Solvents were used as supplied or distilled using standard methods. The reagents were obtained from Aldrich or Fluka. Glyoxal dinitrone was synthesized by condensation of the corresponding aldehyde and *N*-methyl hydroxylamine following a published method [27]. The 3 + 2 dipolarophil cycloaddition reactions of glyoxal dinitrone with styrene or 2-vinylpyridine proceed smoothly yielding arylsubstituted biisoxazolidines. The yields of the products did not change remarkably in view of varying of the solvent (acetonitrile, methanol) and the nitrone/dipolarophile ratio.

3.1.1. 3,3′-Bi{2-methyl-5-(2-pyridyl)}isoxazolidine (L^1)

2-Vinylpyridine (4.8 ml, 43.1 mmol) was added to a hot solution of glyoxal dinitrone (0.50 g, 4.31 mmol) in 20 ml of dry acetonitrile. The mixture was refluxed for 15 h while the reaction was monitored by TLC using an acetone–chloroform (2:1 v/v) mixture as eluent. The solvent was evaporated under reduced pressure yielding a mixture of isomeric 3,3′-biisoxazolidines as was proved by ^{1}H NMR spectra. Addition of 10 ml of acetone to the residue effected crystallization of 0.35 g (25%) of *cis*-,*cis*-3,3′-bi{2-methyl-5-(2-pyridyl)}isoxazolidine as a colorless solid.

The acetone filtrate was evaporated giving a brown oily mixture of *cis–trans*- and *trans–trans*-isomers (ca. 3:1) that was separated by column chromatography (SiO_2, acetone–chloroform 2:1; *cis–trans*-isomer: $R_f = 0.30$; *trans–trans*-isomer: $R_f = 0.45$).

^{1}H NMR data for the three stereoisomers are presented in Table 1. Data for *cis*-,*cis*-3,3′-bi{2-methyl-5-(2-pyridyl)}isoxazolidine: *Anal.* Calc. for $C_{18}H_{22}N_4O_2$: C, 66.24; H, 6.79; N, 17.16. Found: C, 66.85; H, 6.92; N, 17.05%. ^{13}C NMR ($CDCl_3$): δ 42.02 (NCH_3), 48.80 (C^4), 73.70 (C^3), 81.89 (C^5), 123.62 (C^{β}-Py), 125.42 (C^{β}-Py), 139.62 (C^{γ}-Py), 152.08 (C^{α}-Py), 163.52 (ipso-Py).

3.1.2. 3,3′-Bi{2-methyl-5-phenyl}isoxazolidine (L^2)

Styrene (2 ml, 17.2 mmol) was added to a hot solution of glyoxal dinitrone (0.20 g, 1.72 mmol) in dry acetonitrile (10 ml) and the mixture was refluxed for 35 h (TLC: acetone–chloroform 1:1 v/v). The solvent was removed under reduced pressure and the brown oily product was triturated with 5 ml of 2-propanol. This afforded a precipitate of *cis*-,*cis*-3,3′-bi{2-methyl-5-phenyl}isoxazolidine as white flakes (0.084 g, 12%) that was filtered off and recrystallized from ethanol. *Anal*. Calc. for $C_{20}H_{24}N_2O_2$: C, 74.05; H, 7.46; N, 8.63. Found: C, 75.12; H, 7.82; N, 8.43%. ^{1}H NMR ($CDCl_3$): δ 2.28 (m, 1H, H^4), 2.75 (s, 3H, NCH_3), 2.97 (m, 1H, $H^{4'}$), 3.15 (m, 1H, H^3), 5.32 (m, 1H, H^5), 7.25–7.4 (m, 5H, C_6H_5). ^{13}C NMR ($CDCl_3$): δ 44.45 (NCH_3), 48.62 (C^4), 74.87 (C^3), 81.02 (C^5), 129.28 (*p*-Ph), 130.70 (*m*-Ph), 131.46 (*o*-Ph), 143.25 (*ipso*-Ph).

Crystalline *cis–cis*-isomers of $L^1$and L^2 are air-stable and stable in solution, they are soluble in chloroform, acetonitrile and insoluble in 2-propanol, diethyl ether and hexane.

Colorless crystals of *cis–cis*-L^1, suitable for X-ray analysis, were obtained from chloroform–acetonitrile (1:4) solution.

The copper(II) chloride complexes were prepared by reacting the components in methanol/chloroform solutions. In a typical synthesis, solutions of L^1 (0.098 g, 0.3 mmol) in $CHCl_3$ (3 ml) and $CuCl_2 \cdot 2H_2O$ (0.051 g, 0.3 mmol) in 3 ml of methanol were combined and allowed to stand in a vacuum dessicator over $CaCl_2$ for a few days, yielding green needles of the $Cu\{L^1\}Cl_2$ complex. *Anal*. Calc. for $C_{18}H_{22}Cl_2CuN_4O_2$: C, 46.91; H, 4.81; N, 12.16. Found: C, 47.19; H, 4.96; N, 12.03%. For crystallization of a copper(II) chloride complex with L^2 we have used vapour diffusion of 2-propanol into a methanol–chloroform solution of the components (0.039 g, 0.23 mmol $CuCl_2 \cdot 2H_2O$ and 0.147 g, 0.45 mmol L^2), which afforded thin green needles of $Cu\{L^2\}Cl_2 \cdot CHCl_3$ in a period of 5–6 days. *Anal*. Calc. for $C_{21}H_{25}Cl_5CuN_2O_2$: C, 43.63; H, 4.36; N, 4.85. Found: C, 43.91; H, 4.56; N, 5.04%. This chloroform solvate is stable in air for a few days but eventually the crystals became opaque due to the loss of the solvent molecules and disintegration of the structure.

$[Ni\{L^1\}(H_2O)(NO_3)]NO_3$ was prepared using a layering technique. A solution of $Ni(NO_3)_2 \cdot 6H_2O$ (0.037 g, 0.126 mmol) in 2 ml of methanol was layered over a solution of L^1 (0.041 g, 0.126 mmol) in 2 ml of chloroform. Slow interdiffusion of the layers, over a period of 12–15 days, afforded well-developed blue prismatic crystals of the complex (yield 80%). *Anal*. Calc. for $C_{18}H_{24}N_6NiO_9$: C, 41.01; H, 4.59; N, 15.95. Found: C, 41.51; H, 4.87; N, 16.04%.

Unlike this case, 3,3′-bi{2-methyl-5-phenyl}isoxazolidine (L^2) and nickel nitrate gave a mixture of products that were not identified. We were not successful in the preparation of individual compounds for this system.

For the preparation of the pentamethylcyclopentadienyliridium(III) chloride complex, $[Cp^*IrCl]_2Cl_2$ (0.133 g, 0.167 mmol) was dissolved in 10 ml of chloroform and added to a chloroform solution of L^1 (0.109 g, 0.334 mmol). The reaction mixture was stirred at 35 °C for 1.5 h and then the clear solution obtained was evaporated in a vacuum desiccator. Yellow crystals of the $[(Cp^*IrCl_2)_2\{L^1\}]$ complex were obtained in 90% yield, they were washed with hexane and dried in air. ^{1}H NMR ($CDCl_3$): δ 1.55 (s, 15H, Cp*), 2.4 (m, 1H, H^4), 2.82 (s, 3H, NCH_3), 3.15 (m, 1H, $H^{4'}$), 3.2 (m, 1H, H^3), 5.65 (m, 1H, H^5), 7.27 (dd, 1H, Py), 7.72 (m, 2H, Py), 8.9 (d, 1H, Py). $[Cp^*Ir(L^2)Cl]Cl$ was synthesized in a similar fashion. *Anal*. Calc. for $C_{30}H_{39}Cl_2IrN_2O_2$: C, 49.85; H, 5.44; N, 3.88. Found: C, 50.07; H, 5.72; N, 3.54%. H^1 NMR ($CDCl_3$): δ 1.49 (s, 15H, Cp*), 2.60 (m, 1H, H^4), 3.67 (s, 6H, NCH_3), 2.99 (m, 1H, $H^{4'}$), 4.50 (m, 1H, H^3), 5.70 (m, 1H, H^5), 7.1–7.4 (m, 5H, C_6H_5).

Attempted preparation of biisoxazolidine p- and f-block metal complexes failed. However, we have found that L^1 readily forms a molecular complex with uranyl nitrate $[UO_2(CH_3OH)_2(NO_3)_2] \cdot L^1$. A solution of L^1 (0.098 g, 0.3 mmol) in 3 ml of $CHCl_3$ and a solution of $UO_2(NO_3)_2 \cdot 2H_2O$ (0.154 g, 0.3 mmol) in 3 ml of CH_3OH were combined and the mixture was allowed to stand in a vacuum dessicator over $CaCl_2$. The yellow crystalline product was separated, washed with cold methanol and dried in air (yield 70%). *Anal*. Calc. for $C_{20}H_{30}N_6O_{12}U$: C, 30.62; H, 3.85; N, 10.71. Found: C, 30.23; H, 3.64; N, 10.95%. 3,3′-Bi{2-methyl-5-phenyl}isoxazolidine does not co-crystallize with uranyl nitrate under these conditions.

3.2. X-ray crystallography

The measurements for L^1 (**1**), L^2 (**2**) and $Cu\{L^2\}Cl_2 \cdot CHCl_3$ (**3**) were made at 223 K using a Siemens SMART CCD diffractometer (graphite monochromated Mo Kα radiation, $\lambda = 0.71073$ Å, empirical absorption corrections using SADABS [28]). The intensity data for $[Ni\{L^1\}(H_2O)(NO_3)]NO_3$ (**4**) and $[UO_2(CH_3OH)_2(NO_3)_2] \cdot L^1$ (**5**) were collected at 200 K on a Stoe Image Plate Diffraction System (φ oscillation scans 0–188.5°, step $\Delta\varphi = 1°$). The structures were solved by direct methods and refined in the anisotropic approximation using SHELXS-86 and SHELXL-97 [29,30]. In structures **1** and **4** all hydrogen atoms were localized and refined isotropically, while for **3** and **5** the hydrogen atoms were constrained geometrically and considered using the riding model with their isotropic *U* values at 1.2 times the equivalent isotropic *U* value of the atoms to which they are attached. One of two unique biisozaxolidine molecules in structure **2** shows rotational disorder of a phenyl

Table 4
Crystal data for L^1 (**1**), L^2 (**2**), $Cu\{L^2\}Cl_2 \cdot CHCl_3$ (**3**), $[Ni\{L^1\}(H_2O)(NO_3)](NO_3)$ (**4**) and $[UO_2(CH_3OH)_2(NO_3)_2] \cdot L^1$ (**5**)

group with partial contributions of 0.58 and 0.42. The hydrogen atoms of this moiety were not included, while the hydrogen atoms corresponding to the ordered portion were localized and refined isotropically. The maximum of residual electron density in structure **5** (2.44 e Å^{-3}) is located at 0.82 Å from the heavy uranium atom. The crystal data are given in Table 4 and the principal bond lengths and angles are listed in Table 3.

4. Conclusion

The present study demonstrates the potential of geometrically flexible biisoxazolidines as efficient ligands towards metal ions. Coordination preferences of this new ligand system may provide a useful basis for modelling the pathways of metal catalized 1,3-dipolarophil cycloaddition reactions and further transformations of coordinatively immobilized isoxazolidines. They may also be involved in developing strategies for preparative separations of complicated mixtures of cycloaddition products. Our results suggest wider possibilities for designing and fine-tuning the structure and ligand properties of open-chain flexible multidentates and for metal-assisted stabilization of certain molecular conformations.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication Nos. CCDC-262879–262883 (compounds **1**–**5**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www.http://www.ccdc.cam.ac.uk).

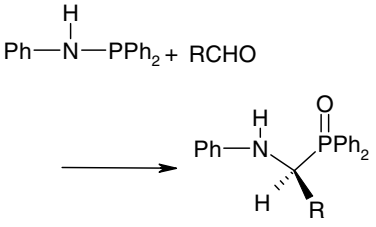
with aldehydes and ketones. The molecular structures and the complexing ability of some of the bisphosphine oxides thus obtained are also described.

2. Results and discussion



The aminophosphines, $Ph_2PN(H)Ph$, $Ph_2PN(^nBu)PPh_2$ and 1,2-$C_6H_4(N(H)PPh_2)_2$ were prepared as described in the literature (see Section 4). The 1,3-phenylenediamine derivative 1,3-$C_6H_4(N(H)PPh_2)_2$ (**1**) was prepared in 46% yield by reacting chlorodiphenylphosphine with 1,3-phenylenediamine in THF in the presence of a catalytic amount of 4-dimethylaminopyridine. The IR spectrum of **1** shows ν_{NH} at 3218 cm^{-1} and the ^{31}P NMR spectrum of **1** exhibits a single resonance at 35.2 ppm. The structural composition was further confirmed by mass spectral and micro analytical data.

The reaction of **1** with two equivalents of paraformaldehyde affords the P–N bond inserted product, 1,3-$C_6H_4(N(H)CH_2P(O)Ph_2)_2$ (**2**) similar to the analogous reaction of $Ph_2PNC_2H_4NPPh_2$ with paraformaldehyde, reported earlier [7b]. The reaction of **1** with one equivalent of paraformaldehyde did not give a monofunctionalized product of the type $Ph_2PN(H)C_6H_4N(H)CH_2P(O)Ph_2$, instead compound **2** was obtained in 35% yield with half of the reactant **1** left unreacted in the solution. The ^{31}P NMR spectrum of **2** shows a single resonance at 28.7 ppm and the methylene protons appear at 2.39 ppm in its ^1H NMR spectrum. Interestingly, the reaction of 1,2-$C_6H_4(N(H)PPh_2)_2$ with two equivalents of paraformaldehyde afforded a similar product but containing three methylene groups as indicated by its ^1H NMR spectrum (Scheme 1). When the reaction was carried out using three equivalents of paraformaldehyde the yield was almost quantitative indicating the insertion of two methylene groups into two P(III)–N bonds and another one between two nitrogen centers through nucleophilic addition to give a product of the type, 1,2-$C_6H_4\{N(CH_2P(O)Ph_2)(\mu\text{-}CH_2)N(CH_2P(O)Ph_2)\}$ (**3**) in quantitative yield. The ^{31}P NMR spectrum of **3** shows a single resonance at 26.6 ppm. In the ^1H NMR spectrum of **3**, the protons due to the methylene groups inserted into the P–N bonds appear at 3.82 ppm as broad singlets, whereas the bridging methylene protons resonate at 4.96 ppm. When the aminophosphines are treated with aromatic aldehydes, the 'CH(R)' groups insert into the P–N bonds followed by oxidation of the phosphorus from P(III) to P(V), whereas aliphatic aldehydes, such as butylaldehyde, afford an α-hydroxy phosphine oxide through P–N bond cleavage [7b]. The reactions of $Ph_2PN(H)Ph$ with RCHO afford P–N inserted products $Ph_2P(O)CH(R)N(H)Ph$ (R = C_6H_4OH-*o*, **4**; 5-BrC_6H_3OH-*p*, **5**; $(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)$, **6**) in 65–85% yield as shown in Eq. (1).

Scheme 1.

The ^{31}P NMR spectra of compounds **5** and **6** show single resonances at 37.8 and 29.2 ppm, respectively. The ^1H NMR spectrum of **5** shows a doublet at 5.5 ppm for the CH protons with a $^2J_{PH}$ coupling of 5.9 Hz whereas for **6** the analogous signal appears as a broad singlet at 5.1 ppm. The spectroscopic data of **4** is given in our previous report [7b].

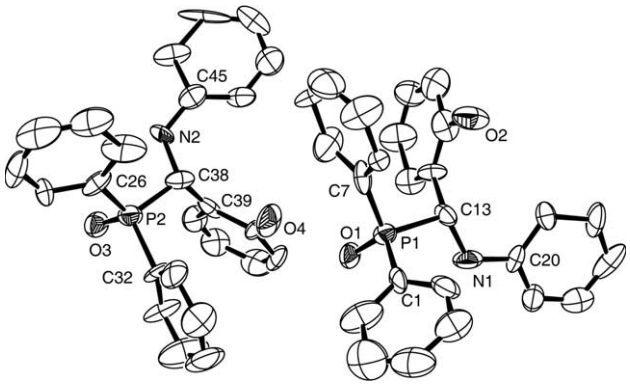
R = C_6H_4OH-*o*, **4**
5-Br-C_6H_3OH-*o*, **5**
$(C_5H_5)Fe(C_5H_4)$, **6**

The structure of $Ph_2P(O)CH(C_6H_4OH\text{-}o)N(H)Ph$ (**4**) was confirmed by single crystal X-ray diffraction studies and is shown in Fig. 1. Crystal data and the details of the structure determination are given in Table 1 while selected bond lengths and inter bond angles are listed in Table 2. The asymmetric unit of compound **4** contains two identical independent molecules but the corresponding bond lengths and bond angles are not significantly different. The P–O bond distances are P(1)–O(1) = 1.522(9), P(2)–O(3) = 1.458(9) Å and the P–C bond distances are in the range 1.720(14)–1.872(11) Å. The geometry around the nitrogen is strictly planar and the sum of the angles is 360°. Although in the lattice the molecules exhibit intra and inter molecular O–H···O type interactions, they are not significantly prominent.



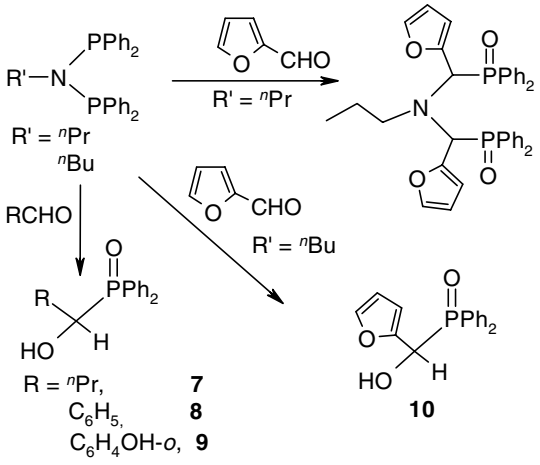


Fig. 1. Molecular structure of $Ph_2P(O)CH(C_6H_4OH\text{-}o)N(H)Ph$ (**4**) with the atom numbering scheme. The ellipsoids are drawn at the 50% probability level.

C(20)–N(1)–C(13)	120.0(10)	C(45)–N(2)–C(38)	121.3(10)

The reactions of $^nBuN(PPh_2)_2$ with RCHO (R = ^{n}Pr, Ph, $C_6H_4OH\text{-}o$, OC_4H_3) gave α-hydroxy phosphine oxides, $Ph_2P(O)CH(OH)R$ (R = ^{n}Pr, **7**; Ph, **8**; $C_6H_4OH\text{-}o$, **9**; OC_4H_3, **10**) in 40–45% yields (Scheme 2). The formation of these products may be due to the prior cleavage of the P–N bond through the elimination of primary amine to form $Ph_2P(O)H$, which then reacts with the aldehyde to give $Ph_2P(O)CH(OH)R$. Compounds **7**–**10** show ν_{OH} around 3200–3250 cm^{-1} in their IR spectra. The ^{31}P NMR spectra of **7**–**10** show a single resonance in the range of 30–37 ppm and the ^1H NMR spectra show doublets around 4.4–5.5 ppm for the CH proton, with $^2J_{PH}$ couplings in the range of 5–10 Hz.

The structure of $Ph_2P(O)CH(OH)C_6H_4OH\text{-}o$ (**9**) is established by single crystal X-ray diffraction studies and the perspective view of the molecule is shown in Fig. 2. The crystallographic data, selected bond distances and inter bond angles are listed in Tables 1 and 3, respectively. The asymmetric unit contains two identical independent molecules but the corresponding bond distances and bond angles are very similar. The structure of **9** shows a distorted tetrahedral geometry around the phosphorus centers. The P=O bond distance varies

Scheme 2.

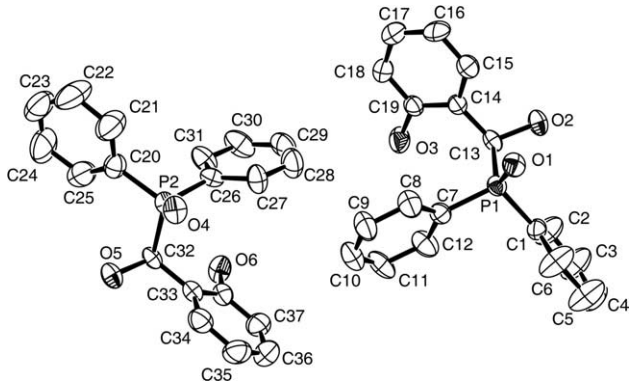

Fig. 2. Molecular structure of $Ph_2P(O)CH(OH)C_6H_4OH$-*o* (**9**) with the atom-numbering scheme.

from 1.486(2) to 1.495(4) Å and the P–C bond distances are in the range of 1.785(5)–1.829(3) Å.

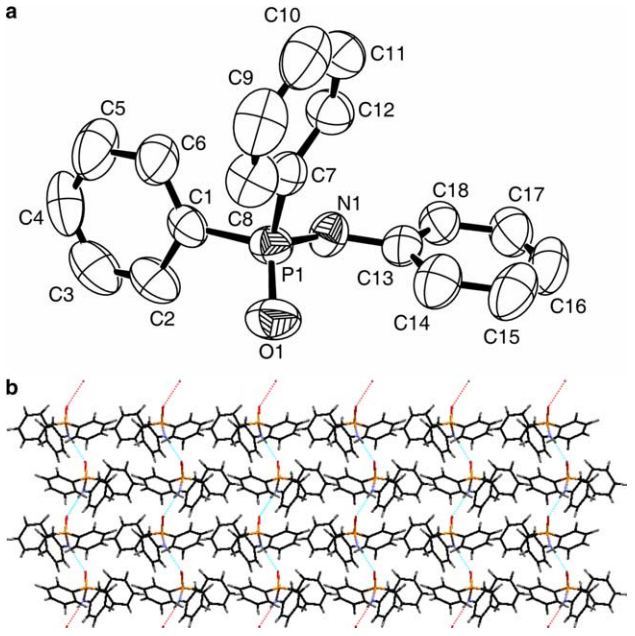
The reactions of the corresponding aminobis(phosphines), $^{n}PrN(PPh_2)_2$ with aldehydes in a 1:2 ratio proceeds in a similar way as described earlier [7b] to give the corresponding α-hydroxy phosphine oxides through P(III)–N bond cleavage, except furfural. The reaction of furfural with the *n*-butyl derivative, $^{n}BuN(PPh_2)_2$, leads to the P(III)–N bond cleavage product, $Ph_2P(O)CH(C_4H_3O)OH$, whereas the *n*-propyl derivative gives the P–N insertion product, $^{n}PrN\{CH(C_4H_3O)P(O)Ph_2\}_2$.

2.1. Reactions of aminophosphines with ketones

The reactions of aminophosphines and aminobis(phosphines) with aldehydes led to the isolation of either P(III)–N bond inserted products or α-hydroxyphosphine oxides via P(III)–N bond cleavage. In order to get more insight into the reactivity of P(III)–N bonds, similar reactions with ketones were carried out with *N*-phenyldiphenylphosphinous amide, $Ph_2PN(H)Ph$ as a representative example.

The reactions of $Ph_2PN(H)Ph$ with aliphatic ketones such as 2-butanone, 4-methyl-2-pentanone and 4-hydroxy acetophenone yielded only the phosphine oxide, $Ph_2P(O)N(H)Ph$ (**11**). The ^{31}P NMR spectrum of **11** shows a single resonance at 18.5 ppm. The structure of **11** was confirmed by a single crystal X-ray structure determination. A perspective view of the molecule **11** is shown in Fig. 3(a) and the selected bond distances and bond angles are given in Table 4. The P–O and P–C distances are comparable with the literature for compounds of a similar type [9–12]. The phosphorus is in a tetrahedral environment as in other phosphine oxides. Compound **11** shows intermolecular P=O...H–N type hydrogen bonding interaction [$d_{H(IN)-O(1)}$ = 2.06(5) Å; $d_{N(1N)-O(1)}$ = 2.807(6) Å; N(1)–H(1N)–O(1) = 169(5)°], thus resulting in a zig-zag arrangement in the lattice as shown in Fig. 3(b).

The reaction of $Ph_2PN(H)Ph$ with benzophenone afforded tetraphenyl diphosphine monoxide $Ph_2PP(O)Ph_2$ (**12**) through P–N bond cleavage as shown in Scheme 3. The formation of product **12** was confirmed



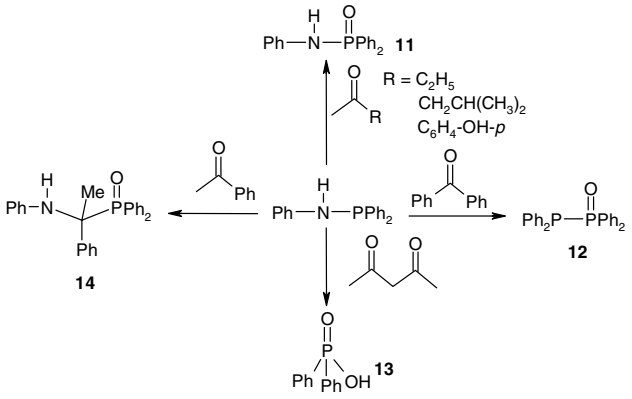


Fig. 3. (a) Molecular structure of $Ph_2P(O)N(H)Ph$ (**11**) with the atom-numbering scheme. (b) Intermolecular hydrogen bonding interaction of P=O of one molecule with N–H of an adjacent molecule in a zig-zag arrangement (view down crystallographic axis *a*).

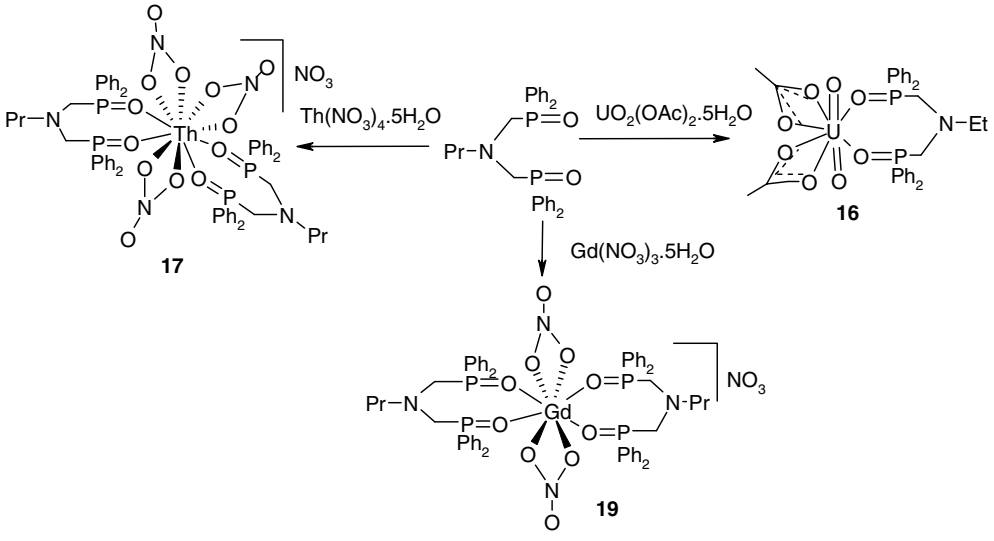

Scheme 3.

by ^{31}P NMR spectral data, which shows two doublets at 36.7 and −21.7 ppm for the P(III) and P(V) centers, respectively with a $^{1}J_{PP}$ coupling of 228 Hz. The reaction of $Ph_2PN(H)Ph$ with acetyl acetone lead to the formation of $Ph_2P(O)OH$ (**13**) through P–N bond cleavage. Compound **13** exhibits a single resonance in its ^{31}P NMR spectrum at 29.6 ppm. When $Ph_2PN(H)Ph$ was treated with acetophenone, insertion of 'C(Me)Ph' into the P–N bond takes place, to afford $Ph_2P(O)C(Me)(Ph)N(H)Ph$ (**14**) in good yield (Scheme 3). The ^{31}P NMR spectrum of **14** shows a single resonance at 29.9 ppm. The structural composition of **14** was further supported by ^{1}H NMR and mass spectral data and by elemental analysis (Scheme 4).

2.2. Coordination chemistry

The phosphine oxides readily react with oxophilic metals to give coordination complexes [13]. The reactions of $Ph_2P(O)CH_2N(H)Ph$ and $(Ph_2P(O)CH_2)_2NEt$ with uranyl acetate in dichloromethane yielded eight-coordinate complexes, *trans*-$[UO_2(OAc)_2\{(Ph_2P(O)CH_2N(H)Ph)_2$-κO,κO$\}]$ (**15**) and *trans*-$[UO_2(OAc)_2\{(Ph_2P(O)CH_2)_2NEt$-κO,κO$\}]$ (**16**), respectively in good yields. The IR spectra of complexes **15** and **16** show a low frequency shift for P=O (∼15 cm^{-1}) compared to the free ligands indicating the coordination to the metal centre. The ^{31}P NMR spectra of complexes **15** and **16** show single resonances at 46.8 and 46.6 ppm, which are considerably deshielded compared to the free ligand values, with coordination shifts of 17.3 and 16.4 ppm, respectively.

The reactions of $(Ph_2P(O)CH_2)_2N^nPr$ with $Th(NO_3)_4 \cdot 5H_2O$ affords a 10-coordinate complex, $[Th(NO_3)_3\{(Ph_2P(O)CH_2)_2N^nPr\}_2](NO_3)$ (**17**). The ^{31}P NMR spectrum of **17** shows a single resonance at 40.1 ppm with a coordination shift of 11 ppm. The IR and ^{1}H NMR spectral data and the micro-analytical data support the proposed structure. The mass spectrum of **17** shows *m*/*z* at 1392 corresponding to the cation. Similarly the reaction of $Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5))N(H)Ph$ (**6**) with $Th(NO_3)_4 \cdot 5H_2O$ in a 4:1 ratio affords a 10-coordinate complex, $[Th(NO_3)_3\{Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5))N(H)Ph\}_4](NO_3)$ (**18**). The ^{31}P NMR spectrum of **18** shows two resonances at 23.9 and 28.2 ppm (broad) whereas the free ligand resonates at −29.2 ppm. The IR and ^{1}H NMR spectral data and the micro-analytical data support the proposed structure. The mass spectrum of **18** shows *m*/*z* at 1394 corresponding to the cation. The reaction of $(Ph_2P(O)CH_2)_2N^nPr$ with $Gd(NO_3)_3 \cdot 5H_2O$ affords an 8-coordinate complex, $[Gd(NO_3)_2\{(Ph_2P(O)CH_2)_2N^nPr\}_2](NO_3)$ (**19**). The ^{31}P NMR spectrum of **19** shows a single resonance at 28.1 ppm. The mass spectrum of **19** shows *m*/*z* at 1256 corresponding to the cation.

Scheme 4.

The reaction of two equivalents of $Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_4))N(H)Ph$ (**6**) with $Co(NO_3)_2 \cdot 6H_2O$ gave a purple coloured octahedral complex, $[Co(NO_3)_2\text{-}\{Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5))NHPh\}_2]$ (**20**) in good yield. The ^{31}P NMR spectra of **20** shows a broad peak around 39 ppm due to the paramagnetic nature of the complex. IR and micro analytical data are consistent with the proposed structure.

3. Conclusions

The reactions of aminophosphines with aldehydes give either P–N inserted products or P–N cleavage products. P–N insertion reactions provide a new route to phosphorus–carbon bond formation whereas P–N cleavage reactions provide α-hydroxy phosphine oxides which can serve as valuable synthons [14] in asymmetric synthesis. Further, P–N inserted products can be used as ligands with oxophilic metal centers. The reactions of both aliphatic and aromatic aldehydes with $^nBuN(PPh_2)_2$ lead to α-hydroxy phosphine oxides via P–N bond cleavage whereas the *n*-propyl derivative gives a P–N inserted product with furfural and α-hydroxy derivatives with other aldehydes. It is observed that these reactions mainly depend on the oxidation state of the phosphorus center and not on the acidic proton present on the nitrogen center. The reactivity also depends on the nature of nitrogen substituents in the aminophosphines. Further investigations to understand the influence of phosphorus substituents on product formation are in progress in our laboratory. Also, this methodology can be adopted to obtain mixed donor ligands which have potential applications in homogeneous catalysis and also in asymmetric synthesis [15].

4. Experimental

All the solvents were purified by conventional procedures and distilled prior to use. $PhN(H)PPh_2$ [16], $RN(PPh_2)_2$ (^nPr, ^nBu [17]) and $1,2\text{-}Ph_2PN(H)C_6H_4\text{-}N(H)PPh_2$ [18] were prepared according to the literature procedures. $Ph_2P(O)CH_2N(H)Ph$ and $[Ph_2P(O)CH_2]_2\text{-}N^nPr$ were prepared as described in our previous report [7b]. 5-Bromo salicylaldehyde was prepared following the reported procedure [19], and all other aldehydes were used after purification except ferrocene carboxaldehyde (Strem). Metal salts were purchased from Loba Chemicals, India and used with out further purification. The ^1H and ^{31}P NMR spectra were recorded using VXR 300 S and Bruker spectrometers; Me_4Si was used as an internal standard for the ^1H NMR and 85% H_3PO_4 as external standard for the ^{31}P NMR. Positive values indicate downfield shifts. IR spectra were recorded on a Nicolet Impact 400 FT IR instrument in KBr disks. Microanalyses were performed on a Carlo Erba model 1112 elemental analyser. The FAB mass spectra were recorded on a JEOL SX 102/DA-6000 mass spectrometer/Data system using Argon/Xenon (6 kV, 10 mA) as the FAB gas. Melting points were recorded in capillary tubes and are uncorrected.

4.1. $1,3\text{-}C_6H_4\{N(H)PPh_2\}_2$ (**1**)

To a solution of *m*-phenylene diamine (1.0 g, 9.24 mmol), Et_3N (1.87 g, 18.4 mmol) and 4-dimethylaminopyridine (0.038 g, 0.31 mmol) in THF (30 mL) at 0 °C, was added dropwise a solution of Ph_2PCl (4.08 g, 18.4 mmol) in THF (20 mL). The reaction mixture was stirred at room temperature for 4 h, the solution was then filtered through celite and the filtrate was concentrated and cooled to give an analytically pure sample of **1**. Yield: 46% (2.02 g, 4.23 mmol), m.p.: 88–92 °C. *Anal*. Calc. for $C_{30}H_{26}N_2P_2$: C, 75.61; H, 5.50; N, 5.88. Found: C, 75.91; H, 5.39; N, 5.83%. FTIR (KBr disk) cm^{-1}: ν_{NH} 3218 s. ^1H NMR ($CDCl_3$): δ 7.21–7.55 (m, *phenyl*). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 35.2 (s). MS (HRMS): 476.16 (M^+).

4.2. $1,3\text{-}C_6H_4\{N(H)CH_2P(O)Ph_2\}_2$ (**2**)

A mixture of 1,3-*N*,*N*′-bis(diphenylphosphino)-diaminobenzene (0.20 g, 0.419 mmol) and paraformaldehyde (0.025 g, 0.839 mmol) in 7 mL of toluene was heated under reflux conditions for 10 h and cooled to room temperature. The solvent was removed under reduced pressure and the residue obtained was washed with hexane (4 × 3 mL) and re-dissolved in a mixture of CH_2Cl_2-hexane (2:1) to give the crystalline product **2**. Yield: 72% (0.160 g, 0.298 mmol), m.p.: 133–136 °C. *Anal*. Calc. for $C_{32}H_{30}N_2O_2P_2$: C, 71.62; H, 5.64; N, 5.22. Found: C, 71.92; H, 5.31; N, 5.25%. FTIR (KBr disk) cm^{-1}: ν_{PO} 1174 s. ^1H NMR (CD_2Cl_2): δ 2.39 (s, CH_2, 4H), 7.15–7.99 (m, *phenyl*, 24H). $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ 28.7 (s). MS (HRMS): 536.18 (M^+).

4.3. $1,2\text{-}C_6H_4NCH_2N(CH_2P(O)Ph_2)_2$ (**3**)

A mixture of 1,2-*N*,*N*′-bis(diphenylphosphino)-diaminobenzene S(0.20 g, 0.419 mmol) and paraformaldehyde (0.037 g, 1.257 mmol) in toluene (7 mL) was refluxed for 10 h. From the cooled reaction mixture, solvent was removed under reduced pressure and the residue obtained was washed with hexane (4 × 3 mL) and redissolved in a mixture of CH_2Cl_2-*n*-hexane (2:1) to give the crystalline product **3**. Yield: 52% (0.120 g, 0.219 mmol), m.p.: 169–172 °C. *Anal*. Calc. for $C_{33}H_{30}N_2O_2P_2$: C, 72.25; H, 5.51; N, 5.11. Found: C, 72.19; H, 5.31; N, 5.17%. FTIR (KBr disk) cm^{-1}: ν_{PO} 1180 s. ^1H NMR ($CDCl_3$): δ 3.82 (br s, P–CH_2–N,

4H), 4.96 (s, N–CH_2–N, 2H), 6.34–8.65 (m, *phenyl*, 24H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 26.6 (s). MS (FAB): 547.21 ($M^+ - 1$).

4.4. General procedure for the preparation of $Ph_2P(O)$-$CH(R)NHPh$ (R = 5-Br-C_6H_3OH-*o*, ferrocenyl)

A mixture of $Ph_2PN(H)Ph$ (0.40 g, 1.44 mmol) and one equivalent of aldehyde, RCHO was stirred at room temperature for 12 h. The resultant slurry was subjected to a vacuum to remove any volatiles and the residue obtained was washed with *n*-hexane (3×5 mL) and crystallized in a mixture of CH_2Cl_2-*n*-hexane (2:1) at 0 °C to give analytically pure products.

4.5. $Ph_2P(O)CH(5\text{-}Br\text{-}C_6H_4OH\text{-}o)N(H)Ph$ (**5**)

Yield: 61% (0.215 g, 0.450 mmol), m.p.: 183–188 °C. *Anal*. Calc. for $C_{25}H_{21}NO_2BrP$: C, 62.78; H, 4.43; N, 2.93. Found: C, 62.79; H, 4.55; N, 2.83%. FTIR (KBr disk) cm^{-1}: ν_{OH} 3382 br s, ν_{NH} 3053 s, ν_{PO} 1150 vs. ^1H NMR ($CDCl_3$): δ 4.68 (br s, N*H*, D_2O exchangeable), 5.49 (dd, C*H*, $^2J_{PH}$ = 5.9 Hz, 1H), 6.60–7.79 (m, *phenyl*, 18H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 37.8 (s).

4.6. $Ph_2P(O)CH\{(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)\}N(H)Ph$ (**6**)

Yield: 66% (0.230 g, 0.500 mmol), m.p.: 175–178 °C. *Anal*. Calc. for $C_{29}H_{26}NOPFe$: C, 70.89; H, 5.33; N, 2.85. Found: C, 70.82; H, 5.36; N, 2.80%. FTIR (KBr disk) cm^{-1}: ν_{NH} 3426 s, ν_{PO} 1173 vs. ^1H NMR ($CDCl_3$): δ 3.90–4.98 (m, *ferrocenyl*, 9H), 5.01 (br s, C*H*, 1H), 6.68–7.72 (m, *phenyl*, 15H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 29.2 (s).

4.7. General procedure for the reaction of $^nBuN(PPh_2)$ ($R = {}^nPr$,) with $R'CHO$ ($R' = {}^nPr$, Ph, OC_4H_3, C_6H_4OH-*o*)

A mixture of $Ph_2PN(^nBu)PPh_2$ (0.400 g, 0.94 mmol) and two equivalents of aldehyde, RCHO (R = ^{n}Pr, Ph, OC_4H_3 and C_6H_4OH-*o*) was stirred at room temperature for 24 h. The resultant slurry was subjected to a vacuum to remove any volatiles and the residue obtained was washed with *n*-hexane (3×5 mL) and crystallized in a mixture of CH_2Cl_2-*n*-hexane (2:1) at 0 °C to give analytically pure products.

4.8. $Ph_2P(O)CH(OH)CH_2CH_2CH_3$ (**7**)

Yield: 42% (0.215 g, 0.784 mmol), m.p.: 116–118 °C. *Anal*. Calc. for $C_{16}H_{19}O_2P$: C, 70.06; H, 6.98. Found: C, 70.67; H, 6.87%. FTIR (KBr disk) cm^{-1}: ν_{OH} 3207 s, ν_{PO} 1179 vs. ^1H NMR ($CDCl_3$): δ 0.85 (t, CH_3, $^3J_{HH}$ = 6.32 Hz, 3H), 1.38 (m, CH_2, 2H), 1.65 (m, CH_2, 2H), 1.73 (br s, O*H*, D_2O exchangeable, 1H), 4.41 (d, C*H*, $^2J_{PH}$ = 10.32 Hz, 2H), 7.43–7.89 (m, *phenyl*, 10H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 31.3 (s).

4.9. $Ph_2P(O)CH(OH)Ph$ (**8**)

Yield: 51% (0.291 g, 0.944 mmol), m.p.: 164–166 °C (dec.). *Anal*. Calc. for $C_{19}H_{17}O_2P$: C, 74.01; H, 5.56. Found: C, 73.86; H, 5.49%. FTIR (KBr disk) cm^{-1}: ν_{OH} 3388 s, ν_{PO} 1163 vs. ^1H NMR ($CDCl_3$): δ 1.83 (br s, OH, D_2O exchangeable), 5.48 (d, C*H*, $^2J_{HH}$ = 5.24 Hz, 1H), 7.13–7.90 (m, *phenyl*, 15H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 30.6 (s).

4.10. $Ph_2P(O)CH(OH)C_6H_4OH$-*o* (**9**)

Yield: 51% (0.311 g, 0.959 mmol), m.p.: 90–92 °C. *Anal*. Calc. for $C_{19}H_{17}O_3P$: C, 70.37; H, 5.28. Found: C, 70.25; H, 5.33%. FTIR (KBr disk) cm^{-1}: ν_{OH} 3229 br s, ν_{PO} 1139 vs. ^1H NMR ($CDCl_3$): δ 4.01 (br s, OH, D_2O exchangeable), 5.45 (d, C*H*, $^2J_{PH}$ = 5.86 Hz, 1H), 6.67–7.82 (m, *phenyl*, 14H), 9.65 (br s, O*H*, D_2O exchangeable). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 37.4 (s).

4.11. $Ph_2P(O)CH(OH)(OC_4H_3)$ (**10**)

Yield: 77% (0.313 g, 1.050 mmol), m.p.: 148–151 °C. *Anal*. Calc. for $C_{17}H_{15}O_3P$: C, 68.45; H, 5.06. Found: C, 68.32; H, 4.93%. FTIR (KBr disk) cm^{-1}: ν_{OH} 3380 br s, ν_{PO} 1154 vs. ^1H NMR ($CDCl_3$): δ 4.77 (br s, OH, D_2O exchangeable), 5.59 (d, C*H*, $^2J_{PH}$ = 5.5 Hz, 1H), 6.23–6.29 (m, *furfuryl*, 2H), 7.18–7.88 (m, *phenyl* & *furfuryl*, 11H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 31.5 (s).

5. Reaction of aminophosphines with ketones

5.1. Reaction of $Ph_2PN(H)Ph$ with $CH_3C(O)R$ ($R = C_2H_5$, $CH_2CH(CH_3)_2$, C_6H_4OH-*p*)

A mixture of $Ph_2PN(H)Ph$ (0.400 g, 1.44 mmol) and $CH_3C(O)R$ (1.44 mmol) in toluene (10 mL) was stirred at room temperature for 10 h. The solution was evaporated under reduced pressure and the residue obtained was crystallized from a 1:1 mixture of CH_2Cl_2–petroleum ether at 0 °C to give analytically pure $Ph_2P(O)N(H)Ph$ (**11**). Yield: 47% (0.20 g, 0.682 mmol) (for $R = C_2H_5$); 55% (0.23 g, 0.784 mmol) (for $R = CH_2CH(CH_3)_2$); 50% (0.21 g, 0.716 mmol) (for $R = C_6H_4OH$-*p*), m.p.: ~230 °C (dec.). *Anal*. Calc. for $C_{18}H_{16}NOP$: C, 73.70; H, 5.49; N, 4.78. Found: C, 73.63; H, 5.55; N, 4.59%. FTIR (KBr disk) cm^{-1}: ν_{NH} 3121 s, ν_{PO} 1183 vs. ^1H NMR ($CDCl_3$): δ 4.39 (d, N*H*, D_2O exchangeable, 1H), 6.70–7.13 (m, N*Ph*, 5H), 7.15–7.77 (m, PPh_2, 10H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 18.5 (s).

5.2. Reaction of $Ph_2PN(H)Ph$ with benzophenone

A mixture of $Ph_2PN(H)Ph$ (0.200 g, 0.7 mmol) and benzophenone (0.131 g, 0.7 mmol) was heated to 75–80 °C with stirring. The melt was cooled to room temperature after 4 h and the volatiles were removed under reduced pressure to give a white residue. The residue obtained was crystallized from CH_2Cl_2–petroleum ether (2:1) mixture at 0 °C to get analytically pure $Ph_2PP(O)Ph_2$ (**12**). Yield: 94% (0.131 g, 0.34 mmol), m.p.: 152–154 °C. *Anal.* Calc. for $C_{24}H_{20}OP_2$: C, 74.62; H, 5.22. Found: C, 74.69; H, 5.33%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ −21.7 (d), 36.7(d); $^1J_{PP}$ = 228.3 Hz.

5.3. Reaction of $Ph_2PN(H)Ph$ with acetylacetone

To a solution of $Ph_2PN(H)Ph$ (1.00 g, 3.60 mmol) in toluene (10 mL) was added acetylacetone (0.360 g, 3.60 mmol) also in toluene (5 mL) and the reaction mixture was stirred at room temperature for 12 h. The solution was then concentrated to 3 mL, diluted with diethyl ether (7 mL) and on storing the solution at room temperature yielded an analytically pure sample identified as $Ph_2P(O)OH$ (**13**). Yield: 77% (0.590 g, 2.70 mmol), m.p.: 170–172 °C (dec.). FTIR (KBr disk) cm^{-1}: ν_{PO} 1181 s. ^1H NMR ($CDCl_3$): δ 7.45–7.88 (m, *phenyl*). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 29.6 (s). MS (FAB): 218.67 (M^+).

5.4. Reaction of $Ph_2PN(H)Ph$ with acetophenone

To a solution of $Ph_2PN(H)Ph$ (0.400 g, 1.44 mmol) in toluene (10 mL), was added acetophenone (0.173 g, 1.44 mmol) and the reaction mixture was allowed to stir at room temperature for 12 h. The solution was then concentrated to 3 mL, diluted with diethyl ether (10 mL) and cooled to 0 °C to give analytically pure $Ph_2P(O)C(CH_3)PhN(H)Ph$ (**14**). Yield: 46% (0.320 g, 0.660 mmol), m.p.: 156–158 °C (dec.). *Anal.* Calc. for $C_{26}H_{24}NOP \cdot CH_2Cl_2$: C, 67.23; H, 5.43; N, 2.90. Found: C, 67.49; H, 5.24; N, 2.79%. ^1H NMR ($CDCl_3$): δ 1.25 (s, CH_3, 3H), 6.91–6.97 (m, *phenyl*, 5H), 7.10–7.92 (m, *phenyl*, 15H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 29.9 (s). MS (FAB): 395 ($M^+ - 2$).

5.5. $[UO_2(CH_3COO)_2(Ph_2P(O)CH_2N(H)Ph)_2]$ (**15**)

Uranyl acetate (0.10 g, 0.23 mmol) in methanol (5 mL) was added to $Ph_2P(O)CH_2N(H)Ph$ (0.146 g, 0.47 mmol) also in methanol (5 mL) and the yellow solution obtained was stirred at room temperature for 2 h. The solvent was evaporated under reduced pressure and the residue was washed with *n*-hexane (2 × 5 mL) and dried to give the crystalline product **15**. Yield: 77% (0.184 g, 0.180 mmol), m.p.: 72–74 °C (dec.). *Anal.* Calc. for $C_{42}H_{42}N_2O_8P_2U$: C, 50.31; H, 4.22; N, 2.79. Found: C, 50.32; H, 4.16; N, 2.67%. FTIR (KBr disk) cm^{-1}: ν_{NH} 3291 s, ν_{CO} 1612 s, ν_{PO} 1138 s. ^1H NMR ($CDCl_3$): δ 0.73 (br s, CH_3, 6H), 4.51 (br s, CH_2, 4H), 6.70–7.60 (m, *phenyl*, 30H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 46.9 (s).

5.6. $[UO_2(CH_3COO)_2\{(Ph_2P(O)CH_2)_2NEt\}]$ (**16**)

A solution of $EtN(CH_2P(O)Ph_2)_2$ (0.056 g, 0.10 mmol) in CH_2Cl_2 (10 mL) was added to $UO_2(OAc)_2$ (0.050 g, 0.10 mmol) also in CH_2Cl_2 (10 mL) and the reaction mixture was stirred at room temperature for 6 h. The solvent was evaporated from the reaction mixture under reduced pressure and the residue obtained was re-crystallized from EtOH–diethyl ether (1:1) at 0 °C to give an analytically pure sample of **16**. Yield: 88% (0.091 g, 0.110 mmol), m.p.: 118–121 °C (dec.). *Anal.* Calc. for $C_{32}H_{35}NO_8P_2U$: C, 44.61; H, 4.09; N 1.63. Found: C, 43.92; H, 3.99; N, 1.51%. FTIR (KBr disk) cm^{-1}: ν_{PO} 1148 s, ν_{CO} 1611 m. ^1H NMR ($CDCl_3$): δ 0.89 (m, CH_3, 6H), 1.25 (s, CH_3, 3H), 2.46 (m, CH_2, 2H), 4.07 (br s, P–CH_2–N, 4H), 7.26–9.92 (m, *phenyl*, 20H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 42.4 (s).

5.7. $[Th(NO_3)_3\{(Ph_2P(O)CH_2)_2N^nPr\}_2]NO_3$ (**17**)

A solution of, $^nPrN(CH_2P(O)Ph_2)_2$ (0.170 g, 0.350 mmol) in ethanol (5 mL) was added to a solution of $Th(NO_3)_4 \cdot 5H_2O$ (0.1 g, 0.175 mmol) also in ethanol (10 mL). The clear solution was allowed to stir at room temperature for 4 h, during which time, the product precipitated out, was filtered and dried. The product was re-crystallized from CH_2Cl_2–diethylether (1:1) mixture. Yield: 76% (0.195 g, 0.121 mmol), m.p.: 109–111 °C (dec.). *Anal.* Calc. for $C_{58}H_{62}N_6O_{16}P_4Th$: C, 47.87; H, 4.29; N, 5.78%. Found: C, 48.11; H, 4.19; N, 5.94%. FTIR (KBr disk) cm^{-1}: ν_{NO3} 1529 vs, ν_{PO} 1138 vs. ^1H NMR ($CDCl_3$): δ 0.26 (t, CH_3, $^3J_{HH}$ = 7.00 Hz, 3H), 0.81(m, CH_2, 2H), 3.15 (m, CH_2, 2H), 3.97 (s, P–CH_2–N, 4H), 6.87–7.73 (m, *phenyl*, 20H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 40.1 (s). MS (FAB): 1392.4 ($M^+ - NO_3$).

5.8. $[Th(NO_3)_3\{Ph_2P(O)CH(C_5H_4FeC_5H_5)N(H)Ph\}_4]NO_3$ (**18**)

A solution of $Ph_2P(O)CH_2N(H)C_5H_4FeC_5H_5$ (0.103 g, 0.021 mmol) in CH_2Cl_2 (5 mL) was added to a solution of $Th(NO_3)_4 \cdot 5H_2O$ (0.03 g, 0.05 mmol) in ethanol (10 mL). The clear solution was allowed to stir at room temperature for 4 h, during which time, the product precipitated out, was filtered and dried. The product was re-crystallized from CH_2Cl_2–diethylether (1:1) mixture. Yield: 64% (0.082 g, 0.034 mmol), m.p.: 152–154 °C. *Anal.* Calc. for $C_{116}H_{104}N_8O_{16}P_4Fe_4Th \cdot 3CH_2Cl_2$: C, 52.93; H, 4.11; N, 4.15. Found: C, 52.74; H, 4.07; N,

4.13%. FTIR (KBr disk) cm^{-1}: ν_{NO_3} 1515 s, ν_{PO} 1138 vs. ^1H NMR ($CDCl_3$): signals are broad, so not incorporated and the ^{31}P signal is also slightly broad in this case. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 23.9 (s). MS (FAB): 2382 ($M^+ - 1 - NO_3$).

5.9. $[Gd(NO_3)_2\{(Ph_2P(O)CH_2)_2N^nPr\}_2]NO_3$ (**19**)

A solution of the dioxide, $^nPrN(CH_2P(O)Ph_2)_2$ (0.225 g, 0.460 mmol) in CH_2Cl_2 (5 mL) was added to a solution of $Gd(NO_3)_3 \cdot 5H_2O$ (0.1 g, 0.230 mmol) also in ethanol (10 mL). The clear solution was allowed to stir at room temperature for 4 h, during which time, the product precipitated out, was filtered and dried. The product was washed with diethylether and re-crystallized from MeOH–CH_2Cl_2 (1:1) mixture. Yield: 84% (0.256 g, 0.194 mmol), m.p.: 110–114 °C (dec.). *Anal.* Calc. for $C_{58}H_{62}N_5O_{13}P_4Gd \cdot CH_2Cl_2$: C, 50.50; H, 4.60; N, 4.99. Found: C, 50.37; H, 4.65; N, 4.86%. FTIR (KBr disk) cm^{-1}: ν_{NO_3} 1490 vs, ν_{PO} 1159 s. ^1H NMR (DMSO-d_6): δ 0.29 (br s, CH_3, 3H), 1.78 (br s, CH_2, 2H), 2.51 (br s, CH_2, 2H), 3.57 (br s, DMSO & P–CH_2–N), 7.48–7.79 (br m, *phenyl*, 20H). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ 28.1 (br s). MS (FAB): 1256 ($M^+ - NO_3$).

5.10. $[Co(O_2NO)_2(Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5))N(H)Ph)_2]$ (**20**)

To an ethanolic solution (5 mL) of $Co(NO_3)_2 \cdot 6H_2O$ (0.030 g, 0.10 mmol), $Ph_2P(O)CH((\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5))$-N(H)Ph (0.101 g, 0.20 mmol) also in ethanol (10 mL) was added and the mixture was stirred for 2 h at room temperature. The resultant brown solution was evaporated to dryness and the residue was washed with *n*-hexane (3 × 5 mL) to give the analytically pure product **20**. Yield: 92% (0.110 g, 0.094 mmol), m.p.: 116–120 °C (dec.). *Anal.* Calc. for $C_{58}H_{52}N_4O_8P_2CoFe_2$: C, 59.76; H, 4.49; N, 4.81. Found: C, 59.69; H, 4.56; N, 4.86%. FTIR (KBr disk) cm^{-1}: ν_{NH} 3384 br m, ν_{NO3} 1388 s, ν_{PO} 1143 vs. $^{31}P\{^1H\}$ NMR ($CDCl_3$ &DMSO-d_6): δ 38.7 (br s).

5.11. X-ray Crystallography

Crystals of compounds **4**, **9** and **11** obtained as above were mounted on pyrex resin. A Nonius MACH3 diffractometer was used for the unit cell determination and the intensity data collection. The initially obtained unit cell parameters were refined by accurately centering randomly selected reflections. Periodic monitoring of check reflections showed the stability of the intensity data. Details of crystal and data collection are given in Table 1. The structures were solved by direct methods (SHELXS 97) and refined using SHELXL 97 software [20]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All the hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

6. Supplementary material

Full details of data collection and structure refinement have been deposited with Cambridge Crystallographic Data Center, CCDC reference numbers 245668, 245669 and 245670 for compounds **4**, **9** and **11**, respectively. Copies of this information can be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit @ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Acknowledgements

We are grateful to the Department of Science and Technology (DST) and CSIR, New Delhi, India for generous support. SP thanks CSIR, New Delhi, India for JRF and SRF fellowships. The X-ray structural studies were carried out at the National Single Crystal X-ray Diffraction Facility, Indian Institute of Technology, Bombay. We also thank RSIC, Mumbai, Sophisticated Instrumentation Facility (SIF), Bangalore, for the spectral facility. The referees' suggestions at the revision stage were very helpful.

Symmetry transformations used to generate equivalent atoms: #1 $-x+2, -y+1, -z+2$.

M–X–M link by steric repulsion. One such ligand system we are focusing on is *cis*,*trans*-1,3,5-triaminocyclohexane (*tach*), a multifunctional synthon, that upon protonation can be used to engineer supramolecular solid-state structures. For instance we have recently reported a trinuclear cluster based upon *tach*, $\{(CuCl_2\text{-}(tachH))_3Cl\}$, which incorporates both coordinative and hydrogen bonds; this is because the *tach* ligand can accommodate multiple coordination modes, and its amino groups can act as both hydrogen bond donors and acceptors [11]. Under more basic conditions, the amino groups are not fully protonated and different types of discrete molecular species are formed. We herein report the reaction of *tach* and $CuCl_2$ which produces a dimeric complex of $s = 1/2$ Cu^{II} centers that features a single, linear Cu–Cl–Cu linking group (see Table 1).

2. Experimental

2.1. Materials, measurements, and calculations

cis,*trans*-1,3,5-Triaminocyclohexane (*tach*) was synthesized according to [12]; all other reagents were of analytical grade, purchased commercially and used as obtained. IR spectra were recorded on a Jasco FTIR-410 spectrometer using a *Golden Gate* single reflection diamond ATR setting for solid material. UV/VIS spectra were recorded on a Shimadzu UV-3101PC UV–VIS–NIR Scanning Spectrophotometer. Extended Hückel calculations were performed using the YAEHMOP 3.03 package [13]. The program's default parameters were employed.

2.2. Preparation of [(μ2-chloro)-di-{syn-bis(cis,trans-1,3,5-triaminocyclohexane-κ2-N,N′)-copper(II)}]-trichloride dihydrochloride (1)

A methanolic solution (15 ml) of copper(II) chloride anhydrous (58 mg, 0.43 mmol) was added to a solution of *tach* (110 mg, 0.85 mmol) in methanol (25 ml) giving an instant color change from colorless to dark blue. Reducing the volume to 2 ml and crystallization by diffusion of ether yielded dark blue crystals of **1** suitable for single crystal X-ray analysis. Amorphous material was obtained by addition of ether (10 ml) and filtration. Yield: 14 mg (0.02 mmol, 10% based on Cu) crystals, 54 mg (0.08 mmol, 37%) amorphous solid. M.p. 195 °C (dec.). The identity of **1** was confirmed by IR, UV/Vis spectroscopy and elemental analysis. IR spectrum (in cm^{-1}; s = strong, m = medium): 3217(s), 3116(s), 2920(m), 1609(s), 1558(s), 1458(s), 1346(s), 1165(s), 1119(m), 918(s). UV/Vis (MeOH) $\lambda(\varepsilon)$/nm (M^{-1} cm^{-1}): 247 (3235), 301 (1822, shoulder), 328 (1070, minimum), 355 (1518), 352 (442), 571 (106). MS (ES-TOF+) *m*/*z* (%) 491 (100, $[Cu_2(tach)_2Cl_3]^+$), 419 (5, $[Cu_2(tach)_2Cl - 2H]^+$), 356 (8, $[Cu(tach)_2Cl]^+$), 290 (32, $[Cu_2(tach)Cl - 2H]^+$), 227 (33, $[Cu(tach)Cl]^+$). Elemental analysis for $C_{24}H_{60}Cl_4Cu_2N_{12} \cdot 2HCl \cdot H_2O$ ($M = 948.72$ g mol^{-1}), found (expected) %: C, 33.36 (32.88); H, 8.09 (7.36); N, 18.88 (19.17).

2.3. Single-crystal X-ray structure

Crystallographic data was collected on a Rigaku R-axis image plate area detector (graphite monochromatized Mo Kα radiation, $\lambda = 0.71073$ Å) at 293 K on a needle-shaped single crystal with dimensions $0.3 \times 0.15 \times 0.03$ mm^3. The crystal system was found to be monoclinic, space group $P2_1/n$, $a = 8.726(2)$, $b = 18.500(4)$, $c = 13.341(3)$ Å, $\beta = 96.731(2)°$, $V = 2138.8(9)$ $Å^3$, $Z = 2$, $\rho_c = 1.473$ g cm^{-3}. A total of 9933 reflections were collected.

2.4. Magnetic measurements

Susceptibility data of a polycrystalline sample of **1** were recorded using a Quantum Design MPMS-5 SQUID magnetometer over the temperature range 2–290 K for various magnetic fields (0.1–5.0 T). All susceptibility data were corrected for diamagnetic and temperature-independent paramagnetic contributions ($\chi_{dia/TIP}$(**1**) = -410×10^{-6} emu mol^{-1}). Magnetization measurements at 2.0 and 25 K indicated the presence of a small percentage (1.5%) of an $s = 1/2$ species, which was attributed to disassociated $Cu(tach)_2$ dimer halves. Corresponding $s = 1/2$-Brillouin function fits to the

experimental field-dependence of the magnetization confirmed an isotropic g factor of 2.15. Intermolecular dipole–dipole interactions are negligible due to the large spacing between the dimeric units with closest Cu–Cu distances between neighboring $\{Cu_2Cl\}$ cations of 7.4 Å.

3. Results and discussion

3.1. Synthesis

The *tach* ligand system allows several coordination modes due to its two *cis* and one *trans* positioned amino groups that are connected to the rigid cyclohexane framework [11]. For a stoichiometric *tach*:metal cation ratio of 2:1, the preferred coordination is represented by a chelating binding mode in which the two *cis*-positioned amino groups assume an axial orientation with regard to the cyclohexane framework in its chair conformation, while the third amino group remains uncoordinated in an equatorial position. This coordination mode is targeted in the reaction of the *tach* base with copper(II) chloride in a water/methanol solution at unadjusted pH (11.0), which results in the formation of the partially protonated dinuclear copper(II) complex $[(Cu(tachH)(tach))_2(\mu\text{-}Cl)]^{5+} = \{Cu_2Cl\}^{5+}$ which was isolated as its chloride salt $[(Cu(tachH)(tach))_2(\mu\text{-}Cl)]Cl_5 \cdot H_2O$ (**1**).

3.2. Crystal structure

The single-crystal X-ray structure reveals D_{2h}-symmetric dinuclear Cu^{2+} complexes, consisting of two symmetry-equivalent halves. Two *tach* ligands coordinate to each copper center in a *syn* fashion via *bis*-bidentate coordination of two $-NH_2$ groups per *tach* molecule, with slightly elongated N–C bonds (1.501–1.511 Å) compared to the non-coordinated N–C bonds (1.478–1.500 Å). The cyclohexane ring planes of the two coordinated *tach* ligands are separated by 5.58(6) Å. This coordination mode results in a near-square-planar coordination environment around the copper(II) center (N1–N2 and N4–N5: 2.95 Å, N1–N4 and N2–N5: 2.85 Å) and the Cu position only slightly deviates from the coordination plane. Cu–N bond lengths range from 2.047 to 2.058 Å. Two of the resulting C_{2v}-symmetric Cu(*tach*)$_2$ units are then linked by a linear μ_2-bridging chloro ligand that completes the square pyramidal coordination geometry around the copper(II) centers (Fig. 1). On average, half of the non-coordinated, equatorially oriented amino residues of the *tach* ligands are protonated as shown by elemental analysis and single crystal X-ray diffraction, and **1** may be classified as a di-hydrochloride salt. As discussed above, the linear μ_2-chloro bridging motif between two copper(II) centers is rare and with a copper(II)-chloro distance of 2.646(2) Å, falls in the range observed for the few reported Cu^{II}–Cl–Cu^{II}-type

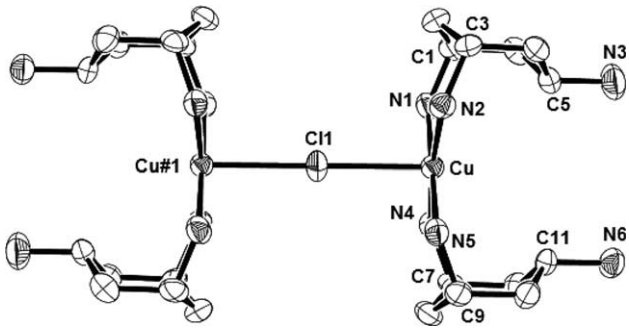

Fig. 1. Thermal ellipsoid (50%) ORTEP-3 representation of the $\{Cu_2Cl\}^{5+}$ cation in **1**, seen along one of the C_2 axes.

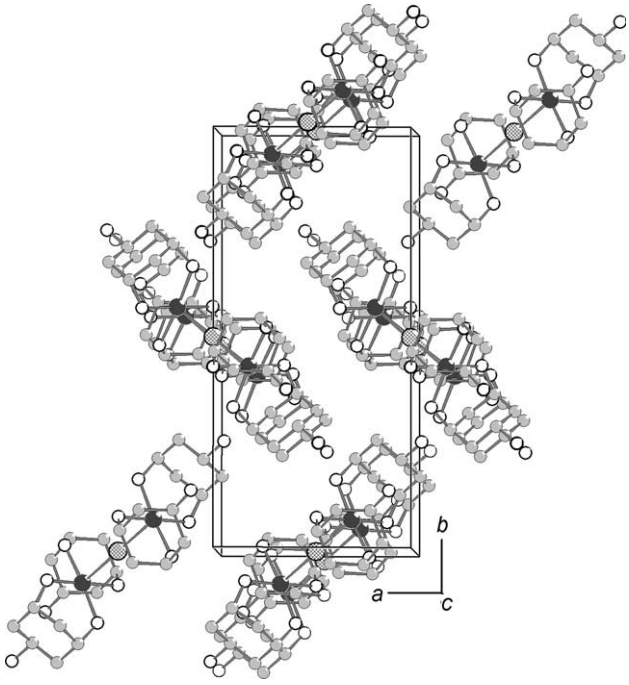

Fig. 2. Schematic representation of the $\{Cu_2Cl\}^{5+}$ dimers' packing in the crystal lattice of **1**, seen approximately along the crystallographic c axis and showing the dimensions of one unit cell (Cu: dark grey, Cl: hatched, C: grey, N: white spheres; counter ions and solvent molecules are omitted).

complexes [6–10]. In the crystal lattice of **1**, the $\{Cu_2Cl\}$ units are stacked along the crystallographic c axis in a fishbone arrangement (Fig. 2), while being hexagonally arranged around the a axis (Fig. 3).

3.3. Magnetic properties

The measured magnetic susceptibility indicates weak antiferromagnetic coupling between the two $s = 1/2$ Cu^{II} centers and follows the Curie–Weiss law with a Weiss temperature of −0.17 K. The situation of a discrete dimer of $s = 1/2$ centers can be modeled using a simple Heisenberg Hamiltonian $\boldsymbol{H} = -J\mathbf{S}_A\mathbf{S}_B$, the eigenstates of which result in the Bleaney–Bowers equation. Here,

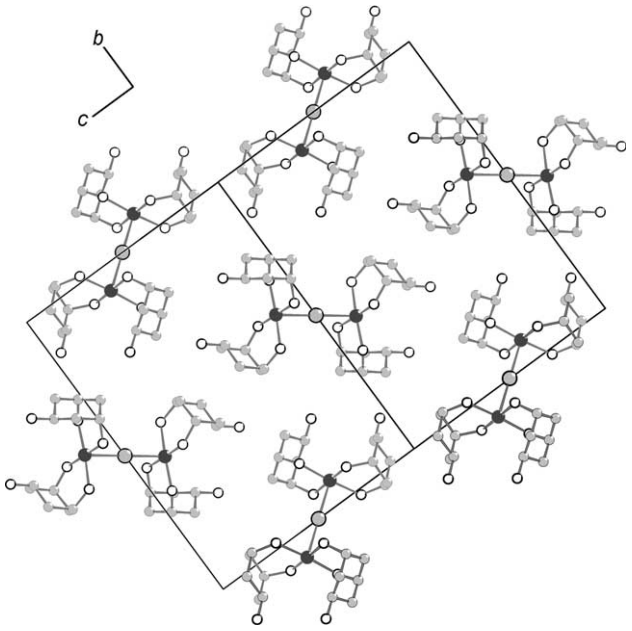

Fig. 3. Crystal packing of **1** along the crystallographic *a* axis. The $\{Cu_2Cl\}^{5+}$ cations are arranged hexagonally around the *a* axis (same codes as in Fig. 2).

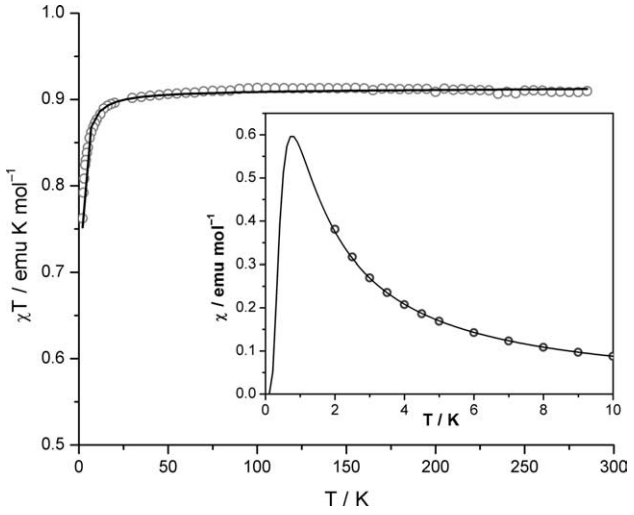

Fig. 4. Temperature dependence of χT for **1** at 0.1 T (experimental data: grey circles, data calculated from least-squares fit: solid line). Inset: the magnetic susceptibility at low temperatures displaying a maximum at 0.8 K (the experimental data was corrected for the determined paramagnetic impurity contribution, the simulated curve is correspondingly calculated for $\alpha = 0$, i.e., representing the pure dimer contribution).

a least-squares fit of the experimentally derived susceptibility data was performed using a modified Bleaney–Bowers equation

$$\chi = \frac{2N_A g^2 \mu_B^2}{kT(3 + e^{-J/kT})}(1-\alpha) + \frac{N_A g^2 \mu_B^2}{2kT}\alpha,$$

where α represents the fraction of an $s = 1/2$ impurity, i.e., dissociated dimer halves. This yielded $J/k = -1.24$ K ($J = -0.86$ cm^{-1}), an isotropic g value of $g_{iso} = 2.15$ (cmp. Section 2.4), and a paramagnetic impurity fraction of $\alpha = 1.5\%$ (Fig. 4). The least-squares fit yielded a correlation factor of 0.994. The relatively high percentage of uncoupled, paramagnetic dimer halves reflects the weak bonding via the Cu-μ-Cl–Cu bridge. The low value of the magnetic exchange can be explained by the axial Jahn–Teller distortion of the Cu^{II} coordination environment, with the nitrogen positions of the coordinating *tach* amino groups providing a strong crystal field and forming an equatorial basal plane to which the Cu–Cl bond vector is oriented perpendicular, defining the pyramidal apex. This causes the two unpaired electrons to reside in molecular orbitals of dominantly Cu(3d) $d_{x^2-y^2}$ character, interacting with the nitrogen ligands, while the (unoccupied) d_{z^2} atomic orbitals of the Cu centers that strongly interact with the Cl(2p) orbitals are only weakly mixed into the magnetic molecular orbitals, thereby limiting the magnetic exchange between the Cu centers. This ligand-field argument is also directly substantiated by simple Extended Hückel-MO calculations that verify the dominating atomic orbital contributions to the magnetically relevant frontier molecular orbitals (Fig. 5).

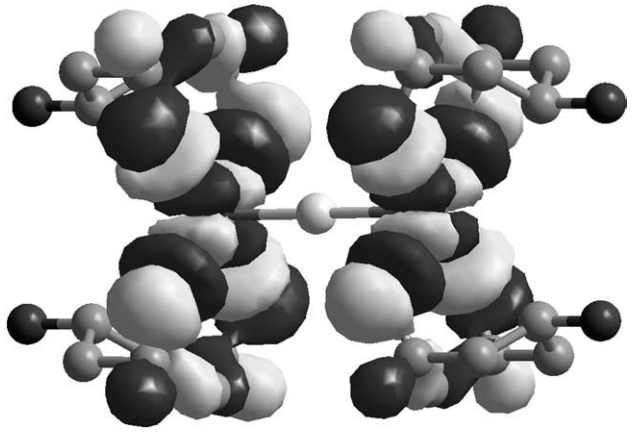

Fig. 5. An overlay representation of one of the two degenerated highest occupied molecular orbitals in the $\{Cu_2Cl\}^{5+}$ cations (omitting all H positions for clarity), illustrating the dominant $d_{x^2-y^2}$ character of these magnetic molecular orbitals.

manganese citrate coordination polymers $\{[Mn^{II}(H_2O)_6][Mn^{II}(C_6H_5O_7)(H_2O)]_2 \cdot 2H_2O\}_n$ [13] and $[Mn(C_6H_6O_7)(H_2O)]_n$ [14] are known so far. Manganese has been known to be involved in the active centers of some metalloenzymes [15]. The participation of manganese in the oxygen-evolving complex (OEC) of photosystem II (PSII) has been proven to be unequivocal and especially important [16]. It is known that the OEC is a bimetallic cluster of 4Mn/Ca, in which calcium is also essential for catalytic activity [17] and the Ca^{2+} ion is believed to be linked by a carboxylic acid residue to the Mn aggregate [18]. Recently, crystallographic data have begun to give the topological arrangement of the Ca ion in the Mn_4 cluster of the OEC [19]. There are three Mn complexes in which calcium exists as a discrete counterion [20]. Recently the Mn/Ca complex $[Mn_{13}Ca_2O_{10}(OH)_2(OMe)_2(O_2CPh)_{18}(H_2O)_4]$, containing the $[Mn_4CaO_4]$ sub-unit, has been reported by Christou [21a] and one Mn/Ca coordination polymer [21b] was also reported. We have also reported several Mn dicarboxylate complexes [22]. In the preparation of novel Mn/Ca (or alkali) bimetallic and Mn citrate complexes, a synthetic system including Mn and Ca (or alkali) metal ions and citric acid has been used. Bimetallic Mn/Ca and Mn/Na citrate and two Mn citrate coordination polymers are obtained and reported in this paper.

2. Experimental

All manipulations were performed under aerobic conditions, and all commercially available reagents were used as received. IR spectra were recorded on a Magna-75-FT-IR spectrophotometer as KBr pellets. The variable temperature susceptibility was measured on a model CF-1 superconducting magnetometer with the crystalline sample kept in a capsule at 5–300 K. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms of the complexes determined. Elemental analyses were performed by Germany Elemental Analyzer Vario EL III.

2.1. $[MnNa(Hcit)]_n$ (1)

To 15 ml of methanolic solution containing CH_3ONa (0.22 g, 4.0 mmol), 0.39 g of $MnCl_2 \cdot 4H_2O$ (2.0 mmol) and 0.42 g of citric acid monohydrate (2.0 mmol) were added. The slurry mixture was sealed into a teflon tube with a space volume of 23 ml and heated for 3 days at 160 °C under autogenous pressure. Prism light red crystals (0.20 g, yield 38%) suitable for X-ray determination were collected. *Anal.* Calc. for $C_6H_5MnNaO_7$: C, 26.99; H, 1.89; Mn, 20.58. Found: C, 27.13; H, 1.98; Mn, 21.23%. IR (KBr, cm^{-1}): 1664(m), 1606(s), 1578(s), 1541(m), 1429(s), 1408(s), 1390(m), 1340(s).

2.2. $[MnCa_2(Hcit)_2(H_2O)_4]_n$ (2)

To 15 ml of H_2O, $MnCO_3$ (0.12 g, 1.0 mmol), $Ca(NO_3)_2$ (0.32 g, 1.95 mmol) and citric acid monohydrate (0.42 g, 2.0 mmol) were added and dissolved. The solution was sealed into a teflon tube with a space volume of 23 ml and heated at 160 °C under autogenous pressure for 3 days. Colorless plate crystals (0.35 g, yield 60%) suitable for X-ray determination were collected. *Anal.* Calc. for $C_{12}H_{18}Ca_2MnO_{18}$: C, 24.62; H, 3.10; Ca, 13.69; Mn, 9.39. Found: C, 24.68; H, 3.12; Ca, 13.71; Mn, 9.35%. IR (KBr, cm^{-1}): 3480(s), 3396(s), 1616(s), 1562(s), 1537(s), 1465(m), 1429(s), 1384(s).

2.3. $[\{Mn(Hcit)(H_2O)_2\}_2Mn(H_2O)_4]_n \cdot 6nH_2O$ (3)

Citric acid (0.42 g, 2.0 mmol) and $Mn(OAc)_2 \cdot 4H_2O$ (0.25 g, 1.0 mmol) were dissolved in 15 ml of MeOH/H_2O (v/v, 2:1), then 0.22 g of MeONa (4.0 mmol) was added. The solution was sealed into a teflon tube with a space volume of 23 ml and heated at 150 °C under autogenous pressure for 3 days. Colorless rhombic crystals (0.078 g, yield 31% based on Mn used) were collected. *Anal.* Calc. for $C_{12}H_{38}Mn_3O_{28}$: C, 18.12; H, 4.82; Mn, 20.73. Found: C, 18.36; H, 4.92; Mn, 20.96%. IR (KBr, cm^{-1}): 3446(br), 3396(s), 1616(s), 1574(s), 1419(s), 1394(s), 1375(s), 525(m).

2.4. $[\{Mn(Hcit)(H_2O)_2\}_2Mn(H_2O)_2]_n \cdot 4nH_2O$ (4)

Citric acid (0.42 g, 2.0 mmol) and $Mn(ClO_4)_2 \cdot 6H_2O$ (0.36 g, 1.0 mmol) were dissolved in 30 ml of DMF and the solution was stirred at room temperature for 2 h. Then 0.27 g of imidazole (4.0 mmol) was added and continuously stirred for 14 h to resulting in a red solution, which was allowed to stand for two months to deposit colorless block crystals of **4** (0.13 g, yield 54% based on Mn used). *Anal.* Calc. for $C_{12}H_{30}Mn_3O_{24}$: C, 19.93; H, 4.18; Mn, 22.79. Found: C, 19.92; H, 4.14; Mn, 22.93%. IR (KBr, cm^{-1}): 3426(br), 3253(w), 1564(s, br), 1439(s), 1417(s), 1389(s), 521(m).

2.5. $[Mn(H_2cit)(H_2O)]_n$ (5)

The synthetic procedure of **2** was utilized in the absence of $Ca(NO_3)_2$, affording colorless insoluble prism crystals which were collected resulting in 0.22 g (yield 84%). *Anal.* Calc. for $C_6H_8MnO_8$: C, 27.39; H, 3.07; Mn, 20.88. Found: C, 27.05; H, 3.16; Mn, 20.65%. IR (KBr, cm^{-1}): 3369(br), 2973(m), 2922(m), 2809(m), 2687(m), 2618(m), 2532(m), 1733(s), 1616(s), 1562(s), 1537(s), 1465(m), 1429(s), 1384(s). The crystal structure was identified by X-ray diffraction and was found to be identical with a known compound [14]. When $MnCO_3$:

$Ca(NO_3)_2$:citric acid = 4–5:1:8, the same product **5** was also isolated.

2.6. X-ray data collection and structure determination

Crystals of **1** and **2** were mounted on a Smart CCD diffractometer and the crystals of **3** and **4** on a Rigaku AFC5R diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). Intensity data were corrected for Lorentz and polarization effects. Structure solutions and refinements were performed with the SHELXTL program [23]. Crystallographic data are given in Table 1. Hydrogen atoms were included at calculated positions with isotropic thermal parameters proportional to those of the connected atoms.

3. Results and discussion

3.1. Synthesis

This work has performed the assembly of manganese citrate complexes in which bimetallic Mn/Na or Mn/Ca citrate complexes have been obtained. In order to obtain Mn/Na bimetallic complexes, an excess of NaOMe has been used and has proved to be useful for the entering of the sodium ions into the extended structure of the coordination polymer **1**. Similarly in preparing the Mn/Ca citrate complex, a Mn/Ca mole ratio of 2:1 has been used and the Mn/Ca bimetallic complex **2** has been produced. Interestingly, various Mn salts (chloride, nitrate, sulfate and acetate) have been tried for the Mn/Ca citrate complex, however, our efforts have not yet succeeded except for using $MnCO_3$, which can react with $Ca(NO_3)_2$ in a mole radio of 1:2 leading to the formation of **2**. A similar procedure with a $MnCO_3/Ca(NO_3)_2$ mole radio of 1:1 has also produced the same complex **2** rather than a Mn_1Ca_1 complex, implying the thermodynamic stability of the $MnCa_2$ complex. We have also tried to use larger $MnCO_3/Ca(NO_3)_2$ mole radios of 4:1 or 5:1 for getting the desired Mn_4Ca_1 complex, which is a suitable bimetallic component for the OEC, however only a manganese citrate coordination polymer $[Mn(H_2cit)(H_2O)]_n$ (**5**) has been obtained. It is considered that a large amount of carbonate ions results in the deposition of $CaCO_3$, removing the calcium ion from the reaction system and leading to the lack of the calcium in the product. Another two manganese-only complexes **3** and **4** have been obtained in solvothermal and conventional solution methods, respectively. In the synthesis of **4**, imidazole has been used with the original intention to prepare a Mn citrate complex containing imidazole in the coordination sphere of the manganese. Consequently complex **4** was separated as the only product. Meanwhile for the same reaction system in the absence of imidazole it has proved to be difficult to deposit crystals of complex **4**. Perhaps imidazole is favorable to adjust the acidity of the reaction solution for the separation of **4**.

3.2. Structure

3.2.1. $[NaMn(Hcit)]_n$

The structure of **1** is represented in Fig. 1 with the simplest unit NaMn(Hcit) unit showing the coordination spheres of both Mn and Na ions. Selected bond distances and angles around the metal ions are listed in Table 2. The manganese ion locates at the center of slight distorted octahedron. Each Mn ion is surrounded by four citrates, one of which affords three oxygen atoms from two different carboxylate groups and the hydroxyl, respectively forming five- and six-membered chelating rings sharing a Mn–$O_{hydroxyl}$ edge. The tridentate chelation formed by two carboxylate groups (one central, one terminal) and one hydroxy group is the most common configuration for citrate trianion binding to a metal ion and is also found in all complexes in this work. The other three citrate trianions coordinate to the Mn ion by one carboxylate O atom. The sodium ion links five citrate trianions, each of which affords one carboxylate O atom to construct the distorted trigonal bipyramidal geometry of the sodium ion with an axial O–Na–O angle of 170.6(2)°. Double (μ-$O_{carboxylate}$)($\mu_{1,3}$-OCO) and triple (μ-$O_{carboxylate}$)$_3$ bridges exist between neighboring Mn and Na ions with the shortest Mn···Na separation of 3.223(2) Å in the Mn(μ-$O_{carboxylate}$)$_3$Na unit and 3.512(2) Å in the Mn(μ-$O_{carboxylate}$)(μ-OCO)Na unit. These units are fused to each other by edge-sharing to form a grid-like chain. Citrate trianions span between the chains by both terminal caboxylate groups as shown in Fig. 2. Two neighboring Mn ions are correlated by a carboxylate bridge in a *syn*, *anti*-mode with the shortest Mn···Mn separation of 5.44 Å. Three carboxylate arms of the citrate, together with the hydroxyl, outspread in the lattice space and link 9 metal ions (Scheme 1), constructing a complicated 3-D network structure. This is a novel coordination mode for the citrate trianion and

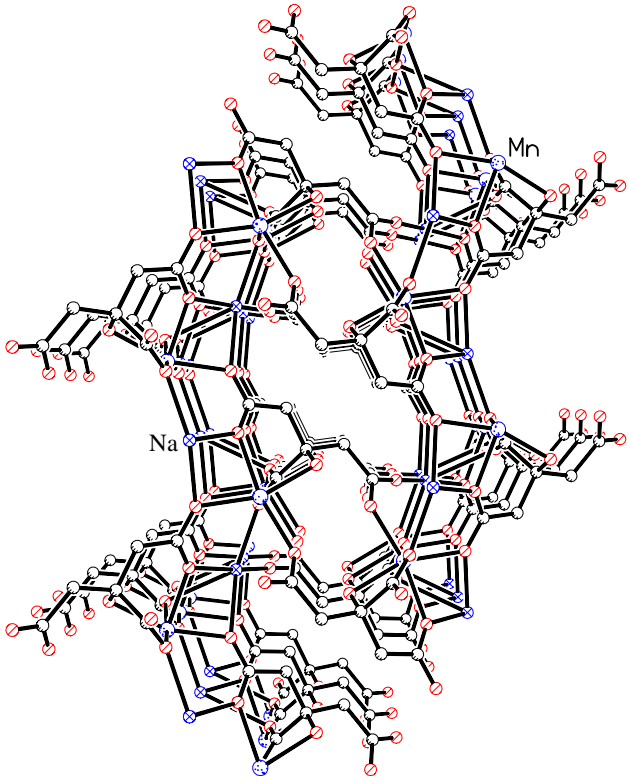

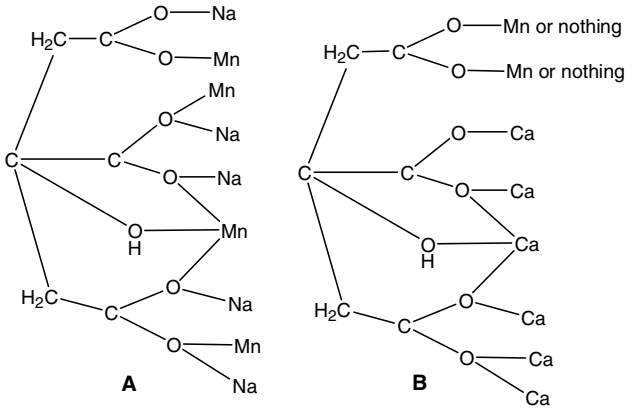

Fig. 2. View of the extended 3-D structure of $[MnNa(C_6H_4O_7)]_n$. Three carboxylate arms of the citrate together with the hydroxyl coordinate to the metal ions and outspread in the lattice space to construct a 3-D network structure.

Scheme 1. Coordination modes of the citrate in complexes **1** and **2**. (A) Nine metal ions are linked by all the seven oxygen donors of the citrate for **1** and (B) 6 Ca ions are linked by hydroxyl and two carboxylate groups leaving a carboxylate free or to link two Mn ions for **2**.

also the maximum number of the metal ions encountered so far around a citrate ligand. In order to identify the oxidation state of the Mn ion in **1**, bond valence sum (BVS) calculations [24] give a value of 2.10 for the Mn ion, indicating a 2+ oxidation state. Meanwhile, The EPR spectrum was recorded on a Bruker-ER420 spectrometer at X-band for the complex at room temperature and 77 K as solid samples, showing a strong signal at $g = 2$. Commonly, the integer spin $S = 2$Mn(III) ion is very difficult to observe with traditional perpendicular polarization EPR spectroscopy at X-band. So this also implies the existence of the Mn(II) ion rather than the Mn(III) ion in the complex. So as to keep the electroneutrality of the compound, the citrate should retain a hydroxyl proton. The Mo–$O_{hydroxyl}$ distance of 2.270(3) Å falls into the normal range found for Mn–$O_{hydroxyl}$ distances (2.166–2.278 Å) of other Mn(II) citrate complexes and is obviously larger than that of the

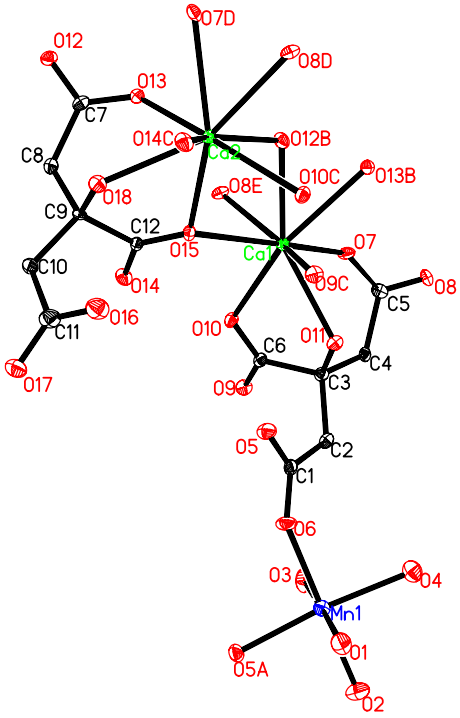

Fig. 3. The unit structure of complex **2** contains two crystallographically unique Ca(II) ions together with a Mn(II) ion in the asymmetric unit.

Mn(III) citrate complex $(NH_4)_5[Mn(C_6H_4O_7)_2]$ (1.885 Å) [12]. Moreover, the absence of characteristic IR absorptions around 1700 cm^{-1}, expected for the vibration of protonated carboxyl (COOH), indicates that all the carboxyl groups in **1** are deprotonated.

3.2.2. $[MnCa_2(Hcit)_2(H_2O)_4]_n$

Complex **2** is the third example of Mn/Ca complexes in which both Mn and Ca are correlated via ligand bridge(s). Only two such Mn/Ca bimetal complexes are

known [21]. Interestingly, the calcium citrate coordination complex has not yet been structurally characterized, though a crystal structure of Ca(H_2citrate) [25] is known in which discrete Ca^{2+} cations and the citrate dianions were found. In the structure of **2** there are two crystallographically unique Ca(II) ions together with a Mn(II) ion in the asymmetric unit. The structure of the unit is shown in Fig. 3 and selected bond distances and angles are listed in Table 3. The two independent Ca1 and Ca2 are eight-coordinate, being enclosed in the center distorted dodecahedrons with eight apices of oxygen atoms from 4–5 citrate ligands, while the coordination sphere of the Mn ion contains 2 caboxylate oxygen atoms and four aqua molecules. The Ca ions are correlated by $\mu_{1,1}$- and $\mu_{1,3}$-carboxylate bridges to create a two-dimensional Ca layer at the a-c face, while the Mn ions are linked by $\mu_{1,3}$-carboxylate bridges in a *syn–anti* configuration to form a helix chain along the *a* axis (Fig. 4 right). The Mn helix chains extend between the neighboring Ca layers. The Mn(II) and Ca(II) ions are connected by the whole citrate backbone using its carboxylate arms and the hydroxyl group, finally constructing a three dimensional architecture of the complex as shown in Fig. 4. Interestingly, both the crystallographically unique citrate ligands use the hydroxyl and two carboxylate groups to link six Ca ions by the aforementioned tridentate chelation and the μ-$O_{carboxylate}$ bridges in the same manner (Scheme 1B). While the third carboxylate group either links two Mn ions by O5 and O6 atoms (Mn1–O5A, 2.168(5) Å; Mn1–O6, 2.131(5) Å) or leaves itself free (O16 and O17 are free). Isometric C11–O17 (1.250(9) Å) and C11–O16 (1.259(10) Å) bonds support the deprotonation of the carboxyl group to which C11 belongs. Meanwhile, the absence of a characteristic COOH absorption ($\sim$1700 cm^{-1}) also implies no proton existing in all carboxyl groups. It should be pointed out that these two coordination modes shown in Scheme 1B are also novel and have not been reported previously.

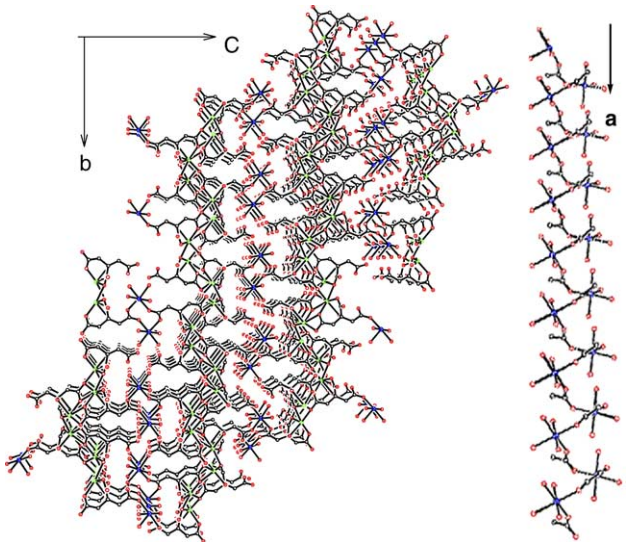

Fig. 4. The packing diagram for complex **2** exhibits a Ca_2Mn citrate sandwich array at the b-c face (left) and a [Mn($\mu_{1,3}$-OCO)]$_n$ helix chain along the *a* axis (right).

3.2.3. [{Mn(Hcit)(H_2O)$_2$}$_2$Mn(H_2O)$_4$]$_n$ · 6nH_2O (**3**) and [{Mn(Hcit)(H_2O)$_2$}$_2$Mn(H_2O)$_2$]$_n$ · 4nH_2O (**4**)

Both complexes **3** and **4** have similar formulas and contain the same Mn(Hcit)(H_2O)$_2$ structural unit with a Hcit tridentate chelation to a Mn ion. Both the Mn(Hcit)(H_2O)$_2$ units are coupled in **3** and **4** by the second terminal carboxylate group to form a centrosymmetrical dimer [Mn(Hcit)(H_2O)$_2$]$_2$ as depicted in Fig. 5. It is noted that a dimeric structure is rare for metal citrate complexes and only a Ni citrate complex [26] has such dimeric structure. In addition, there is another type of Mn ion existing in the octahedral fragments, Mn(H_2O)$_4$($O_{carboxylate}$)$_2$ in **3** and Mn(H_2O)$_2$($O_{carboxylate}$)$_4$ in **4**. In the structure of **3**, the Mn1 ion in the dimer is connected by the carboxylate bridge in a *syn–anti* mode to the Mn2 ion of the Mn(H_2O)$_4$($O_{carboxylate}$)$_2$ fragment. The dimer and the Mn(H_2O)$_4$($O_{carboxylate}$)$_2$ fragment

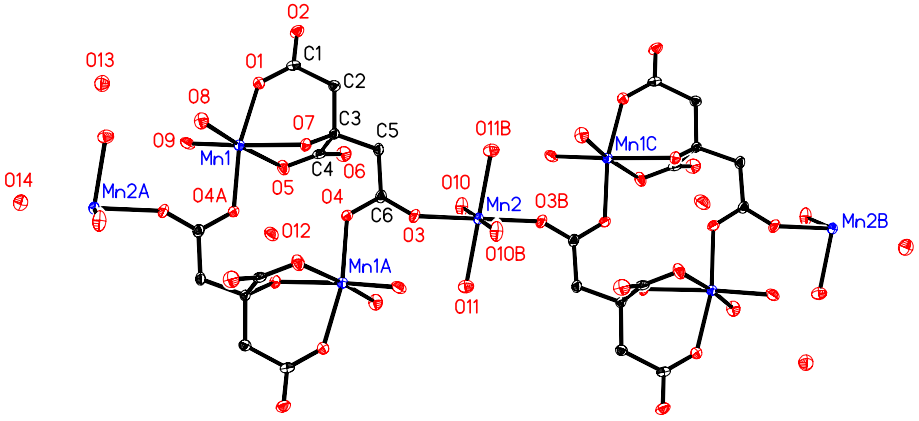

Fig. 5. 1-D unlimited chain structure of complex **3** with selected atom-labelling scheme. The [Mn(Hcit)(H_2O)$_2$]$_2$ dimer and the Mn(H_2O)$_4$-($O_{carboxylate}$)$_2$ unit array alternately to form a 1-D chain.

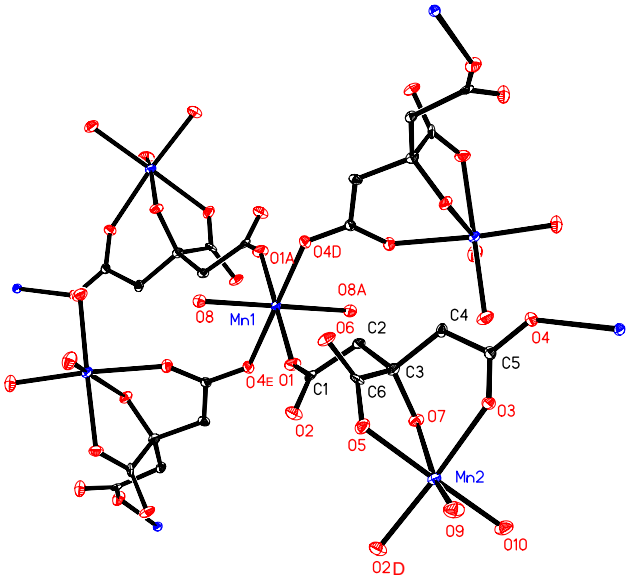

Fig. 6. Structure of **4** with selected atom-labelling scheme. A Mn-$(H_2O)_2(O_{carboxylate})_4$ fragment is enclosed by four $[Mn(Hcit)(H_2O)_2]$ units which are coupled to become the respective $[Mn(Hcit)(H_2O)_2]_2$ dimer (omitted for clarity).

alternately array to construct a one-dimensional chain structure of **3** as shown in Fig. 5. Different from the structure of **3**, complex **4** possesses a 3-D network structure. The Mn1 ions existing in the $Mn(H_2O)_2$-$(O_{carboxylate})_4$ fragment link to the other Mn2 ions at an equatorial plane (O1, O1A, O4D, O4E) as shown in Fig. 6. There are two bridging manners between Mn1 and Mn2 ions, one of which is via the $\mu_{1,3}$-OCO bridges in the *syn–anti* mode along the opposed direction, the other is via the Hcit backbone involving O1, C1, C2, C3 and the hydroxyl. Consequently the $Mn(H_2O)_2$-$(O_{carboxylate})_4$ fragments are surrounded by four dimeric units and extend along various orientations to construct a 3-D network structure (Fig. 7). Selected bond distances and angles are listed in Table 4 for both the complexes, exhibiting unobvious distinction of the same type of bonds, such as Mn–O_{H2O}: 2.154(4)–2.161(5) Å for **3** and 2.153(5)–2.175(6) Å for **4**. The presence of coordinate and solvate H_2O molecules make extensive hydrogen bonding interactions in the lattice of both the complexes. All the hydrogen bonding interactions are listed in Table 5. The hydrogen bonding interactions connect neighboring one-dimensional chains in **3** to become a three-dimensional supramolecular structure.

3.2.4. $[Mn(H_2cit)(H_2O)]_n$ (5)

The structure of **5** has been reported in the literature [14]. In order to account for the magnetic behaviors (vide infra) of the complex it is necessary to point out that the structure is constructed by series of $Mn(\mu_{1,3}$-$OCO)(\mu_{1,1}$-$O_{carboxylate})Mn$ chains, which are connected to each other by extensive hydrogen bonding interactions as shown in Fig. 8.

3.3. IR spectra

IR spectra of these complexes display characteristic features of the coordinated citrate [5,12]. The carbonyls of the citrate ligand exhibit antisymmetric stretching vibrations $\nu_{as}(COO^-)$ in the range from 1664 to 1541 cm^{-1}, and symmetric stretching vibrations $\nu_s(COO^-)$ from 1465 to 1340 cm^{-1}. In comparison with the corresponding vibrations of free citric acid, numerous bands are shifted to lower frequencies, indicating that the coordination of the oxygen donor to the metal ion weakens the C=O bonds. These assignments are in agreement with other reported metal citrate complexes [5,12]. No signal appears in the region between 1700 and 1760 cm^{-1} implying that all the citrate carboxyls in complexes **1**–**4** are deprotonated, while a strong vibration appears at 1734 cm^{-1} indicating a protonated cabboxylate group existing in **5**. This has been confirmed by the X-ray crystal structures of these complexes and is in agreement with other metal citrate complexes [5a,5b]. The carboxylate groups in **1** and **2** are coordinated to both alkali (or alkaline earth) and transition metal ions in various modes (Scheme 1), exhibiting abundant vibrations in the ν_{as}- and ν_s-(COO^-) regions (Table 6). The

$\Delta(\nu_{as}-\nu_s)$ values are smaller than 200 cm^{-1} for **3** and **4** which is an indication that all the carboxylato groups adopt the μ-OCO bridging coordination mode [27]. Also the $\Delta(\nu_{as}-\nu_s)$ value (<200 cm^{-1}) for **2** is considered to stem from the bridging coordination modes of most carboxylate groups. Complex **5** has the $\Delta(\nu_{as}-\nu_s)$ value being of the order of 300 cm^{-1}, implying the presence of free and unidentately coordinated carboxylato groups, which have been found in its crystal structure [14]. However, complex **1** contains all bridging carboxylate groups but has a larger $\Delta(\nu_{as}-\nu_s)$ value. This contravention would be explained by the involvement of highly unsymmetrical bridging [27] that can be seen as pseudo-unidentate coordination owing to the longer Na–O distances than the sum of atomic covalent radii. In addition, coordinate or solvate H_2O molecules exist in complexes **2**, **3**, **4** and **5**, and exhibit broad signals in the region of 3250–3481 cm^{-1}. Additional medium strong bands for complex **5** were found at 2973–2532 cm^{-1}, originating in the hydrogen-bonded protonated carboxylato groups [5a].

3.4. Magnetic property

The magnetic properties of **1** are illustrated as the temperature dependence of the effective magnetic moments (μ_{eff}) in Fig. 9. At room temperature, μ_{eff} amounts to 5.08 BM, which is lower than the value expected for independent spin $S = 5/2$ (5.92 BM) and close to the value for $S = 2$ (4.90 BM). However the structural parameters and BVS as well as the color of the crystals of **1** did not support the existence of the Mn(III) ion. With the

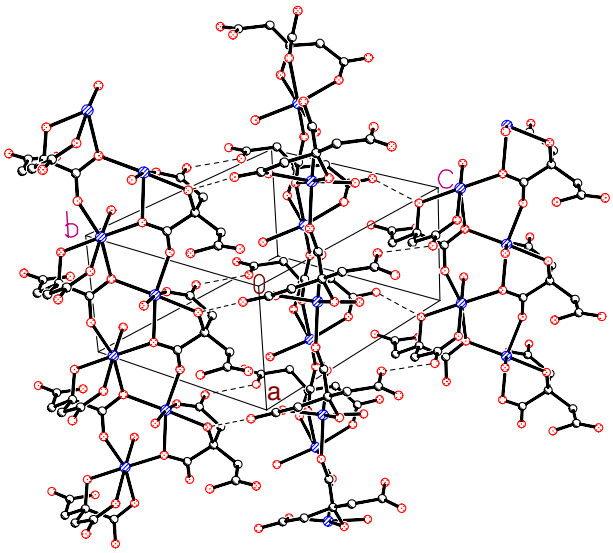

Fig. 8. Structure of complex **5** showing the $[Mn(\mu_{1,3}\text{-}OCO)(\mu_{1,1}\text{-}O_{carboxylate})]_n$ chains along the *a*-axis. Dotted lines show the hydrogen bonding interaction between the chains.

decrease of the temperature in the range of 300–30 K, the μ_{eff} value decreases slightly and turns to rapidly decrease in the further decrease of the temperature, indicating antiferromagnetic interactions between the neighboring Mn(II) ions. In the $1/\chi_M$ versus T plot (insert of Fig. 9), the observed susceptibilities are well-fitted to the Curie–Weiss law with Weiss constants $\theta = -5.23$ K and $C = 3.38$ K cm^3 mol^{-1}.

For complexes **2**, **3** and **5**, their magnetic behaviors as the temperature dependence of the effective magnetic moments (μ_{eff}) are illustrated in Fig. 10. At room temperature, μ_{eff} amounts to 5.79 and 5.50 BM for **2** and **5**, respectively, slightly lower than the value (5.92 BM) expected for an isolated Mn ion ($S = 5/2$), while μ_{eff} amounts to 10.22 BM for **3**, close to the value (10.24 BM) expected for three uncoupled Mn ions ($S = 5/2$). With the temperature decreasing in the range of 300–30 K, the μ_{eff} value decreases slightly and then rapidly decreases with further lower temperatures, indicating antiferromagnetic interactions between the Mn(II) ions for these complexes. To quantitatively analyze the magnetic behavior of **2**, Eq. (1) [28] for a homonuclear uniform chain was used to fit its experimental data, in which J represents the coupling interaction between neighboring paramagnetic centers in the $[Mn(\mu\text{-}CO_2)]_n$ helix chain.

$$\chi_{chain} = \left(\frac{Ng^2\beta^2}{KT}\right)[A + Bx^2][1 + Cx + Dx^3]^{-1}, \quad (1)$$

where $A = 2.9167$, $B = 208.04$, $C = 15.543$, $D = 2707.2$ and $x = |J|/kT$. It is reasonable to ignore the interaction between the helix chains belonging to different $[Ca_2(citrate)_2]_n$ layers. The least-squares fitting of the experimental data led to $J = -0.118$ cm^{-1}, $g = 2.00$ and $R = 3.51 \times 10^{-4}$, showing weak antiferromagnetic interactions within the helix chain. The agreement factor R is defined as $R = \sum[(\chi_M T)^{cal} - (\chi_M T)^{obsd}]^2/\sum[(\chi_M T)^{obsd}]^2$.

A model containing a linear Mn_3 system was used for fitting the experimental magnetic data of **3** by invoking an exchange pathway through the carboxylate bridges, in which the magnetic exchange interaction (J) is considered to exist between neighboring Mn1 and Mn2 sites.

$$Mn1\underline{J}Mn2\underline{J}Mn1A \ldots\ldots ZJ' \ldots\ldots Mn1\underline{J}Mn2\underline{J}Mn1A \ldots\ldots$$

The spin–spin coupling Hamiltonian $\hat{H} = -2J(\hat{S}_{Mn1}\text{-}\hat{S}_{Mn2} + \hat{S}_{Mn2}\hat{S}_{Mn1A})$ was presented and the molar susceptibility expression (Eq. (2)) was used to give the susceptibilities of the trinuclear linear system.

$$\chi_{tri} = \frac{Ng^2\beta^2}{3kT}\left[\frac{A}{B}\right], \quad (2)$$

$$\begin{aligned} A = {} & 2040e^{-32x} + 1860e^{-17x} + 858e^{-4x} + 495e^{7x} + 252e^{16x} \\ & + 105e^{23x} + 1365e^{-27x} + 858e^{-14x} + 495e^{-3x} \\ & + 252e^{6x} + 105e^{13x} + 30e^{18x} + 858e^{-22x} + 492e^{-11x} \\ & + 252e^{-2x} + 105e^{5x} + 30e^{10x} + 3e^{13x} + 252e^{-8x} \\ & + 105e^{-x} + 30e^{4x} + 252e^{-12x} + 105e^{-5x} + 30 + 105e^{-7x}, \\ B = {} & 32e^{-32x} + 48e^{-17x} + 24e^{-4x} + 24e^{7x} + 16e^{16x} \\ & + 12e^{23x} + 28e^{-27x} + 24e^{-14x} + 20e^{-3x} \\ & + 16e^{6x} + 12e^{13x} + 8e^{18x} + 24e^{-22x} + 20e^{-11x} \\ & + 16e^{-2x} + 12e^{5x} + 8e^{10x} + 4e^{13x} + 16e^{-8x} \\ & + 12e^{-x} + 8e^{4x} + 16e^{-12x} + 12e^{-5x} + 8 + 12e^{-7x}, \\ x = {} & \frac{-J}{kT}. \end{aligned}$$

A molecular field approximation [29] was employed to treat the interaction between the trinuclear systems according to Eq. (3).

$$\chi_M = \frac{\chi_{tri}}{1 - (2ZJ'/Ng^2\beta^2)\chi_{tri}}. \quad (3)$$

Table 6
Relevant infrared vibrations (cm^{-1}) for complexes **1**–**5** and citric acid

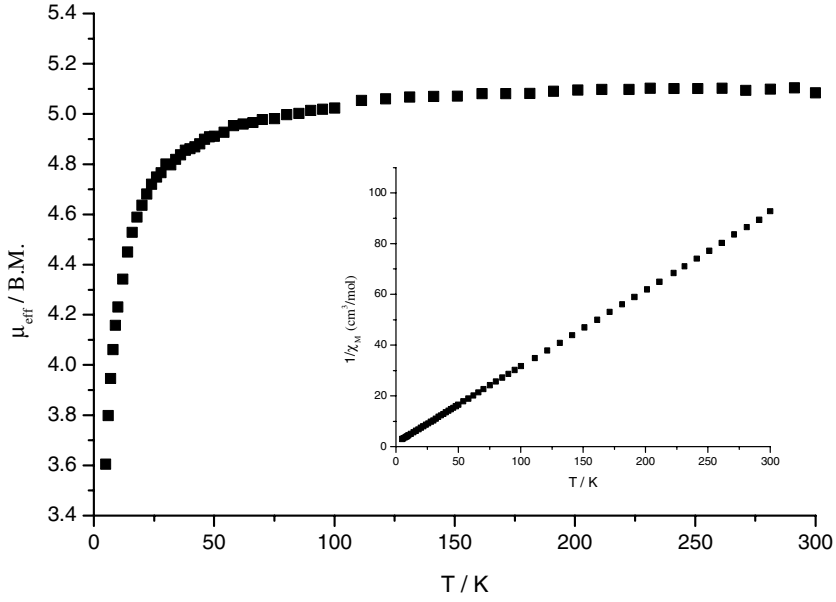

Fig. 9. The temperature dependence of the effective magnetic moments (μ_{eff}) for complex **1**. The insert represents the $1/\chi_M$ versus T plot.

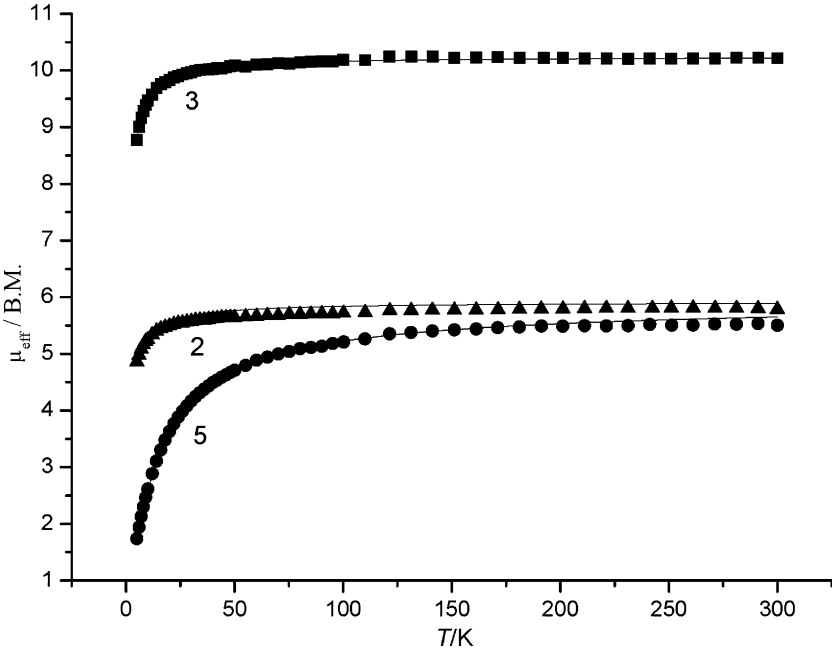

Fig. 10. The temperature dependence of the effective magnetic moments (μ_{eff}) for complexes **2** (triangle), **3** (square) and **5** (circle). The solid lines represent the calculated values.

The best fitting curves are depicted in Fig. 10 for **3**. The best fitting parameters are $g = 2.00$, $J = -0.105$ cm^{-1}, $ZJ' = -2.06 \times 10^{-2}$ cm^{-1} and $R = 8.74 \times 10^{-6}$, showing weak antiferromagnetic exchange interactions between the paramagnetic sites.

According to the structure shown in Fig. 8, Eq. (1) for the model of homonuclear uniform chain was used to treat the magnetic data of **5** as above did for **2**. Also, the molecular field approximation term was applied to estimate the interaction between the chains by using Eq. (3), in which χ_{tri} was revised as χ_{chain}. The best fitting parameters are $g = 2.00$, $J = -1.00$ cm^{-1}, $ZJ' = -4.98 \times 10^{-2}$ cm^{-1} and $R = 2.79 \times 10^{-4}$, showing weak antiferromagnetic exchange interactions between the paramagnetic sites.

All of the negative J values fall in the usual range for bridged carboxylate Mn(II) compounds [30]. The magnitude in the absolute value $|J|$ follows the order: $|J|$

(**2**) ≈ |*J*| (**3**) < |*J*| (**5**). As would be expected on the basis of the respective geometries, there is an efficient overlap between the 3d magnetic orbital of the Mn(II) sites and the 2p magnetic orbital of the oxygen of the carboxylate group in the order *syn–syn* > *anti–anti* > *syn–anti* [31,32]. The smaller |*J*| values of **2** and **3** can be reasonably attributed to the *syn–anti* bridging mode of the carboxylate group, while complex **5** contains both bridging modes: single atomic $\mu_{1,1}$-carboxylate bridging and the *syn–syn* $\mu_{1,3}$-OCO bridging (Fig. 8). Ref. [33] has collected and compared magnetic coupling data in various carboxylate-bridged Mn(II) complexes in an ascending order: *syn–anti* $\mu_{1,3}$-OCO bridge < $\mu_{1,1}$-carboxylato (i.e. monoatomic) bridge < *syn–syn* $\mu_{1,3}$-OCO bridge. So it is expected that complex **5** should have the largest |*J*| value among three Mn(II) complexes. Obviously smaller *ZJ′* values ensure the rationality of using the mean molecular field approximation model [34] and also show that the magnetic interaction via either the citrate backbone in **3** or the hydrogen-bonding supramolecular connect in **5** should be weaker than that via the carboxylate bridges in the respective complexes.

4. Conclusion

Four novel Mn citrate complexes have been reported, in which **1** and **2** are bimetallic citrate coordination polymers containing three novel coordination modes of the citrate trianion and showing 3-dimensional structures. Complexes **3** and **4** contain $[Mn(Hcit)(H_2O)_2]_2$ dimeric units which are connected to $Mn(H_2O)_4$ and $Mn(H_2O)_2$ fragments, respectively, forming a 1D chain in **3** and a 3D network in **4**. These manganese complexes have been characterized by crystal structure, IR spectra and magnetism. It is noteworthy to point out that the Mn/Ca citrate complex **2** belongs to rare Mn/Ca complex family which is attractive because of the involvement of the Mn/Ca cluster in the oxygen-evolving complex (OEC) in PSII. Our attempts to connect both Mn and Ca via a ligand bridge are successful in this work though complex **2** has not been directly relevant to the structure of the OEC. The further research will focus on the preparation and characterization of bimetallic Mn/Ca clusters, in which carboxylate and oxide bridges should be considered as major bridges to link both the Mn and Ca ions for the purpose of obtaining access to the structure of the OEC.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited in the Cambridge Crystallographic Data Centre with CCDC Nos. 257191–257194 for compounds **1**–**4**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1IZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

solids [1-(4′-nitrobenzyl)-4-aminopyridinium]-bis(maleonitriledithiolato)nickel([$NO_2BzPyNH_2$][Ni(mnt)$_2$]) (**1**) and [4-aminopyridinium]-bis(maleonitriledithiolato)-platinum ([$NO_2BzPyNH_2$][Pt(mnt)$_2$])(**2**). To the best of our knowledge, a uniform chain exhibiting an unusual magnetic transition is very rare in the Ni(mnt)$_2$ complexes.

2. Experimental

2.1. General materials and techniques

The starting materials, 1-(4′-nitrobenzyl)-4-aminopyridinium bromide ([$NO_2BzPyNH_2$]Br), and disodium maleonitriledithiolate (Na_2mnt) were synthesized following the literature procedures [19,20]. A similar method for preparing [Bu_4N]$_2$[Ni(mnt)$_2$] was utilized to prepare [$NO_2BzPyNH_2$]$_2$[Ni(mnt)$_2$] and [$NO_2BzPyNH_2$]$_2$[Pt(mnt)$_2$] [20].

Elemental analyses were run on a Model 240 Perkin–Elmer C H N instrument. IR spectra were recorded on an IF66V FT-IR (400–4000 cm^{-1} region) spectrophotometer in KBr pellets. Electronic spectra were recorded on a Shimadzu UV-3100 spectrophotometer. All solution concentrations were ca. 10^{-5} mol dm^{-3} in CH_3CN. The electrospray-mass spectra [ESI-MS] were determined on a Finnigan LCQ mass spectrograph, sample concentration ca. 1.0 mmol dm^{-3}. DSC was carried out with a Perkin–Elmer calorimeter. Thermal analyses of crushed polycrystalline samples for **1** placed in an aluminum crucible were performed on warming (rate of 20 K mol^{-1}) from 98 to 293 K. Magnetic susceptibility data on crushed polycrystalline samples of **1** and **2** were collected over the temperature range of 2–300 K using a Quantum Design MPMS-5S super-conducting quantum interference device (SQUID) magnetometer, and the experimental data were corrected for diamagnetism of the constituent atoms estimated from Pascal's constants.

2.2. Syntheses of complexes

2.2.1. [$NO_2BzPyNH_2$]$_2$[Ni(mnt)$_2$] (**1**)

[$NO_2BzPyNH_2$]$_2$[Ni(mnt)$_2$] (0.800 g, 1.0 mmol) was dissolved in 30 cm^3 MeCN, then a MeCN solution (10 cm^3) of I_2 (0.150 g, 0.59 mmol) was slowly added, the mixture was stirred for 1 h, and then 100 cm^3 CH_3OH was added. After the mixture was allowed to stand overnight, 0.508 g dark microcrystals produced were filtered off, washed with CH_3OH and Et_2O, and dried in a vacuum. Yield: 89.3%. *Anal.* Calc. for $C_{20}H_{12}NiN_7S_4O_2$: C, 42.19; H, 2.12; N, 17.22. Found: C, 42.12; H, 2.23; N, 17.16%. IR (cm^{-1}): 3380.4s, 3073.1w, 2207.1s, 1651.3s, 1606.6m, 1565.4m, 1536.6s, 1518.6m, 1454.2s, 1346.1s.

Single crystals suitable for X-ray structure analysis were obtained by evaporating a solution of **1** in a mixed solution of MeCN and *i*-PrOH (1:2 v/v).

2.2.2. [$NO_2BzPyNH_2$][Pt(mnt)$_2$] (**2**)

The procedure for preparing **2** was similar to that for **1**. Yield: 87.5%. *Anal.* Calc. for $C_{20}H_{12}PtN_7S_4O_2$: C, 34.04; H, 1.71; N, 13.89. Found: C, 34.12; H, 1.84; N, 13.76%. IR (cm^{-1}): 3371.9s, 3070.4w, 2205.9s, 1648.2s, 1604.8m, 1564.4m, 1535.2s, 1508.5m, 1449.8s, 1332.8m.

Single crystals suitable for X-ray structure analysis were obtained by evaporating a solution of **2** in a mixed solution of MeCN and *i*-BuOH (1:2 v/v).

2.3. Single-crystal X-ray structure determination

Measurements of the studied complexes **1** and **2** were performed on a Smart APEX CCD area detector using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by the ω scan mode within the angular range $1.87° < \theta < 26.0°$ for **1** and $1.96° < \theta < 25.0°$ for **2**. Space group, lattice parameters and other relevant information are listed in Table 1. The structures were solved by direct methods and refined on F^2 by full-matrix least-squares, employing Bruker's SHELXTL [21]. All non-hydrogen atoms were refined with anisotropic thermal parameters. All H atoms were placed in calculated positions, assigned fixed isotropic displacement parameters 1.2 times the equivalent isotropic U value of the attached atom, and allowed to ride on their respective parent atoms.

3. Results and discussion

3.1. Descriptions of the structures

3.1.1. X-ray structure of **1**

Complex **1** crystallizes in the monoclinic space group $P2_1/c$ at room temperature. Selected bond distances, bond angles and intermolecular Ni···Ni, Ni···S and S···S distances are summarized in Table 2. An ORTEP drawing of **1** with non-hydrogen atomic labelling in an asymmetric unit is shown in Fig. 1. The Ni(III) ion in the [Ni(mnt)$_2$]$^-$ anion is coordinated by four sulfur atoms of two mnt^{2-} ligands, and exhibits square-planar coordination geometry. The CN groups are slightly tipped out of the plane, and the deviations from the plane are −0.4477 Å for N(1), −0.4875 Å for N(2), −0.1285 Å for N(3) and −0.2619 Å for N(4). The average S–Ni–S bond angle within the five-membered ring is 90.0(5)°, and the average Ni–S bond distance is 2.139(1) Å, these values are in agreement with those found in other [Ni(mnt)$_2$]$^-$ complexes [22]. The cation [$NO_2BzPyNH_2$]$^+$, adopts a conformation in which the benzene and pyridine rings are almost perpendicular to the reference plane C(14)–C(15)–N(5) (dihedral angles

of 90.4° and 91.0°, respectively). The phenyl ring and the pyridine ring make a dihedral angle of 112.5°. The plane defined by S(1)S(2)Ni(1)S(3)S(4) with the phenyl and pyridine rings make dihedral angles of 17.2° and 113.8°, respectively. The most notable structural feature of **1** is that the anions and cations possess a stacking pattern with well-separated columns along the direction of the c-axis (Fig. 2). Within an anionic column, the nearest Ni···Ni distance is 3.855 Å, and the nearest S···S and Ni···S contacts are 3.725 and 3.664 Å, respectively.

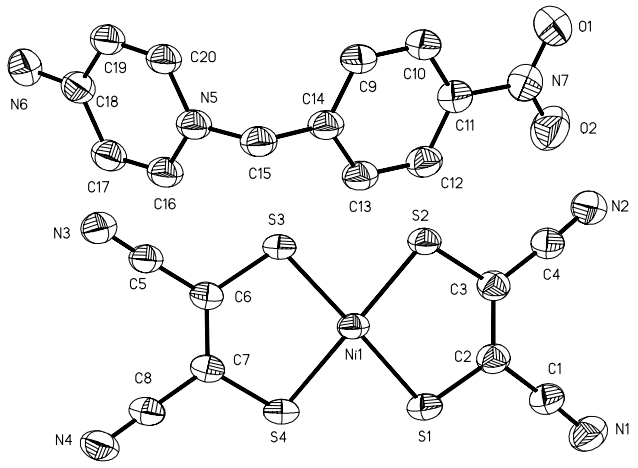

Fig. 1. ORTEP plot (30% probability ellipsoids) showing the molecule structure of **1**.

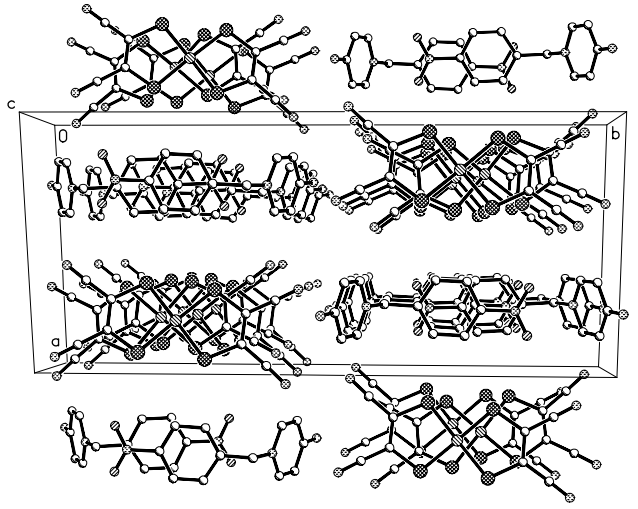

Fig. 2. The packing diagram of a unit cell for **1** as viewed along the *c*-axis.

Therefore, the Ni(III) ions within a $[Ni(mnt)_2]^-$ anionic column form a 1D uniformly spaced chain through intermolecular Ni···S, S···S, Ni···Ni or π···π interactions (Fig. 3(a)). The adjacent cations stack into a column via a boat-type conformation (Fig. 3(b)). The contact distances between the nitrogen atom of the NO_2 group and neighboring phenyl rings are 3.562 and 3.799 Å, respectively. So the cations form a 1D chain via π–π interactions between the NO_2 group and benzene rings. The closest Ni···Ni separation between anionic chains is 12.604 Å, which is significantly longer than that of the Ni···Ni separation within a chain (3.855 Å). Therefore, **1** is an ideal 1D uniform magnetic chain system from the point of view of the structure. There are three intermolecular hydrogen bonds between the anions and cations in the crystal structure of **1** (Table 3).

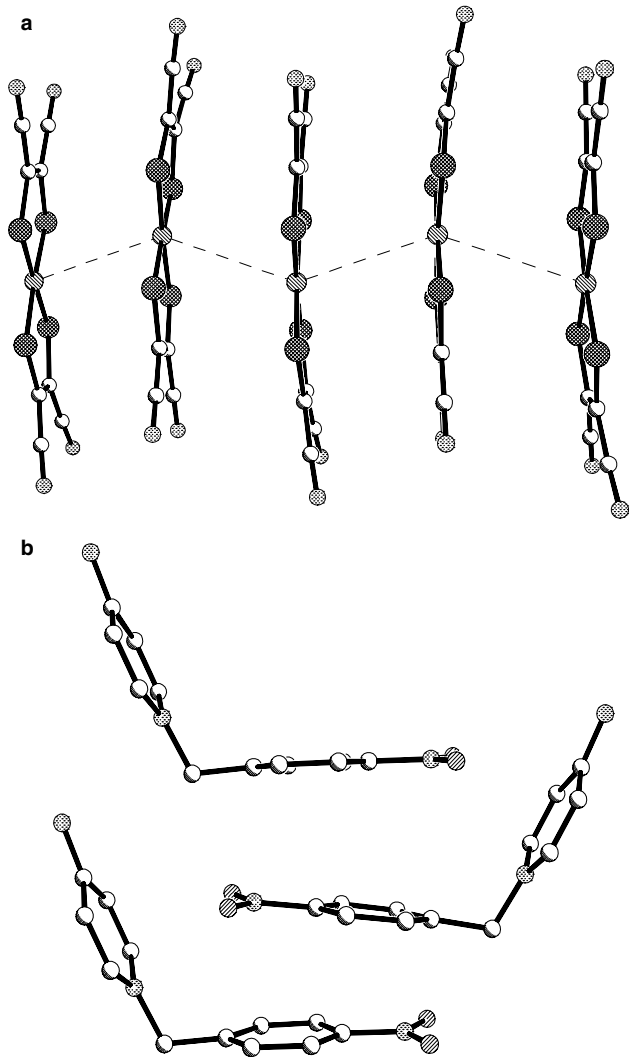

Fig. 3. (a) Side view of the anions stack of **1** showing the uniform space linear-chain of $[Ni(mnt)_2]^-$. (b) Side view of the cations stack of **1**.

3.1.2. *X-ray structure of* **2**

The coordination geometry of the $[Pt(mnt)_2]$ anion is essentially identical to that described above for **1**, while the stacking pattern of the $[Pt(mnt)_2]$ anion and $[NO_2Bz\text{-}PyNH_2]$ cation in **2** is significantly different from that of **1**. Selected bond distances, bond angles and intermolecular Pt···Pt, Pt···S and S···S distances are summarized in Table 2. The cation is situated above the plane of the $[Pt(mnt)_2]$ anion (Fig. 4(a)) in which the dihedral angles between the S(1)S(2)Pt(1)S(3)S(4) plane and phenyl and pyridine rings are 84.8° and 135.6°, respectively. The reference plane defined by C(14)–C(15)–N(5) and the aromatic rings make dihedral angles of 37.4° for the phenyl ring and 115.8 for pyridine ring. The $Pt(mnt)_2^-$ anions of **2** form a dimer with a Pt···Pt distance 3.511 Å and a S···S distance 3.488 Å, which is significantly different from that of **1**. Obviously, the short contacts of M···M, S···S and π–π interactions in **2** are smaller than those of **1**, therefore it is possible that the

interaction between $M(mnt)_2^-$ anions in **2** may be stronger than that in **1**, and **2** forms a dimer structure (Fig. 4(b)). It is worth noting that five intermolecular hydrogen bonds between anions and cations were observed in the crystal structure of **2**, as listed in Table 3. The anion–anion, anion–cation and cation–cation contacts may play important roles in crystal packing and the stabilization of **2**.

3.2. Infrared spectra

The infrared spectra of the two complexes **1** and **2** are very much consistent with the structural data presented above. The bands at 3380.4(s) and 1651.3(s) cm^{-1} for **1**, and 3371.9 and 1648.2 cm^{-1} for **2** are attributable to N–H stretching and bending of the amino group. The bands at 3073.1 and 3070.4 cm^{-1} are due to the stretching vibration frequencies of C–H in the aromatic ring. The complexes **1** and **2** show one strong band at 2207.1 and 2205.9 cm^{-1}, respectively, which are CN stretching bands. The ν(C=N) and ν(C=C) bands for the pyridine ring and phenyl ring are located at 1606.6, 1565.4 and 1518.6 cm^{-1} for **1**, and 1604.8, 1564.4, and 1508.5 cm^{-1} for **2**. The ν(C=C) band of mnt^{2-} is at 1452.2 cm^{-1} for **1** and 1449.8 cm^{-1} for **2**. The $\nu(NO_2)$ bands of complexes **1** and **2** are presented at 1536.6, 1346.1 cm^{-1} and 1535.2, 1332.8 cm^{-1}.

3.3. Electronic absorption spectra and electrospray mass spectra

The UV–Vis absorption spectra of **1** and **2** were measured in CH_3CN solvent in the region of 230–1200 nm (Table 4). All bands are attributed to the anionic portions of these compounds. The characteristic bands of **1** at 859.6, 473.0, 374.0 and 271.0 nm, are assigned as $L(\pi) \rightarrow M$, $L(\sigma) \rightarrow M$, $L^* \rightarrow L$ and $L(\sigma) \rightarrow M$, respectively, which is basically similar to those of $[(n\text{-}C_4H_9)_4N][Ni(mnt)_2]$ [23]. The bands of **2** are similar to those of **1**. The negative-ion and positive-ion ESI-MS spectra of **1** and **2** in MeCN solution show that the mass spectrum is dominated by the 230.2 peak, which is due to $[NO_2BzPyNH_2]^+$, the peaks at 340.3 and 476.3 are assigned to $[Ni(mnt)_2 + H]^-$ and $[Pt(mnt)_2 + H]^-$, respectively.

3.4. Magnetic properties

The temperature dependence of the magnetic susceptibility for **1** and **2** is measured under an applied field of 1000 Oe in the temperature range 2–300 K. The plot of χ_m versus T for **1** is shown in Fig. 5, where χ_m is the magnetic susceptibility per nickel atom corrected by the diamagnetic contribution. For the complex **1**, the

Table 4

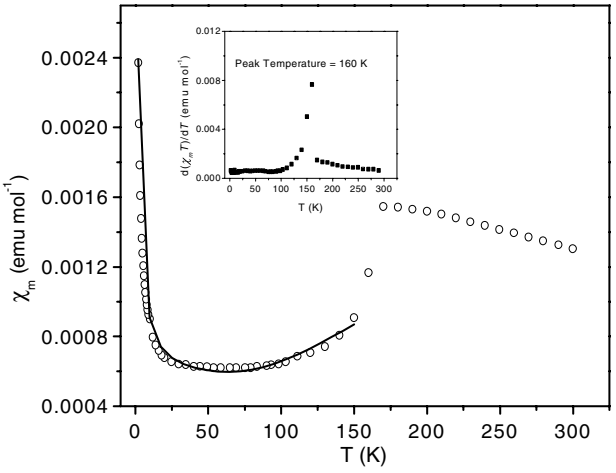

Fig. 5. Plots of χ_m vs. T for **1** (inset: plots of $d(\chi_m T)/dT$ vs. T). The solid line are reproduced from the theoretical calculations and detailed fitting procedure described in the text.

overall magnetic behaviors correspond to a paramagnetic system with an antiferromagnetic coupling interaction. As the temperature decreases, the value of $\chi_m T$ slightly decreases from 0.391 emu K mol^{-1} at 300 K (the value is somewhat higher than that expected for magnetically isolated Ni(III) ions) to 0.187 emu K mol^{-1} at 160 K for **1**. In the LT phase, as the samples are continuously cooled, the magnetic susceptibilities decrease exponentially (Fig. 5), indicating that **1** exhibits the characteristics of a spin gap system [24]. On increasing of temperature back to the original one, the same $\chi_m - T$ curves are obtained without hysteresis effect. These findings indicate that complex **1** undergoes a reversible phase transition. The phase transition temperature is evaluated as the temperature at the maximum of the $d(\chi_m T)/dT$ derivative, that is ~160 K for **1** (inset of Fig. 5).

The spin-gapped system has attracted extensive interest recently [25–28], but it is very rare for Ni(III) complexes [18]. The magnetic susceptibilities of **1** may be estimated by the formula:

$$\chi_m = \alpha \exp\left(-\frac{\Delta}{k_b T}\right)\left(\frac{1}{T}\right) + \frac{C}{T} + \chi_0, \quad (1)$$

where α is a constant value corresponding to the dispersion of the excitation energy, Δ is the magnitude of the spin gap, χ_0 contributes from the core diamagnetism and the possible Van Vleck paramagnetism, and the other symbols have their usual meanings [29]. The best fit curves are shown in Fig. 5, and the corresponding parameters are given as follows: $\alpha = 1.28$, $\Delta/k_b = 494.97$ K, $\chi_0 = -5.3 \times 10^{-4}$ emu mol^{-1}, $C = 3.7 \times 10^{-3}$ emu K mol^{-1} and $R = 2.2 \times 10^{-5}$ (R is defined as $\Sigma(\chi_m^{calcd} - \chi_m^{obsd})^2/(\chi_m^{obsd})^2$). The value of the parameter $2\Delta/k_b T_c$ (T_c is the transition temperature) is estimated to be 7.84 on the basis of the above results, which is higher than the ideal value of 3.53 derived from the BCS formula in a weak coupling regime. These results suggest that the short-range magnetic correlations within a chain are not fully developed and intrinsic magneto elastic instability of a 1D system cannot be considered as a driving force for this transition; that is, the transition is not a pure spin-Peierls transition [18]. The origins of the phase transition for **1** is attributed to cooperative interactions of Ni···S bonding, interplane repulsion of the $[Ni(mnt)_2]^-$ anions, π···π stacking interactions between of adjacent cations, spin–lattice interactions and spin–spin coupled interaction between nearest-neighbor anions [30–32].

Complex **2** is expected to be diamagnetic on account of the dimerized structure.

3.5. Thermodynamic properties

To obtain additional information about the thermodynamic properties of the observed phase transition of **1**, DSC measurements on **1** were performed. The power-compensated DSC traces for **1** from 98 to 293 K at a warming rate of 20 K min^{-1} are displayed in Fig. 6. For **1**, an abruptly endothermic peak in the

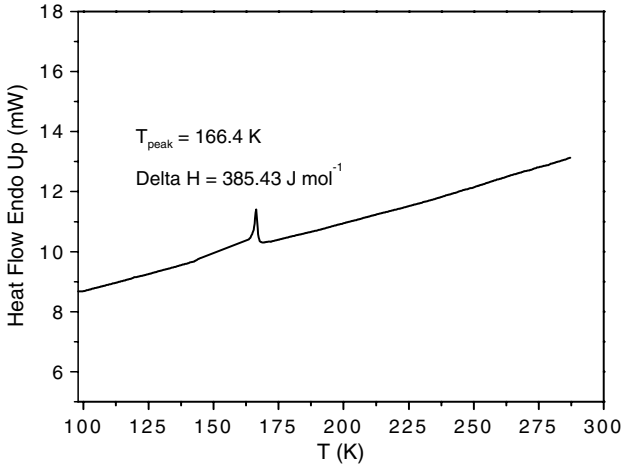

Fig. 6. DSC plot for **1**.

DSC trace is observed, and the phase transition temperature determined from thermal analysis is 166.4 K, close to the value measured from magnetic susceptibility measurements. The endothermic enthalpy change ($\Delta H = 385.43\ \mathrm{J\ mol^{-1}}$) was estimated from the peak area. Therefore, the result of thermal analysis of **1** further confirms that the magnetic phase transition observed is first-order [33,34]. According to the equation $\Delta S = \Delta H/T_c$ and ΔH estimated above, the estimated entropy change from DSC experiments is $2.31\ \mathrm{J\ mol^{-1}}$, which is much less than the magnetic transition entropy ($5.76\ \mathrm{J\ mol^{-1}\ K}$) calculated according to $\Delta S = R\ln[(2S_{HT}+1)/(2S_{LT}+1)$, This is expected from the short-range order effects between nearest-neighbor spins in the HT phase [35].

4. Conclusion

Here, we have reported the syntheses, spectra, crystal structures and magnetic properties of two new ion-pair complexes containing the $M(mnt)_2^-$ anion (M = Ni, Pt). The $Ni(mnt)_2^-$ anions and cations of complex **1** form completely segregated stacking columns, and the Ni(III) ions of **1** forms a 1D zigzag chain with an interatomic Ni···Ni distance of 3.855 Å within a $Ni(mnt)_2^-$ column, while **2** is dimer. The measurement of the temperature dependence of the magnetic susceptibilities reveal that **1** undergoes a magnetic transition around 160 K and exhibits antiferromagnetic interactions in the high-temperature phase and spin gap systems in the low-temperature phase, while **2** is diamagnetic. The phase transition is first order for **1** as determined by DSC analyses. The different magnetic properties of **1** and **2** are associated with the different packing pattern of the $M(mnt)_2^-$ anion in these two complexes.

5. Supplementary materials

The crystallographic data for **1** and **2** have been deposited at the Cambridge Crystallographic Data Center as supplementary publication Nos. CCDC-242502 and 252467. Copies of the data may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Scheme 2. Molecular structures of the ligands.

as the monodentate nitrito linkage isomers in the solid state. Therefore, the steric and electronic factors of the co-ligand may impart interesting findings in nitrite coordination. For the present study we have chosen 4-(2-aminoethyl)morpholine (Scheme 2) as the co-ligand, which should exert nearly equal steric and electronic effects in comparison with 1-(2-aminoethyl)piperidine (Scheme 2), with the view to obtain some interesting results. We report herein the synthesis and characterization of nitro and nitrito complexes of nickel (II) of 4-(2-aminoethyl)morpholine and the X-ray single crystal structure analysis of the nitro species.

2. Experimental

2.1. Materials

4-(2-Aminoethyl)morpholine was purchased from Aldrich Chemical Company Inc. and used as received. Potassium hexanitronickelate (II) monohydrate was prepared using a standard method [6b]. All other chemicals used were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer; the nickel (II) content was estimated gravimetrically [12]. The IR spectrum (4000–400 cm^{-1}) was taken at 27 °C using a SHIMADZU FTIR-8400S and KBr was used as the medium. The electronic spectrum (1400–200 nm) was obtained at 27 °C using a SHIMADZU UV-3101PC, and Nujol was used as a medium as well as a reference. The magnetic susceptibility was measured at 27 °C using an EG and G PAR 155 vibrating sample magnetometer, and $Hg[Co(SCN)_4]$ was used as a reference material; diamagnetic corrections were made using Pascal's constants [13]. Molar conductances were measured using a Systronic 304 conductivity meter, where the cell constant was calibrated with 0.02 M KCl solution and dry dichloromethane was used as the solvent.

2.3. Synthesis of the complexes

The nitro $[NiL_2(NO_2)_2]$ (**1a**) and nitrito $[NiL_2(ONO)_2]$ (**1b**) complexes were synthesized by adding the ligand L (2 mmol) in methanol (5 mL) dropwise to a methanolic suspension (10 mL) of potassium hexanitronickelate (II) monohydrate (1 mmol) with vigorous stirring. Initially a clear green solution was formed, but within a few minutes a blue-violet precipitate also appeared. After 1 h of stirring the mixture was filtered and the green colored filtrate part was kept in a $CaCl_2$ desiccator. After a few days, brown-colored crystals (**1a**) separated out from the green solution. Yield 65%. *Anal.* Calc. for $C_{12}H_{28}N_6O_6Ni$: C, 38.0; H, 7.4; N, 22.2; Ni, 15.5. Found: C, 38.0; H, 7.3; N, 22.1; Ni, 15.6%. $\mu_{eff} = 3.2$ μ_M. λ_{max}(Nujol) = 1264, 1182, 535, 371 nm. The blue-violet precipitate part was dissolved in excess methanol, and the resulting green colored solution was kept in a $CaCl_2$ desiccator. After a few days a blue-violet species was deposited at the sidewalls of the beaker and brown crystals were formed at the bottom of the beaker. After crystallization of the blue-violet species, complex **1b** was isolated in pure form. Yield: 25%. *Anal.* Calc. for $C_{12}H_{28}N_6O_6Ni$: C, 38.0; H, 7.4; N, 22.2; Ni, 15.5%. Found: C, 38.1; H, 7.3; N, 22.0; Ni, 15.4%. $\mu_{eff} = 3.2$ μ_M. λ_{max}(Nujol) = 1255, 1192, 588, 412 nm.

2.4. X-ray data collection and structure determination

A single crystal suitable for X-ray data collection was mounted on Bruker SMART CCD diffractometer equipped with a graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation source. The program SMART [14] was used for collecting frames of data, indexing reflection and determination of lattice parameters, SAINT [14] for integration of the intensity of reflections and scaling, and SADABS [15] for absorption correction. A total 2977 reflections were measured and 2366 were assumed observed applying the condition $I > 2\sigma(I)$. The structure was solved by direct methods using the SHELXS-97 [16] computer program and refined by full-matrix least squares methods on F^2, using the SHELXL-97 [17] program with anisotropic displacement parameters for all non-hydrogen atoms. Selected crystallographic data and refinement details are displayed in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

When a methanolic solution of L was added to a methanolic suspension of potassium hexanitronickelate (II) monohydrate, a blue-violet precipitate was formed within a few minutes, during the stirring. On filtration a green colored solution was obtained which on keeping yielded complex **1a**. After repeated crystallization of the blue-violet species, complex **1b** was obtained in the pure form. Complex **1a** was the major and thermodynamically controlled product, whereas complex **1b** was the minor and kinetically controlled product. The composition of the complexes **1a** (brown) and **1b** (blue-violet) have been assigned as $NiL_2(NO_2)_2$ on the basis of elemental analyses. Magnetic susceptibility measurements of **1a** and **1b** reveal that nickel (II) is in an octahedral configuration in both complexes and electronic spectral data of the complexes suggest that they have octahedral geometry around the nickel (II) centre. IR spectral studies are observed to be immensely helpful to elucidate the binding mode of the nitrite ion in its complexes. The three fundamental vibrational modes of the nitrite group (C_{2v} symmetry) are all IR active and the band positions are shifted upon coordination. The brown species **1a** exhibits IR bands at 1333, 1310 and 808 cm^{-1} assigned to $\nu_{as}(NO_2)$, $\nu_s(NO_2)$ and $\delta(NO_2)$, respectively. Both $\nu_{as}(NO_2)$ and $\nu_s(NO_2)$ are shifted to higher frequencies as compared to the free nitrite ion (1329 and 1264 cm^{-1}) suggesting that the nitrite ion is coordinated via the N atom [2,11a]. The blue-violet species **1b** shows two sets of bands for $\nu_{as}(NO_2)$ (1365 and 1331 cm^{-1}) and $\nu_s(NO_2)$ (1318 and 1304 cm^{-1}) in its IR spectrum. The complex **1b** may be either the monodentate nitrito species or the nitrito(O,O) species. Generally, nitrito species exhibit $\nu_{as}(NO_2)$ at a higher frequency (observed for **1b**) and $\nu_s(NO_2)$ at a lower frequency (not observed for **1b**) than the free nitrite ion frequencies [11a,18]. On the other hand, nitrito(O,O) species show a lowering of

O1–N5–O2	120.3(4)

both $\nu_{as}(NO_2)$ and $\nu_s(NO_2)$ in comparison to free ion frequencies. Therefore, from the IR spectrum of **1b** it is difficult to assign the coordination mode of the nitrite ion in it. Now the electronic spectral and electrolytic conductance studies may impart some light on the mode of nitrite ion coordination especially in **1b**. Electronic spectral data indicate that both **1a** and **1b** possess octahedral geometry around nickel (II) and since they exhibit further splitting in the d–d band in the near-IR region they should have a *trans*-configuration [19]. The electrolytic conductance measurements in dichloromethane suggest that both **1a** and **1b** are non-conducting ($\Lambda_m = 7.1$ and 4.3 Ω^{-1} cm^2 mol^{-1} for **1a** and **1b**, respectively). Since **1b** shows non-electrolytic behavior in non-coordinating solvents like dichloromethane it should be a nitrito species not the nitrito(O,O) species. From the above results it may be assumed that both **1a** and **1b** possess a *trans*-octahedral geometry, and **1a** and **1b** are, respectively, the nitro and nitrito linkage isomers.

The ORTEP view of complex **1a** with the atom numbering scheme has been depicted in Fig. 1. The selected bond lengths and bond angles are shown in Table 2. The hydrogen bonding is presented in Table 3. The structure consists of a discrete $NiL_2(NO_2)_2$ molecule and the nickel atom occupies an inversion center. The coordination polyhedron around the metal atom may be best described as a distorted octahedron. The four nitrogen atoms of the diamine part of the ligands (N1, N2 and their centrosymmetrically related atoms) define the equatorial plane and the two nitrogen atoms belonging to the nitro groups (N5 and its centrosymmetric counter part) coordinate in *trans* axial positions. The Ni–N (amine) distances, ranging between 2.032(4) and 2.372(3) Å, are consistence with the corresponding values observed in similar systems. The discrepancy between the two Ni–N distances is a consequence of the steric constraints imposed by the bulky morpholine group. The crystal packing diagram of **1a**, done by using program PLATON99 [20], is shown in Fig. 2 which reveals a two dimensional infinite chain structure through a hydrogen bonding network.

The proposition made regarding the structure of complex **1a** and the coordination mode of the nitrite ions in it by routine physicochemical techniques have been established unambiguously through the X-ray single crystal structure analysis of **1a**. Our efforts to synthesize single crystals of **1b** yielded no results. However, routine physicochemical studies suggest that **1b** should be a monodentate nitrito species with a *trans*-octahedral

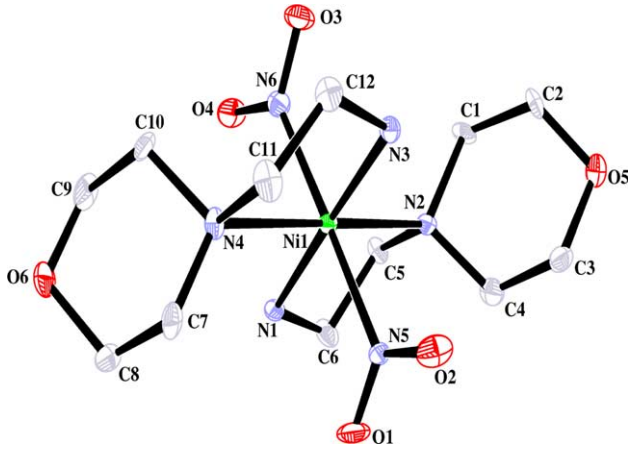

Fig. 1. ORTEP [21] diagram of *trans*-$[NiL_2(NO_2)_2]$ (**1a**) [L = 4-(2-aminoethyl)morpholine] with the atom numbering scheme. Ellipsoids are drawn at 50% probability.

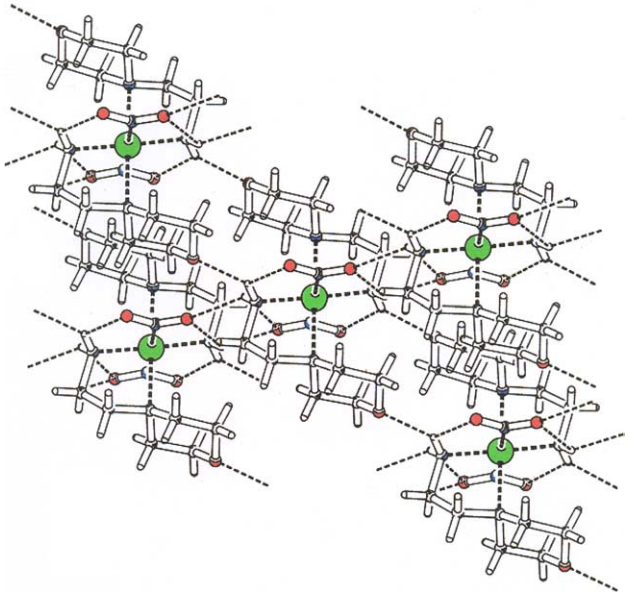

Fig. 2. Crystal packing diagram of *trans*-$[NiL_2(NO_2)_2]$ (**1a**) [L = 4-(2-aminoethyl)morpholine] and H-bonds (-----) in the crystal structure.

configuration. Therefore, the bulkiness of the morpholine moiety in the ligand 4-(2-aminoethyl)morpholine is just the optimum to stabilize both the nitro and nitrito isomers in the solid state as we observed earlier only in one case with the ligand 1-(2-aminoethyl)piperidine.

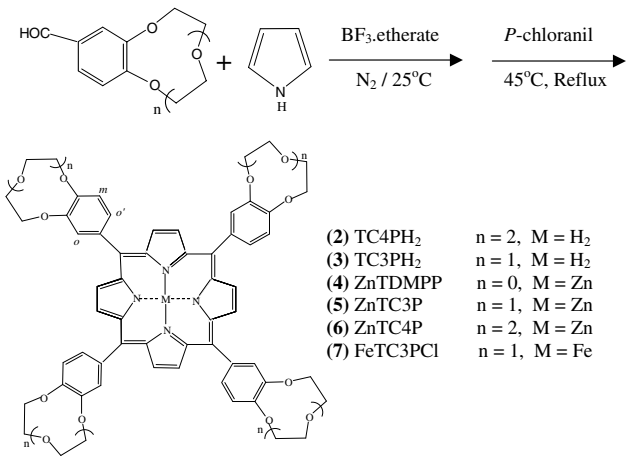
spectrophoto-meter. ^{1}H NMR, ^{13}C NMR and ^{27}Al NMR spectra were recorded in $CDCl_3$ using a 500 MHz Bruker instrument.

All solvents and reagents used in the synthesis were of reagent grade quality. The solvents used for spectroscopic work were purified and distilled prior to use. Pyrrole, benzaldehyde, 4-methoxy benzaldehyde, 3,4-dimethoxy benzaldehyde, sodium sulfate, lithium hydroxide monohydrate, hexamethylenetetramine, trifluoroacetic acid, 3,4,5,6-tetrachloro-1,2-benzoquinone (*p*-chloranil), BF_3 etherate, 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ), 1,2-bis(2-chloroethoxy)ethane, barium chlorate monohydrate, magnesium nitrate hexahydrate, aluminum nitrate nonahydrate, sodium perchlorate monohydrate, calcium nitrate tetrahydrate, ammonium hexafluorophosphate, dichloromethane, chloroform, methanol, *n*-hexane and acetonitrile were purchased from Merck. Iron (II) chloride tetrahydrate, zinc acetate dihydrate, potassium perchlorate, *N*,*N*-dimethylformamide (DMF) and alumina for chromatography were obtained from Fluka.

2.2. Synthesis of porphyrins and crown ether appended porphyrins

2.2.1. 5,10,15,20-Tetraphenylporphyrin, $TPPH_2$, and 5,10,15,20-tetrakis(3,4-dimethoxyphenyl)porphyrin, $TDMPPH_2$ (1)



$TPPH_2$ and $TDMPPH_2$ (**1**) were synthesized by Lindsey's method [6] using benzaldehyde and 3,4-dimethoxy benzaldehyde, respectively. The yields were 47% for $TPPH_2$ and 45% for $TDMPPH_2$.

2.2.2. 5,10,15,20-tetrakis(benzo-12-crown-4)porphyrin, $TC4PH_2$ (2), and 5,10,15,20-tetrakis(benzo-9-crown-3)-porphyrin, $TC3PH_2$ (3)

4-Formyl benzo-12-crown-4 and 4-formyl benzo-9-crown-3 were synthesized and purified by literature methods [7]. The compounds (**2**) and (**3**) were synthesized by a modification of Lindsey's method. Correspondingly benzaldehyde (1.5×10^{-2} mol) and pyrrole (1.5×10^{-2} mol) were dissolved in dichloromethane (1 L) and $BF_3 \cdot OEt_3$ (10^{-3} mol) was added to this solution. The mixture was stirred at room temperature for 15 min in the dark and then *p*-chloranil (0.011 mol) was added and refluxed for 1 h. Then the solvent was removed under reduced pressure and the crude material was chromatographed on a basic alumina column eluted with chloroform. The first purple cut, the crown-appended porphyrin, was collected. Further purification was achieved by recrystallization of these compounds in chloroform/methanol solution. The yields were 37% for (**2**) and 35% for (**3**).

2.2.3. Metallation of free base porphyrins

The metallation reactions of (**1**), (**2**) and (**3**) with Zn^{2+} and Fe^{3+} ions were performed using an established procedure [8]. The progress of these reactions was monitored by UV–Vis spectrophotometry and the isolated products were chromatographed on a neutral alumina column to yield 80–85% of (**4**), (**5**), (**6**) and (**7**) (Scheme 1). Compound (**8**), which is an iron μ-oxo dimer of (**7**), was prepared by dissolving 500 mg of compound (**7**) in 50 ml toluene. This was refluxed in the presence of a few pellets of KOH for 2 h. Removal of the solvent gave the crude product, which was loaded onto an alumina column and then eluted with dichloromethane to obtain the pure product.

Scheme 1.

3. Results and discussion

3.1. Synthesis of $TDMPPH_2$ (1), $TC4PH_2$ (2) and $TC3PH_2$ (3)

The above compounds were synthesized according to Lindsey's method [6] in 47–35% yields. The preparation method is shown in Scheme 1. The yields of the crown-appended porphyrins were found to be reduced by around 10% relative to tetraphenylporphyrins. UV–Vis measurement of the soret bands suggests that before chromatography the compounds (**1**), (**2**) and (**3**) were formed in similar yields. Thus relatively significant amounts of crown porphyrins were lost during chromatography. $TDMPPH_2$ (**1**), has a similar structure to (**2**) and (**3**) with regard to substitution in the phenyl rings of the porphyrin macrocycle. So, compound (**1**) can be used in analogy with crown-appended porphyrins, for spectroscopic characterization and chemical investigation. IR spectra of (**2**) and (**3**) have shown new signals at 1250–1290 s, which are absent in (**1**) and were assigned to ν_{c-o} in the crown rings.

3.2. UV–Vis spectral studies

UV–Vis data for compounds (**1**–**8**) have been collected in Table 1. The $TC4PH_2$ (**2**) spectrum resembled

Table 1
UV–Vis spectroscopic data in $CHCl_3$ at room temperature for the porphyrin compounds

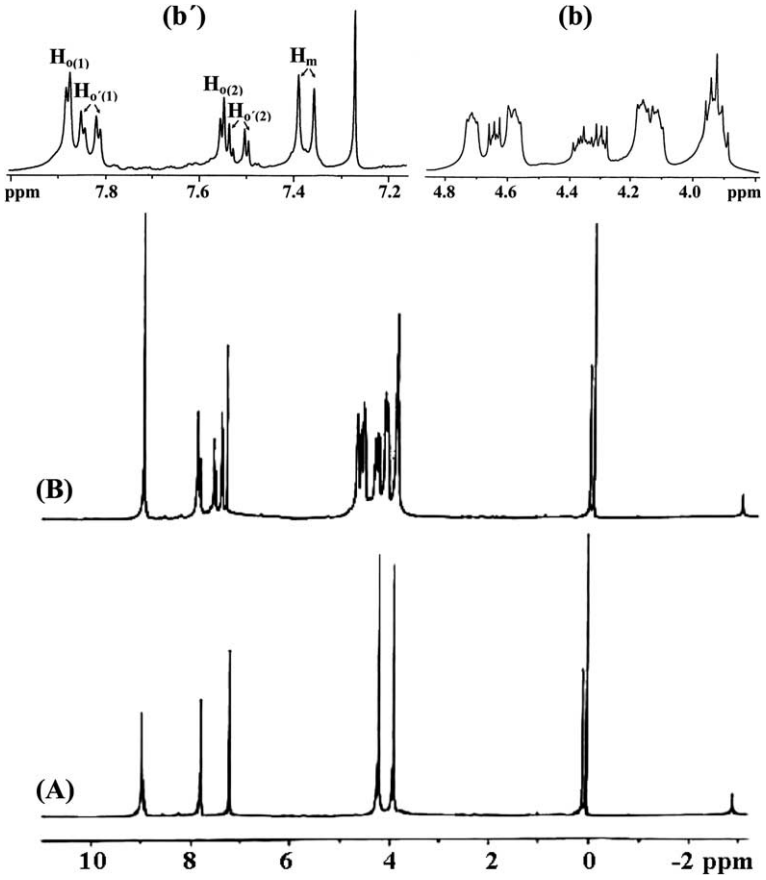
Compound	λ_{max} (nm)	
	Soret band (log ε)	Q bands (log ε)
$TPPH_2$	418(5.60)	516(4.27), 550(3.90), 590(3.72), 646(3.53)
(**1**) $TDMPPH_2$	424(5.51)	520(4.38), 556(4.29), 594(4.02), 650(4.03)
(**2**) $TC4PH_2$	423(5.56)	517(4.20), 555(3.98), 592(3.78), 647(3.64)
(**3**) $TC3PH_2$	421(5.41)	516(4.15), 554(3.93), 592(3.77), 647(3.61)
(**4**) ZnTDMPP	430(5.71)	556(4.43), 602(3.95)
(**5**) ZnTC3P	426(5.33)	559(3.99), 597(3.69)
(**6**) ZnTC4P	425	550, 589
(**7**) FeTC3PCl	421	511, 580
(**8**) $(FeTC3P)_2O$	418(5.34)	570(4.32), 620(4.13)

that for $TDMPPH_2$ (**1**), having soret bands at 423 and 424 nm, respectively. The substitution of two mesityl groups on each phenyl ring of the porphyrin macrocycle in (**1**) results in a 6 nm red shift in its soret band in comparison with $TPPH_2$. π-Donation of the meso aryl groups to the porphyrin macrocycle is strengthened by the OCH_3/OCH_2 π-donation and results in red shifts for compounds (**1**) and (**2**) [9]. The lower red shift for compound (**3**) compared to compound (**4**) may indicate less efficient conjugation of the lone pair electrons of the two oxygen atoms that are directly attached to the phenyl rings, and therefore less effective π-donation to the porphyrin macrocycle [10]. This lower red shift in (**3**) might be interpreted by the lesser electron-donating ability of the nine-membered crown ring as compared to (**1**) and (**4**). This could be the result of the restricted orientation of attached oxygen atoms to the phenyl rings in (**3**) that results from the rigid nine-membered crown ring cavity [11].

UV–Vis spectroscopy is a strong tool for following the metallation of the porphyrins. Generally, both the position and number of bands would change upon metallation. The disappearance of four Q-bands in the free base porphyrin and the appearance of two new Q-bands in the metalloprphyrins [12] confirm preparations of the metallated products (**4**–**8**).

3.3. NMR spectral studies

^1H NMR spectra of compounds (**1**) and (**3**) are shown in trace A and B of Fig. 1. The eight multiplets



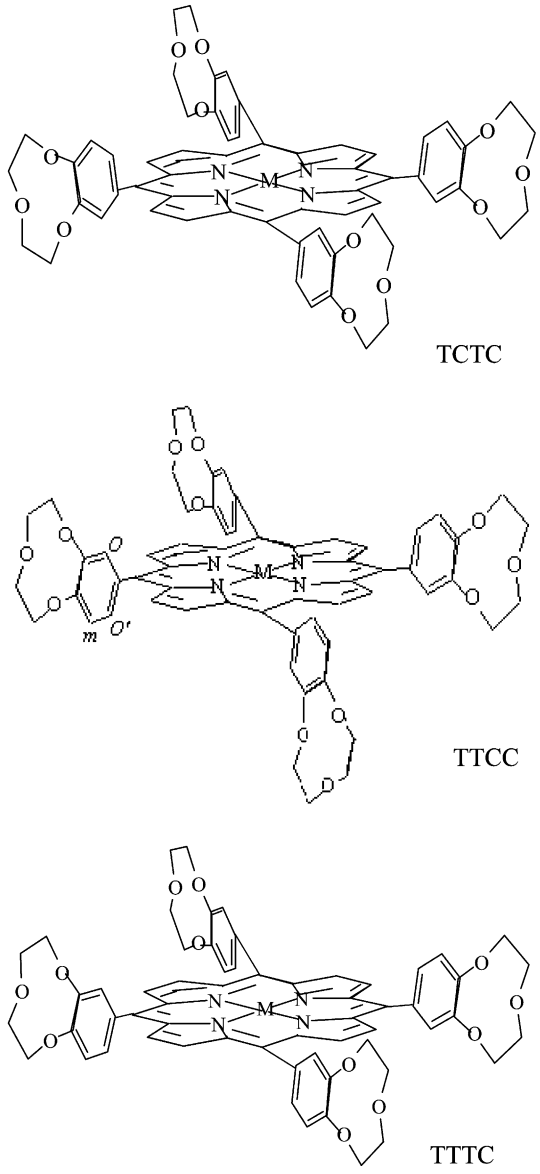


Fig. 1. 500 MHz ^1H NMR spectra of $TDMPPH_2$ (A) and $TC3PH_2$ (B) in $CDCl_3$ at room temperature. The expanded 3.8–4.8 ppm (b) and 7.2–8.0 ppm (b′) regions of the $TC3PH_2$ ^1H NMR spectrum.

in the 3.9–4.7 ppm region correspond to the four methylene hydrogen atoms of the crown cavities. The number of peaks and the pattern of the splitting is more complicated to interpret compared to the expected four triplets, and this confirms different structural isomers. A similar pattern has been observed for the ortho hydrogens atoms of the phenyl rings. The aromatic region of the benzo-9-crown-3 moiety in the ^{1}H NMR spectrum in Fig. 1 (b′ trace), clearly shows two sets of d,d and dd peaks with very close *J*-values. $H_{o'}$(**1**) and $H_{o'}$(**2**) correspond to one stereoisomer while H_o(**1**) and H_o(**2**) indicate the existence of a second. A single doublet H_m peak is shared for both isomers. Therefore, the splitting pattern of the benzo-9-crown-3 aromatic hydrogens clearly confirms the existence of two distinct atropoisomers for this compound (Scheme 2).

Scheme 2.

The ^{13}C NMR spectrum of (**3**), Fig. 2, comparing to $TPPH_2$ shows new signals which correspond to crown ether rings carbons. Signals at 148.5 and 150.3 ppm were assigned to phenyl C–O carbons and the signal at 136.7 ppm to the remaining quaternary carbon in the phenyl rings. Porphyrins carbons are spread out from 118–130 ppm, similar to $TPPH_2$, except that the ortho phenyl signals are sharper in the crown substituted porphyrin here. The most interesting signals in the ^{13}C NMR spectrum arise from carbons of the crown ether cavity which are spread out in the 70–75 ppm region. Ideally we would expect to see four different signals due to 4 methylene carbons in the crown ring of compound (**3**), whereas there are two sets of four different signals with an approximate ratio of 1:2. The NMR spectra indicate the presence of 2 of 3 stereoisomers for compound (**3**). Our attempt to separate these isomers failed. However, based on stability and statistics, we assume that these isomers are T–C–T–C (major) and T–T–C–C (minor). Other authors have reported only the T–C–T–C isomer with larger size crown-appended porphyrins [13].

The ^{1}H NMR of the Zn complex (**5**) compared to (**4**) is presented in Table 2. The same pattern of NMR signals is seen for both (**4**) and (**5**) as expected, and confirms the metallation of (**5**). Details of ^{1}H NMR data for compounds (**1**–**8**) are presented in Table 2. The ^{1}H NMR spectrum of FeTC3PCl (**7**), is presented in trace a of Fig. 3. The pattern of the ^{1}H NMR signals is similar to TPPFeCl [14]. The pyrrole hydrogen signals at 80 ppm at 25 °C in $CDCl_3$ confirm the high-spin iron (III) species. The

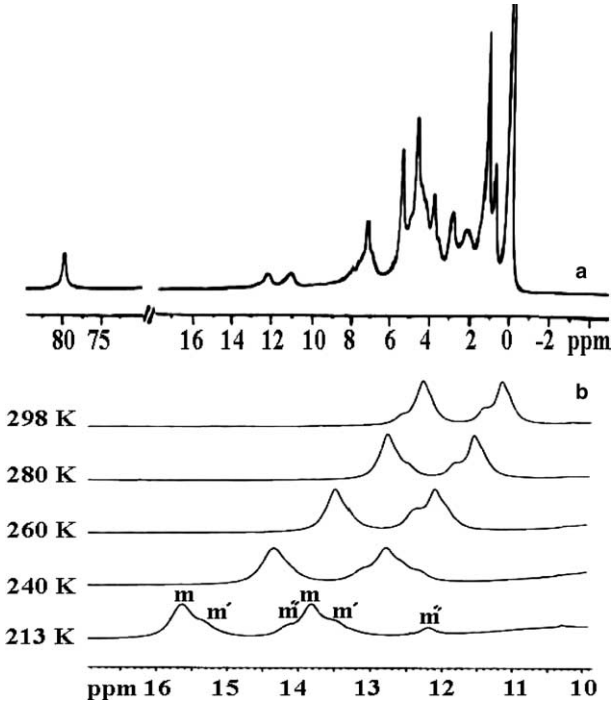
Table 2
^{1}H NMR spectroscopic data in $CHCl_3$ at room temperature for the porphyrin compounds

Compound	δ (ppm)					
	$H_{pyrrole}$	$H_{o,o'}$	H_m	H_{OMe}	H_{crown}	H_N
(**1**) $TDMPPH_2$	8.93 (s, 8H)	7.81 (s, 4H), 7.79 (d, 4H)	7.28 (d, 4H)	4.12, 3.80 (d, 24H)		−2.71 (s, 2H)
(**2**) $TC4PH_2$	8.89 (s, 8H)	[7.84 (d, 4H), 7.78 (dd, 4H)]$_1$ [7.56 (m, 4H)]$_2$	7.33 (d, 4H)		4.49–3.65 (m, 48H)	−2.81 (s, 2H)
(**3**) $TC3PH_2$	8.94 (s, 8H)	[7.87 (d, 4H), 7.83 (dd, 4H)]$_1$ [5.56 (d, 2H), 7.52 (dd, 2H)]$_2$	7.37 (d, 4H)		4.73–3.90 (m, 32H)	−2.80 (s, 2H)
(**4**) ZnTDMPP	9.01 (s, 8H)	7.78 (s, 4H), 7.75 (d, 4H)	7.25 (d, 4H)	4.10 (d, 24H)		
(**5**) ZnTC3P	8.83 (s, 8H)	7.53–7.64 (m, 12H)	7.35 (d, 4H)		4.23–3.49 (m, 32H)	
(**6**) ZnTC4P	8.98 (s, 8H)	7.64–7.67 (m, 12H)	7.30 (d, 4H)		4.25–3.65 (m, 48H)	
(**7**) FeTC3PCl	80.1 (s, 8H)	7.20–7.23 (m, 4H)	11.5 (d, 12H)		3.8–5.1 (m, 32H)	
(**8**) $(FeTC3P)_2O$	13.5 (s, 8H)	7.19–7.24 (m, 4H)	11.3 (d, 12H)		3.7–5.0 (m, 32H)	



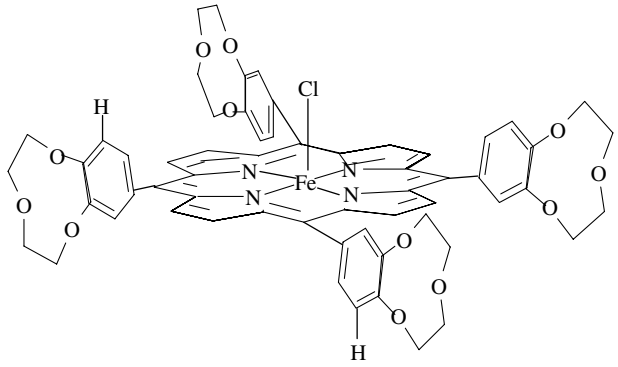


Fig. 3. 500 MHz ^{1}H NMR spectrum of FeTC3PCl (**7**), in $CDCl_3$ at room temperature (a). Variable temperature NMR of the meta position hydrogens indicating three stereoisomers T–T–T–T, T–T–T–C and T–C–T–C (b).

meta-hydrogens on the phenyl rings are usually split [15] to two sets with equal intensities. This confirms that two of the four meta hydrogens are in the same direction as the axial chloro ligand while the other two are on the opposite side, as shown in Scheme 3.

Here two kinds of meta hydrogens (m, m′), seen at ambient temperature, are in accord with the existence of two stereoisomers seen in this compound. Variable temperature studies, shown in trace b of Fig. 3, confirm the existence of a third stereoisomer at 213 K, as a trace compound. However, these stereoisomers, possibly atropoisomers, were seen in the range of 40 to −70 °C and did not show significant dynamic behavior. Any attempt to isolate these isomers was unsuccessful.

Scheme 3. Showing only two of the four meta hydrogens.

3.4. Interaction of metal ions with compounds (2) and (3)

Addition of metal ions Na^+, K^+, NH_4^+, Ca^{2+} and Ba^{2+} to the free base porphyrins (**2**) and (**3**), and to their metalloporphyrins (**5**), (**6**) and (**7**) induced no significant UV–Vis spectral change. However, marked changes were observed when the Al^{3+} ion was added to compound (**2**) or (**3**). Addition of Al^{3+} ions to (**3**) resulted in a significant red shift of the soret band from 421 to 453 nm with isobestic points at 433 and 502 nm. Similar absorption spectral changes and fluorescence intensity changes were observed upon addition of Al^{3+} to (**2**). The discussed spectral changes are consistent with π-acid DDQ or TCNE adduct formation with the porphyrin macrocycle [14], where the macrocycle itself interacts with the acids. The inset b of Fig. 4, confirms that the Al^{3+}/porphyrin (**3**) mole ratio in the resulting complex is about 5 which means that Al^{3+} interacts with 4 crown rings as well as a porphyrin macrocycle here [16]. Similar spectral changes were also observed in the presence of a large excess of the Mg^{2+} cation.

For further investigation of the complexation process, FeTC3PCl and $(FeTC3P)_2O$ were titrated with $Al(NO_3)_3$ under the same conditions as for the free base porphyrins. The results are presented in Fig. 5. Trace b of Fig. 5 shows that the ratio of Al^{3+}/porphyrin in the resulting complex is 4. In controversy with the free base porphyrins, the soret

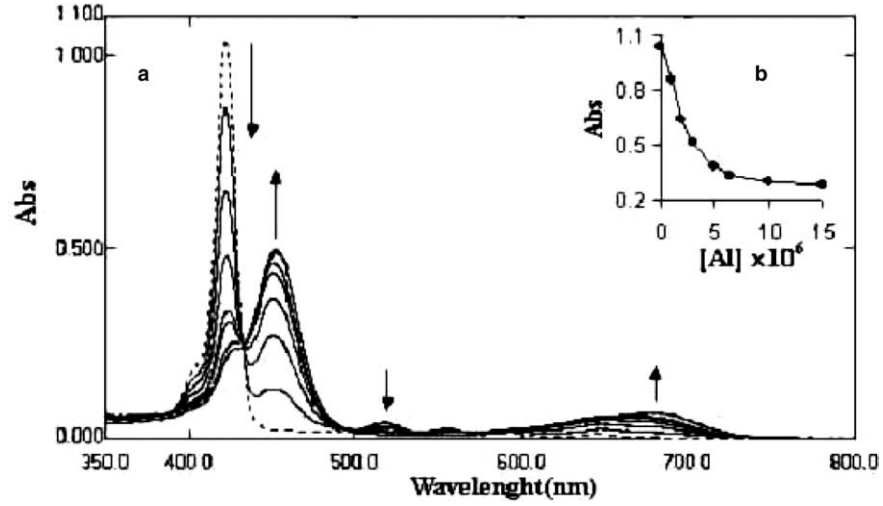

Fig. 4. Absorption spectrum of (**3**) in $CHCl_3$:MeOH (2:1) upon addition of $Al(NO_3)_3$ at room temperature (2.85×10^{-6} M) (a); plot of [metal ion] $\times 10^6$ vs. absorption at room temperature, $\lambda_{max} = 421.5$ nm (b).

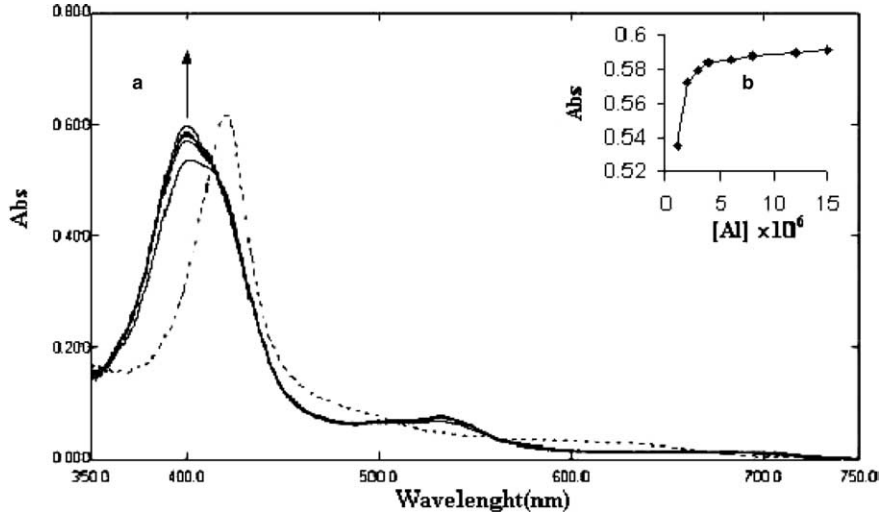

Fig. 5. Absorption spectra of (**7**) in $CHCl_3$:MeOH (2:1) upon addition of $Al(NO_3)_3$ at room temperature (10^{-6} M) (a); plot of [metal ion] $\times 10^6$ vs. absorption at room temperature, $\lambda_{max} = 421.5$ nm (b).

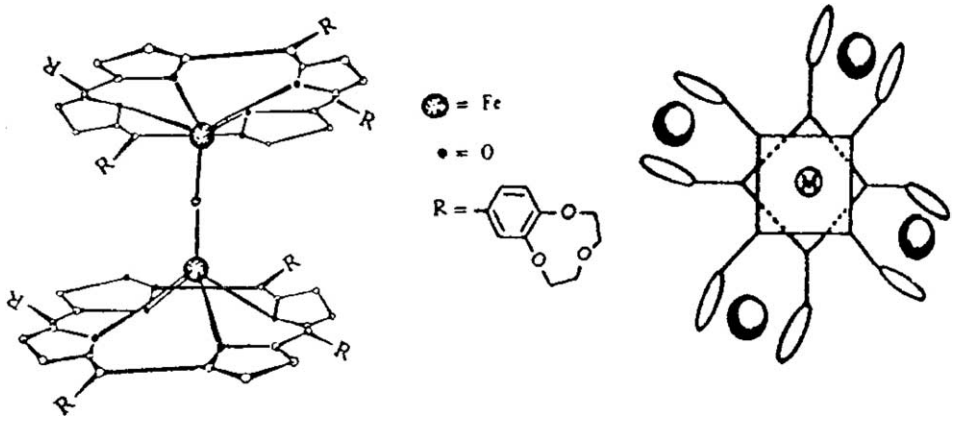

Fig. 6. Proposed structure of the porphyrin dimer induced by Al^{3+}.

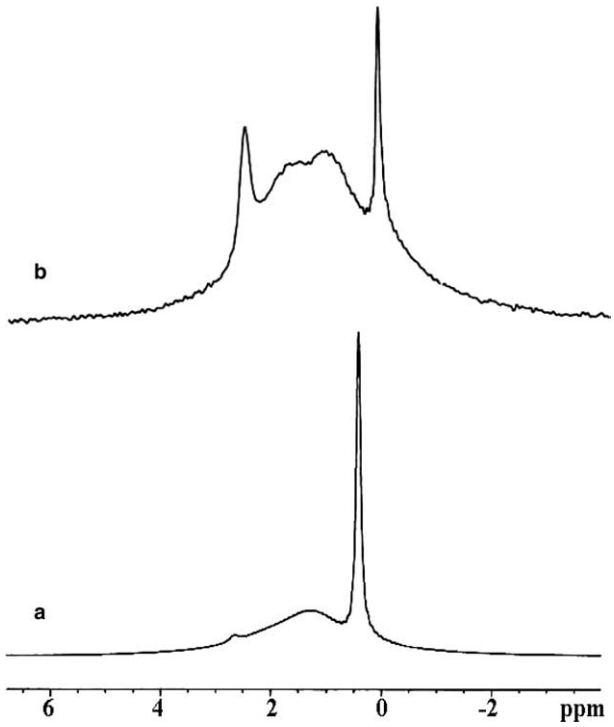

Fig. 7. ^{27}Al NMR spectrum of $Al(NO_3)_3 \cdot 9H_2O$ in $CDCl_3$/MeOH at room temperature (a); TC3PH$_2$ upon addition of $Al(NO_3)_3 \cdot 9H_2O$ (b).

band in these metallated porphyrins shows a blue shift. This kind of blue shift has also been reported for the interaction of metal ions with similar other substituted crown-ether porphyrins [17]. So, we conclude that the Al^{3+} ion could coordinate to the crown cavities as well as the porphyrin core in the free base porphyrins. The proposed structures are presented in Fig. 6.

In addition, the ^{27}Al NMR spectrum of (**3**) upon addition of Al^{3+} under the same conditions was followed to confirm the interaction of Al^{3+} with the crown ether porphyrin. Trace (a) of Fig. 7 shows the ^{27}Al NMR spectrum of $Al(NO_3)_3$ in $CDCl_3$:CD_3OD, 2:1 at 25 °C. Addition of a 10-fold excess of $Al(NO_3)_3$ to compound (**3**) in the same solvent mixture results in the spectral change shown in trace (b) of Fig. 7. The relatively sharp signal at 2.8 ppm could be assigned to the Al^{3+} ion coordinated to the porphyrin macrocycle and a broad signal in the region 1.5–2.5 ppm to the complex formed from the interaction of Al^{3+} species to the crown rings [18].

complexes inhibit DNA biosynthesis at molecular levels through blocking the activity of ribonucleotide diphosphate reductase (RDR), a key enzyme involved in the transformation of DNA to RNA [3]. Another possible mode of action involves binding of complex molecules at the minor groove of the DNA helical structure through intercalation thus preventing the unwinding of DNA [4].

Quinones, as a class of naturally occurring ligands [5], exhibit a wide range of biological activities. It is reported that β-lapachone, a naturally occurring 1,2–naphthoquinone derivative [6], inhibits tumor growth in rats implanted with W-256 carcinoma. Similarly, it is found to be cytotoxic to a variety of human cancer cell lines wherein the mechanistic aspects revealed that these compounds hamper the DNA repair enzymes [7] as well as can induce DNA-TOPO II-mediated cleave of DNA in an ATP-independent manner and these effects may be decisive in the cytotoxicity of these compounds [8]. The cytotoxicity of quinonoidal compounds is mainly through intercalation, inhibition of DNA and RNA, breaking of DNA strands, alteration of cell membrane functions and free radical initiated alkylation [9]. Previously, we have reported [10] that iron (III) and copper (II) complexes of 2-hydroxy-1,4-naphthoquinone-1-thiosemicarbazone inhibit DNA synthesis when evaluated for their in vitro antitumor activity against P-388 Lymphocytic cells. Recently, we have investigated [11] the antitumor properties and mechanisms of transition metal complexes of 1,2-naphthoquinone-thiosemicarbazone against MCF-7 human breast cancer cells as well as their DNA cleavage activities with circular double stranded plasmid DNA pBR-322. In former studies, it was observed that these complexes can only stabilize the single-strand nicked DNA [12] but not double-strand breakage intermediates, while in later case the quantitative conversion was found with super coiled DNA to linearized DNA in the presence of H_2O_2. Moreover, these complexes exerted a substantial effect on topoisomerase II activity. Screening of antiproliferative activities of 9,10-phenanthrenequinone thiosemicarbazone and its metal complexes [13] against the T47D human breast cancer cell line showed that these cytotoxic compounds possess antitumor action via inhibition of steroid binding to the cognitive receptor or by preventing the dimerisation of the estrogen receptor.

In a continuation of our recent efforts in understanding the coordination propensities of thiosemicarbazones, we have investigated the structural and electrochemical features of transition metal complexes with a variety of thiosemicarbazones [14]. The present communication describes the synthesis and structural elucidation of iron (II), iron (III), cobalt (II) and copper (II) complexes of 2-thiosemicarbazido-1,4-naphthoquinone (Fig. 1; NQTSC) involving either thione or thiol coordination.

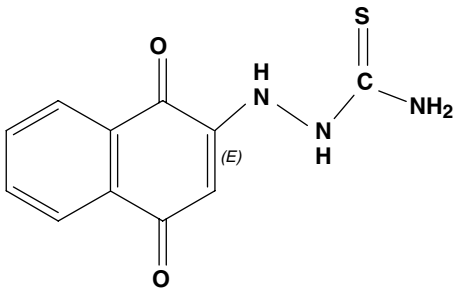

Fig. 1. The 2-Thiosemicarbazido-1,4-naphthoquinone (NQTSC) ligating system.

2. Experimental

All the chemicals used in the present studies were of AnalaR grade, products of Fluka A.G. and were used as received. The solvents were purified by literature methods.

2.1. Synthesis of NQTSC

NQTSC was synthesized according to the procedure described earlier [14d].

2.2. Preparation of complexes

2.2.1. Thionato complexes

0.002 mole of NQTSC was dissolved in 15 ml methanol and the solution was degassed with a N_2 stream for 5 min. 0.001 mole of each of iron (II) chloride tetrahydrate (0.20 g), iron (III) chloride hexahydrate (0.27 g), cobalt (II) chloride hexahydrate (0.24 g) and copper (II) chloride dihydrate (0.17 g) were dissolved in 10 ml of methanol and these solutions were degassed for 5 min with N_2. The metal solutions were added to the ligand solution dropwise under N_2 in a Schlenk assembly with constant stirring. The pH of solution was adjusted to between 3 and 4 using 10% HCl solution in methanol. The reaction mixture was stirred for 1 h after which the organic solvent was stripped off on rotary evaporator under vacuum and the mixture was kept overnight in a refrigerator. The precipitated complexes were filtered, washed with acetone and dried under vacuum over $CaCl_2$. The complexes thus obtained are hereafter referred as:

Iron (II) complex; A-1, iron (III) complex; A-2, cobalt (II) complex; A-3, copper (II) complex; A-4.

2.2.2. Thiolato complexes

The synthesis of these complexes was carried out essentially in a similar manner as described above except that the pH of the reaction mixture was adjusted to ~8 using a 6% methanolic solution of NH_3. The complexes thus obtained are hereafter referred as:

Iron (II) complex; B-1, iron (III) complex; B-2, cobalt (II) complex; B-3, copper (II) complex; B-4.

2.3. Physical measurements

Elemental analyses were carried out using a Hosli-Holland C, H, N analyzer. The magnetic susceptibility measurements between 300 and 16 K were carried out on a Faraday type magnetic balance with a continuous flow of He in a Flow Closed-cycled refrigerator which was calibrated with $Hg[Co(SCN)_4]$. The IR spectra were recorded on a Perkin–Elmer 283-B FTIR spectrometer using KBr discs while the UV–Vis spectral measurements of DMSO solutions were made on a Shimadzu UV-300 spectrophotometer. The X-band ESR spectra at 298 and 77 K were recorded on a Varian 109-ESR spectrophotometer with 100 kHz modulation amplitude. Mössbauer spectra were recorded on a conventional constant acceleration electrochemical drive coupled to a ND-100 multi-channel analyzer operating in the time mode. The isomer shifts were measured against natural α-iron foil. Cyclic voltammetric experiments were performed on a BAS CV-27 assembly equipped with an X–Y recorder. Measurements were made on degassed 10 mM DMSO solutions of the complexes (N_2 bubbled for 15 min prior to measurements) containing 0.1 M tetraethyl ammonium perchlorate as a supporting electrolyte. The working system consisted of Pt–inlay (working), Pt–disc (auxiliary) and Ag/AgCl (reference) electrodes. The Ag/AgCl reference electrode was calibrated with the ferricinium/ferrocene redox couple located at $E_{1/2} = +0.40$ V ($\Delta E_q = 0.06$ V).

3. Results and discussion

Interaction of NQTSC with transition metal salts under two different synthetic conditions yielded red or dark brown colored complexes which are insoluble in common organic solvents such as benzene, chloroform but are soluble in DMF and DMSO. The analytical and conductivity data (Table 1) indicate a $[ML_2]Cl_2$ composition for A-1 to A-4, $[ML_2]$ for B-1, B-3 and B-4 while B-2 has a $[ML_2]Cl$ stoichiometry indicating that complexes A-1 to A-4 probably possess thionato sulfur binding while B-1 to B-4 involve thiolato sulfur coordination.

3.1. Infrared spectra

Thiosemicarbazone ligands, in principle, exhibit thione ↔ thiol tautomerism due to the presence of a thioamide –NH–C=S linkage [1]. The absence of a ν(S–H) absorption near 2570 cm^{-1} with a band around 3140 cm^{-1} from a $\nu(^2N–H)$ stretch for NQTSC signifies that the thione form of the ligand exists in the solid state. The bands at 3260 and 3410 cm^{-1} are attributed to asymmetric and symmetric stretching vibration of the NH_2 functionality [14a] and it is expected that these bands undergo appreciable changes upon complexation with metal ions (Table 2). NQTSC may bind through thione (C=S), thiol (–C–SH) or both as a consequence of tautomerism. In the present studies, all these three possibilities are observed as evidenced from the respective band position of the ν(C=S) vibration. NQTSC exhibits characteristic ν(C=S) bands 1290

[a] In cm^{-1}.

and 860 cm^{-1} which are red shifted by ~50 and 40 cm^{-1}, respectively, in the spectra of metal complexes [14b]. On the other hand, the $\nu(^1N–H)$ vibration from the same linkage undergoes a downward shift of about 30 cm^{-1} for all the complexes suggesting its coordination while the $\nu(^2N–H)$ vibration disappears suggesting deprotonation of the $^2N–H$ proton thus generating thiolato sulfur which is one of the coordinating centers for B-1 to B-4. In addition, a new band appears around 1580 cm^{-1} due to the formation of the –C=N chromophore as a result of thiol formation. These complexes exhibit characteristic $\nu(M–S)$ vibrations in the region 340–360 cm^{-1}. The quinone carbonyl stretches are observed at two different frequencies. The $\nu(^4C=O)$ band at 1650 cm^{-1} for NQTSC does not show any change after complexation while the other quinone carbonyl absorption $\nu(^1C=O)$ displays a substantial decrease by ~30 cm^{-1} in the spectra of the complexes [11a]. It implies that the ^1C-quinone carbonyl is one of the coordinating centers, that is further confirmed by a new band at about 510 cm^{-1} due to a $\nu(M–O)$ vibration. A downward shift of 50 cm^{-1} for the $\nu(C–N^1)$ vibration from the thiosemicarbazide linkage, along with a characteristic $\nu(M–N)$ stretch at about 440 cm^{-1}, is indicative of hydrazinic nitrogen coordination [15].

3.2. Iron (II) complexes

The dark-red colored iron (II) complexes of NQTSC (A-1 and B-1) exhibit room temperature magnetic moments of 3.87 and 3.76 BM, respectively, which neither correspond to high-spin nor low-spin states. In order to determine the magnetic properties of these complexes, variable temperature magnetic susceptibility measurements were carried out in the range 16–273 K (Fig. 2). It can be seen from the nature of this graph that the magnetic moment remains almost constant throughout the entire temperature range thus ruling out the possibility of a thermal equilibrium between high-spin and low-spin states as well as antiferromagnetically coupled iron

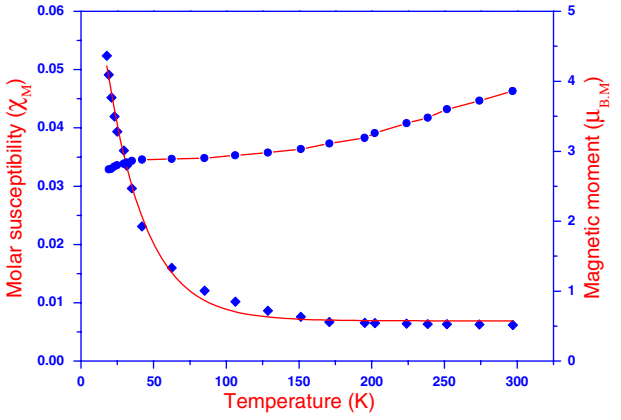

Fig. 2. Temperature dependence of magnetic susceptibility (♦) and effective magnetic moment (●) of A-1.

centers. Careful literature survey revealed that there exists an intermediate spin-state ($S = 1$) for iron (II) complexes wherein it was argued that ligand fields of moderate strength probably control the spin-state as well as impart deviation from octahedral geometry [16]. The susceptibilities for these compounds can be approximated by the Curie–Weiss expression, and the Weiss constant θ was found to be −9 and −12 K for A-1 and B-1, respectively. Moreover, the magnetic measurements in DMSO at 300 K using Evan's method [17] do not reveal any appreciable change in magnetic moment value (3.91 BM) suggesting a similar magnetic behavior both in solution and in the solid state. This observation, together with rather small θ values indicate that these complexes possess an unusual intermediate $S = 1$ ground state.

The molar susceptibilities of the spin-triplet state in a tetragonal (D_{4h}) ligand field [18] is given by the expression

$$\chi_M = (2N\beta^2/3)\{[g_\parallel^2 e^{(-D/kT)}/kT(1 + 2e^{(-D/kT)})] + [g_\perp^2(1 - e^{(-D/kT)}/D(1 + 2e^{(-D/kT)}))]\}, \quad (1)$$

where the terms involved have usual meanings.

In the limit of very low temperatures, this expression can be modified to

$$\chi_M = (4N\beta^2 g_\perp/3D) \text{ when } kT <<<< D. \quad (2)$$

By simulating the susceptibility data utilizing the equation mentioned above, the best fit for the magnetic data can be obtained with $g = 2.74$ and $D = 9.3$ and 10.6 cm^{-1} for A-1 and B-1, respectively. The zero-field splitting values (D) observed for these compounds are considerably lower than those observed for square planar complexes [19], while they are slightly higher than those for octahedral complexes [20]. Small values of D reveal that the intermixing of an excited state with the ground state is minimal and magnetic perturbations are negligible at lower temperatures.

Such behavior is further confirmed by carrying out Mössbauer measurements on these compounds. The zero-field Mössbauer spectra of both the complexes at 298 K exhibit a single quadrupole split doublet (Fig. 3), characteristic of a $S = 1$ ground state [21]. Table 3 summarizes the data on zero-field splitting (D), isomer shift (IS) and quadrupole splitting (EQ) for A-1 and B-1. It can be seen from this table that smaller values of isomer shift signifies the extent of covalent character in the metal-ligand bonding while the lesser values of quadrupole splitting denotes the extent of deviation from idealized geometry. Both these values indicate that there is appreciable covalency in the ironthiosemicarbazone bonding as well as the structure of these complexes being moderately distorted from octahedral geometry. The higher value for B-1 seems to be originating from the difference in the type of sulfur atom bonded to iron (II) center. Moreover, smaller D values suggest negligible mixing of energy states.

The electronic spectra of both the complexes exhibit a prominent peak around 16000 cm^{-1} with a shoulder at about 12300 cm^{-1}. These bands are assigned based on the spectral evidences for mixed ligand complexes of iron (II) with oxalate, maleate, phenanthroline and bipyridine [22]. Although, the exact assignments are not reported for these absorptions, the first band predominantly arises from metal-ligand charge transfer while the second absorption is thought to originate from d–d transitions.

3.3. Iron (III) complexes

Room temperature magnetic moments for A-2 and B-2 neither corresponds to high-spin nor low-spin states (Table 1) and probably suggest that they exhibit either spin-equilibrium behavior or belong to an intermediate $S = 3/2$ spin state. In order to ascertain the exact magnetic properties, variable temperature magnetic susceptibility measurements were carried out in the temperature range 16–300 K (Fig. 4). A plot of temperature vs. magnetization data indicate that they do not fit with a thermally accessible spin-state conversion and clearly reflect the presence of an unusual $S = 3/2$ spin state. Moreover,

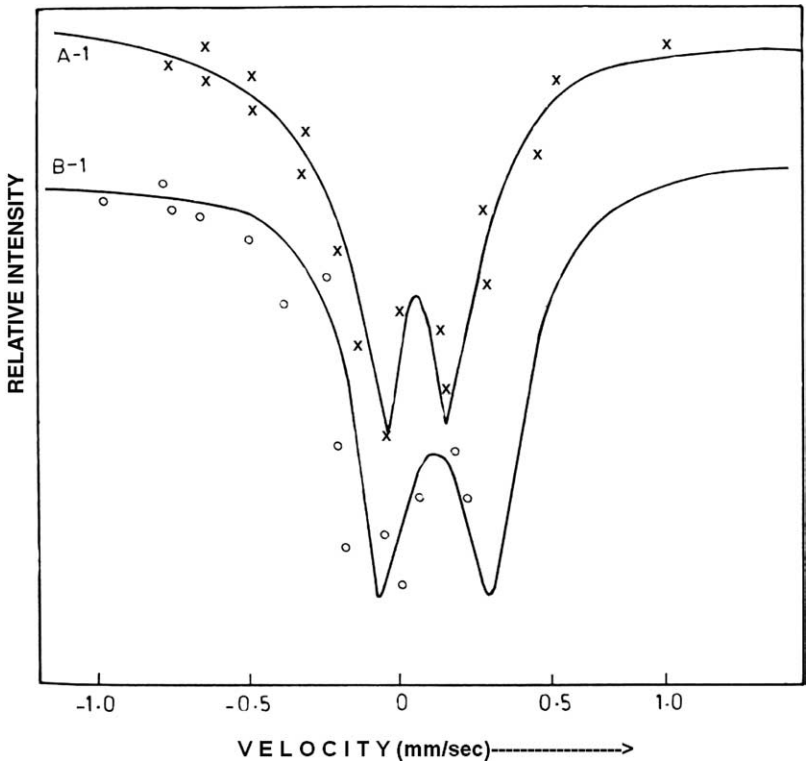

Fig. 3. Mössbauer spectra of A-1 (×) and B-1 (○) at 298 K.

Table 3
Zero-field splitting (D), 'g' values and Mössbauer parameters for iron (II), iron (III) and cobalt (II) complexes of NQTSC

Complex	D, cm^{-1}	g value		IS[a] (δ, mm s^{-1})	QS[a] (ΔE_q mm s^{-1})

[a] Relative to α-iron foil.

at lower temperature, there is no significant drop in magnetic moments, signifying the absence of exchange coupled dimeric iron (III) centers.

The existence of such an intermediate spin-state has been reported for prophyrin [23], dithicarbamate [24] and thiosemicarbazone complexes [1,25]. It is observed that such magnetic behavior originates from either square pyramidal or tetragonal geometries with a weak axial ligand field where the $d_{x^2-y^2}$ orbital lies well above the d_{z^2} orbital in energy and remains unoccupied. Many of these compounds possess magnetic moments in the range 4.2–5.5 BM and this behavior is explained on the basis of quantum admixing of $S = 3/2$ and 5/2 states, presumably through spin–orbit coupling as the energy separation between these states is very small. This feature is recognized with an unusual $g = 4$ signal in the EPR spectrum as well as a drop in the magnetic moment at lower temperatures. Using the crystal field model, Mitra et al. [26] have established that the extent of mixing of the $^6A_1$ with $^4A_2$ state is about 40% for prophyrin complexes. The other justification for the higher magnetic moments is attributed to a large zero-field splitting component leading to unequal population of Kramer's doublets originating from the $S = 3/2$ state, a feature usually found to be associated with prophyrin complexes.

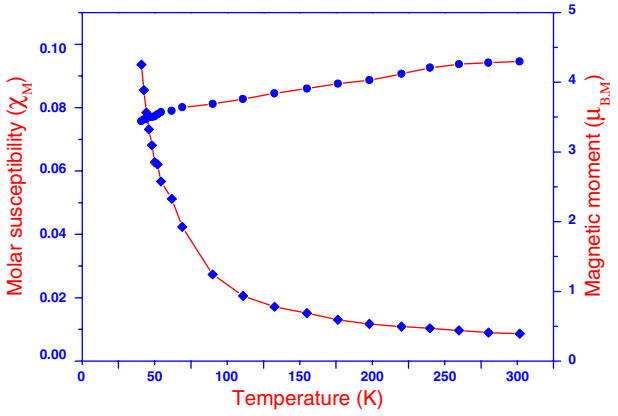

Fig. 4. Temperature dependence of magnetic susceptibility (♦) and effective magnetic moment (●) of B-2.

According to perturbation theory [27], $g_\perp = 4$ and $g_\parallel = 2$ signals are expected when $M_s = \pm 1/2$ doublet is the ground state. ESR spectra of A-2 and B-2 at 298 K can be interpreted in terms of a rhombic pattern exhibiting signals around $g = 2$ (assigned to the $-1/2 \rightarrow +1/2$ transition) and less resolved band at $g = 4$ (Table 3). However, at 77 K (Fig. 5), the former band is found to split as a consequence of rhombic symmetry while there is an enhancement in the intensity of the $g = 4$ signal suggesting a thermal population of the $M_s = -1/2$ state. The zero-field splitting (ZFS) parameter (D) calculated for these two compounds by fitting the experimental ESR data is summarized in Table 3. A positive D value is indicative of $M_s = \pm 1/2$ as the ground state with the first excited state ($M_s = \pm 3/2$) placed at 2D above this level, with the contribution from the E parameter assumed to be zero. A significantly larger value of the ZFS was observed for dithiocarbamate complexes [28] wherein it was argued that at lower temperatures, the population of the $M_s = \pm 3/2$ doublet is negligible with very weak magnetic exchanges.

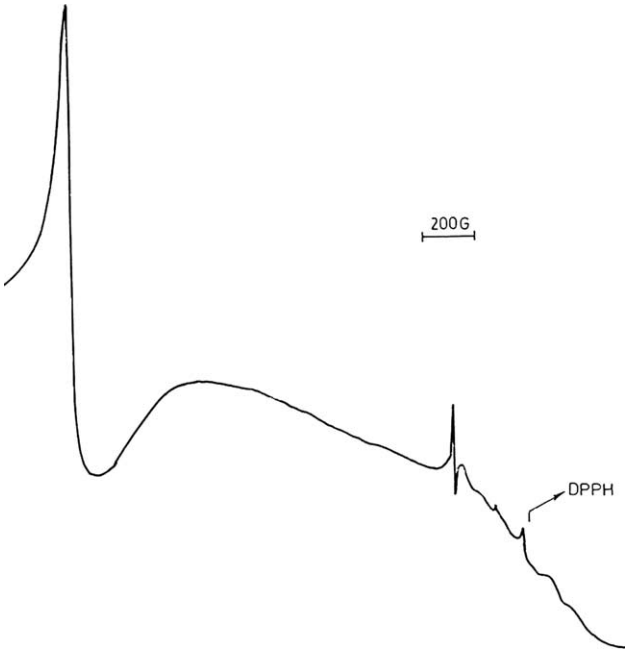

Fig. 5. X-band ESR spectrum of B-2 in DMSO solution at 77 K.

A-2 and B-2 exhibit three electronic transitions in their absorption spectra recorded in DMSO solvent. Out of these absorptions, the first two bands are assigned to $d_{xy} \rightarrow d_{xz}/d_{yz}$ and $d_{xy} \rightarrow d_{z^2}$ transitions while the third band originates from charge-transfer characteristics of metal-thiosemicarbazones [29]. B-2 shows these bands on the higher energy side as compared to A-2, suggesting the weak ligand field for the thione sulfur against the thiol sulfur.

3.4. Cobalt (II) complexes

Although, the interaction of NQTSC with cobalt (II) chloride essentially yields octahedral complexes A-3 and B-3, their magnetic properties are found to be significantly different, with the former complex exhibiting diamagnetism corresponding to a cobalt (III) species while the later compound possesses a low-spin cobalt (II) center with a magnetic moment of 1.86 BM. It has been reported earlier that the interaction of thiosemicarbazones with cobalt (II) yields mixed tautomeric complexes containing both thione and thiol sulfur binding. Such a mixed tautomeric coordination seems to be promoted by trivalent transition metal ions such as Cr(III), Fe(III) and Co(III). We have also observed similar features in cobalt (III) and chromium (III) complexes of pyruvic acid thiosemicarbazone and 2-ketobutyric acid thiosemicarbazone [14a,14b]. Thus, A-3 involves a similar type of binding for NQTSC with both thione and thiol coordination. The supportive evidence for octahedral geometry is obtained from its electronic spectrum wherein three transitions are observed at 13 605, 15 700 and 21 880 cm^{-1} corresponding to $^1A \rightarrow {}^3T_{1g}$, $^1A \rightarrow {}^3T_{2g}$ and $^1A \rightarrow {}^1T_{1g}$ transitions, respectively [30]. The evaluation of ligand field parameters such as $10D_q$ (17 375 cm^{-1}), B (416 cm^{-1}), C (1664 cm^{-1}) and β (0.40) is indicative of a weaker ligand field for NQTSC as compared to other thiosemicarbazone ligands [1] as well as appreciable covalency in the cobalt–ligand bonding.

B-3 exhibits a magnetic moment of 1.86 BM, corresponding to low-spin octahedral cobalt (II) species, which is slightly higher than the spin-only value of 1.73 BM and probably can be explained on the basis of a greater contribution of the orbital angular momentum to the ground state. The ESR spectrum (Table 3) exhibits an axial magnetic symmetry with two principle g values: $g_\perp = 2.12$ and $g_\parallel = 2.003$. The calculation of the spin concentration yields 8.20×10^{20} spins per g, i.e. ≅1 unpaired electron per B-3 molecule [31]. The shift of the $g_\perp$ value towards higher fields indicates the greater strength of the axial bonding as compared to the equatorial ligand field strength [32,33]. The optical spectra of low spin complexes with a ^2D ground term in a D_{4h} crystal field show two characteristic transitions assigned to $^2B_{2g} \rightarrow {}^2A_{1g}$ and $^2B_{2g} \rightarrow {}^2E_g$ with the later band receiving some contribution from charge-transfer features. For B-3, these transitions can be seen at 17 920 and 22 150 cm^{-1}, respectively.

3.5. Copper (II) complexes

The room temperature magnetic moments for A-4 and B-4 are 2.14 and 1.96 BM. The contribution from lower symmetry (D_{2h}) to effective D_{4h} symmetry [34] is found to be 27.17% and 13.30%, respectively. The high value for A-4 probably reflects the weaker thione coordination leading to a larger distortion at the axial position as compared to the thiol binding for B-4. It has been established that six coordinate copper (II) complexes possess elongated tetragonal or rhombic distortions in an octahedral field and display three spin-allowed transitions assigned to $^2B_{1g} \rightarrow {}^2A_{1g}$ (γ_1), $^2B_{1g} \rightarrow {}^2B_{1g}$ (γ_2) and $^2B_{1g} \rightarrow {}^2E_g$ (γ_3) absorptions [30]. However, the first transition usually appears as a shoulder and sometimes overlaps with the later transition (γ_2). A-4 and B-4, exhibit two bands around 17 000 and 23 000 cm^{-1} corresponding to the second and third transitions attributed to $\Delta_\parallel$ and $\Delta_\perp$, respectively (Table 4). The ESR spectra of A-4 and B-4 in the solid state at 298 and 77 K consist of two-principle g values: $g_\parallel = 2.205$ and $g_\perp = 2.054$, consistent with $d_{x^2-y^2}$ ground state in a tetragonal ligand field. However at 300 K, the spectra exhibit four fairly well resolved components originating from −3/2, −1/2, 1/2 and 3/2 transitions ($\Delta M_s = 1$). The signal corresponding to $M_I = -3/2$ clearly splits into five peaks because of superhyperfine coupling with hydrazinic nitrogen

Table 4
ESR spectral data for A-4 and B-4

β^2	0.8178	0.7996
β'^2	0.9235	0.9266
δ^2	1.0	1.0
δ'^2	0.7750	0.7541

[a] In cm^{-1}.

atoms of bound ligand molecules, with a splitting of about 16*G*. From this spectrum, the isotropic spectrochemical splitting factor (g_0), isotropic hyperfine splitting constant ($^{Cu}A_0$) and isotropic ligand super-hyperfine constant ($^{N}A_0$) are calculated and these are subsequently used in the evaluation of other spectral parameters.

The effective spin-Hamiltonian describing the EPR spectra of copper (II) complexes in tetragonal (D_{4h}) crystal field [35] can be written as:

$$H = \beta[g_{\parallel}H_zS_z + g_{\perp}(H_xS_x + H_yS_y)] + {}^{Cu}A_{\parallel}S_zI_z(\mathrm{Cu}) + {}^{Cu}A_{\perp}[S_xI_x(\mathrm{Cu}) + S_yI_y(\mathrm{Cu})] + [{}^{N}A_{\parallel}S_zI_z(N) + {}^{N}A_{\perp}\{S_xI_x(N) + S_yI_y(N)\}], \quad (3)$$

where the terms involved have their usual meanings.

The low temperature (77 K) DMSO frozen glass EPR spectra (Fig. 6) of these complexes display four line copper hyperfine lines, characteristic of monomeric copper (II) complexes with a $g_{\perp}$ component with well resolved superhyperfine interactions due to two hydrazinic nitrogen atoms of NQTSC. Kivelson and Nieman [36] have pointed out that compounds having $g_{\parallel} \geqslant 2.3$ are ionic in nature while those with $g < 2.3$ are covalent in character. The $g_{\parallel}$ values for A-4 and B-4 reveal appreciable covalency with $d_{x^2-y^2}$ as the ground state. From the low temperature ESR spectra, various bonding parameters such as in-plane σ-bonding, in-plane π-bonding as well as out-of-plane π-bonding are evaluated [14d] in order to understand the nature of the metal–ligand bonding in these complexes (Table 4). The orbital reduction factors, viz. $K_{\parallel}$ and $K_{\perp}$, are calculated using the equations $g_{\parallel} = 2.0023\ \{1-(4K_{\parallel}\lambda/\Delta_{\parallel})\}$ and $g_{\parallel} = 2.0023\ \{1-(K_{\perp}\lambda/\Delta_{\perp})\}$. For pure σ-bonding $K_{\parallel} \cong K_{\perp} \cong 0.77$ while $K_{\parallel} < K_{\perp}$ signifies in-plane π-bonding, with $K_{\parallel} > K_{\perp}$ accounting for out-of-plane π-bonding. Also, $G > 4$ indicates negligible interaction between two copper centers.

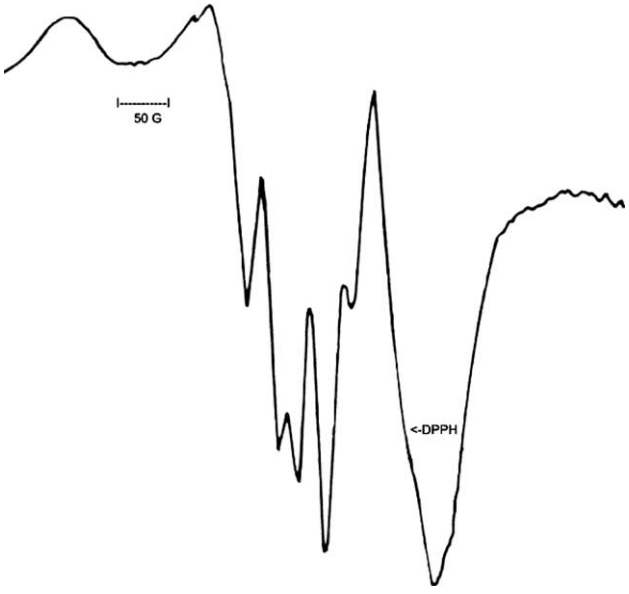

Fig. 6. X-band ESR spectrum of B-4 in DMSO solution at 77 K.

It has been observed [37] that the contribution of the 4s orbital to σ-bonding between metal and ligand donor atom orbitals is predominant in those complexes with α^2 values greater than 0.70. For the present complexes, these values are less than this value, which supports a ground term with purely 3d character. As the ^{14}N tensor is perpendicular to the *z*-axis in D_{4h} symmetry, the superhyperfine splitting along $Cu_{\parallel}$ features corresponds to $^{N}A_{\perp}$ while that on $Cu_{\perp}$, it is found to be equal to $\sqrt{2[(^{N}A_{\parallel})^2 + (^{N}A_{\parallel})^2]^{1/2}}$. There exist relatively sharp features for nitrogen coupling as evidenced from the low temperature spectra of these complexes. The anisotropy observed in the superhyperfine structure suggests that the unpaired electron is delocalized over the ligand orbitals presumably through in-plane σ- and π-bonding as well as out-of-plane π-bonding interactions [38].

The spin-densities in 2s and 2p orbitals of the nitrogen atom can be calculated [39] using the relations $\rho_{2s} = {}^{N}A_0/A_s$ and $\rho_{2p} = {}^{N}A_{\parallel}/A_p$ where A_s (550*G*) and A_p (34.1*G*) are the nitrogen hyperfine splitting parameters when the electron is residing entirely in 2s and 2p orbitals, respectively. Employing these relations, it is observed that there exists appreciable electron density on the nitrogen orbitals accounting for in-plane σ-bonding as well as in-plane π-bonding. Moreover, these values also signify the extent of electron delocalization between metal-ligand bonding. The estimation of such electron densities in 2s and 2p orbitals of the nitrogen atom amounts for a p:s ratio (2.333 and 2.323 for A-4 and B-4) which is in excess of the value expected for the sp^2 hybridization that would indicate a transfer of spin density from metal to ligand through π-bonding interactions. This excess of electron density (ca. 0.33) is obviously donated from copper and corresponds to the net amount of electron density contributed towards σ-bond formation as corroborated by the α^2 parameter. It may be argued that this unpaired electron spends about 33% of its time on donor sites of the coordinated NQTSC ligand and thus attributes for greater covalency as evidenced from the evaluation of the other bonding parameters. Inspection of Table 4 reveals that β^2 and β'^2 values support the appreciable covalency in the metal–ligand bonding, suggesting that the electron density transfers are promoted through low lying vacant π-orbitals on the sulfur atom.

3.6. Electrochemistry

The cyclic voltammetric behavior of NQTSC and its metal complexes is carried out in DMSO solution containing 0.1 M TEAP as the supporting electrolyte and the data is summarized in Table 5. It is well established that quinonoidal compounds exhibit two reversible

Table 5
Cyclic voltammetric data[a] (V) for iron (II), iron (III), cobalt (II) and copper (II) complexes of NQTSC

Compound	E_{pc}[a]	E_{pa}[a]	$E_{1/2}$	% Reversibility (i_{pc}/i_{pa})
A-1	+0.200	+0.330	+0.265	95

	+0.175	+0.280	+0.2275	97

[a] At scan rate 0.1 V s^{-1}.

cathodic peaks corresponding to quinone → semiquinone and semiquinone → catechol redox couples [5]. The parent 2-hydroxy-1,4-naphthoquinone (lawsone) exhibits the corresponding reduction peaks at −0.34 and −0.98 V, respectively [11a]. Upon derivatisation with thiosemicarbazide (NQTSC), the former peak is shifted to a more negative potential (−0.55 V) while the second peak is lost with the appearance of a new peak at −1.20 V, assigned to the reduction of the azomethine linkage of the thiosemicarbazide side chain; a behavior usually observed for many thiosemicarbazone ligands.

The voltammetric responses for A-1 and B-1 exhibit an oxidative couple at positive to Ag/AgCl in the range 0.2–0.3 V assigned to the Fe(II)/Fe(III) pair [40]. Quasi-reversibility of this wave is inferred from the peak potential separation $\Delta E_p > 125$ mV as well as the cathodic to anodic current intensity ratio. It can be seen from the data that B-2 is more susceptible to oxidation as compared to A-1, suggesting the effect of the type of sulfur binding. Such a difference stems from the fact that thiolato sulfur induces a more covalent character in Fe–S bonding as compared to thionato sulfur. This can be attributed to the charge accumulation capability of the thione (C=S) linkage against the thiol (C–S) chromophore.

In the DMSO solutions containing TEAP, A-2 and B-2 exhibit nearly identical electrochemical response. The cyclic voltammogram of A-2 (Fig. 7) shows one wave at +0.130 with its counterpart at +0.200 V, attributed to Fe(III)/Fe(II) in the range 0 to +1.0 V. Similar behavior is also displayed by B-2 at a more positive potential. As NQTSC is electrochemically inactive in this potential range, this behavior could be explained on the basis of a metal centered wave originating from reduction of the ferric centers [41]. It seems that the

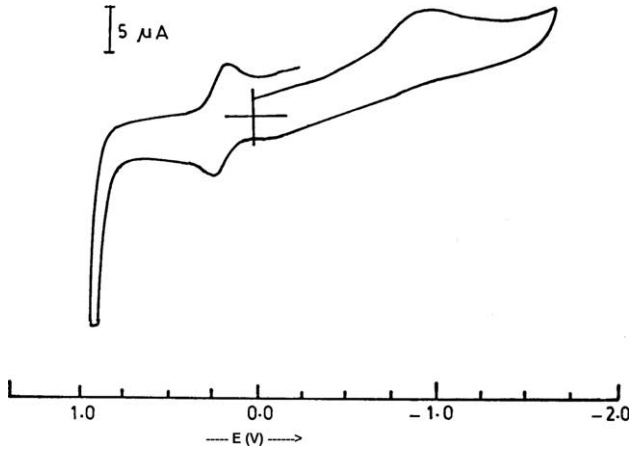

Fig. 7. Cyclic voltammogram for A-2 in DMSO at 0.1 V s^{-1} scan rate.

complex molecule does not experience any structural changes that accompany the reduction process, probably due to the rigidity of the ONS ligating system. The reversible nature of this reduction peak can be ascertained with scan rate dependence studies (Fig. 8), wherein it is observed that the current peak linearly varies with scan rate (γ) in the range 100–700 mV s^{-1} thus indicating a diffusion controlled mechanism, although at higher

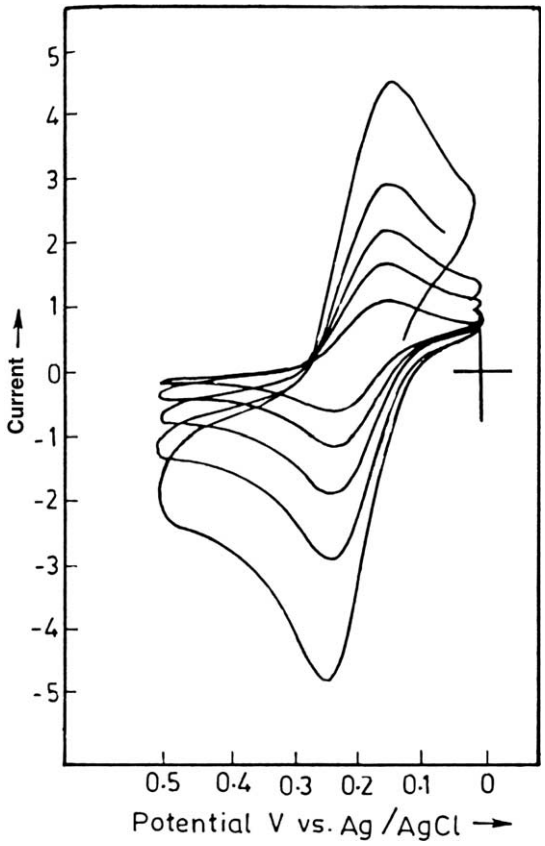

Fig. 8. Scan rate dependence of A-2 at different scan rates ($v = 20$, 50, 100, 200 and 500 V s^{-1}).

scan rates a weak adsorption of the complex at the electrode surface was observed. The peak separation $\Delta E_p = E_p^c - E_p^a$ of about 70 mV was noticed, as expected for a reversible one-electron reduction process [42]. At a slower scan rate, the shape and peak separation was about 70 mV but increased up to 100 mV when the scan rate changed from 100 to 700 mV s^{-1}. The reversible character of this couple was also confirmed by the observation of the cathodic shift of E_p^c of about 30 mV for a fivefold increase in the scan rate. A reduction wave exhibits a linear relationship between scan rate and current function (μA) and the ratio of anodic to cathodic peak current i_p^a/i_p^c is equal to unity suggesting that the iron (II) complex formed in the electro-reduction process is stable within the timescale of the experiment. B-2 exhibits a more positive potential as compared to A-2 indicating the influence of the type of sulfur coordination. On the cathodic scan in the range 0 to −2 V, both these complexes display an irreversible wave around −0.96 V probably originating from reduction of the azomethine linkage.

The cobalt complex of NQTSC (A-3) exhibits a cathodic reduction peak at −0.810 V with its anodic wave at −0.300 V, corresponding to the Co(III)/Co(II) quasi-reversible redox couple [43], having a peak separation of ~0.500 V. It is observed that the anodic peak is broad as against the sharp nature of the cathodic curve, suggesting that the rate of electron transfer is very slow as compared to mass transfer at the electrode surface, as evidenced from negligible deposition of the complex at the electrode surface. On the other hand, B-3 displays somewhat different electrochemical behavior in DMSO solution with the metal-based redox changes occurring at relatively higher potentials. On the cathodic side, the irreversible reduction peak at −0.775 V, assigned to the Co(II)/Co(I) process, undergoes electro-deposition upon the reverse scan thus signifying the formation of an unstable Co(I) complex. Similar behavior is observed when the anodic scans are recorded wherein the irreversible Co(III)/Co(II) couple occurs at +0.95 V indicating that there exists slow electrode to complex electron transfer kinetics and it is likely responsible for the irreversible nature of this peak [44].

The cyclic voltammogram for copper (II) complexes exhibit metal centered electrochemical processes (Fig. 9). Inspection of this figure indicates that the reduction wave (peak A) and it's oxidation counterpart (peak C) are related to the Cu(II)/Cu(I) reduction process in the range 0 to −2 V while on the anodic side (in the range 0 to +2), there exists an oxidation curve (peak E) with its cathodic peak (G). The other peaks are related to either quinone redox forms (peaks B, D and F) or coupled chemical reactions. Some of these species do not exist in the initial scan when the scan directions are reversed and exhibit intensity enhancement only on repetitive scanning.

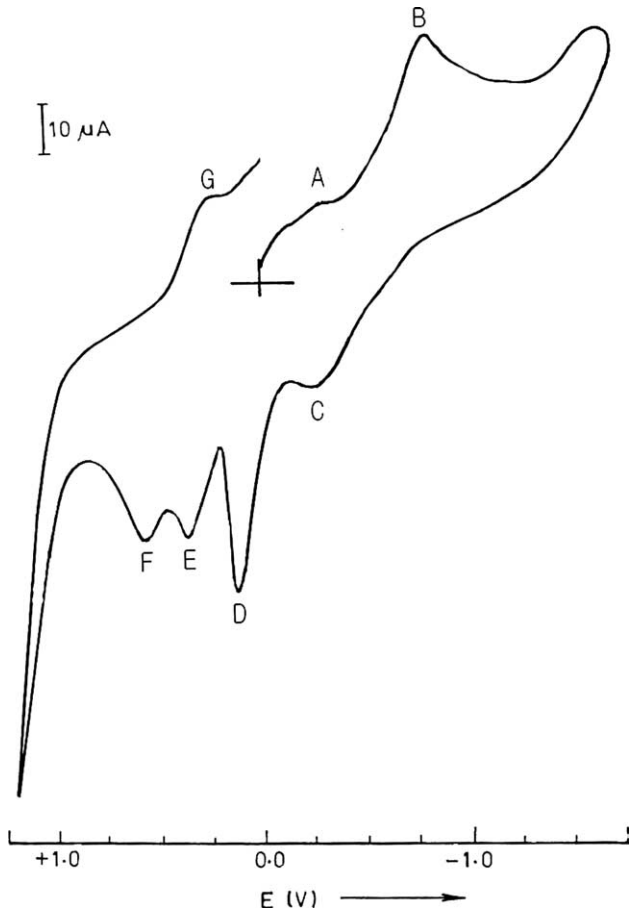

Fig. 9. Cyclic voltammogram of A-4 in DMSO at 0.1 V s^{-1} scan rate.

Analysis of the cyclic voltammetric response of peak A/C indicates that this process originates from a quasi-reversible Cu(II)/Cu(I) redox couple with a peak-to-peak separation (ΔE_p) of about 100 mV and the ratio of i_{pa}/i_{pc} is less than unity. In the absence of either uncompensated solution resistance or anomalous electrode surface effects, the marked departure of ΔE_p from 59 mV can be qualitatively assumed as an index of occurrence of significant geometrical reorganizations accompanying the redox changes [45]. It is expected that the Cu(II)/Cu(I) couple experiences some structural reorganization barrier while undergoing the reduction process. Patterson and Holm [46] have shown that softer ligands tend to favor more positive $E_{1/2}$ values while hard acids give rise to more negative values. The redox potentials observed for the present complexes indicate the moderate character for NQTSC implying that there exists appreciable tetragonal distortion in the structural arrangement of A-4 and B-4, probably due to deformation in the chelate rings of the coordinated thiosemicarbazone.

The cyclic voltammetric behavior of A-4 and B-4 between +1 to 0 V exhibit cathodic response (peak E) in the range 275–405 mV with its counterpart (peak G) in

the range 370–535 mV. This feature corresponds to a quasi-reversible Cu(III)/Cu(II) redox process [47] as indicated by ΔE_p values as well as the non-equivalent current intensities of the cathodic and anodic peaks (% I_{pc}/I_{pa}). The redox process associated with oxidation of Cu(II) to Cu(III) may probably originate due to the presence of the thione/thiol sulfur center and the redox active quinone moiety. Since the quinone ring is planar and the thiosemicarbazide side chain is flexible, the ligand can adopt different conformations so as to fit the smaller sized Cu(III) ion, thus favoring the oxidation process. Moreover, this oxidation step results in the formation of a low-spin d^8 Cu(III) state with preference for a square planar geometry [48]. It is quite likely that this process does not proceed via a change in geometry of the complex in DMSO solution. This fact is clearly reflected in Table 5, indicating that the Cu(III) state can be stabilized at a relatively lower oxidation potential. The redox potentials observed for A-4 and B-4 are significantly lower than those reported earlier for thiosemicarbazone complexes [1] thus reflecting the influence of the electronic features of the redox active quinone moiety.

4. Conclusion

The interaction of NQTSC with iron (II), iron (III), cobalt (II) and copper (II) leads to formation of two different types of complexes containing coordination of thione/thiol or both the tautomers. Ferrous compounds exhibit an unusual spin triplet ground state ($S = 1$) with smaller ZFS values, indicating that NQTSC exerts a moderate ligand field as well as appropriate geometry responsible for fine-tuning of the magnetic properties. Similar behavior is also found to be present for ferric complexes possessing a spin quartet state ($S = 3/2$) thus suggestive of the potential of the thiosemicarbazone ligand for inducing uncharacteristic magnetic behavior. Moreover, there exists a reasonable amount of distortion in the octahedral geometry as a consequence of appreciable mixing of excited states. It is significant to note that the type of sulfur coordination as well as effective symmetry around the metal centers strongly influences the magnetic properties, thus stabilizing abnormal spin-states. Mixed tautomeric complexes are formed with iron (III) and cobalt (III) complexes under acidic conditions suggesting a lower pK_a value for NQTSC. There exists appreciable covalency in the metal-ligand bonding as well as a significant amount of tetragonal distortion in the octahedral geometry as evidenced from the ESR spectral measurements on the copper (II) complexes. The estimation of various bonding parameters indicate that substantial delocalization has occurred within the chelate rings of NQTSC mediated via in-plane π-bonding along with σ-donation, thus resulting in an increased structural stability. Metal-centered processes that are strongly influenced by the nature of sulfur binding dominate the redox behavior of these complexes. In general, thiol coordination seems to favor an oxidation process at lower potentials whereas a thione sulfur substantially manipulates the reduction behavior of these complexes.

1. Introduction

In the second half of the last century many aminopolycarboxylate ligands, structurally related to edta (the ethylenediaminetetraacetate ion), have been prepared and used to form hexadentate complexes with transition metal ions [1,2]. One such ligand is the 1,3-propanediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate ion (1,3-pddadp), Fig. 1(a), having a lengthened diamine and two carboxylate chains with respect to edta. In the reactions between 1,3-pddadp and metal ions with hexadentate coordination of this ligand, theoretically three geometrical isomers are possible: *trans*(O_5), *trans*(O_5O_6) and *trans*(O_6); where O_5 and O_6 refer to the five- and six-membered N–O rings, respectively, Fig. 1(b). The same geometrical isomers are also possible for hexadentate $[M(eddadp)]^{n-}$ (where eddadp is the ethylenediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate ion) complexes, and for these complexes it was found that six-membered β-alaninate rings serve better for the formation of less-strained G rings, favoring the *trans*(O_5) geometry [2–13]. Contrary to this, all possible isomers of the $[M(1,3\text{-pddadp})]^{n-}$ complex have been reported for Cr(III) [14], but only two isomers (*trans*(O_5O_6) and *trans*(O_6) for Co(III) [15,16] and *trans*(O_5) and *trans*-(O_5O_6) for Rh(III) [17,18] and Ni(II) [19]) have been isolated and characterized. In addition, only one dominant isomer of the same complex (*trans*(O_6)) of Cu(II) [20] has been described. The so far available X-ray data are limited to: *trans*(O_6)-[Cr(1,3-pddadp)]$^-$ [14], *trans* (O_6)-[Co(1,3-pddadp)]$^-$ [16,21], *trans*(O_5)-[Rh(1,3-pddadp)]$^-$ [18], *trans*(O_5O_6)-[Rh(1,3-pddadp)]$^-$ [18], *trans*(O_5)-[Ni(1,3-pddadp)]$^{2-}$ [19] and *trans*(O_6)-[Cu(1,3-pddadp)]$^{2-}$ [20] complexes.

In the reaction of the 1,3-pddadp ligand with Co(III) ion two geometrical isomers (*trans*(O_5O_6) and *trans*(O_6)) of the hexadentate [Co(1,3-pddadp)]$^-$ complex have been obtained, resolved and characterized [15]. The $(+)_{546}$-*trans*(O_5O_6)-[Co(1,3-pddadp)]$^-$ and $(+)_{546}$-*trans*-(O_6)-[Co(1,3-pddadp)]$^-$ enantiomers, with a positive CD peak at the lowest energy in the first spin-allowed d–d absorption band region, were tentatively assigned the *Λ* absolute configuration. The *trans*(O_6) geometry of [Co(1,3-pddadp)]$^-$ has been established in the crystal structure of racemate *trans*(O_6)-K[Co(1,3-pddadp)] · $3H_2O$ [16], as well as in the crystal structure of optically pure compounds: $(-)_{589}$-*trans*(O_6)-$K_{1/2}(H_5O_2)_{1/2}$[Co(1,3-pddadp)] · $2H_2O$ [21] and $(-)_{589}$-*trans*(O_6)-Li[Co(1,3-pddadp)] · $7H_2O$ [21]. The crystallographic studies of Co(III) amine carboxylates have been of particular interest in connection with different kinds of "mysteries" of hydronium ions [21]. Namely, it has been found that minor variations in composition and/or stereochemistry of Co(III) amine carboxylates are sufficient to influence the crystallization of the hydronium ion or the mixed potassium–hydronium salts, as evidenced in the crystal structure of $(-)_{589}$-*trans*(O_6)-$K_{1/2}(H_5O_2)_{1/2}$[Co-(1,3-pddadp)] · $2H_2O$ [21].

The characterization of the *trans*(O_5O_6) geometry of the [Co(1,3-pddadp)]$^-$ complex using crystallographic methods is described here first. In addition, molecular mechanics (MM) calculations were applied for establishing the relative energies of the three geometrical isomers: *trans*(O_5), *trans*(O_5O_6) and *trans*(O_6) of the [Co(1,3-pddadp)]$^-$ complex.

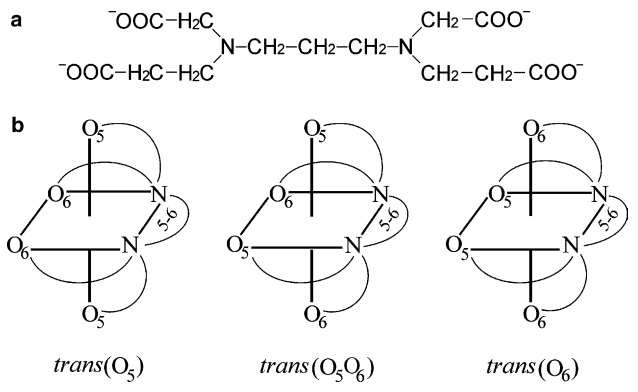

Fig. 1. Formula of the 1,3-pddadp ligand (a); and possible geometrical isomers of the hexadentate $[M(1,3\text{-pddadp})]^{n-}$ and/or $[M(eddadp)]^{n-}$ complex (b); O_5 and O_6 refer to the five- and six-membered N–O rings, respectively.

2. Experimental

The investigated complex *trans*(O_5O_6)-[Co(1,3-pddadp)]$^-$ was prepared according to the previously described procedure [15]. Recrystallization of this complex was accomplished from hot water by adding ethanol and cooling of the solution in a refrigerator.

2.1. Crystallographic data collection and refinement of the structure

For the hexadentate *trans*(O_5O_6)-K[Co(1,3-pddadp)] · $3H_2O$ complex, X-ray analysis was performed on the basis of the reflection intensities measured at 293 K on a KM4CCD kappa-geometry diffractometer [22] using graphite monochromated Mo Kα radiation.

Crystal data: $KCoC_{13}H_{24}N_2O_{11}$ (FW = 482.37), monoclinic, space group $P2/c$, $a = 14.591(3)$, $b = 9.815(2)$, $c = 12.922(3)$ Å, $\beta = 94.06(3)°$, $V = 1845.9(7)$ Å^3, $Z = 4$, $D_{calc} = 1.736$ g cm^{-3}, λ (Mo Kα) = 0.71073 Å, $T = 293$ K, $\mu = 1.218$ mm^{-1}, $F(000) = 1000$.

The structure was solved by direct methods using SHELXS97 [23] and refined by least-squares techniques with SHELXL97 [24] to $R = 0.057$ and $Rw = 0.151$. Anisotropic thermal parameters were employed for the non-hydrogen atoms. The positions of the hydrogen atoms attached to the C-atoms were calculated at standardized distances of 0.96 Å. An attempt to localize water hydro-

gens on subsequent difference Fourier maps was not fully successful. Moreover, one of the hydrogen atoms connected to O4W formed a very short non-bonding contact with its inversion related equivalent (H6W···H6W($2-x$, $-y$, $-z$) 1.21 Å). Therefore, we have assumed the presence of a disordered configuration, with half occupancy of one of the two O4W water hydrogens, but the alternative position of this hydrogen atom could not be determined on the subsequent difference Fourier maps. We were also unable to locate one of the two hydrogen atoms connected to O1W. During the structure determination process it became obvious that this hydrogen must also be disordered, this time over the two sites that are related by a twofold axis. The disorder model for the H-atom positions allowed us to postulate the presence, in the crystal, of statistically distributed, anti-parallel homodromic hydrogen bonded water chains (see Fig. 1S in the supplementary material). All OW–H distances have been standardized to a value of 0.85 Å. The hydrogen atoms were refined using a "riding model" with isotropic temperature factors 30% higher than the isotropic equivalent for the atom to which the H-atom was bonded. A Siemens Stereochemical Workstation was used to prepare the drawings [25].

2.2. Molecular mechanics calculations

Conformational analysis of the three geometrical isomers of the $[Co(1,3\text{-pddadp})]^-$ complex was carried out using the consistent force field (CFF) conformational program [26] with force field parameters particularized earlier [27,28]. The only new parameters are for the cobalt atom and the values are given in Table 1. The conformational energy was calculated from the following equation:

$$E_{\text{total}} = \Sigma E_{\text{b}} + \Sigma E_{\theta} + \Sigma E_{\varphi} + \Sigma E_{\text{nb}} + \Sigma E_{\text{e}}, \quad (1)$$

where the summations are over all energy contributions from bond stretching (E_{b}), angle bending (E_{θ}), torsion angle (E_{φ}), non-bonded (E_{nb}) and electrostatic interactions (E_{e}). The potential functions and parameters constituting the energy terms in Eq. (1) have been described previously [29], and we used essentially the same forms in this study, except the type for the non-bonded potential function. In this work we used the Lennard–Jones '12-6' rather then the Lennard–Jones '9-6' type function and this approach proved to be quite adequate for the present study. With this potential function we recalculated the conformations of the $[Cr(ed3p)(H_2O)]$ (ed3p is the ethylenediamine-*N*,*N*,*N*′-tri-3-propionate) and $[Cr(ed3a)(H_2O)]$ (ed3a is the ethylenediamine-*N*,*N*,*N*′-triacetate) complexes and obtained practically the same results as previously reported [27,28].

The force field is parameterized on the basis of the two different types of carbon atom (sp^3 – (C) and sp^2 – (C′) carbons), two different types of oxygen atom (carbonyl (O′) and coordinated (O) oxygens), one type of hydrogen (H) and of nitrogen (N), as well as the central metal atom (Co). Comprehensive preliminary calculations did not justify the distinction between aliphatic carbons from glycinate, β-alaninate and 1,3-propanediamine chelate rings. All the stable conformers were found by energy minimization of the numerous theoretically possible initial structures having all the permissible conformations of 1,3-propanediamine and β-alaninate rings. By this strategy we believe that we have achieved a comprehensive and reliable spanning of the three geometrical isomers of $[Co(1,3\text{-pddadp})]^-$. The procedure used in the generation of the initial structures is similar to that in our previous paper [27].

Geometry optimizations were carried out using the combination of steepest-descent, Davidon–Fletcher–Powell and Newton–Raphson methods [26]. The steepest-descent and Davidon–Fletcher–Powell methods were

mostly used, in that order, for initial exploratory searches and minimizations of conformations far from equilibrium. The number of iterations varied widely in the optimization experiments. In particularly difficult cases it was necessary to alternate between these two procedures more than once. To approach true minima Newton–Raphson iterations were always employed. Geometry optimizations were carried out down to an energy rms gradient of $<10^{-6}$ kJ/mol Å.

ORTEP III for Windows [30] was used to depict the energy-minimized structures.

3. Results and discussion

3.1. The crystal structure of the *trans*(O_5O_6)-K[Co(1,3-pddadp)] · $3H_2O$ complex

The ORTEP diagram of the *trans*(O_5O_6)-[Co(1,3-pddadp)]$^{-}$ complex anion is presented in Fig. 2, where the numbering scheme adopted for the respective atoms is also given. Selected bond distances and valence angles are listed in Table 2.

The Co(III) ion is encircled by all of the donating atoms (2N and 4O) of the 1,3-pddadp ligand to form an octahedral geometry. The complex anion [Co(1,3-pddadp)]$^{-}$ represents a *trans*(O_5O_6) isomer with the two (R) rings (glycinate R_1 and β-alaninate R_2) in the *trans* positions and the two (G) rings (β-alaninate G_1 and glycinate G_2) coordinated in the equatorial plane making a 5–6–6 ring system in the G-plane (Fig. 2). The format for describing the various chelate rings formed in these kinds of chelates was credited to Weakliem and Hoard [31]. We have compared the mode and degree of puckering of the chelate rings observed in the presented *trans*(O_5O_6)-[Co(1,3-pddadp)]$^{-}$ complex with those for *trans*(O_6)-[Co(1,3-pddadp)]$^{-}$ complexes [16] having a 5–6–5 combination of the ring members in the G-plane. The results are presented in the form of Table 1S in the supplementary material. In both *trans* (O_5O_6) and *trans*(O_6) complexes of Co(III), the six-membered diamine (T) ring adopts a nearly perfect *twist-boat* conformation. The helicity of the six-membered diamine ring is δ for the enantiomorph presented in Fig. 2 of Λ configuration. The same is observed for

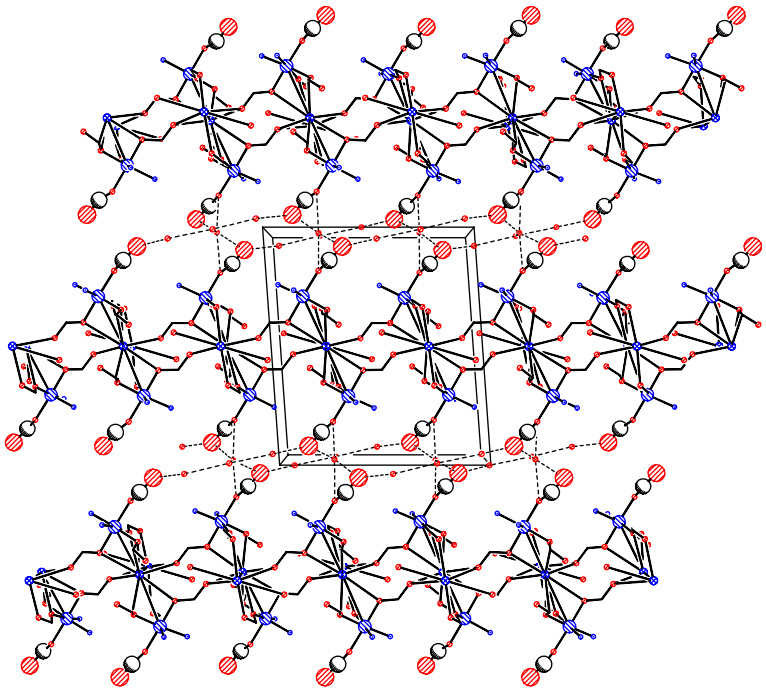

Fig. 3. Packing in the crystal structure of *trans*(O_5O_6)-K[Co(1,3-pddadp)] · $3H_2O$ showing the separation of ionic and water layers. Atoms involved in carbonyl dipolar interactions operating between the layers are marked by substantially bigger circles. H-atoms have been omitted for clarity.

the *trans*(O_6)-[Co(1,3-pddadp)]$^-$ complex of *Λ* configuration. In these two complexes the six-membered β-alaninate rings coordinated in axial positions are very distorted and their distortion from the ideal conformations is so severe that they cannot be uniquely described by the commonly used conventions. Contrary to this, the six-membered β-alaninate ring of equatorial orientation in *trans*(O_5O_6)-[Co(1,3-pddadp)]$^-$ adopts an almost ideal *half-chair* form. The five-membered glycinate rings coordinated in the G-plane display different conformational modes (*envelope* in the *trans*(O_5O_6) Co(III) complex and *twist* in the *trans*(O_6) Co(III) complex), however, the degree of puckering of these rings is nearly the same (20.6–23.6°). In the [Co(1,3-pddadp)]$^-$ complexes of *trans*(O_5O_6) and *trans*(O_6) geometry the six-membered diamine rings (T rings) also exhibit nearly the same degree of ring puckering (the average torsion angle magnitude sums 41.7° and 44.1°, respectively). Similar values for the average torsion angle moduli have been observed in the [Co(1,3-pdta)]$^-$ (41.1°) (where 1,3-pdta is the 1,3-propanediaminetetraacetate ion), [Rh(1,3-pdta)]$^-$ (40.9°) and *trans*(O_5O_6)-[Rh(1,3-pddadp)]$^-$ (42.5°) complexes in which the six-membered diamine rings adopt the same *twist-boat* conformation [18]. The equatorially coordinated glycinates in the *trans*(O_5O_6)-[Co(1,3-pddadp)]$^-$ and *trans*(O_6)-[Co(1,3-pddadp)]$^-$ complexes are highly puckered, while that one coordinated in the axial position in the *trans*(O_5O_6) isomer is nearly *planar*. However, the six-membered β-alaninate rings display nearly the same degree of ring puckering, independent of their axial or equatorial orientation, so they seem to be the less easy to modify with respect to the glycinates. The values of the average torsion angle magnitudes cover a range from 31.8° to 35.7°. Similar behavior of β-alaninate rings has also been observed in the [Rh(1,3-pddadp)]$^-$ complexes of *trans*(O_5) and *trans*-(O_5O_6) geometry [18].

In the crystal structure of *trans*(O_5O_6)-K[Co(1,3-pddadp)] · $3H_2O$, potassium ions (K1 and K2), as well as O1W and O3W water solvent molecules, are settled on a twofold axis of symmetry. K1 is octacoordinated with six carbonyl oxygen atoms (O4, O2^{i}, O6^{ii}, O4^{iii}, O2^{iv} and O6^{v}; symmetry codes: i = $-x+1$, $y-1$, $-z+0.5$; ii = $-x+1$, $-y+1$, $-z$; iii = $-x+1$, y, $-z+0.5$; iv = x, $y-1$, z and v = x, $-y+1$, $z+0.5$) from six different but symmetry-related 1,3-pddadp ligands and with two symmetry-related water molecules O2W^{ii} and O2W^{v}. The coordination polyhedron formed around K1 is distorted in shape and can be described as a square antiprism. K2 is surrounded by eight carboxylate oxygen atoms (O1, O1^{iii}, O3, O3^{iii}, O5, O5^{iii}, O6^{ii} and O6^{v}) from four symmetry-related ligands. The two carbonyl oxygen atoms O6^{ii} and O6^{v} are shared between the K1 and K2 ions. The coordination polyhedron around K2 is midway between bi-capped trigonal prism and bi-capped trigonal antiprism with a twist angle *Φ*[1] [32] of 30.7°.

[1] *Φ* (calculated applying method 1 reported in [32]) is the average value of the three pseudotorsion angles that are measured along the line joining the centroids of two nearly parallel triangular faces of a bi-capped trigonal prism and adopt absolute values in the range 0–60°.

