bond orders lead to the increase or decrease in the corresponding bond lengths in the complex, when placed in an electric field. Optimization of the geometry of $[Mo_6S_8(CN)_6]^{6-}$ in the electric field showed that the changes in the cluster's geometry happen according to the changes in the bond orders in the initial complex with unperturbed geometry (Table 7). However, the effective charges of the Mo atoms (and only the Mo atoms) alter in an unexpected manner, which formally corresponds to the charge flow in the direction of the electric field vector. Possibly this effect reflects the overall reorganization of the bonding in the cluster in the electric field.

6. Discussion

The uniform electron density inside the inner part of the complex reminds us of Thomson's model of the atom with the positively charged atomic nuclei inserted in the electronic jelly. This inspired us to discuss a possible model of the clusters under consideration.

The substantial electron density on the faces and the edges of the metal octahedron resembles a model of the cluster with the electrons distributed on the surface of a sphere. For the description of such a cluster electronic structure, the model of free electrons and simultaneously the theory of tensor surface harmonics (TSH) are used. The TSH theory was developed in framework of the free electron model and uses the theoretical group determination of the nodal structure of cluster molecular orbitals in obvious form [17–20]. According to this theory the atoms M of the cluster M_n are located on the surface of the sphere, and every atom M is described by angle coordinates θ_i and φ_i. The cluster electrons are freely moving on the surface of the sphere that imitates the idealized cluster. The electron wave functions for M_n are the solutions of the Schrödinger equation for the particle on the sphere; these solutions conform to the energy values that depend on their nodal characteristics. So long as the atoms M in the real cluster form a non-spherical polyhedron, the orbitals and energies of the real cluster are determined from the analogous parameters for the spherical cluster using the perturbation theory taking into account the real symmetry of the cluster.

The observation that there is noticeable electron density in the inner parts of the clusters studied in this work, permits the expansion of the above-mentioned model. Let us distinguish two parts in the cluster volume: the inner part consisting of M_6S_8 octahedron and the outer layer of (CN^-) or CO groups. As was shown, the main part of the electron density is localized on the core atomic orbitals and is regarded as fixed inside the corresponding atomic spheres. In our model we also added the electrons on the molecular orbitals with significant contribution from the CN^- or CO ligands to this fixed frame. These electrons together with atomic nuclei generate potential for the movement of the active valence electrons. This potential is approximately a

Table 8
Correlation between the irreducible representation of the spherical symmetry group O(3) and of its subgroup O_h

l	O(3) states	O_h irreducible representation
0	S	a_{1g}
1	P	t_{1u}
2	D	t_{2g}, e_g
3	F	a_{2u}, t_{1u}, t_{2u}
4	G	a_{1g}, e_g, t_{1g}, t_{2g}
5	H	e_u, $2t_{1u}$, t_{2u}
6	I	a_{1g}, a_{2g}, e_g, t_{1g}, $2t_{2g}$

spherical one; moreover, it is almost constant within the inner part of the clusters under consideration. Such a model resembles the state of electrons inside the alkali metal clusters [21]. The solutions of the corresponding Schrödinger equation can be classified as the eigenfunctions of the $\hat{L}^2$ operator (1s, 1p, 1d, etc.). The corresponding one-electron levels are $(2l+1)$-fold degenerated. In the cluster field of the O_h symmetry these levels are split and the new crystal field one electron states are transformed according to the irreducible representations of the O_h point group (see Table 8). So it is possible to arrange a set of nl states taking into account the crystal field splitting and to bring them into correlation with the calculated MO levels. Such a scheme (after deleting from the MO scheme molecular orbitals with substantial contribution from CN^- groups) is the same for the both cyanoclusters, studied in this work (Tables 2 and 3). The tentative correlation of the calculated MOs and the "spherical potential solutions" is presented in Fig. 5. It is worth mentioning that some of the irreducible representations (IRs) are unique: thus, IR a_{2u} is present only in the "f"-subset, IR a_{2g} is present only in the "h"-subset. This facilitates the assignment of the calculated MOs to the different l-subgroups and clarifies the sequence of energies of different O(3) states.

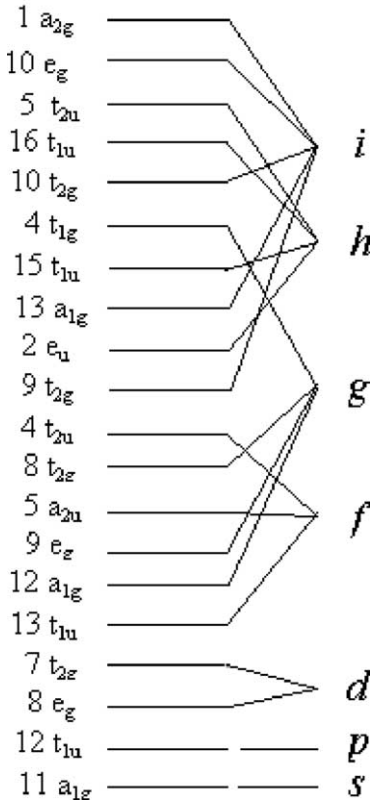

Fig. 5. Tentative correlation between the calculated O_h and suggested O(3) energy levels.

The resulting molecular orbital scheme differs from that of the natrium cluster: the energy goes up with the increasing value of the l quantum number, whereas in the Na_n clusters 2p, 2d and other states appear. The suggested model includes the TSH model as a limiting case with negligible electronic density in the inner part of the cluster.

The results for the clusters embedded in an electric field showed that the structure of such compounds is very flexible and sensitive to external disturbances. The data concerning attachment of new ligands to the clusters [5] or mononuclear complexes [4b] appears to confirm such a suggestion. This problem needs further investigation.

7. Conclusion

The results of the present study demonstrated the common nature of the inner M_6 part of the clusters regardless of the nature of the surrounding ligands. The high (and almost equal) values of the polarizability of the compounds under investigation confirms this thesis and demonstrated the possibility of the strong deformation of their geometrical structure due to the change of the cluster composition or inclusion of the additional ligands.

Abstract

Bis(diphenylphosphino)methane dioxide compounds of uranyl nitrate and uranyl bis(β-diketonates) have been synthesized and characterized by spectroscopic and X-ray diffraction methods. Monodentate, bidentate chelate and bridging bidentate modes of coordination for this ligand have been established from the single-crystal X-ray diffraction studies of its compounds, $[UO_2(DBM)_2DPPMO]$, $[UO_2(NO_3)_2DPPMO]$ and $[\{UO_2(DBM)_2\}_2DPPMO]$, respectively.

1. Introduction

Many multifunctional phosphine oxide (PO) based ligands have been examined for the separation of minor actinides from highly active nuclear waste solution [1–6] and the structures of their lanthanide [7–15] and actinide compounds [16–23] have also been reported. Solvent extraction properties of a variety of bi-functional diphosphine dioxides with actinide and lanthanide ions [24–27] have been examined and some of their lanthanide compounds [28,29] have also been characterized structurally. However, there is no structural study on diphosphine dioxide–actinide compounds, except some IR, molecular weight and conductance data [30–34]. In view of the lack of structural reports on diphosphine dioxide actinide compounds, we felt it important to study such complexes with a relatively simple diphosphine dioxide, e.g., bis(diphenylphosphino)methane dioxide, in order to establish the fundamental structural properties. This ligand can act in three possible modes to bond with the metal ion, as shown in Fig. 1.

The chelating mode of bonding is well established for this ligand in alkali, alkaline earth, main group and lanthanide metal ion compounds [28,29,35–45]. The bridging bidentate mode of bonding is also reported in a few of its compounds [46–49]. However, the monodentate mode of bonding has only been reported in one compound, $[Cl_3LRe(DPPMO)]$, so far [50]. We report herein the compounds of bis(diphenylphosphino)methane dioxide with the uranyl ion, which together show all modes of coordination for this ligand.

2. Experimental

2.1. Materials and measurements

All solvents are analytical grade and used as such without further purification. Bis(diphenylphosphino)methane (DPPM), thenoyl trifluoroacetone (HTTA), benzoyl trifluoroacetone (HBTA), dibenzoyl methane (HDBM) and benzoyl acetone (HBA) were obtained from commercial sources. The starting compounds $[UO_2(OO)_2 \cdot 2H_2O]$ (OO = β-diketonate ligand)

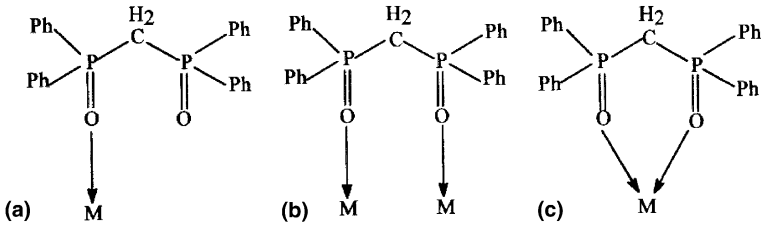

Fig. 1. Different modes of coordination for the DPPMO ligand: (a) monodentate, (b) bridging bidentate, and (c) bidentate chelating.

were prepared according to the reported methods [51]. FT-IR spectra for all compounds were measured on a JASCO FT-IR-610 instrument using Nujol mull. The ^{1}H and $^{31}P\{^{1}H\}$ NMR spectra were recorded on a BRUKER 500 MHz instrument operating at 500 and 202.5 MHz, respectively. The peaks are assigned relative to internal $CHCl_3$ (for ^{1}H) or external 85% H_3PO_4 (for ^{31}P). The Analytical chemistry division of Bhabha Atomic Research Center, Mumbai, performed the carbon, hydrogen and nitrogen analyses.

2.2. Synthesis of $[(C_6H_5)_2P(O)CH_2P(O)(C_6H_5)_2]$ (DPPMO)

To a suspension of bis(diphenylphosphino)methane (DPPM) (10 mg, 0.026 mol) in methanol, H_2O_2 (7 ml of 30% H_2O_2) was added slowly with stirring. The solution became clear on stirring and deposited a white solid. The solvent was removed under vacuum, the resulting solid was extracted with hot methanol and filtered. The hot solution on standing deposited a white crystalline solid (yield, 10.1 mg, 93.5%). *Anal*. Calc. for $C_{25}H_{22}P_2O_2$: C, 72.1; H, 5.3. Found: C, 72.0; H, 5.4%. IR (Nujol mull, KBr, ν cm^{-1}): 1204 (PO). ^{1}H NMR ($CDCl_3$, δ ppm): 3.52 (t, $J(PH) = 15$ Hz, 2H, CH_2); 7.32–7.44 (m, 12H, C_6H_5), 7.71–7.75 (m, 8H, C_6H_5). $^{31}P\{^{1}H\}$ ($CDCl_3$, δ ppm): 23.30 (s).

2.3. Synthesis of $[UO_2(NO_3)_2 \cdot DPPMO]$ (1)

To a hot ethanol solution of DPPMO (200 mg, 0.48 mmol), $[UO_2(NO_3)_2 \cdot 6H_2O]$ in ethanol (241.3 mg, 0.48 mmol) was added and refluxed for 15 min. The resulting solid product was filtered, washed with ethanol and dried. This solid was recrystallized from a methanol/ethanol mixture as a yellow crystalline solid (yield, 370 mg, 95%). *Anal*. Calc. for $C_{25}H_{22}P_2O_{10}N_2U$: C, 37.0; H, 2.7; N, 3.5. Found: C, 37.0; H, 2.5; N, 3.4%. IR (Nujol mull, KBr, ν cm^{-1}): 1523, 1307, 1275 (NO_3); 1139 (PO); 929 (O=U=O). ^{1}H NMR (CD_3COCD_3, δ ppm) : 4.99 (t, $J(PH) = 13$ Hz, CH_2); 7.64–7.67 (t), 7.76–7.79 (t), 8.22–8.26 (m) (C_6H_5, DPPMO). $^{31}P\{^{1}H\}$(CD_3COCD_3, δ ppm): 39. 9 (s).

2.4. Synthesis of $[UO_2(DBM)_2 \cdot DPPMO]$ (2)

To a hot chloroform solution of $[UO_2(DBM)_2 \cdot 2H_2O]$ (250 mg, 0.332 mmol), DPPMO (138.3 mg, 0.332 mmol) was added and refluxed for 3 h. The clear solution was filtered and layered with dodecane. The solution on evaporation yielded a red colored crystalline product. It was filtered, washed with hexane and dried (yield, 350 mg, 93%). *Anal*. Calc. for $C_{55}H_{44}P_2O_8U$: C, 58.3; H, 3.9. Found: C, 57.9; H, 4.1%. mixture of mononuclear compound **4** and dinuclear compound **7**).

2.7. Synthesis of $[\{UO_2(DBM)_2\}_2 \cdot DPPMO]$ (**5**)

To a hot chloroform solution of $[UO_2(DBM)_2 \cdot 2H_2O]$ (400 mg, 0.544 mmol), DPPMO (113.3 mg, 0. 272 mmol) was added and refluxed for 3 h. The clear solution was filtered and layered with dodecane. The solution on evaporation yielded a red colored crystalline product. It was filtered, washed with hexane and dried (yield, 470 mg, 96%). *Anal*. Calc. for $C_{85}H_{66}P_2O_{14}U_2$: C, 55.2; H, 3.6. Found: C, 55.8; H, 3.8%. IR (Nujol mull, KBr, ν cm^{-1}): 1590 (br, CO, DBM); 1152 (PO, DPPMO); 905 (O=U=O). ^{1}H NMR ($CDCl_3$, δ ppm): 4.64 (br, s, CH_2, DPPMO); 6.97 (s, CH, DBM), 7.16–8.66 (m, br, C_6H_5 of DPPMO + DBM). $^{31}P\{^1H\}$ ($CDCl_3$, δ ppm): 38.73 (s).

2.8. Synthesis of $[\{UO_2(TTA)_2\}_2 \cdot DPPMO]$ (**6**)

To a hot chloroform solution of $[UO_2(TTA)_2 \cdot 2H_2O]$ (200 mg, 0.267 mmol), DPPMO (55.6 mg, 0.133 mmol) was added and refluxed for 3 h. The clear solution was filtered and layered with dodecane. The solution on evaporation yielded a red colored product. It was filtered, washed with hexane and dried (yield, 230 mg, 93%). *Anal*. Calc. for $C_{57}H_{38}P_2O_{14}F_{12}S_4U_2$: C, 37.2; H, 2.1. Found: C, 37.6; H, 2.4%. IR (Nujol mull, KBr, ν cm^{-1}): 1612–1594 (br, CO, DBM); 1137 (PO, DPPMO); 921 (O=U=O). ^{1}H NMR ($CDCl_3$, δ ppm): 5.10 (t, CH_2, DPPMO); 6.81, 6.85 (s, CH, TTA), 7.18–8.32 (m, br, C_6H_5 of DPPMO and C_4H_3S of TTA). $^{31}P\{^1H\}$ ($CDCl_3$, δ ppm): 42.13 (s) and 41.87 (s).

2.9. Synthesis of $[\{UO_2(BTA)_2\}_2 \cdot DPPMO]$ (**7**)

To a chloroform solution of $[UO_2(BTA)_2 \cdot 2H_2O]$ (250 mg, 0.3396 mmol), DPPMO (70.65 mg, 0.1698 mmol) was added and refluxed for 3 h. The clear solution was filtered and layered with dodecane. The solution on evaporation yielded a yellow colored crystalline product. It was filtered, washed with hexane and dried (yield, 300 mg, 92.6%). *Anal*. Calc. for $C_{65}H_{46}P_2O_{14}F_{12}U_2$: C, 43.0; H, 2.5. Found: C, 43.1; H, 2.4%. 2.10. Synthesis of $[\{UO_2(BA)_2\}_2 \cdot DPPMO]$ (**8**)

To a hot chloroform solution of $[UO_2(BA)_2 \cdot 2H_2O]$ (300 mg, 0.477 mmol), DPPMO (99.36 mg, 0.2388 mmol) was added and refluxed for 3 h. The clear solution was filtered and layered with dodecane. The solution on evaporation yielded an orange colored product. It was filtered, washed with hexane and dried (yield, 325 mg, 85%). *Anal*. Calc. for $C_{65}H_{58}P_2O_{14}U_2$: C, 48.7; H, 3.6. Found: C, 48.3; H, 3.4%. IR (Nujol mull, KBr, ν cm^{-1}): 1590 (br, CO, BA); 1148 (PO, DPPMO); 908 (O=U=O). ^{1}H NMR ($CDCl_3$, δ ppm): 2.22 (s, br, CH_3); 2.79 (s, br, CH_3); 4.92 (s, br, CH_2, DPPMO); 6.55 (br, s, CH, BA), 7.21–8.5 (m, br, C_6H_5 of DPPMO + BA). $^{31}P\{^1H\}$ ($CDCl_3$, δ ppm): 38.45 (s) and 38.07 (s).

2.11. Crystal structure determination

Data for all three crystals **1**, **2** and **5** were measured with Mo Kα radiation ($\lambda = 0.71073$ Å) using the MARresearch Image Plate System. The crystals were positioned at 70 mm from the Image Plate. One hundred frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the

XDS program [52]. The structures were solved using direct methods with the SHELX-86 program [53]. The non-hydrogen atoms were refined with anisotropic thermal parameters in all cases. The hydrogen atoms bonded to carbon atoms were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atoms to which they were attached. Empirical absorption corrections were carried out using the DIFABS program [54]. The structures were refined to convergence on F^2 using SHELXL [55]. Selected crystallographic data for all the compounds are summarized in Table 1.

3. Results and discussion

3.1. Uranyl nitrate–DPPMO compound [$UO_2(NO_3)_2 \cdot DPPMO$] (1)

The reaction of $[UO_2(NO_3)_2 \cdot 6H_2O]$ with bis(diphenylphosphino)methane dioxide in ethanol yielded **1**. The IR spectrum of **1** shows that the water molecules from the starting compound $[UO_2(NO_3)_2 \cdot 6H_2O]$ are replaced completely by the DPPMO ligand. It suggests further that the ligand coordinates through both the phosphine oxide oxygen atoms to the uranyl group ($\Delta\nu_{PO} = 65$ cm^{-1}). The $^{31}P\{^1H\}$ NMR of **1** shows a single resonance at 39.9 ppm which is deshielded by ca. 16 ppm with respect to the free ligand. The ^1H NMR spectrum of **1** shows that the CH_2 protons of the DPPMO ligand are deshielded by ca. 1.42 ppm with respect to the free ligand. It supports further the coordination of both the phosphine oxide oxygen atoms to the uranyl group. The carbon, hydrogen and nitrogen analysis revealed that the ratio of $UO_2(NO_3)_2$ to DPPMO is 1:1 in **1**. The molecular weight determination on similar type of compounds $[UO_2(NO_3)_2X]$ (where X = EBDPM or CHDPH) reported earlier, revealed a monomeric structure [32] with bis(phosphine) oxide, acting as a chelating ligand. By comparison, the viscosity measurements revealed a polymeric structure [32] with bis(phosphine) oxide acting as a bridging bidentate ligand. The structure of **1** was determined by the X-ray diffraction method and confirms the chelating mode of coordination for this ligand.

3.2. Molecular structure of [$UO_2(NO_3)_2DPPMO$] (1)

The molecular structure of **1** is shown in Fig. 2 and selected interatomic bond distances and angles are given in Table 2. The structure shows that the uranium atom is surrounded by eight oxygen atoms in a hexagonal bipyramidal geometry. The four oxygen atoms of the nitrate groups and two oxygen atoms of DPPMO forms a planar hexagon and these six oxygen atom atoms are coplanar to within 0.07 Å. The observed (average) bond distances between U–$O_{(uranyl)}$ (1.775(11) Å) U–$O_{(nitrate)}$ (2.5398(12) Å) and U–$O_{(DPPMO)}$ (2.386(9) Å) agree well with the earlier reported uranyl nitrate, phosphine oxide compound $[UO_2(NO_3)_2(PPh_3O)_2]$ [56]. In $[UO_2(NO_3)_2(PPh_3O)_2]$ all the groups are *trans* to each other, i.e., phosphine oxide *trans* to phosphine oxide and nitrate *trans* to nitrate group. However, in **1** the phosphine

oxide and nitrate groups are *cis* to each other, due to the chelating nature of the DPPMO ligand. The six membered metallocyclic ring formed by the DPPMO ligand is severely folded with an angle of 52.8° between the plane of U(1), O(11), O(12) and of the P(1), C(2) and P(3) atoms. The bond angles and lengths around the phosphine oxide part of the molecule agree well with earlier reported lanthanide DPPMO compounds [28,29].

3.3. Mononuclear compound $[UO_2(DBM)_2DPPMO]$ (2)

The 1:1 reaction of $[UO_2(DBM)_2 \cdot 2H_2O]$ with DPPMO in chloroform yielded **2**. The IR spectrum of **2** shows that the water molecules from the starting compound are completely replaced by the DPPMO ligand. It suggests further, that the DPPMO ligand coordinates through one of the phosphine oxide oxygen atoms to the uranyl group and the other one is free. This observation is further supported by the $^{31}P\{^1H\}$ NMR spectrum, which displayed two resonances with equal intensities, with one deshielded by ca. 15 ppm and other with very little change with respect to the free ligand. The ^1H NMR of **2** showed a single resonance for the CH_2 protons of DPPMO and is deshielded by 0.37 ppm with respect to the free ligand. The deshielding of CH_2 protrons in **2** is much smaller as compared to **1**, where the DPPMO is bonded through both PO oxygen atoms to the uranyl group. The structure of **2** was determined by single-crystal X-ray diffraction methods and confirms the spectral interpretation.

3.4. Molecular structure of $[UO_2(DBM)_2\ DPPMO]$

The molecular structure of **2** is shown in Fig. 3 and selected interatomic bond distances and angles are given in Table 2. The structure shows that the uranium atom is surrounded by seven oxygen atom in a pentagonal bipyramidal geometry. The four oxygen atoms of DBM and one oxygen of DPPMO form a planar pentagon and these oxygen atoms are coplanar to within 0.06 Å. The structure shows clearly that the DPPMO is acting as a monodentate ligand and is bonded through one of the phosphine oxide oxygen atoms (O11) to the uranyl group, and the other oxygen atom is free (O21). The observed average bond lengths for $U–O_{(uranyl)}$ (1.778(7) Å) [56–61], $U–O_{(DBM)}$ (2.3663(8) Å) [58–60] and $U–O_{(DPPMO)}$ (2.384(7) Å) [56,60,61] agree well with earlier reported values. The bond lengths and angles around the DPPMO part of the molecule agree well with an earlier reported rhenium–DPPMO compound $[Cl_3LRe(DPPMO)]$ [50].

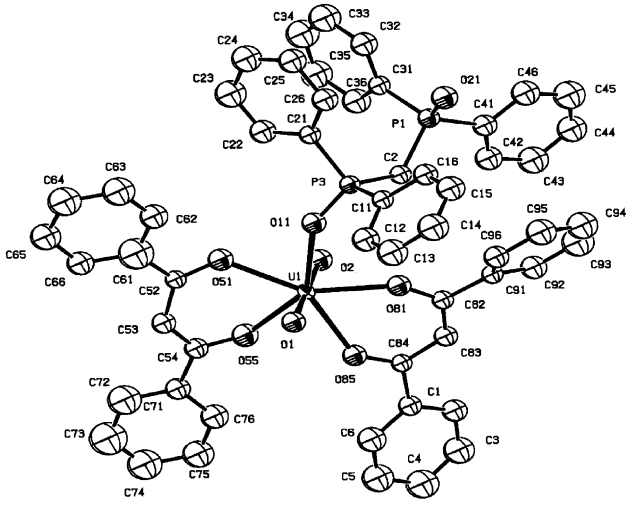

Fig. 3. Molecular structure of $[UO_2(DBM)_2DPPMO]$ with ellipsoids at 50% probability.

Attempts to prepare (pure) 1:1 compounds of $[UO_2(TTA)_2]$ and $[UO_2(BTA)_2]$ with DPPMO (**3** and **4**, similar to **2**), yielded a mixture of mononuclear and dinuclear compounds (similar to **5**–**8**), revealed from ^1H and ^{31}P NMR spectroscopy.

3.5. Dinuclear compounds $[\{UO_2(OO)_2\}_2DPPMO]$ (5–8)

The 2:1 reaction of $[UO_2(OO)_2 \cdot 2H_2O]$ (where, OO = TTA, DBM, BTA or BA) with DPPMO in chloroform yielded **5**–**8**. The IR spectra of **5**–**8** showed that the water molecules from the starting compound are completely replaced by the DPPMO ligand. It suggests further that the DPPMO is coordinating through both the phosphine oxide oxygen atoms to the uranyl group. This observation is further supported by the $^{31}P\{^1H\}$ NMR spectra, which displayed one (DBM) or two (TTA, BTA or BA) resonances, which were deshielded by ca. 13–16 ppm with respect to the free ligand. The presence of two resonances for TTA, BTA or BA show that they are existing as a mixture of two isomeric products, viz., *cis–cis* or *trans–cis* [62]. The ^1H NMR spectra of **5**–**8** showed a single resonance for the CH_2 protons of DPPM which was deshielded by ca. 1.12–1.6 ppm with respect to the free ligand. The deshielding of CH_2 protons in **5**–**8** is much larger as compared to **2**–**4**, where the DPPMO is bonded through one of the PO oxygen atoms and acts as a monodentate ligand. The structure of **5** was determined by single-crystal X-ray diffraction methods and confirms our spectral observations.

3.6. Molecular structure of $[\{UO_2(DBM)_2\}_2DPPMO]$ (5)

The molecular structure of **5** is shown in Fig. 4 and selected interatomic bond distances and angles are given in Table 2. The structure shows a centrosymmetric dimer with the two halves of the $[UO_2(DBM)_2]$ moieties

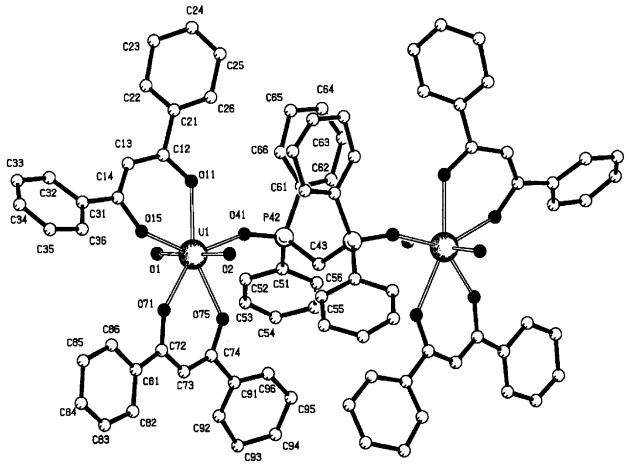

Fig. 4. Molecular structure of $[\{UO_2(DBM)_2\}_2DPPMO]$.

bridged by a DPPMO ligand. The geometry around each individual uranium atom is pentagonal bipyramidal with four oxygen atoms from DBM and one from phosphine oxide forming a planar pentagon, and these oxygen atoms are coplanar to within 0.07 Å. The structure also contains solvent water and methanol molecules with 25% occupancy which are not included in Fig. 4, for clarity. The bond lengths and angles around the uranium atoms are normal [58–60].

It is interesting to note that an attempt to prepare a dinuclear compound $[Cl_3LRe(DPPMO)ReLCl_3]$ from $[Cl_3LRe(DPPMO)]$ (where L = 2-(p-chlorophenyl-azo)-1-methylimidazole), similar to the one that is reported here, was not successful in rhenium compounds [50]. The authors stated that the uncoordinated or free phosphine oxide group in $[Cl_3LRe(DPPMO)]$ is sterically overcrowded [O(2)···P(1) 3.57 Å, O(2)···C(11) 3.55 Å] and therefore it may not allow the second molecule of $ReLCl_3$ to approach to form a dinuclear compound. However, in the present case, the uncoordinated or free phosphine oxide in **2** is relatively much more overcrowded (P(3)···O(21) 3.493 Å, O(21)···C(21) 3.555 Å, O(21)···C(11) 3.77 Å, O(21)···C(21) 3.224 Å) compared to the distances observed in the rhenium compound $[Cl_3LRe(DPPMO)]$ and despite these contacts is still able to form the dinuclear compound **5**. It suggests clearly that the steric crowding around the free phosphine oxide is not an important factor for the formation of the dinuclear compounds as stated in the report of the structure of $[Cl_3LRe(DPPMO)]$.

4. Conclusion

The first structurally characterized bis(phosphine)dioxide compounds of the uranyl ion, **1**, **2** and **5** show that it can act as a bidentate chelating, monodentate or bridging bidentate ligand, depending upon the anions used. Different modes of coordination for the DPPMO ligand can be controlled by suitably selecting the anion and the stoichiometry of the uranyl-bis(β-diketonates) used.

Abstract

A gallophosphate compound, $[C_6H_{10}(NH_3)_2]Ga_2P_2O_8(OH)_2$ (named JGP-5) has been synthesized hydrothermally by using *trans*-1,4-diaminocyclohexane as the template. It has been characterized by X-ray powder diffraction (XRD), elemental analysis, inductively coupled plasma (ICP) and TGA analysis, and structurally determined by single-crystal X-ray diffraction analysis. JGP-5 crystallizes in the monoclinic, space group *Cc*, with $a = 25.740(5)$, $b = 5.412(1)$, $c = 9.888(2)$ Å, $\beta = 94.32(3)°$, $V = 1373.5(5)$ Å^3 and $Z = 4$. The 2D anionic framework of JGP-5 is built up from vertex linkage of $GaO_4(OH)_2$ octahedra and HPO_4 tetrahedra, forming a gallophosphate sheet with three- and six-membered channels along the *a*-axis direction. The organic amines display a strong templating effect on the inorganic layer.

1. Introduction

In the past 20 years, the synthesis of new open-framework metal phosphates has attracted considerable attention because of their potential applications in catalysis, adsorption and separation [1–3]. Among the metal phosphates, gallophosphates constitute an important family. Since the discovery of the $GaPO_4$-14 molecular sieves in 1985, many novel gallophosphates with 1D, 2D and 3D structures have been synthesized successfully under hydrothermal or solvothermal conditions [4–6]. The structures of these compounds are built mainly from GaO_4 tetrahedra, GaO_5 trigonal bipyramids, GaO_6 octahedra, or their combination, and PO_4 tetrahedra, but examples of single polyhedra are also known [7–9]. The syntheses typically involve the addition of organic amines. It is proposed that in most cases, the amines act as a structure-directing agent (template) when their shapes are related to the frameworks. Among the various organic amines used, the family of diaminoalkanes is more effective than that of monoaminoalkanes to display a strong templating effect in the formation of gallophosphates with open architecture [10–14].

In recent years, we have devoted efforts toward the synthesis of metal phosphates with novel topologies [15–22]. In the case of gallium, we obtained a new layered gallophosphate with a Ga/P ratio of non-unity [23]. In this paper, we describe the synthesis and structure of a 2D gallophosphate $[C_6H_{10}(NH_3)_2]Ga_2P_2O_8(OH)_2$ (named JGP-5), using *trans*-1,4-diaminocyclohexane as the template.

2. Experimental

JGP-5 is synthesized under hydrothermal conditions. The chemical sources used in the synthesis were an amorphous gallium oxide, which was prepared by heating a gallium oxide hydroxide at 400 °C for 3 h (gallium oxide hydroxide was prepared by direct reaction of gallium metal with water at 220 °C under

autogenous pressure for 3 days), phosphoric acid (Beijing Chemical Plant, 85%) and *trans*-1,4-diaminocyclohexane (1,4-DACH, Aldrich).

2.1. Synthesis and characterization

JGP-5 was hydrothermally prepared from a reaction mixture of 1 Ga_2O_3:1 H_3PO_4:0.8 1,4-DACH:185 H_2O (molar ratio, pH 7) with vigorous stirring. The mixture was then aged at room temperature for 1 h, transferred to the Teflon-lined stainless steel autoclave and then heated under autogenous pressure at 180 °C for 3 days. The product was washed with distilled water and dried overnight at 50 °C to give colorless crystals.

The powder X-ray diffraction (XRD) patterns were recorded on a Siemens D5005 diffractometer with Cu Kα radiation ($\lambda = 1.5418$ Å). The elemental analyses were performed on a Perkin–Elmer 2400 elemental analyzer and the inductively coupled plasma (ICP) analysis on a Perkin–Elmer Optima 3300 DV ICP instrument. Thermogravimetric analysis (TGA) was conducted on a Netzsch STA 449C thermogravimetric analyzer with a heating rate of 10 °C min^{-1} in air. IR spectra were recorded on a Nicolet Impact 410 FTIR spectrometer using KBr pellets.

2.2. Determination of crystal structure

A suitable single crystal of JGP-5 was selected for single-crystal XRD analysis. The structural analysis was performed on a Rigaku R-AXIS RAPID IP diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data were collected at a temperature of 193 ± 1 K. Data processing were accomplished with the Process-Auto processing program [24]. The structures were solved by direct methods and refined by full-matrix, least squares based on F^2 using the SHELXTL 5.1 software package [25]. The gallium and phosphorus atoms were first located, and carbon, nitrogen, oxygen atoms and the hydrogen atoms residing in the organic amine molecules were located geometrically. All non-hydrogen atoms were refined anisotropically. The Flack x parameter of JGP-5 was 0.00(6), indicative of correct absolute structure. Crystal data and details of data collection and refinement are given in Table 1.

Table 1
Crystal data and structure refinement for JGP-5

Identification code	JGP-5

[b] $wR_2 = [\sum[w(F_o^2 - F_c^2)^2] / \sum[w(F_o^2)^2]]^{1/2}$.

3. Results and discussion

3.1. Characterization of JGP-5

The XRD pattern for JGP-5 is entirely consistent with those simulated on the basis of the single-crystal structure. The diffraction peaks in both measured and simulated patterns correspond well to each other in position, indicating the phase purity of the as-synthesized samples. *Anal.* Calc. for JGP-5: Ga, 29.08; (29.15); P, 12.92; (12.99); C, 15.02; (14.97); H, 3.75; (3.80); N, 5.84. Found: Ga, 29.15; P, 12.92; C, 14.97; H, 3.80; N, 5.81%.

The IR spectrum of the JGP-5 compound is assigned as follows: The bands in the 3200–2800 cm^{-1} region are typically attributed to H-bonded O–H and N–H groups. The bands in the 1600–1100 cm^{-1} region are ascribed to vibrations of the 1,4-DACH template. The band at 1130 cm^{-1} is associated with the stretching vibrations of Ga–O groups and the band at 1033 cm^{-1} is attributed to vibration of PO_4 groups.

The thermal behavior of JGP-5 was investigated by TGA thermal analyses. The total weight loss of JGP-5 occurs in two steps. The first weight loss of ca. 24.29% in the range 345–590 °C corresponds to the removal of the template (calc. 24.21%). The second weight loss of ca. 6.84% in the range 590–760 °C corresponds to the removal of the hydroxyl groups (calc. 7.09%). After the removal of the organic templates, XRD analysis indicates that the structure of JGP-5 collapses and recrystallization into a dense phase ($GaPO_4$-quartz) occurs.

3.2. Description of the structure

As seen in Fig. 1, the asymmetric unit consists of 22 distinct non-hydrogen atoms, 14 atoms belong to the host atoms or framework atoms consisting of 2 Ga, 2 P and 10 O atoms, and 8 atoms to the guest atoms, being 6 C and 2 N atoms in the structure of JGP-5. Ga(1) and Ga(2) are both octahedrally coordinated and share two tri-bridging hydroxyl groups (–O(4)H and –O(8)H) with adjacent Ga atoms and P atoms (Ga–O: 2.00(2)–2.19(2) Å), two bridging oxygens with adjacent Ga atoms (Ga–O: 1.84(2)–1.96(2) Å), and two bridging oxygen with adjacent P atoms (Ga–O: 1.90(2)–2.01(2) Å). P(1) and P(2) are both tetrahedrally coordinated and share one tri-bridging hydroxyl group with adjacent Ga atoms (P–O: 1.57(2) and 1.58(2) Å, respectively), two bridging oxygen with adjacent Ga atoms (P–O: 1.53(2)–1.57(2) Å) and one shorter P–O bond corresponding to a terminal oxygen moiety (P–O: 1.52(2) and 1.48(2) Å, respectively). In addition, this asymmetric unit also includes one diprotonated *trans*-1,4-DACH. The selected bond lengths and angles are listed in Table 2.

The 2D anionic framework of JGP-5 is built up from vertex linkage of $GaO_4(OH)_2$ octahedra and HPO_4 tetrahedra. This inorganic framework may be viewed as stacking of 1D $[GaO_4(OH)_2]_n$ polyhedra chain, linked by HPO_4 tetrahedra acting as pillars, forming a 2D gallophosphate sheet with three- and six-membered channels along the *a*-axis direction as shown in Fig. 2.

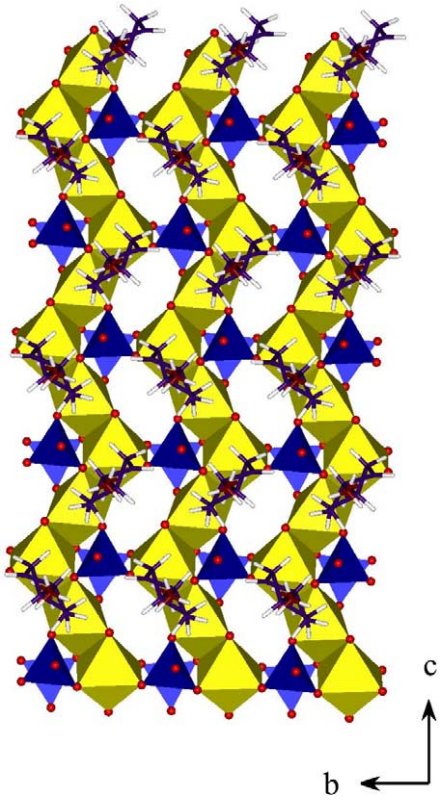

Fig. 2. Polyhedral view of JGP-5 along the *a*-axis direction.

