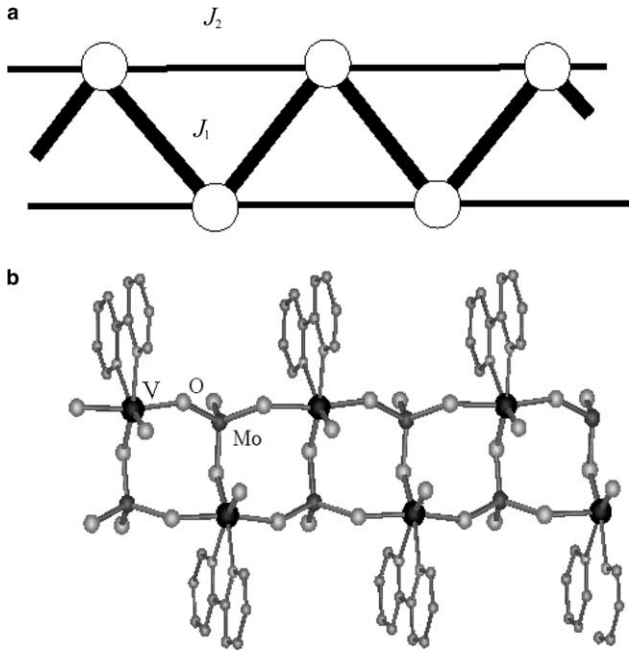

Fig. 1. (a) Schematic diagram for the zigzag spin chain. Open circles represent $S = 1/2$. (b) Crystal structure of [VO(μ_3-MoO_4)(2,2′-bpy)]. H atoms are not shown for clarity.

description in [7]. V_2O_5, V_2O_3, $Na_2MoO_4 \cdot 2H_2O$, MoO_3, 2,2′-bipyridine in the molar ratio of 1:1:2:2:4 in 8 ml water was heated in teflon-lined autoclave for 48 h at 473 K. V_2O_3 was made from V_2O_5, reduced under H_2 gas flow at 1173 K. All measurements were carried out on powder samples. Quality of the specimen was checked by powder-X ray diffraction method. The magnetic susceptibility $\chi(T)$ was measured using the Quantum Design PPMS (physical properties measurements system) in the temperature range between 2.0 and 280 K in an applied field of 0.1 T. The high field magnetization curve was measured at 4.2 K up to about 35 T using an induction method in a pulsed magnetic field.

3. Results

Filled circles in Fig. 2 show the temperature dependence of $\chi(T)$. Very small and broad maximum is observed at around 230 K. $\chi(T)$ increased as decreasing temperature. In the temperature range between 280 and 30 K, $\chi(T)$ approximately followed Curie–Weiss law with Weiss temperature of about −40 K, which indicates that dominant interaction is antiferromagnetic.

Thick line in Fig. 3 shows the magnetization curve M of [VO(μ_3-MoO_4)(2,2′-bpy)] measured at 4.2 K. M increases almost linearly as increasing the magnetic field. No spin gap is observed in the magnetization process, suggesting that the ground state is in the gapless phase with $j < j_c$ An expected saturation magnetization for

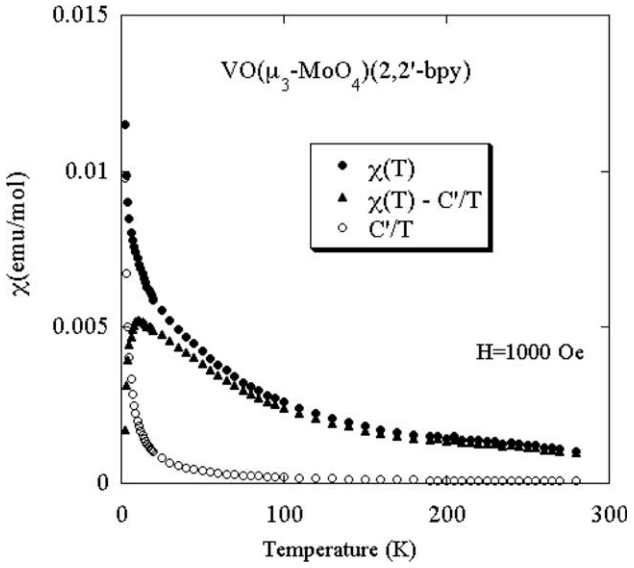

Fig. 2. Temperature dependence of $\chi(T)$ for [VO(μ_3-MoO_4)(2,2′-bpy)] (filled circles). Open circles are Curie contribution C'/T from magnetic impurities with Curie constant C'. Closed triangles are $\chi(T) - C'/T$.

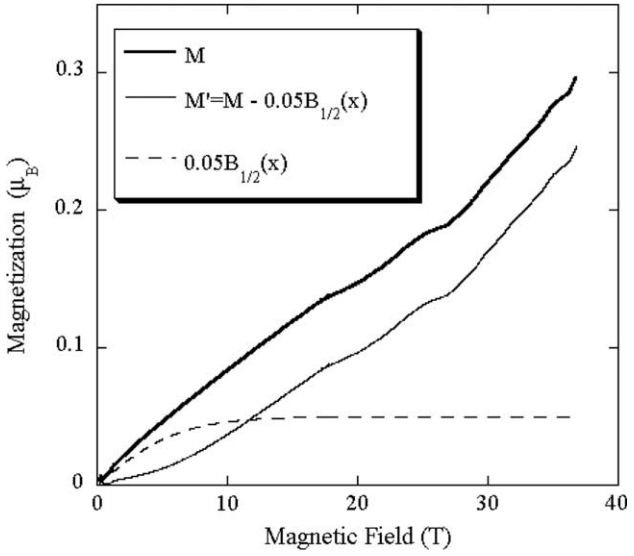

Fig. 3. High field magnetization M of [VO(μ_3-MoO_4)(2,2′-bpy)] at 4.2 K (thick line). Dotted line is Brillouin function for $S = 1/2$ with 5% spin concentration where $x = \mu_B H/k_B T$. Thin line is $M' = M - 0.05B_{1/2}(x)$.

V^{4+} ($S = 1/2$) is about $g\mu_B S \approx 1\ \mu_B$, where μ_B is Bohr mageneton and g is Lande's g-factor. M does not saturate even at 35 T, which suggests that large antiferromagnetic interactions between V^{4+} ions are present in this material.

4. Discussion

It is well known that $\chi(T)$ of 1D antiferromagnet has broad peak at the temperature corresponding to the

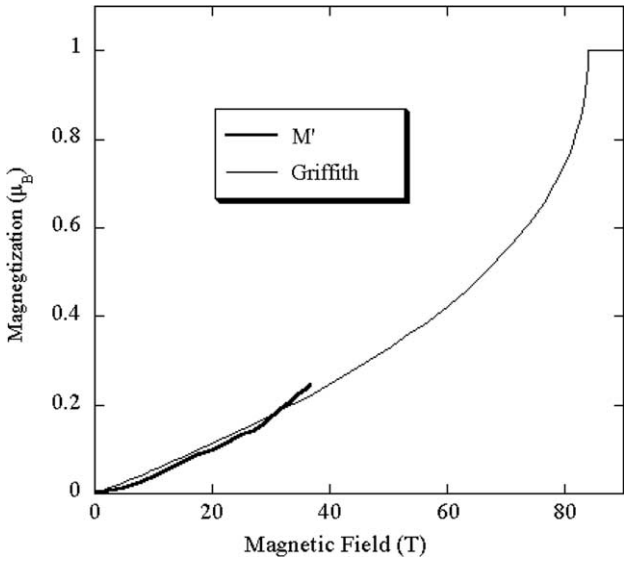

Fig. 4. Comparison of the bulk part magnetization M' of [VO(μ_3-MoO_4)(2,2′-bpy)] with the theoretical curve for $S = 1/2$ 1D HAF calculated at $T = 0$ with the saturation field 84 T.

magnetic exchange interaction, as a reflection of a short range magnetic ordering. Our $\chi(T)$ of [VO(μ_3-MoO_4)-(2,2′-bpy)] does not show such a peak, although the crystal structure is 1D-like and the presence of magnetic interaction is suggested by the magnetization curve. A Curie contribution from small amount of magnetic impurities may mask the low temperature part of $\chi(T)$ to prevent the observation of the broad peak. It is rather difficult to estimate a concentration n of the magnetic impurities from $\chi(T)$ data. Instead, we try to determine n using the magnetization data. The magnetic impurities manifest themselves as a Brillouin function curve $B_s(x)$ where $x = \mu_B H/k_B T$, S is magnitude of spin, H is magnetic field and k_B is Boltzmann constant. Since $B_s(\mu_B H/k_B T)$ saturates easily in higher field, it is sometimes not so difficult to separate the impurities part from bulk part of the magnetization curve. The low field (<5 T) part of the magnetization curve of [VO(μ_3-MoO_4)(2,2′-bpy)] is well fitted by 0.05 $B_{1/2}(x)$ as shown in dotted curve in Fig. 3. The value of n is thus determined to be 0.05 if magnetic impurities have $S = 1/2$. M' in Fig. 3 indicates the bulk part of M after subtraction of the impurity part 0.05 $B_{1/2}(x)$. Let us analyze M' to estimate a saturation field H_s. The magnetization curve for the zigzag chain has been calculated [8]. According to [8], the magnetization curve for the zigzag spin chain is almost independent on the interaction ratio j if $j < j_c$ as far as the magnetic field is lower than about 3 quarters of H_s. Since our M' is far from saturation, it is safe to compare M' with a theoretical curve for 1D HAF without nnn interaction, which was calculated by Griffith [9]. Fig. 4 is the fitting result of M' with the theoretical curve at $T = 0$ using $H_s = 84$ T. A relation between H_s and J_1 is given by an expression $H_s = 2J_1 k_B/g\mu_B$ for $j < j_c$ [10], with which we can estimate a value of J_1/k_B to be about 56 K assuming $g = 2$.

Next, we would like to discuss $\chi(T)$ data. The concentration n of the impurities have estimated to be 0.05 from the magnetization. The Curie constant C' of the magnetic impurities is given as $C' = ng^2\mu_B^2 S(S+1)/3k_B = 0.019$ assuming $S = 1/2$ and $g = 2$.

Filled triangles and open circles in Fig. 2 show a bulk part of the magnetic susceptibility ($\chi_{bulk}(T) = \chi(T) - C'/T$) and C'/T, respectively. At around 11 K, there appears a maximum in $\chi_{bulk}(T)$, which resembles the broad peak at T_{max} often observed in 1D HAF. In case of the 1D HAF without J_2, $k_B T_{max}/J_1 \approx 0.641$ [11]. For [VO(μ_3-MoO_4)(2,2′-bpy)], the ratio $k_B T_{max}/J_1$ between $T_{max} = 11$ K and $J_1/k_B = 56$ K is about $0.2 < 0.641$. We have calculated the temperature dependence of susceptibility of the zigzag spin model for several values of j using the exact diagonalization method for a finite spin chain with N spins up to $N = 10$ [3]. This calculation shows that T_{max} decreases as increasing j, or increasing the spin frustration effect. The observed result that $k_B T_{max}/J_1$ is smaller than the expected value for the 1D HAF without J_2 thus indicates there are non-zero J_2 in [VO(μ_3-MoO_4)(2,2′-bpy)]. In our tentative calculation, N was so small that quantitative comparison between the experimental result and the calculation is difficult.

In summary, $\chi(T)$ and high field magnetization up to 35 T on the model compound for $S = 1/2$ zigzag antiferromagnetic system, [VO(μ_3-MoO_4)(2,2′-bpy)] were measured and reported. No spin gap was observed in the magnetization curve measured at 4.2 K. The magnetization curve was compared with theoretical curve to estimate the nearest-neighbor exchange interaction J_1 to be 56 K. The intrinsic magnetic susceptibility had maximum at around $T_{max} = 11$ K. A ratio T_{max}/J_1 was found to be much less than that expected for one-dimensional antiferromagnet without frustrating next-nearest-neighbor interaction. This result is discussed in terms of the spin frustration.

percolation model. Systematic studies on macroscopic effects of the disordered magnetic structures (fragmentation of magnetic domain) on magnetic and magneto-optical properties will give insight into the control of these physical properties. We report magnetic properties and Faraday ellipticity spectra of the trimetallic solid solutions, $\{[Ni(1,1\text{-dmen})_2]_2[Fe_{(1-x)}Co_x(CN)_6]\}tfs \cdot nH_2O$ ($x = 0.0$, 0.12, 0.23, 0.35, 0.47, 0.54, 0.57, 0.64, 0.72, 0.81, 1.0; 1,1-dmen = 1,1-dimethylethylenediamine, tfs^- = trifluoromethanesulfonate ion) which have a two-dimensional grid structure.

2. Experimental

2.1. Synthesis

All reagents were purchased and used without further purification. Trimetallic solid solutions, $\{[Ni(1,1\text{-dmen})_2]_2[Fe_{(1-x)}Co_x(CN)_6]\}tfs \cdot nH_2O$ ($x = 0.0$, 0.12, 0.23, 0.35, 0.47, 0.54, 0.57, 0.64, 0.72, 0.81, 1.0), were prepared as plate-like crystals by the reaction of mixture of $K_3[Fe(CN)_6]$ and $K_3[Co(CN)_6]$ in each mixing ratio (a total of 0.5 mmol), $[Ni(1,1\text{-dmen})_3]Cl_2$ (1 mmol) and small excess of Natfs (4 mmol) in water [6]. Color of the crystals changes from dark brown to purple with increasing x value. All compounds were efflorescent. Elemental analyses of carbon, hydrogen, and nitrogen were obtained at the Service Center for Elemental Analysis at Kyushu University. The ratios of Fe:Co (x) were determined by Rigaku ZSX-100s X-ray florescence spectrometer.

2.2. X-ray crystallography

X-ray diffraction data were collected at −30 °C on Rigaku Mercury CCD diffractmeter with graphite-monochromated Mo Kα radiation ($\lambda = 0.71070$ Å). Because of the efflorescent nature, single crystals were sealed in a glass capillary. The maximum 2θ value is 55.0°. A total of 1240 oscillation images were collected on five sweep setting. Crystallographic data for compounds ($x = 0.0$ and 1.0) have been deposited with the Cambridge Crystallographic Data Centre (CCDC-189360 and CCDC-189361).

2.3. Magnetic susceptibility measurements

DC and AC magnetic susceptibility data were collected by using a Quantum Design MPMS-5XL SQUID magnetometer in the temperatures range 2–300 K (under applied field of 500 G). Data were corrected for the magnetization of the sample holder and capsule used. Diamagnetic corrections for the constituting atoms were made using Pascal's constants.

2.4. Faraday spectrum

The Faraday spectra were measured on a JASCO J-820 circular dichroism spectrometer using KBr disks in the range of 200–800 nm under 200 G. KBr disks containing ca. 1% of sample were prepared by applying a pressure of 8000 kg/cm^2.

3. Results and discussion

3.1. IR spectrum

IR spectrum (on KBr disk) of FeNi assembly ($x = 0.0$) shows two ν(C≡N) bands at 2144 and 2113 cm^{-1}. The IR band at 2144 cm^{-1} is attributed to the bridging cyanide groups. Also, CoNi assembly ($x = 1.0$) shows two ν(C≡N) bands at 2157 and 2126 cm^{-1}. The other compounds with $x = 0.12$–0.81 show several ν(C≡N) bands whose intensities correspond to x value.

3.2. Crystal structures

X-ray crystallographic results revealed that all compounds form same structure in the same space group ($P2_1/n$). The asymmetric unit consists of one $[M(CN)_6]^{3-}$, one tfs^-, one $[Ni(1,1\text{-dmen})_2]^{2+}$ (Ni3), two $[Ni(1,1\text{-dmen})_2]^{2+}$ moieties (Ni1 and Ni2) and several water molecules. In these solutions, $[Fe(CN)_6]^{3-}$ and $[Co(CN)_6]^{3-}$ units were not distinguished independently and were treated as average unit, $[M(CN)_6]^{3-}$. The $[M(CN)_6]^{3-}$ ion coordinates to four adjacent $[Ni(1,1\text{-dmen})_2]^{2+}$ units with its four cyano nitrogens in a plane. In the lattice, they form a two-dimensional grid structure extended by M–CN–Ni linkages (Fig. 1). Each tfs^- ion locates at the center of the square cavity in the grid and the oxygen atoms of sulfonyl group form hydrogen bonds with amino protons of 1,1-dmen. The lattice water molecules locate between the layers. Average M–CN–Ni distances, d, are listed in Table 1. The d values slightly decrease with increase of x value, whereas, the intersheet distances do not change almostly.

These crystallographic results suggest that these crystals are not mixture of FeNi and CoNi assemblies and $[Fe(CN)_6]^{3-}$ and $[Co(CN)_6]^{3-}$ units statistically disperse in the two-dimensional grid structure.

3.3. Magnetic properties

Magnetic susceptibility measurements were performed in the temperature range of 2–300 K.

χ_M versus T plots of compounds with $x < 0.64$ show an abrupt increase below 10 K, suggesting a ferromagnetic ordering over the lattice (Fig. 2). The saturation magneti-

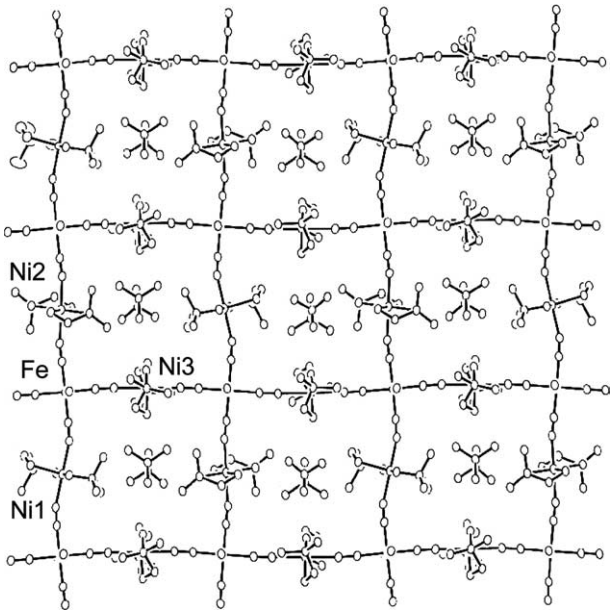

Fig. 1. Two-dimensional grid structure of FeNi assembly ($x = 0.0$).

Table 1
Average M–CN–Ni distance d, and T_c of solid solutions

x	d (Å)	T_c (K)
0.00	10.359	8.9
0.12	10.344	8.3
0.23	10.323	7.0
0.35	10.300	5.4
0.47	10.296	3.6
0.54	10.292	3.0
0.57	10.285	2.4
0.64	10.288	
0.72	10.276	
0.81	10.272	
1.00	10.266	

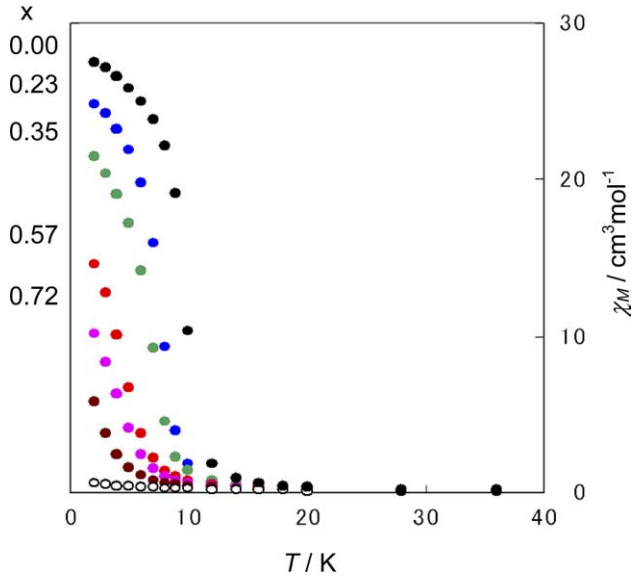

Fig. 2. Temperature dependences of magnetic susceptibility χ_M of solid solutions ($x = 0.0$–1.0).

zation value for $x = 0.0$ is 4.96 $N\beta$ at 5 T, which agrees with the expected value for ferromagnetically coupled one low-spin Fe^{III} ($S = 1/2$) and two Ni^{II} ($S = 1$) ions. The ferromagnetic interaction is explained by strict orthogonality of the magnetic orbitals of the adjacent Fe^{III} and Ni^{II} ions. The saturation value decreases down to 4.02 $N\beta$ with increasing x value. The phase transition temperature (T_c) was confirmed by weak field magnetic studies and AC susceptibility measurements. Compounds with $x > 0.64$ show no magnetic phase transition above 2 K. The phase transition temperature, T_c, decreases and the shapes of χ' versus T and χ'' versus T plots sharpens with increase of x value (Fig. 3).

These results also suggest the statistical dispersion of $[Co(CN)_6]^{3-}$ into the 2-D grid sheet and fragmentation of $Fe^{III}Ni^{II}$ magnetic domain structure by diamagnetic Co^{III} ions. Critical point for vanishing the spontaneous magnetization was estimated at $x = 0.76$ by linear extrapolation. On the other hand, theoretical critical value for 2-D bond percolation model is 0.5. The increase of critical value can be explained that the paramagnetic Ni(II) ions always exist in the 2-D grid independent of x values. Assembly with $x = 0.64$ shows a frequency

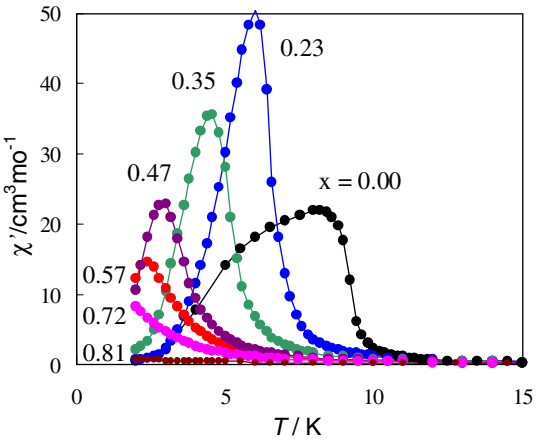

Fig. 3. χ' vs. T plots of solid solutions ($x = 0.0$–1.0).

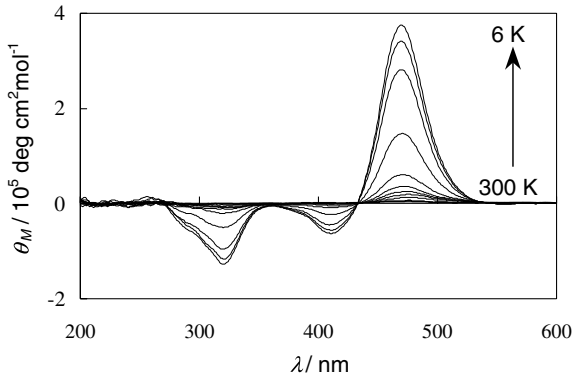

Fig. 4. Temperature dependence of Faraday ellipticity spectra of FeNi assembly ($x = 0.0$) under the external magnetic field of 200 G.

dependence in ac susceptibility. This behavior can be regarded as magnetically disordered state, spin-glass, originated from reduction of magnetic cluster size, though its magnetic relaxation behavior was not completely simulated by theoretical equation.

3.4. Magneto-optical properties

Temperature dependence of MCD spectra for compound with $x = 0.0$ under 200 G is given in Fig. 4. With decreasing temperature the molar Faraday ellipticity θ_M values around 470, 407 and 318 nm are enhanced. Especially, the θ_M value at 470 nm increased more than 100 times after magnetic phase transition. These results indicate that the MCD around 470 nm is associated with the ligand-to-metal charge transfer (LMCT: $^2T_{1u}$ (σ t_{1u}) $\rightarrow$ $^2T_{2g}$ (Fe t_{2g})) band of Fe–CN [18]. The θ_M versus T plots show a sharp increase at 9 K ($\approx T_c$), and this behavior is in harmony with χ_M versus T plots. The large enhancement in the Faraday ellipticity evidently arises from the ferromagnetic ordering over the lattice. The d-d transition bands of Fe(III) and Ni(II) show negligible contribution for θ_M, because the intensity of Laporte-forbidden d-d transition is quite weaker than that of Laporte-allowed LMCT band.

Faraday ellipticity remarkably decrease with the increase of x value (Fig. 5). The reasons of the decrease are explained as follows:

1. Decrease of magnetization value due to the increase of diamagnetic ratio and the fragmentation of magnetic domain.
2. Decrease of LMCT band of Fe–CN having large absorption coefficient.

The maximum value of Faraday ellipticity of CoNi assembly ($x = 1.0$) is less than 1/10 000 of FeNi assembly ($x = 0.0$), because it is a paramagnet and its LMCT is very weak.

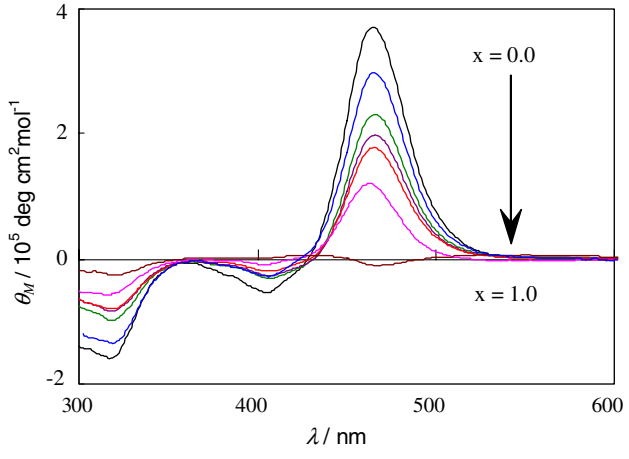

Fig. 5. Faraday ellipticity spectra of solid solution ($x = 0.0$–1.0).

4. Conclusion

Eleven $Fe_{(1-x)}^{III}Co_x^{III}Ni^{II}$ solid solutions, $\{[Ni(1,1\text{-dmen})_2]_2[Fe_{(1-x)}Co_x(CN)_6]\}tfs \cdot nH_2O$, have been prepared as crystals and evaluated their magnetic and magneto-optical properties systematically. They formed same two-dimensional grid sheet structure with statistical dispersion of $[Fe(CN)_6]^{3-}$ and $[Co(CN)_6]^{3-}$ units. Magnetic phase transition temperature T_c and molar Faraday ellipticity θ_M values decrease with increasing x value because of the fragmentation of magnetic domain by diamagnetic Co^{III} ions. Construction of magnetically disordered states in ordered crystal structures and modulation of magneto-optical properties were achieved by insertion of diamagnetic $[Co(CN)_6]^{3-}$ unit into $Fe^{III}Ni^{II}$ ferromagnetic framework. Compounds with large x value ($x > 0.64$) potentially show spin-glass or quantum magnet-like behavior based on nano-sized-domains generated by the fragmentation. Studies on magnetic and magneto-optical properties of the trimetallic compounds are under way together with related compounds.

Scheme 1.

comparison with the spin-ladder salt of (anilinium)([18]crown-6)[Ni(dmit)$_2$] (**C**). The slight change of supramolecular cation caused a large change in magnetic properties (see Scheme 1).

2. Experimental

Single crystals of **A** and **B** were prepared by a slow diffusion method in acetonitrile. Crystallographic data were collected by a Rigaku Raxis-Rapid diffractometer using Mo Kα (λ = 0.71073 Å) radiation from a graphite monochromator. The space groups of salts **A** and **B** were $P\bar{1}$. Cell parameters of salt **A**: a = 13.489(2) Å, b = 12.642(2) Å, c = 10.893(1) Å, α = 77.213(5)°, β = 75.079(3)°, γ = 80.564(4)°, V = 1739.1(3) Å^3, salt **B**: a = 13.4729(9) Å, b = 12.6900(7) Å, c = 11.2143(5) Å, α = 75.331(1)°, β = 74.668(2)°, γ = 82.044(2)°, V = 1783.6(2) Å^3. The temperature dependent magnetic susceptibility was measured using a Quantum Design MPMS-XL SQUID magnetometer for polycrystalline samples. Static magnetic susceptibilities were measured in an applied magnetic field of 1 T for all samples.

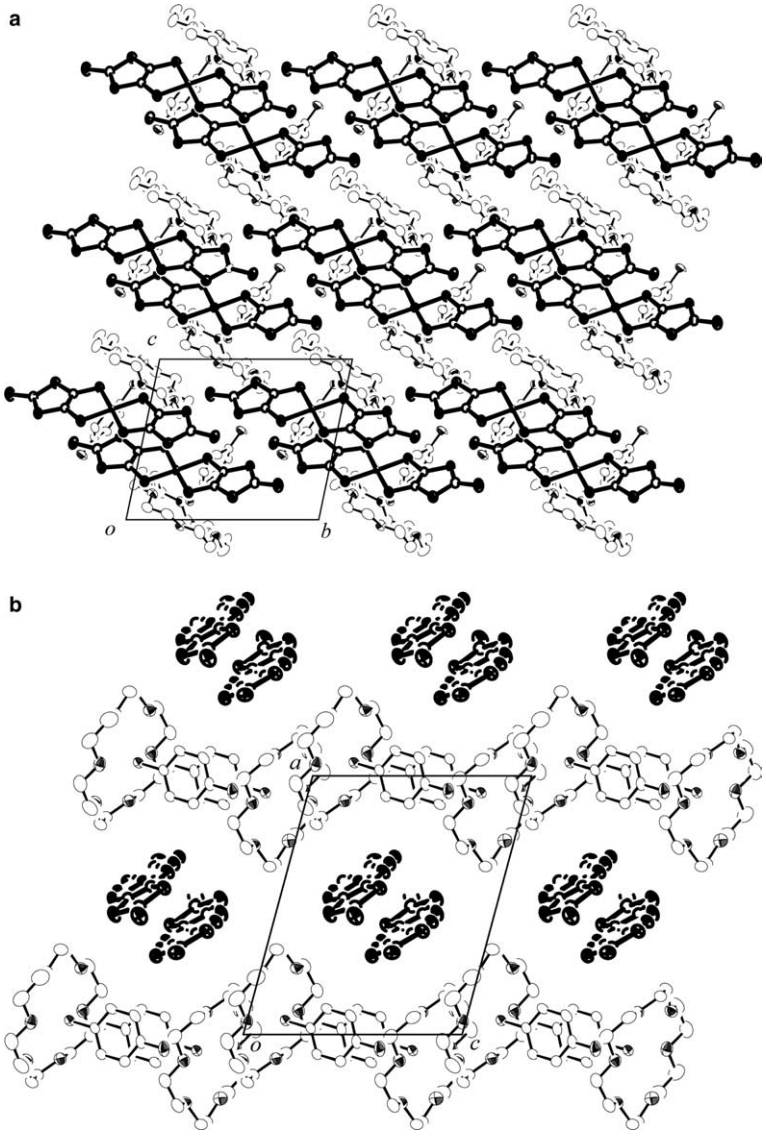

Fig. 1. Crystal structure of (4-fluoroanilinium)([18]crown-6)[Ni(dmit)$_2$] (**A**) viewed along the (a) a- and (b) b-axis.

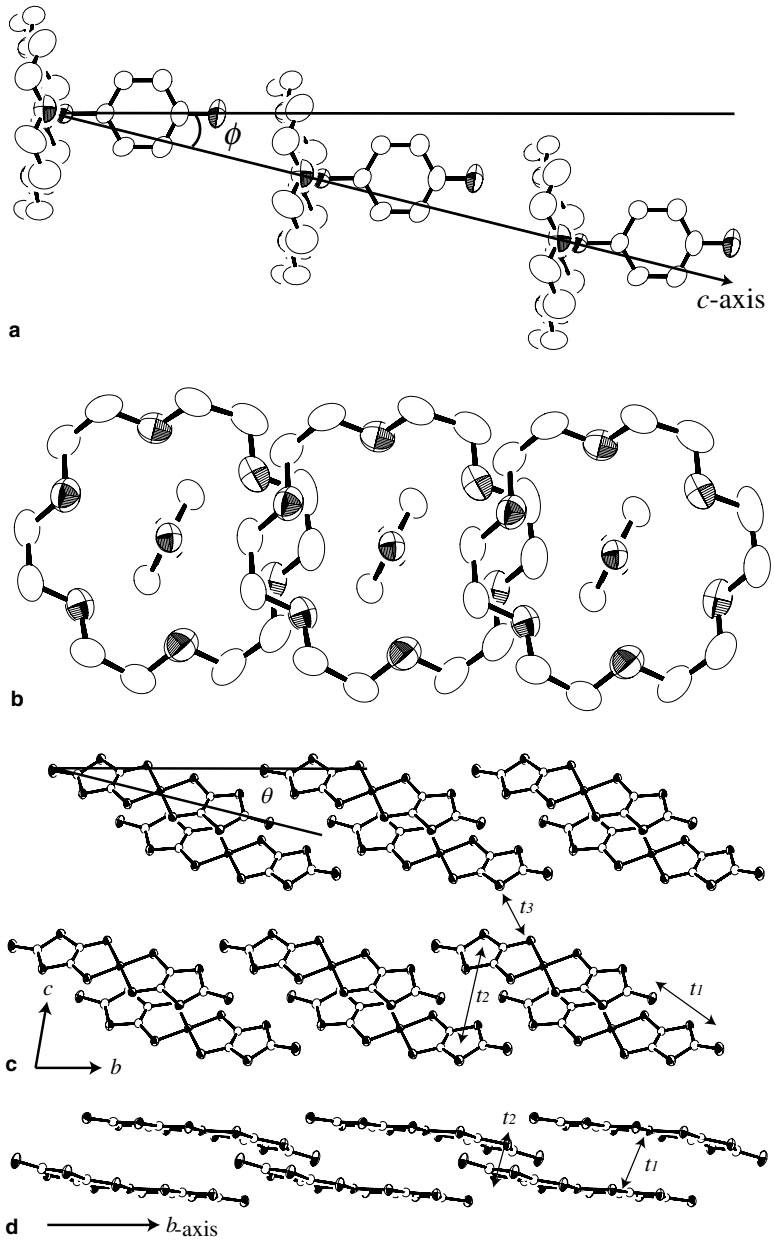

Fig. 2. Supramolecular cation structure of the salt **A** viewed along the (a) *b*- and *c*-axis. One-dimensional arrangement of $[Ni(dmit)_2]^-$ π-dimers in the salt **A** viewed along the (c) *a*- and (d) *c*-axis.

3. Results and discussion

Fig. 1 shows the crystal structure of salt **A**, which was isomorphous to that of salt **B**. In both salts, ammonium moiety of 4-fluoro- and 4-methyl-anilinium cations was completely included into the cavity of [18]crown-6 by hydrogen bonding (N–H···O). The hydrogen bonding lengths between nitrogen atom of ammonium unit and oxygen atom of crown ether were 2.884(7)–2.958(9) and 2.80(1)–2.99(1) Å in salt **A** and **B**, respectively, which are in the range of ordinary N–H···O length (2.87 Å) [13]. The arrangements of supramolecules are shown in Fig. 2(a) and (b). Each cation was regularly stacked along the *c*-axis, which formed cation layer within the *bc*-plane. The cation layers were separated by the $[Ni(dmit)_2]^-$ anion layers along the *a*-axis.

Fig. 2(c) and (d) show the $[Ni(dmit)_2]^-$ arrangements and intermolecular interactions modes between $[Ni(dmit)_2]^-$ anions. The $[Ni(dmit)_2]^-$ molecules formed the π-dimer, which arranged along the *b*-axis. The absolute magnitude of intermolecular interactions were evaluated from the transfer integrals between $[Ni(dmit)_2]^-$ molecules by using extended Hückel molecular orbital calculations [14]. The most effective interactions in the salts **A** and **B** were observed as the intradimer interaction of $t_{A1} = 80.7$ and $t_{B1} = 82.9$ meV, respectively. The

interdimer interactions along the *b*-axis of salts **A** and **B** were $t_{A2} = 17.3$ and $t_{B2} = 13.3$ meV, respectively, while the interchain interactions along the *c*-axis were observed as $t_{A3} = 8.7$ and $t_{B3} = 18.9$ meV, respectively. Since the magnetic exchange interaction (J) is proportional to the square of transfer integral (t^2), the ratio between the intradimer and interdimer magnetic exchange interactions (J_{intra}/J_{inter}) of salts **A** and **B** were estimated as 22 and 19, respectively. Large magnetic anisotropies of the J_{intra} and J_{inter} values suggest that the magnetic behaviour is governed by that of π-dimer of $[Ni(dmit)_2]^-$.

Fig. 3 shows the temperature dependent magnetic susceptibilities of salts **A** and **B**. Curie impurities of 3.93×10^{-3} and 2.01×10^{-3} emu K mol^{-1} for salts **A** and **B**, respectively, have been subtracted. The temperature dependent magnetic susceptibilities of salts **A** and **B** showed a broad maximum around 100 and 115 K, respectively. These magnetic behaviours have been typically observed in materials with the magnetic ground state of spin singlet. Since the crystal structures of salts **A** and **B** suggested that the π-dimer structure govern the magnetic behaviour, the singlet–triplet thermal excitation model,

$$\chi = \frac{C}{T}\frac{4\exp(-2J/k_BT)}{1+3\exp(-2J/k_BT)},$$

was applied for fitting the magnetic susceptibilities of salts **A** and **B**. Fixed Curie constants (C) of 0.394 emu K mol^{-1} ($g = 2.0500$) was employed the fitting [5,6]. The intradimer magnetic exchange energy ($2J/k_B$) of salts **A** and **B** were estimated to be −160 and −170 K, respectively, from the fitting. Similar $2J/k_B$ values of salts **A** and **B** consistent with the magnitude of the calculated intradimer transfer integrals ($t_{A1} = 80.7$ and $t_{B1} = 82.9$ meV).

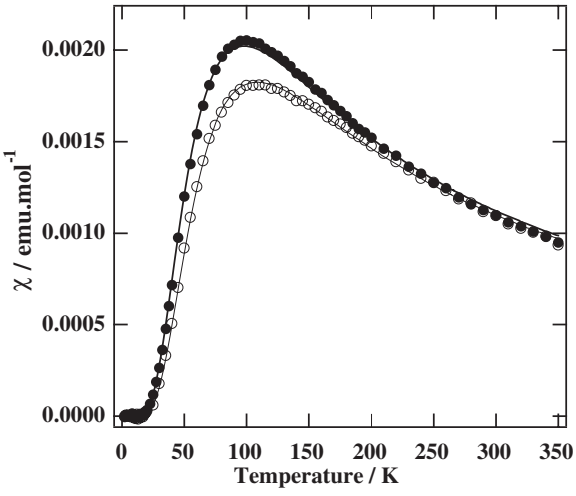

Fig. 3. Temperature dependent molar magnetic susceptibilities of the salts **A** (●) and **B** (○). The solid curves are a fit of the singlet–triplet thermal excitation model (see text).

The crystal structures of salt **A** and **B** are slightly different from the salt **C**, in which the anilinium moiety in supramolecular cation has no substitute at *para* position. However, the magnetic behaviours are large different to each other. The structural parameter of the angle (ϕ) between the C–N bond of anilinium cation and the *c*-axis is a good measure of the structural change in cation arrangement (see Fig. 2(a)). The magnitude of ϕ for salts **A** and **B** were 30.3° and 28.6°, respectively, while the angle ϕ for spin-ladder salt **C** ($\phi = 5.22°$) was much smaller than those of salts **A** and **B**.

The substitution of fluorine atom and methyl group expands the supramolecular cation structure, which caused the distorted stacking of supramolecular cation along the *c*-axis advantage as for the dense packing of cations. The cation arrangements in the *bc*-plane affected the $[Ni(dmit)_2]^-$ arrangement to form isolated dimers rather than dimer chains observed in the salt **C**. As a result, the angles between the long axis of $[Ni(dmit)_2]^-$ and the *b*-axis (θ) of salts **A** and **B** become 24.5° and 24.6°, respectively, which is much large than that of salt **C**. The large angle of θ distorted the stacking of $[Ni(dmit)_2]^-$ molecules along the *b*-axis preventing the interdimer interactions in salts **A** and **B** along ladder-leg direction, which is one of the most important interactions for spin ladder structure.

4. Summary

In conclusion, two supramolecular cations of (4-fluoroanilinium)([18]crown-6) and (4-methylanilinium)([18]crown-6) were introduced into the magnetic $[Ni(dmit)_2]^-$ salts. Basic $[Ni(dmit)_2]^-$ arrangement within the crystals was π-dimer, which arranged along the *b*-axis. The formations of magnetically isolated π-dimer were confirmed by temperature dependent magnetic susceptibility and calculations of intermolecular transfer integrals.

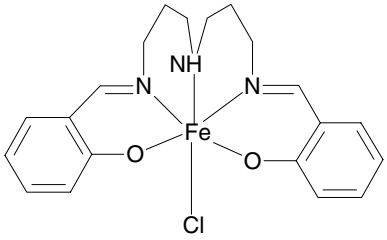

Fig. 1. Structure of the [Fe(^{5}L)Cl] precursor.

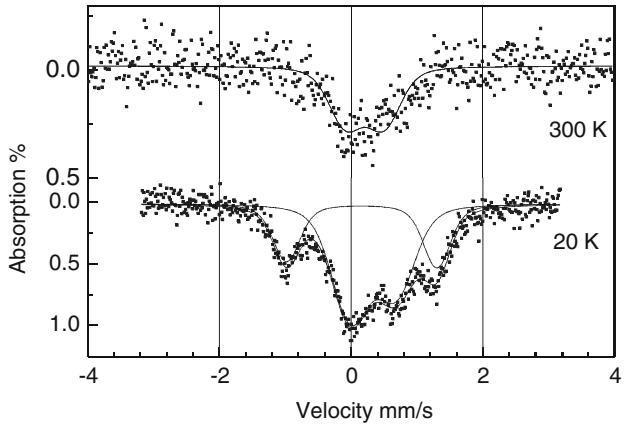

Fig. 2. Mössbauer spectra of the nonanuclear complex [Mo^{IV}{(CN)-$Fe^{III}(^5L)$}$_8$]Cl_4 at 300 and 20 K.

The Mössbauer parameters of Co-star and the Mo-star in comparison with the mononuclear precursor clearly indicate coordination. Apparently the Mo-star deviates much stronger in isomer shift and quadrupol splitting than the Co-star. This is attributed to the sterical possibilities in the heptanuclear and nonanuclear structure.

The hepta- and nonanuclear star-complexes have been characterized by IR spectrum. No evidence for a splitting of the characteristic C–N stretching vibration band indicates a highly symmetric coordination sphere around the central Co(III) and Mo(IV) metal centers, i.e., either all or no cyanides are bridged. The shift of the CN-band from 2200 to 2129 cm^{-1} indicate a bridge. This confirms the conclusion indicated by Mössbauer spectroscopy.

At 20 K in both Co- and Mo-star in addition to the Fe(III) in the high-spin state a second doublet appears which is characteristic for an Fe(III) in the low-spin state [16].

This indicates that in the heptanuclear complex [Co^{III}{(CN)$Fe^{III}(^5L)$}$_6$]Cl_3 clearly a thermally induced transition between an HS to LS state exists. The area fraction of the respective doublets A(Fe^{III}-high-spin):A(Fe^{III}-low-spin) is 65.7:34.3. For the nonanuclear complex [Mo^{IV}{(CN)$Fe^{III}(^5L)$}$_8$]Cl_4 clearly this indicates a thermally induced transition between a high-spin and low-spin state. The area fraction of the respective doublets A(Fe^{III}-high-spin):A(Fe^{III}-low-spin) is 68:32.

In both cases, several Fe(III) centers exhibit electronic switching. This enables us to talk about a multiple electronic transition. This is the first example for electronic switching in a hepta- and nonanuclear complex compound.

Magnetic investigations are in progress and will further resolve the switching in our stars. The difficulties in the evaluation of the magnetic properties, such as coupling, in pure high-spin compounds usually rises, at least exponentially, with the number of spin centers in the molecule. Now the hepta- and nonanuclear-stars exhibit on top of the usual high-spin problems they change to different total high-spin states as a function of temperature.

The technological transfer from the molecular switchability in mononuclear spin transition to multinuclear systems has been achieved. The hepta- and nonanuclear star-shaped compounds open a new dimension and new synergism will be on our road.

2. Experimental

2.1. Ligand $^5LH_2$ and precursor [Fe(^{5}L)Cl]

Ligand $^5LH_2$ and precursor [Fe(^{5}L)Cl] are prepared as described in the literature [10]. The powder was characterized by its IR spectrum and mass spectrum (m/z: 393.1; FeL^+). The precursor $K_4[Mo(CN)_8]\cdot 2H_2O$ was prepared in analogy to Furman and Miller [15]. Yield

Table 1
Mössbauer parameters of the heptanuclear complex [Co^{III}{(CN)$Fe^{III}(^5L)$}$_6$]Cl_3 and nonanuclear complex [Mo^{IV}{(CN)$Fe^{III}(^5L)$}$_8$]Cl_4 at 300 and 20 K

Temperature (K)	Fe(III) HS state			Fe(III) LS state		
	δ (mm/s)	Δ (mm/s)	Fraction (%)	δ (mm/s)	Δ (mm/s)	Fraction (%)
[(^{5}3,3-LFeNC)$_8$Mo]Cl_4

300	0.278	0.775	100			
20	0.356	0.7	65.7	0.267	2.47	34.3

(after double recrystallization): 18.3% rel. to Mo (3.2 g; 6.4 mmol). *Anal*. Calc. for $C_8H_4K_4MoN_8O_2$: C, 19.31; N, 22.60; H, 0.80. Found: C, 19.25; N, 23.15; H, 1.08%. IR(KBr): $\nu(cm^{-1}) = 3400–3600\ cm^{-1}$ (water), 2050–2200 cm^{-1} (C≡N, val.; splitted), 1617 cm^{-1} (water), 496 cm^{-1} (Mo–C, val.).

2.2. Heptanuclear complex $[Co^{III}\{(CN)Fe^{III}(^5L)\}_6]Cl_3$

Heptanuclear complex $[Co^{III}\{(CN)Fe^{III}(^5L)\}_6]Cl_3$ is prepared in analogy to the literature [10]. Yield: 380 mg = 0.012 mmol, 85% based on Co. Elemental *Anal*. Calc. for $C_{126}H_{138}Cl_3CoFe_6N_{24}O_{12}$: C, 56.45; N, 12.54; H, 5.19. Experimental: C, 49.88; N, 11.35; H, 6.17%. IR (KBr): $\nu(cm^{-1}) = 3422\ cm^{-1}$ (N–H, val.), 2930 cm^{-1} (CH_2, val.), 2142 cm^{-1} (C≡N, val.), 1625 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.3. Nonanuclear complex $[Mo^{IV}\{(CN)Fe^{III}(^5L)\}_8]Cl_4$

Nonanuclear complex $[Mo^{IV}\{(CN)Fe^{III}(^5L)\}_8]Cl_4$ is prepared in analogy to the literature [10]. Yield 35% rel. to Mo. *Anal*. Calc.: $C_{168}H_{184}Cl_4Fe_8MoN_{32}O_{16}$: C, 56.18; N, 12.48; H, 5.16. Found: C, 51.43; N, 13.37; H, 5.73%. Note that low carbon content is commonly observed and based on incomplete decomposition to CO_2 due to formation of very stable metal carbides. This is supported by mass spectroscopy: FD MS $m/z = 393.8$ (59.96%, $[^5$3,3-LFe$]^+$); MALDI TOF $m/z = 392.9$ (95%, $[^5$3,3-LFe$]^+$). IR (KBr): $\nu(cm^{-1}) = 3420\ cm^{-1}$ (N–H, val.), 2925 cm^{-1} (CH_2, val.), 2129 cm^{-1} (C=N, val.; single), 1628 cm^{-1} (C=N, val.), 1600–1500 cm^{-1} (aromat. C=C, val.), 760–750 cm^{-1} (C–H, o. o. p.).

2.4. Mössbauer spectroscopy

Mössbauer spectroscopy is performed in a conventional spectrometer in scanning the Mössbauer spectra at 20 K and room temperature (^{57}Co/Rh source kept at room temperature; isomeric shifts are relative to the source).

After the discovery of light induced excited spin state trapping (LIESST) [15], a number of investigations of the metastable photo-excited HS states have been studied. There the relaxation curves of HS fraction show a typical sigmoidal shape, associated with "self-accelerated" relaxation [16–18]. A dynamical mean-field treatment [21,22] of Wajnflasz and Pick [19,20] with the Arrhenius transition probability reproduced well this behavior, which gives the microscopic origin of the Hauser's formula [16–18].

Relaxation curve of the HS fraction from the photo-excited HS states with the two-step relaxation was observed recently [6]. The first fast relaxation and next slow relaxation, which cannot be explained by the mean-field (MF) theory. We reproduced this two-step relaxation by a Monte Carlo (MC) method [23].

In this paper, we present the equilibrium properties with a variety of two-step phase transition and the non-equilibrium properties with the two-step relaxation of the HS fraction using a MC method.

2. Models and methods

We consider the model introduced by Bousseksou et al. [8], which is an extension of the Wajnflasz and Pick (WP) [19–22,24] model to the case of the two-equivalent sublattices coupled 'antiferromagnetically'

$$\hat{H} = -J^{AA}\sum_{\langle i\in A, j\in A\rangle} S_i^A S_j^A - J^{BB}\sum_{\langle i\in B, j\in B\rangle} S_i^B S_j^B - J^{AB}\sum_{\langle i\in A, j\in B\rangle} S_i^A S_j^B + \Delta\sum_i \left(S_i^A + S_i^B\right),$$
$$S_i = \underbrace{-1,\ldots,-1}_{u},\ \underbrace{1,\ldots 1}_{r}, \tag{1}$$

where the states $S = -1$ and 1 denote the LS and HS states, respectively. J^{AA} and J^{BB} are the 'ferromagnetic' ($J^{AA} > 0$, $J^{BB} > 0$) intrasublattice interactions and J^{AB} is the AF ($J^{AB} < 0$) intersublattice interaction.

The potential energy of the LS and HS states is shown schematically in Fig. 1(a). The degeneracy u and r for the LS and HS state comes from the angular momentum, the spin momentum, the molecular vibration and the phonon degrees of freedom. The parameter Δ is the ligand-field energy. Here, we assume that Δ is the same for the two sublattices. The 'NaCl' lattice structure (fcc) for the two sublattices A and B is considered (Fig. 1(b)). Thus, the coordination numbers between and within sublattices are given by $z_{AB} = 6$ for A–B bonds and $z_{AA} = z_{BB} = z = 12$ for A–A and B–B bonds.

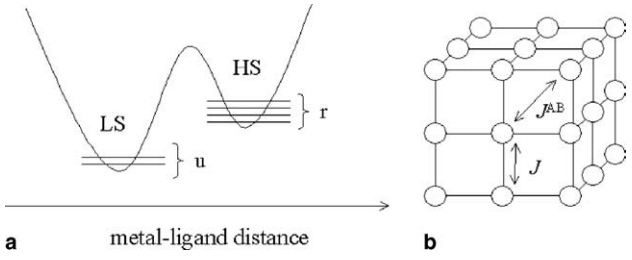

Fig. 1. (a) Schematic diagram of the potential energy of the LS and HS states. The degeneracy of LS state and HS state is taken into account. The axis denotes metal–ligand distance. (b) The model (fcc lattice) with coupling $J(>0)$ and $J^{AB}(<0)$.

We consider the case of equivalent sublattices, then we take $J^{AA} = J^{BB} = J$. Using a temperature dependent field, this model can be expressed formally as follows [21,22]:

$$\hat{H} = -J\sum_{\langle i\in A, j\in A\rangle} S_i^A S_j^A - J\sum_{\langle i\in B, j\in B\rangle} S_i^B S_j^B - J^{AB}\sum_{\langle i\in A, j\in B\rangle} S_i^A S_j^B + \left(\Delta - \frac{\ln g}{2\beta}\right)\sum_i \left(S_i^A + S_i^B\right),$$
$$\text{with } g = \frac{r}{u}, \quad \beta = \frac{1}{k_B T}, \tag{2}$$

where the degeneracy effect is renormalized into the parameter g. The degeneracy ratio g increases up to 100–1000 and becomes temperature-dependent [21,22]. However, for simplicity, we take $g = 100$. The parameter Δ is set as $\Delta = 400$ K, which gives a realistic order of magnitude for the transition temperature.

In order to study the dynamical properties of the system, we use the general master equation

$$\frac{d}{dt}P(S_1\cdots S_k\cdots S_N, t) = -\frac{1}{\tau}\sum_k\sum_{S_k\neq S_k'} W_k(S_k\to S_k')P(S_1\cdots S_k\cdots S_N, t) + \frac{1}{\tau}\sum_k\sum_{S_k\neq S_k'} W_k(S_k'\to S_k)P(S_1\cdots S_k'\cdots S_N, t), \tag{3}$$

where $P(S_1\cdots S_k\cdots S_N, t)$ is the probability of the state $\{S_1\cdots S_k\cdots S_N\}$ at time t and $W_k(S_k\to S_k')$ is the transition probability at the kth site.

We adopt the Arrhenius dynamics, which is suitable to describe experimental data for the relaxation process from the HS state [21,22]. The transition probability is given by

$$\frac{1}{\tau}W_k(S_k\to S_k') = \frac{1}{2\tau_0}\exp(-\beta(E_0 + S_k y)), \tag{4}$$

where S_k is one of the states (± 1) and S_k' is the other state ($S_k' \neq S_k$) and $y = J\sum_A S^A + J^{AB}\sum_B S^B - \Delta + \frac{\ln g}{2\beta}$. Here, E_0 denotes an intramolecular energy barrier, and τ_0 is a quantity related to the time scale. We take $\tau_0 = 1$.

The system has two intrinsic order parameters. One is the fraction of HS molecules defined by

$$f_{HS} = \frac{m_F + 1}{2}. \tag{5}$$

Here, we define the quantity $m_F = \frac{m_A + m_B}{2}$, where the magnetization $m_A = \frac{1}{N}\sum_{i\in A}\langle S_i^A\rangle$ and $m_B = \frac{1}{N}\sum_{i\in B}\langle S_i^B\rangle$ are

the net 'magnetization' per site in the sublattices A and B, respectively. N is the number of all A and B sites, and $\langle\cdots\rangle$ denotes the thermodynamical average. The magnetization m_{F} expresses the degree of 'ferromagnetic' order (i.e., HS–HS, or LS–LS) and f_{HS} takes a value between 0 and 1. The other order parameter is given by

$$m_{\mathrm{AF}} = \frac{m_{\mathrm{A}} - m_{\mathrm{B}}}{2}. \tag{6}$$

This order parameter expresses the degree of the 'antiferromagnetic' (i.e., LS–HS or HS–LS) order.

3. Static and dynamical properties

Two-step phase transitions by the MC method are shown in Fig. 2. The temperature dependence of the HS fraction is shown in Fig. 2(a) and the temperature dependence of AF order parameter is shown in Fig. 2(b). Here, 10 000–50 000 MC steps are taken as waiting time to make the system reach the equilibrium state, and then we perform 10 000–50 000 MC steps for measuring the thermodynamical quantities (f_{HS}). The parameter J^{AB} is set as $J^{\mathrm{AB}} = -12$ K and J is changed as $J =$ 40 K (○), 16 K (◇), and 12 K (×).

The system size is $L^3 = 20^3$. In the low temperatures the system is in the LS phase (all down state) as depicted in Fig. 2 (c)-(I). As the temperature is increased, a transition occurs and f_{HS} reaches the value $f_{\mathrm{HS}} = 1/2$. Then a plateau region appears and the other transition occurs leading to the HS phase (Fig. 2(c)-(III)). This plateau region shows the presence of the phase of the AF order as depicted in Fig. 2(c)-(II). Here, we find three typical two-step transitions: (i) first-order transition at the lower transition temperature and first-order transition at the higher transition temperature as the case $J = 40$ K; (ii) first-order transition at the lower transition temperature and gradual transition at the higher transition temperature as the case $J = 16$ K; (iii) gradual transition at the lower transition temperature and gradual transition at the higher transition temperature as the case $J = 12$ K.

In the following, we discuss the condition of these three cases [6,23]. We define T_{C} as the critical temperature of 3D fcc Ising model, which is given by $T_{\mathrm{C}} = 9.79524\,J$ [25]. Here, we also define T_{C1} and T_{C2} as

$$T_{\mathrm{C1}} = \frac{2\Delta - 2z_{\mathrm{AB}}|J_{\mathrm{A}}|}{k_{\mathrm{B}} \ln g} \quad \text{and}$$
$$T_{\mathrm{C2}} = \frac{2\Delta + 2z_{\mathrm{AB}}|J_{\mathrm{AB}}|}{k_{\mathrm{B}} \ln g}. \tag{7}$$

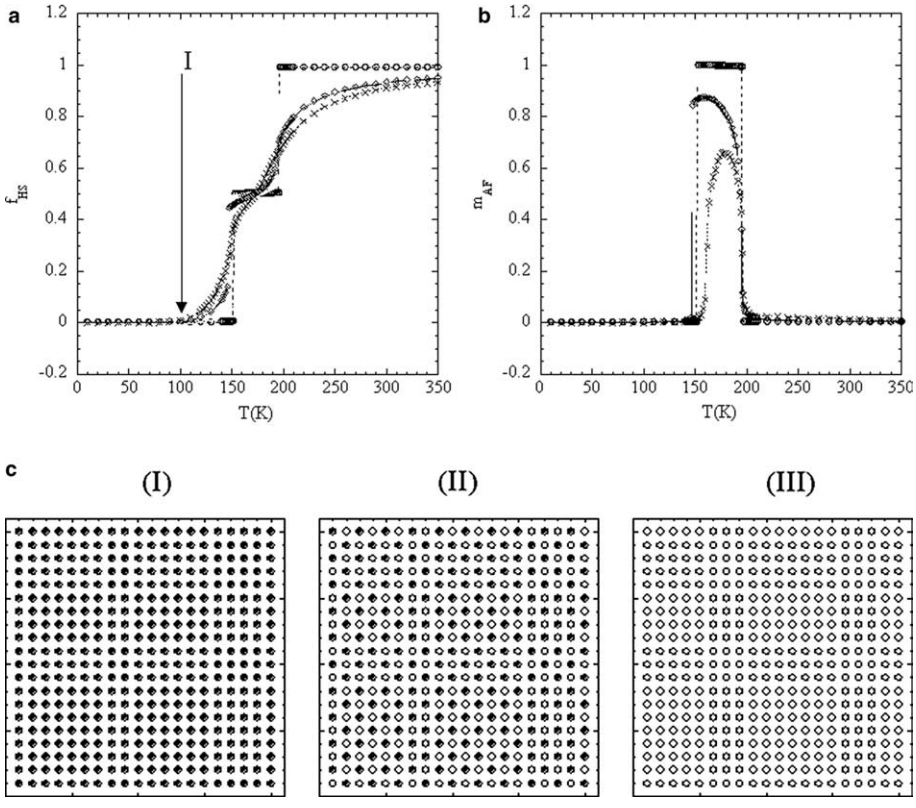

Fig. 2. (a) Temperature dependence of f_{HS} of two-step transitions. $J^{\mathrm{AB}} = -12$ K. $J = 40$ K (○), 16 K (◇), and 12 K (×). The point I is the initial point of the relaxation dynamics. (b) Temperature dependence of the m_{AF} of two-step transitions. (c) Ordered states on the x–y (or y–z) plane of the lattice. (I) LS phase, (II) AF phase, and (III) HS phase.

The temperatures T_{C1} and T_{C2} correspond to the transition temperatures of sharp double first-order transitions [6,23]. Which type of transition occurs depends on values of T_C, T_{C1} and T_{C2}.

When $T_{C1} < T_{C2} < T_C$, first-order transition occurs twice. When $T_{C1} < T_C < T_{C2}$, a first-order transition occurs at T_{C1}, while a gradual transition occurs around T_{C2}. When $T_C < T_{C1} < T_{C2}$, two successive gradual transitions occur.

Next, we study the relaxation dynamics from the HS phase. We investigate the case of $J = 40$ K, in which a strong metastable AF phase exists in the low-temperature region near the lower transition temperature. We take the saturated HS state ($f_{HS} = 1$) at $T = 105$ K as the initial state depicted by I in Fig. 2(a) and observe the relaxation to the LS state.

Relaxation curves of the two order parameters f_{HS} and m_{AF} are observed, respectively, in Fig. 3(a) and (b). The bold line is the average relaxation curve obtained by sampling of 10 independent processes with different sequences of random numbers. We found that the relaxation process consists of two distinct regimes. Fast relaxation with a sigmoidal (convex) shape takes place from the saturated HS fraction ($f_{HS} = 1$) to half of it ($f_{HS} \simeq 0.5$), and slow concave relaxation to the LS phase ($f_{HS} = 0$) follows. The former relaxation with a sigmoidal shape occurs from the HS to AF state and this is due to the Arrhenius dynamics. On the other hand the latter relaxation is that from the AF to LS state. Because the AF state is a strong metastable state, this relaxation is governed by the nucleation process [23].

From the view point of the most probable path (MPP) on the mean-filed free energy, a potential barrier exists between the AF and LS states as we found in the contour diagram before [23]. There the relaxation from the metastable AF phase to LS phase depends on the energy barrier height and temperature. When the thermal fluctuation overcomes this potential energy barrier, relaxation to the LS state occurs.

In Fig. 3(c), an example of nucleation of the LS state in the AF phase is shown. The nucleation process occurs stochastically and the time of the jump is distributed widely as the Poisson process [26]. As a result, the sample-averaged relaxation shows an exponential (concave) relaxation. This shape agrees with the experimental result very well [6]. The mean field theory [6] does not reproduce concave relaxation but convex relaxation where the thermal fluctuation is not taken into account. The introduction of short-range correlations by different analytical methods [27] leads to obtain long tail behavior [28,29] In Fig. 3(a), the thin lines are examples of relaxation with different sequences of random numbers. The upper thin solid line shows a case where the state stays long in the metastable AF state. Here, the concave relaxation curve is observed, which is similar to that obtained by the mean-filed results. On the other hand, the AF state lives in a very short period in the case of the lower thin line.

4. Summary and discussion

We have investigated the static and dynamical properties of the two-step spin-crossover compounds. Using an extended WP-model which consists of two-equivalent sublattices with an intra- ('ferro') interaction and an inter- ('antiferro') sublattice interaction, we present several types of two-step transitions. It was found with this model that basically there exists three types of two-step transitions. In the first case, a first-order transition occurs twice. In the second case, a first-order transition occurs at the lower transition temperature and a gradual transition occurs at the higher transition temperature. In the third case two successive gradual transitions occur. The condition for three types of the two-step transition was also given.

We have studied the relaxation from the fully saturated HS state, which simulates the relaxation from the photo excited saturated high spin state. It was found that the relaxation of the HS fraction consists of two parts. First, fast relation from the HS to AF state occurs. A sigmoidal shape is reproduced in the initial stage

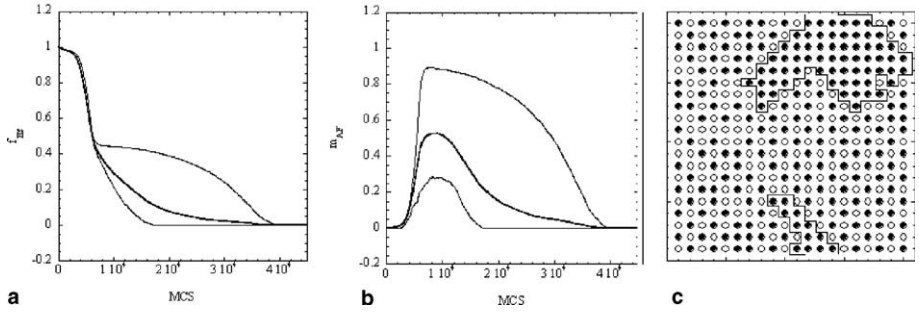

Fig. 3. (a) Relaxation of f_{HS} at $T = 105$ K. The bold line is the average of 10 samples. Thin solid lines are examples of one randon number sequence. (b) Relaxation of m_{AF} at $T = 105$ K. The bold line is the average of 10 samples. Thin solid lines are examples of one randon number sequence. (c) Droplet of the LS state (•) in the AF phase.

of the relaxation, which is typical in relaxations of spin-crossover compounds in experiments. This sigmoidal shape is due to the Arrhenius transition probability in the Monte Carlo simulation as has been pointed out in the mean-field theory [6].

Following the fast relaxation, the slow relaxation from the AF to LS state occurs. When a droplet of the LS state grows in the AF phase and the size of the droplet becomes over the critical droplet, nucleation occurs, which is a stochastic process. If the nucleation rate is low, the stochastic single-nucleation process appears where the AF state relaxes to the LS state suddenly as a Poisson process. On the other hand, if the nucleation rate is high the system shows the multi-nucleation (Avrami) relaxation. They give concave slow relaxation as the average process. This two-step relaxation, i.e., fast sigmoidal and slow exponential relaxation, agree with that found in the experiments [6] very well.

We discussed here the dynamics only focusing on the relaxation from the HS state. Elucidation of various dynamical aspects by photoinduced phenomena [30,31] would be an important problem in the future. In the case of simple spin models as the present treatment, the stable state relaxes rather fast through the local nucleation. More realistic treatment of the elasticity would be a key to investigate a large scale separation of the phases which was observed in the experiment [32].

approximation were revealed by accurate measurements on spin transition solids, resulting in a moderate increase of the quantum yield along the photo-excitation process [9–11]. In case of direct competition between opposite photo-excitation processes, light-induced bistability was even observed [11]. However such a non-linear effect will be discarded here, because of the prominent role of the non-linear relaxation;

(ii) the high-spin (HS) towards low-spin (LS) relaxation is a cooperative process [12,13], highly non-linear, leading to typical sigmoidal relaxation curves; the "self-accelerated" character of the relaxation is explained in terms of an internal pressure which is built-up by the depopulation of the metastable HS state, which lowers the E_{HL} barrier energy;

(iii) the thermal effects generated by irradiation are discarded in the present approach.

The assumption of a linear dependence of the barrier energy on the population of the metastable state leads to simple mean-field expressions of the HS → LS cooperative relaxation rate (noted H → L in the following). The present expressions of the H → L and L → H relaxation rates refer to the properties of isolated molecules, obtained when the effects of HS and LS neighbouring molecules cancel each other. The are, respectively, written:

$$k_{HL}(T,n) = k_{HL}(T,1/2)\exp[-\alpha(n-1/2)], \quad (1)$$

$$k_{LH}(T,n) = k_{LH}(T,1/2)\exp[+\alpha(n-1/2)], \quad (2)$$

where $n = n_{HS}$ is the population of the metastable state. The ± signs in the exponential factors result from opposite variations of the E_{HL} and E_{LH} barrier energies driven by the internal pressure effect. The self-acceleration parameter α is associated with steric interactions in the solid. In the thermal activation regime, according to both experiments [14], mean-field [12] and microscopic [15] models, it is written:

$$\alpha = 2zJ/k_BT \quad (3)$$

with z the number of interacting neighbours, and J the intermolecular interaction parameter. Accordingly, the relaxation rates are written:

$$k_{HL}(T,n) = k_\infty \exp(-E_{HL}/k_BT)\exp[-\alpha(n-1/2)], \quad (4)$$

$$k_{LH}(T,n) = gk_\infty \exp(-E_{LH}/k_BT)\exp[+\alpha(n-1/2)] \quad (5)$$

with $g = g_{HS}/g_{LS}$ the "effective" degeneracy ratio of the states, accounting for both electronic and vibrational effects [16].

2. The master equation

In all situations the combination of photo-excitation and relaxation processes governs the evolution of the system. This combination is expressed through the so-called *master equation*, i.e., the evolution equation written in terms of transition rates. The mean-field macroscopic form for a two-state system follows:

$$\begin{aligned} dn/dt = {} & [1-n(t)][I_{LH}\eta_{LH}\sigma_{LH} + k_{LH}(T,n)] \\ & - n(t)[I_{HL}\eta_{HL}\sigma_{HL} + k_{HL}(T,n)], \end{aligned} \quad (6)$$

where $I_{LH}\eta_{LH}\sigma_{LH}$, $I_{HL}\eta_{HL}\sigma_{HL}$ are the photo-excitation terms accounting for light intensities, quantum yields and absorption cross sections. For convenience, we define optical rates in similarity with relaxation rates, and we also use specific notations for the thermal and optical contributions to the master equation:

$$dn/dt = F(n) = F^{therm}(n) + F^{opt}(n), \quad \text{with}$$

$$F^{therm}(n) = [1-n(t)]k_{LH}^{therm}(T,n) - n(t)k_{HL}^{therm}(T,n),$$

$$F^{opt}(n) = [1-n(t)]k_{LH}^{opt} - n(t)k_{HL}^{opt}.$$

It is worth mentioning that the master equation can be used beyond the mean-field approach. In microscopic models, a set of N coupled equations for N microscopic variables has to be solved, see [15] for Ising-like systems.

The master equation provides the description of all static and dynamic properties of the switcheable system: (i) the thermal equilibrium which spontaneously occurs in the dark (including thermal hysteresis), (ii) the low-temperature photo-stationary states (including the light-induced instability and subsequent light-induced hystereses), (iii) intensity thresholds in the case of steady irradiation processes and (iv) temporal evolution for steady and transient thermal and irradiation processes.

3. Master equation approach of the spontaneous spin equilibrium

It is easily shown [15] that the MFMME approach is formally equivalent to the mean-field Ising-like model [17–19] and to the regular solution model in the Bragg approximation [20]. The correspondence relations are $\ln g = \Delta S/R$ and $E_{HS} - E_{HL} = \Delta = \Delta H/R$, where ΔS, ΔH are the molar entropy and enthalpy changes upon L → H spin conversion. The static and photo-stationary processes obey the simple condition $F(n) = 0$, i.e.,

$$F^{therm}(n) = -F^{opt}(n). \quad (7)$$

In the dark Eq. (7) has to be set to zero and leads to the so-called "detailed balance equation"

$$(1-n_{equ})k_{LH}^{therm} = n_{equ}k_{HL}^{therm}, \quad (8)$$

which correlates the ratios of equilibrium populations and of relaxation rates. Straightforward transformation of Eq. (8) leads to

$$\begin{aligned} n_{equ}/(1-n_{equ}) &= k_{LH}^{therm}/k_{HL}^{therm} \\ &= g\exp[-(E_{LH}-E_{HL})/k_BT] \\ &\quad \times \exp[2\alpha(n_{equ}-1/2)], \end{aligned} \quad (9)$$

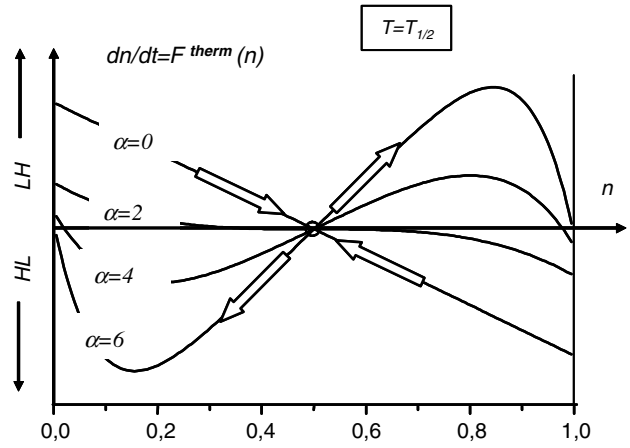

Fig. 1. Spin equilibrium in the dark, in the static MFMME approach: graphical resolution at equilibrium temperature, leading to the instability condition $\alpha > 2$.

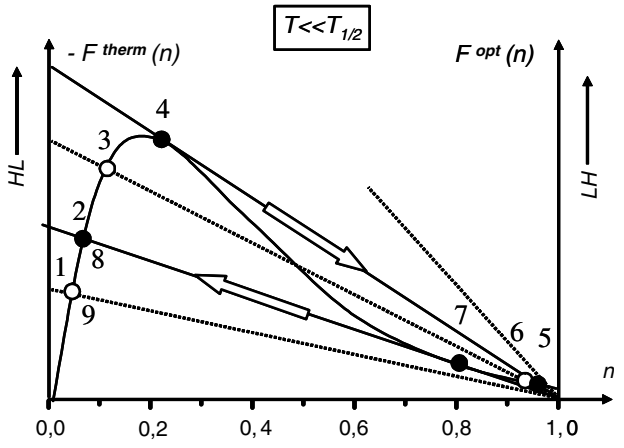

Fig. 2. Light-induced instability in the static MFMME approach, at constant temperature. Straight lines stand for optical terms, at different intensities (slope $-k_{\mathrm{LH}}^{\mathrm{opt}}$). The light-induced optical hysteresis (LIOH) loop is generated along the isothermal sequence $1 \rightarrow 9$. The threshold situations ($\alpha > 4$) are indicated by open arrows.

which becomes at equilibrium temperature $T_{1/2}$ (defined as the spin states equipopulation):

$$T_{1/2} = (E_{\mathrm{LH}} - E_{\mathrm{HL}})/k_{\mathrm{B}} \ln g. \tag{10}$$

Eq. (10) is exactly the mean-field Ising result. We show in Fig. 1 the graphical investigation of the stability of the solution $n = 1/2$ at $T_{1/2}$ using the MFMME approach, as follows:

$$\begin{aligned} \mathrm{d}n/\mathrm{d}t|_{T=T_{1/2}} &= F^{\mathrm{therm}}(n)|_{T=T_{1/2}} \\ &= \{(1-n)\exp[\alpha(n-1/2)] \\ &\quad -n\exp[-\alpha(n-1/2)]\} k_{\mathrm{HL}}(T_{1/2}, 1/2), \end{aligned} \tag{11}$$

which by the way is an odd function of n, centred at $n = 1/2$, represented in Fig. 1. The sense of the spontaneous evolution at the vicinity of $n = 1/2$ is inferred from the sign of the slope of $F(n)$, which is expressed as follows:

$$\mathrm{d}F^{\mathrm{therm}}(n)/\mathrm{d}n|_{n=1/2, T=T1/2} = (\alpha - 2) k_{\mathrm{HL}}(T_{1/2}, 1/2) \tag{12}$$

Instability occurs for a positive slope, leading to the instability condition $\alpha > 2$, equivalent to the mean-field Ising-like result: $zJ > k_{\mathrm{B}} T_{1/2}$.

4. Light-induced instability at low temperature

The low-temperature situation has been already described in [1]. The L → H relaxation can be neglected, as easily seen from Eq. (8). Considering only the L → H optical term, the photo-stationary state Eq. (7) takes the simple form:

$$\begin{aligned} (1-n) k_{\mathrm{LH}}^{\mathrm{opt}} &= (1-n) I_{\mathrm{LH}} \eta_{\mathrm{LH}} \sigma_{\mathrm{LH}} \\ &= n k_{\infty} \exp(-E_{\mathrm{HL}}/k_{\mathrm{B}}T) \exp[-\alpha(n-1/2)], \end{aligned} \tag{13}$$

which provides analytical expressions for $T(n, I)$ and $I(T, n)$ but not for $n(T, I)$. The phase diagram of the photo-stationary states in (T, n, I) space was therefore described analytically. For brevity we refer to [21]; see also [1,22] for light-induced optical hysteresis (LIOH). It is worth noting that the threshold value $\alpha = 4$ for the light-induced instability is twice larger than that derived in Section 3 for the spontaneous instability at $T_{1/2}$. We show in Fig. 2 the graphical determination of the photo-stationary states, in a case which fulfils the instability condition $\alpha > 4$. The solutions are given by the intersects between the curve associated with the relaxation terms, $-F^{\mathrm{therm}}(n)$, and the straight line associated with the photo-excitation term $F^{\mathrm{opt}}(n)$. The slope of the straight line is proportional to the irradiation intensity.

The analytical expression of the light-induced equilibrium temperature (at $n = 1/2$) will be useful here. It is straightforwardly derived from Eq. (13) (after [23]):

$$T_{1/2}^{*} = E_{\mathrm{HL}}/k_{\mathrm{B}} \ln(k_{\infty}/k_{\mathrm{LH}}^{\mathrm{opt}}). \tag{14}$$

Eq. (14) univocally correlates the light-induced equilibrium temperature $T_{1/2}^{*}$ and the photo-excitation rate $k_{\mathrm{LH}}^{\mathrm{opt}}$. The use of the reduced value $k_{\mathrm{LH}}^{\mathrm{opt}}/k_{\infty}$ will be very useful for the quantitative analysis of the experimental results, since it by-passes the difficult estimations of the quantum yield and optical absorption effects in the sample.

5. Photo-switching in the spontaneous thermal hysteresis

We now focus on the switching processes performed at the thermal equilibrium temperature, but the method could be applied at any temperature in the thermal loop.

In Fig. 3 we show the graphical resolution of the photo-stationary states at equilibrium temperature, following Eq. (7). The threshold situations obey the specific condition $\mathrm{d}F^{\mathrm{therm}}/\mathrm{d}n = -\mathrm{d}F^{\mathrm{opt}}/\mathrm{d}n$, leading to the characteristic conditions for intensity thresholds:

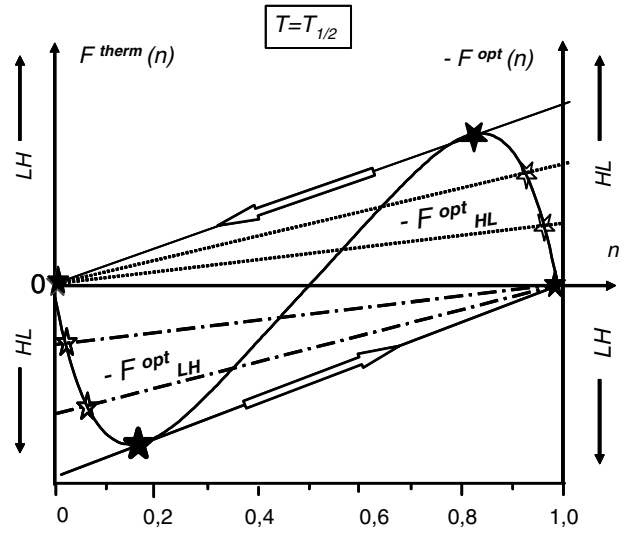

Fig. 3. The static MFMME approach to the intensity thresholds in the thermal hysteresis loop, at equilibrium temperature, for the L → H (bottom) and H → L (top) photo-processes. Straight lines correspond to optical terms. The threshold situations are indicated by open arrows.

$$F(n) = 0, \quad \mathrm{d}F(n)/\mathrm{d}n = 0. \tag{15}$$

The set of coupled non-linear Eq. (15) has no analytical solution and has to be solved numerically. The symmetry properties of Fig. 3 result in an interesting property: the equality of threshold values for L → H and H → L optical rates at $T = T_{1/2}$; of course the intensity values are expected to differ, owing to the different quantum yields and cross sections for the opposite processes.

6. Reversible photo-switching by combination of opposite optical rates

The MFMME approach provides a simple illustration to the case of combined L → H and H → L photo-processes, proposed in [3] for explaining the opposite effects induced by irradiation using the same wavelength at different temperatures: L → H for $T > T_{1/2}$, H → L for $T < T_{1/2}$. Indeed, the mean-field description possesses the essential ingredients of the Domino effect [24,25]: cooperativity and metastability of the initial state. Therefore the MFMME is capable of providing a qualitative approach to the problem. In Fig. 4 we show the graphical determination of the photo-stationary states, in the case of equal (for simplicity) optical rates of the opposite processes, at temperatures above and below $T_{1/2}$, within the hysteresis loop. The optical term in case of opposite processes, $F^{\mathrm{opt}}(n) = (1-n)k_{\mathrm{LH}}^{\mathrm{opt}} - nk_{\mathrm{LH}}^{\mathrm{opt}}$, is represented by a linear function which intersects the n-axis at a value which depends on the ratio between the opposite rates, $n_{\mathrm{equ}}^{\mathrm{opt}} = k_{\mathrm{LH}}^{\mathrm{opt}}/(k_{\mathrm{LH}}^{\mathrm{opt}} + k_{\mathrm{HL}}^{\mathrm{opt}})$, which obviously belongs to the $[0,1]$ interval. It can be clearly seen from this figure that the same irradiation will drive the light-induced thermal

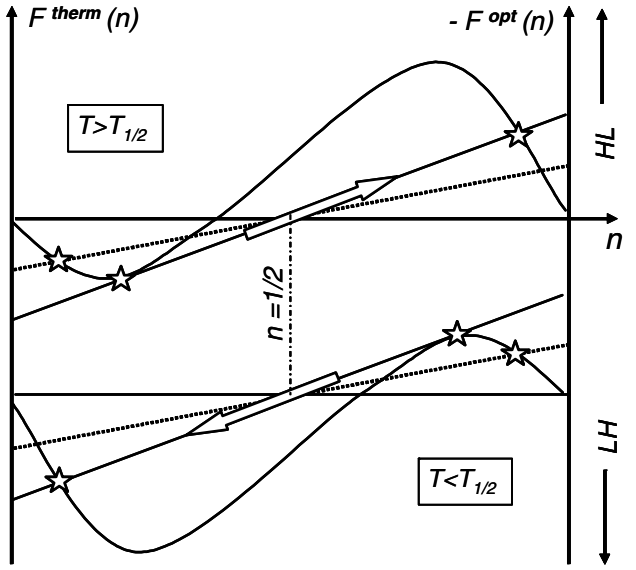

Fig. 4. The competition between optical and relaxation rates, within the thermal hysteresis loop, in the case of combined L → H, H → L photo-processes. The straight lines stand for photo-excitation at different intensities. The threshold situations are indicated by open arrows.

equilibrium towards the HS state for $T > T_{1/2}$, and towards the LS state for $T < T_{1/2}$.

7. Kinetic photo-switching in the spontaneous thermal hysteresis

The MFMME enables to calculate the time dependence of the HS and LS populations. In Fig. 5 we show computed $n(t)$ curves for different intensities above the

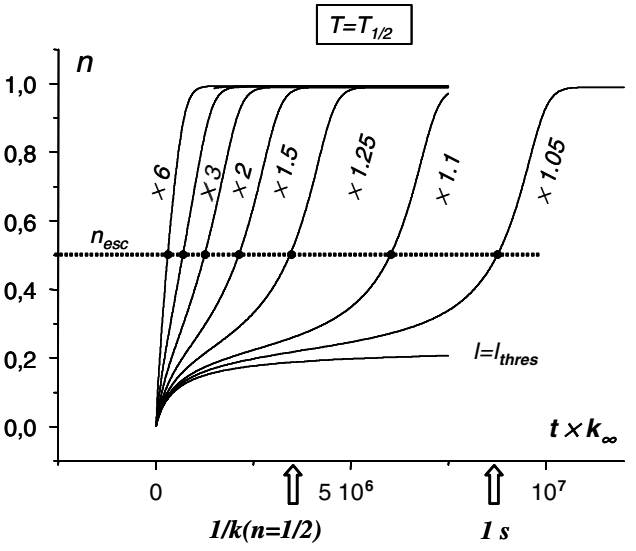

Fig. 5. The $n(t)$ dependence at the equilibrium temperature, for different intensities, and the corresponding escape times $t_{1/2}$, computed using parameter values determined in Section 8.

threshold value, at $T_{1/2}$. Beyond $n = 1/2$, the system can spontaneously decay towards the metastable macroscopic HS state, i.e., irradiation can be switched off. In other words, $n = 1/2$ and $t(n = 1/2) = t_{1/2}$ can be named, respectively, *escape population* and *escape time* of the system from the macroscopic metastable LS state. Similar calculations can be performed at different temperatures, then leading to different values of $t(I, n = n_{esc}(T)) = t_{esc}(T, I)$. The $n_{esc}(T)$ values belong to the instable branch of the spontaneous equilibrium in the thermal hysteresis range and can be easily derived from static calculations.

The plot of the computed relationship between intensity and escape time is presented in Fig. 6 (left scale). A useful interpretation of this plot can be made in terms of a *kinetic intensity threshold*, i.e., the minimum intensity $I^{kin}_{thres.}(t_{irrad.})$ needed to switch the system, for a given irradiation time $t_{irrad.}$. The crucial physical quantity, from application viewpoint, is the *energy threshold* $E_{thres.}(t_{irrad.}) = I^{kin}_{thres.}(t_{irrad.}) \times t_{irrad.}$, which we also plotted in Fig. 6 (right scale); the observed quasi-linear dependence $E_{thres.}(t_{irrad.})$ illustrates the increasing effect of relaxation which proceeds at a quasi-constant rate during the first stage of the switching process.

We now briefly discuss the switching processes induced by pulsed irradiation. A priori short irradiation times have to be preferred, the duration of which should typically compare to the inverse relaxation rates, $1/k_{HL}(T_{1/2}, n = 1/2) = 1/k_{LH}(T_{1/2}, n = 1/2) = 340$ ms with the parameter values used in the present work.

The Energy threshold expected at the limit of very short pulses is irrespective of the relaxation effects. The limiting value of the effective yield of the switching process, i.e., the ratio transformed molecules/absorbed photons then results from the simple balance between the total population created by irradiation and the escape population [2]. It is expressed by the ratio $\eta^{eff}_{LH} = \eta_{LH}/n_{esc.}$ (intrinsic quantum yield/ escape population). The value $2\eta_{LH}$ is then expected at $T_{1/2}$, and should sizably increase on approaching the HS edge of the thermal hysteresis loop. Of course the theoretical value of the escape population value is highly model dependent, and should be drastically lowered in presence of an efficient Domino effect.

8. Experimental data and discussion

We now describe the experimental data recorded for the photomagnetic Prussian Blue Analogue by the Versailles group on $Na_{0.32}Co[Fe(CN)_6]_{0.74}\cdot 3.4H_2O$, synthesized by the Tokyo group, here denoted compound (**1**). In a previous report we analysed the magnetic data recorded during the relaxation process of the metastable state obtained by thermal quenching of the high-temperature phase [26]. Selected relaxation curves are shown in Fig. 7.

The quantitative analysis of the data is briefly reported here (after [26]): calorimetric measurements provided a direct estimate of the degeneracy ratio (Section 3); the measured $\Delta S = 60(10)$ J K^{-1} mol^{-1}, led to $\ln g = \Delta S/R = 7(1)$; the width and location of the thermal hysteresis loop were used to determine the static parameter values: $\Delta = 1600(300)$ K, $zJ \sim 310$ K; subsequent analysis of the self-accelerated relaxation curves, according to Eqs. (4) and (5), with the fixed value $zJ = 310$ K led to the dynamic parameter values: $E_H(n = 1/2) = 3420$ K, $k_\infty \sim 8 \times 10^6$ s^{-1} [26]; a good fit was obtained by introducing a Gaussian distribution of barrier energies ($\sigma_E = 185$ K), associated with the various local environments due to non-stoichiometry of the compound; chemical inhomogeneities at the macroscopic scale were assigned to be responsible for the bent shape of the thermal hysteresis loop.

We now report reflectivity data, see Fig. 8, which actually provide the first experimental example of

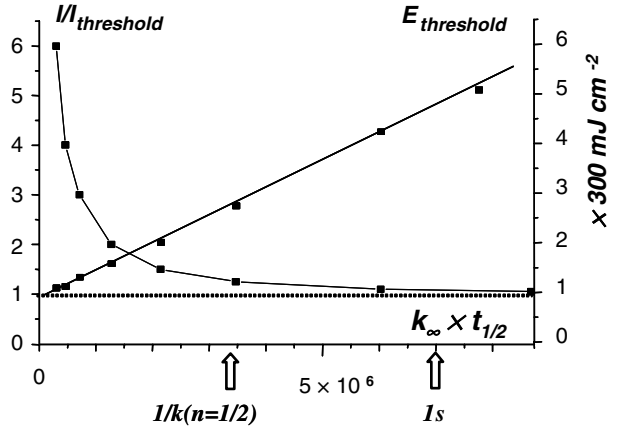

Fig. 6. Computed dependence of the kinetic intensity threshold (left scale) and energy threshold (right scale) with the irradiation time. Parameter values are those of Fig. 5.