The crystalline *trans*(O_5O_6)-K[Co(1,3-pddadp)] · $3H_2O$ complex is a two-dimensional polymer (Fig. 3). It consists of (1 0 0) layers (see Fig. 2S in the supplementary material) built up of potassium ions, situated on twofold symmetry axes, joined by bridging oxygen atoms (O6 and its symmetrical equivalent) and by bridging carboxylate groups (O3–C6–O4 and its twofold symmetry equivalent along the *b*-axis, and O5–C10–O6 and its centrosymmetric equivalent along the *c*-axis). The construction of the polymeric layer structure formed by the potassium ions and their first coordination sphere is further supported by hydrogen bonds between the O2W water molecule coordinated to K1 and one of the uncoordinated carboxylate oxygens (O2) (Fig. 3). The Co1 octahedra are situated on both sides of the layer formed by cationic polyhedra, and are joined exclusively to K2 polyhedra by sharing one of the triangular faces of the Co1 octahedron. Consequently, the approach of the complex anion by the complex cation takes place from the side of the planar glycinate R_1 ring.

The consecutive ionic layers are separated by layers formed by hydrogen bonded non-coordinated water molecules (O1W and O3W, situated on a twofold axis, and O4W in a general position) and O7–C11–O8 carboxylate groups (Fig. 3). Two of these water molecules (O1W and O4W) have one of the two hydrogen atoms disordered (O1W around a twofold axis, O4W around the centre of symmetry) in a way that allows formation of antiparallel homodromic chains of hydrogen-bonded water molecules, statistically distributed in the crystal, running along the *c*-axis, which are graphically illustrated in Fig. 1S in the supplementary material. Hydrogen bond distances and angles are listed in Table 2S in the supplementary material. Interactions between neighbouring layers formed by the complex molecules include, besides hydrogen bonds, dipolar interactions between antiparallel C11=O8 carbonyl groups around the centre of symmetry (Fig. 3).

3.2. Strain analysis of Co(III)-edta-type chelates

The results of a comparative study of the strain characteristics of a related series of Co(III)-edta-type chelates are given in Table 3. The major contributions to strain were considered to be: (i) the octahedral angles around the Co(III) ion, (ii) the ring angle sums of the various kinds of rings, (iii) the Co–O–C bond angles, and (iv) the bond angles that the chelating nitrogen atom makes with its connectors.

The greatest octahedral distortion has been observed for the $[Co(edta)]^-$ (**7**) [31,33] complex (48°) having a 5–5–5 combination of the ring members in an equatorial plane. Introducing the six-membered β-alaninate ring(s) in the $[Co(edta)]^-$ (**7**) [31,33] system causes a decrease of octahedral strain as evidenced by $\Sigma\Delta(O_h)$ values calculated for the *trans*(O_5)-$[Co(eddadp)]^-$ (**4**) [8] (31°), *trans*(O_5)-$[Co(ed3ap)]^-$ (**5**) [34] (29°) and $[Co(edtp)]^-$ (**6**) [13] (29°) complexes. However, an increase of octahedral strain was observed when some of the glycinate rings in the $[Co(1,3\text{-}pdta)]^-$ (**3**) [35] complex are replaced by six-membered β-alaninate rings, as can be seen from the comparison of $\Sigma\Delta(O_h)$ values for the *trans*(O_5O_6)-$[Co(1,3\text{-}pddadp)]^-$ (**1**) (36°) and *trans*(O_6)-$[Co(1,3\text{-}pddadp)]^-$ (**2**) [16] (38°) complexes with that of $[Co(1,3\text{-}pdta)]^-$ (**3**) [35] (34°). Mostly due to the strain formed by chelation of in-plane glycinate rings, manifested

[a] Abbreviations of ligands: 1,3-pddadp = 1,3-propanediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate, 1,3-pdta = 1,3-propanediaminetetraacetate, eddadp = ethylenediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate, ed3ap = ethylenediamine-*N*,*N*,*N*′-triacetate-*N*′-3-propionate, edtp = ethylenediamine-*N*,*N*,*N*′,*N*′-tetra-3-propionate and edta = ethylenediaminetetraacetate.

[b] $\Sigma\Delta(O_h)$ is the sum of the absolute values of the deviations from 90° of the L–Co–L′ bite angles. All values rounded off to the nearest degree.

[c] $\Delta\Sigma$(ring) is the deviation from the ideal of the corresponding chelate rings' bond angle sum. A mean value of the two rings (R or G) is reported for complexes having an approx. C_2 molecular symmetry.

[d] Δ(Co–O–C) (ring) is the mean value of the deviation of the corresponding rings' Co–O–C bond angle from 109.5°.

[e] $\Sigma\Delta$(N) is the sum of the absolute values of the deviations from 109.5° of the six bond angles made by the nitrogen atoms. A mean value for the two nitrogens is reported.

[f] For the complexes (**1**) and (**5**) having C_1 molecular symmetry two values are reported.

in octahedral bond angles, the *trans*(O_6)-[Co(1,3-pddadp)]$^-$ [16] complex with a 5–6–5 ring system in the G-plane is more strained than *trans* (O_5O_6)-[Co(1,3-pddadp)]$^-$ having an in-plane 5–6–6 combination of the ring members. The strain formed around the chelating nitrogen atoms in [Co(1,3-pddadp)]$^-$ complexes of *trans*(O_5O_6) and *trans*(O_6) geometry is practically the same. As expected five-membered chelate rings coordinated in-plane are much more strained than those coordinated in axial positions. Of all the ethylenediamine rings observed in complexes (**4**–**7**), the greatest strain was registered for the ethylenediamine ring in the [Co(edtp)]$^-$ (**6**) [13] complex with the ligand ethylenediamine-*N*,*N*,*N*′,*N*′-tetra-3-propionate, which is able to form only six-membered carboxylato rings. For this ring the deviation from the ideal sum of chelate ring bond angles is −14°. For the analyzed Co(III) chelates the greatest strain among in-plane coordinated glycinates was registered for the glycinate ring in the *trans*(O_5)-[Co(ed3ap)]$^-$ (**5**) complex for which the total deviation sums −13°. The total deviation of six-membered chelate rings is positive and is the greatest for in-plane coordinated β-alaninate rings in the *trans*-(O_5O_6)-[Co(1,3-pddadp)]$^-$ (**1**) and *trans*(O_5)-[Co(ed-3ap)]$^-$ (**5**) complexes (+44°). The in-plane β-alaninate rings of the *trans*(O_5)-[Co(eddadp)]$^-$ (**4**) complex are less strained, favoring the *trans*(O_5) geometry, as expected for [M(eddadp)]$^{n-}$ complexes [2–13]. The two N-geminal β-alaninate rings (R and G) in [Co(edtp)]$^-$ (**6**) show the same positive total deviation of ca. 41°. The bond angles of the M–O–C fragment are expected to be between 109.5° and 120°, depending on the degree of covalency of the M–O bond [13]. These bond angles in the β-alaninate rings are as high as 130°. In general, these values are larger for the G β-alaninate rings than for the R β-alaninate rings and for Co(III) chelates are in the range 18–24° versus 17–21°.

3.3. Molecular mechanics results

The energy minimization and geometry optimization procedure resulted in several stable conformations for each geometrical isomer, *trans*(O_5), *trans*(O_5O_6) and *trans*(O_6), regardless of the initial conformation we started with. The structural parameters for the resulting most stable energy-minimized structures, as well as a comparison with the X-ray structures, are presented in Table 4. Ortep illustrations for each of the resulting structures are shown in Fig. 4.

Calculated energies for *trans*(O_5), *trans*(O_5O_6) and *trans*(O_6) isomers of [Co(1,3-pddadp)]$^-$ show that the *trans*(O_5O_6) isomer represents the most stable one

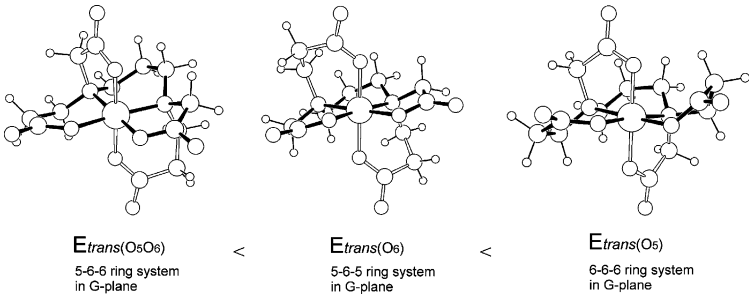

Fig. 4. Ortep illustrations of the energy-minimized structures of the three isomers of $[Co(1,3\text{-pddadp})]^-$.

(Table 4), but the energy differences between isomers are rather small and result mostly form torsional contributions to the total energy. The analysis of the torsional contributions to the total strain shows that in *trans*(O_5) and *trans*(O_6) isomers the strain is pronounced mainly in endocyclic torsions involving M–O and O–C′ bonds in the β-alaninate rings (G and R rings, respectively). In addition, in these β-alaninate rings we also noticed significant deviation from planarity of the coordinated carboxylato moiety, as indicated by the M–O–C′–O′ torsion angles of nearly 160° for all chelate rings considered. In the crystal structure of the *trans*(O_6)-$[Co(1,3\text{-pddadp})]^-$ complex the mean M–O–C′–O′ torsion angle in the axially coordinated β-alaninate rings is 154°. This might be the reason for greater torsional contributions to the total energy in the case of the *trans*(O_5) and *trans*(O_6) isomers.

The geometries of the calculated structures are in good agreement with the corresponding structures for which X-ray data are available (the *trans*(O_5O_6)-$[Co(1,3\text{-pddadp})]^-$ complex presented here and the earlier reported *trans*(O_6)-$[Co(1,3\text{-pddadp})]^-$ [16]). The lowest energy conformer corresponds to the configuration that has been found in the X-ray structure presented in this paper. The total energy of the minimized structures for three geometrical isomers of $[Co(1,3\text{-pddadp})]^-$ increases in the order $E_{total}(trans(O_5O_6)) < E_{total}(trans(O_6)) < E_{total}(trans(O_5))$, Table 4.

4. Concluding remarks

For the ligands having the ethylenediamine fragment and mixed five- and six-membered carboxylate arms (ed3ap [34,36] and eddadp [2–13]) geometrical isomers are possible that differ in the number (0, 1, or 2) of six-membered rings lying in the equatorial plane (G-plane). These ligands generally minimize strain by forming isomers that have six-membered ring(s) in the G-plane [2,13]. In the so far well known reactions of Co(III), [3,4,8] Cr(III), [6,10] Fe(III), [7] Rh(III) [5,9] and Ni(II) [12] with the ligand ethylenediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate (eddadp) the *trans*(O_5) geometry (Fig. 1(b)) is favored due to the lower steric strain formed by chelation of the two in-plane β-alaninate rings [2,13]. However, in the case of the 1,3-propanediamine-*N*,*N*′-diacetato-*N*,*N*′-di-3-propionato (1,3-pddadp) complex, especially with small metal ions such as Co(III) (0.685 Å), [37] the *trans*(O_5) isomer should be sterically disfavored because of the concentration of all three six-membered rings in the equatorial plane. The 6–6–6 combination of the chelate rings in the girdle plane has been observed in the *trans*(O_5) isomer of the 1,3-pddadp complex containing the Rh(III) ion, with an ionic radius of 0.805 Å [18], but has not been so far obtained for Co(III) [15,16], with an ionic radius of 0.685 Å. Of the two isomers that have been isolated for the $[Co(1,3\text{-pddadp})]^-$ system, i.e., *trans*(O_5O_6) and *trans*(O_6), the lowest energy conformer corresponds to the *trans*(O_5O_6) configuration that has been found in the X-ray structure presented here. In addition, it has also been observed that the *trans*(O_5O_6) isomer of the $[Co(1,3\text{-pddadp})]^-$ complex is slightly more free from octahedral strain with respect to the *trans*(O_6) configuration of the same complex.

2. Experimental

2.1. Physical measurements

Elemental analyses were performed on a Perkin–Elmer-2400 CHN/O analyzer. Infrared spectra were recorded on a Perkin–Elmer Model 983 spectrophotometer with the sample prepared as KBr pellets. Electronic spectra were recorded on a Hitachi-300 spectrophotometer. The ^{1}H NMR and ^{13}C{^{1}H} NMR spectra were recorded in acetone-d_6 and $CDCl_3$ solvents with TMS as internal standard and recorded on a Bruker ACF-300 (300 MHz) spectrometer, the coupling constants J being given in Hz. Electro-chemical studies (in acetonitrile) were performed with a PARC electrochemistry system as described elsewhere [13]. In cyclic voltametry (CV) the following parameters were used, namely, the scan rate 100 mV s^{-1} and the formal potential $E^0 = 0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are the anodic and cathodic peak potentials, respectively; and ΔE_p is the peak-to-peak separation.

2.2. Materials and methods

All chemicals used were of reagent grade. All reactions were carried out in distilled and dried solvents. Rhodium chloride and iridium chloride were purchased from Arora Matthey Ltd., and used as received. Pyridine 2-carboxaldehyde (Fluka) was used as received. All liquid aromatic amines were reagent grade and were distilled prior to use, while solid aromatic amines were used as such. The ligands C_5H_4N-2-CH=NC_6H_4-*p*-X (where X = H, CH_3, OCH_3, Cl, NO_2) [14], and the precursor complexes [{(η^5-C_5Me_5)M(μ-Cl)Cl}$_2$] (where M = Rh (**1**) and Ir (**2**)) [15] were prepared by known literature methods. The purification of acetonitrile and the preparation of tetrabutylammonium perchlorate [Bu$^n_4$N][ClO_4], used as solvent and supporting electrolyte, respectively, in the electrochemical experiments, were performed following a literature method [16].

2.3. Synthesis of [(η^5-C_5Me_5)RhCl(C_5H_5N-2-CH=NC_6H_4-p-X)]$^+$ (**3a-e**), (X = H (**3a**), CH_3 (**3b**), OCH_3 (**3c**), Cl (**3d**), NO_2 (**3e**))

The following general procedure was used for the preparation of these five complexes:

Method 1: A mixture of the starting complex [{(η^5-C_5Me_5)Rh(μ-Cl)Cl}$_2$] (**1**) (100 mg, 0.110 mmol), the appropriate Schiff base ligand **2-PP** (0.242 mmol) and NH_4PF_6 (0.242 mmol) was stirred in methanol–acetone (20/10 v/v mixture) for 6 h until the color of the solution changed from red to orange. The solvent was removed in vacuo, the residue dissolved in dichloromethane (5 ml), and the solution filtered to remove ammonium chloride. The orange solution was concentrated to 2 ml, when addition of excess hexane gave the orange-yellow complex, which was separated and dried under vacuum.

Method 2: A mixture of the complex [{(η^5-C_5Me_5)Rh(μ-Cl)Cl}$_2$] (**1**) (100 mg, 0.110 mmol), the ligand **2-PP** (0.242 mmol) and NH_4PF_6 (0.242 mmol) was stirred in methanol (20 ml) for a few hours, whereupon the orange-yellow product separated out. The orange-yellow product was centrifuged, washed with diethyl ether and dried under vacuum.

3a. Yield: 152 mg, (78%). IR (KBr pellets, cm^{-1}): $\nu_{(C=N)}$ 1593 (s), $\nu_{(P-F)}$ 844 (s).

^{1}H NMR ($CDCl_3$ and acetone-d_6, δ): 1.56 (s, 15H, C_5Me_5), 7.32–7.56 (m, 3H, Ph), 7.64 (d, 2H, J_{H-H} = 6.53 Hz, Ph), 8.03–8.55 (m, 3H, py), 8.97 (d, 1H, J_{H-H} = 4.86 Hz, py), 9.24 (s, 1H, imine C–H).

^{13}C NMR (acetone-d_6, δ): 7.60 (CH_3, C_5Me_5), 97.53 (C, C_5Me_5), 122.44, 129.43, 129.79, 131.36 (Ph), 140.34, 148.80, 152.66, 154.04, 155.32 (py), 166.97 (C–H).

3. Crystallographic investigations

Crystals suitable for X-ray diffraction study for compound **3d**[BF_4] were grown by slow diffusion of hexane

into an acetonitrile solution of **3d**[BF_4], and for compound **4e**[PF_6] by slow diffusion of hexane into a dichloromethane solution of **4e**[PF_6]. The orange crystals of compounds **3d**[BF_4] and **4e**[PF_6] were mounted on a Bruker Apex CCD diffractometer in a full reciprocal sphere equipped with a CCD detector, and were used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation at 293(2) K, with 0.3° ω scan mode and 10 s per frame. The intensity data were corrected for Lorentz and polarization effects. Absorption corrections were done using the SAINT program [17]. A summary of the crystal data, data collection parameters and convergence results is compiled in Table 1. An empirical absorption correction was made by modelling a transmission surface by spherical harmonics employing equivalent reflections with $I > 2\sigma(I)$ (program SADABS) [18]. The structures were solved by direct methods [19]. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2 using the SHELXL-97 software [20]. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of an isotropic refinement and as per the ''riding'' model. Figs. 3 and 4 display the ORTEP [21] representations of the molecules with 50% probability thermal ellipsoids. Refinement converged at final R_1 values of 0.0366 and 0.0313 (for observed data F) for compounds **3d**[BF_4] and **4e**[PF_6], respectively.

4. Results and discussion

The dinuclear complexes [{(η^5-C_5Me_5)M(μ-Cl)Cl}$_2$] {M = Rh (**1**) and Ir (**2**)} undergo a bridge cleavage reaction with *N*,*N*′-donor Schiff base ligands (**2-PP**) in methanol to yield cationic complexes **3** and **4** (Scheme 1), respectively. These complexes are isolated as the hexafluorophosphate salts. The orange-yellow complexes are air-stable microcrystalline solids, partially soluble in chloroform, methanol and benzene, soluble in dichloromethane, acetone and insoluble in hexane, petroleum ether and diethyl ether.

The infrared spectra of these complexes show a strong band in the range 1593–1633 cm^{-1} due to the $\nu_{C=N}$ group of the Schiff base ligand, and a strong band in the range 837–844 cm^{-1} due to the ν_{P-F} mode of the PF_6^- group. The complexes **3e** and **4e** exhibit the characteristic bands for ν_{NO_2} (asymmetric stretch at 1527 cm^{-1} and symmetric stretch at 1346 cm^{-1}). The ^{1}H NMR spectral data of these complexes along with their assignments are recorded in the experimental section. In the ^{1}H NMR spectra of these complexes, the methyl group of the pentamethylcyclopentadienyl protons appears as a singlet in the range 1.47–1.82 ppm, which are shifted downfield as compared to that in the precursor complexes. A downfield shift in the position of the Cp* protons might result from the change in electron density on the metal center due to chelation of the Schiff base ligands through their nitrogen atoms. The multiplet observed in the range 7.32–8.61 ppm is due to the phenyl protons of the amine group and the *N*-heterocyclic ring of the ligands (**2-PP**), these resonance values being consistent with the reported values [8]. The ^{13}C {^{1}H} NMR spectra of complexes **3** and **4** exhibit resonances for the methyl carbons of the pentamethylcyclopentadienyl group at around 8.00 ppm and for the ring carbons at around 90.12–98.37 ppm. The resonance observed in the range 158.56–171.26 ppm is assigned to the imine group of the ligand (**2-PP**). The spectra also show resonances in the range 98.46–157.83 ppm for the aromatic carbon of the phenyl group and pyridyl group carbons (see Fig. 1).

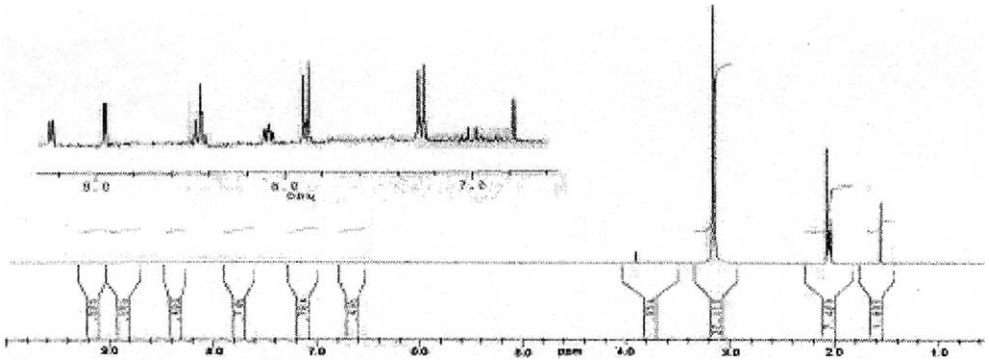

Fig. 1. ^{1}H NMR spectrum of complex $[(\eta^5\text{-}C_5Me_5)RhCl(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{-}p\text{-}OMe)]^+$ (**3c**) in acetone-d_6.

The electronic absorption spectra for rhodium (III) and iridium (III) Schiff base complexes typically contains π–π* and *n*–π* bands in the ultraviolet region The interaction of the filled dπ (t_2g) orbitals on rhodium (III) and iridium (III) with low lying π* orbitals on the Schiff base imine (C=N) ligands should provide a metal-to-ligand charge transfer (MLCT) transition (t_2g-π*) in the electronic spectra of these complexes [22–24] with the transition energy of these bands varying with the nature of the ligands acting as π-acceptors. The electronic spectra of these complexes in acetone exhibit bands in the range of 344–387 nm. This low-energy absorption is assigned to a Rh dπ (or Ir dπ) to ligand π* metal-to-ligand charge transfer (MLCT) transition (see Fig. 2).

Electron transfer properties of the representative compound **3a**[PF_6] are studied in acetonitrile solvent by cyclic voltametry. The first reduction wave of this rhodium (III) complex occurs at around −0.544 V and the corresponding oxidation wave at −0.113 V; it shows a quasi-reversible plot (ΔE = −431 mV). This is assigned to the Rh(III)/Rh(II) couple [Eq. (1)]. The second reduction wave occurs at −1.199 V and the corresponding oxidation wave −0.824 V; this also shows a quasi-reversible plot (ΔE = −375 mV), which is a two-electron transfer Rh(III)/Rh(I) couple. We have also observed here the Rh(III)/Rh(II) and Rh(II)/Rh(I) couple.

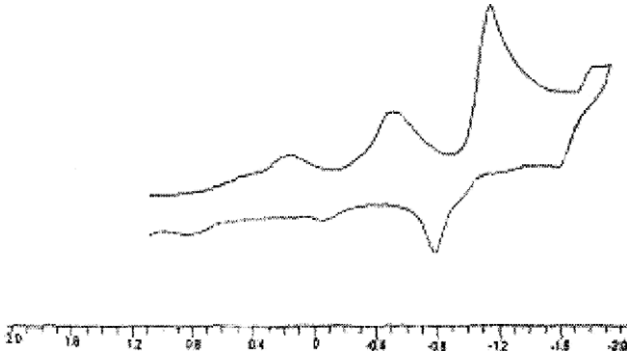

Fig. 2. Cyclic voltammogram of complex $[(\eta^5\text{-}C_5Me_5)RhCl(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_5)]^+$ (**3a**) in acetonitrile using a Pt-disk milli electrode at 298 K, SCE reference and TBAP (0.1 M) supporting electrolyte.

$$[(\eta^5 - C_5Me_5)RhCl(2 - PP)]^+ + e^- \leftrightarrows [(\eta^5 - C_5Me_5)RhCl(2 - PP)] \quad (1)$$

In general, ligand effects appear in the Ru(IV/III) and Ru(III/II) redox potentials. Ligand effects on the Ru(III/II) couple are well known, where Ru(III/II) potentials are influenced along with the ligand. Ru(II) is stabilized by the contribution of dπ–π* (L) back bonding in the presence of the ligands. The replacement of a Schiff-base ligand by the strongly electron-donating pentamethylcyclopentadienyl group destabilizes the lower rhodium oxidation states, making reduction more difficult. Indeed, in our observation the reduction potential for the +3/+1 couple of $[Cp^*RhCl(2\text{-}PP)]^+$ falling may arise from the intermediate $[Rh(Cp^*)_2]^+$ and $[Rh(2\text{-}PP)_3]^{3+}$.

5. Molecular structures

Single crystal X-ray structure determinations were carried out for compounds **3d** and **4e** for confirmation of their formulae and structure. The rhodium atom compound **3d** and the iridium atom compound **4e** are coordinated to two nitrogen atoms of the Schiff base (**2-PP**) ligand, one chloride ion and the pentamethylcyclopentadienyl molecule in a η^5-fashion leading to the usual 'three-legged piano stool' structures. The geometry around the metal atom can be regarded as distorted octahedral if the η^5-pentamethylcyclopentadienyl moieties are assumed to occupy three facial-coordinated positions. A summary of the single-crystal X-ray structure analyses is shown in Table 1. Selected bond lengths and bond angles are given in Tables 2 and 3. The ORTEP drawings of compounds **3d** and **4e** are shown in Figs. 3 and 4, respectively.

The tetrafluoroborate salt of complex $[(\eta^5\text{-}C_5Me_5)RhCl(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{-}p\text{-}Cl)]^+$**3d** and hexafluorophosphate salt of complex $[(\eta^5\text{-}C_5Me_5)IrCl(C_5H_4N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{-}p\text{-}NO_2)]^+$ **4e** crystallize in the monoclinic space group $P2_1/n$ (Figs. 3 and 4). The two metal-centroid distances are indistinguishable (1.791 Å). The bond distances between the rhodium and iridium metal

atoms and the chelated ligand nitrogen atoms are similar to each other (~2.1 Å). There is no significant difference in the C–C bond lengths in the pentamethylcyclopentadienyl ring, all being about 1.42

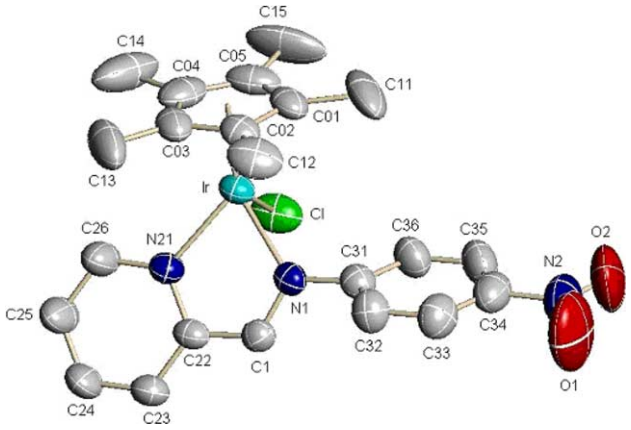

Fig. 4. ORTEP representation of the complex **4e** with 50% probability thermal ellipsoids. Hydrogens and PF_6^- are omitted for clarity.

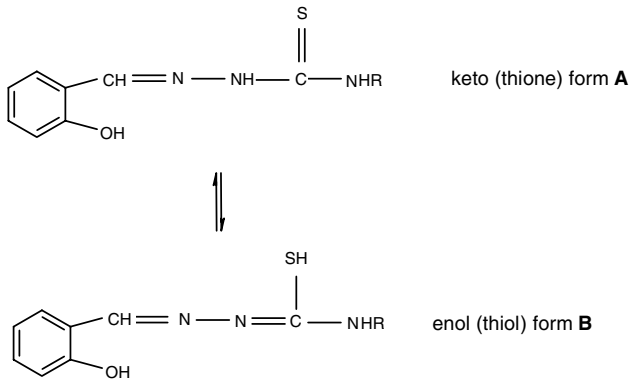
Å and pointing to π-electron delocalization in the ring. Furthermore, the five membered ring is planar as evident in the nearly equal bond distances between metal atom and the ring carbons. The Rh–Cl and Ir–Cl bond distances are 2.3756(7) and 2.3726(11) Å, respectively, which are closely similar to another related two-coordinated chelating polypyridyl rhodium complex $[Cp^*RhCl(Phterpy)]^+$ (2.3984(1)) [25].

6. Concluding remarks

We have observed interesting phenomena in the case of the pentamethylcyclopentadienyl compounds of **1** and **2**, which distinguish them from the analogous pentamethylcyclopentadienyl or indenyl ruthenium (II) systems, even though these are all isoelectronic. Unlike in the case of the compounds **1** and **2**, the reactions of Schiff bases with the $[(\eta^5\text{-}Cp^*)Ru(PPh_3)_2Cl]$ and $[(\eta^5\text{-ind.})Ru(PPh_3)_2Cl]$ systems yielded complexes without any organic group. In order to obtain similar complexes for these cases, one has to start from the acetonitrile complexes.

Acknowledgements

We thank Professor R.H. Duncan Lyngdoh for his help in preparing the manuscript and Dr. A. Lemtur for helpful discussions in the electrochemistry part.



Appendix A. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC 265789 for complex **3d**[BF_4] and CCDC 265788 for

complex **4e**[PF_6]. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: Int. code +(44) 1223/336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2005.04.034.

Scheme 1.

decrease of negative charge at the substituted N hydrazinic atom [8].

The thiosemicarbazone ligands can act as tridentate ligands (**A** form) being coordinated through the deprotonated phenolic O, imino N and thiocarbonyl S, or as doubly negatively charged tridentate ligands by losing another proton from the tautomeric mercapto group (**B** form) (Scheme 1) [8].

The biological activity, particularly antitumour activity of this class of compounds is most probably associated with their structures [9–11] as it was found for thiosemicarbazone copper(II) complexes.

2. Experimental

The starting complex $[MoO_2(acac)_2]$ [12], salicylaldehyde and 3-methoxysalicylaldehyde 4-methylthiosemicarbazone were prepared as described in the literature [7]. Acetonitrile was of reagent grade and used as purchased. Methanol was dried over magnesium ethoxide.

C, H and N analyses were provided by the Analytical Services Laboratory of Rudjer Bošković Institute, Zagreb. Molybdenum was determined according to the already known method [13]. Infrared spectra were recorded in KBr with an FTIR 1600 Fourier transform spectrophotometer in the 4500–450 cm^{-1} region. Thermogravimetric analyses were measured on a Mettler TG 50 thermobalance using aluminum crucibles under oxygen atmosphere with a heating rate of 5 °C min^{-1}. For all experiments the temperature ranged from 25 to 600 °C. The results were developed by applying the Mettler STAR^e 6.1. programme.

2.1. Syntheses of molybdenum(VI) complexes: *I, II, 1a, 2a, 2b*

A mixture of $[MoO_2(C_5H_7O_2)_2]$ (0.30 g, 0.92 mmol) and salicylaldehyde 4-methylthiosemicarbazone (0.19 g, 0.92 mmol) for **I** (or 3-methoxysalicylaldehyde 4-methylthiosemicarbazone 0.22 g, 0.92 mmol for **II)** in acetonitrile (40 cm^3) was refluxed for 6 h for **I** and 20 h for **II**, respectively. The brown products **I** or **II** were deposited during refluxing of the reaction mixture and filtered off. The orange crystals **2b** were obtained from the filtrate when it was left at room temperature for two weeks.

(**I**) Yield: 0.23 g, 74.58%. *Anal.* Calc. for $C_9H_9MoN_3O_3S$: C, 32.3; H, 2.7; Mo, 28.6; N, 12.5; S, 9.6. Found: C, 32.0; H, 2.6; Mo, 28.4; N, 12.4; S, 9.8%.

2.2. X-ray crystallography

Diffraction intensity data for **1**, **1a**, **2**, **2a** and **2b** were collected by ω-scans on Oxford Diffraction Xcalibur CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and reduced using the CRYSALIS software package [14]. Crystal data, experimental conditions and final refinement parameters are summarized in Table 1. The structures were solved using SHELXS97 [15]: the structures of ligands **1** and **2** by direct methods, and the structures of complexes **1a**, **2a** and **2b** by the Patterson method. The refinement procedure by the full-matrix least-squares method based on F^2 against all reflections included anisotropic displacement parameters for all non-hydrogen atoms. All hydrogen atoms were located in the difference Fourier maps. Those with poor geometry were then refined with restraints. Hydrogen atoms in **1** and **2** were refined isotropically except the methyl H atoms in both structures for which only the torsion angles and grouped isotropic temperature

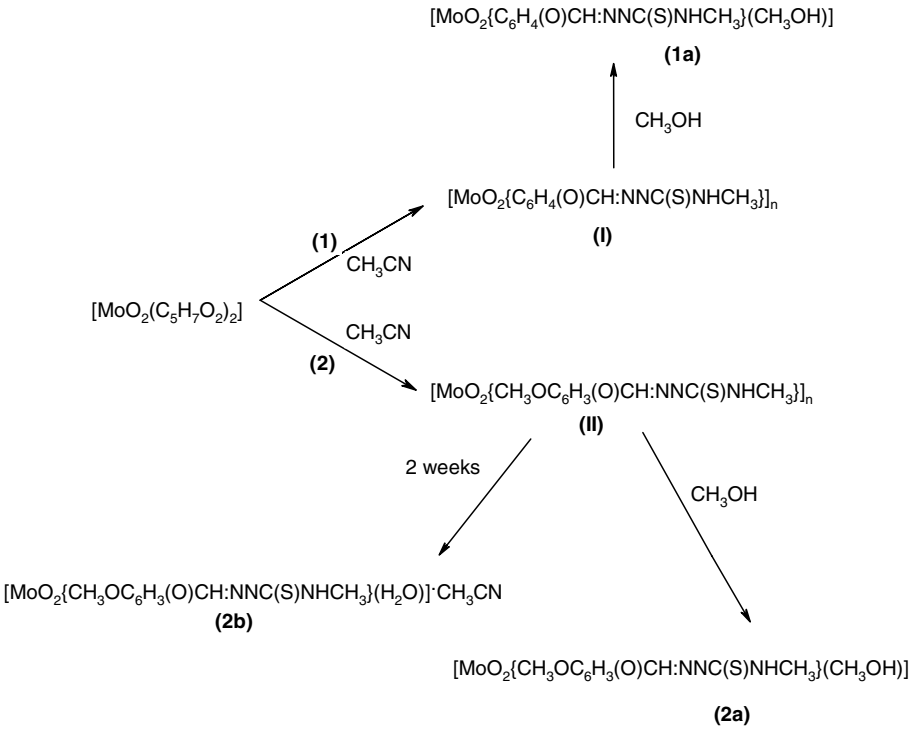
factor were refined while the geometry was kept fixed. In the structures of the complexes, only H atoms refined isotropically were H atoms bound to the oxygen atoms in **2a**, and H atoms attached to C1 and to the heteroatoms in **2b**, while the other H atoms were refined using the riding model. The structure of **1a** was refined as twinned and consisted of two components with opposite polarities. The final BASF coefficient (Flack's parameter *x*) for **1a** was 0.48(3) [16,17]. Refinement was performed using SHELXL97 [18], geometry calculations were done using PLATON [19,20] and PARST [21,22], and the structure drawings were prepared using ORTEP [23].

2.3. NMR spectroscopy

All one- (^{1}H and APT), and gradient-selected two-dimensional (gCOSY, gHSQC and gHMBC) NMR spectra were recorded at ambient temperature on a Bruker Avance DRX500 and Bruker Avance DPX 300 spectrometers equipped with 5 mm inverse detection probe and dual probe, respectively. Sample concentration in DMSO-d_6 was 20 mg ml^{-1}. TMS was used as the internal standard.



The typical spectral conditions for one-dimensional ^{1}H and ^{13}C (APT) spectra were as follows. The spectra were recorded using 64K data points and spectral widths of 7700 and 32 000 Hz for ^{1}H and ^{13}C experiments, respectively. Digital resolution was 0.12 and 0.48 Hz per point, respectively. The number of scans was 16 for ^{1}H and 500–1000 for APT spectra.

The COSY spectra were recorded under the following conditions: spectral width was 7700 Hz in both dimensions, 2K data points were applied in time domain and 512 increments were collected for each data set with linear prediction and zero filling to 2K. 8 scans were applied for each increment. Digital resolution was 6.50 Hz per point in both dimensions. The gradient selected inverse ^{1}H–^{13}C correlation experiments, gHSQC and gHMBC were recorded using the acquisition matrix of $1K \times 256$ with 16 and 32 scans, respectively, and processed with $2K \times 1K$ transformed matrix. The spectral width was 6600 Hz in f2 dimension and 32 000 Hz in f1 dimension for both experiments. Digital resolution was 3.25 Hz per point and 30.70 Hz per point in f2 and f1, respectively. HMBC spectra were recorded using a low-pass *J*-filter (3.4 s) and a delay for long-range coupling of 65 ms.

3. Results and discussion

3.1. Synthesis of the complexes

As a part of our studies [24–26] on molybdenum complexes with oxygen, sulfur and/or nitrogen donor

(1) $C_6H_4(OH)CH{:}NNC(SH)NHCH_3$ H_2SalTSC-4-Me

(2) $CH_3OC_6H_3(OH)CH{:}NNC(SH)NHCH_3$ H_2VanTSC-4-Me

Scheme 2.

ligands we describe here the syntheses and structures of molybdenum(VI) complexes coordinated by salicylaldehyde or by 3-methoxysalicylaldehyde 4-methylthiosemicarbazone ligand (Scheme 2). The brown polymeric complexes $[MoO_2\{SalTSC\text{-}4\text{-}Me\}]_n$ (**I**) and $[MoO_2\{VanTSC\text{-}4\text{-}Me\}]_n$ (**II**) were obtained by the reaction of $[MoO_2(C_5H_7O_2)_2]$ with a stoichiometric amount of corresponding thiosemicarbazone ligand in acetonitrile.

The monomeric complex $[MoO_2\{VanTSC\text{-}4\text{-}Me\}(H_2O)] \cdot CH_3CN$ (**2b**) was obtained when the filtrate of **II** was left at room temperature for two weeks. In **2b**, the molybdenum atom is additionally coordinated by a water molecule most probably from the atmospheric moisture and stabilized by the solvated acetonitrile molecule. Also, it should be mentioned that such a product was obtained only when the ligand was 3-methoxysalicylaldehyde 4-methylthiosemicarbazone. All attempts to isolate

In **1a** and **2a** two crystallographically independent complex molecules are labelled **A** and **B**.

the mononuclear molybdenum(VI) complex coordinated by a water molecule after isolation of complex **I** were unsuccessful even if some water was added to the solution. We believe that the electronic effect of the methoxy group attached to the phenolic ring 3-methoxysalicylaldehyde is responsible for the formation of this aqua complex.

We were also able to isolate monomeric orange crystals of $[MoO_2\{SalTSC\text{-}4\text{-}Me\}(CH_3OH)]$ (**1a**) and $[MoO_2\{VanTSC\text{-}4\text{-}Me\}(CH_3OH)]$ (**2a**) from the methanolic solution of **I** and **II**.

The IR data for thiosemicarbazone ligands are in accordance with the literature data [27]. The IR spectra of the complexes **I** and **II** showed characteristic strong vibrations at 806 and 808 cm^{-1}, respectively, assigned to the bridging Mo–O···Mo group which were absent in the case of mononuclear **1a**, **2a** and **2b** complexes. Also **I** and **II** showed single stretching frequencies at 920 and 923 cm^{-1}, respectively, assigned to ν(Mo=O), while the IR spectra of all three mononuclear complexes with the *cis*-MoO_2 core showed usual doublet at 933 and 891 cm^{-1} in **1a**, 934 and 889 cm^{-1} in **2a** and 932 and 892 cm^{-1} in **2b**.

The thermal analysis data of complexes **1a** and **2a** showed that their ligands decomposed in the range 224–554 °C and 222–512 °C, respectively, while those of complexes **1a**, **2a** and **2b** revealed two main processes:

(1) loss of coordinated methanol, water or acetonitrile within the range 92–141 °C in **1a**, 30–92 °C in **2a**; loss of coordinated water and acetonitrile in one step 30–95 °C in **2b**,
(2) complex decomposition occurring within the range 170–507 °C for **I**, 221–514 °C for **II** and 210–530 °C for **2b**.

3.2. Structural studies

Comparison of the selected bond distances, bond angles and torsion angles of the free ligands **1** and **2** and of their complexes **1a**, **2a** and **2b** is given in Table 2. Hydrogen bonding parameters are listed in Table 3.

3.2.1. Structures of ligands

Figs. 1 and 2 show ORTEP plots of the structures of the free ligand molecules **1** and **2**. Both molecules are found to be in the thioketo tautomeric form with the distances C3–S1 [1.6833(13) in **1** and 1.695(2) in **2**] and N2–C3 [1.3501(16) in **1** and 1.363(3) in **2**] similar to those found in the analogous thiosemicarbazone compounds [8,28–34]. The bond distances (Table 2) suggest electron delocalization throughout the thiosemicarbazone chain. The ligand molecules consist of two nearly planar moieties connected by a single N1–N2 bond: *N*-methylthioureide

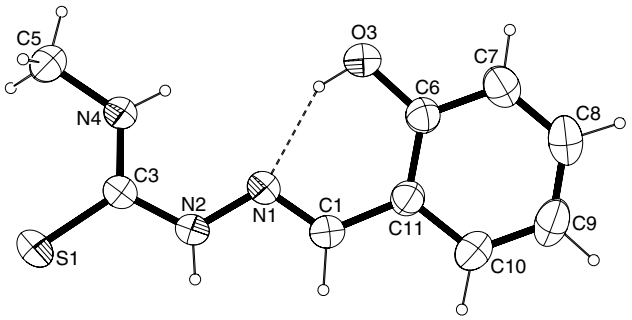

Fig. 1. ORTEP plot of the ligand molecule **1** with the atom labelling scheme. Ellipsoids are drawn at the 50% probability level. The O3–H3···N1 hydrogen bond is denoted by dashed line.

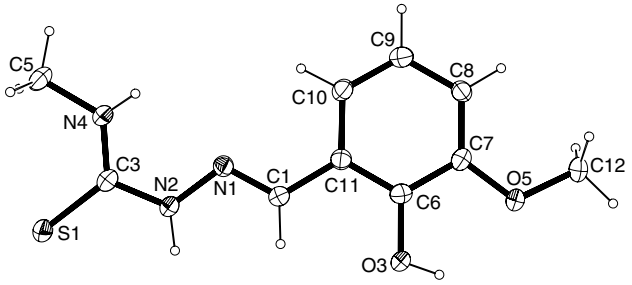

Fig. 2. ORTEP plot of the ligand molecule **2** with the atom labelling scheme. Ellipsoids are drawn at the 50% probability level.

fragment comprising N2, C3, S1, N4 and C5 [mean plane deviation of 0.007(6) Å in **1** and 0.0070(1) Å in **2**] and salicylaldimine fragment comprising N1, C1, C6–C11 and O3 [mean plane deviation of 0.0154(1) Å in **1** and 0.0160(1) Å in **2**]. Dihedral angles between these two planes are 12.54(3)° and 12.27(1)° for **1** and **2**, respectively. The atoms O5 and C12 from the methoxy group in **2**, although rather coplanar with others from the salicylaldimine fragment [mean plane deviation of 0.0237(1) Å], were excluded from the planarity calculations for the sake of comparability.

The striking difference between the molecular structures of the two ligands is the orientation of the phenyl ring moiety. In **1** the *syn* conformation of the C6 atom in respect to the N1 atom [torsion angle C6–C11–C1–N1 = 1.4(2)°] is stabilized by the intramolecular resonance-assisted O3–H3···N1 hydrogen bond, while in **2** the atoms C6 and N1 are *anti* to each other [torsion angle C6–C11–C1–N1 = –177.3(2)°] and O3–H3···O5 and O3–H3···S1 ($2-x$, $1-y$, $1-z$) hydrogen bonds are formed (Table 3). This seems to confirm an already given observation for the structures of the salicylaldehyde thiosemicarbazone derivates [31]: the intramolecular hydrogen bond between the hydroxyl group and the azomethine N atom would not be formed if another potential hydrogen bond acceptor for the hydroxyl H atom is present.

In the crystal structure of **1** molecules are interconnected by the N2–H2···O3 ($1+x$, y, z) hydrogen bonds thus forming chains parallel to the crystallographic *a* axis. In **2** a pair of molecules related by a centre of symmetry dimerize by forming the N2–H2···O3 ($2-x$, $1-y$, $1-z$) and O3–H3···S1 ($2-x$, $1-y$, $1-z$) hydrogen bonds. In both ligand structures there is an intramolecular hydrogen-bond-like contact N4–H4···N1.

3.2.2. Structures of complexes

Complex molecules found in the crystal structures of **1a** and **2a** are shown in Figs. 3 and 4, respectively. The asymmetric unit of structures **1a** and **2a** consists of two crystallographically independent complex molecules denoted as **A** and **B**. In **2b** the complex molecules cocrystallize with molecules of acetonitrile (Fig. 5).

The complex molecules consist of the *cis*-$[MoO_2]^{2+}$ core to which the doubly deprotonated tridentate ligand (**1** in **1a**; **2** in **2a** and **2b**) is meridionally bonded through the S1, N1 and O3 atoms. The sixth site of the distorted octahedral coordination around Mo is occupied either by methanol (in **1a** and **2a**) or water molecules (in **2b**).

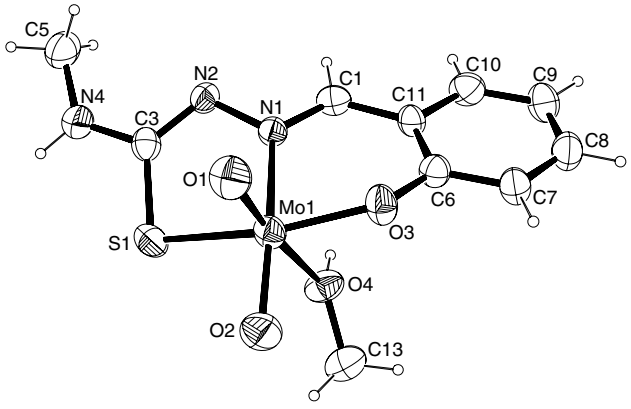

Fig. 3. ORTEP plot of the complex molecule **1aA** with the atom labelling scheme. Ellipsoids are drawn at the 50% probability level.

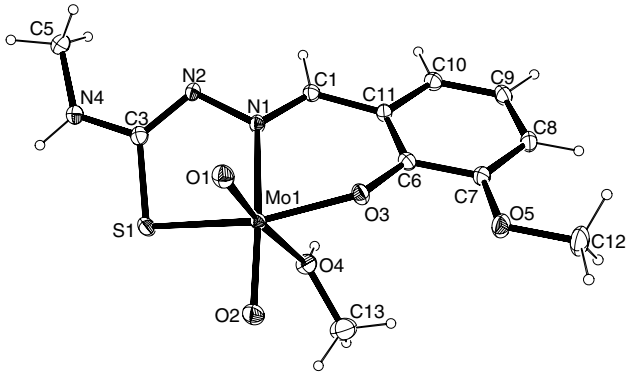

Fig. 4. ORTEP plot of the complex molecule **2aB** with the atom labelling scheme. Ellipsoids are drawn at the 50% probability level.

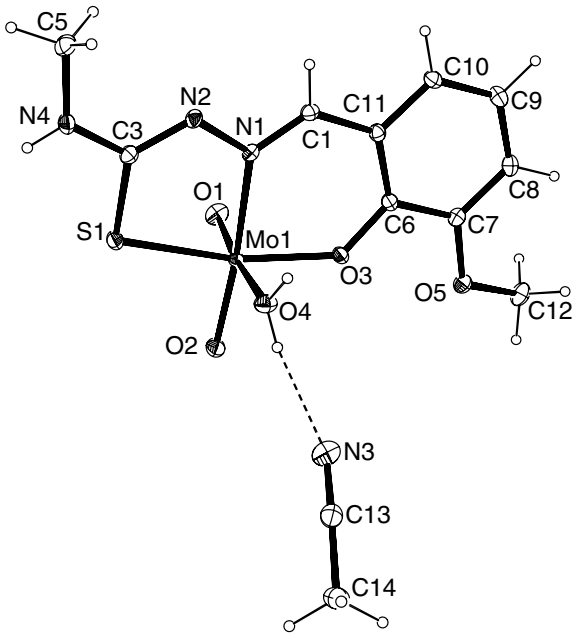

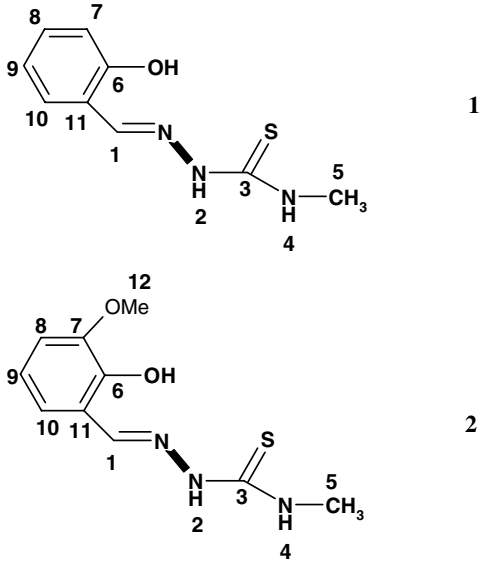

Fig. 5. ORTEP plot of the asymmetric unit of **2b** with the atom labelling scheme. Ellipsoids are drawn at the 50% probability level. The O4–H42···N3 hydrogen bond is represented by dashed line.

In all of the complex compounds, the Mo=O bond lengths [1.686(3)–1.7206(16) Å] and the O=Mo=O bond angles [104.92(7)–105.7(2)°] have values which are usual for *cis*-dioxomolybenum(VI) complexes. Also, the bond distances of Mo1–S1 [2.4047(13)–2.4504(4) Å], Mo1–N1 [2.236(3)–2.2733(12) Å] and Mo1–O3 [1.927(3)–1.9359(10) Å] are similar to those found in other thiosemicarbazonato molybdenum(VI) complexes [35–40]. The bond distances Mo1–O4 [2.359(2)–2.400(3) Å in **1a** and **2a**; 2.308(1) Å in **2b**] are significantly larger compared to the Mo1–O3.

As indicated by the bond distances N2–C3 [1.305(5)–1.319(6) Å] and C3–S1 [1.751(1)–1.766(4) Å], the ligands in the complexes are bonded in their enthiol form, i.e., in the tautomeric form different from that found in the structures of the free ligands (cf. in Table 2). In both bonded ligands, the C5 atom from the *N*-methyl group is *trans* relative to the S1 atom, while in the free ligands it is in the *cis* conformation. In order for ligands **1** and **2** to chelate the $[MoO_2]^{2+}$ moiety through the ONS donor set, as in the studied complexes, rotation of ~180° around the N2–C3 bond is necessary. Additionally for **2**, the phenyl ring moiety has to flip around the C11–C1 bond (Table 2). The 5- and 6-membered chelate rings thus formed (Mo1–N1–N2–C3–S1 and Mo1–O3–C6–C11–C1–N1) are not planar, but are rather puckered. In **1a** and **2a** the 5-membered chelate ring is close to the envelope conformation with Mo1 being the atom most out of the mean plane of the ring [ϕ_2 amounting to −3.5(2)° in the complex molecule **2aB** and 175.4(4)–176.8(2)° in **1a** and **2aA**], while the conformation of the 6-membered ring is nearly a screw-boat with the Mo1 and O3 atoms at the opposite sides of the mean plane of the ring [ϕ_2 amounting to −154.0(4)° in **2aB** and 24.1(4)–27.1(8)° in **1a** and **2aA**; θ amounting to −113.1(4)° in **2aB** and 65.8(8)–66.6(8)° in **1a** and **2aA**] [41,42]. The 5-membered chelate ring in **2b** is nearly planar [mean deviation of 0.0131(9) Å], but with conformation closer to twisted than to the envelope [ϕ_2 = 61(2)°] with C3 and S1 at the opposite sides of the mean plane. The 6-membered chelate ring conformation is almost an envelope with Mo1 being the atom most out of the mean plane of the ring [ϕ_2 = 7.7(3)° and θ = 59.2(3)°] [41,42].

Mean plane deviations for the *N*-methylthioureide [0.015(3) Å and 0.015(4) Å in **1a**; 0.010(2) and 0.012(2) Å in **2a**; 0.032(1) Å in **2b**] and the salicylaldimine [0.026(4) Å and 0.024(4) Å in **1a**; 0.034(2) Å and 0.030(2) Å in **2a**; 0.018(1) Å in **2b**] fragments (defined above for the structures of the ligands) show that in the molecules of the complexes these two fragments retain their planarity. But, in **1a** and **2a** dihedral angles between calculated RMS planes through the fragments [34.00(10)° and 36.64(9)° in **1a**; 35.05(4)° and 36.40(4)° in **2a**] are significantly different from those found in the free ligands. Also, torsion angles C1–N1–N2–C3 differ (Table 2), indicating rotation around the N1–N2 bond upon ligand binding. This is accompanied by the N1–N2 bond lengthening of ~0.02–0.04 Å. In **2b** the dihedral angle between the two fragments [10.74(4)°] and the C1–N1–N2–C3 torsion angle are both similar to those in **2**, but the N1–N2 bond lengthening of ~0.03 Å still occurs upon ligand binding.

In the crystal structure of **1a** two crystallographically independent molecules are bonded into dimers

OH	9.87				9.17			

by the O4A–H41A···N2B hydrogen bond. Such dimers are further connected in the infinite chain parallel to *b* axis by the O4B–H41B···N2A (x, $1 + y$, z) hydrogen bonds. Different chains are interlinked together by the hydrogen bonds formed between the amino N4–H4 and terminal oxygen O2 of the neighbouring molecule (Table 3).

Two molecules in the asymmetric unit of **2a** are connected by the N4A–H4A···O2B hydrogen bond. Similarly to **1a**, in the crystal structure of **2a**, there are also intermolecular hydrogen bonds between the amino N4–H4 and terminal oxygen O2 of the neighbouring molecule and between the methanol O4–H41 and the imine N2 from the symmetry equivalent molecule.

One hydrogen atom from the coordinated water molecule in the structure of **2b** participates in the hydrogen bonding with the cocrystallized acetonitrile molecule (Fig. 5), while the other hydrogen atom is part of the hydrogen bond with the imine N2 atom from the molecule related by an inversion centre. The centrosymmetrical dimers formed in this way are further connected by the intermolecular hydrogen bonds between the amino N4–H4 and the terminal oxygen O2 (also observed in **1a** and **2a**).

3.3. NMR spectroscopy

The complete ^{1}H and ^{13}C atom assignments in DMSO-d_6 were made on the basis of the combined use of several one- (^{1}H and APT sequences) and two-dimensional homo- and heteronuclear experiments (COSY, HSQC and HMBC sequences). The proton and carbon chemical shifts of the ligands **1** and **2** (Scheme 3) and complexes **1a** and **2a** are given in Table 4.

The observed chemical shift values are similar to those reported previously for the related thiosemicarbazone ligands and their molybdenum(VI) complexes [40]. In the proton NMR spectra of the free ligands a broad OH signal was observed at 9–10 ppm indicating a participation of this hydroxyl proton in an intramolecular O–H···N1 hydrogen bonds in DMSO, which is in line with our previous results. Carbon chemical shifts and HMBC correlation peaks have confirmed that both ligands exist in the thioketo form in solution, as also found in the solid state. The absence of OH and N2H protons in the proton spectra of **1a** and **2a** corroborates a formation of the complexes with molybdenum. An up-field shift of N4H protons of about 1 ppm (Table 4) is in accordance with this. Slight coordination induced down-field shifts have also been observed for H1 protons. The largest changes in carbon chemical shifts in **1a** and **2a** have been found for carbons at the two interacting sites, C-1 and C-3. The down-field shifts of up to 13.4 ppm for the former and up-field shifts of approximately 11.0 ppm for the latter were observed. The shielding effects at C-3 arised from two contributions, i.e. from a coordination induced-shift and from the formation of an imine C=N bond in the complex instead of a thiocarbonyl C=S bond in the ligand. The carbon atoms at the third interacting site, e.g., C-6 exhibited only moderate chemical shift changes, as already found for the related molybdenum complexes with thiosemicarbazone donors.

4. Supplementary material

CCDC nos. 260969, 260970, 260971, 260972 and 260973 contain the supplementary crystallographic data for compounds **1**, **1a**, **2**, **2a** and **2b**, respectively. These data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif, or by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336033.

homoleptic species had been crystallographically characterized, including $[Zr(OR)_4 \cdot nHOR]_x$ {OR = OCH_2CH_3 (OEt), $n = 0$, $x = 4$ [17]; $OCH(CH_3)_2$ (OPr^i), $n = 1$, $x = 2$ [18,19]} while several mixed alkoxy Zr (and Ti) compounds have been reported [19,20]. Due to this limited supply of useful precursors, it was necessary to develop a new family of similarly ligated species that possessed different structural arrangements. Previously, we have used a series of structurally characterized carboxylic acid (H-ORc, Fig. 1(a)–(e)) modified $Ti(OR)_4$ [OR = OPr^i; $OCH_2C(CH_3)_3$ (ONep)], to generate anatase (TiO_2) films of varied densities [21,22]. Due to our success with the congener system, we followed a similar approach to study ZrO_2 thin films.

The widespread utility of ZrO_2 thin films [1–12] makes it of interest to determine the optimal precursors that will control the densification of the final films. A search of the literature reveals only a few $Zr(OR)_4$ have been crystallographically characterized, including $[Zr_2(\mu_3\text{-OEt})(\mu\text{-OEt})(OEt)_5]_2$ [17] (**1**) [18,19], $[Zr(\mu\text{-}OPr^i)(ONep)_3(H\text{-}ONep)]_2$ [20], Zr(1,2,5,6-di-*O*-isopropylidene-α-D-glucfuranose)$_4$(py)$_2$ [23], and $[(\mu\text{-THME})Zr_2(OPr^i)_5]_2$ [19] (THME = tris(hydroxymethyl)ethane). The dinuclear compounds adopt a standard edge-shared bi-octahedral geometry using two alcohol ligands to complete their geometry.

Several unusual $Zr(OR)_4$ species, derivatized with a variety of H-ORc-modifiers have been reported as: $Zr_6O_2(OPr^n)_{16}(O_2C\text{-}C_{10}H_6O)_2(Pr^iO\text{-}H)_2$, $Zr_{10}O_6(OH)_4(O_2C\text{-}C_6H_4OH)_8(O_2C\text{-}C_6H_4O)_8 \cdot 6H\text{-}OPr$ [24], $[Zr_6(OH)_4O_4(acrylate)_{10}]_2(\mu\text{-acrylate})$ [25], $Zr_6(OH)_4O_4(O_2CR)_{12}(PrOH\text{-}Pr^n)$ (R = Ph, CMe=CH_2) [25], $Zr_6(\mu_3\text{-O})_2(\mu\text{-EtOEt})_6(\mu\text{-}C_3H_2O_2Me)(C_3H_2O_2Me)_4(EtOEt)$ [26], and $Zr_6(\mu_3\text{-O})_2(\mu\text{-OMe})_4(\mu\text{-}C_3H_2O_2Me)_6(C_3H_2O_2Me)_8(EtOEt)_2$ [27]. It is of note that additional ORc-modified mixed metal alkoxide [26,27] and oxo hydroxy [28–30] compounds have also been reported.

From these compounds, it is obvious that a systematic series of ORc-modified $Zr(OR)_4$ compounds was not available to initiate a study on the densification of ZrO_2 thin films. Therefore, it was necessary to synthesize a novel family of ORc-modified $Zr(OR)_4$ precursors that had similar hydrolysis and condensation routes but were structurally varied. These compounds would then be used to generate thin films of ZrO_2 to explore the effects these subtle structural changes had on the density of the final films. The products we isolated, their characterization, and the affect their structures have on the final film densification are presented.

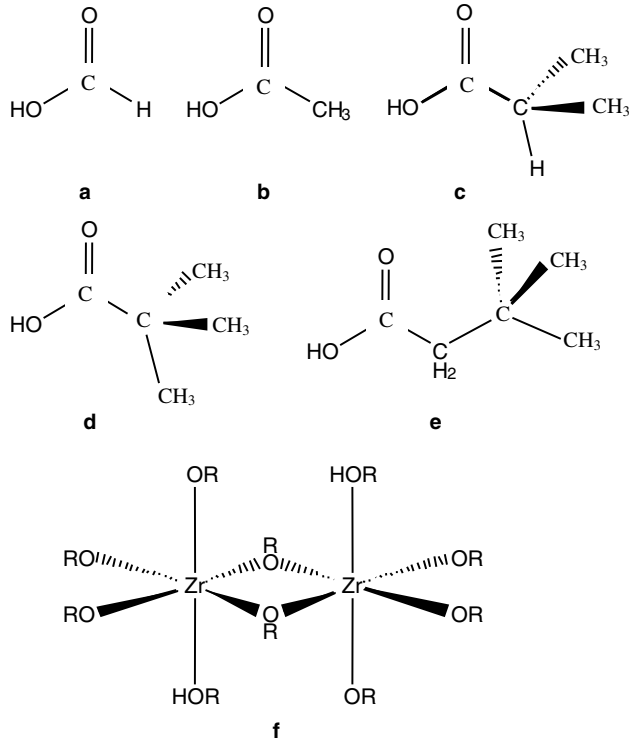

Fig. 1. Schematic representation of the various carboxylic acid (H-ORc) modifiers (a) formic acid (H-O_2CH or H-OFc), (b) acetic acid (H-O_2CH_3 or H-OAc), (c) iso-butyric acid (H-$O_2CH(CH_3)_2$ or H-OPc), (d) trimethyl acetic acid (H-$O_2C(CH_3)_3$ or H-OBc), (e) *t*-butyl acetic acid (H-$O_2CH_2C(CH_3)_3$ or H-ONc), and (f) $[Zr(\mu\text{-OR})(OR)_3H\text{-OR}]_2$ (OR = $OCHMe_2$; **1**).

2. Results and discussion

Since $[Zr(OPr^i)_4 \cdot H\text{-}OPr^i]_2$ (**1**, Fig. 1(f)) was commercially available, we initiated our study by modifying the ligand set of **1** with a series of carboxylic acids (H-ORc), including formic acid (H-O_2CH or H-OFc), acetic acid (H-O_2CCH_3 or H-OAc), isobutyric acid (H-$O_2CCH(CH_3)_2$ or H-OPc), trimethyl acetic aid (H-$O_2CC(CH_3)_3$ or H-OBc), and *t*-butyl acetic acid (H-$O_2CCH_2C(CH_3)_3$ or H-ONc). Schematic representations of the H-ORc structures are shown in Fig. 1(a)–(e). For H-ORc-modified **1** (Fig. 1(f)), the following compounds were characterized as: $Zr_4(\mu_4\text{-O})(\mu\text{-O})(\mu\text{-OFc})_2(\mu\text{-}OPr^i)_4(OPr^i)_6$ (**2**), $Zr_3(\mu_3\text{-O})(\mu\text{-OAc})_3(OAc)_2(\mu\text{-}OPr^i)_2(OPr^i)_3$ (**3**), $[Zr_2(\mu\text{-OPc})_2(\mu\text{-}OPr^i)_2(OPr^i)_4]_2$ (**4**), $Zr_2(\mu\text{-OBc})(\mu\text{-}OPr^i)_2(OPr^i)_5 \cdot (H\text{-}OPr^i)(H\text{-}OPr^i)$ (**5**), and $Zr_2(\mu\text{-ONc})(ONc)(\mu\text{-}OPr^i)_2(OPr^i)_4(H\text{-}OPr^i)$ (**6**). Due to its structural variation in comparison to **1**, we furthered our precursor set by modifying the novel compound $[Zr_3(\mu_3\text{-O})(\mu_3\text{-ONep})(\mu\text{-ONep})_3(ONep)_6]$ (**7**) with the same set of ORc modifiers. These products were identified as: $Zr_3(\mu_z\text{-O})(\mu\text{-OAc})_3(\mu\text{-ONep})_2(ONep)_5$ (**8**), $Zr_5(\mu\text{-O})_3(\mu\text{-OPc})_6(\mu\text{-ONep})_2(ONep)_6$ (**9**), $[Zr(\mu\text{-OPc})(\mu\text{-ONep})(ONep)_2]_2$ (**10**), and $Zr_5(\mu\text{-O})_3(\mu\text{-ONc})_6(\mu\text{-ONep})_2\text{-}(ONep)_6(H\text{-}ONep)1/2(C_7H_8)$ (**11**). This new family (**2**–**11**) of ORc-modified $Zr(OR)_4$ were characterized by a variety of analytical techniques and subsequently used to investigate the structural influences the precursors have on the final densification of ZrO_2 thin films.

2.1. Syntheses of ORc-modified $Zr(OR)_4$

The synthesis of precursors was initiated with the commercially available **1** (Fig. 1(f)) and the appropriate H-ORc (Fig. 1(a)–(e)). After stirring for 12 h, all of the reactions remained clear and were set aside to allow slow evaporation of volatile material. If X-ray quality crystals were not isolated in a short time frame, then the reaction volume was drastically reduced by rotary evaporation and the mixture cooled to −35 °C until crystals formed. Figs. 2–6 show the plots of the solved structures of **2**–**6**, respectively. FTIR spectra of **2**–**6** revealed the standard OPr^i peaks with a notable shift of the C=O stretch of the ORc ligand which is consistent with it being coordinated to a metal center. For **2** and **4**, no OH stretches were observed; however, for **3**, **5**, and **6** a strong broad OH stretch was noted. The resulting powders were very air-sensitive but elemental analyses were found to be consistent with the solid state structure.

Previously, we have reported the synthesis of $[Zr(\mu\text{-}OPr^i)(ONep)_3\cdot(H\text{-}ONep)]_2$ [22]. This compound was initially used in our development of acceptable precursors for production of ZrO_2 thin films; however, the products isolated were identical to those noted for **7** (vide infra).

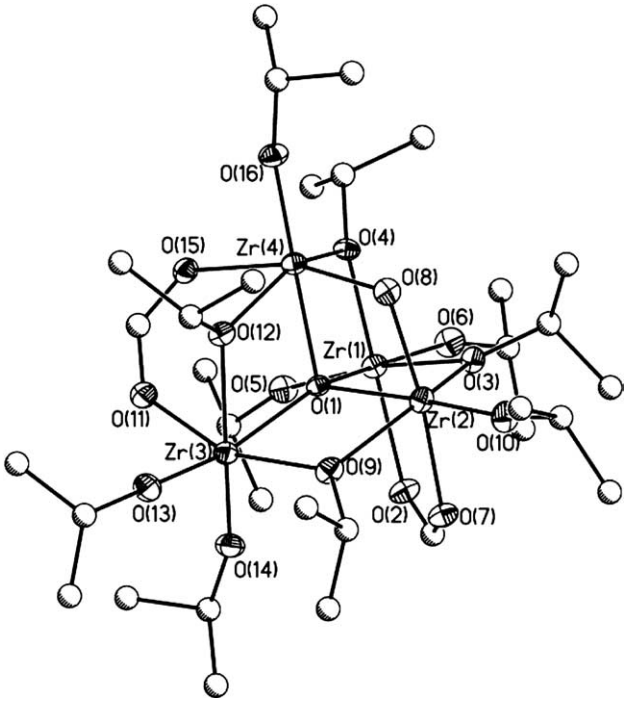

Fig. 2. Structure plot of **2**. Thermal ellipsoids of heavy atoms are drawn at the 30% level, hydrogen atoms are omitted, and carbon atoms are shown as stick and ball for clarity. Selected bond distances (Å): Zr(1)–O(1) 2.178(2); Zr(1)–O(2) 2.234(2); Zr(1)–O(4) 2.154(2); Zr(1)–O(3) 1.932(3); Zr(1)–O(5) 1.914(3); Zr(1)–O(6) 2.180(3). Selected bond angles (°): O(5)–Zr(1)–O(6) 90.82(10); O(5)–Zr(1)–O(4) 100.93(10); O(5)–Zr(1)–O(2) 168.75(10); O(5)–Zr(1)–O(1) 96.22(10); O(5)–Zr(1)–O(3) 100.25(11); O(6)–Zr(1)–O(3) 75.38(7); O(4)–Zr(1)–O(3) 83.70(6); O(2)–Zr(1)–O(3) 88.37(10); O(1)–Zr(1)–O(3) 163.53(10).

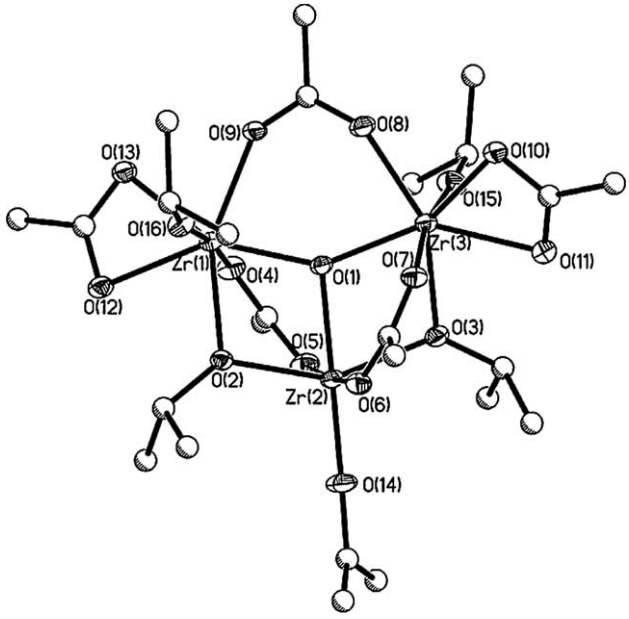

Fig. 3. Structure plot of **3**. Thermal ellipsoids of heavy atoms are drawn at the 30% level, hydrogen atoms are omitted, and carbon atoms are shown as stick and ball for clarity. Selected bond distances (Å): Zr(1)–O(1) 2.078(2); Zr(1)–O(2) 2.185(3); Zr(1)–O(4) 2.254(3); Zr(1)–O(9) 2.212(2); Zr(1)–O(12) 2.295(3); Zr(1)–O(13) 2.265(3); Zr(1)–O(16) 1.891(2); Zr(2)–O(1) 2.102(2): Zr(2)–O(2) 2.095(3); Zr(2)–O(3) 2.098(2); Zr(2)–O(5) 2.162(3); Zr(2)–O(6) 2.145(3); Zr(2)–O(14) 1.926(2). This is not unexpected since the less sterically hindering OPr^i ligand would be the most susceptible to exchange and hydrolysis, leaving only ONep ligands for structural influences. Therefore, the full series for this precursor was not pursued.

From an in situ generated amide, the ONep derivative of Zr was isolated as **7** (Eq. (1)), an off white powder. This compound was selected for further modification since the trinuclear central core should allow for a wide range of structural variations in comparison to the OPr^i derivatives. The OFc reaction yielded a precipitate that could not be re-dissolved. All of the remaining H-ORc modifications were undertaken using toluene as the solvent with no color changes or precipitates observed. Figs. 7–11 show the plots of structure plots of **7** and the ORc modified species **8**–**11**. The FT-IR spectra of these compounds revealed standard ONep stretches and bends intermixed with stretches that indicated the ORc ligand was coordinated to the Zr metal center. No –OH stretches were observed. The elemental analysis of **8**–**11** proved to be inconsistent with the solid

state structures; however, when a molecule of solvent (i.e., toluene) was included the analyses fell within the acceptable range of error.

$$ZrCl_4 + 4LiNMe_2 \xrightarrow{tol} Zr(NMe_2)_4 \xrightarrow[+4HONep]{-4LiCl} 1/3Zr_3(O)(ONep)_{10} \quad (1)$$

2.2. Single crystal X-ray structures of ORc-modified $Zr(OR)_4$

In order to determine the solid state structures of **2**–**11**, single crystal X-ray analysis were undertaken. The crystal of **2**–**11** were found to be very air sensitive and therefore were handled under inert conditions to minimize exposure to atmospheric conditions while the crystals were being mounted. Discussions concerning the structural aspects of **1**–**11** are detailed below.

2.2.1. Single crystal X-ray structures of OPr^i derivatives

The commercially available **1** is shown in Fig. 1(f) and several reports on its structure are available [18,19]. Each Zr metal center is octahedrally (Oh) bound by two μ-OPr^i, three terminal OPr^i, and one coordinated

H-OPr^i molecule. This molecule is very robust and has been used as a sterically hindering ligand for other metal centers [31–35]. Therefore, it was expected that we would observe structures that possessed multiplets of the dinuclear subunit, substituted with ORc ligands.

The OFc derivative of **1** was isolated as the tetranuclear species **2** (Fig. 2), wherein, the four Zr atoms are tetrahedrally (Td) arranged around a μ_4-O. Another oxide is present as μ-O atom linking two of the four Zr atoms with the remaining ligands asymmetrically arranged around this central core: four μ-OPr^i, six terminal OPr^i, and two μ-OFc ligands. Both OFc ligands bridge two different Zr atoms. This arrangement was unexpected because compound **2** is structurally identical to the OFc derivative of Ti(OPr^i)$_4$ (''Ti-OPr^i/OFc'') described as a face-shared corner-missing cube structure, [Ti$_4$(μ_4-O)(μ-O)(μ-OFc)(μ-OPr^i)$_4$(OPr^i)$_6$] [22]. The basic core structure of **2** appears to have significantly altered the dinuclear starting material **1** but **2** can be thought of as two of the dinuclear species of **1** bound perpendicularly by OFc and O ligands.

By increasing the steric bulk of the ORc ligand from a –H (OFc) to a –CH$_3$ (OAc) group, the nuclearity of the resulting product **3** was reduced to a trinuclear species (Fig. 3). The molecule possesses a C_2 center of symmetry with two Zr atoms adopting a pentagonal bipyramidal (PBP) geometry whereas the unique Zr atom adopted an Oh geometry. The three Zr metal centers surround a μ_3-O with a symmetric distribution of a single μ-OAc, two μ-OPr^i, and a terminal OPr^i for each metal center. The unique Zr metal center bridges to each of the PBP-coordinated Zr metal centers using a μ-OAc ligand. Finishing the PBP coordination of these Zr metal centers is a chelating OAc ligand. Based on the previous reported stability of **1**, it was surprising that the central core was so easily disrupted by HOAc forming a structure similar to ''Ti-ONep/OFc'' complex which generated the highest dense films of TiO$_2$ [22].

For compound **4**, even though the steric bulk of the pendant chain of OPc (CH(CH$_3$)$_2$) is greater than the OAc (CH$_3$), an increase in nuclearity was observed (see Fig. 4) possibly due to the lack of oxo formation. The structure possesses a C_{2h} symmetry where the two sub-moieties are linked by μ-OPc ligands. These smaller units consist of two Zr metal centers bridged by two OPr^i, one μ-OPc ligand, and two terminal OPr^i ligands. This molecule can be thought of as linking two OPc substituted moieties of **1** (multiplet of the subunit). There are no similar Ti based structures known.

Introduction of the most sterically demanding ligand investigated, OBc, led to the isolation of the simple substituted complex **5**, shown in Fig. 5. This molecule consists of two Oh-coordinated Zr atoms bridged by

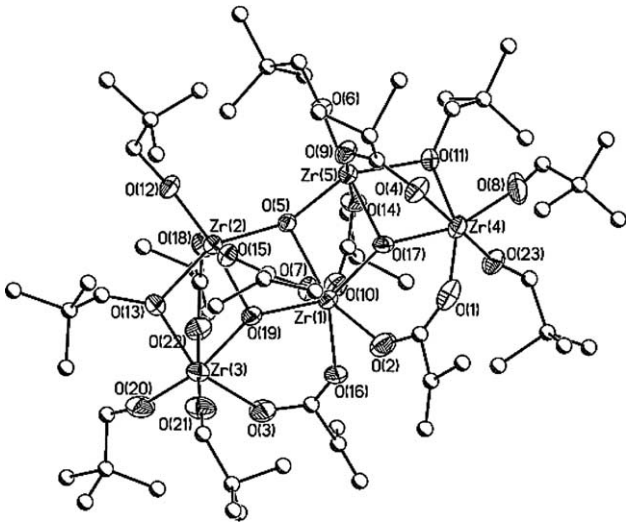

Fig. 9. Structure plot of **9**. Thermal ellipsoids of heavy atoms are drawn at the 30% level, hydrogen atoms are omitted, and carbon atoms are shown as stick and ball for clarity. two μ-OPr^i and one μ-OBc ligands. The coordination is completed by three OPr^i ligands. Due to charge balance, one of these ligands must be an H-OPr^i with an additional H-OPr^i was also found in the unit cell. From bond distances and angles, it appears that there is H-bonding between the unit cell H-OPr^i, free H-OPr^i, and terminal OPr^i. Compound **6** was dinuclear as well with a similar arrangement with one μ-ONc, one terminal ONc, two μ-OPr^i, four OPr^i, and a bound H-OPr^i. A structure plot of **6** is shown in Fig. 6. The H-OPr^i also appears to be H-bound to the terminal acid. Both **5** and **6** are similar to what was observed for the "Ti-OPr^i/OBc" species [22] and again show retention of the Zr dinuclear subunit.

2.2.2. Single crystal X-ray structures of ONep derivatives

The structure of **7** is a symmetric trinuclear species with μ_3-O and μ_3-ONep ligands (see Fig. 7). The three Zr atoms are bridged by a μ-ONep ligand and the final Oh coordination is filled by terminal ONep ligands. In contrast, for the Ti-ONep system, generated through the same reaction pathway, a halide was retained [36]. The variation in the structure of **7** in comparison to **1** was of interest to further modify with ORc ligands to increase the number of precursors for thin film investigation. Modification with H-OFc, yielded precipitates that could not be re-dissolved and X-ray quality crystals from the H-OBc derivatives could not be isolated in our hands.

Modification of **7** with H-OAc led to the trinuclear species **8** (Fig. 8). The central core of **8** is similar to **7**

with the μ_3-O bridging the three Oh-coordinated Zr metal centers. Two μ-ONep and two μ-OAc ligands bridge to Zr(1) from Zr(2) and Zr(3). The latter metal centers are bridged by a single μ-OAc ligand. Zr(1) finishes its coordination by binding one terminal ONep ligand whereas Zr(2) and Zr(3) possess two terminal ONep ligands. From this structure, the general constructs of **7** were found to be stable with simple OR–ORc exchanges. The constructs of compound **8** are similar to **3** and the "Ti-OPr^i/OFc" complex [22].

For the OPc derivative of **7**, two species were isolated, **9** and **10**. Compound **9** appears to be the major product based on the elemental analysis and numerous single crystal experiments. Compound **9** is a ladder-like structure containing five Zr atoms (see Fig. 9). The molecule contains a C_2 center of symmetry that creates three types of Zr atoms (ratios of 2:1:2). The unique Zr has no terminal ONep ligands but uses four μ-OPc and three μ_3-O ligands to form a PBP geometry around the 7-coordinated Zr atoms. Two Oh-coordinated Zr atoms have one terminal ONep ligand and to μ-OPc, two μ_3-O, and one μ-ONep set of ligands. The final two Zr are Oh bound with two OPc, two terminal ONep, one μ-ONep, and one μ_3-O ligand sets. Compound **9** is unique in the previously identified Group 4 OR-ORc structure types [22] and reveals the disruption of the trinuclear **7**. Another structure was isolated from this reaction mixture, **10** (Fig. 10). This compound is a simple dinuclear species with two μ-ONep, two μ-OPc, and four terminal ONep ligands filling the Oh geometry of the two Zr atoms; however, **10** is similar to the structure noted for the "Ti-ONep/OBc" species [22]. Compound **11** is structurally similar to **9** with ONc ligands replacing the OPc ligands and is shown in Fig. 11.

2.3. Solution behavior of ORc-modified $Zr(OR)_4$ species

Since the precursor will necessarily be dissolved in a solvent prior to spin-cast deposition, it is important, if possible, to understand their solution behavior. To investigate whether the solid state structure were retained in solution, NMR studies were undertaken by dissolving crystals of **2**–**11** in toluene-d_8. The ^{1}H NMR spectra did not reveal a great deal of information concerning the structural aspects of **2**–**6** due to the numerous, overlapping peaks that were present. As previously reported for the Ti system [22], rapid ligand-exchange processes are common for these types of species and would explain the complicated NMR spectra. For each sample resonances were clearly present for OPr^i and the appropriate ORc ligands. In an attempt to further clarify the solution behavior, ^{13}C NMR spectra were obtained for **2**–**6**. The resonances associated with the ORc ligands should yield the most information concerning the solution behavior of these compounds. If the solid state structures are retained in solution, for **2**,**4**, and **6**, a 1:1 ratio of ORc carbon (R-CO_2) resonances should be observed, for **3**, a 2:2:1 ratio and for **5** only one resonance should be observed. For **2**, only one set of broad ^{13}C resonance was noted for the disparate OPr^i ligands and a very weak but broad OFc resonance. The spectrum of **3** also showed numerous broad peaks for the OPr^i peaks but only a single broad OAc resonance. Compounds **4** and **5** did not yield high quality spectra due to the low solubility of these compounds. The spectrum of **6** revealed the presence of two types of ONc ligands and multiple resonances for the OPr^i ligands.

The ONep derivatives (**8**, **9**, and **11**) are expected to yield a 2:1 ratio of ligand resonances (**9** and **11** may also display a 2:2:1 ratio). Again, due to the complexity of the ^{1}H NMR spectrum for each sample, information concerning the nuclearity of these compounds could not be discerned; however, the appropriate ligand resonances for the various samples were noted. From the ^{13}C NMR spectra, only a single resonance for **8** was observed. With rapid ONep ligand exchange the unequivalent ORc ligands could easily become equivalent and therefore a singlet is not unexpected. For **9**, the expected three resonances were noted. In contrast, compound **11** revealed only a single broad resonance for the ONc derivative; however, the alkyl peaks were also broad. These results indicated that a great deal of ligand scrambling is occurring.

Although solution behavior was difficult to establish because of low compound solubility and observed ligand scrambling, we assumed, based on the similarity of structures between the Ti and Zr systems, that similar solution behavior should occur. For the Ti system, ligand scrambling did not alter the general constructs [22] and this concept was applied to the Zr system described here.

2.4. Thin film behavior of ORc-modified $Zr(OR)_4$

It was of interest to determine how the various structural changes of these compounds affected the densification of the final ZrO_2 thin films. For the Ti system, the oxo species appeared to assist in holding the compounds together during hydrolysis and trinuclear species with some oxo ligands present were found to be the best precursors to generate highly dense anatase thin films [22].

Due to the low solubility of the Zr compounds it was difficult to generate solutions that produced films without cracks or large defects. The defects formed during film processing are most likely due to the increased steric hindrance of the ONep ligand preventing controlled cross-linking resulting from exposure to ambient humidity to form the necessary extended Zr–O–Zr network of a film. Instead, upon condensation the limited interaction would cause *closo*-structures to form, negating extended networks causing cracks. This general argument also can be used to explain the poor properties

of all of the ONep derivatives in comparison to the smaller OPr^i species.

Acceptable films were generated from solutions of **3**–**5**. In contrast to the characteristics of the optimal precursors for generation of dense antase films, none of the Zr compounds that made the best films possess oxo moieties but are simply the substituted compounds. From the films that could be analyzed, it was discovered that by increasing the steric bulk of the pendant ORc ligand increased the film thickness which ranged from 2500 to 2700 Å. However, due to the poor quality, additional ligand manipulation will be necessary to fully explore higher density films. In general, it appears that the same trends observed for the anatase system did not apply to the zirconium oxide thin films. This is most likely due to the different hydrolysis rates of the two metal cations. Efforts to improve the solubility of the Zr precursors are underway in order to garner a larger set of useful precursors necessary to adequately explore the densification of zirconium oxide thin films.

3. Summary and conclusions

We have synthesized and characterized a series of ORc-modified $Zr(OR)_4$ species using commercially available **1** and specialty precursor **7**. The molecules of the OPr^i derivatives range from simple substitutions of ORc for OR groups resulting in tetranuclear (**4**) and dinuclear (**5** and **6**) species to partially hydrolyzed trinuclear species (**2** and **3**). For the derivatives of **7**, the majority of species had an oxo group present but this may be a reflection of the starting materials composition. The nuclearity of these species was either tri- (**8**) or pentanuclear (**9** and **11**). Surprisingly, the previously unobserved structure type was found for two acid modifiers in this system. Of these species, three (**3**–**5**) generated acceptable quality films which could be monitored for film thickness and densification. The remainder produced cracked films. For **3**–**5**, the larger pendant ORc chains generated the thickest films.

4. Experimental

All compounds described below were handled with rigorous exclusion of air and water using standard Schlenk line and glove box techniques. All solvents were used as received from Aldrich in sure seal bottles. H-OFc (Aldrich) and H-OAc (Fisher) were dried and freshly distilled, immediately prior to use. The following compounds were stored under argon upon receipt (Aldrich) and used without further purification: H-ONep, H-OPc, H-OBc, H-ONc, **1**, $ZrCl_4$, and $LiNMe_2$. Samples for all analyses were prepared from dried crystalline material.

4.1. Physical measurements

FT-IR data were obtained on a Bruker Vector 22 MIR Spectrometer using KBr pellets under an atmosphere of flowing nitrogen. Elemental analyses were performed on a Perkin–Elmer 2400 CHN-S/O Elemental Analyzer. All NMR samples were handled and stored under an argon atmosphere and re-dissolved in toluene-d_8 at saturated solution concentrations immediately prior to use. All solution spectra were obtained on a Bruker DRX400 spectrometer at 399.8 and 100.1 MHz for ^1H and ^{13}C experiments, respectively. A 5 mm broadband probe was used for all experiments. The ^1H NMR spectra were obtained using a direct single pulse excitation, with a 10 s recycle delay and 8 signal averages. The $^{13}C\{^1H\}$ NMR spectra were obtained using a WALTZ-16 composite pulse ^1H decoupling, a 5 s recycle delay and a $\pi/4$ pulse excitation.

4.2. General synthesis of ORc-modified $Zr(OR)_4$

The appropriate $Zr(OR)_4$ (**1** or **7**) was dissolved in toluene and then added via pipette to a stirring mixture of the desired carboxylic acid (H-ORc, Fig. 1) already dissolved in toluene. After 12 h, the reaction was allowed sit to slowly evaporate the volatile material until crystals formed. If crystals did not form, the reaction mixture was further concentrated by rotary evaporation and then placed into a freezer (−35 °C) until crystals formed. Scale and analytical data are presented for each compound (vide infra).

4.2.1. $Zr_4(O)_2(OFc)_2(OPr^i)_{10}$ (**2**)

Used **1** (0.500 g, 1.29 mmol), H-OFc (0.0590 g, 1.29 mmol) and ~10 mL of toluene. Yield 0.390 g (56.1%). FT-IR (KBr, cm^{-1}) 2969(s), 2931(s), 2864(s,sh), 2626(m), 2364(w), 2345(w), 1590(s), 1463(s), 1375(s), 1338(s,sh), 1167(s), 1051(w,sh), 1018(s), 955(s), 847(s). Elemental *Anal.* Calc. for $Zr_4O_{16}C_{32}H_{72}$: C, 35.66; H, 6.73. Found: C, 35.63; H, 6.36%.

4.2.2. $Zr_3(O)(OAc)_5(OPr^i)_5$ (**3**)

Used **1** (0.500 g, 1.29 mmol), H-OAc (0.0770 g, 1.29 mmol) and ~10 mL of toluene, heated for 10 min until solution went clear. Yield 0.350 g (46.3%). FT-IR (KBr, cm^{-1}) 2969(s), 2932(m), 2863(w), 2625(w), 1548(s), 1450(s), 1375(m), 1363(m,sh), 1337(w), 1168(s), 1049(sh), 1017(s), 947(s), 847(m), 826(m,sh), 653(m), 617(m), 554(s), 461(s). Elemental *Anal.* Calc. for $Zr_3O_{16}C_{25}H_{50}$: C, 34.11; H, 5.72. Found: C, 34.04; H, 5.62%.

4.2.3. $[Zr_2(OPc)_2(OPr^i)_6]_2$ (**4**)

Used **1** (0.500 g, 1.29 mmol), H-OPc (0.113 g, 1.29 mmol) and ~10 mL of toluene, heated for 10 min until solution went clear. Yield 0.370 g (40.4%). FT-IR

(KBr, cm^{-1}) 2970(s), 2932(m), 2868(m), 2624(w), 2367(w), 2345(w), 1578(s), 1561(s,sh), 1510(w), 1476(m), 1439(s), 1375(s), 1362(s,sh), 1338(m), 1301(m), 1262(w), 1169(s), 1099(sh), 1021(s), 1009(sh), 974(m), 847(m), 824(m), 775(w), 654(m), 542(s), 462(s). Elemental *Anal.* Calc. for $Zr_2O_{10}C_{26}H_{56}$: C, 43.91; H, 7.94. Found: C, 44.16; H, 7.61%.

4.2.4. $Zr_2(OBc)(OPr^i)_7(H\text{-}OPr^i)(H\text{-}OPr^i)$ (**5**)

Used **1** (0.500 g, 1.29 mmol), H-OBc (0.132 g, 1.29 mmol) and ~10 mL of toluene. Yield 0.400 g (38.1%). FT-IR (KBr, cm^{-1}) 2969(s), 2930(m), 2865(w), 2625(w), 2346(w), 1583(s,sh), 1561(s), 1509(w), 1485(s), 1460(m,sh), 1431(s), 1407(w,sh), 1374(s), 1361(s), 1339(m), 1229(m), 1171(s), 1023(s), 945(s), 898(w), 847(m), 822(m), 791(w), 601(s), 561(s), 545(s), 461(s), 432(w,sh), 407(m). Elemental *Anal.* Calc. for $C_{32}H_{74}O_{11}Zr_2$: C, 47.02; H, 9.12. Found: C, 46.82; H, 8.87%.

4.2.5. $Zr_2(\mu\text{-}ONc)(H\text{-}ONc)(OPr^i)_7$ (**6**)

Used **1** (0.500 g, 1.29 mmol), H-ONc (0.150 g, 1.29 mmol) and ~10 mL of toluene. Yield 0.430 g (40.2%). FT-IR (KBr, cm^{-1}) 2966(s), 2867(s,sh), 2625(m), 1561(s), 1459(s), 1337(s,sh), 1307(m), 1277(m), 1237(m), 1168(s), 1022(s), 948(s), 847(m), 821(m), 726(m), 628(sh), 548(s), 462(s), 411(s, sh). Elemental *Anal.* Calc. for $Zr_2O_{11}C_{33}H_{72}$: C, 47.91; H, 8.77. Found: C, 47.56; H, 8.43%.

4.2.6. $Zr_3(O)(ONep)_{10}$ (**7**)

$Zr(NMe_2)_4$ was synthesized from the reaction of $ZrCl_4$ (1.00 g, 4.29 mmol) and $LiNMe_2$ (0.876 g, 17.1 mmol) in THF (~8 mL). The precipitate was removed by centrifugation, the soluble fraction dried, extracted with hexanes, and dried by rotary evaporation. The $Zr(NMe_2)_4$ (0.869 g, 3.24 mmol) powder was re-dissolved in toluene (~5 mL), H-ONep (1.28 g, 14.6 mmol) in toluene (~5 mL) was added and the reaction was allowed to stir. After 8 h, the resultant mixture was warmed (~60 °C) for 1 h, allowed to cool to room temperature and all of the volatile material removed in vacuo. The resultant white powder was dissolved in a warmed solution of hexanes and toluene (3:1) and allowed to cool to room temperature. X-ray quality crystals were isolated. Yield 1.06 g (63.8%). FT-IR (KBr, cm^{-1}) 2952(s), 2866(s,sh), 2701(w,sh), 2363(m), 2345(m), 1479(s), 1467(m,sh), 1395(s), 1362(s), 1259(m), 1144(s), 1056(m), 1026(w,sh), 958(w), 901(w), 617(m), 517(m), 455(m). ^1H NMR (400 MHz, toluene-d_8) δ 3.84 (2H, s, $OCH_2C(CH_3)_3$), 1.02, 0.97 (12.8H, s, $OCH_2C(CH_3)_3$). $^{13}C\{^1H\}$ NMR (100.1 MHz, toluene-d_6) δ 77.7 ($OCH_2C(CH_3)_3$), 24.7, ($OCH_2C(CH_3)_3$), 28.1, 27.3 ($OCH_2C(CH_3)_3$). Elemental *Anal.* Calc. for $C_{50}H_{110}O_{11}Zr_3$: C, 51.72; H, 9.54. Found: C, 52.20; H, 9.54%.

4.2.7. $Zr_3(O)(OAc)_3(ONep)_7$ (**8**)

Used **7** (0.500 g, 0.431 mmol), H-OAc (0.0780 g, 0.431 mmol), and ~10 mL of toluene. Yield 0.300 g (64.7%). FT-IR (KBr, cm^{-1}) 2953(s), 2906(w), 2867(s), 2834(s,sh), 2704(w), 2362(w), 2344(w), 1572(s), 1479(s), 1458(s), 1396(s), 1362(s), 1296(w). 1260(w), 1143(s), 1120(s,sh), 1060(m), 1023(s), 994(m), 936(m), 921(m), 751(m), 632(s), 588(m), 538(s), 453(s). 4.2.8. $Zr_5(O)_3(OPc)_6(ONep)_8$ (**9**)

Used **7** (0.500 g, 0.431 mmol), H-OPc (0.114 g, 0.431 mmol) and ~10 ml of toluene, heated for 10 min until solution went clear. Yield 0.198 g (86.8%). FT-IR (KBr,cm^{-1}) 2953(s), 2868(s), 2796(w), 2701(m), 2362(m), 2344(m), 1562(s), 1523(w,sh), 1476(s), 1431(s), 1395 (w,sh), 1678(w), 1368(m), 1298(s), 1266(w,sh), 1128(s), 1088(w,sh), 1055(w,sh), 1037(m), 1026(m), 1010(s), 964 (w), 935(s), 901(m), 861(m), 840(w), 763(w,sh), 750(m), 623(s), 579(s), 527(s), 456(s). Elemental *Anal.* Calc. for $Zr_5O_{23}C_{64}H_{130}$: C, 44.59; H, 7.60. Found: C, 46.31; H, 7.12%.

4.2.9. $Zr_5(O)_3(ONc)_6(ONep)_8(H\text{-}ONep)1/2(C_7H_8)$ (**11**)

Used **7** (0.500 g, 0.431 mmol), H-ONc (0.150 g, 0.431 mmol) and ~10 mL of toluene. Yield 0.390 g (74.4%). FT-IR (KBr, cm^{-1}) 2955(s), 2907(m), 2870(w), 2719(w), 2370(w), 2345(w), 1708(s), 1612(m,sh), 1571(s), 1528(w,sh), 1459(s), 1414(s), 1367(s), 1307(s), 1276(s), 1235(s), 1198(m), 1145(m), 1047(m), 1035(w,sh), 978(m), 936(w), 910(m), 811(m), 757(m), 726(m), 691(m), 640(s), 593(s), 500(m,sh), 449(m), 411(s). Elemental *Anal.* Calc. for $C_{84.5}H_{170}O_{24}Zr_5$: C, 50.09; H, 8.46 and for solvent free: Calc. for $C_{75}H_{155}O_{23}Zr_5$: C, 47.89; H, 8.30. Found: C, 48.12; H, 8.77%.

4.3. General X-ray crystal structure information [37]

Each crystal was mounted onto a thin glass fiber from a pool of Fluorolube™ and immediately placed under a liquid N_2 boil-off stream, on a Bruker AXS diffractometer. The radiation used was graphite monochromatized Mo Kα radiation ($\lambda = 0.7107$ Å). The lattice parameters were optimized from a least-squares calculation on carefully centered reflections. Lattice determination and data collection were carried out using SMART version 5.054 software. Data reduction was performed using SAINT version 6.01 software. The structure refinement was performed using XSHELL 3.0 software. The data were corrected for absorption using the SADABS program within the SAINT software package.

Each structure was solved using direct methods. This procedure yielded the heavy atoms, along with a number

of the C atoms. Subsequent Fourier synthesis yielded the remaining C atom positions. The crystal structures of metal alkoxides are often plagued by disorder in the pendant chain of the ligand. The different orientations adopted causes larger *R*-values than normally observed for other structures. When possible, the hydrogen atoms were fixed in positions of ideal geometry and refined within the XSHELL software. These idealized hydrogen atoms had their isotropic temperature factors fixed at 1.2 or 1.5 times the equivalent isotropic *U* of the C atoms for which they were bonded. The final refinement of each compound included anisotropic thermal parameters on all non-hydrogen atoms. Additional information concerning the data collection and final structural solutions of **2**–**11** can be found in the supplemental information. Data collection parameters for **2**–**11** are given in Table 1. Descriptions of the problems encountered for the less well behaved structure solutions are described below.

4.3.1. General X-ray crystal structure information for alkoxide ligands of 2–11

Final crystal solutions that contain alkoxides are notorious for positional disorder behavior problems. The carbon atoms of the alkoxide ligands (OPr^i or ONep) of these compounds show significant translational disorder. Attempts were made to model this disorder by distributing the positions of the C over several sites. These attempts proved fruitless as the disorder does not display clearly defined positions for the partial occupied sites. Hence, these attempts were abandoned in favor of one large thermal ellipsoid for many of the OR ligands in these structures. Specific information can be found in the Supplemental information.

4.3.2. Specific X-ray crystal structure information for 5

A coordinated solvent molecule of ($H\text{-}OPr^i$) was observed in the lattice. Hydrogen bond lengths for the solvent were H(7)–O(11) = 1.742 Å and H(11)–O(1) = 1.827 Å. Significant positional disorder was observed for the methyl groups on the OBc ligand. Two possible orientations of the methyl groups were refined resulting in C(12)/C(12′), C(13)/C(13′), and C(14)/C(14′) methyl pairs each with 0.5 site occupancy.

4.3.3. Specific X-ray crystal structure information for 6

Disorder of a terminal methyl group of the ONc led to expected bond deviations and large atomic displacement parameters due to fractional occupancy as well as ill-defined site location resulting from the ligand disorder (the other fraction of the site is found with the C11 terminal methyl).

4.3.4. Specific X-ray crystal structure information for 7

Two disordered hexane solvent molecules were located within the cell and were modeled using the PLATON/SQUEEZE program (ver. 01-11-99). The SQUEEZE

program located the solvent centers at (0.037, 3/3, 0.402) and (−0.030, 1/4, 0.598), with a potential volume of 744.2 Å^3 and electron count of 90 electrons/cell, consistent with two hexane molecules.

4.3.5. Specific X-ray crystal structure information for ***9***

One of the terminal methyl carbon attached to a translationally disordered OPc acid group occupies multiple site locations which leads to spatially disordered C(55) and C(56) methyl carbons. Attempts were made to model this disorder, however a simple disorder model for this ligand was not possible. Partially occupied sites tended to elongate severely and often became non-positive definite. The modeling of the disorder was abandon in favor of the individual C(55) and C(56) carbon sites with abnormally large thermal ellipsoids, with the understanding that these ellipsoids represent the large variability of methyl carbon atoms from molecule to molecule. C(16) possesses a high U_{eq} in comparison to other atoms because it is located on a terminal ONep ligand which has rotational disorder. The apparent rotational disorder displayed on this ligand does not affect all the carbons. In fact the rotation appears to pivot about the central C(17) carbon which allows this carbon to be relatively well defined; all the associated carbon atoms bond to this atom, however tend to displace due to the rotation. O(7) is also bound to a translationally disordered yielding large thermal ellipsoids for the associated carbons while the O7 which is more rigidly bound to the Zr(5) atom remains relatively fixed.

4.3.6. Specific X-ray crystal structure information for ***11***

One ONc ligand (O10, O11) showed rotational disordering of carbon atoms and was modeled by split (0.5 occupancy) methyl C sites C36/C36′ and C38/C38′. Due to the disorder, hydrogen atoms were not refined on these split sites, however 12 hydrogens were added to the contents of the unit cell during the final refinement to properly calculate the crystal data. An H-ONep molecule was located in the unit cell. This molecule is centered at (0.288, 0.307, 0.370). A disordered toluene solvent molecule was observed in the unit cell. The toluene was centered at (0, 1/2, 0). Attempts to model the disordered toluene failed. The solvent electron density was modeled using PLATON/SQUEEZE (ver. 01-11-99), which located a potential solvent volume of 281.4 Å^3 and an electron count of 46 electrons/cell consistent with one toluene molecule.

4.4. Thin film production

Thin films of all new compounds were generated using standard sol–gel spin cast deposition methods [22,38]. The general preparatory route involved generating under an argon atmosphere an ~0.40 M precursor solution with the appropriate compound dissolved in toluene. The solution was then transferred to a syringe, removed from the glovebox and the precursor solution deposited onto a platinized silicon substrate. The wafer was spun at 3000 rpm for 30 s and was then transferred to a hot plate at 300 °C to initiate crystallization. The wafer was removed from the heat after no more color changes were observed (~30 s), the wafer was removed, allowed to cool, and then another layer added. This was repeated so that 3 layers were deposited. The films were then fired in a furnace at 550 °C for one hour under ambient atmosphere. Subsequently, the films were analyzed using standard ellipsometry techniques at three different times during the film making process, (i) preheat, (ii) post hot plate, and (iii) post fire.

Acknowledgments

Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000. bulky silylamido ligands that can be potentially utilized as ligand-transfer reagents in reactions with CO_2. Although the bulky silylamine ligands $HN(SiMe_3)(R)$ (R = –$SiPh_2{}^tBu$ [36], –$Si(SiMe_3)_3$ [37], –$SiPh_3$ [38a], and adamantyl (ad)) [38b] have been previously prepared, few examples were reported to use their lithium derivatives as transmetallating agents [14,39]. With the exception of the structural characterization of $\{LiN(SiMe_3)[Si(SiMe_3)_3]\}_2$ [37], surprisingly little is known about the spectroscopic and structural details of these key $Li[N(SiMe_3)(SiR_3)]$ species in which nitrogen is bound to both a –$SiMe_3$ group and a significantly sterically crowded –SiR_3 moiety.

We now report the syntheses and structural characterizations of the dimeric lithium amides $\{Li[N(SiMe_3)(SiPh_2{}^tBu)]\}_2$ (**1**) and $\{Li[N(SiMe_3)(SiPh_3)]\}_2$ (**2**). Addition of an excess of coordinating solvents such as thf, py, or hmpa provide monomeric derivatives containing two solvent molecules per complex. These monomeric compounds are extremely soluble in hydrocarbon solvents, allowing the formation of colorless crystals at low temperature. We also describe the synthesis and characterization of $Li\{N(SiMe_3)[Si(SiMe_3)_3]\}(py)_2$ (**7**), prepared directly from the secondary amide and pyridine Finally, in an entirely unexpected reaction, we describe the synthesis of a more complex lithium amide **8** derived from the reaction of in situ generated $Li[N(ad)(SiMe_3)]$ with CaI_2.

2. Experimental

2.1. General considerations

All manipulations were carried out in an Ar-filled glove box or by using standard Schlenk techniques [40]. Anhydrous solvents were purchased from Aldrich or Fisher Scientific Company, after which they were stored in the glove box over 4 Å molecular sieves. Anhydrous CaI_2 and *n*-BuLi (2.5 M in hexane) were purchased from Aldrich. $(Me_3Si)(R)NH$ (R = –$SiPh_2{}^tBu$, –$SiPh_3$, –$Si(SiMe_3)_3$, and adamantyl) were synthesized by literature procedures [36–38]. ^1H and ^{13}C NMR spectra were obtained on a Bruker AMX 250 spectrometer using C_6D_6 as solvent. Infrared spectra were obtained as KBr pellets utilizing a Bruker Vector 22 Model spectrophotometer. Characteristic peaks are listed. It should be noted that the IR spectra are complex, particularly in the fingerprint region between 1500 and 500 cm^{-1}. Elemental analyses for carbon, hydrogen, and nitrogen were measured in sealed volatile sample pans using a Perkin–Elmer series II CHNS/O 2400 analyzer, or performed commercially at Desert Analytics, Tucson, Arizona. Despite the fact that an additional oxidizer (WO_3) was added during the analyses for CHN, in several cases the analyzed carbon content was lower than the calculated value. However, this was not the case with the hydrogen or nitrogen analyses. In none of the duplicate sample preparations sent for analysis did we ever see an elevated carbon content – the carbon content was consistently slightly lower than expected.

2.2. $[LiN(SiMe_3)(SiPh_2{}^tBu)]_2$ (1)

($^tBuPh_2Si$)(Me_3Si)NH (3.28 g, 10.0 mmol) dissolved in 50 mL hexane was cooled to 0 °C in an ice bath and treated with *n*-BuLi (4.0 mL, 10.0 mmol). The solution was stirred overnight at room temperature. The solution was reduced to 30 mL and cooled to −20 °C to yield **1** as colorless crystals (2.86 g, 86%); m.p. 136–138 °C. ^1H NMR (C_6D_6): δ 0.21 (s, 18H, SiMe_3), 1.06 (s, 18H, CMe_3), 7.16 (m, 15H, C_6H_5), 7.57 (m, 4H, C_6H_5). ^{13}C NMR (C_6D_6): δ 6.09 (SiMe_3), 20.55 (CMe$_3$), 29.70 (SiCMe_3), 128.49 (C_6H_5), 129.24 (C_6H_5), 135.84 (C_6H_5), 140.53 (C_6H_5). IR (cm^{-1}): 3376 (w), 3064–2895 (br, m), 1965 (m), 1893 (m), 1811 (m), 1576 (m), 1556 (w). *Anal.* Calc. for $C_{38}H_{56}N_6Si_4Li_2$: C, 68.42; H, 8.46; N, 4.22. Found: C, 68.18; H, 8.82; N, 4.05%.

2.3. $[LiN(SiMe_3)(SiPh_3)]_2$ (2)

Similar to **1**, **2** was synthesized by the treatment of (Ph_3Si)(Me_3Si)NH (3.47 g, 9.98 mmol) with *n*-BuLi (4.0 mL, 10.0 mmol) in 80 mL hexane. After workup as in **1**, cooling to −20 °C yielded **2** as colorless crystals (2.79 g, 79%); m.p. 165–166 °C. ^1H NMR (C_6D_6): δ 0.10 (s, 18H, SiMe_3), 7.15 (m, 24H, C_6H_5), 7.64 (m, 6H, C_6H_5). ^{13}C NMR (C_6D_6): δ 6.55 (SiMe_3), 128.46 (C_6H_5), 129.36 (C_6H_5), 135.88 (C_6H_5), 140.35 (C_6H_5). IR (cm^{-1}): 3339 (w), 3064 (m), 2953 (m), 1954 (m), 1893 (m), 1821 (m), 1472 (s), 1586 (s), 1545 (m). *Anal.* Calc. for $C_{42}H_{48}N_2Si_4Li_2$: C, 71.35; H, 6.84; N, 3.96. Found: C, 71.24; H, 6.97; N, 3.89%.

2.4. $[(^tBuPh_2Si)(Me_3Si)N]Li(thf)_2$ (3)

Compound **1** (0.67 g, 1.00 mmol) was dissolved in 60 mL hexane, and then treated with an excess of thf (0.43 g, 6.0 mmol) at room temperature. The solution was stirred for 1 h, then the solvent was removed under vacuum. The crude product was recrystallized from hexane at −20 °C to give colorless crystals of **3** (0.76 g, 80%); m.p. 100–101 °C. ^1H NMR (C_6D_6): δ 0.41 (s, 9H, SiMe_3), 1.22 (t, 8H, –CH_2–, $^3J_{H-H}$ = 6.5 Hz), 1.46 (s, 9H, CMe_3), 3.20 (t, 8H, –OCH_2–, $^3J_{H-H}$ = 6.5 Hz), 7.20 (m, 8H, C_6H_5), 8.04 (m, 2H, C_6H_5). ^{13}C NMR (C_6D_6): δ 6.76 (SiMe_3), 21.05 (CMe$_3$), 25.16 (–CH$_2$–), 29.26 (CMe_3), 68.19 (–OCH$_2$–), 127.21 (C_6H_5), 127.61 (C_6H_5), 136.17 (C_6H_5), 145.26 (C_6H_5). IR (cm^{-1}): 3370 (m), 2955 (br, s), 1958 (m), 1893 (m), 1822 (m), 1589

(m). *Anal*. Calc. for $C_{27}H_{44}NO_2Si_2Li$: C, 67.88; H, 9.28; N, 2.93. Found: C, 65.96; H, 9.03; N, 3.12%.

2.5. [(^{t}BuPh$_2$Si)(Me$_3$Si)N]Li(py)$_2$ (4)

Compound **4** was obtained by addition of excess py (0.37 g, 4.74 mmol) to a solution of **1** (0.53 g, 0.79 mmol) dissolved in 60 mL hexane. After workup as in **3** the crude product was recrystallized from hexane at −20 °C to form colorless crystals of **4** (0.64 g, 82%); m.p. 114–116 °C. ^{1}H NMR (C_6D_6): δ 0.49 (s, 9H, Si*Me*$_3$), 1.48 (s, 9H, C*Me*$_3$), 6.58 (m, 4H, C_5H_5N), 6.92 (m, 2H, C_5H_5N), 7.17 (m, 8H, C_6H_5), 8.04 (m, 2H, C_6H_5), 8.10 (m, 4H, C_5H_5N). ^{13}C NMR (C_6D_6): δ 7.05 (Si*Me*$_3$), 21.15 (*C*Me$_3$), 29.42 (C*Me*$_3$), 124.19 (C_5H_5N), 127.21 (C_6H_5), 127.61 (C_6H_5), 136.40 (C_6H_5), 137.28 (C_5H_5N), 145.34 (C_6H_5), 149.47 (C_5H_5N). IR (cm^{-1}): 3365 (w), 3068 (m), 2960 (br, m), 1975 (m), 1944 (m), 1903 (m), 1586 (m), 1556 (w). *Anal*. Calc. for $C_{29}H_{38}N_3Si_2Li$: C, 70.83; H, 7.79; N, 8.55. Found: C, 69.85; H, 7.71; N, 8.10%.

2.6. [(^{t}BuPh$_2$Si)(Me$_3$Si)N]Li(hmpa)$_2$ (5)

Complex **5** was obtained by addition of excess hmpa (1.81 g, 10.1 mmol) to a solution of **1** (1.12 g, 1.68 mmol) dissolved in 60 mL hexane. After workup as in **3** the crude product was recrystallized from hexane at −20 °C to form colorless crystals of **5** (1.76 g, 76%); m.p. 118–119 °C. ^{1}H NMR (C_6D_6): δ 0.37 (s, 9H, Si*Me*$_3$), 1.43 (s, 9H, C*Me*$_3$), 2.32 (d, 36H, $^3J_{P-H}$ = 9.45 Hz, (*Me*$_2$N)$_3$PO), 7.30 (m, 8H, C_6H_5), 8.20 (m, 2H, C_6H_5). ^{13}C NMR (C_6D_6): δ 6.66 (Si*Me*$_3$), 21.05 (*C*Me$_3$), 29.75 (C*Me*$_3$), 36.76 ((*Me*$_2$N)$_3$PO), 126.57 (C_6H_5), 126.72 (C_6H_5), 136.95 (C_6H_5), 146.82 (C_6H_5). IR (cm^{-1}): 3222 (m), 2889 (br, s), 2364 (m), 2179 (m). *Anal*. Calc. for $C_{31}H_{64}N_7O_2P_2Si_2Li$: C, 53.81; H, 9.32; N, 14.17. Found: C, 52.62; H, 8.94; N, 14.24%.

2.7. [(Ph$_3$Si)(Me$_3$Si)N]Li(py)$_2$ (6)

Compound **6** was obtained by addition of excess py (0.63 g, 8.0 mmol) to a solution of **2** (0.71 g, 1.0 mmol) dissolved in 50 mL hexane. After workup as in **3** the crude product was recrystallized from hexane at −20 °C to yield colorless crystals of **6** (0.87 g, 85%); m.p. 131–133 °C. ^{1}H NMR (C_6D_6): δ 0.41 (s, 9H, Si*Me*$_3$), 6.49 (m, 4H, C_5H_5N), 6.82 (m, 2H, C_5H_5N), 7.18 (m, 12H, C_6H_5), 7.99 (m, 3H, C_6H_5), 8.06 (m, 4H, C_5H_5N). ^{13}C NMR (C_6D_6): δ 6.64 (Si*Me*$_3$), 124.17 (C_5H_5N), 127.48 (C_6H_5), 127.61 (C_6H_5), 136.16 (C_6H_5), 137.23 (C_5H_5N), 145.38 (C_6H_5), 149.44 (C_5H_5N). IR (cm^{-1}): 3346 (m), 1954 (w), 1883 (w), 1822 (w), 1597 (s), 1556 (w). *Anal*. Calc. for $C_{31}H_{34}N_3Si_2Li$: C, 72.76; H, 6.70; N, 8.21. Found: C, 70.89; H, 7.02; N, 7.90%.

2.8. {[(Me$_3$Si)$_3$Si](Me$_3$Si)N}Li(py)$_2$ (7)

HN(SiMe$_3$)[Si(SiMe$_3$)$_3$] (3.36 g, 10.0 mmol) in 60 mL hexane was treated with *n*-BuLi (4 mL, 10.0 mmol) at room temperature to generate the Li salt. This solution was not isolated but treated directly with an excess of py (3.16 g, 40.0 mmol) for 1 h. The solvents were removed under vacuum and the crude product was recrystallized from hexane at −20 °C to give colorless crystals of **7** (3.95 g, 79%); m.p. 97–98 °C. ^{1}H NMR (C_6D_6): δ 0.66 (s, 9 H, Si*Me*$_3$), 0.75 (s, 27H, (Si(Si*Me*$_3$)$_3$)), 7.14 (m, 4H, C_5H_5N), 7.43 (m, 2H, C_5H_5N), 8.97 (m, 4H, C_5H_5N). ^{13}C NMR (C_6D_6): δ 2.49 (Si(Si*Me*$_3$)$_3$), 6.55 (Si*Me*$_3$), 124.31 (C_5H_5N), 137.31 (C_5H_5N), 150.06 (C_5H_5N). IR (cm^{-1}): 3376 (w), 2947 (br, m), 1900 (m), 2149 (w), 1893 (m), 1472 (s), 1464 (s). *Anal*. Calc. for $C_{22}H_{46}N_3Si_5Li$: C, 52.85; H, 9.27; N, 8.40. Found: C, 51.94; H, 8.60; N, 7.98%.

2.9. [(ad)(SiMe$_3$)N]$_2$Li$_3$(μ_3-I)(thf)$_2$ (8)

[(ad)(Me$_3$Si)N]Li was prepared from (ad)(Me$_3$Si)NH (2.23 g, 9.98 mmol) and *n*-BuLi (4.0 mL, 10.0 mmol), and was then treated with anhydrous CaI_2 (0.92 g, 5.0 mmol) in 50 mL thf. The mixture was stirred overnight and evaporated to dryness. The residue was held under vacuum for 6 h and was extracted with 70 mL hexane, and the extracts were filtered through Celite filter aid. The hexane was removed to yield a crude product (ca. 2.7 g). Recrystallization from a toluene/hexane solution at −20 °C afforded pure **8** as colorless crystals (1.33 g, 55% based on Li); m.p. 122–124 °C. ^{1}H NMR (C_6D_6): δ 0.38 (s, 18 H, Si*Me*$_3$), 1.26 (t, 8H, –C*H*$_2$–, $^3J_{H-H}$ = 6.7 Hz), 1.68 (m, 6H, –C*H*–), 1.95 (m, 12H, –C*H*$_2$–), 2.14 (m, 12H, –C*H*$_2$–), 3.64 (t, 8H, –OC*H*$_2$–, $^3J_{H-H}$ = 6.7 Hz). ^{13}C NMR (C_6D_6): δ 7.15 (Si*Me*$_3$), 25.23 (–*C*H$_2$–), 31.16 (–*C*H$_2$–), 37.03 (–*C*H$_2$–), 51.42 (–*C*H–), 53.06 (N*C*), 69.22 (–O*C*H$_2$–). IR (cm^{-1}): 3335 (w), 1955 (m), 1893 (m), 1822 (m), 1586 (m), 1545 (w). *Anal*. Calc. for $C_{34}H_{62}N_2O_2Si_2ILi_3$: C, 55.58; H, 8.51; N, 3.81. Found: C, 55.20; H, 9.21; N, 3.64%.

2.10. X-ray crystallography

Crystallography data for **1**–**8** are given in Tables 1 and 2. As all of the compounds are extremely air-sensitive the crystals were always handled under inert atmosphere, covered with oil and immediately transferred to the N_2 stream of the diffractometer. Data were collected at 218 K on Bruker P4/CCD (**1**, **3**, **4**, **6**, **8**) and at 100 K on Smart Apex CCD (**2**, **5**, **7**) diffractometers using Mo Kα radiation (λ = 0.71073 Å). Absorption corrections were applied for all data by SADABS. Non-hydrogen atoms in all structures were refined with anisotropic displacement coefficients except the C atoms in the disordered thf molecules

in **3** and **8** and the disordered NMe_2 groups in **5** that were refined with isotropic thermal parameters. All H atoms were treated as idealized contribution, except the H atoms of the disordered thf molecules in **3** and **5** that were not taken into consideration. The Flack parameter for non-centrosymmetrical structure of **1** is 0.0(1). All software and sources of scattering factors are contained in the SHELXTL (5.10) program package (G. Sheldrick, Bruker XRD, Madison, WI) [41].

3. Results and discussion

3.1. Syntheses and characterization of 1–8

Treatment of either (^{t}BuPh$_2$Si)(Me$_3$Si)NH or (Ph$_3$Si)(Me$_3$Si)NH with 1 equiv of *n*-BuLi in hexane results in high isolated yields of **1** and **2**, respectively. Addition of a multimolar excess of the donor solvents thf, py, or HMPA to **1** afforded the solvated monomeric lithium salts Li[N(SiMe$_3$)(SiPh$_2$^{t}Bu)](L)$_2$ (L = thf (**3**); py (**4**); hmpa (**5**)), while addition of excess py to **2** afforded Li[N(SiMe$_3$)(SiPh$_3$)](py)$_2$ (**6**). Crystals suitable for X-ray diffraction analyses can be obtained via crystallization from their saturated hexane solutions at −20 °C. While all compounds are air- and moisture-sensitive as expected, the dimeric complexes **1** and **2** appear to be more stable than the corresponding monomeric derivatives, whether in solution or the solid state. All the compounds have been well characterized by ^{1}H and ^{13}C NMR spectra and the solid state structures further established by X-ray crystallography.

The ^{1}H and ^{13}C NMR spectra of the new compounds **1**–**6** are straightforward to interpret, and assignments are given in the Experimental. Briefly, the basic backbone structures of the amido ligands are shown to continue in each of these compounds, and **1** and **2** are further marked by the absence of solvent ligands in the NMR spectra. In **3**–**6** the solvent ligands are present, and integrated ratios in the ^{1}H NMR spectra indicate that there are two-coordinated solvent ligands per Li atom. However, the NMR data do not indicate the overall nuclearity of the species **1**–**6**, and so we had to result to X-ray crystallography to determine the solid state structures (vide infra).

The addition of *n*-BuLi to [(Me$_3$Si)$_3$Si](Me$_3$Si)NH in hexane solution afforded {LiN(SiMe$_3$)[Si(SiMe$_3$)$_3$]}$_2$, which had been previously reported by Westerhausen [37]. This dimeric complex was not isolated, but rather the in situ generated compound was treated with excess pyridine to produce the solvated monomeric compound **7**. As above, **7** has been fully characterized by ^{1}H and ^{13}C NMR spectra as well as X-ray diffraction analysis. While NMR indicated retention of the basic backbone structure again there was no indication of the overall nuclearity of **7**. Interestingly, treatment of LiN[(SiMe$_3$)(ad)], generated from the reaction of HN[(SiMe$_3$)(ad)] with *n*-BuLi in thf, with anhydrous CaI$_2$ afforded the unusual lithium amide **8** in moderate yields rather than the expected calcium bis(amide) species. We propose that the initially formed metathesis product LiI combines with unreacted {LiN[(SiMe$_3$)(ad)]} to give **8**, along with undetermined side products containing Ca, amide, and I. While ^{1}H and ^{13}C NMR spectra together could not suggest the structure of **8**, we eventually confirmed this unusual structure by X-ray diffraction analysis. **8** is an extremely air- and moisture sensitive complex that is unstable in thf solutions, but relatively stable when isolated in the solid state.

3.2. Solid state structures of dimeric lithium amides 1 and 2

The X-ray structures of **1** and **2** are shown in Figs. 1 and 2 while selected bond distances and angles are given in Table 3. **1** and **2** are solvent-free dimeric compounds with very similar structures. The core structure consists of an N$_2$Li$_2$ ring. The central (μ_2-N)$_2$Li$_2$ cycle in **1** is not planar; the dihedral angle between the Li(1)–Li(2)–N(1) and Li(1)–Li(2)–N(2) planes is 15.1(4)°. The N(1)–Li(1), N(1)–Li(2), N(2)–Li(1), and N(2)–Li(2) distances in **1** are 2.007(6), 2.021(6), 2.079(6) and 2.065(6) Å, respectively. These values are quite comparable to the related distances in **2**, which are 1.974(5), 2.000(5), 2.003(5), and 2.052(5) Å for the corresponding bonds lengths in **2**. The structure of **1** indicated as well that there are several close interactions of the ligands with the electron-deficient bridging Li atoms. The short Li(1)···C(23), Li(1)···C(24), Li(2)···C(4) and Li(2)···C(5) contacts (all in the 2.40–2.55 Å range) in **1** indicate interactions between lithium and carbon atoms of the ligands, and that the ligands do not serve as simple spectator ligands. Similarly short Li···C distances are also found in [LiN(CH$_2$Ph)]$_3$ and [LiN(SiMe$_2$Ph)]$_2$ where Li π bonding is assumed to occur as well [4,42]. The relative short Li···H distances of ca. 2.20 Å suggest there are some bonding (agostic) type interactions between lithium and the hydrogen atoms on either the Me$_3$Si– or phenyl groups. As was seen in **1**, the phenyl groups in **2** interact with the two lithium cations in a π-bonding fashion [42],

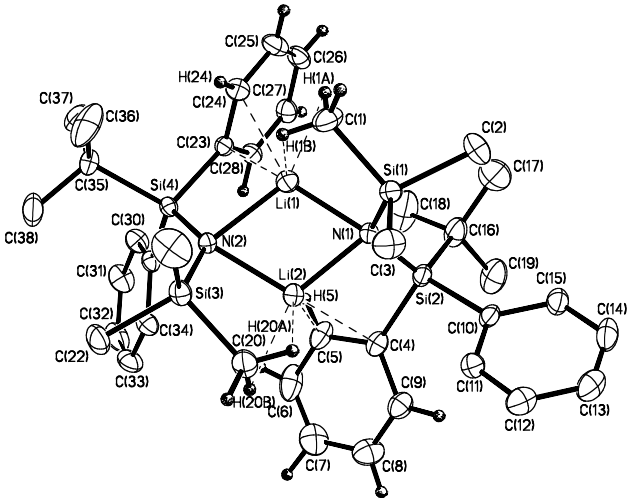

Fig. 1. X-ray structure of **1** (30% ellipsoids). The H atoms of Me and Ph groups involved in coordination to the Li atoms are shown for clarity. The shortest Li···H and Li···C contacts are shown by dashed lines.

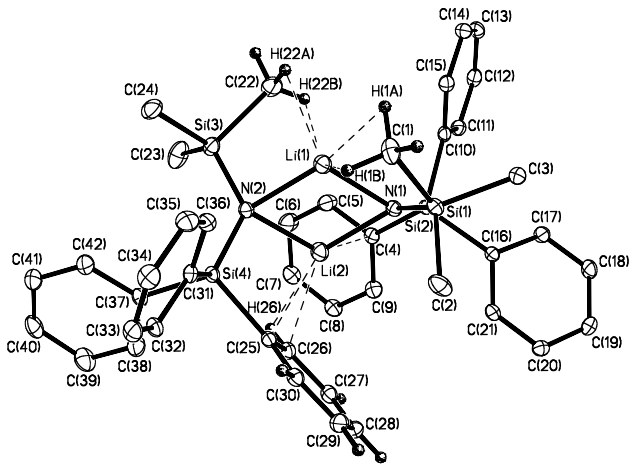

Fig. 2. X-ray structure of **2** (30% ellipsoids). Only the H atoms of Me and Ph groups involved in bonding to the Li atoms are shown for clarity. The shortest Li···H contacts are shown by dashed lines.

Table 3
Selected bond lengths (Å) and angles (°) for **1** and **2**

	1	**2**
Li(1)–N(1)	2.007(6)	1.974(5)
Li(2)–N(1)	2.021(6)	2.000(5)
Li(2)–N(2)	2.065(6)	2.052(5)
Li(1)–N(2)	2.079(6)	2.003(5)
Li(1)···Li(2)	2.343(8)	2.329(7)
Li(1)···C(24)	2.510(6)	
Li(1)···C(23)	2.427(6)	
Li(2)···C(5)	2.411(7)	
Li(2)···C(4)	2.525(6)	
Li(1)···C(22)		2.376(6)
Li(2)···C(25)		2.501(6)
Li(1)···C(1)		2.408(6)
Li(2)···C(26)		2.361(6)
Li(1)–N(1)–Li(2)	71.2(2)	71.8(2)
N(1)–Li(1)–N(2)	108.6(3)	110.4(2)
Li(2)–N(2)–Li(1)	68.9(2)	70.1(2)
N(1)–Li(2)–N(2)	108.6(3)	107.5(2)

as may be seen by the short distances of Li(2)–C(25) (2.501(6) Å) and Li(2)–C(26) (2.361(6) Å). Additionally, the agostic-type interactions between lithium cations and the hydrogen atoms from either the Me_3Si– or phenyl groups can be also found in **2**. The two N–Li–N angles in **1** are the same (108.6(3)°) and similar to the corresponding angles in **2** (110.4(2)°, 107.5(2)°). The acute Li–N–Li angles of 71.2(2)° and 68.9(2)° vary slightly from the corresponding angles in **2**, 71.8(2)° and 70.1(2)°. In the related compound $[LiN(SiMe_3)(SiMe_2Ph)]_2$ this angle is 71.70(12)° [43]. Generally, the N–Li–N angles found in **1** and **2** are greatly smaller than those found in $[LiN(SiMe_3)_2]_3$ (92.00(2)°) [1a], $[LiN(SiMe_3)Ph]_2[N(SiMe_3)\ PhLi]_2$ (77.2(3)°, 77.3(3)°) [43], and $[LiN(SiMe_3)_2]_2$ 80(3)° (measured by electron diffraction) [44].

*3.3. Solid state structures of solvated monomeric lithium amides **3**–**7***

The X-ray structures of **3**–**7** are presented (Figs. 3–7 and Table 4). Compounds **3**, **4**, and **5** utilize the ligand $–N(SiMe_3)(SiPh_2{}^tBu)$ while compounds **6** and **7** derive from the amido ligands $–N(SiMe_3)(SiPh_3)$ and $–N(SiMe_3)[Si(SiMe_3)]$, respectively. The molecular structures of **3**–**7** are quite similar; they are monomeric with three-coordinate lithium cations bound to one ligand nitrogen atom along with two solvent molecules. The Li–N bond lengths in **3**, **4**, and **5** were found to be quite comparable, ranging in length from 1.939(4) to 1.964(6) Å. These values are significantly shorter than the Li–N bond lengths in the dimeric compound **1** (average 2.04 Å.) The Li–O bond lengths in **3** (thf) and **5** (hmpa) differ by 0.054 Å on average. The Li–O bond lengths 1.920(5) and 1.934(5) Å in **3** are comparable to those found in $Li(thf)_2[N(SiPh_3)_2]$ (1.945(4) Å) [32], and slightly longer than those in $Li(thf)_2[N(SiMePh_2)_2]$ 1.907(3) Å [32]. The Li–O bond lengths of **5** (1.865(6) and 1.876(6) Å) are noticeably shorter than those in $[Li(OC_6H_2\text{-}4\text{-}Me\text{-}2,6\text{-}{}^tBu_2(OEt_2))]_2$ 1.961(11) Å [45] and $\{Li[N(SiMe_3)_2](OEt_2)\}_2$ 1.95(2) Å [46], and comparable to that seen in $[\{Li_2(\mu\text{-}[N(SiMe_3)_2])(\mu\text{-TEMPO})\cdot\ 2TEMPO\}^+\{Mg[N(SiMe_3)_2]_3\}^-]$, 1.821(6) Å (TEMPO = 2,2,6,6-tetramethy-1-piperidinyloxy) [47]. It is interesting to note that the O–Li–O angle in **5** is significantly larger by ca. 5.5° than that in **3**. The widened O–Li–O angle in **5** can be attributed to the larger volumetric requirements for the two solvent molecules of hmpa versus the smaller thf.

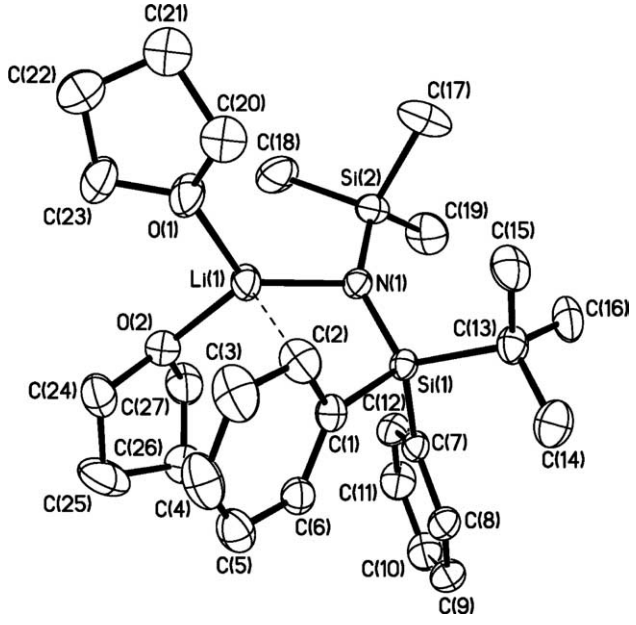

Fig. 3. X-ray structure of **3** (30% ellipsoids). The H atoms are omitted for clarity. The shortest Li···C contact is shown by dashed lines.

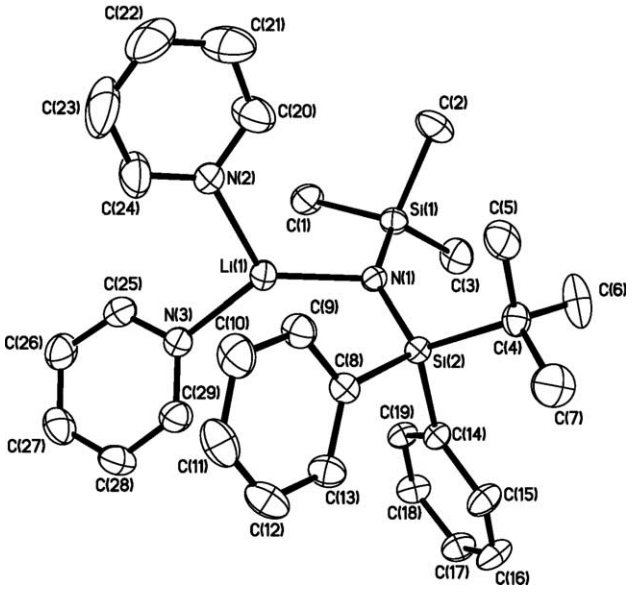

Fig. 4. X-ray structure of **4** (30% ellipsoids). The H atoms are omitted for clarity.

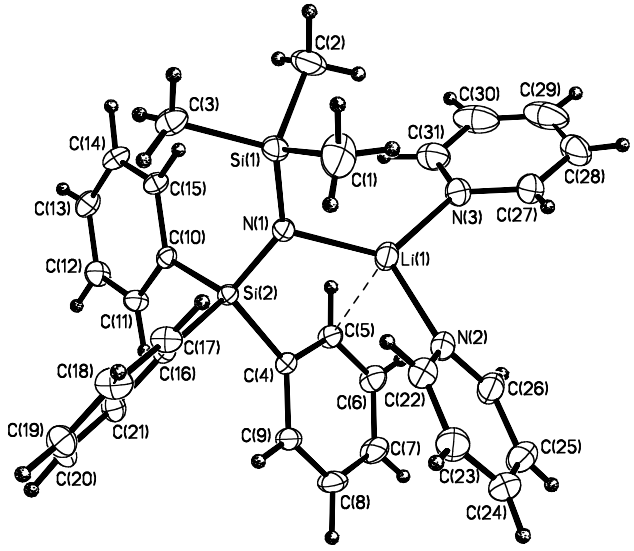

Fig. 6. X-ray structure of **6** (30% ellipsoids). For clarity, only H atoms in the groups involved in coordination to the Li atoms are shown. The shortest Li···C contact is shown by a dashed line.

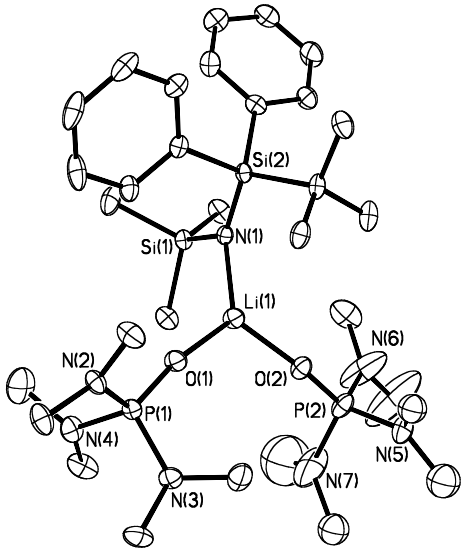

Fig. 5. X-ray structure of **5** (30% ellipsoids). The H atoms are omitted for clarity.

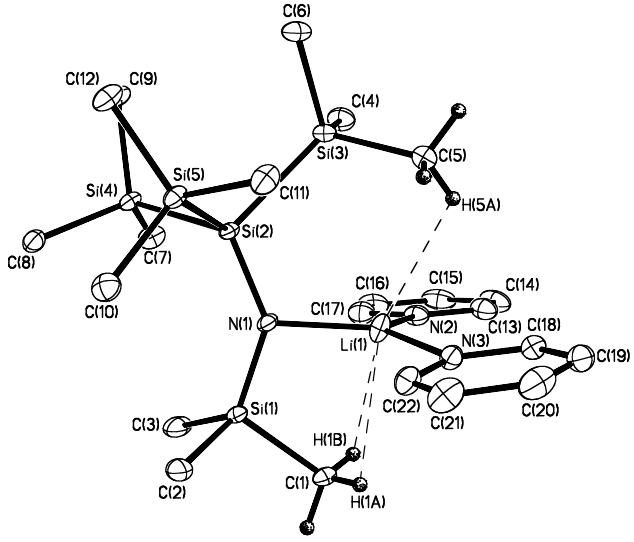

Fig. 7. X-ray structure of **7** (50% ellipsoids). For clarity, only the H atoms of the Me groups involved in coordination to Li are shown. The shortest Li···H contacts are shown by dashed lines.

Compounds **4**, **6**, and **7** all have two molecules of py per Li as the coordinating solvent. There are two symmetrically independent molecules in the crystal structure of **4**. The bond lengths between donating nitrogen atoms and lithium in **4** (2.072(4) (2.072(5)) and 2.038(4) (2.043(4)) Å) are comparable to those in **6** (2.019(4) and 2.043(4) Å), $\{(Li[N(SiMe_3)_2]\cdot py\}_2$ 2.05(1) Å, $\{Mg[N(SiMe_3)_2]_3Li\cdot(py)\}$ 2.083(3) Å, $\{Mg[N(SiMe_3)_2]_2(Bu)Li\cdot py\}$ 2.065(5) Å [48], and they are substantially shorter than those in $\{Li[N(SiMe_3)_2]$ (pmdien)}, 2.265(6) Å, and $[Li[N(SiMe_3)_2])$ $(PhCH_2NMe_2)]_2$, 2.240(4) Å [49]. The N(2)–Li(1)–N(3) angles in the two independent molecules in **4** (106.6(2)° and 113.3(2)°) are comparable with the corresponding angle in **6** (110.8(2)°). Additionally, another interesting feature of the structure of **6** and **3** is the weak molecular interaction that occurs between lithium and a carbon atom in one of the phenyl groups, as judged by the short Li···C distances of 2.779(7) and 2.783(5) Å, respectively in **3** and **6**. The bond length N(1)–Li(1) of 1.930(4) Å in **7** is slightly shorter than is seen in the dimeric complex $[Li\{N[SiMe_3][Si(SiMe_3)_3]\}]_2$ (2.006(7) Å) [37]. Compared with **4** and **6**, compound **7** has the largest N–Li–N angle of 125.6(2)°. Moreover, the short contact distances

For **4** the values for two independent molecules are given.

(ca. 2.90 Å) between lithium and the hydrogen atoms on the pendant $SiMe_3$ group suggest that the agostic interactions are again present in **7**.

3.4. Solid state structure of trilithium amide **8**

Interestingly, compound **8** was isolated from the reaction of $LiN(SiMe_3)(ad)$ with CaI_2 in thf rather than the anticipated calcium (bis)amide. ^1H and ^{13}C NMR spectra indicated that **8** had both $–SiMe_3$ and adamantyl groups, indicating that the ligand remained intact. However, this information was insufficient to postulate an actual structure for **8**. An X-ray diffraction study (Fig. 8 and Table 5) revealed a structure that was unexpected. X-ray analysis revealed that instead of the Ca amide we were attempting to prepare we had instead produced a dimeric Li amide complexed with LiI and thf solvent. We propose that the Li amide reacts with the CaI_2 to form initially a mixed amido/iodo calcium complex, which is not isolated (Scheme 1). The LiI formed in the metathesis reaction reacts with the starting Li amide, thus generating **8** and unidentified side products. As our

R = adamantyl

8

Scheme 1.

ligand/Ca stoichiometry of 2:1 was geared to produce a Ca bis(amide), the side products formed in addition to **8** must contain at least Ca, I, and amide. The structure shows that two four-membered rings containing I, Li, N, and Li atoms are fused via a common Li–I bond, in which the three lithium atoms have a three-coordinate environment. One of the lithium atoms is uniquely bonded to two ligand nitrogen atoms and one iodine atom, and the other two lithium atoms are bonded to one ligand nitrogen atom, one iodine atom, and one thf molecule. In the crystal structure there are two symmetrically independent molecules of **8** with the same structure. Similar structures containing a μ_3-I bonded to lithium atom(s) can be found in $[(thf)_3Li_3(\mu_3\text{-}I)\{Te(N^tBu)_3\}]$ [50], $\{Li(thf)_2[Te_2(N^tBu)_4](\mu_3\text{-}I)[LiI(Te_2(N^tBu)_4)]\}$ [50], and $[(thf)_3Li_3(\mu_3\text{-}I)\{S(N^tBu)_3\}]$ [51]. The two bulky adamantly groups attached to the amide ligands are located on opposite sides of the fused rings and situated as far away from each other as possible. The Li(1)–I(1) and Li(2)–I(1) bond lengths in **8** are almost identical (2.742(6) (2.735(6)) and 2.736(6) (2.756(6)) Å, respectively) but are much shorter than the unique bridging bond length of Li(3)–I(1) bond length of 3.109(5) (3.126(6)) Å. The same situation is also found in the similar structure of $\{[(^nBu)(C(N^tBu)_2)]_2\}Li_3(\mu_3\text{-}I)(thf)_2$, where the bridging Li(3)–I(1) bond length is significantly longer than the two other Li–I bonds [52]. In addition, the longer bond lengths seen in **8** between the two ligand nitrogen atoms and Li(3) (average 2.04(1) Å for both independent molecules) compared to the comparable bond lengths for Li(1)–N(1) or Li(2)–N(2) (average 1.963(9) Å for both independent molecules) indicate that the ligand nitrogen atoms are more weakly bound to the Li(3) atom. Interestingly, this weak bonding can lead to close interactions between Li(3) and the H atoms in the pendant ad or $–SiMe_3$ groups. This can be seen by noting the short distances of Li(3)···H(5A) and Li(3)···H(22B) (ca. 2.90 Å). Additionally, the N(1)–Li(3)–N(2) angle is somewhat distorted from linearity (165.1(3)° (165.4(3)°)), giving a slightly bent T-shape to Li(3).

4. Summary

In summary, we have synthesized dimeric lithium amides **1** and **2** containing bulky ligands, and described the Li···H agostic interactions in the molecules. In **1** and **2**, ligand nitrogen atoms are bridged with two lithium atoms consisting of four-membered N_2Li_2 ring with two-coordinate lithium centers. The monomeric compounds **3**–**6** derived from solvation of **1** and **2** displayed three-coordinate lithium atoms bonded to the nitrogen of one amido ligand and an additional two solvent molecules. Compound **7** has also been shown to be a monomeric three-coordinated lithium derivative, with the electron-deficient lithium atom contributing to agostic type interactions with the H atoms from the $–SiMe_3$ group. Compound **8** provided an unusual structure with two fused four-membered rings via a Li–I bridge. In this molecule one of three lithium atoms is bonded to two ligand nitrogen atoms and the μ_3-bridging iodine atom, while the other two lithium atoms are coordinated to one ligand nitrogen atom, one thf solvent molecule, and the bridging iodine atom. Each lithium atom adopts a three-coordinate geometry. The Li···H agostic interactions were seen between the Li and H atoms on the adamantyl and $SiMe_3$ groups. This work describes a number of structurally characterized silylamido-containing lithium amides that can now be used in various synthetic applications, including our own interests in the synthesis of main group metal amides and their interactions with carbon dioxide [35].

from sodium. *cis*-$Ru(bpy)_2Cl_2$ was synthesized according to the literature procedures [11].

2.2. Physical characterization

NMR spectra were recorded on a Bruker AVANCE 400 MHz or a Bruker ACP 200 MHz spectrometer using $CDCl_3$ for the free ligands and CD_3CN for the complex with TMS as internal reference. UV–Vis–NIR absorption spectra were recorded using a Shimadzu 3101 PC spectrometer. IR spectra were obtained using a Bruker Vector 22 FT using KBr.

Electrochemical measurements were made with a BAS 50 W using a conventional three electrode cell. Steady-state photoluminescence (PL) spectra were obtained with a Spex Fluorolog that had been calibrated with a standard NIST tungsten–halogen lamp.

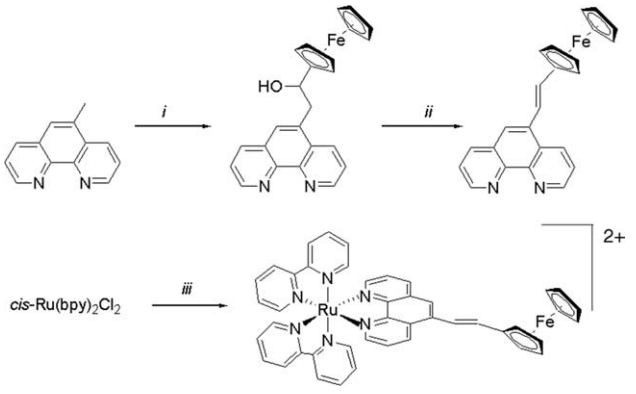
2.3. Synthesis

2.3.1. 1,10-Phenanthroline-5-yl-1,2-ferrocenylethanol

0.88 g of 5-methyl-1,10-phenanthroline (4.5 mmol) were dissolved in 20 mL of dry THF. The solution was cooled in a liquid nitrogen–ethanol bath. To the chilled solution 2.5 mL of lithium diisopropylamide, LDA 2.0 M were added. The dark solution formed was stirred for 1 h; the liquid nitrogen–ethanol bath was then changed for an ice-bath and 1.1 g of ferrocene carboxaldehyde (5 mmol) in 15 mL of dry THF were added. The solution was stirred overnight, subsequently quenched with water and extracted four times with chloroform (15 mL). The organic phase was dried with anhydrous sodium sulfate and the solvent eliminated. The solid obtained was purified by alumina chromatography using increasing polarity hexanes–diethyl ether–dichloromethane mixtures as mobile phase. Evaporation of the solvent gave 0.97 g of pure compound with a 52% yield. IR (KBr cm^{-1}) 3226, 1618, 1045, 752, 738, ^1H RMN 400 MHz ($CDCl_3$) 9.18 (1H, dd), 9.15 (1H, dd), 8.41 (1H, dd), 8.16 (1H, dd), 7.6 (3H, m), 4.80 (CH, m), 4.32 (1H, cp, s), 4.22 (5H, cp, s), 4.18 (1H, cp, s), 4.13 (1H, cp, s), 3.46 (CH2, m), 2.3 (OH, s): ^{13}C RMN 150.3, 150.1, 146.1, 135.8, 133.8, 132.9, 128.7, 128.5, 127.6, 123.5, 122.9, 93.8, 70.5, 68.7, 68.6, 68.4, 67.9, 65.1, 41.8.

2.3.2. 5-[(E)-2-ferrocenylvynil]-1,10-phenanthroline (fcvp)

0.5 g of 1,10-phenanthroline-5-yl-1,2-ferrocenylethanol (1.22 mmol) and 0.3 g of pyridinium-*p*-toluene sulfonate (1.22 mmol) in 30 mL of toluene, were refluxed for 6 h. After that period the solvent was eliminated. Water was added to the solid and the resulting mixture was extracted with 4 portions of chloroform (15 mL). The organic phase was dried with anhydrous sodium sulfate and the solvent evaporated under vacuum. The resulting solid was purified by alumina chromatography. 0.40 g of an orange solid were obtained with a 82% yield. IR (KBr, cm^{-1}) 1628, 1597, 1420, 820, 735, ^1H RMN 400 MHz ($CDCl_3$) 9.21 (1H, dd), 9.14 (1H, dd), 8.55 (1H, dd), 8.24 (1H, dd), 7.90 (1H, s), 7.67 (1H, dd), 7.61 (1H,), 7.35 (1H, d), 7.06 (1H, d), 4.57 (2H pt), 4.37 (2H pt), 4.21 (5H s): ^{13}C RMN 150.4, 150.1, 146.7, 146.1, 135.9, 134.9, 132.7, 129.0, 127.7, 123.7, 123.1, 122.5, 121.4, 83.138, 69.9, 69.7, 67.6. *Anal.* Calc. for $C_{24}H_{18}N_2Fe$: C, 73.86; H, 4.65; N, 7.18. Found: C, 72.91; H, 4.77; N, 7.17%.



2.3.3. $[Ru(bpy)_2(fcvp)](PF_6)_2$

A solution of fcvp (0.5 mmol) and *cis*-$Ru(bpy)_2Cl_2$ (0.5 mmol) in H_2O/MeOH (1:2) (25 mL) were refluxed for 4 h. The solvent was evaporated until dryness. Water was added and the resulting solution filtered. NH_4PF_6 was added to the aqueous phase to induce the precipitation of the complex. The solid was filtered off and washed with water and ethylic ether. The orange brown solid was dissolved in acetonitrile and precipitated by the addition of a large quantity of ethyl ether. Yield 80% IR (KBr, cm^{-1}) 1630, 1606, 841, ^1H RMN 400 MHz (CD_3CN, ppm) 8.91 (d, 1H), 8.53 (m, 5H), 8.40 (s, 1H), 8.12 (m, 3H), 8.05 (m, 3H), 8.05 (m, 6H), 7.91 (d, 2H), 7.8 (dd, 1H), 7.72 (dd, 1H), 7.56 (m, 2H), 7.48 (m, 3H), 7.35 (d, 1H), 7.26 (m, 2H), 4.80 (s, 2H), 4.51 (s, 2H), 4.29 (s, 5H). *Anal.* Calc. for $C_{42}H_{32}F_{12}FeN_6P_2Ru$: C, 47.25; H, 3.02; N, 7.87. Found: C, 46.92; H, 3.21; N, 7.54%.

3. Results and discussion

3.1. Synthesis

The ligand 5-[(*E*)-2-ferrocenylvinyl]-1,10-phenanthroline, fcvp was synthesized in two steps following the literature methods [12] for similar compounds (Scheme 1). The first step consisted in the lithiation of

Scheme 1. Synthetic route of fcvp ligand: (i) LDA, ferrocene carboxaldehyde; (ii) pyridinium *p*-toluenesulfonate; (iii) EtOH/H_2O, NH_4PF_6.

5-methyl-1,10-phenanthroline with lithium diisopropylamide with the subsequent addition of ferrocene carboxaldehyde to form 2-(1,10-phenanthrolin-5-yl)-1-ferrocenylethanol. The second step was the dehydration of the former ligand with pyridinium *p*-toluenesulfonate to obtain the desired ligand.

The ruthenium complex was synthesized by reaction with *cis*-$Ru(bpy)Cl_2$ and isolated as the hexafluorophosphate salt.

3.2. NMR

The ^1H NMR of the fcvp ligand, Fig. 1 shows a set of seven signals for the phenanthroline ring protons denoting their magnetic inequivalence. The highest displacement in chemical shift, compared to 1,10-phenanthroline, is observed for proton 4 which moves lowfield from 8.20 to 8.58 ppm (see Fig. 1 for numbering). On the other hand, proton 6 moves high field compared to 1,10-phenanthroline.

The AB system in the ethene bridge appears relatively lowfield (7.36 and 7.04 ppm) with a coupling constant, $J_{AB} = 15.4$ Hz which indicates a *trans* geometry [13] for the ligand. The inset in Fig. 1 shows the characteristic pattern of proton signals for the monosubstituted and the unsubstituted cp rings [14].

In the ^1H NMR of the $[Ru(bpy)_2fcvp]^{2+}$ overlap of the bipyridine and fcvp ligand signals are observed. The complete assignation of the ^1H NMR spectrum was made using bidimensional techniques, Fig. 2.

The ligand fcvp maintains the set of 7 signals for the phenanthroline region. The chemical shifts of these signals are quite similar than the free ligand with the sole exception of protons 7 and 1 that move high field due to the diamagnetic currents produced by the bipyridine rings in the pseudooctahedric geometry [15].

As commonly observed for heteroleptic ruthenium complexes of the $[Ru(bpy)_2LL]$ type, two sets of signals were found for the bipyridine rings.

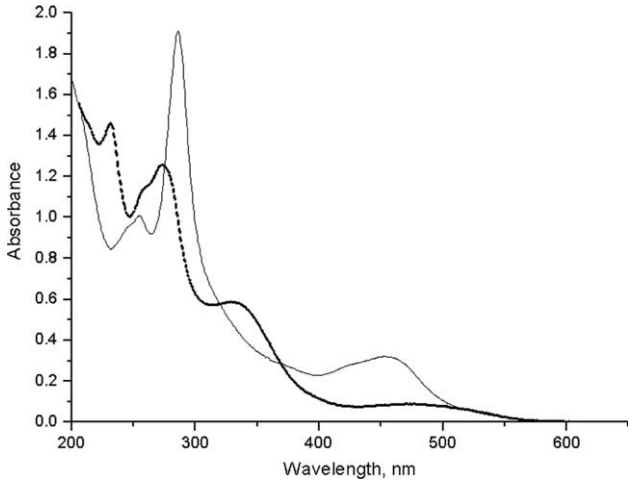

Fig. 3. UV–Vis spectra of fcvp ligand (dotted line) and $[Ru(bpy)_2(fcvp)](PF_6)_2$ complex (solid line) in acetonitrile.

3.3. Electronic spectra

The electronic spectra of the free ligand (Fig. 3) present two low energy absorption bands, which are present in most of the ferrocenyl-acceptor compounds. Barlow et al. [16] proposed a model to explain these absorptions. In this model, the lowest energy band arises from the transition between mainly non-bonding metal orbitals $(d(\pi)^6_{Fc})$ to an empty π^* orbital in the π acceptor, in this case the phenanthroline ring (π^*_{phen}). This transition differs from the reported for ferrocene, since it is more intense and displaced to the red. The second low energy transition is assigned to a transition between the highest occupied cyclopentadienyl cp, orbital and the acceptor region. Nevertheless this absorption band is probably overlapped with $\pi \rightarrow \pi^*$ phenanthroline bands.

In order to obtain information about the structure and orbital energy levels of the fcvp ligand DFT calculations[1] were performed with the GAUSSIAN [17] software package. The optimized geometries show that the phenanthroline and the ferrocenyl unit are not coplanar due to steric repulsions between the protons of the bridge and the phenanthroline ring. The eclipsed conformation of the metallocene was found to be the global minima in agreement with calculations for the ferrocene unit [18].

The LUMO (Fig. 4(b)) corresponds to the π acceptor orbital predicted by the Barlow's model while the HOMO (Fig. 4(a)) and the HOMO − 1 correspond to the metal centered non-bonding orbitals. The highest occupied cp molecular orbital was the HOMO − 6 and not the HOMO − 2 as should be expected. The energy level of this orbital is similar to π orbitals of the phenanthroline ring. This is in agreement with the possible overlap of the second ferrocene to ligand charge transfer band with $\pi \rightarrow \pi^*$ phenanthroline bands.

The visible absorption spectra of the $[Ru(bpy)_2fcvp]^{2+}$ complex (Fig. 3) on the other hand is dominated by $(d(\pi)^6) \rightarrow (d(\pi)^5(\pi)^1)$ MLCT bands characteristic of the polypyridinic ruthenium complexes. The lowest energy ferrocene to ligand charge transfer transition is also observable in the complex and appears as a shoulder on the MLCT band.

3.4. Electrochemistry

The half-wave potentials of the ligand fcvp as well its ruthenium complex are reported in Table 1.The cyclic voltammogram of the fcvp ligand shows a reversible oxidation at 0.55 V versus SCE, assigned to the ferrocenyl moiety. It is shifted to more positive potentials than the corresponding free ferrocene oxidation (0.41 V versus SCE), evidencing, therefore, that the phenanthroline region is behaving as an electron acceptor. In the complex, the reversible couple assigned to the ferrocene unit appears at almost the same potential than in the free fcvp ligand, denoting a poor interaction of the Fe and the Ru centers. Towards more positive potentials, an irreversible oxidation peak was observed at 1.37 V. This peak was assigned to the oxidation of the ruthenium center. This oxidation potential is very close to the one observed for the $[Ru(bpy)_2(phen)]^{2+}$ complex (phen = 1,10-phenanthroline). The current associated to this oxidation is, nevertheless, higher than the expected for a one-electron process, considering the ferrocene oxidation as a reference.

This behavior was observed in similar compounds [19] and could possibly be due to a intermolecular reduction of the Ru^{3+} generated by any other unoxidized ferrocene moieties attached to other surrounding complexes [20].

In order to analyze further, the degree of communication between the metal centers a mixed valence complex was generated in situ by the stoichiometric addition of a cerium salt[2] and the presence of an intervalence transfer band in it investigated. This procedure generates the mixed valence complex $[Ru^{II}(bpy)_2(fcvp^+)]^{3+}$, where ruthenium it is in a formal oxidation state 2+ while iron is in a 3+ formal oxidation state.

The UV–Vis–NIR spectra of the $[Ru(bpy)_2(fcvp)]^{2+}$ complex before and after the addition of the cerium salt it is presented in Fig. 5. The observable changes in the spectra are the bleach of the ferrocene to phenanthroline charge transfer and the merging of a low intensity band at 800 nm. Low intensity intervalence bands in ruthe-

[1] Optimized geometries were obtained using the B3LYP functional with a LANL2DZ basis set. A frequency analysis was also done, showing that all the frequencies were real and positive, indicating that an energy minimum was reached.

[2] Similar results were obtained by oxidation at controlled potential, 0.7 V, in 0.1 M TBAH acetonitrile solution.

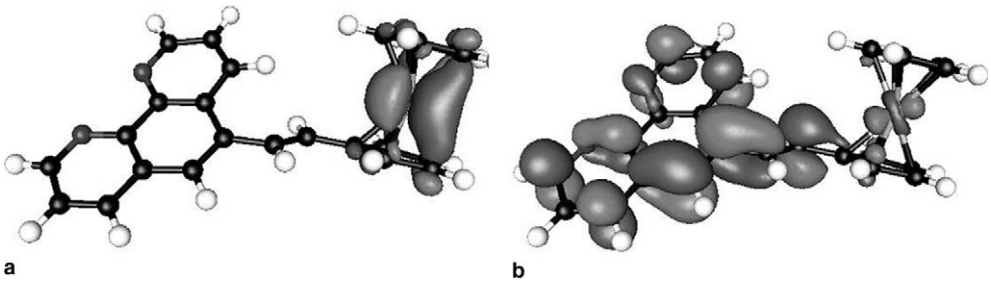

Fig. 4. HOMO (a) and LUMO (b) 0.032 a.u. isosurfaces of the fcvp ligand.

Table 1
$E_{1/2}$ potentials for fcvp ligand and its ruthenium complex in acetonitrile[a]

	$E_{1/2}$ Fc^+/Fc	$E_{1/2}$ $Ru^{III/II}$	$E_{1/2}$ $Ru^{II*/+}$
fcvp	0.55		
$[Ru(bpy)_2(fcvp)]^{2+}$	0.50	1.37	0.80[b]
$[Ru(bpy)_2(phen)]^{2+}$		1.32	0.85[b]

[a] $E_{1/2}$ values vs. the saturated calomel electrode (SCE) in 0.1 M $N(n\text{-}C_4H_9)_4PF_6/CH_3CN$ at room temperature.
[b] Calculated from the E_{00} energy obtained from fits of 77 K emission spectrum [18].

nium ferrocene mixed valence complexes have been reported [21]; nevertheless a band of these characteristics can also be assigned to the oxidized fc+ moiety. The presence of a similar band in the oxidized form of the fcvp free ligand, as well as in related ligands [22], and the general behavior of the complex described in the preceding paragraphs, supports the assignment of the 800 nm band to a transition in the oxidized fc+ moiety, and not to an intervalence transfer band. Therefore, little, if any interaction between the Ru and Fe centers is observed in the $[Ru(bpy)_2(fcvp)]^{2+}$ complex in the ground state.

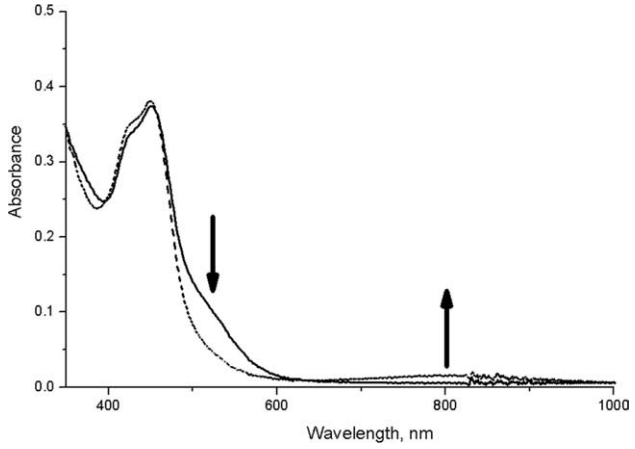

Fig. 5. Vis–NIR spectra of complex $[Ru^{II}(bpy)_2(fc^{II}vp)]^{2+}$ before (solid line) and after (dotted line) the addition of 1 equivalent of Ce^{IV} in acetonitrile.

3.5. Photophysics

In contrast with most of the polypyridinic ruthenium complexes which show photoluminescence at room temperature, no emission was observed for the complex $[Ru(bpy)_2(fcvp)](PF_6)_2$.[3]

There is evidence that in the thermal equilibrated excited state of the $[Ru(bpy)_2(phen)]^{2+}$ complex the electron resides in one of the bipyridine ligands [24]. It can be expected that in the $[Ru(bpy)_2(fcvp)]^{2+}$ complex the bipyridine ligands remain as the acceptor ligand.

It is well know that ferrocene is an effective quencher of the excited triplet state in ruthenium complexes [23].

The absence of emission therefore can be attributed to an intramolecular excited state electron transfer process between ferrocene and ruthenium III which is the formal oxidation state of this metal in the excited state.

Therefore, after excitation an electron from the ruthenium center should be transferred to a bipyridine ligand. The MLCT emissive excited state is then reductively quenched by an electron transfer from the ferrocene moiety to the ruthenium center

$$[Ru^{III}(bpy^-)(bpy)(fcvp^{II})]^* \rightarrow [Ru^{II}(bpy^-)(bpy)(fcvp^{III})]^* (\Delta G^0 \approx -0.3\ \text{eV}) \quad (1)$$

The driving force for this process, Eq. (1), was estimated according to the literature methods [8] from the oxidation potentials of the metal centers and the free energy stored in the excited state, which was assumed to be equal to the parent complex $[Ru(bpy)_2(phen)]^{2+}$. Although the electron transfer process is thermodynamically allowed, and is the most probably quenching route, an energy transfer mechanism for the quenching of the photoluminescence cannot be completely ruled out.

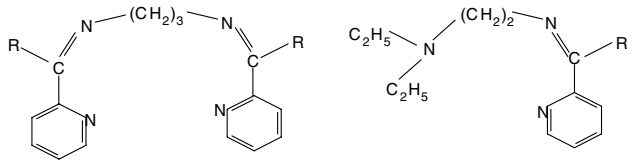
[3] During the photoluminescence experiments some emission was observed but it was assigned to traces of $[Ru(bpy)_3]^{2+}$ complex due to the very low quantum yields and similar lifetimes.

4. Conclusions

The synthesis of a new ferrocenyl donor ligand was achieved in relative good yield. The donor ability of the ferrocene unit was observed by the presence of ferrocene to ligand charge transfer bands.

The bis bypyridine ruthenium complex synthesized with this ligand shows little, if any, interaction between the metal centers in the ground state. The electrochemical results and the properties of the mixed valence complex are in agreement with this behavior.

Nevertheless, the absence of the characteristic emission of Ru-polypyridinic complexes in $[Ru(bpy)_2(fcvp)]^{2+}$ manifests an interaction in the excited state, probably through an electron transfer process. Further photophysical studies are needed to confirm these hypotheses.



From the solar energy conversion point of view this process could be helpful to achieve a long distance charge separation in the excited state, and therefore avoiding undesired recombination processes.

Acknowledgments

We gratefully acknowledge Professor Gerald Meyer (Johns Hopkins University) for useful discussions and comments. This work was supported by CONICYT (doctoral thesis support grant to A.D.), FONDECYT Lineas Complementarias 890007, and FONDECYT 1020517.

different oxidation states. We have successfully isolated six cobalt(II) and six cobalt(III) mononuclear complexes of the types $[Co(L^1)(X)_2]$ (**1a**–**1f**) and $[Co(L^2)(X)_3]$ (**2a**–**2f**) [L^1 = *N*,*N*′-(bis(pyridin-2-yl)formylidene)propane-1,3-diamine (pfpd) or *N*,*N*′-(bis(pyridin-2-yl)benzylidene)propane-1,3-diamine (pbpd); L^2 = (*N*,*N*-diethyl, *N*′-(pyridin-2-yl)formylidene)ethane-1,2-diamine (pfed) or (*N*,*N*-diethyl,*N*′-(pyridin-2-yl)benzylidene)ethane-1,2-diamine (pbed), Scheme 1; X = N_3^-, NCS^- or NCO^-] using one-pot reactions of cobalt(II) salt, L and pseudohalide in 1:1:2 and 1:1:3 molar ratios, respectively, at room temperature in methanol–water solvent mixtures. All the complexes are characterized using microanalytical, spectroscopic, magnetic, electrochemical and other physicochemical results. In two representative cases, $[Co(pfpd)(NCS)_2]$ (**1c**) and $[Co(pbed)(N_3)_3]$ (**2b**), crystal structures have been solved by X-ray diffraction measurements to define the coordination spheres. This paper has addressed the details of syntheses, structures and properties of these new complexes and focused on the stabilization of metal oxidation levels through judicious choice of Schiff base-pseudohalide combinations.

2. Experimental

2.1. Materials

High purity 2-benzoylpyridine (Lancaster, UK), pyridine-2-carboxaldehyde (Lancaster, UK), *N*,*N*-diethylethane-1,2-diamine (SRL, India), propane-1,2-diamine (SRL, India), cobalt nitrate hexahydrate (E. Merck, India), sodium azide (E. Merck, India), ammonium thiocyanate (E. Merck, India), and sodium cyanate (Lancaster, UK) were used as received. Cobalt perchlorate hexahydrate was prepared on treatment of cobalt carbonate (E. Merck, India) with perchloric acid (E. Merck) followed by slow evaporation on a steam bath, filtration through a fine glass-frit and preservation in a desiccator containing concentrated sulphuric acid (E. Merck, India) for subsequent use. Purification of MeCN and preparation of supporting electrolyte ($[Et_4N][ClO_4]$) for electrochemical work were executed following reported method [14]. All other chemicals were of analytical grade and were used without further purification.

Caution! Perchlorate and azide compounds of metal ions are potentially explosive especially in presence of organic ligands. Only a small amount of the materials should be prepared and handled with care.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a Jasco FT-IR Model 420 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry MeCN was used as solvent. Room-temperature magnetic susceptibilities of powder samples were done on a PAR 155 vibrating sample magnetometer, with $Hg[Co(SCN)_4]$ as the reference. Diamagnetic corrections were made using Pascal's constants. Ground state absorption and steady-state fluorescence measurements were made with a Jasco Model V-530 UV–Vis spectrophotometer and Hitachi Model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, Model 199; hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photomultiplier tube were, respectively, used as the excitation source and for the fluorescence detection. Electrochemical measurements (cyclic voltammetry, CV) were made with a computer controlled EG&G PARC VersaStat Model 270 electrochemical instrument using a platinum disk working electrode as described elsewhere [15]. The solution was IR-compensated and the results were collected at 298 K. The following parameters and relations were used: scan rate (v), 50 mV s^{-1}; formal potential $E^\circ = 0.5(E_{pa} + E_{pc})$ where E_{pa} and E_{pc} are anodic and cathodic peak potentials, respectively; ΔE_p is the peak-to-peak separation. The potentials are referenced to a saturated calomel electrode (SCE) and are uncorrected for junction contributions.

2.3. Preparation of Schiff bases

The Schiff bases pfpd, pbpd, pfed and pbed were prepared following a reported [11a] procedure with a little modification.

2.3.1. *N,N′-(bis(pyridin-2-yl)formylidene)-propane-1,3-diamine (pfpd) and N,N′-(bis(pyridin-2-yl)-benzylidene)propane-1,3-diamine (pbpd)*

Propane-1,3-diamine (0.074 g, 1 mmol) and pyridine-2-carboxaldehyde (0.214 g, 2 mmol) were mixed together and refluxed in dehydrated alcohol (25 cm^3) for 10 h. The yellow solution that resulted was concentrated on

a steam-bath and dried in vacuo over $CaCl_2$ to a yellow solid. Yield: 0.176 g (70%). pbpd was prepared (yield, 74%) using similar procedure except that 2-bezoylpyridine instead of pyridine-2-caboxaldehyde was used. *Anal*. Calc. for $C_{15}H_{16}N_4$ (pfpd): C, 71.4; H, 6.4; N, 22.2. Found: C, 72.0; H, 6.7; N, 22.5%. IR (KBr disc, cm^{-1}): ν(C=N) 1594. UV–Vis (MeCN): λ_{max}, 260 and 392 nm. Found: C, 80.4; H, 5.8; N, 14.2%. *Anal*. Calc. $C_{27}H_{24}N_4$ (pbpd): C, 80.2; H, 6.0; N, 13.9%. IR (KBr disc, cm^{-1}): ν(C=N) 1595. UV–Vis (MeCN): λ_{max}, 260 and 390 nm.

2.3.2. (N,N-diethyl,N′-(pyridin-2-yl)formylidene)-ethane-1,2-diamine (pfed) and (N,N-diethyl,N′-(pyridin-2-yl)benzylidene)-ethane-1,2-diamine (pbed)

The procedure is similar to the synthesis of pfpd/pbpd except that the reaction time is longer. *N*,*N*-diethylethane-1,2-diamine (0.116 g, 1 mmol) and pyridine-2-carboxaldehyde (0.107 g, 1 mmol) were refluxed in dehydrated alcohol (30 cm^3) for 12 h. The yellow solution was processed as above in case of pfpd to yield a semisolid, which was stored in vacuo over $CaCl_2$ for subsequent use. Yield: 0.153 g (75%). Pbed was prepared (yield, 78%) similarly using 2-benzoylpyridine instead of pyridine-2-carboxaldehyde. *Anal*. Calc. for $C_{12}H_{19}N_3$ (pfed): C, 70.2; H, 9.3; N, 20.4. Found: C, 70.4; H, 9.0; N, 20.7%. IR (KBr disc, cm^{-1}): ν(C=N) 1592. UV–Vis (MeCN): λ_{max}, 242 and 370 nm. Found: C, 76.3; H, 8.4; N, 14.6%. *Anal*. Calc. $C_{18}H_{23}N_3$ (pbed): C, 76.8; H, 8.3; N, 14.9%. IR (KBr disc, cm^{-1}): ν(C=N) 1590. UV–Vis (MeCN): λ_{max}, 245 and 372 nm.

2.4. Preparation of the complexes

Mononuclear type 1 complexes were prepared from both nitrate and perchlorate salts of cobalt(II) using 1:1:2 mole ratio of the metal salts, tetradentate blockers (pfpd and pbpd) and pseudohalides (azide, thiocyanate and cyanate). Type 2 compounds were isolated using a 1:1:3 ratio of the cobalt(II) salts, tridentate Schiff bases (pfed and pbed) and the pseudohalides. The typical syntheses with perchlorate salt are described below.

2.4.1. [Co(pfpd)$(N_3)_2$] (**1a**) and [Co(pbpd)$(N_3)_2$] (**1b**)

A methanolic solution (5 cm^3) of faint yellow pfpd (0.126 g, 1 mmol) was added dropwise to a pink Co$(ClO_4)_2 \cdot 6H_2O$ (0.183 g, 1 mmol) solution (5 cm^3) in the same solvent. To this NaN_3 (0.065 g, 2 mmol) in water (5 cm^3) was added slowly. The final red solution was filtered and left for slow evaporation in air at room temperature. After 3–4 days fine red microcrystalline product of **1a** separated out, which was filtered, washed with methanol and dried in vacuo over $CaCl_2$. Yield: 0.138 g (70%). Compound **1b** was prepared (yield, 72%) similarly except that pbpd instead of pfpd was used. *Anal*. Calc. for $C_{15}H_{16}N_{10}Co$ (**1a**): C, 45.58; H, 4.08; N, 35.43. Found: C, 45.72; H, 4.02; N, 35.65%. *Anal*. Calc. for $C_{27}H_{24}N_{10}Co$ (**1b**): C, 59.23; H, 4.42; N, 25.58. Found: C, 59.42; H, 4.45; N, 25.82%.

2.4.2. [Co(pfpd)$(NCS)_2$] (**1c**) and [Co(pbpd)$(NCS)_2$] (**1d**)

These were prepared (yield, 70–75%) using the same reaction condition and reaction stoichiometry as described in **1a/1b** except that NH_4NCS (2 mmol) in water (5 cm^3) instead of NaN_3 was added. The reaction solution was processed as above to result in crystalline **1c/1d**. *Anal*. Calc. for $C_{17}H_{16}N_6S_2Co$ (**1c**): C, 47.77; H, 3.77; N, 19.66. Found: C, 47.68; H, 4.72; N, 19.18%. *Anal*. Calc. for $C_{29}H_{24}N_6S_2Co$ (**1d**): C, 60.09; H, 4.17; N, 14.49. Found: C, 60.35; H, 4.22; N, 14.28.%.

2.4.3. [Co(pfpd)$(NCO)_2$] (**1e**) and [Co(pbpd)$(NCO)_2$] (**1f**)

These were also prepared (yield, 70–75%) using the same procedure as described in **1a/1b** except that NaNCO (2 mmol) in water (5 cm^3) instead of NaN_3 was added. *Anal*. Calc. for $C_{17}H_{16}N_6O_2Co$ (**1e**): C, 51.65; H, 4.08; N, 21.26. Found: C, 51.68; H, 4.10; N, 21.23%. *Anal*. Calc. for $C_{29}H_{24}N_6O_2Co$ (**1f**): C, 63.62; H, 4.42; N, 15.35. Found: C, 63.65; H, 4.40; N, 15.38%.

2.4.4. [Co(pfed)$(N_3)_3$] (**2a**) and [Co(pbed)$(N_3)_3$] (**2b**)

To a methanolic solution (5 cm^3) of Co$(ClO_4)_2 \cdot 6H_2O$ (0.183 g, 1 mmol) were added pfed (0.103 g, 1 mmol) in the same solvent (5 cm^3) and NaN_3 (0.098 g, 3 mmol) in water (5 cm^3). The deep wine red solution was filtered and was kept for slow evaporation. After 7 days **2a** was separated, washed with methanol and dried in vacuo over $CaCl_2$. Yield: 0.146 g (75%). Compound **2b** was prepared (yield, 72%) using a similar procedure as described above except that pbed instead of pfed was used. *Anal*. Calc. for $C_{12}H_{19}N_{12}Co$ (**2a**): C, 36.93; H, 4.91; N, 43.06. Found: C, 36.76; H, 3.84; N, 43.24%. *Anal*. Calc. for $C_{18}H_{23}N_{12}Co$ (**2b**): C, 46.35; H, 4.97; N, 36.04. Found: C, 46.27; H, 4.89; N, 36.22%.

2.4.5. [Co(pfed)$(NCS)_3$] (**2c**) and [Co(pbed)$(NCS)_3$] (**2d**)

These were prepared (yield, 70–72%) using the same reaction condition and reaction stoichiometry as described in **2a/2b** except that NH_4NCS (3 mmol) in water (5 cm^3) instead of NaN_3 was added. The reaction solution was processed as above to result in crystalline **2c/2d**. *Anal*. Calc. for $C_{15}H_{19}N_{12}S_3Co$ (**2c**): C, 34.48; H, 3.66; N, 32.17. Found: C, 34.60; H, 3.58; N, 32.10%. *Anal*. Calc. for $C_{21}H_{23}N_{12}S_3Co$ (**2d**): C, 42.13; H, 3.87; N, 28.08. Found: C, 42.25; H, 3.76; N, 28.25%.

2.4.6. [Co(pfed)(NCO)$_3$] (2e) and [Co(pbed)(NCO)$_3$] (**2f**)

These were also prepared (yield, 70–74%) using the same procedure as described in **2a**/**2b** except that NaNCO (3 mmol) in water (5 cm^3) instead of NaN_3 was added. *Anal*. Calc. for $C_{15}H_{19}N_{12}O_3Co$ (**2e**): C, 37.98; H, 4.04; N, 35.44. Found: C, 37.66; H, 4.07; N, 35.53%. *Anal*. Calc. for $C_{21}H_{23}N_{12}O_3Co$ (**2f**): C, 45.82; H, 4.21; N, 30.54. Found: C, 45.85; H, 4.01; N, 30.71%.

2.5. X-ray crystallographic analysis

Red single crystals of **1c** and dark brown crystals of **2b** suitable for X-ray analyses were obtained by slow evaporation of MeOH–H_2O (2:1) solutions of the reaction mixtures at room temperature (298 K). Diffraction data were measured at 293(2) K on a Siemens SMART CCD diffractometer equipped with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation. The unit cell parameters were determined by least-squares method using all observed reflections. A summary of the crystallographic data and structure refinement parameters is given in Table 1. Of 12050 and 13562 collected reflections, 4378 and 4956 unique reflections were recorded using ω-scan technique for **1c** and **2b**, respectively. The intensity data were corrected for Lorentzian polarization effects and an empirical absorption correction based on ψ scans was employed [16]. The structures were solved by the heavy atom method using SHELXS-97 [17] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using a riding model. In the final difference Fourier map the residual maxima and minima for **1c** and **2b** were 0.268 and −0.241 and 0.501 and −0.346 e Å^{-3}, respectively. All calculations were carried out using SHELXL-97 [18].

3. Results and discussion

3.1. Synthesis and formulation

The hexacoordinated mononuclear complex [Co(pfpd)(NCS)$_2$] (**1c**) was initially formed in aqueous methanolic solution containing a 1:1:1 mixture of $Co(ClO_4)_2 \cdot 6H_2O$, pfpd and NH_4NCS – a reactant ratio expected to yield a dithiocyanato bridged dinuclear species of the composition $[(pfpd)Co^{II}(NCS)_2Co^{II}(pfpd)](ClO_4)_2$. However, microanalyses showed a 1:1:2 ratio of metal, blocking ligand and pseudohalide, and in the IR spectrum, no presence of perchlorate bands was noticed. Reactant ratio corresponding to the product stoichiometry afforded better yield of **1c**. An effort to get dinuclear

species, in which the starting material was changed to $Co(NO_3)_2 \cdot 6H_2O$, and a 1:1:1 molar ratio of the nitrate salt, ligand and pseudohalide followed by addition of extraneous KPF_6 (2 equivalent) produced **1c** with lower yield. Use of a 1:1:2 molar ratio of nitrate salt, Schiff base and azide results in **1c** in good yield. The different syntheses are reproducible. Change of ligands from pfpd to pbpd and the pseudohalides from NCS^- to N_3^- and NCO^- showed similar behaviour and compounds $[Co(pfpd)(N_3)_2]$ (**1a**), $[Co(pbpd)(N_3)_2]$ (**1b**), $[Co(pbpd)(NCS)_2]$ (**1d**), $[Co(pfpd)(NCO)_2]$ (**1e**) and $[Co(pbpd)(NCO)_2]$ (**1f**) were isolated. Changing the tetradentate Schiff bases (L^1 = pfpd or pbpd) to tridentate Schiff bases (L^2 = pfed or pbed) and use of metal perchlorate, organic ligand and pseudohalide in 1:1:1.5 molar ratio – a reactant ratio expected to yield a triazido bridged dinuclear species of the composition $[(L^2)Co^{III}(N_3)_3Co^{III}(L^2)]ClO_4$, resulted mononuclear complexes of the type $[Co(L^2)(X)_3]$ (L = pfed, $X = N_3^-$, **2a**; NCS^-, **2b**; NCO^-, **2c**; L = pbed, $X = N_3^-$, **2d**; NCS^-, **2e**; NCO^-, **2f**). Microanalyses showed a 1:1:3 ratio of metal, blocking ligand and pseudohalide, and once again in the IR spectrum, no presence of perchlorate bands was noticed. Use of required molar ratios of the building units corresponding to formulation of the product afforded better yields of **2**. With a view to getting tribridged dinuclear species, the starting material was changed to $Co(NO_3)_2 \cdot 6H_2O$, and a 1:1:1.5 molar ratio of the nitrate salt, ligand and pseudohalide followed by addition of extraneous KPF_6 (1 equivalent). This also produced **2** but in lower yield. Use of a 1:1:3 molar ratio of nitrate salt, Schiff base and azide results in **2** in good yield. Once again all these syntheses are reproducible.

The complexes **1** and **2** are sufficiently stable in air and in the presence of moisture. Analytical data for all the complexes are consistent with the calculated values. The compounds are soluble in a range of common organic solvents like methanol, acetonitrile, dimethylformamide and dimethylsulphoxide but are insoluble in water. In MeCN they behave as non-electrolytes as are indicated [19] by their very low Λ_M ($\sim$5 Ω^{-1} cm^2 mol^{-1}) values. Room-temperature solid-phase magnetic susceptibility measurements show that type **1** complexes behave as three-electron paramagnets with μ_{eff} value $\sim$3.9 BM whereas type **2** compounds are diamagnetic (singlet ground state with t_{2g}^6 configuration) (Table 2). In the IR spectra, the most striking observation in type **1** complexes is a sharp, single, intense band of the pseudohalides. Compounds **1a** and **1b** show the asymmetric stretch as a strong band at about 2030 cm^{-1}. Compounds **1c** and **1d** exhibit ν_{as}(CN) stretching vibration at about 2100 cm^{-1}. The position of the signal strongly suggests N-coordination of bound isothiocyanate [10]. Compounds **1e** and **1f** display asymmetric cyanate stretching vibration at about 2050 cm^{-1} which is substantially higher than the free ion value [20] and is consistent [21] with N-bonding rather O-bonding. The single band in each case is in line with the presence of *trans*-CoX_2 ($X = N_3^-$, NCS^-, NCO^-) frame in $[Co(L^1)(X)_2]$. Three distinct splittings (vide Table 2) of asymmetric stretching vibrations of the terminal pseudohalides in type **2** compounds are strongly suggestive of the less symmetric *meridional* structure over the more symmetric *facial* arrangement. The ν(C=N) stretching vibrations of the metal bound Schiff bases are seen at around 1590 cm^{-1}. Several bands in the range 2800–3000 cm^{-1} are assigned to the aliphatic ν(CH) stretching vibration of ligand. All other characteristic L vibrations are seen in the 1600–600 cm^{-1} range. X-ray structures of **1c** and **2b** show definite proof of this hypothesis.

The complexes exhibit several absorption bands in MeCN solutions in the 200–900 nm range. The high

intensity band below 400 nm is of ligand origin assignable [11b] to intraligand n–π*/π–π* transition. Above this wavelength the transitions are LMCT for cobalt(III) complexes and MLCT type for cobalt(II) members as are evident from their intensity values (Table 2). The bands show systematic blue shift in going from type **1** to type **2** complexes. The spectral pattern supports [22] six-coordinate distorted octahedral symmetry around cobalt centre.

3.2. X-ray crystal structures

3.2.1. Crystal structure of [Co(pfpd)(NCS)$_2$] (**1c**)

An ORTEP view with atom numbering scheme of the mononuclear dithiocyanato complex, **1c**, is shown in Fig. 1. Selected bond lengths and angles relevant to the coordination sphere are listed in Table 3. The cobalt(II) centre is best described as a distorted octahedron with a CoN_6 chromophore. Distortion from the ideal octahedral geometry is due to the asymmetric nature of the bound tetradentate Schiff base and the deviations of the refine angles (90°/180°) formed at the metal centre (Table 3). The coordination includes two pyridine nitrogens [N(3), N(6)], two imine nitrogens [N(4), N(5)] of the Schiff base and two nitrogens [N(1), N(2)] of the terminal thiocyanates. The equatorial positions are occupied with the four nitrogen atoms [N(3), N(4), N(5) and N(6)] of the tetradentate ligand while the nitrogens [N(1), N(2)] of the isothiocyanato groups are placed at the axial positions. The degrees of distortion of the coordination sphere are reflected in the *cisoid* [77.11(7)–113.07(7)°] and the *transoid* angles [169.47(7)–174.59(7)°]. The equatorial Co–N distances are in the range [2.0982(17)–2.1695(18) Å], comparable to the corresponding values in similar systems [1–3]. Axial

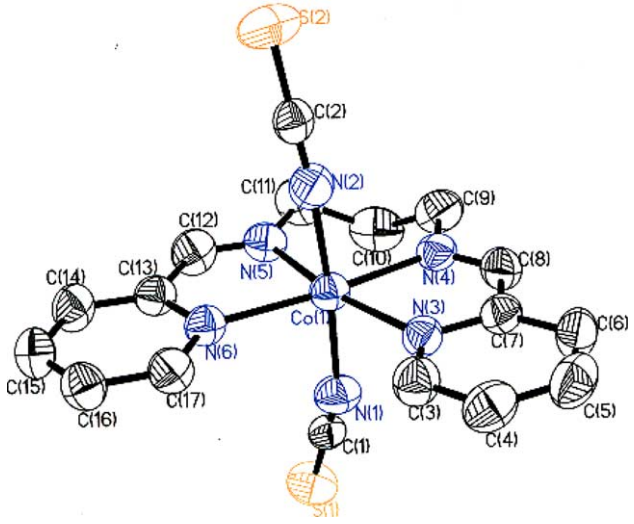

Fig. 1. ORTEP view of [Co(pfpd)(NCS)$_2$] (**1c**) with atom numbering scheme and 40% probability ellipsoids for all non-hydrogen atoms.

Table 3
Selected bond lengths (Å) and bond angles (°) for [Co(pfpd)(NCS)$_2$] (**1c**)

Bond distances (Å)	
Co(1)–N(2)	2.0813(18)
Co(1)–N(1)	2.0844(19)
Co(1)–N(4)	2.0982(17)
Co(1)–N(5)	2.1061(18)
Co(1)–N(6)	2.1591(17)
Co(1)–N(3)	2.1695(18)
S(1)–C(1)	1.621(2)
S(2)–C(2)	1.618(2)
N(1)–C(1)	1.160(1)
N(2)–C(2)	1.152(2)
Bond angles (°)	
N(2)–Co(1)–N(1)	174.59(7)
N(2)–Co(1)–N(4)	93.73(7)
N(1)–Co(1)–N(4)	91.64(7)
N(2)–Co(1)–N(5)	89.91(7)
N(1)–Co(1)–N(5)	90.54(7)
N(4)–Co(1)–N(5)	92.45(8)
N(2)–Co(1)–N(6)	87.27(7)
N(1)–Co(1)–N(6)	87.56(7)
N(4)–Co(1)–N(6)	169.80(8)
N(5)–Co(1)–N(6)	77.40(7)
N(2)–Co(1)–N(3)	89.49(7)
N(1)–Co(1)–N(3)	91.05(7)
N(4)–Co(1)–N(3)	77.11(7)
N(5)–Co(1)–N(3)	169.47(7)
N(6)–Co(1)–N(3)	113.07(7)
C(1)–N(1)–Co(1)	156.96(19)
C(2)–N(2)–Co(1)	170.25(19)
N(1)–C(1)–S(1)	178.7(2)
N(2)–C(2)–S(2)	178.7(2)

Co–N distances [2.0813(18)–2.0844(19) Å] indicate stronger coordination of the anionic isothiocyanate over neutral Schiff base. The *trans* N1–Co1–N2 angle has a value [174.59(7)°] close to the ideal 180.00°. The angles N(6)–Co(1)–N(5), N(5)–Co(1)–N(4) and N(4)–Co(1)–N(3) in the equatorial plane have values 77.40(7)°, 92.45(8)° and 77.11(7)°, respectively, which are much less than the N(3)–Co(1)–N(6) angle [113.07(7)°] where N(3) and N(6) belong to the two ends of the tetradentate Schiff base. Both isothiocyanates are almost linear with the same N–C–S angle 178.7(2)°. N–C [1.152(2)–1.160(2) Å] and C–S [1.618(2)–1.621(2) Å] bond lengths are as expected for N-coordination [12]. The bond lengths and angles pertaining the ligand network are close to expected values [9–11]. The propylenic part [N(5)–C(11)–C(10)–C(9)–N(4)] of the Schiff base is to some extent puckered. The sequestering of cobalt(II) by four hard N donor centres of the tetradentate chelator (pfpd) imparts hardness to the metal centre even in low oxidation state; this influences preferential N-coordination of both the terminal NCS^- ions through electronegative hard N donor centres (Fig. 1) ignoring the other possibilities, viz., both S-coordination and N- plus S-coordinations.

3.2.2. Crystal structure of [Co(pbed)(N_3)$_3$] (**2b**)

An ORTEP diagram of the mononuclear triazido compound **2b**, is displayed in Fig. 2. Selected bond lengths and angles pertaining to the coordination sphere are set in Table 4. The cobalt(III) centre adopts a distorted octahedral coordination sphere with a CoN_6 chromophore. Three nitrogen atoms [N(10), N(11), N(12)] of the tridentate Schiff base in combination with three nitrogen atoms [N(1), N(4), N(7)] of three different azides in a *meridional* alignment complete octahedral coordination of the metal ion. The equatorial positions are occupied by the three nitrogen atoms [N(10), N(11), N(12)] of the tridentate blocker and one nitrogen atom [N(4)] of the terminal azide while other two nitrogen atoms [N(1), N(7)] of the two azides are placed at the axial positions. Distortion from the ideal octahedral geometry is due to the asymmetric nature of the bound tridentate Schiff base and the deviations of the refine angles (90°/180°) formed at the metal centre (Table 4). The degrees of distortion from an ideal octahedral (90°) geometry are reflected in the *cisoid* [87.64(8)–96.69(8)°] and the *transoid* [167.90(7)–177.26(8)°] angles. Azide Co–N distances [1.9451(19)–1.9801(18) Å] indicate stronger coordination of the anionic terminals over those [1.8858(17)–2.0544(18) Å] of neutral Schiff base chelator. The azide terminals are almost linear with N–N–N angles 175.6(2)–177.7(2)°. N(1)–N(2) [1.185(2) Å], N(4)–N(5) [1.198(2) Å] and N(7)–N(8) [1.198(2) Å] distances are longer than the N(2)–N(3) [1.158(2) Å], N(5)–N(6) [1.150(3) Å] and N(8)–N(9) [1.160(2) Å] in usual manner [9–11] reflecting N(1), N(4) and N(7) connection of the pseudohalides. The ethylenic part [N(11)–C(13)–C(14)–N(10)] of the Schiff base is also to some extent puckered (Fig. 2) which has significant effect on variation of equatorial angles.

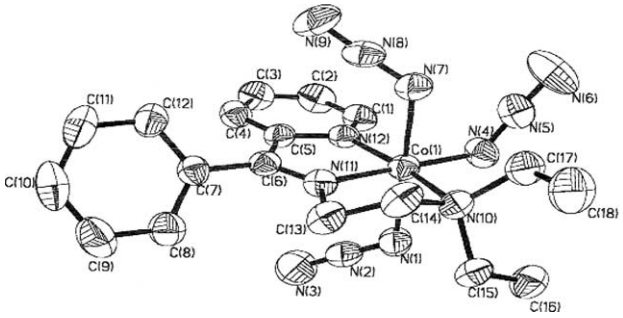

Fig. 2. ORTEP plot of [Co(pbed)(N_3)$_3$] (**2b**) with atom numbering scheme and 40% probability ellipsoids for all non-hydrogen atoms.

N(9)–N(8)–N(7)	177.7(2)

3.3. Electrochemical properties

The electroactivity of the complexes was examined in MeCN solutions using cyclic voltammetry (CV) at a platinum-working electrode. A representative voltammogram is shown in Fig. 3. The complexes show (Table 2) nearly reversible (ΔE_p = 70–90 mV) oxidative response (for type **1**) and reductive response (for type **2**) presumably due to Co^{III}–Co^{II} couple as is shown in the following reactions:

$$[Co^{III}(L^1)(X)_2]^{1+} + e^- \rightleftharpoons [Co^{II}(L^1)(X)_2] \quad (1)$$

$$[Co^{III}(L^2)(X)_3] + e^- \rightleftharpoons [Co^{II}(L^2)(X)_3]^{1-} \quad (2)$$

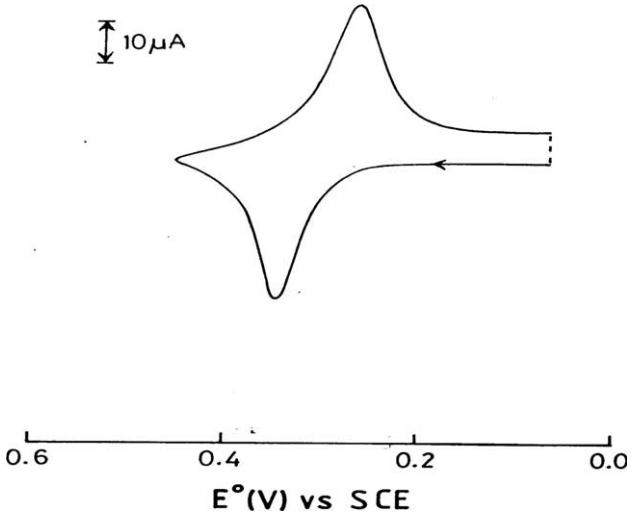

Fig. 3. Cyclic voltammogram of **2b** in MeCN at 298 K.

Table 5
Photophysical data for **1c** and **2b**

Compound	Emission (λ/nm)		Lifetime (ns)
	Fluorescence[a]	Phosphorescence[b]	
1c	478	550	2.33
2b	476	548	2.42

[a] In MeOH at room temperature (298 K).
[b] In MeOH at 77 K.

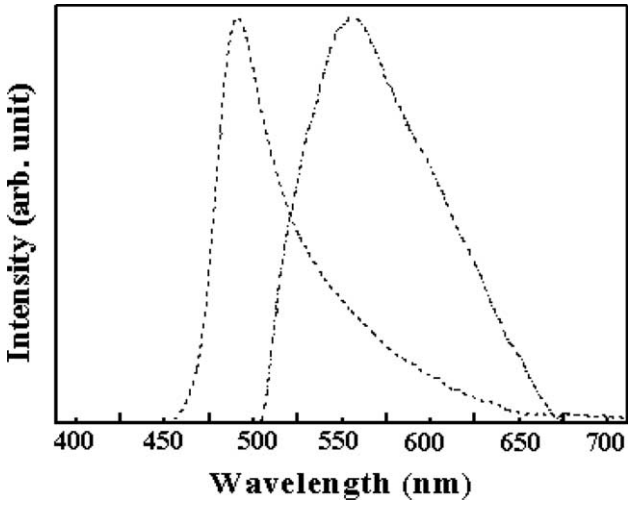

Fig. 4. Fluorescence (- - - - - -) in MeOH solution at 298 K, phosphorescence (·—·—·) in MeOH glass at 77 K of **1c**.

The responses are reproducible with no trace of decomposition after a number of cycles. The formal potentials lie close to ~0.3 V versus SCE. One-electron nature of the couple was verified with cobalt(II)azido complexes of arylazoimidazole ligands [23].

3.4. Luminescence properties

The spectroscopic data of selected complexes in methanol solutions and glasses are listed in Table 5. Compound **1c** shows emission at 478 nm while compound **2b** has a band at 476 nm at 298 K. These are assignable to intraligand $^1(\pi–\pi^*)$ fluorescence. A representative pattern is shown in Fig. 4. The lifetimes for **1c** and **2b** are 2.33 and 2.42 ns, respectively. In glassy solutions (77 K) a red shift is observable (550 nm for **1c** and 548 nm for **2b**) which is presumably due to $^3(\pi–\pi^*)$ phosphorescence [10].

4. Conclusion

We have prepared two different sets of cobalt(II) and cobalt(III) pseudohalide complexes by changing denticities of the Schiff base blockers. Structures of two representative complexes, $[Co(pfpd)(NCS)_2]$ (**1c**) and $[Co(pbed)(N_3)_3]$ (**2b**), are solved by X-ray study. Spectroscopic, electrochemical and other physicochemical properties strongly suggest that the structures **1a**, **1b** and **1d**–**1f** are cognate with **1c**, whereas **2a** and **2c**–**2f** with **2b**. The neutral tetradentate Schiff bases in combination with two monodentate pseudohalide ions satisfy hexacoordination of cobalt(II) as well as its charge; such a combination simultaneously satisfying both coordination number and charge of central ion results in stabilization of +2 oxidation state of the central. Similarly, judicious choice of one tridentate neutral Schiff base ligand and three pseudohalide ions satisfies hexacoordination of the central ion and its +3 oxidation level. This work shows that control of oxidation state of metal ion can be done through judicious choice of ligand matrices so as to satisfy coordination number and charge of metal ions simultaneously. The new complexes are good examples of luminous materials.

5. Supplementary data

Crystallographic data for the structure analysis have been deposited with the Cambridge Crystallographic Data Centre Nos. 210735 for $[Co(pfpd)(NCS)_2]$ (**1c**) and 240924 for $[Co(pbed)(N_3)_3]$ (**2b**). Copies of this information can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Based on the previous considerations, we are initiating a line of investigation on the coordination chemistry of compounds containing thiazine and 2-aminobenzimidazole rings. In this paper, we report the characterization by elemental analysis, infrared spectra (IR), ultraviolet and visible spectra (UV–Vis), single crystal X-ray diffraction, proton nuclear magnetic resonance (^{1}H NMR) and carbon nuclear magnetic resonance (^{13}C NMR) of *N*-(5,6-dihydro-4H-1,3-thiazin-2-yl)-2-aminobenzimidazole (BzTz). Contrary to what we had thought, the ligand BzTz acts as monodentate through nitrogen atom of benzimidazole ring, the thiazine ring being uncoordinated. Thus, the Cd(II) and Co(II) complexes have been isolated and their characterization has been carried out by means of elemental analysis, IR and X-ray diffraction. The cobalt complex has also been characterized through UV–Vis-NIR diffuse reflectance and magnetic susceptibility measurement, and whereas, in the case of the cadmium complex, through proton nuclear magnetic resonance (^{1}H NMR), carbon nuclear magnetic resonance (^{13}C NMR) and ultraviolet and visible spectra (UV–Vis).

2. Experimental

2.1. Preparation of N-(5,6-dihydro-4H-1,3-thiazin-2-yl)-2-aminobenzimidazole (BzTz)

BzTz was prepared according to the procedure reported by Haugwitz et al. [18]. The resulting oil was flash chromatographed using 2:1 v/v glyme/ether as eluent. Last fraction contained BzTz. The product was recrystallized from glyme. ^{1}H NMR ($CDCl_3$): δ 7.74 (d, J = 8.1 Hz, 1H), 7.34 (d, J = 7.9 Hz, 1H), 7.14 (t, J = 7.6 Hz, 1H), 7.01 (t, J = 7.7 Hz, 1H), 6.45 (s, 2H), 3.90 (t, J = 5.5 Hz, 2H), 3.22 (t, J = 6.0 Hz, 2H), 1.98 (m, 2H); ^{13}C NMR ($CDCl_3$): δ 153.3, 147.9, 142.0, 131.0, 122.8, 119.5, 116.2, 112.2, 46.5, 26.9, 19.1. *Anal.* Calc. for $C_{11}H_{12}N_4S$: C, 56.87; H, 5.21; N, 24.12; S, 13.80. Found: C, 56.72; H, 5.24; N, 23.83; S, 14.05%. UV–Vis (EtOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 211 (22 693), 242 (21 171), 280 (7034).

2.2. Preparation of [$CoCl_2$(BzTz)$_2$]

This complex was prepared by reacting a methanol solution (1 mL) of $CoCl_2 \cdot 6H_2O$ (102.4 mg, 0.43 mmol) with a methanol solution (15 mL) of BzTz (100 mg, 0.43 mmol), obtaining blue powder which was dissolved in chloroform and by means of liquid-vapour diffusion of ether over this chloroform solution, blue crystals were isolated (110.5 mg, 43.2%). The crystals were filtrated and washed with cold ether and air-dried. *Anal.* Calc. for $C_{22}H_{24}CoN_8S_2Cl_2$: C, 44.45; H, 4.07; N, 18.85; S, 10.79. Found: C, 44.15; H, 4.11; N, 18.65; S, 10.59%.

2.3. Preparation of [$CdCl_2$(BzTz)$_2$]

This complex was prepared by reacting a methanol solution (1 mL) of $CdCl_2 \cdot 2.5H_2O$ (98.3 mg, 0.43 mmol) with a methanol solution (15 mL) of BzTz (100 mg, 0.43 mmol), being obtained colourless crystals after a slow evaporation of the solution at room temperature (125.0 mg, 44.9%). The crystals were filtrated and washed with cold ether and air-dried. ^{1}H NMR ($CDCl_3$): δ 7.76 (s, 2H), 7.75 (d, J = 8.4 Hz, 1H), 7.59 (d, J = 7.6 Hz, 1H), 7.13 (t, J = 7.6 Hz, 1H), 7.03 (t, J = 8.0 Hz, 1H), 3.96 (t, J = 5.6 Hz, 2H), 3.29 (t, J = 6.0 Hz, 2H), 2.05 (m, 2H); ^{13}C NMR ($CDCl_3$): δ 154.5, 147.8, 138.2, 129.4, 124.1, 121.1, 115.4, 112.8, 46.6, 27.2, 19.0. *Anal.* Calc. for $C_{22}H_{24}CdN_8S_2Cl_2$: C, 40.78; H, 3.73; N, 17.30; S, 9.90. Found: C, 40.54; H, 3.87; N, 17.09; S, 9.63%. UV–Vis (EtOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 208 (65 207), 243 (36 740), 276 (11 507).

2.4. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen and sulfur were performed by microanalytical methods using a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Electronic spectra in solution of ligand and the cadmium complex were measured on a Shimadzu UV-3101 PC using a 10 mm quartz cell. The UV–Vis-NIR reflectance spectra for the cobalt complex in the 200–1800 nm range was registered from a pellet of the sample, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic measurement was made at room temperature on a magnetometer with pendulum MANICS DSM8, equipped with helium continuous-flow cryostat and an electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature-independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants. ^{1}H and ^{13}C NMR spectra were obtained with a Bruker AM 400 instrument at 400 and 100 MHz, respectively, in $CDCl_3$ using Me_4Si as internal standard.

2.5. Crystal structure determinations

Experimental details of crystal structure determinations including crystal data, data collection, structure determination and refinement parameters for BzTz, [$CoCl_2$(BzTz)$_2$] and [$CdCl_2$(BzTz)$_2$] are listed in Table 1. X-ray diffraction measurements were performed at room temperature (298 K) using a Bruker SMART CCD diffractometer equipped with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) using the ϕ–ω

[b] $R = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.
[c] The goodness-of-fit (GOF) equals $\{\sum[w(F_o^2 - F_c^2)^2]/(N_{rflns} - N_{params})\}^{1/2}$.

scan technique. The first 50 frames were recollected at the end of data collection to monitor for decay. Empirical absorption corrections were applied using program SADABS. The structures were solved by direct methods and subsequent Fourier differences using the WINGX package [19] and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. In the structure of the cobalt complex, only one of the two thiazine shows a dynamic disorder affecting C(3) and C(3A) atoms, being the value of the refined occupancy 0.52(4) for C(3) and 0.48(4) for C(3A). Hydrogen atoms attached to carbon and nitrogen atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding carbon and nitrogen atoms.

3. Results and discussion

3.1. Description of the structures

The single crystal X-ray diffraction analysis revealed that the crystals of BzTz are made up of monoclinic unit cells, each containing eight BzTz. A diagram of the molecular structure and the numbering system used is shown in Fig. 1. Selected bond lengths and angles are listed in Table 2.

In the S–C(1)–N(1)–C(2)–C(3)–C(4) ring, the short endocyclic C=N bond [C(1)–N(1) = 1.264(2) Å] is

accompanied by an high N–C–S angle [N(1)–C(1)–S = 129.4(1)°] and a relatively long S^{II}–C(sp^2) bond [S–C(1) = 1.759(2) Å], which is characteristic of a 5,6-dihydro-4H-1,3-thiazine ring [20]. Likewise, the bond distances and angles of the benzimidazole ring system are comparable to those obtained earlier for the free benzimidazole [21].

The thiazine ring shows a conformation near to half-boat with the C(3) atom deviating 0.710 Å above the plane formed by S, C(1), N(1), C(2) and C(4) [maximum least square plane deviation for C(4) = 0.038 Å]. This geometry is proved by the puckering parameters $Q = 0.523$ Å, $\theta = 54.3°$ and $\phi = 178.8°$, calculated according to Cremer and Pople [22]. As was to be expected, the benzimidazole ring system is essentially planar with maximum least square plane deviations for C(10) [0.041 Å].

The crystal structure is stabilized by an hydrogen-bond network in which thiazinic N(1) and benzimidazolinic N(3) nitrogen atoms act as acceptors of hydrogen, whereas nitrogen atom of amino group N(4) acts as donor. A diagram showing this network is given in Fig. 2.

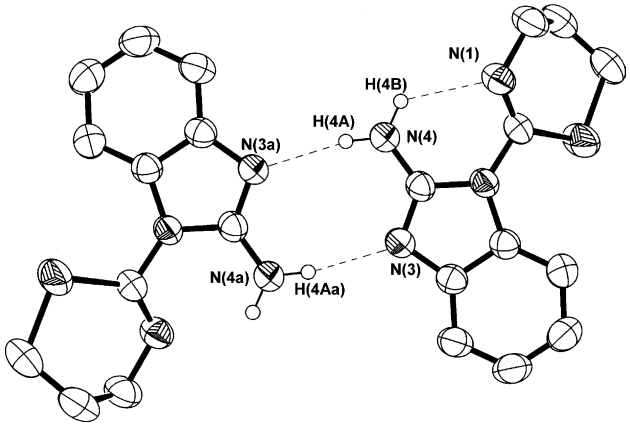

Fig. 2. View of the hydrogen bond network of BzTz.

The structure of $[CoCl_2(BzTz)_2]$ consists of discrete neutral monomeric units in which the environment around the cobalt(II) atom may be described as a distorted tetrahedral geometry. The metallic atom is coordinated by two chlorine atoms [Co–Cl(1) = 2.242(2) Å; Co–Cl(2) = 2.258(2) Å] and two benzimidazole nitrogen atoms from two BzTz ligands [Co–N(3) = 2.022(4) Å; Co–N(7) = 2.019(4) Å]. The overall view and labelling of the atoms of cobalt complex are displayed in Fig. 3. Table 3 lists selected bond lengths, angles and hydrogen-bond parameters.

The Co–Cl bond lengths are similar and comparable to the calculated average value [2.242(27) Å] for 116 tetrahedral cobalt(II) complexes with a chromophore group $CoCl_2N_2$ obtained from CONQUEST software [23] from the Cambridge Structural Database (CSD) [24]. Likewise, the $Co–N_{benzimidazole}$ bond distances are slightly shorter than the mean value [2.082(73) Å] calculated for 7 cobalt(II) complexes collected in CSD. The ligand–metal–ligand bite angles differ from the ideal value of 109.5° varying between 113.3(1)° [Cl(1)–Co–Cl(2)] and 102.6(2)° [N(3)–Co–N(7)].

The thiazine ring S(2)–C(12)–N(5)–C(13)–C(14)–C(15) shows a conformation near to half-boat with the C(14) atom deviating 0.454 Å above the plane formed by S(2), C(12), N(5), C(13) and C(15) [maximum least square plane deviation for C(15) = 0.015 Å]. This geometry is proved by the puckering parameters $Q = 0.338$ Å, $\phi = 245.2°$ and $\theta = 49.7°$ [22].

The other thiazine ring shows two conformations due to disorder. One of them shows an intermediate form between half-chair and half-boat [$Q = 0.373$ Å, $\phi = 260.1°$ and $\theta = 50.5°$] [22], with the C(3) and C(4) atoms deviating 0.395 and −0.156 Å, respectively, from the plane formed by S(1), C(1), N(1) and C(2) [maximum least square plane deviation for C(2) = 0.005 Å]. On the contrary, the second conformation is near to half-boat [$Q = 0.335$ Å, $\phi = 46.8°$ and $\theta = 123.0°$] [22], with the apex at C(3A). This atom is out of the plane

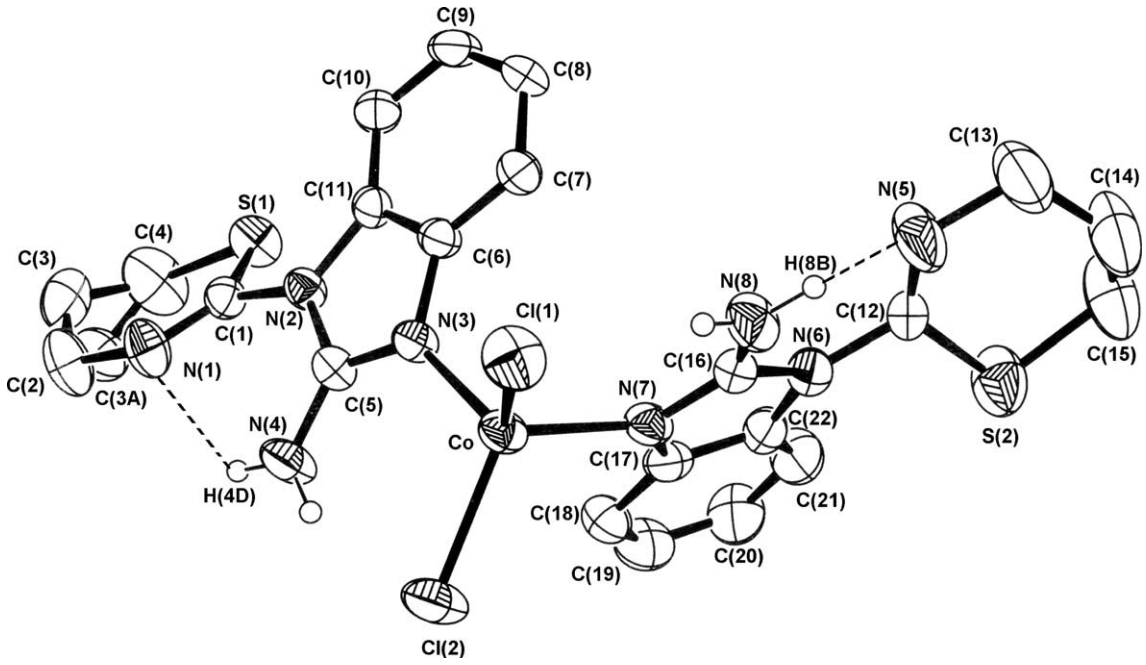

Fig. 3. Molecular structure of $[CoCl_2(BzTz)_2]$, showing the atom-numbering scheme. The thermal ellipsoids are drawn at the 40% probability level. Figure includes a view of the hydrogen bonds.

formed by S(1), C(1), N(1) and C(2) [maximum least square plane deviation for C(4) = 0.092 Å].

Finally, the crystal structure presents an hydrogen-bond network in which the nitrogen atoms of thiazine rings N(1) and N(5) act as acceptors of hydrogen, whereas the nitrogen atoms of amino groups N(4) and N(8) act as donors. A diagram showing this network is given in Fig. 3.

The molecular structure of $[CdCl_2(BzTz)_2]$ with the atomic labelling is shown in Fig. 4. Selected bond

lengths, angles and hydrogen-bond parameters are given in Table 3.

The cadmium(II) complex is bound to two chlorine atoms [Cd–Cl(1) = 2.441(7) Å; Cd–Cl(2) = 2.414(7) Å] and two benzimidazole nitrogen atoms from two BzTz ligands [Cd–N(3) = 2.265(2) Å; Cd–N(7) = 2.233(2) Å]. The distortion of the tetrahedral environment of the cadmium(II) ion is higher than in cobalt(II) complex, being indicated by the ligand–metal–ligand bite angles that vary between 120.6(1)° [Cl(1)–Cd–N(3)] and 100.4(1)° [Cl(1)–Cd–Cl(1)].

The Cd–Cl distances are comparable to the calculated average value [2.481(69) Å] for 87 four-coordinated cadmium(II) complexes found in CSD. Finally, the Cd–$N_{benzimidazole}$ bond distances are slightly shorter than found in $[Cd(BBP–H)_2]$ [2.331(73) Å] [25].

The values of the puckering parameters for thiazine ring S(1)–C(1)–N(1)–C(2)–C(3)–C(4), calculated according to Cremer and Pople [22], are $Q = 0.500$ Å, $\phi = 262.4°$ and $\theta = 50.1°$, whereas for the other thiazine ring S(2)–C(12)–N(5)–C(13)–C(14)–C(15) are $Q = 0.377$ Å, $\phi = 73.4°$ and $\theta = 128.6°$. These values indicate that the first one shows a conformation near to half-chair with the atoms C(3) and C(4) deviating by 0.498 and −0.246 Å, respectively, above the plane formed by S(1), C(1), N(1) and C(2) [maximum least square plane deviation for N(1) = 0.006 Å]. The second one presents a conformation near to half-boat, with the apex at C(14), deviating 0.502 Å from the plane formed by S(2), C(12), N(5), C(13) and C(15) [maximum least square plane deviation for C(15) = 0.048 Å].

The crystal structure presents an hydrogen-bond network in which chloro ligand Cl(1) and nitrogen atoms N(1) and N(5) act as acceptors of hydrogen, whereas nitrogen atoms of amino groups N(4) and N(8) act as donors. A diagram showing this network is given in Fig. 4.

In benzimidazole system of both complexes, the formation of the metal–$N_{benzimidazole}$ bond results in an increase the N(3)–C(5) [or N(7)–C(16)] and N(3)–C(6) [or N(7)–C(17)] distances with respect to the structure of free BzTz.

Finally, it should be pointed out that BzTz acts in both complexes as a monodentate ligand through nitrogen atom of benzimidazole ring, whereas the thiazine ring and amino group being uncoordinated. This fact could be due to existence of a intramolecular hydrogen bond between amine group and thiazine nitrogen atom in free ligand. This hydrogen bond exists in complexes and avoids coordination through the mentioned nitrogen atoms.

3.2. Physical measurements

The observed molar magnetic susceptibility for $[CoCl_2(BzTz)_2]$ was corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature ($\mu_{eff} = 4.52$ BM). This value is consistent with an tetrahedral environment around cobalt(II) [3,26–28].

The diffuse reflectance spectrum shows one intense band at 37 037 cm^{-1} (270 nm), which is assigned to transitions $\pi \rightarrow \pi^*$ of the organic ligand corresponding to a displaced B-bond of benzene. Moreover, the spectrum exhibits two main bands that have intensities consistent with spin-allowed d–d transitions. These bands may be assigned as: ν_2 [$^4A_2(F) \rightarrow {}^4T_1(F)$] (7259 cm^{-1}) and ν_3 [$^4A_2(F) \rightarrow {}^4T_1(P)$] (15 873 cm^{-1}) transitions, in an idealized T_d symmetry. It must be pointed out that the ν_2 assignment has been made by calculating the barycenter of three bands (8929, 7102, 5924 cm^{-1}) of approximately equal intensity in the solid-state spectrum [29]. The ligand-field parameters, $10D_q$ and B, were calculated

Abbreviations. (s) strong; (m) medium; (w) weak; (v) very.

using the following known relationships [30] for tetrahedral d^7 complexes:

$$\nu_2[^4A_2(F) \rightarrow {}^4T_1(F)] = 15D_q + (15/2)B - 1/2[(-6D_q + 15B)^2 + 64(D_q)^2]^{1/2},$$

$$\nu_3[^4A_2(F) \rightarrow {}^4T_1(P)] = 15D_q + (15/2)B + 1/2[(-6D_q + 15B)^2 + 64(D_q)^2]^{1/2}.$$

The calculated values of the ligand-field parameters $10D_q = 4225\ cm^{-1}$ and $B = 697\ cm^{-1}$ are in fair agreement with the predicted values for tetrahedral complexes and are consistent with the presence of a chromophore group $[CoN_2Cl_2]$ [3,28,31–33].

The IR spectrum of BzTz in the 4000–370 cm^{-1} region shows the presence of bands due to thiazine ring vibrations at 1662 (Ψ_1), 964 (Ψ_2), 920 (Ψ_3), 878 (Ψ_4), 717 (Ψ_5), 694 (Ψ_6), 669 (Ψ_7), 606 (Ψ_8), 501 (ϕ_1) and 465 (ϕ_2) cm^{-1} [3,4,34,35].

Likewise, the spectrum of the ligand exhibits bands assignable to the benzimidazole ring vibrations at 1622, 1607, 1498, 1462, 1402, 1364, 1346, 1299 and 1258 cm^{-1} for stretching vibrations (ν); at 1012, 900, 842, 646, 618 and 434 cm^{-1} for bending in-plane vibrations (δ in p.b.); at 568 cm^{-1} for bending out-of-plane vibration (δ o.p.b.); and at 559 cm^{-1} for torsion vibration (τ) [36–39].

Moreover, the bands of NH_2 vibration are detected at 3424, 3402 [$\nu(NH_2)$], 1541 [$\delta(NH_2)$], 1346 [$\omega(NH_2)$] and 1012 [$r(NH_2)$] cm^{-1} [40–43]. Finally, band assignable to ν(C–N) vibration is registered at 1078 cm^{-1} [40,44].

In the 4000–370 cm^{-1} region of the IR spectra of $[CoCl_2(BzTz)_2]$ and $[CdCl_2(BzTz)_2]$ complexes the observed bands due to the organic moiety vibrations are shown in Table 4.

As can be observed in Table 4, the bands assignable to stretching vibration of the benzimidazole ring suffer,

in general, a shift to lower frequencies which substantiate the coordination through the benzimidazole nitrogen atom.

The far IR spectra $[CoCl_2(BzTz)_2]$ and $[CdCl_2(BzTz)_2]$ show absorption bands assignable to metal–ligand stretching vibrations. Thus, the Co(II) spectrum shows a bands at 330 and 302 cm^{-1} corresponding to the ν(Co–Cl) vibration [3,28,45–47], whereas, band at 251 cm^{-1} corresponding to the ν(Co–$N_{benzimidazole}$) vibration in accord with literature data for this type of bonds [48]. In the Cd(II) spectrum, the bands at 278 and 249 cm^{-1} could be attributed to the ν(Cd–Cl) vibration [49]. Finally, band at 203 cm^{-1} is tentatively assigned to the (Cd–$N_{benzimidazole}$) vibration, according to the consulted bibliography for cadmium complexes containing imidazole derivative ligands [50,51].

As usual [52], the coordination to the d^{10} Cd(II) ion shifts the ^1H NMR signals of the complex downfield from those of the free ligand ($\Delta\delta \approx 0.0$ to 0.2 ppm). The major downfield shifts of the H-7 (δ 7.34 ppm in BzTz; 7.60 in complex) and NH_2 (δ 6.45 ppm in BzTz; 7.76 in complex) signals are attributable to coordination through the benzimidazole nitrogen atom [25]. The trends in the shifts in carbon-13 spectroscopy are less straightforward. However, in the ^{13}C NMR spectra of cadmium complex the shift of C5 signal (δ 142.0 ppm in BzTz; 138.2 in complex) to higher field is in consonance with coordination through the benzimidazole nitrogen atom. This conclusion is supported by the X-ray diffraction structure of $[CdCl_2(BzTz)_2]$. The chemical shifts of the other carbon atoms in the compound are similar to free ligand.

4. Supplementary material

CCDC 267998, 267999 and 268000 corresponding to BzTz, $[CoCl_2(BzTz)_2]$ and $[CdCl_2(BzTz)_2]$ contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

(R = Me **1**, *n*-Bu **2**, $PhCH_2$ **3**, Cy **4**, Ph **5**). The X-ray crystallography data show that the tin atoms of complexes **1**–**5** are all five-coordinated with distorted trigonal bipyramidal geometry. Interestingly, complexes **1**–**4** exhibit 1D polymeric chains through Sn and N intermolecular interactions.

2. Experimental

2.1. Materials and measurements

Trimethyltin chloride, tri-*n*-butyltin chloride, triphenyltin chloride, tricyclohexyltin chloride and 5-phenyl-1,3,4-oxadiazole-2-thiol were commercially available, and they were used without further purification. Tribenzyltin chloride was prepared by a standard method reported in the literature [11]. The melting points were obtained with Kofler micro melting point apparatus and are uncorrected. Infrared-spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs and sodium chloride optics. ^{1}H and ^{13}C NMR spectra were recorded on Varian Mercury Plus 400 spectrometer operating at 400 and 100.6 MHz, respectively. The spectra were acquired at room temperature (298 K) unless otherwise specified; ^{13}C spectra are broadband proton decoupled. The chemical shifts were reported in ppm with respect to the references and were stated relative to external tetramethylsilane (TMS) for ^{1}H and ^{13}C NMR. Elemental analyses were performed with a PE-2400II apparatus.

2.2. Syntheses of the complexes *1*–*5*

The general route of synthesis is shown in the following. The reaction was carried out under nitrogen atmosphere. The 5-phenyl-1,3,4-oxadiazole-2-thiol (1 mmol) was added to the solution of benzene 20 ml with sodium ethoxide (1 mmol), then add R_3SnCl (1 mmol) to the mixture, continuing the reaction for 12 h at 40 °C. After cooling down to the room temperature, the solution was filtered. The solvent of the filtrate was gradually removed by evaporation under vacuum until solid product was obtained. The solid was then recrystallized from dichloromethane-*n*-hexane. Colorless crystal was formed.

2.2.1. $Me_3Sn[S(C_8H_5N_2O)]$ (*1*)

Yield, 70%; m.p. 116–118 °C. *Anal.* Calc. for $C_{11}H_{14}N_2OSSn$: C, 38.74; H, 4.14; N, 8.21. Found: C, 38.65; H, 4.04; N, 8.10%. ^{1}H NMR ($CDCl_3$): δ 7.24–7.83 (m, 5H,C_6H_5–C), 0.76 (s, 9H, Sn–CH_3) ppm. ^{13}C NMR: δ 145.7 (C-1 ligand), 136.6 (C-2), 136.6 (C-2′), 128.4 (C-3), 128.4 (C-3′), 129.5 (C-4), 168.2 (C–S), 168.7 (C–Ph), 8.11 (Me) ppm. IR (KBr, cm^{-1}): ν(C=N) 1584, $\nu(Sn–C)_{as}$ 530, $\nu(Sn–C)_s$ 504, ν(Sn–S) 313, ν(Sn–N) 486.

2.2.2. $(n\text{-}Bu)_3Sn[S(C_8H_5N_2O)]$ (*2*)

Yield, 74%; m.p. 69–72 °C. *Anal.* Calc. for $C_{20}H_{32}N_2OSSn$: C, 51.41; H, 6.90; N, 6.00. Found: C, 51.50; H, 6.70; N, 6.22%. ^{1}H NMR ($CDCl_3$): δ 7.25–7.82 (m, 5H, C_6H_5–C), 0.85–1.68 (s, 27H, Sn–C_4H_9) ppm. ^{13}C NMR: δ 145.6 (C-1 ligand), 136.5 (C-2), 136.5 (C-2′), 128.3 (C-3), 128.3 (C-3′), 129.4 (C-4), 168.3 (C–S), 168.8 (C–Ph), 13.5, 26.3, 27.5, 29.2 (*n*-Bu) ppm. IR (KBr, cm^{-1}): ν(C=N) 1586, $\nu(Sn–C)_{as}$ 528, $\nu(Sn–C)_s$ 502, ν(Sn–S) 315, ν(Sn–N) 485.

2.2.3. $(PhCH_2)_3Sn[S(C_8H_5N_2O)]$ (*3*)

Yield, 76%; m.p. 125–127 °C. *Anal.* Calc. for $C_{29}H_{26}N_2OSSn$: C, 61.18; H, 4.60; N, 4.92. Found: C, 61.05; H, 4.41; N, 4.80%. ^{1}H NMR ($CDCl_3$): δ 7.31–7.47 (m, 5H, C_6H_5–C), 6.91–7.17 (m, 15H, Sn–$CH_2C_6H_5$), 2.76 (s, 6H, Sn–$CH_2C_6H_5$). ^{13}C NMR: δ 145.5 (C-1 ligand), 136.4 (C-2), 136.4 (C-2′), 128.2 (C-3), 128.2 (C-3′), 129.3 (C-4), 168.1 (C–S), 168.6 (C–Ph), 37.4 (CH_2–Ph), 127.5 (*m*-C), 128.7 (*p*-C), 127.6 (*o*-C), 124.5 (*i*-C) ppm. IR (KBr, cm^{-1}): ν(C=N) 1596 $\nu(Sn–C)_{as}$ 460, $\nu(Sn–C)_s$ 437, ν(Sn–S) 308, ν(Sn–N) 484.

2.2.4. $Cy_3Sn[S(C_8H_5N_2O)]$ (*4*)

Yield, 77%; m.p. 120–121 °C. *Anal.* Calc. for $C_{26}H_{38}N_2OSSn$: C, 57.26; H, 7.02; N, 5.14. Found: C, 57.15; H, 7.11; N, 5.05%. ^{1}H NMR ($CDCl_3$): δ 7.21–7.41 (m, 5H, C_6H_5–C), 0.82–1.65 (m, 33H, Sn–C_6H_{33}). ^{13}C NMR: δ 145.3 (C-1 ligand), 136.2 (C-2), 136.2 (C-2′), 128.2 (C-3), 128.2 (C-3′), 129.2 (C-4), 168.3 (C–S), 168.6 (C–Ph), 26.6 (*m*-C), 26.5 (*p*-C), 26.8 (*o*-C), 27.5 (*i*-C) ppm. IR (KBr, cm^{-1}): ν(C=N) 1592, $\nu(Sn–C)_{as}$ 450, $\nu(Sn–C)_s$ 427, ν(Sn–S) 307, ν(Sn–N) 483.

2.2.5. $Ph_3Sn[S(C_8H_5N_2O)]$ (*5*)

Yield, 75%; m.p. 185–187 °C. *Anal.* Calc. for $C_{26}H_{20}N_2OSSn$: C, 59.23; H, 3.82; N, 5.31. Found: C, 59.11; H, 3.71; N, 5.22%. ^{1}H NMR ($CDCl_3$): δ 7.21–7.42 (m, 5H, C_6H_5–C), 7.45–7.76 (m, 15H, Sn–C_6H_5) ppm. ^{13}C NMR: δ 145.2 (C-1 ligand), 136.3 (C-2), 136.3 (C-2′), 128.1 (C-3), 128.1 (C-3′), 129.1 (C-4), 168.0 (C–S), 168.5 (C–Ph), 127.9 (*m*-C), 129.0 (*p*-C), 136.4 (*o*-C), 148.5 (*i*-C) ppm. IR (KBr, cm^{-1}): ν(C=N) 1590, $\nu(Sn–C)_{as}$ 464, $\nu(Sn–C)_s$ 429, ν(Sn–S) 311.

2.3. X-ray crystallographic studies of complexes *1*–*5*

Crystals were mounted in Lindemann capillaries under nitrogen. All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 298(2) K. A semi-empirical absorption correction was applied to the data. The structure was solved by direct methods using SHELXS-97 and refined against F^2 by full-matrix least squares using SHELXL-97. Hydrogen atoms were placed in calculated

3. Results and discussion

3.1. Syntheses of complexes 1–5

The synthesis procedure is given in Scheme 1.

3.2. IR spectroscopic studies of complexes 1–5

Comparing the IR spectra of the free ligand with complexes **1**–**5**, the band at 2560–2430 cm^{-1}, which appears in the spectra of the free ligand as the ν(S–H) vibration, is absent in those of complexes **1**–**5** thus indicating metal–ligand bond formation through this site. In the far-IR spectra, the absorption about 310 cm^{-1} region for all complexes **1**–**5**, which is absent in the spectrum of the ligand, is assigned to the Sn–S stretching mode of the vibration and all the values are located within the range for Sn–S vibration observed in common organotin derivatives of thiolate (300–400 cm^{-1}) [12,13]. In organotin complexes, the IR spectra can provide useful information concerning the geometry of the SnC_n moiety [14]. In the case of our complexes, for triorganotin(IV) derivatives, two bands were assigned to asymmetric and symmetric Sn–C vibrations. Thus suggesting non-planar SnC_3 fragments for triorganotins. The middle intensity bands observed at about 1600 cm^{-1} in the spectra of all complexes have been assignable to ν(C=N) according to the literatures [15,16], which suggested the coordination of free ligand to these complexes is through sulfur atoms via thiol form.

Scheme 1.

3.3. ^1H and ^{13}C NMR data of complexes 1–5

^{1}H NMR data showed that the signal of the –SH proton in the spectrum of the ligand is absent in all of the complexes, indicating the removal of the –SH proton and the formation of Sn–S bonds. The formation accords well with what the IR data have revealed. Moreover, the ^{1}H NMR spectra show that the chemical shifts of the phenyl group (Sn–C_6H_5) in complex **5**,

7.45–7.76 ppm, and those of methylene connected directly with tin in complex **3**, 2.76 ppm, upfield shift as compared with those of their corresponding precursors. All these data are similar to those cases in literature [17], indicating there may exist novel coordination of the ligand to tin atom for all the five complexes **1**–**5**. In addition, the resonance of the phenyl group connected with the oxadiazole ring (C–C_6H_5) appears at 7.21–7.83 ppm for all complexes **1**–**5**.

The structural changes occurring in ligand upon deprotonation and coordination to the Sn atom should be reflected by the changes in the ^{13}C NMR spectra of our complexes. If the ligand chelate tin through thiolate form, C–S should be further low frequency in the spectra of all complexes compared with those in free ligands. As shown above, the chemical shifts of C–S in complexes **1**–**5** are shifted by 8 ppm to low frequency compared with the free ligand (δ 176.2 ppm), indicating that the ligands involved in these complexes act as thiolate form. All of the above analyses are confirmed by X-ray diffraction.

3.4. Crystal structures of complexes *1*–*5*

The crystal structures and polymeric chains of complexes **1**–**4** are shown in Figs. 1–8, respectively. And the crystal structure and cell packing diagram of complex **5** are shown in Figs. 9 and 10. All H atoms have been omitted for the purpose of clarity. Table 1 lists the crystal data and structure refinement parameters for complexes **1**–**5** and their selected bond lengths and angles are shown in Tables 2–6, respectively.

3.4.1. $Me_3Sn[S(C_8H_5N_2O)]$ (*1*), $(n\text{-}Bu)_3Sn[S(C_8H_5N_2O)]$ (*2*), $(PhCH_2)_3Sn[S(C_8H_5N_2O)]$ (*3*) and $Cy_3Sn[S(C_8H_5N_2O)]$ (*4*)

For complexes **1**–**4**, the X-ray diffraction investigation has shown that they exhibit 1D polymeric chains through intermolecular Sn–N bonds. The central tin atoms in complexes **1**–**4** are all five-coordinate with the *trans*-trigonal–bipyramidal geometry. The methyl carbons in complex **1**, the methylene carbons which are next to tin in complex **2**, the methylene carbons in complex **3** and the –CH– carbons in complex **4** are in equatorial positions and the axial positions are occupied by the sulfur atom and the nitrogen atom of a neighboring molecule, respectively. The sum of equatorial angles are 359.4° (C(10)#1–Sn(1)–C(10) (123.4(5)°), C(10)#1–Sn(1)–C(9) (118.0(3)°) and C(9)–Sn(1)–C(10) (118.0(3)°)), in complex **1**; 359.9° (C(25)–Sn(1)–C(21) (118.7(5)°), C(25)–Sn(1)–C(17) (124.7(6)°) and C(21)–Sn(1)–C(17) (116.5(5)°)), in complex **2**; 358.04° (C(23)–Sn(1)–C(9) (116.42(14)°), C(23)–Sn(1)–C(16) (111.64(14)°) and C(9)–Sn(1)–C(16) (129.98(13)°)), in complex **3**; 359.86° (C(7)–Sn(1)–C(13) (122.50(14)°), C(7)–Sn(1)–C(1) (121.21(12)°) and C(13)–Sn(1)–C(1) (116.15(13)°)), in complex **4**, respectively. They are all

deviating from 180°, thus they are all distorted trigonal–bipyramidal geometry.

All the Sn–S bond lengths Sn(1)–S(1)#1 (2.713(4) Å) for complex **1**; Sn(1)–S(2)#1 (2.765(3) Å) for complex **2**; Sn(1)–S(1)#1 (2.6565(11) Å) for complex **3**; Sn(1)–S(1) (2.8108(8) Å) for complex **4**, are a little longer than the covalent radii of Sn and S (2.42 Å) [18,19], and quite shorter than the van der Waals radii of of Sn and S (4.00 Å) [20]. Concerning Sn–N bond lengths, the values are Sn(1)–N(1)#2 (2.450(12) Å) for complex **1**; Sn(1)–N(1) (2.415(6) Å) for complex **2**; Sn(1)–N(1) (2.455(3) Å) for complex **3**; Sn(1)–N(1) (2.524(2) Å) for complex **4**, respectively. All these lie in the range recorded in the Cambridge Crystallographic Database from 2.27 to 2.58 Å [21b], slightly greater than the sum of the covalent radii of tin and nitrogen atoms (2.15 Å) but considerably less than the van der Waals radii of the two atoms (3.74 Å) [21a].

The intramolecular interaction distances of Sn, N(2)#1 and/or Sn, O(1)#1 are: 3.158 and 3.278(9) Å for complex **1**; 3.310 and 3.583 Å for complex **2**; 3.206 and 3.127 Å for complex **3**; 3.397 Å for complex **4**, respectively. All the bond distances are within the van der Waals radii of Sn and N atoms (3.74 Å) [21a] and Sn and O atoms (3.68 Å) [22a]. But they are much longer than the values recorded in the Cambridge Crystallographic Database (Sn–N 2.27–2.58 Å) [21b] and Sn–O (2.61–3.02 Å) [22b,c], and cannot be regarded as weak coordination bonds.

Further, most Sn–S and Sn–N bond lengths in complexes **1**–**4** are comparable with those in organotin(IV) derivatives from heterocyclic thionates containing a nitrogen atom (or more), such as organotin thiotetrazoles complexes (Sn–S 2.477(4)–2.614(5) Å and Sn–N 2.464(5)–2.810(7) Å) [6,10a]. To some extent, our ligand has some resemblance with thiotetrazoles. Due to the multidentate nature of the oxadiazole and tetrazole ring, both of them have the possibility to act as a fulcrum through which lattice construction is orchestrated in one or more dimensions [23]. And polymeric chains of complexes **1**–**4** in this paper are covalently linked through intermolecular Sn–N bonds, while organotin thiotetrazoles complexes prefer to adopt both covalent bond and all kinds of hydrogen bonding to construct polymeric chain, 2D zigzag sheets and 3D arrays [24].

3.4.2. $Ph_3Sn[S(C_8H_5N_2O)]$ (**5**)

For complex **5**, the central tin atom forms four primary bonds: three to the phenyl groups and one to the sulfur atom. The Sn–S bond length (2.476(8) Å) lies toward the middle of the range reported for triphenyltin heteoarenethiolates (2.405–2.481 Å) [18,19]. This bond length is a little longer than the sum of covalent radii of Sn and S atoms (2.42 Å) [18,19], but is considerably shorter than the sum of van der Waals radii of Sn and S atoms (4.00 Å) [20]. And it is similar to that found in $Ph_3Sn[S(C_7H_5N_4O)]$ (2.4760(17) Å) [9] and $Ph_3Sn(S–C_2SN_2–S)SnPh_3$ (2.467(2) Å) [8]. Besides, there exist intramolecular Sn···N weak interaction, common observed in triphenyltin heteroarenethiolates [25]. The Sn···N bond length (2.896(12) Å) is midway between the sums of the covalent radii and van der Waals radii of tin and nitrogen (2.15–3.74 Å) [21a] and can be regarded as weak coordination bond. Including the Sn···N weak interaction, the geometry at tin in complex **5** becomes distorted *cis*-trigonal–bipyramidal with the axial-tin-axial angle C(15)–Sn(1)–N(1) (157.9(3)°). As a result of the Sn···N weak coordination bond, though the C–Sn–C bond angles are close to the theoretical tetrahedral angle, the C–Sn–S bond angles are more acute or obtuse than it, largest deviations occurring in C(9)–Sn(1)–S(1) 109.7(2)°, C(15)–Sn(1)–S(1) 98.9(2)° and C(21)–Sn(1)–S(1) 107.3(3)°. In the oxadiazole, the C–S bond distance (C(1)–S(1) 1.708(11) Å) lies between the average value of the double C=S bond in thioureas (1.681 Å) and the single C–S bond in the C–S–Me fragment (1.789 Å) [26], suggesting that the C–S bond has some double-bond character in the deprotonated oxadiazole.

4. Conclusions

A series of organotin(IV) complexes based on 5-phenyl-1,3,4-oxadiazole-2-thiol have been synthesized and characterized. Detailed studies on the structures and spectra of these complexes indicate that the stereo-constraints from the R groups of trialkyltin chloride have great influence on the final coordination mode and crystal structures. Methyl, *n*-butyl, benzyl, cyclohexyl have the smaller spatial resistance, consequently, complexes **1**–**4** adopt the same coordination modes and exhibit 1D polymeric chains through Sn and N intermolecular interactions, respectively. But, phenyl has the bigger stereo-constraints and prevents another ligand chelating the central tin atom, so, complex **5** does not form a 1D polymeric chain. Therefore, we conclude that the decrease of stereo-constraints may benefit the coordination of nitrogen atoms.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication nos. CCDC-257756 for **1**, 238959 for **2**, 257755 for **3**, 261920 for **4** and 238958 for **5**. Copies of the data can be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK,

fax: +44 1223 336033, e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk.

reported several macromonocyclic metal complexes, which are of interest for availing magneto-structural correlations and as useful model for electrochemical studies. Our previous works [26–30] report the magnetic and electrochemical properties of various acyclic and macromonocyclic copper(II), Mn(III) and Ni(II) complexes of the following type of ligand (**I**):

(**I**)

Our recent works [31–33] focused on synthesis and characterization of new macrobicyclic tricompartmental copper(II) complexes containing nitrogen and oxygen donor atoms. Herein we report the interesting chemistry (redox-driven translocation of reduced metal ion) observed in electrochemical studies of synthesized unsymmetrical tricompartmental macrobicyclic nickel(II) complexes and also their catalytic studies. The role of Ni(II) ion in promoting the hydrolysis of phosphate esters [34,35] has been the subject of considerable study and a great deal is now known. The mechanism of 4-nitrophenyl phosphate (NPP) hydrolysis involves the concerted binding of the substrate molecule on one metal centre and the nucleophilic attack of water or hydroxide ion at the other metal centre.

2. Experimental

Elemental analysis was carried out on a Carlo Erba Model 1106 elemental analyzer. ^{1}H NMR spectra were recorded using FX-80-Q Fourier transition NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–800 nm. IR spectra were recorded on a Hitachi 270-50 spectrophotometer on KBr disks in the range 4000–250 cm^{-1}. The mass spectra were obtained on JEOL DX-303 mass spectrometer. The electrospray (ES) mass spectra of the complexes were obtained on a micromass Quatro II triple quadropole mass spectrometer. Molar conductivity was measured by using an Elico model SX 80 conductivity bridge using freshly prepared solution of the complex in CH_3CN. Cyclic Voltammograms were obtained on CHI600A (CHI Instruments Co., USA) electrochemical analyzer using DMF. The measurements were carried out under oxygen free condition by purging nitrogen gas, using a three electrode cell in which glassy carbon electrode was working electrode, saturated Ag/AgCl electrode was reference electrode and platinum wire was used as auxiliary electrode. Glassy carbon electrode surface was pretreated by metallographic polishing with alumina on a velvet cloth (abraded with fine grade of emery paper), followed by ultrasonic cleaning in double distilled water and washing with small amount of highly diluted acid and DMF. Two separate double step chronocoulometry experiments were carried out for the binuclear nickel(II) complexes in the first and second reduction/oxidation potential range under oxygen free condition. The plots have been corrected for background. Ferrocene/Ferrocenium (1+) couple was used as standard and $E_{1/2}$ of the Ferrocene/Ferrocenium (Fc/Fc^+) couple under the experimental condition is 470 mV in DMF and ΔE_p for Fc/Fc^+ is 70 mV. Tetra(*n*-butyl)ammonium perchlorate (TBAP) was used as supporting electrolyte. The kinetic investigation of hydrolysis of 4-nitrophenyl phosphate was carried out spectrophotometrically by choosing the strongest absorbance at 420 nm and monitoring the increase in the absorbance at this wavelength as a function of time. A plot of $\log(A_\infty/A_\infty - A_t)$ versus time was made for each complexes and the rate constant of hydrolysis of 4-nitrophenyl phosphate was calculated. All the kinetic studies were carried out in DMF solvent at room temperature (25 °C).

2.1. Materials

5-Methylsalicyladehyde [36], 3-chloromethyl-5-methylsalicylaldehyde [37] and 3,4:9,10-dibenzo-1,13-diaza-5,9-dioxacycloheptadecane [38,39] were prepared from the literature methods. TBAP used as supporting electrolyte in electrochemical measurement was purchased from Fluka and recrystallised from hot methanol. [*Caution*! TBAP is potentially explosive; hence care should be taken in handling the compound.] DMF and CH_3CN were obtained from E. MERCK.

Methanol was sufficiently added to acetonitrile fractionated at high reflux until the boiling temperature rises from 60 to 80 °C and the distillate became optically clear. Sodium hydride was added and the mixture was refluxed for 15 min and then distilled rapidly.

DMF can be azeotropically distilled with benzene (10% v/v, previously dried over CaH_2) at atmospheric pressure; water and benzene distill at <80 °C. The liquid remaining in the distillation flask was dried further by adding $MgSO_4$. After the flask and its contents were shaken for 1 day, an additional amount of $MgSO_4$

was added and the DMF was distilled at a pressure of 15–20 mmHg.

All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.2. Synthesis of precursor compound

2.2.1. 3,4:9,10-Dibenzo-1,13[N,N′-bis{(3-formyl-2-hydroxy-5-methyl)benzyl}diaza]-5,9-dioxacycloheptadecane (Precursor compound)

A mixture of 3,4:9,10-dibenzo-1,13-diaza-5,9-dioxacycloheptadecane (1.088 g, 3.2 mmol) and triethylamine (1.32 g, 6.4 mmol) in 30 ml of THF was added slowly to a stirred solution of 3-chloromethyl-5-methylsalicylaldehyde (1.16 g, 6.4 mmol) in 30 ml of THF. After the addition was over the stirring was continued further for one more hour. The whole solution was then refluxed under water bath for 3 h and was allowed to cool on standing at room temperature. Copious water was added to this solution to dissolve any salt obtained. Then the required compound was extracted in organic medium using chloroform. The extraction was repeated for two to three times. A pale yellow compound was obtained on evaporation of solvent at room temperature (25 °C). Light yellow microcrystals were obtained on recrystallization from chloroform. Yield: 1.61 g (79%), m.p.: 81 °C. *Anal.* Calc. data for $C_{39}H_{44}O_6N_2$: C, 73.58; H, 6.91; N, 4.40. Found: C, 73.69; H, 7.08; N, 4.65%. IR data (ν cm^{-1}): 1670 (νC=O, s), 3396 (νOH, br). ^{1}H NMR (δ ppm in $CDCl_3$): 10.0 (s, 2H, CHO protons), 7.2 (m, 12H, aromatic protons), 4.5 (m, 4H, methylene protons attached to oxygen atom), 3.8 (m, 8H, benzylic protons), 3.5 (s, 4H, methylene protons attached to nitrogen atom), 2.3 (s, 6H, CH_3 protons attached to aromatic ring), 2.1 (s, 4H, CH_2 protons attached to alkyl chain. Mass (EI) *m/z*: 636 (m^+).

2.3. Synthesis of macrobicyclic mononuclear nickel(II) complexes

2.3.1. [NiL^1](ClO$_4$)

A methanolic solution (20 ml) of nickel(II)perchlorate hexahydrate (0.694 g, 1.9 mmol) [*Caution*! Nickel(II) perchlorate salt is potentially explosive; hence care should be taken in handling the compound.] was added to the hot solution of precursor compound (1.208 g, 1.9 mmol) in 25 ml of $CHCl_3$ followed by the addition of 1,2-diaminoethane (0.128 g, 1.9 mmol) in 5 ml of methanol. The solution was refluxed on water bath for 24 h. After the reaction was over, the solution was filtered at hot condition and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, the orange red compound was obtained, washed with methanol and dried in vacuum. Yield: 1.24 g (76%). *Anal.* Calc. data for $C_{43}H_{50}O_8N_5ClNi$: C, 60.13; H, 5.82; N, 8.15. Found: C, 60.22; H, 5.94; N, 8.21%. Selected IR (KBr): 1624 (s), 1091 (s), 627 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 155. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 599 (177), 364 (13 100), 252 (37 100).