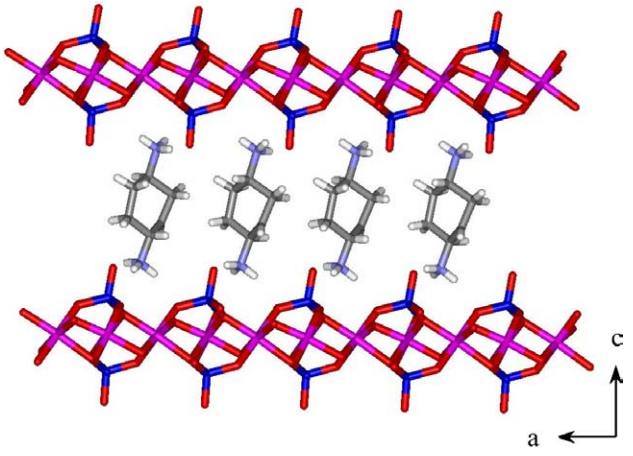

Fig. 3. Stick view of JGP-5 along the *b*-axis direction.

Table 3
Hydrogen bonds for JGP-5 (Å and °)

D–H···A	*d*(H···A)	*d*(D···A)	Angle (D–H···A)
N1–H1A···O5 #1	2.090	2.793	135.19
N1–H1A···O6 #2	2.386	3.235	159.51
N1–H1B···O6 #1	2.014	2.831	151.90
N1–H1C···O1 #1	2.038	2.892	160.69
N2–H2A···O2	2.049	2.849	149.12
N2–H2A···O3	2.643	3.383	141.30
N2–H2B···O3 #3	1.841	2.718	167.95
N2–H2D···O10 #3	2.279	3.068	147.52

Symmetry transformations used to generate equivalent atoms: #1, $x+1/2, y+1/2, z$; #2, $x+1/2, y-1/2, z$; #3, $x, -y, z-1/2$.

This chain is linked by edge-sharing $GaO_4(OH)_2$ octahedra, forming an infinite Ga–O–Ga–O–Ga zigzag chain along the *c*-axis direction. Each common edge is composed of one bridging oxygen and one tri-bridging hydroxyl group. A similar layer structure has also been observed for MIL-35 [26], the difference is that in MIL-35, edge-sharing $GaO_4(OH)_2$ octahedra are linked together via the fluorine atoms, whereas in JGP-5, the linkage corresponds to the oxygen atoms.

The diprotonated *trans*-1,4-DACH are intercalated in the space between the layers and neutralize the negative charge of the inorganic framework (Fig. 3). The 2D framework of JGP-5 is stabilized by the strong hydrogen bonds involving the hydrogen atoms attached to the nitrogen of the *trans*-1,4-DACH and the framework oxygen atoms. Detailed information about the hydrogen bonds is summarized in Table 3.

The organic amines have a strong and definite templating effect on the inorganic layer and exhibit a similar arrangement to the zig–zag chains (Fig. 2). Adjacent amines along the *c*-axis direction are oriented approximately vertically, while those along the *b*-axis direction are parallel to each other. These facts indicate that the guest organic amine molecule possesses a molecular recognition ability for the inorganic host. Perhaps the gallophosphate layer is not formed before the organic amine is incorporated.

4. Conclusion

We have characterized an organically templated gallophosphate JGP-5. JGP-5 exhibits a 2D layered structure intercalating *trans*-1,4-DACH. The organic amines display a strong templating effect on the inorganic layer.

5. Supplementary materials

Crystallographic data for JGP-5 has been deposited with the Cambridge Crystallographic Data Center, CCDC No. 213678. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2, IEZ, UK (fax: +44-1233-336-033, e-mail: deposit@ccdc.cam.ac.uk or http//www.ccdc.cam.ac.uk).

Abstract

A new ferrocene-containing enaminone [$C_5H_5FeC_5H_4C(O)CH{=}C\text{-}(NHAr)CH_3$] (**HL**, Ar = 2-$CH_3OC_6H_4$) and its copper(II) complex (**I**, L_2Cu) have been synthesized and characterized by elemental analysis, ^{1}H NMR, IR, UV and X-ray crystallography. The enaminone **HL** in the solid state exists as a mixture of two rotation-constrained conformers. Complex **I** is planar in which the enaminone acts as a monoanionic bidentate ligand and both ferrocenyl groups are anti to each other.

1. Introduction

In the last decade non-metallocene complexes of Group IV metals have attracted much interest as possible alternatives for olefin polymerization catalysts using N_4-macrocycles, porphrins, tripodal amides, mixed cyclopentadienyl-amides and Schiff bases as spectator ligands [1–5]. Because the anions [R′C(O)CHC-(NAr)R]$^-$ generated from enaminones [R′C(O)CHC-(HNAr)R] offer potential isoelectronic alternatives to the cyclopentadienyl-based anion and can be used as good chelating ligands for transition metals, enaminones have been extensively investigated [6–8]. However, owing to very few X-ray diffraction studies, so far the structure of the above enaminones has resulted in inconsistencies and remains uncertain [9–11]. So we have initiated a systematic study on organometallic enaminones, and as part of this work we report on the syntheses and crystal structures of a new ferrocenyl enaminone and its copper complex [12–14].

2. Experimental

2.1. Reagents and general procedures

All chemicals used were of reagent grade. Acetylferrocene was synthesized from ferrocene according to the literature method [15]. Ferrocenoylacetone [$C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$] was synthesized by acylation of acetylferrocene on the substituted cyclopentadienyl ring using ethyl acetate in THF in the presence of sodium ethoxide [12,16]. Progress of the reactions was monitored by TLC. The ^{1}H NMR spectrum was recorded with a Bruker Avance 500 spectrometer using TMS as an external standard in $CDCl_3$. IR spectra were recorded on a Perkin–Elmer 402 as KBr disks in the range of 400–4000 cm^{-1}. UV spectra were measured with a Shimadzu UV-240 spectrometer using a solution in DMF. C, H and N analyses were performed on an Elementa Vario EL III instrument. Melting points were measured on a Yanagimoto apparatus and are uncorrected.

2.2. Synthesis of enaminone

A solution of ferrocenoylacetone (2.7 g, 10 mmol), 2-methoxyaniline (2.44 g, 20 mmol) and a catalytic trace

amount of *p*-TsOH (ca. 10 mg) in 20 ml of toluene was refluxed with a Dean–Stark apparatus to remove water for 2 h. The solvent was evaporated under vacuum, and the residue was recrystallized from petroleum ether (60–90 °C) to afford 2.76 g (90%) of **HL** as a red crystalline solid. M.p. 112.5–113 °C. *Anal*. Calc. for $C_{21}H_{21}NFeO_2$: C, 60.82; H, 5.76; N, 2.29. Found: C, 61.07; H, 5.92; N, 2.11%. IR (KBr disk): ν(C=C) and ν(C=O) 1556, 1562, 1598, 1603 (vs), ν(NH) 3091 (s) cm^{-1}. UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$) 261 (3.3) (*B*-band); 366 (1.9) (*K*-band). ^{1}H NMR ($CDCl_3$): δ2.10 (s, 3H, CH_3), 3.88 (s, 3H, OCH_3), 4.19 (s, 5H, C_5H_5), 4.39 (pseudo-singlet, 2H, 2 (H^3, H^4) of C_5H_4 ring), 4.79 (pseudo-singlet, 2H, 2 (H^2, H^5) of C_5H_4 ring), 5.50 (s, 1H, CH), 6.89–6.95, 7.12–7.18 (2m, 4H, C_6H_4), 12.40 (s, 1H, NH).

2.3. Synthesis of copper complex

A solution of 1 mmol of the enaminone ligand (**HL**) in absolute ethanol (10 ml) was added dropwise to a stirred solution of 0.5 mmol of copper acetate monohydrate in the same solvent (10 ml). The mixture was stirred for 24 h at room temperature and then filtered to afford the crude product. The resulting solid was recrystallized from CH_2Cl_2 and petroleum ether (60–90 °C) to give the complex **I** as a brown solid, yield: 0.284 g (70%). M.p. 207–208 °C. *Anal*. Calc. for $C_{42}H_{40}N_2O_4Fe_2Cu$: C, 62.12; H, 4.96; N, 3.45. Found: C, 61.74; H, 4.78; N, 3.21%. IR (KBr disk): ν(C=C) 1513 (vs), ν(C=O) 1565 (m) cm^{-1}. UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$) 277 (2.07), 360 (3.42) (*K*-band).

2.4. Crystal structure determinations

Single crystals of enaminone **HL** for X-ray analysis were obtained by slow evaporation of its solution in CH_2Cl_2 and petroleum ether at room temperature. Single crystals of complex **I** for structure determination were obtained by petroleum ether (60–90 °C) diffusion into the CH_2Cl_2 solution at 4 °C. X-ray data were collected on an Enraf-Nonius CAD4 diffractometer for enaminone **HL** and a Bruker SMART CCD area detector diffractometer for complex **I** using graphite-monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å) at 293 K. The intensity data were corrected using PSI-scan for enaminone **HL** and Multi-scan for complex **I**. The structure was solved by direct methods and refined by full-matrix least-squares methods based on F^2 with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were placed in their calculated

positions, assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. All computations were carried out using SHELXS-97 and SHELXL-97 Programs [17]. ORTEP views were made with ORTEP-3 for Windows [18]. Details of the data collection and structure refinement parameters are given in Table 1. Selected bond distances (Å) and angles (°) are listed in Table 2 (enaminone **HL**) and 3 (complex **I**).

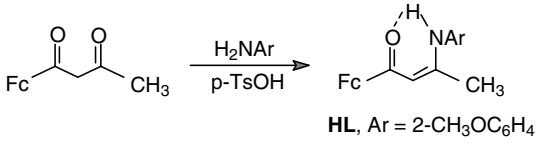
3. Results and discussion

3.1. Syntheses of enaminone and its complex

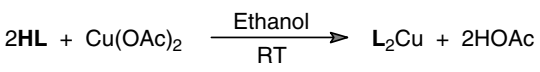
Syntheses of the enaminone and its complex are represented in Schemes 1 and 2. Reaction of ferrocenoylacetone $[C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3]$ and 2-methoxyaniline in the presence of a catalytic trace amount of *p*-toluenesulfonic acid in refluxing toluene via removal of water using a Dean–Stark apparatus affords the enaminone **HL** in a yield of 90%. The enaminone **HL** can react with the copper(II) ion forming the neutral complex **I** with the release of HOAc. TLC analysis of the complex **I** shows that it exists as a single isomer, however that of the enaminone also displays one spot on a silica gel plate.

3.2. Spectra of enaminone and its complex

The ligand **HL** in $CDCl_3$ exhibits the unsubstituted cyclopentadienyl ring proton signal at δ4.19 ppm and substituted cyclopentadienyl ring proton signals at δ4.39 ppm (3,4-position) and δ4.79 ppm (2,5-position). The chemical shift at δ5.50 ppm may be due to the CH proton. The methyl protons of the C(O)CHC(NHAr)CH_3 moiety show a singlet at δ2.10 ppm whereas the absorption of the methoxyl group attached to the benzene ring appears as a singlet at δ3.88 ppm. The proton signal of the NH at δ12.40 ppm disappeared upon deuteration. The downfield position of this signal maybe results mainly from the intramolecular hydrogen bonding. Therefore, the above evidence is in accordance with the proposed structure of the ligand shown in Scheme 1 and further supported by its crystal structure [6,8,12]. As described below, although in the solid state the enaminone **HL** exists as a mixture of isomers **A** and **B**, in solution various rotational isomers can change into each other rapidly at room temperature and therefore in



Scheme 1. Synthesis of enaminone **HL**.



Scheme 2. Synthesis of complex **I**.

its ^{1}H NMR spectrum the enaminone **HL** shows average resonances and the TLC analysis displays one spot as mentioned above.

The complex **I** in its IR spectrum displays significant changes as compared to the ligand. The band at ca. 3080 cm^{-1} in the spectrum of the ligand is due to ν(NH) and does not occur in that of complex **I**. This suggests that the enaminone is coordinated to the copper ion in the monoanionic form. Furthermore, the strong bands assignable to stretching vibrations of the skeleton C=C and C=O groups, which are observed at 1556–1562 and 1598–1603 cm^{-1} in the ligand, are all red-shifted to 1513 and 1565 cm^{-1} in complex **I** [3,8,12]. The spectrum of the ligand in the solid state shows two sets of absorptions of the skeleton C=O and C=C groups and therefore indicates the enaminone **HL** exists as a mixture of two isomers as mentioned above. More interestingly, this has been confirmed by its X-ray crystal structure determination.

In the UV spectra of the enaminone **HL** and complex **I**, the shorter wavelength absorption at 261–277 nm may be assigned to the *B*-band of cyclopentadienyl or benzene rings and the other at 360–366 nm to the *K*-band. The former displays a bathochromic shift whereas the latter shows an inverse shift compared with the free ligand [19]. However, theoretically planar copper complex **I** should exhibit a d–d absorption, in fact, the band of complex **I** is not observed because the weak d–d transition is obscured by other intense absorptions [19,20].

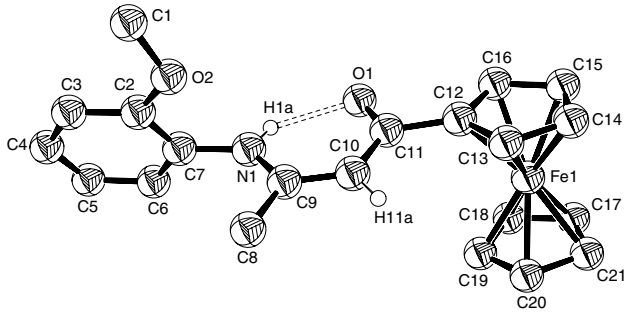


Fig. 1. An ORTEP plot of the isomer **A** in the asymmetric unit of enaminone **HL**. The atoms are drawn with 50% probability ellipsoids.

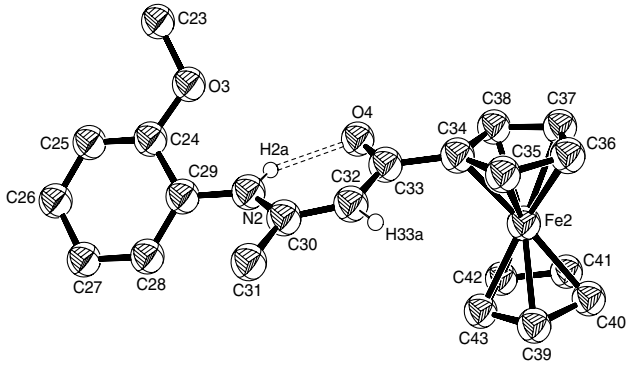

Fig. 2. An ORTEP plot of the isomer **B** in the asymmetric unit of enaminone **HL**. The atoms are drawn with 50% probability ellipsoids.

3.3. Crystal structure of enaminone and its complex

3.3.1. Crystal structure of *HL*

Enaminones with the general formula [R′C(O)CHC(NHAr)R] mentioned above may have the following four isomers: *E*-s-*E*, *E*-s-*Z*, *Z*-s-*E* and *Z*-s-*Z* in which *E* and *Z* refer to two possible geometric arrangements for the carbon–carbon double bond and s-*E* and s-*Z* to both isomerisms about the carbon–carbon single bond between the carbon–carbon and carbon–oxygen double bonds [12,21,22].

The enaminone **HL** crystallizes in the monoclinic space group of $P2_1/c$. In the asymmetric unit are two independent molecules contained, as seen from their ORTEP plots shown in Figs. 1 and 2, the geometry and bonding of them (isomer **A** and isomer **B**) are similar. Main difference results from the different dihedral angles of skeleton O=C–C=C–N and the benzene ring, in other words the different torsion angles of C(6)–C(7)–N(1)–C(9) for isomer **A** and C(24)–C(29)–N(2)–C(30) for isomer **B** (108.29° and 136.24°). Therefore, they belong to conformational isomers which in the solid state are rotation-constrained and the enaminone **HL** exists in the *Z*-s-*Z* form. As indicated by its ^{1}H NMR spectrum and TLC analysis, the two conformers must interconvert so rapidly that they cannot be isolated. Interestingly, the torsion angles C(1)–O(2)–C(2)–C(3) for isomer **A** and C(23)–O(3)–C(24)–C(25) for isomer **B** are −15.20° and 17.93°, indicating the methyl attached to the oxygen atom is not coplanar with the corresponding benzene ring. In order to minimize the steric repulsions, methyl groups attached to oxygen atoms all are bent toward the direction far away from the methyl groups bonded to the skeleton O=C–C=C–N. All atoms in the skeleton O=C–C=C–N can be regarded as sp^2 hybridized. As shown by the comparison of the C=O, C–C, C=C and C–N distances (Table 2) with the corresponding pure double or single bond distances ($C(sp^2)$=O≈1.20, $C(sp^2)$–$C(sp^2)$≈1.48, $C(sp^2)$=$C(sp^2)$≈1.33 and $C(sp^2)$–$N(sp^2)$≈1.44 Å), **HL** exhibits partial delocalization of the O=C–C=C–N system [9,12]. That the H···O distances (1.952 Å for isomer **A** and 1.950 Å for isomer **B**) are significantly shorter than the sum of the van der Waals radii (2.72 Å) indicates the existence of intramolecular hydrogen bonding; this is also in accordance with spectroscopic data [9,23]. The mean C–C distance in the benzene rings is 1.37(1) Å for isomer **A** and 1.38(1) Å for isomer **B**. The mean C–C distances in the cyclopentadienyl rings with and without the side-

chain (1.41(1) and 1.40 (2) Å for isomer **A** and 1.41(1) and 1.41 (1) Å for isomer **B**) are almost equal to the value of 1.41 Å in ferrocene [12]. However, the average distances of iron to carbon in the ferrocenyl group with and without the side-chain (2.034(9) and 2.023(9) Å for isomer **A** and 2.034(8) and 2.044(9) Å for isomer **B**) are slightly shorter than the value of 2.045 Å in ferrocene [12].

3.3.2. Crystal structure of complex *I*

Generally a four-coordinate copper(II) complex may possess eight stereoisomers: planar-*cis*-anti, planar-*cis*-syn, planar-*trans*-anti, planar-*trans*-syn, tetrahedral-*cis*-anti, tetrahedral-*cis*-syn, tetrahedral-*trans*-anti and tetrahedral-*trans*-syn where planar or tetrahedral refers to the coordination geometry of the central metal ion, *cis* or *trans* to isomerism of donor atoms and anti or syn to the two arrangements of both ferrocenyl groups with respect to the mean plane with the central metal ion and donor atoms [12,24,25]. Therefore, to determine its structure, a single-crystal X-ray diffraction analysis on complex **I** was carried out. The molecular structure of complex **I** together with the atomic numbering is shown in Fig. 3. It is worth noting that complex **I** is centrosymmetric. The metal atom displays a planar coordination geometry surrounded by two nitrogen atoms and two oxygen atoms of two deprotonated ligands ($\mathbf{L}^-$), so complex **I** exists only in the planar-*trans*-anti form, which is further supported by the above-described TLC analysis. More interestingly, unlike the complex $[C_5H_5FeC_5H_4C(O)CH{=}C(NC_6H_5)CH_3]_2Cu$, both ferrocenyl groups in complex **I** are anti to each other [12]. In view of the Fe···Fe distance of 10.959 Å, it may be concluded that one ferrocenyl group in complex **I** does not interact sterically with the other and therefore, the anti isomer can be isolated [12,14]. However, up until now the reason that the corresponding syn isomer does not appear is not clear, but doubtless for this, more work needs to be done in the future. As expected, both six-membered chelate rings are planar. In order to decrease the steric strain from the methyl and methoxyl groups, benzene rings are nearly vertical to the above chelate planes (torsion angles of C(13)–N(1)–C(15)–C(16) and Cu(1)–N(1)–C(15)–C(16) are 92.2(5)° and −86.6(4)°). Like the ligand, the torsion angle of C(19)–C(20)–O(2)–C(21) is 4.83°, indicating the methyl group attached to the oxygen atom is not coplanar with the corresponding benzene ring. Angles O(1)–Cu–N(1) and O(1)–Cu–N(1a), which are 92.1(1)° and 87.9(1)(5)°, are slightly smaller than the corresponding values observed in related structures [12,26,27]. Values of angles O(1)–Cu–O(1a) and N(1)–Cu–N(1a) are 180.000(1)° and 180.000(1)°, and therefore, indicate that the coordination geometry about the copper ion is planar as mentioned above [12]. The bonds between the copper atom and the donor sites of the deprotonated ligand (Cu–O(1) = 1.895(3) Å and Cu–N(1) = 1.982(3) Å) are within the range of values normally found for these bonds [26,27]. Unlike the related complex mentioned above, the structural features of two $\mathbf{L}^-$ ions (Table 3) are the same. Each of them exhibits O(1)–C(11), C(11)–C(12), C(12)–C(13) and N(1)–C(13) bond distances of 1.272(4), 1.350(5), 1.399(5) and 1.310(5) Å whereas the corresponding bond distances of **HL** are 1.25(1), 1.42 (1), 1.36(1) and 1.34(1) Å for isomer **A** and 1.236(9), 1.43 (1), 1.37(1) and 1.35(1) Å for isomer **B**. These suggest that the O=C–C=C–N system of complex **I** has more delocalization than that of the free ligand [12]. The mean C–C distance in the benzene rings is 1.372(6) Å and is almost equal to the corresponding distance of **HL**. Similarly, the mean C–C distances in the cyclopentadienyl rings with and without the side-chain are 1.410(5) and 1.394(7) Å, and these are very close to the mean value of 1.41 Å in **HL**. However, the average distances of iron to carbon in the ferrocenyl group with and without the side-chain are 2.018(4) and 2.016(4) Å, and these are shorter than the corresponding distances of **HL** [12].

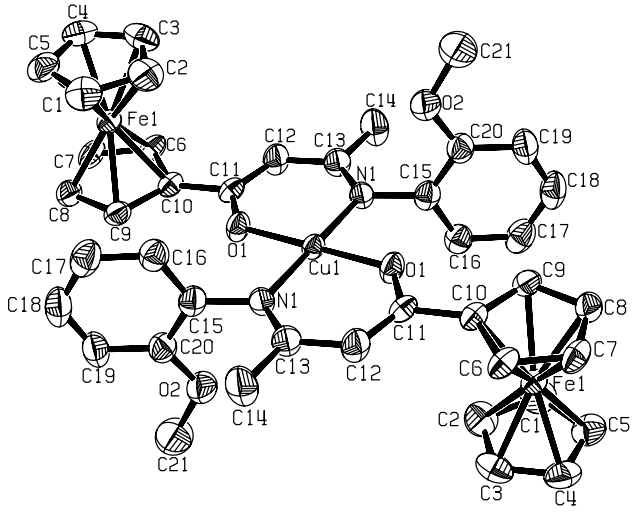

Fig. 3. An ORTEP plot of complex **I**. The atoms are drawn with 50% probability ellipsoids.

4. Conclusion

Reaction of ferrocenoylacetone and *o*-anisidine in the presence of a catalytic amount of *p*-toluenesulfonic acid yields a *Z*-s-*Z* enaminone **HL** $[C_5H_5FeC_5H_4C(O)CH{=}C(NHAr)CH_3]$ (Ar = 2-$CH_3OC_6H_4$). Reaction of enaminone **HL** and copper acetate affords a planar complex **I** in which the enaminone coordinates to the copper ion as a monoanionic bidentate ligand via carbonyl oxygen and enamine nitrogen atoms after deprotonation.

5. Supplementary material

Full crystallographic data (CCDC No. 229432 for enaminone **HL** and CCDC No. 229433 for complex **I**) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

A series of organotin(IV) complexes with 1-(4-hydroxyphenyl)-1*H*-tetrazole-5-thiol of the type, $R_nSn[S(C_7H_5N_4O)]_{4-n}\cdot L$ ($n=3$, $L=0$: R = Me (**1**), *n*-Bu (**2**), Ph (**3**); $n=3$, $L=0.5C_2H_5OH\cdot 0.5H_2O$, $R=PhCH_2$ (**4**); $n=2$, $L=H_2O$, R = Me (**5**); $n=2$, $L=0$: R = *n*-Bu (**6**), Ph (**7**), $PhCH_2$ (**8**)) have been synthesized. All the complexes **1**–**8** have been characterized by elemental, IR and ^1H NMR analyses. Among them complexes **3**, **4**, **5** and **6** have also been characterized by X-ray crystallography diffraction analyses, which revealed the 1D ribbons of complexes **3** and **5** and the 2D network of complex **6** due to the versatile intermolecular hydrogen bonds O–H···X (X = O, N, S) in the crystallographic structures. Moreover, strong π–π stacking interactions are found in complexes **4** and **5**.

1. Introduction

Increasing investigation of organotin(IV) complexes has been focused on acquiring well-defined solid-state structures to learn the nature of their versatile coordination chemistry [1], especially that of some organotin(IV) derivatives from heterocyclic thionates containing a nitrogen atom (or more) and an adjacent, exocyclic thioketo group [2–4]. In our previous work, we studied the coordination chemistry of two ligands of such kind: 2-mercaptonicotinic acid (Hmnc) and 2,5-dimercapto-1,3,4-thiodiazole (bismuthiol-I), which possess one and two deprotonated heterocyclic thioamide group $(N–C–S)^-$, respectively. The X-ray analyses revealed that the former act as thiol form but the primary bond of the latter to the tin atom varies dramatically according to distinct R of the precursor R_nSnCl_{4-n} [5,6]. These results indicate there are several factors can influence the topologies of the organotin derivatives from heterocyclic thionates such as the special geometries of ligand, the spacial resistant from R, etc. To continue our studies in this field, we choose another fascinating heterocyclic thionate: 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol, which possesses one –SH and one –OH group, through which primary bonds to tin atoms are likely formed. Moreover, the three potential coordination nitrogen atoms of tetrazole make the ligand act as a fulcrum about which lattice construction is orchestrated in one or more dimensions.

In this paper, we report some details of the syntheses and characterizations of a series of organotin(IV) complexes with the ligand of the type $R_nSn[S(C_7H_5N_4O)]_{4-n}\cdot L$ ($n = 3$, $L = 0$: $R = Me$ (**1**), *n*-Bu (**2**), Ph (**3**); $n = 3$, $L = 0.5C_2H_5OH\cdot 0.5H_2O$, $R = PhCH_2$ (**4**); $n = 2$, $L = H_2O$, $R = Me$ (**5**); $n = 2$, $L = 0$: $R = n$-Bu (**6**), Ph (**7**), $PhCH_2$ (**8**)). X-ray crystallography of complexes **3**, **4**, **5** and **6** show that all the complexes contain the thiol form of the ligand, i.e. the ligand is linked to the organometal moiety primarily through sulfur, resembling as Hmnc and 1-phenyl-1*H*-tetrazole-5-thiol [5,7]. Interestingly, the versatile hydrogen bonding, O–H···X (X = O, N, S), and strong π–π stacking interactions are found.

2. Experimental

2.1. Materials and measurements

Trimethyltin chloride, tri-*n*-butyltin chloride, triphenyltin chloride, dimethyltin dichloride, di-*n*-butyltin dichloride, diphenyltin dichloride and 1-(4-hydroxyphenyl)-1*H*-tetrazole-5-thiol were commercially available, and they were used without further purification. Tribenzyltin chloride and dibenzyltin chloride were prepared by a standard method reported in the literature [8]. The melting points were obtained with Kofler micro melting point apparatus and are uncorrected. Infrared-spectra were recorded on a Nicolet-460 spectrophotometer using KBr disks and sodium chloride optics. ^{1}H NMR spectra were obtained on a JEOL-FX-90Q spectrometer, chemical shifts were given in ppm relative to Me_4Si in $CDCl_3$ solvent. Elemental analyses were performed with a PE-2400II apparatus.

2.2. Syntheses of the complexes **1**–**8**

2.2.1. $Me_3Sn[S(C_7H_5N_4O)]$ (**1**)

The reaction was carried out under nitrogen atmosphere. The 1-(4-hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.194 g, 1 mmol) was added to the solution of ethanol 20 ml with sodium ethoxide (0.068 g, 1 mmol), and the mixture was stirred for 10 min, then add Me_3SnCl (0.199 g, 1 mmol) to the mixture, continuing the reaction for 12 h at 45 °C. After cooling down to the room temperature, the solution was filtered. The solvent of the filtrate was gradually removed by evaporation under vacuum until solid product was obtained. The solid was then recrystallized from ether. White crystal was formed. Yield, 65%. m.p. 118–120 °C. *Anal*. Calc. for $C_{10}H_{14}N_4OSSn$: C, 33.64; H, 3.95; N, 15.69. Found: C, 33.68; H, 3.95; N, 15.70%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.23–7.38 (m, 4H,C_6H_4–N), 0.75 (s, 9H, Sn–CH_3) ppm. IR (KBr, cm^{-1}): ν(C=N) 1600, $\nu(Sn–C)_{as}$ 536, $\nu(Sn–C)_s$ 504, ν(Sn–S) 312.

2.2.2. $(n\text{-}Bu)_3Sn[S(C_7H_5N_4O)]$ (**2**)

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.194 g, 1 mmol), sodium ethoxide (0.068 g, 1 mmol) and (n-Bu)$_3$SnCl (0.326 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from ether–petroleum. White crystal was formed. Yield, 74%. m.p. 67–69 °C. *Anal*. Calc. for $C_{19}H_{32}N_4OSSn$: C, 47.22; H, 6.67; N, 11.59. Found: C, 47.26; H, 6.57; N, 11.70%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.25–7.38 (m, 4H,C_6H_4–N), 0.84–1.71 (m, 27H, Sn–C_4H_9) ppm. IR (KBr, cm^{-1}): ν(C=N) 1601, $\nu(Sn–C)_{as}$ 445, $\nu(Sn–C)_s$ 425, ν(Sn–S) 309.

2.2.3. $Ph_3Sn[S(C_7H_5N_4O)]$ (**3**)

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.194 g, 1 mmol), sodium ethoxide (0.068 g, 1 mmol) and Ph_3SnCl (0.385 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from hexane-dichloromethane. White crystal was formed. Yield, 72%. m.p. 184–186 °C. *Anal*. Calc. for $C_{25}H_{20}N_4OSSn$: C, 55.27; H, 3.71; N, 10.31. Found: C, 55.31; H, 3.76; N, 10.32%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.18–7.37 (m, 4H,C_6H_4–N), 7.46–7.79 (m, 15H, Sn–C_6H_5) ppm. IR (KBr, cm^{-1}): ν(C=N) 1599, $\nu(Sn–C)_{as}$ 444, $\nu(Sn–C)_s$ 409, ν(Sn–S) 310.

2.2.4. $(PhCH_2)_3Sn[S(C_7H_5N_4O)]\cdot 0.5C_2H_5OH\cdot 0.5H_2O$ (**4**)

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.194 g, 1 mmol), sodium ethoxide (0.068 g, 1 mmol) and $(PhCH_2)_3SnCl$ (0.427 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from dichloromethane. White crystal was formed. The crystal suitable for X-ray diffraction was grown from ethanol (95%). Yield, 78%. m.p. 124–126 °C. *Anal*. Calc. for $C_{29}H_{30}N_4O_2SSn$: C, 56.42; H, 4.90; N, 9.08. Found: C, 56.47; H, 4.86; N, 9.14%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.30 (m, 4H,C_6H_4–N), 6.88–7.15 (m, 15H, Sn–$CH_2C_6H_5$), 3.74 (m, 1H, CH_3CH_2-OH), 2.78 (s, 6H, Sn–$CH_2C_6H_5$), 1.25 (t, 1.5H, CH_3CH_2 OH) ppm. IR (KBr, cm^{-1}): ν(C=N) 1599, $\nu(Sn–C)_{as}$ 450, $\nu(Sn–C)_s$ 427, ν(Sn–S) 309.

2.2.5. $Me_2Sn[S(C_7H_5N_4O)]_2\cdot H_2O$ (**5**)

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.388 g, 2 mmol), sodium ethoxide (0.136 g, 2 mmol) and Me_2SnCl_2 (0.220 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from ether–petroleum. White crystal was formed. The crystal suitable for X-ray diffraction was grown from ethanol (95%). Yield, 70%. m.p. 126–128 °C. *Anal*. Calc. for $C_{16}H_{18}N_8O_3S_2Sn$: C, 34.74; H, 3.28; N, 20.26. Found: C, 34.84; H, 3.23; N, 20.07%. ^{1}H

NMR (90 MHz, $CDCl_3$): δ 7.26–7.40 (m, 8H,C_6H_4–N), 1.42 (s, 6H, Sn–CH_3) ppm. IR (KBr, cm^{-1}): ν(C=N) 1600, $\nu(Sn–C)_{as}$ 476, $\nu(Sn–C)_s$ 450, ν(Sn–S) 310.

*2.2.6. (n-Bu)$_2$Sn[S(C$_7$H$_5$N$_4$O)]$_2$ (**6**)*

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.388 g, 2 mmol), sodium ethoxide (0.136 g, 2 mmol) and $(n\text{-}Bu)_2SnCl_2$ (0.304 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from ether–petroleum. White crystal was formed. Yield, 76%. m.p. 128–130 °C. *Anal*. Calc. for $C_{22}H_{28}N_8O_2S_2Sn$: C, 42.66; H, 4.56; N, 18.09. Found: C, 42.75; H, 4.49; N, 18.20%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.20–7.37 (m, 8H,C_6H_4–N), 0.86–2.12 (m, 18H, Sn–C_4H_9) ppm. IR (KBr, cm^{-1}): ν(C=N) 1600, $\nu(Sn–C)_{as}$ 441, $\nu(Sn–C)_s$ 425, ν(Sn–S) 315.

*2.2.7. Ph$_2$Sn[S(C$_7$H$_5$N$_4$O)]$_2$ (**7**)*

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.388 g, 2 mmol), sodium ethoxide (0.136 g, 2 mmol) and Ph_2SnCl_2 (0.344 g, 1 mmol), reaction time 12 h, temperature 50 °C. Recrystallized from ether–petroleum. White crystal was formed. Yield, 67%. m.p. 168–170 °C. *Anal*. Calc. for $C_{26}H_{20}N_8O_2S_2Sn$: C, 47.36; H, 3.06; N, 17.00. Found: C, 47.48; H, 2.91; N, 17.12%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.20–7.33 (m, 8H,C_6H_4–N), 7.46–7.79 (m, 10H, Sn–C_6H_5) ppm. IR (KBr, cm^{-1}): ν(C=N) 1601, $\nu(Sn–C)_{as}$ 444, $\nu(Sn–C)_s$ 415, ν(Sn–S) 309.

*2.2.8. (PhCH$_2$)$_2$Sn[S(C$_7$H$_5$N$_4$O)]$_2$ (**8**)*

The synthesis procedure was the same as **1**. 1-(4-Hydroxyphenyl)-1*H*-tetrazole-5-thiol (0.388 g, 2 mmol), sodium ethoxide (0.136 g, 2 mmol) and $(PhCH_2)_2SnCl_2$ (0.372 g, 1 mmol), reaction time 12 h, temperature 45 °C. Recrystallized from ether–petroleum. White crystal was formed. Yield, 79%. m.p. 112–114 °C. *Anal*. Calc. for $C_{28}H_{24}N_8O_2S_2Sn$: C, 48.92; H, 3.52; N, 16.30. Found: C, 49.02; H, 3.59; N, 16.39%. ^{1}H NMR (90 MHz, $CDCl_3$): δ 7.17–7.42 (m, 8H, C_6H_4–N), 6.82–7.05 (m, 10H, Sn–$CH_2C_6H_5$), 3.52 (s, 4H, Sn–$CH_2C_6H_5$) ppm. IR (KBr, cm^{-1}): ν(C=N) 1600, $\nu(Sn–C)_{as}$ 440, $\nu(Sn–C)_s$ 421, ν(Sn–S) 310.

2.3. X-ray crystallographic studies of complexes **3**, **4**, **5** and **6**

Crystals were mounted in Lindemann capillaries under nitrogen. All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298(2) K. A semi-empirical absorption correction was applied to the data. The structure was solved by direct methods using SHELXL-97 and refined against F^2 by full-matrix least-squares using SHELXL-97. Hydrogen atoms were placed in calculated positions. Crystal data and experimental details of the structure determinations are listed in Table 1.

Scheme 1.

3. Results and discussion

3.1. Syntheses of the complexes *1–8*

The synthesis procedure is given in Scheme 1.

3.2. IR spectroscopic studies of the complexes *1–8*

The explicit feature in the IR spectra of the eight complexes **1–8** is the absence of the band in the region 2550–2430 cm^{-1}, which appears in the free ligand as the ν(S–H) vibration, thus indicating metal–ligand bond formation through this site. In the far-IR spectra, the absorption about 310 cm^{-1} region for all complexes **1–8**, which is absent in the spectrum of the ligand, is assigned to the Sn–S stretching mode of the vibration and all the values are located within the range for Sn–S vibration observed in common organotin derivatives of thiolate (300–400 cm^{-1}) [9,10]. In organotin compounds, the IR spectra can provide useful information concerning the geometry of the SnC_n moiety [11]. In the case of our compounds, for both di- and triorganotin(IV) derivatives, two bands were assigned to asymmetric and symmetric Sn–C vibrations. Thus suggesting nonlinear SnC_2 units for diorganotins and non-planar SnC_3 fragments for triorganotins, respectively. The middle intensity bands observed at about 1600 cm^{-1} in the spectra of all complexes have been assignable to ν(C=N) according to literatures [12,13], which suggested the coordinates of free ligand to these complexes is through sulfur atoms via thiol form.