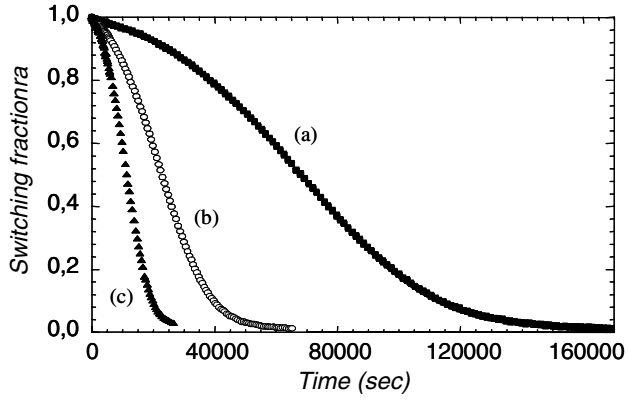

Fig. 7. The relaxation of the thermally quenched state of **1** at several temperatures, (a) 130 K, (b) 135 K, (c) 140 K, after [26]. The sigmoidal character of the curves evidences the self-accelerated relaxation.

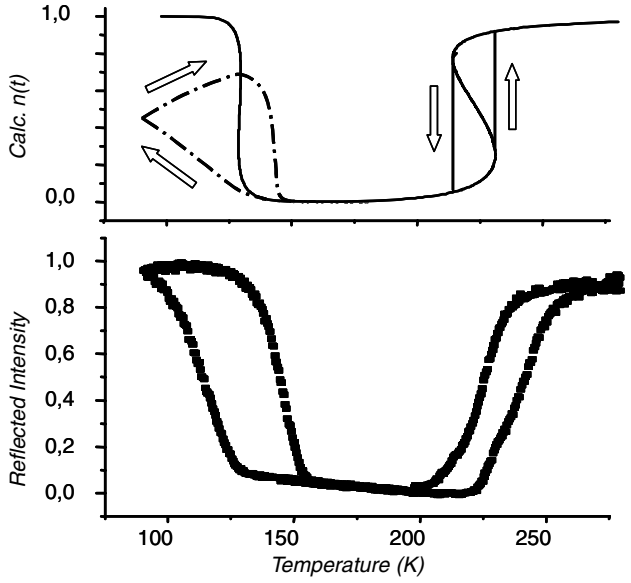

Fig. 8. The spontaneous (right) and light-induced (left) thermal hystereses of **1** recorded by optical reflectivity at 700 nm, 5 mW cm^{-2}. Top figure shows MFMME computed curves: photo-stationary states (full line); kinetic treatment (dotted line).

light-induced thermal hysteresis (LITH) in the cobalt hexacyanoferrate series. Reflectivity measurements have been preferred to magnetic measurements, because they limit the effects of optical absorption through the sample, see [10] for example. However the quantitative character of these reflectivity data, even after the usual Kubelka–Munk treatment remains questionable, mostly because diffusion cannot be correctly accounted for, due to the experimental set-up using quasi-specular reflection. We shall therefore resume the quantitative data from Fig. 8 to the approximate values of the switching temperatures of the TH and LITH loops.

The light-induced equilibrium temperature, according to Eq. (14), is univocally related to the optical rate in reduced units. The experimental value $T^{*}_{1/2} \sim 130$ K yields $k^{\mathrm{opt}}_{\mathrm{LH}}/k_{\infty} \sim 3.8 \times 10^{12}$, a value which specifically refers to the experimental conditions and sample used for the Versailles LITH experiments (see for example [5,10,27,28]). We reported in Fig. 8 (top) several curves computed through the MFMME approach. The static parameter values, $\Delta = 1617$ K, $zJ = 305$ K have been slightly adjusted in order to better fit the reflectivity data. The computed quasi-static LITH loop (full line) is narrow, due to the self-acceleration factor value, $\alpha(130\ \mathrm{K}) = 2zJ/k_{\mathrm{B}}T = 2 \times (305/130) \cong 4.7$, which is not in large excess to the threshold value $\alpha = 4$. The computed loop accounting for the experimental kinetics (sweeping rate 0.1 K/min, dotted line) better compares to the experimental switching temperatures. However some obvious differences remain, e.g., the uncompleted saturation of the system at the turning point (90 K).

The properties of the photo-induced transition obviously differ from those expected from the thermal transition, in the present case. Literature data relevant to the comparison between LITH and TH are yet scarce [14,29,30]. They exclusively dealt with spin transition compounds, and so far indicated a good agreement to the correlation between the widths of the LITH and TH loops. A tentative explanation for this striking discrepancy observed here might be the difference recently reported between the thermally quenched and photo-excited states [31]. Therefore we plan to measure the relaxation curves of the photo-excited state of **1**, after properly solving the conflicting requirements of accurate measurements and low optical absorption. Further effects might be responsible for the bent shape of the LITH curve, again the distribution of chemical composition at the microscopic and macroscopic scales, but also the irradiation intensity distribution which is inherent to the optical absorption process [26].

Straightforward calculations following the strategy described in Section 5 give for the present system, at the equilibrium temperature of 231 K, a photo-excitation rate threshold value 600 times larger than the one used for the LITH experiment. It immediately follows, in the approximation of linear photo-excitation, that the corresponding intensity should be 600 times larger, i.e., $\sim$3 W cm^{-2}. Such a large specific intensity is expected to induce an excessive warming up of the sample. Therefore transient photo-excitations, such as those provided by one-shot laser pulses [2–4], were obviously needed. Actually, the energy threshold values calculated according to Section 5 $\sim$300 mJ cm^{-2}, are far too large with respect to the experimental values, $\sim$15 mJ cm^{-2}. Such a discrepancy finally supports the previous reports of anomalously large values of the effective quantum yield [2,3], i.e., the occurrence of a sizeable Domino effect, and strongly motivates us for further treatments of the master equation beyond the mean-field approximation (see, e.g. [32]). Also, the non-linear character of the photo-excitation terms [10,11] may sizeably contribute to the instability of the system under irradiation, and therefore requires quantitative experimental investigations on the tracks of [9].

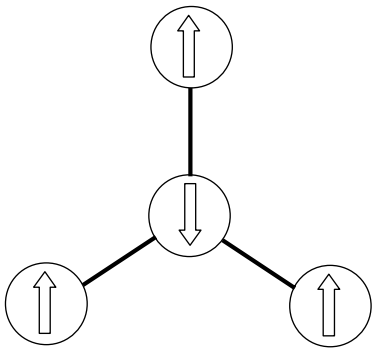

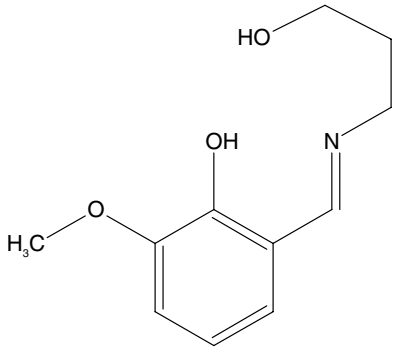

Fig. 1. Spin rationalisation for the $S = 5$ ground state of Fe_4 propellers.

Scheme 1. Schiff-base ligand, L, formed by condensing *o*-vanillin with 3-amino-1-propanol.

$thme^{3-}$ ligands to give $Fe_4(thme)_2(dpm)_6$ [7]. Here we report the synthesis, characterisation and magnetic behaviour of a compound containing similar Fe_4O_6 core but using a different ligand system (Scheme 1) and also a related dinuclear complex with pentacoordinate iron centres with coordination geometries similar to those for two of the Fe(III) centres in the tetranuclear complex.

2. Experimental

The reagents, $FeCl_2 \cdot 4H_2O$ (Fluka), triethylamine (Riedel-de-Haën), *o*-vanillin (Lancaster), aminopropanol (Fluka) and methanol, were used without further purification.

2.1. Synthesis and characterisation

2.1.1. $[Fe_2(vap)_2Cl_2]$ (**1**)

A methanolic solution containing *o*-vanillin (1 mmol, 152 mg) and 3-amino-1-propanol (1 mmol, 75 mg) stirred for 20 min was added to a methanolic solution of $FeCl_2 \cdot 4H_2O$ (1 mmol, 198 mg). Dark brown crystalline rods formed after 1 d. Yield: 180 mg/ 60%. *Anal*. Calc. $C_{22}H_{26}Fe_2N_2O_6Cl_2$: C, 44.25; H, 4.39; N, 4.70. Found: C, 44.02; H, 4.45; N, 4.61%. Infra-red (cm^{-1}): 2926 (m), 2867 (m), 2828 (m), 1610 (s), 1556 (m), 1469 (m), 1450 (m), 1440 (m), 1315 (m), 1253 (m), 1224 (m), 1054 (m), 736 (m), 560 (m), 515 (m), 434 (w).

2.1.2. $[Fe_4(vap)_4(CH_3O)_2Cl_2]$ (**2**)

The procedure for **1** was repeated with the addition of triethylamine (1 mmol, 101 mg) to the ligand solution. Dark brown crystalline prisms of **2** formed after standing for 1 d. Yield: 176 mg/ 59%. *Anal*. Calc. $C_{46}H_{58}Fe_4N_4O_{14}Cl_2$: C, 46.61; H, 4.73; N, 4.73. Found: C, 45.13; H, 4.83; N, 4.65%. Infra-red (cm^{-1}): 2923 (m), 2862 (m), 2830 (w), 1623 (s), 1599 (w), 1552 (w), 1470 (m), 1440 (m), 1313 (m), 1246 (m), 1223 (m), 1050 (m), 735 (m), 496 (m), 433 (w).

2.2. Determination of crystal structure

Data for **1** and **2** were measured on Bruker SMART Apex and Stoe IPDS area detector diffractometers, respectively, using graphite-monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined by full-matrix least-squares against F^2 for all data, using the SHELXTL software package [8]. All non-H atoms were refined anisotropically; H-atoms were either fully refined isotropically (**1**) or placed in calculated positions (**2**).

Crystal data and details of the data collection and structural refinement are summarised in Table 1. Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 256909 and 256910. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK: http://www.ccdc.cam.ac.uk/perl/catreq/catreq.cgi, e-mail: data_request@ccdc.cam.ac.uk, or fax: +44 1223 336033.

2.3. Magnetic properties

Magnetic measurements were performed using a Quantum Design SQUID MPMS-XL susceptometer. Measurements were performed on a polycrystalline sample of 9.2 mg (**1**) and 10.7 mg (**2**) in the range 1.8–300 K using a 0.1 T field. The magnetic data were corrected for the diamagnetic contribution calculated from Pascal's constants [9].

3. Results and discussion

3.1. Description of the structure

The structure of the dinuclear complex **1** is shown in Fig. 2. In the centrosymmetric complex, the $(vap)^{2-}$

ligands each chelate a ferric cation Fe(1) through the imine nitrogen and the deprotonated propanol and phenol oxygens, resulting in a *mer* geometry for the coordinated ligand. Each of the propanol oxygens also bridges to the other iron centre. This results in two equivalent and nearly symmetric alkoxy bridges with an Fe(1)···Fe(1′) separation of 3.1495(7) Å. The coordination environment about Fe(1) is completed by a chloride ligand Cl(1). The geometry can best be described as square-pyramidal with Cl(1) in the axial position. Fe(1) is displaced by 0.553 Å out of the O_3N plane towards Cl(1), with the Cl–Fe–O and Cl–Fe–N angles all in the range 100.96–110.12°.

The nearest atom to Fe(1) *trans* to Cl(1) is a methoxy hydrogen at 3.711 Å from Fe(1). There are no significant π–π stacking interactions. The closest intermolecular contacts are from C(4), the carbon atom of the imino group, to O(2) (3.450 Å) and O(3) (3.329 Å) of the molecule at $x - 1/2$, $-y + 3/2$, $z - 1/2$.

The structure of the tetranuclear complex **2** is shown in Fig. 3, with selected geometric parameters listed in Table 2. The central iron Fe(1) is bridged to three further iron atoms, via pairs of alkoxy bridges. Unlike in the previously reported examples, the three sets of bridges are not equivalent, The peripheral iron Fe(2) has an octahedral geometry with the two $(vap)^{2-}$ ligands *mer*-chelated, such that the two propanol oxygens are *cis* to each other. These two oxygens form bridges between Fe(2) and the central Fe(1). The two other peripheral irons, Fe(3) and Fe(4), are penta-coordinated with a distorted square-based pyramidal geometry. For both there is a single $(vap)^{2-}$ ligand occupying three sites of the base of the iron, an axial chloride ligand and a bridging methoxy ligand bridging to the central Fe(1). A

Fe(1)–O(11)	2.051(3)	Fe(1)–O(11)–Fe(4)	104.34(14)
Fe(4)–O(11)	1.948(3)		
Fe(1)–O(14)	2.003(3)	Fe(1)–O(14)–Fe(4)	106.26(14)
Fe(4)–O(14)	1.946(3)		
Fe(3)–Cl(1)	2.2266(15)		
Fe(4)–Cl(2)	2.2328(15)		

further bridge to Fe(1) is provided by the deprotonated propanol oxygen of the ligand. The coordination geometries around Fe(3) and Fe(4) are very similar to that observed about Fe(1) in complex **1**. Whilst the two bridges between Fe(1) and Fe(2), involving O(1) and O(4), are essentially symmetrical, the other four bridges are unsymmetrical. In each case the Fe(1)–O distance is significantly longer (by 0.052–0.098 Å) than the corresponding ones to the pentacoordinate Fe(3) and Fe(4). Also the Fe–O–Fe angle for the methoxy bridge is slightly larger than that for the corresponding propanol bridge. The small differences in geometries within the three linkages is most clearly shown in the Fe···Fe separations: 3.2043(9) Å for Fe(1)–Fe(2), compared to 3.1468(8) and 3.1591(10) Å for Fe(1)–Fe(3) and Fe(1)–Fe(4), respectively. The bonding situation for Fe(3) and Fe(4) is the same as that seen for Fe(1) in the asymmetric unit of compound **1**, i.e., square-pyramidal with an axial chloride and an O_3N coordination set in the square base.

The clusters of Gatteschi, Saalfrank and Mallah contain exclusively hexacoordinate Fe(III) centres with D_{3d} molecular symmetry which is crystallographically imposed only for the $Fe_4(thme)_2(dpm)_6$ cluster of Gatteschi. For **2**, the cluster is on a general position with the idealised symmetry reduced to C_2. Nevertheless the geometry of the central $\{Fe_4(\mu\text{-}OR)_6\}$ core in **2** does not deviate greatly from D_{3d} symmetry.

3.2. Magnetic behaviour

Magnetic susceptibility measurements have been performed for compounds **1** and **2**, from 300 to 1.8 K at 0.1 T. For **1**, χT decreases gradually from 4.98 to 0.05 $cm^3\,K\,mol^{-1}$ between 300 and 1.8 K indicating dominant antiferromagnetic interaction between Fe(III) $S = 5/2$ magnetic centres (Fig. S1, Supplementary Data). The dinuclear nature of **1** is clear from the structural analysis and no efficient magnetic pathway has been identified between dinuclear complexes. Therefore, **1** can be seen as a isolated dimer of Fe(III) and magnetic measurements can be modelled in terms of a simple Heisenberg model of $S = 5/2$ dimer with the Hamiltonian $H = -2JS_{Fe_1}S_{Fe_2}$ [10]. The best set of parameters obtained with this model is $g = 2.08$ and $J/k_B = -27.6$ K.

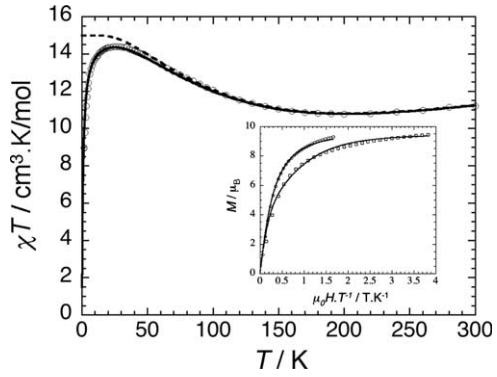

Fig. 4. Temperature dependence of the χT product for **2** at 0.1 T. Solid and dotted lines are the best fit obtained with the Heisenberg $S = 5/2$ tetramer model with and without inter-tetramer interactions (see text). Inset: Reduced magnetisation plot (M vs. H/T) including data at 1.83 and 4.2 K between 0 and 7 T. The solid line is the best fit obtained considering only the $S = 5$ ground state and its anisotropy D (see text).

For **2**, the χT product slightly decreases from 11.3 $cm^3\,K\,mol^{-1}$ at 300 K to 10.8 $cm^3\,K\,mol^{-1}$ at 200 K where it reaches a rounded minimum (Fig. 4). At lower temperature, χT increases and attains a maximum of 14.4 $cm^3\,K\,mol^{-1}$ at 24 K. Below this temperature, the χT decreases down to 8.9 $cm^3\,K\,mol^{-1}$ at 1.83 K.

This complicated thermal behaviour is typical of what has been seen for this type of Fe_4 compounds [3,7] where the antiferromagnetic interaction between the central Fe(III) and peripheral Fe(III) leads to an $S = 5$ ground state. Therefore the magnetic susceptibility of **2** was modelled using the following Heisenberg Hamiltonian $H = -2J(S_{Fe_1} \cdot (S_{Fe_2} + S_{Fe_3} + S_{Fe_4}))$ and the MAGPACK program for numerical simulation [11,12]. The best set of parameters obtained: $g = 2.0$ and $J/k_B = -21.0$ K only reproduces the experimental data down to 60 K. Therefore inter-tetramer interactions have been introduced in the frame of the mean-field approximation, using the following definition [10,13] of the susceptibility:

$$\chi = \frac{\chi_{tetramer}}{1 - \frac{2zJ'}{Ng^2\mu_B^2}\chi_{tetramer}}$$

and yielding a new set of parameters: $g = 2.0$, $J/k_B = -21.0$ K and $zJ/k_B = -0.05$ K giving a fit in excellent agreement with the experimental results (Fig. 4). The value of J thus obtained compares well with other values in the literature for similar compounds as well as for the dimer **1** (see Table 3).

The final decrease of the χT versus T plot can also be qualitatively reproduced by introducing a zero-field splitting term, D, in excess of −4 K for each Fe(III), which, however, is not physically acceptable. Nevertheless, there is no doubt that this low temperature behaviour, which is well simulated by the inter-tetramer interactions, also includes a contribution from the anisotropy of the system (D) as observed in related systems [3,7]. This term can be evaluated using reduced magnetisation plots (M versus H/T), assuming that only the $S = 5$ ground state is populated below 5 K and neglecting inter-tetramer interactions. In the case of $Fe_4(thme)_2(dpm)_6$ the value thus obtained of −0.6 K was confirmed using high-field EPR measurements [7]. Using this method on compound **2** we obtain a D value of −0.45(5) K (inset Fig. 4), falling in the range of those reported for this type of Fe_4 complex (see Table 3).

Comparing **2** with the Fe_4 propeller compounds in the literature reveals that the bonding is similar with significant distortion of the central Fe coordination environment (see Tables 2 and 3). Thus, as for the other Fe_4 complexes, the anisotropy and $S = 5$ ground state should lead to SMM behaviour. Such behaviour was not observed for **2** above 1.83 K using ac measurements with frequencies up to 1500 Hz. Therefore microSQUID measurements were performed (Fig. 5). Rather surprisingly these show no evidence of hysteresis even down to 0.04 K posing the question, "What makes a single molecule magnet?"

A careful examination of the detailed bonding situation does not provide any obvious answer. Although for $Fe_4(thme)_2(dpm)_6$ it was suggested that the bite angles for the central Fe are responsible for the enhanced SMM behaviour [7], here the corresponding angles should be even more favourable. Whereas in the case of $Fe_4(thme)_2(dpm)_6$ D_{3d} symmetry is crystallographically imposed, for the SMMs $Fe_4(CH_3O)_6(dpm)_6$ and $Fe_4(thme)_2(C_3H_7OH)_6Cl_6$ [14], as for compound **2**, this is not the case. The effect of trigonal compression and rotation on the magnetic anisotropy of an FeO_6 chro-

mophore such as that found at the centre of these complexes and its effect on SMM behaviour has been discussed previously [7,15,16]. The two types of distortion are defined by the angles θ and φ, whose values are 57.74° and 60° respectively for a regular octahedron. Angular overlap model calculations show that trigonal compression, quantified by the angle θ, leads to a positive single ion D value and rotation of an octahedral face about the threefold axis, quantified by φ, favours a negative D value [15]. Comparing the parameters for all four compounds again leads to the conclusion that there is no reason why compound **2** should not show SMM behaviour. For example, compound **2** has a larger extent of trigonal rotation ($\varphi = 36.1°$) than $Fe_4(CH_3O)_6(dpm)_6$ ($\varphi = 41.8°$) for essentially the same extent of trigonal compression ($\theta = 57.4°$ and 57.3°, respectively). In fact, the only significant difference in the structure of **2** is the presence of the two five coordinate peripheral irons. Does this fact somehow abolish the SMM behaviour? One possibility is that for compound **2** there is a large transverse anisotropy (E term) which is allowed by symmetry in this case. A similar situation where a Ni_4 cluster with a negative D term fails to show SMM behaviour has been observed and found to be the result of a large E term [17]. This could be checked using, for example, high-field EPR experiments.

4. Conclusion

The new Fe_4 propeller compound, $Fe_4(vap)_4(CH_3O)_2Cl_2$, has structural features expected to give rise to SMM behaviour, as has been observed for similar compounds of this type. In addition, the magnetic susceptibility measurements are also in line with those of such compounds. Surprisingly, we find no evidence for SMM behaviour. The reasons why such effects are not present are currently unclear, but might be the result of transverse zero-field splitting terms. This proposal will be investigated in future studies, perhaps answering the question, "What makes a single molecule magnet?"

Scheme 1. Synthesis of **OTBN**.

A zinc chelate of 1,3-dithiol-2-thione [4] (**1**) was reacted with *n*-bromooctadecane to afford 4,5-bis(octadecylthio)-1,3-dithiol-2-thione (**2**). On the other hand, 5-formyl-benzo-1,3-dithiol-2-one (**3**) was converted to an acetal derivative, 5-[1,3-dioxolan-2-yl]-benzo-1,3-dithiol-2-one (**4**), to protect the formyl moiety in the following coupling reaction [5]. A cross-coupling reaction between 4,5-bis(octadecylthio)-1,3-dithiol-2-thione (**2**) and acetal derivative (**4**) was conducted in triethylphosphite to obtain benzo-TTF derivative (**5**). After deprotecting the acetal unit, the resulted formyl derivative (**6**) was reacted with 2,3-dimethyl-2,3-bishydroxyaminobutane to obtain cyclic-bishydroxylamine (**7**) as a radical precursor. The final product, **OTBN**, was obtained as brown powders by the oxidation of precursor **7** with PbO_2 in a reasonable yield.

OTBN showed IR absorption peaks around 3010–2740 and 1470–1350 cm^{-1}; the former bands were assigned to the C–H stretching modes of long alkyl chains and the latter were assigned to N–O and C–N stretching modes of the nitronyl nitroxide group, respectively. The ESR spectrum of **OTBN** in benzene solution showed five lines ($g = 2.0061$, $a_N = 0.75$ mT) which were assigned to the nitronyl nitroxide group. The cyclic voltammogram of **OTBN** in a benzonitrile solution in the presence of 0.1 M tetrabuthylammonium perchlorate as an electrolyte showed three reversible redox waves at 0.64, 0.90 and 0.98 V versus Ag|AgCl. Judging from the redox potentials of **5** (0.60 and 0.95 V versus Ag|AgCl) and phenyl nitronyl nitroxide (**PhNN**) (0.86 V versus Ag|AgCl), the first and the third redox potentials of **OTBN** are assigned to the oxidation potentials of the donor unit, and the second oxidation potential of **OTBN** is assigned to the oxidation potential of the radical unit, respectively. Since **OTBN** can be regarded as a good electronic donor molecule, judged from the first oxidation potential, localized spin on the radical moiety will be intact during the hole injection by application of the gate voltage in the FET measurement.

3. Optical and magnetic properties of powder and film samples of OTBN

A THF solution of **OTBN** shows green color and its UV spectrum is characterized by the presence of bands at 235–330 and 530–770 nm as shown in Fig. 1(a). The former band can be assigned to the donor unit and the latter to the radical, indicating that the electronic structure of **OTBN** consists of the donor and radical units. Differential scanning calorimetric measurement of **OTBN** exhibited an endothermic peak at 54 °C in the temperature increasing process and an exothermic peak at 44 °C in the cooling process. When a color change of the sample was observed under an optical microscope on a hot plate, being sandwiched by a pair of glass plates, it was found that brownish powders changed to green liquid in the heating process, accompanied by the decrease of the absorption peak at 500 nm as shown in Fig. 1(b). The green liquid changed to an uniform brown film with cooling the sample, exhibiting a good fabricating ability of the sample. This color change of **OTBN** from brown to green may be interpreted as follows. Since the **OTBN** molecules are ordered at least locally in a thin film, an intermolecular coupling of transition dipole moments shifts the absorption to the longer wavelength, causing the increase of the intensity of absorption at 500 nm. On the other hand, the absorption at 500 nm decreases at higher temperature than 54 °C, presumably because the orientation of donor radicals becomes disordered in the fused state, diminishing

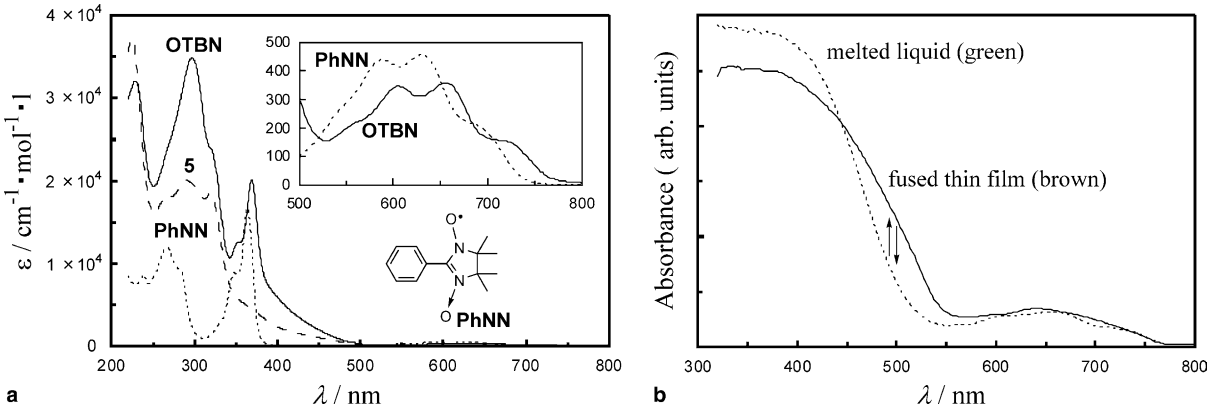

Fig. 1. (a) UV spectra of **OTBN** and reference compounds (**5** and **PhNN**) in THF solution. (b) UV spectra of a fused solid (solid line) and a melted liquid (dotted line) of **OTBN** fabricated between a pair of Pyrex glass.

the excitonic coupling. Since the extinction of the polarized light was not observed on the fused sample, a long range ordering of the molecular alignment is not achieved in the solid. The absorption spectra of the film before and after the melting is practically the same, suggesting that the donor radical is not deactivated in the melting–freezing cycles. Incidentally, the color of the sample turned to orange when the sample was heated above 65 °C. This means that the radical unit is decomposed, leaving the donor unit intact.

The magnetic susceptibility of the powdered and the fused samples of **OTBN** was measured by a SQUID magnetometer. The temperature dependence of the χT values of both samples are shown in Fig. 2. The both traces are practically the same and the χT values increase at lower temperatures, indicating the presence of the ferromagnetic intermolecular interaction. These traces were simulated using the Curie–Weiss law; Curie constants and Weiss constants of both samples were evaluated to be 0.385 emu K mol^{-1} and +0.47 K for the as-grown powder, and 0.385 emu K mol^{-1} and +0.45 K for the fused film, respectively. These ferromagnetic intermolecular interactions may be originated from the alignment of nitronyl nitroxide. The ferromagnetic

alignment of NN must be achieved by the dispersion force of long alkyl chains (Fig. 3). The fact that the ferromagnetic interaction remains constant before and after melting the powdered sample suggests that the local molecular alignment is preserved during the melting–freezing cycles.

4. Construction and measurement of FET device using organic donor, acceptor, and donor radical

In an organic FET device, the change of the passing current in an organic layer between drain and source electrodes is detected as a function of the gate voltage. Fig. 4 shows a bottom-contact type FET device in which the n-doped silicon wafer and a SiO_2 layer are utilized as the gate electrode and the insulating layer, respectively. Source and drain electrodes are prepared on the insulating layer by deposition of gold. An organic film is fabricated between the drain and source electrodes on the insulating layer by a sublimation, spin-coating, or casting method. Fig. 4(b) shows the FET substrate equipped with interdigited electrodes, each facing electrodes of which operate as a pair of drain and source electrodes. Since organic materials generally show high resistivity, interdigited electrodes with a narrow gap are required to explore the conducting property of organic materials. Consequently, interdigited electrodes with a gap of 20, 10, 5, and 2 μm are used in the current study.

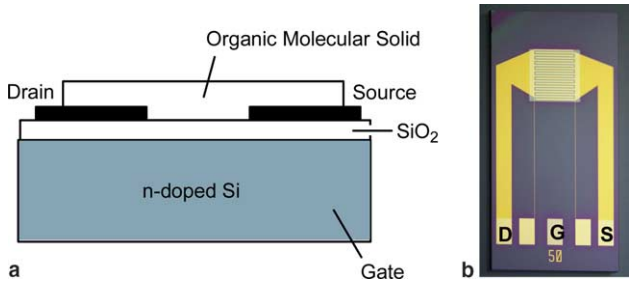

Fig. 4. (a) Geometry of a bottom-contact type organic FET device. (b) A substrate for fabricating the organic field-effect transistor having interdigited electrodes as a of drain and source electrodes. The area of the interdigited electrodes is 2×2 mm.

4.1. FET characteristics of *TTF*, *TCNQ*

Fabrication of a film of an organic molecule is usually performed by a casting method for polymers or sublimation for small molecules. However, we found that a cast film obtained from a solution of a crystalline sample exhibits clear FET characteristics, using interdigited electrodes with a small gap. The obtained results on a typical organic donor or acceptor (**TTF**, **TCNQ**) are shown in Fig. 5. When the negative gate voltage was applied to a cast film sample of **TTF** through the insulating layer, the current between drain and source electrodes (I_{DS}) increased by p-doping of organic layer, exhibiting a distinct FET characteristic. In contrast, the cast film sample of **TCNQ** exhibits a FET characteristic when the positive gate voltage is applied [6]. Incidentally, such FET characteristics were detected when the electrodes with a smaller gap of 2 or 5 μm are used, but not by electrodes with larger gaps, such as 10 or 20 μm. These results suggest that even small crystals obtained by the casting method can bridge over the electrodes with narrow gaps. Accordingly, this method is useful for exploring the conductivity of organic molecules which afford small size crystals.

4.2. FET characteristics of TTC_{18}-TTF

If tight packing of donor units is achieved in a neutral assembly, it is expected to manifest good FET characteristics. In this respect, it is interesting to examine the FET characteristic of **TTC$_{18}$-TTF** in which octadecyl chains

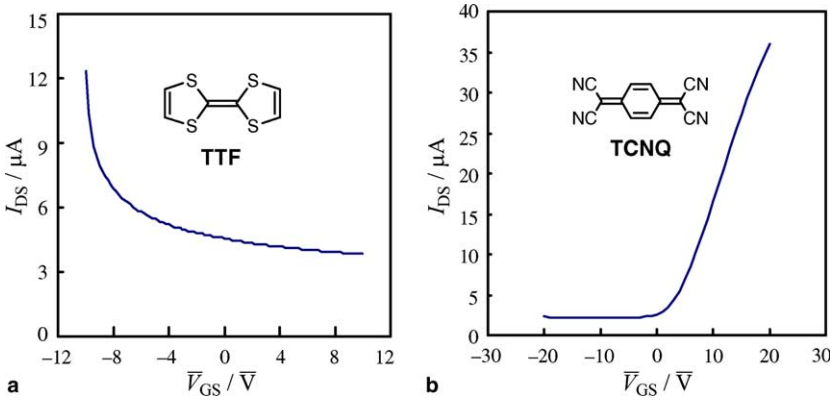

Fig. 5. FET characteristics of typical donor and acceptor exhibited on the interdigited drain source electrodes with a gap of 5 μm. The thickness of an insulating layer (SiO_2) is 180 nm: (a) FET characteristics of **TTF** with the drain–source voltage (V_{DS}) of 1 V; (b) FET characteristics of **TCNQ** with the drain–source voltage (V_{DS}) of 10 V.

are introduced to the bis(ethylenedithio)-TTF skeleton. It has been reported that the neutral crystal of **TTC_{18}-TTF** shows high conductivity due to the fastener-effect of long alkyl chains [7]. Accordingly, a film sample of **TTC_{18}-TTF** was formed on the substrate with 2 μm gap interdigited electrodes and the FET characteristic of **TTC_{18}-TTF** was measured.

Fig. 6 shows the FET characteristic of a cast film of **TTC_{18}-TTF** which was formed by evaporating a dichloromethane solution of **TTC_{18}-TTF**. The ON/OFF ratio turned out to be 10:1, and it increased up to 215:1 when the melting–freezing cycle was performed, taking an advantage of the low melting point of **TTC_{18}-TTF** (92 °C) [8]. The above results suggest that the introduction of long alkyl chains is effective for constructing a FET device from the aspect of the fabrication of donor units.

4.3. FET characteristics of *OTBN*

Since **OTBN** carries long alkyl chains as **TTC_{18}-TTF**, it is expected to provide a thin film by a melting–freezing method. The FET measurement was performed on the **OTBN** film prepared by the melting–freezing method. The FET characteristic of the **OTBN** film is shown in Fig. 7. Although the ON/OFF ratio is small, the drain current is changed by changing the gate voltage. From the *I–V* dependence between the drain and the source, the mobility in the **OTBN** film was evaluated to be 5×10^{-9} cm^2 V^{-1} S^{-1} according to Eq. (1)

$$\mu = \frac{\partial I_{DS}}{\partial V_{GS}} \left(\frac{L}{C_1 \cdot W \cdot V_{DS}} \right), \tag{1}$$

where L is the gap length, C_i is the capacitance per area and W is the gap width. The mobility of the sample may be increased by optimizing the condition of the film-formation. Incidentally, the small ON/OFF ratio may be partly derived from the pre-doping of the sample.

Since the interaction between the localized spin of the donor unit and conduction electrons which run along the donor stack is small, if any, it is indispensable to measure the conductance at cryogenic temperatures to detect the magneto-resistance effect. Although the FET measurement was performed at 4.2 K, no I_{DS} was detected at all even when a high gate voltage ($V_G = -50$ V,

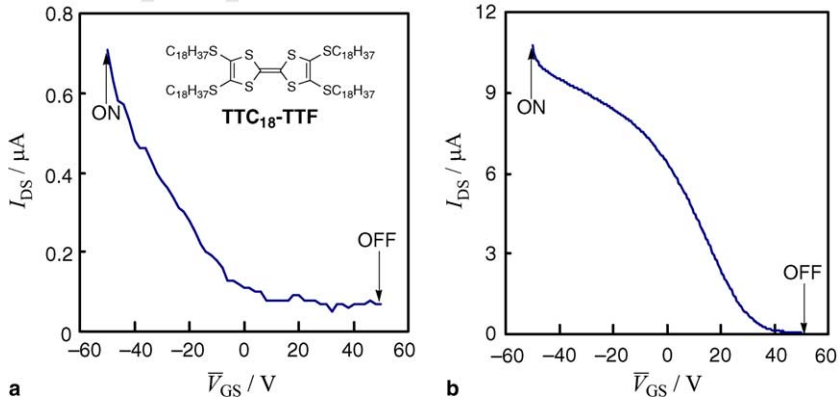

Fig. 6. FET characteristics of **TTC_{18}-TTF** exhibited on an interdigited drain source electrodes with a gap of 2 mm; the thickness of the insulating (SiO_2) was 180 nm. The voltage between drain and source (V_{DS}) was 10 V in both cases. (a) FET characteristics of a cast film of **TTC_{18}-TTF** from a solution of dichloromethane. ON/OFF ratio of I_{DS} between V_G of −50 and 50 V was 10:1. (b) FET characteristics of a film sample of **TTC_{18}-TTF** fabricated by the melting–freezing method. ON/OFF ratio of I_{DS} between $\bar{V}_{GS}$ of −50 and 50 V was 215:1.

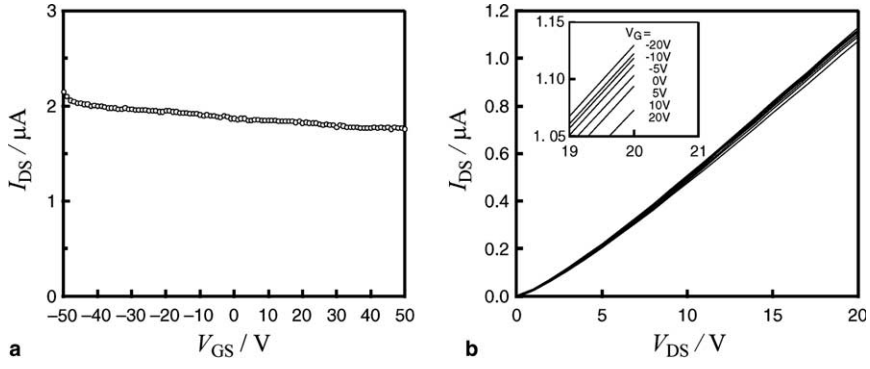

Fig. 7. FET characteristic of **OBTN** measured by the interdigited drain and source electrodes with a gap of 2 μm; the thickness of the insulating layer (SiO_2) is 195 nm. (a) Increase of I_{DS} with the decrease of gate voltage ($\bar{V}_{GS}$) from +50 to −50 V for $V_{DS} = 30$ V. (b) Change of *I–V* characteristics by variation of $\bar{V}_{GS}$.

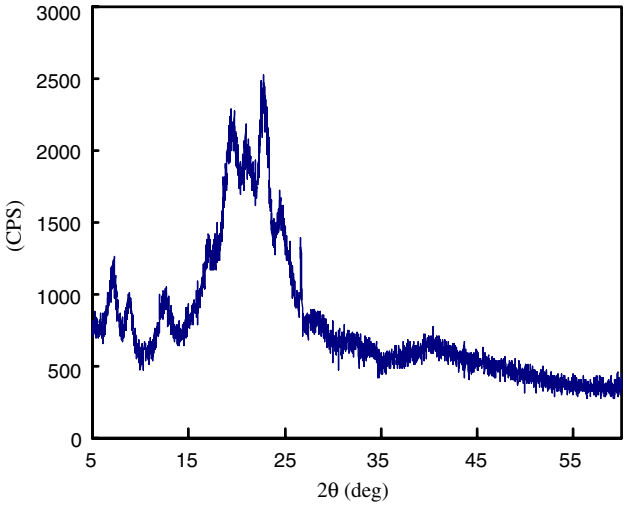

Fig. 8. Thin film X-ray diffraction pattern of **OBTN**.

$V_{DS} = 100$ V) was applied. This means that the hole-mobility was suppressed considerably at cryogenic temperatures.

The thin layer X-ray diffraction experiment was performed on the **OTBN** film. Observation of the diffraction peaks indicated the ordering of donor radicals in the film, but the peak-width of the diffraction was substantially broadened as shown in Fig. 8. The crystallite size of the sample was estimated to be about 10 nm on the basis of the analysis of the broad peak-width by Scherrer formula (Eq. (2)) [9].

$$\text{Crystal size (Å)} = \frac{0.9\lambda}{\beta \cos\theta}, \tag{2}$$

where λ is the wavelength, β is the half-width and 2θ is the Bragg angle. This means that about 10–20 molecules are aligned locally in the sample. This size of the crystalline is too small to interconnect the 2 μm gap of the interdigited electrodes. Judging from the above result, the electron hopping between crystallites is suppressed entirely at cryogenic temperature, although the inter-crystallites electron hopping occurs appreciably at room temperature. If the fabrication process is improved and the crystallite size is enlarged sufficiently, the FET characteristics of **OTBN** at low temperature may be detected.

5. Summary

A bottom-contact type FET device with interdigited electrodes as a pair of drain and source electrodes was constructed, and the FET characteristics of cast films of **TTF**, **TCNQ**, and **TTC$_{18}$-TTF** were observed. The FET characteristics of a donor radical of **OTBN** was also observed, although the hole mobility in the organic layer was very small. However, the FET effect was not observed at lower temperatures presumably due to the suppression of the inter-crystallite hopping of electrons. It would be extremely interesting to observe the FET characteristics of donor radicals at lower temperatures in order to examine the interaction between an organic localized spin and conduction electrons [10].

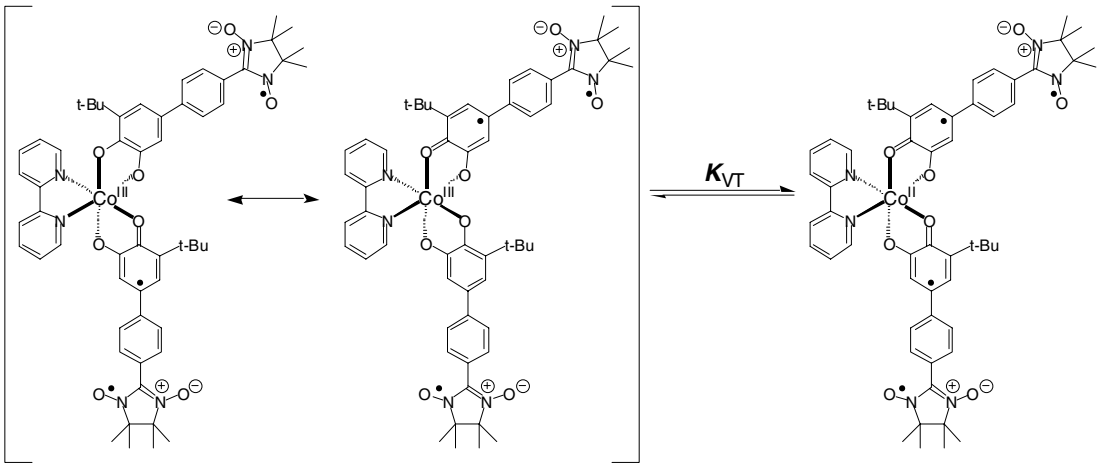

Fig. 1. Mixed-valency and valence tautomerism inherent to complex **1**.

The valence tautomeric equilibrium was studied using variable temperature infrared spectroscopy of amorphous films cast from methylene chloride by measuring the intensity of the intervalence charge transfer band characteristic of the Co^{III} form [3,33]. Representative spectra are shown in Fig. 2, and normalized intensity vs. temperature data are shown in Fig. 3.

The data in Fig. 3 were fit according to the equation [33]:

$$x_{Co^{III}} = 1/[\exp(\Delta H^{\circ}/RT - \Delta S^{\circ}/R) + 1]$$

where $x_{Co^{III}}$ is the mole fraction of the cobalt(III) form of the valence tautomer. The results of the fit are $\Delta H^{\circ} = 9.2$ kcal mol^{-1} and $\Delta S^{\circ} = +22$ cal K^{-1} mol^{-1}. These thermodynamic parameters are slightly smaller than those reported by Pierpont for Co(bpy)(3,5-DBSQ)(3,5-DBCat) valence tautomer [25], and are in line with the redox potential differences [18] between 3,5-di-*tert*-butylorthoquinone and our phenylnitronylnitroxide–orthoquinone [32].

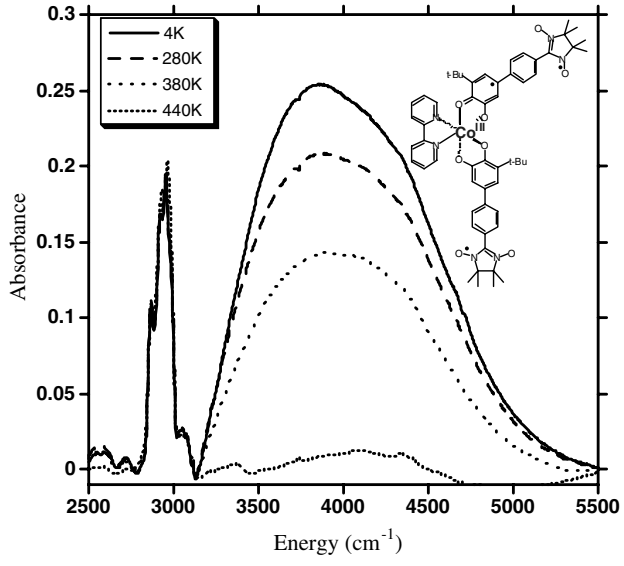

Fig. 2. Intervalence charge transfer (IVCT) band of **1** recorded on a film cast from methylene chloride. Bottom to top: 440–4 K.

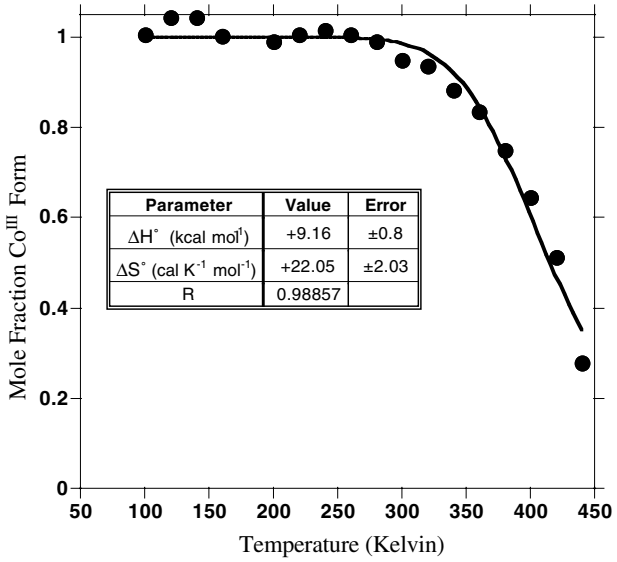

Fig. 3. Mole fraction of Co^{III}-form of **1** (from IVCT band) as a function of temperature. Data were fit according to equation in text.

As mentioned previously, the Co^{III} form of **1** might exhibit double exchange. This contribution to the stabilization of high-spin ground states is the result of the "single-site" semiquinone–nitronylnitroxide ferromagnetic exchange coupling and intramolecular electron transfer between the mixed-valent catecholate and semiquinone dyad. However, the Co^{III} forms of all known valence tautomers are vibronically trapped at low temperature such that catecholate and semiquinone bond lengths are readily distinguished [33]. This indicates that the mixed-valency in the crystalline state is in the Class I to early Class II limit within the Robin and Day scheme [27]. Although the catecholate and semiquinone moieties

are vibronically trapped at low-temperatures in the solid state, and do not show evidence for an appreciable thermal rate of electron exchange between the two sites, this does not preclude electron delocalization. In fact, this represents and interesting case where the off-diagonal electronic coupling matrix element, H_{ab}, is large enough to mix the SQ and CAT wavefunctions, but not large enough to reduce the thermal barrier, E_{th}, for facile thermal electron transfer between the two sites. The intense intervalence charge transfer (IT) transition shown in Fig. 2 provides key evidence for this system being classified in the Class II limit. Assuming simple harmonic potential surfaces and a small H_{ab}, the energy of this IVCT transition can be used to place an upper limit on the thermal barrier for electron transfer between vibronically trapped SQ and CAT sites. Since $E_{th} = E_{IT}/4$ in this limit, the barrier for electron exchange is $\sim$1000 cm^{-1}, which agrees with the valence trapping observed in the X-ray structures of Co^{III} valence tautomers [33]. Typically, a detailed analysis of the IVCT bandshape as a function of temperature is required to determine the degree of wavefunction mixing (electron delocalization) between the mixed valent sites in the Class II limit. We present here an introduction to a method that utilizes radical pendants as reporters of electron delocalization between mixed valent SQ and NN donors in the Co^{III} form of valence tautomeric **1**.

It is common for valence tautomers to display thermodynamic parameters for the valence tautomeric transition that are highly dependent on the matrix environment of the molecule. Thus, solution, polymer film, thin film and crystalline samples all display different entropic and enthalpic contributions to the relative stabilization of the Co^{II} and Co^{III} forms [33]. The magnetic data for a polycrystalline sample of **1** are shown in Fig. 4. The effective magnetic moment decreases from 3.35 μ_B at 350 K to 3.20 μ_B at 175 K. This decrease is indicative of the expected $Co^{II} \rightarrow Co^{III}$ conversion as the temperature is lowered, consistent with the valence tautomeric equilibrium. The magnetic data differ from the infrared results in that more of the Co^{II} form is observed in the latter experiments. The μ_{eff} value at $\sim$200 K is that anticipated for uncoupled $S_a = 1$ and $S_b = 1/2$ spins. Intramolecular exchange interactions in SQ–Ph–NN have been shown to be ferromagnetic, yielding a triplet ground state with $\boldsymbol{J} \sim 100$ cm^{-1} [34]. Thus, S_a represents the spin of the SQ–Ph–NN ligand and S_b that of CAT–Ph–NN. At temperatures below $\sim$150 K, μ_{eff} begins to increase. This is indicative of ferromagnetic *interligand* exchange interactions being operative. Below ca. 30 K, μ_{eff} decreases rapidly due to antiferromagnetic intermolecular interactions, common to nitronylnitroxide radicals [4]. The μ_{eff} data were fit to a field-independent triplet–doublet exchange model according to $\boldsymbol{H} = -2\boldsymbol{J}S_aS_b$ and incorporating intermolecular interactions via a mean-field approximation. The best-fit to the data is presented in Fig. 4, and the relevant spin–Hamiltonian parameters determined are $g = 2.00$ (fixed), $J = +4.7$ cm^{-1}, and $zJ' = -0.6$ cm^{-1}, with the inclusion of a small diamagnetic term.

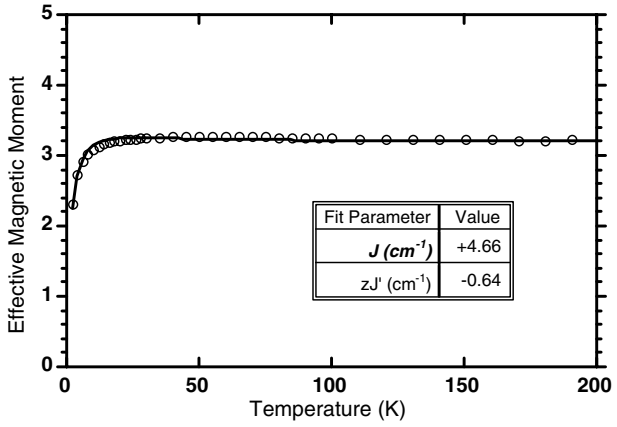

Fig. 4. Effective magnetic moment (B.M) of **1** as a function of temperature between 2 and 200 K.

The presence of interligand exchange is somewhat unanticipated, as the superexchange interactions must occur through a diamagnetic Co^{III} ion, and diamagnetic CAT–Ph. The shortest through-bond superexchange pathway incorporates 11 bonds, including two metal–ligand bonds. It would be remarkable if this represented a superexchange pathway capable of promoting "long-range" ferromagnetic exchange between the SQ–Ph–NN ligand and the NN of CAT–Ph–NN. The appearance of the intense IVCT band provides a key clue as to how to explain this apparent paradox. The intensity of an IVCT band, I_{IT}, is proportional to the square of the overlap intergral between the two molecular orbitals (primarily CAT and SQ in origin) involved in the one-electron promotion. This overlap relates directly to the mixing between SQ–Co^{III}–CAT and CAT–Co^{III}–SQ potential surfaces mediated by H_{ab} in the Robin and Day Class II scheme. This requires electron delocalization between the formal SQ and CAT ligand fragments. Thus, partial delocalization of the SQ unpaired electron onto the CAT moiety provides a convenient way to explain the presence of the intense IT band and ferromagnetic exchange coupling between S_a and S_b. Future work will serve to quantify this mixing, relate it to H_{ab}, and correlate the magnitude of the interligand ferromagnetic exchange with the nature of the interligand IVCT band.

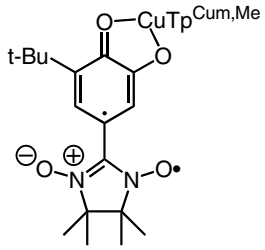

Fig. 1. Structure of (**NNSQ**)CuTp^{Cum,Me}.

where k is a two-electron exchange integral describing the self-repulsion of the overlap density, H_{ab} is the electronic coupling matrix element between orbitals a and b, and U is the single site Coulomb repulsion integral. Since H_{ab} is proportional to the overlap integral, $\langle a|b\rangle$, [4] ferromagnetic coupling is favored when the magnetic orbitals are either strictly or accidentally orthogonal. Under these conditions, $\langle a|b\rangle = 0$ and J reduces to $2k$. For organic biradicals, analysis of intramolecular exchange coupling is simplified by the fact that, within the active electron approximation [3], typically only two magnetic orbitals, a and b, are involved. In such cases, J simply reduces to (2)[2]

$$J = J_{\mathrm{F}} + J_{\mathrm{AF}} = 2k_{ab} - \frac{4H_{ab}^2}{U}. \tag{2}$$

When organic bi- and polyradicals possess orthogonal SOMOs the electronic coupling matrix element, H_{11}, is zero. The presence of a large overlap density, $\rho(i)$ [3], results in an appreciable value for the two-electron exchange integral, k, and a ferromagnetic interaction results [3]

$$k = \int_{\mathrm{space}} \rho(1)\rho(2) r_{12}^{-1}\, \mathrm{d}\tau. \tag{3}$$

This model has been particularly useful for understanding the exchange interaction in non-disjoint [5] symmetric- and non-disjoint unsymmetrical biradicals [2,6–10].

Herein, we use a valence bond configuration interaction (VBCI) model to explain the electronic origin of strong ferromagnetic exchange coupling in an organic biradical ligand. To our knowledge, this is the first time that the VBCI model has been used to examine ferromagnetic exchange interactions in an organic biradical. Moreover, the electronic origin of the high spin ground state is supported by the appearance of an intramolecular charge transfer (ILCT) transition in the biradical ligand **NNSQ**, where **NN** is nitronyl nitroxide and **SQ** is 5-*tert*-butyl-semiquinone (Fig. 1). The VBCI model has been used to understand excited state contributions to the ground state intramolecular exchange interaction, J, in multinuclear transition metal systems [11–19]. Thus, our use of a VBCI model in donor–acceptor biradicals (vide infra) links exchange coupling studies of inorganic systems with their organic counterparts, and provides a connection between heretofore unrelated systems.

[2] Within the active-electron approximation, the intramolecular exchange interaction, J, is expressed as a sum over all antiferromagnetic and ferromagnetic pathways, see [3].

2. Experimental

2.1. Electronic absorption spectroscopy

Electronic absorption spectra were collected using a double beam Hitachi U-3501 UV–Vis–NIR spectrophotometer capable of scanning the wavelength region between 185 and 3200 nm. Wavelength calibration was done against the deuterium 656.10 nm line. Background corrections were accomplished by first scanning neat solvent over the relevant wavelength range in the spectroscopic cell to be used for sample. Room temperature (300 K) spectra were collected in CH_2Cl_2 at 2.0 nm resolution in a single-beam configuration using masked spectrosil quartz cells.

2.2. Electron paramagnetic resonance (EPR) spectroscopy

Frozen glass EPR spectra were measured at X-band (~9.3 GHz) using a Bruker EMX spectrometer. Low temperature EPR measurements were performed using 2-methyl tetrahydrofuran as a glassing agent, and the temperature was held at 4 K in an Oxford liquid helium flow cryostat. Calculation of the $g_{\|}$ and $g_{\perp}$ $\Delta m_{\mathrm{s}} = \pm 1$ EPR line positions were performed using closed form expressions for the eigenvalues of an $S_{\mathrm{T}} = 3/2$ system with the magnetic field oriented parallel and perpendicular to the molecular z-axis.

2.3. Magnetic circular dichroism (MCD) spectroscopy

Low temperature MCD spectra were collected on a system consisting of a Jasco J600 CD spectropolarimeter employing Hamamatsu photomultiplier tubes of either S-1 or S-20 response, an Oxford Instruments SM4000-7T superconducting magneto-optical cryostat (0–7 T, 1.4–300 K), and an ITC503 Oxford Instruments temperature controller. The spectrometer was calibrated for circular dichroism intensity with camphorsulfonic acid and the wavelength was calibrated using Nd-doped glass. All spectra were collected at 2.0 nm resolution at a temperature of 5 K in an applied magnetic field of 7 T. Samples were prepared for low temperature (5 K) MCD spectrosocopy by dissolving the complex in toluene and polystyrene, then casting thin polymer films. The polystyrene films were then housed in a custom designed sample cell. Depolarization of the incident radiation by the sample

was determined by comparing the intrinsic circular dichroism of a standard Ni(+)-tartrate solution positioned in front of and then in back of each sample.

3. Results and analysis

3.1. Electronic absorption spectroscopy

The room temperature electronic absorption spectrum of (**NNSQ**)CuTp^{Cum,Me} is presented in Fig. 2. Relevant band maxima occur at ~11 000 ($\varepsilon \sim 625\ M^{-1}\ cm^{-1}$), ~18 000 ($\varepsilon \sim 1875\ M^{-1}\ cm^{-1}$), 24 500 ($\varepsilon \sim 13\,500\ M^{-1}\ cm^{-1}$), and 29 000 cm^{-1} ($\varepsilon \sim 13\,000\ M^{-1}\ cm^{-1}$). The ~24 500 cm^{-1} band is not present in absorption spectra of the constituent **SQ** and **NN** chromophores found in (**SQ**)ZnTp^{Cum,Me} and the aryl nitronyl nitroxide, Ph–**NN**. This behavior is consistent with the presence of an intraligand ILCT charge transfer transition from the donor (**SQ**) fragment to the acceptor (**NN**) fragment.

3.2. Magnetic circular dichroism spectroscopy

The low temperature MCD data for (**NNSQ**)-CuTp^{Cum,Me} is also presented in Fig. 2 for direct comparison with the electronic absorption spectrum. There are two types of maxima found in the MCD spectrum of (**NNSQ**)CuTp^{Cum,Me}, and these either correspond with, or do not correspond with, the observed absorption maxima. The bulk of the MCD intensity is negative, indicative of a large degree of out-of-state spin–orbit mixing between the excited states and the ground state wavefunction. This type of mixing is also responsible for zero-field splitting of the ground spin state (vide infra). Finally, the MCD features in the ILCT region possesses comparatively low intensity and indicate that very little orbital angular momentum arising from the paramagnetic Cu(II) center is mixed into the excited state responsible for the 29 000 cm^{-1} transition. This provides further support that the 29 000 cm^{-1} band is an ILCT transition.

3.3. Electron paramagnetic resonance spectroscopy

The 5 K X-band frozen glass EPR spectrum of (**NNSQ**)CuTp^{Cum,Me} is presented in Fig. 3, and is typical of an $S_T = 3/2$ ground state. Resonances centered at ~1770, and ~3380 G are typical of $S_T = 3/2$ centers with $D > h\nu$ and represent transitions from molecules oriented perpendicular (xy) and parallel (z) the applied magnetic field direction. A small rhombic anisotropy is evident on the low-field, perpendicular resonance. Additional weak resonances are observed at higher magnetic fields (~5650 and ~6900 G).

Analysis of the EPR spectrum of (**NNSQ**)CuTp^{Cum,Me} is accomplished by constructing resonance line positions as a function of the axial zero-field parameter, D, within an $|S_T = 3/2, m_s\rangle$ basis (Fig. 4). The appropriate spin-Hamiltonian is

$$H = g_{\|}\beta H \cdot \hat{S}_z + g_{\perp}\beta H \cdot \hat{S}_x + D[\hat{S}_z^2 - S_T(S_T+1)/3]. \quad (4)$$

Manual adjustment of the g-values and the axial zero-field splitting parameter, D, were used to generate an appropriate simulation of the resonant line positions, and this analysis yielded a value of $|D| \sim 0.5\ cm^{-1}$ for (**NNSQ**)CuTp^{Cum,Me}.

3.4. The valence bond configuration interaction (VBCI) Model

For organic biradicals, the intramolecular exchange coupling is often described within the active electron approximation [3], where only two magnetic orbitals are involved. Alternatively, the exchange interaction in heterospin biradicals of the donor–acceptor type [20–33] may be described by a VBCI model. The biradical ligand **NNSQ** is a donor–acceptor molecule that has been shown to possess a strong intramolecular ferromagnetic

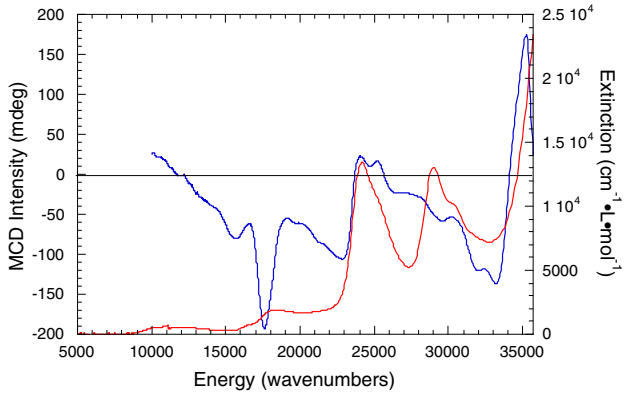

Fig. 2. 5 K MCD, 300 K Absorption overlay. MCD spectra were collected as polystyrene thin films and absorption spectra were recorded in CH_2Cl_2.

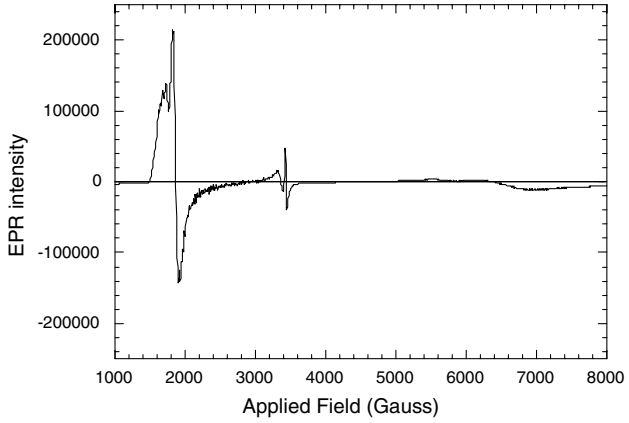

Fig. 3. 5 K X-band EPR spectrum of (**NNSQ**)CuTp^{Cum,Me}. EPR spectra were collected as a 2-methyl tetrahydrofuran glass.

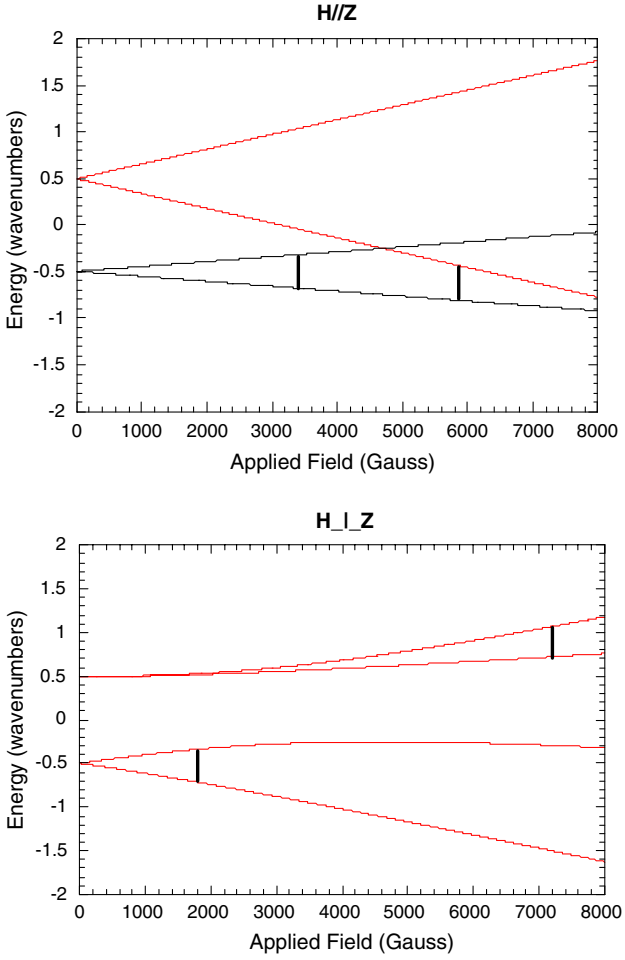

Fig. 4. X-band resonant line positions (vertical lines) calculated for an $S_T = 3/2$ center with $|D| = 0.5$. Two EPR resonances are anticipated with this D value for molecules oriented in the parallel and perpendicular directions relative to the applied magnetic field.

exchange interaction [22,34]. An orbital and state energy diagram for (**NNSQ**)ZnTp^{Cum,Me} is presented in Fig. 5 using **NN** and **SQ** fragment orbitals as initial basis functions. Since the **NN** and **SQ** SOMO fragments are orthogonal, the electronic coupling matrix element,

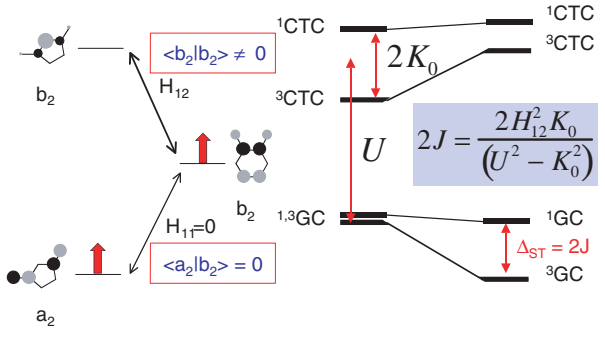

Fig. 5. Frontier orbitals and configurations for the **NNSQ** biradical ligand. Symmetry labels are for idealized C_{2v} symmetry of the donor (**SQ**) and acceptor (**NN**) fragments.

H_{11}, is zero and the singlet (^{1}GC) and triplet (^{3}GC) ground configurations are degenerate in first-order. Therefore, within the active electron approximation, J_{NN-SQ}, $= 0$ is predicted since both H_{11} and k_{11} are zero. The predicted exchange interaction is in stark contrast to what is observed experimentally for this and related donor–acceptor biradicals [24,35]. The intraligand exchange interaction in (**NNSQ**)CuTp^{Cum,Me} was previously shown to be strongly ferromagnetic with an upper limit estimated to be $J_{NN-SQ} \approx +550\ cm^{-1}$. To understand the electronic origin of this strong ferromagnetic exchange interaction, we must proceed beyond the active electron approximation and include virtual orbitals.

According to Fig. 5 a **SQ** $\rightarrow$ **NN** charge transfer (ILCT) transition is anticipated since $H_{12} \neq 0$. Thus, electronic absorption spectroscopy should be a sensitive probe of H_{12}, with the intensity of the ILCT transition being proportional to the square of the electronic coupling matrix element ($I_{ILCT} \propto {H_{12}}^2$). The electronic absorption spectrum in Fig. 2 reveals the presence of an ILCT transition in (**NNSQ**)CuTp^{Cum,Me} that is not present in the constituent chromophores and can be tentatively assigned as a **SQ** $\pi \rightarrow$ **NN** π^* ILCT transition. The extent to which the $a_2^1 b_2^1$ ^{3}CT configuration mixes into the ^{3}GC $a_2^1 b_2^1$ ground configuration will result in an energetic stabilization of ^{3}GC and a high-spin triplet ground state.

To determine the magnitude of the ^{3}GC state stabilization relative to the ^{1}GC state in non-disjoint biradicals, a perturbative expression has be derived within this simple three orbital model. According to this model, the ground state singlet–triplet gap, $2J$, is

$$2J = \frac{2H_{12}^2 K_0}{U^2 - K_0^2}, \tag{5}$$

where K_0 is a single-site exchange integral that splits the $a_2^1 b_2^1$ singlet and triplet excited state configurations (Hund's rule). Eq. (5) shows that the ferromagnetic interaction is maximized in heterospin biradicals when (1) the electronic coupling matrix element that connects one monomer fragment SOMO and the other monomer fragment LUMO is maximized, (2) the single-site exchange integral is large, and (3) the intramolecular ILCT energy ($U - K_0$) is low. Thus, these represent key design criteria for the synthesis of donor–acceptor heterospin biradicals with high-spin ground states.

4. Discussion

A key connection may be made between the VBCI model and the origin of ferromagnetic interactions in the active electron approximation. The magnitude of H_{12} is proportional to the $\langle \mathbf{SQ}(b_2)|\mathbf{NN}(b_2)\rangle$ overlap

integral, which describes the degree of mixing between these two orbitals. This orbital mixing results in some **NN**(b_2) orbital character being mixed into the **SQ**(b_2) SOMO. In the active electron approximation, the SOMO–SOMO overlap is still zero, but there is significant overlap *density* between atomic orbitals localized on the NN fragments of the two SOMO's [3]. This results from the admixture of the **NN** b_2 LUMO into the **SQ** b_2 SOMO, and yields a key relationship between the origins of the ferromagnetic exchange interaction within the VBCI and active electron approximations for heterospin biradicals

$$\frac{H_{12}^2 K_0}{U^2 - K_0^2} = \int_{\text{space}} \rho(1)\rho(2) r_{12}^{-1}\, \mathrm{d}\tau. \tag{6}$$

It is of interest to note that (**NNSQ**)CuTp$^{\text{Cum,Me}}$ possesses a sizable axial anisotropy, $|D|$, of $\sim 0.5\ \text{cm}^{-1}$. This is relatively remarkable for a spin quartet complex that is formed from three different $S_i = 1/2$ spin carriers (Cu(II), **NN**, and **SQ**), two of which possess no appreciable orbital angular momentum. A large value of $|D|$ has also been observed by Gatteschi and coworkers in a Cu–semiquinone complex [36]. A large uniaxial anisotropy is important in the design of single-molecule magnets that possess high blocking temperatures. Thus, the **SQNN** ligand fragment may represent a key design element in the construction of new hybrid organic/inorganic single-molecule magnets.

In summary, utilization of a VBCI model as applied to organic biradicals provides key design criteria for the synthesis of new high-spin organic and hybrid metal–organic molecular materials, which can be monitored conveniently by optical spectroscopies. Stabilization of the zero-field split ^{3}GC is strongly dependent on the magnitude of the electronic coupling matrix element, H_{12}, that describes the efficiency of electron transfer from the **SQ** donor to the **NN** acceptor. Future work will detail the preparation of new donor–bridge–acceptor biradicals dyads, their spectroscopic and magnetic characterization, accurate evaluation of H_{ab}, and the relationship of H_{ab} to the nature of the bridge fragment in D–bridge–A heterospin biradicals.

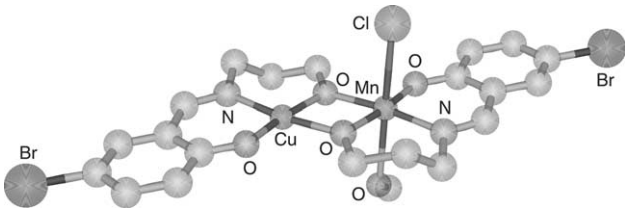

Fig. 1. Molecular structure of $Mn^{III}Cu^{II}(5\text{-Br-sap})_2Cl(MeOH)$. The axial positions of the Mn^{3+} ion are occupied by chloride ion and oxygen, and these positions exhibit Jahn–Teller elongation.

15 K. Hysteresis of magnetization is observed below ~0.5 K by SQUID magnetometer with the slow sweep (<0.1 T/min) of the external field, and the blocking temperature T_B is suggested to be approximately 0.5 K from the AC-susceptibility measurements [1].

NMR has been a powerful tool to study molecular magnets from a microscopic viewpoint. In this paper, we present the experimental results of ^1H and ^{55}Mn NMR of the MnCu cluster in the temperature range down to 0.4 K.

2. Experiments

A single crystal of MnCu cluster was used for our experiments. The magnetic field was always applied along *c*-axis, which is the magnetic easy axis of the crystal. We used a conventional pulsed NMR method and the NMR spectrum was recorded by measuring the intensity of the spin-echo, while sweeping the value of the applied field. The experiments at very low temperatures down to 0.4 K were performed with liquid ^3He.

3. Experimental results and discussion

Fig. 2 shows ^1H NMR spectra observed at several temperatures with the operating frequency of 128.1 MHz. It should be found that the spectrum has several peaks which are widely shifted below about 3 K. This fact suggests that the static magnetic moment is stabilized rapidly with decreasing temperature even above the blocking temperature $T_B \sim 0.5$ K. Then, in this temperature region, one can expect that NMR of Mn nuclei is possible under zero or small external field due to the static and strong hyperfine field caused from the magnetic moment of Mn^{3+}. In fact, we found ^{55}Mn NMR signal of MnCu cluster below about 1.5 K under the applied field around 2 T. Fig. 3 shows ^{55}Mn NMR spectra recorded by sweeping the field applied along the easy axis at $T \sim 1.2$ K. Note that, for Mn_{12} cluster magnets, ^{55}Mn NMR signal has not been detected above the blocking temperature. As shown in Fig. 3, each peak shifted toward higher field as the frequency was reduced. This fact is adequate for the quadrupole-split ^{55}Mn

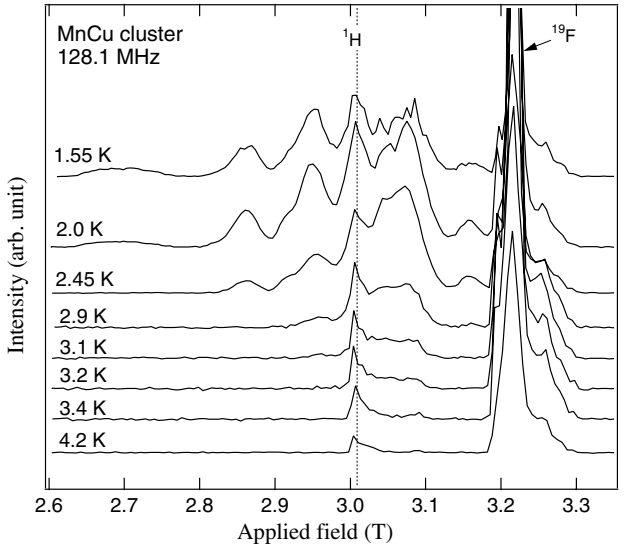

Fig. 2. ^1H NMR spectra observed at several temperatures with the operating frequency of 128.1 MHz. The dotted line shows the zero shift position of ^1H. The spectrum has several peaks and they are widely shifted below about 3 K. ^{19}F was contained in a sample holder, which yields the higher field peaks.

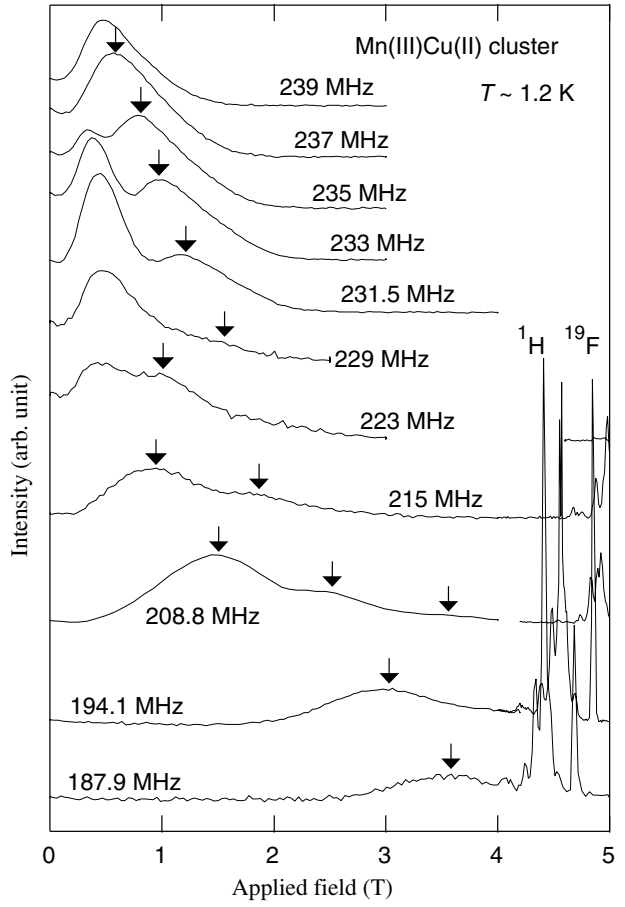

Fig. 3. Field-sweep ^{55}Mn NMR spectra obtained at ~1.2 K at several values of the operating frequency. The magnetic field is applied along the *c*-axis. The arrows indicate ^{55}Mn resonance peaks.

NMR ($I = 5/2$) of Mn^{3+} ions whose moments are nearly parallel to the external field, as discussed below. Because the nuclear spin–spin relaxation time T_2 became very short as the field was decreased, NMR signal was strongly damped near zero field. Then, non-essential peaks appeared around 0.4 T. From these results, we obtain the frequency–field diagram of ^{55}Mn NMR peaks as shown in Fig. 4. Three resonance lines from fivefold quadrupole-split lines for ^{55}Mn nuclei ($I = 5/2$) are clearly observed, and each line shifts as,

$$\nu_i(H) = \nu_i(0) - \frac{^{55}\gamma}{2\pi}H, \tag{2}$$

where $^{55}\gamma/2\pi = 10.55$ MHz/T is the gyromagnetic ratio of ^{55}Mn, except for the non-essential peaks around 0.4 T marked as crosses (+). Then, we found the quadrupole-split of ^{55}Mn to be 9.3 MHz. Because the outside lines arising from the transitions I_z: $\pm 3/2 \leftrightarrow \pm 5/2$ have small intensity as compared to the central three lines, we believe that the center of the observed three lines corresponds to the central transition I_z: $1/2 \leftrightarrow -1/2$. Therefore, the central resonance line at zero field will appear at $\nu_0 = 234$ MHz which correspond to the hyperfine field of $H_N = \nu_0/^{55}\gamma = 22.3$ T. This value of the central resonance line is much smaller than those for Mn^{3+} sites in Mn12Ac, 279.4 and 364.4 MHz [2].

Generally, the magnetic hyperfine field $\boldsymbol{H}_N$ caused at nuclear position consists of the Fermi-contact term $\boldsymbol{H}_F$, dipolar term $\boldsymbol{H}_d$ and orbital term $\boldsymbol{H}_l$, resulting from the corresponding components of the magnetic hyperfine interactions. The Fermi-contact term, which is attributed to the core polarization of inner s electron caused by 3d-electron spins, is dominant in magnitude among the three terms, and opposite in direction to the electronic magnetic moment. Therefore, the above results

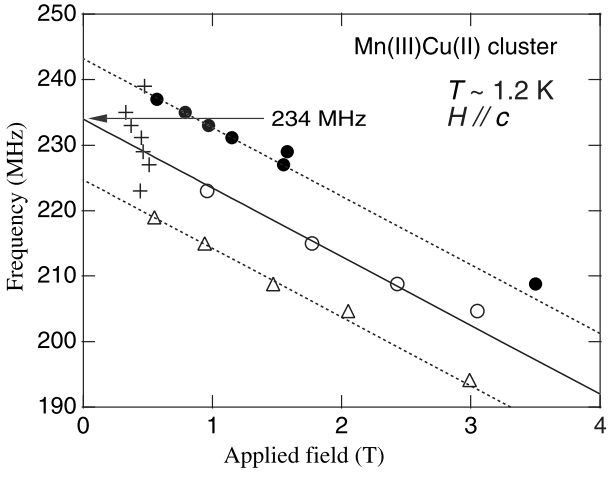

Fig. 4. Frequency–field diagram of ^{55}Mn NMR peaks on the basis of the observed spectra shown in Fig. 3. The non-essential peaks around 0.4 T are marked as crosses (+). The solid and the dotted lines show the field dependences of the central and the next to the central resonance lines of ^{55}Mn nuclei ($I = 5/2$), respectively. The central resonance frequency at zero external field is estimated to be 234 MHz.

that each line shifts as in Eq. (2) are natural when the magnetic moment is directed nearly parallel to the external field. For an orbital doublet ion such as Mn^{3+}, the hyperfine field is rather complicated as compared to orbital singlet ion such as Mn^{2+}, Mn^{4+}, etc., because the electronic ground-state wave function is anisotropic due to Jahn–Teller effect, which causes a considerable amount of the dipolar hyperfine field. The contribution of the dipolar term to the total hyperfine field depends on the angle θ between the magnetic moment and the tetragonal axis of the crystal field. Here, we neglect the orbital term because it is much smaller than other terms for most cases [2].

After all, the value of the magnetic hyperfine field H_N is expressed in terms of isotropic term H_F and anisotropic one H_d as,

$$H_N = H_F + \tfrac{1}{2}(3\cos^2\theta - 1)H_d. \tag{3}$$

It should be noted here that H_F is negative (opposite to the electronic magnetic moment) and H_d is positive, then H_N is negative because $|H_F| > H_d$ normally. In fact, our results suggest the negative value of H_N as shown in Fig. 4. Therefore, the absolute value of the hyperfine field H_N is smallest in case of $\theta = 0°$, namely, the electronic magnetic moment is parallel to the tetragonal axis. Then, let us discuss the absolute value of H_N from now on.

For Mn12Ac, the values of H_F and H_d have been obtained by taking into account the reduction of the local magnetic moments on the manganese ions, which yields the reduction of these values as compared to the values for free manganese ions [2]. For the first approximation, if we use here the values of H_F and H_d for Mn^{3+} in Mn12Ac, we obtain $|H_N| = 25.5$ T for $\theta = 0°$ from Eq. (3). This value is a little larger than our result, 22.3 T. Our results infer that the local moment on Mn^{3+} in MnCu cluster is similarly (or more) reduced as compared to the cases of Mn12 clusters. The followings should be noted: If $\theta = 0°$, which means the magnetic moment is tilted from the crystal c axis by approximately $\pm 20°$, the frequency–field diagram shown in Fig. 4 should be modified to $\nu_i(H) = \nu_i(0) - {}^{55}\gamma H/2\pi \times \cos 20°$. Even though the magnetic moment is tilted, the obtained results of $\nu_i(H)$ shows still in fairly good agreement within the experimental error. In order to clarify the direction of the magnetic moment, the detailed experiments are necessary.

Here, we also present the preliminary results at much lower temperatures. As the temperature was lowered, the spin-echo intensity increased and T_2 became longer, then we can measure the NMR spectrum near zero field. Fig. 5 shows the spectrum recorded at 0.4 K with the sweep rate of 0.4 T/min from the negative to the positive values of the field, which means the reversal of the field crossing the zero field. The hysteresis of the spectrum was observed in ± 0.4 T around zero field. As shown in

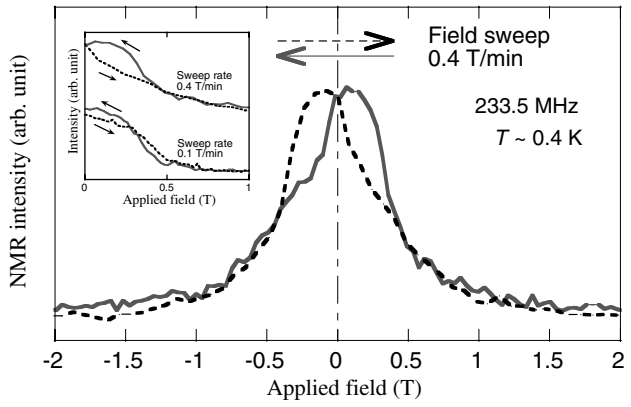

Fig. 5. Field-sweep spectrum obtained at 0.4 K which shows a hysteresis clearly around zero field. The field is increased from −3 to +3 T crossing the zero field for the gray line; the field is swept oppositely for the dashed line, by the same sweep rate of 0.4 T/min. Inset: Comparison between the different values of the sweep rate. The faster the field is swept, the wider the hysteresis becomes.

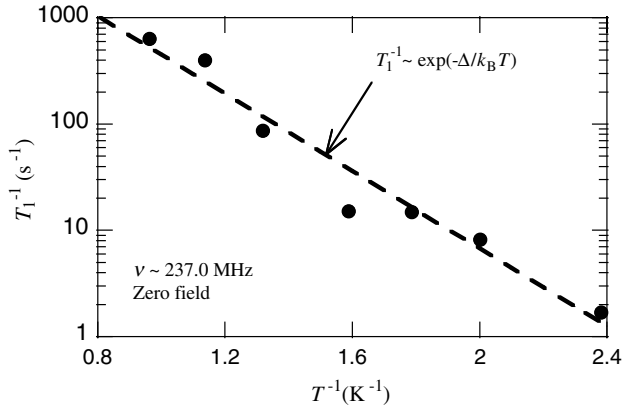

Fig. 6. The nuclear spin-lattice relaxation rate T_1^{-1} of ^{55}Mn vs. inverse temperature $1/T$ under zero external field. T_1^{-1} shows the activation type behavior, $T_1^{-1} \sim \exp(-\Delta/k_B)$ with $\Delta/k_B = 4.2$ K.

the inset, it was also found that the faster the field was swept the wider the hysteresis became. These behaviors are to be attributed to the slow relaxation of the electronic magnetization. Such a hysteresis of NMR spectrum related to the magnetization reversal was clearly shown in Mn12Ac [7].

The temperature dependence of the nuclear spin-lattice relaxation rate T_1^{-1} of ^{55}Mn under zero external field is shown in Fig. 6. The activation type behavior, $T_1^{-1} \sim \exp(-\Delta/k_B)$, was obtained with $\Delta/k_B = 4.2$ K. If we assume that Δ is associated with the energy gap between $S_z = \pm 5/2$ and $\pm 3/2$, Δ/k_B is $4D/k_B \simeq 10$ K. Since our data are rather scattered to date, we will perform further measurements. One may consider that such an activation type behavior of T_1^{-1} suggests no magnetic long-range order down to 0.4 K, because normally T_1^{-1} shows divergent behavior around ordering temperature due to the critical slowing down. However, we should be careful to distinguish by ^{55}Mn NMR the critical slowing down from the slowing down of the reversal probability of the magnetization of each molecule. The further experiments and the detailed discussions will appear elsewhere.

2. Experimental

2.1. Materials and measurements

All reagents and materials used for synthesis were reagent grade and used without further purification.

IR spectra were recorded with KBr pellets on a Brucker EQUINOX 55 FT-spectrometer. ^{1}H, ^{13}C, ^{31}PNMR spectra were taken on an AM-500 spectrometer operating at 500 MHZ, using DMF as solvent.

2.2. Synthesis

The crystal used for X-ray diffraction experiment was obtained as follow: 0.8 g of $Na_2WO_4 \cdot 2H_2O$ and 0.5 g of Na_3PO_4 were dissolved in 30 ml CH_3OH, adjusting its pH to 3.0 with hydrochloric acid, 0.1 g DB18C6 was added, stirring about 20 h, the solution was filtered, the residue was dried at room temperature, then transferred into a Teflon-Steel autoclave inside programmable electric furnace reactor with 20 ml CH_3CN as solvent. Solvothermal reaction lasted for 20 h at 423.15 K, then cooled to room temperature naturally. Yellow prism suitable for single crystal X-ray diffraction experiment was obtained. *Anal*. Calc. C, 19.10; H, 1.97; N, 1.01. Found: C, 19.12; H, 1.94; N, 1.01%. Selected bond lengths and angles are listed in Table 3.