2.3.2. [NiL^2](ClO$_4$)

[NiL^2](ClO$_4$) was synthesized by following the previously described procedure for [NiL^1](ClO$_4$), using 1,3-diaminopropane instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.22 g (73%). *Anal.* Calc. data for $C_{44}H_{52}O_8N_5ClNi$: C, 60.55; H, 5.96; N, 8.02. Found: C, 60.61; H, 6.03; N, 8.15%. Selected IR (KBr): 1625 (s), 1100 (s), 626 (s) cm^{-1}. ^{1}H NMR (δ ppm in CH_3CN): 8.0 (s, 2H, protons in CH=N), 6.6 to 7.1 (m, 12H, aromatic protons), 3.9 (m, 4H, methylene protons attached to oxygen atom), 2.1 (m, 2H, methylene protons attached to CH_2–O), 4.5 (s, 4H, benzylic protons attached to $^+$NH in the amine compartment), 3.6 (s, 4H, benzylic protons attached to N in the amine compartment), 3.2 (s, 2H, methylene protons attached to $^+$NH in the amine compartment), 1.7 (s, 2H, methylene protons attached to $^+$NH–CH_2 in the amine compartment), 1.3 (s, 2H, methylene protons attached to N–CH_2 in the amine compartment), 2.3 (s, 2H, methylene protons attached to N in the amine compartment), 2.3 (s, 6H, aromatic CH_3 protons), 3.4 (s, 4H, CH_2 protons attached to imine nitrogen), 1.6 (s, 2H, CH_2 protons attached to CH_2–N=). ^{13}C NMR (δ ppm in CH_3CN): 163 (s, carbon in CH=N), 118, 124, 128, 130, 133 and 155 (m, aromatic carbons in imine compartment), 114, 120, 123, 126, 129 and 159 (m, aromatic carbons in ether oxygen compartment), 69 (m, 2C, carbons in *C*H_2–O), 31 (m, 1C, carbon in *C*H_2–CH_2–O), 49 (s, 4C, benzylic carbons attached to $^+$NH and N in the amine compartment), 53 (s, 1C, methylene carbon in *C*H_2–$^+$NH and carbon in *C*H_2–N), 24 (s, 1C, methylene carbon in *C*H_2–CH_2–$^+$NH), 28 (s, 1C, methylene carbon in *C*H_2–CH_2–N), 22 (s, 2C, carbons in Ar–*C*H_3), 164 (s, 2C, carbons in Ar–*C*H=N), 34 (s, 2C, carbons in =N–*C*H_2–*C*H_2–N=), 21 (s, 1C, carbon in *C*H_2–CH_2–N=). Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 139. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 610 (168), 376 (15 700), 263 (34 000).

2.3.3. [NiL^3](ClO$_4$)

[NiL^3](ClO$_4$) was synthesized by following the previously described procedure for [NiL^1](ClO$_4$), using 1, 4-diaminobutane instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.34 g (80%). *Anal.* Calc. data for $C_{46}H_{54}O_8N_5ClNi$: C, 62.30; H, 6.09; N, 7.90. Found: C, 62.44; H, 6.20; N, 8.01%. Selected IR (KBr): 1622 (s), 1090 (s), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 144. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 636 (139), 372 (15 900), 258 (30 600).

2.3.4. $[NiL^4](ClO_4)$

$[NiL^4](ClO_4)$ was synthesized by following the previously described procedure for $[NiL^1](ClO_4)$, using *o*-phenylenediamine instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.36 g (79%). *Anal*. Calc. data for $C_{47}H_{50}O_8N_5ClNi$: C, 62.25; H, 5.51; N, 7.72. Found: C, 62.41; H, 5.69; N, 7.86%. Selected IR (KBr): 1620 (s), 1100 (s), 628 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 158. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 632 (150), 401 (15 600), 360 (17 300), 256 (38 700).

2.3.5. $[NiL^5](ClO_4)$

$[NiL^5](ClO_4)$ was synthesized by following the previously described procedure for $[NiL^1](ClO_4)$, using 1,8-diaminonaphthalene instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.43 g (79%). *Anal*. Calc. data for $C_{51}H_{52}O_8N_5ClNi$: C, 64.01; H, 5.43; N, 7.32. Found : C, 64.19; H, 5.58; N, 7.48%. Selected IR (KBr): 1625 (s), 1099 (s), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 150. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 665 (161), 410 (15 600), 370 (16 100), 262 (32 100).

2.4. Synthesis of macrobicyclic binuclear nickel(II) complexes

2.4.1. $[Ni_2L^1](ClO_4)_2$

A methanolic solution (20 ml) of nickel(II)perchlorate hexahydrate (0.694 g, 1.9 mmol) [*Caution*! Nickel(II) perchlorate salt is potentially explosive; hence care should be taken in handling the compound.] was added to the hot solution of PC (1.208 g, 1.9 mmol) in 25 ml of $CHCl_3$ followed by the addition of 1,2-diaminoethane (0.128 g, 1.9 mmol) and triethylamine (0.265 g, 1.9 mmol) in 5 ml of methanol. After 1 h, nickel(II) perchlorate (0.694 g, 1.9 mmol) in 20 ml of methanol was added and the whole reaction mixture was refluxed on water bath for 24 h. After the reaction was over, the reaction mixture was filtered and allowed for standing at room temperature (25 °C). After slow evaporation of the solvent at 25 °C, the orange red compound obtained was washed with methanol and dried in vacuum. Yield: 1.60 g (80%). *Anal*. Calc. data for $C_{45}H_{52}O_{12}N_6Cl_2Ni_2$: C, 51.13; H, 4.92; N, 7.95. Found: C, 51.29; H, 5.08; N, 8.10%. Selected IR (KBr): 1625 (s), 1100 (m), 626 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 282. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 599 (231), 362 (11 900), 255 (38 200). Mass (ES) *m*/*z*: 974 (m^+).

2.4.2. $[Ni_2L^2](ClO_4)_2$

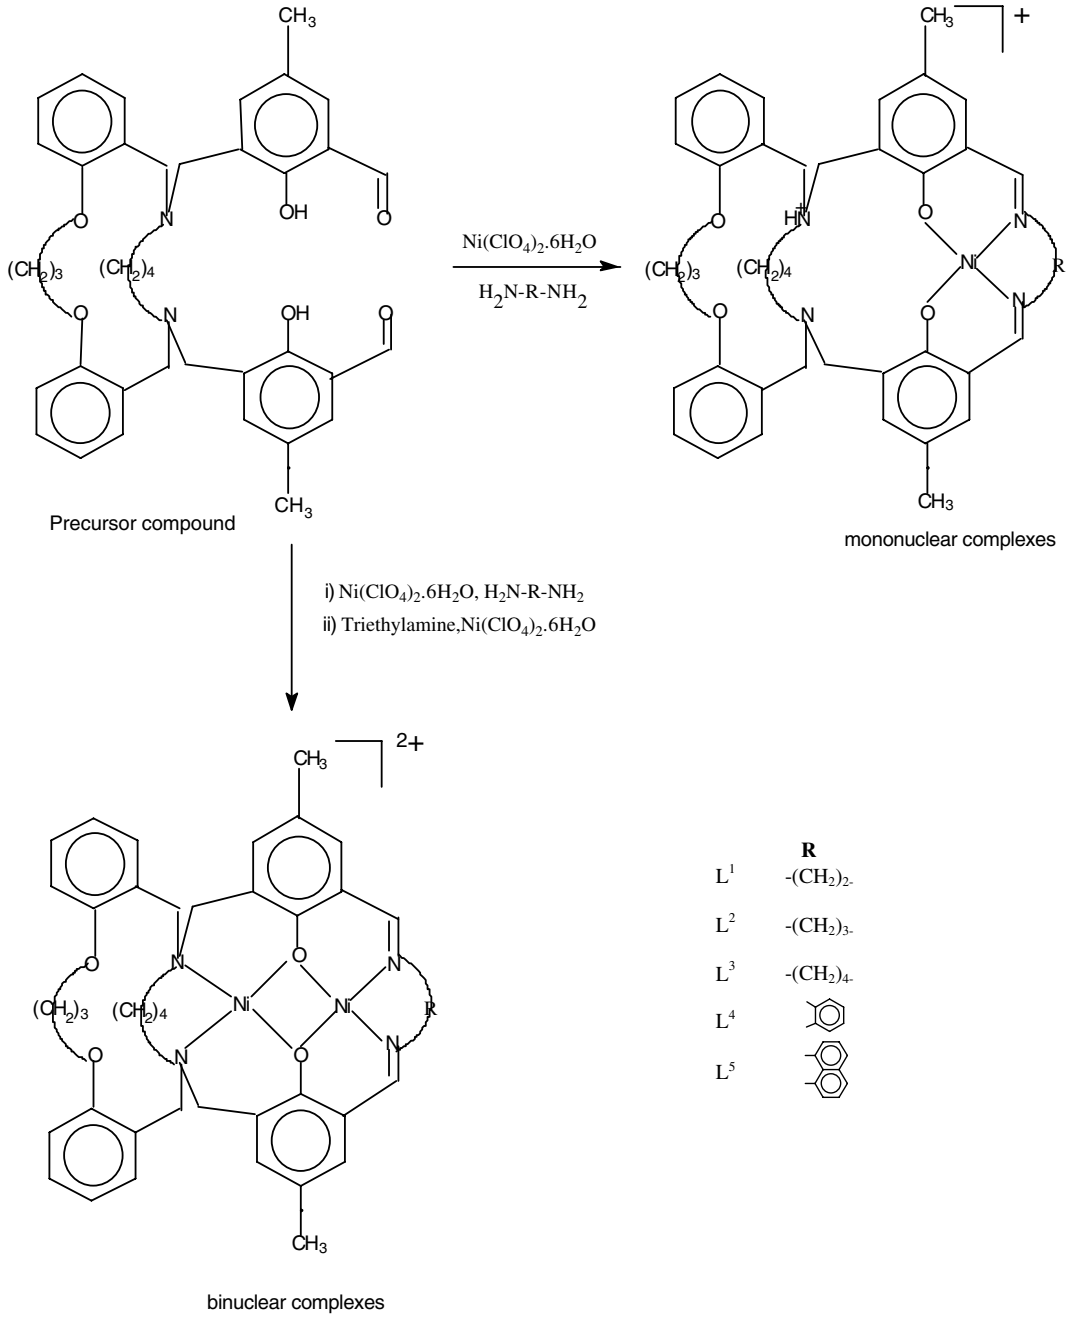
$[Ni_2L^2](ClO_4)_2$ was synthesized by following the previously described procedure for $[Ni_2L^1](ClO_4)_2$, using 1,3-diaminopropane instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.59 g (78%). *Anal*. Calc. data for $C_{46}H_{54}O_{12}N_6Cl_2Ni_2$: C, 51.58; H, 5.04; N, 7.85. Found: C, 51.71; H, 5.16; N, 8.02%. Selected IR (KBr): 1624 (s), 1100 (m), 627 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 280. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 615 (242), 374 (12 850), 265 (32 300).

2.4.3. $[Ni_2L^3](ClO_4)_2$

$[Ni_2L^3](ClO_4)_2$ was synthesized by following the previously described procedure for $[Ni_2L^1](ClO_4)_2$, using 1,4-diaminobutane instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.55 g (75%). *Anal*. Calc. data for $C_{47}H_{56}O_{12}N_6Cl_2Ni_2$: C, 52.02; H, 5.23, N, 7.74. Found: C, 52.21; H, 5.38; N, 7.83%. Selected IR (KBr): 1622 (s), 1098 (m), 628 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 298. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 630 (224), 370 (12 300), 260 (32 500).

2.4.4. $[Ni_2L^4](ClO_4)_2$

$[Ni_2L^4](ClO_4)_2$ was synthesized by following the previously described procedure for $[Ni_2L^1](ClO_4)_2$, using *o*-phenylenediamine instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.58 g (72%). *Anal*. Calc. data for $C_{49}H_{52}O_{12}N_6Cl_2Ni_2$: C, 53.26; H, 4.71, N, 7.60. Found: C, 53.40; H, 4.88; N, 7.74%. Selected IR (KBr): 1620 (s), 1100 (m), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 310. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 620 (265), 410 (14 500), 362 (14 100), 258 (37 200).



2.4.5. $[Ni_2L^5](ClO_4)_2$

$[Ni_2L^5](ClO_4)_2$ was synthesized by following the previously described procedure for $[Ni_2L^1](ClO_4)_2$, using 1,8-diaminonaphthalene instead of 1,2-diaminoethane. The compound obtained was orange red. Yield: 1.58 g (72%). *Anal*. Calc. data for $C_{53}H_{56}O_{12}N_6Cl_2Ni_2$: C, 55.11; H, 4.68, N, 7.27. Found: C, 55.29; H, 4.84; N, 7.39%. Selected IR (KBr): 1622 (s), 1099 (m), 626 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 299. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 660 (268), 405 (14 700), 371 (16 220), 263 (36 820).

In all cases we could obtain only microcrystals and attempts to obtain the crystals suitable for X-ray analysis were unsuccessful.

3. Results and discussion

Schiff's base condensation of the precursor compounds with diamines in the presence of metal ion by template method results into various macrobicyclic mono and binuclear nickel(II) complexes. Scheme 1 represents the synthetic pathway of mono and binuclear complexes. Our previous studies [31,32] rationalize the crystal structure of another series of similar type of copper(II) complexes Hence, in accordance with this, it is

Scheme 1. Synthesis of macrobicyclic mono and binuclear nickel(II) complexes.

proposed that the geometry around nickel(II) ion is distorted square planar and in the mononuclear complexes, one of the tertiary nitrogen atoms is protonated. Conductivity measurements indicate that mono and binuclear nickel(II) complexes are 1:1 and 1:2 electrolyte type, respectively. Extensive spectral, electrochemical and kinetic studies of the complexes were carried out.

3.1. Spectral studies

The IR spectra of the complexes show ν(C=N) peak [40] at 1620–1625 cm^{-1}. The effective Schiff's base condensation is evidenced by the formation of this new peak and the disappearance of the ν(C=O) peak at 1674 cm^{-1} in the complexes. The peaks appeared near 1100 and 620 cm^{-1} are characteristics of the uncoordinated perchlorate ion. The electronic spectra of the complexes show three main transitions. A weak band observed in the range 599–665 nm is due to d–d transition of the metal ion. On moving from the complexes of ligand L^1 to L^3 and L^4 to L^5, an increase in λ_{max} (red shift) [41] of the d–d transition of Ni(II) ion in the complexes was observed for both mono and binuclear copper(II) complexes. A moderate intensive band observed in the range

360–376 nm is due to ligand to metal charge transfer transition and the strong band observed in the range 252–263 nm is due to intraligand charge transfer transition [42]. Apart from these, additional peaks are observed for the complexes of ligands L^4 to L^5 due to the presence of aromatic ring in the imine nitrogen compartment. All the nickel(II) complexes are diamagnetic [30,43–45] and ESR silent.

3.2. Electrochemistry

The conductivity measurements [46,47] of the complexes in acetonitrile indicate that the mononuclear nickel(II) complexes are of 1:1 (139–158 Λ_m/S cm^2 mol^{-1}) electrolyte type and binuclear nickel(II) complexes are 1:2 (280–310 Λ_m/S cm^2 mol^{-1}) electrolyte type. Electrochemical properties of the complexes reported in the present work were studied by cyclic voltammetry in the potential range 0 to −1.6 V and 0 to +1.6 V in dimethylformamide containing 10^{-1} M tetra(*n*-butyl)-ammonium perchlorate. All the nickel(II) complexes undergo both reduction and oxidation in cathodic and anodic potential, respectively. Since the macrobicyclic complexes of ditopic ligands contain non-equivalent compartments, the translocation process has also been studied electrochemically using redox-driven mechanism.

3.2.1. Chronocoulometry study

Chronocoulometry [48] is an alternative and very useful mode for recording the electrochemical response. This is especially valuable for the study of surface process. The main two components of this technique are single step and double step experiments. The double step experiment is considered to be more versatile and generally in this case two curves are obtained. The first curve is due to the addition of the charge at the electrode and the second curve is obtained due to the reverse process, i.e., the removal of charge from the electrode surface. If the magnitude of slope of both the curves is same then it is said to be reversible and if the magnitude varies it is said to be quasireversible. Hence, in order to examine the nature of the process, two separate double step chronocoulometry experiments were carried out for binuclear nickel(II) complexes both in cathodic and anodic potential. In each experiment, two curves are obtained and from the studies it is inferred that the calculated magnitude of slope of both the curves varies and hence they are said to be quasireversible in nature. Figs. 1 and 2 represent the double step chronocoulometry response of binuclear nickel(II) complex $[Ni_2L^3](ClO_4)_2$ in cathodic and anodic potential, respectively.

3.2.2. Cyclic voltammetry study

3.2.2.1. Reduction at cathode. The cyclic voltammograms for the mononuclear complexes are shown in Fig. 3.

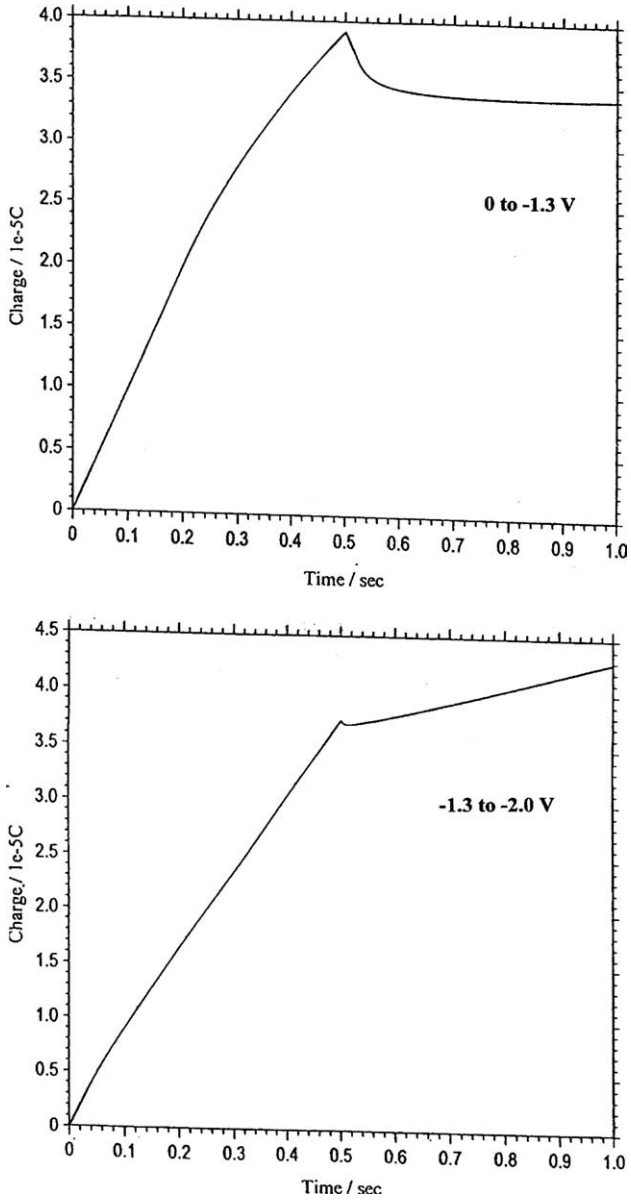


Fig. 1. Double step chronocoulometry response of binuclear complex $[Ni_2L^3](ClO_4)_2$ in reduction process.

Each voltammogram shows one quasireversible reduction wave at negative potential in the range −0.83 to −1.07 V. Controlled potential electrolysis carried out at 100 mV more negative than the reduction wave reveals the consumption of one electron per molecule ($n = 0.94$) and the experiment reports that the couple corresponding to one electron transfer process. Fig. 4 represents the cyclic voltammograms of the binuclear complexes. Binuclear complexes show two quasireversible reduction waves. The first reduction potential ranges from −0.95 to −1.29 V and the second reduction potential falls in the range −1.32 to −1.67 V. Tables 1 and 2 represent the electrochemical data of nickel(II) complexes in cathodic and anodic potential, respectively. Controlled potential electrolysis also carried out

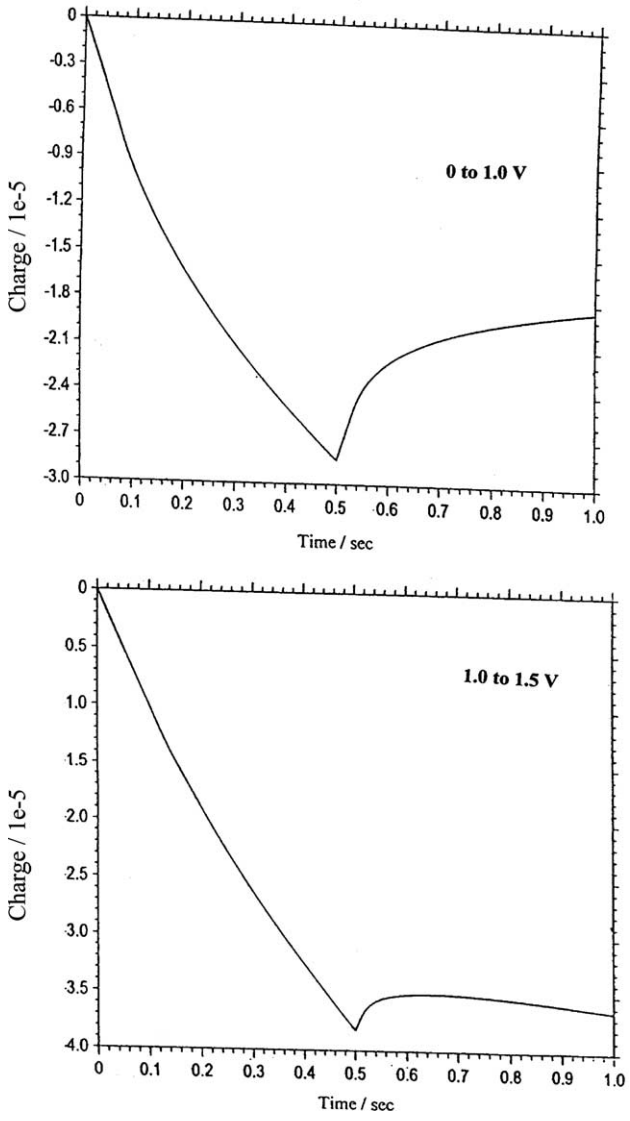

Fig. 2. Double step chronocoulometry response of binuclear complex $[Ni_2L^3](ClO_4)_2$ in oxidation process.

and the experiment reports that the each couple corresponding to one electron transfer process. So, the two redox processes are assigned as follows:

$$Ni^{II}Ni^{II} \rightleftharpoons Ni^{II}Ni^{I} \rightleftharpoons Ni^{I}Ni^{I}$$

The conproportionation constant for the equilibrium

$$Ni^{II}Ni^{II} + Ni^{I}Ni^{I} \overset{K_{con}}{\rightleftharpoons} 2Ni^{II}Ni^{I}$$

was calculated using the relationship $\log K_{con} = \Delta E/0.0591$.

The electrochemical behaviour of the complexes was compared on the basis of macrocyclic ring size. The reduction potential of the mononuclear nickel(II) complexes of ligands L^1 to L^3 and L^4 to L^5 shifts anodically from -0.89 to -0.82 V and from -1.01 to -0.91 V, respectively, as the macrocyclic ring size increases due to the presence of bulky group. This imparts more flexibility to the macrocycle [24,30,49,50] and tries to stabilize nickel(I) complex. In this case, the calculated ΔE values for quasireversible waves are generally larger and this may be due to the occurrence of electrochemical interconversion (translocation) [51] of reduced cation Ni(I) from the rigid imine nitrogen compartment

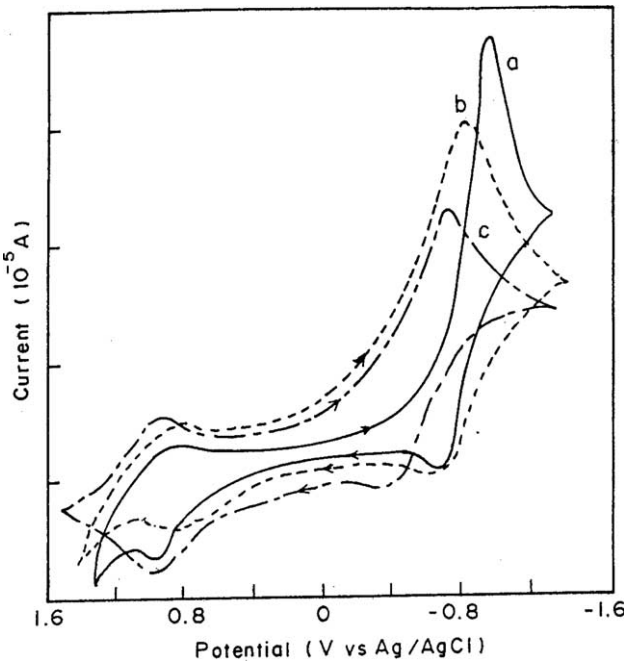

Fig. 3. Cyclic votammograms of the mononuclear nickel(II) complexes (1×10^{-3} M): (a) $[NiL^1](ClO_4)$, (b) $[NiL^2](ClO_4)$, (c) $[NiL^3](ClO_4)$.

(N_2O_2) to flexible tertiary nitrogen compartment (N_2O_2), which favours the tetrahedral geometry. The larger ΔE values indicate that the reduction process is associated with ECE mechanism. The decrease in ΔE value is observed as the chain length between two imine nitrogens increases and this eases the translocation process [31–33,51–54] moving from the complexes of ligands L^1 to L^3 and L^4 to L^5.

As the size of macrocycle is increased, shifting of both first and second reduction potentials towards anodic is observed for the binuclear nickel(II) complexes. For example the complex $[Ni_2L^1](ClO_4)_2$ has $E^1_{pc} = -1.25$ and $E^2_{pc} = -1.64$ V, which is more negative compared to the complex $[Ni_2L^2](ClO_4)_2$ ($E^1_{pc} = -1.21$ and $E^2_{pc} = -1.45$ V) and the same observation is inferred for the complexes of ligand L^{4-5} also. Thus due to the presence of bulky group in the imine nitrogen compartment, the whole macrocyclic ring becomes more flexible and hence undergoes easy reduction. Thus the large size of cavity easily holds the reduced cation and stabilizes the formation of Ni(I) in both the compartment. Concern in the calculation of K_{con} values of binuclear Ni(II) complexes leads to another interesting feature that the variation of K_{con} is random and not uniform as the macrocyclic ring size increases which has no explanation.

From the cyclic voltammetric studies it can be stated that the complexes containing aromatic diimines get reduced at higher negative potential than that of the complexes containing aliphatic diimine, even though it is expected to stabilize Ni(I) more effectively. The reason may be due to the increased stability of the macrocyclic systems due to aromatic and less deviation from planarity.

3.2.2.2. Oxidation at anode. The cyclic voltammograms of nickel(II) complexes obtained at positive potential region ranging from 0 to +1.5 V show one electron transfer waves. The oxidation process is also quasireversible in nature. It is obvious to say that the increase in macrocyclic ring size influences the oxidation potential to less extend only and no uniform variation is observed. Hence, the influence of macrocyclic ring size is unpredictable. The oxidation process can be assigned as follows:

$$Ni^{II}Ni^{II} \rightleftharpoons Ni^{II}Ni^{III} \rightleftharpoons Ni^{III}Ni^{III}$$

3.3. Kinetic studies of hydrolysis of 4-nitrophenylphosphate

The investigation of the kinetic studies of the nickel(II) complexes implies that the complexes act as model for phosphate hydrolase. The kinetics of the hydrolysis of 4-nitrophenyl phosphate was carried out using an equal concentration of the complex catalyst and tetramethylammonium hydroxide (10^{-3} M) and 4-nitrophenyl phosphate (10^{-1} M). The chromophore leaving group 4-nitrophenolate, which is the hydrolysis product of the substrate was monitored at 420 nm. The course of the reaction was followed at 420 nm nearly 45 min at regular time interval. The slope was determined by monitoring the growth of 420 nm band of the product 4-nitrophenolate ion. We have carried out the reaction in the absence of metal complex. No detectable hydrolysis of test substrate was observed when the metal complex was absent. We have also carried out the hydrolysis of 4-nitrophenyl phosphate for various concentration of the metal complex. A linear relationship for rate and the complex concentration obtained for the complex shows a pseudo first order dependence on the complex concentration. This clearly shows that this is truly catalytic.

Plots of $\log(A_\infty/A_\infty - A_t)$ versus time for catalytic activity of the mono and binuclear complexes hydrolysis for 4-nitrophenyl phosphate are obtained and shown in Figs. 5 and 6, respectively. The rate constant values are also reported in Table 3. The first apparent result was that the reactivities of the complexes differ significantly, as the size of macrocycle increases. The binuclear complexes have higher activities than the mononuclear complexes [55–59]. For example the binuclear complexes $[Ni_2L^1](ClO_4)_2$, $[Ni_2L^2](ClO_4)_2$, $[Ni_2L^3](ClO_4)$, $[Ni_2L^4](ClO_4)_2$ and $[Ni_2L^4](ClO_4)_2$ have the rate constant values 1.98×10^{-2}, 3.34×10^{-2}, 4.15×10^{-2}, 1.86×10^{-2} and $2.67\times10^{-2}\,min^{-1}$, respectively, whereas the mononuclear complexes $[NiL^1](ClO_4)$, $[NiL^2](ClO_4)$, $[NiL^3](ClO_4)$, $[NiL^4](ClO_4)$ and $[NiL^5](ClO_4)$ have the rate constant values 1.80×10^{-3}, 2.04×10^{-3}, 2.40×10^{-3}, 1.36×10^{-3} and $1.68\times10^{-3}\,min^{-1}$, respectively. This simply shows that the presence of two metal ions in close proximity enhances the catalytic activity in binuclear complexes than that of mononuclear complexes, which contain single metal ion and hence the rate constant values of binuclear complexes are comparatively high. This is due to the fact that the mononuclear complexes proceed via S_N1 type of reaction mechanism wherein, the external hydroxide ion coordinate to the metal ion, followed by deprotonation of OH and formation of an intermediate with the phosphate group and then cleavage of the bond to form the phenolate anion, along with

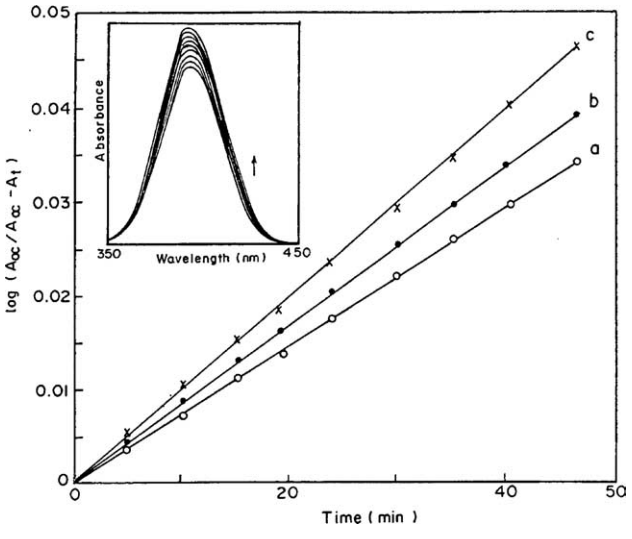

Fig. 5. Catalytic activity of mononuclear nickel(II) complexes for hydrolysis of 4-nitrophenylphosphate: (a) $[NiL^1](ClO_4)$, (b) $[NiL^2](ClO_4)$, (c) $[NiL^3](ClO_4)$.

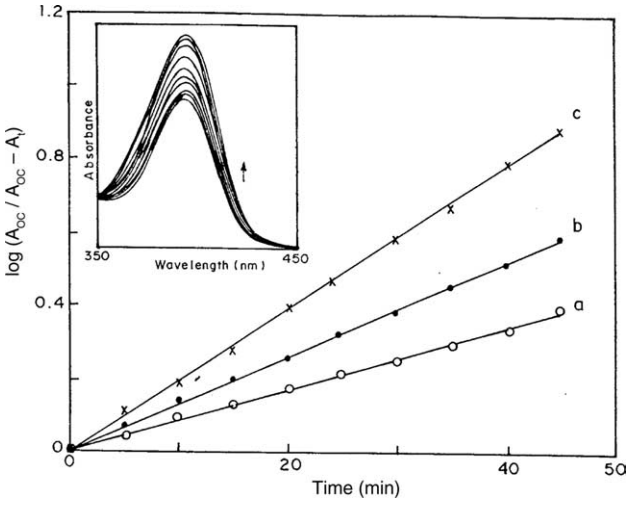

Fig. 6. Catalytic activity of binuclear nickel(II) complexes for hydrolysis of 4-nitrophenylphosphate: (a) $[Ni_2L^1](ClO_4)_2$, (b) $[Ni_2L^2](ClO_4)_2$, (c) $[Ni_2L^3](ClO_4)_2$.

Table 3
Catalytic activity[a] of mono and binuclear nickel(II) complexes for hydrolysis of 4-nitrophenyl phosphate

Complexes	Rate constant (min^{-1})
$[NiL^1](ClO_4)$	1.80×10^{-3}
$[NiL^2](ClO_4)$	2.04×10^{-3}
$[NiL^3](ClO_4)$	2.40×10^{-3}
$[NiL^4](ClO_4)$	1.36×10^{-3}
$[NiL^5](ClO_4)$	1.68×10^{-3}
$[Ni_2L^1](ClO_4)_2$	1.98×10^{-2}
$[Ni_2L^2](ClO_4)_2$	3.34×10^{-2}
$[Ni_2L^3](ClO_4)_2$	4.15×10^{-2}
$[Ni_2L^4](ClO_4)_2$	1.86×10^{-2}
$[Ni_2L^5](ClO_4)_2$	2.67×10^{-2}

[a] Measured spectrophotometrically in DMF medium. Concentration of the complexes and tetramethylammonium hydroxide: 1×10^{-3} M, concentration of 4-nitrophenyl phosphate: 1×10^{-1} M.

hydroxylation of the phosphate group. The binuclear nickel(II) complexes follow a concerted S_N2 type of mechanism where the nucleophile OH^- adds to one of the Ni ions and the phosphate is bound to the other metal ion. Here, bond formation and bond breakage, occur at the same time. The mechanism of the hydrolysis has already been reported [35,60,61]. The catalytic activities of both mono and binuclear complexes are found to increase as the macrocyclic ring size increases due to the intrinsic flexibility. The catalytic activity of the complexes containing aromatic diimines is found to be less than that of the complexes containing aliphatic diimines. This can be explained that the planarity, which is associated with aromatic ring, imparts less catalytic efficiency due to the rigidity of the systems as observed in the case of electrochemical reduction of the complexes.

4. Conclusion

This work involves the synthesis of lateral macrobicyclic compartmental nickel(II) complexes with phenolate bridging atoms. Various macrobicyclic mono and binuclear nickel(II) complexes have been synthesized and their extensive spectral, electrochemical and catalytic studies were carried out with significant modification in the ligand framework. The increase in macrocyclic ring size in the ligand framework influences the reduction (electrochemical) and catalytic properties of the complexes whereas it has no influence on the oxidation (electrochemical) properties of the complexes.

2. Experimental

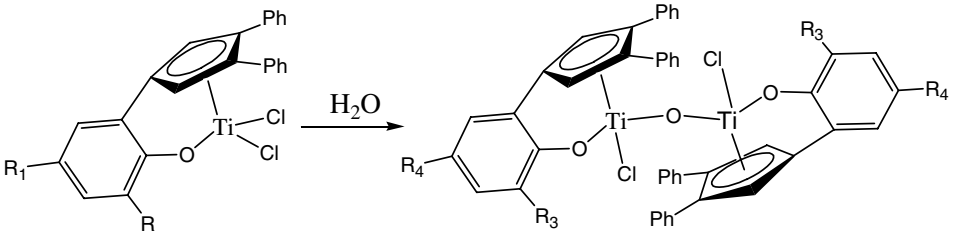
2.1. General comments

All non-hydrolytic procedures were carried out under a nitrogen atmosphere (ultra-high purity) using standard schlenk techniques [30]. Solvents were dried and distilled prior to use [31]. Polymerization grade ethene was further purified by passage through columns of 10 A molecular sieves and MnO. Al(^{i}Bu)$_3$, ^{n}BuLi and $TiCl_4$ were purchased from Aldrich. 2-(3, 4-diphenyl cyclopentadienyl)-4, 6-di-*tert*-butyl phenoxytitanium dichloride (**1**), 2-(3, 4-diphenyl cyclopentadienyl)-6-*tert*-butyl phenoxytitanium dichloride (**2**) [28], and $Ph_3C^+B(C_6F_5)^-$ [32–34] were prepared according to literature procedures. NMR spectra were measured using a Varian Unity-400 or Varian Mercury-300 NMR spectrometer. Hydrolysis reactions were carried out in air using commercial solvents without purification.

2.2. Preparation of {[η^5;η^1-2-(3,4-Ph_2Cp)-4,6-di-^{t}Bu-C_6H_2O]TiCl}$_2$O (**3**)

Complex **1** (100 mg, 0.185 mmol) was dissolved in CH_2Cl_2 (20 mL), the color of the solution changed slowly from red to yellow (Scheme 1). After 24 h, the solvent was removed to leave a yellow solid. Recrystallization from CH_2Cl_2:hexane (1:3) gave pure **3** as orange yellow crystals (88.3 mg, 93.0%). *Anal.* Calc. for $C_{62}H_{64}Cl_2O_3Ti_2$ (1023.81): C, 72.73; H, 6.30. Found: C, 72.67; H, 6.25%. ESI-MS, *m/z*: 927.6 $[M - {}^tBu - 3CH_2 + 2H]^+$, 814.4 $[M - 2{}^tBu - 2Cl - 2CH_2 + 3H]^+$, 701.4 $[M - 2{}^tBu - 2CO - 6CH_2 - 2Cl + 2H]^+$; MALDI-MS, *m/z*: 842.7 $[M - 2CO - 4CH_2 - 2Cl + 2H]$, 422.7 $[ligand]^+$. ^{1}H NMR ($CDCl_3$, 300 MHz; 298 K) δ 6.73–7.58 (m, 24H, Ph), 6.81 (d, $^4J_{H-H} = 3$ Hz, 2H, Cp), 4.49 (d, $^4J_{H-H} = 3$ Hz, 2H, Cp), 1.40 (s, 18H, Ph–^{t}Bu), 1.30 (s, 18H, Ph–^{t}Bu). ^{13}C NMR ($CDCl_3$, 75 MHz; 298 K) δ 171.8, 145.7, 143.8, 134.9, 133.4, 132.8, 131.3, 130.4, 130.3, 129.8, 129.6, 129.5, 128.5, 128.3, 128.2, 128.0, 126.6, 124.0, 122.8, 35.3, 35.1, 32.1, 29.9 ppm.

2.3. Preparation of {[η^5;η^1-2-(3,4-Ph_2Cp)-6-^{t}Bu-C_6H_3O]TiCl}$_2$O (**4**)



Complex **4** (100 mg, 0.207 mmol) was prepared in the same way as described above for the synthesis of **3** (Scheme 1). Pure **4** (86 mg, 91.2% was obtained as yellow solid); *Anal.* Calc. for $C_{54}H_{48}Cl_2O_3Ti_2$ (911.60): C, 71.15; H, 5.31. Found: C, 71.09; H, 5.27%. ESI-MS, *m/z*: 814.4 $[M - 2Cl - 2CH_2 + 1H]^+$, 701.4 $[M - 2CO - 4CH_2 - 2Cl - 2Me + 2H]^+$; MALDI-MS, *m/z*: 730.8 $[M - 2CO - 4CH_2 - 2Cl + 2H]^+$, 366.7 $[ligand]^+$. ^{1}H NMR ($CDCl_3$, 300 MHz; 298 K) δ 6.77–7.59 (m, 26H, Ph and 2H, Cp), 4.60 (d, $^4J_{H-H} = 3$ Hz, 2H, Cp), 1.29 (s, 18H, Ph–^{t}Bu). ^{13}C NMR ($CDCl_3$, 75 MHz; 298 K) δ 174.0, 143.7, 136.1, 134.4, 132.3, 131.5, 130.4, 130.1, 129.9, 129.8, 129.6, 128.7, 128.4, 128.3, 128.0, 127.0, 126.5, 125.9, 122.3, 35.0, 29.7 ppm.

2.4. X-ray structure determinations of *3*

Single crystals of **3** suitable for X-ray structural analysis were obtained from solution of CH_2Cl_2:hexane (V/V = 1/3). Diffraction data were collected at 293 K on a Bruker SMART-CCD diffractometer (graphite-monochromated Mo Kα-radiation: $\lambda = 0.71073$ Å). Details of the crystal data, data collections, and structure refinements are summarized in Table 1. The structure was solved by direct method [35] and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically and the hydrogen atoms were included in idealized position. All calculations were performed using the SHELXTL [36] crystallographic software packages.

2.5. Polymerization reactions

A dry 250 mL steel autoclave was charged with 70 mL of toluene, thermostated at desired temperature and saturated with ethene (1.0 bar). The polymerization reaction was started by injection of a mixture of catalyst and Al(^{i}Bu)$_3$ in toluene (5 mL) and a solution of $Ph_3C^+B(C_6F_5)_4^-$ in toluene (5 mL) at the same time.

Scheme 1. Synthetic procedure of complexes **3**–**4**.

Table 1
Crystal data and structural refinements details for **3**

Empirical formula	$C_{31}H_{32}ClO_{1.50}Ti$
Formula weight	511.92
Crystal system	monoclinic
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Space group	*C*2/*c*
a (Å)	24.863(5)
b (Å)	9.902(2)
c (Å)	23.726(6)
β (°)	106.540(5)
Volume (Å^3)	5599(2)
Z	8
D_c (g cm^{-3})	1.215
F(0 0 0)	2152
Absorption coefficient (mm^{-1})	0.423
Scan type	$\omega - 2\theta$
2θ Range (°)	$3.42 \leqslant 2\theta \leqslant 46.56$
Reflections collected	6354
Reflections unique (R_{int})	3983 (0.0381)
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	3983/7/312
Goodness-of-fit on F^2	0.917
Final *R* indices [$I > 2\sigma(I)$]	$R1 = 0.0522$, $wR_2 = 0.1155$
R indices (all data)	$R_1 = 0.1047$, $wR_2 = 0.1327$
Largest difference peak and hole (e Å^{-3})	0.355 and −0.281

The vessel was repressurized to needed pressure with ethene immediately and the pressure was kept by continuously feeding monomer. After 30 min, the polymerization was quenched by injecting acidified methanol [HCl (3 M):methanol = 1:1]. The mixture was stirred overnight and the polymer was collected by filtration, washed with water, methanol, and dried in vacuo.

3. Results and discussions

3.1. Synthesis and analysis of complexes 3 and 4

It has been found that complexes **1** and **2** are stable to air and moisture in solid state and can be left in air for several days without obvious change [28]. They also exhibit good thermostability and could be heated to about 200 °C without decomposition. However, complexes **1** and **2** can be easily hydrolyzed in solution to produce corresponding dimeric oxo-bridged complexes **3** and **4**, which can be obtained in high yields by dissolving **1** and **2** in wet solvent, such as CH_2Cl_2, toluene, and hexanes. Similar hydrolysis reaction for titanocene type complexes has been reported previously [37–39]. In some instances, stable polynuclear oxo-bridged species containing dimer, trimer and tetramer had been produced by aerobic oxidation [40] or hydrolysis processes [41–45]. In our case, only the dimeric hydrolytic product **3** or **4** has been obtained and no polynuclear oxo-bridged complex has been observed.

^{1}H and ^{13}C NMR spectra of **3** and **4** are obviously complicated than those of **1** and **2**, which could be attributed to that the dimeric oxo-bridged complexes **3** and **4** both adopt a chiral environment about Ti atom. For this reason, the two phenyl groups on the Cp ring and the two protons of the Cp group of **3** and **4** are inequivalent. As a result, the number of inequivalent C in ^{13}C NMR spectra of **3** and **4** is six more than that of complexes **1** and **2**, respectively. Due to steric repulsion between two units of the molecule, the ^{1}H NMR signal for one of the two protons shifts to high-field ($\delta = 4.49$ ppm for **3**, $\delta = 4.60$ ppm for **4**), while the signal for the other proton does not change very much compared to the Cp protons of complexes **1** and **2** [28] (6.81 ppm for **3**, the signal for **6** is mixed with the signals of the Ph protons). The coupling constant ($^4J_{H-H}$) of the two protons for **3** and **4** are both about 3 Hz.

3.2. Crystal structure of 3

The molecular structure of complex **3** was determined by single crystal diffraction analysis. The ORTEP drawing of the molecular structure is shown in Fig. 1. The selected bond lengths and angles are summarized in Table 2. The molecular structure consists of two {[η^5;η^1-2-(3,4-Ph_2Cp)-4,6-di-^{t}Bu-butyl-C_6H_2O]TiCl} units linked by Ti–O–Ti linkage. Selected bond lengths and angles for one unit will be used in subsequent discussions. The whole molecule adopts a C_2-symmetric structure. The geometry around titanium can be described as pseudo-tetrahedral, which is defined by a substituted cyclopentadienyl ring, a chloride atom, and two oxygen atoms (one is from the oxo-bridge, the other is from the phenoxy). The Cp(cent)–Ti1–O2 angle of 105.9° is slightly smaller than the one in **2**

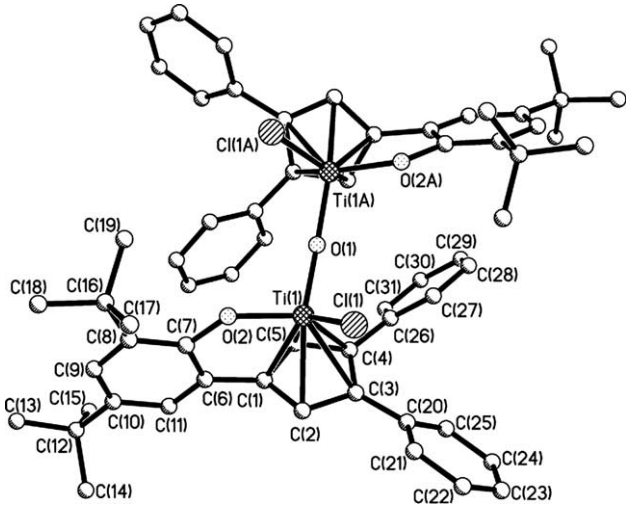


Fig. 1. Structure of complex **3**. (Thermal ellipsoids are drawn at the 30% probability level.)

Table 2
Selected bond lengths and angles for complex **3**

Ti(1)–O(1)	1.8125(9)
Ti(1)–C(1)	2.332 (4)
Ti(1)–C(3)	2.470(4)
Ti(1)–C(5)	2.309(4)
O(2)–C(7)	1.377(4)
C(1)–C(6)	1.473(5)
C(4)–C(26)	1.483(5)
Ti(1)–H(5)	2.861
O(1)–Ti(1)–O(2)	104.16(10)
Cp1(cent)–Ti(1)–O(1)	119.1
Ti(1)–Cp1(cent)–C(1)	87.1
C(1)–C(6)–C(7)	113.7(4)
C(7)–O(2)–Ti(1)	128.9(3)
Ti(1)–O(2)	1.842(3)
Ti(1)–C(2)	2.385(4)
Ti(1)–C(4)	2.396(4)
Ti(1)–Cl(1)	2.2607(15)

Ti(1)–H(2)	2.957
O(2)–Ti(1)–Cl(1)	106.58(10)
O(1)–Ti(1)–Cl(1)	102.48(11)
Cp1(cent)–Ti(1)–O(2)	105.9
C(6)–C(1)–Cp(cent)	169.3
C(6)–C(7)–O(2)	114.5(4)

(106.7°) [28], indicating similar sterically open features for **3** to complexes **1** and **2** as catalyst precursors. The Ti1–C_{ring} (av.) distance of 2.378 Å is slightly longer than the one in **2** 2.362 Å. The distances of Ti1–C2 2.384(5) Å and Ti1–C3 (2.470(4) Å) are longer than the one of Ti1–C5 (2.309(4)) and Ti1–C4 (2.396(4)), respectively, which could be obviously attributed to the sterical repulsion between the bulky ligands on the two Ti atoms. The phenolate plane – Cp plane dihedral angle is 86.0° and the (phenolate)C–C(ring) vector is bent 10.3° from the Cp ring plane. The corresponding data for **2** are 86.5° and 9.4°, reflecting more steric strain in **3** than in **2**. The Ti–O2 bond lengths of 1.842(3) Å is shorter than that in **2** (1.818(4) Å) and the Ti–O–C7 angles of 128.9(3)° is larger than the one in **2** (129.8(4)°), indicating less Ti–O double-bond character in complex **3** [17,46–48].

3.3. Ethene polymerization studies

Complexes **3** and **4** were studied as ethene polymerization catalysts and the results were summarized in Table 3. Upon activation with $Al(^iBu)_3$ and $Ph_3C^+B(C_6F_5)_4^-$, complexes **3** and **4** both show good catalytic activity for ethene polymerization, producing polyethylenes with moderate molecular weights and melting temperatures. The order of the catalytic activity for ethene polymerization under similar conditions (see run 2, 5 on Table 3) is **3** > **4**, which could be attributed to the nature of the substituents on the phenolate. As seen from the structures of complexes **3** and **4**, the electron-donating effect of the ^{t}Bu group at the *para* position of the phenolate would increase the catalytic activity of complex **3**. For both **3** and **4**, the catalytic activity increases with the increase in Al/Ti ratio and reaches the highest catalytic activities with the Al/Ti ratio about 40. Further increasing in the Al/Ti ratio results in decrease in the catalytic activity. Under the same conditions the catalytic activities for ethene polymerization of complexes **3** ($1.8–3.1 \times 10^6$ g polymer/mol Ti) and **4** ($1.3–2.3 \times 10^6$ g polymer/mol Ti) are roughly equal to those of their corresponding dichloride complexes **1** ($1.9–3.2 \times 10^6$ g polymer/mol Ti) and **2** ($1.3–2.0 \times 10^6$ g polymer/mol Ti) [28], which could be explained by that the catalytic active species produced during the polymerization from **1** and **2** should be the same as that produced from **3** and **4**.

4. Conclusions

Two new dimeric oxo-bridged cyclopentadienyloxochlorotitanium(IV) complexes **3** and **4** have been synthesized by hydrolysis of the corresponding dichlorides **1** and **2**. Structures of **3** and **4** have been confirmed by ^{1}H and ^{13}C NMR spectra and X-ray crystallography. When activated with $^iBu_3Al$ and $Ph_3C^+B(C_6F_5)_4^-$, complexes **3** and **4** exhibit reasonable catalytic activity for ethylene polymerization, producing polyethylenes with moderate molecular weights and melting temperatures.

Table 3
Summary of ethene polymerization catalyzed by complexes **3** and **4** (activated by $Ph_3C^+[B(C_6F_5)_4]^-$)[a]

Run	Catalyst	Al:Ti	T (°C)	Amount of polymer (g)	Activity[b]	$M\eta$[c] $\times 10^{-4}$	T_m (°C)[d]

5. Supplementary data

^{1}H and ^{13}C NMR spectra for **3** and **4** are available in supplementary data. The Crystallographic data for **3** has been deposited with Cambridge Crystallographic Data Center as supplementary publication number CCDC: 225984. Copies of this information can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail deposit@ccdc.cam.ac.uk).

nitrogen atmosphere. The mixture was heated at 80 °C under nitrogen atmosphere for 16 h. The reaction mixture was hydrolyzed slowly with 100 ml of degassed ice water and then concentrated NH_4OH was added to become pH 9 and to precipitate $Al(OH)_3$. After filtration, a yellow solid was obtained by adding 20 ml of an aqueous HPF_6. The precipitation was filtered, and dried in vacuo. The dried crude product was treated with 50 ml of CH_2Cl_2. The CH_2Cl_2 solution was filtered and concentrated to 5 ml by evaporation. Then a large amount of ether was added to give yellow microcrystals (*o*-complex: 0.881 g, 20.4%. *m*-complex: 1.02 g, 23.6%. *p*-complex: 0.915 g, 21.2%.). The insoluble product to CH_2Cl_2 was treated with a large amount of acetone until all yellow residue was dissolved and then filtered. The acetone solution was evaporated to give yellow microcrystals (*o*-complex: 3.15 g, 47.6%. *m*-complex: 2.35 g, 35.4%. *p*-complex: 2.11 g, 31.8%.). *Anal*. mononuclear *o*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 5.14(5H), 6.15–6.44(4H), 6.81–8.16(10H). FAB Mass 351 ([CpFe(*o*-terphenyl)]$^+$). Dinuclear *o*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 4.95(10H), 6.04(4H), 6.21(6H), 7.78(2H), 8.00(2H). FAB Mass 617 ([[(CpFe)$_2$(*o*-terphenyl)]$^{2+}$-PF_6^-]$^+$). Mononuclear *m*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 4.88(5H), 6.54–6.83(4H), 7.26–7.91(10H). FAB Mass 351 ([CpFe(*m*-terphenyl)]$^+$). Dinuclear *m*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 4.99(10H), 6.38(2H), 6.47(4H), 6.78(4H), 7.78(1H), 8.04(2H), 8.16(2H). FAB Mass 617 ([[(CpFe)$_2$(*m*-terphenyl)]$^{2+}PF_6^-$]$^+$). Mononuclear *p*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 5.12(5H), 6.83–7.14(4H), 7.61–7.90(10H). FAB Mass 351 ([CpFe(*p*-terphenyl)]$^+$). Dinuclear *p*-complex: ^{1}H NMR(δ/ppm, CD_3CN) 4.98(10H), 6.38(2H), 6.47(4H), 6.74(4H), 8.03 (4H). FAB Mass 617 ([[(CpFe)$_2$(*p*-terphenyl)]$^{2+}PF_6^-$]$^+$).

2.2. X-ray crystal structural analyses

Single crystals for X-ray crystallography of mononuclear and dinuclear *o*-, *m*-, and *p*-terphenyl complexes except for mononuclear *m*-isomer were obtained by the following method. The mononuclear complexes were dissolved in dichloromethane, while the dinuclear complexes were in acetone and then they were put in the hexane atmosphere at −15 °C. After several weeks single crystals for X-ray structural analysis were obtained as yellow column-shape crystals. They were cut so that the longest side was less than 0.5 mm. All measurements were made on Mac Science DIP 2030 imaging plate area detector using graphite-monochromated Mo Kα radiation. The cell parameters and intensities for the reflection were estimated by program package of Mac DENZO [12]. The crystal structures were solved by direct methods and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically, while hydrogen atoms were refined isotropically. All calculations were performed with the CrystalStructure crystallographic software packages of Rigaku and Molecular Structure Corporation [13]. Table 1 summarizes crystallographic data and experimental details.

2.3. ^{57}Fe Mössbauer spectroscopic measurements

A ^{57}Co(Rh) source moving in a constant-acceleration mode was used for ^{57}Fe Mössbauer spectroscopic measurements. ^{57}Fe Mössbauer spectra at 78 K were obtained by using a Wissel spectrometer. The ^{57}Fe Mössbauer parameters were obtained by least-squares fitting to Lorentzian peaks. The isomer shift values are referred to metallic iron.

Table 1
Details of crystal structure determinations

[a] $R = \sum\|F_o| - |F_c\|/\sum|F_o|$.
[b] $R_w = (\sum w(|F_o| - |F_c|)^2/\sum w|F_o|^2)^{1/2}$.

3. Results and discussion

3.1. Syntheses and separations

We have synthesized the present arene complexes by ligand exchange reaction between ferrocene and terphenyl [4]. The reaction products include mononuclear and dinuclear complexes. Total yield changes depending on isomer, which is attributable to the difference in melting point among *o*-(58–59 °C), *m*-(86–87 °C), and *p*-terphenyl(213–216 °C). The mononuclear and dinuclear products were isolated by using the difference in solubility; mononuclear complex is soluble to dichloromethane, while dinuclear complex is not soluble to dichloromethane but soluble to acetone. The difference in solubility is maybe caused by the difference in charge between monocation and dication. The molar ratio of the mononuclear to the dinuclear complex was dependent on the isomer: i.e., 3:7 for *o*-derivative, while 2:3 for *m*- and *p*-derivatives. The trinuclear complex is not obtained, maybe because of large decrease in electron density on the third benzene ring.

3.2. X-ray crystallography

Figs. 1 and 2 show ORTEP drawings for mononuclear *o*- and *p*-terphenyl complex cations, respectively. It can easily be seen that the $FeCp^+$ is introduced to the central benzene ring in both isomers. Figs. 3–5 show ORTEP drawings for dinuclear *o*-, *m*-, and *p*-terphenyl complex cations, respectively. It can also easily be seen that the two $FeCp^+$ are introduced to the terminal benzene rings in all isomers. Figs. 1–5 also reveal that all benzenes are not coplanar. The Cp ring has very anisotropic thermal ellipsoids especially in dinuclear *m*- and *p*-terphenyl complex cations. This suggests the rotation of Cp ring around 5-fold axis.

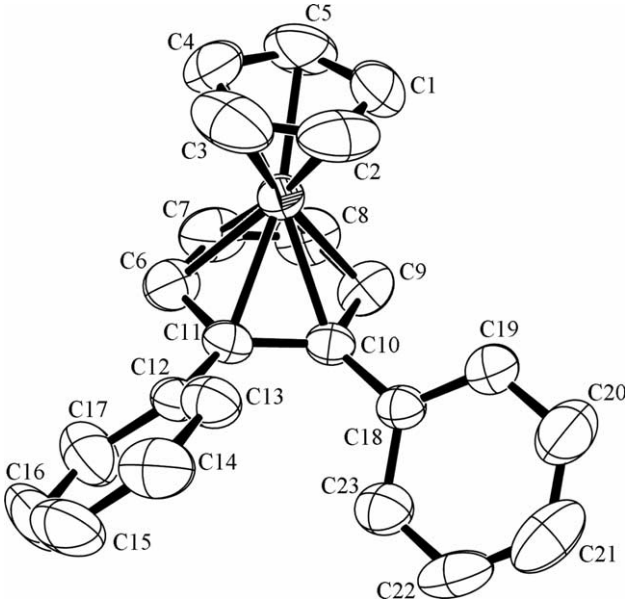

Fig. 1. ORTEP drawing of mononuclear *o*-terphenyl complex cation with 50% probability drawing ellipsoids.

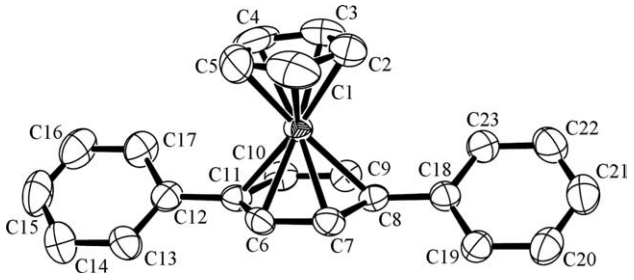

Fig. 2. ORTEP drawing of mononuclear *p*-terphenyl complex cation with 50% probability drawing ellipsoids.

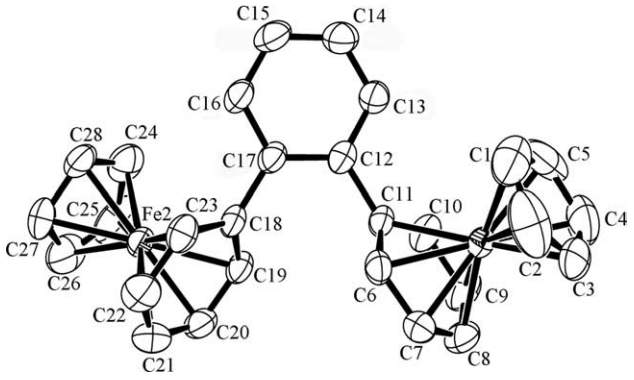

Fig. 3. ORTEP drawing of dinuclear *o*-terphenyl complex cation with 50% probability drawing ellipsoids.

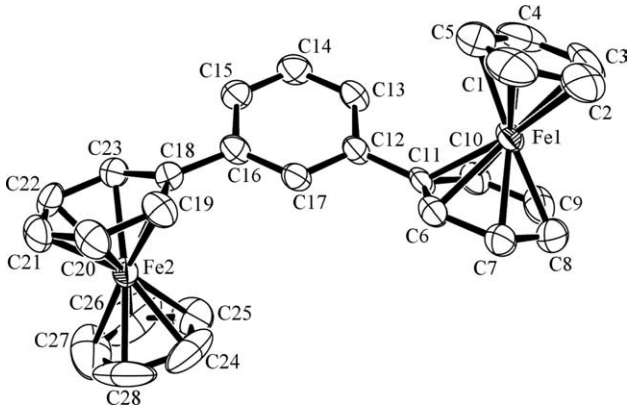

Fig. 4. ORTEP drawing of dinuclear *m*-terphenyl complex cation with 50% probability drawing ellipsoids.

Crystallographic data are listed in Table 1, and selected bond distances and angles are summarized in Table 2. The average C–C distance in the central benzene ring is longer by 0.02–0.03 Å than those of terminal benzene rings in the mononuclear *o*- and *p*-terphenyl complexes. The average C–C distances in the terminal benzene rings are longer by 0.01–0.02 Å than that of central benzene ring in the dinuclear *o*-, *m*-, and *p*-terphenyl

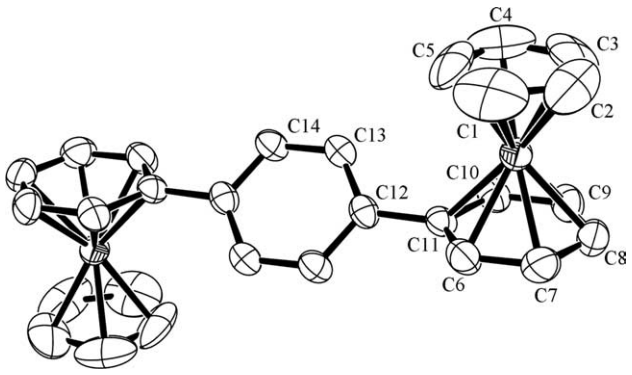

Fig. 5. ORTEP drawing of dinuclear *p*-terphenyl complex cation with 50% probability drawing ellipsoids.

complexes. The change in C–C distance by coordination is more drastic in mononuclear complexes than in dinuclear complexes.

The dihedral angles between the neighboring benzene rings are also summarized in Table 2. There is not significant difference in the angle between mononuclear and dinuclear terphenyl complexes in each isomer. The angles for mononuclear and dinuclear *o*-terphenyl complexes are apparently larger than those of the corresponding mononuclear and dinuclear *m*- and *p*-complexes, suggesting ortho effect. The dihedral angles are 52.61° and 52.02° for mononuclear *o*-complex and 51.18° and 52.51° for dinuclear *o*-complex. This is interesting because these values approach to the average value of those of the metal-free *o*-terphenyl (62.1° and 42.5°) [14]. The difference of dihedral angles in metal-free *o*-terphenyl was explained by the difference in intermolecular interactions in the lattice [14]. We thought that the packing effect around the present *o*-terphenyl complex cations and then the interaction of the cation with its surroundings become more symmetric.

Dinuclear *o*- and *m*-complexes contain acetone molecule as solvent molecule, while dinuclear *p*-complex does not. As a result, two irons are not equivalent for *o*- and *m*-complexes, while equivalent for *p*-complex.

3.3. ^{57}Fe Mössbauer spectroscopy

^{57}Fe Mössbauer spectroscopy was applied to know the electronic state of the present complexes. As the dinuclear *o*-, *m*-terphenyl complexes include solvent molecule, the measurement was done at 78 K by using single crystals. Typical ^{57}Fe Mössbauer spectrum is shown in Fig. 6. A ferrocene-like single doublet is seen. All other complexes also showed the similar single doublet. The ^{57}Fe Mössbauer parameters (isomer shift (IS) and quadrupole splitting (QS)) are summarized in Table 3. The Mössbauer parameters are similar to each other and to [{BenzeneFeCp}$^+$][PF_6^-]. The decrease in QS value of the present arene complexes(1.65–1.75 mm s^{-1})

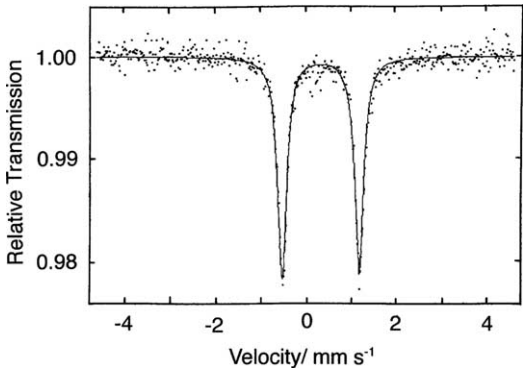

Fig. 6. ^{57}Fe Mössbauer spectrum of dinuclear *o*-terphenyl complex at 78 K.

Table 3
^{57}Fe Mössbauer parameters at 78 K

Sample	IS (mm s^{-1})	QS (mm s^{-1})	Γ (mm s^{-1})
Mononuclear *o*-complex	0.55	1.71	0.33

C–C(central) (Å)	1.407(4)	1.392(2)	1.394(3)	1.416(3)	1.398(3)
C–C(terminal) (Å)	1.386(4)	1.410(2)	1.402(3)	1.385(3)	1.405(3)

compared to ferrocene (2.4 mm s^{-1}) is explained by the interaction of the e_{2g} d orbitals with the ring orbitals [8]. Although the X-ray crystal structural analyses showed that the two iron sites are slightly different in the dinuclear *o*- and *m*-terphenyl complexes, the slight difference in the site does not appear in the Mössbauer spectra. And the difference between the mononuclear and the dinuclear complexes does not significantly appear in the ^{57}Fe Mössbauer spectra. Close inspection, however, reveals that *o*-terphenyl complexes show slightly larger QS value.

4. Conclusion

We succeeded to obtain mononuclear and dinuclear arene complexes of *o*-, *m*-, and *p*-terphenyl and to separate them by using the difference in solubility. We confirmed that $FeCp^+$ was introduced to the central benzene in the mononuclear complexes, while they were introduced to the terminal benzenes in the dinuclear complexes.

Acknowledgments

We thank Dr. T. Oda of Hiroshima University for supporting X-ray structural analysis.

Appendix A. Supplementary data

Crystallographic data for the structural analysis have been deposited at the Cambridge Crystallographic Data Centre, CCDC 249481–249485. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http//www.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.07.002.

early transition metal derivatives [12], but more recent work [13], including this paper, addresses the disparity [14].

Phenoxides are anionic oxygen-donor ligands that often bridge metal centers and typically bind hard metal centers in relatively high oxidation states. In transition metal compounds requiring monodentate phenoxides, one method to prevent bridging by the electron-rich oxygen donors, is to furnish the ligand with bulky substituents at the 2- and 6-positions. Our laboratory has demonstrated an alternative approach, namely that the bridging propensity may be reduced by extensive fluorination of the phenyl ring as in OC_6F_5 (OAr^F) or $OC_6H_3(CF_3)_2$ (OAr′) [13]. This modification is an electronic approach, instead of a steric one, and thus results in metal centers that may still bind to other ligands for catalysis or more complex structure development. All monodentate phenoxide ligands are simple X-type ligands in the MLXZ classification system [15], but their steric and electronic properties differ significantly. Herein we describe four more compounds with monodentate fluoroaryloxides whose simple OC_6H_5 analogs have not been reported in all cases. These compounds serve to develop further comparisons of OPh and OAr^F as ligands as well as increase the number of known and structurally characterized monodentate M–OAr^F and M–OAr′ linkages.

2. Experimental

2.1. General considerations

All studies were carried out at room temperature on a Schlenk line or in a nitrogen- or argon-filled glovebox. For solvents dried in stills, methylene chloride and deuterated methylene chloride were refluxed over CaH_2. THF and hexane were refluxed over potassium and toluene was refluxed over sodium. All solvents were refluxed under nitrogen or argon. Some work was also done with solvents (hexanes, CH_2Cl_2, and toluene) dried in a nitrogen-filled MBraun SPS (solvent purification system) using Al_2O_3. Celite was dried overnight in vacuo while heated to 125 °C with an oil bath. $TlOC_6F_5$ ($TlOAr^F$) and $TlOC_6H_3(CF_3)_2$ (TlOAr′) were prepared according to our previously reported procedures [13]. [(Ph_3P)Au(OPh)] was prepared from [(Ph_3P)AuCl] and KOPh [16]. All other reagents were obtained commercially and were not purified further. NMR spectra were measured on a Varian 300 MHz, Bruker 300 or 400 MHz spectrometer. UV–Vis data were recorded with a Varian Cary 50 spectrometer. ^1H and ^{13}C chemical shifts were referenced to $(CH_3)_4Si$ via the resonance of residual protiosolvent (^1H) or the ^{13}C resonance of the solvent. ^{19}F shifts were referenced to external $CFCl_3$. ^{31}P shifts were referenced to internal $(MeO)_3PO_4$ or external 85% H_3PO_4. Microanalyses were performed by H. Kolbe Microanalytisches Laboratorium, Mülheim an der Ruhr, BRD.

2.2. Synthesis of $[(Ph_3P)_2Ni(OAr^F)_2]$ (**1a**)

In a 25 ml round bottom flask a portion of $TlOAr^F$ (0.3014 g, 0.7780 mmol) was dissolved in ~10 ml CH_2Cl_2. $(PPh_3)_2NiCl_2$ (0.2529 g, 0.3866 mmol) was added to the reaction mixture. The reaction mixture turned a dark red-brown color and a white precipitate also evolved. The reaction was left to stir overnight at room temperature, and was filtered through Celite to remove TlCl. The mixture was concentrated in vacuo and recrystallized from CH_2Cl_2 and hexanes (1:1). Dark brown crystals were collected in 56% yield (0.2039 g). ^1H NMR, (δ, ppm, CD_2Cl_2) 6.780 (t, 6 H, *para*, $^3J = 7.38$ Hz), 7.347 (t, 12H, *ortho*, $^3J = 7.83$ Hz), 7.696 (t, 12H, *meta*, $^3J = 7.38$ Hz). ^{19}F {^1H} NMR, (δ, ppm, CD_2Cl_2) −153.99 (*o*, m), −171.04 (*m*, m), −177.47 (*p*, m). UV–Vis (CH_2Cl_2) [λ_{max}, nm (ε_M, $cm^{-1}\,M^{-1}$)] 456.0 (3698). *Anal.* Calc. for $C_{48}H_{30}O_2F_{10}P_2Ni$: C, 60.73; H, 3.19. Found: C, 60.68; H, 3.21%.

2.3. Synthesis of $[(PPh_3)_2Ni(OAr')_2]$ (**1b**)

In a 25 ml round bottom flask a portion of TlOAr′ (0.3003 g, 0.7744 mmol) was dissolved in ~10 ml CH_2Cl_2. $(PPh_3)_2NiCl_2$ (0.2535 g, 0.3872 mmol) was added to the reaction mixture. The reaction mixture turned a dark red-brown color and a white precipitate also evolved. The reaction was left to stir overnight at room temperature, and was filtered through Celite to remove TlCl. The mixture was concentrated in vacuo and recrystallized from CH_2Cl_2 and hexanes (1:1). Dark brown crystals (0.3629 g) were collected in 90% yield. ^1H NMR, (δ, ppm, CD_2Cl_2) 6.350 (br, 2H, *para*-OAr′), 7.211 (br, 4H, *ortho*-OAr′), 7.260 (t, 12H, *meta*, $^3J = 2.85$ Hz), 7.680 (m, 18H, *ortho* + *para*). ^{19}F {^1H} NMR, (δ, ppm, CD_2Cl_2) −63.27 (CF_3, s). UV–Vis (CH_2Cl_2) [λ_{max}, nm (ε_M, $cm^{-1}\,M^{-1}$)] 446.0 (2905), *Anal.* Calc. for $C_{52}H_{36}O_2F_{12}P_2Ni$: C, 59.97; H, 3.48. Found: C, 59.77; H, 3.41%.

2.4. Synthesis of $[(COD)Pt(OAr^F)_2]$ (**2**)

A portion of $[(COD)_2PtCl_2]$ (151.5 mg, 0.4049 mmol) was dissolved in 5 mL of CH_2Cl_2 and 2 equivalents of $KOAr^F$ (179.9 mg, 0.8098 mmol) in 5 mL of THF were added. The solution immediately turned pale yellow and a white precipitate (presumably KCl) was observed. The solution was allowed to stir overnight and then the precipitate was removed via filtration through Celite. The solution was concentrated to dryness in vacuo, and the crude very pale yellow product was recrystallized from CH_2Cl_2 and hexanes. X-ray quality crystals

were grown from the same mixture. Recrystallized yield 167 mg (61.6%). ^{1}H NMR (δ, ppm, CD_2Cl_2) 2.714 (q, CH_2, 4H, $^3J_{HH} = 8.0$ Hz), 3.262 (m, CH_2, 4H), 5.759 (t, CH, 4H, $^3J_{HH} = 28.8$ Hz). ^{13}C {^{1}H} NMR, (δ, ppm, CD_2Cl_2) 31.29 (s, CH_2), 100.97 (t, CH, $^1J_{CPt} = 76.7$ Hz). ^{19}F {^{1}H} NMR, (δ, ppm, CD_2Cl_2) −158.25 (*o*, d, $^3J_{FF} = 21.2$ Hz), −164.55 (*m*, t, $^3J_{FF} = 21.5$ Hz), −158.25 (*p*, t of t, $^3J_{FF} = 15.2$, 6.2 Hz). UV–Vis (CH_2Cl_2) [λ_{max}, nm (ε_M, $cm^{-1}\,M^{-1}$)] 233 (15200), 280 (8660). *Anal.* Calc. for $C_{20}H_{10}O_2F_{10}Pt$: C, 35.89; H, 1.81; F, 28.38. Found: C, 35.91; H, 1.79; F, 28.42%.

2.5. Synthesis of [(Ph$_3$P)Au(OAr^F)] (3)

A portion of [(Ph_3P)AuCl] (100.0 mg, 0.2021 mmol) was dissolved in 5 mL of CH_2Cl_2. One equivalent of $KOAr^F$ (44.9 mg, 0.2021 mmol) was dissolved in 2 mL of THF and the solutions mixed together. No obvious color changes were observed. After stirring for several hours, the solvents were removed in vacuo and the crude product dissolved in 5 mL of CH_2Cl_2 and filtered through Celite to remove presumed KCl. A saturated solution of the product in CH_2Cl_2 (~1 mL) was prepared and layered with an equal volume of hexanes to yield colorless crystalline material, including crystals suitable for X-ray diffraction. Recrystallized yield 60 mg (46.2%). ^{1}H NMR (δ, ppm, CD_2Cl_2) 7.53 (br, Ph). ^{13}C {^{1}H} NMR, (δ, ppm, CD_2Cl_2) 120.14 (s, *ipso*-OC_6F_5), 128.54 (s, *m*-*C*F), 128.99 (s, *p*-*C*F), 129.41 (s, *o*-*C*F), 129.82 (d, *m*, *C*H, $^1J_{CP} = 12.1$ Hz), 132.63 (d, *p*, *C*H, $^1J_{CP} = 12.1$ Hz), 134.72 (d, *o*, *C*H, $^1J_{CP} = 13.61$ Hz). ^{19}F {^{1}H} NMR, (δ, ppm, CD_2Cl_2) −164.65 (*o*, m,), −168.89 (*m*, m,), −180.10 (*p*, m). ^{31}P (δ, ppm, CD_2Cl_2) 24.61. UV–Vis (CH_2Cl_2) [λ_{max}, nm (ε_M, $cm^{-1}\,M^{-1}$)] 236 (30,200), 268 (4460), 276 (3540). *Anal.* Calc. for $C_{24}H_{15}OF_6PAu$: C, 44.89; H, 2.35; F, 14.79. Found: C, 44.97; H, 2.28; F, 14.67%.

2.6. X-ray crystallography

A summary of crystal data, details of data collections and refinement parameters for all compounds are given in Table 1. X-ray diffraction data were collected using Mo Kα radiation ($\lambda = 0.71073$ Å) on a Bruker SMART APEX CCD (**1a**, **1b**, **2**) and a Siemens P4/CCD (**3**) diffractometers [17]. Space groups were determined through inspection of systematic absences (**1a**, **1b**) and intensity statistics (**2**, **3**). All data were corrected for absorption by SADABS [18] The structures were solved using direct methods or the Patterson function and difference map techniques, and were refined by full-matrix least squares procedures on F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. The H atoms in **1a** and **2** were found from the F-map and refined with isotropic thermal parameters. In **1b** and **3** the H atoms were treated as idealized contributions. All software and sources of scattering factors are contained in the SHELXTL program package [19].

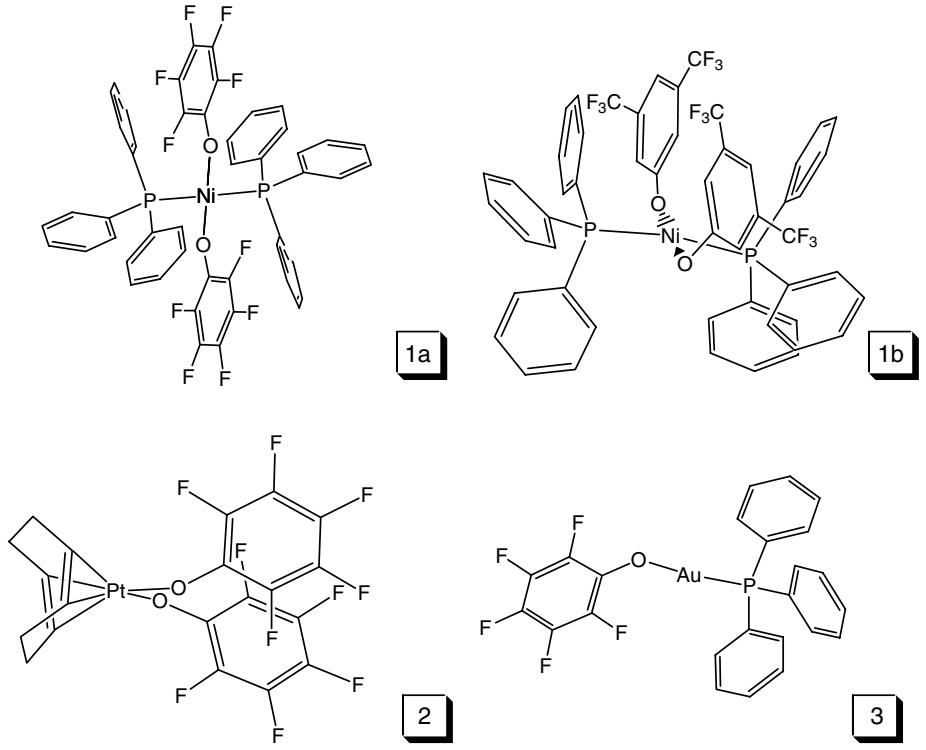
3. Results and discussion



The four compounds whose crystal structures are reported herein are shown in Scheme 1. The compounds add to the library of monodentate fluorinated aryloxide compounds reported by our group [13] and others. Extensive structural and spectroscopic studies of the $[Co(OAr^F)_4]^{2-}$ and $[Cu(OAr^F)_4]^{2-}$ anions in comparison with the well-known $[CoCl_4]^{2-}$ and $[CuCl_4]^{2-}$ anions demonstrated that the pentafluorophenoxide ligand generates a similar but slightly stronger ligand field than Cl^-, consistent with qualitative expectations for the more electronegative oxygen ligand. Attempts to make $[M(OPh)_4]^{2-}$ by analogous routes with perhydro OC_6H_5 led to exclusive formation of $[(PhO)_2M(\mu\text{-}OPh)_2M(OPh)_2]^{2-}$ (M = Co, Cu) [13] anions with bridging phenoxide ligands. These results suggested that highly electronegative substituents on the aryloxide ring reduce the electron density at the metal center and decrease the bridging propensity of the aryloxide oxygen atom. Described herein are further investigations of the late transition metals with these highly fluorinated aryloxide ligands and the effects of reduced electron density on compound stability.

3.1. Synthesis

Successful synthesis of isolable metal–phenoxide compounds results from control of the strongly nucleophilic character of the oxygen donor atom. Many different strategies have been used to prevent polymerization through bridging aryloxides or reduction of the metal center. The most common approach is incorporation of the aryloxide into a chelate ring (e.g., salen, salicylate, quinolate) or a macrocycle (calixarene). Table 2 contains the results of several searches in the Cambridge Structural Database V5.25 (CSD) [20] to put into context the compounds discussed herein. These values represent the crystallographically characterized subset of known compounds and are therefore not an exhaustive survey of all known compounds. They provide a quantitative picture of the relative distribution of different types of compounds in the literature.

3.1.1. Nickel

Nickel aryloxide bonds are typically prepared with chelating ligands, e.g., salen, as shown in Table 2, or additional soft and somewhat π-accepting ligands in the coordination sphere to balance the powerful donation from the aryloxide, with phosphines being the most common. Interestingly, a survey [20] of structurally characterized $[(Ph_3P)_2NiX_2]$ compounds (27 examples) reveals no compounds with strongly Lewis basic X^- ligands (F^-, CH_3^-) or oxygen donor atoms. Instead softer ligands with π-acceptor character and/or sulfur donor atoms are found with such electron rich ligands. Nickel phosphine complexes with hard ligands have more electron donating phosphines as in $[(Me_3P)_2Ni(o\text{-}OC_6H_4\text{-}Cl)_2]$ [21], $[(Me_3P)_2Ni(OPh)(Me)]$ [22], $[(Et_3P)_2Ni(C_5F_4N)(OPh)]$ [23], $[(Me_3P)_2NiMe(OAr^F)]$

Scheme 1.

[a] Numbers in parentheses are estimated deviations of the last significant.

[24], $[(Me_3P)_2Ni(OAr)_2]$ [25], and *trans*-$[(Bz_3P)_2NiH(OPh)]\cdot HOPh$ [26]. More rarely nickel–aryloxide linkages are found with other strongly electron donating ligands as observed in $[(Cp^*)(Et_3P)Ni(p\text{-}OC_6H_4Me)]$ [27] and $[(py)_3Ni(2,4,6\text{-}OC_6Cl_3H_2)_2]$ [28]. Nickel–aryloxide linkages have also been prepared with chelating O,P-ligands that possess both hard and soft donor atoms [29–31]. Usually the phenoxide is a monodentate ligand but a few examples of bridging phenoxides have been studied with allyl ligands such as $[Ni(\eta^3\text{-allyl})(\mu_2\text{-OAr})]_2$ in diene polymerization [32–34] and bridging phenoxide compounds have also been stabilized by the multidentate Klaui ligand [35].

The present report addresses the effect of fluorination in comparisons of OAr^F and OAr′ versus OPh and O-*m*-$C_6H_3(CH_3)_2$ complexes. Toward that end only a handful of nickel compounds with fluoroaryloxide ligands have been reported previously including the anion [36] $[Ni_2(C_6F_5)_4(\mu_2\text{-}OAr^F)_2]^{2-}$ and the neutral species $[Ni(\eta^3\text{-allyl})(\mu_2\text{-}OAr^F)]_2$ and $[Ni(\eta^3\text{-allyl})(\mu_2\text{-}OAr')]_2$ which were studied as diene polymerization activators [32]. The polymeric $[Ni(OAr^F)_2]_\infty$ has also been reported [37,38].

Simple reaction of $[(Ph_3P)_2NiCl_2]$ with the appropriate TlOAr reagent yielded compounds **1a** and **1b** as brown crystalline compounds. Under the same conditions, reaction between $[(Ph_3P)_2NiBr_2]$ and TlOAr led to insoluble materials. It has been previously reported that $[(Ph_3P)_2NiCl_2]$ compounds are sensitive to reduction to Ni(I) with strong nucleophiles such as $[NR_2]^-$ and it may be that Ni(II) compounds with less electronegative halides are more susceptible to such reduction under nucleophilic attack [39]. Too strongly basic ligands may lead to Ph_3P dissociation and subsequent decomposition or reduction of Ni(II) to Ni(I) or Ni(0). A similar sensitivity for **1a** and **1b** to that previously observed for $[(Ph_3P)_2NiCl_2]$ in CH_2Cl_2 [40–42] and $CHCl_3$ [43] was noted. Attempts to synthesize these compounds in THF, however, by methods analogous to those described below for CH_2Cl_2 were unsuccessful and led to colorless solutions with orange-brown precipitates. $[(Ph_3P)_2NiCl_2]$ has been isolated in both tetrahedral [44–47] (blue-green) and square-planar [46,48,49] (deep red) forms but no evidence for a tetrahedral form of **1a** or **1b** has been observed. The square planar form of $[(Ph_3P)_2NiCl_2]$ has been characterized only in the presence of CH_2Cl_2 or $ClCH_2CH_2Cl$ whereas crystals of the tetrahedral isomer were prepared from neat ethanol. Some Ni(II) compounds exhibit a tetrahedral form in non-coordinating solvents and an octahedral form in donor solvents such as DMF [50] or DMSO [43] in which solvent molecules are bound in two of six coordination sites. Compounds **1a** and **1b** are infinitely stable in the solid state but the orange-brown CH_2Cl_2 or acetone solutions turn pale-yellow over time, the latter much more rapidly. A time-dependent UV–Vis study of **1b** in CH_2Cl_2 showed only decay of the **1b** absorbances and no new colored species (Supplementary Figure 1).

Attempts to prepare the non-fluorinated analogs of **1a** and **1b** were unsuccessful. Reaction of $[(Ph_3P)_2NiCl_2]$ with either KOPh or TlOPh in THF led to pale yellow or yellow-orange solutions similar to the results of decomposition of **1a**. These results could indicate reduction of Ni to Ni(I) ($[(Ph_3P)_3NiCl]$ is yellow, for example) or Ni(0), but no clean products have been isolated. Reaction of $[(Ph_3P)_2NiCl_2]$ with TlOPh in CH_2Cl_2 led to insoluble orange powders. The insoluble orange powders could be a reduced Ni species or a polymeric Ni(II) compound formed by loss of phosphine. Two equivalents of KO–*m*-$C_6H_3(CH_3)_2$ when reacted with $[(Ph_3P)_2NiCl_2]$ produced copious amounts of an insoluble brown/tan powder and yellow solution. These observations suggest that the formation of Ni–OAr bonds in **1a** and **1b** relies on the electron-withdrawing properties of OAr^F and OAr′ to be stable on a $[(Ph_3P)_2Ni]^{2+}$ center. The formation of **1a** and **1b**, themselves somewhat unstable in solution, is clearly made possible by the fluorination of the aryloxide rings, in the absence of which, soluble Ni(II) compounds are not obtained.

3.1.2. Platinum

Reaction of $[(COD)PtCl_2]$ with two equivalents of $KOAr^F$ in THF cleanly afforded $[(COD)Pt(OAr^F)_2]$ with no sign of Pt metal formation. (Use of thallium reagents was avoided in the platinum and gold chemistry because heterometallic M–Tl species sometimes have resulted instead of thallium halide precipitation [51].) Platinum bis(aryloxide) complexes of the form $[L_2Pt(OAr)_2]$ are relatively rare [52], with mono(aryloxides) $[L_2Pt(OAr)X]$ being more common. Platinum(II) aryloxide compounds summarized in Table 2 follow some of the same trends as Ni(II) species, although there are far fewer of the heavier congener because Pt(II) preferentially binds heavier chalcogenides and this type of compound has been studied more frequently. Consistent with this preference for softer ligands is the much greater fraction of phosphine-bearing compounds for Pt versus Ni. Of the 14 Pt–OAr compounds that have neither a phosphine nor a *O*,*N* chelate ring, only 5 do not have the phenoxide involved in any chelate ring. There are two L_2PtX_2 cases, [(bpy)Pt(OPh)Me] [53] and $[(\eta^3\text{-}Me_2N\text{-}C_6H_4\text{-}CHCH_2)Pt(OAr^F)Cl]$ [54] and one example each of $[L_3PtX]^+$, $[(terpy)Pt(3,4\text{-}OC_6H_3Me_2)]BF_4$, [55] and $[LPtX_3]^-$, $(Et_4N)[Pt(C_6F_5)_2(CO)\{p\text{-}OC_6H_4(NO_2)\}]$ [56], and one Pt(IV) species, $[(bpy)Pt(Me)_2I(OPh)]$ [53].

Conspicuously absent are terminal platinum aryloxides with π-accepting ligands as demonstrated in **2**. The most similar known compound to **2** is the catecholate derivative $[(COD)Pt(O_2C_6H_4)]$ [57]. No report existed of $[(COD)Pt(OPh)_2]$ prior to our work and attempts to make $[(COD)Pt(OPh)_2]$ by a route analogous to **2** led

to black-brown precipitates, suggestive of Pt reduction. These observations suggest that an electron-withdrawing aryloxide such as OAr^F is required to stabilize Pt–OAr linkages in the absence of phosphines or chelates and prevent ligand loss (COD) and subsequent metal reduction. Platinum compounds with OAr^F as a ligand are also exceedingly rare [54,56,58,59].

3.1.3. Gold

Synthesis of $[(Ph_3P)Au(OAr^F)]$ (**3**) was achieved via the straightforward metathesis of $[(Ph_3P)AuCl]$ with $KOAr^F$ at room temperature. No evidence of gold reduction was observed. Compounds with gold(I)–oxygen bonds are relatively fewer in the literature compared to gold(I)–phosphorous or gold(I)–sulfur because of the relative hardness of oxygen ligands and the demonstrated preference of gold for softer chalcogenide ligands [60]. Only a few gold complexes with phenoxide ligands have been reported in the literature [12,61], and the data in Table 2 show only seven crystallographically characterized species with acyclic Au–O–Ar linkages, six containing Au(I) [62–66] and one with Au(III) [67]. Each of these Au(I) examples has a tertiary phosphine *trans* to the aryloxide ligand. The perhydro derivative $[(Ph_3P)Au(OPh)]$ has been reported [16] but not characterized with X-ray diffraction or UV–Vis spectroscopy.

3.2. Structural characterization

There are only six crystallographically characterized compounds [20] with $[P_2NiO_2]$ coordination sphere. Among these, five compounds have chelating ligands and one is an octahedral compound with two bidentate acetylacetonate-type ligands.

The nickel compounds $[(Ph_3P)_2Ni(OAr^F)_2]$ (**1a**) and $[(Ph_3P)_2Ni(OAr')_2]$ (**1b**) both contain square-planar nickel centers with *trans* Ph_3P ligands. Square planar $[(Ph_3P)_2NiX_2]$ complexes are more rare than tetrahedral isomers, but not unknown. The nickel atom in **1a**, shown in Fig. 1, sits on a center of inversion such that one half of the molecule is in the asymmetric unit. Selected distances and angles are listed in Table 3. The Ni–PPh_3 distance is well within the range of other four-coordinate Ni(II)–PPh_3 bond lengths. In a search of the Cambridge structural database (CSD) V5.25 [20], 85 such compounds were found with an average Ni–P bond length of 2.22(5) Å. The angles around Ni (Table 3) are virtually 90/180°. The only crystallographically characterized Ni–OAr^F species both have bridging phenoxide ligands with necessarily longer average Ni–O bond lengths of 1.933 [36] and 2.058(3) [35] Å compared to **1a**.

The structure of **1b**, shown in Fig. 2, is largely similar to that of **1a**. The most noticeable difference is that both phenyl groups are on the same side of the NiO_2P_2 plane, an artifact of crystal packing, whereas in solution free

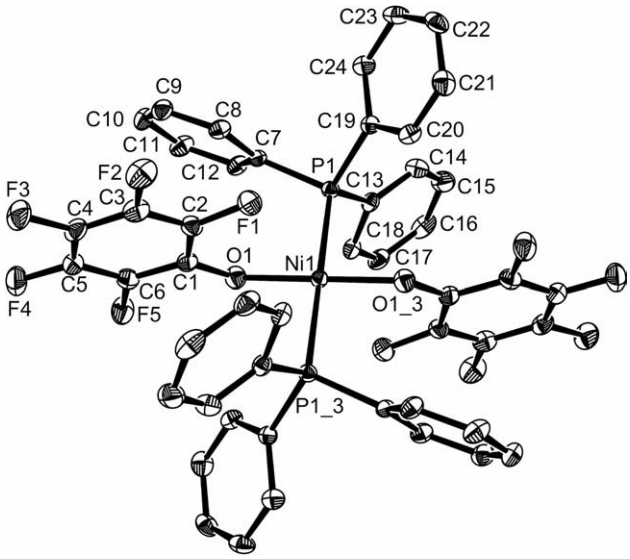

Fig. 1. ORTEP diagram of $[(Ph_3P)_2Ni(OAr^F)_2]$ (**1a**). Hydrogen atoms have been omitted for clarity. Selected distances (Å) and angles (°): Ni1–O1 1.852(2), Ni1–P1 2.2862(7), O1–C1 1.334(3); O1–Ni1–P1, 88.88(7), O1–Ni1–P1_3, 91.12(7), Ni1–O1–C1, 126.71(19). Ellipsoids are shown at the 50% probability level.

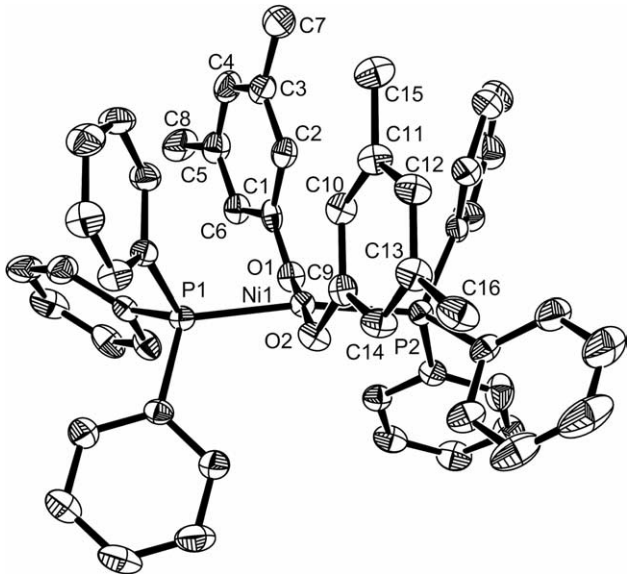

Fig. 2. ORTEP diagram of $[(Ph_3P)_2Ni(OAr')_2]$ (**1b**). Hydrogen and fluorine atoms have been omitted for clarity. Selected distances (Å) and angles (°): Ni1–O1 1.858(3), Ni1–O2 1.856(2), Ni1–P1, 2.2383(10), Ni1–P2, 2.2422(10), O1–C1, 1.281(5), O2–C9, 1.322(4); O2–Ni1–O1, 178.49(12), O1–Ni1–P1, 94.50(8), O1–Ni1–P2, 86.32(8), O2–Ni1–P1, 84.97(8), O2–Ni1–P2, 93.94(9), P1–Ni1–P2, 169.35(4), Ni1–O1–C1, 122.4(2), Ni1–O2–C9, 121.0(2). Ellipsoids are shown at the 50% probability level.

rotation about the C–O bonds is expected. At this writing, except for **1b**, crystallographically characterized OAr′ linkages have been reported only in $[M(OAr')_4]^{2-}$ compounds [13] and the $[(Ar'O)_2H]^-$ anion [68]. Again the distances and angles at the nickel center are within the range of related complexes in the literature.

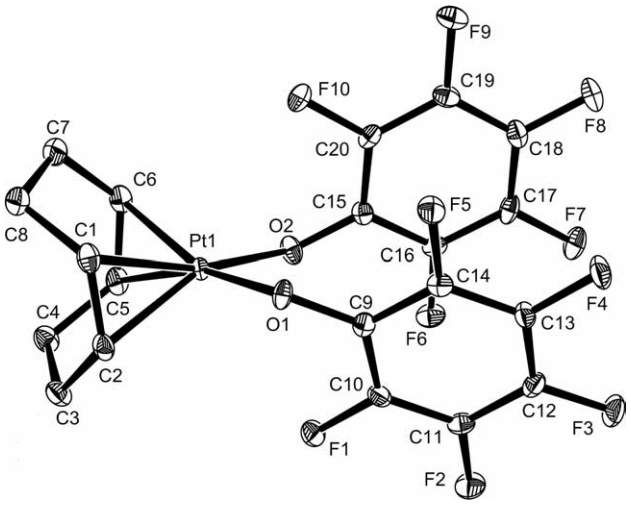

Fig. 3. ORTEP diagram of $[(COD)Pt(OAr^F)_2]$ (**2**). Hydrogen atoms have been omitted for clarity. Selected distances (Å) and angles (°): Pt1–O1 2.014(2), Pt1–O2 2.019(2), Pt1–C1 2.153(3), Pt1–C2 2.141(3), Pt1–C5 2.146(3), Pt1–C6 2.134(3), C1–C2 1.409(5), C5–C6 1.397(5), O1–C9 1.328(4), O2–C15 1.336(3); Pt1–O1–C9 122.63(19), Pt1–O2–C15 122.59(19), O1–Pt1–O2 94.95(9). Ellipsoids are shown at the 50% probability level.

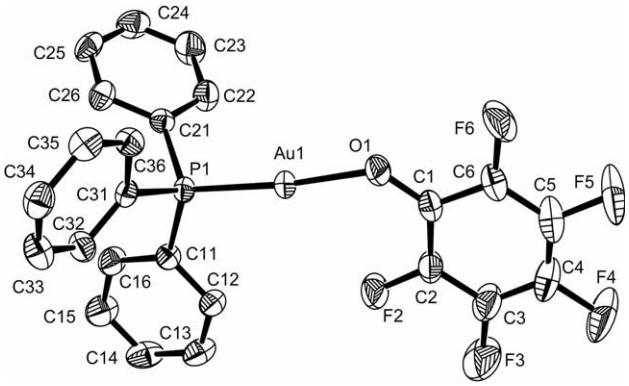

Fig. 4. ORTEP diagram of $[(Ph_3P)Au(OAr^F)]$ (**3**). Hydrogen atoms have been omitted for clarity. Selected distances (Å) and angles (°): Au1–P1, 2.1978(11), Au1–O1 2.028(3), O1–C1 1.291(6); Au1–O1–C1 128.5(3), P1–Au1–O1, 172.76(9). Ellipsoids are shown at the 50% probability level.

The crystal structure of **2** is shown with an ORTEP in Fig. 3, clearly demonstrating that this compound is a member of the L_2MX_2 ligand class [15]. The cyclooctadiene ligand is bound in a η^4-mode with the C=C bonds perpendicular to the PtO_2 plane. A plethora of structurally characterized $[(COD)Pt]^{2+}$ compounds exist, but relatively few with hard oxygen donor ligands, consistent with the soft character of Pt(II) [69,70], and only nine with a $[(COD)Pt(O)_2]$ coordination sphere, according to a CSD search. The most relevant structural comparison is that with [(COD)Pt(catecholate)] in which the doubly-deprotonated catechol ligand forms a five-membered chelate ring with platinum [57]. The Pt–O bonds have lengths (Å) of 1.972 and 1.978 in contrast to the slightly longer average bond length in **2** of 2.017(2). The less basic OC_6F_5 ligand has been shown previously to form slightly longer bonds [13]. The average Pt–C bond lengths (Å) are virtually the same in **2**, 2.144(8), and the catecholate compound, 2.156(12). Slightly shorter Pt–C bonds in **2** are consistent with less donating fluorinated arlyoxide ligands that result in more electron donation by the COD ligand. The coordinated COD bonds in **2** have lengths consistent with double bonds and within the range of 1.37(4) Å in 205 crystallographically characterized [20] $[(COD)Pt]^{2+}$ units. To our knowledge, only one prior report exists of a crystallographically characterized Pt–OAr^F bond, namely that in $[(o\text{-}Me_2NC_6H_4\text{-}CHCH_2)Pt(OAr^F)Cl]$ [54] which has Pt–O and O–C bond lengths of 2.017(5) and 1.341(9) Å, respectively. The former bond is virtually identical with that in **2** and the latter is somewhat longer.

Fig. 4 shows an ORTEP of compound **3** with a simple LMX [15] motif. The geometry at Au is virtually linear, as are the vast majority of Au(I) complexes [69,70]. The gold phenoxide bond is 2.028(3) Å in length and the Au–O–C angle is 128.5(3)°. The parameters are quite similar to those of the five crystallographically characterized Au(I) phenoxide compounds mentioned above that have average Au–O distances of 2.03(1) Å and Au–O–C angles of 126(4)°. The intraligand distances and angles are unexceptional.

3.3. Spectroscopy

The ^1H NMR chemical shifts in **1a** and **1b** are unexceptional. Both phosphine and aryloxide ligands are observed, though the signals decay over several hours. When the solution colors have become pale or colorless, only resonances for Ph_3P are visible in the ^1H and ^{31}P NMR spectra. No ^{31}P NMR signals for coordinated phosphine were observed, perhaps due to some paramagnetic character of the decomposition products. In the ^{19}F NMR spectrum of **1a**, three signals for the *ortho*, *meta*, and *para* fluorine atoms are observed but the $^3J_{FF}$ coupling is not resolved, in contrast to the spectrum of compound **2** (vide infra). A singlet is observed for the CF_3 groups in **1b**. The ^1H, ^{13}C, and ^{19}F NMR spectra of **2** show bound COD and OAr^F ligands and are unexceptional compared to other $[(COD)PtX_2]$ complexes with oxygen-donor ligands in the literature [57,71]. The NMR spectra for **3** are consistent with the solid-state structure shown in Fig. 4 and otherwise unremarkable.

UV–Vis spectra for $[(COD)PtCl_2]$ and **2** are shown in Supplementary Figure 2. Consistent with previous comparisons of Cl^- versus OAr^{F-} as ligands [13], the extinction coefficients increase significantly upon changing halide to aryloxide, but the spectra are largely similar. Increased absorbance above 300 nm is consistent with

the pale yellow color of **2** versus the colorless starting material. UV–Vis spectra for **3** are compared with [(Ph$_3$P)AuOPh] and [(Ph$_3$P)AuCl] in Supplementary Figure 3. Again the aryloxide derivatives absorb with greater intensity than the halide, but no significant shifts of the λ_{max} values are observed, suggesting these transitions do not involve exclusively the X ligand, but are largely π–π* transitions in the phosphine phenyl rings.

4. Summary

The late-transition metal complexes [(Ph$_3$P)$_2$Ni(OAr^F)$_2$] (**1a**), [(Ph$_3$P)$_2$Ni(OAr′)$_2$] (**1b**), and [(COD)Pt(OAr^F)$_2$] (**2**) have been prepared and spectroscopically as well as structurally characterized. The compound [(Ph$_3$P)Au(OAr^F)] (**3**) for which a preliminary synthetic report exists, was also structurally and spectroscopically characterized. These four compounds exemplify the conditions under which electronic modification of aryloxide ligands enables less common metal aryloxide bonds to be formed. For late transition metals that prefer softer, less donating ligands such as phosphorous or sulfur donors, these monodentate aryloxide compounds are unusual species. Among the four compounds, a perhydro analog is known only for [(Ph$_3$P)Au(OAr^F)]. Attempts to make non-fluorinated analogs of the nickel and platinum compounds resulted in metal precipitation, insoluble products, or other evidence of metal reduction instead of complex formation. The balance of electronic effects from anionic X-type ligands and neutral L-type ligands in this study suggests that highly basic aryloxides promote ligand dissociation for weaker L donors, which can lead to metal reduction and complex decomposition.

Acknowledgments

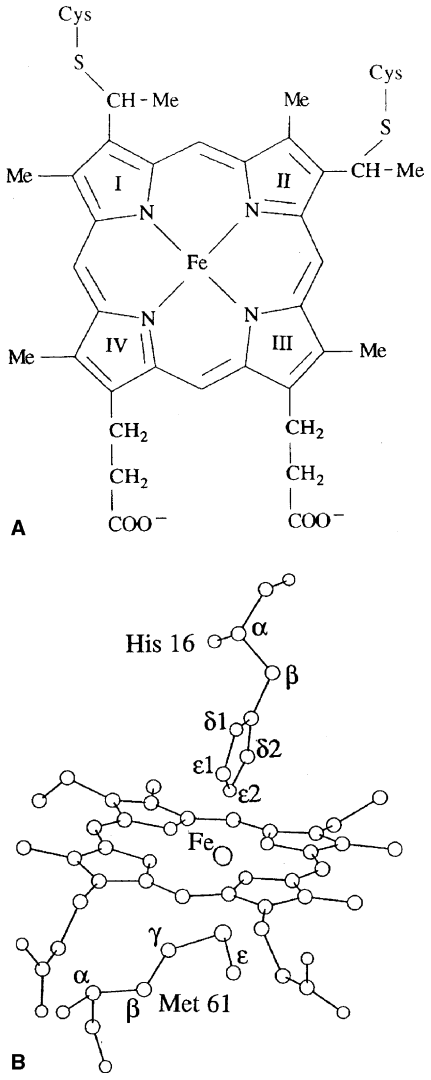

Fig. 1. The heme group of cytochrome *c*-551 from *Pae.* (A) Protoporphyrin IX ring. The nomenclature utilized for a protoporphyrin IX ring is of the IUPAC-IUB. (B) Spatial relationships of the heme group and the axial ligands, His-16 and Met-61.

protoporphyrin IX ring [6–8]. The pK_a value obtained is 6.2 for the oxidized form of the protein [6]. Additionally, data from EPR and electronic spectroscopy studies at pH >9.4 demonstrate the existence of a high spin species brought about by replacement of the iron ligand from the Met-61 thioether sulfur by other weak ligands, probably OH^- [9,10]. At higher pH values (pH >11) the existence of low-spin ferricyt *c*-551 has been proposed [9].

In the last two decades, paramagnetic ^{1}H NMR spectroscopy has been applied to different metalloproteins studies [11–13]. In particular information about coordination characteristics as well as the electronic properties for active sites in solution, by the study of isotropically shifted resonances and relaxation times, can be obtained. A number of previous reports have studied the assignment of heme protons on the oxidized form of the protein by means of heteronuclear multiple quantum coherence [14,15] or 2D ^{1}H NMR paramagnetic spectroscopy [16,17]. The present article reports on further research of the electronic properties and coordination geometry of ferricyt *c*-551 from *Pae* at high pH by using ^{1}H NMR of paramagnetic systems.

2. Experimental

2.1. Materials

All compounds used were analytical grade chemicals and purchased from Sigma and Merck. DEAE-Sephacel and CM-Sephadex (Pharmacia) were used for ion exchange chromatography. Sephadex-G100 (Pharmacia) was used for size-exclusion chromatography. D_2O (99.9%) was obtained from SDS Chemical. The protein was concentrated by using Amicon Model 8200 ultrafiltration cells equipped with PLBC 062 Millipore membranes and an ultrafree-15 centrifugal filter device from Millipore. Sample concentrations for ^{1}H NMR were 3–4 mM in protein dissolved in D_2O or in 95% H_2O/5% D_2O. Because the cyt *c*-551 sample is not totally in the oxidized form, an excess of potassium ferricyanide was added to the sample before the NMR experiments. The measurements were carried out with 20 mM potassium phosphate buffer at various pH values.

2.2. Bacterial growth and protein purification

Cytochrome *c*-551 was extracted from *P. aeruginosa* (CECT110) grown anaerobically at 35 °C in the medium described by Parr et al. [18] and purified in the partially oxidized state as described earlier [18,19]. The Bradford colorimetric assay [20] was used to determine the total amount of protein in the sample. Purified cyt *c*-551 shows a single band in PAGE and an UV–Vis spectral ratio in the reduced form of the protein $(A_{551} - A_{570})/A_{280}$ of 1.13–1.17 [21]. The cyt *c*-551 concentration was measured spectrophotometrically by means of the molar extinction coefficient for the reduced form of the protein $\varepsilon_{551} = 28.3 \times 10^3\ M^{-1}\ cm^{-1}$ [21].

2.3. Physical techniques

The optical spectra in the UV–Vis region were recorded on a Varian Cary 1 or a Shimadzu UV-2401PC recording spectrophotometer using 1 cm path length cuvettes. pH values of solutions were measured with a Crison micropH2000 pH meter provided with a Crison microelectrode. The pD measurements were corrected by the isotope effect.

NMR spectra were recorded on a Varian Unity 400 spectrometer operating at 400 MHz. One-dimensional spectra were recorded in H_2O or D_2O solvents using

the super-WEFT (water-eliminated Fourier transform) multipulse sequence [22] (d_1–180°–τ–90°–acq, where d_1 is the relaxation delay and acq the acquisition time) to eliminate the H_2O or HDO signal. Relaxation delay times of 20–50 ms, τ delay of 80–120 ms and acquisition times of 50–150 ms were used. The spectral widths ranged from 30 to 80 kHz for all experiments. 1D spectra were processed using exponential line-broadening weighting functions as apodization with values of 20–40 Hz. Chemical shifts were referenced to residual solvent protons of D_2O resonating at 4.81 ppm (293 K) relative to TMS. The longitudinal relaxation times of the hyperfine shifted resonances were determined by using the inversion recovery pulse sequence [23] (d_1–180°–τ–90°–acq); seventeen values of τ were selected between 0.5 and 200 ms, (d_1 + acq) values were at least five times the longest expected T_1 value, ranging from 80 to 200 ms, and the number of scans was 5000. The T_1 values were calculated from the inversion-recovery equation. Transverse relaxation times were obtained by measuring the line broadening of the isotropically shifted signals at half-height through the equation $T_2^{-1} = \pi\Delta\nu_{1/2}$.

2D NOESY or EXSY experiments were recorded in the hypercomplex mode [24]. All 2D experiments in H_2O or D_2O were performed with presaturation of the H_2O or HDO residual signal. Ranges of NMR parameters were utilized to overcome the diverse ^1H relaxation time. The mixing time varied from 3 to 40 ms. The parameter ranges are as follows: 1024–2048 number of scans, acquisition times of 40–100 ms, relaxation delays of 20–50 ms, 30–60 kHz spectral widths in both dimensions, 256–512 number of t_1 increments and 512–2048 number of points in the t_2 dimension. In addition, NOESY or EXSY were processed with Fourier-transforming using square sine bell weighting functions shifted 60° or 75° and the number of points used for processing were 1024 or 2048 in both dimensions. At the same time, 2D experiments were base line corrected. NMR data were processed on a SUN Sparc 5 station using the VNMRX 4.3B program.

3. Results and discussion

3.1. ^1H NMR spectrum of ferricyt c-551 at high pH

The ^1H NMR spectrum of ferricyt *c*-551 in H_2O as solvent (pH 8.9, 303 K, 20 mM potassium phosphate) is shown in Fig. 2, bottom. The spectrum shows the same pattern of chemical shifts as the spectrum of the oxidized low-spin ferricyt *c*-551 acquired at pD = 7.2 and described previously [17]. The resolved hyperfine shifted signals of low-spin ferricyt *c*-551 have been assigned to heme group protons as well as to protons of Met-61, which directly coordinates the iron and other residues near the heme group such as Cys-12, Gly-24, Ile-48 and Trp-56 [17].

When the pH is increased from 8.9 to 11.4 for the low-spin ferricyt *c*-551, the hyperfine shifted signals disappear in a slow exchange regime on the NMR timescale and, at the same time, another group of broader signals appears at pH values greater than 10.8 (Fig. 2, top). The ^1H NMR spectrum of ferricyt *c*-551 at pH 11.4 displays, in the downfield region, 10 relatively well resolved hyperfine shifted signals (a′–j′) and six other non-resolved signals (A′–F′). Additionally, in the upfield region, it displays three shifted signals (l′–n′). When the spectrum of ferricyt *c*-551 at pH 11.4 is acquired in D_2O no change is detected. The proton

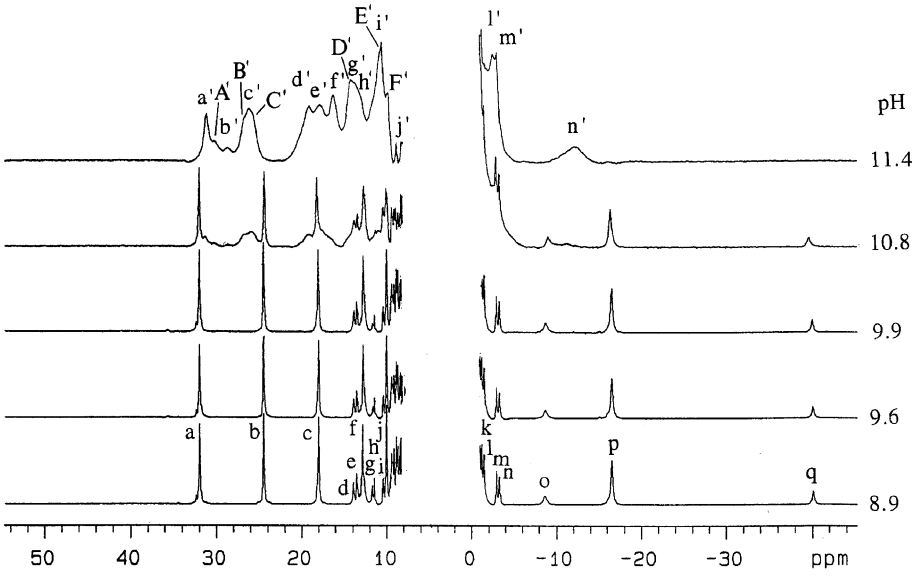

Fig. 2. Proton NMR spectra of ferricyt *c*-551 in H_2O at different pH values (8.9–11.4), 303 K and 3.3 mM protein sample.

longitudinal relaxation time values (T_1) and linewidths at half-height for the hyperfine-shifted resonances are reported in Table 1. The signals have linewidths from about 1000 Hz for signal n′ to ~300–400 Hz for signal a′. The longitudinal relaxation time values are relatively short from 1 ms, in the case of signal n′, to 48 ms for signal f′. The ^{1}H NMR spectra of ferricyt *c*-551 from *Pae* in the oxidized form at high pH, from 9 to 11.4, exhibit a drastic change if compared to the spectrum in acid or neutral media. Thus, the hyperfine shifted signals are broader with decreasing isotropic shift at high field. Additionally, the T_1 values of the low-spin iron(III) hemoprotein are smaller by about approximately 80–100 ms [25], while in the case of specie at high pH the T_1 values are as small as ~1 ms. The T_1 values are somewhat larger than in normal high-spin systems and this has been interpreted as being due to a relatively small zero-field splitting (ZFS) [25]. These results are consistent with the presence of a high-spin d^5 iron(III) in the oxidized forms of the protein. EPR studies [9] are in agreement with this electronic structure and confirm that the high-spin iron(III) cyt *c*-551 species has one soft ligand bound to the heme core. Moreover, Mössbauer spectra of ferricytochrome *c*-551 at high pH could help to confirm the final coordination number. Because the transition between pH 10.8 and 11.4 is steep, no intermediate pH values can be useful to assess the nature of the transition and determine the number of protons involved in the process. At higher pH than 11.4 no changes have been detected in the NMR spectra.

2D saturation transfer experiments were recorded on a sample at pH ~10.8, containing the low-spin species, and on high-spin species of the metalloprotein. In Fig. 3, some exchange cross-peaks are detected between signals outside the diamagnetic region. On the basis of the NMR assignment for low-spin ferricyt *c*-551 [17] the signals labelled c′, d′ and g′ can be assigned to the 12^1, 2^1 and 18^1 methyls, respectively (Fig. 3). Surprisingly, no signals are found in the typical high-spin hemoprotein methyl region, approximately from 50 to 100 ppm. In addition, the existence of exchange connectivities between the signal j and f′ confirms the assignment to 13^{1b}-CH of propionic acid number 13 (see the assignment in Table 1). In spite of very diverse acquisition and processing parameters no more exchange cross-peaks were found. The very short value of T_1 observed for the signal n′ suggests the assignment of the signal to one of the coordinated ligands since this is influenced by the paramagnetic effect of the metallic center with more intensity. Moreover, it is of interest to note that when the experiment was carried out in D_2O the shifted signals are the same as we observed in H_2O, showing the absence of the exchangeable NH proton that corresponds to the coordinated histidine. This is in agreement with the deprotonation of the axial ligand His-16, coordinated to the iron(III) heme group. Consequently, the deprotonated His-16 is more electron-withdrawing and the Fe–N_{His16} bond is shorter and the Fe–S_{Met61} bond is longer, allowing finally the complete decoordination of the ligand Met-61, the iron site remaining as a pentacoordinate system.

Table 1
^{1}H NMR (400 MHz) parameters of the hyperfine-shifted resonances in ferricyt *c*-551 from *Pseudomonas aeruginosa* at pH 11.4 and 303 K

Signal	δ (ppm)	T_1 (ms)	$\Delta\nu_{1/2}$ (Hz)	T_2 (ms)	Assignment

[a] Measured at 323 K.
[b] Overlap prevents measurement of this value.
[c] Measured at 293 K.
[d] Measured at 313 K.

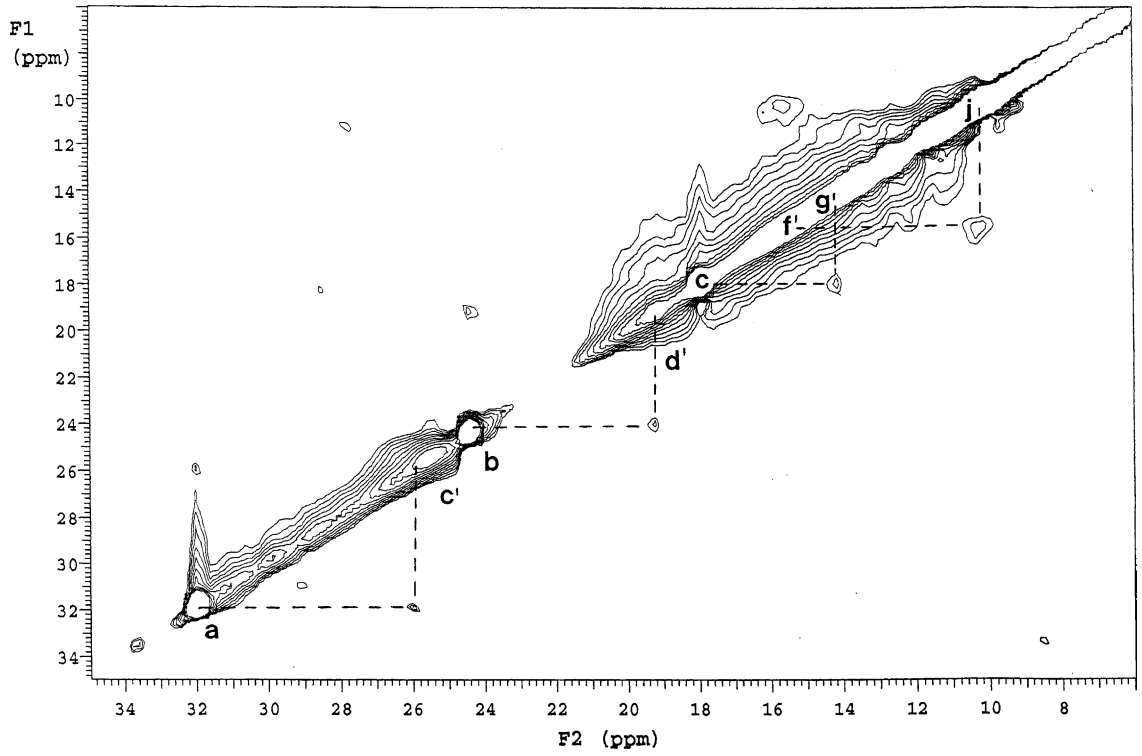

Fig. 3. Portion of 400 MHz EXSY map of ferricyt *c*-551 in H_2O solvent at 303 K and pH 10.8. The sample contained low spin Fe(III) and high-spin Fe(III) forms of the protein. Other conditions are given in the text.

At this point, it is interesting to remark that ferricyt *c*-551 in basic medium (pH 11.4) without exposure to light and in an inert atmosphere is stable for 48–72 h, after which it is progressively altered and the metalloprotein is not stable. In neutral medium certain instability has already been observed for ferricyt *c*-551 [16,26]. This process has been associated with the photoreduction mechanism of the iron(III) and is brought about by free radicals provided by amines or hydroxyl species.

3.2. Temperature dependence of the isotropically shifted signals

Variable temperature ^{1}H NMR spectra of ferricyt *c*-551 at pH 11.4 were registered in the range from 283 to 323 K. The temperature dependence of some non-overlapped isotropically shifted resonances is plotted as a function of $1/T$ (Fig. 4). All isotropically shifted signals follow a Curie behavior whereas the signals a′, h′ and n′ are more temperature dependent with a significant intercept value at infinite temperature, −3.2, −3.0 and −6.1 ppm, respectively. These results are indicative of some pseudocontact contribution to the hyperfine shifted signals, and are compatible with the existence of high-spin iron(III) complexes with the $^6A_1$ ground state ($S = 5/2$). The small dipolar contribution to the shift is due to the presence of a zero-field splitting and that is characteristic of high-spin iron(III) porphyrins

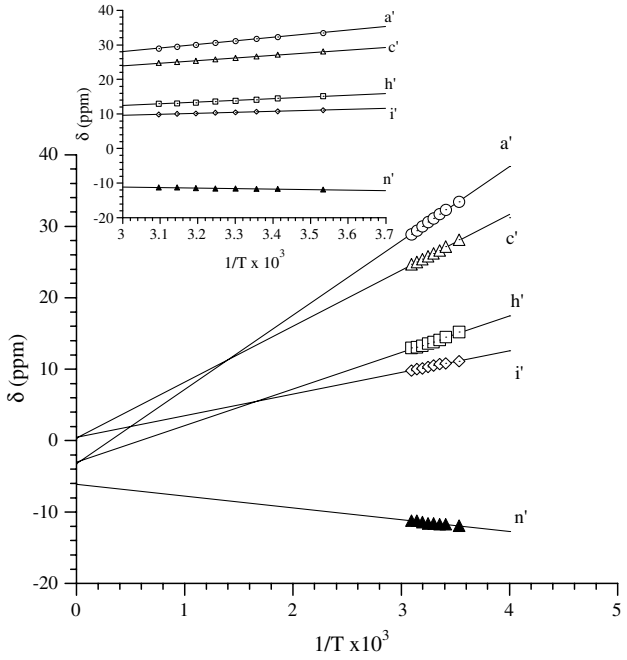

Fig. 4. Temperature dependence of the hyperfine shifted resonances of ferricyt *c*-551 in H_2O at pH 11.4 between 10 and 50 °C. The insert shows a plot with an expanded $1/T$ axis.

[27–30]. At this point, it is interesting to note that while the temperature dependence in the case of low-spin iron(III) cyt *c* is of both the Curie and anti-Curie type

[31–34], we observed only the Curie type. This behavior is characteristic of high-spin iron(III) porphyrins [29,30] and, consequently, of high-spin ferricyt *c*-551. In addition, the temperature dependence of the hyperfine shifted resonances in oxidized cyt *c*-551 at high pH suggests that these differences in the spin state are due to a possible modification in the coordination site of the heme group that is, naturally, responsible for the electronic transfer function of the metalloprotein cyt *c*-551. On the other hand, the protein is not damaged after exposure to 323 K and pH 11.4 because the spectra were reproducible and completely reversible in the temperature range 10–50 °C. In addition, it has been reported that the oxidized form of mesophile *Pae* cyt *c*-551 was thermostable at least up to 70 °C [35,36].

3.3. Comparisons of the spin crossover between ferricyt c-551 from Pae and other ferricytochromes c

Because the cytochromes *c* are relatively small electronic transfer hemoproteins, several research groups have investigated cytochromes *c* in general and, in particular, on the cyt *c*-551 from *Pae*, see for example the references [35,37–42]. Our study of the pH effect in the interval 9–11.5 reveals a drastic change in the protein, with Fe(III) experiencing a change in spin of from $S = 1/2$ to $S = 5/2$ on increasing the pH to 10.8 or above. A decrease in the relaxation times, T_1, and an increase in the linewidth of the new signals accompanies this change, suggesting a change in coordination geometry or at least the decoordination of one axial ligand coordinated to the heme group. Thus, we can think that the Met-61 axial ligand would be replaced with ligands like OH^-. This hypothesis agrees with data from an EPR study reported on cytochrome *c*-551 in the oxidized form with varying pH [9] that presented similar conclusions which refers to the substitution of the Met-61 axial ligand for other weaker ligands near to the group heme. Surprisingly, however, these authors postulate the formation of low-spin cyt *c*-551 at pH values >11 [9].

The change of the axial ligand at alkaline pH for ferricyt *c*-551 not only has been studied by means of EPR techniques, but also electronic [9,10] and IR [43,44] spectroscopy. From the electronic absorption studies for an alkaline solution of *Pae* cyt *c*-551, Li et al. [10] conclude that the Met-61 ligand is replaced by OH^-. Moreover, the RR spectra show that at alkaline pH, the heme iron and methionine sulfur bond is cleaved and replaced by another ligand, for example lysine, but the heme iron to histidine nitrogen bond remains intact. Studies on ferricytochromes *c* from other sources reach similar conclusions [31,32,45,46]. Some differences between them can be exposed. Timkovich and Cork [32] suggest that the methionine ligand is displaced at high pH (pH up to 10) for ferricyt *c*-554 from *Alcaligenes faecalis*. Ferricyt *c*-551 from *Rhodocyclus gelatinosus* exhibits changes in the NMR spectra at pH ~8 that are attributed to a new form of the cytochrome [31]. The alkaline conformational changes of tuna and horse ferricytochromes *c* have been studied by FTIR spectroscopy [45]. The optical spectrum shows a pH dependence in the interval of pH 8–12 and it has been proposed that the ionization of a heme propionate of mitochondrial cyt *c* cause the alkaline transition, and thus a transition from a low-spin iron(III) to high-spin iron(III) electronic state [45]. At the same time, the conformational change triggers the dissociation of the coordinated methionine and its replacement for another hard ligand, perhaps a lysine [45,47]. A similar behavior to the one observed for the ferricyt *c*-551 from *Pae* has been studied in ferricyt *c*-550 from *Thiobacillus versutus* [46,48]. In this case, when the pH increases over 11 for ferricyt *c*-550, a new species is detected, and again a change in the iron(III) coordination has been suggested [46]. This change has been tentatively identified later as a species with a Lys-His^- ligation of the heme iron(III) by means of EPR [48]. The results obtained for *T. versutus* cyt *c*-550 Met100Lys mutant, at pH >11, show the Lys-His^- coordination of the heme iron, that it is similar with those observed for the alkaline form of wild-type cyt *c* [49]. On the other hand, Gadsby and Thomson [50] have reported the assignment of axial ligands of ferric ion in some low-spin cytochromes at high pH by means of near-IR MCD data and EPR spectra. These are horse heart cytochrome c at pD 11.0 with Lys/His as ligands of heme and cytochrome *b*-562 from *Escherichia coli* at pD 10.5 with Met/His^- as ligands of heme.

As mentioned above, the deprotonation of the histidine amino-acid coordinated to the iron of the heme

Fig. 5. Portion of the alignment, including the coordinated His, of some mitochondrial and bacterial cytochromes *c*: (A) *Pseudomonas aeruginosa* cyt *c*-551 [51], (B) horse heart cyt *c*-550 [52], (C) skipjack tuna cyt *c*-550,[1] (D) *Thiobacillus versutus* cyt *c*-550 [53], (E) *Rhodocyclus gelatinosus* cyt *c*-551.[1] Amino-acid sequence number refers to *Pae* cyt *c*-551. The asterisks denote the hydrophobic amino-acids.

[1] Swissprot Database.

group at high pH can trigger the decoordination of Met axially bound to iron(III) and consequently the alkaline transition. The observed differences in alkaline conformation change for different ferricytochromes *c* can be related to the hydrophobic amino-acid next to the histidine residue that is coordinated to the iron (Fig. 5). Thus, with an increase in the hydrophobicity, the deprotonation of the coordinated histidine occurs at higher pH and this is in agreement with the fact that the alkaline conformation change is detected at higher pH. It is remarkable that the alkaline conformation change for ferricyt *c*-551 from *Pae* is similar to that reported for ferricyt *c*-550 from *T. versutus* and appears at pH 11–12. At the same time, the hydrophobic environment in these cases is similar and more hydrophobic than that of horse heart, tuna or *Rhodocyclus gelatinosus* ferricyt *c*, see Fig. 5.

4. Conclusions

The ^{1}H NMR spectra of ferricyt *c*-551 in the oxidized form, in basic medium between pH 9 and 11.4, demonstrate a drastic change compared to spectra acquired in acid or neutral medium. The signals broaden and the isotropic shift decreases. Additionally, whereas in the low-spin Fe(III) hemoprotein the longitudinal relaxation times are between 80 and 200 ms, for the high-spin species, the longitudinal relaxation time varied from 1 to 48 ms. On the other hand, the temperature dependence of the hyperfine shift indicates a weak dipolar contribution. These results are consistent with the existence of a paramagnetic center that presents a small magnetic anisotropy. The high-spin iron(III) probably forms a penta or hexacoordinated geometry and an $^6A_1$ ground state with a spin of $S = 5/2$ in which the orbital contribution is very low and the magnetic anisotropy would be negligible. The isotropically shifted resonances present essentially a contact contribution. In our case, the dipolar contribution is practically non-existent as it is observed in the isotropically shifted proton resonances as a function of temperature, which confirms the penta or hexacoordinated geometry expected for a complex of high-spin iron(III). The results show that a change of spin state from low-spin iron(III) to high-spin iron(III) has been produced for a pH of 10.8. This change of spin state is probably associated with deprotonation of the axially coordinated amino-acid, His-16, which would provoke the dissociation of the second axial amino-acid, Met-61.

on the aniline or salicylaldehyde moieties have stimulated their possible antioxidant activity and ability to form stable phenoxyl- or semiquinone type radical complexes on chemical oxidation or reduction [15]. In some cases the complexation of these ligands was accomplished by non-predictable redox-reactions depending on the nature of the ligands, solvents and oxidants [15,16]. The introduction of bulky groups in these ligands influences the redox reactivity and overall catalytic properties of the complexes [2b,15c,16]. In this study, we present the synthesis, spectroscopic and electrochemical behaviour of a new series of *N*,*N*′-polymethylenebis(3,5-di-*tert*-butylsalicylaldiminato)nickel(II) complexes, $Ni(L_x)$, [H_2L_x = *N*,*N*′-bis(3,5-di-*tert*-butylsalicylidene)-polymethylenediamines] (Scheme 1).

2. Experimental

2.1. Preparation of the ligands and the complexes

All the ligands and their Ni(II) complexes were prepared according to the methods in the literature [17–19] and the analyses of the compounds were made by comparing the spectroscopic results with the reported ones [17,20–24].

2.2. Electrochemistry

Voltammetric recordings were made using Volta Lab PGZ 301 Dynamic Voltammetry. A platinum-bead working, platinum-coil counter electrode and saturated calomel reference electrode (SCE) were used for CV measurements. Cyclic voltammograms (CV) were recorded under N_2 gas atmosphere in DMF at room temperature. The concentration of the complexes was 0.001 M in the electrolyte solution, where commercially obtained [*n*-$(C_4H_9)_4N$]BF_4 was used as a supporting electrolyte. The voltage scan rate during the CV measurements was 100 mV/s. Controlled potential electrolysis at the anodic peak potential was carried out with a Ag-wire reference electrode after making a correction between the SCE and the Ag-wire (280 mV for SCE, and the oxidation potential of the ferrocene/ferrocenium couple was found to be 0.84 V versus SCE and 0.56 V versus Ag-wire, in our system). The oxidation process was followed in situ on a Hewlett Packard UV–Vis HP 8453A diode array spectrophotometer. Platinum gauze electrodes were used as the working and the counter electrodes. N_2 gas was bubbled through the electrolysis solution for stirring purposes between the scans.

2.3. Electron paramagnetic resonance spectroscopy (EPR)

The EPR spectrum of the electrochemically generated product, $Ni^{III}(L_x)$, was recorded by using a Varian E12 spectrometer in a quartz EPR cell in liquid nitrogen where diphenylpicrylhydrazyl (DPPH) was used as a reference.

3. Results and discussion

3.1. Voltammetric studies

The electrochemical data for all the Ni(II) complexes obtained in this study are presented in Table 1. The vol-

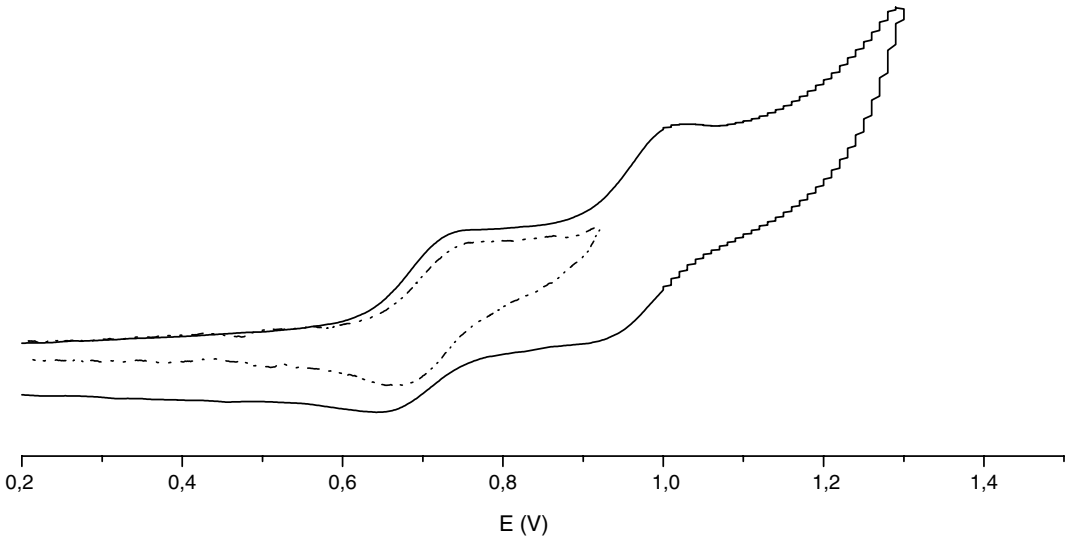
tammograms of all the Ni(II) complexes exhibits two step oxidation processes in DMF at room temperature under N_2 gas atmosphere. As shown in Fig. 1 and Table 1, the first oxidation peak potential of all the Ni(II) complexes, except Ni(L_5) and Ni(L_6), reveals a reversible electron transfer from 0.68 to 0.90 V versus SCE.

A linear dependence, which was observed between i_p and $V^{1/2}$ and between E_p and i_p as the voltage scan rate (V) increased, indicates a diffusion controlled electron exchange reaction. The plot of current function ($i_p/(C \cdot V^{1/2})$ versus Log V gave a straight line parallel to the horizontal axis (Log V) for the first oxidation peak potential, indicating a reversible electrode exchange reaction according to Nicholson–Shain criteria [25]. Furthermore, the ratio i_{pc}/i_{pa} was independent of scan rate and equal to unity for scan rates changing from 100 mV/s to 1 V/s.

The number of electrons transferred at the first oxidation peak was found to be one by using a digital coulometer. Since the integrated area under the second oxidation peak is twice the area under the first anodic peak, a $2e^-$ transfer was assigned for the second anodic peak.

The oxidation potentials (Table 1) are dependent on the diamine bridge, [=N–$(CH)_n$–N=]. More positive potentials are obtained as the methylene-group chain (Scheme 1) decreases from $n = 4$ to 2. It is known that the oxidation potentials of tetradentate N_2O_2 salen type systems are markedly dependent on the imine bridges and the salicylaldehyde moieties. For the metal centered one electron processes, the anodic peak potentials shift to more positive values with electron withdrawing substituents, whereas electron donating groups have the opposite effect [26]. Moreover, an increase in the length of the bridging N–$(CH_2)_n$–N chain ($n = 2$–4) was expected initially to increase the steric strain in the ligand ring [27]. However, for nickel(II), increasing n ($n = 2$–4) leads to an effective weakening of the ligand field strength [24]. A weak ligand field leads to a decrease in the energy levels of the d-orbitals in our complexes. This decrease must be due to an increase in the size of the ligand cavity with the $(CH_2)_{2-4}$ bridge. When the chelate ring size decreases, the in-plane ligand field strength increases [9].

The redox behaviour of Ni(L_5)and Ni(L_6) was different from the other Ni(II) complexes. The voltammograms of these complexes consist of two irreversible oxidation peaks at around 0.84 and 1.11 V for Ni(L_5) and at 0.83 and 1.16 V for Ni(L_6) versus SCE. The geometry of Ni(L_x) ($x = 2$–4) gradually changes from square planar to pseudo-tetrahedral, resulting in a cathodic shift in their redox potentials. These complexes, unlike other complexes containing macrocyclic ligands, afford easier access to mixed donor environments, and the open equatorial ring size of these ligands can accommodate the metal size, which changes upon oxidation/reduction [8,28]. The difference in the electronic absorption spectra and the electrochemical behaviour of Ni(L_5) and Ni(L_6) is most probably related to their structural reorganization as dinuclear complexes (Scheme 2). As shown in Scheme 2, the size of the chelating cavity is smaller than that of other Ni(II) complexes, although the length of methylene bridge increases. The chelate ring geometry of Ni(L_5) and Ni(L_6) can be assumed as similar to that of Ni(L_2). It should be noted that if the oxidation state of Ni(III) in these complexes is less stabilized due to steric hindrance of the bulky ligand structure, the decomposition of the oxidized species can be possible as well. However, the electrochemistry of these complexes have not been studied in detail here.



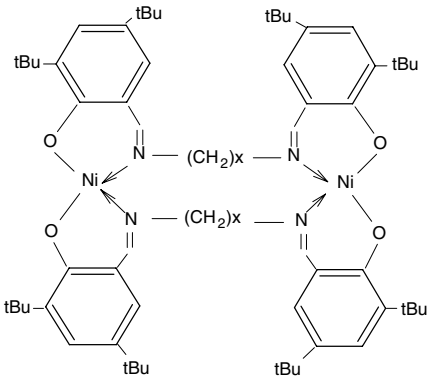


Fig. 1. Cyclic voltammogram of 0.001 M Ni(L_3) in DMF at room temperature vs. SCE (VSR = 100 mV/s).

Scheme 2.

3.2. Electrochemical oxidation of Ni(L_x) complexes

Electrochemical oxidation of Ni(L_3) solution was carried out approximately at 70 mV more positive potential than its first oxidation peak potential (0.74 V) in DMF versus Ag-wire at −10 °C. The changes in the electronic absorption spectrum of the complex were followed in situ by measuring the spectra during the electrolysis every 10-mC interval (Fig. 2(a)). The electronic absorption spectrum of the original complex in DMF contains two absorption bands at 355 and 426 nm in the working range of 265–1100 nm. During the oxidation, the band at 355 nm shifted to 350 nm with an increase in its intensity, while the intensity of the band at 426 nm decreased gradually. A new band at 505 nm formed with two-well defined isosbestic points at 406 and 449 nm, until the end of the $1e^-$ transfer. This process produces a change in color of the electrolyte solution from yellow to pink, implying the formation of a new species.

The EPR spectrum of the electrochemically produced pink product (Fig. 3(a)) at 77 K exhibited three well separated g-values of $g_1(g_x) = 2.24$, $g_2(g_y) = 2.21$ and $g_3(g_z) = 2.014$, indicating rhombic stereochemistry, where g_1 and g_2 refer to the lowest and highest magnetic field g values, respectively [6–12]. A large g-tensor anisotropy ($g_{avr} \gg 2$) and d^7-low spin ($S = 1/2$) electron configuration demonstrates the formation of Ni(III), which has a typical d^7-low spin ($t_2^6e^1$) configuration [6,11]. The observed spectral pattern is consistent with Ni(III) in a tetragonal geometry (g_x, $g_y > g_z$) and $^2A_{1g}$ [$(d_z^2)^1$] ground state, rather than square-planar geometry ($g_z > g_x$, g_y) [29]. No superhyperfine splitting was assignable due to the equatorial nitrogens in any of the three g regions. Addition of excess pyridine to the freshly prepared $[Ni^{III}(L_3)]^+$ solution in DMF resulted in an axial spectrum ($g_x \cong g_y$) with $g_\perp > g_\parallel$ and three-line hyperfine splitting in the $g_\parallel$ component. The g_x and g_y values are approximately equal and are not resolved. The appearance of three lines splitting in the $g_\parallel$ region with $a_\parallel = 8$ G (0.00748 cm^{-1}) suggests a single pyridine molecule bound to the axial positions of the $[Ni^{III}(L_3)]^+$ complex (inset of Fig. 3(a)) [13,14]. These results suggests that the initial $[Ni^{III}(L_3)(DMF)_2]^+$ complex in the presence of pyridine is converted to a tetragonally elongated octahedral monopyridine adduct, $[Ni^{III}(L_3)(DMF)(Py)]^+$ or penta-coordinated $[Ni^{III}(L_3)(Py)]^+$ complex having axially coordinated pyridine in a square pyramidal geometry (C_{4v}). It is known that both these geometries possess the $(d_{xy})^2(d_{z^2})^1$ ground state with the relation g_x, $g_y > g_z \approx 2$ [30].

Consequently, the electrode reaction, which is consistent with the $1e^-$ reversible oxidation process of the Ni(L_3) complex at its first anodic peak potential in DMF, can be proposed as follows:

$$[Ni^{II}(L_3)] \rightleftharpoons [Ni^{III}(L_3)]^+ + e^- \quad (1)$$

$$[Ni^{III}(L_3)]^+ + S \rightarrow [Ni^{III}(L_3)(S)]^+ \quad \text{(where S = solvent)} \quad (2)$$

This process is followed by a decay path of the electrochemically generated Ni(III) species back to the neutral Ni(II) complex. The decay occurs in a few seconds at room temperature. Decay of the Ni(III) species (Fig. 4) that was studied at −10 °C indicates a second order rate law with a rate constant $k = 5.00 \times 10^{-4}$ L/mol s. The previous studies on the decomposition of Ni(III) complexes with macrocyclic ligands [8], reveal that an intramolecular electron transfer mechanism should be operative from the ligand to the Ni(III) center to form radical species. Thus, further reactions following the reversible electron transfer are as follows:

$$[Ni^{III}(L_3)(S)]^+ \rightarrow [Ni^{II}(L_3^{\bullet+})(S)] \quad (3)$$

$$2[Ni^{II}(L_3^{\bullet+})(S)] \rightarrow [Ni^{II}(L_3)(S)] + [Ni^{II}(L_3^{ox})(S)] \quad \text{(slow)}$$

$$\text{(where } L^{ox} = \text{the two electron oxidised ligand)} \quad (4)$$

$$[Ni^{II}(L_3^{ox})(S)] \rightarrow Ni^{II}(solv) + (L_3^{ox}) + S \quad (5)$$

The electronic absorption spectra recorded in situ imply that only half of the original complex was recovered and the other half decomposed to the free ligand and Ni(II) species. The characteristic absorption band of the free ligand (328 nm) could not be observed in the electronic absorption spectrum of the solution after the decay, since the skirt of the highly intense band at 350 nm obscured this region completely. These observations support our proposed mechanism. Studies on the decay kinetics have still to be continued.

The second oxidation peak that appears in the CV of Ni(L_3) was assigned as the stepwise oxidation of the two aromatic rings of the ligand. The electrochemical oxidation of the complex, which was carried out

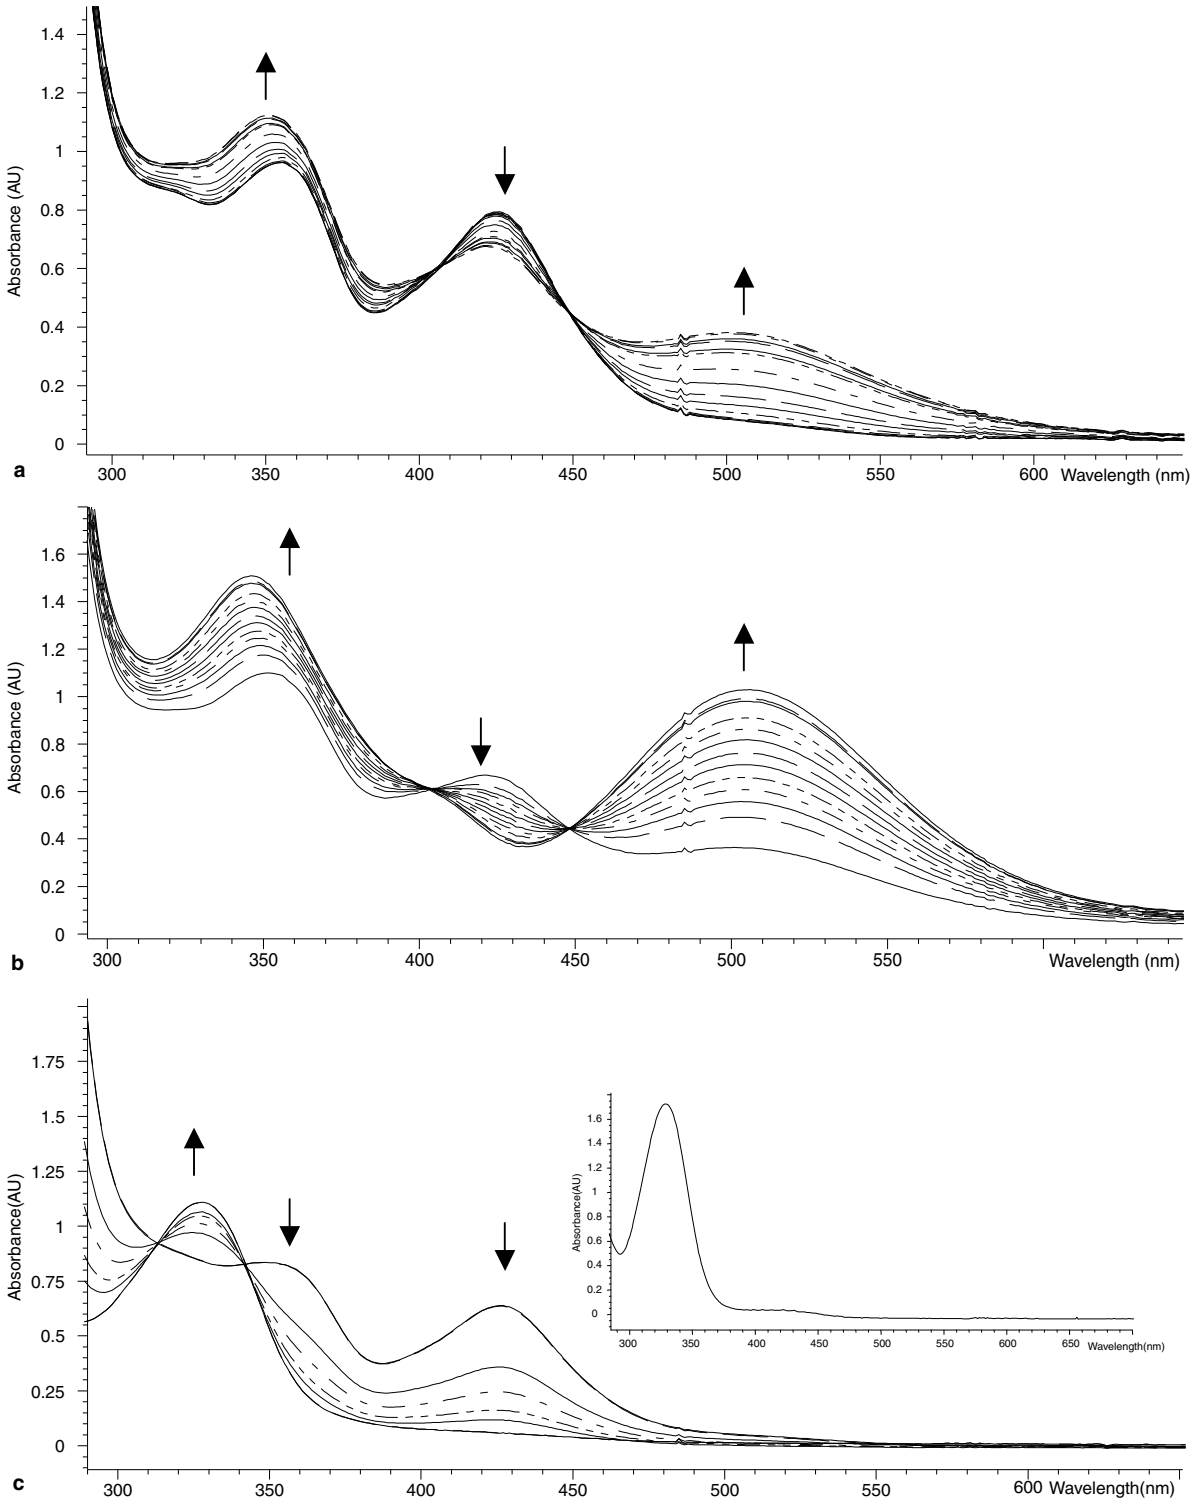

Fig. 2. (a) The changes in the electronic absorption spectrum of 1.2×10^{-3}M Ni(L_3) during the electro-oxidation at its first electrode potential vs Ag-wire. There are 10 mC intervals between the two scans; (b) the spectral changes that are obtained during the electrolysis at the second oxidation peak potential; (c) the spectral changes that are obtained after the third electron transfer; inset: the electronic absorption spectrum of the free H_2L_3 ligand.

at the second anodic peak potential after the one electron transfer, yielded a red product solution with an increase in the intensity of the absorption band at 505 nm. The spectral changes showed two sharp isosbestic points at 406 and 454 nm. While the absorption band at 350 nm shifted to 345 nm with an increase in its intensity, the band at around 416 nm disappeared completely (Fig. 2(b)).

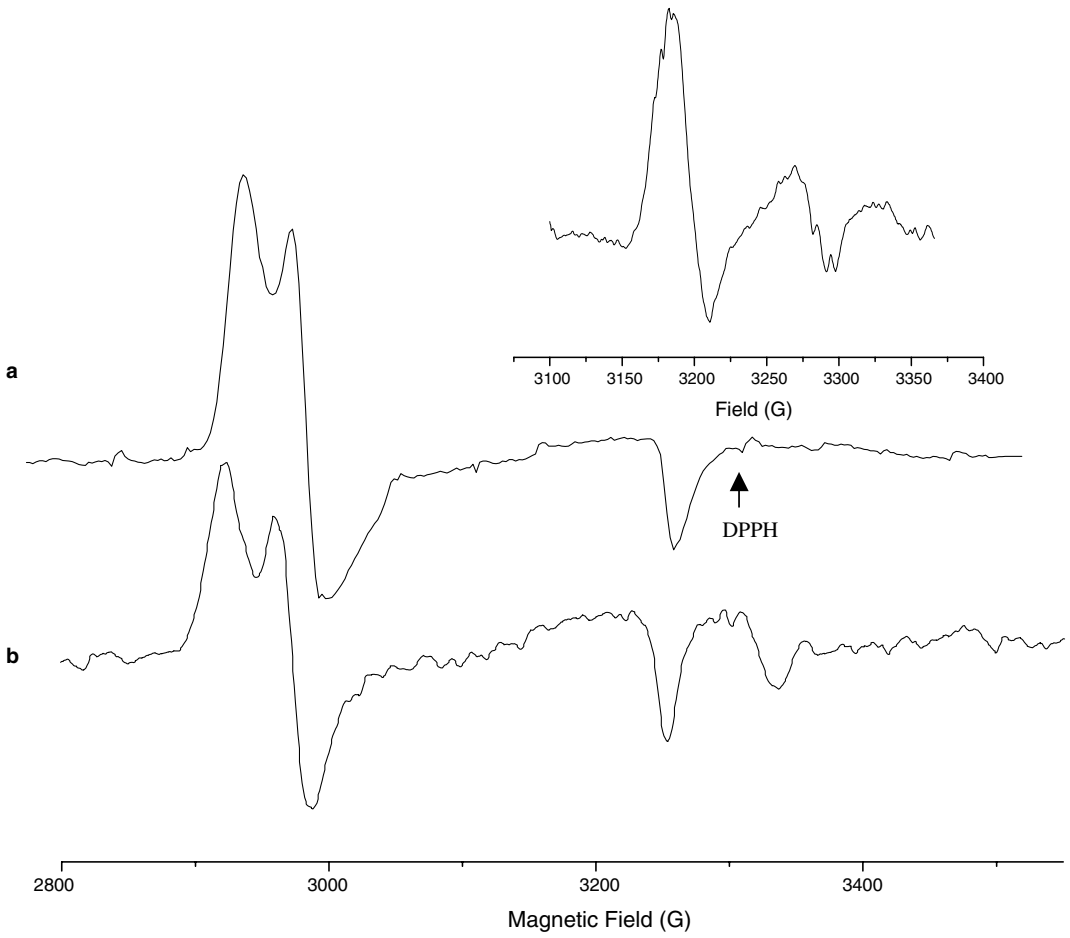

Fig. 3. (a) EPR spectrum of the electrochemically generated Ni(III) species at 77 K; (b) EPR spectrum of the product obtained after the second electron transfer at 77 K; inset: EPR spectrum of the pyridine adduct of the electrochemically generated Ni(III) species at 77 K.

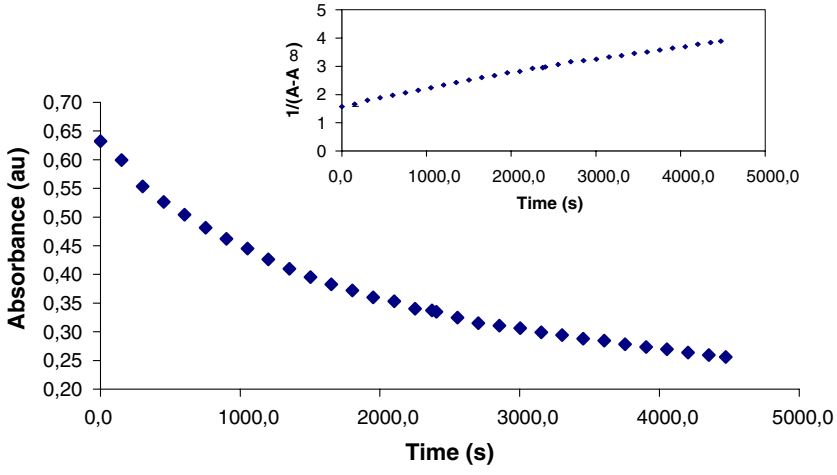

Fig. 4. Time traces for the decay of Ni(III) species at −10 °C in DMF; inset: second order fit for the decay of Ni(III) species.

The EPR spectrum of the electrochemically generated red solution demonstrated the characteristic Ni(III) signals as well as a broad feature at 77 K which can be assigned to a ligand radical species (Fig. 3(b)) by the formation of a coordinated phenoxy-radical structure in the electrolyte solution.

$$[Ni^{III}(L_3)(S)]^+ \rightarrow [Ni^{III}(L_3^{\bullet+})(S)]^+ + e^- \quad (6)$$

When the oxidation process continued at the same electrode potential as the second electron transfer, the electronic spectrum was changed completely. All the bands corresponding to the complex solution disappeared and a new highly intense characteristic band of the ligand at 328 nm was formed (Fig. 2(c)).

The radical ligand species obtained after the one electron transfer at the second oxidation peak potential is stabilised by the *tert*-butyl groups of the aromatic ring. Thus, the decomposition of the complex was not observed on the CV timescale and the reduction peak observed after the second anodic peak is proposed as the reduction of the red product back to the original complex. The observation of no new oxidation or reduction peak formation in the voltammograms after this cathodic electron transfer also supports our assignment.

Similar electrochemical results were obtained for the Ni(L_1), Ni(L_2) and Ni(L_4) complexes. In each case, a red product was obtained at the end of the two-electron transfer process, implying the formation of the same product that was observed in the oxidation of the Ni(L_3) complex.

4. Conclusions

The electrochemical behaviours of Ni(L_x) are different from those reported for analogous salen type Ni(II) complexes with polymethylene bridges. This feature seems to be due to the steric requirements of the *tert*-butyl groups on the 3,3′-positions of the salicylic fragments. The first oxidation peaks in the cyclic voltammograms of Ni(L_1), Ni(L_2), Ni(L_3) and Ni(L_4) complexes appear at 0.90, 0.84, 0.74 and 0.68 V, respectively, versus SCE in DMF. The reversible one electron process corresponds to the oxidation of the metal center, producing Ni(III) species with solvent molecule coordination. EPR spectra taken in liquid nitrogen supported the formation of a penta-coordinated Ni(III) complex as well. The second oxidation peak observed at around 1.0 V for all complexes was assigned as an electron transfer from a ligand based orbital by formation of a coordinated phenoxy radical.

In order to identify the final products of the electrooxidation, electrolysis of the complexes were followed in situ by UV–Vis spectrophotometry. In the case of Ni(L_3), well-defined isosbestic points were observed in the electronic spectrum, implying only one type of electrode reaction. Similar electrochemical results were obtained for Ni(L_1), Ni(L_2) and Ni(L_4).

A comparison of the first oxidation peak potentials suggests that: (i) more positive potentials are obtained as the methylene group chain decreases from 4 to 2, however the steric strain in the ligand ring increases in the reverse order; (ii) the methylene group with a long C-chain in the aliphatic diamine bridge destabilises the complex; (iii) the steric hindrance is effective on the stability of the Ni(II) state; (iv) the donation ability of the N atoms decreases as the hole cavity gets smaller. So, the basicity strength of the ligands can be ordered as $(L_4) > (L_3) > (L_2) > (L_1)$.

presence of azide ions, and isolated a 3:4:2 Cd:(nic$^-$):azide (**1**) and a 1:1:1 Zn:(nic$^-$):azide (**2**) complex.

2. Experimental

2.1. Material and instrumentation

C, H, N elemental analyses were carried out using a Perkin–Elmer analyzer, Cd and Zn were analyzed by a Perkin–Elmer Analyst 300, AAS atomic absorption spectrometer. Infrared spectra were recorded on a Bruker IFS-125 model FT-IR spectrophotometer as KBr pellets. Raman spectra were recorded on a BRUKER IFS 6/s FT-Raman spectrometer with Nd:CYAG laser wavelength (1064 nm) as the light source. ^{1}H NMR and ^{13}C NMR (DMSO-d_6) spectra were recorded on a Jeol JNM-ECA 500 MHz spectrometer. TGA and DTA were carried out on a Shimadzu-50H under a nitrogen flow rate 30 ml/min. Nicotinic acid was purchased from Aldrich Company and other chemicals were of analytical grade quality and used as received.

Caution. Metal azide complexes are potentially explosives. Only a small amount of material should be prepared and handled with caution.

2.2. Synthesis

2.2.1. $[Cd_3(nic)_4(N_3)_2(H_2O)_2]$ (**1**)

To an aqueous solution (20 cm^3) of $3CdSO_4 \cdot 8H_2O$ (0.77 g, 1.0 mmol, 3 mmol in Cd^{2+}) nicotinic acid (0.74 g, 6 mmol) in methanol/water (15 cm^3) was added, followed by dropwise addition of an aqueous solution of NaN_3(0.65 g, 10 mmol) with continuous stirring. The mixture was heated, filtered off, boiled again and the final clear mixture was allowed to cool gradually to room temperature then placed in a refrigerator for several days. Yellow crystals suitable for X-ray measurement were collected, dried in air, with a yield of ~85%. *Anal.* Calc.: C, 30.48; H, 2.13; N, 14.81; Cd, 35.66. Found: C, 30.38; H, 2.23; N, 14.74; Cd, 35.69%. ^{1}H NMR (DMSO-d_6): δ 7.53 (t, 4H), 8.34 (d, 4H), 8.67 (s, 4H), 9.19 (s, 4H); ^{13}C NMR (DMSO-d_6): δ 124.24, 131.22, 138.60, 151.24, 151.72 and 170.82.

2.2.2. [Zn(nic)(N$_3$)] (2)

This complex was prepared by mixing zinc sulfate $ZnSO_4 \cdot 7H_2O$ (0.50 g, 1.74 mmol) in water (30 cm^3) with nicotinic acid (0.43 g, 3.5 mmol) in ethanol/water (20 cm^3). An aqueous solution of NaN_3 (0.65 g, 10 mmol) was added dropwise with continuous stirring. The final mixture was then allowed to stand for several days to yield pale brown crystals of the complex suitable for X-ray diffraction (65% yield). *Anal.* data for the complex $C_6H_4N_4O_4Zn$: Calc.: C, 31.40; H, 1.76; N, 24.41; Zn, 28.48. Found: C, 31.38; H, 1.82; N, 24.56; Zn, 28.53%. ^{1}H NMR (DMSO-d_6): δ 7.57 (t, 1H), 8.58 (d, 1H), 8.64 (d, 1H), 9.08 (s, 1H); ^{13}C NMR (DMSO-d_6): δ 124.78, 131.41, 139.31, 150.69, 151.51 and 169.65.

2.3. X-ray crystallography

All diffraction data were collected using a Siemens SMART CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å, graphite monochromator). The crystals were cooled to 173(2) K by a flow of nitrogen gas using the LT-2A device. A full sphere of reciprocal lattices were scanned by 0.3° steps in ω with a crystal-to-detector distance of 3.97 cm. Preliminary orientation matrices were obtained from the first frames using SMART [21].

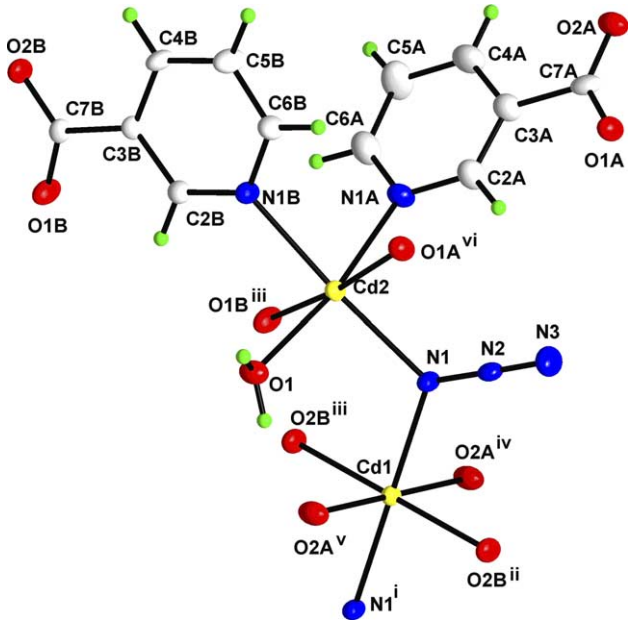

Fig. 1. Numbering scheme of $[Cd_3(nic)_4(N_3)_2\ (H_2O)_2]_n$ complex **1** and atomic displacement ellipsoids draw at the 50% probability level. Note that just a part of the tri-nuclear complex is shown, the rest of it is symmetry dependent. For symmetry codes see Table 3.

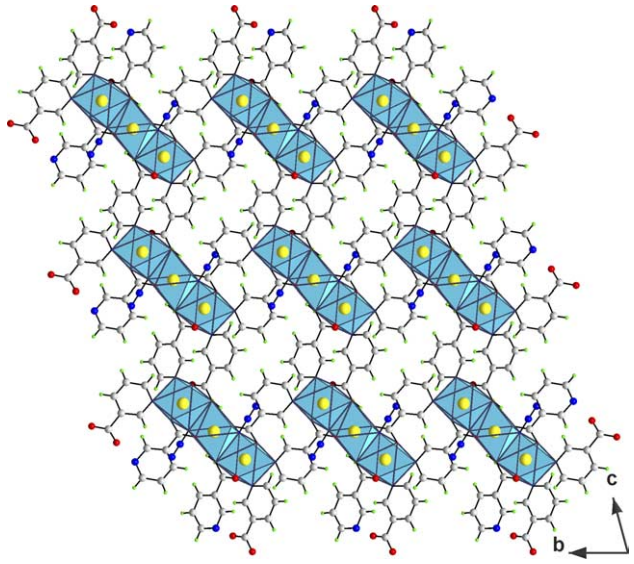

Fig. 2. A 4 × 4 superunit with coordination polyhedra of $[Cd_3(nic)_4(N_3)_2(H_2O)_2]_n$ complex **1**. Projection along the *a*-axis.

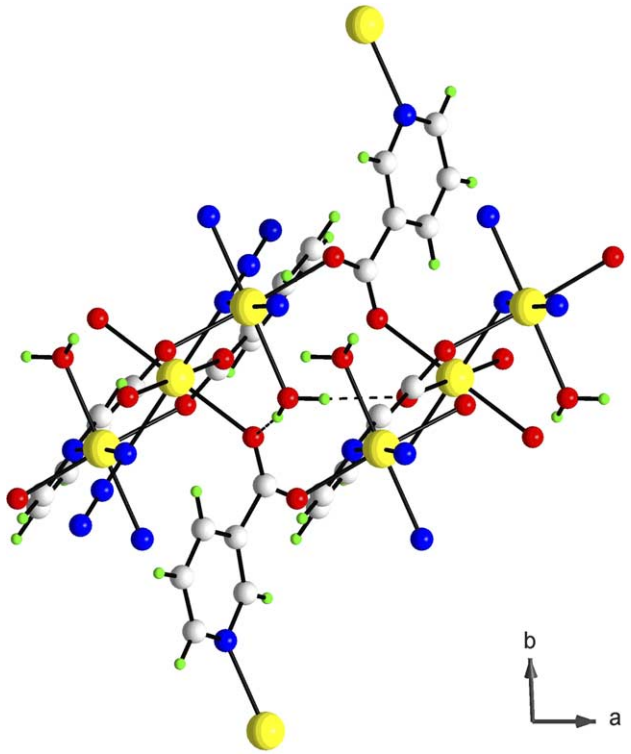

Fig. 3. A projection along the *c*-axis of **1**. Both ligands and hydrogen bonds, with the water molecule as a donor, bridging perpendicularly to the planes of the trinuclear units.

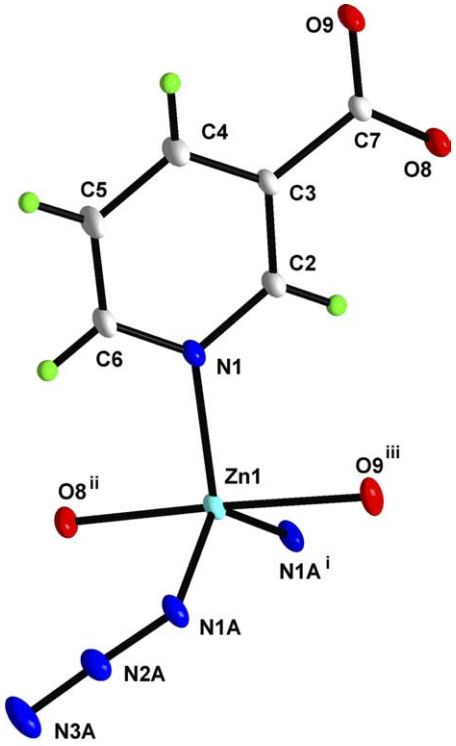

Fig. 4. Numbering scheme of $[Zn(nic)(N_3)_2]_n$ complex **2** and atomic displacement ellipsoids at the 50% probability level.

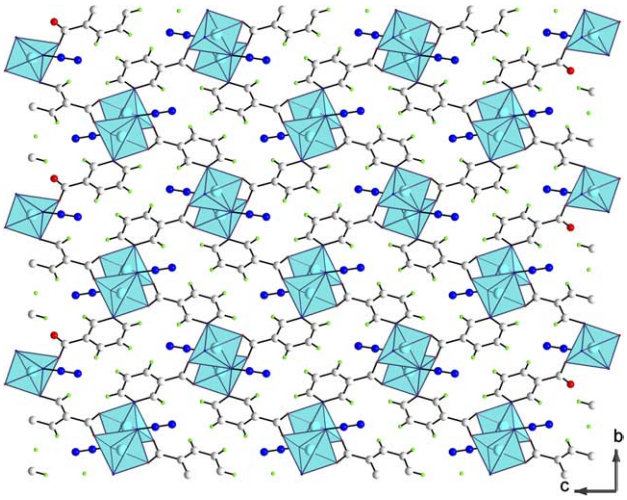

Fig. 5. Projection of the complex **2** structure along the *a*-axis. Coordination polyhedra for Zn atoms are shown.

The collected frames were integrated using the preliminary orientation matrices which were updated every 100 frames. Final cell parameters were obtained by refinement of the positions of reflections with $I > 10\sigma(I)$ after integration of all the frames using SAINT [21]. The data were empirically corrected for absorption and other effects using the SADABS [22] program. The structures were solved by direct methods and refined by full-matrix least squares on all F^2 data using SHELXTL software [23]. The non-H atoms were refined anisotropically, while hydrogen atoms were refined isotropically with use of geometrical restrains. The crystallographic and refinement data are summarized in Table 1. Selected bond distances and bond angles are given in Tables 2 and 4 for complexes **1** and **2**, respectively. Molecular graphics (Figs. 1–5) were prepared using the DIAMOND [24] program Table 3.

3. Results and discussion

The reaction between cadmium(II) and zinc(II) ions and nicotinic acid in the presence of the azide ion afforded 3:4 and 1:1 complexes, respectively. Complexes **1** and **2** are insoluble in non-polar solvents, e.g., benzene, CCl_4, etc. and in polar solvents, e.g., H_2O, MeOH, EtOH, $CHCl_3$, acetone, etc. indicating their polymeric nature. Both complexes are slightly soluble in DMSO. The ^1H NMR spectra of these complexes in DMSO suggest a partial substitution of the azido ligands by DMSO.

3.1. Structures

3.1.1. $[Cd_3(nic)_4(N_3)_2(H_2O)_2]_n$ (1)

X-ray single crystal structure determination reveals that complex **1** has a 3D network structure consisting of a novel linear, trinuclear unit containing three Cd(II) atoms, four nicotinate anions, two azide ions and two aqua molecules as shown in Fig. 1. All the three cadmium atoms are hexa-coordinated in a distorted octahedral environment. The central cadmium atom Cd1 is surrounded by two N atoms of two $\mu_{1,1}$-azido groups at [Cd–N 2.285(4) Å] and four O atoms of four different μ-N,O,O′-nicotinate anions [Cd–O 2.330(3) and 2.315-(3) Å], having a CdN_2O_4 chromophore. Each of the other two Cd atoms (Cd2) is surrounded by two hetero nitrogen atoms of two bridging μ-N,O,O′-tridentate nicotinate anions [Cd–N 2.348(4) and 2.351(4) Å]; one N atom of a bridging ($\mu_{1,1}$-N_3) group [Cd–N 2.296(4) Å] and three O atoms from two bridging carboxylate groups of two different nicotinate anions [Cd–O 2.277(3) and 2.324(3) Å] and one aqua molecule [Cd–O 2.304(4) Å]. Fig. 2 presents a 4×4 superunit with coordination polyhedra of the complex illustrating each nicotinate anion bridging one unit through its hetero nitrogen atom and other units through its carboxylate oxygen, assembling a sheet structure. The water molecule is further H-bonded to a neighboring unit [H···OH, 1.87(3) and 2.00(2) Å], Fig. 3. The Cd–O distances are shorter than those reported in other Cd(II) carboxylate structures, Cd–O 2.502(7) and 2.732(7) Å [25].

3.1.2. $[Zn(nic)(N_3)]_n$ (2)

Complex **2** crystallizes in the non-centrosymmetric space group $P2_12_12_1$, representing a right handed chiral complex from achiral molecules. The atom labelling scheme for complex **2** is shown in Fig. 4. The absolute structure was determined with Flack's parameter [26] being so good (0.001(8)) as to indicate that it has been unequivocally determined. The structure of **2** reveals a Zn(II) to nicotinate anion ratio of 1:1 as predicted from the elemental analysis. In this structure, the zinc atom is located at the center of a trigonal bipyramidal structure. The two axial positions of the trigonal bipyramidal structure are occupied by two oxygen atoms of two carboxylate groups [Zn–O 2.0651(9) and 2.1898(10) Å] from two different nicotinate anions with an O–Zn–O angle of 177.82(4)°. This is different from the bidendate O,O′-nicotinate anion in $[Ln_2(nic)_6(H_2O)_4]$ complexes, in which the two O atoms of the carboxylate group bind the same Ln atom, forming a four membered ring [8]. At the equatorial positions the zinc atom is linked by three nitrogen atoms, one N hetero atom [Zn–N 2.0484(11) Å] of the nicotinate anion and two N atoms of 2 ($\mu_{1,1}$-N_3) groups [Zn–N 2.0325(11) and 2.0523(11) Å]. The nicotinate anion, therefore behaves as a N,O,O′-tridentate bridging ligand, as in complex **1**, giving rise to a 3D structure for complex **2**, Fig. 5. The Zn–N and Zn–O bond lengths fall within the range found for other similar complexes, Zn–N 2.040(8) Å and Zn–O 2.152 Å for [Zn(H-pic)(pic)Cl] [12]. It is also comparable to the bonds in the dimeric Zn_2N_2 unit of the structure of

$[Zn(dpa)(N_3)(NO_3)]_2$ (dpa = 2,2′-dipyridylamine) [Zn–N 2.090(2) and 2.130(2) Å] [27]. The larger $N(1A)^{i}$–Zn(1)–N(1A) bond angle [128.20(3)°] is due to the Zn_2N_2 unit which has a $Zn(1)^{vi}$–N(1A)–Zn(1) bond angle of 111.96(5)°. The reported $[Zn_3(bpy)_3(hip)_2]\cdot 5H_2O$ complex has two different penta coordinated Zn(II) ions in a trigonal bipyramidal geometry with Zn–L (L = O, N) distances in the range of 1.997(9)–2.257(14) Å and bond angles in the equatorial plane in the range of 98.2(5)–142.3(5)° [28]. The bridging azide ion is asymmetric [N(1A)–N(2A) 1.2205(14) Å and N(2A)–N(3A) 1.1443(16) Å] and linear [N(3A)–N(2A)–N(1A) 178.08-(16)°].

3.2. Spectra

The room temperature IR spectra of the crystalline nicotinic acid and the sodium salt of nicotinic acid, and also the IR and Raman spectra of $[Cd_3(nic)_4(N_3)_2(H_2O)_2]_n$ complex **1** and $[Zn(nic)(N_3)]_n$ complex **2**, are given with tentative assignments of the bands in Table 5. In the high energy region complex **1** exhibits a strong broad band around 3400 cm^{-1} corresponding to the water molecules coordinated to the Cd(II) ions bridging the trinuclear units. Hydrogen bonding of the type N···H–O is indicated in the free acid by the presence of broad, medium strong bands near 2450 and 1880 cm^{-1} (IR) [29]. These bands are completely absent in the spectra of the solid complexes **1** and **2**, as well as the corresponding sodium salt [30]. The vibration frequencies of the free nicotinic acid in a KBr pellet at 1715 vs, br, ν(C=O) and 1640 s cm^{-1}, ν_{as}(–COO^-) (IR) [31,32] disappeared in both IR and Raman spectra of the complexes **1** and **2**. Instead the spectra of **1** and **2** show strong peaks around 1609 vs, (IR) and 1612 w cm^{-1} (Raman) and 1617 vs, (IR) and 1610 w cm^{-1} (Raman), respectively. These results indicate that only the nicotinate anions are coordinated to the Cd(II) and Zn(II) ions through their carboxylate oxygen atoms. The bands related to the pyridine ring in the IR spectra of **1** and **2** show systematic shifts in accordance with those found for pyridine complexes [33]. Thus, the nicotinate anions in both complexes **1** and **2** are coordinating via their carboxylate O atoms and the hetero N atoms.

The peaks at 2070 (vs), 1289 (m) cm^{-1} (IR) and 2110 (s), 1294 (vs) cm^{-1} (Raman) for **1** and 2100 (vs), 1292 (m) cm^{-1} (IR) and 2070 (m), 1290 (w) cm^{-1} (Raman) for **2** were assigned as (ν_{as}-N_3) and (ν_s-N_3), respectively. This is in agreement with the asymmetric nature of the bridging ($\mu_{1,1}$-N_3) groups [N(1)–N(2), 1.211(5) and N(2)–N(3), 1.146(5) Å for

complex **1** and N(1A)–N(2A), 1.2205(14) and N(2A)–N(3A), 1.1443(16) Å for complex **2**].

3.3. Thermal analysis

The TGA and DTA curves for complexes **1** and **2** are given in Fig. 6. As these complexes are expected to be explosives we used small amounts for such thermal analyses, as suggested previously for thermal decomposition measurements of azido compounds. [34] Complex **1** is stable until 180 °C, after which it decomposes (180–230 °C), losing one H_2O molecule (Exp. 1.95%, Theor. 1.91%), followed by the loss of the other H_2O molecule and one N_3 group (Exp. 6.6%, Theor. 6.3%), and then a third stage (305–350 °C), with a weight loss of 4.9%, corresponds to loss of the second N_3 group. These three stages are successive and appear as stages of one step ending at 350 °C. This appears in the DTA curve as a very weak endothermal peak at 241 °C. In the next step (350–440 °C) the weight loss is 38.73%, which corresponds to the loss of three nicotinates, (Theor. 38.69%), the loss of the forth nicotinate molecule starts at 440 °C (Exp. 12.8%, Theor. 12.9%). This last step appears in the DTA curve as two overlapped exotherms at 450 and 458 °C (Fig. 6). The weight of the final residue of 35.6% suggests that some explosion occurred since the residue is found to be CdO, as indicated by X-ray powder diffraction. Accordingly the residue should be 40.6%, which is much higher than the experimental value.

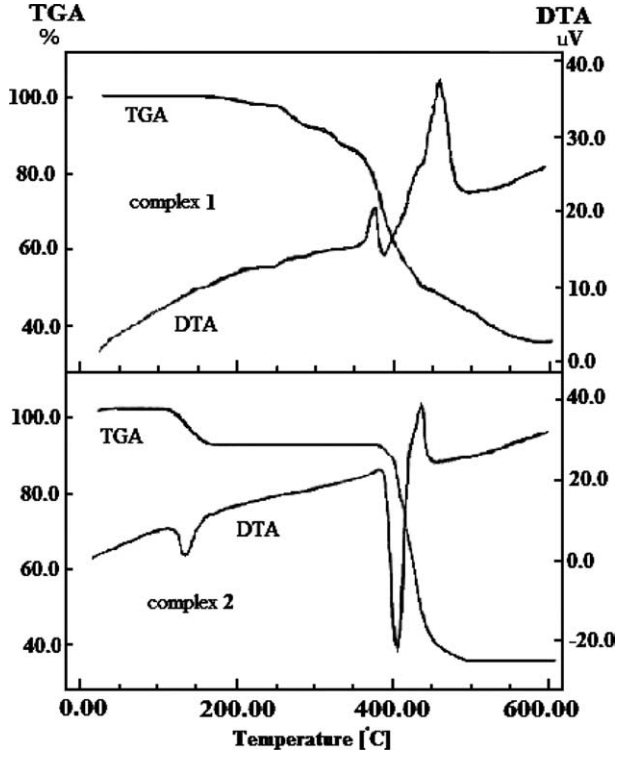

Fig. 6. Thermal behaviour of complexes **1** and **2**.

The TGA curve for complex **2** shows only two steps; the first step starts around 120 °C, followed by a long plateau. The weight loss of 8.9% in this step corresponds to the loss of a half N_3 ion (Theor. 9.1%). This step appears as an endotherm at 135 °C in the DTA curve. The second step starts at 375 °C with a weight loss of 57% suggesting a loss of the other half N_3 ion, CO and pyridine radical (Theor. 55.3%), leaving a ZnO residue of 35% (Theor. 35.6%).

Acknowledgments

This work was supported by the Swedish Research Council through the SIDA-Swedish Research Links Program (Grant No. 348-2002-6879). We are grateful to Prof. Vratislav Langer (Department of Environmental Inorganic Chemistry, Chalmers University of Technology) for his advice, the use of his equipment and computational facilities. Thanks to Prof. Yehia Badr, Cairo University, Egypt for the Raman measurements.

Appendix A. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition numbers: CCDC 258680 and 258681 for **1** and **2**, respectively. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.05.026.

(0D) units in **1** and **2** self-assemble via O–H···N and N–H···O hydrogen bonds resulting in 2D sheets, which thereby yield 3D supramolecular architectures through π···π and C–H···π interactions. Both complexes behave as luminous materials, which can be correlated to their supramolecular networks.

2. Experimental

2.1. Materials

High purity 2,2′-dipyridylamine (Fluka, Germany), nickel acetate tetrahydrate (E. Merck, India), zinc acetate dihydrate (E. Merck, India) and sodium azide (E. Merck, India) were purchased from the respective concerns and used as received. All other chemicals and solvents were of analytical reagent grade. For electrochemical work the solvent DMF was purified and the supporting electrolyte [*n*-Bu_4N][ClO_4] was prepared following a reported procedure [23].

Caution! Azido compounds of metal ions are potentially explosive. Only a small amount of material should be prepared and handled with care.

2.2. Physical measurement

Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr pellet, 4000–300 cm^{-1}) were recorded using a Jasco FT-IR Model 420 or Perkin–Elmer RX 1 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01(M) KCl solution and DMF was used as solvent. Ground state absorption and steady-state fluorescence measurements were made with a Jasco Model V-530 UV–Vis spectrophotometer and Hitachi Model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, Model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photomultiplier tube were, respectively, used as the excitation source and the fluorescence detector. Room-temperature solid phase magnetic susceptibility was measured at 25 °C with a PAR 155 vibrating sample magnetometer using Hg[$Co(SCN)_4$] as the reference. Diamagnetic corrections were made using Pascal's constants. Thermal analysis (TG-DTA) was carried out using a Shimadzu DT-30 thermal analyzer under N_2. Cyclic voltammetry (CV) experiments were carried out (in DMF solution) with the use of a computer controlled EG&G PARC VersaStat Model 270 electrochemical instrument at a platinum disk working electrode as described elsewhere [24].

2.3. Preparation of the complexes

Complex **1** was obtained from both the metal nitrate and acetate using a 1:2:2 mole ratio of the metal salt, dpa and azide. However, for the preparation of **2**, zinc acetate was required; use of zinc nitrate always led to the complex [$Zn(dpa)(N_3)_2$] [13a].

2.3.1. $[Ni(dpa)_2(N_3)_2]\cdot H_2O$ (**1**)

The synthesis with nickel acetate is described. dpa (0.11 g, 0.648 mmol) in acetonitrile (5 cm^3) was added slowly to a $Ni(OAc)_2\cdot 4H_2O$ (0.08 g, 0.343 mmol) solution (10 cm^3) in the same solvent. NaN_3 (0.042 g, 0.648 mmol) in water (5 cm^3) was added dropwise to it. After filtration through a fine glass frit, the supernatant blue solution was kept in air for slow evaporation. After a week blue crystals of **1** were deposited, which were separated by filtration and dried in vacuo over silica gel indicator. Yield: 0.129 g (75%). *Anal*. Calc. for $C_{20}H_{20}N_{12}ONi$ (**1**): C, 47.74; H, 4.01; N, 33.40. Found: C, 47.52; H, 3.92; N, 33.14%. IR (KBr, cm^{-1}): *ν*(N–H) 3300; *ν*(N=N=N) 2060, 2038; *ν*(C=N) 1590. UV–Vis (*λ*, nm): 315, 590 (sh) and 956 (sh). μ_{eff}: 2.92 BM. Λ_M (DMF, Ω^{-1} cm^2 mol^{-1}): 5. E° (DMF): 1.22 V.

2.3.2. $[Zn(dpa)_2(N_3)_2]\cdot H_2O$ (**2**)

An acetonitrile solution (5 cm^3) of dpa (0.11 g, 0.628 mmol) was added to a solution of $Zn(OAc)_2\,.\,2H_2O$ (0.10 g, 0.324 mmol) in the same solvent (10 cm^3) followed by NaN_3 (0.043 g, 0.656 mmol) in water (5 cm^3). The mixture was filtered and the supernatant liquid was kept in air for slow evaporation. After a few days **2** was separated, washed with toluene and dried in vacuo over silica gel indicator. Yield: 0.218 g (70%). *Anal*. Calc. for $C_{20}H_{20}N_{12}OZn$ (**2**): C, 47.12; H, 3.95; N, 32.97. Found: C, 47.18; H, 3.90; N, 32.85%. IR (KBr, cm^{-1}): *ν*(N–H) 3300 (br); *ν*(N=N=N) 2062, 2038; *ν*(C=N) 1590. Λ_M (DMF, Ω^{-1} cm^2 mol^{-1}): 5. UV–Vis (*λ*, nm): 255, 315.

2.4. X-ray diffraction study

Single crystals of the title complexes **1** and **2** were obtained by slow evaporation of 3:1 MeCN–H_2O solutions of the reaction mixtures. Diffraction data were collected on a Siemens SMART diffractometer equipped with a graphite monochromator and Mo Kα ($\lambda = 0.71073$ Å) radiation. The intensity data were corrected for Lorentz and polarisation effects and *φ* and *ω* scan absorption correction was employed using the SAINT [25] and SADABS [26] programs for the complexes. The structures were solved by the Patterson syntheses using SHELXS-97 [27] and followed by successive Fourier and difference Fourier syntheses. Full-matrix least-squares refinements on F^2 were carried out using SHELXL-97 [28]. The hydrogen atoms were fixed geomet-

rically and refined using a riding model. All non-hydrogen atoms were anisotropically refined. The water hydrogens were first located from the difference maps and then were constrained to ride on the carrier oxygen atom with U_{iso} values also constrained to $1.2U_{eq}$ of the carrier atom for refinement. In the final difference Fourier map the residual maxima and minima were 0.33 and −0.38 e Å^{-3} for **1**, 0.30 and −0.44 e Å^{-3} for **2**, respectively. All calculations were carried out using PLATON-99 [29] and ORTEP-32 [30]. The crystal data, data collection parameters and the results of analyses of **1** and **2** can be found in Table 1.

3. Results and discussion

3.1. Synthesis and formulation

Hexacoordinated mononuclear blue compound **1** was obtained as a crystalline product through the single-pot reaction of a 1:2:2 mole ratio of the metal acetate/nitrate, organic blocker and the pseudohalide in an aqueous acetonitrile solution. The use of the nitrate salt in the case of zinc leads to the tetracoordinated $[Zn(dpa)(N_3)_2]$ species, which is in conformity with earlier reports of Bose et al. [13a]. However, with the use of zinc(II) acetate, hexacoordinated colourless **2** was obtained in good yield. The complexes were characterized using microanalytical, spectroscopic, magnetic and physicochemical results. The air stable moisture insensitive products are insoluble in common solvents like water, methanol, ethanol, dichloromethane and acetonitrile, but are moderately soluble in dimethylformamide and dimethylsulfoxide on warming. In DMF solutions they show non-electrolytic behaviour [31] as is evident from low Λ_M values. Room temperature solid phase magnetic measurements show that **1** is a two-electron paramagnet with a moment close to the spin only value, whereas **2** behaves as a diamagnet. In the IR spectra, **1** and **2** display two characteristic azido stretches, which is in conformity with a mutual *cis* alignment of the two terminal pseudihalides [32]. Complexes **1** and **2** show superposable IR spectra, with a slight frequency shift particularly at $\nu(N_3)$. Reflectance spectra [**1**: λ, 315, 592, 956 nm; **2**: λ, 255, 315 nm] in nujol and electronic spectra in DMF solutions are akin in each complex reflecting a similar gross geometric structure and electronic structure in the solid state and in solution [33]. Thermal study (TG-DTA) reveals a weight loss of 3.46% and 3.54% at 60–80 °C, corresponding to loss of one crystalline water molecule in **1** and **2**, respectively. In the CV, a quasi-reversible (ΔE_p = 170 mV) oxidative response due to the Ni^{III}/Ni^{II} couple is observable in **1**. The formal potential lies close to ca. 1.2 V versus SCE. The one-electron nature of the couple was verified with comparison to a standard sample [34]. Compound **2** was found to be electro-inactive as expected for a d^{10}-ion.

3.2. X-ray structures

The structural analyses show that **1** and **2** are isomorphous and consist of mononuclear (0D) units which are further engaged in cooperative intermolecular hydrogen bondings and π···π and C–H···π interactions among themselves to result in a 3D supramolecular continuum. The ORTEP diagram with the atom numbering scheme of the mononuclear units in **1** and **2** are shown in Figs. 1 and 2, respectively. The perspective view of the 1D chain through O–H···N hydrogen bonds leading to a 1D sheet, the 2D sheet formed by interwoven O–H···N and N–H···O hydrogen bonds, and the 3D continuum formed by face-to-face π···π and edge-to-face C–H···π interactions in one case, **1**, are given in Figs. 3–5, respectively. Selected bond distances and bond angles relevant to the metal coordination spheres in **1** and **2** are given in Table 2. The significant hydrogen bonding, π···π and C–H···π interaction parameters are set in Table 3.

The coordination polyhedron around both metal centres in **1** and **2** is best described as a distorted octahedron with a MN_6 chromophore. The coordination includes two chelated tailored diimines (–N=C–NH–C=N–) ligated by four pyridine N atoms (N1, N3, N4, N6) and two terminal azide N atoms (N7, N10). Three pyridine nitrogens (N1, N4, N6) of two different dpa units and

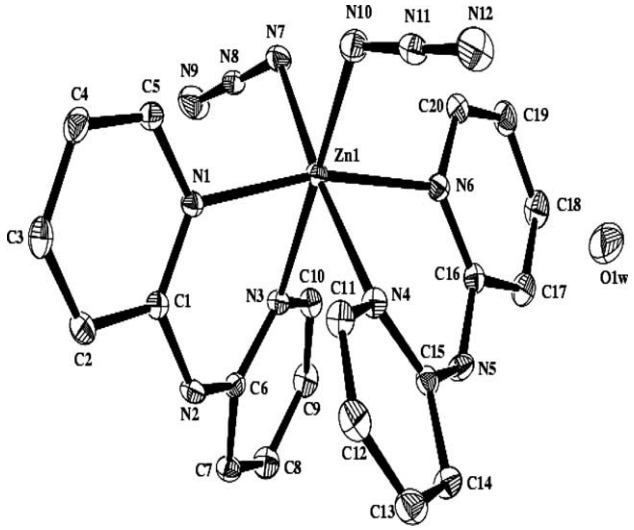

Fig. 2. ORTEP diagram of $[Zn(dpa)_2(N_3)_2]\cdot H_2O$ (**2**) with the atom labelling scheme and 40% probability ellipsoids for all non-hydrogen atoms.

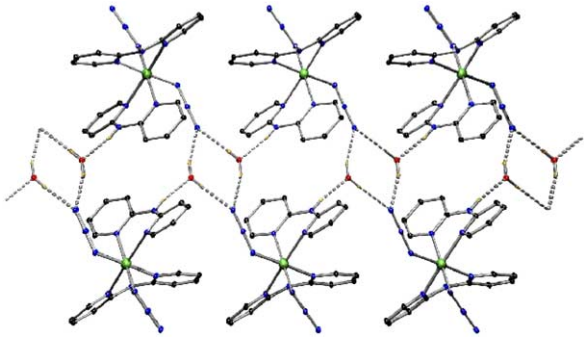

Fig. 3. View of the cyclic $R_2^4(8)$ formed by the water donor in **1**.

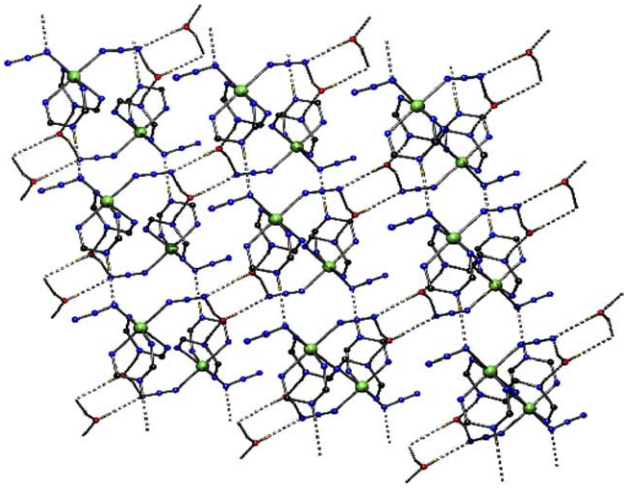

Fig. 4. View of the 2D sheet built by the monomeric units of **1** through hydrogen bonding (for clarity the pyridine part of the dpa ligand has been omitted).

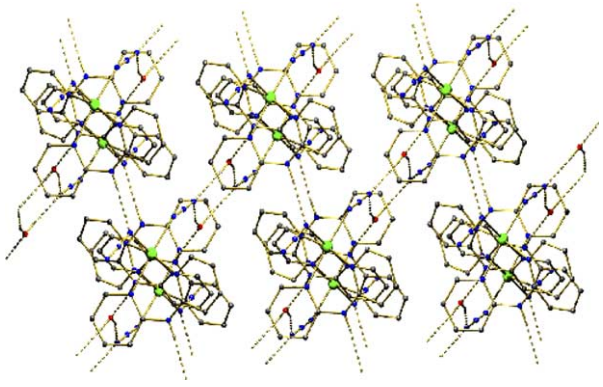

Fig. 5. 3D supramolecular network in **1** using weak interactions (hydrogen bonding, π stacking and C–H···π interactions).

one nitrogen (N7) of the pendant azido group define the equatorial plane around the metal(II) centre. The *trans* axial sites are occupied by one nitrogen (N3) from the remaining pyridine ring of a dpa unit and one nitrogen (N10) from the other pendant azido ligand (Figs. 1 and 2). The basal nitrogen atoms are planar with a rms deviation of 0.0425 and 0.059 Å, in **1** and **2**, respectively. The maximum deviation of any equatorial atom (N3) from the mean plane around nickel(II) in **1** and around zinc(II) in **2** are 0.045(2) and 0.064(2) Å, respectively. Deviations of nickel(II) and zinc(II) from the mean plane towards the azido nitrogen (N10) are about 0.048(1) and 0.127 (1) Å, respectively.

Table 2
Selected bond distances (Å) and bond angles (°) for **1** and **2**

N(3)–Ni(1)–N(6)	91.32(9)	N(3)–Zn(1)–N(6)	88.71(7)
N(3)–Ni(1)–N(7)	88.69(10)	N(3)–Zn(1)–N(7)	93.77(7)
N(3)–Ni(1)–N(10)	174.90(10)	N(3)–Zn(1)–N(10)	175.35(8)
N(4)–Ni(1)–N(6)	83.67(9)	N(4)–Zn(1)–N(6)	80.38(7)
N(4)–Ni(1)–N(7)	177.92(10)	N(4)–Zn(1)–N(7)	174.48(7)
N(4)–Ni(1)–N(10)	92.96(9)	N(4)–Zn(1)–N(10)	88.20(8)
N(6)–Ni(1)–N(7)	94.26(9)	N(6)–Zn(1)–N(7)	94.63(7)
N(6)–Ni(1)–N(10)	92.10(9)	N(6)–Zn(1)–N(10)	93.98(8)

All the six Ni–N bond lengths in **1** lie within a close range [2.085(2)–2.124(3) Å] and are consistent with the corresponding values of nickel(II)–N systems [20,21] and in **2** there are lengthened Zn–N bonds [2.1149(19) –2.2423(18) Å] which are consistent with the corresponding values of Zn(II)–N systems [19]. In both compounds the azido ligands are linear and mutually in a *cis* alignment. The dpa bites [N1–Ni–N3 83.86(9)°, N4–Ni–N6 83.67(9)° in **1** and N1–Zn1–N3 81.30(6)°, N4–Zn1–N6 80.38(7)° in **2**] are similar. In **1** the ranges of the *cisoid* and the *transoid* angles are 83.67(9)–94.26(9)° and 172.15(9)–177.92(10)°, respectively, and those in complex **2** are 80.38(7)–95.61(7)° and 166.12(6)–175.35(8)°, respectively, which reflect the degrees of distortion from the ideal octahedral geometry (Table 2). The dpa ligands are not planar as reflected by the dihedral angles between the planar pyridine rings (N1, C1 → C5 and N3, C6 → C10; N4, C11 → C15 and N6, C16 → C20) which are 21.9(2)°, 28.1(2)° for **1** and 25.6(1)° 18.2(1)° for **2**.

The packing diagram of **1** in the *ab*-plane exhibits a 2D supramolecular architecture arising from two types of hydrogen bondings (Figs. 3 and 4). The solvent water molecule (O1W) and amine nitrogen atoms (N2, N5) play a vital role in the formation of the 2D sheet. Four neighbouring mononuclear units are held together through hydrogen bondings between the donor water molecule and azide acceptor [O1W···N9 2.878(5) Å, ∠O1W–H1W1···N9 162(4)°; O1W···N9 2.938(5) Å, ∠O1W–H2W1···N9 175(6)°]. The O–H···N bonds generate a cyclic motif $R_2^4(8)$ in Etter's graph notation [35]. This, in turn, results in a 1D chain (Fig. 3). These 1D chains are connected through hydrogen bonding between the amine nitrogen donors (N2, N5) and the water and azido nitrogen (N10) acceptors [N2···O1W 2.863(4) Å, ∠N2–H2N···O1W 170(3)°; N5···N10 3.107(4) Å, ∠N5–H5N···O1W 176(4)°]. These two types of hydrogen bondings are interwoven and facilitate the formation of a 2D supramolecular sheet in the *ab*-plane (Fig. 4). The same overall average N···O distance (2.89 Å) between hydrogen-bonded groups is indicative of the presence of moderate directional hydrogen bonding, which may be used in crystal engineering. The pyridyl planes (N6–C16–C17–C18–C19–C20) from adjacent sheets form face-to-face π···π and intramolecular C–H···π interactions, resulting in a 3D continuum (Fig. 5). The dihedral angle between the pyridyl rings is 0.0° and the perpendicular distance between the baricenters of these planes is about 3.521 Å. In each sheet, the Ni···Ni separation between the nearest neighbours is 7.66 Å.

3.3. Luminescence spectra

The spectroscopic data are listed in Table 4. The emission energy of **1** and **2** in DMF solutions at 298 K is almost same ($\lambda_{max} \approx 350$ nm) and is assignable to intraligand fluorescence [19,20]. The lifetimes of the fluorescence of **1** and **2** are 2.62 and 2.60 ns, respectively. In glassy solutions (DMF at 77 K) both fluoresce and $^3(\pi-\pi^*)$ phosphorescence is observed at 425 nm. In the solid state they show a distinct emission band at 374 nm, differing from their fluorescence spectra in DMF.

Table 4
Luminescence data for **1** and **2**

Sample	Absorption (λ/nm)	Emission (λ/nm)			Lifetime (ns)
		Fluorescence	Phosphorescence	Solid state	
dpa	314	349	425	366	2.58
1	315	350	425	374	2.62
2	315	352	425	374	2.60

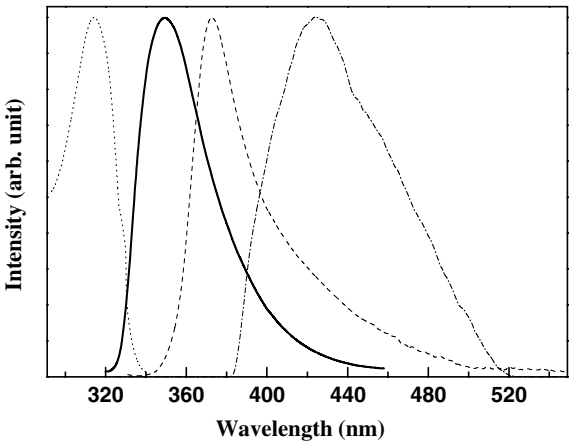

Fig. 6. Emission spectra of **1**: UV in DMF solution at 298 K (·····), fluorescence (——), phosphorescence in DMF glassy solution (- – – -), solid state at 298 K (- - - - - -).

This emission is expected to be due to excimer formation arising from the π···π aromatic stacking in the solid state and due to the similar strength of π···π stacking in both the complexes (Fig. 6).

4. Conclusion

We have shown that dpa can be used towards crystal design in combination with azide terminals leading to 3D network structures through cooperative forces from 0D building blocks. An emphasis has been made to show how the use of such non-covalent forces may be effectively harnessed to synthesize non-molecular solids of varied architectures [4a,13a]. The long-range structural motif ensures further study of dpa in combination with different pseudohalides like thiocyanate, cyanate, selenocyanate and carboxylates such as acetate around different 3d and 4d metal ions. The preparation of these compounds illustrates a potentially versatile approach to the construction of uncharged inorganic organic hybrid luminous materials.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication Nos. CCDC 202628 (**1**) and 239455 (**2**). Copies of this information can be obtained, free of charge, from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

and structural characterization of several $M^{II}{}_2$- $[M^{IV}(CN)_8]\cdot nH_2O$ [13h–13n] ($2 \leqslant n \leqslant 9$) and amine-functionalized networks been described [13b,14]; analogues containing $Cu^{II}/Mo(CN)_8{}^{n-}$ and $Co^{II/III}/\ W(CN)_8{}^{n-}$ units are reported to exhibit reversible photo-induced magnetization changes and we anticipate that incorporation of such bistable materials into electronic circuitry may ultimately afford molecule-based nanoscale switchable devices [13a,13b,13l–13n,15].

While we experienced limited success in crystallizing octacyanometalate networks via hydrothermal and slow diffusion methods, we began to explore the utility of amine ligands to direct and limit the number of cyano linkages formed between transition metal centers. Bidentate amines such as ethylenediamine (en) and 1,3-propanediamine (tn), find extensive use in the preparation of so-called "expanded Prussian blue solids" [16], but surprisingly few octacyanometalate derivatives are known [14a–14g,15,17]; octacyanometalate clusters containing these amines are also relatively rare [18].

In the present contribution, we describe the synthesis, structural, spectroscopic, and magnetic characterization of three unusual amine-expanded octacyanometalate(IV) networks that crystallize from aqueous mixtures of amines, octacyanometalate, and divalent transition metal salts.

2. Experimental

2.1. General considerations

All operations were conducted in the dark. Solvents were distilled under dinitrogen from CaH_2 (acetonitrile), Mg turnings (methanol), or sodium–benzophenone (diethyl ether). Deionized water, ammonium hydroxide (Malinkrodt), and $CuCl_2\cdot 2H_2O$ (Baker) were used as received. The preparation of $K_4[Mo(CN)_8]\cdot 2H_2O$ [19,20], $K_4[W(CN)_8]\cdot 2H_2O$ [21], and $Ni(OTs)_2$ [22] are described elsewhere while $Cs_3[Mo(CN)_8]\cdot 4H_2O$ [13o,21,23] and $[Ni(tn)_3][OTs]_2$ [22] were prepared via modifications to previously described procedures. The IR spectra were recorded as Nujol mulls between KBr plates on a Mattson Galaxy 5200 FTIR instrument. Room-temperature magnetic susceptibility measurements were conducted on a Johnson–Matthey Magnetic Susceptibility Balance. Variable temperature magnetic measurements were conducted on Quantum Design MPMS or MPMS2 SQUID magnetometers located at the Frederick Seitz Materials Characterization Laboratory at the University of Illinois at Urbana-Champaign. Photomagnetic studies were conducted using a Quantum Design Fiber Optic Sample Holder (FOSH) using infrared filtered white, red (Meade #23A), or blue (Meade #80A) light from a Dolan Jenner Fiber-Lite source. Diamagnetic corrections were estimated using Pascal's constants [24]: $\chi_{dia} = -200.32\times 10^{-6}\ cm^3\ mol^{-1}$ for **1**, $-458.32\times 10^{-6}\ cm^3\ mol^{-1}$ for **2**, $-464.32\times 10^{-6}\ cm^3\ mol^{-1}$ for **3**, and $-848.92\times 10^{-6}\ cm^3\ mol^{-1}$ for **4**. Microanalyses were performed by the University of Illinois Microanalytical Laboratory.

2.2. Preparation of complexes and networks

2.2.1. $[Ni^{II}(tn)_3][OTs]_2$ (**1**)

An aqueous (20 mL) solution of $Ni(OTs)_2$ (3.57 g, 7.02 mmol) was prepared by heating (100 °C) and 1,3-propanediamine (3.0 mL, 35.9 mmol) was added affording a purple suspension. The mixture was filtered and the filtrate was concentrated (10 mL) by heating to boiling. The concentrated mixture was allowed to stand at −20 °C for 2 h and then warm to room temperature. The purple crystals were isolated by suction filtration and were washed with EtOH (2×10 mL), Et_2O (10 mL), and dried under vacuum at room temperature for 2 h. Yield: 2.99 g (71.7%). *Anal.* Calc. for $C_{23}H_{45}N_6NiS_2O_{6.5}$: C, 43.48; H, 7.64; N, 13.21. Found: C, 43.52; H, 7.08; N, 12.94%. A hot methanol (40 mL) solution of $Ni(OTs)_2$ (1.54 g, 1.57 mmol) was treated with 1,3-propanediamine (2.64 mL, 3.56 mmol) and was allowed to cool to room temperature. Additional MeOH (85 mL) was added and addition of $K_4[Mo(CN)_8]\cdot 2H_2O$ (0.95 g, 1.91 mmol) in water (7 mL) afforded brown crystals within 1 h; the slow deposition of crystals ceased after four weeks at room temperature. The brown needles were isolated by suction filtration and washed with water (10 mL), EtOH (10 mL), Et_2O (3×10 mL), and dried under vacuum at room temperature overnight. Yield: 0.305 g (49.1%). *Anal.* Calc. for $C_{18}H_{46}N_{18}Ni_2O_7Mo$: C, 30.07; H, 7.09; N, 28.07. Found: C, 30.51; H, 6.01; N, 27.66%. 2.3. Structure determinations and refinements

Crystals of **2** and **3** were grown from aqueous $[Ni(tn)_3][OTs]_2$ or $Ni(OTs)_2$/1,3-propanediamine mixtures treated with either $K_4Mo(CN)_8\cdot 2H_2O$ (**2**) or $K_4W(CN)_8\cdot 2H_2O$ (**3**). Crystals of **4** were grown from aqueous ammonia solutions of $CuCl_2\cdot 4H_2O$ and $Cs_3Mo(CN)_8$. X-ray diffraction data were collected at 90.0(2) K on a Nonius kappaCCD diffractometer from irregular shaped crystals mounted in Paratone-N oil on glass fibers. Initial cell parameters were obtained (DENZO) [25] from ten 1° frames and were refined via a least-squares scheme using all data-collection frames (SCALEPACK) [26]. Lorentz/polarization corrections were applied during data reduction. The structures were solved by direct methods (SHELXS97) [26] and completed

by difference Fourier methods (SHELXL97) [26]. Refinement was performed against F^2 by weighted full-matrix least-squares (SHELXL97) [26] and empirical absorption corrections (either SCALEPACK [25] or SADABS [26]) were applied. Hydrogen atoms were found in difference maps and subsequently placed at calculated positions using suitable riding models with isotropic displacement parameters derived from their carrier atoms. Non-hydrogen atoms were refined with anisotropic displacement parameters. Atomic scattering factors were taken from the International Tables for Crystallography vol. C [27]. Crystal data, relevant details of the structure determinations, and selected geometrical parameters are provided in Tables 1–3.

3. Results and discussion

3.1. Synthesis and spectroscopic characterization

We have previously described that a series of bi- and trimetallic clusters and salts, rather than networks, are obtained when aqueous $[M^{II}(en)_3][OTs]_2$($OTs^- = p$-toluenesulfonate) is treated with $M(CN)_8^{n-}$ ($M = Mo^{IV,V}$, $W^{IV,V}$). We rationalized that substitution of ethylenediamine (en) for 1,3-propanediamine (tn), would afford kinetically labile $Ni^{II}(tn)_3^{2+}$ ions that undergo dissociative tn loss, forming reactive *cis*-$Ni^{II}(tn)_2(OH_2)_2^{2+}$ intermediates, and a series of amine-expanded octacyanometalate networks of $[Ni^{II}(tn)_2]_2[M^{IV}(CN)_8] \cdot nH_2O$ and $[Ni^{II}(tn)_2]_3[M^{V}(CN)_8]_2 \cdot nH_2O$ stoichiometry. Indeed, treatment of either aqueous mixtures of nickel(II) tosylate and 1,3-propanediamine or $[Ni^{II}(tn)_3][OTs]_2$ with $M(CN)_8^{n-}$ ($M = Mo^{IV,V}$, $W^{IV,V}$) affords isostructural one-dimensional networks of {[*trans*-$Ni^{II}(tn)_2(OH_2)$][*trans*-$Ni^{II}(tn)_2$][(μ-NC)$_3M^{IV}(CN)_5$] · $6H_2O$}.(M^{IV} = Mo, **2**; W, **3**) stoichiometry.

Rationalizing that bidentate amines may hinder the formation of two- and three-dimensional networks, we reasoned that unidentate donors such as ammonia may facilitate greater network dimensionality. However, attempts to prepare two-dimensional copper(II) substituted analogues described by Meske and co-workers consistently met with failure [14f]. Treatment of copper(II) chloride dihydrate with cesium octacyanomolybdate(V) in aqueous ammonia unexpectedly affords a three-dimensional network of $Cs_4[Cu^{II}(OH_2)_4]_2[Cu^{II}(NH_3)]_4[Mo^{IV}(CN)_8]_4 \cdot 2H_2O$ stoichiometry, via $Mo^{V}(CN)_8^{3-}$ reduction; such behavior has been previously reported [28,29].

The infrared spectra of **2**–**4** suggest that bridging and terminal cyano ligands are present and the cyano stretching absorptions (ν_{CN}) range from 2061 to 2172 cm^{-1}. The highest energy ν_{CN} absorptions are found for the Cu^{II} derivative, consistent with the formation of M^{II}–NC–M^{IV} units and depopulation of the cyanide 5σ orbital; increasing π-backbonding progressing from Cu^{II} to Ni^{II} compensates this effect and progressively lowers the ν_{CN} absorption energies from 2172 to 2153 cm^{-1} for **4** and **2**, respectively [30]. These ν_{CN} absorptions are shifted to higher energies relative to those found for $K_4Mo(CN)_8 \cdot 2H_2O$ (2126, 2012,

2060 cm^{-1}) and $K_4W(CN)_8\cdot 2H_2O$ (2125, 2095, 2056 cm^{-1}) [31], and are comparable to those exhibited by a variety of networks containing copper(II) and nickel(II) centers [14]. Unfortunately, the infrared characterization of $[M^{II}(NH_3)_4]_2[Mo^{IV}(CN)_8]\cdot 2H_2O$ (M^{II} = Co, Ni) lattices have not been reported [13f].

Generally, $M^{IV}(CN)_8^{4-}$ compounds exhibit cyano stretching absorptions that range from 2060 to 2160 (ionic) and 2085 to 2141 cm^{-1} (cyanide-bridged) [17,18,31–33]. The ν_{CN} absorptions of bridging cyanides are often found at higher energies than terminal ones, but this assumption is only applicable to compounds derived from bridged metal centers that do not function as donor–acceptor pairs. If kinematic effects, or the mechanical restraint of cyanide motion in M–CN–M′ units, are operative between the cyanide-bridged donor and acceptor centers, the ν_{CN} absorptions are expected to move to higher energies [30,34]. If however, increased π-backbonding compensates the kinematic effect by decreasing the C–N bond order, then red-shifted ν_{CN} absorptions that scale as a function of the donor–acceptor charge-transfer absorption oscillator strength, will be observed [30,34]. Assuming that π-backbonding effects are minor, we tentatively assign the bridging and terminal cyano stretching absorptions as those near 2140 and 2080 cm^{-1}, respectively.

3.2. Crystallographic studies

Crystals of **2** and **3** are in the $P\bar{1}$ space group and crystallize as one-dimensional chains of $\{[trans\text{-}Ni^{II}(tn)_2(OH_2)][trans\text{-}Ni^{II}(tn)_2][(\mu\text{-}NC)_3M^{IV}(CN)_5]\cdot 6H_2O\}$. stoichiometry (Table 1). The winding 1-D chains are composed of $[trans\text{-}(\mu\text{-}CN)Ni^{II}(tn)_2(\mu\text{-}NC)M^{IV}(CN)_6]$. ($M^{IV}$ = Mo, **2**; W, **3**) linkages with appended *trans*-Ni-$(tn)_2(OH_2)$ units that propagate parallel to the crystallographic *a* direction (Figs. 1 and 2). These "T-shaped chains" pack via inversion centers around a channel of lattice water molecules that are hydrogen bonded to adjacent cyanide, ammine, and aquo ligands along the crystallographic *c* direction. Coordination networks containing similar chain-like species have recently been reported by Kahn et al. we postulate that **2** and **3** are the efflorescent crystals described by Gao et al. [14e,15e].

Extensive interchain hydrogen bonding interactions are present between lattice water, aquo ligands, and terminal cyanides in **2** and **3**. The nearest neighbor contacts for **2** range from 2.685(5) (O(2WA)···O(3WA)) to 2.869(5) Å (N(6DD)···O(1WA)) while those for **3** range from 2.792(4) (O(1A)···O(1WB)) to 3.060(4) Å (O(5WC)···O(6WA)). Additional hydrogen bonding interactions (ca. 3.0–3.1 Å) are also present between lattice waters and coordinated tn and aquo ligands.

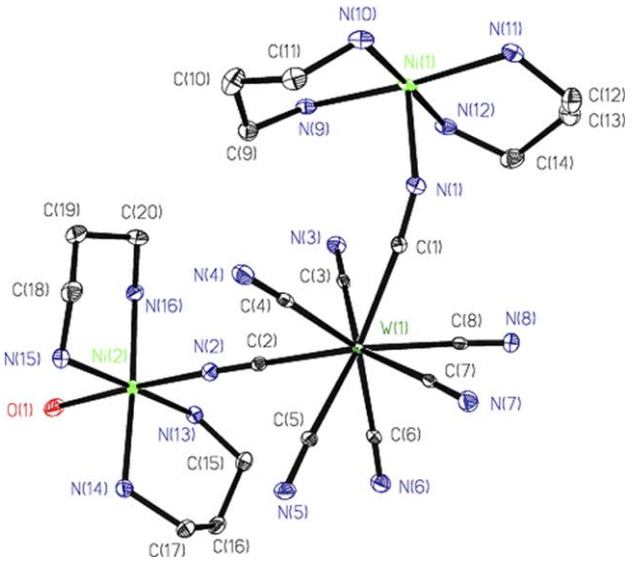

Fig. 1. X-ray structure of asymmetric unit of **3**. Hydrogen atoms are omitted for clarity and ellipsoids are at the 50% probability level.

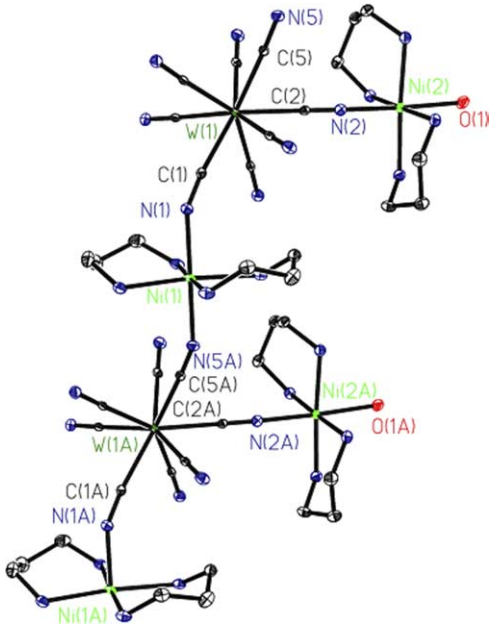

Fig. 2. X-ray structure of **3**. Hydrogen atoms and lattice water are omitted for clarity and all ellipsoids are at the 50% level.

Each three-connected $M^{IV}(CN)_8^{4-}$ center adopts a distorted square antiprismatic geometry and forms cyanide linkages to adjacent *trans*-$Ni^{II}(tn)_2(\mu\text{-}NC)_2$ and *trans*-(μ-CN) $Ni^{II}(tn)_2(OH_2)$ units. The average M^{IV}–C bond distances are 2.160(3) and 2.162(2) Å, while the C–M^{IV}–C bond angles range from 69.42(10)° to 143.58(10)° and 71.30(7)° to 144.96(8)°, for **2** and **3**, respectively (Tables 2 and 3). Cyanide nitrogen atoms N_1, N_2, and N_3 form μ-CN linkages to adjacent $Ni^{II}(tn)_2$ and $Ni^{II}(tn)_2(OH_2)$ fragments, whose M^{IV}–C bond distances range from 2.149(3) to 2.173(3) and 2.157(2) to 2.177(2) Å, for **2** and **3**, respectively. These M^{IV}–C and M^{II}–N bond distances are comparable to previously reported values.

The one-dimensional chain backbones are comprised of *trans*-$Ni^{II}(tn)_2(\mu\text{-}NC)_2$ units connected via cyanide linkages to each octacyanometalate(IV) center. The Ni–N_{tn} bond distances within each fragment range from 2.088(2) to 2.137(2) and 2.040(2) to 2.0384(18) Å while the Ni–$N_{cyanide}$ bond distances are nearly identical, ranging from 2.069(2) to 2.091(3) and 2.072(4) to 2.093(5) Å for **2** and **3**, respectively. For **2** and **3**, the nickel(II)–nitrile N–Ni(1)–N bond angles are nearly linear, 176.5(3)° and 176.5(3)° while the N_{tn}–Ni–$N_{cyanide}$ bond angles are nearly 90° (Tables 2 and 3).

Appended to each chain via a single bridging cyanide are *trans*-(μ-CN)$Ni^{II}(tn)_2(OH_2)$ units. These fragments exhibit slightly longer Ni–$N_{cyanide}$ and Ni–N_{tn} bond distances in comparison to the *trans*-$Ni^{II}(tn)_2(\mu\text{-}NC)_2$ fragments, with Ni–$N_{cyanide}$ bond distances of 2.040(2) and 2.0384(18) Å, and Ni–N_{tn} bond distances ranging from 2.088(2) to 2.137(2) and 2.0875(18) to 2.1384(18) Å, for **2** and **3**, respectively (Table 2). The Ni(1)–N(1)–C(1) and O(1)–Ni(1)–N(1) bond angles are described in Table 3.

Crystals of **4** are in the monoclinic *C*2/*m* space group (Table 1) and consist of anionic two-dimensional sheets containing an infinite array of distorted $\{Cs[(H_3N)Cu^{II}(\mu\text{-}NC)_5Mo^{IV}(CN)_3]_4\}_n^{3n-}$ box-like units (Fig. 3). The copper(II) and molybdenum(IV) centers reside in alternate corners of each box and are connected via μ-CN linkages, forming anionic

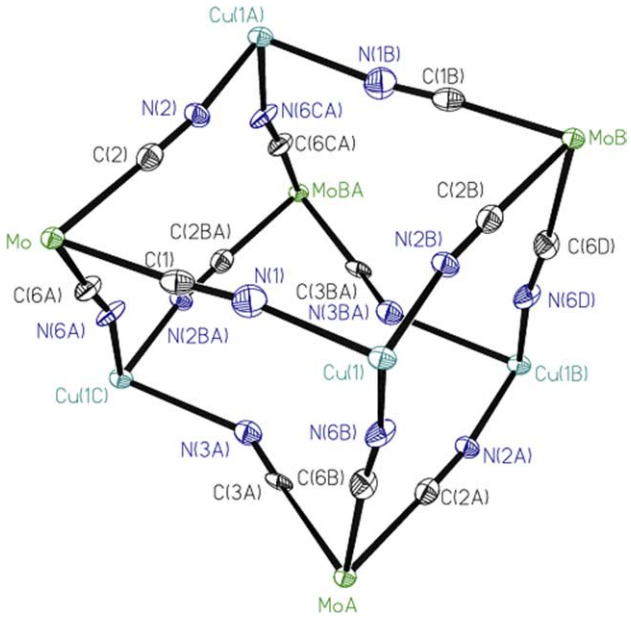

Fig. 3. X-ray structure of **4** showing distorted square portion of anionic 2-D sheet. Ellipsoids are at the 50% probability level and ammonia ligands, hydrogen atoms, cesium cations, and selected cyanides are eliminated for clarity.

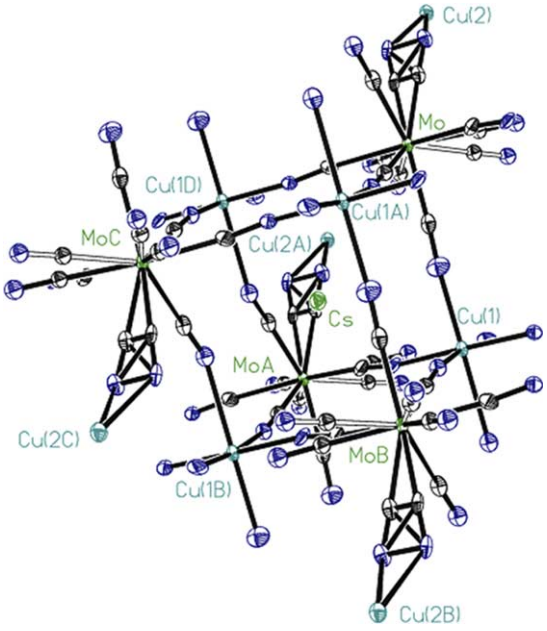

Fig. 4. X-ray structure of **4** showing distorted square portion of anionic 2-D sheet. Ellipsoids are at the 50% probability level and selected cyanide carbon and all aqua and hydrogen atoms are eliminated for clarity. Only nitrogen atoms (dark blue), carbon (black), copper (pale blue), and molybdenum (green). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

$\{Cs[(H_3N)Cu^{II}(\mu\text{-}NC)_5Mo^{IV}(CN)_3]_4\}_n^{4n-}$ slabs (Fig. 4). The parallel slabs are connected via disordered cyanides to *trans*-$Cu^{II}(OH_2)_4(\mu\text{-}NC)_2$ units that also exhibit canting along the Jahn–Teller N–Cu–N bond axis (Fig. 5). Overall, **4** adopts an unusual and complicated three-dimensional structure of $Cs_4[Cu^{II}(OH_2)_4]_2[Cu^{II}(NH_3)]_4$-$[Mo^{IV}(CN)_8]_4 \cdot 2H_2O$ stoichiometry (Fig. 6).

For **4**, the average Mo–C bond lengths of the $Mo^{IV}(\mu\text{-}CN)_6(CN)_2^{4-}$ centers range from 2.152(12) to 2.184(16) Å (Table 2). The cyanides linked to adjacent Cu^{II} centers range from 2.152(12) (Mo–C(1)) to 2.170(12) (Mo–C(2)) while those connected to Cu^{II} centers external to the sheet range from 2.147(12) (Mo–C(4)) to 2.184(16) (Mo–C(5)). The longest Mo–C bonds are found for terminal cyanides (2.184(16) Å) while cyanides *trans*- to the ammine in $(H_3N)Cu(\mu\text{-}NC)_5$ are comparatively shorter (2.170(12) Å); the *cis*-cyanides range from 2.152(12) to 2.161(11) Å (Table 2). Overall, the $Mo^{IV}(CN)_8^{4-}$ centers exhibit Mo–C–N bond angles ranging from 72.6(5)° to 146.2(5)° and adopt a distorted square anitprismatic coordination geometry (Table 3).

The Cu–N bond distances for the highly distorted $(H_3N)Cu(\mu\text{-}NC)_5^{3-}$ units range from 1.985(8) to 2.575(9) Å for **4**. Tetragonal elongation along N(1)–Cu(1)–N(3A) bond vector in each $(H_3N)Cu(\mu\text{-}NC)_5$ fragment affords comparatively longer Cu–N bond distances, 2.257(9) (N_1–Cu_1) and 2.575(9) Å (N_{3A}–Cu_1), relative to either the Cu_1–NH_3 (1.985(8) Å, Cu_1–N_7),

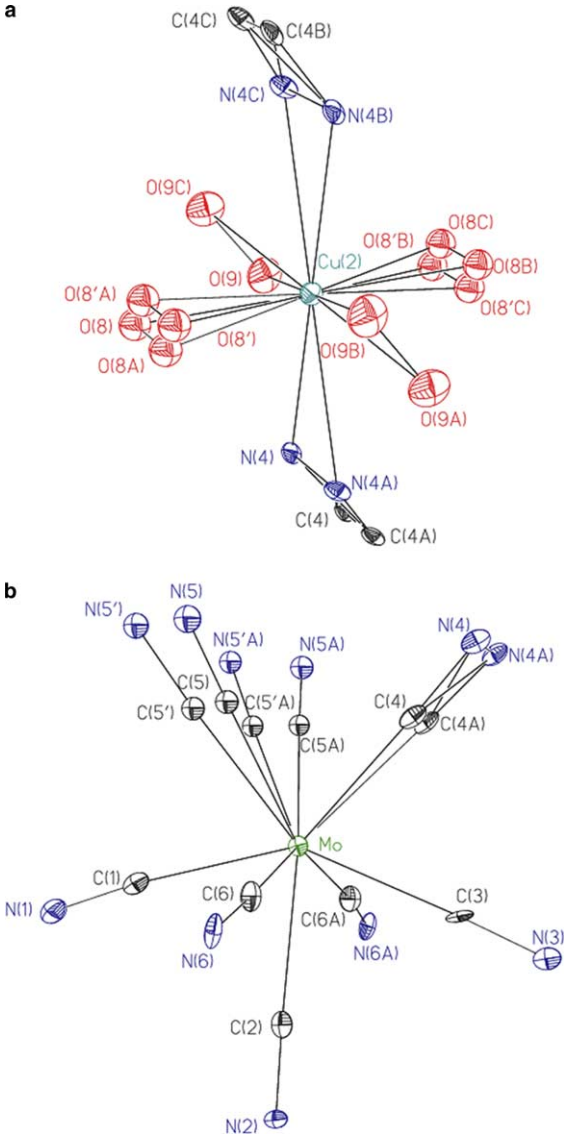

Fig. 5. X-ray structure of interlayer-bridged copper (a) and intralayer molybdenum centers (b) in **4**. Ellipsoids are at the 20% level.

or remaining cyanide linkages (ca. 2.020(10) Å ; Table 2). The N–Cu_1–N bond angles range from 90.61(17)° to 94.6(3)° (Table 3) and we conclude that the Jahn–Teller axis lies along the N(1)–Cu(1)–N(3A) bond vector.

In comparison, the *trans*-$Cu(OH_2)_4(\mu\text{-}NC)_2$ fragments connecting each sheet clearly show that the Jahn–Teller axis lies along the N(4)–Cu(2)–N(4A) vector. Rather long Cu–N bond distances (2.477(11) Å) are found between the copper and disordered cyanides with average Cu–O values of 2.04(3) Å. The copper atoms occupy crystallographically equivalent positions where the cyano and aquo ligands are disordered via canting (26.5°) along the Jahn–Teller axis (Fig. 5). Overall, incorporation of Jahn–Teller distorted copper(II) ions into **4** affords a rather complicated, unusual, and highly distorted three-dimensional structure (Fig. 6).

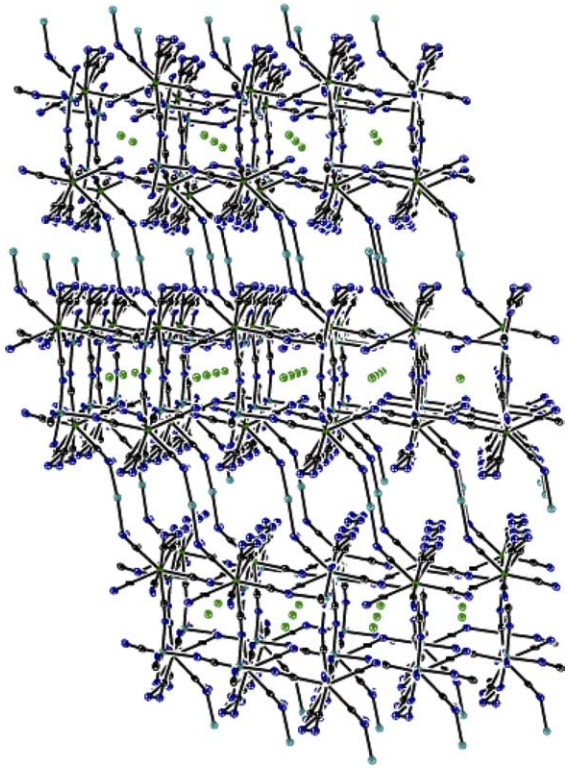

Fig. 6. X-ray structure of **4** showing connectivity of anionic 2-D sheets (center) via *trans*-(μ-CN)Cu(OH_2)$_4$(μ-NC) linkages down the *b* axis. Ellipsoids are at the 50% level and only carbon (black), cesium (green), copper (pale blue), nitrogen (blue), and molybdenum (dark green) are shown for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.3. Magnetic studies

Given that each lattice contains diamagnetic centers, we did not initiate extensive magnetic studies. The room temperature effective magnetic moments (μ_{eff}) of **2**–**4** using crushed crystals indicate that the $M^{IV}(CN)_8^{4-}$ (M^{IV} = Mo, W) centers are diamagnetic and that the paramagnetism of each network is due to the divalent transition metal centers (Ni, Cu) present. The calculated μ_{eff} values expected, assuming that $g = 2$, for a 2:1 ratio of paramagnetic (M^{II}) and diamagnetic (M^{IV}) centers is 4.0 μ_B for **2** and **3**; a 6:4 ratio of Cu^{II} to Mo^{IV} centers would afford a value of 4.24 μ_B for **4**. The experimental values are close to those expected and are 4.53, 4.41, and 4.34 μ_B for **2**–**4**, respectively. Assuming that spin-orbit coupling effects are operative, then the calculated *g* values are 2.27, 2.21, and 2.05 for the Ni^{II} and Cu^{II} centers in **2**–**4**, respectively [24,35,36].

4. Conclusions

In summary, a series of one- and three-dimensional octacyanometalate(IV) networks containing 1,3-propanediamine and ammine ligands have been synthesized and characterized via structural and magnetic methods. The distorted square antiprismatic $M^{IV}(CN)_8^{4-}$ centers are diamagnetic and the paramagnetism of each network originates from the Ni^{II} and Cu^{II} centers present. The photomagnetic properties of each network will be reported in a subsequent manuscript.

5. Supplementary material

CCDC numbers 263402–263404 contain the supplementary crystallographic data for this paper. These data may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or via www.ccdc.cam.ac.uk/data_request/cif.

The composition of heterocyclic products was dependent on a number of factors. If triethylamine was present (as an acceptor of released HCl), the four-membered heterocyclic compounds of diazadiphosphetidine type with P–N–P–N rings were formed, while the compounds with five-membered P–N–N–C–S heterocycles were obtained in the reactions that were carried out in an absence of the HCl acceptor. It is worth to mention the molecular structure of the reaction product for its unusual structure where a three-coordinate positively charged carbon atom is present in the heterocycle. This positive charge is compensated by a negative charge on the exocyclic sulfur atoms.

A planar heterocyclic compound with the five membered P–N–C–N–N cycle, pyridinium salt of 3-sulfido-3,5-dithioxo-1,2,4,3λ^5-triazaphospholidine, was the product of the reaction between **I** and non-subsituted thiosemicarbazide [10] carried out in acetonitrile in the presence of pyridine.

This article deals with the study of reactions of chlorodithiophosphoric acid pyridiniumbetaine **I** (py · PS_2Cl) with 4-methyl- and 4-ethylthiosemicarbazide that can be considered potential four-functional nucleophiles. The formation of new heterocyclic compounds was expected.

2. Experimental

All reactions were performed under dry nitrogen in anhydrous solvents using conventional Schlenk techniques with the exception of preparations of thiosemicarbazide derivatives. All chemicals were used as supplied (Aldrich, Lachema). Solvents were dried by standard methods and were distilled prior to their use [11]. Chlorodithiophosphoric acid pyridiniumbetaine (**I**) [12] and thiosemicarbazide derivatives [13] were prepared according to the known procedures. The ^{31}P NMR spectra were measured in acetonitrile or pyridine using a Bruker AVANCE DRX 300 instrument and were referenced to H_3PO_4 (85%). The IR spectra were recorded in Nujol mulls on a Bruker IFS 28 spectrometer. The Raman spectra of solid samples were collected in Raman capillaries on a Bruker Equinox X55/S instrument (see Table 1).

Diffraction data were collected on a KUMA KM-4 κ-axis diffractometer equipped with CCD detector with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Because of the small absorption coefficients the absorption correction was neglected. All the structures were solved by direct methods and refined by full-matrix least-squares methods using anisotropic thermal parameters for the non-hydrogen atoms. The hydrogen atoms on N1 and N2 were refined isotropically; all other hydrogens were placed in calculated idealized positions and refined as riding. The software packages used were: XCALIBUR CCD system [14] for the data collection/reduction, and SHELXTL [15] for the structure solution, refinement, and drawing preparation (thermal ellipsoids are drawn at the 50% probability level). Lattice parameters and other crystallographic data for **II** and **III** are given in Table 2, selected bond lengths and angles in Table 3, and hydrogen bonding parameters in Table 4. The molecular structures are drawn in Figs. 1 and 2.

2.1. Reaction of py · PS_2Cl (*I*) with thiosemicarbazide derivatives

The solution of **I** was prepared in acetonitrile. Pyridine and the solid thiosemicarbazide derivative were added to obtain a 1:1:1 molar ratio of components (Table 1). The reaction mixture was stirred on a magnetic stirrer at ambient temperature for 48 h. The extent of the reaction was followed by ^{31}P NMR spectroscopy. A white solid product was precipitated in the course of the reaction. It was filtered off by a Schlenk frit and dried under vacuum. Further portions of the product were obtained after partially concentrating the filtrates.

2.2. Pyridinium salt of 4-methyl-3-sulfido-3, 5-dithioxo-1,2,4,3λ^5-triazaphospholidine (*II*)

White powder, yield: 93% (with respect to **I**). ^{31}P NMR (acetonitrile): δ 112.8 ppm, quartet, ^3J[P–H] = 8.63 Hz. IR: 3211 w, 3125 m, 3092 m, 3061 m, 3042 m, 2725 m, 1633 m, 1603 m, 1523 s, 1478 vs, 1457 vs, 1351 m, 1273

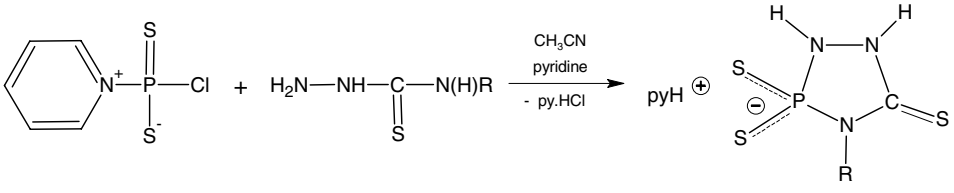
3. Discussion

The formation of the heterocyclic compounds **II** and **III** in the course of reactions between **I** and monosubstituted thiosemicarbazide derivatives (R = methyl, ethyl) is described in Eq. (1). Asimilar mechanism was found when the reaction of **I** with non-substituted thiosemicarbazide was studied [10]. The ^{31}P NMR spectra of products **II** and **III** were very simple. Only one signal was observed, which was split to the corresponding multiplet by the coupling between phosphorus and hydrogen nuclei of the organic moiety. No further interactions between phosphorus and nitrogen atoms or N–H protons were observed in the NMR spectra.



Many absorption bands above 3000 cm^{-1} were present in the IR spectra of **II** and **III**. These signals belong to the C–H bonds in the pyridinium cation. The bands above 3200 cm^{-1} can be ascribed to the N–H vibrations. Deformation vibrations of **N**–H groups (nitrogen atoms are present in the P–N–C–**N**–**N** cycle) were found at 1523 and 1532 cm^{-1} for **II** and **III**. In both cases the bands at 749 and 718 cm^{-1} (compound **II**) and 746 and 714 cm^{-1} (compound **III**) belong to P–S vibrations (ν_s, ν_{as}) in PS_2 groups, signals at 1480 cm^{-1} (1478 cm^{-1} for **II**, 1485 cm^{-1} for **III**) correspond to deformation vibrations of methyl groups.

Molecular structures of **II** and **III** were definitely confirmed by the X-ray diffraction analysis (Figs. 1 and 2). Single crystals of **II** and **III** were grown from concentrated acetonitrile solutions at room temperature over a few days. Pyridinium chloride (a by-product) was found in the crystal lattice in both cases.

The crystals of **II** are monoclinic (space group $P2_1/c$), **III** crystallizes as triclinic (space group $P\bar{1}$). Nevertheless, the molecular structures of **II** and **III** are very similar and can be compared to the structure of 3-sulfido-3,5-dithioxo-1,2,4,3λ^5-triazaphospholidine pyridinium salt **IV** [10], containing an analogous non-substituted P–N–C–N–N cycle. The five-membered rings in compounds **II**–**IV** show different degree of deviation from planarity. The ring in **IV** is the most planar (the r.m.s. deviation from the P(1)–N(1)–N(2)–C(1)–N(3) plane is 0.0400 Å), the five-membered rings of **II** and **III** are remarkably more distorted (r.m.s. deviations 0.1126 Å for **II** and 0.0795 Å for **III**).

The presence of pyridinium chloride in the crystal lattices of both **II** and **III** results in two kinds of intermolecular interactions (Figs. 3 and 4). First, the hydrogen bonding between the hydrogen atoms of N–H groups and chlorine atoms, and second, the interaction of exocyclic S(3) atom with hydrogen atom of the pyridinium cation. The hydrogen bonding parameters are summarized in Table 4.

The substitution in the position 4 led to changes in bond lengths and angles when compared with the non-substituted P–N–C–N–N cycle in **IV** [10]. With the

R= methyl (**II**)
R= ethyl (**III**)
R= H (**IV**), ref [10]

(1)

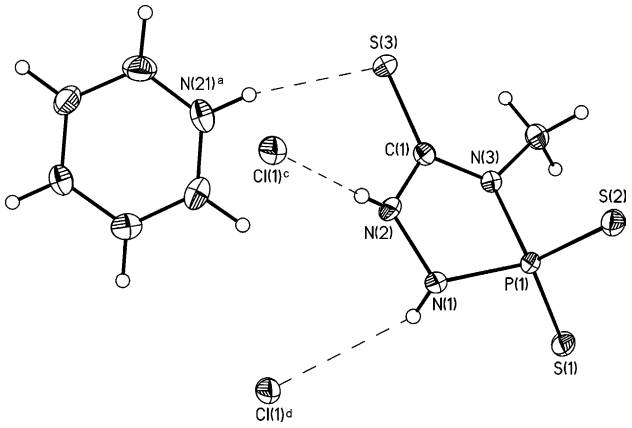


Fig. 3. H-bonding in the crystal structure of **II**. For symmetry transformations see Table 4.

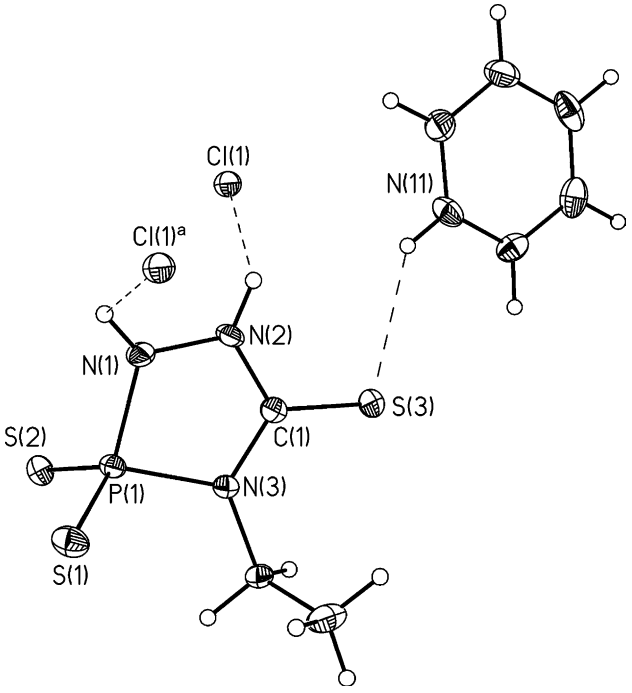

Fig. 4. H-bonding in the crystal structure of **III**. For symmetry transformations see Table 4.

exception of the N(3)–C(1) bonding distance, the elongation of practically all bonds was observed. Especially the extension of P(1)–N(3) from 1.699(2) Å in **IV** to 1.741(2) Å in **II**, and 1.738(2) Å in **III**, respectively, can be considered very significant. Two bond angles are contracted in the substituted cycles, namely P(1)–N(3)–C(1) (115.2(1)° in **IV**), and P(1)–N(1)–N(2) (110.1(1)° in **IV**). All other internal bond angles are slightly greater. As a result of the above mentioned changes, the size of the substituted rings increased.

The C(1)–S(3) lengths are practically identical in both **II** and **III**. The value of this parameter argues for a double bond character of this interaction (C=S 1.676 Å [10], 1.697 Å [16], 1.66–1.68 Å [17]). The lengths of both P–S bonds in **II** are very similar, which is in agreement with our conception of the delocalization of the negative charge. However, the P–S bond lengths in **III** differ slightly more (about 0.01 Å). Thus we can say that the negative charge is more localized on the S(2) atom, which is accordingly more distant from the phosphorus. No intermolecular interactions between the sulfur atoms bonded to phosphorus and hydrogens of pyridinium cation were observed.

To conclude, we have prepared and structurally characterized two anionic heterocyclic rings. We have found that the substitution in the rings is accompanied by variations in the internal bonding parameters as well as in the overall conformation of the cycles. However, because of the numerous intermolecular contacts in the solid phase, it is very uncertain to attribute the deformations within the cycles exclusively to the influence of the substituents. The preparation of the crystals without strongly interacting by-products (pyridinium chloride) or theoretical calculations on our derivatives would be helpful in better understanding of bonding in these interesting main-group heterocycles.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre. Copies are available from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk, or on the web http://www.ccdc.cam.ac.uk on request, quoting CCDC Nos. 261275 and 261276 for compounds **II** and **III**.

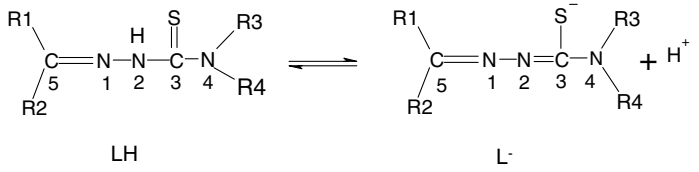

Fig. 1. Protonated and deprotonated forms of the thiosemicarbazone ligands.