3.3. ^1H NMR data of the complexes *1–8*

^1H NMR data showed that the signal of the –SH proton in the spectrum of the ligand is absent in all of the complexes, indicating the removal of the –SH proton and the formation of Sn–S bonds. The formation accords well with what the IR data have revealed. Moreover, the ^1H NMR spectra show that the chemical shifts of the phenyl group (Sn–C_6H_5) in complexes **3** and **7**, 7.46–7.79 ppm, and those of methylene connected directly with tin in complexes **2**, **4**, **6** and **8**, 1.71–3.52 ppm, upfield shift as compared with those of their corresponding precursors. All these data are similar to those cases appear in literature [14], indicating there may exist novel coordination of the ligand to tin atom for all the eight complexes **1–8**. In addition, the resonance of the phenyl group connected with nitrogen atom and hydroxyl group (N–C_6H_4–OH) appears at 7.17–7.42 ppm for all complexes **1–8**.

3.4. Crystal structures of complexes *3, 4, 5* and *6*

3.4.1. $Ph_3Sn[S(C_7H_5N_4O)]$ (*3*)

For complex **3**, the asymmetric unit contains two monomers A and B (Fig. 1), which are crystallographically nonequivalent. The conformations of the two independent molecules A and B are almost the same, with only small differences in bond lengths and bond angles (see Table 2). The compound is formed by discrete molecules in which the tin atom is indeed bound to the sulfur atom of the tetrazolate, which together with the phenyl groups defines a distorted tetrahedron around

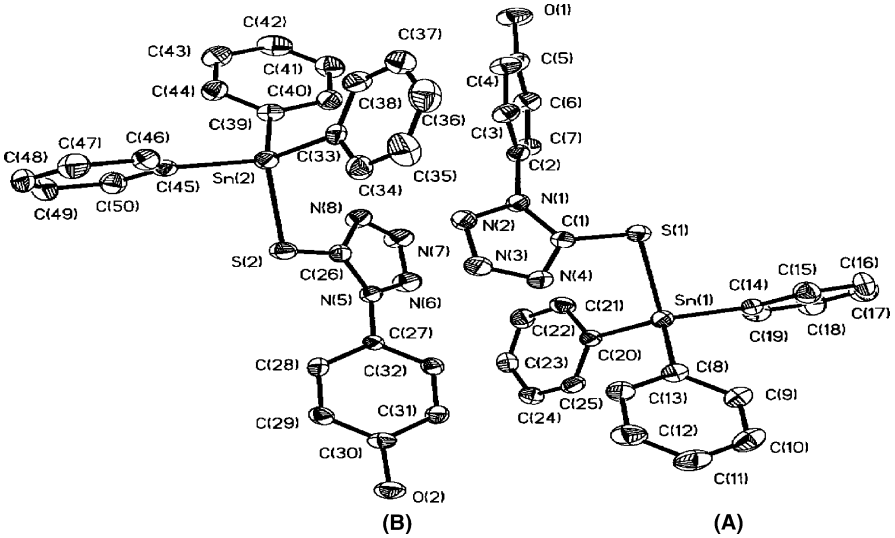

Fig. 1. Molecular structure of the complex **3**.

Table 2
Selected bond lengths (Å) and bond angles (°) for complex **3**

Molecule A		Molecule B	
Bond lengths			
Sn(1)–C(8)	2.128(6)	Sn(2)–C(39)	2.122(6)
Sn(1)–C(20)	2.136(6)	Sn(2)–C(45)	2.129(5)
Sn(1)–C(14)	2.152(5)	Sn(2)–C(33)	2.138(6)
Sn(1)–S(1)	2.4760(17)	Sn(2)–S(2)	2.4726(17)
Sn(1)···N(4)	3.330(6)	Sn(2)···N(8)	3.487(6)
N(4)–C(1)	1.313(7)	N(8)–C(26)	1.315(7)
S(1)–C(1)	1.740(5)	S(2)–C(26)	1.727(6)
Bond angles			
C(8)–Sn(1)–C(20)	112.4(2)	C(39)–Sn(2)–C(45)	112.1(2)
C(8)–Sn(1)–C(14)	110.1(2)	C(45)–Sn(2)–C(33)	110.3(2)
C(20)–Sn(1)–C(14)	111.9(2)	C(39)–Sn(2)–C(33)	111.2(2)
C(8)–Sn(1)–S(1)	119.28(15)	C(39)–Sn(2)–S(2)	119.55(15)
C(20)–Sn(1)–S(1)	104.81(15)	C(33)–Sn(2)–S(2)	108.24(16)
C(14)–Sn(1)–S(1)	97.31(15)	C(45)–Sn(2)–S(2)	94.07(14)
C(1)–S(1)–Sn(1)	99.83(18)	C(26)-S(2)–Sn(2)	105.8(2)
N(4)–C(1)–S(1)	126.9(4)	N(8)–C(26)–S(2)	126.9(4)

the tin atom. There is also an intramolecular tin–nitrogen short contact (Sn(1)···N(4) 3.330(6) Å for A and Sn(2)···N(8) 3.487(6) Å for B), shorter than the sum of the van der Waals radii (3.75 Å) [15]. The C–Sn–C bond angles are close to the theoretical tetrahedral angle but the C–Sn–S bond angles more acute or obtuse than it, largest deviations occurring in C(8)–Sn(1)–S(1) 119.28(15)° for A and C(39)–Sn(2)–S(2) 119.55(15)° for B; C(14)–Sn(1)–S(1) 97.31(15)° for A and C(45)–Sn(2)–S(2) 94.07(14)° for B. This is possibly due to the secondary interaction (Sn(1)···N(4) for A and Sn(2)···N(8) for B). The Sn–S bond length (Sn(1)–S(1) 2.4760(17) Å for A and Sn(2)–S(2) 2.4726(17) Å for B) lies toward the middle of the range reported for triphenyltin heteroarenethiolates (2.405–2.481 Å) [16,17] and approach the sum of the covalent radii of tin and sulfur (2.42 Å) [18]. In the tetrazolate, the C–S bond distance (C(1)–S(1) 1.740(5) Å for A and C(26)–S(2) 1.727(6) Å for B) lies between the average value for the double C=S bond in thioureas (1.681 Å) and the single C–S bond in the C–S–Me fragment (1.789 Å) [19], suggesting that the C–S bond has some double-bond character in the deprotonated tetrazole.

Moreover, the discrete molecules of complex **3** associate in a 1D ribbon by hydrogen bonds (O(1)–H(1)···N(3) 2.911 Å, O(1)–H(1)–N(3) 157.88° for A; O(2)–H(2)···N(7) 2.857 Å, O(1)–H(1)–N(3) 148.77° for B). A view of the extended ribbon is shown in Fig. 2.

3.4.2. $(PhCH_2)_3Sn[S(C_7H_5N_4O)]\cdot 0.5C_2H_5OH\cdot 0.5H_2O$ (**4**)

The X-ray diffraction investigation of complex **4** has shown two independent molecules in the unit cell, which are alternatively associated in a polymeric chain through intermolecular dative N → Sn bonds. The differences in the bond lengths and angles within the two molecules might be the result of packing effects in the crystal. The molecular structure of complex **4** is shown in Fig. 3. Selected bond lengths and angels are listed in Table 3.

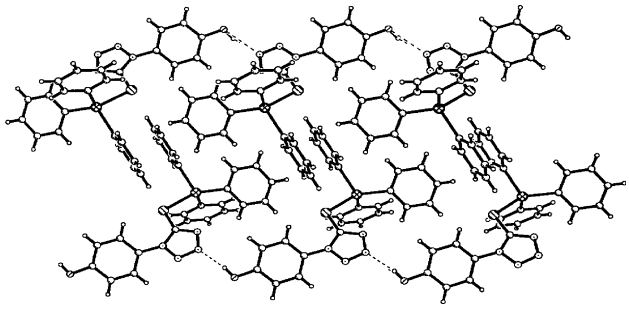

Fig. 2. perspective view showing the 1D ribbon of the complex **3**.

In the monomeric units the tetrazolethiolato ligand is primarily coordinated through the sulfur atom: Sn(1)–S(1) 2.5812(14) Å, Sn(2)–S(2) 2.6260(15) Å. They are slightly longer than the sum of the covalent radii (2.42 Å) [18]. This is consistent with the thiol form of the ligand in the previously reported molecular structure of Bz_3SnSCN_4Ph [7c], and in contrast to the primary coordination suggested on the basis of IR data. It is similar to the complex **3**, there are also secondary intramolecular tin–nitrogen short contacts (Sn(1)···N(4) 3.289(4) Å and Sn(2)···N(8) 3.311(4) Å), shorter than the sum of the van der Waals radii (3.75 Å) [15]. In the crystal, the molecules of complex **3** associated in polymeric chains through intermolecular, dative tin–nitrogen bonds (Sn(1)–N(7A) 2.604(4) Å and Sn(2)–N(3) 2.557(4) Å). This leads to an increase in the tin coordination number to 5. The coordination polyhedron around the central tin atom can be described as distorted trigonal bipyramidal. The methylene carbons are in equatorial positions and the axial ones are occupied by the sulfur atom of the ligand and a nitrogen atom of a neighboring molecule, respectively.

The component $(PhCH_2)_3Sn[S(C_7H_5N_4O)]$ crystallizes with 0.5 molecules of ethanol and 0.5 molecules of water while the water molecule shows no short contacts, the ethanol is involved in two hydrogen bonds, both as a donor (O(3)–H(3A)···O(2) 2.735 Å, O(3)–H(3A)–O(2) 169.33°) and as an acceptor (O(2)–H(33)···O(3) 2.735 Å, O(2)–H(33)–O(3) 168.41°). Moreover, the polymeric chain in the unit cell associates in a dimeric form with another chain through the O(1)–H(5)···S(1) (O(1)···S(1) 3.338 Å, O(1)–H(5)–S(1) 155.93°) hydrogen bond. The crystal structure of **4** shows ring-stacking interactions, each hydroxyphenyl group involved O–H···S hydrogen bond is arrange face-to-face at a distance of 3.744 Å and shows significant π–π stacking interactions, as reported in the literatures [20]. A view of the unit cell of **4** showing hydrogen bonds and π–π stacking interactions is given in Fig. 4.

*3.4.3. $Me_2Sn[S(C_7H_5N_4O)]_2 \cdot H_2O$ (**5**) and $(n\text{-}Bu)_2Sn[S(C_7H_5N_4O)]_2$ (**6**)*

Selected bond lengths and bond angles for **5** and **6** are given in Tables 4 and 5, respectively. The molecular structures of **5** and **6** are shown in Figs. 5 and 6. In contrast with the triorganotin derivatives mentioned above, the coordination of diorganotin derivatives is different. In both complexes **5** and **6**, the tin atom establishes covalent bonds with the two heterocyclic sulfur atoms, apart from the two methyl or methylene carbons, and interacts intramolecularly with the unsubstituted nitrogen atoms of the ring thioamide moiety (N(4), N(4A) for **5** and N(4), N(8) for **6**). The Sn–C bond lengths (2.050(15) and 2.111(14) Å in **5**; 2.134(6) and 2.150(7) Å in **6**) are quite close to those previously described in the literature [6]. The Sn–S bond distances (2.505(4) Å in **5**; 2.4740(19) and 2.4716(19) Å in **6**) are very close to the sum of the corresponding covalent radii

S(1)–Sn(1)–N(4)	56.73(9)	N(8)–C(8)–S(2)	126.0(4)
C(15)–Sn(1)–N(8)	81.85(17)		

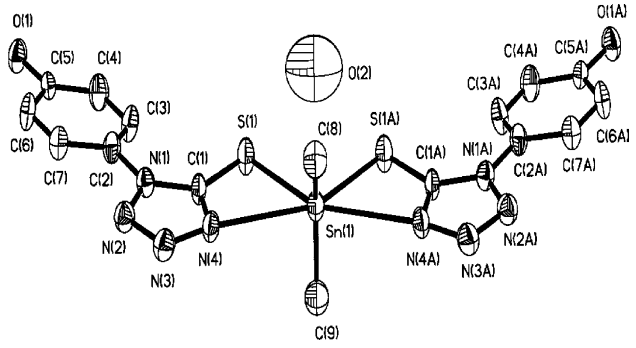

Fig. 5. Molecular structure of the complex **5**.

(2.42 Å) [18], and is similar to the distances found in other Sn(IV) complexes of the terazolethiolato with metal–sulfur primary bonds, viz. 2.474(3)–2.614(5) Å. It is worth noting that in complex **5** the Sn–N bond length is shorten (2.704(8) Å) than those reported in analogous diorganotin derivatives of 1-phenyl-1*H*-tetrazole-5-

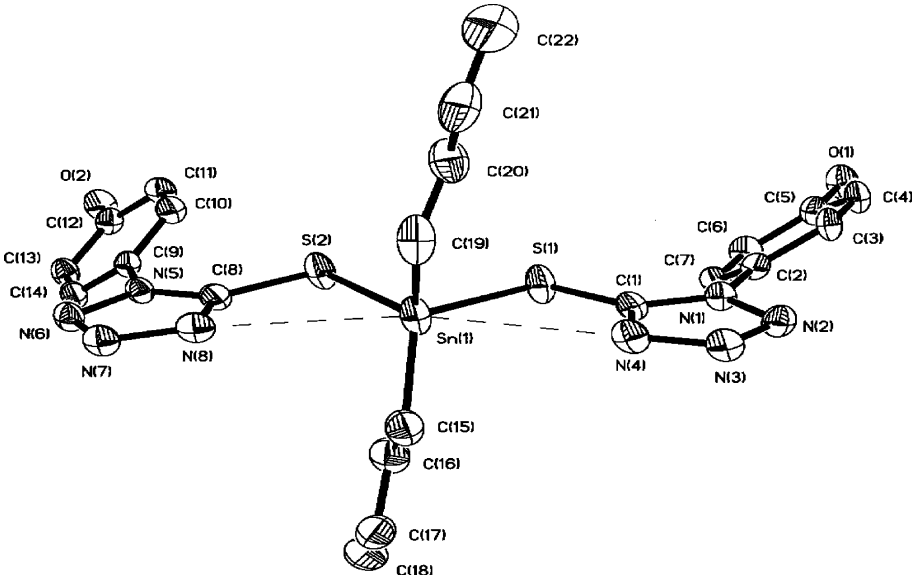

Fig. 6. Molecular structure of the complex **6**.

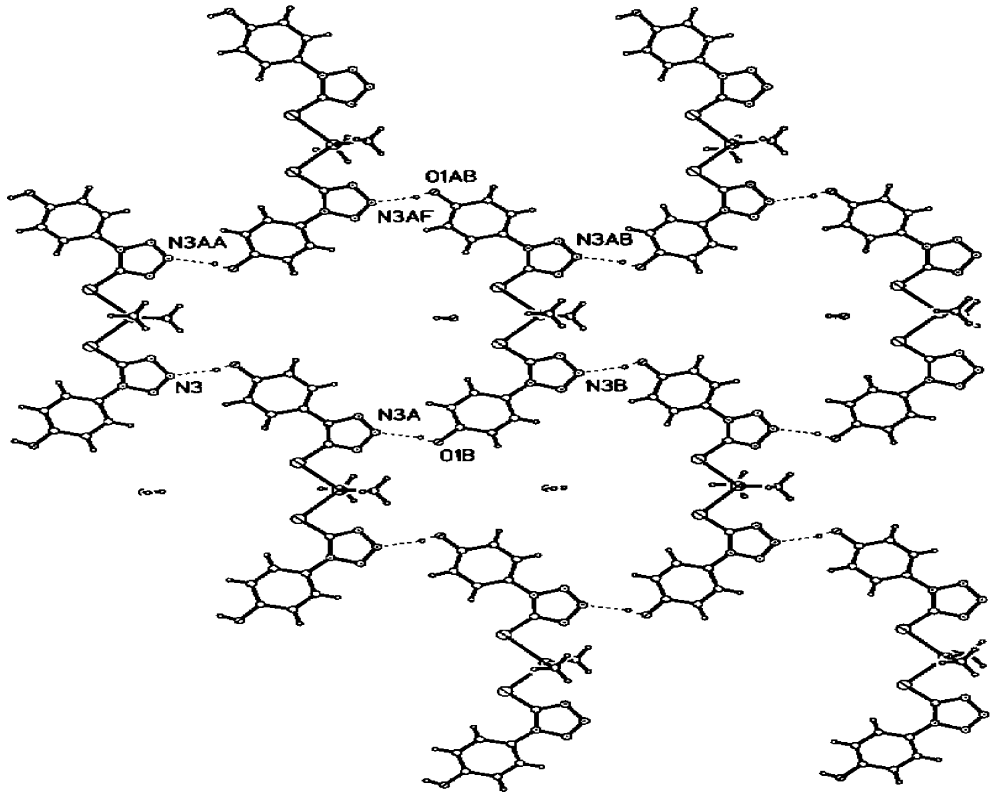

Fig. 7. perspective view showing the 2D network of the complex **5**.

thilato (2.975(5) [7a] and 2.947(4) Å [7b]). But in complex **6** the Sn–N bond lengths are longer (3.154(5) Å and 3.175(5) Å), although they all lie within the sum of their respective van der Walls radii (3.75 Å).

The establishment of such intramolecular tin–nitrogen interactions brings the present structure rather far from a regular tetrahedron, i.e. despite the fact that the complexes' core angles (S(1)–Sn(1)–C(9) 103.6(3)° and S(1)–Sn(1)–C(8) 107.5(3)° for **5**; S(1)–Sn(1)–C(15) 107.78(18)°, S(1)–Sn(1)–C(19) 107.83(17)°, S(2)–Sn(1)–C(15) 108.55(17)° and S(2)–Sn(1)–C(19) 109.64(17)° for **6**) are close the expected tetrahedral value, the C–Sn–C angle (134.8(6)° for **5** and 129.2(3)° for **6**) is more obtuse due to the occurrence of the Sn–N secondary interactions in a plane bisecting it, with the concomitant decrease of the S–Sn–S angle (91.50(17)° for **5** and 84.87(8)° for **6**). The geometry around the metal may thus be viewed, alternatively, as a distorted trapezoidal bipyramid, with the two methyl or methylene carbons in bent axial positions and the trapezoidal plane being defined by the two Sn–S covalent bonds and the two Sn–N secondary interactions.

In the complex **5**, the hydrogen bonding between the hydroxyl of ligand and nitrogen atom adjacent molecule (O(1)–H(1)···N(3) 2.750 Å, O(1)–H(1)–N(3) 167.89°) is recognized, which contributes to construct the 2D network of **5** (see Fig. 7). It is worthy noting that no short contacts have been found though the main component $Me_2Sn[S(C_7H_5N_4O)]_2$ crystallizes with one water molecule. Moreover, ring-stacking interactions are shown in the complex **5**. The orientation is such that the phenyl ring substituents 'face' other phenyl ring on neighboring layer at a distance of 3.677 Å and show significant π–π stacking interactions [20]. A view of the crystal packing along the *a* axis is shown in Fig. 8. As for **6**, the hydrogen bonds are also found (O(1)–H(1)···N(3) 2.892 Å, O(1)–H(1)–N(3) 138.73° and O(2)–H(2)···N(7) 2.886 Å, O(1)–H(1)–N(3) 139.08°) and its discrete molecules are

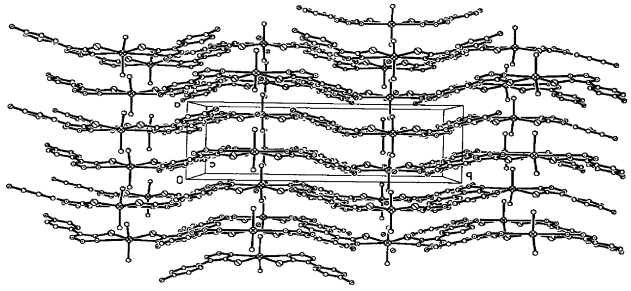

Fig. 8. Packing diagram of complex **5**, showing π–π stacking interactions.

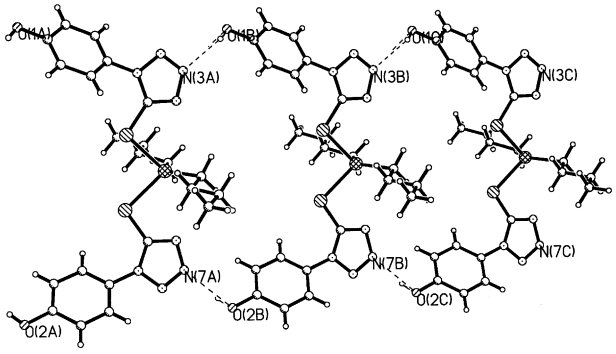

Fig. 9. perspective view showing the 1D ribbon of the complex **6**.

connected to 1D ribbon through hydrogen bonding (see Fig. 9).

4. Conclusions

A series of organotin(IV) complexes based on 1-(4-hydroxyphenyl)-1*H*-tetrazole-5-thiol have been synthesized and characterized. Detailed studies on the structures and spectra of these complexes indicate that there exist such an inclination that the structures of those dialkyltin complexes are likely to construct distorted trapezoidal bipyramidal geometry and those trialkyltin complexes are apt to have diverse geometry. The complex **3** is formed by discrete molecules but the molecules of complex **4** associates in polymeric chains through intermolecular, dative $N \rightarrow Sn$ bonds. Such differences may attribute to the fact that the stereo-constraints of $PhCH_2$-groups are smaller than that of Ph-groups. Consequently, it can be concluded that the decrease of stereo-constraints may benefit the coordination of nitrogen atoms.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Center as Supplementary Publication Nos. CCDC-220182, 222015, 222017, 220175. Copies of the data can be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Four polymetallic iron complexes have been synthesised by a high-temperature route. Two complexes have a $[Fe_6O_2(OH)_2]^{12+}$ core, one containing benzoate ligands and the other pivalates. The other two have a $[Fe_{11}O_6(OH)_6]^{15+}$ core, with benzoate or *t*-butylacetate bridging ligands, respectively. These complexes have been characterised by X-ray crystallography, elemental analysis and magnetochemistry. All four complexes consist of Fe^{III} ions, and anti-ferromagnetic exchange between the metal centres lead to low spin ground states.

1. Introduction

Interest in transition metal polynuclear complexes has developed rapidly over the past decade due to the interesting magnetic properties of some of these complexes, e.g., $[Mn_{12}O_{12}(O_2CCH_3)_{16}(H_2O)_4]$ shows slow relaxation of magnetisation at low temperatures [1]. Our research group is interested in developing routes to these types of complexes. We have been investigating a procedure that involves heating simple transition metal carboxylates under an inert atmosphere at temperatures ranging from 200 to 400 °C. This method was first employed by Gerbeleu and co-workers [2] who synthesised a dodecanuclear Cr^{III} complex, $[Cr_{12}O_9(OH)_3(O_2CC(CH_3)_3)_{15}]$, by heating a Cr^{III} trimethylacetate starting material in a furnace to 400 °C. Our research group has adopted this technique and have reported the preparation of five Cr^{III} polynuclear complexes, $[Cr_8(OH)_8(O_2CC_6H_5)_{16}]$ [3], $[Cr_8O_4(O_2CC_6H_5])_6]$ [3], $[Cr_{12}O_8(O_2CCH(CH_3)_2)_{20}(H_2O)_4]$ [4], $[Cr_6O_2(OH)_2(O_2CC(CH_3)_3)_{11}][Cr_6O_4(O_2CC(CH_3)_3)_{11}]$ [5], $[Cr_8$- $(OH)_8(O_2CC_6H_4Cl)_{16}]$ [5], and a one-dimensional Mn polymer, $[Mn_4(O_2CC_6H_5)_8(CH_3CH_2OH)_6]_n$ [5]. We have also re-made the dodecanuclear chromium cage and studied its magnetic and spectroscopic behaviour in detail [6].

Further exploitation of this technique using simple Fe carboxylates has resulted in the formation of four Fe^{III} polynuclear complexes; $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}(THF)_2]$ (**1**), $[Fe_6O_2(OH)_2(O_2CC_5H_6)_{12}(H_2O_2)_2]$ (**2**), $[Fe_{11}O_6(OH)_6(O_2CC_5H_6)_{15}]$ (**3**) and $[Fe_{11}O_6(OH)_6(O_2CCH_2C(CH_3)_3)_{15}]$ (**4**). The syntheses, X-ray crystal structures and magnetic properties of each of these complexes are discussed.

2. Experimental

2.1. Synthesis

2.1.1. $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}(THF)_2]\cdot 2THF$ (1)

A mixture of H_2O (125 cm^3), KOH (5.05 g, 0.09 mol) and $(CH_3)_3CCO_2H$ (18.4 g, 0.18 mol) was heated, with stirring, to 80 °C. Small portions of $FeCl_2\cdot 4H_2O$ (9.00 g, 0.05 mol) were added and an orange precipitate formed. The mixture was cooled to room temperature and the precipitate was filtered, washed with hot H_2O

doi:10.1016/j.poly.2004.03.012

and dried in vacuo. The precipitate, likely to be crude $[Fe_3O(O_2CC(CH_3)_3)_6(H_2O)_3]$, (4.30 g) was heated to 300 °C for 5 min in a tube furnace under N_2. The brown solid that results (1.69 g) was dissolved in THF (40 cm^3) and red crystals of **1** formed by slow evaporation after 5 days in 9% yield. *Anal.* Calc. (Found) for **1**: C, 46.44 (46.53); H, 7.22 (7.18); N, 0(0)%.

2.1.2. $[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(H_2O)_2]\cdot C_6H_5CO_2H\cdot 4.33CH_2Cl_2$ (**2**)

$[Fe_3O(O_2CC_6H_5)_6(\ _2O)_2(MeCN)]$ (2.53 g, 2.56 mmol) was first synthesised by the literature procedure [7], and then heated to 300 °C for 5 min in a tube furnace under N_2. The dark brown crude product (1.83 g) was dissolved in CH_2Cl_2 (50 cm^3) and red crystals of **2** formed by slow evaporation after 9 days in 17% yield. *Anal.* Calc. (Found) for $\mathbf{2}\cdot C_6H_5CO_2H.CH_2Cl_2$: C, 52.68 (52.04); H, 3.56 (3.62); N, 0 (0)%.

2.1.3. $[Fe_{11}O_6(OH)_6(O_2CC_6H_5)_{15}]\cdot 13MeCN$ (**3**)

Crude $[Fe_3O(O_2CC_6H_5)_6(H_2O)_3](NO_3)$ was prepared by slowly adding $Fe(NO_3)_3\cdot 9H_2O$ (0.06 mol, 24.24 g) to a mixture of H_2O (75 cm^3), EtOH (75 cm^3), KOH (0.12 mol, 6.73 g) and $C_6H_5CO_2H$ (0.12 mol, 14.66 g). The resulting orange precipitate was filtered and dried in vacuo, yield 94%.

The crude $[Fe_3O(O_2CC_6H_5)_6(H_2O)_3](NO_3)$ (2.14 g, 2.09 mmol) was heated to 300 °C for 5 min in a tube furnace under N_2. The red/orange solid crude product (1.32 g) was dissolved in MeCN (35 cm^3) and red crystals of **3** formed by slow evaporation after 4 days in 21% yield. *Anal.* Calc. (Found) for $\mathbf{3}\cdot$MeCN: C, 48.13 (49.54); H, 3.17 (3.18); N, 0.52 (0.49)%.

2.1.4. $[Fe_{11}O_6(OH)_6(O_2CCH_2C(CH_3)_3)_{15}]\cdot 2.5MeCN$ (**4**)

A mixture of H_2O (125 cm^3), KOH (5.05 g, 0.09 mol) and $(CH_3)_3CCH_2CO_2H$ (10.45 g, 0.18 mol, 11.46 cm^3) was heated, with stirring, to 80 °C in a round bottom flask. Small portions of $FeCl_2\cdot 4H_2O$ (9.00 g, 0.05 mol) were added and an orange precipitate formed. The mixture was cooled to room temperature and the precipitate was filtered, washed with hot H_2O and dried in vacuo. The precipitate, likely to be crude $[Fe_3O(O_2CCH_2C(CH_3)_3)_6(H_2O)_3]$, (3.50 g) was heated to 300 °C for 15 min in a tube furnace under N_2. The brown solid product (1.47 g) was dissolved in acetone (40 cm^3) and red crystals of **4** formed when MeCN (10 cm^3) was diffused into this solution after 2 days in 14% yield. *Anal.* Calc. (Found) for **4**: C, 42.56 (43.00); H, 6.79 (6.76); N, 0 (0)%.

2.2. Crystal structures

Data for **1** and **3** were collected on a Stoe Stadi-4 four-circle diffractometer and for **2** and **4** on a Bruker Smart APEX CCD area detector. Both diffractometers were fitted with an Oxford Cryosystems low-temperature device [8] and used graphite monochromated Mo Kα radiation with ω–θ scans for **1** and **3** and ω-scans for **2** and **4**. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 228440–228443. All refinements were against F^2 and used SHELXL-PC [9].

3. Results and discussion

3.1. Synthesis

Four Fe^{III} polynuclear complexes have been synthesised by heating simple Fe carboxylates in a tube furnace under inert conditions. Heating a crude solid sample of $[Fe_3O(O_2CC(CH_3)_3)_6(H_2O)_3]$ to 300 °C followed by crystallisation from THF has produced a hexanuclear Fe^{111} complex, $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}(THF)_2]$ (**1**). This complex has the same $[Fe_6O_2(OH)_2]^{12+}$ core as $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}]$ prepared by Gerbeleu et al. [10], and $[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(C_4H_8O_2)(H_2O)]$ synthesised by Micklitz and Lippard [11]. Using the same procedure used in the formation of **1**, another hexanuclear complex has been prepared with the $[Fe_6O_2(OH)_2]^{12+}$ core. $[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(H_2O)_2]$ (**2**) was synthesised by heating a solid sample of $[Fe_3O(O_2CC_6H_5)_6(H_2O)_2(MeCN)]$ to 300 °C and crystals of **2** were obtained from CH_2Cl_2.

Two undecanuclear complexes $[Fe_{11}O_6(OH)_6(O_2CC_6H_5)_{15}]$ (**3**) and $[Fe_{11}O_6(OH)_6(O_2CCH_2C(CH_3)_3)_{15}]$ (**4**) have also been prepared via the high-temperature route. **3** was first synthesised by Lippard and co-workers [12,13] who dissolved $(Et_4N)_2[Fe_2OCl_6]$ in MeCN and added sodium benzoate. To obtain crystals they then allowed water to diffuse into the solution. We have produced the same complex by heating a crude solid sample of $[Fe_3O(O_2CC_6H_5)_6(H_2O)_3](NO_3)$ to 300 °C and subsequently crystallising from MeCN. Synthesis of **4** was achieved by heating $[Fe_3O(O_2CCH_2C(CH_3)_3)_6(H_2O)_3]$ to 300 °C followed by dissolving the product in acetone and allowing MeCN to diffuse into the solution.

3.2. Structure descriptions

3.2.1. $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}(THF)_2]\cdot 2THF$ (**1**)

A SCHAKAL [14] representation of the structure of **1** is shown in Fig. 1. Tables of the crystallographic data and selected bond lengths and bond angles for **1** are given in Tables 1 and 2, respectively. There are two oxo-centred trimer units linked by two μ_2 hydroxide ligands

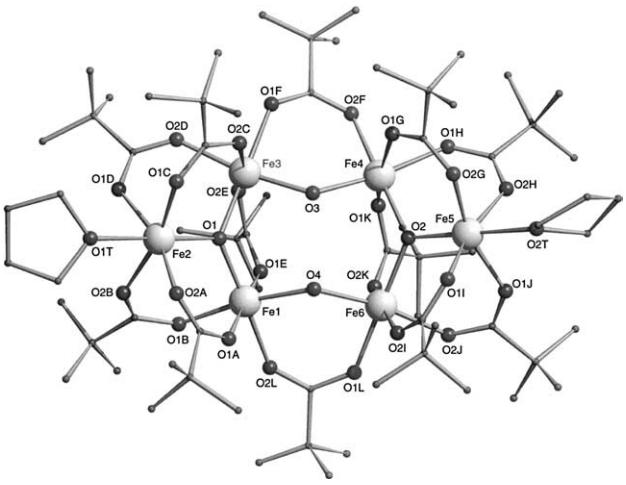

Fig. 1. The structure of **1** in the crystal.

O3 and O4, and two 1,3-bridging trimethylacetate ligands. The first trimer unit comprises Fe1, Fe2 and Fe3, and the second Fe4, Fe5 and Fe6. Coordination around Fe2 and Fe5 is the same, with terminal THF ligands attached to both. Fe2 is linked to Fe1 and Fe3 through a μ_3-oxo atom O1 and Fe5 bridges to Fe4 and Fe6 in the same fashion through O2. There are two 1,3-bridging trimethylacetate on each edge of the triangles, i.e., Fe2···Fe1, Fe2···Fe3, Fe4···Fe5 and Fe5···Fe6. All of the Fe atoms in this complex are in the +3 oxidation state and have distorted octahedral geometry.

Examination of the bond lengths between the Fe atoms and the μ_3-oxo atoms of **1** reveals that each of the trimer units is asymmetric. The bond length of Fe2–O1 is 1.8561(15) Å and Fe5–O2 is 1.8640(16) Å. These bond lengths are much shorter than the other bonds involving the μ_3-oxide (av. 1.96 Å). This may be related to the bond length of Fe2–O1T and Fe5–O2T, both of which are longer than expected at 2.2306(18) and 2.1887(19) Å, respectively.

3.2.2. $[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(H_2O)_2]\cdot C_6H_5CO_2H\cdot 4.33CH_2Cl_2$ (**2**)

Fig. 2 shows a SCHAKAL [14] representation of the structure of **2**. Crystallographic data for **2** is given in Table 1 and selected bond lengths and bond angles for **2** are given in Table 3. The structure and connectivity of **2** is the same as **1** with H_2O replacing the THF ligands coordinated to Fe2 and Fe5, and the trimethylacetate ligands are replaced by benzoate ligands. Just like **1**, the Fe atoms are all in the +3 oxidation state and have octahedral geometry. Again, each of the trimer units is asymmetric due to the short Fe2–O1 and Fe5–O2 bonds. These bond lengths are comparable with those observed for **1**. The Fe–O(H_2O) bond lengths are slightly elongated at 2.1027(19) Å for Fe2–O1 W and 2.1456(17) Å for Fe5–O2W.

3.2.3. $[Fe_{11}O_6(OH)_6O_2CC_6H_5)_{15}]\cdot 13MeCN$ (**3**)

The structure of **3** is depicted in Fig. 3 by a SCHAKAL representation [14]. Table 1 contains the, crystallographic data for **3** and Table 4 displays selected bond lengths and angles for **3**. Alone, the Fe atoms in **3** form a distorted pentacapped trigonal prism with Fe1, Fe7 and Fe9 forming one of the triangular faces of the trigonal prism and Fe3, Fe6 and Fe10 forming the other triangular face. Fe2, Fe4 and Fe11 cap the rectangular faces and Fe5 and Fe8 cap the triangular faces of the trigonal prism. This structure has non-crystallographic D_3 symmetry with a C_3 axis along Fe5 and Fe8 and three C_2 axes formed by Fe2, Fe4 and Fe11 bisecting the C_3 axis.

The triangular faces of the trigonal prism are twisted. This twist angle can be calculated by measuring the dihedral angle between the Fe atoms at the corners of the two triangular faces of the prism that represent one edge

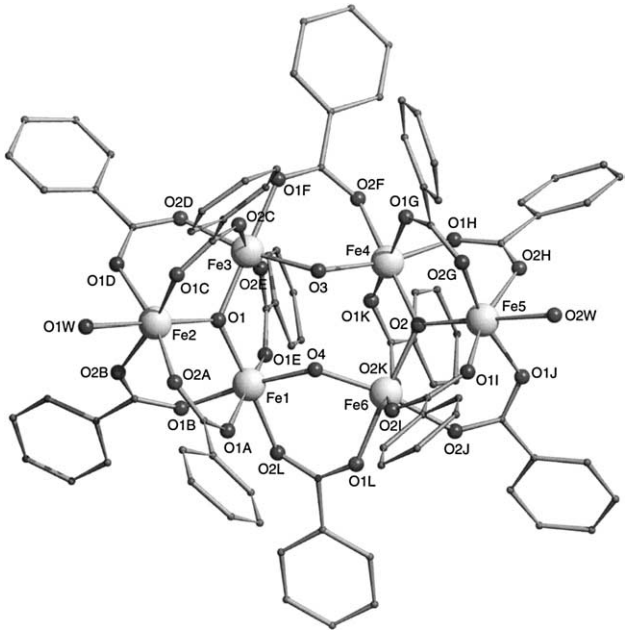

Fig. 2. The structure of **2** in the crystal.

of the rectangular faces and the two Fe atoms on the C_3 axis. For Fe1, Fe8, Fe5 and Fe3 the dihedral angle is 15.97°, for Fe6, Fe5, Fe8 and Fe7 it is 16.86° and for Fe9, Fe8, Fe5 and Fe10 it is 20.06°.