2.3. X-ray crystallography

Yellow crystal measuring $0.30 \times 0.20 \times 0.15$ mm, $[Na(DB18C6)(CH_3CN)]_3$ [α-$PW_{12}O_{40}$] was obtained by solvothermal reaction method. At 293 K, the crystal data is collected by Rigaku RAXIS RAPID IP equipped with graphite monochromated Mo Kα radiation. The procedure for data reduction was carried out by SAINT PLUS, and the structure was solved by direct method and refined by use of SHELEX 97. Crystallography data are summarized in Table 1.

3. Results and discussion

3.1. IR spectra

The IR spectra of title compounds exhibit four characteristic asymmetric vibrations, resulting from the heteropolyanions with the α-Keggin structure. Comparing the IR spectra with that of α-$H_3PW_{12}O_{40}$ [15], the peaks belong to the W=Ot bonds shifts from 982 to 981 cm^{-1}, and the W–Ob and W–Oc bonds shift from 890 810 to 895 815 cm^{-1} (Ot = terminal oxygen, Ob = bridged oxygen of tow octahedral sharing a corner, Oc = bridged oxygen sharing an edge); the P–O bonds appear at nearly identical frequencies ($\nu_{(P-O)}$ = 1079 cm^{-1}) to that found for α-$H_3PW_{12}O_{40}$. This shows that polyanions retain the basic α-Keggin structure, yet a little distortion for the coordination influence, and that is in consistent with the result of single crystal X-ray diffraction experiment. Characteristic vibrations of DB18C6, α-$H_3PW_{12}O_{40}$ and the title compound are listed in Table 2. Features at 2937, 1506, 1455, 1254, and 1218 cm^{-1} are characteristic

of dibenzo-18-crown-6. In comparison with the free dibenzo-18-crown-6 molecule, ν(C–O) of the compounds shifts from 1231 to 1218 cm^{-1}, which illustrating the crown ether are coordinated to sodium ions.

3.2. NMR spectra

The ^{1}H NMR spectrum contains four sharp signals in a relative ratio 1:1:2:2 (6.91, 6.80, 4.08 and 3.85 ppm) assigned to the aromatic and alky^{l} H atoms of dibenzo-18-crown-6 and a peak at 2.02 ppm related to the H atom of CH_3CN. Six resonances (149.33, 122.49, 112.92, 70.62, 68.90 and 2.00) are exhibited in ^{13}C NMR spectrum, which associated with three aromatic and two alkyl C atoms of DB18C6 and the C atom of $–CH_3$, respectively. The ^{13}C resonance (119.27 ppm) bonded to N atom in CH_3CN has been clarified by gUMBC spectrum (see Fig. 1), which is too weak to be observed in ^{13}C NMR spectrum due to its too low relaxation rate. The ^{31}P chemical shift of title complex is 15.49 ppm in solid state while is 12.75 ppm in DMF solution, showing that a little downfield shift took place on going from solid state to solution.

3.3. Crystal structure

The super molecular complex, shown in Fig. 2, contains an $[\alpha\text{-}PW_{12}O_{40}]^{3-}$ anion and three $[Na(DB18C6)(CH_3CN)]^{+}$ units. $[\alpha\text{-}PW_{12}O_{40}]^{3-}$ reported by Keggin in 1933 shows overall Td symmetry and is based on a central PO_4 tetrahedron surrounded by 12 WO_6 octahedrons arranged in four groups of three edge-shared octahedron W_3O_{13}. The W_3O_{13} triplet linked by shared corners to each other and to central PO_4 tetrahedron [8]. As depicted in Fig. 2, each of sodium cations is located in the cavity of dibenzo-18-crown-6 (DB18C6) with six Na–O bonds and associated with the terminal O atoms of $[\alpha\text{-}PW_{12}O_{40}]^{3-}$ and the N atom of CH_3CN from two sides of the distorted DB18C6 plane. The three terminal O atoms linked with sodium ion are from a single W_3O_{13} triplet of the α-Keggin tungstophosphate anion. The complex $[Na(DB18C6)(CH_3CN)]_3[\alpha\text{-}PW_{12}O_{40}]$, is a neutral and discrete molecule, which is packed in the crystal via van der waals forces seen in Fig. 3.

The three sodium cations are identical in coordination environment and space sphere and the three sodium crown cation units were associated with a single W_3O_{13} triplet by tree Na–O–W bonds. Due to steric hindrance $[Na(DB18C6)(CH_3CN)]_3[\alpha\text{-}PW_{12}O_{40}]$ forms discrete molecule other than polymer. Noritaka et al. has reported the synthesis an structure of $[(CH_3)N_4Na_2H][\alpha\text{-}PW_{12}O_{40}]$, which forms extended three-dimensional structure [16]. Structure of such crown ether-polyoxometalates compounds depend on the coordination interactions between the Na^{+} ions and the terminal oxygen atoms of the α-Keggin anion and the Van der Waals force among organic components.

Organic–inorganic hybrid compounds including heteropolyanions and crown ether reported usually use heteropolyanions as precursor [5,14,6], in which organic and inorganic moieties were connected by electronic interaction or covalent bonds. In our work, $NaWO_4 \cdot 2H_2O$ instead of polyanions was used. It is all known that the structure of polyoxometalates is sensitive to PH, so, we adjusted PH in range of 1–4 with hydrochloric acid, the same compounds was obtained. As usual, it is difficult to assigning the position of C atom connected with N atom by multi-bonds in ^{13}C spectrum because the intensity of ^{13}C resonance of the C atom is too weak to be observed due to its too low relaxation rate, but it has been determined easily by gUMBC spectrum in our paper.

2. Experimental

2.1. Compound preparations

All manipulations were performed under aerobic conditions using materials and solvents as received.

2.1.1. $[Mn_{11}O_2(OH)_2(nmpd)(pdmH)_5(pdm)_5Cl_6]\cdot 4MeCN$ (1)

Treatment of a solution of $MnCl_2\cdot 4H_2O$ (0.75 mmol, 0.15 g), $pdmH_2$ (2.5 mmol, 0.34 g) and $nmpdH_2$ (0.75 mmol, 0.10 g) in a mixture of MeCN/MeOH (35 mL/5 mL) with one equivalent of NMe_4OH (0.25 mmol, 0.10 mL) results in the formation of a dark brown solution. This was allowed to stand undisturbed for two days, and during this time large, needle-shaped brown crystals slowly crystallized of a material identified by crystallography as $[Mn^{III}_7Mn^{II}_4O_2(OH)_2(nmpd)(pdmH)_5(pdm)_5Cl_6]\cdot 4MeCN$ ($\mathbf{1}\cdot 4MeCN$). These crystals were isolated by filtration in 64% yield. *Anal*. Calc. for dried (**1**): C, 38.17; H, 4.45; N, 5.44. Found: C, 38.29; H, 4.68; N, 5.69%.

2.1.2. $[Mn_{25}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]Cl_2\cdot 12MeCN$ (2)

A stirred, pale brown slurry of $MnCl_2\cdot 4H_2O$ (0.75 mmol, 0.15 g), $pdmH_2$ (2.5 mmol, 0.34 g) and NaN_3 (2.5 mmol, 0.16 g) in MeCN/MeOH (20 mL/10 mL) was treated with NMe_4OH (0.25 mmol, 0.10 mL). This resulted in a dark brown solution, which was allowed to stand undisturbed for a few weeks during which time $[Mn^{IV}Mn^{III}_{18}Mn^{II}_6O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]Cl_2\cdot 12MeCN$ ($\mathbf{2}\cdot 12MeCN$) slowly crystallized. The black crystals were isolated in ~30% yield. *Anal*. Calc. for dried (**2**): C, 25.72; H, 2.36; N, 17.14. Found: C, 26.01; H, 2.68; N, 17.15%.

3. Results and discussion

3.1. Structural description of $[Mn_{11}O_2(OH)_2(nmpd)(pdmH)_5(pdm)_5Cl_6]\cdot 4MeCN$ ($\mathbf{1}\cdot 4MeCN$)

A labeled ORTEP plot and the central core of **1** are presented in Figs. 1 and 2, respectively. Complex $\mathbf{1}\cdot 4MeCN$ crystallizes in the monoclinic space group $P2_1/c$ with the asymmetric unit consisting of the cluster and four molecules of acetonitrile. The cluster is trapped-valence $Mn^{III}_7Mn^{II}_4$ and has an unusual undecanuclear cage structure, with seven central manganese ions (Mn3, Mn4, Mn5, Mn6, Mn7, Mn8, Mn9) held together by two μ_4-O atoms (O13, O8). Two dinuclear Mn^{III}–Mn^{II} units (Mn2–Mn1, Mn10–Mn11) are linked to each end of the Mn_7 core via μ_3-alkoxide oxygen atoms (O4, O18) provided by pdm ligands. Furthermore, two hydroxide ions (O5, O17) and alkoxide

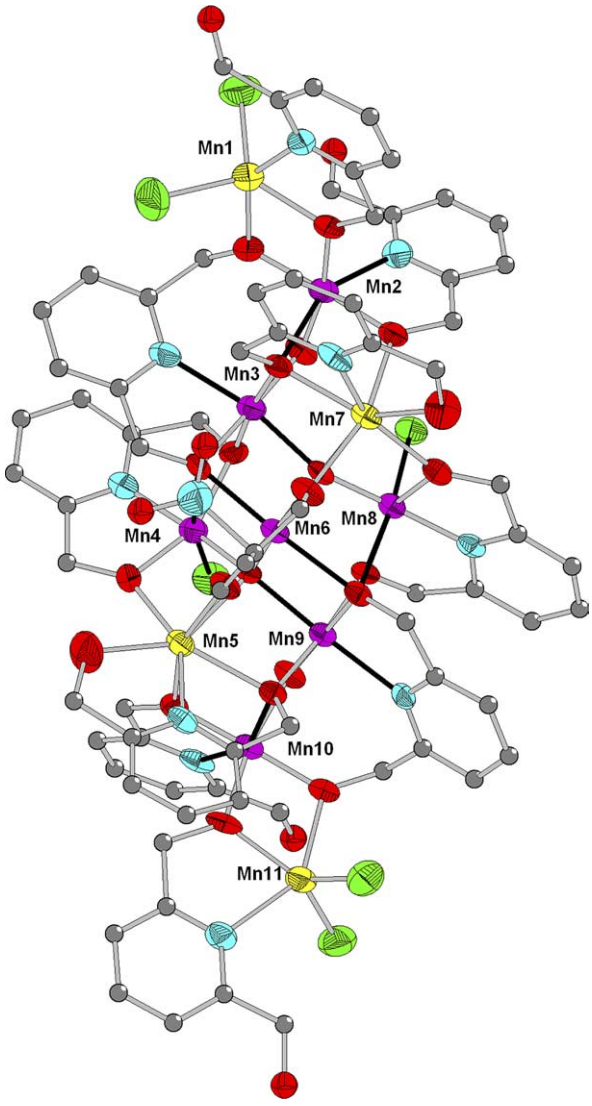

Fig. 1. ORTEP representation at the 50% probability level of complex **1**. All H atoms have been removed for clarity. Color code: purple, Mn^{III}; yellow, Mn^{II}; pale green, Cl; red, O; blue, N; gray, C.

oxygen atoms (O1, O2, O3, O7, O9, O10, O11, O12, O13, O15, O16, O19, O21, O22) from pdm and nmpd ligands provide additional bridges between the Mn ions. The coordination spheres of the Mn ions are completed by N atoms from pdm groups and six terminal Cl^- ions. The hydroxide oxygen atoms (O5 and O17), as well as the uncoordinated oxygen atoms (O25, O26, O27 and O28) are protonated, as confirmed by bond valence sum calculations; their H atoms were included in calculated, idealized positions and were refined riding on their parent atoms.

Inspection of the bond distances and bond valence sum calculations reveal that the Mn(2), Mn(3), Mn(4), Mn(6), Mn(8), Mn(9) and Mn(10) are in oxidation state Mn^{III} while the remainder of the metal ions are Mn^{II} (Figs. 1 and 2). All Mn^{III} centers display Jahn–Teller (JT) distortions as expected for high spin d^4 ions in near

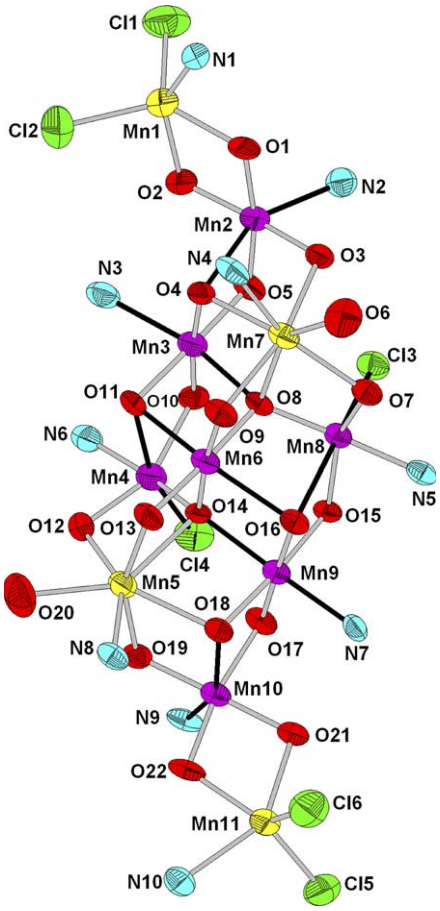

Fig. 2. Labeled ORTEP representation of the central core of complex **1**. JT axes are indicated as solid black bonds.

octahedral geometry. These take the form of axial elongations, and the JT axes are indicated as solid black bonds in Figs. 1 and 2. A close look at the crystal packing reveals no evidence of intermolecular hydrogen bonding interactions between molecules; however, intermolecular pi-stacking interactions involving the phenyl rings of pdm^{2-} ligands from neighboring Mn_{11} clusters are observed.

3.2. Structural description of $[Mn_{25}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]Cl_2 \cdot 12MeCN$ (**2**)

Complex **2** crystallizes in the triclinic space group $P\bar{1}$. The Mn_{25} cation lies on an inversion center and has a barrel-like structure (Fig. 3). Inspection of the structural features reveals twelve μ_4-O^{2-}, six μ_3-O^{2-} and two μ_3-OH^- ions holding the core together, as well as chelating/bridging pdm^{2-}/$pdmH^-$, and both terminal and bridging N_3^- groups. The metal oxidation states and the protonation levels of O^{2-}, OH^-, pdm^{2-} and $pdmH^-$ O atoms were established by Mn and O bond valence sum calculations, inspection of metric parameters, and detection of Mn^{III} JT elongation axes. The core of the cation may be dissected into five parallel layers of three types with an **ABCBA** arrangement (Fig. 4). Layer **A** is a Mn^{II}_3 triangular unit (Mn1, Mn2, Mn4) with a capping μ_3-OH^- ion; layer **B** is a Mn^{III}_6 triangle (Mn3, Mn5, Mn6, Mn7, Mn8, Mn9) that can be described as three corner sharing Mn^{III} triangles; and layer **C** consists of a Mn^{III}_6 hexagon (Mn11, Mn12, Mn13, Mn11a, Mn12a, Mn13a) in the center

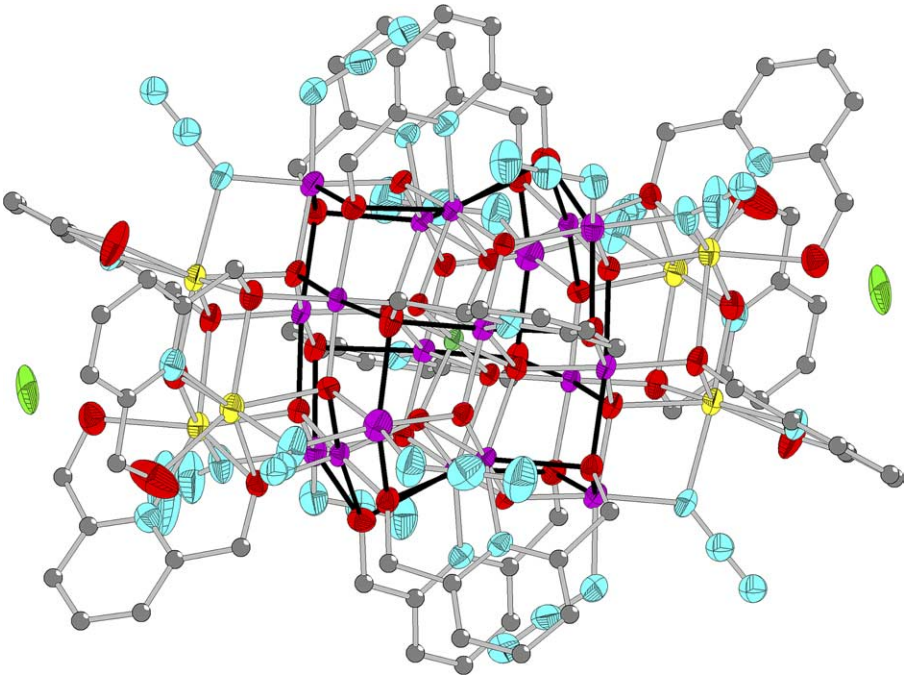

Fig. 3. ORTEP representation at the 50% probability level of the centrosymmetric complex **2**. H atoms have been removed for clarity. Color code: green, Mn^{IV}; purple, Mn^{III}; yellow, Mn^{II}; pale green, Cl; red, O; blue, N; gray, C.

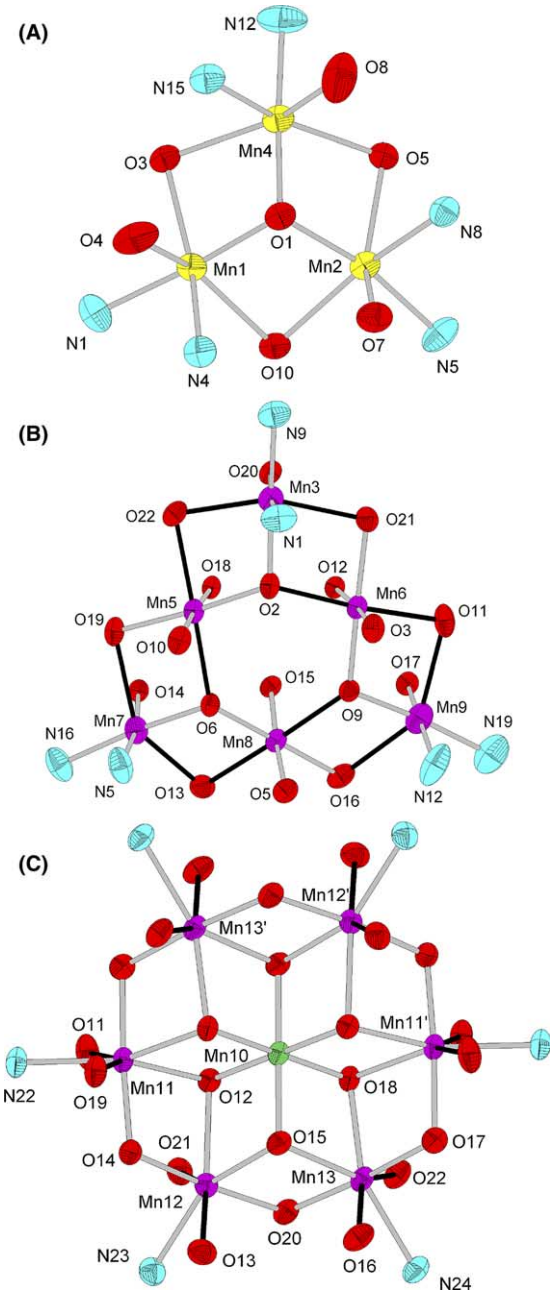

Fig. 4. Three types of constituent layers of the centrosymmetric complex **2**, color coded for clarity. Atom color code: green, Mn^{IV}; purple, Mn^{III}; yellow, Mn^{II}; red, O; blue, N. JT axes are indicated as solid black bonds.

of which is held the Mn^{IV} ion (Mn10) by the bridging O^{2-} ions. Layer **C** is reminiscent of the well known Anderson-type structure seen in some Mn complexes [20]. Each layer is linked to its neighboring layers by a combination of oxide, alkoxide and/or azide bridging groups. The outer coordination shell is occupied by pdm^{2-}, $pdmH^{-}$ and terminal azide ligands (Fig. 3). In addition, inspection of the crystal packing reveals no evidence of intermolecular hydrogen-bonding interactions between molecules.

3.3. Magnetochemistry

3.3.1. DC Magnetic susceptibility

The magnetic properties of **1** and **2** were investigated by solid state magnetic susceptibility (χ_M) measurements in the 5.0–300 K range in a DC field of 1000 Oe (0.1 Tesla); the resulting data are shown in Figs. 5 and 6, respectively, as $\chi_M T$ versus T plots. For complex **1**, the $\chi_M T$ value increases steadily from 40.2 $cm^3\,K\,mol^{-1}$ at 300 K to a maximum of 48.3 $cm^3\,K\,mol^{-1}$ at 25 K, before dropping rapidly to 40.2 $cm^3\,K\,mol^{-1}$ at 5 K. For complex **2**, the $\chi_M T$ value steadily increases from 88.4 $cm^3\,K\,mol^{-1}$ at 300 K to a maximum of 310 $cm^3\,K\,mol^{-1}$ at 15 K, before

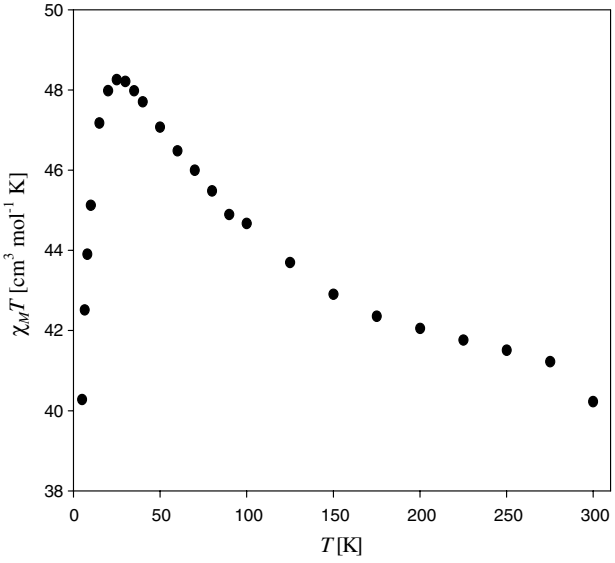

Fig. 5. Plot of $\chi_M T$ vs. T for complex **1** at 1 kG.

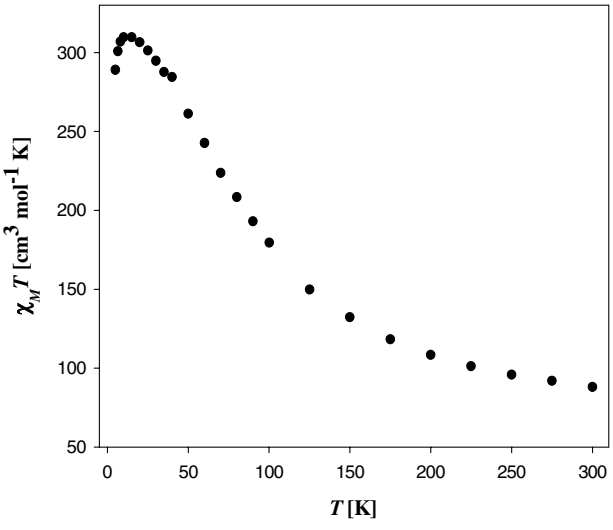

Fig. 6. Plot of $\chi_M T$ vs. T for complex **2** at 1 kG.

dropping to 289 cm^3 K mol^{-1} at 5.0 K. In each case the data suggest a very large ground state spin value. The final decrease of the $\chi_M T$ at the lowest temperatures is likely due to Zeeman effects and weak intermolecular exchange interactions. The 25 K peak value for complex **1** suggests an $S = 10$ spin ground state value, whereas the 15 K peak value for the Mn_{25} cation suggests either an $S = 49/2$ or 51/2 state, whose spin-only ($g = 2$) values would be 337.8 and 312.4 cm^3 K mol^{-1}, respectively.

In order to identify the ground states, magnetization (M) data in the 1.8–4.0 K and 0.1–7 T ranges were collected and fit by matrix diagonalization to a model that assumes only the ground state is populated, includes axial zero-field splitting ($D\hat{S}_z^2$) and Zeeman interactions, and incorporates a full powder average.

For complex **1**, we could not get an acceptable fit under any reasonable conditions, and we attribute this to the population of low-lying excited states, even at these low temperatures. For complex **2**, we used only low fields ($\leqslant$8 kG) to avoid problems associated with M_S levels from excited states with higher S values crossing with the ground state, which would lead to an erroneously high value for the ground state S. The fitting (solid lines in Fig. 7) of the magnetization data gave $S = 51/2$, $D = -0.021(1)$ cm^{-1}, and $g = 1.87(1)$. The fits for $S = 49/2$ and 53/2 were only slightly inferior, and on the basis of the magnetization fits alone, we therefore conclude that the ground state spin of **2** is $S = 51/2 \pm 1$.

An $S = 51/2$ ground state and negative D value suggested that **2** might have a sufficient barrier to magnetization relaxation to be an SMM. The upper limit to this barrier is given by $(S^2 - 1/4)|D|$ for a half-integer spin, or only 14.3 cm^{-1} for **2**, but the actual (or effective) barrier will be significantly less due to QTM through the barrier.

3.3.2. AC Magnetic susceptibility

AC susceptibility measurements were carried out on both samples in the 1.8–10 K temperature range to obtain reliable ground state spin values and assess whether the complexes might be SMMs. For complex **1**, no out-of-phase signal was observed whereas for complex **2** the presence of a frequency-dependent signal was observed below 3 K. The latter suggests **2** might be an SMM. The in-phase data extrapolated to 0 K indicate spin ground states of $S = 10$ and $S = 51/2$ for complexes **1** and **2**, respectively.

3.3.3. Single crystal magnetic measurements

The confirmation of possible SMM behavior requires the observation of hysteresis loops. Single crystals of **1** and **2** were therefore investigated using a micro-SQUID [21], and the obtained M versus applied DC field sweeps are shown in Figs. 8 and 9, respectively. Hysteresis loops, the diagnostic property of a magnet, were observed below ~0.7 K, their coercivities increasing with decreasing temperature, as expected for the superparamagnet-like properties of a SMM. The loops do not exhibit the step-like features indicative of QTM, but it is possible that steps are present but smeared out by broadening effects from dipolar and transverse fields, low-lying excited states, and/or a distribution of molecular environments. The low temperature at which both complexes are SMMs is clearly due to a small D value, which is consistent with the nearly perpendicular disposition of the Mn^{III} JT axes, the primary source of the molecular anisotropy.

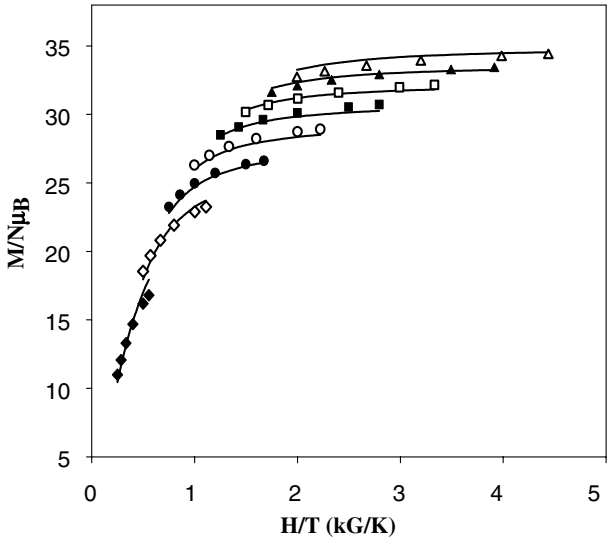

Fig. 7. Plot of reduced magnetization ($M/N\mu_B$) vs. H/T for **2** at 8 (△), 7 (▲), 6 (□), 5 (■), 4 (○), 3 (●), 2 (◇) and 1 (◆) kG. The solid lines are the fit; see the text for the fitting parameters.

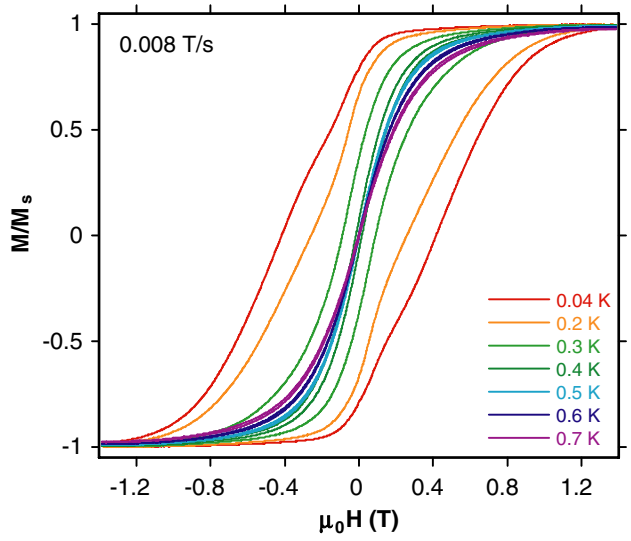

Fig. 8. Magnetization (M) vs. field ($\mu_0 H$) hysteresis loops for single crystals of **1** at the indicated temperatures.

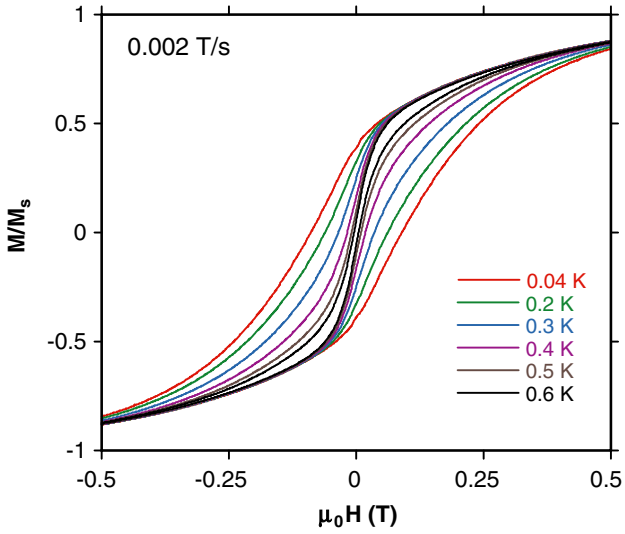

Fig. 9. Magnetization (M) vs. field ($\mu_0 H$) hysteresis loops for single crystals of **2** at the indicated temperatures.

4. Conclusions

A mixed chelate strategy has been used to synthesize two new SMMs $[Mn_{11}O_2(OH)_2(nmpd)(pdmH)_5(pdm)_5Cl_6]\cdot 4MeCN$ (**1**) and $[Mn_{25}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]Cl_2\cdot 12MeCN$ (**2**). Complexes **1** and **2** have novel core topologies containing seven Mn^{III} and four Mn^{II} ions for the former complex and one Mn^{IV}, eighteen Mn^{III} and six Mn^{II} ions for the latter. Both complexes are amongst the largest spin and size SMMs reported to date. Complex **2**, in addition to being the largest mixed-valent $Mn^{II}/Mn^{III}/Mn^{IV}$ cluster and the largest spin SMM to date, also has the largest spin ($S = 51/2$) for any molecular species, the same as that suggested for the cyano-bridged $Mn^{II}{}_9Mn^{V}{}_6$ complex [22].

5. Supplementary material

Crystallographic data have been deposited with Cambridge Crystallographic Data Centre, CCDC Nos. 238515 and 266403. Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1233 336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Reports on experimental demonstrations: Or molecular magnetism is attractive! ☆

In the following section, three contributions are presented at the ICMM'04 Conference in Tsukuba as experimental demonstrations. The opportunity for such Demo's at an ICMM was offered for the first time by the organizers of the Tsukuba meeting. The basic idea behind these presentations is that molecular magnetism is growing as a scientific discipline and it appears important to now present it to the students and to the general public in an attractive manner.

Chemistry and physics in molecular magnetism can give rise to beautiful, attractive, visually spectacular demonstrations: bright colours, colour changes, shiny crystals, laboratory experiments, and new magnetism-based equipment and devices, as shown by the presenters of the Demo's session in Tsukuba. Beyond the necessity for scientists to develop citizen awareness and to present complex results in a simple manner, it is hoped that such attractive demonstrations that put emphasis on visually spectacular aspects of the discipline can help to attract the most curious and talented students towards our domain.

In Tsukuba, the demonstrations were presented in a place dedicated to this purpose and were accompanied by posters, computer presentations, and video-projections.

The ICMM International Scientific Committee has decided to continue the Demo experience at the ICMM'06 Conference on Vancouver Island in August 2006. We hope that the publication in *Polyhedron* of these three pioneering contributions will encourage the participants of this next ICMM meeting to prepare a large number of even more attractive presentations, which would allow us to gather together a significant volume of didactic documents to be widely used in our universities to demonstrate that, indeed, molecular magnetism is attractive!

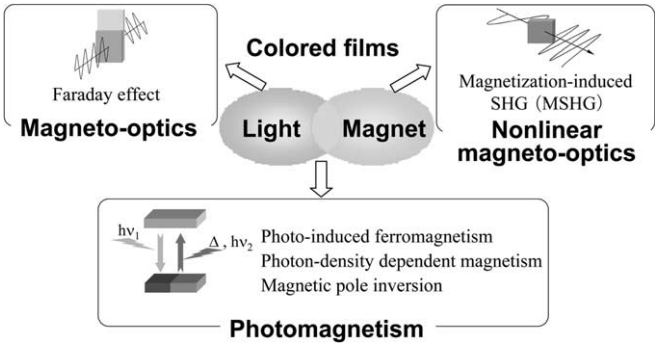

Fig. 1. Magneto-optical phenomenon in colored magnetic films.

ing process. Nafion® 117 membrane (2 cm × 4 cm) is immersed in an aqueous solution of $M^{II}Cl_2$ (10 mM) for 24 h. This membrane is put in an aqueous solution of $K_3[Cr^{III}(CN)_6]$ (10 mM) for 24 h, to deposit Prussian blue analogs on both sides of Nafion film. To remove M^{II} ions from Nafion membrane, these films are dipped into an aqueous solution of KCl (1 M) for 20 min and it is rinsed with distilled water and dried under air. Elemental analyses determined by an inductively coupled plasma (ICP) show that the ratio of M^{II} to Cr^{III} of these films are 3:2. The prepared films shows various colors, i.e., pink (M = Co), yellowish green (M = Ni), and green (M = Cu) (Fig. 2(a)). The CN stretching frequencies in the IR spectra of these films at 2178 cm^{-1} (M = Co), 2176 cm^{-1} (M = Ni), and 2171 cm^{-1} (M = Cu) correspond to those of powder-type of samples prepared by mixing $M^{II}Cl_2$ and $K_3[Cr^{III}(CN)_6]$ aqueous solutions [1,12,13]. Their thicknesses determined by a laser profile micrometer are 320 nm (M = Co), 350 nm (M = Ni), and 400 nm (M = Cu).

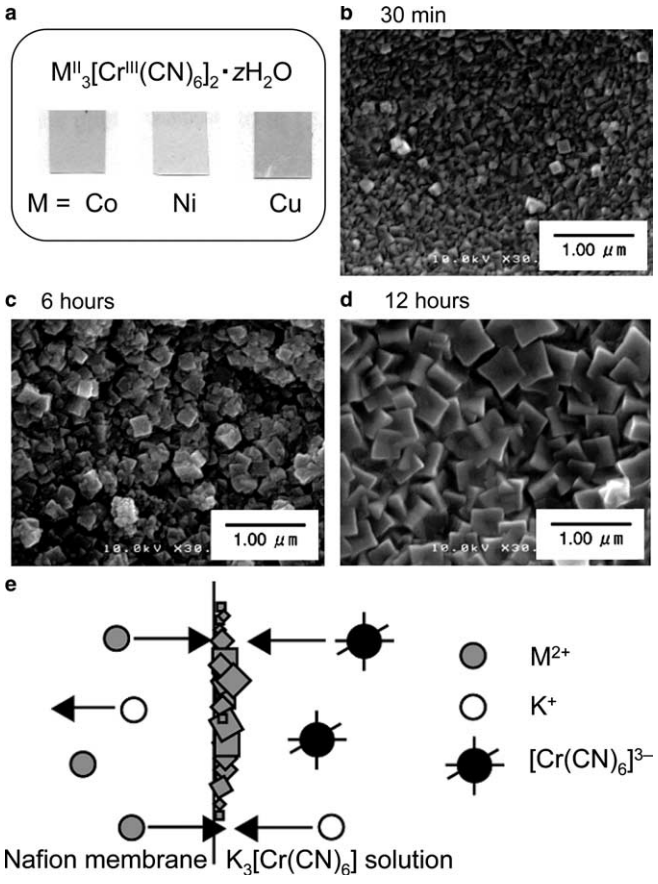

Fig. 2. The photographs for $M^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ films (a) and SEM images of the growth process for $Cu^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ film; (b) 30 min, (c) 6 h, and (d) 12 h. (e) Schematic illustration of the growth process.

Scanning electron microscopy (SEM) images show that the sizes of the crystals are 150 ± 50 nm (M = Co), 80 ± 20 nm (M = Ni), and 300 ± 100 nm (M = Cu). Fig. 2 shows the growth process of the $Cu^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ film. After 30 min, the size of deposited crystals is c.a. 100 nm (Fig. 2(b)). After that, the cubic-type of crystals are observed and the crystal size grows up to c.a. 300 nm (Fig. 2(c) and (d)). In Fig. 2(e), the growth process of the $M^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ film is schematically described. When a Nafion membrane containing M^{II} ion is dipped into a $K_3[Cr^{III}(CN)_6]$ solution, M^{II} ion coordinates to $[Cr^{III}(CN)_6]^{3-}$ ion depending on the diffusion rate of M^{II} ions in Nafion membrane, to form $M^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ microcrystallines on the surface of membrane.

The field-cooled magnetization versus temperature plots for the films in an external magnetic field (B_0) of 10 G showed T_c of 28 K (M = Co), 70 K (M = Ni), and 70 K (M = Cu). These T_c values almost correspond to reported values of powder-type samples, i.e., T_c = 30 K (M = Co) [1,12], 72 K (M = Ni) [1,13,14], 66 K (M = Cu) [1,14].

3. Electrochemical synthesis of Prussian blue analog-based magnetic films

The thin films composed of $(Fe^{II}_xCr^{II}_{1-x})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ are prepared by reducing aqueous solutions containing three compounds simultaneously, $K_3[Cr(CN)_6]$, $CrCl_3$ and $FeCl_3$, where the mixing ratio x_{mix} (=Fe^{III}/(Fe^{III}+Cr^{III})) is controlled. When we keep the reduction potential at −0.84 V versus saturated calomel electrode and load electrical capacity of 600 mC, insoluble polynuclear metal cyanides thin films with a thickness of c.a. 2 μm are thus deposited on an electrode surface as thin films. The elemental analyses show that the experimentally obtained x values depend on the x_{mix} values of metal ions in the prepared solutions, e.g., $x = 0.04$ ($x_{mix} = 0.05$), $x = 0.08$ ($x_{mix} = 0.10$), $x = 0.11$ ($x_{mix} = 0.13$), $x = 0.13$ ($x_{mix} = 0.15$), $x = 0.20$ ($x_{mix} = 0.20$), $x = 0.31$ ($x_{mix} = 0.30$), and $x = 0.42$ ($x_{mix} = 0.40$). The X-ray powder diffraction patterns for all the films are consistent with the face-centered cubic structure. The lattice constants increase successively from 10.39 to 10.62 Å with increasing x. Moreover, the CN stretching frequencies in the IR spectra for the films decrease continuously from 2189 to 2161 cm^{-1}. The colors of obtained $(Fe^{II}_xCr^{II}_{1-x})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ transparent films change depending on x. For example, the film for $x = 0$ is colorless, that for $x = 0.20$ is violet, that for $x = 0.42$ is red, and that for $x = 1$ is orange

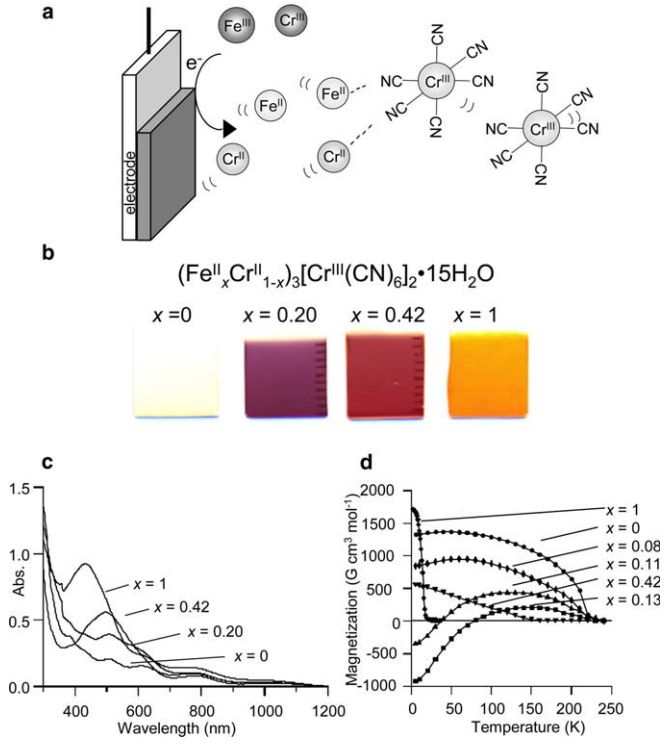

Fig. 3. (a) Schematic diagram illustrating electrochemical synthesis of magnetic thin films. (b) The photographs of obtained transparent and colored $(Fe^{II}_xCr^{II}_{1-x})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ films. (c) UV–Vis spectra of those films. (d) Magnetization vs. temperature curves ($B_0 = 10$ G).

(Fig. 3(b)). This color change is due to the shift of the intervalence transfer (IT) band of Fe^{II} and Cr^{III} in the visible region [15], e.g., $\lambda_{max} = 434$ nm ($x = 1$); 496 nm ($x = 0.42$); 506 nm ($x = 0.20$); 510 and 610 nm ($x = 0$) (Fig. 3(c)). It is known that the wavelength of IT band depends on magnitudes of the vibronic coupling with asymmetrical distortion of each coordination sphere of metal ions and the intensity is proportional to the square of transfer integrals. Therefore, in a series of $(Fe^{II}_xCr^{II}_{1-x})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ films, magnitudes of vibronic coupling parameters and transfer integrals are supposed to be continuously changed from those of Fe^{II}–Cr^{III} to those of Cr^{II}–Cr^{III} with decreasing x. In fact, frequencies of CN stretching and lattice constants continuously shift, indicating that distance between metal ions of $(Fe^{II}_xCr^{II}_{1-x})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ are averaged values of the distance of Fe^{II}–Cr^{III} and Cr^{II}–Cr^{III} as a function of x.

Magnetic susceptibility and magnetization of obtained thin films depend strongly on the x values. The saturation magnetizations (M_s) vary in a systematic fashion as a function of x. Minimum values of the M_s are found with the film of x value close to 0.11. This is because parallel spins (Cr^{III} and Fe^{II}) and anti-parallel spins (Cr^{II}) can be partially or even completely canceled, depending on the x. In addition, the magnetization versus temperature curves below T_c exhibit various types of behavior depending on x ($B_0 = 10$ G) (Fig. 3(d)). Particularly, those compounds in which x are 0.11–0.15 exhibited negative values of magnetization below particular temperatures (compensation temperatures, T_{comp}). The observed T_{comp} of 110 K for $x = 0.15$ is the highest value among molecule-based magnets. This phenomenon is observed because the positive magnetization due to the Cr^{II} sublattice and the negative magnetizations due to the Fe^{II} and Cr^{III} sublattices have different temperature dependences.

4. Magneto-optical effects

Magneto-optical effects are based on the interaction between light and magnetism. Faraday effect, which is one of the magneto-optical effects, is observed when linear polarized light propagates through magnetically ordered materials. Previously, we have observed the Faraday effect of $K^{I}_{0.62}V^{II}_{0.98}V^{III}_{1.02}[Cr^{III}(CN)_6]_{1.88} \cdot 13H_2O$ film with a high T_c of 310 K (Fig. 4) [6]. Here, we show magneto-optical effects of the films of $M^{II}_3[Cr^{III}(CN)_6]_2 \cdot zH_2O$ on Nafion membrane in the ferromagnetic region measured using magneto-optical meter. The Faraday ellipticity (F.E.) spectra for films at 7 K in $B_0 = 500$ G after the application of 1 T are shown in Fig. 5. For M = Co, the dispersive peak is observed around 470 nm with intensity of ± 80 deg cm^{-1} (Fig. 5(a)). For M = Ni, there exist two broad peaks with intensities of 200 and -200 deg cm^{-1} around 440 and 610 nm, respectively (Fig. 5(b)). For M = Cu, a negative peak with intensity of -210 deg cm^{-1} is observed around 550 nm (Fig. 5(c)). From the simulation of F.E. spectra based on the Faraday spectral analysis, the observed F.E. spectra are assigned to the following. For M = Co, the dispersive peak around 470 nm is due to $^4T_{1g} \rightarrow {}^4T_{1g}$ transition on octahedrally coordinated Co^{II} ion. For M = Ni, the peaks around 440 and 610 nm are due to $^3A_{2g} \rightarrow {}^3T_{1g}$ (^3P) and $^3A_{2g} \rightarrow {}^3T_{1g}$ (^3F) on Ni^{II} ion, respectively. For M = Cu, the peak around 550 nm is due to the sum of transitions $^2B_{1g} \rightarrow {}^2E_g$ (556 nm), $^2B_{1g} \rightarrow {}^2B_{2g}$ (625 nm), and $^2B_{1g} \rightarrow {}^2A_{1g}$ (710 nm) on Cu^{II} ion.

5. Nonlinear magneto-optical effects

Let us focus our attention on nonlinear optical effects in molecule-based magnets. Recently, second harmonic

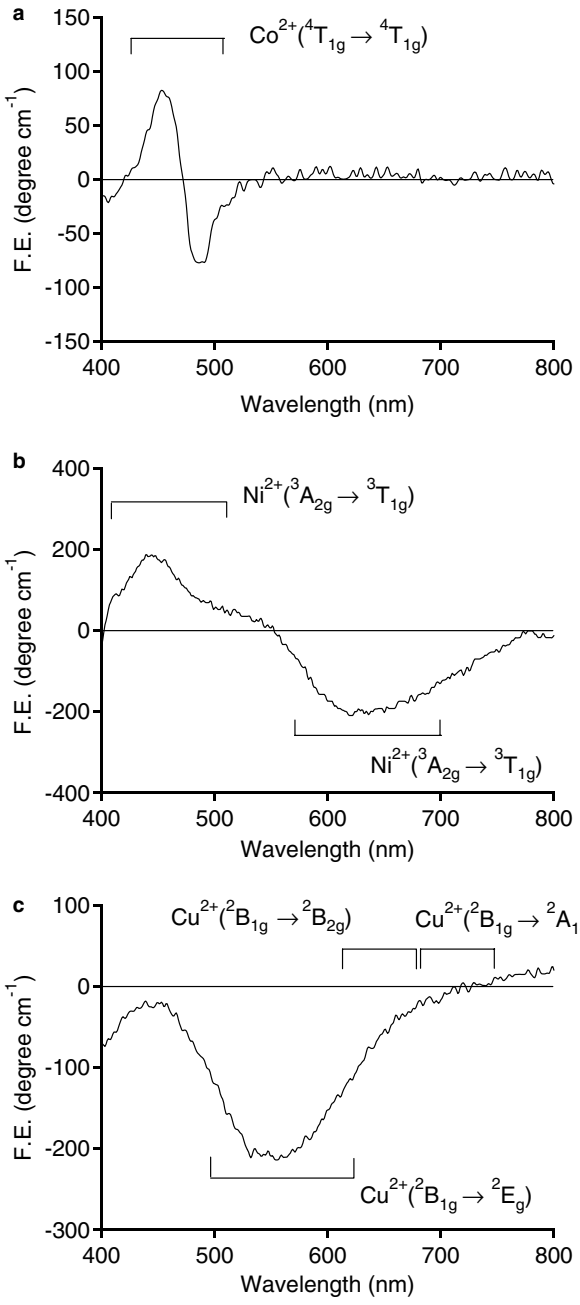

Fig. 5. Faraday ellipticity (F.E.) spectra for $M_3^{II}[Cr^{III}(CN)_6]_2 \cdot zH_2O$ films at 7 K under 500 G after the application of 1 T: (a) M = Co; (b) Ni; (c) Cu.

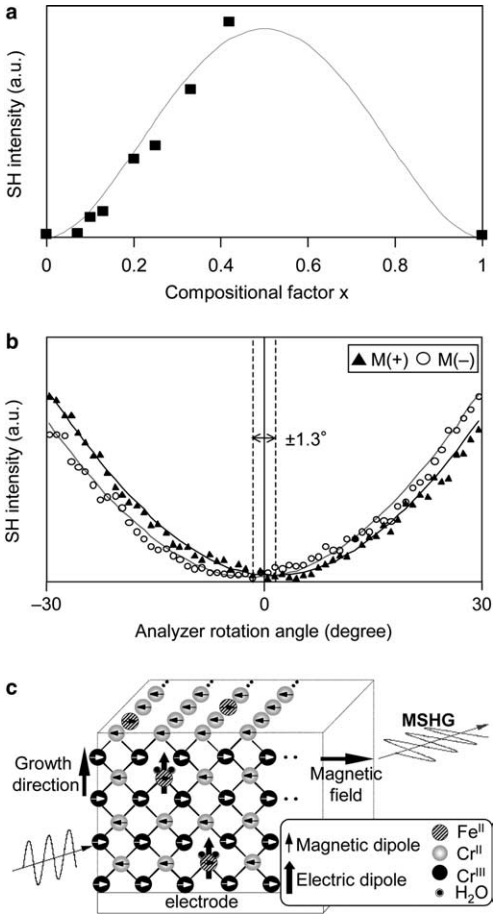

Fig. 6. (a) The SH intensity of Pin-Pout polarization combination vs. x in the film of $(Fe_x^{II}Cr_{1-x}^{II})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ (the incident angle: 45°). (b) The SH intensity vs. the analyzer angle in the film for $x = 0.31$ in an applied magnetic field of 10 kOe at 50 K. The analyzer angle of 0° corresponds to the direction of s-polarized SH radiation. (c) Schematic structure of the ternary metal Prussian blue analog film involving both electric and magnetic dipoles.

generation (SHG) from the surface of magnetic materials, the so-called magnetization-induced SHG (MSHG), is being actively investigated. This new optical phenomenon is useful for observing surface magnetism because the rotation angle of this effect is much larger than that of the linear Kerr effect. In contrast, SHG arising from bulk magnetic materials has been observed in a limited number of cases to date. This is because most conventional ferromagnetic materials have a centrosymmetric structure, and hence, SHG from their bulk is forbidden in the electricdipole approximation. However, electrochemically synthesized $(Fe_x^{II}Cr_{1-x}^{II})_3[Cr^{III}(CN)_6]_2 \cdot 15H_2O$ $(0 < x \leqslant 0.42)$ magnetic films exhibit strong SHG from their bulk (Fig. 6(a)) [10,11]. This SH activity is induced by the preferred orientation of the noncentrosymmetric monoclinic structure. In this system, the electric-dipole moment contributing to SHG is the CN–Fe^{II}–OH_2 site. The magnetic effect on the polarization of SH radiation using a film with $x = 0.31$ are measured. Although the second harmonic (SH) wave does not rotate in the presence of an external magnetic field at 300 K, rotation of the SH wave is observed at 50 K below T_c (Fig. 6(b)). Moreover, reversing the applied magnetic field inverts the rotational direction. The rotation angle of the SH wave is approximately 1.3°, which is much larger than the Faraday rotation angle of 0.079° at 50 K in an applied magnetic field of 10 kOe. The magnetic linear term of $\chi_{ijkL}^{magn(1)}$ explains this SH rotation because reversing the magnetic field inverts the rotational direction. The optical symmetry of the present films in the paramagnetic region is $C_{\infty v}$ because of the out-of-plane orientation of the polycrystals with a C_2 space group. Below T_c, the $\chi_{ijkL}^{magn(1)}$ term is added to the SH susceptibility, and hence, SH wave rotates.

6. Conclusion

In summary, we have prepared transparent colored magnetic thin films composed of Prussian blue analogs by an ion-exchange and an electrochemical method. These films made it possible to observe their Faraday spectra in the visible region. Colored magnetic films have the potential to allow us to develop new types of magneto-optical devices such as opto-magnetic memory devices by selecting specific types of laser color. In addition, the transmitted MSHG in colored magnetic film will give us the possibility of a new optics due to the interaction between electric polarization and magnetic polarizations.

spectacular. Prussian blue precipitate is not dangerous and can be discarded. It is also possible to destroy it using hypochlorite under a hood.

3. "Attracted" Prussian blue analogue

A few tens of milligrams of powder of the room-temperature magnet **1**, [VCr], are placed in a glass tube under argon. The tube is placed on an overhead projector, perfectly horizontal. When a powerful permanent magnet is approached, the part containing the molecule-based magnet is attracted by the permanent magnet (translation or rotation of the tube). Do the experiment again, approaching the magnet from another side. It is also possible to attract the powder when displacing slowly the magnet along the tube. The synthesis of [VCr], **1**, can be found in [1,2,7].

4. "Oscillating magnet" device

The principle of the device is shown in Fig. 1(a) and a photograph is given in Fig. 1(b).

A few milligrams of [VCr], **1** are sealed in a glass vessel under argon and suspended at the bottom of a pendulum [vertical, position (2) in absence of permanent magnet]. It is then cycled between its two magnetic states: the 3D-ordered ferrimagnetic state, when $T < T_C$, and the paramagnetic one, when $T > T_C$. The three steps are: (i) the room temperature magnet [VCr] is cold ($T < T_C$, ferrimagnetic state). It is attracted (→) by the permanent magnet and deviates from the vertical direction towards position (1). The light beam is focused at this position (1), just above the permanent magnet and heats the sample, the temperature of which increases; (ii) when $T > T_C$, the hot [VCr] magnet is in the paramagnetic state. It is no more attracted strongly and moves away from the magnet (←) under the influence of its own weight. It is then air-cooled and its temperature decreases; (iii) when $T < T_C$, the cold [VCr] magnet is attracted again by the permanent magnet (→) and come back to position (1). The system is ready for a new oscillation. The period of the oscillations, the nature of the movement (periodic, (dis)continuous, chaotic, etc.) can be modified by playing on the parameters of the system: amount of sample, length of the pendulum, position of the permanent magnet, focus of the beam, power of the lamp, etc. In the device presented, all the parameters can be tuned at will.

The demonstration can be used to illustrate what is a "Curie temperature", T_C: paramagnetic disorder above

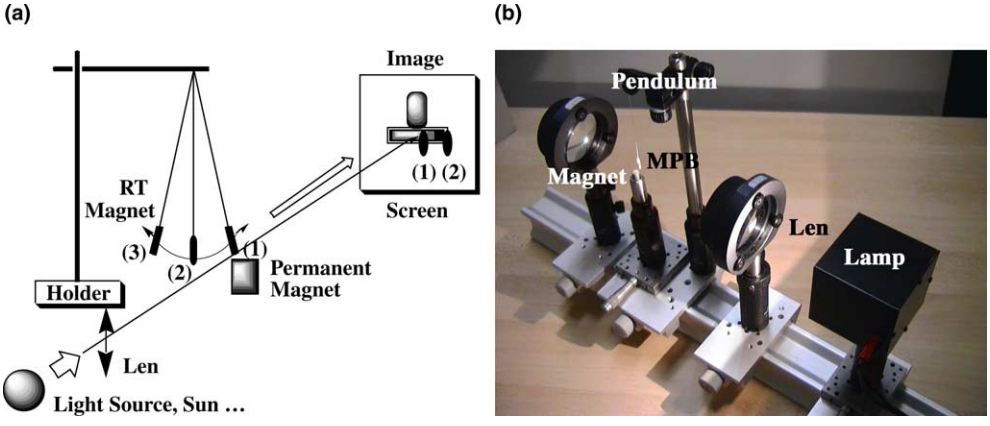

Fig. 1. (a) Principle of an "oscillating" magnet; (b) experimental device.

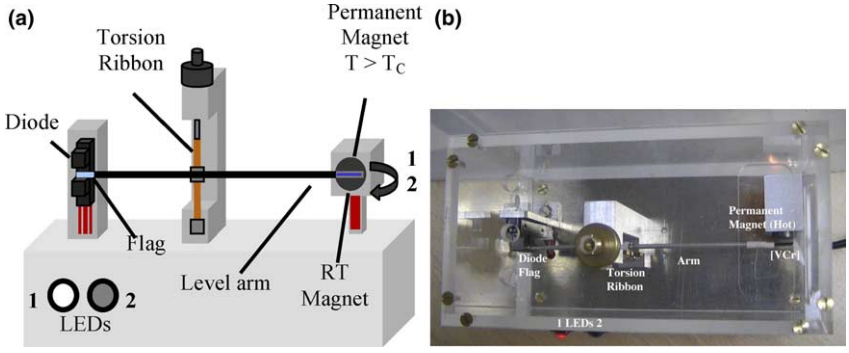

Fig. 2. (a) Scheme of the magnetic switch device; (b) photograph.

T_C (no attraction) and long range magnetic order below T_C (attraction). T_C is the temperature when the thermal quantum kT is close to the interaction J between the magnetic neighbours. The demonstrator is an example of a thermodynamical machine working between two energy baths with close temperatures (light and shadow) allowing the conversion of light into mechanical energy, free of charge!

A first account of the device was proposed in [8]. A different form of the same experiment "flying magnet" is presented in [6].

5. Magnetic switch and thermal probe device

The scheme of the device is shown in Fig. 2(a) and a photograph is given in Fig. 2(b). The device consists of diamagnetic horizontal arm (aluminum tube) coupled to a vertical torsion ribbon. The [VCr] magnet sealed in a glass vessel under argon is fixed at one end of the arm.

Close to this side of the arm, a permanent magnet is fixed and heated by a microresistance to a temperature $T > T_C$; the temperature is tunable. A thin metallic plate used as a flag is fixed at the opposite end of the arm. When the arm rotates, it moves in front of a photodiode and triggers the switching on/off of two warning LEDs (1 and 2). The device can be considered as a magnetic switch or a thermal probe: the [VCr] magnet can take two positions (1 and 2): when $T_{[VCr]} < T_C$, it is attracted (1) by the permanent magnet and a red LED, 1, is switched on. When in contact with the hot permanent magnet the [VCr] temperature increases; when $T_{[VCr]} > T_C$, it is repelled (2) by the mechanical couple applied to the arm by the torsion ribbon. The green LED, 2, is switched on. These demonstrations were presented in front of many audiences and science festivals. They revealed quite effective to demonstrate concepts in physics (Curie temperature) or in chemistry (Lewis acid–base chemistry, chemistry is beautiful, molecular magnetic materials can find their way to applications). Other demonstrators are being prepared [9]. Indeed, room temperature magnetic Prussian blues are attractive!

by sulfonic acid group) behaves as counter anion as well as transparent substrate. Here, we demonstrate the spin crossover phenomenon for [Fe(II)(H-trz)$_3$]-Nafion.

2. Preparation

2.1. Nafion

Nafion, which was developed by DuPont Company as an ion-exchange resin in 1960s, is used for many industrial applications due to its mechanical strength, chemical stability and permselectivity [8]. Nafion is composed of a polytetrafluoroethylene backbone with perfluorinated ether side chains terminated by sulfonic acid groups as shown in Fig. 1. In the case of Nafion N117, $x = 6$, $y = 1$, $m = 1$, the pendant $-SO_3H$ groups in the perfluorinated ionomer are known to form clusters of 40 Å diameter separated by a distance of 50 Å and interconnected through channels of 10 Å when they are swollen in water [9].

2.2. Preparation of [Fe(R-trz)$_3$]-Nafion (R = H, NH$_2$)

The spin crossover complex film [Fe(R-trz)$_3$]-Nafion, was prepared as follows [10]. The acid form of Nafion was immersed in an aqueous solution of $FeSO_4$. The mobile anions (SO_4^-) were more or less completely excluded from the polymer matrix because their electrical negative charge was identical to that of the ion-exchange group (a sulfonic acid; $-SO_3^-$) in the polymer matrix. After being immersed in the solution for 2 h, the film was rinsed in methanol, then it was immersed in a methanol solution of R-trz at 330 K (Fig. 2). One hour later, the film was picked up and washed with methanol, then dried under a nitrogen atmosphere.

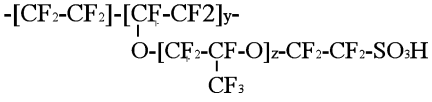

Fig. 1. Molecular formula of Nafion 117: $x = 6$, $y = 1$, $z = 1$.

3. Physical properties and demonstration

3.1. Structure analysis

In order to prove that the one-dimensional Fe(II) chain structure [Fe(R-trz)$_3$]$_n$, is formed on Nafion film, the Fe K-edge EXAFS spectra were measured [10] in the conventional transmission mode at BL-10B in the Photon Factory (operation energy of 2.5 GeV and stored current of 400–200 mA) in the Institute of Materials Structure Science, Tsukuba. A water-cooled Si(3 1 1) channel-cut crystal was employed as a monochromator.

As shown in Fig. 3, a noticeable feature is the existence of peak around 7 Å. In the case of EXAFS spectra for isolated complexes, any distinct peak does not appear in this range. However, in the case that Fe atoms are arranged in a straight chain, the multiple scattering is generally enhanced [11], which causes the appearance of peak appears at long radius region. The peak at about 7 Å corresponds to the Fe–Fe–Fe multiple scattering, which proves the existence of straight one-dimensional Fe chain structure such as [Fe(Htrz)$_2$(trz)](BF$_4$) [12].

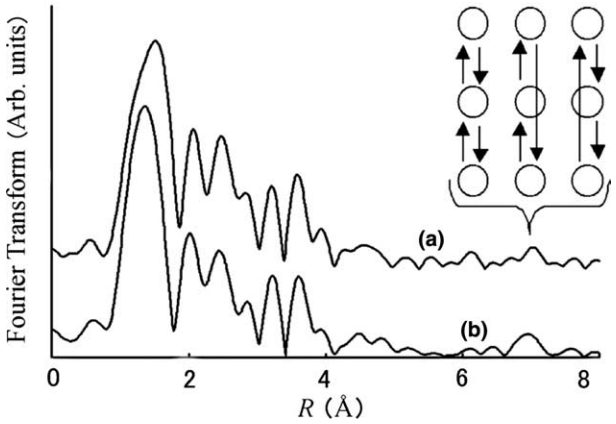

Fig. 3. Fourier transforms of Fe K-edge EXAFS oscillation function $k^3\chi(k)$ for (a) [Fe(H-trz)$_3$]-Nafion and (b) [Fe(NH$_2$-trz)$_3$]-Nafion [10]. Inset shows the multiple scattering from the next nearest neighbor Fe–Fe–Fe shell which is responsible for the EXAFS spectrum at about 7 Å.

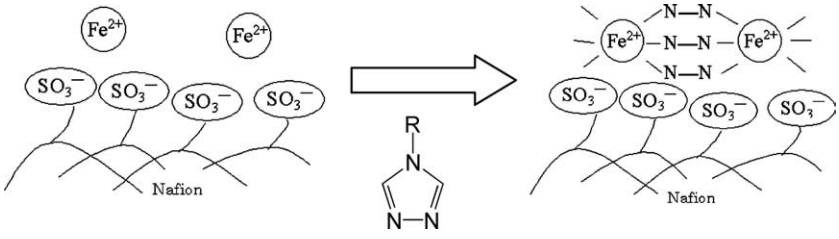

Fig. 2. Schematic preparation process of [Fe(R-trz)$_3$]-Nafion. N–N represents 4-R-trz.

3.2. Magnetic properties

The magnetic behavior of [Fe(H-trz)$_3$]-Nafion is shown in Fig. 4, where the spin transition takes place at about 260 K and finishes at about 320 K. The thermal hysteresis width is estimated at 3 K. In connection with the thermal hysteresis width of the spin transition for [Fe(R-trz)$_3$] complexes, the following should be noted. In the case of [Fe(NH$_2$-trz)$_3$](C$_n$H$_{2n+1}$SO$_3$)$_2 \cdot 2$H$_2$O [7], the hysteresis width of the spin transition decreases from 19 to 6 K, with increasing the length of counter anion from $n = 1$ to $n = 9$. For the complexes of $n > 5$, the hysteresis width is almost the same value of 6 K, which is attributed to the intra-chain interaction in [Fe(NH$_2$-trz)$_3$]$_n$. Therefore, it is considered that the hysteresis width ($\Delta T = 3$ K) of the spin transition for [Fe(H-trz)$_3$]-Nafion film is attributed to the cooperative effect due to the intra-chain interaction in [Fe(H-trz)$_3$]$_n$.

Fig. 4 also indicates the residual paramagnetic fraction below 200 K, which is attributed to the high spin state of Fe(II). In the case of the high spin state (^{5}T$_{2g}$) of Fe(II), ESR signal cannot be observed around 200 K because of rapid spin–lattice relaxation. On the other hand, the high spin state of Fe(III) can be observed even at room temperature. In fact, an ESR signal of [Fe(H-trz)$_3$]-Nafion appears below 10 K. The line profile of ESR is typical of the high spin state of Fe(II).

The residual high spin fraction of Fe(II) is probably attributed to the terminal Fe(II) site in the oligomer of [Fe(H-trz)$_3$]$_n$ on Nafion film. In the Fe(II) trimer complex [Fe$_3$(Et-trz)$_6$(H$_2$O)$_6$](CF$_3$SO$_3$)$_6$ [13], the central Fe(II) site undergoes the LS–HS transition at about 200 K, while the spin state of the terminal Fe(II) sites is the HS state between 2 and 300 K.

From the analysis of the EXAFS spectra and the magnetic susceptibility, it is obvious that the polymeric [Fe(H-trz)$_3$]$_n$ is formed in Nafion film, which is shown in Fig. 5.

Now, we demonstrate the spin transition of transparent spin crossover complex film [Fe(H-trz)$_3$]-Nafion, as thermo-chromism, which is shown in Fig. 6. The color of [Fe(H-trz)$_3$]-Nafion is colorless at room temperature. However, its color becomes purple with decreasing temperature, reflecting the spin crossover phenomenon. Note that the colors of the HS state ($t_{2g}^4\ e_g^2$, $S = 2$) and the LS state (t_{2g}^6, $S = 0$) of [Fe^{II}(R-trz)$_3$]X$_2 \cdot n$H$_2$O (R = H, NH$_2$; X = ClO$_4$, etc.), are colorless and purple, respectively. In fact, the absorption spectrum of [Fe(H-trz)$_3$]-Nafion shows two broad bands at 18 500 and 24 500 cm^{-1} corresponding to the ^{1}A$_{1g} \rightarrow {}^1$T$_{1g}$ and ^{1}A$_{1g} \rightarrow {}^1$T$_{2g}$ transitions, respectively, in the LS state ($S = 0$), while it shows a broad band at 12 500 cm^{-1}

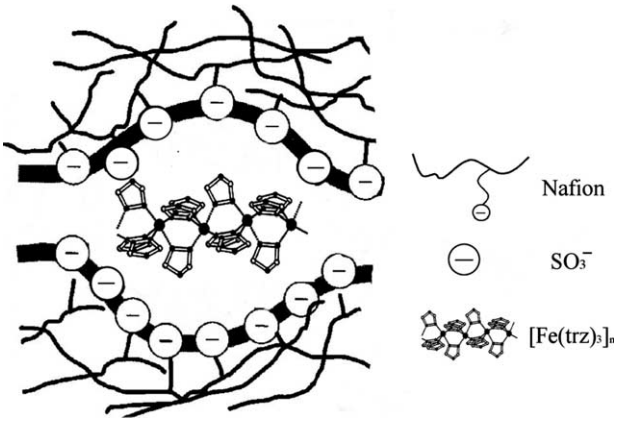

Fig. 5. Schematical representation of the oligomer of [Fe(Htrz)$_3$]$_n$ embedded in Nafion film.

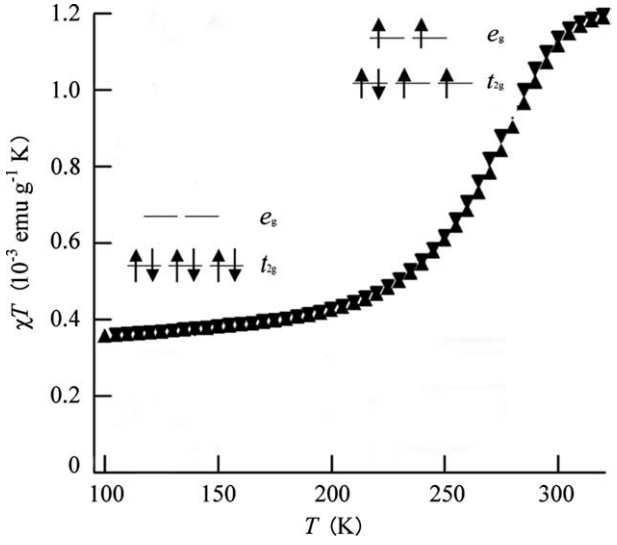

Fig. 4. χT as a function of temperature for [Fe(H-trz)$_3$]-Nafion in cooling mode (▼) and heating mode (▲).

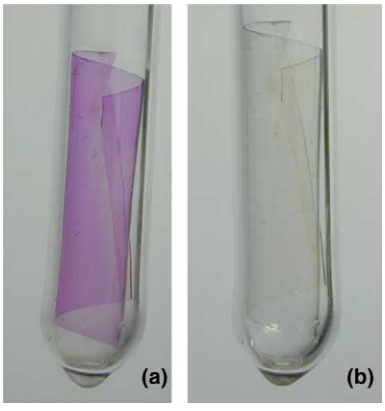

Fig. 6. Demonstration of the thermochromism due to the spin crossover phenomenon for [Fe(H-trz)$_3$]-Nafion, (a) purple in the low-spin state ($T = 77$ K) and (b) colorless in the high-spin state ($T = 300$ K).

corresponding to the $^5T_{2g} \rightarrow {}^5E_g$ transition in the HS state ($S = 2$).

3.3. LIESST

Fig. 7 shows the photoinduced transmission change $\Delta T/T$ ($E_{probe} = 2.54$ eV) at 4.2 K: open circles, closed circles, and triangles represent the data obtained at the power density of $P = 450$, 250, and 40 mW/cm^2, respectively [14]. The photo-irradiation at $E_{ex} = 2.41$ eV, which selectively excites the LS state, is expected to induce the spin state transition. At $P = 450$ mW/cm^2, the $\Delta T/T$ value steeply increases under photo-irradiation, and reached ~7%. This transmission change corresponds to the photo-induced HS fraction of 70%. This photoinduced $\Delta T/T$ signal decreases to ~5% at $P \sim 200$ mW/cm^2, and disappears at 40 mW/cm^2. Fig. 7 shows the P-dependence of the $\Delta T/T$, and a threshold value is found at ~60 mW/cm^2, as indicated by downward arrow. Such a threshold behavior may be ascribed to the critical nucleation of the photo-generated HS clusters. Fig. 7(c) shows the temperature dependence of the photoinduced $\Delta T/T$ value at $P = 350$ mW/cm^2. With the increase of temperature, the $\Delta T/T$ value decreases at 80 K, then disappears above 150 K. We observed no trace of the photoinduced LS–HS transition when we excited the film at 1.55 eV (800 mW/cm^2) and at 4.2 K. This characteristic temperature dependence and photon energy dependence rule out the conventional thermal effect as the origin of the photoinduced LS–HS transition.

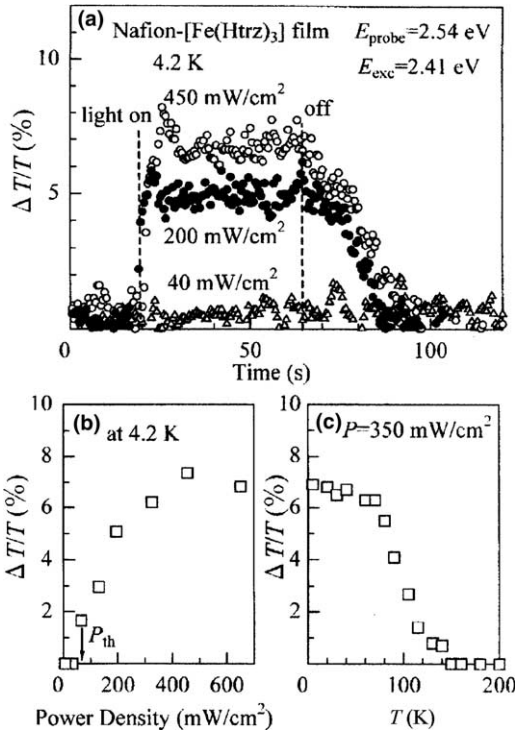

Fig. 7. (a) Temporal evolution of the transmission change $\Delta T/T$ of [Fe(H-trz)$_3$]-Nafion film at 4.2 K during and after photoirradiation at various irradiation power densities P [14]. (b) P-dependence of the $\Delta T/T$ value at 4.2 K. The downward arrow indicates a threshold value Pth of the power density. (c) Temperature dependence of the $\Delta T/T$ value under photoirradiation of $P \sim 350$ mW/cm^2.

4. Conclusion

We have succeeded in synthesizing the transparent [Fe(H-trz)$_3$] complex film by using ion-exchange film (Nafion) as counter anion, which shows the spin crossover phenomenon at about 260 K. In our preparation process, it is possible to prepare the homogeneous [Fe(R-trz)$_3$] complex film of 300 mm × 300 mm. From the analysis of Fe K-edge EXAFS spectra, we could prove the existence of one-dimensional Fe chain structure [Fe(H-trz)$_3$]$_n$, on Nafion film. Moreover, the LIESST effect was observed for [Fe(H-trz)$_3$]-Nafion at 4.2 K. The development of transparent [Fe(H-trz)$_3$]-Nafion film will open a large field of photonic molecular devices based on spin crossover phenomenon.

The syntheses and structural characterization of $[Zn(NCS)_2(4\text{-PDS})]_n$, $[Fe(NCS)_2(4\text{-PDS})_2 \cdot 4H_2O]_n$ and $\{[Co(4\text{-PDS})_2][Cl]_2 \cdot 2CH_3OH\}_n$ form the subject of this report.

2. Experimental

2.1. General procedures

All manipulations were carried out under an atmosphere of dry, oxygen-free nitrogen using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated by refluxing over the appropriate reagents before use. Methanol was purified by distillation from magnesium. IR spectra were recorded on a Bio-Rad FTs-7 spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer, Perkin–Elmer CHN-2400 analyzer or HERAEUS VaruoEL analyzer.

2.2. Starting materials

The complexes $Zn(NO_3)_2 \cdot 6H_2O$, $CoCl_2 \cdot 6H_2O$, $FeSO_4 \cdot 7H_2O$ and NH_4SCN were used as obtained from commercial sources without further purification. The reagent 4-PDS (4-PDS = 4,4′-dipyridyldisulfide) was purchased from Aldrich.

2.3. Preparation of $[Zn(NCS)_2(4\text{-PDS})]_n$

$Zn(NO_3)_2 \cdot 6H_2O$ (0.19 g, 1 mmol), NH_4SCN (0.15 g, 2 mmol) and 4-PDS (0.22 g, 1 mmol) were placed in a flask containing 10 mL CH_3OH. The mixture was stirred at room temperature for 0.5 h to yield a white precipitate. The white solid was filtered off, washed with CH_3OH and then dried under vacuum. Yield: 0.29 g (72%). *Anal.* Calc. for $C_{12}H_8ZnN_4S_2$: C, 35.84; H, 1.99; N, 13.94. Found: C, 35.48; H, 1.96; N, 14.02%. IR (KBr disk): 3077(m), 2074(m), 1593(s), 1540(s), 1486(m), 1424(m), 1324(m), 1223(m), 1102(m), 1063 (m), 1028(m), 991(s), 964(s), 822(m), 718(m), 500(m). Colourless crystals suitable for X-ray diffraction were grown by slow diffusion of layered CH_3OH and H_2O solutions over three days.

2.4. Preparation of $[Fe(NCS)_2(4\text{-PDS})_2 \cdot 4H_2O]_n$

$FeSO_4 \cdot 7H_2O$ (0.40 g, 1.0 mmol), NH_4SCN (0.15 g, 2.0 mmol) and 4-PDS (0.44 g, 2.0 mmol) were placed

(c) Packing diagram of **1**, showing the NCS···S–S(4-PDS) interactions among the chains.

filtered off, washed with CH_3OH and then dried under vacuum. Yield: 0.39 g (62%). *Anal.* Calc. for $C_{22}H_{24}N_4O_2S_4Cl_2Co$: C, 41.64; H, 3.81; N, 8.83. Found: C, 41.42; H, 3.71; N, 8.61%. IR (KBr disk): 3060(br), 1581(m), 1543(m), 1477(m), 1314(s), 1212(m), 1098(s), 1059(m), 991(s), 804(m), 771(m), 496(s). Blue crystals suitable for X-ray diffraction were grown by slow diffusion of layered CH_3OH and H_2O solutions over three days.

3. X-ray crystallography

The diffraction data of **1**–**3** were collected on a Siemens CCD diffractometer, which was equipped with graphite-monochromated Mo Kα (Kα = 0.71073 Å) radiation. Data reduction was carried out by standard methods with the use of well-established computational procedures [7].

The structures were solved and refined by full-matrix least-squares methods [8]. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1.

4. Results and discussion

4.1. Syntheses

The reactions of $Zn(NO_3)_2 \cdot 6H_2O$ and $FeSO_4 \cdot 7H_2O$ with 4-PDS (4-PDS = 4,4′-dipyridyldisulfide) and NH_4SCN in CH_3OH afforded the complexes $[Zn(NCS)_2(4\text{-PDS})]_n$ (**1**) and $[Fe(NCS)_2(4\text{-PDS})_2 \cdot 4H_2O]_n$ (**2**), respectively. Complex **3**, $\{[Co(4\text{-PDS})_2][Cl]_2 \cdot 2CH_3OH\}_n$, was prepared by the reaction of $CoCl_2 \cdot 6H_2O$ with 4-PDS in CH_3OH.

4.2. Structure of $[Zn(NCS)_2(4\text{-PDS})]_n$ (1)

Fig. 1(a) shows the local coordination of the Zn(II) metal center, and selected bond distances and angles are listed in Table 2. The single crystal X-ray structure shows that **1** is a coordination polymer consisting of $Zn(4\text{-PDS})(SCN)_2$, which forms one-dimensional zigzag chains (Fig. 1(b)). The distorted tetrahedral Zn(II) metal center is achieved by means of two bridging 4-PDS ligands and two terminal N-bonded NCS^- anions. The distances of the Zn–N bonds (2.007(9) and 2.054(8) Å) to the 4-PDS ligands are significantly longer than those to the NCS^- groups, which are 1.92(1) and 1.93(3) Å. The two independent NCS^- groups are almost linear with the same N–C–S angle of 173 (1)°, while the two Zn–N–C bond angles are significantly different at 170(1)° and 162(1)°, to N(3) and N(4), respectively. The Zn···Zn distance in the molecular chain is 5.561 Å. It is noted that short distances between the sulfur atoms of the 4-PDS ligands and center of the pyridyl rings, 3.501 and 3.508 Å, are observed between the chains.

Table 2
Selected bond distances (Å) and angles (°) for **1**–**3**

Symmetry transformations used to generate equivalent atoms: **1**: #1 $x, y, z-1$; #2 $x, y, z+1$, **2**: #1 $-x+1/2, -y+1/2, z$; #2 $x, y, z-1$; #3 $-x+1/2, -y+1/2, z-1$; #4 $x, y, z+1$, **3**: #1 $-x+1, -y+3, -z+1$; #2 $-x+1, -y+2, -z+2$; #3 $x, y+1, z-1$; #4 $x, y-1, z+1$.

4.3. Structure of $[Fe(NCS)_2(4\text{-PDS})_2 \cdot 4H_2O]_n$

Fig. 2(a) shows the local coordination of the Fe(II) metal center, and selected bond distances and angles are listed in Table 2. The single crystal X-ray structure shows that **2** is a coordination polymer consisting of Fe(4-PDS)(SCN), which forms one-dimensional metallocycles (Fig. 2(b)). The distorted octahedral Fe(II) metal center is achieved by means of four bridging

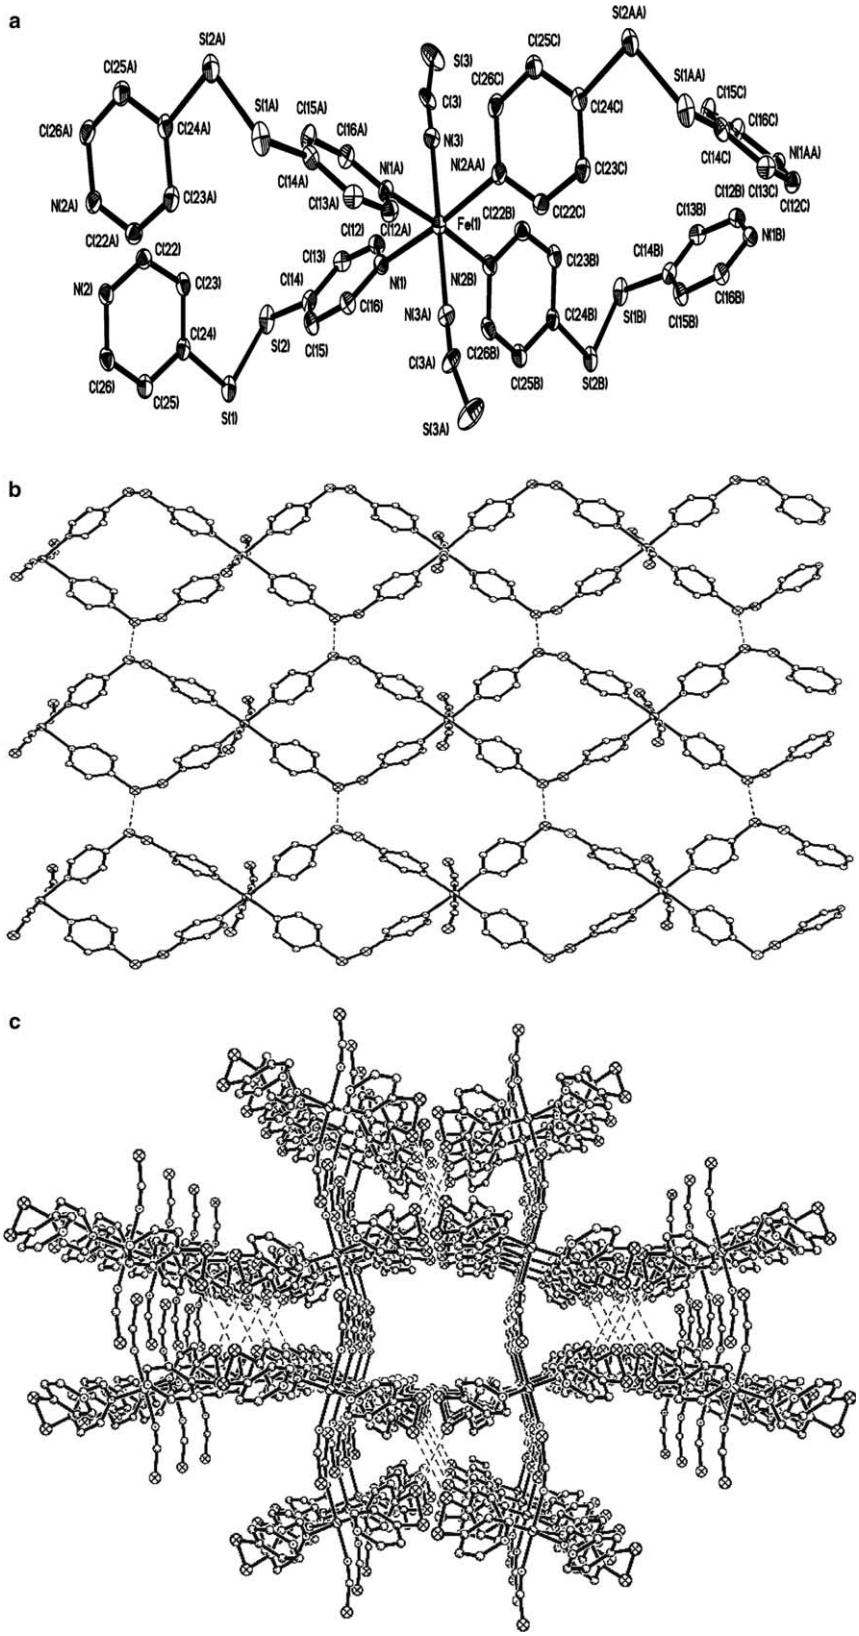

Fig. 2. (a) An ORTEP diagram of the local coordination of Fe in **2**. (b) An ORTEP diagram showing the infinite one-dimensional channel-type chains which are linked by the (4-PDS)S–S···S–S(4-PDS) interactions. (c) An ORTEP diagram showing the 2-D sheets penetrating into each other through S···S interactions, forming d–d cavities that are occupied by the water molecules. The hydrogen atoms and water molecules are removed for clarity.

4-PDS ligands and two *trans* N-bonded NCS^- anions. The Fe–N bond lengths involving the NCS^- groups, 2.072(4) Å are shorter than those involving the 4-PDS ligands, which are 2.249(5) and 2.234(5) Å for N(1) and N(2)#2, respectively. The C(3)–N(3)–Fe(1) bond angle is 169.0(5)°, while the N–C–S bond angles is 164.2 (8)°. The adjacent iron atoms are bridged by 4-PDS ligands to form 22-membered macrocyclic building units. The Fe ··· Fe distance (10.956 Å) in the molecular chain of **2** is longer than that found in a similar one-dimensional channel-type chain complex $[Fe(NCS)_2(bpa)_2]_n$ (bpa = 1,2-bis(4-pyridyl)-ethane) [9], which is 9.995(3) Å, indicating that the bpa ligand, which contains a $-CH_2-CH_2-$ group, is more flexible than the 4-PDS ligand.

One of the remarkable features in complexes **1** and **2** is that weak S···S interactions interlink the molecular chains. In complex **1**, weak S···S (3.64 Å) interactions are formed between adjacent chains through the sulfur atoms of the thiocyanato groups and the sulfur atoms of 4-PDS molecules (Fig. 1(c)). In complex **2**, the S···S weak interactions (3.52 Å), which interlink the one-dimensional metallocycles into 2-D sheets, are formed between adjacent chains through the sulfur atoms of 4-PDS ligands. In fact, the 2-D sheets interpenetrate each other through the S···S interactions, forming a unique 3-D structure with large cavities that are occupied by the water molecules (Fig. 2(c)). The S···S distances of complexes **1** and **2**, which are 3.64 and 3.52 Å, respectively, are shorter than twice the van der Waals radius of sulfur (3.7 Å). S···S interactions have been observed in several compounds, such as $[4,4'\text{-bipyH}_2][M(NCS)_4]$ ($M = Mn^{2+}$, Co^{2+} or Zn^{2+}; 4,4′-bipy = 4,4′-bipyridine) [10], Cu_2Cl_4L (L = 2,5-bis(2-pyridylmethylsufanylmethyl)pyrazine) [11] and $[Hg_2(C_5H_4S_5)_2Cl_4]_n$($C_5H_4S_5$ = 4,5-ethylenedithio-1,3-dithiole- 2-thione) [12]. However, although several complexes containing 4-PDS ligands are known (Table 3, vide infra), only one complex $[Ag(4\text{-PDS}) \cdot NO_3 \cdot (CH_3CN)_{0.5}]$ was reported to show insignificant S···S interactions (3.73 Å) between the chains.