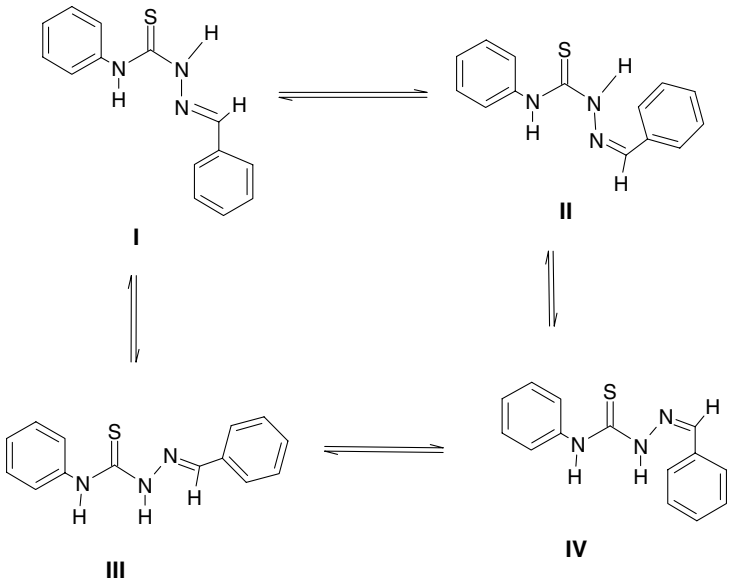

Fig. 2. Planar conformations of benzaldehyde 4-(phenyl)-thiosemicarbazone.

found that the thiosemicarbazonate(1^-) moiety is coordinated to dimethyl thallium(III) as a N,S chelating ligand, forming either a four-membered or a five-membered chelate ring depending on the substituent on the N(4) atom. The four-membered chelate ring was also observed [4–6] for organometallic derivatives of group 13 elements (Al, Ga and In), for Pd as well as another dimethyl thallium(III) complex. Bhattacharya et al. [2] tried to rationalize the formation of the four-membered chelate ring in terms of the known crystal structures [7] of benzaldehyde thiosemicarbazone and the corresponding ruthenium(II) and osmium(II) complexes. They argued that in the solid state the benzaldehyde thiosemicarbazone exists in form I (Fig. 2). Deprotonation of the N(2)–H proton can easily lead to the formation of a four-membered chelate ring. However, formation of a five-membered chelate ring requires rotation of 180° about the C(3)–N(2) bond to give form III.

Bhattacharya et al. also showed that formation of the five-membered chelate ring by form III results in a steric interaction between the ortho hydrogen of the phenyl ring of the benzaldehyde moiety with the metal atom, as well as between the two thiosemicarbazone moieties. Accordingly they reported that it is this steric factor which is responsible for the stabilization of the relatively uncommon four-membered chelate ring in these complexes compared to the more usual five-membered chelate rings. In this communication, we will examine this hypothesis more closely both from the viewpoint of available experimental results as well as quantum chemical calculations. Quantum chemical calculations of ruthenium complexes are quite popular today as they help to better understand the observed structural and experimental data. The most common methodologies adapted are DFT [8–11], INDO/S [11,12] and PM3 [9,13].

2. Experimental

2.1. Materials

Commercial ruthenium trichloride ($RuCl_3 \cdot xH_2O$), purchased from Arora Matthey (Kolkata, India), was processed by repeated evaporation to dryness with conc. HCl. $Ru(PPh_3)_3Cl_2$ was prepared by the published procedure [14]. The ligand, 4-(phenyl)thiosemicarbazone of benzaldehyde (BzTscHbz),was prepared by a modification of the published procedure [15]. Acetonitrile used for spectroscopic and electrochemical studies was purified according to a reported method [16]. Tetraethylam-

monium perchlorate (TEAP), used for the electrochemical work, was prepared as reported in the literature [17]. All other chemicals are of analytical grade and were used without further purification.

2.2. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 240 C,H,N analyzer. UV–Vis spectra were recorded using a JASCO 7850 spectrophotometer. Magnetic susceptibilities were measured with a PAR Model 155 vibrating sample magnetometer with $Hg[Co(SCN)_4]$ as the calibrant. ^{1}H NMR spectra were recorded on a Bruker AVANCE DPX 300 MHz spectrometer using $Si(CH_3)_4$ as internal standard. Cyclic voltammetry was carried out using a PAR Versastat instrument driven by E-chem software. A three-electrode configuration with Pt working and auxiliary electrodes, Ag/AgCl reference electrode and TEAP as supporting electrolyte was used. The potentials were calibrated against the ferrocene/ferrocenium couple.

2.3. Synthesis of the complexes

Safety note! Perchlorate salts of organic and metallo-organic species are potentially explosive, and although we have not encountered any problems in our work, nevertheless they should be handled with care.

2.3.1. Synthesis of cis-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**), $[Ru_2(PPh_3)_2(BzTscbz)_4]$ (**1b**)

To a 30 ml methanolic solution of BzTscHbz (128 mg, 0.5 mmol), Et_3N (50 mg, 0.5 mol) was added, followed by the addition of solid $[Ru(PPh_3)_3Cl_2]$ (240 mg, 0.25 mmol). After 3 h of reflux, a shining yellow precipitate was collected by filtration and washed thoroughly with cold methanol. Recrystallization of the product from 1:1 dichloromethane–hexane solution in nitrogen atmosphere leads to two types of crystals, golden yellow (**1a**) and red (**1b**). The products were separated mechanically under a microscope. Yield: **1a**, 170 mg (60%), **1b**, 52 mg (12.5%). *Anal*. Calc. for $RuC_{64}H_{54}N_6S_2P_2$ (**1a**): C, 67.78; H, 4.76; N, 7.41% Found: C, 67.81; H, 4.80; N, 7.42%; electronic spectra (dichloromethane solution, λ_{max}/nm, ε/L mol^{-1} cm^{-1}) 431[a] (6178), 340 (20758), 265[a] (43247), 227 (78586), ([a]shoulder); ^{1}H NMR ($CDCl_3$, 300 MHz), δ 9.06 (s, 2H), 8.01 (s, 2H), 7.41–7.38 (m, 4H), 7.36–7.30 (m, 12H), 7.28–7.21 (m, 14H), 7.17–7.12 (t, 8H, $J = 7.1$ Hz), 7.05–6.96 (m, 12H); Cyclic voltammetric data[b]: ($E_{1/2}$ in V (ΔE_p in mV)) Ru^{II}/Ru^{III}, 0.51 (107); Ru^{III}/Ru^{IV}, 1.25 (238); ([b]in CH_2Cl_2, 50 mV s^{-1} scan rate). *Anal*. Calc. for $Ru_2C_{92}H_{78}N_{12}S_4P_2$ (**1b**): C, 63.37; H, 4.47; N, 9.64% Found: C, 63.43; H, 4.51; N, 9.61%; electronic spectra (dichloromethane solution) 418[a] (8576), 340[a] (19113), 260[a] (41168), 228 (80866) ([a]shoulder); ^{1}H NMR ($CDCl_3$, 300 MHz), δ 8.39 (s, 2H), 8.27 (d, 2H, $J = 6.9$ Hz), 7.81 (d, 2H, $J = 12.0$ Hz), 7.60 (d, 2H, 7.4 Hz), 7.26–7.20 (m, 14H), 7.09–6.94 (m, 24H), 6.92–6.79 (m, 24H), 6.69–6.67 (d, 8H, $J = 7.7$ Hz).

2.3.2. Synthesis of $[Ru(PPh_3)_2(BzTscHbz)_2](ClO_4)_2$ (**2**)

To a 30 ml hot methanolic solution of the ligand BzTscHbz (128 mg, 0.5 mmol), solid $[Ru(PPh_3)_3Cl_2]$ (240 mg, 0.25 mmol) was added. The mixture was then refluxed for 3 h. The resulting orange yellow solution was concentrated to about 10 ml in a rotary evaporator; a 2 ml aqueous saturated solution of $NaClO_4$ was then added. The resulting precipitate was collected by filtration, washed with water and then dried over fused $CaCl_2$. Recrystallization of the crude product from 1:1 dichloromethane–hexane solution gave the analytically pure compound; yield 190 mg (57%). *Anal*. Calc. for $RuC_{64}H_{56}N_6S_2P_2Cl_2O_8$: C, 57.57; H, 4.19; N, 6.29% Found: C, 57.73; H, 4.21; N, 6.31%; electronic spectra (dichloromethane solution, λ_{max}/nm, ε/L mol^{-1} cm^{-1}) 400[a](3946), 337[a](9866), 252(45387), ([a]shoulder); ^{1}H NMR ($CDCl_3$, 300 MHz), δ 8.97 (s, 2H), 7.83 (s, 4H), 7.68–7.61 (m, 8H), 7.52–7.43 (m, 12H), 7.32–7.16 (m, 30H). Differential pulse voltammetric data[b]: ($E_{1/2}$ in V) Ru^{II}/Ru^{III}, 0.86; Ru^{III}/Ru^{IV}, 1.28 ([b]in CH_2Cl_2, 20 mV s^{-1} scan rate).

2.4. Computation

The total energy (E_{tot}) of the ligands and energy barriers (E_b) for transformation between the conformers depicted in Fig. 2 were calculated by PM3 [18], as well as DFT [19] methods. The PM3 calculations were carried out on the MM^+ optimized structure of the molecules using CIS involving 10 occupied and 10 unoccupied orbitals. A window based HYPERCHEM program [20] was used for both MM^+ and PM3 calculations and the default parameters of the program were adapted. The energy barriers for rotation around C(5)=N(1) and N(2)–C(3) bonds were calculated by changing the appropriate torsion angles between 0° and 180° and calculating the E_{tot} at each step and taking the difference of E_{tot} between its maximum value and that for a torsion angle of 0°. The DFT calculations on the ligand were carried out using the GAUSSIAN-98 program [21] and B3LYP/6-31+G* methodology, whereas for the calculations on the model transition metal complexes the ADF program [22] was used. For all elements the ZORA approximation was used together with the default TZP basis sets using a small core. In addition Vosko, Wilk and Nusair's local exchange correlation potential was used [23] together with Becke's non-local exchange [24] and Perdew's correlation corrections [25]. With GAUSSIAN-98 and ADF

programs, geometry optimization was carried out using the default criteria for convergence.

2.5. X-ray crystallography

Single crystals of the complex *cis*-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**) were grown by slow evaporation from a dichloromethane–hexane solution of the complex in nitrogen atmosphere. Data were measured with Mo Kα radiation using the MAR research Image Plate System The crystal was positioned at 70 mm from the Image Plate. 100 frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [26] to provide 10413 independent reflections. The structure was solved using direct methods with the SHELX-86 program [27]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. An empirical absorption correction was applied using DIFABS [28]. The structure was refined on F^2 using SHELXL [29] to R_1 0.1105, wR_2 0.1645 for 4179 reflections with $I > 2\sigma(I)$. The high R-value was due to the poor quality of the crystals, which led to mis-shapen spots in the diffraction pattern. Crystal data for **1a** appear in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

Reaction of $Ru(PPh_3)_3Cl_2$ with BzTscHbz in refluxing methanol in the presence of Et_3N results in the precipitation of a yellow product. On recrystallization from a dichloromethane-hexane mixture in nitrogen atmosphere two types of crystals were obtained. The major product was golden yellow needles, which was formulated as *cis*-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**) and the other product was some red rhombic crystals formulated as $[Ru_2(PPh_3)_2(BzTscbz)_4]$ (**1b**). $[Ru(PPh_3)_2(BzTscHbz)_2](ClO_4)_2$ (**2**) was obtained using a similar procedure as above, except Et_3N was not added during the reaction and the compound was precipitated by addition of 2ml of saturated methanolic solution of $NaClO_4$. Elemental analyses and spectroscopic data for the complexes are consistent with the proposed formulations. In the NMR spectra, the two C–H protons of the coordinated thiosemicarbazones of **1a** and **2** appear at δ 9.06 and 8.97, respectively, as a broad singlet, whereas the four C–H protons of the four ligands of **1b** appear at δ 8.39 and 8.27. The signals at δ 8.01, 7.83 may be due to the N–H protons of **1a** and **2**, respectively. The two doublets at δ 7.81 and 7.60 for **1b** may be assigned as N–H protons. All other protons appear in the aromatic region as multiplets and overlapping signals.

Room temperature magnetic moment measurement indicates all the complexes are diamagnetic; hence ruthenium is in the +2 oxidation state. Complex **2** behaves as a 1:2 electrolyte in MeCN solution ($\Lambda_M = 230\ \Omega^{-1}\ cm^2\ mol^{-1}$), indicating the thiosemicarbazone ligands act as neutral N–S donors in this complex. The products **1a** and **1b** were separated mechanically under a microscope and X-ray crystal structures of both were determined.

3.2. Description of the crystal structures for (*1a*) and (*1b*)

The selected bond distances and bond angles for *cis*-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**) are summarized in Table 2. In the compound *cis*-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**) the coordination geometry of Ru(II) is similar to that observed earlier [2], where two P atoms as well as two nitrogen atoms are cis to each other, while the sulfur atoms are trans to each other (Fig. 3).

The average bond distances are Ru–P, 2.314 Å; Ru–S, 2.439 Å; Ru–N, 2.140 Å and the bite angle for the four-membered chelate ring is 65.20°. This may be compared with the values reported [30] (average Ru–P,

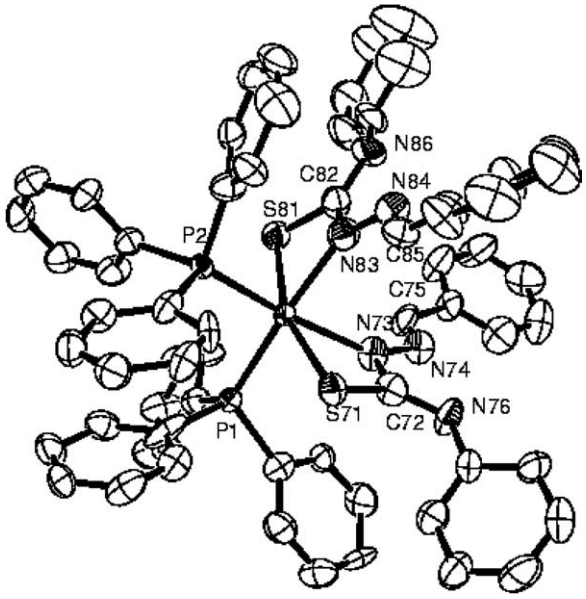

Fig. 3. ORTEP diagram and atom numbering scheme for *cis*-$[Ru(PPh_3)_2(BzTscbz)_2]$ (**1a**). Hydrogen atoms are omitted for clarity. Thermal ellipsoids are at 25% probability.

2.382 Å; Ru–S, 2.368 Å; Ru–N, 2.145 Å, bite angle for the five-membered chelate is 81.65°) for *cis*-$[Ru(PPh_3)(CyTscHPy)_2](ClO_4)_2$ (**3**) (where for CyTscPy $R_1 = H$, $R_2 = Py$, $R_3 = H$, $R_4 =$ cyclohexyl in Fig. 1), which has identical donor atoms (*cis*-P_2, *cis*-N_2, *trans*-S_2) to those reported here but the two thiosemicarbazone moieties are in the protonated form and coordinate in a more conventional way forming five-membered chelate rings. Normally, the anionic chelates are expected to have shorter bond lengths than the corresponding neutral variety. However, in this case the Ru–P bonds are shorter in **1a** than in **3**, while the Ru–S distances are longer in **1a**, clearly indicating that the Ru–S bond in the four-membered chelate ring is much weaker compared to that in the five-membered ring.

The lack of good crystal quality of **1b** resulted in poor refinement of the structure to an R_1 value of 0.25 so that no detailed comment on the dimensions can be made. [Crystal data, **1b**, $Ru_2C_{92}H_{78}N_{12}S_4P_2$, triclinic, $Z = 4$, $a = 16.042(17)$ Å, $b = 16.471(19)$ Å, $c = 18.238(19)$ Å, $\alpha = 76.63(1)°$, $\beta = 76.39(1)°$, $\gamma = 66.36(1)°$, $V = 4448.1$ Å^3, $D_{calc} = 1.302$ g cm^{-3}]. However, the atoms in the structure could be located well enough to show that there are two independent centrosymmetric dimers in the unit cell in which the two Ru(II) centers are bridged by two thiolato sulfur atoms. Each Ru(II) center is coordinated by one PPh_3 and two thiosemicarbazonate moieties, of which one thiosemicarbazonate forms a four-membered chelate ring while the other one forms a five-membered chelate ring, and it is the thiolato group belonging to the later variety which is responsible for bridging the Ru(II) centers (Fig. 4).

3.3. Probable structure of *2*

We have also synthesized the complex $[Ru(PPh_3)_2(BzTscHbz)_2](ClO_4)_2$ (**2**) containing the non-deprotonated thiosemicarbazone ligand. Although we have not been able to get a single crystal of the compound, the similarities of electronic spectra and the E^0[Ru(III)/Ru(II)] values of this complex with those reported by Ghosh et al. [30] suggest that it has a similar structure to one of their complexes, i.e., *cis*-P_2, *trans*-S_2, *cis*-N_2, where the thiosemicarbazone is coordinated as a five-membered chelating N,S donor. This is further corroborated by the fact that the addition of a dilute solution of a base such as Et_3N to a solution of **2** in dichloromethane or acetonitrile does not generate the spectra of **1a**.

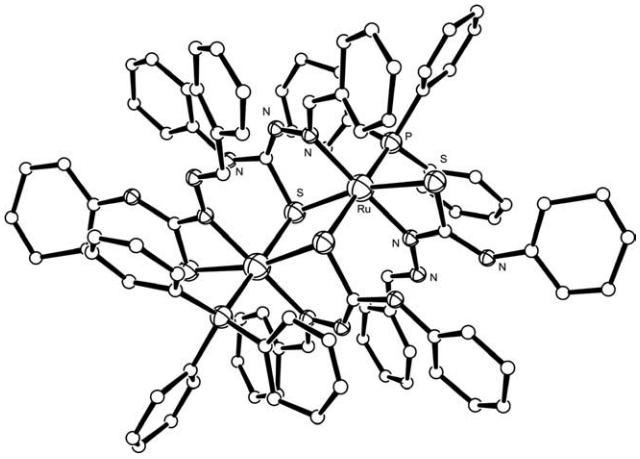

Fig. 4. X-ray structure of centrosymmetric $[Ru_2(PPh_3)_2(BzTscbz)_4]$ (**1b**). Hydrogen atoms are omitted for clarity.

Similarly, addition of dilute acid to a dichloromethane solution of **1a** does not generate the spectra of **2**. If the thiosemicarbazone is coordinated to both **1a** and **2** in a similar manner, then rapid interconversion between them is expected due to acid or base addition, which is not the case here. It may also be noted that so far in all the structurally characterized thiosemicarbazone complexes, when it is found to form a four-membered chelate ring, it is always present in the deprotonated form. Thus, on the basis of the above discussion, it is logical to conclude in **2** that thiosemicarbazone is present as a five-membered chelate ring.

3.4. Relative stability of four-membered versus five-membered chelate rings

In the light of the above results, we can reassess the possible binding modes of thiosemicarbazones in general and benzaldehyde thiosemicarbazone in particular. Benzaldehyde thiosemicarbazone can exist in the four conformations depicted in Fig. 2. Some important results of the quantum chemical calculations on these conformers are summarized in Table 3. It may be noted from the table that although the E_{tot} values for each conformer substantially differ between the two methods of calculations, the relative stabilities of the conformers as well as the E_{b1} value (see below) given by the semi-empirical PM3 method and more accurate DFT method are quite similar. In the solid state BzTscHbz exists in form I as revealed by the crystal structure determination [7]. When it coordinates in this form it has to undergo deprotonation of N(2)H followed by four-membered chelate ring formation. Form II can also participate in a similar four-membered chelate ring formation. However, conversion of form I to form II requires crossing of an energy barrier of ~45 kcal mol^{-1} (E_{b1}), without any benefit of additional bond energy; rather the phenyl ring will undergo steric repulsion with the rings of the tri(phenyl) phosphine and thus this form has not been found to coordinate.

Table 3
The E_{tot}^{rel} values for the different conformers of BzTscHbz

Conformer	Method of calculation	E_{tot}^{rel} (kcal mol^{-1})
I	PM3	0.0
	DFT	0.0
II	PM3	−0.40
	DFT	3.58
III	PM3	10.85
	DFT	11.02
IV	PM3	11.67
	DFT	15.59

E_{tot}^{rel} is the E_{tot} values of different conformers relative to conformer I, whose E_{tot} value is −58295.40 (PM3)/−692628.45 (DFT).

From these energies, the barriers for rotation about the C(5)=N(1) (E_{b1}) and N(2)–C(3) (E_{b2}) bonds can be calculated as 48.0, 15.5 kcal mol^{-1}, respectively, with PM3 and 45.6 and 31.3 kcal mol^{-1}, respectively, with DFT methods.

Forming a five-membered chelate ring requires either form III or form IV. However, it was shown by Bhattachyarya et al. [2] that coordination in form III results in severe steric strain. So like form II, form III has never been found to be coordinated in metal complexes. Thus, formation of a five-membered chelated complex requires form IV and crossing of an energy barrier of 45–50 kcal mol^{-1}, equivalent to the energy of a chemical bond, which is readily available in a chemical reaction like the present one where a psuedo-five coordinated Ru(II) is converted to a six coordinated species and deprotonations take place (considering the crystal field stabilization energy (CFSE) of Ru^{II} ~ 350 kcal mol^{-1}, solvation energy of a proton in MeOH ~ 180 kcal mol^{-1} and proton affinity of Et_3N ~ 230 kcal mol^{-1}). The benefit of stronger bond formation should lead to the coordination by form IV, in preference to form I, i.e., the metal complex containing the five-membered chelate ring with form IV should be thermodynamically more stable compared to one containing the four-membered chelate ring with form I. This is particularly so as form I is only ~16 kcal mol^{-1} more stable than form IV according to the DFT calculations. The structure determination of two Ni(II) complexes [31] containing (4-fluoro)benzldehyde thiosemicarbazonate(−1) and (4-*N*,*N*-dimethylamino)benzaldehyde S-benzyl dithiocarbazate(−1) as well as the Ru(II) complex of the more sterically encumbered ligand pyridine-2-aldehyde(4-cyclohexyl) thiosemicarbazone, all containing the five-membered chelate ring, bears testimony to the above hypothesis.

3.5. DFT calculations

We have also carried out DFT calculations on Ru complexes with these types of ligands using the ADF program. We first used two model complexes with less bulky ligands, namely $Ru(MeTscMe)_2(PMe_3)_2$, where MeTscMe is the 4-(methyl)thiosemicarbazone of acetaldehyde and $Ru(BzTscbz)_2(PMe_3)_2$. We then performed calculations on $Ru(BzTscbz)_2(PPh_3)_2$ as well. All models were constrained in C_2 symmetry and their geometry refined to convergence. The crystal structure of $Ru(BzTscbz)_2(PPh_3)_2$ has a structure only slightly distorted from C_2 symmetry. The results of the ADF calculations are given in Table 4.

From the results it is clear that five-membered chelate containing metal complexes are always thermodynamically more stable than the corresponding four-membered chelate containing complexes, even when the steric bulk of the axial phosphines are increased from PMe_3 to PPh_3. Indeed it is clear that steric effects of

Table 4

the bulky phenyl rings compared to those of the methyl groups do not favour one type of chelation over another. It would appear that the electronic effects are of paramount importance.

The bond lengths shown in Table 4 indicate that the Ru–S and Ru–N bond lengths are significantly shorter in the five-membered chelation mode for all three complexes. Details of the frontier orbitals in the 5 and 4 chelation mode of *trans*-[Ru(BzTscbz)$_2$(PPh$_3$)$_2$] are given in Table 5.

As is apparent from the pattern of frontier orbitals there are very few differences between the 4 and 5 chelation modes. The HOMO–LUMO gaps are 0.064257 and 0.070675 a.u., respectively, so the gap is slightly larger for the 5 chelation mode. However, the contribution of the atoms to the HOMO orbitals are very similar with the top three having major contributions only from the metal and sulfur atoms. However, HOMO − 3 and the LUMO both are orbitals, which do not include the metal atom in any way.

4. Conclusion

The quantum chemical calculations on the metal complexes discussed above as well as the crystal structure data of the vast majority of structurally characterized thiosemicarbazone complexes clearly suggest that for the thiosemicarbazone complexes, five-membered chelate rings are thermodynamically more stable than the four-membered chelate rings, as is intuitively expected. In fact by suitable substitution on the N(4), and/or on the C atom attached to N(1) one can get either the five-membered chelate or both the four- and five-membered chelates as shown in this work as well as in the works of Casas and Ghosh et al. [3,30]. Casas and co-workers [32] have also demonstrated that even when R_2 is a bulky substituent such as ferrocenyl, both five- and four-membered chelate complexes can be isolated. Similarly in [PbPh$_2$(EtGTSC)$_2$] (where HEtGTSC = thiosemicarbazone of ethylglyoxalate), one arm of the thiosemicarbazone moiety forms a four-membered chelate ring whereas the other thiosemicarbazone arm forms a five-membered chelate ring [33]. They concluded that although the five-membered chelate ring may be more stable, the four-membered ring retains the N(4)–H···N(1) hydrogen bond that is present in the free ligand. Thus, a small difference in weak interactions or in the steric requirement of the packing may decide the actual coordination mode.

advantage that photoisomerization can be induced by light irradiation at room temperature [10].

Conventionally, it has been well known that a series of certain Schiff base complexes, namely bis(*N*-alkyl-salicylideneimine)copper (II) or nickel (II), exhibit flexible structural changes of coordination environment from square planar to tetrahedral depending on various conditions [11]. For the Ni(II) complexes, both square planar [12–14] and tetrahedral [15–17] complexes have been obtained by steric and/or electronic requirements of the ligands. Furthermore, these complexes also exhibit structural isomerization caused by a thermally induced structural phase transition [18,19] and paramagnetism when they are dissolved in inert organic solvents [20–22]. Many aspects of the stereochemistry of Cu(II) complexes are similar to that of Ni(II) complexes. Very recently, light promoted trimerization at room temperature has been reported for a certain Schiff base Cu(II) complex [23]. Unfortunately, we could not observed photo-responsive properties of some square planar bis-(*N*-alkyl-salicylideneimine)copper (II) complexes [24–26] as well as compressed tetrahedral chiral ones [27,28] solely in the solid state at room temperature. However, various excellent merits will be provided by organic/inorganic hybrid self-assembling systems which consist of photochromic organic compounds and Schiff base complexes; for example applications for spin crossover systems, tunable homogeneous molecular catalysts, and molecular recognition based on chirality and so on. No such supramolecular systems have been reported to date.

Herein, we describe the crystal structures and electronic properties of two new Ni(II) complexes incorporating 3,5-dichloro-substituted Schiff base ligands (Scheme 1). We have also investigated flexible structural changes by steric and/or electronic natures of their ligands, external conditions such as a thermally induced structural phase transition, and negative solvatochromism. Furthermore, we have attempted to construct a supramolecular solvatochromism system by using a photochromic solute, 4-hydroxyazobenzene. After UV light irradiation, we have successfully detected a slight conformational change of the chiral ligands by means of absorption and CD spectra for the first time.

2. Experimental

2.1. Materials

Chemicals of the highest commercial grade available (Aldrich and Wako) were used as received without further purification.

2.2. Physical measurements

Elemental analyses (C, H, N) were carried out on an Elementar Vario EL analyzer at Keio University. Infrared spectra were recorded using Nujol mulls on a BIORAD FTS-60A spectrophotometer in the range 4000–400 cm^{-1} at 298 K. Thermal analysis was performed on a SHIMADZU DSC-60 differential scanning calorimeter (DSC), where the heating rate was 10 K min^{-1} in the range 313–673 K. Diffuse reflectance spectra were measured on a JASCO V-560 spectrophotometer equipped with an integrating sphere in the range 850–220 nm at 298 K. Absorption spectra were measured on a JASCO V-560 spectrophotometer in the range 900–200 nm at 298 K. Circular dichroism (CD) spectra were measured on a JASCO J-720WI spectropolarimeter in the range 900–200 nm at 298 K. Magnetic susceptibility was measured with a Sherwood Scientific magnetic susceptibility balance at 298 K. Magnetic data were corrected for the magnetization of diamagnetic contributions, which were estimated from Pascal constants. The magnetic properties were investigated with a Quantum Design MPMS-5S superconducting quantum interference device magnetometer (SQUID) at an applied field 5000 Oe in a temperature range 2–300 K. XPS were recorded on a JEOL JPS-9000MC spectrometer at 298 K. ESR spectra were measured using a JEOL JES-RE3X X band ESR spectrometer at 298 K. Semi-empirical molecular orbital calculations were performed with the program ZINDO in a CAChe software package based on the crystal structures determined.

2.3. Synthesis of bis(*N*-*R*-1-phenylethyl-3,5-dichloro-salicydenaminato)nickel (II) (**1**)

Treatment of 3,5-dichlorosalicylaldehyde (1.91 g, 10.0 mmol), *R*-1-phenylethylamine (1.33 g, 11.0 mmol) and nickel (II) acetate tetrahydrate (1.24 g, 5.00 mmol) in methanol (150 mL) at 318 K for 3 h gave rise to deep green crude precipitates. Recrystallization from an acetone solution at 298 K over a period of several days yielded brown prismatic single crystals (**1**) suitable for X-ray crystallography. *Anal.* Calc. for $C_{30}H_{24}N_2Cl_4$-

NiO_2: C, 56.04; H, 3.45; N, 4.36. Found: C, 55.75; H, 3.18; N, 4.27%. IR (KBr): 1616 cm^{-1} (C=N), 442 cm^{-1} (Ni–N), 420 cm^{-1} (Ni–O). M.p. 580 K (decomposition). $\mu_{eff}/\mu_{B.M.} = 2.98$ at 298 K. XPS Ni2p$_{3/2}$ 831 eV.

2.4. Synthesis of bis(N-2-propyl-3,5-dichlorosalicydenaminato)nickel (II) (2)

Treatment of 3,5-dichlorosalicylaldehyde (1.91 g, 10.0 mmol), 2-propylamine (1.24 g, 21.0 mmol) and nickel (II) acetate tetrahydrate (1.24 g, 5.00 mmol) in methanol (150 mL) at 318 K for 3 h gave rise to deep green crude precipitates. Recrystallization from an acetone solution at 298 K over a period of several days yielded green prismatic single crystals (**2**) suitable for X-ray crystallography. *Anal.* Calc. for $C_{20}H_{20}N_2Cl_4NiO_2$: C, 46.12; H, 3.87; N, 5.38. Found: C, 46.08; H, 4.03; N, 5.36%. IR (KBr): 1620 cm^{-1} (C=N), 446 cm^{-1} (Ni–N), 419 cm^{-1} (Ni–O). M.p. 587 K (decomposition). $\mu_{eff}/\mu_{B.M.} = 0$ (diamagnetic) at 298 K. XPS Ni2p$_{3/2}$ 832 eV.

2.5. X-ray crystallography

Intensity data were collected on a Rigaku AFC-7R four-circle diffractometer. The structures were solved by direct methods using SIR92 [29] and expanded by Fourier techniques. The structures were refined on F^2 anisotropically for non-hydrogen atoms by full-matrix least-squares methods with SHLEXL97 [30] on the teXsan program package [31]. Empirical absorption corrections were applied based on ψ scans; scaled transmission factors for **1** and **2** were 0.719–0.797 and 0.613–0.660, respectively. No significant decay in the intensity of three standard reflections was observed throughout the data collection. The hydrogen atoms were located at geometrically calculated positions, C–H = 0.950 Å, and refined isotropically. All the non-hydrogen atoms were refined anisotropically. Crystallographic data for **1** and **2** are summarized in Table 1.

3. Results and discussion

3.1. Crystal structure of 1

The molecular structure of **1** is depicted in Fig. 1. Selected bond lengths and angles are given in Table 2. The molecule of **1** possess a C_2 axis passing through the central nickel atom, and the absolute configuration was found to be $\Lambda(R,R)$ for the single crystal examined. The complex **1** affords a compressed tetrahedral [NiN_2O_2] coordination geometry taking an umbrella conformation. In contrast to analogous Cu(II) complexes [28,32], the phenyl moieties of the ligands are faced to the inside of the molecule. The bond angles

[b] $R_w = (\sum w(|F_o|-|F_c|)^2/\sum w|F_o|^2)^{1/2}$, $w = 1/(\sigma^2(F_o) + (0.1P)^2)$ for **1**, and $w = 1/(\sigma^2(F_o) + (0.1322P)^2 + 0.2552P)$ for **2**, where $P = (F_o^2 + 2|F_c^2|)/3$.

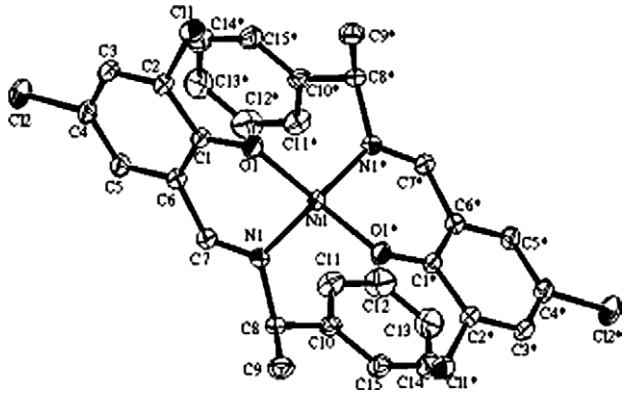

Fig. 1. The molecular structure of **1** showing the atom labelling scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are omitted for clarity. Atoms marked with *'s are expanded by the symmetry operation $(-x-2, y, -z-2)$.

Table 2
Selected geometric parameters (Å, °) for **1**

Ni1–N1	2.013(3)
O1–C1	1.299(4)
N1–C8	1.490(4)
C2–Cl1	1.745(4)
Ni1–O1	1.905(2)
N1–C7	1.275(5)
C6–C7	1. 456(4)
C4–Cl2	1.734(4)
N1–Ni1–O1	92.8(1)
N1–Ni1–N1*	116.3(2)
Ni1–N1–C7	121.3(2)
Ni1–O1–C1	126.1(2)
N1–Ni1–O1*	107.5(1)
O1–Ni1–O1*	141.4(2)
Ni1–N1–C8	122.8(2)
N1–C7–C6	127.8(3)

Atoms marked with *'s are expanded by the symmetry operation $(-x-2, y, -z-2)$.

are N1–Ni1–O1 = 92.8(1)°, N1–Ni1–O1* = 107.5(1)°, N1–Ni1–N1* = 116.3(2)° and O1–Ni1–O1* = 141.4(2)°. The dihedral angles between the C1/O1/Ni1/N1/C7/C6 plane and C1*/O1*/Ni1/N1*/C7*/C6* plane is 100.0(1)°, in other words the deviation of the interplanar angle from 90° is 10.0(1)°, showing significant non-coplanarity of the $[NiN_2O_2]$ plane and the six-membered chelate ring. The bond distances are Ni1–N1 = 2.013(3) Å and Ni1–O1 = 1.905(2) Å, which are comparable with analogous tetrahedrally distorted Ni(II) complexes incorporating Schiff base ligands [15–17], and appreciably longer than those of the square planar complexes [12–14]. Comparing analogous tetrahedrally distorted complexes [24], the present imine double bond distance of N1=C7 = 1.275(5) Å suggests that the σ coordination bonds are weak in dπ–pπ interaction. In the crystals, there are no remarkable intermolecular hydrogen bonds and π–π interactions within van der Waals radii [33]. Thus, the crystal packing may be dominated by non-covalent and weak van der Waals forces. The molecular arrangement shows one-dimensional chains along the crystallographic *a* axis.

3.2. Crystal structure of **2**

The molecular structure of **2** is depicted in Fig. 2. Selected bond lengths and angles are given in Table 3. Complex **2** affords a square planar *trans*-$[NiN_2O_2]$ coordination geometry, whose central Ni(II) atom lies on the center of symmetry. Similar to analogous Cu(II) complexes [34], steric effects of the 2-propyl moieties and electron withdrawing by Cl-substituents lead to this square planar coordination environment. Indeed, no structural features indicating steric repulsion due to the 2-propyl moieties can be observed for **2**. The

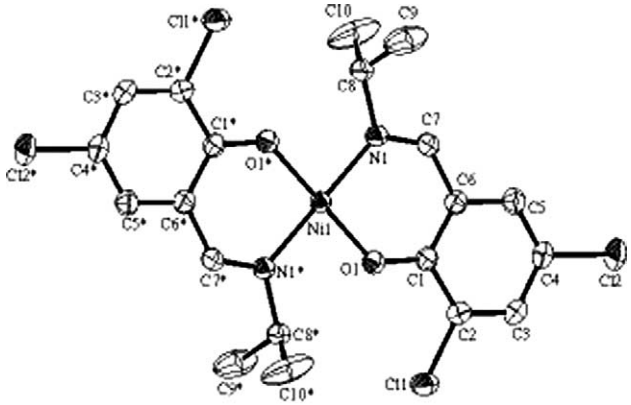

Fig. 2. The molecular structure of **2** showing the atom labelling scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are omitted for clarity. Atoms marked with *'s are expanded by the symmetry operation $(2-x, -y, -z)$.

Table 3
Selected geometric parameters (Å, °) for **2**

Ni1–N1	1.949(3)
O1–C1	1.293(5)
N1–C8	1.499(5)
C2–Cl1	1.734(4)
Ni1–O1	1.834(3)
N1–C7	1.275(5)
C6–C7	1.432(5)
C4–Cl2	1.750(5)
N1–Ni1–O1	92.4(1)
N1–Ni1–N1*	180.0
Ni1–N1–C7	124.0(3)
Ni1–O1–C1	131.4(2)
N1–Ni1–O1*	87.6(1)
O1–Ni1–O1*	180.0
Ni1–N1–C8	121.0(3)
N1–C7–C6	128.3(4)

Atoms marked with *'s are expanded by the symmetry operation $(2-x, -y, -z)$.

cis-N1–Ni1–O1 and *cis*-N1–Ni1–O1* bond angles are 92.4(1)° and 87.6(1)°, respectively. The bond distances are Ni1–N1 = 1.949(3) Å and Ni1–O1 = 1.834(3) Å, which are comparable with analogous square planar Ni(II) complexes such as **1**. The imine double bond distance N1=C7 = 1.275(5) Å of **2** is identical to that of **1**, which suggests that the electronic effects on the imine double bonds are more important than the geometric factors in the case of **1** and **2** [35]. In the crystals, there are no remarkable intermolecular hydrogen bonds and π–π interactions. The anti-parallel orientation of the molecular planes is found along the crystallographic *c* axis.

3.3. Calculations

Selected results of semi-empirical calculations (ZINDO) [36,37] are summarized in Table 4. Single point calculations of the heat of formation of the crystal structures determined are 315.5 and 255.4 kJ mol^{-1} for **1** and **2**, respectively.The dipole moments of the overall molecules **1** and **2** were evaluated to be 1.76 and 0.07 Debye, respectively. The very small value of **2** is ascribed to planarity and high symmetry of the molecules. On the other hand, the larger dipole moment of **1** is induced by distortion of the overall molecular structure containing Cl-substituents in the ligands.

The formal charges on the coordinating O and N atoms of the bidentate ligands and Ni(II) ions have been calculated and the net atomic charges thus obtained have been averaged. The formal charges on the Ni(II) ions are 0.813 and 0.792 for **1** and **2**, respectively, which indicates that the more tetrahedrally distorted coordination environment prevents charge distribution through coordination bonds. In contrast to the Ni(II) ions, considerable differences are not observed for the N and O atom. The averaged formal charges on the N atoms are −0.647 and −0.628, and the O atoms are −0.357 and −0.354 for **1** and **2**, respectively. Hence, we cannot discuss charge transfer bands based on these calculated formal charges on the coordinating N and O atoms for **1** and **2** at present. Indeed, the correlation between the average negative charge of the coordinating N and O atoms and the peaks of the electronic spectra may not be simple, because electronic spectra consist of several types of transitions. The calculation estimates that the predominant peak of the lowest component of π–π transitions is 32600 and 32300 cm^{-1} for **1** and **2**, respectively.

3.4. IR and electronic spectra and magnetic properties in the solid state

In the IR spectra of **1** and **2**, the imine C=N vibrations are observed at 1616 and 1620 cm^{-1}, respectively. Moreover, the Ni–N vibrations are found at 442 and 446 cm^{-1} and the Ni–O vibrations are found at 420 and 419 cm^{-1} for **1** and **2**, respectively. These peaks are in agreement with related complexes regardless of the degree of distortion of the coordination environment. In contrast to some other examples [11], the IR spectra are not sensitive to distortion of the coordination environment for the present complexes.

As shown in the diffuse reflectance electronic spectra (Fig. 3), the ligand field transition band(s) measured with the diffuse reflectance technique at 298 K are found at 13600 and 17100 cm^{-1} for **1** and 15500 cm^{-1} for **2**. These values are consistent with a common ligand field transition for tetrahedrally distorted planar or square planar [NiN_2O_2] chromophores, respectively. In addition, continuous broad bands over 24000 and 32000 cm^{-1} can be assigned to LMCT bands and π–π* transitions, respectively. The features of the d–d bands suggest that distortion of the coordination environment from square planar (**2**) to compressed tetrahedral (**1**) results in the spin state of the ground state, $S = 0$ or $S = 1$, respectively [38].

A polycrystalline sample of the square planar complex **2** exhibits diamagnetism at 298 K. On the other

Table 4
Summary of the results of ZINDO calculations for **1** and **2**

	1	**2**
Heat of formation (kJ mol^{-1})	315.5	255.4
Dipole moment (Debye)	1.76	0.07
HOMO–LUMO gap (eV)	7.406	7.466
Formal charge Ni	0.813	0.792
N	−0.647	−0.628
O	−0.357	−0.354
Predominant components of π–π* transitions (cm^{-1})	32600 (HOMO → LUMO) 40500 (HOMO − 6 → LUMO) 44600 (HOMO → LUMO + 4) 51200 (HOMO − 6 → LUMO + 4)	32300 (HOMO − 2 → LUMO + 1) 43700 (HOMO − 6 → LUMO) 48300 (HOMO − 4 → LUMO + 1)

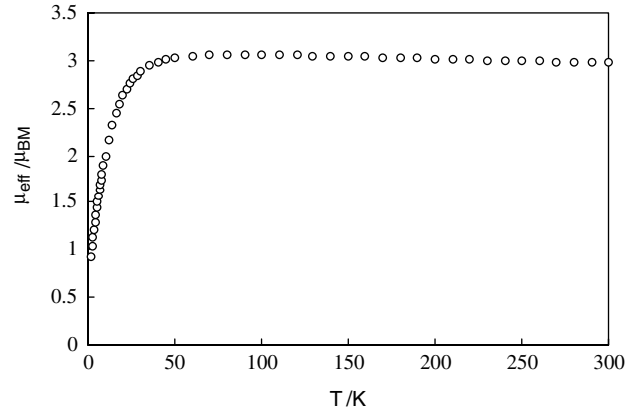

Fig. 4. Temperature dependence of effective magnetic moment (μ_{eff}) for **1**.

hand, magnetic measurement of compressed tetrahedral **1** reveals that mononuclear **1** obeys the Curie–Weiss law at low temperatures above ca. 20 K, because the effective magnetic moment stays almost temperature-independent. Fig. 4 shows the effective magnetic moment of polycrystalline samples in a range 2–300 K. The data were analyzed by the Curie–Weiss equation [$\chi_M = C/(T-\theta)$], giving a negative Weiss temperature (θ) of $-10.0(1)$ K with $C = 1.19(1)$ cm^3 K mol^{-1}. The effective magnetic moment (μ_{eff}) value of 2.98 B.M. at 298 K is slightly larger than the theoretical spin-only value of 2.83 B.M. for the $S = 1$ systems. The fact that the μ_{eff} value decreases to a small positive constant (0.924 B.M at 2 K) suggests that the ground state has a negative zero-field splitting parameter (D) with Kramers doublet, $|S,M_S\rangle = |1,+1\rangle$ or $|1,-1\rangle$ [39].

3.5. Thermally induced structural phase transition

It is well known that the related Ni(II) or Cu(II) complexes incorporating Schiff base ligands exhibit a thermally induced structural phase transition [11,18,19]. On heating from room temperature, square planar or compressed tetrahedral complexes turn into tetrahedral ones generally. The DSC curves of heating show an endothermic peak at 456 and 453 K for **1** and **2**, respectively. In analogy with related complexes, the structural phase transition may be ascribed to a transformation from a low temperature phase (compressed tetrahedral) into a high temperature phase (closer to tetrahedral). In addition, the structural phase transition seems to be irreversible. Further heating of the complexes results in decomposition at 580 and 587 K for **1** and **2**, respectively. However, such a structural phase transition could not be induced by light irradiation of any wavelength, though a certain Schiff base ligand itself exhibits both thermochromism and photochromism [40,41].

3.6. Absorption spectra in various solvents

A summary of the absorption spectra in several solvents and some physical properties of the solvents employed are given in Table 5. The general appearance of the solution and solid electronic spectra are considerably different from each other, and the absorption spectrum of **1** is quite similar to that of **2**, which suggests that the coordination geometries are different in solution (closer to tetrahedral) to that in the solid (compressed tetrahedral for **1** or square planar for **2**). The weak band at around 16000 cm^{-1} is assigned to d–d transitions. According to a discussion based on group theory [42] (approximately, in D_{2h} symmetry), ligand field bands consist of a spin-forbidden transition $^1A_g \rightarrow {}^3B_{1g}$ related to $d_{xy} \rightarrow d_{x^2-y^2}$ orbital excitation at around 12000 cm^{-1}, a spin-allowed $^1A_g \rightarrow {}^1B_{1g}$ transition related to $d_{xy} \rightarrow d_{x^2-y^2}$ orbital excitation at around 16000 cm^{-1}, and a $^1A_g \rightarrow {}^1B_{3g}$ d–d transition related to $d_{yz} \rightarrow d_{x^2-y^2}$ orbital excitation overlapped with a $^1A_g \rightarrow {}^1B_{2g}$ charge transition band around 20000 cm^{-1}. On the other hand, the strong band at around 30000 cm^{-1} is assigned to π–π* excitations due to imine groups. The absorption bands in the UV region would be ascribed to $^1A_g \rightarrow {}^1B_{2g}$ at around 24000 cm^{-1}, $^1A_g \rightarrow {}^1B_{3u}$,$^1B_{2u}$ at around 28000 cm^{-1} and $^1A_g \rightarrow {}^1B_{3u}$ at around 30000 cm^{-1}. The last one is ascribed to the electric-dipole allowed exciton coupling mode due to imine π–π* transitions.

In the CD spectrum of **1** in chloroform solution, positive and negative weak peaks in the d–d region are observed at 18200 and 20400 cm^{-1}, respectively. While positive strong peaks are observed at 23000, 24700, 26600 and 30800 cm^{-1}, which are assigned to π–π* transitions. The CD spectral pattern corresponds to the $\Lambda(R,R)$ absolute configuration of **1** determined in the solid state. However, as far as we know, there have not been reported CD data for analogous complexes incorporating identical ligands [28,43]. Thus, we could not discuss the spectral features involving their intensity at present.

Table 5
Maximum absorbance wavenumbers of d–d and π–π bands of **1** and **2** in various solutions, 0.01 mM at 25 °C

Solvents	Acetone	Methanol	Chloroform
μ (Debye)	3.11	2.97	1.11

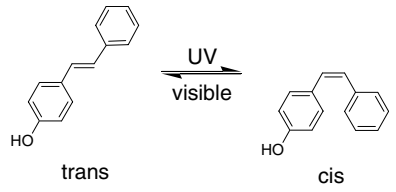
$(\varepsilon-1)(\varepsilon+2)-(n^2-1)/(n^2+2)$	0.649349	0.711608	0.293582
d–d peaks (cm^{-1})			
1	16500	16300	15900
2	16500	16300	16100
π–π* peaks (cm^{-1})			
1	31500	25500	29400
2	31700	25600	29400



The values of the dipole moment μ, dielectric constant ε, refractive index n_D^{20}.

Furthermore, the predominant d–d and π–π* peaks are sensitive to the polarity of the solvents, which is well known for the related Ni(II) and Cu(II) complexes [44,45]. The peaks of both the d–d band and the π–π* band shift to higher energies in solvents of increasing polarity. This significant negative solvatochromic behavior is in accordance with the interaction of the dipole moment of the solute complexes and the surrounding solvent. According to the theory of dielectric polarization, negative solvatochromism is expected for transitions from a state with a high dipole moment to a state with a smaller one. It suggests that short-range interactions between the dipole moment of the solute and the solvent can induce structural changes of the solute complexes in accordance with the alignment of the transition moment for ground and excited states of a certain transition [46].

3.7. Towards solvatochromism induced by a photochromic solute

In this way, we have also attempted to tune solvatochromism of the complex by means of a doping photochromic solute in solution. At first, we have confirmed that neither precipitates nor a solution of **1** solely exhibit any spectral changes by light irradiation. Next, we prepared a 0.01 mM chloroform solution of **1** containing equimolar 4-hydroxyazobenzene (4HAZ). It is well known that irradiation of UV and visible light results in reversible photoisomerization of 4HAZ to *cis* and *trans* forms (Scheme 2) in solution. The dipole moment of the *cis* and *trans* forms could be evaluated by the ZINDO method to be ca. 3 and almost 0 Debye, respectively. It should be noted that 4HAZ is hardly expected to coordinate to this four-coordinated Ni(II) complex to generate a six-coordinated Ni(II) complex in solution.

As shown in Fig. 5, the absorption spectrum shows a weak peak at around 23000 cm^{-1} and strong peak at 29000 cm^{-1}. The latter is attributed to overlap of **1** and very intense π–π* bands of 4HAZ. The corresponding ESR spectrum resonance occurs at $g = 2.11$, which is comparable to the values for **2** and 4HAZ as well as any analogous Schiff base Ni(II) complexes. This result does

Scheme 2. Photoisomerization of 4-hydroxyazobenzene (4HAZ).

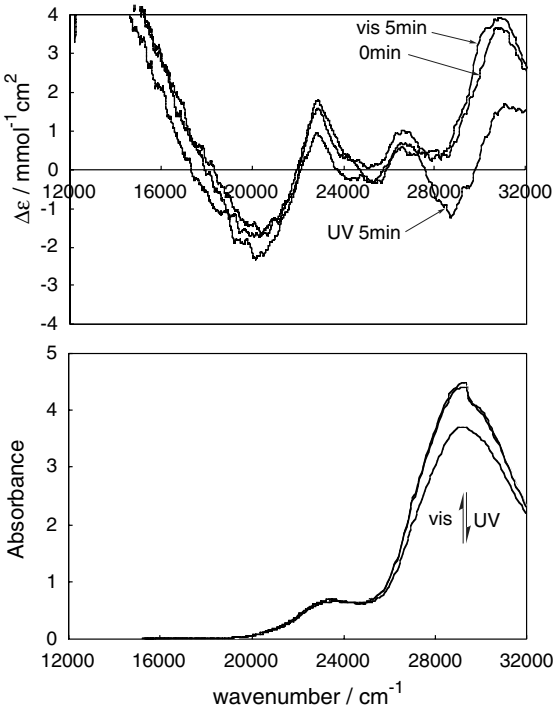


Fig. 5. Absorption spectra (below) and CD spectra (above) of 0.01 mM of **1** and 4HAZ at 298 K before and after UV or visible light irradiation for 5 min.

not suggest the appearance of radical or (de)protonated species nor other supramolecular structures such as a helix involving 4HAZ and **1** in solution. UV or visible light irradiation for 5 min resulted in a reversible decrease or increase of the intensity of the peak at 29 000 cm^{-1}. The corresponding CD spectrum (Fig. 5) exhibits a negative peak of the d–d band at 20 000 cm^{-1} and positive peaks of the π–π* bands at 23 000, 27 000 and 31 000 cm^{-1} in the initial state. Slight spectral changes could be observed after visible light irradiation for 5 min, a decrease of the intensities at 23 000 and 31 000 cm^{-1}, and the appearance of a negative peak at 29 000 cm^{-1} could be observed after UV light irradiation for 5 min. However, **2** and 4HAZ did not exhibit such changes of the absorption spectrum. This fact suggests that π–π interaction between the phenyl moieties of both complex (**1**) and 4HAZ solute is important for the photo-induced spectral change of **1** and 4HAZ.

In general, the rotatory strength between ground (0) and excited (a) states, R_{0a}, is given by Eq. (1) [45]

$$R_{0a} = \mathrm{Im}\langle 0 \mid \mathbf{P} \mid a\rangle\langle a \mid \mathbf{M} \mid 0\rangle = c\,|\mathbf{P}||\mathbf{M}|\cos(\mathbf{P},\mathbf{M}), \quad (1)$$

where **P**, **M** and (**P, M**) denote electric and magnetic dipole operators and the angles between them. According to the experimental results, the geometrically possible range of the angle (**P**, **M**), and dynamic equilibria of the related Ni(II) complexes in solutions [47], the spectral change of the CD spectra in the π–π* region can be attributed to a slight conformational change of the pendant phenyl moieties in the chiral ligands of **1** through short-range dipole–dipole and/or π–π interactions. However, the coordination environment and *Λ*(*R*,*R*) absolute configuration [48] or spin state [49] are conserved still within such a slight change of dipole moment, only 3 Debye. The magnitude is sufficiently smaller than the differences in dipole moment of the several solvents investigated.

4. Concluding remarks

The syntheses, structures, thermodynamical and electronic properties have been reported for two new Ni(II) complexes. These flexible complexes can easily vary their coordination geometries by introduction of steric and electronic substitutents, structural phase transition by heating, and dissolving in various solvents. The absorption spectra in various solvents also exhibit solvatochromism by the polarity of various organic solvents in accordance with the relationship between molecular structures and dipole moment, similar to conventional analogous complexes. In addition, we have firstly attempted *solvatochromism induced by a photochromic solute*, which results in only slight conformational changes of the chiral ligands. This new approach based on supramolecular photochemistry has the possibility of designing optical-magnetic switching materials, nanoscaled molecular machines and tuning homogeneous (chiral) catalysts of transition metal complexes [50] without photochromic groups in their ligands [4]. Detailed and extended studies for analogous systems are underway now.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC with deposition numbers 263944 and 263945 for **1** and **2**, respectively. Copies of this information can be obtained from The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgments

This work was supported by Grant-in-Aid for the 21st Century COE program 'KEIO Life Conjugate Chemistry' from the Ministry of Education, Culture, Sports, Science and Technology, Japan. The authors thank Professor Yohru Yamada and Dr. Taketo Ikeno (Keio University) for the use of the DSC apparatus, Professor Hidenari Inoue (Keio University) for the use of the CD spectrometer, and Professor Katsuya Inoue (Institute for Molecular Scicence) for the use of the SQUID instrument.

Phosphorus fractions lower than 0.01 are omitted.

[a] Ref. [5]. The possible formation the hydroxo species $AlOH^{2+}$, $Al_2(OH)_2^{4+}$ and $Al_3(OH)_4^{5+}$ was considered, adding to the model the values $\log\beta_{101} = -4.55$, $\log\beta_{202} = -7.6$ and $\log\beta_{304} = -13.4$, calculated from the literature [8]. The equilibrium concentration of these species was found to be negligible in all solutions used.

which the NMR spectra were recorded were significantly different from those of the potentiometric investigation. We have therefore obtained new NMR data under the same conditions as were used in the EMF study and have made semi-quantitative assignments of the NMR peaks. We have previously reported the results of a similar investigation of NMR data with regard to phosphato complexes of beryllium(II) [6].

2. Notation

Reagents: Al^{3+}, H_2O and H_3PO_4

Equilibria: $pAl^{3+} + qH_2O + rH_3PO_4 \rightleftarrows Al_pH_{-q}(H_3PO_4)_r^{3p-q} + qH^+$,
$\beta_{p,q,r}(p,q,r)^{3p-q} = Al_pH_{-q}(H_3PO_4)_r^{3p-q}$

C_M: total concentration (mol dm^{-3}) of aluminium

C_P: total concentration (mol dm^{-3}) of phosphate

P_{pqr}: concentration of phosphorus in the species $(p,q,r)^{3p-q}$ as a fraction of the total phosphorus concentration, $P_{pqr} = r[Al_pH_{-q}(H_3PO_4)_r^{3p-q}]/C_P$

I_X: area under peak(s) X as a fraction of the total peak area. X may represent a single peak or the sum of many peaks

δ_{pqr}: chemical shift (ppm) of the peak originating from the species $(p,q,r)^{3p-q}$

δ_X: chemical shift (ppm) of peak X

3. Experimental

3.1. Chemicals and analysis

Test solutions were prepared with analytical grade commercial products and analysed as described in the potentiometric work [5]. The composition of each solution used in this study is given in Table 1.

3.2. NMR measurements

$^{31}P\{^1H\}$ NMR spectra were recorded at 121.42 MHz using a Varian VXR 300 Spectrometer. The probe temperature was 25 ± 1 °C. The field-frequency stabilisation was established by means of a coaxial capillary tube filled with D_2O. All ^{31}P chemical shifts are reported in ppm toward higher frequency with respect to external reference consisting of 85% commercial H_3PO_4. The chemical shifts therefore refer to the dimer $(H_3PO_4)_2$, which, according to Wertz and Cook [7], is the predominant species present in 85% phosphoric acid. No corrections were made for differences in bulk susceptibilities.

4. Results

Observed ^{31}P NMR spectra are shown in Fig. 1. On the basis of the shape of the spectral bands, it can

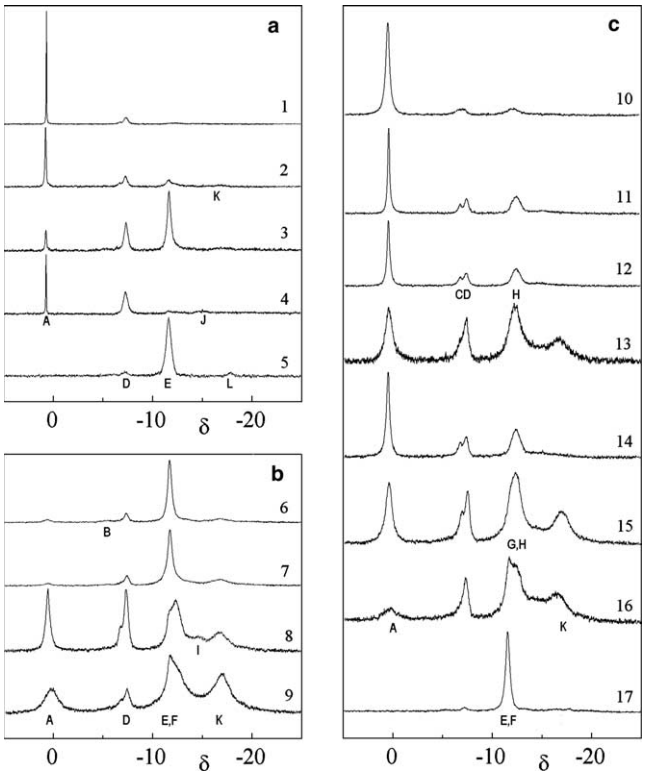

Fig. 1. ^{31}P NMR spectra at 25 °C of solutions 1–17 (Table 1). (a) $C_P = 0.01$ mol dm^{-3}, (b) $0.03 \leqslant C_P \leqslant 0.07$ mol dm^{-3}, and (c) $C_P = 0.1$ mol dm^{-3}. Capital letters refer to assignments in Table 2.

generally assumed that there is slow exchange, on the NMR time scale, at the aluminium centre. This implies that each phosphorus atom in a complex should give rise to a signal whose area, as a fraction of the total area, is equal to the concentration of phosphorus in the complex as a fraction of the total phosphorus concentration. Fractional phosphorus concentrations, calculated using equilibrium constants determined in the potentiometric investigation [5], are shown in Table 1. The assignment was based on the principle that the fractional area of each peak should be equal to the sum of the fractional concentrations of the species contributing to the peak. Observed chemical shifts are given in Table 2.

The species $(361)^{3+}$ and $(383)^{+}$ never attain a phosphorus content of more than 1% of the total. The signals for these species was not sought in the spectra.

4.1. Peak A: fast proton exchange

The chemical shift of peak A is dependent on [H$^+$], due to fast proton exchange. Its value is the mol-fraction-weighted average of the chemical shifts of all the species contributing to the peak, as expressed as in Eq. (1). To a first approximation peak A may be assigned to the species (001)

Table 2
Peaks in ^{31}P NMR spectra

Peak	δ (ppm)	Assignment
A	0.3–0.9	H_3PO_4–$H_2PO_4^-$, in part $Al_3H_{-6}(H_3PO_4)_4^{3+}$, $Al_3H_{-8}(H_3PO_4)_5^{+}$
B	−5.4	not assigned
C	−6.80 ± 0.04	$Al(H_2PO_4)_2^{+}$
D	−7.37 ± 0.06	$AlH_2PO_4^{2+}$, $Al(H_2PO_4)_2^{+}$
E	−11.52 ± 0.04	$Al_3H_{-5}(H_3PO_4)_2^{4+}$
F	−11.68 ± 0.03	$Al_3H_{-6}(H_3PO_4)_3^{3+}$
G	−12.20	$Al_3H_{-8}(H_3PO_4)_5^{+}$
H	−12.44 ± 0.05	$Al(H_2PO_4)_2^{+}$
I	−13.8	not assigned
J	−15.10	not assigned
K	−16.3 to −17.0	$Al_3H_{-6}(H_3PO_4)_4^{3+}$
L	−17.76 to −17.94	not assigned

$$\delta_A = \frac{\sum P_{pqr}\delta_{pqr}}{\sum P_{pqr}} \quad (1)$$

(H_3PO_4) and $(011)^-$ ($H_2PO_4^-$). Peak integrals agree to within 10% or better with the sum $P_{001} + P_{011}$. Furthermore, the plot δ_A versus $P_{011}/(P_{001} + P_{011})$ (Fig. 2) indicates that the majority of the points falls on the straight line fitting the data of solutions 18, 19 and 20 (circles) in which aluminium(III) was absent. Points well away from the straight line indicate that other species are in fast exchange. For example, in solutions 18–20 some of phosphorus is present in form of dimers (002) ($H_6(PO_4)_2$) and $(012)^-$ ($H_5(PO_4)_2^-$. To explain the shift of A in absence of aluminium(III) we postulated that $\delta_{002} = 0$ ppm, since the reference solution of aqueous 85% phosphoric acid contains practically only $H_6(PO_4)_2$, and, furthermore, that $\delta_{011} = 0.91 \pm 0.01$ ppm as it results from the chemical shift observed for solution 20 where more than 99% of phosphorus is given by $H_2PO_4^-$. On account of these δ_{002} and δ_{011} values, we calculated from data of solutions 18 and 19 $\delta_{001} = 0.63 \pm 0.03$ ppm and $\delta_{012} = 0.37 \pm 0.15$ ppm. The error limits were estimated by error propagation from the error on δ_{011}.

Solutions 7, 9, 14, 15 and 16 have δ_A values well off the straight line. It is noteworthy that the signals are

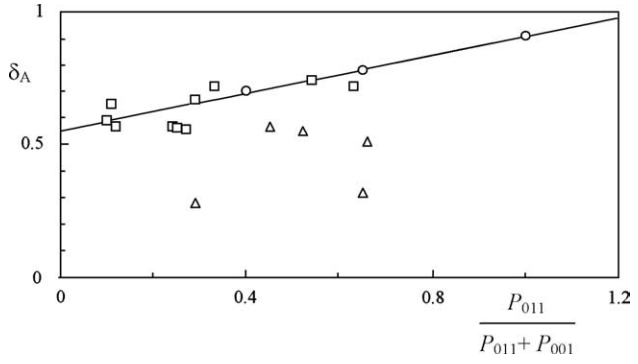

Fig. 2. Chemical shifts of peak A, δ_A, as a function of $P_{011}/(P_{001} + P_{011})$. Circles refer to solutions 18, 19 and 20; triangles to solutions 7, 9, 14, 15 and 16; squares to remaining solutions in Table 1. The straight line represents equation: $0.57 + 0.34P_{011}/(P_{001} + P_{011})$.

broad whereas peaks whose shifts fall near the straight line are sharp. Probably, peak A broadens due to a dynamic process involving free and metal coordinated phosphate groups present in species other than H_3PO_4 and $H_2PO_4^-$. In the mentioned solutions, there is an abundant percentage of the species $(364)^{3+}$ and $(385)^{+}$. We suggest that in these complexes there are loosely bound phosphate groups which can exchange rapidly with free H_3PO_4 and $H_2PO_4^-$. The $(364)^{3+}$ species may result from the addition of H_3PO_4 to $(363)^{3+}$ either through replacement of water molecules in the coordination sphere of the metal to produce a form symbolised as ζ-$(364)^{3+}$ or through association by hydrogen bonds with coordinated water and phosphate groups to give a complex which we denote as ε-$(364)^{3+}$ form. The ε-$(364)^{3+}$ form would contribute to A with a fraction of phosphorus $P_\varepsilon = 1/4P_{364}(1 + K_{\varepsilon\zeta})^{-1}$, where $K_{\varepsilon\zeta}$ is the equilibrium constant for ε-$(364)^{3+} \rightleftarrows \zeta$-$(364)^{3+}$. The ζ form would resonate in a different region of the spectrum. Similarly, $(385)^{+}$ should be an equilibrium mixture of a η-$(385)^{+}$ form, in which two phosphate are hydrogen bonded to coordinated phosphate groups and water, and of a θ-$(385)^{+}$ form with groups directly coordinated by the metal. Therefore, indicating with $K_{\eta\theta}$ the constant for η-$(385)^{+} \rightleftarrows \theta$-$(385)^{+}$ one has the fraction of phosphorus contributing to A, i.e., $P_\eta = (2/5)P_{385}$-$(1 + K_{\eta\theta})^{-1}$. According to these definitions the intensity of peak A and its shift can be expressed as (2) and (3). The sum $P_{001} + P_{011} + P_{002} + P_{012}$

$$I_A = P_{001} + P_{011} + P_{002} + P_{012} + \frac{P_{364}}{4(1+K_{\varepsilon\zeta})} + \frac{2P_{385}}{5(1+K_{\eta\theta})}, \tag{2}$$

$$\delta_A = \frac{\delta_{001}P_{001} + \delta_{011}P_{011} + \delta_{012}P_{012} + \frac{P_{364}\delta_\varepsilon}{4(1+K_{\varepsilon\zeta})} + \frac{2P_{385}\delta_\eta}{5(1+K_{\eta\theta})}}{I_A}, \tag{3}$$

accounts for more than 90% of I_A. Thus, the terms relative to species $(364)^{3+}$ and $(385)^{+}$ contribute negligibly to I_A within experimental error. It is sufficient that $K_{\varepsilon\zeta}$ and $K_{\eta\theta}$ have values just superior to unity to make the last two terms on the right-hand side of Eq. (2) less than 10% of I_A. On the contrary, the influence of quantities in Eq. (3) corresponding to species $(364)^{3+}$ and $(385)^{+}$ may be significant primarily due to the magnifying effect of δ_ε and δ_η. Assuming that $I_A \approx P_{001} + P_{011} + P_{002} + P_{012}$ the most probable $\delta'_\varepsilon = \delta_\varepsilon(1 + K_{\varepsilon\zeta})^{-1}$ and $\delta'_\eta = \delta_\eta(1 + K_{\eta\theta})^{-1}$ were calculated by a standard least squares procedure in which $\delta_{001} = 0.63$ ppm, $\delta_{011} = 0.91$ ppm, $\delta_{012} = 0.37$ ppm and $\delta_{002} = 0$ as established above, were kept constant. This treatment led to $\delta'_\varepsilon = -0.30 \pm 0.05$, $\delta'_\eta = -0.30 \pm 0.05$ and $\sigma(\delta_A) = 0.05$ ppm. The results of the δ_A data analysis can be visualized by plotting the values, cleaned from the contributions of the metal complexes, versus $P_{011}/(P_{001} + P_{011})$. As Fig. 3 shows, the fitting between these values, ${}^*\delta_A$ in Eq. (4), and the straight line drown with $\delta_{001} = 0.63$ ppm and

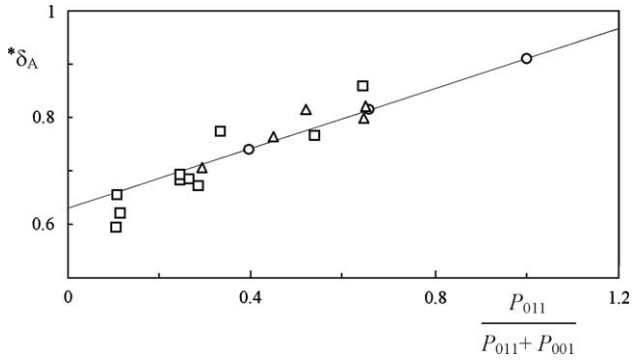

Fig. 3. ${}^*\delta_A$, Eq. (4), as a function of $P_{011}/(P_{001} + P_{011})$. The straight line represents equation $0.63 + 0.28P_{011}/(P_{001} + P_{011})$.

$$^*\delta_A = \frac{I_A\delta_A - 0.37P_{012} + 0.30 \cdot 0.25P_{364} + 0.30 \cdot 0.40P_{385}}{P_{001} + P_{011}} = \delta_{001} + \frac{(\delta_{011} - \delta_{001})P_{011}}{P_{001} + P_{011}} \tag{4}$$

$\delta_{011} - \delta_{001} = 0.28$ ppm is satisfactory. The standard deviation from the linear dependence amounts to 0.03 ppm.

4.2. Peaks C, D and H: complexes mononuclear in Al

On the basis of the potentiometric model [5], the main aluminium complex present in solutions 10, 11 and 12 has the composition $(122)^{+}$ $(Al(H_2PO_4)_2^{+})$. In the spectra of these solutions three peaks are observed: C −6.71, D −7.42 and H −12.48 ppm. Peaks C and D are partly overlapped in the spectra of solution 10. Therefore, the complex with general composition $(122)^{+}$ should be an equilibrium mixture of isomers. The global area of the three peaks, $I_C + I_D + I_H$, in spectra relative to solutions 10, 11 and 12 matches P_{122} within 0.08. Furthermore, the distribution of the phosphorus in the various signals follows approximately the expressions $(I_C + I_D)/P_{122} \approx 0.4$ and $I_H/P_{122} \approx 0.6$, so that $I_H/(I_C + P_D) \approx 1.5$. In a few cases, as for instance solution 4, $I_H/(I_C + I_D)$ is much lower than 1.5 indicating the presence of a complex differing from $(122)^{+}$ but resonating in the vicinity of peak D. Probably the new complex is $AlH_2PO_4^{2+}$, since, for data relative to solution 4, one has $P_{111} = 0.40$ which is close to $I_D = 0.47$. Therefore, the intensity of peaks C and D are explained within the limits of experimental error by assuming $I_C + I_D = P_{111} + 0.4P_{122}$. The results of evaluations, given in Table 3, show the good agreement between measured and expected signal intensity. From the residuals between measured and calculated peak area, a standard deviation of 0.05 was estimated. It proved convenient for further analysis to separate peaks C and D from spectra giving distinct but in part overlapping bands.

Table 3
Resolution of peaks C and D

Solution	$I_C + I_D$	$P_{111} + 0.40P_{122}$	I_C	$I_C/(I_C + I_D - P_{111})$
1	0.31	0.22	0.09 ± 0.02	$0.4_7 \pm 0.1$
2	0.24	0.20	0.05 ± 0.01	$0.3_6 \pm 0.1$
4	0.47	0.48		
8	0.20	0.22		
9	0.11_5	0.06	0.03 ± 0.02	0.3 ± 0.2
10	0.11	0.14		
11	0.23	0.23	0.09 ± 0.01	0.56 ± 0.06
12	0.18	0.23	0.07 ± 0.01	$0.6_3 \pm 0.1$
13	0.16	0.19		
14	0.18	0.12	0.08/0.01	0.50 ± 0.06
15	0.14	0.07	0.06 ± 0.03	$0.4_6 \pm 0.2$
16	0.16	0.14		

We postulated no overlapping in the outsides of the bands so that the area of the left-hand side of C is due only to the species originating that signal. The areas were computed with the old honoured method of counting squares beneath the curve. From the results presented in Table 3 we estimate that $I_C/P_{122} = 0.2 \pm 0.1$, therefore, C originates from 20% of the total phosphorus in the $(122)^+$ species. Furthermore, as reported in Table 3, the ratio $I_C/(I_C + I_D - P_{111}) = 0.5$ within the limits of estimated uncertainty corroborates the hypothesis that peak D stems from 20% of P_{122}. In conclusion peaks C, H and part of D are likely attributable to isomers of $Al(H_2PO_4)_2^+$, whereas part of D originates from $AlH_2PO_4^{3+}$. Peak C and the part of D arising from $(122)^+$ have comparable intensity. Therefore, they might stem from the same complex having not equivalent P atoms.

4.3. Peaks E, F, G and K: complexes trinuclear in Al

Peak E is observed as an intense signal at −11.52 ppm in spectra obtained from solution 5. The species $(352)^{4+}$ predominates in this solution, making the assignment straightforward.

With solutions 6 and 7 peak F is observed, close to peak E. The $(363)^{3+}$ complex has a relatively high concentration in these solutions. The fractional intensity of peak F is equal, within experimental error, to the sum $P_{363} + P_{352}$, as shown in Table 4. It was concluded that peak F is due to $(363)^{3+}$ with a significant contribution from $(352)^{4+}$.

Peak G at −12.20 ppm partly overlaps peak H. The latter was assigned to 60% $(122)^+$. Table 5 shows that the peak area is in reasonable agreement with $P_{385} + 0.60P_{122}$. It seems therefore reasonable to assign peak G to the species $(385)^+$.

Table 4
Comparison of the fraction of phosphorus in the species $(363)^{3+}$ and $(352)^{4+}$ with the area of NMR peak E

Solution	I_F	$P_{363} + P_{352}$
6	0.72	0.77
7	0.66	0.63
17	0.80	0.92

Table 5
Comparison of the fraction of phosphorus in the species $(385)^+$ and $(122)^+$ with the area of NMR peak G

Solution	I_G	$P_{385} + 0.60P_{122}$
8	0.39	0.43
14	0.41	0.42
15	0.44	0.56

Table 6
Comparison of the fraction of phosphorus in the species $(364)^{3+}$ with the area of NMR peak K

Solution	I_K	P_{364}
2	0.09	0.08
6	0.13	0.06
7	0.23	0.14
8	0.17	0.25
9	0.24	0.21
12	0.09	0.08
13	0.18	0.19
14	0.14	0.18
15	0.19	0.11
16	0.35	0.37

Peak K was observed in several spectra as a broad band in the region from −16.3 to −17.0 ppm. The fractional intensity of the signal is in modest agreement with the phosphorus percentage in the $(364)^{3+}$ complex, as shown in Table 6. This peak was therefore assigned to the species $(364)^{3+}$.

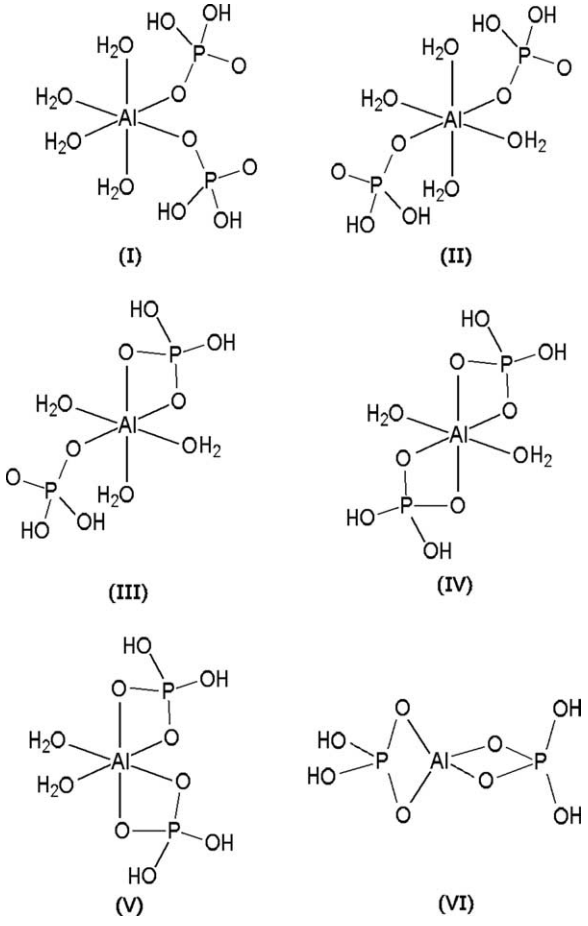
4.4. Unassigned peaks

Peak B was only found in solution 6 as a weak broad signal at −5.4 ppm. It does not appear to correlate with any species identified in the potentiometric investigation [5]. Peaks I, J and L have been observed as weak broad signals. They appear only in spectra obtained from solutions whose Al and P concentration falls outside the range explored during the potentiometric study so may correspond to species not detectable in that study [5].

5. Discussion

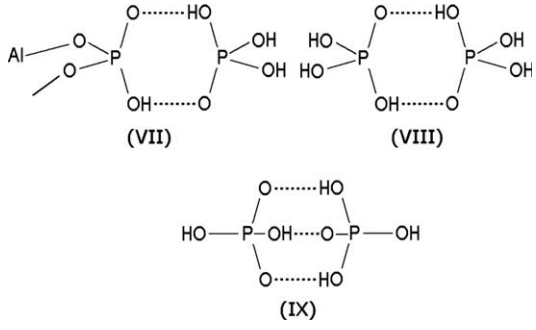
The most important conclusion of the present investigation is that NMR spectroscopy can be used to support a complicated equilibrium model derived from potentiometric data by correlating fractional NMR peak intensities with fractional concentrations calculated with the equilibrium model. In a system with slow exchange, such as the one studied here, the use of NMR data as independent source of information to derive a chemical model would be possible only with a spectrometer of very high resolution and sensitivity.

Potentiometry is a powerful tool for the determination of stability constants, but it only provides so-called macro-constants. NMR spectrometry, on the other hand, can provide information on micro-species, that is, species having the same stoichiometry or isomers in common parlance. In Scheme 1, we show some of the possible isomers of the ion $Al(H_2PO_4)_2^+$. There are possibilities of *cis*/*trans* isomerism and *monodentate* or *bidentate* phosphate binding. Three peaks, C, D and H, have been assigned to this complex.



We believe that the forms (I) and (II) are less likely to be present because for the reaction $AlH_2PO_4^{2+} + H_3PO_4 \rightleftarrows Al(H_2PO_4)_2^+ + H^+$, $\log K = 0.91$, is higher than $\log\beta_{111}$ (0.13). This means that the disproportion $2AlH_2PO_4^{2+} \rightleftarrows Al(H_2PO_4)_2^+ + Al^{3+}$ is favoured. The extra stabilization of $Al(H_2PO_4)_2^+$ against $AlH_2PO_4^{2+}$ is consistent with the formation of chelate rings in (III) to (VI) and/or with coordination changes from the octahedral (I) to (V) to the tetrahedral (VI). Then two hypotheses can be formulated: (i) the presence of (III) with inequivalent phosphorus nuclei gives rise to C and D of equal intensity, consequently, only one of (IV) to (VI) is sufficient to explain the resonance H; (ii) if (III) is absent the three peaks are due to (IV), (V) and (VI).

It is the more likely that hypothesis (i) is correct as peak D has a contribution from $AlH_2PO_4^{2+}$ which most probably contains a monodentate phosphate group. Thus peak C may derive from a bidentate dihydrogenphosphate group. There is a remarkable difference between the chemical shifts of C and D on the one hand and H on the other. This could well be because H corresponds to the tetrahedral structure (VI) while all the other monomeric complexes are octahedral.



Peaks G and K, assigned to $(385)^+$ and $(364)^{3+}$, are apparently inert on the NMR time-scale, but both species appear to be involved in the fast proton exchange which causes the chemical shift of peak A to vary with $-\log[H^+]$. This suggests the presence in their structures of loosely bound phosphate groups. In the section devoted to peak A the isomers ε-$(364)^{3+}$, ζ-$(364)^{3+}$, η-$(385)^+$ and θ-$(385)^+$ were assumed to explain the anomalies in the shift of A. The ε-$(364)^{3+}$ and η-$(38)^+$ forms could contain in their molecule fragments as (VII) in Scheme 2, in which phosphate groups are bound through hydrogen bonds to groups coordinated by the metal. This hypothesis is consistent with the tendency [9] of phosphoric acid and its conjugate bases to dimerise to form (VIII), (IX) and similar species. Structural data in solution for (VIII) were obtained by Wertz and Cook [7].

5.1. Comparison with previous NMR results

The ^{31}P chemical shifts observed by various authors under different experimental conditions are summarised in Fig. 4. The more numerous signals found by Wilson et al. [4] might be due, in spite of higher temperature, to lower phosphate concentration. In fact, Akitt et al. [1], noticed that ^{31}P resonances tend to coalesce at increasing phosphoric acid concentration. Thus, a progressive sharpening of the peaks occurs as the phosphate concentration is reduced. The plethora of peaks in our spectra may be due fact that the solutions were relatively dilute (≤0.1 M).

Scheme 1.

Scheme 2.

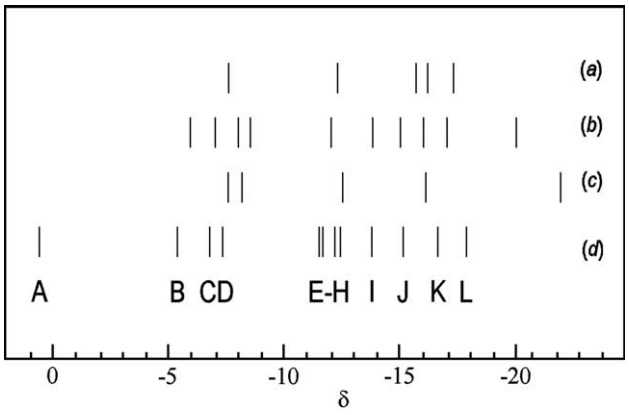


Fig. 4. Comparison of the ^{31}P chemical shift (δ/ppm) reported in the literature and those observed in the present study. (a) Ref. [1]: $T = -15$ °C, $0.4 \leqslant C_P \leqslant 10$ mol dm^{-3}; (b) Ref. [4]: $T = -5$ °C, $C_P = 0.2$ mol dm^{-3}; (c) Ref. [2]: $T = -15$ °C, $0.5 \leqslant C_P \leqslant 6$ mol dm^{-3}; (d) this work: $T = 25$ °C, $0.01 \leqslant C_P \leqslant 0.10$ mol dm^{-3}. Capital letters refer to assignments in Table 3.

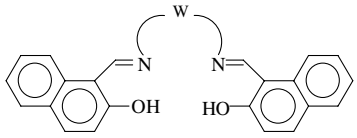

The findings of Akitt et al. [1] are in good agreement with those of Rudolph and Steger [2]. These workers used almost identical experimental conditions. Their spectra are less well resolved than those of Wilson et al. [4]. There is substantial agreement between our data and that of Wilson and co-workers. The chemical shifts shown in Fig. 4 probably equate to B, C, D, G, I, J and K in Table 2, with the exception of shifts at −8.5 and −20 ppm. Different experimental conditions probably account for the presence of E and F in our spectra only, and the signals at −8.5 ppm (the forth from the left) and −20 ppm (the most upfield one) in the spectra of Wilson and co-workers [4].

Scheme 1. Structure of the tetradentate Schiff bases.

the chemistry of ruthenium bi- or polypyridyl complexes, the luminescent chemistry of ruthenium(II) complexes containing Schiff bases is not well developed. Furthermore, metal complexes of ruthenium containing triphenylphosphine or arsine, nitrogen and oxygen donor ligands are found to be effective catalysts for oxidation [13,14]. In particular, the selective oxidation of alcohols into carbonyl compounds by metal complexes is well documented in the literature [15–17]. Sharpless et al. [18] carried out a yield oriented study of oxidation of cholesterol, geranial, etc., catalyzed by ruthenium complexes in the presence of *N*-methylmorpholine-*N*-oxide (NMO) and *N*-*N*-dimethylaniline-*N*-oxide, and only a very few reports are available on the oxidation chemistry using NMO as co-oxidant.

In view of the rich photophysical and catalytic properties of organometallic ruthenium complexes, the introduction of Schiff bases with a 2N2O donor set to ruthenium(II) carbonyl complexes containing triphenylphosphine/triphenylarsine and heterocyclic bases has been carried out. As an extension of our preliminary communication [19–21] and to provide further insight on the catalytic and emission behaviors, an extensive series of ruthenium(II) carbonyl complexes containing tetradentate Schiff bases have been synthesized and characterized. Further, the redox and luminescent properties are also reported along with the catalytic activity of ruthenium(II) complexes towards oxidation of primary and secondary alcohols. The tetradentate Schiff bases were derived from condensation of 2-hydroxy-1-naphthaldehyde with the appropriate diamines. The following Schiff bases were used to prepare the new ruthenium(II) complexes shown in Scheme 1.

2. Experimental

2.1. Material and physical measurements

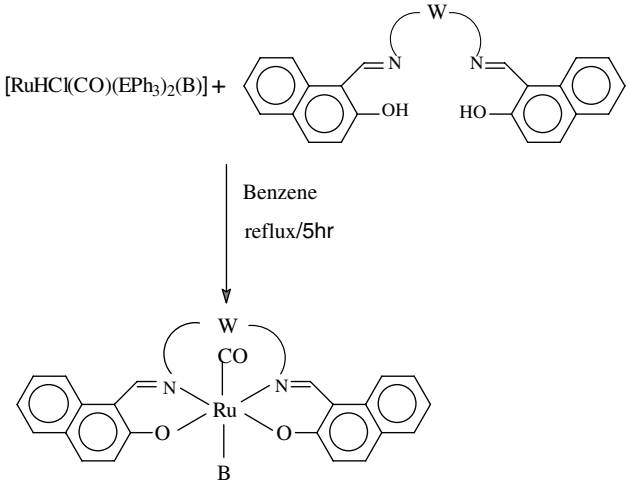
The Schiff bases were prepared in 80–90% yield by condensation of two mole equivalents of 2-hydroxy-1-naphthaldehyde and one mole equivalent of the corresponding diamine by following the reported procedure [22]. All the reagents used were chemically pure or analytical reagent grade. Solvents were purified and dried according to standard procedures. $RuCl_3 \cdot 3H_2O$ was purchased from Loba chemie pvt Ltd. Bombay, India and was used without further purification. [RuHCl(CO)$(PPh_3)_3$] [23], [RuHCl(CO)$(PPh_3)_2$ (B)] [24] (where B = py (or) pip) and [RuHCl(CO)$(AsPh_3)_3$] [25] were prepared by reported literature methods.

The analysis of carbon, hydrogen and nitrogen were performed on a Carlo Erba 1160 and a model 240 Perkin–Elmer CHN analyzer at the Central Drug Research Institute, Lucknow, India. IR spectra were recorded in KBR pellets in the 4000–200 cm^{-1} region in a Jasco 400 plus spectrophotometer. Electronic spectra were recorded in CH_2Cl_2 solution with a Cary 300 Bio UV–Vis Varian spectrophotometer in the range of 800–200 nm. ^1H NMR spectra were recorded on a Bruker 400 MHz instrument using TMS as an internal reference. Emission intensity measurements were carried out by using a Jasco FP-6500 spectrofluorimeter with 5 nm exit slit. Cyclic voltammetric measurements were carried out on a Bio Analytical System (BAS) model CV-50W electrochemical analyzer using acetonitrile as solvent. Melting points were recorded with a Boetius micro-heating table and are uncorrected. The catalytic yields were determined using HP 6890 series GC-FID with a DP-5 column of 30 m length, 0.32 mm diameter and 0.25 μm film thickness.

2.2. Synthesis of Ru(II) carbonyl Schiff base complexes

All the new complexes were prepared by the following general procedure. To a solution of [RuHCl(CO)-$(EPh_3)_2$ (B)] (where E = P; B = PPh_3, py (or) pip) and [RuHCl(CO)$(AsPh_3)_3$] (100 mg; 0.10–0.13 mmol) in benzene the appropriate Schiff base (39–53 mg; 0.10–0.13 mmol) was added and heated under reflux for 5 h. The resulting solution was concentrated to ca. 3 cm^3 and cooled. Light petroleum (60–80 °C) (5 cm^3) was then added whereupon the complex separated out. The solid was filtered off, washed and recrystallized from CH_2Cl_2/light petroleum ether mixture and dried in vacuo. The purity of the compounds were checked by TLC (yield: 65–70%).

2.3. Catalytic oxidation



Catalytic oxidation of primary alcohols to the corresponding aldehydes and secondary alcohols to ketones by ruthenium(II) carbonyl complexes was studied in the presence of NMO as co-oxidant. A typical reaction using the complex [Ru(CO)(PPh_3)(L1)] as a catalyst, and primary or secondary alcohol as substrates at a 1:100 molar ratio is described as follows. A solution of ruthenium complex **1** (0.01 mmol) in 20 $cm^3CH_2Cl_2$ was added to the solution of substrate (1 mmol) and

NMO (3 mmol). The solution mixture was refluxed for 3 h and the solvent was then evaporated from the mother liquor under reduced pressure. The residue was then extracted with pet. ether (60–80 °C) (20 cm^3) and was analyzed by GC. The oxidation products are known and are commercially available, and were identified by GC co-injection with authentic commercial samples.

3. Results and discussions

Complexes of the general formula [Ru(CO)(B)(L)]- (where B = PPh_3, $AsPh_3$, py (or) pip; L = dibasic tetradentate Schiff bases) were synthesized by the reactions of [RuHCl(CO)(PPh_3)$_3$], [RuHCl(CO)(PPh_3)$_2$(py)], [RuHCl(CO)(PPh_3)$_2$(pip)] (or) [RuHCl(CO)($AsPh_3$)$_3$] with the respective tetradentate Schiff bases in a 1:1 molar ratio in benzene as shown in Scheme 2.

The analytical data for the new complexes agree well with the proposed molecular formula (Table 1). In all the reactions it has been observed that the Schiff bases behave as dibasic tetradentate ligands by substituting for the chloride ion, hydride ion and two triphenylphosphine/arsine ligands from each mole of the starting complexes to form the mononuclear complexes. These observations do indicate a more labile nature of the Ru–P bond compared to the Ru–N bond of the heterocyclic nitrogen bases in these complexes. The difference in the strength of Ru–P/As and R–N bonds may be explained as being due to the better σ donating ability of the nitrogen bases compared to that of triphenylphosphine/arsine. The Schiff base ruthenium(II) complexes are highly colored, stable to air and light, and soluble in chloroform, methylene chloride, benzene, DMF and DMSO.

Scheme 2. Formation of Ru(II) carbonyl Schiff base complexes (where E = P; B = PPh_3, py or pip; E = As, B = $AsPh_3$ W = –$(CH_2)_2$–, –$(CH_2)_3$–, –$(CH(CH_3)CH_2)$–, –(C_6H_4)–).

3.1. Spectroscopic characterization

The important IR absorption bands for the synthesized complexes are shown in (Table 2). The observed bands may be classified into those originating from the ligands and those arising from the bonds formed between Ru(II) and the coordinating sites. The free Schiff base ligands showed a strong band in the region 1628–1640 cm^{-1}, which is characteristic of the azomethine (>C=N) group [19]. Coordination of the Schiff bases to the metal through the nitrogen atom is expected to reduce the electron density in the azomethine link and lower the $\gamma_{C=N}$ absorption frequency. The band due to $\gamma_{C=N}$ is shifted to lower frequencies and appears around 1615–1625 cm^{-1}, indicating coordination of the azomethine nitrogen to the ruthenium metal [26]. A strong band observed at 1310–1330 cm^{-1} in the free Schiff bases has been assigned to phenolic C–O stretching. On complexation this band is shifted to a higher frequency range 1321–1360 cm^{-1}, indicating coordination through the phenolic oxygen. This has been further supported by the disappearance of the broad γ_{OH} band around 3395–3410 cm^{-1} in the complexes, indicating deprotonation of the phenolic proton prior to coordination [27]. The coordination of the azomethine nitrogen and phenolic oxygen are further supported by the appearance of two bands at 510–540 and 400–460 cm^{-1} due to γ_{M-O} [27] and γ_{M-N} [28], respectively. The spectra of all the complexes are dominated by a sharp band between 1925 and 1950 cm^{-1} due to a terminal $\gamma_{C\equiv O}$ group. In addition, other characteristic bands due to PPh_3 and $AsPh_3$ are also present around 1435 cm^{-1} in the spectra of all the Schiff base complexes. A medium intensity band is observed in the 1020 cm^{-1} region, characteristic of the coordinated pyridine or piperidine [28].

The ^{1}H NMR spectra of all the complexes were recorded to confirm the binding of the Schiff base to the ruthenium ion (Table 3). The spectra of all the complexes showed a singlet in the region δ 8.90–9.54 ppm, which has been assigned to the azomethine proton (>C=N). The position of the azomethine signal in the complexes is downfield in comparison with that of the free ligands, suggesting deshielding of the azomethine proton due to its coordination to ruthenium through the azomethine nitrogen. Multiplets are observed around δ 6.45–8.50 ppm in all the complexes and have been assigned to the aromatic protons of triphenylphosphine, triphenylarsine, pyridine and naphthalene Schiff base ligands [29]. Two methylene protons appear as one triplet in the region δ 3.53–3.83 ppm in **1**, **5**, **9** and **13**. For the complexes **3**, **7**, **11** and **15**, the signal for the methylene protons appear as one triplet and one quintet in the region 3.65–3.85 ppm and δ 2.17–2.44 ppm, respectively [30]. A broad singlet appears in the region δ 1.2–1.4 ppm for the methylene protons

and another singlet in the region δ 10.10–10.30 ppm for the NH protons in **9**, **11** and **12**. A sharp singlet observed for the OH protons of all the ligands in the region δ 14.0 ppm disappeared in all the complexes. A representative spectrum of the complex [Ru(CO)(PPh_3)(L4)] is shown in Fig. 1.

The electronic absorption spectra of all the complexes in dichloromethane showed three to four bands in the region 263–779 nm. All the Schiff base ruthenium complexes are diamagnetic, indicating the presence of ruthenium in the +2 oxidation state. The ground state of ruthenium(II) in an octahedral environment is $^1A_{1g}$, arising from the t_{2g}^6 configuration, and the excited states corresponding to the $t_{2g}^5e_g^1$ configuration are $^3T_{1g}$, $^3T_{2g}$, $^1T_{1g}$ and $^1T_{2g}$. Hence, four bands corresponding to the transitions $^1A_{1g} \rightarrow {}^3T_{1g}$, $^1A_{1g} \rightarrow {}^3T_{2g}$, $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ are possible in order of the increasing energy.

The bands around 779–589 nm and 485–406 nm are assigned to $^1A_{1g} \rightarrow {}^1T_{1g}$ [20,31] and charge transfer (CT) transitions respectively are listed in Table 2. The charge transfer bands observed in all the complexes due to M $\rightarrow$ L transitions are possible in the visible region [31–33]. Moreover, the presence of carbonyl, triphenylphospine/arsine and heterocyclic bases as ligands, which are capable of producing strong ligand field e_g^*

levels place these levels relatively high in energy. Therefore, the lowest charge bands due to excitation of an electron from the metal t_{2g} level to an unfilled molecular orbital derived from the π* level of the ligands should appear in the relatively high energy region compared to those due to $t_{2g} \rightarrow e_g^*$ transitions [32–34]. The other high intensity bands in the 344–269 nm region were characterized by ligand-centered (LC) bands and have been designated as π–π* and *n*–π* transitions for the electrons localized on the azomethine group of the Schiff bases [33]. The pattern of the electronic spectra of all the complexes indicated the presence of an octahedral environment around the ruthenium(II) ion, similar to that of other ruthenium(II) octahedral complexes [21].

Emission properties of the ruthenium(II) Schiff base complexes were examined in dichloromethane solution at room temperature, and excitation and emission maxima are listed in Table 2. In the present series, the excitation of all the complexes was made at their charge transfer bands and the emission maxima of the complexes have experienced a positive shift of the order of 50–90 nm. The emission maxima fall in the range 471–552 nm and a representative spectrum is shown in Fig. 2. The observed CT luminescence in these complexes may be due to the presence of di-imine functions. It is likely that the emission originates from the lowest energy metal to ligand charge transfer (MLCT) state, probably derived from the excitation involving a $d\pi(Ru) \rightarrow \pi^*$ (di-imine) MLCT transition, and similar MLCT transitions are observed in ruthenium(II) bipyridyl complexes [34,35]. The slightly lower MLCT transition energy is probably due to the chelate ring of the complexes. In the complexes **4**, **8**, **12** and **16** it is observed that an increase in the rigidity of the ligand results in an increase in the emission maxima. If increased rigidity of the complexes is solely responsible for potential emission changes then it would be expected that this is because of the ligands present in the complexes [36].

3.2. Electrochemistry of the complexes

The redox properties of all the complexes were investigated in acetonitrile solution by cyclic voltammetry and the redox potentials are expressed with reference to Ag/AgCl. The cyclic voltammograms of all the complexes (1×10^{-3}) display one quasi-reversible oxidation with $E_{1/2}$ values 0.76–1.04 V and one irreversible reduction, with respect to the SCE. In general, the changes in oxidation and reduction potential are probably due to the relative stabilization of the ruthenium(II) state over ruthenium(III) by a combination of σ and π effects exhibited by the ligand. A representative voltammogram of [Ru(CO)($AsPh_3$)(L4)] is shown in Fig. 3 and voltammetric data are presented in Table 4. The oxidation observed is quasi-reversible in nature, characterized by a rather

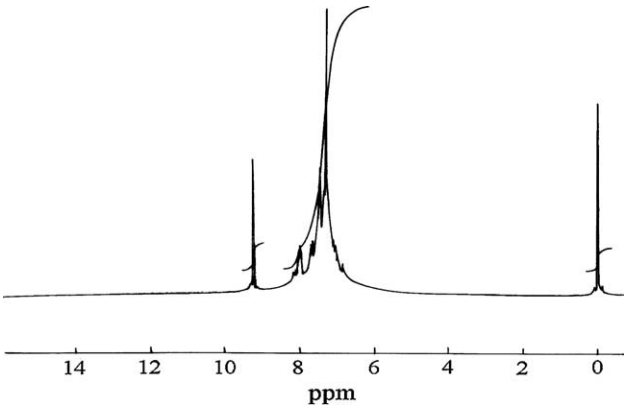

Fig. 1. ^{1}H NMR spectrum of [Ru(CO)(PPh_3)(L4)].

large peak-to-peak separation (ΔE_p) of 110–220 mV and the cathodic peak current (i_{pc}) is less than the anodic peak current(i_{pa}). The one electron nature of this oxidation has been verified by comparing its current height (i_{pa}) with that of the standard ferrocene–ferrocenium couple under identical experimental conditions [37].

The reason for the irreversibility observed for reductive response of all the complexes may be due to a short lived reduced state of the metal ion [38] or due to oxidative degradation of the ligands [39]. The reduction potential of Ru(II) complexes are affected by chelate rings of the ligands and it is observed that the reduction potential of complexes with a larger chelate ring is more than that of complexes with a smaller chelate ring. Further, an irreversible ligand based reduction peak is observed in the range −0.96 to −1.18 V, which corresponds to reduction of the azomethine(−C=N) moiety of the Schiff base ligands, and the reduction occurred at more negative values.

It has also been observed from the electrochemical data that there is not much variation in the redox potential due to triphenylphosphine, triphenylarsine, pyridine or piperidine [21]. Hence, it is inferred from the electrochemical data that the present ligand system is ideally suitable for stabilizing the higher oxidation state of ruthenium.

3.3. Catalytic activity of the complexes

Catalytic oxidation of primary alcohols and secondary alcohols by the synthesized ruthenium(II) carbonyl Schiff base complex [Ru(CO)(PPh_3)(L1)] was carried out in CH_2Cl_2 in the presence of NMO, and the by product water was removed by using molecular sieves. Complex **1** oxidizes primary alcohols to the corresponding aldehydes and secondary alcohols to ketones with high yield and the results are listed in Table 5 (entries 1–8). The aldehydes or ketones formed after 3 h of refluxing were determined by GC and there was no detectable oxidation in the absence of ruthenium complex.

R,R'=alkyl (or) aryl (or) H

14	1.09	0.98	110	1.04	−0.85	−1.02
15	0.90	1.08	180	0.99	−0.79	−0.97
16	0.87	1.01	140	0.94	−0.88	−1.11

Supporting electrolyte: NBu_4ClO_4 (0.005 M); complex: 0.001 M; solvent: CH_3CN; $\Delta E_p = E_{pa} - E_{pc}$ where E_{pa} and E_{pc} are anodic and cathodic potentials, respectively; $E_{1/2} = 0.5(E_{pa} + E_{pc})$; scan rate: 100 mV s^{-1}.

Results of the present investigation suggest that the complexes are able to react efficiently with NMO to yield a high valent ruthenium-oxo species [2,40] capable of oxygen atom transfer to alcohols. This was further supported by spectral changes that occur by addition of NMO to a dichloromethane solution of the ruthenium(II) complexes. The appearance of a peak at 390 nm is attributed to the formation of Ru^{IV}=O species, which is in conformity with other oxo ruthenium(IV) complexes [2,41,42]. Further support in favor of the formation of such species was identified from the IR spectrum of the solid mass (obtained by evaporation of the resultant solution to dryness), which showed a band at 860 cm^{-1}, characteristic of Ru^{IV}=O species [2,40,41].

The oxidation of benzylalcohol to benzaldehyde resulted in 89% conversion. Unsaturated cinnamylalcohol was oxidized to cinannamaldehyde with 95% conversion, without cleavage of carbon–carbon double bonds. This is an important characteristic of the ruthenium/NMO system. Further, the complex effectively catalyzes the oxidation of aliphatic alcohols such as butane-2-ol, methylpropylcarbinol and isobutylmethylcarbinol to the corresponding ketones with high conversions. In the case of benzoin the oxidation product was isolated and characterized by melting point, IR and ^{1}H NMR. Moreover, the complex efficiently catalyzes the oxidation of five and six membered cyclic alcohols to the corresponding ketones with conversions of 99% and 92%, respectively. This reaction provides a new environmentally friendly route to the conversion of alcoholic functions to carbonyl group and water is the only by product during the course of the reaction. It has been observed that complex **1** has a better catalytic efficiency in the case of oxidation of primary and secondary alcohols when compared to an earlier report [42–44] on similar ruthenium complexes as catalysts in the presence of NMO/*t*-BuOOH. Hence, it is relevant from the cyclic voltammetric data that the oxidation effected by catalysts is likely to occur via higher ruthenium oxidation states, which are easily accessible through chemical oxidation with co-oxidants like NMO, *t*-BuOOH, PhIO etc. [42].

Table 5
Catalytic oxidation of alcohols to the corresponding aldehydes and ketones with complex **1** in the presence of NMO

Entry	Substrate	Product	Conversion (%)[b]	Turnover[c]
1			89	89
2			95	95
3			99	99
4			92.2	92.2
5			46[a]	46
6			88	88
7			99	99
8			99	99

Substrate (1 mmol); NMO (3 mmol); complex (0.01 mmol): solvent dichloromethane.

[a] Isolated yield, characterized by melting point, ^{1}H NMR and IR.

[b] Yield determined by GC and comparing with the analyses of authentic samples.

[c] Moles of product per mole of catalyst.

4. Conclusion

A new family of ruthenium(II) carbonyl complexes containing tetradentate Schiff bases were synthesized and characterized. These complexes are found to have luminescent properties and attempts will be made for further investigation on this study. The oxidation of alcohols to carbonyl compounds has been studied with NMO in the presence of catalyst **1** and high yields were obtained.

Acknowledgment

We express sincere thanks to the Sophisticated Instrument Facility, Indian Institute of Science, Bangalore for providing the NMR facility.

The studies show dependence of these reactions on the starting material, N-donor ligand, solvent and temperature. Although the factors determining the formation of the $Re_2O_3^{4+}$ complexes have not been formalised, water seems to be a source of the bridging oxo group. No intermediates have been isolated in the syntheses mentioned above, but the formation of intermediate hydroxo-species seems to be crucial [1–22].

These findings prompted us to explore the reactions of $[ReOBr_3(OAsPh_3)(Asph_3)]$ with pyrazine (pyz) and pyridazine (pyd) in acetone at room temperature. Two dinuclear complexes, $[\{ReOBr_2(pyz)_2\}_2(\mu\text{-}O)]$ with a linear O═Re–O–Re═O backbone (**1**) and $[\{ReOBr_2\}_2(\mu\text{-}O)(\mu\text{-}pyd)_2]$ with a bent $Re_2O_3^{4+}$ core (**2**), have been isolated. Here, we report the syntheses, crystal and molecular structures, spectroscopic investigations and the density functional theory (DFT) calculations for the complexes **1** and **2**.

Only a few calculations concerning the nature of the bonding could be found in the literature for transition metal oxocomplexes. Dunitz and Orgel [25] were the first who based on crystal-field considerations presented a molecular orbital energy ordering for the Ru–O–Ru core in $[Ru_2OCl_{10}]^{4-}$ and explained the unusual features of the complex – diamagnetism, short Ru–O bond length and the linear geometry of the Ru–O–Ru group. Since then many authors used the Dunitz and Orgel molecular orbital diagram to discuss the $[Cl_5M\text{–}O\text{–}MCl_5]^{n-}$ anions with linear and bent bridges (M = Ru(IV), Os(IV), Re(IV), Re(III), W(IV)) [26–32]. The ab initio calculations were done for the $[Cl_5Ru\text{–}O\text{–}RuCl_5]^{4-}$ anion with the GAMESS and EXTEN-97 programs [33]. Currently, density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [34–37]. Therefore, we have chosen this tool for performing a study of the electronic structure of $[\{ReOBr_2(pyz)_2\}_2(\mu\text{-}O)]$ (**1**) with a linear Re_2O_3 core and $[\{ReOBr_2\}_2(\mu\text{-}O)(\mu\text{-}pyd)_2]$ (**2**) with a bent Re_2O_3 unit. In order to obtain additional information about binding in the complexes **1** and **2**, we have applied NBO analysis.

The time-dependent DFT method (TDDFT) has been applied to calculate the spin-allowed singlet-singlet electronic transitions of complexes **1** and **2**, and the UV–Vis spectra of these compounds have been discussed on this basis.

2. Experimental

2.1. General procedure

All manipulations and reactions were carried out open to the atmosphere. All solvents were of reagent grade and were used as received. Ammonium perrhenate, triphenylarsine, pyrazine and pyridazine were purchased from Aldrich and used as received. The $[ReOBr_3(AsPh_3)(OAsPh_3)]$ complex was prepared according to the literature method [38].

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of potassium bromide pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV-VIS 8500 in the range 800–200 nm in deoxygenated CH_2Cl_2 solution for **1** and dmso for **2**. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[\{ReOBr_2(pyz)_2\}_2(\mu\text{-}O)]$ (1)

$[ReOBr_3(AsPh_3)(OAsPh_3)]$ (O.5g, 0.47 mmol) was suspended in a solution of pyrazine (0.1g, 1.25 mmol) in acetone (60 ml) and the reaction mixture was stirred for 24 h. Diethyl ether (100 ml) was added and green precipitate of **1** was filtered. The crystals suitable for X-ray investigation were obtained by slow diffusion of diethyl ether into an acetone solution of **1**. (Yield 65%).

IR of **1** (KBr, cm^{-1}) 3084 (w), 3049 (w), 2979 (w), 1714 (s), 1590 (m), 1423 (s), 1361 (m), 1229 (m), 1163 (m), 1124 (m), 1062 (m), 973 (m), 810 (m) 709 (s), 674 (vs), 531 (w), 472 (m).

Anal. Calc. for $C_{19}H_{22}N_8Br_4O_4Re_2$ (**1**): C, 20.40; H, 1.98; N, 10.02. Found: C, 20.50; H, 2.08; N, 10.12%.

2.3. Preparation of $[\{ReOBr_2\}_2(\mu\text{-}O)(\mu\text{-}pyd)_2]$ (2)

A procedure similar to that for **1** was used with $[ReOBr_3(AsPh_3)(OAsPh_3)]$ (O.5g, 0.47 mmol) and pyridazine (0.1g, 1.25 mmol). Dark green crystals of **2** were collected in 60% yield, and crystals suitable for X-ray structure determination were obtained by slow diffusion of diethyl ether into an acetone solution of **2**.

IR of **2** (KBr, cm^{-1}) 3094 (m), 3063 (m), 3002 (w), 1700 (s), 1581 (m), 1450 (s), 1417 (s), 1366 (m), 1307 (s), 1227 (m), 1075 (m), 1001 (m) 957 (s), 780 (s), 757(s), 742 (s), 682 (vs), 534 (w), 503 (m), 444 (m).

Anal. Calc. for $C_{11}H_{14}N_4Br_4O_4Re_2$ (**2**): C, 13.79; H, 1.47; N, 5.85. Found: C, 13.92; H, 1.58; N, 5.94%.

2.4. Crystal structure determination and refinement

The X-ray intensity data of **1** and **2** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector. 20 and 48 s exposure times were used respectively and reflections were collected up to $\theta = 25.11°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 3138 and 7270 strongest reflections respectively for **1** and **2**. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical

absorption corrections [39] were applied. The structures were solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix least-squares technique. The hydrogen atoms bonded to the aromatic atoms were treated as ''riding'' on their parent carbon atoms and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent atom. The methyl groups were allowed to rotate about their local threefold axis. SHELXS-97 [40], SHELXL-97 [41] and SHELXTL [42] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

The GAUSSIAN-03 program [43] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [44,45]. The electronic spectrum was calculated with the TDDFT method [46]. The LANL2DZ basis set [47] with additional d (with exponent $\alpha=0.3811$) and f (with exponent $\alpha=2.033$) functions was used on the rhenium, 6-31G(d) on the bromine, nitrogen and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations.

Natural bond orbital (NBO) calculations were performed with the NBO code [48] included in GAUSSIAN-03.

4. Results and discussion

4.1. Preparation

Treatment of the $[ReOBr_3(AsPh_3)(OAsPh_3)]$ complex with an excess of pyrazine (pyz) in acetone at ambient temperature leads to the $[\{ReOBr_2(pyz)_2\}_2(\mu\text{-}O)]$ complex (**1**) with a nearly linear O═Re–O–Re═O moiety and four terminal pyz ligands, whereas the reaction of $[ReOBr_3(AsPh_3)(OAsPh_3)]$ with pyridazine (pyd) affords $[\{ReOBr_2\}_2(\mu\text{-}O)(\mu\text{-}pyd)_2]$ (**2**) with a bent Re_2O_3 unit and two Re centers linked through two bridging pyridazine molecules and an oxo group.

The formation of the above mentioned dinuclear complexes doubtlessly involves water and intermediate hydroxo-species [1–22]. Both the reactions have been carried out in air and without special drying of acetone, so that some water has been present in the reaction

systems. Different positions of the nitrogen atoms in the rings of pyrazine and pyridazine can explain the formation of the different (with terminal or bridging N-donor ligands) dinuclear oxo complexes in the reaction with the oxo complex.

4.2. Infrared data

The IR spectra of **1** and **2** show sharp bands at 973 and 957 cm^{-1} assignable to the symmetric Re=O stretch. The strong bands at 674 for **1** and 682 cm^{-1} for **2** result from overlapping of the antisymmetric Re–O–Re stretching modes with the aromatic ring out-of-plane deformation vibrations. In comparison with the $[(ReCl_5)_2(\mu\text{-}O)]^{4-}$ complex with an antisymmetric ν_{as}(Re–O–Re) stretching mode in the range 850–855 cm^{-1}[49], a significant reduction in the frequency of ν_{as}(Re–O–Re) is observed for compounds **1** and **2**. It is a consequence of the electron-withdrawing effect of the terminal Re=O groups causing a relative weakening of the bridging Re–O bonds.

4.3. Crystal structure

Both the complexes crystallise as solvates **1** · CH_3COCH_3 and **2** · CH_3COCH_3, respectively. The accurate cell parameters and crystal data for **1** · CH_3COCH_3 and **2** · CH_3COCH_3 are given in Table 1. The acetone molecules from the crystallization are not bonded to any other atom, with the exception of some rather weak hydrogen bonds. The weak intra- and intermolecular hydrogen bonds [50,51] of **1** · CH_3COCH_3 and **2** · $CH_3COCH_3$are presented in Table 2.

Table 2

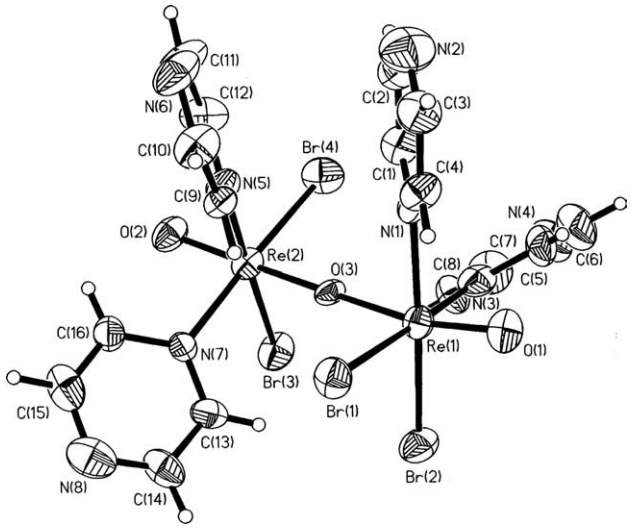

Fig. 1. The molecular structure of **1**.

The molecular structure of **1** is shown in Fig. 1. The structure presents a nearly linear O=Re–O–Re=O unit with the rhenium atoms in a pseudo-octahedral coordination environment, slightly displaced from the N_2Br_2 mean plane towards the terminal oxo ligand. The halves of the dimer are rotated about the Re–O–Re fragment away from an eclipsed conformation: thus one nitrogen ligand on each Re atom is stacked with the corresponding one on the second Re. These pyrazine molecules are determined as stacking ligands (L_s), while the others N-donors are designated as terminal ones (L_t). The selected pseudo-torsion angles describing the relative arrangement of the respecting substituents for **1** are collected in Table 3. This arrangement avoids short contacts between the L_t ligands in different halves of the dimer and allows some stacking to take place between the L_s ligands.

The structure of **2** reveals the presence of two rhenium(V) centers linked through two bridging pyridazine molecues and an oxo group (Fig. 2). Due to the geometric constraints of the two bridging N-donor ligands the $\{Re_2O_3\}$ core in **2** is bent with a Re–O–Re angle equal to 128.3(6)°.

The most important bond lengths and angles for compounds **1** and **2** are reported in Tables 3 and 4, respectively. The departure from the ideal octahedron in **1** is mainly attributed to the electronic repulsion of the short Re=O bond. For complex **2** the bridging N–N ligands introduce some additional strain.

The Re–N, Re–$O_{terminal}$ and Re–$O_{bridging}$ bond lengths in **1** and **2** agree well with the comparable values found in rhenium compounds with a O=Re–O–Re=O framework [1–22]. The Re–$O_{terminal}$ bond lengths, mean 1.698 and 1.675 Å for **1** and **2** respectively, correspond to the values reported for mononuclear mono-oxo d^2 rhenium complexes with an average

Table 3

Re–$O_{terminal}$ distance of 1.691Å [52]. The Re–$O_{terminal}$ bonds of **1** and **2** appear therefore to be normal triple bonds. The Re–$O_{bridging}$ bond distances of 1.929 and

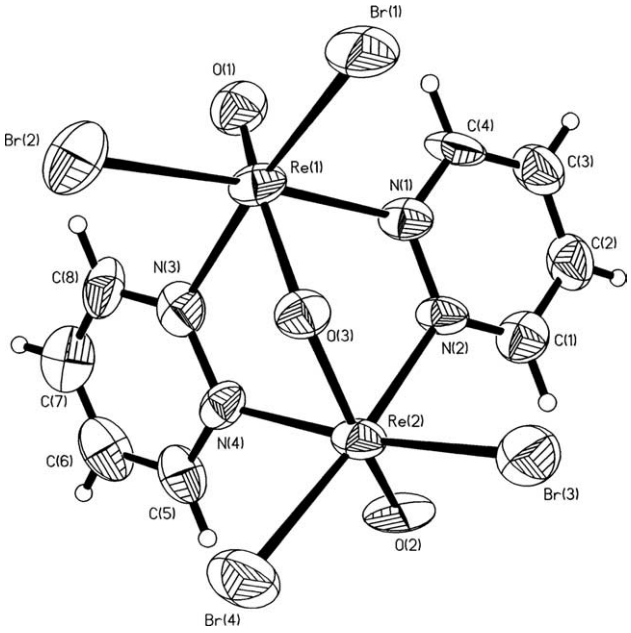

Fig. 2. The molecular structure of **2**.

1.898 Å for **1** and **2** suggest that a small amount of overlap also occurs between the d_{xz} and d_{yz} rhenium orbitals and the suitable p orbitals of the bridging oxygen. An ideal single Re–O bond length, predicted by the use of Pauling's covalent radius for oxygen and Cotton and Lippard's value for the octahedral covalent radius of rhenium(V), should be ca. 2.04 Å [53].

4.4. NBO analysis

Table 5 presents the occupancies and hybridization of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligands for the complexes **1** and **2**. Table 6 shows the occupancies and atomic orbital compositions of the lone pairs (LP) of the oxo ligands, as well as the character of the acceptor orbital and stabilization energies (ΔE_{ij}) for the corresponding donor-acceptor interactions for **1** and **2**. The interactions between 'filled' (donor) Lewis-type NBOs and 'empty' (acceptor) non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure. The stabilization energy ΔE_{ij} (kcal/mol) associated with delocalization is estimated by the second–order perturbative as

$$\Delta E_{ij} = q_i(F(i,j)^2)/(\varepsilon_j - \varepsilon_i),$$

where q_i is the donor orbital occupancy, ε_i, ε_j are diagonal elements (orbital energies) and $F(i,j)$ is the off-diagonal NBO Fock matrix element [54].

[a] BD denotes 2-center bond.
[b] Denotes antibond NBO.

For each Re atom of **1** and **2**, two natural Re–O_t bond orbitals were detected. They are all polarized towards the oxygen atom (ca. 68%), and the p oxygen orbitals and d rhenium orbitals are involved in the Re–O_t bond formation. The atomic orbital compositions of the detected Re–O_t bond orbitals (Table 5) indicate their π character. The non-detected $\sigma_{Re–Ot}$ bonds have character of predominantly Coulomb-type interactions between the central ion and ligands [55]. Each terminal oxo ligand of **1** and **2** has two lone pairs, and the electron density from one of them (for each atom) is strongly delocalized into non-Lewis rhenium orbitals (Table 6). In complex **1**, the bridging oxygen ligand has four lone pairs (LP) and the Re–O_b bonds were not detected indicating predominant Coulomb-type Re–ligand interactions. The LP orbitals of σ symmetry of the bridging oxo ligand interact with the empty d and sd Re orbitals, whereas LP orbitals of π symmetry interact with $\pi^*_{Re–O(t)}$ orbitals. In both cases significant loss of occupancy from LP orbitals of bridging oxo ligand can be noticed.

In complex **2**, one Re–O_b bond orbital was detected and consequently the bridging oxo ligand has three LP orbitals. The detected Re(1)–O(3) bond is strongly polarized towards the bridging oxygen atom (ca. 85%), and the s and p oxygen orbitals and s and d rhenium orbitals take part the bond formation. The non-detected Re(1)–O(3) bond has predominantly ionic character. A larger loss of occupancy can be noticed from the lone pair orbitals of π symmetry interacting with $\pi^*_{Re–O(t)}$ orbitals.

4.5. Geometry optimisation

The optimised geometric parameters of **1** and **2** are gathered in Tables 3 and 4, respectively. A good agreement with the experimental values can be noticed for the Re–O and Re–N bond lengths. Larger differences between calculated and experimental bond lengths are seen for Re–Br distances, the maximum deviations for

Re–Br bond lengths are equal to 0.08 and 0.044 Å for **1** and **2**, respectively.

4.6. Charge distribution

Table 7 presents the atomic charges from the natural population analysis (NPA) for complexes **1** and **2**. The calculated charges on the rhenium atoms are considerably lower than the formal charge of +5. The population of the d_{xy}, d_{xz}, d_{yz}, $d_{x^2-y^2}$ and d_{z^2} orbitals of the central atoms in **1** and **2** is as follows: complex **1** – Re(1): 0.964, 0.861, 1.569, 0.920 and 1.067; Re(2): 0.972, 0.860, 1.562, 0.916 and 1,070; complex **2** – Re(1) and Re(2): 0.881, 1.118, 0.968, 1.381 and 1.069. This is a result of significant charge donation from oxo ligands, bromine ions and N-heterocyle molecules. The Re centers of **2** are less positive in comparison with the metal ions of **1**. In both complexes **1** and **2**, considerable differences in the values of charges are observed for the terminal and bridging oxo ligands–less negative are the terminal oxo ligands, which indicates the higher electron density delocalization from the terminal ligands towards the rhenium centers and corresponds to differences in the Re–O_t and Re–O_b bonds lengths. The higher charge donation from the terminal oxo ligands can be noticed for the linear complex, whereas the bridging oxo ligand is less negative in the complex **2**.

4.7. Electronic structure

The energy and character of the selected MOs for **1** and **2** are presented in Table 8. The rhenium atoms in

Table 7
Atomic charges from the natural population analysis (NPA) for **1** and **2**

Atom	**1**	**2**
Re(1)	1.16	1.12
Re(2)	1.16	1.12
O(1)	−0.46	−0.51
O(2)	−0.46	−0.51
O(3)	−0.82	−0.75
N(1)	−0.45	−0.23
N(2)	−0.40	−0.23
N(3)	−0.45	−0.23
N(4)	−0.40	−0.23
N(5)	−0.45	
N(6)	−0.40	
N(7)	−0.45	
N(8)	−0.40	
Br(1)	−0.39	−0.28
Br(2)	−0.30	−0.28
Br(3)	−0.30	−0.28
Br(4)	−0.39	−0.28

both **1** and **2** possess the d^2 configuration, the two highest MOs of these compounds are of d type with antibonding contributions from p_π bromine orbitals. The remaining eight d-type orbitals of rhenium are found among unoccuppied MOs. In the case of **1**, the d_{xz} and d_{yz} rhenium orbitals make the largest contribution into the LUMO, LUMO + 1, LUMO + 6 and LUMO + 7 orbitals, and they bear antibonding character towards the oxygen atoms. The participation of the d_{xz} and d_{yz} orbitals in the other molecular orbitals of **1** do not reach 10%. In complex **2** the d_{xz} and d_{yz} rhenium orbitals are dispersed among a larger number of the molecular orbitals. The significant participations of the d_{xz} and d_{yz} orbitals are shown in LUMO, LUMO + 1, LUMO + 2, LUMO + 3, LUMO + 6 and LUMO + 7. In all of them the d_{xz} and d_{yz} orbitals bear antibonding character towards the oxygen atoms. The π orbitals of the pyridazine rings also contribute to the LUMO, LUMO + 1, LUMO + 2 orbitals. Figs. 3 and 4 present the energy and contours of the occupied and unoccupied molecular orbitals with the largest contributions of d rhenium orbitals for **1** and **2**, respectively. As it can be seen from Figs. 3 and 4, each molecular orbital is a plus or minus combination of the symmetry equivalent d orbitals of the two rhenium atoms.

4.8. Electronic spectra

The experimental and calculated electronic spectra of **1** and **2** are presented in Figs. 5 and 6, respectively. Each calculated transition in Figs. 5(b) and 6(b) was represented by a gaussian function with the height equal to the oscillator strength and the width equal to 0.04.

The investigated complexes are of large size and the number of basis functions is equal to 590 and 406 for **1** and **2**, respectively. Eighty electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectra of **1** and **2** were calculated to ~280 nm, so the shortest wavelength experimental bands cannot be assigned to the calculated transitions. However, considering that the solution spectra of pyrazine and pyridazine exhibit

intense absorption bands in the 260–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations for these complexes.

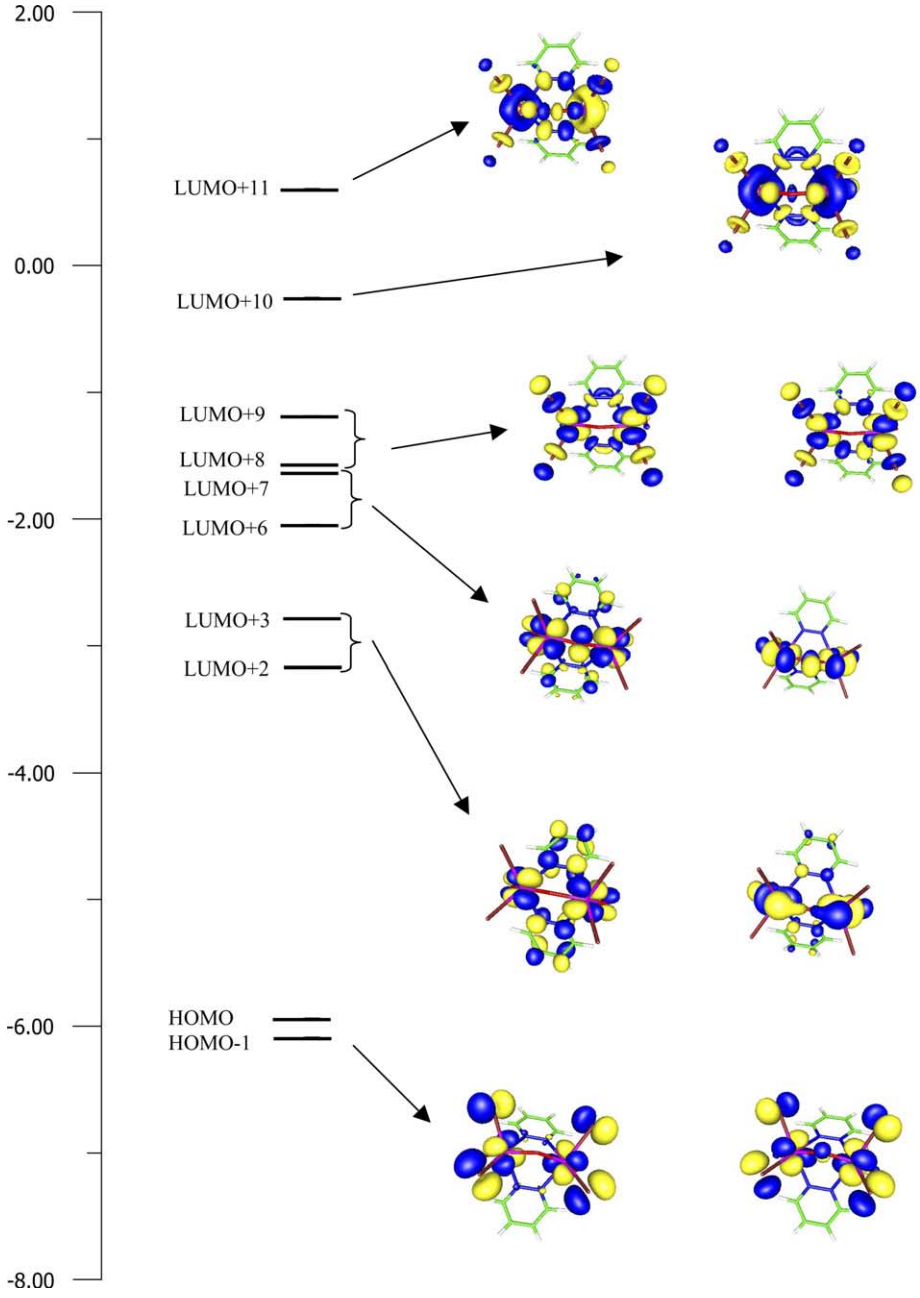
4.9. *[{ReOBr$_2$(pyz)$_2$}$_2$(μ-O)] (**1**)*

The longest wavelength experimental band at 675.4 nm is attributed to the transitions of d → d character with small oscillator strengths calculated in the range 785–700 nm.

The absorption band at 486.2 nm is assigned to the electronic transitions of MLCT d → π^*_{pyz} character calculated in the range 447–418 nm.

The next experimental band at 389.6 nm corresponds to the electronic transitions calculated between 415 and 380 nm. These transitions are mainly of LMCT (π(Br)/π(O) → d) character.

The transitions calculated between 365 and 290 nm are ascribed to the experimental band at 331.4 nm. They are of LLCT (π(Br)/π(O) → π*(pyz)) and MLCT d → π^*_{pyz} and LMCT (σ(Br)/σ(N) → d) character.



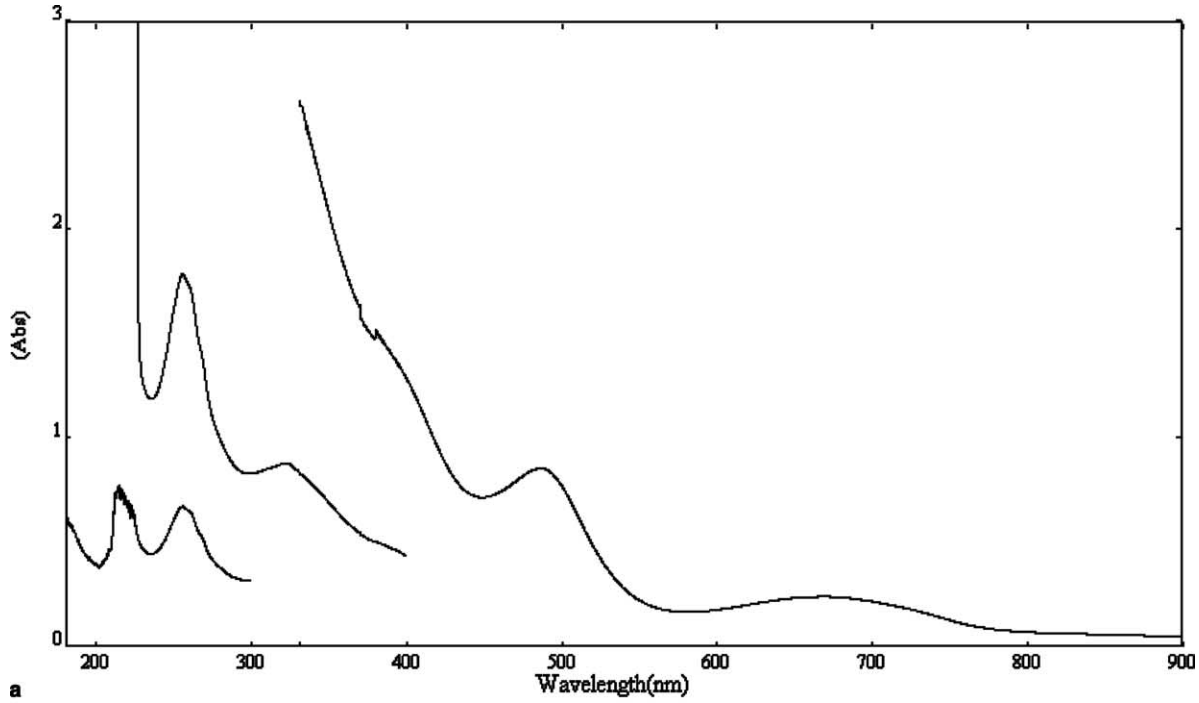


Fig. 4. The energy (eV), character and contours of the occupied and unoccupied molecular orbitals of **2** with the largest contributions of the d rhenium orbitals.

*4.10. [{$ReOBr_2$}$_2$(μ-O)(μ-pyd)$_2$] (**2**)*

The longest wavelength experimental band of complex **2** is very broad and asymmetrical. It spreads from 850 nm to 555 nm and its maximum lies at 675 nm. Similar to complex **1** this band corresponds mainly to the transitions from HOMO and HOMO − 1 to LUMO and LUMO + 1 orbitals. However, due to a significant participation of π* orbitals of the pyridazine ligands in the LUMO and LUMO + 1 orbitals, the character of the electronic transitions corresponding to the band is ascribed as d → d/π*(pyd). This experimental band is more intense in comparison with complex **1** and the calculated oscillator strengths for transitions in this region are considerably higher for complex **2**.

The absorption band at 430.0 nm is assigned to the electronic transitions calculated in the range 520–370 nm. These transitions are π(Br)/π(O) → d/π*(pyd), π(Br) → d/π*(pyd), d → π*(pyd) and d → d in origin.

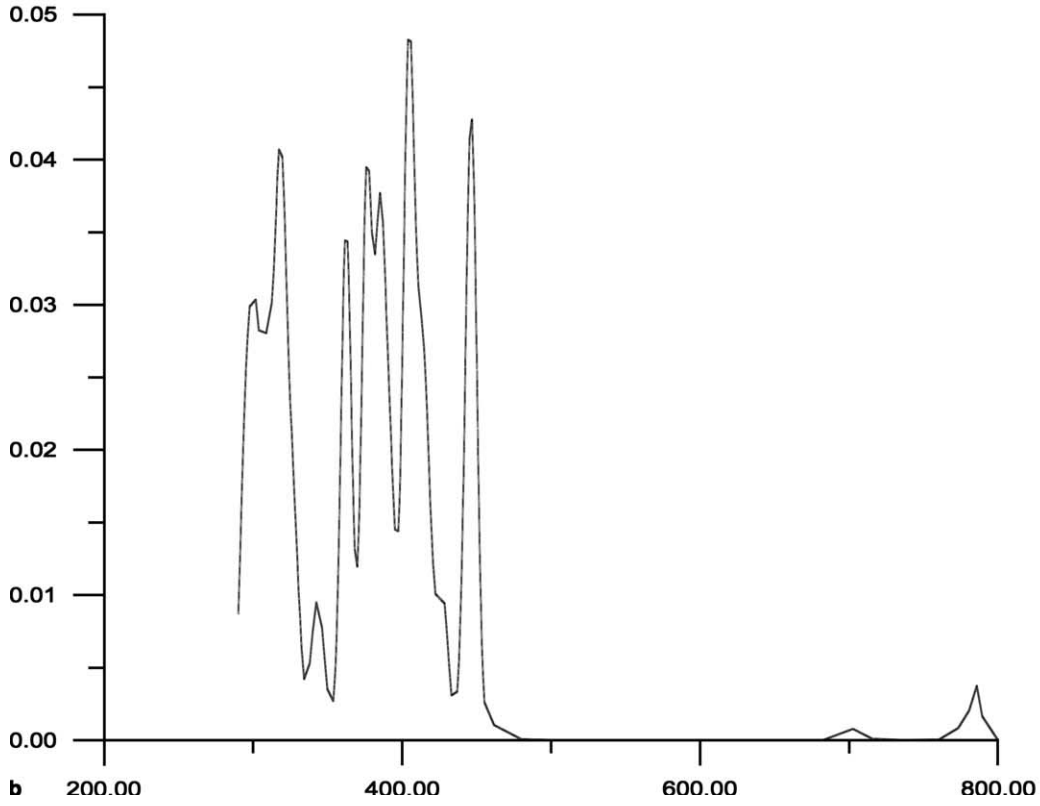

Fig. 5. The experimental (a) and calculated (b) electronic absorption spectrum of **1**.

The experimental bands at 331.2 and 273.2 nm correspond mainly to the transitions of LMCT ($\pi(Br)/\pi(O) \rightarrow d$) and LLCT ($\pi(Br)/\pi(O) \rightarrow \pi^*(pyd)$) character.

Generally, the $\pi(Br)/\pi(O) \rightarrow d$ transitions of the complex with a bent $Re_2O_3^{4+}$ unit are shifted to higher energy in comparison with that one containing a linear O═Re–O–Re═O backbone.

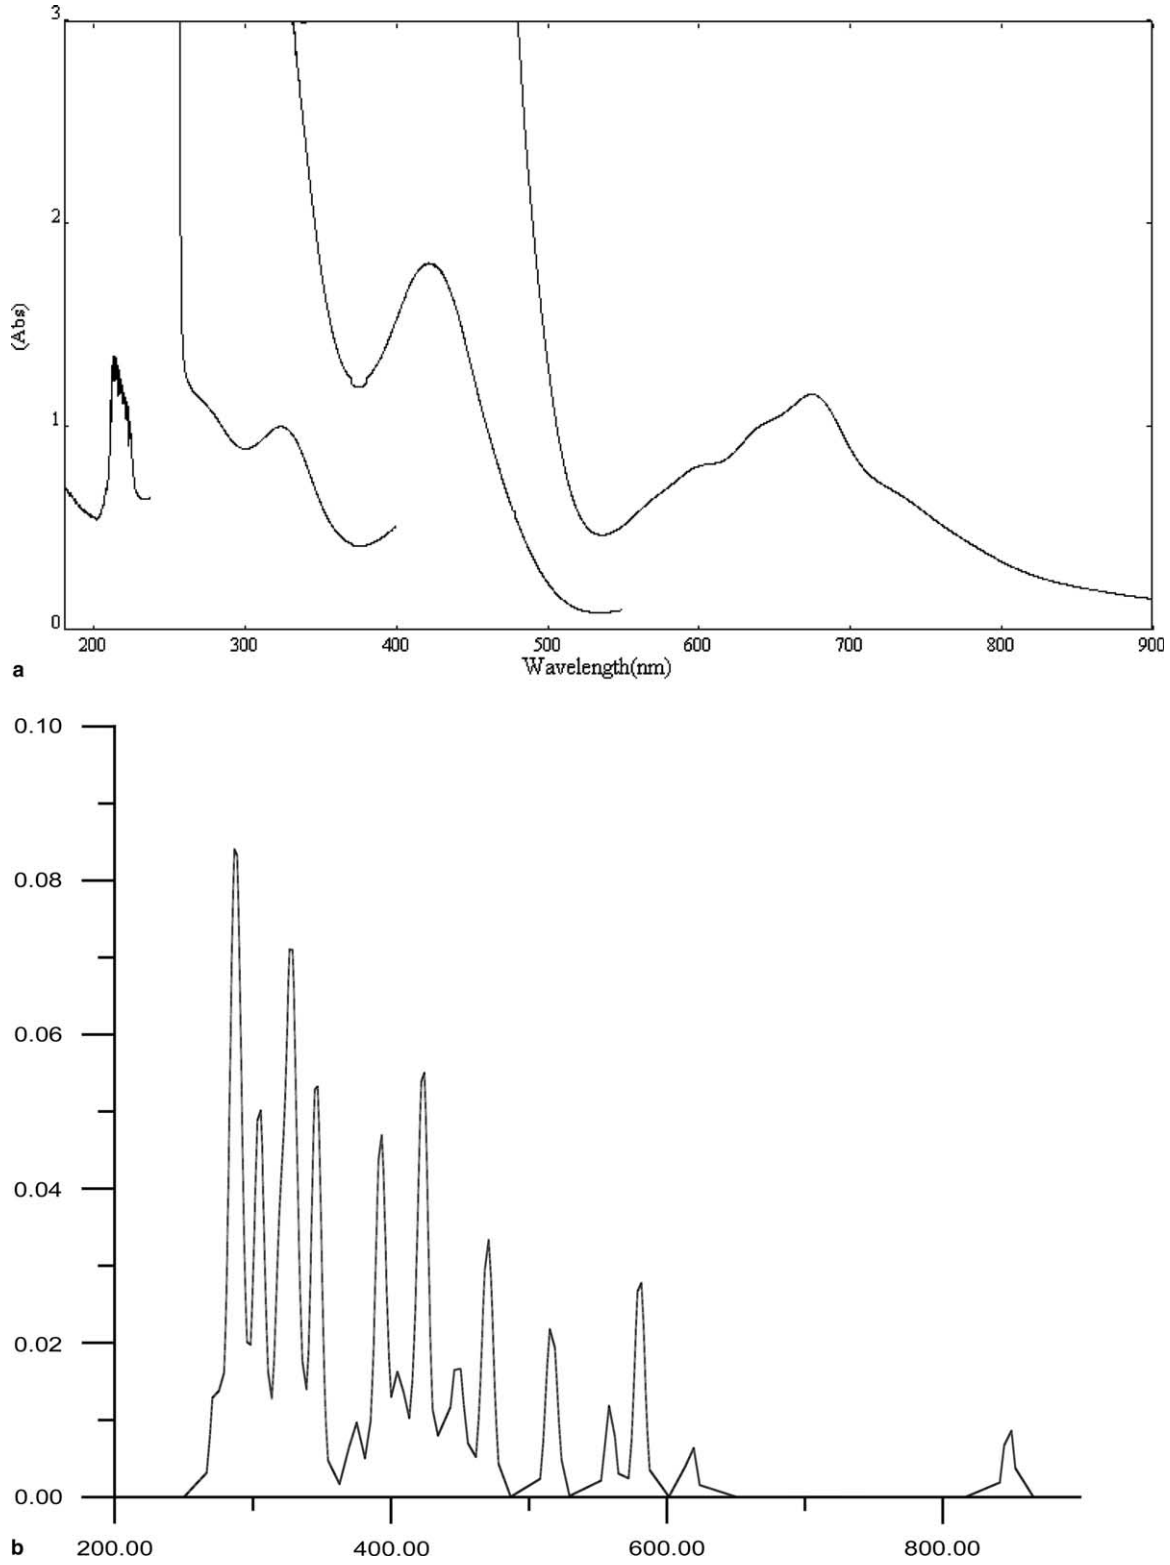

Fig. 6. The experimental (a) and calculated (b) electronic absorption spectrum of **2**.

5. Conclusions

The DFT calculations performed for two rhenium oxo complexes with linear (**1**) and bent (**2**) structures show that the investigated complexes have the rhenium atoms in a d^2 electronic configuration. The bending of the Re_2O_3 unit in **2** is a consequence of steric congestion introduced by two coordinated pyridazine bridging

ligands. For both complexes, NBO analysis confirms the presence of a triple bond between the rhenium atoms and terminal oxo ligands. The Re–O_b bonds have character of predominant Coulomb-type Re–ligand interactions, and a significant loss of occupancy from the LP orbitals of the bridging oxo ligand can be noticed for both **1** and **2**. The considerable differences in values of charges observed for the terminal and bridging oxo ligands also indicates the higher electron density delocalization from the terminal ligands towards the rhenium centers and corresponds to differences in the Re–O_t and Re–O_b bonds lengths.

6. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the depositions numbers: 264637 for $C_{19}H_{22}Br_4N_8O_4Re_2$ and 264638 for $C_{11}H_{14}Br_4N_4O_4Re_2$.

Acknowledgements

The Gaussian03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland under calculational Grant No. 51/96.

The crystallographic part was financed by funds allocated by the Ministry of Scientific Research and Information Technology to the Institute of General and Ecological Chemistry, Technical University of Łódź.

Scheme 1. Hydrolysis reaction of tetracyanoethylene to produce the tricyanoethenolate ligand.

This consideration notwithstanding, there are examples of compounds in which one of the nitrile N atoms are coordinated rather than the O atom [7]. It has also been noted in several instances that the anion is outer-sphere rather than being coordinated to metal centers [4a,4c].

In this paper, we report two new Fe(II) and Co(II) compounds in which the tricyanoethenolate ligand coordinates via two of its three nitrile N atoms which leads to the formation of two-dimensional sheets. Since the study of this derivative of TCNE as a bridging ligand for magnetic materials has not been explored very well, we undertook measurements of the magnetic properties of the layered materials. The results indicate that the metal spins are essentially isolated paramagnets with no evidence of coupling through the tricyanoethenolate bridging ligand.

2. Experimental

2.1. Materials and methods

The tetracyanoethylene (TCNE) ligand was obtained from TCI and purified by sublimation before use. The starting materials $Fe_4Cl_8(THF)_6$ and $Co_4Cl_8(THF)_6$ were prepared according to the literature procedures [8]. All operations were carried out under a N_2 atmosphere using standard Schlenk line techniques. Solvents were distilled prior to use from the appropriate drying agents.

2.2. Synthesis

2.2.1. $\{Fe(C_5N_3O)_2(CH_3CN)_2\}_\infty$ (1)

A mixture of $Fe_4Cl_8(THF)_6$ (0.094 g, 0.10 mmol), TCNE (0.104 g, 0.80 mmol) in acetonitrile (20 mL) was stirred for three days at room temperature to yield a green solution and a tan precipitate. The precipitate was removed by filtration and the filtrate was layered with diethyl ether to yield colorless, diffraction quality crystals in ~13% yield based on the Fe content in the starting material.

2.2.2. $\{Co(C_5N_3O)_2(C_4H_4O)_2\}_\infty$ (2)

A mixture of $Co_4Cl_8(THF)_6$ (0.095 g, 0.10 mmol), TCNE (0.104 g, 0.80 mmol) in tetrahydrofuran (25 mL) was refluxed for two days yielding a light blue solution and a blue precipitate. The precipitate was removed by filtration and the filtrate was layered with hexane to yield large, yellow, X-ray quality crystals in ~5% yield based on the Co content in the starting material.

2.3. X-ray crystallography

Single crystal X-ray intensities were collected on a Bruker SMART CCD area detector diffractometer at 110(2) K for **1** and at 173(2) K for **2**. The frames were integrated with the Bruker SAINT software package [9]. The data were corrected for absorption using SADABS [10] and the structures solved (by direct methods) and refined using X-SEED [11], a graphical interface to the SHELX [12]. Electron density syntheses indicated that the TCNE ion had undergone a decomposition reaction, where one of the nitrile groups had been lost and replaced by an O^- group. At this stage, we were not sure that the atom labeled O1 was an O atom because the C–O bond was shorter and the C–C bond shorter than normal, and an O^- group would seem to be the preferred site for binding to metal cations. The data for (**1**) were used to explore the effect of interchanging O and N atoms for the atom labeled O1 and to establish its identity as oxygen. Refinement as an O atom led to lower values for R_1 (0.028 instead of 0.035 for (**1**)), lower residual electron densities (0.25, −0.22 e Å^3 instead 0.57 and −0.27 for (**1**)) and displacement parameters. Further evidence that this atom is correctly assigned as O was obtained by analyzing the hydrogen bonds accepted by this atom. This atom accepts two hydrogen bonds with an approximate H···O···H angle of 95°. The C–O and central C–C distances (1.218(2) and 1.423(2) Å for **1**) are similar to those of other ethanolate complexes

2.4. Physical measurements

Infrared spectra were measured as Nujol mulls between KBr plates on a Nicolet 740 FT-IR spectrometer. Magnetic susceptibility and magnetization measurements were carried out with a Quantum Design SQUID magnetometer MPMS-XL. DC magnetic measurements were performed with an applied field of 1000 G in the 2–300 K temperature range. The data were corrected for diamagnetic contributions by use of Pascal's constants [13].

3. Results and discussion

3.1. Synthesis and infrared spectra

The reactions of $Fe_4Cl_8(THF)_6$ and $Co_4Cl_8(THF)_6$ with TCNE lead to the formation of crystals of the polymers $\{Fe(C_5N_3O)_2(CH_3CN)_2\}_\infty$ and $\{Fe(C_5N_3O)_2(C_4H_4O)_2\}_\infty$. The exact mechanism of the presence of $[OC(CN)C(CN)_2]^-$ in the products can been ascertained from their IR spectra based on a comparison to the known compounds listed [4a]. The broad and intense bands at 1591 cm^{-1} for (**1**) and 1601 cm^{-1} for (**2**) are due to the C=O stretching vibration [4a], whereas the features at 2240 and 2211 cm^{-1} for (**1**) and 2244 and 2211 cm^{-1} for (**2**) can be attributed to CN stretches.

3.2. Descriptions of the structures

The structures of the title compounds consist of infinite, two-dimensional sheets of $[Fe(C_5N_3O)_2(CH_3CN)_2]$ and $[Co(C_5N_3O)_2(C_4H_4O)_2]$ units with Miller indices [1 0 1] in **1** and [1 0 0] in **2** (Figs. 1 and 3). Both compounds crystallize in the space group $P2_1/n$ with the metal atoms on inversion centers. The 1,2,2-tricyanoe-

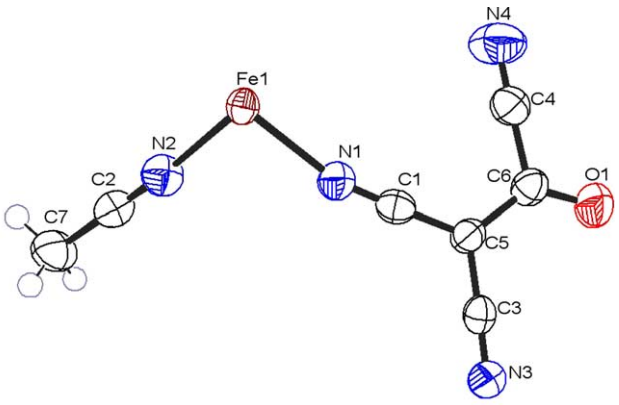

Fig. 1. Thermal ellipsoid plot of the asymmetric unit in$\{Fe(C_5N_3O)_2(CH_3CN)_2\}_\infty$ (**1**) drawn at the 50% probability level.

thenolate ion is bidentate and binds to the metal atoms via two of its three CN groups and not the O atom. The ligands are bound to the Co and Fe ions head-on, i.e., the coordinating CN groups are attached to the same C atom of the central C–C bond (see Fig. 2). Acetonitrile (in **1**) and tetrahydrofuran (in **2**) molecules are coordinated to Fe and Co atoms in the axial positions. The Fe and Co atoms are in nearly ideal octahedral coordination environments. The two independent Fe–N bonds in **1** are slightly different (2.139(2) and 2.142(2) Å). The independent Co–N and Co–O bonds in **2** are also slightly different (2.072(3) and 2.085(3) Å). The C–O bond distances (1.218(2) Å in **1** and 1.226(4) Å in **2**) are shorter than C–O single bond distances, and the C–C distances between atoms C4 and C5 (1.421(2) Å in **1** and 1.423(4) Å) in **2** are also much shorter than C–C single bond distances. The low basicity of the O atom can be attributed delocalization of negative charge. The partial negative charge on this O atom is stabilized since this O in involved in weak hydrogen bonds from methyl hydrogen atoms of coordinated acetonitrile solvent molecules in **1** and from $-CH_2-$ groups of coordinated tetrahydrofuran solvent molecules in **2** (Figs. 3 and 4).

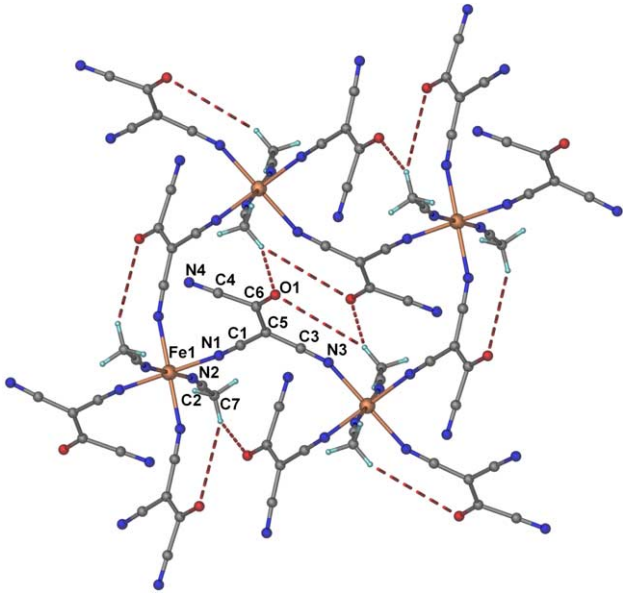

Fig. 2. Packing diagram of compound **1** illustrating the O interactions to methyl hydrogen atoms of coordinated acetonitrile solvent molecules in **1**.

3.3. Magnetic properties of compounds *1* and *2*

Magnetic susceptibility measurements of complexes **1** and **2** were performed on crushed crystals of the compounds. Random crystals from the batches were selected from the samples used for the SQUID and subjected to unit cell determinations. These results are shown in Fig. 5.

The value of χT at 300 K is 3.8 emu mol^{-1} K for compound **1**, which is in good agreement with the expected value for isolated high spin Fe(II) ions ($S = 2$ and $g = 2.25$) in a magnetically dilute sample. The χT

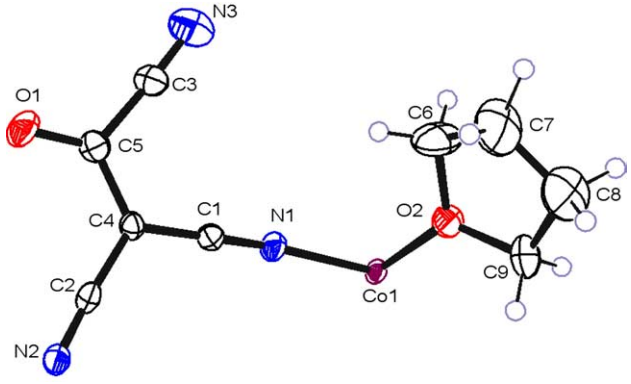

Fig. 3. Thermal ellipsoid plot of the asymmetric unit in $\{Co(C_5N_5O)_2(C_4H_4O)_2\}_\infty$ (**2**) drawn at the 50% probability level.

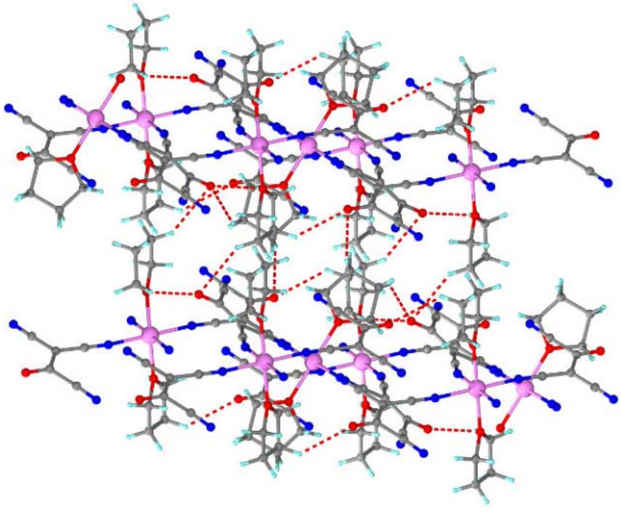

Fig. 4. Packing diagram of compound **2** illustrating the O interactions to hydrogen atoms of coordinated THF solvent molecules in **2**.

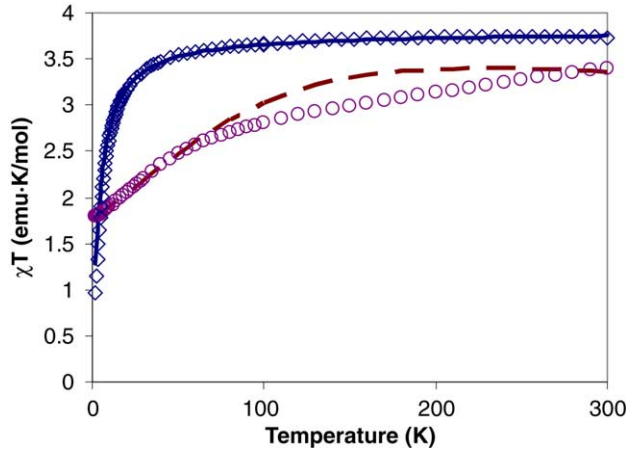

Fig. 5. Plots of $\chi_m T$ vs. T for $[Fe(C_5N_3O)_2(CH_3CN)_2]_\infty$ (**1**) (blue diamond) and $[\{Co(C_5N_3O)_2(C_4H_4O)_2\}_\infty]$ (**2**) (purple circles). The solid line is a fit of the data for (**1**) to the Curie–Weiss law and the dashed line corresponds to the best fit obtained with Eq. (1) for (**2**).

value continuously decreases from room temperature and reaches a value of 1 emu mol^{-1} K at 1.8 K. The temperature dependence of $1/\chi$ between 300 and 2 K approximates Curie–Weiss behavior with $C = 3.8$ emu mol^{-1} K and $\theta = -3.9$ K. The negative sign of the Curie–Weiss constant may indicate antiferromagnetic interactions or zero-field splitting effects.

The value of χT at 300 K is 3.4 emu mol^{-1} K for compound **2**, which is in good agreement with the expected value for isolated high spin Co(II) ions with an orbital contribution ($S = 3/2$ and $g = 2.8$) in a magnetically dilute sample. The χT value continuously decreases from room temperature and reaches a value of 1.8 emu mol^{-1} K at 1.8 K. The temperature dependence of $1/\chi$ between 300 and 50 K approximates Curie–Weiss behavior with $C = 3.8$ emu mol^{-1} K and $\theta = -40$ K. The negative Curie–Weiss constant indicates a dominant spin–orbit coupling effects for Co(II) ion.

The ground state for high-spin octahedral Co(II) is a $^4T_{1g}$, which is subject to unquenched spin–orbit coupling. The Hamiltonian for spin–orbit coupling is written as: $H = -\lambda LS$. The χT expression for a mononuclear Co(II) complex in an octahedral environment is provided in Eq. (1) [11].

$$\chi_{Co}T = \frac{\frac{7(3-A)^2x}{5} + \frac{12(2+A)^2}{25A} + \left\{\frac{2(11-2A)^2x}{45} + \frac{176(2+A)^2}{675A}\right\}x\exp\left(\frac{-5Ax}{2}\right) + \left\{\frac{(5+A)^2x}{9} - \frac{20(2+A)^2}{27A}\right\}\exp(-4Ax)}{\frac{8x}{3}\left\{3 + 2\exp\left(\frac{-5Ax}{2}\right) + \exp(-4Ax)\right\}}. \quad (1)$$

In this equation, $x = \lambda/k_BT$, (λ is the spin–orbit coupling parameter which is -170 cm^{-1} for the free ion) and A is a measure of the crystal field strength due to the inter-electronic repulsions (1.5 for a weak field, 1.0 for a strong field and 1.32 for a free ion). Using Eq. (1), we obtained a fit for the magnetic susceptibility data in the temperature range of 2–300 K with parameters $\lambda = -110$ cm^{-1}, and $A = 1.5$. The fitting is indicative of the usual problems associated with the anisotropy of the Co(II) ion. In both cases, there is no indication that the bridging ligand facilitates superexchange interactions between the metal ions whose closest separations in the compounds are 7.805 Å (Fe···Fe) and 7.441 Å (Co···Co).

4. Conclusions

In this study, two new coordination polymers $\{Fe(C_5N_3O)_2(CH_3CN)_2\}_\infty$ (**1**) and $\{Co(C_5N_3O)_2(C_4H_4O)_2\}_\infty$ (**2**) have been prepared and their structures and magnetic properties have been determined. The two complexes represent rare examples in which the tricyanoethenolate ligand coordinates via two of its three nitrile N atoms which leads to the formation of two-dimensional sheets. Although delocalization of negative charge on the tricyanoethenolate ligand may be expected to facilitate on magnetic exchange interactions, magnetic susceptibility measurements of compounds **1** and **2** indicate that the metal spins are essentially isolated paramagnets with little or no coupling being evident.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with Cambridge Crystallographic Data Center, CCDC Nos. 267178 and 267179 for compounds **1** and **2**, respectively. Copies of this information may be obtained free from the Director, CCDC, 12 Union Road, Cambridge CB2 1EW, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.com.ac.uk).

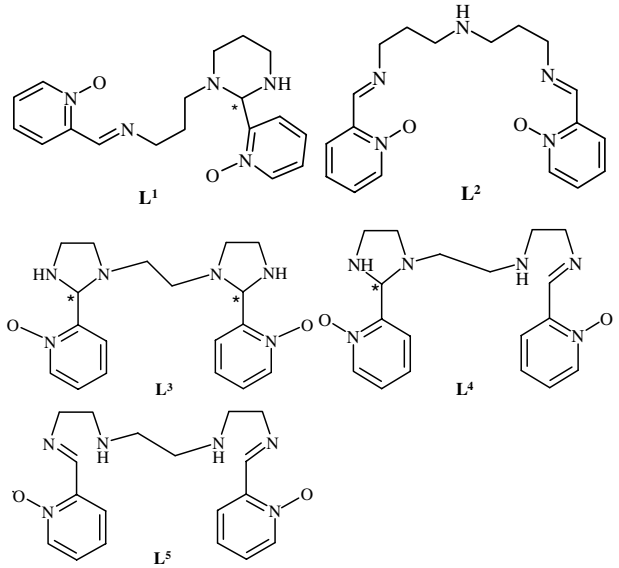

Fig. 1. Two isomers of the condensation product of 2-pyridinecarboxaldehyde N-oxide with dipropylenetriamine ($\mathbf{L^1}$ and $\mathbf{L^2}$) and three isomers of the condensation product of 2-pyridinecarboxaldehyde N-oxide with triethylenetetramine ($\mathbf{L^3}$, $\mathbf{L^4}$ and $\mathbf{L^5}$). *, chiral centre.

of four different complexes of Cu(II), Zn(II) and Fe(III) were reported with all possible isomers $\mathbf{L^3}$, $\mathbf{L^4}$ and $\mathbf{L^5}$ (Fig. 1) of the ligand as condensation product of 2-pyridinecarboxaldehyde N-oxide with triethylenetetramine [6]. In addition, liberation of one pyridine N-oxide fragment is possible during complexation [7] as shown in the system of 2-pyridinecarboxaldehyde N-oxide/diethylenetriamine in excess of copper (II) cations.

In this work, we present the structure of the copper (II) complex with the isomer $\mathbf{L^2}$. The solvatochromism and isomerisation of the ligand from $\mathbf{L^1}$ to $\mathbf{L^2}$ during complexation on copper were also studied in situ by electronic spectra as well as the solvatochromism and isomerisation of the ligand from $\mathbf{L^3}$ to $\mathbf{L^4}$ during complexation on copper in situ.

2. Experimental

Ligand preparation: Preparation of the ligands $\mathbf{L^1}$ and $\mathbf{L^3}$ and their detailed characterisation by ^{1}H and ^{13}C NMR and IR spectra is given elsewhere [1].

Complex preparation: All starting compounds and solvents were used as commercial products (copper perchlorate, acetonitrile, Fluka; ethanol, methanol, DMSO, Mikrochem) of analytical grade without any purification. 2-pyridinecarboxaldehyde-N-oxide was prepared according to the literature [8].

*$[Cu(L^2)](ClO_4)_2$ – complex (**1**)*: A solution of 0.185 g (0.5 mmol) of $Cu(ClO_4)_2 \cdot 6H_2O$ in ethanol (5 cm^3) was slowly added to a solution of 0.171 g (0.5 mmol) of the ligand $\mathbf{L^1}$ in ethanol (15 cm^3) under stirring at room temperature. A green solid immediately precipitated. The additional ethanol (30 cm^3) was added and the mixture was boiled for 30 min. Then the mixture was let to cool spontaneously under stirring for 3 h. The green product was filtered off, washed with ether and air-dried. Yield 0.159 g (53%), m.p. explosive decomposition above 200 °C. *Anal.* Calc. for $C_{18}H_{23}N_5O_{10}Cl_2Cu$ (M = 603.86): C, 35.8; H, 3.84; N, 11.6. Found: C, 35.4; H, 3.42; N, 11.4%. Soluble in acetone, alcohols, DMSO, pyridine, acetonitrile; insoluble in diethylether.

Single crystals of **1** for X-ray analysis were prepared by isothermal recrystallisation from acetonitrile.

*$[CuL^4(ClO_4)](ClO_4)$ – Method 1, complex (**2**)*: Preparation of this complex from the methanolic solutions and its detailed characterisation is given elsewhere [6].

*Method 2, complex **2a***: A solution of 0.185 g (0.5 mmol) of $Cu(ClO_4)_2 \cdot 6H_2O$ in dimethylformamide (3 cm^3) was slowly added to a solution of 0.178 g (0.5 mmol) of the ligand $\mathbf{L^3}$ in dimethylformamide (15 cm^3) under stirring at room temperature. A violet solution was formed. Chloroform (100 cm^3) was slowly added under stirring to precipitate a violet solid product that was filtered off, washed with chloroform and air-dried. Yield 0.186 g (62%).

*Method 3, complex **2b***: A solution of 0.185 g (0.5 mmol) of $Cu(ClO_4)_2 \cdot 6H_2O$ in DMSO (1.5 cm^3) was slowly added to a solution of 0.178 g (0.5 mmol) of the ligand $\mathbf{L^3}$ in DMSO (7.5 cm^3) under stirring at room temperature. A violet solution was formed. Then ether (60 cm^3) was slowly added under stirring to precipitate violet solid product that was filtered off, washed with ether and air-dried. Yield 0.254 g (86%).

*Method 4, complex **2c***: 0.185 g (0.5 mmol) of solid $Cu(ClO_4)_2 \cdot 6H_2O$ and 0.178 g (0.5 mmol) of the solid ligand $\mathbf{L^3}$ were stirred in DMSO (5 cm^3) at room temperature for 1 h. The formed dark violet solution was let to spontaneously evaporate one week. Then a dark violet polycrystalline solid was separated.

Caution! Heating of concentrated solutions of perchlorates can cause an explosion.

Physical measurements: Elemental (C, H, N) analyses were carried out by a commercial Automatic Elemental Analyzer Flash EA 1112 CHNS-O/MAS 200 (Thermo Finnigan).

*Crystal data of complex **1***: A suitable single crystal was mounted on a SMART diffractometer (Bruker-AXS) with a CCD area detector. Graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used for all measurements. The crystal-to-detector distance was 4.40 cm. A hemisphere of data was collected by a combination of three sets of exposures at 294 K. Each set had a different ϕ angle for the crystal, and each exposure took 20 s and covered 0.3° in ω. The data were corrected for polarization and Lorentz effects, and an empirical absorption correction (SADABS) was applied [9]. The cell dimensions were refined with all unique reflections.

Structure determination. The structures were solved by direct methods (SHELXS-86) [10a]. Refinement was carried out with the full-matrix least-squares method based on F^2 (SHELXL-97) [10b] with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were inserted only at non-disordered atoms (see below) in calculated positions and refined riding with the corresponding atom. Due to a disorder in the alkyl chains the C atoms C11, C12, and C14 were refined in two independent positions each with occupancy of 0.5. No H atoms were added at the disordered and adjacent C atoms. The oxygen atoms of the two perchlorate anions were also disordered and were refined each in two positions with occupancy of 0.5 for the O30, O31, O32 and O33 and with an occupancy ratio of 0.8:0.2 for O40, O41, O42 and O43.

X-ray powder pattern of **1** was collected on Stoe Stadi P transmission diffractometer equipped with a curved Ge (1 1 1) monochromator placed in the primary beam and a linear PSD. In order to achieve a better resolution Mo Kα radiation was used. The measured range of 2θ was 3–50° at room temperature.

The X-band EPR spectra of polycrystalline powdered samples **1** and **2** were recorded on a Bruker EMX spectrometer equipped with a variable temperature unit. Line positions were measured accurately using internal field markers generated by an NMR gauss-meter, while the microwave frequency was measured by a microwave frequency counter. 100 kHz magnetic field modulation (peak-to-peak amplitude ≈3 G) was used.

The EPR spectra were simulated on an IBM compatible computer using either program QPOW [11] developed by R.L. Belford (University of Illinois, Urbana) or commercially available program SIMFONIA [12].

IR spectra of the complexes were measured on PU 9800 FTIR (Philips) spectrometer in the nujol suspension at room temperature in the range 4000–400 cm^{-1} with the resolution of 1 cm^{-1} using a mirror velocity of 2.0 mm s^{-1}.

Electron spectra were measured on Specord M 400 (Carl Zeiss) in the range of 350–900 nm in different solutions at room temperature in 1 cm cell. Electron spectra were measured by two methods: In the first case (Method 1) the measured spectra were of solutions prepared by dissolution of the complexes **1** and **2** in different solvents. The solvents and concentrations are summarised in Table 1.

In the second case (Method 2) solutions of the ligand and copper perchlorate were mixed directly in measuring cell and inserted into spectrometer. These operations had to be made as fast as possible. The solvents and concentrations are summarised in Table 1.

Table 1
Solvents and concentrations for ES investigation of the complexes **1** and **2** by dissolution (Method 1) and by preparation "in situ" (Method 2)

Solvent	Concentration (mmol dm^{-3})

Nitromethane	2.1		2.5	

3. Results and discussion

The structure of ***1***: The structure of the complex **1** (crystal data is shown in Table 2) consists of $[CuL^2]^+$ cations and ClO_4^- anions. The copper atom reveals a trigonal bipyramidal coordination by three nitrogen atoms and two oxygens of the two pyridine N-oxide groups of the ligand. Both imine nitrogen atoms (N(9) and N(17)) occupy the axial position while the equatorial plane is formed by the remaining amine nitrogen (N(13)) and by both oxygen atoms from the pyridine N-oxide groups (O(1) and O(25)). The axial N–Cu–N angle of the trigonal pyramid is with 176.60(12)° only slightly distorted and the equatorial plane is also nearly perfect with a maximum deviation of the Cu atom 0.019 Å out of this plane. However the equatorial angles are distorted, while two of them are smaller than the expected 120° (O(1)–Cu(1)–N(13): 115.08(14)°; N(13)–

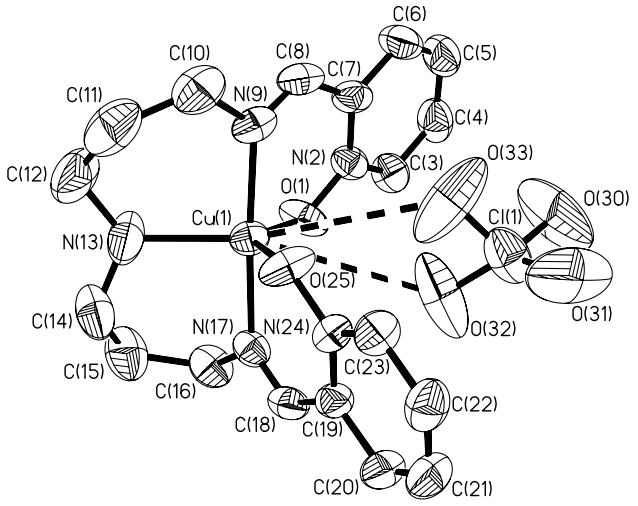

Fig. 2. ORTEP view of $[CuL^2](ClO_4)^+$ fragment (hydrogen atoms are excluded for clarity, thermal ellipsoids of 50% probability level).

Cu(1)–O(25): 110.95(14)°) one is substantially larger (O(1)–Cu(1)–O(25): 133.92(12)°). In the formed gap of the coordination polyhedron a very weak interaction with the oxygen atoms of a perchlorate groups were found (Cu(1)–O(32): 3.442(1) Å and at Cu(1)–O(33): 3.495(1) Å) (Fig. 2). These distances are too long even for a semi-coordination description of this interaction, which is different from those of our previous works [6,7] where the ligands were coordinated to the central metal atom through all donor atoms and the coordination sphere was completed by oxygen atom from perchlorate group at longer distance (2.689, 2.819 Å, respectively) forming distorted octahedra with coordination 4 + 1 + 1.

The double bonds within Schiff-bases are as short as N(17)–C(18) = 1.264(4) Å and C(8)–N(9) = 1.266(5) Å. These distances are almost the same as those in the previously described compounds [6,7]. Selected bond lengths and angles are presented in Table 3.

Table 3
Selected bond lengths (Å) and angles (°) for **1**

Bond length (Å)		Bond angles (°)	
Cu(1)–N(17)	1.953(3)	N(17)–Cu(1)–N(9)	176.60(12)
Cu(1)–N(13)	2.100(3)	N(17)–Cu(1)–O(1)	88.82(10)
Cu(1)–N(9)	1.953(3)	N(9)–Cu(1)–O(1)	89.49(11)
Cu(1)–O(25)	2.021(2)	N(17)–Cu(1)–O(25)	88.97(10)
Cu(1)–O(1)	2.010(2)	N(9)–Cu(1)–O(25)	90.07(10)
N(17)–C(18)	1.264(4)	O(1)–Cu(1)–O(25)	133.92(12)
C(8)–N(9)	1.266(5)	N(17)–Cu(1)–N(13)	90.31(13)
O(1)–N(2)	1.326(3)	N(9)–Cu(1)–N(13)	93.08(14)
N(24)–O(25)	1.327(3)	O(1)–Cu(1)–N(13)	115.08(14)
Cu(1)–O(32)	3.442(1)	O(25)–Cu(1)–N(13)	110.95(14)
Cu(1)–O(33)	3.495(1)		

Because of a disorder of the C-atoms of the alkyl chain C(11), C(12), and C(14) no hydrogen atoms were added at the disordered and adjacent carbon atoms. Consequently, no hydrogen atom was found for N(13) even though it is highly expected, because there is no reason for N(13) to be imine nitrogen instead of amine one. Furthermore, if N(13) would be an imine nitrogen then the ligand would have a negative charge and there is no indication in the structure for a possible compensation. The packing of the structure in the unit cell is shown in Fig. 3.

*X-ray powder patterns of **1***: In order to check whether a powdered sample of **1** is the same compound as solved from single crystals the powder pattern was recorded. Powder diffraction pattern of **1** was successfully indexed by Stoe WINXPOW 1.2 program using Louër's routine [13,14] using the first 21 diffraction lines. Obtained ' 90.70°) are close to the cell parameters from single crystal. Thus it was concluded that the complex **1** has the identical structure as powder (prepared by fast precipitation

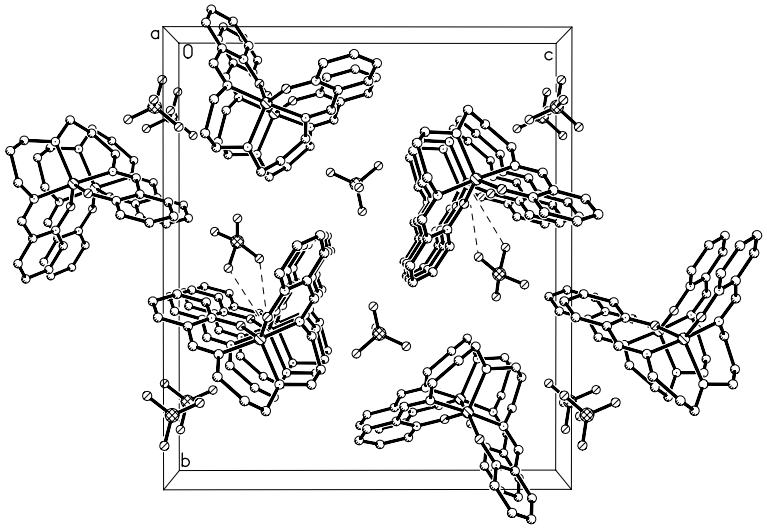

Fig. 3. The packing of the structure in the unit cell.

from ethanol) and single crystal (slowly grown from acetonitrile solution).

EPR spectra of the complexes: The EPR spectrum of **1** measured in polycrystalline form is shown in Fig. 4. The EPR data , $g_\perp = 2.241$ and $g_\parallel = 1.998$, are typical for the copper (II) complexes in distorted trigonal-bipyramidal (TBP) crystal field symmetry (exhibiting d_{z^2} ground state), in agreement with the conclusions from X-ray measurements. The EPR spectrum of **2** (Fig. 4) exhibits also d_{z^2} ground electronic state of the copper (II) ion, however with shifted perpendicular band towards higher magnetic field. Computer simulation of the EPR spectrum of **2** provided following EPR data: $g_\perp = 2.139$ and $g_\parallel = 2.065$.

In the case of the compressed configuration of the coordination polyhedron of $[CuL^2]^{2+}$ (or $[CuL^2(ClO_4)]^{+}$) fragment, the perpendicular and parallel components of the axially symmetrical *g*-tensor can be described, in the crystal field theory approximation, by the equations

$$g_\perp = 2.0023 + 6\lambda/\Delta E(a_1' \rightarrow e''), \quad g_\parallel = 2.0023 \tag{1}$$

where λ is the spin–orbital interaction constant of the Cu(II) ion. From Eq. (1) is clear that for a compressed TBP structure computer simulation provides $g_\perp > g_\parallel \sim 2.0023$. The relation $g_\perp > g_\parallel \sim 2.0023$ holds for the EPR spectra of both compounds under study.

In the elongated TBP configuration of the Cu(II) ion, the ground electronic state is the doubly degenerated e' state. According to the Jahn-Teller theorem [15], this orbital degeneracy of the ground state must be removed. Thus, any distortion leads to a new electronic state, either $d_{x^2-y^2}$ or d_{xy}. The compressed TBP configuration for **1** points to the ground electronic state of the copper. This is consistent with the parameters of the EPR spectra obtained, which satisfy the relation $g_\perp > g_\parallel \sim 2.0023$. Generally, five coordinated complexes can adopt either trigonal–bipyramidal geometry (TBP, D_{3h}), or square–pyramidal geometry (SP, C_{4v}), or intermediate geometry (C_{2v} symmetry). The X-ray data for the complex **1** revealed, that the chromophore $\{CuN_3O_2\}$ of this complex adopts slightly distorted trigonal bi-pyramid geometry, thus based also on EPR data, no exact point group symmetry was assigned to the complex **1** (see also below).

In our previous paper [7], we studied copper complexes with the Schiff base mono- and bis-condensation products of 2-pyridinecarboxaldehyde-N-oxide with diethylenetriamine (triamine of ethylene bridges). From the point of view of EPR spectroscopy all of these complexes exhibit $d_{x^2-y^2}$ ground state of copper (II). On the contrary, copper complexes of 2-pyridinecarboxaldehyde N-oxide with triamine of propylene bridges (complex **1**) or tetramine of ethylene bridges (complex **2**), presented in this work, exhibit relatively rare, d_{z^2} ground electronic state of copper.

Infrared spectra of 1: According to infrared spectra, we can suggest the presence of some structural segments. Valence vibrations of N–H of the secondary cyclic amines can be observed in the range of 3380–3205 cm^{-1}. The range of valence vibrations of N–H of secondary aliphatic amines is quite narrow around 3330 cm^{-1} [16]. According to infrared spectra, the form $\mathbf{L^1}$ in the pure ligand is expected. The characteristic IR vibrations of the ligand $\mathbf{L^1}$ are the following: $\nu_{\nu(N-H)} = 3260\ cm^{-1}$ (strong), $\nu_{\delta(N-H)} = 1566\ cm^{-1}$ (weak), $\nu_{\nu(N-O)} = 1234\ cm^{-1}$ (strong), $\nu_{\delta(C=N)} = 1634\ cm^{-1}$ (strong).

The characteristic IR vibrations of the complex **1** are the following: $\nu_{\nu(N-H)} = 3252\ cm^{-1}$ (medium), $\nu_{\delta(N-H)} = 1563\ cm^{-1}$ (medium), $\nu_{\nu(N-O)} = 1203\ cm^{-1}$ (strong), $\nu_{\nu(C=N)} = 1658\ cm^{-1}$ (strong), $\nu_3(ClO_4) = 1087\ cm^{-1}$

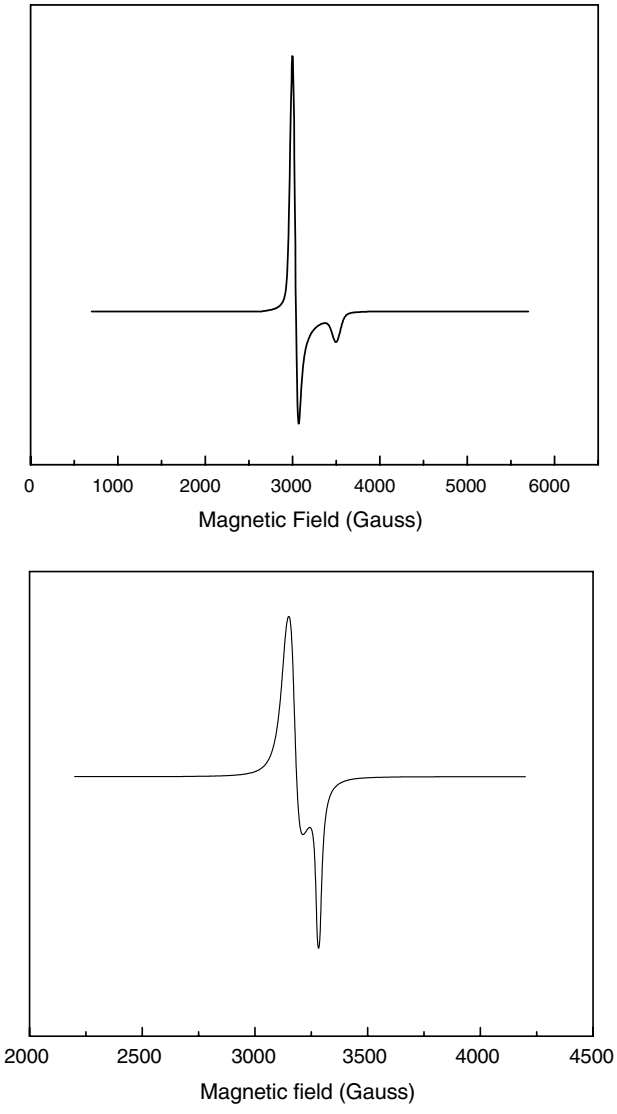

Fig. 4. The EPR spectrum of **1** and **2** in polycrystalline form.

(strong, broad), $v_4(ClO_4) = 622\ cm^{-1}$ (strong), vibrations at 432 cm^{-1} (weak) and 455 cm^{-1} (weak) (and expected below 400 cm^{-1}; out of our measuring limit) can be attributed to M–O and M–N, vibrations.

Generally, after coordination the position of some vibrations would change. Thus in the case of the complexes it is difficult to distinguish between different isomers based only on N–H vibrations. The position of $v_{\nu(N-H)} = 3252\ cm^{-1}$ is far from the range for secondary aliphatic amines and thus the formation of secondary cyclic amines would be expected in contradiction to the structure determination.

As can be seen, the positions of valence C=N vibration of the imino- group in the complex **1** has shifted to higher energies and the valence N–O vibration has shifted to lower energies in comparison with the pure ligand. Both vibrations are sensitive to the coordination of the ligand to metal atom. The relatively high wave number of C=N vibration was also observed in other copper complexes [6,7,17]. It is probably due to coordination properties of the ligand.

Vibrations v_3 of perchlorate groups are relatively broad with gentle structure. This indicates observed distortion of perchlorate groups. The presence of hydrogen bonding network cannot be excluded as well.

IR spectra of the complexes ***2***, ***2a–c***: (Detailed assignment of vibrations of the complex **2** is given elsewhere [6]. The presence of two N–H valence vibrations in the powdered samples indicates the presence of both secondary cyclic and secondary aliphatic amine groups. Thus the powdered sample is the same as in the single crystal.) These complexes were prepared in order to obtain the copper complexes with the ligand in a different isomeric form. However, the IR spectra of all four complexes are perfectly identical without any contribution from solvents. One could expect that in the case of DMF or DMSO the ligand in the isomeric form $\mathbf{L^3}$ should be present as was observed in the zinc complex [6]. It was explained that the donor number of DMSO is so strong that it occupies two coordination places of zinc atom and the ligand remaining four ones, thus forming the isomer $\mathbf{L^3}$ instead of $\mathbf{L^5}$ when the complex was prepared from methanol. Furthermore the high hardness of the central atom M (which serves for a measure of the Lewis acidity), may lead to a preference for the [ML^5] complex with the hexadentate ligand $\mathbf{L^5}$. Thus, the presence of the ligand in the form $\mathbf{L^4}$ in the copper complex prepared from DMSO seems to be in contradiction with expectation. We may try an explanation by the rule "similar likes similar". If zinc is a very strong (hard) acid (in terms of Pearson's theory) it will attract a strong base like DMSO. The copper is a soft (or middle) acid and does not prefer to interact with strong bases like DMSO. The result is the formation of the same copper complexes from different solvents. The isomeric form $\mathbf{L^4}$ is then the result of the competition between acidity of a central atom and acidity of the –C=N– site [6]. Methanol, on the other hand, is more acidic than basic and it will therefore not interact with the copper atom and instead the oxygen atom from perchlorate will do.

Electron spectra: For the d^9 complexes the free-atom ground ^2D term splits to the ^2E_g and $^2T_{2g}$ terms in the octahedral symmetry (or to $^2T_2$ and ^2E terms in tetrahedral symmetry). Here only one transition could be observed. These terms may undergo further splitting to A, B and eventually E type terms by lowering the symmetry. The final number of terms and their order thus depends on the degree of distortion. For D_{4h} and D_{3d} symmetries one should expect three transitions and in all other lower symmetries four transitions should be observed. But the energy levels may lie too close to each other so that two different transitions will not be observed separately. Taking into consideration the nature of the ligand it should be clear that all formed complexes probably will have highly asymmetric coordination spheres. Moreover, d–d transitions are forbidden by selection rules and thus they are very weak and difficult or impossible to observe.

Electron spectra of the complex ***1***: The electron spectra of the complex **1** in different solutions (see Section 2 – Method 1) are shown in Fig. 5. In fact the d–d transitions were observed in the range of 470–640 nm. Based on the arguments given above we are not able to estimate the coordination sphere of the copper centres based on electron spectra alone. From structural results the coordination polyhedron does not exhibit any symmetry (C_1).

Two separated bands can be observed in all spectra, except ethylenediamine solution. Generally, the band at higher energies (lower wave lengths) is only present as shoulders and bands at lower energies are observed either as real band with maximum or as shoulder as well. In ethylenediamine solution only one band was observed

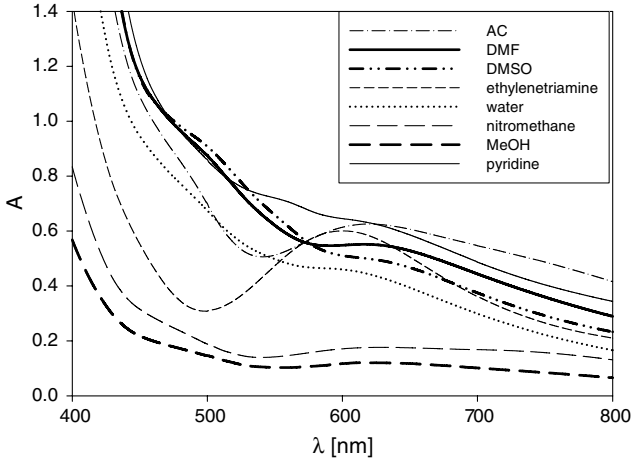

Fig. 5. Electron spectra of the complex **1** in different solvents.

because the complex may decompose. The data are summarized in Table 4.

Relatively vivid solvatochromic effect was observed. The directly observed bands both λ^1_{max} and λ^2_{max} were correlated with solvent properties. The parameters like acceptor number, donor number [18], dielectric constants and dipole momentum were investigated. But, no reasonable dependence was observed. As the solvents used are chemically fairly different we classified them into four groups with similar properties (DMF and DMSO; AC and nitromethane; water and methanol; ethylenediamine and pyridine). Similar trends can be found in all investigated parameters; acceptor number, donor number, dielectric constant and dipole momentum correlations.

Also electron spectra "in situ" in different solutions were measured (see Section 2 – Method 2). "In situ" means a period of less then 30 s between the replacing of the mixed solutions into the spectrometer and launching the measurement. The zero on the time axis in the following figures denotes the starting time. The complexation reactions start 20–30 s earlier.

In the case of water (Fig. 6), methanol (Fig. 7) and DMSO logarithmic shape of the absorbance dependency on time for observed λ_{max} was found. During this time probably isomerisation reaction of the ligand from the form $\mathbf{L^1}$ to $\mathbf{L^2}$ takes place.

In the case of AC and DMF solutions completely different shape of absorbance dependence on time was found (Fig. 8). Gradual decrease of the absorbance was observed. If we assign this evolution also to the isomerisation reaction the mechanism in AC and DMF solutions is different from that in water, methanol and DMSO solutions.

Electron spectra of the complex **2**: The electron spectra of the complex **2** in different solutions (see Section 2 – Method 1) are shown in Fig. 9. In fact the d–d transitions were observed in the range of 500–620 nm. No symmetry of the coordination polyhedron can be expected as in the complex **1**.

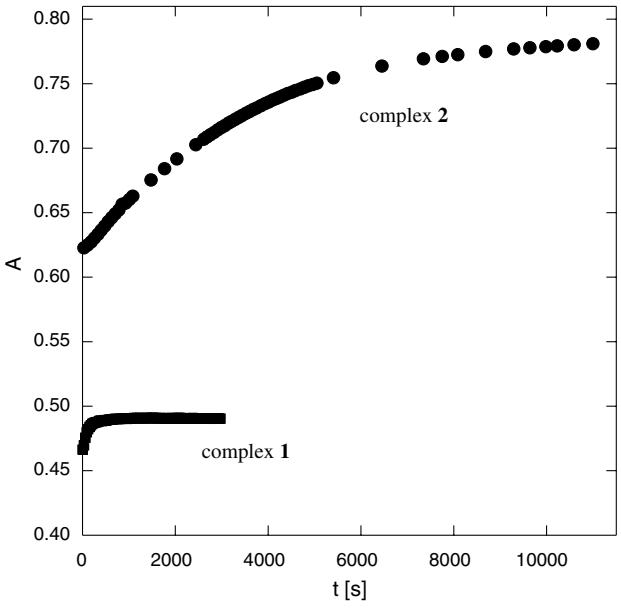

Fig. 6. Time dependence of absorbance in water "in situ" solution at $\lambda^1_{max} = 590$ for **1** and at $\lambda^1_{max} = 576$/nm for **2**.

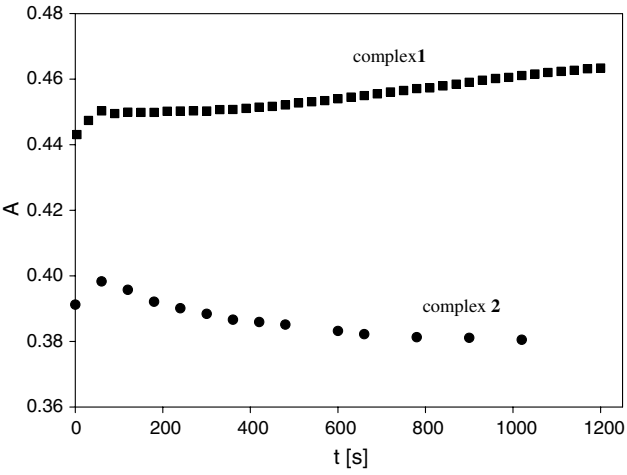

Fig. 7. Time dependence of absorbance in methanol "in situ" solution at $\lambda^1_{max} = 620$ for **1** and at $\lambda^1_{max} = 562$ for **2**.

Table 4
Solvents and values of λ_{max} of d–d transitions of the complexes **1** and **2**

Solvent	Complex **1**		Complex **2**		
	λ^1_{max} [nm]	λ^2_{max} [nm]	λ^1_{max} (λ^1_{calc}) [nm]	λ^2_{max} (λ^2_{calc}) [nm]	R
Water	590	479	576 (603)	–(542)	0.9999
DMSO	613	488	560 (599)	510 sh (518)	0.9991
DMF	615	489	557 (585)	510 sh (502)	0.9995
Acetonitrile	620	475	578 (591)	500 (488)	0.9987
Nitromethane	633	476	592 (589)	505 (484)	0.9987
Methanol	620	474	562 (612)	–(524)	0.9988
Ethylenediamine	600		606		
Pyridine	602	545	616		

In brackets are the values of λ obtained by deconvolution of the bands into two peaks, R is discrepancy factor.
sh, shoulder.

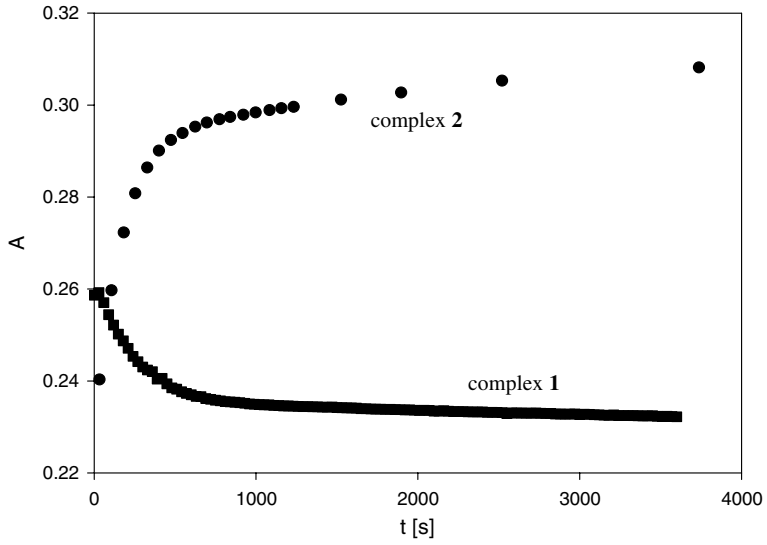

Fig. 8. Time dependence of absorbance in DMF "in situ" solution at $\lambda^1_{max} = 615$ for **1** and at $\lambda^1_{max} = 557$ nm for **2**.

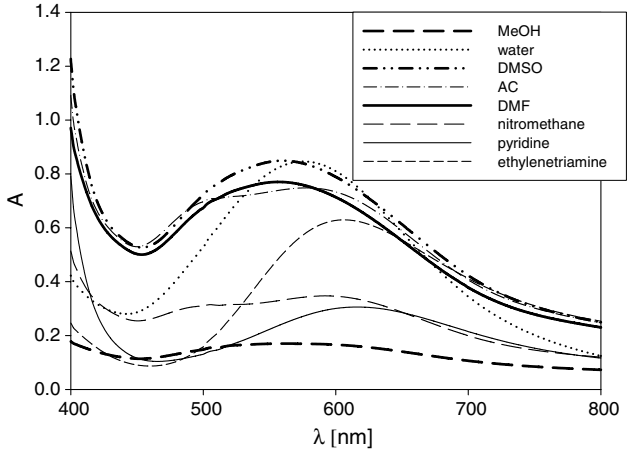

Fig. 9. Electron spectra of the complex **2** in different solvents.

In nitromethane and acetonitrile two well-separated bands are observed. In water, methanol, DMSO and DMF only one band seems to be present. It implies to the idea that these one-band spectra are probably composed from two badly resolved bands. Consequently, the deconvolution method was used to obtain two bands positions. The data are summarized in Table 4 together with bands obtained by direct observation of the spectra.

In the case of pyridine and ethylenediamine the situation is quite different. The bands are centred at considerably lower energies (higher wave lengths). Further, the complexes can decompose in these solvents to form $[Cu(en)_3]^{2+}$ and $[Cu(py)_6]^{2+}$ complex cations with higher symmetry, thus the deconvolution was omitted. The decomposition of the complex **2** can be supported by the observation when complex $Cu_2(DAP)Cl_4 \cdot 2H_2O$ (DAP = condensation product of 2-pyridinecarboxaldehyde N-oxide with diethylenetriamine) [7] was recrystallised from pyridine providing the complex $[CuCl_2(py)_2]$. The presence of only one band in the ethylenediamine solution in the complex **1** at very similar position as in the complex **2** supports the decomposition of both complexes.

We can conclude that solvatochromic effect was observed, similarly as in the complex **1**. We tried to find a similar correlation between solvents properties and the position of the transition bands maxima. Two different analyses were performed. In the first case the directly observed bands λ^1_{max} were correlated with solvent properties, in the second case both bands obtained from deconvolution calculations were correlated. We obtained similar results as in the complex **1**. No apparent dependence was observed, for the same reasons as above. However, when the observed band maxima λ^1_{max} and the λ^1_{calc} were used for correlation, we could conclude that the similar solvents were placed to each other. Again four groups of solvents can be suggested (DMF and DMSO; AC and nitromethane; water and methanol; ethylenediamine and pyridine). Similar trends can be found in all investigated parameters; acceptor number, donor number, dielectric constant and dipole momentum correlations.

With the comparison of the complex **1** the two bands are closer to each other. It means that energy difference between these two sets of transitions is lower in the case of the complex **2**.

Also electron spectra "in situ" in different solutions were measured (see Section 2 – Method 2). In water (Fig. 6), DMF (Fig. 8) and DMSO logarithmic shape of the absorbance dependency on time for observed λ_{max} was found. During this time probably an isomerisation reaction of the ligand from the form $\mathbf{L^3}$ to $\mathbf{L^4}$ takes place. In the case of water, the maximum of the absorbance seems not to be reached after two hours. This

may be due to a decomposition of the ligand in water. The isothermal recrystallisation of the complex **2** from water led to the $[Cu(pyc)_2]\cdot 2H_2O$ complex (pycH = pyridine-2-carboxylic acid) [19].

In methanolic solution completely different shape, gradual decrease of absorbance dependence on time, was found (Fig. 7). If we assign this evolution also to the isomerisation reaction then the mechanism in methanol solutions is different than in water, DMF and DMSO solutions.

The time evolution of absorbances of the complexes **1** and **2** for DMSO and water solutions exhibits logarithm dependence. Surprisingly, the absorbance evolutions of the complexes **1** and **2** are opposite to each other in the DMF solutions (exponential for **1** and logarithm for **2**) and methanol (logarithm for **1** and exponential for **2**) as well.

4. Conclusions

By single crystal analysis the structure of the complex **1** was solved. In the structure, the ligand exists in the form of aliphatic polyamine containing two Schiff bases in contrary to the free form of the ligand with one pyrimidine ring and one Schiff base. No hydrogen bonds were identified.

X-ray powder analysis demonstrated identical structures for fast precipitated and slowly crystallised forms of the complex **1**.

By EPR spectra measured in polycrystalline form it was concluded distorted trigonal-bipyramidal (TBP) geometry for the complex **1** and d_{x^2} ground electronic state of copper (II) for both complexes **1** and **2**.

IR spectra confirmed the identity of fast precipitated and slowly crystallised forms of the complex **2**. Preparation of the complexes in different solvents and by template method result in the formation of the complexes with the same isomer form of the ligand.

By ES spectra vivid solvatochromic effect was observed for both complexes **1** and **2**. It was suggested that similar solvents cause similar equilibrium in the system. From time dependent measurement of absorbances it can be suggested that at least two different ways of isomerisation of the ligand during complexation exist.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 265970 for **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: 44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

synthesis of asymmetrically dibridged dicopper(II) complexes using *p*-hydroxycinnamic acid as the carboxylate. The Schiff base H_3L with two acetylacetoneimine moieties is similar to H_3L' that has two salicylaldimine groups. Herein, we report the synthesis, crystal structure and the magnetic properties of the complexes $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)(MeOH)]\cdot MeOH$ (**1**·MeOH) and $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)]\cdot H_2O$ (**2**·H_2O). The significant observation of this study is the crystal structures of the complexes showing formation of different types of supramolecular structures. The complex **2**·H_2O forms a helical structure through intermolecular hydrogen bonding interactions involving only the carboxylate ligands. The lattice water is non-covalently bound to the Schiff base of the dinuclear unit and does not take part in the supramolecular structure formation.

2. Experimental

2.1. Materials and measurements

All reagents and chemicals were purchased from commercial sources and used as received. The solvents were purified following reported procedures [13]. The Schiff base *N*,*N*′-1,3-diyl-bis(acetylacetoneimine)propan-2-ol (H_3L) and the dicopper(II) precursor complex, $[Cu_2L(O_2CMe)]$ were prepared by literature methods [14]. The elemental analysis was done using a Thermo Finnigan FLASH EA 1112 CHN analyzer. The electronic and infrared spectral data were obtained from Lambda 55 and Perkin–Elmer Spectrum One FT-IR spectrometers, respectively. Variable temperature magnetic susceptibility data for the polycrystalline samples were obtained in the temperature range 18–300 K using a Model 300 Lewis-coil-force magnetometer of George Associates Inc. (Berkeley, USA) make equipped with a Cahn balance and a closed cycle cryostat (Air products). $Hg[Co(NCS)_4]$ was used as a standard. Experimental susceptibility data were corrected for diamagnetic contributions and temperature independent paramagnetism ($N_\alpha = 60\times10^{-6}$ cm^3 M^{-1} per copper). The molar magnetic susceptibilities were fitted to the modified Bleany–Bowers expression by means of a least-squares computer program [15,16]. The Hamiltonian and susceptibility equation used are: $\hat{\boldsymbol{H}} = -2J(\hat{\boldsymbol{S}}_1\cdot\hat{\boldsymbol{S}}_2)$ ($\boldsymbol{S}_1 = \boldsymbol{S}_2 = 1/2$ for a d^9–d^9 dicopper(II) core) and $\chi_{Cu} = [Ng^2\beta^2/k(T-\theta)][3+\exp(-2J/k(T-\theta))]^{-1}(1-\rho) + (Ng_1^2\beta^2/4kT)\rho + N_\alpha$, where ρ is the fraction of monomeric impurity and $2J$ is the singlet–triplet separation energy. The magnetic moments were calculated in μ_B unit. TGA measurements were made using a Mettler Toledo Star thermal analyzer.

2.2. Preparation of $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)(MeOH)]$ (**1**)

Complex $[Cu_2L(O_2CMe)]$ (0.15 g, 0.33 mmol) in MeOH (10 mL) was reacted with the sodium salt of *p*-hydroxycinnamic acid, prepared in situ by reacting the carboxylic acid (0.056 g, 0.33 mmol) with NaOH (0.013 g, 0.33 mmol) in methanol (5 mL), and the reaction mixture was refluxed for 30 min, followed by cooling to an ambient temperature. The solution was filtered and the filtrate on slow evaporation gave the green product in ~70% yield. Single crystals of composition **1**·MeOH, suitable for X-ray diffraction, were obtained from the mother liquor. *Anal.* Calc. for $C_{23}H_{30}N_2O_7Cu_2$ (**1**): C, 48.24; H, 5.10; N, 4.89. Found: C, 48.02; H, 5.24; N, 5.13%. Electronic spectral data in DMSO [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 632 (350), 315 (126000), 290 (109000). FT-IR (KBr phase), cm^{-1}: 3400br, 2920w, 1612s, 1508s, 1400s, 1272s, 1169m, 1013m, 942m, 833m, 701m (br, broad; s, strong; m, medium; w, weak). Magnetic moment (μ_{eff}) per copper in the dimeric unit: 1.63 μ_B at 300 K; 0.17 μ_B at 18 K; $2J = -160$ cm^{-1} from the theoretical fitting with $g = 2.13$, $\rho = 0.004$, $g_1 = 2.2$, $R = 8.5\times10^{-3}$.

2.3. Preparation of $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)]$ (**2**)

The dimeric precursor $[Cu_2L(O_2CMe)]$ (0.22 g, 0.49 mmol) in 1-propanol (20 mL) was reacted with the sodium salt of *p*-hydroxycinnamic acid, prepared in situ by reacting the carboxylic acid (0.082 g, 0.49 mmol) with NaOH (0.019 g, 0.47 mmol) in 1-propanol (10 mL) and the reaction mixture was refluxed for 30 min, followed by cooling to room temperature. The solution was filtered and the filtrate on slow evaporation gave the green product in ~65% yield. *Anal.* Calc. for $C_{22}H_{28}N_2O_7Cu_2$ (**2**): C, 47.22; H, 5.04; N, 5.00. Found: C, 47.29; H, 5.08; N, 5.12%. Electronic spectral data in DMSO [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 630 (320), 315 (132000), 285 (100000). FT-IR (KBr phase, cm^{-1}): 3510br, 3001w, 1640s, 1606s, 1550s, 1514s, 1397s, 1281s, 1250s, 1162s, 1015m, 986m, 831s, 761m, 712m. Magnetic moment (μ_{eff}) per copper: 1.67 μ_B at 300 K; 0.17 μ_B at 18 K; $2J = -132$ cm^{-1} from the theoretical fitting with $g = 2.07$, $\rho = 0.005$, $g_1 = 2.14$, $R = 2.8\times10^{-2}$. Single crystals of **2**·H_2O were obtained on slow evaporation of the mother liquor in the presence of a trace quantity of water.

2.4. X-ray crystallographic studies

Single crystals of the complexes $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)(MeOH)]\cdot MeOH$ (**1**·MeOH) and $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)]\cdot H_2O$ (**2**·H_2O) of the respective sizes $0.49\times0.21\times0.13$ and

$0.26 \times 0.18 \times 0.11$ mm^3 were mounted on glass fibers with epoxy cement. All geometric and intensity data were collected using a Bruker SMART APEX CCD diffractometer having a fine focus 1.75 kW sealed tube Mo Kα X-ray source with increasing ω (width of 0.3° per frame) at a scan speed of 5 s/frame for **1**·MeOH and 12 s/frame for **2**·H_2O. A total of 20 555 reflections were collected for **1** in the range $1.47 \leqslant \theta \leqslant 27.18°$ of which 4356 reflections with $I \geqslant 2\sigma(I)$ were used for structure solution using 361 parameters. For **2**·H_2O, a total of 16 283 reflections were collected in the range $2.0 \leqslant \theta \leqslant 24.71°$, of which 3457 reflections with $I \geqslant 2\sigma(I)$ were used for structure solution using 310 parameters. The hydrogen atoms attached to the carbon atoms, except two methanol molecules in **1**·MeOH, were fixed in their calculated positions and refined using a riding model for both the structures. The hydrogen atoms of the copper-bound and lattice methanol molecules were located in the difference Fourier maps and were refined isotropically. In both the structures, the hydrogen atom of the *p*-hydroxy group was located in the difference Fourier map and was refined isotropically. The hydrogen atoms of the lattice water in **2**·H_2O were also located from the difference Fourier map and blocked after refining for the last few cycles to lower the shift/e.s.d. values. All the non-hydrogen atoms in the structures were refined anisotropically. The structure solution and refinement were made using the SHELX system of programs [17]. The perspective views of the molecules were obtained by ORTEP [18]. Selected crystallographic data are given in Table 1.

Table 1
Crystallographic data for [$Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4$-*p*-OH)(MeOH)]·MeOH (**1**·MeOH) and [$Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4$-*p*-OH)]·$H_2O$ (**2**·H_2O)

3. Results and discussion

3.1. Synthesis and general aspects

Dicopper(II) complexes **1** and **2** are prepared in good yield by substituting the acetate of the precursor complex [$Cu_2L(O_2CMe)$] having a pentadentate trianionic Schiff base *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis-(acetylacetoneimine) (H_3L) by the carboxylate ligand, HO-*p*-$C_6H_4{-}CH{=}CH{-}CO_2^-$ in methanol or propanol solvent. We have prepared the complex from two different solvents with an objective to isolate supramolecular host structures stabilized by different lattice guest molecules (Scheme 1). The choice of propanol as a reaction medium is to isolate a complex with lattice water molecule(s) as propanol is less likely to support a supramolecular structure by hydrogen bonding interactions. The complexes are characterized from the analytical and spectral data. They are crystallized as [$Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4$-*p*-OH)(MeOH)]·MeOH (**1**·MeOH) and [$Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4$-*p*-OH)]·$H_2O$ (**2**·H_2O) and are structurally characterized by single crystal X-ray crystallography. The complexes are soluble in polar organic solvents and display a d–d band in the electronic spectra at ~630 nm in DMSO.

3.2. Crystal structures

Both the complexes crystallize in the centrosymmetric monoclinic space group $P2_1/n$ with four dicopper units in the unit cell, having alternating chains of opposite helical chirality in the crystal. Selected bond distance and bond angle data are given in Table 2. The crystal structure of **1**·MeOH shows the presence of a dicopper(II) complex with a (μ-alkoxo)(μ-carboxylate)-dicopper(II) core in which the Cu(1) atom has a square

Scheme 1. Synthetic scheme for the complexes **1** and **2**.

planar $CuNO_3$ coordination geometry and the Cu(2) atom has a square pyramidal (4 + 1) coordination geometry, giving a Cu···Cu distance of 3.504(1) Å (Fig. 1). The Schiff base ligand displays a pentadentate mode of coordination with the alkoxo oxygen atom bridging the copper centers. The Cu(2) atom is bonded to a methanol ligand at the elongated axial site. The basal planes at the metal centers are nearly coplanar, forming an angle of 10.1(1)°. The —CH=CHC_6H_4— moiety of the *p*-hydroxycinnamate in **1**·MeOH is nearly planar giving an angle of 7.3(3)° between the planes having the $^-$OOC—CH=CH— group and the aromatic C_6H_4 ring. The cinnamate ligand forms an angle of 5.1(1)° with the coordination plane of the $\{Cu_2L\}^+$ moiety. The complex self assembles into a supramolecular structure through hydrogen bonding interactions (Fig. 2). There are two types of intermolecular hydrogen bonding interactions observed in this crystal structure. The copper-bound methanol ligand is involved in the hydrogen bonding interactions with the terminal Schiff base oxygen forming a non-covalently bound "tetrameric" unit [Fig. 2(a); O(7)···O(1)#1, 2.969(5) Å; O(7)–H(25)··· O(1)#1, 162.0°; #1: $-x+1, -y+1, -z+2$]. The other hydrogen-bonding network forms a supramolecular structure involving the lattice methanol molecule, the pendant hydroxy group of the carboxylate and the terminal oxygen atom of the Schiff base (Fig. 2(b)). The O(6)···O(8) and O(8)···O(3)#2 distances are 2.709(6) and 2.812(6) Å, respectively (#2: $-x+1/2+1, -y+1/2, -z+1/2+1$). The hydrogen bonds are nearly linear as evidenced from the O(6)–H(6)···O(8) and O(8)–H(26)···O(3)#2 angles of 167.5° and 163.8°, respectively.

The crystal structure of **2**·H_2O has a (μ-alkoxo)(μ-carboxylate)dicopper(II) core formed by the pentadentate Schiff base (L) and the bridging carboxylate. The copper centers have a square planar $CuNO_3$

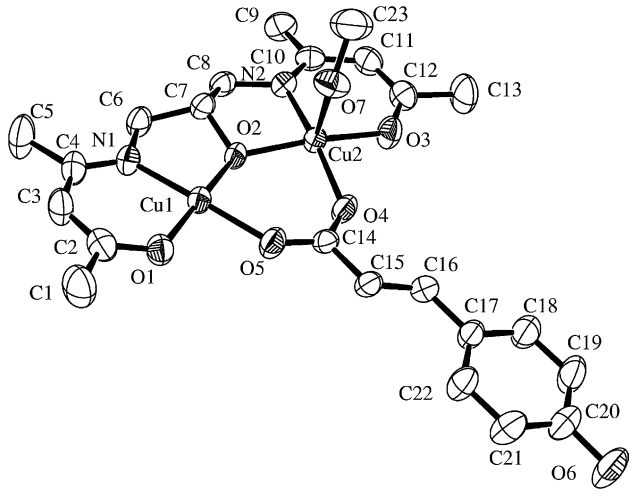

Fig. 1. ORTEP view of the complex [$Cu_2L(O_2C$—CH=CH—C_6H_4-*p*-OH)(MeOH)]·MeOH (**1**·MeOH).

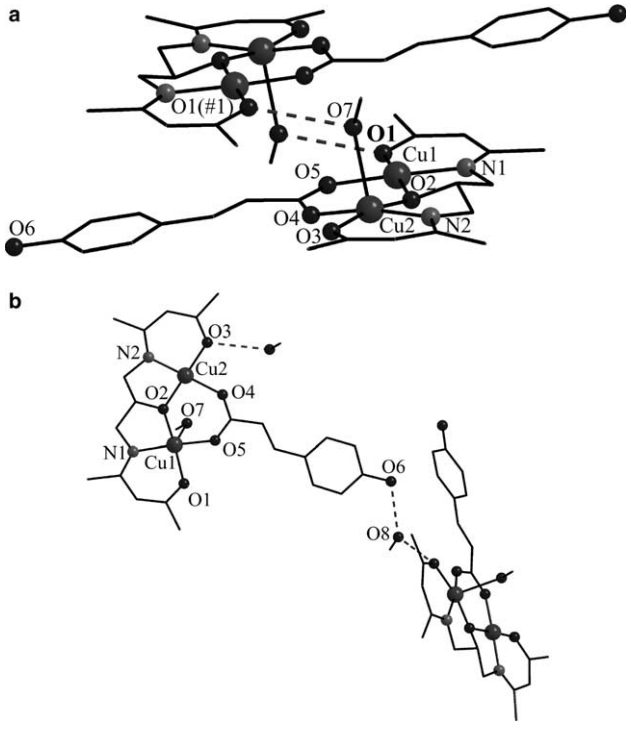

Fig. 2. (a) The hydrogen bonding interactions involving the copper-bound methanol ligand and the terminal oxygen atom of the Schiff base in **1**·MeOH. (b) The hydrogen bonding interactions involving the *p*-hydroxy group of the carboxylate, lattice methanol and the oxygen atom of the Schiff base in **1**·MeOH.

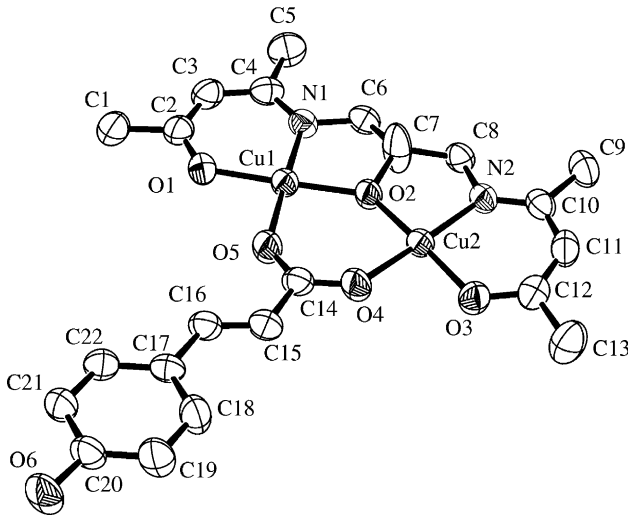

Fig. 3. ORTEP view of the complex in $[Cu_2L(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)]\cdot H_2O$ ($\mathbf{2}\cdot H_2O$).

coordination geometry, giving a Cu···Cu distance of 3.501(1) Å (Fig. 3). The basal planes at the copper(II) centers are nearly coplanar, forming an angle of 5.2(1)°. The $-CH{=}CHC_6H_4-$ moiety of the *p*-hydroxycinnamate is nearly planar giving an angle of 4.2(3)° between the $-CH{=}CH-$ group and the aromatic C_6H_4 ring. The cinnamate ligand forms an angle of 5.8(1)° with the coordination plane of the $\{Cu_2L\}^+$ moiety. This is in contrast to its analogous complex $[Cu_2L'(O_2C{-}CH{=}CH{-}C_6H_4\text{-}p\text{-}OH)]\cdot 2H_2O$, having the Schiff base *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine) (H_3L'), forming an angle of ~30° between the plane of $\{Cu_2L'\}$ and the *p*-hydroxycinnamate ligand. The essentially planar structure in $\mathbf{2}\cdot 2H_2O$ could be due to the absence of any steric rigidity in comparison to H_3L' that has two salicylaldimine moieties. Complex $\mathbf{2}\cdot H_2O$ self assembles in a unique way to form a helical supramolecular structure through bifurcated hydrogen bonding interactions involving the *p*-hydroxy group of the carboxylate and the terminal oxygen atom O(1) of the Schiff base and one oxygen atom of the bridging carboxylate O(5) [Fig. 4; O(6)···O(1)#1, 2.899(4) Å, O(6)–H(6)··· O(1)#1, 144.7°; O(6)··· O(5)#1, 2.975(4) Å, O(6)–H(6)···O(5)#1, 144.9°; #1: $-x+1/2+1, +y+1/2, -z+1/2+1$]. This is in contrast to the helical structure of its H_3L' analog that involves the *p*-hydroxy group of the carboxylate and the phenoxo atom of the Schiff base (L′) in the hydrogen bonding interactions. The O(7) lattice water molecule in $\mathbf{2}\cdot H_2O$ is hydrogen bonded to the terminal oxygen atom O(3) of the Schiff base belonging to the binuclear complex [O(7)···O(3), 2.902(6) Å; O(7)–H(7B)···O(3), 178.9°]. The lattice water in $\mathbf{2}\cdot H_2O$ does not take part in the helical structure formation but could be partially responsible for the overall planarity of the carboxylate and the $\{Cu_2L\}^+$ moieties.

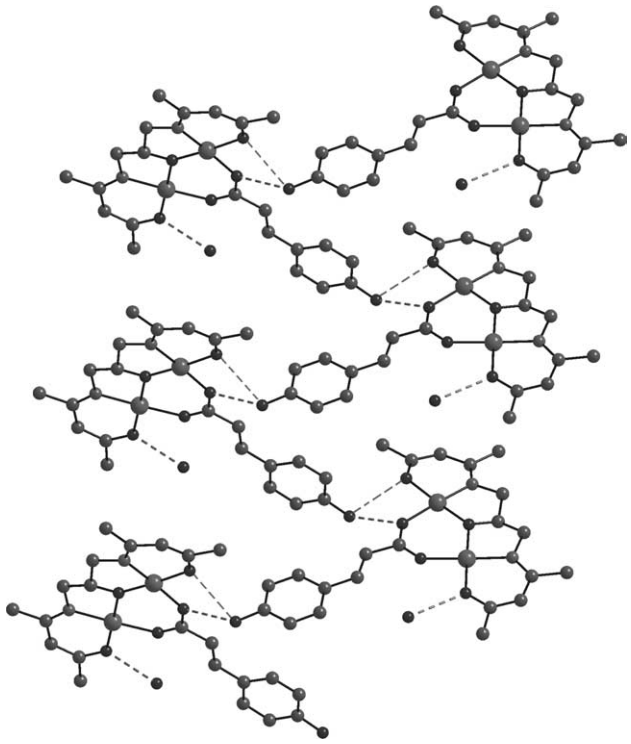

Fig. 4. Perspective view of the self-assembled helical supramolecular structure of $\mathbf{2}\cdot H_2O$. The bifurcated hydrogen bond is shown (---).

3.3. Magnetic properties

The variable-temperature magnetic susceptibility data for the complexes in the temperature range 300–18 K show an antiferromagnetic (AF) behavior of the complexes (Fig. 5). The magnetic moment values (per copper) of ~1.7 μ_B at 300 K and ~0.2 μ_B at 18 K indicate significant AF spin–spin coupling in the asymmetrically dibridged dicopper(II) core. The theoretical fittings of the magnetic susceptibility data, obtained by using the modified Bleaney–Bowers expression, gave the sin-

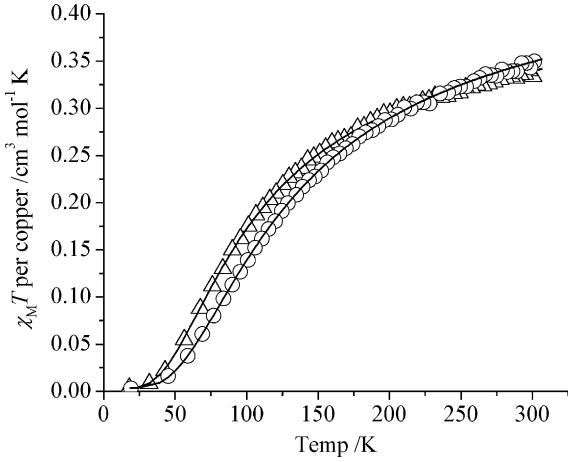

Fig. 5. $\chi_M T$ vs. T plots for the complexes **1** and **2**. The solid lines show the theoretical fit to the experimental data (△, **1**; ○, **2**).

glet–triplet energy separation ($2J$) value of $-160\ cm^{-1}$ for **1** and $-132\ cm^{-1}$ for **2**, with the singlet as the ground state [16]. Complexes **1** and **2** belong to the class of asymmetrically dibridged dicopper(II) complexes in which the nature and magnitude of the intramolecular magnetic exchange interactions in the $\{Cu_2(\mu\text{-}OR)(\mu\text{-}O_2CR)\}$ core primarily depend upon the Cu–O–Cu angle [14,19–28]. The lower magnitude of the $2J$ value, even with a large Cu–O–Cu angle of ~130°, is attributed to the counter-complimentary nature of overlap of the magnetic orbitals and is directly proportional to the energy separation of the symmetric and antisymmetric combinations of magnetic orbitals. It is interesting to note that complex **1** with a lower Cu–O–Cu angle of 130.6(1)° has greater AF interaction than complex **2** that has a Cu–O–Cu angle of 132.7(1)°. The difference could be due to stronger Cu–O (carboxylate) bonds in **2** than in **1**. Complexes **1** and **2** differ considerably in their supramolecular structures due to the involvement of the oxygen atoms in the non-covalent interactions. They also differ in the core structure where **1** has four and five coordinate copper centers, while the copper atoms in **2** have a four coordinate geometry. Again, the average Cu–O distance in the $\mu\text{-}O_2CR$ bridge of **1**·MeOH is 1.96 Å and the same for **2**·H_2O is 1.94 Å. The coordinating planes having copper atoms Cu(1) and Cu(2) have a dihedral angle of 9.54(7)° in **1**·MeOH and 5.14(6)° for **2**·H_2O. The observation of higher overall counter-complimentary effect in **2** in comparison to **1** could be due to the structural variations involving the carboxylate bridge and the supramolecular helices.

3.4. Thermogravimetric studies

Complex **1**·MeOH shows a weight loss of 4.1% in the temperature range of 50–115 °C, which is lower than the calculated percentage of 5.3% for the lattice methanol (Fig. 6). The discrepancy could be due to the labile nature of the lattice methanol at room temperature. Further, it is noticed that the copper bound methanol is not released in this temperature range, possibly due to the participation of the copper-bound methanol in the non-covalent "tetrameric" structure formation. We have observed a weight loss of ~40% above 225 °C. This could be due to the degradation of the complex above this temperature. Complex **2**·H_2O shows the TGA graph with a weight loss of 3.0% in the temperature range of 110–140 °C, which is in accordance of the theoretical value of 3.22% (Fig. 6). A further weight loss of ~46% is observed above 240 °C due to possible degradation of the complex.

In summary, two new asymmetrically dibridged dicopper(II) complexes with a pentadentate Schiff base and *p*-hydroxycinnamate are prepared and structurally characterized by X-ray crystallography. The complexes form helical supramolecular structures involving hydrogen bonding interactions. The crystal structure of the complex with a lattice water molecule differs considerably from its analogous structure having the Schiff base *N*,*N*′-1,3-diyl-bis(salicylaldiminato)propan-2-ol (H_3L'). The angle between the plane of $\{Cu_2L\}$ with the carboxylate plane in **2**·H_2O is ~6°, while the angle involving $\{Cu_2L'\}$ and the carboxylate in the reported structure is ~30° [11]. The helix formation in **2**·H_2O involves the bridging and pendant *p*-hydroxy group oxygen atoms of the carboxylate through hydrogen bonding interactions along with the terminal oxygen atom of the Schiff base. Its analogous complex having the H_3L' ligand forms a helix of a different structure [11,12]. The present work shows the significant effect of the pentadentate Schiff base in the self-assembly process of supramolecular helix formation with different structural conformations.

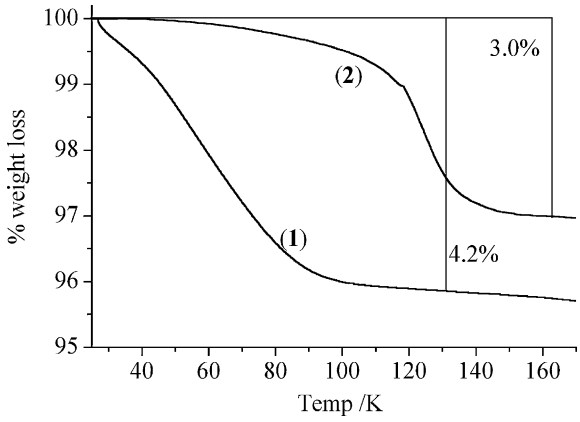

Fig. 6. Thermogravimetric plots of (a) **1**·MeOH and (b) **2**·H_2O showing weight loss of the sample with increasing temperature.

2. Experimental

2.1. Synthesis

2.1.1. Boc–Gly–ΔPhe–Gly–Gly–ΔPhe Gly–OMe, Boc–Gly–ΔAla–Gly–Gly–ΔAla–Gly–OMe

TEA (0.029 ml, 0.21 mmol) was added to a solution of Boc–Gly–ΔPhe–Gly (0.038 g, 0.1 mmol), Gly–ΔPhe–Gly–OMe*TFAOH (0.041 g, 0.1 mmol) or Boc–Gly–ΔAla–Gly (0.030 g, 0.1 mmol), Gly–ΔAla–Gly–OMe*TFAOH (0.033 g, 0.1 mmol) in 3 ml ACN and stirred for 15 min. Then TBTU (0.043 g, 0.105 mmol) was added. The reaction was carried out for 24 h at room temperature. ACN was removed under reduced pressure. The resulting oil was dissolved in 20 ml EtOAc and washed successively with 1 M HCl (4 × 2 ml), saturated potassium bicarbonate (4 × 2 ml) and brine 2 ml. The organic layer was dried over $MgSO_4$, and then the drying agent was removed by filtration. The product was crystallized from EtOAc–MeOH (40:1 v/v)/hexane.

Yield: 0.063 g (97%), tt = 188–191 °C (*E*)(*E*); 0.062 g (96%), tt = 145–147 °C (*Z*)(*Z*); 0.032 g (65%), tt = 141.5–143.5 °C ΔAla–ΔAla.

Elemental *Anal*. Calc. for $C_{32}H_{38}N_6O_9$ (650.676): C, 59.06; H, 5.89; N, 12.92. Found: C, 59.26; H, 5.80; N, 13.03%.

Elemental *Anal*. Calc. for $C_{20}H_{30}N_6O_9$ (498.492): C, 49.19; H, 6.07; N, 16.86. Found: C, 49.40; H, 6.17; N, 16.65%.

HPLC column Alltech Alltima, C-18 5 micrometer, 150 × 4.6 mm. A – H_2O; B – ACN, A:B = 40:60 flow rate 1 ml/min, purity 97.9%.

2.1.2. Boc–Gly–ΔPhe–Gly–ΔPhe–Ala–OMe

TEA (0.014 ml, 0.1 mmol) was added to a solution of Boc–Gly–ΔPhe (0.032 g, 0.1 mmol), Gly–ΔPhe–Ala–OMe*TFAOH (0.042 g, 0.1 mmol) in 0.5 ml THF and stirred for 15 min. Then DMT-MM (0.028 g, 0.1 mmol) was added. The reaction was carried out for 6 h at room temperature. The precipitate was filtered out and then filtrate was evaporated to an oil. The resulting oil was dissolved in 20 ml EtOAc and washed successively with 1 M HCl (4 × 3 ml), saturated potassium bicarbonate (4 × 3 ml) and brine 3 ml. The organic layer was dried with $MgSO_4$ and then the drying agent was removed by filtration. The product was crystallized from *i*-PrOH/hexane. Yield 0.057 g (94%), tt = 194 °C decomp.

Elemental *Anal*. Calc. for $C_{31}H_{37}N_5O_8$ (607.662): C, 61.27; H, 6.14; N, 11.52. Found: C, 61.09; H, 5.99; N, 11.70%.

HPLC column Alltech Alltima, C-18 5 micrometer, 150 × 4.6 mm. A – H_2O; B – ACN, A:B = 40:60 flow rate 1 ml/min, purity 98%.

2.1.3. Deprotection –OMe

Sodium hydroxide 1 M (0.125 ml) was added to a solution of the peptides (0.1 mmol) in 0.6 ml methanol and the reaction mixture was stirred at room temperature for 1 h. Then the reaction mixture was acidified by 1 M hydrochloric acid to pH 3, finally brine 5 ml was added and the product extracted with EtOAc (5 × 3 ml). The collected organic layer was washed with hydrochloric acid 0.5 M (2 × 3 ml) and brine (2 × 3 ml). The organic layer was dried over $MgSO_4$ (1 h only). The drying agent was removed by filtration. The products were crystallized from EtOAc–MeOH (4:1 v/v)/hexane.

Yield: 0.054 g (85%), tt = 198 °C – decomp. (*E*)(*E*); 0.056 g (88%), tt = 180–184 °C – decomp. (*Z*)(*Z*).

Elemental *Anal*. Calc. for $C_{31}H_{36}N_6O_9$ (636.66): C, 58.43; H, 5.70; N, 13.20. Found: C, 58.27; H, 5.80; N, 13.34%.

HPLC column Alltech Alltima, C-18 5 micrometer, 150 × 4.6 mm. A – H_2O; B – ACN, A:B = 40:60 flow rate 1 ml/min, purity 98.5%.

2.1.4. B–G–ΔA–G–G–ΔA–G–OH

Precipitated by hexane, yield 0.043 g (88%).

Elemental *Anal*. Calc. for $C_{19}H_{28}N_6O_9$ (484.465): C, 47.10; H, 5.82; N, 17.35. Found: C, 47.33; H, 5.92; N, 17.23%.

2.1.5. B–G–ΔPhe–G–ΔPhe–A–OH

The product was crystallized from EtOAc–MeOH (4:1 v/v)/hexane, yield 0.059 g (99%), tt = 204 °C decomp.

Elemental *Anal*. Calc. for $C_{30}H_{35}N_5O_8$: C, 60.70; H, 5.94; N, 11.80. Found: C, 60.88; H, 5.88; N, 11.99%.

HPLC column Alltech Alltima, C-18, 5 micrometer, 150 × 4.6 mm. A – H_2O; B – ACN, A:B = 40:60 flow rate 1 ml/min, purity 98.8%.

2.1.6. Boc-deprotection

The Boc-protected dehydro-peptides 0.1 mmol were dissolved in 0.5 ml dichloromethane, 1 ml anhydrous trifluoroacetic acid and 0.1 ml aniosole and stirred at room temperature for 20 min. Then dichloromethane was added and the volatile components of the reaction mixture were purified by adding 10 ml diethyl ether followed by evaporation. This procedure was repeated three times. The resulting trifluoroacetates peptides were dissolved in 3 ml isopropanol and the products were precipitated by hexane.

Yield: G–ΔPhe–G–G–ΔPhe–G*TFAOH 0.0514 g (79%) (*E*)(*E*), 0.052 g (80%) (*Z*)(*Z*).

Elemental *Anal*. Calc. for $C_{28}H_{29}N_6O_9F_3$ (650.567): C, 51.69; H, 4.49; N, 12.92. Found: C, 51.77; H, 4.56; N, 13.00%.

Yield: G–ΔA–G–G–ΔA–G*TFAOH 0.038 g (75%).

Elemental *Anal*. Calc. for $C_{16}H_{21}N_6O_9F_3$ (498.372): C, 38.56; H, 4.25; N, 16.86. Found: C, 38.69; H, 4.45; N, 16.68%.

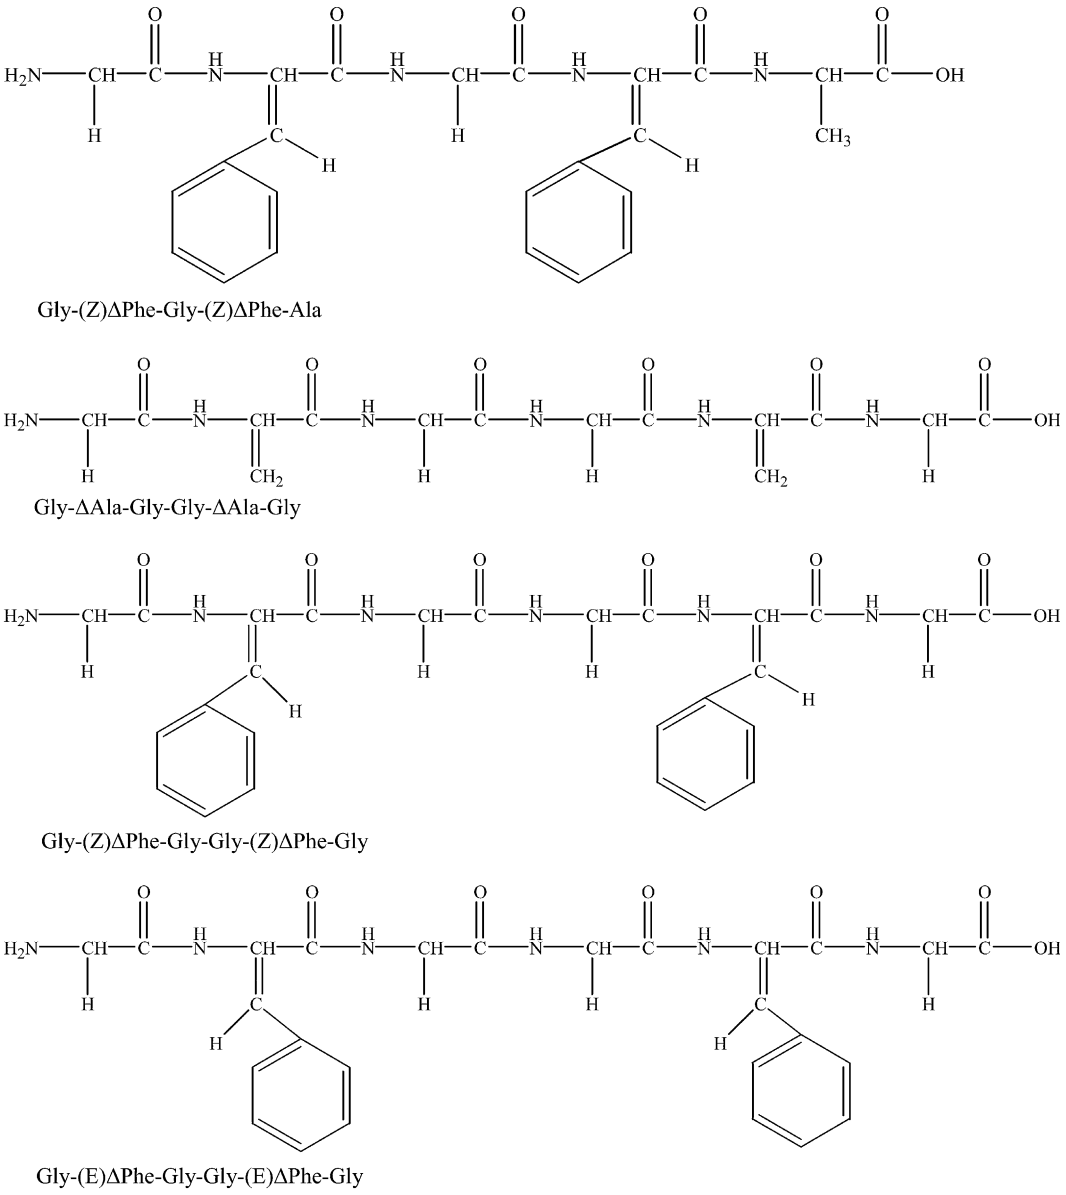
Yield: G–ΔPhe–G–ΔPhe–A*TFAOH 0.060 g (99%).

Elemental *Anal*. Calc. for $C_{27}H_{28}N_5O_8F_3$ (607.542): C, 53.38; H, 4.64; N, 11.53. Found: C, 53.49; H, 4.78; N 11.42%.

2.2. Potentiometric studies

The stability constants for the proton and Cu(II) complexes were calculated from titration curves carried out at 25 °C. Alkali was added from a 0.250 ml micrometer syringe, which was calibrated by weight titrations of standard materials. The metal ion concentration was 1×10^{-3} M and the metal-to-ligand ratios were 1:1. The pH-metric titrations were performed in 0.1 M KNO_3 on a MOLSPIN pH-meter system using a Russell CMAW 711 semi micro combined electrode calibrated in hydrogen ion concentration using HNO_3, and three titrations were performed for each system. A SUPERQUAD [9] computer program was used for stability constant calculations. Standard deviations quoted were computed by SUPERQUAD and refer to random errors only. They are, however, a good indication of the importance of a particular species in the equilibrium.

2.3. Spectroscopic studies



Absorption spectra were recorded on a Perkin Elmer Lambda Bio-20 spectrophotometer, circular dichroism (CD) spectra on a JASCO J 715 spectropolarimeter in the 850–200 nm range and electron paramagnetic resonance (EPR) spectra on a Bruker ESP 300E spectrometer at X-band frequency (9.4 GHz) at 120 K. The metal concentration in these measurements were adjusted to 1×10^{-3} M and the metal-to-ligand rations were 1:1. The spectroscopic parameters were obtained at the maximum concentration of the particular species.

3. Results and discussion

The stability constants for the proton and Cu^{2+} complexes are given in Table 1. All ligands (Scheme 1) have two protonation constants [$\log K(NH_2)$ and $\log K(COO^-)$] assigned to amino and carboxyl groups. The protonation constants of amino groups as well as those of carboxyl groups are similar for all the studied ligands. In comparison to pentaGly, insertion of the dehydro-amino acid residue into the peptide sequence makes the proton from the amino group more acidic; the value of $\log K(NH_2)$ for dehydro-peptides is lower than for pentaGlycine (Table 1). The protonation constant for the carboxyl group is similar for the studied ligands as well as for pentaGlycine.

Scheme 1.

Coordination of Cu^{+2} ions starts at the nitrogen of the amino group and then the oxygen of the adjacent carbonyl group, except for ligands having two (*Z*)ΔPhe residues. In the latter case the $CuH_{-1}L$ complex is formed as the first main species (Table 1). When the pH increases, the $CuH_{-2}L$ complex is formed by all ligands. The EPR parameters for all the ligands, as well as UV–Vis spectra for the (*E*)Phe(*E*)Phe isomer and ligands with two ΔAla residues (Table 2), suggest three nitrogen atoms bound to the metal ion. This complex is formed by coordination of a second amide nitrogen and the binding mode for this complex is $\{NH_2, 2 \cdot N^-\}$. With a further the pH increase, the studied ligands form complexes losing the proton from the next amide bond [10] (Table 1) and the $CuH_{-3}L$ complex with a $\{NH_2, 3 \cdot N^-\}$ binding mode is formed. The spectroscopic parameters (Table 2) confirm that four nitrogen atoms are coordinated to copper ion.

The final complex formed at high pH is $CuH_{-4}L$. The spectroscopic parameters for the $CuH_{-4}L$ complex are the same as for $CuH_{-3}L$. It supports four nitrogen coordination to the Cu^{2+} ion. The CD spectra of the chiral pentapeptide (Scheme 1) obtained from $CuH_{-3}L$ and $CuH_{-4}L$ complexes are very similar to each other (Table 2), suggesting that the formation of the latter complex could derive from the partial hydrolysis of the former species.

Figs. 1 and 2 show a competition between the binding of the Cu^{+2} ion by hexapeptide and chiral pentapeptide with two the (*Z*)ΔPhe residues. Below pH 6 hexapeptide

forms a more stable complex $CuH_{-1}L$ (Figs. 1 and 2), while above pH 6 the pentapeptide is more efficient (Fig. 2). It could derive from the closer vicinity of the (*Z*)ΔPhe residues in the pentapeptide ligand and formation of the more stable $CuH_{-3}L$ complex with the $\{NH_2, 3 \cdot N^-\}$ binding mode.

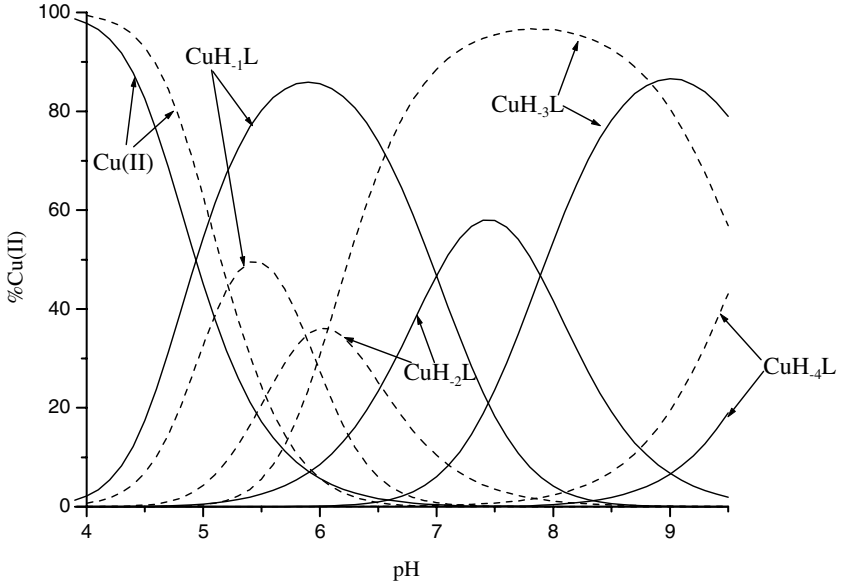

Fig. 1. Species distribution curves for Cu(II)–Gly–(*Z*)ΔPhe–Gly–Gly–(*Z*)ΔPhe–Gly (solid line) and Cu(II)–Gly–(*Z*)ΔPhe–Gly–(*Z*)ΔPhe–Ala (dashed line) complexes at 25 °C and $I = 0.1$ mol dm^{-3} KNO_3. Metal concentration 1×10^{-3} mol dm^{-3}. Ligand to metal ratio 1:1.

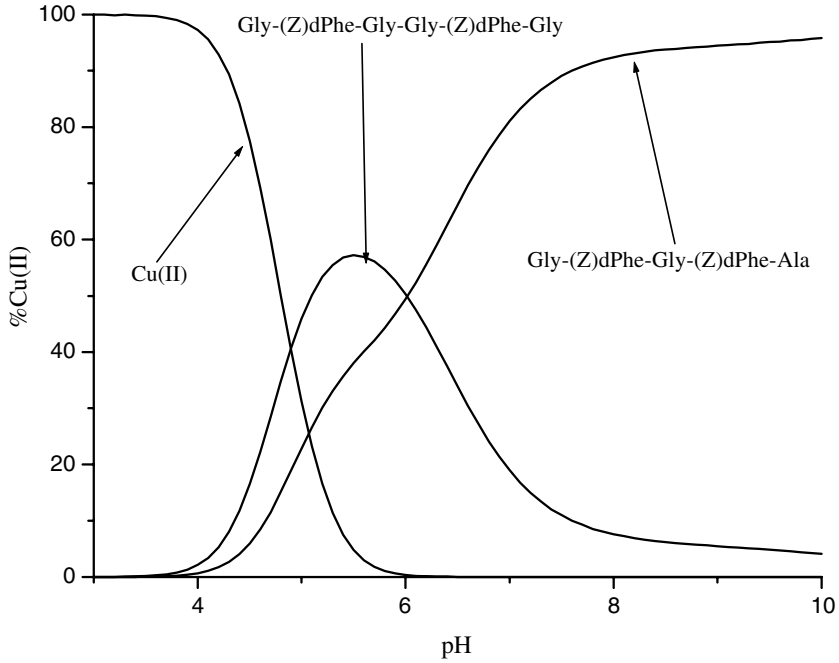

Fig. 2. Competition diagrams for Cu(II)–Gly–(*Z*)ΔPhe–Gly–Gly–(*Z*)ΔPhe–Gly and Gly–Gly–(*Z*)ΔPhe–Gly–(*Z*)ΔPhe–Ala in binding of Cu(II) ions as a function of pH for 1:1:1 (ligand 1:metal:ligand 2) molar ratio and metal concentration 1×10^{-3} mol dm^{-3}.