Fe1, Fe3, Fe6, Fe7, Fe9 and Fe10 have the same coordination environment. Each of which is linked to another Fe atom of the trigonal prism along the edge of the rectangular face by one 1,3-bridging benzoate ligand and two μ_3-hydroxide ligands. For example Fe1 bridges to Fe3 through the benzoate ligand F and the μ_3-hydroxide ligands O6 and O7. There is one μ_3-oxo ligand connecting each of the trigonal prism Fe atoms to one rectangular face capping Fe atom and one triangular face capping Fe atom. There are also two 1,3-bridging benzoate ligands, which join the Fe atom of the trigonal prism to the two different capping Fe atoms. For example Fe1 is connected to Fe2 and Fe8 through the μ_3-oxo ligand O2 and Fe1 is linked to Fe2 via the benzoate ligand A and to Fe8 through the benzoate ligand C. All of the Fe atoms have distorted octahedral geometry and are in the +3 oxidation state.

Fe–O($O_2CC_6H_5$) bond lengths range from 1.946 to 2.122 Å, Fe–O(OH) bond lengths range from 2.044 to 2.143 Å and Fe–O(O) bond lengths range from 1.877 to 1.945 Å. The difference between the Fe–O(OH) and Fe–O(O) ranges clearly shows that the O atoms O1, O4, O6, O7, O9 and O11 are OH ligands. There are four MeCN molecules hydrogen bonded to four μ_3-OH ligands, O1, O6, O7 and O9. These O(H)–N hydrogen bond lengths range from 2.820 to 2.943 Å. This gives confirmation to the presence of the H atom attached to the O atom at these sites.

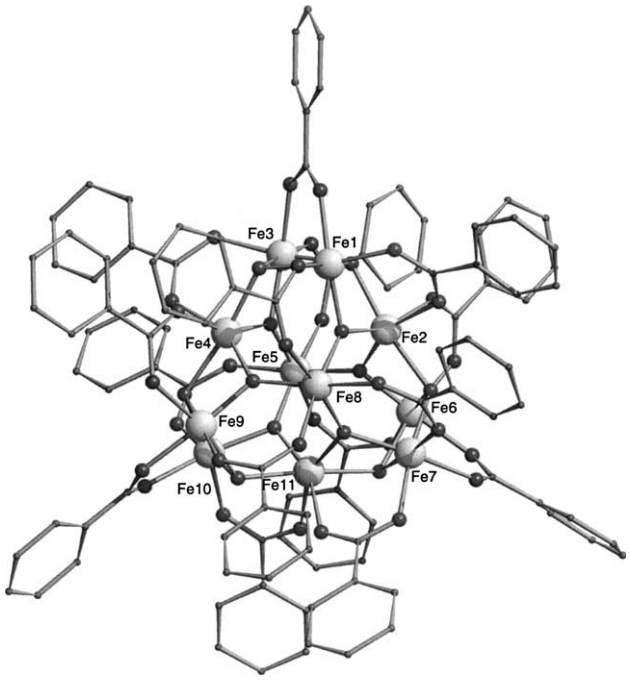

Fig. 3. The structure of **3** in the crystal.

3.2.4. $[Fe_{11}O_6(OH)_6(O_2CCH_2C(CH_3)_3)_{15}]\cdot 2.5MeCN$ (**4**)

Shown in Fig. 4 is a SCHAKAL representation [14] of **4**. Crystallographic data for **4** is listed in Table 1 and the selected bond lengths and angles are given in Table 5. The structure and connectivity of **4** is the same as **3** with *t*-butylacetate replacing the benzoate ligands. The Fe atoms are in the +3 oxidation state and have distorted octahedral geometry. Fe–O(O_2CR) bond lengths range from 1.937 to 2.156 Å, Fe–O(OH) bond lengths range from 2.044 to 2.153 Å and Fe–O(O) bond lengths range from 1.893 to 1.932 Å. These ranges are in good agreement with the equivalent ranges for **3**. As was seen in **3** the difference between the Fe–O(OH) and Fe–O(O) bond length ranges shows that the O atoms O1, O2, O7, O8, O9 and O10 are OH ligands. The Fe atoms of **4** also form a twisted trigonal prism and the twist angles are 18.03°, 18.07° and 18.19°. There is only one MeCN molecule hydrogen bonded to a μ_3-OH ligand, O2. The O(H)–N hydrogen bond length is 2.822 Å.

3.3. Structural comparisons

$[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(H_2O)(C_4H_8O_2)]$ by Micklitz and Lippard [11] has an almost identical structure to **1** and **2**. The only differences being the carboxylate and the coordinated solvent present. There is another similar hexanuclear Fe complex, $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}]$ synthesised by Gerbeleu et al. [10], that makes use of the same carboxylate as **1** but has a different connectivity. $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}]$ has two oxo-centred

trimer units that are joined by two μ_3-hydroxide ligands and four 1,3-bridging trimethylacetate ligands. In **1** and **2**, Fe2 and Fe5 have solvent ligands coordinated. The corresponding Fe atoms in $[Fe_6O_2(OH)_2(O_2CC(CH_3)_3)_{12}]$ are five coordinate with trigonal bipyramidal geometry.

Lippard and co-workers [12,13] prepared two crystal forms of **3** using a completely different technique. In one

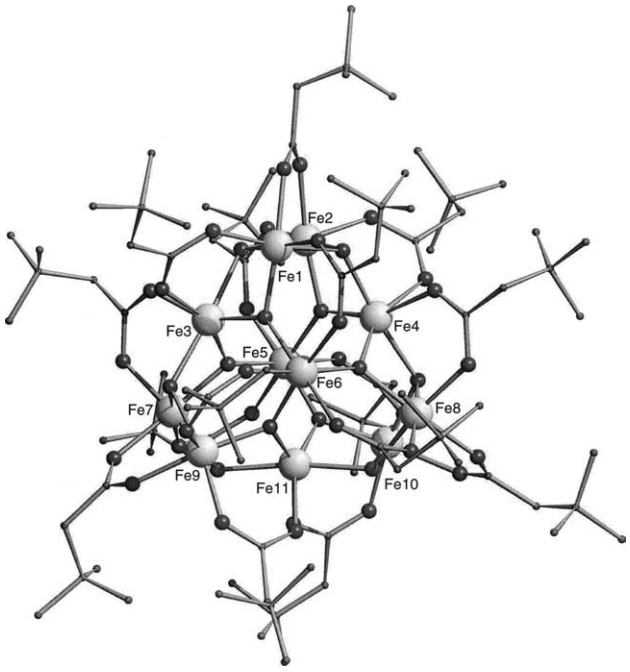

Fig. 4. The structure of **4** in the crystal.

of the crystal forms that was synthesised by Lippard and co-workers, MeCN is present. This would suggest that the unit cell for **3** should be the same but there is a subtle difference, **3** has an additional five molecules of MeCN per molecule of **3**. This has made the unit cell for **3** slightly bigger than the unit cell for the same complex produced by Lippard and co-workers. They also observed that four MeCN were hydrogen bonded to four of the μ_3-OH ligands. The O(H)–N hydrogen bond lengths range from 2.82 to 2.91 Å. This is the same as was observed for **3** and **4**. Bond length ranges are also similar to what was seen in **3** and **4**; Fe–O($O_2CC_6H_5$) are between 1.93 and 2.13 Å, Fe–O(OH) are 2.03–2.16 Å and Fe–O(O) are 1.88–1.94 Å. Lippard and co-workers also found that the Fe atoms formed a twisted prism and the twist angles they have recorded are 16.2°, 16.9° and 19.9°, this compliments our own findings for **3**.

In the other crystal form synthesised by Lippard and co-workers the cell is rhombohedral and has crystallographic D_3, symmetry. There are six THF molecules hydrogen bonded to each of the six μ_3-OH ligands with a O(H)–O distance of 2.78 Å. Fe–O($O_2CC_6H_5$) bond lengths range from 1.967 to 2.106 Å, Fe–O(OH) range from 2.061 to 2.078 Å and Fe–O(O) from 1.826 to 1.926 Å. Again these ranges are comparable with those seen in **3** and **4**. The symmetry of this crystal form means there is only one twist angle of 17.4°, which is similar to the angles observed in **3** and **4**.

A further pentacapped trigonal prism of Fe^{III} centres has been reported by Frey et al. [15], featuring a keto-carboxylate ligand. In that molecule, the ketone func-

tions are found H-bonded to the surface hydroxide groups of the $\{Fe_{11}\}$ cage.

3.4. Magnetism

Variable temperature magnetic susceptibilities of powdered samples of **1** and **2** were measured between 1.8 and 300 K in a magnetic field of 100 G (Fig. 5). At room temperature $\chi_m T$ for **1** is 8.62 emu K mol^{-1}, which is similar to the value obtained for **2** of 8.34 emu K mol^{-1}. The expected room temperature $\chi_m T$ value, with $g = 2.00$, for both complexes is 26.25 emu K mol^{-4}. This suggests that there is a very strong anti-ferromagnetic exchange between the Fe^{III} centres. $\chi_m T$ decreases as the temperature is decreased and **1** reaches 1.71 emu K mol^{-1} at 1.8 K and **2** goes to 0.23 emu K mol^{-1} at 1.8 K. The curves for **1** and **2** are similar in shape and the curve for **1** has a sharp down turn at 1.8 K which appears to be heading for 0 emu K mol^{-1} at 0 K. Both **1** and **2** have an $S = 0$ ground state. $[Fe_6O_2(OH)_2(O_2CC_6H_5)_{12}(H_2O)(C_4H_8O_2)]$ also shows anti-ferromagnetic exchange and has a room temperature magnetic moment

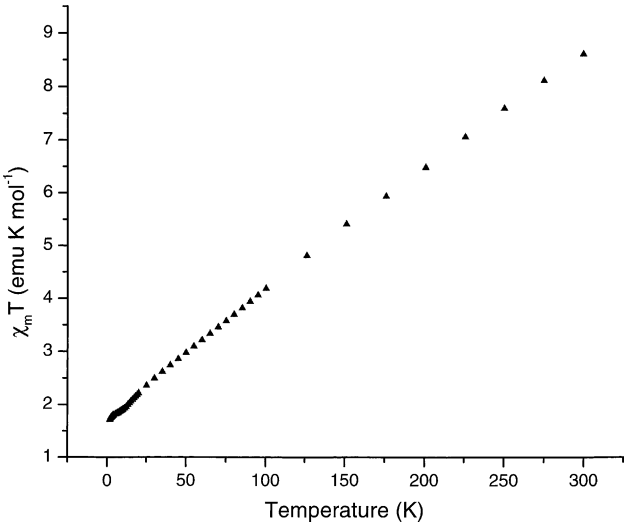

Fig. 5. Variable temperature magnetic behaviour of **1**, illustrated as a plot of $\chi_m T$ against T. The behaviour of **2** is very similar.

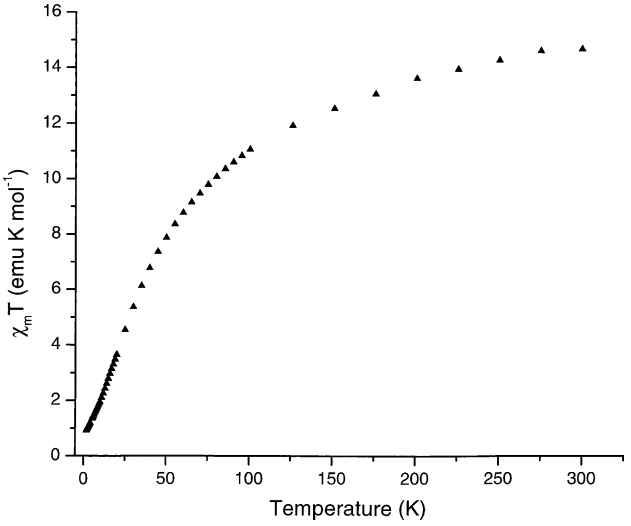

Fig. 6. Variable temperature magnetic behaviour of **3**, illustrated as a plot of $\chi_m T$ against T.

of 7.33 μ_B which decreases to 0.62 μ_B at 2 K [11]. Room temperature magnetic moments for **1** and **2** are 8.30 and 8.17 μ_B, respectively. These values decrease to 3.70 μ_B for **1** and 1.35 μ_B for **2** at 2 K.

Fig. 6 shows the variable temperature magnetic susceptibility of a powdered sample of **3**. This was measured in a magnetic field of 100 G between 1.8 and 300 K. Room temperature value for $\chi_m T$ is 14.71 emu K mol^{-1}. This decreases as the temperature decreases to 0.92 emu K mol^{-1} at 1.8 K. The expected room temperature value for 11 non-interacting Fe^{III} centres with $g = 2.00$ is 48.13 emu K mol^{-1}. There is a large difference between the theoretical and experimental room temperature value of $\chi_m T$. This suggests that there are very strong anti-ferromagnetic exchanges between the Fe centres. Lippard and co-workers [13] found that the magnetic moment of their product crystallised from THF at 298 K was 13.92 μ_B, and that this decreases to 3.32 μ_B at 2.6 K. **3** has a magnetic moment of 10.85 μ_B at 300 K and 2.71 μ_B at 1.8 K.

4. Conclusions

The high-temperature method used in the preparation of complexes **1**, **2**, **3** and **4** is an alternative to the usual methods that are employed in the synthesis of complexes of this nature. Unfortunately, where for chromium new clusters resulted [3–5], for iron only cages closely related to known compounds have resulted. This probably reflects the fact that much more cluster chemistry is known for Fe^{III} than was known for Cr^{III} when we began this project. Complexes **1** and **2** are new additions to the family of structures with the $[Fe_6O_2(OH)_2]^{12+}$ core, while **3** and **4** join the family of undecanuclear iron cages based on pentacapped trigonal prisms. This core is very similar to that found in the dodecanuclear chromium cage $[Cr_{12}O_9(OH)_3(O_2CC(CH_3)_3)_{15}]$, the difference being that the chromium cage has a central Cr^{III} centre.

As similar structures to **1**–**4** have been reported previously, it is debatable whether the high temperature employed in the synthesis is a requirement for the synthesis. However, the undecanuclear complexes are difficult to make in good yield [7], therefore there is some merit in this new approach. **3** and **4** cannot be made by refluxing the substrates in the recrystallisation solvents. The yields we find are poor to moderate, in the range 10–20%, and alternate routes to the complexes could be higher yielding. It is doubtful that the complexes are sufficiently interesting that they merit studies to optimise yields.

Abstract

Complexes of the formulae $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(C_5H_5N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{–}p\text{-}X)]^+$ [X = H (**2a**), CH_3 (**2b**), OCH_3 (**2c**), Cl (**2d**), NO_2 (**2e**)] and $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(C_5H_5N\text{-}2\text{-}CH{=}N\text{–}C_6H_{11})]^+$ (**3**) were prepared by reacting *para*-substituted *N*-(pyrid-2-ylmethylene)-phenylamines (**2-PP**) and *N*-(pyrid-2-ylmethylene)cyclohexylamine (**2-PC**) with $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ (**1**) in methanol. These complexes have been isolated as hexa-fluorophosphate salts. Representative complex **2c** has been established by single crystal X-ray diffraction analysis. Complex **2c** crystallizes in the orthorhombic space group P_{bcn}, with $a = 21.1560$ (11) Å, $b = 18.3972$ (9) Å and $c = 17.5130$ (9) Å, $V = 6816.3$ (6) Å^3 and $z = 8$. All these complexes were characterized by FT-IR, ^{1}H NMR and ^{31}P{^{1}H} NMR spectroscopy.

Keywords: Cyclopentadienyl; Schiff bases; Pyridine-2-carboxaldehyde; Ruthenium

1. Introduction

As a part of our continuing investigation of the complexes of η^5-cyclopentadienyl-ruthenium(II) [1], η^5-indenylruthenium(II) [2], η^5-cyclopentadienylosmium(II) [3] and η^6-areneruthenium(II) [4] with a variety of nitrogen-based ligands, we here report the syntheses of complexes of the cyclopentadienylruthenium(II) system with some chelating Schiff base ligands. Considerable interest has arisen in the chemistry of ruthenium (II) complexes having Schiff bases [5] or chelating nitrogen heterocyclic ligands [6] because of their photochemical and catalytic activities [7]. Steric factors play an important role compared to electronic factors in the structure and chemistry of these complexes. We had earlier reported the reaction of η^5-indenylruthenium(II) [8] and η^6-arene-ruthenium(II) [9] with Schiff base ligands. During the reactions involving the analogous pentamethylcyclopentadienyl or indenyl systems, the products did not show evidence of binding of these organic ligands, simple coordination compounds being formed instead. Although these groups can provide more electron density to the metal for binding, their large bulk compared to the cyclopentadienyl ligand prevents effective binding. This observation indicates steric factors playing a major role compared to electronic factors. However, relatively fewer reports are available in the literature for the analogous cyclopentadienylruthenium(II) Schiff base complexes [10]. We report here the synthesis and characterization of new cationic cyclopentadienylruthenium(II) complexes with *N*,*N*′-donor Schiff base ligands, viz., various

para-substituted *N*-(pyrid-2-ylmethylene) phenylamines (**2-PP**) and *N*-(pyrid-2-ylmethylene)cyclohexylamine (**2-PC**). The molecular structure of the complex $[(\eta^5\text{-}C_5H_5)Ru(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{–}p\text{-}OCH_3)(PPh_3)]PF_6$ as solved by X-ray crystallography is reported here as well.

2. Experimental

2.1. General remarks

All reactions were carried out in distilled and dried solvents under a dry nitrogen atmosphere. $RuCl_3 \cdot 3H_2O$ was purchased from Arora Matthey Ltd. and used as such. Pyridine-2-carboxaldehyde (Fluka) was purchased and used as received. All liquid amines were reagent grade and distilled prior to use, while solid amines were used as such. Elemental analyses were performed in a Perkin–Elmer-2400 CHN/O analyzer. Infrared spectra were recorded on a Perkin–Elmer-model 983 spectrophotometer with the sample prepared as KBr pellets. Electronic spectra were recorded on a Hitachi-300 spectrophotometer. Conductivity measurements were performed in Wayne Kerr automatic precision bridge B-905. The ^1H NMR spectra were recorded in $CDCl_3$ solvent (with tetramethylsilane as the internal standard) on a Bruker ACF-400 MHz spectrometer, coupling constants J being given in hertz (hz). $^{31}P\{^1H\}$ NMR chemical shifts were recorded relative to H_3PO_4 (85%). The ligands $C_5H_4N\text{-}2\text{-}CH{=}C_6H_4\text{–}p\text{-}X$ (where X = H, CH_3, OCH_3, Cl, NO_2) [11], and the precursor complex $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ (**1**) [12] were prepared following literature methods.

2.2. Preparation of $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(C_5H_5N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{–}p\text{-}X)]PF_6$ (**2a**–**e**), (X = H (**2a**), CH_3 (**2b**), OCH_3 (**2c**), Cl (**2d**), NO_2 (**2e**)

The following general procedure was used for preparation of these five complexes:

The mixture of the starting complex $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ (0.1 g, 0.110 mmol), the appropriate Schiff base ligand **2-PP** (0.165 mmol) and NH_4PF_6 (0.165 mmol) was refluxed in methanol (40 ml) whereby the orange color suspension gradually changed to a dark brown solution. It was refluxed for 6 h, and the solvent then rotary evaporated. The residue was dissolved in dichloromethane and filtered through a short silica gel column to remove insoluble material. The filtrate was again concentrated to about 2 ml, whereupon addition of excess hexane gave the desired complexes (**2a**–**e**) as dark brown solids. The solid was washed with diethyl ether and dried under vacuum to afford an 80–85% yield of the complexes.

2.3. Preparation of $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(\mathbf{2\text{-}PC})]PF_6$ (**3**)

This complex was prepared in a similar manner to that of the preparation of (**2a**–**e**), except that the ligand **2-PC** was used instead of **2-PP** to yield the dark brown solid complex in 80% yield.

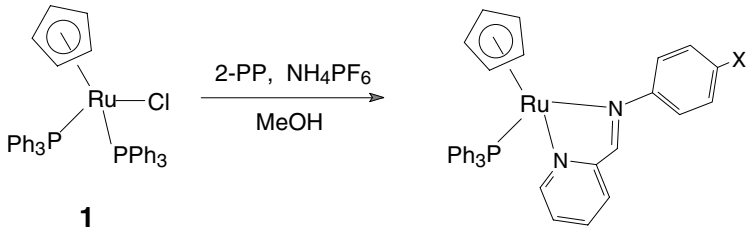
3. Structure analysis and refinement

X-ray quality crystals of the complex **2c** were grown by slow diffusion of hexane into a dichloromethane solution. A brown crystal of complex **2c** was mounted on a Bruker Apex CCD diffractometer in a full reciprocal sphere equipped with CCD detector and used for data collection. X-ray intensity data were collected with graphite mono-chromated Mo Kα radiation at 293(2) K, with 0.3° scans in ω scan mode and 10-s exposure time per frame. The intensity data were corrected for Lorentz and polarization effects through the SAINT program [13]. A summary of the crystal data, data collection parameters and convergence results are compiled in Table 3. An empirical absorption correction was made by modeling a transmission surface by spherical harmonics employing equivalent reflections with $I > 3\sigma(I)$ (program SADABS) [14]. The structure was solved by direct methods [15]. All the non-hydrogen atoms were refined anisotropically using the full-matrix least-squares technique on F^2 using the SHELXL 97 software [16]. All the hydrogen atom positions were found from difference Fourier synthesis after four cycles of anisotropic refinement and as ''riding'' model. Fig. 1 is the ORTEP [17] representation of the molecules with 50% probability thermal ellipsoids displayed. Refinement coverage at a final value of $R_1 = 0.0462$ (for observed data F) and at value of $wR_2 = 0.1192$, respectively (for unique data F^2).

4. Results and discussion

The synthetic reaction of the cyclopentadienyl complex **1** with excess of *N*,*N*′-donor Schiff base ligands, viz., **2-PP** and **2-PC**, in methanol under refluxing condition resulted in the formation of brown colored and air-stable cationic complexes of the type **2** (Scheme 1) by dissociation of one of the triphenylphosphines and chloride ligand. Here, we would like to point out that when similar reactions were carried out with complexes bearing the substituted analogue Cp^* and the indenyl group instead, the resulting complexes had no organic groups bound to the metal.

These complexes are highly soluble in polar solvents such as chloroform, dichloromethane, etc., but insoluble in non-polar solvents such as hexane, pentane, etc.



1

X = H, CH_3, OCH_3, Cl, NO_2 (2a-e)

2-PP = N-(pyrid-2-ylmethylene)phenylamine

Scheme 1.

These complexes were characterized by using analytical, IR, ^{1}H and ^{31}P NMR spectroscopic techniques. The data, as presented in Table 1, support the formation of these complexes. The X-ray structure of the representative complex **2c** was determined to confirm the structure of the complex. The IR spectra of these complexes show a strong band in the range of 1602–1584 cm^{-1} due to the $\nu_{C=N}$ group of the Schiff base ligand. In addition, the IR spectra contain strong bands due to the phenyl groups of triphenylphosphine and a strong band at 840 cm^{-1} due to the ν_{P-F} of the PF_6 group. Complex **2e** shows the characteristic bands for ν_{NO2} (asymmetric stretch at 1523 cm^{-1} and symmetric stretch 1346 cm^{-1}).

In the ^{1}H NMR spectra of these complexes, the cyclopentadienyl ring protons display a sharp singlet at 4.7 ppm. The presence of η-Cp, PPh_3 and **2-PP** or **2-PC** in a 1:1:1 ratio is inferred from the areas obtained upon peak integration of the ^{1}H NMR spectra. The resonance of the *ortho* proton of the pyridine ring of the ligand is observed as a doublet in the range 9.28–8.45 ppm in these complexes. The multiplet observed in the range 8.13–6.76 ppm is due to the phenyl protons of the triphenylphosphine moiety, the amine group and the *N*-heterocyclic ring of the ligands (**2-PP** or **2-PC**). The ^{31}P NMR spectra of the complexes **2** and **3** exhibit a single sharp resonance for triphenylphosphine around 47 ppm, whereas the starting complex [(η^5-Cp)Ru(PPh_3)$_2$Cl] (**1**) exhibits it at 42 ppm for both triphenylphosphines indicating the cationic nature of these complexes. The ionic nature of these complexes was confirmed by carrying out conductivity measurements (Table 2).

The electronic spectra and conductivity data of these complexes are shown in Table 2. The electronic spectra of these complexes in dichloromethane exhibit bands in the range of 428–461 nm. This low-energy absorption is assigned to a Ru dπ to ligand π* metal-to-ligand charge transfer (MLCT) transition. The molar conductivity of the complexes in acetonitrile solvent ranges from 123.0 to 150.0 S cm^2 mol^{-1}, suggesting that these complexes are ionically dissociated in the ratio of 1:1 [18].

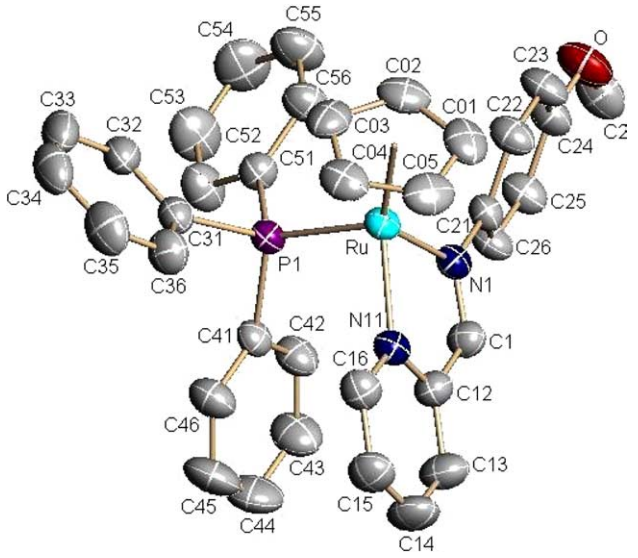

Fig. 1. ORTEP drawing of compound **2c** with 50% probability thermal ellipsoids. Hydrogen atoms and PF_6 omitted for clarity.

5. Crystal structure of 2c

The structure of complex **2c** is shown in Fig. 1. Representative bond length and bond angle values are listed in Table 4. The ruthenium atom is coordinated to two nitrogen atoms of the Schiff base ligand, one triphenylphosphine ligand and a pentahapto-bound cyclopentadienyl ligand. The geometry around the metal atom can be regarded as distorted octahedral if the η^5-cyclopentadienyl group is assumed to occupy three facial coordinated positions.

The $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(C_5H_5N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{–}p\text{-}OCH_3)]PF_6$ complex crystallizes in the orthorhombic space group P_{bcn}. The cyclopentadienyl group is clearly bonded in a pentahapto fashion to the metal. Three of the Ru–C bond lengths, viz., those involving the C(03), C(04) and C(05), are shorter (2.191, 2.182 and 2.196 Å) than the other two bonds involving the C(01) and C(02) carbon atoms (2.214 and 2.211 Å). The average Ru–C distance is 2.199 Å, whereas the distance between the ruthenium atom and the centroid of the ring is 1.837 Å at the axis $x = 0.0947$, $y = 0.0534$ and $z = 0.4796$. The Ru–P bond length is 2.3100 Å, which is within the usual range of Ru–P bond distances (2.20–2.43 Å) [19]. The ruthenium atom is directly coordinated to two nitrogen atoms of the Schiff base ligand with an average distance of 2.090 Å. The bite angle of the chelating ligand is 76.42(8°), not very different from that in other related complexes [20]. The geometry of the complex is octahedral (of the piano-stool type) with the cyclopentadienyl moiety occupying three coordination sites. This is evident in the nearly 90° values for the bond angle N(1)–Ru–P(1) between the non-cyclopentadienyl ligands (90.39(6)°) and for the bond angle N(11)–Ru–P(1) (92.67(6)°) at the metal centre. The orientation of the phenyl group of the amine is similar to the observed mutually perpendicular orientation found for similar types of ligand in arene ruthenium complexes [9].

[a] Ruthenium to centroid of Cp.

6. Conclusion

We have observed interesting phenomena in the case of the cyclopentadienyl complex **1**, which distinguish it from the analogous pentamethylcyclopentadienyl or indenyl ruthenium systems. Unlike the case of the complex **1**, the reactions of Schiff bases with the [(η^5-Cp*)Ru(PPh_3)$_2$Cl] and [(η^5-ind.)Ru(PPh_3)$_2$Cl] systems yield complexes without any organic group. We suggest that in order to obtain complexes bound to organic ligands for these cases, one has to start from acetonitrile complexes. The reactions of [(η^5-Cp)Ru(PPh_3)$_2$Cl] with Schiff base ligands, viz, *para*-substituted *N*-(pyrid-2-yl methylene)phenylamines and *N*-(pyrid-2-ylmethylene)-cyclohexylamine, in methanol yielded complexes **2a**–**e** of the type [[(η^5-Cp)Ru(PPh_3)(**2-PP**)]X and [(η^5-Cp)Ru (PPh_3)(**2-PC**)]X]. The molecular structure of the representative complex **2c** has been characterized by single crystal X-ray diffraction analysis.

7. Supplementary material

Crystallographic data for the structural analysis have been deposited at the Cambridge Crystallographic Data Centre (CCDC), CCDC No. 231959 for complex **2c**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk; website: www: http://www.ccdc.cam.ac.uk).

Abstract

Mixed-ligand Ni(II) complexes involving thiodiglycolate(2−) anion (tdga) and nitrogen-donor ligands in the coordination sphere have been prepared. The complexes of composition $[Ni(bpy)(tdga)(H_2O)]\cdot 4H_2O$ (**1**), $[(en)Ni(\mu\text{-}tdga)_2Ni(en)]\cdot 4H_2O$ (**2**), $[Ni(phen)(tdga)(H_2O)]$ (**3**), $[Ni(1,8\text{-}dan)(tdga)(H_2O)]$ (**4**), $[Ni(nphen)(tdga)(H_2O)]\cdot H_2O$ (**5**), $[Ni(ampy)(tdga)(H_2O)]$ (**6**), where bpy = 2,2′-bipyridine, en = ethylenediamine, phen = 1,10-phenanthroline, 1,8-dan = 1,8-diaminonaphthalene, nphen = 5-nitro-1,10-phenanthroline and ampy = 2-(aminomethyl)-pyridine, have been characterized by elemental analysis, IR and UV–Vis spectroscopies, and magnetic susceptibility measurements. Room temperature effective magnetic moments for **1**–**6** are ranging from 3.06 to 3.28 μ_{eff}/μ_B. and thus indicating that nickel atoms are six-coordinated in a deformed octahedral arrangement in all the prepared complexes. This conclusion has been confirmed by single-crystal X-ray analysis of $[Ni(bpy)(tdga)(H_2O)]\cdot 4H_2O$ (**1**). A binuclear structure of complex $[(en)Ni(\mu\text{-}tdga)_2Ni(en)]\cdot 4H_2O$ (**2**) has been anticipated in connection with study of its magnetic properties over the 1.8–300 K temperature range ($J = -4.35$ cm^{-1}, $D = 5.53$ cm^{-1}, $zJ = -0.94$ cm^{-1} for $g = 2.00$) and unambiguously proved by a single-crystal X-ray analysis.

1. Introduction

Transition metal complexes of carboxylic acids are in the interests of many research workers for many years. The complexes are often studied not only for their interesting magnetic properties but also for their biological occurrence in living organisms in metalloenzymes. It is well known that there are many possibilities for bonding of carboxylato group including also bridging properties [1,2]. More complicated systems are obtained in the case of polycarboxylic acids in comparison with monocarboxylic ones. For instance, thiodiglycolic acid belongs to dicarboxylic acids and moreover, it contains sulfur atom which can also takes part in coordination to central atom. To date, some transition metal complexes involving thiodiglycolic acid were characterized by single-crystal X-ray analysis, e.g. Cd(II), Zn(II), Ni(II), Cu(II) and Nd(III) [3–9]. From the X-ray study follows that the compounds can be either mononuclear, with one- or two-coordinated carboxylato groups, or polynuclear with tdga mostly forming linear chains having uncoordinated sulfur atom. The coordination sphere of a central atom in these systems may be completed by coordination of water molecules and/or nitrogen-donor ligands.

In our recent work, we have prepared and studied binuclear copper(II) complexes of the composition

$[(phen)_2Cu(\mu\text{-tdga})Cu(phen)](NO_3)_2 \cdot 5H_2O$ and $[(H_2O)(pmdien)Cu(\mu\text{-tdga})Cu(pmdien)(H_2O)](ClO_4)_2$, where pmdien = *N*,*N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine. It has been proved by single-crystal X-ray analysis that the complexes are bridged by thiodiglycolate dianion in different coordination modes. Magnetic susceptibility measurements over the 1.9–300 K temperature range revealed weak antiferromagnetic interactions between copper atoms in both complexes [10]. Our effort to prepare Mn(II) complex with tdga bridge has led to the synthesis of $[Mn(phen)_2(H_2O)_2][Mn(phen)_2(tdga)](tdga) \cdot 13H_2O$. Its crystal and molecular structure proved coordination of tdga to one Mn(II) center by two oxygens of both carboxylato groups leading to the formation of an eight-membered ring. A sulfur atom is not coordinated to Mn(II) ion in the case and one uncoordinated tdga dianion is also present in the structure [11].

In this paper, we report the results of study on mixed-ligand nickel(II) complexes involving a combination of the thiodiglycolate(2−) anion (tdga) and nitrogen-donor ligands in the coordination sphere. The aim of the present work was also to prove a coordination mode of thiodiglycolic acid to nickel centers and to compare our findings with published results. We have decided to use bidentate aromatic as well as aliphatic nitrogen-donor ligands for the replacement of coordinated water molecules in the starting $[Ni(tdga)(H_2O)_3]$ complex. Molecular structures of two complexes were determined by single-crystal X-ray analysis. Surprisingly, the complex **2** is dinuclear with bridging thiodiglycolato dianion having composition of $[(en)Ni(\mu\text{-tdga})_2Ni(en)] \cdot 4H_2O$.

2. Experimental

2.1. Materials and methods

The C, H, N, S analyses were carried out on an EA 1108 instrument (Fisons). IR and diffuse-reflectance spectra in Nujol mulls were recorded on a Specord M 80 and on a Specord M 40 (Carl Zeiss, Jena), respectively. Magnetochemical data for **1**–**6** were obtained by Faraday method at 293 K using a Sartorius M-25D electrobalance. $Hg[Co(SCN)_4]$ was used as a calibrant. The correction for diamagnetism was calculated using Pascal's constants [12]. The magnetic susceptibility of the powdered sample **2** was measured over the temperature range 1.8–300 K using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T. Magnetization was made at magnetic field 0.5 T. The SQUID magnetometer was calibrated with a palladium rod sample for which the gram magnetic susceptibility was taken as 5.30×10^{-6} cm^3 g^{-1} at $T = 293.1$ K. Diamagnetic correction is based on substracting the sample-holder signal and the contribution χ_{dia} estimated from the Pascal constants as -289×10^{-6} cm^3 mol^{-1}. The temperature independent paramagnetism of the Ni^{2+} centers

$$\chi_{tip} = \frac{8N\beta^2}{10\,Dq},$$

was used as $+215 \times 10^{-6}$ cm^3 mol^{-1}.

2.2. Syntheses

2.2.1. $[Ni(tdga)(H_2O)_3]$

A solution of $tdgaH_2$ (1.5 g, 10 mmol) dissolved in water (20 cm^2) was added to a well-stirred suspension of $NiCO_3 \cdot 2Ni(OH)_2 \cdot 4H_2O$ (3.76 g, 10 mmol) in water (100 cm^2). The reaction mixture was stirred and heated at 80 °C for 3 h. A small amount of insoluble nickel salt was filtered off. The solution was left for crystallization at ambient temperature. After two weeks thick green needles were filtered off and washed several times with small amount of cold water, and dried in air. Yield: 68%. *Anal.* Calc.: C, 18.4; H, 3.9; S, 12.3. Found: C, 18.8; H, 3.9; S, 12.0%.

2.2.2. General preparation of $[Ni(bpy)(tdga)(H_2O)] \cdot 4H_2O$ (**1**), $[(en)Ni(\mu\text{-tdga})_2Ni(en)] \cdot 4H_2O$ (**2**), $[Ni(phen)(tdga)(H_2O)]$ (**3**), $[Ni(1,8\text{-dan})(tdga)(H_2O)]$ (**4**), $[Ni(nphen)(tdga)(H_2O)] \cdot H_2O$ (**5**), $[Ni(ampy)(tdga)(H_2O)]$ (**6**)

The complexes were prepared by reaction of $[Ni(tdga)(H_2O)_3]$ (0.26 g, 1 mmol) with appropriate bidentate ligand (1.2 mmol). $[Ni(tdga)(H_2O)_3]$ was dissolved in 50 cm^3 of water and then, ligands dissolved in ethanol were added during stirring. A change in color of solution was observed. The reaction mixture was heated at 80 °C for 30 min. and left for crystallization at ambient temperature. Crystals or crystalline solids were obtained approximately after a week. These were filtered off and washed with small amounts of cold water and dried in air.

2.2.2.1. $[Ni(bpy)(tdga)(H_2O)] \cdot 4H_2O$ (**1**). Color: blue. Yield: 82%. *Anal.* Calc.: C, 44.1; H, 3.7; N, 7.4; S, 8.4. Found: C, 43.9; H, 3.6; N, 7.2; S, 7.8%. UV–Vis (nm): λ_{max} 300, 585. IR (cm^{-1}): 1620 m (ν_{as}COO), 1384 s (ν_{sym}COO). $\mu_{eff}/\mu_B = 3.20$.