4.4. Structure of $\{[Co(4\text{-PDS})_2][Cl]_2 \cdot 2CH_3OH\}_n$

Fig. 3(a) shows the local coordination of the Co(II) metal center, and selected bond distances and angles are listed in Table 2. The single crystal X-ray structure shows that **3** is a coordination polymer consisting of Co(4-PDS), which forms one-dimensional metallocycles (Fig. 3(b)). The distorted square planar Co(II) metal center is achieved by means of four bridging 4-PDS ligands. The two independent Co–N bond lengths are 2.054(2) and 2.061(3) Å. The adjacent cobalt atoms are bridged by 4-PDS ligands to form 1-D chains based on the 22-membered macrocyclic building units. The Co···Co distance in the molecular chain is 10.207 Å.

Table 3
S–S distances (Å) and C–S–S–C torsion angles (°) for some reported complexes containing 4-PDS ligands

Complex	S–S	C–S–S–C	Reference
1	2.028(1)	91.2	this work
2	2.026(1)	80.9	this work
3	2.031(3)	91.5	this work
$[Ag(4\text{-PDS})_2 \cdot PF_6]$	2.028(2)	91.4(2)	[17]
$[Ag(4\text{-PDS})_2 \cdot ClO_4]$	2.033(1)	89.7(1)	[17]
$[Ag(4\text{-PDS})_2 \cdot OTs]$	1.984(6)	95.5(8)	[17]
$[Ag(4\text{-PDS})_2 \cdot NO_3 \cdot (CH_3CN)_{0.5}]$	2.022(4)	83.8(6)	[17]
[4-PDS · Cu(hfac)]	2.029(2)	88.1(2)	[18]
[4-PDS · Mn(hfac)]	2.031(5)	91.6(6)	[18]
trans-$\{[RuCl(pdma)_2\}_2$-(μ-(4-PDS))$[I_3]_2\}$	2.029(6)	86.6	[19]
$[Zn_7(\mu_4\text{-}O_2)(CH_3CO_2)_{10}$-(μ-(4-PDS))$]_n$	2.021(7)	61.8(5)	[20]
$[Cd(4\text{-PDS})_2(H_2O)_2] \cdot 2NO_3 \cdot 2EtOH \cdot 2H_2O$	2.033(2)	90	[21]

Interestingly, the non-coordinated chloride ions, occupying the axial positions of the square planar metal centers, interact with the Co metal atoms through weak Co···Cl (2.916 Å) bonding. Each chloride atom also interacts with four phenyl hydrogen atoms of the 4-PDS ligands and the hydroxyl hydrogen atoms of the methanol molecules through C–H···Cl (H···Cl = 2.561, 2.638, 2.657 and 2.584 and ∠C–H···Cl = 134.5°, 132.3°, 129.2° and 135.8°; H···Cl = 2.055 Å and ∠O–H···Cl = 174.7°, respectively), hydrogen bonds (Fig. 3(c)). The oxygen atoms of the methanol molecules also interact with the sulfur atoms (S···O = 3.209) of the adjacent chains to form a 2-D network (Fig. 3(d)). Weak C–H···Cl hydrogen bonds have been observed in many compounds, such as CuCl(Pyz) [13], $CdCl_2$(Pyz) [14] and Cu_2Cl_2(Pyz) [15] and have been well established [16]. In this complex, no S···S weak interaction was found, presumably due to the formation of the C–H···Cl hydrogen bonds and the packing of the CH_3OH solvent molecules.

4.5. Conformation of the 4-PDS ligands

Table 3 shows the S–S distances and C–S–S–C torsion angles for some reported complexes containing 4-PDS ligands. The S–S bond distances are 2.208(1), 2.026(1) and 2.031(3) Å, while the S–C–C–S torsion angles are 91.2°, 80.9° and 91.5° for complexes **1**–**3**, respectively. These values are comparable to those in the other reported complexes. The 4-PDS ligand has been reported to show axial chirality, i.e., the *P* and *M*-forms of an optical antipode [17]. Based on Mochida's definition, each 1-D chain in complex **1** is chiral and is represented by either –*M*-(M)-*M*-(M)-*M*- or *P*-(M)-*P*-(M)-*P*-. The complex consists of a 1:1 ratio of *P* and *M*-chains, and is thus achiral. Complexes **2** and **3** can be envisioned as double-strand one dimensional coordination polymers. In **2**, each strand adopts either

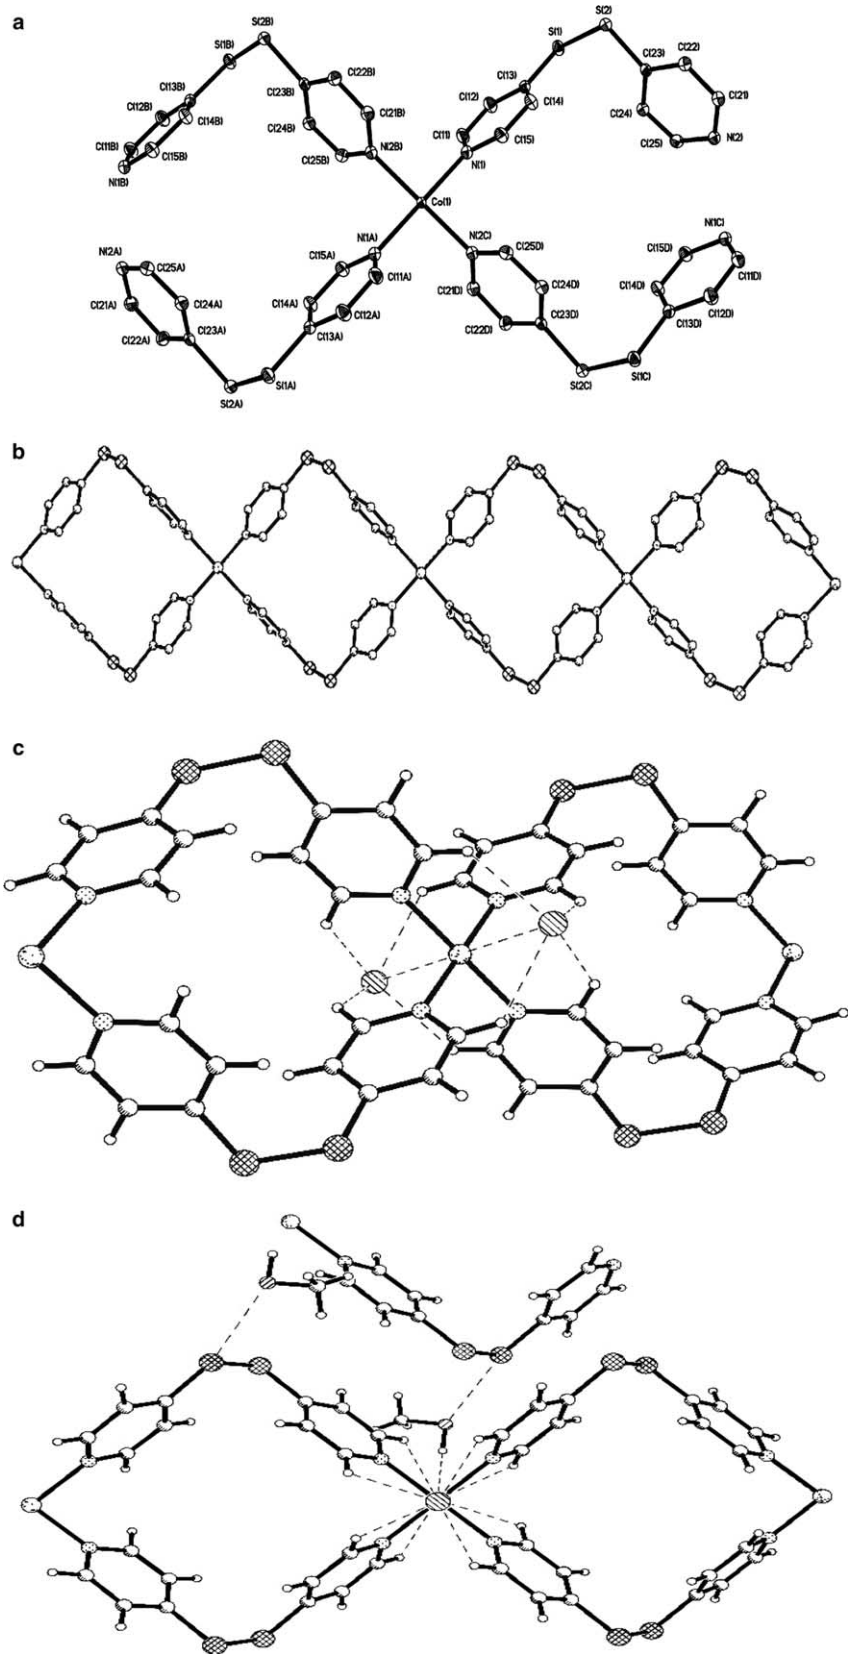

Fig. 3. (a) An ORTEP diagram of the local coordination of Co in **3**. (b) An ORTEP diagram showing the infinite one-dimensional channel-type chains. (c) An ORTEP diagram showing the interactions among the chloride atoms and the cobalt metal centers, where the O–H···Cl and S···O interactions to the methanol molecules are omitted for clarity. (d) A view looking down the Cl–Co–Cl axis, showing the O–H···Cl and S···O interactions between the chains.

P or *M* configurations, forming enantiomeric pairs, while each strand in complex **3** adopts the alternating P-(M)-M-(M)-P achiral conformation.

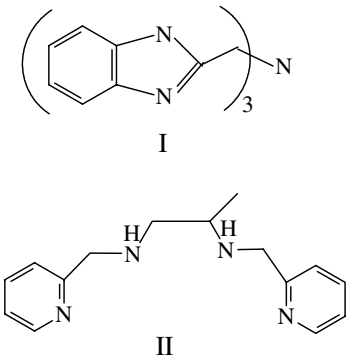

Chart 1.

the structural characterization of organic ligands, solvent system, temperature, pH of the solution, ratio of metal to ligand and counter ions [9–15]. An alteration in any of these factors often results in new complexes with different structural topologies and functions.

Herein, we report the reaction of the tripodal ligand tris(2-benzimidazolylmethyl)amine (ntb) (**I**, Chart 1) with copper chloride and ferric chloride, resulting in the formation of the complexes $[Cu(ntb)Cl]_2[CuCl_4]\cdot 2H_2O$ (**1**) and $[Fe(ntb)Cl_2]Cl\cdot 3H_2O$ (**2**). Each ntb ligand possesses three NH groups that are potential hydrogen-bond donors [16]. In both the complexes, the interaction between cations and anions via bifurcated (N–H···O) and (N–H···Cl) hydrogen-bonds provide extended networks. Well-defined hexagonal channels have also been identified in the assembly of the iron complex. Thus, the present study would serve as an elegant example of the use of different counter ions to effect supramolecular change of a cationic complex.

Of specific relevance to the above, we note that octahedral complexes of tetradentate ligands with reactive sites in a *cis* configuration affords an additional feature in that the *cis* orientation is ideal for coordination/insertion polymerization [17]. There has been a scarcity of information on the structural features of complexes derived from the Fe(bispicpn) moiety (bispicpn = *N*,*N*′-*bis*(2-pyridylmethyl)-1,2-propanediamine, **II**) (Chart 1) [18] and, thereby, the present study has been extended to establish proper synthetic strategies that could lead to any well-defined structural analogue. It may be noted that though the ligands ntb and bispicpn are structurally different, they belong to the N_4 system and form hexacoordinated molecules having the same counter anion (Cl^-). The notable distinguishing feature is that they lead to different extended frameworks.

Paskaly et al. [19] had successfully utilized the N_4 tripodal ligands bis(*N*-methylimidazole-2-yl)(picolyl)-amine and bis(picolyl)(*N*-methylimidazole-2-yl)amine in the synthesis of Fe-containing functional models of catechol dioxygenases. Examples with copper complexes showing such activity are not abundant. The crystal structure and catecholase like activity of a mononuclear complex $[Cu(EDTB)]^{2+}$ (EDTB = *N*,*N*,*N*′,*N*′-tetrakis (2′-benzimidazolylmethyl)-1,2-ethanediamine) have been reported very recently [20]. Therefore, it is a reasonable strategy to explore whether the new complexes derived from ntb and bispicpn with copper and iron can catalyze the oxidation of substituted catechols. The oxidizing activity of these complexes with 3,5-di-*tert*-butylcatechol have been studied in DMF. The copper complex (**1**) actually exhibits (very weak) catecholase activity, whereas the two iron complexes **2** and **3** show very weak dioxygenase activity. The catechol dioxygenase activity of **2** is, however, slightly higher than that of **3**.

2. Experimental

2.1. Materials

All materials used were of reagent grade. *o*-Phenylenediamine, nitrilotriacetic acid, pyridine-2-carboxaldehyde, copper chloride dihydrate, anhydrous ferric chloride and ferric chloride hexahydrate were of analytical reagent grade (Aldrich) and used without further purification. 1,2-Diaminopropane and ethylene glycol were distilled prior to the reaction. All other chemicals, e.g., MeOH, acetonitrile were of reagent grade. Distilled water was used throughout.

2.2. Physical measurements

Microanalysis (CHN) was performed in a Perkin–Elmer 240C elemental analyzer. IR spectra were obtained on a Nicolet MAGNA-IR 750 spectrometer with samples prepared as KBr pellets. Spectral and kinetic measurements were performed in an UV–Vis spectrophotometer (UV-2100, Shimadzu, Japan) equipped with thermostated cell compartments. Cyclic voltammetry was performed at a platinum electrode using an EG&G PARC electrochemical analysis system (Model 250/5/0) in DMF under dry nitrogen atmosphere in conventional three electrode configurations with a scan rate of 0.05 V s^{-1}. Oxygenated products were isolated by preparative TLC and column chromatography using 1:10 v/v of EtOAc and pet ether. NMR spectra were recorded with a Bruker AC 300 apparatus using $SiMe_4$ (δ_0) as an internal standard. DSC was recorded on a Perkin–Elmer DSC 7 instrument.

2.3. Preparation of the ligands

2.3.1. Tris(2-benzimidazolylmethyl)amine (ntb)

This has been synthesized following the procedure reported by Oki et al. [21].

2.3.2. N,N′-bis(2-pyridylmethyl)-1,2-propanediamine(bispicpn)

The ligand was synthesized by a modification of the previously reported method of Michelsen et al. [22]. Pure 1,2-diaminopropane (25 mmol, 2.15 cm^3) was allowed to react with pyridine-2-carboxaldehyde (50 mmol, 4.75 cm^3) in absolute ethanol (30 cm^3) by refluxing the mixture for 10 min. To this solution sodium borohydride (0.066 mmol, 2.5 g) was added in small portions over a period of 3 h. The solution was left overnight and warmed to boiling for 1 h. To the resulting solution hydrochloric acid (7.5 cm^3, 12 M) was added and when the gas evolution had ceased, the solution was made alkaline with a NaOH solution (10 cm^3, 5 M). Precipitated sodium borate was filtered off and the volume of the filtrate was reduced by evaporation under reduced pressure. The remaining solution was extracted with $CHCl_3$. The crude product of *N*,*N*′-bis(2-pyridylmethyl)-1,2-propanediamine were obtained as a viscous liquid by evaporation of the $CHCl_3$ solution (Yield: 66%).

2.4. Preparation of the complexes

2.4.1. [Cu(ntb)Cl]$_2$[CuCl$_4$] · 2H$_2$O (1)

To a 10 cm^3 acetonitrile solution of copper chloride dihydrate (0.85 g, 0.5 mmol) was added an acetonitrile (20 cm^3) solution of ntb (0.204 g, 0.5 mmol) and stirred. A clear green solution was thereby formed which was filtered to remove any suspended materials. The solution was kept in air and after 2 days prismatic pale brown crystals of **1** were formed. It was filtered and washed first by the mother liquor followed by diethyl ether and dried in air (Yield: 75% based on Cu). *Anal.* Calc. for $[Cu(ntb)Cl]_2[CuCl_4]\cdot 2H_2O$ ($Cu_3C_{48}H_{46}N_{14}O_2Cl_6$) ($F_w = 2445.13$): C, 23.56; H, 1.88; N, 8.02. Found: C, 23.12; H, 1.78; N, 7.97%. UV–Vis (MeOH) [$\lambda_{max}(\varepsilon)$]: 366 nm (630 M^{-1} cm^{-1}), 758 nm (154 M^{-1} cm^{-1}). IR (KBr pellet): 3063–3415 cm^{-1} (for H-bonded water molecules), 744 cm^{-1} (for out-of-plane bending vibrations of the *o*-disubstituted phenyl rings of the ntb ligand).

2.4.2. [Fe(ntb)Cl$_2$]Cl · 3H$_2$O (2)

To an acetonitrile (10 cm^3) solution containing ferric chloride hexahydrate (0.135 g, 0.5 mmol) was added an acetonitrile solution (20 cm^3) of ntb (0.204 g, 0.5 mmol) and the resulting solution was kept at room temperature for 3 h to give bright red needle shaped crystals upon slow evaporation of the solvent. The crystals were then filtered and washed first by the mother liquor followed by diethyl ether and dried in air (Yield: 78% based on Fe). *Anal.* Calc. for $[Fe^{III}(ntb)Cl_2]Cl\cdot 3H_2O$ ($FeC_{24}H_{27}N_7O_3Cl_3$) ($F_w = 623.73$): C, 46.17; H, 4.33; N, 15.71. Found: C, 46.05; H, 4.45; N, 15.54%. UV–Vis (MeOH) [$\lambda_{max}(\varepsilon)$]: 255 nm (6500 M^{-1} cm^{-1}), 280 nm (8200 M^{-1} cm^{-1}), IR (KBr pellet): 3045–3446 cm^{-1} (for H-bonded water molecules), 747 cm^{-1} (for out-of-plane bending vibrations of the *o*-disubstituted phenyl rings of the ntb ligand).

2.4.3. [Fe(bispicpn)Cl$_2$]Cl (3)

To a 10 cm^3 acetonitrile solution containing anhydrous ferric chloride (0.081 g, 0.5 mmol) was added an acetonitrile solution (20 cm^3) of bispicpn (0.13g, 0.5 mmol) and the resulting solution was left standing at room temperature. After 3–4 h orange-yellow crystals were isolated (Yield: 88% based on Fe). *Anal.* Calc. for [Fe(bispicpn)Cl$_2$]Cl ($FeC_{15}H_{19}N_4Cl_3$) ($F_w = 417.54$): C, 43.11; H, 4.55; N, 13.41. Found: C, 43.21; H, 4.46; N, 13.29%. [$\lambda_{max}(\varepsilon)$]: 598 nm (97 M^{-1} cm^{-1}), 494 nm (134 M^{-1} cm^{-1}), 453 nm (181 M^{-1} cm^{-1}).

2.5. Crystal structure determination and structural refinements of complexes 1, 2 and 3

Crystal data and other experimental details for **1**, **2** and **3** are reported in Table 1. The diffraction experiments concerning **1** and **2** were carried out on a Bruker SMART CCD area-detector diffractometer at 200 K. No crystal decay was observed, so that no time-decay correction was needed. The collected frames were processed with the software SAINT [23], and an empirical absorption correction was applied (SADABS) [24] to the collected reflections. The calculations were performed using the Personal Structure Determination Package [25] and the physical constants tabulated therein [26]. The structures were solved by direct methods (SHELXS) [27] and refined by full-matrix least-squares using all reflections and minimising the function $\sum w(F_o^2 - kF_c^2)^2$ (refinement on F^2). Anisotropic thermal factors were refined for all the non-hydrogen atoms. The hydrogen atoms of the water molecules were detected in the final Fourier maps and not refined. The remaining hydrogen atoms were placed in their ideal positions (C–H or N–H = 0.97 Å) with the thermal parameter *B* 1.10 times that of the atom to which they are attached, and not refined. In the final Fourier maps the maximum residuals were 0.90(13) e $Å^{-3}$ at 0.87 Å from Cl(1) and 0.85(25) e $Å^{-3}$ at 0.94 Å from Cl(1) for **1** and **2**, respectively.

A single crystal of the complex **3** was collected and mounted on an automatic Bruker P4 diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell dimensions and intensity data were measured at 296 K. The structure was solved by direct methods, refined by full-matrix least-squares based on F^2 with anisotropic thermal parameters for non-hydrogen atoms using Bruker SHELXTL (data reduction), SHELXS [28] (structure solution) and SHELXL [29] (structure refinement). The hydrogen atoms were included in structure factor calculations in their idealized positions.

[a] $R_1 = [\sum(|F_o^2 - kF_c^2|)/\sum F_o^2]$, $wR_2 = [\sum w/(F_o^2 - kF_c^2)^2/\sum w(F_o^2)^2]^{1/2}$.
[b] $[w(F_o^2 - kF_c^2)^2/(N_o - N_v)]^{1/2}$, where $w = 4F_o^2/\sigma(F_o^2)^2$, $\sigma(F_o^2) = [\sigma^2(F_o^2) + (pF_o^2)^2]^{1/2}$, N_o is the number of observations, N_v the number of variables, and $p = 0.04$ for **1** and 0.03 for **2**.

3. Results and discussion

3.1. Crystal structure of $[Cu(ntb)Cl]_2[CuCl_4] \cdot 2H_2O$ (*1*)

An ORTEP drawing of the complex with the atom labelling scheme is shown in Fig. 1. The selected bond distances and angles are given in Table 2. The unit cell consists of eight $[Cu(ntb)Cl]^+$ cations, four $CuCl_4^{2-}$ anions and eight water molecules as solvent of crystallization. Copper atoms in the cation and the anion differ in their geometry. In the cation, the geometry of the central copper atom is intermediate between square-pyramidal and trigonal bipyramidal in which two N atoms of the benzimidazole and the amine N atom occupy the equatorial positions, and one of the nitrogen atoms from benzimidazole occupies the axial position. The remaining site of the equatorial plane is occupied by a Cl^- ion. Addison et al. [30] had proposed and defined an angular structural parameter as an index of trigonality in five coordinated systems. By this standard, the coordination geometry of $[Cu(ntb)Cl]^+$ in the solid state is described as being 28% ($\tau = 0.28$) along the pathway of distortion from square-pyramidal towards trigonal bipyramidal. A recent report by Wu et al. [31] on the structural aspect of $[Cu(ntb)(H_2O)](ClO_4)_2 \cdot C_6H_7NO \cdot H_2O$ described the coordination geometry of copper as distorted trigonal bipyramidal with approximate site symmetry $C3$. The geometry of the central metal ion in the anionic part is a distorted tetrahedron occupied by four Cl^- atoms. The $Cu–N_{amine}$ distance in the cation is 2.2440(15) Å and the average distance of equatorial $Cu–N_{benzimidazole}$ is 1.966 Å. The distance between the copper and axial nitrogen is 2.1264(15) Å. These bond distances compare well with previously reported compounds of a similar type [32]. Wu et al. [31] reported the Cu–N(amine) bond distance as 2.096(3) Å. In the $CuCl_4^{2-}$ moiety, the average Cu–Cl bond length is 2.2433 Å. This unit along with two water molecules participate in hydrogen bonding interactions with the benzimidazole nitrogens, generating a 3D architecture (Fig. 2). The four chloride ions of the $CuCl_4^{2-}$ unit provide two different types of H-bonding interactions. Two chloride ions form H bonds with benzimidazole N–H, while the other two are involved in bifurcated H-bonding with a water molecule and benzimidazole N–H to form a 3D framework. The distance between the two Cu centers of the $[Cu(ntb)Cl]^+$ units is 9.643 Å while the Cu atoms of $[Cu(ntb)Cl]^+$ and $CuCl_4^{2-}$ units are 7.0393 Å apart.

3.2. Crystal structure of $[Fe(ntb)Cl_2]Cl \cdot 3H_2O$ (*2*)

An ORTEP drawing of the complex with the atom labelling scheme is shown in Fig. 3. The selected bond distances and angles are given in Table 3. The molecule consists of the cation $[Fe(ntb)Cl_2]^+$ and the anion Cl^- with three solvated water molecules. The central Fe(III) ion displays a distorted octahedral environment, the ligating atoms being two chlorine and four nitrogen

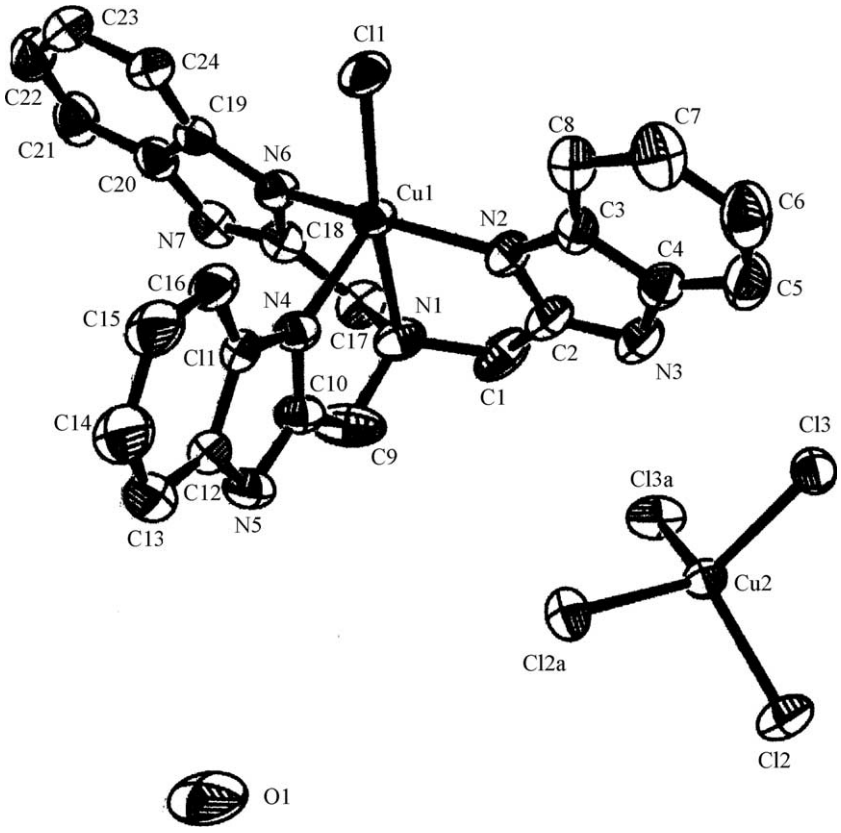

Fig. 1. ORTEP diagram of complex **1**. Hydrogen atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level.

atoms from the ntb ligand. The *cis* orientation of the two chlorine atoms is indicated by the Cl(1)–Fe–Cl(2) bond angle of 96.8(1)°, comparable to that observed for other *cis*-dichloro species [33]. The equatorial plane is defined by N(2), N(4), N(6) and Cl(2). An apical nitrogen N(1) and another chloride Cl(1) occupy the axial positions. The N-Fe–N *cis* bond angle, imposed by the rigid heterocyclic rings of ntb deviate significantly from 90°, the largest deviation being in the N1–Fe–N2 angle (73.9(1)°). The Fe–Cl(1) and Fe–Cl(2) bond distances of 2.212(1) and 2.350(1) Å, respectively, are in accord with those found in related structures [33]. The average bond distance between the Fe(III) ion and the equatorial

nitrogen atoms is 2.123 Å, which is much shorter than the axial bond length of 2.363(2) Å, as expected [33].

3.3. Description of the hexagonal channel

There are several interesting features apparent from crystal packing diagram of complex **2** (Fig. 4). Intermolecular H-bonding affords a six-membered channel comprising of four water molecules and two Cl^- ions (Figs. 5(a) and (b)). The volume of the channel is 315.1 $Å^3$ which is 22.9% of the unit cell 1378.3 $Å^3$ [34]. The volume is calculated by neglecting the presence of water molecules and chlorine atoms for simplification. If the calculation is repeated by keeping water molecules and chlorine atoms, there is still a space of 39.6 $Å^3$ which is 2.9% that of the unit cell volume. The magnitude is smaller than a hydrogen bonded H_2O-molecule (40 $Å^3$) and thus the fourth water molecule cannot be seen in the unit cell. The space-filling model for the compound shows a nice projection of the vacant cavities occupied by the guest water molecules and the chlorine counter anions. A notable feature apparent from the view is that the packing forms a helical propagation along the diagonal of the crystallographic axes *b* and *c* (Fig. 6) [34]. Calculations done for the diagonal lengths of the hexagonal channel show an average value of 6.080 Å (Fig. 5(b)) [35].

3.4. Crystal structure of [Fe(bispicpn)Cl_2]Cl (**3**)

An ORTEP drawing of the complex with the atom labelling scheme is shown in Fig. 7. The selected bond distances and angles are given in Table 4. The structure consists of a $[Fe^{III}(bispicpn)Cl_2]^+$ cation and a Cl^- counter ion. The geometry of the central metal ion is a distorted octahedron in which the equatorial positions are occupied by N1A, N1B, N2B and Cl1 whereas N2A and Cl2 occupy the axial positions. The *cis*-dichloro arrangement of the two chlorine atoms is confirmed by the Cl1–Fe–Cl2 angle of 101.07°. The average

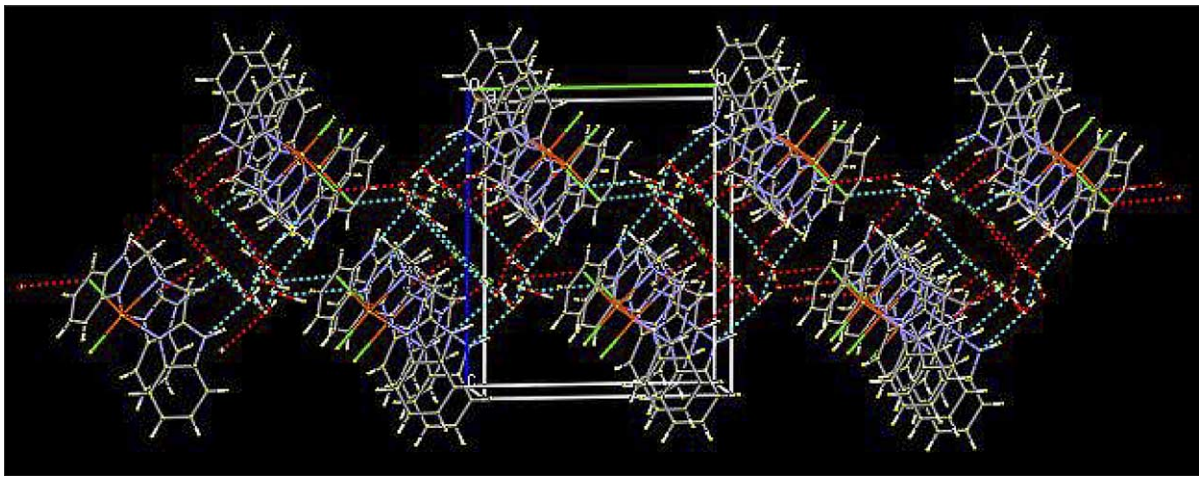

Fig. 4. Crystal packing diagram of complex **2** in the *ab*-plane.

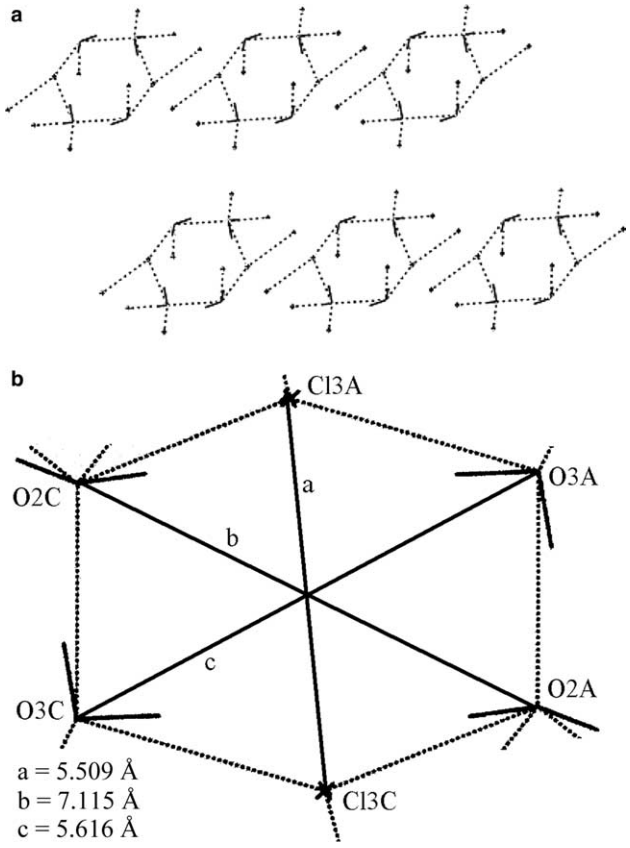

Fig. 5. Hexagonal pores in the crystal packing of complex **2**.

equatorial Fe(III)–nitrogen bond length is 2.170 Å, which is comparable to that observed for other Fe(III)–Schiff base complexes [36]. The axial Fe–N_{amine} distance is 2.166(3) Å. The axial and equatorial Fe(III)–Cl distances are 2.2887(9) and 2.2962(8) Å, respectively, as expected for high-spin Fe(III) complexes [36,37]. The mononuclear fragments are bound together via H-bonding utilizing the chloride counter ion and amine hydrogens, forming a 1D chain as depicted in Fig. 8.

4. Electrochemical studies

The cyclic voltammograms of the complexes **1**–**3** are shown in Fig. 9. The redox potentials are summarized in Table 5. Complex **1** exhibits two reversible one-electron redox couples with $E_{1/2}$ at +0.530 and −0.031 V versus Fc/Fc^{+}. These are in good agreement with those reported by Su et al. [32]. The corresponding redox couples may be shown as follows:

$$[Cu(ntb)Cl]^{1+} \rightleftharpoons [Cu(ntb)Cl]^{0} \rightleftharpoons [Cu(ntb)Cl]^{1-}$$

It is also evident that the $CuCl_4^{2-}$ unit does not undergo electron transfer in the available potential range. The irreversible couple observed at +1.0 V could be assigned to the oxidation of the ntb ligand.

The cyclic voltammogram of complex **2** displays a quasi-reversible Fe(III)/Fe(II) redox reaction occurring at $E_{1/2} = +0.23$ V, which is similar to that observed previously [33]. Another irreversible oxidation at +1.1 V, similar to that observed for complex **1**, was attributed to the oxidation of the benzimidazole rings.

The nature of the cyclic voltammogram of **3** is qualitatively similar to that of **2**. The reversible Fe(III)/Fe(II) redox couple occurs with $E_{1/2} = +0.115$ V and the irreversible oxidation of the bispicpn ligand occurs at +1.014 V [36].

5. Catalytic activity for oxidation of 3,5-di-*tert*-butylcatechol

We have examined the catalytic activity of complexes **1**–**3** for oxidation of 3,5-di-*tert*-butylcatechol (3,

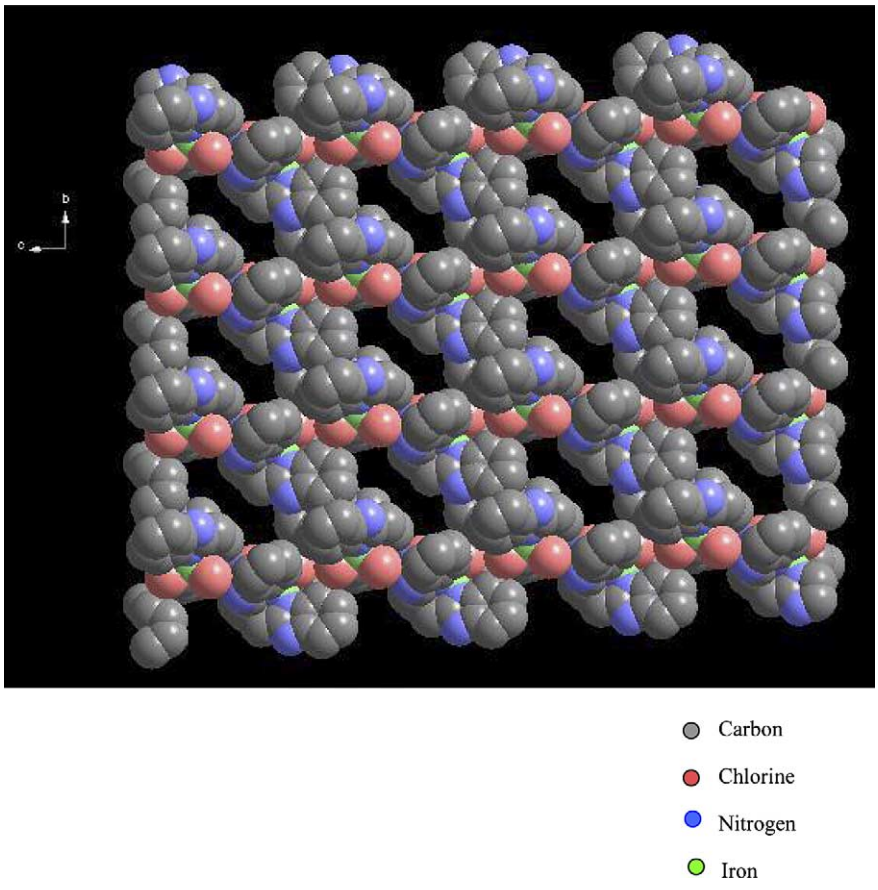

Fig. 6. Space-filling model of the hexagonal pores of complex **2**.

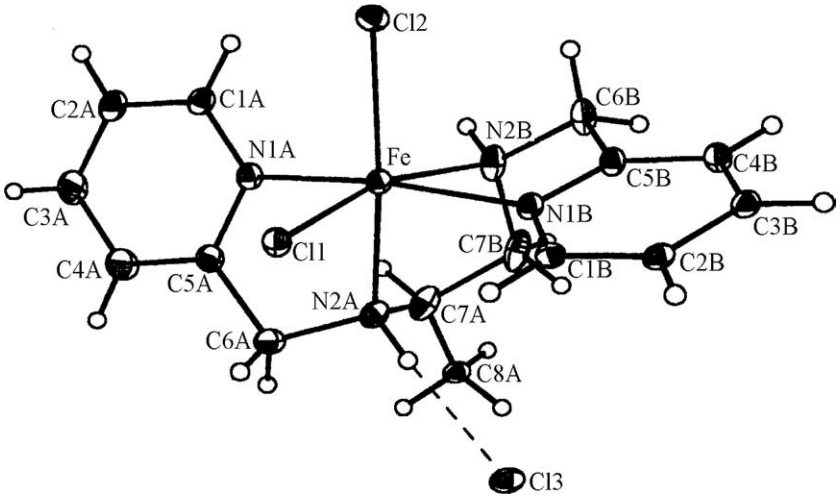
5-DTBC) by O_2 in air saturated DMF solution at 20 °C. The reactivity studies were performed in DMF solution because of the good solubility of the complexes as well as of the substrate and of its products. Kinetic measurements were made for all of the complexes in DMF at 20 °C. For this purpose 10^{-4} mol dm^{-3} solutions of the complexes in DMF were treated with 10^{-3} mol dm^{-3} 3,5-di-*tert*-butylcatechol



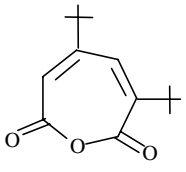


Fig. 7. ORTEP diagram of complex **3**. Hydrogen atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level.

in the presence of air. Reaction of the complexes with 3,5-di-*tert*-butylcatechol yields a solution whose spectra are significantly different from that of the complexes. In the solution the peak at 366 nm, which is due to the π(benzimidazole) $\rightarrow$ Cu(II) LMCT transitions, vanishes [38]. Simultaneously, a band at exactly 400 nm appears that is indicative of the oxidation from 3,5-di-*tert*-butylcatechol to 3,5-di-*tert*-butyl-*o*-quinone [39]. The course of the reaction was followed at 400 nm at regular time intervals. The trace of the reaction is shown in Fig. 10. The iron complexes all react with 3,5-di-*tert*-butylcatechol in presence of dioxygen to yield products due to the oxidative cleavage of the catechol ring. NMR techniques were used to identify the products of the oxidative cleavage. They afford intradiol cleavage products in a major yield that is consistent with the trend noted earlier [40]. The two main products isolated from the reaction mixture are 3,5-di-*tert*-butyl-1-oxacyclohepta-3,5-diene-2,7-dione and 3,5-di-*tert*-butyl-5-(carboxymethyl)-2-furanone [40] as shown here:

Ia

Ib

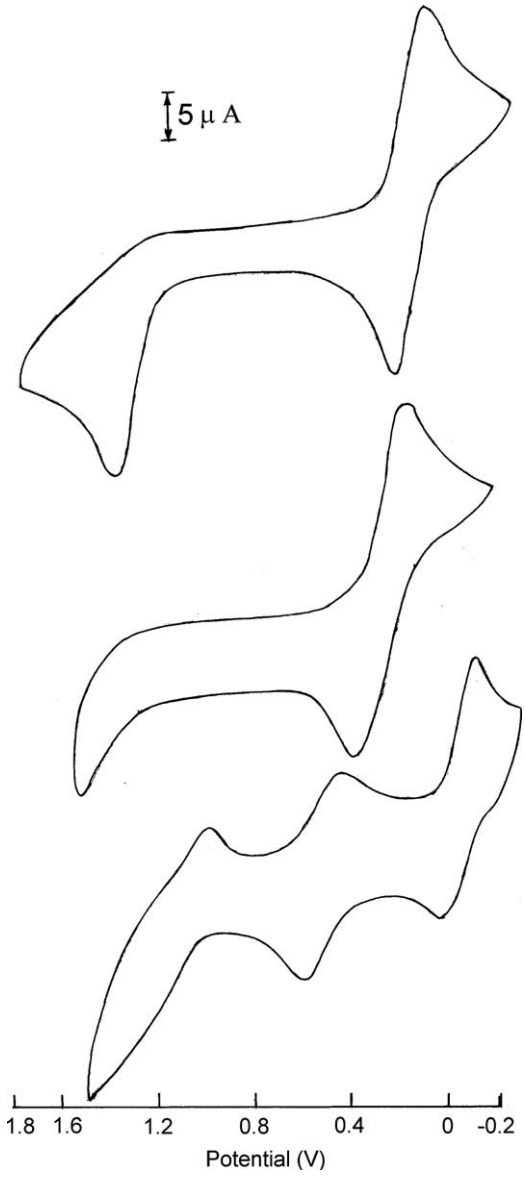

Fig. 9. Cyclic voltammograms (scan rate 50 mV s^{-1}) of complexes **1**, **2** and **3** in DMF at a platinum electrode with ferrocene as an internal standard and TEAP as supporting electrolyte.

In the presence of an excess of substituted catechol, the pseudo-first-order constants were deduced from simulations and the second-order

Table 5
Cyclic voltammetric results for complexes **1**, **2** and **3** at 298 K

Complex	E_1 (V)			E_2 (V)		
	E_{pa} (V)	E_{pc} (V)	$E_{1/2}$ (V)	E_{pa} (V)	E_{pc} (V)	$E_{1/2}$ (V)
1	0.035	−0.097	−0.031	0.605	0.45	0.53
2	0.330	0.133	0.231			
3	0.164	0.067	0.115			

constants (Table 6) were calculated assuming $[O_2] = 4.86 \times 10^{-3}$ M in DMF at 20 °C by using the following equation [40b]:

$$k_{O_2} = k_{obs}/[O_2].$$

Inspection of the data reveals that complex **2** shows enhanced catalytic activity in comparison to that of **3**. The latter reacts approximately four times slower than **2**. Such enhancement in rates is well documented in recent reports [41]. A correlation between the rate of oxidation and the $E_{1/2}$ values of the two iron complexes can be established. The easier the metal complex is reduced, the higher is its catalytic activity. Complex **2** is found to have the higher catalytic activity regarding oxidation of 3,5-di-*tert*-butylcatechol as it is more easily reducible than **3**.

Table 6
Comparison of the kinetic parameters for complexes **1**, **2** and **3**

Complex	k_{obs} (M^{-1} s^{-1})	Yield of products (%)
$[Cu(ntb)Cl]_2[CuCl_4] \cdot 2H_2O$	4.1	3,5-Ditertiary butylquinone (95%)
$[Fe(ntb)Cl_2]Cl \cdot 3H_2O$	3.4×10^{-2}	Ia, Ib (55%, 40%)
$[Fe(bispicpn)Cl_2]Cl$	9.032×10^{-3}	Ia, Ib (67%, 34%)

Kinetic conditions: $[3,5\text{-di-}tert\text{-butylcatechol}] = 1 \times 10^{-3}$ M, $[Complex] = 1 \times 10^{-4}$ M, $T = 20$ °C. The second-order rate constants of the reaction were calculated by using the equation $k_{O_2} = k_{obs}/[O_2]$. The solubility of O_2 in DMF at 20 °C is 4.86×10^{-3} M. The k_{obs} values are the average of three determinations which differ by ±5%.

6. Thermal studies

To investigate the thermal stability of complexes **1** and **2**, we performed Differential Scanning Calorimetry (DSC). In the temperature range 50–100 °C, a single endothermic peak could be observed at 82 °C with $\Delta H = -70.7$ J g^{-1} for complex **1**. For complex **2**, the experiment was performed in the temperature range 70–110 °C. The endothermic peak appears at 99.9 °C having $\Delta H = -164.8$ J g^{-1}. These are related to the loss of hydrogen bonded water molecules in both the complexes.

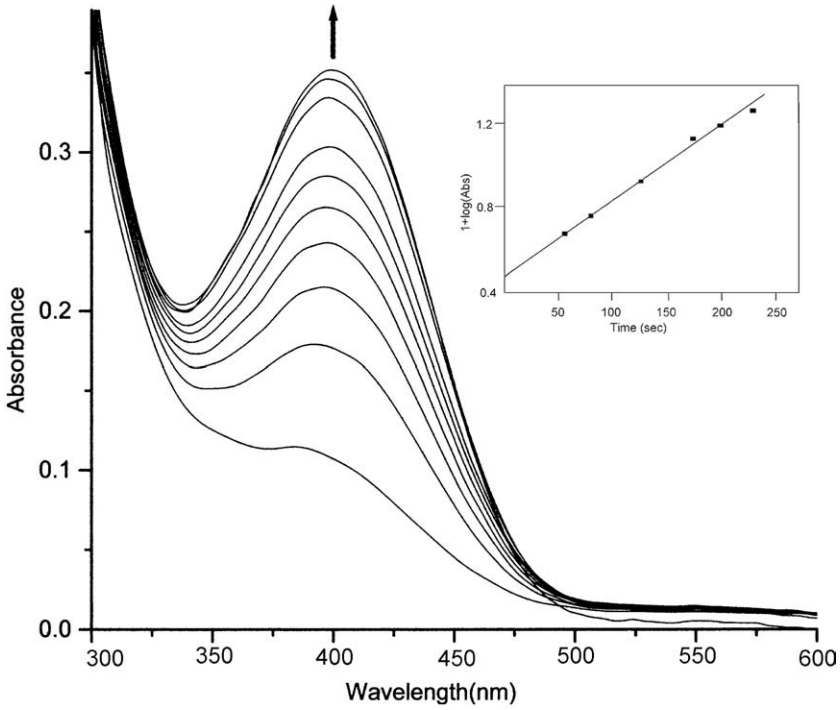

Fig. 10. Progress of the reaction of $[Cu(ntb)Cl]_2[CuCl_4] \cdot 2H_2O$ with O_2 in DMF solution. The appearance of the *o*-quinone band at 400 nm was monitored. Conditions: $[3,5\text{-di-}tert\text{-butylcatechol}] = 1 \times 10^{-3}$ M, $[Complex] = 1 \times 10^{-4}$ M, Temperature = 20 °C. Inset: Plot of $[1 + \log(Abs)]$ vs. time for the reaction of $[Cu(ntb)Cl]_2[CuCl_4] \cdot 2H_2O$ with O_2 at 20 °C in DMF solution at 400 nm.

temperature [20]. (2) Photo-switching of characteristic properties of molecular compounds, for instance chiral molecular recognition, spin crossover and conformational conversion, can be available in contrast to other inorganic solid compounds such as Prussian blue analogues.

In this context, flexible transition metal complexes are suitable as a component of such photo-switching materials. Classically, some Cu(II) or Ni(II) complexes incorporating Schiff base ligands [21] have been known to exhibit flexibility from a square planar to a tetrahedral coordination environment by introduction of various substituents, and show structural phase transitions by heating [22–30]. Especially, Ni(II) complexes exhibit not only flexibility of the coordination environment [31–38] but also interesting magnetic behavior; diamagnetic square planar complexes change into paramagnetic tetrahedral complexes when a complex adopts such coordination geometries in the solid state, or when one is dissolved in solution, so called *solution paramagnetism* [39–41].

Herein, we report structural features, electronic properties, thermally-induced structural phase transition and absorption spectra depending on the solvent for ten Cu(II) complexes with 3,5-halogen-substituted Schiff base ligands (Scheme 1). Crystal structures of two new complexes, bis(*N*-*R*-1-phenylethyl- and *N*-*R*,*S*-2-butyl-5-bromosalicydenaminato-κ^2N,O)copper(II), are also described. Furthermore, we successfully observed a spectral change of d–d and π–π* bands of the complex caused by *cis–trans* photoisomerization of 4-hydroxyazobenzene (4HAZ) for an organic/inorganic system involving bis-(*N*-*R*-1-phenylethyl-3,5-dichlorosalicydenaminato-κ^2N,O)copper-(II) and 4HAZ in chloroform solution.

Scheme 1. Molecular structures of **1**–**10**.

2. Experimental

2.1. Materials

Chemicals of the highest commercial grade available (Aldrich and Wako) were used as received without further purification.

2.2. Physical measurements

Elemental analyses (C, H, N) were carried out on an Elementar Vario EL analyser at Keio University. Infrared spectra were recorded using Nujol mulls on a BIORAD FTS-60A spectrophotometer in the range 4000–400 cm^{-1} at 298 K. Thermal analysis was performed on a SHIMADZU DSC-60 differential scanning calorimeter (DSC), where the heating rate was 10 K min^{-1} in the range of 313–673 K. Diffuse reflectance spectra were measured on a JASCO V-560 spectrophotometer equipped with an integrating sphere in the range 850–220 nm at 298 K. Absorption spectra were measured on a JASCO V-560 spectrophotometer in the range 900–200 nm at 298 K. Magnetic susceptibility was measured with a Sherwood Scientific magnetic susceptibility balance at 298 K. Magnetic data were corrected for the magnetization of diamagnetic contributions, which were estimated from Pascal constants. The magnetic properties were investigated with a Quantum Design MPMS-5S superconducting quantum interference device magnetometer (SQUID) at an applied field of 5000 Oe in a temperature range 5–250 K. Semi-empirical molecular orbital calculations were performed with the program ZINDO [42,43] in the CAChe software package based on the crystal structures determined.

2.3. Syntheses of complexes

2.3.1. Bis(*N*-*R*-1-phenylethyl-3,5-dichlorosalicydenaminato)copper(II) (*1*)

To a methanol solution (150 cm^3) of copper(II) acetate (0.91 g, 5.00 mmol), 3,5-dichlorosalicylaldehyde (1.91 g, 10.0 mmol), and *R*-1-phenylethylamine (1.21 g, 10.0 mmol) were added and stirred at 45 °C for 2 h. The resulting brown precipitates were collected by filtration and recrystallized from acetone/methanol. Yield 64.8%. *Anal*. Calc. for $C_{30}H_{24}N_2Cl_4CuO_2$: C, 55.44; H, 3.72; N, 2.31. Found: C, 55.37; H, 3.98; N, 4.09%. IR (KBr) $\nu_{C=N}$ 1623 cm^{-1}, ν_{Cu-N} 445 cm^{-1}, ν_{Cu-O} 419 cm^{-1}, m.p. 483 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.73$ at 298 K.

2.3.2. Bis(*N*-*R*,*S*-1-phenylethyl-3,5-dibromoosalicydenaminato)copper(II) (*2*)

The same procedure as for **1** afforded the condensation of 3,5-dibromosalicylaldehyde (2.80 g, 10.0 mmol) and *racemic* 1-phenylethylamine (1.21 g, 10.0 mmol).

Yield 74.5%. *Anal*. Calc. for $C_{30}H_{24}Br_4CuN_2O_2$: C, 43.64; H, 2.92; N, 3.38. Found: C, 43.77; H, 2.72; N, 3.25%. IR (KBr) $\nu_{C=N}$ 1617 cm^{-1}, ν_{Cu-N} 444 cm^{-1}, ν_{Cu-O} 424 cm^{-1}, m.p. 478 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.47$ at 298 K.

2.3.3. Bis(N-R,S-1-phenylethyl-5-chlorosalicydenaminato)copper(II) (3)

The same procedure as for **1** afforded the condensation of 5-chlorosalicylaldehyde (1.57 g, 10.0 mmol) and *racemic* 1-phenylethylamine (1.21 g, 10.0 mmol). Yield 49.6%. *Anal*. Calc. for $C_{30}H_{26}Cl_2CuN_2O_2$: C, 62.02; H, 4.51; N, 4.82. Found: C, 62.07; H, 4.29; N, 4.70%. IR (KBr) $\nu_{C=N}$ 1621 cm^{-1}, ν_{Cu-N} 465 cm^{-1}, ν_{Cu-O} 419 cm^{-1}, m.p. 474 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.66$ at 298 K.

2.3.4. Bis(N-R-1-phenylethyl-5-bromosalicydenaminato)copper(II) (4)

The same procedure as for **1** afforded the condensation of 5-bromosalicylaldehyde (2.01 g, 10.0 mmol) and *R*-1-phenylethylamine (1.21 g, 10.0 mmol). Yield 24.4%. *Anal*. Calc. for $C_{30}H_{26}Br_2CuN_2O_2$: C, 53.79; H, 3.91; N, 4.18. Found: C, 53.60; H, 3.69; N, 4.11%. IR (KBr) $\nu_{C=N}$ 1620 cm^{-1}, ν_{Cu-N} 463 cm^{-1}, ν_{Cu-O} 418 cm^{-1}, m.p. 469 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.91$ at 298 K. Brown plate-like single crystals suitable for X-ray crystallography were grown from the filtrate over a period of a few days at 298 K.

2.3.5. Bis(N-S-2-butyl-3,5-dichlorosalicydenaminato)copper(II) (5)

The similar procedure as for **1** afforded the condensation of 3,5-dichlorosalicylaldehyde (0.96 g, 5.00 mmol) and *S*-2-butylamine (0.37 g, 5.00 mmol). Yield 25.8%. *Anal*. Calc. for $C_{22}H_{24}Cl_4CuN_2O_2$: C, 47.71; H, 4.37; N, 5.06. Found: C, 47.76; H, 3.94; N, 5.09%. IR (KBr) $\nu_{C=N}$ 1622 cm^{-1}, ν_{Cu-N} 447 cm^{-1}, ν_{Cu-O} 419 cm^{-1}, m.p. 484 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.53$ at 298 K.

2.3.6. Bis(N-R,S-2-butyl-3,5-dibromosalicydenaminato)copper(II) (6)

The similar procedure as for **1** afforded the condensation of 3,5-dibromosalicylaldehyde (1.40 g, 5.00 mmol) and racemic 2-butylamine (0.37 g, 5.00 mmol). Yield 26.9%. *Anal*. Calc. for $C_{22}H_{24}Br_4CuN_2O_2$: C, 36.12; H, 3.31; N, 3.83. Found: C, 36.50; H, 2.97; N, 3.84%. IR (KBr) $\nu_{C=N}$ 1620 cm^{-1}, ν_{Cu-N} 446 cm^{-1}, ν_{Cu-O} 420 cm^{-1}, m.p. 459 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.48$ at 298 K.

2.3.7. Bis(N-R,S-2-butyl-5-chlorosalicydenaminato)copper(II) (7)

The similar procedure as for **1** afforded the condensation of 5-chlorosalicylaldehyde (0.78 g, 5.00 mmol) and racemic 2-butylamine (0.37 g, 5.00 mmol). Yield 46.4%. *Anal*. Calc. for $C_{22}H_{26}Cl_2CuN_2O_2$: C, 54.49; H, 4.40; N, 5.78. Found: C, 54.46; H, 4.53; N, 5.72%. IR (KBr) $\nu_{C=N}$ 1618 cm^{-1}, ν_{Cu-N} 459 cm^{-1}, ν_{Cu-O} 436 cm^{-1}, m.p. 475 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.55$ at 298 K.

2.3.8. Bis(N-R,S-2-butyl-5-bromosalicydenaminato)copper(II) (8)

The similar procedure as for **1** afforded the condensation of 5-bromosalicylaldehyde (1.01 g, 5.00 mmol) and racemic 2-butylamine (0.37 g, 5.00 mmol). Yield 49.7%. *Anal*. Calc. for $C_{22}H_{26}Br_2CuN_2O_2$: C, 46.05; H, 4.57; N, 4.88. Found: C, 46.10; H, 4.84; N, 4.81%. IR (KBr) $\nu_{C=N}$ 1616 cm^{-1}, ν_{Cu-N} 459 cm^{-1}, ν_{Cu-O} 426 cm^{-1}, m.p. 473 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.69$ at 298 K. Brown plate-like single crystals suitable for X-ray crystallography were grown from the filtrate over a period of a few days at 298 K.

2.3.9. Bis(N-2-propyl-5-chlorosalicydenaminato)copper(II) (9)

The same procedure as for **1** afforded the condensation of 5-chlorosalicylaldehyde (1.57 g, 10.0 mmol) and 2-propylamine (0.59 g, 10.0 mmol). Yield 50.9%. *Anal*. Calc. for $C_{20}H_{22}Cl_2CuN_2O_2$: C, 52.58; H, 4.85; N, 6.13. Found: C, 52.39; H, 5.16; N, 6.21%. IR (KBr) $\nu_{C=N}$ 1626 cm^{-1},

[a] $R = \sum\|F_o| - |F_c\|/\sum|F_o|$.

[b] $R_w = (\sum w(|F_o| - |F_c|)^2/\sum w|F_o|^2)^{1/2}$, $w = 1/(\sigma^2(F_o) + (0.0286P)^2 + 1.2163P)$ for **4**, $w = 1/(\sigma^2(F_o) + (0.1P)^2)$ for **8**, where $P = (F_o^2 + 2F_c^2)/3$.

ν_{Cu-N} 453 cm^{-1}, ν_{Cu-O} 432 cm^{-1}, m.p. 469 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.55$ at 298 K.

2.3.10. Bis(N-2-propyl-5-bromosalicydenaminato) copper(II) (**10**)

The same procedure as for **1** afforded the condensation of 5-bromosalicylaldehyde (2.01 g, 10.0 mmol) and 2-propylamine (0.59 g, 10.0 mmol). Yield 54.1%. *Anal.* Calc. for $C_{20}H_{22}Br_2CuN_2O_2$: C, 44.01; H, 4.06; N, 5.13. Found: C, 44.01; H, 4.28; N, 5.05%. IR (KBr) $\nu_{C=N}$ 1624 cm^{-1}, ν_{Cu-N} 451 cm^{-1}, ν_{Cu-O} 429 cm^{-1}, m.p. 481 K (decomposition). Magnetic moment $\mu_{eff}/\mu_{BM} = 1.54$ at 298 K.

2.4. X-ray crystallography

Intensity data of **4** and **8** were collected on a Rigaku AFC-7R four-circle diffractometer at 297 K using graphite-monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å). The structures were solved by direct methods using SIR92 [44] and expanded by Fourier techniques. The structures were refined on F^2 anisotropically for non-hydrogen atoms by full-matrix least-squares methods with SHLEXL97 [45] on a teXsan program package [46]. Empirical absorption corrections were applied based on ψ scans. No significant decay in the intensity of three standard reflections was observed throughout the data collection. The hydrogen atoms were located at geometrically calculated position with C–H = 0.950 Å and refined isotropically. All the non-hydrogen atoms were refined anisotropically. Crystallographic data for **4** and **8** are summarized in Table 1. The crystal structures of **1** [30] and **5** [29] have been already reported elsewhere.

3. Results and discussion

3.1. Description of the structure of *4*

The molecular structure of **4** is depicted in Fig. 1, and selected bond distances and angles of **4** are given in Table 2. Complex **4** adopts a compressed tetrahedral *trans*-[CuN_2O_2] coordination environment, which is ascribed to bulky 1-phenylethyl moieties of the ligands.

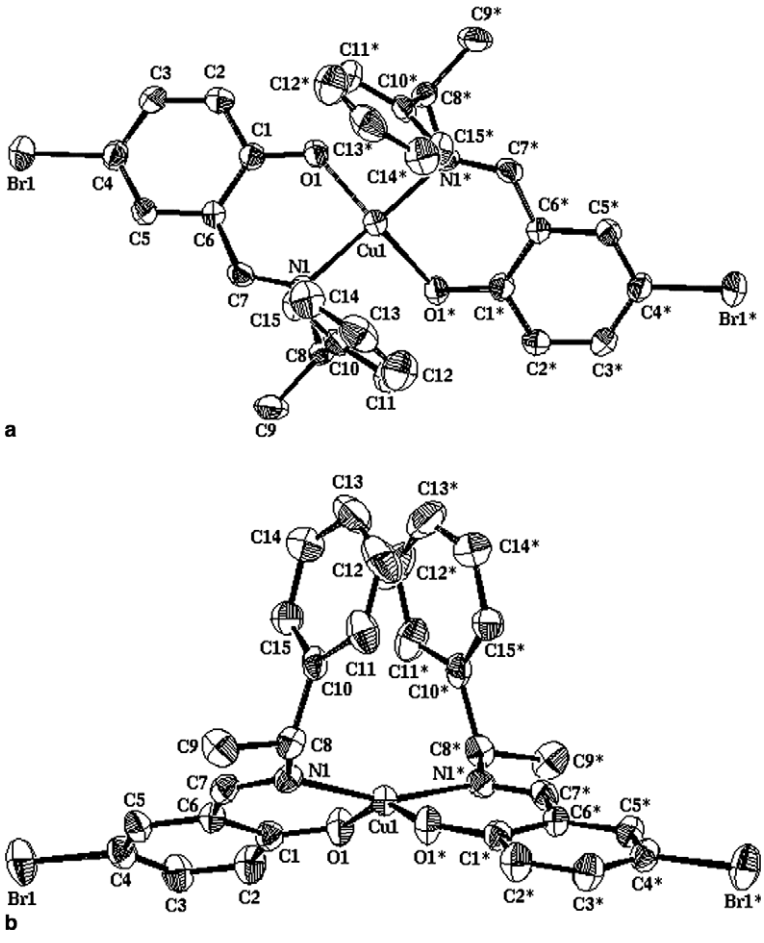

Fig. 1. The molecular structure of **4** showing the atom-labelling scheme (a) top view and (b) side view. Displacement ellipsoids are drawn at the 30% probability level. H atoms are omitted for clarity.

Table 2
Selected geometric parameters (Å, °) for **4**

Atoms marked with *'s are expanded by the symmetry operation $(-x-1, y, -z-2)$.

The *trans*-N1–Cu1–N1* and *trans*-O1–Cu1–O1* bond angles are 159.4(2)° and 151.7(3)°, respectively, whereas the *cis*-N1–Cu1–O1 and *cis*-N1*–Cu1–O1 bond angles are 93.0(2)° and 92.0(2)°, respectively. The Cu1–N1 and Cu1–O1 bond distances are 1.890(4) and 1.972(4) Å, respectively, and the C7=N1 imine bond length is 1.296(6) Å. There are no remarkable bond distances and angles for analogous compressed tetrahedral complexes [27,30]. The central Cu(II) ion is located at the center of symmetry along the C_2 axis. Since only *R*-enantiomers of 1-phenylethylamine were used for the preparations, the absolute configuration was found to be $\Delta(R,R)$ for the examined crystal of **4**. As for the related bis[(*N*-*R*-1-phenylethyl)(3- or 5-halogen-)salicylideneaminato]M(II) complexes, 3,5-Cl-substituted Cu(II) complex (**1**) of $\Delta(R,R)$ absolute configuration was reported with Cu–N = 1.984(4) Å, Cu–O = 1.890(3) Å, *trans*-N–Cu–N = 144.7(2)° and *trans*-O–Cu–O = 150.9 (1)° [30]. Unsubstituted Cu(II) [27], 3-EtO Cu(II) [30] and 3-Cl Zn(II) complexes [47] were reported to be $\Lambda(R,R)$ absolute configuration. The pendant *R*-1-phenylethylamine groups of the ligands are on the same side of the salicydenaminato plane, and the dihedral angle between the C1/C2/C3/C4/C5/C6 mean plane and the C10/C11/C12/C13/C14 mean planes is 89.5(3)°. Intramolecular and intermolecular hydrogen bonds could not be detectable within van der Waals radii [48], crystal packing as well as chiral molecular recognition of **4** are dominated only by weak van der Waals forces during preparation or crystallization.

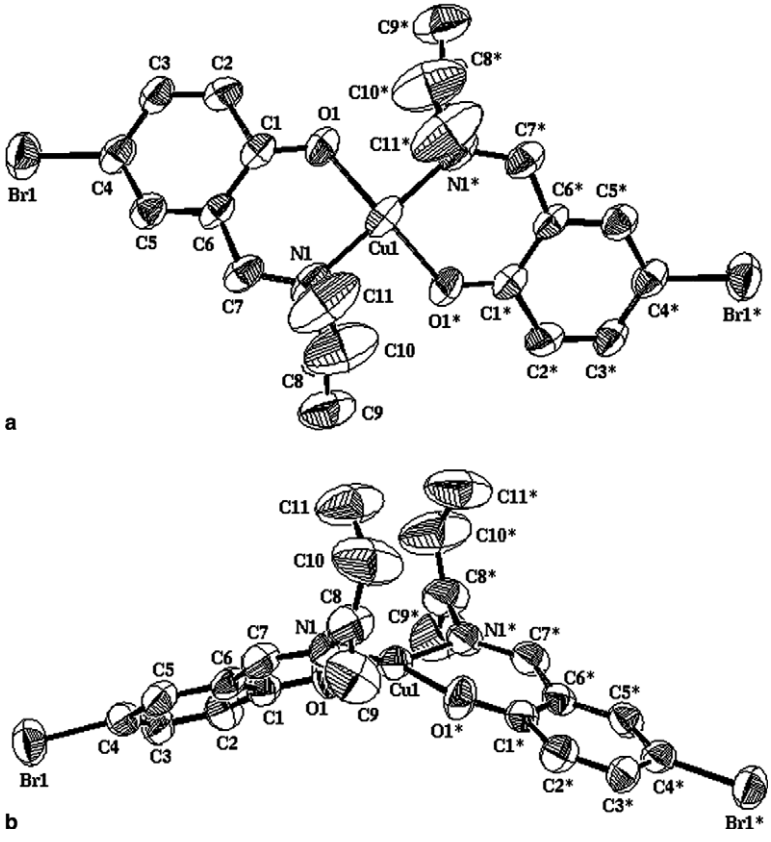

Fig. 2. The molecular structure of **8** showing the atom-labelling scheme (a) top view and (b) side view. Displacement ellipsoids are drawn at the 30% probability level. H atoms are omitted for clarity.

3.2. Description of structure of **8**

The molecular structure of **8** is depicted in Fig. 2, and selected bond distances and angles of **8** are given in Table 3. Complex **8** adopts a compressed tetrahedral *trans*-[CuN_2O_2] coordination geometry similar to **4**. This structural feature suggests that steric hindrance of the ethyl groups is sufficiently effective for distortion of the coordination environment when electron-withdrawing Br-groups are introduced. The central Cu(II) ion is on the center of symmetry. The *trans*-N1–Cu1–N1* and *trans*-O1–Cu1–O1* bond angles are 157.9(3)° and 151.0(3)°, respectively, whereas the *cis*-N1–Cu1–O1 and *cis*-N1*–Cu1–O1 bond angles are 93.3(2)° and 92.2(2)°, respectively. The Cu1–N1 and Cu1–O1 bond distances are 1.966(6) and 1.865(4) Å, respectively, and the C7=N1 imine bond length is 1.339(9) Å. The degree of distortion from square planar towards tetrahedral environment of **8** is larger than that of **4**, which leads to elongate both Cu–N and Cu–O coordination bonds of **8**. The other geometric parameters in the Schiff base ligands do not deviate significantly from the corresponding common values. Selected geometrical parameters of **5** were reported to be Cu–N = 1.969(4) and 1.971(4) Å, Cu–O = 1.886(3) and 1.892(3) Å, *trans*-N–Cu–N = 158.4(2)° and *trans*-O–Cu–O = 158.7(1)° [29]. Both sides of the 2-butyl pendant groups are on the apical side of the umbrella molecular plane. Intramolecular and intermolecular hydrogen bonds are not detectable within van der Waals radii [48] for **8**.

Table 3
Selected geometric parameters (Å, °) for **8**

Atoms marked with *'s are expanded by the symmetry operation $(-x-1, y, -z-1/2)$.

3.3. IR spectroscopy

In general, the IR spectra of the analogous free protonated ligands show an imine C=N band around 1635 cm^{-1}, and the disappearance of a C=O peak around 1700 cm^{-1} is indicative of a condensation reaction giving Schiff base ligands [49]. The IR spectra of all the complexes **1**–**10** show the imine C=N bands around 1620 cm^{-1}, and it is found that the C=N bands of the Cu(II) complexes are shifted by about 10 cm^{-1} to the lower energy regions compared to the free protonated ligands [50]. In addition, the Cu–N and Cu–O vibrations are found around 450 and 420 cm^{-1}, respectively. These spectral characteristics are due to the coordination of the imine nitrogens to the metal ions [51]. These peaks are in agreement with related complexes, regardless of the degree of distortion of the *trans*-[CuN_2O_2] coordination environment. The IR spectra are not sensitive to distortion of coordination environment for the present complexes.

3.4. Diffuse reflectance electronic spectroscopy and magnetic properties

The diffuse reflectance electronic spectra of **1**–**10** were recorded at room temperature, and the overall spectral features are similar to that of analogous complexes. The small differences of the spectral features can be classified into five patterns: (i) **1** and **2**, with 1-phenylethylamine moieties and 3,5-substituents, show a broad d–d band in the region 17 000–19 000 cm^{-1} and a strong continuous band in the higher energy region over 22 000 cm^{-1}; (ii) **3** and **4**, with 1-phenylethylamine moieties and 5-substituents, show a broad d–d band in the region 16 000–19 000 cm^{-1} and a strong continuous band in the higher energy region over 23 000 cm^{-1}; (iii) **5** and **6**, with 2-butylamine moieties and 3,5-substituents, show a strong d–d band around 15 000 cm^{-1} and a strong continuous band in the higher energy region over 23 000 cm^{-1}; (iv) **7** and **8**, with 2-butylamine moieties and 5-substituents, show a broad d–d band in the region 16 000–19 000 cm^{-1} and a strong continuous band in the higher energy region over 22 000 cm^{-1}; (v) **9** and **10**, with 2-propylamine moieties and 3,5-substituents, show a strong d–d band around 14 000 cm^{-1} and a continuous band in the higher energy region over 22 000 cm^{-1}. In this way, d–d bands are more sensitive to coordination geometries and electron-withdrawing groups of the ligands than π–π* bands in the case of solid state spectra. Generally, tetrahedral complexes show a d–d band at lower energies, which shift to higher energies on moving from tetrahedral to square planar environments [52]. Apparently, the number of halogen substituents (only 5- or both 3- and 5-) is more effective than the kind of halogen (Cl or Br) substituents. The absence of pendant π-conjugated phenyl

groups in the Schiff base ligands results in the π–π* region.

Theoretically, for Cu(II) complexes (effective symmetry C_{2v} point group) of the ^2D state three transitions, $^2A_1(d_{z^2}) \leftarrow {}^2A_1(d_{x^2-y^2})$, $^2B_1(d_{zx}) \leftarrow {}^2A_1(d_{x^2-y^2})$ and $^2B_2(d_{yz}) \leftarrow {}^2A_1(d_{x^2-y^2})$, are allowed, and a broad d–d band is their convolution. A strong band in the UV region is due to an overlap of the π–π* transition [47,53] and phenolate O atoms of the ligand to Cu(II) metal charge transfer transition. These transitions are related not only to *trans*-[CuN_2O_2] coordination geometries but also the net atomic charge on the coordinating atoms (O and N) of the ligands.

The effective magnetic moments (μ_{eff}) of mononuclear Cu(II) complexes **1**–**10** at 298 K are in the range from ca. 1.4 to 1.9 B.M., which is reasonable compared to the theoretical spin-only value of 1.73 B.M. for $S = 1/2$ systems with a single unpaired electron sited in an essentially $d_{x^2-y^2}$ orbital, the ^2D state. In contrast to the electronic spectra, the effective magnetic moment is not sensitive to distortion of the *trans*-[CuN_2O_2] coordination environment for the present complexes. In order to confirm that there is little or no intermolecular antiferromagnetic coupling, we also investigated variable-temperature (5–250 K) magnetic susceptibility behavior for **1**, whose crystal structure has been determined. Complex **1** obeys the Curie–Weiss law approximately, that is the χ_M^{-1} versus T plot is a linear graph. Thus, in the absence of X-ray structural proof, except for **1**, **4**, **5** and **8**, the effective magnetic moments demonstrate the nature of the mononuclear complexes.

Table 4
Temperature (K) of the phase transition and decomposition by DSC for **1**–**10**

	Phase transition	Decomposition
1	419	556
2	484	547
3	474	547
4	412	542
5	396	557
6	410	532
7	412	548
8	400	544
9	444	542
10	446	554

3.5. Structural phase transition

It has been investigated that the analogous Cu(II) and Ni(II) complexes exhibit a thermally-induced structural phase transition by heating regardless of the coordination geometries (square planar or tetrahedral) at room temperature [21,37]. The temperature of the structural phase transition (endothermic peaks) and decomposition (exothermic peaks) in the DSC curves for **1**–**10** are summarized in Table 4. In analogy with the related Cu(II) complexes [21], the structural phase transition may be ascribed to a transformation from a low temperature phase (compressed tetrahedral) into a high temperature phase (close to right tetrahedral). The relationship between the transition temperature and chemical structures is unclear still. Because of the lability of the compounds, we could not carry out quantitative measurements. The structural phase transition seems to be irreversible for **1**–**10**.

Furthermore, we have examined the possibility of a photo-induced structural phase transition of microcrystalline samples for **1**–**10** with IR spectroscopy in the solid state at room temperature. After irradiation of UV or visible light for 5 min at room temperature, no spectral changes could be detected for **1**–**10**. On the other hand, certain thermochromic Cu(II) complexes also exhibited photochromism in the solid state at low temperature [7,10]. Thus, at least, the present experimental facts support the stability of the Cu(II) complexes against UV or visible light at room temperature.

3.6. Calculation

A summary of the results of ZINDO calculations for **1**, **4**, **5** and **8**, whose crystal structures are known, is listed in Table 5. The dipole moment of the overall molecules were evaluated to be 6.029, 5.033, 4.166 and 4.215 D for **1**, **4**, **5** and **8**, respectively. It can be expected that both introduction of 3,5-halogen substituents and deviation from square molecules as well as breaking

Table 5
Summary of the results of ZINDO calculations for **1**, **4**, **5** and **8**

	1	4	5	8
Heat of formation (kJ mol^{-1})	325.2	295.9	255.4	251.8
Dipole moment (D)	6.029	5.033	4.166	4.215
HOMO–LUMO gap (eV)	8.20	8.09	7.88	7.77
Formal charge Cu	0.196	0.250	0.204	0.200
N	−0.129	−0.084	−0.143	−0.156
O	−0.456	−0.433	−0.483	−0.463
Calculated predominant π–π* transitions (cm^{-1})	32700	33100	31200	29700
	45700	36100	34400	32900
	51300	48300	45700	44400

molecular symmetry lead to an increase of the magnitude of dipole moment. The numbers and kinds of 3,5-halogen substituents are invariable factors for a given molecule, whereas distortion of the overall molecular structure can induce polarity depending on the molecular conformation. Thus, the dipole moment can interact between the complexes and the surrounding species in solution.

The formal charges on the Cu(II) ions are 0.196, 0.250, 0.204 and 0.200 for **1**, **4**, **5** and **8**, respectively. On the other hand, the averaged values on the coordination N atoms are −0.129, −0.084, −0.143 and −0.156, and O atoms are −0.456, −0.433, −0.483 and −0.463 for **1**, **4**, **5**, and **8**, respectively. As indicated for these values, tetrahedral distortion of the coordination environment plays a role in distribution of charge from the coordination atoms to the metal ions through coordination bonds. Although these electronic features are advantageous for charge transfer transitions, it is difficult to estimate their contribution in electronic spectra. Further, π–π* bands consist of several components in the UV regions as calculations exhibit even for the X-ray structures.

3.7. Electronic absorption spectroscopy in various solvents

Fig. 3 shows the electronic absorption spectra and CD spectra of **1** in 0.1 mmol dm^{-3} chloroform solution at 298 K. The reason why **1** is employed for the following investigation and discussion is that **1** displays the largest dipole moment in the solid state and incorporates chiral ligands whose CD spectrum is detectable. Additionally, bulky 1-phenylethyl moieties and electron-withdrawing 3,5-Cl-substituents may enhance the flexibility of **1**. The absorption spectrum of **1** exhibits a broad d–d band in the region 16000–20000 cm^{-1} and a strong π–π* band in the region 24000–28000 cm^{-1}. The corresponding CD spectrum of **1** shows a positive peak around 15000 cm^{-1} and a negative peak around 18000 cm^{-1} in the d–d region, and a negative peak around 23000 cm^{-1} and a positive peak around 25000 cm^{-1} in the π–π* region. The d–d band can be ascribed to convolution of three allowed transitions, $^2A_1(d_{x^2-y^2}) \rightarrow {}^2A_1(d_{z^2})$, $^2A_1(d_{x^2-y^2}) \rightarrow {}^2B_1(d_{xz})$, $^2A_1(d_{x^2-y^2}) \rightarrow {}^2B_2(d_{yz})$, in C_{2v} symmetry. The sign of the CD peaks seems to be reasonable with respect to the Δ(*R*,*R*) absolute configuration of **1**. The change of coordination geometry of **1** and conformation of its ligands in solution may attribute to the difference between absorption spectra and diffuse reflectance spectra.

The electronic absorption spectra were also recorded for **1**–**10** in various solvents, *N*,*N*′-dimethylformamide (DMF) ($\mu = 3.82$; $\varepsilon = 36.710$; $n_D^{20} = 1.428$), acetone ($\mu = 3.11$; $\varepsilon = 20.700$; $n_D^{20} = 1.356$), methanol ($\mu = 2.97$; $\varepsilon = 32.630$; $n_D^{20} = 1.326$), chloroform ($\mu = 1.11$; $\varepsilon = 4.806$; $n_D^{20} = 1.444$) and toluene ($\mu = 0.37$; $\varepsilon = 2.438$; $n_D^{20} = 1.494$) (the figures in parentheses denote dipole moment, μ(D), dielectric constant, ε, and refractive index, n_D^{20}) [15]. The predominant peaks of π–π* bands (ν cm^{-1} and log ε dm^3 mol^{-1} cm^{-1}) are shown in Table 6. The results show that the π–π* bands are sensitive to the physical properties of the solvents for **1**–**10**. However, the shifts of the d–d band, depending on solvents or concentrations (1, 0.1, and 0.01 mmol dm^{-3}), are relatively small for **1**–**10**. Therefore, we can conclude that the changes of polarity of the solvent lead to structural changes of the complexes associated with conformation of the π-conjugated pendant groups of the Schiff base ligands.

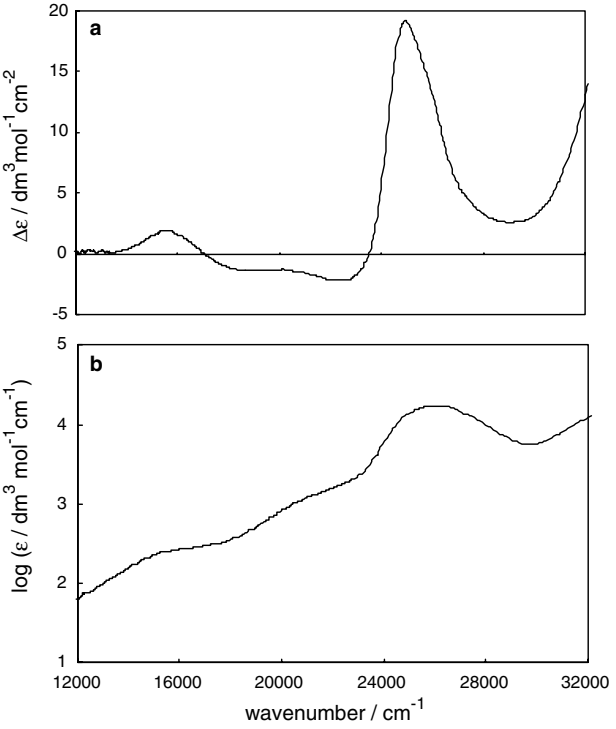

Fig. 3. The electronic (a) CD and (b) absorption spectra of **1** in 0.1 $mmol^{-1}$ dm^3 $CHCl_3$ solution at 298 K.

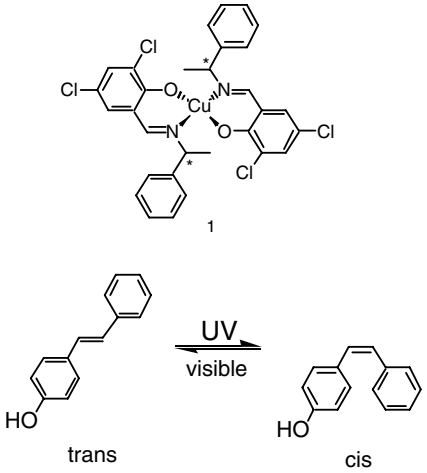

In an attempt to produce *solvatochromism induced by a photochromic solute*, we have measured the absorption spectra of a 0.1 mmol dm^{-3} chloroform solution of **1** containing equimolar 4-hydroxyazobenzene (4HAZ) (Scheme 2). It is well known that irradiation with UV and visible light results in reversible photoisomerization of 4HAZ to the *cis* forms (μ = ca. 3 D) and the *trans* forms (μ = almost 0 D). For a solution of only 4HAZ (Fig. 4(a)), irradiation with UV and visible light for 5 min, which is enough time to saturate the photoisomerization reaction, to the solution results in reversible spectral changes of the π–π* band of 4HAZ around 29000 cm^{-1}. On the other hand, for a solution containing 4HAZ and **1**, very slight and relatively large spectral changes could be observed at ca. 23000 cm^{-1} and ca. 31000 cm^{-1}. Taking into account the absorption spectrum

Table 6

The figures marked with ^{sh} denotes a shoulder, and the remaining ones are bands.

of only **1** (Fig. 3(b)), the former band and the latter band are ascribed to d–d and π–π* bands of **1**. The spectral change caused by the photoisomerization of 4HAZ may be ascribed mainly to a conformational change of the pendant 1-phenylethylamine moiety of the ligands (Fig. 4(b)). The possibility of supramolecular helical structures of 4HAZ induced by **1** as chiral dopants in the solution can be denied, because the spectral changes are detected not by CD spectra but by absorption spectra. The fact that solvatochromic behavior mainly affects the π–π* bands, as indicated in Table 6, and the magnitude of the difference of dipole moment photoisomerization of 4HAZ may support this interpretation. Although the other complexes also exhibit spectral shifts depending on the solvent, we could not observe photoisomerization caused by 4HAZ. The appropriate pendant 1-phenylethylamine moiety and molecular flexibility enhanced by electron-withdrawing substituents are necessary for the complex served for this experiment.

Scheme 2. Molecular structure of **1** and *cis–trans* photoisomerization of 4HAZ.

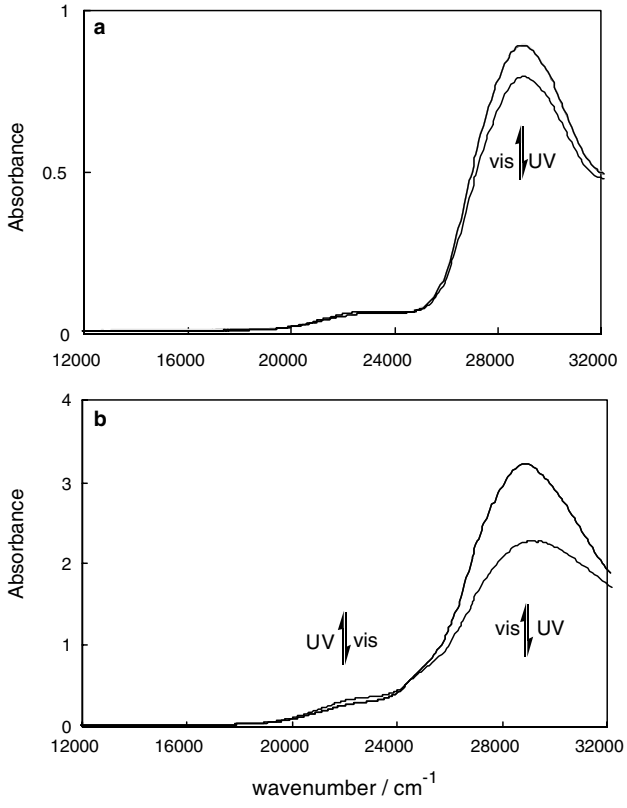

Fig. 4. The absorption spectra of (a) only 4HAZ and (b) 4HAZ and **1** in 0.1 $mmol^{-1}\ dm^3$ $CHCl_3$ solution at 298 K before and after UV or visible light irradiation for 5 min.

4. Concluding remarks

Crystal structures of two new Cu(II) complexes and systematical comparisons of structural features, thermodynamical behavior and electronic or optical properties have been reported for a series of ten related Cu(II) complexes incorporating 3,5-halogen-substituted Schiff base ligands. The pronounced solvatochromic behavior of the absorption spectra can be detected in the π–π* bands rather than the d–d bands for **1**–**10**. As for a chloroform solution of **1**, which has the largest dipole moment in the solid state among **1**–**10** and chiral ligands, and containing equimolar 4HAZ, we have examined solvatochromism of **1** induced by the photochromic solute. Irradiation of light resulted in spectral changes in the π–π* regions and little difference in the d–d regions. Further studies to apply to other nano-structured supramolecular systems of complexes and homogeneous chiral catalysts of transition metal complexes [54] without photochromic functional groups in ligands are underway.

5. Supplementary materials

Crystallographic data for the structural analyses are deposited with the Cambridge Crystallographic Data Centre, CCDC with deposition numbers 265611 and 265612 for **4** and **8**, respectively. Copies of this information can be obtained from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

This work was supported by Grant-in-Aid for the 21st Century COE program 'KEIO Life Conjugate Chemistry' from the Ministry of Education, Culture, Sports, Science and Technology, Japan. The authors thank Professor Yohru Yamada and Dr. Taketo Ikeno (Keio University) for the use of the DSC apparatus, Professor Hidenari Inoue (keio University) for the use of the CD spectrometer and Professor Katsuya Inoue (Institute for Molecular Science) for the use of the SQUID instrument.

1. Introduction

Complexes containing 1,1-dithiolato ligands have been used as fungicides, pesticides, vulcanization accelerators, flotation agents, lubricant additives and in deposition of ZnS or CdS thin films by metal organic chemical vapor deposition [1]. 1,1-Dithiolate ligands have recently attracted much attention mainly because of the interesting photophysical properties derived from their extensive electron delocalization onto all of the ligand atoms [2]. Indeed, the increasing renewed attention paid nowadays to these species arises from their high stability, solvatochromic behavior, room-temperature luminescence in solution [3] and their status as excellent candidates for applications such as photocatalysis [4]. A lot of work is currently taking place to find how the excited-state properties can be altered in a predictable manner through systematic ligand modification [4a]. In addition the variable coordination modes of 1,1-dithiolate ligands to metals make the structural studies more interesting [5]. The 1,1-dithiolate ligands have also been used to stabilize unusually high oxidation states [6] or to facilitate the syntheses of clusters [5,7], and to the syntheses of inorganic–organic hybrid materials, which have a potential in various applications such as electrical conductivity, magnetism [8], ion exchange, separation and catalysis [9].