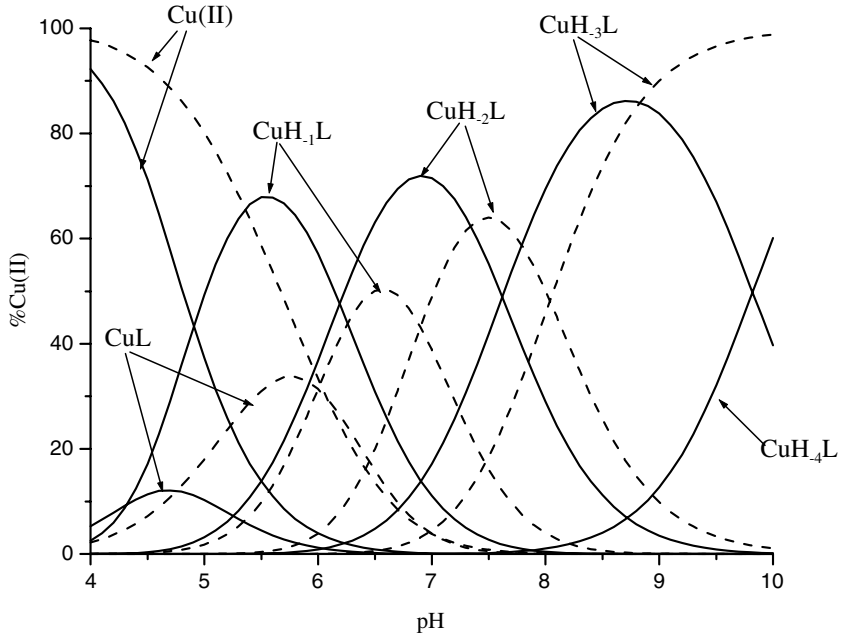

Fig. 3. Species distribution curves for Cu(II)–Gly–ΔAla–Gly–Gly–ΔAla–Gly (solid line) and Cu(II)–pentaglycine (dashed line) complexes at 25 °C and $I = 0.1$ mol dm^{-3} KNO_3. Metal concentration 1×10^{-3} mol dm^{-3}. Ligand to metal ratio 1:1.

As it shows in Fig. 3, the insertion of two dehydroamino acid residues into the peptide sequence makes the ligand distinctly more effective in metal ion binding when compared to the pentaglycine. Interestingly, at physiological pH both ligands form $CuH_{-2}L$ complexes with a $\{NH_2, 2 \cdot N^-\}$ binding mode (Fig. 3).

A comparison of the binding ability of (*Z*)ΔPhe(*Z*)-ΔPhe and (*E*)ΔPhe(*E*)ΔPhe is given in Fig. 4. The competition diagram for both ligands is shown in Fig. 5. The former ligand binds Cu^{2+} more effectively below pH 7. Up to this pH value the (*Z*,*Z*) isomer forms a very stable $CuH_{-1}L$ complex, while above pH 7 the isomer

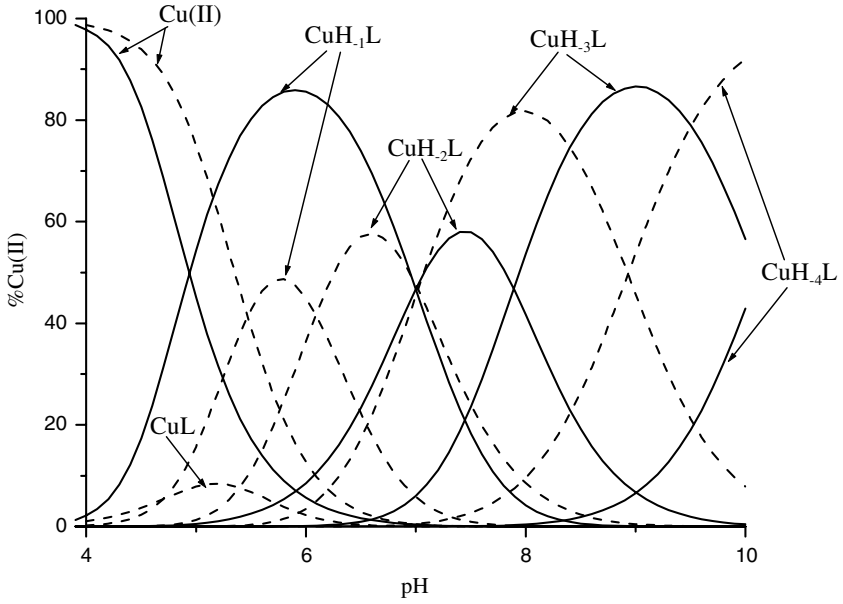

Fig. 4. Species distribution curves for Cu(II)–Gly–(*Z*)ΔPhe–Gly–Gly–(*Z*)ΔPhe–Gly (solid line) and Cu(II)–Gly–(*E*)ΔPhe–Gly–Gly–(*E*)ΔPhe–Gly (dashed line) complexes at 25 °C and $I = 0.1$ mol dm^{-3} KNO_3. Metal concentration 1×10^{-3} mol dm^{-3}. Ligand to metal ratio 1:1.

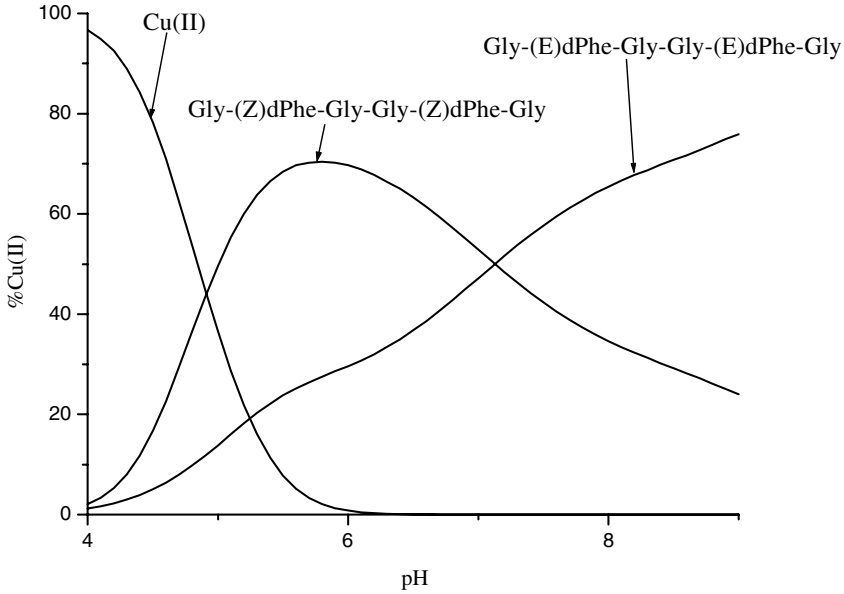

Fig. 5. Competition diagrams for Cu(II)–Gly–(*Z*)ΔPhe–Gly–Gly–(*Z*)ΔPhe–Gly and Gly–Gly–(*E*)ΔPhe–Gly–Gly–(*E*)ΔPhe–Gly in binding of Cu(II) ions as a function of pH for 1:1:1 (ligand 1:metal:ligand 2) molar ratio and metal concentration 1×10^{-3} mol dm^{-3}.

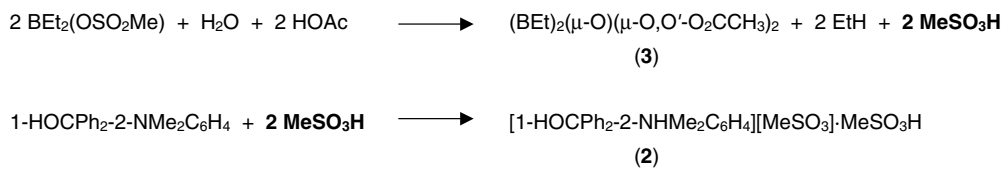
E, which forms the $CuH_{-3}L$ species easier, is more effective (Figs. 4 and 5). In the $CuH_{-1}L$ complex, the metal ion is coordinated to a nitrogen from an amino group and an amide nitrogen from the first dehydro-residue. A greater influence of the double bond on the amide nitrogen is observed in the (*Z*) residue than in the (*E*) residue [8]. It makes the $CuH_{-1}L$ complex more stable for the (*Z*,*Z*) isomer. The dehydro-residue in position 5 has no impact on metal ion binding. For this reason the formation of the $CuH_{-3}L$ complex is independent of the dehydro-amino acid residue. The higher stability of the $CuH_{-3}L$ complex for the (*E*,*E*) isomer may be caused by steric reasons.



4. Conclusions

The data discussed above indicates that the bis-dehydro-hexapeptides binds metal ions with similar efficiency as bis-dehydro-pentapeptides and are much more effective than pentaglycine. The dehydro-amino acid residue at position 5 in the bis-dehydro-hexapeptides

has insignificant impact on the efficiency of Cu^{+2} binding as well as on coordination of the third amide nitrogen. The increase of the distance between two dehydro-amino acid residues has no significant influence on the coordination of the metal ion to the second dehydro-amino group.

Scheme 1. Proposed mechanism for the formation of **2** and **3**.

H_2O (from glacial acetic acid) and HOAc react with $BEt_2(OSO_2Me)$ to give compound **3**, ethane and methylsulfonic acid. The last-named then reacts with the organic compound 1-$HOCPh_2$-2-$NMe_2C_6H_4$ to afford the ammonium methylsulfonate **2**. Correspondingly, compound **2** was also obtained from **1** and methylsulfonic acid. Compound **3** was previously prepared by the reaction of triethylboroxin with acetic acid anhydride and structurally characterized [8].

2.2. Spectroscopic properties

In the ^1H NMR spectrum of **2**, the $N(CH_3)_2$ protons give rise to one singlet at 2.78 ppm and one singlet for the Me protons of $MeSO_3$ and $MeSO_3H$ at 2.95 ppm. The NH and OH protons are not observed, while the proton of the methylsulfonic acid (S–OH) is observed as a broad signal at ca. 12.1 ppm. In the ^{13}C NMR spectrum of **2**, the $N(CH_3)_2$ carbon atoms appear as one singlet at 47.7 ppm, while the $MeSO_3$ and $MeSO_3H$ carbon atoms are observed as one singlet at 40.0 ppm. The ^{13}C NMR signal for the C–O carbon atom appears at 84.5 ppm.

2.3. Molecular structure of 2

In **2** (Fig. 1), the three components [1-$HOCPh_2$-2-$NHMe_2C_6H_4$]$^+$, $[MeSO_3]^-$ and $MeSO_3H$ are associated via two intermolecular hydrogen bonds [11] between the cation [1-$HOCPh_2$-2-$NHMe_2C_6H_4$]$^+$ and the $MeSO_3^-$ anion [O(1)–H(1O)···O(4): O(1)–H(1O) 0.78(2), H(1O)···O(4) 1.98(2), O(1)···O(4) 2.752(2) Å, O(1)–H(1O)···O(4) 166(2)°], and between the $MeSO_3^-$ anion and a neutral sulfonic acid molecule, $MeSO_3H$ [O(5)–H(5O)···O(2): O(5)–H(5O) 0.96(3), H(5O)···O(2) 1.53(3), O(5)···O(2) 2.483(2) Å, O(5)–H(5O)···O(2) 174(3)°]. This type of hydrogen bonding in acid salts of general formula $M^+X^- \cdot HX$ (with $X = MeSO_3$ in the present case) can be classified as a Type B structure (with crystallographically non-equivalent anion X and neutral molecule HX) according to Speakman [12]. The structure of a related *p*-toluenesulfonic acid/*p*-toluenesulfonate salt, (3*S*,4*S*)-3-methoxy-4-methylammoniopyrrolidine *p*-toluenesulfonic acid *p*-toluenesulfonate was reported, where the main interest was, however, in the determination of the absolute configuration of the ammonium cation rather than hydrogen bonding. Thus, no details concerning O···O or O···N distances were reported [13].

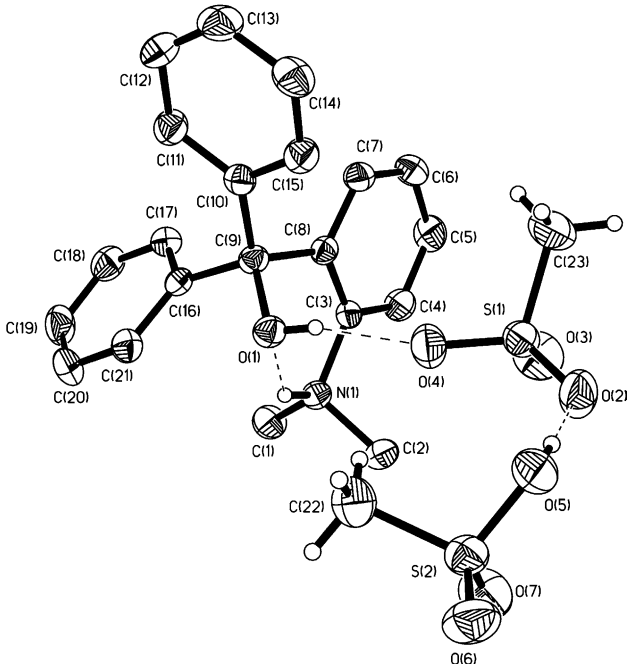

Fig. 1. Molecular structure of **2** (ORTEP, 50% probability, SHELXTL PLUS; XP [15], hydrogen atoms of Ph and NMe_2 groups omitted for clarity).

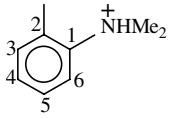
In **2**, additionally an intramolecular N(1)–H···O(1) hydrogen bond [N(1)–H 0.90(2), H···O(1) 1.99(2), N(1)···O(1) 2.738(2) Å, N(1)–H···O(1) 139(2)°] is observed in the cation [1-$HOCPh_2$-2-$NHMe_2C_6H_4$]$^+$. The intramolecular N(1)–H···O(1) hydrogen bond is weaker than the intramolecular O(1)–H···N(1) hydrogen bond in the related organic compound **1** [O(1)–H(1) 0.95(2), H(1)···N(1) 1.82(2), O(1)···N(1) 2.659(2) Å, O(1)–H(1)···N(1) 146(2)°] [10]. The bond lengths and angles of **2** not discussed above are normal and in agreement with those observed for the corresponding organic ligand **1** [10].

3. Experimental

3.1. General



All experiments were carried out under purified dry nitrogen. Solvents were dried and freshly distilled under

nitrogen. The NMR spectra were recorded in $CDCl_3$ with an AVANCE DRX 400 spectrometer (Bruker): ^1H (400.1 MHz) and ^{13}C NMR spectra (100.6 MHz) with tetramethylsilane as external standard. Infrared spectra were recorded with a Perkin–Elmer System 2000 FT-IR spectrometer between 4000 and 400 cm^{-1} using KBr disks. Elemental analyses were determined with a VARIO EL (Heraeus). Melting points (Gallenkamp) are uncorrected. 1-$HOCPh_2$-2-$NMe_2C_6H_4$ [10] and $BEt_2(OSO_2CH_3)$ [5] were prepared according to the literature methods.

*[1-$HOCPh_2$-2-$NHMe_2C_6H_4$][$MeSO_3$] · $MeSO_3H$ (**2**) and ($BEt)_2(\mu$-$O)(\mu$-O,O'-$O_2CCH_3)_2$ (**3**)* Refluxing 1-$HOCPh_2$-2-$NMe_2C_6H_4$ (**1**; 0.5 g, 1.65 mmol) with BEt_2-(OSO_2CH_3) (0.3 g, 1.65 mmol) in the presence of acetic acid (1.4 g, 23.33 mmol) in 150 ml toluene for 2 h afforded a red oily residue. After removal of the solvent in vacuum at r.t. the red oily residue was separated by column chromatography (70/230 mesh silica gel/hexane), whereby two products were obtained. The first product was recrystallized from diethyl ether at 20 °C to give colorless crystals of **2** in 20% yield (0.16 g). M.p. 129–132 °C. The second product **3** was obtained as colorless crystals from toluene at −30 °C. The NMR data are in agreement with those reported in the literature [8].

*[1-$HOCPh_2$-2-$NHMe_2C_6H_4$][$MeSO_3$] · $MeSO_3H$ (**2**)* was independently prepared from **1** and $MeSO_3H$. $MeSO_3H$ (0.317 g, 3 mmol) was added very slowly to a solution of **1** (0.50 g, 1.6 mmol) in 10 ml THF. White crystals of **2** formed at room temperature overnight. Yield: 0.47 g (57%). M.p. 127 °C.

Spectroscopic data of **2** obtained as described above and as described here are identical.

4. X-ray crystallographic study

Crystallographic data are given in Table 1. Data [λ (Mo Kα) = 0.71073 Å] were collected with a Siemens CCD (SMART) diffractometer. All observed reflections were used for determination of the unit cell parameters. Empirical absorption correction with SADABS [14]. The structure was solved by direct methods (SHELXTL PLUS [15]). H atoms located by difference maps and refined isotropically.

Acknowledgments

We thank Mrs. A. Scholz and Dr. P. Lönnecke, University of Leipzig, for the independent synthesis of **2** from **1** and $MeSO_3H$.

Appendix A. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 264739 for **2**. These data can be obtained from Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK, fax: (internat.) +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk or on the web http://www.ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2005.06.002.

directly to cobalt cations to form porous layers. A different type of SbS_2^- chain is found in $(CH_3NH_3)_2Sb_2S_4$ [15], where $Sb_2S_4^{2-}$ units, each consisting of a pair of edge-sharing SbS_3 trigonal pyramids, are linked by secondary Sb···S interactions to generate an infinite chain.

Although it is believed that simple thioantimonate ions play a fundamental role in the crystallisation of new structure types under solvothermal conditions, it is rare to observe such species totally isolated in the solid products of these reactions. The few known examples include the SbS_3^{3-} anion, found isolated in M_3SbS_3 (M = Cu, Ag, Tl) [16–18], and the Sb(V)-containing SbS_4^{3-} tetrahedron in $Cr(en)_3SbS_4$ [19]. The more complex $Sb_4S_8^{4-}$ heteroring is found isolated in $[Ni(C_4H_{13}N_3)_2]_2Sb_4S_8$ [20] and $[Ni(C_3H_{10}N_2)_3]_2Sb_4S_8 \cdot 2H_2O$ [21], whilst discrete $Sb_3S_6^{3-}$ units have been identified in $[Ni(C_4H_{13}N_3)_2]_3(Sb_3S_6)_2$ [22]. Although a number of compounds have been formulated with the Sb_2S_5 stoichiometry, they do not contain discrete $Sb_2S_5^{4-}$ ions. For example, in $Ca_2Sb_2S_5$ [23], isolated SbS_3^{3-} and $Sb_2S_4^{2-}$ units coexist, whilst in compounds $Mn_2(L)Sb_2S_5$ (L = methylamine [24], ethylenediamine [25] and 1,3-diaminopropane [26]), the antimony–sulfide unit is incorporated with manganese into heterocubane-like moieties, linkage of which generates infinite rod-like structural units. In addition, in the compounds $[M(C_6H_8N_4)]_2Sb_2S_5$ (M = Co, Mn) [27], $Sb_2S_5^{4-}$ behaves as a ligand by coordinating to two $[M(tren)]^{2+}$ complexes via sulfur.

The present work is concerned with the $Sb_2S_5^{4-}$ anion, of which there is only one known example of a discrete ion; namely, $Sr_2Sb_2S_5 \cdot 15H_2O$ [28]. Although $Ba_2As_2Q_5$ (Q = S, Se) [29] has analogous stoichiometry, this structure contains isolated AsQ_3^{3-} and $As(Q)_2Q_2$ units rather than $As_2Q_5^{4-}$ anions. Here, we describe the synthesis and characterisation of a new templated antimony sulfide, $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**), which represents the first example of a material in which isolated $Sb_2S_5^{4-}$ anions crystallise with complex transition-metal cations. Furthermore, we demonstrate that a relatively modest rise of 25 K in the preparation temperature causes these $Sb_2S_5^{4-}$ units to polymerise to generate infinite SbS_2^- chains in the compound $[Fe(en)_3]_2Sb_4S_8$ (**2**), providing support for the view that relatively simple molecular units play a key role in crystallisation from the complex heterogeneous mixtures that constitute a solvothermal reaction.

2. Experimental

2.1. Synthesis and characterisation

The compounds $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**) and $[Fe(en)_3]_2Sb_4S_8$ (**2**) were prepared under solvothermal conditions in a Teflon-lined stainless steel autoclave with an inner volume of 23 ml. For **1**, Sb_2S_3 (0.679 g, 2 mmol), $FeCl_2 \cdot 4H_2O$ (0.296 g, 1.5 mmol), S (0.160 g, 5 mmol) and 5 ml ethylenediamine (en, Aldrich, 99%), with approximate molar composition Sb:Fe:S:en of 4:1.5:11:75, were thoroughly mixed, heated at 413 K for 4 days and cooled to room temperature at a cooling rate of 20 K h^{-1}. The solid product was filtered, washed in ethylenediamine and dried in air at room temperature. The product consisted of yellow plates, identified by single-crystal X-ray diffraction as $Fe(en)_3Sb_4S_7$ [7], darker yellow "golf ball" like crystals of **1** as a minor phase, together with an unidentified black polycrystalline powder. CHN analysis of a handpicked sample of **1**: *Anal.* Calc. for $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$: C, 16.28; H, 5.58; N, 18.99. Found: C, 16.29; H, 5.61; N, 18.45%. For **2**, the composition of the reagents was identical to that used for **1**, but the mixture was heated for 4 days at 438 K. The cooling regime and product washing were as above. The product consisted of orange crystals of **2** along with an unidentified black polycrystalline powder. CHN analysis of a handpicked sample of **2**: *Anal.* Calc. for $[Fe(en)_3]_2Sb_4S_8$: C, 11.89; H, 3.98; N, 13.82. Found: C, 11.74; H, 4.06; N, 13.64%.

Magnetic susceptibility measurements were performed using a Quantum Design MPMS2 SQUID susceptometer. About 2 mg of hand-picked crystals of each of the title compounds were loaded into a gelatine capsule at room temperature and data were collected over the temperature range ($5 \leqslant T/K \leqslant 300$) after cooling in the measuring field of 1000 G. Data were corrected for the diamagnetism of the gelatine capsule and for intrinsic core diamagnetism.

2.2. Crystal structure determination

Single-crystal X-ray diffraction data for **1** were collected at room temperature using a Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data were processed using the DENZO and SCALEPACK programs [30]. Corresponding intensity data for **2** were collected at 100 K using a Bruker Nonius X8 Apex diffractometer also using Mo Kα radiation ($\lambda = 0.71073$ Å) and data were processed using the APEX-2 software [31]. The structures were solved by direct methods using the program SIR-92 [32], which located all Fe, Sb and S atoms. Subsequent Fourier calculations and least-square refinements on *F* were carried out using the CRYSTALS program suite [33]. The C and N atoms of the amine were located in difference Fourier maps for **1** and **2**, together with the oxygen atom of a water molecule for **1**. Hydrogen atoms were placed geometrically on the C and N atoms after each cycle of refinement in each case. In the final cycles, positional and anisotropic thermal parameters for all non-hydrogen atoms were refined, together with the occupancy factor of the oxygen atom, for which a value

of 0.55(3) was obtained. The crystal of **1** is an inversion twin with refined Flack parameter 0.53(6). Crystallographic and refinement details are given in Table 1. Crystallographic data for structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre.

3. Results and discussion

The local coordination and atom labelling scheme of the $Sb_2S_5^{4-}$ anion and distinct $[Fe(en)_3]^{2+}$ cations found in $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**) are depicted in Fig. 1. Selected bond lengths, angles and valence sums are presented in Table 2. Magnetic susceptibility data for **1** clearly indicate paramagnetism (Fig. 2(a)). However, a plot of reciprocal susceptibility as a function of temperature exhibits pronounced curvature below 200 K. Above this temperature, the plot is sufficiently linear to enable fitting of a Curie–Weiss expression, yielding a Curie constant of 7.1(1) cm^3 K mol^{-1} and Weiss constant of $\theta = -115.6(4)$ K. This corresponds to an effective magnetic moment per iron atom of 5.34 μ_B, which is somewhat higher than the spin-only value of 4.89 μ_B calculated for octahedral *hs*-Fe^{2+}. This enhancement of the spin-only moment is typical for *hs*-Fe^{2+} and is associated with the orbital contribution arising from the $^5T_{2g}$ ground state of the ion. The orbital degeneracy of this ground state, leading to a temperature-dependent

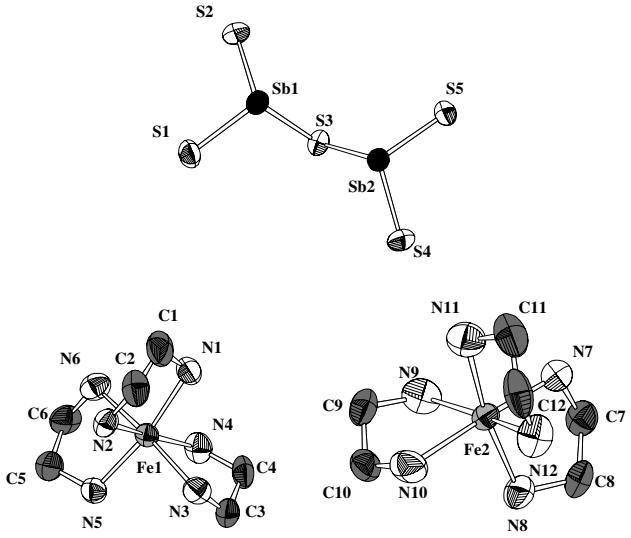

Fig. 1. Local coordination of the anionic and cationic components of $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**), showing the atom labelling scheme and thermal ellipsoids at 50% probability The two crystallographically distinct iron complexes possess different conformations.

effective magnetic moment, may also be responsible for the marked curvature of the plot of reciprocal susceptibility as a function of temperature and for an unrealistic Weiss constant, which in a magnetically dilute system such as this is essentially an empirical parameter and not an indicator of exchange interactions.

The crystal structure of **1** consists of isolated $Sb_2S_5^{4-}$ anions, constructed from two SbS_3^{3-} trigonal pyramids sharing a common vertex, together with two crystallographically distinct iron cations complexed by ethylenediamine ligands. In the anionic part of the structure, the bridging Sb–S distances are 2.503(2) and 2.481(2) Å, whilst the terminal Sb–S bonds are significantly shorter, ranging between 2.371(2) and 2.378(3) Å. The S–Sb–S angles lie in the range 101.05(8)–103.52(8)°. These distances and angles are in good agreement with those of the $Sb_2S_5^{4-}$ unit in $Sr_2Sb_2S_5 \cdot 15H_2O$ [28]. Bond valence sums [34] for **1** are consistent with a formal oxidation state of +3 for each antimony atom (Table 2). The Fe–N distances in the two $[Fe(en)_3]^{2+}$ cations range from 2.162(8) to 2.249(8) Å with (*cis*) N–Fe–N angles lying between 78.6(3)° and 96.1(4)°, comparing well with values previously reported for Fe(II)–ethylenediamine complexes [35]. All Fe(1) complexes have the Λ(δδδ) conformation, whilst those containing Fe(2) are Δ(λλλ).

The isolated $Sb_2S_5^{4-}$ ions are arranged in sheets which lie in the *bc*-plane, with the Sb(1)–Sb(2) axis inclined at ca. 50° to this plane (Fig. 3). Within these sheets, the molecular anions lie in rows parallel to the [0 0 1] direction, with an alternation of the direction of the molecular axis between successive rows in the [0 1 0] direction. The sheets are non-planar and contain depressions in which the $[Fe(en)_3]^{2+}$ cations are located. These mixed anion–cation sheets are stacked along the

[1 0 0] direction, such that neighbouring sheets are displaced by $c/2$ with respect to each other (Fig. 4). A network of hydrogen bonds links molecules within the layers and in neighbouring layers. The nitrogen atoms of the ethylenediamine ligands of both Fe(1) and Fe(2) are all within hydrogen-bonding distance to the sulfur atoms of the $Sb_2S_5^{4-}$ anions (N···S = 3.41–3.79 Å). In addition, N(1) also forms a hydrogen bond to O(1) of the water molecule (N(1)···O(1) = 3.16 Å).

The structure differs from that of $Sr_2Sb_2S_5 \cdot 15H_2O$, the only other reported example of a material containing isolated $Sb_2S_5^{4-}$ anions [28]. In $Sr_2Sb_2S_5 \cdot 15H_2O$, a unit cell translation of molecular anions along [1 0 0] generates rows of ions, with neighbouring rows along [0 1 0] being displaced by $(\frac{1}{2}\,0\,0)$. This packing produces almost planar anionic layers parallel to the *ab*-plane that are interleaved with layers of hydrated strontium cations (Fig. 5). This contrasts with the rippled layers of $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$, in which layers contain both cations and anions. The plane containing the Sb–S–Sb linkage of the $Sb_2S_5^{4-}$ unit is approximately parallel to the crystallographic *ab*-plane, whereas in $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$, the analogous molecular plane is directed at ca. 60° to the plane in which the anions and cations are located. Compounds $[M(en)_3]_2Sb_2Se_5$ (M = Fe [35] and Mn [36]), containing the selenium analogue of $Sb_2S_5^{4-}$ described here, have been reported to crystallise in the space groups *Pbca* and $P2_1/n$, respectively, indicating different packing arrangements to that of the thioantimonate. The molecular anion in the iron-containing antimony–selenide was also found to be disordered over two symmetry-related positions [36].

The local coordination and atom labelling scheme of **2** is depicted in Fig. 6. Significant bond lengths and angles are presented in Table 3. Reciprocal magnetic susceptibility data for **2** also exhibit curvature (Fig. 2(b)), although this is less pronounced than for **1**. Fitting a Curie–Weiss expression to the high-temperature data (>200 K), produces a Curie constant of 6.1(1) cm^3 K mol^{-1} and a Weiss constant of $\theta = -20.5(4)$ K. The former corresponds to an effective magnetic moment of 4.94(5) μ_B per Fe atom, consistent with the presence of octahedral *hs*-Fe^{2+}. Bond-valence sums [34] indicate a formal oxidation state of +3 for each antimony atom (Table 3).

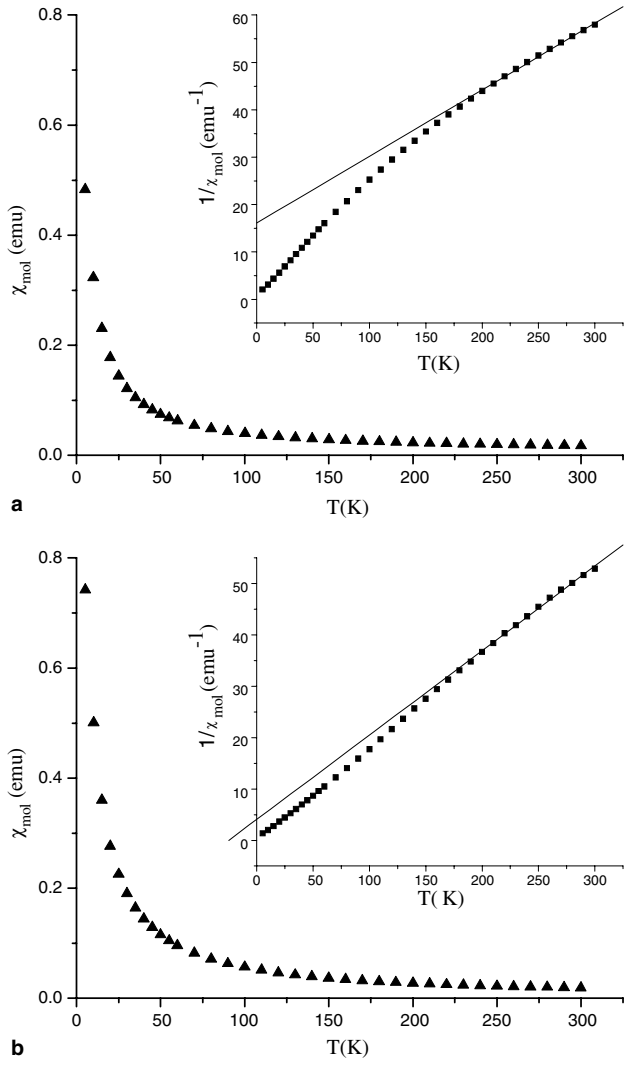

Fig. 2. Field-cooled magnetic susceptibility data and inverse susceptibility data (inset) for (a) $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ and (b) $[Fe(en)_3]_2Sb_4S_8$. The solid line shows the fit to the Curie–Weiss expression above 200 K.

The crystal structure of $[Fe(en)_3]_2Sb_4S_8$ (**2**) is very similar to those of $[M(en)_3]_2Sb_4S_8$ (M = Co, Ni) [7], consistent with the suggestion, based on comparison of unit cell parameters, that all three materials are isostructural. Compound **2** contains SbS_2^- chains directed along [0 0 1] (Fig. 7). The SbS_2^- chains may be considered as a polymeric version of the $Sb_2S_5^{4-}$ dimeric units

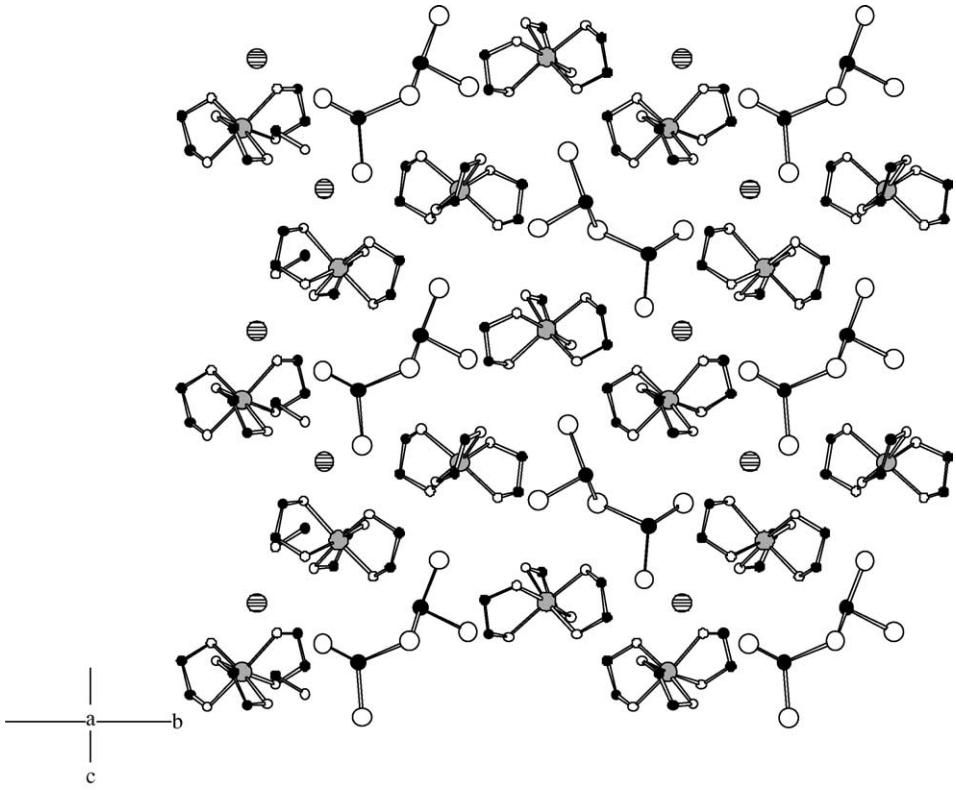

Fig. 3. View along [1 0 0] of one layer of $Sb_2S_5^{4-}$ anions and $Fe(en)_3^{2+}$ cationic complexes in **1**. *Key*: antimony, large solid circles; sulfur, large open circles; iron, large shaded circles; carbon, small solid circles; nitrogen, small open circles; oxygen, large hashed circles.

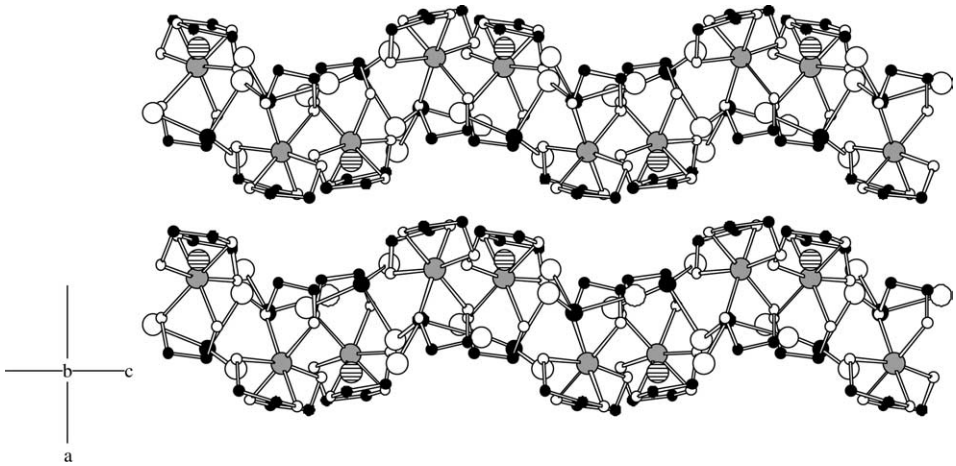

Fig. 4. View along [0 1 0] of the stacking of the layers of $Sb_2S_5^{4-}$ anions and $Fe(en)_3^{2+}$ cationic complexes in $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**). *Key* as for Fig. 3.

found in **1**, in which vertex linking of SbS_3^{3-} trigonal pyramids is extended into infinite chains. There are two crystallographically distinct SbS_2^- chains, in which the bridging Sb–S bond distances range from 2.458(2) to 2.484(2) Å. The terminal Sb–S distances are slightly shorter and lie in the range 2.317(2)–2.364(2) Å. S–Sb–S angles range from 99.95(5)° to 100.15(5)°, which are typical for pyramidal SbS_3 units. Unusually for this class of material, there is only one longer Sb···S interaction (Sb(3)···S(8′) = 3.62 Å) within the sum of the van der Waals' radii of antimony and sulfur (ca. 3.8 Å), which corresponds to a very weak intrachain Sb···S secondary interaction in one of the anionic chains. The SbS_2^- chains are essentially isolated, as

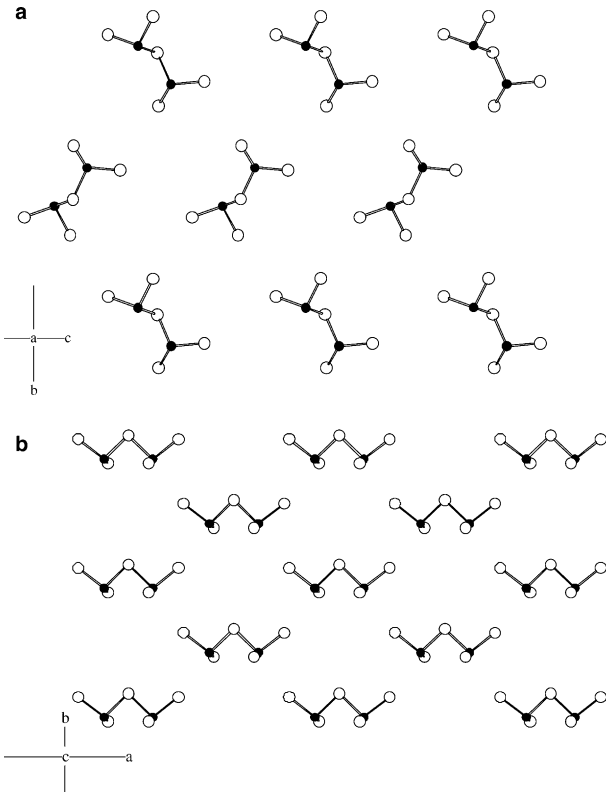

Fig. 5. Comparison of the arrangements of the $Sb_2S_5^{4-}$ anions in a single layer of (a) $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ and (b) $SrSb_2S_5 \cdot 0.15H_2O$ [28]. For clarity, the $Fe(en)_3^{2+}$ cations are omitted from the former. *Key* as for Fig. 3.

each is surrounded by discrete $Fe(en)_3^{2+}$ complexes in both the [1 0 0] and [0 1 0] directions. There are two crystallographically distinct iron cations, in which. the Fe–N distances range from 2.184(4) to 2.241(5) Å, while

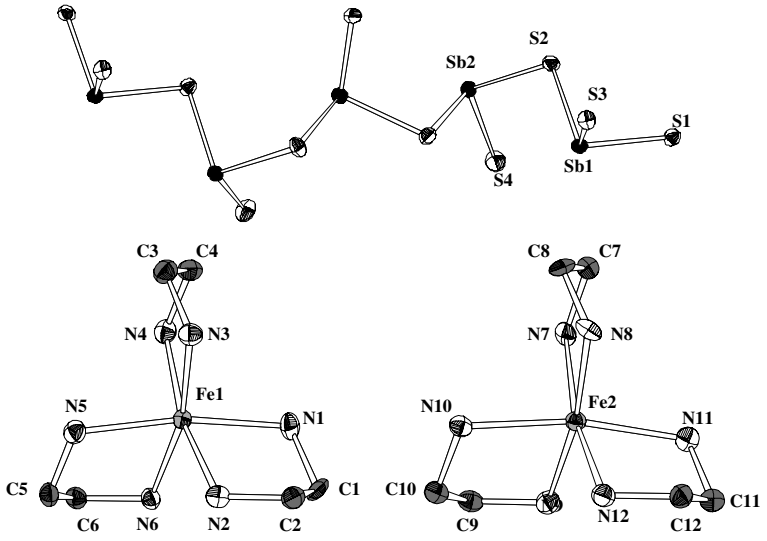

Fig. 6. Local coordination of the anions and cations in $[Fe(en)_3]_2Sb_4S_8$ (**2**) showing the atom labelling scheme and thermal ellipsoids at 50% probability (**2**). The second SbS_2^- chain containing Sb(3), Sb(4) and S(5)–S(8) has essentially the same atomic arrangement as the one shown. For each of the crystallographically distinct iron complexes, only one of the two conformations is shown.

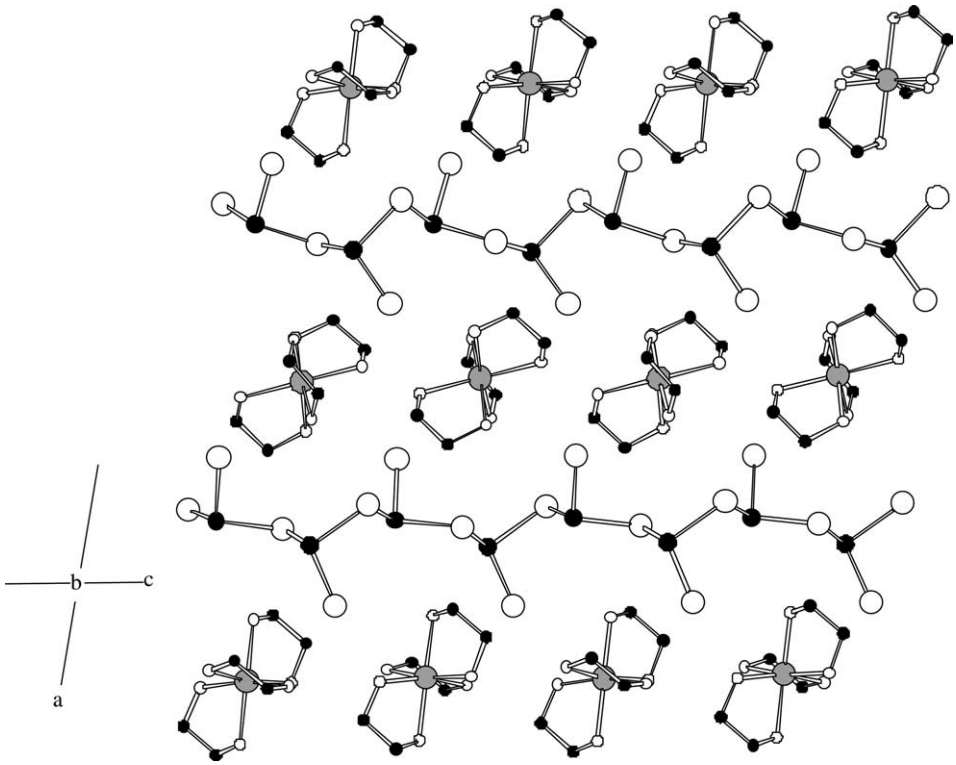

Fig. 7. View along [0 1 0] of the arrangement of SbS_2^- chains and $Fe(en)_3^{2+}$ cations in $[Fe(en)_3]_2Sb_4S_8$ (**2**). *Key* as for Fig. 3.

(*cis*) N–Fe–N angles lie between 78.9(2)° and 97.8(2)°. These are similar to the bond lengths and angles of the $[Fe(en)_3]^{2+}$ cations in $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (Table 2). Chains of Fe(1) or Fe(2) cations are directed along the *c*-axis, with neighbouring cations being related by the *c*-glide plane, thereby generating an alternating arrangement of complexes with Δ(λλλ) and Λ(δδδ) conformations, similar to that observed in $[Co(en)_3]Sb_2S_4$ [7]. Sulfur–nitrogen distances in the range of 3.32–3.50 Å, suggest an extensive network of hydrogen bonds between anions and cations.

In conclusion, we have succeeded in synthesising, in the presence of ethylenediamine, the new compound $[Fe(en)_3]_2Sb_2S_5 \cdot 0.55H_2O$ (**1**), which provides the first example of a thioantimonate(III) templated by a cationic transition-metal complex to contain discrete $Sb_2S_5^{4-}$ anions. This result is in marked contrast with previous reactions carried out in ethylenediamine, which usually generate $Sb_4S_7^{2-}$ chains. The isolation of the $Sb_2S_5^{4-}$ anion provides support for the growing belief that synthesis of thioantimonates under solvothermal conditions proceeds via relatively simple molecular building blocks. Further support for this view is provided by our observation that a relatively modest increase in reaction temperature produces, from the same reaction mixture, a product, $[Fe(en)_3]_2Sb_4S_8$ (**2**), in which the thioantimonate network may be considered to arise from the polymerisation of $Sb_2S_5^{4-}$ units to form infinite SbS_2^- chains.

4. Supplementary material

CCDC-245806 (**1**) and CCDC-245807 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or at www.ccdc.cam.ac.uk/conts/retrieving.html).

Acknowledgements

The authors acknowledge financial support for this work from the UK EPSRC and thank Dr A.R. Cowley, University of Oxford, for assistance in the collection of single-crystal X-ray diffraction data. A.M.C. also thanks The Leverhulme Trust for a Research Fellowship.

$Na_2SiO_3 \cdot 9H_2O$, 99% $Na_2WO_4 \cdot 2H_2O$, 99% $Na_2MoO_4 \cdot 2H_2O$, 99% 1,4-dioxane, 99.5% KCl, and 35–37% hydrochloric acid (Wako). Infrared absorption spectra were recorded as a KBr pellet on a JASCO FT/IR-460 spectrometer.

2.2. Preparation

0.73 g (3 mmol) of $Na_2MoO_4 \cdot 2H_2O$ was dissolved in 7 mL water, followed by the addition of 10 mL of 12 M HCl and 10 mL of 1,4-dioxane. To this solution, 2.45 g (1 mmol) of $Na_9SiW_9O_{34}H \cdot 23H_2O$ [15] and 1.49 g (20 mmol) of KCl in 10 mL water were added. Yellow plate crystals of the title compound precipitated after a day.

2.3. Crystal structure determination

$K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}] \cdot 9H_2O$ (formula weight 2929.10) crystallizes in orthorhombic, space group *Pnma* (no. 62) with $a = 20.4174(12)$ Å, $b = 15.3906(5)$ Å, $c = 12.9537(9)$ Å, $Z = 4$. A crystal with the dimension of $0.12 \times 0.12 \times 0.04$ mm was mounted on a Rigaku RAXIS RAPID imaging plate diffractometer with a rotating anode X-ray generator (Mo Kα radiation, $\lambda = 0.71069$ Å). Diffraction images were collected by the oscillation method at 93 K. A total of 33 507 reflections were indexed and integrated using PROCESS-AUTO [16], of which 4670 were unique ($R_{int} = 0.0704$). The effect of absorption was corrected by the numerical method [17] based on the crystal shape measured using a CCD camera [18]. The structure was solved by the direct method using SHELXS-97 [19] and refined by the full-matrix least-squares method on F^2 using SHELXL-97 [20]. The final agreement factors are $R_1 = 0.0348$ for 4483 reflections with $F_o^2 > 2\sigma(F_o^2)$ and $wR_2 = 0.0771$ for all reflections.

3. Results and discussion

The title compound, $K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}] \cdot 9H_2O$, crystallized in the isomorphous structure with $K_4[\beta\text{-}SiW_{12}O_{40}] \cdot 9H_2O$ [21] and $K_4[\beta_1\text{-}SiMoW_{11}O_{40}] \cdot 9H_2O$ [11]. The $[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]^{4-}$ anion exhibits the β-isomer [22] of the Keggin [8] structure and the arrangement of its nine W atoms conform to the A-type β-XM_9 geometry [23]. The anion consists of three MoW_2O_{13} units of edge-sharing one MoO_6 and two WO_6 octahedra and one W_3O_{13} unit of edge-sharing three WO_6 octahedra. The W_3O_{13} unit is rotated by 60° with respect to the α-Keggin structure. The three Mo atoms occupy the three metal positions at the opposite side of the β-junction, which is the same arrangement with the A-β-$[PMo_3W_9O_{40}]^{3-}$ anion in A-β-$[N(CH_3)_4]_3[PMo_3W_9O_{40}]$ [13] and A-β-$[N(C_4H_9)_4]_3[PMo_3W_9O_{40}]$ [14] and is rationally expected from the structure of the precursor, $Na_9SiW_9O_{34}H \cdot 23H_2O$ [24]. The $[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]^{4-}$ anion is located on the crystallographic mirror plane and thus the half of the anion is crystallographically independent. Fig. 1 illustrates the structure of the anion and the geometrical parameters are summarized in Table 1. Oxygen atoms are numbered as follows: O1–O7 for the terminal O atoms, O8–O14 for the μ_2-O atoms at the linkage of corner-shared octahedra, O15–O21 for the μ_2-O atoms at the linkage of edge-shared octahedra and O22–O24 for the μ_4-O atoms bridging three Mo/W atoms and the central Si atom.

In the $[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]^{4-}$ anion, the distances of the terminal W–O bonds [1.705–1.713 Å, average 1.709 Å] are longer by ca. 0.03 Å than those of the terminal Mo–O bonds [1.668 and 1.678 Å]. The distances to the μ_4-O atoms (O22–O24) that are *trans* to the terminal W/Mo–O bonds are in turn ca. 0.04 Å shorter for the W atoms [2.325–2.376 Å, average 2.338 Å] than for the Mo atoms [2.379 and 2.381 Å]. As for the doubly bridging oxygen atoms (O8–O21), no distinct differences are observed: 1.878–1.965 Å [average 1.919 Å] for Mo–μ_2-O and 1.891–1.954 Å [average 1.919 Å] for W–μ_2-O. The Mo···W distances for the edge-shared octahedra (those within the same MoW_2O_{13} units) are 3.351–3.384 Å [average 3.362 Å], which is slightly longer than the W···W distances for the edge-shared octahedra [3.301–3.346 Å, average 3.323 Å]. The W···W and W···Mo distances between two $(MoW)_3O_{13}$ units seem to be more strongly affected by the geometrical distortion upon forming the β-isomer [25] than the substitu-

Table 2
Comparison of the infrared absorption data between $K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]\cdot 9H_2O$ and $K_4[\beta\text{-}SiW_{12}O_{40}]\cdot 9H_2O$

Compound	ν (cm^{-1})	Ref.
$K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]\cdot 9H_2O$	1011(w), 979(s), 912(vs), 860(vw), 788(vs), 546(w), 520(m)	this work
$K_4[\beta\text{-}SiW_{12}O_{40}]\cdot 9H_2O$	1018(w), 984(s), 917(vs), 865(vw), 791(vs), 550(sh), 530(m), 510(sh)	[26]

tion with Mo: W···W distances at the β junction [3.656–3.660 Å, average 3.658 Å] are shorter than the other W···W and W···Mo distances [3.697–3.749 Å, average 3.721 Å].

The infrared absorption spectroscopic data of $K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]\cdot 9H_2O$ are listed in Table 2 together with those for $K_4[\beta\text{-}SiW_{12}O_{40}]\cdot 9H_2O$ cited from [26]. For the α-isomers, Rocchiccioli-Deltcheff et al. [27] reported that the vibrational frequencies for the terminal M–O stretching modes are lower for the molybdates than for the tungstates. The same tendency can be retrieved from the data of the β-isomers [26]. The shifts in the wavenumbers by changing from $K_4[\beta\text{-}SiW_{12}O_{40}]\cdot 9H_2O$ to $K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]\cdot 9H_2O$ are approximately 20–40% of those by changing from $[(n\text{-}C_4H_9)_4N]_4[\beta\text{-}SiW_{12}O_{40}]$ to $[(n\text{-}C_4H_9)_4N]_4[\beta\text{-}SiMo_{12}O_{40}]$ and from $[(n\text{-}C_4H_9)_4N]_4[\beta\text{-}GeW_{12}O_{40}]$ to $[(n\text{-}C_4H_9)_4N]_4[\beta\text{-}GeMo_{12}O_{40}]\cdot xH_2O$, reflecting the partial substitution of W with Mo.

4. Supplementary material

Crystallographic data for $K_4[A\text{-}\beta\text{-}SiMo_3W_9O_{40}]\cdot 9H_2O$ have been deposited with the Fachinformationszentrum Karlsruhe, CSD-No. 415281.

Acknowledgments

T.O. thanks CREST (Core Research for Evolutional Science and Technology), the Japanese Science and Technology Agency (JST) and the Japanese Society for the Promotion of Science (Grant-in-Aid for Scientific Research No. 15550047) for partial funding for this research.

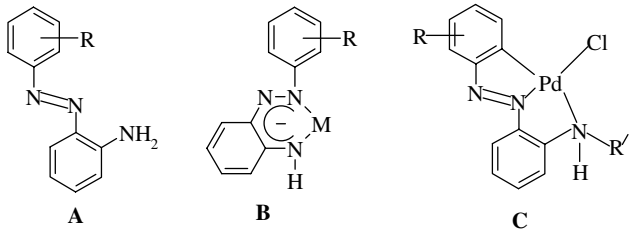

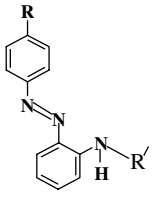

Chart 1.

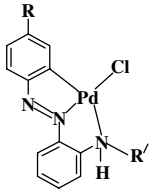
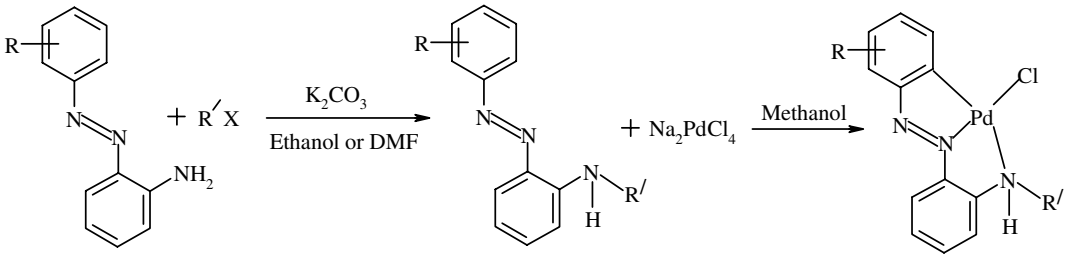
structure of one of the complexes has been determined to confirm the molecular structure. Weak unsupported dimers have been recognized in the crystal lattice.

2. Results and discussion



2.1. Syntheses

The orange coloured 2-arylazo-1*N*-alkyl aniline, **1a**–**11a** (Chart 2) ligands were prepared by refluxing 2-(arylazo) anilines with the appropriate alkyl halide in ethanol or DMF in the presence of potassium carbonate (Scheme 1). The product formations were monitored on a TLC plate. Eleven ligands were prepared by modifying R′ and R as given in Chart 2. The R′ substituents were chosen on the basis of increasing chain length (H_3C–, H_5C_2–, $H_{17}C_8$–,) and varying the probable binding sites (CH_2=CH–CH_2–, 2-$MeOC_6H_4CH_2$–, $C_6H_5CH_2$–, EtO_2CCH_2–). Reaction of **1a**–**11a** with sodium tetrachloropalladate in methanol at room temperature afforded brown coloured complexes of composition **1b**–**11b** (Scheme 1) as shown in (Chart 1). The orthopalladated complexes are formed upon substitution of the *ortho* aryl proton from the azobenzene fragment of the ligand precursors **1a**–**11a**. Eleven orthopalladated complexes were prepared, where the binding modes (C,N,N) of the ligands were identical (^{1}H NMR and X-ray, see below), unlike 2-(arylazo) aniline [6]. One of the important observations is the coordination of the secondary amino nitrogen without dissociating the proton. In the case of other azoamine ligands, the secondary amino groups bind the metals only when the amino proton gets dissociated [7]. Thus the complexes, **1b**–**11b**, are the first family of orthopalladated azoamine molecules. The formation of a metal–carbon bond has been presumed to occur as a result of prior binding with a suitable hetero donor atom fulfilling the electronic criteria and appropriate geometry about the metal with respect to the *ortho* carbon atom.



Ligand

Ligand	R	R′	Complex
1a	H	CH_3	**1b**
2a	CH_3	CH_3	**2b**
3a	H	C_2H_5	**3b**
4a	CH_3	C_2H_5	**4b**
5a	CH_3	C_8H_{17}	**5b**
6a	CH_3	CH_2CHCH_2	**6b**
7a	CH_3	2-$MeOC_6H_4CH_2$	**7b**
8a	H	CH_2Ph	**8b**
9a	CH_3	CH_2Ph	**9b**
10a	Cl	CH_2Ph	**10b**
11a	CH_3	$CH_2CO_2C_2H_5$	**11b**

Complex

Chart 2.

Scheme 1.

2.2. Characterisation

The ligands, **1a**–**11a**, and the corresponding orthopalladated complexes, **1b**–**11b**, exhibit characteristic UV–Vis spectra. Representative spectra for **9a** and **9b** have been shown in Fig. 1. It is interesting to observe that the UV–Vis spectra of all the brown orthopalladated complexes are similar, with a low energy split band in the range 490–470 nm and a structured band within the range 410–360 nm. The spectral data for all the ligands and complexes are collected in Table 1.

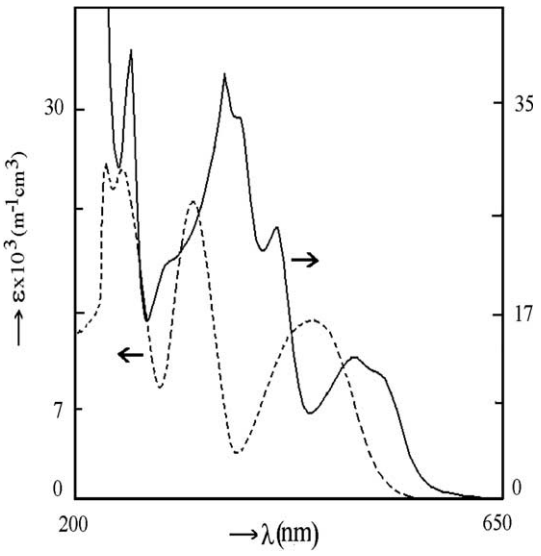


Fig. 1. UV–Vis spectra of **9a** (---) and **9b** (—). The arrows indicate scales of the corresponding spectra.

The ligands, **1a**–**11a**, displayed a ν_{N-H} absorption as a single band in the range of 3488–3413 cm^{-1}, whereas for the complexes **1b**–**11b**, the ν_{N-H} band appeared within the range 3283–3071 cm^{-1} in the IR spectra. The $\nu_{N=N}$ band (1518–1506 cm^{-1}) of all the ligands shifted to lower frequency (1394–1383 cm^{-1}) in the complexes, consistent with coordination of the azo nitrogen. The ν_{Pd-Cl} absorption of the palladium complexes was observed in the range 296–288 cm^{-1}. The spectral data for all the ligands and complexes are collected in Table 1.

The ^1H NMR spectra of all the ligands and complexes were recorded. The spectra are consistent with the composition and structure. However, to avoid unnecessary inclusion, we have tabulated only the data for the complexes in Table 2. The ^1H NMR data of the ligands are given in Table 3.

Some important features of the ^1H NMR spectra that occur upon palladation are as follows: (i) The N–H resonance of the ligands (δ 9.58–8.60) is shifted to upfield (δ 8.12–6.38) in the complexes; (ii) The aromatic proton count of the complexes is one less than that of the ligands indicating orthometallation. Further, the complexes where R is Me display a singlet within the range (δ 7.29–6.61) in the aromatic region, consistent with the orthometallation. (iii) The equivalent methylene protons

11b[d]	6.82(s, 1H), 6.83(d, 1H), 7.23(t, 1H), 7.45–7.51(m, 3H) 7.55(d, 1H)	1.22(t, 3H), 4.20(m, 2H), 4.22(d, 1H), 4.40(d, 1H)	2.06(s, 3H)	6.73(b, 1H)

[a] In ppm.
[b] X = multiplicity (m = multiplet, s = singlet, d = doublet, t = triplet, b = broad), *n* = proton count.
[c] In DMSO-d_6.
[d] In $CDCl_3$.

(N–CH_2–) of R′ in the ligands become inequivalent in the complexes (excepting R′ = CH_2Ph), diagnostic for binding of the amino nitrogen. All of these features have been shown in Fig. 2, in representative spectra for **6a** and **6b**. (iv) The N–H proton resonance of the metal complexes vanishes upon shaking with D_2O, confirming its non-dissociation upon coordination.

2.3. X-ray structure

The suitable crystals of **9b** were grown by slow diffusion of hexane into a dichloromethane solution. The crystals are triclinic and the space group is $P\bar{1}$. A perspective view with the atom numbering scheme is given in Fig. 3. Selected bond distances and angles are collected in Table 4.

The asymmetric unit of **9b** contains two molecules, which are held as a weak dimer with a non-covalent Pd···Pd interaction. The geometry and bond parameters are similar in the two molecules. The molecular structure of each monomer molecule exhibits a distorted square planar geometry about the palladium, where the anionic ligand (**9a**)$^-$ binds the metal in a tridentate (C,N,N) fashion. A chloride ligand completes the tetracoordination about Pd(II). The Pd–Cl and Pd–N(azo) distances (2.312(2) and 1.943(4) Å, respectively), are within the normal range [7b]. The Pd–C bond length (1.986(5) Å) is also matched well with the Pd–C lengths

Table 3
^{1}H NMR spectra of the ligands, **1a**–**11a**

Compound	δ[a] (X, *n*H)[b]			
	Aromatic protons	Non-aromatic protons	*p*-CH_3	N–H

11a[c]	6.63(d, 1H), 6.86(t, 1H), 7.28(m, 3H), 7.81–7.90(m, 3H)	1.25–1.36(m, 3H), 4.08(s, 2H), 4.28–4.32(m, 2H)	2.42(s, 3H)	8.93(b, 1H)

[a] In ppm.
[b] X = multiplicity (m = multiplet, s = singlet, d = doublet, t = triplet, b = broad), *n* = proton count.
[c] In $CDCl_3$.

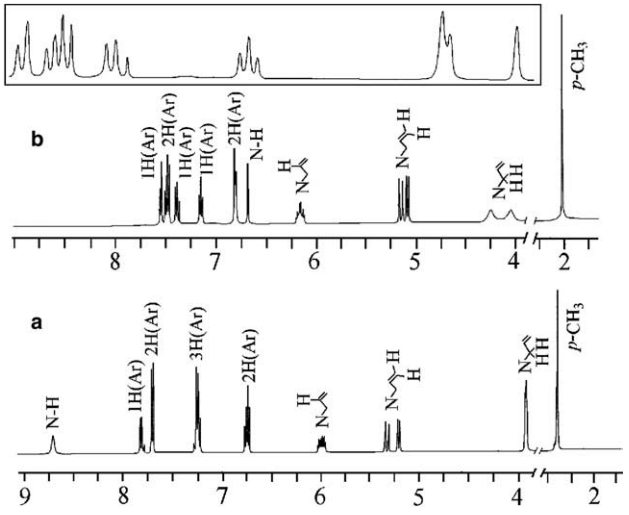

Fig. 2. The ^{1}H NMR spectra of (a) **6a** and (b) **6b** in $CDCl_3$, where *n* of *n*H(Ar) stands for the proton count. The expansion of the aromatic region (δ 6.81–7.54) of **6b** has been shown in the inset.

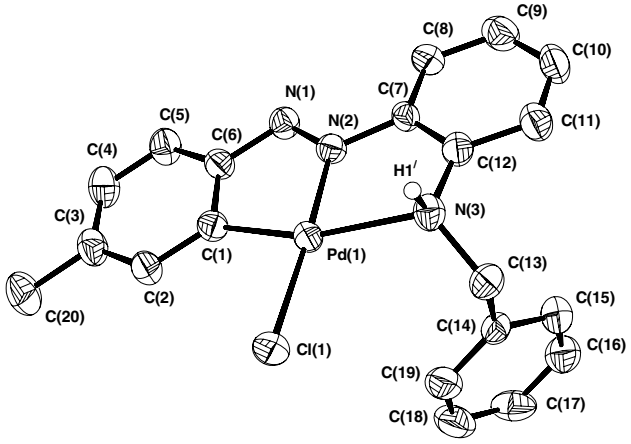

Fig. 3. Perspective view of **9b** with the atom numbering scheme. Hydrogen atoms excepting on N3 are omitted for clarity.

in other orthopalladated azo benzene complexes [8]. The Pd–N(amine) bond length (2.194(1) Å) is much longer than the Pd–N(azo) distance, presumably as a consequence of the stronger *trans* influence of the aryl carbon [9]. The N(3)–Pd–C(1) (161.17(19)°) and N(2)–Pd–Cl (177.06(13)°) bond angles deviate a little from linearity. The chelate ring bite angles are also considerably smaller [N(2)–Pd–N(3), 81.75(17)°; N(2)–Pd–C(1), 79.5(2)°] than the ideal values (90°) of a square geometry, although the atoms within the coordination sphere lie on a plane (mean deviation 0.01 Å). In fact the whole molecule, excepting the benzyl group, is planar (mean deviation 0.05 Å).

Table 4
Selected bond distances (Å) and angles (°) for **9b**

Pd(1)–C(1)	1.986(1)
Pd(1)–N(2)	1.942(1)
Pd(1)–N(3)	2.194(1)
Pd(1)–Cl(1)	2.312(2)
N(1)–C(6)	1.399(1)
N(1)–N(2)	1.266(1)
N(2)–C(7)	1.431(1)
C(7)–C(12)	1.391(1)
C(1)–C(6)	1.413(1)
N(3)–C(12)	1.465(1)
N(2)–Pd(1)–C(1)	79.5(2)
N(2)–Pd(1)–N(3)	81.7(2)
C(1)–Pd(1)–N(3)	161.1(2)
N(2)–Pd(1)–Cl(1)	177.0(1)
C(1)–Pd(1)–Cl(1)	97.9(2)
N(3)–Pd(1)–Cl(1)	100.7(1)
C(12)–N(3)–Pd(1)	106.2(3)

The dimer contained in the asymmetric unit, is held in a staggered conformation (dihedral angle is 60°) with three non-bonding inter-monomeric interactions, Pd···Pd, 3.301 Å; N(amine)···Cl, 3.256 Å and N(amine)···Pd, 3.635 Å. The dimeric unit with the non-bonding interactions is shown in Fig. 4.

However, in the packing of the molecule, no infinite stacking has been observed, where the discrete dimers are arranged in a regular pattern in the crystal lattice. A partial packing diagram has been shown in Fig. 5.

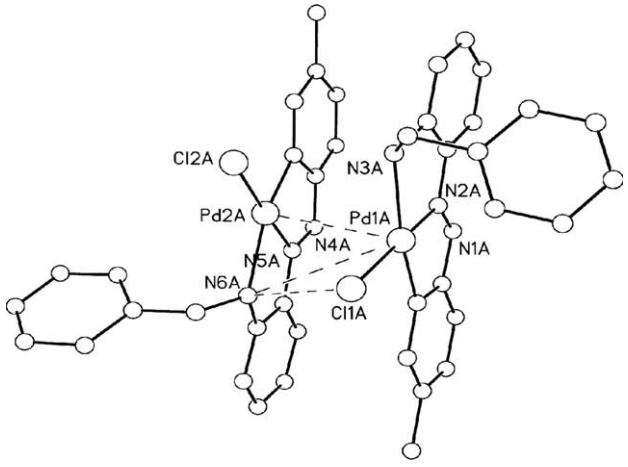

Fig. 4. A view of the dimeric unit of **9b**. The broken lines indicate the weak interactions.

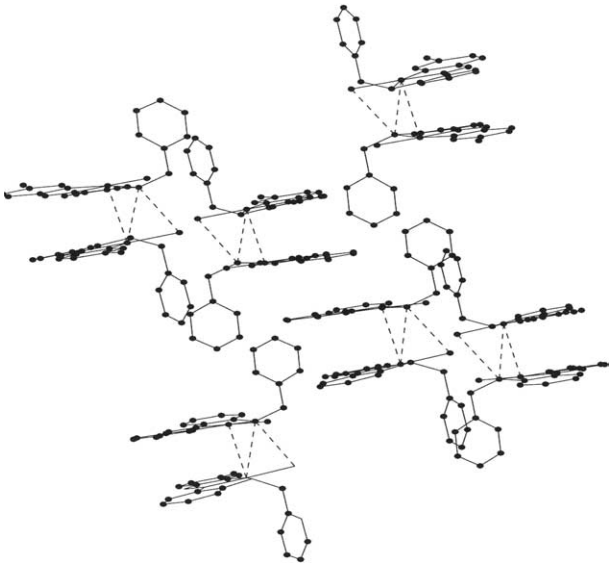

Fig. 5. Partial packing diagram of complex **9b** along the *c*-axis.

3. Experimental

3.1. Materials

The solvents used in the reactions were of reagent grade obtained from E. Merck, Kolkata, India, and were purified and dried by reported procedures [6]. The 2-(arylazo) anilines were prepared according to a reported procedure [6]. Palladium chloride, benzyl chloride, methyl iodide, ethyl bromide and potassium carbonate were purchased from E. Merck, Kolkata, India. Allyl chloride, ethyl chloroacetate, *n*-bromooctane and *o*-cresol were purchased from SRL, Mumbay, India. Disodium tetrachloropalladate was prepared by a reported procedure [6].

3.2. Syntheses of ligands

3.2.1. *1a* and *2a*

To prepare the ligands **1a** and **2a**, methyl iodide (0.095 cm^3, 1.52 mmol) was refluxed for 2 h with 2-(phenylazo) aniline (0.3 g, 1.52 mmol) and 2-(*p*-tolylazo) aniline (0.32 g, 1.52 mmol), respectively, in 30 cm^3 ethanol in the presence of 1 g of K_2CO_3. From the orange solid mass that was obtained after evaporation of ethanol, the ligands **1a** and **2a** were isolated by column chromatography on silica gel (60–120 mesh). The eluent was petroleum ether. Upon evaporation of the solvent, the orange-red semi-solid of pure ligand was obtained. Yield: **1a**, 65%; **2a**, 70%. *Anal*. Calc. for $C_{13}H_{13}N_3$, **1a**: C, 73.93; H, 6.16; N, 19.90. Found: C, 73.90; H, 6.10; N, 19.85%. Calc. for $C_{14}H_{15}N_3$, **2a**: C, 74.66; H, 6.66; N, 18.66. Found: C, 74.61; H, 6.68; N, 18.62%.

3.2.2. *3a* and *4a*

The ligands **3a** and **4a** were prepared following the same procedure as described in the case of **1a** and **2a** using ethyl bromide (0.114 cm^3, 1.52 mmol) in place of methyl iodide. The refluxing time was 4 h. Yield **3a**, 50%; **4a**, 65%. *Anal*. Calc. for $C_{14}H_{15}N_3$, **3a**: C, 74.66; H, 6.66; N, 18.66. Found: C, 74.63; H, 6.65; N, 17.05%. *Anal*. Calc. for $C_{15}H_{17}N_3$, **4a**: C, 75.31; H, 7.11; N, 17.57. Found: C, 75.27; H, 7.10; N, 17.53%.

3.2.3. *5a, 6a and 7a*

5a, **6a** and **7a** were prepared by refluxing 2-(*p*-tolylazo) aniline (0.32 g, 1.52 mmol) with *n*-bromooctane (0.264 cm^3, 1.52 mmol), allyl chloride (0.125 cm^3, 1.52 mmol) and 2-bromomethyl anisole (0.305 g, 1.52 mmol), respectively, in 30 cm^3 ethanol in the presence of 1 g of $K_2CO_3$for 4 h. The ligands were purified by the same procedure as described above. Yield: **5a**, 65%; **6a**, 65%; **7a**, 65%. *Anal.* Calc. for $C_{21}H_{29}N_3$, **5a**: C, 78.01; H, 8.97; N, 13.00. Found: C, 78.00; H, 8.91; N, 13.07%. *Anal*. Calc. for $C_{16}H_{17}N_3$, **6a**: C, 76.49; H, 6.77; N, 16.73. Found: C, 76.45; H, 6.75; N, 16.75%. *Anal*. Calc. for $C_{21}H_{21}N_3O$, **7a**: C, 76.13; H, 6.34; N, 12.69. Found: C, 76.10; H, 6.30; N, 12.70%.

3.2.4. *8a, 9a and 10a*

8a, **9a** and **10a** ligands were prepared by refluxing benzyl chloride (0.193 cm^3, 1.52 mmol) with 2-(phenylazo) aniline (0.3 g, 1.52 mmol), 2-(*p*-tolylazo) aniline (0.32 g, 1.52 mmol) and 2-(*p*-chlorophenylazo) aniline (0.352 g, 1.52 mmol), respectively, in 30 cm^3 ethanol and 1 g of K_2CO_3 for 4 h. The ligands were purified by the same procedure as described above. Yield: **8a**, 50%; **9a**, 65%; **10a**, 50%. *Anal*. Calc. for $C_{19}H_{17}N_3$, **8a**: C, 79.44; H, 5.97; N, 14.63. Found: C, 79.70; H, 6.10; N, 14.55%. *Anal*. Calc. for $C_{20}H_{19}N_3$, **9a**: C, 79.69; H, 6.36; N, 13.95. Found: C, 79.70; H, 6.40; N, 13.97%. *Anal*. Calc. for $C_{19}H_{16}N_3Cl$, **10a**: C, 70.90; H, 5.00; N, 13.00. Found: C, 70.70; H, 5.30; N, 13.40%.

3.2.5. *11a*

2-(*p*-Tolylazo) aniline (0.32 g, 1.52 mmol) was mixed with ethyl chloroacetate (0.185 cm^3, 1.52 mmol) in 30 cm^3 DMF. 1 g of K_2CO_3 was added to this mixture and which was then refluxed for 4 h. From the orange solid mass that was obtained after evaporation of DMF, the ligand **11a** was isolated by column chromatography on silica gel (60–120 mesh). The eluent was petroleum ether. Upon evaporation of solvent the orange-red semi-solid of pure ligand was obtained. Yield: 65%. *Anal.* Calc. for $C_{17}H_{19}N_3O_2$, **11a**: C, 68.68; H, 6.39; N, 14.14. Found: C, 68.65; H, 6.40; N, 14.10%.

3.3. Syntheses of complexes

3.3.1. *1b*

A solution of **1a** (0.110 g, 0.52 mmol) in 10 cm^3 methanol was added to a solution of Na_2PdCl_4 (0.150 g, 0.52 mmol) in 5 cm^3 methanol. The mixture was stirred for 8 h. The dark solid precipitate was separated by filtration and purified by column chromatography using silica gel (60–120 mesh). The eluent was toluene-acetonitrile mixed solvent (90/10 v/v) and upon evaporation of the solvent, dark red solid **1b** was obtained. Yield: 55%. *Anal*. Calc. for $C_{13}H_{12}N_3PdCl$: C, 44.32; H, 3.40; N, 11.93. Found: C, 44.29; H, 3.35; N, 11.40%.

3.3.2. *2b–11b*

The complexes **2b**–**11b** were prepared following a similar procedure as described in the case of **1b**, but the durations of the reactions were different. These are 8 h for **2b**–**4b**, 6 h for **5b**, 7 h for **6b**, 15 h for **7b**, 5 h for **8b**–**10b** and 15 h for **11b**.

Yield: **2b**, 60%; **3b**, 40%; **4b**, 60%; **5b**, 60%; **6b**, 50%; **7b**, 45%; **8b**, 60%; **9b**, 70%; **10b**, 30%; **11b**, 30%. *Anal*. Calc. for $C_{14}H_{14}N_3PdCl$, **2b**: C, 45.91; H, 3.82; N, 11.47. Found: C, 45.90; H, 3.85; N, 11.95%. *Anal*. Calc. for $C_{14}H_{14}N_3PdCl$, **3b**: C, 45.91; H, 3.82; N, 11.47. Found: C, 45.87; H, 3.80; N, 11.45%. *Anal*. Calc. for $C_{15}H_{16}N_3PdCl$, **4b**: C, 47.37; H, 4.21; N, 11.05. Found: C, 47.35; H, 4.15; N, 11.00%. *Anal*. 3.4. Physical measurements

Microanalyses (C,H,N) were performed using a Perkin–Elmer 240C elemental analyzer. Infrared spectra were recorded on a Perkin–Elmer L120-00A FT-IR spectrometer with the samples prepared in KBr pellets. Electronic spectra were recorded on a Shimadzu UV-2401 PC spectrophotometer. ^1H NMR spectra were obtained on Brucker AC-200, Brucker Avance DPX 300, Brucker Avance DPX 400 and Brucker Avance RPX 500 NMR spectrometers in $CDCl_3$, DMSO-d_6, D_2O using TMS as the internal standard.

3.5. Crystallography

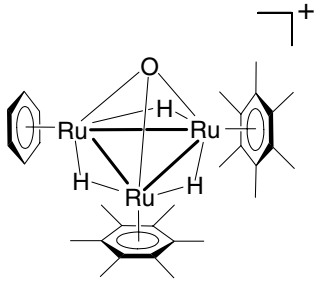
Data of **9b** was collected by the ω-scan technique on a Nicolet R3m/v diffractometer with Mo Kα radiation monochromated by a graphite crystal. The structure solution was done by direct methods with the SHELXS-97 program. Full-matrix least-squares refinements were performed using the SHELX-97 program (PC version). All non-hydrogen atoms were refined anisotropically using reflections $I > 2\sigma(I)$. Hydrogen atoms were included at calculated positions. The crystal data and data collection parameters are listed in Table 5.

Table 5
Crystallographic data for **9b**

Chemical formula	$C_{20}H_{18}ClN_3Pd$
Formula weight	442.22
Space group	$P\bar{1}$
Crystal system	triclinic
a (Å)	10.802(5)
b (Å)	13.159(5)
c (Å)	14.397(8)
α (°)	102.17(3)
β (°)	110.25(4)
γ (°)	98.65(4)
λ (Å)	0.71073
V (Å^3)	1820.2(15)
Z	4
Temperature (K)	293(2)
ρ_{cald} (Mg/m^3)	1.614
μ (mm^{-1})	1.173
$F(000)$	888
R(all data)	$R_1 = 0.0730$, $wR_2 = 0.1080$
Unique reflections/$[I > 2\sigma(I)]$	6770/6400 [$R_{int} = 0.0277$]
R_1[a]/GOF[b]	0.0419/1.065
wR_2[c] $[I > 2\sigma(I)]$	0.0969

[a] Observation criterion: $I > 2\sigma(I)$. $R_1 = \sum \|F_o| - |F_o\| / \sum |F_o|$.
[b] GOF $= [\sum [w(F_o^2 - F_c^2)^2]/(n-p)]^{1/2}$.
[c] $wR_2 = [\sum [w(F_o^2 - F_c^2)^2] / \sum [w(F_o^2)^2]]^{1/2}$, where $w = 1/\sigma^2(F_o^2) + (aP)^2 + bP$, $P = (F_o^2 + 2F_c^2)/3$.

4. Supplementary data



Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Reference Number 212758. Copies of this information may be obtained free from the Director, CCDC, 12 Union Road, Cambridge CB2 1EW, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.com.ac.uk).

1

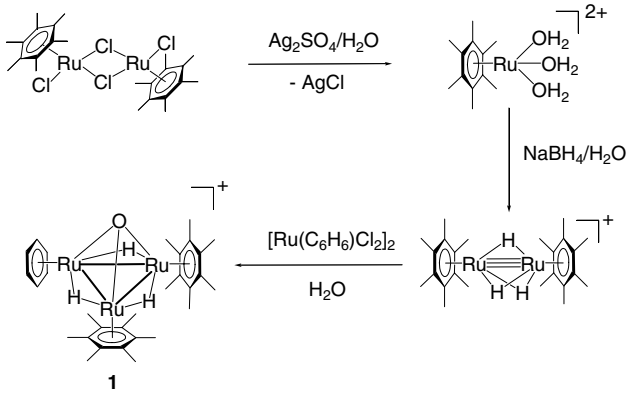
However, for *benzene* hydrogenation catalysis derived from organometallic precatalysts the true nature of the catalytic species has remained a debatable point (''is it homogeneous or heterogeneous catalysis?'') [4]. In the case of the putative homogeneous $[(C_8H_{17})_3Me][RhCl_4]$ ion pair catalyst [5], Finke and co-workers [6] were able to demonstrate that rhodium(0) nanoclusters are the true catalysts (''soluble analogs of heterogeneous catalysts''). Benzene and other arene hydrogenation catalysts have been reviewed recently by Finke [7] and by Dyson [8], and the question of the true nature of the catalytic species in arene hydrogenation catalysis beginning with soluble metal complexes has been critically addressed by Finke et al. [9].

Prior to addressing the ''is it homogeneous or heterogeneous catalysis?'' question for benzene hydrogenation beginning with [**1**][BF_4] [9,10], it proved necessary to develop an improved synthesis for the quantities of **1** that were required, since it is difficult to obtain pure [**1**][BF_4] by crystallization according to the original procedure [1]. In addition, we decided to study the redox properties and the ligand exchange processes of this cluster in detail. It is these topics that are the focus of the present paper.

Elsewhere we report our collaborative kinetic studies of the benzene hydrogenation catalyzed by **1**, transmission electron microscopy studies of the reaction mixture and high-pressure in situ NMR measurements of the reaction of **1** with H_2 in D_2O, results which rule out **1** as the true catalyst. Instead, Ru(0) nanoparticles formed in small quantities from **1** under hydrogen pressure are implicated as the true catalytically active species [11]. The development of an improved synthesis of **1** was crucial to those as well as future studies of **1**, a synthesis which is reported as part of what follows.

2. Results and discussion

2.1. Improved synthesis of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)][BF_4]$ ([1][BF_4])



The well-known mononuclear triaqua complex $[Ru(C_6H_6)(H_2O)_3]^{2+}$ [12], formed in situ from the chloro-bridged precursor $[Ru(C_6H_6)Cl_2]_2$ [13] in aqueous solution, reacts with the electron-deficient dinuclear trihydrido complex $[H_3Ru_2(C_6Me_6)_2]^+$ [14] to give the trinuclear cluster cation $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ (**1**), isolated as tetrafluoroborate salt. Herein, we report an improved synthesis and purification of [**1**][BF_4] based on chromatographic methods. The steps of the synthesis are summarised in Scheme 1.

Key modifications of the original procedure are: (i) the slow (dropwise) addition of the aqueous $NaBH_4$ solution via an oxygen-free cannula with cooling to 10 °C in order to avoid foaming; and (ii) purification of the [**1**][BF_4] precipitate by preparative thin-layer chromatography on silica-gel using a dichloromethane–acetone mixture (2:1) as eluant to remove $NaBF_4$, by-products and other contaminats. The details are given in Section 4.

2.2. Aerobic oxidation of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ (1) to $[H_2Ru_3(C_6H_6)(C_6Me_6)_2(O)(OH)]^+$ (2)

Exposure of an aqueous solution of [**1**][BF_4] to air gives the oxidised cluster $[H_2Ru_3(C_6H_6)(C_6Me_6)_2(O)(OH)]^+$ (**2**), although **1** is not noticeably air-sensitive in its solid form. This reaction is best carried out in aqueous solution under atmospheric pressure of air, the complete conversion of **1** into **2** taking about 4 days. An NMR study of the conversion of **1** into **2**, carried out at 27 °C in D_2O solution with approximately 10 equivalents of O_2 (with respect to **1**), shows no indication of any detectable intermediary species. On the other hand, under hydrogen pressure (60 bars) at 110 °C, **2** converts back quantitatively into **1** within 2 h (see Fig. 1).

The reversible transformation of **1** into **2** in aqueous solution suggests interesting redox properties of these clusters. Hence, these were studied by electrochemical methods as detailed in the next section.

1

Scheme 1.

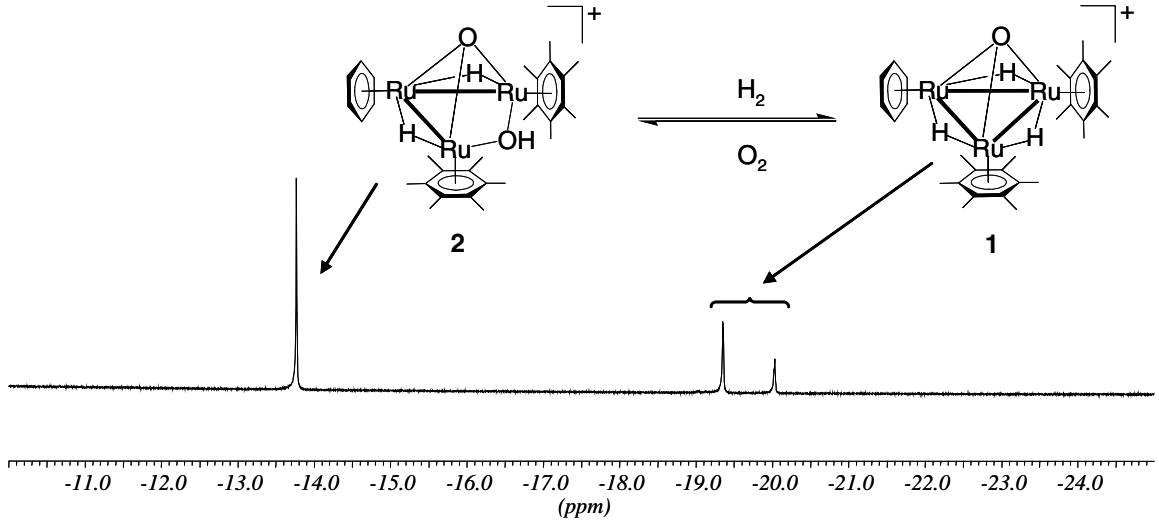


Fig. 1. Conversion of **2** into **1** with molecular hydrogen and the conversion of **1** back into **2** with 0.5 equivalent of molecular oxygen. The ^{1}H NMR spectrum shows a D_2O solution of both **1** and **2**. (The enlargement reveals the hydride signal of **2** being a singlet at $\delta = -13.77$ ppm, while the hydride signals of **1** show the expected multiplicities [$\delta = -19.35$ ppm (doublet) and $\delta = -20.03$ ppm (triplet)] in a 2:1 integral ratio).

2.3. Electrochemical properties of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ (1) and $[H_2Ru_3(C_6H_6)(C_6Me_6)_2(O)(OH)]^+$ (2)

Cyclic voltammetry (scan rate 0.1 V s^{-1}) of **1** (Fig. 2) in a deoxygenated solution of acetonitrile shows, in the potential range 0 to +1.5 V versus SCE, three successive anodic peaks ($E_{pa_1} = +0.52$ V versus SCE; $E_{pa_2} = +0.90$ V versus SCE; $E_{pa_3} = +1.29$ V versus SCE). Only the first one corresponds to a chemically and electrochemically reversible system ($E_{pa_1} = +0.52$ V versus SCE; $E_{pc_1} = +0.45$ V versus SCE). The same behaviour was observed at a glassy carbon or a platinum electrode using either 0.1 M $LiClO_4$ or 0.1 M $BuNClO_4$ containing H_2O (10%), as electrolyte.

Complex **2** in acetonitrile is irreversibly oxidised at a potential (+0.46 V versus SCE) close to **1** (Fig. 3). Consequently, the anodic oxidation of **1** cannot give **2** as final product. Other ill-defined irreversible waves are observed at higher potential. Moreover, **1** and **2** are not reduced in the potential range 0 to −2 V versus SCE.

Bulk electrolysis at a working potential corresponding to the plateau of the first anodic wave (+0.6 V versus SCE) of **1** and **2** in deoxygenated acetonitrile both involve about 2–3 F per mol. Electrolysis of **1** was monitored by voltammetry at a platinum rotating disc

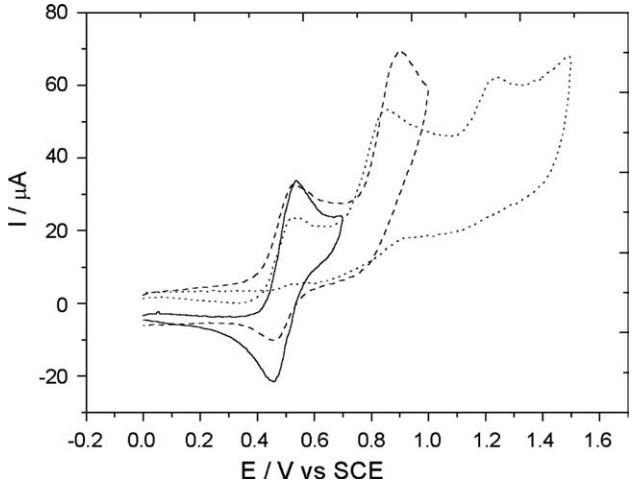

Fig. 2. Cyclic voltammetry of a saturated solution of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)][BF_4]$ in acetonitrile +0.1 M Bu_4NClO_4 at a glassy carbon electrode, by varying the potential from 0 V_{SCE} to 0.7 V_{SCE} (——), 1 V_{SCE} (----) and 1.5 V_{SCE} (···). Scan rate: 0.1 V s^{-1}.

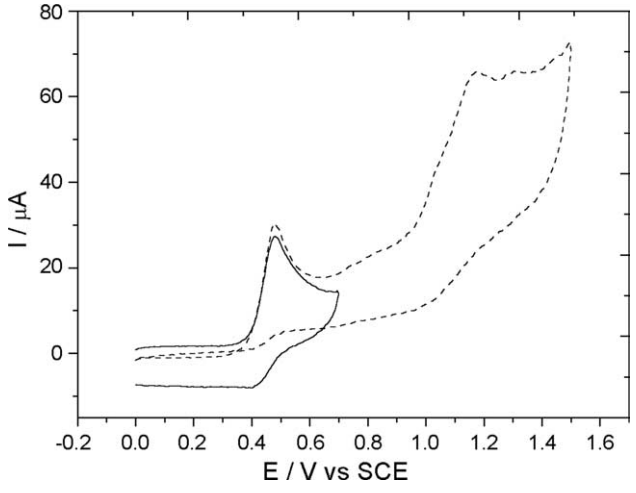

Fig. 3. Cyclic voltammetry of a saturated solution of $[H_2Ru_3(C_6H_6)(C_6Me_6)_2(O)(OH)][BF_4]$ (3×10^{-3} mol L^{-1}) in acetonitrile +0.1 M Bu_4NClO_4 at a glassy carbon electrode, by varying the potential from 0 V_{SCE} to 0.7 V_{SCE} (—) and 1.5 V_{SCE} (----). Scan rate: 0.1 V s^{-1}.

electrode. The first anodic wave ($E_{1/2} = +0.48$ V versus SCE) decreased during electrolysis without the appearance of the expected reversible cathodic wave observed by cyclic voltammetry of **1**. A transient cathodic wave ($E_{1/2} = -0.03$ V versus SCE) which totally disappeared at the end of electrolysis was observed.

Thus, under the time scale of a macroscale electrolysis, the product resulting from the anodic oxidation of **1** is not stable enough to be isolated. After work up, $[(C_6Me_6)_2Ru_2(OH)_3]^+$ was identified from the mixture of decomposition products. After electrolysis of **2**, $[(C_6Me_6)_2Ru_2(OH)_3]^+$ was also identified from the mixture of isolated products by electrospray mass spectrometry of the acetone extract.

In summary, the redox behaviour of **1** and **2** is more complicated than it appears from the reversible aerobic oxidation of **1**–**2** in aqueous solution: under electrochemical conditions and in the absence of H^+, **1** and **2** surprisingly do not interconvert.

2.4. Ligand exchange studies

The catalytic activity of **1** for the hydrogenation of arenes evokes the question whether or not the arene and/or hydrido ligands in **1** are involved in the catalytic process. This is why we studied ligand exchange reactions of **1** with arenes, with molecular hydrogen and with water.

Previously we observed that the hydrogenation of hexadeutero-benzene, C_6D_6, catalysed by $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ (**1**) under biphasic conditions (catalyst/substrate ratio 1:1000, 110 °C, 60 bar) yields the expected 1,2,3,4,5,6-hexadeuterocyclohexane, while cluster **1** still contains one C_6H_6 and two C_6Me_6 ligands (and no coordinated C_6D_6) after the catalytic reaction, according to NMR and MS data [15]. It was of interest, therefore, to study the exchange reactions of **1** with other arenes: in the case of toluene hydrogenation (catalyst/substrate ratio 1:1000, 110 °C, 60 bar), exchange of the benzene ligand for a toluene molecule is indeed observed. While the ^1H NMR spectrum of the organometallic residue of the aqueous phase dissolved in D_2O showed only the expected signals of **1**, the electrospray mass spectrum of the organometallic residue revealed a small amount of the toluene-exchanged cluster $[H_3Ru_3(C_6H_5Me)(C_6Me_6)_2(O)]^+$ (**3**). Given that this cluster is not visible in the NMR spectrum, we estimate its presence to less than 5%. The same exchange (less than 5%) takes place by heating a mixture of toluene with an aqueous solution of **1** (1000:1) for 2 h to 110 °C without hydrogen pressure. However, in all cases the extent of the arene exchange in **1** is <5%.

High-pressure in situ NMR measurements of the reaction of **1** with D_2 in D_2O and of the deuterated derivative $[D_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ (**1a**) with H_2 in H_2O were performed in order to study the possible H/D and D/H exchange reactions affecting hydrido and deuterido ligands, respectively (Eqs. (1) and (2)).

$$\underset{\mathbf{1}}{[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+} \xrightarrow[D_2O]{D_2} \underset{\mathbf{1a}}{[D_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+} \quad (1)$$

$$\underset{\mathbf{1a}}{[D_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+} \xrightarrow[H_2O]{H_2} \underset{\mathbf{1}}{[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+} \quad (2)$$

Under a pressure of 50 bar of D_2 (or H_2, respectively) we observed complete H/D exchange according to Eqs. (1) and (2) at 90 °C over a period of 6 h (Fig. 4). The exchange reaction does not take place at temperatures below 80 °C, however. As shown in Fig. 4, partially deuterated derivatives $[H_2DRu_3(C_6H_6)(C_6Me_6)_2(O)]^+$ and $[HD_2Ru_3(C_6H_6)(C_6Me_6)_2(O)]^+$ are not observed, at least not in concentrations detectable by NMR.

Hydrogen (or deuterium) pressure is required for the H/D exchange process: an NMR study of **1** in D_2O without D_2 (or **1a** in H_2O without H_2) reveals that the hydride signals of the cluster remain unchanged even

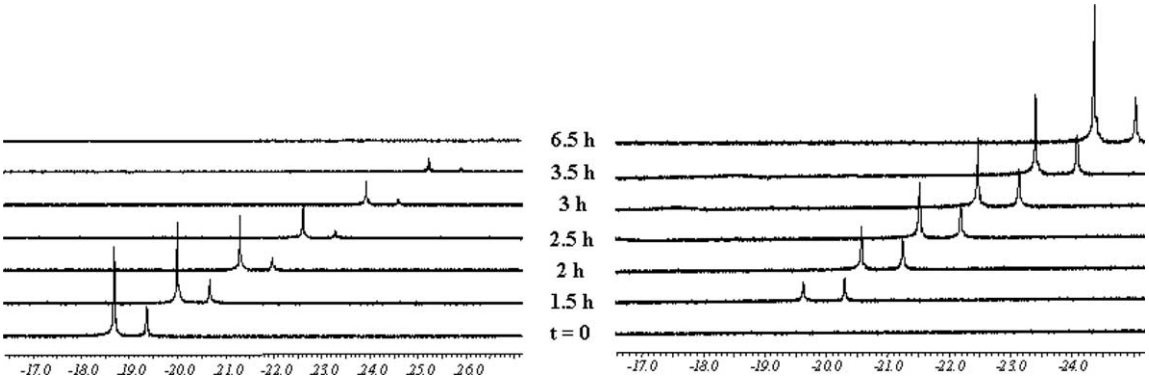

Fig. 4. NMR spectra showing H/D exchange reaction affecting hydrido ligands in **1** (on the left) and D/H exchange reaction affecting deuterido ligands in **1a** at 90 °C under 50 bar of D_2 in D_2O and 50 bar of H_2 in H_2O, respectively.

at 90 °C over a period of 24 h. That is, there is no exchange of the hydrido ligands in **1** with water even at 90 °C.

3. Summary

In conclusion, an improved preparation resulting in 51% of pure [**1**][BF_4] (185 mg scale) has been reported. We have also surveyed the electrochemistry and H/D and arene exchange reactions of [**1**][BF_4]. The results show that while [**1**][BF_4] is a novel composition and structure organometallic complex, it is quite stable and relatively unreactive. These findings are consistent with our conclusions elsewhere that trace $Ru(0)_n$ nanoclusters are the true benzene hydrogenation catalyst derived from [**1**][BF_4] and not this otherwise interesting organometallic complex itself.

4. Experimental

4.1. Syntheses

General remarks: All manipulations were carried out in an inert argon atmosphere using standard Schlenk techniques unless stated otherwise. Filtrations were carried out using a Mülheim apparatus. Doubly distilled water was degassed and saturated with argon prior to use. Organic solvents used for chromatography were distilled under argon prior to use. Silica-gel G used for preparative thin-layer (20 × 20 cm) chromatography was purchased from Macherey-Nagel GmbH. NMR spectra were recorded using a Bruker 400 MHz spectrometer. Electrospray mass spectra were obtained in positive-ion mode using a LCQ Finnigan mass spectrometer. Deuterated NMR solvents were purchased from Cambridge Isotope Laboratories, Inc. The starting dinuclear complexes $[Ru(C_6Me_6)Cl_2]_2$ [16] and $[Ru(C_6H_6)Cl_2]_2$ [13] were prepared according to published methods.

4.1.1. Improved preparation of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)][BF_4]$ ([1][BF_4])

In a 250 mL brown-glass Schlenk tube, 300 mg (0.449 mmol) of $[Ru(C_6Me_6)Cl_2]_2$ were mixed with a solution of 282 mg (0.904 mmol) of Ag_2SO_4 in 30 mL of water. The suspension was stirred at room temperature until the orange solid has completely dissolved to give a yellow solution of $[Ru(C_6Me_6)(H_2O)_3]^{2+}$ (around one hour). The white precipitate of AgCl formed was removed from the aqueous solution by filtration through filter pulp. The resulting clear yellow filtrate was cooled in an ice-bath for 30 min. In a separate 50 mL Schlenk tube, 75 mg (1.974 mmol) of $NaBH_4$ were dissolved in 15 mL of water at room temperature. After stirring for 5 min, the $NaBH_4$ solution was transferred very slowly through a cannula into the ice-bath-cooled $[Ru(C_6Me_6)(H_2O)_3][SO_4]$ solution. The colour of the solution changed to black, due to the formation of $[H_3Ru_2(C_6Me_6)_2]^+$. The resulting solution was immediately filtered through filter pulp under argon to remove unsoluble black particles. To the dark solution containing $[H_3Ru_2(C_6Me_6)_2]^+$, solid $[Ru(C_6H_6)Cl_2]_2$ (210 mg, 0.420 mmol) was added. The mixture was stirred at room temperature, until the orange solid had completely dissolved. Then, the solution was transferred under argon into a 300 mL closed Schlenk pressure tube and stirred under argon pressure (two atmospheres) at 60 °C for 3 days.

During this time, the colour of the solution changed from black to red. After cooling to room temperature, the red solution containing **1** was filtered through filter pulp. Then a large excess of solid $NaBF_4$ was added to the filtrate to precipitate [**1**][BF_4]. After stirring for one hour at room temperature, the red precipitate was centrifuged in air (1500 rpm, 10 min), the aqueous solution was removed from the centrifuge tube with a glass pipette. The red solid was dissolved in CH_2Cl_2 and again filtered through filter pulp to eliminate excess $NaBF_4$. Then the methylene chloride solution was concentrated to 15 mL in vacuo. The resulting solution was subjected to preparative thin-layer chromatography on silica-gel using CH_2Cl_2/acetone (2/1) as eluant. The pure [**1**][BF_4] was extracted from the main red band with acetone. Evaporation of acetone under vacuum gave 185 mg (51%) of [**1**][BF_4] as a red powder.

Spectroscopic data for **1**: ^{1}H NMR (400 MHz, acetone-d_6): $\delta = -19.93$ (t, 1H, $^2J = 3.84$ Hz, Ru-*H*), −19.08 (d, 2H, $^2J = 3.84$ Hz, Ru-*H*), 2.31 (s, 36H, $C_6(CH_3)_6$), 5.70 (s, 6H, C_6H_6). $^{13}C\{^1H\}$ (50 MHz, acetone-d_6): $\delta = 17.48$, 71.45, 95.06. MS (ESI positive mode, in acetone): *m*/*z*: 726 $[M + 2H]^+$.

4.1.2. Preparation of $[H_3Ru_3(C_6H_6)(C_6Me_6)_2(O)(OH)][BF_4]$ ([2][BF_4])

In a Schlenk pressure tube, a red solution of 50 mg (0.062 mmol) of [**1**][BF_4] in 80 mL of water were heated at 50 °C under about 3 bars of air during 3 days. The resulting orange-yellow solution was filtered through filter pulp, and then the water was removed by evaporation under reduced pressure. The residue was dissolved in 5 mL of CH_2Cl_2 and subjected to preparative thin-layer chromatography on silica-gel using CH_2Cl_2/acetone (2/1) as eluant. The pure [**2**][BF_4] was extracted from the main orange band with acetone. Evaporation of acetone under vacuum gave 20 mg (39%) of [**2**][BF_4] as an orange powder.

Spectroscopic data for **2**: ^{1}H NMR (400 MHz, acetone-d_6): $\delta = -13.67$ (s, 2H, Ru-*H*), 2.15 (s, 36H, $C_6(CH_3)_6$), 5.82 (s, 6H, C_6H_6). MS (ESI positive mode, in acetone): *m*/*z*: 742 $[M + H]^+$.

4.1.3. Preparation of $[D_3Ru_3(C_6H_6)(C_6Me_6)_2(O)][BF_4]$ ($[\mathbf{1a}][BF_4]$)

The deuterated derivative [**1a**][BF_4] was prepared and purified according to the same procedure as [**1**][BF_4], water being replaced by heavy water and $NaBH_4$ being replaced by $NaBD_4$. However, the yield is significantly lower (less than 20%).

Spectroscopic data for **1a**: ^{1}H NMR (400 MHz, acetone-d_6): $\delta = 2.31$ (s, 36H, $C_6(CH_3)_6$), 5.70 (s, 6H, C_6H_6). $^{13}C\{^1H\}$ (50 MHz, acetone-d_6): $\delta = 17.48$, 71.45, 95.06. MS (ESI positive mode, in acetone): m/z: 728 $[M + H]^+$.

4.2. Electrochemical studies

Conventional electrochemical equipment was used for cyclic voltammetry and voltammetry at a rotating disc electrode (EG&G Princeton applied Research Model 362 scanning potentiostat with an XY recorder or a power Lab/4SP, Scope version 3.6.10, ADInstrument). For both cyclic voltammetry or voltammetry at a rotating disc electrode ($\omega = 2000$ rpm), the working electrode was a disc of glassy carbon (3 mm diameter) or platinum (1 mm diameter). All potentials referred to the saturated calomel electrode (SCE) and were not corrected for the ohmic drop. The $E_{1/2}$ and ΔE_p of ferrocene in our cell were + 0.40 V versus SCE and 0.08 V versus SCE, respectively.

Controlled potential electrolyses were performed in a divided cell [17] equipped with a planar platinum electrode (4 cm diameter). The coulometric measurements were determined with a current integrator Tacussel IG5. Electrolyses under continuous bubbling of nitrogen generally involve 3×10^{-5}–8×10^{-5} mol of substance **1** or **2** in 50 mL of non-dried CH_3CN containing 0.2 M $LiClO_4$ as electrolyte. After electrolysis of **1** and **2**, water (50 mL) was added to the electrolysed solution. Acetonitrile was removed in vacuo before adding an aqueous solution of HBF_4. The resulting solution was extracted twice with CH_2Cl_2 which was dried over magnesium sulfate and evaporated in vacuo. The resultant red solid was washed with diethyl ether.

4.3. Ligand exchange studies

4.3.1. Arene exchange study

In a 300 mL closed Schlenk pressure tube was stirred a mixture of an aqueous solution of [**1**][BF_4] (10 mg, 1.23×10^{-5} mol, 10 mL) with toluene (1.32 mL, 12.3 mmol) for 2 h at 110 °C. After cooling, the toluene was removed by decanting and extraction with 5 mL of diethyl ether followed by evaporation of the aqueous solution to dryness under reduce pressure. The red residue was analysed by ^{1}H NMR spectroscopy and by mass spectrometry.

4.3.2. Hydride exchange studies (high-pressure NMR experiments)

All H–D or D–H exchange experiments were carried out under oxygen-free conditions using glove box and Schlenk techniques. D_2O (99.9%) was purchased from Cambridge Isotope Laboratories, whereas D_2 was purchased from Linde. Experiments under pressure were carried out in a 10 mm medium pressure sapphire NMR-tube [18] under 5 MPa of H_2 or D_2 pressure. Spectra were collected on a Bruker DRX 400 MHz instrument, the integrals were calculated using the WIN-NMR program and the ^{1}H chemical shifts were referenced to 3-trimethylsilyl-1-propanesulfonic acid Na salt (TSPSANa), external standard.

The exchange reactions were carried out at 363 K temperature, using **1a** or **1** under 50 bars of H_2 or D_2 pressure in solvent H_2O or D_2O, respectively. The time delays between spectra are 10 min in case of D–H exchange and 20 min in case of H–D exchange. In case of D–H exchange, the measurements were carried out in sweep off mode and use a water suppression pulse sequence (1-3-3-1) because of lack of lock and the presence of the large H_2O signal [19].

even though the apda ligand was bonded in a tetradentate fashion. Yet another study showed that apda can also act as a tridentate ligand with the pronated β-alaninato arm opened in the formation of [Co(dien)(Hapda)]ClO_4 [11]. This obvious versatility leaves the possibility to synthesise and characterise complexes with very interesting bonding modes and kinetic behaviour.

Furthermore, the strain experienced by the bonded glycinate arms of these tripod type ligands make for very interesting study. According to Weakliem et al. [12] unstrained glycinate rings should be planar with the sum of the endocyclic angles in the ring equal to 538.4°. The reasons for the strain on these rings have been of interest. It was suggested earlier that it could be due to a combined effect of hydrogen bonding and van der Waals forces and the angular strain on the co-ordinated nitrogen atom of the tripod ligand. It was also shown that the presence of large cationic species do not increase the strain to a visible degree [8]. Furthermore, it is peculiar that the in-plane *R* rings experience the least strain in all the complexes studied.

Thirdly, very little work has been done on the subject of ^1H NMR spectroscopy of cobalt(III)-tripod type ligand complexes. A recent study showed how ^1H NMR can be used effectively to determine the conformation of cobalt(III)-nta complexes [8]. The crystallographic study of [Co(apda)$(H_2O)_2$] did not include ^1H NMR spectroscopy data [9].

This paper deals with the synthesis and molecular and crystal structure of $[Co(H_2O)_6] \cdot [Co(Hapda)_2]_2 \cdot H_2O$ as well as the influence of pH on solutions of $[Co(Hapda)_2]_2^{2-}$. The aim of the present work is to study the co-ordination modes of the apda ligand and to provide more information for the identification of Co(III)-tripod type ligands by ^1H NMR. The strain in the glycinato rings of the apda ligand is also discussed.

2. Experimental

2.1. Synthesis of N-(2-carboxyethyl)iminodiacetic acid (apda)

N-(2-carboxyethyl)iminodiacetic acid (apda) was synthesised according to a method obtained from Niclós-Gutiérrez [10]. Chloroacetic acid (10.84 g, 115 mmol) was neutralized by adding potassium hydroxide (6.42 g, 118.5 mmol) in a N_2 atmosphere over a period of 20 min at 5 °C. β-alanin (5.00 g, 56 mmol), neutralized with potassium hydroxide (3.14 g, 56 mmol), was added to the chloroacetic acid solution. The solution was refluxed in a water bath for 5 h under N_2, while adding potassium hydroxide (6.42 g, 115 mmol) over the first 30 min of heating (ca. 90 °C). The solution was cooled to room temperature and the pH was adjusted to ~6.5 with hydrochloric acid (6 M). The solution was concentrated under vacuum (60 °C) until potassium hydroxide crystals separated out. The resulting solution was then cooled to room temperature and the potassium hydroxide crystals were filtered off. The pH was adjusted to 2.5 with the aid of hydrochloric acid (6 M) and the solution was allowed to stand overnight, while the N-(2-carboxyethyl)iminodiacetic acid (apda) precipitated. The precipitate was filtered off and re-crystallized from water (60 °C).

(apda): yield 67%. Important infrared data (KBr, cm^{-1}): *ν*(COOH) 1706 (s). ^1H NMR (D_2O, ppm) *δ*: 3.08 (s, 2H), 3.61 (d, 2H), 3.78 (s, 2H), 4.17 (d, 2H).

2.2. Synthesis of $[Co(apda)(H_2O)_2] \cdot H_2O$

[Co(apda)$(H_2O)_2$] was prepared similar to the method described by Tsuchiya and co-workers [1]. $CoCl_2 \cdot 6H_2O$ (5.7 g, 24.3 mmol) was added to a 25 cm^3 solution containing apda (5 g, 24.3 mmol) and $KHCO_3$ (5 g, 50 mmol). The mixture was heated on a water bath for about 1 h. The solution was then placed on an ice bath and H_2O_2 (1 cm^3, 30%) was added after which it was stirred for 30 min. The pH of the resultant solution was adjusted to 3 with $HClO_4$ (6 M) and stirred for another 2 h. Ethanol (200 cm^3) was added to the mixture until precipitation occurred. The precipitate was re-dissolved in the minimum amount of water. Purple crystals separated out after 24 h.

[Co(apda)$(H_2O)_2$]: yield 44%. Important infrared data (KBr, cm^{-1}): *ν*(COOH) 1670 (s), 1580 (m). ^1H NMR (D_2O, ppm) *δ*: 2.57 (d, 1H), 2.80 (m, 2H), 3.47 (m, 2H), 3.78 (d, 1H), 3.97 (d, 1H), 4.18 (d, 1H). UV–Vis (λ_{max} (nm) (ε, M^{-1} cm^{-1})): 209.9 (1.48×10^4), 240.0 (1.29×10^4), 400.0 (1.07×10^2), 559.9 (1.63×10^2).

2.3. Synthesis of $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$

$CoCl_2 \cdot 6H_2O$ (5.7 g, 24.3 mmol) was added to a 25 cm^3 solution containing apda (5 g, 24.3 mmol) and $KHCO_3$ (5 g, 50 mmol). The mixture was heated on a water bath for about 1 h, placed on an ice bath and H_2O_2 (1 cm^3, 30%) was added. After stirring for approximately 20 min, the pH of the mixture was adjusted to 2. This was stirred at room temperature for 24 h. Ethanol (200 cm^3) was added to the mixture and the complex precipitated. The precipitate was washed with ice water and then re-dissolved in warm water, ca. 60 °C after which pink crystals, suitable for X-ray crystallography, separated out (10 h).

$[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$: yield 12%. Important infrared data (KBr, cm^{-1}): *ν*(COOH) 1705(m),

1597(s). UV–Vis (λ_{max} (nm) (ε, M^{-1} cm^{-1})): 230.0 (3.59×10^4); 375.0 (1.68×10^2), 540.0 (1.96×10^2).

2.4. Synthesis of $Na[Co(Hapda)_2] \cdot xH_2O$

An ion-exchange column was filled with sufficient strong-base anion-exchange resin to give a 20 cm column. The column was washed with NH_3 (6 M, 50 cm^3) followed by water (100 cm^3) and HCl (2 M, 100 cm^3). $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$ (3.00 g, 2.7 mmol) was introduced into the column to separate the anionic species $[Co(Hapda)_2]^{3-}$ from the cationic counter ion, $[Co(H_2O)_6]^{2+}$. The column was washed with water (200 cm^3) and the $Na[Co(Hapda)_2] \cdot xH_2O$ was eluted with NaCl (2 M, 150 cm^3). The solution was evaporated until a pink precipitate was formed. The precipitate was filtered and washed with ice cold water (50 cm^3). The precipitate was re-crystallised from hot water (ca. 60 °C). Unfortunately the crystals obtained were not suitable for X-ray diffraction data collection.

$Na[Co(Hapda)_2] \cdot xH_2O$: Important infrared data (KBr, cm^{-1}): ν(COOH) 1702(s), 1609(m). ^1H NMR (D_2O, ppm) δ: 2.77 (t, 4H), 3.59 (d, 4H), 3.74 (t, 4H), 4.18 (d, 4H). UV–Vis (λ_{max} (nm) (ε, M^{-1} cm^{-1})): 230.0 (1.50×10^4), 365.1 (8.4×10^1), 515.0 (5.6×10^1).

2.5. X-ray data collection, solution of the structure and refinement

Intensity data were collected on a Bruker SMART 1K CCD area detector diffractometer with graphite monochromated Mo Kα radiation (50 kV, 30 mA). The collection method involved ω-scans of width 0.3°. Data reduction was carried out using the program SAINT+ [13] and absorption corrections were made using the program SADABS [14].

The crystal structure was solved by direct methods using SHELXTL [15]. Non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full matrix least-squares calculations based on F^2 using SHELXTL. With the exception of hydrogen atoms involved in hydrogen bonding, all hydrogen atoms were first located in the difference map then positioned geometrically and allowed to ride on their respective parent atoms. Hydrogen atoms involved in hydrogen bonding were placed from the difference map, restrained to reasonable O–H distances using DFIX and refined isotropically. Diagrams and publication material were generated using SHELXTL and DIAMOND [16]. A summary of the crystal data, experimental details and refinement results is given in Table 1.

2.6. Spectroscopic studies

Routine IR spectra were recorded on a Digilab FTS2000 FT-IR spectrometer. UV–Vis spectra were recorded on a Cary spectrophotometer. ^1H NMR spectra were recorded on a 300 MHz Bruker spectrometer.

Table 1
Crystal data and structure refinement for $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$

Empirical formula	$C_{28}H_{52}Co_3N_4O_{32}$
Formula weight	1133.53

Completeness to theta = 26.00°	99.0%
Absorption correction	semi-empirical from equivalents
Maximum and minimum transmission	0.8819 and 0.6540
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	4079/10/348
Goodness-of-fit on $F2$	1.012
Final R indices [$I > 2\sigma(I)$]	R_1 = 0.0366, wR_2 = 0.0754
R indices (all data)	R_1 = 0.0555, wR_2 = 0.0816
Largest difference peak and hole (e Å^{-3})	0.311 and −0.480

3. Results and discussion

3.1. Description of the structure

Bond distances and angles between selected non-hydrogen atoms are given in Table 2. Hydrogen bonding interactions are represented in Table 3. Relevant torsion angles, endocyclic angles of the glycinato rings and the calculated distances of Co and N from the CCOO planes are given in Table 4. The numbering scheme for one of the anionic units is shown in the perspective drawing in Fig. 1.

The compound consists of two anionic cobalt(III)-Hapda units and one $[Co(H_2O)_6]^{2+}$ unit [Co(2)] which acts as a counter ion. Hapda acts as a tridentate ligand in both units, the propionate arm being open in both cases. This imply that the Co(III) centres are surrounded by four oxygen atoms and two nitrogen atoms.

Table 2
Selected bond distances (Å) and angles for the anionic units, $[Co(Hapda)_2]^-$

Bond distance (Å)	
Co(1)–O(3)	1.880(2)

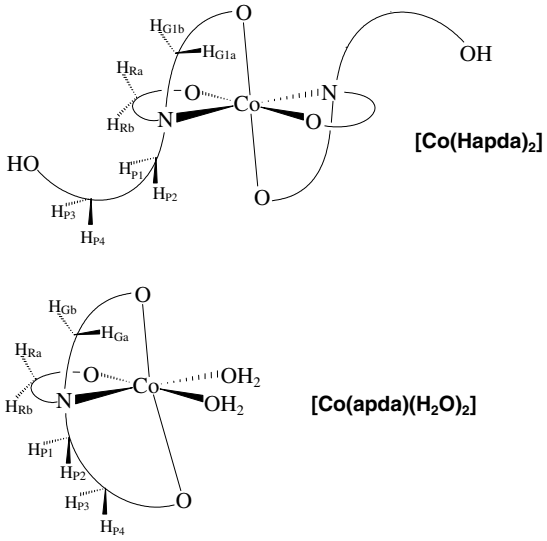

Fig. 1. Sketch of different Co-apda complexes, illustrating relevant H atoms in ^1H NMR spectroscopy.

The octahedral cation, $[Co(H_2O)_6]^{2+}$, is slightly distorted, but centro-symmetric, with the atom Co(2) at the inversion centre. The Co–O distances vary between 2.051(2) and 2.115(2) Å and the right angles between 86.97(11)° and 93.03(11)°. This compares very well with several different crystal structures with $[Co(H_2O)_6]^{2+}$ as counter ion [17–19].

Close inspection indicates that the two cobalt(III) units are not similar in terms of octahedral distortion around the metal centre. Unit A has a very slightly distorted octahedron around the cobalt(III) centre with the O–Co–O, O–Co–N and N–Co–N bonding angles ranging between 87.84(9)° and 92.16(9)°. The O–Co–O, O–Co–N and N–Co–N bonding angles in unit B however, vary between 85.07(9)° and 94.93(9)°. The Co–nitrogen bonding distances vary between 1.973(2) and 1.976(2) Å, while the Co–oxygen distances vary between 1.8794(19) and 1.9005(19) Å for both A and B. The rest of the N–C, C–C and C–O bond distances of the apda

Table 4
Endocyclic angles, distances of N and Co from the CCOO planes and torsion angles for both anionic units, $[Co(Hapda)_2]^-$, A and B

	Anionic unit A		Anionic unit B	
	G	*R*	*G*	*R*

[a] Two carbon atoms, one carboxylate oxygen and a metal bonded oxygen.

ligand are all considered normal and agree well with those found for $[Co(apda)(H_2O)_2]$ and other similar tripod type ligands like nta (nta = nitrilotriacetic acid) [4,9,20].

The sums of the endocyclic angles of the rings in the two cobalt(III) units are 536.52° and 540.47° for A and 539.33° and 527.77° for B. This information is very interesting since it seems that the glycinate rings in A has almost zero strain according to Weakliem and Hoard [12], while the *G* ring in B is quite severely strained. Both the glycinate rings in [Co(dien)(Hapda)]-ClO_4 were almost planar, indicating almost zero strain [11].

The nitrogen tetrahedra of A and B are both slightly distorted but are the same within experimental error. C–N–C angles for A vary between 110.1(2)° and 112.5(2)° compared to 110.6(2) to 111.8(2) for B.

The angular strain around the nitrogen atom of Hapda can be demonstrated by the non-planarity of the *G* rings, see Table 4. Deviations of N from the CCOO planes vary between 0.155(5) and 0.346(5) Å for anionic unit A and 0.124(5) and 0.562(5) Å for anionic unit B. Similarly the out-of-plane distances for cobalt were calculated to be between 0.037(4) and 0.157(4) Å for anionic unit A and between 0.059(4) and 0.225(4) Å for anionic unit B. The deviation of N from the planes decrease in the order $G > R$ for both anionic units, while the deviation of Co from the planes increase in the order $G > R$ for both anionic units. The main reason for this is possibly that the nitrogen atom is more displaced from the CCOO plane (0.346(5) and 0.562(5) Å) in the *G* rings of anionic unit A and B, respectively. This forces the Co atom into the *G* plane and out of the *R* plane (Co distance from *R* plane in anionic unit A and B is surprisingly long, 0.157(4) and 0.225(4) Å, respectively).

From the above discussion, it is obvious that A and B differ only in terms of the strain experienced by the glycinato rings of the apda ligand. All the other bonding information seems to be the same within experimental error. The only reasonable explanation then could only be that these rings experience different external pushing/pulling effects due to intermolecular hydrogen bonding and other van der Waals interactions.

3.2. Spectral properties

The IR spectrum obtained for $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$ shows stretching frequencies at 1705 and 1597 cm^{-1}. These values point towards the presence of both coordinated and uncoordinated carboxylate groups [21] as expected. The observed COO-stretching for $Na[Co(Hapda)_2] \cdot xH_2O$ at 1702 and 1609 cm^{-1} compares very well with that of $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$. In the case of $[Co(apda)(H_2O)_2]$, the spectrum shows frequencies at 1670 and 1580 cm^{-1}, which is consistent with the spectrum obtained by Gladkikh et al. for this complex [9] and which points to coordinated COO groups.

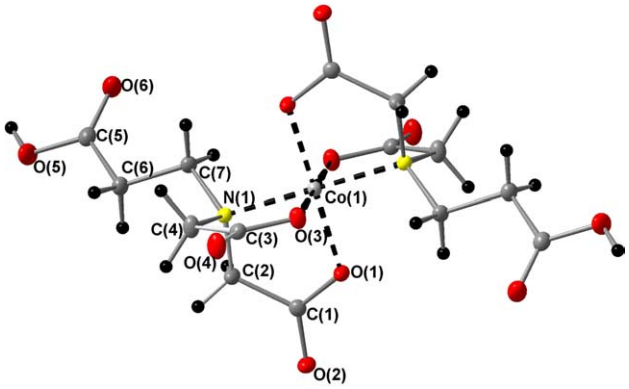

Fig. 2. Perspective drawing of anionic Unit A.

Usable ^1H NMR spectra of $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$ could not be obtained due to paramagnetic interference from the Co(II) counter ion. Spectra of $[Co(apda)(H_2O)_2]$ and $Na[Co(Hapda)_2] \cdot xH_2O$ are represented in Figs. 3 and 4. The spectrum of $[Co(apda)(H_2O)_2]$ indicates that all the protons are non-equivalent as expected. The glycinate *G* ring protons (H_{Ga} and H_{Gb} in Fig. 2) and *R* ring protons (H_{Ra} and H_{Rb}) all experience a different chemical environment and are therefore non-equivalent. This result in three distinctive doublets with an AB pattern with centers between 3.6 and 4.5 ppm and a fourth doublet in the 3.5 ppm region (see Fig. 3). The multiplet at 3.5 ppm and the other downfield peaks are assigned to the β-alaninato ring protons, which are all non-equivalent. This is confirmed with the spectrum of the free ligand, which shows two triplets between 2.5 and 3.5 ppm (4 β-alaninato protons) and the singlet observed between 3.5 and 4 ppm (glycinate protons).

The spectrum of $[Co_2(Hapda)_2]^-$ is somewhat simpler in that two distinctive triplets are observed at ~2.8 and 3.8 ppm, indicating that the β-alaninato arm is opened.

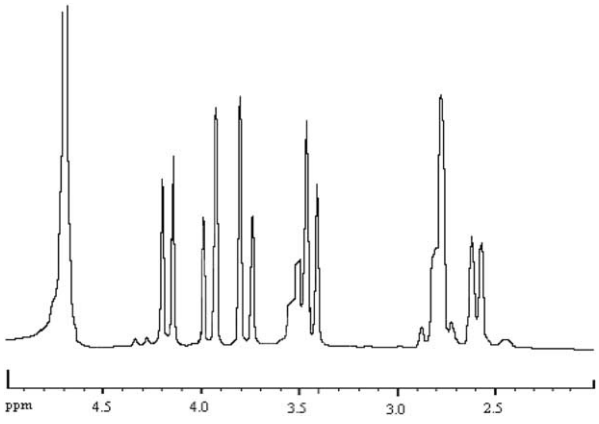

Fig. 3. ^1H NMR spectrum of $[Co(apda)(H_2O)_2]$.

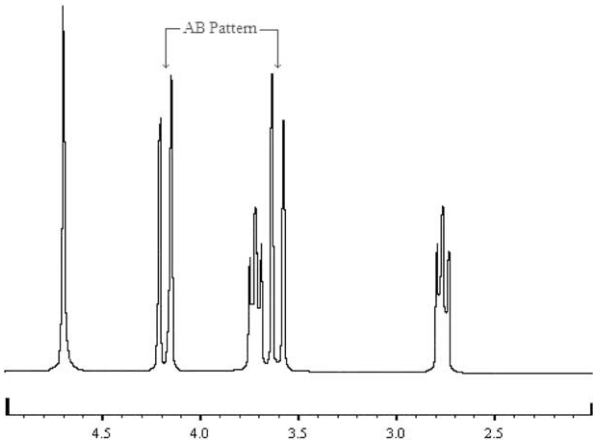

Fig. 4. ^{1}H NMR spectrum of $Na[Co(Hapda)_2] \cdot xH_2O$.

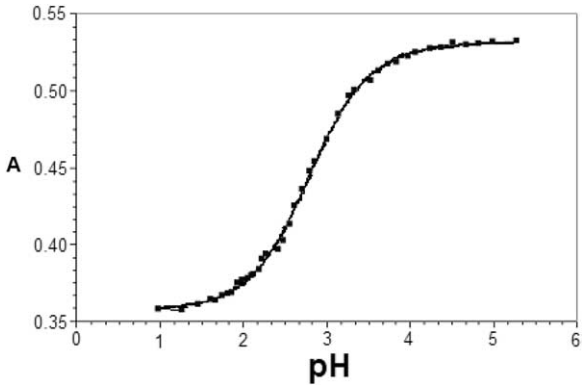

Fig. 5. Plot of Abs. (λ = 348 nm) vs. pH for $[Co(apda)_2]^{3-}$ (4.5×10^{-3} M), 25 °C, μ = 1.0 M ($NaClO_4$).

The disappearance of the singlet observed for the free ligand and the appearance of two doublets with an AB pattern at ~3.6 and 4.2 ppm, both integrating for four protons, indicate that the glycinate protons keep some equivalency. If all the protons were non-equivalent one would have expected four doublets integrating for one proton each. In this case, H_{Ga} is equivalent with H_{Rb}, while H_{Gb} and H_{Ra} are equivalent. These observations for $Na[Co(Hapda)_2] \cdot xH_2O$ are consistent with the structural data reported for $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$. This fact together with the i.r. and UV–Vis data suggests that the anionic unit, $[Co_2(Hapda)_2]^-$, is the same for both these complexes.

3.3. pH dependance of $[Co(Hapda)_2]^-$

The pH of solutions upon dissolving crystals of $Na[Co(Hapda)_2] \cdot xH_2O$ is ca. 5.5. The UV–Vis spectrum shows an immediate decrease in absorption at both the absorption maximum at 515 nm and the shoulder at 365 nm upon lowering the pH from ~5.5 to 2. The pH was adjusted to 5.5 again (KOH, 1 M) and the spectrum recorded. This resulted in the immediate increase in absorption at 515 and 365 nm to its original position, indicating a reversible process.

In another experiment the pH of a solution of $Na[Co(Hapda)_2] \cdot xH_2O$ was adjusted to 1 and kept over time. No change in the absorption spectrum was observed indicating that solutions of $[Co(Hapda)_2]^-$ is stable at pH 1 for several hours.

It was also observed that the final UV–Vis spectra at pH 2 is similar to the spectra obtained from the reaction solutions from which the crystals of $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$ were obtained, indicating that the final product at pH ~ 2 is $[Co(Hapda)_2]^-$. An initial potentiometric titration revealed that the mole ratio of H^+-ions:complex ion is 2:1 between pH 6 and 2. This diprotic behaviour of $[Co(Hapda)_2]^-$ is illustrated in Eqs. (1) and (2).

$$[Co(Hapda)_2]^- \overset{K_{a_1}}{\rightleftharpoons} [Co(Hapda)(apda)]^{2-} + H^+ \quad (1)$$

$$[Co(Hapda)(apda)]^{2-} \overset{K_{a_2}}{\rightleftharpoons} [Co(apda)_2]^{3-} + H^+ \quad (2)$$

The acid dissociation constants of $[Co(Hapda)_2]^-$ and $[Co(Hapda)(apda)]^{2-}$, K_{a_1} and K_{a_2}, were spectrophotometrically determined at λ = 348 nm at 25 °C by adjusting the pH of a $[Co(apda)_2]^{3-}$ solution from pH 5.28 to 0.98 (4.5×10^{-3} M) with HCl (1 M) and immediately measuring the absorbance. The spectrophotometric data were fitted to Eq. (3) (solid line in Fig. 5) and the values for pK_{a_1} and pK_{a_2} were determined as 2.6(1) and 2.8(1), respectively.

$$A_{tot} = \frac{A_a + A_h(K_{a_1}/[H^+]) + A_0(K_{a_1}K_{a_2}/[H^+]^2)}{K_{a_1}/[H^+] + (K_{a_1}K_{a_2}/[H^+]^2)}. \quad (3)$$

In Eq. (3), A_{tot} is the absorbance at a specific $[H^+]$, A_a = absorbance of the H_2A species, A_0 = absorbance of A^{2-}, A_h = absorbance of the HA^- species and K_{a_1} and K_{a_2} the acid dissociation constants.

The values for K_{a_1} and K_{a_2} are very close. This is to be expected since the chemical environments of $[Co(Hapda)_2]^-$ and $[Co(Hapda)(apda)]^{2-}$ are very similar.

4. Conclusion

In summary, a novel Co(III) complex, $[Co(H_2O)_6][Co(Hapda)_2]_2 \cdot H_2O$, has been synthesised and structurally characterised. The X-ray crystallographic data points to the fact that the strain in glycinato rings of Co(III) complexes with tripod type ligands could be attributed to packing effects.

The value of ^{1}H NMR as an identification tool for these complexes has been highlighted with the spectra of the title complex and $[Co(apda)(H_2O)_2]$. The difference in chemical environment of bonded and unbonded arms of tripod ligands like apda, enables the scientist to

determine whether tri- or tetradentate bonding has occurred.

5. Supplementary material

Crystallographic data reported in this paper have been deposited with the CCDC, No. 244 034. those of the penicillin group. Cephalosporins interfere with the synthesis of the bacterial cell wall and consequently, act as bactericides [10]. With epidemic strains of bacteria often being resistant to several antibiotics, and the growing problem worldwide of Gram-negative antimicrobial resistance, cephalosporins, rather than penicillin, constitute the essential tool with which to face this problem [11,12].

Considerable attention has been paid recently to the synthesis and characterization of siderophore analogues. Siderophores are low-molecular-weight organic ligands (0.5–1.5 kDa) with high affinity and specificity for iron. Under iron-limiting conditions, siderophores are excreted by cyanobacteria and heterotrophic bacteria [13–15]. Due to their attributes, this type of compound has been investigated for clinical use in the detoxification of certain metals [16]. Among them, there have been characterized siderophores containing thiazine rings, such as the desferrithiocin analogue DL-2-(3-hydroxypyridin-2-yl)-4H-5,6-dihydro-1,3-thiazine-4-carboxylic acid [17]. Unfortunately, many of these substances cannot be crystallized as single crystals of appropriate size and quality for conventional single-crystal diffractometry. For such cases, therefore, the structure has to be determined by powder diffractometry, which is very far from being routine.

The method followed in this study to resolve the crystal structure of the title compound can be categorized as one of the so-called 'direct-space methods' [18]. Here, a structural model of the compound is first elaborated and then optimized by molecular modelling without reference to the experimental XRD pattern. Subsequently, these molecules are placed arbitrarily within the unit cell previously determined from the diffraction data. The position of the molecules is then modified by global optimization techniques (typically Monte Carlo methods, genetic algorithms, or grid search methods) with the objective of finding the best agreement between the theoretical and experimental XRD patterns (the comparison between both patterns is quantified in terms of the *R*-factors). Finally, the best model of the crystal structure is refined using the Rietveld method.

This is the methodological framework of the present study, which determines the crystal structure of the title zinc(II) coordination compound from powder diffraction data. Because of the challenge represented by the alternative to the conventional single-crystal diffractometry and the biological reasons mentioned above, we report the characterization by elemental analysis, infrared (IR) spectroscopy, and X-ray powder diffractometry of the zinc(II) complex [$ZnCl_2$(TdTz)] [TdTz = 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)thiazolidine]. In addition, we report the crystal structure of the TdTz ligand determined by X-ray single-crystal diffractometry.

2. Experimental

2.1. Preparation of 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)thiazolidine (TdTz)

The synthesis of the TdTz ligand was performed according to the procedure reported elsewhere [19], and was recrystallized from ethanol 96% (1.5 g; 53%).

2.2. Preparation of [$ZnCl_2$(TdTz)]

The [$ZnCl_2$(TdTz)] complex was isolated from an ethanol–water solution of $ZnCl_2$ (39.4 mg, 0.3 mmol) that was added to an ethanol–water solution of TdTz (100 mg, 0.3 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After a few days, colourless crystals were isolated from the solution (83 mg, 60%). The crystals were first separated by filtration, then washed with cold ether and finally air-dried. *Anal*. Calc. for $C_{13}H_{13}Cl_4ZnN_3S_2$: C, 32.36; H, 2.71; N, 8.71; S, 13.29. Found: C, 32.74; H, 2.85; N, 8.83; S, 13.19%.

2.3. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen, and sulfur were performed by microanalytical methods using a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer from KBr pellets for the 4000–370 cm^{-1} range, and on a Perkin–Elmer FT-IR 1700X spectrophotometer from polyethylene pellets for the 500–150 cm^{-1} range.

2.4. Crystal structure determinations

Crystals of the TdTz ligand with the appropriate size and quality for X-ray single-crystal diffractometry were isolated and used for the structural analysis. Unfortunately, this was not possible for the [$ZnCl_2$(TdTz)] complex, and therefore its crystal structure was determined by X-ray powder diffractometry. The crystals resulting from the synthesis of the [$ZnCl_2$(TdTz)] complex were highly elongated needles (aspect ratio of about 20) with lengths ranging from 100 to 800 μm (see Fig. 1). To avoid texture effects in the XRD pattern, these crystals were ground to a fine powder consisting of equiaxed particles (aspect ratio of about 1.1) with sizes ranging from 0.5 to 5 μm (see Fig. 2).

The experimental details of the crystal structure determination, including crystal data, data collection, structure determination, and refinement are listed in Table 1 for the ligand. X-ray single-crystal diffraction measurements were performed using a Bruker SMART CCD diffractometer. The first fifty frames were collected at the completion of data recording to monitor

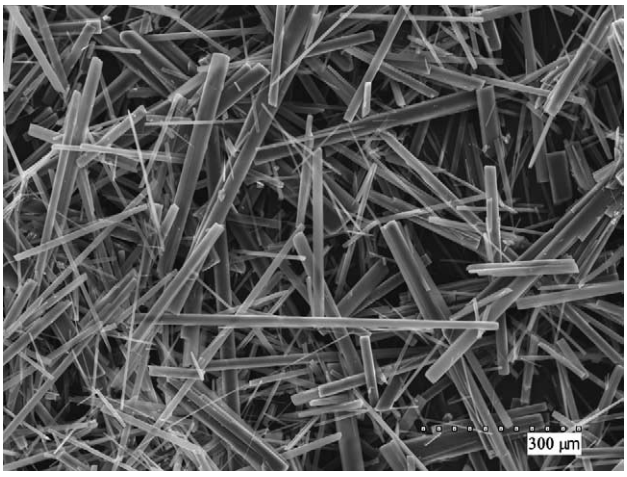

Fig. 1. Scanning electron microscopy image of the [$ZnCl_2$(TdTz)] complex crystals in the as-synthesized condition.

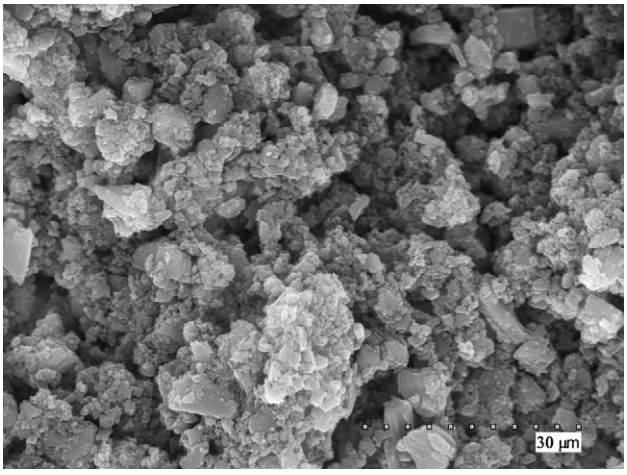

Fig. 2. Scanning electron microscopy image of the powder particles obtained after milling the [$ZnCl_2$(TdTz)] complex crystals.

for decay. Absorption corrections were applied using the program SADABS. The crystal structure was solved by means of direct methods and subsequent Fourier differences using the WINGX package [20], followed by a full-matrix least-squares refinement. The H atoms attached to the C atoms were positioned geometrically with the U_{iso} values derived from the U_{eq} values of the corresponding C atom. In the structure of ligand, C(3) and C(4) are disordered at two sites and refined with occupancy of two alternate orientations constrained to unity. The EADP restraints were applied to the disordered atoms to achieve convergence during least-squares refinement. The refined occupancy factor was 0.62 for orientation named A and 0.38 for orientation named B.

The XRD pattern for the structural determination of the complex was obtained via conventional powder diffractometry. Table 2 gives the experimental and set-up conditions used. Sample preparation included spreading the fine powder onto the holder (about 3 mm thick) and pressing slightly with a glass slide to ensure a flat surface.

3. Results and discussion

3.1. Description of the crystal structure of the organic ligand (TdTz)

The X-ray single-crystal study of the TdTz ligand showed that the crystals are made up of monoclinic unit cells, each one containing four TdTz molecules. Fig. 3 is a diagram of the molecular structure with the atomic labelling. Selected bond lengths and angles are given in Table 3.

In the S(1)–C(1)–N(1)–C(2)–C(3)–C(4) ring, the short endocyclic C=N bond [C(1)–N(1) = 1.259(3) Å] is accompanied by a high S–C–N angle [S(1)–C(1)–N(1) = 127.3(2)°] and a relatively large S^{II}-C(sp^2) bond [S(1)–C(1) = 1.762(2) Å]. This is characteristic of a thiazine ring, as was deduced from comparison with 24 compounds containing a thiazine ring in their structure, obtained by the CONQUEST software [21] from the Cambridge Structural Database (CSD) [22] [mean values: C(1)–N(1) = 1.276 Å; S(1)–C(1)–N(1) = 128.5°; S(1)–C(1) = 1.751 Å]. In contrast, the S(2)–C(5)–N(2)–C(6)–C(7) ring shows a smaller S–C–N angle [S(2)–C(5)–N(2) = 111.2(2)°] and a short exocyclic C=N bond [C(5)–N(3) = 1.261(3) Å], which are indicative of an imino-thiazolidine form [23]. It is known that the imino tautomers can exist as two geometrical isomers, *syn* (*Z*) and *anti* (*E*), although in this crystal only *Z* isomers were observed.

The thiazolidine ring is essentially planar, with maximum mean-plane deviation for C(6) (0.037 Å). Due to the disorder found in C(3) and C(4), discussion of the thiazine ring conformation is pointless.

The crystal structure presents a static disorder affecting the Cl atom linked to the aromatic ring in position 3, due to an alternation of the Cl(1A)–H10 and Cl(1B)–H12 pairs with occupancy degrees of 48% and 52%, respectively.

The least-squares plane of the imino-thiazolidine moiety is practically coplanar to the best plane of the thiazine (8.2°) and is rotated 89.3° with respect to the least-squares plane of the 3,4-dichlorophenyl ring.

3.2. Spectroscopic study

The IR spectrum of the TdTz organic-ligand has been described elsewhere [19]. The IR spectrum of the complex [$ZnCl_2$(TdTz)] shows bands assignable to: the thiazine ring vibrations at 1545 (Ψ_1), 1006 (Ψ_2), 943 (Ψ_3), 838 (Ψ_4), 757 and 748 (Ψ_5), 721 (Ψ_6), 628 (Ψ_7), 589 (Ψ_8), and 538 cm^{-1} (ϕ_1) [25–27]; the thiazolidine ring vibrations at 1030 (νn_1), 914 (νn_2), 893 (νn_3), 696 (νn_4), 671 (νn_5), and 475 cm^{-1} (δn_2) [28,29]; and the 3,4-dichlorophenyl ring vibrations at 1588 (8b), 1463 (19b), 1373 (19a), 1251 (14), and 1119 (1) cm^{-1} [25]. Other relevant bands are observed at 1613 [ν(C=N)$_{imine}$], 1357 [ν(C–N)], and 1064 cm^{-1} [ν(C–Cl)$_{ortho}$] [30,31].

Comparison of the strong ν(C=N)$_{imine}$ absorption of the complex (1613 cm^{-1}) to that of the uncoordinated imine function of the ligand (1631 cm^{-1}) shows the former to be significantly shifted to a lower wavenumber. The same is the case with the in-plane stretching vibration corresponding to ν(C=N) skeletal vibration of the heterocyclic ring (Ψ_1 of the complex: 1545 cm^{-1}), which is also shifted towards lower wavenumbers compared to the free ligand (1604 cm^{-1}). One may hence deduce coordination via the imino nitrogens of the ligand [32–35].

The far IR spectrum of this complex shows the presence of three bands due to the metal–ligand stretching vibrations at 330, 304, and 218 cm^{-1}. Of these, the band at 330 cm^{-1} may include the ν(Zn–N_{imino}) vibration [32–34,36] and one ν(Zn–Cl) vibration [37,38], whereas the band at 304 cm^{-1} is assigned to the other ν(Zn–Cl) vibration [37,38]. Finally, the band at 218 cm^{-1} is assignable to ν(Zn–$N_{thiazine}$), in good agreement with the literature data for several complexes containing thiazoline or thiazine derivative ligands [19,38–40].

The results of this study together with the elemental analysis allow one to deduce a tetra-coordinated geometry for the complex.

3.3. Structural determination of the complex

The sequence used in the determination of the structure from the XRD pattern was: data reduction and indexing, molecular modelling, use of direct-space methods with a 'Monte–Carlo/parallel tempering' search algorithm, and finally Rietveld refinement [18].

3.3.1. Data reduction and indexing

The peak positions were identified using a derivative-based algorithm that is implemented in CELREF [41]. The XRD pattern was then indexed in the monoclinic system using the CRYSFIRE software package [42]; the best solution was obtained with the *TREOR90* indexer, and had a de Wolff figure-of-merit of $M(20) = 39.5$. By analyzing the XRD data with CHECKCELL [43] we obtained $a = 10.640(1)$ Å, $b = 9.019(1)$ Å, $c = 20.435(2)$ Å, $\beta = 108.35(1)°$, and $V = 1861(4)$ Å^3, whereas the space group was unambiguously found to be $P12_1/c1$. From this space group, we deduced the existence within the monoclinic unit cell of four molecules of $C_{13}H_{13}Zn_1N_3S_2Cl_4$. This result is in clear agreement with the experimental density of 1.72(1) Mg m^{-3} determined by the Archimedes method.

In this first stage, we also performed the Le Bail fit implemented as an option in the FULLPROF program [44,45], which will be used later for the final Rietveld refinement. The Le Bail fit, which makes no reference to any structure model, had a threefold objective: (1) to assess the goodness of the space group and the choice of cell; (2) to estimate the shape and width of the Bragg reflections, and the instrumental shifts; and (3) to evaluate the error not associated with the structure model. The *R*-factors obtained were $R_{wp} = 0.058$ and $R_p = 0.045$.

3.3.2. Molecular modelling

A first approximation to the molecular structure inside the crystal was obtained by molecular optimization using semi-empirical methods, since the compounds bonded by the weak van der Waals–London interaction (and perhaps hydrogen bonds) remain almost unmodified when switching from the isolated molecules to the crystalline states. We used the AM1, PM3, MNDO, and MNDO/d force fields included in the HYPERCHEM software package [46], with the starting model built from IR-spectroscopy data and the ligand structure determined by single-crystal diffractometry. The best optimization was obtained with MNDO/d (binding energy $E_b = -3530$ kcal mol^{-1}), with a conclusive difference in E_b of 12 kcal mol^{-1} with respect to the second-best optimized model.

3.3.3. Monte Carlo methods

The crystal structure was determined by Monte Carlo methods, using the 'parallel tempering' algorithm implemented in the FOX software package [47]. The structure was described in the Z-matrix formalism, which is especially useful for organic molecules of relative complexity [48,49]. In this formalism the geometry of the molecules is described by the bond distances, the bond angles, and the dihedral angles between the different atoms [50]. From the optimized molecular structure, the corresponding Fenske–Hall Z-matrix was built using the BABEL program [51], with the heavy Zn atom as pivot. In a first step we treated the molecule as a rigid body, and only refined the six translational and rotational degrees of freedom. After 800 000 movements, the weighted residual was $R_{wp} = 0.169$. To check for "uniqueness", this step was repeated several times using different random starting positions for the Zn pivot and molecule orientations. In the next step we relaxed the constraints on the Z-matrix parameters, and, after 450 000 additional movements, the weighted residual decreased to $R_{wp} = 0.148$. The Z-matrix coordinates were next converted to crystallographic coordinates for the Rietveld refinement.

3.3.4. Rietveld refinement

According to the Le Bail criterion [52], the final refinement of the structures determined from powder diffractometry must be performed using the Rietveld method [53]. We used the FULLPROF program implemented in the WINPLOTR software package [44,45], and refined the following items: background (cubic spline interpolation), scale factor, instrumental shifts, cell parameters, atomic positions (excluding the H atoms, which were rigidly linked to their bonding atoms), and Debye–Waller atomic thermal parameters, as well as the shape, width, and asymmetry of the Bragg reflections assumed to have pseudo-Voigtian form. The Rietveld refinement was initialized using the profile and instrumental parameters obtained previously with the Le Bail fit. In a first step the molecule was treated as rigid body, and then the atomic coordinates were refined applying restrains on bond lengths and angles. The final residuals were $\chi^2_r = 6.23$, $R_{wp} = 0.093$, $R_p = 0.071$, and $R_F = 0.106$, and the refined cell parameters were $a = 10.612(6)$ Å, $b = 9.006(5)$ Å, $c = 20.385(9)$ Å, and $\beta = 108.364(3)°$. Comparison of this R_{wp} value with that obtained from the Le Bail fit showed that the error associated with the structural model was small – 3.5% – thereby confirming the validity of the crystal structure. The plotted output from the Rietveld analysis is shown in Fig. 4. Table 4 gives the most representative crystallographic parameters. Fig. 5 shows a representation of the refined crystal structure.

3.4. Description of the structure of [$ZnCl_2$(*TdTz*)]

We discuss next the crystal structure of the zinc(II) complex, although our interpretation should be treated with caution since the crystallographic data were

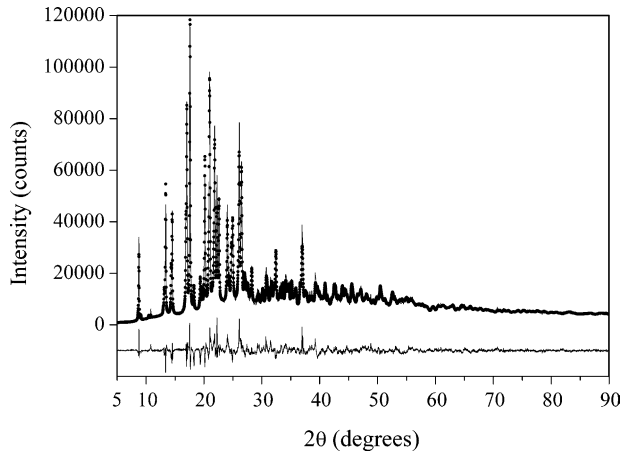

Fig. 4. Plot output from the Rietveld analysis of the X-ray diffraction pattern corresponding to the [$ZnCl_2$(TdTz)] complex. Points are the experimental X-ray diffraction data; the solid line is the calculated pattern; the residuals are plotted at the bottom.

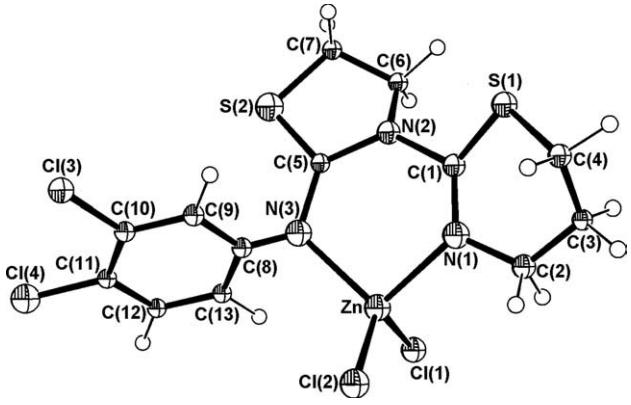

Fig. 6. Molecular structure of the [$ZnCl_2$(TdTz)] complex, showing the atom numbering scheme. The thermal ellipsoids are drawn at the 50% level.

The crystal's structure is a monoclinic lattice with four complex molecules per unit cell. The zinc(II) is bound to two chlorine atoms [Zn–Cl(1) = 2.158(5) Å; Zn–Cl(2) = 2.145(4) Å], one thiazine nitrogen [Zn–N(1) = 2.273(5) Å], and one imino nitrogen [Zn–N(3) = 2.237(4) Å] in a distorted tetrahedral geometry.

The [$ZnCl_2$(TdTz)] complex is the first compound with a 1,3-thiazine linked to zinc(II) that has been characterized structurally. The Zn–Cl bond lengths are slightly shorter than the average value [2.225(30) Å] calculated for 161 tetrahedral zinc(II) complexes with a chromophore group $ZnCl_2N_2$ found in a survey using the CSD. The $Zn–N_{imino}$ bond distance is comparable to the mean value [2.037(26) Å] calculated from the 62 crystal structures with chromophore group $ZnCl_2N_2$ and imino nitrogen contained in the CSD.

The ligand–metal–ligand bite angles differ from the ideal value of 109.5°, varying between 115.3(3)° [N(3)–Zn–Cl(2)] and 97.4(2)° [N(3)–Zn–N(1)].

The six-membered chelate ring Zn–N(1)–C(1)–N(2)–C(5)–N(3) [$Q = 0.324$ Å; $\theta = 60.9°$; $\phi = 1.6°$] [24] has a near to half-boat conformation, with the Zn atom deviating 0.532 Å from the plane formed by N(1)–C(1)–N(2)–C(5)–N(3) [the maximum mean-plane deviation for N(2) is 0.025 Å]. The puckering parameters calculated for the thiazine ring S(1)–C(1)–N(1)–C(2)–C(3)–C(4) [$Q = 0.547$ Å; $\theta = 73.5°$; $\phi = 288.1°$] indicate a near to twist-boat conformation according to Cremer and Pople [24]. Finally, the thiazolidine ring S(2)–C(5)–N(2)–C(6)–C(7) has a near to half-chair conformation, with the N(2) and C(6) atoms deviating 0.270 and 0.337 Å from the plane formed by S(2), C(5), and C(7), respectively.

As can be observed, the organic moiety in this complex preserves the imino-thiazolidine form detected in the TdTz ligand. The main difference is due to the different degree of rotation of the thiazine ring around the C(1)–N(2) bond, which permits electron donation through N(1) [torsion angles: S(1)–C(1)–N(2)–C(6) = 48.9° in the complex; −178.7° in the TdTz]. Similarly, there has been a rotation of the 3,4-dichlorophenyl ring around the C(8)–N(3) bond [torsion angles: C(9)–C(8)–N(3)–C(5) = −39.8° in the complex; −95.4° in the TdTz]. These two findings may be explainable in terms of crystal packing effects.

4. Supplementary material

CCDC 268601, corresponding to [TdTz], and CCDC 268602, to [$ZnCl_2$(TdTz)], contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

a chemical point of view these medications represent aminoalcohols, forming stable chelate mono- and binuclear complexes with copper(II), which have been thoroughly examined and characterized [4–6,9–11]. In some cases we were able to prove directly that the corresponding copper complexes are more active and have longer biological effects compared to the pure non-coordinated drugs [11,12].

Developing further the above ideas, it seemed challenging to study other aminoalcohols that have been used as medicines for treatment of different diseases and to try to clarify the following major topics: do they also form complexes with copper; are their compositions and structures analogous to those of the β-blocker complexes and finally – what is the biological effect of their copper complexes compared to the pure non-complexed drugs. The medication selected for the present study was the β_2-adrenergetic agonist Clenbuterol: 4-amino-α-(*t*-butylaminomethyl)-3,5-dichlorobenzyl alcohol hydrochloride, used in the clinical practice as a bronchodilator in the treatment of bronchial asthma, as bronchorelaxant and tokolytic agent in a series of other respiratory diseases. Due to its influence on the heart and respiratory rates it is used also as a doping agent.

HL

Although formally an aminoalcohol, Clenbuterol differs from the β-blockers by two features: (i) the aminoalcohol chain is directly attached to the phenyl ring and not through an oxygen atom as in the β-blockers; (ii) there is a second donor group ($-NH_2$) in the phenyl ring of HL capable of coordination, although it is sterically hindered by the two adjacent chlorine atoms. These differences in the ligand structure could change the complexation of copper, its homeostasis and hence – the effect of the drug.

Even the first preliminary experiments have shown that the aminoalcohol HL forms two types of complexes, depending mainly on the molar metal-to-ligand ratio and the solvent used as a reaction medium. With an excess of the ligand (M:HL = 1:10), in the presence of NaOH (HL·HCl:NaOH = 1:2) and in methanolic solution, the mononuclear violet complex **2** was obtained, while with comparable amounts of the reagents (M:HL = 1:1) and in a mixed solvent of higher polarity (CH_3OH + DMSO), 50% v/v, the binuclear green complex **1** was formed.

2. Experimental

2.1. Materials and synthesis

The aminoalcohol Clenbuterol, HL·HCl was supplied by Sopharma, Bulgaria, and used without any further purification. $CuCl_2 \cdot 2H_2O$ and NaOH were obtained from Riedel E. de Haën AG, CH_3OH from Fluka and DMSO from Merck. All reagents and solvents used were of analytical grade.

The binuclear complex **1** was obtained at ambient temperature when a 0.025 M solution of the ligand in DMSO (0.0784 g HL·HCl in 10 cm^3 DMSO) was mixed with 0.025 M $CuCl_2$ (0.0426 g $CuCl_2 \cdot 2H_2O$ in 10 cm^3 DMSO). Dropwise addition of 0.025 M NaOH (0.0200 g NaOH in 20 cm^3 CH_3OH) to the latter solution resulted in a green coloration, the molar ratio of the reagents being Cu:HL·HCl:NaOH = 1:1:2. Green prismatic crystals began to form and precipitate after one day at room temperature. The crystals were filtered, washed with 5 cm^3 of the DMSO + CH_3OH mixed solvent and dried over P_2O_5. Yield 40%; Chemical analysis: Calc. for $Cu_2L_2Cl_2 \cdot 4DMSO$: C, 36.16; H, 5.50; N, 5.27; Cl, 20.01; Cu, 11.96. Found: C, 35.88; H, 5.37; N, 5.38; Cl, 19.79; Cu, 11.42%. Melting point 157 °C.

The mononuclear complex **2** was obtained from a MeOH solution in the presence of a large excess of the ligand. A methanolic 0.025 M solution of HL·HCl (0.0784 g in 10 cm^3 MeOH) was mixed with 0.025 M $CuCl_2 \cdot 2H_2O$ (0.0043 g in 1.0 cm^3 MeOH) at a molar ratio Cu:HL·HCl = 1:10, followed by dropwise addition of 0.025 M NaOH in MeOH; HL·HCl:NaOH = 1:2. The above procedures led to a blue-violet coloration and violet crystals precipitated after 2 days at room temperature. They were filtered, washed with 5 cm^3 MeOH and dried over P_2O_5 (yield ca 21%). Calc. for $CuL_2 \cdot 2CH_3OH$: C, 45.92; H, 6.23; N, 8.24; Cl, 20.85; Cu, 9.34. Found: C, 46.32; H, 5.89; N, 8.59; Cl, 21.58; Cu, 8.92%. Melting point 111 °C.

2.2. Instrumentation and analysis

Electronic spectra were obtained on a Specord UV–Vis (Carl-Zeiss, Jena) instrument. IR spectra were recorded in the range 4000–400 cm^{-1} on a Specord-75 IR spectrometer, and in the range 500–75 cm^{-1} on a Bruker 113 V instrument in polyethylene. Thermogravimetric analyses were performed using a Perkin–Elmer TGS-2 instrument. The EPR spectra in the X-band were obtained with an ERS 220/Q instrument, using Mn/ZnS standard. Magnetic susceptibilities were measured between 2 and 300 K in a magnetic field of 1 kOe using a commercial SQUID magnetometer (Quantum Design MPMS-XL) with sensitivity in the range of 10^{-7} emu. The data were corrected for the diamagnetic response of the sample holder and for the diamagnetic contribu-

tion from the sample (Pascal's constants). Elemental analyses were performed according to classical methods: C, H were determined as CO_2 and H_2O, N through the Dumas' method, chlorine by titration with $Hg(NO_3)_2$ after wet digestion of the sample. Copper was determined by atomic absorption after wet digestion of the sample.

For the structure determinations a rod-shaped green crystal, $0.20 \times 0.06 \times 0.05$ mm in size, of compound **1** and a rod-shaped violet crystal, $0.24 \times 0.05 \times 0.06$ mm in size, of compound **2** were selected and mounted on a SIEMENS SMART X-ray diffractometer with a 1 K CCD area detector. Data sets were collected at room temperature using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Hemispheres of data (1271 frames each at 5 cm detector distance) were collected using a narrow-frame method with scan widths of 0.30° in ω and an exposure time of 30 s/frame. The first 50 frames were measured again at the end of each data collection to monitor instrument and crystal stability. The data were integrated using the Siemens SAINT program [16]. The program SADABS was used for the absorption corrections [17]. Both structures were solved by direct methods and refined by full matrix least-squares techniques with the SHELX 97 software package [18]. Initially all non-hydrogen atoms were found from the Fourier maps. For compound **1** the hydrogen atoms have been added to the refinement model and their thermal parameters refined isotropically. Supplementary calculations when the hydrogen atoms were added and refined as riding models by using the appropriate AFIX commands resulted in a less satisfactory model not included in this manuscript [18]. The refinement of compound **2** has been carried out introducing all hydrogen atoms as riding models [18]. The main crystallographic details for complexes **1** and **2** are summarized in Table 1.

3. Results and discussion

3.1. Binuclear $Cu_2L_2Cl_2 \cdot 4DMSO$ complex *1*

3.1.1. X-ray data and crystal structure

The experimental data revealed that the green complex **1** has a binuclear structure with a general formula of $Cu_2L_2Cl_2 \cdot 4DMSO$. In the structure all atoms occupy general (2i: x, y, z) positions. The asymmetric unit of the title compound consists of one copper and one Cl atom, one ligand and two DMSO molecules, i.e., one half of the complex and solvent molecules (Fig. 1). Each copper atom is coordinated by one terminal chlorine, one nitrogen and two oxygen atoms

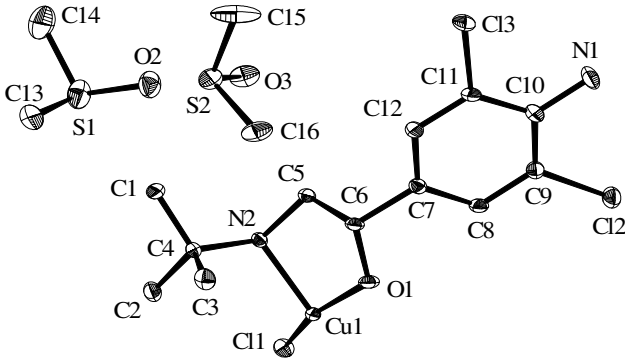

Fig. 1. Asymmetric unit, 50% thermal ellipsoids and labelling scheme of the binuclear complex **1**.

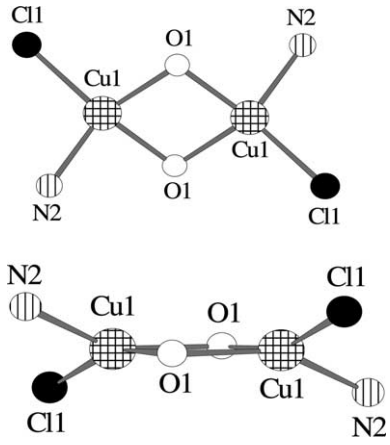

Fig. 2. Copper coordination of the binuclear complex **1**.

of two different ligand molecules (Fig. 2). Both oxygen atoms are connected to two adjacent copper atoms and thus act as bridges between them. The Cu_2O_2 structural core represents a flat rhomboid (distorted plain square) with Cu–O distances of 1.914(1) and 1.926(1) Å and O–Cu–O angles of 78.09(7)° (Table 2). The nitrogen and chlorine atoms completing the copper coordination reside out of the Cu_2O_2 plane at angles of 16.77(6)° and 17.02(6)°, respectively (Fig. 2, Table 2), the corresponding Cu–N and Cu–Cl distances being essentially the same as found in other similar complexes [12].

Each molecule of the binuclear complex participates also in the formation of H-bonds with four molecules of DMSO, two of them bonded with hydrogen atoms of the coordinated NH functions and two with the uncoordinated free NH_2 groups of the ligands (Fig. 3). Due to the different length of the two type H-bonds (N1–H13 = 0.86(1) Å, H13···O2 = 2.13(2) Å, N2–H1 = 0.80(1) Å and H1···O3 = 2.16(2) Å, Table 2), they differ in their bond-strength, confirmed also by the corresponding thermogravimetric data (see below).

The overall structure of complex **1** could be described as a layered one consisting of slabs of $Cu_2L_2Cl_2$ molecules oriented parallel to the *ab* plane, separated by double layers of solvent DMSO molecules (Fig. 4).

3.1.2. Thermogravimetric data

The thermogravimetric (TG) study revealed that in the temperature range 110–195 °C the mass of the complex diminished by 29.1%, equivalent to the release of four molecules of DMSO. The relatively low temperature for the beginning of the process could be related to the fact that DMSO is not directly coordinated to copper(II) but is incorporated in the crystal lattice by hydrogen bond formation.

The process of the DMSO removal proceeds in two stages. The first one that takes place at 110–165 °C is obviously due to the loss of the two DMSO molecules bound by weaker H-bonds with the hydrogens from the NH-functions (O3···H1, $r = 2.16(2)$ Å), while the last two DMSO molecules are associated with the hydrogens of the NH_2 group (O2···H13, $r = 2.13(2)$ Å) and are lost at higher temperatures (165–195 °C).

3.1.3. EPR and magnetochemical data

The intramolecular distance between the two copper(II) centres needs special attention, as it determines to a great extent the magnetochemical and EPR behaviour of the complex. In both frozen solution and solid samples at 77 K the green binuclear complex **1** is EPR silent and does not show any signals, a fact that correlates well with the short Cu–Cu distance of about 2.98 Å (Table 1). Evidently, the close vicinity and the proper orientation of the corresponding overlapping orbitals lead to a significant antiferromagnetic exchange interaction and to quenching of the signal.

These conclusions are in accordance with the magnetochemical data as well. As can be seen in Fig. 5, the

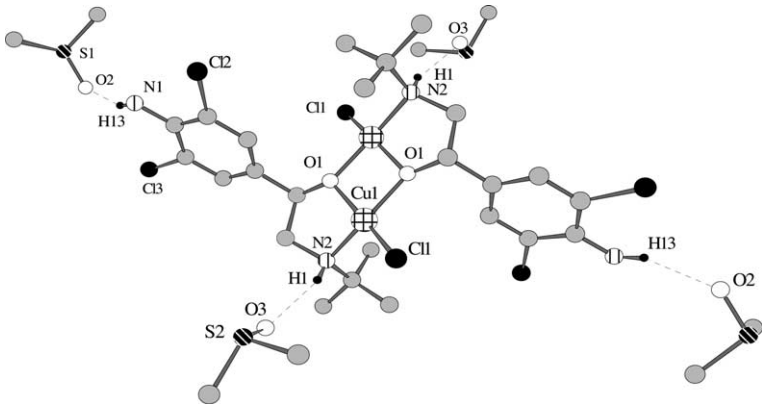

Fig. 3. Connectivity and H-bonding in $Cu_2L_2Cl_2 \cdot 4DMSO$.

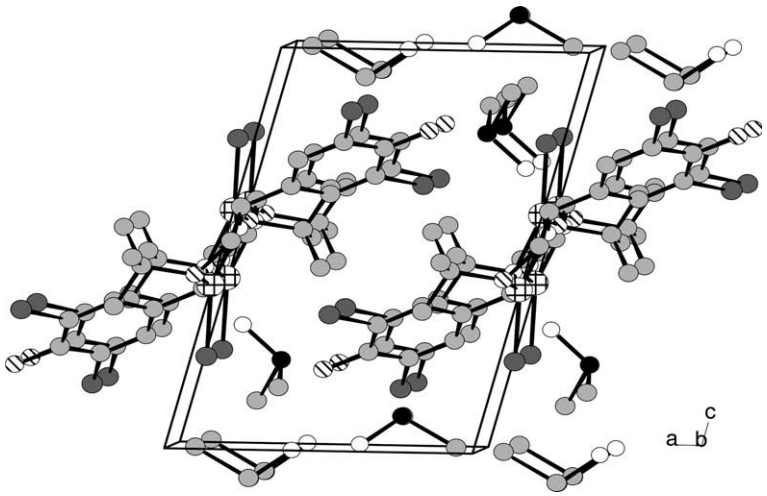

Fig. 4. Unit cell and 3-D packing of the binuclear complex **1**. The copper, nitrogen, chlorine, sulfur, carbon and oxygen atoms are shown as cross-hatched, hatched, dark-grey, black, grey and open circles, respectively, hydrogen atoms are omitted for clarity.

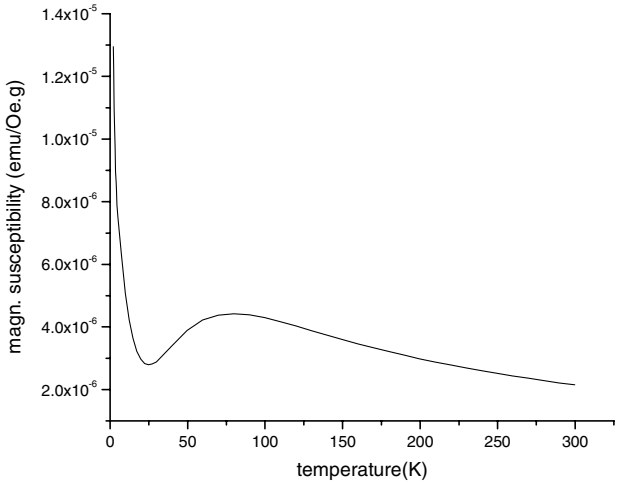

Fig. 5. Magnetic susceptibility vs. T for the binuclear complex **1**, measured at 1 kOe applied field.

magnetic susceptibility versus temperature curve has a complicated character with a maximum at T_N 80 K and an exponential course at lower temperatures. This later increase is signalling a paramagnetic contribution to the susceptibility at very low temperatures. At 125–300 K the Curie–Weiss law is followed with a large correlation coefficient of $R = 0.9993$. The effective magnetic moment calculated from the experimental data is 2.71 BM (the Weiss constant $C_m = 0.92$). Note that subtraction of the low-temperature paramagnetic component has negligible effect on both, the value of the effective magnetic moment and T_N. The absolute value of the paramagnetic asymptotic temperature, $\theta_N \approx -80$ K, is close to T_N suggesting that a paramagnetic-antiferromagnetic transition takes place at 80 K. The experimentally found magnetic moment is close to the theoretical one, which for a crystal field of $\Delta = 3000$ cm^{-1} is 2.65 BM [19–21]. Obviously, at temperatures over 125 K the antiferromagnetic interactions vanish and the Cu(II) centres show their paramagnetic character.

3.1.4. Electronic spectra

The binuclear complex **1** shows absorption bands at 750 and 380 nm in the mixed MeOH + DMSO solvent

described above. The first relatively weak band was assigned to a d–d transition in a near square-planar copper(II) structure, while the second more intense one at 380 nm ($\varepsilon \approx 460\,l\,mol^{-1}\,cm^{-1}$) was attributed to a charge-transfer transition O → Cu. The last band is typical for copper(II) polynuclear complexes with bridging oxygen atoms of the type Cu–O–Cu [22–24].

3.1.5. IR spectra

The pure ligand HL·HCl shows absorption bands at 3400, 3355, 3320–3120 cm^{-1} within the range 3500–3000 cm^{-1}, which are assigned to the stretching vibrations of hydroxyl, imino and aminogroups engaged in H-bonding of the intra- and intermolecular type [25]. This assignment is also supported by the fact that the coordination with Cu(II) leads to a pronounced decrease of the absorbance in the 2800–2300 cm^{-1} range due to the formation of H-bonds. Complex **1** shows only three bands at 3420, 3330 and 3180 cm^{-1}, ascribed to $\nu_{as}(NH_2)$, $\nu_{sym}(NH_2)$ and ν(NH). The reduction of the number of bands in this range after complexation could be related to deprotonation of the hydroxyl group and hence to the disappearance of the ν(OH) stretching vibration. At the same time three new bands in the far IR-spectrum appear at 490, 382 and 254 cm^{-1}, assigned to ν(Cu–N), ν(Cu–O) and ν(Cu–Cl), respectively [25]. Another broad and intensive band appears at 1030 cm^{-1} attributed to the stretching vibration ν(S=O) of the SO-group from the DMSO molecules [25].

3.2. Mononuclear $CuL_2 \cdot 2CH_3OH$ complex 2

3.2.1. X-ray data and crystal structure

The X-ray analysis and structure refinement showed that the violet compound **2** is a mononuclear complex with a square-planar structure and a general formula of $CuL_2 \cdot 2CH_3OH$. In the structure the copper atoms are located on an inversion centre and occupy one crystallographically independent special position (1c: 0, 1/2, 0), while all other atoms occupy general (2i: x, y, z) positions. The asymmetric unit of the complex consists of one copper atom, one ligand molecule, coordinated through its oxygen and nitrogen atoms, and one CH_3OH molecule, i.e., one half of the complex and solvent molecules (Fig. 6). The CuO_2N_2 core has a nearly square-planar structure with O–Cu–O and N–Cu–N angles of 180° (Fig. 7, Table 3). The Cu–O and Cu–N distances (Table 3) are in good agreement with those for other aminoalcohol complexes of Cu(II) [7,12]. The methanol molecules included in the overall structure are not directly coordinated to Cu(II) but form hydrogen bonds of the type $CH_3OH\cdots O$ with the oxygen atom of the ligand (Fig. 8) with O2–H15 and H15···O1 distances of 0.778(2) and 1.870(2) Å, respectively.

3.2.2. Electronic, IR and EPR spectra

The electronic spectrum of the mononuclear complex **2** in methanol shows one broad asymmetric absorption band at 580 nm ($\varepsilon \approx 200\ l\ mol^{-1}\ cm^{-1}$) assigned to the d–d transition in a distorted tetragonal structure of the Cu(II) complex, where copper is bound with oxygen and nitrogen donor atoms.

The IR spectrum of **2** shows five bands in the 3470–3100 cm^{-1} range, assigned to the stretching vibrations of NH_2 and NH, shifted as a result of the coordination to Cu(II), and of (OH) from CH_3OH. In addition two new bands in the far IR spectrum appeared at 490 and 396 cm^{-1}, ascribed to ν(Cu–N) and ν(Cu–O), respectively [25]. The strong absorbance of the free ligand in the 2800–2300 cm^{-1} range is reduced in intensity due to the ligand coordination and the H-bond rupture caused by it.

The X-band EPR spectra of the complex, both in the solid phase and in frozen solutions (77 K), are typical for mononuclear paramagnetic Cu(II) complexes. The EPR parameters $g_{\|} = 2.245$, $g_{\perp} = 2.022$, $A = 160$ G and the relation $g_{\|} > g_{\perp}$ show that the unpaired d-electron of Cu(II) occupies predominately the $d_{x^2-y^2}$-orbital. Thus the formation of a strongly distorted (practically a square-planar) complex was confirmed again. The frozen solution spectra reveal also an unresolved SHFS from ^{14}N in the perpendicular magnetic field, due to the coordination of the NH-function to Cu(II). The same solution shows an isotropic signal with $g_{iso} = 2.120$ and $A_{iso} = 68$ G at 293 K. The experimental EPR data correlate well with those reported for similar copper(II) complexes [12].

4. Conclusions

Clenbuterol forms two complexes with copper(II) – the binuclear $Cu_2L_2Cl_2 \cdot 4DMSO$ and the mononuclear $CuL_2 \cdot 2CH_3OH$, acting as a bidentate chelate forming ligand with its imino and deprotonated hydroxyl functions. In both complexes copper has a slightly distorted square-planar coordination. In complex **1** the two copper atoms are linked together through oxygen atom bridges from two ligand molecules. Thus the coordination sphere around each of the two Cu centres includes two oxygen, one nitrogen and one terminal Cl atom. In complex **2** Cu(II) is coordinated with two oxygen and two nitrogen atoms from two ligand molecules.

The relatively short distance between the two copper atoms in **1** is responsible for a strong antiferromagnetic exchange interaction, that determines its interesting magnetic properties – a complete quenching of the EPR signals and a specific temperature dependence of the magnetic susceptibility. As for complex **2**, it shows the typical behaviour of a normal paramagnetic Cu(II) complex.

In the solid phase, solvent molecules (4DMSO or $2CH_3OH$ per molecule of the complex) are also incorporated in the crystal lattice, linked through H-bonds with the ligand. There is a marked difference, however, between the bonding of the two solvents. In **1** the DMSO molecules with their S=O groups serve as H-atom acceptors, the hydrogen atoms of the bond coming from NH and NH_2 of the ligand, while in **2** the H-atom acceptor is the oxygen of the deprotonated ligand, the H-atom donor being the OH function of CH_3OH.

5. Supplementary information

Full crystallographic details have been deposited in *cif*-format with the Cambridge Crystallographic Data Centre, CCDC 268587 for **1** and 268588 for **2**. Copies of this information can be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk, Web: http://www.ccdc.cam.ac.uk/conts/retrieving/html.

[25] K. Nakamoto, Infrared and Raman Spectra of Inorganic and Coordination Compounds, 5th ed., Wiley, New York, Toronto, 1997.

For example, the mononuclear complex [Co(L-cys-*N*,*S*)$_3$] shows only the Δ isomer due to the large energy gap between the Δ and Λ diastereomers [8,9]. For trinuclear Co(III) complexes with L-cys-*N*,*S* and D-pen-*N*,*S* ligands, interesting synthetic behavior was observed [10–14], that is, the selectivities sometimes show a difference between L-cys-*N*,*S* and D-pen-*N*,*S* ligands, because of the structural effect of the two methyl groups on the carbon atom next to the sulfur atom in the D-pen-*N*,*S* ligand [10,11]. However, the L-cys-*N*,*S* and D-pen-*N*,*S* complexes are not good models for aet polynuclear complexes by virtue of the carboxyl group, which greatly influences the stereoselectivity of polynuclear structures by forming intermolecular hydrogen bonds [12–14]. On the other hand, the reaction using optically active *R*-1,2-propanediamine (*R*-pn) gave optically active metal centers, e.g., the configuration of [Co(*R*-pn)$_3$]$^{3+}$ is mainly a Δ configuration [15,16]. It has been reported that the polynuclear complexes ΔΔ-[M{Co(aet)$_2$(*R*-pn)}$_2$]$^{4+}$ (M = Ni^{II}, Pd^{II}, Pt^{II}) and Δ-[M(bpy){Co(aet)$_2$(*R*-pn)}]$^{3+}$ (M = Pd^{II}, Pt^{II}), have been stereoselectively obtained with an optically active ligand *R*-pn [17–20]. In these complexes, all *R*-pn chelate rings take a λ conformation because the methyl groups of *R*-pn take equatorial configurations. Therefore, introduction of chirality by a methyl group on the carbon atom next to the sulfur atom can play a role in not only stereochemical and electrochemical effects for thiolato sulfur atoms, but also stereoselective formation of S-bridged polynuclear complexes.

Recently, we have reported the aggregation of polynuclear structures using the *racemic* penicillaminate ligand. The reaction of [Co(D-pen-*N*,*O*,*S*)(L-pen-*N*,*O*,*S*)]$^-$ with $HgCl_2$ did not give [Hg{Co(D-pen-*N*,*O*,*S*)(L-pen-*N*,*O*,*S*)}$_2$] but [Hg{Co(D-pen-*N*,*O*,*S*)$_2$}{Co(L-pen-*N*,*O*,*S*)$_2$}], accompanied by ligand-exchange on the mononuclear Co^{III} units [21]. Based on these observations, we designed 1-amino-2-propanethiolate (1-Meaet) as an aet derivative, which has a methyl group on the carbon atom next to the bridging sulfur atom. The methyl group does not form intramolecular hydrogen bonds and behaves as a small optically active center, distinct from the carboxylate group in L-cys-*N*,*S*, D-pen-*N*,*S* and L-pen-*N*,*S*. Therefore, the 1-Meaet ligand is expected to affect the stereoselective formation of S-bridged polynuclear complexes. In the [M(1-Meaet)$_3$] type unit, however, too many isomers were possible due to the Δ,Λ isomer and *R*,*S* configurations. Accordingly, it is convenient that the Ni(II) ion is used to construct polynuclear structures because of the simple geometry of the mononuclear unit [Ni(1-Meaet)$_2$] and substitution activity of the Ni(II) ion.

In this work, the structural and spectroscopic behaviors of mononuclear and polynuclear Ni(II) complexes with aet and the 1-Meaet ligand were investigated. First, the spectroscopic properties of the mononuclear complexes [Ni(aet)$_2$] and [Ni(1-Meaet)$_2$] are discussed. It is important to know the properties of the mononuclear units deeply when the structural and chemical properties of the polynuclear structures are approached. Moreover, the environment around the sulfur atom in the complexes is known at ease without difficult structural analysis, when the spectroscopic behavior of the sulfur compounds is ascertained [22–29]. Further, the synthesis and characterization of trinuclear complexes [Ni{Ni(1-Meaet)$_2$}$_2$]$^{2+}$, hexanuclear complexes [Pd$_2$-{M(1-Meaet)$_2$}$_4$]$^{4+}$ (M = Ni^{II}, Pd^{II}), and dinuclear complexes [Pt(bpy){Ni(1-Meaet)$_2$(L)}]$^{2+}$ (L = (H$_2$O)$_2$, bpy) are reported. The structures of [Pd$_2${Ni$_{0.6}$Pd$_{0.4}$-(1-Meaet)$_2$}$_4$]$^{4+}$ and [Pt(bpy){Ni(1-Meaet)$_2$(bpy)}]$^{2+}$ were determined by X-ray diffraction. Spectral properties are discussed for all complexes. Furthermore, ligand optical selectivity for each complex was observed and these complexes are compared with the corresponding aet complexes [30–33].

2. Experimental

2.1. Materials

The complexes [Ni(aet)$_2$] (**1a**) [34], [Ni{Ni(aet)$_2$}$_2$]$^{2+}$ (**2a**) [30], [Pd$_2${Ni(aet)$_2$}$_4$]$^{4+}$ (**3a**) [31], [Pt(bpy){Ni(aet)$_2$-(H$_2$O)$_2$}]$^{2+}$ (**4a**) [33], [Pt(bpy){Ni(aet)$_2$(bpy)}]$^{2+}$ (**5a**) [33] and [PtCl$_2$(bpy)] [35,36] were prepared by procedures similar to those in the literatures. The reagents were purchased from Tokyo Kasei Kogyo Co., Ltd., Wako Pure Chemical Ind., Ltd., Kanto Chemical Co., Inc. and Aldrich Chemical Co., Inc. All the chemicals were of reagent grade and were used without further purification.

2.2. Synthesis of the ligand

The ligand was prepared by modified methods of the literature [37,38].

2.2.1. 1-Amino-2-propylsulfate

A mixture of 1-amino-2-propanol (75.1 g, 1.0 mol) and carbon tetrachloride (400 cm^3) was cooled in a salt–ice bath. Chlorosulfonic acid (116.5 g, 1.0 mol) was added slowly to the cooled mixture. The reaction mixture was kept for 1 d and carbon tetrachloride was removed with vacuo. The crude solid was crushed with methanol (500 cm^3) and isolated by filtration. A pure white powder of 1-amino-2-propylsulfate was obtained by recrystallization from water/methanol. Yield: 63.2 g (41%). Calc. for $NH_2CH_2CH(CH_3)OSO_3H = C_3H_9NO_4S$: C, 23.22; H, 5.85; N, 9.03. Found: C, 23.35; H, 5.66; N, 9.15%. ^{1}H NMR in D_2O (δ (ppm) from DSS): 1.40 (3H, d, $J = 6.5$ Hz, CC*H*$_3$), 3.12 (1H, dd, $J = 8.8$ and 13.7 Hz, NC*H*$_2$), 3.27 (1H, dd, $J = 2.9$ and 13.7 Hz, NC*H*$_2$), 4.72 (1H, m, OC*H*).

2.2.2. 5-Methyl-2-thiazolidinethione

To a suspension containing 1-amino-2-propylsulfate (135 g, 0.87 mol) and carbon disulfide (79.5 g, 1.05 mol) in 50% ethanol (500 cm^3) was added NaOH (80 g, 2.0 mol) in water (200 cm^3) slowly in a salt–ice bath. After refluxing the reaction mixture for 40 min, ethanol was removed by evaporation. White crystals of 5-methyl-2-thiazolidinethione were obtained by recrystallization from water. Yield: 63.3 g (48%). Calc. for $NHCH_2CH(CH_3)SCS = C_4H_7NS_2$: C, 36.06; H, 5.30; N, 10.51. Found: C, 35.72; H, 5.37; N, 10.22%. ^1H NMR in D_2O (δ (ppm) from DSS): 1.43 (3H, d, $J = 6.5$ Hz, CCH_3), 3.71 (1H, dd, $J = 4.1$ and 11.3 Hz, NCH_2), 4.10 (1H, m, SC*H*), 4.13 (1H, dd, $J = 7.1$ and 11.3 Hz, NCH_2).

2.2.3. 1-Amino-2-propanethiol hydrochloride (1-MeaetH·HCl)

A suspension of 5-methyl-2-thiazolidinethione (19.8 g, 0.15 mol) in 6 M HCl (100 cm^3) was refluxed for 1 week. After evaporation to an oil, a white precipitate of 1-MeaetH·HCl was obtained by addition of a large amount of ethanol. Yield: 13.2 g (50%). Calc. for $NH_2CH_2CH(CH_3)SH\cdot HCl\cdot 0.75(H_2O) = C_3H_{11.5}ClNO_{0.75}S$: C, 25.53; H, 8.21; N, 9.92. Found: C, 26.07; H, 8.00; N, 9.90%. ^1H NMR in D_2O (δ (ppm) from DSS): 1.41 (3H, d, $J = 6.9$ Hz, CCH_3), 2.99 (1H, dd, $J = 8.9$ and 12.8 Hz, NCH_2), 3.16 (1H, m, SC*H*), 3.25 (1H, dd, $J = 5.1$ and 12.9 Hz, NCH_2).

2.3. Synthesis of the complexes

2.3.1. [Ni(1-Meaet)$_2$] (**1b**)

A solution containing 1-MeaetH·HCl (10.2 g, 0.080 mol) and NaOH (6.4 g, 0.16 mol) in water (100 cm^3) was added dropwise to a solution containing $NiCl_2\cdot 6H_2O$ (9.51 g, 0.040 mol) in water (100 cm^3). The mixture was stirred at 95 °C for 10 min. After cooling to room temperature, the resulting green precipitate was collected by filtration and washed with a large amount of water and methanol. Yield: 9.96 g (83%). Calc. for $[Ni(1\text{-}Meaet)_2] = C_6H_{16}N_2NiS_2$: C, 30.15; H, 6.75; N, 11.72. Found: C, 30.16; H, 6.61; N, 11.68%.

2.3.2. [Ni{Ni(1-Meaet)$_2$}$_2$]Cl$_2$ (**2b**Cl$_2$)

A solution containing $NiCl_2\cdot 6H_2O$ (2.4 g, 10 mmol) in ethanol (50 cm^3) was added dropwise to a suspension containing [Ni(1-Meaet)$_2$] (0.48 g, 2.0 mmol) in ethanol (30 cm^3). The mixed solution was stirred at room temperature for 1 h. The resulting brown powder was collected by filtration and washed with ethanol. Yield: 0.27 g (44%). Calc. for $[Ni\{Ni(1\text{-}Meaet)_2\}_2]Cl_2 = C_{12}H_{32}Cl_2N_4Ni_3S_4$: C, 23.72; H, 5.31; N, 9.22. Found: C, 23.62; H, 5.44; N, 9.09%.

2.3.3. [Pd$_2${Ni$_{0.6}$Pd$_{0.4}$(1-Meaet)$_2$}$_4$]Br$_4$ (**3b**Br$_4$)

To a green suspension containing [Ni(1-Meaet)$_2$] (0.71 g, 2.4 mmol) in water (50 cm^3) was added $Na_2[PdCl_4]$ (0.35 g, 1.2 mmol). The mixture was stirred at 40 °C for 2 h, which gave a deep red solution. After the mixture was allowed to stand at room temperature for 1 h, the [Ni(1-Meaet)$_2$] was filtered out. Addition of sat. NaBr aq. (20 cm^3) gave deep red crystals, which were washed with small amount of methanol–ethanol (1:1). One of the crystals was used for X-ray structural analysis. Yield: 0.41 g (43%). Pd:Ni = 3.66:2.34 (ICP analysis). Calc. for $[Pd_2\{Ni_{0.6}Pd_{0.4}(1\text{-}Meaet)_2\}_4]Br_4\cdot H_2O = C_{24}H_{66}Br_4N_8Ni_{2.4}OPd_{3.6}S_8$: C, 18.21; H, 4.20; N, 7.08. Found: C, 18.25; H, 4.34; N, 7.07%.

2.3.4. [Pt(bpy){Ni(1-Meaet)$_2$(H$_2$O)$_2$}](NO$_3$)$_2$ (**4b**(NO$_3$)$_2$)

To a suspension containing [$PtCl_2$(bpy)] (0.51 g, 1.2 mmol) in water (25 cm^3) was added [Ni(1-Meaet)$_2$] (0.36 g, 1.2 mmol). The mixture was stirred at 40 °C for 1 h, whereupon the mixture became a yellow-brown solution. After filtering off the unreacted materials, to the yellow-brown filtrate was added a saturated $NaNO_3$ solution (30 cm^3). The mixture was allowed to stand at room temperature for 3 d and the resulting yellow-brown crystals were collected by filtration. Yield: 0.55 g (61%). Calc. for [Pt(bpy){Ni(1-Meaet)$_2$(H$_2$O)$_2$}](NO$_3$)$_2$ = $C_{16}H_{28}N_6NiO_8PtS_2$: C, 25.61; H, 3.76; N, 11.20. Found: C, 25.56; H, 3.66; N, 11.51%.

2.3.5. [Pt(bpy){Ni(1-Meaet)$_2$(bpy)}](NO$_3$)$_2$ (**5b**(NO$_3$)$_2$)

To a solution containing [Pt(bpy){Ni(1-Meaet)$_2$(H$_2$O)$_2$}](NO$_3$)$_2$ (0.15 g, 0.2 mmol) in water (30 cm^3) was added 2,2′-bipyridine (0.030 g, 0.1 mmol). The mixture was stirred at 50 °C for 10 min, whereupon the color of the solution changed from yellow-brown to red-brown. To the solution was added a small amount of a saturated $NaNO_3$ solution, followed by standing at room temperature for 3 d. The resulting microcrystals were collected by filtration. One of the crystals was used for X-ray structural analysis. Yield: 0.11 g (59%). Calc. for [Pt(bpy){Ni(1-Meaet)$_2$(bpy)}](NO$_3$)$_2$·2H$_2$O = $C_{26}H_{32}N_8NiO_8PtS_2$: C, 34.60; H, 3.57; N, 12.42. Found: C, 34.88; H, 3.79; N, 12.45%.

2.4. Measurements

The elemental analysis (C, H, and N) was performed by the Research Facility Center for Science and Technology or the Department of Chemistry in the University of Tsukuba. The concentrations of the metal ions in the complexes were determined with a NIPPON Jarell-Ash ICPA-575 spectrophotometer. The UV/Vis absorption spectra were recorded with a JASCO V-570 spectrophotometer and solid state diffuse

reflectance (DR) spectra were recorded with the JASCO V-570 spectrophotometer equipped with an integrating sphere apparatus (JASCO ISN-470) using powder samples diluted with MgO. The IR and far-IR spectra were recorded with a JASCO FT/IR-550 spectrometer using KBr disks in the range 4600–400 cm^{-1} and Nujol mulls between polyethylene plates in the range 650–50 cm^{-1}. The Raman spectra were obtained on a JASCO RFT-200 laser Raman spectrophotometer using KBr disks with excitation by a YAG laser line (1064 nm). The ^{1}H and ^{13}C NMR spectra were recorded with a BRUKER AM-600 or AM-500 NMR spectrometer in D_2O and sodium 4,4-dimethyl-4-silapentane-1-sulfonate (DSS) was used as an internal reference. The sulfur K-edge XAS measurement was carried out in the fluorescence mode at the beamline BL-9A of the Photon Factory, High Energy Accelerator Research Organization (KEK-PF) using synchrotron radiation at 2.5 GeV with an average current of 400 mA. X-rays were monochromatized with a Si(1 1 1) double crystal monochromator and higher orders were reduced with a pair of Ni-coated flat mirrors [39,40]. The energy of the peaks of $Na_2S_2O_3 \cdot H_2O$ was assumed as 2472.02 eV. All the measurements were carried out at room temperature.

2.5. X-ray structure determination

Single crystal X-ray data collections were performed on a Rigaku R-AXIS RAPID (**3b**$Br_4 \cdot 4H_2O$) or a Rigaku Mercury CCD (**5b**$(NO_3)_2$) area detector with graphite-monochromatized Mo Kα (0.71069 Å) radiation. The intensity data were collected up to 55° at 296 K. The crystal data and experimental parameters are listed in Table 1. The positions of most non-hydrogen atoms were determined by a direct method (SIR-92 [41]) and some remaining atom positions were found by successive difference Fourier techniques (DIRDIF-99) [42]. The structures were refined by full-matrix least-square techniques using anisotropic thermal parameters for non-hydrogen atoms. In **3b**$Br_4 \cdot 4H_2O$, the mixed Ni/Pd sites (0.6Ni + 0.4Pd) atoms (M1 and M2) were refined as Ni atoms with a site occupancy factor of 1.277, according to the reported method [31], and no hydrogen atoms were included in the refinement. In **5b**$(NO_3)_2$, the disordered C16 and C27 atoms were refined with a site occupancy factor 0.5, and all hydrogen atoms except those connect to disordered carbon atoms were included in the refinement but restrained to ride on the atoms (C–H = N–H = 0.95 Å, $U(H) = 1.2U(C, N)$). The calculations were performed using the CrystalStructure crystallographic software package [43].

3. Results and discussion

3.1. Synthesis and properties of the ligand

1-MeaetH·HCl was prepared by modified methods of the literature [37,38]. There was a very simple description

Table 1
Crystallographic data for $[Pd_2\{Ni_{0.6}Pd_{0.4}(1\text{-Meaet})_2\}_4]Br_4 \cdot 4H_2O$ (**3b**$Br_4 \cdot 4H_2O$) and $[Pt(bpy)\{Ni(1\text{-Meaet})_2(bpy)\}](NO_3)_2$ (**5b**$(NO_3)_2$)

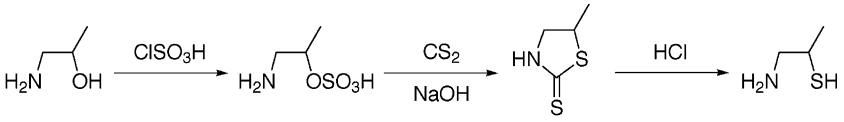
[b] $R_w = [\sum w(|F_o| - |F_c|)^2/\sum wF_o^2]^{1/2}$, $w = 1/(0.0001F_o^2 + 3\sigma F_o^2 + 0.5)$ for **3b**$Br_4 \cdot 4H_2O$ and $1/(0.005F_o^2 + \sigma F_o^2)$ for **5b**$(NO_3)_2$.

with an aminothiol series in the literature, therefore the synthesis of 1-MeaetH·HCl was examined and was improved in detail. This ligand was obtained by a three step reaction (Scheme 1), and the compounds of each step and the desired ligand were characterized by elemental analysis and ^{1}H NMR spectra. The first step reaction is violent, even when the reaction was carried out on a salt–ice bath, to give 1-amino-2-propylsulfate. Elevation of the reaction temperature accelerates side reactions. The second step reaction gave 5-methyl-2-thiazolidinethione with ring formation reaction of 1-amino-2-propylsulfate and carbon disulfide. The third step reaction in 6 M HCl aqueous solution is a ring opening reaction giving 1-MeaetH·HCl. This ligand is soluble in water and less soluble to general organic solvents, and can be purified by washing with an organic solvent to remove 5-methyl-2-thiazolidinethione.

3.2. Synthesis and spectrochemical properties of the mononuclear complexes

The mononuclear complex [Ni(1-Meaet)$_2$] (**1b**) was prepared by a modified method of the corresponding aet complex [Ni(aet)$_2$] (**1a**), which involved the reaction of the 1-Meaet ligand with the Ni(II) ion in basic aqueous solution (Scheme 2). These neutral complexes **1a** and **1b** are not soluble in general solvents, but are soluble in acidic water following protonation on the sulfur atoms of coordinated thiolato group.



Scheme 2.

	2472.2	2472.2	1s-σ*(S–C)

It is well known that the bonding relation of metal ion and donor atoms is reflected in the vibration spectra of the far-IR region about 600–100 cm^{-1}. By comparing with the Raman spectral data, the far-IR spectrum is more accurately attributed. The far-IR and Raman spectra are shown in Fig. 1. These data were assigned by a comparison to the spectra of complexes containing aet and related compounds [44–47] (Table 2). In general, the metal–amino stretching band is weaker than the metal–thiolato stretching band, which is discussed well in the literature [45–48]. The Ni–S stretching band of **1b** was observed at a higher region than that of **1a**, whereas the Ni–N band of **1b** was observed at a very similar region to that of **1a**. Namely, the Ni–S bands were influenced in the far-IR and Raman spectra by the methyl group on the carbon atom next to the sulfur atom. In addition, the far-IR and Raman spectra show complementary bands to each other, showing a *trans*(*S*)-N_2S_2 geometry.

Scheme 1.

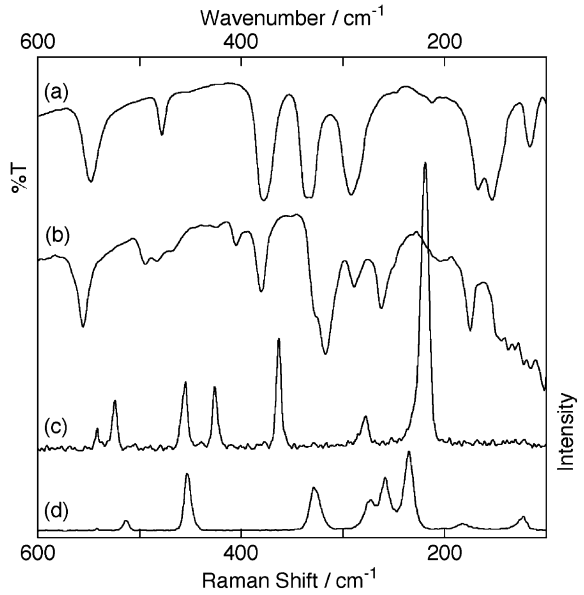

Fig. 1. Far-IR spectra of $[Ni(aet)_2]$ (**1a**) (a) and $[Ni(1\text{-}Meaet)_2]$ (**1b**) (b); Raman spectra of **1b** (c) and **1a** (d).

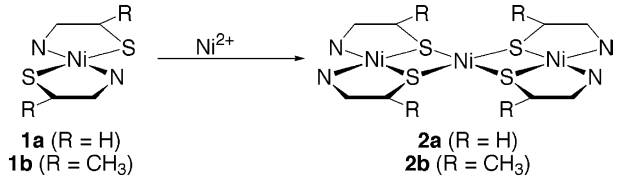
The sulfur atom has four X-ray absorption bands at ca. 2472, 229, 165 and 164 eV which derive from $1S_{1/2}$, $2S_{1/2}$, $2P_{1/2}$ and $2P_{3/2}$, respectively [22]. In the mononuclear complexes, the sulfur atoms have bonding only to carbon and metal ions. Recently, the analysis of the X-ray absorption spectrum of the ligand has paid attention to the relationship between the coordinated atom and metal ion. It is reported that the ligand K-edge spectra involve the nature of the electron transition from the 1s to np orbital [22–29]. The energy changes for the 3p orbital of the sulfur atom due to the effect of metal ion, and the transition energy from 1s to 3p also changes. In **1a** and **1b** there are two absorption bands at 2470 and 2472 eV in agreement with each other (Table 2). The band at 2470.3 eV in **1a** is shifted to 2470.6 eV in the isomeric metal complex $[Pd(aet)_2]$, regardless that the band at 2472.2 eV in **1a** is observed in same region in $[Pd(aet)_2]$ [49]. Consequently, the shifted band seems to be assigned to the transition from the S 1s orbital to the antibonding orbital of the S–M bond, and the unshifted band was assigned to the transition from the S 1s orbital to the σ* orbital of S–C bond.

3.3. Synthesis and spectrochemical properties of linear-type trinuclear complexes



The reaction of $[Ni(1\text{-}Meaet)_2]$ (**1b**) with $NiCl_2\cdot 6H_2O$ in ethanol gave the S-bridged trinuclear complex, $[Ni\{Ni(1\text{-}Meaet)_2\}_2]Cl_2$ (**2b**Cl_2), which was not obtained in aqueous solution, different from the corresponding aet complex, $[Ni\{Ni(aet)_2\}_2]Cl_2$ (**2a**Cl_2) (Scheme 3). **2b** is soluble in water and methanol, but it easily decomposes to Ni(II) ion and ligand, and cannot be recrystallized conveniently. Namely, **2b** cannot retain its structure in a donating solvent such as water. This reflects the lower coordination ability of 1-Meaet compared to aet. Accordingly, all the measurements were carried out in the solid state.

The IR spectral pattern of **2b**Cl_2 shows more broadening than that of **2a**Cl_2 (Fig. S2), similar to those of the corresponding mononuclear complexes **1b** and **1a**. This behavior may depend on the existence of the diastereomers of **2b**Cl_2. In the far-IR spectra, the same phenomenon was observed (Fig. S3). On the other hand, DR spectral data of **2b**Cl_2, summarized in Table 3, exhibit some DR bands which are in good agreement with those of **2a**Cl_2. Consequently, **2b**Cl_2 is in agreement for a trinuclear alignment on the metal center like **2a**Cl_2 [30], although some diastereomers in **2b**Cl_2 differ from the aet derivative **2a**Cl_2.

3.4. Synthesis, structure and spectrochemical properties of pinwheel-like hexanuclear complexes

Syntheses of the complex $[Pd_2\{Ni_{0.6}Pd_{0.4}(1\text{-}Meaet)_2\}_4]^{4+}$ (**3b**) was achieved by the reaction of the mononuclear complex $[Ni(1\text{-}Meaet)_2]$ (**1b**) with 0.5 M equivalents $Na_2[PdCl_4]$ in water under moderate conditions (Scheme 4), in accord with the preparation of $[Pd_2\{Ni(aet)_2\}_4]^{4+}$ (**3a**) [31]. The partial substitution of the Ni(II) ion by the Pd(II) ion occurred during the reaction of **3b**. The ratio of metal ions was determined by ICP analysis. In contrast, no metal substitutions were observed for the corresponding aet complex **3a** [31]. From these facts, the coordination bonds of the Ni(II) and sulfur atoms for **3b** are weaker than those of **3a**. In the formation of **2b**, a similar synthetic behavior was observed.

X-ray structural analysis of **3b**$Br_4\cdot 4H_2O$ showed the presence of two crystallographically independent complex

cations, bromide anions and water molecules. A perspective drawing of one of the two complex cations of **3b** is shown in Fig. 2. The selected bond distances and angles are listed in Table 4. The structures of the two complex cations resemble each other well. The ICP analysis for **3b** gave a value of Ni:Pd = 2.4:3.6. Therefore, it was assigned that **3b** consists of four square-planar *cis*(*S*)-[M(1-Meaet)$_2$] (M = 0.6Ni + 0.4Pd) units and two central Pd atoms. Two S atoms in each of the four *cis*(*S*)-[M(1-Meaet)$_2$] units bind to two Pd atoms such that each Pd atom is situated in a square-planar environment. As a result, four S atoms in each PdS_4 plane are required to have the same absolute configuration, completing a pinwheel-like S-bridged hexanuclear structure with C_{4h} symmetry similar to **3a** [31]. The angles around the Pd atom are approximately 90°, which suggest substantially an ideal square-planar structure. The angles around the M (0.6Ni + 0.4Pd) atom also suggest a square-planar configuration. This structure is in agreement with that of **3a**. The Pd···Pd distances of **3b** (average 3.073(3) Å) are intermediate between **3a** (3.0240(7) Å) and $[Pd_2\{Pd(aet)_2\}_4]^{4+}$ (3.1886(6) Å) [31]. Considering the chirality due to the asymmetric carbon atom of the 1-Meaet ligand in the *cis*(*S*)-[M(1-Meaet)$_2$] unit, three isomers, *RR*, *RS* and *SS*, are possible. In the solid state structure, the complex cation exhibits the *RS* isomer with high selectively. When four square-planar *cis*(*S*)-[M(1-Meaet)$_2$] units coordinate to

two square-planar Pd(II) ions by the pinwheel-like structure, a δλ conformation of two 1-Meaet chelate rings is required. Since the *R* configuration for a λ conformation and the *S* configuration for a δ conformation are more stable, it seems that in the polynuclear structures a configuration with the lowest steric hindrance is attained in spite of the existence of many diastereomers in the mononuclear complex **1b**.

The IR spectra of **3b** suggest the stereoselective formation of a hexanuclear geometry in Fig. S4. The IR spectral patterns are relatively sharp in **3b**Br_4, unlike the Ni(II) mononuclear complex **1b** and trinuclear complex **2b**. A small broad pattern for **3b**Br_4 compared to that for **3a**Br_4 derives from the mixed metal mononuclear units.

The ^1H and ^{13}C NMR spectra of **3b** showed complicated signals and the chemical shifts could not be assigned clearly (Fig. 3 and Table 5). This may be attributed to the fact that many metal substituted isomers coexist for this complex in solution. In the case of the corresponding aet complex, **3a**, the ^1H NMR spectrum showed simple signals for CH_2 and the ^{13}C NMR spectrum showed only two sharp signals for carbons neighbouring to S and N [31]. On the other hand, the absorption spectra in the UV/Vis region of **3a** and **3b** in water exhibit characteristic bands as illustrated in Fig. 4. Their data are summarized in Table 5. The absorption intensity in the region 15–50 × 10^3 cm^{-1} for **3b** was smaller than that for **3a** because the Ni ratio of **3b** is smaller than that of **3a**. Thus, the partial metal substitution of the mononuclear unit was clearly observed in the NMR and UV/Vis spectra.

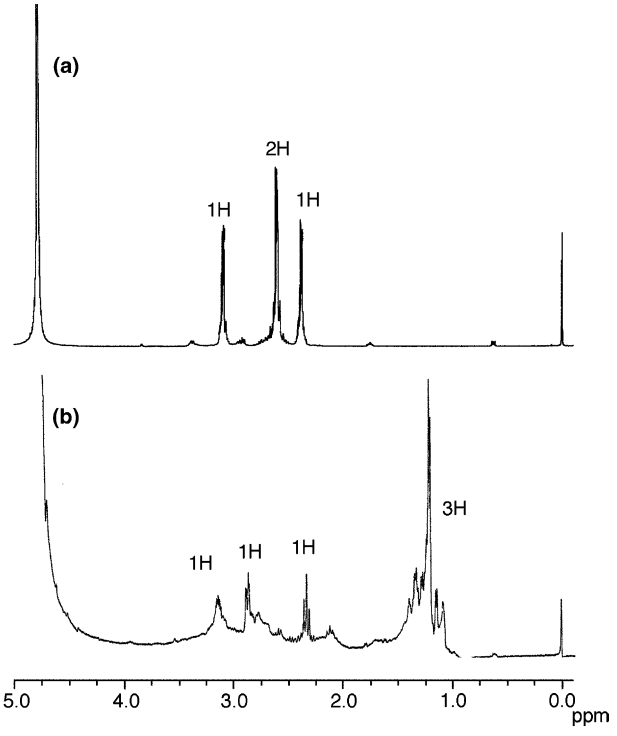

Fig. 3. ^1H NMR spectra of $[Pd_2\{Ni(aet)_2\}_4]^{4+}$ (**3a**) (a) and $[Pd_2\{Ni_{0.6}Pd_{0.4}(1\text{-Meaet})_2\}_4]^{4+}$ (**3b**) (b).

3.5. Synthesis, structure and spectrochemical properties of heteroleptic dinuclear complexes

The dinuclear complexes $[Pt(bpy)\{Ni(1\text{-Meaet})_2(H_2O)_2\}]^{2+}$ (**4b**) and $[Pt(bpy)\{Ni(1\text{-Meaet})_2(bpy)\}]^{2+}$ (**5b**) were prepared using 1-MeaetH·HCl by the same methods as those for $[Pt(bpy)\{Ni(aet)_2(H_2O)_2\}]^{2+}$ (**4a**) and $[Pt(bpy)\{Ni(aet)_2(bpy)\}]^{2+}$ (**5a**) (Scheme 5). The reaction of $[Ni(1\text{-Meaet})_2]$ (**1b**) with $[PtCl_2(bpy)]$ in water at 40 °C gave the heterodinuclear complex **4b**. Two chloride ligands, which are replaced easily by other ligands, are coordinated in $[PtCl_2(bpy)]$. Therefore, the heterodinuclear geometry of **4b** was controlled by the substitution reaction to the metalloligand **1b**. The coordinated water molecules were further replaced by a bpy ligand, and gave the dinuclear complex **5b**. Addition of nitrate ion to the reaction mixture gave single crystals, whereas the presence of the bromide ion caused the dissociation of the bpy ligand.

The X-ray structural analysis for **5b**$(NO_3)_2$ revealed the presence of a discrete divalent hetero-ligand complex cation and two nitrate anions. A perspective drawing of the complex cation is given in Fig. 5. Selected bond distances and angles are listed in Table 6. The complex cation contains one Ni atom and one Pt atom to form the dinuclear complex. The Ni atom in **5b** is surrounded by two 1-Meaet ligands and one bpy ligand, having an approximately octahedral geometry. The Pt atom has a square planar geometry, which has been coordinated by two bridged S atoms from the Ni(II) mononuclear unit and two N atoms from bpy. There is pseudo C_2 symmetry on the Pt–Ni axis. The Pt···Ni distance in **5b** is similar to that in **5a** (3.4987(8) Å) [32,33]. The Ni–S (average 2.446(3) Å), Pt–S (average 2.308(3) Å) distances, and related bonding are very similar to those of **5a**. The introduction of the methyl group has no effect on the bond distances and angles. Considering the absolute configurations (Δ and Λ) of the *cis*(*S*)-[Ni(1-Meaet)$_2$(bpy)] unit and the chirality due to the asymmetric carbon atoms (*R* and *S*) of the 1-Meaet ligand, three isomers Δ_{RR}/Λ_{SS}, Δ_{RS}/Λ_{RS} and Δ_{SS}/Λ_{RR} are possible. In the crystal, the complex cation exists as a mixed crystal of Δ_{RR}/Λ_{SS} and Δ_{RS}/Λ_{RS} isomers. The representative Λ isomer is indicated in Fig. 5. The PdS_4 plane and the NiS_2N_2 plane with δλ conformation in **3b** are bent, whereas the PtS_2N_2 plane and the NiS_2N_2 equatorial plane in **5b** are essentially coplanar. Therefore, when the Λ unit coordinates to the square-planar Pt(II) ion, the δδ conformation of two 1-Meaet chelate rings is required. Although the *SS* configuration for the δδ conformation is the most stable, a secondary stable *RS* configuration is also formed due to incomplete stereo-

existence of free nitrate ion. These spectral patterns of 1-Meaet complexes are relatively sharp, which indicate that only a few isomers are in the complex as discussed in the structural section.

As illustrated in Fig. 6, the absorption spectra of **4b** and **5b**, and those of the corresponding aet complexes in water exhibit characteristic bands in the region 15–50×10^3 cm^{-1}. Their data are summarized in Table 7. Both 1-Meaet dinuclear complexes exhibit weak absorption bands at about 11.5 and 17.5×10^3 cm^{-1}. Similar absorption bands were also observed for aet dinuclear complexes and related Ni(II) mononuclear complexes,

in which the bands have been assigned as spin-allowed d–d transitions, $^3A_{2g} \rightarrow {}^3T_{2g}$ and $^3A_{2g} \rightarrow {}^1T_{2g}$, respectively, from the lower energy side [50–53]. Further, characteristic intense bands in the region 30–35 × 10^3 cm^{-1} were observed, which are assigned to the π system in the ligand. Comparing the spectral pattern of **4b** and **5b**, the absorption intensity of **4b** ($\varepsilon = 11\,800$ mol^{-1} dm^3 cm^{-1}) is about half that of **5b** ($\varepsilon = 26\,900$ mol^{-1} dm^3 cm^1), depending on the number of bpy ligands as reported earlier for the corresponding aet complexes [33].

4. Summary

In this work, the structures and spectrochemical properties of nickel(II) complexes have been discussed. The 1-Meaet ligand, which has a chiral center on the carbon next to the coordinated sulfur atom, was newly used. The spectroscopic behavior of the mononuclear complexes [Ni(aet)$_2$] and [Ni(1-Meaet)$_2$] was discussed in detail using DR, IR, far-IR, Raman and sulfur K-edge X-ray absorption spectra. The spectrochemical properties of mononuclear complexes are very important and useful for the investigation of S-bridged polynuclear complexes. Further, the 1-Meaet ligand was used for the synthesis of polynuclear complexes. By the introduction of the methyl group, the nucleophilicity of the coordinated sulfur atom seems to be lower considering the instability of the solution state of [Ni{Ni(1-Meaet)$_2$}$_2$]$^{2+}$ (**2b**) and the metal displacement behavior of [Pd$_2${Ni$_{0.6}$Pd$_{0.4}$(1-Meaet)$_2$}$_4$]$^{4+}$ (**3b**). It is difficult to observe the *R*,*S* and δ,λ selectivity of the *racemic* ligand without X-ray crystal structures. The crystal structure of **3b** consists only of the [M(*R*-1-Meaet)(*S*-1-Meaet)] (M = 0.6Ni + 0.4Pd) unit with a δλ conformation, which assembled without steric hindrance. This indicates that not only conformation but also configuration of the 1-Meaet ligand are selected perfectly in the bent S-bridged structure. On the other hand, the crystal structure of [Pt(bpy){Ni(1-Meaet)$_2$-(bpy)}]$^{2+}$ (**5b**) consists of Δ_{RR}/Λ_{SS} and Δ_{RS}/Λ_{RS}-[Ni(1-Meaet)$_2$(bpy)] units with λλ/δδ conformation. This suggests that the configuration of the ligand shows weak selectivity although the conformation of the ligand is selected in the planar S-bridged structure. Thus, the ligand selectivity on polynuclearization is very closely related to the structures of polynuclear complexes with substitution active metal ions.

2. Experimental

2.1. Materials and syntheses

All chemicals and solvents used in this work were of AR grade.

Caution!! Although no problems were encountered in this study, transition metal perchlorate is potentially explosive and should be handled with proper precautions.

The ligand *N*,*N*-dimethyl-*N*′-(pyrid-2-ylmethyl)-ethylenediamine (L) was synthesized according to the published procedure [10]. IR spectra were recorded as KBr discs on a Shimadzu IR-408 infrared spectrophotometer in the 4000–600 cm^{-1} region. The ultraviolet, visible, and near IR spectra were measured on a Hitachi UV-330 UV–Vis–NIR spectrophotometer using water as the solvent. Elemental analyses (C, H, N) were performed on a Perkin–Elmer 240C analyser. Magnetic susceptibility measurements of crystalline samples were carried out in the temperature range 2–300 K on a Maglab system 2000 magnetometer.

2.1.1. $[Ni_2L_2(\mu\text{-}SCN)_2(SCN)_2]\cdot 2H_2O$ (**1**)

To a methanol solution of $NiCl_2\cdot 6H_2O$ (1 mmol) and L (1 mmol) was added a concentrated aqueous solution of NH_4SCN (0.5 mmol). The resulting mixture was stirred for 4 h and then filtered. The blue single crystals suitable for X-ray analysis were obtained by slow evaporation of the filtrate. Yield: 66.06 mg (71%). *Anal.* for $C_{24}H_{38}N_{10}Ni_2O_2S_4$: Found. C, 38.7; H, 5.2; N, 18.8%. Calc. C, 38.7; H, 5.2; N, 18.8%. Selected IR data (KBr, ν cm^{-1}): 2110, 1600, 1009, 765. UV–Vis–NIR (λ_{max}, nm) (ε, $dm^3\,mol^{-1}\,cm^{-1}$) (H_2O): 986 (23.03), 586 (15.28), 362 (39.98).

2.1.2. $[Ni_2L_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]\cdot CH_3OH$ (**2**)

NaN_3 (0.5 mmol) in 10 ml of 5:1 (V:V) methanol–water solution was added to a methanol solution (10 ml) containing 1 mmol of $NiCl_2\cdot 6H_2O$ and 1 mmol of ligand L. The mixture was stirred for 4 h and then filtered. The blue single crystals were obtained by slow evaporation of the filtrate. Yield: 54.47 mg (68%). *Anal.* for $C_{21}H_{38}N_{18}Ni_2O$: Found. C, 37.4; H, 5.6; N, 37.3%. Calc. C, 37.3, H, 5.7, N, 37.3%. Selected IR data (KBr, ν cm^{-1}): 2040, 1600, 1470, 1430, 1100, 1020, 770. UV–Vis–NIR (λ_{max}, nm) (ε, $dm^3\,mol^{-1}\,cm^{-1}$) (H_2O): 992 (20.81), 594 (15.13), 365 (30.43).

2.1.3. $[Ni_2L_2(H_2O)_2(\mu_2\text{-}C_2O_4)]\cdot 2ClO_4$ (**3**)

$Ni(ClO_4)_2\cdot 6H_2O$ (1 mmol) was added to a methanol solution (5 ml) of the Ligand L (1 mmol). The mixture was stirred for 1 h and a concentrated aqueous solution of $K_2C_2O_4\cdot 6H_2O$ (1 mmol) was added slowly. The resulting solution was stirred for another 2 h and then filtered. The blue single crystals suitable for X-ray analysis were obtained by slow evaporation of the filtrate. Yield: 303.58 mg (76%). *Anal.* for $C_{24}H_{38}N_{10}Ni_2O_2S_4$: Found. C, 33.1; H, 4.7; N, 10.6%. Calc. C, 33.1; H, 4.8; N, 10.5%. Selected IR data (KBr, ν cm^{-1}):, 1651, 1600, 1471, 1444, 1313, 1121, 1108, 1091, 799, 626. UV–Vis–NIR (λ_{max}, nm) (ε, $dm^3\,mol^{-1}\,cm^{-1}$) (H_2O): 986 (12.79), 586 (13.19), 360 (22.13).

2.2. X-ray data collection and crystal structure determination

Single crystal X-ray diffraction studies were performed on a Bruker Smart 1000 CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and semi-emperical absorption corrections were applied. The non-hydrogen atoms were located by direct phase determination and full-matrix least-squares refinement on F^2, while the hydrogen atoms for non-water protons were treated using the riding mode. Further details of the structural analyses are summarized in Table 1. All calculations were carried out using SHELXS-97 [11], SHELXL-97 [12] programs.

3. Results and discussion

3.1. Spectroscopic characterization

The IR spectra of binuclear species **1**–**3** show medium bands at ca. 1600 cm^{-1}, which were assigned to the ν(pyridyl) stretching. The ν(CN) stretching frequency of **1** was found at 2110 cm^{-1}, and the $\nu(N_3^-)$ stretching frequency of **2** at 2040 cm^{-1}. In the IR spectrum of **3** bonds at 1651, 799, and 1300–1400 cm^{-1} are attributed to ν(COO), δ(COO) and ν_s(COO), respectively, demonstrating the coordination of the oxalate group. The solution electronic spectra in water exhibit three major transitions at 360–365, 586–594, and 986–992 nm at 298 K, which is tentatively attributed to the electronic transitions $^3A_{2g} \rightarrow {}^3T_{1g}(P)$, $^3A_{2g} \rightarrow {}^3T_{1g}$, and $^3A_{2g} \rightarrow {}^3T_{2g}$. This spectrum is d-d charge-transfer bands in the octahedron Ni(II) surrounding [13].

3.2. Description of the structure

The structures of **1**, **2** and **3** with atom numbering are shown in Figs. 1–3, respectively. The selected bond distances and angles of **1**, **2** and **3** are listed in Table 2.

The X-ray diffraction of **1** reveals a neutral centrosymmetric binuclear entity $[Ni_2L_2(\mu\text{-}SCN)_2(SCN)_2]$ (Fig. 1) together with two crystallization water molecules. In the dimeric unit, two Ni(II) atoms are bridged by two thiocyanate ligands in an end-to-end fashion with the Ni···Ni separation of 5.750 Å. One S atom and one N atom from two different bridging thiocyanate

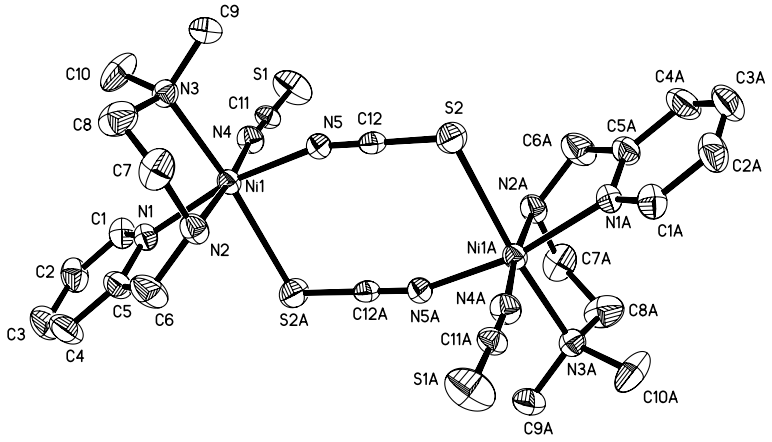

Fig. 1. View of complex **1** showing the numbering scheme. Themal ellipsoids were drawn with 30% probability. (Hydrogen atoms and water molecules are omitted for clarity.)

ligands, one N atom from a terminal SCN^- and three N atoms from one tridentate ligand L coordinate to the Ni(II) atom to complete a distorted octahedral coordination geometry. The Ni–N bond lengths are in the range of 2.030–2.158 Å, in which the bond length of Ni1–N3 (tertiary amine) is the longest. The Ni–S distance is 2.635 Å, which is similar to that reported for thiocyanate bridging nickel complexes [2,14–16]. The Ni–S–C and Ni–N–C angles for bridging SCN^- groups are 102.7 and 162.4°, respectively. In comparison, the Ni–N–C angles for terminal SCN^- groups are 173.2°. The dihedral angle formed by the mean-plane $(NCS)_2$ and the N–Ni–S plane is 13.4°.

There are two independent dinuclear [Ni–Ni] units and two disordered methanol molecules in **2** (Fig. 2). Each Ni(II) atom is coordinated by three N atoms from one tridentate ligand L, one N atom from one terminal azido ligand, and two N atoms from two azido bridging ligands. The two azido ligands link two Ni(II) atoms in an end-on form resulting in the Ni···Ni separation of 3.395 and 3.333 Å for molecules 1 and 2, respectively. It is noteworthy that the longest Ni–N bond is the Ni–N (tertiary amine) bond for molecule 1, while it is the Ni–N (bridging azido ligand) bond for molecule 2. All of the Ni–N (bridging azido) bonds in both molecules rang from 2.142(3) to 2.200(3) Å, which are close to the values reported in other end-on azido Ni(II) complexes [2,17]. The Ni–N–Ni angles are 103.3 and 100.3 for molecules 1 and 2, respectively.

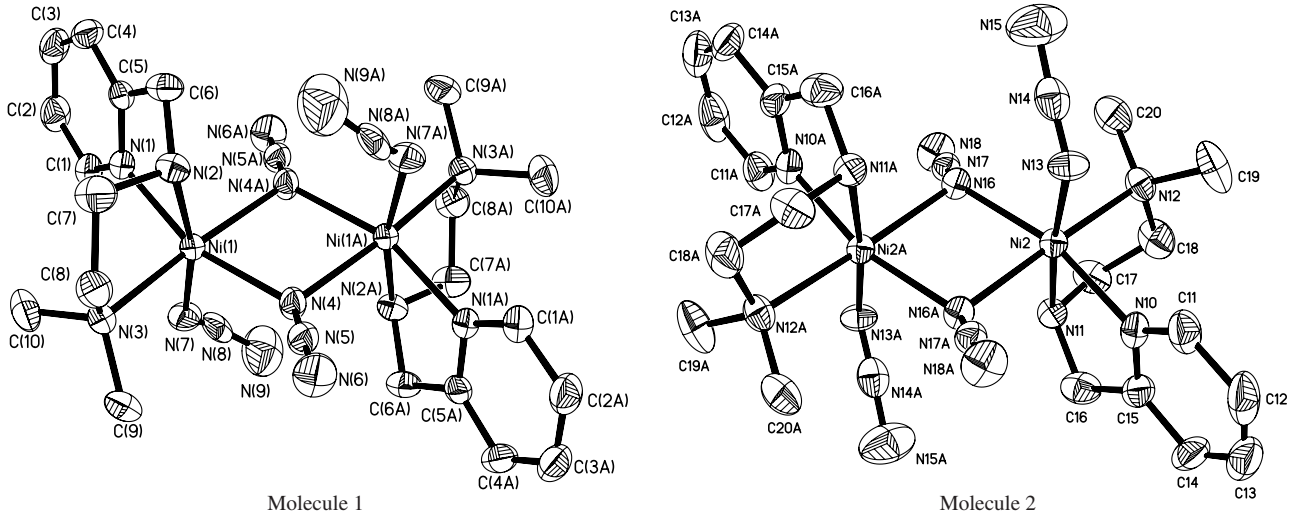

Fig. 2. View of the two independent molecules in complex **2** showing the numbering scheme.

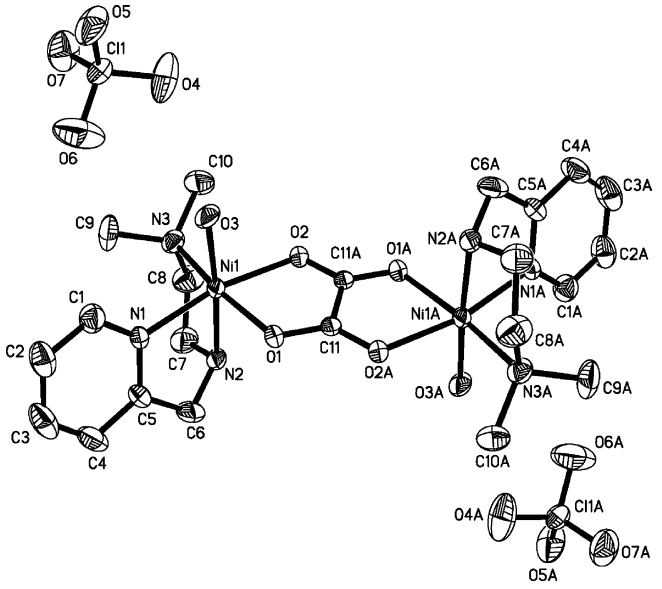

Fig. 3. View of complex **3** showing the numbering scheme (the methanol molecule is omitted for clarity).

As shown in Fig. 3, the structure of **3** contains one $[Ni_2L_2(H_2O)_2(\mu_2\text{-}C_2O_4)]^{2+}$ and two ClO_4^- anions. The dinuclear unit consists of two $[Ni(II)LH_2O]^{2+}$ subunits bridged by a bis-bidentate oxalate dianion. Each Ni(II) atom has a distorted octahedral coordination geometry, completed by three N atoms from the tridentate ligand L, two O atoms from the oxalate dianion, and one water O atom. The Ni–N bond lengths vary from 2.060(4) to 2.147(5) Å, close to those in **1** and **2**. The Ni···Ni separation (5.390 Å) is comparable well to that in the reported dinuclear oxalato-bridged complexes [18–22]. In the oxalate dianion, the C–O bond lengths are 1.249(6) and 1.255(6) Å and the C–C bond length is 1.537(11) Å. The $C_2O_4^{2-}$ ion is planar (maximum deviation, 0.0020 Å), while the two Ni(II) atoms deviate by 0.0847 Å from the plane. The bite angle formed by the Ni(II) atom and the two O atoms of oxalate ligand is 80.6° which is typical for oxalato-bridged binuclear complex [8,9,22,23].

3.3. Magnetic properties

The magnetic behavior of the dinuclear Ni(II) complexes could be interpreted using isotropic spin Hamiltonian $H = -2JS_1S_2$, where $S_1 = S_2 = 1$ and J is the exchange integral. The experimental data have been fitted to the expression [24]

$$\chi_M = \frac{2Ng^2\beta^2}{k(T-\theta)}\left[\frac{5+\exp(-4J/kT)}{5+3\exp(-4J/kT)+\exp(-6J/kT)}\right]. \quad (1)$$

Symmetry transformations used to generate the equivalent atoms: complex **1**, A: $-x$, $-y+1$, $-z+1$; complex **2**, A: $-x+1$, $-y+1$, $-z$; B: $-x$, $-y+1$, $-z+1$.

The magnetic behavior of **1** is shown in Fig. 4 by plotting χ_M and μ_{eff} vs. T. The μ_{eff} at room temperature is $4.10\mu_B$ which is slightly larger than the expected value for two uncoupled $S=1$ canters (the theoretical value with $g=2$, $\mu_{eff}=4.0\mu_B$). As the temperature is lowed, μ_{eff} increases to $4.76\mu_B$ at 7 K, and then decreases to $4.73\mu_B$ at 5 K. A least-squares fit of the data to the equation yields the values of $J=3.90\ cm^{-1}$, $g=2.03$, $\theta=0.3$, $R=4.0\times10^{-3}$. This is indicative of the presence of ferromagnetic interactions in **1**. The decrease of μ_{eff} from $4.76\mu_B$ at 7 K to $4.73\mu_B$ at 5 K may be due to intermolecular interactions or (and) single-ion zero-field splitting.

In according to the Goodenough–Kanamori rules [24], the ferromagnetism in the idealized structures with the idealized angles of Ni–N–C and Ni–S–C (180° and 90°) can be explained in terms of $e_g\|\sigma\perp\pi\|e'_g$ pathways. With these idealized angles, the overlap is zero and the orthogonality of the orbitals creates the possibility of ferromagnetism. Hendrickson [25] assumes that for a symmetric bridging situation, the antiferromagnetic coupling is enhanced. In **1**, the angles of Ni–N–C and Ni–S–C are 102.67° and 162.4°, respectively, which show less pronounced rectangular geometry. Thus it has a smaller J value of ca. 3.9 cm^{-1}. The J value is lower than the values (6.3 and 8.8 cm^{-1}) for dinuclear thiocyanato and selenocyanato derivatives with the angles of Ni–S–C/Ni–Se–C (96.2° and 97.4°) and Ni–N–C (166.7° and 169.1°) [2,26]. On the other hand, the observed value corresponds well with the value of 4.3–4.9 cm^{-1} found for the dinuclear thiocyanato Ni(II) complexex with the angles of Ni–S–C (100.0–100.7°) and Ni–N–C (159.0–167.0°) [26–28].

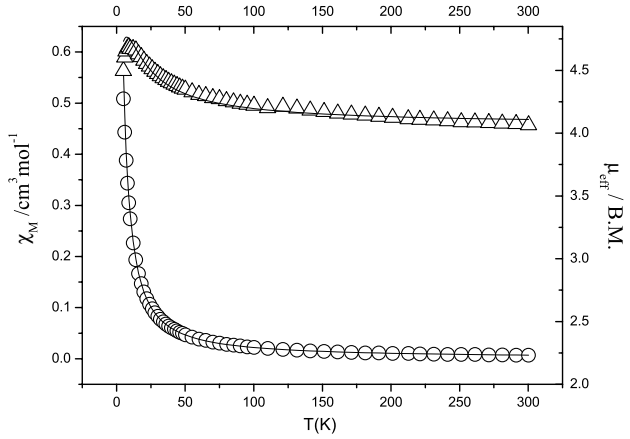

Fig. 4. A plot for complex **1** of temperature dependence of χ_M (○) vs. T and μ_{eff} (△) vs. T. The solid lines are theoretical fits based on Eq. (1).

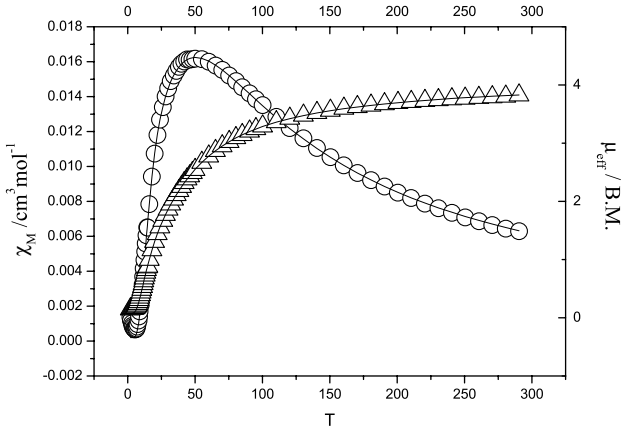

Fig. 6. A plot for complex **3** of temperature dependence of χ_M (○) vs. T and μ_{eff} (△) vs. T. The solid lines are theoretical fits based on Eq. (1).

The magnetic susceptibility measurement of **2** is plotted in Fig. 5. At 300 K, the μ_{eff} value is 4.08 μ_B, which compares well to the theoretical value of 4.0 μ_B. When the temperature is lowered, μ_{eff} rises smoothly to reach a maximum of 4.30μ_B at 28 K and then decreases down to a value of 3.87μ_B at 5 K. The best fit of the data to Eq. (1) in the high-temperature region 28–300 K yields magnetic parameters of $g = 2.03$, $J = 1.91\ cm^{-1}$, and $R = 1.8 \times 10^{-4}$. The result is consistence with the ferromagnetic coupling for dibridged azido Ni(II) in $\mu_{1,1}$ fashion [2,17].

The magnetic behavior of **3** is shown in Fig. 6. At 300 K the μ_{eff} value is 3.83μ_B, which is slightly smaller than the theoretical value. When the temperature is lowered, μ_{eff} decreases smoothly. A least-squares fit of the data to the Eq. (1) yields the values of $J = -17.1\ cm^{-1}$, $g = 2.00$, $R = 6.7 \times 10^{-4}$. The exchange integrals J found for **3** shows that the ferromagnetic coupling is the extent of overlap between the magnetic orbitals of the paramagnetic nickel ions and the μ-oxalato bridging ligand. For Ni(II) complexes in octahedral geometry, the unpaired electron resides in a $d_{x^2-y^2}$ type orbital, which is aligned to allow overlap with the oxalate σ-orbitals. For **3**, the observed J value of $-17.1\ cm^{-1}$ is in agreement with the antiferromagnetic interaction ($J = -11.25$ to $-39.0\ cm^{-1}$) observed in other oxalato-bridged Ni(II) complexes [8,9,17].

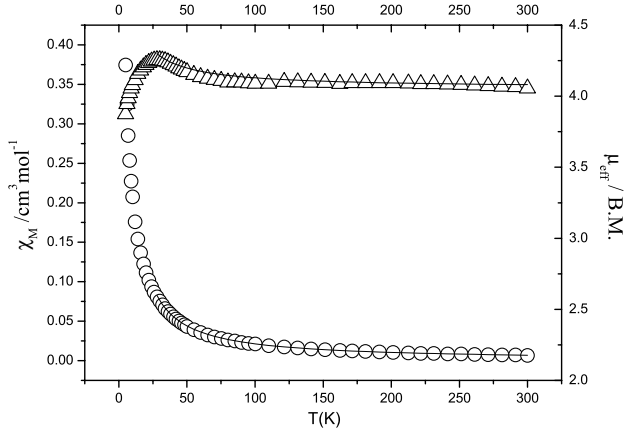

Fig. 5. A plot for complex **2** of temperature dependence of χ_M (○) vs. T and μ_{eff} (△) vs. T. The solid lines are theoretical fits based on Eq. (1).

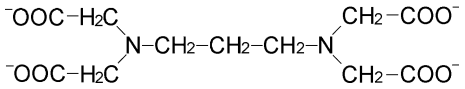

Fig. 1. Formula of ligand 1,3-propanediaminetetraacetate ion.

Recently, with aim to investigate the stereochemical properties of 1,3-pdta complexes with spherically symmetric metal ions of different size we have prepared homometallic $[Mg(H_2O)_6][Mg(1,3\text{-pdta})]\cdot 2H_2O$ and $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ complexes, and their crystal structures were determined by X-ray crystallography [8]. While the crystals of $[Mg(H_2O)_6]$-$[Mg(1,3\text{-pdta})]\cdot 2H_2O$ [8] complex appeared isomorphic with those of other $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ (M(II),M′(II) = Mg,Cu [5a]; Mn,Cu [5b]; Mg,Ni [6]; Mg,Co [7]; and Co,Co [7]) complexes, in the case of $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ [8] complex we have obtained the coordination number higher than six. Moreover, in the solid state $[Ca(H_2O)_3Ca(1,3\text{-pdta})$-$(H_2O)]\cdot 2H_2O$ [8] displayed substantially different packing pattern than that observed for the $[M(H_2O)_6]$ $[M'(1,3\text{-pdta})]\cdot 2H_2O$ series.

This work is a continuation of our study concerned with the structural characteristics of 1,3-pdta complexes containing different metal(II) ions. We report here the syntheses and characterization of hexadentate $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), $[Zn(H_2O)_6][Zn$-$(1,3\text{-pdta})]\cdot 2H_2O$ (**2**) and $[Mg(H_2O)_6][Cd(1,3\text{-pdta})$-$(H_2O)]\cdot 2H_2O$ (**3**) complexes. The structures of **1**, **2** and **3** were studied by single-crystal X-ray crystallography. IR, ^{1}H NMR and ^{13}C NMR spectral data for **1**, **2** and **3** have also been reported here.

2. Experimental

2.1. Compounds preparation

All commercially obtained reagent-grade chemicals were used without further purification. The preparation of barium (1,3-propanediaminetetraacetato)barium(II) dihydrate, $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$, has been reported elsewhere [5a,15].

2.1.1. Preparation of hexaaquamagnesium (1,3-propanediaminetetraacetato)zincate(II) dihydrate, $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (1)

$ZnSO_4\cdot 7H_2O$ (2.87 g; 0.01 mol) was dissolved in 25 cm^3 of distilled water at 60 °C. To this solution, solid $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g; 0.01 mol) was added and the reaction mixture was heated (60 °C) with stirring for 30 min. Then, $MgSO_4\cdot 6H_2O$ (2.28 g; 0.01 mol) was added and stirring was continued for 30 min. The precipitated barium sulphate was filtered out. To the obtained filtrate 5–6 cm^3 of ethanol was added and the solution was left to stand in a refrigerator overnight. The colourless crystals of $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), were collected, washed with ethanol, and air-dried. The yield was 1.25 g (23%). *Anal.* Calc. for $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), $MgZnC_{11}H_{30}N_2O_{16}$ (FW = 536.05): C, 24.65; H, 5.64; N, 5.23. Found: C, 24.28; H, 5.80; N, 5.45%. Selected IR frequencies (KBr, cm^{-1}): ν_{asym}(COO–Zn) 1610, ν_{sym} (COO–Zn) 1414. ^{1}H NMR (200 MHz, D_2O): δ 3.29 (AB pattern, 4CH$_2$(gly), δ_A 3.41, δ_B 3.18, $J_{AB} = 16.65$ Hz), 2.98 (t, 2CH$_2$(1,3-pd)), 1.65 (m, CH$_2$(1,3-pd)). ^{13}C NMR (200 MHz, D_2O): δ 181.33 (4COO$^-$), 64.51 (4CH$_2$(gly)), 61.71 (2CH$_2$(1,3-pd)), 25.74 (CH$_2$(1,3-pd)).

2.1.2. Preparation of hexaaquazinc (1,3-propanediaminetetraacetato)zincate(II) dihydrate, $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (2)

$ZnSO_4\cdot 7H_2O$ (5.75 g; 0.02 mol) was dissolved in 25 cm^3 of distilled water at 60 °C. To this solution, solid $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g; 0.01 mol) was added and the reaction mixture was heated (60 °C) with stirring for 1 h. The precipitated barium sulphate was filtered out. To the obtained filtrate 5–6 cm^3 of ethanol was added and the solution was left to stand in a refrigerator overnight. The colourless crystals of $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**2**) were collected, washed with ethanol, and air-dried. The yield was 4.50 g (78%). The crystalline $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**2**) was also obtained from the reaction mixture containing $Ba[Ba$-$(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g; 0.01 mol), $3CdSO_4\cdot 8H_2O$ (2.56 g; 0.003 mol) and $ZnSO_4\cdot 7H_2O$ (2.87 g; 0.01 mol), as evidenced by X-ray crystallography. *Anal.* Calc. for $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**2**), $Zn_2C_{11}H_{30}N_2O_{16}$ (FW = 577.11): C, 22.89; H, 5.24; N, 4.85. Found: C, 22.17; H, 5.03; N, 4.67%. Selected IR frequencies (KBr, cm^{-1}): ν_{asym}(COO–Zn) 1599, ν_{sym} (COO–Zn) 1404. ^{1}H NMR (200 MHz, D_2O): δ 3.32 (AB pattern, 4CH$_2$(gly), δ_A 3.43, δ_B 3.21, $J_{AB} = 16.69$ Hz), 2.99 (t, 2CH$_2$(1,3-pd)), 1.67 (m, CH$_2$(1,3-pd)). ^{13}C NMR (200 MHz, D_2O): δ 181.38 (4COO$^-$), 64.47 (4CH$_2$(gly)), 61.76 (2CH$_2$(1,3-pd)), 25.76 (CH$_2$(1,3-pd)).

2.1.3. Preparation of hexaaquamagnesium (aqua)(1,3-propanediaminetetraacetato)cadmate(II) dihydrate, $[Mg(H_2O)_6][Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (3)

$3CdSO_4\cdot 8H_2O$ (2.56 g; 0.003 mol) was dissolved in 25 cm^3 of distilled water at 60 °C. To this solution, solid $Ba[Ba(1,3\text{-pdta})]\cdot 2H_2O$ (6.13 g; 0.01 mol) was added and the reaction mixture was heated (60 °C) with stirring for 30 min. Then, $MgSO_4\cdot 6H_2O$ (2.28 g; 0.01 mol) was added and stirring was continued for 30 min. The precipitated $BaSO_4$ was filtered out. To the obtained filtrate 5–6 cm^3 of ethanol was added and the solution was left to stand in a refrigerator overnight. The colourless crystals of $[Mg(H_2O)_6][Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**), were collected, washed with ethanol, and air-dried. The yield

was 4.10 g (68%). *Anal.* Calc. for $[Mg(H_2O)_6][Cd(1,3\text{-}pdta)(H_2O)]\cdot 2H_2O$ (**3**), $MgCdC_{11}H_{32}N_2O_{17}$ (FW = 601.10): C, 21.98; H, 5.37; N, 4.66. Found: C, 22.16; H, 5.37; N, 4.67%. Selected IR frequencies (KBr, cm^{-1}): ν_{asym}(COO–Cd) 1600, ν_{sym}(COO–Cd) 1410. ^1H NMR (200 MHz, D_2O): δ 3.12 (AB pattern, $4CH_2$(gly), δ_A 3.22, δ_B 3.03, $J_{AB} = 16.26$ Hz), 2.79 (t, $2CH_2$(1,3-pd)), 1.83 (m, CH_2(1,3-pd)); ^{13}C NMR (200 MHz, D_2O): δ 180.69, 180.58 ($4COO^-$), 62.87 ($4CH_2$(gly)), 61.86 ($2CH_2$(1,3-pd)), 25.10 (CH_2(1,3-pd)).

2.2. Physical measurements

The IR spectra in the solid state were recorded on a Perkin–Elmer Spectrum One FT-IR Spectrometer using KBr pellets. ^1H NMR and ^{13}C NMR spectra of D_2O solutions containing 3-trimethylsilylpropane-1-sulfonate (TSP) as internal reference were recorded with a Varian Gemini 200 MHz spectrometer. Elemental microanalyses for carbon, hydrogen, and nitrogen were done by the Department of Chemistry, University of Belgrade, Serbia.