2.2.2.2. $[(en)Ni(\mu\text{-tdga})_2Ni(en)] \cdot 4H_2O$ (**2**). Color: blue. Yield: 86%. *Anal.* Calc.: C, 23.8; H, 5.3; N, 9.2; S, 10.6. Found: C, 23.9; H, 5.3; N, 9.1; S, 10.4%. UV–Vis (nm): λ_{max} 255, 365, 585. IR (cm^{-1}): 1600 m (ν_{as}COO), 1380 s (ν_{sym}COO). $\mu_{eff}/\mu_B = 3.06$.

2.3. Crystal structure determinations

Crystals of **1** and **2** were obtained by slow evaporation of water solutions of the complexes. The all X-ray data were collected on a four-circle κ-axis KUMA KM-4 diffractometer (KUMA Diffraction, Wroclaw) equipped with an Oxford Cryostream cooler. X-ray data of **1** were collected at 150 K using graphite-monochromated Mo Kα radiation, a scintillation point detector and ω–2θ scan technique. Data reduction was performed using DataredC (KUMA Diffraction, Wroclaw) software. X-ray data of **2** were collected at 120 K using Mo Kα radiation monochromated by monochromator Enhance (Oxford Diffraction Ltd.), a CCD area detector and rotation method with ω-scan. The CrysAlis (Oxford Diffraction Ltd.) software was used for data reduction. The structures were solved using the direct methods (SHELXS-97) [13]. Both structures were refined anisotropically on F^2 using full-matrix least-squares procedure (SHELXL-97) [14]. H atoms attached to C and N atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding C and N atoms. H atoms attached to O atoms were refined with a DFIX (SHELXL-97, [14]) restraint of 0.95(2) Å and free variables were used to describe the U_{iso}(H) values of H atoms attached at individual water molecules. Crystal data and structure refinements for **1** and **2** are given in Table 1.

3. Results and discussion

3.1. Physical techniques

Our initial attempts to obtain bridged nickel(II)–thiodiglycolate complexes by reaction of nickel(II) nitrate

or perchlorate with amines and sodium salt of thiodiglycolic acid were unsuccessful. We have obtained viscous substances only. These have been treated with acetone or diethylether to receive powder material but samples thus obtained were hygroscopic and not suitable for performing of elemental analysis. That is why we have changed a manner of synthesis. We have used $[Ni(tdga)(H_2O)_3]$ as a starting material and we have tried to perform substitution of coordinated water molecules by a bidentate N-donor ligand. Thus we have succeeded in preparation of complexes **1**–**6** and characterized them by elemental analyses (see Section 2), IR and diffuse reflectance spectra and by magnetochemical measurement. Moreover, our findings were confirmed by complete X-ray analyses of two complexes.

The characteristic bands of carboxylate and nitrogen ligands are present in the IR spectra of the complexes and in comparison with the free ligands they are mostly shifted to lower frequencies. However, possible overlapping of main characteristic bands of the ligands complicates a detailed interpretation of the IR spectra. The IR spectra of all complexes contain very strong peaks at ca. 1580 cm^{-1} attributable to $\nu_{as}(COO^-)$, whereas peaks observed in 1384–1372 cm^{-1} range may be assigned to $\nu_s(COO^-)$. However, in the same range (1655–1430 cm^{-1}) peaks attributable to the C=C and C=N ring stretching vibrations of heterocycles occur. The $\Delta\nu$ value of carboxylate vibrations of approximatelly 200 cm^{-1} indicates that COO^- groups behave as a monodentate ligand [15]. The ν(N–H) bands extend from 3450–3250 cm^{-1} and appear in the spectra of the complexes (**2**, **4**, **6**) containing amine ligands [16].

All the nickel complexes have their magnetic moments in the range of 3.06–3.28 μ_{eff}/μ_B. These values are typical for deformed octahedrally coordinated nickel(II) ion. Moreover, the positions of bands found in diffusion-reflection spectra of the complexes are in good agreement with this assumption. In general, the spectra of the complexes are very similar. One set of bands attributable to the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transition was observed in the 605–585 nm region, whereas the bands at 370–350 nm are probably due to the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transition. However, the bands in the latter region can be also assigned to the π–π^* transition. The bands observed in the range 325–255 nm can be connected with CT or π–π^* transitions [17].

3.2. Crystal structures of $[Ni(bpy)(tdga)(H_2O)]\cdot 4H_2O$ (*1*) and $[(en)Ni(\mu\text{-}tdga)_2Ni(en)]\cdot 4H_2O$ (*2*)

Molecular structures of **1** and **2** are depicted in Figs. 1 and 2, respectively, while selected bond lengths and angles are listed in Tables 2 and 3. The structure of $[Ni(bpy)(tdga)(H_2O)]\cdot 4H_2O$ (**1**) consists of an electroneutral nickel complex and four crystal water molecules. The coordination polyhedron around the nickel atom

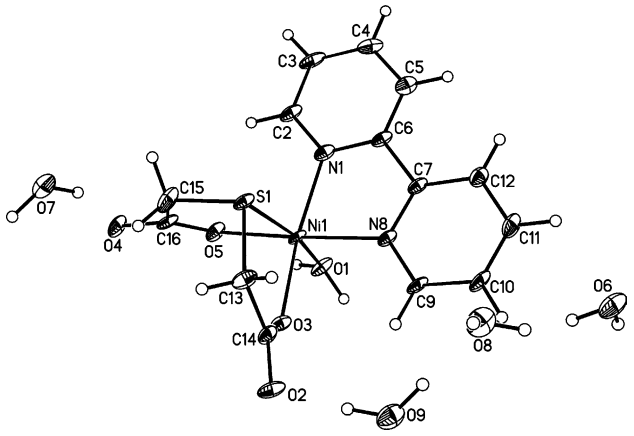

Fig. 1. The structure of $[Ni(bpy)(tdga)(H_2O)]\cdot 4H_2O$ (**1**) (ORTEPIII, [19]). Displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small spheres of arbitrary radii.

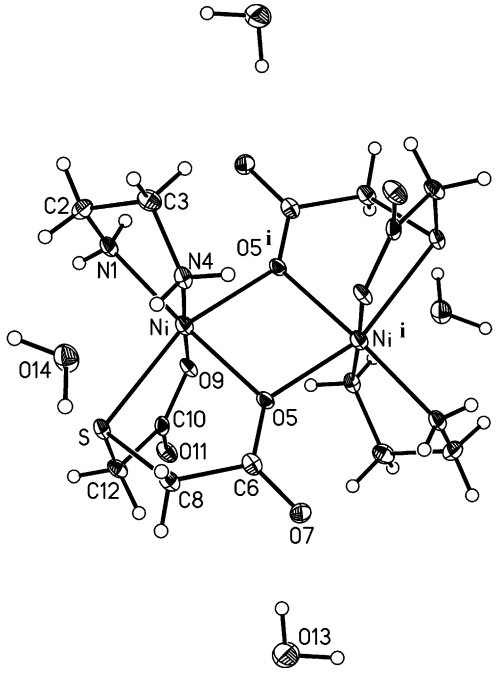

Fig. 2. The structure of centrosymmetric dimer $[(en)Ni(\mu\text{-}tdga)_2Ni(en)]\cdot 4H_2O$ (**2**). Displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small spheres of arbitrary radii. Symmetry code: (i) $-x+1, -y, -z+1$.

can be described as a deformed octahedron with a NiN_2SO_3 chromophore. Thus, nickel is coordinated by two nitrogen atoms of bpy, oxygen atoms of water molecule and thiodiglycolate dianion. The dianion is coordinated via sulfur atom and two oxygens from two carboxylato groups. The structure is very similar to that found for $[Zn(bpy)(tdga)(H_2O)]\cdot 4H_2O$ [5].In $[(en)Ni(\mu\text{-}tdga)_2Ni(en)]\cdot 4H_2O$ (**2**), two oxygen atoms of the tdga ligands form bridges between two Ni(II) ions. Each of two tdga anions is coordinated to nickel via one sulfur atom and two oxygens of different carboxylato groups. The remaining coordination positions on each of two

nickel atoms are occupied by two nitrogens from ethylenediamine. The coordination geometry around the nickel atoms is distorted octahedron with a N_2O_3S donor arrangement.

3.3. Temperature dependence of magnetic susceptibility of 2

The effective magnetic moment of **2**, calculated from $\mu_{\text{eff}} = 2.83\ (\chi_{\text{Ni}^{2+}})^{1/2}$ (BM), decreases from 3.06 BM at 300 K to 0.26 BM at 1.8 K (see Fig. 3). The μ_{eff} value at room temperature is characteristic for nickel(II) complexes in distorted octahedral coordination sphere. In the temperature range 50–300 K, susceptibility data obey Curie–Weiss law $[1/\chi_{\text{M}} = C(T-\theta)]$ with $C = 1.217$ cm^3 K mol^{-1} and $\theta = -1.17$ K, respectively.

For the description of the magnetic susceptibility data the equation, obtained by Ginsberg et al. [18] and the Hamiltonian, was employed

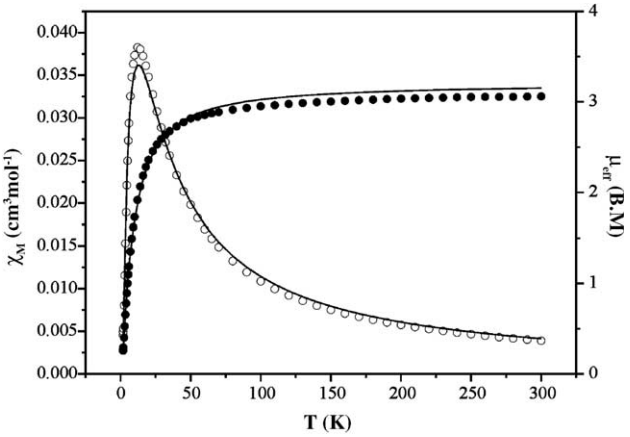

Fig. 3. Plot of the magnetic data for (**2**), χ_{M} {experimental (○) and calculated data (full line)} vs. temperature (K) and temperature dependence of μ_{eff} for (**2**) {experimental (●) and calculated data (full line)} using results from Ginsberg equation.

$$H = -2J\hat{S}_1\hat{S}_2 - D\left(\hat{S}_1Z^2 + \hat{S}_2Z^2\right) - 2zJ'\hat{S}_i\langle\hat{S}_i\rangle - g_iBH\hat{S}_i.$$

The symbols have their usual meanings. The magnetic susceptibility of the polycrystalline sample per gram-atom of Ni^{2+} is

$$\chi_{\text{A}} = \frac{Ng^2\beta^2}{3k}\left\{\frac{F_1(J,D,T)}{T - 4Z'J'F_1(J,D,T)} + \frac{2F'(J,D,T)}{1 - 4Z'J'F'(J,D,T)}\right\} + N\alpha,$$

where

$$F'(J,D,T) = \frac{1}{D}F_2(J,D,T) + \frac{3C_2^2}{3J-\delta}F_3(J,D,T) + \frac{3C_1^2}{3J+\delta}F_4(J,D,T),$$

$$F_1(J,D,T) = \frac{1 + e^{4J/kT} + 4e^{4J/kT}e^{D/kT}}{2 + e^{D/kT} + e^{J/kT}e^{-\delta/kT} + e^{J/kT}e^{\delta/kT} + 2e^{4J/kT} + 2e^{4J/kT}e^{D/kT}},$$

$$F_2(J,D,T) = \frac{2e^{4J/kT}e^{D/kT} + e^{D/kT} - 1 - 2e^{4J/kT}}{2 + e^{D/kT} + e^{J/kT}e^{-\delta/kT} + e^{J/kT}e^{\delta/kT} + 2e^{4J/kT} + 2e^{4J/kT}e^{D/kT}},$$

$$F_3(J,D,T) = \frac{e^{4J/kT} - e^{J/kT}e^{\delta/kT}}{2 + e^{D/kT} + e^{J/kT}e^{-\delta/kT} + e^{J/kT}e^{\delta/kT} + 2e^{4J/kT} + 2e^{4J/kT}e^{D/kT}},$$

$$F_4(J,D,T) = \frac{e^{4J/kT} - e^{J/kT}e^{-\delta/kT}}{2 + e^{D/kT} + e^{J/kT}e^{-\delta/kT} + e^{J/kT}e^{\delta/kT} + 2e^{4J/kT} + 2e^{4J/kT}e^{D/kT}},$$

$$\delta = [(3J+D)^2 - 8JD]^{1/2},$$

$$C_1 = 2\sqrt{2D}\Big/\left[(9J - D + 3\delta)^2 + 8D^2\right]^{1/2},$$

$$C_2 = (9J - D + 3\delta) \Big/ \left[(9J - D + 3\delta)^2 + 8D^2\right]^{1/2}.$$

The values of exchange parameters were determined by least-square procedure and the minimization of the function R was the criterion used to determine the best fit

$$R = \sqrt{\frac{\sum_{i=1}^{n}\left[(\chi_M)_i^{exp} - (\chi_M)_i^{calc}\right]^2 \Big/ \left[(\chi_M)_i^{exp}\right]^2}{n}}.$$

Least-square fits to the experimental data were obtained for $J = -4.35$ cm^{-1}, $D = 5.53$ cm^{-1}, $zJ' = -0.94$ cm^{-1}, $g = 2.00$ and $R = 4.41 \times 10^{-2}$.

However, it can be noticed, that in the higher temperature range, the fitting of theoretical and experimental data was not satisfactory.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 212990 and 212991 for complexes **1** and **2**, respectively. Abstract

An extended series of lanthanides (Ln) in their Ln^{III} oxidation state was reacted with $[\alpha_2\text{-}P_2W_{17}O_{61}]^{10-}$ (HPA) and the formation constants were determined for the complexes. The technique was the competition between this lacunary heteropolyanion and Arsenazo III for complexation of the same lanthanide. Unlike the usually featureless spectra of the Ln–HPA derivative, the visible spectra of the Arsenazo III complexes, in the presence of HPA, remain sharp, well-defined and could be recorded without interference from the Ln:HPA complexes formed simultaneously. These spectra were compared to those obtained with the same concentration of lanthanide in the absence of the heteropolyanion. Previous knowledge of the formation constants for Arsenazo III complexes with each lanthanide was necessary, so that those pertaining to the heteropolyanion complexes were left as the only unknowns in the set of equations. The 1:1 and 1:2 types of Ln:HPA complexes were found to coexist easily. Typically, values of $\log\beta_1 = 9.66$ and $\log\beta_2 = 16.26$ were found for the apparent formation constants corrected for acidity and other complexation effects in the case of the Ce^{3+} cation. Such values explain the coexistence of the two types of complexes in dilute solutions, with the possibility to keep a majority of a single species in solution under drastic concentration conditions. The same observation holds for all the series of Ln^{III} species examined in this work, because the formation constants are close from one lanthanide to the next. The comparison with the few values of formation constants available in the literature is satisfactory.

1. Introduction

The diversity of the properties of polyoxometalates and of the associated applications maintains the study of these chemicals at a high level [1–10]. Part of their interest, which is emphasized in the following, must be traced to their ability to generate lacunary species and then metal cation substituted derivatives. Much impetus was triggered by the pioneering remark by Baker [11] that monosubstituted heteropolyanions can be considered as the analogues of metallated porphyrins, and used in catalytic processes with the advantage over their organic counterparts of thermal stability, robustness and inertness toward oxidizing environments. A primary direction, not necessarily aimed at catalysis, had also received extensive attention: it concerns the use of lacunary polyoxometalates in the sequestration and/or separation of ions, particularly in nuclear waste treatment [10,12–42]. Peacock and Weakley [39] were the first to demonstrate that rare-earth cations are easily complexed by lacunary heteropolyanions. More specifically, the monovacant Dawson anion α_1- and α_2-$[P_2W_{17}O_{61}]^{10-}$ isomers are known to be obtained by removal of one $[WO]^{4+}$ group from the saturated anion $[P_2W_{18}O_{62}]^{6-}$. They were shown to function

doi:10.1016/j.poly.2004.03.014

as strong tetradentate ligands, [10,12–16,23–25,42] with high formation constants with transition metal and rare-earth ions [12,15,17–22]. Cerium appears as a favorite among lanthanide (Ln) studies and its heteropolyanion complexes are numerous [14,15,39–46]. Despite continuous efforts since the work of Peacock and Weakley [39], only recently were the problems of stoichiometry, structures and stabilities talked about for their own interest, and are beginning to receive satisfactory and complete solutions. Taking more specifically α_2-$[P_2W_{17}O_{61}]^{10-}$ as a representative ligand, the existence of 1:1 and 1:2 (Ln:heteropolyanion) complexes has long been noted [39]. Mostly, these species were detected and characterized by spectroscopic and electrochemical methods [15,42]. However, most attempts to isolate a solid from an equimolar mixture of $Ce(NO_3)_3$ and α_2-$K_{10}[P_2W_{17}O_{61}]$ yielded salts of the 1:2 complexes. To our knowledge, only in one case [15] was reported the successful isolation of the 1:1 complex, until the recent work by Pope et al. [46] indicating that the use of a threefold excess of Ce^{3+} has permitted this complex to be obtained as a pure crystalline ammonium salt. The structural analysis of the latter reveals a dimeric head-to-head anion, thus featuring a 2:2 complex in the solid state. Characterization of this complex in water by ^{31}P NMR, also supported by ^{183}W NMR data, reveals a complicated overall "monomer–dimer" equilibrium in solution [46]. Recently, 1:1 Ln:$[\alpha_2$-$P_2W_{17}O_{61}]^{10-}$ complexes were isolated for a series of lanthanides [47]. In slight contrast with the aforementioned Ce^{3+} complex in the solid state, the X-ray structure of the Eu^{3+} analogue revealed two identical [Eu-$(H_2O)_3(\alpha_2$-$P_2W_{17}O_{61})]^{7-}$ moieties, connected through two Eu–O–W bonds, one from each polyoxometalate unit, but which were not head-to-head. The solution studies indicated, however, that the molecules dissociate in solution to form the monomeric $[Ln(H_2O)_4(\alpha_2$-$P_2W_{17}O_{61})]^{7-}$ species.

With the aim to get a further understanding of the lability of such complexes in solution, the present paper describes the determination of formation constants of the various complexes of an extended series of lanthanide cations, including Ce^{3+}, with α_2-$[P_2W_{17}O_{61}]^{10-}$.

2. Experimental

2.1. Apparatus

UV–visible spectra were recorded on Perkin–Elmer Lambda 19 spectrophotometer coupled to a computer. The spectra were recorded from 800 to 400 nm using 1.000-cm quartz cuvettes.

All pH measurements were made on a Tacussel LPH 430T pH meter with a Tacussel combination pH glass electrode. Calibration of the pH meter was checked at regular intervals.

2.2. Reagents

Pure water was used throughout. It was obtained by passing through a Millipore RiOs unit and subsequently through a Millipore Q water purification set. All the chemicals were of high-purity grade and were used as received. Arsenazo III as a disodium salt (98%) and monochloroacetic acid (99+%) were obtained from Aldrich and sodium hydroxide from Prolabo. All the lanthanides were obtained as nitrate salts from Alfa Aesar (99.99%). The α_2 isomer, $K_{10}[\alpha_2$-$P_2W_{17}O_{61}]$, was prepared following literature methods [12]. It was standardized as described in the literature [14]. The pH 3.50 electrolyte was usually made up of 0.1 M $CH_2ClCOONa$ + $CH_2ClCOOH$.

Experiments were performed at the laboratory temperature.

2.3. Procedure

The general procedure was the competition between α_2-$[P_2W_{17}O_{61}]^{10-}$ (HPA) and Arsenazo III (Ar) for complexation of the same lanthanide. Arsenazo III is the common designation of {3,6-bis[(2-arsonophenyl)-azo]-4,5-dihydroxy-2,7-naphthalenedisulfonic acid}; the overall formula of the disodium salt reads: $C_{22}H_{16}As_2Na_2N_4O_{14}S_2$ (the anion is abbreviated as Ar in the following). This bis-azo derivative of chromotropic acid forms stable complexes with a large variety of ions over a wide pH range [48]. Specifically, it is extensively used for spectrophotometric biomedical analysis of various ions including Ca^{2+} and Al^{3+}.

The Arsenazo III solutions were standardized by means of spectrophotometric titration with a standard solution of $FeCl_3$ and lanthanide solutions with EDTA as described in detail elsewhere [49]. The concentrations of Arsenazo III stock solutions in the pH 3.5 buffer ranged from 4.00×10^{-5} to 4.73×10^{-5} M. Typically, the following concentrations were determined for lanthanide solutions: Nd, 1.45×10^{-3} M; La, 1.55×10^{-3} M; Dy, 2.23×10^{-3} M; Sm, 1.07×10^{-3} M; Eu, 1.24×10^{-3} M; Gd, 2.34×10^{-3} M; Ho, 2.12×10^{-3} M; Tb, 1.45×10^{-3} M; Yb, 2.20×10^{-3} M; Ce, 1.60×10^{-3} M; Pr, 2.00×10^{-3} M.

Finally, in a representative experiment, the quartz cuvette contained 1.5 or 2 mL of the Arsenazo III solution, 1.5 or 1 mL of the pH 3.50 buffer and 10–100 μL of the HPA solution, depending on the initial concentration of the corresponding stock solution. The initial concentration of HPA in the cuvette thus ranges from 1×10^{-5} to 2.34×10^{-5} M. Aliquots of 4 or 5 μL of lanthanide solution were added and the absorbance of Arsenazo III and its complexes were recorded after each addition. The experiments were stopped when the absorbances no longer varied.

Calculations of the apparent formation constants were then carried out as explained in the following.

3. Results and discussion

3.1. Formation constants of Ln:HPA and Ln:HPA$_2$ complexes

The determination of formation constants was carried out by UV–visible spectrometry. The following reason dictated this choice: it was desirable to apply the same technique to a large selection of lanthanide cations. As most of them were not expected to present easily tractable redox properties, potentiometric measurements appear limited to only few examples. One spectrophotometric possibility was exemplified previously [15] by the study of the competition between Ce^{3+} and Zn^{2+} or Co^{2+} for complexation by α_2-$[P_2W_{17}O_{61}]^{10-}$. In the present work, the selected technique consists of studying the competition between two ligands for the complexation of the same Ln cation. It is assumed that the complex formation constants with the reference ligand are known from separate experiments; also it is desirable that the formation constants with the new ligand be sufficiently close to those of the reference ligand, in order that good accuracy could be achieved in the determination of the unknown values. With these guidelines and literature indications [49–52], Arsenazo III was selected as the reference ligand. Its interactions with lanthanides were investigated in some detail [49–52]. In particular, Arsenazo III was shown to build up the same type of complex with lanthanides, a very useful remark to minimize modelization time in the series. Furthermore, the literature values for formation constants with lanthanides [49,50] are in the range expected for Ln:HPA complexes, with regard to the very few published constants for the latter [15,17,53]. Also, the chromophore groups in the ligand facilitate the spectrophotometric study in the visible domain. Finally, we have checked that Arsenazo III is stable in acidic solution.

3.1.1. Formation constants of Ln:Ar complexes: a reevaluation [49]

Published formation constant values for Ln:Ar complexes [50] were obtained with solutions containing at the utmost 5.68×10^{-6} M Arsenazo III. The conclusion was that dilute solutions of this ligand react in a 1:1 ratio with the lanthanides at pH 3.5 with formation constants ranging from 2×10^7 to 8×10^7 M^{-1}. Completeness of the reaction is an important assumption behind these results. For larger concentrations of Arsenazo III, a new determination of these formation constants, without any a priori assumption, was warranted, at least as a cross-check of previous conclusions. Actually, it turns out that three Ln:Ar complexes are currently formed in equilibrium, with a definite tendency to obtain the 1:1 and 2:2 complexes in the presence of a slight excess of Ln. The apparent formation constants for the three complexes were published elsewhere [49] and are gathered here in Table 1, for use in the following.

Table 1
Formation constants of Arsenazo III–lanthanide complexes calculated by the Taylor expansion method

Lanthanide	$\log K_{11}$	$\log K_{12}$	$\log K_{22}$
La	5.06	9.73	14.97
Ce	5.19	9.87	15.27
Pr	4.88	9.56	14.58
Nd	5.32	9.90	15.37

Eu	5.15	9.98	15.43
Gd	5.08	9.93	15.35
Tb	4.97	9.68	14.87
Dy	5.13	9.93	15.37
Ho	5.12	9.97	15.45
Yb	5.11	9.92	15.33

For further details, see text and reference [49].

3.1.2. Formation constants of Ln:HPA complexes

It is worth noting that Ln:HPA complexes are colorless. Therefore, during the competition of HPA and Arsenazo III for complexation of a common Ln, the spectrum in the visible wavelength domain pertains essentially to Arsenazo III and its complexes. Typically, Fig. 1 illustrates this point by showing the two spectra obtained with a selected initial concentration of Arsenazo III and the addition of the same amount of lanthanide, but with the presence of HPA in one of the experiments. However, possible interference in the observed spectrum arising from a mixed complex deserves

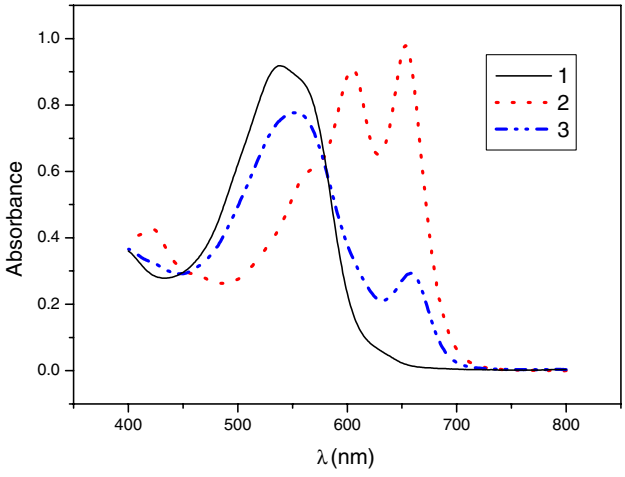

Fig. 1. Selected spectra associated with the titration of Arsenazo III with La^{3+} at pH 3.50, in the absence and presence of HPA; [Arsenazo III] = 2.67×10^{-5} M. 1, Arsenazo III alone; 2, Arsenazo III without HPA, $V_{La^{3+}} = 45$ μL; 3, Arsenazo III with HPA, [HPA] = 2.08×10^{-5} M, $V_{La^{3+}} = 45$ μL.

consideration. As a matter of fact, the possibility exists that a mixed Ar:Ln:HPA complex be formed in solution. Spectral deconvolution of the spectra before and during the competition was helpful to answer this question.

Spectral deconvolution. To illustrate the procedure, Fig. 2 shows the spectrum of Arsenazo III in the presence of α_2-$[P_2W_{17}O_{61}]^{10-}$ and an example of its evolution upon addition of La^{3+}. A detailed description of the procedure, based on the additivity of Beer–Lambert's law, has been given elsewhere [49]. Free Arsenazo III has a spectrum consisting of a broadband peaking around 540 nm. The spectrum of the La^{3+}-complex displays two sharp peaks at 606 nm and 654 nm for La_2Ar_2 and $LaAr_2$, respectively, and a broadband peaking around 601 nm for LaAr [49]. The concentrations of the various species in solution are needed for the determination of the complex formation constants.

Each spectrum can be decomposed into a sum of several Gaussian-type spectra. The software Origin 5.0 was used for this purpose. The following criteria were taken as guides: for the fitting accuracy to the experimental spectra, the correlation coefficient must be larger than 0.995; for significance of the deconvolution, each Gaussian component is characterized by its peak wavelength and its half-peak width: in favorable cases, the peak wavelength identifies a species in solution; whenever these characteristics reach stable values during a deconvolution process, the absorbance at the peak of the Gaussian component might be considered to represent the concentration of the species actually present in the reaction mixture through Beer-Lambert's law.

These guidelines were followed to generate the deconvolution shown in Fig. 2. Other pertinent details can be found in the reference cited [49]. Fig. 3(a) shows the overall absorbance variations observed for Arsenazo III at 538 nm and for a new peak at 654 nm. However, these

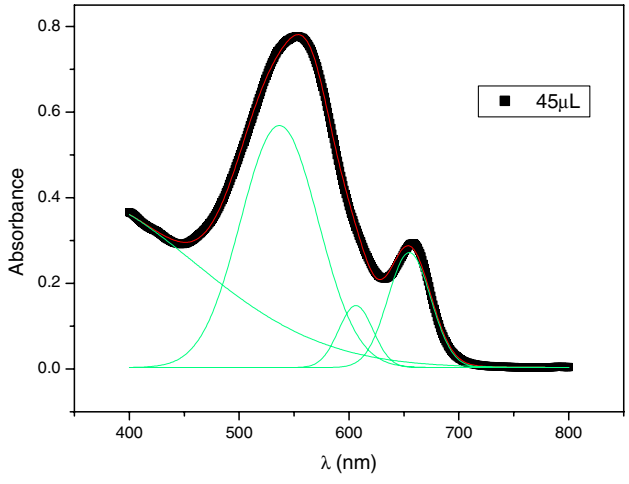

Fig. 2. Deconvolution into Gaussians of spectrum 3 of Fig. 1.

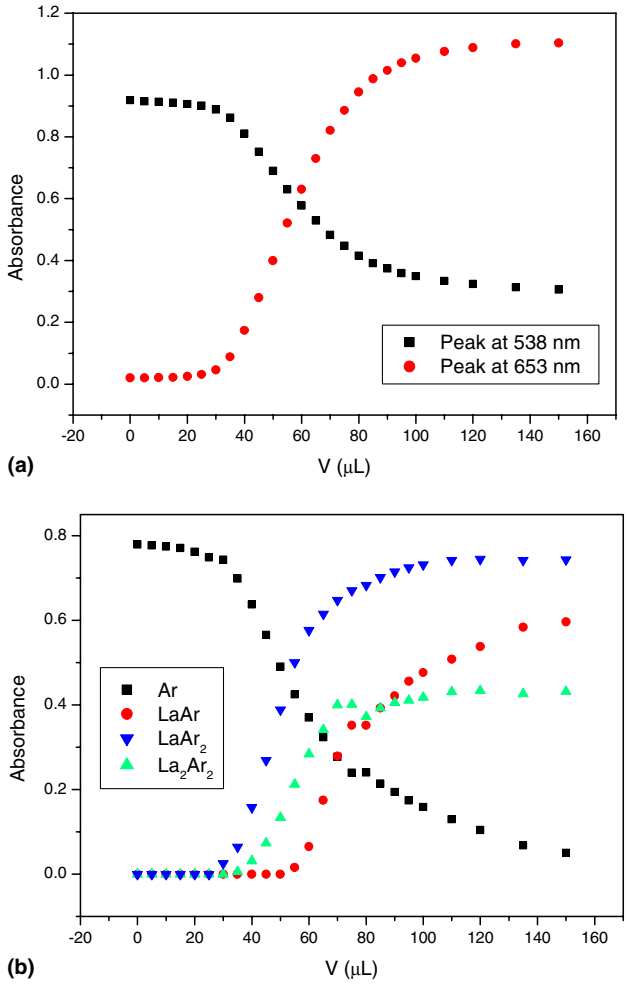

Fig. 3. Variations of the peak absorbances during the titration of Arsenazo III as a function of the added volume of a 1.55×10^{-3} M solution of La^{3+} at pH 3.50; [Arsenazo III] $= 2.67 \times 10^{-5}$ M and [HPA] $= 2.05 \times 10^{-5}$ M: (a) before the spectral deconvolution and (b) variations of the absorbance peaks of the Gaussians after the deconvolution.

experimental points represent overlapping spectra. Fig. 3(b) gives detailed variations of absorbances measured from Gaussian-type deconvoluted spectra from which accurate calculations could be undertaken.

Such spectral deconvolution was carried out for La through Yb, with the exception of Er. It was observed (see Tables S1 and S2 in the Supplementary Materials) that the peak wavelength locations and the half-peak widths for the various Gaussian deconvoluted spectra do not vary in the absence or presence of HPA; they also remain constant during the competition process of the two ligands for complexation of Ln up to its completion. The same remark is valid for Ln:Arsenazo III complexes in the absence or presence of HPA. Importantly, it is also observed that, during the competition process, no new peak appeared in the system of deconvoluted spectra, which would have indicated the build up of a

new complex. These observations, together, rule out any significant formation of a mixed complex, Ar:Ln:HPA. Therefore, the conditions are fulfilled for a quantitative analysis of the competition process between Arsenazo III and HPA for complexation of lanthanides.

Apparent formation constants of the various Ln:HPA complexes. In agreement with experimental evidence firmly established in the pertinent literature, two main equilibria must be considered (overall charges of the species are omitted in the equations):

$$\mathrm{HPA} + \mathrm{Ln} \leftrightarrows \mathrm{LnHPA} \quad \text{apparent formation constant } \beta'_1, \tag{1}$$

$$2\mathrm{HPA} + \mathrm{Ln} \leftrightarrows \mathrm{LnHPA_2} \quad \text{apparent formation constant } \beta'_2. \tag{2}$$

These equilibria are in competition with the simultaneous consumption of Ln by Arsenazo III.

$$\mathrm{Ar} + \mathrm{Ln} \rightleftarrows \mathrm{LnAr} \quad \text{apparent formation constant } K_{11},$$

$$2\mathrm{Ar} + \mathrm{Ln} \rightleftarrows \mathrm{LnAr_2} \quad \text{apparent formation constant } K_{12},$$

$$2\mathrm{Ar} + 2\mathrm{Ln} \rightleftarrows \mathrm{Ln_2Ar_2} \quad \text{apparent formation constant } K_{22}$$

for which the apparent formation constants were determined previously [49] and recalled in Table 1.

The set of equations from which the values of β'_1 and β'_2 are extracted was solved with the matter conservation equations and the necessary conditions for the equilibria relationships (see Appendix A). An example of the solution is illustrated by the representative case of La^{3+} complexes with HPA. Obviously, the relevant concentrations for this calculation are those pertaining to the domain where the consumption of La^{3+} by Arsenazo III or by both ligands is realized. Therefore, we found that the absorbance profile for Arsenazo III during the complexation process can be fitted to a Maclaurin polynomial series of the general form:

$$y = p_0 + p_1(x - x_0) + p_2(x - x_0)^2 + p_3(x - x_0)^3 + p_4(x - x_0)^4 + \cdots$$

The parameters p_0–p_5 were calculated using the Origin 5.0 software. The results are shown in Fig. 4. It is worth noting the very good correlation coefficient for this fitting.

Finally, the relevant set of equations to be solved are presented in Appendix A. The apparent formation constants in our experimental conditions ensue. These values are designated by β'_1 and β'_2, respectively, and are gathered in Table 2.

3.2. Corrections of apparent formation constant values

Corrections for acidity and complexation of HPA by other cations are needed. As a matter of fact, α_2-$[P_2W_{17}O_{61}]^{10-}$ has three acidity constants, and is also complexed by alkaline cations [54].

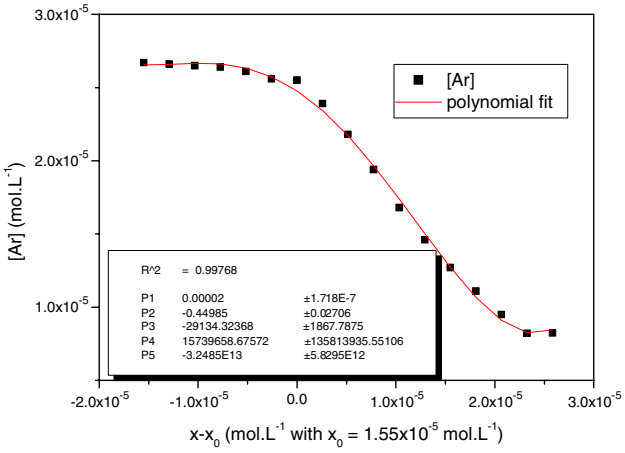

Fig. 4. Maclaurin polynomial fitting of the concentration of Ar as a function the operational concentration ($x - x_0$).

Comparison with the few published literature values. For further details, see text.

where $[HPA]^{app}$ is the apparent concentration, [HPA] represents the effective concentration, $\alpha_{HPA(H)}$ the protonation coefficient, $\alpha_{HPA(Na)}$ the complexation coefficient by Na^+. These αs are known as Ringböm coefficients.

These values indicate that the HPA is partly protonated and also complexed at pH 3.5 and 0.1 M Na^+ medium where the complexation by lanthanides is carried out. Then the apparent formation constants defined previously actually read:

$$HPA + Ln \rightleftarrows LnHPA, \quad \beta_1' = \frac{[LnHPA]^{app}}{[HPA]^{app}[Ln^{3+}]^{app}},$$

$$2HPA + Ln^{3+} \rightleftarrows LnHPA_2, \quad \beta_2' = \frac{[LnHPA_2]^{app}}{([HPA]^{app})^2[Ln^{3+}]^{app}}.$$

If it is assumed that the effective concentrations of LnHPA, $LnHPA_2$ and Ln are equal to their respective apparent concentrations, then the relationship for $[HPA]^{app}$ leads to:

$$\beta_1 = \beta_1'(\alpha_{HPA(H)} + \alpha_{HPA(Na)} - 1)$$

and

$$\beta_2 = \beta_2'(\alpha_{HPA(H)} + \alpha_{HPA(Na)} - 1)^2.$$

In our experimental conditions, pH 3.5 and $[Na^+] = 0.1$ M, $\alpha_{HPA(H)} + \alpha_{HPA(Na)} - 1 = 64.18$. The final results, after these corrections, are gathered in Table 3. In the same Table, the few values available in the literature are gathered for comparison. No corrections were made for the values already extrapolated to zero ionic strength [17]. Corrections from medium effects were carried out in the case where a pH 6 and 1.0 M Na^+ medium was used [53]. The correction coefficient is: $\alpha_{HPA(H)} + \alpha_{HPA(Na)} - 1 = 355.8$. The comparison turns out to be satisfactory in the cases where it is possible.