Previously we reported the synthesis and spectroscopic investigation of some mixed-ligand nickel(II) and copper(II) chelates containing diamine or phosphine and 1,1-dithiolate ligands [10]. The results of these studies indicated that their spectroscopic properties and magnetic behavior strongly depend upon structural details of both the diamine or phosphine and the dithiolate ligands. In this work we describe the synthesis and structural characterization of: (a) nickel(II) and copper(II) complexes containing 1,1-disubstituted-2,2-ethylene-dithiolates; (b) a series of neutral ternary nickel(II) chelates with *N*-donor, *N*-acceptor, cross-conjugated nitrogenous bases and 1,1-dithiolate; and (c) the fascinating sulfur-rich dithiole ligand. Further the structures of (2,2′-bipyridine)(1-cyano-1-phenyl-2,2-ethylenedithiolato) nickel(II) [Ni(bipy)CPD], tetrabutylammonium(1-cyano-1-chlorophenyl-2,2-ethylenedithiolate)copper(II) ($(n\text{-}Bu_4N)_2[Cu(CCPD)_2]$) and the novel 5-amino-4(4-chlorophenyl)-[1,2] dithiole-3-thione ligand (ACDT) were elucidated by X-ray diffraction studies. To the best of our knowledge, this is the first X-ray study of a nickel(II) complex with a 1,1-dithiolate having molecular interactions in the solid state, and the first 1-cyano-1-chlorophenyl-2,2-ethylenedithiolato complex of any metal, and the second X-ray analysis for copper(II) complexes [21a] with 1,1-dithiolate ligands.

2. Experimental

2.1. Reagents

The nitrogenous bases, enR, *N*,*N*′-diphenyl-1,2-diaminoethane (PhenPh), *N*,*N*′-dibenzyl-1,2-diaminoethane (BenB), *cis*-1,2-diaminocyclohexane (C × NN), 2-(aminomethyl)pyridine (ampy), 2,2′-bipyridine (bipy) and 2,2′-dipyridylamine (dipyamH) were purchased from Aldrich. The nitriles, malononitrile ($NCCH_2CN$), ethyl cyanoacetate ($NCCH_2COOC_2H_5$), cyanoacetamide ($NCCH_2CONH_2$) chlorobenzyl cyanide ($NCCH_2C_6H_4Cl$), benzyl cyanide ($NCCH_2C_6H_5$), tetrabutylammonium bromide ($n\text{-}Bu_4NBr$) and tetraethylammonium bromide (Et_4NBr) were procured from Merck. Copper(II) chloride dehydrate, $CuCl_2 \cdot 2H_2O$, nickel(II) chloride hexahydrate, $NiCl_2 \cdot 6H_2O$ and sodium hydride (NaH, as 55% suspension) were procured from Fluka. The dithiolate ligand salts disodium 1-cyano-1-chlorophenyl-2,2-ethylenedithiloate dehydrate ($Na_2CCPD \cdot 2H_2O$), disodium 1-cyano-1-phenyl-2,2-ethylenedithiolate dihydrate ($Na_2CPD \cdot 2H_2O$), disodium 1,1-dicyano-2,2-ethylenedithiolate trihydrate ($Na(i\text{-}MNT) \cdot 3H_2O$), dipotassium 1-cyano-1-carboethoxy-2,2-ethylenedithiolate hydrate ($K_2CED \cdot H_2O$) and dipotassium 1-cyano-1-carbamyl-2,2-ethylenedithiolate dehydrate ($K_2CCED \cdot 2H_2O$) were prepared by the literature procedures [11,12].

2.1.1. Synthesis of homoleptic nickel(II) and copper(II) chelates

The new chelates $[R_4N]_2[M(S_2C{=}C(CN)Y)_2]$ (Y = Cl-ph, ph, COOEt, $CONH_2$) were prepared according to the following general method.

To a methanolic solution (ca. 100 cm^3) containing 4 mmol of the appropriate 1,1-dithiolate salt, 4 mmol of tetrabutylammonium bromide ($n\text{-}Bu_4NBr$) or tetraethylammonium bromide (Et_4NBr) were added. Upon dissolution, the mixture was filtered slowly into a conical flask containing 2 mmol metal chloride dissolved in 20 cm^3 of methanol while stirring. Water was added dropwise under continuous stirring to the reaction mixture. To complete the reaction, stirring was continued for about 1 h. The resultant precipitate was separated by filtration, washed several times with water and dried in air. The complex was purified by dissolving it in acetone, filtering and reprecipitating it by addition of water, then separating by filtration.

2.1.2. Synthesis of 5-amino-4(4-chlorophenyl)-[1,2] dithiole-3-thione

Yellow crystals of the new dithiol ligand (ACDT) of appropriate dimensions suitable for X-ray diffraction analysis were obtained from a slow evaporation of a

water solution of the ligand $Na_2CCPD \cdot 2H_2O$ and lanthanum chloride heptahydrate ($LaCl_3 \cdot 7H_2O$).

2.1.3. Synthesis of mixed-ligand nickel(II) chelates

The new compounds [Ni(enR) $S_2C{=}C(CN)Y$] (Y = CN,Ph, COOEt, $CONH_2$) were prepared according to the following general method.

To a methanolic solution (~40 cm^3) containing 5 mmol of the nitrogenous base, enR, an equimolar amount of the 1,1-dithiolate salt was added. Upon dissolution the mixture was transferred dropwise to a 100 ml conical flask containing 5 mmol $NiCl_2 \cdot 6H_2O$ dissolved in ~20 cm^3 of methanol while stirring continuously. To complete the reaction the stirring was continued for 1 h and then was left undisturbed for a while. The resultant precipitate was separated by filtration and transferred to a beaker. Mixing with water and subsequent filtration ensured removal of unreacted reagents and inorganic salts. The solid product was washed several times with water and finally with a small volume of cold methanol, and then air dried.

2.2. Physical measurements and determinations

Elemental analyses, melting points, molar conductivities in nitromethane, magnetic susceptibility measurements, infrared and electronic spectra were determined as described before [10c]. The compounds prepared, their elemental analyses and some other data are listed in Tables 1 and 2.

2.3. X-ray single crystal structure determination of $(n\text{-}Bu_4N)_2[Cu(CCPD)_2]$, [Ni(bipy)CPD] and ACDT

The data were collected using a STOE Imaging plate diffraction system (IPDS) equipped with Mo Kα radiation. The structure solution was performed with SHELXS-97 [13] and structure refinement was done against F^2 using SHELXL-97 [14]. All non-hydrogen atoms were refined using anisotropic displacement parameters. The hydrogen atoms were positioned with idealized geometries ($d_{C-H} = 0.95$ Å), and refined with fixed isotropic displacement parameters according to the riding

model [$U_{iso} = 1.2 \times U_{eq}$(C)]. A special feature of the refinement is that in (n-$Bu_4N)_2$[Cu(CCPD)$_2$] some carbon atoms of the 6-membered aromatic ring which is attached to the chloro atom and the chloro atom itself shows some disordering. However, no reasonable split models were found. Selected crystal data and results of the structure refinement as well as bond lengths and angles are found in Tables 3, 8, 9 and 10.

3. Results and discussion

The simultaneous reaction of nickel(II) or copper(II) with 1,1-dithiolato anions $(S_2C{=}C(CN)Y)^{2-}$ and tetrabutylammonium bromide (n-Bu_4NBr) or tetraethylammonium bromide (Et_4NBr) in a 1:2:2 molar ratio, respectively, produces compounds corresponding to the general formulas $[R_4N]_2[M(S_2C{=}C(CN)Y)_2]$, (R = n-Bu, Et, M = Ni(II), Cu(II), Y = phCl (CCPD), ph (CPD), COOEt (CED), $CONH_2$-(CCED)). The new chelates are insoluble in water and soluble in organic solvents. The copper(II) complexes are paramagnetic with magnetic moments, μ_{eff}, in the range 1.65–1.82 m_B and the nickel(II) complexes are diamagnetic. Their electrical conductance values in nitromethane (Table 1) and their solid state magnetic susceptibilities indicate 2:1 type electrolytes, mononuclear compounds.

The concurrent reaction of nickel with equimolar quantities of nitrogenous bases, enR, and the 1,1-dithiolato anions, $(S_2C{=}C(CN)Y)^{2-}$, affords neutral mixed-ligand compounds corresponding to the general formula [Ni(enR)S_2C=C(CN)Y] (Y = CN, Ph, COOEt, $CONH_2$). The compounds are almost insoluble in methanol, ethanol and acetone while their solubility in dimethylformamide (DMF) and dimethylsulfoxide (DMSO) is considerable. Their low electrical conductance values ($\Lambda_m \approx 15$ S cm^2 mol^{-1}) in DMF and their solid state magnetic susceptibility indicate neutral, mononuclear diamagnetic compounds and only the compounds of the [Ni(enR)CPD] series were found to be paramagnetic with magnetic moments, μ_{eff}, in the range 1.7 to 2.3 m_B. This behavior in the solid state merits some comments. It is well known that nickel(II) has a tendency to achieve coordination numbers exceeding four by accepting ligands in the vacant coordination sites, or by aggregation of the parent compounds [10b,15]. Ligands with sulfur donor atoms may instigate intermolecular interactions of the type M–S···M, provided that the arrangement of the monomers in the unit cell permits such interactions. For instance, the molecules in the unit cell of [Ni(bipy)CPD] are arranged

in pairs as shown in Fig. 1(a). Each pair of molecules form two weak intermolecular Ni···S bond interactions at a distance of 3.617 Å (Fig. 1(b)). According to the classic paper by Bondi [16], the sum of the van der Waals radii of nickel and sulfur is 3.4 Å. There is wide agreement that this is an underestimation [17,18]. The Paramagnetism of solid [Ni(bipy)CPD] suggests the same arrangement of the monomers and long range interactions, not uncommon in compounds with dithiolato ligands [18–22]. This notion is supported by the change in the magnetic behavior of [Ni(bipy)CPD], observed when magnetic susceptibility measurements were performed in solutions. This compound is sufficiently soluble in acetone permitting the determination of χ_{mol} by Evans' method. The propensity towards aggregation in the [Ni(enR)CPD] complexes is probably due to the residual Lewis acidity of the nickel atoms as well as the basicity of the sulfur atoms. Further information

on the mode of interaction of the ligands and the structure of the compounds under consideration were obtained from their IR and the electronic excitation spectra.

3.1. Infrared spectra

The infrared spectra of the complexes have been interpreted in the light of earlier investigations [1a,10]. The dianion of the 1,1-dithiol contains the C═CS_2, C≡N and Y (Y = CN, Ph, phCl, COOEt, $CONH_2$) functional groups. The absorptions due to the multiple bond in each group are immediately distinguishable and identified with the very strong bands observed in specific regions of the spectrum. For instance, in K_2S_2C═C(CN)$CONH_2$ the ν(C≡N) and ν(C═O) bands appear at 2172 and 1646 cm^{-1}, respectively, while the ν(C═CS_2) band absorbs at 1340 cm^{-1}. Upon chelation

of the dianions these bands are strongly shifted to higher wavenumbers (Tables 4 and 5) since in these planar ligands the extensive π-conjugated system permits a drift of electron density towards the sulfur atoms that results in a shortening of the C≡N, C=O and C=C bonds. The exact frequency of each band is influenced not only by the groups present in the 1,1-dithiolato dianion, but also by the donor strength of the chelated nitrogenous base. Actually, the frequency of the *ν*(C=O) vibration in the chelates [Ni(PhenPh)CED], [Ni(dipyam)CED], and in the complexes of the dithiolate CCED coincides with that of the corresponding free 1,1-dithiolato dianion, probably because of the enhanced double bond character of the bond between the carbonylic carbon atom and the oxygen and nitrogen atoms of the OEt and NH_2 groups. The asymmetric and symmetric stretching vibrations of the $=CS_2$ group generally appear in the 945–900 and the 920–870 cm^{-1} regions, respectively. The stretching vibration of the M–S bond is observed at 370(±30) cm^{-1}.

The absorptions occurring in the region ~3300 to 3200 cm^{-1} are due to the N–H stretching vibrations of partially substituted 1,2-diamines and are shifted to wavenumbers lower than those encountered in the free 1,2-diamines [23]. These shifts and the band near 490(±30) cm^{-1} suggest that the nitrogenous bases chelate, as expected. Bidentate coordination and chelation

of the dianion of the 1,1-dithiol suggest the band at 370(±30) cm^{-1} and the bands due to the asymmetric and symmetric vibrations of the $=CS_2$ fragment (Tables 4, 5).

3.2. Electronic excitation spectra

The electronic excitation spectra of the chelates were studied in the visible and the near-infrared region, in the solid state and in solution employing solvents with very different donor ability. Because of the low solubility of the majority of the mixed-ligand complexes, polar solvents with appreciable donor strength were used to obtain the solution spectra. The most interesting feature of these spectra is the band in the region 1.55–1.66 μm^{-1} and for mixed-ligand complexes 1.55–1.87 μm^{-1} (Tables 6 and 7), which may be ascribed to a ligand field (LF) transition for reasons of intensity and energetic considerations.

The energy of the LF band of the homoleptic complexes depends slightly on the nature of dithiolate ligands. The dithiolate ligand field strength (CCPD ∼ CCED < CED ∼ CPD) is related to the ability of their substituents Y to resist electron drift towards the sulfur atoms. The LF band of the complexes has almost the same energy, both in their solid state spectra and those employing solvents with different donor ability (CH_2Cl_2, DMSO, CH_3CN and pyridine). This is probably due to the nucleophilic interaction of the polar solvent molecules with the ligand, leaving the metal unaffected.

In the solid state spectra of the mixed-ligand chelates, the change in the excitation energy may be accounted for by taking into consideration the influence of the substituents Y on the strength of the ligand field (LF) in the chelates [Ni(dipyamH)S_2C=C(CN)Y]. In the diamagnetic compounds of the dianions *i*-MNT, CCED and CED, the LF excitation energy reflects the ability of the Y group to resist electron delocalization towards their sulfur atoms (*i*-MNT ⩾ CCED > CED). The low LF excitation energy of [Ni(dipyamH)CPD] is not consistent with the above explanation since the electron withdrawing ability of the phenyl group is rather restricted. However, the magnetic behavior of the [Ni(enR)CPD] chelates is at variance with the behavior of the other nickel(II) chelates and suggests intermolecular interactions, presumably along the z axis, that change the symmetry of the field in which the nickel(II)

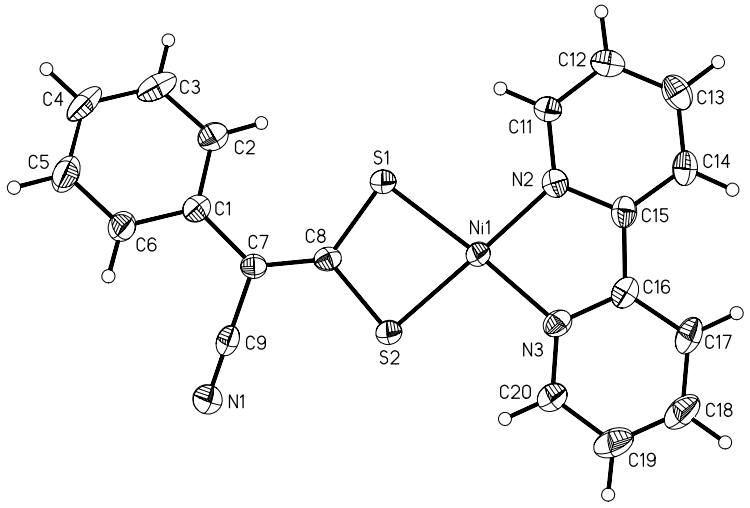

Fig. 4. Structure of [Ni(bipy)CPD] in the crystal with thermal ellipsoids at the 50% probability level.

exists. The existence of axial donor-acceptor interactions is supported by the red shift of the LF band of the other [Ni(dipyamH)(S_2C=C(CN)Y)] chelates when the absorption spectra are obtained in solvents of enhanced donicity and the appearance of an additional band at $\sim$1.1 μm^{-1}, when employing pyridine as solvent. In the case of the compound [Ni(dipyam)CPD] the energy of the LF excitation remains unaltered upon dissolution in DMSO or pyridine. This suggests that the axial S···Ni···S interactions that are eliminated upon dissolution are compensated by the nickel–solvent interactions.

The strength of the field applied by the nitrogenous base is nicely mirrored in the energy of the LF bands in the [Ni(enR)CED] chelates. The weak donating ability of dipyamH does not contribute significantly to the electron density on the nickel atom thus permitting coordination of strong polar molecules, i.e. pyridine or DMSO. On the other hand, the powerful electron donor C × NN upon ligation increases the electron population on the sulfur atoms. Consequently, the intermolecular axial interactions are enhanced while the energy of the transitions within the *d* manifold diminishes. The intermolecular interactions explain the magnetic behavior of the [Ni(enR)S_2C=(CN)Y] chelates and the blue shift observed upon dissolution when the axial interactions are disrupted. In the case of compounds with nitrogenous bases possessing intermediate donor ability, such as bipy and BenB, the energy of the LF transition is the same in solution and in the solid state. Proof that the NiN_2S_2 chromophore is planar was acquired from the X-ray structure determination of [Ni(bipy)CPD].

3.2.1. Description of the structure of $(n\text{-}Bu_4N)_2$-[Cu(CCPD)$_2$]

The structure of the anion is shown in Fig. 2, while selected bond lengths and angles are given in Table 8. There are three molecules per unit cell. The copper atom lies on a crystallographic center of symmetry which requires the CuS_4 unit to be strictly planar. This plane forms a small dihedral angle (1.35°) with the best plane through the S_2C=C–CN fragment of the CCPD ligand. This conformation has been observed in many sulfur chelates which contain a planar MS_4 group [24,6c]. The plane of the phenyl ring makes an angle of 8.87° with the CuS_4 plane. The average Cu–S bond length (2.204 Å) in the present structure is shorter by $\sim$0.099 Å to that reported [21a] for the only other four-coordinated, S-bonded Cu(II) complex with a 1,1-dithiolate chelate, (2.303 Å) in $[Bu_4N]_2$[Cu(*i*-MNT)$_2$], which most probably accounts for the different ability of the ph-Cl and C≡N groups of the dithiolate ligands to resist the electron delocalization towards the sulfur atoms. A distorted square planar coordination environment around the copper ion is evident in the S–Cu–S angles, 78.39(2)° and 101.61(2)°, respectively. There is no intermolecular Cu–S or Cu–Cu interaction in the solid state, with the shortest distances being 10.366 and 9.523 Å, respectively. This feature might be a result of the electronic effects and the unit cell packing caused by the bulky quaternary ammonium cations which occupy much of the space and prevent any intermolecular Cu–S or Cu–Cu interaction [21a].

3.2.2. Description of the structure of ACDT

A thermal ellipsoid drawing of the novel sulfur-rich ligand is presented in Fig. 3. The selected bond lengths

Table 11
Experimental average bond lengths (Å) of some [Ni(enR)S_2C=C(CN)Y] chelates

	Compound	Average bond distance (Å)				Ref.
		⟨S_2C=C⟩	⟨C–S⟩	⟨Ni–S⟩	⟨Ni–N⟩	
1	[Ni(Et_2en)*i*-MNT]	1.384(3)	1.716(3)	2.199(8)	1.955(2)	[10a]
2	[Ni(Et_2en)CPD]	1.367(3)	1.741(3)	2.179(1)	1.965(2)	[28]
3	[Ni(bipy)CPD]	1.367(6)	1.746(3)	2.181(2)	1.919(3)	this work
4	[Ni(Me_4en)CPD]	1.366(5)	1.733(3)	2.178(1)	1.974(3)	[28]

and angles are given in Table 9. There are three crystallographically independent molecules in the asymmetric unit which differ in the torsion angles between both rings. Three carbon atoms link with two sulfur atoms forming a five-membered ring. The observed C–S distances are smaller than expected for a C–S single bond (1.82 Å) [25]. The exocyclic S3–Cl bond length is 1.688(2) Å which is longer than the corresponding distance of 1.661(8) Å in dmit ligand [4b] but shorter than the distance found in another dmit ligand [18a]. The S–S bond distance, 2.070(1) Å, is within the normal range (2.007(3)–2.396(3) Å) found for sulfur-rich dithiolate metal complexes [21a]. The C1–C2 bond length, 1.404(3) Å, is similar to the corresponding bond distances in salts of the *i*-MNT ligand [26]. All observed intramolecular bond lengths in the sulfur ring indicate delocalization of the π-electron system.

3.2.3. Description of the structure of [Ni(bipy)CPD]

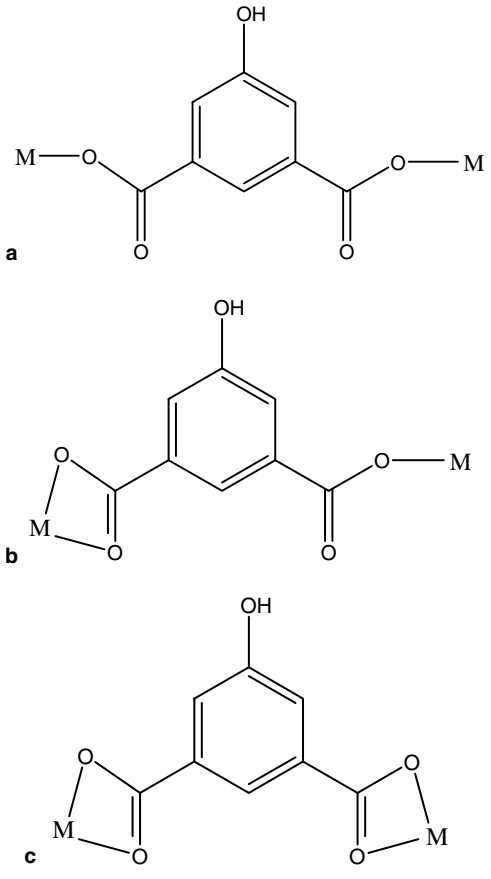
In the unit cell there are six nickel atoms (Fig. 1(a)). In the immediate vicinity of each nickel atom exist two sulfur and, at shorter distance, two nitrogen atoms (Fig. 4). The sulfur atoms of the dianion of 1,1-dithiol form a bite angle of 78.2(1)° while the bite angle of the 2,2′-bipyridine is 83.4(2)° and reaffirm that the bidentate ligands chelate. Intramolecular bond distances and angles are given in Table 10. The nitrogen atoms are in the plane defined by nickel and the sulfur atoms. In the same plane lie the atoms of the ethene group and the cyano group. The phenyl group, however, forms a dihedral angle of 17.5° with the plane of the NiN_2S_2 chromophore probably because of steric and electronic effects. The S_2C=C–CN fragment of the ligand (CPD) assumes a planar conformation and the bond distances indicate extensive π-conjugation. Actually the C(8)–C(7) distance is characteristic of a bond localized between two C(sp^2) atoms [27], whilst the lengths of the intervening C(7)–C(9) bond and the terminal N≡C bond suggest delocalization. The mean deviation of the 2,2′-bipyridine from planarity is 0.0281 Å, and the torsion angle of the two ring with the chelation ring ($NiN_2C_{15}C_{16}N_3$) is 0.5°.

It is of interest to compare the average lengths of the characteristic bonds in [Ni(bipy)CPD] and the reported chelates [Ni(Et_2en)*i*-MNT] [10a], [Ni(Et_2en)CPD] and [Ni(Me_4en)CPD] [28]. In these compounds the S_2C=C, C–S, Ni–S and Ni–N bond lengths (Table 11) suggest that an electron drift from the X and Y substituent groups of the 1,1-dithiolato ligands towards the sulfur atoms takes place and becomes more intense in the case of the CPD chelate. Consequently, the intensity of the nickel–nitrogen interaction diminishes.

4. Supplementary material

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 236938–236940 for compounds ACDT, (n-Bu_4N)$_2$[Cu(CCPD)$_2$], [Ni(bipy)CPD], respectively. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, fax: +44 1223 366 033, e-mail: deposit@ccdc.ac.uk or on the web www: http://www.ccdc.cam.ac.uk.

Acknowledgments



The efforts and cooperation of Professor Dr. Wolfgang Bensch, The Director of the Institute of Inorganic Chemistry, Christain–Albrechts University of Kiel in Germany, are highly appreciated and acknowledged. We are also very grateful for Dr. Christian Näther and Inke Jeß from the University of Kiel for the structure determination of ACDT, (n-Bu_4N)$_2$[Cu(CCPD)$_2$] and [Ni(bipy)CPD].

it can adopt different conformations to take part in coordination [21–24]. (2) The aim of combining OH-H_2BDC into the reaction system is to simplify the control and modulation of the final results, because the deprotonated carboxylate groups, which possess rich coordination modes (Scheme 1), may act as anionic groups and afford neutral metal-organic frameworks. (3) The hydroxyl group (–OH) can provide hydrogen bonding interactions with other groups and further stabilize the structures. On the other hand, the architectures from mixed ligands of bpp and di- or poly-carboxylate ligands, to our knowledge, are still rare to date [20,25,26], although some metal-organic frameworks from the direct assembly of bpp and metal ions have been investigated [22–24]. Herein, we wish to report the syntheses and characterizations of three interpenetrated coordination polymers, $\{[Co(bpp)(OH\text{-}BDC)]\cdot H_2O\}_n$ (**1**), $[Ni(bpp)_{1.5}(H_2O)(OH\text{-}BDC)]_n$ (**2**) and $\{[Cd(bpp)(H_2O)(OH\text{-}BDC)]\cdot 2H_2O\}_n$ (**3**), assembly from bpp, OH-H_2BDC with Co^{II}, Ni^{II} and Cd^{II} ions, respectively. All of the three compounds display interpenetrated structures. Exo-bidentate bpp in **1** and **3** adopts a TG conformation, while bpp in **2** acts as a terminal and exo-bidentate ligand with TT and TG conformations, respectively.

Scheme 1. The coordination modes of OH-BDC in compounds **1**–**3**.

2. Experimental

2.1. Materials and physical measures

1,3-bis(4-pyridyl)propane and 5-hydroxyisophthalic acid were purchased from Aldrich and used without further purification, all the other reagents were commercially available and used as purchased. Thermal analyses were performed using a TGA/SDTA851 instrument with a heating rate of 15 °C/min in a nitrogen stream. IR spectra as KBr disks were recorded on a Magna 750 FT–IR spectrophotometer. Elementary analyses were carried out by the elementary analysis group of this institute on an Elementary Vario ELIII analyzer.

2.2. Syntheses of the compounds

2.2.1. Preparation of $\{[Co(bpp)(OH\text{-}BDC)]\cdot H_2O\}_n$ (**1**)

A mixture of $Co(NO_3)_2\cdot 6H_2O$ (0.058 g, 0.20 mmol), 5-hydroxyisophthalic acid (0.032 g, 0.20 mmol), 1,3-bis(4-pyridyl)propane (0.040 g, 0.20 mmol) and NaOH (0.016 g, 0.40 mmol) in distilled water (18 mL) was sealed in a 25 mL stainless reactor with a Teflon liner and heated to 165 °C for 96 h. After cooling to room temperature over 24 h, cube-shaped red crystals of **1** were obtained. Yield: 41%. Elementary *Anal*. Calc. for $C_{21}H_{20}CoN_2O_6$ (455.32): C, 55.40; H, 4.43; N, 6.15. Found: C, 55.38; H, 4.51; N, 6.11%. IR (KBr, cm^{-1}): 3400 (m), 2927 (w), 1615 (s), 1575 (vs), 1401 (vs), 1373 (s), 1276 (s), 1018 (m), 785 (s), 723 (s), 519 (m).

2.2.2. Preparation of $[Ni(bpp)_{1.5}(H_2O)(OH\text{-}BDC)]_n$ (**2**)

A mixture of $Ni(NO_3)_2\cdot 6H_2O$ (0.073 g, 0.25 mmol), 5-hydroxyisophthalic acid (0.045 g, 0.25 mmol), 1,3-bis(4-pyridyl)propane (0.050 g, 0.25 mmol) and NaOH (0.020 g, 0.50 mmol) in distilled water (18 mL) was sealed in a 25 mL stainless reactor with a Teflon liner and heated to 170 °C for 96 h. After cooling to room temperature over 24 h, block green crystals of **2** were obtained. Yield: 64%. Elementary *Anal*. Calc. for $C_{27.5}H_{27}NiN_3O_6$ (554.23): C, 59.60; H, 4.91; N, 7.58. Found: C, 59.62; H, 5.02; N, 7.49%. IR (KBr, cm^{-1}): 3354 (w), 1616 (s), 1562 (vs), 1452 (s), 1412 (vs), 1357 (vs), 1277 (m), 1068 (m), 800 (s), 727 (s), 523 (m).

2.2.3. Preparation of $\{[Cd(bpp)(H_2O)(OH\text{-}BDC)]\cdot 2H_2O\}_n$ (**3**)

A mixture of $Cd(NO_3)_2\cdot 4H_2O$ (0.077g, 0.25 mmol), 5-hydroxyisophthalic acid (0.045 g, 0.25 mmol), 1,3-bis(4-pyridyl)propane (0.050 g, 0.25 mmol) and NaOH (0.020 g, 0.50 mmol) in distilled water (18 mL) was sealed in a 25 mL stainless reactor with a Teflon liner and heated to 170 °C for 96 h. After cooling to room

temperature over 24 h, block yellow crystals of **3** were obtained. Yield: 45%. Elementary *Anal.* Calc. for $C_{21}H_{24}CdN_2O_8$ (544.82): C, 46.30; H, 4.44; N, 5.14. Found: C, 46.31; H, 4.39; N, 5.18%. IR (KBr, cm^{-1}): 3385 (w), 1616 (s), 1554 (vs), 1427 (s), 1377 (vs), 1277 (m), 1227 (m), 1016 (m), 978 (w), 779 (s), 737 (s), 575 (m).

2.2.4. X-ray crystallographic study

Measurement of **1** was conducted on a Rigaku Mercury CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Reflections (14335) were collected at −100 °C, of which 4327 reflections were unique [27]. Intensity data for **2** and **3** were measured on a Siemens Smart CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å) at room temperature, the empirical absorption corrections were applied by using the SADABS program [28]. The structures for **1**–**3** were solved by direct methods [29] and refined on F^2 by full-matrix least-squares using the SHELXL-97 program package [30]. The positions of H atoms were generated geometrically (C–H bond fixed at 0.96 Å), assigned isotropic thermal parameters and allowed to ride on their parent carbon atoms before the final cycle of refinement. For **2**, the carbon atom (C15) is handled as disordered at two positions each with an occupancy of 50%. Crystal data and structure determination summaries for **1**–**3** are summarized in Table 1, selected bonds and angles in Table 2.

3. Results and discussion

3.1. Syntheses and characterizations

Compounds **1**–**3** were synthesized through the hydrothermal reactions of bpp, OH-H_2BDC with Co^{II}, Ni^{II} and Cd^{II} salts, respectively. Similar to the previous reports by us and some other groups, the –OH group of HO-H_2BDC is not involved in coordination to the transition metal ions and only serves as a donor for hydrogen bonds to stabilize the structures of **1**–**3** (see below), however, the –OH group as an electron-donating group may influence the self-assembly process although the reaction mechanism still remains unclear, because the expected results were not obtained when using *m*-isophthalic acid (H_2BDC) instead of HO-H_2BDC under the same hydrothermal condition. The IR spectra of the three compounds exhibit strong characteristic vibrational bands of the carboxylate groups. For **1**, the characteristic bands of the carboxylate groups are shown at 1575 cm^{-1} for the antisymmetric stretching band and

Symmetry code: for **1** (A) $x+1/2, -y+5/2, z-1/2$; (B) $x+1/2, -y+3/2, z+1/2$. **2** (B) $x+1, y, z$. **3** (A) $x, -y+1, z-1/2$; (B) $x-1/2, y+1/2, z$.

1401 cm^{-1} for the symmetric stretching band. The separation (Δ) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ is 174 cm^{-1}. For **2**, one antisymmetric stretching band (1562 cm^{-1}) and two symmetric stretching bands (1412 and 1357 cm^{-1}) are exhibited, the Δ values are 150 and 205 cm^{-1}, respectively. For **3**, the typical antisymmetric and symmetric stretching bands of carboxylate groups are at 1564 and 1387 cm^{-1}, with a Δ value ca. 177 cm^{-1}. The results are consistent with the different coordination modes of the carboxylate groups in the three compounds, one coordination mode in **1** and **3**, two coordination modes in **2** (Scheme 1) [31].

To study the stability of the three compounds, thermogravimetric analyses (TGA) were performed on polycrystalline samples in nitrogen atmosphere. For **1**, the weight loss of 4.08% from 160 to 279 °C is equivalent to the loss of one free water molecule per formula unit (ca. 3.96%), indicating the presence of hydrogen bonding interactions. After 317 °C, the decomposition of the framework starts. For **2**, the thermogravimetric analysis shows that there is no weight loss up to 360 °C, where the entirely decomposition of **2** starts. For **3**, the weight loss of 6.78% (calculated: 6.61%) from 45 to 134 °C, is attributed to the loss of two free water molecules per formula unit. Complete decomposition of the framework starts after 415 °C.

3.1.1. Crystal structure of compound *1*

Single-crystal X-ray diffraction analysis reveals that **1** is a fourfold interpenetrated *adamantanoid* structure. As shown in Fig. 1, each Co^{II} center is in a distorted tetrahedral geometry, which is seldom displayed in cobalt-carboxylate compounds [32]. Two nitrogen atoms from different bpp ligands and two monodentate carboxylate oxygen atoms from different OH-BDC ligands coordinate to the metal center. The average distances of Co–N and Co–O are 1.986(4) and 2.048(1) Å, respectively. OH-BDC acts as a bis-monodentate ligand to link the Co^{II} centers (Scheme 1(a)). The hydroxyl group (–OH) does not take part in coordination, but it is involved in a

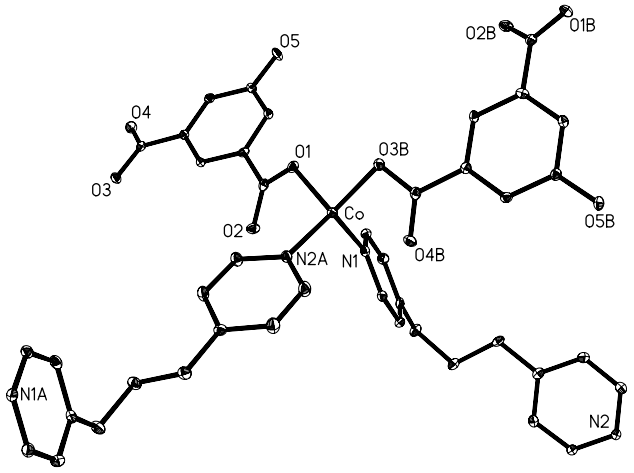

Fig. 1. ORTEP drawing of the coordination environment around Co^{II} in **1** with the thermal ellipsoids at the 30% probability level.

strong hydrogen bonding interaction with a free water molecule (O5–H···OW, 2.692 Å), which is consistent with the result of the TGA. Bpp in a TG conformation bridges the Co^{II} centers, the dihedral angle between the two pyridine rings is 80.6°. Thus, ten Co^{II} centers are connected by twelve bridging ligands, namely six bpp and six OH-BDC, generating a *adamantanoid* cage, which is further extended into a three-dimensional structure (Fig. 2). The separations of the adjacent Co···Co atoms bridged by bpp and OH–BDC are 12.657 and 9.711 Å, respectively. The long spacers between coordination sites result in large cavities within the *adamantanoid* cages. In order to minimize the big void cavities and stabilize the framework by nature, the potential voids are effectively filled via mutual interpenetration of three independent equivalent frameworks, generating a fourfold interpenetrated *adamantanoid* architecture (Fig. 3). Free water molecules are accommodated inside the framework and further shrink the void spaces. Another isomorphous complex, $\{[Zn(bpp)(OH\text{-}BDC)](H_2O)\}_n$, has been obtained and published by us in another report [26].

3.1.2. Crystal structure of compound **2**

Compound **2** is a polythreaded structure constructed through interpenetration of long arms of neutral one-dimensional molecular ladders. As shown in Fig. 4, each Ni^{II} center is in a highly distorted octahedral coordination geometry. Four oxygen atoms from one water molecule, one mono- and one chelating carboxylate groups of different OH-BDC ligands comprise the equatorial plane. Two nitrogen atoms from different conformational bpp ligands occupy the axial positions with the N1–Ni–N2 bond angle being 177.6(1)°. The deviation of the Ni^{II} center from the O_4 equatorial mean plane of the octahedron toward the apical nitrogen atom is 0.232 Å. The Ni–N and Ni–O bond distances are all within the normal ranges. OH-BDC behaves as a bridge through its mono- and chelating carboxylate groups to link different metal centers (Scheme 1(b)). Likewise, the hydroxyl group (–OH) does not participate in coordination, it is involved in a hydrogen bonding interaction with the coordinated water molecule [OW–H···O5^{i} 2.803 Å, (i) $x + 1/2$, $-y + 1/2$, $z + 1/2$].

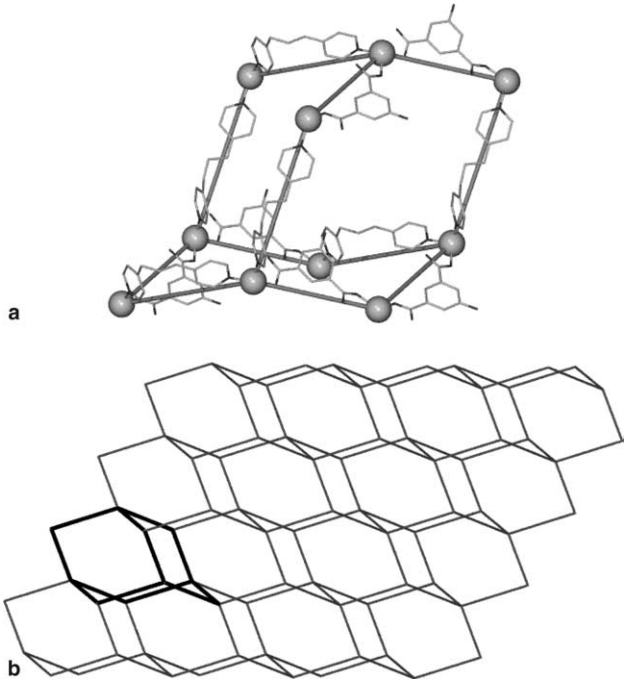

Fig. 2. (a) View of a single *adamantanoid* cage. (b) Perspective view of the three-dimensional *adamantanoid* structure in **1**. For clarity only the Co^{II} centers are shown, with the bonds representing the bridging ligands.

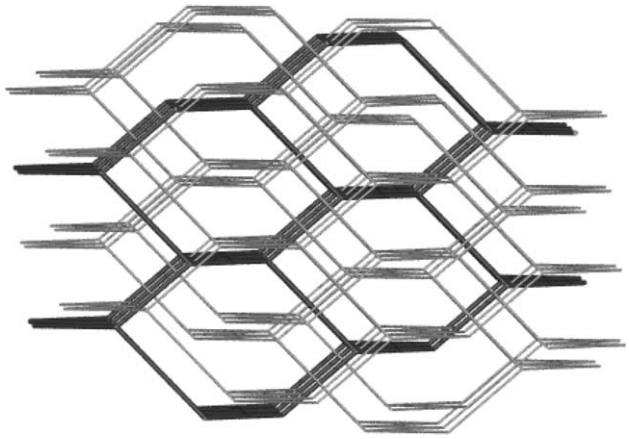

Fig. 3. Perspective view of the fourfold interpenetrated *adamantanoid* network in **1** with bridging ligands and water molecules omitted for clarity.

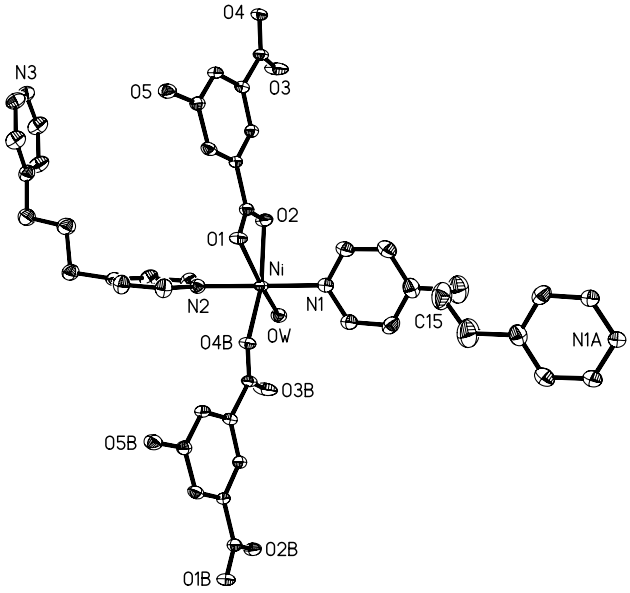

Fig. 4. ORTEP drawing of the coordination environment around Ni^{II} in **2** with the thermal ellipsoids at the 30% probability level.

The most interesting feature of this structure is that there are two types of conformational bpp ligands with different coordination modes [22]. One with the two pyridyl rings being parallel adopts a TG conformation through bridging two Ni^{II} centers. The other possesses a TT conformation and serves as a terminal ligand, the dihedral angle between the two pyridyl rings is 79.6°. As shown in Fig. 5, the TG conformational bpp ligand and OH-BDC engage neighboring Ni^{II} centers into a one-dimensional neutral molecular ladder containing $[Ni_4(bpp)_2(OH\text{-}BDC)_2]$ rectangles (14.023×10.155 Å^2). The TT conformational bpp ligand behaves as a lateral arm of the ladder through its one pyridyl ring coordinating to a Ni^{II} center, which prevents the formation of an extended motif. It is noteworthy that due to the absence of large solvent or guest molecules to fill the void space in the molecular ladder during assembly process, the terminal TT conformational bpp as long arms are threaded into $[Ni_4(bpp)_2(OH\text{-}BDC)_2]$ rectangles of an adjacent molecular ladder. Each rectangle is oppositely penetrated by two lateral arms from different molecular ladders, but there are no $\pi\cdots\pi$ interactions between the two mutual parallel and stagger pyridyl rings (Fig. 6). Such penetration not only effectively fills into the void space of the rectangles, but also results in a polythreaded polymeric structure. The hydrogen bonding interactions between coordinated water molecules and uncoordinated carboxylate oxygen atoms of OH-BDC [OW–H$\cdots$O3^{ii} 2.589 Å; symmetry code: (ii) $x+1, y, z$] as well as the above-mentioned between the coordinated water molecules and hydroxyl groups of OH-BDC further stabilize the whole structural framework. Although some polythreaded architectures from molecular ladders with both inner rungs and lateral arms have been reported [33–35], the structural motif constructed by bpp with different conformations and a dicarboxylate ligand is still unprecedented.

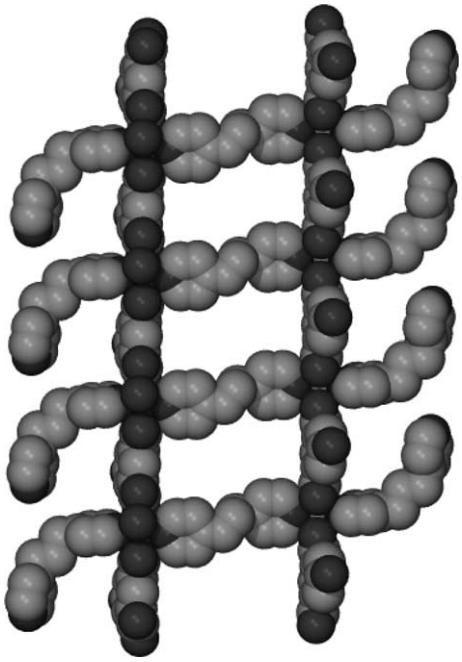

Fig. 5. Space-filling representation of a one-dimensional neutral molecular ladder with long arms.

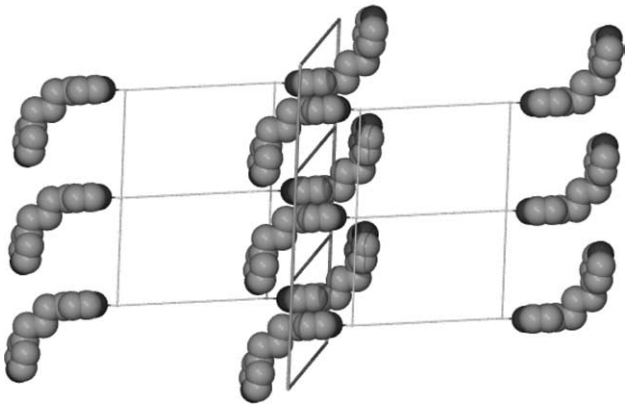

Fig. 6. Perspective view of the polythreaded polymeric structure in **2**, with the bonds representing OH-BDC and exo-bidentate bpp.

3.1.3. Crystal structure of compound *3*

Compound **3** is a twofold interpenetrated three-dimensional framework with free water molecules as space fillers. As shown in Fig. 7, each Cd^{II} center is in a distorted pentagonal bipyramidal geometry. Two chelating carboxylate groups from different OH-BDC ligands and one pyridyl nitrogen atom from a bpp ligand comprise the equatorial basal plane, one water molecule and one pyridyl nitrogen atom from the other bpp ligand occupy the apical sites [OW1–Cd–N1 168.5(2)°]. The Cd^{II} center is displaced about 0.221 Å

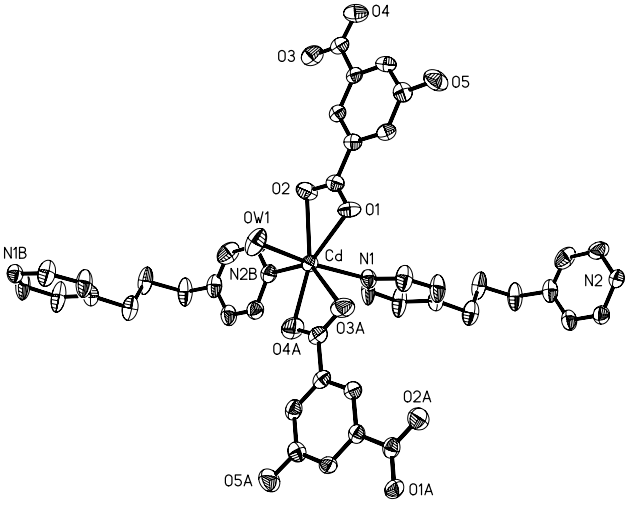

Fig. 7. ORTEP drawing of the coordination environment around Cd^{II} in **3** with the thermal ellipsoids at the 30% probability level.

from the equatorial plane towards the axial donor atom. The Cd–O and Cd–N bond distances are in the range 2.284(5)–2.614(5) Å and 2.324(6)–2.341(5) Å, respectively. Different from **1** and **2**, OH-BDC acts as a chelating bis-bidentate ligand (Scheme 1(c)) and bridges different Cd^{II} centers to give rise to a one-dimensional metal-carboxylate chain (Fig. 8). Exo-bidentate bpp adopts a TG conformation with the dihedral angle between two pyridyl rings being 79.4°, which is similar to that in **1**. Thus bpp links the adjacent one-dimensional chain into a three-dimensional framework with large channels (Fig. 9). The Cd···Cd distances bridged by bpp and OH-BDC are 11.967 and 10.117 Å, respectively. In order to shrink the void space and stabilize the final product, the three-dimensional network is interpenetrated into itself to generate an interwining network (Fig. 10). Free water molecules are accommodated in the residual empties and further stabilize the structural framework through extensive hydrogen bonding interactions between coordinated water molecules and carboxylate oxygen atoms of OH-BDC [OW1–H···O1^{i} 2.679 Å, (i) $-x+1, -y+1, -z+1$], between coordinated water molecules and free water molecules [OW1–H···OW3^{ii} 2.856 Å, (ii) $-x+1, y, -z+3/2$], between free water molecules and carboxylate oxygen atoms of OH-BDC [OW2–H···O2^{ii} 2.900 Å], between free water molecules and free water molecules [OW4–H···OW5 2.116 Å], as well as between hydroxyl groups of OH-BDC and free water molecules [O5–H···OW5 2.700 Å].

4. Conclusions

The hydrothermal reactions of 1,3-bis(4-pyridyl)propane (bpp), 5-hydroxyisophthalic acid (OH-H_2BDC) and different metal salts produced three interpenetrated or polythreaded coordination polymers. The long flexible bpp adopts different conformations to link the metal ions. Owing to the existence of large voids from long metal–metal distances bridged by bpp and OH-BDC, all of the three compounds exhibit interpenetrated structures. This research also demonstrated that the presence of anionic groups (carboxylate groups) can simplify the design and construction of the compounds.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited in the Cambridge Crystallographic Data Center as

supplementary publication, CCDC Nos. 240643–240645 for complexes **1**–**3**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (internet) +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk). or www at http://www.ccdc.cam.ac.uk].

cadmium–terephthalate systems either monodentate or chelating bidentate terminal ligands have been used [26,27]. Only one compound has been reported with a tetradentate terminal ligand and the resulting compound is mononuclear [30]. No compound with a tridentate blocking ligand is reported to date. Schiff base type ligands are easily prepared, highly variable and offer a good control on the metal coordination sphere by occupying a square plane of an octahedron or trigonal plane of a trigonal biypramid and leaving the axial bonding sites free for the desired extended coordination [31,32].

In this paper, we report the synthesis of two complexes of cadmium terephthalate using a tridentate (L^1) and a tetradentate (L^2) terminal Schiff base type ligand by the conventional solution method and their crystal structure analyses.

L^1

L^2

2. Experimental

2.1. Materials and physical measurements

Commercially available solvents, 2-acetyl-pyridine, *N*,*N*′-diethylethylenediamine, ethylenediamine, cadmium acetate dihydrate and sodium terephthalate were used without further purification. Elemental analyses were carried out using a Perkin–Elmer 240C elemental analyzer. IR spectra were recorded in KBr (4500–500 cm^{-1}) using a Perkin–Elmer R XI FT-IR spectrophotometer. The thermal analyses (TG-DTA) were carried out on a Mettler Toledo TGA/SDTA 851 thermal analyser in a dynamic atmosphere of dinitrogen (flow rate: 30 $cm^3\ min^{-1}$). The sample was heated in an alumina crucible.

2.2. Preparations

2.2.1. (*E*)-N^1,N^1-diethyl-N^2-(1-(pyridin-2-yl)-ethylidene)-ethane-1,2-diamine (L^1)

N,*N*′-diethylethylenediamine (1.74 g, 15 mmol) and 2-acetylpyridine (1.815 g, 15 mmol) in a 1:1 molar ratio were refluxed in 30 mL of dry methanol for 4 h. The resulting solution was evaporated under reduced pressure to obtain a yellow semi-solid mass. The mass was then extracted thrice (3 × 10 mL) with *n*-hexane which on slow evaporation gave a pale yellow product. Yield: 2.792 g (85%). *Anal*. Calc. for $C_{13}H_{21}N_3$: C, 71.23; H, 9.58; N, 19.17. Found: C, 71.10; H, 9.75; N, 19.02%. IR (ν/cm^{-1}): 1648 ($\nu_{C=N}$).

2.2.2. *N*,*N*′-bis-(1-pyridin-2-yl-ethylidene)-ethane-1,2-diamine (L^2)

This ligand was prepared by a procedure similar to that for L^1, by starting with ethylenediamine (0.9 g, 15 mmol) and 2-acetyl-pyridine (3.639 g, 30 mmol) in a 1:2 molar ratio to obtain a yellow liquid. Light yellow microcrystals were obtained by recrystallization from *n*-hexane. Yield: 90%. *Anal*. Calc. for $C_{16}H_{18}N_4$: C, 72.22; H, 6.75; N, 21.09. Found: C, 72.05; H, 6.88; N, 21.01%. IR (ν/cm^{-1}): 1681 ($\nu_{C=N}$).

2.2.3. Catena-poly[bis{(μ-terephthalato-$\kappa^4O^1,O^{1\prime}:O^4,O^{4\prime}$)-((*E*)-$N^1$,$N^1$-diethyl-$N^2$-(1-(pyridin-2-yl)ethylidene)-ethane-1,2-diamine)-cadmium (II)}nonahydrate], $_\infty^1\{[Cd_2(\mu\text{-}O_2C\text{-}C_6H_4\text{-}CO_2)_2\{2\text{-}C_5H_4N\text{-}C(CH_3)=N\text{-}CH_2CH_2\text{-}N(C_2H_5)_2\}_2]\cdot 9H_2O\}$ (**1**)

A methanolic solution of $Cd(OAc)_2\cdot 2H_2O$ (0.532 g, 2 mmol) and a hot methanolic solution (10 ml) of ligand L^1 (0.438 g, 2 mmol) were added to an aqueous solution of sodium terephthalate (0.42 g, 2 mmol) with constant stirring. The resulting solution was filtered and the filtrate allowed to stand at room temperature for two days to yield colorless plate-like crystals. Yield: 1.976 g (87%). *Anal*. Calc. for $C_{42}H_{68}Cd_2N_6O_{17}$: C, 43.72; H, 5.94; N, 7.28. Found: C, 43.54; H, 5.65; N, 7.36%. IR (ν/cm^{-1}): 3410 (br, ν_{H_2O}), 1572 and 1398 (ν_{CO_2}), 1653 ($\nu_{C=N}$).

2.2.4. [Di-aqua-bis{*N*,*N*′-bis-(1-pyridin-2-yl-ethylidene)-ethane-1,2- diamine}(μ-terephthalato-$\kappa^4O^1,O^{1\prime}:O^4,O^{4\prime}$)-di-cadmium(II)]-terephthalate decahydrate, [{$Cd(H_2O)$-{2-C_5H_4N-$C(CH_3)$=*N*-CH_2CH_2-*N*=$C(CH_3)$-C_5H_4N-2}}$_2$(μ-O_2C-C_6H_4-CO_2)](O_2C-C_6H_4-CO_2)·$10H_2O$ (**2**)

The title compound was prepared by a similar procedure as for **1** using ligand L^2 (0.532 g, 2 mmol) to give colorless crystals. Yield: 1.106 g (85%). *Anal*. Calc. for $C_{24}H_{34}CdN_4O_{10}$: C, 44.24; H, 5.26; N, 8.61. Found: C, 44.30; H, 5.11; N, 8.75%. IR (ν/cm^{-1}): 3410 (br, ν_{H_2O}), 1570 and 1381 (ν_{CO_2}), 1654 ($\nu_{C=N}$).

2.3. X-ray crystallography

Diffraction data was collected at $T = 293(2)$ K for **1** and at $T = 227(2)$ K for **2** by the ω-scan method with Mo Kα radiation ($\lambda = 0.71073$ Å) and the use of a graphite monochromator on a Bruker AXS CCD diffractometer. Data collection and cell refinement were done with SMART [33], data reduction with SAINT [33]. An experimental absorption correction was performed with SADABS [34]. The structure was solved by direct

methods (SHELXS-97) [35]; refinement was done by full-matrix least-squares on F^2 using the SHELXL-97 program suite [35]. All non-hydrogen positions were found and refined with anisotropic temperature factors. In **1** and **2** the hydrogen atoms were calculated with appropriate riding models (AFIX 43 for aromatic hydrogens on pyridine and terephthalate, AFIX 23 for CH_2, AFIX 33 for CH_3) and $U_{eq(H)} = 1.2\ U_{eq(C)}$ for CH and CH_2 and $U_{eq(H)} = 1.5\ U_{eq(C)}$ for CH_3. In **1** the hydrogen atoms on the oxygen atoms of water of crystallization (nine disordered oxygen atoms per formula unit) were neither found nor calculated. In **2** the hydrogen atoms on the aqua ligand and solvent water molecules were found and refined with $U_{eq(H)} = 1.5\ U_{eq(O)}$. In **1** and **2** the five and six strongest peaks, respectively, of the residual electron density are in the near vicinity (within 1.0 Å) of the cadmium atom. Graphics were computed with DIAMOND [36]. Supramolecular interactions (hydrogen bonds, C–H $\cdots\pi$ contacts) were calculated with PLATON for windows [37–39]. For complex **1** the quality of the overall crystallographic refinement is not too good, due to encorporated and disordered water of crystallization. The water of crystallization (nine H_2O per formula unit) is not discussed further nor included in the figures below for reasons of clarity. The metal–ligand moiety could be clearly refined, however. Crystal data are listed in Table 1 and bond angles in Tables 2 and 3 for complexes **1** and **2**, respectively.

3. Results and discussions

3.1. IR spectra

For complexes **1** and **2** strong absorption bands appear at 1572 and 1570 cm^{-1} for the asymmetric stretching and 1398 and 1381 cm^{-1} for the symmetric stretching of the carboxylate groups, respectively. The binding modes of the carboxylate ligands can be accessed on the basis of the difference (Δ) between the asymmetric stretching ν_a (CO_2^-) and symmetric stretching ν_s (CO_2^-) [40]. The Δ value for **1** is 174 cm^{-1} and for

2 is 189 cm^{-1}. The separation is consistent with binding modes as found in the structural analysis. The broad band in the region of 3410 cm^{-1} for both complexes could be assigned to the stretching vibration of the water molecules involved in hydrogen bonding. The imine (C═N) vibration appears at 1653 and 1654 cm^{-1} for complexes **1** and **2**, respectively.

3.2. Description of the structures

Compound **1** is a 1D polymeric zig-zag chain. Two crystallographically different cadmium centers (Cd1 and Cd2 along with their ligands) alternate along the chain (Fig. 1).

Each cadmium atom is coordinated by three nitrogen donors from the tridentate chelating (neutral) (*E*)-N^1, N^1-diethyl-N^2-(1-(pyridin-2-yl)ethylidene)ethane-1,2-diamine ligand and four oxygen donors from two bis-bidentate bridging (crystallographically different)

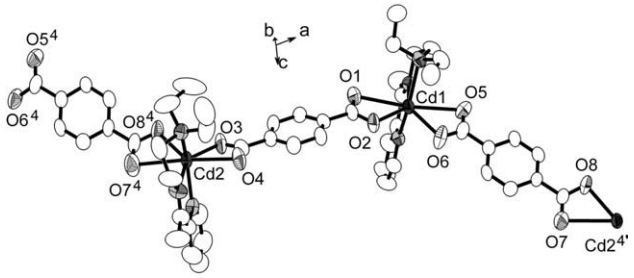

Fig. 1. Short chain segment of **1** with the two different cadmium centers. Symmetry transformations: [4] $= x-2, -y+3/2, z-1/2$; [4′] $= x-1, -y+3/2, z+1/2$.

terephthalate ligands. The coordination environment around cadmium can be described as a distorted trigonal bipyramid (Figs. 2 and 3). The repeat unit along the chain encompasses four cadmium centers (Fig. 4).

There is no element of helicity along the chain propagation axis. The chains do not run along the 2_1-crystallographic axes (parallel to the *b*-axis) but perpendicular to the *b*-axis. All chains are parallel to each other (Fig. 5). Neighbouring chains can be thought of as stacked in planes coplanar with the *ac*-plane. Along the *b*-axis these "planes" are shifted with respect to each other (Fig. 5). The space in-between neighbouring chains – visible in the space-filling representation in Fig. 5 – is filled by water molecules of crystallization (nine H_2O molecules per formula unit). The water arrangement cannot be discussed in more detail because neither could a certain disorder of the oxygen atoms be clearly resolved nor the hydrogen atoms be determined. There are no π–π interactions discernable in the interchain packing in **1**. The shortest centroid-centroid contact for two almost parallel aromatic rings (interplanar angle 8.9°) is found between the pyridyl moieties on the two different Cd1 and Cd2 centers in adjacent chains (symmetry relation $-x$, $-1/2+y$, $1/2-z$ or $-x$, $1/2+y$, $1/2-z$). The centroid–centroid contact of 5.36 Å together with the "slip angle" between the centroid–centroid vector and the normal to the plane of ~50° excludes any meaningful π-overlap (see below) [14h].

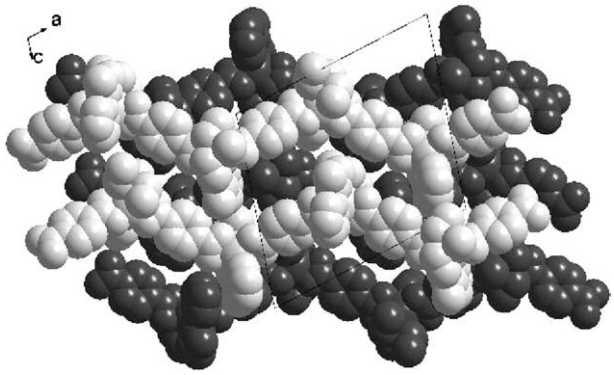

Fig. 5. Packing diagram for the parallel chains (space-filling representation) in **1** with the unit-cell outline included. Chains in different "planes" are differentiated by dark and light grey shading.

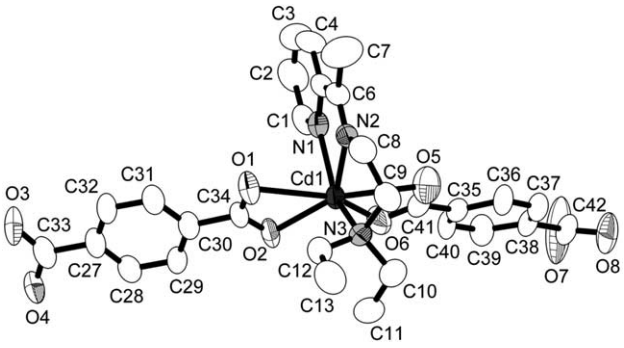

Fig. 2. Coordination environment around Cd1 in **1**; 50% thermal ellipsoids. Symmetry transformation: $^4 = x-2, -y+3/2, z-1/2$.

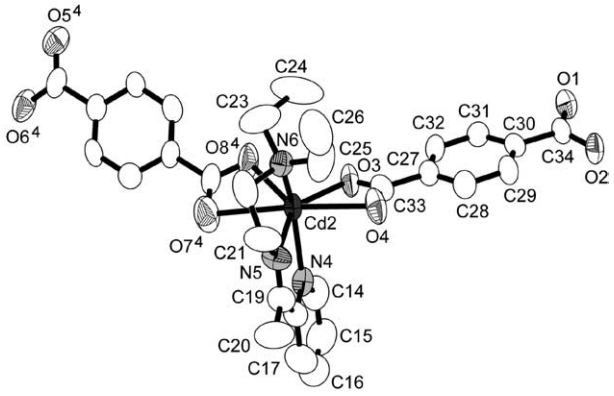

Fig. 3. Coordination environment around Cd2 in **1**; 50% thermal ellipsoids. Symmetry transformation: $^4 = x-2, -y+3/2, z-1/2$.

With respect to the Cd-terephthalate zigzag chain structure in **1**, similar chains with bis-bidentate benzene-1,4-dicarboxylate (bdc) bridges are found in $_\infty{}^1[Cd(\mu\text{-bdc})(NH_3)_2]$ [26] and $_\infty{}^1\{[Cd(\mu\text{-bdc})(H_2O)_3]\cdot 4H_2O\}$, both with an interchain hydrogen-bonding network [41], or in $_\infty{}^3\{[Ph_3PCH_2Ph][Cd(\mu\text{-bdc})Cl]\cdot 2H_2O\}$ as part of a 3D framework with bridging chloro ligands [27d]. Other terephthalato-bridged cadmium coordination polymers contain tetrakis-monodentate ligands in $_\infty{}^3[Cd(\mu_4\text{-bdc})_{1/2}Cl(1,10\text{-phen})]$ [27c] or bis-tridentate terephthalato ligands in $_\infty{}^3[Cd(\mu_4\text{-bdc})(\text{pyridine})]$

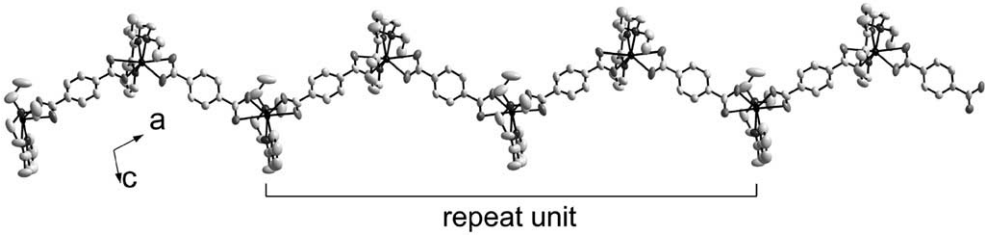

Fig. 4. Longer chain segment of **1** showing the repeat unit of four cadmium centers.

[27a], bridging between four cadmium ions as part of a 3D framework. Noteworthy, the last two structures have been obtained through hydrothermal reactions of 1,4-dicyanobenzene by its slow hydrolysis into terephthalic acid.

Compound **2** consists of centrosymmetric dinuclear (''dimeric'') and cationic complexes with each of the two (symmetry related) cadmium atoms being coordinated by the tetradentate chelating *N*,*N*′-bis-(1-pyridin-2-yl-ethylidene)-ethane-1,2-diamine ligand and an aqua ligand (Fig. 6). The terephthalato ligand bridges between the two cadmium atoms utilizing all of its four oxygen donor atoms. Both of the two carboxylate oxygen atoms coordinate to a cadmium atom with equal Cd–O bond lengths to give a four-membered chelate ring. Thus, each cadmium atom is coordinated by four nitrogen and three oxygen donors in what could be described as a distorted pentagonal bipyramid. The atoms O10–Cd–O2, which form the largest angle (165°) around Cd, present the axis of the bipyramid. The distorted pentagonal plane is formed by Cd–N1–N2–N3–N4–O1 (the largest deviation from that plane is 0.66 Å). From the plane formed by the nitrogen chelating ligand with the metal (Cd–N1–N2–N3–N4), the largest deviation would be 0.21 Å and the axis Cd–O1 would form an angle of 39.4° with that plane. The center of the bridging terephthalate ligand is also a center of inversion which renders the two halves of the dinuclear complex symmetry equivalent.

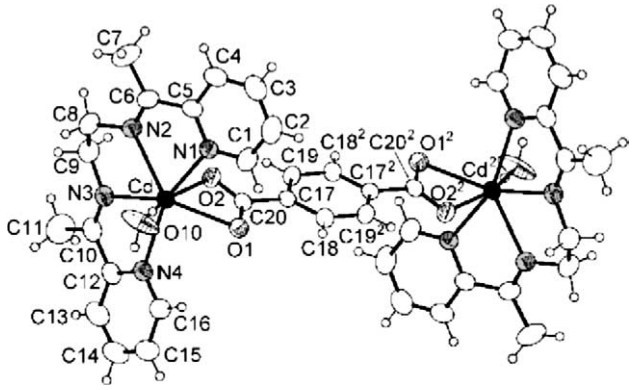

Fig. 6. Molecular structure of the centrosymmetric cationic dinuclear complex of **2**; 50% thermal ellipsoids. Symmetry transformation: $^{2} = -x+1, -y+2, -z$.

The dinuclear complex still has a single positive charge which is balanced by a ''free'', that is, hydrogen-bonded terephthalate anion. The dinuclear complexes form layers parallel to the *ac*-plane of the crystal lattice (Fig. 7). In between, that is sandwiched by the complex layers, are the terephthalate anions together with the water molecules of crystallization. The hydrogen-bonding network, where the aqua ligand and the carboxylate oxygen atoms of the bridging terephthalato ligand also participate, is shown in Fig. 7. Details of the hydrogen-bonding interactions are listed in Table 4.

The intermolecular packing between the complexes of **2**, within the layers formed parallel to the *ac*-plane, shows a rather strong π-stacking interaction [14h] between the parallel (because they are symmetry related) pyridyl planes of N4–C12–C13–C14–C15–C16 with a slip angle of 20.3°, a vertical displacement between the

D, donor, H, hydrogen bond acceptor; symmetry relations: $' = x, y-1, z$; $'' = x, y-1, z-1$; $''' = x-1, y, z$; $^{2} = -x+1, -y+2, -z+1$; $^{2''} = -x+1, -y+2, -z+2$; $^{2'''} = -x+2, -y+1, -z+1$; $^{2v} = -x+2, -y+2, -z+1$.

ring centroids of 1.3 Å, a centroid separation of 3.76 Å and an interplanar separation of 3.53 Å. In comparison the pyridyl planes of N1-C1-C2-C3-C4-C5 exhibit no π-interaction because of their very large slip angle of 37.5°, despite an interplanar distance of 3.60 Å. The symmetry related pyridyl planes of N1 have a vertical displacement between the ring centroids of 2.75 Å (centroid separation 4.53 Å) [14h,42–47]. π-Interactions with rather long centroid–centroid distances >3.9 Å, large slip angles (>30°) and vertical displacements (>2.0 Å) between the ring centroids are very weak to negligible.

To the best of our knowledge, among the plethora of terephthalate bridged architectures compound **2** is only the second example where one dicarboxylate ligand joins the metal centers through coordination bonds while a second dicarboxylate anion connects through H-bonds. Here, the terephthalate anions have both a discrete coordination and a H-bonding role in the supramolecular framework construction. The other example is $[\{Zn(tmtsc)(OH_2)\}_2(\mu\text{-terephthalate})](terephthalate)\cdot 2H_2O$ [tmtsc = 1,1,4-trimethylthiosemicarbazide] [48]. Also, a copper complex, $[Cu_2(2,2'\text{-bipy})_4(\mu\text{-terephthalate})](terephthalate)$ is known where one terephthalate links the Cu-centers and the second one balances the charge as a free anion [49].

3.3. Thermal analysis

The simultaneous TG-DTA curves of complex **1** reveal that upon heating it starts to lose water molecules at 30 °C and the dehydration continues up to 80 °C (Fig. 8). The observed weight loss (13.0%) is slightly lower than the calculated one (14.1%, corresponding to nine water molecules of crystallization per formula unit) because the loss of water molecules starts at room temperature and during drying of the sample some of the water molecules are lost. The crystalline sample

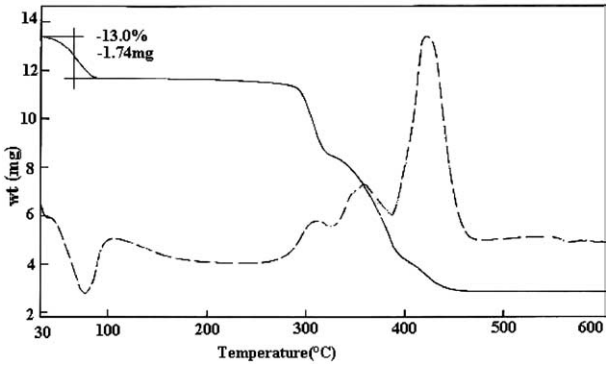

Fig. 8. The TG (——-) and DTA (-----) curves of compound **1** (heating rate: 5 °C/min).

turns into amorphous powders upon removal of water molecules. The dehydrated species is stable up to 260 °C and does not re-absorb any water on exposure to humid atmosphere suggesting that the framework integrity breaks down once the water molecules are lost. Compound **2** starts to lose its water molecules ca. 30 °C and both the crystalline and coordinated water are lost completely at 80 °C in a single step. The observed percentage of weight loss of a freshly prepared sample (16.5%) corresponds to the loss of six water molecules (per reduced formula unit, calc: 16.6%). However, on keeping the sample at room temperature the water molecules are lost gradually and consequently the percentage of water loss may not correspond to the molecular formulae if the sample is not freshly prepared. The anhydrous species is stable up to 240 °C. Here also reabsorption of water molecules does not take place on exposure of the anhydrous species to open air.

4. Conclusion

Herein, we reported two cadmium(II) complexes of terephthalate having nitrogen containing tridentate and tetradentate Schiff-base blocking ligands. Compound **1**, with a tridentate ligand, is a 1D polymeric chain whereas compound **2** with tetradentate ligand is a very rare type of dinuclear complex. In both complexes the water of crystallization is involved in a strong H-bonding network. In complex **2** the intemolecular packing is controlled by typical π-stacking interactions between pyridyl planes.

proton nuclear magnetic resonance (^{1}H NMR), carbon nuclear magnetic resonance (^{13}C NMR), single-crystal X-ray diffraction, elemental analysis and infrared spectroscopy (IR). The Cu(II) and Ni(II) complexes have been isolated and their characterization has been carried out by means of elemental analysis, IR, UV–Vis–NIR diffuse reflectance, X-ray diffraction and magnetic susceptibility measurement, and in addition the copper complex has been characterized through EPR spectroscopy.

2. Experimental

2.1. General procedures

All chemicals were of reagent grade and used without any further purification. 2-Acetyl-2-thiazoline was synthesized according to the method described by Doornbos and Peer [20]. Chemical analyses of carbon, hydrogen, nitrogen and sulfur were performed by microanalytical methods using a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Electronic spectra in a solution of the ligand were measured on a Shimadzu UV-3101 PC using a 10 mm quartz cell. The UV–Vis–NIR reflectance spectra for each complex in the 200–1200 nm range was registered from a pellet of the sample, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic measurement was made at room temperature on a magnetometer with a pendulum MANICS DSM8, equipped with a helium continuous-flow cryostat and an electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature-independent paramagnetism and diamagnetic contributions, which were estimated from the Pascal constants. The EPR spectrum was recorded at room temperature on a BRUKER ESM-300 spectrometer using X band microwave frequencies. ^{1}H and ^{13}C NMR spectra were obtained with a Bruker AM 400 instrument at 400 and 100 MHz, respectively, in DMSO using Me_4Si as the internal standard.

2.2. Synthesis of 2-acetyl-2-thiazoline semicarbazone (ATsc)

To a solution containing 2-acetyl-2-thiazoline (1.00 g, 0.008 mol) and potassium acetate (1.55 g, 0.016 mmol) in 10 mL ethanol 50%, was added a solution of semicarbazide hydrochloride (0,87 g, 0.008 mmol) in 30 mL ethanol 50%, and the resulting solution was heated to reflux for 7 h. Then the solution was cooled and a white powder appeared (1.41 g, 97%). This solid was recrystallized from methanol, yielding prismatic crystals, of considerable size (ca. 0.6 mm), suitable for X-ray diffraction.

^{1}H NMR (DMSO): δ 9.92 (s, 1H, NH), 4.3 (t, $J = 8.3$ Hz, 2H, CH_2–N), 3.22 (t, $J = 8.3$ Hz, 2H, CH_2–S), 2.10 (s, 3H, CH_3); ^{13}C NMR (DMSO): δ 168.53 C(1), 156.23 C(6), 141.04 C(4), 65.10 C(2), 31.79 C(3), 13.04 C(5). *Anal.* Calc. for $C_6H_{10}N_4SO$: C, 38.70; H, 5.41; N, 30.09; S, 17.21. Found: C, 38.68; H, 5.75; N, 29.72; S, 16.99%. UV–Vis (MeOH): λ_{max}, nm; (ε, L mol^{-1} cm^{-1}) 266 (30 090).

2.3. Preparation of [$CuCl_2$(ATsc)]

This complex was prepared by reacting a methanol solution (2 mL) of $CuCl_2 \cdot 2H_2O$ (93 mg, 0.51 mmol) with a methanol solution (40 mL) of ATsc (100 mg, 0.51 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After a day, green prismatic crystals of considerable size (ca. 0.5 mm) were isolated from the solution (173 mg, 73%). The crystals were separated by filtration, washed with cold ether and air-dried. *Anal.* Calc. for $C_6H_{10}Cl_2CuN_4OS$: C, 22.47; H, 3.14; N, 17.47; S, 10.00. Found: C, 22.69; H, 3.41; N, 17.40; S, 9.61%.

2.4. Preparation of [$Ni(ATsc)_2$]$(NO_3)_2 \cdot H_2O$

This complex was prepared by reacting a methanol solution (2 mL) of $Ni(NO_3)_2 \cdot 6H_2O$ (155 mg, 0.51 mmol) with a methanol solution (40 mL) of ATsc (100 mg, 0.51 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After several weeks, dark green prismatic crystals of considerable size (ca. 0.4 mm) were isolated from the solution (72 mg, 47%). The crystals were separated by filtration, washed with cold ether and air-dried. *Anal.* Calc. for $C_{12}H_{22}N_{10}NiO_9S_2$: C, 25.15; H, 3.87; N, 24.44; S, 11.19. Found: C, 24.81; H, 4.10; N, 24.07; S, 10.87%.

2.5. Crystal structure determinations

Experimental details of the crystal structure determinations, including crystal data, data collection, structure determination and refinement parameters for ATsc, [$CuCl_2$(ATsc)] and [$Ni(ATsc)_2$]$(NO_3)_2 \cdot H_2O$, are listed in Table 1. X-ray diffraction measurements were performed using a Bruker SMART CCD diffractometer. The first fifty frames were measured at the end of the data collection to monitor instrument and crystal stability. Absorption corrections were applied using the program SADABS. The structures were solved by direct methods and subsequent Fourier differences using the WINGX package [21] and refined by full-matrix least-squares on F^2, assuming anisotropic displacement parameters for non-hydrogen atoms. The hydrogen atoms on ATsc were obtained from a difference Fourier synthesis and refined without any constrains, excepting hydrogen atoms of methyl group which were calculated

Table 1
Crystal data, data collection and refinement details for ATsc, $[CuCl_2(ATsc)]$ and $[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$

Complex	ATsc	$[CuCl_2(ATsc)]$	$[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$

[b] $R = \{\sum [w(F_o^2 - F_c^2)^2] / \sum [w(F_o^2)^2]\}^{1/2}$.
[c] $\mathrm{GOF} = \{\sum [w(F_o^2 - F_c^2)^2] / (N_{rflns} - N_{params})\}^{1/2}$.

in ideal positions. In the complexes, all hydrogen atoms attached to carbon and nitrogen atoms were positioned geometrically, with U_{iso} values derived from U_{eq} values of the corresponding carbon and nitrogen atoms. In the nickel complex, the hydrogen atoms of the water molecule were ignored. Diagrams were generated using ORTEP3 for Windows [22].

3. Results and discussion

3.1. Description of the structures

An ORTEP diagram of the molecular structure of ATsc is shown in Fig. 1. Bond lengths, angles and hydrogen-bond parameters are listed in Table 2.

In the S–C(1)–N(1)–C(2)–C(3) ring, the short endocyclic C=N bond [C(1)–N(1) = 1.266(2) Å] is accompanied by a high N–C–S angle [N(1)–C(1)–S = 118.2(1)°] and a relatively long S^{II}–C(sp^2) bond [S–C(1) = 1.770(1) Å], which is characteristic of a thiazoline ring

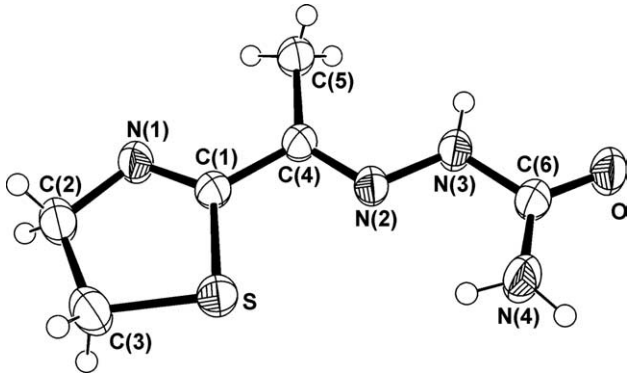

Fig. 1. Crystal structure of ATsc, showing the atom-numbering scheme. The thermal ellipsoids are plotted at the 40% probability level.

Table 2
Bond lengths (Å), angles (°) and hydrogen-bond parameters for ATsc

[23]. It is known that the imino tautomers can exist as two geometric isomers, *syn* (*Z*) and *anti* (*E*), but in this crystal, only the *E* isomers have been observed.

The thiazoline ring shows a conformation near to envelope with the C(3) atom deviating 0.139 Å above the plane formed by S, C(1), N(1) and C(2). This geometry is proved by the puckering parameters $Q = 0.090$ Å and $\phi = 135.5°$, calculated according to Cremer and Pople [24]. As was to be expected, the semicarbazone group C(4)–N(2)–N(3)–C(6)–O–N(4) is essentially planar with maximum least square plane deviations for N(3) [0.032 Å].

The molecular units of ATsc are linked by hydrogen bonds in a one dimensional chain parallel to the *c*-direction, in which carbonyl oxygen atom and thiazolinic N(1) nitrogen atom act as acceptors of hydrogen, whereas the aminic nitrogen atoms of the semicarbazone group, N(3) and N(4), act as donors. A diagram showing the hydrogen-bonds is given in Fig. 2.

The molecular structure of $[CuCl_2(ATsc)]$ with the atomic labelling is shown in Fig. 3. Selected bond lengths, angles and hydrogen-bond parameters are given in Table 3.

The copper(II) complex is five-coordinate, defining a square-pyramidal coordination polyhedron. The shape of the polyhedron has been quantified following two methods reported in the bibliography [25,26] and the results are summarized in Table 4. Both Δ and τ parameters assign a slightly distorted square pyramid for the coordination environment. The equatorial positions are occupied by a chloro ligand [Cu–Cl(2) = 2.223(1) Å], one carbonyl oxygen atom [Cu–O = 2.036(2) Å], one thiazolinic nitrogen atom [Cu–N(1) = 1.999(2) Å] and one iminic nitrogen atom [Cu–N(2) = 1.983(2) Å]. The

axial position is occupied by the Cl(1) ligand at a distance of 2.500(1) Å from the copper atom. The Cl(1)–metal–basal ligand angles vary from the ideal value for a square pyramid (90°) and they range between 101.8(1)° [Cl(1)–Cu–Cl(2)] and 95.1(1)° [N(2)–Cu–Cl(1)]. Likewise, the basal ligand–metal–basal ligand angles differ from the ideal value of 90°, varying between 100.5(1)° [N(1)–Cu–Cl(2)] and 77.5(1)° [N(2)–Cu–O].

The Cu–Cl basal bond distance is similar to the average value [2.259(43) Å] calculated using the data of 25 square pyramidal copper(II) complexes with an Cl_2N_2O environment, obtained with the CONQUEST software [27] from the Cambridge Structural Database (CSD) [28]. In the same way, the Cu–Cl axial bond distance is comparable to the mean value 2.540(92) Å obtained from 17 complexes collected in the CSD using the data of crystal structures of square pyramidal copper(II) complexes with the chromophore group $CuCl_2N_2O$. Likewise, the Cu–O_{ketone} and Cu–N_{imine} distances are comparable to the mean

N(4)–H(4B)···Cl(2)	$-x+1/2$, $y-1/2$, $z+1/2$	3.316(2)	153
N(4)–H(4A)···Cl(1)	x, $y-1$, z	3.300(2)	168

values 2.044(140) and 1.967(54) Å, respectively, found using the data of 12 copper(II) complexes bonded to a semicarbazone moiety obtained from the CSD. Finally, the Cu–$N_{thiazoline}$ bond length is similar to the calculated average value [1.952(38) Å] collected for 12 copper(II) complexes in the CSD.

The five-membered chelate ring Cu–N(1)–C(1)–C(4)–N(2) is essentially planar with maximum mean plane deviation for N(2) (0.040 Å). On the contrary, the chelate ring Cu–N(2)–N(3)–C(6)–O presents a conformation near to half-chair [$q = 0.130$ Å; $\phi = 13.5°$] [24], with Cu and N(2) deviating −0.168 and 0.082 Å, respectively, from the plane formed by N(3), C(6) and O.

For the thiazoline ring, the puckering parameters $q = 0.202$ Å, $\phi = -41.8°$ [26] indicate a conformation near to envelope with the C(3) atom deviating 0.316 Å above the mean plane formed by S, C(1), N(1) and C(2).

Finally, the crystal structure presents a two-dimensional hydrogen-bond network perpendicular to the a-axis in which chloro ligands Cl(1) and Cl(2) act as acceptors of hydrogen, whereas nitrogen atoms N(3) and N(4) act as donors. A diagram showing this network is given in Fig. 4.

The X-ray study of the nickel(II) complex revealed that the crystals are made up of monoclinic unit cells, each containing eight $[Ni(ATsc)_2]^{2+}$ cations, sixteen nitrate anions and eight water molecules held together by hydrogen bonds. The overall view and labelling of the atoms of complex cation are displayed in Fig. 5. Table 5 lists the selected bond lengths, angles and hydrogen-bond parameters.

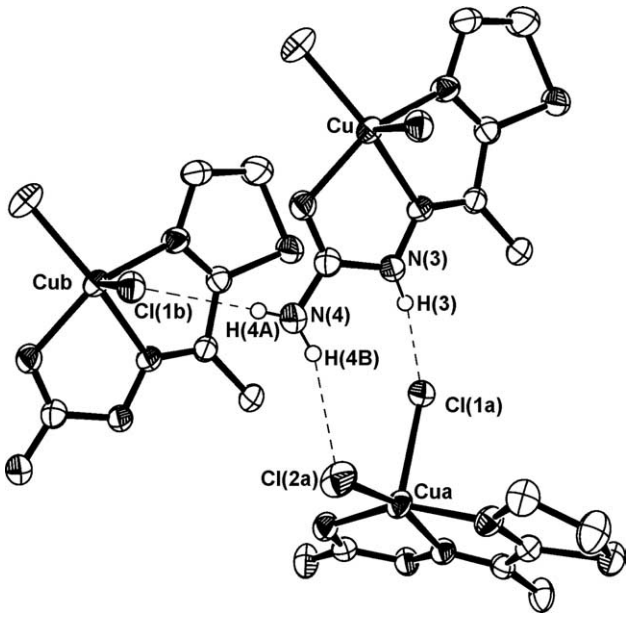

Fig. 4. View of the hydrogen bonds of $[CuCl_2(ATsc)]$.

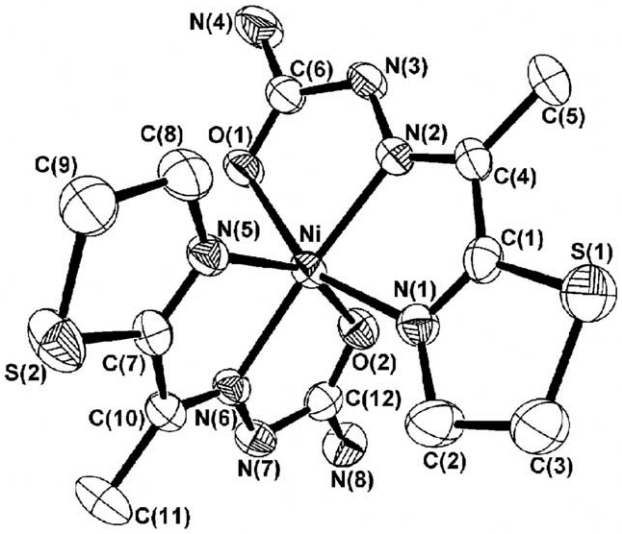

Fig. 5. Molecular structure of cation complex $[Ni(ATsc)_2]^{2+}$, showing the atom-numbering scheme. The thermal ellipsoids are drawn at the 40% probability level.

The complex cation possesses approximately a non-crystallographic C_2 symmetry, with the twofold axis placed at the bisector of the O(1)–Ni–O(2) angle.

The environment around the nickel(II) atom may be described as a distorted octahedral geometry with the ligand–metal–ligand bite angles varying between 76.9(1)° [N(2)–Ni–O(1)] and 107.5(1)° [N(2)–Ni–O(2)]. The metallic atom is coordinated by two carbonyl oxygen atoms [av. Ni–O = 2.103 Å], two thiazolinic nitrogen atoms [av. Ni–N = 2.073 Å] and two iminic nitrogen atoms [av. Ni–N = 2.010 Å].