2.3. Crystallographic data collection and refinement of the structures

The crystal data for **1**, **2** and **3** and the parameters of data collection are summarized in Table 1. The intensity data were measured with a KM4CCD kappa-geometry diffractometer [16] using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 130 K for **1** and **2**, and 293 K for **3**. The structures were solved by direct methods using SHELXS-97 [17] and refined by least-squares techniques with SHELXL-97 [18]. The intensity data were corrected for Lp effects as well as for absorption in the case of **1**, **2** and **3** and for extinction in the case of **3**. Anisotropic thermal parameters were employed for the non-hydrogen atoms. The positions of H-atoms attached to the C-atoms were calculated at standardized distances of 0.96 Å, and refined in a so-called "riding model" with the atomic displacement parameters 30% higher than the displacement parameters for the atoms to which they are bonded. All of the water hydrogen atoms were located from subsequent difference Fourier maps

and refined isotropically except for the O5W solvent water hydrogen in **2** which was also refined as riding. In the crystal structure of **3**, carbon atom C2, as well as hydrogen atoms attached to C1 are disordered and were refined with occupation number 0.5. A Siemens Stereochemical Workstation was used to prepare drawings [19].

3. Results and discussion

3.1. Crystallization of divalent metal ions with 1,3-propanediaminetetraacetato ligand

Numerous attempts to obtain crystalline Co(II) complexes with 1,3-pdta ligand (1,3-pdta = 1,3-propanediaminetetraacetate ion) and alkaline metals as counter ions have not been successful. The crystalline product obtained from aqueous solutions containing a combination of either Na^+ and Co^{2+} or Li^+ and Co^{2+} cations and 1,3-propanediaminetetraacetate ion contained solely the hexadentate $[Co(H_2O)_6][Co(1,3\text{-pdta})]\cdot 2H_2O$ complex. We have recently reported the crystal structure of this complex and of the isomorphic Co(II) complex with Mg(II) as counter cation which have been prepared using the same facile method for the preparation of M(II)-1,3-pdta complexes as described previously [7].

Analogously, we have witnessed frequent occurrence of only one type of crystals obtained from the aqueous solutions containing 1,3-propanediaminetetraacetate ion and Mg^{2+}, Zn^{2+} and Cd^{2+} cations. From the solution containing Zn^{2+} and Cd^{2+} cations we have obtained as the solely crystalline product the $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**2**) complex, isomorphic with the other complexes of $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ type [5–8], instead of the expected ZnCd(1,3-pdta) complex. Combination of Mg^{2+} and Zn^{2+} ions has lead to the $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**1**) complex, again isomorphic with the complexes mentioned above. However, using Cd^{2+} ion in combination with Mg^{2+}, we were able to obtain seven-coordinate $[Mg(H_2O)_6][Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**) complex, different from those of $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ type [5–8], but isomorphic with the $[Mg(H_2O)_6][Mn(edta)(H_2O)]\cdot 2H_2O$ [20] analogue. The complexes of coordination number (CN) higher than six with 1,3-pdta ligand are very rare, and so far only one such complex, i.e., $[Ca(H_2O)_3Ca(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ [8] (CN = 8), has been prepared and characterized. Presented in this paper, the $[Mg(H_2O)_6][Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**), having the CN equal to 7, constitutes the second case. Complex **3** is also the first example of the transition metal complex with 1,3-pdta ligand that possesses the CN higher than 6.

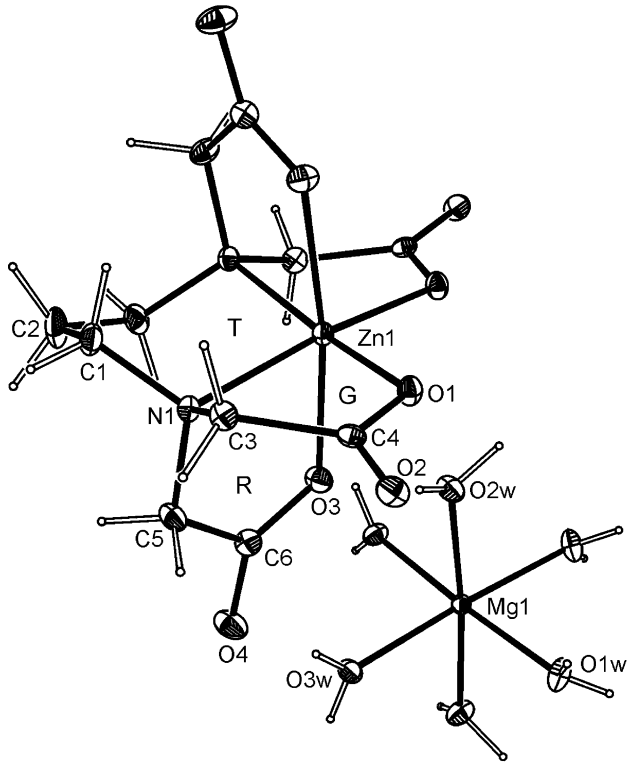

Fig. 2. The ORTEP drawing of the $[Zn(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ octahedra. Generation of the second half of the complex anion and cation requires the symmetry operations $x, -y-0.5, -z+0.5$ and $x, -y-1.5, -z+0.5$, respectively. Thermal ellipsoids are drawn at the 40% probability level.

3.2. The crystal structures of $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (1) and $[Zn(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (2) complexes

The crystals of **1** and **2** are isomorphic with those of $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ type complexes [5–8]. An ORTEP drawing of the $[Mg(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ (**1**), is depicted in Fig. 2, where the numbering scheme adopted for the respective atoms is also given. Metal–ligand bond lengths and valence angles around metal ions are listed in Table 2.

The structural units of **1** and **2** consist of discrete $[Zn(1,3\text{-pdta})]^{2-}$ and $[M^{II}(H_2O)_6]^{2+}$ [M(II) = Mg (**1**) or Zn (**2**)] octahedra, and two water solvent molecules all of which lie on a twofold axis of symmetry. The highest symmetry (C_2) axis of the complex anion passes through the Zn and C2 atoms and bisects the N1–Zn1–N1[a] bond angle ([a]stands for the symmetry operation $x, -y-0.5, -z+0.5$) making the two out-of-plane glycinate rings (R rings), as well as the two in-plane glycinate rings (G rings), identical. The R rings are almost flat, while the G-rings are much more puckered and are halfway between an *envelope* and *twist* conformations. The conformation of the six-membered 1,3-propanediamine ring (T ring) is *twist-boat*. The mean deviation from octahe-

[A] The average values of metal–ligand bond distances and valence angles for $[Zn(1,3\text{-pdta})]^{2-}$ units are given.

dral angles (ΔO_h) for $[Zn(1,3\text{-pdta})]^{2-}$on average equals to 5.85°, which indicates a nearly regular octahedral geometry of the complex anion.

Table 3 lists bond lengths to the metal(II) atoms in octahedral $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ (M(II), M′(II) = Mg,Cu [5a]; Mn,Cu [5b]; Mg,Ni [6]; Mg,Co [7]; Co,Co [7] and Mg,Mg [8]) complexes and the mean deviation from octahedral angles (av. ΔO_h). Among the complexes listed, $[Ni(1,3\text{-pdta})]^{2-}$ [6] in which the Ni–N and Ni–O_R bonds are equal in length, is the closest to the ideal octahedral geometry. On the contrary, in the $[Mg(1,3\text{-pdta})]^{2-}$ [8] complex, which is the most distorted, the Mg–N bond lengths are significantly longer than the corresponding Mg–O bonds, in line with the observation that for edta-like complexes of predominantly electrostatic binding metal ions the interactions of such metals with amine nitrogens are relatively weak. As can be seen from Table 3, influence of charge

[b] Low-temperature data.

compensating cations on the distortion of $[M(1,3\text{-pdta})]^{2-}$ complexes is not significant (compare $[M^{II}(H_2O)_6][Cu(1,3\text{-pdta})]\cdot 2H_2O$ (M(II) = Mg [5a] and Mn [5b]) and $[M^{II}(H_2O)_6][Zn(1,3\text{-pdta})]\cdot 2H_2O$ [M(II) = Mg (**1**) and Zn (**2**)] complexes). However, compared with similar complexes of Co(III) [1] and Rh(III) [2] with the same 1,3-pdta ligand for which ΔO_h values sum 2.8° and 4.7°, respectively, all complexes listed in Table 3 display greater degree of octahedral distortion. Moreover, the out-of-plane *trans* O–M–O bond angles in $[M(1,3\text{-pdta})]^{2-}$ (M(II) = Cu [5], Ni [6], Co [7], Mg [8] and Zn) are much more bent than the corresponding ones in $[Co(1,3\text{-pdta})]^{-}$ and $[Rh(1,3\text{-pdta})]^{-}$ complexes. For the $[M(1,3\text{-pdta})]^{2-}$ (M(II) = Cu [5], Ni [6], Co [7], Mg [8] and Zn) complexes these *trans* bond angles are in the range 168.4–175.1°, while in $[Co(1,3\text{-pdta})]^{-}$ and $[Rh(1,3\text{-pdta})]^{-}$ complexes they are almost linear (180°). This is to be expected owing to the fact that virtually all Co(III) complexes, being low-spin, produce particularly high crystal field stabilization energy (CFSE) and this effect is expected to be even more marked in the case of heavier element (Rh(III)).

Similar to other crystal structures of divalent metal ions with 1,3-pdta ligand, the discrete $[Zn(1,3\text{-pdta})]^{2-}$ and $[M^{II}(H_2O)_6]^{2+}$ octahedra [M(II) = Mg for **1** and Zn for **2**] alternate in the crystal in such a way that each complex anion is surrounded by six complex cations situated at the corners of a distorted octahedron and vice versa. As a result, not only the first but also the second metal coordination sphere displays nearly octahedral geometry. Such an alternating arrangement of the cationic and anionic species might indicate nearly spherical charge distribution on each of the complex units, which is consistent with their first coordination sphere being close to a regular octahedron.

The packing in the structure is determined by an extended network of relatively strong hydrogen bonds predominantly involving water molecules [coordinated to M (M = Mg(II) for **1** and Zn(II) for **2**) or two water solvent molecules] and carboxylate oxygens. The two-coordination octahedra are connected via hydrogen bonds in three dimensions.

3.3. The crystal structure of $[Mg(H_2O)_6]$-$[Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**) complex

An ORTEP drawing of the $[Mg(H_2O)_6][Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**) complex, is depicted in Fig. 3, where the numbering scheme adopted for the respective atoms is also given. Metal–ligand bond lengths and valence angles around metal ions are listed in Table 2.

The structural unit of **3** consists of discrete complex ions: $[Cd(1,3\text{-pdta})(H_2O)]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ which are situated on twofold axis of symmetry and inversion centre, respectively, and two symmetry related water solvent molecules (O5W and O5W^{d}, where the symmetry code d: $-x+1, -y+1, -z+2$). The highest symmetry (C_2) axis of the complex anion passes through the Cd1 and O1W atoms making the two out-of-plane glycinate rings (R rings), as well as the two in-plane glycinate rings (G rings), identical. The central carbon atom (C2) of the six-membered 1,3-propanediamine ring and hydrogen atoms attached to C1 are statistically distributed about the twofold symmetry axis. The Cd1 has

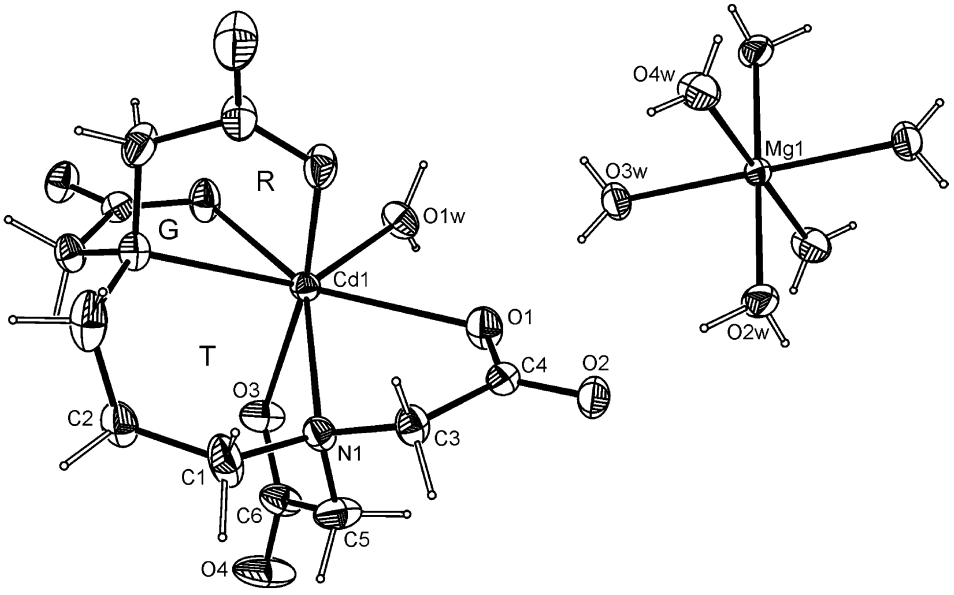

Fig. 3. The ORTEP drawing of the $[Cd(1,3\text{-pdta})(H_2O)]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ polyhedra. Generation of the second half of the complex anion and cation requires the symmetry operations $-x+1, y, -z+1.5$ and $-x+1, -y+1, -z+2$, respectively. Thermal ellipsoids are drawn at the 40% probability level.

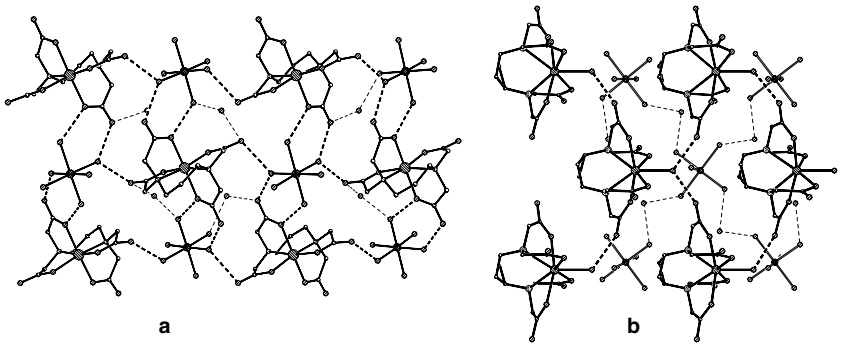

Fig. 4. (a) View of the (1 0 0) layer shows $[Zn(1,3\text{-pdta})]^{2-}$ and $[Mg(H_2O)_6]^{2+}$ polyhedra, present in **1**, connected by hydrogen bonds that propagate throughout the entire crystal. (b) View along [0 0 1] shows alternating layers of $[Cd(1,3\text{-pdta})(H_2O)]^{2-}$ anions (full lines) and $[Mg(H_2O)_6]^{2+}$ cations (open lines), present in **3**. Hydrogen bonds between crystalline and coordinated water molecules, and between water molecules and carboxylate oxygens operate within and between the cationic and anionic layers.

sevenfold coordination: with hexadentate 1,3-pdta ligand and one water molecule O1W. The coordination polyhedron formed around Cd1 is distorted pentagonal bipyramid (PB) with in-plane *cis* bond angles in the range 66.84–90.93°, and with very bent out-of-plane *trans* bond angle (O3–Cd1–O3^c) of 162.84°. Among in-plane *cis* bond angles, O1–Cd1–O1W is the closest to the value of 72° expected for ideal PB structure, while the largest deviation is observed for diamine bite angle (N1–Cd1–N1^c) which sums 90.93°. Conformations of the chelate rings are found to be *envelope* for the glycinates and almost ideal *sofa* for the six-membered diamine ring, while almost perfect twist-boat conformation was present in **1** and **2**. The Mg1 ion is coordinated with six water molecules and forms almost an ideal octahedral structure.

Packing in the crystal structure of $[Mg(H_2O)_6]$-$[Cd(1,3\text{-pdta})(H_2O)]\cdot 2H_2O$ (**3**) complex differs from that of $[M(H_2O)_6][M'(1,3\text{-pdta})]\cdot 2H_2O$ type (M(II), M′(II) = Mg,Cu [5a]; Mn,Cu [5b]; Mg,Ni [6]; Mg,Co [7]; Co,Co [7]; Mg,Mg [8]; Mg,Zn (**1**) and Zn,Zn (**2**)) complexes. While in the above mentioned isomorphic crystals an alternating cation/anion arrangement propagates throughout the entire crystal (Fig. 4(a)), in **3** the cationic and anionic species are separated into the alternating cationic and anionic layers propagating along [0 0 1] (Fig. 4(b)). Anionic layers are polar and loosely packed, thus allowing for static disorder within the 1,3-pdta ring (vide supra). The complex anions self-assemble within the layer by means of hydrogen bonds between a water molecule coordinated to Cd (O1W) and two O4 carboxylate oxygens belonging to two molecules related to each other by a unit translation along x. Hydrogen bonds within cationic layers involve both crystalline (O5W) and coordinated (to Mg) water molecules (O2W and O4W). Apart from electrostatic interactions, the cationic and anionic layers are joined together via water/carboxylate type of hydrogen bonds. Except for crystalline water molecule, which displays dual hydrogen bond functionality, all coordinated water molecules act solely as hydrogen bond donors to all carboxylate oxygens acting as acceptors.

4. Conclusion

The present study and previous investigations have shown how the change in length of the methylene chain in the amino fragment of the edta-type ligand and the type of the charge compensating cations influence the mode of crystallization of edta-type complexes. The results can be summarized as follows: (1) 1,3-pdta ligand under the hexadentate coordination favours the formation of octahedral complexes with metal(II) ions with ionic radii of about 0.8–0.9 Å. (2) Complexes of this type form isomorphic crystals in which the charge compensating cations are the divalent cations in a form of aqua ions. (3) For metal ions with ionic radii exceeding 0.9 Å, the CN equal to 7, with 1,3-pdta ligand acting as hexadentate, is to be expected.

5. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers CCDC 260104, 260105 and 260106 for complexes **1**, **2** and **3**, respectively.

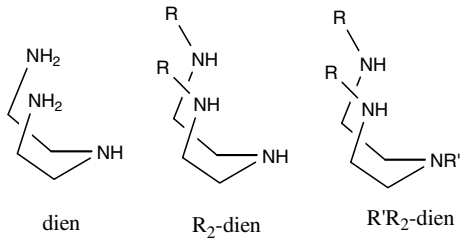

Fig. 1. Diethylenetriamine and derivatives (R or R′ = alkyl, aryl, silyl or a combination).

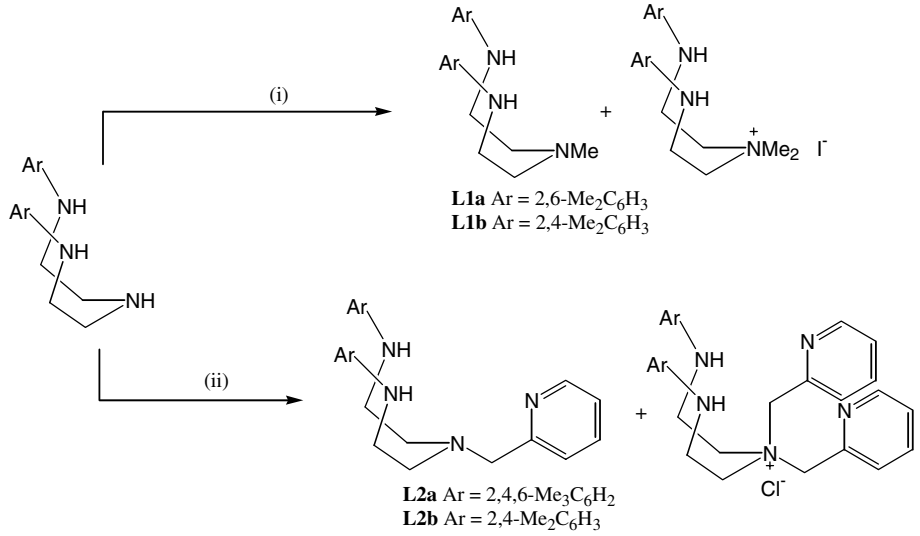
Ar_2-dien-supported metal halide complexes. Notably, the cobalt-containing examples exhibit, on activation with methylaluminoxane (MAO), some activity for the oligomerisation of ethylene [9]. In this article we are concerned with derivatising the central amine in Ar_2-dien with an alkyl group or with a potential donor group, 2-pyridylmethyl (2-picolyl), and examining the resultant coordination chemistry with divalent iron and cobalt halide precursors.

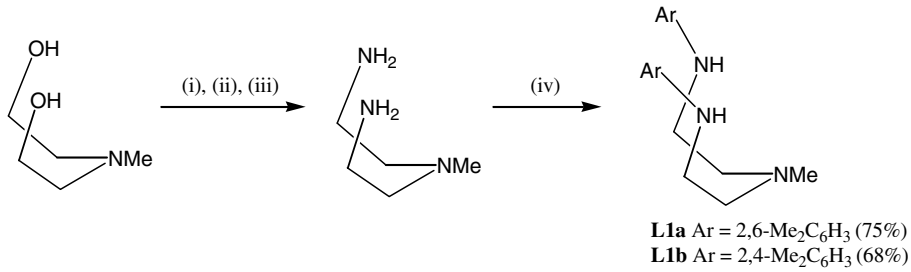
2. Results and discussion

2.1. Synthesis of the ligands



The ligands, $(ArHNCH_2CH_2)_2NMe$ (Ar = 2,6-$Me_2C_6H_3$ **L1a**, 2,4-$Me_2C_6H_3$ **L1b**), could be prepared in modest yield by treating $(ArHNCH_2CH_2)_2NH$ with MeI under conditions established by Schrock et al. for the preparation of $(MesHNCH_2CH_2)_2NMe$ [7a]. However, we have found this approach for the synthesis of **L1a** and **L1b** to be hampered by the ready formation of ammonium salts of the type $((ArHNCH_2CH_2)_2NMe_2)I^-$ (Scheme 1).

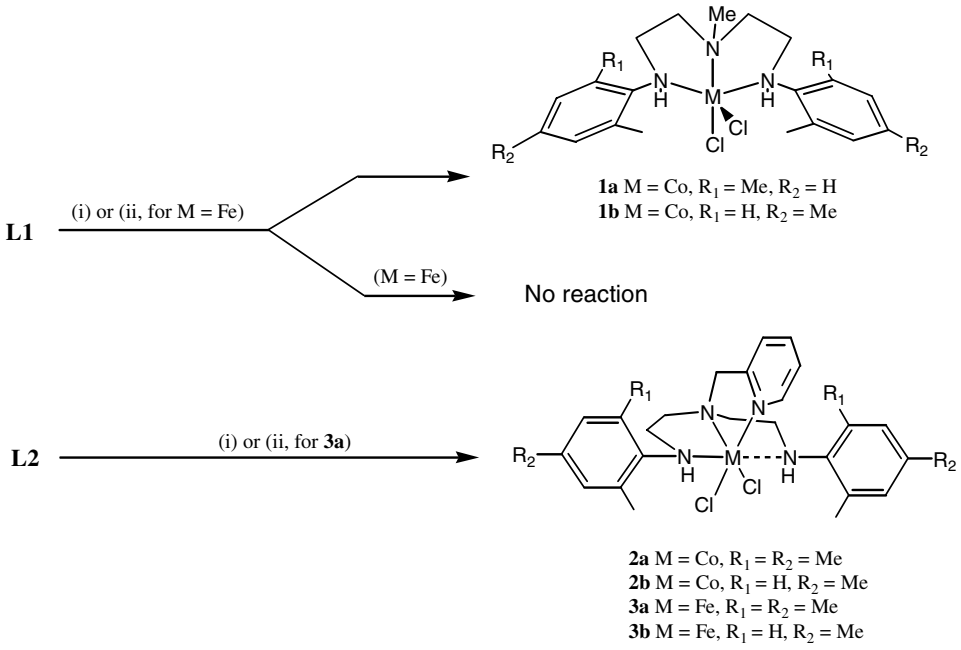
To circumvent this problem, we have employed a palladium catalysed N-C(aryl) coupling reaction of *N*-methyldiethylenetriamine (prepared from *N*-methyldiethanolamine [10]) with two equivalents of the corresponding aryl bromide using experimental conditions established by Buchwald and Hartwig [11]. Following work-up **L1a** and **L1b** could be isolated as the sole product in high yield (Scheme 2).



The picolyl-substituted ligands, $(ArHNCH_2CH_2)_2\{(2\text{-}C_5H_4N)CH_2\}N$ (Ar = 2,4,6-$Me_3C_6H_2$ **L2a** [12], 2,4-$Me_2C_6H_3$ **L2b**) could be prepared in modest yield from $(ArHNCH_2CH_2)_2NH$ (Ar = 2,4,6-$Me_3C_6H_2$, 2,4-$Me_2C_6H_3$) by treating them with 2-picolyl chloride hydrochloride in acetonitrile at 55 °C in the presence of potassium carbonate (Scheme 1). Following purification on an alumina column, **L2a** and **L2b** could be isolated as yellow oils. All the new ligands have been characterised by IR, ^1H and ^{13}C NMR spectroscopy, mass spectrometry (see Section 4).

2.2. Synthesis of the complexes

The reaction of **L1a** and **L1b** with $CoCl_2$ in *n*-butanol at elevated temperatures gave complexes $[\{(ArHNCH_2CH_2)_2NMe\}CoCl_2]$ (Ar = 2,6-$Me_2C_6H_3$ **1a**, 2,4-$Me_2C_6H_3$ **1b**) in high yield (Scheme 3), respectively. The corresponding reactions of **L1** with $FeCl_2$ in *n*-butanol at elevated temperature or with $FeCl_2(THF)_{1.5}$ in tetrahydrofuran at ambient temperature gave only unreacted starting materials. Complexes **1a** and **1b** have been characterised by FAB mass spectrometry, infrared spectroscopy, magnetic susceptibility and by elemental analysis (see Table 1). In addition, a crystal of **1a** has been the subject of a single crystal X-ray diffraction study.



Scheme 1. Reagents and conditions: (i) K_2CO_3, 0 °C, MeI; (ii) K_2CO_3, 55 °C, $C_5H_4NCH_2Cl \cdot HCl$.

L1a Ar = 2,6-$Me_2C_6H_3$ (75%)
L1b Ar = 2,4-$Me_2C_6H_3$ (68%)

Scheme 2. Reagents and conditions: (i) Phthalimide, heat [10]; (ii) H^+; (iii) NaOH; (iv) Ar–Br, $Pd_2(dba)_3$ (0.5 mol%), *rac*-BINAP, $NaOBu^t$, toluene, heat.

1a M = Co, R_1 = Me, R_2 = H
1b M = Co, R_1 = H, R_2 = Me

2a M = Co, $R_1 = R_2$ = Me
2b M = Co, R_1 = H, R_2 = Me
3a M = Fe, $R_1 = R_2$ = Me
3b M = Fe, R_1 = H, R_2 = Me

Scheme 3. Reagents and conditions: (i) MCl_2, *n*-BuOH, heat; (ii) $FeCl_2(THF)_{1.5}$, THF, room temperature.

Cl(1)–Co(1)–Cl(2)	118.72(6)

N,*N*,*N*-chelate and two terminal chloride ligands. The geometry at the cobalt(II) centre may be best described as distorted trigonal bipyramidal with the equatorial plane defined by N(2), Cl(1) and Cl(2) [N(2)–Co(1)–Cl(1) 132.81(10)°, N(2)–Co(1)–Cl(2) 108.46(10)°] and the axial sites by N(1) and N(3) [N(1)–Co(1)–N(3) 156.94(12)°]. The *N*,*N*,*N*-chelate is bound in a *meridional* configuration and contains two five-membered chelate rings, the bite angle for each being 80.24(13)° [N(1)–Co(1)–N(2)] and 80.49(12)° [N(2)–Co(1)–N(3)]. The *ortho*-methyl groups of the *N*-aryl substituents are positioned above and below the plane defined by N(1)–N(2)–N(3)–Co(1) [max. deviation from plane: Co(1) 0.170 Å] with C2A and C12A pointing in a similar direction to Cl(2). There is a difference in the Co–N bond lengths with the central Co–N being shorter than the terminal Co–N bond lengths [Co(1)–N(2) 2.088(3) Å versus Co(1)–N(1) 2.274(4) Å, Co(1)–N(3) 2.289(4) Å]. The two Co–Cl bond distances are asymmetric with Co–Cl(2) being ca. 0.07 Å longer than Co–Cl(1). The Cl(1)–Co(1)–Cl(2) bond angle of 118.72(6)° falls in the mid-range for those found in related five-coordinate cobalt(II) dichloride complexes [9,13]. Complex **1a** has two chiral centres at N(1) and N(3) and crystallises with the relative configuration being distinct. The structural features of **1a** closely resemble those observed for the related complexes [{$(ArNHCH_2CH_2)_2$-NH}$CoCl_2$] (Ar = 2,6-$Me_2C_6H_3$, 2,4, 6-$Me_3C_6H_2$) [9].

The FAB mass spectrometric data for **1a** and **1b** reveal molecular ions peaks along with fragmentation peaks corresponding to the loss of chloride ions; no peaks are evident for dimeric species. In their IR spectra, the υ(N–H) absorption band is seen at ca. 3270 cm^{-1} and is ca. 100 cm^{-1} lower in wavenumber than in the free-ligands (**L1a** and **L1b**). The room temperature magnetic susceptibility measurements (Evans Balance) for **1a** and **1b** afforded magnetic moments of ca. 3.95 BM, characteristic of high spin cobalt(II) configurations ($S = 3/2$) containing three unpaired electrons. Attempts to acquire assignable paramagnetically shifted ^1H NMR spectra in acetonitrile-d_3 at room temperature proved unsuccessful.

It is uncertain as to why a stable complex (under the conditions employed) containing **L1** cannot be isolated with iron chloride. It is noteworthy that we have also been similarly unsuccessful in isolating iron complexes with the non-methylated counterpart of **L1**, $(ArHNCH_2CH_2)_2NH$ [9]. Replacement of one $ArHNCH_2CH_2$ arm in $(ArHNCH_2CH_2)_2NH$ with a picolyl group has, however, afforded isolable complexes with iron chloride [14]. It would appear that the π-acceptor capability of the pyridyl donor plays a key role in complex stability.

Interaction of **L2a** or **L2b** with MCl_2 in *n*-butanol at elevated temperatures gave complexes [{$ArNHCH_2$-

$CH_2\}_2\{(2\text{-}C_5H_4N)CH_2\}NMCl_2]$ (M = Co, Ar = 2,4,6-$Me_3C_6H_2$ **2a**, 2,4-$Me_2C_6H_3$ **2b**; M = Fe, Ar = 2,4,6-$Me_3C_6H_2$ **3a**, 2,4-$Me_2C_6H_3$ **3b**) in good yield. Complexes **3a** and **3b** can also be prepared from the reaction of $FeCl_2(THF)_{1.5}$ with **L2** in tetrahydrofuran at room temperature (Scheme 1). Complexes **2** and **3** have been characterised by FAB mass spectrometry, infrared spectroscopy, magnetic susceptibility and by elemental analysis (see Table 1). In addition, crystals of **2a** · CH_2Cl_2 and **3a** · MeCN have been the subject of a single crystal X-ray diffraction study.

Pale blue crystals of **2a** · CH_2Cl_2 and golden crystals of **3a** · MeCN suitable for X-ray determinations were grown by layering dichloromethane and acetonitrile solutions of the complexes with hexane at ambient temperature, respectively. The molecular structures of **2a** and **3a** are essentially the same and only **3a** will be discussed in any detail. A view of **3a** is shown in Fig. 3; selected bond distances and angles for both complexes are listed in Table 3.

Table 3
Selected bond distances (Å) and angles (°) for **2a** · CH_2Cl_2 and **3a** · MeCN

	2a · CH_2Cl_2 (M = Co)	**3a** · MeCN (M = Fe)
Bond lengths		
M(1)–N(1)	2.217(2)	2.248(4)
M(1)–N(2)	2.117(2)	2.165(5)
M(1)–N(3)	2.202(2)	2.319(4)
M(1) ··· N(4)	2.795(2)	2.597(4)
M(1)–Cl(1)	2.3219(8)	2.3215(17)

Bond angles		
N(1)–M(1)–N(2)	78.38(9)	77.89(18)
N(1)–M(1)–N(3)	80.45(8)	78.13(15)
N(2)–M(1)–N(3)	109.98(8)	104.89(16)
N(1)–M(1)–Cl(1)	172.95(6)	170.73(13)
N(2)–M(1)–Cl(1)	94.59(6)	93.23(14)
N(3)–M(1)–Cl(1)	101.65(7)	101.90(12)
N(1)–M(1)–Cl(2)	91.70(6)	92.44(13)
N(2)–M(1)–Cl(2)	160.27(6)	166.94(14)
N(3)–M(1)–Cl(2)	84.71(6)	81.31(12)
Cl(1)–M(1)–Cl(2)	95.19(3)	96.73(6)

The structure of **3a** consists of a single iron centre bound by an *N*,*N*,*N*,*N*-chelate and two monodentate chloride ligands to form a geometry that can be best described as a distorted octahedral. The pyridyl donor [N(2)] is *trans* to Cl(2) and the tertiary amine N(1) is *trans* to Cl(1) leaving the mesityl-substituted amines located mutually *trans*. There is considerable variation in the Fe–N bond lengths with the distance to the pyridyl donor being the shortest [Fe(1)–N(2) 2.165(5) Å] followed by the distance to the tertiary amine [Fe(1)–N(1) 2.248(4) Å]. Despite the same substitution pattern on N(3) and N(4), the Fe–N(4) [2.597(4) Å] bond distance is significantly longer than that for Fe–N(3) [2.319(4) Å] and ca. 0.3 Å longer than that found for the corresponding distance in related ferrous complexes [9,14]. Indeed in **2a** this asymmetry is even more dramatic [Co(1)–N(4) 2.795(2) Å vs. Co(1)–N(3) 2.202(2) Å] to the point where a weak interaction offers a more suitable description. The origin of the elongation of the M(1)–N(4) distance is likely to be steric; the pyridyl donor, due to geometry constraints within the ligand framework, is inclined more towards one aryl-amine than the other with the result than an *ortho*-methyl group [C(28)] hinders efficient coordination of N(4). Unfortunately, single crystals of **2b** and **3b**, which lack one *o*-Me group per aryl ring, could not be grown in order to demonstrate this steric effect. Notably, in $[\{(ArNHCH_2CH_2)\{(2\text{-}C_5H_4N)CH_2\}_2N\}FeCl_2]$ (Ar = 2,4-$Me_2C_6H_3$, 2,6-$Me_3C_6H_2$) effective coordination of the aryl-amine arm occurs for the 2,4-Me_2Ph derivative but not for the 2,6-Me_2Ph derivative [14]. The two Fe–Cl bond distances are asymmetric with Fe–Cl(2) being ca. 0.16 Å longer than Fe–Cl(1), presumably as a consequence of the *trans*-coordinated pyridyl group.

The IR spectra of **2a** and **3a** both show broad υ(NH) absorption bands at ca. 3200 cm^{-1} which, in comparison with the free ligand **L1a**, are shifted to

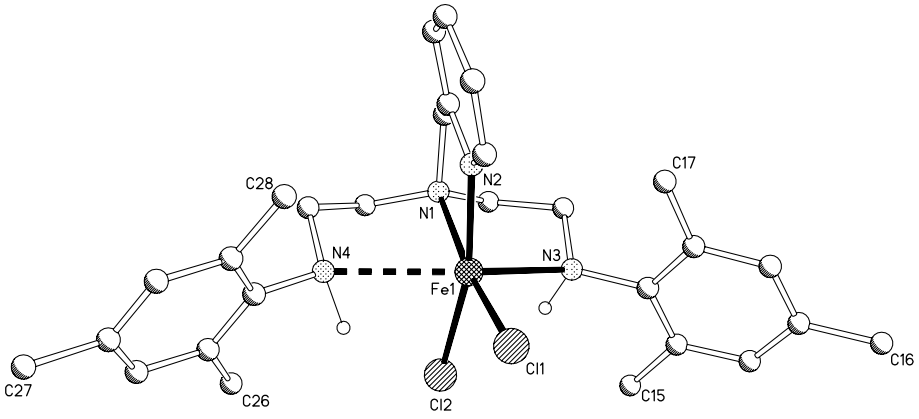

Fig. 3. Molecular structure of **3a** including the atom numbering scheme. All hydrogen atoms except for H3 and H4 have been omitted for clarity.

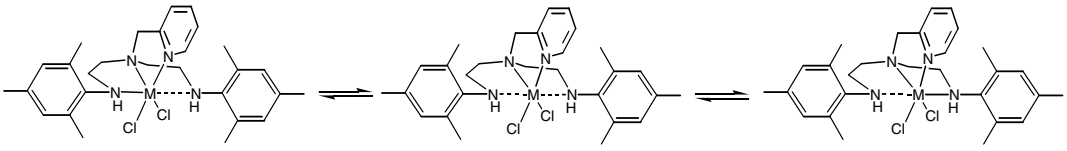
lower wavenumber by ca. 100 cm^{-1} (Table 1). Similar shifts in wavenumber are observed for **2b** and **3b**. The room temperature magnetic susceptibility measurements for **2** and **3** indicate high spin behaviour with the iron(II) complexes (**2**) displaying magnetic moments of ca. 5.0 BM (consistent with four unpaired electrons) and ca. 3.9 BM for the cobalt(II) complexes (consistent with three unpaired electrons).

Solution state studies performed on complexes **2a** and **3a** in acetonitrile-d_3 at room temperature support their paramagnetic nature with broad shifted ^{1}H NMR spectra in the range of −10.0 to 130.0 ppm (see Section 4). Interpretation of the paramagnetic ^{1}H NMR spectra can be achieved by comparison of chemical shifts and relaxation times (T_1) to related metal(II) complexes such as $[\{(ArNHCH_2CH_2\}\{(C_5H_4N)CH_2\}NH\}MCl_2]$ (M = Fe, Co) [9] and to previously reported polypyridyl metal(II) systems [15–17].

For **2a** the protons of the coordinated pyridyl arm display characteristic chemical shifts and relaxation times [H_α, $\delta = 97.0$; $H_\beta/H_{\beta'}$, $\delta = 50.3/46.8$ ($T_1 = 10.1$ and 16.4 ms); H_γ, $\delta = 0.3$ ($T_1 = 31.0$ ms)]. The methylene protons are not observed, possibly as a consequence of the significant broadening of the spectrum. The aromatic region can be assigned as: Ar–H_m at $\delta = 9.3$ ($T_1 = 39.4$ ms), ArMe_p at $\delta = 11.5$ ($T_1 = 135$ ms) and Ar-Me_o at $\delta = -4.8$ ($T_1 = 2.8$ ms). For **3a** the H_α of the coordinated pyridyl arm is shifted downfield the most at $\delta = 128.6$, whilst $H_{\beta/\beta'}$ appear as sharp signals at $\delta = 53.6$ and 52.1 ($T_1 = 13.1$ and 11.1 ms) and H_γ is the most upfield at $\delta = 18.2$ ($T_1 = 42.3$ ms). The methylene protons are exceedingly broad and shifted downfield at $\delta \approx 115$ and 35. The aromatic region can be assigned as: ArMe_p at $\delta = 13.3$ ($T_1 = 40.5$ ms), Ar–H_m at $\delta = 12.0$ ($T_1 = 150$ ms) and ArMe_o at $\delta = 8.7$ ($T_1 = 3.1$ ms).

It is noteworthy that, despite the inequivalence of the aryl-amine arms in **2a** and **3a** in the solid state, their behaviour in solution at ambient temperature reveals signals (albeit rather broad) consistent with one type of aryl group environment. Scheme 4 illustrates a series of equilibria that could account for the apparent C_2 symmetry in solution.

Complexes **1a** and **1b**, on activation with MAO (300 eq.; conditions, 1 bar ethylene, room temperature, in toluene), are modest catalysts for the oligomerisation of ethylene, (ca. 45 g mmol/h/bar) giving a broad range of linear and branched products including α-olefins, internal olefins, vinylidenes and trisubstituted olefins. In contrast, **2** and **3** show scarcely any activity; it would seem likely that the additional nitrogen donor in the supporting ligand makes the metal centre too electron rich.



3. Conclusions

In conclusion, a series of new aryl-substituted dien ligands (**L1** and **L2**) containing a central tertiary amine have been prepared and fully characterised. Tetradentate coordination is possible for **L2** in iron(II) and cobalt(II) complexes; the effect of steric bulk on efficient coordination is apparent. Coordination of **L1** as a tridentate ligand has only been observed in cobalt(II) halide complexes. The **L1**-supported cobalt systems show some activity as precatalysts for ethylene oligomerisation.

4. Experimental

4.1. General

All reactions were carried out under an atmosphere of dry, oxygen-free nitrogen, using standard Schlenk techniques or in a nitrogen purged glove box. Solvents were distilled under nitrogen from appropriate drying agents and degassed prior to use [18]. The infrared spectra were recorded as Nujol mulls between 0.5 mm NaCl plates or on a Perkin–Elmer 1600 series or in the solid state using a Perkin–Elmer spectrum one FT-IR spectrometer The ES and the FAB mass spectra were recorded using a micromass Quattra LC mass spectrometer and a Kratos Concept spectrometer with methanol or NBA as the matrix respectively. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker ARX spectrometer (250 or 300 MHz); chemical shifts (ppm) are referred to the residual protic solvent peaks; relaxation times (T_1) are in seconds. Magnetic susceptibility studies were performed using an Evans Balance (Johnson Matthey) at room temperature. The magnetic moment was calculated following standard methods [19] and corrections for underlying diamagnetism were applied to data [20]. Elemental analyses were performed at the Department of Chemistry, University of North London by Dr S. Boyer.

Scheme 4. Possible interconversion occurring in solution for **2a** or **3a**.

The reagents, 2-picolyl chloride hydrochloride, sodium *t*-butoxide, the aryl halides and the metal dichlorides were purchased from Aldrich Chemical Co. and used without further purification. *rac*-BINAP was purchased from Strem Chemical Co. The compounds, $Pd_2(dba)_3$ [21], $(H_2NCH_2CH_2)_2NMe$ [10], $FeCl_2(THF)_{1.5}$ [22] and $(ArNHCH_2CH_2)_2NH$ (Ar = 2,4,6-$Me_3C_6H_2$ [3], 2,4-$Me_2C_6H_3$ [23]) were prepared according to previously reported procedures. All other chemicals were obtained commercially and used without further purification.

4.2. Synthesis of *L1*

(a) **L1a**, Ar = 2,6-$Me_2C_6H_3$: An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $(H_2NCH_2CH_2)_2NMe$ (1.20 g, 10.3 mmol), 2-bromo-*m*-xylene (2.74 ml, 3.81 g, 20.6 mmol), $Pd_2(dba)_3$ (0.047 g, 0.052 mmol, 0.005 eq.), *rac*-BINAP (0.096 g, 0.155 mmol, 0.015 eq.), $NaOBu^t$ (2.97 g, 30.9 mmol) and toluene (40 ml). The reaction mixture was heated at reflux and stirred for a period of 4 days. After cooling to room temperature, the solvent was removed under reduced pressure to afford an oily residue. The residue was dissolved in diethyl ether (30 ml) and washed with water (3×30 ml) and saturated NaCl solution (3×30 ml). The organic layer was separated and dried over $MgSO_4$. The solvent was removed under reduced pressure and the residue left under vacuum at 50 °C for 24 h to give [{(2,6-$Me_2C_6H_3$)$HNCH_2CH_2$}$_2$NMe] (**L1a**) as a viscous oil. Yield: 75% (2.50 g, 7.73 mmol). Compound **L1a**: ES mass spectrum, *m*/*z* 326 ($M^+ + H$). IR (cm^{-1}): 3357 (NH, medium). NMR ($CDCl_3$, 293 K): ^1H NMR, δ 6.90 (d, 4H, ^3J(HH) 7.2, Ar-H_m), 6.74 (t, 2H, Ar-H_p), 3.03 (t, 4H, ^3J(HH) 6.0, CH_2), 2.55 (t, 4H, CH_2), 2.21 (s, 12H, Me_o) and 2.19 (s, 3H, N–Me). ^{13}C (^1H composite pulse decoupled), δ 146.9 (s, C, Ar), 129.3 (s, C, Ar), 129.2 (s, C, Ar), 121.8 (s, C, Ar), 58.7 (s, CH_2), 46.1 (s, CH_2), 41.7 (s, N–Me) and 19.1 (s, Me_o).

(b) **L1b**, Ar = 2,4-$Me_2C_6H_3$: Using the same procedure and molar quantities of reagents as above in 4.2(a) employing 4-bromo-*m*-xylene (2.78 cm^3, 3.81 g, 20.6 mmol) as the aryl bromide, [{(2,4-$Me_2C_6H_3$)-$HNCH_2CH_2$}$_2$NMe] (**L1b**) was isolated as a viscous red oil. Yield: 68% (2.27 g, 6.97 mmol). Compound **L1b**: ES mass spectrum, *m*/*z* 326 ($M^+ + H$). IR (cm^{-1}): 3347 (NH, medium). NMR ($CDCl_3$, 293 K): ^1H NMR, δ 6.82 (m, 4H, Ar–H), 6.45 (d, 2H, ^3J(HH) 8.1, Ar–H), 3.20 (t, 4H, ^3J(HH) 6.0, CH_2), 2.71 (t, 4H, CH_2), 2.14 (s, 6H, Me_o), 2.05 (s, 6H, Me_p) and 2.10 (s, 3H, N–Me). ^{13}C (^1H composite pulse decoupled), δ 144.6 (s, C, Ar), 131.3 (s, C, Ar), 127.7 (s, C, Ar), 126.4 (s, Ar), 122.8 (s, C, Ar), 110.5 (s, C, Ar), 48.7 (s, CH_2), 44.2 (s, CH_2), 41.8 (s, N-Me), 20.7 (s, Me_p) and 17.9 (s, Me_o).

4.3. Synthesis of *L2*

(a) **L2a**, Ar = 2,4,6-$Me_3C_6H_2$: An oven dried Schlenk flask was charged with [{(2,4,6-$Me_3C_6H_2$)-$HNCH_2CH_2$}$_2$NH] (0.50 g, 1.54 mmol), 2-picolyl chloride hydrochloride (0.380 g, 2.31 mmol), K_2CO_3 (0.457 g, 4.62 mmol) and acetonitrile (40 ml). The reaction mixture was heated to 55 °C and stirred for a period of three days. After cooling to room temperature, the solution was filtered and the solvent removed under reduced pressure to afford an oily residue. The residue was dissolved in diethyl ether (30 ml) and washed with water (3×30 ml). The organic phases were combined and concentrated on a rotary evaporator to give a brown oil. The crude product was purified via alumina column chromatography employing ethyl acetate and hexane (1:4) as the eluting solvents to give {(2,4,6-$Me_3C_6H_2$)$NHCH_2$-CH_2}$_2${(2-C_5H_4N)CH_2}N (**L2a**) as a yellow oil. Yield: 31% (0.202 g, 0.48 mmol). Compound **L2a**: ES mass spectrum: *m*/*z* 431 $[M + H]^+$. IR (cm^{-1}): 3356 (N–H, medium), 1590 (C = $N_{pyridine}$). NMR ($CDCl_3$, 293 K): ^1H NMR, δ 8.45 (dd, 1H, ^3J(HH) 5.0, ^4J(HH) 1.0, PyC*H*), 7.55 (dt, 1H, ^3J(HH) 7.0, ^4J(HH) 1.8, PyC*H*), 7.39 (d, 1H, ^3J(HH) 7.9, PyC*H*), 7.07 (m, 1H, PyC*H*), 6.70 (s, 4H, ArC*H*), 3.80 (s, 2H, PyCH_2), 3.22 (br s, 2H, N–*H*), 3.0 (t, 4H, CH_2), 2.74 (t, 4H, ^3J(HH) 6.0, CH_2) and 2.13 (s, 18H, *Me*). ^{13}C NMR (^1H composite pulse decoupled): δ 159.4 (s, C, Py), 149.2 (s, C, Py), 143.7 (s, C, Ar), 136.4 (s, C, Py), 130.9 (s, C, Ar), 129.4 (s, C, Ar), 129.3 (s, C, Ar), 123.0 (s, C, Py), 122.1 (s, C, Py), 60.5 (s, Py*C*H_2), 55.1 (s, *C*H_2), 46.1 (s, *C*H_2), 20.6 (s, Me_p) and 18.5 (s, Me_o).

(b) **L2b**, Ar = 2,4-$Me_2C_6H_3$: Using the same procedure and molar quantities of reagents as above in 4.3(a) employing [{(2,4-$Me_2C_6H_3$)$HNCH_2CH_2$}$_2$NH] (0.49 g, 1.54 mmol), 2-picolyl chloride hydrochloride 0.380 g, 2.31 mmol), K_2CO_3 (0.457 g, 4.62 mmol) gave {(2,4-$Me_3C_6H_3$)$NHCH_2CH_2$}$_2${(2-C_5H_4N)CH_2}-N (**L2b**) as a yellow oil. Yield: 29% (0.184 g, 0.47 mmol). Compound **L2b**: ES mass spectrum: *m*/*z* 403 $[M + H]^+$. IR (cm^{-1}): 3371 (N–H, medium). NMR ($CDCl_3$, 293 K):^1H NMR, δ 8.61 (dd, 1H, ^3J(HH) 5.8, ^4J(HH) 1.1, PyC*H*), 7.51 (dt, 1H, ^3J(HH) 7.0, ^4J(HH) 1.8, PyC*H*), 7.46 (d, 1H,^3J(HH) 7.9, PyC*H*), 7.05 (m, 1H, PyC*H*), 6.90 (m, 4H, Ar–H), 6.45 (d, 2H, ^3J(HH) 8.1, Ar–H), 3.86 (s, 2H, PyCH_2), 3.55 (m, 4H, CH_2), 3.20 (m, 4H, CH_2), 2.12 (s, 6H, Me_p) and 2.00 (s, 6H, Me_o). ^{13}C NMR (^1H composite pulse decoupled), δ 160.2 (s, C, Py), 149.5 (s, C, Py), 143.9 (s, C, Ar), 136.4 (s, C, Py), 131.3 (s, C, Ar), 127.7 (s, C, Ar), 126.4 (s, C, Ar), 122.8 (s, C, Ar), 122.5 (s, C, Py), 122.3 (s, C, Py), 110.5 (s, C, Ar), 59.9 (s, Py*C*H_2), 48.7 (s, *C*H_2), 44.2 (s, *C*H_2), 20.7 (s, Me_p) and 17.9 (s, Me_o).

4.4. Synthesis of (1)

(a) **1a**, Ar = 2,6-$Me_2C_6H_3$: An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $CoCl_2$ (0.040 g, 0.32 mmol) in *n*-BuOH (5 ml) at 90 °C and a solution of **L1a** (0.105 g, 0.32 mmol) in *n*-BuOH was introduced to form a green solution. After being stirred at 90 °C for 1 h, the reaction was allowed to cool to room temperature. The reaction mixture was concentrated and hexane added to induce precipitation of the product. The suspension was stirred overnight, filtered, washed with hexane (2 × 30 ml) and dried under reduced pressure to give [{((2,6-$Me_2C_6H_3$)$NHCH_2CH_2$)}$_2$N-Me}$CoCl_2$] (**1a**) as a pale blue solid. Layering of an acetonitrile solution of **1a** with hexane gave **1a** as pale blue crystals suitable for a single crystal X-ray structure determination. Yield: 75% (0.110 g, 0.24 mmol).

(b) **1b**, Ar = 2,4-$Me_2C_6H_3$: Using the same procedure and molar quantities of reagents as above in 4.4(a) employing **L1b** (0.104 g, 0.32 mmol) and $CoCl_2$ (0.042 g, 0.32 mmol), gave [{((2,4-$Me_2C_6H_3$)$NHCH_2CH_2$)}$_2$NMe $CoCl_2$] (**1b**) as a pale blue solid. Yield: 71% (0.103 g, 0.23 mmol).

4.5. Synthesis of (2)

(a) **2a**, Ar = 2,4,6-$Me_3C_6H_2$: An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $CoCl_2$ (0.020 g, 0.15 mmol) in *n*-BuOH (5 ml) and the reaction stirred at 90 °C until dissolution. **L2a** (0.065 g, 0.15 mmol) in *n*-BuOH (2 ml) was added and the reaction mixture stirred at 90 °C for 20 min. Following concentration of the reaction mixture hexane was added to induce precipitation of the product. The suspension was stirred overnight, filtered, washed with hexane (2 × 30 ml) and dried under reduced pressure to afford [{(2,4,6-$Me_2C_6H_2$)-$NHCH_2CH_2$)}$_2${(2- C_5H_4N)CH_2}N}$CoCl_2$] (**2a**) as a pale blue solid. Layering of a acetonitrile solution of **2a** with hexane gave pale blue crystals suitable for a single crystal X-ray diffraction study. Yield: 81% (0.068 g, 0.12 mmol). ^{1}H NMR (acetonitrile-d_3, 293 K): δ 97.0 (H_α), 50.3 (10.1 ms, H_β or $H_{\beta'}$), 46.8 (16.4 ms, H_β or $H_{\beta'}$), 11.5 (135 ms, $ArMe_p$), 9.3 (39.4 ms, Ar–H_m), 0.31 (31.0 ms, H_γ) and −4.8 (2.8 ms, $ArMe_o$).

(b) **2b**, Ar = 2,4-$Me_2C_6H_3$: Using the same procedure and molar quantities of reagents as above in 4.5(a) employing **L2b** (0.061 g, 0.15 mmol) and $CoCl_2$ (0.020 g, 0.15 mmol), gave [{(2,4-$Me_2C_6H_3$)-$NHCH_2$-CH_2)}$_2${(2-C_5H_4N)CH_2}N}$CoCl_2$] (**2b**) as a pale blue solid. Yield: 65% (0.052 g, 0.10 mmol).

4.6. Synthesis of (3)

(a) **3a**, Ar = 2,4,6-$Me_2C_6H_2$: An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $FeCl_2(THF)_{1.5}$ (0.108 g, 0.47 mmol) in THF (10 ml) and a solution of **L2a** (0.200 g, 0.47 mmol) in THF (5 ml) was introduced to form a yellow solution. After being stirred at room temperature for 24 h, the reaction mixture was concentrated and hexane added to induce precipitation of the product. The suspension was stirred overnight, filtered, washed with hexane (2 × 30 ml) and dried under reduced pressure to give [{(2,4,6-$Me_2C_6H_2$)$NHCH_2CH_2$)}$_2${(2-C_5H_4N)CH_2}N}$FeCl_2$] (**3a**) as a pale yellow solid. Layering of an acetonitrile solution of **3a** with hexane gave **3a** as golden crystals suitable for a single crystal X-ray structure determination. Yield: 80% (0.212 g, 0.38 mmol). ^{1}H NMR (acetonitrile-d_3, 293 K): δ 128.6 (H_α), 115.0 (very broad, CH_2), 53.6 (13.1 ms, H_β or $H_{\beta'}$), 52.1 (11.1 ms, H_β or $H_{\beta'}$), 35.0 (very broad, CH_2), 18.2 (42.3 ms, H_γ) 13.3 (40.5 ms, Ar–Me_p), 12.0 (150.0 ms, Ar–H_m), and 8.7 (3.1 ms, $ArMe_o$).

(b) **3b**, Ar = 2,4-$Me_2C_6H_3$: An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $FeCl_2$ (0.019 g, 0.15 mmol) in *n*-BuOH (5 ml) and the reaction stirred at 90 °C until dissolution. **L2b** (0.063 g, 0.15 mmol) in *n*-BuOH (2 ml) was added and the reaction mixture stirred at 90 °C for 20 min. Following concentration of the reaction mixture hexane was added to induce precipitation of the product. The suspension was stirred overnight, filtered, washed with hexane (2 × 30 ml) and dried under reduced pressure to afford [{(2,4-$Me_2C_6H_3$)$NHCH_2CH_2$)}$_2${(2-C_5H_4N)-CH_2}N}$FeCl_2$] (**2a**) as a pale yellow solid. Yield: 65% (0.053 g, 0.10 mmol).

4.7. Ethylene oligomerisation

The precatalyst (**1**–**3**) (0.01 mmol) was added to a Schlenk tube, dissolved or suspended in toluene (40 ml) and MAO (4.0 mmol, 400 equiv.) introduced. The tube was purged with ethylene and the contents stirred under 1 bar ethylene at room temperature for the duration of the test. After 0.5 h the test was terminated by the addition of dilute aqueous hydrogen chloride. The organic phase was separated, analysed by GC and then the solvent removed by distillation and the residue analysed by NMR spectroscopy.

4.8. Crystallography

Data for **1a** and **3a** were collected on a Bruker P4 diffractometer while that for **2a** on a Bruker APEX 2000 CCD diffractometer. Details of data collection, refinement and crystal data are listed in Table 4. The data were corrected for Lorentz and polarisation effects and empirical absorption corrections applied. Structure solution by Patterson methods and structure refinement on F^2 employed SHELXTL version 6.10 [24,25]. Hydrogen

Table 4
Crystallographic and data processing parameters for complexes **1a**, **2a** and **3a**

Complex	**1a**	**2a**	**3a**
Formula	$C_{21}H_{31}Cl_2CoN_3$	$C_{28}H_{38}Cl_2CoN_4 \cdot CH_2Cl_2$	$C_{28}H_{38}Cl_2FeN_4 \cdot CH_3CN$
M	455.32	645.38	596.41
Crystal size (mm)	$0.52 \times 0.33 \times 0.14$	$0.11 \times 0.18 \times 0.32$	$0.15 \times 0.03 \times 0.03$
Temperature (K)	200(2)	150(2)	120(2)

All data	$R_1 = 0.0906$, $wR_2 = 0.1399$	$R_1 = 0.0463$, $wR_2 = 0.0789$	$R_1 = 0.2275$, $wR_2 = 0.1298$
Goodness of fit on F^2 (all data)	1.019	0.961	0.870

Data in common: graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å; $R_1 = \sum\|F_o| - |F_c\|/\sum|F_o|$, $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$, $w^{-1} = [\sigma^2(F_o)^2 + (aP)^2], P = [\max(F_o^2, 0) + 2(F_c^2)]/3$, where a is a constant adjusted by the program; goodness of fit $= [\sum(F_o^2 - F_c^2)2/(n-p)]^{1/2}$ where n is the number of reflections and p the number of parameters.

atoms were included in calculated positions (C–H = 0.96 Å) riding on the bonded atom with isotropic displacement parameters set to 1.5 U_{eq}(C) for methyl H atoms and 1.2 U_{eq}(C) for all other H atoms. All non-H atoms were refined with anisotropic displacement parameters.

5. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 269720-269722. Copies of the information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail deposit@ccdc.cam.ac.uk or at www.ccdc.cam.ac.uk).

Acknowledgements

We thank the EPSRC (to CJD), ExxonMobil (to CJD) and the Nuffield Foundation for an Undergraduate Summer Bursary (to SJH) for financial assistance. Financial and equipment support from the Department of Chemistry at the University of Leicester and the Royal Society are gratefully acknowledged. Johnson Matthey PLC are thanked for their loan of palladium chloride.

2. Experimental

2.1. Materials and physical measurements

(−)-Menthyl acrylate and triphenyltin hydride were prepared according to the respective reported methods [19,20]. The other chemicals were of reagent grade and were used without further purification. Carbon and hydrogen analyses were obtained using a Perkin–Elmer 2400 Series II elemental analyzer. Melting points were measured on an X-4 microscopic melting point apparatus. Optical activities were determined by using Wzz-3 digital auto-polarimeter. IR spectra were recorded on a Nicolet 470 FT-IR spectrophotometer using KBr discs in the range 4000–400 cm^{-1}. ^1H and ^{13}C NMR spectral data were collected using a Bruker Avance DMX500 FT-NMR spectrometer with $CDCl_3$ as solvent and TMS as internal standard. ^{119}Sn NMR spectra were recorded in $CDCl_3$ on a Varian Mercury Vx300 spectrometer using Me_4Sn as an internal reference.

2.2. Synthesis of [2-((−)-menthoxycarbonyl)ethyl]-triphenyltin (*1*)

Triphenyltin hydride (8.78 g, 25 mmol), (−)-menthyl acrylate (6.31 g, 30 mmol) and azodiisobutyronitrile (AIBN) (0.1 g) were dissolved in 150 mL of dry tetrahydrofuran (THF) under a nitrogen atmosphere. The mixture was stirred for 12 h under reflux, and the solvent was evaporated off. The residue was recrystallized from ethanol to yield 9.02 g of **1** as a white crystalline solid. Yield 64%, m.p. 105–106 °C, $[\alpha]_D^{20}$ −21.7° (c, 0.59, CH_2Cl_2). *Anal*. Calc. for $C_{31}H_{38}O_2Sn$: C, 66.33; H, 6.82. Found: C, 66.26; H, 6.73%. IR (KBr): 1720 (vs, C=O) cm^{-1}. ^1H NMR (500 MHz, $CDCl_3$) δ : 0.68 (d, J = 7.1 Hz, 3H, CH_3), 0.83 (d, J = 7.0 Hz, 3H, CH_3), 0.85 (d, J = 7.0 Hz, 3H, CH_3), 0.76–1.78 (m, 9H, Men), 1.66 (t, J = 7.5 Hz, $^2J(^{119/117}Sn–^1H)$ = 56/53 Hz, 2H, CH_2Sn), 2.68 (t, J = 7.5 Hz, $^3J(^{119}Sn–^1H)$ = 65 Hz, 2H, $COCH_2$), 4.60 (dt, J_{ae} = 4.4 Hz, J_{aa} = 11.0 Hz, 1H, CHO), 7.35–7.37 (m, 9H, *p*-H and *m*-H), 7.54–7.57 (m, 6H, $^3J(^{119}Sn–^1H)$ = 45 Hz, *o*-H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 16.32, 20.76, 22.00, 23.38, 26.19, 31.27, 34.21, 40.67, 46.89, 74.29 (Men), 5.57 ($^1J(^{119/117}Sn–^{13}C)$ = 402/382 Hz, CH_2Sn), 31.02 ($^2J(^{119}Sn–^{13}C)$ = 21 Hz, CH_2CO), 174.47 (C=O), 128.45 ($^3J(^{119}Sn–^{13}C)$ = 49 Hz, *m*-C), 128.84 ($^4J(^{119}Sn–^{13}C)$ = 11 Hz, *p*-C), 137.09 ($^2J(^{119}Sn–^{13}C)$ = 36 Hz, *o*-C), 138.82 ($J(^{119/117}Sn–^{13}C)$ = 503/481 Hz, *i*-C). ^{119}Sn NMR (111.9 MHz, $CDCl_3$) δ: −100.2.

2.3. Synthesis of [2-((−)-menthoxycarbonyl)ethyl]-diphenyltin chloride (*2*)

A solution of iodonium chloride (0.81 g, 5 mmol) in chloroform (50 mL) was slowly added dropwise with stirring to a solution of **1** (2.81 g, 5 mmol) in chloroform (50 mL) at −5 °C. The colour of iodonium chloride disappeared immediately. The resulting colourless solution was allowed to warm to room temperature and stirred for 1 h. The solvent was evaporated off at reduced pressure. Prolonged pumping to remove iodobenzene obtained an oily product, which was further purified by column chromatography on silica gel with ether/petroleum ether (30–60°) (1/9) as eluant. Yield 1.93 g (74%), $[\alpha]_D^{20}$ −40.2° (c, 0.27, CH_2Cl_2). *Anal*. Calc. for $C_{25}H_{33}ClO_2Sn$: C, 57.78; H, 6.40. Found: C, 57.49; H, 6.33%. IR (film): 1667 (vs, C=O) cm^{-1}. ^1H NMR (500 MHz, $CDCl_3$) δ: 0.66 (d, J = 6.9 Hz, 3H, CH_3), 0.85 (d, J = 6.9 Hz, 3H, CH_3), 0.90 (d, J = 6.9 Hz, 3H, CH_3), 0.82–1.88 (m, 9H, Men), 1.75 (t, J = 7.5 Hz, $^2J(^{119/117}Sn–^1H)$ = 78/75 Hz, 2H, CH_2Sn), 2.82 (t, J = 7.5 Hz, $^3J(^{119}Sn–^1H)$ = 101 Hz, 2H, $COCH_2$), 4.83 (dt, J_{ae} = 4.3 Hz, J_{aa} = 11.1 Hz, 1H, CHO), 7.33–7.41 (m, 6H, *p*-H and *m*-H), 7.79–7.84 (m, 4H, $^3J(^{119}Sn–^1H)$ = 62 Hz, *o*-H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 16.30, 20.75, 22.01, 23.33, 26.18, 31.25, 34.20, 40.65, 46.87, 78.66 (Men), 14.96 ($^1J(^{119/117}Sn–^{13}C)$ = 550/524 Hz, CH_2Sn), 30.33 ($^2J(^{119}Sn–^{13}C)$ = 37 Hz, CH_2CO), 180.04 (C=O), 128.50 ($^3J(^{119}Sn–^{13}C)$ = 66.2 Hz, *m*-C), 129.43 ($^4J(^{119}Sn–^{13}C)$ = 15 Hz, *p*-C), 136.36 ($^2J(^{119}Sn–^{13}C)$ = 49.6 Hz, *o*-C), 139.92 (*i*-C). ^{119}Sn NMR (111.9 MHz, $CDCl_3$) δ: −74.6.

2.4. Synthesis of [2-((−)-menthoxycarbonyl)ethyl]-phenyltin dichloride (*3*)

This compound was prepared in a manner analogous to that of **2**, using **1** (1.40 g, 2.5 mmol) and iodonium chloride (0.81 g, 5 mmol) in chloroform (100 mL) at room temperature. After removal of all volatiles in vacuo, the remaining solid was crystallized from hexane–chloroform (1:1, v/v). Yield 61%, m.p. 117–118 °C, $[\alpha]_D^{20}$ −50.2° (c, 0.52, CH_2Cl_2). *Anal*. Calc. for $C_{19}H_{28}Cl_2O_2Sn$: C, 47.74; H, 5.90. Found: C, 47.76; H, 5.83%. IR (KBr): 1649 (vs, C=O) cm^{-1}. ^1H NMR (500 MHz, $CDCl_3$), δ: 0.75 (d, J = 6.9 Hz, 3H, CH_3), 0.89 (d, J = 7.0 Hz, 3H, CH_3), 0.92 (d, J = 6.5 Hz, 3H, CH_3), 0.87–2.00 (m, 9H, Men), 1.96 (t, J = 7.5 Hz, 2H, $^2J(^{119/117}Sn–^1H)$ = 85/82 Hz, CH_2Sn), 2.93 (t, J = 7.7 Hz, $^3J(^{119/117}Sn–^1H)$ = 135/129 Hz, 2H, $COCH_2$), 4.91 (dt, J_{aa} = 10.9 Hz, J_{ae} = 4.5 Hz, 1H, CHO), 7.45–7.49 (m, 3H, *p*-H and *m*-H), 7.91–7.92 (m, 2H, $^3J(^{119}Sn–^1H)$ = 86 Hz, *o*-H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 16.50, 20.86, 22.11, 23.44, 26.52, 31.55, 34.08, 40.70, 47.11, 79.43 (Men), 20.09 ($^1J(^{119/117}Sn–^{13}C)$ = 664/624 Hz, CH_2Sn), 29.23 ($^2J(^{119}Sn–^{13}C)$ = 50 Hz, CH_2CO), 180.56 ($^2J(^{119}Sn–^{13}C)$ = 70.2 Hz, C=O), 129.18 ($^3J(^{119}Sn–^{13}C)$ = 90 Hz, *m*-C), 131.01 ($^4J(^{119}Sn–^{13}C)$ = 18 Hz, *p*-C), 135.71 ($^2J(^{119}Sn–^{13}C)$ = 63.4 Hz, *o*-C), 141.23 (*i*-C). ^{119}Sn NMR (111.9 MHz, $CDCl_3$) δ: −56.3.

2.5. Synthesis of 2-((−)-menthoxycarbonyl)ethyltin-trichloride (4)

This compound was prepared according to a similar method for $MeOCOCH_2CH_2SnCl_3$ [1]: $SnCl_2$ (4.75 g, 25 mmol) and (−)-menthyl acrylate (5.25 g, 25 mmol) in 100 mL of dichloromethane were placed in a 250 mL three-neck flask equipped with a reflux condenser, a mechanical stirrer and a gas inlet tube. Through the stirred suspension was bubbled anhydrous hydrogen chloride at room temperature until a homogeneous solution was obtained. After removal of solvent at reduced pressure, the remaining solid was recrystallized from hexane–chloroform (3:1, v/v) to give colorless crystals (8.37 g). Yield 77%, m.p. 115–116 °C, $[\alpha]_D^{20}$ −62.1° (c, 0.51, CH_2Cl_2). *Anal.* Calc. for $C_{13}H_{23}Cl_3O_2Sn$: C, 35.78; H, 5.31. Found: C, 35.75; H, 5.23%. IR (KBr): 1645 (vs, C=O) cm^{-1}. ^1H NMR (500 MHz, $CDCl_3$), δ: 0.77 (d, $J = 7.0$ Hz, 3H, CH_3), 0.91 (d, $J = 7.0$ Hz, 3H, CH_3), 0.93 (d, $J = 6.6$ Hz, 3H, CH_3), 0.87–2.01 (m, 9H, Men), 2.20 (t, $J = 7.6$ Hz, $^2J(^{119/117}Sn–^1H) = 109/105$ Hz, 2H, CH_2Sn), 2.91 (t, $J = 7.6$ Hz, $^3J(^{119/117}Sn–^1H) = 198/184$ Hz, 2H, $COCH_2$), 4.97 (dt, $J_{aa} = 10.9$ Hz, $J_{ae} = 4.5$ Hz, 1H, CHO), ^{13}C NMR (125 MHz, $CDCl_3$), δ: 16.45, 20.85, 22.06, 23.37, 26.60, 31.50, 33.99, 40.48, 47.09, 81.27 (Men), 24.18 ($^1J(^{119/117}Sn–^{13}C) = 833/796$ Hz, CH_2Sn), 28.24 ($^2J(^{119}Sn–^{13}C) = 67$ Hz, CH_2CO), 180.64 ($^2J(^{119}Sn–^{13}C) = 140$ Hz, C=O). ^{119}Sn NMR (111.9 MHz, $CDCl_3$) δ: −116.6.

2.6. Synthesis of the dietherate of dimeric 2-((−)-menthoxycarbonyl)ethyltin dichloride hydroxide (5 · 2(C2H5)2O)

A solution of compound **4** (0.44 g, 1 mmol) in diethyl ether (50 mL) with a little added water was stirred for 2 h at room temperature. The solution was evaporated slowly at room temperature and crystals containing two molecular ethers as crystalline solvent, $\mathbf{5} \cdot 2(C_2H_5)_2O$, were obtained in 78% yield. M.p. 88–89 °C, $[\alpha]_D^{20}$ −54.6° (c, 0.09, dioxane). *Anal.* Calc. for $C_{26}H_{48}Cl_4O_6Sn_2 \cdot 2(C_2H_5)_2O$: C, 41.49; H, 6.96. Found: C, 41.17; H, 6.72%. IR (KBr): 3420 (s, OH), 1642 (vs, C=O) cm^{-1}.

2.7. Crystal structure determination of compounds 1, 3, 4 and 5 · 2(C2H5)2O

The colorless single crystals were obtained from chloroform–hexane (1:2, v/v) for **1**, **3** and **4**, and from ether for $\mathbf{5} \cdot 2(C_2H_5)_2O$ by slow evaporation. The intensity data for crystals of the compounds were measured at 295(2) K on a Bruker P4 four-circle diffractometer or a Bruker Smart Apex area-detector fitted with graphite monochromatized Mo Kα radiation (0.71073 Å) using the omega scan technique. The structures were solved by direct methods [21] and refined by a full-matrix least squares procedure based on F^2 using the SHELXL-97 [22]. The non-hydrogen atoms were refined anisotropically, and hydrogen atoms were placed at calculated positions and

were included in the refinement in the riding-model approximation. The absolute configurations of the compounds were confirmed by the X-ray study [23]. The crystallographic parameters and refinements are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

Compound **1** was synthesized by hydrostannation [24] of (−)-menthyl acrylate with triphenyltin hydride using AIBN as a catalyst in THF. The reaction of **1** with iodonium chloride in 1:1 and 1:2 molar ratios yielded the corresponding chloride **2** and dichloride **3**, respectively. The hydrolysis of compound **4**, obtained from the reaction of (−)-menthyl acrylate with $SnCl_2$/HCl in dichloromethane, afforded compound **5**, isolated as a diethetate ($\mathbf{5}\cdot 2(C_2H_5)_2O$). The equations are as follows:

$$CH_2{=}CHCO_2Men + Ph_3SnH \rightarrow \underset{\mathbf{1}}{1\ MenOCOCH_2CH_2SnPh_3}$$

$$\mathbf{1} + n\mathrm{ICl} \rightarrow MenOCOCH_2CH_2SnCl_nPh_{3-n} + n\mathrm{PhI} \quad n=1,\mathbf{2};\ n=2,\mathbf{3}$$

$$CH_2{=}CHCO_2Men + SnCl_2 + HCl \rightarrow \underset{\mathbf{4}}{MenOCOCH_2CH_2SnCl_3}$$

$$2\,\mathbf{4} + 2H_2O + 2(C_2H_5)_2O \rightarrow \underset{\mathbf{5}\cdot 2(C_2H_5)_2O}{[MenOCOCH_2CH_2SnCl_2(OH)]_2\cdot 2(C_2H_5)_2O} + 2\,HCl$$

Compound **2** is an oily product and other compounds are colorless crystalline solids with sharp melting points. Compounds **1**–**4** are soluble in general organic solvents, whilst compound $\mathbf{5}\cdot 2(C_2H_5)_2O$ is only slightly soluble in dichloromethane, methanol and acetone.

3.2. IR spectroscopy

Among the stretching modes, the carbonyl band ν(C=O) in the 1640–1740 cm^{-1} region is known to depend on the nature of coordination of the carbonyl oxygen to metal [5,25]. The ν(C=O) band of **1** (1720 cm^{-1}) is in the same region as that of the free esters (~1730 cm^{-1}), whereas the bands of compounds $\mathbf{2}$–$\mathbf{5}\cdot 2(C_2H_5)_2O$ exhibit a remarkable red shift and appear in the range of 1642–1667 cm^{-1}. These results clearly indicate that the carbonyl is coordinated to the tin atom in compounds $\mathbf{2}$–$\mathbf{5}\cdot 2(C_2H_5)_2O$ and is not in **1** [5,20]. From **1** to $\mathbf{5}\cdot 2(C_2H_5)_2O$, with the increasing of Lewis acidity of the tin center, the stretching vibrations of the carbonyl generally shift to lower wavenumber, from 1720 to 1642 cm^{-1}. The fact that there is almost no variation of the carbonyl frequency between the pure compound and a solution of dichloromethane for $\mathbf{2}$–$\mathbf{5}\cdot 2(C_2H_5)_2O$ indicates the C=O → Sn coordination is intramolecular coordination [5,25].

3.3. NMR spectroscopy

The ^1H and ^{13}C resonance assignments and coupling constants obtained for compounds **1**–**4** are given in the experimental details. The NMR data of compound **5** were not determined due to the small solubility in $CDCl_3$ and CD_3COCD_3. The assignments of ^1H and ^{13}C of CH_2Sn in compounds **1**–**4**, $MenOCOCH_2CH_2SnCl_nPh_{3-n}$ (n = 0–3), were made from the lower $^2J(^{119}Sn{-}^1H)$ (56–109 Hz) and $^2J(^{119}Sn{-}^{13}C)$ (21–67 Hz) couplings compared with the corresponding $^3J(^{119}Sn{-}^1H)$ (65–198 Hz) and $^1J(^{119}Sn{-}^{13}C)$ (402–833 Hz) couplings, respectively. The δ (^1H and ^{13}C) values of CH_2Sn and the coupling constants ^2J(Sn–H) and ^1J(Sn–C) increase consecutively in the sequence $\mathbf{1} < \mathbf{2} < \mathbf{3} < \mathbf{4}$, which is consistent with the increasing of electron withdrawing ability of $SnCl_nPh_{3-n}$ (n = 0–3) in $MenOCOCH_2CH_2SnCl_nPh_{3-n}$. The NMR data also support the presence of carbonyl oxygen to tin coordination in compounds **2**–**4**. The δ values of the CHO proton of menthoxyl in **2**–**4** show a downfield shift ($\Delta\delta$ = ~0.3) compared with that in **1** and the ^{13}C δ values of CHO and C=O in **2**–**4** are deshielded by $\Delta\delta$ = ~5 and $\Delta\delta$ = ~6, respectively, relative to those of **1** because the coordination of carbonyl to tin (CHOC=O → Sn) causes the deshielding of CHOCO. The stepwise increasing of chemical shift (^1H and ^{13}C) of CHOCO from **1** to **4** indicates that the intramolecular interactions between the C=O and Sn strengthen in the order $\mathbf{1} < \mathbf{2} < \mathbf{3} < \mathbf{4}$. The ^{119} Sn chemical shifts depend on the number and nature of the groups coordinated with tin central atom. The ^{119}Sn chemical shift of compounds **1**–**4** is −100.2, −74.6, −56.3 and −116.6, respectively, in agreement with that found in four-coordinated $MeOCOCH_2CH_2SnPh_3$ (−99.8) [26] and five-coordinated $MeOCOCH_2CH_2SnCl_3$ (−115.0) [27].

3.4. Molecular structures of *1*, *3*, *4* and $\mathbf{5}\cdot 2(C_2H_5)_2O$

The molecular structures of **1**, **3**, **4** and $\mathbf{5}\cdot 2(C_2H_5)_2O$ are shown in Figs. 1–4 respectively, and selected interatomic parameters are given in Tables 2–5. The coordination geometry of the tin atom in compound **1** is a distorted tetrahedral geometry with the range of angles around tin being 105.5(1)–113.1(1)°. The Sn(1)···O(1) separation (3.342(4) Å) is shorter than the sum of Van der Waals radii of tin and oxygen (3.73 Å) [28] and much larger than the sum of the covalent radii (2.07 Å) [28], indicating there is a weak interaction between O(1) and Sn(1). Thus, the O(1) atom exerts a steric influence and contributes to the distortion of the

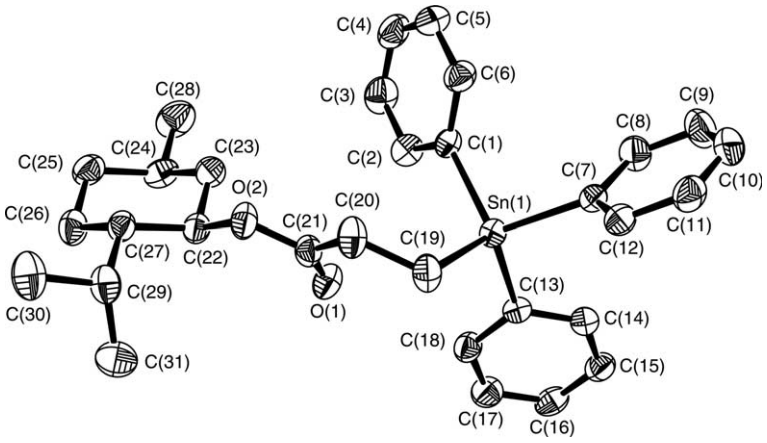

Fig. 1. Molecular structure of compound **1**.

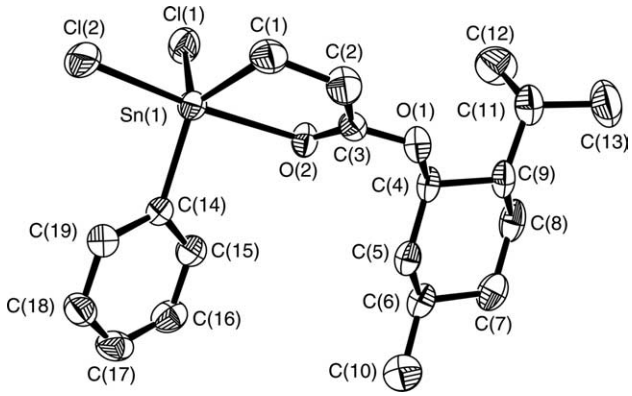

Fig. 2. Molecular structure of compound **3**.

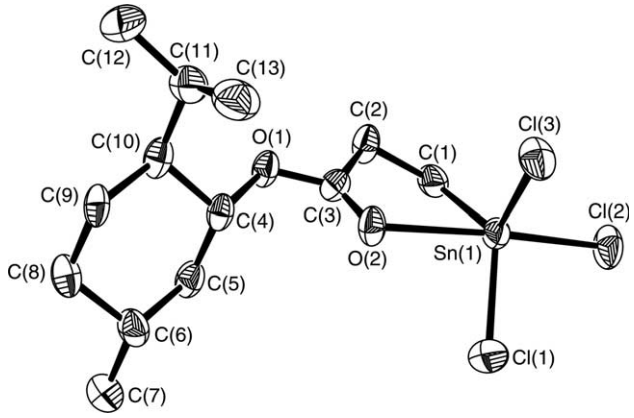

Fig. 3. Molecular structure of compound **4**.

geometry at the tin atom. The closest non-hydrogen intermolecular contact in the lattice of **1** is C(24)$\cdots$O(2)^{i} (3.632(1) Å) (symmetry code i: $-x+2$, $y-1/2$, $-z+2$), indicating the compound is a discrete molecule with no close intermolecular contacts.

The Sn atom in **3** is five coordinated and possesses a distorted trigonal bipyramid geometry with the trigonal plane defined by C(1), C(14) and Cl(1) atoms and the axial positions occupied by the Cl(2) and O(2) atoms, with the Cl(2)–Sn(1)–O(2) angle being 172.87(8)°. The three bond angles on the trigonal plane are in the range 110.4(1)–132.3(2)°. The Sn(1)–O(2) distance of 2.424(3) Å is in the range of a normal Sn–O coordination bond length [9,13], clearly indicating significant bonding interactions between the Sn atom and O(1) atom of the carbonyl group. The formation of the five-membered chelate ring causes a small contraction of the O(2)–C(3)–C(2) angle (122.9(4)°) in **3** compared with that (126.0(3)°) of **1**. The axial Sn(1)–Cl(2) (2.397(1) Å) is longer than the equatorial Sn(1)–Cl(1) (2.343(1) Å).

The geometry around the tin atom in compound **4** is a distorted trigonal bipyramid with C(1), Cl(1) and Cl(3) in the equatorial positions and Cl(2) and O(2) in the axial positions through intramolecular carbonyl oxygen to tin coordination. The three bond angles on the trigonal plane are in the range 108.4(1)–128.0(3)°, and the Cl(2)–Sn(1)–O(2) angle is 173.9(2)°. The distortion may be caused partly by the small bite angle of O(2)–Sn(1)–C(1) (74.9(3)°) with the concomitant expansion of

Cl(2)–Sn(1)–C(1) (101.9(3)°). The intramolecular Sn(1)–O(2) bond (2.397(7) Å) in **4** is slightly longer than that found in $MeOCOCH_2CH_2SnCl_3$ (2.347(5) Å) [2] and *c*-$C_6H_{11}OCOCH_2CH_2SnCl_3$ (2.362(3) Å) [4]. The axial Sn(1)–Cl(2) (2.371(3) Å) is longer than the equatorial Sn(1)–Cl(1) (2.301(4) Å) and Sn(1)–Cl(3) (2.304(3) Å), which is consistent with $MeOCOCH_2CH_2SnCl_3$ [2] and *c*-$C_6H_{11}OCOCH_2CH_2SnCl_3$ [4]. The unit acts as a chelating ligand by utilizing the carbonyl oxygen as an additional donor center.

Compound **5** in **5** · $2(C_2H_5)_2O$ exists as a non-centrosymmetrically six-coordinated dimer with bridging hydroxyl groups. Each tin atom is coordinated by two chloride atoms occupying mutually *cis* positions and a carbon and a carbonyl oxygen from the chelating $COCH_2CH_2$ moiety. The remaining positions in the distorted octahedral coordination geometry about each tin atom are occupied by two μ_2-hydroxide groups. The major distortions in the tin atom geometries may be traced to the acute angles induced by the Sn_2O_2 ring (O(1)–Sn(1)–O(2) 70.3(1)°, O(1)–Sn(2)–O(2) 69.8(1)°) and five-membered chelate CSnO ring (C(1)–Sn(1)–O(3) 77.4(2)°, C(14)–Sn(2)–O(5) 77.5(2)°). The Sn–O distances within the four-membered rings are not symmetrical, with the bond *trans* to a carbon atom being shorter (Sn(1)–O(2) 2.023(3) Å, Sn(2)–O(1) 2.022(3) Å) than that *trans* to a chlorine atom (Sn(1)–O(1) 2.122(3) Å, Sn(2)–O(2) 2.148(3) Å), which are comparable with those found in [*n*-$BuSn(OH)Cl_2(H_2O)]_2$ [29], [*i*-$PrSn(OH)Cl_2(H_2O)]_2$ [30], [$EtSn(OH)Cl_2(H_2O)]_2$ [31] and $[(H_2O)(OH)Cl_2Sn(CH_2)_3SnCl_2(OH)(H_2O)]_n$ [32]. The Sn–O distances in the five-membered chelate rings are Sn(1)–O(3) 2.317(3) Å and Sn(2)–O(5) 2.321(3) Å, which are shorter than that of the six-coordinated $EtOCOCH_2CH_2SnCl_3 \cdot OSBu_2$ [10]. The two Sn–Cl distances around each tin center are significantly different, which is similar to those of [*n*-$BuSn(OH)Cl_2(H_2O)]_2$ [29], [*i*-$PrSn(OH)Cl_2(H_2O)]_2$ [30], [$EtSn(OH)Cl_2(H_2O)]_2$ [31] and $[(H_2O)(OH)Cl_2Sn(CH_2)_3SnCl_2(OH)(H_2O)]_n$ [32]. There is intermolecular hydrogen bonding in the lattices (Fig. 5). The diethyl ether molecule is hydrogen bonded to the oxygen of the Sn_2O_2 ring. For O(1)–H(1)···O(8)^{i}, H(1)···O(8)^{i} is 1.98 Å, O(1)···O(8)^{i} is 2.78 Å and O(1)–H(1)···O(8)^{i} 160.8°(symmetry code i: $1-x$, $-1/2+y$, $1-z$). For O(2)–H(2)···O(7)^{ii}, H(2)···O(7)^{ii} is 1.90 Å, O(2)···O(7)^{ii} is 2.73 Å and O(2)–H(2)···O(7)^{ii} is 176.8° (symmetry code ii: x, y, $-1+z$).

From **1** to **5** · $2(C_2H_5)_2O$, the stepwise shortening of the distances between the carbonyl O and Sn (from 3.342(4) to 2.317(3) Å) indicates an increasing degree of O–Sn donor–acceptor interaction, which is consistent with the increasing Lewis acidity of the central tin atom.

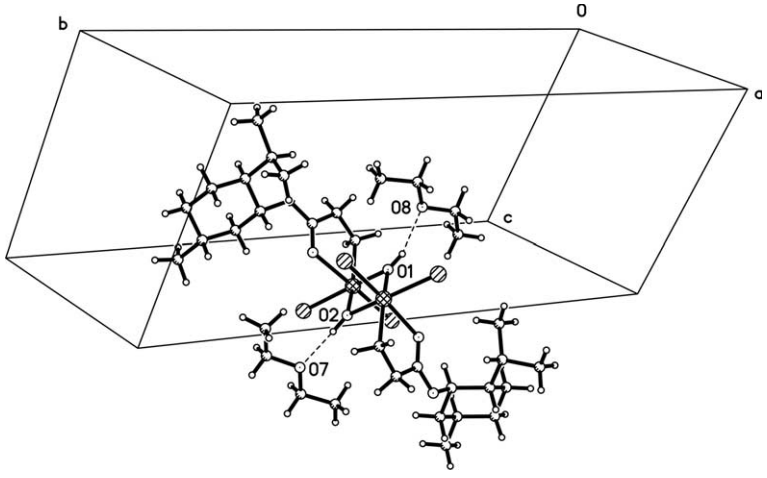

Fig. 5. Hydrogen-bonding interactions between **5** and ether in **5** · $2(C_2H_5)_2O$.

Table 6
Torsion angles (°) for the chelating rings in **3**, **4** and **5** · $2C_4H_{10}O$

Torsion angles	**3**	**4**	Torsion angles	**5** · $2C_4H_{10}O$
Sn(1)–C(1)–C(2)–C(3)	16.1(6)	−32.9(10)	Sn(1)–C(1)–C(2)–C(3)	−17.8(6)
Sn(1)–O(2)–C(3)–C(2)	−5.9(5)	−4.2(13)	Sn(1)–O(3)–C(3)–C(2)	−6.1(5)
C(3)–O(2)–Sn(1)–C(1)	11.1(3)	−11.6(7)	C(3)–O(3)–Sn(1)–C(1)	−3.3(3)
O(2)–Sn(1)–C(1)–C(2)	−13.7(4)	3.6(7)	O(3)–Sn(1)–C(1)–C(2)	11.1(4)
			Sn(2)–C(14)–C(15)–C(16)	10.8(7)
			Sn(2)–O(5)–C(16)–C(15)	−0.6(6)
			C(16)–O(5)–Sn(2)–C(14)	5.1(3)
			O(5)–Sn(2)–C(14)–C(15)	−8.2(5)

The slight forcing of the O–Sn coordination (C=O → Sn and HO → Sn) leads to a shift toward octahedral in the tetrahedron–trigonal bipyramid–octahedron path. The five-membered chelate ring formed by intramolecular carbonyl to tin bonding exhibits a near envelope conformation in **3**–**5** · $2(C_2H_5)_2O$ (see Table 6). The distance of the C=O bond in **3** (1.217(5) Å), **4** (1.21(1) Å) and **5** (1.226(5) and 1.233(5) Å) is significant longer when compared with **1** (1.182(6) Å), which is caused by the transfer of electron density from C=O to tin in **3**–**5** · $2(C_2H_5)_2O$.

Since the first report of ferromagnetism in a molecule-based material, the charge-transfer salt $[Fe(Cp^*)_2]$ TCNE (TCNE = tetracyanoethylene), in 1986, [5,6] similar charge transfer salts with different transition metal bisdithiolene anions have been studied. These salts show different types of structures and a variety of magnetic behaviours, becoming model systems for the study of magnetic interactions in molecular solids [7].

The sulfur rich dithiolate ligands have been extensively explored in this context because the S–S interactions improve both the magnitude and dimensionality of the solid state interactions. Much less effort has been devoted to other extended dithiolene π-ligands containing different heteroatoms like N and O. However, it was recently demonstrated with pyrazinediselenate [8,9] and pyrazinedithiolate [10] Cu complexes that N atoms in these type of ligands can act as an extra coordinating site providing an additional degree of freedom in the crystal engineering of these solids. These pyrazine type complexes were also used as anions in the preparation of an unusual type of charge transfer salt with a unique type of transitions [11–13]. Therefore there is substantial interest in studying similar complexes based on N containing dithiolene ligands such as 2,3-dicyano-5,6-dimercaptopyrazyne (dcdmp), which has been a lot less explored. The monoanionic Ni complex with this ligand $Ni(dcdmp)_2^-$ [14] was reported initially almost 10 years ago and more recently we reported the Au analogue [15], which has already been used to prepare charge transfer salts with TTF type donors [16].

Pursuing an effort to explore complexes of this ligand with other metals, and the possible use of these complexes as building blocks in novel molecular materials, we report in this paper the synthesis and characterization of the $Cu(dcdmp)_2$ complex, in both monoanionic and dianionic forms, and we describe a salt of this Cu^{II} complex with decamethylferrocenium displaying a large anisotropic paramagnetic behaviour but with no ordering down to 2 K.

2. Experimental

2.1. Synthesis

3: Tetrabutylammonium salt of copper (II) bis-2,3-dicyano-5,6-dimercaptopyrazyne, $[n\text{-}Bu_4N]_2Cu(dcdmp)_2$: to a suspension of sodium sulfate monohydrate (241 mg, 1×10^{-3} mol) in acetone (40 ml) was added, under stirring, a solution of 5,6-dichloro-2,3-dicyanopyrazine (100 mg, 5.02×10^{-4} mol) in acetone (10 ml). The formed red solution was filtered and added to a solution of copper chloride (43 mg, 2.51×10^{-4} mol) in acetone (2 ml), turning to an orange-brown mixture. The inorganic precipitate was removed and the liquor added to 1 ml of a solution of tetrabutylammonium bromide (162 mg, 5.02×10^{-4} mol) in acetone, giving rise to a brown-red solution. The stirring was maintained in all steps until no visible modification was observed. This solution was then filtered and slow evaporation of the solvent was allowed. The brown-gold solid obtained was filtered and recrystallised in acetone to afford plate shape crystals suitable for X-ray diffraction measurements. Yield: 22% (52.5 mg); Mp: 213–215 °C; IR (KBr): $\tilde{\nu}=440$ (m), 744 (s, C–S), 987 (s), 897 (m), 1525–1222 (m, s, pyrazine ring), 2220 (s, C≡N), 2427 (w, –N=C–), 2871–2958 (s, C–H aliphat) cm^{-1}. UV–Vis (CH_3CN): $\lambda_{max}=1724$ nm. *Anal.* Calc. for CHNS ($C_{44}H_{72}N_{10}S_4Cu$): C, 56.64; H, 7.77; N, 15.01; S, 13.75. Found: C, 56.43; H, 8.06; N, 15.31; S, 13.51%.

4: Tetrabutylammonium salt of copper (III) bis-2,3-dicyano-5,6-dimercaptopyrazyne, $n\text{-}Bu_4NCu(dcdmp)_2$: to a solution of **3** (310 mg, 3.3×10^{-4} mol) in acetone (150 ml) was added, under stirring, an acetone solution (50 ml) of I_2 (360 g, 1.4×10^{-3} mol). The stirring was maintained for 1 h with no visible alterations of the color and then ~80% of the solvent was slowly evaporated, under nitrogen, over 3 days. After filtering, and washing with cold acetone, brown needle shape crystals suitable for X-ray measurements were obtained. Yield: 77% (176 mg); Mp: 260–262 °C. IR (KBr): $\tilde{\nu}=429$ (w), 733 (w, C–S), 1450–1177 (m, s, pyrazine ring), 2231 (m, C≡N), 2360 (m, –N=C–), 2964–2874 (s, C–H aliphat) cm^{-1}. UV–Vis (CH_3CN): $\lambda_{max}=1729$ nm. *Anal.* Calc. for CHNS ($C_{28}H_{36}N_9S_4Cu$): C, 48.71; H, 5.26; N, 18.26; S, 18.57. Found: C, 49.17; H, 4.22; N, 18.53; S, 18.81%.

5: Decamethylferrocinium salt of copper (II) bis-2,3-dicyano-5,6-dimercaptopyrazyne, $[Fe(Cp^*)_2]_2[Cu(dcdmp)_2]$: Two saturated solutions of $(n\text{-}Bu4N)_2[Cu(dcdmp)_2]$ (50 mg, 5.36×10^{-5} mol) and $Fe(Cp^*)_2BF_4$ (44 mg, 1.0×10^{-4} mol) in acetonitrile (<20 ml) were added together under stirring. Almost immediately a crystalline yellow-gold precipitate appeared. The best needle shape crystals, suitable for X-ray measurements, were obtained by recrystallisation in acetonitrile, followed by slow evaporation of the solvent. Yield 70%. *Anal.* Calc. for CHNS ($C_{52}H_{60}N_8S_4CuFe$): C, 56.75; H, 5.49; N, 10.18; S, 11.65. Found: C, 57.28; H, 4.56; N, 10.21; S, 11.58%.

2.2. X-ray structure determination

The data collection for compound **3** was performed at room temperature on an Enraf–Nonius CAD4 diffractometer, equipped with graphite monochromatised Mo Kα radiation ($\lambda=0.71073$ Å), in the $\omega-2\theta$ scan mode. A semi-empirical absorption correction was applied based on ψ-scans ($T_{max}=0.9999$, $T_{min}=0.8953$). For compound **5** the data were collected at 100(2) K on a Bruker AXS SMART APEX CCD detector diffractometer using graphite-monochromatised Mo Kα radia-

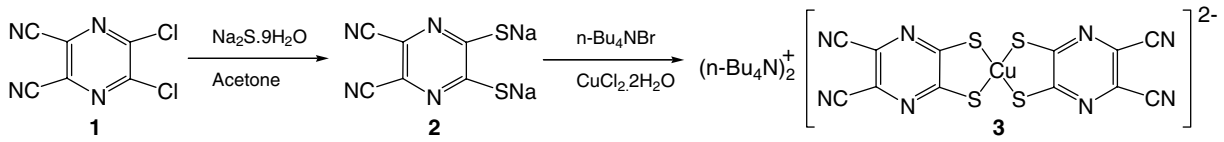
tion ($\lambda = 0.71073$ Å) in the ϕ and ω scans. No absorption correction was applied.

The structures were solved by direct methods using SIR97 [17] and refined by full-matrix least-squares methods using the program SHELXL97 [18] and the WINGX software package [19]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in idealised positions and allowed to refine riding on the parent C atom. Molecular graphics were prepared using ORTEP 3 [20] and SCHAKAL-97 [21]. Crystal data and structure refinement are summarised in Table 1.

2.3. Magnetic properties

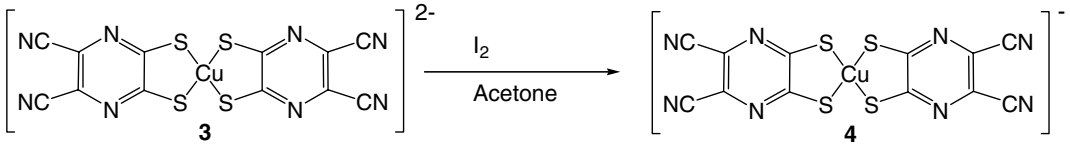
Magnetic measurements were performed using either a longitudinal Faraday system (Oxford Instruments) with a 7 T superconducting magnet for static measurements in the range 2–300 K or a Maglab 2000 system (Oxford Instruments) for magnetisation and AC-susceptibility under fields up to 12 T and down to 1.5 K. The Faraday system was used with a magnetic field of 5 T and forward and reverse gradient fields of 1 T/m. A polycrystalline sample (10–15 mg) was placed inside a previously calibrated thin wall Teflon bucket. The force was measured with a microbalance (Sartorius S3D-V). The Maglab 2000 system was used for magnetisation measurements of similar polycrystalline samples at different magnetic fields using an extraction technique and for AC susceptibility measurements using an AC field of 1 Oersted. Magnetization data were corrected for contributions due to the sample holder and core diamagnetism, estimated from tabulated Pascal constants as -5.9734×10^{-4} and -3.8744×10^{-4} emu-mol^{-1} for **3** and **5**, respectively.

EPR spectra at room temperature were obtained with an X-Band Bruker ESP 300E spectrometer equipped with a microwave bridge ER041XK, a rectangular cavity operating in T102 mode and a Field controller ER 032M system. The modulation amplitude was kept well below the line width and the microwave power well below saturation.



3. Results and discussion

3.1. Synthesis



The synthesis of the copper complex **3** was performed following a standard procedure used for the preparation of dithiolates from dichlorides (Scheme 1), similar to that used to prepare the Ni and Au analogues [14]. The dithiolate ligand (**2**) in solution was obtained from the corresponding chloride salt (**1**) by treatment with Na_2S in acetone. This ligand, without intermediate isolation, was successively reacted with copper chloride and n-Bu_4NBr, also in acetone solutions, followed by slow evaporation of the solvent under an inert atmosphere, to give the copper (II) complex (**3**) that was obtained as gold-brown plate shaped crystals (Scheme 1). The elemental analysis is consistent with a 2:1 stoichiometry, as confirmed by the X-ray crystal structure determination.

Upon oxidation of **3**, with iodine, the corresponding copper (III) complex, **4**, was obtained as gold-brown needle shaped crystals (Scheme 2).

Cyclic voltammetry of **3** in acetonitrile shows a pair of reversible redox waves at 0.206 V vs. Ag/AgCl, ascribed to the couple $[Cu(dcdmp)_2]^-/[Cu(dcdmp)_2]^{2-}$, with no other processes visible in the range up to 1.0 V. These results should be compared with those obtained in Cu complexes with related ligands, namely $Cu(pdt)_2$ (−0.33 V vs. Ag/AgCl) [10] and $Cu(dcbdt)_2$, where dcbdt = dicyano benzene dithiolate (−0.07 V vs. $Ag/AgNO_3$) [22]. As expected, the two cyano groups in the dcdmp ligand make the oxidation more difficult than in the pdt complex and stabilize the dianion, which was readily oxidised to the monoanion by air exposure in the case of $Cu(pdt)_2$. The occurrence of just one reversible redox process in $Cu(dcdmp)_2$ points out to a not so significantly extended ligand contribution to the frontier orbitals of this complex, the oxidation being essentially Cu and S4 centered, as with $Cu(pdt)_2$ [10]. This contrasts with $Cu(dcbdt)_2$ where around 1 V there are additional oxidation processes associated with the formation of partially oxidised species [22] (see Fig. 1).

Scheme 1.

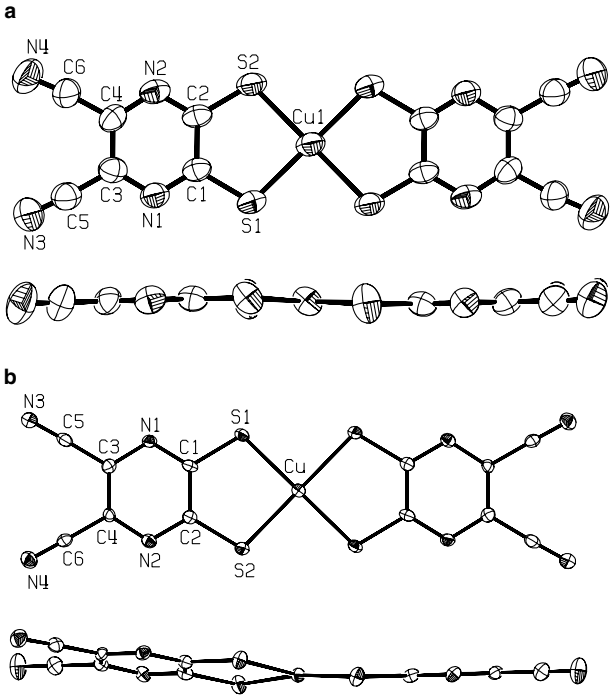

Fig. 2. ORTEP views with thermal ellipsoids at 50% probability and atomic numbering scheme of $Cu(dcdmp)^{2-}$ in **3** (a) and in **5** (b).

3.2. Structural characterisation

The crystal quality made it possible to solve the crystal structures of compounds **3** and **5**. Although the crystal quality of **4** was not sufficient to accurately refine the crystal structure, the final agreement factors were $R_1 = 0.126$ and $wR_2 = 0.283$, the unit cell parameters obtained ($a = 35.281(4)$ Å, $b = 9.501(1)$ Å, $c = 21.885(2)$ Å and $\beta = 109.842(9)°$, monoclinic space group $C2_1/c$), clearly indicate that this Cu compound is isostructural with the corresponding gold analogue [15].

As expected, in both **3** and **5** the $Cu(dcdmp)_2^{2-}$ anion presents a square planar coordination geometry (Fig. 2). However, while in **3** the anion is essentially planar with only a slight chair type distortion (the atomic deviations from the average molecular plane are less than 0.09 Å, see Fig. 2) in complex **5** there is a small but significant important tetrahedral distortion of the coordinating sulfur atoms. These distortions are certainly due to the several C–H···S hydrogen bonds formed between S1 and the Cp* ring of the cations as discussed in more detail below. These interactions twist the two ligands towards opposite directions, where the S2 atom does not interact with any neighbouring atom. Therefore, the non-planarity of the $[Cu(dcdmp)_2]^{2-}$ anion, in **5**, is denoted by a dihedral angle between the average plane of the two ligands of 13.14°.

The Cu–S bond lengths in the anions are 2.2398(14) and 2.2821(13) Å, in complex **3** and 2.2418(7) and 2.2888(7) Å in **5**. Although all these values lie in the typical range of Cu^{II} complexes it is worth referring that in both compounds two Cu–S bond lengths are on the upper side of this range while the other two are close

to the opposite limit. In both complexes, within experimental uncertainty, the dcdmp ligands are identical, presenting a geometry also very close to that found in the corresponding Ni and Au analogues [15] (see Table 2). The $Fe(Cp^*)_2$ units adopt the most common geometry of the metallocenium cations [5,23].

The tetrabutylammonium salt **3**, crystallises in the triclinic system, space group $P\bar{1}$, $Z = 1$, with unit cell parameters $a = 9.9512(6)$ Å, $b = 10.541(1)$ Å, $c = 13.221(1)$ Å, $\alpha = 69.756(9)°$, $\beta = 88.112(6)°$ and $\gamma = 79.658(7)°$. The unit cell contains one independent $[Cu(dcdmp)_2]^{2-}$ anion, with the metal located at an inversion centre, and one independent tetrabutylammonium cation. The crystal structure can be seen as well segregated layers (a, $b - c$) of cations and anions, alternating along $b + c$. There are no short contacts between species of the same layer and the only significant interactions observed are hydrogen bonds, both of C–H···N and C–H···S types, between cations and anions in neighbouring layers. All the sulfur and the terminal nitrogen atoms of the anion species are involved in these interactions (Fig. 3, Table 3).

Salt **5** crystallises in the monoclinic system, space group $C2/c$, $Z = 4$, with unit cell parameters $a = 15.891(1)$ Å, $b = 10.5133(7)$ Å, $c = 30.264(3)$ Å and $\beta = 91.105(2)°$. The unit cell contains two independent $Fe(Cp^*)_2$ cations and one independent $[Cu(dcdmp)_2]^{2-}$ complex, with the Cu atom at an inversion center. Its crystal structure consists of columns along b of alternated dianions and side-by-side pairs of cations, $\ldots A^{2-}(D^+D^+)A^{2-}(D^+D^+)\ldots$ The unit cell contains four columns which are parallel to each other but arranged out-of-registry. This structural motive belongs to the so called type IV structure according to the classification scheme of metalloceniun bisdithiolene salts proposed by Gama and Duarte [7]. However, among this type IV structures, **5** is a rare case where the dithiolate is in the dianionic state, previously observed only for the $Cu(mnt)_2^{2-}$ analogue [24]. All other examples of type IV structure previously known are based on monoanionic dithiolate complexes, with an extra anion in the structure to balance the charge. The main difference in the structure of **5** relative to that of $[Fe(Cp^*)_2]_2$-$Cu(mnt)_2$ is the orientation of the $Fe(Cp^*)_2$ cations that are rotated with the Cp* plane almost 90° relative to the mnt ligand, while in this $Cu(dcdmp)_2$ salt the Cp* planes are almost parallel to the ligands (Fig. 4).

In the crystal structure of **5** the anions are well isolated from each other with no direct contacts. Each anion has short contacts with 10 different close neighbouring $[Fe(Cp^*)_2]^+$ cations, all being hydrogen bonds of different types (see Table 4 and Figs. 5 and 6). Along the column, with cations I–IV, the observed interactions are of the C–H···S and C–H···C type. The contacts with the four cations placed closer at the ends of the long axis of the anions (VI, VII, IX, X) are of C–H···N type, while the interactions with the other two cations closer to the centre of the anion (V, VIII) are exclusively of the C–H···S type. The only significant cation–cation short contact is between the pairs positioned side-by-side in the same column (I and II, III and IV), which present an H···H contact.

Probably due to these interactions, the cations axes in these pairs are not exactly parallel to each other and the dihedral angle between the average planes of the two molecules is close to 3°. In each metallocenium the Cp* rings are not exactly parallel, making a dihedral angle of (1.4°) a distortion related with the asymmetry of the hydrogen bonds in the two rings. Apart from this slight deviation between the two Cp* rings of each cation, their planes are almost parallel to the dcdmp ligands, being well centered over the pyrazine ring. However the average distance between the pyrazine and the Cp* rings (3.576 Å) do not denote a very significant π–π interaction, probably due to the size of the methyl groups that prevent a closer interaction between these rings. The shorter distances between these rings are denoted by the distances N2···C13 (3.419 Å) and C2···C14 (3.500 Å), exceeding only by 5 and 3%, respectively, the sum of the Van der Waals radii. As mentioned above the more significant short contacts between these units are the previously referred hydrogen bonds, which probably also preclude the development of a more significant π–π interaction.

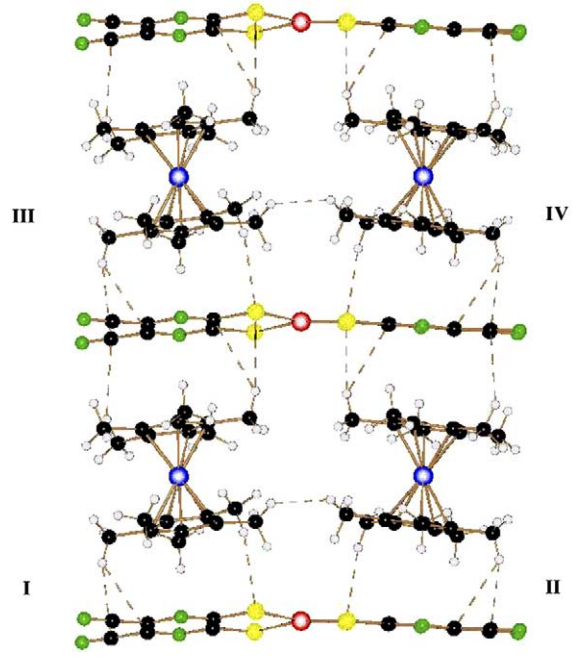

Fig. 5. Partial view of one $\ldots D^+D^+A^-D^+D^+A^- \ldots$ chain in the crystal structure of **5**.

3.3. Magnetic characterisation

As expected for Cu(III) in a square planar coordination geometry, **4** is diamagnetic while **3**, a the Cu(II) complex that is a d^9 species, is paramagnetic. This is confirmed by EPR and magnetisation measurements. Single crystal EPR data for **3** shows, at room temperature, a single line between 34 and 82 G wide and *g* values of 2.024 and 2.040. At room temperature the effective magnetic moment, μ_{eff}, of 1.70 μ_B, is very close to the value of 1.76 μ_B predicted for independent $S = 1/2$ spins with $\langle g_{Cu} \rangle = 2.03$. As shown in Fig. 7, μ_{eff} shows a slight increase upon cooling, until ca. 15 K where a maximum of 1.75 μ_B is observed and it decreases for lower temperatures. The analysis of the crystal structure suggests that the magnetic interactions in **3** must be very weak, as the anionic radicals are isolated by the diamagnetic TBA^+ cations. This is in good agreement with the magnetization isothermal obtained at 1.7 K (see Fig. 8), which follows closely the calculated Brillouin function, with the experimental values only slightly inferior to the calculated ones, as expected for a system of spins with a very weak AFM coupling. At high applied magnetic fields the magnetization saturates at a value of 1.0149 $N\mu_B$, in good agreement with the calculated value of $M_S = gS = 1.015\ N\mu_B$.

In the case of **5**, the magnetic measurements are expected to show paramagnetic contributions both from the acceptors, $[Cu(dcdmp)_2]^{2-}$, and the donors, $[Fe(Cp^*)_2]^+$. The paramagnetic susceptibility of this compound does not follows a Curie–Weiss behaviour, instead the effective magnetic moment shows a maximum at ca. 70 K, as shown in Fig. 7, concerning the measurements obtained with a compressed pellet. At room temperature $\mu_{eff} = 3.56\ \mu_B$, a value lower than

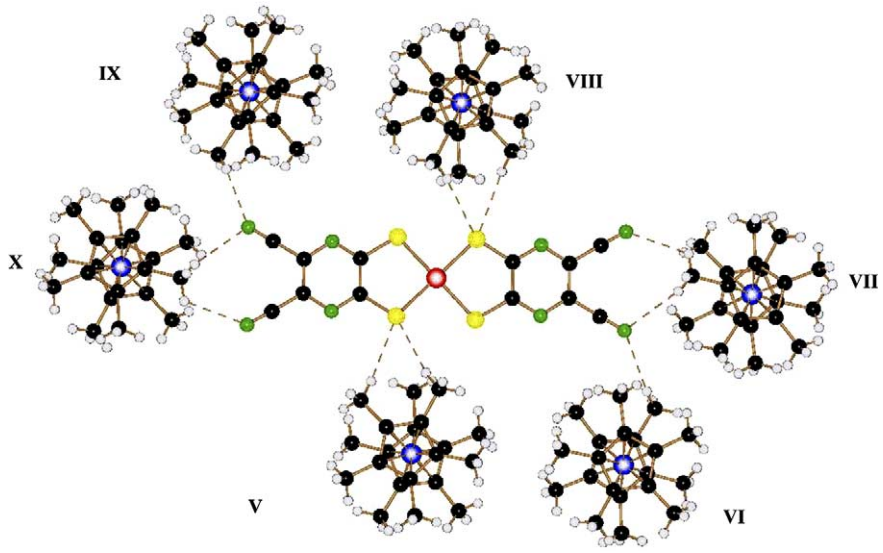

Fig. 6. Partial view along b of the crystal structure of **5** showing the interactions between one anion and the cations in neighbouring chains.

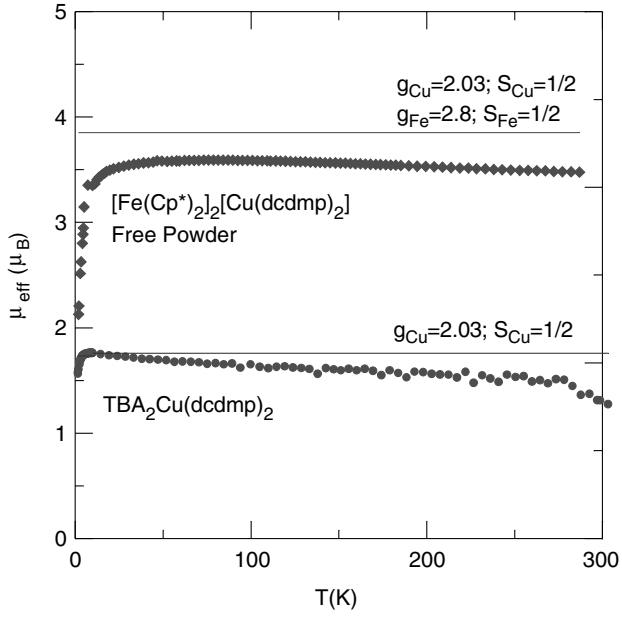

Fig. 7. Effective magnetic moment, μ_{eff}, of **3** (circles) and **5** (squares), as a function of temperature at 5 and 2 T, respectively.

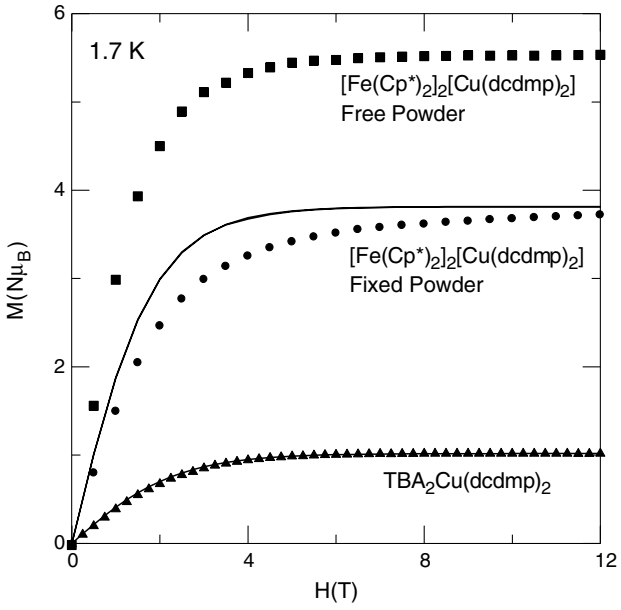

Fig. 8. Isothermal magnetisation at 1.7 K of **3** (triangles) and **5**, as fixed (circles) and free (squares) powder samples.

the calculated one, 3.854 μ_B, for a spin system with $S_A = 1/2$ and $S_D = 1/2$ and $\langle g_A \rangle = 2.03$ and $\langle g_D \rangle = 2.8$ [5]. This difference can be attributed to an AFM coupling between the donors and the acceptors. It should be noted that the magnetisation measurements (effective magnetic moment) give significantly different results for a fixed powder (in a compressed pellet) and in a polycrystalline sample with powder free to rotate. This is ascribed to a large anisotropy due to the g factor anisotropy of the donor, $[Fe(Cp^*)_2]^+$, with $g_{\parallel} = 4.4$ and $g_{\perp} = 1.4$ [5].

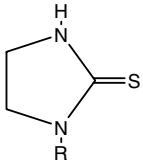
The unusual temperature dependence of μ_{eff}, namely the increase of μ_{eff} from room temperature down to 70 K, can be ascribed to a ferrimagnetic (FIM) like behaviour induced by an AFM intrachain DA coupling, which could lead to a spin arrangement in the DDAD-DA chains as $\cdots\uparrow\uparrow\downarrow\uparrow\uparrow\downarrow\cdots$, with $S_D = S_A = 1/2$. This effect is expected to be further enhanced by the fact that g_D ($\sim$2.8) is considerably larger than g_A ($\sim$2). At low temperatures, the antiferromagnetic nature of the dominant interactions is also confirmed by the isothermal magnetization curves, as shown in Fig. 8 for measurements

obtained at 1.7 K. The experimental magnetisation values are lower than those predicted by the Brillouin function. At high fields the magnetization approaches 3.75 $N\mu_B$, in good agreement with the calculated value for the saturation magnetization $M_S = g_A S_A + 2g_D S_D = 3.815\ N\mu_B$. AC magnetic susceptibility measurements show no sign of magnetic ordering down to 1.5 K. This absence of magnetic order is consistent with the fact that the intrachain DA magnetic interactions are not expected to be very strong and the interchain interactions are expected to be weak.

4. Conclusion

The $Cu(dcdmp)_2$ complex was prepared in both dianionic and monoanionic states as air stable compounds. The $[Fe(Cp^*)_2]_2[Cu(dcdmp)_2]$ salt, in spite of a structure favourable for ferrimagnetic behaviour, does not shows any magnetic ordering down to 1.7 K. The magnetic properties show, however, a large anisotropy, ascribed to the *g*-factor anisotropy of the $Fe(Cp^*)_2^+$ cations.

5. Supplementary material



Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre. The deposition numbers are CCDC-269571 and CCDC-269572 for compounds **3** and **5**, respectively. Copies of the data can be obtained free of charge upon application to the director of CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +441223/336/033, e-mail deposit@ccdc.cam.ac.uk].

synthesis of metal complexes with heterocyclic thiones [5]. In addition to other advantages, the fact that the same metal can be used as the starting material avoids the presence in solution of other anionic species that are competitors for the ligand under investigation. This situation means that the nature of the compounds obtained can differ from those prepared using more traditional methods. In a similar way to other heterocyclic thiones, such as pyridine-2-thione or pyrimidine-2-thione, these ligands can show a large degree of versatility in their coordination forms, yielding complexes with unusual geometries, variable nuclearity and great structural diversity. Moreover, there is experimental evidence that the nature and location of the substituent in the heterocyclic ring is important in determining the structure of metal-heterocyclic thionate complexes and, for this reason, we decided to study the influence of the nature of different substituents in the N-heterocyclic ring (Scheme 1) on the structure of the corresponding complexes [5]. The structural and spectral characterization of these complexes is also included in this report.

2. Experimental

2.1. General considerations

Copper and silver (Aldrich) were used as plates (ca. 2×2 cm). 1-Methylethylenediamine, 1-ethylethylenediamine, 1-isopropylethylenediamine, 1-propylethylenediamine and carbon disulfide (Aldrich) were used as supplied.

Elemental analysis was performed using a Carlo-Erba EA microanalyser. IR spectra were recorded as KBr mulls on a Bruker IFS-66V spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AMX 300 MHz instrument using $CDCl_3$ as solvent. Chemical shifts were recorded against TMS as the internal standard. The mass spectra (FAB) were recorded on a Micromass Autospec spectrometer, with 3-nitrobenzyl alcohol as the matrix.

2.2. Preparation of ligands

The ligands were synthesized by reaction of the appropriately substituted R-ethylenediamine and carbon disulfide in methanol–water using slight modifications of the standard literature procedure [18] (see Scheme 2).

Details are given for a representative example.

2.2.1. 1-Propylimidazolidine-2-thione (1-PrImSH)

Carbon disulfide (0.6 ml, 9.95 mmol) was added dropwise to a cooled (ice bath) solution of 1-propylethylenediamine (3.64 g, 35.7 mmol) in ethanol (9 ml) and water (9 ml). A white precipitate was formed. The reaction mixture was heated at 60 °C and a further quantity of carbon disulfide (3 ml, 49.7 mmol) was added. The precipitate initially dissolved but shortly after a large amount of white solid precipitated out. The reaction mixture was heated under reflux (110 °C) for 1 h and conc. HCl (0.5 ml) was added. The mixture was heated under reflux for a further 10 h. The reaction mixture was cooled and stored in a freezer. The resulting precipitate was filtered off and washed with cold acetone to give the desired ligand (2.78 g, 53.6%). *Anal.* Calc. for $C_6H_{12}N_2S$: C, 49.9; H, 8.4; N, 19.4; S, 22.2. Found: C, 49.8; H, 8.1; N, 19.3; S, 22.0%. IR (KBr, cm^{-1}): 3192 s, br, 2950 m, 2920 m, 2860 m, 1497 vs, br, 1465 s, 1450 s, 1375 m, 1315 s, 1300 s, 1270 s, 1230 vs, 1180 w, 1130 m, 1120 m, 1080 w, 1030 w, 960 m, 890 w, 800 vw, 670 m, 612 m, 510 m, 340 w, 290 vw. ^{1}H NMR ($CDCl_3$, ppm): 6.57 (s, 1H, NH); 3.44–3.68 (m, 8H, H4, H5 and CH_2), 0.88 (t, 3H, CH_3). ^{13}C NMR ($CDCl_3$, ppm): 183.6 (C2), 48.3 (C5), 41.8 (C4), 48.8 (N-*CH_2), 20.8 (*CH_2–CH_3), 11.5 (CH_3).

2.2.2. 1-Ethylimidazolidine-2-thione (1-EtImSH)

1-Ethylethylenediamine (2.53 g, 28.7 mmol) and CS_2 (2.55 ml, 42.2 mmol) gave the corresponding ligand (2.58 g, 70.9%). *Anal.* Calc. for $C_5H_{10}N_2S$: C, 46.1; H, 7.7; N, 21.5; S, 24.6. Found: C, 45.9; H, 7.9; N, 21.0; S, 23.9%. 2.2.4. 1-isopropylimidazolidine-2-thione (1-^{i}PrImSH)

The diamine (9.13 g, 91.3 mmol) and CS_2 (9.22 ml, 127.6 mmol) gave the corresponding ligand (6.94 g, 52.3%). *Anal*. Calc. for $C_6H_{12}N_2S$: C, 49.9; H, 8.4; N, 19.4; S, 22.2. Found: C, 49.7; H, 8.2; N, 19.2; S, 22.3%. IR (KBr, cm^{-1}): 3280 vs, 2960 s, 2920 w, 2860 m, 1505 vs, 1490 s, 1460 s, 1440 s, 1365 m, 1330 m, 1260 s, br, 1205 w, 1190 w, 1160 m, 1125 m, 1060 s, 960 s, 740 w, 670 m, 620 m, 605 s, 520 m, 490 m, 425 w, 376 w. ^{1}H NMR ($CDCl_3$, ppm): 6.17 (s, 1H, NH): 3.51–3.63 (m, 4H, H4, H5); 4.77 (m, 1 H, CH), 1.16 (d, 6H, CH_3). ^{13}C NMR ($CDCl_3$, ppm): 182.7 (C2), 43.2 (C5), 41.9 (C4), 47.2 (CH–Pr), 19.8 (CH_3).

2.3. Electrochemical synthesis

The electrochemical method used in the synthesis of the complexes was similar to that described earlier [19]. The anode consisted of metal foil suspended from a platinum wire and the cathode was a platinum wire. The ligand was dissolved in acetonitrile and a small amount of tetramethylammonium perchlorate was added to the solution as an electrolyte carrier. Applied voltages of 10–15 V allowed sufficient current flow for smooth dissolution of the metal. Nitrogen was bubbled through the solution during electrolysis to provide an inert atmosphere and also to stir the reaction mixture. Under these conditions the cell can be summarised as $M_{(+)}$/CH_3CN + 1-RImSH/$Pt_{(-)}$. M = Cu, Ag.

2.3.1. [Cu(1-MeImS)]

Electrochemical oxidation of a copper anode in a solution of 1-MeImSH (0.190 g, 1.65 mmol) in acetonitrile (40 ml) at 20 V and 10 mA for 4 h caused 95 mg of copper to be dissolved, $E_f = 1.0$ mol F^{-1}. During the electrolysis process, hydrogen was evolved at the cathode and at the end of the reaction an insoluble crystalline solid was observed at the bottom of the vessel. The solid was filtered off, washed with acetonitrile and ether, and dried under vacuum. *Anal.* Calc. for $C_4H_7CuN_2S$: C, 26.9; H, 3.9; N, 15.7; S, 17.9%. Found: C, 27.0; H, 3.8; N, 15.5; S, 17.5%. IR (KBr, cm^{-1}): 2910 m, 2850 m, 1515 vs, 1470 m, 1450 m, 1420 m, 1380 s, 1300 vs, 1270 vs, 1180 w, 1100 vs, 1005 w, 980 vw, 950 m, 630 s, 480 m, 420 vw, 315 vw.

2.3.2. [Cu(1-EtImS)]

1-EtImSH (0.190 g, 1.47 mmol) in acetonitrile (40 ml); 21 V; 10 mA; 2 h; 50 mg of copper dissolved, $E_f = 1.1$ mol F^{-1}. *Anal.* Calc. for $C_5H_9CuN_2S$: C, 31.2; H, 4.7; N, 14.5; S, 16.6. Found: C, 31.2; H, 5.1; N, 14.2; S, 16.1%. IR (KBr, cm^{-1}): 2950 m, 2910 m, 2850 m, 1515 vs, 1470 w, 1445 m, 1430 m, 1395 s, 1370 w, 1350 m, 1290 m, 1240 vs, br, 1180 m, 1115 s, 1080 w, 1065 w, 1015 m, 985 vw, 950 w, 936 w, 780 w, 620 m, 480 m, 315 vw. ^{1}H NMR ($CDCl_3$, ppm): 3.45–3.47 (m, 6H, H4, H5, CH_2); 1.14 (t, 3H, CH_3). FAB (*m*/*z*): $[Cu_4(1\text{-EtImS})_3]^+$ 642, $[Cu_3(1\text{-EtImS})_2]^+$ 447, $[Cu_2(1\text{-EtImS})_2]^+$ 382, $[Cu_2(1\text{-EtImS})_2\text{–}CH_3]^+$ 367, $[Cu_2(1\text{-EtImS})_2\text{-Et}]^+$ 323, $[Cu(1\text{-EtImS})]^+$ 191, $[1\text{-EtImS}]^+$ 129. Crystals suitable for X-ray studies were obtained directly from the cell.

2.3.3. [Cu(1-PrImS)]

1-PrImSH (0.190 g, 1.30 mmol) in acetonitrile (50 ml); 16 V, 10 mA, 3.5 h; 84 mg of copper dissolved, $E_f = 1.0$. *Anal.* Calc. for $C_6H_{11}CuN_2S$: C, 34.8; H, 5.4; N, 13.5; S, 15.5. Found: C, 34.9; H, 5.5; N, 13.5; S, 16.1%. IR (KBr, cm^{-1}): 2950 m, 2910 w, 2850 w, 1510 s, 1450, m, 1390 s, 1340 w, 1290 s, 1270 m, 1235 m, 1210 s, 1175 w, 1115 s, 1020 w, 960 vw, 860 vw, 670 w, 625 m, 470 m. ^{1}H NMR ($CDCl_3$, ppm): 3.35–3.52 (m, 4H, H4, H5, N–CH_2); 1.55 (m, 2H, C*H_2–CH_3), 0.91 (t, 3H, CH_3). FAB (*m*/*z*): $[Cu_4(1\text{-PrImS})_4]^+$ 826, $[Cu_4(1\text{-PrImS})_3]^+$ 683, $[Cu_3(1\text{-PrImS})_3]^+$ 620, $[Cu_2(1\text{-PrImS})_3]^+$ 559, $[Cu_3(1\text{-PrImS})_2]^+$ 477, $[Cu_2(1\text{-PrImS})_2]^+$ 413, $[Cu_2(1\text{-PrImS})]^+$ 267, $[Cu(1\text{-PrImS})]^+$ 207, $[1\text{-PrImS}]^+$ 143. Crystals suitable for X-ray studies were obtained directly from the cell.

2.3.4. [Cu(1-^{i}PrImS)]

1-^{i}PrImSH (0.193 g, 1.30 mmol) in acetonitrile (40 ml), 25 V, 10 mA, 3.5 h, 85 mg of metal dissolved, $E_f = 1.0$. *Anal.* Calc. for $C_6H_{11}CuN_2S$: C, 34.8; H, 5.4; N, 13.5; S, 15.5. Found: C, 34.8; H, 5.6; N, 13.5; S, 14.8%. IR (KBr, cm^{-1}): 2960 m, 2920 w, 2860 w, 1510 vs, 1445 m, 1390 s, 1355 m, 1330 w, 1290 s, 1245 s, br, 1200 m, 1180 w, 1165 w, 1115 m, 1055 s, 1015 w, 960 w, 635 m, 610 s, 525 m, 475 m, 430 m. ^{1}H NMR ($CDCl_3$, ppm): 3.37–3.50 (m, 4H, H4, H5); 4.46 (s, H, CH), 1.14 (s, 6H, CH_3).

2.3.5. [Ag(1-MeImS)]

Electrochemical oxidation of a silver anode in a solution of 1-MeImSH (0.190 g, 1.65 mmol) in acetonitrile (40 ml) at 23 V and 10 mA for 4 h caused 161 mg of silver to be dissolved, $E_f = 1.0$ mol F^{-1}. During the electrolysis process, hydrogen was evolved at the cathode and at the end of the reaction needles of a crystalline solid was observed at the bottom of the vessel. The solid was filtered off, washed with acetonitrile and ether, and dried under vacuum. *Anal.* Calc. for $C_4H_7AgN_2S$:

C, 21.5; H, 3.2; N, 12.6; S, 14.4. Found: C, 21.5; H, 3.2; N, 11.9; S, 14.4%. IR (KBr, cm^{-1}): 2900 w, 2840 w, 1500s, 1470 w, 1440 w, 1410 w, 1380 m, 1295 s, 1265 s, 1180 w, 1100 vs, 1000 w, 950 m, 630 m, 490 m, 420 w, 330 w.

2.3.6. [Ag(1-EtImS)]

1-EtImSH (0.190 g, 1.47 mmol) in acetonitrile (40 ml); 26 V; 10 mA; 3.5 h; 148 mg of silver dissolved, $E_f = 1.1$ mol F^{-1}. *Anal.* Calc. for $C_5H_9AgN_2S$: C, 25.3; H, 3.8; N, 11.8; S, 13.5. Found: C, 25.3; H, 3.8; N, 11.2; S, 13.4%. IR (KBr, cm^{-1}): 2960 m, 2910 m, 2850 m, 1500 vs, br, 1440 w, 1380 m, 1340 w, 1290 m, 1230 vs, br, 1115 s, 1070 m, 1020 w, 990 vw, 950 w, 790 w, 625 m, 500 m, 340 w. ^{1}H NMR ($CDCl_3$, ppm): 3.48–3.68 (m, 4H, H4, H5); 3.75 (t, 2H, CH_2), 1.16 (t, 3H, CH_3). FAB (*m/z*): $[Ag_4(1\text{-EtImS})_5\text{-}CH_3]^+$ 1063, $[Ag(1\text{-EtImS})_3]^+$ 711, $[Ag_2(1\text{-EtImS})_2]^+$ 474, $[Ag(1\text{-EtImS})_2]^+$ 367, $[Ag(1\text{-EtImS})]^+$ 237.

2.3.7. [Ag(1-PrImS)]

1-PrImSH (0.190 g, 1.30 mmol) in acetonitrile (50 ml); 25 V, 10 mA, 3.5 h; 146 mg of silver dissolved, $E_f = 1.0$ mol F^{-1}. *Anal.* Calc. for $C_6H_{11}AgN_2S$: C, 28.7; H, 4.4; N, 11.2; S, 12.8. Found: C, 28.0; H, 4.7; N, 10.5; S, 12.2%. IR (KBr, cm^{-1}): 2940 m, 2910 m, 2855 m, 1515 vs, 1550 m, 1395 m, 1370 w, 1290 m, 1270 m, 1240 m, 1205 s, 1115 s, 1005 m, 955 m, 890 w, 740 w, 625 m, 480 m, 440 w. ^{1}H NMR ($CDCl_3$, ppm): 3.34–3.68 (m, 4H, H4, H5); 3.72 (t, 2H, N-CH_2), 1.57 (m, 2H, C*H_2–CH_3), 0.91 (t, 3H, CH_3). FAB (*m/z*): $[Ag_4(1\text{-PrImS})_3]^+$ 861, $[Ag_3(1\text{-PrImS})_3]^+$ 754, $[Ag_2(1\text{-PrImS})_3]^+$ 647, $[Ag_3(1\text{-PrImS})_2]^+$ 609, $[Ag_2(1\text{-PrImS})_2]^+$ 502, $[Ag(1\text{-PrImS})_2]^+$ 395, $Ag_2(1\text{-PrImS})]^+$ 358, $[Ag(1\text{-PrImS})]^+$ 251, $[(1\text{-PrImS})]^+$ 143. Crystals suitable for X-ray studies were obtained directly from the cell.

2.3.8. [Ag(1-^{i}PrImS)]

1-^{i}PrImSH (0.193 g, 1.30 mmol) in acetonitrile (40 ml), 21 V, 10 mA, 2.5 h, 100 mg of silver dissolved, $E_f = 0.99$ mol F^{-1}. *Anal.* Calc. $C_6H_{11}AgN_2S$: C, 28.7; H, 4.4; N, 11.2; S, 12.8. Found: C, 28.7; H, 4.2; N, 11.0; S, 12.6%. IR (KBr, cm^{-1}): 2960 m, 2920 m, 2860 m, 1500 vs, br, 1440 m, 1390 s, 1360 m, 1295 s, 1250 vs, 1200 m, 1115 m, 1045 s, 1005 m, 960 m, 635 vw, 610 m, 525 m, 475 m, 425 w. ^{1}H NMR ($CDCl_3$, ppm): 3.51–3.89 (m, 4H, H4, H5); 4.60 (s, H, CH); 1.06 (s, 6H, CH_3). ^{13}C NMR ($CDCl_3$, ppm): 180.4 (C2), 43.5(C5), 42.4(C4), 47.4 (*CH-Pr), 19.9 (^{i}Pr). FAB (*m/z*): $[Ag_4(1\text{-}^i\text{PrImS})_4{}^+\text{-}CH_3]$ 986, $[Ag_4(1\text{-}^i\text{PrImS})_3]^+$ 860, $[Ag_3(1\text{-}^i\text{PrImS})_3]^+$ 753, $[Ag_2(1\text{-}^i\text{PrImS})_3]^+$ 649, $[Ag_3(1\text{-}^i\text{PrImS})_2]^+$ 609, $[Ag_2(1\text{-}^i\text{PrImS})_2]^+$ 503, $[Ag(1\text{-}^i\text{PrImS})_2]^+$ 395, $[Ag(1\text{-}^i\text{PrImS})]^+$ 251, $[1\text{-}^i\text{PrImS}]^+$ 143. Crystals suitable for X-ray studies were obtained directly from the cell.

2.4. X-ray crystallographic studies

Intensity data sets for all compounds were collected with the use of a Smart-CCD-1000 Bruker diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å) equipped with a grafite monochromator. All crystals were measured at 293 K. The ω scan technique was employed to measure intensities in all crystals. No decomposition of the crystals occurred during data collection. The intensities of all data sets were corrected for Lorentz and polarization effects. Absorption effects were corrected using the program SADABS [20]. The crystal structures of all compounds were solved by direct methods. Crystallographic programs used for structure solution and refinement were those of SHELX-97 [21]. Atomic scattering factors and anomalous-dispersion corrections for all atoms were taken from International Tables for X-ray Crystallography [22]. Missing atoms were located in the difference Fourier map and included in subsequent refinement cycles. The structures were refined by full-matrix least-squares refinement on F^2. Hydrogen atoms were placed geometrically with C–H distances of 0.96–0.97 Å and refined using a riding model with U_{iso} constrained at 1.2 (for non-methyl groups) and 1.5 (for methyl groups) times U_{eq} of the carrier C atom. For all structures non-hydrogen atoms were anisotropically refined, and in the last cycles of refinement a weighting scheme was used, where weights are calculated from the following formula $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = (F_o^2 + 2F_c^2)/3$.

Due to the use of room-temperature data, the N-side chains of all compounds display high thermal disorder, specially the propyl groups of compound **3** and the isopropyl groups of compound **4**. Attempts to explain the disorder considering split positions affected convergence and were disregarded.

Table 1 summarizes pertinent details of the data collections and structure refinements, while Tables 2–5 lists important geometrical data for all compounds. Ortep3 [23] drawings with the numbering scheme used are shown in Figs. 1, 2, 5 and 6.

3. Results and discussion

The anodic oxidation of copper or silver in an electrochemical cell containing an acetonitrile solution of the ligand 1-RImSH gives complexes of formula [M(1-RImS)], in which M is Cu or Ag and 1-RImS represents the anionic form of the ligand.

The compounds are sparingly soluble in acetonitrile and they are therefore obtained directly from the cell as crystalline solids. In some cases the quality of the crystals obtained is suitable for X-ray diffraction studies. The complexes are partially soluble in various chlorinated solvents such as chloroform and

dichloromethane, which allows solution studies using techniques such as NMR spectroscopy; the low solubility of the compound in which R = Me precluded this type of study.

The electrochemical efficiency value – defined by the relationship between the number of moles of metal dissolved per mole of charge circulated through the cell – was around 1 mol F^{-1} in all cases. This fact, along with the evolution of hydrogen gas at the cathode, is consistent with the following reaction mechanism:

$$\text{Cathode}: \text{1-RImSH} + 1e^- \rightarrow 1/2H_2 + \text{1-RImS}^-$$

$$\text{Anode}: \text{1-RImS}^- + M \rightarrow [M(\text{1-RImS})] + 1e^-$$

M = Cu, Ag

Attempts were made to obtain mixed complexes that would incorporate an additional ligand in the coordination sphere of the metal. Depending on the nature of the metal ion in question, different phosphines were used as coligands and these were either monodentate (triphenylphosphine) or bidentate [bis(diphenylphosphino)methane (dppm) or 1,2-bis(diphenylphosphine)ethane (dppe)]. The addition of these new ligands to the electrochemical cell gave rise to complexes whose analytical data are consistent with the formula [M(RImS)], meaning that the

phosphine ligand was not incorporated within the coordination sphere. The lack of solubility of these species and their rapid precipitation from the reaction solution could impede the incorporation of the phosphine. For this reason, attempts were made to react the complexes, which had previously been obtained electrochemically, with the appropriate phosphine under reflux in a suitable

solvent. Unfortunately, this approach did not give the desired results. This behavior is in marked contrast to that observed when similar reactions are carried out on silver and copper complexes of pyridine and pyrimidine-2-thionates, which give rise to dinuclear compounds with stoichiometries such as $[Cu_2(6\text{-}^t\text{BuM}E_2\text{SipyS})_2(\text{dppm})_2]$ [24], $[Cu_2(3\text{-M}E_3\text{SipyS})_2(\text{dppe})_3]$ [25], or $[Ag_2\{4,6\text{-(Ph, Me)pymS}\}_2(\text{dppe})_2]$ [26].

The IR spectra of the complexes confirm the presence of the ligands coordinated to the metal. The band attributable to ν(N–H), which appears at 3200–3180 cm^{-1} in the free ligands, is absent in the spectra of the complexes – indicating that in the complexes the ligands are in the deprotonated form. This situation is confirmed by the disappearance of the Δ(N–H) bending band, which in the free ligands is observed in the range 600–670 cm^{-1}. In addition, the ν(C–S) bands of the free ligands, which appear between 520 and 510 cm^{-1}, are shifted to lower wavenumbers in the complexes (500 and 475 cm^{-1}) with respect to the free ligands. This shift is consistent with a decrease in the order of the (C–S) bond due to coordination with the metal.

The ^{1}H NMR spectra of the complexes do not contain a signal for the NH proton, which in the free ligands appears in the range 6.0–6.5 ppm, and this is the result of deprotonation of the ligand. The spectra of the different complexes show signals for all of the ring protons and these appear in the range 3.3–3.7 ppm. Signals due to the R groups appear at higher field in the complexes than in the ligands.

The ^{13}C NMR spectrum could only be recorded for $[Ag(1\text{-}^i\text{PrImS})]_6$ due to the low solubility of the other compounds. However, this spectrum shows all of the expected signals and the main change observed is the shift in the C_2 signal, which is at higher field than that in the free ligand. This is probably due to the reduction in the order of the C–S bond [27]. This finding again provides evidence that the thionato form of the ligand predominates in the complex.

The FAB spectrum of [Cu(1-PrImS)] shows a peak at m/z 826, due to the molecular ion of the tetrameric species $[Cu_4(1\text{-PrImS})_4]^+$, with the appropriate isotope distribution, a peak at m/z 683, corresponding to $[Cu_4(1\text{-PrImS})_3]^+$, which is formed by the loss of one ligand from the tetrameric species, along with other peaks at m/z 620, 477, 413, and 267 corresponding to different fragments of the tetrameric compound, $[Cu_3(1\text{-PrImS})_3]^+$, $[Cu_3(1\text{-PrImS})_2]^+$, $[Cu_2(1\text{-PrImS})_2]^+$ and $[Cu_2(1\text{-PrImS})]^+$, respectively. In the case of $[Cu_4(1\text{-EtImS})_4]$, the FAB spectrum does not show the molecular ion peak but does show a peak associated with $[Cu(1\text{-EtImS})]^+$ at $m/z = 191$ as well as peaks due to the fragments $[Cu_4(1\text{-EtImS})_3]^+$, $[Cu_3(1\text{-EtImS})_2]^+$ and $[Cu_2(1\text{-EtImS})_2]^+$, at $m/z = 642$, 447 and 382, respectively.

The FAB mass spectra of the silver complexes [Ag(1-PrImS)] and $[Ag(1\text{-}^i\text{PrImS})]$ do not show molecular ion peaks, $[Ag_6(1\text{-RImS})_6]$, but do contain peaks that can be assigned to fragments of these molecular ions. For example, the spectrum of $[Ag_6(1\text{-}^i\text{PrImS})_6]$ contains a peak corresponding to the tetrameric species with the loss of a methyl group, $[Ag_4(1\text{-}^i\text{PrImS})_4\text{-CH}_3]$ at $m/z = 989$. In both cases peaks are also observed at $m/z = 860$, 753, 609, 502, 395 and 251, and these can be assigned to the fragments $[Ag_4(1\text{-RImS})_3]^+$, $[Ag_4(1\text{-RImS})_3]^+$, $[Ag_3(1\text{-RImS})_2]^+$, $[Ag_2(1\text{-RImS})_2]^+$, $[Ag(1\text{-RImS})_2]^+$ and $[Ag(1\text{-RImS})]^+$, respectively. As in the copper complexes, the peak clusters have the appropriate isotope distribution.

The complexes [Cu(1-EtImS)] (**1**), [Cu(1-PrImS)] (**2**), [Ag(1-PrImS)] (**3**) and $[Ag(1\text{-}^i\text{PrImS})]$ (**4**) were studied by X-ray diffraction.

3.1. Crystal and molecular structures of [Cu(1-EtImS)] (1) and [Cu(1-PrImS)] (2)

The structures of **1** and **2** are shown in Figs. 1 and 2, respectively. Crystallographic data are shown in Tables 1–3 along with bond distances and angles.

The two compounds are isostructural, with four molecules per unit cell. The compounds consist of neutral tetrameric units formed by four copper atoms and four *N*-alkyl-2-mercaptoimidazolidine ligands, which are related in a pairwise manner by a two-fold rotation axis. In this arrangement the four imidazolidine rings in each unit (which are essentially planar) are disposed in two groups that are practically perpendicular to one another. The copper atoms are arranged in a distorted tetrahedral disposition; the Cu–Cu distances are in the range 2.6288(9)–2.9908(13) Å in **1** and 2.6338(6)–3.0219(8) Å in **2**. These distances are longer than those found in the elemental copper itself (2.40 Å) [28] and are not consistent with the existence of interactions between the metal centers. Each ligand is bonded to three copper centers – two through a sulfur atom that acts as a bridge and the other through the nitrogen atom. In this way the ligand is located above the center of each of the four faces of the tetrahedron formed by the metal atoms, acting as a μ^2-N,S(η^2-S; η^1-N) triple bridge and a five-electron donor. The environment of each of the metal atoms is distorted trigonal $[CuS_2N]$ with each of the donor atoms belonging to a different ligand. The angles around the metal (see Tables 2 and 3) are clearly different and are far from the theoretical value of 120° expected for a regular geometry. On the other hand, the metal atom is slightly out of the plane that contains the three donor atoms, with distances to these planes in the range 0.03–0.05 Å.

The bond distances between the bridging sulfur and the two metal centers are slightly different to those between the metal and fully bonded sulfur. This gives rise

to a situation where there is an asymmetric bridge, with distances between 2.2472(9) and 2.2572(14) Å for the shortest and 2.3074(10) and 2.3408(15) Å for the longest distance. However, it should be noted that none of these distances are significantly different to the average Cu–S bond distances [29–31] found in other complexes with heterocyclic thiones – with a trigonal geometry around each metal center. The Cu–N distances, average value of 1.981(4) Å for **1** and 1.976(3) Å for **2**, are also similar to those found in the complexes mentioned above; e.g., that found in the copper complex with the ligand 1-methylimidazol-2-thione [32], which has an average Cu–N distance of 1.985(3) Å. The S–C bond distances, which have average values of 1.765(5) Å for **1** and 1.754(3) Å for **2**, are very similar to those found in other complexes with heterocyclic thiones in which the ligand is coordinated to the metal in its thiolate form [33].

The crystal packing of **1**, see Figs. 3 and 4, shows that each unit interacts with other units through non-classic hydrogen bonds. One of the hydrogens on C7 in each of the imidazolidine ligands L2 (N3, N4, C6–C10) is involved in a bifurcated intermolecular hydrogen bond (Fig. 3) [34]; one of the interactions is of the C–H···S type [35,36] and the other is C–H···π [37–39] with the double bond C6#2═N3#2 belonging to a ligand that is equivalent by symmetry. These interactions are established along the crystallographic *c* axis. For symmetry reasons, carbon atom C7#1 of the ligand L2#1 forms the same interaction with another neighboring complex molecule and these are also along the *c* axis (see Fig. 3).

It can be seen from Fig. 4 that, besides the interactions discussed above, one of the hydrogen atoms of the methyl group (C10) in each of the imidazolidine ligands involved in the aforementioned interactions also establishes an intermolecular C–H···S hydrogen-bonding interaction. Another of the hydrogen atoms from the same methyl group forms a C–H···π interaction

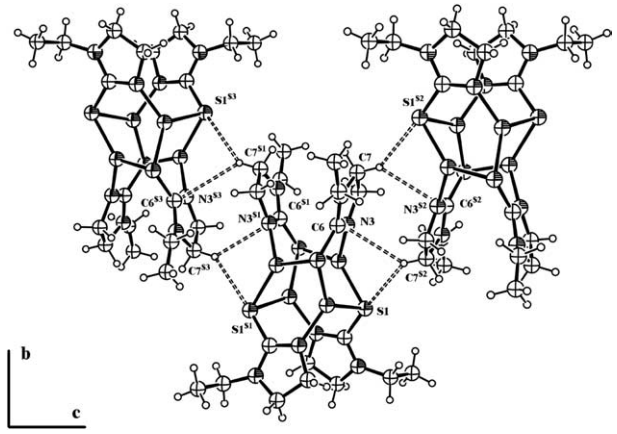

Fig. 3. The crystal packing of **1**, viewed along the *a* axis. Dashed lines show the C–H···π and the C–H···S interactions. [Symmetry codes: #1 = $-x$, y, $-z+1/2$; #2 = $-x$, $-y+1$, $-z+1$; #3 = x, $-y+1$, $z-1/2$.]

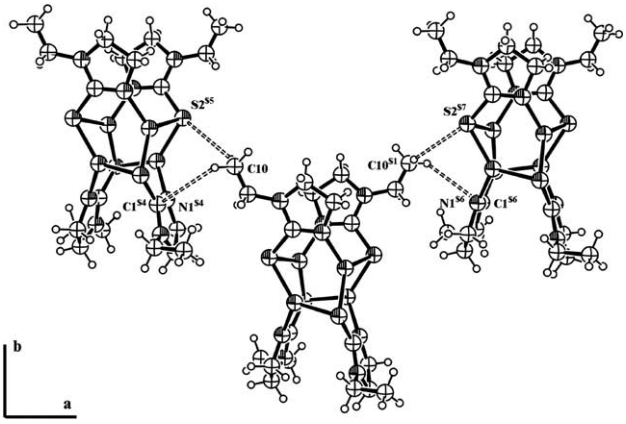

Fig. 4. The crystal packing of **1**, viewed along the *c* axis. Dashed lines show the C–H···π and the C–H···S interactions. [Symmetry codes: #1 = $-x, y, -z+1/2$; #4 = $x-1/2, y+1/2, z$; #5 = $-x-1/2, y+1/2, -z+1/2$; #6 = $-x+1/2, y+1/2, -z+1/2$; #7 = $x+1/2, y+1/2, z$.]

with the double bond C1#4═N1#4 belonging to a non-equivalent ligand from a neighboring tetrameric unit. These interactions are established along the crystallographic *a* axis, i.e., perpendicular to the interactions discussed above. In a similar way, the carbon atom C10#1 from the equivalent ligand L2#2 in the same tetramer also forms the same interactions along the *a* axis, as can be seen in Fig. 4.

The crystal packing of compound **2** [Cu(1-PrImS)] also shows these types of interactions along the *c* and *a* axes. In this case, however, the interactions involve the methyl group on the *N*-propyl unit rather than the ethyl group as in **1**. Given that the propyl is larger than the ethyl group and that the interactions in which they are involved are directed along the *a* axis, the tetrameric units along this axis are separated by a greater distance in complex **2** than in **1**. This situation is reflected in the crystal cell parameters of the two compounds (Table 1), which are very similar apart from the *a* parameter [16.9794(4) Å in compound **1** and 19.7292(2) Å in compound **2**].

3.2. Crystal and molecular structure of [Ag(1-PrImS)] (**3**) and [Ag(1-^{i}PrImS)] (**4**)

The crystal structures of compounds **3** and **4** are shown in Figs. 3 and 4, respectively. Crystallographic data and bond distances and angles are given in Tables 1, 4 and 5, respectively.

The two complexes are isostructural and both consist of hexameric units with the six silver atoms located at the vertices of a highly distorted octahedron. The unit cell contains two different complex molecules and each of these has a center of symmetry located at the center of the Ag_6S_6 unit. The differences between the two units for each of the complexes arise due to the disposition of

the *N*-alkyl chain (propyl for **3** and isopropyl for **4**) (see Figs. 5 and 6).

The distances between the silver atoms are in the range 2.9508–3.3335 Å and, although the shortest values are not significantly different to those found in metallic silver (2.88 Å) [40], the absence of interactions between the metal centers can be deduced.

Each of the thiolate ligands is bonded to three different metal centers, which define one of the faces of the octahedron. These ligands are bound through their nitrogen and sulfur atoms, with the sulfur acting as a bridge between two metals in a μ^2-N,S(η^2-S; η^1-N) five-electron donor system. On the other hand, each silver atom is bonded to the sulfur atoms from two ligands and the nitrogen atom of a third ligand. The geometry is distorted trigonal [AgS_2N] and the silver atoms are markedly displaced from the plane containing the donor atoms, with out-of-plane distances of between 0.3864 and 0.2945 Å.

The Ag–S [2.459(4)–2.542(3) Å] and Ag–N [2.198(11)–2.255(8) Å] bond distances are very similar to those found in other silver complexes with heterocyclic thione derivatives with a trigonal geometry around the metal center [31,41]. The average S–C bond distances are 1.747 Å for **3** and 1.750 Å for **4**, and these indicate that the ligand is coordinated to the metal in the thiolate form [33].

An alternative way to describe this structure is to consider it as a *paddlewheel* whose center consists of the two Ag_6S_6 rings and the six paddles are the ligand fragments that act as bridges between the two Ag_6S_6 rings. The paddles are not arranged in a uniform way around the wheel, as shown by the angles between each pair of imidazolidine ligands. This arrangement means that in each hexamer there are two larger 'holes' and within these 'holes' the weak interactions between hexamers arise that determine the crystal packing. The crystal packing arrangements in compounds **3** and **4** involve weak interactions between one unit and another that is equivalent by symmetry. Interactions do not occur between non-equivalent units.

It can be seen in Fig. 7 that one of the hydrogen atoms on C15 is involved in a C–H···N hydrogen bond [42,43] and the other hydrogen forms a C–H···π interaction with the C7=N3 double bond belonging to a symmetry equivalent ligand of a unit 1 neighbor. For symmetry reasons, the equivalent carbon C15#1 is involved in the same type of interactions and this situation causes these units to pack parallel to the crystallographic *a* axis, as can be seen in Fig. 7.

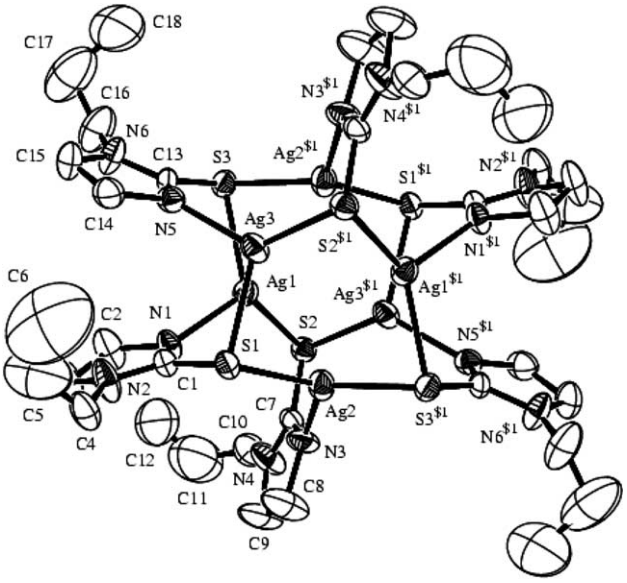

Fig. 5. ORTEP drawing of the molecular structure of [Ag(1-PrImS)] (**3**) showing 30% probability ellipsoids.

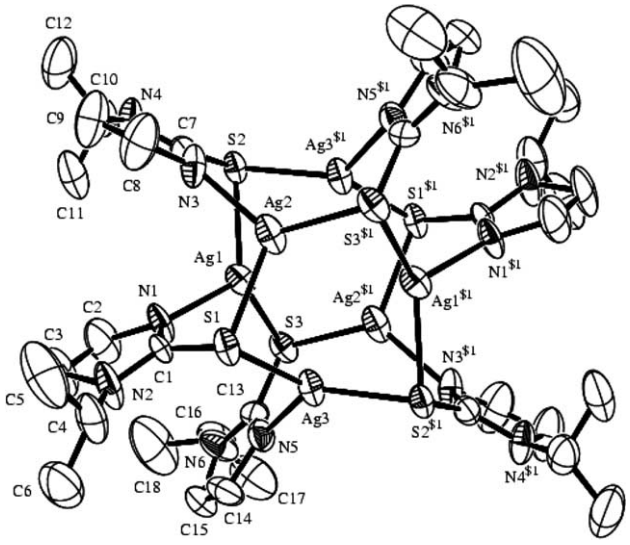

Fig. 6. ORTEP drawing of the molecular structure of [Ag(1-^{i}PrImS)] (**4**) showing 40% probability ellipsoids.

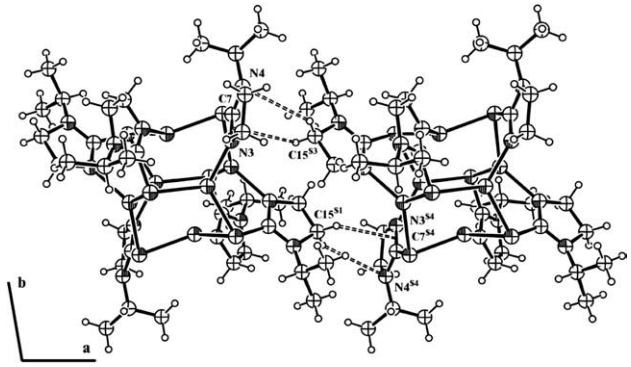

Fig. 7. Interaction between units 1 in the crystal packing of **4**, viewed along the *c* axis. Dashed lines show the C–H···π and the C–H···N interactions. [Symmetry codes: #1 = $-x+2$, $-y$, $-z$; #3 = $x+1$, y, z; #4 = $-x+3$, $-y$, $-z$.]

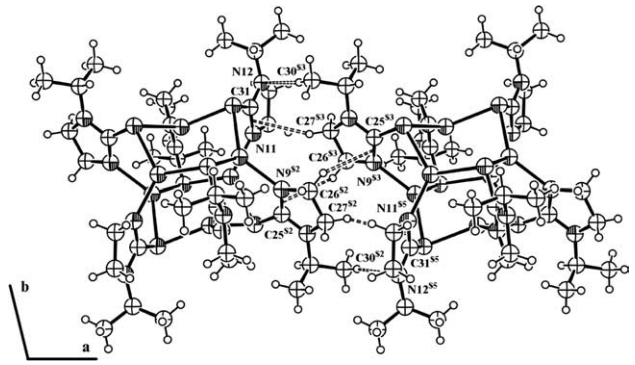

Fig. 8. Interaction between units 2 in the crystal packing of **4**, viewed along the *c* axis. Dashed lines show the C–H···π and the C–H···N interactions. [Symmetry codes: #2 = $-x+2$, $-y+1$, $-z+1$; #3 = $x+1$, y, z; #5 = $-x+3$, $-y+1$, $-z+1$.]

The interactions between units 2 in compound **4** are represented in Fig. 8. The different dispositions of the *N*-alkyl chains in compounds **3** and **4** do not have a significant impact on the packing arrangement, although a slight change in the distances between neighboring hexamers is evident. These differences are also apparent in the interaction parameters and give rise to other new interactions. As shown in Fig. 8, the significant interactions are C–H···π between a hydrogen on C27 and the C31=N11 double bond of a hexameric unit 2 neighbor (analogous to the interaction between C15 and C7=N3 for units 1) and the interaction between a hydrogen on C26 and the C25=N9 double bond of a unit 2 neighbor (analogous to the interactions between C14 and C13=N5 for units 1 – although in this case the distance was to long to be considered). The different disposition of the N-^{i}propyl chain in compound **4** means that the C–H···N interaction in units 1 between a carbon in the imidazolidine ring (C15) and the *N*-alkyl nitrogen (N4) is, in this case, established between a hydrogen of a methyl of the ^{i}propyl group (C30) and the *N*-alkyl nitrogen (denoted in unit 2 as N12).

In a similar way to the arrangement for units 1, the equivalent carbons C26#2, C27#2 and C30#2 are involved in the same types of interaction for symmetry reasons. This causes units 2 to pack parallel to the crystallographic *a* axis, as shown in Fig. 8.

4. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-270945-270948 for (**1**)–(**4**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (internat.) +44-1223/336-033; e-mail: deposit@ccdc.cam.ac.uk).

compound (−)-DIOP, construct higher nuclearity linked clusters and potential asymmetric hydrogenation catalysts, Herein, we report the synthesis and characterization of four new Ru–Co mixed-metal linked tetrahedral clusters, $[(\mu_3\text{-E})RuCo_2(CO)_8]_2$((−)-DIOP) (E = Se, **1**; S, **2**), $[(\mu_3\text{-E})RuCoMo(CO)_7(CpC(O)CH_3)]_2$((−)-DIOP) (E = Se, **3**, S, **4**) and a mono-tetrahedral cluster $[(\mu_3\text{-Se})RuCoMo(CO)_6(CpC(O)CH_3)$((−)-DIOP)] (**5**), which was obtained by the reaction of **1** with $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4C(O)CH_3)]$ at 60 °C. The structure of cluster **1** has been determined by single-crystal X-ray diffraction. All clusters were characterized by C, H elemental analysis, IR and ^{1}H NMR spectroscopy. To further confirm the structures of these cluster products, the clusters **1**, **2**, **4**, **5** also were characterized by ^{31}P NMR spectroscopy.

2. Experimental

2.1. General details

All preparative work was carried out under an atmosphere of pure nitrogen by using standard Schlenk or vacuum-line techniques. Solvents were carefully dried: *n*-hexane, petroleum ether (60–90 °C) and THF were dried and deoxygenated by distillation from sodium benzophenone ketyl, and dichloromethane was distilled from calcium hydride. Chromatographic separations were carried out using silica gel columns (160–200 mesh) of varying length. Thin-layer chromatography (TLC) was performed on commercial Merck plates coated with a 0.20 mm layer of silica gel.

Infrared spectra were recorded in NaCl cells on a Bruker 120 HR FT-IR spectrophotometer. Absorptions are designated in cm^{-1} relative to an internal laser standard. Spectra of compounds in the solid state were recorded as pressed KBr discs. NMR spectra were measured on a Bruker AM-400 MHz spectrometer in chloroform-d_1 solvent. All ^{1}H NMR chemical shifts are relative to tetramethylsilane. ^{31}P NMR positive chemical shifts are downfield from 85% H_3PO_4 as external reference. Elemental analyses (C, H) were performed on a Carlo-Erba 1106 type analyzer.

$(\mu_3\text{-E})RuCo_2(CO)_9$ (E = S, Se) [24], $[(\mu_3\text{-E})RuCoMo(CO)_8(CpC(O)CH_3)]$ (E = S, Se) [25,26], $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4COCH_3)]$ [27] were prepared according to literature method with little modification and (−)-DIOP was commercial sample.

2.2. Synthesis of cluster *1* and *2*

To a solution of $(\mu_3\text{-Se})RuCo_2(CO)_9$ (166 mg, 0.30 mmol) in 20 ml of *n*-hexane at room temperature was added dropwise a solution of (−)-DIOP (75 mg, 0.15 mmol) in 5 ml of CH_2Cl_2 under nitrogen. The mixture was stirred at room temperature for 2 h. During the stirring the color of the solution gradually changed from brown-red to black-red and monitoring by TLC showed the disappearance of the starting material. After hexane was removed, the residue was extracted by a small amount of CH_2Cl_2 and transferred to the top of a 2.5×40 cm silica gel chromatography column. Elution with CH_2Cl_2:petroleum ether (1:3) afforded the major brown-red band. Condensing the solvent and crystallization at −20 °C gave black crystals $[(\mu_3\text{-Se})RuCo_2(CO)_8]_2$((−)-DIOP) (**1**) (210 mg, 90.8%, based on (−)-DIOP). *Anal*. Calc. for $[C_{47}H_{32}O_{18}Se_2P_2Co_4Ru_2]$: C, 36.60; H, 2.09. Found: C, 36.67; H, 2.02%. IR (KBr disc): *ν*(Ar–H) 3054w; *ν*(CO) 2084s, 2051vs, 2011vs, 1964s, 1872m cm^{-1}; ^{1}H NMR: *δ* 7.64–7.12 (m, 20H, $4C_6H_5$), 3.93–3.83 (d, 2H, 2CH), 2.62–2.37 (m, 4H, $2CH_2$), 1.27 (s, 6H, $2CH_3$). ^{31}P NMR: *δ* 53.21 (s, PCo), 52.04 (s, PCo).

The preparation procedure for cluster **2** was similar to that of cluster **1**.

$[(\mu_3\text{-S})RuCo_2(CO)_8]_2$((−)-DIOP) (**2**) (195 mg, 89.7%. based on (−)-DIOP). *Anal*. Calc. for $[C_{47}H_{32}O_{18}S_2P_2Co_4Ru_2]$: C, 38.97; H, 2.23. Found: C, 39.12; H, 2.35%. IR (cm^{-1}): *ν*(Ar–H) 3058w; *ν*(CO) 2085(s), 2047(vs), 2012(vs), 1881(m). ^{1}H NMR: *δ* 7.67–7.38 (m, 20H, $4C_6H_5$), 3.97–3.81 (m, 2H, 2CH), 2.68–2.37 (m, 4H, $2CH_2$), 1.28 (s, 6H, $2CH_3$).^{31}P NMR: *δ* 50.46 (s, PCo), 48.83 (s, PCo).

2.3. Synthesis of cluster *3* and *4*

$(\mu_3\text{-Se})RuCoMo(CO)_8(CpC(O)CH_3)$ (200 mg, 0.30 m mol) reacted with (−)-DIOP (75 mg, 0.15 mmol) in 25 ml of CH_2Cl_2:*n*-hexane (1:1) at room temperature for 6 h with stirring. Removal of the solvent under reduced pressure and the residue was purified by chromatography on silica gel using THF/petroleum ether (2:5) as an eluent and gave the major black-red band $[(\mu_3\text{-Se})RuCoMo(CO)_7(CpC(O)CH_3)]_2$((−)-DIOP) (**3**) (116 mg, 43.6%, based on (−)-DIOP). *Anal*. Calc. for $[C_{59}H_{46}O_{18}Se_2P_2Co_2Mo_2Ru_2]$: C, 39.93; H, 2.61. Found: C, 40.12; H, 2.58%. IR (cm^{-1}): *ν*(Ar–H) 3056w; *ν*(CO) 2066s, 1997vs, 1964vs, 1887m, 1801m; *ν*(C=O) 1680m. ^{1}H NMR: *δ* 7.61–6.98 (m, 20H, $4C_6H_5$), 5.83–5.00 (m, 8H, $2C_5H_4$), 3.75–3.58 (m, 2H, 2CH), 2.58–2.15 (m, 10H, $2CH_2$, $2CH_3$), 1.25 (s, 6H, $2CH_3$).

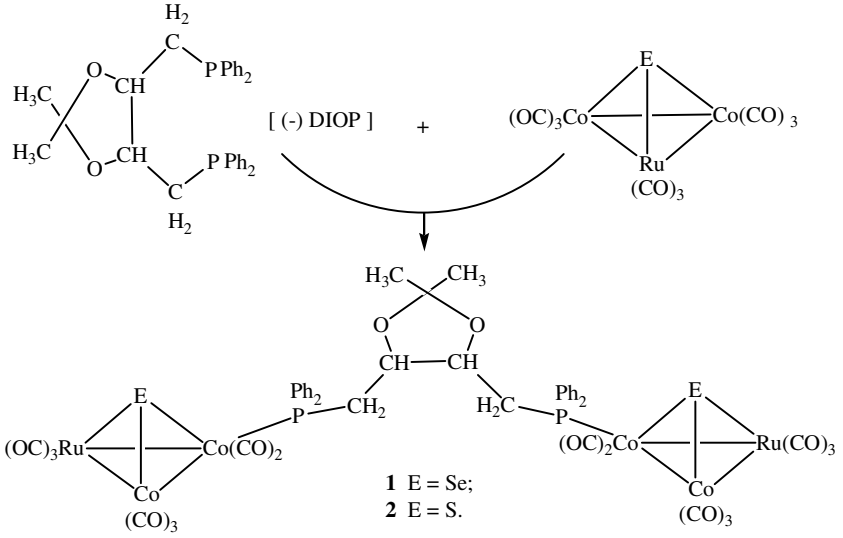
In the same manner, the cluster **4** was prepared.

$[(\mu_3\text{-S})RuCoMo(CO)_7(CpC(O)CH_3)]_2$((−)-DIOP) (**4**) (128 mg, 50.8%, based on (−)-DIOP). *Anal*. Calc. for $[C_{59}H_{46}O_{18}S_2P_2Co_2Mo_2Ru_2]$: C, 42.16; H, 2.76. Found: C, 42.37; H, 2.86%. IR (cm^{-1}): *ν*(Ar–H) 3056w; *ν*(CO) 2068s, 2000vs, 1969vs, 1936m, 1867m,; *ν*(C=O) 1679m, 1634. ^{1}H NMR: *δ* 7.64–6.98 (m, 20H, $4C_6H_5$), 5.94–4.89 (m, 8H, $2C_5H_4$), 3.91 (s, 2H, 2CH), 2.66–2.17 (m, 10H, $2CH_2$, $2CH_3$), 1.25 (s, 6H, $2CH_3$). ^{31}P NMR: *δ* 49.45 (s, PCo), 48.37 (s, PCo).

2.4. Reaction of 1 with Na[Mo(CO)$_3$-(η^5-C$_5$H$_4$CO CH$_3$)]

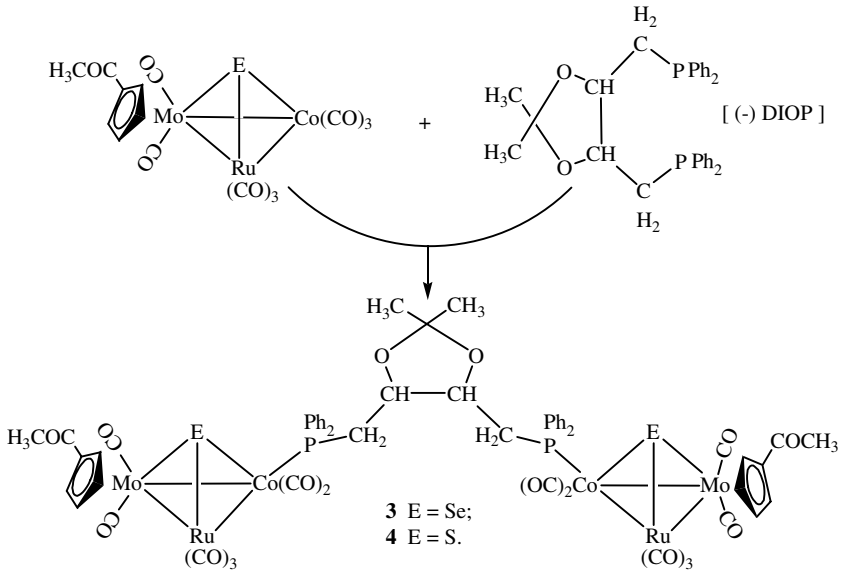
$Mo(CO)_6$ (64 mg, 0.24 mmol) was added to a solution of $Na(C_5H_4COCH_3)$ (32 mg, 0.24 mmol) in 25 ml of THF. The mixture was refluxed for 15 h and cooled to room temperature. Then 154 mg (0.1 mmol) of cluster **1** was added and the mixture was stirred at 60 °C for another 1 h. The solvent was removed in vacuo, the residue was extracted by a small amount of CH_2Cl_2 and the extract was subjected to a 2.5×40 cm silica gel column chromatography. CH_2Cl_2:petroleum ether (5:2) eluted a known cluster complex (μ_3-Se)RuCoMo(CO)$_8$(CpC(O)CH$_3$) and a black-red band [(μ_3-Se)RuCoMo(CO)$_6$(CpC(O)CH$_3$)((−)-DIOP)] (**5**) (96 mg, 43.2%, based on **1**). *Anal*. Calc. for [$C_{44}H_{39}O_9SeP_2CoMoRu$]: C, 47.49; H, 3.54. Found: C, 47.56; H, 3.37%. IR (cm^{-1}): *v*(Ar–H) 3056w; *v*(CO) 2072s, 2033s 2005vs, 1945s, 1890m; *v*(C═O) 1684m. ^{1}H NMR: δ 7.38–6.98 (s, br, 20H, 4C$_6$H$_5$), 5.89–5.47 (m, 4H, C$_5$H$_4$), 3.78–3.66 (s, 2H, 2CH), 2.53–2.19 (m, 7H, 2CH$_2$, CH$_3$), 1.25 (s, 6H, 2CH$_3$). ^{31}P NMR: δ 52.38 (s, PCo), 38.83 (s, PRu).

2.5. Crystal data of cluster 1



Suitable crystals of cluster **1** were obtained from *n*-hexane/CH_2Cl_2 at −20 °C. The crystals were mounted on a glass fiber. Preliminary examination and data collection were performed with Mo Kα radiation (λ = 0.71073 Å) on a Bruker CCD APEX diffractometer equipped with graphite monochromator for cluster **1**. The empirical absorption corrections were applied using the SADABS [28] program. The structures were solved by direct methods and expanded using Fourier techniques and all non-hydrogen atoms were refined anisotropically by full-matrix least-squares on F^2 using the SHELXL-97 [29] crystallographic program package. Hydrogen atoms were added according to geometrical method. It should be note that the cluster **1** possesses a chiral structure as result of the absolute structure parameter, i.e. flack factor (−0.01(2)) and extinction coefficient (0.0031(3)) [30].

3. Results and discussion



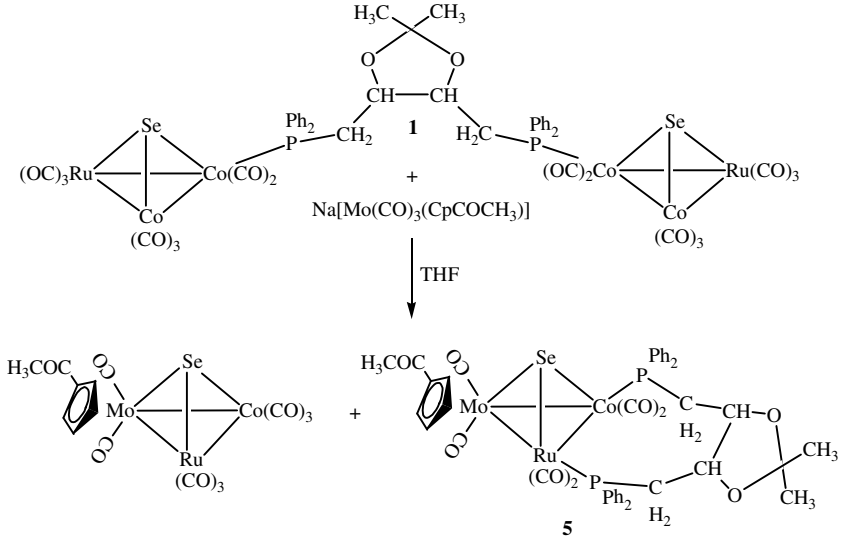
3.1. Synthesis of clusters 1–4

The reactions described in this work are summarized in Schemes 1 and 2. In order to investigate the metallosite selectivity in carbonyl substitution of Ru–Co heteronuclear tetrahedral cluster derivatives and construct higher nuclearity linked clusters and potential asymmetric hydrogenation catalysts, we treated the cluster [(μ_3-E)RuCo$_2$(CO)$_9$] (E = Se, S) and [(μ_3-E)RuCoMo(CpC(O)CH$_3$)(CO)$_8$] (E = Se, S) in *n*-hexane or THF with diphosphine compound (−)-DIOP in 1:1 and 2:1 molar ratio at room temperature and obtained four new linked tetrahedral cluster derivatives [(μ_3-E)RuCo$_2$(CO)$_8$]$_2$((−)-DIOP) (E = Se, **1**; S, **2**), [(μ_3-E)RuCoMo(CO)$_7$(CpC(O)CH$_3$)]$_2$((−)-DIOP) (E = Se, **3**; S, **4**) as the major products, respectively.

During the substituted reactions, the color of solution changed from brown-red to black-red. The Ru–Co–Co cluster reacts readily with (−)-DIOP, but the Ru–Co–Mo cluster reacts hard under the conditions and the yields of **3** and **4** are much lower than that of **1** and **2**. This may be due to the presence of the CpC(O)CH$_3$ group increasing the electron density on the metals in the clusters [(μ_3-E)RuCoM(CO)$_8$(CpC(O)CH$_3$)] (E = Se, S), which would make the CO ligand substituted difficulty by (−)-DIOP at room temperature. These new

Scheme 1.

Scheme 2.



cluster complexes **1**–**4** are stable in air in solid state and soluble in common organic solvents.

3.2. Reaction of cluster *1* with $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4COCH_3)]$

To learn more about the metallic exchange reaction in the linked tetrahedral carbonyl cluster, the reaction of the cluster **1** with $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4COCH_3)]$ in 1:1 molar ratio was checked in THF at 60 °C. During the reaction, the (−)-DIOP bridge of cluster **1** broke to give a known metallic exchange product $(\mu_3\text{-Se})RuCoMo(CO)_8(CpC(O)CH_3)$ [23] and a new (−)-DIOP substituted tetrahedral cluster $[(\mu_3\text{-Se})RuCoMo(CO)_6(CpC(O)CH_3)((-)\text{-DIOP})]$ (**5**) (see Scheme 3). Unfortunately, we did not get the analogous $[(\mu_3\text{-Se})RuCo_2(CO)_7((-)\text{-DIOP})]$ cluster and other linked metallic exchange products. It is likely that the metallic exchange reaction and the broken course of (−)-DIOP bridge are simultaneous under this condition. Further studies on the metallic exchange reactions of the linked mixed-metal clusters are currently underway.

3.3. Characterization of clusters *1*–*5*

The IR spectra of all clusters show a weak absorption band around 3056 cm^{-1} and intense absorption bands in the range 2084–1801 cm^{-1}, characteristic of the benzene

Scheme 3.

rings of (−)-DIOP and the terminal carbonyl and semi-bridging carbonyl ligand, respectively. Comparing the IR spectra of **1** and **5** with that of the parent cluster [(μ_3-Se)RuCo$_2$(CO)$_9$], it can be seen that the highest value of terminal CO stretching frequencies shift from 2101 cm^{-1} [24] toward the lower value 2084 cm^{-1} (**1**), further to the value 2072 cm^{-1}(**5**), resulting from the carbonyl ligands are replaced, step-by-step, by two PPh_2 groups in the tetrahedral unit of the cluster **1** and **5**, respectively. This is consistent with our knowledge that the PPh_2 group behaves as a stronger σ-donor and a weaker π-acceptor, when compared to the CO ligand, increasing the electron density on the metals in the clusters. It should be noted that in the IR spectra of **3** and **4**, besides the terminal and semi-bridging carbonyl absorption bands, there are absorption bands at 1680 cm^{-1}, which are characteristic of acetyl bonded to the cyclopentadienyl ring.

The ^{1}H NMR spectra of all of clusters **1**–**5** are consistent with the (−)-DIOP substituted cluster structure and show the presence of hydrogen atoms in their corresponding organic groups. The signals at about δ 7.67–6.98 are caused by the protons of phenyl ring in the ^{1}H NMR spectra of clusters **1**–**5**. The signals at 3.97–3.58 reveal the protons of the CH group of the (−)-DIOP and the signals at δ 2.68–2.15 which can be assigned to methylene protons (CH_2) of the (−)-DIOP and the protons of methyl bonded to cyclopentadienyl ring. For the protons of the methyl of the (−)-DIOP, the ^{1}H NMR spectra of clusters **1**–**5** exhibit a singlet around δ 1.25, respectively. In addition, the signals at 5.94–4.89 also reveal the presence of the protons of the cyclopentadienyl moiety in the ^{1}H NMR spectra of clusters **3**–**5**.

The ^{31}P NMR spectrum of cluster **1** is consistent with the structure established by X-ray analysis. Thus the two singlets observed at δ 53.21 and 52.04 are assigned to terminal P atoms (labeled P1 and P2, respectively, in Fig. 1). The ^{31}P NMR spectra of clusters **2** and **4** are similar to that of cluster **1** and show two singlets at the range δ 50.46–48.37, respectively, assigned to the P atoms bonded to Co atoms. For the cluster **5**, the signals

observed at δ 52.38 and δ 38.83 are assigned to the P atoms bonded to Co atom and Ru atom, respectively. It is similar to that described by P. Braunstein [22].

On the basis of the above described for **5**, we propose its structure as the following form: [(μ_3-Se)RuCoMo-$(CO)_6$($CpC(O)CH_3$)((−)-DIOP)] in which the $Mo(CO)_2$-($CpC(O)CH_3$) unit substituted the $Co(CO)_3$ fragment of the $SeRuCo_2$ core forming a chiral tetrahedral cluster and one phosphorus atom of the (−)-DIOP bonded to Co atom, another coordinated to Ru atom not to Mo atom.

3.4. Crystal structure of cluster *1*

The crystal structure of cluster **1** was determined by X-ray structural analyses. Crystal data and experimental details for **1** are collected in Table 1. Table 2 gives the selected bond lengths and angles. An ORTEP drawing of **1** with numbering is shown in Fig. 1.

As seen in Fig. 1, the structure of cluster **1** contains two slightly distorted tetrahedral cores $SeRuCo_2$, which are connected via (−)-DIOP as a bridging unit. The phosphorus atoms of (−)-DIOP ligand substituted one carbonyl of one of two cobalt atoms of each $SeRuCo_2$ core, respectively, and the average bond distance between the cobalt atom and phosphorus atom is 2.187 Å. So, both $SeRuCo_2$ cores can be looked as chiral units resulting from the different coordination environments of the two cobalt atoms in each tetrahedral framework, to our knowledge. Additionally, the μ_3-Se ligand may be viewed as a 4-electron donor, with the result that each $SeRuCo_2$ core contains a total of 48 electrons and is electronically saturated. This may be the reason that the kind of cluster can present stably in the air in solid state. It is worthy to note that the carbonyls of C(8)–O(8) and C(16)–O(16) attached to Co(2) and Co(4) atoms belong to semi-bridging, due to its asymmetric parameter $\alpha = (d_2 - d_1)/d_1 = 0.42, 0.52$, respectively, fall in the range of α value defined for semi-bridging carbonyl's by Curtis [31]. The coexistence of both terminal and semi-bridging carbonyls are in good agreement with the IR spectrum showing several strong absorption bands from 2084 to 1872 cm^{-1} of cluster **1**.

According to the crystal structure of cluster **1** and that of above described, it can be suggested that during the reactions of SeRuCoM (M = Co, Mo) heteronuclear tetrahedral cluster with (−)-DIOP, the metallosite selectivity in carbonyl substitution of Ru, Co and Mo follows as the series of Co > Ru > Mo.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 261513 for cluster **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgments

We are grateful to the National Science Foundation of China for the financial support of this work. We

thank Dr. Yan-Long Gu for donation of the sample of (−)-DIOP.

Preface

The IX International Conference on Molecule-based Magnets (ICMM 2004) was held from October 4 to 8, 2004 at the International Conference Hall in Tsukuba, Japan. There were more than 400 participants, including 130 participants from 18 countries other than Japan. The organizers are indebted to all the participants for the great success of the Conference, which was brought about by their extremely active participation. The organizers are also happy to hear that approximately 150 excellent papers are appearing in this special issue of *Polyhedron* published by Elsevier as the Proceedings of ICMM 2004.

The research area of the conference, so-called 'molecular magnetism', originated from the discovery of high spin molecules and organic ferromagnets. Since then, this research field has expanded rapidly by absorbing many related fields. As a result, photo-magnets, ferromagnetic transition metal complexes, single-molecule magnets, etc. have been discovered in the last decade or so, and the ICMM conferences have been the most important occasions to report the hottest results in the field.

Topics covered by the ICMM meetings have changed drastically in recent years. Their interest has leaped from the stage of searching for molecular magnets with high T_c to a new stage of developing dynamic spin systems where molecular spins play an essential role. Researchers have also been aiming to create a new frontier by amalgamating molecular spins with nano-spins and/or bio-spins. In order to cover these new trends, the ICMM 2004 organizers arranged new sessions on nano-spins and bio-spins; in these sessions, spin-electronics using spin-polarized molecules, and spin-imaging techniques using novel spin-labels, etc., were discussed as hot topics.

Let us briefly revisit the main topics of the Conference. On the first day, R.C. Haddon gave a plenary lecture on the design and physical properties of phenalenyl radicals and their charge transfer complexes. S. Tarucha addressed the basis and application of quantum dots made of semiconductors in his plenary lecture. Nine lectures followed the plenary talks, including the design and preparation of new phenalenyl radicals, and the development of batteries using radical polymers. There was also a pioneering report on Mössbauer spectroscopic exploration of soils and rocks on Mars. In the evening there were six lectures in the bio-spin session: detailed studies of in vivo ESR spectroscopy using spin-labeled molecules, a high magnetic field effect on supramolecular systems, including living tissues, and bio-mineralization of ferrites in bacteria. Novel directions of self-assembling spin molecules were discussed involving spin molecules carrying a nucleic acid unit.

On the second day, the plenary lecture of G. Christou was presented on single-molecule magnets and exchange-bias tunneling of two interacting clusters. He also powerfully addressed some future aspects of single-molecule magnetism. In the quantum spin session that followed there were 12 lectures, including novel quantum-spin phenomena based on organic–inorganic hybrid magnets, and the extensive current research on single-chain magnets. Fine results obtained from a new tool, such as micro-SQUID, were also presented. The first multi-functional session started in the evening, focusing on properties of conducting magnets, and results involving spin-valve systems were also presented there.

On the third day, the multi-functional session continued with 14 excellent lectures on cooperative effects and related new topics exhibited by spin-crossover complexes. The topics of the second multi-functional spin session concentrated on opto-magnetic functions. Chiral-magnets and photo-magnets were the main topics in this session.

On the morning of the final day, M.E. Welland gave a plenary lecture on the characteristic domain patterns and the applications of nano-magnets. Thereafter, new directions of photo-active spins systems were discussed, such as a photo-induced phase transition of organic radical crystals, photo-switching using the photo-chromic spin-coupler, and spin-alignment in the photo-excited states of π-radicals.

Poster sessions were presented in the evening of the first and second Conference days. It is to be stressed that 346 excellent posters were presented in a hot atmosphere. It should also be mentioned that "demo-presentations" were held as a new program in ICMM 2004. Spectacular demo-experiments to show the beauty of molecular magnetism were performed. This program was greeted with great applause, and enthusiastic support was given to continue the program in the next ICMM Conference in Vancouver.

doi:10.1016/S0277-5387(05)00666-2

All throughout the Conference, presentations on manipulating spin systems arising from quantum effects of molecular spins drew much attention from the participants. They are convinced that this field has grown up as a big interdisciplinary field between physics, chemistry, biology, and theoretical science. It may be said that ICMM 2004 has succeeded in manifesting a new horizon of "molecular magnetism".

Finally, the organizers hope that this special issue of *Polyhedron* will recall the enthusiasm exhibited by the participants in ICMM 2004, and at the same time will provide a guide for your future work.

and the most studied to date due to its large spin ($S = 10$) and high symmetry (S_4). The Mn_{12} family also possesses the largest blocking temperature ($T_B \sim 3$ K) against magnetization relaxation of any SMM. Only recently has a detailed understanding emerged concerning the symmetry breaking responsible for the QTM in $Mn_{12}Ac$ [68–70]. Hence, $Mn_{12}Ac$ and the Mn_{12} family remain an attractive and productive area for further research area.

One of our goals over the last several years has been to develop an arsenal of methods for modifying the Mn_{12} family of SMMs in a variety of controllable and useful ways. In these molecules, the central inorganic Mn/O core is contained within a shell of organic ligands, and one goal has therefore been the modification of this organic periphery (shell) via ligand substitution reactions. Among other things, this would allow us to tune the solubility, redox and magnetic properties of the molecules. Another objective has been to obtain Mn_{12} complexes in different oxidation states to investigate the influence of the electron count on various properties of the molecules. A further but more subtle way of modifying the molecules is to grow the crystals from various solvents, which can lead to variations in the space group and precise solvent content of the crystals, and this in turn leads to variations in the local site-symmetry and environment around the molecule. While the latter variation might be predicted to lead to insignificant changes to the properties of the molecule, in fact we have found these changes to lead to surprisingly large effects. All the above controlled modifications will be summarized in more detail in this paper, and these have greatly advanced our knowledge and understanding of the properties of these Mn_{12} SMMs.

In addition to modifying known types of SMMs, we have also continued to seek new synthetic methods to new structural types of high-nuclearity Mn clusters that might have interesting structural and/or magnetic properties, and that might be new SMMs. We shall also describe a number of new results along these lines. For example, the use of MeOH in some reactions has led to the synthesis of new clusters of nuclearities Mn_{12} [71], Mn_{16} [61], and Mn_{84} [67], and all of these have been discovered to be new SMMs. In addition, recent work with polydentate chelates containing alcohol groups has yielded a new Mn_{12} cluster with an interesting loop structure, which is also a new SMM. All these will be described in this report.

2. Modification of single-molecule magnets

2.1. Carboxylate substitution

Several procedures have been developed to replace the $MeCO_2^-$ ligands of $Mn_{12}Ac$ with almost any other type of carboxylate group, leading to increased solubility in organic solvents and greatly altered redox properties [41,72]. Methods have also been developed to obtain Mn_{12} complexes containing more than one type of peripheral bridging ligand (the four H_2O ligands are terminal). One such strategy involves the site-specific replacement of some of the bound carboxylates to give either: (i) mixed-carboxylate complexes of formula $[Mn_{12}O_{12}(O_2CR)_8(O_2CR')_8(H_2O)_4]$ [73] or (ii) mixed organic–inorganic ligation in the complex $[Mn_{12}O_{12}(O_2CR)_{12}(NO_3)_4(H_2O)_4]$, which contains bridging NO_3^- groups and is thus the first Mn_{12} complex to contain non-organic bridging ligands [34]. Subsequently, we showed that it is also possible to site-specifically substitute half the carboxylate groups with: (i) benzenesulfonate ($PhSO_3^-$) groups to give $[Mn_{12}O_{12}(O_2CMe)_8(O_3SPh)_8(H_2O)_4]$ [33] with the $PhSO_3^-$ groups occupying axial positions on the Mn_{12} cluster or (ii) with diphenylphosphinate ($Ph_2PO_2^-$) groups to give $[Mn_{12}O_{12}(O_2CMe)_8(O_2PPh_2)_8(H_2O)_4]$ with both axial and equatorial $Ph_2PO_2^-$ groups [30]. One such transformation is summarized as an example in Eq. (1), for the $PhSO_3H$ reaction.

$$[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4] + 8PhSO_3H \rightarrow [Mn_{12}O_{12}(O_2CMe)_8(O_3SPh)_8(H_2O)_4] + 8MeCO_2H \quad (1)$$

Considerable insight has been obtained from these chemical modifications on the Mn_{12} SMM, leading to much new magnetostructural knowledge and information on this important family of SMMs.

2.2. Reduced Mn_{12} complexes

The feasibility of chemically reducing a Mn_{12} SMM was initially established by the observation of quasi-reversible oxidation and reduction processes in the cyclic voltammograms. The oxidation processes are at rather high potentials, but the reduction processes are much more accessible, and it was therefore decided to initially seek isolation of one-electron reduced species. For this purpose, the reducing agent chosen was I^- because of its sufficient, yet mild reducing strength, its ready availability as a variety of salts of organic cations, and the high solubility of many of the latter in organic solvents. Indeed, chemical reduction of the $[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]$ complexes with C^+I^- (C^+ is NR_4^+, PPh_4^+, etc.) in MeCN or CH_2Cl_2 was found to provide a convenient route to the corresponding salts of the $[Mn_{12}]^-$ anions in good (>50%) yield. The C^+I^- reagent provides the required cation, and the only byproduct is elemental I_2, which is easy to remove (Eq. (2)).

$$[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4] + I^- \rightarrow [Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]^- + \tfrac{1}{2}I_2 \quad (2)$$

It has been proven by X-ray crystallography that the added electron is localized on an outer (originally Mn^{III}) ion rather than an inner (cubane) Mn^{IV} ion, producing a trapped-valence $Mn^{II}Mn_7^{III}Mn_4^{IV}$ anion. These $[Mn_{12}]^-$ compounds have a half-integer ground state spin of $S = 19/2$ in almost all the cases studied [41–43], with $S = 21/2$ occasionally being reported [45]. In addition, they retain the SMM properties of the neutral Mn_{12} species, and are of particular interest for studying QTM in half-integer spin species; QTM is not allowed in such complexes in the absence of an applied field.

The carboxylate substitution reactions mentioned above have allowed the incorporation onto the Mn_{12} core of carboxylate groups containing strongly electron-withdrawing substituents (e.g., $CHCl_2CO_2^-$ groups), and these raise the reduction potentials to the point that the second reduction is also within the capability of our reductant of choice, iodide I^-. Thus, clean, two-electron reduction to $[Mn_{12}]^{2-}$ salts has consequently also been successfully accomplished (Eq. (3)) [46–49].

$$[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4] + 2I^- \rightarrow [Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]^{2-} + I_2 \quad (3)$$

As for the $[Mn_{12}]^-$ anion, the extra electrons in $[Mn_{12}]^-$ are localized on outer (originally Mn^{III}) ions rather than on inner (cubane) Mn^{IV} ions, producing a trapped-valence $Mn_2^{II}Mn_6^{III}Mn_4^{IV}$ anion. In contrast to the $[Mn_{12}]^-$ salts, the ground state spin is again an integer $S = 10$ for two-electron reduced species. In addition, they retain the SMM properties of the neutral Mn_{12} species and $[Mn_{12}]^-$ species. In fact, a detailed examination of the magnetic properties of the $[Mn_{12}]^z$ ($z = 0$, $1-$, $2-$) series has shown that although they are all SMMs, they show a decreasing effective barrier to magnetization relaxation (U_{eff}), which is primarily due to the decreasing magnitude of the axial anisotropy parameter $|D|$ as the Mn^{III} content of the clusters decreases; Jahn-Teller distorted Mn^{III} ions are the main source of anisotropy in the Mn_{12} molecules. All three Mn_{12} oxidation states display resonant QTM, and this work thus provides useful comparisons of QTM in half-integer versus integer spin systems, as well as of quantum phase interference.

2.3. High-symmetry Mn_{12} complexes

Among all Mn_{12} complexes to date, Mn_{12}Ac has become the most widely studied SMM, not only because it

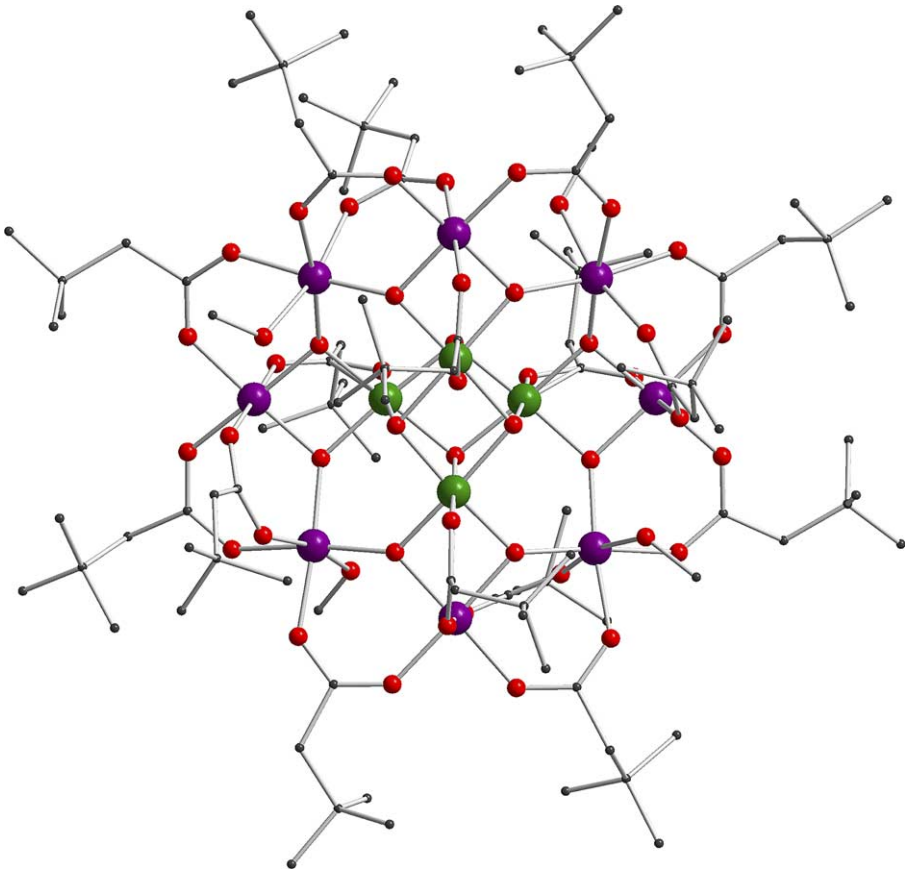

Fig. 1. The structure of $[Mn_{12}O_{12}(O_2CCH_2{}^tBu)_{16}(MeOH)_4]$, excluding hydrogen atoms. Color code: green, Mn^{IV}; purple, Mn^{III}; red, O; gray, C.

was the first to be recognized as an SMM but also because of its high spin of $S = 10$ and its high molecular symmetry (S_4). These factors contribute to the largest blocking temperature ($T_B \sim 3$ K) against magnetization relaxation of any known SMM. Recently, an improved understanding has emerged concerning the symmetry breaking responsible for the QTM in $Mn_{12}Ac$ [68–70]. Disorder associated with the acetic acid solvent leads to discrete local environments, resulting in a significant fraction of the molecules (>50%) possessing twofold symmetry with a rhombic crystal-field parameter $E \sim 0.01$ cm^{-1} [69]. In effect, the $Mn_{12}Ac$ complex is a mixture of species with different site symmetries, only some of which are truly axial, and it is clear that it is therefore *not* an ideal Mn_{12} for detailed study using models that assume axial symmetry in the spin Hamiltonians. We have thus been exploring the synthesis and study of other Mn_{12} complexes with true axial symmetry in order to finally obtain the real properties of axially symmetric Mn_{12} SMMs.

In 2001, the high symmetry (space group $I4_1/a$) $[Mn_{12}O_{12}(O_2CCH_2Br)_{16}(H_2O)_4] \cdot 4CH_2Cl_2$ ($Mn_{12}BrAc$) complex was reported by An et al. [26]. This was prepared using our ligand substitution reaction with bromoacetic acid. This complex is overall similar to $Mn_{12}Ac$ in its structure and magnetic properties, except

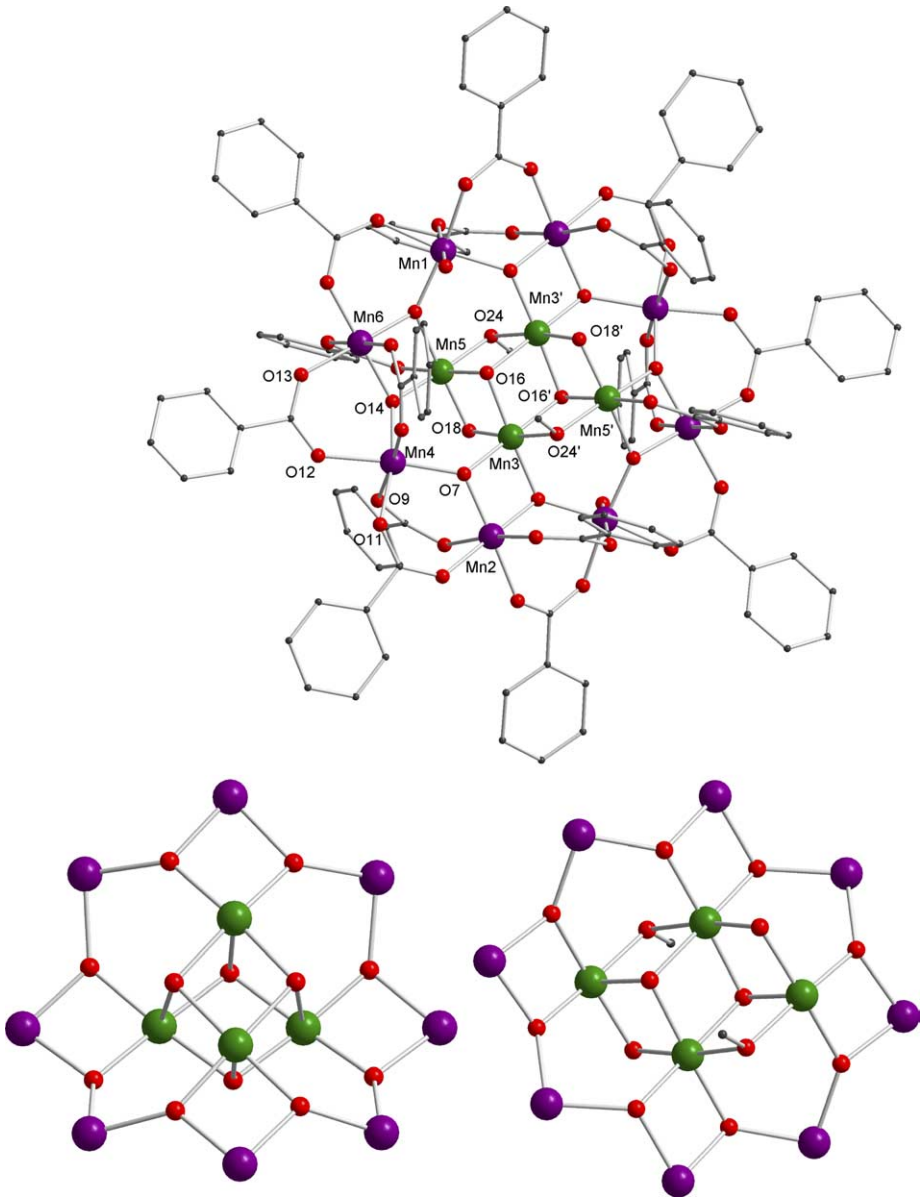

Fig. 2. The structure of the anion of $[Mn_{12}O_{12}(OMe)_2(O_2CPh)_{16}(H_2O)_2]$, excluding hydrogen atoms. Color code: green, Mn^{IV}; purple, Mn^{III}; red, O; gray, C. Bottom: Comparison of the cores of "normal" $[Mn_{12}]$ (left) and the anion of "flat" $[Mn_{12}]$ (bottom).

that it is much 'cleaner,' not being composed of a mixture of species with very different environments. We have recently investigated the properties of this complex in depth using micro-SQUID, high-frequency EPR and ^{55}Mn NMR techniques, in all cases using single crystals. All measurements reveal far superior quality data than for Mn_{12}Ac [74,75]. Given this improvement, we have also sought other high-symmetry Mn_{12} complexes, and have recently prepared $[Mn_{12}O_{12}(O_2CCH_2{}^tBu)_{16}(MeOH)_4]\cdot MeOH$, ($Mn_{12}{}^tBuAc$), (Fig. 1), which crystallizes in the high-symmetry space group $I\bar{4}$ [76]. In $Mn_{12}{}^tBuAc$, there is only one MeOH solvent molecule of crystallization, which sits on an S_4 symmetry axis and does not perturb the magnetic properties of this complex. Furthermore, the large bulky ^{t}BuAc groups more efficiently separate the clusters from their neighbors, minimizing inter-cluster interactions. Preliminary magnetic studies reveal the characteristic behavior of the Mn_{12} family. However, the data are remarkably clean and allow deeper insights into the fine details of the physical properties of Mn_{12} SMMs than has proven possible in the past.

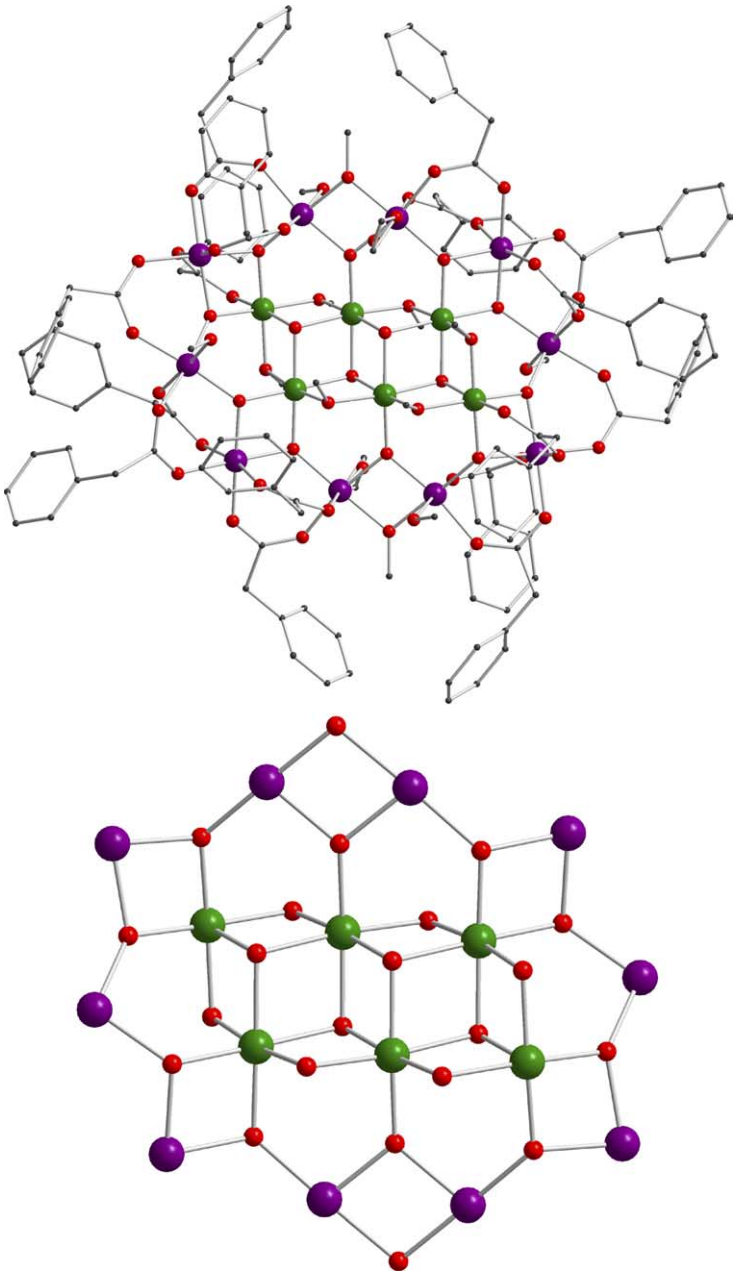

Fig. 3. The structure of $[Mn_{16}O_{16}(OMe)_6(O_2CCH_2Ph)_{16}(MeOH)_6]$ and its planar central core (bottom). Hydrogen atoms have been omitted for clarity. Color code: green, Mn^{IV}; purple, Mn^{III}; red, O; gray, C.

3. Some new procedures to SMMs

3.1. Reductive aggregation

The standard synthesis of $Mn_{12}Ac$ consists of the comproportionation reaction between $Mn(O_2CMe)_2 \cdot 4H_2O$ and $KMnO_4$ in 60% aqueous acetic acid. This is a convenient procedure involving oxidation of Mn^{II} ions and concomitant reduction of Mn^{VII} ions, producing a product at the $8Mn^{III}$, $4Mn^{IV}$ oxidation level. The Mn^{II}:Mn^{VII} reaction ratio can readily be varied, as can other reaction conditions and the presence of other reagents such as chelates. Various complexes, including mixed-valent Mn^{IV}/Mn^{III} [4–9,24–49,51–53] and Mn^{III}/Mn^{II} [7,8] species, can thus be obtained. As part of our general search of new synthetic methods to Mn_x clusters, a new procedure was developed in which the Mn^{II} source was omitted and MeOH was used as both the reducing agent for Mn^{VII} and as a potential source of MeO^- bridging ligands, in the presence also of excess carboxylic acid to prevent formation of manganese oxides and/or hydroxides. The procedure, which we have termed 'reductive aggregation,' proved its worth with the synthesis of $(N^nBu_4)_2[Mn_{12}O_{12}(OMe)_2(O_2CPh)_{16}(H_2O)_2]$ (Fig. 2) when benzoic acid was employed [71]; this is a new cluster type and SMM not available, at least to date, by any other route. It has since been possible to isolate two different analogues of this new structural type of Mn_{12} complex, $[Mn_{12}O_{10}(OMe)_3(OH)^-(O_2CC_6H_3F_2)_{16}(MeOH)_2] \cdot 4MeOH$ and $[Mn_{12}O_{10}(OMe)_4(O_2C^tBu)_{16}(MeOH)_2]$. These complexes all have significant structural similarity with $[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]$, all comprising a non-planar Mn_8^{III} ring around a central Mn_4^{IV} unit, but the central core of the new type of Mn_{12} cluster now contains alkoxide bridges. In effect, the central $[Mn_4O_4]$ cubane

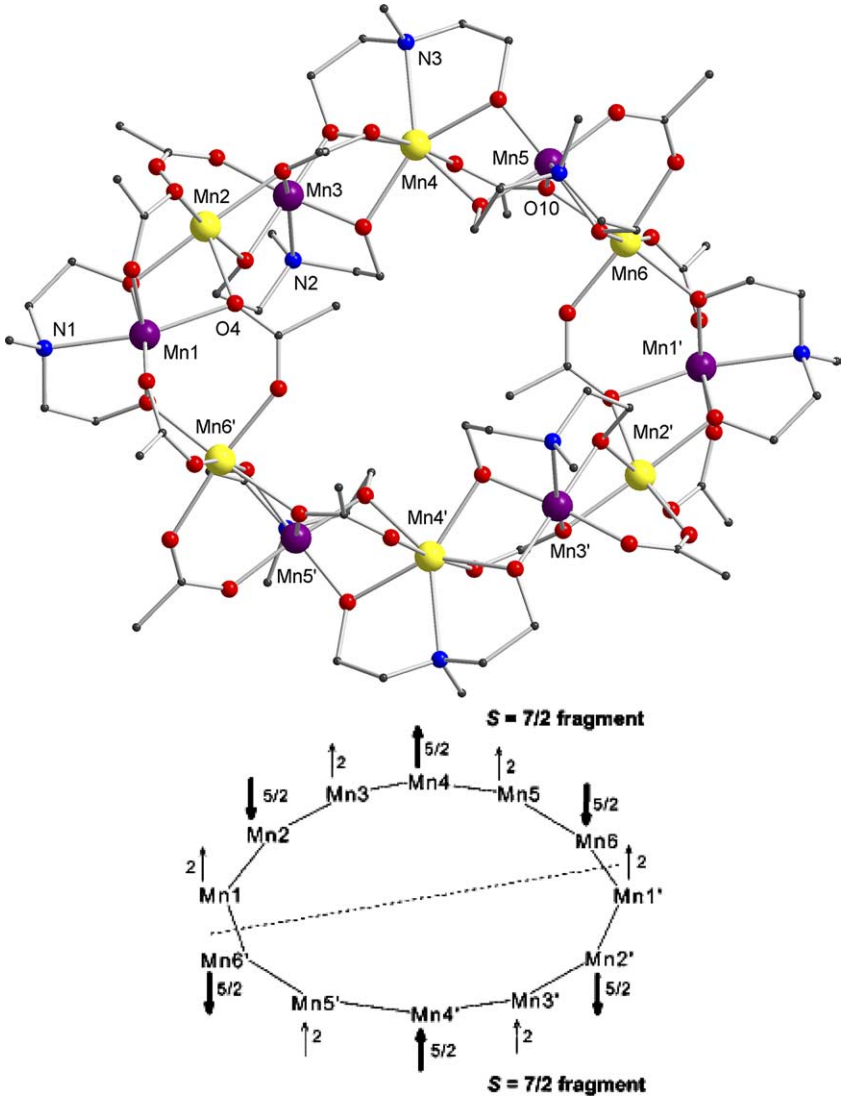

Fig. 4. The structure of $[Mn_{12}(O_2CMe)_{14}(mda)_8]$, excluding hydrogen atoms. Color code: yellow, Mn^{II}; purple, Mn^{III}; red, O; blue, N; gray, C. Bottom: Depiction of the spin alignments in the $S = 7$ ground state of the Mn_{12} loop as predicted by the DFT calculations.

of normal Mn_{12} complexes has been flattened, with the four central Mn^{IV} ions now forming a planar Mn_4 rhombus, i.e., the central core unit is a defect dicubane rather than a cubane (Fig. 2, bottom). In addition, the number of alkoxide bridges in the central core differs for all three of the new type of Mn_{12} clusters, ranging from two for the benzoate cluster, three for the difluorobenzoate cluster, and four for the pivalate cluster. Hence, these complexes represent the progressive replacement of oxide-bridges by alkoxide ones within the central core of $[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]$. In spite of their difference in the structure of the central core compared with normal Mn_{12} SMMs, the new types of Mn_{12} complexes still retain a significant barrier to magnetization relaxation, and they are thus SMMs, exhibiting hysteresis loops at low temperatures.

The new reductive aggregation procedure to Mn_x clusters has been subjected to further investigation by the use of various carboxylic acids. It was subsequently found that the reaction of phenylacetic acid, chloroacetic acid and bromoacetic acid with $N^nBu_4MnO_4$ in MeOH did not give further examples of the new Mn_{12} type of complex mentioned above, but instead a family of $[Mn_{16}O_{16}(OMe)_6(O_2CR)_{16}(MeOH)_6]$ complexes was obtained. These are similar but not identical to the Mn_{16} complex reported by Murray and co-workers [60]. The reductive aggregation reactions are clearly very complicated, and the reaction solutions likely contain a complicated mixture of several species in equilibrium, with factors such as relative solubility, lattice energies, crystallization kinetics and others determining the identity of the isolated product. One (or more) of these factors is undoubtedly the reason that changing the

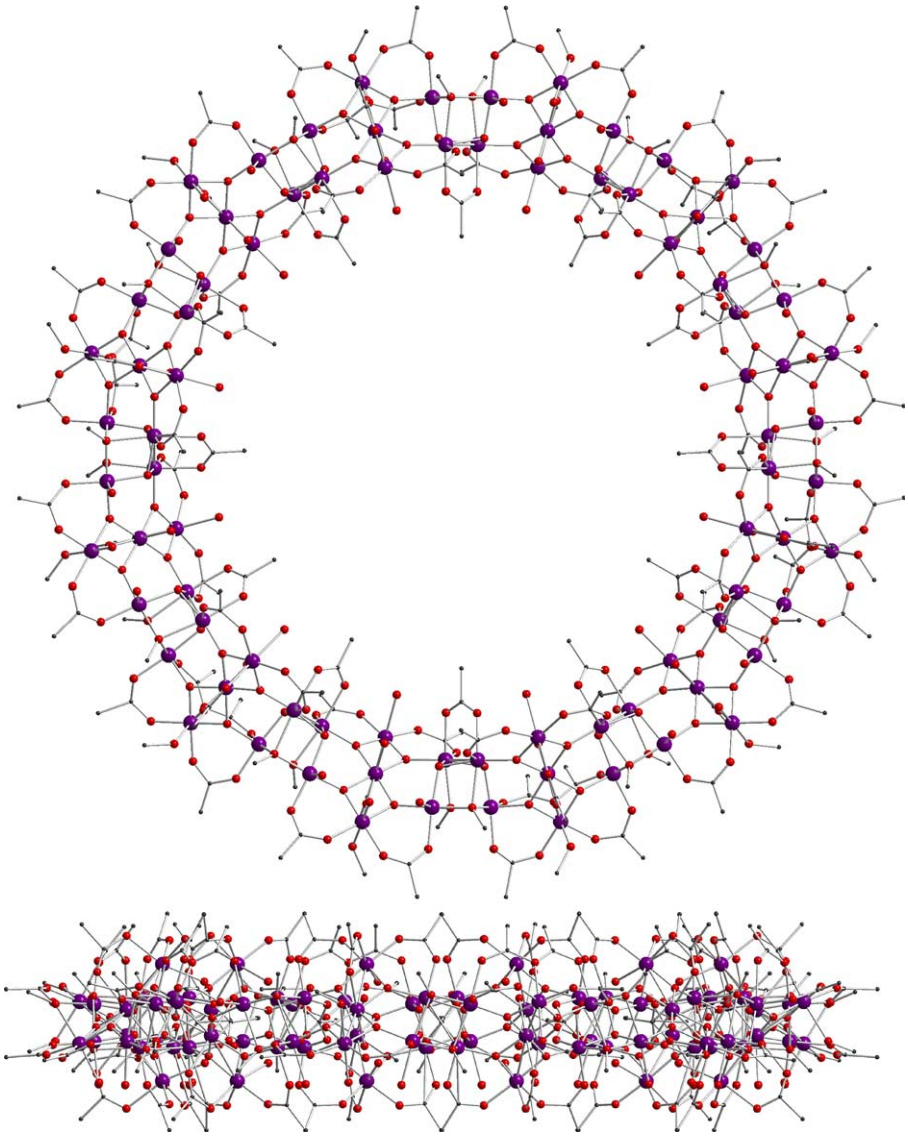

Fig. 5. The structure of the Mn_{84} torus, excluding hydrogen atoms. Bottom: Side-view of the molecule emphasizing its planarity.

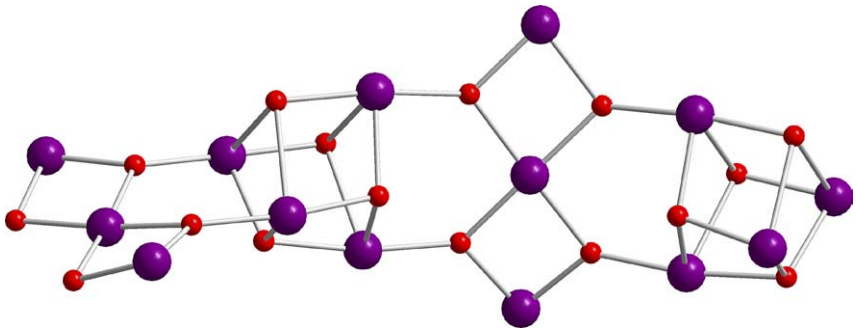

Fig. 6. The repeating [Mn_{14}] unit that represents the contents of the asymmetric unit; for clarity, carbon atoms and hydrogen atoms have been omitted.

carboxylic acid used from benzoic acid to the ones mentioned causes a major change in the isolated product from a Mn_{12} species to a Mn_{16} one. Furthermore, the three carboxylic acids employed are all derivatives of acetic acid, and it is thus interesting that when acetic acid itself was used, the product was the previously reported $[Mn_{84}O_{72}(O_2CMe)_{78}(OMe)_{24}(MeOH)_{12}(H_2O)_{42}(OH)_6]$ [67]. This contrasts with the fact that it was the acetate cluster $[Mn_{16}O_{16}(OMe)_6(O_2CMe)_{16}(MeOH)_3(H_2O)_3]$ that was obtained by Murray and co-workers [60] from the comproportionation reaction of $Mn(NO_3)_2$and $N^nBu_4MnO_4$ in excess MeOH; Murray's compound is essentially isostructural with the above Mn_{16} clusters, except for the terminal H_2O molecules replacing three of the MeOH molecules.

The phenylacetate Mn_{16} cluster (Fig. 3) has a roughly planar core comprising six Mn^{IV} and 10 Mn^{III} ions bridged by 14 μ_3-O^{2-}, two μ-O^{2-}, six μ-MeO^- and 16 μ-$PhCH_2CO_2^-$ groups (Fig. 3, bottom). The six Mn^{IV} ions are located within a central $[Mn_6^{IV}(\mu_3\text{-}O)_4(\mu\text{-}O)_2(\mu\text{-}MeO)_4]^{8+}$ core, with the six Mn^{IV} ions planar and the bridging O atoms above and below this plane, reminiscent of the planar CdI_2-type sheet structure. Encapsulating the central core is a non-planar ring of 10 Mn^{III} atoms to which it is connected by 10 μ_3-O^{2-} ions in the plane of the molecule and two μ-$PhCH_2CO_2^-$ groups one above and one below the plane. Thus, a useful description is as a small piece of a Mn oxide mineral held within a non-planar ring of Mn^{III} ions. The remaining 14 μ-$PhCH_2CO_2^-$ ligands, two μ-MeO^- groups (bridging Mn1 and Mn7a, and their symmetry equivalents) and six terminal MeOH molecules provide the peripheral ligation of the complete complex.

The Mn_{16} complexes have $S = 2$ ground states, and single-crystal magnetization versus DC field scans down to 0.04 K for the phenylacetate Mn_{16} cluster show hysteresis loops at <1 K, confirming SMM behaviour. No clear steps characteristic of QTM were observed in the hysteresis loops. Hence, although this compound has a small ground state, the near-parallel alignment of the Mn^{III} Jahn-Teller elongation axes provides sufficient molecular anisotropy to result in a small barrier to magnetization relaxation and hysteresis loops at very low temperatures.

3.2. Reactions with N-methyl-diethanolamine

Recently, we have been exploring the products from reactions employing alcohol-based ligands such as *N*-methyldiethanolamine ($mdaH_2$) to complement our previous work with the less flexible 2-hydroxymethylpyridine (hmpH) and pyridine-2,6-bis(dimethanol)

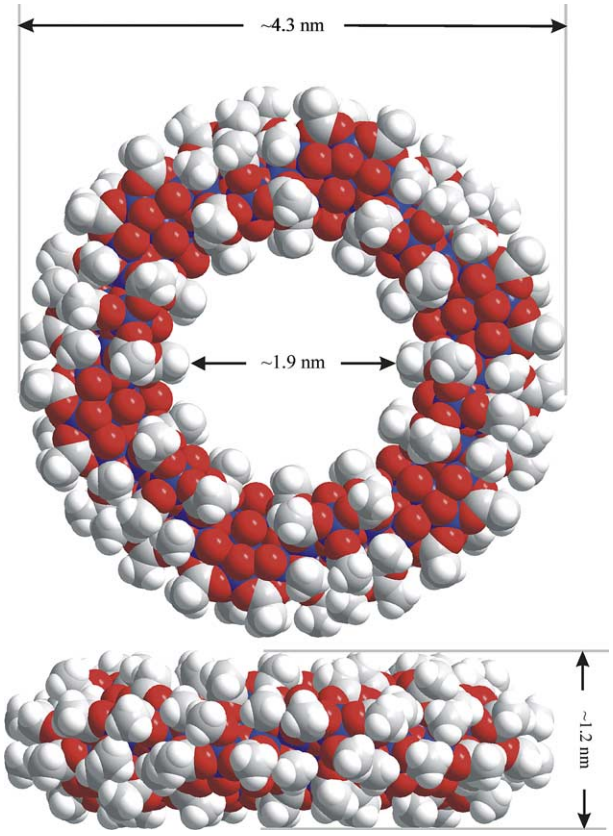

Fig. 7. Space-filling representations (including hydrogen atoms) from viewpoints perpendicular (top) and parallel (bottom) to the plane of the torus, showing the dimensions of the molecule and its central hole.

($pdmH_2$). With this reagent, we have isolated mixed-valent $[Mn_{12}(O_2CMe)_{14}(mda)_8]$ ($Mn_6^{II}Mn_6^{III}$), whose structure consists of a centrosymmetric Mn_{12} loop with a chair conformation (Fig. 4). All the manganese centers are six-coordinate except Mn^{II} ions Mn4 and Mn4′, which have a very distorted pentagonal-bipyramidal coordination sphere. Six mda^{2-} ligands each chelate a Mn^{III} ion, and the two alkoxide O atoms bridge to the adjacent Mn^{II} ions. The other two mda^{2-} groups chelate Mn^{II} ions and bridge by their alkoxide O atoms to Mn^{III} ions. As a result, the mda^{2-} groups alternate between being axial and equatorial with respect to the plane of the Mn_{12} loop. Each Mn_2 pair is additionally bridged by an acetate group in its familiar η^1,η^1,μ(*syn*, *syn*) binding mode on the outside of the loop, whereas the final two acetate groups bridge in a rarer η^1,η^2,μ^3 mode on the inside of the loop. This Mn_{12} loop complex has also been reported by others [57]. The complex has a relatively large ground-state spin value of $S = 7$: this is unusually intermediate in magnitude for a single-stranded Mn_6^{II}, Mn_6^{III} loop complex: antiferromagnetic or ferromagnetic Mn^{II}/Mn^{III} exchange interactions would be expected to give $S = 3$ or 27 ground states, respectively, so it is clear that there must be both types of interaction within this low-symmetry complex. To probe this further, we have carried out DFT calculations [77–81], and found both ferro- and antiferromagnetic interactions to be present, with all the J values being very weak, in the range $4.0 > J > -4.6$ cm^{-1}. This range is fully consistent with values for $Mn^{II}Mn^{III}$ exchange parameters, which are always weak and either side of zero, depending on the bridges [82]. Within the uncertainty of the DFT calculation, the Mn1–Mn6′ and Mn1′–Mn6 interactions are calculated to be 0.0 cm^{-1}: in fact, they are almost certainly either very weakly positive or negative. Since the spin of each half of the molecule is calculated to be $S = 7/2$, positive Mn1–Mn6′ and Mn1′–Mn6 interactions would give a ground-state spin of $S = 0$ while negative Mn1–Mn6′ and Mn1′–Mn6 interactions give $S = 7$ for the complete molecule (Fig. 4, bottom). On the basis of the magnetization data that clearly rule out an $S = 0$ ground state, we conclude that the ground state is $S = 7$, resulting from the spin alignments in (Fig. 4, bottom), in complete agreement with the magnetization studies.

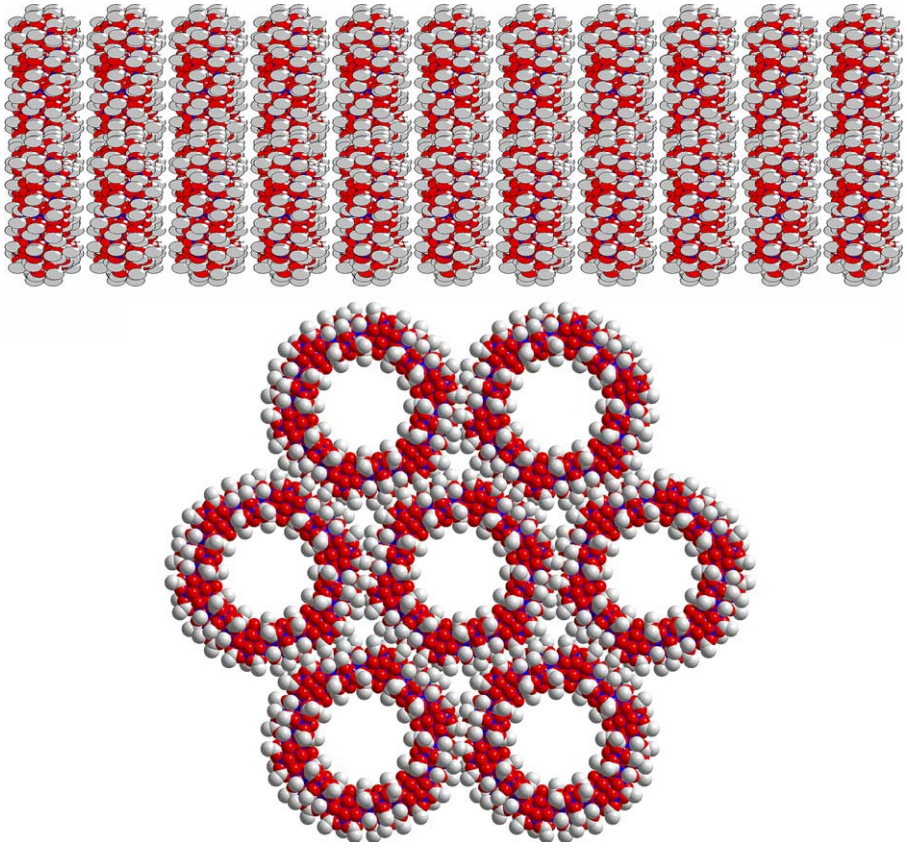

Fig. 8. Top: Ordered arrangement of Mn_{84} molecules (excluding hydrogen atoms) into two adjacent supramolecular nanotubes viewed perpendicular to the propagation axis; this view emphasizes the exact registry of molecules in adjacent tubes and thus the sheet-like structure formed. Bottom: A view along the propagation axes of seven tubes showing the hexagonal packing of neighbors within a single sheet of molecules (excluding hydrogen atoms).

3.3. Methanolysis routes to a Mn_{84} torus

We have long sought to synthesize SMMs of very large dimensions (by molecular standards) to probe whether products from the molecular (or bottom-up) approach to nanoscale magnetic materials can reach the size regime of the traditional (or top-down) approach. As part of these efforts, we have obtained $[Mn_{84}O_{72}(O_2CMe)_{78}(OMe)_{24}(MeOH)_{12}(H_2O)_{42}(OH)_6]$ (Mn_{84}) from the reaction of $Mn_{12}Ac$ with $N^nBu_4MnO_4$ in MeOH. The structure (Fig. 5) comprises a giant Mn_{84} torus with a >4 nm diameter composed of alternating near-linear $[Mn_3O_4]$ and cubic $[Mn_4]$ subunits (Fig. 6). All the Mn ions are Mn^{III}. The Mn_{84} complex exhibits hysteresis and QTM and is thus the largest SMM prepared to date. A better appreciation of the structure and the size of the molecule is provided by the space-filling plots of Fig. 7, which show that the torus has a diameter of about 4.3 nm and a thickness of about 1.2 nm, with a central hole of diameter 1.9 nm. The Mn_{84} molecules order within the crystal in an aesthetically pleasing manner, giving nanotubular stacks parallel to the crystal c axis and to their neighbors (Fig. 8). This yields a hexagonal close packing analogous to densely packed straws in a box. The crystalline structure of Mn_{84} thus displays extensive cylindrical channel formation along one dimension. Molecules in neighboring chains are exactly adjacent (Fig. 8), and thus the structure may be alternatively described as consisting of graphite-like Mn_{84} sheets lying on top of each other with perfect registry.

4. Conclusions

The field of single-molecule magnets, or molecular nanomagnets, continues to grow and branch out in several directions. We have tried in this short review to emphasize the importance of obtaining synthetic control over obtained species, so that they can be modified in desirable ways. This thus allows expansion of a particular structural type into a family of related species that are invaluable in probing the various factors that affect the observed magnetic properties. We have also tried to emphasize the variety of species that can be obtained in Mn chemistry, which continues to be the richest source of SMMs, as the number of synthetic methods continues to increase.

Scheme 1.

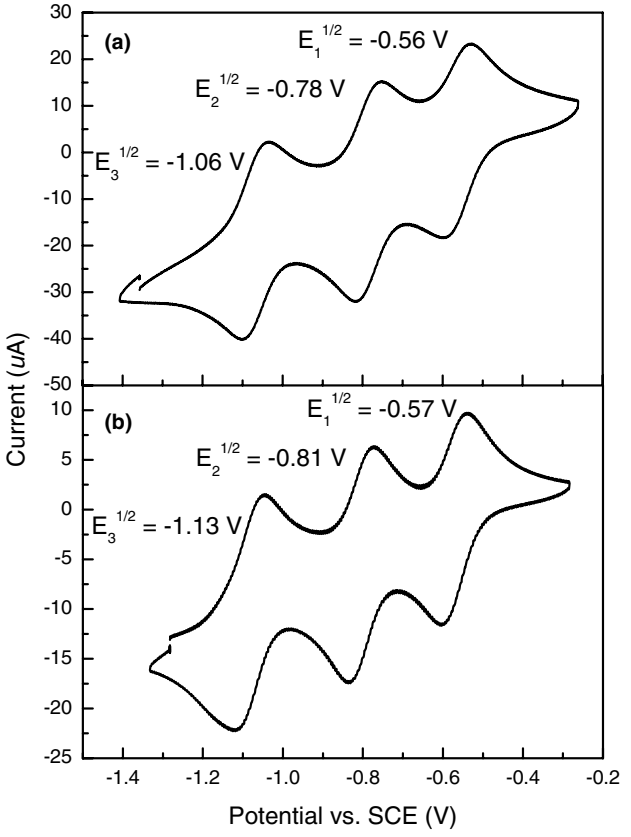
than that of the propyl (**2**) and pentyl (**4**) radicals [6,7] (see Scheme 1).

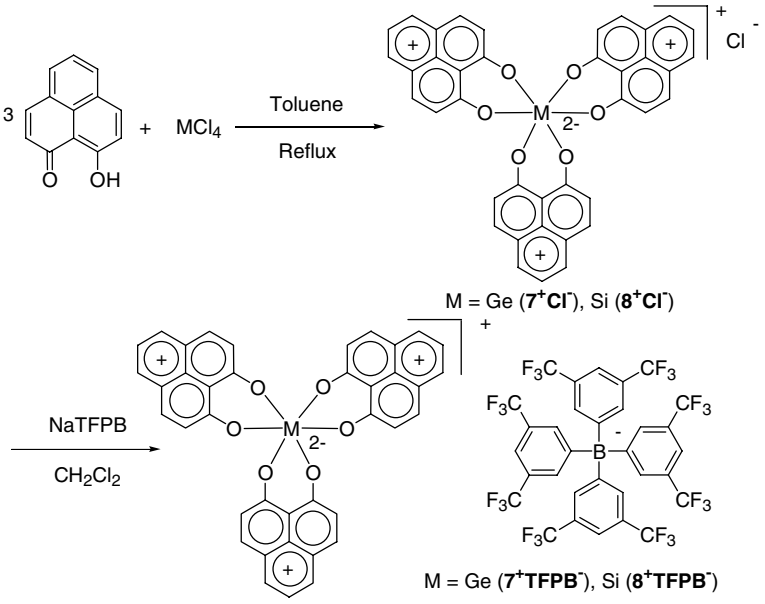
In the present paper, we report the synthesis, redox properties and solid state structures of hexacoordinated germanium ($\mathbf{7}^{+}\mathbf{TFPB}^{-}$) and silicon ($\mathbf{8}^{+}\mathbf{TFPB}^{-}$) cations containing three phenalenyl (PLY) units; such octahedral silicon and germanium complexes with 9-oxophenalenone ligands are not well known.

2. Results and discussion

2.1. Synthesis

The synthetic procedure for the preparation of $\mathbf{7}^{+}\mathbf{TFPB}^{-}$ and $\mathbf{8}^{+}\mathbf{TFPB}^{-}$ are shown in Scheme 2. A toluene solution of 9-hydroxyphenalenone was treated with $GeCl_4$ and $SiCl_4$ to obtain the corresponding chloride salts which were used as such for the next reaction without further purification. The chloride salts are quite insoluble in most common organic solvent but are sparingly soluble in dichloromethane. The anion exchange reactions were performed in dry dichloromethane at





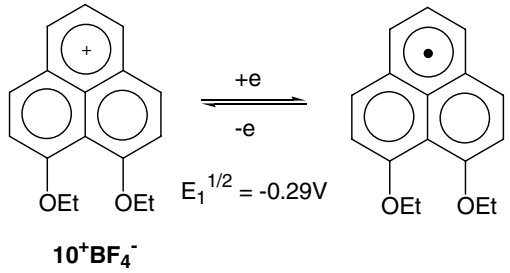


Fig. 1. Cyclic voltammetry of: (a) $\mathbf{7}^{+}\mathbf{TFPB}^{-}$ and (b) $\mathbf{8}^{+}\mathbf{TFPB}^{-}$ in acetonitrile, reference to SCE via internal ferrocene (not shown).

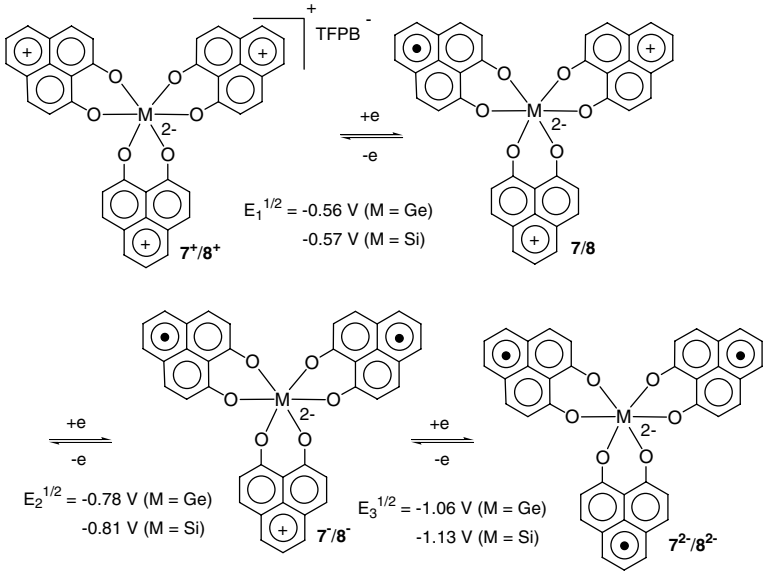
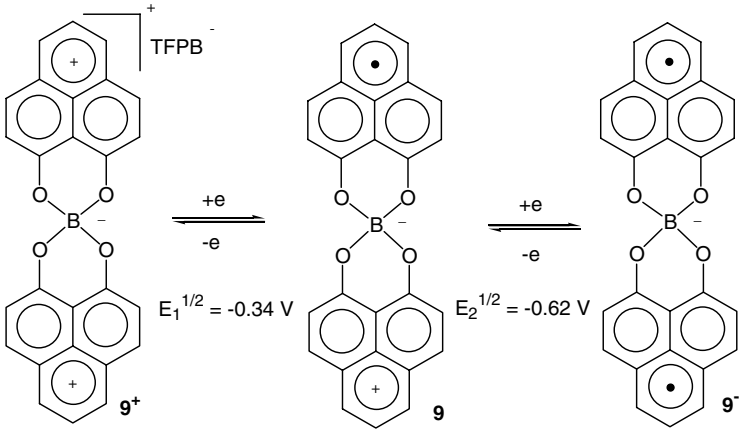
Scheme 2.



room temperature. Addition of solid sodium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate (NaTFPB) leads to dissolution of the cations due to the formation of the TFPB salt. The excess chloride salt and the NaCl formed during the reaction were separated by filtration. Compound $\mathbf{7}^{+}\mathbf{TFPB}^{-}$ and $\mathbf{8}^{+}\mathbf{TFPB}^{-}$ were found to be stable in the solid state and in solution at room temperature.



Scheme 5.

2.2. Electrochemistry

The cyclic voltammetry of $\mathbf{7}^{+}\mathbf{TFPB}^{-}$ and $\mathbf{8}^{+}\mathbf{TFPB}^{-}$ exhibit three reversible redox waves at $E_1^{1/2} = -0.56$ V, $E_2^{1/2} = -0.78$ V, $E_3^{1/2} = -1.06$ V and $E_1^{1/2} = -0.57$ V, $E_2^{1/2} = -0.81$ V and $E_3^{1/2} = -1.13$ V versus SCE (Fig. 1) corresponding to the successive reduction to radical, anion and dianion of the phenalenyl moiety (Scheme 3). The relative ease of reduction of these complexes follows the electronegativities of the central atoms: Ge, 2.02; Si, 1.74. The potentials may be compared to the reduction potentials observed for $\mathbf{9}^{+}$: $E_1^{1/2} = -0.34$ V and $E_2^{1/2} = -0.62$ V (Scheme 4), and $\mathbf{10}^{+}$: $E_1^{1/2} = -0.29$ V versus SCE (Scheme 5). The ease of the first reduction of these compounds follows the order: $\mathbf{10}^{+} > \mathbf{9}^{+} > \mathbf{7}^{+}$ and $\mathbf{8}^{+}$, which is in the sequence of 1,

Scheme 4.

2 and 3 phenalenyl units per molecule. This sequence may be understood by considering the degree of charge that is localized in a single phenalenyl ring in the complexes – clearly one PLY ring bears most of the charge density in the salt $\mathbf{10}^+$, and along this series it is apparent that any given PLY unit will bear a lower positive charge in the salt as the number of the PLY units increases and, therefore, the first electron transfer will become progressively more difficult. This is in agreement with the bond length data for the salts $\mathbf{7}^+$, $\mathbf{8}^+$ and the beryllium compound, [8] shown in Table 3 where it may be seen that the C1–O1 and C9–O2 bond lengths are 1.302, 1.296, 1.287 and 1.300, 1.308, 1.290 Å, respectively. The bond length should be a sensitive indicator of the degree of charge separation in the complexes with longer bond lengths associated with a greater degree of charge separation. A six-coordinated silicon (IV) complex with a tripodal phenalenyl-based hexadentate ligand was recently shown to undergo three reductions at potentials of −0.97, −1.19 and −1.43 V versus SCE [9], due to reduction to the radical, anion and dianion. This compound is more difficult to reduce than $\mathbf{7}^+\mathbf{TFPB}^-$ and $\mathbf{8}^+\mathbf{TFPB}^-$, because of the presence of nitrogen in the coordination sphere of silicon.

The disproportionation potential of $\mathbf{7}^+$ and $\mathbf{8}^+$, $\Delta E_{2-1} = E_2^{1/2} - E_1^{1/2} = -0.22$ and -0.24 V versus SCE, are considerably lower in magnitude than the values found for the boron compounds previously reported [3–5]. Table 1 lists the results of the cyclic voltammetry experiments carried out on salts $\mathbf{1}^+$, $\mathbf{2}^+$, $\mathbf{3}^+$, $\mathbf{4}^+$, $\mathbf{5}^+$, $\mathbf{6}^+$ (with BPh_4^- as the counterion) together with the new compounds. The small ΔE_{2-1} value seen in $\mathbf{7}^+$ and $\mathbf{8}^+$ can be explained in terms of the reduction in the electron repulsion by the delocalization of the charge over the three PLY sites. The ΔE_{2-1} value largely determines the on-site Coulomb correlation energy (U) in the solid state and is well established as an important discriminator for organic metals [10,11]. The three reduction waves in the cyclic voltammogram indicate that it is possible to introduce one electron into each of the PLY ring (Scheme 3).

Table 1
Half-wave potentials[a] and the disproportionation potentials of various tetraphenylborate and TFPB salts

Cation	$E_1^{1/2}$	$E_2^{1/2}$	$E_3^{1/2}$	ΔE_{2-1}	References
$\mathbf{7}^+\mathbf{TFPB}^-$	−0.56	−0.78	−1.06	−0.22	this work

2.3. Crystallography

Single crystals of $\mathbf{7}^+\mathbf{TFPB}^-$ and $\mathbf{8}^+\mathbf{TFPB}^-$ were grown from diethyl ether and hexane solution at room temperature and studied by single crystal X-ray diffraction. Crystallization of $\mathbf{7}^+\mathbf{TFPB}^-$ and $\mathbf{8}^+\mathbf{TFPB}^-$ gave needle like crystals of diethyl ether solvates, which belong to the triclinic space group $P\bar{1}$, with two molecules per unit cell. Table 2 provides crystal data of compound $\mathbf{7}^+\mathbf{TFPB}^-$ and $\mathbf{8}^+\mathbf{TFPB}^-$. An ORTEP plot of the molecular structure of $\mathbf{7}^+\mathbf{TFPB}^-$ and $\mathbf{8}^+\mathbf{TFPB}^-$ are shown in Fig. 2.