4. Concluding remarks

The lability of 1:1 and 1:2 Ln:HPA complexes in solution and, in several examples, the intriguing isolation of only one of these two complexes in the solid state can be rationalized with the knowledge of their formation constants. In the present work, such values were determined for an extended series of lanthanides in the presence of the lacunary heteropolyanion α_2-$[P_2W_{17}O_{61}]^{10-}$. Even though appropriate corrections could be carried out to obtain absolute formation constant values, apparent constants might suffice as significant guides when particular experimental conditions are selected. Then, the relative closeness of the formation constants for 1:1 and 1:2 complexes would explain readily the difficulty in avoiding the monomer–dimer equilibria in solution. As expected, calculations confirm easily that this shortcoming is particularly sensitive when a pure 1:2 complex, dissolved in micromolar and submicromolar concentrations in solution, is very significantly reversed to the corresponding monomer. Another conclusion concerns the methodology. The satisfactory comparison with the few values available in the literature and obtained by completely different methods, supports the present way of handling the data. In particular, it is confirmed that only a few accurate and appropriately selected experimental points are sufficient to evaluate the formation constants of Ln/HPA complexes.

Finally, the problem remains as to the actual catalytic species in electrocatalytic processes based on necessarily dilute solutions of these complexes. Work in progress will discuss this problem.

Acknowledgements

This work was supported by the CNRS (UMR 8000) and the University Paris XI. The participation of

G. Laurent and H. Pereira in the early parts of this work is thankfully acknowledged.

Appendix A

For the sake of clarity, the following notations are used: Ar designates Arsenazo III; HPA stands for the lacunary heteropolyanion α_2-$[P_2W_{17}O_{61}]^{10-}$ and Ln stands for any lanthanide; the overall concentration of Arsenazo III reads C_{Ar}, that of HPA C_{HPA} and that of any lanthanide C_{Ln}, the corresponding equilibrium concentrations will be noted: [Ar], [HPA] and [Ln], respectively. The other equilibrium concentrations of the various complexes read respectively: [LnAr]; [$LnAr_2$]; [Ln_2Ar_2]; [LnHPA] and [$LnHPA_2$].

The following relationships hold:

Matter conservation.

$$C_{Ar} = [Ar] + [LnAr] + 2[LnAr_2] + 2[Ln_2Ar_2],$$

$$C_{Ln} = [Ln] + [ArLn] + [LnAr_2] + 2[Ln_2Ar_2] + [LnHPA] + [LnHPA_2],$$

$$C_{HPA} = [HPA] + [HPALn] + 2[LnHPA_2],$$

Equilibrium constants

$$K_{11} = \frac{[LnAr]}{[Ar][Ln]},$$

$$K_{12} = \frac{[LnAr_2]}{[Ar]^2[Ln]},$$

$$K_{22} = \frac{[Ln_2Ar_2]}{[Ar]^2[Ln]^2},$$

$$\beta_1 = \frac{[LnHPA]}{[Ln][HPA]},$$

$$\beta_2 = \frac{[LnHPA_2]}{[Ln][HPA]^2}.$$

The first derivatives with respect to C_{Ln} are necessary and read:

$$0 = \frac{d[Ar]}{dC_{Ln}} + \frac{d[LnAr]}{dC_{Ln}} + 2\frac{d[LnAr_2]}{dC_{Ln}} + 2\frac{d[Ln_2Ar_2]}{dC_{Ln}},$$

$$1 = \frac{d[Ln]}{dC_{Ln}} + \frac{d[LnAr]}{dC_{Ln}} + \frac{d[LnAr_2]}{dC_{Ln}} + 2\frac{d[Ln_2Ar_2]}{dC_{Ln}} + \frac{d[LnHPA]}{dC_{Ln}} + \frac{d[LnHPA_2]}{dC_{Ln}},$$

$$0 = \frac{d[HPA]}{dC_{Ln}} + \frac{d[LnHPA]}{dC_{Ln}} + 2\frac{d[LnHPA_2]}{dC_{Ln}},$$

$$\frac{d[LnAr]}{dC_{Ln}} = K_{11}\left([Ln]\frac{d[Ar]}{dC_{Ln}} + [Ar]\frac{d[Ln]}{dC_{Ln}}\right),$$

$$\frac{d[LnAr_2]}{dC_{Ln}} = K_{12}\left(2[Ar][Ln]\frac{d[Ar]}{dC_{Ln}} + [Ar]^2\frac{d[Ln]}{dC_{Ln}}\right),$$

$$\frac{d[Ln_2Ar_2]}{dC_{Ln}} = 2K_{22}\left([Ar][Ln]^2\frac{d[Ar]}{dC_{Ln}} + [Ar]^2[Ln]\frac{d[Ln]}{dC_{Ln}}\right),$$

$$\frac{d[LnHPA]}{dC_{Ln}} = \beta_1\left([Ln]\frac{d[HPA]}{dC_{Ln}} + [HPA]\frac{d[Ln]}{dC_{Ln}}\right),$$

$$\frac{d[LnHPA_2]}{dC_{Ln}} = \beta_2\left(2[HPA][Ln]\frac{d[HPA]}{dC_{Ln}} + [HPA]^2\frac{d[Ln]}{dC_{Ln}}\right).$$

Using the Maclaurin expansion, the already known values are: [Ar], $d[Ar]/dC_{Ln}$, C_{Ar}, C_{Ln}, C_{HPA}, K_{11}, K_{12} and K_{22}. Then, [Ln] and $d[Ln]/dC_{Ln}$ are calculated through the following equalities:

$$[Ln] = \Big\{ -(2K_{12}[Ar] + K_{11}) + \sqrt{(2K_{12}[Ar] + K_{11})^2 - 8K_{22}([Ar] - C_{Ar})} \Big\} \Big/ \{2K_{22}[Ar]\},$$

$$\frac{d[Ln]}{dC_{Ln}} = \Big\{ -(1 + K_{11}[Ln] + 4K_{12}[Ln][Ar] + 4K_{22}[Ln]^2[Ar])\frac{d[Ar]}{dC_{Ln}} \Big\} \Big/ \Big\{K_{11}[Ar] + 2K_{12}[Ar]^2 + 4K_{22}[Ln][Ar]^2\Big\}.$$

Putting o and p to designate the following expressions:

$$o = 2K_{22}[Ar]^2[Ln]^2 + (K_{12}[Ar]^2 + K_{11}[Ar] + 1)[Ln]$$

and

$$p = (1 + K_{11}[Ar] + K_{12}[Ar]^2 + 4K_{22}[Ln][Ar]^2)\frac{d[Ln]}{dC_{Ln}} + (K_{11}[Ln] + 2K_{12}[Ln][Ar] + 4K_{22}[Ln]^2[Ar])\frac{d[Ar]}{dC_{Ln}}$$

the set of equations to solve reads:

$$[HPA] + \beta_1[HPA][Ln] + 2\beta_2[HPA]^2[Ln] = C_{HPA},$$

$$\beta_1[HPA][Ln] + \beta_2[HPA]^2[Ln] + o = C_{Ln},$$

$$(1 + \beta_1[Ln] + 4\beta_2[Ln][HPA])\frac{d[HPA]}{dC_{Ln}} + (\beta_1[HPA] + 2\beta_2[HPA]^2)\frac{d[Ln]}{dC_{Ln}} = 0,$$

$$(\beta_1[\mathrm{ln}] + 2\beta_2[\mathrm{ln}][\mathrm{HPA}])\frac{\mathrm{d}[\mathrm{HPA}]}{\mathrm{d}C_{\mathrm{Ln}}} + (\beta_1[\mathrm{HPA}] + \beta_2[\mathrm{HPA}]^2)\frac{\mathrm{d}[\mathrm{Ln}]}{\mathrm{d}C_{\mathrm{Ln}}} + p = 1.$$

The apparent formation constants gathered in Table 2 ensue.

Abstract

Deprotonation of 2-acetylpyridine with KH in THF afford a potassium enolate compound (**2**) which reacts with $Zr(NEt_2)_2Cl_2(THF)_2$ and $Ti(NMe_2)_2Cl_2$ to yield $[CH_2{=}C(C_5H_4N)O\text{-}\kappa^2N,O]_2M(NR_2)_2$ (M = Zr, R = Et, **3**; M = Ti, R = Me, **4**) in 84% and 76% yield, respectively. Deprotonation of imines derived from 2-acetylpyridine, $(2,6\text{-}Me_2C_6H_3)N{=}C(C_5H_4N)(CH_3)$ (**5**) and $(2,6\text{-}i Pr_2C_6H_3)N{=}C(C_5H_4N)(CH_3)$ (**6**), affords potassium enamides, $K[(2,6\text{-}Me_2C_6H_3)N\text{–}C(C_5H_4N)(=CH_2)]$ (**7**) and $K[(2,6\text{-}iPr_2C_6H_3)N\text{-}(C_5H_4N)(=CH_2)]$ (**8**). Reactions of the potassium salt **7** with $Zr(NEt_2)_2Cl_2(THF)_2$ and $Ti(NMe_2)_2Cl_2$ afford pyridineenamido complexes, $[(2,6\text{-}Me_2C_6H_3)NC(C_5H_4N)(=CH_2)\text{-}\kappa^2N,N]_2M(NR_2)_2$ (M = Zr, R = Et, **9**; M = Ti, R = Me, **10**). Reaction of **8** with $Zr(NEt_2)_2Cl_2(THF)_2$ affords $[(2,6\text{-}iPr_2C_6H_3)NC(C_5H_4N)(=CH_2)]_2Zr(NEt_2)_2$ (**11**) but the reaction of **8** with $Ti(NMe_2)_2Cl_2$ yields $[(2,6\text{-}iPrC_6H_3)NC(C_5H_4N)(=CH_2)]TiCl(NMe_2)_2$ (**12**). Addition of excess $AlMe_3$ to **3** or **4** results in transmetallation of Zr or Ti to Al to afford an aluminum enolate complex, $[CH_2{=}C(C_5H_4N)(OAlMe_3)\text{-}\kappa^2N,O]AlMe_2$ (**13**). Addition of $AlMe_3$ to **12** results in the formation of a transmetallated complex, $[(2,6\text{-}iPr_2C_6H_3)NC(C_5H_4N)(=CH_2)]AlMe_2$ (**14**). The solid structures of **4, 11, 13** and **14** were determined by X-ray crystallography.

Keywords: Enolato; Enamido; Zirconium; Titanium; Aluminum

1. Introduction

A great deal of effort has been devoted in developing single site polymerization catalysts in both academic and industrial fields [1]. Metal complexes beyond metallocenes using various ligand systems including chelating diamido [2] and phenoxy-imine [3–5] have been developed and expansion from group 4 metal complexes to complexes based on the late transition metals [6] has been achieved. Bazan and Lee have described some metal complexes based on carboxylato [7], carboxamido [8] and enamido ligands [9]. The complexes are characteristic since the ligands have an electron-rich atom to which a Lewis acidic cocatalyst can bind to afford zwitterionic active complexes (Eq. (1)). A novel activation reaction was successfully applied to nickel complexes and recently it was expanded to the early transition metal complexes with an enamido ligand [10]. Herein, we report preparation of pyridineenolato and pyridineenamido complexes of titanium, zirconium and aluminum. The complexes have an electron-rich methylene carbon to which a Lewis acidic cocatalyst can bind.

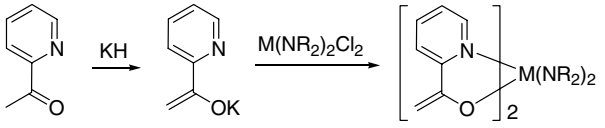
2. Results and discussion

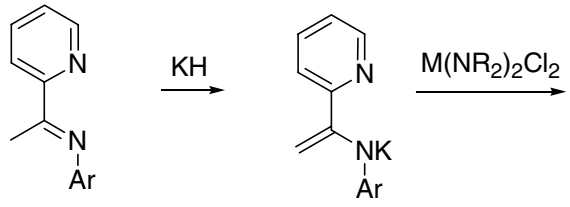
2.1. Synthesis and characterization

Deprotonation of 2-acetylpyridine is successfully conducted by KH in THF (Eq. (2)). Addition of $Zr(NEt_2)_2Cl_2(THF)_2$ and $Ti(NMe_2)_2Cl_2$ to the potassium enolate salt **2** results in clean formation of the desired enolato complexes, $[CH_2{=}C(C_5H_4N)O\text{-}\kappa^2N,O]_2M(NR_2)_2$ (M = Zr, R = Et, **3**; M = Ti, R = Me, **4**) in 84% and 76% yield, respectively (Eq. (2)). The characteristic methylene proton signals are observed at 4.99 and 4.82 ppm for **3** and at 4.99 and 4.78 ppm for **4** as singlets in the ^1H NMR spectra (C_6D_6). The $=CH_2$ carbon signals are observed at 87.63 and 85.48 ppm for **3** and **4,** respectively, in the ^{13}C NMR spectra (C_6D_6). Single crystals of **4** suitable for X-ray crystallography were obtained by recrystallization in toluene and the solid structure was confirmed.

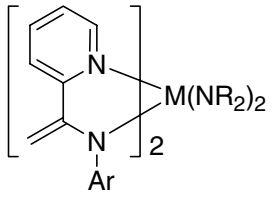


(2)

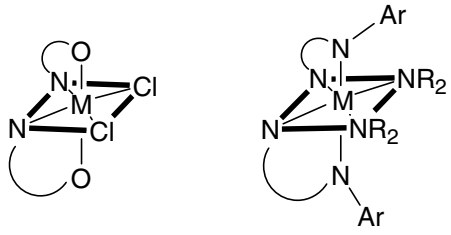
Syntheses of the imine compounds **5** [11] and **6** [12] have been reported. The deprotonation is carried out cleanly by KH in THF (Eq. (3)). The potassium salts are readily soluble in a cosolvent of benzene and THF (v/v, ~5:1) and are characterized by the ^1H and ^{13}C NMR spectra. Reaction of the potassium salts with $Zr(NEt_2)_2Cl_2(THF)_2$ and $Ti(NMe_2)_2Cl_2$ yields the desired pyridineenamido complexes **9**–**11** (Eq. (3)). The complexes were isolated by recrystallization in toluene.



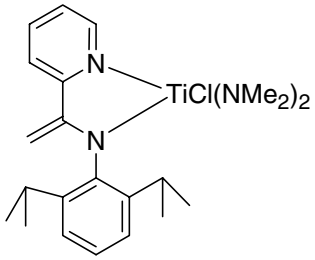
(3)



The enamido ligand is ambiphilic. Either nitrogen or methylene carbon can coordinate to the metal center [9]. Observation of two singlet signals at 4.8–3.7 ppm in the ^1H NMR spectra (C_6D_6) and observation of a signal at 79–89 ppm in the ^{13}C NMR spectra support that the nitrogen coordinates as depicted in Eq. (3). If two pyridineenamido ligands and two dialkylamido ligands coordinate to the metal center to form an octahedral complex, eight stereochemical structures are possible as the case in the phenoxy-imine complexes [4]. In case of the phenoxy-imine complexes, the most stable isomer was calculated to have the structure shown below and actually only the most stable complex was obtained. X-ray crystallographic studies of a single crystal of **11** obtained by recrystallization in toluene reveal that the complex has similar stereochemical structure as observed for the phenoxy-imine complexes, with a *cis*-relationship between the two dialkylamide ligands and a *trans*-relationship between the two amido nitrogen atoms. Since similar signal patterns are observed for **9** and **10** in the ^1H and ^{13}C NMR spectra, we presume they have a similar stereochemical structure as observed for **11**.



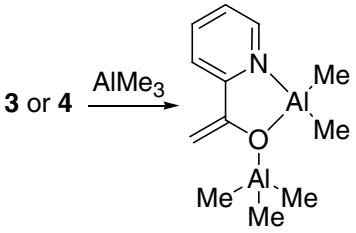
In the case of the reaction of potassium salt **8** with $Ti(NMe_2)_2Cl_2$, the desired complex is not obtained. The major product isolated by recrystallization in toluene can be assigned to the structure **12** by the analysis of the ^1H NMR spectrum. The relative intensity of the dimethylamido methyl signal is twice that observed for **10** and only one broad septet isopropyl CH signal and two doublet isopropyl CH_3 signals are observed. In the ^1H NMR spectrum of **11,** two septet isopropyl CH signals and four doublet isopropyl CH_3 signals are observed.



12

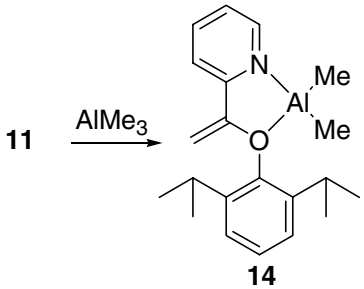
Transformation of the bis(dialkylamido) complex to the dichloro or dialkyl complex is desired because the latter is effectively activated with a common cocatalyst such as MAO or $B(C_6F_5)_3$. When chlorinating reagent,

Me_3SiCl or Me_2SiCl_2, is reacted with **3**–**4** and **9**–**11,** a complex mixture of products is observed in the ^1H NMR spectra. When alkylating reagent, $AlMe_3$ (10 equivalents) is reacted with the enolate complex **3**, aiming to obtain the dimethyl zirconium complex, the ^1H NMR spectrum indicates that a complex is formed cleanly. The complete set of signals for the pyridineenolate ligand is observed in the ^1H NMR spectra but two methyl signals are observed at −0.04 and −0.27 ppm with integration values of 9 and 6. The ^1H and ^{13}C NMR spectra of the reaction product between **4** and $AlMe_3$ are exactly the same as those observed for the reaction product of **3**. Single crystals suitable for X-ray crystallography were obtained by recrystallization in pentane at −30 °C and the molecular structure was determined. The product is an $AlMe_3$-coordinated enolatodimethylaluminum complex (Eq. (4)).



13 (4)

Several sets of signals are observed in the ^1H NMR spectrum when sterically hindered complex **11** is reacted with $AlMe_3$. The main product is deposited from pentane solution at −30 °C as single crystals, which are suitable for X-ray crystallography. The X-ray crystallographic studies of the product reveal that the main product is a transmetallated aluminum complex as shown in Eq. (5).



14 (5)

2.2. X-ray crystallographic studies

The solid structure of **4** and selected bond distances and angles are shown in Fig. 1. It shows a distorted octahedral structure with a *trans*-relationship between the two oxygen atoms and a *cis*-relationship between the two dimethylamido ligands. All atoms in the pyridineenolate ligand and the titanium atom are situated in a plane and hence the dihedral angle of C(8)–C(13)–O(2)–Ti(1), C(11)–C(12)–N(2)–Ti(1) and C(9)–C(8)–C(13)–O(2) are measured to be 1.9°, −179.4° and −179.7°, respectively. The C(6)–C(7) distance (1.335(4) Å) and the C(13)–C(14) distance (1.324(4) Å) are indicative of a double bond between these two atoms. The O(1)–C(6) distance (1.327(4) Å) and the O(2)–C(13) distance (1.336(4) Å) are indicative of a shortened single bond by resonance. The dimethylamido nitrogen atoms are almost trigonal planar (sum of bonding angles, 359.8° and 357.1°) indicating π-electron donation to the titanium metal.

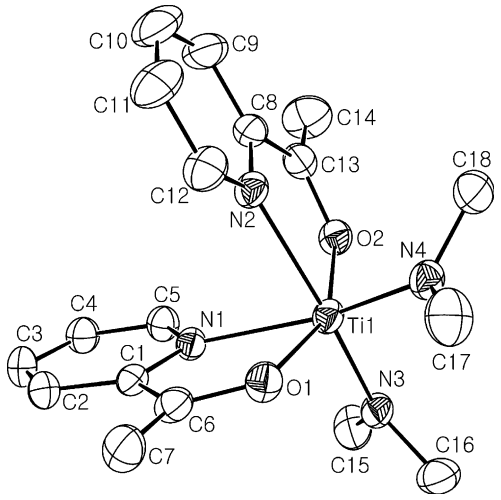


Fig. 1. Thermal ellipsoid plot (30% probability level) of the structure of **4**. Selected bond distances (Å) and angles (°): Ti(1)–O(1), 1.949(2); Ti(1)–O(2), 1.923(2); Ti(1)–N(1), 2.282(2); Ti(1)–N(2), 2.269(2); Ti(1)–N(3), 1.929(2); Ti(1)–N(4), 1.914(3); O(1)–C(6), 1.327(4); O(2)–C(13), 1.336(4); C(6)–C(7), 1.335(4); C(13)–C(14), 1.324(4); O(2)–Ti(1)–O(1), 154.51(9); N(4)–Ti(1)–N(1), 159.75(10); N(3)–Ti(1)–N(2), 164.92(10); C(6)–O(1)–Ti(1), 126.10(18); C(13)–O(2)–Ti(1), 126.12(19).

The solid structure of **11** and selected bond distances and angles are shown in Fig. 2. It also shows a distorted octahedral structure. The two amido nitrogen atoms are in a *trans*-relationship and the two dimethylamido ligands are situated in a *cis*-relationship. The Zr–N distances are in the order of Zr–NEt_2 (2.078(3) and 2.058(3) Å) <Zr–N(amido) (2.278(3) and 2.279(2) Å) <Zr–N(pyridine) (2.420(3) and 2.429(3) Å). A ring, (Zr(1)–N(3)–C(20)–C(25)–N(4)), formed by chelation is coplanar (dihedral angles of N(3)–C(20)–C(25)–N(4) and C(20)–C(25)–N(4)–Zr(1) are 1.6° and −0.3°, respectively) while the other ring (Zr(1)–N(1)–C(1)–C(6)–N(2)) is slightly out of coplanarity (dihedral angles of N(1)–C(1)–C(6)–N(2) and C(1)–C(6)–N(2)–Zr(1) are 11.3° and −19.1°, respectively). The aryl rings are almost perpendicular to the plane formed by chelation (dihedral angles of C(6)–N(2)–C(8)–C(9) and C(25)–N(4)–C(27)–C(28) are −76.4° and 78.5°, respectively). The C(6)–C(7) distance (1.366(5) Å) and the C(25)–C(26) distance (1.347(4) Å) are indicative of a double bond although they are slightly longer than the corresponding distances observed for the enolate complex **4**. All the diethylamido nitrogens and amido nitrogens show trigonal planar

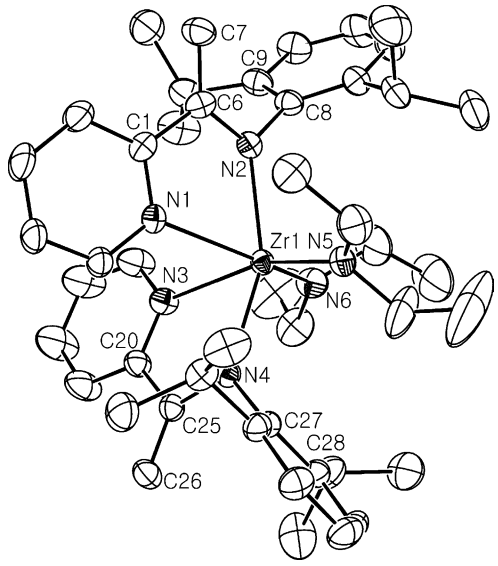

Fig. 2. Thermal ellipsoid plot (30% probability level) of the structure of **11**. Selected bond distances (Å) and angles (°): Zr(1)–N(1), 2.420(3); Zr(1)–N(2), 2.278(3); Zr(1)–N(3), 2.429(3); Zr(1)–N(4), 2.279(2); Zr(1)–N(5), 2.078(3); Zr(1)–N(6), 2.058(3); N(2)–C(6), 1.390(4); N(4)–C(25), 1.391(4); C(6)–C(7), 1.366(5); C(25)–C(26), 1.347(4); N(2)–Zr(1)–N(4), 155.95(9); N(6)–Zr(1)–N(1), 147.50(12); N(5)–Zr(1)–N(3), 158.64(10); C(25)–N(4)–Zr(1), 123.20(19); C(6)–N(2)–Zr(1), 120.5(2).

structure and hence the sum of bonding angles around N(2), N(4), N(5) and N(6) are calculated to be 359.9°, 359.6°, 359.7° and 359.9°, respectively.

The solid structure of **13** and selected bond distances and angles are shown in Fig. 3. Two aluminum atoms show a distorted tetrahedral structure. All the atoms on the pyridineenamide ligand and the two aluminum atoms are almost situated in a plane (dihedral angles of C(4)–C(5)–N(1)–Al(1) and C(5)–N(1)–Al(1)–Al(2) are −178.2° and 177.7°, respectively). The oxygen atom

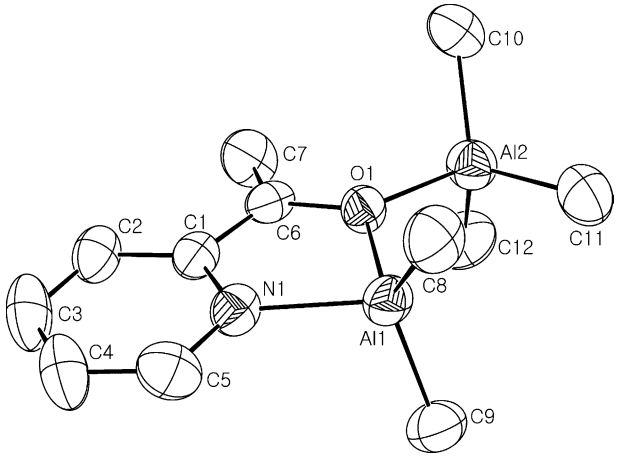

Fig. 3. Thermal ellipsoid plot (30% probability level) of the structure of **13**. Selected bond distances (Å) and angles (°): Al(1)–O(1), 1.847(6); Al(1)–N(1), 1.980(8); Al(1)–C(8), 1.941(9); Al(1)–C(9), 1.929(9); Al(2)–O(1), 1.934(6); Al(2)–C(10), 1.951(10); Al(2)–C(11), 1.962(11); Al(2)–C(12), 1.972(11); O(1)–C(6), 1.390(10); C(6)–C(7), 1.306(11); C(6)–O(1)–Al(1), 117.0(6); C(6)–O(1)–Al(2), 124.1(6); Al(1)–O(1)–Al(2), 116.9(3).

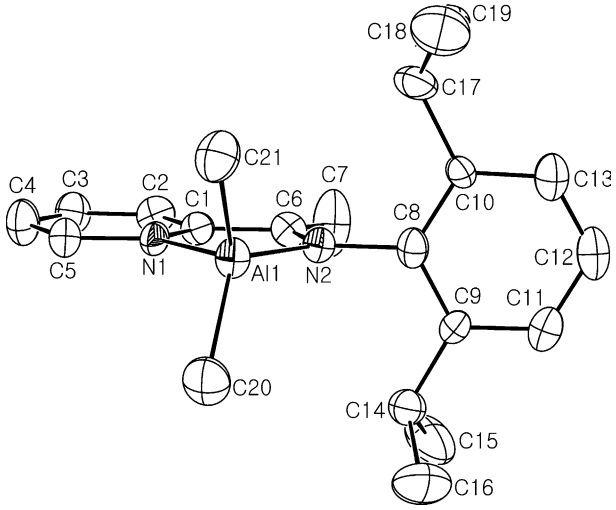

Fig. 4. Thermal ellipsoid plot (30% probability level) of the structure of **14**.

shows almost a trigonal planar structure (sum of bonding angle, 358.0°). The Al(1)–O(1) distance (1.847(6) Å) is shorter than the Al(2)–O(1) distance (1.934(6) Å) and the Al(1)–C distances (1.941(9) and 1.929(9) Å) are shorter as well than the Al(2)–C distances (1.951(10), 1.962(11) and 1.972(11) Å).

The solid structure of **14** is shown in Fig. 4. The final R indices for the refinement are too high ($R_1 = 0.1573$, $wR_2 = 0.3676$) to do quantitative analysis for the bond distances and angles, but it can be seen that Al(1), C(6), N(2) and all the atoms in the pyridine ring are coplanar and the 2,6-diisopropyl benzene ring is perpendicular to the plane.

3. Experimental

3.1. General considerations

All manipulations were performed under an inert atmosphere using standard glove box and Schlenk techniques. Toluene, pentane, THF and C_6D_6 were distilled from benzophenone ketyl. $Zr(NEt_2)_2Cl_2(THF)_2$ [13] and $Ti(NMe_2)_2Cl_2$ [14] were prepared according to the literature method. ^1H NMR (400 MHz) and ^{13}C NMR (100 MHz) spectra were recorded on a Varian Mercury plus 400. Elemental analyses were carried out on a Perkin–Elmer 2400 CHN microanalyzer.

3.2. Synthesis of $CH_2{=}C(C_5H_4N)OK$ (**2**)

2-Acetylpyridine (1.00 g, 8.25 mmol) and KH (0.331 g, 8.25 mmol) were weighed in a flask and cold THF (10 ml, −30 °C) was added. The solution was stirred for 4 h at room temperature. The precipitated solid was filtered and washed with THF to give a white solid (1.13 g, 86%). The solid was not soluble in pyridine, benzene or THF.

3.3. Synthesis of $[CH_2{=}C(C_5H_4N)O\text{-}\kappa^2N,O]_2Zr(NEt_2)_2$ (**3**)

$ZrCl_2(NEt_2)_2(THF)_2$ (1.41 g, 3.14 mmol) was dissolved in THF (20 ml) and solid **2** (1.00 g, 6.28 mmol) was added in one portion at room temperature. The solution was stirred overnight. Solvent was removed by vacuum. The product was extracted with toluene (15 ml × 2) and the toluene was removed by vacuum to give a yellow solid (1.25 g, 84%) which was analytically pure. ^{1}H NMR (C_6D_6): δ 8.51 (dt, $J = 5.6$, 1.2 Hz, 1H, py-H^6), 7.01 (d, $J = 8.0$ Hz, 1H, py-H^3), 6.60 (ddd, $J = 8.0$, 7.2, 1.2 Hz, 1H, py-H^4), 6.29 (ddd, $J = 7.2$, 5.6, 1.2 Hz, 1H, py-H^5), 4.99 (s, 1H, =CH$_2$), 4.82 (s, 1H, =CH$_2$), 3.73 (q, $J = 6.8$ Hz, 4H, C*H*$_2$CH$_3$), 1.21 (t, $J = 6.8$ Hz, 6H, CH$_2$C*H*$_3$) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 162.31, 157.90, 146.68, 137.33, 122.37, 119.86, 87.63 (=*C*H$_2$), 44.54 (*C*H$_2$CH$_3$), 16.11 (CH$_2$*C*H$_3$) ppm. *Anal.* Calc. ($C_{22}H_{32}N_4O_2Zr$): C, 55.54; H, 6.78; N, 11.78. Found: C, 55.72; H, 6.53; N, 11.38%.

3.4. Synthesis of $[CH_2{=}C(C_5H_4N)O\text{-}\kappa^2N,O]_2Ti(NMe_2)_2$ (**4**)

The complex was synthesized using the same procedure and conditions as for **3,** but with $TiCl_2(NMe_2)_2$ (0.500 g, 2.42 mmol) and the potassium salt **2** (0.770 g, 4.84 mmol). The analytically pure red solid was isolated by extraction with toluene (0.690 g, 76%). Single crystals suitable for X-ray crystallography were obtained by recrystallization in toluene at −30 °C. ^{1}H NMR (C_6D_6): δ 8.57 (dt, $J = 5.6$, 1.2 Hz, 1H, py-H^6), 7.01 (dd, $J = 6.8$, 1.2 Hz, 1H, py-H^3), 6.64 (ddd, $J = 8.8$, 6.8, 1.2 Hz, 1H, py-H^4), 6.34 (ddd, $J = 7.2$, 5.6, 1.2 Hz, 1H, py-H^5), 4.99 (s, 1H, =CH$_2$), 4.78 (s, 1H, =CH$_2$), 3.57 (s, 6 H, CH$_3$) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 163.88, 157.12, 146.39, 136.99, 122.34, 119.47, 85.48 (=CH$_2$), 48.20 (CH$_3$) ppm. *Anal.* Calc. ($C_{18}H_{24}N_4O_2Ti$): C, 57.46; H, 6.43; N, 14.89. Found: C, 57.03; H, 6.73; N, 14.59%.

3.5. Synthesis of $K[(2,6\text{-}Me_2C_6H_3)N\text{–}C(C_5H_4N)(=CH_2)]$ (**7**)

A solution of **5** (1.20 g, 5.35 mmol) in THF (20 ml) was added to a slurry of KH (0.429 g, 1.07 mmol) in THF (5.0 ml) and the resulting mixture was stirred for one day at room temperature. The dark brown solution was filtered and solvent was removed under vacuum. The residue was triturated in pentane to give a greenish yellow solid. The yield was 1.15 g (82%). ^{1}H NMR (C_6D_6:THF-d_8, 5:1): δ 7.95 (d, $J = 8.0$ Hz, 1H, py-H^6), 7.44 (d, $J = 5.2$ Hz, 1H, py-H^3), 7.24 (d, $J = 7.2$ Hz, 2H, ph-H$^{3\text{ and }5}$), 7.13 (td, $J = 8.0$, 1.6 Hz, 1H, py-H^5), 6.95 (t, $J = 7.2$ Hz, 1H, ph-H^4), 6.62 (dd, $J = 7.2$, 5.2 Hz, 1H, py-H^4), 4.11 (s, 1H, =CH$_2$), 3.29 (s, 1H, =CH$_2$), 2.30 (s, 6H, CH$_3$) ppm. ^{13}C{^{1}H}NMR (C_6D_6:THF-d_8, 5:1) δ 169.57, 158.59, 154.57, 148.16, 135.32, 131.75, 128.65, 121.93, 120.77, 118.79, 69.40 (=CH$_2$), 19.21 (CH$_3$) ppm.

3.6. Synthesis of $K[(2,6\text{-}iPr_2C_6H_3)N(C_5H_4N)(=CH_2)]$ (**8**)

This salt was synthesized using the same procedure and conditions for **7,** but with **6** (1.61 g, 5.74 mmol) and KH (0.461 g, 11.5 mmol). The mixture was stirred for two days. The yield was 1.61 g (88%). ^{1}H NMR (C_6D_6:THF-d_8, 5:1): δ 7.99 (d, $J = 8.0$ Hz, 1H, py-H^6), 7.70 (d, $J = 5.2$ Hz, 1H, py-H^3), 7.33 (d, $J = 7.2$ Hz, 2H, ph-H$^{3\text{ and }5}$), 7.20 (t, $J = 7.2$ Hz, 1H, ph-H^4), 7.12 (td, $J = 8.0$, 1.6 Hz, 1H, py-H^5), 6.64 (td, $J = 8.0$, 1.2 Hz, 1H, py-H^4), 4.15 (s, 1H, =CH$_2$), 3.52 (septet, $J = 7.2$ Hz, 2H, C*H*(CH$_3$)$_2$), 3.26 (s, 1H, =CH$_2$), 1.51 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$), 1.16 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$) ppm. ^{13}C{^{1}H}NMR (C_6D_6:THF-d_8, 5:1) δ 164.24, 157.92, 155.83, 147.85, 142.87, 135.49, 123.54, 122.45, 120.84, 119.90, 71.60 (=CH$_2$), 27.81 (CH(*C*H$_3$)$_2$), 26.75 (CH(*C*H$_3$)$_2$), 26.02 (*C*H(CH$_3$)$_2$) ppm.

3.7. Synthesis of $[(2,6\text{-}Me_2C_6H_3)NC(C_5H_4N)(=CH_2)\text{-}\kappa^2N,N]_2Zr(NEt_2)_2$ (**9**)

$ZrCl_2(NEt_2)_2(THF)_2$ (0.523 g, 1.16 mmol) and potassium salt **7** (0.609 g, 2.32 mmol) were weighed in a flask and THF (30 ml) was added. The resulting solution was stirred for two days. Solvent was removed under vacuum to give a black residue which was dissolved in toluene (40 ml). The solution was filtered and solvent was reduced to ~10 ml, at which point yellow solids precipitated. The deposited solid was collected by filtration (0.486 g, 61%). ^{1}H NMR (C_6D_6): δ 8.80 (br d, $J = 4.8$ Hz, 1H, py-H^6), 7.41 (d, $J = 8.4$ Hz, 1H, py-H^3), 7.20 (d, $J = 7.2$ Hz, 1H, ph-H$^{3\text{ or }5}$), 7.14 (d, $J = 7.2$ Hz, 1H, ph-H$^{3\text{ or }5}$), 7.03 (t, $J = 7.2$ Hz, 1H, ph-H^4), 6.71 (br t, $J = 7.2$ Hz, 1H, py-H^5), 6.23 (br t, $J = 6.0$ Hz, 1H, py-H^4), 4.60 (s, 1H, =CH$_2$), 3.89 (s, 1H, =CH$_2$), 3.22 (dq, $J = 14$, 7.2 Hz, 2H, NC*H*$_2$CH$_3$), 2.75 (dq, $J = 14$, 7.2 Hz, 2H, NC*H*$_2$CH$_3$), 2.64 (s, 3H, CH$_3$), 2.51 (s, 3H, CH$_3$), 0.71 (t, $J = 7.2$ Hz, 6H, CH$_2$C*H*$_3$). ^{13}C{^{1}H}NMR (C_6D_6) δ 158.77, 153.27, 151.58, 147.79, 137.10, 136.59, 134.97, 129.32, 128.80, 124.06, 121.19, 120.98, 83.30 (=*C*H$_2$), 42.07 (CH$_2$*C*H$_3$), 22.36 (CH$_3$), 20.46 (CH$_3$), 13.36 (*C*H$_2$CH$_3$) ppm. *Anal.* Calc. ($C_{38}H_{50}N_6Zr$): C, 66.92; H, 7.39; N, 12.32. Found: C, 67.23; H, 7.45; N, 12.11%.