The Ni–O_{ketone} and Ni–N_{imine} bond lengths have been compared with the mean value calculated with the data of 5 nickel(II) complexes bonded to a semicarbazone moiety obtained from the CSD. Thus, these bond lengths are in good agreement with the mean value of 2.107(35) Å for the Ni–O_{ketone} distance and 1.993(35) Å for the Ni–N_{iminne} distance Finally, the Ni–$N_{thiazoline}$ bond lengths are closer to that found in $[Ni(PyTT)_2(H_2O)_2]Cl_2 \cdot 2H_2O$ (2.061(2) Å) [29], but somewhat longer than that observed in $[Ni(TzHy)_2(H_2O)_2]Cl_2 \cdot 3H_2O$ (2.027(3) Å) [30].

The five-membered chelate rings are essentially planar. The maximum deviation in relation to the corresponding mean plane are produced for N(2) (0.007 Å) [chelate ring Ni–O(1)–C(6)–N(3)–N(2)], N(1) (0.046 Å) [chelate ring Ni–N(2)–C(4)–C(1)–N(1)], N(6) (0.012 Å) [chelate ring Ni–O(2)–C(12)–N(7)–N(6)] and C(7) (0.027 Å) [chelate ring Ni–N(6)–C(10)–C(7)–N(5)].

The thiazoline ring S(1)–C(1)–N(1)–C(2)–C(3) is essentially planar with maximum mean plane deviation for C(3) (0.069 Å). However, the other thiazoline ring S(2)–C(7)–N(5)–C(8)–C(9) shows a conformation near to envelope [$q = 0.096$ Å and $\phi = 134.6°$] [24] with the

apex at C(9). This atom is 0.144 Å out of the mean plane formed by S(2), C(7), N(5) and C(8).

The crystal structure is stabilized by a network of hydrogen-bonds, which forms chains along the [110] direction, in which nitrogen atoms N(3), N(4), N(7) and N(8) act as hydrogen donors, the oxygen atoms of nitrate ions and the crystallisation water molecule act as acceptors.

Finally, it should be pointed out that the main difference in both complexes with respect to the structure of free ATsc is due to the different degree of rotation of the thiazoline ring around the C(1)–C(4) [or C(7)–C(10)] bond, which permits the coordination through thiazoline nitrogen atoms [torsion angle S–C(1)–C(4)–N(2) = 177.7° in $[CuCl_2(ATsc)]$; S(1)–C(1)–C(4)–N(2) = −179.3° and S(2)–C(7)–C(10)–N(6) = −177.0° in $[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$; 4.4° in ATsc]. Similarly, the formation of the complexes requires rotation around the C(6)–N(3) [or C(12)–N(7)] bond, which permits the coordination through the carbonyl oxygen atoms [N(2)–N(3)–C(6)–O = −3.7° in $[CuCl_2(ATsc)]$; N(2)–N(3)–C(6)–O(1) = −0.9° and N(6)–N(7)–C(12)–O(2) = −1.0° in $[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$; 177.5° in ATsc].

3.2. IR spectra

The IR spectrum of ATsc in the 4000–370 cm^{-1} region shows the presence of bands due to the thiazoline ring vibration at 1584 (W_1), 1007 (W_2), 925 (W_3), 762 (W_4), 724 (W_5), 682 (W_6), 592 (W_8), 530 (W_7) and 430 (Γ_1) cm^{-1} [29,31,32]. Moreover, the bands registered at 1685 and 1584 cm^{-1}can be assigned to [ν(C=O)] and [ν(C=N)] vibrations respectively [33,34].

The IR spectra of complexes in the 4000–370 cm^{-1} region show the presence of bands due to ring vibrations as in show in Table 6. Other relevant bands are registered at 1667 [ν(C=O)] and 1651 cm^{-1} [ν(C=N)] for $[CuCl_2(ATsc)]$ and at 1671 [ν(C=O)] and 1645 cm^{-1} [ν(C=N)] for $[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$.

In the low-frequency range, five bands assignable to metal–ligand stretching vibrations are observed for $[CuCl_2(ATsc)]$ spectra and three bands for $[Ni(ATsc)_2](NO_3)_2 \cdot H_2O$ spectra. Thus, in the Cu(II) spectrum the

Abbreviations: (s) strong; (m) medium; (w) weak; (v) very.

band at 363 cm^{-1} corresponds to a $\nu(Cu–O_{ketone})$ vibration, in accord with the literature data for this type of bond [33]. The band at 338 $cm^{-1}$is assigned to one ν(Cu–Cl) vibration [35] and the band at 321 cm^{-1} could include the $\nu(Cu–N_{imino})$ vibration [36] and the other ν(Cu–Cl) vibration [35]. The band at 228 cm^{-1} is attributed to $\nu(Cu–N_{thiazoline})$ [36]. Finally, the Ni(II) spectrum shows a first band at 361 cm^{-1}, corresponding to a $\nu(Ni–O_{ketone})$ vibration [33], a second band at 332 cm^{-1} is assigned to the $\nu(Ni–N_{imino})$ vibration [37–39] and the last band can be attributed to a $\nu(Ni–N_{thiazoline})$ vibration [29,31], according to the consulted bibliography.

3.3. Electronic spectra

The reflectance spectrum of the copper complex consists of a broad d–d asymmetric band centred at 12470 cm^{-1}. Presumably all four d–d transitions ($^2A[(d_{x^2-y^2})^1] \rightarrow {}^2A[(d_{z^2})^1], {}^2A[(d_{xy})^1], {}^2A[(d_{xz})^1], {}^2A[(d_{yz})^1]$) of the square-pyramidal geometry [40] are responsible for this band. Likewise, the spectrum shows a strong absorption at 32260 cm^{-1} (309 nm) which may be associated with a charge transfer band.

The electronic spectrum of the nickel complex shows one intense band at 32680 cm^{-1}(360 nm), which is assigned to a charge transfer band. Moreover, the spectrum exhibits bands at 11494, 12658 (sh) and 16835 cm^{-1}, all of which were of low intensity. These bands may be assigned as: $\nu_1[{}^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)]$ (11494 cm^{-1}), $^3A_{2g}(F) \rightarrow {}^1E_g(D)$ (12658 cm^{-1}) and $\nu_2[{}^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)]$ (16835 cm^{-1}) transitions, in an idealized O_h symmetry. The position of the observed d–d transitions permits the calculation of the ligand field parameters, $10Dq$ and B, using the following known relationships [41]:

$$\nu_1[{}^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)] = 10Dq,$$
$$\nu_2[{}^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)] = (1/2)(15B + 30Dq) - (1/2)[(15B - 10Dq)^2 + 12B \cdot 10Dq]^{1/2}.$$

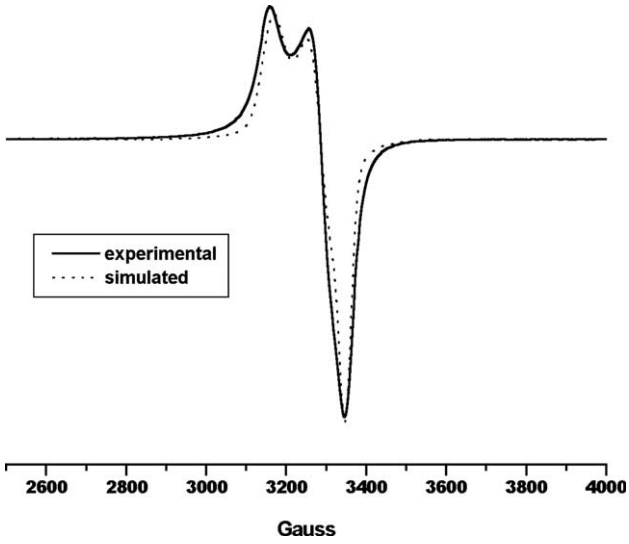

Fig. 6. Experimental and simulated polycrystalline EPR spectrum of [$CuCl_2$(ATsc)].

The calculated values of the ligand field parameters $10Dq = 11494$ cm^{-1} and $B = 568$ cm^{-1} are consistent with the presence of a chromophore group [$Ni^{II}N_4O_2$] [29,42].

3.4. Magnetic susceptibility and EPR spectra

The observed molar magnetic susceptibility for the copper complex was corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moment at room temperature ($\mu = 2.01$ BM). This value is in the range 1.9–2.2 BM, which allows the exclusion of metal–metal interactions, supporting a monomeric structural formulation for this compound [43].

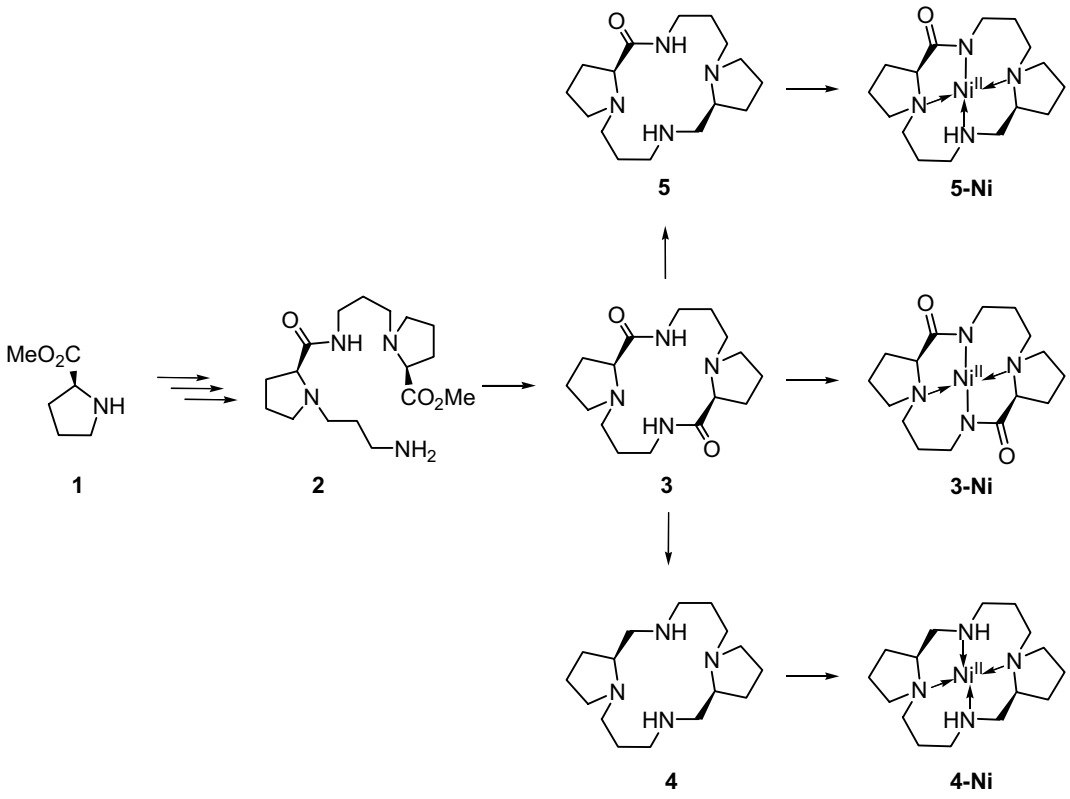
Fig. 6 shows the EPR spectrum of the polycrystalline copper(II) complex at X-band microwave frequencies.

The EPR value was obtained by simulation [44]. The EPR spectrum is rhombic with g parameters $g_1 = 2.09$; $g_2 = 2.12$ and $g_3 = 2.21$. The value for the R parameter [$R = (g_2 - g_1)/(g_3 - g_2)$] is 0.33, i.e., lower than 1, thus indicating that the unpaired electron is located in a $d_{x^2-y^2}$ orbital [45] associated with a square-pyramidal stereochemistry, in good agreement with the crystallographic results [46].

The corrected magnetic moment measured for the nickel complex was $\mu = 3.31$ BM, which can be related to an octahedral environment [42].

4. Supplementary material

CCDC 271095, 271096 and 271097 corresponding to ATsc, [$CuCl_2$(ATsc)] and [$Ni(ATsc)_2$]$(NO_3)_2 \cdot H_2O$ contain the supplementary crystallographic data for this



paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Scheme 1.

dioxocyclam **3**. A few simple transformations of L-proline ester **1** led to the aminoester **2** which underwent a cyclization reaction yielding dioxocyclam **3** (Scheme 1). We examined different macrocyclization conditions such as basic catalysis or high-pressure technique and found that the best results were obtained when sodium methoxide as the base and methanol as the solvent were applied (82% yield). Having prepared the macrocyclic compound we decided to transform it into the poliamino analogue **4**. The reduction with the $BH_3 \cdot Me_2S$ complex led to the cyclam derivative **4** in a good yield (75%). By carrying out the reaction under more gentle conditions we were able to reduce only one amide group and obtain monooxocyclam **5** in 57% yield.

All cyclam derivatives **3**–**5** easily form complexes with transition metals. Amide ligands **3** and **5** upon addition of nickel acetate into their methanol solutions undergo deprotonation on the amide groups, thus forming complexes: $[Ni^{2+}(\mathbf{3}^{2-})]$ (denoted as **3-Ni**) and $[Ni^{2+}(\mathbf{5}^{-})](Cl^{-})$ (denoted as **5-Ni**). In the case of the reduced all-amine ligand **4**, a complex of the stochiometry $[Ni^{2+}(\mathbf{4})(AcO^{-})(H_2O)]Cl^{-}$ (denoted as **4-Ni**) is formed.

The X-ray structure of the complex **3-Ni** is illustrated in Fig. 1. The two amide hydrogen atoms have been removed during the complexation process, forming a neutral complex. Nickel is four-coordinated and its coordination geometry can be described as tetrahedrally distorted square planar. The tetrahedral twist, defined as the deviation of atoms from the least-square plane through the nitrogen atoms is ± 0.28 Å with the nickel ion positioned 0.05 Å beyond the plane. The Ni–N bonding distances are characteristic for a low-spin complex (Table 1) [12]. Bonding distances to the deprotonated amide nitrogens are shorter by ca. 0.06 Å than those to amine nitrogen atoms. The five-membered chelate rings formed by Ni1–N1–C1–C2–N2 (and Ni1–N1′–C1′–C2′–N2′) are almost planar, while the 6-membered rings exhibit chair-like conformations. Although the planar coordination geometry of nickel is highly distorted, the mutual position of the chelate rings resembles the *trans*-I (*R*,*S*,*R*,*S*) conformation in the notation approved for the parent cyclam system [13]. Previously, it has been shown that for square-planar nickel complexes of simple cyclams the most stable form is the *trans*-III conformation (and in many cases the only one observed) [14]. However, for some substituted cyclams, the *trans*-I conformation, observed also by us, has also been reported as a minor component [15]. The important feature of this complex from the catalytic point of view is that both proline rings are positioned on the same side of the macrocycle, which shields one side of the metal center completely and leaves the other one exposed.

In the case of the monoreduced ligand **5**, during the reaction with nickel (II) acetate, one amide group is

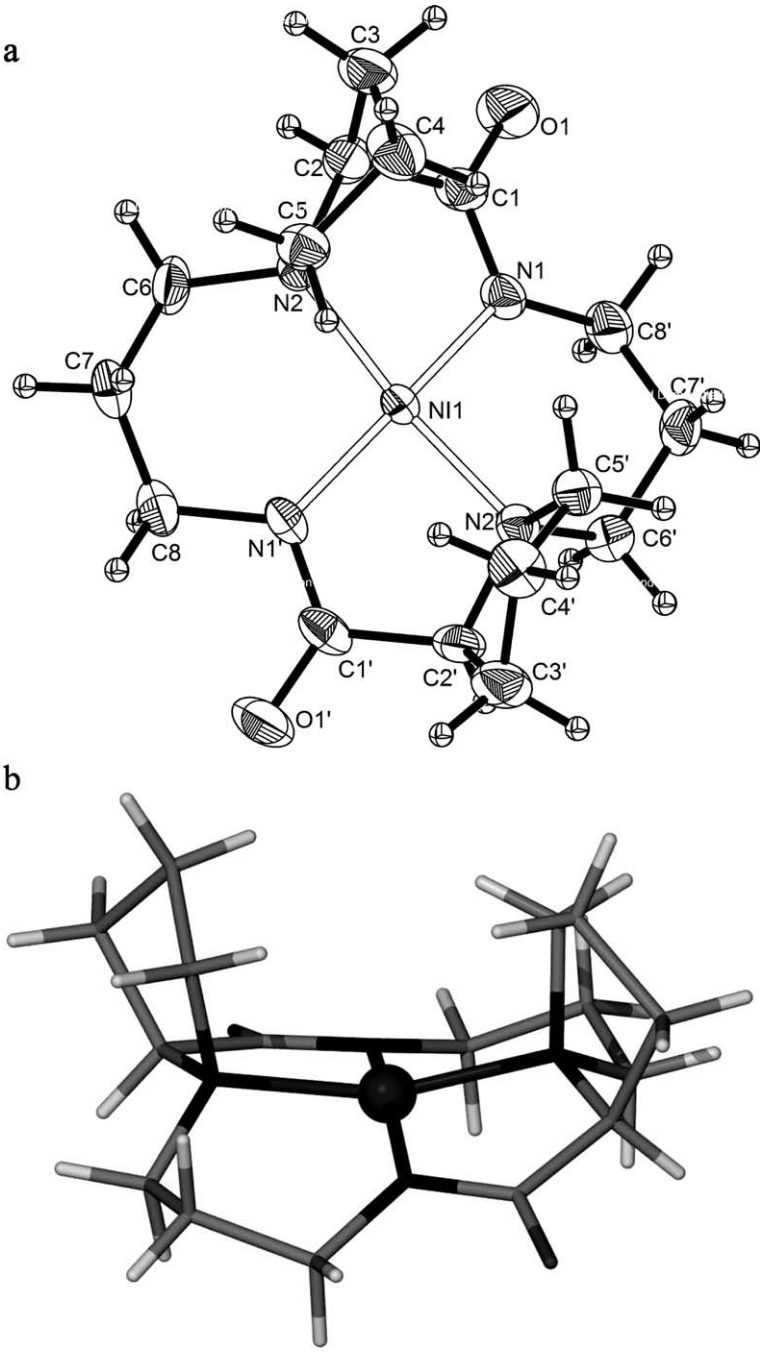

Fig. 1. X-ray structure of **3-Ni**: $[Ni^{2+}(\mathbf{3}^{2-})]\cdot H_2O$. (a) ORTEP presentation in the plane of the macroring. (b) Stick presentation in the plane perpendicular to the macroring.

deprotonated while all the amino groups form coordination bonds. During re-crystallization of the complex from CH_2Cl_2 the acetate counterion exchanges with chloride to give a complex of the stoichiometry $[Ni^{2+}(\mathbf{5}^{-})](Cl^{-})\cdot(H_2O)_2$ (denoted as **5-Ni**) as proven by micro- and X-ray analysis (the ability of carboxylates to exchange with chloride from chlorinated solvents has been observed by us many times during other independent experiments). X-ray analysis shows that the nickel coordination geometry for **5-Ni** is square planar, highly tetrahedrally twisted, with Ni–N distances characteristic for a low-spin complex (Table 1). The distortion from square planar geometry is ± 0.26 Å with the nickel ion positioned 0.02 Å beyond the plane. Again two proline rings shield effectively only one side of the macrocycle, while the other side is exposed. It is interesting to note that the Cl^{-} counterion remains far from the cationic center. The chloride is hydrogen bonded with the amine hydrogen and two water molecules, while the exposed

	Ni1–N4	1.956(3)

side of the macrocycle interacts with the neighboring macrocycle (see Fig. 2).

A completely different coordination environment is observed for the interaction of the reduced, all-amine ligand **4** with nickel (II). The complex stoichiometry, proved by microanalysis, was found to be $\mathbf{4}\cdot Ni^{2+}\cdot 2AcO^{-}$. However, again upon crystallization from CH_2Cl_2 one of the acetate counterions underwent exchange and the stoichiometry found by X-ray analysis is $[Ni^{2+}(\mathbf{4})(AcO^{-})(H_2O)]Cl^{-}$ (denoted as **4-Ni**). In the crystal of **4-Ni** (Fig. 3) two independent molecules are observed, however, both of them have identical conformations and coordination geometries. The nickel cation resides in a six-coordinate octahedral environment interacting with four amine nitrogen atoms, an acetate anion and a water molecule. Such an octahedral coordination is the most common for high-spin complexes (92% of all high-spin complexes) [12]. Indeed, the Ni–N bonding distances are also in agreement with that conclusion (Table 1). The conformation of the macrocycle, in the notation approved for cyclams, is *cis*-V (*R*,*R*,*R*,*R*). For octahedral complexes of *N*-substituted ligands the most common conformation is *trans*-III (52% of all octahedral complexes) [15], however, as observed by us, the *cis*-V conformation is the second most common (39%).

It has been suggested that a *cis*-V conformation of cyclam complexes is crucial for biological activity. In vivo, bislactam based biologically active anti-HIV agents, are believed to interact with a receptor's carboxylate side chains and the presence of carboxylate anions induces a *cis*-V conformation of the complex in the active site [16]. It has also been postulated recently that acetate promotes a *cis*-V conformation for a cyclam–Zn complex [17]. Our structure can be considered as an additional crystallographic hint for the hypothesis that such a conformation might be acetate-driven.

2.1. Conformational changes during complexation

In the preceding communication [11], we have presented the structures of the free ligands **3** and **5**. It is noteworthy that in both cases amide groups were perpendicular to the mean plane of the macrorings, and the carbonyl oxygen atoms were pointing to the same side. Proline rings for the free ligands were in the plane of the macrorings. During complexation the macrocycles rearranged considerably. The carbonyl oxygen atoms are now parallel to the mean plane of the macrorings and the proline rings are perpendicular.

3. Conclusions

We have reported the synthesis and the structures of nickel (II) complexes of chiral cyclams originating from L-proline. X-ray structure analyses indicate that for the complexes, contrary to the free ligands, the chiral proline rings shield only one side of the molecule, the other side remaining exposed. Thus, for future modifications, the structures suggest that substitution at the lower part of the macrocycle (opposite to the proline rings) should be made.

4. Experimental

4.1. General remarks

X-ray measurements were performed using a MACH-3 diffractometer (Enraf-Nonius) in the Institute of Organic Chemistry, Polish Academy of Sciences. The structures were solved and refined using the programs SHELXS-97 (Sheldrick, 1990) and SHELXL-97 (Sheldrick, 1997) respectively. The program X-SEED was used as an interface to the SHELX programs, and to prepare the figures [18]. Cyclam derivatives were prepared according to previously described procedures [11].

4.2. Synthesis

3-Ni: Equimolar amounts of dioxocyclam **3** and nickel (II) acetate were dissolved in methanol and heated up to reflux with stirring. The complex formation was manifested by a color change from green into dark red and acetic acid secretion. The methanol was removed under vacuo to give a red oil which was crystallised from diethyl ether.

Dark red crystals; m.p. 247 °C; $[\alpha]_D^{20} = -294$ ($c = 0.0468$ in MeOH); ^{1}H NMR (500 MHz, $CDCl_3$, 30 °C, TMS): $\delta = 4.79$–4.73 (m, 2H), 3.30–3.23 (m, 4H), 2.99 (dt, 2H, $J_1 = 14.1$ Hz, $J_2 = 4.0$Hz), 2.78–2.70 (m, 2H), 2.28–2.21 (m, 2H), 2.19–2.21 (m, 2H), 2.07–1.95 (m, 4H), 1.93–1.82 (m, 4H), 1.64–1.57 (m,

2. Experimental

2.1. Materials and methods

All operations were carried out in air at room temperature. The starting materials $[Et_4N]_2[MS_4]$ (M = Mo, W) were prepared according to the literature procedures [7], and the compound $CuSBu^t$ was prepared by treating $Cu(NO_3)_2 \cdot 3H_2O$ with $HSBu^t$ in ethanol. Other chemicals were obtained from commercial sources and used as received.

Infrared spectra were recorded on a Nicolet Magna 750 FT-IR spectrophotometer as KBr pellets. Electronic spectra were recorded on a Lambda 35 spectrophotometer in MeCN solution between 600 and 200 nm. Cyclic voltammograms were performed on a microcomputer-based electrochemical analyzer LK-98A. The measurements were conducted in a DMF solution under nitrogen atmosphere with Bu_4NClO_4 as supporting electrolyte. Elemental analyses were performed in the Elemental Analysis Laboratories at our institute.

2.2. Synthesis of $[Et_4N]_4[\{MS_4Cu_2(\mu\text{-}SBu^t)\}_4]$ (**1**, M = Mo; **2**, M = W)

An MeCN solution (15 mL) of $[Et_4N]_2[MoS_4]$ (0.24 g, 0.5 mmol) and $CuSBu^t$ (0.15 g, 1.0 mmol) was stirred at room temperature for 0.5 h and then filtered, ^{i}PrOH (15 mL) was added to the resulting filtrate slowly and the solution was allowed to stand in air for several days to afford **1** as brown crystals. Yield (0.21 g, 74%). Yellow crystals of **2** (0.28 g, 85%) were obtained by a similar way as for **1** except $[Et_4N]_2[WS_4]$ (0.29 g, 0.5 mmol)was used instead of $[Et_4N]_2[MoS_4]$. Recrystallization by vapor diffusion of ^{i}PrOH into a DMF solution of **2** afforded crystals suitable for X-ray diffraction. *Anal.* Calc. for **1**: C, 25.26; H, 5.09; N, 2.46. Found: C, 25.42; H, 4.78; N, 2.45%. *Anal.* Calc. for **2**: C, 21.88; H, 4.41; N, 2.13. Found: C, 22.01; H, 4.11; N, 2.08%. IR (KBr pellet, cm^{-1}) for **1**: ν(Mo–S): 465 (s); for **2**: ν(W–S): 451 (s). UV–Vis (MeCN) λ_{max}/nm (ε_{max}/M^{-1} cm^{-1}) for **1**: 491 (17200), 311 (67500), 262 (55900), 248 (55400); for **2**: 408 (20400), 289 (80400), 235 (54900).

2.3. Synthesis of $\{[Et_4N]_2[MS_4Cu_2(SSS)]\}_n$ (**3**, M = Mo; **4**, M = W)

A DMF solution (10 mL) of $[Et_4N]_2[MoS_4]$ (0.24 g, 0.5 mmol) and CuCl (0.10 g, 1.0 mmol) was stirred for 0.5 h. To this brown suspension was added K_2SSS (0.23 g, 1.0 mmol) and the brown precipitate gradually dissolved. After further stirring for 3.0 h, the resultant solution was filtered. Brown crystals of **3** (0.22 g) were isolated by vapor diffusion of ^{i}PrOH into the filtrate in a 60% yield. Cluster **4** was synthesized in a similar way as for **3** except that $[Et_4N]_2[WS_4]$ (0.29 g, 0.5 mmol) was used instead of $[Et_4N]_2[MoS_4]$ in a 56% yield. *Anal.* Calc. for **3**: C, 28.46; H, 5.27; N, 7.38. Found: C, 28.35; H, 5.06; N, 7.35%. *Anal.* Calc. for **4**: C, 25.50; H, 4.72; N, 6.61. Found: C, 25.43; H, 4.45; N, 6.60%. IR (KBr pellet, cm^{-1}) for **3**: ν(Mo–S): 467 (s); for **4:** ν(W–S): 453 (s). UV–Vis (MeCN) λ_{max}/nm (ε_{max}/M^{-1} cm^{-1}) for **3**: 505 (6100) (sh), 342 (10300), 290 (8900); for **4**: 422 (6500), 310 (10900).

2.4. Structure determinations

The crystallographic data for **2** and **4** are listed in Table 1. Intensity data were collected at room temperature on a Rigaku Mercury CCD area-detector diffractometer with a graphite monochromator utilizing Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods [8a] and refined on F^2 by full-matrix least-squares using the SHELXL-97 program package [8b]. All non-hydrogen atoms were refined anisotropically. The organic hydrogen atoms were generated geometrically (C–H 0.96 Å).

3. Results and discussion

3.1. Synthesis

Treatment of $[Et_4N]_2[MS_4]$ (M = Mo, W) with 2 equiv. of $CuSBu^t$ in acetonitrile leads to the formation of two molecular squares **1** and **2**. The formation of **1** and **2** was unexpected since the reactions of $[MS_4]^{2-}$ (M = Mo, W) with CuL normally give rise to linear cluster compounds, e.g. $[LCuMS_4CuL]^{2-}$ (L = CN, SCN,

Cl) [9–11]. Clusters **1** and **2** are the first examples where four $CuMS_4Cu$ fragments are linked by thiolato ligands to form a square structural configuration. By using bidentate bis-thiolato ligands, clusters with different structural types can be obtained. Thus treatment of polymeric anions $[MS_4(CuCl)_2]^{2-}$ (M = Mo, W, prepared in situ by the reaction of $[Et_4N]_2[MS_4]$ with 2 equiv. of CuCl in DMF) with K_2SSS (SSS = 1,3,4-thiadiazole-2,5-dithiolate) yields **3** and **4**, which are helical chain polymers. While polymeric linear chains of Mo(W)/Cu/S clusters are common, **3** and **4** appear to be the first polymeric helical chains in the Mo(W)/Cu/S system reported.

3.2. Infrared and UV–Vis spectra

The IR spectra of **1**–**4** show the typical absorptions for the W–S stretching vibrations in the range of 400–520 cm^{-1}, as reported for many other Mo(W)/Cu/S clusters [12]. The spectra of **1**–**4** each exhibits a single sharp band in this region indicates symmetrical coordination around the MS_4^{2-} core [13]. As a general trend for the Mo(W)–S stretching vibration, an obvious red-shift occurs when the number of coordinated hetero-metal atoms increased [14]. Moreover, for isostructural clusters, the Mo–S vibration bands are displayed a little to higher frequency than those of their corresponding W–S bonds [15]. For **3** and **4**, strong peaks arising from coordinated 1,3,4-thiadiazole-2,5-dithiolato ligands also appear at 1182, 1171, 1041 and 999 cm^{-1} [16].

The electronic spectra of **1**–**4** are dominated by three absorptions in the 235–505 nm range that are attributable to ligand-to-metal charge transfer transitions of the $[MS_4]^{2-}$ (M = Mo, W) moieties [17]. Compared with $[Et_4N][MoS_4]$, the longest wavelength absorptions of **1** (505 nm) are red-shifted due to the coordination of CuL units to the central MoS_4^{2-} core [18]. The electronic spectra of the W clusters are similar in profile, wavelength, and intensity of the absorption bands to that found in $(NH_4)_2WS_4$.

3.3. Cyclic voltammetry

The redox properties of clusters **1**–**4** in DMF solution have been studied by cyclic voltammetry. Compared to the studies of the clusters with MOS_3Cu_n (M = Mo, W; $n = 2, 3$) fragments, the reduction behavior of the clusters with MS_4 (M = Mo, W) is not so rich and has been rarely studied [18,19]. The cyclic voltammograms data of **1**–**4** and some relative compounds have been shown in Table 2. The waves ranging from 0.59 to 0.84 V are attributed to the irreversible oxidation of copper (I). The $E_{2(red)}$–$E_{5(red)}$ cathodic waves are associated with the irreversible reduction of M^{IV} (M = Mo, W).

3.4. Description of the crystal structure of $[Et_4N]_4[\{WS_4Cu_2(\mu\text{-}SBu^t)\}_4]$ (2)

The molecular structure of **2** is shown in Fig. 1 and selected bond lengths and angles are listed in Table 3. The 12 metals together with four sulfur atoms from $\{SBu^t\}^-$ ligands are nearly coplanar with the mean deviation of 0.07 Å. The configuration of twelve metal atoms and four S atoms of the thiolato ligands can be approximately described as a square, in which the S atoms form the corners of the square with the Cu–S–Cu angles being 85.9(1)° and 88.1(1)°. In each side of the

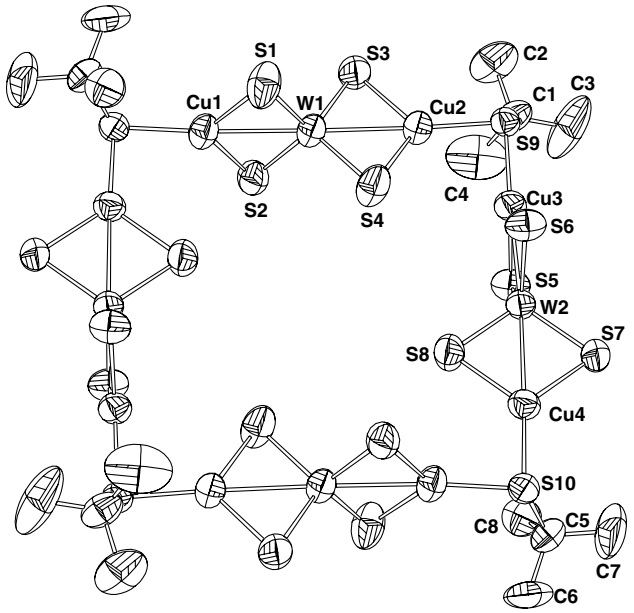

Fig. 1. Structure and labeling of the $[\{WS_4Cu_2(\mu\text{-}SBu^t)\}_4]^{4-}$ anion of **2** (50% probability displacement ellipsoids). The hydrogen atoms are omitted for clarity.

Symmetry transformations used to generate equivalent atoms: (i) $x+1, -y, -z+1$.

square, the (Bu^t)SCuS$_2$WS$_2$CuS(Bu^t) fragment is nearly linear, with the average Cu–W–Cu and S(Bu^t)–Cu–W angles being 176.88° and 174.60°, respectively. Each W atom of the structure is at the center of an essentially tetrahedral WS$_4$ unit in which the W–S bond lengths are almost equal. The WS$_4$ unit acts as a bidentate ligand to coordinate Cu atoms with the W–Cu bond lengths varying from 2.638(2) to 2.653(2) Å. These lie towards the shortest end of the reported range of W–Cu bond distances (2.621–2.784 Å) [20], indicating significant interactions between these heteronuclear metal atoms. In addition, weak interactions between adjacent Cu atoms are also found in the cluster [Cu(2)–Cu(3): 2.985(2); Cu(1)–Cu(4)^{i}: 3.058(2) Å]. All the Cu atoms are in an approximately trigonal environment with the sum of the S–Cu–S angles for each Cu ranging from 359.35° to 359.92°.

3.5. Description of the crystal structure of $\{[Et_4N]_2[WS_4Cu_2(SSS)]\}_n$ (**4**)

Cluster **4** contains linear CuS$_2$WS$_2$Cu fragments that are linked by bridging SSS^{2-} ligands to form a polymeric chain. An ORTEP drawing of a portion of the anion is shown in Fig. 2 and the important bond lengths and angles are listed in Table 4. The configuration of the polymeric anion can be viewed as a helical chain that propagates along the crystallographic *b* axis. For clarity, a simplified diagram with only metal atoms is given in Fig. 3. It is seen that the polymeric anion forms a helical chain with a pitch (length per turn) of 11.84 Å. Although many polymeric chains of Mo(W)/Cu/S clusters with other bridging ligands such as SCN$^-$ or halogen ligands have been reported, species with a helical configuration like **4** have not been previously observed. Each repeated CuS$_2$WS$_2$Cu unit involves short Cu–W distances [2.647(1) and 2.652(1) Å] and an approximately linear

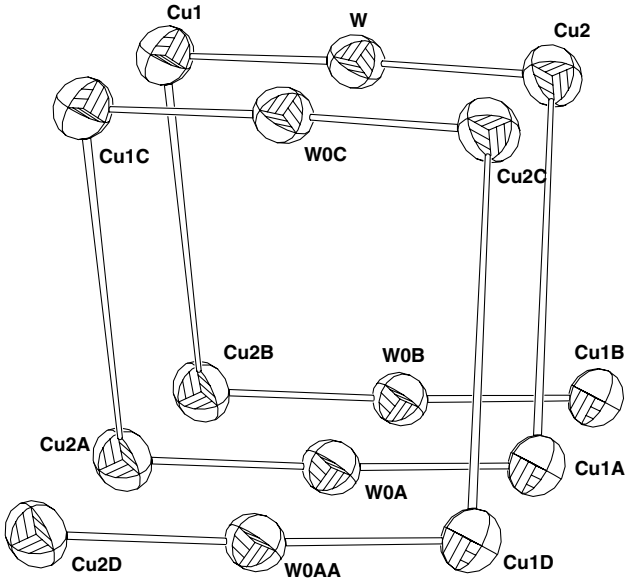

Fig. 3. Simplified diagram of the anionic helical chain of **4** (only metal atoms have been showed for clarity).

Cu–W–Cu array [176.20(3)°], as previously observed in the discrete complex anion of $[Ph_4P]_2[ClCuS_2WS_2CuCl]$ [11]. The tungsten atoms have an essentially tetrahedral geometry while the copper atoms adopt approximately trigonal planar geometries. For each SSS^{2-} ligand, the ring system and the thiolato sulfur atoms and two adjacent WS_2Cu planes are almost coplanar. Besides, all the sulphur atoms of SSS^{2-} ligands point to the center of the helix and the neighboring thiadiazoles are oriented in opposite directions along the chain.

4. Conclusion

By using linear CuS_2MS_2Cu (M = Mo, W) subunits as building blocks and thiolato ligands as linkers, we have successfully constructed four new Mo(W)/Cu/S clusters. With the monodentate SBu^{t-} ligand, molecular squares **1** and **2** have been isolated, respectively. However, with the bidentate bis-thiolato SSS^{2-} ligand, two helical chain polymers **3** and **4** were obtained. The correct choices of subunits and linkers appear critical for the construction of clusters with certain shapes. It should, therefore, be possible to make molecular squares with larger cavities or with other cluster geometries by choosing other Mo(W)/Cu/S building blocks and thiolato ligands.

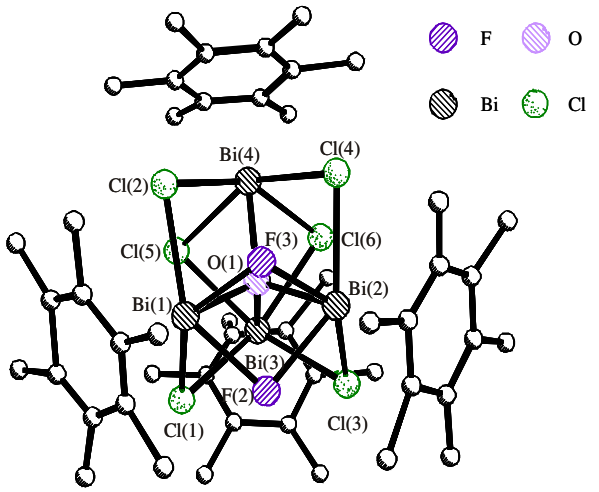

Fig. 1. The crystal structure of the $\{[Bi_4OF_2Cl_6](C_6Me_6)_4\}^{2+}$ cation.

found that the $[Bi_5][AsF_6]_3$ salt has sufficient solubility in SO_2 for the [17] metathesis reaction, replacing the $[AsF_6]^-$ anion (0.110 nm^3 [18]) by the larger $[Al(OC(CF_3)_3)_4]^-$ anion (0.758 nm^3 [19]). The estimated lattice energy of the $[Bi_5][Al(OC(CF_3)_3)_4]_3$ of 1571 kJ/mol is about 900 kJ/mol lower than that of the $[Bi_5][AsF_6]_3$ 2467 kJ/mol[1] and is therefore comparable in energy to those of the SO_2 soluble salts containing homopolyatomic cations of group 16, e.g., $U_{POT}([S_4][AsF_6]_2) = 1557$ kJ/mol, $U_{POT}([Se_4][AsF_6]_2) = 1544$ kJ/mol, $[Te_4][AsF_6]_2$, 1518 kJ/mol.[1]

2. Results and discussion

2.1. Reaction of $[Bi_5][AsF_6]_3$ and $Li[Al(OC(CF_3)_3)_4]$ in SO_2

The reaction of SO_2 soluble $Li[Al(OC(CF_3)_3)_4]$ and $NO[SbF_6]$ [17] gave the insoluble $Li[SbF_6]$ (s) and $NO[Al(OC(CF_3)_3)_4]$. In contrast the corresponding reaction of $Li[Al(OC(CF_3)_3)_4]$ and excess of the weakly soluble $[Bi_5][AsF_6]_3$ afforded insoluble $Li[AsF_6]$ and the reaction product $[Bi_x][Al(OC(CF_3)_3)_4]_3$ (**1**), x close to 4.33 according to the elemental analysis (Eq. (1)), contaminated with 10% of starting material $Li[Al(OC(CF_3)_3)_4]$, determined by quantitative ^7Li NMR

$$3Li[Al(OC(CF_3)_3)_4] + [Bi_5][AsF_6]_3 \xrightarrow{SO_2,r.t.} [Bi_x][Al(OC(CF_3)_3)_4]_3 + 3Li[AsF_6](s) \quad (1)$$

The bismuth containing product is very soluble in SO_2 and contains $[Al(OC(CF_3)_3)_4]^-$ anion [^{19}F, ^{27}Al NMR] showing that the anion has remained a spectator anion. The UV–Vis spectrum contained the band maxima (Table 1, column 2, actual spectra see S.I.) at 405, 450, 523 nm (Table 1) and 347 nm (shoulder) close to those of $[Bi_5]^{3+}$, $[Bi_8]^{2+}$ and probably $[Bi_9]^{5+}$ cations (Table 1) (a full interpretation of the UV spectra of $[Bi_5]^{3+}$, $[Bi_8]^{2+}$, $[Bi_9]^{5+}$ is given in [20]). The digital Gaussian deconvolution of the UV–Vis spectrum yielded the relative intensities of the bands allowing to calculate the molar absorptivities 5.1×10^3 (409 nm), 4.6×10^3 (453 nm), 3.1×10^3 (517 nm), 1×10^2 (804 nm), which are in agreement with the literature data for the $[Bi_5]^{3+}$ or $[Bi_8]^{2+}$ [24,7b,26]. Resolved bands arising from the presence of $[Bi]^+$ cation were not detected, however, a better fit of the calculated curve was obtained by postulating a weak band of $[Bi]^+$ 677 nm superimposed upon the more intense $[Bi_5]^{3+}$ (or $[Bi_8]^{2+}$) absorptions

$$3[Bi_5]^{3+} \overset{SO_2,r.t.}{\rightleftarrows} [Bi_8]^{2+} + 7[Bi]^+$$
$$2[Bi_5]^{3+} \rightleftarrows [Bi_9]^{5+} + [Bi]^+ \quad (2)$$

Thus, the SO_2 solution of the reaction product contained a mixture $[Bi_5]^{3+}$, $[Bi_8]^{2+}$, $[Bi_9]^{5+}$ and the $[Bi]^+$. The given cations could be generated by Eqs. (2) from the $[Bi_5]^{3+}$. We note that $[Sb_8][GaCl_4]$ was isolated from solutions of $SbCl_3$ in the Ga–$GaCl_3$–benzene system [21], whereas previously $[Bi_5]^{3+}$ and $[Bi]^+$ have been observed in Bi–$GaCl_3$–benzene solutions [7] and a products suggested to be $[M_5][GaCl_4]_3$ (M = Sb, Bi) were isolated from the MCl_3–Ga–$GaCl_3$ molten salt systems [4c].

The major IR absorption bands of the reaction products are due to the nonafluorobutoxide ligands. The bands at 832, 864 cm^{-1}, which are not observed in the spectrum of $Li[Al(OC(CF_3)_3)_4]$ have been assigned [22] to the Al–O vibrations of **1**. Energies of these bands are close to those of $Li[Al(OC(CF_3)_3)_4]$ (S.I., Section 2) with differences ca. 10 cm^{-1}. Thus, the local geometry around the Al atom in **1** is distorted and lower symmetry than tetrahedral, much like that in the $Li[Al(OC(CF_3)_3)_4]$, as the bismuth cation could have strong Bi–F and Bi–O contacts reminiscent of those of $[Li]^+$ in $Li[Al(OC(CF_3)_3)_4]$[2] [23].

2.2. Reaction of $[Bi_5][AsF_6]_3$ with $Li[Al(OC(CF_3)_3)_4]$ and C_6Me_6 in CH_2Cl_2

The metathesis reaction of $[Bi_5][AsF_6]_3$ and $Li[Al(OC(CF_3)_3)_4]$ in the presence of C_6Me_6 in CH_2Cl_2 yields dark brown, $Li[Al(OC(CF_3)_3)_4]$ free, highly soluble regularly

[1] Lattice energies have been calculated using the volume-based equation given in [18]. Volume of $[Bi_5]^{3+}$ 0.143 nm^3 was obtained by subtracting the three volumes of $[AlCl_4]^-$ anion 0.156 nm^3 from the molecular volume of the $[Bi_5][AlCl_4]_3$ 0.611 nm^3 [4b]. Volume of the $[AsF_6]$ was taken from [18], lattice energies of $[M_4][AsF_6]_2$ M = S, Se, Te were taken from [18].

[2] $[Li]^+$ in the $Li[Al(OC(CF_3)_2Ph)_4]$ [23a] and $Li[Al(OC(CF_3)_3)_4]$ [23b] is coordinated to the 2 oxygen and 4 fluorine atoms of the ligand, lowering the local symmetry around aluminium atom from T_d to C_{2v}.

Table 1
UV–Vis bands (nm) found in this study for product of interaction of $[Bi_5][AsF_6]_3$ and $Li[Al(OC(CF_3)_3)_4]$ in SO_2 (A), and for compound **4** in DCE – dichloroethane compared with the literature data on cationic bismuth clusters

A in SO_2	**4** in DCE	$[Bi_5]^{3+}$ in H_2SO_4 [4d]	$[Bi_5]^{3+}$ in NaCl–$AlCl_3$ [24]	$[Bi]^+$ in NaCl–$AlCl_3$ [24,25]	$[Bi]^+$ in $GaCl_3$–NaCl [7b]	$[Bi_8]^{2+}$ in Bi–$GaCl_3$ (175 °C) [7b]	$[Bi_8]^{2+}$ in $AlCl_3$–NaCl (250 °C) [26]	$[Bi_9]^{5+}$ in MeBzImCl/$AlCl_3$ melt [20]
347 [0.71] (9.4×10^3)	348 (8.7×10^3)	362 (2.39×10^3)	345[b]				350 (1.2×10^3)

[d]	875[c] (4×10^2)	821 (1.8×10^2)	875 (5.0×10^2)					

Absorption maxima are given in nm with molar absorptivities in brackets and relative intensities in square brackets.
[a] Band maxima is not resolved and obtained only by Gaussian deconvolution.
[b] Observed in the reflectance spectrum.
[c] Very broad signal.
[d] Instrumental cut off at 820 nm.
[e] Relative intensities and molar absorptivities are not given.

shaped crystals, which did not diffract X-rays. The reaction product is interpreted as a salt containing the $[Bi_5]^{3+}$ cation, e.g., $[Bi_5(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_3$ (**2**) based on the elemental analysis (Eq. (3))

$$3Li[Al(OC(CF_3)_3)_4] + [Bi_5][AsF_6]_3 + 4C_6Me_6 \xrightarrow[+5\,^\circ C]{CH_2Cl_2} [Bi_5(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_3 + 3Li[AsF_6] \quad (3)$$

2

The UV–Vis spectrum (Table 1, spectrum is shown in the S.I. Figs. 8 and 9) of **2** in $C_2H_4Cl_2$ was consistent with $[Bi_5]^{3+}$, $[Bi_8]^{2+}$, $[Bi_9]^{5+}$ cations in solution as well as $[Bi]^+$. Reported band maxima of $[Bi_5]^{3+}$ and $[Bi_8]^{2+}$ and that at 450 nm for the $[Bi_9]^{5+}$ are close to each other, hence these cations might be in equilibrium with **2** (Eq. (2)) in $C_2H_4Cl_2$. The molar absorptivities of $[Bi_5]^{3+}$ in **2** are in the same range but higher, as those of $[Bi_5]^{3+}$ in NaCl–$AlCl_3$ melts, strongly supporting our assignment of the bands to $[Bi_5]^{3+}$ and the presence of $[Bi]^+$, $[Bi_8]^{2+}$ and probably $[Bi_9]^{5+}$.

The IR absorption bands of C_6Me_6 in **2** are slightly shifted from those of C_6Me_6 (Tables 2 and 3), implying weak interaction between the bismuth cation and C_6Me_6. In addition, the IR spectrum contains only one Al–O band 832 cm^{-1} in the range 800–900 cm^{-1} [22] consistent with T_d site symmetry around the aluminium atom and very weak cation–anion interaction in **2**.

2.3. Evidence for $[Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2 \cdot C_6Me_6$

Crystals of **2** $\{[Bi_5(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_3\}$ were deposited from the reaction mixture during a period of 1–6 days. For the next 10 days, crystals of **2** were contaminated with yellow crystals assigned to **3** and $[C_6Me_6H][Al(OC(CF_3)_3)_4]$[3] and after an additional 5 days only yellow and orange crystals of **3**, $[C_6Me_6H][Al(OC(CF_3)_3)_4]$ and colourless crystals[4] were obtained.

We propose that the homopolyatomic cations generated in the metathesis reaction in CH_2Cl_2 are very chem-

[3] Yellow crystals **4** refined in *C*1, $a = 9.825$, $b = 20.046$, $c = 21.148$, $\alpha \approx \beta \approx \gamma \approx 90°$, $Z = 2$ to the *R* factor close to 25% and was consistent with the presence of $[Al(OC(CF_3)_3)_4]^-$ and $\{C_6Me_6\}$ or ($[C_6Me_6H]^+$) moieties. Problem of disordering $-C(CF_3)_3$ groups in the anion precluded further refinement. It could be $Li[Al(OC(CF_3)_3)_4] \cdot C_6Me_6$ or $[C_6Me_6H][Al(OC(CF_3)_3)_4]$. A ^7Li resonance was not observed at r.t. and low temperature for the solution of yellow reaction product, hence $[C_6Me_6H][Al(OC(CF_3)_3)_4]$ formulation seems to be more feasible, additional IR evidence of $[C_6Me_6H]^+$ is described in Section 4.

[4] Colourless crystals that deposits from solution in a period of 1 month at −24 °C refined in *C*1, $a = 14.330(2)$, $b = 18.114(3)$, $c = 22.492(4)$, $\alpha = 84.252(2)$, $\beta = 72.851(2)$, $\gamma = 82.616(2)$, $Z = 4$ to the *R* factor close to 20%. The proposed structure obtained at this point of refinement consistent of $[Al(OC(CF_3)_3)_4]^-$ and $[Al_7O_4F_{14}]^-$ and/or $[Al_7O_3F_{15}]$ moieties. Problem of disordering $-C(CF_3)_3$ groups in the anion precluded further refinement.

Table 2
Raman of **2**, bands of $[Al(OC(CF_3)_3)_4]^-$ anion (assignment see [17,22b,22c]) are omitted for clarity

Observed band	Literature data	Assignment

		1596		$[C_6Me_6H]^{+a}$

[a] Band at 1590 cm^{-1} is one of the characteristic benzoid C=C skeletal stretching modes of the carbocation [48].

ically active and abstract oxygen and fluorine from the nonafluorobutoxide ligand of the $[Al(OC(CF_3)_3)_4]^-$ anion and chlorine from the CH_2Cl_2 (see S.I. for a detailed discussion). Abstraction of oxygen and fluorine from the $[Al(OC(CF_3)_3)_4]^-$ was observed previously by degradation of phosphorus iodine cations[5] [27]. Bismuth alkoxides $Bi(OR_f)_3$ $R_f = (C_6H_2(CF_3)_3)$ [28,29] decomposed with C–F activation. C–Cl activation by electrophilic metal centers followed by the chlorine transfer to the metal have been observed for a wide range of metals [30] (e.g., for $CHCl_3$ by the rhodium complex $LRh(CO)_2$ L = tris(3,5-dimethyl,4-chloropyrazolyl)borate [30a]).

The salt **3** · C_6Me_6 (Fig. 1) is the first example of a 1:2 salt of the bulky polyfluoroalkoxyaluminate anion, the first example of a discrete oxygen-centered tetrahedral arrangement of group 15, and a rare example of a Bi(III) fluoride complex [31,32]. Four-coordinate oxygen centers have been reported in bismuth alkoxide clusters having complex oligomeric structures (i.e., $Bi_4(\mu_4\text{-}O)(\mu\text{-}OR)_6\{\mu_3\text{-}OBi(\mu\text{-}OR)_3\}_2(C_6H_5CH_3)$) [33] as well as for main group [34,35], d-block [36,37] and f-block [38,39] metal complexes. The structure of **3** · C_6Me_6 was obtained from crystals of poor quality, albeit many unsuccessful attempts made to improve their quality. However, the connectivity in $[Bi_4OF_2Cl_6]^{2+}$ has been established and the data clearly show the presence of C_6Me_6 and the $[Al(OC(CF_3)_3)_4]^-$ anion. The quality of the X-ray structure does not allow unambiguous assignment of the bridging light atoms as oxygen or fluorine within the $Bi_4X_2Cl_4Y$ core and the atom type assignment has been made based on chemical arguments – bond valence theory, ESR and NMR data. The sum of four Bi–O(1) contacts is 2.17 v.u. and consistent with a valence of 2 for oxygen, while four Bi–(F1) contacts would give 1.64 v.u.[6] [40] for fluorine, strongly supporting the assignment of the central atom as oxygen. In addition, a Bi_4F_5 would result in a mixed oxidation state for bismuth and 1 unpaired electron for the dication. However, an ESR signal was not detected for the solid sample, as well as a solution of **3** · C_6Me_6. The same method was applied to assign F2 and F3. The sum of two Bi–F(2), Bi–F(3) contacts is 0.71 and 0.67 v.u., while two Bi–O(2) and Bi–O(3) contacts would give 0.97 and 0.95 v.u., hence bridging atoms are most likely fluorine. In addition, the fluorine NMR spectrum of the freshly prepared SO_2 solution of **3** · C_6Me_6 at −70 °C shows major ^{19}F and ^{27}Al NMR resonances of the $[Al(OC(CF_3)_3)_4]^-$ anion and a minor singlet resonance at −220.5 ppm in the ^{19}F NMR attributed to the fluorine atoms in the $[Bi_4OF_2Cl_6]^{2+}$ cation.

The dication contains four bismuth atoms at the apex of an oxygen centered distorted tetrahedron, linked across the edges by bridging halogen atoms (Figs. 2 and 3). The Bi1–F–Bi2 and Bi(1,2)–Cl–Bi(3,4) angles in **3** are close to 90° within 2° and the Bi3–Cl–Bi4 angles are 83.0(4)° and 85.0(4)°. Also, the estimated Bi4–Bi3 distance is 3.602(1) Å, shorter than the Bi1–Bi2 and Bi3–Bi4 contacts 3.93(±0.04) Å. Each bismuth atom is capped by a weakly bound η^6 C_6Me_6 ring[7] [41,42]

[5] The proposed [27a,27b] decomposition mechanism of the salt of $[P_2I_3]^+$ involved the formation of a tight ion pair $[P_2I_3]^+[Al(OC(CF_3)_3)_4]^-$ followed by liberation of $[P_2I_3][OC(CF_3)_3]$ and the very strong Lewis acid $Al(OC(CF_3)_3)_3$ which abstract fluorine from the $[OC(CF_3)_3]$ and react with the $[Al(OC(CF_3)_3)_4]^-$ forming dimeric anion $[(OC(CF_3)_3)_3Al(\mu\text{-}F)Al(OC(CF_3)_3)_3]^-$. The phosphorus iodine cation abstract oxygen from the $[OC(CF_3)_3]$ forming P_2O_3, P_4, C_4F_8. The final products of decomposition were $[P_2I_3][(OC(CF_3)_3)_3Al(\mu\text{-}F)Al(OC(CF_3)_3)_3]$, phosphorus oxide, phosphorus alkoxide, P_4 and fluorocarbon species.

[6] Values used: Bi(+3)–F(−1) $R_o = 1.99$, $B = 0.37$, Bi(+3)–O(−2) $R_o = 2.094$, $B = 0.37$, Bi(+3)–Cl(−1) $R_o = 2.48$, $B = 0.37$.

[7] The separation distances between Bi(1) and C(301)–C(306) aromatic ring 2.69 Å, Bi(2) and C(101)–C(106) aromatic ring 2.67 Å, Bi(3) and C(401)–C(406) aromatic ring 2.75 Å, Bi(4) and C(201)–C(206) aromatic ring 2.61 Å.

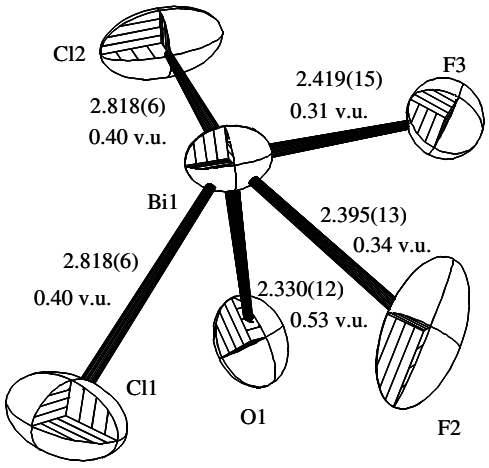

Fig. 2. Environment of the Bi(1) atom in **3**, neighbouring bismuth atom and C_6Me_6 molecules are omitted for clarity.

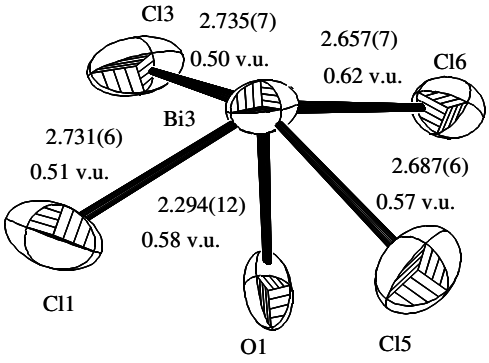

Fig. 3. Environment of the Bi(3) atom in **3**, neighbouring bismuth atom and C_6Me_6 molecules are omitted for clarity.

approximately perpendicular to the corresponding Bi–O bond as illustrated in Fig. 1. The bismuth halogen dication core may be formally regarded as constructed from one $[BiF_2]^+$ moiety, three $[BiCl_2]^+$ units, and $[O]^{2-}$ which donates electron density to the four bismuth atoms with the sum of the Bi–O valency units calculated at 2.14(2) v.u.[6] [40].

In VESPR terms [43], the first coordination around Bi1 and Bi2 can be described as $AX_2X'_2YE$ (X = Cl, X′ = F, Y = O, E = lone pair) and that of Bi3 and Bi4 as AX_4YE illustrated for Bi1 and Bi3 in Figs. 2 and 3, respectively, which include bond distances and valence units. The corresponding figures for Bi2 and Bi4 are included in the Supplemental materials. All the F–Bi–F, F–Bi–Cl, Cl–Bi–Cl, O–Bi–F and O–Bi–Cl angles in **3** are in the range 72.3–76.4°. The sum of the valence units around Bi3 is 2.78 v.u. (Bi1 is 1.98 v.u., Bi2 2.05 v.u., Bi4 2.66 v.u.), the remaining Bi valence units are derived from the donation of electrons from the C_6Me_6 ring to the positively charged bismuth in to the second coordination sphere of bismuth.

We have estimated the lattice energy $U_{POT}([Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2)$ as 912 kJ/mol[8] [44]. This is significantly larger than that of 1:1 salt with the same anion, $U_{POT}(Li[Al(OC(CF_3)_3)_4])$ 361 kJ/mol [19], but smaller than the 1:2 salts $U_{POT}(Ca[NO_3]_2)$ 2209 kJ/mol and $U_{POT}(MgI_2)$ 1944 kJ/mol [18 (Table 2)]. Therefore, the higher solubility of $\mathbf{3}\cdot C_6Me_6$ in SO_2 compared with the poor solubility of $Ca(NO_3)_2$ and MgI_2 may arise from the smaller lattice energy of 1:2 salts with the large anion.

The X-ray microanalysis confirms that $\mathbf{3}\cdot C_6Me_6$ contains Bi and Cl, as well as Al, F, C and O (S.I.). The EI-MS shows $[C_6Me_6^+]$ and as well as fluorocarbon cations derived from $[Al(OC(CF_3)_3)_4]^-$ on decomposition of $\mathbf{3}\cdot C_6Me_6$. The IR spectrum of $\mathbf{3}\cdot C_6Me_6$ contains very strong absorption bands of the perfluorinated ligand of the anion. One Al–O band of the $[Al(OC(CF_3)_3)_4]^-$ anion was detected at 833 cm^{-1} consistent with an almost tetrahedral symmetry at the aluminium center. The observed absorption bands of the C_6Me_6 in $\mathbf{3}\cdot C_6Me_6$ (Table 3) are shifted slightly higher in energy, relative to the band for free C_6Me_6 [47], due to coordination to the $[Bi_4OF_2Cl_6]^{2+}$ cation. For comparison, the Ln(III) complexes $[LnCl_2(C_6Me_6)][AlCl_4]_3$ Ln = Nd, Sm, Gd, Yb exhibit the out of plane mode at 770–780 cm^{-1} and $\nu(CH_3)$ vibrations at 1010–1030 cm^{-1} [45], close to those of **3**.

3. Conclusions

Evidence is presented that we have prepared the SO_2, CH_2Cl_2 and $C_2H_4Cl_2$ soluble salts $[Bi_x][Al(OC(CF_3)_3)_4]$ (**1**) and $[Bi_5(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_3$ (**2**), in a moderate yields by the metathesis reaction between $[Bi_5][AsF_6]_3$ and $Li[Al(OC(CF_3)_3)_4]$ in SO_2 solution and in a solution of CH_2Cl_2 that contained C_6Me_6. This implies that the metathesis reaction in the presence of appropriate donor ligand (arene) in SO_2 and CH_2Cl_2 may generate several of the related salts containing bismuth polyatomic cations. The UV–Vis of solutions of **1** in SO_2 and **2** in $C_2H_4Cl_2$ were consistent with the presence of $[Bi_5]^{3+}$, $[Bi_8]^{2+}$, $[Bi_9]^{5+}$ and $[Bi]^+$.

The bismuth homopolyatomic cations were shown to be chemically reactive and the novel 1:2 salt $[Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2\cdot C_6Me_6$ containing the bismuth cluster cation $[Bi_4OF_2Cl_6]^{2+}$ was isolated from a solution of **2** in CH_2Cl_2. Formation of $[Bi_4OF_2Cl_6]^{2+}$ may be regarded as a self assembly of bismuth halide and oxohalide moieties, however, it is difficult to assess

[8] The volume of the C_6Me_6 ($V_m = 0.252$ nm^3) [44] was subtracted from the volume of $\mathbf{3}\cdot C_6Me_6$ ($V_m = 3.402$ nm^3), obtained from crystallographic data in order to provide the volume of **3** ($V_m = 3.150$ nm^3). The obtained volume was used for calculation of U_{POT}(**3**) using Eq. (3) [18] and parameters $\alpha = 133.5$, $\beta = 60.9$.

the features that governed the $[Bi_4OF_2Cl_6]$ stoichiometry by decomposition of the bismuth homopolyatomic cations under the prevailing experimental conditions. We propose that the process involved fluorine and oxygen transfer from the nonafluorobutoxide ligand and chlorine transfer from the CH_2Cl_2 and conclude that the bulky anion facilitates the formation of a discrete oxygen-centered fluorine- and chlorine-bridged bismuth cluster in a complex with hexamethylbenzene.

4. Experimental

4.1. General remarks

All operations were performed using standard Schlenk line techniques under a purified nitrogen atmosphere. Solid reagents and crystals were manipulated in a Vacuum Atmospheres Dri-Lab equipped with a Dri-Train (HE-493) and 1 kg of 3 Å molecular sieves contained in an internal circulating drying unit. Reactions in SO_2 were carried out in a jointless, single apparatus fitted with Teflon in glass Rotoflo valves (HP 6K) and consisting of two thick walled bulbs ($V = 50$ ml) linked by a glass tube incorporating a sintered fine-porosity glass frit. The compounds $[Bi_5][AsF_6]_3 \cdot SO_2$ and $Li[Al(OC(CF_3)_3)_4]$ were prepared by the literature methods [23a,4d] and the identity of $[Bi_5][AsF_6]_3 \cdot SO_2$ was supported by IR. The IR spectrum of $Li[Al(OC(CF_3)_3)_4]$ included in the S.I. has not been previously reported. Sulfur dioxide was dried over P_2O_5 and distilled prior to use. CH_2Cl_2 and $CDCl_3$ were dried over CaH_2 and degassed. NMR spectra were recorded using Varian 400 NMR spectrometer. Proton and ^{13}C chemical shifts are reported in δ units downfield from Me_4Si with the solvent as the reference signal. $CClF_3$ was used as a reference for ^{19}F spectra and aqueous solutions of $AlCl_3$ and $Li[ClO_4]$ were used as a references in ^{27}Al and ^{7}Li NMR spectra, respectively. NMR samples were prepared in 10 and 5 mm thick walled NMR tubes fitted with J. Young valves. Mass spectra were recorded using a KRATOS ms 50 TC mass spectrometer equipped with the EI source, 30 ev. by the direct inlet method from samples sealed in dried glass m.p.t. tubes. FT-IR spectra (resolution 1 cm^{-1}, 128 scans) were recorded using a Thermo Nicolet spectrometer (Nexus 470 FT-IR). FT-Raman spectra were obtained from neat samples, sealed under nitrogen atmosphere in glass capillaries, using Bruker RFS 100 FT-Raman spectrometer incorporating a Nd:YAG laser (emission wavelength: 1.06 μm; maximum output laser power: 80 mW), 1000 scans, resolution 4 cm^{-1}. We attempted to record FT-Raman spectra of all species; however, the coloured samples **1** and **3** showed fluorescence, compound **2** gave a Raman spectrum with a low signal-to-noise ratio. The UV–Vis spectrum of **1** in SO_2 was measured using HP-8452A diode array spectrophotometer, at room temperature, 300–820 nm range, 14 mg of solid containing 90% **1** and 10% $Li[Al(OC(CF_3)_3)_4]$ in (6 g, 4.11 ml) of SO_2 0.1 cm cell. The compound **2** were measured using a Cary 5E UV–Vis–NIR spectrometer, at room temperature, in 0.2 cm cells. Two spectra, one containing data collected from 3000 to 400 nm and one from 800 to 300 nm were measured using 23.5 mg of sample **2** and 3.8636 g of $C_2H_4Cl_2$. Melting points were measured in sealed capillary tubes under nitrogen and are not corrected. X-ray microanalysis was performed with a JEOL JSM-6400 SEM, equipped with an Edax Genesis X-ray micro analyser. Operating conditions: vacuum close to 10^{-6} Torr, accelerating voltage 15 kV, probe current 1.5 nA, spectra collection time 60 s. Samples were coated with carbon, using an Edwards vacuum evaporator. Elemental analysis was carried out by Galbraith Laboratories, Inc.

$wR_2 = (\sum[w(F_o^2 - F_c^2)^2]/\sum[F_o^4])^{1/2}$, $R_1 = \sum||F_o| - |F_c||/\sum|F_o|$, weight $= 1/[\sigma^2(F_o^2) + (0.0745 * P)^2]$; where $P = (\max(F_o^2, 0) + 2 * F_c^2)/3$.

4.2. Preparation of salts **1**

A dried two bulbed (50 ml) vessel equipped with Teflon in glass with Rotoflo valves (HP 6K), was charged with the $Li[Al(OC(CF_3)_3)_4]$ (0.8 g, 0.8 mmol) and $[Bi_5][AsF_6]_3 \cdot SO_2$ (2.7 g, 1.6 mmol). SO_2 (15 ml) was condensed onto the mixture of reagents at −196 °C. The resulting mixture was rigorously stirred at r.t. for 5 days. A dark brown solution was filtered from 2.6 g of yellow insoluble solid and SO_2 was removed under dynamic vacuum to give a brown solid. Yield: 0.9 g, 70% based on the Eq. (1). The relative amount of $Li[Al(OC(CF_3)_3)_4]$ in the reaction product was established as 10% by measuring the intensity of the ^{7}Li NMR resonance relative to that in the spectrum of a solution of $Li[Al(OC(CF_3)_3)_4]$ in SO_2 at a known concentration. **1** could be a mixture of individual compounds. Result of elemental analysis could be interpreted based on the model 90% of $[Bi_5(SO_2)_3][Al(OC(CF_3)_3)_4]_3$ and 10% of $Li[Al(OC(CF_3)_3)_4]$ or alternatively $[Bi_{4.33}][Al(OC(CF_3)_3)_4]_3$ and 10% of $Li[Al(OC(CF_3)_3)_4]$: Calc. C, 14.49; Bi, 22.73; F, 51.65. Found: C, 14.24; Bi, 21.41; F, 51.73%. EI-MS (30 eV, heating r.t. −170 °C): *m/z* (%) = 706 (1) [An^+–$C_3F_{11}O$], 691 (1) [An^+–$C(CF_3)_3$–3F], 504 (30) [An^+–$C(CF_3)_3$–$3CF_3$–2F], 489 (10) [An^+–L–$C_3F_{10}O$], 371 (2) [An^+–2L–CF_3–3F], 302 (4) [An^+–2L–$2CF_3$–3F], 287 (12) [An^+–$2C(CF_3)_3$–$3CF_3$–2F], 64 (25) [SO_2^+], An = $[Al(OC(CF_3)_3)_4]$, L = $OC(CF_3)_3$, non-volatile solid residue left, calculated theoretical isotopes distribution matched that experimentally observed for all peaks. ^{27}Al NMR (104.2 MHz, SO_2, r.t.), δ_{Al} (ppm) = 32.5 (s, $[Al(OC\text{-}(CF_3)_3)_4]^-$). ^{19}F NMR (376.3 MHz, SO_2, r.t.), δ_F (ppm) = −72.4; −74.1 decomposition products of $[Al(OC(CF_3)_3)_4]^-$, −74.9 (s, $[Al(OC(CF_3)_3)_4]^-$); IR (KBr, cm^{-1}, Nujol): 1377 (s), 1364 (m), 1355 (s), 1299 (s), 1273 (s), 1247 (s), 1215 (s), 1173 (s), 1120 (m), 972 (vs), 892 (w), 864 (w), 841 (m), 832 (m), 798 (m), 781 (w), 770 (w), 760 (w), 755 (w), 744 (w), 726 (vs), 620 (w), 580 (m), 571 (m), 561 (m), 550 (w), 537 (s), 480 (m), 450 (m), 397 (w).

Note: The metathesis reaction between the poorly SO_2 soluble $[Bi_5][AsF_6]_3$ and 2,3 equivalents of highly soluble $Li[Al(OC(CF_3)_3)_4]$ in SO_2 followed by removal of the insoluble products afforded a mixture of $[Bi_x][Al(OC(CF_3)_3)_4]$ and $Li[Al(OC(CF_3)_3)_4]$ (IR, ^{7}Li NMR, EI-MS), with the $Li[Al(OC(CF_3)_3)_4]$ as the major product.

4.3. Preparation of $[Bi_5(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_3$ (**2**)

A mixture of $Li[Al(OC(CF_3)_3)_4]$ (1.87 g, 1.9 mmol), $[Bi_5][AsF_6]_3$ (3.1 g, 1.9 mmol) and C_6Me_6 (0.6 g, 3.8 mmol) in a 100 ml Schlenk flask was stirred in CH_2Cl_2 (40 ml) for 4 h. The dark brown solution was filtered and concentrated to approximately 4 ml and held at −24 °C for 2 days. The dark brown (almost black) crystals that formed were separated by filtration. The next crop of the crystalline dark brown solid was obtained from the supernatant solution by crystallization at −24 °C for 2 days. Yield of $[Bi_5(C_6Me_6)_4][Al(OC\text{-}(CF_3)_3)_4]_3$ (1.64 g, 55% based the $Li[Al(OC(CF_3)_3)_4]$). $C_{96}H_{72}F_{108}O_{12}Al_3Bi_5$: Calc. C, 25.07; H, 1.56; F, 44.66; Al, 1.76; Bi, 22.74. Found: C, 24.84; H, 2.01; F, 43.80; Al, 1.26; Bi, 23.91%. 184–186 °C decomposition. EI-MS (30 eV, heating r.t. −170 °C): *m/z* (%) = 197 (5) [$L^+ - 2F$], 167 (17) [$L^+ - CF_3$], 162 (100) [$C_6Me_6^+$], 147 (12) [$L^+ - CF_4$], 97 (15) [$L^+ - C_2F_3O$], L = $OC(CF_3)_3$. A non-volatile solid residue remained. ^{27}Al NMR (104.2 MHz, SO_2, r.t.); δ_{Al} (ppm) = 31.6. ^{19}F NMR (376.3 MHz, SO_2, r.t.), δ_F (ppm) = −75.9 (s); ^{13}C NMR (100.6 MHz, SO_2, r.t.), δ_C (ppm) = 16.5 (C_6Me_6), 121.7 (q, $C(CF_3)_3$, J = 291 Hz), 134.3 (C_6Me_6); ^{1}H NMR (400 MHz, SO_2, r.t.), δ_H (ppm) = 5.2 (s), 4.7 (s), 3.3 (s), 3.1(s), 2.8 (s), 2.6 (s, C_6Me_6 in complex, major signal, relative intensity 85%), 2.5 (s), 2.1 (s), 2.0 (s). The 5.2–2.7 and 2.1–2.0 ppm minor resonances are assigned to the products of oxidation of C_6Me_6, see Supplemental materials, relative intensity is measured relative to all resonances in spectrum; IR of **2** (KBr, cm^{-1}, Nujol): 1301 (vs), 1276 (vs), 1241 (vs), 1216 (vs), 1165 (s), 1135 (m), 1074 (w, C_6Me_6, Table 5), 1062 (w, C_6Me_6), 1018 (vw, C_6Me_6), 973 (vs), 832 (m, Al–O), 793 (w, C_6Me_6), 755 (w), 728 (vs), 571 (w), 561 (m), 537 (m), 447 (m).

Note: keeping the supernatant solution longer than 5 days at −24 °C lead to formation of yellow crystals **3**, **4** and a grey powder Bi (X-ray elemental microanalysis).

4.4. Isolation of $[Bi_4OF_2Cl_6(C_6Me_6)_4]$-$[Al(OC(CF_3)_3)_4]_2 \cdot C_6Me_6$ **3** $\cdot C_6Me_6$: and $[C_6Me_6H][Al(OC(CF_3)_3)_4]$ (**4**)

A mixture of $Li[Al(OC(CF_3)_3)_4]$ (1.5 g, 1.5 mmol), $[Bi_5][AsF_6]_3$ (0.86 g, 0.5 mmol) and C_6Me_6 (0.4 g, 2.5 mmol) in CH_2Cl_2 (40 ml) was stirred for 4 h in a 100 ml Schlenk flask. The dark brown solution was filtered and concentrated to approximately 10 ml and left at −24 °C for 2 weeks. Yellow crystals, a red-brown solid and a grey powder (Bi, X-ray elemental microanalysis) deposited. The solution was filtered and concentrated to 2–3 ml and held at −24 °C for 3 weeks. Orange crystals (yellow as a powder) formed and were separated manually (0.45 g) from the reaction products. The resulting crystals were a mixture of **3** $\cdot C_6Me_6$, **4** (yellow)[3] and colourless crystals,[4] the presence of the $[C_6Me_6H]^+$ cation was confirmed by IR. Result of elemental analysis was interpreted based on the model 75% of **3** $\cdot C_6Me_6$ and 25% of **4**: Calc. C, 28.93; H, 2.17; F, 42.88. Found: C, 30.31; H, 2.16; F, 42.89%.

Compound $[Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2 \cdot C_6Me_6$ **3** · C_6Me_6: EI-MS (30 eV, heating r.t. −170 °C): *m/z* (%) = 679 (4) [An^+–$C(CF_3)_3$–CF_3], 477 (20) [An^+–L–$C(CF_3)_3$–2F], 461 (10) [An^+–2L–2F], 447 (2), [An^+–$2C(CF_3)_3$–C_2F_4], 443 (10) [An^+–L–$C(CF_3)_3$–CF_3], 162 (100) [$C_6Me_6^+$], non-volatile black solid residue remained; ^{19}F NMR (376.3 MHz, $CDCl_3$, r.t.), δ_F (ppm) = −74.1 (s), −75.3 (s); ^1H NMR (400 MHz, $CDCl_3$, r.t.), δ_H (ppm) = 3.8 (s), 2.3 (s). The compound was very poorly soluble in $CDCl_3$, initially dissolved in SO_2 followed by the deposition of a solid over 10–30 min. NMR spectra were measured for the freshly prepared clear SO_2 solution at low temperature. ^{19}F NMR (376.3 MHz, SO_2, −70 °C), δ_F (ppm) = −73.9 (s), −75.0 (s), −75.5 (s), −195.1 (s, Al–F), −220.6 (s, Bi–F); ^1H NMR (400 MHz, SO_2, −70 °C), δ_H (ppm) = 7.4 ($\Delta\omega_{1/2}$ 91 Hz), 4.9 ($\Delta\omega_{1/2}$ 13 Hz, 2H, $C_6Me_5H_2OC(CF_3)_3$), 4.56 (s, $\Delta\omega_{1/2}$ 1.3 Hz, 2H, $(C_6Me_6)_2CH_2$), 3.20 ($\Delta\omega_{1/2}$ 3 Hz, weak), 3.13 ($\Delta\omega_{1/2}$ 3 Hz, 3H, C_6Me_5-$CH_2OC(CF_3)_3$), 3.05 ($\Delta\omega_{1/2}$ 3 Hz, 3H, $(C_6Me_6)_2CH_2$), 2.95 ($\Delta\omega_{1/2}$ 3 Hz, 6H, $C_6Me_5CH_2OC(CF_3)_3$), 2.86 ($\Delta\omega_{1/2}$ 3 Hz, 6H, $(C_6Me_6)_2CH_2$), 2.64 ($\Delta\omega_{1/2}$ 3 Hz, 6H, $C_6Me_5CH_2OC(CF_3)_3$), 2.58 ($\Delta\omega_{1/2}$ 3 Hz, 6H, $(C_6Me_6)_2$-CH_2), 2.40 ($\Delta\omega_{1/2}$ 9 Hz), 1.85 ($\Delta\omega_{1/2}$ 3 Hz, weak), 1.76 ($\Delta\omega_{1/2}$ 3 Hz C_6Me_6 or $[C_6Me_6H]^+$), 0.47–0.35 (aliphatic protons). ^{27}Al NMR (104.2 MHz, CH_2Cl_2, r.t.); δ_{Al} (ppm) = 31.6 (s). IR (KBr, cm^{-1}, Nujol): 1593 (w), 1300 (vs), 1277 (vs), 1251 (vs), 1240 (vs), 1218 (vs), 1165 (s), 1102 (w, C_6Me_6), 1069 (w, C_6Me_6), 1022 (w, C_6Me_6), 973 (vs), 831 (m), 780 (sh, C_6Me_6), 728 (w), 623 (w, Al–F*), 610 (w, Al–F*), 569 (w), 560 (m), 537 (m), 447 (m), * impurity of aluminium fluoride complexes resulted by degradation of $[Al(OC(CF_3)_3)_4]^-$.

Compound $[C_6Me_6H][Al(OC(CF_3)_3)_4]$ (**4**): EI-MS (30 eV, heating r.t. −170 °C): *m/z* (%) = 850 (5) [An^+–C_2F_4O], 675 (8) [An^+–L–3F], 536 (1) [An^+–L–$2CF_3$–3F], 478 (10) [An^+–2L–F], 477 (20) [An^+–L–$C(CF_3)_3$–2F], 461 (10) [An^+–2L–2F], 447 (2), [An^+–$2C(CF_3)_3$–C_2F_4], 445 (10) [An^+–L–$C(CF_3)_3$–CF_3], 443 (10) [An^+–L–$C(CF_3)_3$–CF_3], 441 (10) [An^+–2L–3F], 162 (100) [$C_6Me_6^+$]; NMR spectra of **4** are similar to that of **3** since the yellow crystals are a mixture of both compounds. IR (KBr, cm^{-1}, Nujol): 3300 (br), 1596 (m, $[C_6Me_6H]^+$), 1301 (vs), 1276 (vs), 1251 (vs), 1240 (vs), 1217 (vs), 1165 (s), 1071 (w, $[C_6Me_6H]^+$), 1061 (w, $[C_6Me_6H]^+$), 973 (vs), 889 (w, $[C_6Me_6H]^+$), 831 (m), 756 (w), 728 (w), 682 (w, $[C_6Me_6H]^+$), 571 (w), 560 (w), 537 (w), 447 (m). Absorption band at 1590 cm^{-1} is one of the characteristic benzoid C=C skeletal stretching modes of the carbocations [48].

4.5. Crystal growth and X-ray crystallography

Crystals of **3** · C_6Me_6 were grown from a saturated supernatant solution in CH_2Cl_2 at −24 °C. Single crystals were coated with Paratone-N oil, mounted using a glass fibre and frozen in the cold nitrogen stream of the goniometer. A hemisphere of data was collected on a Bruker AXS P4/SMART 1000 diffractometer using ω and θ scans with a scan width of 0.3° and 30 s exposure times. The detector distance was 5 cm. The data were reduced (SAINT) [49] and corrected for absorption (SADABS) [50]. The structure was solved by direct methods and refined by full-matrix least squares on F^2 (SHELXTL) [51] (Table 4). The compound was a racemic mixture. Anisotropic refinement was employed for all Bi, Cl and Al atoms and F2–F3, O1–O9 and C1–C8. All other atoms were refined isotropically. Hydrogen atoms were included in calculated positions and refined using a riding model. Hexamethylbenzene molecules were restraint to equal distances within the ring and between the methyl groups. CF_3 groups were refined as regular tetrahedra with fixed bond distances of 1.32 Å. The isotropic thermal parameter for C72 was fixed. Refinement was non-convergent and anisotropic refinement lead to many non-positive definites.

Acknowledgement

Acknowledgement is made to NSERC (Canada) and PRF(Canada) for financial support and Neil Buford, Heather Phillips (Dallhouse University) for attempts to measure FT-Raman spectra, Dr. Dr. Kathryn E. Preuss, for measuring of UV–Vis spectra in dichloroethane.

Appendix A. Supplementary data

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Center as Supplementary Publication No. CCDC 250743. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.ukor http://www.ccdc.cam.ac.uk). X-ray microanalysis of reaction products, NMR Reactions in situ and NMR investigation of oxidation of C_6Me_6, IR spectrum of $Li[Al(OC(CF_3)_3)_4]$ 350–4000 cm^{-1}, UV–Vis spectra 300–800 and 400–1100 cm^{-1}, structure **3** · C_6Me_6, details of discussion. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.06.032.

known LiPc is isostructural (on a molecular level) with MgPc, yet is deficient by one electron, so may be an appropriate p-dopant for MgPc. The aluminum phthalocyanine radical, AlPc, on the other hand, would be an isostructural n-dopant for the normal-valent phthalocyanines.

Because most unfunctionalized phthalocyanine complexes have extremely low solubilities in organic solvents, we have examined 2,3,9,10,16,17,23,24-octa(pentoxy)phthalocyanines (denoted Pc*, Fig. 1). Octa(alkoxy)phthalocyanines are discotic liquid crystals over various temperature ranges, depending upon the alkoxy group [10]; the free base of the octapentoxy derivative is a normal crystalline phase up to 121 °C [11].

There is one previous report of the synthesis of a monolithium octa(alkoxy)phthalocyanine [12] and its electrical and magnetic properties were investigated [13]. However, other monolithium octa(alkoxy)phthalocyanines synthesized by the reported method were contaminated by the corresponding free-base phthalocyanine [12]. We report improved syntheses of both Li_2Pc* and LiPc* that are presumably applicable to any octa(alkoxy)phthalocyanine.

All known aluminum phthalocyanines have an axial substituent such as chloride or an alkoxide on the aluminum, such that the oxidation state of the phthalocyanine ring is the usual −2. A few ring-substituted chloroaluminum and alkoxyaluminum phthalocyanines have been reported [14]. No aluminum phthalocyanine radicals have been previously isolated. There is a published report of the in situ chemical reduction of several metal phthalocyanine complexes (including ClAlPc) and their UV–visible spectroscopy, but none of these reduced species were isolated or studied by other methods [15]. The reduction of the photoexcited triplet state of ClAlPc by aromatic amines and the decay of the resulting radical has been studied spectroscopically [16]. Reduction of a related phthalocyanine complex, chloroindium tetra(*tert*-butyl)phthalocyanine, leads to an In–In bonded dimer [17]. Herein we report the first isolation and characterization of an aluminum phthalocyanine radical, AlPc*, where the oxidation state of the phthalocyanine ring is −3.

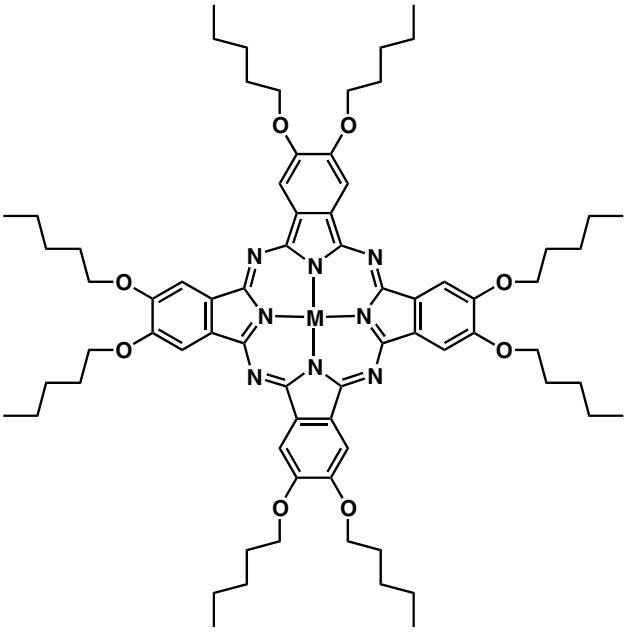

Fig. 1. Octa(pentoxy)phthalocyanine, MPc*. M = H_2, Li_2, Mg, AlCl, Li, or Al.

2. Experimental

2.1. General procedures and materials

Reactions involving metal phthalocyanines were carried out under a nitrogen atmosphere using glove box and Schlenk line techniques. Tetrahydrofuran was distilled from purple sodium/benzophenone. Heptane, toluene and benzene were distilled from sodium/benzophenone with added tetraglyme. Hydroquinone was recrystallized from toluene/ethyl acetate. The reagent 1,2-dicyano-4,5-dipentoxybenzene was synthesized by literature procedures [18,19]. Ferrocenium hexafluorophosphate, $[Cp_2Fe][PF_6]$, was synthesized by the oxidation of ferrocene with sulfuric acid followed by precipitation from aqueous solution with NH_4PF_6 and recrystallization from acetone/ether [20]. All other chemicals were reagent grade and used as received. ^1H and ^{13}C NMR spectra were recorded on a Varian Mercury 300 NMR spectrometer using solvent residual as internal standard. UV–Vis spectra were recorded on a Varian Cary 100 spectrophotometer. ESR spectra were obtained on a Bruker ER200 X-band spectrometer with 0.10 G modulation. Cyclic voltammetry and solid-state conductivity measurements were performed under an inert atmosphere with an EG&G/PAR 263A potentiostat as described previously [9]. Cyclic voltammetry was performed in THF solution with 0.10 M $[NBu_4][PF_6]$ supporting electrolyte, and all electrochemical potentials are relative to internal ferrocene$^{0/+}$ at 0 V. Measurements of solution-phase magnetic susceptibility by the Evans method were performed as described previously [9]. Pressed-pellet electrical conductivity was determined as described previously [9].