The molecular geometry around germanium and silicon are approximately octahedral, consisting of three bidentate chelating PLY ligands. The plane of the three PLY rings in $\mathbf{7}^+\mathbf{TFPB}^-$ reveal some distortion from the ideal octahedral symmetry; their dihedral angles are 84°

Table 2

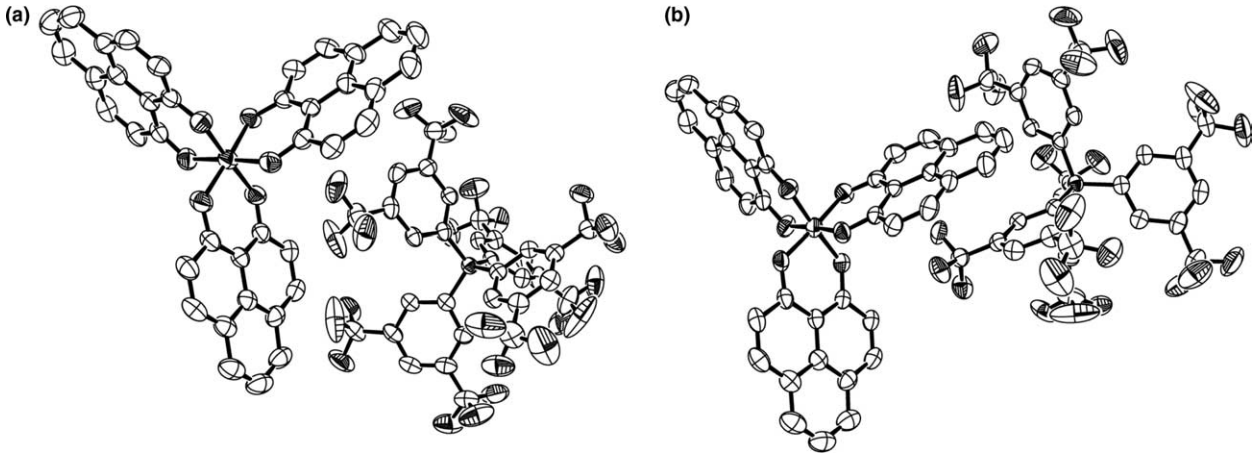

Fig. 2. ORTEP diagram of the molecular structure of: (a) $7^{+}TFPB^{-}$ and (b) $8^{+}TFPB^{-}$.

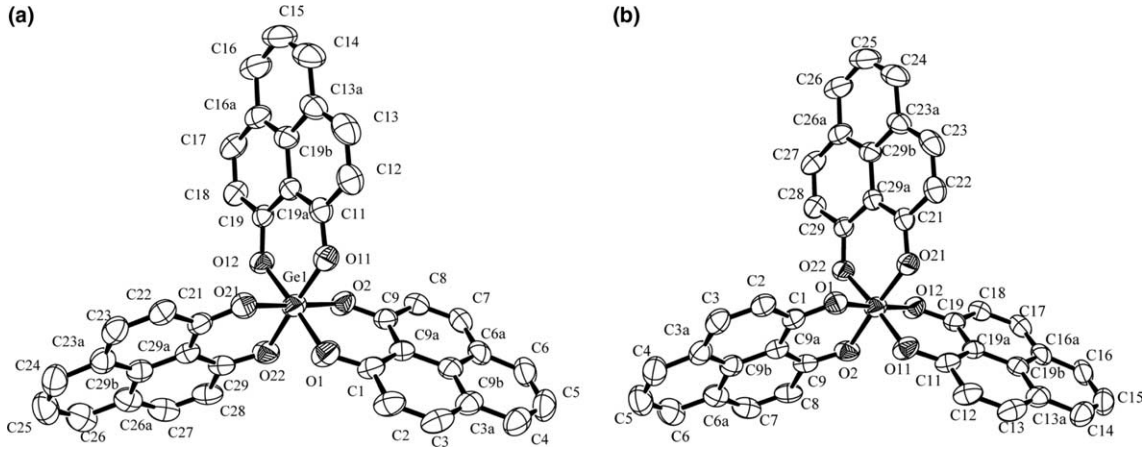

Fig. 3. ORTEP diagram of the molecular structure of: (a) $7^{+}TFPB^{-}$ and (b) $8^{+}TFPB^{-}$ (only the cation part) and the numbering of the atoms.

(C_1–C_{9b}, C_{11}–C_{19b}), 80.5° (C_{11}–C_{19b}, C_{21}–C_{29b}) and 102.9° (C_{21}–C_{29b}, C_1–C_{9b}) (see Fig. 3), rather than 90° as expected in ideal octahedral symmetry. The corresponding dihedral angles for the silicon compound are 83.8°, 80.1° and 102.8°. The dihedral angles are different from that observed in the *cis*-hexacoordinate (tropolonato)$_2$ $SiPh_2$ (an α-diketonate compound) in which the angle of the two tropolonate chelating planes is 81.1° [12]. The structure distorts so that the metal atom deviates from the chelate-ring plane, and this has been noted in studies of several acetylacetonato complexes and is ascribed to the packing forces in the crystals [13]. The comparison of the bond lengths in Table 3 indicates that there is a considerable amount of charge separation in the cationic complexes of germanium and silicon as reflected by the C–O bond lengths in these compounds.

The structure of the counter anion (TFPB) also deviates from the ideal tetrahedral geometry and this is probably due to the presence of bulky substituents (CF_3) on the phenyl ring. In the crystal structure of $7^{+}TFPB^{-}$ four out of eight CF_3 groups in the counter anion show disorder. In compound $8^{+}TFPB^{-}$ all the CF_3 groups were refined as disordered CF_3.

In the molecular structure of the salt ($7^{+}TFPB^{-}$), each cation is involved in π–π interactions with two neighbouring molecules and thus these cations form chains in the solid state (Fig. 4). The chain formation

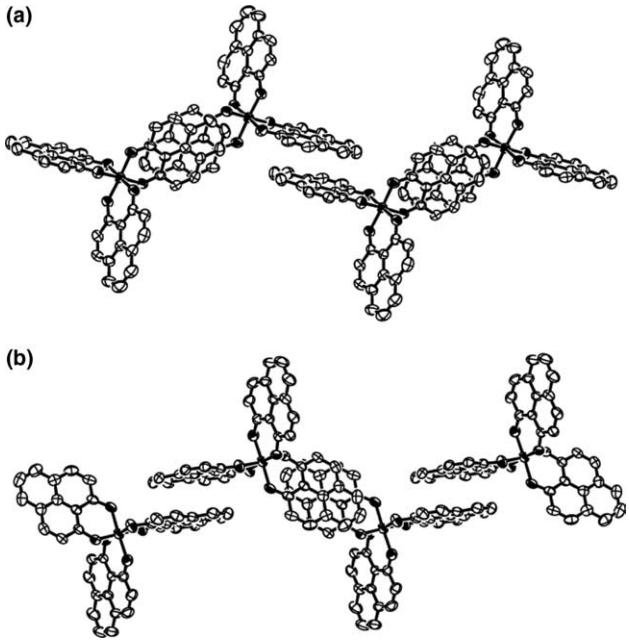

Fig. 4. Packing diagram of the cations (7^+) in the lattice, showing the overlap between four of the neighbouring cations: (a) and (b) are perpendicular views of each of the two sets of phenalenyl units.

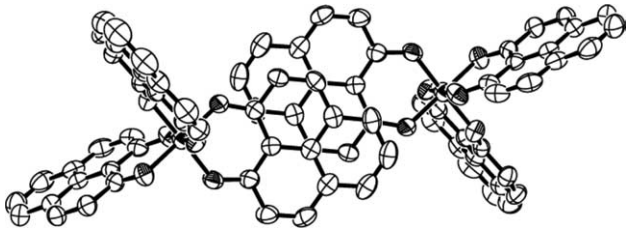

Fig. 5. Overlap between a pair of cations 7^+.

occurs along the *Z*-direction of the unit cell. Out of the three two PLY are involved in π-dimer chain formation. But the C–C distances of the PLY carbon with the nearest neighbour are not identical. There are two sets of C–C distances are shown in the Fig. 6. The shortest C–C distance observed is 3.274 Å for compound $\mathbf{7^+TFPB^-}$ and 3.297 Å for compound $\mathbf{8^+TFPB^-}$. The projection of cation 7^+ (Fig. 5) demonstrates the almost perfect superposition of some of the carbon atoms in the π-dimers. A similar packing pattern was observed for cation 8^+ which are not shown in the figure.

3. Experimental

3.1. Materials and methods

All manipulations were carried out under an atmosphere of argon using standard Schlenk techniques. Solvents were dried and distilled according to the standard procedures. Toluene was distilled from sodium benzophenone ketyl immediately before use. Dichloromethane was distilled from anhydrous CaH_2 before use. Germanium tetrachloride and silicon tetrachloride (Aldrich) were all commercial products and were used as received. 9-Hydroxyphenalenone and sodium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate (NaTFPB) were synthesized according to literature procedures [14,15]. Melting points are uncorrected. Infrared spectra were recorded on a Nicolet Nexus 670 FT-IR spectrometer (at 2 cm^{-1} resolution). ^1H NMR spectra were run on a Varian Inova 300 MHz NMR spectrometer. Elemental analysis were performed by Microanalysis Laboratory (School of Chemical Science, University of Illinois, Urbana, IL).

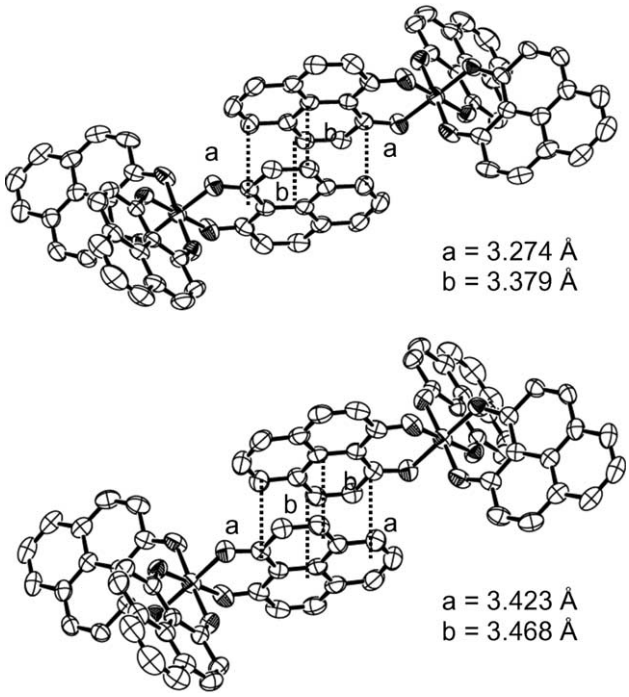

Fig. 6. The closest distances between a pair of cations 7^+.

3.2. Preparation of 7^+Cl^-

9-Hydroxyphenalenone (1.96 g, 10 mmol) in anhydrous toluene (50 mL) was treated with germanium tetrachloride (0.71 g, 3.3 mmol) under argon and the mixture was refluxed for 12 h. The yellow solid was isolated by filtration (1.5 g, 32%). Melting point: Compound does not melt till 380 °C. ^1H NMR (CD_3OD); δ 8.28 (d, 6H), 8.18 (d, 6H), 7.69 (t, 3H), 7.18 (d, 6H). IR (ATR, 4000–600 cm^{-1}): 3002 (w), 2986 (w), 1622 (m), 1570 (s), 1496 (s), 1467 (w), 1429 (w), 1353 (w), 1335 (w), 1322 (w), 1273 (s), 1238 (m), 1181 (w), 1142 (w), 1129 (w), 982 (w), 851 (s), 763 (s), 750 (s), 701 (w), 682 (w).

3.3. Preparation of 7^+TFPB^-

A mixture of $\mathbf{7^+Cl^-}$ (1.02 g, 1.47 mmol) and NaTFPB (1.15 g, 1.30 mmol) was added to 100 mL of dry

CH_2Cl_2. The mixture was stirred for 3 h until all yellow solids went into the solution and a white solid had precipitated. The yellow solution was filtered and the solvent was evaporated to give a brownish-yellow solid. Crystallization from ether–hexane (10:1) gave yellow needles. Yield: 1.85 g (93%); m.p. 98 °C. ^{1}H NMR ($CDCl_3$): δ 8.36 (d, 6H), 8.28 (d, 6H), 7.79 (t, 3H), 7.72 (br, 8H), 7.48 (br, 4H), 7.28 (d, 6H). IR (ATR, 4000–600 cm^{-1}): 3050 (w), 3028 (w), 1627 (w), 1618 (w), 1568 (m), 1496 (m), 1470 (w), 1434 (w), 1354 (w), 1336 (w), 1273 (s), 1241 (m), 1122 (s), 987 (w), 854 (w), 759 (w), 712 (w). *Anal*. Calc. for $C_{71}H_{33}BO_6GeF_{24}$: C, 56.05; H, 2.19; B, 0.71; Ge, 4.77. Found: C, 57.80; H, 2.71; B, 0.69; Ge, 4.39%.

3.4. Preparation of 8^+Cl^-

9-Hydroxyphenalenone (2.4 g, 12.2 mmol) was dissolved in 50 mL of dry toluene followed by addition of $SiCl_4$ (4 mL, 4 mmol) in dichloromethane. The reaction mixture was refluxed for 8 h. The yellow solid was isolated by filtration (3.0 g, 86%). When a melting point determination was attempted, the salt turned brown (~290 °C). ^{1}H NMR (CD_3OD): δ 8.60 (d, 6H), 8.48 (d, 6H), 7.91 (t, 3H), 7.26 (d, 6H). IR (ATR, 4000–600 cm^{-1}): 3004 (w), 2987 (w), 1621 (w), 1571 (w), 1501 (w), 1343 (w), 1274 (m), 1256 (m), 1144 (w), 1125 (w), 993 (w), 852 (w), 764 (s), 749 (s), 652 (m), 641 (s).

3.5. Preparation of 8^+TFPB^-

Synthesis of $\mathbf{8^+TFPB^-}$ is exactly the same as the preparation of $\mathbf{7^+TFPB^-}$. Yield: 1.8 g (88%); m.p. 84 °C. ^{1}H NMR ($CDCl_3$); δ 8.37 (d, 6H), 8.26 (d, 6H), 7.78 (t, 3H), 7.70 (br, 8H), 7.45 (br, 4H), 7.24 (d, 6H). IR (ATR, 4000–600 cm^{-1}): 3004 (w), 2987 (w), 1621 (w), 1576 (m), 1504 (m), 1349 (m), 1275 (s), 1240 (w), 1119 (s), 993 (w), 851 (m), 764 (m), 751 (m). *Anal*. Calc. for $C_{71}H_{33}BO_6SiF_{24}$: C, 57.74; H, 2.24. Found: C, 57.95; H, 2.11%.

3.6. X-ray crystallography

Data were collected on a Bruker SMART 1000 platform-CCD X-ray diffractometer system (Mo radiation, $\lambda = 0.71073$ Å, 50 kV/40 mA power) at 223 K. The orange crystal gave a triclinic unit cell (space group $P\bar{1}$, $z = 2$), with unit cell parameters $a = 12.2965(16)$ Å, $b = 17.104(2)$ Å, $c = 18.536(2)$ Å, $\alpha = 75.645(3)°$, $\beta = 82.109(3)°$, $\gamma = 74.879(2)°$ and $V = 3635.0(8)$ Å^3 for compound $\mathbf{7^+TFPB^-}$ and $a = 12.297(2)$ Å, $b = 17.124(3)$ Å, $c = 18.505(3)$ Å, $\alpha = 75.762(3)°$, $\beta = 82.337(4)°$, $\gamma = 74.869(3)°$ and $V = 3636.0(11)$ Å^3 for compound $\mathbf{8^+TFPB^-}$. The structure ($\mathbf{7^+TFPB^-}$) was refined with 14870 reflections, yielding $R[I > 2\sigma(I)]$, $R_1 = 0.0543$, $wR_2 = 0.1489$, and R indices for all data $R_1 = 0.0758$ and $wR_2 = 0.1676$ (Table 2). The structure of $\mathbf{8^+TFPB^-}$ was refined with 14864 reflections, yielding $R[I > 2\sigma(I)]$, $R_1 = 0.0589$, $wR_2 = 0.1557$, and R indices for all data $R_1 = 0.0949$, and $wR_2 = 0.1873$ (Table 2). Full details, including bond lengths and bond angles, are given in the supporting Information.

3.7. Cyclic voltammetry

Cyclic Voltammetry was performed using a PINE Bipotentiostat, model AFCC1BP1, with scan rates 50–100 mV s^{-1} on solutions (<10^{-3} M) of $\mathbf{7^+TFPB^-}$ and $\mathbf{8^+TFPB^-}$ in CH_3CN (dried by distillation from P_2O_5 and CaH_2) containing 0.1 M tetra-*n*-butylammonium hexafluorophosphate as supporting electrolyte. Potentials were scanned with respect to the quasi-reference electrode in a single compartment cell fitted with Pt electrodes and referenced to the Fc/Fc^+ couple of ferrocene at 0.38 V versus SCE [16]. The $E_{pa} - E_{pc}$ separation of the reversible couples was within 10% of that of the Fc/Fc^+ couple.

4. Summary and conclusions

In summary, two new cationic tris-(9-oxophenalenone) germanium (IV) and silicon (IV) of $\mathbf{7^+}$ and $\mathbf{8^+}$ have been synthesized in high yield and high purity. Cyclic voltammetry indicated these complexes could be easily reduced to its corresponding radical. The hexacoordinated geometry was determined by single crystal X-ray diffraction analysis in the solid state. Molecular structure also shows a π–π interaction between the two neighboring PLY plane and a one-dimensional chain like structure in the solid state.

5. Supplementary material

Crystallographic data have been deposited at the Cambridge Crystallographic Data Center, CCDC Reference Nos. 265567 ($\mathbf{7^+TFPB^-}$) and 265568 ($\mathbf{8^+TFPB^-}$). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc. cam.ac.uk).

Scheme 1.

$(H_2O)]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$, $[Mn_6(O)_2\ Piv_{10}(NIT\text{-}p\text{-}Py)_4]\cdot\ 0.5C_7H_{16}$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2(HPiv)_2]$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)]\cdot C_6H_{14}$, analyzing the factors that hinder bridging coordination of NIT-R when $R \neq CH_3$.

NIT-R, R = H, Me, Et, *p*-Py, *n*-Bu-Pz

2. Experimental

2.1. Synthesis

All the solvents were commercially available and used as received. The $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ and $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ clusters were prepared by using the method described elsewhere [1]. Nitronyl nitroxides 4,4,5,5-tetramethyl-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (NIT-H), 2,4,4,5,5-pentamethyl-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (NIT-Me), 4,4,5,5-tetramethyl-2-ethyl-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (NIT-Et), 4,4,5,5-tetramethyl-2-(pyridine-4′-yl)-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (NIT-*p*-Py), and 4,4,5,5-tetramethyl-2-(1′-*n*-butyl-pyrazole-4′-yl)-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (NIT-*n*-Bu-Pz) were prepared by the procedure of [2].

2.1.1. $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]\cdot 0.5CH_2Cl_2$

$[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ (0.1 g, 0.029 mmol) was dissolved while stirring in CH_2Cl_2 (4 ml). The resulting solution was carefully dropped through a glass filter to a solution of NIT-H (0.036 g, 0.230 mmol) in CH_2Cl_2 (2 ml) in such a way as to let the drops go down the wall of the flask. Then heptane (5 ml) was carefully added in the same manner without stirring. After storing the reaction mixture at 4 °C for a few days, dark red crystals formed which decomposed in air, losing the CH_2Cl_2 crystallization molecules. Yield 58%. *Anal.* Calc. for $Mn_6C_{78}H_{142}N_8O_{30}$: C, 46.8; H, 7.2; N, 5.6; (for the unsolvated product). Found: C, 47.1; H, 7.3; N, 5.1%. $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]\cdot 0.5CH_2Cl_2$ is formed in a $CH_2Cl_2/n\text{-}C_7H_{16}$ or $CH_2Cl_2/n\text{-}C_6H_{14}$ mixture with a reagent ratio of $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$/NIT-H of 1/8 or 1/16; it is also formed in the reaction of $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ or $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ (see Section 2.1.4) with NIT-H in a $CH_2Cl_2/n\text{-}C_7H_{16}$ mixture.

2.1.2. $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3\ HPiv]\cdot 0.5C_7H_{16}$

This compound was prepared as described above. The reaction mixture was allowed to stay for a few days at room temperature to give crimson crystals. Yield 60%. *Anal.* Calc. for $Mn_6C_{82}H_{151}N_6O_{30}$: C, 48.5; H, 7.5; N, 4.1%. Found: C, 49.2; H, 7.6; N, 4.5%. $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$ formed when the reaction was conducted in CH_2Cl_2 or heptane. A mixture of these solvents provided optimum conditions for growth of quality crystals. Varying the initial reagent ratio $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$/NIT-Et (1:8, 1:16, 1:40) did not affect the composition of the final product.

2.1.3. $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_4]$

$[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ (0.05 g, 0.015 mmol) was dissolved with stirring in CH_2Cl_2 (4 ml). The resulting solution was carefully dropped through a glass filter to a solution of NIT-Et (0.032 g, 0.172 mmol) in CH_2Cl_2 (1 ml) in such a way that the drops were let down the wall of the flask. Then heptane (5 ml) was carefully added in the same manner without stirring. After storing the solution at room temperature for a few days, crystals of two types formed: crimson plates of $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$ and dark red bulky crystals of $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_4]$. The crystals were filtered off, washed with cold heptane, dried in air, and mechanically separated. Yield 0.030 g (50% based on the total mass of the product). The same product mixture was obtained by varying the starting reagent ratio from 1/12 to 1/24 or by using $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ as the starting reagent (see Section 2.1.4). *Anal.* Calc. for $Mn_6C_{86}H_{158}N_8O_{30}$: C, 48.8; H, 7.9; N, 4.6. Found: C, 48.9; H, 7.5; N, 5.3%.

2.1.4. $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$

$[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ (0.05 g, 0.029 mmol) was dissolved with stirring and heating to 50 °C in EtOAc (4 ml). The resulting solution was kept for a few days

at room temperature. This gave plate-like tawny crystals, which gradually decomposed in air, losing ethyl acetate molecules. Yield 50%. *Anal.* Calc. for $Mn_{12}C_{104}H_{186}O_{46}$: C, 44.1; H, 6.6. Found: C, 43.7; H, 6.7%. The same compound is formed in the presence of NIT-R, where R = H, Et.

2.1.5. $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$

$[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ C (0.05 g, 0.029 mmol) was dissolved with stirring and heating to 50 °C in acetone (10 ml). The resulting solution was added to the solution of NIT-Et (0.011 g, 0.059 mmol) in acetone (1 ml). After storing the solution for a few days at room temperature, brown plate-like crystals formed. They were filtered off and dried in air. Yield 57%. *Anal.* Calc. for $Mn_6C_{56}H_{104}O_{25}$: C, 44.6; H, 7.0. Found: C, 44.9; H 6.8%. The same compound is formed if the solution contains NIT-Me or NIT-H.

2.1.6. $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$ and $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]\cdot 0.5C_7H_{16}$

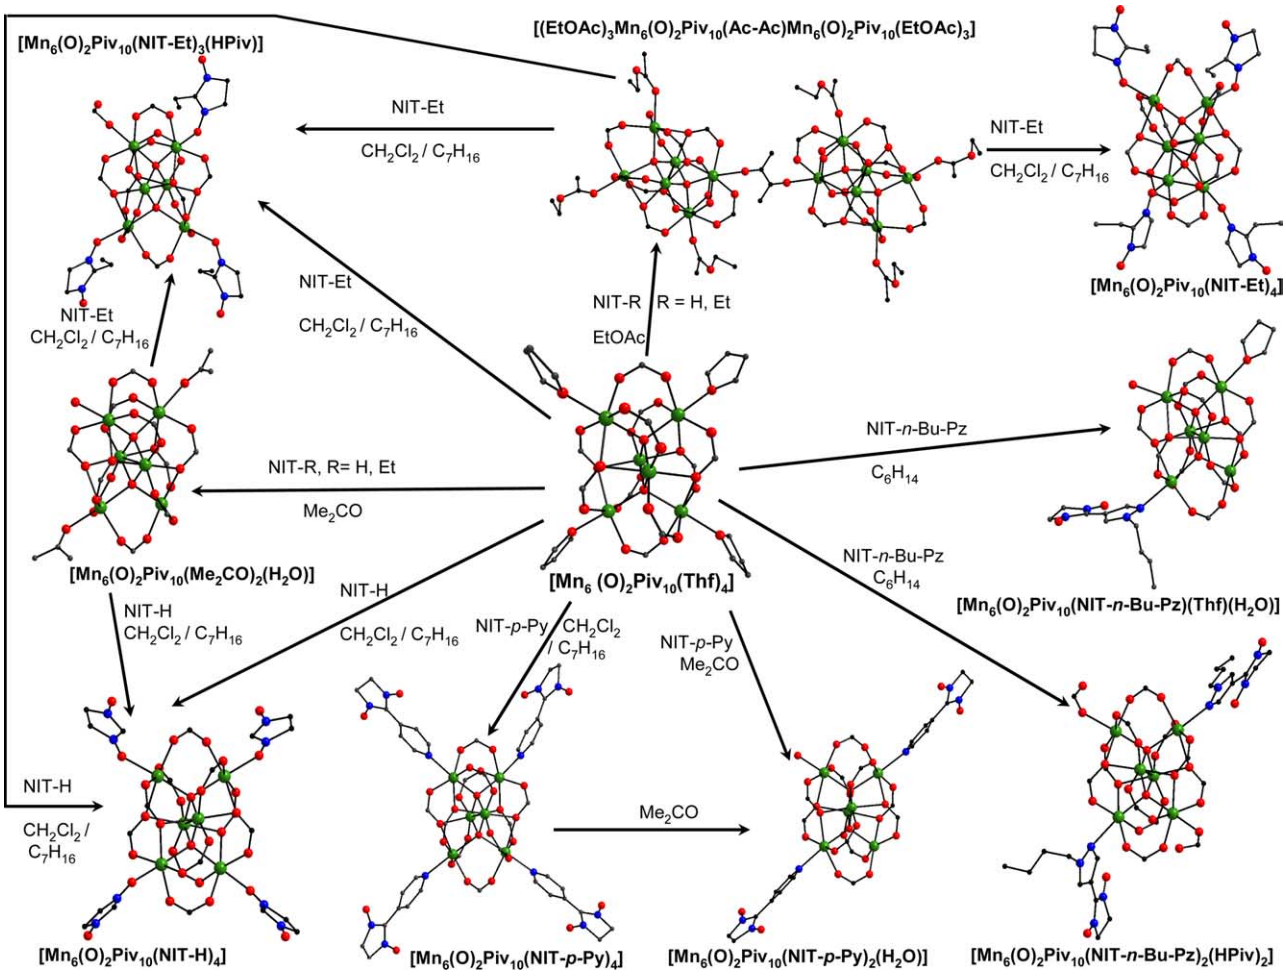
The synthetic procedure for $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$ is identical to the one described in Section 2.1.1. After storing the reaction mixture for a few days at room temperature, the dark gray crystals were filtered off, washed with cold heptane, and dried in air. Yield 83%. *Anal.* Calc. for $Mn_6C_{98}H_{154}N_{12}O_{30}$: C, 51.0; H, 6.7; N, 7.3. Found: C, 51.8; H, 7.2; N, 7.0%. Using $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ as the starting compound in an analogous procedure leads to a crystalline product containing solvated heptane molecules. Yield 95%. *Anal.* Calc. for $Mn_{12}C_{203}H_{324}N_{24}O_{60}$: C, 51.7; H, 6.9; N, 7.1. Found: C, 51.1; H, 6.7; N, 7.4%.

2.1.7. $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]$

The synthetic procedure is similar to the one described in Section 2.1.5. As the starting cluster one uses $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ or $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$. The procedure is not sensitive to the initial cluster/nitroxide ratio. Yield 84%. *Anal.* Calc. for $Mn_6C_{74}H_{124}N_6O_{27}$: C, 47.7; H, 6.7; N, 4.5. Found: C, 47.7; H, 6.8; N, 4.1%.

2.1.8. $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2(HPiv)_2]$ and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)]\cdot C_6H_{14}$

A sample of $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ (0.1 g, 0.055 mmol) was dissolved with stirring and heating to 50 °C in hexane (10 ml). The resulting solution was filtered, and a solution of *n*-Bu-Pz (0.008–0.032 g, 0.028–0.11 mmol) in hexane (3 ml) was added to it. Storing the solution for 3 days at room temperature resulted in a conglomerate of hardly isolable $[Mn_6(O)2\text{-}Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2(HPiv)_2]$ and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)]\cdot C_6H_{14}$ crystals and starting $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ crystals. The mixture occasionally contained $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2\text{-}(HPiv)_2]$ or $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)]\cdot C_6H_{14}$ single crystals, which were selected for an X-ray diffraction study.



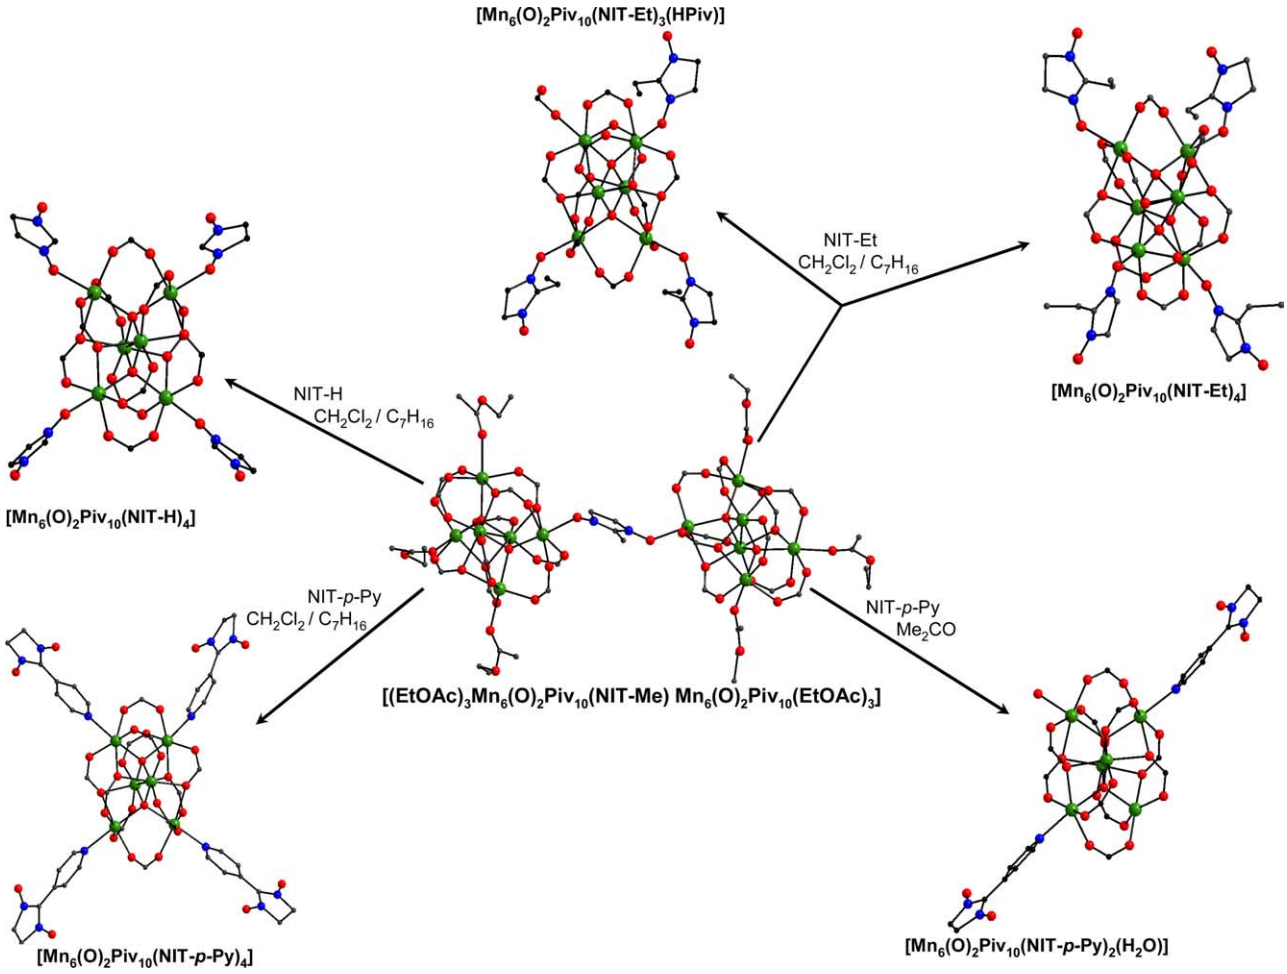
2.2. X-ray crystallography and magnetic measurements

The single crystal diffraction data were collected on a SMART APEX CCD (Bruker AXS) automatic diffractometer (Mo radiation, an absorption correction applied using the Bruker SADABS program, version 2.03). The structures were solved by direct methods. The full-matrix least-squares refinement was carried out anisotropically for non-hydrogen atoms. The H atoms were mostly generated theoretically. The methyl H atoms were refined isotropically as rigid groups. All structure solution and refinement calculations were performed with SHELX-97 and Bruker SHELXTL Version 6.12. All magnetic measurements were carried out on an MPMS-5S SQUID magnetometer (Quantum Design) in the temperature range of 1.9–300 K. Molar magnetic susceptibility was calculated using corrections for the diamagnetism of the compounds. The effective magnetic moment was calculated as $\mu_{eff} = (8\chi T)^{1/2}$.

3. Results and discussion

3.1. Synthesis of compounds

As shown in [1], NIT-Me reacts with $[Mn_6(O)_2\text{-}Piv_{10}(Thf)_4]\cdot Thf$, forming a 1D polymer $[Mn_6(O)_2\text{-}Piv_{10}(Thf)_2(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(Thf)(CH_2Cl_2)(NIT\text{-}Me)]$ when the reaction is conducted in CH_2Cl_2; a 3D polymer $[Mn_6(O)_2Piv_{10}(NIT\text{-}Me)_2]$ is generated in hexane or heptane, and dumbbel-like $[(EtOAc)_3Mn_6(O)_2\text{-}Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ molecules are produced in ethyl acetate. The solvent used proved to be the critical factor governing the formation of a particular compound, while the initial reagent ratio $[Mn_6(O)_2Piv_{10}]$/NIT-Me was inessential to the composition of the product mixture. It is important that in all $[Mn_6(O)_2Piv_{10}]$ compounds, the fragments were linked by NIT-Me bridging molecules. Using the synthetic approaches reported in [1], we tried to expand the scope of heterospin compounds based on the $[Mn_6(O)_2Piv_{10}]$ polymetallic unit and NIT-R, where R = H, Et, *p*-Py, *n*-Bu-Pz. It appeared, however, that replacement of NIT-Me even by its close analogs NIT-H and NIT-Et leads to absolutely different products, where nitroxide performs only the monodentate function. Without going into details of synthesis (represented together with interconversions in Schemes 2 and 3), we discuss the key points.



Scheme 2.

3.1.1. Starting polymetallic matrix

Along with the $[Mn_6(O)_2Piv_{10}(Thf)_4]$ hexanuclear polymetallic matrix, we also used the 12-nuclear $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ as the starting component. As can be seen by comparing Schemes 2 and 3, the reaction of $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ or $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ with NIT-R gave almost the same products. Minor discrepancies were observed in two cases. First, the reaction of $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ with NIT-*p*-Py always gave $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$ crystals, while the reaction of $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ with NIT-*p*-Py in the solid state reproducibly formed the solvate of this complex, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]\cdot 0.5C_7H_{16}$. Second, the interaction of NIT-Et with $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ led to the formation of only $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$; the reaction with $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ resulted in a mixture of $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$ and $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_4]$ crystals, which were separated mechanically.

3.1.2. Reactions of the polynuclear compounds with the solvent

It is common knowledge that polynuclear carboxylates exhibit activity in transformations of organic substrates, including organic solvents used in the synthesis. We encountered transformation of solvent molecules in only one case, namely, when investigating the products of the reaction of $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ with NIT-H or NIT-Et in ethyl acetate (EtOAc). From the reaction mixture we always isolated the 12-nuclear crystalline product $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ containing the bridging diacetyl molecule (Scheme 2). The nitroxide remained in solution and had no pronounced effect on the process. The same product crystallized with the same yield from the reaction mixture under similar conditions when $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$ was simply dissolved in EtOAc. It should be noted that NIT-Me and NIT-R (R = H, Et) differ substantially in their chemical behavior. As indicated in Scheme 1, NIT-Me reacts with $[Mn_6(O)_2Piv_{10}(Thf)_4]\cdot Thf$. The reaction also forms a 12-nuclear compound, $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$, but the

Scheme 3.

bridging function in it is performed by the nitroxide molecule. This large discrepancy in the chemical behavior of NIT-Me and NIT-R (R = H, Et) deserves special attention, and we will further return to this discussion.

3.1.3. Stereochemical lability of the $[Mn_6(O)_2Piv_{10}]$ fragment

It was noted [1] that the solvent used was a critical factor determining the formation of a particular compound during the reaction of $[Mn_6(O)_2Piv_{10}(Thf)_4] \cdot Thf$ with NIT-Me (Scheme 1). The solvent effect was still more significant when we tried to use acetone. After $[Mn_6(O)_2Piv_{10}(Thf)_4] \cdot Thf$ was mixed with NIT-R (R = H, Me or Et), $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ was the only product that crystallized from the solution (Scheme 2). The same product separated from an acetone solution without a nitroxide addition. Thus nitronyl nitroxides bearing no additional donor fragments cannot compete with acetone molecules in an acetone solution for the coordination sites of the $[Mn_6(O)_2Piv_{10}]$ polymetallic fragment. This prompted us to employ NIT-*p*-Py and NIT-*n*-Bu-Pz as more powerful donors. Indeed, $[Mn_6(O)_2Piv_{10}(Thf)_4] \cdot Thf$ or $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ react vigorously with NIT-*p*-Py in acetone. The $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]$ product, which formed at any reagent ratio (Schemes 2 and 3), topologically corresponds almost exactly with $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ molecules. The $[Mn_6(O)_2Piv_{10}]$ fragment is considerably distorted so that one of the terminal Mn(II) atoms is drawn into the polynuclear framework, losing its ligand-coordinating ability. The other three terminal Mn(II) atoms coordinate the water molecule (all syntheses were performed in open apparatuses, without taking any precautions to keep out air moisture) and the two *trans* NIT-*p*-Py or Me_2CO molecules. Stated differently, the distorted $[Mn_6(O)_2Piv_{10}]$ fragment of $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ is completely preserved when NIT-*p*-Py molecules are substituted for acetone molecules. The same fragment is present in the structure of $Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)] \cdot 0.5C_6H_{14}$ (Scheme 2), which (as noted in Section 2) was isolated as single crystals.

3.2. Structural data

In $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv] \cdot 0.5C_7H_{16}$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_4]$, $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2(HPiv)_2]$ molecules, $[Mn^{II}_4Mn^{III}_2(O)_2(Piv)_{10}]$ is the nucleus (Fig. 1). As in other derivatives of this polymetallic nucleus [3], in these molecules the distance between the internal Mn^{III} ions (Mn1–Mn2 2.800–2.845 Å) is much shorter than the distances to the terminal Mn(3-6) atoms (3.067–3.248 Å) and the Mn3–Mn4 and Mn5–Mn6 distances, which are longer than 3.5 Å (Table 1). The Mn1 and Mn2 atoms are common to the two oxo-centered $[Mn_4O]$ tetrahedra (Fig. 1). In the tetrahedra, the Mn–O distances to the internal Mn(1–2) atoms (1.863–1.934 Å) are much shorter than the analogous distances to the terminal Mn(3–6) atoms (2.085–2.221 Å). Importantly, the Mn3–Mn4 and Mn5–Mn6 edges are not parallel; they form an angle of ~24°, which favors a 3-D diamond-like structure. An example of a compound with this structure is found in [1]. All compounds under study have molecular structures. Each (internal) Mn atom is surrounded by a distorted octahedron formed by four O atoms of the bridging Piv ligands and two μ_4-O atoms, lying inside the $[Mn_4O]$ tetrahedra. For terminal Mn atoms, however, only five of six vertices are occupied by the O atoms of the bridging pivalates and the μ_4-O atoms. The other coordination sites of the four terminal Mn atoms are occupied by the O atoms of the monodentate NIT-R, EtOAc, and Ac–Ac ligands or by the N atoms of NIT-*p*-Py and NIT-*n*-Bu-Pz. Table 1 lists selected bond lengths.

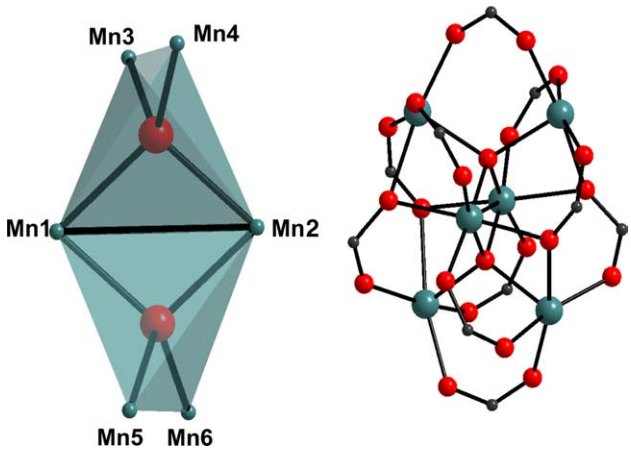


Fig. 1. Two edge-sharing $\{Mn_4O\}$ tetrahedra and the symmetrical $\{Mn_6(O)_2(Piv)_{10}\}$ fragment.

In $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]$ and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)] \cdot C_6H_{14}$, the terminal Mn atom that faces the atom having H_2O in its environment is surrounded by a square pyramid. The $[Mn_6O_2(piv)_{10}]$ nucleus is distorted, the distortion being especially pronounced

for $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)(H_2O)] \cdot C_6H_{14}$, in which all three terminal monodentate ligands are different (Table 1).

Structural data obtained in this work provide a clue to the understanding of differences in the chemical behavior of NIT-R (R = H, Me, Et). Recall that replacement of NIT-Me even by its closest analogs NIT-H or NIT-Et leads to absolutely different products where the nitroxide performs only the monodentate function (Sections 3.1 and 3.1.2).

It appeared that NIT-Et cannot perform the bridging function for steric reasons. This can readily be verified if the structure of the $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ molecule is represented by a space-filling model (Fig. 2(a)). A transition from NIT-Me to NIT-Et is only possible at a sacrifice of the bridging function because otherwise there is no space for the ethyl fragment. Substitution of the CH_3 groups by the C_2H_5 groups leads to an inadmissible overlap between the methyl fragment of the ethyl group and the trimethyl acetate groups of the polymetallic nucleus (Fig. 2(b)). Therefore, bridging coordination of nitronyl nitroxide is impossible with bulkier alkyl groups R in NIT-R. In other words, in compounds based on the $[Mn_6(O)_2Piv_{10}]$ unit, the bridging type of coordination is possible for NIT-Me or NIT-H alone when we are concerned with the group of nitronyl nitroxides under discussion. However, the arrangement of NIT-H molecules in the isolated $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4] \cdot 0.5CH_2Cl_2$ was radically different from that in compounds with NIT-Me (or NIT-Et). In the polynuclear complexes of $[Mn_6(O)_2Piv_{10}]$ with NIT-Me or NIT-Et, the torsion angle between the plane of the C, N, and O atoms of the ·O–N–C=N → O nitronyl nitroxide fragment and the plane of the N, O, and Mn atoms (Fig. 3) varies from 54.8° to 106.9° for all compounds under study. This kind of nitroxide coordination minimizes steric hindrance to the trimethyl acetate groups (Fig. 2(a)), placing the groups one after another. In $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4] \cdot 0.5CH_2Cl_2$, the ·O–N–C=N → O fragment is almost perpendicular to the equatorial plane of the Mn octahedron. The MnONC torsion angle (marked by triangles in Fig. 3) is up to 5.7°. With this type of radical orientation, the bridging function of NIT-H can hardly be realized because the two $[Mn_6O_2(piv)_{10}]$ fragments should be in strictly opposite positions (i.e., in an eclipsed conformation), inevitably leading to an overlap between the trimethyl acetate groups. This situation is illustrated by Fig. 4. The space-filling model includes two $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]$ molecules. Their mutual orientation is such that each molecule faces the NIT-H oxygen atom (denoted by O_L in the figure) on the periphery of the other molecule to form a bridge of two terminal NIT-H molecules by the counter-motion of the molecules. It can readily be verified that the methyl groups of the trimethyl acetate groups will simply overlap each other. It is difficult to explain this specific orientation of NIT-H molecules relative to the $[Mn_6O_2(piv)_{10}]$ unit, hindering the bridging type of nitroxide coordination and hence the generation of highly dimensional structures. This may be the consequence of the electronic effects because the inductive

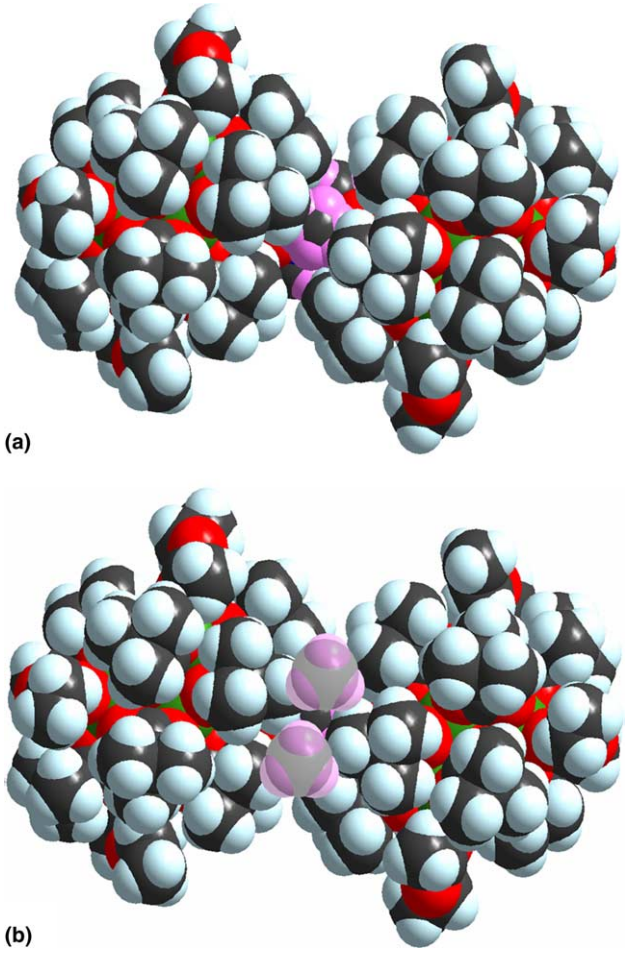

Fig. 2. Space-filling view of the $[(EtOAc)_3Mn_6(O)_2Piv_{10}(NIT\text{-}Me)\text{-}Mn_6(O)_2Piv_{10}(EtOAc)_3]$ molecule (a), showing the unacceptable overlap between the methyl group and the trimethyl acetate fragment in the case of NIT-Et (b).

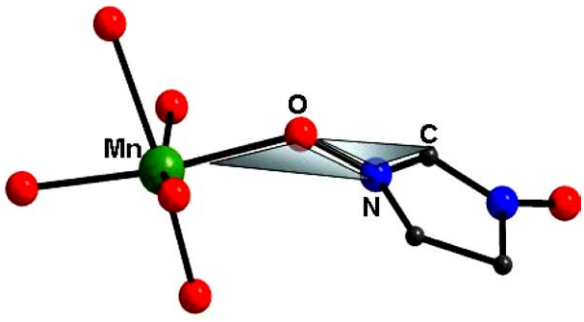

Fig. 3. Torsion angle (triangles) between the plane of the C, N, and O atoms of the ·O–N–C=N → O fragment and the plane of N, O, and Mn atoms.

effect of the H atom differs substantially from that of the CH_3 group. Moreover, the donor ability of the O atoms of the nitronyl nitroxide fragment of NIT-H is much weaker than that of NIT-Me.

Thus the bridging function of the nitronyl nitroxide fragment between the $[Mn_6O_2(piv)_{10}]$ units was realized for NIT-Me but not for NIT-H and NIT-Et. To obtain highly dimensional structures with bridging NIT-R ($R = C_nH_{2n+1}$, $n > 1$) it is reasonable to employ polymetallic nuclei whose carboxylate ligands contain less bulky substituents compared to $-C(CH_3)_3$ to provide high solubility of the polymetallic nucleus in organic solvents.

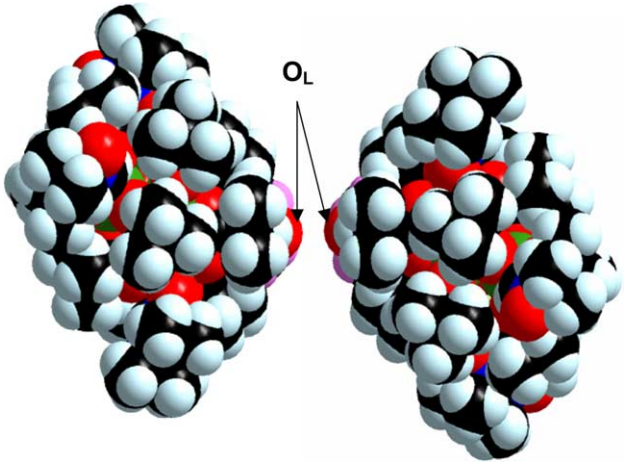

Fig. 4. $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]$ fragments facing each other by their NIT-H molecules, the arrangement that permits linkage into a bridge by the counter-motion.

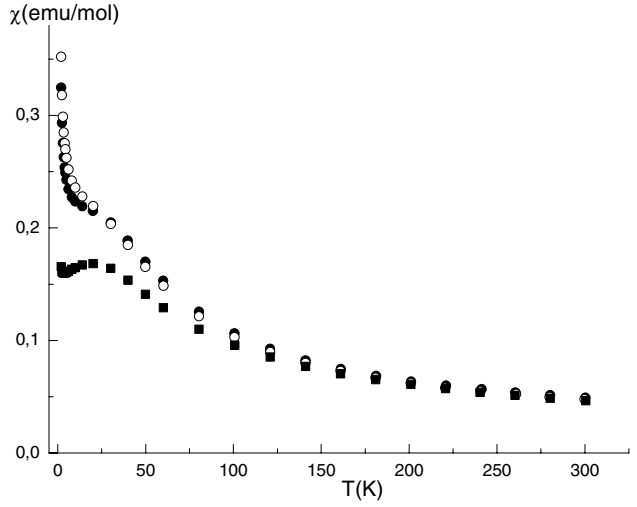

Fig. 7. Temperature dependences of magnetic susceptibility (χ) for $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$ (●), $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv] \cdot 0.5C_7H_{16}$ (○) and $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]0.5CH_2Cl_2$ (■).

3.3. Magnetic properties

The magnetic properties of the compounds are illustrated by the temperature dependence of the molar magnetic susceptibility (Figs. 5–8). For $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ and $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$, having no paramagnetic ligands (Fig. 5), the $\chi(T)$ curve shows a broad maximum, which points to antiferromagnetic interaction in $[Mn_6(O)_2Piv_{10}]$ exchange clusters. Above the temperature of the maximum, the curve obeys the Curie–Weiss law with the constants listed in Table 2. The magnetic properties of hexanuclear carboxylates of $[Mn_6(O)_2(RCOO)_{10}(L)_4]$ type, where L is a monodentate

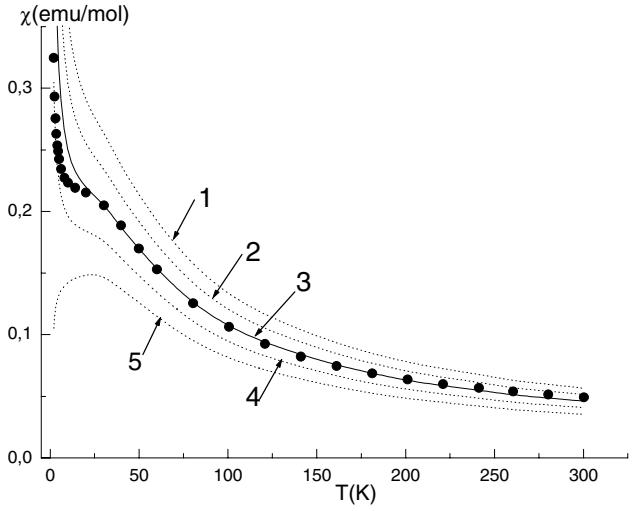

Fig. 8. Experimental temperature dependence of magnetic susceptibility (χ) for $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$ (•) and theoretical curves for different cases described in the text.

diamagnetic ligand (Py, EtOH, CH_3CN) exhibiting spin frustration, are well documented [4]. Based on the results of these studies, one would expect that at high temperatures the effective magnetic moment (μ_{ef}) of $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ and $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$ will tend to the theoretical values of 12.0 and 17.1μ_B, respectively. It was assumed that in the $[Mn_6(O)_2Piv_{10}]$ cluster unit, the moments of the two internal Mn(III) ions lying at very short distances of ~2.8 Å fully compensate each other as a result of a strong antiferromagnetic interaction [3c,4a,4b]. Indeed, the experimental values of μ_{eff} for these compounds tend to approach these values at 300 K (Table 2).

It is assumed that there is a strong antiferromagnetic exchange between the internal Mn(III) ions, leading to complete spin coupling between the two ions. Then the magnetic moments of the complexes (including complexes with nitroxides) are evaluated by the formula $\mu_{calc}{}^2 = 4(\mu_{MnII})^2 + n_R(\mu_R)2$, where μ_{MnII} is the magnetic moment of the high-spin Mn(II) ion, μ_R is the magnetic moment of the nitroxide, and n_R is the number of radicals in the molecule. Fig. 6 presents data for $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]\cdot 0.5C_6H_{14}$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]\cdot C_6H_{14}$, in which the nitronyl nitroxide fragment is not coordinated and is far from the $[Mn_6(O)_2Piv_{10}]$ unit (Schemes 2 and 3). The $\chi(T)$ curves contain a kink in the region of the maximum for clusters having no radicals (Fig. 5). To evaluate the coupling between the odd electrons of the terminal Mn(II) atoms and the radicals, we use the curve (solid line in Fig. 6) obtained as the sum of the magnetic susceptibility of the hexanuclear $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$ cluster and four independent susceptibilities of NIT-*p*-Py: $\chi_{clust\,+\,4R} = \chi_{clust} + 4(0.375/T)$. As can be seen from Fig. 6, the dependence thus obtained (solid line) reproduces the experimental data well, indicating that there is weak exchange between the Mn(II) ions and the nitroxides via the pyridine ring. Good agreement between the experimental and calculated effective magnetic moments also follows from Table 2.

The most interesting results were obtained for $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]\cdot 0.5CH_2Cl_2$. As the magnetic properties of these compounds are similar (Fig. 7), the $\chi(T)$ dependence is discussed for $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$ alone (Fig. 8). Fig. 8 shows five calculated curves for cases when (1) the terminal Mn(II) ions do not interact with all coordinated nitroxides (dotted curve 1); (2) the spin of one of the nitroxides is completely coupled to one of the electrons of the coordinating Mn(II) ion (dotted curve 2); (3) the spins of two nitroxides are completely coupled to the electrons of two Mn(II) ions (solid line 3); (4) the spins of the three nitroxides are completely coupled to the electrons of the three Mn(II) ions (dotted curve 4); and (5) the spin of each of the four coordinated nitroxides cancels the moment of one of the five odd electrons on each of the four terminal Mn(II) ions (dotted curve 5). As can be seen in Fig. 8, solid line 3 is the only curve that reproduces the experimental data well. In the low-temperature range, it slightly deflects from the experimental values due to the neglect of weak inter- and intramolecular interactions. If these interactions are taken into account by Weiss constant −3.5 K, then in the low-temperature region we also achieve good agreement with the experimental data. Thus analysis of the $\chi(T)$ dependence for

Table 2
Magnetic characteristics of the compounds

Compound	C (emu K mol^{-1})	$-\theta$ (K)	$\mu_{eff} = \sqrt{8C}/\mu_B$	μ_{calc}/μ_B
$[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4]\cdot 0.5CH_2Cl_2$	17.76	88	11.9	12.3
$[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv]\cdot 0.5C_7H_{16}$	17.29	72	11.8	12.2
$[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$	17.87	73	12.0	12.3
$[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$	17.97	48	12.0	11.8
$[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac\text{–}Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$	36.47	42	17.1	16.7
$[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$	18.56	37	12.2	12.3
$[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]\cdot 0.5C_6H_{14}$	19.06	30	12.4	12.3
$[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]\cdot C_6H_{14}$	19.16	41	12.4	12.1

$[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$ unambiguously showed that the odd electrons of the two coordinated NIT-Et are completely coupled to one of the electrons of the two coordinating Mn(II) ions, while the odd electrons of the other two coordinated NIT-Et interact very weakly with the odd electrons of the other two Mn(II) ions. The results of structural analysis indicated that the magnetic data completely correlate with structural data for the compound. Indeed, in $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$, the $Mn–O_{NO}$ distances of two nitroxides are much shorter than those of the other two (2.221 and 2.275 Å, Table 1). As would be expected, extension of the $Mn–O_{NO}$ bond by ~0.055 Å drastically weakens exchange interactions in {Mn–'O–N<} exchange clusters. The strong antiferromagnetic interactions between the odd electrons of Mn(II) and the nitroxides lying at short distances (~2.2 Å) lead to larger values of θ for $[Mn_6Piv_{10}(O)_2(NIT\text{-}Et)_4]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv] \cdot 0.5C_7H_{16}$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4] \cdot 0.5CH_2Cl_2$ compared to other compounds under study (Table 2).

4. Supplementary material

Crystal data for the structural analysis for $[Mn_6(O)_2Piv_{10}(NIT\text{-}H)_4] \cdot 0.5CH_2Cl_2$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_3HPiv] \cdot 0.5C_7H_{16}$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}Et)_4]$, $[(EtOAc)_3Mn_6(O)_2Piv_{10}(Ac–Ac)Mn_6(O)_2Piv_{10}(EtOAc)_3]$, $[Mn_6(O)_2Piv_{10}(Me_2CO)_2(H_2O)]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_4] \cdot 0.5C_7H_{16}$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}p\text{-}Py)_2(H_2O)]$, $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)_2(HPiv)_2]$, and $[Mn_6(O)_2Piv_{10}(NIT\text{-}n\text{-}Bu\text{-}Pz)(Thf)\ (H_2O)] \cdot C_6H_{14}$ have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 250482, 250483, 250487-250493, and 250752. Fig. 1. Polymer chain with a 'head-to-head' motif in $Cu(hfac)_2L^{Et}$.

Mn and Co (or Ni) for M because Mn is suitable to replace the Cu atoms in the CuO_6 coordination units of $Cu(hfac)_2L^{Et}$ polymer chains, while Co (or Ni) conveniently replaces the Cu atoms in the CuO_4N_2 units (Fig. 1). We succeeded in synthesizing solid solutions, whose structure and magnetic properties are described here along with their synthesis.

2. Experimental

2.1. Synthesis

All the solvents were commercially available and used as received. Nitronyl nitroxide 4,4,5,5-tetramethyl-2-(1′-ethyl-pyrazole-4′-yl)-4,5-dihydro-1*H*-imidazolyl-3-oxide-1-oxyl (L^{Et}) and $Cu(hfac)_2L^{Et}$ were prepared by the procedure of [6].

2.1.1. $Mn(hfac)_2L^{Et}$

A sample of $Mn(hfac)_2 \cdot 2H_2O$ (101 mg, 20 mmol) was dissolved in diethyl ether (3 ml). The solution was added through a filter to a solution of L^{Et} (50 mg, 20 mmol) in diethyl ether (2 ml). Hexane (15 ml) was added to the resulting mixture, and the mixture was allowed to stay in an open flask at 5 °C for 1 or 2 days. After approximately one half of the mother solution had evaporated, the greenish blue crystals were filtered off, washed with hexane, and dried in air. The complex is readily soluble in diethyl ether, THF, and acetone, but practically insoluble in benzene and saturated hydrocarbons. Yield 83%. *Anal.* Calc. for $MnC_{22}H_{21}N_4O_6F_{12}$: C, 36.7; H, 2.9; N, 7.8; F, 31.7. Found: C, 36.7; H, 2.8; N, 7.4; F, 31.2%.

2.1.2. $Ni(hfac)_2L^{Et}$ and $Co(hfac)_2L^{Et}$

The complexes were prepared by a similar procedure using THF instead of diethyl ether and heptane instead of hexane. The complexes separated as conglomerates of finely disperse, dark indigo blue crystals. They are well soluble in acetone, sparingly soluble in THF, and practically insoluble in benzene and saturated hydrocarbons. Yield 80–85%. *Anal.* Calc. for $NiC_{22}H_{21}N_4O_6F_{12}$: C, 36.5; H, 2.9; N, 7.8; F, 31.5. Found: C, 36.8; H, 2.9; N, 7.7; F, 31.4%. *Anal.* Calc. for $CoC_{22}H_{21}N_4O_6F_{12}$: C, 36.5; H, 2.9; N, 7.7; F, 31.5%. Found: C, 36.3; H, 3.0; N, 7.4; F, 31.3.%. $Co(hfac)_2L^{Et}$ single crystals were obtained as follows. $Co(hfac)_2 \cdot 2H_2O$ (101 mg, 20 mmol) and L^{Et} (50 mg, 20 mmol) were dissolved in acetone (5 ml), and hexane (10 ml) was added. The reaction mixture was heated to boiling while intermittently shaking the flask. Thin plates of dark indigo blue crystals formed after a while in the hot solution. The crystals were filtered off and washed with hexane. Yield 30%.

2.1.3. $Mn_xCu_{1-x}(hfac)_2L^{Et}$

A mixture of $Cu(hfac)_2L^{Et}$ and $Mn(hfac)_2L^{Et}$ or $Cu(hfac)_2$ and $Mn(hfac)_2$ with L^{Et}, in which the mole fraction $x = \nu_{Mn}/(\nu_{Mn} + \nu_{Cu})$ was varied from 0.10 to 0.45 (the total mass of the sample was 150 ± 1 mg), was dissolved in a mixture of acetone (2 ml) and CH_2Cl_2 (4 ml). Then hexane (8 ml) was added. The resulting solutions were allowed to slowly evaporate at 5 °C. After 5 days, the crystals of $Mn_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions were filtered off, washed with hexane, dried in air, and used for magnetic measurements and XRD analysis. Yields were 50–70%.

2.1.4. $Co_xCu_{1-x}(hfac)_2L^{Et}$

A mixture of $Cu(hfac)_2L^{Et}$ and $Co(hfac)_2L^{Et}$ or $Cu(hfac)_2$ and $Co(hfac)_2$ with L^{Et}, in which the mole fraction $x = \nu_{Co}/(\nu_{Co} + \nu_{Cu})$ was varied from 0.02 to 0.12 (the total mass of the sample was 150 ± 1 mg), was dissolved in acetone (2 ml). Then hexane (10 ml) was added. The resulting solutions were allowed to slowly evaporate at 5 °C. After 3 or 4 days, the crystals of $Co_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions were filtered off, washed with hexane, dried in air, and used for magnetic measurements and XRD analysis. Yields were 45–70%.

2.1.5. $Ni_xCu_{1-x}(hfac)_2L^{Et}$

A mixture of $Cu(hfac)_2L^{Et}$ and $Ni(hfac)_2L^{Et}$ or $Cu(hfac)_2$ and $Ni(hfac)_2$ with L^{Et}, where the mole fraction $x = \nu_{Ni}/(\nu_{Ni} + \nu_{Cu})$ was varied from 0.02 to 0.12 (the total mass of the sample was 150 ± 1 mg), was dissolved in a mixture of acetone (1.5 ml) and CH_2Cl_2 (2 ml). Then hexane (10 ml) was added. The resulting solutions were allowed to slowly evaporate at 5 °C. After 4 or 5 days, the crystals of $Ni_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions were filtered off, washed with hexane, dried in air, and used for magnetic measurements and XRD analysis. Yields were 45–75%.

2.2. Metal determination

Samples of $Mn_xCu_{1-x}(hfac)_2L^{Et}$, $Co_xCu_{1-x}(hfac)_2L^{Et}$, and $Ni_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions were dissolved in ethanol. Metal determination for these mixed-metal samples was carried out by the atomic

absorption technique (with atomization in air-acetylene flame on a Hitachi Z-8000 atomic absorption spectrophotometer) using the calibrating curves preliminarily obtained for ethanolic solutions of $Cu(hfac)_2L^{Et}$ and $M(hfac)_2L^{Et}$ with known concentrations of M and Cu.

2.3. X-ray crystallography

The intensity data for the single crystals of the compounds were collected on a SMART APEX (Bruker AXS) automatic diffractometer using the standard procedure (Mo radiation). The structures were solved by direct methods and refined by the full-matrix least-squares procedure anisotropically for non-hydrogen atoms and isotropically for hydrogens. The H atoms were located in difference electron density syntheses. All calculations were fulfilled with the SHELXTL program package. The crystal data are given in Tables 6–8.

2.4. Magnetic measurements

All measurements were carried out on an MPMS-5S SQUID magnetometer (Quantum Design) in the temperature range 2–300 K and on Faraday balance in the temperature range 77–300 K with a magnetic field of up to 5 kOe. Molar magnetic susceptibility was calculated using diamagnetic corrections for the complexes.

3. Results and discussion

Investigation of the dynamics of CuO_6 and CuO_4N_2 coordination units in the region of the phase transition of the $Cu(hfac)_2L^{Et}$ single crystal indicated that the Cu–O_L and Cu–N distances in the crystallographically independent centrosymmetric CuO_6 and CuO_4N_2 units are shortened when the temperature decreases from

295 to 221 K (Table 1). As the temperature decreases further from 218 to 115 K, the Cu–N distances are shortened from 2.133(2) to 2.055(4) Å, while the Cu–O_L distances are lengthened from 2.242(2) to 2.281(3) Å. The changes in the Cu–O_L and Cu–N distances are generally nonlinear, the maximum of the derivatives $\partial d_{Cu-OL}/\partial T$ and $\partial d_{Cu-N}/\partial T$ lying in the temperature range adjacent to 220 K (Fig. 2), i.e., in the region of the magnetic anomaly.

According to XRD data, $Mn(hfac)_2L^{Et}$ and $Co(hfac)_2L^{Et}$ proved to be isostructural with $Cu(hfac)_2L^{Et}$. Like $Cu(hfac)_2L^{Et}$, they have a polymer chain structure with a "head-to-head" motif of the chain, resulting from bridging coordination of L^{Et} via the imine N atom of the pyrazole ring and one of the O atoms of the nitronyl nitroxide fragment (Fig. 1). The chain has centrosymmetric coordination units of two types – MO_6 and MO_4N_2. While in the Cu(II) complex the Cu(II) Jahn-Teller ions are surrounded by a square bipyramid, in the Mn(II) and Co(II) complexes the coordination polyhedron is nearly isometric. The M–O_L distances in MO_6 coordination units (at room temperature) are 2.075(3)–2.156(2) Å (Table 2), and the M–N distances in MO_4N_2 units are 2.174(4)–2.299(2) Å; the M–O_{hfac} distance to the O atom of the hexafluoroacetylacetonate ligand is ~2.1 Å. In the Mn(II) and Co(II) complexes, the M–O_L and M–N distances change insignificantly at reduced temperatures. When solid $Mn(hfac)_2L^{Et}$ and $Co(hfac)_2L^{Et}$ are cooled, the MO_6 and MO_4N_2 units are uniformly compressed, with M–O_L and M–N distances decreasing by no more than 0.025 Å (Table 2). We failed to grow X-ray quality $Ni(hfac)_2L^{Et}$ single crystals. According to X-ray powder diffraction patterns, $Ni(hfac)_2L^{Et}$ is isostructural with $Co(hfac)_2L^{Et}$.

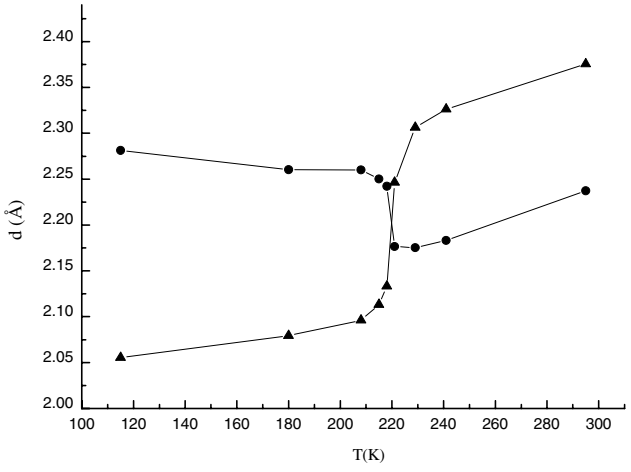

Fig. 2. Variation of Cu–O_L (●) and Cu–N (▲) bond lengths in CuO_6 and CuO_4N_2 coordination units, respectively.

The dependences $\mu_{eff}(T)$ for $M(hfac)_2L^{Et}$ (M = Mn, Co, Ni) are very similar. Fig. 3 shows the experimental dependence $\mu_{eff}(T)$ and the theoretical curve for $Mn(hfac)_2L^{Et}$ as an example. The theoretical curve corresponds to the optimal parameters $g_M = 2.0$, $J/k = -110$ K, $J'z/k = -0.017$ K of the spin Hamiltonian $\hat{H} = -2J(\hat{s}_{NO}\hat{s}_M + \hat{s}_M\hat{s}_{NO}) - \beta(2g_M\hat{s}M + 2g_{NO}\hat{s}_{NO})H - 2J'z\hat{S}\langle\hat{S}\rangle$ that includes spin coupling in the exchange cluster, Zeeman interaction, and weak interchain and intercluster interactions. Due to the strong antiferromagnetic interactions in $\gtrdot$N–·O–Mn^{2+}–O·–N$\lessdot$ exchange clusters, the spins of the coordinated $\gtrdot$N–·O groups are completely coupled to the two spins of Mn^{2+} at $T < 140$ K. Below this temperature, magnetic susceptibility has contributions only from the residual moments of these exchange clusters ($s = 3/2$) and the moments of the Mn^{2+} ions located in MnO_4N_2 coordination units ($s = 5/2$). Therefore, the dependence $\mu_{eff}(T)$ calculated for the $\{Mn(hfac)_2L^{Et}\}$ fragment tends to the theoretical

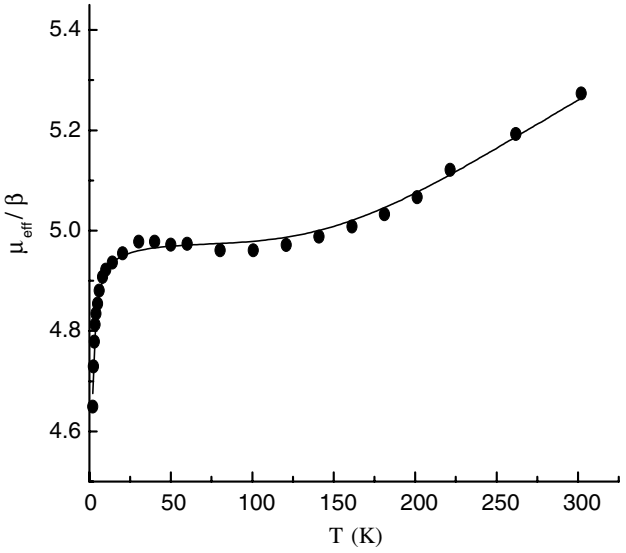

Fig. 3. Dependence $\mu_{eff}(T)$ for $Mn(hfac)_2L^{Et}$.

value of $\mu = \sqrt{0.5 \times 15 + 0.5 \times 35} = 5\beta$. Further decrease in μ_{eff} at $T < 10$ is explained by the weak interchain and intercluster interactions.

For solid $Mn(hfac)_2L^{Et}$, $Co(hfac)_2L^{Et}$, and $Ni(hfac)_2L^{Et}$, the $\mu_{eff}(T)$ curves did not show any anomalies; the character of the curves suggests that there are strong antiferromagnetic exchange interactions in $\gtrdot$N–·O–M(II)–O·–N$\lessdot$ exchange clusters. For $Cu(hfac)_2L^{Et}$, however, the $\mu_{eff}(T)$ curve showed that at 220 K μ_{eff} increased dramatically, and antiferromagnetic exchange interactions changed to ferromagnetic (Fig. 5(a), $x = 0$). At room temperature the value of μ_{eff} is close to the theoretical value of 2.45β for a system of almost uncoupled spins of Cu(II) and nitroxide as calculated for the $\{Cu(hfac)_2L^{Et}\}$ fragment. When the complex is cooled from room temperature to ~225 K, the value of μ_{eff} gradually decreases to $\sim 2.4\beta$ because in the temperature range 225–300 K, antiferromagnetic interactions dominate in the $\gtrdot$N–·O–Cu(II)–O·–N$\lessdot$ exchange clusters of $Cu(hfac)_2L^{Et}$ in view of the short Cu–O_L axial distance (2.237 Å) in the octahedral CuO_6 units [6,8]. Below the transition temperature, the Cu–O_L distances are lengthened (Table 1), and ferromagnetic interactions start to dominate in $\gtrdot$N–·O–Cu(II)–O·–N$\lessdot$ exchange clusters so that μ_{eff} increases until the temperature has reached ~25 K. A detailed description of this unusual spin transition and evaluation of exchange integrals for the high- ($J/k = -121$ K) and low-temperature regions ($J/k = 41.7$ K) are given elsewhere [6,8]. Below this temperature, μ_{eff} quickly decreases because of antiferromagnetic intermolecular exchange interactions.

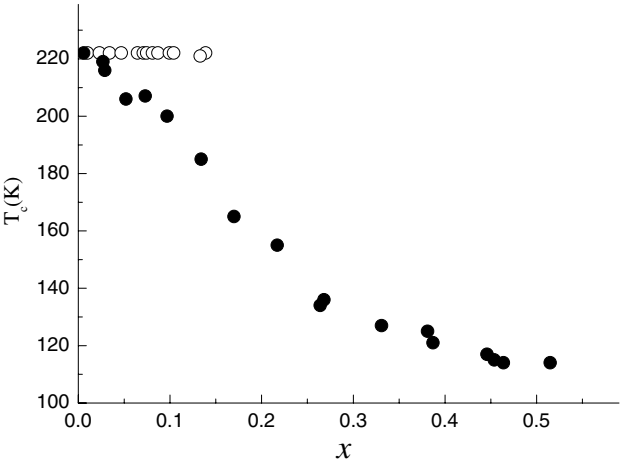

Fig. 4. Dependence of the transition temperature on the composition of $Mn_xCu_{1-x}(hfac)_2L^{Et}$ (●) and $Ni_xCu_{1-x}(hfac)_2L^{Et}$ (○) solid solutions.

The isostructural character of $M(hfac)_2L^{Et}$, where M = Cu, Mn, Co, Ni, is a favorable factor for the formation of $M_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions. Note that $Mn_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions obtained as described in Experimental generally separated as perfect single crystals irrespective of the mole fraction $x = \nu_M/(\nu_M + \nu_{Cu})$ of the second metal in the starting reaction mixture. The quality of $Co_xCu_{1-x}(hfac)_2L^{Et}$ and $Ni_xCu_{1-x}(hfac)_2L^{Et}$ crystals deteriorated markedly when x increased to 0.5. Also note that all solid solution crystals grew in kinetic but not thermodynamic equilibrium conditions because they formed in the course of gradual evaporation of the solvent from the mother solution. Nevertheless, when repeated in similar conditions for systems with different total samples of the starting compounds and different solvent mixtures, experiments gave well reproducible results.

As mentioned above, when choosing the second metal (M) we assumed that Mn will replace Cu atoms in the CuO_6 units of $Cu(hfac)_2L^{Et}$ polymer chains, while Co (or Ni) will substitute Cu atoms in the CuO_4N_2 units (Fig. 1). X-ray diffraction analysis for $M_xCu_{1-x}(hfac)_2L^{Et}$ confirmed this assumption. Tables 3 and 4 illustrate how M–O_L and M–N bond lengths change in series of $M_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions. For $Mn_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions, the M–O_L distances of the MO_6 units decrease when the mole fraction of Mn increases, while the M–N distances of the MO_4N_2 units remain the same as in pure $Cu(hfac)_2L^{Et}$ (2.375 Å). The reverse is true for $Co_xCu_{1-x}(hfac)_2L^{Et}$. As the mole fraction of Co increases, the M–N distances of the MO_4N_2 units are gradually shortened due to the incorporation of Co(II) ions. In the MO_6 units, the M–O_L bond lengths remain unchanged.

The magnetic properties of the solid solutions also change differently when a second metal is incorporated in different coordination units. In $Mn_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions, the transition temperature decreases monotonously from 220 to 115 K when x increases from 0 to ~0.5. When $x > 0.5$, the transition is completely suppressed by the incorporated manganese (Fig. 4).

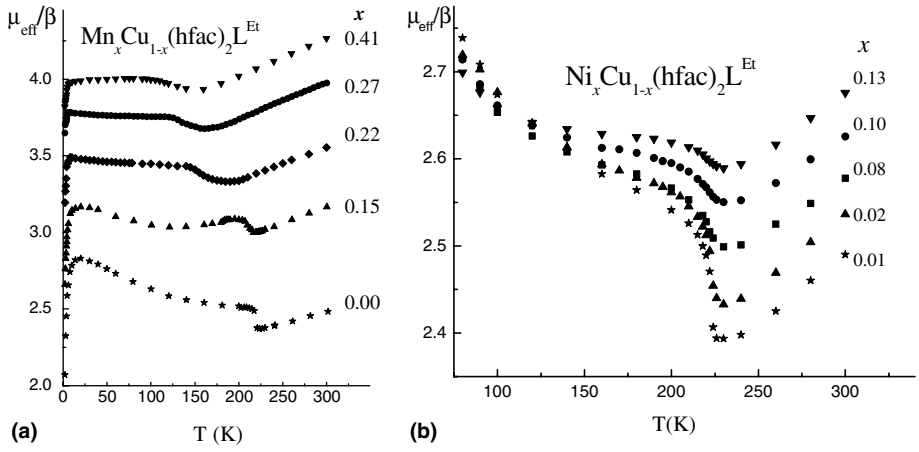

Fig. 5. Dependences $\mu_{eff}(T, x)$ for $Mn_xCu_{1-x}(hfac)_2L^{Et}$ (a) and $Ni_xCu_{1-x}(hfac)_2L^{Et}$ (b).

For $Ni_xCu_{1-x}(hfac)_2L^{Et}$, substitution of Cu(II) ions does not affect the transition temperature until x becomes ~0.2 (Fig. 4), but in the range $0.20 < x < 0.25$, the transition is suppressed.

Fig. 5 shows selected experimental dependences $\mu_{eff}(T)$ for mixed-metal solid solutions with different values of x. As Cu(II) ions are replaced by Mn(II) ions in the series of $Mn_xCu_{1-x}(hfac)_2L^{Et}$ solid solutions, the transition occurs at lower temperatures and becomes more diffuse (Fig. 5(a)). That is, incorporation of Mn in the chains leads to increased "rigidity" of MO_6 units and of the crystal in general. Therefore, more profound cooling is needed to achieve a transition through rearrangement of the remaining CuO_6 coordination units containing $\gtrdot$N–˙O–Cu(II)–O˙–N$\lessdot$ exchange clusters. This is supported, for example, by crystal structure investigations of the $Mn_{0.22}Cu_{0.78}(hfac)_2L^{Et}$ solid solution at different temperatures. It appeared that the M-O_L distances in the MO_6 polyhedra increase only at $T < 140$ K (Table 5). Therefore, cooling the crystal to low temperatures is needed to achieve rearrangement of the remaining CuO_6 coordination units containing $\gtrdot$N–˙O–Cu(II)–O˙–N$\lessdot$ exchange clusters. This completely agrees with magnetochemical experimental data (Fig. 5). When $x = 0.41$ (Fig. 5(a)), i.e., in situations when the MO_6 units are completely occupied by manganese, the transition is barely visible; μ_{eff} does not increase with decreasing temperature because this behavior of $\mu_{eff}(T)$ is not inherent in $Mn(hfac)_2L^{Et}$ (Fig. 3).

For $Ni_xCu_{1-x}(hfac)_2L^{Et}$ and $Co_xCu_{1-x}(hfac)_2L^{Et}$ solutions, the dependence $\mu_{eff}(T)$ behaves differently when x increases than it does in the same case for $Mn_xCu_{1-x}(hfac)_2L^{Et}$. For $Ni_xCu_{1-x}(hfac)_2L^{Et}$ (as well as $Co_xCu_{1-x}(hfac)_2L^{Et}$) solutions with low values of $x = 0.15$, the transition temperature does not change (Figs. 4 and 5(b)), but at higher values of x, the transition is suppressed. Unlike Mn ions, Ni (or Co) ions enter the MO_4N_2 units without changing the CuO_6 units, whose dynamics is just responsible for the magnetic effect. On the other hand, because of the similarity between the ionic radii of Ni(II) (or Co(II)) and Cu(II), minor additions of Ni(II) (or Co(II)) to the MO_4N_2 units ($x = 0.15$) do not markedly perturb the structure of $Cu(hfac)_2L^{Et}$ in general, and the temperature of the magnetic anomaly remains unaltered. However, at certain critical values of $x > 0.2$, the Ni(II) (or Co(II)) ions, not possessing the Jahn-Teller nature, start to hinder the shortening of M–N distances in the MO_4N_2 units, thereby indirectly violating the dynamics of CuO_6 coordination units. This is supported by the observed lengthening of Cu–O_L distances in $\gtrdot$N–˙O–Cu(II)–O˙–N$\lessdot$ exchange clusters with concomitant pronounced shortening of M–N distances in the MO_4N_2 units of $Ni_{0.08}Cu_{0.92}(hfac)_2L^{Et}$ (Table 5). When the motion of NiO_4N_2 (or CoO_4N_2) units is no longer possible ($x > 0.2$), the dynamics of the CuO_6 units responsible for the magnetic anomaly is also suppressed. For $x < 0.2$, however, the character of the structural motions of CuO_6 and MO_4N_2 units in the region of the phase transition does not change.

Thus we have synthesized new compounds, $M_xCu_{1-x}(hfac)_2L^{Et}$, from the class of heterospin systems liable to undergo thermally induced spin transitions. By varying the metal and the value of x one can alter the temperature of the magnetic anomaly and its character.

4. Supplementary material

Crystal data for structural analysis of the investigated compounds have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 250780–250810. Copies of this information may be obtained free of charge from The Director, CCDC,

$M(NO_3)_2$, M = Mn^{II}, **1**; Co^{II}, **2**; Ni^{II}, **3**; Cu^{II}, **4**, with **4NOPy-OMe** and their magnetic properties were investigated by X-ray structure analysis and SQUID magneto/susceptometry, respectively.

4NOPy **4NOPy-OMe**

2. Experimental

2.1. General

Melting points were recorded with a MEL-TEMP heating block and were uncorrected. Elemental analysis was performed in the analytical center of Kyushu University.

2.2. X-ray crystal and molecular structure analyses

Crystallographic data and experimental details for the complexes **1**–**4** are summarized in Table 1. The selected suitable single crystals were glued on a glass fiber by epoxy resin. All the X-ray data were collected on a Rigaku Raxis-Rapid diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). Reflections were collected at 123 ± 1 K for complex **1** and **2**, and 296 ± 1 K for **3** and **4**, respectively. The structures were solved by direct methods (SIR92) [6] and expanded using Fourier techniques (DIRDIF94) [7]. The refinements were converged using the full-matrix least-squares method of Crystal Structure software package [8] to give space group as *Pbcn*, for the complexes. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were found by standard method or from differential electron map and refined isotropically.

2.3. Measurements and analyses of magnetic properties

Magnetic susceptibility data were obtained on Quantum Design MPMS2 and MPMS5S SQUID susceptometer and corrected for the magnetization of the sample holder and capsule. The diamagnetic contributions to the samples were estimated from Pascal's constants [9].

2.4. Preparation

Pyridine ligand, **4NOPy-OMe**, was prepared by the procedure reported in the literature [4]. The solution of **4NOPy-OMe** in ether (ca. 0.05 M) was used for the complexation with metal ion immediately after the preparation without further purification. Hydrated metal nitrate was used as received.

2.4.1. $Mn(NO_3)_2$(**4NOPy-OMe**)$_2$ (**1**)

To a solution of $Mn(NO_3)_2 \cdot (H_2O)_6$ (141 mg, 0.49 mmol) in acetonitrile (30 ml) was added **4NOPy-OMe** ethereal solution (1.05 mmol). The mixture was evaporated to 10 ml and filtered. On the red solution of the filtrate in test tube, ether was load slowly and carefully without disturb. After keeping in a refrigerator for several days, orange prism single crystal was collected by filtration. Yield: 36 mg (12.3%), m.p., 145–8 °C (decomp.). *Anal.* Calc. for $MnC_{22}H_{34}N_6O_{10}$: C, 44.23; H, 5.74; N, 14.07. Found: C, 44.01; H, 5.78; N, 13.94%.

2.4.2. $Co(NO_3)_2$(**4NOPy-OMe**)$_2$ (**2**)

To a solution of $Co(NO_3)_2 \cdot (H_2O)_6$ (52 mg, 0.18 mmol) in acetonitrile (2 ml), **4NOPy-OMe** (0.4 mmol) in ether (20 ml) was added. The mixture was kept at −30 °C for several days. Dark orange cubic crystals appeared and were filtered off. Yield: 26 mg (24.2%), m.p. 147–52 °C (decomp.). *Anal*. Calc. for $CoC_{22}H_{34}N_6O_{10}$: C, 43.93; H, 5.70; N, 13.97. Found: C, 43.63; H, 5.72; N, 14.01%.

2.4.3. $Ni(NO_3)_2$(**4NOPy-OMe**)$_2$ (**3**)

On a solution of $Ni(NO_3)_2 \cdot (H_2O)_6$ (65 mg, 0.22 mmol) in acetonitrile (2 ml), ethereal solution of **4NOPy-OMe** (10 ml, 0.5 mmol) was loaded slowly. The mixture was kept untouched in refrigerator for one day. Pale brownish green scale crystal appeared and the solvent was removed by a pipette carefully. The remained single crystal was washed by ether and dried under the atmosphere. Yield: 14 mg (11.0%). m.p. 152–8 °C (decomp.). *Anal*. Calc. for $NiC_{22}H_{34}N_6O_{10}$, C, 43.95; H, 5.70; N, 13.98. Found: C, 43.91; H, 5.66; N, 13.63%.

2.4.4. $Cu(NO_3)_2$(**4NOPy-OMe**)$_2$ (**4**)

The copper complex **4** was prepared by the procedure similar to the one for the nickel complex **3** using $Cu(NO_3)_2 \cdot (H_2O)_3$ in place with $Ni(NO_3)_2 \cdot (H_2O)_6$. Brownish green scale crystal was collected by filtration. Yield: 35 mg (31.7%). m.p. 155–61 °C (decomp.). *Anal*. Calc. for $CuC_{22}H_{34}N_6O_{10}$: C, 43.60; H, 5.65; N, 13.87. Found: C, 43.33; H, 5.62; N, 13.86%.

3. Results and discussion

3.1. X-ray crystal and molecular structures

The single crystals for the complexes, **1**–**4** were isolated successfully and were stable under the atmosphere condition.

Four complexes, **1**–**4** are isostructural with space group *Pbcn* (#60) and $Z = 4$. Each complex has a C_2 axis through metal ion and the coordination geometry is a distorted octahedral. The metal ion is surrounded by two methoxy oxygen atoms, two pyridine nitrogen atoms, and two (or four) nitrate oxygen atoms in which the first ligands, and the second and third ones coordinate in *trans*- and *cis*-configurations, respectively. In the complexes **4**, large disorders of the coordination of nitrates are observed. ORTEP drawing of the molecular structure for the cobalt complex **2** is shown in Fig. 1.

The bond lengths of M–N(pyridine) are 2.258 Å (Mn–N), 2.075 Å (Co–N), 2.061 Å (Ni–N) and 2.021 Å (Cu–N), respectively. The bond lengths of M–O2 (methoxy); 2.381, 2.208, 2.117 and 2.464 Å for **1**–**4**, respectively, are long, compared with the ones for M–N(pyridine), indicating that methoxy oxygen atoms

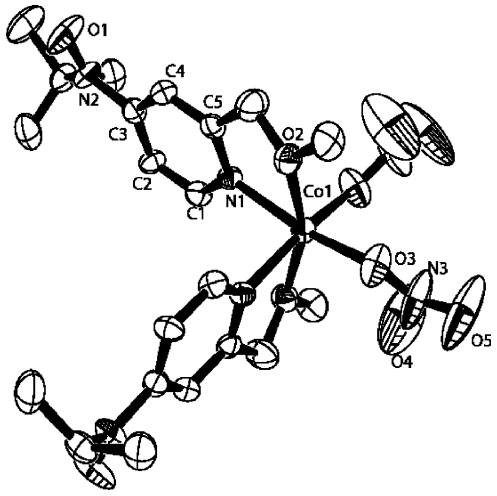

Fig. 1. ORTEP drawing of the molecular structures for **2** showing 50% probabilities ellipsoids, hydrogen atoms are omitted for clarity.

coordinate to metal ions weakly. In four complexes, the bond angles of O2–M–O2′, which are the longest bond axes, are strongly distorted; 147.01°, 160.89°, 157.97°, and 163.78° for **1**, **2**, **3** and **4**, respectively. The dihedral angles between radical moiety (defined as the plane O1N2C3) and pyridine plane (defined as the plane C1C3C5) are found to be 15.21°, 15.07°, 18.54°, and 14.46° for **1**, **2**, **3** and **4**, respectively. From these small dihedral angles, the significant magnetic exchange coupling between the metal ion and aminoxyl centers would be expected to take place in the complexes. Selected bond lengths, bond angles, and dihedral angles are given in Table 2. In crystal packing for four complexes, no short contacts within 4 Å between neighboring molecules were observed.

3.2. Magnetic properties of $M(NO_3)_2$ (**4NOPy-OMe**)$_2$, *M = Mn, **1**; Co, **2**; Ni, **3**; Cu, **4***

The pulverized crystals of all complexes were used as the samples. Temperature dependences of the molar

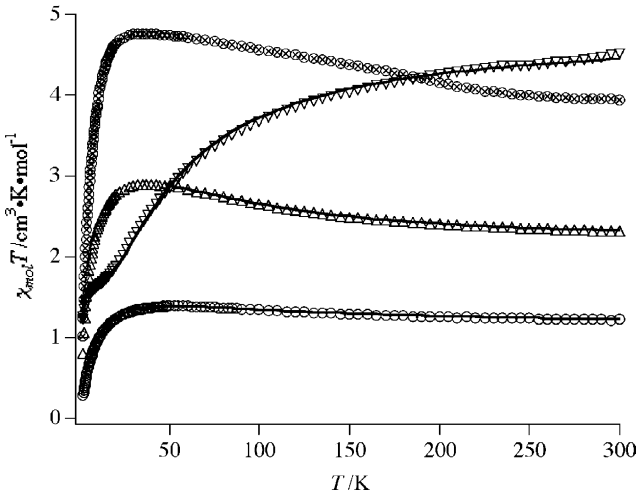

Fig. 2. Temperature dependence of molar susceptibilities as expressed by $\chi_{mol}T$ vs. T plots for complex **1** (▽), **2** (⊗), **3** (△), **4** (○). The solid curves are theoretical ones as described in the text.

paramagnetic susceptibilities χ_{mol} for all complexes were measured at the constant field of 5 kOe in the temperature range of 2–300 K. The $\chi_{mol}T$ versus T plot for four complexes is shown in Fig. 2.

3.2.1. $Mn(NO_3)_2$(*4NOPy-OMe*)$_2$ (*1*)

As the temperature was lowered, the $\chi_{mol}T$ value gradually decreased, reaching a plateau of 1.75 $cm^3\,K\,mol^{-1}$ at ca. 10 K, and then abruptly decreased (1.14 $cm^3\,K\,mol^{-1}$ at 2 K). The $\chi_{mol}T$ value of complex **1** at 300 K was 4.35 $cm^3\,K\,mol^{-1}$, which was slightly smaller than the theoretical one ($\chi_{mol}T = 5.13$ $cm^3\,K\,mol^{-1}$) calculated for isolated two radicals ($S = 1/2$) and Mn(II) ion ($S = 5/2$). Observed thermal profile of $\chi_{mol}T$ values is a typical antiferromagnetic behavior, indicating that the magnetic coupling between aminoxyl radicals and Mn(II) ion through pyridine rings is antiferromagnetic. The abrupt decrease below 10 K might be due to the intermolecular antiferromagnetic interaction. The $\chi_{mol}T$ versus T plot for the complex **1** was analyzed quantitatively based on a triangle three spin model, S_1–S_{Mn}–S_2; $H = -2J(S_{Mn}S_1 + S_{Mn}S_2)$. Equation (1) [10] for three spins with $S_1 = S_2 = 1/2$ and $S_{Mn} = 5/2$ was fitted to the experimental data by means of a least-squares method,

$$\chi_{mol}T = \frac{Ng^2\beta^2T}{4k_B(T-\theta)}\,\frac{85\exp(5J/k_BT) + 35\exp(-2J/k_BT) + 10\exp(-7J/k_BT) + 35}{4\exp(5J/k_BT) + 3\exp(-2J/k_BT) + 2\exp(-7J/k_BT) + 3}. \quad (1)$$

All the symbols have their usual meaning. The best fitting parameters were $J = -13.4 \pm 0.1$ K, $g = 1.940 \pm 0.002$, $\theta = -0.78 \pm 0.02$ K. The signs of J and θ values indicate that both intra- and intermolecular magnetic interactions are antiferromagnetic. The theoretical curve is represented by a solid line in Fig. 2.

3.2.2. $Co(NO_3)_2$(*4NOPy-OMe*)$_2$ (*2*)

When the temperature decreased, the $\chi_{mol}T$ values for the complex **2** gradually increased, reached a round maximum of 4.761 $cm^3\,K\,mol^{-1}$ at 35 K and then decrease rapidly to 1.01 $cm^3\,K\,mol^{-1}$ at 2 K. The $\chi_{mol}T$ value of 3.94 $cm^3\,K\,mol^{-1}$ at 300 K is larger than the spin-only one (2.63) for isolated two radicals ($S = 1/2$) and cobalt ion ($S = 3/2$). The difference could be interpreted as the contribution of spin-orbit coupling of cobalt ion, which is often observed in octahedral coordinated cobalt ion with $^4T_{1g}$ ground state [9]. The increase of $\chi_{mol}T$ values between 35 and 300 K strongly suggest the ferromagnetic interaction between aminoxyl radicals and the cobalt ion. The decrease below 20 K is due to the intermolecular antiferromagnetic interaction and/or the effect of zero-field splitting of cobalt ion.

3.2.3. $Ni(NO_3)_2$(*4NOPy-OMe*)$_2$ (*3*)

As temperature is lowered from 300 to 2 K, the $\chi_{mol}T$ values for the complex **3** increased, reached a round maximum of 2.90 $cm^3\,K\,mol^{-1}$ at 38 K, and then steeply decreased. The $\chi_{mol}T$ value of 2.32 $cm^3\,K\,mol^{-1}$ at 300 K is larger than spin only one (1.75 $cm^3\,K\,mol^{-1}$) with isolated two radicals ($S = 1/2$) and a nickel ion ($S = 2/2$). The thermal behavior of $\chi_{mol}T$ values in the temperature range of 300–38 K indicate that the aminoxyl radicals interact with the nickel ion ferromagnetically to form a high-spin species with $S = 4/2$. The rapid decrease of $\chi_{mol}T$ value below 30 K might be due to the intermolecular antiferromagnetic interaction and/or the effect of zero-field splitting of nickel ion.

Considering that the orbital contribution of nickel ion is insignificant at high temperature, the $\chi_{mol}T$ versus T plot for the complex **3** was analyzed quantitatively based on a triangle three spin model, S_1–S_{Ni}–S_2; $H = -2J(S_{Mn}S_1 + S_{Mn}S_2)$. Equation (2) for three spins with $S_1 = S_2 = 1/2$ and $S_{Ni} = 2/2$ was fitted to the experimental data between 50 and 300 K by means of a least-squares method [10],

$$\chi_{mol}T = \frac{2Ng^2\beta^2T}{k_B(T-\theta)}\left[\frac{5\exp(4J/k_BT) + 1 + \exp(2J/k_BT)}{5\exp(4J/k_BT) + 3 + \exp(-2J/k_BT) + 3\exp(2J/k_BT)} + N\alpha\right]. \quad (2)$$

All symbols have their usual meaning and $N\alpha$ is temperature independent paramagnetism. The best fitting parameters were $J/k_B = 48.7 \pm 2.1$ K, $g = 2.07 \pm 0.02$, $\theta = -2.82 \pm 0.41$ K and $N\alpha = 473 \times 10^{-6}$. The signs of J and θ values indicate that intra- and intermolecular magnetic interactions are ferro- and antiferromagnetic, respectively. The theoretical curve is represented by a solid line in Fig. 2.

3.2.4. $Cu(NO_3)_2$(*4NOPy-OMe*)$_2$ (*4*)

With cooling the temperature, the $\chi_{mol}T$ values for the complex **4** gradually increased, reached the round maximum ($\chi_{mol}T$ values of 1.39 $cm^3\,K\,mol^{-1}$ at 53 K), and then decreases sharply below 30 K. The $\chi_{mol}T$ values of 1.22 $cm^3\,K\,mol^{-1}$ at 300 K is consistent with the spin-only one (1.13) calculated with two isolated aminoxyl radicals ($S = 1/2$) and a copper ion ($S = 1/2$). This thermal profile of $\chi_{mol}T$ values suggests that the intra- and intermolecular interactions in this complex are ferro- and antiferromagnetic respectively. The $\chi_{mol}T$ versus T plot for the complex **4** was analyzed quantitatively based on a linear three spin model, S_1–S_{Cu}–S_2; $H = -2J(S_{Cu}S_1 + S_{Cu}S_2)$. Equation (3) for three spins with $S_1 = S_2 = S_{Cu} = 1/2$ was fitted to the experimental data by means of a least-squares method [11],

$$\chi_{mol}T = \frac{Ng^2\beta^2T}{3k_B(T-\theta)}\,\frac{60\exp(3J/k_BT) + 6\exp(2J/k_BT) + 6}{16\exp(3J/k_BT) + 8\exp(2J/k_BT) + 8}. \quad (3)$$

All symbols have their usual meaning. The best fit gives $J/k_B = 57.0 \pm 1.2$ K, $g = 2.002 \pm 0.002$, and $\theta = -9.8 \pm 0.07$ K. The theoretical curve is represented by a solid line in Fig. 2.

4. Conclusion

Four complexes of $M(NO_3)_2$, M = Mn^{II}, **1**; Co^{II}, **2**; Ni^{II}, **3**; and Cu^{II}, **4**, coordinated with **4NOPy-OMe** were prepared and their molecular structures were revealed by an X-ray crystal structure analysis. Their magnetic properties were investigated by SQUID magneto/susceptometry. Temperature dependence of $\chi_{mol}T$ values indicated that the exchange coupling between metal ion and aminoxyl radicals was antiferromagnetic for Mn ion and were ferromagnetic for Co, Ni, and Cu ions. By the fitting experiments based on the spin Hamiltonian, $H = -2J(S_1S_M + S_MS_2)$, the exchange coupling parameters, J/k_B, were estimated to be -13.4 ± 0.1, 48.7 ± 2.1, and 57.0 ± 1.2 K for the complex **1**, **3**, and **4**, respectively. Interestingly, the magnitude of J/k_B values in the complex **1**, **3** and **4** are comparable with those for the corresponding $M(hfac)_2$(**4NOPy**)$_2$, hfac = hexafluoroacetylacetonato, reported in literatures [11,12].

The bidentate ligand, **4NOPy-OMe**, is found to form the 1:2 complexes with various metal ions and to interact magnetically with metal ion. Therefore, the anisotropic metal ion coordinated with **4NOPy-OMe** is expected to form a low dimensional magnetic complex having a structural anisotropy through the intermolecular magnetic interaction. Research work along this line is in progress.

5. Supplementary material

Full crystallographic data (CCDC Nos. 250534, 250690, 250691 and 250692 for complex **1**, **4**, **2** and **3** have been deposited at the Cambridge Crystallographic Database Center and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

molecules are sometimes hard to give complexes. This result prompts us to prepare diradical-ion salts and complexes to obtain compounds composed of mono- and di-radicals. In this paper, we present magnetic behavior of two diradical cation salts of (2,6-PYBNN)$^{\bullet}$ and a diradical anion salt of (2,4-POBNN)$^{\bullet}$ by investigating temperature dependence of magnetic susceptibility and magnetization isotherms at low temperatures.

2. Experimental

The diradicals, of which molecular structures are shown in Fig. 1, were prepared according to the procedures reported [4] and purified through column chromatography. The diradical cation salt (2,6-PYBNN)$^{\bullet+}Cl^{-}$ was prepared by the reaction between the neutral diradical (2,6-PYBNN)$^{\bullet}$ in a dichloromethane solution and hydrogen chloride diluted in an aqueous solution, while the diradical cation salt $(2,6\text{-PYBNN})^{\bullet+}BF_4^{-}$ was obtained by the reaction of the diradical in dichloromethane with tetrafluoroboric acid dissolved in methanol. The diradical anion salt $(C_4H_9)_4N^{+}$(2,4-POBNN)$^{\bullet-}$ was prepared by dissolving the neutral diradical (2,4-POBNN)$^{\bullet}$ directly into a methanol solution of tetrabutylammonium hydroxide. The molecular structures of these diradical ion salts are also shown in Fig. 1. The magnetization isotherms up to 7 T and magnetic susceptibility over the temperature range from 1.8 to 300 K was measured by using two Quantum Design MPMSXL7 SQUID (superconducting quantum interference device) magnetometers. The contribution of the diamagnetism to the susceptibility was subtracted by extrapolating the temperature dependence of susceptibility to high temperatures, at which the Curie–Weiss law is applicable.

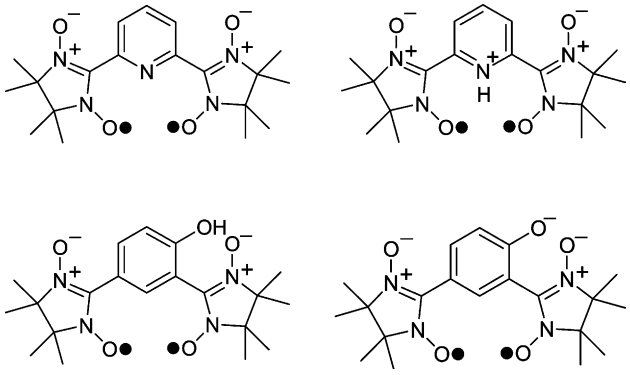

Fig. 1. The molecular structures of the diradicals (2,6-PYBNN)$^{\bullet}$ (top left) and (2,4-POBNN)$^{\bullet}$ (bottom left), the diradical ion (2,6-PYBNN)$^{\bullet+}$ (top right), and the diradical anion (2,4-POBNN)$^{\bullet-}$ (bottom right).

3. Results and discussion

Fig. 2 shows the temperature dependence of the product of paramagnetic susceptibility χ_p and temperature T of the diradical cation salts (2,6-PYBNN)$^{\bullet+}Cl^{-}$ (represented by open circles) and $(2,6\text{-PYBNN})^{\bullet+}BF_4^{-}$ (open triangles) together with that of neutral diradical (2,6-PYBNN)$^{\bullet}$ (crosses). As shown in Fig. 2, the product, χ_pT, of (2,6-PYBNN)$^{\bullet}$ decreases monotonously upon lowering the temperature down to about 20 K. However, a plateau is observed below 20 K. This magnetic behavior is already interpreted [5] successfully in terms of the four-spin linear tetramer model [6] with the intramolecular FM interaction $J/k = +10$ K and intermolecular AFM interaction $J'/k = -57$ K, where J and J' is respectively the intra- and inter-molecular exchange coupling constants and k is the Boltzmann constant.

In $(2,6\text{-PYBNN})^{\bullet+}BF_4^{-}$, χ_pT decreases monotonously down to 1.8 K as shown in Fig. 2. This behavior is interpreted by considering the interacting triplet molecule model by using the following equation [7]

$$\chi_pT = (2Ng^2\mu_B^2/k)\{3 + \exp[2J/(kT)]\}^{-1}[T/(T-\theta)], \quad (1)$$

where N is the number of molecules, g the g factor, μ_B the Bohr magneton and θ the Weiss constant. By fitting the experimental data to Eq. (1), $J/k = +9.0$ K and $\theta = -15.5$ K are obtained as represented by the solid line for open triangles in Fig. 2. The intramolecular coupling constant $J/k = +9.0$ K is FM and close to $J/k = +10$ K obtained for (2,6-PYBNN)$^{\bullet}$, which is the precursory neutral diradical of the salt. In contrast, the intermolecular interaction J'/k is reduced from -57 to -15.5 K, which is derived from the Weiss constant θ by using the relation for $S = 1/2$ spins based on the molecular mean-field theory [8]

$$J'/k = 2\theta/z, \quad (2)$$

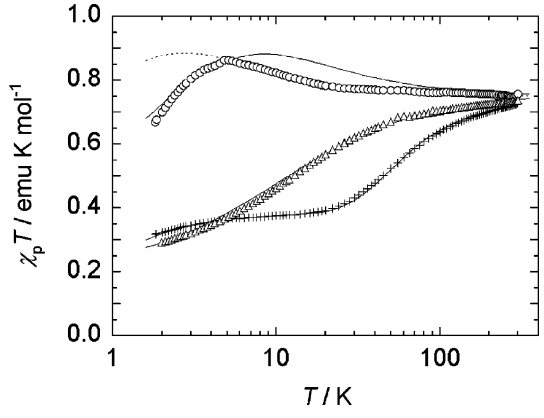

Fig. 2. Temperature dependence of χ_pT of (2,6-PYBNN)$^{\bullet+}Cl^{-}$, $(2,6\text{-PYBNN})^{\bullet+}BF_4^{-}$ and (2,6-PYBNN)$^{\bullet}$ are shown by the open circles, open triangles and crosses, respectively. Theoretical fitting for each compound by using Eq. (1) (see the text) is represented by a solid or dashed line.

where z is the number of neighboring molecules interacting with each other and assumed to be 2 in this case, although the crystal structure of (2,6-PYBNN)$^{\bullet+}BF_4^-$ is not known yet. If z is more than 2, J'/k would be further reduced. The results mentioned above suggest that the intermolecular magnetic interaction is considerably reduced in the diradical cation salt due probably to the presence of counter anions in the solid, whereas the intramolecular magnetic interaction is not so much affected in the salt because of its molecular origin.

A most remarkable change in magnetism occurs in the diradical salt (2,6-PYBNN)$^{\bullet+}Cl^-$. As shown in Fig. 2, χ_pT increases monotonously down to 4.5 K. At 4.5 K, however, χ_pT decreases to some extent suddenly and below 4.5 K decreases monotonically down to 1.8 K, which is the lowest temperature examined by us. This behavior indicates that a magnetic phase transition occurs around 4.5 K in (2,6-PYBNN)$^{\bullet+}Cl^-$. The temperature dependences of χ_pT of both high- and low-temperature (HT and LT) phases are interpreted by considering the interacting triplet molecule model discussed above. From the best fits of the experimental data to Eq. (1), J/k = +9.0 K and θ = −0.75 K for the LT phase and J/k = +3.0 K and θ = −0.24 K for the HT phase are obtained as represented by the solid and dashed lines, respectively, for the open circles in Fig. 2. The intramolecular FM interaction J/k = +9.0 K obtained for the LT phase is close to that observed in (2,6-PYBNN)$^{\bullet}$. The intermolecular AFM interaction, however, is significantly reduced in (2,6-PYBNN)$^{\bullet+}Cl^-$. The value of θ = −0.75 K is only less than 1/50 of that observed in (2,6-PYBNN)$^{\bullet}$. The large reduction of intermolecular AFM interaction might be due to the increase of intermolecular distances by incorporating the Cl^- anion into the solid. Both the intramolecular FM interaction and intermolecular AFM interaction are further reduced in the HT phase. To discuss further, however, it is indispensable to know crystal structures of both phases and nature of the phase transition.

The intramolecular FM interaction of (2,6-PYBNN)$^{\bullet}$ becomes explicit in the diradical salt (2,6-PYBNN)$^{\bullet+}Cl^-$ because of the strong reduction of the intermolecular AFM interaction, which hides the contribution of the intramolecular FM interaction coexisted. A clear evidence for the FM interaction is obtained in the temperature dependence of magnetic susceptibility exhibiting increase of χ_pT with the decrease of temperature as shown in Fig. 2. Another evidence for the intramolecular FM interaction is observed in the magnetization isotherms of (2,6-PYBNN)$^{\bullet+}Cl^-$ at temperatures below 10 K. Fig. 3 shows the magnetization isotherms of (2,6-PYBNN)$^{\bullet+}Cl^-$ at 1.85 (represented by open circles), 2.8 (closed circles), 4.5 (open triangles) and 10 K (close triangles). The magnetization isotherm at 1.85 K follows the Brillouin-function curve for S = 1/2 represented by the dashed line in Fig. 3. However, the magnetization

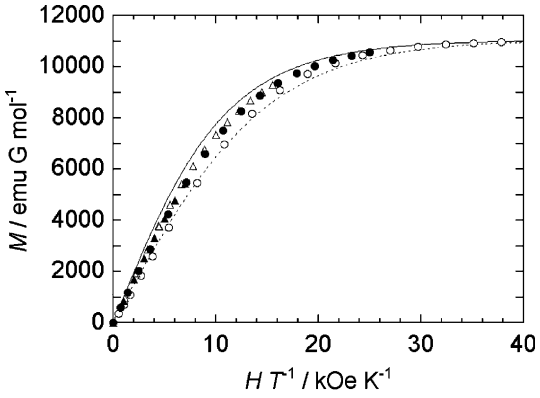

Fig. 3. Magnetization isotherms of (2,6-PYBNN)$^{\bullet+}Cl^-$ at 1.85, 2.8, 4.5 and 10 K are shown by the open circles, closed circles, open triangles and closed triangles, respectively. Theoretical curves based on the Brillouin function for S = 1/2 and 1 are represented by dashed and solid lines, respectively.

isotherm at 2.8 K deviates from the S = 1/2 line and tends to follow the Brillouin-function curve for S = 1 represented by the solid line in Fig. 3. The magnetization isotherm at 4.5 K, just below the phase transition temperature, is more close to the S = 1 line, while that at 10 K becomes to be near the S = 1/2 line again. The magnetization isotherms following the S = 1 line are clear evidence for the existence of triplet state, i.e., the intramolecular FM interaction in (2,6-PYBNN)$^{\bullet+}Cl^-$. In contrast, the magnetization isotherms of (2,6-PYBNN)$^{\bullet}$ follow the S = 1/2 line at any low temperatures [9].

In summary, the intramolecular FM interaction of the diradical (2,6-PYBNN)$^{\bullet}$ is maintained when it forms diradical cation salts. This result suggests us that molecular complexes combined (2,6-PYBNN)$^{\bullet}$ with monoradicals would give magnetic systems, in which two spin centers with different spin multiplicities are incorporated.

Fig. 4 shows the temperature dependence of χ_pT of the diradical anion salt $(C_4H_9)N^+$(2,4-POBNN)$^{\bullet-}$ (represented by open circles) together with that of (2,4-POBNN)$^{\bullet}$ (crosses). The diradical anion salt shows low and almost constant χ_pT values below 100 K, while the values increase steeply with increasing temperature above 100 K. The temperature dependence of χ_pT of $(C_4H_9)_4N^+$(2,4-POBNN)$^{\bullet-}$ at temperatures higher than 100 K is interpreted in terms of thermally excited triplet state by using Eq. (1) with J'/k = −515 K and θ = 0 K as represented by the solid line for the open circles in Fig. 4. A very strong intermolecular AFM interaction of J'/k = −850 K, which is beyond that observed in our diradical anion salt, have recently been reported for the aminoxyl diradical, biphenyl-3,5-diylbis(*t*-butyl nitroxide) [10]. The deviation towards higher values observed around 60 K appears to be a contribution of paramagnetic susceptibility due to adsorbed dioxygen onto the sample, since the magnitude of the deviation varies sample to sample and the temperature dependence of the deviating

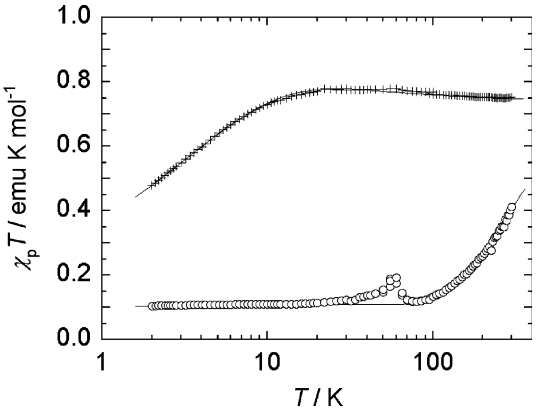

Fig. 4. Temperature dependence of $\chi_p T$ of $(C_4H_9)N^+(2,4\text{-POBNN})^{\bullet\bullet-}$ and (2,4-POBNN)•• are shown by open circles and crosses, respectively. Theoretical fitting for each compound with Eq. (1) (see the text) is represented by a solid line.

portion follows approximately that observed in dioxygen solid [11]. The strong intermolecular AFM interaction hides the intramolecular FM interaction observed in the precursor neutral diradical (2,4-POBNN)••.

As was reported [12], the temperature dependence of (2,4-POBNN)•• is explained in terms of the interacting triplet molecule model by using Eq. (1) with the intramolecular FM interaction $J/k = +15$ K and the intermolecular AFM interaction $\theta = -3.3$ K as shown by the solid line for the crosses in Fig. 4. The intramolecular FM interaction observed in (2,4-POBNN)•• suggests that this diradical would also be a promising candidate for preparing purely organic ferrimagnets. Unfortunately, however, it is unclear from the results obtained for the diradical anion salt shown here that the diradical anion $(2,4\text{-POBNN})^{\bullet\bullet-}$ maintains the intramolecular FM interactions or not, because the very strong intermolecular AFM interaction conceals the FM interaction coexist.

4. Conclusion

In conclusion, we have suggested that the diradical ion salts of (2,6-PYBNN)•• are promising candidates of molecular components to yield purely organic ferrimagnets, since the intramolecular FM interactions could be maintained when (2,6-PYBNN)•• forms diradical cation salts and complexes as shown here. It was hard to conclude whether the intramolecular FM interaction is maintained or not in the diradical anion salts of (2,4-POBNN)•• because of strong intermolecular AFM interaction hides the FM contribution. To confirm these results and to acquire further insight into the magnetism in diradical ion compounds, preparations and magnetic studies of molecular complexes consisting of these diradical ions and organic monoradical counter-ions are currently in progress.

Acknowledgments

This work was in part carried out using facilities of the Institute for Solid State Physics, the University of Tokyo. One of the authors (T.S.) is grateful to Professor H. Mori for using the SQUID magnetometer.

mixed-valence molecular systems [3]. To our knowledge, however, no study was reported for TAA cation radical–metal ion correlation systems.

As part of our work on functionalized mono- and oligomeric TAAs, we have been studying various TAA derivatives with a 4-pyridyl group as a metal coordination site. These compounds give relatively stable cation radicals, but their association constants toward metal complexes, such as zinc tetraphenylporphyrin, are not sufficiently large to allow various spectroscopic measurements. Many studies have been devoted to the chemistry of copper complexes of ligands with bis(2-picolyl)amine moieties as biomimetic models of copper proteins [4]. The coordination site is known to react with various metal ions to give complexes with large stability constants. In view of the potential relevance to biological metal sites with a nearby radical center, we here report on a tridentate ligand, 4,4′-dimethyl-4″-[*N*,*N*′-bis(2-pyridylmethyl)aminomethyl]-triphenylamine (**1**) and its copper complex **2** (Fig. 1). The complex **2** is expected to give a novel complex species with a stable pendent radical upon one electron oxidation.

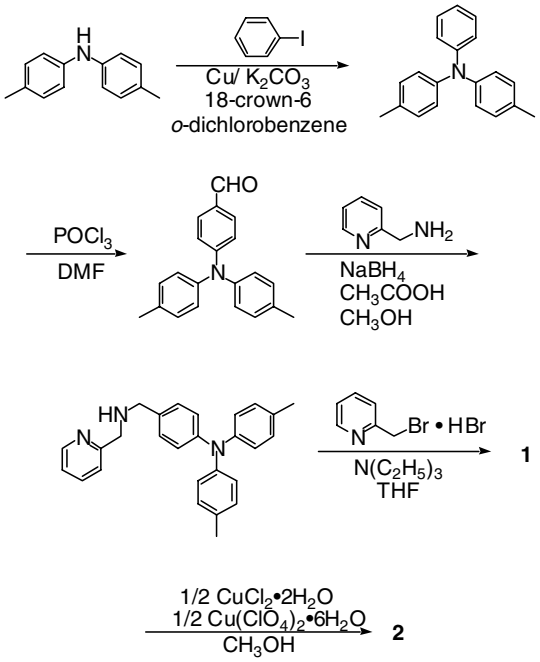

Fig. 2. Synthetic route of **1** and **2.**

2. Experimental

Synthetic detail will be reported elsewhere. All new compounds were fully characterized by spectroscopic methods or elemental analysis. Data only for **1** and **2** are given below.

1;^{1}H NMR ($CDCl_3$); δ 2.30 (s, 6H), 3.65 (s, 2H), 3.83 (s, 4H), 6.92–7.29 (m, 14H) 7.56–7.67 (m, 4H), 8.50 (d, 2H, J = 5.1 Hz).

2; Blue crystal, *Anal*. Calc. for $C_{33}H_{32}N_4CuCl_2O_4$: C, 58.24; N, 4.72; H, 8.03. Found: C, 58.02; N, 4.72; H, 8.02%.

3. Results and discussion

3.1. Synthesis of the ligand and the Cu(II) complex

The ligand, 4,4′-dimethyl-4″-[*N*,*N*′-bis(2-pyridylmethyl)aminomethyl]triphenyl-amine, was synthesized as shown in Fig. 2. Ullmann coupling reaction of di-*p*-tolylamine with iodobenzene gave 4,4′-dimethyltriphenylamine in 29% yield. This compound in turn was transformed into 4-formyl-4′,4″-dimethyltriphenylamine by the reaction with phosphoryl chloride. The formylation occurred specifically and successfully at the *para* position of triarylamine. Treatment of 4-formyl-4′,4″-dimethyltriphenylamine with 2-picolylamine and sodium borohydride gave the secondary amine, 4,4′-dimethyl-4″-[*N*-(2-pyridylmethyl)aminomethyl]triphenylamine. This compound then was reacted with 2-(bromomethyl)pyridine hydrobromide under a basic condition to give the target compound, **1**, in excellent isolated yield (72%). The corresponding copper complex **2** was prepared by reacting **1** with copper (II) chloride/copper (II) perchrorate.

3.2. UV/Vis spectrum and cyclic voltammetry measurements

In order to examine the spectroscopic properties of the ligand and the metal complexes, UV/Vis spectrum

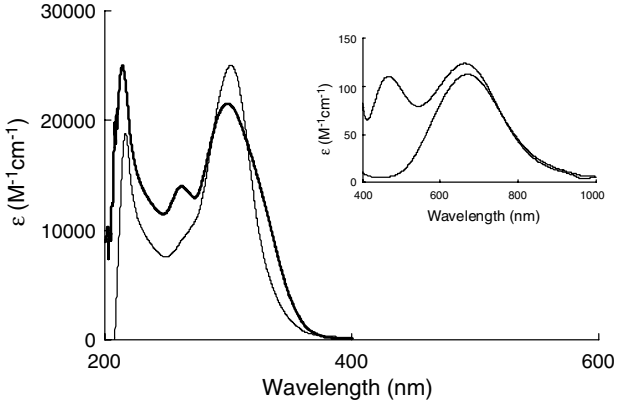

Fig. 3. UV/Vis spectra of **1** (plain), **2** (bold) in *n*-butyronitrile. Inset: UV/Vis spectra (bold), **3** (plain) in *n*-butyronitrile (expanded around 700 nm).

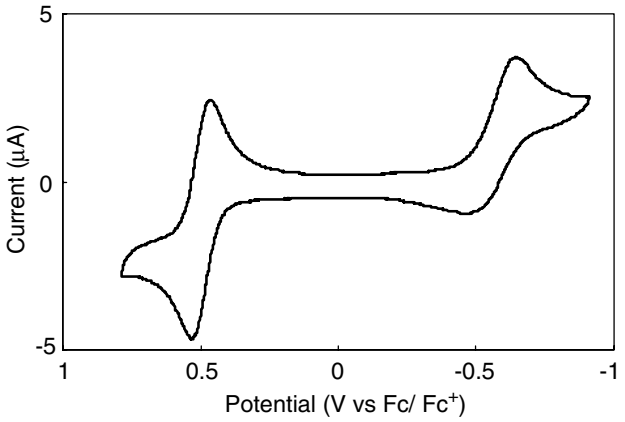

Fig. 4. The cyclic voltammogram of **2** in *n*-butyronitrile.

measurements were examined. The spectrum of those compounds are shown in Fig. 3. In *n*-butyronitrile solution, the ligand and the copper complex exhibited a strong absorption around 300 nm, respectively, which is characteristic for triarylamine chromophores [5]. In addition, the copper complex exhibited two weak absorptions at 468 nm ($\varepsilon = 110\ M^{-1}\ cm^{-1}$) and 666 nm ($\varepsilon = 124\ M^{-1}\ cm^{-1}$). The latter can be assigned to the d–d transition of the copper (II) ion. As no peak was observed around 468 nm for copper *N*,*N*-bis(2-pyridylmethyl)aminomethylbenzene (**3**), which has no triarylamino group, the absorption at 468 nm for the copper complex would indicate some interaction between the triarylamino group and the copper (II) ion.

3.3. Cyclic voltammetric measurements

Electrochemical behavior of the copper complex was studied by cyclic voltammetry in *n*-butyronitrile at ambient temperature. Upon sweeping anodically, ligand **1** showed one set of reversible redox waves ($E^0 = 0.464$ V versus Fc/Fc^+), which can be assigned to the one electron oxidation process ($TAA/TAA^{+\cdot}$). Besides the oxidation peak, an irreversible shoulder oxidation peak ($E_{ox} = 0.414$ V versus Fc/Fc^+) was also observed, which can be assigned to the one electron oxidation of the bis(2-picolylamino)aminomethylbenzene site. Upon sweeping anodically, copper complex **2** exhibited reversible redox waves ($E^0 = 0.475$ V versus Fc/Fc^+) as shown in Fig. 4, which can be similarly assigned to the one electron oxidation process of the TAA unit. No significant difference in the redox potential of the TAA moiety was observed between the ligand and the complex. A shoulder peak observed for **1** was not shown due to the complexation of the bis(2-picolylamino)amino group with Cu(II) ion. On the other hand, upon sweeping cathodically, one set of quasi-reversible redox waves ($E^0 = -0.630$ V versus Fc/Fc^+) was observed. Upon repeating sweeps several times in potential ranging from 1.0 to – 1.0 (V versus Fc/Fc^+), no decrease in the current peak intensity was observed, indicating the three possible species (Cu(I)-TAA, Cu(II)-TAA and Cu(II)-TAA^+) are stable in terms of the time scale of cyclic voltammetry.

3.4. ESR measurements

The magnetic properties of **2** and its oxidized species were examined by ESR measurements in acetonitrile/propionitrile (1:1) at 77 K. Tri(*p*-tolyl)amine cation radical (**4**) and (**3**) were also examined under the same conditions for comparison (Fig. 5). Compound **2** gave

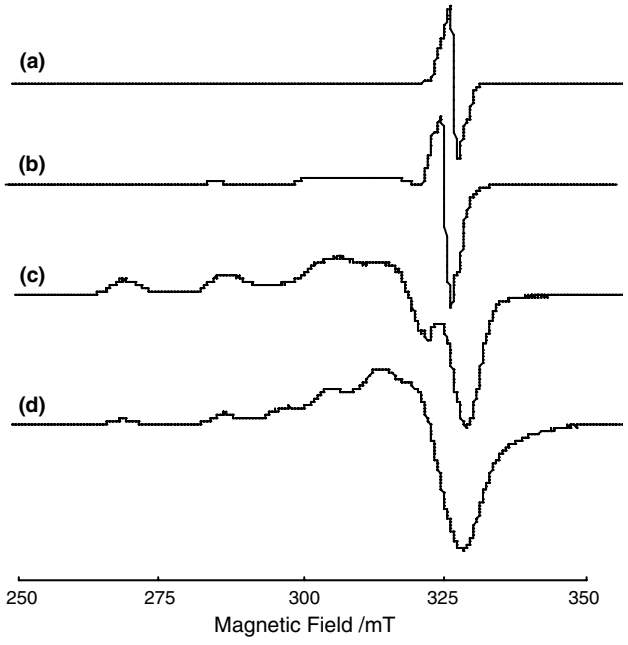

Fig. 5. ESR spectra of (a) **4**, (b) the 1:1 mixture of **3** and **4**, (c) **2** and (d) the 1:1 mixture of **2** and CAN in CH_3CN/C_2H_5CN (1:1) at 77 K.

an ESR hyperfine absorption shown in Fig. 5(c), which is characteristic of copper bis(2-picolyl)amine complexes. Upon addition of one equivalent of cerium ammonium nitrate (CAN), the color of the solution immediately changed from light blue to deep purple, which revealed the generation of the TAA cation radical chromophore. The ESR spectrum of the oxidized species is shown in Fig. 5(d). Obviously, the spectrum is different from that of the 1:1 mixture of **3** and **4** (Fig. 5(b)), which can be assigned to the sum of the spectrum of each species, suggesting the occurrence of intramolecular magnetic interaction between Cu(II) and the TAA radical. [1]

The detailed analysis of the spectrum is now in progress to identify spin multiplicities and magnetic parameters by invoking pulse-ESR based 2D electron spin transient nutation spectrsoscopy.

4. Conclusions

A novel ligand having a redox active triarylamine group and a coordinating group was designed and synthesized. The corresponding copper complex was also successfully prepared. The cyclic voltammetric study revealed that the copper complex gave a novel complex species with a pendent radical, Cu(II)-TAA$^{+\cdot}$. The ESR study of the Cu(II)-TAA$^{+\cdot}$ species suggested intramolecular spin–spin coupling. Preparation of various metal complexes, such as Co(II) and Fe(II) complexes, of this ligand, and molecular design and organic synthesis of novel π-extended ligands are under way.

[1] The degree of an intramolecular interaction through a methylene unit is controversial. However, the hyperconjugation effect of the methylene unit in **2** would be large enough to be operative as the intramolecular interaction between the metal and cation radical unit.

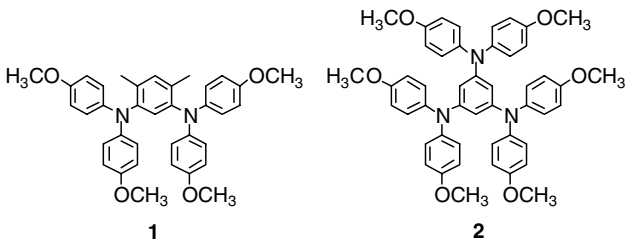

Fig. 1. Structures of *N*,*N*,*N*′,*N*′-tetrakis(4-anisyl)-4,6-dimethyl-1,3-phenylenediamine (**1**) and *N*,*N*,*N*′,*N*′,*N*″,*N*″-hexakis(4-anisyl)-1,3,5-phenylenetriamine (**2**).

Monomeric triarylamines with various substituents at their *para* positions are widely known to give extremely stable monocation radicals upon chemical or electrochemical oxidation [3]. However, as previously pointed out by Stickley et al. [2f], the stability of monomeric cation radical is not always a sufficient indicator of the stability of the corresponding oligocationic states of extended oligoarylamines.

As part of our work, we have recently designed and synthesized a series of tetraaryl-*m*-phenylenediamines having various substituents varying in electronic nature at their peripheral rings [2j]. The electron transfer stopped-flow (ETSF) method revealed that the stability of the monocationic states does not depend on the electronic nature of the substituent. On the other hand, the stability of the dicationic state strongly depends on the electronic nature of the substituent. Especially, the compound with methoxy groups, strong electron-donating groups, gave very stable dication $\mathbf{1}^{2+}$, which did not decay over 1 min. In contrast, the compound with electron-withdrawing chloro groups gave very unstable dication, which disappeared completely less than 5 s. These results suggest that introduction of electron-donating groups, which can raise the HOMO energy level, is effective to stabilize the corresponding dicationic states.

Very recently, Ito et al. [2h] reported that highly brominated *meta*-connected oligoarylamines (**3**, **4**) shown in Fig. 2 gave the stable corresponding dicationic states in solution, which exhibited ground states triplets. The report surprised us. These compounds have many electron-withdrawing bromo groups, which would lower the HOMO energy levels significantly, leading to the thermodynamically unstable mono- and oligocationic states. In the systems, bromine atoms on **3** and **4** seem to play an unknown important role to stabilize the dicationic states.

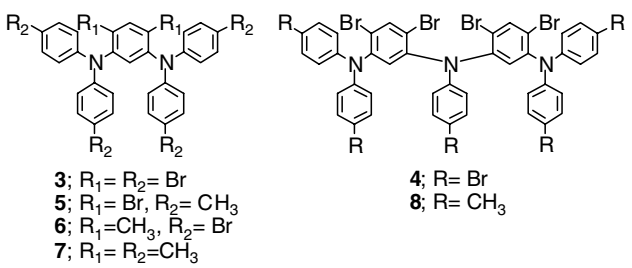

Fig. 2. Structures of tertaaryl-*m*-phenylenediamines (**3**, **5**, **6**, **7**) and 3,3′-bis(diphenylamino)triphenylamines (**4**, **8**).

In this study, we designed and synthesized three types of bromo substituted tetraaryl-*m*-phenylenediamines and examined the stabilities of the corresponding mono- and dicationic states by using the ETSF method, and elucidated the role of bromo groups in the system. Furthermore, based on the principles obtained for the diamines, we also designed and successfully synthesized a one-dimensional triamine, 3,3′-bis(diphenylamino)triphenylamine, which is expected to give a ground-state quartet upon three-electron oxidation.

2. Experimental

2.1. Synthesis of *N,N,N′,N′*-tetrakis(p-bromophenyl)-4,6-dibromo-1,3-phenylenediamine (*3*)

A mixture of 0.2 g (4.84×10^{-4} mol) of *N*,*N*,*N*′,*N*′-tetraphenyl-1,3-phenylenediamine, 1.39 g (4.36×10^{-3} mol) of pyridinium hydrobromide perbromide in 6 ml of benzene/ethanol (1:1) was heated under reflux for 90 min. The resulting solution was washed with aqueous sodium thiosulfate, extracted with ethyl acetate, and dried over sodium sulfate. The solvent was distilled off under reduced pressure. The obtained crude crystals were recrystallized from ethanol to give gray crystals (0.49 g, yield 87%). ^{1}H NMR ($CDCl_3$); δ 6.76 (d, 8H, J = 8.4 Hz), 7.32 (d, 8H, J = 8.4 Hz), 6.97 (s, 1H), 7.89 (s, 1H)

Compounds **5**, **6** and **8** were also synthesized and purified by the similar method described above.

Compound **5**: purple crystal (yield 92%), ^{1}H NMR ($CDCl_3$); δ 2,27 (s, 12H), 6.81 (d, 8H, J = 8.5 Hz), 7.00 (d, 8H, J = 8.5 Hz), 7.02 (s, 1H), 7.25 (s, 1H), compound **6**: colorless crystal (yield 98%), ^{1}H NMR ($CDCl_3$); δ 1.97 (s, 6H), 6.77 (d, 8H, J = 8.9 Hz), 6.82 (s, 1H), 7.11 (s, 1H), 7.27 (d, 8H, J = 8.9 Hz). Compound **8**: colorless crystal (yield 78.3%), ^{1}H NMR ($CDCl_3$); δ 2,21 (s, 15H), 6.59–6.97 (m, 20H), 7.21 (s 1H), 7.34 (s, 1H), 7.64 (s, 1H), 7.70 (s, 1H).

3. Results and discussion

3.1. Molecular design and organic synthesis

The brominated diamine **3** has two types of bromo atoms. In order to examine which bromo atom makes larger contribution towards the stabilization of the dication $\mathbf{3}^{2+}$, we designed two types of bromo-substituted

derivatives **5** and **6**. The former has two bromine atoms on the central ring, and the latter has four bromine atoms on the peripheral rings. Bromination of the corresponding diamines with an excess amount of pyridinium hydrobromide perbromide gave **5** and **6** in 92% and 98% isolated yield, respectively. Similarly, the compound **3** was also synthesized for comparison (yield 87%).

3.2. Cyclic voltammetry measurements

For all compounds, **3**, **5** and **6**, cyclic voltammetry in *n*-butyronitrile at ambient temperature revealed two chemically reversible one-electron transfers, indicating stable mono- and dications in solution. Reflecting the electronic nature of the substituents, a derivative with more bromo groups shifted more anodically (**3**; $E_1^0 = 0.824$ V, $E_2^0 = 0.940$ V; **5**; $E_1^0 = 0.574$ V, $E_2^0 = 0.708$ V; **6**; $E_1^0 = 0.647$ V, $E_2^0 = 0.813$ V versus Fc/Fc^+).

3.3. Electron transfer stopped-flow method

The detail of the ETSF method was described previously [4,5]. The ETSF measurements were carried out in dehydrated acetonitrile (AN) as a solvent at ambient temperature. In this study, tris(2,4-dibromophenyl)amine cation radical ($TDBPA^{+\cdot}$)[1] was employed. Compound **3**, upon mixing with one equivalent of $TDBPA^{+\cdot}$, exhibited an absorption peak at 758 nm, and no decrease in the peak intensity was observed over 1 min, indicating the very stable monocation (Fig. 3). The molar absorptivity (ε) of $\mathbf{3}^{+\cdot}$ was determined to be 2.49×10^4 M^{-1} cm^{-1} at 758 nm. Under the same condition, compounds **5** and **6** also gave very stable monocations, respectively ($\mathbf{5}^{+\cdot}$: $\lambda_{max} = 738$ nm, $\varepsilon = 2.55 \times 10^4$ M^{-1} cm^{-1}; $\mathbf{6}^{+\cdot}$: $\lambda_{max} = 698$ nm, $\varepsilon = 2.54 \times 10^4$ M^{-1} cm^{-1}). These results indicate that the number of bromine atom and position of substituents are not important factors to govern the stability of the mono cationic state.

On the other hand, compound **3**, upon mixing with two equivalents of $TDBPA^{+\cdot}$, exhibited an absorption peak of the dication $\mathbf{3}^{2+}$ at 770 nm, red shifted by 12 nm than that of $\mathbf{3}^{+}$. The ε value for $\mathbf{3}^{2+}$ was about two times that of $\mathbf{3}^{+}$, being characteristic of tetraaryl-*m*-phenylenediamine systems. Surprisingly, despite expecting the thermodynamic unstability for $\mathbf{3}^{2+}$, the dication $\mathbf{3}^{2+}$ was more stable. No significant decrease in the peak intensity was observed over 1 min (Fig. 4). Similarly, compound **5** gave stable dication $\mathbf{5}^{2+}$ ($\lambda_{max} = 748$ nm, $\varepsilon = 5.78 \times 10^4$ M^{-1} cm^{-1}). However, compound **6** gave very unstable dication $\mathbf{6}^{2+}$ ($\lambda_{max} = 738$ nm, $\varepsilon = 5.59 \times 10^4$ M^{-1} cm^{-1}), which disappeared completely within 4 s. Judging from the redox potentials

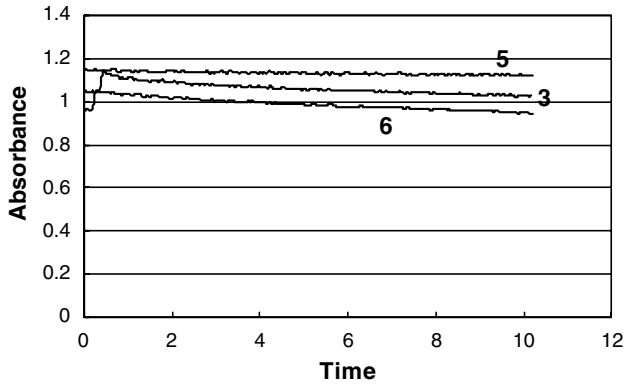

Fig. 3. Time profiles in the absorbance maximum observed after mixing an AN solution of 0.10 mM $TDBPA^{+\cdot}$ with an AN solution of 0.10 mM **3**, **5** and **6**.

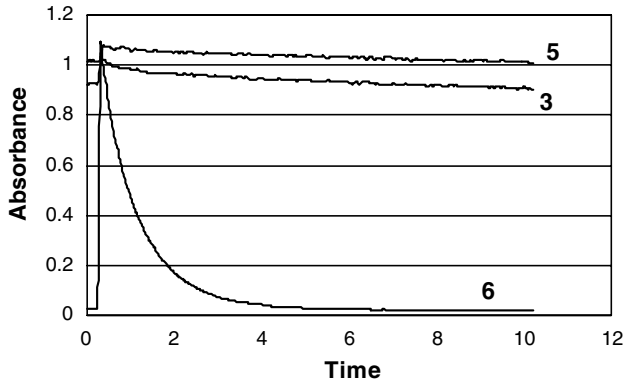

Fig. 4. Time profiles in the absorbance maximum observed after mixing an AN solution of 0.10 mM $TDBPA^{+\cdot}$ with an AN solution of 0.05 mM **3**, **5** and **6**.

for **3**, **5** and **6**, dication $\mathbf{6}^{2+}$ would be thermodynamically the most stable species, being inconsistent with the results of the ETSF measurements. Previously, we examined the stability of dication $\mathbf{7}^{2+}$, which has six methyl groups on both the central and the peripheral rings [2j]: CV measurements showed two reversible couples ($E_1^0 = 0.391$ V, $E_2^0 = 0.593$ V versus Fc/Fc^+).

Nevertheless, the dication $\mathbf{7}^{2+}$ decomposed gradually under the same ETSF measurement condition. Considering the relationship between the molecular structures and the stabilities of the corresponding dications, compounds **6** and **7**, which have methyl groups on the central ring, gave the unstable dications, while compounds **3** and **5** with bromo groups on the central ring gave the stable dications. In the previous study, we demonstrated that the introduction of methyl groups into the central ring of non-substituted tetraphenyl-*m*-phenylenediamine remarkably improves the stabilities of the mono- and dicationic states [2e]. However, the present study revealed that the bromo group on the central ring can be a better protecting unit to prolong the life time of the dication. The mechanism of the

[1] TDBPA was synthesized by WAKO Pure Chemicals Ltd. after receiving our special order. See also [5].

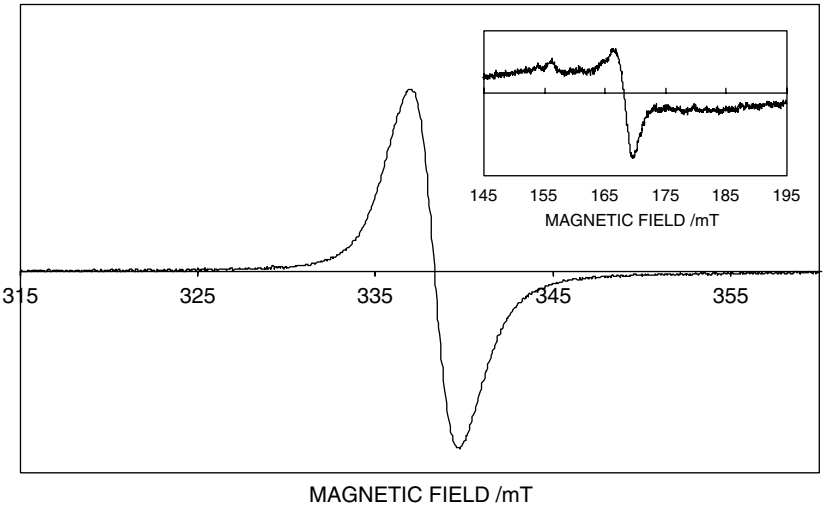

Fig. 5. ESR spectrum of the randomly oriented **8** oxidized by two equivalents of $SbCl_5$ observed at 5 K in an allowed ESR transition region (inset: in the $\Delta M_s = \pm 2$ region). The microwave frequency was 9.48078 GHz.

stabilization is not fully clear yet; the introduction of the bromo group might suppress decomposition reactions, such as intramolecular hydrogen abstraction.

Then, we have extended this work to include the study of 3,3′-bis(diarylamino)triphenylamine, which is a suitable synthetic target as a model precursor for one-dimensional positively charged high-spin systems. Previously, Ito et al. [2h] reported the highly brominated derivative **4**, which gave stable dication upon two-electron oxidation. However, they failed to detect the trication with polybromo substitutions. With this result in mind, we designed and synthesized compound **8**, which has only four bromo groups on the two central rings. The compound **8** is expected to give more thermodynamically stable mono- and oligocations than those of **4**. The CV measurement of **8** showed the generation of both stable dication $\mathbf{8}^{2+}$ and moderately stable trication $\mathbf{8}^{3+}$ at ambient temperature ($E_1^0 = 0.605$ V (2e transfer), $E_2^0 = 1.07$ V (1e transfer) versus Fc/Fc^+).

ETSF examination of **8** revealed that the mono-, di- and tricationic states give a broad absorption around 730 nm, respectively ($\mathbf{8}^{+}$: $\lambda_{max} = 732$ nm, $\varepsilon = 2.06 \times 10^4$ M^{-1} cm^{-1}; $\mathbf{8}^{2+}$: $\lambda_{max} = 732$ nm, $\varepsilon = 4.30 \times 10^4$ M^{-1} cm^{-1}; $\mathbf{8}^{3+}$: $\lambda_{max} = 736$ nm, $\varepsilon = 6.07 \times 10^4$ M^{-1} cm^{-1}). The ratio of ε formonocation:dication:trication of **8** was nearly 1:2:3, as expected. The quantum chemistry-based rationale for this expectation will be given elsewhere.

3.4. ESR measurements

In order to examine the electronic structures of $\mathbf{8}^{2+}$ and $\mathbf{8}^{3+}$, particularly top identify the spin multiplicity in the ground state, ESR measurements of chemically oxidized **8** were carried out at liquid-helium temperature. Upon addition of two equivalents of $SbCl_5$ into CH_2Cl_2 solution of **8**, the color of the solution immediately turned blue, indicating the generation of oxidized species. The continuous-wave ESR spectrum of the randomly oriented oxidized species at 5 K is shown in Fig. 5. There appeared a broad line in an allowed ESR transition region. Furthermore, a weak forbidden transition was also observed in the $\Delta M_s = \pm 2$ region, clearly indicating the presence of spin-triplet species (Fig. 5). No signal was observed in the $\Delta M_s = \pm 3$ region. The temperature dependence of the signal intensities in the $\Delta M_s = \pm 2$ region showed that the dicationic state $\mathbf{8}^{3+}$ is spin-triplet in the ground state.

On the other hand, upon addition of three equivalents of $SbCl_5$, the color of solution of **8** similarly turned blue immediately, however, followed by rapid discoloration to red in a few seconds, suggesting the occurrence of rapid decomposition reaction of $\mathbf{8}^{3+}$.

4. Conclusions

In order to elucidate the role of bromo groups on the stabilization of the oligocationic species reported by Ito et al., we have systematically designed and synthesized three types of brominated tetraaryl-*m*-phenylenediamines, **3**, **5** and **6**. Cyclic voltammetry and ETSF measurements have revealed that the bromo groups, over methyl groups, on the central aromatic ring can stabilize the dicationic states effectively. These results serve for establishing guidelines for molecular designing of charged high-spin molecular systems in a more sophisticated way.

Furthermore, based on the knowledge, tetra-brominated 3,3′-bis(diarylamino)triphenylamine (**8**) was synthesized, which gave a moderately stable tricationic state. This is the first report on detection of a one-dimensional oligoarylamine-based tricationic state. Conventional continuous-wave ESR study of chemically oxidized **8** showed that the dication $\mathbf{8}^{2+}$ is spin-triplet in

the ground state. The tricationic $\mathbf{8}^{3+}$ was not stable enough in a time scale for the conventional ESR sampling. Further stabilization of $\mathbf{8}^{3+}$ by chemical modification is underway.

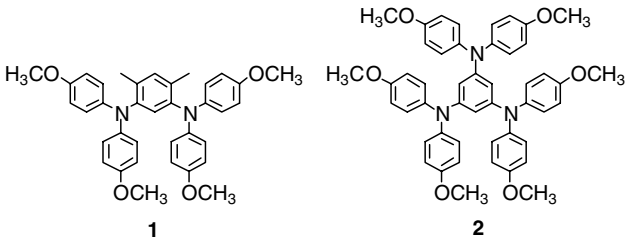

Fig. 1. Structures of *N*,*N*,*N*′,*N*′-tetrakis(*p*-anisyl)-4,6-dimethyl-1,3-phenylenediamine (**1**) and *N*,*N*,*N*′,*N*′,*N*″,*N*″-hexakis(*p*-anisyl)-1,3,5-phenylenetriamine (**2**).

cursors. For example, poly(aryl)carbenes of particular π-electron networks, well known high-spin molecules, can usually survive only at low temperature, and their precursors, polydiazo derivatives, are thermally and photochemically unstable except several cases. On the other hand, we have shown that the structural modification of tetraphenyl-*m*-phenylenediamine by suitable substituents is quite effective in stabilizing the dicationic states, which are stable even at ambient temperature [2c,2j].

Those oligoarylamines described above have no functional group available for further extension of their π-electron network, preventing us from utilizing them in organic syntheses. So, we attempted to design and synthesize functionalized tetraaryl-*m*-phenylenediamines. Generally, aryl halides are widely used as convenient compounds in conventional and modern organometallic syntheses. Until now, numerous organic syntheses using aryl halides have been reported. Among them, Sonogashira coupling [3] is an attractive and powerful method for syntheses of acetylene bridged compounds in excellent yields. In fact, the coupling has been utilized in many laboratories for syntheses of natural and artificial molecules. In this study, we propose two types of iodinated tetraaryl-1,3-phenylenediamines (**3** and **4**) as "synthons" for molecular devices and supramolecular systems. Furthermore, using Sonogashira coupling, the compounds can be transformed into highly extended tetraaryl-*m*-phenylenediamines.

2. Results and discussion

2.1. Molecular designs and syntheses of target molecules

As target molecules, we chose *N*,*N*,*N*′,*N*′-tetrakis(4-iodophenyl)-4,6-dimethyl-1,3-phenylenediamine (**3**) and *N*-(4-iodophenyl)-*N*,*N*′,*N*′-tris(4-methylphenyl)-4,6-dimethyl-1,3-phenylenediamine (**4**). In the compounds, the reactive iodo groups are introduced at the *para*-positions of the peripheral aryl ring, and in the middle part of the molecules, the 4,6-positions of the central aryl ring are capped with methyl groups, which can enhance the stabilities of the mono- and dicationic states of tetraaryl-*m*-phenylenediamines. The synthetic routes of **3** and **4** are shown in Fig. 2.

Synthesis of **3**: 5-Nitro-2,4-xylidine was reduced with tin dichloride/hydrochloric acid in ethanol to give 4,6-dimethyl-1,3-phenylenediamine (**5**), which was reacted with iodobenzene under Ullmann coupling condition [4] to give *N*,*N*,*N*′,*N*′-tetraphenyl-4,6-dimethyl-1,3-phenylenediamine (**6**) (yield 56% for the two steps). This compound was iodinated with potassium iodide/potassium iodate in acetic acid to give **3**, which was purified by column chromatography ($CHCl_3$/*n*-hexane = 1/3) in 93% isolated yield.

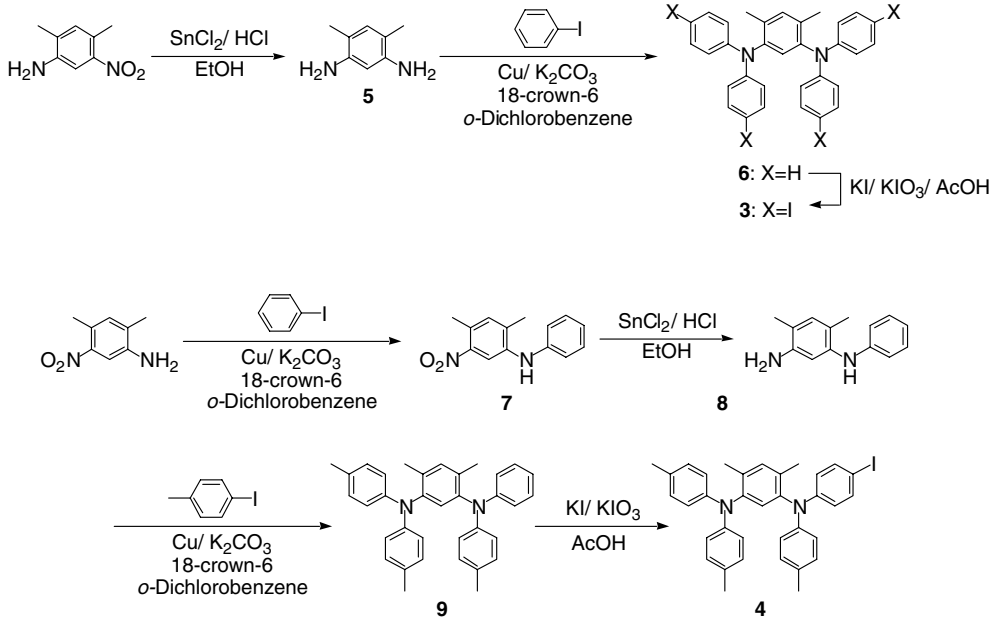

Fig. 2. Synthetic routes for **3** and **4**.

3: ^{1}H NMR δ 1.97 (s 6H), 6.65 (d, 8H, J = 8.91 Hz), 6.82 (s, 1H), 7.10 (s, 1H), 7.38 (d, 8H, J = 8.91 Hz).

Synthesis of **4**: 5-Nitro-2,4-xylidine was reacted with iodobenzene to give *N*-diphenyl-5-nitro-2,4-xylidine (**7**) in 35% isolated yield. Stoichiometrically, only one equivalent of iodobenzene is required to obtain **7**, however, the best result was obtained when 5-nitro-2,4-xylidine was reacted with iodobenzene in the ratio of 1:2 under reflux for 7 h. Prolonged reaction time gave the undesired di-substituted compound, *N*,*N*-diphenyl-5-nitro-2,4-xylidine, predominantly. The compound **7** was quantitatively reduced with tin dichloride/hydrochloric acid in ethanol to give *N*-phenyl-4,6-dimethyl-1,3-phenylenediamine (**8**), which was reacted with an excess amount of *p*-iodotoluene under Ullmann coupling reaction to give *N*,*N*′,*N*′-tris(4-methylphenyl)-*N*-phenyl-4,6-dimethyl-1,3-phenylenediamine (**9**), in 49% isolated yield. Compound **9** was iodinated with potassium iodide/ potassium iodate in acetic acid to give **4**, which was purified by column chromatography ($CHCl_3$/*n*-hexane = 1/5) in quantitative yield.

4: ^{1}H NMR δ 1.97 (s, 3H), 1.99 (s, 3H), 2.25 (s, 6H), 2.31 (s, 3H), 6.62 (d, 2H, J = 8.90 Hz), 6.80 (d, 4H, J = 8.40 Hz), 6.87 (d, 2H, J = 8.90 Hz), 6.89 (d, 2H, J = 8.90 Hz), 6.90 (s, 1H), 7.00 (d, 4H, J = 8.40 Hz), 7.06 (s, 1H), 7.37 (d, 2H, J = 8.90 Hz).

2.2. π-Extension using Sonogashira coupling

In order to examine the reactivity of **3** and **4**, various acetylene compounds were coupled with them under Sonogashira coupling condition [3a] to obtaine π-extended tetraaryl-*m*-phenylenediamines (**10a**–**e** and **11a**–**d**) shown in Fig. 3. The synthetic procedure of **10a** is described below.

Compound **3** was mixed with a catalytic amount of copper iodide, dichlorobis (triphenylphosphine) palladium (II) and six equivalents of trimethylsilylacetylene, and stirred under argon atmosphere for 12 h at ambient temperature. The obtained crude oil was purified by column chromatography ($CHCl_3$/*n*-hexane = 1/1) in 98% yield. Compounds **10c**–**e** and **11a, c**–**d** were also prepared in a similar manner. Compounds **10b** and **11b** were prepared by desilylation of **10a** and **11a** in the presence of potassium carbonate in methanol/THF in quantitative yield. The NMR spectra of these molecules are consistent with their assigned structures.

2.3. UV/Vis spectroscopic and cyclic voltammetry measurements

Compounds **3** exhibited a broad absorption band around 300 nm in chloroform, which is characteristic of triarylamine chromophores. Comparing with the UV/Vis spectrum of **1**, no significant difference was observed between **1** and **3**, indicating their similar electronic structures. Also compound **4** exhibited a similar absorption band (λ_{max} = 301 nm). Upon cyclic voltammetry in *n*-butyronitrile with 0.1 M Bu4NPF6 as a supporting electrolyte, Compounds **3** and **4** showed two sets of reversible redox couples (**3**: $E_1^0 = 679$ mV, $E_2^0 = 854$ mV versus Fc/Fc^+, **4**: $E_1^0 = 428$ mV, $E_2^0 = 678$ mV versus Fc/Fc^+), respectively. These results indicate that **3** and **4** yield the stable mono- and dications upon consecutive oxidation.

The UV/Vis spectra of **10a–e** in chloroform exhibited a broad absorption maximum around 375 nm, which are remarkably red-shifted in comparison with that of **1**. On the other hand, the UV/Vis spectra of **11a–d** in chloroform exhibited an absorption maximum around 300 nm. Besides the absorption peak, another absorption was observed around 360 nm. The spectra of **10e** and **11d** are shown in Fig. 4 as representative cases. A preliminary study revealed that **10a–d** and

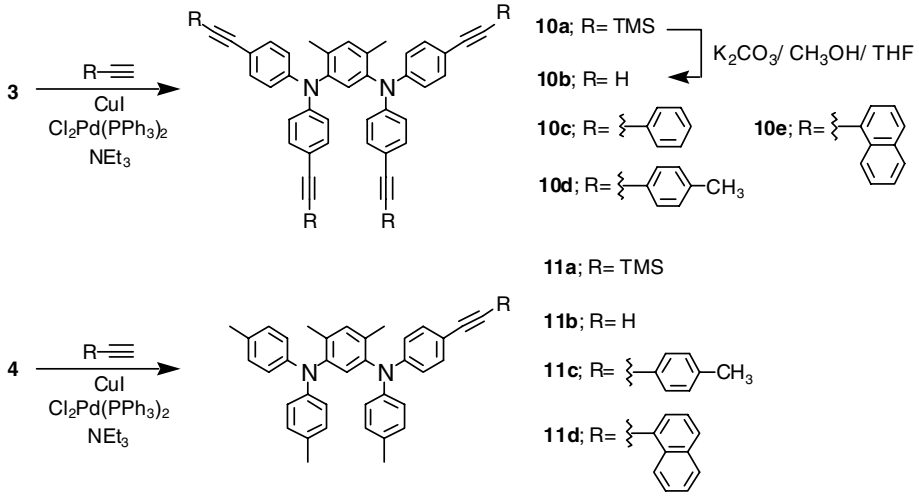

Fig. 3. Synthetic routes for **10a–e** and **11a–d**.

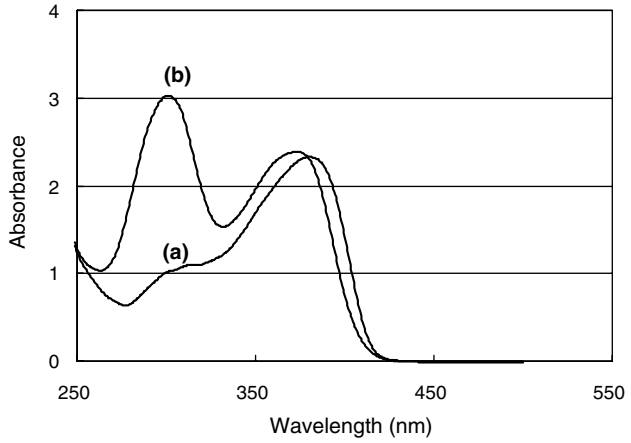

Fig. 4. Absorption spectra of: (a) **10e**, (b) **11d** in chloroform.

11c–**11d** exhibit fluorescent emission upon irradiation of ultraviolet light.

Compounds **10a** showed well resolved two sets of reversible redox couples ($E_1^0 = 608$ mV, $E_2^0 = 753$ mV versus Fc/Fc$^+$), however, compounds **10b** showed the first oxidation wave at 550 (versus Fc/Fc$^+$), followed by two oxidation peaks upon further sweeping, and no reduction wave was observed, indicating that monocation radical **10b**$^{+\cdot}$ is unstable. Similarly, compounds **10c**–**e** showed similar complicated voltammograms, suggesting the generation of unstable monocation radicals.

Compound **11a** showed two sets of reversible redox couples ($E_1^0 = 430$ mV, $E_2^0 = 660$ mV versus Fc/Fc$^+$), while compound **11b** showed the first reversible redox couple and the second quasi-reversible redox couple ($E_1^0 = 434$ mV, $E_2^0 = 678$ mV versus Fc/Fc$^+$). Similarly, compounds **11c**–**d** gave stable monocation radical and fairly unstable dication, respectively (**11c**: $E_1^0 = 429$ mV, $E_2^0 = 612$ mV, **11d**: $E_1^0 = 430$ mV, $E_2^0 = 617$ mV versus Fc/Fc$^+$).

2.4. Electron transfer stopped-flow method measurements

As a novel method to observe the absorption spectra of short-lived cation radicals in solution, one of the authors (M.O.) has proposed electron transfer stopped-flow (ETSF) method [5,6]. Using this technique, the absorption spectra of aromatic amine cation radicals were successfully detected, and the kinetic processes were analyzed. The ETSF measurements were carried out in dehydrated acetonitrile (AN) as a solvent at ambient temperature. Depending on the oxidation potential of each compound, tris(4-bromophenyl)amine cation radical (TBPA$^{+\cdot}$) or tris(2,4-dibromophenyl)amine cation radical (TDBPA$^{+\cdot}$), more powerful oxidizing reagents, are employed.[1] The formal potential of TDBPA$^{+\cdot}$/TDBPA couple is 1.06 V versus Fc/Fc$^+$, which is 0.44 V positive to that of TBPA$^{+\cdot}$/TBPA couple. In this study, TDBPA$^{+\cdot}$ was employed.

Compound **10a**, upon mixing with one equivalent of TDBPA$^{+\cdot}$, exhibited a broad absorption peak at 816 nm (Fig. 5), and any significant decrease in the peak intensity was not observed over 1 min. Compared with the spectrum of **1**$^{+\cdot}$ [2j], the λ_{max} of **10a**$^{+\cdot}$ is extremely red shifted by 131 nm, indicating the occurrence of effective π-network extension. The molar absorptivity (ε) of **10a**$^{+\cdot}$ was determined to be 2.19×10^4 M^{-1} cm^{-1} at 816 nm. Similarly, mixing with two equivalent of TDBPA$^{+\cdot}$, **10a** showed an absorption peak at 842 nm ($\varepsilon = 4.41 \times 10^4$ M^{-1} cm^{-1}), which was slightly reduced over 10 s.

On the other hand, upon mixing with one equivalent of TDBPA$^{+\cdot}$, compound **10b**, TMS deprotected compounds, exhibited a weak absorption peak at 710 nm ($\varepsilon = 1.05 \times 10^4$ M^{-1} cm^{-1}) (Fig. 5), any significant decrease in the peak intensity was not observed over 1 min. It seems that the peak is derived from monocation radical **10a**$^{+\cdot}$. No significant difference in electronic structure between **10a**$^{+\cdot}$ and **10b**$^{+\cdot}$ would be expected. However, compared with the spectrum of **10a**$^{+\cdot}$, λ_{max} of **10b** upon one electron oxidation is much red shifted, and the intensity of the peak at 710 nm is about one-fourth of that of **10a**$^{+\cdot}$ at 816 nm. Moreover, no spectrum change was observed by changing the substrate/oxidizing reagent concentration ratio. On the basis of the results described above, we concluded that the lifetime of **10b**$^{+\cdot}$ is too short to be determined even by the ETSF method, and that the species observed is not **10b**$^{+\cdot}$ but other stable species produced by follow-up reactions. Decomposition process is not clear yet, but an AM1 calculation suggested that both compounds **10a** and **10b** have large electron densities at the terminal acetylene carbon atoms. Bulky trimethylsilyl substituent in **10a** would protect the site effectively, suppressing

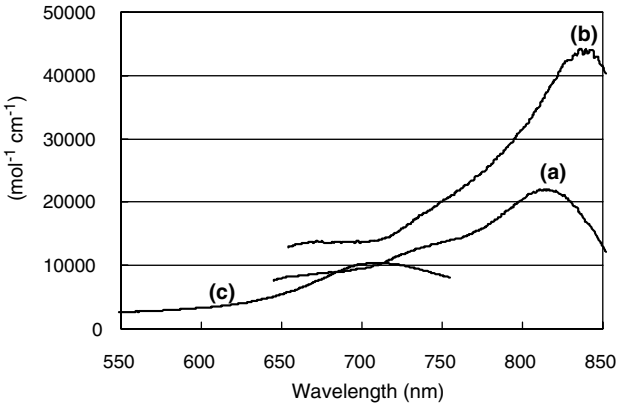

Fig. 5. Absorption spectra observed after mixing of an AN solution of 0.10 mM TDBPA$^{+\cdot}$ with an AN solution of: (a) 0.10 mM of **10a**; (b) 0.05 mM of **10a**; (c) 0.10 mM of **11a**.

[1] TDBPA was synthesized by WAKO Pure Chemicals Ltd. after receiving our special order. See also Ref. [5].

follow-up reactions. Similar to **10b**, both compounds **10c** and **10d** gave very unstable monocation radicals. The ETSF measurements for **11a–d** are now underway.

As ETSF measurements revealed that **10a** gives the corresponding mono- and dicationic states, we tried to carry out ESR measurements of the species. We selected $SbCl_5$ as an oxidant, which is widely used for electron oxidation of various organic compounds. Upon addition of two equivalents of $SbCl_5$ into a CH_2Cl_2 solution of **10a**, the color of the solution immediately turned blue, however, followed by rapid discoloration to red in less than a few seconds at ambient temperature. Any dominant fine-structure spectra attributable to the short-lived high-spin entities in solution could not be identified at glassy solvents at low temperature: Only trace from the short-lived triplet species or monocationic ones was detected by conventional continuous wave ESR spectroscopy. This indicated the occurrence of rapid follow-up reactions in solution at ambient temperature. Surprisingly, addition of one equivalent of $SbCl_5$ gave a similar result. These results indicate that both the mono- and dicationic states are very unstable under the condition. Other oxidants such as cerium ammonium nitrate (CAN)/AN were met with failure. Resolution of these difficulties is the target of future work, exploring alternative oxidants.

3. Summary

In conclusion, we have designed and successfully synthesized iodinated tetraaryl-1,3-phenylenediamines (**3** and **4**). In designing novel molecular devices and supramolecular systems, these compounds will serve as intriguing building blocks, which are expected to exhibit triplet ground states upon two electron oxidation. Starting from **3** and **4**, highly π-extended tetraaryl-1,3-phenylenediamines (**10a–e**, **11a–d**) have been synthesized in excellent yields by Sonogashira coupling. The ETSF measurements showed that only **10a** gives the stable dication, probably due to steric protection. Unfortunately, **10b–e** gave very short-lived monocation radicals. We are currently exploring effective aryl groups that can protect the acetylene site. Molecular designs and syntheses of novel photochemically or electrochemically active derivatives coupled with **3** or **4** are also in progress.

2. Experimental

The anions TEMPO–NHCO–(*o*-, *m*-, *p*-)$C_6H_4SO_3^-$ (**N1**, **N2**, **N3**), TEMPO–N(CH_3)CO–(*o*-, *p*-)$C_6H_4SO_3^-$ (**M1**, **M3**), and TEMPO–OCO–(*o*-, *m*-, *p*-)$C_6H_4SO_3^-$ (**O1**, **O2**, **O3**) were prepared by the condensation reaction of HOOC–(*o*-, *m*-, *p*-)$C_6H_4SO_3^-$ with TEMPO–NH_2, TEMPO–N(CH_3)H, and TEMPO–OH, respectively, in the presence of dicyclohexylcarbodiimide (DCC) and dimethylaminopyridine (DMAP) in 30 mL of CH_2Cl_2 at room temperature with stirring over a few days. Metathesis with $PPh_4 \cdot Br$ gave their PPh_4 salts (yields: 40, 59, 16, 26, 8, 25, and 6% for the **N1**, **N3**, **M1**, **M3**, **O1**, **O2**, and **O3** salts, respectively), as orange crystals. $PPh_4 \cdot$ **N2** was obtained as an orange tar and metathesis with $N(CH_3)_4 \cdot Cl$ yielded the crystalline product (20% yield). Their TTF salts were prepared by metathesis of $(TTF)_3(BF_4)_2$ and their organic cation salts in CH_3CN or a mixture of CH_3CN and CH_3OH. The BEDT-TTF salt of **M1** was obtained by electrocrystallization in PhCl with BEDT-TTF and $PPh_4 \cdot$ **M1**. All materials were identified by X-ray analysis. Single crystal X-ray diffraction data were collected using a Quantum CCD area detector on a Rigaku AFC-7R diffractometer or Rigaku AFC-5R 4-circle diffractometer at room temperature. The Mo Kα radiation was used for all crystals. All calculations were performed by teXsan for Windows version 1.06 and CRYSTALS version 12. Electrical resistivity measurements were carried out by the conventional four probe method. Magnetic susceptibility measurements of polycrystalline samples from 2 to 300 K were measured with a Quantum Design MPMS5SH magnetometer.

3. Results and discussion

3.1. PPh_4 and $N(CH_3)_4$ salts

The crystal data of seven tetraphenylphosphonium and one tetramethylammonium salts are listed in Table 1.

The amido, *N*-methylamido, and ester (–NHCO–, –N(CH_3)CO–, and –OCO–) bonds of all anions apart from **M1** have *trans* conformation. **M1** only has *cis* conformation. For example, molecular structures of **N3**, **M1**, and **O2** of their PPh_4 salts are shown in Fig. 1. There are no magnetically important short contacts between the TEMPO moieties for all salts because the anions are surrounded by the relatively large organic cations and/or the incorporated solvent molecules. The results indicate that magnetic interactions are unlikely. Indeed the **N1**, **N2**, **N3**, **M1**, **M3**, **O1**, **O2**, and **O3** salts show Curie–Weiss behaviours with C (emu K mol^{-1})/θ (K) = 0.369/−0.17, 0.376/−0.31, 0.334/0.25, 0.360/−0.03, 0.377/−1.91, 0.362/−0.18, 0.329/−0.16, and 0.354/0.00, respectively. In addition, the incorporated diethylether of the **O2** salt is so heavily disordered that the hydrogen atoms on the solvent were not included in the refinement procedure. The other incorporated molecules also have large thermal ellipsoids, suggesting dynamic disorder.

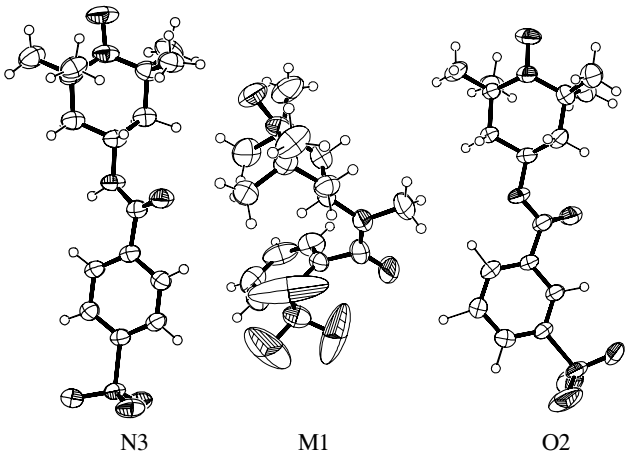

Fig. 1. Molecular structures of **N3**, **M1**, and **O2** in their PPh_4 salts.

3.2. TTF salts

The crystal data of five TTF salts together with a BEDT-TTF salt are shown in Table 2. Now we focus on the TTF salts. In the five salts, each TTF is a monocation and forms a face-to-face dimer, indicating the formation of a spin singlet. Thus, the TTF dimers in all salts are non-magnetic. There are many S···S interactions between both TTF cations of the dimers. On the other hand, there is no or one short S···S contact between dimers for all TTF salts, indicating a poor conduction pathway, and low electrical conductivities for all salts. Actually, the electrical resistivity of more than 10^6 Ω cm are observed for all TTF salts.

The **N2**, **O1**, and **O3** salts have a centrosymmetric TEMPO···TTF···TTF···TEMPO unit, in which the two TTF molecules form a face-to-face dimer which interacts with the TEMPO parts, as shown in Fig. 2. Many short S···S contacts between both TTFs and one or two short contacts between an S or C atom of TTF and the spin centre O atom of TEMPO are observed. However, no direct interactions between the TEMPO parts are observed. Therefore, the magnetic interaction between TEMPO parts via the intraunit route is likely. Their temperature-dependent magnetic susceptibilities are explained, however, by an ordinary Curie–Weiss model with C = 0.379, 0.365, and 0.361 emu K mol^{-1} and θ = +0.06, −0.17, and +0.07 K for the **N2**, **O1**, and **O3** salts, respectively. The small Weiss constants ($\ll$1 K) indicate that there are little magnetic interactions between the two TEMPO moieties

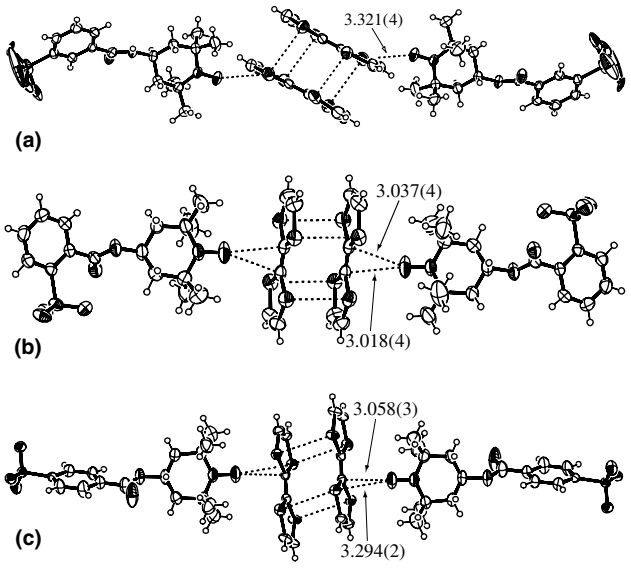

Fig. 2. Structures of the TEMPO···TTF···TTF···TEMPO units in (a) (TTF)(**N2**) · CH_3CN, (b) (TTF)(**O1**) · $0.5CH_3CN$, and (c) (TTF)(**O3**). Dashed lines indicates short S···S (<3.70 Å), S···O (<3.35 Å), and O···C (<3.25 Å) contacts.

via the TTF dimer in the TEMPO···TTF···TTF···TEMPO unit.

The **N3** and **M3** salts do not have any interactions between TEMPO and TTF but have an interaction between TEMPOs. The networks of the TEMPO moieties in the **N3** salt are shown in Fig. 3. The O atom of the spin centre of TEMPO interacts with both an ethylene group and the amino group of the nearest TEMPO to form a 1-D magnetic network along the *n* axis. According to McConnell's theory, both contacts can mediate a ferromagnetic interaction [25]. Actually, the magnetic behaviour is explained by the 1-D ferromagnetic Heisenberg model with $C = 0.331$ emu K mol^{-1} and $\theta = 0.16$ K. In addition, there is positional disorder of three sulfonate O atoms, and each atom refined over two possible positions. The elongated displacement ellipsoids of the O atoms suggest rotational disorder of the $-SO_3$ group.

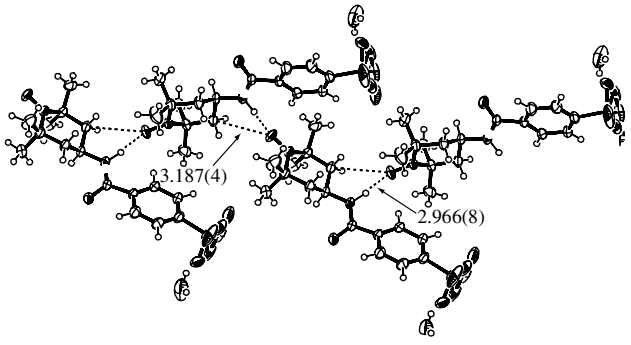

Fig. 3. TEMPO–TEMPO interactions in (TTF)(**N3**) · $0.33H_2O$.

The crystal structure of the **M3** salt is shown in Fig. 4. There are one TTF cation, one **M3** anion, and one water molecule in the asymmetric unit. The TTF cations form dimers which stack along the *a* axis to form a 1-D column, though the interdimer interaction is weak. There are many short S···O contacts between S atoms of TTF and O atoms of both sulfonate and amido as shown in Fig. 4. A magnetically important interaction between the TTF S atoms and the TEMPO O atom was not observed. However, a magnetically important interaction, a short contact (labeled A in Fig. 4) between the O atom of TEMPO and a methylene group of the adjacent TEMPO moiety was observed. Through the interactions, the anions form a 1-D magnetic chain along the *a* axis (see Fig. 4). According to the McConnell's theory, the contact can mediate the ferromagnetic interaction [25]. The distance of the contact of 3.37(2) Å, however, is slightly larger than their van der Waals distance (3.35 Å), suggesting that the interaction is weak. This crystallographic information suggests that the salt is a weak 1-D ferromagnet. However, the magnetic susceptibility data does not obey a 1-D ferromagnetic nor antiferromagnetic Heisenberg model but obeys a Curie–Weiss model with $C = 0.376$ emu K mol^{-1} and $\theta = -7.75$ K. The relatively large negative Weiss constant indicates that there are relatively large magnetic interactions. We have tried to deduce if this occurs through space. The shortest O···O distance of 5.407(2) Å is, however, somewhat longer for the large Weiss constant. Interactions between TTF and **M3** (see Fig. 4) may play some role. In addition, the anion has *cis* conformation in the TTF salt, though it has *trans* conformation in the starting material, (PPh_4)(**M3**) · CH_3CN as mentioned in the Section 3.1.

3.3. BEDT-TTF salt

So far, we have obtained only one BEDT-TTF salt, α-(BEDT-TTF)$_3$(**M1**)$_2$ · $8H_2O$. The crystal structure is shown in Fig. 5.

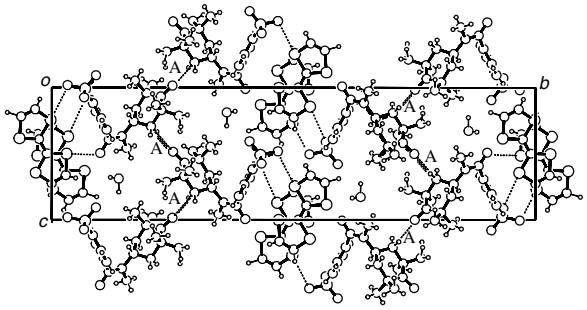

Fig. 4. Projection of the crystal structure of (TTF)(**M3**) · H_2O down the *a* axis. Thinner dashed lines indicate short S···O contacts (<3.35 Å) and thicker dashed lines labeled A indicate short O···C contact of 3.37(2) Å between the TEMPO parts.

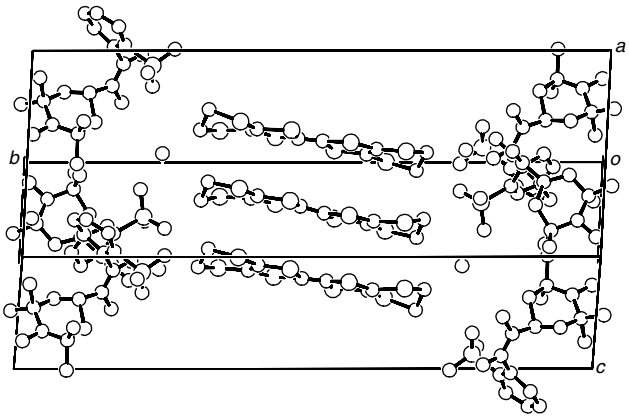

Fig. 5. Crystal structure of α-(BEDT-TTF)$_3$(**M1**)$_2 \cdot 8H_2O$.

In the asymmetric unit, there are one and a half donors, one anion, and four water molecules. The donor forms a trimer about a centre of symmetry. It stacks along the *a* axis and the stacks interact with each other, giving an α-type 2-D conducting sheet (Fig. 6). The formal charge of +2 on each BEDT-TTF trimer is calculated, so that each trimer has two spins which form a spin singlet, suggesting that the trimer is non-magnetic and the salt is a band insulator. Actually, the salt shows semiconductive behaviour with a room temperature electrical resistivity of $1.6 \times 10^3\ \Omega$ cm and an activation energy of 0.95 eV.

Neither the interaction between the BEDT-TTF cation and the TEMPO moiety nor the interaction between the TEMPO parts is observed. Thus, any magnetic interactions are unlikely. Nevertheless, a Curie–Weiss behaviour with a relatively large Weiss constant (C = 0.281 emu K mol^{-1} and $\theta = -3.64$ K) was observed. In addition, the observed shortest O···O distance of 5.908(2) Å suggests that through-space interaction between the TEMPO parts is also unlikely. The CT interaction between TEMPO and BEDT-TTF may play some part in the magnetic interaction.

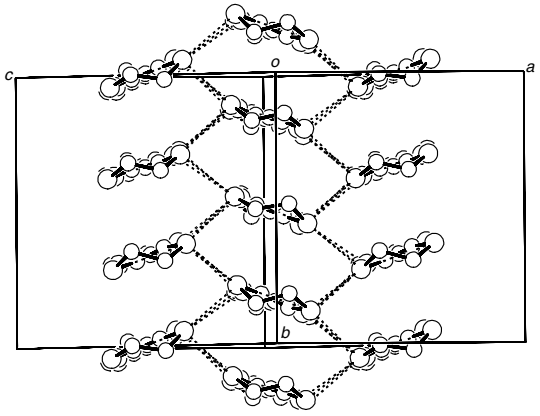

Fig. 6. Donor packing arrangement of α-(BEDT-TTF)$_3$(**M1**)$_2 \cdot 8H_2O$. Dashed lines indicate short S···S contacts less than 3.7 Å.

4. Conclusion

We have found new TTF- and BEDT-TTF-based CT salts that include a genuine organic magnetic anion, TEMPO–A–CO–(*o*-, *m*-, *p*-)$C_6H_4SO_3^-$(A = NH, NCH_3, O). The (TTF)(TEMPO–NHCO–*m*-$C_6H_4SO_3$ (**N2**)) · CH_3CN, (TTF)(TEMPO–OCO–*o*-$C_6H_4SO_3$ (**O1**)) · $0.5CH_3CN$, and (TTF)(TEMPO–OCO–*p*-$C_6H_4SO_3$ (**O3**)) salts contain the TEMPO···TTF··· TTF···TEMPO unit. Both spin centre O atoms of TEMPO interact via TTF face-to-face dimer through short S···O contacts. However, the Weiss constants of their salts are much less than 1 K, indicating little magnetic interaction. On the other hand, the (TTF)(TEMPO–NCH_3CO–*p*-$C_6H_4SO_3$ (**M3**)) · H_2O and (BEDT-TTF)$_3$(TEMPO–NCH_3CO–*o*-$C_6H_4SO_3$ (**M1**))$_2 \cdot 8H_2O$ salts have no crystallographically significant short contacts that can mediate magnetic interactions between the TEMPO spin centres, but have relatively large Weiss constants. Further investigation to establish the origin of magnetic interactions is now in progress.

5. Supplementary material

Full crystallographic data (CCDC 255996 for (PPh_4)(**N1**) · CH_3CN, CCDC 255997 for (NMe_4)(**N2**), CCDC 255998 for (PPh_4)(**N3**) · CH_3CN, CCDC 255999 for (PPh_4)(**M1**) · CH_3COCH_3, CCDC 256000 for (PPh_4)(**M3**) · CH_3COCH_3, CCDC 256001 for (PPh_4)(**O1**) · $0.5C_6H_6$, CCDC 256002 for (PPh_4)(**O2**) · $C_2H_5OC_2H_5$, CCDC 256003 for (PPh_4)(**O3**), CCDC 256004 for (TTF)(**N2**) · CH_3CN, CCDC 256005 for (TTF)(**N3**) · $0.33H_2O$, CCDC 256006 for (TTF)(**M3**) · H_2O, CCDC 256007 for (TTF)(**O1**) · $0.5CH_3CN$, CCDC 256008 for (TTF)(**O3**), and CCDC 256009 for (ET)$_3$(**M1**)$_2 \cdot 8H_2O$) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director CCDC, 12 Union Road, Cambridge, CB21EZ, UK (Fax: +44-1223-336-033; Email: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

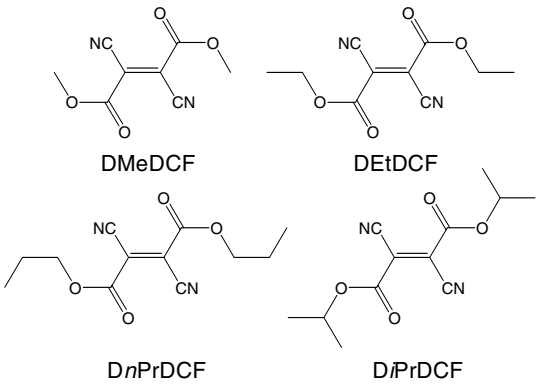

Fig. 1. One-electron acceptors discussed in this paper.

below 5.4 K [4]. The structure of both of these compounds can be characterized as pseudo-one-dimensional stacks with ferromagnetic interactions within the stack (as indicated by a positive θ value) but with interstack interactions that appears to change sign as the result of adding two methylene groups to the acceptor in going from DMeDCF to DEtDCF. At the time of those publications, due to a lack of a crystal structure for the diethyl homolog, we speculated that the change in magnetic properties was solely the result of the added bulk leading to an increasing the separation between stacks, an idea that we here show was not entirely correct.

To investigate this family of compounds further and to help to more firmly establish a structure–property relationship, two yet more bulky acceptors, di-*n*-propyl dicyanofumarate (D*n*PrDCF) and di-isopropyl dicyanofumarate (D*i*PrDCF) (Fig. 1) and their corresponding decamethylchromocene CT salts were prepared by adapting previously published methods [5]. Single crystal X-ray diffraction analysis of these compounds and comparison to the dimethyl and diethyl homologs has revealed a clear correlation between molecular packing and magnetic properties. The corresponding manganese analogs have also been prepared and, assuming these have the same structure as the chromium compounds, similarly clear patterns relating structure and behavior are apparent.

2. Experimental

2.1. General considerations

Preparations of air-sensitive compounds were carried out in a nitrogen-filled vacuum atmospheres glove box and by using standard Schlenk techniques. Decamethylchromocene and decamethylmanganocene were purchased from Strem Chemicals. All other reagents were purchased from Aldrich or Alfa. Reagents were used as received except as noted below. Dichloromethane was distilled from P_2O_5. Diethyl ether was distilled from Na/benzophenone. All solvents were degassed with glove box N_2 prior to use. Di-*n*-propyl dicyanofumarate and di-isopropyl dicyanofumarate were synthesized by adaptation of the previously published route [5]. Elemental analyses were performed by Desert Analytics, Tucson, AZ.

2.2. Magnetic measurements

All the magnetic measurements were performed on a 7 T Quantum Design MPMS SQUID magnetometer. Measurements of magnetization as a function of temperature were performed from 1.8 to 300 K and in a 1000 G applied field. Powder samples were cooled in zero applied field and measured upon warming. Samples were prepared as previously described [6]. The amplitude of the oscillating magnetic field used for ac susceptibility measurements was 3.5 Oe with zero dc bias field and at frequencies of 1, 10, 100, and 1000 Hz. Diamagnetic corrections were applied based on Pascal's constants for χT and χ^{-1} versus T plots but no corrections were applied to the M versus H or ac data. Magnetic measurements were performed on partially or fully desolvated materials except for one ac susceptibility experiment performed on $[CrCp^*_2][DiPrDCF] \cdot 2CH_2Cl_2$ in the presence of excess mother liquor.

2.3. X-ray crystallography

Dark Red plates ($0.12 \times 0.12 \times 0.055$ mm^3) of $[CrCp^*_2]$-[D*i*PrDCF], **4** were crystallized from dichloromethane by slow diffusion of pentane at room temperature in the glovebox. The chosen crystal was mounted on a nylon CryoLoop™ (Hampton Research) with Krytox® Oil (DuPont) and centered on the goniometer of an Oxford Diffraction Xcalibur2™ diffractometer equipped with a Sapphire 2™ CCD detector. The data collection routine, unit cell refinement, and data processing were carried out with the program CrysAlis [7]. The Laue symmetry was consistent with the triclinic space group $P\bar{1}$. The structure was solved by direct methods using Sir92 [8] via the WinGX [9] graphical user interface. The structure was refined using the SHELXTL NT program package [10]. The asymmetric unit of the structure comprises 0.5 crystallographically independent $[CrCp^*_2][DiPrDCF]$ formula unit and one CH_2Cl_2 solvate. The final refinement model involved anisotropic displacement parameters for non-hydrogen atoms and a riding model for all hydrogen atoms. The program package SHELXTL NT was used for molecular graphics generation [8].

2.4. Decamethylchromocenium di-n-propyl dicyanofumarate $[CrCp^*_2][DnPrDCF]$ (3)

Decamethylchromocene (55 mg, 1.7×10^{-4} mol) was dissolved in 2 ml of CH_2Cl_2. To this solution was added a solution of di-*n*-propyldicyanofumarate (40 mg,

1.6×10^{-4} mol) in 2 ml of CH_2Cl_2. Immediately, the color of the solution turned from yellow to brown. After the solution had stirred for 0.5 h at room temperature, 12 ml of diethyl ether was slowly added to precipitate an air-sensitive, brown solid. This solid was filtered, washed with diethyl ether, and dried in vacuo. Yield: 44 mg (48%). *Anal.* Calc. for $[CrCp^*_2][DnPrDCF] \cdot 2CH_2Cl_2$, $C_{33}H_{46}N_2O_4Cl_2Cr$: C, 60.27; H, 7.05; N, 4.26. Found: C, 59.46; H, 7.31; N, 4.23%.

2.5. Decamethylchromocenium di-isopropyl dicyanofumarate [$CrCp^*_2$][DiPrDCF] (4)

This salt was synthesized using the same procedure as above starting with di-isopropyl dicyanofumarate. Yield: 27 mg (29%). *Anal.* Calc. for $[CrCp^*_2][DiPrDCF] \cdot 2CH_2Cl_2$, $C_{33}H_{46}N_2O_4Cl_2Cr$: C, 60.27; H, 7.05; N, 4.26. Found: C, 59.82; H, 7.42; N, 4.41%.

2.6. Decamethylmanganocenium di-n-propyl dicyanofumarate [$MnCp^*_2$][DnPrDCF] (5)

Under nitrogen, decamethylmanganocene (51 mg, 1.6×10^{-4} mol) was dissolved in 2 ml of CH_2Cl_2, and the solution was cooled to −77 °C using a dry ice/acetone bath. To this solution was added a solution of di-*n*-propyl dicyanofumarate (37 mg, 1.5×10^{-4} mol) in 3 ml CH_2Cl_2. The solution turned from yellow to brown after addition of a few drops. After the solution had stirred for 0.5 h at −77 °C, 12 ml of diethyl ether was slowly added to precipitate a greenish brown solid. This solid was collected on a pre-cooled glass frit by vacuum filtration and washed with diethyl ether. The solid was dried in vacuo at low temperature for 2 h, then 0.5 h at room temperature. Yield: 72 mg (88%). *Anal.* Calc. for $[MnCp^*_2][DnPrDCF] \cdot 0.05CH_2Cl_2$, $C_{32.05}H_{44.1}N_2O_4Cl_{0.1}Mn$: C, 66.38; H, 7.66; N, 4.83. Found: C, 65.72; H, 7.92; N, 4.83%.

2.7. Decamethylmanganocenium di-isopropyl dicyanofumarate [$MnCp^*_2$][DiPrDCF] (6)

This salt was synthesized using the same procedure as above, starting with di-isopropyl dicyanofumarate. Yield: 65 mg (79%). *Anal.* Calc. for $[MnCp^*_2][DiPrDCF] \cdot 0.05CH_2Cl_2$, $C_{32.05}H_{44.1}N_2O_4Cl_{0.1}Mn$: C, 66.38; H, 7.66; N, 4.83. Found: C, 66.85; H, 7.45; N, 4.71%.

3. Results and discussion

3.1. Structures

Compounds **3** and **4** have been prepared by adapting previously published procedures and their properties are quite reminiscent of compound **2**. All three compounds crystallize as dichloromethane solvates with two solvent molecules and one CT salt formula unit in the unit cell. The structure of **2** was previously published and the structure of **4** is shown in Fig. 2 and the parameters given in Table 1. Compound **3** does not crystallize as well, but a low resolution structure solution reveals the symmetry and parameters of the unit cell as well as the packing motif. The isomorphous structures of **2**–**4** are comprised of pseudo-one-dimensional stacks of alternating donors and acceptors. One of the methyl groups of each isopropyl group in **4** is pointed in the direction of the metallocene and that increases the distance between the donor and acceptor within a stack slightly, due to a steric interaction. The *n*-propyl of **3**, like the ethyl compound of **2**, and the methyl compound of **1** (which crystallizes in the orthorhombic space group *Pnma*) are essentially planar (Figs. 2 and 3). Together, **1**–**4** form a homologous series.

The principal differences between the structures of **1** and **2**–**4** are that:

(1) Whereas for **1**, the metallocene is exactly above the middle of the inversion center of the acceptor, in **2**–**4** there is a slight offset of approximately 0.6 ± 0.2 Å, with a greater shift for isopropyl and essentially equivalent smaller shifts for Et and *n*-Pr.
(2) In the structures of **2**–**4**, the donors and acceptors are offset slightly in the direction of the stacking axis, so that they form a stepped structure.
(3) The methyl groups on the metallocene are eclipsed for **1**, but staggered for **2**–**4**.
(4) **2**–**4** are all dichloromethane solvates, whereas **1** is unsolvated.
(5) Perhaps most importantly, when viewed down the stacking axis, the donors in **1** form a zig-zag chain, whereas for **2**–**4**, they form linear chains. The effect of this and the presence of solvent molecules is a

3.2. Magnetic properties

Previously, we have identified that ferromagnetic $[CrCp^*_2][DMeDCF]$ crystallizes in the space group, *Pnma*, and we assume that the manganese analog, $[MnCp^*_2][DMeDCF]$, also has this structure. The unit cell, which is orthorhombic (Fig. 3), has four formula units in the unit cell arranged as four mixed stacks of donors and acceptors in two adjacent pairs, with one pair shifted with respect to the other stack by one-half repeat unit. Similar patterns have been observed for

ferromagnetic [$FeCp^*_2$][TCNE] which crystallizes in *C*2/*c*, a monoclinic space group with eight formula units in the unit cell [11]. However, what we observe here is that when we move to higher homologs of the dialkyl dicyanofumarate family, we crystallize in the lower triclinic symmetry and we observe a change to antiferromagnetic (metamagnetic) order. As described below, this behavior is seen for compounds **2**–**4**.

3.3. Decamethylchromocenium salts

Measurements of χT versus temperature, χ^{-1} versus temperature, magnetization versus applied field at 1.8 K and ac susceptibility at 1 Hz (Figs. 6–11) reveal that **3** (*n*-propyl) and **4** (isopropyl) are metamagnets with $T_N = 4.6$ and 3.9 K, respectively. The compounds obey the Curie–Weiss law with $\theta = 28$ and 19 K, respectively. Metamagnetism is indicated by frequency-independent peaks in χ' and no non-zero χ'' in each plot. The critical field, above which the magnetization switches from antiferromagnetic to ferromagnetic-like, for each of these two compounds is very small, consistent with the lack of single ion anisotropy for Cr^{3+}, which in this geometry, has a ^4A ground state. The saturation magnetization for each compound approaches 22 340 emu-G/mol expected for four unpaired spins with $g = 2.0$. The previously reported behavior of **2** is also that of a metamagnet with $T_N = 5.4$ K and similar other magnetic properties. These data are consistent with the observed isomorphous structures with the possibility of a weak trend toward lower ordering temperatures with the bulkier di-isopropyl dicyanofumarate ligand.

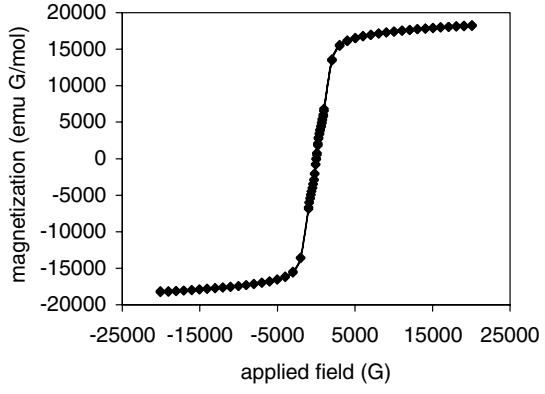

Fig. 7. M vs. H for [$CrCp^*_2$][D*n*PrDCF] at 1.8 K.

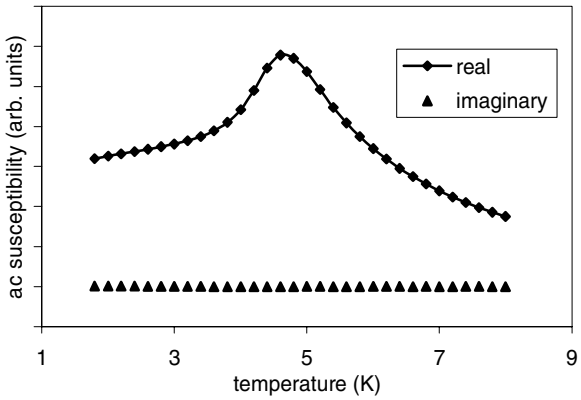

Fig. 8. Ac susceptibility for [$CrCp^*_2$][D*n*PrDCF].

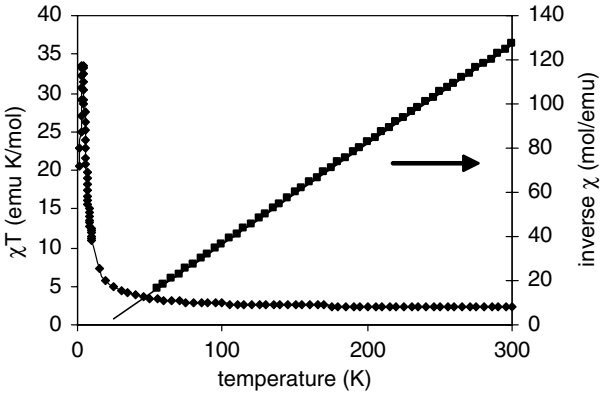

Fig. 9. χT vs. T (◆) and χ^{-1} vs. T (■) for [$CrCp^*_2$][D*i*PrDCF].

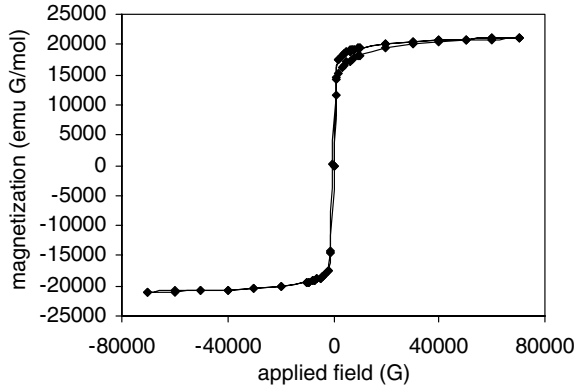

Fig. 10. M vs. H for [$CrCp^*_2$][D*i*PrDCF] at 1.8 K.

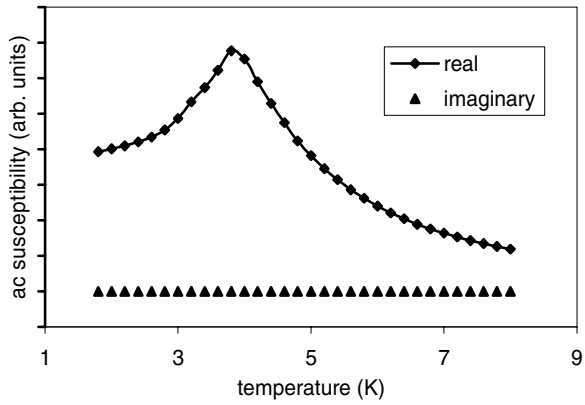

Fig. 11. Ac susceptibility for $[CrCp^*_2][DiPrDCF]$.

Because both of the samples described above are partially desolvated, the ac susceptibility of a fully solvated sample was determined. Fig. 12 illustrates the frequency-independent ac susceptibility of $[CrCp^*_2][DiPrDCF]\cdot 2CH_2Cl_2$, which required that the data be collected in the presence of excess dichloromethane mother liquor. As can be seen, the solvated sample is still a metamagnet, although there is a slight lowering of T_N and sharpening of the peak in χ' relative to the data from the partially desolvated compound. This is consistent with preservation of the single crystal structure with its solvent of crystallization intact, which causes the stacks to be further apart but also makes the interstack separation (and interaction) more uniform.

3.4. Decamethylmanganocenium salts

Compounds **5** and **6**, the manganese analogs of **3** and **4**, respectively, have also been prepared. These compounds have not been successfully crystallized because they are not stable in solution except at very low temperatures as has been seen previously for the dimethyl and diethyl esters. In fact, under the synthesis conditions, the materials are almost completely desolvated, as indicated by elemental analysis results. As a result, the crystallinity is destroyed and no X-ray powder diffraction is observed, although the compounds do exhibit reproducible magnetic properties (vide infra).

The plots of χT versus temperature and χ^{-1} versus temperature for **5** and **6** (Figs. 13 and 16, respectively)

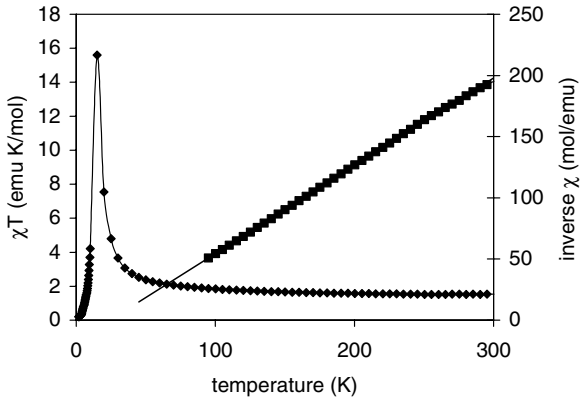

Fig. 13. χT vs. T (◆) and χ^{-1} vs. T (■) for $[MnCp^*_2][DnPrDCF]$.

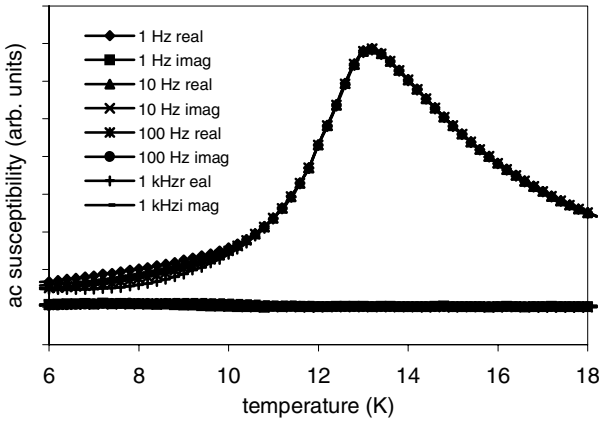

Fig. 14. Ac susceptibility for $[MnCp^*_2][DnPrDCF]$.

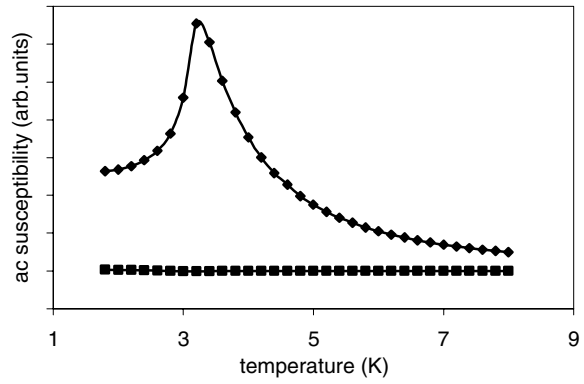

Fig. 12. Ac susceptibility for $[CrCp^*_2][DiPrDCF]\cdot 2CH_2Cl_2$.

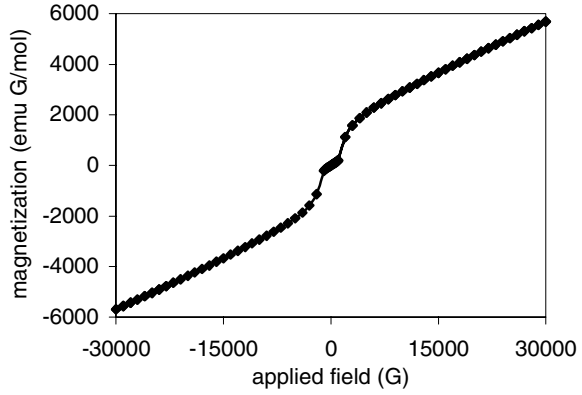

Fig. 15. M vs. H for $[MnCp^*_2][DnPrDCF]$ at 13 K.

suggest dominant ferromagnetic coupling, with $\theta = 24$ and 7.3 K, respectively. But the more revealing data are the ac susceptibility and the magnetization versus applied field (M versus H) plots. Figs. 14 and 17 show the ac susceptibility data for **5** and **6** which in each case is characterized by what appears to be a frequency independent antiferromagnetic phase transition followed at lower temperature by a frequency dependent region indicative of a glassy magnetic state. We have previously speculated that the glassy region is due to additional antiferromagnetic interstack interactions that become significant as the temperature is lowered.

M versus H data (Figs. 15 and 18, respectively), collected at a temperature just below the peak in χ' as determined from the ac data for each compound, exhibit the characteristic shape of a metamagnet. Well below these temperatures (Figs. 19 and 20), at 1.8 K, in the glassy state, however, a wide hystersis loop opens up, just as seen previously for $[MnCp^*_2][DEtDCF]$ (**8**). For **5**, at 1.8 K, the coercive field is 1.3 T and the remanance is 5500 emu-G/mol whereas for **6**, the coercive field is 1.3 T and the remanance is 8000 emu-G/mol. In neither case does the magnetization in 7 T applied field approach even close to the expected value for co-linear spins, indicating some canting of the manganese moments.

In contrast, $[MnCp^*_2][DMeDCF]$ (**7**), is a ferromagnet with $T_c = 10$ K, paralleling exactly the behavior observed in the chromium family.

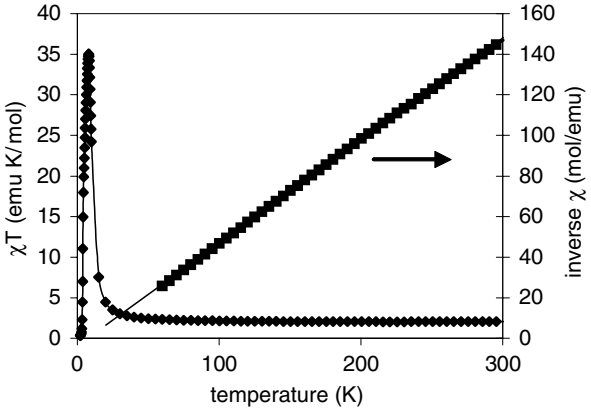

Fig. 16. χT vs. T (◆) and χ^{-1} vs. T (■) for $[MnCp^*_2][DiPrDCF]$.

Table 2
Magnetic and structural data for all compounds in this paper

$[CrCp^*_2][DMeDCF]$	FM, 5.7 K	*Pnma*	$[MnCp^*_2][DMeDCF]$	FM, 10 K
$[CrCp^*_2][DEtDCF]$	MM, 5.4 K	$P\bar{1}$	$[MnCp^*_2][DEtDCF]$	MM, 12 K
$[CrCp^*_2][DiPrDCF]$	MM, 3.9 K	$P\bar{1}$	$[MnCp^*_2][DiPrDCF]$	MM, 9.3 K
$[CrCp^*_2][DnPrDCF]$	MM, 4.6 K	$P\bar{1}$	$[MnCp^*_2][DnPrDCF]$	MM, 13.4 K

The manganese structures are assumed to be the same as their chromium analogs. $P\bar{1}$ structures listed are for solvated crystals.

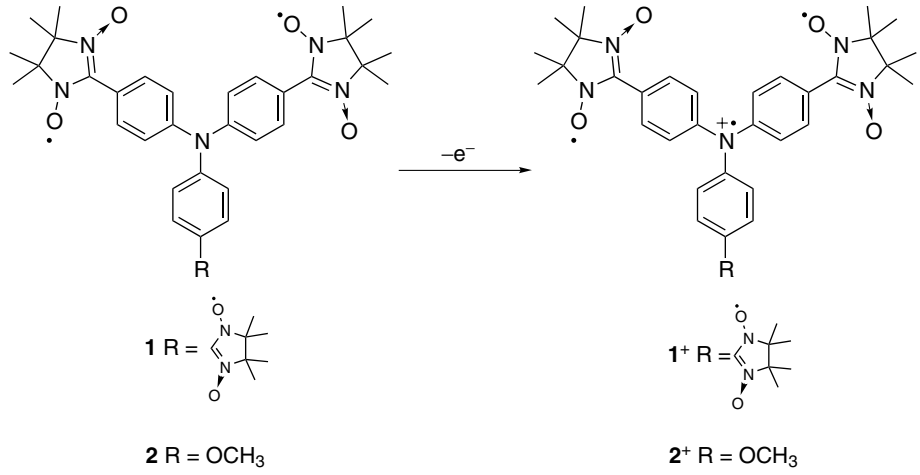
4. Summary

Decamethylmetallocene-based CT salts are excellent examples of pseudo-one-dimensional materials exhibiting magnetic long range order that must arise solely from through-space interactions because the solids feature only non-covalent interactions between the spin centers. As such, they are excellent platforms on which to base experiments that seek to understand how order is achieved by systematic variation of the building blocks. In this paper, we have established that there is a correlation between crystal packing and three-dimensional magnetic order as summarized in Table 2.

Furthermore, in both the decamethylchromocene and decamethylmanganocene families, the sterically more demanding di-isopropyl dicyanofumarate enforces greater intrastack separation, which results in lower θ values and ordering temperatures. It should be noted that single crystals are solvated, whereas most of the magnetic measurements were performed on partially or fully desolvated powders. However, one ac experiment was performed in the presence of excess solvent and the behavior is qualitatively similar, with the difference being a sharpening in the peak in χ' and slight lowering of temperature at which the peak occurs. This is consistent with the expectation of greater interstack separation and greater interstack uniformity in the crystalline materials.

Although our previous supposition that the switch from ferromagnetism to metamagnetism results from simply separating the stacks to a greater extent was not entirely correct, we now have a more complete and satisfying picture in which the change in magnetic behavior is brought about by a change in crystal packing. However, the details of how the specific intrastack and interstack interactions give rise to magnetic order remain to be determined.

Acknowledgments



We thank the NSF (Grant CHE-0131128) for funding the purchase of the Oxford Diffraction Xcalibur2 single crystal diffractometer and (Grant CHE-023488) for partially funding the purchase of the SQUID magnetometer. We thank the CCDC for use of the Mercury program for visualizing crystal structures.

Scheme 1.

(δ77.0 ppm) for ^{13}C NMR. IR spectra were recorded using KBr disks on a JASCO FT/IR-460Plus spectrometer. ESR spectra were recorded on a JEOL JES-SRE2X or a JEOL JES-TE200 spectrometer, and a Mn^{2+}/MnO solid solution was used as a reference for the determination of g values and hyperfine coupling constants. Magnetic susceptibilities of the powder samples were measured by a Quantum Design MPMS-5S system. The raw data were corrected for both the magnetization of sample holder alone and the diamagnetic contribution of the sample itself. The estimation of the diamagnetic contribution was done by using Pascal's constants. Elemental analyses were performed by Center for Organic Elemental Microanalysis, Kyoto University. Toluene and *n*-butyronitrile were distilled from CaH_2 under an argon atmosphere, acetonitrile was dried over molecular sieves 3A, and benzonitrile was dried through alumina (ICN, Alumina N, Akt. I) column with bubbling of argon, just before use. All the other purchased reagents and solvents were used without further purification. Column chromatography was performed using silica gel (Kanto Chemical Co., Inc., Silica gel 60N, spherical neutral).

2.2. Tris(4-formylphenyl)amine (7)

7 was prepared by the modified method of literature procedure [15]. To a solution of imidazole (2.50 g, 36.0 mmol) in acetonitrile (30 mL) was added dropwise trifluoroacetic anhydride (16.00 g, 75.4 mmol) under an argon atmosphere. The mixture was refluxed for 1 h, and then cooled by removal of the oil bath. Triphenylamine (2.50 g, 9.99 mmol) was added to the mixture, and then the reaction mixture was refluxed for 20 h. After cooling to room temperature, the reaction mixture was treated with ice to give a green precipitate, which was filtrated and washed with water. The precipitate was dissolved in CH_2Cl_2, washed with saturated aqueous $NaHCO_3$, and dried over $MgSO_4$, and the solvent was removed under reduced pressure to afford a greenish yellow solid (9.77 g), which was used for the next step without further purification.

To a suspension of this crude product (9.77 g) in acetonitrile (200 mL) was added a dilute hydrochloric acid (20 mL of conc. hydrochloric acid and 100 mL of water) under an argon atmosphere. The mixture was refluxed for 4 h, and extracted with Et_2O after cooling and neutralization with saturated aqueous Na_2CO_3 at 0 °C. The organic layer was dried over $MgSO_4$, and the solvent was removed under reduced pressure. The residue was chromatographed on silica gel (CH_2Cl_2:*n*-hexane = 3:1 as eluent), and washed with hot ethyl acetate and *n*-hexane to afford **7** (2.12 g, 64 %) as a yellow solid: IR(KBr) 2805, 2729, 1697 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ 9.94 (s, 3H), 7.84 (d, J = 8.7 Hz, 6H), 7.25 (d, J = 8.7 Hz, 6H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 190.3, 151.1, 132.5, 131.4, 124.5. *Anal.* Calc. for $C_{21}H_{15}NO_3$: C, 76.58; H, 4.59; N, 4.25; O, 14.57. Found: C, 76.30; H, 4.50; N, 4.14; O, 14.54%.

2.3. Tris[4-(1-oxyl-3-oxide-4,4,5,5-tetramethylimidazolin-2-yl)phenyl]amine (1)

A reaction flask equipped with a Soxhlet apparatus filled with molecular sieves 4A was charged with **7** (0.65 g, 1.98 mg), 2,3-bis(hydroxyamino)-2,3-dimethyl butane (1.41 g, 9.51 mmol) and 2,3-bis(hydroxyamino)-2,3-dimethylbutane sulfate (0.47 g, 1.90 mmol) in methanol (150 mL), and refluxed for 18 h under an argon atmosphere. The reaction mixture was concentrated by evaporation, and the resulting precipitate was collected and washed with cold methanol to afford a yellowish white solid (0.64 g). The further purification was not performed.

To a solution of the product (0.64 g) in dichloromethane (36 mL) and methanol (3.6 mL) was added a

solution of $NaIO_4$ (0.48 g, 2.24 mmol) in water (3.6 mL). The mixture was stirred for 30 min in the open air. The organic layer was separated, dried over $MgSO_4$ and the solvent was removed under reduced pressure. The residue was chromatographed on silica gel (ethyl acetate:*n*-hexane = 4:1 as eluent), concentrated by evacuation of solvent, and washed with the mixed solvent (CH_2Cl_2:*n*-hexane = 1:9) to afford **1** (30.8 mg, 2%) as a blue solid: ESR (toluene) 13 lines, $g = 2.007$, $|a_N| = 2.5$ G.

2.4. N,N-diphenyl-4-methoxyphenylamine (4)

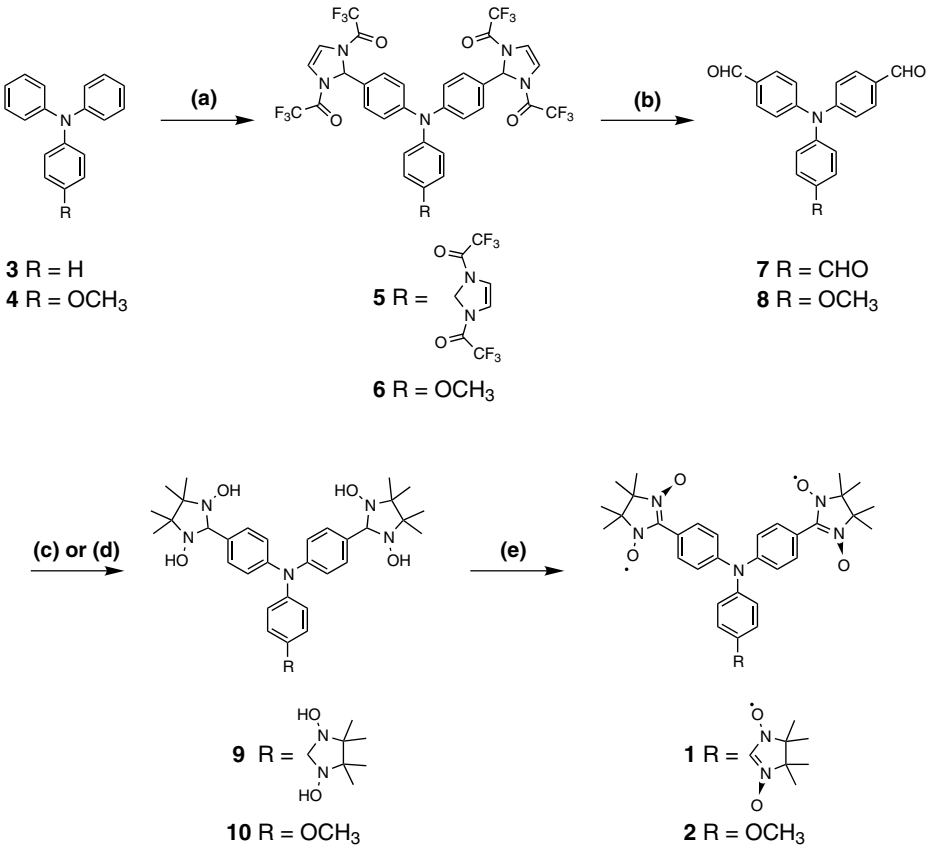
4 was prepared by the modified method of literature procedure [16]. A mixture of 4-iodoanisole (7.65 g, 32.7 mmol), diphenylamine (5.53 g, 32.7 mmol), CuI (0.15 g, 0.79 mmol) and KO*t*-Bu (11.0 g, 98.0 mmol) in toluene (120 mL) was refluxed under argon atmosphere for 1 day. After cooling to room temperature, the solvent was evaporated. Water and CH_2Cl_2 was added to the residue, and the organic layer was separated, dried over $MgSO_4$ and evaporated. The residue was chromatographed on silica gel (ethyl acetate:CH_2Cl_2:*n*-hexane = 1:9:30) to afford **4** (4.27 g, 47%) as a yellow solid: ^{1}H NMR (400 MHz, $CDCl_3$) δ 7.19 (dd, $J = 8.5$, 7.3 Hz, 4H), 7.06 (d, $J = 9.0$ Hz, 2H), 7.02 (dd, $J = 7.3$, 1.2 Hz, 4H), 6.93 (tt, $J = 7.3$, 1.2 Hz, 2H), 6.83 (d, $J = 9.0$ Hz, 2H), 3.79 (s, 3H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 156.0, 148.1, 140.7, 129.0, 127.2, 122.8, 121.8, 114.7, 55.5. *Anal*. Calc. for $C_{19}H_{17}NO$: C, 82.88; H, 6.22; N, 5.09; O, 5.81. Found: C, 82.82; H, 6.08; N, 5.07; O, 5.66%.

2.5. N,N-Bis(4-formylphenyl)-4-methoxyphenylamine (8)

8 was prepared by the similar method of literature procedure [15]. To a solution of imidazole (2.72 g, 40.0 mmol) in acetonitrile (80 mL) was added dropwise trifluoroacetic anhydride (16.80 g, 80.0 mmol) under an argon atmosphere. The mixture was refluxed for 30 min, and then cooled by removal of the oil bath. **4** (4.27 g, 15.5 mmol) was added to the mixture, and then the reaction mixture was refluxed for 1 day. After cooling to room temperature, the reaction mixture was treated with ice to give a green precipitate, which was filtrated and washed with water.

The precipitate was suspended in acetonitrile (200 mL) and a dilute hydrochloric acid (36 mL of conc. hydrochloric acid and 144 mL of water) under an argon atmosphere. The mixture was refluxed for 4 h, and extracted with Et_2O after cooling and neutralization with saturated aqueous K_2CO_3 at 0 °C. The organic layer was dried over $MgSO_4$, and the solvent was removed under reduced pressure. The residue was chromatographed on silica gel (ethyl acetate:*n*-hexane = 1:4 as eluent) to afford **8** (2.89 g, 56%) as a yellow solid: IR(KBr) 2835, 2739, 1686, 1040 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) δ 9.87 (s, 2H), 7.75 (d, $J = 8.3$ Hz, 4H), 7.16 (d, $J = 8.3$ Hz, 4H), 7.11 (d, $J = 8.3$ Hz, 2H), 6.94 (d, $J = 8.3$ Hz, 2H), 3.84 (s, 3H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 190.3, 158.0, 152.0, 138.0, 131.2, 130.8, 128.8, 122.0, 115.4, 55.6. *Anal.* Calc. for $C_{21}H_{17}NO_3$: C, 76.12; H, 5.17; N, 4.23; O, 14.49. Found: C, 75.98; H, 5.31; N, 4.26; O, 14.60%.

2.6. N,N-Bis[4-(1-oxyl-3-oxide-4,4,5,5-tetramethyl imidazolin-2-yl)phenyl]-4-methoxyphenylamine (2)



A reaction flask equipped with a Soxhlet apparatus filled with molecular sieves 4A was charged with 2,3-bis(hydroxyamino)-2,3-dimethylbutane sulfate (1.30 g, 5.28 mmol) and K_2CO_3 (2.42 g, 17.5 mmol) in methanol (150 mL). To the mixture was added **8** (0.58 g, 1.75 mmol) under an argon atmosphere, and refluxed for 1 day. The reaction mixture was filtered, and the organic layer was separated after adding CH_2Cl_2 and water, dried over $MgSO_4$, and the solvent was removed under reduced pressure to afford a yellow solid (0.85 g).

To a solution of the product in dichloromethane (58 mL) and methanol (5.8 mL) was added a solution of $NaIO_4$ (0.29 g, 1.35 mmol) in water (5.8 mL). The mixture was stirred for 1 h in the open air. The organic layer was separated, dried over $MgSO_4$ and the solvent was removed under reduced pressure. The residue was chromatographed on silica gel (ethyl acetate:*n*-hexane = 3:1 as eluent) to afford **2** (50 mg, 5%) as a blue solid: ESR (toluene) nine lines, $g = 2.007$, $|a_N| = 3.7$ G.

3. Results and discussion

3.1. Synthesis

To synthesize our target molecules **1** and **2** according to the Ullman's method [17], trialdehyde **7** and dialdehyde **8** become key compounds. However, the usual Vilsmeier-Haack formylation of triphenylamine produces **7** in very low yield in spite of using the vigorous reaction conditions [18]. Therefore, we attempted to synthesize **7** and **8** by another method [15]. The synthetic routes of **1** and **2** were summarized in Scheme 2. First of all, imidazole was reacted with trifluoroacetic anhydride to generate the electrophilic *N*,*N*′-bis(trifluoroacetyl)imidazolium ion. The generated imidazolium ion was treated with the corresponding triphenylamines **3** and **4** to afford tris- and bisadduct **5** and **6**. These adducts were readily hydrolyzed to give **7** and **8** under the acidic condition. The resulting aldehydes were condensed with 2,3-bis(hydroxyamino)-2,3-dimethylbutane to give the corresponding hydroxylamine **9** and **10**. Finally, **1** and

Scheme 2. Reagents and conditions: (a) imidazole, trifluoroacetic anhydride, CH_3CN; (b) HCl aq, acetonitrile; (c) 2,3-bis(hydroxyamino)-2,3-dimethylbutane, 2,3-bis(hydroxyamino)-2,3-dimethylbutane sulfate, CH_3OH; (d) 2,3-bis(hydroxyamino)-2,3-dimethylbutane sulfate, K_2CO_3, CH_3OH; (e) $NaIO_4$, H_2O, CH_2Cl_2, CH_3OH.

2 were obtained by the oxidation of hydroxylamine with sodium periodate.

3.2. Electrochemical property

The electrochemical properties for **1** and **2** were investigated by the cyclic voltammetry in benzonitrile at 25 °C. The oxidation potentials versus ferrocene/ferrocenium are summarized together with their related compounds in Table 1, and the cyclic voltammogram of **2** is shown in Fig. 1. Judging from the oxidation potentials and the current ratio of the reference compounds, 2-phenyl-4,4,5,5-tetramethylimidazoline-1-oxyl-3-oxide (**11**), triphenylamine (**12**) and 4-methoxytriphenylamine (**13**), the first oxidation process of **1** can be ascribed to the simultaneous three-electron oxidation of the corresponding three nitronyl nitroxide moieties, while the first and second oxidation processes of **2** to stepwise one-electron oxidations of the two nitroxide moieties.

Table 1
Redox potentials (V) of **1**, **2** and their related compounds[a]

	E_1	E_2	E_3
1	+0.30[b]		
2	+0.26	+0.34	+0.80
11	+0.32		
12	+0.51[c]		
13	+0.38		

[a] 0.1 M n-Bu_4BF_4 in PhCN, potential vs. Fc/Fc^+, Pt electrode, 25 °C, scan rate 100 mV s^{-1}.
[b] Quasi-three-electron transfer.
[c] Irreversible oxidation process represented by anodic peak potential.

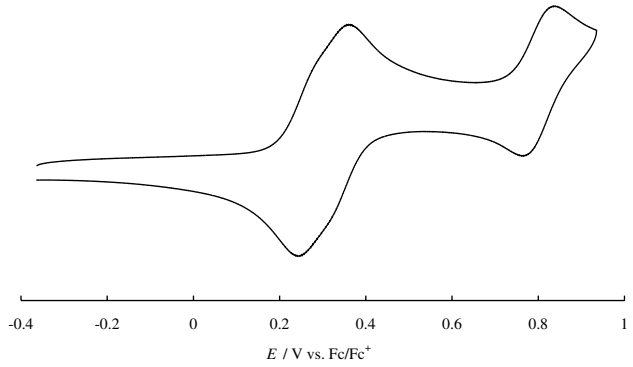


Fig. 1. Cyclic voltammogram of **2** in benzonitrile containing 0.1 M n-Bu_4BF_4 on a platinum electrode.

On the other hand, the oxidation process for the triphenylamine moiety of **1** was not observed in the range of potential window, whereas the potential value +0.80 V of **2** was due to the oxidation of triphenylamine moiety. This is probably because **1** has a considerable amount of positive charges after oxidation of the three nitronyl nitroxide moieties and, hence, the triphenylamine moiety becomes no longer oxidizable, as compared with **2**. The oxidation potential for the triphenylamine moiety of **2** increases by 0.42 V compared with **13** owing to such a charging effect of the oxidized nitronyl nitroxide moieties.

3.3. Magnetic property

Magnetic measurements of triradical **1** and diradical **2** were carried out on a SQUID susceptometer from 300 to 2 K. The temperature dependences of the molar magnetic susceptibilities (χ_m) of the microcrystalline samples were measured at a constant field of 500 G. The plot of $\chi_m T$ versus T for **1** and **2** are shown in Fig. 2.

The $\chi_m T$ value of **1** at 300 K was close to the theoretical one of 1.125 emu K mol^{-1} for isolated three spins of 1/2. On lowering the temperature, the $\chi_m T$ value decreased gradually and reached 0.28 emu K mol^{-1} at 2 K, indicating the antiferromagnetic interaction between radical spins.

The magnetic interaction in a nonsymmetrical triangular three spin system [13,14,19,20] can be described by the spin Hamiltonian (Eq. (1)), where J_{ij} is the exchange coupling constant between $\boldsymbol{S}_i$ and $\boldsymbol{S}_j$. In this case, the $\chi_m T$ is expressed by Eq. (2) as a function of Δ_1 and Δ_2 defined by Eqs. (3) and (4), which are the energy differences between the two spin doublet states and the one between the spin doublet state and the spin quartet state, where f is the purity factor for the sample, N_A the Avogadro number, g the g-factor, k_B the Boltzmann constant, μ_B the Bohr magneton, and θ the Weiss constant. Herein, we assumed the same g value for the three multiplets and, furthermore, the value was fixed $g = 2$ in the fitting procedure for simplicity.

$$H = -2(J_{12}\boldsymbol{S}_1\boldsymbol{S}_2 + J_{23}\boldsymbol{S}_2\boldsymbol{S}_3 + J_{31}\boldsymbol{S}_3\boldsymbol{S}_1), \tag{1}$$

$$\chi_m T = f\frac{N_A g^2 \mu_B^2}{4k_B}\frac{1+\exp(-\Delta_1/k_B T)+10\exp(-\Delta_2/k_B T)}{1+\exp(-\Delta_1/k_B T)+2\exp(-\Delta_2/k_B T)} \times \frac{T}{(T-\theta)}, \tag{2}$$

$$\Delta_1 = 2(J_{12}^2 + J_{23}^2 + J_{31}^2 - J_{12}J_{23} - J_{23}J_{31} - J_{31}J_{12})^{1/2}, \tag{3}$$

$$\Delta_2 = \Delta_1/2 - (J_{12} + J_{23} + J_{31}). \tag{4}$$

Since the crystal structure of **1** is not unknown to date, we carried out the least-squares fitting procedure by assuming the equilateral triangle for three spins, where $J = J_{12} = J_{23} = J_{31}$ and $\Delta_1 = 0$ gives Eq. (5). The best fit to the data was $f = 0.998 \pm 0.001$, $J/k_B = -3.93 \pm 0.06$ K and $\theta = -0.62 \pm 0.05$ K, roughly indicating the quartet state was above the doubly degenerate doublet states by ca. $3J/k_B = 12$ K. It was revealed that the intramolecular antiferromagnetic interaction of **1** was much smaller than that of tris[4-(*N*-oxy-*N*-*tert*-butylamino)phenyl]amine in the case of assuming the equilateral triangle model ($J/k_B = -135 \pm 3$ K) [13,14].

$$\chi_m T = f\frac{N_A g^2 \mu_B^2}{4k_B}\frac{1+5\exp(3J/k_B T)}{1+\exp(3J/k_B T)}\frac{T}{(T-\theta)}. \tag{5}$$

The $\chi_m T$ value of **2** at 300 K was relatively smaller than the theoretical one of 0.75 emu K mol^{-1} for isolated two spins of 1/2. Considering the $\chi_m T$ value of 0.64 emu K mol^{-1} in the wide temperature range, it seems to be not due to the antiferromagnetic interaction but to the experimental errors on weighing a sample or to the purity of a sample. As the temperature was lowered, the $\chi_m T$ value decreased gradually and reached 0.18 emu K mol^{-1} at 2 K, indicating the antiferromagnetic interaction between radical spins. The observed data were analyzed by the modified Bleaney–Bowers [21] equation for singlet–triplet model (Eq. (6)) to give the best fit parameters: $f = 0.8665 \pm 0.0006$, $J/k_B = -1.85 \pm 0.03$ K and $\theta = -1.21 \pm 0.04$ K.

$$\chi_m T = f\frac{2N_A g^2 \mu_B^2}{k_B}\frac{1}{3+\exp(-2J/k_B T)}\frac{T}{(T-\theta)}. \tag{6}$$

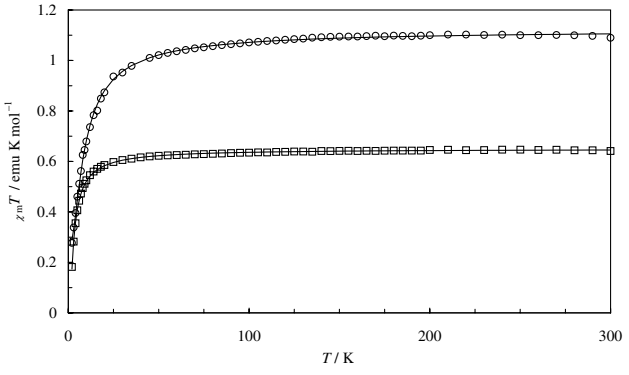

Fig. 2. Temperature dependence of $\chi_m T$ of **1** (○) and **2** (□) under a field of 500 G. The solid line represents the best theoretical fit to the data (see text).

3.4. ESR spectroscopy

The ESR spectrum in toluene at room temperature showed a 13-line pattern centered at $g = 2.007$ with a hyperfine coupling constant $|a_N| = 2.5$ G due to six equivalent nitrogen atoms for **1**, and a 9-line pattern ($g = 2.007$, $|a_N| = 3.7$ G) due to four equivalent nitrogen

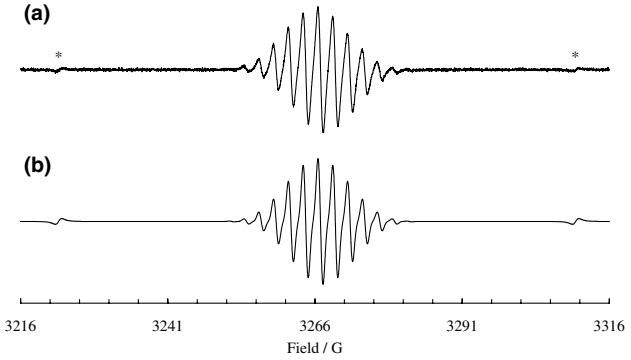

Fig. 3. ESR spectrum of **1** in toluene (5×10^{-5} M) at room temperature (a) and its simulation (b) ($|a_N| = 2.5$ G, $\Delta H_{pp} = 0.86$ G). The asterisks in the spectrum show the signals due to the Mn^{2+} standard.

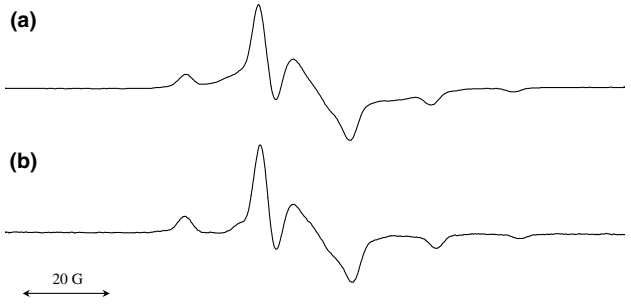

Fig. 4. ESR spectra of (a) **2** oxidized with tris(4-bromophenyl)aminium hexachloroantimonate and (b) monoradical **11** in frozen *n*-butyronitrile solution at 123 K.

atoms for **2**. For instance, the solution ESR spectrum of **1** is shown in Fig. 3. The hyperfine coupling constants of **1** and **2** were estimated to one third and a half of the hyperfine coupling constant ($|a_N| = 7.4$ G) of monoradical **11**, respectively. This indicates that the exchange interactions between radical spins in triradical **1** and diradical **2** are larger than the hyperfine interaction.

After treated with tris(4-bromophenyl)aminium hexachloroantimonate as an oxidizing agent, **1** and **2** in frozen *n*-butyronitrile at 123 K did not show the fine-structured spectra attributed to spin-quintet or quartet species. Instead of the fine-structured spectra, the observed spectra were similar to that of mono nitronyl nitroxide **11**, as shown in Fig. 4. This is consistent with the electrochemical result that the nitronyl nitroxide moieties of **1** and **2** are oxidized more easily than the triphenylamine moieties.

4. Summary

The syntheses of triradical **1** and diradical **2** having the triphenylamine skeleton were succeeded, and it is found that their neutral radicals in the solid states showed weak antiferromagnetic interactions between radical spins. However, the electrochemical and ESR measurements showed the nitronyl nitroxide moieties had the lower oxidation potentials than the core triphenylamine moieties even in the case of electron-donating methoxy-group-substitution (**2**). Therefore, in order to generate triphenylaminium cation radical and, furthermore, enhance the intramolecular ferromagnetic interaction, it is necessary to introduce more electron-donating substituent, e.g. *N*,*N*-dimethylamino group, to lower the oxidation potential. Actually, 4-*N*,*N*-dimethylaminotriphenylamine exhibits the first oxidation potential of −0.05 V. The syntheses of novel triphenylamine derivatives with nitroxide radicals are currently being undertaken, and their results will be reported in the future.

of acetonitrile (dehydrated) under argon atmosphere in a water- and oxygen-free grove-box. The suspension was heated to 80 °C for 130 h in an airtight glass container. Then the suspension was filtrated, and washing the residual with 100 ml of acetonitrile (dehydrated), 100 ml of ethanol (dehydrated) and 100 ml of dichloromethane gave anhydrous CoC_2 as beige powder. It is noted that, according to the ICP analysis, anhydrous CoC_2 contains ca. 35% of CaC_2 as raw material. Consequently, the results of the magnetism shown later are obtained by dividing the measured value by 0.65. Hydrous CoC_2 for magnetic measurement was obtained by exposing anhydrous CoC_2 to air (25 °C, humidity 70%). Though hydrous CoC_2 can also be formed by water-exposure in short time, slow water absorption in air atmosphere allow us to measure the magnetism of the intermediate state between hydrous and anhydrous. For the powder X-ray diffraction (XRD) measurement, hydrous CoC_2 was prepared by washing the air-exposed (2 days) sample with water to remove $Ca(OH)_2$. We confirmed that the peak position and width of CoC_2 are not changed by water exposure, while the peaks of CaC_2 and $Ca(OH)_2$ disappear after washing with water.

XRD pattern of hydrous CoC_2 was measured with *Mac science* MXP^{3}VA Powder X-ray Diffractometer at 293 K, using Cu Kα radiation (λ = 1.5418 Å). That of anhydrous CoC_2 encapsulated in glass tube (0.03ϕ) was carried out at the beam line 1A of the Photon Factory in KEK, using synchrotron radiation (λ = 0.9988 Å). Magnetic susceptibilities were measured by using *Quantum-Design* MPMS-XL SQUID magnetometer for powder sample embedded in epoxy resin to keep CoC_2 nanoparticles from rotating.

3. Results and discussion

Before analyzing the crystal structure, it is necessary to guess the rough structural model of CoC_2. According to the crystal structures of the related materials CaC_2 [5] and MgC_2 [6], it is suggested that Co^{2+} dications and C_2^{2-} dianions are stacked alternately like as NaCl-type structure. In addition, XRD pattern of CoC_2 approximately depends only on the arrangement of Co^{2+} dication due to its larger scattering factor than that of C_2^{2-}. The observed XRD pattern of anhydrous CoC_2 contaminated with CaC_2 is shown in Fig. 1. The observed pattern is well fitted by the two calculated patterns; one is CaC_2 based on the reported structure [5], and the other is the fcc-arrangement of Co^{2+} sublattices with the lattice constants $a = b = c = 4.82$ Å. The isotropic structure of Co^{2+} dications indicates the static or dynamic orientation disorder of C_2^{2-} like as CaC_2 IV [5], or else the lattice is distorted and the symmetry becomes low such as tetragonal or orthorhombic where the diffraction peaks split. The structural model of anhydrous

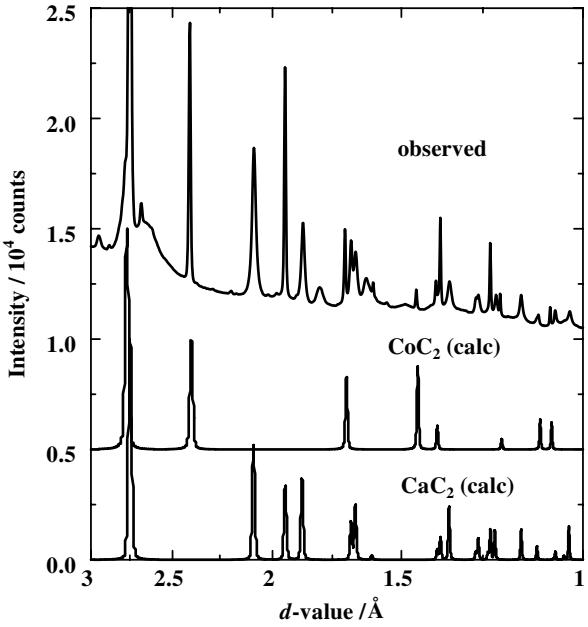

Fig. 1. The observed XRD patterns of anhydrous CoC_2 measured with synchrotron radiation (λ = 0.9988 Å) and the calculated patterns of anhydrous CoC_2 and CaC_2 (raw material). The observed pattern and calculated pattern of anhydrous CoC_2 are vertically shifted by 0.75 and 0.5×10^4, respectively, for clarify. In the calculation of the pattern of anhydrous CoC_2, the body-centered lattice of Co^{2+} sublattice was assumed and the lattice parameters are decided as the calculated pattern reproduces the observed one.

CoC_2 is shown in Fig. 2(b), where only a part of the unit cell is shown to compare with the structure of the hydrous CoC_2 discussed later. Incidentally, the peaks of CoC_2 are fairly sharp, from which the crystallite size D of CoC_2 is estimated as $D > 45$ nm by using Scherrer formula [7].

The air-exposure changes the peak position and width drastically as shown in Fig. 2(a). The observed XRD pattern of hydrous CoC_2 shows good agreement with that expected from the EXAFS result suggesting the MgC_2-type structure.[2] Contrary to anhydrous CoC_2, C_2^{2-} dianions are ordered in hydrous CoC_2 and the Co^{2+} dications forms body-centered tetragonal lattice as shown in Fig. 2(c). In the structure, Co^{2+} dications and C_2^{2-} dianions form alternate chains elongated parallel to the c-axis, which shrinks through air-exposure, while the a- and b-axes related to the inter-chain directions are expanded by the absorbed water. Judging from the crystal structures, intra-chain Co^{2+}–C_2^{2-}–Co^{2+} exchange interaction becomes stronger in hydrous phase due to the shorter Co^{2+}–C_2^{2-} distance and orientation ordering of C_2^{2-}, while the inter-chain interaction becomes weaker due to the longer inter-chain distances. The structural change cut the CoC_2

[2] The structural analysis based on the EXAFS results will be submitted to another journal by K. Kosugi.

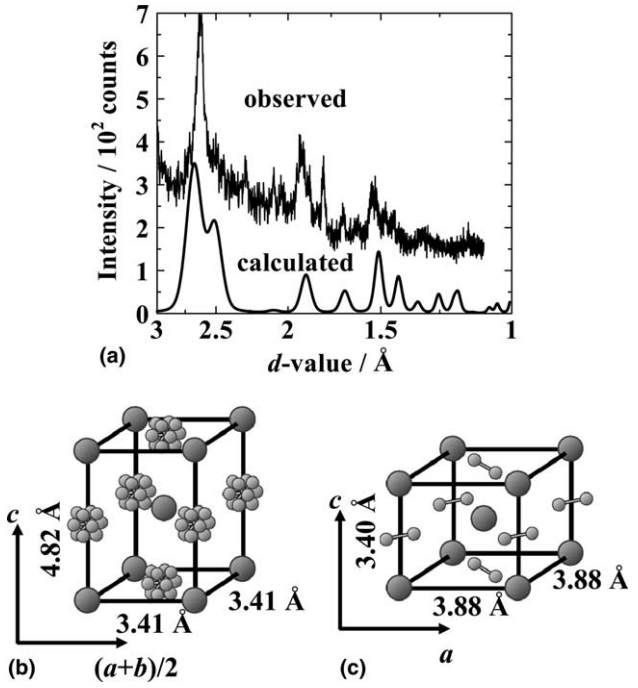

Fig. 2. (a) The observed and the calculated XRD pattern of hydrous CoC_2. The calculation is based on the structure shown in Fig. 2(c), which is consistent with the EXAFS result. (b, c) The expected crystal structures and lattice constants of anhydrous (b) and hydrous (c) CoC_2 based on the observed XRD pattern.