3.8. Synthesis of $[(2,6\text{-}Me_2C_6H_3)NC(C_5H_4N)(=CH_2)\text{-}\kappa^2N,N]_2Ti(NMe_2)_2$ (**10**)

The complex was synthesized using the same procedure and conditions for **9,** but with $TiCl_2(NMe_2)_2$ (0.174 g, 0.840 mmol) and the potassium salt **7** (0.440 g,

1.68 mmol). The solution was stirred for two days at 50 °C. The complex was purified by recrystallization in toluene at −30 °C. The yield was 0.140 g (29%). ^{1}H NMR (C_6D_6): δ 8.70 (d, $J = 4.8$ Hz, 1H, py-H^6), 7.48 (d, $J = 8.4$ Hz, 1H, py-H^3), 7.23 (d, $J = 7.6$ Hz, 1H, ph-H$^{3\text{ or }5}$), 7.15 (d, $J = 7.6$ Hz, 1H, ph-H$^{3\text{ or }5}$), 7.04 (t, $J = 7.2$ Hz, 1H, ph-H^4), 6.74 (td, $J = 7.6$, 2.0 Hz, 1H, py-H^5), 6.21 (td, $J = 6.4$, 0.8 Hz, 1H, py-H^4), 4.50 (s, 1H, =CH_2), 3.89 (s, 1H, =CH_2), 2.63 (s, 6H, CH_3), 2.45 (s, 3H, CH_3). ^{13}C{^{1}H}NMR (C_6D_6) δ 158.09, 153.88, 153.69, 147.67, 136.45, 135.68, 134.51, 129.56, 129.02, 123.73, 121.13, 120.83, 78.95 (=CH_2), 48.13 (NCH_3), 23.21 (CH_3), 20.13 (CH_3) ppm. *Anal.* Calc. ($C_{34}H_{42}N_6Ti$): C, 70.09; H, 7.27; N, 14.42. Found: C, 69.71; H, 7.52; N, 14.11%.

3.9. Synthesis of [(2,6-iPr$_2$C$_6$H$_3$)NC(C$_5$H$_4$N)(=CH$_2$)]$_2$Zr(NEt$_2$)$_2$ (11)

The complex was synthesized using the same procedure and conditions for **9,** but with $ZrCl_2(NEt_2)_2(THF)_2$ (0.707 g, 1.57 mmol) and the potassium salt **8** (1.00 g, 3.14 mmol). The solution was stirred for one day at room temperature. The crystals, which were analytically pure and suitable for X-ray crystallography, were obtained by recrystallization in toluene at −30 °C. The yield was 0.742 g (60%). ^{1}H NMR (C_6D_6): δ 8.70 (d, $J = 5.6$ Hz, 1H, py-H^6), 7.50–7.24 (m, 4H), 6.76 (td, $J = 7.2$, 1.2 Hz, 1H, py-H^5), 6.44 (t, $J = 6.4$ Hz, 1H, py-H^4), 4.79 (s, 1H, =CH_2), 4.11 (septet, $J = 6.8$ Hz, 2H, C*H*(CH_3)$_2$), 3.78 (s, 1H, =CH_2), 3.43 (septet, $J = 6.8$ Hz, 2H, C*H*(CH_3)$_2$), 3.33 (dq, $J = 14$, 6.8 Hz, 2H, NCH_2), 2.77 (dq, $J = 14$, 6.8 Hz, 2H, NCH_2), 1.50 (d, $J = 6.8$ Hz, 3H, CH(C*H*$_3$)$_2$), 1.48 (d, $J = 6.8$ Hz, 3H, CH(C*H*$_3$)$_2$), 1.44 (d, $J = 6.8$ Hz, 3H, CH(C*H*$_3$)$_2$), 1.34 (d, $J = 6.8$ Hz, 3H, CH(C*H*$_3$)$_2$), 0.70 (t, $J = 7.2$ Hz, 6H, NCH_2CH_3) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 159.15, 156.34, 151.30, 147.61, 146.28, 144.65, 137.20, 124.96, 124.70, 124.19, 121.01, 120.85, 89.13 (=CH_2), 43.42 (NCH_2), 29.03, 28.00, 27.79, 27.43, 25.76, 24.65, 14.15 (NCH_2CH_3) ppm. *Anal.* Calc. ($C_{46}H_{66}N_6Zr$): C, 69.56; H, 8.38; N, 10.58. Found: C, 69.43; H, 8.42; N, 10.21%.

3.10. Synthesis of [(2,6-iPr$_2$C$_6$H$_3$)NC(C$_5$H$_4$N)(=CH$_2$)]TiCl(NMe$_2$)$_2$ (12)

The complex was synthesized using the same procedure and conditions for **9,** but with $TiCl_2(NMe_2)_2$ (0.325 g, 1.57 mmol) and the potassium salt **8** (1.00 g, 3.14 mmol). The solution was stirred for one day at room temperature. The single crystals, which were analytically pure, were obtained by recrystallization in toluene at −30 °C. The yield was 0.445 g (63%). ^{1}H NMR (C_6D_6): δ 8.52 (d, $J = 5.2$ Hz, 1H, py-H^6), 7.28–7.10 (m, 4H), 6.87 (td, $J = 7.2$, 0.8 Hz, 1H, py-H^5), 6.49 (t, $J = 6.0$ Hz, 1H, py-H^4), 4.56 (s, 1H, =CH_2), 3.75 (s, 1H, =CH_2), 3.29 (br septet, $J = 6.8$ Hz, 2H, C*H*(CH_3)$_2$), 3.01 (s, 12H, NCH_3), 1.26 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$), 1.25 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 156.52, 155.44, 149.01, 147.40, 142.84, 137.12, 125.56, 123.64, 122.55, 119.61, 87.96 (=CH_2), 47.2 (br NCH_3), 28.86 (*C*H(CH_3)$_2$), 27.20 (CH(*C*H$_3$)$_2$), 24.18 (CH(*C*H$_3$)$_2$) ppm. *Anal.* Calc. ($C_{23}H_{35}N_4ClTi$): C, 61.27; H, 7.84; N, 12.43. Found: C, 60.88; H, 7.89; N, 12.33%.

3.11. Synthesis of [CH$_2$=C(C$_5$H$_4$N)(OAlMe$_3$)-κ^2N,O]AlMe$_2$ (13)

Complex **3** (0.100 g, 0.210 mmol) was dissolved in benzene (3.0 ml) and $AlMe_3$ (0.15 g, 2.10 mmol) was added. The solution was stirred at room temperature overnight. All volatiles were completely removed under high vacuum at room temperature. Pentane was added and the solution was filtered over celite. White crystals were deposited when the solution was stored at −30 °C. The yield was 45 mg (43%). ^{1}H NMR (C_6D_6): δ 7.17 (d, $J = 6.8$ Hz, 1H, py-H^6), 6.72 (td, $J = 6.8$, 0.8 Hz, 1H, py-H^4), 6.62 (d, $J = 8.8$ Hz, 1H, py-H^3), 6.31 (t, $J = 6.4$ Hz, 1H, py-H^5), 5.56 (d, $J = 3.6$ Hz, 1H, =CH_2), 4.86 (d, $J = 3.6$ Hz, 1H, =CH_2), −0.04 (s, 9H, $AlCH_3$), −0.27 (s, 6H, $AlCH_3$) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 151.54, 150.37, 142.53, 140.59, 124.40, 120.30, 97.94 (=*C*H$_2$), −6.20 (br, AlC), −7.87 (br, AlC) ppm. *Anal.* Calc. ($C_{12}H_{21}NOAl_2$): C, 57.82; H, 8.51; N, 5.62. Found: C, 57.55; H, 8.15; N, 5.33%.

3.12. Synthesis of [(2,6-iPr$_2$C$_6$H$_3$)NC(C$_5$H$_4$N)(=CH$_2$)]AlMe$_2$ (14)

The complex was synthesized using the same procedure and conditions for **13,** but with **11** (0.100 g, 0.126 mmol) and $AlMe_3$ (0.024 ml, 0.252 mmol) in benzene (1.0 ml). The solvent was removed by vacuum and the residue was extracted with pentane. Light yellow single crystals were deposited when the pentane solution was stored at −30 °C overnight (20 mg, 24%).

^{1}H NMR (C_6D_6): δ 7.46 (d, $J = 5.6$ Hz, 1H, py-H^6), 7.19 (t, $J = 8.4$ Hz, 1H, py-H^3), 6.70 (ddd, $J = 8.0$, 7.2, 1.2 Hz, 1H, py-H^5), 6.26 (ddd, $J = 7.2$, 5.2, 1.2 Hz, 1H, py-H^4), 4.55 (d, $J = 1.2$ Hz, 1H, =CH_2), 3.86 (d, $J = 1.2$ Hz, 1H, =CH_2), 3.58 (septet, $J = 7.2$ Hz, 2H, C*H*(CH_3)$_2$), 1.39 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$), 1.36 (d, $J = 7.2$ Hz, 6H, CH(C*H*$_3$)$_2$), −0.28 (s, 8H, $AlCH_3$) ppm. ^{13}C{^{1}H}NMR (C_6D_6) δ 156.28, 150.26, 147.22, 142.68, 139.13, 126.24, 124.48, 122.90, 120.87, 84.26 (=*C*H$_2$), 28.35, 26.41, 25.21, −8.49 (AlC) ppm. *Anal.* Calc. ($C_{21}H_{29}N_2Al$): C, 74.96; H, 8.71; N, 8.33. Found: C, 74.62; H, 8.52; N, 8.45%.

[a] Data collected at 293(2) K with Mo Kα radiation (λ (Kα) = 0.7107), $R(F) = \sum ||F_o| - |F_c|| / \sum |F_o|$ with $F_o > 2.0\sigma(I)$, $R_w = [\sum[w(F_o^2 - F_c^2)^2] / \sum[w(F_o^2)^2]]^{1/2}$ with $F_o > 2.0\sigma(I)$.

3.13. Crystallographic studies

Crystals of **4, 11, 13** and **14** coated with grease (Apiezon N) were mounted inside a thin glass tube with epoxy glue and placed on an Enraf-Nonius CCD single crystal X-ray diffractometer. The structures were solved by direct methods (SHELXS-97) [15] and refined against all F^2 data (SHELXS-97). All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were treated as idealized contributions. The crystal data and refinement results are summarized in Table 1.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Center (**4**: CCDC no. 230878; **8**: CCDC no. 230879; **13**: CCDC no. 230880; **14**: CCDC no. 230881). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033: e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A number of oxomolybdenum (VI) and (IV) complexes with potentially tridentate ONS donor Schiff bases of S-benzyl and S-methyl dithiocarbazates with salicylaldehyde have been synthesized. The Mo(VI) complexes are *cis*-dioxo, MoO_2L (where L = H_2L^1 and H_2L^2) with one coordination site available for substrate binding. The Mo(IV) complexes, MoOL, are derived from the corresponding Mo(VI)-dioxo complexes by oxo abstraction with PPh_3. The complexes were characterized by elemental analysis, UV, IR and ^1H NMR spectroscopy, magnetic susceptibility measurement, molar conductivities in solution and by cyclic voltammetry. Two of the complexes MoO_2L^1 and MoO_2L^2 were crystallographically characterized. The structures reveal that the molybdenum acceptor center is present in a distorted octahedral NO_4S donor environment.

1. Introduction

Chemistry of higher valent molybdenum ligated to mixed hard–soft nitrogen–sulfur donor ligands is a field of current interest. Interest of inorganic and bioinorganic chemists increased manifold with the revelation that some oxido-reductases, hydrogenase, xanthine oxidase, DMSO reductase and other oxo-transferases containing Mo(VI) and Mo(IV) as their prosthetic groups are ligated to a multidentate ligand framework through NS/NSO donor points [1–4]. Also sulfur donor centers in a mixed hard–soft ligand system are known to stabilize uncommon oxidation states to generate less familiar coordination numbers and to participate in diverse types of chemical and electrochemical reactions [5–13].

Several oxomolybdenum (VI), (V) and (IV) complexes with various bi-, tri- and tetradentate NS, SS and ONS donor systems have been reported [14–22] to simulate many characteristic properties of the active sites of molybdoenzymes. However, a survey of the relevant literature has failed to locate any study on oxomolybdenum complexes of Schiff bases derived by the condensation of salicylaldehyde with S-benzyl and S-methyl dithiocarbazates, acting as diacidic tridentate ONS donor ligands.

Our main aim is to study the chemistry of oxometal cations bonded to mixed hard–soft NS donors in general and modeling of the active sites of molybdoenzymes in particular. It is to be noted that our work is one of the few instances of the use of substituted thiocarbazate ligands in the modeling of the molybdenum binding site of the molybdenum cofactors. We report here a set of Mo(VI)-dioxo and Mo(IV)-oxo complexes of the above ligands. Such tridentate chelating ligands form complexes like MoO_2L or MoOL, possessing one or two "open" coordination sites that can be utilized for substrate binding. In this work we report on the synthesis of Mo(VI) complexes of the type MoO_2L and $MoO_2L \cdot B$ (where B is a neutral monodentate Lewis base) and also of Mo(IV) complexes of the type MoOL and MoOL(N–N) (where N–N is a neutral bidentate donor like bipy or *o*-phen). Oxo abstraction from Mo(VI)-dioxo complexes with the help of PPh_3 has been successfully carried out to generate the corresponding Mo(IV) species. All the complexes have been characterized by elemental analysis, magnetic susceptibility measurement in the solid state, molar conductivity in solution and various spectroscopic (NMR, IR, UV–Vis) methods. Electrochemical characteristics of the complexes were examined by cyclic voltammetry at a platinum disc electrode in DMF solution with TEAP as supporting electrolyte. All the complexes are found to be diamagnetic and non-electrolytic in nature. Crystal and molecular structures of two complexes MoO_2L^1 and $MoO_2L^2 \cdot H_2O$ have been determined by the single crystal X-ray diffraction technique.

2. Results and discussion

2.1. Synthesis and characterization of the ligand

The Schiff base ligands (H_2L^1 and H_2L^2) were prepared by condensing S-benzyl and S-methyl dithiocarbazates [23] with salicylaldehyde in ethanol. The ligands have been satisfactorily characterized by elemental analysis (Table 1), IR and ^1H NMR data.

2.2. Synthesis and characterization of molybdenum (VI) and (IV) complexes

Dioxo molybdenum (VI) complexes (**1a** and **1b**) of formula MoO_2L^1 and $MoO_2L^2 \cdot H_2O$ were prepared [7a] by refluxing $MoO_2(acac)_2$ with the appropriate ligand in 1:1 molar proportion using methanol as solvent. The Mo(VI) complexes (**1c**–**1j**) of general formula MoO_2LB (where B = γ-picoline, imidazole, thiophene and THF) were also prepared by refluxing **1a** and **1b** with the corresponding neutral monodentate Lewis base in methanol medium. The base B is coordinated in the sixth coordination position. All the compounds are orange-red crystalline solids. Oxomolybdenum (IV) complexes (**2a** and **2b**) of general formula MoOL, dark brown solids, and the complexes (**2c**–**2f**) of general formula MoOL(bipy/*o*-phen), dark green solids, were prepared by oxo-abstraction reaction of **1a** and **1b** with PPh_3in the presence of bipy/*o*-phen in CH_2Cl_2 medium, respectively. All the compounds are air-stable, insoluble in water and are diamagnetic in nature [24]. All of them are readily soluble in polar solvents like CH_2Cl_2,

Table 2
Cyclic voltammetric peak potential data (V vs. SCE) in DMF solution at 298 K

Compound	Cathodic peak potential		Anodic peak potential E_A (in V)
	E_{C_I} (in V)	$E_{C_{II}}$ (in V)	
MoO_2L^1	−0.20	−1.01	
$MoO_2L^2 \cdot H_2O$	−0.16	−1.13	
$MoOL^1$		−0.99	+0.48
$MoOL^2$		−1.02	+0.45

Solvent: DMF (dry,d egassed); supporting electrolyte: 0.1 M TEAP; solution strength 10^{-3} M; electrode: platinum; reference electrode: SCE; scan rate: 200 mV s^{-1}.

CH_3CN and DMF, etc. Molar conductivity data in 10^{-3}(M) CH_2Cl_2 solution indicate that they are non-electrolytes. Electronic spectra of all the complexes were recorded in CH_2Cl_2 and cyclic-voltammograms of some representative compounds were recorded in DMF (Table 2).

2.3. Crystal structure of the complexes *1a* and *1b*

The molecular structure and atom-numbering schemes of the complexes **1a** and **1b** are shown in Figs. 1–3. Experimental details are given in Table 3 and selected bond lengths and bond angles are in Tables 4 and 5. In both complexes **1a** and **1b** the ligands H_2L^1 and H_2L^2 behave in a dianionic tridentate manner, the donor points O(3), N (1), S (1) occupying a meridonial plane [25,26] and N(1) is situated *trans* to the oxo-oxygen O(1). As the structures of the two complexes are quite similar, that of complex **1a** is discussed in detail and the points of differences are pointed out at the end. Along with the two oxo-oxygens, O(1) and O(2), the three ONS donor points of the ligand complete the five coordinate environment around the Mo(VI) acceptor center in complex **1a**, the disposition of the donor points being roughly square pyramidal. The sixth coordination site, *trans* to the oxo-oxygen O(2), is occupied by an oxo-oxygen O(2A) of the next neighboring complex molecule and this pattern is repeated leading to a chain of MoO_2L molecules (Fig. 2). The dianionic tridentate ligand is found to form 1 five-membered and 1 six-membered metallocycle involving the MoO_2^{2+}core, the bite angles N(1)MoS(1) and N(1)MoO(3) being 76.2(3)° and 84.9(4)°, respectively.

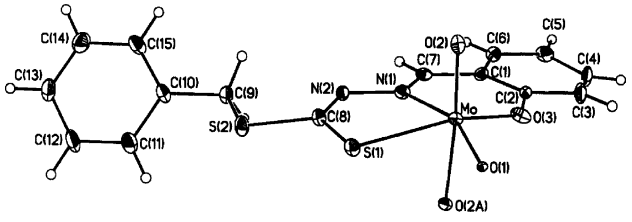

Fig. 1. ORTEP plot of complex **1a** [MoO_2L^1].

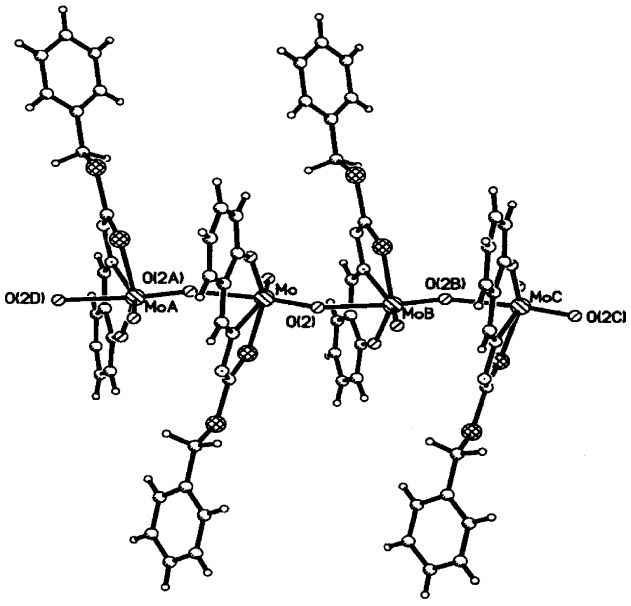

Fig. 2. Stacking diagram of complex **1a**.

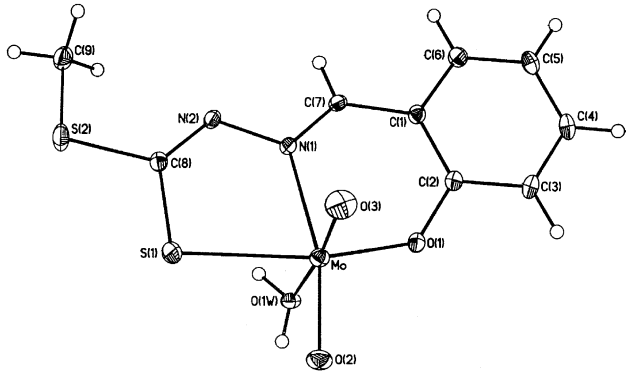

Fig. 3. ORTEP plot of complex **1b** [MoO_2L^2, H_2O].

The overall coordination geometry around the Mo(VI) acceptor can be described as distorted octahedral. The Schiff-base ligand is bonded to the MoO_2^{2+} core in a planar fashion involving the *xy*-plane through the phenolate oxygen O(3), the thioenolate sulfur S(1) and the imine nitrogen N(1), the oxo group O(1) lying *trans* to N(1). The oxo-oxygen O(2) is found to occupy one apical position while other apex is occupied by an oxo-oxygen O(2A) of the nearest neighbor complex molecule, the O(2)–Mo–O(2A) angle being 169.46(16)°. This may be visualized as an effect of stacking of the complex molecules along the *z*-axis. The length of the Mo–O(2A) bond (2.32 Å) is considerably longer than the other Mo–O bonds, the longest of which [Mo–O(3)] is 1.956(10) Å. This is indicative of weaker coordination by the oxo-oxygen O(2A) and suggests that this is expected to be the point of maximum reactivity of the complex. This structural feature points to a reactivity pattern in which this Mo–O(2A) bond can be broken on

treatment with a monodentate heterocyclic Lewis base which will coordinate at this point. This expectation is realized in the facile formation of the complexes $MoO_2L \cdot B$, where B is a neutral monodentate Lewis base like imidazole, picoline, THF, thiophene, etc.

The O(2)=Mo=O(1) bond angle of 106.0(4)° and the Mo=O bond lengths Mo=O(1) = 1.659(7), Mo=O(2) = 1.721(10) Å are unexceptional [27–30]. The imine nitrogen N(1) is *trans* to the oxo-oxygen O(1) and the Mo–N(1) bond length of 2.260(10) Å is rather long due to *trans* effect. The C(8)–N(2) length [1.311(16) Å] is close to usual C=N bond length [31,32]. The Mo–S distance of 2.438(4) Å is very near to the values observed in the case of similar molybdenum complexes [26,33,34].

Careful analysis of the bond length and bond angles data leads to the overall conclusion that complex **1a** has a highly distorted octahedral coordination around the Mo(VI) acceptor center with the Mo center slightly displaced from the median square plane described by N(1), O(3), O(1), S(1) towards the apical oxo-oxygen O(2). The sixth position in the coordination octahedron of the Mo(VI) center is taken up by one of the oxo-oxygen O(2A) of the immediate neighbor complex **1a** and a type of chain is formed by the stacking of the complex **1a** molecules along the z-axis. The unusually longer Mo–O(2A) bond length identifies it as the potential center of reactivity.

A rather unusual but noteworthy feature of complex **1a** is the length of the bridging Mo–O(2A) bond. Though it is a molybdenum–oxygen double bond it has been lengthened considerably [2.32(10) Å] from its usual value of around ~1.70 Å. It is also to be noted that it is practically equal to the Mo–O(1W) single bond length in the complex **1b** [29] (Fig. 3). The coordinated water molecule in complex **1b** is found to take part in inter molecular hydrogen bonding involving four molecules

of the unit cell and is expected to increase the stability of the complex system. TG data of the two complexes bear out this connection.

In both the complexes **1a** and **1b**, the molybdenum (VI) acceptor center is present in a distorted octahedral NO_4S donor surrounding, the points of difference being, in complex **1a**, one among the four oxygen atoms is a Mo=O oxygen of the immediate neighbor molecule while in complex **1b** this oxygen is from a coordinated water. Almost all the comparable bond lengths and bond angles are closely similar and the center of reactivity in both the complexes is detected as the point *trans* to one oxo-oxygen. Experiments on activity towards neutral monodentate Lewis bases have led to similar products.

2.4. IR and ^1H NMR studies

A few characteristic infrared absorption frequencies of both the ligands and their complexes are given in Sections 3.3 and 3.4. All physico-chemical properties of the complexes support dianionic tridentate SNO chelation of the ligands. Both the ligands exhibit two broad IR bands of medium intensity in the 3430–3100 cm^{-1} region, the higher frequency one is due to the ν(O–H) mode while the lower ones are assigned to the ν(N–H) vibrations [35]. The presence of these O–H and N–H hydrogens are also revealed in the X-ray crystal structure of the complexes **1a** and **1b**. Two strong ν(C=N) bands at 1617 and 1619 cm^{-1} for H_2L^1 and H_2L^2 of the free ligands are red-shifted to 1590–1600 and 1592–1604 cm^{-1}, respectively, in the corresponding complexes indicating the coordination of the azomethene nitrogen [36,37] to the metal ion. A strong ν(C=S) band was observed in the 1311–1315 cm^{-1} region for the ligands, which disappeared upon complex formation. A new band in the 634–542 cm^{-1} region was observed for complexes and is assigned to ν(Mo–N) [29,35]. The complexes exhibit a medium intensity band around 374–397 cm^{-1} which may be assigned to ν(Mo–S) [20]. Like most of the *cis*-dioxomolybdenum (VI) complexes, two IR bands are observed in the 979–897 cm^{-1} region, the higher frequency band originating from the anti-symmetric while the lower one from the symmetric stretching mode of the $[MoO_2]^{2+}$ moiety [29,38,39]. In the spectra of the $[Mo^{IV}$(bipy/*o*-phen)] complexes the $(Mo{=}O)_t$ band is located near 970 cm^{-1} and as expected [40], reduction of the oxidation state of molybdenum from VI to IV has the effect of lowering the $(Mo{=}O)_t$ stretch from the value observed in $MoOL^1$ and $MoOL^2$.

^1H NMR data for the ligands and complexes **1a** and **1b** are summarized in Sections 3.3 and 3.4. The relatively broad signal at δ 10.72 and 10.02 in the ^1H NMR spectra corresponding to O–H and N–H of the ligand (H_2L^1), respectively, are found to disappear as a result of complexation. The signal at δ 8.04 of the ligand has shifted downfield to δ 9.00, indicating coordination from the azomethene nitrogen in the NMR spectrum of the complex **1a**. The methylene protons of the ligand and the complex appearing at δ 4.59 and 4.41 indicate that the S-benzyl sulfur is not involved in the coordination. The nine aromatic protons appear as multiplets within the range δ 7.24–7.43 (7 protons) and 6.92–6.98 (2 protons) for the ligand. In complex **1b** with the ligand (H_2L^2) similar changes of the signal positions in the ^1H NMR spectra have been observed. The signals at δ 10.24 and 10.09 for the O–H and N–H protons of the ligand are found to disappear due to complex formation. The methyl protons of the ligand and the complex appear at nearly the same position.

2.5. Electrochemical properties

Dioxomolybdenum (VI) complexes (**1a**–**1d**, **1g**, **1h**): Cyclic voltammograms of the ligands and complexes at a platinum electrode were recorded in dry degassed DMF containing 0.1M TEAP as the supporting electrolyte over a potential range of 0.0 to −1.5 V. The numerical data are given in Table 2 and representative voltammograms are shown in Fig. 4. In the case of complexes $Mo^{VI}O_2L^1$ and $Mo^{VI}O_2L^2 \cdot H_2O$ only one irreversible reductive response could be located in the potential range 0.0 to −1.3 V within the potential window scanned. This response is assigned to a metal-centered $2e^-$ process [31]. Two-electron involvement is established by comparison of the current height with authentic $2e^-$ species. On scan reversal an irreversible oxidative response is located in the −0.16 V to −0.20 V range. This is probably due to the oxidation of the species produced in the range −1.01 to −1.13 V by cathodic reduction followed by chemical reaction with the medium. Cyclic voltammograms of the ligands and their

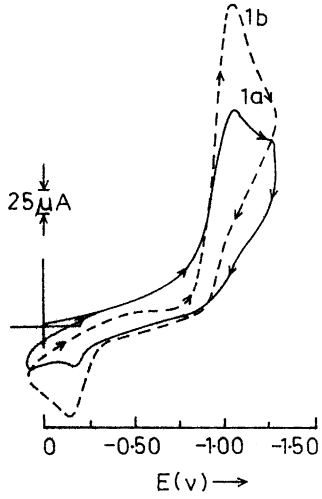

Fig. 4. Cyclic voltammograms for complex **1a** (—) and **1b** (----) in DMF solution.

zinc complexes did not exhibit any reductive response within the potential window scanned. The nature of the voltammograms is found to be independent of scan rate, the normal scan rate being 200 mV/s. The cyclic voltammogram of the $MoO_2L \cdot B$ (where B is a monodentate Lewis base like picoline, imidazole, thiophene, etc.) exhibits little difference from those of the parent complexes and therefore the actual species in solution are $MoO_2L(DMF)$. This is confirmed by recording the electronic spectra of the Mo(VI) complexes and its adducts $MoO_2L.B$ in DMF which exhibit identical spectral features.

Oxomolybdenum (IV) complexes (**2a**, **2b**): Under comparable conditions and in the potential range 0 to +1.3 V the Mo(IV) complexes exhibit one oxidative responses in the 0.45–0.48 V region (Fig. 5). This is assigned to a $2e^-$ oxidation of Mo(IV) to Mo(VI). The $2e^-$ nature of the processes is established by comparing the current height with an authentic $2e^-$system [6,41,42].

2.6. Electronic spectra

Electronic spectra of the Mo(VI) complexes were recorded in dichloromethane solution and the spectral data are presented with the complexes in Section 3.4. The lowest energy absorption maxima are located in the 392–406 nm range and may be assigned [21] to S(pπ)–Mo(dπ) LMCT transition caused by the promotion of an electron from the filled HOMO of the ligand of primarily sulfur pπ character to the empty LUMO of molybdenum dπ character. Other LMCT bands are observed in the region 392–276 nm [6,26,32,41]. These bands may be assigned to the nitrogen to molybdenum and the oxygen to molybdenum charge transfer transitions [21]. The bands appearing below 276 nm are due to intra-ligand transitions. Electronic spectra of Mo(IV) oxo compounds exhibit [33,40] one low-energy charge transfer in the 656–666 nm region.

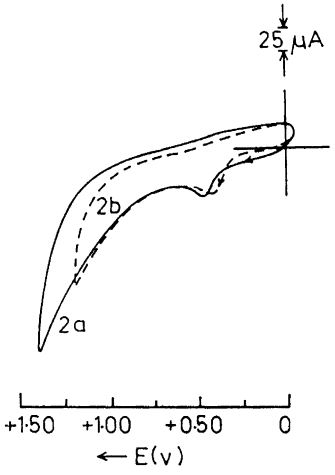

Fig. 5. Cyclic voltammograms for complex **2a** [$MoOL^1$] (—) and **2b** [$MoOL^2$] (----) in DMF solution.

2.7. Study of the reactivity of dioxomolybdenum (VI) and oxomolybdenum (IV) complexes

The dioxomolybdenum (VI) complexes **1a** and **1b** are prepared and isolated from methanol, of which **1a** is found to be oligomeric in the solid state due to weak coordination between the molecules (Fig. 2), while **1b** has a coordinated water molecule. The weak coordination of water is apparent from TG-DTA data of the $MoO_2L^2 \cdot H_2O$ species, which exhibited ready loss of water within the range 120–160 °C. This is substantiated by the facile replacement of the water molecule by a monodentate Lewis base yielding the corresponding MoO_2L^1B and MoO_2L^2B compounds. Again, when these compounds are dissolved in coordinating solvents such as DMF/DMSO the monodentate ligand B is readily replaced by the solvent molecule as is evident from their electronic spectra and electrochemical results. The oxomolybdenum (IV) complexes $MoOL^1$ and $MoOL^2$ have been isolated from CH_3OH/CH_3CN medium, the isolated complexes do not contain any solvent molecules. However, these compounds are found to react readily with 2,2′-bipyridyl/*o*-phenanthrolin to give air stable six-coordinated complexes $MoOL^1$(N–N) and $MoOL^2$(N–N). The complexes $MoO_2L^1$and MoO_2L^2 exhibit oxotransfer to the substrate PPh_3 when reacted with PPh_3 in CH_3OH/CH_3CN medium. It has been observed that a band around 400 nm due to $S(p\pi) \rightarrow Mo(d\pi)$ LMCT transition in the parent complex is shifted to lower energy (~450 nm) and a new band appears around 630 nm. The isolated complexes $MoOL^1$ and $MoOL^2$ have also shown similar spectral features. The oxotransfer reaction may be represented as

$$Mo^{VI}O_2L + PPh_3 \overset{CH_3CN}{\rightarrow} Mo^{IV}OL + OPPh_3$$

which may be considered as a two-electron redox/oxygen atom transfer process. The oxygen atom transfer from the substrate DMSO to the system $MoOL^1$ (**2a**) and $MoOL^2$ (**2b**) has also been studied spectrophotometrically in DMF solution. The parent complex MoOL exhibits a low-energy band around 630 nm with a low ε value and an intense band at ~450 nm. When a drop of DMSO is added to the solution of **2a** and **2b** in DMF, the intensity of the band at ~450 nm is found to decrease slowly and ultimately disappear within 10 min when a new band characteristic of a complex of the type MoO_2L appears around ~400 nm. These observations clearly indicate [43,44] the transfer of an oxygen atom from DMSO to the MoO^{2+} core, leading to the formation of MoO_2^{2+} species and Me_2S. The reaction may be represented as

$$MoOL + DMSO \xrightarrow{DMF} MoO_2L + Me_2S$$

The complexes MoO_2L^1 and MoO_2L^2 are isolated from concentrated DMSO solution of the corresponding MoOL type complexes by adding excess ether. The MoO_2L type complexes precipitated out and are characterized by elemental analysis and spectroscopic techniques.

3. Experimental

3.1. Materials

$[MoO_2(acac)_2]$ was prepared as described in the literature [45]. Reagent grade solvents were dried and distilled prior to use. All other chemicals used for preparative work were of reagent grade and were employed without further purification.

3.2. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 240 C, H, N analyzer. The NMR spectra were recorded on a Bruker 300 L NMR Spectrometer operating at 300 MHz with TMS as internal standard. IR spectra were recorded as KBr pellets on a Perkin–Elmer model 883 Infrared spectrophotometer. Electronic spectra were recorded on a HITACHI U-3501 UV–Vis recording spectrophotometer. Magnetic susceptibility was measured with a PAR model 155 vibrating sample magnetometer with $Hg[Co(SCN)_4]$ as calibrant. Electrochemical data were collected on a BAS CV-27 electrochemical analyzer and a BAS model X-Y recorder at 298 K using a Pt working electrode, Pt auxiliary electrode and Ag/AgCl reference electrode. Voltammograms were recorded in DMF solution of the metal complexes containing 0.1 M TEAP as supporting electroyte.

3.3. Schiff base ligand preparation

3.3.1. S-benzyl-β-N(2-hydroxyphenyl)methylenedithiocarbazate (H_2L^1)

A mixture of 10 ml (0.2 mol) hydrazine hydrate and 11.2 g (0.2 mol) KOH in 70 ml of 90% ethanol was cooled down to −10 °C. 15 ml (0.25 mol) of carbon disulfide was added dropwise with constant stirring. The yellow oil which had formed was separated and dissolved in 60 ml of previously cooled 40% ethanol. To this 23 ml (0.2 mol) of benzyl chloride was added slowly with vigorous stirring. The white product which formed was collected and after re-crystallization from benzene was dissolved in 50 ml of absolute ethanol. To this solution was added 21.5 ml (0.2 mol) of salicylaldehyde in 50 ml ethanol. The resultant mixture was heated on a steam bath for about 10 min. The crystals which settled down were filtered off, washed with ethanol, re-crystallized from benzene and dried in vacuo. Yield ~80%, m.p. ~185 °C.

IR (KBr Pellet), cm^{-1}: $\nu_{(N-H)}$ 3100 (m), $\nu_{(O-H)}$ 3425 (sh), $\nu_{(C=N)}$ 1617 (s), 1604 (s), $\nu_{(C=S)}$ 1311 (s), ^1H NMR(dmso-d_6): (–CH=N–) 8.04 s (1), ($–CH_2–$) 4.59 s (2), (–NH–) 10.02 s, (aromatic –OH) 10.72 b (1), (aromatic proton) 6.92–6.98 m (2), 7.24–7.43 m (7).

3.3.2. S-methyl-β-N(2-hydroxyphenyl)methylenedithiocarbazate (H_2L^2)

This was prepared by following the same procedure only by taking 12.5 ml (0.2 mol) of methyl iodide instead of benzyl chloride. Yield ~80%, m.p. ~210 °C.

IR (KBr Pellet), cm^{-1}: $\nu_{(N-H)}$ 3112 (m), $\nu_{(O-H)}$ 3430 (sh), $\nu_{(C=N)}$ 1619 (s), 1604 (m), $\nu_{(C=S)}$ 1315 (s), ^1H NMR(dmso-d_6): (–CH=N–) 8.01 s (1), ($–CH_2–$) nf, (–NH–) 10.09 s (1), ($–CH_3$) 2.56 s (3), (aromatic –OH) 10.24 b (1), (aromatic proton) 6.93–7.06 m (2), 7.25–7.40 m (2).