2.2. H_2Pc*

Hydroquinone (0.552 g, 5.02 mmol) and 1,2-dicyano-4,5-dipentoxybenzene (5.18 g, 17.3 mmol) were sealed in a Teflon-lined steel bomb and heated to 200 °C for 20 h. The crude product was stirred twice with 150 mL portions of hot ethanol for 30 min and filtered. The dark

green insoluble residue was dissolved in CH_2Cl_2 and filtered through silica gel. The filtrate was concentrated and the product precipitated from CH_2Cl_2/ethanol as a green powder (3.76 g, 72.5%). ^{1}H NMR (C_6D_6): −3.62 (s, 2H), 1.15 (t, 24H, $J = 7.2$ Hz), 1.51–1.63 (m, 16H), 1.63–1.76 (m, 16H), 2.01–2.16 (m, 16H), 4.07 (br, 16H), 8.31 (s, 8H). ^{13}C NMR ($CDCl_3$): 14.22, 22.92, 28.84, 29.69, 69.63, 105.21, 129.66, 147.54, 151.47. UV–Vis in THF; nm, ε (L mol^{-1} cm^{-1}): 698, 3.3×10^5; 660, 2.7×10^5; 644, 1.1×10^5; 598, 6.0×10^4; 426, 7.7×10^4; 348, 1.8×10^5; 295, 1.3×10^5.

2.3. Li_2Pc*

THF (150 mL) was vacuum transferred to a mixture of H_2Pc* (2.164 g, 1.798 mmol) and lithium bis(trimethylsilyl)amide (0.661 g, 3.96 mmol). The reaction mixture was stirred at 22 °C for 2 h and at reflux for 18 h. Volatiles were removed under reduced pressure. The solid was dissolved in a heptane/THF mixture, precipitated by partial evaporation of the solvent, and isolated by filtration to yield a green powder (1.860 g, 85%). ^{1}H NMR (THF-d_8, 22 °C): 1.03 (t, 24H, $J = 6.9$ Hz), 1.47–1.61 (m, 16H), 1.63–1.74 (m, 16H), 1.96–2.08 (m, 16H), 4.46 (t, 16H, $J = 6.3$ Hz), 8.88 (s, 8H). ^{13}C NMR (THF-d_8, 55 °C): 14.45, 23.46, 29.58, 30.56, 70.75, 108.11, 135.89, 151.63, 155.35. UV–Vis in THF; nm, ε (L mol^{-1} cm^{-1}): 661, 2.7×10^5; 631, 3.9×10^4; 598, 4.0×10^4; 357, 1.1×10^5; 282, 6.2×10^4. *Anal.* calc. for $C_{72}H_{96}N_8O_8Li_2$: C, 71.15; H, 7.96; N, 9.22. Found: C, 71.27; H, 7.90; N, 9.25%.

2.4. $LiPc$*

THF (40 mL) was vacuum transferred to a mixture of Li_2Pc* (448 mg, 0.368 mmol) and $[Cp_2Fe][PF_6]$ (122 mg, 0.368 mmol). The solution was stirred at 22 °C for 12 h. Black solid precipitated. The reaction mixture was further refluxed for 18 h. When cooled to 22 °C the product precipitated and it was isolated by filtration and washed with THF. The dark black-green solid was purified by dissolving in hot THF and precipitation at 22 °C. Yield: 385 mg, 87%. ^{1}H NMR (C_6D_6): 0.97 (t, 24H, $J =$ 7.2 Hz), 1.27–1.44 (br, 32H), 1.66–1.84 (br, 16H), 2.80–4.80 (br, 16H). ^{13}C NMR (C_6D_6): 14.25, 22.99, 28.75, 29.82. HRMS (EI) calc. for $C_{72}H_{96}O_8N_8Li$ (M^+) 1207.7511. Found: 1207.7548. UV–Vis in THF; nm, ε (L mol^{-1} cm^{-1}): 785, 1.9×10^4; 699, 1.7×10^4; 661, 1.5×10^4; 506, 6.8×10^4; 418, 4.3×10^4; 342, 1.0×10^5; 284, 8.3×10^4.

2.5. $MgPc$*

THF (70 mL) was vacuum transferred into a flask containing Li_2Pc* (350 mg, 0.288 mmol) and $MgCl_2$ (28 mg, 0.294 mmol). The reaction mixture was stirred at reflux for 12 h. The solvent was removed under reduced pressure and the residue was dissolved in toluene and filtered to remove LiCl. The product was dissolved in a THF/heptane mixture and precipitated by evaporation of some of the solvent to give a deep green solid. Yield: 315 mg, 89%. ^{1}H NMR (C_6D_6): 0.96 (t, 24H, $J = 6.9$ Hz), 1.1–1.3 (m, 32H), 1.40 (m, 16H), 3.54 (br s, 16H), 8.45 (s, 8H). ^{13}C NMR (C_6D_6): 14.75, 23.29, 28.85, 29.63, 70.15, 107.08, 133.77, 150.84, 153.82. UV–Vis in THF; nm, ε (L mol^{-1} cm^{-1}): 673, 3.2×10^5; 644, 3.9×10^4; 609, 4.1×10^4; 409, 1.1×10^4; 363, 6.3×10^4; 347, 8.0×10^4; 289, 5.7×10^4. *Anal.* calc. for $C_{72}H_{96}N_8O_8Mg$: C, 70.54; H, 7.89; N, 9.14. Found: C, 70.97; H, 8.22; N, 9.16%.

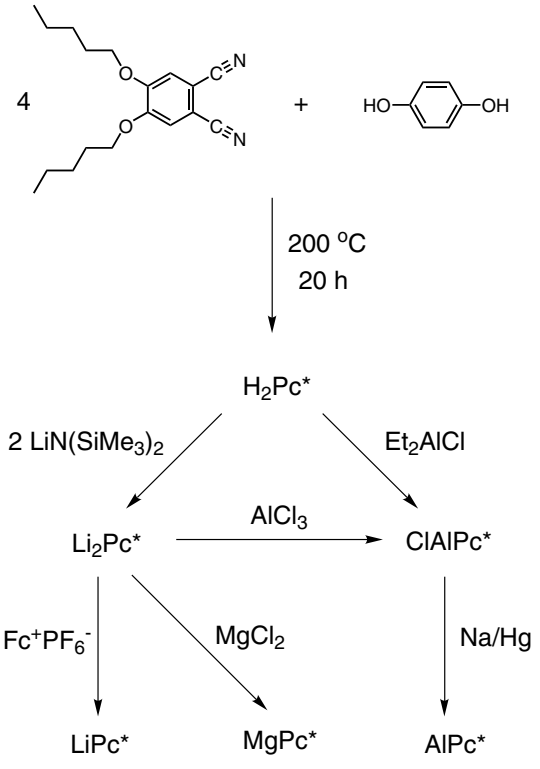
2.6. $ClAlPc$*

THF (50 mL) was vacuum transferred into a flask containing Li_2Pc* (1.00 g, 0.831 mmol) and $AlCl_3$ (121 mg, 0.914 mmol). The reaction mixture was stirred at 22 °C for 24 h and at reflux for another 24 h. The solvent was removed under reduced pressure and the product dried under vacuum at 80 °C for 3 h. The dark green solid residue was dissolved in hot toluene and filtered to remove the LiCl. Toluene was removed under reduced pressure. Crystallization from heptane/benzene (reflux to 22 °C) gave the product as dark green solid, which was held under vacuum at 80 °C for 2 h. Yield: 0.910 g, 87%. Alternatively, ClAlPc* can be prepared by the reaction of H_2Pc* and diethylaluminum chloride in CH_2Cl_2, similar to a reported preparation of chloroaluminum tetraphenylporphyrin [21]. ^{1}H NMR (THF-d_8 + DMSO-d_6): 1.08 (t, 24H, $J = 7.8$ Hz), 1.53–1.68 (m, 16H), 1.72–1.83 (m, 16H), 2.06–2.19 (m, 16H), 4.67 (t, 16H, $J = 6.3$ Hz), 9.11 (s, 8H). ^{13}C NMR (THF-d_8 + DMSO-d_6, 55 °C): 14.54, 23.46, 29.48, 30.34, 70.79, 107.65, 132.57, 142.68, 153.62. UV–Vis in THF; nm, ε (L mol^{-1} cm^{-1}): 684, 9.1×10^4; 656, 1.4×10^4; 616, 1.3×10^4; 430, 9.2×10^3; 368, 3.8×10^4; 298, 1.5×10^4.

2.7. $AlPc$*

THF (70 mL) was vacuum transferred into a flask containing ClAlPc* (360 mg, 0.285 mmol) and Na/Hg (8.4 mg, 0.365 mmol Na in 840 mg Hg). The mixture was stirred for 4 h at 22 °C, yielding a purple solution. Volatiles were removed under vacuum, 70 mL toluene was added, and the mixture was filtered. Toluene was removed under vacuum and 60 mL THF and 20 mL heptane were added to dissolve the residue. Evaporation of the solution under vacuum to 10 mL yielded a red-purple precipitate, which was collected by filtration and dried under vacuum for 4 h. Yield: 280 mg, 80%. ^{1}H NMR (C_6D_6): 0.40 (br s, 24H), 0.58 (br s, 32H), 3.5 (br s, 16H), 9.4 (br s, 16H). UV–Vis in THF; nm,

ε (L mol^{-1} cm^{-1}) (contains some oxidized species): 682, 2.2×10^4; 660, 2.1×10^4; 614, 3.8×10^4; 584, 4.8×10^4; 563, 2.5×10^4; 542, 1.7×10^4; 397, 3.5×10^4; 338, 4.3×10^4; 285, 3.6×10^4. *Anal.* calc. for $C_{72}H_{96}N_8O_8Al$: C, 70.39; H, 7.88; N, 9.12. Found: C, 70.14; H, 7.98; N, 9.05%.



2.8. Co-crystallization of AlPc* and H_2Pc*

AlPc* (20 mg, 0.016 mmol) and H_2Pc* (174 mg, 0.144 mmol) were dissolved in THF (12 mL) and heptane (8 mL) to give a green solution. The solution was slowly concentrated to 6 mL to give a green precipitate. The precipitate was collected by filtration and dried under vacuum for 2 h to yield 174 mg cocrystals.

3. Results and discussion

3.1. Synthesis

The reactions used in the preparation of our phthalocyanine complexes are summarized in Scheme 1. A few 2,3,9,10,16,17,23,24-octa(alkoxy)phthalocyanine derivatives have been synthesized before [19]. We found it most convenient to synthesize free-base octa(pentoxy)phthalocyanine (H_2Pc*, Fig. 1) by a route analogous to one previously reported for the high-purity synthesis of the free base of unfunctionalized phthalocyanine (H_2Pc) [4] and phthalocyanine polymers [22]. The appropriate dicyanobenzene, 1,2-dicyano-4,5-dipentoxybenzene, was reduced by hydroquinone in a Teflon-lined vessel at 200 °C to yield H_2Pc*. It has been noted that standard preparations of metallophthalocyanines result in impurities that are very difficult to separate from the desired MPc and these impurities can have significant effects on the electrical properties of molecular crystals of the phthalocyanines [4]. In contrast, synthesis of H_2Pc by hydroquinone reduction of 1,2-dicyanobenzene and subsequent metalation of H_2Pc results in very pure MPc. The method therefore seemed like the best route to high-purity MPc*. In addition, synthesis of H_2Pc* by the hydroquinone reaction results in higher yields than previously reported methods and does not require chromatographic purification.

Scheme 1. Synthesis of free-base octa(pentoxy)phthalocyanine and several metal complexes.

The dilithium derivative Li_2Pc* was obtained by deprotonation of H_2Pc* with $LiN(SiMe_3)_2$ (similar reactions have been used in the preparation of alkali metal porphyrins [23]). As in the reported syntheses of monolithium porphyrins radicals [24], oxidation of Li_2Pc* with one equivalent of ferrocenium hexafluorophosphate yields the monolithium phthalocyanine radical LiPc*. As noted in Section 1, this route is a distinct improvement over the reported electrochemical synthesis [12].

The standard synthesis of ClAlPc entails the reaction of 1,2-dicyanobenzene with $AlCl_3$ in quinoline [25], but the analogous reaction of 1,2-dicyano-4,5-dipentoxybenzene with $AlCl_3$ was unsuccessful. We found that either the reaction of Li_2Pc* with $AlCl_3$ or the reaction of H_2Pc* with Et_2AlCl gives ClAlPc* cleanly. Reduction of ClAlPc* with one equivalent of sodium amalgam in THF yields the very air-sensitive AlPc*. The radical AlPc* is indefinitely stable at room temperature in the solid state or solution, as long as it is not exposed to air.

3.2. Spectroscopy

3.2.1. NMR

Of the diamagnetic compounds studied, H_2Pc*, MgPc*, and Li_2Pc* have normal ^{1}H NMR spectra. For example, the ^{1}H NMR spectrum of H_2Pc* displays the expected five resonances of the pentyl groups, an aromatic resonance at 8.31 ppm, and the upfield N–H resonance at −3.62 ppm. The final diamagnetic compound examined, ClAlPc*, exhibits extra, broad resonances in its ^{1}H NMR spectrum in THF-d_8. If a few drops of DMSO-d_6 is added to the THF-d_8 solution, the ^{1}H NMR spectrum appears normal, possibly because Cl-bridged aggregates are broken up by the coordination of DMSO to the aluminum.

The ^{13}C NMR spectrum of Li_2Pc* in THF-d_8 at 22 °C has several more than the expected nine reso-

nances. When Li_2Pc^* in THF-d_8 was warmed to 55 °C, the ^{13}C NMR spectrum collapsed to nine sharp resonances. It is possible that there is some aggregation of the Li_2Pc^* in solution at 22 °C that causes the splitting of resonances, a phenomenon that has been observed previously [26], and may involve the formation of ion pairs of the type $[Li(THF)_4]_m[Li_{2n-m}Pc^*_n]$ [23].

For the two paramagnetic species, LiPc* and AlPc*, only some of the possible NMR resonances are observed. The ^1H NMR spectrum of LiPc* displays all five of the pentyl resonances but none for the ring protons; in the ^{13}C NMR spectrum, resonances from only the four outermost carbons of the pentyl groups could be observed. We were unable to observe a ^{13}C NMR spectrum of AlPc* in C_6D_6. Its ^1H NMR spectrum is unusual, with the resonances for the methyl groups and the outer two methylenes of the pentyl groups shifted upfield to about 0.5 ppm. The other methylenes are seen at 3.5 and 9.4 ppm. No resonance for the ring protons was observed. A possible explanation for the unusual chemical shifts of the methyl group and outer methylenes of AlPc* (a phenomenon not observed in LiPc*) is that the Lewis acidic aluminum centers form dative bonds with the oxygens of the pentoxy groups on other molecules. For example, a dimeric structure could form in which a molecule forms an $O \rightarrow Al$ bond with another molecule and a $Al \leftarrow O$ bond with the same partner. The configurations formed by these dative interactions would place the pentoxy groups in close proximity to another molecule's ring system, affecting the chemical shift of the aliphatic protons. If a solution of AlPc* in C_6D_6 is treated with I_2, a ^1H NMR spectrum very similar to that of ClAlPc* is observed, indicating that the radical has been oxidized back to the closed-shell species IAlPc*.

3.2.2. ESR

Both LiPc* and AlPc* display strong ESR signals as dilute solutions in benzene. In neither case could the hyperfine coupling to individual nuclei be distinguished, and instead one broad absorption was observed. In each molecule there is hyperfine coupling to two sets of four equivalent nitrogen atoms and one set of eight equivalent hydrogen atoms, in addition to coupling to lithium and aluminum, respectively. It is therefore not surprising that the individual hyperfine couplings cannot be resolved. Similar single-line ESR spectra have been observed for LiPc [6] and monolithium octa(dodecyloxy)phthalocyanine [13]. The *g*-value of LiPc* is 2.0003 (measured relative to external $TCNE^-$ at $g = 2.00278$ [27]) and the peak-to-peak width is 6.0 G. The *g*-value of AlPc* is 2.0010 and the peak-to-peak width is 5.0 G.

3.2.3. UV–Vis

Phthalocyanines with peripheral substituents have a strong tendency to form loosely associated dimers, trimers, and larger aggregates in solution, and the visible spectra of the aggregates can differ significantly from that of the monomers [2]. All of our UV–Vis spectra were obtained from very dilute solutions (10^{-5}–10^{-4} M) in THF, and appear to be consistent with monomeric species. A thorough study of the aggregation of an octa(alkoxy)phthalocyanine free base in dodecane solution and the effect of aggregation on the visible spectrum of the compound has been published [28], and the published spectrum of a monomeric species agrees very well with our spectrum of H_2Pc^* in THF.

UV–Vis spectra of Li_2Pc^* and LiPc* are similar to those of their respective unsubstituted phthalocyanines Li_2Pc and LiPc [6]. Li_2Pc^* has a Q band at 661 nm, a Soret band at 357 nm, and an N band at 282 nm. When Li_2Pc^* is oxidized to LiPc*, the Q band shifts to significantly higher energy at 506 nm, while the Soret band and N band are relatively unperturbed at 342 nm and 284 nm, respectively. The Q band is due to a HOMO–LUMO transition. Oxidation of Li_2Pc^* to LiPc* converts the HOMO to a singly occupied molecular orbital (SOMO) and the shift in the Q band is due to the fact that the transition no longer involves the unpairing of two electrons in the same orbital [29]. The Soret and N bands shift little because they are due to transitions from lower-energy MOs to the LUMO. New bands appear in the spectrum of LiPc* because of the existence of new transitions to the SOMO. A full analysis of the UV–Vis spectra of ring-oxidized and ring-reduced phthalocyanine complexes has been published [29].

The spectrum of ClAlPc* has a Q band at 684 nm and a Soret band at 368 nm, similar to published values for ClAlPc [29]. With the very low concentrations used to obtain UV–Vis spectra, it was not possible to obtain a clean spectrum of the AlPc* radical without oxidation; a detailed interpretation of the AlPc* spectrum was therefore not attempted.

3.3. Solution-phase magnetic susceptibility

The Evans method [30] was used to determine the magnetic moment of LiPc* and AlPc* in C_6D_6 solution. The assumption of similar volume diamagnetic susceptibilities for the analytes and C_6D_6 allowed the use of a previously described equation [9,31]:

$$\mu_{\text{eff}} = 0.0437\sqrt{\frac{\Delta f \cdot T}{M}}, \tag{1}$$

where μ_{eff} is the effective magnetic moment in Bohr magnetons (μ_B), Δf is the shift in frequency of the analyte solution resonance versus that of the neat reference (in ppm), T is the temperature in Kelvins, and M is the molarity of the solution of analyte. Eq. (1) gives the paramagnetic susceptibility directly, with no diamagnetic correction necessary. A 0.0374 M solution of AlPc* at 20 °C led to a shift of 0.198 ppm in the

C_6D_5H resonance, implying a magnetic moment of 1.72 μ_B, very close to the theoretical value of 1.73 μ_B for one unpaired electron.

The solution-phase magnetic susceptibility of LiPc* is much lower than would be expected for one unpaired electron per molecule. Solutions of LiPc* in C_6D_6 of concentration 0.0215, 0.0291, and 0.0385 M at 21 °C caused shifts of 0.013, 0.018, and 0.023 ppm, respectively, in the C_6D_5H resonance. All of these measurements imply a concentration of molecules with an unpaired spin of about a factor of nine lower than the actual concentration of LiPc*. Aggregation of LiPc* in solution with spin-pairing of the molecules within the aggregates could explain the lower-than-expected paramagnetism. An average aggregate size of about five molecules would account for the observed shift, under the assumption that odd-number-of-molecule aggregates have one unpaired spin and even-number-of-molecule aggregates are diamagnetic. It is surprising that the magnetic moment is attenuated by the same factor in C_6D_6 solutions of different concentrations. A 0.0326 M solution of LiPc* in $CDCl_3$ displayed no paramagnetic shift compared to the reference solution at 21 °C, but when heated to 55 °C exhibited a shift of 0.014 ppm. The behavior in $CDCl_3$ is consistent with dimers or higher aggregates that partly dissociate to monomers at higher temperature.

3.4. Solid-state conductivity

As noted in Section 1, two known phthalocyanine radicals, LiPc and $LuPc_2$, are electrical conductors. We therefore investigated the solid-state conductivity of LiPc* and AlPc*. Polycrystalline samples were pressed between two freshly cleaned copper contacts. Because these were two-point measurements, we measured a series of sample masses for each substance to examine the influence of contact resistance. The cross-sectional area of the pressed pellets in our apparatus is constant, so the thickness of the sample, and therefore its measured resistance, will increase in direct proportion to the sample mass if the contact resistance is not significant. Current was measured as a function of applied potential from 0 to +3 V to −3 to 0 V. Measurements for LiPc* and AlPc* are shown in Fig. 2. For both materials an approximately linear increase in resistance with sample mass was observed.

The resistance of each LiPc* sample was calculated from the slope of its current–voltage plot. If a density of 1.0 g/cm^3 is assumed for LiPc*, its conductivity can be calculated; the average value is $8 \times 10^{-11}\ \Omega^{-1}\ cm^{-1}$. That is significantly lower than the value for single-crystal (unfunctionalized) LiPc, $2 \times 10^{-3}\ \Omega^{-1}\ cm^{-1}$ [7]. LiPc* presumably crystallizes in the columnar structure of similarly functionalized phthalocyanines [11], and electrical transport occurs almost exclusively along the

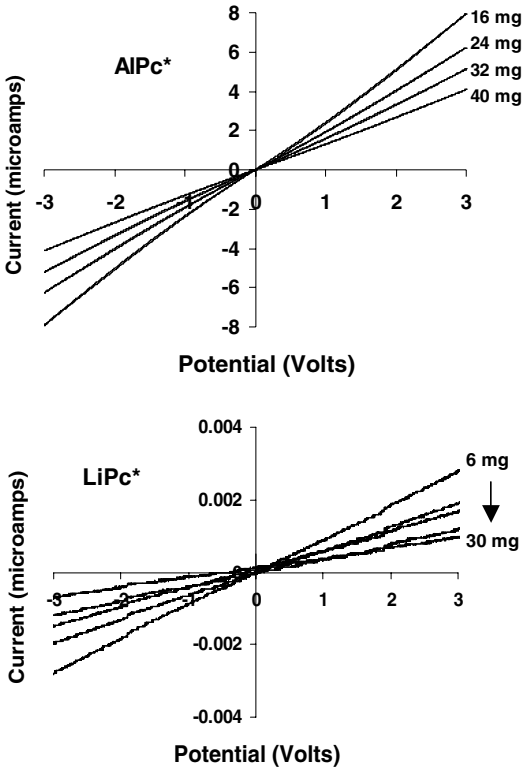


Fig. 2. Current vs. potential measurements for pressed pellets of AlPc* and LiPc*. Samples of mass 16, 24, 32, and 40 mg of AlPc* were examined, and samples of mass 6, 12, 18, 24, and 30 mg of LiPc* were examined.

columns [13]. Polycrystalline LiPc* might then be pictured as bundles of insulated wires in a mixture of random orientations, and it is not surprising that its bulk conductivity is much lower than single-crystalline LiPc.

The data from polycrystalline AlPc* were treated in the same manner as that from LiPc*. The conductivity in this case was $5 \times 10^{-7}\ \Omega^{-1}\ cm^{-1}$, almost four orders of magnitude greater than that of LiPc*. If AlPc is more conductive than LiPc by the same factor, the single-crystal conductivity of AlPc would be $12\ \Omega^{-1}\ cm^{-1}$, which is quite high for a single-component material. That theoretical conductivity can be compared to that of the most conductive single-component molecular conductor, which is $400\ \Omega^{-1}\ cm^{-1}$ [32]. Investigations into the synthesis and crystallization of the parent AlPc are currently under way.

The electrical conductivity of a material can be described by

$$\sigma = ne\mu, \tag{2}$$

where n is the concentration of free carriers (electrons or holes), e is the electron charge, and μ is the mobility of the carriers. The generation of intrinsic carriers in a molecular material occurs through a thermally activated charge transfer from one neutral molecule, M, to another:

$$MM \rightleftharpoons M^+M^- \tag{3}$$

The activation energy for this process, E_a (in eV), is given approximately by the difference between the oxidation and reduction potentials of M ($\Delta E_{1/2}$, in V) times the electron charge. The concentration of carriers is exponentially related to E_a [13]:

$$n = n_0 \exp\left(\frac{-E_a}{2k_B T}\right), \quad (4)$$

where n_0 is the concentration of M in the crystal. So, at a given temperature, the conductivity of a molecular material is determined by E_a and the carrier mobilities. If LiPc* and AlPc* have similar carrier mobilities, their relative conductivities will be determined solely by their values of E_a, or approximately by $\Delta E_{1/2}$ for the two molecules. The $\Delta E_{1/2}$ of LiPc* can only be estimated because its oxidation is irreversible. The separation between the oxidative waves of LiPc*$^-$ and LiPc* is 0.77 V, so that was used as the estimate of $\Delta E_{1/2}$. (The $\Delta E_{1/2}$ of LiPc was reported to be a similar 0.83 V [6].) The $\Delta E_{1/2}$ of AlPc* is 0.66 V (see below and Table 1). If these values are used for E_a in Eq. (4), one finds that the conductivity of AlPc* should be about one order of magnitude larger than LiPc*. So imperfect agreement is found with the experimental values, but the redox potentials do correctly predict that AlPc* is a better conductor than LiPc*.

Another explanation for the large difference in conductivity between LiPc* and AlPc* could be that their packing in the solid state is significantly different. Octa(alkoxy)phthalocyanines generally pack as stacked disks, but dative bonding between oxygen on one AlPc* molecule with the aluminum on another could lead to a very different solid state structure. If that is the case, carrier mobilities in LiPc* and AlPc* could be quite different, and that could account for their widely different conductivity.

3.5. Electrochemistry

Solution-phase measurements of electrochemical redox potentials provide an estimate of the electronic energy levels of molecules in a molecular crystal. We have examined the electrochemistry of LiPc* and AlPc* to determine their viability as p- and n-dopants, respectively, for normal-valent phthalocyanines such as MgPc* and H_2Pc*. Table 1 lists the redox potentials of H_2Pc*, MgPc*, LiPc*, and AlPc* obtained by cyclic voltammetry in THF (referenced to the ferrocene$^{+/0}$ couple at 0 V). From these values the approximate energy level diagrams of MgPc* and H_2Pc* doped with AlPc* and LiPc* shown in Fig. 3 can be constructed. Interestingly, the donor level of AlPc* in MgPc* is about 0.5 eV from the conduction band edge, while the acceptor level of LiPc* in MgPc* is a similar distance of about 0.6 eV from the valence band edge. H_2Pc* is more easily reduced than MgPc*; the donor level of AlPc* in H_2Pc* is only 0.3 eV from the conduction band edge. The system of H_2Pc* doped with AlPc* therefore presents the best possibility of observing electrical doping.

Table 1
Oxidation and reduction potentials of LiPc*, MgPc*, H_2Pc*, and AlPc* in THF vs. ferrocene$^{+/0}$ at 0 V

	MPc*$^{(0/-)}$	MPc*$^{(+/0)}$
Li	−0.54	~0.23 (irr)
Mg	−1.61	0.08
H_2	−1.40	~0.3 (irr)
Al	−1.77	−1.11

The oxidation of LiPc* is irreversible and the oxidation of H_2Pc* is quasi-reversible.

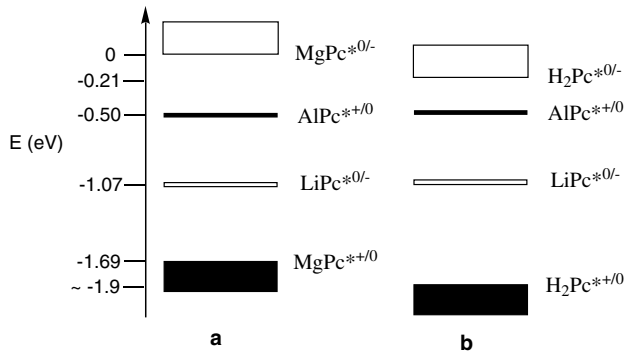

Fig. 3. (a) Relative energy levels of the donor AlPc*, acceptor LiPc*, and the valence and conduction bands of MgPc*. (b) Relative energy levels of the donor AlPc*, acceptor LiPc*, and the valence and conduction bands of H_2Pc*. All are derived from solution-phase electrochemical measurements.

3.6. Doping of H_2Pc* with AlPc*

We anticipated that the cocrystallization of two isostructural phthalocyanines would be straightforward. Previous studies of octakis((dodecyloxy)methyl)phthalocyanine found that solid solutions of the free-base and copper complex were easily prepared by recrystallization of a mixture of the compounds from hexane [33]. Co-precipitation of a 1:9 mixture of AlPc* and H_2Pc* from a heptane-THF mixture yielded a dark green powder. Examination of the powder under a microscope showed no signs of phase separation of the green H_2Pc* and blue AlPc*. There was no significant difference in the powder X-ray diffraction patterns of H_2Pc* and H_2Pc*doped with AlPc*, indicating that the crystal structure of H_2Pc* was maintained with the AlPc* dopant present. A sample of the cocrystallized material was pressed into a pellet and tested for electrical conductivity, but none was detected. Thus it appears that an isostructural n-dopant with a donor level within ~0.3 eV of the host conduction band is not significantly ionized at room temperature.

4. Conclusions

Several octa(pentoxy)phthalocyanine complexes have been synthesized by improved methods and the first synthesis of an aluminum phthalocyanine radical, AlPc*, was presented. Solid-state LiPc* is an electrical conductor with a pressed-pellet conductivity of $8 \times 10^{-11}\ \Omega^{-1}\ cm^{-1}$, while solid AlPc* is a significantly better conductor with a conductivity of $5 \times 10^{-7}\ \Omega^{-1}\ cm^{-1}$. Solution-phase electrochemical measurements indicate that in H_2Pc* doped with AlPc* the donor level of AlPc* lies ~0.3 eV from the conduction band edge of H_2Pc*, but the doped material does not have significant electrical conductivity at room temperature. Electrical doping by isostructural n-dopants will require dopants with donor levels that are very near or even above the conduction band edge of the host molecular semiconductor.

reagents were commercially available and were used without further purification.

2.1. Synthesis

A mixture of $[(C_6H_6)RuCl_2]_2$ (0.25 g; 5×10^{-4} mol) and 7,8-benzoquinoline (0.2 g; $\sim 1 \times 10^{-3}$ mol) or 8-hydroxyquinoline (0.25 g; 1.7×10^{-3} mol) in methanol (100 cm^{-3}) was refluxed for 4 h, cooled and filtered. The crystals suitable for X-ray crystal analysis are obtained by slow evaporation of the reaction mixture.

2.1.1. *[(C6H6)RuCl(C13H8N)] (1)*

Yield 79%. IR (KBr): 3067 (ν_{CH}), 3048 (ν_{CH}), 1618 (ν_{ring}), 1567 (ν_{CN}), 1447 ($\nu_{C=C}$), 1408 ($\nu_{ring} + \nu_{CH}$), 1323 (δ_{CH}), 1105 (δ_{CH}), 837 (γ_{CH}), 530 (ν_{Ru-N}). UV–VIS (CH_2Cl_2, λ nm ($\log \varepsilon$)): 381.6 (2.37), 291.2 (2.78), 220.4 (3.24), 215.8 (3.27). ^1H NMR: ($CDCl_3$, ppm) 9.55 (d, H1), 8.47 (d, H10), 8.19 (d, H3), 7.79 (d, H6), 7.76 (d, H5), 7.59 (m, H2; H8), 7.45 (m, H9), 5.59 (s, C_6H_6). ^{13}C NMR ($CDCl_3$, ppm): 176.3 (C19), 152.8 (C7), 136.6 (C14), 135.8 (C18), 134.7 (C15), 134.3 (C9), 129.8 (C13), 129.5 (C10), 127.3 (C17), 122.9 (C12), 121.4 (C8), 121.3 (C16), 86.6 (C_6H_6) *Anal*. Calc. for: C, 63.76; H, 4.28; Cl, 7.53; N, 2.97; Ru, 21.46. Found: C, 63.73; H, 4.25; N, 2.95%.

2.1.2. *[Ru(C9H6NO)3] · CH3OH (2)*

Yield 82%. IR (KBr): 3053 (ν_{CH}), 1566 (ν_{CN}), 1497 (ν_{ring}), 1457 ($\nu_{C=C}$), 1373 ($\nu_{ring} + \nu_{CH}$), 1315 (δ_{CH}), 1105 ($\nu_{CO} + \delta_{CH}$), 823 (γ_{CH}), 742 (ν_{Ru-O}), 525, 411 ($\nu_{Ru-O} + \nu_{Ru-N}$). UV–VIS (CH_2Cl_2, λ nm ($\log \varepsilon$)): 700.2 (1.99), 499.6 (sh), 433.4 (2.39), 252.0 (3.28), 223.8 (3.21). *Anal*. Calc. for: C, 60.78; H, 3.40; N, 7.88; O, 9.00; Ru, 18.94. Found: C, 60.743; H, 3.37; N, 7.90%.

2.2. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of KBr pellet. Electronic spectra were measured on a Lab Alliance UV–VIS 8500 spectrophotometer in the range of 800–280 nm in deoxygenated dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer. The ^1H and ^{13}C NMR spectra were obtained at room temperature in $CDCl_3$ using INOVA 300 spectrometer.

The magnetic measurements of the powdered samples was measured over the temperature range 1.8–300 K using a Quantum Design SQUID – based MPMSXL-5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T measurements. Measurements sample of compounds were made at magnetic field 0.5 T. The SQUID magnetometer was calibrated with the palladium rod sample. Corrections are based on subtracting the sample – holder signal and contribution χ_D estimated from the Pascal constants and equal -288×10^{-6} cm^3 mol^{-1}. The t.i.p. per Ru^{3+} center was assumed to be 115×10^{-6} cm^3 mol^{-1}. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$(BM).

EPR spectra were recorded at room temperature and 77 K on a Bruker ESP 300 spectrometer operating at X-band equipped with an ER 035M Bruker NMR gaussmeter and HP 5350B Hewlett-Packard microwave frequency counter. The spectrum at 4.5 K temperature was measured with a X-band Radioplan SE/X 2543 Spectrometer.

2.3. DFT calculations

GAUSSIAN-03 program [24] was used in the calculations. The geometry optimisation was carried out with the DFT method with the use of B3LYP functional [25,26]. The electronic spectrum was calculated using the TDDFT method [17].

The calculation was performed using the DZVP basis set [27] with *f* functions with exponents 1.94722036 and 0.748930908 on ruthenium atom, and polarization functions to all other atoms: 6–31g(2d,p) – chlorine, 6–31g** – carbon, nitrogen and 6–31g(d,p) on hydrogen atoms.

2.4. Crystal structures determination and refinement

An orange prism crystal of 1 and black prism crystal of 2 were mounted in turn on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at temperature of 288.0(2) K for complex **1** and 293.0(2) K for **2**, with ω scan mode. A 6 and 4 s exposure times were used respectively and all Ewald sphere reflections were collected up to $2\theta = 50$. The unit cell parameters were determined from least-squares refinement of the setting angles of 13997 and 13489 strongest reflections for complex **1** and **2**, respectively. Details concerning crystal data and refinement are given in Table 1. Examination of two reference frames monitored after each 20 frames measured showed respectively −12.3% and 37.2% loss of the intensity. During the data reduction, the above decay correction coefficient was taken into account. Lorentz, polarization, and numerical absorption [28] corrections were applied. The structures were solved by Patterson method. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique on F^2. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent atom with individual isotropic temperature factor equal 1.2 times the value of equivalent temperature factor of the parent

atom SHELXS-97 [29], SHELXL-97 [30] and SHELXTL [31] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

The reactions of the ruthenium(II) benzene complex $[(C_6H_6)RuCl_2]_2$ with 7,8-benzoquinoline and 8-hydroxyquinoline have been performed. Refluxing the complex $[(C_6H_6)RuCl_2]_2$ with an excess of 7,8-benzoquinoline in methanol leads to the half-sandwich $[(C_6H_6)RuCl(C_{13}H_8N)]$ (**1**) complex in good yield. When the 8-hydroxyquinoline ligand was used in the reaction the analogous product was not occurred. In this case the ruthenium(II) was oxidized to Ru(III) and the $[Ru(C_9H_6NO)_3]$ (**2**) complex was isolated. The elemental analyses of the complexes are in good agreement with their formulation. The IR spectra of the complexes are consistent with its molecular structures. The bands of C=C and C=N stretching modes are observed at 1447, 1457 cm^{-1} and 1567, 1566 cm^{-1} for complexes **1** and **2**, respectively. The ν_{Ru-N} frequencies are visible at 530 cm^{-1} for complex **1** and with ν_{Ru-O} at 525, 411 cm^{-1} for complex **2**.

In the ^{1}H NMR spectrum of compound **1** the protons of C_6H_6 ligand appears as a singlet at 5.95 ppm. The other signals are attributed to the 7,8-benzoquinoline ligand (details are given in Section 2). The ^{13}C NMR spectrum of this complex display singlet at 86.6 ppm corresponds to the co-ordinated η^6-C_6H_6 ligand and set of signals attributed to benzoquinoline ligand. The C(19) resonance appears as a triplet shifted to 176.3 ppm what confirms the structure of the complex.

3.1. Crystal structures

The $[(C_6H_6)RuCl(C_{13}H_8N)]$ complex crystallises in the orthorhombic space group *Pbca*. The molecular structure of the compound is shown in Fig. 1. The selected bond lengths and angles are listed in Table 2. The ruthenium atom is π-bonded to the benzene ring with an average Ru–C distance of 2.200(4) Å (range 2.142(4)–2.273(3) Å) whereas the distance between the ruthenium atom and the centroid of the ring is 1.701 Å and is consistent with those reported for the other Ru(II) η^6-arene complexes [3d,32,33]. The ruthenium atom is also directly co-ordinated to nitrogen atom of benzoquinoline ligand with a distance of 2.100(2) Å to N atom and to carbon atom with a distance of 2.068(3) Å. The Ru–Cl bond length is 2.4204(7) Å. The angle of the

C(4)–Ru(1)–C(6)	69.22(18)	65.08

chelating ligand (C(19)–Ru–(N1) 79.06(10)° and the angles between benzoquinoline and chlorine ligands (85.54(7)° (N(1)–Ru–(Cl1), 86.80(7)° (C(19)–Ru–(Cl1)) are close to those observed in the ruthenium arene compounds [34a,34b,34c]. In the structure exist three intramolecular weak hydrogen bonds [44–46] C(2)–H(2)···Cl(1#$-x,-y,-z$), C(4)–H(4)Cl(1#$-x+0.5,y+0.5,z$) and C(13)–H(13)Cl(1#$-x,y+0.5,-z+0.5$) (D···A distances 3.529(4), 3.676(4) and 3.645(3) Å, D–H···A angles 136.3°, 161.7° and 148.1°, respectively). In this way an infinite three-dimensional hydrogen-bonded net is created.

The complex **2** $[Ru(C_9H_6NO)_3]\cdot CH_3OH$ crystallizes in the monoclinic space group $P21/n$. The methanol molecule is approximately 1:1 disordered over two positions. The molecular structure of the compound is shown in Fig. 2. The selected bond lengths and angles are listed in Table 3. The complex adopts a distorted octahedral type of geometry. The maximum distortion is visible in angles between O(1)–Ru(1)–O(21) and N(21)–Ru(1)–O(21) 170.78° and 80.29°, respectively. The Ru–N and Ru–O bond lengths and the angles are comparable with literature values [41–43]. The two intermolecular hydrogen bond [44–46] linking the OH group of methanol and oxygen from hydroxyquinoline ligand O(99A)–H(99O)···O(1) (D···A distance 2.791(6) Å, D–H···A angle 157.7°), C(23)–H(23)···O(99A)(1#$-x+1/2,\ y-1/2,-z+1/2$) (D···A distance 3.231(10) Å, D–H···A angle 134.9°) are observed. In this way an infinite one-dimensional hydrogen-bonded chain along *b*-axis is created. I addition in the structure exists one intramolecular weak hydrogen bond between quinoline C(26)–H(26) and O(21#$-x+3/2,\ y-1/2,-z+1/2$) (D···A distance 3.330(3) Å, D–H···A angle 150.8°).

3.2. Geometry and electronic structure

The optimised geometry parameters for the complex **1** are given in Table 2. The optimised bond distances and angles agree well with the experimental values. The largest differences were found for the ruthenium–benzene carbons distances. The calculated Ru–benzene distance is 1.781 Å.

The formal charge of ruthenium is +2 in this complex. The calculated charge on the ruthenium atom, obtained from natural population analysis, is close 0.665. The population of the d_{xy}, d_{xz}, d_{yz}, $d_{x^2-y^2}$ and d_{z^2} orbitals of the central atom is following 0.933, 1.686, 1.636, 1.764 and 1.032, respectively. This is a result of charge donation from chloride ion and 7,8-benzoquinoline ligand. The charge on the chloride ligand is higher than −1 (−0.551); the charge on 7,8-benzoquinoline nitrogen atom is negative and amounts to −0.419 and on the donor C(19) is close to zero with negative sign (−0.0823). The HOMO–LUMO gap is 3.51 eV.

In Fig. 3 the molecular orbital diagram of complex **1** is presented with the several contours of molecular orbitals (HOMO – Fig. 3(a), LUMO – Fig. 3(b)). The HOMO, HOMO − 1 and HOMO − 3 orbitals are d ruthenium type with the admixture of π chlorine orbitals. The HOMO − 2 is π chlorine orbital. The combinations of π chlorine and d metal orbitals create the

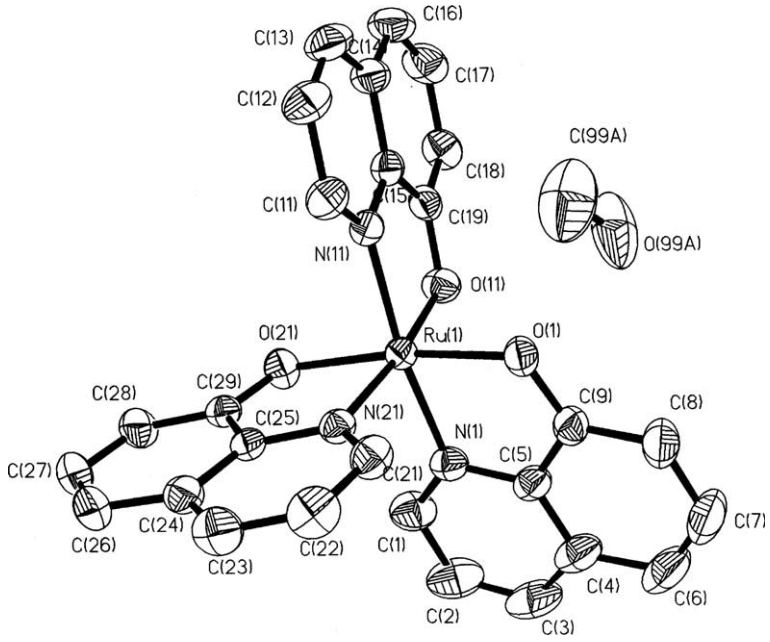

Fig. 2. ORTEP drawing of $[Ru(C_9H_6NO)_3]\cdot CH_3OH$ with 50% probability displacement ellipsoids. Hydrogen atoms were omitted for clarity.

O(21)–Ru(1)–O(11)	92.47(6)	94.73

HOMO − 5 and HOMO − 6 molecular orbitals of the complex. HOMO − 7 and HOMO − 8 are the σ chlorine orbital. The 7,8-benzoquinoline ligand has a significant contribution in the HOMO − 4 and HOMO − 9, HOMO − 10 molecular orbitals. The lone pair of benzoquinoline nitrogen atoms is visible in HOMO − 10.

The bonding between benzene and ruthenium is formed by the two π orbitals of e_{1g} symmetry (π_2 and π_3) and the empty d orbitals of the metal atom (donation from benzene to ruthenium). The resulting bonding orbitals are HOMO − 12 and HOMO − 13, the antibonding are LUMO + 1 and LUMO + 3. In the back-donation (metal to ligand) the occupied $d_{x^2-y^2}$ and d_{xz} metal orbitals and empty π_4^*, π_5^* benzene orbitals participate (HOMO − 1, HOMO and LUMO + 4, LUMO + 6). The LUMO and LUMO + 2 molecular orbitals are composed of benzoquinoline rings. The ruthenium d orbitals hold shares in LUMO + 5. The σ chlorine orbitals participate in the LUMO + 1 and LUMO + 4 molecular orbitals.

The optimised geometry parameters for the complex **2** are given in Table 3. The complex is paramagnetic and the geometry was optimised for low and high spin state. The calculated energy of triplet state is lower about 4.5 kcal/mol. The predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data. The largest differences were found for the Ru(1)–N(21) distance (∼0.05 Å) and for O(1)–Ru(1)–O(21) angle (3.11°). In the investigated complex are 135 α and 134 β occupied molecular orbitals. Among the occupied MOs of the complex the largest numbers constitute orbitals of the 8-hydroxyquinoline ligand which are not relevant for the discussion. The energy and character of upper valence molecular orbitals are given in Table 4. The d_{yz}, d_{xy}, d_{zx} orbitals of ruthenium are visible in the MO-s HOMO, HOMO − 3 and HOMO − 4 with α spin and in the HOMO, HOMO − 2 and HOMO − 4 with β spin. The molecular orbitals are mixed with the π orbitals of the 8-hydroxyquinoline ligands but the α HOMO − 3 and β HOMO − 2 MO have predominately d character. The d_{z^2} and $d_{x^2-y^2}$ orbitals are visible in LUMO + 10 and LUMO + 11 MO orbitals with α spin and in the LUMO + 12, LUMO + 13 – β spin with an antibonding

admixture of the nitrogen and oxygen orbitals of ($L + 10,12$) and π ($L + 11,13$) character. Some admixture of ruthenium d orbitals play role in the LUMO and LUMO + 2 MO with β spin.

3.3. Electronic spectrum

The spin-allowed, singlet transitions were calculated with the TDDFT method. The experimental spectrum of the complex **1** shows bands at 381.6, 291.2, 220.4, 215.8 nm. The measured (solid line) and calculated (doted line) electronic spectra are shown in Fig. 4. Each calculated transition in Fig. 4 was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.05.

With the use of the TDDFT method 90, electronic transitions were calculated for $[(C_6H_6)RuCl(C_{13}H_8N)]$ using the DZVP with *f* functions basis set on ruthenium atom (dotted line in Fig. 4). The calculated spectra are in good agreement with the experimental one.

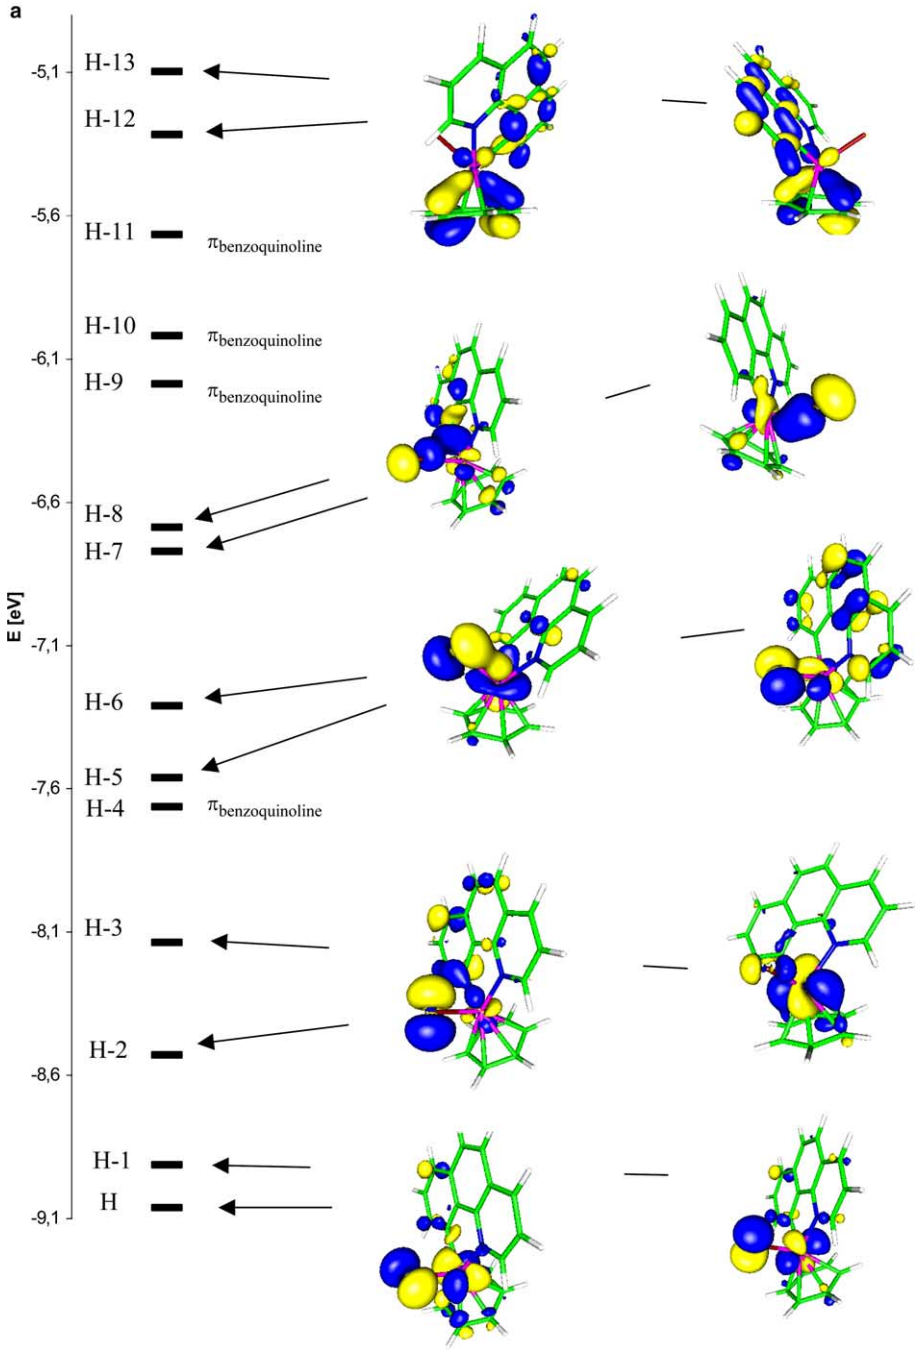

Fig. 3. The molecular orbital diagram (a) HOMO (b) LUMO orbitals of $[(C_6H_6)RuCl(C_{13}H_8N)]$.

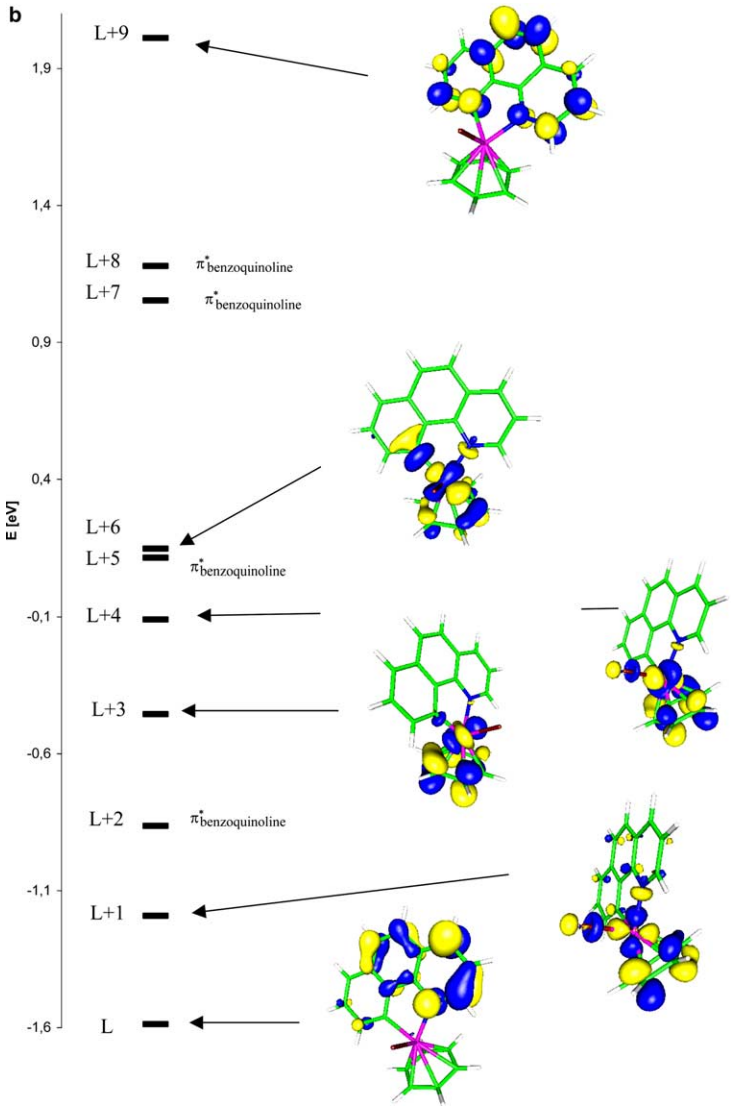

Fig. 3 (*continued*)

The first experimental band at 381.6 nm consists of $d \rightarrow d$ (LF) and $d \rightarrow \pi^*_{bq}$ (MLCT) transitions. The next band at 291.2 nm is consisted from intra- and interligand transitions $\pi_{Cl} \rightarrow \pi^*_{bq}, \pi_{Cl} \rightarrow \pi^*_{benz}, \pi_{bq} \rightarrow \pi^*_{bq}$ with the admixture of $d \rightarrow \pi^*_{benz}$ transition. The LMCT ($d \rightarrow \pi^*_{benz}$) transition is visible in the band at 220.4 nm. The $\pi_{benz} \rightarrow d$ transition has a contribution in the band at 215.8 nm with the interligand CT ($\pi_{bq} \rightarrow \pi^*_{benz}, \pi_{Cl} \rightarrow \pi^*_{benz}, \pi_{Cl} \rightarrow \pi^*_{bq}$) excitations.

The 7,8-benzoquinoline ligand has a significant influence on the spectrum. The transitions with this ligand (MLCT, LMCT, LLCT) occur in the whole spectrum of the complex.

The UV–VIS spectrum of complex with 8-hydroxyquinoline (**2**) was predicted by TDDFT method and the 200 electronic transitions are calculated. The experimental and calculated electronic spectra of $[Ru(C_9H_6NO)_3]$ are presented in Fig. 5. Each calculated transition in Fig. 4 was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.05. The UV–VIS spectrum of $[Ru(C_9H_6NO)_3]$ was calculated only to 290 nm, so the shortest wavelength experimental bands are not assigned to the calculated transitions.

The UV–VIS spectrum of the complex displayed broad band with maximum at 700.2 nm (14 281 cm^{-1}) resulted from d–d transitions and assigned to $^2T_{2g} \rightarrow {}^4T_{1g}$. In the range of this band was calculated the transition assigned to $^2T_{2g} \rightarrow {}^4T_{2g}$ at 628.7 nm (15 905 cm^{-1}). The shoulder at 499.6 nm (20 016 cm^{-1}) of the next unsymmetrical bands with maximum at 433.4 nm (23 073 cm^{-1}) has been attributed to $^2T_{2g} \rightarrow {}^2A_{1g}$, $^2T_{1g}$ transitions. In the band were calculated the MLCT ($d \rightarrow \pi^*_{quin}$) and LMCT ($\pi_{quin} \rightarrow d$) transitions.

Table 4
The energy and character of upper valence MO of $[Ru(C_9H_6NO)_3]$

MO	α spin		β spin	
	E (eV)	Character	*E* (eV)	Character

3.4. Magnetic properties

The magnetic susceptibilities of solid complex $[Ru(C_9H_6NO)_3]\cdot CH_3OH$ was determined over the temperature range 1.8–300 K. Plots of reciprocal magnetic

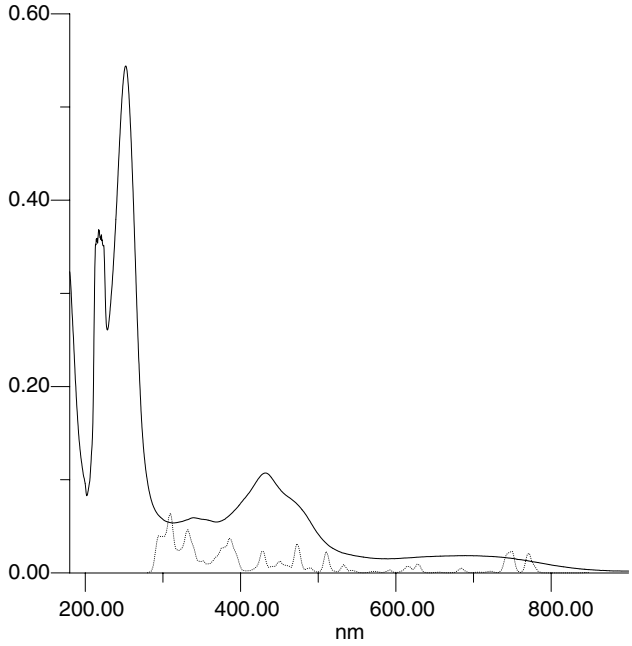

Fig. 5. UV–VIS spectrum of $[Ru(C_9H_6NO)_3]$ (solid line – experimental; doted line – calculated).

susceptibility χ_M and $\chi_M T$ product versus temperature are given in Fig. 6. The value $\chi_M T$ of at 300 K equals 0.441 $cm^3\,mol^{-1}\,K$ (1.87 B.M.). The value of $\chi_M T$ product decreases only slightly with temperature lowering. In the low-temperature range (below 50 K), a more evident decrease of the value of $\chi_M T$ is observed with continuous decrease of the temperature to 0.202 $cm^3\,mol^{-1}\,K$ (1.25 B.M.) at 1.8 K. The decrease of the value $\chi_M T$ in the low-temperature range is caused by occurrence of antiferromagnetic interactions between Ru(III) ions.

On such situation the magnetic data was fitted using the simplest susceptibility equation with a molecular field correction [47]:

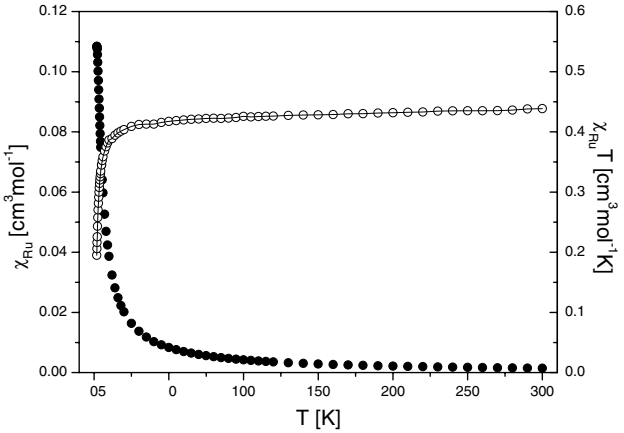

Fig. 6. Plots of the magnetic data for complex $[Ru(C_9H_6NO)_3]\cdot CH_3OH$ experimental χ_M(●) vs. *T* and $\chi_M T$ (○) vs. *T*. The solid line are the calculated curves.

Table 5
EPR data of $[Ru(C_9H_6NO)_3]\cdot CH_3OH$

Temperature T (K)	δ_{Hpp}[a] (Gs)	Spectroscopic splitting factor g_{iso}	hv (GHz)
293	542	2.074	9.769166
77	487	2.148	9.579125
4.5	463	2.156	9.253920

[a] Peak to peak linewidth.

$$\chi_M = \frac{N\beta^2 g^2}{3kT} S(S+1),$$

$$\chi_M^e = \frac{\chi_M}{1 - \frac{2zJ'}{N\beta^2 g^2}\cdot \chi_M},$$

where N is the Avogadro's number, g – the spectroscopic splitting factor, β – the Bohr magneton, k – the Boltzmann constant and zJ' – intermolecular exchange parameter. The best fit parameters are $g = 2.15$, $zJ' = -2.12\ cm^{-1}$ and agreement factor $R = 3.01 \times 10^{-3}$.

The values Curie and Weiss constants determined from the relation $1/\chi_M T = f(T)$ over temperature range 50–300 K are equal to $0.442\ cm^3\ mol^{-1}$ and -3.9 K, respectively. A negative value of Weiss constant suggests the antiferromagnetic coupling of the ruthenium centers in the crystal lattice.

EPR spectrum of $[Ru(C_9H_6NO)_3]\cdot CH_3OH$ complex for the whole temperature range 4.5–293 K indicates single isotropic line only characteristic for Ru^{3+} magnetic center with spin equal to 1/2 (Table 5).

4. Supplementary material

More details of the crystal structure determinations have been deposited with the Cambridge Crystallographic Data Centre with the deposition number: CCDC 266801 for complex **1** and CCDC 266800 for **2**.

reaction of ethane-1,2-diamine with benzylidene acetone [1,2] crystallises as the *meso*-isomer mL^1. In polar solvents L^1 is present as an equilibrium mixture of, among other compounds, the *meso*-, mL^1, and *rac*-, rL^1, isomers. Reduction of L^1 by using $NaBH_4$ in ethanol yields three isomers of 5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane, in ca. 83, 15 and <1% yields, respectively [2,3], see the Scheme 1. The major (83%) product is the 5*RS*,7*RS*,12*SR*,14*SR*, *meso–meso*-isomer, mmL^2, formed by reduction of mL^1 [4]. The second (15%) product is the 5*RS*,7*RS*,12*RS*,14*RS*, *rac–rac*-isomer, rrL^2, formed by reduction of the rL^1 present in solutions of mL^1 in polar solvents. The third isomer is now shown to have the 5*SR*,7*RS*,12*SR*,14*SR*, *rac–meso*-configuration, rmL^2, also formed by reduction of mL^1.

The reaction of mL^1 with nickel(II) perchlorate in alcohols yields mixtures of the *meso*- and *rac*-isomeric macrocycle compounds $[Ni(mL^1)](ClO_4)_2$ and $[Ni(rL^1)](ClO_4)_2$, in proportions depending on reaction conditions. Procedures for separating these isomers have been described [5] and the structure of $[Ni(rL^1)](ClO_4)_2$ reported [6].

Reduction of the imine functions of $[Ni(mL^1)](ClO_4)_2$ by using $NaBH_4$ in acetonitrile/methanol yields the isomeric cyclic amine cations $[Ni(mmL^2)]^{2+}$ and $[Ni(rmL^2)]^{2+}$ in ca. 8:1 mol ratio [7], while similar reduction of $[Ni(rL^2)]^{2+}$ forms the cation $[Ni(rrL^2)]^{2+}$ [8]. The isomeric nickel(II) cations are also formed by reaction with nickel(II) of the isomeric amines formed by reduction of ethanol solutions of mL^1.

Scheme 1. Showing the preparation of the isomeric $[Ni(L^2)]^{2+}$ cations.

1.2. Stereochemistry of coordinated 5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane isomers

Compounds of mmL^2 with cobalt(III) [9], rhodium(III) [9] and nickel(II) [7] have been described. Structures have been reported for mmL^2 [4] and compounds with the 1*RS*,4*RS*,5*SR*,7*SR*,8*SR*,11*SR*,12*RS*,14*RS* configuration: *trans*-β-$[Ni(mmL^2)(NO_2\text{-}N)_2]$ [7], *trans*-β-$[Cu(mmL^2)(NO_3)_2]$ [10] and *trans*-β-$[Cu(mmL^2)(NCB(Ph)_3)_2]$ [11].

Most nickel(II) compounds of mmL^2 have the macrocycle in planar coordination with the *N*-configuration 1*R*,4*R*,8*S*,11*S* (III [12], labelled as β), as $S = 1$ (singlet ground state) salts, e.g., β-$[Ni(mmL^2)](ClO_4)_2$, or as $S = 3$ (triplet ground state) *trans*-di-ligand octahedral compounds *trans*-β-$[Ni(mmL^2)X_2]$. Relatively unstable compounds with chelates α-$[Ni(mmL^2)(A)]ClO_4$ (A = $acac^-$ = pentane-2,4-dionato and $1/2C_2O_4^{2-}$) were prepared. The structure of the $acac^-$ compound shows the macrocycle in folded coordination with *N*-configuration V [7]. Reaction of the $acac^-$ compound with acid yields the metastable $S = 1$ square-planar compound δ-$[Ni(mmL^2)](ClO_4)_2$, shown to have the *N*-configuration II with overall configuration 1*RS*,4*RS*,5*SR*,7*SR*,8*SR*,11*RS*,12*RS*,14*RS*. This is stable as the solid and in acid solution, but in neutral or basic solution readily reverts to the stable β-configuration [7].

In contrast, most compounds of rrL^2 with nickel(II) have the macrocycle in folded coordination with *N*-configuration 1*R*,4*R*,8*R*,11*R* (V, labelled α) with two *cis* additional ligands, or a chelate, completing octahedral coordination; the structure of *cis*-α-$[Ni(rrL^2)(acac)]ClO_4$ was reported [8]. In perchloric acid this forms the cation *cis*-α-$[Ni(rrL^2)(H_2O)_2]^{2+}$ with the same configuration. In basic solution this isomerises to form the $S = 1$ square planar γ-$[Ni(rrL^2)]^{2+}$ cation with the *N*-configuration 1*R*,4*S*,8*R*,11*S* (I, labelled as γ); the structure of γ-$[Ni(rrL^2)][ZnCl_4] \cdot MeNO_2$ was reported [8]. This cation is stable as solid perchlorate and tetrachlorozincate salts. Solutions of the perchlorate salt are stable, but in the presence of anions of better coordinating ability the cation isomerises to the α-configuration, with formation of chelate or *cis*-dianionato species.

In this communication preparations of compounds of $[Ni(rmL^2)]^{2+}$ are described. Molecular mechanics calculations [7] suggested that the square planar cation $[Ni(rmL^2)]^{2+}$ would have similar strain energies for configuration III (1*S*,4*S*,5*S*,7*R*,8*R*,11*R*,12*S*,14*S*, with one methyl substituent axially oriented and the other equatorially oriented) and for configuration II (1*S*,4*R*,5*S*,7*R*,8*R*,11*R*,12*S*,14*S*, with one six-membered chelate ring in a twist-boat conformation, for which all substituents are equatorially oriented). An X-ray

structural characterisation of *cis*-α-[Ni(mmL^2)(acac)]-ClO_4 enables comparison with the mmL^2 [7] and rrL^2 [8] isomeric compounds.

2. Results

2.1. Reduction of $[Ni(mL^1)](ClO_4)_2$

The imine groups of $[Ni(mL^1)](ClO_4)_2$ are rapidly reduced by using $NaBH_4$ in acetonitrile plus a protic solvent (water, or one of the lower alcohols, with the highest yield obtained using 1:1 acetonitrile:methanol). The major product crystallises as *trans*-β-[Ni(mmL^2)-$(MeCN)_2](ClO_4)_2$, with the *meso–meso* isomer of the macrocycle (ca. 83% yield) [7]. Sparingly soluble blue-violet *cis*-α-[Ni(rmL^2)(acac)]ClO_4 precipitates in ca. 13% yield when pentane-2,4-dione and base are added to the filtrate. Alternatively, if the filtrate is acidified with dilute perchloric acid and allowed to evaporate then orange β-$[Ni(rmL^2)](ClO_4)_2 \cdot 0.5H_2O$ crystallises.

2.2. Reduction of mL^1

The isomer of 5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane which was isolated in <1% yield from the reduction of mL^1 by $NaBH_4$ in ethanol [3] reacted with nickel(II) thiocyanate in ethanol to yield a purple solution from which blue-violet crystals of *trans*-β-$[Ni(rmL^2)(NCS)_2]$ were isolated, see 5.1. Other compounds were prepared from this *trans*-β-[Ni(rmL^2)$(NCS)_2]$ after removal of the NCS^- by reaction with silver perchlorate, or by use of ion exchangers, but these were all identical to, and more easily prepared from, the $[Ni(rmL^2)]^{2+}$ compounds obtained by reduction of $[Ni(mL^1)](ClO_4)_2$.

2.3. Compounds of $[Ni(rmL^2)]^{2+}$

Blue-violet *cis*-α-$[Ni(rmL^2)(H_2O)_2](ClO_4)_2$ crystallises when *cis*-α-[Ni(rmL^2)(acac)]ClO_4 is acidified with perchloric acid. This forms a blue-violet solution in water (in which it is sparingly soluble), but an orange coloured solution in methanol, acetone or nitromethane, indicating the formation of $S = 1$ square-planar nickel(II) cations. The di-aqua compound crystallises from these solutions on evaporation, indicating retention of configuration.

The *cis*-α-$[Ni(rmL^2)(H_2O)_2]^{2+}$ cation persists in acid solution, but slowly in neutral solution, rapidly in basic solution, isomerises irreversibly to the stable orange $S = 1$ square-planar cation β-$[Ni(rmL^2)]^{2+}$. Orange β-$[Ni(rmL^2)](ClO_4)_2$ crystallises from poorly coordinating solvents; the purple adduct *trans*-β-[Ni(rmL^2)-$(MeCN)_2](ClO_4)_2$ crystallises from acetonitrile and blue-violet adducts crystallise from DMF/propan-2-ol or DMSO/propan-2-ol. These are all similar to, but much more soluble than their $[Ni(mmL^2)]^{2+}$ analogues [7]. The facile separation of the $[Ni(rmL^2)]^{2+}$ and $[Ni(mmL^2)]^{2+}$ isomers (see 5.2) is facilitated by the greater solubility in acetonitrile/methanol of *trans*-β-$[Ni(rmL^2)(MeCN)_2](ClO_4)_2$ than the mmL^2 isomeric compound.

Treatment of a solution in methanol of *cis*-α-[Ni(rmL^2)(acac)]ClO_4 with HCl or HBr results in the formation of hydrated blue compounds, which do not contain perchlorate, probably hydrates of the *cis*-dihalido compounds. In basic or neutral solution these halide compounds isomerise to form blue-violet β-*trans*-dihalido compounds, which are also formed from β-$[Ni(rmL^2)(HCO_3)_2]$ (below) and HCl or HBr. Compounds *trans*-β-$[Ni(rmL^2)X_2]$, $X^- = NO_2^-$, NCS^- and HCO_3^-, are formed by reaction of β-$[Ni(rmL^2)](ClO_4)_2$ with a salt of the appropriate anion X^- in methanol/water, or from β-$[Ni(rmL^2)(HCO_3)_2]$ and the appropriate acid HX. Reaction of β-$[Ni(rmL^2)](ClO_4)_2$ with oxalate forms *trans*-μ-oxalato-β-$[Ni(rmL^2)(C_2O_4)] \cdot H_2O$, while reaction of *cis*-α-[Ni(rmL^2)(acac)]ClO_4 with oxalic acid forms the chelate compound *cis*-α-$[\{Ni(rmL^2)\}_2$-$(C_2O_4)](ClO_4)_2$, which isomerises to the *trans*-form in base (as also observed for the $[Ni(mmL^2)]^{2+}$ analogue [7]). Compounds of the potentially chelating anions $NO_3^-, NO_2^-, MeCO_2^-$ and HCO_3^- were isolated only as *trans*-unidentate coordinated β-isomer compounds (again as for their $[Ni(mmL^2)]^{2+}$ analogues, and unlike $[Ni(rrL^2)]^{2+}$ for which these anions coordinate as chelates). Addition of a solution containing $[Ni(CN)_4]^{2-}$ to a solution of $[Ni(rmL^2)]^{2+}$ resulted in the precipitation of sparingly soluble $[\{Ni(rmL^2)\}\{Ni(CN)_4\}] \cdot H_2O$. This has *ν*(CN) bands in the IR similar to those of the mL^2 and rrL^2 analogues, and of other compounds with $\{$-Ni(L)-NC-Ni(CN)$_2$-CN-$\}_n$ chain polymeric structures [13–16].

3. Structural studies

3.1. 1SR,4SR,5SR,7RS,8RS,11RS,12SR,14SR-(5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane $\kappa^4N^1,N^4,N^8,N^{11}$)nickel(II) perchlorate hemi-hydrate, β-$[Ni(rmL^2)](ClO_4)_2 \cdot 0.5H_2O$

The structure of a crystal of orange coloured $[Ni(rmL^2)](ClO_4)_2$ grown from acetone/water was determined by X-ray diffraction, to establish the *N*-configuration present, see Table 1 for details.

The structure was solved and refined in space group $P2_1$, with no imposed symmetry. The structure shows disorder, though the macrocylic cation was well resolved, showing the nickel(II) ion in square-planar coordination by the four nitrogen atoms of the macrocycle with the chiral nitrogen centres in configuration (III, β).

[a] Crystallographic data files have been deposited with the Cambridge Crystallographic Data Centre.
[b] Diffraction data was collected using a Siemens CCD diffractometer in ω scan mode, using graphite monochromaticized Mo Kα radiation (λ 0.71073 Å).
[c] Semi-empirical absorption corrections were made using the ψ-scan method [18].
[d] Structures were solved and refined on F^2 using SHELXS-97 and SHELXL-97 [19]. Anisotropic thermal parameters were used for all non-H atoms, with H-atoms in calculated positions and riding.
[e] Data with $F^2 > 2\sigma(F^2)$.
[f] Flack parameter [20] = −0.06(5).

The five-membered chelate rings have gauche conformations with the $\delta\lambda$ configuration and the six-membered rings have chair conformations.

For configuration III in planar coordination the anticipated structure would have both phenyl substituents equatorially oriented and one methyl substituent equatorially and the other axially oriented. The structure found for the perchlorate salt has both phenyl substituents equatorially oriented, but both methyl substituents have half-occupancy of equatorially and axially oriented sites, resulting in a disordered racemate.

The disorder of the methyl groups was modelled with equatorial sites C51A and C12B, and axial sites C51B, and C12A. Site occupancy factors (sof) refined as free variables were within 3σ of the 0.5 values required for chiral balance. Refinement of models with either one of C51A and C12B or C51B and C12A removed from the calculations led to increases in R-values, with large residual peaks at the "omitted" site. Axial or equatorial orientation of the methyl substituents would be expected to cause differences in ring conformation, and superposition of these conformational variants may account for the relatively large adp values observed for many of the atoms.

The results could also be interpreted with disorder of two cations, one with both methyl groups equatorial and the other with both groups axial. However, these would represent different configurations of the macrocycle, $[Ni(mmL^2)]^{2+}$ for the di-equatorial form, and an as yet unobserved isomer for the di-axial arrangement, which is improbable.

The perchlorate ions are located axially with respect to the square-planar nickel(II) cation, with Ni–O11 and Ni–O21 ca. 2.9 Å, indicating only weak interactions. Disorder of these ions was modelled with trigonal bipyramidal arrangements, with three full occupancy "equatorial" oxygen sites, and partial occupancy "axial" oxygen sites. Short Cl–$O_{equatorial}$ distances but long Cl–O_{axial} distances, together with bond angles ca. 90° for O_{axial}–Cl–$O_{equatorial}$ and ca. 120° for $O_{equatorial}$–Cl–$O_{equatorial}$ suggest the presence of two half-occupancy tetrahedral ions, sharing three "equatorial" oxygen sites. A persistent residual peak near oxygen atom site O14 was assigned as a fractional occupancy water oxygen atom site, O1, with O1–O14 = 1.45(1) Å (so sites O1 and O14 cannot be occupied simultaneously). The chlorine site Cl1 could be split into sites Cl1 and Cl1A, separated by 0.39(1) Å. Refinement of sof of the chlorine and oxygen sites indicated that the equatorial sites O11, O12 and O13 have full occupancy, but sof of the two chlorine sites, the axial oxygen sites and of water O1 were all within 3σ of 0.5, so the sof were fixed at 0.5 for final refinement.

The perchlorate ion including Cl2 has a similar trigonal bypyramidal arrangement that was similarly modelled, except that the chlorine site was not successfully split and there was no resolvable residual water oxygen peak associated with this perchlorate ion. Refinement of sof indicated full occupancy for the "equatorial" sites O21, O22 and O23 and occupancies for the "axial" sites O24 of 0.68(3) and for O25 of 0.32(3).

Hydrogen atoms bound to C5, C12 and O1 were not modelled. Large adp values for Cl and O atoms, and residual peaks near these atoms, indicate that this model only approximates the disorder present for the perchlorate ions.

All NH groups form H-bonds with perchlorate oxygen atoms, N11 with the alternative partial occupancy water oxygen atom O1 and perchlorate oxygen atom O15. See the legend to Fig. 1 for significant dimensions.

As the structure is pseudo-centrosymmetrical it was also refined in space group $P2_1/c$, for which the asymmetric unit consists of half the cation and one perchlorate ion. The dimensions for the cation in this solution were not significantly altered, with half-occupancy axial and equatorially oriented methyl substituent sites present. The single perchlorate ion and water sites of

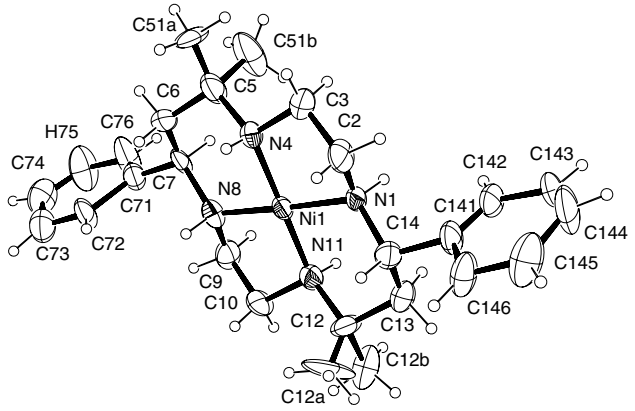

Fig. 1. The cation of *trans*-β-[Ni(rmL^2)(ClO$_4$)$_2$]·1/2H$_2$O, drawn [17] with displacement ellipsoids at the 30% confidence level, with hydrogen atoms as circles of arbitrary radius. Note the half-occupancy axial and equatorial sites for the methyl substituents. Distances within the coordination sphere are Ni–N1 = 1.96, Ni–N4 = 1.96, Ni–N8 = 1.95, Ni–N11 = 1.93, Ni–O11 = 2.92 and Ni–O21 = 2.88 Å, s.u. = 0.01 Å, with angles N1–Ni–N4 = 85.9(4), N1–Ni–N8 = 177.6(6), Ni–Ni–N11 = 94.1(4), N4–Ni–N8 = 92.7(4), N4–Ni–N11 = 179.8(6) and O11–Ni–O21 = 178.5(5)°. Angles N–Ni–O11 and N–Ni–O21 were in the range 84–95°. The N$_4$ group shows tetrahedral displacements of ±0.012(7) Å, with the Ni displaced from the N$_4$ plane by 0.015(8) Å. Displacement of ring atoms from the N$_4$ plane are: C2 −0.39, C3 0.34, C5 0.69, C6 0.32, C7 0.69, C9 0.37, C10 −0.36, C12 −0.83, C13 −0.36, C14 −0.80 Å (s.u. 0.02 Å). The NH groups, perchlorate and water oxygen atoms are linked by N–H···O hydrogen bonding {H–O, N–O/Å, N–H···O/°}: N1–H1···O13 [2.24, 3.102(2), 157]; N4–H4···O24 [2.13, 3.02(2), 148]; N8–H8···O21 [2.11, 3.01(2), 164]; N11–H11···O14 [2.21, 3.05(2), 155] and N11–H11···O1 [2.16, 3.03(2), 161].

$P2_1/c$ were averages of the two $P2_1$ solution sites. The R factors for this solution were $R_1 = 0.066$ [$>2\sigma(I)$], 0.961 (all data), cf. 0.046 and 0.076 for the solution in $P2_1/c$.

3.2. *cis-1SR,4SR,5SR,7RS,8SR,11SR,12SR,14SR-(5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane $\kappa^4N^1,N^4,N^8,N^{11}$)(pentane-2,4-dionato κ^2O,O')-nickel(II) perchlorate, cis-α-[Ni(rmL^2)(acac)]ClO$_4$*

The structure of a crystal of lavender coloured *cis*-α-[Ni(rmL^2)(acac)]ClO$_4$ grown from acetone/water was determined by X-ray diffractometry, see Table 1 for details.

The nickel(II) ion is in octahedral coordination by the tetradentate macrocycle rmL^2, folded adjacent to the phenyl substituents (N1–Ni–N8 fold-line), and chelate pentane-2,4-dionate, see Fig. 2. Both six-membered chelate rings have chair conformations; the ring including Ni,N4,N8 has both substituents equatorially oriented, the ring including Ni,N1,N11 has the methyl substituent equatorially oriented and the phenyl substituent axially oriented. This phenyl ring is approximately parallel with the O$_2$C$_3$ plane of the acac$^-$ chelate (inclination of these planes 5.2°, separation ca. 4.4 Å).

The perchlorate ion lies in the cleft in the folded macrocycle opposite the acac$^-$ chelate, with very weak hydrogen bonds between perchlorate oxygen atoms and the fold-line N–H groups N1–H1···O3 {N–O, H–O/Å,

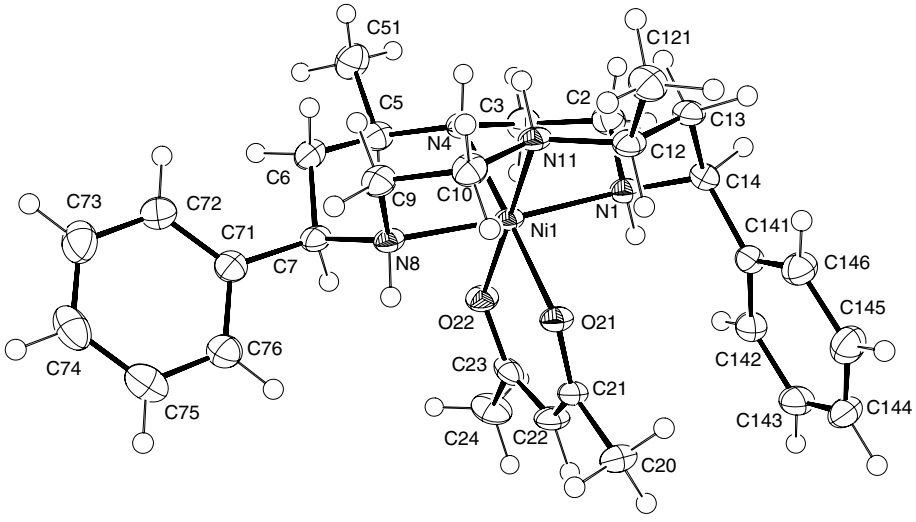

Fig. 2. The cation of *cis*-α-[Ni(rmL^2)(acac)]ClO$_4$, drawn as for Fig. 1 (except for the displacement ellipsoids which are at the 50% confidence level). Significant bond lengths are: Ni–N1 = 2.107(2), Ni–N4 = 2.125(2), Ni–N8 = 2.082(2), Ni–N11 = 2.126(2), Ni–O21 = 2.028(1), Ni–O22 = 2.028(1), O21–C21 = 1.267(3), O22–C23 = 1.264(3), C21–C20 = 1.509(3), C21–C22 = 1.399(3), C23–C22 = 1.390(3) and C23–C24) = 1.515(3) Å. Significant bond angles are: N1–Ni–N4 = 84.70(6), N8–Ni–N4 = 92.99(6), N8–Ni–N11 = 84.47(6), N1–Ni–N11 = 93.17(6), N4–Ni–N11 = 98.16(6), N1–Ni–N8 = 176.45(6), O21–Ni–N1 = 94.64(6), O21–Ni–N4 = 175.98(6), O21–Ni–N8 = 87.85(6), O21–Ni–N11 = 85.83(6), O21–Ni–N4 = 175.98(6), O22–Ni–N1 = 90.71(6), O22–Ni–N11 = 174.71(6), O22–Ni–N4 = 85.77(6), O22–Ni–N8 = 91.81(6), O22–Ni–N11 = 174.71(6) and O21–Ni–O22 = 90.27(6)°. Displacements (Å, s.u < 0.005 Å) from relevant chelate N–Ni–N planes: C2 0.13, C3 −0.56 (gauche); C5 0.77, C51 0.51, C6 0.47, C7 0.86, C71 0.92 (chair, with substituents C51 and C71 equatorial); C9 0.19, C10 −0.50 (gauche); C12 0.87, C121 0.90, C13 0.38, C14 0.33, C141 2.22 (chair, with C121 equatorial and C141 axial). The O$_2$C$_3$ group of the acac$^-$ ligand is approximately coplanar (mean deviation from plane 0.023 Å), with the Ni 0.29 Å from this plane. Intra-cyclic torsion angles, commencing with C14–N1–C2–C3, are: −165.8°, 56.0°, 175.3°, 169.4°, −65.4°, 70.6°, 68.2°, −165.9°, 55.7°, −169.0°, 178.9°, −77.4°, 67.4°, 77.9°.

N–H···O/°} [3.133(5), 2.30, 149]; N8–H8···O1 [3.058(5), 2.61, 162] and to the non-fold-line N–H groups of another cation N4–H4···O4^{i} [3.095(5), 2.25, 151]; N11–H11···O2^{i} [3.279(5), 2.39, 159], symmetry operation i = $-x$, $y + 1/2$, $-z + 1/2$.

3.3. Comparison of isomeric $[Ni(L^2)(acac)]^+$ cations.

The structures of the three isomeric compounds [Ni(L^2)(acac)]ClO$_4$, L^2 = rrL^2 [8], mmL^2 [7], and rmL^2 [this work] have now been determined. These are similar, but with significant structural differences. The mean Ni–N and Ni–O distances for the compounds are similar: *cis*-[Ni(rmL^2)(acac)]ClO$_4$ 2.110(3) and 2.028(1); *cis*-[Ni(rrL^2)(acac)]ClO$_4$ 2.114(6) and 2.019(4) and *cis*-[Ni(mmL^2)(acac)]ClO$_4$ 2.121(6) and 2.042(3) Å, respectively. The Ni atom lies in the C_3O_2 plane of the acac$^-$ chelate for the twofold-symmetric rrL^2 compound, while it is displaced from this plane by 0.11 and 0.29 Å, respectively, for the rmL^2 and mmL^2 compounds. The arrangement of anion and cation is generally similar for the three isomeric compounds, with the perchlorate ion lying in the cleft in the folded macrocycle opposite the acac$^-$ chelate and weakly hydrogen bonded to the non-fold-line NH groups, and to the fold-line N–H groups of another cation to generate a network. For *cis*-[Ni(rmL^2)(acac)]ClO$_4$ the perchlorate oxygen atoms are well resolved with no indication of disorder, while the perchlorate ion is rotationally disordered for the other two compounds.

The cations *cis*-[Ni(mmL^2)(acac)]$^+$ and centrosymmetrical *cis*-[Ni(rrL^2)(acac)]$^+$ both have the macrocycle folded along N^4–Ni–N^{11}, adjacent to the methyl substituents, while *cis*-[Ni(rmL^2)(acac)]$^+$ is folded along N^1–Ni–N^8, adjacent to the phenyl substituents, see Fig. 3. In principle all three isomers could fold either way. For *cis*-[Ni(rrL^2)(acac)]$^+$ the least strained forms of the two possible folding modes have different chiral arrangements; the observed N^4–Ni–N^{11} folded form has the same chirality for the four carbon and four nitrogen asymmetric centres, while the N^1–Ni–N^8 folded form would require the nitrogen and carbon centres to have opposite chiralities. This cation has all substituents equatorially oriented on chair conformation six-membered chelate rings for both folding modes. For *cis*-[Ni(rmL^2)(acac)]$^+$ the two possible folding arrangements have different chiralities (the observed N^1–Ni–N^8 folding, 1*R*,4*S*,5*S*,7*R*(axial),8*S*,11*S*,12*S*,14*S* and N^4–Ni–N^{11} folding, 1*R*,4*R*,5*R*,7*S*(axial),8*R*,11*R*,12*R*, 14*R*) both with one phenyl substituent axially oriented for chair conformation six-membered chelate rings. Adoption of an asymmetric boat conformation for the chelate ring would orient this phenyl group pseudo-equatorially, but apparently the increased strain energy for the unfavourable conformation is greater than the gain from the more favourable substituent orientation. For *cis*-[Ni(mmL^2)(acac)]$^+$ both folding modes have the same chiralities, with both substituents on one chair conformation six-membered chelate ring axially oriented. This chelate ring can adopt one of two asymmetric boat conformations, which orient one of the substituents pseudo-equatorially, the other pseudo-axially. The observed structure has N^4–Ni–N^{11} folding with an asymmetric boat conformation with the phenyl substituent pseudo-equatorially and the methyl substituent pseudo-axially oriented. In this case the strain energy reduction from more favourable substituent orientation is greater than the increase from the unfavourable ring conformation.