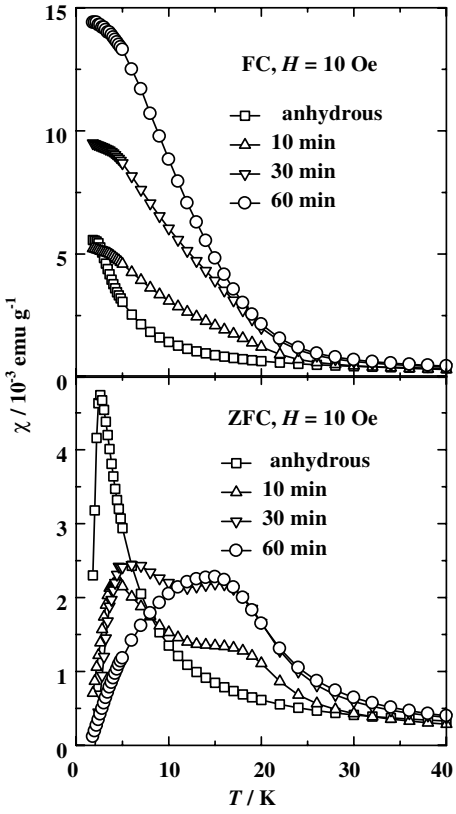

Fig. 3. Field-cooled in 10 Oe (top) and zero-field-cooled (bottom) magnetic susceptibilities of anhydrous, 10, 30 and 60 min air-exposed CoC_2 measured with the external field $H = 10$ Oe.

particle into many small structural domains having the crystallite size $D \sim 10$ nm, resulting in the broad peak widths of the hydrous CoC_2.

As mentioned in the discussion about the XRD results, it is expected that the magnetism of CoC_2 is also changed owing to the change of the inter- and intra-chain interaction by water absorption. The field-cooled (FC, $H = 10$ Oe) and zero-field-cooled (ZFC) magnetic susceptibility of anhydrous, 10, 30 and 60 min air-exposed CoC_2 are shown in Fig. 3. In the anhydrous phase, χ obeys the Curie–Weiss law in the high temperature range above ca. 70 K with Curie constant $C = 1.1$ emu K/mol and antiferromagnetic (AF) Weiss temperature $\Theta = -10$ K, the former of which is obviously larger than the value of Co^{2+} dication ($C = 0.375$), suggesting the short-range strong ferromagnetic (FM) interaction. The paramagnetic behavior despite the strong FM interaction indicates the smallness of the ferromagnetic domains. Below 2.5 K, the anhydrous CoC_2 shows ferromagnetism as discussed in later, but the FM part is only less than 8%. When CoC_2 is exposed to air, the Curie constant increases from 1.1 to 2.8 emu K/mol as the exposure time increases from 0 to 60 min suggesting the extension of the FM domains, while Θ changes from -10 to -3 K suggesting the weakening of the AF interaction between FM domains. The enhance of the ferromagnetism is also clearly seen in the FC and ZFC susceptibility. The FC susceptibility at low temperature increases monotonously as the air-exposure time increases. At the same time, the intension of the FM character raises the peak position of the ZFC susceptibility. Especially, the two peaks of 10 and 30 min air-exposed samples are originated from the coexistence of the low-T_C ferromagnet and high-T_C ferromagnet. Fig. 4 shows the magnetization curves of CoC_2. Anhydrous phase shows only a small hysteresis loop with coercive force $H_C = 120$ Oe and small remanent magnetization $M_{REM} = 0.75$ emu/g. According to the fact that the absorbed water causes the ferromagnetism, the small amount of FM part of anhydrous CoC_2 was probably brought about by the residual water in epoxy resin. In consequence of the expansion of the FM domains, H_C and M_{REM} increase monotonously from 120 to 900 Oe and 0.75 to 2.7 emu/g, respectively, as the air-exposure time increases.

In the following, the mechanism of the water-induced ferromagnetism is discussed. The possible configurations of C_2^{2-} dianions are classified into three types; that is, Co^{2+}–Co^{2+} direction and the molecular axis of C_2^{2-} are perpendicular, parallel or neither as shown in Fig. 5(a) (I), (II) and (III), respectively. In the paramagnetic anhydrous phase, the configuration of C_2^{2-} dianions is the mixture of the three possible configurations because

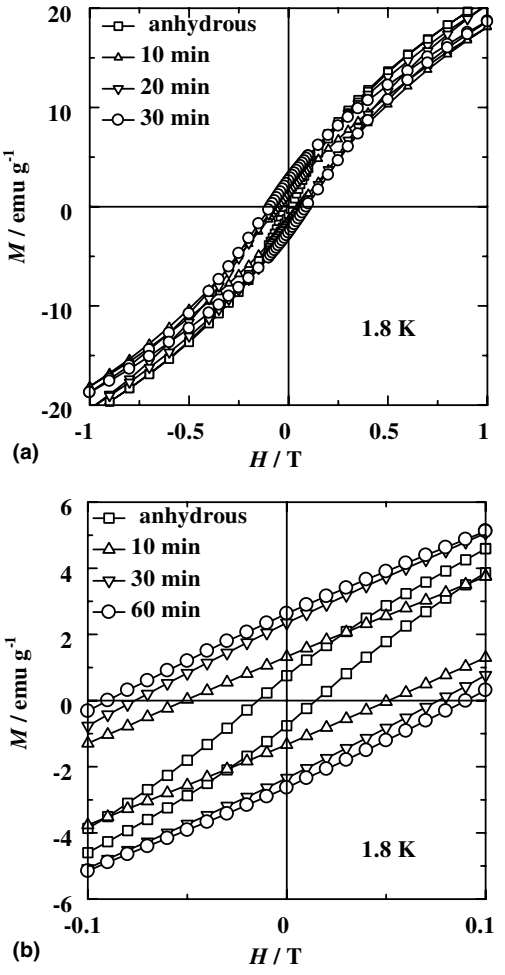

Fig. 4. (a) Magnetization curves of anhydrous, 10, 30 and 60 min air-exposed CoC_2 at 1.8 K. (b) The enlargement of the magnetization curves near the origin.

of the orientation disorder of C_2^{2-} dianions. On the other hand, only the perpendicular configuration is allowed in the hydrous phase where the ferromagnetism is observed. Judging from these facts, it is concluded that the perpendicular configuration brings about the FM interaction between Co^{2+} dications, while the other two configurations causes only the very weak FM or AF interaction. Here, we summarize the experimental findings on the this interaction model. In anhydrous CoC_2, strong FM and weak FM/AF interactions are mixed, resulting in the small FM domains as shown in Fig. 5(b). The small FM domains have the larger Curie constant than that of a single Co^{2+} dication, but the smallness of the FM domains keeps CoC_2 superparamagnet. After the air/water exposure, the orientation of C_2^{2-} dianions are aligned by absorbed water, where the many spins of Co^{2+} dications are connected ferromagnetically as shown in Fig. 5(b). The larger FM domain shows larger Curie constant, high-Curie temperature and large hysteresis loop as observed.

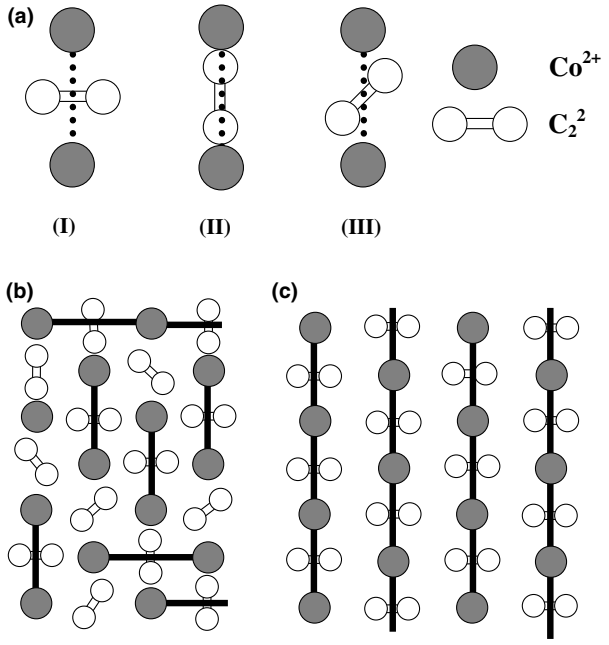

Fig. 5. (a) The three possible configurations of C_2^{2-} dianions; perpendicular (I), parallel (II) and intermediate (III). (b) The magnetic structural model of anhydrous CoC_2. The ferromagnetic domains are cut into the small parts by the disorder of C_2^{2-} dianions. The bold lines in (b) and (c) indicates the FM interaction caused by the perpendicular configuration of C_2^{2-} dianions. (c) The magnetic structural model of hydrous CoC_2. The order of C_2^{2-} dianions caused by the absorbed water brings about the long one dimensional ferromagnetic domains, resulting in the ferromagnetism.

4. Summary

As-prepared anhydrous CoC_2 nanoparticle having a large structural domain is characterized by the orientation disorder of C_2^{2-} dianions. The disorder brings about the mixture of the strong FM and weak FM/AFM interactions, resulting in the small FM domains and superparamagnetism. The nanoparticle promptly absorbs the water in air-atmosphere, bringing about the orientation ordering of C_2^{2-} dianions and the lattice expansion in *a*- and *b*-axes. Though the anisotropic structural expansion cut the nanoparticles into small structural domains, the structural change aligns the strong FM interactions one dimensionally, resulting in the larger FM domains which shows ferromagnetism. In conclusion, CoC_2 is the first molecule-based magnet showing the water-induced ferromagnetism owing to the flexibility of the orientation of C_2^{2-} dianions.

magnetic systems; that is, two-dimensional magnetic layers where the exchange interaction, J, in one dimension is different from the exchange in the second dimension, J'. Rectangular systems allow for the study of magnetic behavior between one- and two-dimensions. If we define J' as the smaller of the two exchange constants, then the ratio J'/J can vary from 0 (a linear chain, one-dimensional) to 1 (a square lattice, two-dimensional). The Cu(pyrazine)Cl_2 model system provides an exceptional opportunity since a family of compounds can be prepared using substituted pyrazines. By varying the structure of the pyrazine, one can change the value of J_{pz} (through the pyrazine moiety) while maintaining a relatively constant value of J_X (through the bihalide bridge). The bihalide bridge can also be varied by substituting bromide for chloride. This will give a series of compounds with different values of J'/J, potentially ranging from near zero to near one. Here we report the preparation and magnetic susceptibility behavior of (2,5-dmpz)copper(II) chloride (**1**), and (2,6-dmpz)$_2$copper(II) chloride (**2**) [2,5-dmpz = 2,5-dimethylpyrazine; 2,6-dmpz = 2,6-dimethylpyrazine].

2. Experimental

Reagents were purchased from Aldrich or Aesar Chemical and used without further purification. Infrared spectra were recorded on a Paragon 500 Spectrophotometer and referenced to polystyrene. The composition of **1** and **2** was confirmed by combustion analysis (Marine Science Institute, University of California, Santa Barbara, CA 93106).

2.1. (2,5-Dmpz)copper(II) chloride (*1*)

A solution of $CuCl_2$ (1.34 g, 10 mmol) in 50 ml of methanol was added to a solution of 2,5-dmpz (1.08 g, 10 mmol) in 50 ml of methanol. The solution was stirred at room temperature for an hour and the resulting slurry filtered to give a green powder, 0.76 g (31%). The filtrate was left to evaporate slowly at room temperature, yielding green needles suitable for X-ray diffraction. CHN for $C_{12}H_{16}N_4Cl_2Cu$ Calc.: C, 29.71; H, 3.32; N, 11.55. Found: C, 29.61; H, 3.45; N, 11.29%. IR (KCl) – ν 3129w, 3038m, 2946w, 1506s, 1375m, 1347m, 1161m, 1089m, 1134w, 990w, 882m cm^{-1}.

2.2. (2,6-Dmpz)$_2$ copper(II) chloride (*2*)

A solution of $CuCl_2$ (1.34 g, 10 mmol) in 50 ml of methanol was added to a solution of 2,6-dmpz (1.08 g, 10 mmol) in 50 ml of methanol. The solution was stirred at room temperature for an hour and the resulting slurry filtered to give a light blue powder, 0.63 g (40%). The filtrate was left to evaporate slowly at room temperature, but only additional powder was obtained. CHN for $C_{12}H_{16}N_4Cl_2Cu$ Calc.: C, 41.09; H, 4.60; N, 15.97. Found: C, 40.78; H, 4.72; N, 15.46%. IR (KCl) – ν 3079w, 2965w, 2928w, 1534m, 1427m, 1378m, 1256m, 1167s, 1023m, 947w, 866m, 731m, 497m cm^{-1}.

2.3. X-ray data collection and refinement for *1*

$C_6H_8Cl_2CuN_2$; Crystal system, monoclinic; space group, $P2_1/c$; $Z = 2$; unit cell dimensions: a = 6.7493(13) Å, b = 10.667(2) Å, c = 6.3102(13) Å; β = 106.81(3) μ = 3.058 mm^{-1}; θ range = 3.69–30.05°; Total reflections collected = 5458 [1239 independent; R_{int} = 0.0386]; completeness to θ = 30.05°, 97%. Crystals of compound **1** were removed from the flask and covered with a layer of hydrocarbon oil. A green needle-shaped crystal, 0.40 mm × 0.09 mm × 0.05 mm, was selected and attached to a glass fiber. Data for **1** were collected at 293(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, λ = 0.71073 Å) equipped with a Cryocool NeverIce low temperature device. Data were measured using omega scans of 0.3° per frame for 5 s, and a full sphere of data was collected. A total of 2132 frames were collected with a final resolution of 0.77 Å. The first 50 frames were recollected at the end of data collection to monitor for decay. Cell parameters were retrieved using SMART [10] software and refined using SAINTPLUS [11] on all observed reflections. Data reduction and correction for Lp and decay were performed using the SAINTPLUS software. Absorption corrections were applied using SADABS [12]. The structure was solved by direct methods and refined by least squares method on F^2 using the SHELXTL program package [13]. The structure was solved in the space group $P2(1)/c$ (# 14) by analysis of systematic absences. Non-hydrogen atoms were refined anisotropically. No decomposition was observed during data collection. Hydrogen atoms were place in calculated positions and refined as a riding model with fixed isotropic U's. Full-matrix least-squares refinement on F^2 for 1239 data and 52 parameters gave final R indices of R_1 = 0.0375, wR_2 = 0.0984 [$I > 2\sigma(I)$ and R_1 = 0.0465, wR_2 = 0.1036 (all data). Largest final difference peak and hole were 0.53 and −0.54 e$^-$/Å^3. Complete crystallographic data are available (see Supplementary Material). Selected bond distances and angles are given in Table 1.

2.4. Magnetic studies

The magnetic susceptibility of polycrystalline samples of **1** and **2** were studied in a field of 1000 Oe using a Quantum Design MPMS-XL SQUID Magnetometer. Corrections were made for the temperature independent magnetism of the Cu(II) ion ($\chi_{TIP} = 60 \times 10^{-6}$ emu/mol) and for the diamagnetic contributions calculated from Pascal's constants.

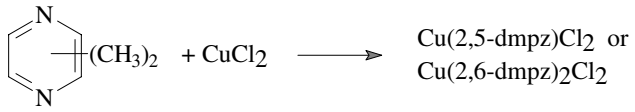

Table 1

3. Results and discussion

Reaction of copper(II) chloride with the corresponding dimethylpyrazine in aqueous solution gave Cu(2,5-dmpz)Cl_2 (**1**), or Cu(2,6-dmpz)$_2Cl_2$ (**2**);

(2,5-dmpz) or
(2,6-dmpz)

Single crystals of **1**, suitable for X-ray diffraction, were grown by slow evaporation. Relevant bond lengths and angles are given in Table 1. The molecular unit and a portion of one chain are shown in Fig. 1.

The structure of **1** consists of alternating copper(II) ions and 2,5-dmpz ligands forming chains parallel to the *a*-axis. The Cu(II) ions sit on a crystallographic inversion center and are nearly square planar. The pyrazine rings are canted approximately 80° from the Cu coordination plane. The pyrazine rings themselves show typical bond lengths and angles.

The Cu–N bond [2.004(2) Å] is somewhat short when compared to other Cu(II) 2,5-dmpz complexes such as the acetonitrile adduct of the current complex, Cu(2,5-dmpz)$Cl_2 \cdot CH_3CN$ (2.07 Å) [14] and Cu_2(2,5-dmpz)$[N(CN)_2]_4$ (2.06 Å) [15] and is intermediate in length compared to Cu(I) 2,5-dmpz complexes such as Cu(2,5-dmpz)Cl (1.985 Å) [14], Cu(2,5-dmpz)$_2(PF_6)$ (2.13 Å]) [16] and Cu_2(2,5-dmpz)$_3(BF_4)_2$ (1.97 and 2.08 Å) [16]. The Cu–Cl bond [2.2334(8) Å] is significantly shorter than that in the Cu(I) analog (2.41 Å) [14] and slightly shorter than is observed in the acetonitrile adduct (2.26 Å) [14].

The chains pack in the crystal to form a diamond pattern (see Fig. 2) with short chlorine–chlorine contacts (3.93 Å). The corresponding Cu–Cl···Cl angles are 80.1° and 166.0° and the Cu–Cl···Cl–Cu torsion angle is 104.5°. The potential for through-space contacts between halide ions to provide a significant magnetic superexchange pathway has been well documented, with chloride ions providing weaker exchange than bromide ions [17]. Each Cl ion is in close contact with two additional Cl ions from neighboring chains via identical pathways, generating a two-dimensional superexchange network perpendicular to the pyrazine bridged chains.

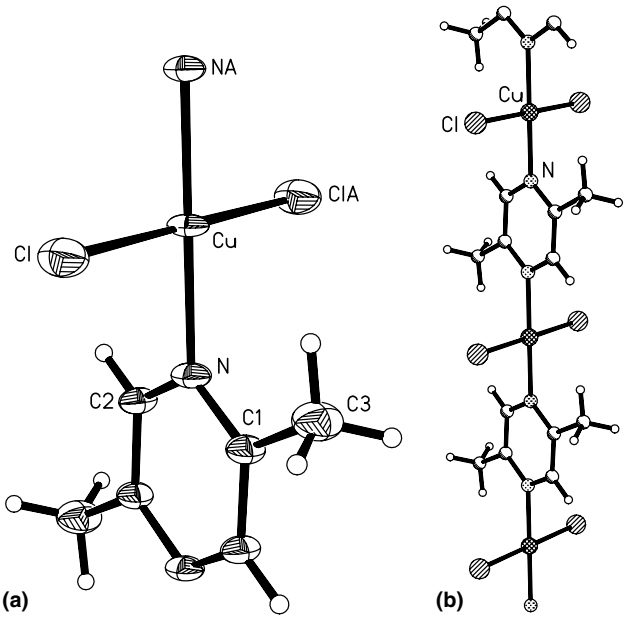

Fig. 1. (a) A plot of the molecular unit of **1** showing 50% probability ellipsoids. Only those atoms in the asymmetric unit and Cu coordination sphere are labeled. H-atoms were placed geometrically and are shown as spheres of arbitrary size. (b) A portion of the chain structure of **1**.

3.1. Magnetic susceptibility results

We use the 2*J* form of the Heisenberg Hamiltonian

$$H = -2J \sum S_i \cdot S_{I+1},$$

where a negative value of *J* corresponds to antiferromagnetic interactions. Susceptibility data were collected for **1** (Fig. 3) and **2** (Fig. 4) from 1.8 to 325 K on powder samples.

The magnetic susceptibility of **1** increases with decreasing temperature reaching a maximum near 10 K and then begins to decrease slowly until near 5 K where there is an abrupt change in slope, signifying a possible phase transition. At high temperatures the χT product approaches 0.41, typical of Cu(II) complexes. Similarly, susceptibility data for **2** show an increase in value at lower temperatures, reaching a local maximum near 13 K and then continuing to rise, suggesting the presence of a paramagnetic impurity in the sample. The χT product nears 0.42 at high temperatures, again in good agreement with expected values.

The discontinuity near 5 K in the susceptibility data for **1** (Fig. 3(a)) suggests the presence of a phase

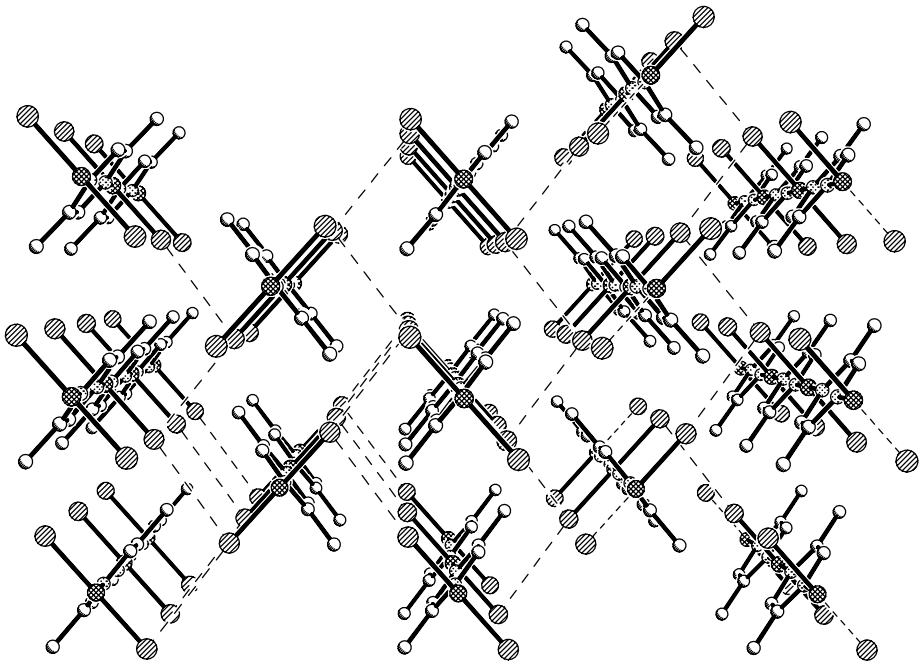

Fig. 2. Packing diagram of **1** viewed parallel to the *a*-axis showing the short intermolecular Cl···Cl contacts (dotted lines).

transition in the sample. Examination of the crystal structure shows two possible superexchange pathways, one via the bridging 2,5-dmpz ligands, linking the Cu(II) ion into chains (Fig. 1(b)) and a second via close non-bonding contacts between the halide ions (double halide exchange), linking the chains into a three-dimensional network (Fig. 2). Pyrazine and substituted pyrazines are well known to provide a superexchange pathway in the range $-5 < 2J < -25$ [1,5–7] while the double halide exchange for chlorides is generally small, but can be as high as 27 K [17a,17e,18]. No theoretical model exists at present for an antiferromagnetic three-dimensional system with two exchange values (J for a chain and J' for the interaction between the chains), so the susceptibility data were fit to the expression for the molar susceptibility χ_{mol} of the $S = 1/2$ Heisenberg antiferromagnetic linear chain [19], both with and without a mean-field correction [20] and over several different temperature ranges above 5 K (see Table 2). The best fit to the data is shown in Fig. 5(a).

It is clear that the available models to analyze the data for **1** are inadequate from the variability of both

3D	18–325	0.437	−10.2(5)	−6.5(2)
3D	10–325	0.425	−23.7(5)	−2.15(2)
3D	5–325	0.423	−13.5(1)	−4.8(1)

[a] 1D = uniform chain, 3D = uniform chain with mean field correction for four nearest neighbors.

the Curie constant (C) and the values for the exchange constant within (J) and between (J') the pyrazine-bridged chains as the temperature range of the fit is varied. The structure indicates that there should be significant interactions between the chains, so the linear chain model is inappropriate, but at the same time, the mean-field correction is only valid when the interaction between the changes is only a small fraction of the interaction within the chains. Our estimates for the values of the two exchange interactions are $2J = -20(5)$ K and $2J' = -4(2)$ K. More precise values will require the development of an appropriate analytical model.

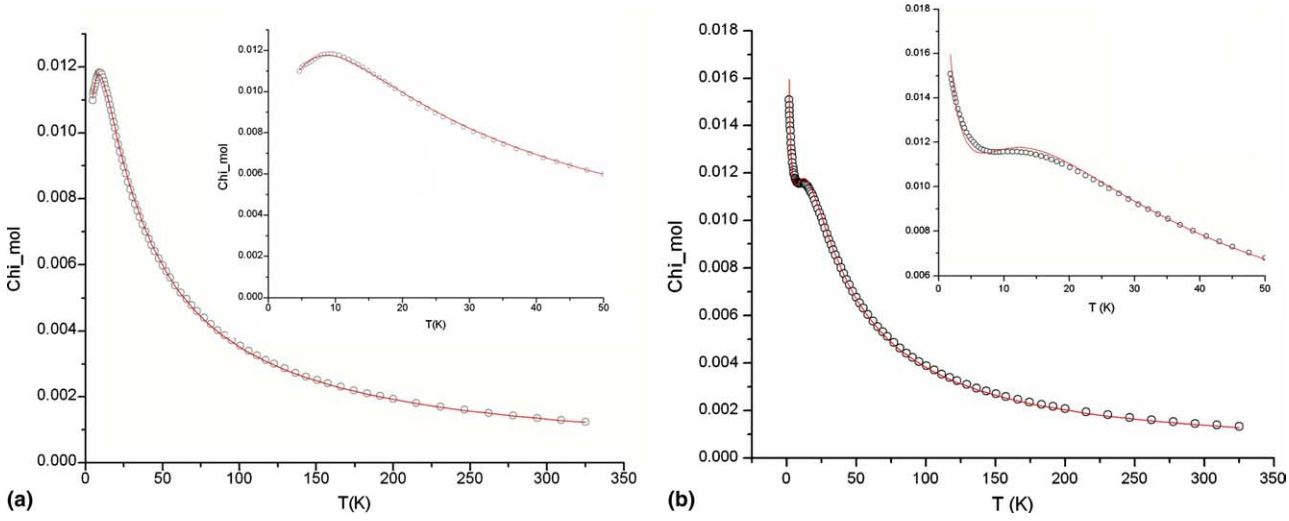

Fig. 5. (a) Theoretical fit (solid line) to the magnetic susceptibility (○) as a function of temperature for **1**. The inset is an expansion of the region from 0 to 50 K. See text for detail of the fitting procedure. (b) Theoretical fit of a uniform chain model (solid line) to the magnetic susceptibility (○) as a function of temperature for **2**. The inset is an expansion of the region from 0 to 50 K.

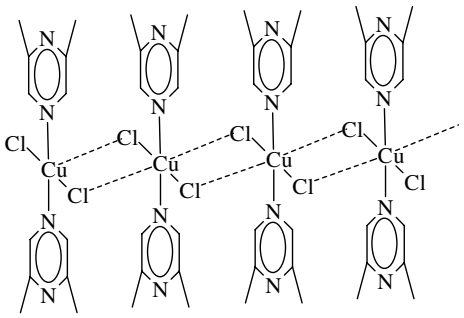

Fig. 6. Proposed structure of compound **2**.

The magnetic behavior of the 2,6-dmpz complex **2** is straightforward (Fig. 4). Although we attempted the preparation of the corresponding mono(2,6-dmpz) complex, bridged by the pyrazine ligand, combustion analysis and magnetic data indicated that the correct formula of the complex is $Cu(2,6\text{-dmpz})_2Cl_2$. The structure of the molecule is, therefore, most likely that of a bihalide bridged chain (see Fig. 6) as has been observed previously for $Cu(py)_2Cl_2$ and related substituted pyridine complexes [9]. It is most likely that the 2,6-dmpz molecules are coordinated through the nitrogen remote from the methyl groups to reduce steric hindrance about the metal center. Although there are complexes where the 2,6-dmpz ligand is known to bridge [21], all reported structures to date show bonding to the distal nitrogen [22]. The magnetic data were therefore fit to a uniform Heisenberg chain model (Fig. 5(b)) [19]. The data converged at values of $C = 0.415(3)$ and $2J = 22.7(2)$ K, allowing for a 3.33(5)% paramagnetic impurity.

4. Conclusions

The ability of pyrazines to provide an effective superexchange pathway has been further demonstrated in compound **1**. In addition, the structure provides an excellent opportunity for further study of the crossover from one-dimensional to three-dimensional behavior. The magnetic data show that the superexchange through double chloride bridge is substantial compared to the exchange through the pyrazine and the symmetry of the packing requires that the exchange is identical for each chain to four nearest neighbors. Future work in this area will require development of an appropriate theoretical model, but we hope that the existence of a model compound to test such a theory will make the problem attractive. Finally, the differing steric requirements of the different substitution patterns on the pyrazine ring are shown in compound **2**, where the desired 2,6-dmpz-bridged complex did not form, in favor of the less sterically demanding chloride-bridged chain. The fact that the corresponding $CuBr_2$ complex, $Cu(2,6\text{-dmpz})Br_2$ exists as pyrazine-bridged chains [23] demonstrate that small changes in the coordination environment can make substantial changes in the structure of the complex.

5. Supplementary material

Crystallographic data have been deposited with the CCDC (12 Union Rd., Cambridge, CB21EZ, UK, fax: +44-1233-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) and are available on request quoting the deposition number 250636.

Found: C, 36.1; N, 10.3; H, 1.77%. *Anal.* Calc. for $C_{41}H_{23.5}N_{10.5}F_2S_8Pt_2$ (**2**): C, 36.5; N, 10.9; H, 1.76. Found: C, 36.2; N, 10.7; H, 1.79%.

2.2. X-ray crystallography

The diffraction data were collected at 298 K on a Rigaku R-AXIS RAPID IP area detector for **2**. Structures were solved by direct methods and refined by the full-matrix least-square method on F^2 using SHELXL-97 program [7]. All non-hydrogen atoms were treated anisotropically and the hydrogen atoms were introduced at calculated positions. Crystal data for **2**: $C_{41}H_{23.5}N_{10.5}F_2S_8Pt_2$, $T = 298(2)$ K, space group $P\bar{1}$, $a = 11.1571(4)$ Å, $b = 11.2031(5)$ Å, $c = 21.3037(10)$ Å, $\alpha = 98.115(3)°$, $\beta = 94.016(2)°$, $\gamma = 114.643(2)°$, $V = 2371.37(18)$ Å^3, $Z = 2$, $\rho_{calc} = 1.888$ g cm^{-3}; 33 467 measured ($3.00° \leqslant \theta \leqslant 27.48°$), 10 764 ($R_{int} = 0.1155$) unique, 7758 observed ($I > 2.00\sigma(I)$). Lorentz polarization absorption corrections ($\mu = 6.296$ mm^{-1}), 291 parameters. R_1(on F^2) = 0.1099, wR_2(on F^2) = 0.2708, residual electron density: 3.91 (closed to S(4)) and −3.01 (closed to Pt(1)) e Å^{-3}.

2.3. Magnetic susceptibility measurements

Magnetic susceptibility of polycrystalline sample was measured in 2–350 K using a Quantum Design MPMS XL superconducting quantum interference device (SQUID) magnetometer.

2.4. Molecular orbital calculations

The spin dimer analyses for the neighboring $[Pt(mnt)_2]^-$ anions were performed within the tight-binding approximation using extended Hückel molecular orbital calculations [8]. The SOMO of $[Pt(mnt)_2]^-$ anion was used as the basis functions, the extended Hückel parameters for Slater-type atomic orbitals were taken from [9].

3. Results and discussion

3.1. Structural descriptions

*Stacking structure of $[Pt(mnt)_2]^-$ anions in **1** [6].* The asymmetric unit contains three crystallographically independent $[Pt(mnt)_2]^-$ anions, the S–Pt–S chelate angles and Pt–S bond lengths in them are in agreement with those reported $[Pt(mnt)_2]^-$ compounds [10]. The molecular planes, defined by coordination S atoms, of containing Pt(1) and Pt(2) are nearly parallel to each other with a dihedron of 1.21°, while the molecular plane including Pt(3) is approximately perpendicular to that including Pt(1) and Pt(2) (the dihedral angle between the entries of Pt(3) and Pt(2) is 85.3°). Symmetry-generated anions containing Pt(1) and Pt(2) stack into columns along *b*-axis, and the inter-planar separations between adjacent anions within a column are alternately 3.540 Å between anions containing Pt(1) and Pt(2) and 3.634 Å between anions containing Pt(1) and Pt(1) $(1 - x, -y, 1 - z)$. Symmetry-generated anions containing Pt(3) dimerize, the separation between planes in a dimer is 3.488 Å. These dimers connect the anionic columns into 2D anionic networks, via S···S interactions, in *ab* plane (Fig. 1).

*Crystal structure of **2**.* Compound **2** crystallizes in $P\bar{1}$ space group with two couples of $[Pt(mnt)_2]^-$ and 1-(4′-fluorobenzyl)pyridinium, and one half solvent molecule, MeCN, in an asymmetric unit. The molecular structures both cations and anions in **2** are similar to, but the stack structures are different from **1**. Two crystallographically independent anions are almost parallel to each other, the dihedral angle between mean molecular planes, defined by coordination S atoms, is only 1.7°. The distortion from planarity of anion is observed in both Pt(1) and Pt(2) entries owing to CN groups being departure from the mean molecular plane, the terminal N atoms of CN are away the mean plane from 0.09 to 0.28 Å in Pt(1) entry, while 0.31–0.41 Å in Pt(2) entry. As shown in Fig. 2(a), the anions are stacked face-to-face along *ab* direction to form a fourfold anionic subunit. In each subunit, the stack is regular, two types of independent Pt···Pt distances are 3.552 Å between Pt(1) and Pt(2), 4.373 Å between Pt(2) and Pt(2) $(1 - x, 2 - y, 2 - z)$, respectively, and corresponding inter-planar separations alternate as 3.569 and 4.883 Å. The neighboring fourfold anionic subunits form a 2D anionic layer, which is approximately perpendicular to [1 1 1] axis, via weakly lateral S···S interactions (The S···S separations are in the range of 3.515–3.854 Å).

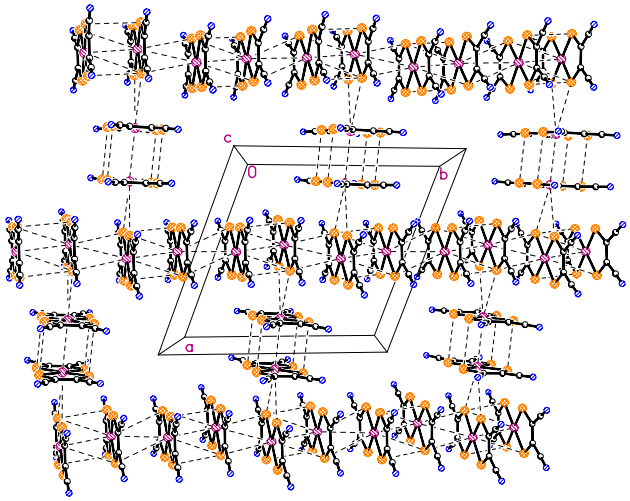

Fig. 1. 2D anionic networks in *ab* plane, projected along *c*-axis in **1**.

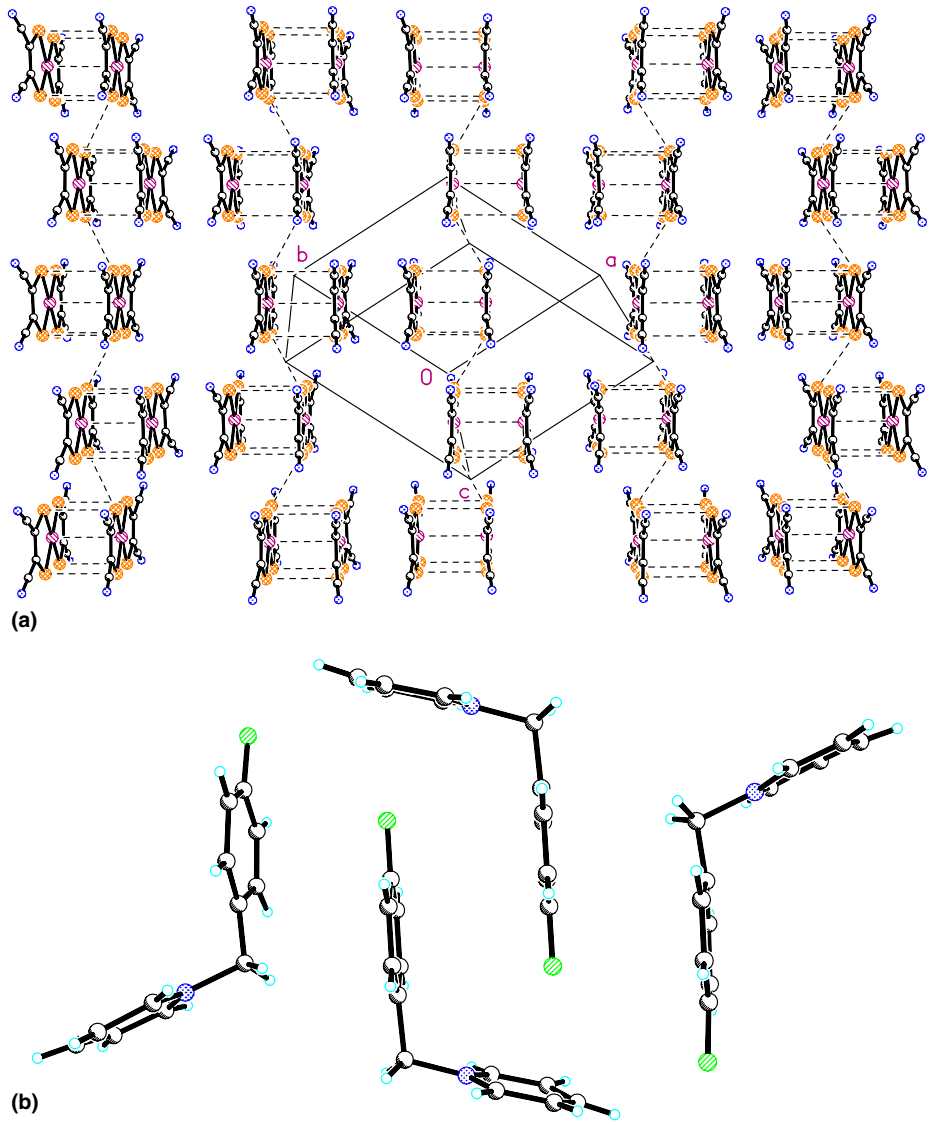

Fig. 2. (a) 2D anionic layer projected along the direction of [1 1 1] axis and (b) a cationic subunit in **2**.

Two crystallographic independent cations also stack into a fourfold subunit in a fashion of F(1)···F(2)···F(2)···F(1) (Fig. 2(b)). Two neighboring benzene rings, containing F(1) and F(2), are nearly parallel to each other with a small dihedral angle of 8.3°, the inter-planar space is 3.57 Å for the overlap pairs of F(1)···F(2) and 3.65 Å of F(2)···F(2). No any significant π···π stack interaction is observed in the cationic fourfold subunit. The anionic layers are completely separated by the intermediate cations.

3.2. Magnetic properties

The plots of $\chi_m(T)$–T both **1** and **2** are displayed in Fig. 3, and their magnetic behaviors exhibit the character with antiferromagnetically coupled interactions between nearest neighboring spins.

For an AFM coupling domination system, the magnetic exchange constant between two spins can be described as

$$J_{AF} \propto -(2t)^2/U_{eff}, \quad (1)$$

where U_{eff} is the effective on-site Coulomb repulsion and nearly constant for a defined magnetic solid, t is transfer integral between the spin sites and proportional to the overlap integral of the interaction magnetic orbitals [11]. For a sake of simplification, t is defined as $-10S$ eV (S is overlap integral). The anionic intermolecular interaction schemes are illustrated in Fig. 4, and the calculations for the transfer integral were performed within a tight-binding approximation using extended Hückel molecular orbital method, and the results indicate that relative stronger AFM interactions involve in two spin dimers, Pt(1) and Pt(2), Pt(3) and Pt(3)

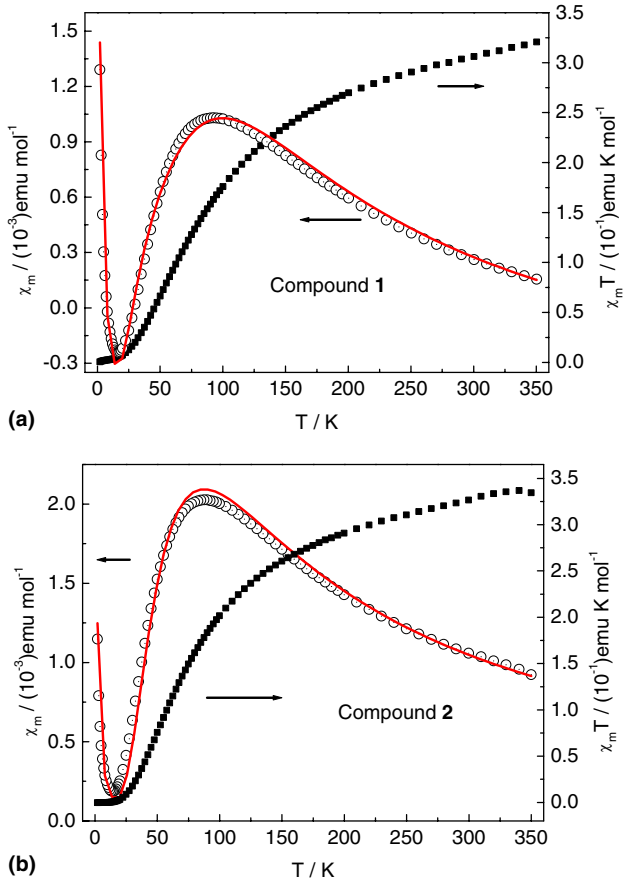

Fig. 3. Plots of χ_m vs. T in **1** (a) and **2** (b), open circles: experimental data and solid lines: theoretic calculations (plots of $\chi_m T$ reproduced after subtracting C and $\chi_0 T$).

$(2-x, 1-y, 1-z)$ in **1**. These qualitative analyses suggest two types of magnetic exchange schemes, an AFM alternating chain with $s = 1/2$ and a spin dimer of $s = 1/2$, can be considered in **1**, thus, we try to fit magnetic susceptibility to the formula:

$$\chi_m = (2/3)\chi_{chain} + (1/3)\chi_{dimer} + C/T + \chi_0 \quad (2)$$

and

$$\chi_{chain} = \frac{Ng^2\mu_B^2}{k_B T} \cdot \frac{A + BX^{-1} + CX^{-2}}{1 + DX^{-1} + EX^{-2} + FX^{-3}}, \quad (3)$$

$$\chi_{dimer} = \frac{Ng^2\mu_B^2}{k_B T} \cdot (3 + \exp(\Delta/k_B T)^{-1}), \quad (4)$$

where Eq. (3) is deduced from spin Hamiltonian $H = -2J\sum_{i=1}^{n/2}[\hat{S}_{2i} \cdot \hat{S}_{2i-1} + \alpha\hat{S}_{2i} \cdot \hat{S}_{2i+1}]$, $X = k_B T/|J|$, $J(<0)$ is coupled constant, α represents an alternating parameter, and A–F are a set of parameters depended on α [12]. Eq. (4) is based on spin Hamiltonian $H = -2J\hat{S}_1 \cdot \hat{S}_2$, in which $\Delta(=2|J|)$ is the energy gap between singlet and triplet state. C/T and χ_0 show the contributions of the magnetic impurity and the sum of diamagnetic and van Vleck paramagnetic parts, respectively. The best fit gives rise to $|J|/k_B = 107.6$ K, $\alpha = 0.012$; $\Delta/k_B = 93.9$ K, $C = 0.0036$ emu K mol^{-1} and $\chi_0 = -7.7 \times 10^{-4}$ emu mol^{-1} with g of 2.0 fixed.

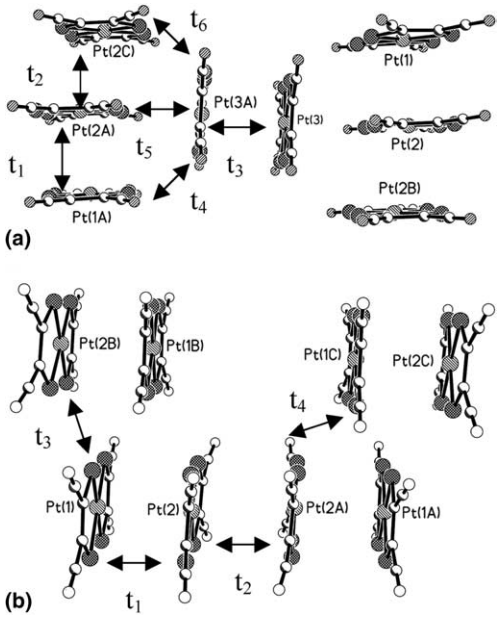

Fig. 4. Intermolecular interaction schemes and transfer integrals in **1** (a, $t_1 = 2.04 \times 10^{-1}$, $t_2 = 3.17 \times 10^{-2}$, $t_3 = 3.71 \times 10^{-1}$, $t_4 = -2.39 \times 10^{-3}$, $t_5 = -5.38 \times 10^{-3}$ and $t_6 = 1.51 \times 10^{-2}$ eV) and **2** (b, $t_1 = -3.14 \times 10^{-1}$, $t_2 = -3.56 \times 10^{-2}$, $t_3 = -9.99 \times 10^{-3}$ and $t_4 = -1.05 \times 10^{-2}$ eV).

Based on the analyses both crystal structural and t values of **2**, approximately, an anionic fourfold subunit is treated as two isolated dimers, and the coupled interactions between dimers are further dealt with molecular field theory [13], thereby χ_m is expressed below

$$\chi_m = \frac{\chi_{dimer}}{[1 - (zJ'/Ng^2\mu_B^2)\chi_{dimer}]} + \frac{C}{T} + \chi_0, \quad (5)$$

the data of χ_m in 2–350 K were simulated by using Eq. (5) to yield the parameters $\Delta/k_B = 141.7$ K, $zJ'/k_B = -2.6$ K, $C = 2.7 \times 10^{-3}$ emu K mol^{-1} and $\chi_0 = -4.0 \times 10^{-5}$ emu mol^{-1} with g factor of 2.0 fixed. The temperature dependence of $\chi_m T$ for **1** and **2** are reproduced by subtracting the sums of C and $\chi_0 T$ and illustrated in Fig. 3.

4. Conclusions

In conclusion, we have presented the structural and magnetic characterizations for two compounds based on [1-(4′-fluorobenzyl)pyridinium][Pt(mnt)$_2$]. Polymorphism is caused from the solvent molecule, MeCN, incorporating into lattice. The anionic stacking patterns in both compounds are distinct difference. The regular stacking columns formed by anions are connected by the anionic dimers to further construct into 2D anionic networks in **1**, while the fourfold anionic subunit develop into anionic layers via lateral S···S interactions in **2**. Two

compounds exhibit magnetic behaviors, with AFM coupled interaction domination, and their magnetic exchange schemes were built on the analyses both crystal structural analyses and extended Hückel molecular orbital calculations. The magnetic property was well explained by an alternating AFM Heisenberg chain with an isolated AFM coupling dimer for **1**, and a spin dimer system with $s = 1/2$ for **2**. The magnetic coupled parameters gained from best fit for both compounds are, on the whole, in agreement with the results of theoretic analyses based on Hückel molecular orbital calculations.

Acknowledgments

The authors thank Professor Ichimura for use of the SQUID magnetometer. Dr. X.M. Ren, a JSPS postdoctoral follow (ID No. P03271), thank Japan Society for the Promotion of Science for financial support.

Appendix A. Supplementary data

Crystallographic data for **2** (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publications (CCDC-249471). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.03.034.

effects, that is with pairs of *cis*-$[Fe(NCX)_2(N)_4]$ chromophores, joined by ligand-to-solvate H-bonding, within unique pseudo-dimeric crystalline species **1** to **3**. Ligand–solvate H-bonding has previously been reported in mononuclear Fe(II) system [1,8–10], thus yielding information on cooperativity between mononuclear SCO centres, but has not, to our knowledge, been observed within a dimeric system. Preliminary aspects of parts of this work have recently been communicated [11]. Variation of the reaction conditions used to make **1**–**3** has led to formation of a family of covalently bridged dinuclear species $[Fe_2(\mu\text{-pypz})_2(pypzH)_2(NCX)_2]2H_2O$, X = S, Se, BH_3, displaying unique one-step high-spin (HS–HS) to low-spin (LS–LS) transitions. These are described separately [12].

2. Experimental

Elemental analyses (C, H, N) were carried out by Campbell Microanalytical Laboratory, University of Otago, Dunedin, New Zealand. IR spectra were recorded on a Perkin–Elmer 1600 Series Fourier Transform Spectrophotometer. Samples were prepared as KBr discs. Commercially available solvents and chemicals were used without further purification. The ligand 2-(1H-pyrazol-3-yl)-pyridine (pypzH) was prepared according to a known procedure [13].

2.1. Synthesis

2.1.1. $\{[Fe(pypzH)_2(NCS)_2]_2(\mu\text{-}OH_2)(H_2O)_2\}\cdot H_2O\cdot MeOH$ (**1**)

To a methanolic solution (15 mL) of $[Fe(H_2O)_6](ClO_4)_2$ (153 mg, 0.42 mmol) (and a pinch of ascorbic acid) was added a solution of KNCS (82 mg, 0.84 mmol) in the same solvent (15 mL), under nitrogen. The mixture was stirred for 15 min then filtered (to remove $KClO_4$) via a cannula into a Schlenk flask containing a solution of pypzH (120 mg, 0.84 mmol) in methanol. Water (5 mL) was added and the solution stirred for 1 h at room temperature, then left to slowly evaporate under nitrogen. The first batch of yellow block-like crystals grew within two days and were filtered off and dried in air. X-ray structural analyses was performed on a single block-like crystal. Infrared spectrum (KBr disk, cm^{-1}): 3417br, 3232sh, 2084s, 1606m, 1567w, 1510w, 1459w, 1432m, 1364w, 1291w, 1250w, 1199w, 1156w, 1091w, 1061w, 1011w, 968w, 927w, 772s, 707w, 636w, 470w, 412w.

2.1.2. $\{[Fe(pypzH)_2(NCSe)_2]_2(\mu\text{-}OH_2)(H_2O)_2\}\cdot H_2O\cdot MeOH$ (**2a**, **2b**)

The complex was made using the same method but substituting the KNCS with KNCSe (122 mg, 0.84 mmol). Ambient temperature (**2b**; 298 K) and nitrogen stream (**2a**; 123 K) X-ray structural analysis was performed on a single-block like crystal. Infrared spectrum (KBr disk, cm^{-1}): 3417br, 3232sh, 2056s, 1606m, 1567w, 1510w, 1459w, 1432m, 1364w, 1291w, 1250w, 1199w, 1156w, 1091w, 1061w, 1011w, 968w, 927w, 772s, 707w, 636w, 470w, 412w.

2.1.3. $\{[Fe(pyimH)_2(NCS)_2]_2(\mu\text{-}MeOH)_2\}\cdot 2MeOH$ (**3**)

To a methanolic solution (15 mL) of $[Fe(H_2O)_6](ClO_4)_2$ (153.12 mg, 0.422 mmol) (and a pinch of ascorbic acid) was added to a solution of KNCS (82 mg, 0.844 mmol) in the same solvent (35 mL). The mixture was stirred for 15 min, filtered to remove the $KClO_4$ precipitate then transferred using a cannula into another Schlenk flask containing a solution of pyimH (120 mg, 0.844 mmol) in methanol. Water (15 mL) was added and the solution stirred for 1 h at room temperature, then left to slowly evaporate under N_2. X-ray structural analysis was performed on an orange/red single crystal. Infrared spectrum (KBr disk, cm^{-1}): 3551sh, 3415br, 2070s, 1701w, 1638sh, 1616m, 1543w, 1473m, 1384w, 1292w, 1150w, 1106w, 962w, 788w, 701w, 621w, 473w.

2.1.4. $\{[Fe(pypzH)_2(NCS)_2](\mu\text{-}OH_2)\}_n$ (**4**)

Only one single crystal of the pseudo-chain **4** was obtained. This was a side product from the recrystallisation of $[Fe(pypzH)(NCS)_2]_2(\mu\text{-bpym})$ [14] using methanol/water (1:1) as a solvent (where bpym is 2,2′-bipyrimidine). Thus, far the pseudo-chain **4** has not been remade by a direct route. The μ-bpym complex is made as follows. To a methanolic solution (15 mL) of $[Fe(H_2O)_6](ClO_4)_2$ (153.12 mg, 0.422 mmol) (and a pinch of ascorbic acid) was added a solution of KNCS (82 mg, 0.844 mmol) in the same solvent (15 mL). The mixture was stirred for 15 min and was filtered to remove the $KClO_4$ precipitated, before addition to a Schlenk flask containing a solution of pypzH (61 mg, 0.422 mmol) in methanol. This solution was stirred for 10 min then a methanolic solution (10 mL) of bpym (33.4 mg, 0.211 mmol) was added dropwise. After stirring (90 min) and warming (60 °C) the precipitate was filtered then washed with Et_2O (3 × 30 mL) and dried in air (yield 0.12 g, 36%). Infrared spectrum (KBr disk, cm^{-1}): 3411br, 2057s, 1638sh, 1606m, 1571m, 1431m, 1406m, 1364w, 1292w, 1215w, 1090w, 1016w, 966w, 927w, 825w, 760m, 710w, 614w, 481w, 406w. Microanalysis: Found: C, 40.14; H, 2.54; N, 23.4%. Calculated for $C_{28}H_{20}N_{14}S_4Fe_2$: C, 42.4; H, 2.5; N, 24.7%.

2.1.5. $[Fe(pypzH)_2(NCS)_2]H_2O$ (**5**)

The complex **5** was prepared as a side product in the preparation of **1**. Following this procedure, the first crop of yellow block-like crystals of **1** grew within two days, and were filtered off. The remaining filtrate was allowed to evaporate for a further week affording crystals of the

monomeric species $[Fe(pypzH)_2(NCS)_2]H_2O$ (**5**). Infrared spectrum (KBr disk, cm^{-1}): 3419br, 2083s, 1607m, 1510w, 1459w, 1324w, 1091m, 968w, 772m, 638m, 472w.

2.2. X-ray crystallographic studies

Table 1 contains the crystallographic data and details for all the structural determinations. All X-ray crystallographic measurements were performed at 123(2) K (except for **2b**, 298(2) K) using a Nonius Kappa CCD diffractometer, fitted with a Mo Kα radiation source and graphite monochromator ($\lambda = 0.71073$). DENZO-SMN [15] was used for data integration and SCALEPACK [15] corrected data for Lorentz-polarisation effects. Direct methods (SHELXS-97) [16] and successive Fourier difference methods with refinement of full-matrix least-squares on F^2_{obs} (SHELXL-97) [16] afforded structural solutions. All non-hydrogen atoms were refined using anisotropic thermal parameters. Hydrogen atoms of coordinated H_2O groups were located in the difference maps and allowed to refine freely with the remaining hydrogen atoms assigned to geometrically idealised positions.

2.3. Magnetic studies

Magnetic measurements were carried out on a Quantum Design MPMS 5 SQUID magnetometer calibrated by us of a standard palladium sample (Quantum Design) of accurately known magnetisation or by use of magnetochemical calibrants such as $CuSO_4 \cdot 5H_2O$. Susceptibility versus temperature studies in the linear portion of the magnetisation versus field curve was made using a field of 1 T. Powdered samples were contained in calibrated gelatine capsules held at the centre of a drinking straw fixed to the end of the sample rod.

3. Results and discussion

3.1. Synthesis and characterization

The *N*,*N*-chelating ligands employed are 2-(1H-pyrazol-3-yl)-pyridine (pypzH) and 2-(1H-imidazol-2-yl)-pyridine (pyimH). The pseudo-dimer $\{cis\text{-}[Fe(pypzH)_2(NCS)_2]_2(\mu\text{-}OH_2)(H_2O)_2\} \cdot H_2O \cdot MeOH$ (**1**), where μ implies H-bonding bridging, was prepared under nitrogen by mixing two equivalents of methanolic pypzH to a methanolic solution of $Fe(NCS)_2$ created in situ from the reaction of $[Fe(H_2O)_6](ClO_4)_2$ and KNCS using a pinch of ascorbic acid to prevent formation of Fe(III), a common approach employed in all Fe(II) preparations. Water was added to the solution and the mixture was stirred, then left to slowly evaporate under nitrogen. Yellow block-like crystals of **1** grew within two days. During the preparation of **1**, slow evaporation of the solution led to crystals of **1**, but after two days, additional yellow crystals of the monomeric compound *cis*-$[Fe(pypzH)_2(NCS)_2]H_2O$ (**5**) were obtained.

$\{cis\text{-}[Fe(pypzH)_2(NCSe)_2]_2(\mu\text{-}OH_2)(H_2O)_2\} \cdot H_2O \cdot MeOH$ (**2a**, **2b**) was prepared in the same way as **1** but employing KNCSe in place of KNCS to generate, in situ, the $Fe(NCSe)_2$ used to generate **2a**/**2b** as yellow block-like crystals. The related, pseudo-dimer of $\{cis\text{-}[Fe(pyimH)_2(NCS)_2]_2(\mu\text{-}MeOH)_2\} \cdot 2MeOH$ (**3**) was prepared in a similar way to the pypzH complexes **1** and **2a**, **2b** via use of a methanolic pyimH solution responsible for generating a methanolate bridged complex in place of the previously described water bridges. Large orange/red block like crystals of the pseudo-dimer **3** formed after a period of four days. One crystal was obtained from re-crystallisation of a dinuclear bipyrimidine bridged complex $[Fe(pypzH)(NCS)_2]_2(\mu\text{-bpym})$ [14] and this showed a novel water-bridged chain formulation $\{cis\text{-}[Fe(pypzH)_2(NCS)_2](\mu\text{-}OH_2)\}_n$ (**4**). Attempts to remake **4** in bulk have given the pseudo-dimer **1** or the monomer **5**. Thus, simply by changing the methanol-to-water ratio in the pypzH/NCS^- reactions, different crystalline products were isolated. In contrast, when the selenocyanate analogue was prepared, only the water-bridged dimer was obtained.

3.2. Description of structures

Compounds **1**, **2a**, **2b** proved to be isostructural and the structure determination of the latter, at 123 K, is illustrated in Fig. 1. Fe–N bond lengths are given in Table 2. The bidentate pypzH ligands occupy four-coordination sites with two *cis*-coordinated anionic ligands of NCSe completing the Fe coordination sphere.

It is interesting to note that the unsymmetrical ligand pypzH presents the pyridyl groups [N(5) and N(8)] in a *cis* orientation with each pyridyl group being *trans* to the anionic NCX ligand. Conversely, if the pypzH ligand offers a pyridyl group *trans* to a pyrazolyl group, with the remaining pyrazolyl and pyridyl groups *trans* to the anionic NCX ligands this is the configuration in the isomeric mononuclear complex *cis*-$[Fe(pypzH)_2(NCS)_2]\text{-}H_2O$ (**5**), described below.

The atoms H(4) and H(7) in **2a** were located in the difference map and refined freely with respective H-bond lengths of 1.946 Å [O(2)H(4)] and 2.052 Å [O(3)H(7)]. Furthermore, the N(7)H(7)–O(3)–H(7′)N(7′) H-bonding is clearly evident with an H(7)–O(3)–H(7′) angle of 72.1°. Each half of the dimer is structurally equivalent with the O(3) atom at half occupancy in the asymmetric unit. The structure was also solved at 298 K, viz. **2b**. As expected, the thermal parameters of the atoms were greater at room temperature compared to 123 K. The average Fe–N distance in **2a** at 123 K is 2.098 Å, but this average increased to 2.163 Å at 298 K. Interestingly, the average Fe^{II} to N-donor distance of 2.161 Å in **1** at

123 K was the same as that in the room temperature structure of **2**. Both structures have typical high spin (HS) Fe^{II}–N distances whereas the selenocyanate structure at 123 K has an average Fe–N distance of 2.098 Å. A difference of 0.0635 Å is observed between 298 and 123 K. For a complete spin transition, from HS to LS,

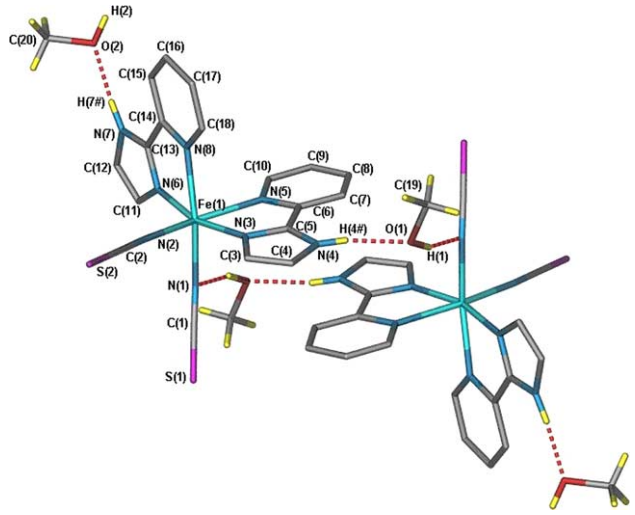

Fig. 2. Molecular structure of the dimer {*cis*-[Fe(pyimH)$_2$(NCS)$_2$]$_2$-(μ-MeOH)$_2$(MeOH)$_2$} (**3**) at 123 K.

the Fe–N bond distance typically decreases by ~0.2 Å [6]. In complex **2**, at 123 K, only about 25% of the HS Fe^{II} centres have undergone a spin-crossover and so only a small decrease in the Fe–N bond length is anticipated, as observed. This structural contraction is further evident from the reduction in the associated unit cell volumes, by 3.1%. Bond angle variations are observed between 298 and 123 K leading to a more regular shape of the [FeN$_6$] core at the lower temperature.

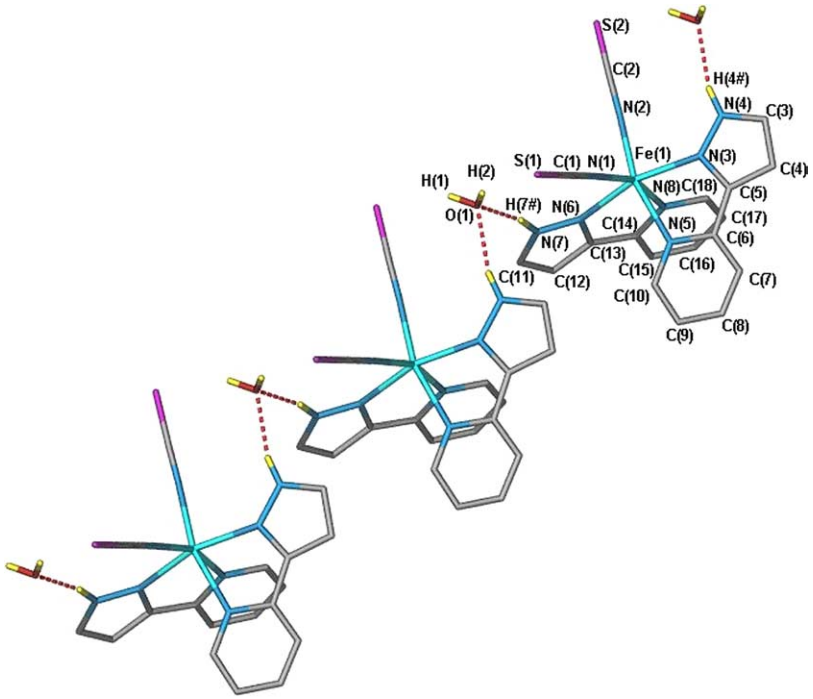

Fig. 3. Chain-like structure of {*cis*-[Fe(pypzH)$_2$(NCS)$_2$](μ-OH$_2$)}$_n$ (**4**) at 123 K.

Compound **3** is also pseudo-dimeric and is bridged by two methanol molecules which are structurally equivalent and H-bonded to the imidazole NH(4) of the molecule, via O(1), and to the thiocyanate N(1) of the other molecule, via H(1) (see Fig. 2). These distances are O(1)–H(4) = 1.94 Å and H(1)–N(1) = 2.09 Å. The overall structure of the dimer is different to that in the pypzH compounds. The bent coordination of the NCS in **3** (C–N–Fe = 149.2°) is unusual and is further evidence for the H-bonding of the MeOH.

The average Fe–N bond length at 123 K in complex **3** is 2.17 Å, comparable to that in the HS pseudo-dimer $\{cis\text{-}[Fe(pypzH)_2(NCS)_2]_2(\mu\text{-}OH_2)\}2H_2O$ (**1**).

In the chain species **4**, water bridging occurs via H-bonding to NH groups of pyrazole rings in neighbouring *cis*-$[Fe(NCS)_2(pypzH)_2]$ molecules. This can be seen in the crystal structure shown in Fig. 3. The packing of the chains is shown in Fig. 4.

The structure of monomer **5** is shown in Fig. 5 and now the pyrazole N(3) is *trans* to pyridine N(8). Only one of the pyrazole NH groups is involved in H-bonding to a single terminal water. The H(4)–O(1) distance is 2.02 Å The average Fe–N distance in the monomer is 2.16 Å, which is a typical Fe–N distance for a HS Fe(II) complex.

The compounds **1**–**5** containing H-bonded ligand contacts raised the significant question of how important H-bonded interactions involving solvate and ligand might be in the SCO behaviour of crystalline Fe^{II} species, be they mono-, bi- or polynuclear. H-bonding "supramolecular" effects have been noted through their influence on ligand field strength and on cooperativity in

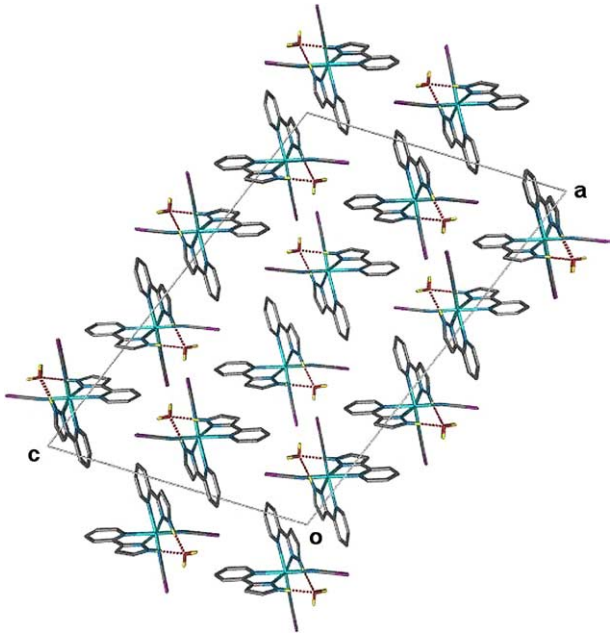

Fig. 4. Packing arrangement of chains of $\{cis\text{-}[Fe(pypzH)_2(NCS)_2]\text{-}(\mu\text{-}OH_2)\}_n$ (**4**) as viewed down the *b*-axis.

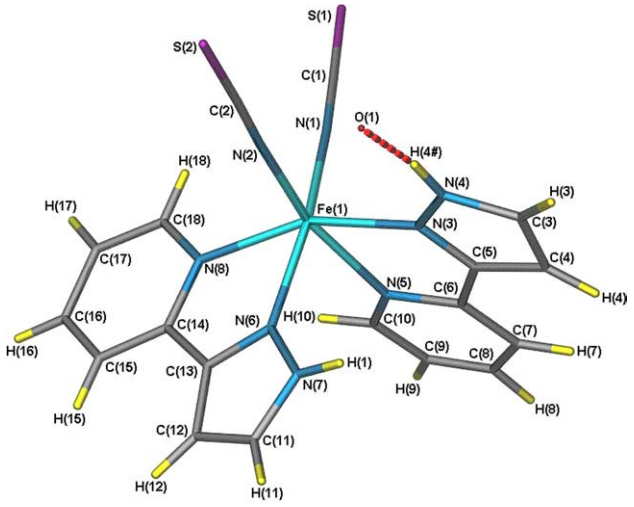

Fig. 5. Molecular structure of the monomer *cis*-$[Fe(pypzH)_2(NCS)_2]H_2O$ (**5**) at 123 K.

mononuclear species [1,4,8,17]. A microporous framework system has also recently been shown to display SCO on those Fe(II) sites which are involved in EtOH···SCN–Fe H-bonding interactions [7]. When the guest EtOH molecules are desorbed the system is high-spin at all temperatures.

3.3. Magnetic properties

Magnetic data show that complex **1** remains HS–HS in the range 4–300 K, μ_{eff} (per Fe) being constant at 5.0 μ_B (χT = 3.125 $cm^3\ mol^{-1}$ K at 300 K) between 300 and 50 K, then decreases to 2.5 μ_B at 2 K because of ligand field and zero-field splitting of the $^5T_{2g}$ derived state (Fig. 6). Any antiferromagnetic exchange coupling contributions, via the ligand–water H-bonding pathways is very weak. Conversely, the NCSe complex **2**, which has a stronger ligand field around each Fe, shows a very gradual 'half' SCO transition corresponding to changes

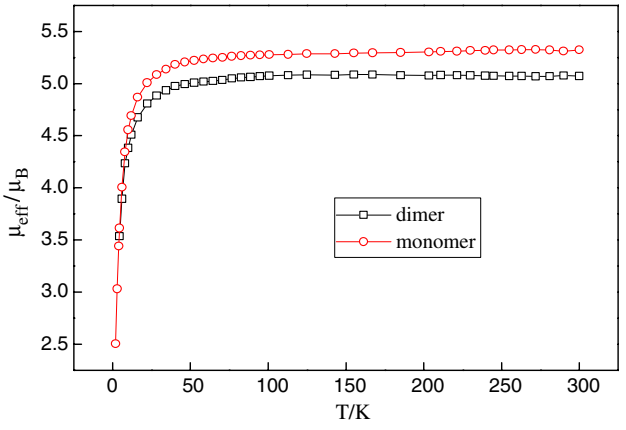

Fig. 6. Magnetic moments, per Fe, of dimeric $\{cis\text{-}[Fe(pypzH)_2(NCS)_2]_2(\mu\text{-}OH_2)(H_2O)_2\} \cdot H_2O \cdot MeOH$ (**1**) and mononuclear *cis*-$[Fe(pypzH)_2(NCS)_2]H_2O$ (**5**) in the range 2–300 K.

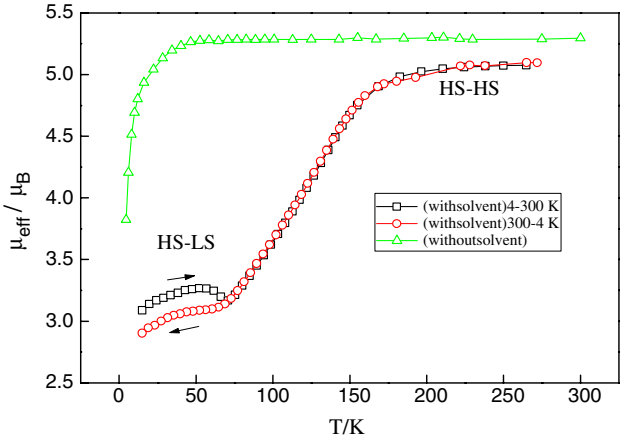

Fig. 7. Magnetic moments, per Fe, of {*cis*-[Fe(pypzH)$_2$(NCSe)$_2$]$_2$-(μ-OH$_2$)(H$_2$O)$_2$} · H$_2$O · MeOH (**2**) plotted as a function of temperature, with and without solvate molecules.

between HS–HS to HS–LS microstates, with no hysteresis, and centred at $T_c \sim 125$ K (Fig. 7). The different values of μ_{eff} observed, on heating and cooling in the range 4–70 K, are due to thermal quenching and consequent trapping of some HS–HS state into the HS–LS state.

The pyimH compound **3** remained in the HS–HS state over the range 4–300 K as seen in the plot of μ_{eff} versus temperature which is very similar to those of **1** and **5**. The observation that complex **2** produces a half SCO transition to yield the HS–LS micro-state below ~70 K, rather than giving a full transition to the LS–LS state, is similar to that observed for the covalently bridged complex [Fe(bpym)(NCSe)$_2$]$_2$(μ-bpym), investigated by Real [6] and for which an absence of thermal hysteresis was also noted. In that case, the stabilisation of a HS–LS state was attributed to intramolecular anti-cooperative interactions, perhaps in conjunction with weak exchange coupling across the bpym bridge. Some other members of the μ-bpym series showed a two-step full SCO, attributed to the cooperativity between dinuclear molecules [6].

Interestingly, when **2** was desolvated by heating, in vacuo, at 80 °C it showed no SCO, but displayed HS–HS magnetic behaviour in the range 2–300 K (Fig. 7). The rapid decrease in μ_{eff} below 50 K was, again, due to zero field splitting effects. Any nearest neighbour exchange coupling is very weak. The H-bonded water bridging is therefore crucial for spin-crossover transitions to occur in the parent complex **2**, not only for modulating the ligand field strength at the Fe(II) centres, but also for providing a new mode of intra-dimer cooperativity, albeit weakly, as judged by the gradual SCO and lack of hysteresis. The H-bonded water molecules shown in Fig. 1 do not H-bond to any neighbouring dimers. The other water and methanol solvate molecules, not shown in Fig. 1, are neither H-bonded to each other or to the dimers. Thus, any inter-dimer cooperativity will be very weak and we believe the intra-dimer contribution is dominant.

The structural equivalence of each Fe chromophore within the dimeric unit in **2**, at 123 K, a temperature above the [HS–LS] plateau, is similar to the equivalence in the two-step μ-bpym system [6]. This contrasts with the trapped HS and LS sites observed within the dinuclear moiety of a recent triazole bridged [HS–LS] example [18]. There are no crystallographic phase transitions occurring in any of these dimeric or dinuclear examples and it is therefore difficult, at this stage, to assign a role, if any, for the H-bonding bridges in stabilizing the HS–LS state in complex **2**.

It can be seen in Fig. 6 that the mononuclear complex *cis*-[Fe(pypzH)$_2$(NCS)$_2$]H$_2$O (**5**) remains HS in the range 4–300 K, μ_{eff} being constant at 5.3 μ_B between 300 and 50 K, then decreasing to 2.5 μ_B at 2 K due to zero-field splitting of the $^5T_{2g}$ derived ground state. The pseudo-dimer {*cis*-[Fe(pypzH)$_2$(NCS)$_2$]$_2$(μ-OH$_2$)(H$_2$O)$_2$} · H$_2$O · MeOH (**1**) behaves similarly. However, bis-chelated monomers such as *cis*-[Fe(2,2′-bipy)$_2$(NCS)$_2$] do show SCO behaviour [1,8] and thus the pypzH ligand produces a weaker ligand field than 2,2′-bipy, probably modulated by the H-bonded water group in **5**.

4. Summary

In this paper, we have described the first example of a family of pseudo-dimeric iron(II) complexes in which {ligand–water–ligand} hydrogen-bonding bridges the two iron centres. The spin-state of the compounds depend upon the X group in the NCX$^-$ co-ligand, the X = Se derivative displaying an incomplete (half) spin-crossover leading to a HS–LS ground state. The X = S derivatives remain HS–HS at all temperatures as does the desolvated X = Se compound. Cooperativity effects are very weak and probably intra-dimer in origin.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 206921, 206922, 206923, 256928, 256929, 256930. the ferromagnetism in α-TDAE-C_{60} and that the transition temperature could be governed by the Hubbard-type negative exchange interaction $\propto -t^2/U$ which depends on the orientation and partially cancels out the direct one. Here, t is the transfer integral and U the on-site Coulomb repulsion energy. This model requires special orientational ordering between the neighboring C_{60} molecules in one-dimensional chain along c-axis [8]. On the other hand, Kawamoto and co-workers [9,10] proposed the importance of the higher order exchange interaction between the neighboring Jahn–Teller orbitals perpendicular to each other, which is successful to reproduce the hydrostatic pressure dependence of the critical temperature [3].

In this report, the uniaxial strain was applied along b-and c-axis to investigate what kind of interaction dominates the ferromagnetism in α-TDAE-C_{60}, which helps to select the models applicable to this system. Since the present study is limited only to a single example for each applied direction, a full report will appear elsewhere.

2. Experimental

Single crystals are prepared with a diffusion technique [4]. Crystallographic axes are determined with X-ray analysis. An epoxy cylinder containing an aligned single crystal put in a coil is set in the Cu–Be clamp-type pressure cell. Magnitude of uniaxial strain is represented by a corresponding pressure applied to a zirconia piston with 6 mm ϕ. A resonance shift of ESR signal is measured at frequencies around 100 MHz [11], which is caused by a demagnetization field due to spontaneous magnetization. It is important to use the low resonance field of several tens of gauss, which does not produce a significant influence on the ferromagnetic transition.

3. Results and discussion

The transition temperature T_C is shown as functions of pressure applied along b- and c-axis together with hydrostatic pressure in Fig. 1, demonstrating anisotropic magnetic interactions. Characteristic features are summarized as follows. (1) The hydrostatic pressure suppresses T_C quadratically, $\propto 1\text{-}P^2$, which can be reproduced well with the orbital ordering model based on the intermolecular cooperative Jahn–Teller distortion (ICJT model) [3,9]. (2) The b-axis strain enhances T_C up to 17.5 K under 4 kbar of the applied pressure. (3) The c-axis strain strongly suppresses the ferromagnetism; 12 K in the minor part and 10 K for the main part of the sample under 1 kbar of the pressure. Interestingly, the b-axis strain also produces a fraction of the sample

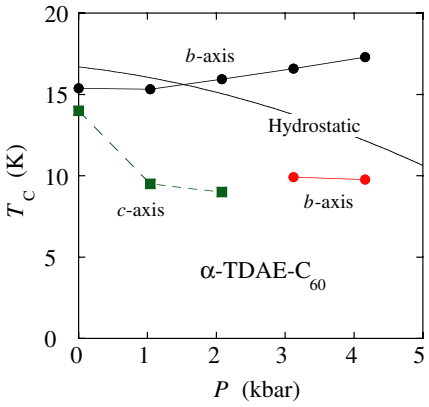

Fig. 1. T_C variations caused by uniaxial strain along b-axis [12] and c-axis, together with by hydrostatic pressure [3].

with the low T_C of about 10 K. The presence of the sub-phase with $T_C \approx 10$ K would relate to a freezing of the flipping between the Jahn–Teller distortion axes around 10 K [13].

To unveil the origin of these pressure dependences of T_C, let me discuss the ICJT mechanism of the high transition temperature. The main reason why the hydrostatic pressure suppresses T_C is a rapid increase of the negative exchange interaction $J \propto -t^2/U$ with pressure, which has been suppressed at ambient pressure because of the cancellation caused by the antiferro-orbital ordered structure with the Jahn–Teller orbitals of the p-like symmetry [3,9]. The important point of this model is such a cancellation of the antiferromagnetic interaction, giving rise to the much less antiferromagnetic than the ferromagnetic interactions coming from the fourth-order perturbation of t. The pressure deteriorates the cancellation, resulting in the suppression of T_C.

The b-axis strain dependence in Fig. 1 requires not only to preserve the cancellation, but also to enhance the ferromagnetic interaction, which can be expected from the increased transfer integrals between neighboring orbitals by pressure. In contrast, the result of the c-axis strain suggests its critical role in strongly disturbing the growth of the cooperative Jahn–Teller distortion, giving rise to the rapid suppression of T_C demonstrated in Fig. 1.

What a structural model do these results meet? There are at least two ways to realize the antiferro-orbital ordered structure, as demonstrated in Fig. 2; (I) the axes of rugby ball structure for the Jahn–Teller distorted C_{60}'s are alternately arranged (parallel and perpendicular) along the c-axis, 1D chain of C_{60}'s, and (II) it aligns always perpendicular to the c-axis and partially fulfills the antiferro-orbital structure in the a–b plane with different a and b lattice constants. The former structure, (I) is preferred from the reasons that the b-axis strain never disturbs the antiferro-orbital ordering in the case (I) and that in the case (II) the b-axis strain directly spoils the

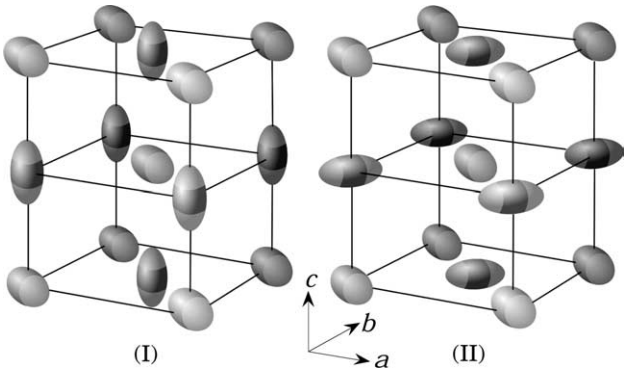

Fig. 2. Two possible antiferro-orbital ordered structures fulfill the requirement by the intermolecular cooperative Jahn–Teller distortion model for the ferromagnetism of TDAE-C_{60}. For simplicity TDAE's are omitted. The angle β of the monoclinic structure is 93.4°.

symmetry required for the cancellation of the antiferromagnetic interaction. This should be consistent with the *c*-axis strain case, too. By virtue of the soft van der Waals coupling, the pressure as small as 1 kbar can easily produce the strain of the order of 0.01 Å between C_{60}'s along *c*-axis, comparable with the expected Jahn–Teller distortion [9]. This suggests that the *c*-axis strain prevents from forming the structure (I) with $T_C = 16$ K, but forces to attain the structure (II) with the lower T_C than the structure (I). Note the possibility of the structure (II) to have $T_C \approx 10$ K corresponding to the second phase in Fig. 1. Therefore, if it were confirmed that the result with the *c*-axis strain was reproducible, and not an artifact caused by a sample degradation suspected because of the somewhat lower T_C than 16 K, the ICJT model would be well consistent with the present uniaxial strain results. Further study and analysis will appear elsewhere.

2-cyano-4,4,5,5-tetramethyl-4,5-dihydro-1*H*-imidazole-1-oxyl-3-oxide (**3**) [2,3] and 2,3-bis(hydroxylamino)-2,3-dimethylbutane [4,5] were described previously.

2.2. Syntheses of compounds

*Potassium salt of 4,4,5,5-tetramethyl-4,5-dihydro-1H-imidazole-1-oxyl-3-oxide-2-carboxylic acid (K(**1**)).*

Procedure 1. A mixture of nitrile **3** (182 mg, 1.0 mmol), KOH (57 mg, 1 mmol), and water (2 ml) was stirred in a round bottom flask (10 ml) for 1 h on an ice bath. Then the flask was connected to a vacuum pump via a liquid nitrogen trap, and water was distilled at a pressure of <1 Torr. The residue was ground with acetone (5 ml), and the solution containing only *4,4,5,5-tetramethyl-4,5-dihydro-1H-imidazole-1-oxyl-3-oxide* (TLC) was decanted. This procedure was repeated three or four times until acetone ceased to color. Yield: 230 mg (96%); violet powder soluble in MeOH, insoluble in acetone and ether. IR (KBr): $\tilde{\nu}$ (cm^{-1}) 540, 669, 731, 784, 893, 1141, 1168, 1207, 1312, 1368, 1535, 1665, 2991, 3425br. *Anal.* Calc. for $C_8H_{12}KN_2O_4\cdot 3H_2O$: C, 32.8; H, 6.2; N, 9.6. Found: C, 33.0; H, 4.6; N, 9.4%.

Stirring a solution of K(**1**) (0.10 g, 0.42 mmol) in EtOH (5 ml) for 24 h gave NN-H (36 mg, 55%).

A mixture of K(**1**) (0.48 g, 2.01 mmol) and I_2 (0.51 g, 1.99 mmol) in DMF (4 ml) was stirred for 1 h. The solvent was removed and the residue was chromatographed on a SiO_2 column ($CHCl_3$ – eluent), giving NN-I (0.31 g, 54%).

Procedure 2. To a stirred solution of glyoxylic acid monohydrate (0.92 g, 1.0 mmol) in water (5 ml) was added K_2CO_3 (1.38 g, 1.0 mmol). Then 2,3-bis(hydroxylamino)-2,3-dimethylbutane (1.48 g, 1.0 mmol) was added. The reaction mixture was stirred until it thickened and allowed to stay in a refrigerator for 1 day. Then water (3 ml) was added to the reaction mixture. The mixture was stirred, and the precipitate was transferred on a filter, squashed, and dried in vacuum. Yield: 1.78 g (74%); white crystals of the *potassium salt of 1,3-dihydroxy-4,4,5,5-tetramethyl-imidazolidine-2-carboxylic acid (**4**)*. IR (KBr): $\tilde{\nu}$ (cm^{-1}) 541, 577, 658, 699, 814, 850, 916, 977, 994, 1019, 1114, 1164, 1299, 1372, 1508, 1616, 2979, 3214br, 3508. *Anal.* Calc. for $C_8H_{15}KN_2O_4\cdot 2H_2O$: C, 34.5; H, 6.7; N, 10.1. Found: C, 34.5; H, 6.6; N, 10.7%.

To a solution of **4** (0.24 g, 1.0 mmol) in water (5 ml) was added PbO_2 (0.81 g, 3.4 mmol). The reaction mixture was stirred for 1.5 h at room temperature and filtered. The product was isolated from the mother solution as was done in procedure 1. Yield: 0.21 g (88%).

*Lithium salt of 4,4,5,5-tetramethyl-1-oxyl-4,5-dihydro-1H-imidazole-2-carboxylic acid (Li(**2**)).* A mixture of nitrile **6** (330 mg, 1.99 mmol), $LiOH\cdot H_2O$ (84 mg, 2.0 mmol), and water (4 ml) was stirred in a round bottom flask (10 ml) for 14 h at room temperature. Water was distilled off at a pressure of <1 Torr. The residue was ground with acetone (5 ml) and then recrystallized from a mixture of MeOH with *i*-PrOH. Yield of Li(**2**) is 368 mg (97%); very thin, coalesced bronze plates. IR (KBr): $\tilde{\nu}$ (cm^{-1}) 568, 587, 618, 764, 804, 895, 1135, 1218, 1248, 1371, 1395, 1451, 1548, 1674, 2934, 2969, 3434br. *Anal.* Calc. for $C_8H_{12}LiN_2O_3$: C, 50.3; H, 6.3; N, 14.7. Found: C, 50.2; H, 6.3; N, 14.4%.

*Potassium salt of 4,4,5,5-tetramethyl-1-oxyl-4,5-dihydro-1H-imidazole-2-carboxylic acid (K(**2**))* was prepared by the reaction of **6** (240 mg, 1.45 mmol) with a solution of KOH (81 mg, 1.45 mmol) in water (2 ml) by a procedure similar to the one used for **Li(2)**. Yield: 95%; bronze plates; the crystals darken above 230 °C, while at 240 °C they acquire a green hue, and decompose above 255 °C with gas evolution. IR (KBr): $\tilde{\nu}$ (cm^{-1}) 563, 594, 756, 796, 808, 882, 1146, 1211, 1234, 1360, 1439, 1482, 1540, 1657, 2936, 2980, 3421br. *Anal.* Calc. for $C_8H_{12}KN_2O_3$: C, 43.0; H, 5.4; N, 12.6. Found: C, 43.0; H, 5.4; N, 12.4%.

*Tetra-n-butyl ammonium salt of 4,4,5,5-tetramethyl-1-oxyl-4,5-dihydro-1H-imidazole-2-carboxylic acid ((n-Bu)$_4$N(**2**))* was prepared by the reaction of **6** (230 mg, 1.39 mmol) with 40% water solution of $(n\text{-Bu})_4NOH$ (0.90 mg, 1.39 mmol) in water (2 ml). After water had been removed, the yield was 510 mg (86%); red–orange oil. IR (KBr): $\tilde{\nu}$ (cm^{-1}) 755, 888, 1029, 1061, 1107, 1146, 1198, 1235, 1362, 1377, 1434, 1488, 1637, 2875, 2962, 3454br. *Anal.* Calc. for $C_{24}H_{48}N_3O_3\cdot 0.5H_2O$: C, 66.1; H, 11.3; N, 9.6. Found: C, 66.0; H, 11.9; N, 7.9%.

*Cu(**2**)$_2$(CH$_3$OH)$_2$.* A solution of $Cu(OAc)_2\cdot H_2O$ (0.0447 g, 0.22 mmol) in MeOH (20 ml) was slowly added to the solution of K(**2**) (0.1000 g, 0.45 mmol) in MeOH (10 ml). The reaction mixture was kept at room temperature for 1 h. The resulting dark green prismatic crystals were filtered off, washed with MeOH, and dried in air. Yield: 48%. *Anal.* Calc. for $C_{18}H_{32}N_4O_8Cu$: C, 43.6; H, 6.5; N, 11.3. Found: C, 43.2; H, 6.2; N, 11.5%.

*Ni(**2**)$_2$(H$_2$O)$_2$ and Co (**2**)$_2$(CH$_3$OH)$_2$* were synthesized by a similar procedure. *Ni(**2**)$_2$(H$_2$O)$_2$* are coalesced greenish brown crystals. Yield: 82%. *Anal.* Calc. for $C_{16}H_{28}N_4O_8Ni$: C, 41.5; H, 6.1; N, 12.1. Found: C, 41.5; H, 6.3; N, 11.9%. *Co(**2**)$_2$(CH$_3$OH)$_2$* are coalesced bronze crystals. Yield: 79%. *Anal.* Calc. for $C_{18}H_{32}N_4O_8Co$: C, 44.0; H, 6.6; N, 11.4. Found: C, 43.8; H, 6.4; N, 11.4%.

*Cu(**2**)$_2$.* Benzene (5 ml) was poured into $Cu(\mathbf{2})_2(CH_3OH)_2$ (0.0500 g, 0.10 mmol). The mixture was allowed to stay for 1 h at 50 °C. The resulting tawny powder was filtered off, washed with benzene, and dried in air. Yield: 95%. *Anal.* Calc. for $C_{16}H_{24}N_4O_6Cu$: C, 44.5; H, 5.6; N, 13.0. Found: C, 44.6; H, 5.6; N, 12.6%.

*Cu(**2**)$_2$(H$_2$O)$_2$.* A solution of $Cu(OAc)_2\cdot H_2O$ (0.0224 g, 0.11 mmol) in EtOH (20 ml) was slowly added at room temperature to the solution of K(**2**) (0.0500 g,

0.22 mmol) in EtOH (10 ml). After 1 h, a green precipitate formed, which was filtered off, washed with ethanol, and dried in air. Yield: 60%. *Anal.* Calc. for $C_{16}H_{28}N_4O_8Cu$: C, 41.1; H, 6.0; N, 12.0. Found: C, 40.8; H, 5.6; N, 11.7%.

*Ni(**2**)$_2$(dipy)·H$_2$O*. A solution of K(**2**) (0.0500 g, 0.22 mmol) and 4,4′-dipyridyl (0.0175 g, 0.11 mmol) in MeOH (5 ml) was slowly added to the solution of $Ni(OAc)_2·4H_2O$ (0.0279 g, 0.11 mmol) in MeOH (5 ml). The green precipitate was filtered off, washed with MeOH, and dried in air. Yield: 60%. *Anal.* Calc. for $C_{26}H_{34}N_6O_7Ni$: C, 51.9; H, 5.7; N, 14.0. Found: C, 52.1; H, 5.3; N, 13.8%.

*Ni(**2**)$_2$(py)$_2$*. A solution of K(**2**) (0.0500 g, 0.22 mmol) and pyridine (0.1 ml) in MeOH (5 ml) was added to the solution of $Ni(OAc)_2·4H_2O$ (0.0279 g, 0.11 mmol) in MeOH (5 ml). The solvent was slowly evaporated to ~2 ml in an air current. The green prismatic crystals were filtered off, washed with *i*-PrOH, and dried in air. Yield: 40%. *Anal.* Calc. for $C_{26}H_{34}N_6O_6Ni$: C, 53.4; H, 5.9; N, 14.4. Found: C, 53.1; H, 5.8; N, 14.2%.

2.2.1. X-ray structure analysis

The data were collected on SMART APEX CCD (Bruker AXS) automatic diffractometer at ambient temperature using the standard procedure (Mo radiation). Several H atoms were localized in difference electron density syntheses; the others were generated theoretically. All structure solution and refinement calculations were carried out with SHELX97 software. The crystallographic data and experimental details are given in Table 1; selected bond lengths and angles are given in Table 2.

2.2.2. Magnetic measurements

The magnetochemical experiment was run on an MPMS-5S (“Quantum Design”) SQUID magnetometer

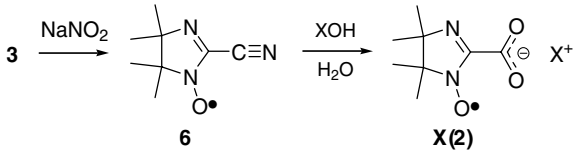
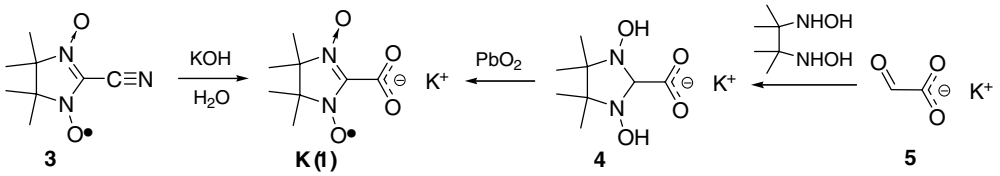
at temperatures from 2 to 300 K in a homogeneous external magnetic field of up to 49.5 kOe. The molar magnetic susceptibility χ was calculated using Pascal's additive scheme including diamagnetic corrections and taking into account temperature-independent paramagnetism of Cu(II) and Ni(II) ions, which were taken to be 60×10^{-6} and 190×10^{-6} cm^3/mol, respectively. For the paramagnetic region, the effective magnetic moment was calculated by the formula $\mu_{\text{eff}} = [(3k/N_A\beta^2)\chi T]^{1/2} \approx (8\chi T)^{1/2}$, where k is Boltzmann's constant, N_A is the Avogadro number, and β is the Bohr magneton. The magnetic phase transition temperature was determined as the extremum of the derivative of magnetic susceptibility with respect to temperature $\partial\chi/\partial T$.



3. Results and discussion

3.1. Syntheses and Properties of NN-COOK (K(1)) and IN-COOM (X(2), X = Li$^+$, K$^+$, (n-Bu)$_4$N$^+$)



Previously, attempts were made to synthesize the NN-COOH acid or its salts. Thus the NN-COOMe ether was subjected to alkaline hydrolysis [1]. An EPR spectroscopic study revealed that the resulting solution contained the NN-COO$^-$ anion, which was stable in an alkaline solution at 0 °C, but was quickly decarboxylated into NN-H by acidifying or using elevated temperatures. An attempt to synthesize NN-COOH by oxidation of 1,3-dihydroxy-4,4,5,5-tetramethylimidazolidin-2-yl-carboxylic acid with $NaIO_4$ led to nitroxide NN-H as the sole product [6]. These data gave strong evidence that NN-COOH and its salts are liable to undergo spontaneous decarboxylation in solution, which makes it difficult to isolate them from the reaction mixture. This difficulty was overcome to a certain extent by Weiss et al. [7], who treated a THF solution of NN-H with LDA and then carboxylated NN-Li with CO_2. However, this reaction is performed in rather stringent conditions, giving only the lithium salt of **1**. We found that the potassium salt K(**1**) can be obtained in mild conditions by hydrolysis of paramagnetic nitrile **3** in the presence of an equimolar amount of KOH (Scheme 1). This reaction is well reproducible and readily controllable because the greenish blue crystals of the starting **3** are gradually dissolved in the course of the reaction to give a dark violet solution. Subsequent treatment of the reaction mixture as described in Section 2 leads to high yields of K(**1**).

K(**1**) is a dark violet powder insoluble in benzene, ether, and acetone and readily soluble in water, MeOH, EtOH, and DMF. Prolonged (for 1 day or more) storage of a solution of K(**1**) in any polar solvent leads to gradual decarboxylation of the salt, giving mainly NN-H (in up to 55% yields). Treatment of a DMF solution of K(**1**) with I_2 forms NN-I in >50% yield. Note that K(**1**) is also obtainable by condensation of aldehyde **5** with 2,3-bis(hydroxylamino)-2,3-dimethylbutane and further oxidation of **4** with PbO_2 (Scheme 1). The physicochemical characteristics of the thus synthesized K(**1**) are identical with the characteristics of the samples synthesized by alkaline hydrolysis of **1**. At room temperature μ_{eff} is 1.72 BM, which is close to the theoretical value of 1.73 BM for uncoupled $s = 1/2$ spins with a g-factor of 2. At reduced temperature the $\mu_{\text{eff}}(T)$ curve decays, indicating that antiferromagnetic intermolecular exchange interactions are dominant (Fig. 2).

The instability of **1** is due to the weak C–C bond between the carboxyl group and the imidazoline ring, both of which are electron acceptors. Taking into account the circumstance that increasing of electron density on carbon atom in α-position to carboxylic group prevents eliminating of carbon dioxide [8], we suggested less aptitude for decarboxylation of carboxylate **2**. This prompted us to synthesize **2**. This reduction product of **1** was expected to show less aptitude for decarboxylation. Compound X(**2**), where X = Li$^+$, K$^+$, (*n*-Bu)$_4$N$^+$, was synthesized by hydrolysis of paramagnetic nitrile **6** in the presence of an equimolar quantity of the corresponding base XOH (X = Li$^+$, K$^+$, (*n*-Bu)$_4$N$^+$). In the course of the reaction, the orange crystals of nitrile **6**, preliminarily obtained by reduction of **3**, gradually dissolved to form a bright red solution (Scheme 2), from which X(**2**) was isolated after removal of water.

Scheme 2.

Scheme 1.

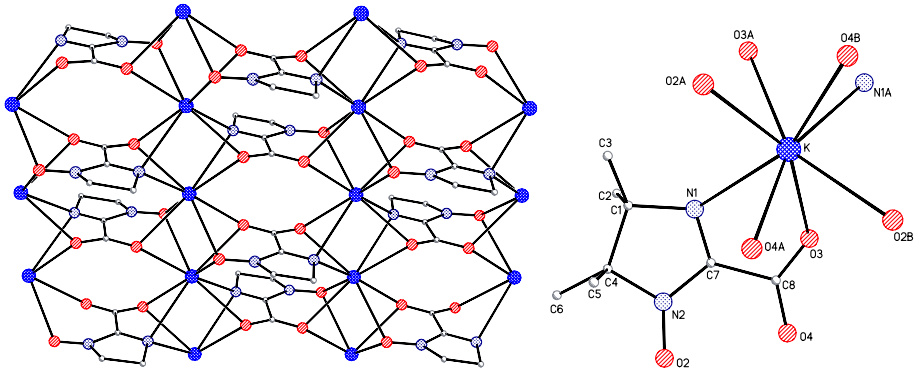


Fig. 1. Fragment of a polymer layer and atomic numbering for K(**2**).

Li(**2**) and K(**2**) are bronze platelike crystals insoluble in benzene, ether, acetone, and 2-propanol, but readily soluble in water, MeOH, EtOH, and DMF. (*n*-Bu)$_4$N(**2**) is a red oil soluble in benzene and CH_2Cl_2. After Li(**2**), K(**2**), and (*n*-Bu)$_4$N(**2**) solutions had been stored at ~0 °C for a few days, TLC did not reveal any decomposition products. A solution of K(**2**) in C_2H_5OH can even withstand boiling. This proves that **2** is much more stable than **1**.

After crystallization from a MeOH–*i*-PrOH mixture, Li(**2**) and K(**2**) were isolated as very thin coalescing bronze plates. For K(**2**) it was possible to perform an X-ray diffraction study and to define its structure. Solid K(**2**) is built from a kind of polymeric layers (Fig. 1). Inside the layer, the K atom is surrounded by a nearly square antiprism, whose bases are bent relative to each other at an angle of ~35°. The K–O distances vary from 2.680(9) to 2.933(10) Å; K–N distances, from 2.917(10) to 2.991(11) Å. The shortest K–K distance in the layer is 3.49(1) Å. The K–K interlayer distances are much longer (at least 11 Å). With this setting, each fragment of **2** is surrounded by four K atoms, and each K atom is surrounded by four fragments of **2**. The distances between the paramagnetic centers in solid K(**2**) are long enough. Therefore, μ_{eff} of this compound is close to 1.73 BM and remains virtually unaltered even at very low temperatures. Unfortunately, numerous attempts to separate quality crystals from conglomerates of Li(**2**) plates failed. For this reason, we failed to investigate the structure of Li(**2**) and to judge the structure of exchange clusters responsible for the ferromagnetic exchange interactions in solid Li(**2**) (Fig. 2).

3.2. Synthesis and structures of coordination compounds

Reaction of K(**1**) with transition metal salts confirmed that **1** is liable to decarboxylation. Addition of transition metal salts to an aqueous solution of K(**1**) merely accelerated the process. After K(**1**) had reacted with $CuCl_2$, the reaction mixture contained small amounts of single crystals, which were shown by X-ray diffraction analysis to be the known NN–NN biradical.

As might be expected, **2** proved to be much more stable in reactions with transition metal salts. The interaction of transition metals with **2**, however, has a number of specific features. If, for example, a solution of a paramagnetic metal salt is added very slowly (for 2 or 3 h or more) to an alcoholic solution of K(**2**), then most of **2** decomposes, preventing one from isolating the desired product. If, however, the solutions of K(**2**) and a transition metal salt are mixed rapidly, the complex also quickly separates as a solid. The product is obtained as a very fine precipitate. Quality single crystals cannot be prepared by further recrystallization of these finely disperse products because they decompose on heating. Single crystals were grown directly from the reaction mixture for Cu(**2**)$_2$(CH$_3$OH)$_2$ and Ni(**2**)$_2$(py)$_2$ complexes alone. A solution of a transition metal salt was carefully dropped for 15–30 min into a solution of K(**2**). The reaction mixture was then allowed to stay at room temperature for 50–70 min from the moment of the start of the

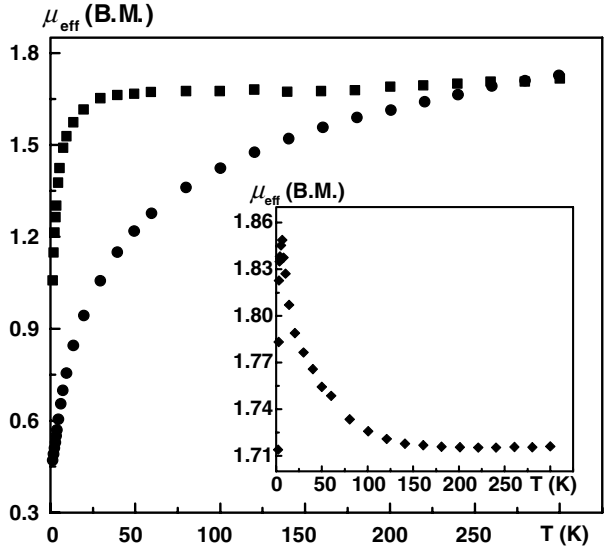

Fig. 2. Dependences $\mu_{eff}(T)$ for K(**1**) (●), K(**2**) (■), and Li(**2**) (inset).

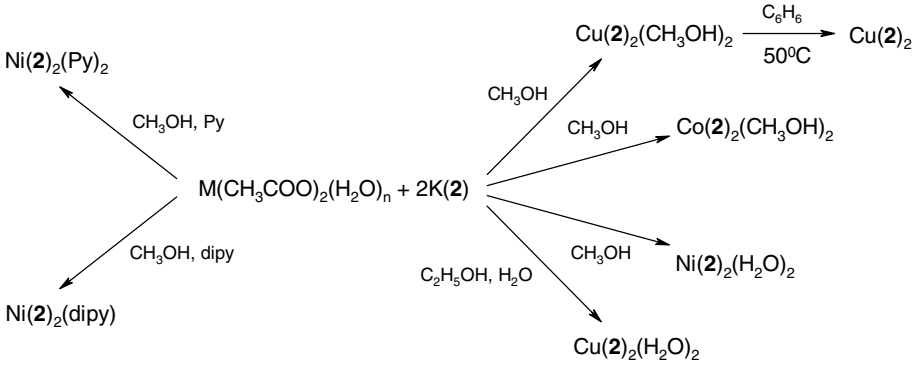

addition, whereupon the crystals were quickly filtered off. If storage in the mother solution is prolonged, the crystals gradually vanish, transforming into soluble decomposition products. Numerous attempts to prepare $Ni(\mathbf{2})_2(H_2O)_2$, $Co(\mathbf{2})_2(CH_3OH)_2$, $Cu(\mathbf{2})_2(H_2O)_2$, and $Ni(\mathbf{2})_2(dipy)\cdot H_2O$ complexes as single crystals by this procedure failed. Stirring $Cu(\mathbf{2})_2(CH_3OH)_2$ crystals in warm (50 °C) benzene yielded finely disperse $Cu(\mathbf{2})_2$ powder. The reactions leading to complexes with **2** are represented below as Scheme 3.

In solid $Cu(\mathbf{2})_2(CH_3OH)_2$, the centrosymmetric square environment of the Cu atom consists of the imine N atoms of the imidazoline ring and the O atoms of the carboxylate groups of the two bidentate molecules **2**; it is completed to a distorted octahedron by the O atoms of the two CH_3OH molecules. The Cu–N, Cu–O, and Cu–O_{OH} distances are 1.981(2), 1.970(2), and 2.410(3) Å, respectively (Fig. 3). The $\{Cu(\mathbf{2})_2(CH_3OH)_2\}$ fragments are combined into chains through H-bonds, which form OH groups of the coordinated alcohol molecules and the O atoms of the paramagnetic ligands not coordinated by the metal atom (Fig. 4). The $O_{OH}\cdots O_{C=O}$ and $O_{OH}\cdots O_{NO}$ distances are 2.845(4) and 2.970(4) Å, respectively.

Solid $Ni(\mathbf{2})_2Py_2$ has a molecular structure. The Ni atom (Table 2) is surrounded by an almost regular octahedron with *cis*-arrangement of the ligands (Fig. 5). In $Ni(\mathbf{2})_2Py_2$, as well as in $Cu(\mathbf{2})_2(CH_3OH)_2$, the N–O distances are 1.256(4)–1.263(3) Å, which are the typical distances of nitroxides. The five-membered chelate rings are nearly planar. The angle between the planes of the atoms of the carboxyl group and the atoms of the CN_2 fragment of the heterocycle is up to 8.

3.3. Magnetic properties

At room temperature, μ_{eff} is 3.55–3.58 BM for Cu(II) complexes and 4.41–4.48 BM for Ni(II) complexes; for $Co(\mathbf{2})_2(CH_3OH)_2$, μ_{eff} (300 K) = 5.71 BM. The observed values of μ_{eff} (300 K) are much higher than the theoretical limits for uncoupled spins of metals and the two nitroxides, which is due to the high efficiency of ferromagnetic exchange channels inside the $\{M(\mathbf{2})_2\}$ bischelate fragments, where M = Cu(II), Ni(II), Co(II). For

Scheme 3.

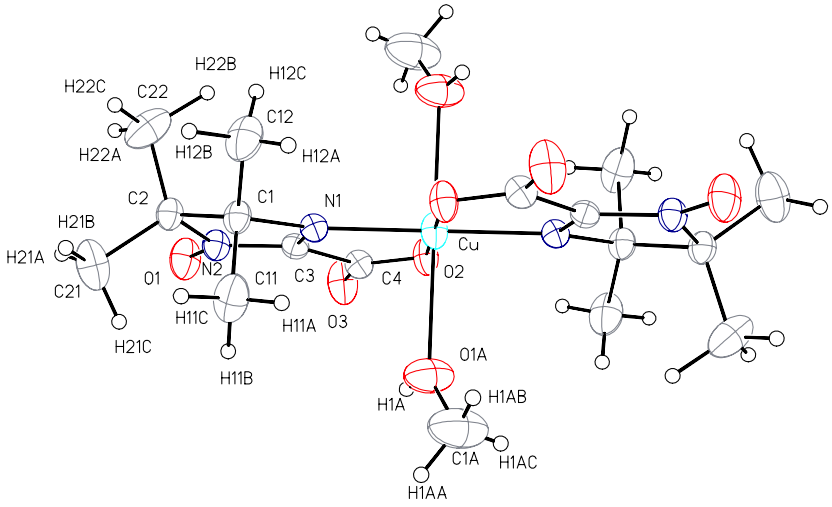

Fig. 3. Structure of $Cu(\mathbf{2})_2(CH_3OH)_2$ and numbering scheme.

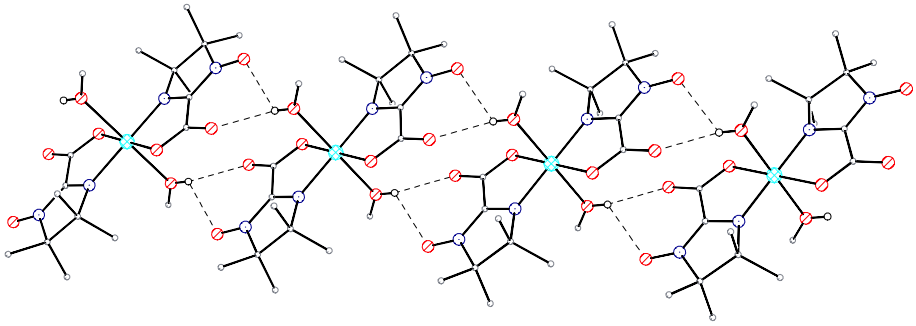

Fig. 4. Chain in the structure of $Cu(\mathbf{2})_2(CH_3OH)_2$.

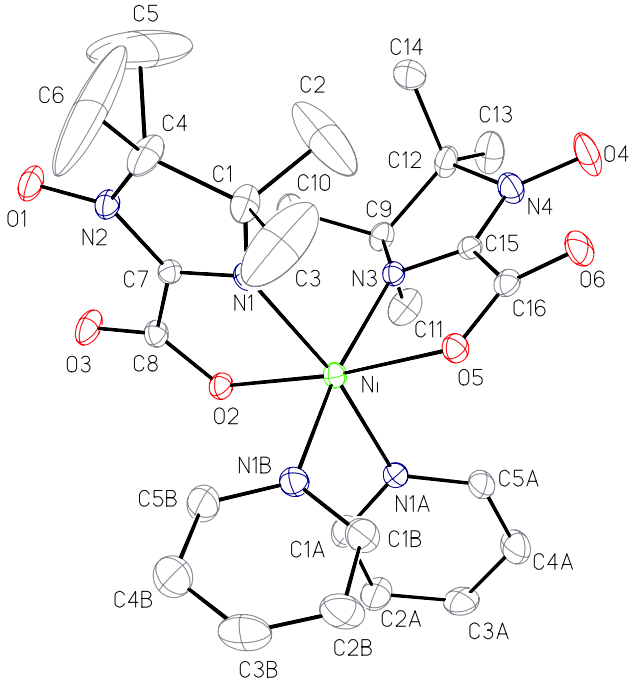

Fig. 5. Structure of $Ni(\mathbf{2})_2Py_2$ and numbering scheme.

$Co(\mathbf{2})_2(CH_3OH)_2$ the low-lying excited levels of Co(II) also make a significant contribution to μ_{eff} (300 K), which is also typical for the octahedral complexes of Co(II) [9] (Figs. 6 and 7). At low temperatures, the $\chi(T)$ functional dependence for $Cu(\mathbf{2})_2(CH_3OH)_2$, $Cu(\mathbf{2})_2(H_2O)_2$, $Ni(\mathbf{2})_2(py)_2$, $Ni(\mathbf{2})_2(H_2O)_2$, and $Co(\mathbf{2})_2(CH_3OH)_2$ shows maxima at 2.2, 2.1, 8, 4, and 3 K, respectively, suggesting that magnetic chains are formed in these solids. The fundamental exchange channels that form the magnetic chain structure are strong ferromagnetic exchange interactions inside $\{M(\mathbf{2})_2\}$ bischelate fragments and weaker antiferromagnetic interactions between $M(\mathbf{2})_2$ bischelates. We evaluated the effective g factors of the metal (g), as well as the exchange parameters inside (J) and between (J_c) the bischelate fragments within the framework of the alternant chain model [10] using the isotropic spin Hamiltonian (Table 3). The corresponding theoretical dependences are presented by solid lines in Figs. 6 and 7.

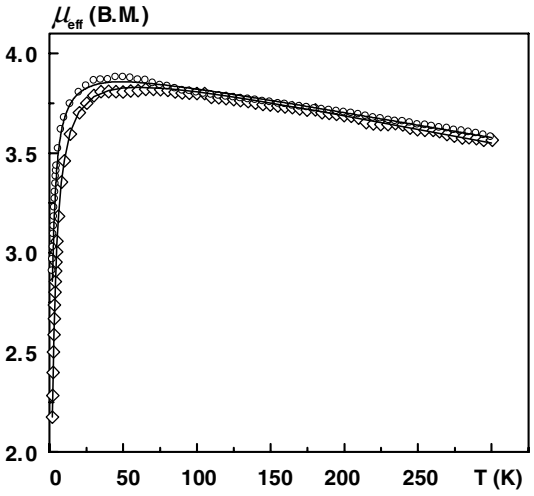

Fig. 6. Dependences $\mu_{eff}(T)$ for $Cu(\mathbf{2})_2(CH_3OH)_2$ (◇) and $Cu(\mathbf{2})_2(H_2O)_2$ (○). Solid lines are theoretical approximation.

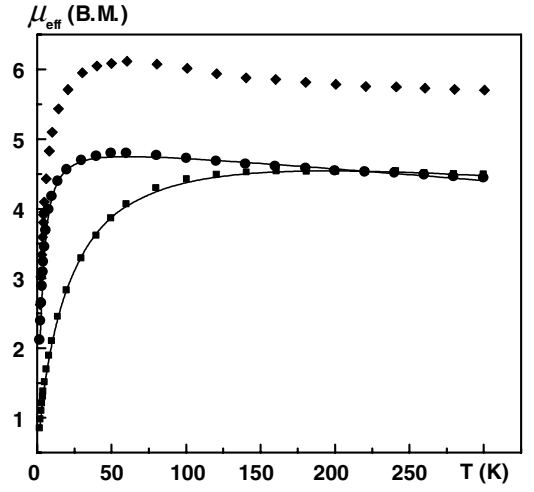

Fig. 7. Dependences $\mu_{eff}(T)$ for $Ni(\mathbf{2})_2(py)_2$ (■), $Ni(\mathbf{2})_2(H_2O)_2$ (●) and $Co(\mathbf{2})_2(CH_3OH)_2$ (◆). Solid lines are theoretical approximation.

For $Cu(\mathbf{2})_2$ at room temperature, μ_{eff} is close to the theoretical limit of 3 BM for three $s = 1/2$ uncoupled spins ($g = 2$). At reduced temperatures, the $\mu_{eff}(T)$ curve

decays, indicating that the antiferromagnetic exchange interactions are dominant. Below 16 K, Cu(**2**)$_2$ is transferred to a magnetically ordered state. Fig. 8 shows zero field cooling magnetization curves ($\sigma(T)$ measured in a magnetic field of 50 Oe during heating and subsequent cooling, and the retentivity curve. From the $\sigma(T)$ dependences obtained it follows that the ordering temperature for the complex is of the order of 16.6 K. The fundamental magnetization curve measured at 2 K (Fig. 9) is linear up to 10 kOe. In stronger magnetic fields, the (σH) curve smoothly departs from linearity, reaching 1650 G cm^3 mol^{-1} at 49.5 kOe. A hysteresis with a loop width of 1050 Oe has been recorded during magnetization reversal for the sample (Fig. 9). The ensuing spontaneous magnetic moment is (σ_s) is 23 G cm^3 mol^{-1}. Note that a hysteresis is observed only for magnetic fields varying from −6 to 6 kOe. Beyond this range, the lines and the reverse σH curves coincide within the limits of the experimental error. Hence, it follows that the *Cu(**2**)$_2$* complex is an antiferromagnet with weak ferromagnetic properties.

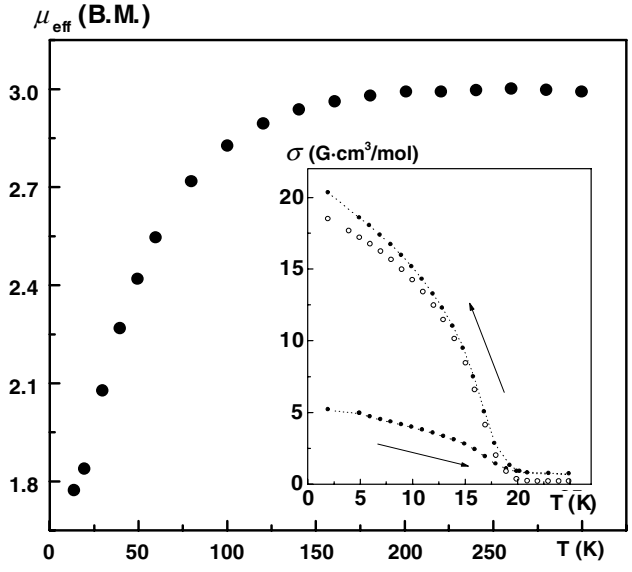

Fig. 8. $\mu_{eff}(T)$ curve in the paramagnetic region for *Cu(**2**)$_2$*. Zero field cooling $\sigma(T)$ curves (•) and residual magnetization curve (○) in the transition area (insert) for *Cu(**2**)$_2$*.

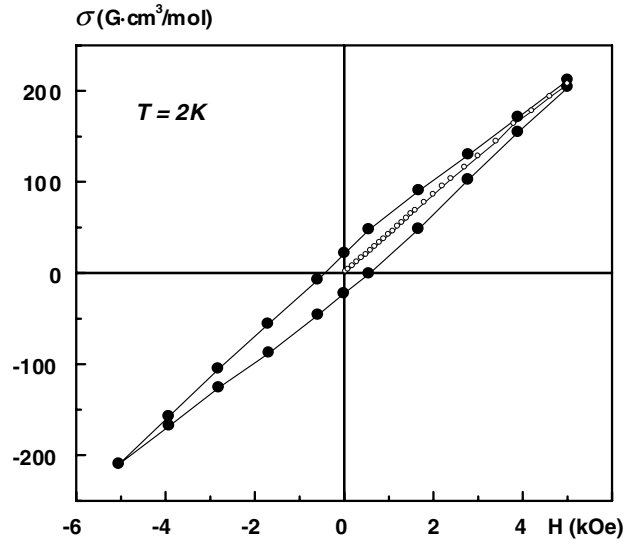

Fig. 9. Main magnetization curve (○) and hysteresis loop (•) for *Cu(**2**)$_2$*.

For Ni(**2**)$_2$(bipy), the magnetic behavior above 5 K (Fig. 10) is similar to the magnetic behavior of *Cu(**2**)$_2$(CH$_3$OH)$_2$*, *Cu(**2**)$_2$(H$_2$O)$_2$*, *Ni(**2**)$_2$(py)$_2$*, *Ni(**2**)$_2$(H$_2$O)$_2$*, or *Co(**2**)$_2$(CH$_3$OH)$_2$*. The calculated exchange parameters are presented in Table 3. Below 5 K, Ni(**2**)$_2$(bipy), like Cu(**2**)$_2$, is a weak ferromagnet with $T_N = 4.6$ K and spontaneous magnetization $\sigma_s = 90$ G cm^3 mol^{-1}. Magnetization reversal for the sample in magnetic fields from −6 to 6 kOe follows the hysteresis curve (Fig. 11) with a loop width of 1680 Oe.

Thus we succeeded in developing an effective procedure for the synthesis of the potassium salt K(**1**). X(**2**) were found to be much more stable, due to which we isolated a series of heterospin complexes with **2**. These compounds are characterized by rather strong ferromagnetic intramolecular exchange interactions. For Cu(**2**)$_2$

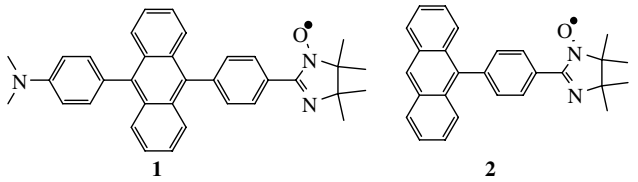

Fig. 1. Molecule studied in this work, **1** and previously reported stable radical, **2** with the excited quartet high-spin state.

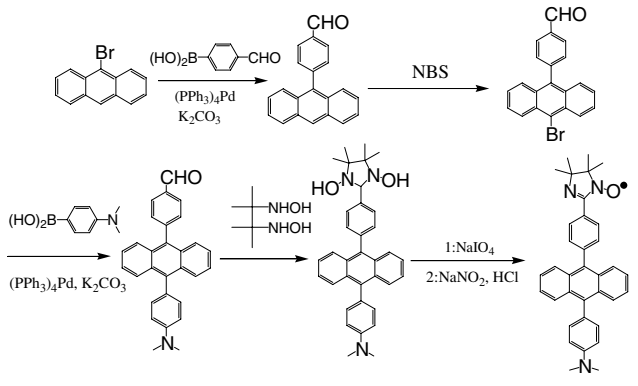

clarify the energy relaxation from the excited high-spin state to the ground state and the photo-induced electron transfer process from the excited state. As a basic study to develop their systems to the functional materials, the charge-transfer complexes based on the stable radicals with the photo-excited high-spin states are important research targets in order to clarify the photo-induced electron transfer from the high-spin excited states.

In this paper, we report the design, synthesis and electronic state of a π-conjugated stable iminonitroxide radical, **1**, electron donor property of which is expected to be improved than that of **2** [1,2] by attaching dimethylamino group. The molecular structures of **1** and **2** are shown in Fig. 1. The electronic and magnetic properties on the ground state were studied by CV, UV–Vis absorption spectra, and ESR. Molecular orbital calculation was also carried out. The spin alignment on the photo-excited state was investigated by a time-resolved ESR (TRESR) experiment. In addition, we also report two CT complexes which are synthesized using **1** as an electron donor.

2. Experimental

2.1. Synthesis of stable radical *1*

2,3-Bis(hydroxyamino)-2,3-dimethylbutane was prepared according to the literature method [13]. Other reagents were used as purchased. Column chromatography was performed on alumina (Merk Aluminum Oxide 60). **1** was synthesized according to Scheme 1. Sample was purified by the column chromatography on toluene.

Scheme 1.

Repeating re-crystalizations from EtOH/toluene gave **1** as red powder: m.p. > 300 °C (Found: C, 81.96; H, 6.67; N, 8.10 requires: C, 82.00; H, 6.68; N, 8.20).

2.2. Preparation of CT complexes

2.2.1. 1-TCNQ

The CT complex was prepared under argon in acetonitrile by the reaction of **1** with TCNQ. In order to accelerate the formation of the complex, the solution was refluxed for 6 h. The residue (excess amount of **1**) was filtered and the solution was evaporated and the precipitate was recrystallized from dichloromethane.

2.2.2. 1-BQF_4

The CT complex was prepared under argon in dichloroethane by mixing **1** with an excess amount of tetrafluoro-1,4-benzoquinone. The mixture was degassed in vacuum and cooled at −20 °C for a few days. The precipitate was filtrated and washed carefully. The dark green powder was purified by removing the contamination of tetrafluoro-1,4-benzoquinone in the precipitate using sublimation method.

The results of the elemental analyses were not sufficient in these complexes. Further improvement of the syntheses and purifications are in progress. Therefore, only the results of the optical absorption and TRESR will be reported and their magnetic properties will be not presented in this paper.

2.3. Measurements

Oxidation potential of **1** was measured by the CV method using a Hokuto Dennko HSV-100 and UV–Vis absorption spectra were obtained with a Hitachi U-3000. Conventional ESR spectra were observed with a JEOL TE300 X-band ESR spectrometer. The ab initio molecular orbital calculations were carried out based on the density functional theory (DFT) using GAUSSIAN 98 [14]. In the ab initio calculations, the STO 6-31G basis sets and UHF Becke 3LYP (UBecke 3LYP) hybrid method were employed. The photo-excited states were investigated by time-resolved ESR (TRESR) method. The detail of our TRESR setup was described in our previous paper [2]. The temperature in the ESR and TRESR measurements was controlled using an Oxford ESR 910 cold He gas flow system.

3. Results and discussion

The oxidation potential value of **1** in acetonitrile solution was 0.44 V on ferrocene which value was ca. 0.35 V smaller than **2**. The optical absorption band assigned to $\pi^* \leftarrow \pi$ transition arising from anthracene moiety was also shifted to longer wavelength. The calculated orbital

energies and molecular orbitals of **1** and **2**, shown in Fig. 2, were consistent with these experimental results. The energy location of π-HOMO of **1** becomes about 0.6 eV higher than that of **2**. These results show that the location of π-HOMO of **1** becomes higher in energy than that of **2** as the result of the attachment of dimethylamino group at the proper position.

The photo-excited state and the photo-induced spin alignment in **1** were investigated by TRESR experiments. Typical TRESR spectrum of **1** observed at 30 K in 2-MTHF glass matrix is shown in Fig. 3 together with the spectral simulation. The simulation was carried out using the eigenfield [15]/exact-diagonalization hybrid method [16] reported previously by taking the dynamic electron spin polarization under zero-magnetic field into account. The spectrum shows well resolved fine-structure splitting. The spectral simulation revealed that the observed TRESR spectrum of **1** has been unambiguously assigned as an excited quartet ($S = 3/2$) spin state (Q). The g value and fine-structure parameters for the quartet state have been determined to be $g(Q) = 2.0043$, $D(Q) = 0.0235\ \mathrm{cm}^{-1}$, $E(Q) = 0.0\ \mathrm{cm}^{-1}$.

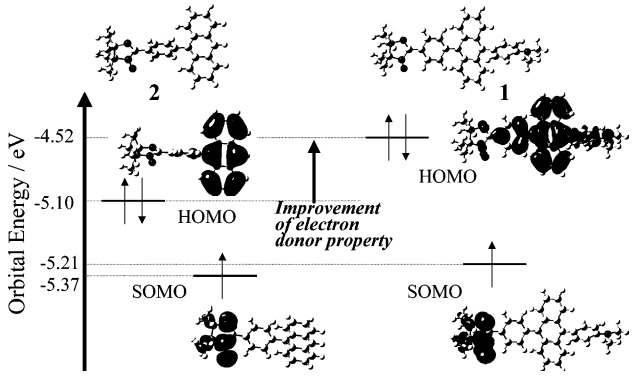

Fig. 2. Orbital energies and molecular orbitals of **1** and **2**.

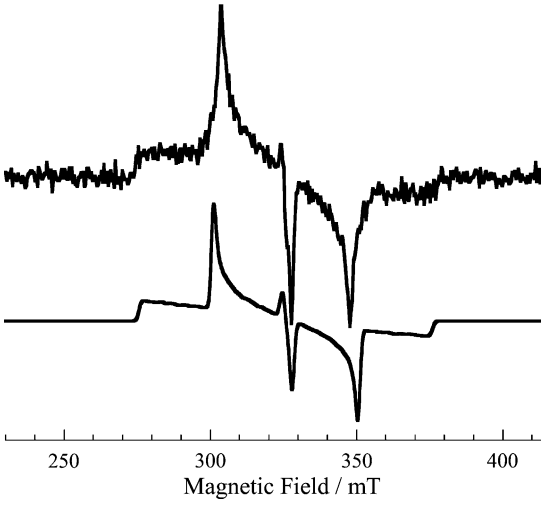

Fig. 3. Typical TRESR spectrum observed at 0.8 μs after LASER excitation.

The magnitude of the fine-structure parameter, D, clearly shows that the observed high-spin excited states are constructed from the ππ* excited metastable triplet state of anthracene and the doublet spin of the dangling radical. The D value of **1** was very close to that of **2** [2]. The characteristic property of the molecule **2** with the excited high-spin state is maintained in **1** and only the property of the electron donor is improved by attaching the dimethylamino group.

Fig. 4 shows the diffuse-reflection absorption spectra of **1**, TCNQ and **1**-TCNQ charge-transfer complex. CT band was clearly observed in **1**-TCNQ. A similar CT complex (1-BQF_4) was also obtained between **1** and BQF_4. A strong Charge-Transfer band was also observed in this case. These results show that **1** can be certainly available as the electron donor for a series of the electron acceptors which one can purchased commercially. The TRESR measurement for **1**-TCNQ gave an absorptive signal shown in Fig. 5. This spectrum was observed in the polar rigid glass matrix (acetonitrile:butylnitrile:

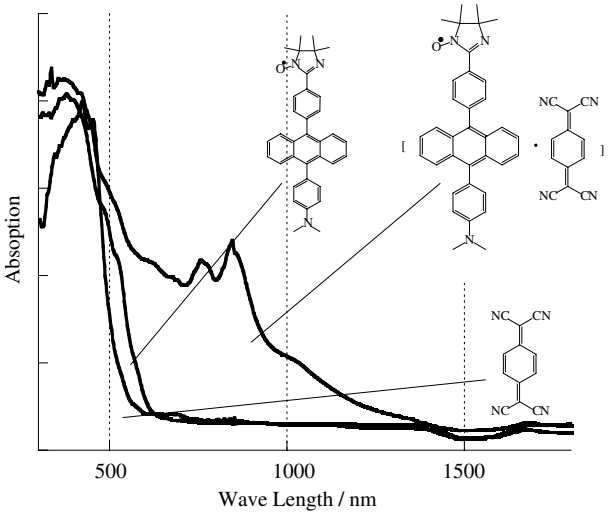

Fig. 4. Diffuse-reflective spectra of **1**, TCNQ and **1**-TCNQ.

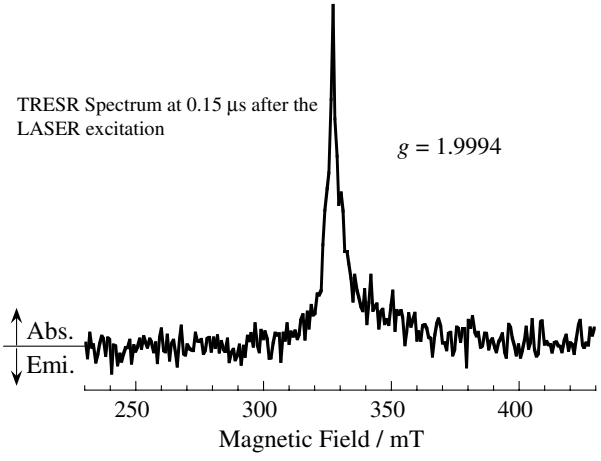

Fig. 5. Typical TRESR of **1**-TCNQ CT Complex.

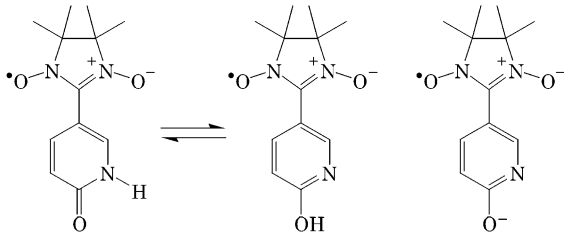
dichloromethane = 1:1:1 mixed solvent). There is a possibility that this signal comes from the photo-induced electron transfer from the excited quartet high-spin state of 1 to the electron acceptor of TCNQ. However, more careful experiments including the experiments by the photo-excitaion of CT band and the combination studies with optical spectra are necessary to identify the origin of this signal. These studies are going in progress.

4. Conclusions



1 was designed based on the ab initio MO calculation and synthesized as the stable radical which electron donor property was improved compared with **2** previously reported. It is confirmed that **1** has the photo-excited high-spin quartet ($S = 3/2$) state as well as **2** by the TRESR experiment. Two CT complexes were synthesized using **1** as an electron donor. A TRESR signal was observed for **1**-TCNQ CT complex which may be arising from the photo-induced electron transfer from the quartet excited state of **1** to the TCNQ acceptor.

Scheme 1.

2. Experimental

2.1. General

The ligand, 5-(4′,4′,5′,5′-tetramethylimidazoline-3′-oxide-1′-oxyl)-2(1*H*)-pyridone, was prepared from corresponding aldehyde precursors according to standard procedures [11,12]. The UV–Vis spectra for DMF solutions were recorded on a JASCO V570 UV/Vis/NIR spectrophotometer. Infrared spectra were recorded on a JASCO FT-IR 230 spectrometer using KBr pellets in the 4000–400 cm^{-1} range. Elemental analyses were performed using a Yanagimoto MT-3 C–H–N coder. ESR spectra were measured on a JEOL JES-TE100 spectrometer (X-band microwave unit). The magnetic susceptibilities were measured with a Quantum Design MPMS-2 SQUID susceptometer in the temperature range of 2–300 K at a constant field of 1 T. Diamagnetic corrections for the samples were determined from Pascal's constants and the literature values.

The X-ray data were collected using Mo Kα radiation on a CCD diffractometer (SMART APEX; Bruker Analytik, GmbH). The structures were solved by direct methods (SIR92 [13]) and refinement converged using full-matrix least squares of the CRYSTALSTRUCTURE [14] program. All non-hydrogen atoms were refined anisotropically. Most of the hydrogen atoms were placed at ideal positions using a rigid model. The tetramethylethylene group in one of the nitronyl nitroxide moieties in **1** was disordered over two sites with occupancy of 1:1; no hydrogens were attached to these methyl carbons. The hydroxyl hydrogen in **2** was located from the Fourier map and refined isotropically. Crystallographic data of **1** and **2** are listed in Table 1, and selected bond lengths and angles are shown in Table 2.

2.2. Preparation of [Cu_2(**L**)$_4$(DMF)$_2$] (**1**)

Sodium methoxide (30 mg, 0.55 mmol) was added to a methanol solution (5 ml) of **HL** (136 mg, 0.54 mmol) cooled in an ice bath. After stirring for 1 h, copper(II) nitrate trihydrate (65 mg, 0.27 mmol) dissolved in methanol (5 ml) was added dropwise. The reaction mixture was stirred overnight at room temperature to obtain light blue powders. The precipitate was dissolved in DMF, and slow evaporation of the solution afforded dark blue plate crystals of [Cu_2(**L**)$_4$(DMF)$_2$] over several weeks, yield 52 mg (30.4%). ESR in DMF solution: a_N = 0.77 mT (2N) at g = 2.007; IR (KBr): ν_{max}/cm^{-1} 1659s, 1611s, 1559m, 1507m, 1394m, 1368m, 1336m, 1133m, 871w, 830, 474w, 437w; λ_{max}/nm (ε/M^{-1} cm^{-1}) (DMF) 286 (36 000), 362 (19 500), 615 (3300). *Anal.* Calc. for $C_{54}H_{74}N_{14}O_{14}Cu_2$: C, 50.69; H, 5.78; N, 15.35. Found: C, 51.06; H, 5.87; N, 15.44%.

2.3. Preparation of trans-[$PdCl_2$(**HL**)$_2$] (**2**)

To a solution of 18-crown-6 ether (84.7 mg, 0.32 mmol) in 2 ml of dichloromethane:methanol (1:1 v/v) solution

was added potassium tetrachloropalladate(II) (26.1 mg, 0.080 mmol). After stirring for 10 min, a methanol solution (2 ml) of **HL** (40.1 mg, 0.16 mmol) was added dropwise. Slow evaporation of the solution afforded deep blue needle crystals of *trans*-[$PdCl_2$(**HL**)$_2$] in a week, yield 41.7 mg (77%). ESR in DMF solution: $a_N = 0.78$ mT (2N) at $g = 2.008$; IR (KBr): ν_{max}/cm^{-1} 1655s, 1613s, 1425m, 1386m, 1371s, 1307m, 1216m, 1134s, 834m, and 543m; λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$) (DMF) 289 (35 000), 312sh (21 500), 365 (10 400), 620 (1460), 672 (1200). *Anal.* Calc. for $C_{24}H_{32}Cl_2N_2O_6Pd$: C, 42.52; H, 4.76; N, 12.40. Found: C, 41.76; H, 4.89; N, 11.63%.

3. Results and discussion

3.1. Preparation and crystal structures

Complexes **1** and **2** were prepared by reactions of deprotonated $\mathbf{L}^-$ with copper(II) nitrate and **HL** with potassium tetrachloropalladate(II), respectively. Complex **1** was found to be a dinuclear paddle-wheel copper complex with deprotonated pyridonate ligands, while **2** was a mononuclear palladium complex with neutral ligands. We also attempted preparation of dinuclear palladium(II) complexes with $\mathbf{L}^-$, but crystalline materials were unobtainable for the reaction.

The structure of **1** in the crystal is shown in Fig. 1. The copper atoms are penta-coordinated to form a square-pyramidal coordination geometry. Four pyridonate ligands are coordinated to the copper atoms as bridging ligands in the equatorial planes and two DMF molecules are ligated at axial positions. This complex has a crystallographic inversion center, and orientation of the four pyridonate ligands confers approximate C_{2h} symmetry upon the complex. The Cu–Cu distance of 2.602(1) Å is slightly longer than those for typical dinuclear copper(II) complexes [2b]. Within the ligands, the pyridonate plane and the nitronyl nitroxide plane are twisted by 20.3° and 37.0° for the two crystallographically independent ligands. The radical moieties are intermolecularly well-separated from each other: the shortest intermolecular distance between the neighboring nitronyl nitroxide groups is 4.29 Å.

Fig. 2(a) shows the molecular structure of **2** in the crystal. The complex has a centrosymmetric structure; the palladium ion is located on the inversion center and coordinated with two **HL** ligands and two chlorine atoms in *trans* positions, exhibiting a square planar coordination geometry. Interestingly, the ligand is in a 2-hydroxypyridine form, in which the nitrogen atoms are coordinated to the metal ion and the phenolic group is hydrogen-bonded to the chlorine atom of the adjacent unit. The hydroxypyridine ring of the ligand is almost perpendicular to the coordination plane of the palladium ion, with the dihedral angle of 91.1(2)°. The dihedral angle between the nitronyl nitroxide plane and the hydroxypyridine ring is 20.7(5)°. Fig. 2(b) shows the packing diagram of the complex. One chlorine atom

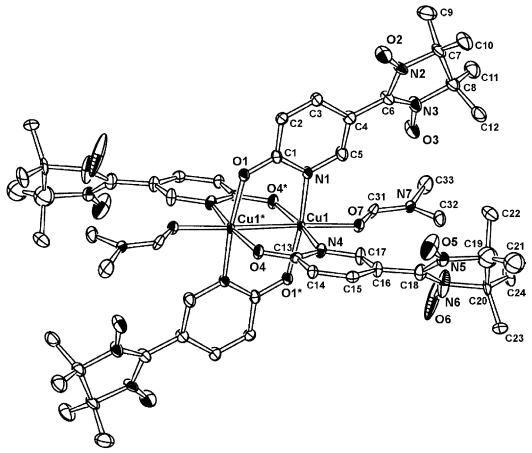

Fig. 1. ORTEP [20] drawing of the molecular structure of **1** showing 50% probability ellipsoids. One of the dimethylethylene groups of the nitronyl nitroxide is disordered over two sites. For clarity, only one moiety is shown.

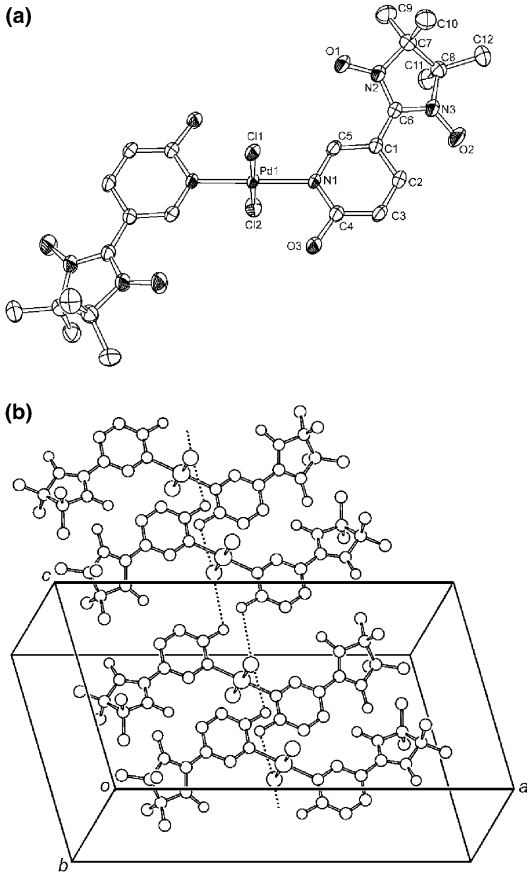

Fig. 2. (a) ORTEP drawing of the molecular structure of **2**, showing 50% probability ellipsoids. (b) Packing diagram of **2**. Hydrogen atoms are omitted for clarity. The dashed lines represents the hydrogen bond along the *c*-axis (O–H···Cl: 3.11 Å).

[Cl(1)] of the complex is hydrogen-bonded by the phenolic groups of two neighboring molecules (–O–H···Cl···H–O–) to form a double-chain hydrogen-bonded network along the *c*-axis, whereas the other chlorine atom Cl(2) is free. The hydrogen-bond distance (O–H···Cl: 3.11 Å) is comparable to those observed in NH···Cl type hydrogen bonds (3.10–3.15 Å) [15]. Several short intermolecular distances exist between the neighboring NO-groups, which are ca. 3.9–4.0 Å.

It has been reported that mononuclear palladium(II) or platinum(II) complexes with pyridone analogues or nucleobases ligands bind metal ions upon deprotonation, producing dinuclear and polynuclear metal complexes [16]. We found that the addition of barium hydroxide to **2** in water exhibit a slight broadening of the ESR spectra, without decomposition, possibly indicating the barium ion binding. Such a radical complex as **2**, bearing additional coordination sites, will be potentially useful for chemical sensing purposes, and useful as a building block for polynuclear metal complexes with radical ligands.

3.2. Magnetic properties

Magnetic susceptibility data for **1** and **2** are shown in Fig. 3 in the form of a χT versus T plot. The room temperature value of χT for **1**, 1.88 emu K mol^{-1}, is markedly smaller than the expected value for an uncorrelated six $S = 1/2$ spin system (2.25 emu K mol^{-1}). The lower value of χT results from the cancellation of the moderately strong antiferromagnetic interaction between the dimeric copper atoms. The χT values decrease steadily with decreasing temperature, then drop rapidly below 10 K. The magnetic susceptibility data were analyzed on the basis of a model consisting of the singlet–triplet term ($\boldsymbol{H} = -2J_{ST}\boldsymbol{S}_a \cdot \boldsymbol{S}_b$) for the dinuclear copper unit and the Curie–Weiss term for the radical spins (Eq. (1)). In that equation, J_{ST} is the exchange coupling of the intramolecular Cu–Cu interaction, n (=4) is the number of organic radicals per dimer, and θ is the intermolecular interaction [16]. The best result was obtained with the parameters $g_{Cu} = 2.2$, $g_{rad} = 2.0$ (fixed), $J_{ST}/k_B = -235$ K, and $\theta = -2.2$ K.

$$\chi = \frac{2Ng_{Cu}^2\mu_B^2}{k_BT[3+\exp(-2J_{ST}/k_BT)]} + n\left[\frac{2Ng_{rad}^2\mu_B^2S(S+1)}{3k_B(T-\theta)}\right] \quad (1)$$

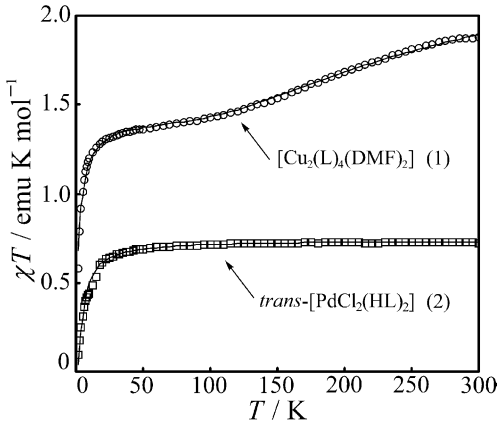

Fig. 3. Plots of χT vs. T for crystalline samples of **1** and **2**. The solid curve corresponds to the data that were fit using the parameters given in the text.

Density functional theory (DFT) calculations of the optimized, i.e., planar, geometry of **L** reveal a small spin density delocalized on the phenolic oxygen, which may engender a metal–radical exchange interaction. However, the magnetic behavior of **1** was analyzed without assuming any such magnetic interactions between the ligands and the metal ions; the interactions are too small to be determined precisely, if at all. This situation is similar to those found in dinuclear copper(II) acetates involving nitroxide pendants [17].

On the other hand, the χT value for **2** at room temperature, 0.74 emu K mol^{-1}, is close to the theoretical one calculated for two $S = 1/2$ non-interacting spins. The χT value showed a rapid decrease below ca. 20 K, suggesting the presence of a marked antiferromagnetic interaction. The magnetic susceptibility was analyzed on the basis of a singlet–triplet model. The parameters of best fit were $g = 1.99$, $J/k_B = -2.78$ K, and $\theta = -2.79$ K. Antiferromagnetic intramolecular interaction may be explained by superexchange through the metal ion; as demonstrated crystallographically, the coordination plane around the metal ion and the hydroxypyridine moiety of the ligand are almost perpendicular to each other, thereby causing the overlap of the 2pπ orbital of the nitrogen atom of the ligand and the d_{xy} orbital of the metal ion [18]. This can be the antiferromagnetic interaction pathway, but the interaction magnitude is small because of the small spin density on the nitrogen.

Previously, we reported the preparation and magnetic properties of a mononuclear platinum(II) complex with pyridyl nitronyl nitroxide radicals, *trans*-[Pt(NH$_3$)$_2$(NITpPy)$_2$](NO$_3$)$_2$ [19]. This complex, which is structurally relevant to **2**, exhibits a Curie–Weiss-like magnetic behavior with only a small antiferromagnetic interaction ($\theta = -1.4$ K). However, **2** exhibited a larger antiferromagnetic interaction that is considered to be intramolecular, as shown above, despite the identical configuration of metal–radical interactions. This is ascribable to the larger spin density on the nitrogen atom of **HL** than that of NITpPy as well as the difference of metal species.

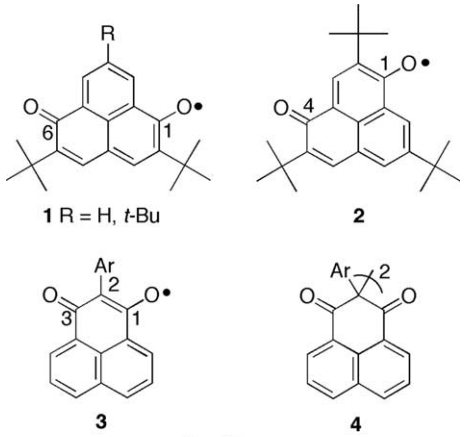
4. Concluding remarks

This study demonstrated that the pyridone-based radical **HL** is useful as a ligand for metal complexes carrying radical moieties. In particular, the dinuclear

complex **1** represents a fundamental polynuclear complex with the open-shell pyridonate ligand. Furthermore, a mononuclear complex like **2** is potentially useful for stepwise construction of polynuclear complexes. Application of the pyridone chemistry to molecular magnetism may allow access to multifunctional compounds of further interest. In addition, construction of complexes involving larger numbers of metals with open-shell pyridone ligands is progressing in our laboratory.

5. Supplementary materials

Crystallographic data for structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 191965 and 250331, respectively, for compounds **1** and **2**. Copies of this information may be obtained from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1133 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).



Acknowledgments

This work was supported financially by a Grant-in-Aid for Scientific Research (No. 12740387) from JSPS. We thank PRESTO, JST for the loan of experimental equipment. We thank Dr. Ryo Horikoshi for elemental analyses. This work was carried out under the Visiting Researcher's Program of the Institute for Solid State Physics, the University of Tokyo.

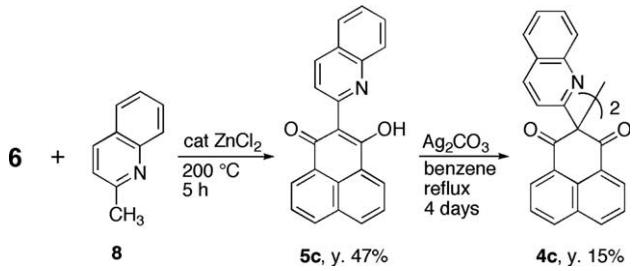
carbon–carbon bond formation at 2-positions [4g]. ESR studies on **3a**, **b** generated by thermal bond cleavage of the dimer **4a**, **b** in a solution state revealed that π-spin density dominantly exists at 2-position and two oxygen atoms, although an appreciable amount of π-spin density is delocalized into 2-aryl groups. In this paper, we discuss a degree of π-spin density delocalization on the phenalenyl skeletons of **3a**–**c** in terms of the dimer structure of **4b** determined by X-ray crystal structure analysis and by variable temperature ^{1}H NMR studies as well as density functional theory calculations of radicals **3a**–**c**.



2. Results and discussion

2.1. Synthesis of dimeric compounds *4a*–*c* from 2-aryl-3-hydroxyphenalenone derivatives

2-Aryl-3-hydroxyphenalenone derivatives **5a**, **b** [7] and **5c** [7b] were respectively prepared in 38%, 21% and 47% yields by the condensation reaction of 1,8-naphthalic anhydride **6** with phenylacetic acid derivatives **7a**, **b** and 2-methylquinoline **8** by the same procedure described in the literature (Schemes 1 and 2). Treatment of **5a**, **b** with an excess amount of oxidants such as PbO_2, Ag_2CO_3 and $K_3[Fe(CN)_6]$–KOH aqueous solution in benzene gave corresponding dimers **4a** [8], **4b** in 67% and 53% yields, respectively. Oxidation of **5c** with an excess amount of Ag_2CO_3 in benzene at 80 °C also gave a dimeric compound **4c** in 15% yield. The structures of **4a**–**c** were determined unambiguously by ^{1}H and ^{13}C NMR, IR, mass spectra and elemental analyses.

Scheme 1.

Scheme 2.

2.2. X-ray crystal structure analysis of *4b*

Single crystals of the dimeric compound **4b** suitable for X-ray crystallographic analysis were obtained by recrystallization from benzene–hexane solution at 4 °C.[1] The crystal contains two benzene molecule as crystal solvent per one **4b** molecule. ORTEP drawing of **4b** shows that a carbon–carbon bond is formed between the 2-positions, which agrees with the results of NMR measurements (vide infra) (Fig. 1). The central C2–C2′ distance (1.579 Å) is longer than the average value of C(sp^3)–C(sp^3) distance (1.53 Å) [9].

[1] Crystal data for **4b**·$(C_6H_6)_2$: $C_{52}H_{38}O_6$, M_r = 758.87, crystal dimensions $0.60 \times 0.60 \times 0.20$ mm^3, monoclinic, space group *C*2/*c* (no. 15), a = 19.010(1), b = 10.2227(7), c = 21.139(2) Å, β = 102.507(1)°, V = 4010.3(5) Å^3, Z = 4, $\rho_{calc.}$ = 1.257 g cm^{-3}, μ = 0.81 cm^{-1}, $2\theta_{max}$ = 55.0°, λ(Mo Kα) = 0.71070 Å, ω scan mode, T = 200 K, 27 129 reflections, of which 4578 were unique and 2557 were included in the refinement [$I > 3.0\sigma(I)$], data corrected for Lorentzian and polarization effects; solution by direct methods (SIR92) and refinement on $|F^2|$ by full-matrix least-squares procedures, 262 parameters, the non-H atoms were refined anisotropically, H atoms were included but not refined, final values R_1 = 0.047, wR_2 = 0.113, GOF = 1.54, maximum positive and negative peaks in ΔF map were ρ_{max} = 0.24 e Å^{-3} and ρ_{min} = −0.21 e Å^{-3}. CCDC-258206 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB21EZ, UK; fax: +44 1223 336 033; or deposit@ccdc.cam.ac.uk).

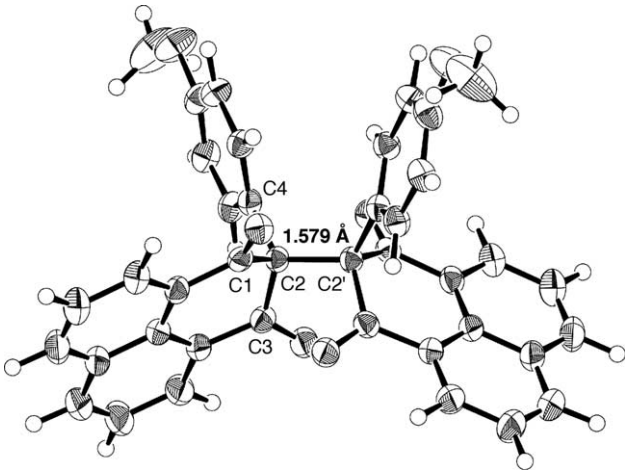


Fig. 1. ORTEP drawing of **4b** · $2C_6H_6$, showing representative atom numbering and bond length.

2.3. Variable temperature ^1H NMR of *4b*

The ^1H NMR spectra in $CDCl_3$ and DMSO-d_6 solutions of **4b** exhibit significant lineshape change in the wide temperature range of −43 to +119 °C, reflecting the occurrence of two types of rate processes (Fig. 2).

The spectrum in $CDCl_3$ at −43 °C, the lowest temperature examined, affords ABCD-type and ABC-DEF-type signals for the aromatic protons of the *p*-methoxyphenyl and the naphthalene moieties, respectively, indicating that two edges of the *p*-methoxyphenyl group as well as those of the naphthalene moiety are magnetically nonequivalent (Figs. 2(a) and (c)). These features show that the compound **4b** adopts in solution a similar conformation as observed in the crystalline state by X-ray crystallography and that internal rotation of both the central C2–C2′ bond and the *p*-methoxyphenyl–C(sp^3) bond is restricted on the NMR timescale.

Upon elevating the temperature, the *p*-methoxyphenyl proton signals broaden and coalesce around room temperature reflecting the increase in the rotation rates of the *p*-methoxyphenyl group. Lineshape analysis [10] of the signals at nine temperatures between −13 and 55 °C in $CDCl_3$ afforded the rate constants of the process at each temperature and the least-square analysis of the Eyring plots gave the following kinetic parameters: $\Delta H^{\ddagger} = 13.3 \pm 0.3$ kcal mol^{-1}, $\Delta S^{\ddagger} = -2.4 \pm 0.9$ cal mol^{-1} K^{-1}, $\Delta G^{\ddagger}(300\ \mathrm{K}) = 14.0$ kcal mol^{-1} (Fig. 2(b)).

At higher temperatures broadening and coalescence of the proton signals due to the naphthalene moiety take place reflecting the occurrence of the interconversion between a chiral conformation due to the central C2–C2′ bond and its enantiomer (Fig. 2(c)). Lineshape analysis of the signals at five temperatures between 83 and 119 °C in DMSO-d_6 and the least-square analysis of the Eyring plots gave the following kinetic parameters: $\Delta H^{\ddagger} = 20.2 \pm 0.6$ kcal mol^{-1}, $\Delta S^{\ddagger} = 2.1 \pm 1.5$ cal mol^{-1} K^{-1}, $\Delta G^{\ddagger}(300\ \mathrm{K}) = 19.6$ kcal mol^{-1} (Fig. 2(d)).

The results of these NMR studies demonstrate that the dimer **4b** possesses a sterically hindered structure.

2.4. DFT calculations of spin density distributions of 3-oxophenalenoxyl derivatives *3a–c*

Spin density distributions of the neutral radicals **3a–c** were calculated by GAUSSIAN 03 at the UBLYP/6-31G(d,p) level of theory (Fig. 3). In **3a** and **3b**, spin

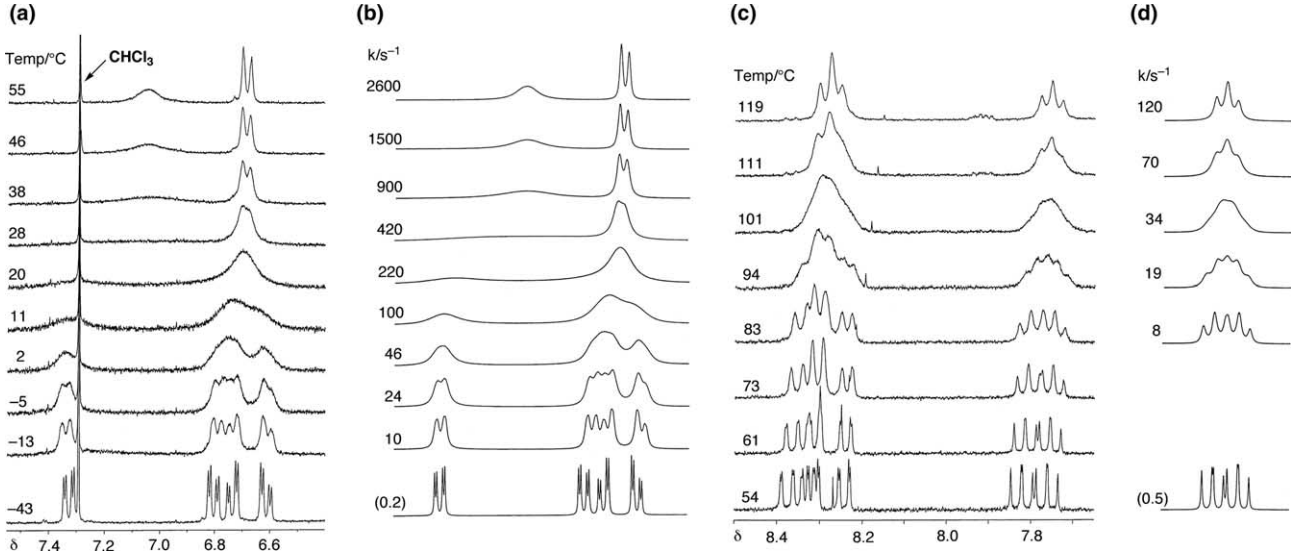

Fig. 2. (a) The observed ^1H NMR spectra in a $CDCl_3$ solution of the *p*-methoxyphenyl region and (c) in a DMSO-d_6 solution of the naphthalene region; (b) and (d) calculated spectra with the best-fit rate constants.

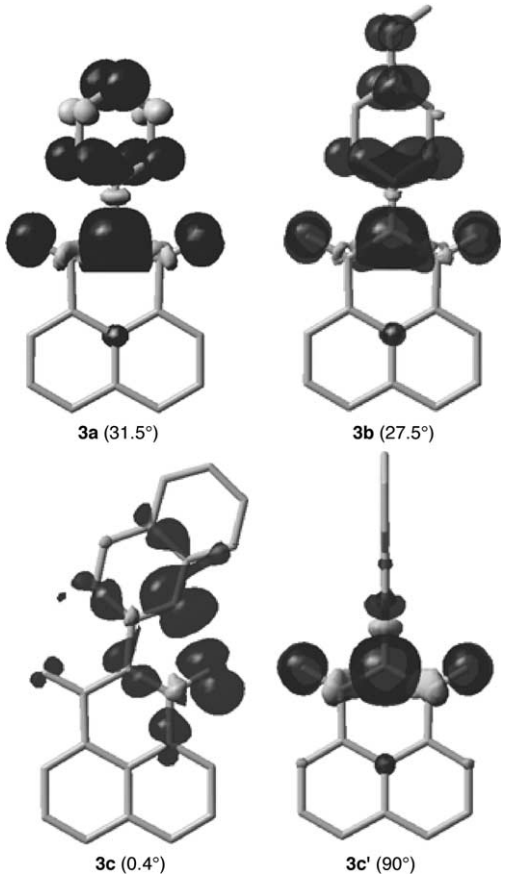

Fig. 3. Spin density distributions for 3-oxophenalenoxyl derivatives with 2-phenyl (**3a**), 2-(*p*-methoxyphenyl) (**3b**) and 2-quinolyl (**3c** and **c′**) calculated at UBLYP/6-31G(d,p) level. Values in parentheses are the torsion angles between aryl moieties and 3-oxophenalenoxyl moieties. Black and gray colors denote positive and negative spin densities, respectively.

densities are dominantly distributed on 2-position, two oxygen atoms and 2-aryl groups, and π-spin delocalization into the whole phenalenyl skeleton is small. These results were in agreement with our previous ESR studies [4g]. In 2-quinolyl derivative **3c**, the calculated spin density distribution shows remarkable difference according to the torsion angle between the quinolyl moiety and 3-oxophenalenoxyl moiety (Fig. 3. **3c**, **3c′**).[2]

3. Conclusion

We synthesized the dimeric compounds **4a**–**c** of 2-aryl-3-oxophenalenoxyl derivatives **3a**–**c** by a carbon–carbon bond formation at 2-positions. The X-ray crystal structure analysis and the variable temperature ^{1}H NMR studies revealed that sterically hindered structure of dimer **4b**. DFT calculations of the radicals **3a**–**c** indicate that π-spin densities dominantly exist at 2-position and the oxygen atoms, although an appreciable amount of them is delocalized into the 2-aryl moieties. These results indicate that the lower stability of 2-aryl-3-oxophenalenoxyl than 4- and 6-oxophenalenoxyl derivatives is ascribable to the smaller spin delocalization into the whole phenalenyl skeleton than that of 6- and 4-oxophenalenoxyl radicals. These studies provide important design criteria for the stable neutral radicals based on phenalenyl system, contributing to the realization of new magnetic materials.

[2] The difference between total energies of two optimized geometries **3c** and **3c′** calculated at UBLYP/6-31G(d,p) level of theory is only 5.98 kcal mol^{-1}.

4. Experimental

4.1. General

4.1.1. General

^{1}H NMR spectra were recorded at 270 and 300 MHz with $CDCl_3$ or DMSO-d_6 as solvent and Me_4Si or residual solvent as an internal standard. Infrared spectra were recorded using KBr plates. 3-nitrobenzyl alcohol was used as matrix for FAB-MS spectra. Elemental analyses were performed at Graduate School of Science in Osaka University and Institute for Molecular Science in Okazaki National Research Institute. X-ray data of **4b** were collected on Rigaku/MSC Mercury CCD with graphite monochromated Mo Kα (λ = 0.71070 Å) radiation at −78 °C. Silica gel 60 (100–200 mesh) was used for column chromatography. Benzene was dried over CaH_2 and distilled under argon prior to use. 2-Phenyl-3-hydroxyphenalenone (**5a**) [7], 2-(*p*-methoxyphenyl)-3-hydroxyphenalenone (**5b**) [7], 2-quinolyl-3-hydroxyphenalenone (**5c**) [7b] and active PbO_2 [11] were prepared and purified by the same procedure described in the literatures.

4.1.2. Typical oxidation procedure

2-Phenyl-3-hydroxyphenalenone (**5a**) (33.5 mg, 123 μmol) was dissolved with benzene (50 mL) under argon atmosphere. To this solution was added an excess amount of PbO_2 and stirred at room temperature under argon atmosphere overnight. The reaction mixture was filtered. The resulting filtrates were concentrated under reduced pressure, and then subjected to silica gel column chromatography.

4.1.3. 2,2-Bis(2-phenyl-2,3-dihydro-3-oxophenalendione) (4a)

Colorless powder; ^{1}H NMR ($CDCl_3$, −50 °C) δ 8.43 (dd, J = 7.3 and 1.1 Hz, 2), 8.41 (dd, J = 7.3 and 1.1 Hz, 2), 8.18 (dd, J = 8.3 and 1.1 Hz, 2), 8.12 (dd, J = 8.3 and 1.1 Hz, 2), 7.72 (dd, J = 8.3 and 7.3 Hz, 2), 7.66 (dd, J = 8.3 and 7.3 Hz, 2), 7.43 (m, 2), 7.28 (m, 4), 7.14 (m, 2), 6.84 (m, 2); ^{13}C NMR (CD_2Cl_2, rt) δ 199.31

Colorless powder; ^1H NMR ($CDCl_3$, rt) δ 8.52 (dd, J = 7.3 and 1.0 Hz, 2), 8.35 (dd, J = 7.3 and 1.0 Hz, 2), 8.08–7.97 (m, 3), 7.87 (d, J = 6.5 Hz, 1), 7.73–7.65 (m, 2), 7.59–7.52 (m, 2), 7.47–7.42 (m, 2); ^{13}C NMR ($CDCl_3$, rt) δ 198.45 (C), 191.41 (C), 155.49 (C), 147.17 (C), 134.86 (CH), 133.96 (CH), 133.49 (CH), 132.68 (C), 129.95 (CH), 129.92 (CH), 129.14 (CH), 128.95 (CH), 127.49 (C), 127.26 (CH), 126.83 (CH), 126.52 (CH), 126.23 (CH), 123.09 (CH); IR (KBr) 1652 cm^{-1}; HRMS-FAB (*m/z*). *Anal*. Calc. for $C_{44}H_{25}O_4N_2$ (M^+ + H): 645.17893. Found: 645.17893.

4.1.6. Valiable temperature NMR

Variable temperature NMR experiments were performed on a Bruker ARX-300 spectrometer operating at 300 MHz. Temperatures were calibrated with a methanol sample or an ethylene glycol sample and are reliable to ±1 °C. Total lineshape analysis was performed by visual matching of experimental spectra with theoretical ones computed on an NEC PC9821Xs personal computer equipped with a Mutoh PP-210 plotter using the DNMR3K program, a modified version of the DNMR3 program [9] converted for use on a personal computer by Dr. Hiroshi Kihara. Temperature dependence of chemical shift differences and T_2 values were properly taken into account.

Scheme 1.

an iminonitroxide derivative **3** with corannulene. In this study, we have shown the π-spin delocalization onto the curved surface π-system of corannulene moiety in terms of ESR/ENDOR/TRIPLE, UV–Vis measurements and density functional theory (DFT) calculations.

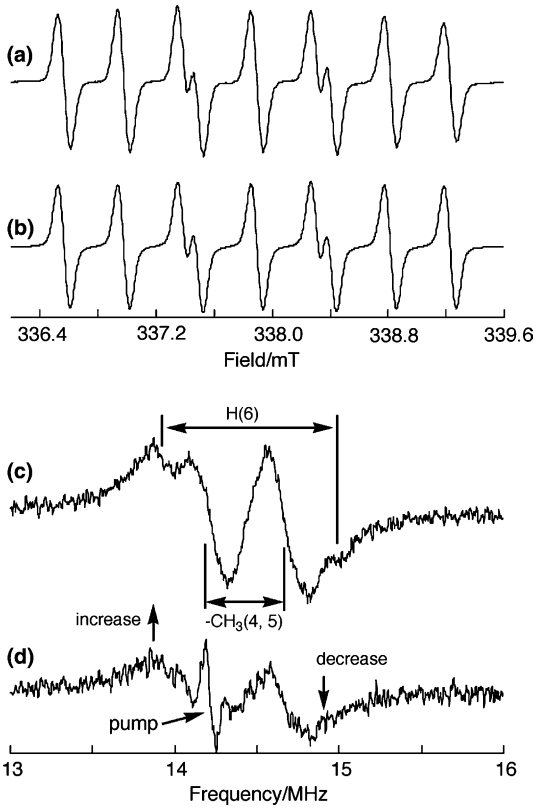

Fig. 1. (a) Observed hyperfine ESR spectrum at 290 K (microwave frequency: 9.493725 GHz) and (b) the corresponding simulated spectrum, (c) ENDOR and (d) TRIPLE (pump frequency: 14.2 MHz) spectra at 270 K for **3** in toluene (3.4×10^{-4} M).

2. Results and discussion

*2.1. Synthesis of iminonitroxide derivative **3** with corannulene*

Radical **3** was synthesized from formylcorannulene **4**[1] in two steps (Scheme 1). The radical precursor **5** was prepared by condensation of **4** with 2,3-bis(hydroxyamino)-2,3-dimethylbutane in toluene at 80 °C. Oxidation of **5** with active PbO_2 in the presence of K_2CO_3 in toluene gave the neutral radical **3** as a vivid red powder. In the solid state, most of the radical **3** remains unchanged in air for a long period of time. The radical is also stable in a toluene solution in the presence of air for a few weeks, indicating that **3** possesses a higher stability than the oxoverdazyl derivative **1** [7].

*2.2. ESR/ENDOR/TRIPLE measurements of the radical **3***

ESR spectrum of radical **3** in degassed toluene solution (3.4×10^{-4} M) at 290 K shows hyperfine splitting arising mainly from the nitrogen atoms of the iminonitroxide moiety (Fig. 1(a)). ENDOR spectroscopy (Fig. 1(c)) at 270 K shows two pairs of splittings attributed to methyl protons on the iminonitroxide and methyne proton on the corannulene skeleton. The relative signs of the hyperfine coupling constants (hfccs) of the two types of protons were determined by TRIPLE spectroscopy (Fig. 1(d)). The spectral simulation (Fig. 1(b)) was satisfactory on the basis of the set of hfccs due to protons obtained by ENDOR spectroscopy and due to two nitrogen atoms. The protons and nitrogens of **3** were assigned in terms of the spin density distribution calculated by the DFT method using the optimized structure[2] [8] (Fig. 2(b) and Table 1). Both the experiment and theoretical calculation show that the degree of π-spin delocalization on the 6-position of **3** from the radical substituent is smaller than that on the corresponding position of the oxoverdazyl derivative **1** [7].

[1] Synthesis of formylcorannulene **4** was carried out by standard procedure; see [7].

[2] In calculation, the spin density at 6-position of **3** is highly affected by the torsion angle between the corannulene moiety and the iminonitroxide moiety. The torsion angle is 10° in the optimized structure calculated at UB3LYP/6-31G level of theory.

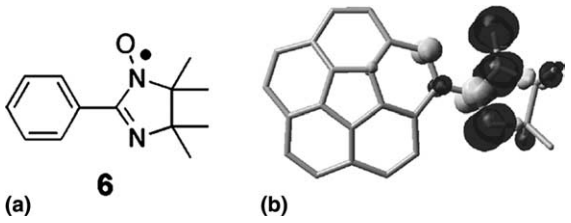

Fig. 2. (a) Molecular structure of **6** and (b) spin density distribution of **3** calculated at UB3LYP/6-31G(d)//UB3LYP/6-31G level. Black and gray colors denote positive and negative spin densities, respectively.

Table 1
Observed and calculated hfccs of proton and nitrogens, and observed *g*-value for **3**

a/mT				*g*-value
$-CH_3$(4, 5)	H(6)	N(1)	N(3)	
−0.011[a]	+0.037[a]	±0.902[b]	±0.413[b]	2.0063
−0.009[c,d]	+0.126[c]	+0.986[c]	+0.667[c]	

[a] The hfccs and the relative signs were determined by ENDOR/TRIPLE spectra in a toluene solution at 270 K.
[b] The hfccs were determined by ESR spectrum in a toluene solution at 290 K and spectral simulation.
[c] These hfccs were calculated for **3** at UB3LYP/6-31G(d)//UB3LYP/6-31G level of theory.
[d] The hfcc of methyl protons were averaged value.

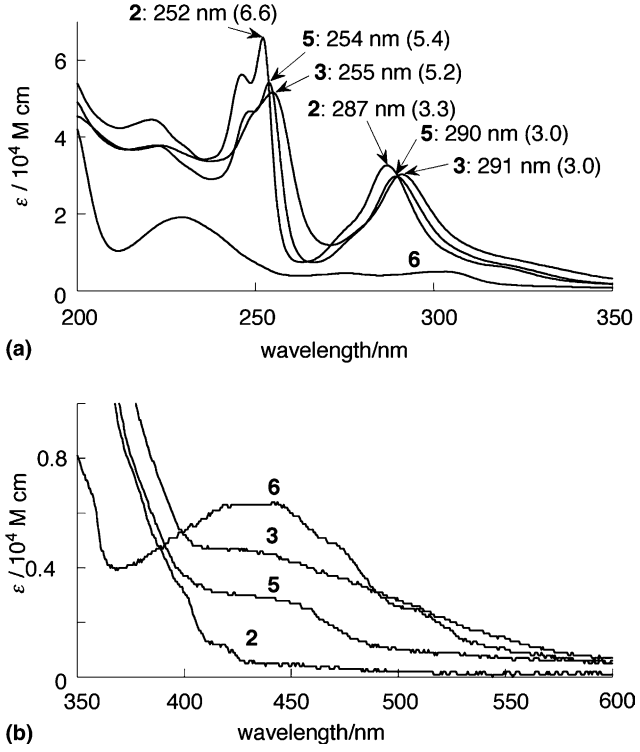

Fig. 3. UV–Vis spectra of **2**, **3**, **5** and **6** in CH_3CN solution (1.0×10^{-5} M). (a) 200–350 nm region and (b) 350–600 nm region. The values in the parentheses of (a) are $\varepsilon/10^4$. The ordinate scale of (b) is magnified seven times than that of (a).

2.3. UV–Vis spectra for 2, 3, 5 and 6

In order to obtain further information on the π-conjugation between the corannulene moiety and the iminonitroxide moiety, we have measured UV–Vis spectra for **2** [9], **3**, **5** and **6** [10] in CH_3CN at room temperature (1.0×10^{-5} M, Fig. 3). The absorption attributed to the iminonitroxide moiety of **3** was observed as a broad band between 400 and 550 nm (Fig. 3(b)). The absorption due to the corannulene moiety of **3** (255 and 291 nm) is broadened compared with **2** and **5**, which shows a similar behavior to the oxoverdazyl derivative **1** [7]. Because the peak maxima for **3** (255 and 291 nm) shift by only 1–4 nm relative to the corresponding peaks for **2** (252 and 287 nm) in the region of 220–350 nm (Fig. 3(a)), it has turned out that the π-conjugation between the corannulene moiety and the iminonitroxide moiety of **3** is weak in the ground state.

3. Conclusion

We have designed and synthesized the iminonitroxide derivative **3** with corannulene as a novel bowl-shaped neutral radical having high stability in air. Our ESR/ENDOR/TRIPLE measurements and DFT calculations have shown that most of the π-spin density is localized on the iminonitroxide moiety, and π-spin delocalization onto the corannulene moiety is smaller than that of the oxoverdazyl derivative **1**. These results are in accord with the UV–Vis spectra, indicating that the π-conjugation between the corannulene moiety and the iminonitroxide moiety of **3** is weak in the ground state.

We believe that high stability of **3** serves as a model to elucidate intermolecular spin–spin interaction in the solid state and investigation of intramolecular spin alignment of the iminonitroxide moiety with a photoexcited triplet state of the corannulene moiety [11,12]. In order to realize a strong intermolecular spin–spin interactions on curved surface π-system in the ground state, design and synthesis of a new bowl-shaped stable neutral radical with a large π-spin delocalization onto the corannulene moiety are now in progress [13].

4. Experimental

4.1. General

^{1}H NMR spectra were recorded at 270 MHz with $CDCl_3$ as solvent and Me_4Si or residual solvent as an internal standard. Infrared spectra were recorded using KBr plates. UV–Vis spectra were recorded in CH_3CN solutions. EI-MS spectra were recorded at 70 eV. Melting points were measured with a hot-stage apparatus and are uncorrected. The liquid-phase ESR, ENDOR,

and TRIPLE spectra were recorded on Bruker ESR/ENDOR spectrometers ESP300/350. R_f values on TLC were recorded on E. Merck precoated (0.25 mm) silica gel 60 F_{254} plates. The plates were sprayed with a solution of 10% phosphomolybdic acid in 95% EtOH and then heated until the spots became clearly visible. Silica gel 60 (100–200 mesh) was used for column chromatography. Toluene was dried over CaH_2 and distilled under argon prior to use. Active PbO_2 [14] was prepared and purified by the same procedure described in the literature. Formylcorannulene **4** [7] and phenyl substituted iminonitroxide derivative **6** [15] were synthesized from corannulene **2** [16] and 2-phenyl-4,4,5,5-tetramethyl-4,5-dihydro-*1H*-imidazol-1-oxyl-3-oxide (phenyl substituted nitronyl nitroxide) [17] according to the literature procedures, respectively. All reactions requiring anhydrous conditions were conducted under argon atmosphere.

4.2. Synthesis of radical precursor 5

Formylcorannulene **5** (160 mg, 0.58 mmol) was placed in a 100-mL Shlenk tube and dissolved with toluene (16 mL) under argon atmosphere. To the mixture was added 2,3-bis(hydroxylamine)-2,3-dimethylbutane (341 mg, 2.30 mmol) and stirred at 80 °C for 24 h. The reaction mixture was cooled to room temperature, and the resulting solid was filtered. The filtrate was poured into 0.1 M pH 7 phosphate buffer and extracted with ethyl acetate (20 mL × 3). The organic extracts were combined and washed with water (50 mL × 2). The organic layer was separated and dried over Na_2SO_4, then filtered and concentrated under reduced pressure, to give crude product as a strong reddish yellow solid. The residue was subjected to silica gel column chromatography with hexane and ethyl acetate (2:1), ethyl acetate and ethyl acetate and EtOH (1:1) as eluant, to give **5** (49%, 111 mg) as a pale yellow powder. M.p. 203–204 °C (dec); TLC R_f 0.54 (ethyl acetate); ^{1}H NMR (500 MHz, $CDCl_3$) δ 1.22 (s, 1), 1.22 (s, 1), 1.31(s, 6), 4.70 (br s, 1), 7.75–7.84 (m, 7), 8.21 (s, 1), 8.22 (s, 1); IR (KBr) 3126, 2973, 2855 cm^{-1}; UV (CH_3CN) λ_{max}, nm (ε): 222 (3.8×10^4), 254 (5.4×10^4), 290 (3.0×10^4); EI-MS, *m/z* 390 (M^+, 2%), 374 (M^+–O, 6%), 276 (M^+–$C_6H_{11}NO$, 38%).

4.3. Synthesis of iminonitroxide derivative 3

A radical precursor **5** (20 mg, 0.05 mmol) was placed in a 20-mL Shlenk tube and dissolved with toluene (6 mL) under argon atmosphere. To the mixture were added potassium carbonate (17 mg, 0.12 mmol) and active PbO_2 (49 mg, 0.21 mmol) and stirred at room temperature for 30 min. The resulting solid was filtered through the celite column. The filtrate was concentrated in vacuo. The residue was subjected to silica gel column chromatography with hexane ~5:1 mixture of hexane and ethyl acetate as eluant, to give **3** (67%, 13.3 mg) as a vivid red powder. M.p. 161–162 °C (dec); TLC R_f 0.43 (hexane/ethyl acetate = 2:1); IR (KBr) 2974 cm^{-1}; UV (CH_3CN) λ_{max}, nm (ε): 224 (3.8×10^4), 255 (5.2×10^4), 291(3.0×10^4); EI-MS, *m/z* 390 ($M^+ + H$, 3%), 389 (M^+, 2%).

2. Experimental

2.1. Compounds preparation

All chemicals and solvents were used as received. All preparations and manipulation were performed under aerobic conditions. $[Mn_{12}O_{12}(O_2CCH_3)_{16}(H_2O)_4]\cdot 2HO_2C_2H_3\cdot 4H_2O$ (**3**) $\cdot 2HO_2C_2H_3\cdot 4H_2O$ was prepared as literature [25].

2.1.1. $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]\cdot 4H_2O$ (**1**) $\cdot 4H_2O$

A slurry of complex $\mathbf{3}\cdot 2HO_2C_2H_3\cdot 4H_2O$ (1.005 g, 0.538 mmol) in CH_2Cl_2 (30 mL) was treated with an excess of the HO_2CCF_2Cl (2.106 g, 16.142 mmol). The mixture was stirred for 12 h and filtered to remove any undissolved solid. The resulting filtrate was layered with hexanes (80 mL), stored and left undisturbed overnight. The resultant black crystals were collected by filtration, dissolved in CH_2Cl_2 (30 mL) and the solution was treated with a further amount of HO_2CCF_2Cl and stirred for 12 h. Hexanes (80 mL) was added and the solution was left undisturbed overnight. The black crystals were collected by filtration, dissolved in CH_2Cl_2 (30 mL). The solution was layered with hexanes (80 mL), stored at room temperature for several days and afforded suitable crystals for the X-ray crystal structure analysis. The resultant black crystals were collected by filtration, washed copiously with hexanes and dried in vacuo. The overall yield of **1** was ~80%. Elemental *Anal.* Calc. for $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]$ (**1**), $C_{32}H_8Cl_{16}F_{32}Mn_{12}O_{48}$: C, 12.83; H, 0.27. Found: C, 12.82; H, 0.32%.

2.1.2. $[PPh_4][Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]\cdot 2H_2O\cdot CH_2Cl_2$ (**2**) $\cdot 2H_2O\cdot CH_2Cl_2$

To a stirred dark brown solution of complex $\mathbf{1}\cdot 4H_2O$ (0.992 g, 0.324 mmol) in CH_2Cl_2 (30 mL) was added solid PPh_4I (0.151 g, 0.324 mmol) and stirred for 30 min. The solution was concentrated to remove I_2 and CH_2Cl_2 by evaporation. When almost all the CH_2Cl_2 had been removed, more CH_2Cl_2 (15 mL) was added and removed by evaporation. The addition and removal of CH_2Cl_2 were repeated until no purple color of I_2. The resulting solid was dissolved in CH_2Cl_2/hexanes (30 mL/30 mL) and filtered to remove any undissolved solid. The solution was layered with hexanes (80 mL), stored at room temperature for several days and afforded suitable crystals for the X-ray crystal structure analysis. The resultant black crystals were collected by filtration, washed copiously with hexanes and dried in vacuo. The overall yield of **2** was ~70%. Elemental *Anal.* Calc. for $[PPh_4]$ $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]$ (**2**), $C_{56}H_{28}Cl_{16}F_{32}Mn_{12}O_{48}P$: C, 20.17; H, 0.84. Found: C, 20.15; H, 0.93%.

2.2. X-ray structure analysis

Crystal data of complex $\mathbf{1}\cdot 4H_2O$: $C_{32}H_{16}Cl_{16}F_{32}Mn_{12}O_{52}$, $M = 3066.93$, black block, crystal dimensions $0.40\times 0.22\times 0.16$ mm, tetragonal, space group $I\bar{4}$, $a = b = 18.6838(1)$ Å, $c = 13.3829(5)$ Å, $V = 4671.76(8)$ Å^3, $Z = 2$, $D_{cal} = 2.180$ Mg/m^3, $F(000) = 2968$, μ(Mo Kα) = 2.175 mm^{-1}. Determination of cell constants and data collections were carried out on an Siemens SMART CCD diffractometer using an ω scan mode in the range $1.54° \leqslant \theta \leqslant 27.50°$ with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 150(1) K. A total of 5338 unique reflections were collected. Data were corrected for absorption effects (SADABS). The structure was solved using the direct method in SHELXS86 [26]. Some disorder problems were observed. Some $-CF_2Cl$ groups showed disorder of their Cl and F atoms (Cl13, Cl14, F5, F6 and F7) in two positions, each was 50% occupation. The final refinement with all non-hydrogen atoms anisotropic except disorder Cl and F atoms by full-matrix least-squares on F^2 (SHELXL93 [27]). Refinement converged at $R_1 = 0.0587$ and $wR_2 = 0.1638$ for 4797 unique data [$I > 2\sigma(I)$], goodness-of-fit = 1.184, where $R_1 = \Sigma\|F_o| - |F_c\|/\Sigma|F_o|$; $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$, and weight scheme $w = 1/[\sigma^2(F_o^2) + (0.0945P)^2 + 15.599P]$, where $P = (F_o^2 + 2F_c^2)/3$. Maximum and minimum peaks in the final difference map were 1.216 and −0.807 e Å^{-3}.

Crystal data of complex $\mathbf{2}\cdot 2H_2O\cdot CH_2Cl_2$: $C_{57}H_{34}Cl_{18}F_{32}Mn_{12}O_{50}P$, $M = 3455.19$, black plate, crystal dimensions $0.25\times 0.25\times 0.10$ mm, monoclinic, space group $P2_1/c$, $a = 18.6623(7)$ Å, $b = 13.3626(5)$ Å, $c = 45.4482(17)$ Å, $\beta = 97.204(2)°$, $V = 11244.3(7)$ Å^3, $Z = 4$, $D_{cal} = 2.041$ Mg/m^3, $F(000) = 6740$, μ(Mo Kα) = 1.878 mm^{-1}. Determination of cell constants and data collections were carried out on a Bruker SMART CCD diffractometer fitted with a CCD-type area detector and a full sphere of data was collected by using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 150(1) K. Data were corrected by semi-empirical from equivalents (multi-scan). Total of 83 487 ($0.90° \leqslant \theta \leqslant 27.50°$) reflections were collected, which yielded 25526 ($R_{int} = 0.0567$) independent reflections. The structure was solved using the direct method in SHELXS97 [26]. Some disorder problems were observed. Seven $-CF_2Cl$ groups showed disorder of their Cl and F atoms (Cl4, F7, F8, Cl5, F9, F10, Cl6, F11, F12, Cl7, F12, F13, Cl11, F21, F22, Cl12, F23, F24, Cl16, F31 and F32) in two positions, each was 50% occupation. The final refinement with all non-hydrogen atoms anisotropic except disorder Cl, F and CH_2Cl_2 atoms by full-matrix least-squares on F^2 (SHELXL97 [27]). Refinement converged at $R_1 = 0.1023$ and $wR_2 = 0.2545$ for 15 591 unique data [$I > 2\sigma(I)$], goodness-of-fit = 1.068, where $R_1 = \Sigma\|F_o| - |F_c\|/\Sigma|F_o|$; $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$, and weight

[b] $I > 2\sigma(I)$.
[c] $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2\}$, $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = (F_o^2 + 2F_c^2)/3$.

scheme $w = 1/[\sigma^2(F_o^2) + (0.1174P^2 + 133.0159P)]$ where $P = (F_o^2 + 2F_c^2)/3$. Maximum and minimum peaks in the final difference map were 1.819 and -1.779 e Å^{-3}. Data collection parameters for complexes **1** and **2** are listed in Table 1.

2.3. Magnetic measurements

Direct current (DC) magnetic susceptibility, magnetization hysteresis and magnetization relaxation decay data were measured by an MPMS-7 Quantum Design SQUID magnetometer equipped with a 7.0 T magnet. Variable-temperature DC magnetic susceptibility data of complexes **1** and **2** were collected for polycrystalline samples in an applied field of 1.0 kG, and in the temperature range 2.00–310.0 K. The samples were embedded in eicosane wax to prevent any torquing of the polycrystalline in the magnetic field. Pascal's constants were used to estimate the diamagnetic corrections for each complex and were subtracted from the experimental molar susceptibility data to give the molar susceptibility [28]. For magnetization hysteresis loop measurements, a polycrystalline of complex **1** was suspended in eicosane at 313 K, oriented in a 7.0 T field and then the eicosane matrix was cooled to room temperature. This gives a waxy cube with the crystals aligned with their easy axes of magnetization parallel. The oriented polycrystalline sample of complex **1** was saturated in a field of +3.0 T then swept down to −3.0 T, and cycled back to +3.0 T at different temperatures between 1.8 and 2.8 K by the reciprocating sample option (RSO) measurement. The data were collected in 200 G decrement/increment step in each hysteresis loop. The magnetization relaxation decay data for oriented polycrystalline sample of complex **1** were collected the magnetization versus time after the applied field turned to zero from 3.0 T between 1.8 and 2.8 K. Alternating current (AC) susceptibility measurements were carried out on a Quantum Design PPMS-9 magnetometer equipped with a 9.0 T magnet and were capable of achieving temperatures 1.8–400 K. AC susceptibility data of complexes **1** and **2** were collected for powdered, microcrystalline samples in an AC field of 1.0 Oe, oscillating in the 250–10 000 Hz range.

3. Results and discussion

3.1. Crystal structure of $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]\cdot 4H_2O$ (**1**) $\cdot 4H_2O$ and $[PPh_4][Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]\cdot 2H_2O\cdot CH_2Cl_2$ (**2**) $\cdot 2H_2O\cdot CH_2Cl_2$

The structure of the complex **1** is shown in Fig. 1, and selected bond distances are listed in Table 2. The structure of complex **1** is quite similar in many respects to the previously characterized [Mn_{12}] complexes [14,16,25]. In addition to one-forth of the Mn_{12} complex, the asymmetric unit was found to contain one H_2O solvate molecules. Some –CF_2Cl groups showed disorder of their Cl and F atoms (Cl13, Cl14, F5, F6 and F7) in two positions, each was 50% occupation. Complex **1** is in $\bar{4}$ symmetry which possesses a [$Mn_{12}(\mu_3\text{-}O)_{12}$] core having a central $[Mn_4^{IV}O_4]^{8+}$ cubane held within a non-planar ring of eight Mn^{III} ions by eight μ_3-O^{2-} ions. The eight Mn^{III} ions separate into two groups of four Mn^{III} ions each. In

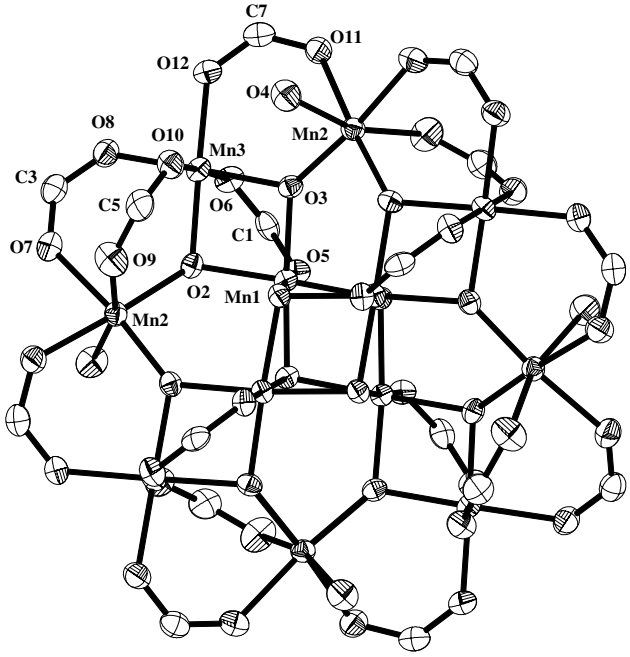

Fig. 1. The X-ray structure of complex **1**. The –CF_2Cl groups of the ligands, and H_2O solvate molecules are omitted for clarity.

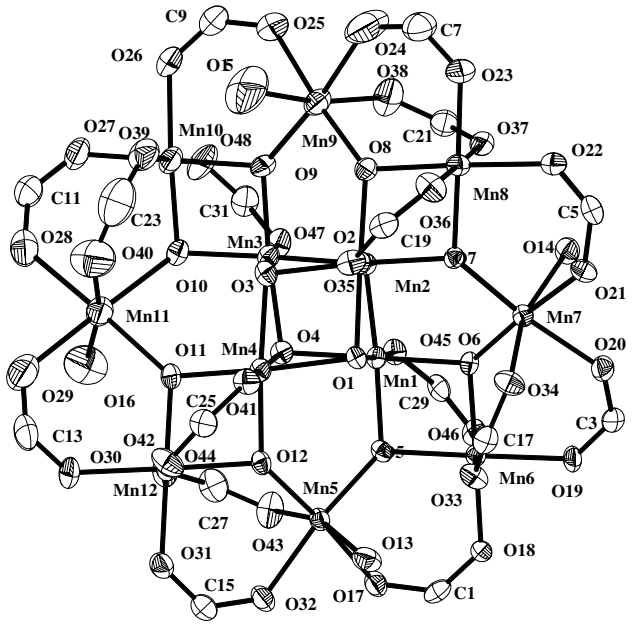

Fig. 2. The X-ray structure of complex **2**. The $-CF_2Cl$ groups of the ligands, PPh_4 ion, and CH_2Cl_2 and H_2O solvate molecules are omitted for clarity.

the first group, each Mn^{III} (Mn3) ion is coordinated to single Mn^{IV} (Mn1) ion via two oxide bridges, while in the second group each Mn^{III} (Mn2) ion is coordinated to two Mn^{IV} (Mn1) via two oxide bridges. Peripheral ligation of complex **1** is proved by 16 η^2-μ_2-carboxylate groups and four H_2O ligands. Complex **1** has one H_2O ligand on each Mn^{III} (Mn2) ion in one set of 4 Mn^{III} ions, which are bonded to two Mn^{IV} ions via two μ_3-O^{2-} ions. The four H_2O ligands of complex **1** are arranged in an alternating up, down, up, down arrangement (1:1:1:1 arrangement), which is quite similar to Mn_{12} acetate complex **3**. The Mn–O bond distances make it clear that all of the atoms in the central cubane are Mn^{IV} ions, while the ring consists of eight Mn^{III} ions. These assignments supported by the marked Jahn–Teller (JT) elongation of the axial Mn^{III}–O bonds (2.144–2.203 AA), which are on average 0.24 Å longer than the analogous equatorial Mn–O bonds (1.881–1.990 Å). The JT distortion in complex **1** appears the mode of an axial elongation of two *trans* bonds and the JT axes are all axially disposed roughly perpendicular to the $Mn_{12}O_{12}$ disk-like core. Consequently, there is a near parallel alignment of the eight Mn^{III} JT axes, which is the origin of the significant magnetic anisotropy that greatly influences the observed magnetic relaxation properties.

An ORTEP plot of complex **2** is shown in Fig. 2, and selected bond distances are given in Table 3. At 150 K, the complex **2** crystallizes in the monoclinic $P2_1/c$ space group with the asymmetric unit consisting of one Mn_{12} molecule, one counter ion PPh_4, two H_2O and one CH_2Cl_2 solvated of crystallization. The anion Mn_{12} moiety is similar to the usual $[Mn_{12}]^-$ complex except that the number and coordination position of water [5,10,14,29,30]. The central cubane $[Mn_4^{IV}O_4]^{7+}$ structure possesses four M^{IV} ions and four μ_3-O^{2-} ions which is held within a non-planar ring of eight Mn^{III}/Mn^{II} ions by eight μ_3-O^{2-} ions. The Mn–O bond distances (1.826–1.967 Å) make it clear that all of Mn atoms in the central cubane are Mn^{IV} ions. These assignments of Mn^{III} ions were supported by the marked Jahn–Teller elongation of the axial Mn–O bonds (2.110–2.235 Å), which are on average 0.247 Å longer than the equatorial Mn–O bonds (1.858–2.043 Å). Fro Mn(11) atom, the equatorial Mn–O bond lengths show a pronounced elongation (2.063–2.135 Å) relative to the equatorial Mn^{III}–O bonds (1.858–2.043 Å). Clearly, the Mn(11) is a Mn^{II} ion, and it does not exhibit a Jahn–Teller distortion as seen for all the Mn^{III} ions in complex **2**. The complex **2** is a valence-tapped $Mn^{II}Mn_7^{III}Mn_4^{IV}$ compound. Peripheral ligation of complex **2** is proved by 16 η^2-μ_3-carboxylate groups and four H_2O ligands. Complex **2** also has a 1:1:1:1 arrangement of H_2O ligands, and the reduction of complex **1** the extra electron is added to Mn(11) without changing the H_2O coordination environment.

In the previous paper on the one-electron reduced Mn_{12} complexes, $[PPh_4][Mn_{12}O_{12}(O_2CEt)_{16}(H_2O)_4]$, $[PPh_4][Mn_{12}O_{12}(O_2CH_2Cl)_{16}(H_2O)_3]$, $[Co(C_5Me_5)_2]$ $[Mn_{12}O_{12}(O_2CC_6F_5)_{16}(H_2O)_4]$, and $[PPh_4][Mn_{12}O_{12}(O_2CC_4H_3\ S)_{16}(H_2O)_2]$, the reduction site was assigned to one of Mn^{III} ions on the basis of the bond valence sum analysis [5,14,29,30]. A bond valence sums is an empirical

value, based on crystallographically determined metal–ligand bond distances, which may be used to calculate the oxidation state of a metal [31]. Bond valence sums(s) are calculated using Eq. (1)

$$S = \exp\left[\frac{r_0 - r}{B}\right], \tag{1}$$

where r is the observed bond length, and r_0 and B are empirically determined parameters. Values for r, are tabulated for Mn^{n+} ($n = 2, 3, 4$).

On the basis of the valence bond sum analysis for complexes **1** and **2** are listed in Table 4. The assignment of +4 oxidation state for Mn(1) and +3 oxidation states for Mn(2) and Mn(3) is reasonable for complex **1**. It is also reasonable to assign the four Mn ions in the central cubane framework [Mn(1)–Mn(4)] as having a +4 oxidation state and the remainder of the Mn ions, except for the Mn(11), as having a +3 oxidation state for

[a] The calculation of a bond valence sums was carried our for each Mn atom, assuming that a Mn atom is either Mn^{II}, Mn^{III}, or Mn^{IV}.

complex **2**. The bond sum value for the Mn(11) ion is closer to 2, indicating a +2 oxidation state. The extra electron is tapped at the Mn(11) ion to form the valence-tapped of $Mn^{II}Mn_7^{III}Mn_4^{IV}$ state in complex **2**. The reduction at a Mn^{III} ion not at a central Mn^{IV} ion is similar to previous results.

3.2. Magnetochemistry

The DC magnetization of **1** and **2** were measured from 2 to 300 K at 1.0 kOe and results are shown in Fig. 3. For complex **1** the value of $\chi_M T$ slowly decreases from 18.3 cm^3 K mol^{-1} at 300.1 K to 16.6 cm^3 K mol^{-1} at 180.1 K, and then increases, reaching a maximum of 47.8 cm^3 K mol^{-1} at 8.0 K, finally decreases to 30.2 cm^3 K mol^{-1} at 2.0 K. The large $\chi_M T$ maximum at low temperature is consistent with $S = 10$ if the g-value equals to 1.86. The data for the one-electron reduced complex **2** show similar temperature dependence; the value of $\chi_M T$ slowly decreases from 20.9 cm^3 K mol^{-1} at 300.1 K to 18.5 cm^3 K mol^{-1} at 170.1 K, and then increases, reaching a maximum of 52.0 cm^3 K mol^{-1} at 7.0 K, finally decreases to 43.1 cm^3 K mol^{-1} at 2.0 K. The large $\chi_M T$ maximum at low temperature is consistent with $S = 21/2$ if the g-value equals to 1.86.

AC magnetic susceptibility studies are an excellent way to detect the slow relaxation of magnetization characteristic of a SMM, which cannot reverse its direction of magnetic moment fast enough to keep in phase with the applied oscillating field while the temperature is lower than its block temperature. The AC susceptibility was obtained for complex **1** in a 1.0 Oe AC field at frequencies (ν) of 250, 500, 750, 1000, 2500, 7500 and 10 000 Hz with a DC field of zero. In Fig. 4(a) are shown

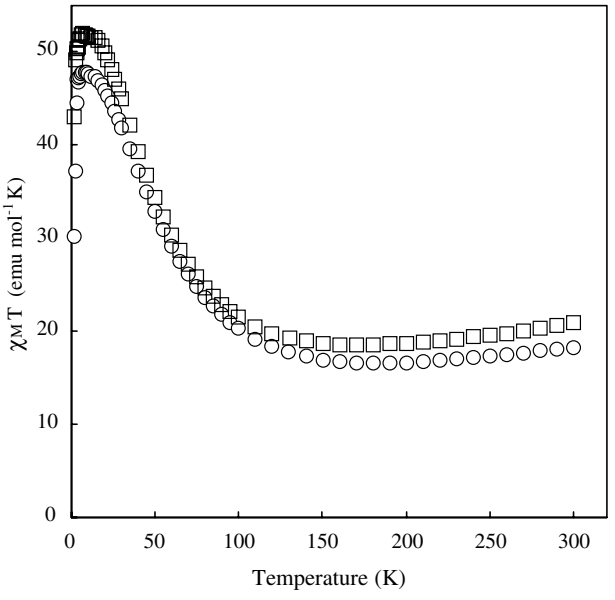

Fig. 3. Plots of $\chi_M T$ vs. temperature for complexes **1** (○) and **2** (□) in an DC field of 1.0 kOe.

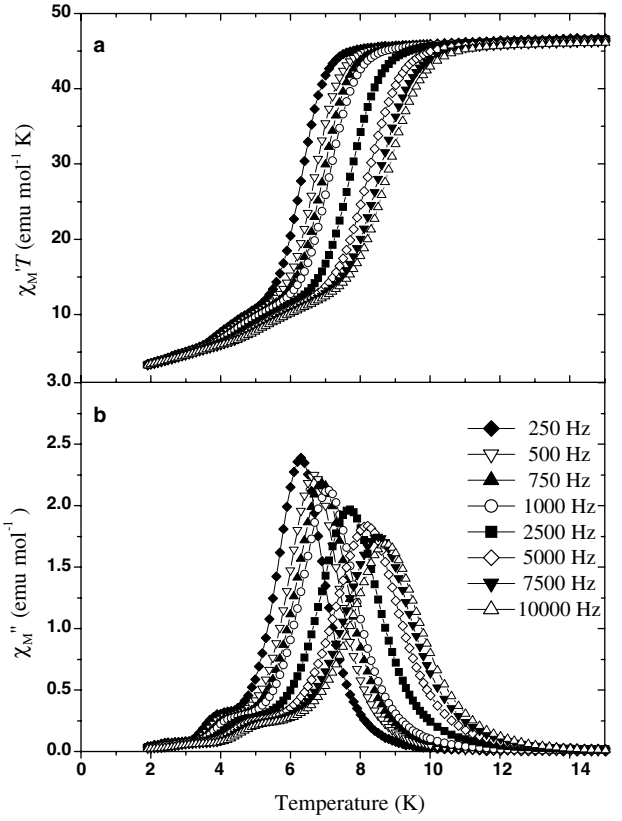

Fig. 4. (a) Plots of $\chi'_M T$ vs. temperature and (b) plots of $\chi''_M T$ vs. temperature for complex **1** in an AC field of 1.0 Oe oscillating at eight different frequencies.

the plots of $\chi' T$ versus temperature, where χ' is the real component of the AC magnetic susceptibility. There is a relatively constant value of $\chi' T \cong 46.5$ cm^3 K mol^{-1} in the 10–15 K range, and this corresponds to the $\chi' T$ value expected for a complex with an $S = 10$ ground state ($g = 1.84$), which showed fairly good agreement to those obtained from DC susceptibility measurement. Also, there are systematic frequency dependence and a "two-step" decrease below 10 K. The decrease in $\chi' T$ is attributable to a relaxation process, thus there are two different regions of relaxation; one in the 5.0–11.0 K range and one in the 3.0–6.5 K range, which are corresponding to the high-temperature (HT) and the low temperature (LT) phases, respectively. These two relaxation processes are also shown in Fig. 4(b), the plots of the out-of-phase χ''AC susceptibility versus temperature, which show predominantly a peak in the 6.3–8.8 K range with a smaller peak in the 3.9–5.1 K range. These two magnetization relaxation processes in Mn_{12} complexes have been elucidated by a Jahn–Teller isomerism [11,15,17,32].

The anisotropy energy barrier U can be calculated by the Arrhenius law, which on the basis the plots of the natural logarithm of the relaxation time τ, when $\tau = 1/(2\pi\nu)$, versus the inverses of the χ'' maximum temper-

ature T_p, which was evaluated from Gauss equation [3]. The anisotropy energy barrier U and pre-exponential factor τ_0, which is the characteristic time of the system, can be estimated by the following equation:

$$\tau = \tau_0 \exp\left[\frac{U}{k_B T_p}\right]. \quad (2)$$

Therefore, by fitting T_p obtained from Fig. 4(b) for different frequency ν, $\tau_0 = 1.33 \times 10^{-9}$ s and $U/k_B = 82.7$ K were obtained for 6.3–8.8 K range, and $\tau_0 = 5.2 \times 10^{-10}$ s and $U/k_B = 56.4$ K were obtained for 3.9–5.1 K. The energy barrier $U/k_B = 82.7$ K is the highest among the Mn_{12} family [17]. For complex **1**, the Jahn–Teller isomerism and/or solvated effect does not been observed any enhancement in AC out-of phase in the low temperature range by drying the sample.

The AC susceptibilities are obtained for complex **2**, in Fig. 5(a) are shown the plots of $\chi'T$ versus temperature. There is a relatively constant value of $\chi'T \cong 53.3\ cm^3\ K\ mol^{-1}$ in the 7–15 K range, and this corresponds to the $\chi'T$ value expected for a complex with an $S = 21/2$ ground state ($g = 1.88$), fairly good agreement to those obtained from DC susceptibility measurement. The decrease in $\chi'T$ is attributable to a relaxation process in the 4.0–9.0 K range. In Fig. 5(b), the plots of the out-of-phase χ'' AC susceptibility versus temperature, which show only a peak in the 4.5–6.4 K range. From the Arrhenius law Eq. (2), the $\tau_0 = 5.93 \times 10^{-10}$ s and $U/k_B = 64.8$ K were obtained for complex **2**. The energy barrier of complex **2** is comparable to those of anionic $[Mn_{12}]^-$ SMMs [29]. For complex **2**, the Jahn–Teller isomerism and/or solvated effect does been observed the enhancement in AC out-of phase in the low temperature range by drying the sample. In Figs. 6(a) and (b) are shown the out-of phase χ'' AC components of complex **2** for drying sample after one day and on week, respectively. These two relaxation processes are also shown in Fig. 6(a), the plots of the out-of-phase χ'' AC susceptibility versus temperature, which show predominantly a peak in the 4.4–5.9 K range with a shoulder peak around 3.0 K. As seen in Fig. 6(b), the lower temperature range relaxation process becomes predominantly after the sample was dried after one week. From the Arrhenius law Eq. (2), the $\tau_0 = 4.26 \times 10^{-9}$ s and $U/k_B = 32.4$ K were obtained for complex **2** in the lower temperature relaxation. The Arrhenius plots for complexes **1** and **2** are shown in Fig. 7. The anisotropy energy barrier U and pre-exponential factor τ_0 are determined from the Arrhenius plots as shown in Table 5. One electron reduction anion

Plots of the natural logarithm of the inverse of the magnetization relaxation time $\ln(1/\tau)$ vs. the inverse of the absolute temperature of $\chi''_M T$ peak for the HT (■) and LT (□) phase of complex **1** and the HT (●) and LT (○) phase of complex **2**. The solid lines represent least-square fits of the data to the Arrhenius equation.

Table 5
The anisotropy energy barrier U and pre-exponential factor τ_0 are determined from Arrhenius plots for complexes **1** and **2**

Complex	Phase	τ_0 (s)	U (K)
1	HT	1.33×10^{-9}	82.7
1	LT	5.2×10^{-10}	56.4
2	HT	5.93×10^{-10}	64.8
2	LT	4.26×10^{-9}	32.4

$[Mn_{12}]^-$ has smaller energy barrier than that of neutral $[Mn_{12}]$, which has also observed for other Mn_{12} complexes [12,18].

The data of hysteresis loops and the first derivative of the hysteresis plots at eight temperatures for complex **1** are shown in Fig. 8(a) and (b), respectively. Steps are clearly seen on these hysteresis loops, as was reported for complex **3** [6]. The value of H_n, which is correspond to resonant tunneling between quantum spin states in 1.8–2.8 K, are summarized in Fig. 9. As the field is decreased from +3.0 T, the first step is seen at zero field, followed by steps around −0.505, −0.969, −1.504, −1.943 and −2.390 T. The spacing between the steps in the hysteresis loops is given as $\Delta H = -D/g\mu_B$, where g is the gyromagnetic factor and μ_B is the Bohr magneton. The parameter D is the magnitude of axial zero-field splitting ($|D|S_Z^2$). From Fig. 9, we calculate the average step size to be $\Delta H = 0.479$ T, $D = 0.644$ K and the anisotropy energy barrier $U = 64.4$ K, which is similar to the value $\Delta H = 0.44$ T obtained for **3**. However, the anisotropy energy $U = 64.4$ K calculated from the hysteresis loops is smaller than $U = 82.7$ K from high temperature range in AC susceptibilities, and greater than $U = 56.4$ K from low temperature range in AC susceptibilities.

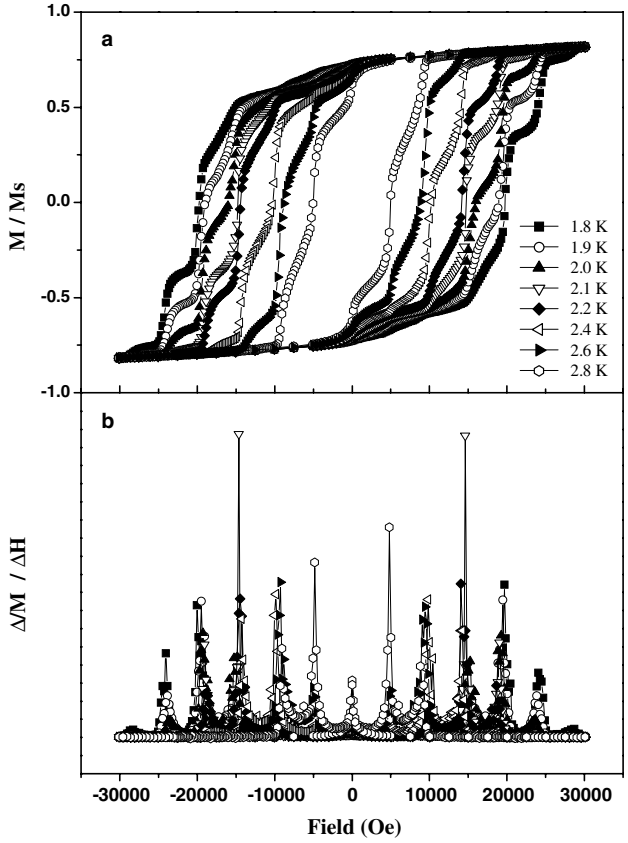

Fig. 8. (a) The plot shows the magnetization hysteresis loops for complex **1** oriented in an eicosane wax matrix at eight different temperatures. (b) The plot is shown a plot of the first derivative of magnetization hysteresis loops.

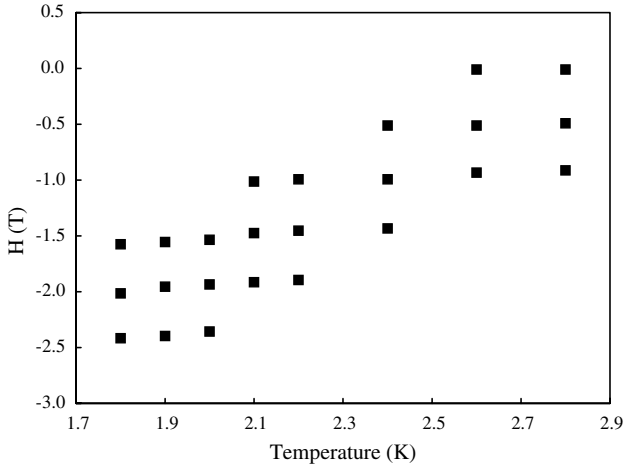

Fig. 9. Field H_n for which is correspond to resonant tunneling between quantum spin states, are plotted vs. temperature for complex **1**.

The magnetization decay experiments for complex **1** were carried out in zero DC field in temperature range of 1.8–2.8 K, as shown in Fig. 10(a). The decay data collected at each temperature are reasonable fit by a single-exponential decay equation (3). M_0 is the initial magnetization, t is the average relaxation time, and B is

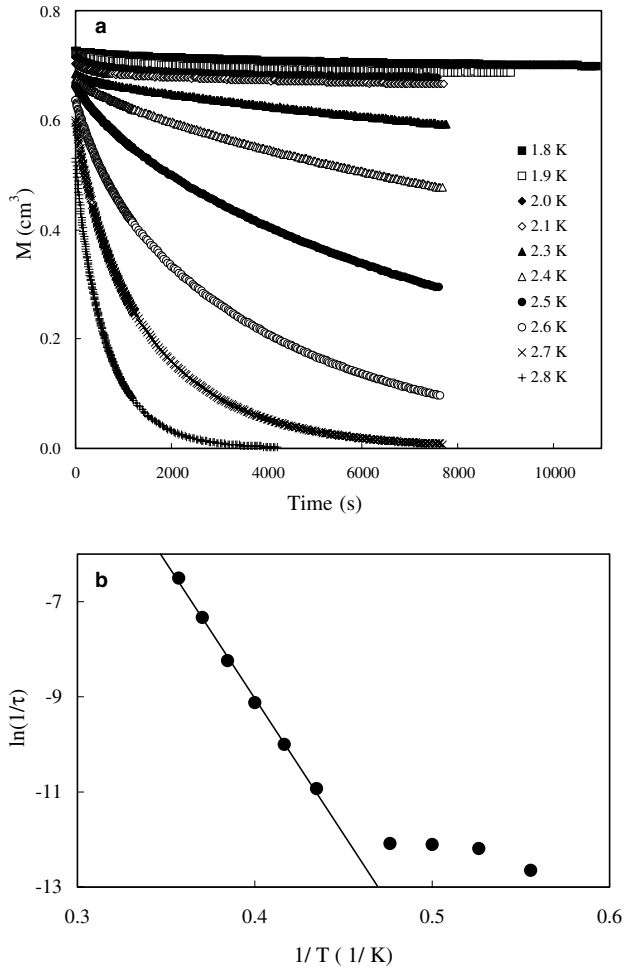

Fig. 10. (a) Magnetization decay plots in zero DC field. (b) Plot of natural logarithm of inverse decay rate ($1/\tau$) vs. inverse of temperature in the temperature range of 1.8–2.8 K for complex **1**.

the width of the distribution. When $B = 1$ the relaxation as a function of time follows a single-exponential decay.

$$M = M_0 \exp\left[-\left(\frac{t}{\tau}\right)^B\right]. \quad (3)$$

The relaxation times obtained using a single-exponential decay are summarized in Table 6. The Arrhenius plot of the natural logarithm of the relaxation rate $1/\tau$ versus 1/T is shown in Fig. 10(b). Least-square fitting of data to Arrhenius equation gives the anisotropy energy barrier $U = 57.0$ K, which is close to the value from the LT AC data.

Table 6
Relaxation fitting parameter M_0 and τ resulting from a single-exponential decay

Temperature (K)	M_0	τ (s)
1.8	0.72	3.12×10^5
1.9	0.71	1.97×10^5
2.0	0.70	1.81×10^5
2.1	0.69	1.77×10^5
2.3	0.67	5.59×10^4
2.4	0.66	2.21×10^4
2.5	0.64	9.15×10^3
2.6	0.59	3.80×10^3
2.7	0.57	1.53×10^3
2.8	0.51	6.68×10^2

4. Conclusion

We have synthesized two Mn_{12} complexes, which showed SMM behavior on AC susceptibility. From the AC and DC magnetic data, complexes **1** and **2** have an $S = 10$ and $S = 21/2$ ground state, respectively. For complex **1**, the anisotropy energy are $U(\mathrm{LT}) = 82.7$ K and $U(\mathrm{LT}) = 56.4$ K obtained from AC out-of-phase singles. For complex **2**, the anisotropy energy are $U(\mathrm{HT}) = 64.8$ K and $U(\mathrm{LT}) = 32.4$ K obtained from AC out-of-phase singles. The step-like hysteresis loops complex **1** show quantum tunneling behavior and the step $\Delta H = 0.479$ T yielded $D = 0.644$ K and $U = 64.4$ K. The magnetization decay data of complex **1**, gave the anisotropy energy barrier $U = 57.0$ K, which is close to the value from the LT AC data.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre under CCDCs 245023 and 245024 for complexes **1** and **2**, respectively. These data can be obtained from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, fax: +44 1223 336033, e-mail: deposit@ccdc.cam.ac.uk.

An oxygen-rich ligand 2,6-bis(hydroxymethyl)-4-methylphenol (H_3L), containing two benzyl alcohol and a phenol groups, has been utilized in a variety of high-nuclearity complexes [20,21]. Although the structure of H_2L^- is similar to pyridine dimethanol ($pdmH_2^-$), the central phenolate of H_2L^- could coordinate as bridge and terminal ligand in contrast to the pyridine of $pdmH_2^-$ which is only as terminal coordination. This coordination ability of H_3L would provide diversity of structures. Here, we present the syntheses of two Mn_4 complexes with 2,6-bis(hydroxymethyl)-4-methylphenol ligand and the magnetic data of both complexes show that they are SMMs with an $S = 9$ ground state.

2. Experimental

2.1. Synthesis

All solvents and reagents were used as received, and no purification of chemical was needed. All reactions were performed under aerobic conditions.

2.1.1. $[Mn_4(HL)_4(MeOH)_4Cl_2]$ (1)

$MnCl_2 \cdot 4H_2O$ (280 mg, 1.42 mmol) and H_3L (170 mg, 1.03 mmol) were dissolved in methanol (12 ml), followed by addition 1 ml of 1 M NaOH in methanol. The solution was stirred 30 min then filtered. The filtrate was layered by Et_2O and the resulting solution slowly gave well-formed brown crystals. Crystals were collected by filtration, washed with MeOH and Et_2O then dried in air. The yield was 12% (55 mg); IR data (KBr disk, cm^{-1}): 3356vs br, 2920s, 2854s, 1637m, 1474vs, 1251s, 1227s, 1161m, 1127m, 994m, 864m, 815s, 623s, 580m, 562m, 546m, 475m. *Anal*. Calc. for $Mn_4C_{40}H_{56}Cl_2O_{16}$: C, 44.3; H, 5.2. Found: C, 42.2, H, 5.2%. The crystallographic sample was maintained in contact with mother liquor to avoid solvent loss and was identified as $\mathbf{1} \cdot 2Et_2O$.

2.1.2. $[Mn_4(HL)_4(MeOH)_4Br_2]$ (2)

Complex **2** was synthesized by the reaction of $MnBr_2 \cdot 4H_2O$ and H_3L analogous to that employed for complex **1**. The yield was 24%; IR data (KBr disk, cm^{-1}): 3340vs br, 2920s, 2854s, 1637m, 1476vs, 1248s, 1230s, 1160m, 1129m, 990m, 863m, 815s, 622s, 583m, 561m, 543m, 473m. *Anal*. Calc. for $Mn_4C_{40}H_{56}Br_2O_{16}$: C, 40.9; H, 4.8. Found: C, 39.2, H, 4.7%. The crystallographic sample was maintained in contact with mother liquor to avoid solvent loss and was identified as $\mathbf{2} \cdot 2Et_2O$.

2.2. Physical measurements

Variable temperature DC magnetic susceptibility measurements were collected on powder samples of complexes **1** and **2**, restrained in eicosane to prevent torquing, on a Quantum Design MPMS SQUID susceptometer equipped with a 7.0 tesla magnet and operating in the range of 1.7–300.0 K. Variable temperature AC magnetic susceptibility measurements were carried out on a Quantum Design PPMS-9 magnetometer equipped with a 9.0 tesla magnet and operating in the range of 2.0–300 K. Diamagnetic corrections were estimated from Pascal's constants [22] and subtracted from the experimental susceptibility data to obtain the molar paramagnetic susceptibility of the compounds.

3. Results and discussion

3.1. Synthesis

The 2,6-bis(hydroxymethyl)-4-methylphenol (H_3L) ligand has been little explored as a chelating ligand in coordination chemistry, although it has been observed in doubly-deprotonated (HL^{2-}) and act as a tridentate ligand [21]. Treatment of H_3L, $MnX_2 \cdot 4H_2O$ and NaOH in a 3:2:2 molar ratios in methanol gave a red-brown color solution. This solution was layered by Et_2O to form brown crystals, which were identified as $[Mn_4(HL)_4(MeOH)_4X_2]$.

3.2. Description of structures

Labeled ORTEP plots of $\mathbf{1} \cdot 2Et_2O$ and $\mathbf{2} \cdot 2Et_2O$ are shown in Figs. 1 and 2, respectively. Complexes **1** and **2** crystallize in the monoclinic space group C_2/c and crystallographic information of both complexes is given in Table 1. The asymmetric unit of complex **1** contains one half molecule and one Et_2O solvent, while complex **2** comprises a complete Mn_4 cluster and two solvated Et_2O. Disregarding the difference in halide bridges, the complexes **1** and **2** are essentially isostructural. The planar diamond core of the clusters is a mixed-valence $Mn^{II}_2Mn^{III}_2$ dicubane held together by two μ_3-O and four μ_2-O. The peripheral ligations are composed of two halide anions, four MeOH and four H_2L^{2-} ligands, of which two types of bonding are observed. One type of H_2L^{2-} ligands is tridentate with a μ_3-OBz bridging, a μ_2-OPh bridging and a BzOH terminally coordinated, in which the bridging oxygens are deprotonated while the terminal coordinated oxygen is protonated. The other type of H_2L^{2-} is bidentate, possessing a deprotonated μ_2-OBz, a deprotonated OPh terminally coordinated and an uncoordinated HOBz. Two terminal Cl^- and four terminal MeOH ligands complete the coordination environment of complex **1**, while complex **2** contains two Br^- ions. In both complexes, all Mn ions are distorted octahedral geometries; oxidation states of Mn are assigned on the basis of bond valence sum calculations (Table 2) [23] and the presence of a Jahn–Teller

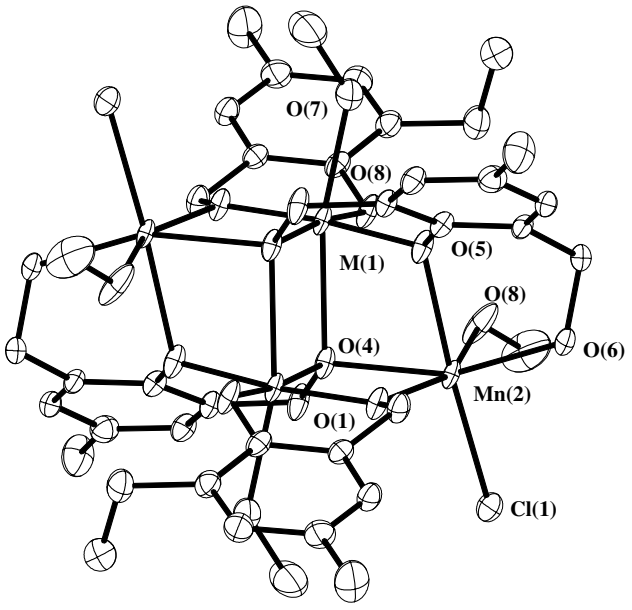

Fig. 1. Crystallographic structure of $[Mn_4(HL)_4(MeOH)_4Cl_2]\cdot 2Et_2O$ (**1**). Thermal ellipsoids at the 50% probability level. The H atoms and solvated molecules have been omitted for clarity.

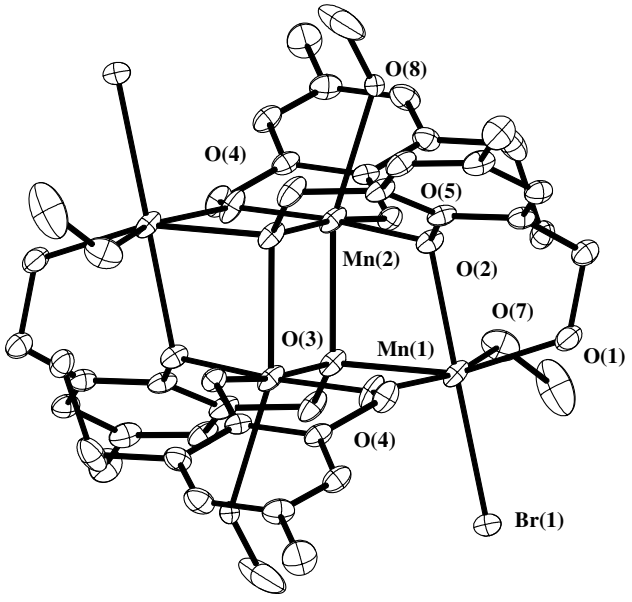

Fig. 2. Crystallographic structure of $[Mn_4(HL)_4(MeOH)_4Br_2]\cdot 2Et_2O$ (**2**). Thermal ellipsoids at the 30% probability level. The H atoms and solvated molecules have been omitted for clarity.

elongation. In complex **2** the O(6), O(6′), O(8) and O(8′) are disorder with 50% occupancy.

3.2.1. $[Mn_4(HL)_4(MeOH)_4Cl_2]$ (**1**)

The asymmetric unit of complex **1** contains one half of the cluster, and a diethyl ether molecule. Mn(2) ions display longer Mn–ligand distances (average 2.24 Å) compared with those for Mn(1) (average 2.01 Å), where Mn(1) shows an elongation of the O(4)–Mn(1)–O(7)

Table 2
Bond valence sums of Mn atoms in complexes **1**

	Complex **1**		Complex **2**	
	Mn(1)	Mn(2)	Mn(1)	Mn(2)
Mn(II)	3.4777	*2.1359*	*2.0015*	3.3949
Mn(III)	*3.2069*	1.9695	1.8457	*3.1305*
Mn(IV)	3.1468	1.9326	1.8111	3.0718

Jahn–Teller distortion These axial Mn(1)–O(4) [2.410(3) Å] and Mn(1)–O(7) [2.212(3) Å] distances are distinctly longer than the equatorial bond lengths [1.868(2)–1.928(2) Å]. Therefore the Mn(1) and Mn(2) ions are assigned as Mn^{III} and Mn^{II}, respectively, which are consistent with the results of BVS calculation.

Two types of intermolecular interactions in the form of hydrogen bond are noticeable. One is the typical type of H-bond of O···H–O, involving the uncoordinated O of the HOBz from HL^{2-} and the O atom from the terminal MeOH ligand [O(3)···O(7′) 2.744 Å] as well as the uncoordinated O atom of the HOBz from the HL^{2-} ligand of a neighboring cluster [O(7)···O(7′) 2.713 Å]. The other one is Mn–Cl···H–O type, involving the terminal Cl atom and O atom of terminal protonated HOBz from HL^{2-} of a neighboring cluster [Cl(1)···O(6′) 3.032 Å]. These H-bond interactions effectively mediate a 2D structure network (Fig. 3).

3.2.2. $[Mn_4(HL)_4(MeOH)_4Br_2]$ (**2**)

The asymmetric unit of complex **2** contains one cluster, and two diethyl ether molecules. Mn(1) ions display

longer Mn–ligand distances (average 2.26 Å) compared with those for Mn(2) (average 2.03 Å), while Mn(2) shows an a elongation of the O(3)–Mn(2)–O(7) Jahn–Teller distortion. Thus axial Mn(2)–O(3) [2.376(3) Å] and Mn(1)–O(7) [2.184(6) Å] are distinctly longer than the equatorial bond lengths [1.870(3)–1.931(2) Å]. Consequently the Mn(1) and Mn(2) ions are assigned as Mn^{II} and Mn^{III}, respectively, which are consistent with the results of BVS calculation.

The intermolecular hydrogen bonding interactions in complex **2** are similar to those in complex **1,** involving the uncoordinated O(6) with 50% occupancy of the HOBz from HL^{2-} and the O(8) with 50% occupancy from the terminal MeOH ligand [O(6)···O(8) 2.920(8) Å] as well as the O(8) of a neighboring cluster [O(6)···O(8A) 2.823(7) Å]. The weak M–Br···H–O bonding interaction involves the terminal Br atom and O atom of the terminal protonated HOBz from HL^{2-} of a neighboring cluster [Br(1)···O(1) 3.212(2) Å]. These interactions link the clusters forming a 2D network (Fig. 4).

3.3. DC magnetic susceptibilities and magnetization

The variable temperature DC magnetic susceptibilities were collected for microcrystalline samples of compounds **1** and **2** in the temperature range of 2–300 K at a magnetic field of 1000 G. The experimental $\chi_M T$ versus temperature plots are depicted in Figs. 5 and 6 for complexes **1** and **2**, respectively. For complex **1**, the value of $\chi_M T$ is 16.82 emu K mol^{-1} at 300 K, which is larger than the spin-only value of a $Mn^{II}{}_2Mn^{III}{}_2$ core (12.50 emu K mol^{-1}) indicating the ferromagnetic interactions within the cluster. As the temperature decreases the value of $\chi_M T$ increases steadily and reaches a maximum of 39.87 emu K mol^{-1} at 14 K, then drops sharply upon further decreasing the temperatures. The magnetic susceptibility of complex **2** displays a very similar behavior of complex **1**, with values of 17.55 emu K mol^{-1} at 300 K and 39.52 emu K mol^{-1} at 16 K. The maximum values of $\chi_M T$ at 14–16 K are corresponding to a high-spin $S = 9$ ground state with $g = 1.93$ and 1.92 for complexes **1** and **2**, respectively. The sharp reduction of $\chi_M T$ below 12 K is likely due to the zero-field splitting and Zeeman effects of the high-spin ground state. The parallel magnetic behaviors of tetranuclear manganese complexes have been reported [17].

In order to characterize the coupling interactions within the cluster, the magnetic susceptibility data were fit to the appropriate theoretical expression, which was driven by the van Vleck equation. Only two dominate exchange pathways are considered in this tetranuclear manganese complex (Fig. 7), and the spin Hamiltonian is given in Eq. (1). The equivalent spin Hamiltonian in Eq. (2) is obtained by applying the Kambe coupling approach Eq. (3). The $\chi_M T$ versus temperature for both complexes were least-squares fit to the van Vleck equation, which includes the eigenvalue expression in Eq. (4).

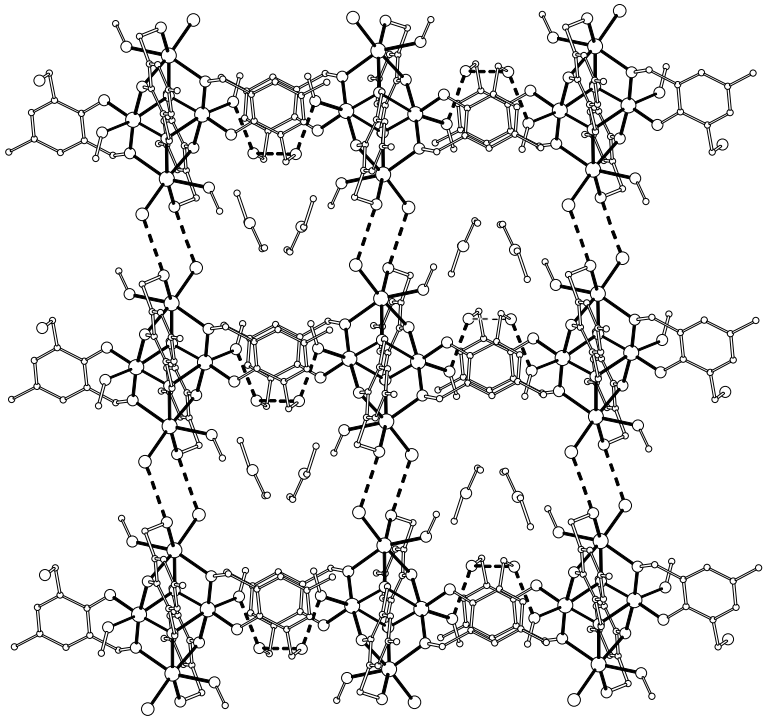

Fig. 3. The hydrogen bonding interactions (dashed line) between adjacent clusters forming a 2D network for complex **1**.

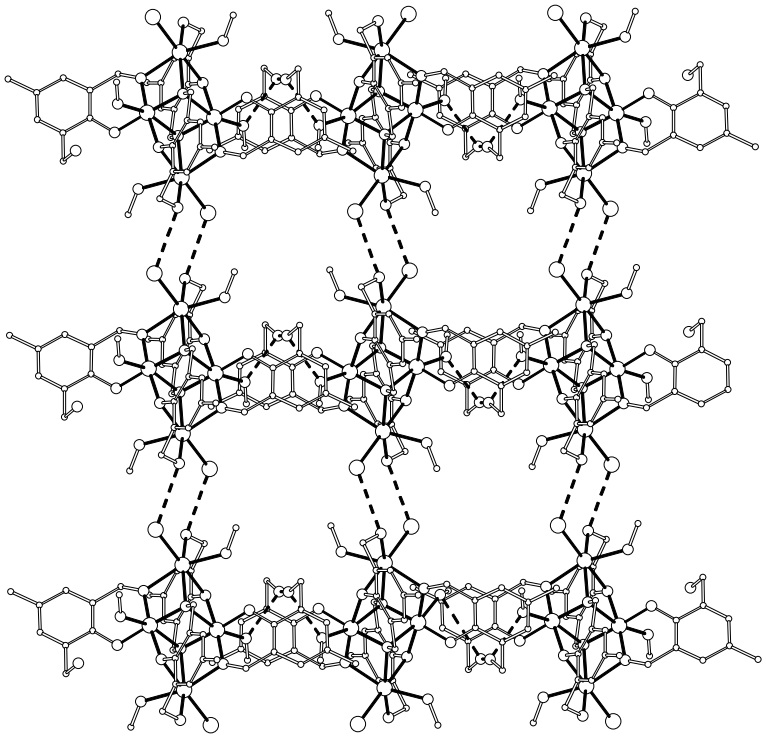

Fig. 4. The hydrogen bonding interactions (dashed line) between adjacent clusters forming a 2D network for complex **2**.

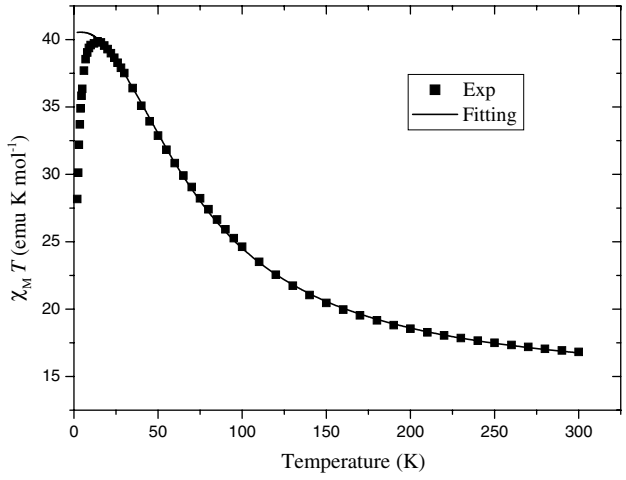

Fig. 5. Plot of $\chi_M T$ vs. temperature for a powder sample of complex **1**. The solid line represents a least-squares fit of the data in the region 16–300 K to the van Vleck equation.

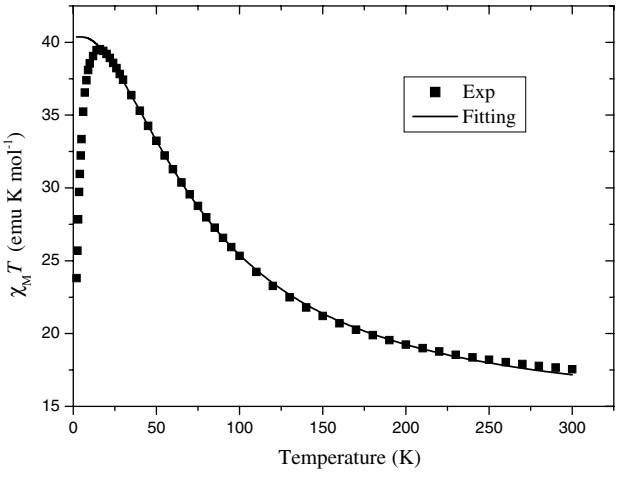

Fig. 6. Plot of $\chi_M T$ vs. temperature for a powder sample of complex **2**. The solid line represents a least-squares fit of the data in the region 14–300 K to the van Vleck equation.

$$H = -2J_{wb}(S_1S_2 + S_1S_4 + S_3S_2 + S_3S_4) - 2J_{bb}(S_1S_3), \quad (1)$$

$$H = -J_{wb}(\hat{S}_T^2 - \hat{S}_A^2 - \widehat{S}_B^2) - J_{bb}(\hat{S}_A^2 - \widehat{S}_1^2 - \widehat{S}_3^2), \quad (2)$$

where

$$\hat{S}_A = \widehat{S}_1 + \widehat{S}_3, \quad \hat{S}_B = \widehat{S}_2 + \widehat{S}_4 \quad \text{and} \quad \hat{S}_T = \widehat{S}_A + \widehat{S}_B. \quad (3)$$

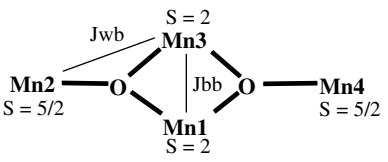

Fig. 7. Diagram showing the definition of atom number and magnetic exchange parameters for the complexes **1** and **2** studied.

The Kambe equivalent operator method gives the eigenvalue expression in Eq. (4).

$$E(S_T) = -J_{wb}[S_T(S_T+1) - S_A(S_A+1) - S_B(S_B+1)] - J_{bb}[(S_A(S_A+1)]. \quad (4)$$

With two $S = 2$ and two $S = 5/2$ interacting ions there are a total of 110 possible states with S_T, the total spin of Mn_4 cluster, ranging from 0 to 9. The data below 14 K for **1** and 16 K for **2** were omitted in the fitting, because zero-field splitting and Zeeman effects are likely to have an effect on the susceptibilities in this temperature range. The results of fitting the experimental data are shown as solid lines in Figs. 5 and 6, with final parameters being $g = 1.89$, $J_{wb} = 3.42\ cm^{-1}$, $J_{bb} = 7.71\ cm^{-1}$ for complex **1**; $g = 1.89$, $J_{wb} = 3.25\ cm^{-1}$, $J_{bb} = 12.46\ cm^{-1}$ for complex **2**, and the temperature independent paramagnetism (TIP) fixed at 600×10^{-6} emu mol^{-1}. It is clear that both molecules are ferromagnetically coupled to give an $S = 9$ ground state. However, the magnitude of the exchange interaction of J_{bb} for complex **2** is almost twice for complex **1**. There is no obvious structural correlation with the exchange coupling interactions, since both complexes are almost isostructural. This kind of phenomenon has been observed also in $[Mn_4(O_2CMe)_2(pdmH)_6](ClO_4)_2 \cdot 2.5H_2O$ [17] and $[Mn_4(hmp)_6Br_2(H_2O)_2]Br_2 \cdot 4H_2O$ [18]. The ground state of complex **1** and **2** are further confirmed by magnetization measurements at 2.0 K up to a 70.0 kG field. In Fig. 8, the $M/N\beta$ values of compounds **1** and **2** are saturated to 17.79 and 18.00, respectively, which corresponds to an $S = 9$ ground state and its saturated magnetization should be $M/N\beta = 2S = 18$.

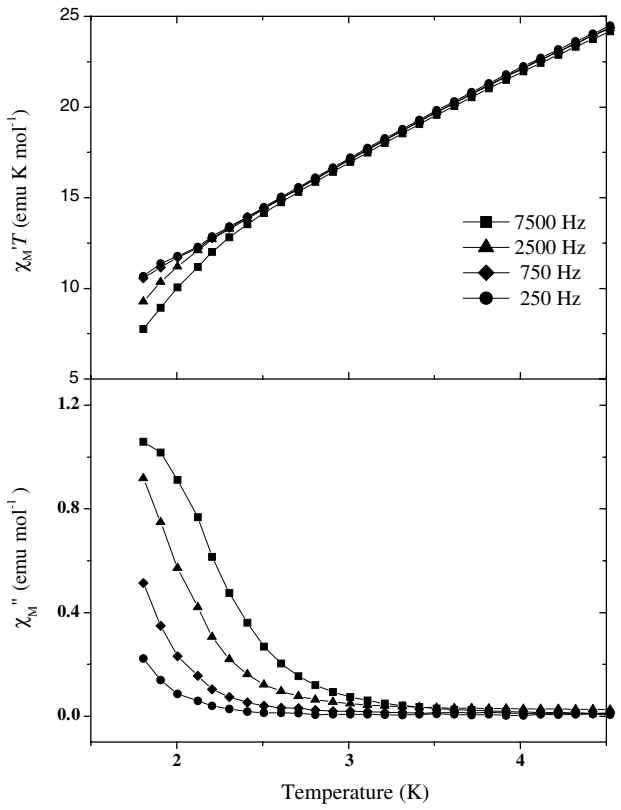

Fig. 9. Plot of $\chi'_M T$ (top) and χ''_M (bottom) vs. temperature for a powder sample of complex **1** in a 1.0 G AC field.

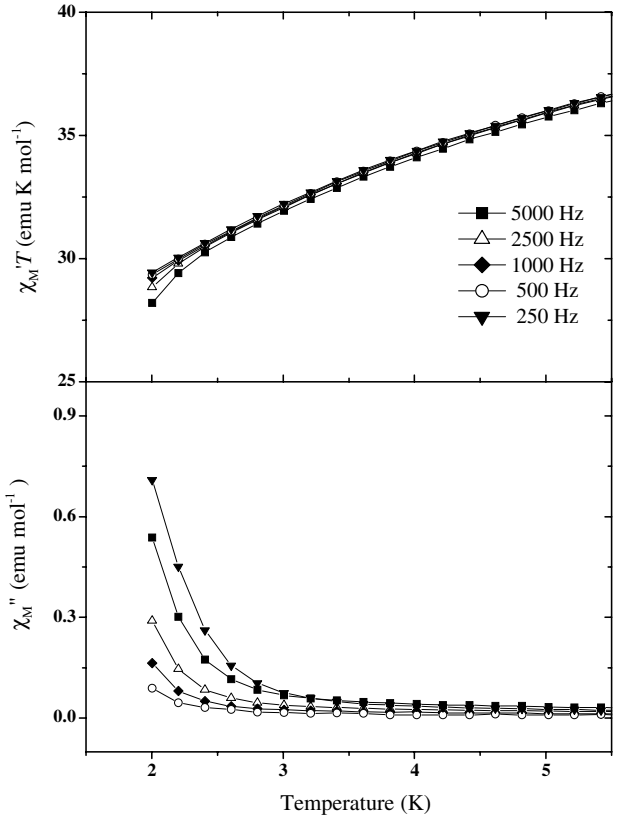

Fig. 10. Plot of $\chi'_M T$ (top) and χ''_M (bottom) vs. temperature for a powder sample of complex **2** in a 1.0 G AC field.

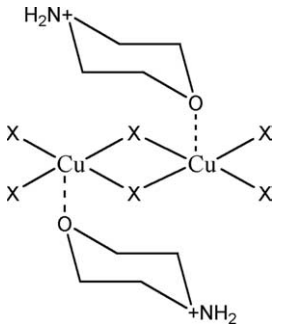
3.4. AC magnetic susceptibilities

Evidence of complexes **1** and **2** function as SMMs was obtained by AC magnetic susceptibility measurements. Being a SMM, it must possess both a large spin ground state and negative zero-field splitting to give rise to an energy barrier between the spin-up and spin-down states. Therefore, if an oscillating magnetic field is applied at low temperature, a reduction in the in-phase ($\chi'_M T$) signal and a corresponding increase in the out-of-phase (χ''_M) signal are seen. The sluggish relaxation of magnetization is due to the energy barrier larger than the thermal energy at low temperature. The AC magnetic susceptibility of powder polycrystalline samples of complexes **1** and **2** were studied in 2.0–10 K range with a 1.0 G AC field oscillating in the range of 250–7500 Hz. Plots of $\chi'_M T$ and χ''_M versus T are given for complexes **1** and **2** in Figs. 9 and 10, respectively. At temperature below 3 K there are significant increases of out-of-phase signals accompanied by collapses of the in-phase signals. The frequency dependence of the AC signals suggests that compounds **1** and **2** are SMMs.

4. Supplementary material



Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre under CCDC Nos. 251047 and 251048 for compounds **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or on the web www: http://www.ccdc.cam.ac.uk.