3.4. Synthesis of complexes

MoO_2L^1 (**1a**). To a filtered solution of 0.33 g (1.0 mmol) of $MoO_2(acac)_2$ in dry methanol (20 ml) was added 0.302 g (1.0 mmol) of the ligand H_2L^1 in 15 ml of dry methanol. The resulting orange solution was refluxed for 2 h. The volume of the solution was then reduced to about 10 ml on a water bath. The orange compound that separated out was filtered, washed with cold methanol and dried in vacuo over anhydrous $CaCl_2$, yield ~80%. The compound was recrystallized from dry methanol.

IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1591(vs), $\nu_{(Mo=O)}$ 946 (s), 981 (m), $\nu_{(Mo-S)}$ 393 (m), $\nu_{(Mo-N)}$ 570 (w) UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 300 (70790), 318 (76570), 370 sh (36790), 400 (27650); ^1H NMR(dmso-d_6): (–CH=N–) 9.00 s (1), ($–CH_2–$) 4.41 s (2), (aromatic proton) 6.91–7.10 m (2), 7.23–7.78 m (7).

$MoO_2L^2 \cdot H_2O$ (**1b**) was prepared similarly using 0.226 g (1.0 mmol) of ligand H_2L^2 with a yield of 75%. IR (KBr Pellet), cm^{-1}: $\nu_{(O-H)}$ 3326 (w), $\nu_{(C=N)}$ 1592 (vs), $\nu_{(Mo=O)}$ 976 (s), 913 (m), $\nu_{(Mo-S)}$ 385 (s), $\nu_{(Mo-N)}$ 633 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 243 (78 710), 277 sh (49 950), 306 (51 040), 394 (19 810); ^1H NMR(dmso-d_6): (–CH=N–) 8.92 s (1), ($–CH_3$) 2.71 s (3), (aromatic proton) 6.91–7.06 m (2), 7.50–7.75 m (2).

The compounds **1c**–**1j** were prepared by refluxing the parent compounds **1a** and **1b** with the appropriate monodentate Lewis base such as γ-picoline, imidazole, thiophene, THF in 1:1.2 mole ratio for ~4 h. The orange-red crystalline solids so formed were filtered, washed with dry methanol and dried in vacuo over anhydrous $CaCl_2$. Yield ~75–80%.

MoO_2L^1(γ-pic) (**1c**): IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1596 (vs), $\nu_{(Mo=O)}$ 929 (vs), 903 (vs), $\nu_{(Mo-S)}$ 381 (m), $\nu_{(Mo-N)}$ 569 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 239 sh (20 524), 277 sh (12 147), 317 (12 378), 391 (40 820).

MoO_2L^2(γ-pic) (**1d**): IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1595 (vs), $\nu_{(Mo=O)}$ 973 (s), 918 (s), $\nu_{(Mo-S)}$ 384 (m), $\nu_{(Mo-N)}$ 630 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 243 (14 644), 277 sh (88 960), 315 (94 390), 398 (30 940).

MoO_2L^1(imz) (**1e**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1598 (vs), $\nu_{(Mo=O)}$ 918 (vs), 897 (s), $\nu_{(Mo-S)}$ 374 (m), $\nu_{(Mo-N)}$ 542 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 274 sh (12 431), 321 (12 645), 401 (27 210).

MoO_2L^2(N-meimz) (**1f**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1596 (vs), $\nu_{(Mo=O)}$ 979 (s), 941 (m), $\nu_{(Mo-S)}$ 381 (m), $\nu_{(Mo-N)}$ 612 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 244 (13 571), 277 sh (86 380), 321 (11 378), 406 sh (21 730).

MoO_2L^1(thiophene) (**1g**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1590 (vs), $\nu_{(Mo=O)}$ 939 (s), 920 (s), $\nu_{(Mo-S)}$ 387 (m), $\nu_{(Mo-N)}$ 570 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 276 (13 462), 306 (12 983), 394 (52 360).

MoO_2L^2(thiophene) (**1h**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1592 (vs), $\nu_{(Mo=O)}$ 976 (vs), 906 (m), $\nu_{(Mo-S)}$ 386 (s), $\nu_{(Mo-N)}$ 634 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 242 (15 954), 276 (10 192), 304 (10 385), 394 (40 950).

MoO_2L^1(THF) (**1i**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1596 (vs), $\nu_{(Mo=O)}$ 937 (s), 920 (m), $\nu_{(Mo-S)}$ 387 (m), $\nu_{(Mo-N)}$ 572 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 276 (93 150), 307 (89 730), 394 (36 050).

MoO_2L^2(THF) (**1j**) IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1592 (vs), $\nu_{(Mo=O)}$ 975 (vs), 931 (s), $\nu_{(Mo-S)}$ 385 (s), $\nu_{(Mo-N)}$ 634 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 242 (15 074), 276 (96 270), 307 (98 250), 392 (38 550).

All Mo(IV) oxo complexes are prepared under purified dinitrogen.

$MoOL^1$ (**2a**). To a refluxing solution of 0.428 g (1.0 mmol) of MoO_2L^1 in 25 ml dry degassed acetonitrile was added 0.393 g (1.5 mmol) of PPh_3 in 15 ml of degassed acetonitrile. The orange-red solution turned dark brown and a brown compound separated within 10 min. This was filtered and washed well with acetonitrile and dried in vacuo over anhydrous $CaCl_2$. Yield ~80%. IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1600 (vs), $\nu_{(Mo=O)}$ 968 (s), $\nu_{(Mo-S)}$ 287 (w), $\nu_{(Mo-N)}$ 626 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 310 (34 550), 411 (28 490), 466 (29 150), 630 (6125).

$MoOL^2$ (**2b**). This compound was prepared by following the methods described above for the preparation of $MoOL^1$ in a yield of 80%. IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1600 (vs), $\nu_{(Mo=O)}$ 966 (vs), $\nu_{(Mo-S)}$ 460 (s), $\nu_{(Mo-N)}$ 626 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 239 (15 647), 277 sh (10 103), 307 sh (98 720), 450 (28 630), 629 (6272).

Compounds **2c**–**2f** were prepared by refluxing the parent compounds **1a** and **1b** with bipyridyl and *o*-phenanthrolin and PPh_3 with a mole ratio 1:10:1.5 in dry degassed dichloromethane for ~1–2 h. The green solutions so formed were poured into *n*-hexane whereupon green solids separated out. These were filtered, washed with dichloromethane and dried in vacuo over anhydrous $CaCl_2$. Yield ~70–75%.

$MoOL^1$(bipy) (**2c**). IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1600 (vs), $\nu_{(Mo=O)}$ 914 (vs), $\nu_{(Mo-S)}$ 401(m), $\nu_{(Mo-N)}$ 630 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 297 (51 720), 360 (14 930), 436 (17 220), 570 (5860), 685 (7170).

$MoOL^2$(bipy) (**2d**). IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1601 (vs), $\nu_{(Mo=O)}$ 940 (vs), $\nu_{(Mo-S)}$ 395(m), $\nu_{(Mo-N)}$ 625 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 287 (17 214), 307 sh (15 262), 341 (10 240), 449 (21 900), 657 sh (7670).

$MoOL^1$ (*o*-phen) (**2e**). IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1595 (s), $\nu_{(Mo=O)}$ 940 (s), $\nu_{(Mo-S)}$ 397 (w), $\nu_{(Mo-N)}$ 619 (m); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 265 (10 488), 314 sh (37 010), 464 sh (17 080), 441 (10 900), 626 (8230).

$MoOL^2$(*o*-phen) (**2f**). IR (KBr Pellet), cm^{-1}: $\nu_{(C=N)}$ 1604 (s), $\nu_{(Mo=O)}$ 920 (vs), $\nu_{(Mo-S)}$ 397 (m), $\nu_{(Mo-N)}$ 619 (s); UV–Vis (CH_2Cl_2) [λ_{max}/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$)]: 267 (60 210), 314 sh (23 420), 360 sh (9220), 444 (10 410), 629 (9250).

3.5. Crystallographic measurements

Complete tabulation of the crystallographic data for complexes **1a** and **1b** were collected on an Enraf-Nonius CAD-4 diffractrometer equipped with graphite-monochromated Mo Kα ($\lambda = 0.71013$ Å) radiation, using ω-scans. Unit-cell dimension and intensity data were measured at 198 and 293 K. The structures were solved by direct methods and refined by full-matrix least-squares based on F^2 with anisotropic displacement parameters of non-hydrogen atoms using XCAD-49 (data reduction) and SHELXTL (absorption correction, structure solution/refinement and molecular graphics). The hydrogen atoms were included in structures factor calculations in their idealized positions. The crystallographic data are summarized in Table 3.

4. Supplementary data

Crystallographic data have been deposited with the CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44-1223-366033; e-mail: deposit@ccdc.cam.ac.uk

or www: http://www.ccdc.cam.ac.uk) and are available on request, quoting the deposition number 159187 and 159188 for the complex **1a** and complex **1b**, respectively.

Acknowledgements

We gratefully acknowledge the help of Dr. S.K. Kar, Department of Chemistry, Calcutta University for recording UV–Vis spectra and also for constant encouragement. Thanks are also due to Dr. C. Sinha, Burdwan University, for providing FT-IR spectral data, Dr. G.C. Mukherjee, Presidency College, Kolkata and Sri A. Hazra for their constant support and interest in this work.

Abstract

We determined crystal structures of $[(PyO)D][AuCl_4]$, $[(PyO)_4D_3][AuCl_4]_3$ and $[(PyO)_3D_2][AuCl_4]_2$ (PyO: pyridine *N*-oxide) at room temperature (1/1, 4/3 and 3/2 D-salts, respectively). The powder X-ray diffraction patterns of these salts (D-salts) were identical to those of the corresponding ones having normal hydrogen (H-salts) unlike the case of $[(PyO)_2D/H][AuCl_4]$. In the crystals of the 4/3 and 3/2 salts, there exist not only the monomer-type protonic adducts of PyO, but also dimer-type adducts in which two PyO units are bridged by a proton. A few types of aggregation of $AuCl_4$ units (sheet and ribbons) were found in these crystals. The variety in the aggregation motif of the anion and that in the structure of the cation seem to be related to the presence of the various salts having several base-to-acid ratios. The isotope effect on the preparation of the salts is discussed. ^{35}Cl NQR and phase transitions of these compounds are also reported.

1. Introduction

It is known that pyridine *N*-oxide (PyO) forms a monomeric hydrogen adduct $[(PyO)H]^+$ in its salts. Examples can be seen in several compounds [1,2]. In addition, PyO has a tendency to form a monovalent diadduct type cation $[(PyO)_2H]^+$, in which the two PyO units are bridged by a proton. This type of cation exists, for instance, in $[(PyO)_2H][AuCl_4]$ [3] and other compounds [4,5]. There is the possibility that both types of cations are incorporated in a salt. In fact, we prepared a compound $[(PyO)_3H_2][AuCl_4]_2$ having a PyO/$HAuCl_4$ ratio of 3/2, which suggests the coexistence of $[(PyO)H]^+$ and $[(PyO)_2H]^+$ in the crystal [4]. Furthermore, we could separate a compound $[(PyO)_4H_3][AuCl_4]_3$ with another PyO/$HAuCl_4$ ratio of 4/3 by controlling the PyO/$HAuCl_4$ ratio in the solution. These findings led us to determine the crystal structures of these compounds to confirm their composition and the structure of the cation.

As a structural change induced by substitution of D for H atom, we recently reported that the structure of the cation $[(PyO)_2D]^+$ in $[(PyO)_2D][AuCl_4]$ and its whole crystal structure itself were dramatically different from those of $[(PyO)_2H][AuCl_4]$ [4]. Since we have been interested in this phenomenon induced by substitution of a hydrogen isotope, a part of this work was devoted to examine the effect of deuteration on the structures of the various salts mentioned above. We also investigated the stability of $[(PyO)_2D][AuCl_4]$ and $[(PyO)_2H][AuCl_4]$ to show that both of them are in stable phases.

The results of DTA/DSC as well as preliminary ^{35}Cl NQR measurements of $[(PyO)_3(H/D)_2][AuCl_4]_2$, $[(PyO)_4H_3][AuCl_4]_3$ and $[(PyO)D][AuCl_4]$ are reported.

We briefly discuss the phase transitions in $[(PyO)_3(H/D)_2][AuCl_4]_2$ and $[(PyO)D][AuCl_4]$.

2. Experimental

2.1. Synthesis

The various complex salts $[(PyO)_m(H/D)_n][AuCl_4]_n$ ($m/n = 1/1$, 4/3, 3/2, 2/1) between PyO and (H/D)$AuCl_4$ were prepared by slow evaporation of aqueous solutions (H_2O or D_2O) containing PyO and (H/D)$AuCl_4$ in the molar ratio shown in Table 1. In the text, following abbreviations will be used; $[(PyO)_m(H/D)_n][AuCl_4]_n$: m/n (H/D)-salt. The 4/3 H-salt was not prepared. $DAuCl_4$ was obtained by dissolving Au_2O_3 in a DCl solution in D_2O. Elemental analyses were carried out at the Center for Organic Elemental Microanalysis, Kyoto University. The results of the analyses have already been reported in [4] for $[(PyO)_2D][AuCl_4]$, $[(PyO)_3H_2][AuCl_4]_2$, $[(PyO)H][AuCl_4]$ and $[(PyO)D][AuCl_4]$. In the following, the results of $[(PyO)_3H_2][AuCl_4]_2$, $[(PyO)_3D_2][AuCl_4]_2$ and $[(PyO)_4D_3][AuCl_4]_3$ are reported. *Anal*. Calc. for $[(PyO)_3H_2][AuCl_4]_2$: C, 18.7; H, 1.8; Cl, 29.4; N, 4.4; O, 5.0. Found: C, 18.4; H, 1.8; Cl, 29.2; N, 4.2; O, 4.8%. *Anal*. Calc. for $[(PyO)_3D_2][AuCl_4]_2$: C, 18.6; H/D, 2.0; Cl, 29.3; N, 4.4; O, 5.0. Found: C, 18.5; H/D, 1.9; Cl, 29.4; N, 4.3; O, 4.8%. *Anal*. Calc. for $[(PyO)_4D_3][AuCl_4]_3$: C, 17.1; H/D, 1.9; Cl, 30.3; N, 4.0; O, 4.6. Found: C, 17.2; H/D, 2.0; Cl, 30.4; N, 4.0; O, 4.3%. The extent of the deuteration has been estimated by use of ^2H NMR measurements of the aqueous solution to be H/D = approximately 15/85 for $[(PyO)_3D_2][AuCl_4]_2$, $[(PyO)_4D_3][AuCl_4]_3$ and $[(PyO)D][AuCl_4]$.

The 3/2 (H/D)-salts and the 4/3 D-salt showed an extraordinarily wide temperature range of melting (see Table 1). This is probably due to gradual decompositions of the salts.

2.2. Physical measurements

X-ray powder patterns were recorded by the use of a Rigaku RINT 2100S diffractometer with Cu Kα radiation. Silicon powder was used as an internal standard of the diffraction angle. DTA and DSC measurements were performed using a home-made apparatus and DSC3100S (Bruker AXS), respectively. For the ^2H NMR measurements of the solution, a JEOL JNM-EX270 NMR spectrometer was employed. The density of the crystal at room temperature was determined by a floating method, using a mixture of *o*-xylene and bromoform or benzene and methylene iodide. A pulsed spectrometer based on the Matec gated amplifier 515A was used for the ^{35}Cl nuclear quadrupole resonance (NQR) measurements. The temperature of the NQR sample was controlled in the range 4.2–300 K using an electronic controller (LakeShore 331) and measured with an accuracy of ±0.5 K by use of a gold +0.07% iron versus chromel thermocouple. Solid-state ^1H NMR experiments were carried out by use of a standard pulsed NMR spectrometer at the Larmor frequency of 42.5 MHz.

2.3. Crystallography

A SMART 1000/CCD diffractometer (Bruker) was employed for the diffraction measurements using graphite monochromated Mo Kα radiation. Data collections were carried out at room temperature. Crystal data and the details of the experiments and refinements are given for the 3/2 D-salt, 4/3 D-salt and 1/1 D-salt in Table 2.

The structures were solved by direct methods and refined by full-matrix least-squares calculations based on F_o^2 with absorption correction (SADABS) using SHELXL-97 [6]. Non-hydrogen atoms of each salt were included in the least-squares calculations with anisotropic displacement parameters.

It was found that the monomeric adduct $[(PyO)D]^+$ in the 1/1 D-salt had a mirror plane, being perpendicular to the ring plane and containing the N–O bond, and a C_2-axis, being normal to the mirror plane and passing through the center of the ring (C_{2h} symmetry) indicating an orientational disorder, in which each of the O, N and relevant C (C1) atoms was located on two sites with an equal population. The positions of the N and C1 atoms

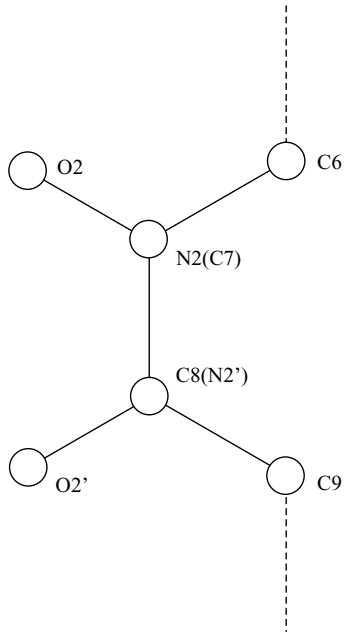
were set to be equal. The D and non-disordered H atoms were found from a difference Fourier map and included in the refinement with isotropic displacement parameters (U_{iso}). The H atom attached to C1 was ignored in the refinement.

The asymmetric unit of the 3/2 D-salt contained a $[(PyO)D]^+$ group having a C_2-axis passing through C6 and C9 as shown in Scheme 1 (C_2 symmetry) and a $[PyO–D–PyO]^+$ group having an inversion center (C_i symmetry).

For the latter group, the bridging D atom was fixed at the center of symmetry, and the positions of the H atoms belonging to the PyO moiety were calculated and they were included in the refinement with U_{iso}. The C_2 symmetry of the $[(PyO)D]^+$ group indicates an orientational disorder of the group. In addition, another disorder was found for the group, because the asymmetric unit of the group had two oxygen atoms (O2 and O2′ shown in Scheme 1) with different populations (0.205 and 0.295, respectively). Owing to this disorder of the $[(PyO)D]^+$ group, the N atom was divided into two sites (N2 and N2′), each overlapping C7 and C8, respectively. The position and U_{ij} of C7 were set equal to those of N2, the population of which being that of O2 (0.205). The same treatment was applied to C8 and N2′. The positions of the H atoms attached to C6 and C9 were calculated and they were included in the refinement with U_{iso}. The rest of the H atoms, as well as the D atom were omitted in the refinement.

The asymmetric unit of the 4/3 D-salt was found to include $[(PyO)D]^+$ and $[PyO–D–PyO]^+$ with a center of symmetry. The positions of H atoms belonging to the PyO moieties in the latter unit were calculated and they were included in the refinement with U_{iso}. The bridging D atom was treated in the way same as that described above. The structure of the PyO moiety of the $[(PyO)D]^+$ unit was considerably distorted and the H atoms could not be found on the Fourier maps. The



Scheme 1. Asymmetric unit of the disordered $[(PyO)D]^+$ group. The vertical broken line indicates 2-fold axis.

positions of the H atoms were calculated and they were included in the refinement with U_{iso}.

3. Results and discussion

3.1. Effect of deuteration on the crystal structures of the 1/1, 4/3 and 3/2 salts

As an isotope effect on crystal structure, we have reported a novel structural difference between the 2/1 H-salt and the 2/1 D-salt [4]. In relation to this phenomenon, we examined the possibility of such an isotope effect on the crystal structures of the 3/2, 4/3 and 1/1 salts. Their X-ray powder patterns revealed, however, that the deuteration did not change their crystal structures.

Since the quality of the single crystals of the deuterated salts was better than that of the normal ones, X-ray crystal structures of the former salts were determined in the present work.

3.2. Stability of the 2/1 H- and 2/1 D-salts

In order to check the possibility that either of the H- or D-salt is in a meta-stable phase, we carried out DTA measurements to get information on their thermal stability. DTA curves of the two salts measured in the 170–385 K region showed no exothermic heat anomaly corresponding to a monotropic transition of a meta-stable phase. We also examined X-ray powder diffraction patterns measured at room temperature for melt-grown crystals of the H- and D-salts or the crystals annealed at ca. 350 K. The diffraction patterns of the melt-grown or the annealed H- and D-salts were identical to those of the corresponding compounds obtained by crystallization from solutions. These results of the DTA and X-ray experiments strongly suggest that both of the H- and D-salts are in stable phases.

3.3. Crystal structures of the 1/1, 4/3 and 3/2 D-salts at room temperature

The 1/1 D-salt contains only $[(PyO)D]^+$, while there exist both $[(PyO)D]^+$ and $[PyO–D–PyO]^+$ in the crystals of the 4/3 D-salt and the 3/2 D-salt. The molar ratio of the monomeric:dimeric adducts in the crystal is 1:1 in the 3/2 salt and 2:1 in the 4/3 salt. These results are consistent with the chemical compositions of the salts.

The geometries of the monomeric and dimeric adducts are listed in Table 3.

The dimeric adducts in the 4/3 D-salt and the 3/2 D-salt are centrosymmetric (C_i symmetry), while the dimeric adduct in the 2/1 D-salt is non-symmetric (C_1 symmetry) [4]. The O···O distance in the dimeric adduct in the 4/3 D-salt (2.44(1) Å) and that in the 3/2 D-salt (2.41(2) Å) are typical for a symmetric O···H···O

[a] The crystal contains one non-symmetric $[PyO-D-PyO]^+$ in the asymmetric unit.
[b] The crystal contains centrosymmetric $[PyO–D–PyO]^+$.
[c] The monomeric adduct in the crystal is disordered (see text).
[d] The N–O length was not reliable owing to the orientational disorder (see text).

hydrogen bond, being comparable with the corresponding values found, for example, in the 2/1 D-salt [4], 2/1 H-salt [3], $[(PyO)_2H]ClO_4$ [5] and $[(2,6\text{-}(CH_3)_2PyO)_2H]$- $[AuCl_4]$ [7]. The N–O bond lengths of the PyO moiety in $[(PyO)D]^+$ found for the 1/1 and 4/3 D-salts are longer than that of the neutral PyO molecule (1.30 Å) [8]. This observation indicates the hydrogenation of the oxygen atom and/or its participation in the formation of a hydrogen bond.

The crystal of the 1/1 D-salt is built by alternating stacking of the layers of $[(PyO)D]^+$ and $[AuCl_4]^-$ (Fig. 1). $[(PyO)D]^+$ has C_{2h} symmetry to result in its orientational disorder, which can be seen in Fig. 1. It should be mentioned that the $[(PyO)D]^+$ groups in the 1/1 salt form a layer structure as shown in Fig. 2. The short intermolecular O···N contact (3.16(2) Å) suggests a certain interaction between the adjacent $[(PyO)D]^+$ groups. There exists a short intermolecular Cl···Cl contact of 3.391(6) Å, which seems to contribute to connect the layers of $[AuCl_4]^-$. The short intermolecular O1···Cl1 length (3.16(2) Å) indicates possibility of N–O–D···Cl hydrogen bonds.

The crystal structures of the 4/3 D-salt and 3/2 D-salt are depicted in Figs. 3 and 4, respectively. Several aggregation motifs of $[AuCl_4]^-$ ions are found in the 1/1, 4/3, 3/2 and 2/1 D-salts. In the crystal of the 1/1 D-salt, one can recognize a planar sheet structure formed by $[AuCl_4]^-$ ions (Fig. 1). If one takes account of a relatively long Au···Cl contact of 3.509 (3) Å in the sheet structure, the formal coordination number of the Au atom is six and the layer structure is formed by vertex-sharing of the $AuCl_6$ octahedrons. A similar layer structure has been reported for $[EtC(OEt)NH_2][AuCl_4]$ [9].

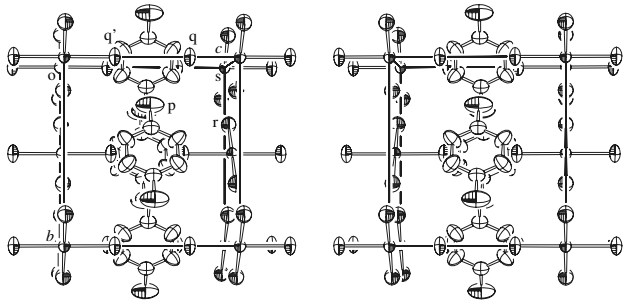

Fig. 1. Crystal structure of the 1/1 D-salt (stereo). Short contacts are Cl1(*q*)···Cl1′(*q*′) (3.391(6) Å), O1···Cl1 (3.16(2) Å) and Cl2···Au (3.509(3) Å). Symbols p, q, q′, r and s denote O1, Cl1, Cl1′, Cl2 and Au, respectively. Symmetry codes: p : $(-x+1.5, y-0.5, -z+1)$; q : $(-x+1, -y+1, -z+1)$; q′ : $(x+1, y-1, z)$; r : $(-x+0.5, y-0.5, -z+1)$ and s : $(x, y-1, z+1)$.

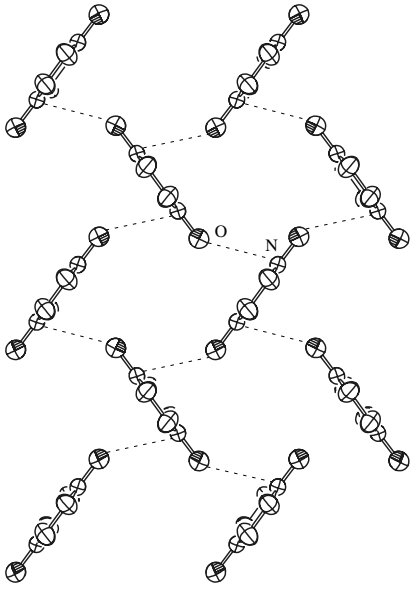

Fig. 2. Layer structure formed by disordered $[(PyO)D]^+$ units in the 1/1 D-salt. The broken lines indicate short O···N contacts of 3.16(2) Å.

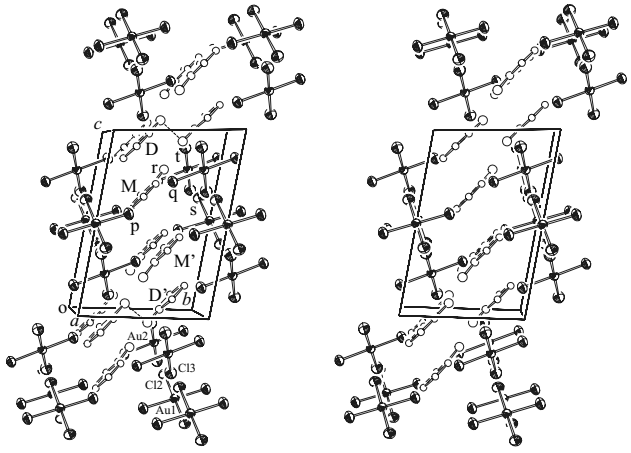

Fig. 3. Crystal structure of the 4/3 D-salt (stereo). D and M indicate $[PyO–D–PyO]^+$ and $[(PyO)D]^+$, respectively. D and D′, M and M′ as well, are related by an inversion center. Symbols p, q, r, s and t are Cl1, Cl4, O1, Cl2 and Cl5, respectively. Symmetry codes: p : $(-x+2, -y+1, -z+1)$; q : (x, y, z); r : (x, y, z); s : $(x-1, y, z)$ and t : $(x-1, y, z)$.

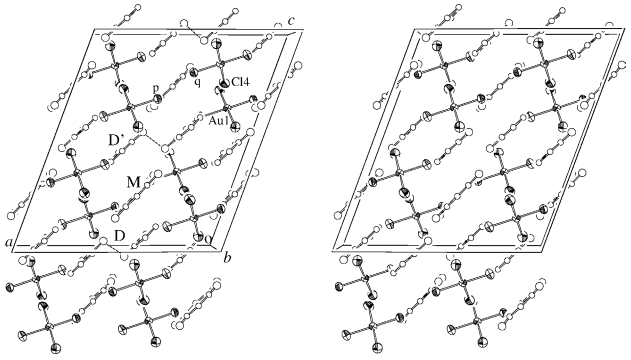

Fig. 4. Crystal structure of the 3/2 D-salt (stereo). D and M denote $[PyO\text{-}D\text{-}PyO]^+$ and $[(PyO)D]^+$ units. Symbols p and q are Cl1 and Cl1′. Symmetry codes: p : $(x+0.5, -y+1.5, z+0.5)$ and q : $(-x+0.5, -y+1.5, -z+1)$.

A ribbon-like aggregation motif of $[AuCl_4]^-$ ions that was found in the 4/3 salt (Fig. 3) can be regarded as a part of the sheet structure observed in the 1/1 D-salt. The Au1···Cl3 and Au2···Cl2 contacts are 3.525(3) and 3.590(3) Å, respectively, being comparable with the Au···Cl contacts found for the chain structures of $[AuCl_4]^-$ ions in [EMIM][$AuCl_4$] and [BMIM][$AuCl_4$] (3.356 and 3.452 Å, respectively) [10]. In the ribbon structure of the 4/3 D-salt, there are six and five coordinations of the Au atom, and vertexes of $AuCl_6$ octahedrons and $AuCl_5$ distorted square pyramids are shared to result in the ribbon.

The crystals of the 3/2 and 2/1 D-salts consist of another type of ribbon structure, each of which can be also regarded formally as a part of the layer structure of the 1/1 salt. The ribbon structure of the 3/2 D-salt has an Au1···Cl4 contact of 3.559(5) Å (Fig. 4). The Au···Cl contact in the 2/1 D-salt amounts to 3.983(2) Å, being comparable to that found for a chain structure of $AuCl_4^-$ ions in $[(H_5O_2)_2$(12-crown-4)$_2][AuCl_4]_2$ (3.845 Å) [11].

In the crystal of the 4/3 D-salt, the ribbons are packed along the crystallographic *a*-axis as shown in Fig. 3. A short Cl···Cl contact (3.612(4) Å of Cl1···Cl4) is observed between the ribbons. A columnar cavity surrounded by four ribbons of $[AuCl_4]_n^-$ is filled by a $[(PyO)D]^+$ (M), a PyO moiety of a $[PyO–D–PyO]^+$ (D) and their inversion-related ones (M′ and D′) as shown in Fig. 3. It is interesting to note that one of the two PyO moieties of a $[PyO–D–PyO]^+$ unit is accommodated in a columnar cavity, while the other one in an adjacent cavity. There are two short intermolecular contacts between the chlorine atoms in the ribbon and an oxygen atom in the PyO group: Cl2···O1 (3.31(1) Å) and Cl5···O1 (3.15(1) Å). The planes of the PyO moieties stack parallel to each other (see Fig. 3).

The crystal structure of the 3/2 D-salt is similar to that of the 4/3 D-salt as can be seen by comparing Figs. 3 and 4. The cavity of the 3/2 D-salt is filled by D, D′ (related to D by 2-fold symmetry axis) and M. The number of the PyO moieties accommodated in a cavity of the 3/2 D-salt is smaller than that of the 4/3 D-salt as a result of the decrease in the width of the ribbon structure. D and M stack almost parallel to each other and M, which is flanked by D and D′, exhibits the disorder mentioned above. There is a short Cl···Cl contact between adjacent ribbons (Cl1···Cl1′ of 3.575(9) Å).

3.4. Characterization of the 1/1, 4/3 and 3/2 D-salts by ^{35}Cl NQR and thermal analysis

For the 4/3 D-salt, we observed the five NQR frequencies (ν) of 29.164, 28.727, 28.625, 28.272 and 27.618 MHz at 77 K. There must be one missing line, since there exist six crystallographically non-equivalent chlorine atoms in the crystal. Previously, we have improperly assigned these frequencies to the 1/1 D-salt [4].

The temperature dependence of the ^{35}Cl NQR frequencies of the 4/3 D-salt is shown in Fig. 5. In the temperature range investigated (77–230 K), ν versus T curves seem to have no anomaly corresponding to a phase transition. The thermal analyses (DTA and DSC) carried out in 150–300 K region also could not detect any anomaly due to a phase transition.

For the 3/2 D-salt, a phase transition was detected at 199 K by the thermal analyses with increasing temperature ($\Delta H = 1.3$ kJ mol^{-1}). For the 3/2 H-salt, it was located at 197 K. The transitions exhibited very slight hysteresis, indicating the first-order nature of the transition. It was suggested from the temperature dependence of the ^{1}H NMR spin–lattice relaxation time of the 3/2 D-salt that at least one of the cationic molecules in the unit cell performs a fast reorientational motion above the phase-transition point. This mobility of the cation shows that the disordered structure found in the crystal structure determination is likely to be a dynamic one. So far, we have found four very broad ^{35}Cl NQR lines at 77 K for the 3/2 D-salt. The crystal structure of the low-temperature phase and details of the NMR/NQR results will be reported in a forthcoming paper.

DTA/DSC curves of the 1/1 D-salt measured in 150–300 K region exhibited a very small thermal anomaly at 273 K (T_{c1}) indicating a phase transition ($\Delta H_{c1} = 0.4$ kJ mol^{-1}). Hysteresis (super-cooling of ca. 30 K) of the transition suggested a first-order nature of the transition. It is very interesting that we could not detect any anomaly in the DTA/DSC curves for the 1/1 H-salt in

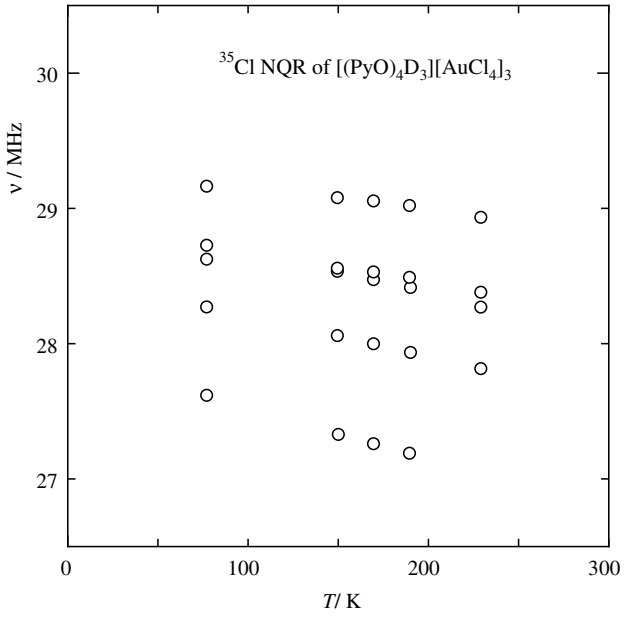

Fig. 5. Temperature dependences of ^{35}Cl NQR frequencies of the 4/3 D-salt.

the temperature range 150–300 K. Such a kind of isotope effect has been reported previously [12,13].

Two ^{35}Cl NQR lines (high- and low-frequency lines) were observed for the 1/1 D-salt at room temperature. When the sample temperature was decreased, the high-frequency line was observed to split drastically into four lines below 70 K (T_{c2}). Thus, from the ^{35}Cl NQR measurements, we have found another phase transition that is more drastic than that at T_{c1}. Moreover, it is interesting that the low-frequency line disappeared before reaching to T_{c2}.

In the region of $T > T_{c2}$, the frequencies (ν) of the two lines decreased monotonously with increasing temperature. No anomaly was detected in the ν versus T curves at T_{c1} within the accuracy of the present frequency measurements. This feature, together with the small value of ΔH_{c1}, indicates quite a subtle structural change at T_{c1}. The presence of the two ^{35}Cl NQR lines is consistent with the crystal structure determined at room temperature having two crystallographically non-equivalent chlorines.

The temperature dependence of the NQR spin–lattice relaxation time T_1 showed an anomalous decrease with decreasing temperature in the region of $T > T_{c2}$. This result suggests a dynamical disorder of the $[(PyO)D]^+$ cations at $T > T_{c2}$, since the ^{35}Cl T_1 behavior can be explained by the relaxation mechanism due to a fluctuation of the electric field gradient caused by reorientational motions between disordered orientations of nearby $[(PyO)D]^+$ cations. The presence of such a motion of the $[(PyO)D]^+$ cation was strongly suggested by the ^{1}H NMR spin–lattice relaxation measurements as well. The details of NMR/NQR measurements will be reported elsewhere.

These conclusions from the NQR and NMR investigations are consistent with the disorder model of the $[(PyO)D]^+$ group proposed in the crystal structure determination. An ordering of the $[(PyO)D]^+$ cation is likely to take place below T_{c2} and hence the transition at T_{c2} seems to be of an order–disorder type.

3.5. Origins of compositional variety and isotope effect on preparation

The present structural analyses revealed that both of the monomeric and dimeric adducts of PyO with proton can be formed in the crystal. In addition, several types of aggregation of $AuCl_4$ units are possible. These structural possibilities found for the cation and anion seem to be a reason why so many salts having different base-to-acid ratio could be formed.

There was a tendency that the base-to-acid molar ratio of the crystal was lower than that of the mother solution in the heavy hydrogen system, while it was found vice versa in the normal hydrogen system (see Table 1). This observation indicates that equilibrium processes in $PyO + (H/D)AuCl_4 + (H/D)_2O$ systems are dependent on the isotopic composition. Similar isotope effects on chemical equilibrium are known, for example, in the enol-enethiol tautomerism of β-thioxoketones [14] and in an acid–base equilibrium [15].

4. Supplementary material

Crystallographic data for the 1/1, 4/3 and 3/2 D-salts have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 219958, 219959 and 219960, respectively. Copies of the information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).