4. Discussion

The cation [Ni(rmL^2)]$^{2+}$ predominantly forms compounds in planar coordination, with nitrogen configuration

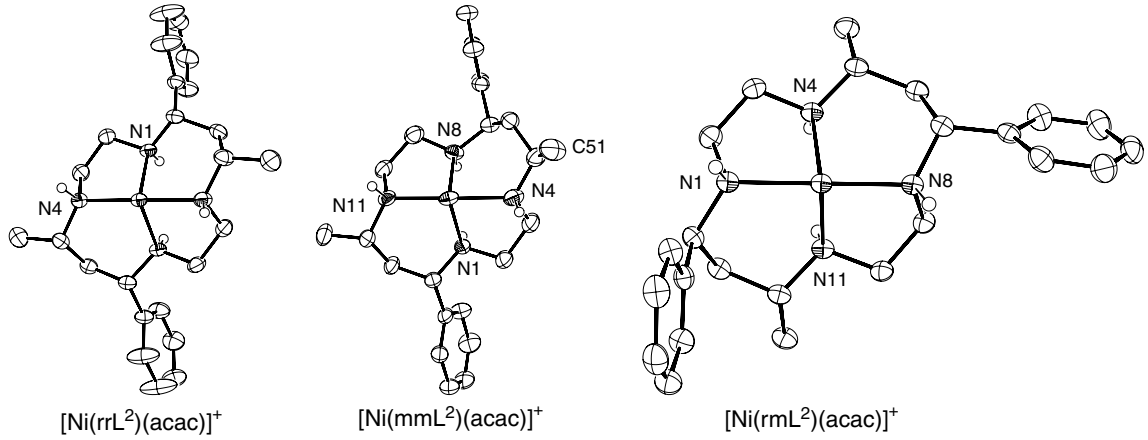

Fig. 3. The cations of the three isomeric [Ni(L^2)(acac)]ClO$_4$ salts, drawn as for Fig. 2, but omitting the pentane-2,4-dionate chelate and H-C atoms, shown from similar perspectives (approximately that of the perchlorate counter-ion). Note the N4–Ni–N11 fold line for [Ni(rrL^2)(acac)]$^+$ and [Ni(mmL^2)(acac)]$^+$ but the N1–Ni–N8 fold line for [Ni(rmL^2)(acac)]$^+$. All substituents are equatorially oriented for [Ni(rrL^2)(acac)]$^+$, one methyl group axially oriented for [Ni(mmL^2)(acac)]$^+$ and one phenyl group axially oriented for [Ni(rmL^2)(acac)]$^+$.

III, in $S = 3$, *trans*-di-ligand or $S = 1$ square planar geometries. The only stable folded coordination, configuration V, compound observed is $S = 3$ [Ni(rmL^2)(acac)]ClO$_4$, though metastable *cis*-α-[Ni(rmL^2)(H$_2$O)$_2$](ClO$_4$)$_2$, –[Ni(rmL^2)Cl$_2$], –[Ni(rmL^2)Br$_2$] and –[{Ni(rmL^2)}$_2$(C$_2$O$_4$)](ClO$_4$)$_2$ have been prepared. The coordination geometry of rmL^2 is thus more similar to that of the mmL^2, rather than the rrL^2, isomer. The differences in properties of these isomeric amines arise from the differing strain energies largely caused by equatorial or axial orientation of the substituents determined by the ligand chirality [7,8]. The cation [Ni(rmL^2)]$^{2+}$ as the perchlorate salt adopts configuration III but rather than a static arrangement with one methyl substituent axially and the other equatorially oriented has a disordered structure with equal occupancies of the two possible arrangements.

5. Experimental

5.1. Preparation of compounds

The perchlorate salts described are not shock-sensitive, and decomposed non-violently when strongly heated. They should still be treated with the caution due to any perchlorate salt.

[Ni(mL^1)](ClO$_4$)$_2$ was prepared and purified from the *C-rac* isomer by crystallisation as the bis(acetontrile) adduct [5]. Any [Ni(rL^1)](ClO$_4$)$_2$ present will reduce to form [Ni(rrL^2)]$^{2+}$ which will contaminate the [Ni(rmL^2)(acac)]ClO$_4$.

The cation [Ni(rmL^2)]$^{2+}$ is very resistant to acid demetallation, so is unaffected by relatively concentrated acid solutions, other than of nitric acid which rapidly oxidises it. The compounds generally have low solubility in water (forming yellow, dissociated solutions), but are often quite soluble in polar organic solvents. The [Ni(rmL^2)]$^{2+}$ compounds in planar coordination are similar to, but generally more soluble than their [Ni(mmL^2)]$^{2+}$ analogues, while compounds in folded coordination are generally similar to their [Ni(rrL^2)]$^{2+}$ counterparts.

5.2. Reduction of 5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene

C-meso-(5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene) was reduced in ethanol by using NaBH$_4$ [3]. The mmL^2 isomer was separated as the sparingly soluble hydrochloride salt, and the filtrates made basic and extracted with light petroleum, the extract solution allowed to evaporate, and successive crops of the crystalline rrL^2 amine filtered off. Ultimately crystals with a different habit formed as the more soluble rmL^2 isomer, contaminated with rrL^2, crystallised in <1% yield. Because of the small yield and high solubility this proved difficult to purify by recrystallisation.

5.3. trans-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane) dithiocyanatonickel(II), trans-β-[Ni(rmL^2)(NCS)$_2$]

Reaction of the crude rmL^2 with nickel(II) thiocyanate in ethanol formed a purple solution from which blue-violet crystals of *trans*-[Ni(rmL^2)(NCS)$_2$] and blue crystals of *cis*-[Ni(rrL^2)(NCS)$_2$] formed. These were repeatedly recrystallised from ethanol until blue-violet crystals, free of the blue material, were obtained. The same product crystallised when NaCNS was added to a solution of β-[Ni(rmL^2)](ClO$_4$)$_2$. *Anal*. Calc. C$_{26}$H$_{38}$N$_6$NiO C, 54.4, H, 6.7, Ni, 10.2. Found: C, 54.6; H, 6.6; Ni, 10.1. Spectra: λ_{max}/nm ν_1(901, 725), ν_2 518; IR ν_{max}/cm^{-1} ν(NH) 3281, 3223, ν(C≡N) 2078vs, 2067sh.

5.4. (5SR,7RS,12SR,14SR-5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)(pentane-2,4-dionato)-nickel(II) perchlorate, cis-α-[Ni(rmL^2)(acac)]ClO$_4$

[Ni(mL^1)](ClO$_4$)$_2$ Purified from the *C-rac* isomer by crystallisation as the bis(acetontrile) adduct, (10 g), was progressively added to a stirred solution of NaBH$_4$ (1.3 g, 1:2 mol proportions) in acetonitrile (25 cm^3) plus methanol (25 cm^3). Effervescence occurred and grey-mauve [Ni(mmL^2)(CH$_3$CN)$_2$](ClO$_4$)$_2$ crystallised, leaving a pale orange coloured solution. After 1 h slight effervescence was observable, indicating the presence of excess BH$_4^-$ (if not a little extra NaBH$_4$ was added). After 2 h, the [Ni(mmL^2)(CH$_3$CN)$_2$](ClO$_4$)$_2$ was filtered off and washed with 1:1 acetonitrile:methanol, retaining the filtrates which contain the rmL^2 compound. The [Ni(mmL^2)(CH$_3$CN)$_2$](ClO$_4$)$_2$ was heated to boiling with 30 cm^3 of the same solvent mixture, then the mixture stirred overnight at ambient temperature. The solid was filtered off and washed as before, retaining the filtrate. The [Ni(mmL^2)(CH$_3$CN)$_2$](ClO$_4$)$_2$ was heated at 80 °C to form the non-solvated compound in ca. 90% yield.

The combined filtrates were boiled, pentane-2,4-dione (2 cm^3) added (care, effervescence may occur if any borohydride remains), followed by hot aqueous ammonia (100 cm^3, 1 mol dm^{-3}) added slowly and the solution then heated near boiling for 30 min. The blue-violet product was filtered from the cold solution and washed with water, sucked dry, then washed with propan-2-ol until the washings were colourless. This was recrystallised from hot acetone/propan-2-ol. Yield: ca. 1.0 g, 10%. *Anal*. Calc. for C$_{29}$H$_{43}$ClN$_4$NiO$_6$: C, 54.6, H, 6.8, Ni, 8.8. Found: C, 54.6, H, 6.7, Ni, 8.7%.

5.5. trans-Di-aqua-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) perchlorate hemihydrate, trans-β-[Ni(rmL^2)-(H$_2$O)$_2$](ClO$_4$)$_2$ · 1/2H$_2$O

Perchloric acid (20 cm^3, 0.1 mol dm^{-3}) was added to [Ni(rmL^2)(acac)]ClO$_4$ (1 g) dissolved in acetone (20 cm^3) and the solution allowed to evaporate, when the blue violet *product* crystallised. This was filtered off and recrystallised by dissolving, without heating, in acetone containing a drop of dilute perchloric acid, to form an orange coloured solution. Perchloric, acid (0.1 mol dm^{-1}) was added until just turbid, and the solution allowed to evaporate as before. The blue-violet crystals were filtered off and washed with ethanol. *Anal*. Calc. for $C_{24}H_{37}Cl_2N_4NiO_{8.5}$: C, 44.5; H, 5.8; N, 8.7; Ni, 10.2. Found: C, 44.4; H, 6.1; N, 8.6; Ni, 10.1%. IR spectrum ν_{max}/cm^{-1} *ν*(OH) ca. 3600br, *ν*(NH) 3172s,sp.

5.6. (5SR,7RS,12SR,14SR-5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) perchlorate hemihydrate, [Ni(rmL^2)](ClO$_4$)$_2$ · 1/2H$_2$O

A drop of ethylamine (or methylamine) solution was added to an orange coloured solution of *cis*-α-[Ni(rmL^2)(H$_2$O)$_2$](ClO$_4$)$_2$ in acetone, and the solution boiled. The solution was then acidified with dilute HClO$_4$ and allowed to evaporate, when the orange *product* crystallised. This was recrystallised by evaporation of an acetone/propan-2-ol solution. *Anal*. Calc. for $C_{24}H_{36}Cl_2N_4NiO_8$: C, 45.2, H, 5.7, N, 8.8; Ni, 9.2. Found: C, 44.9, H, 6.7, N, 8.8; Ni, 9.2%. Calc. for hemi-hydrate $C_{24}H_{37}Cl_2N_4NiO_{8.5}$: C, 44.5, H, 5.8, N, 8.7; Ni, 9.1%. IR spectrum ν_{max}/cm^{-1}*ν*(NH) 3172s,sp. Some samples showed weak *ν*(OH) bands. The structural study of a crystal grown from acetone/water confirmed it was a hemi-hydrate.

5.7. cis-Dichloro-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) Dihydrate, cis-α-[{Ni(rmL^2)$_2$Cl$_2$] · 2H$_2$O}

Concd. HCl was added drop-wise to an acetone solution of *cis*-α-[Ni(rmL^2)(acac)]ClO$_4$ when the blue *product* crystallised. This was filtered off and washed with water and ethanol. *Anal*. Calc. for $C_{24}H_{38}Cl_2N_4NiO_2$: C, 52.4, H, 7.4, N, 10.3. Found: C, 52.8; H, 7.4; N, 10.3%. Spectra: λ_{max}/nm (MeOH) ν_1 (943, 676), ν_2 541; IR ν_{max}/cm^{-1}; *ν*(NH) 3257m,sp; 3228m,sp.

5.8. cis-Dibromo-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) Hemihydrate, cis-α-[{Ni(rmL^2)$_2$Br$_2$] · 1/2H$_2$O}

As for the previous compound, substituting HBr for the HCl, to form the blue *product*. *Anal*. Calc. for $C_{24}H_{36}Cl_2N_4Ni$: C, 56.3, H, 7.5; N, 11.5. Found: C, 56.6; H, 7.7; N, 11.5%. Spectra: λ_{max}/nm (MeOH) ν_1 (943, 676), ν_2 541; IR ν_{max}/cm^{-1}; *ν*(NH) 3257m,sp; 3228m,sp.

5.9. trans-Dichloro-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) Dihydrate, trans-β-[Ni(rmL^2)Cl$_2$] · 2H$_2$O

The blue chloro compound was boiled in methanol/water, when the colour changed from blue to blue-violet and the blue violet product crystallised. This was filtered off and washed with water and ethanol. *Anal*. Calc. for $C_{24}H_{40}Cl_2N_4NiO_2$: C, 52.8, H, 7.4, N, 10.3. Found: C, 52.4; H, 7.4; N, 10.2%. Spectra: λ_{max}/nm (MeOH) ν_1 (943, 676), ν_2 541; IR ν_{max}/cm^{-1}; *ν*(NH) 3259m, 3203s.

5.10. trans-Dibromo-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) hemihydrate, trans-β-[Ni(rmL^2)Br$_2$] · 1/2H$_2$O

The blue *cis*-dibromo compound was boiled in methanol/water, when the colour changed from blue to blue-violet and the blue violet product crystallised. This was filtered off and washed with water and ethanol. *Anal*. Calc. for $C_{24}H_{37}Br_2N_4NiO_{0.5}$: C, 47.4, H, 6.1, N, 9.2. Found: C, 47.3; H, 6.2; N, 9.2%. Spectra: λ_{max}/nm (MeOH) ν_1 (943, 676), ν_2 541; IR ν_{max}/cm^{-1}; *ν*(NH) 3258m, 3202s.

5.11. trans-(5SR,7RS,12SR,14SR-5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)bis(hydrogen carbonato)nickel(II) hydrate, trans-β-[Ni(rmL^2)-(HCO$_3$)$_2$] · H$_2$O

An aqueous solution of NaHCO$_3$ in small excess was added to an acetone/water solution of [Ni(rmL^2)]-(ClO$_4$)$_2$, when the blue-violet product precipitated. This was filtered off and washed with water and acetone. *Anal*. Calc. for $C_{25}H_{37}N_4NiO_7$: C, 50.1; H, 6.2; N, 9.3. Found: C, 50.3; H, 5.9; N, 9.4%. The IR spectrum shows complex absorption 3600-2600 cm^{-1}, very similar to that shown by the mmL^2 analogue [7]; ν_{max}/cm^{-1} *ν*(OH, NH) 3619m, 3529w, 3418w,br, 3270m, 3058w, 3028w; *ν*C(OH), 2687br, 2647; ν_{as}(HCO$_3^-$) 1610vs,sp; ν_s(HCO$_3^-$) 14105s,sp.

5.12. Other trans-β-[Ni(mmL^2)X$_2$] compounds

Compounds *trans*-β-[Ni(mmL^2)X$_2$] were formed by adding an aqueous solution of a soluble salt of the anion X$^-$, usually of Na$^+$ or Li$^+$, to a methanol solution of β-[Ni(rmL^2)](ClO$_4$)$_2$. Alternatively, an aqueous solution of the acid HX was added to a methanol solution of *trans*-β-[Ni(rmL^2)(HCO$_3$)$_2$]. The methanol was allowed to evaporate when the (usually) blue-violet products

crystallised. The products were filtered off, washed with water and recrystallised from hot methanol/propan-2-ol, unless otherwise specified.

5.13. trans-(5SR,7RS,12SR,14SR-5,12-Dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane)dinitronickel(II), trans-β-[Ni(rmL^2)(NO$_2$)$_2$]

The straw-coloured product crystallised when aqueous $NaNO_2$ was added to an acetone/water solution of [Ni(rmL^2)](ClO$_4$)$_2$. This was filtered off and recrystallised from hot acetonitrile/water. *Anal*. Calc. for $C_{24}H_{36}N_6NiO_4$: C, 54.3; H, 6.8; N, 15.8. Found: C, 54.5; H, 6.9; N, 15.8%. IR spectrum: ν_{max}/cm^{-1} ν(NH) (3202, 31830 s, sp; $\nu_{as}(NO_2^-)$ 1377s,sp, $\nu_s(NO_2^-)$ 1264s,sp.

5.14. trans-bis-Acetato-5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane nickel(II) hydrate, trans-β-[Ni(mmL^2)(CH$_3$CO$_2$)$_2$] · H$_2$O

This blue-violet compound was prepared by reaction of the hydrogen carbonato compound with dilute acetic acid and recrystallised from methanol/propan-2-ol. *Anal*. Calc. for $C_{28}H_{42}N_4NiO_4$: C, 60.3; H, 7.6; N, 10.1. Found: C, 60.4; H, 7.7; N, 10.0%. Spectra: λ_{max}/nm (MeOH) ν_1 (1090, 680), ν_2 526 , ν_3 346; IR ν_{max}/cm^{-1} ν(NH) 3246, 3181br, ν_{as}(OCO) 1567vs,br, ν_s(OCO) 1415s.

5.15. μ-Oxalato-bis(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane) oxalato-dinickel(II) perchlorate, cis-μ-C$_2$O$_4$-α-[{Ni(mmL^2)}$_2$-(C$_2$O$_4$)](ClO$_4$)$_2$

Oxalic acid in small excess was added to an acetone solution of [Ni(rmL^2)(acac)]ClO$_4$ in acetone, followed by water. The blue-violet product was filtered, washed with water and then ethanol and recrystallised from acetonitrile/propan-2-ol. *Anal*. Calc. for $C_{25}H_{36}N_4ClNiO_6$: C, 51.5; H, 6.2; N, 9.6. Found: C, 51.2; H, 6.3; N, 9.5%. The compound is stable in acid solution, but in neutral or basic solution slowly converts to the *trans*-β-oxalato compound. IR spectrum ν_{max}/cm^{-1} ν(NH) 3270; ν_{as}(OCO) (1656, 1649, 1644)vs; $\nu_3(ClO_4^-)$ 1084; $\nu_4(ClO_4^-)$ 624.

5.16. catena-μ-Oxalato-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane) oxalatonickel(II) hydrate, {trans-μ-C$_2$O$_4$-β-[Ni(mmL^2)}$_2$-(C$_2$O$_4$)]$_n$ · nH$_2$O

The μ-oxalato compound was prepared from the perchlorate salt in acetone/water by adding diethyl ammonium oxalate, or by reacting [Ni(rmL^2)(HCO$_3$)$_2$] 1.5H$_2$O with oxalic acid in methanol/water. The insoluble blue-violet *product* was filtered off and washed well with hot water *Anal*. Calc. for $C_{26}H_{38}N_4NiO_5$: C, 57.3; H, 7.0; N, 10.3. Found: C, 57.3; H, 6.6; N, 10.2%. IR spectrum ν_{max}/cm^{-1} ν(OH) 3410; ν(NH) 3227, 3170; ν_{as}(OCO) (1565)vs; ν_s(OCO) 1305.

5.17. Catena-di-μ-cyano-(5SR,7RS,12SR,14SR-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane) dinickel(II) Trihydrate trans-μ-CN-α-[{Ni(mmL^2)}-{Ni(CN)$_4$}]$_n$ · 3nH$_2$O

The insoluble blue-violet *product* which precipitated when an aqueous solution of Na$_2$[Ni(CN)$_4$] · 3H$_2$O was added drop-wise to a methanol solution of [Ni(rmL^2)]-(ClO$_4$)$_2$ was filtered off and washed well with water and then methanol. *Anal*. Calc. for $C_{28}H_{42}N_8Ni_2O_3$: C, 51.3; H, 6.4; N, 17.3. Found: C, 51.3; H, 6.3; N, 17.1%. IR spectrum ν_{max}/cm^{-1} ν(OH) 3604; ν(NH) 3443; ν(CN) 2143s, 2127vs; δ(HOH) 1625.

Appendix A. Supplementary data

Crystallographic data has been deposited with the Cambridge Crystallographic Data Centre; [Ni(rmL^2)]-(ClO$_4$)$_2$ · 0.5H$_2$O: CCDC 271481 and [Ni(rmL^2)(acac)]-ClO$_4$: CCDC 271482. Recently, we have developed a straightforward synthetic route to the preparation of the new multitopic ligand 2,3-bis(4,5-dimethylthio-1,3-dithiole-2-ylidene) succinonitrile (**L**) [6]. Ag(I) is a soft metal center with a high affinity for soft nitrogen- and sulfur-containing ligands [7]. In principle, the framework of Ag(I) complexes can vary widely as reported in the literature [8]. As a consequence, we have initiated a study of the network topology based on **L** as a function of counterions. Herein, we present structural studies of coordination networks derived from ligand **L** and two different AgX ($X = NO_3^-, CF_3SO_3^-$) salts.

2. Experimental

2.1. Materials and equipment

Unless stated otherwise, all chemicals were purchased from commercial sources and used as received. IR spectra were recorded on a Perkin–Elmer One FT-IR spectrometer. Elemental analyses were performed on an EA 1110 Elemental Analyzer CHNS Carlo Erba Instruments.

2.2. Synthesis of complex $[Ag_2(\mathbf{L})(NO_3)_2]_n$ (1)

The solution of ligand **L** [5] (10 mg, 0.022 mmol) in 5 ml of dichloromethane was added to one side of an H-tube. A saturated solution of $AgNO_3$ in methanol (5 ml) was added to the other side of the H-tube, and the two sides of the H-tube were carefully connected by methanol and left in dark place at room temperature. After one week, yellowish crystals suitable for X-ray analysis were obtained on the wall of the H-tube. Yield: 10.4 mg (60%). *Anal.* Calc. for $C_{14}H_{12}Ag_2N_4O_6S_8$: C, 20.90; H, 1.50; N, 6.96. Found: C, 20.74; H, 1.40; N, 6.67%. IR (cm^{-1}, *v* KBr): 2182, 1508, 1459, 1434, 1332, 1040, 968, 817, 734.

2.3. Synthesis of complex $[Ag_2(\mathbf{L})(CF_3SO_3)_2]_n$ (2)

Following the same procedure as for the preparation of complex **1**, complex **2** has been obtained as yellowish crystals by the slow diffusion between the solution of ligand **L** (13 mg, 0.028 mmol) in 5 ml of dichloromethane and a saturated solution of $AgCF_3SO_3$ in methanol (5 ml). Yield: 13.7 mg (50%). *Anal.* Calc. for $C_{16}H_{12}Ag_2F_6N_2O_6S_{10}$: C, 19.64; H, 1.24; N, 2.86. Found: C, 19.80; H, 1.15; N, 2.77%. IR (cm^{-1}, *v* KBr): 2190, 1523, 1468, 1281, 1197, 1015, 735, 635, 734.

2.4. Crystallography

Intensity measurements for complexes **1** and **2** were collected on a Stoe Imaging Plate Diffractometer System – Stoe and Cie [9], equipped with a one-circle φ goniometer and a graphite-monochromator. Data collection was performed using Mo Kα radiation ($\lambda = 0.71073$). The structures were solved by Direct methods using the programme SHELXS-97 [10]. The refinement and all further calculations were carried out using SHELXL-97 [11].

The hydrogen atoms were included in calculated positions and treated as riding atoms using SHELXL-97 default parameters. All non-hydrogen atoms were refined anisotropically. An absorption correction was applied using DIFABS [12] ($T_{min} = 0.154$, $T_{max} = 0.627$ for **1**; $T_{min} = 0.714$, $T_{max} = 0.722$ for **2**).

Both compounds crystallize in non-centrosymmetric space groups (**1**: $P2_12_12_1$, **2**: $C2$) as racemic twins (**1**: BASF = 0.48(12); **2**: BASF = 0.69(7)). The crystallographic data of the complexes **1** and **2** are collected in Table 1. Selected bond lengths and angles are given in Tables 2 and 3, respectively.

3. Results and discussion

3.1. Structure of complex $[Ag_2(\mathbf{L})(NO_3)_2]_n$ (1)

The compound crystallizes in an orthorhombic space group ($P2_12_12_1$) with a metal to ligand stoichiometry of 2:1. The coordination geometry around the silver ion is a distorted octahedron (Fig. 1) with a NO_3S_2 coordination sphere. Thus, the metal ion is bonded to two sulfur atoms of ligand **L**, one nitrogen atom of a neighboring ligand **L**, two oxygen atoms of a bridging

nitrate ion in a chelating mode and one oxygen atom of a bridging nitrate ion in a monodentate manner. The average bond distances of Ag–S, Ag–N and Ag–O are 2.774(5), 2.368(13) and 2.558(14) Å, respectively. The greatest deviation from idealized octahedral geometry around the silver ion is observed for the nitrogen and sulfur atoms of ligand, N(1)^{ii}–Ag(1)–S(4) 156.3 (4)° (see Table 2).

Each ligand **L** coordinates four Ag(I) ions, on one side through its sulfur atoms in a chelating mode and on the other side through its nitrogen atoms of the two nitrile groups. Thereby, as illustrated in Fig. 2, an extended coordination network in two dimensions is formed which contains loops of four half **L** molecules and four Ag(I) ions. Furthermore, these 2D networks are interlinked by bridging nitrates through Ag–O–N–O–Ag bonds leading to a Ag···Ag non-bonding distance of 5.31 Å. Overall, due to these bridging NO_3^- anions, a 3D coordination network is generated. Within this network, the shortest S···S distance between the neighboring layers is 5.31 Å, hence significantly longer than the van der Waals radius sum (3.70 Å) [13]. Consequently, the S···S interaction between the neighboring 2D layers is negligible.

3.2. Structure of complex $[Ag_2(L)(CF_3SO_3)_2]_n$ (2)

In order to evaluate the influence of counterions on the coordination behaviour, $AgCF_3SO_3$ was used instead of $AgNO_3$ in the reaction with **L**, whereby a new complex (**2**) was obtained. On the one hand, $CF_3SO_3^-$

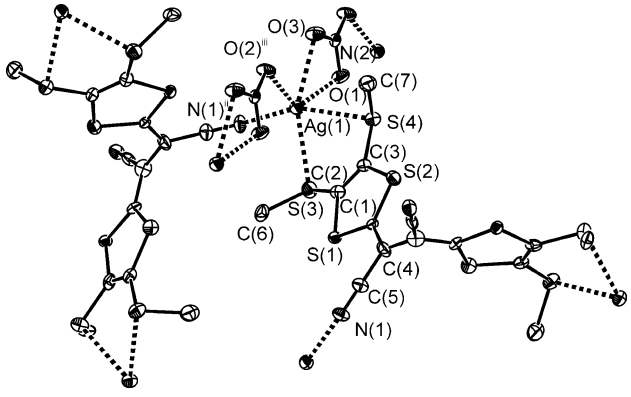

Fig. 1. ORTEP plot (50% probability ellipsoids) showing the Ag(I) coordination sphere of **1**.

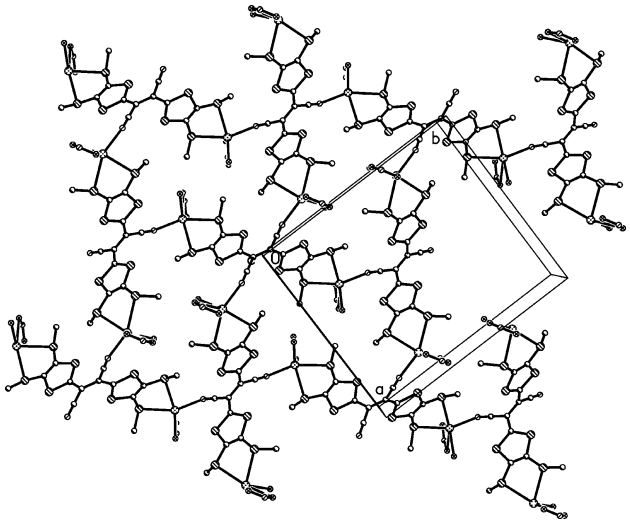

Fig. 2. *ab* projection of the crystal structure of **1**, elucidating the 2D coordination network formed by the $[Ag_2L]$ fragments.

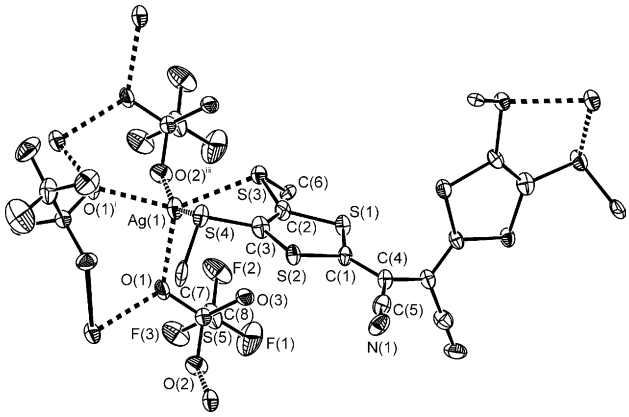

Fig. 3. ORTEP plot (50% probability ellipsoids) showing the Ag(I) coordination sphere of **2**.

is larger than NO_3^-, and on the other hand, its oxygen atoms have a stronger coordination ability than those of NO_3^- [14]. The compound crystallizes in a monoclinic space group (*C*2), again with a metal to ligand stoichiometry of 2:1. Interestingly, as shown in Fig. 3, the silver ions which are bonded to the sulfur atoms of **L** are only bridged by triflate ions and no more coordinated to the nitrogen atoms of the nitrile groups. Specifically, the coordination geometry around the silver ion is distorted square pyramidal with an O_3S_2 coordination sphere. The degree of distortion from the idealized square-pyramidal can be estimated from the geometric parameter τ [15]. If O(1) is chosen as the axial donor atom, α and β are 143.5° and 160.4°, respectively, leading to a τ value of 0.29. The average bond distances of Ag–S and Ag–O are 2.676(3) Å, 2.481(8) Å, respectively (see Table 3), which are distinctly shorter than those of complex **1**.

As illustrated in Fig. 4, **L** adopts a bis-bidentate bonding mode to Ag(I) ions through its sulfur atoms and furthermore, via the bidentate bridging triflate anions, an extended two-dimensional coordination network is formed. Obviously, the nitrile groups of **L** are non-coordinating. The neighboring ligands **L** are parallel to each other with interplanar distances larger than 5.76 Å, indicating that there are no close S···S interactions in **2**, either.

In a systematic investigation of the role of counterions in Ag(I) complexes, it has been concluded that a variety of anions can influence the coordination modes of ligands [16,17]. In the present systems, the NO_3^-

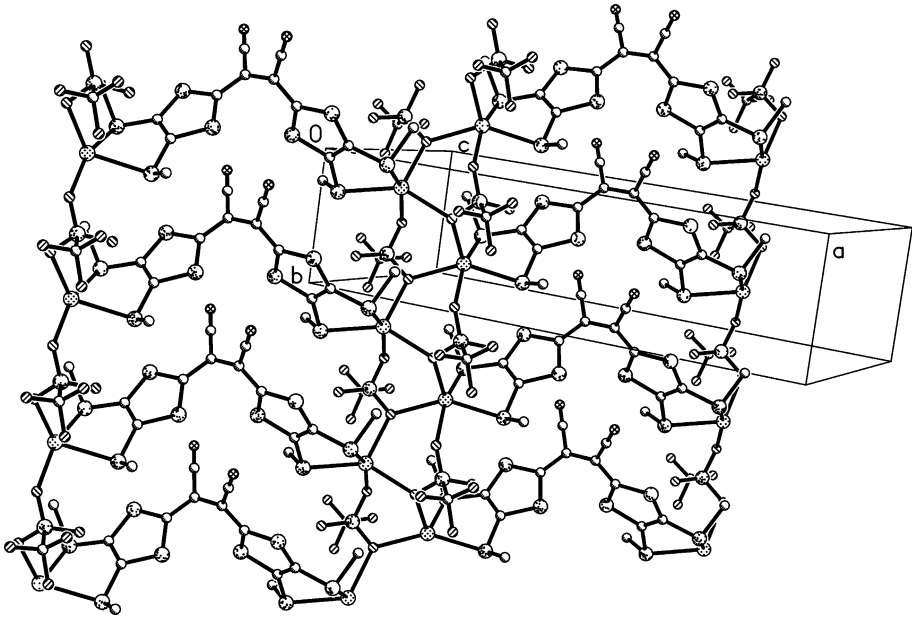

Fig. 4. Perspective view of the undulating 2D coordination network in **2** exhibiting a fragment of one layer.

anion plays a bidentate bridging role in the formation of **1**, so **L** acts as a hexadentate bridging ligand. However, in the case of **2**, the $CF_3SO_3^-$ anion has stronger coordination ability with its oxygen atoms toward Ag(I), thus the ligand **L** takes a bis-bidentate bonding mode with two nitrile groups remaining non-coordinating to Ag(I). In general, the structural differences between **1** and **2** show the profound effect of anions on the framework formation of silver coordination complexes, which nicely reflects their differences in size and coordination strength.

4. Conclusions

In conclusion, in this report we present two new silver complexes **1** and **2** with different structural topologies. In both networks, the bridging of counterions (NO_3^- and $CF_3SO_3^-$) extends the coordination network to 3D and 2D, respectively. The structures, therefore, illustrate how metal coordination assembly in the solid state may be influenced significantly not only by the nature of the counterion, but also by the topicity of the ligand.

2. Experimental

2.1. General

All operations were performed using standard Schlenk line and drybox techniques under an inert atmosphere of nitrogen. THF, toluene, and *n*-hexane were dried by standard methods and degassed prior to use. Benzene-d_6 and toluene-d_8 were dried over Na and distilled under argon. $[U(Tp^{Me2})_2I]$ [6], $[U(Tp^{Me2})_2NPh_2]$ [5] and $[U(Tp^{Me2})_2N(SiMe_3)_2]$ [5] were synthesized by reported methods. HOC_6H_2-2,4,6-Me_3 and 3,5-dimethylpyrazole were sublimed prior to use and the corresponding potassium salts were prepared by reacting a small excess of KH with the appropriate reagents in THF. Phenylacetylene was dried over activated molecular sieves and trap-to-trap distilled before use. Me_3SiBr was trap-to-trap distilled before use and Me_3SnCl (Aldrich) was used without further purification. CpH was obtained by cracking of dicyclopentadiene and the sodium salt was prepared by reaction with a stoichiometric amount of sodium metal in THF. ^1H NMR spectra were recorded on Varian INOVA-300 spectrometer and referenced internally using the residual solvent resonances relative to tetramethylsilane (benzene-d_6, 7.15 ppm, toluene-d_8, 2.09 ppm). IR spectra were recorded on a Perkin–Elmer 577 spectrometer. UV–Vis–near-IR spectra were recorded on a Varian Cary 5G spectrophotometer using 1 cm quartz cells. Carbon, hydrogen and nitrogen analyses were performed in-house using a EA110 CE Instruments automatic analyzer.

2.2. Synthesis

2.2.1. $[U(Tp^{Me2})_2(OC_6H_2$-2,4,6-$Me_3)]$ (**1**)

(a) A solution of HOC_6H_2-2,4,6-Me_3 (10 mg, 0.074 mmol) in toluene was slowly added, at room temperature, to a solution of $[U(Tp^{Me2})_2N(SiMe_3)_2]$ (73 mg, 0.074 mmol) in the same solvent. After stirring overnight, the solvent was removed under vacuum. The dark red solid residue was washed with *n*-hexane and dried under vacuum. Yield: 56% (40 mg, 0.041 mmol). Dark red crystals of **1**, suitable for X-ray diffraction, were grown by recrystallization from a THF/hexane solution.

Anal. Calc. for $C_{39}H_{55}N_{12}B_2OU$: C, 48.41; H, 5.73; N, 17.37. Found: C, 49.46; H, 5.51; N, 17.63. IR (Nujol, cm^{-1}): ν(B–H) 2550. UV–Vis–near-IR (in THF, nm): 529, 668, 899. ^1H NMR (C_6D_6, 20 °C): δ: 21.35 (2H, s, 4-*H*), 20.84 (2H, s, 4-*H*), 18.14 (6H, s, CH_3), 15.79 (6H, s, CH_3), 10.02 (3H, br, H_p), 8.47 (6H, br, H_m), 3.34 (6H, s, CH_3), 2.91 (6H, s, CH_3), −2.30 (6H, s, CH_3), −7.71 (6H, s, CH_3), −9.44 (2H, s, 4-*H*), −55.88 (6H, br, H_o).

(b) A solution of $K(OC_6H_2$-2,4,6-$Me_3)$ (29 mg, 0.16 mmol) in THF was slowly added to a solution of $[U(Tp^{Me2})_2I]$ (157 mg, 0.16 mmol) in the same solvent, at room temperature. After stirring overnight, the white precipitate of KI was filtered off and the solution was evaporated to dryness. The dark red solid residue was washed with *n*-hexane and vacuum-dried. Yield: 84% (130 mg, 0.13 mmol).

2.2.2. $[U(Tp^{Me2})_2(dmpz)]$ (**2**)

A solution of K(3,5-Me_2pz) (18 mg, 0.14 mmol) in THF was slowly added to a solution of $[U(Tp^{Me2})_2I]$ (139 mg, 0.14 mmol) in the same solvent, at room temperature. There was immediate formation of an emerald green mixture. After stirring overnight, the mixture was centrifuged to remove the white precipitate of KI and the solvent was removed under vacuum. Crystallization of the residue from a saturated solution of *n*-hexane yielded an emerald green solid with a yield of 54%. (70 mg, 0.075 mmol). Green crystals, suitable for X-ray diffraction analysis, were obtained by slow concentration of a hexane solution. *Anal*. Calc. for $C_{35}H_{51}N_{14}B_2U$: C, 45.32; H, 5.54; N, 21.14. Found: C, 44.54; H, 5.37; N, 20.75. IR (Nujol, cm^{-1}): ν(B–H) 2500. UV–Vis–near-IR (in THF, nm): 566, 643, 682 (sh), 861, 936, 1039(sh), 1145(sh), 1191, 1240, 1274, 1302(sh). ^1H NMR (C_7D_8, 20 °C): δ 29.49 (1H, s, 4-*H* (dmpz)), 6.98 (6H, s, CH_3(dmpz)), 5.0 (6H, vbr, 4-*H*), 0.18 (6H, s, CH_3). ^1H NMR (C_7D_8, −70 °C): δ 38.74 (1H, s, 4-*H* (dmpz)), 12.78 (6H, s, 3-CH_3), 12.35 (2H, s, 4-*H*), 10.62 (6H, s, CH_3(dmpz)), 9.93 (2H, s, 4-*H*), 7.61 (2H, s, 4-*H*), 3.78 (6H, s, 5-CH_3), −1.07 (6H, s, 5-CH_3), −1.81 (6H, s, 5-CH_3), −21.23 (6H, s, 3-CH_3), −49.99 (6H, s, 3-CH_3).

2.2.3. $[U(Tp^{Me2})_2(2$-$SC_5H_4N)]$ (**3**)

Slow addition of a solution of HSC_5H_4N (17 mg, 0.15 mmol) in THF to a solution of $[U(Tp^{Me2})_2N(SiMe_3)_2]$ (148 mg, 0.15 mmol) in the same solvent resulted in a color change from brown to emerald green. Stirring was maintained for 18 h. Removal of the solvent under vacuum gave an emerald green compound that was further washed with hexane. Yield: 69% (96 mg, 0.10 mmol). An analytically pure compound was obtained by concentration of a THF solution. *Anal*. Calc. for $C_{35}H_{48}N_{13}SB_2UOC_4H_8$: C, 46.17; H, 5.56; N, 17.95. Found: C, 46.11; H, 5.28; N, 17.95. IR (Nujol, cm^{-1}): ν(B–H) 2556. UV–Vis–near-IR (in THF, nm): 576, 633, 778, 949, 936, 1053, 1130, 1247, 1281. ^1H NMR (C_6D_6, 20 °C): δ 40.28 (1H, s, SC_5H_4N) 17.77 (1H, t, SC_5H_4N), 16.72 (1H, d, SC_5H_4N), 13.17 (1H, d, SC_5H_4N), 10.71 (1H, s, 4-*H*), 9.17 (1H, s, 4-*H*), 9.02 (1H, s, 4-*H*), 8.38 (1H, s, 4-*H*), 7.97 (3H, s, CH_3), 6.62 (3H, s, CH_3), 3.96 (1H, s, 4-*H*), 3.57 (4H, m, THF), 2.37 (3H, s, CH_3), 2.22 (3H, s, CH_3), 2.09 (1H, s, 4-*H*), 1.40 (4H, m, THF), 1.15 (3H, s, CH_3), −0.77 (3H, s, CH_3), −1.59 (3H, s, CH_3), −1.84 (3H, s, CH_3), −11.31 (3H, s, CH_3), −12.47 (3H, s, CH_3), −25.70 (3H, s, CH_3), −27.06 (3H, s, CH_3).

2.2.4. [U(Tp^{Me2})$_2$(CCPh)] (4)

A mixture of [U(Tp^{Me2})$_2$I] (169 mg, 0.18 mmol) and HC≡CPh (37 μL, 0.36 mmol) in toluene was stirred with sodium amalgam 0.5% (8 mg, 0.36 mmol) at room temperature for 20 h. During this time the colour of the mixture gradually changed from dark purple to dark green. The solution was then separated from Hg and sodium iodide by centrifugation, evaporated to dryness and the resulting dark green residue was washed several times with *n*-hexane. Yield: 41% (69 g, 0.07 mmol). *Anal.* Calc. for $C_{38}H_{49}N_{12}B_2U$: C, 48.89; H, 5.29; N, 18.00. Found: C, 48.64; H, 5.31; N, 17.38. IR (Nujol, cm^{-1}): *ν*(B–H) 2554, *ν*(C≡C) 2049. 2.2.5. [U(Tp^{Me2})$_2$Cl] (5)

A solution of Me_3SnCl (38 mg, 0.19 mmol) in THF was slowly added to a solution of [U(Tp^{Me2})$_2$N(SiMe$_3$)$_2$] (158 mg, 0.16 mmol) in the same solvent. The mixture was stirred for 18 h at room temperature, during which time the colour gradually turned from brown to dark blue. After centrifugation the solution was evaporated to dryness. The resulting violet solid was further washed with *n*-hexane and vacuum dried. Yield: 78% (108 mg, 0.12 mmol). *Anal.* Calc. for $C_{30}H_{44}N_{12}B_2ClU$: C, 41.52; H, 5.11; N, 19.37. 2.2.6. [U(Tp^{Me2})$_2$Br] (6)

Compound **6** was synthesized as described for **5** by using 22 μL (0.17 mmol) of Me_3SiBr and 167 mg (0.17 mmol) of [U(Tp^{Me2})$_2$N(SiMe$_3$)$_2$]. Compound **6** was obtained as a violet solid with a yield of 88% (136 mg, 0.15 mmol). *Anal.* Calc. for $C_{30}H_{44}N_{12}B_2BrU$: C, 39.50; H, 4.86; N, 18.42. Found: C, 39.02; H, 4.69; N, 18.11. IR (Nujol, cm^{-1}): *ν*(B–H) 2556. UV–Vis–near-IR (in THF, nm): 573, 639(sh), 809, 943(sh), 1040, 1114, 1198, 1243, 1269. ^{1}H NMR (C_6D_6, 20 °C): *δ*: 9.3 (2H, vbr, B–*H*), 7.72 (6H, s, 4-*H*), 1.01 (18H, s, CH_3), −14.21 (18H, s, CH_3).

2.2.7. [U(Tp^{Me2})$_2$(Cp)] (7)

A suspension of NaCp (20 mg, 0.23 mmol) in toluene was slowly added to a solution of [U(Tp^{Me2})$_2$I] (222 mg, 0.23 mmol) in the same solvent, at room temperature. There was immediate formation of a dark green mixture. After stirring for 3 h, the mixture was centrifuged to separate the white precipitate of KI. The solvent was removed under vacuum and the resultant dark green solid was washed with *n*-hexane and vacuum dried. Yield: 76% (156 mg, 0.17 mmol). *Anal.* Calc. for $C_{35}H_{49}N_{12}B_2U$: C, 46.84; H, 5.50; N, 18.73. Found: C, 46.95; H, 5.85; N, 18.84. IR (Nujol, cm^{-1}): *ν*(B–H) 2540, 2524 sh, 2360, 2336. UV–Vis–near-IR (in toluene, nm): 560, 598, 632, 661(sh), 732, 793, 937, 1054, 1094, 1116 (sh), 1196, 1263 e 1291 (sh). ^{1}H NMR (C_6D_6, 20 °C): *δ* 19.45 (1H, s, 4-*H*), 10.46 (3H, s, CH_3), 6.83 (1H, s, 4-*H*), 5.98 (3H, s, CH_3), 3.18 (3H, s, CH_3), 3.03 (2H, s, 4-*H*), 0.58 (2H, s, 4-*H*), −1.14 (3H, s, CH_3), −2.24 (6H, s, CH_3), −3.17 (6H, s, CH_3), −3.93 (5H, s, C_5H_5), −6.52 (6H, s, CH_3), −27.89 (6H, s, CH_3).

2.2.8. Thermolysis of [U(Tp^{Me2})$_2$Cp] (7)

[U(Tp^{Me2})$_2$Cp] (200 mg, 0.29 mmol) was placed in a pyrex tube and heated under vacuum at 160 °C for three days. The colour of the green cyclopentadienyl compound changed gradually to brown. During this change, golden and transparent crystals sublimed on the wall of the tube. The crystals were characterized by X-ray diffraction analysis as being [UCp$_3$(dmpz)] (**8**) and 4,8(dihydro)4,8(dipyrazolyl)pyrazabole (**9**), respectively. The structure of **8** was similar to that reported by Raymond [7] for [UCp$_3$(pz)]. Elemental analysis and the NMR spectrum of the brown solid remaining in the bottom of the pyrex tube were consistent with the formulation of the compound as being [U(Tp^{Me2})(dmpz)$_3$] (**10**). *Anal.* Calc. for $C_{30}H_{43}N_{12}BU$: C, 43.91; H, 5.28; N, 20.48. Found: C, 44.79; H, 5.40; N, 19.87. IR (Nujol, cm^{-1}): *ν*(B–H) 2521. UV–Vis–near-IR (in toluene, nm): 488, 529 (sh), 565 (sh), 611 (w), 675, 693, 872 (br), 1067, 1163, 1209(sh).^{1}H NMR (C_6D_6, 20 °C): *δ* 14.48 (3H, 4-*H* (dmpz)), 7.02 (3H, 4-*H*), 2.23 (9H, 5-CH_3), 0.01 (18H, CH_3 (dmpz)), −8.38 (9H, 3-CH_3).

2.3. X-ray crystallographic analysis

Dark red crystals of **1** were grown from a THF solution layered with *n*-hexane. Green crystals of **2** were grown from a concentrated *n*-hexane solution. Dark blue crystals of **5** were obtained from slow diffusion of *n*-pentane into a toluene solution at 4 °C. The crystals were immersed in Nujol and mounted in thin-walled glass capillaries in a nitrogen filled glove-box. Data were collected at room temperature on an Enraf-Nonius CAD4-diffractometer, with graphite-monochromated Mo Kα radiation, using the *ω*–2*θ* scan technique. The data were corrected [8] for Lorentz and polarization effects, for linear decay and empirically for absorption by Ψ scans. Table 1 summarizes the crystallographic data. The structures were solved by Patterson methods [9] and successive difference Fourier techniques, and refined by full-matrix least squares refinement on F^2 using SHELXL-97 [10]. All the non-hydrogen atoms were refined with anisotropic thermal motion parameters, and the contributions of the hydrogen atoms were included at

3. Results and discussion

3.1. Synthesis

Reaction of $[U(Tp^{Me2})_2N(SiMe_3)_2]$ with HOC_6H_2-2,4,6-Me_3, 3,5-dimethylpyrazole (Hdmpz), 2-mercaptopyridine (HSC_5H_4N) or HCCPh resulted in formation of dark red $[U(Tp^{Me2})_2(OC_6H_2$-2,4,6-$Me_3)]$ (**1**), bright-green $[U(Tp^{Me2})_2(dmpz)]$ (**2**) and $[U(Tp^{Me2})_2(SC_5H_4N)]$ (**3**), and green $[U(Tp^{Me2})_2(CCPh)]$ (**4**), mixed with $HN(SiMe_3)_2$ (Eq. (1))

$$[U(Tp^{Me2})_2N(SiMe_3)_2] + HX \rightarrow [U(Tp^{Me2})_2X] + HN(SiMe_3)_2 \quad (1)$$

where X = OC_6H_2-2,4,6-Me_3, **1**; X = dmpz, **2**; X = SC_5H_4N, **3**; X = CCPh, **4**.

The compounds could be also obtained by protonolysis of $[U(Tp^{Me2})_2NPh_2]$ (NMR experiments), with the exception of compound **4**, as addition of HCCPh to the amidouranium compound resulted in recovery of the starting material.

The amine formed in the above reactions was removed by washing the solid products with *n*-hexane. This procedure is satisfactory except for compound **2** that was obtained in low yield due to its high solubility in hexane. It was found more convenient to prepare this compound by simple halide metathesis of $[U(Tp^{Me2})_2I]$ with K(dmpz). The synthesis of **4** by the acid–base reaction proved to be somewhat unreliable and was found to be accompanied by formation of significant amounts of unidentified side products as shown by ^{1}H NMR spectroscopy. The best route for $[U(Tp^{Me2})_2(CCPh)]$ proved to be the one pot reaction of $[U(Tp^{Me2})_2I]$ [6] with HCCPh in the presence of sodium amalgam or simply sodium metal.

The amido precursor, $[U(Tp^{Me2})_2N(SiMe_3)_2]$, also proved to be a convenient starting material for the synthesis of $[U(Tp^{Me2})_2X]$ complexes (X = halide). Reaction with Me_3SnCl or Me_3SiBr in THF, resulted in a gradual colour change from brown to dark blue. After simple workup, $[U(Tp^{Me2})_2Cl]$ (**5**) and $[U(Tp^{Me2})_2Br]$ (**6**) were obtained as violet powders in high yield.

Attempts to make $[U(Tp^{Me2})_2(Cp)]$ by direct reaction of CpH with either $[U(Tp^{Me2})_2N(SiMe_3)_2]$ or $[U(Tp^{Me2})_2(NPh_2)]$ resulted in recovery of the starting material, even after prolonged reaction times. This lack of reactivity was unexpected, since protonolysis of uranium amides by cyclopentadiene has been described as a suitable route for the synthesis of cyclopentadienyl uranium compounds [4b,4c]. As pointed by some authors, the acidity of a ligand increases upon coordination to a Lewis acidic metal center, since the metal can stabilize the negative charge of the conjugate base [12]. Hence, the inertness of $[U(Tp^{Me2})_2N(SiMe_3)_2]$ and $[U(Tp^{Me2})_2NPh_2]$ towards cyclopentadiene could be due to the reduced basicity of the amido ligand when coordinated to the "$[U(Tp^{Me2})_2]$" fragment. Hence, isolation of $[U(Tp^{Me2})_2(Cp)]$ (**7**) was achieved by metathesis of $[U(Tp^{Me2})_2I]$ with stoichiometric amount of NaCp in toluene.

The compounds are soluble in THF and aromatic solvents, but poorly soluble in aliphatic hydrocarbons, except **2** that is highly soluble in *n*-hexane.

The identity of the compounds was established on the basis of elemental analysis, IR, UV–Vis–near IR, and ^{1}H NMR spectroscopies, and by single crystal X-ray diffraction studies. The electronic spectra of the complexes show several weak absorption bands in the near-IR

region, very similar to those found in other uranium(III) polypyrazolylborate compounds [13].

Infrared spectra of compounds **1**–**6** show the usual ν(B–H) stretch in the 2500–2650 cm^{-1} region, characteristic of a tridentate Tp^{Me2} ligand [14]. The IR spectrum of **4** displays a characteristic C≡C triple bond stretching vibration (ν_{CC}) at 2049 cm^{-1}, which is significantly lower than that of free phenylacetylene ($\nu_{CC} = 2110\ cm^{-1}$). Similar decrease in ν_{CC} was observed for other alkynyluranium complexes [15]. In contrast to the above, the infrared spectrum of **7** exhibits two ν(B–H) stretching vibrations, one centered at 2540 with a shoulder at 2524 cm^{-1} and a doublet centered at 2348 cm^{-1}. The positions of these IR bands are indicative of a κ^3- and a κ^2-coordinated Tp^{Me2} ligands [14], as found in its samarium analogue [Sm(κ^3-Tp^{Me2})(κ^2-Tp^{Me2})(Cp)] [16] which exhibits two ν(B–H) stretching vibrations at 2565 and 2448 cm^{-1}. The low frequency associated with the ν(B–H) stretching vibration of the κ^2-Tp^{Me2} ligand is due to the existence of a Sm···HB agostic interaction. However, the difference in frequency of the two coordination modes in the uranium compound is even larger than in the samarium analog, supporting the existence of a stronger U···HB agostic interaction.

The room temperature ^{1}H NMR spectrum of **1** exhibits six Tp^{Me2} methyl and three 4-H singlets, and one set of resonances for the protons of the aryloxide ligand. The spectrum is consistent with a rigid "U(Tp^{Me2})$_2$" fragment and rapidly rotating OAr ligand about the U-OAr bond resulting in an effective C_2 molecular symmetry. The twofold axis renders the two Tp^{Me2} ligands equivalent but within each the three pyrazolyl rings remain chemically different, giving rise to two signals for the Me-3 and Me-5 groups and one for the H-4 proton of each pyrazolyl group. The room temperature ^{1}H NMR spectrum of **3** showed the expected integration and peak multiplicities for the chalcogenolate protons. In addition, the spectrum featured twelve singlets due to the methyl groups and six due to the H-4 protons of the Tp^{Me2} ligands, indicating inequivalence of all six pyrazolyl rings. Thus the observed spectrum is consistent with a non-symmetric C_1 structure, and is very similar to that of the structurally characterized [Sm(Tp^{Me2})$_2$(η^2-2-C_5H_4N)] [17].

The room temperature ^{1}H NMR spectra of compounds **4**–**6** exhibited three resonances in a 3:3:1 ratio assigned to the Tp^{Me2} ligands. Compound **2** showed a similar pattern but with the resonance assigned to the Me-3 moiety of the pyrazolyl rings collapsed in the baseline. The simple spectra, like those of the samarium analogues indicate that the compounds are fluxional on the NMR time scale, the fluxionality being largely determined by the size of the X-ligand [17–19]. Thus, **4**–**6** are fluxional at all accessible temperatures, while cooling a toluene-d_8 solution of **2** resulted in progressive broadening and shifting of the proton resonances associated with the pyrazolylborate ligands. The resonances due to the protons of the dmpz ligand shifted substantially, because of the temperature dependence of the magnetic susceptibility, but suffered minimal line broadening. At −30 °C three resonances due to the Me-3 protons began to emerge, while the resonances due to Me-5 protons and H-4 protons split into three resonances each at −50 °C. By −80 °C the spectrum consisted of six well-resolved resonances assigned to the methyl groups and three assigned to the 4-H methine protons, consistent with a C_2-symmetric structure.

The ^{1}H NMR spectrum of **7** showed a singlet accounting for five protons, in accord with an η^5-Cp igand. The pyrazolylborate ligands gave rise to four sets of resonances in the ratio 2:2:1:1 as already observed for its samarium analogue and in accordance with the structure found in the solid state for the latter compound [16]. Although no solid state structural characterization has been obtained for **7**, its spectroscopic features point unambiguously to a structure similar to that found for the samarium analogue, [Sm(κ^3-Tp^{Me2})(κ^2-Tp^{Me2})(Cp)] [16]. However, despite the similar structures, the result of the thermolysis of **7** differs markedly from that obtained for the samarium compound [16].

When [U(κ^3-Tp^{Me2})(κ^2-Tp^{Me2})(Cp)] was heated under vacuum at 160 °C for three days, two types of crystals (golden and transparent) sublimed on the walls, leaving behind a brown residue on the bottom of the tube. X-ray analysis of the golden crystals revealed that this compound is [UCp$_3$(dmpz)] (**8**) (see SI). Crystallographic investigation of the transparent crystals showed it to be the known 4,8(dihydro)4,8(dipyrazolyl)pyrazabole (**9**)[1] [20]. The brown residue was investigated by ^{1}H NMR spectroscopy. The spectrum displayed one set of resonances with a 3:3:1 intensity ratio, assigned to a Tp^{Me2} ligand, and two resonances in a 1:6 intensity ratio. Elemental analysis and the NMR spectrum were consistent with the formulation [U(Tp^{Me2})(dmpz)$_3$] (**10**). This was further corroborated by comparison of its ^{1}H NMR spectrum with that of an authentic sample obtained by reacting [U(Tp^{Me2})Cl$_3$(THF)] [21] with 3 equiv of K(dmpz). Hence, thermolysis of **7** results in complete oxidation of the uranium centre and redistribution of the ligands.

It is not surprising that the product of oxidation of uranium(III) retains only one coordinated Tp^{Me2} ligand, since the uranium(IV) centre appears not to be able to

[1] The X-ray structure of **9** has been reported ([20]). We have isolated a different crystalline form of the compound. Crystal data for **9** ($C_{20}H_{30}B_2N_8$, fw = 404.14) are as follows: orthorhombic space group *Pcan* with $a = 11.072(2)$ Å, $b = 14.019(2)$ Å, $c = 14.258(2)$ Å, $V = 2213.2(6)$ Å^3, and $Z = 4$; $D_{calc} = 1.213\ g\ cm^{-3}$: A total of 6573 independent reflexions having 2θ (Mo Kα) < 50 were collected on an Enraf-Nonius CAD4-diffractometer. Least-squares refinement of 136 parameters on 1742 absorption corrected reflexions having $I > 2\sigma(I)$ converged at $R(R_w) = 0.0748(0.1845)$.

accommodate two Tp^{Me2} ligands. It has been reported that while the reaction of UCl_4 with one equiv of Tp^{Me2} ligand gives $[U(Tp^{Me2})Cl_3(THF)]$ [21], the reaction with two equiv of Tp^{Me2} results in the formation of $[U(Tp^{Me2})(dmpz)Cl_2]$ and pyrazabole [22]. Furthermore, a recurring feature of the pyrazolylborate ligands, abundantly documented in the chemical literature, is their vulnerability to fragmentation reactions giving pyrazole or pyrazolyl groups [23]. It is likely that during the thermolysis cleavage of a B–N bond occurs with liberation of a transient $dmpz^-$ or dmpzH moiety. However, addition of dmpzH to $[U(Tp^{Me2})_2(Cp)]$ did not lead to any of the oxidation products formed in the thermolysis. The products obtained were $[U(Tp^{Me2})_2(dmpz)]$, due to the acid–base reaction of $[U(Tp^{Me2})_2(Cp)]$ with Hdmpz, pyrazabole and another species that we were not able to characterize.

Although the mechanism is not clear, the products of the thermolysis clearly reflect the accessibility of the +4 oxidation state for uranium. In contrast, thermolysis of the analogous samarium compound, under the same conditions, results in intramolecular C–H activation with formation of $[Sm(\kappa^3\text{-}(Tp^{Me2})\{HB(3,5\text{-}Me_2pz)_2(C_5H_4)\}]$ [16], due to the absence of an oxidative pathway.

3.2. Crystal structures

The molecular structures of compounds **1**, **2** and **5** are shown in Figs. 1–3, respectively. Selected bond distances and angles are given in Table 2. In compounds **1** and **5** the central uranium ion is seven-coordinate by way of two tridentate pyrazolylborates and the oxygen donor of the aryloxide or the chloride ion, in a pentagonal bipyramidal geometry. In compound **2** the uranium is eight-coordinate by six nitrogen atoms of the two tridentate pyrazolylborate ligands and by two others from the pyrazolide ligand. However, due to its small bite, the midpoint of the pyrazolide ligand can be considered as occupying the seventh coordination site of a pentagonal bipyramid. Although the complexes do not have crystallographically imposed symmetry, the molecules are approximately C_2 symmetric.

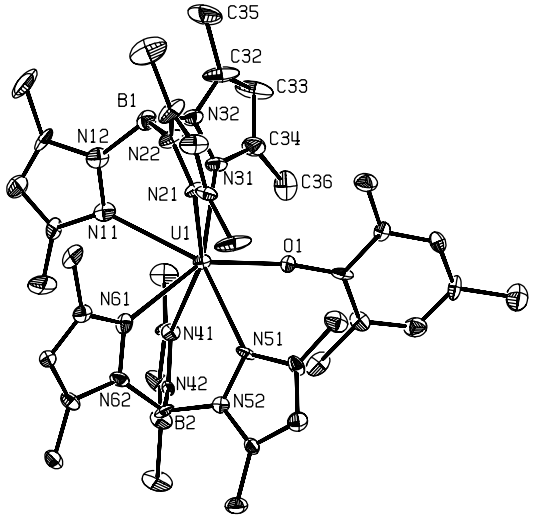

Fig. 1. ORTEP diagram of $[U(Tp^{Me2})_2(OC_6H_2\text{-}2,4,6\text{-}Me_3)]$ using 20% probability ellipsoids.

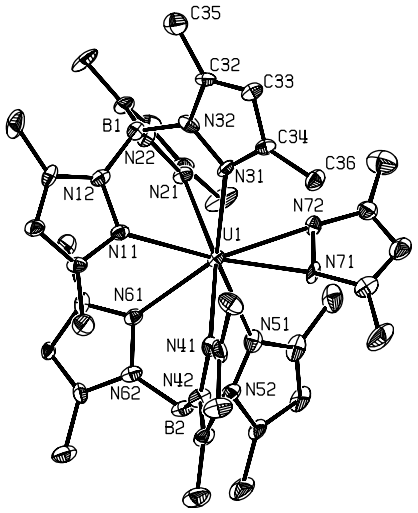

Fig. 2. ORTEP diagram of $[U(Tp^{Me2})_2(dmpz)]$ using 20% probability ellipsoids.

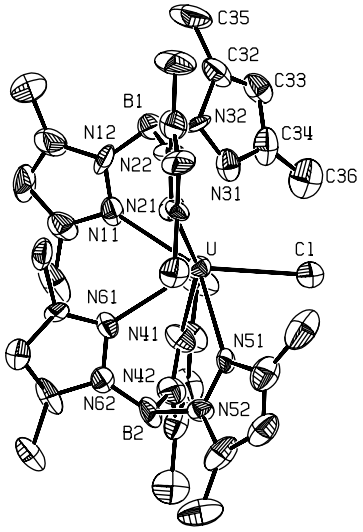

Fig. 3. ORTEP diagram of $[U(Tp^{Me2})_2Cl]$ using 40% probability ellipsoids.

For clarity and ease of comparison the same numbering scheme has been used for all three compounds. The N21 and N41 atoms occupy the apical sites of the pentagonal bipyramid, with the remaining coordinating atoms defining the equatorial plane (rms deviation: 0.1389 for **1**, 0.1924 for **2**, and 0.1946 for **5**). As expected for the less crowded axial sites, the U–N distances are shorter (average 2.544(13) Å in **1**, 2.551(12) Å in **2**, and 2.514(16) Å in **5**) than those in the equatorial girdle (av. 2.677(14) Å in **1**, 2.696(14) Å in **2**, and 2.660(15) Å in **5**). These values compare well with the corresponding

Table 2
Selected bond lengths (Å) and angles (°) for **1**, **2** and **5**

	1	**2**	**5**
Average $(U–N)_{Tpax}$	2.544(13)	2.551(12)	2.514(16)
Average $(U–N)_{Tpeq}$	2.677(14)	2.696(14)	2.660(15)
Range $(U–N)_{Tp}$	2.506(12)–2.697(14)	2.546(12)–2.711(13)	2.500(16)–2.729(15)
U–X	2.159(10)	2.444(11)	2.698(5)
B–U–B	143.7(4)	135.9(4)	142.7(6)
U–O–C	168.2(10)		
N(71)–U–N(72)		32.5 (4)	

distances in $[U(Tp^{Me2})_2(NPh_2)]$ (2.544(6) and 2.66(1) Å) and $[U(Tp^{Me2})_2N(SiMe_3)_2]$ (2.549(5) and 2.73(2) Å) [5]. The somewhat more distorted nature of $[U(Tp^{Me2})_2Cl]$ (**5**), as seen in the wider range of the U–N distances (2.500–2.729 Å) versus 2.506–2.697 Å for **1**, and 2.546–2.711 Å for **2**, can be traced to the less favourable intercalation of the larger, spherical, chloride ion between the pyrazolyl groups N3 and N5 compared with the planar aryloxide and pyrazolide ligands.[2] In fact the structure of $[U(Tp^{Me2})_2I]$ [6], with the very bulky iodide, is severely distorted with one pz ligand side-on bonded to uranium.

The pyrazolylborate ligands in complexes **1**, **2** and **5** are unremarkable, the angles at the boron atoms being essentially tetrahedral. In compound **5** a close contact between C36, the Me-3 carbon of pz ring (N31N32), and the chloride ion can be seen (Cl···C36 is 3.247 Å). Possibly in order to minimize this contact, the U–N31 is very long (2.729 Å). As commonly observed, and also in order to minimize contacts between the methyl groups of the Tp^{Me2} and X ligands, the pyrazolyl rings are twisted about their B–N bonds, with B–N–N–U torsion angles ranging from 2° to 34°. The geometrical requirements of the Tp^{Me2} ligands and the higher coordination number of uranium in complex **1** than in $U(OC_6H_3\text{-}2,6\text{-}^iPr_2)_3$ [24] result in a longer U–O(1) bond length (2.159(10) Å) compared to the corresponding distance of 2.132(8) Å in the latter. The average U–N bond distance of the pyrazolide ligand in complex **2** (2.444(11) Å) compares with the corresponding distance of 2.373(5) Å in the samarium analogue [18], after adjustment for the difference in ionic radii [25]. The U–Cl bond distance of 2.698(5) Å in **5** is the same as those found in the literature for other uranium(III) chlorides [26] and is in accord with those of the analogous lanthanide compounds (samarium, neodymium and lanthanum) [27], taking into account the differences between the ionic radii [25].

[2] The analogous $[U(Tp^{Me2})_2Br]$ appears to be more distorted with U–N distances of 2.45–2.73 Å. Unfortunately poor crystal quality prevented satisfactory structure refinement and hence discussion of the metrical parameters (Y.N. Sun, J. Takats, and V. Day, unpublished results).

4. Conclusions

This work shows that the reactivity of the U–N bond in $[U(Tp^{Me2})_2(NR_2)]$ compounds towards protic substrates and halide source represents a convenient synthetic entry into trivalent organouranium chemistry. Although, in some cases salt metathesis proved to be more suitable. The compounds are structurally similar to the analogous samarium complexes, but the availability of higher oxidation states for uranium leads to a different outcome for the thermolysis of the uranium cyclopentadienyl compound, $[U(Tp^{Me2})_2(Cp)]$.

of the ligands which could be of help in the design of devices with long-term stability and optimized lifetimes of the near infrared emission [3].

The first step in this direction would be to be able to predict the geometrical structures of Ho(III) complexes at a level of accuracy that could be useful for luminescent devices design, for single-molecule magnets design, and for telecommunications research.

In order to be able to predict geometries of rare earth complexes, we had developed earlier the original Sparkle model [4,5], which we recently largely improved and called Sparkle/AM1 [6]. Until now, Sparkle/AM1 had

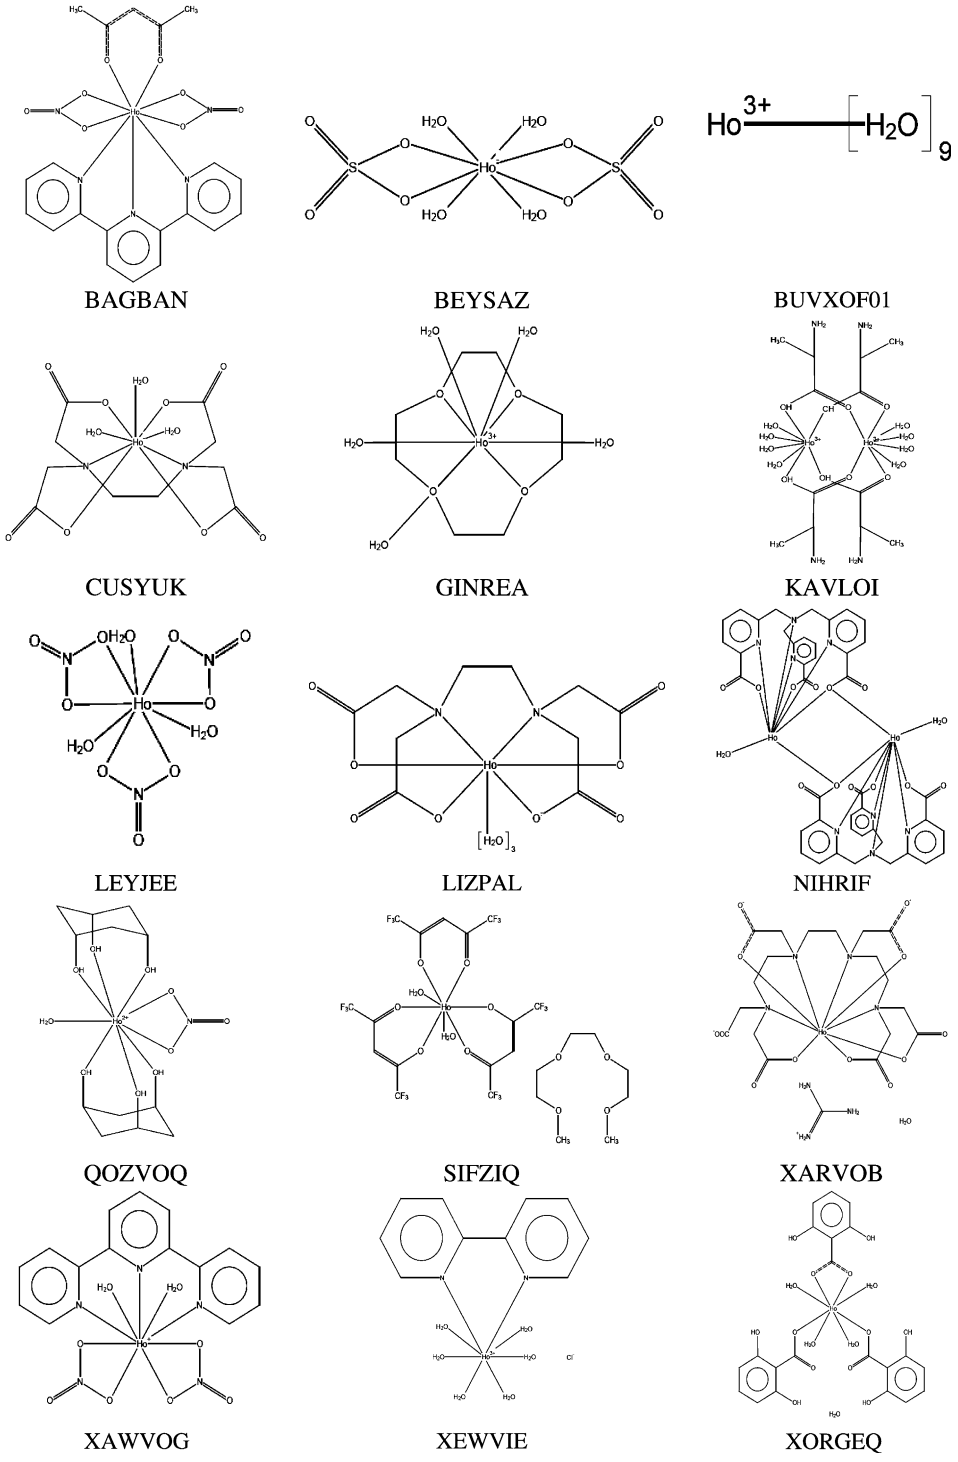

Fig. 1. Schematic two-dimensional representation of the holmium (III) complexes, that constitute the parameterization training set, obtained from the Cambridge Structural Database [7–9].

been only parameterized for Eu(III), Gd(III) and Tb(III) [6]. In the present work, we extend Sparkle/AM1 to Ho(III). The Sparkle/AM1 model replaces the trivalent rare earth ion by a Coulombic charge of $+3e$ superimposed to a repulsive exponential potential of the form $\exp(-\alpha r)$, which accounts for the size of the ion, and uses two Gaussian functions in the core–core repulsion energy term to make it compatible with AM1. That is, Sparkle/AM1 assumes that the rare earth trications behave like simple ions, without any angular steric properties – the angular effects of the f orbitals are assumed to be negligible and are not taken into account. The good agreement between predicted and observed rare earth ion complex structures, as also evidenced below for Ho(III), is a powerful evidence for the effectiveness of this idea.

2. Results and discussion

The Sparkle/AM1 parameterization procedure for Ho(III) is essentially the same as the one described in our previous work on Eu(III), Gd(III) and Tb(III) [6]. Accordingly, we only considered high quality crystallographic structures (R factor $< 5\%$) taken from the "Cambridge Structural Database 2003" (CSD) [7–9]. Ligands important for luminescence and telecommunications research, coordinate to the Ho(III) ion almost exclusively via oxygen or nitrogen atoms, and comprise approximately 75% of all Ho(III) structures available in CSD. As such, we considered all 27 available structures with nitrogen or oxygen as coordinating atoms and classified the various extant ligands into the following types: β-diketone, nitrate, monodentate, bidentate, tridentate and polydentate. We further considered diholmium complexes, where the two Ho(III) ions face each other. From a suitable cluster analysis of all complexes [6], a subset of fifteen different representative structures of Ho(III) complexes was chosen and are presented in Fig. 1.

To find the parameters, we carried out a non-linear minimization of an eight-dimension response function, using a combination of Newton–Raphson and simplex methods, aimed at finding one of its local minima, which ideally should be close enough to the global minimum, if not the global minimum itself, and make chemical sense. The heat of formation of the Ho(III) ion in Sparkle/AM1 was obtained by adding to the heat of atomization of holmium [10], its first three ionization potentials, yielding 1009.6 kcal mol^{-1}. Finally, the atomic mass of Ho(III) was set at 164.9303 amu [10]. The Sparkle/AM1 parameters obtained for Ho(III) are shown in Table 1.

In the validation procedure, we used a set of 12 more complexes, also of high crystallographic quality, for a total of 27 coordination compounds considered, and clustered according to their predominant ligand group as in Table 2.

Table 1
Parameters for the Sparkle/AM1 model for the Ho(III) ion

	Sparkle/AM1 – Ho(III)
GSS	58.0375569983
ALP	3.5558255806
a_1	0.9819487665
b_1	8.9158636523
c_1	1.7513929352
a_2	0.5454296933
b_2	8.6358143694
c_2	3.0176828845

Table 2
Number of holmium (III) complexes in the validation set, classified according to their predominant ligand group

Ligand group number	Ligand type	Number of structures
1	β-Diketone	2
2	Nitrate	4
3	Monodentate	7
4	Bidentate	2
5	Polydentate	9
6	Diholmium	3

As accuracy measure, we used the average unsigned mean error for each complex i, UME_i, defined as

$$UME_i = \frac{1}{n_i}\sum_{j=1}^{n}\left|R_{i,j}^{\mathrm{CSD}} - R_{i,j}^{\mathrm{calc}}\right|, \quad (1)$$

where n_i is the number of ligand atoms directly coordinating the rare earth ion. As for Eu(III), Gd(III) and Tb(III) [6], two cases have been examined: (i) UMEs involving the interatomic distances R_j between the holmium central ion and the atoms of the coordination polyhedron, as well as the interatomic distances R_j between all atoms of the coordination polyhedron, and (ii) $\mathrm{UME}_{(\mathrm{Ho-L})}$s involving only the interatomic distances R_j between the holmium central ion and the atoms of the coordination polyhedron, important in luminescent complex design and to telecommunications research.

Table 3 shows the values of UMEs for all 27 complexes considered and the graphical representations of the UME, and of the $\mathrm{UME}_{(\mathrm{Ho-L})}$s, are shown in parts (a) and (b) of Fig. 2, respectively. Clearly, total UMEs are larger than the $\mathrm{UME}_{(\mathrm{Ho-L})}$s. Indeed, whereas the maximum UME is 0.32 Å, the largest $\mathrm{UME}_{(\mathrm{Ho-L})}$ is only 0.10 Å, indicating that holmium ligand atom distances are more accurately described than the whole coordination polyhedron. And fortunately that is so, because for luminescent complex design, accurate description of distances between the directly coordinating atoms and the central rare earth ion are more important than the whole coordination polyhedron. That is because, to predict the luminescence quantum yield of a rare earth complex, one usually starts by characterizing the interaction

Table 3
Values of the coordination numbers, CNs, and unsigned mean errors, UMEs, for Sparkle/AM1, as compared to the respective experimental crystallographic values, obtained from the Cambridge Structural Database [7–9], for each of the 27 holmium (III) complexes

[a] The structures are identified by their respective codes of reference from the Cambridge Structural Database 2003 [7–9].

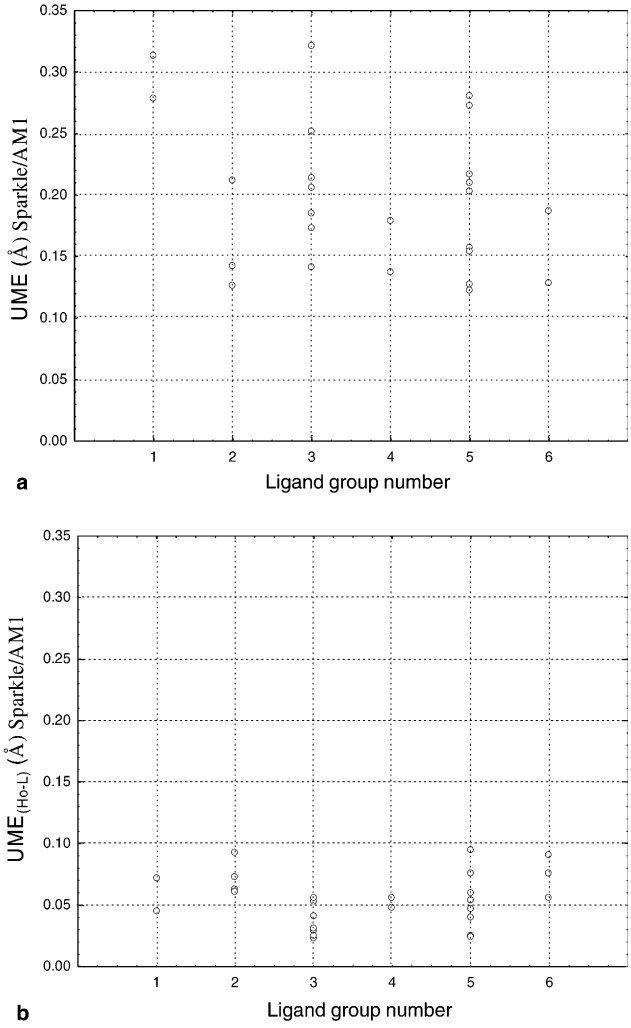

Fig. 2. Unsigned mean errors for each of the 27 holmium (III) complexes, assembled according to the ligand group numbers defined in Table 2. (a) The UMEs and (b) the $UME_{(Ho-L)}$s. The same scale has been used in both to facilitate comparison.

between the ligands and the central ion through the ligand field parameters,, which, within the simple overlap model [11,12], possesses a dependence which goes with the third, the fifth, and even with the seventh power of the ligand–rare earth interatomic distances.

In Table 4, we present Sparkle/AM1 unsigned mean errors for specific types of bond distances, not only for Ho(III) but also for the previously published Eu(III), Gd(III) and Tb(III). Indeed, the same patterns that appeared for the previous ions are reproduced in the case of Ho(III), showing they are all comparable parameterizations. Once again, the very important rare earth ion–ligand atom distances are the most accurately predicted of all interatomic distances.

In a previous paper [6], we performed a series of ab initio effective core potential, ECP, calculations on a set of seven Eu(III) complexes [6] using STO-3G, 3-21G and 6-31G* basis sets, and the average unsigned mean error obtained for all Eu–L and L–L′ distances, where L is a ligand atom directly coordinated to the Eu(III) ion, varied from 0.11 Å for 3-21G to 0.16 Å for 6-31G* ab initio/ECP calculations. The same values

Table 4
Sparkle/AM1 unsigned mean errors for all distances involving the central rare earth ion, Ln, and the ligand atoms of the coordination polyhedron, L, for 96 Eu(III) [6] complexes; 70 Gd(III) [6] complexes; 42 Tb(III) [6] complexes, and all 27 Ho(III) complexes considered

Model	Unsigned mean errors for specific types of distances (Å)					
	Ln–Ln	Ln–O	Ln–N	L–L′	Ln–L and Ln–Ln	Ln–L, Ln–Ln and L–L′
Sparkle/AM1 – Eu [6]	0.1624	0.0848	0.0880	0.2170	0.0900	0.1900
Sparkle/AM1 – Gd [6]	0.1830	0.0600	0.0735	0.2082	0.0658	0.1781
Sparkle/AM1 – Tb [6]	0.2251	0.0754	0.0440	0.2123	0.0746	0.1823
Sparkle/AM1 – Ho	0.2108	0.0555	0.0409	0.2258	0.0547	0.1897

for Eu(III) Sparkle/AM1 for these complexes was 0.11 Å, clearly showing all possess approximately the same geometry prediction accuracy. Moreover, ab initio/ECP calculations on rare earth complexes are so time consuming that, to the best of our knowledge, the largest calculation ever reported on one such complex is our [6] ab initio/6-31G* full geometry optimization of XICHUM (CSD code), a dieuropium complex possessing 134 atoms. While the Sparkle/AM1 full geometry optimization of such complex took only about an hour on an Athlon 1.53 GHz with 1 GB of DDR memory, the 6-31G*/ECP took many months of CPU on the same computer to finally yield a geometry of comparable accuracy.

3. Conclusion

Sparkle/AM1 parameters for Ho(III) are defined here at the same level of quality of the previously introduced Sparkle/AM1 parameters for Eu(III), Gd(III) and Tb(III), and generate geometries of a quality comparable to present day rare earth complex ab initio calculations. Indeed, Sparkle/AM1 geometries may, for example, be used as excellent first guesses of structures of Ho(III) complexes to be further refined in crystallographic structural research, or as a point to proceed with higher level ab initio calculations.

Having obtained the Ho(III) complex optimized geometry, the possibilities that open up for researchers are innumerous. For luminescence research [13], for example, the triplet level of the ligands in their bound conformation can be determined via INDO/CI calculations [14]; the various vibrational frequencies of the complex can be calculated in order to search for high energy vibrations that might quench the luminescence process [15]; and so forth.

Sparkle/AM1 is the only quantum mechanical semiempirical model presently available for the calculation of Ho(III) complexes and may prove useful in molecular design for various applications.

Acknowledgments

We appreciate the financial support from CNPq (Brazilian agency), and also grants from the Instituto do Milênio de Materiais Complexos, FACEPE (Programa Primeiros Projetos) and Construção do Conhecimento por Agrupamento de Dados (CoCADa). We also thank CENAPAD (Centro Nacional de Processamento de Alto Desempenho) at Campinas, Brazil, for having made available to us their computational facilities. Finally, we gratefully acknowledge the Cambridge Crystallographic Data Centre for the Cambridge Structural Database.

Appendix A. Supplementary data

Instructions and examples on how to implement the Ho(III) Sparkle/AM1 model in Mopac93r2. Parts of the codes of subroutines Block.f, Calpar.f and Rotate.f that need to be changed, as well as their modified versions for Ho(III). Examples of Mopac93r2 crystallographic geometry input (.dat) and optimized geometry summary output (.arc) files from Sparkle/AM1 calculations for the Ho(III) complex XEQMEL and for the diholmium complex NIHRIF. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2005.06.027.

2. Experimental

All manipulations were carried out in a dry nitrogen atmosphere using Schlenk technique or a glove box. $Ni(NH_3)_6Cl_2$ was obtained from $NiCl_2 \cdot 6H_2O$ (Merck) according to [11]. Dimethylaminoethanol and formic and acetic acids were purchased from Aldrich and dried via prolonged storage on pre-treated granulated molecular sieves. IR spectra were recorded on a Perkin–Elmer IR-1720X spectrometer, using Nujol mulls between KBr plates. UV–Vis spectra were obtained on a Hitachi U 2001 Spectrophotometer for approximately 0.05 M solutions in toluene.

2.1. Preparation of $Ni_6(OH)_2(OR)_8(HCOO)_2(C_7H_8)$ ($R = CH_2CH_2N(CH_3)_2$) (1)

2.1.1. Isolation

The synthesis technique was developed on a basis of the method of $Ni(OR)_2$ ($R = CH(CH_3)CH_2N(CH_3)_2$) synthesis [1]: 0.22 g of sodium (9.56 mmol) was dissolved in a mixture of 1 cm^3 of $HOCH_2CH_2N(CH_3)_2$ and 10 cm^3 toluene and refluxed until clear solution was obtained. 1.03 g of $Ni(NH_3)_6Cl_2$ (4.81 mmol) was added to the cooled yellow solution. The latter was then heated to reflux and maintained at this temperature for 2 h approximately. The NaCl formed was separated by decantation. The solvent was evaporated in vacuo, and the solid compound was dissolved in hot toluene. The resulting solution was left overnight at −15 °C to give a small crop of air-sensitive dark green crystals of compound **1**.

2.1.2. Synthesis

The metathesis reaction and separation of NaCl were carried out exactly as in (a). 0.073 g of HCOOH (1.6 mmol) was added to the cooled solution. The solvent was evaporated in vacuo, and the solid compound was dissolved in hot toluene. The resulting solution was left overnight at −15 °C to give air-sensitive dark green crystals of compound **1**. Yield 0.64 g (65%). IR (cm^{-1}): 3236 (m), 1611, 1277 (w), 1244 (vw), 1169 (vw), 1092 (s), 1027 (m), 954 (m), 892 (vw), 882 (w), 790 (w), 698 (w), 627 (vs), 590 (vs), 482 (m), 451 (m), 420 (w). UV–Vis, λ, nm (ε, $M^{-1}\,cm^{-1}$): 672 (24), 764 (16).

2.2. Isolation of $Ni(CH_3COO)_2(HOR)_2$ ($R = CH_2CH_2N\text{-}(CH_3)_2$) (2)

The experiment analogous to that described above for the preparation of **1**, but using the acetic instead of the formic acid. 0.096 g of CH_3COOH (1.6 mmol) were added to the cooled solution. The solvent was evaporated in vacuo, and the solid compound was re-dissolved in hot toluene. The resulting solution was left overnight at −15 °C to give air-sensitive bluish-green crystals of compound **2**. Yield 0.181 g (64%). IR (cm^{-1}): 1544 (s), 1349 (m), 1333 (m), 1275 (m), 1248 (m), 1182 (m), 1169 (m), 1060 (s), 1028 (s), 951 (m), 914 (m), 880 (s), 784 (m), 665 (vs), 572 (s), 507 (w), 478(m). UV–Vis, λ, nm (ε, $M^{-1}\,cm^{-1}$): 653 (46).

2.3. Preparation of $Ni_6(OH)_2(OR)_8(CH_3COO)_2$ ($R = CH_2CH_2N\text{-}(CH_3)_2$) (3)

The synthesis has been carried out as above but only 0.024 g of CH_3COOH (0.4 mmol) were added to the cooled solution. The solvent was evaporated in vacuo, and the solid compound was re-dissolved in hot toluene. The resulting solution was left overnight at −15 °C to give air-sensitive dark green crystal of compound **1**. Yield 0.434 g (89% in relation to CH_3COOH). IR (cm^{-1}): 3318 (m), 1598 (vs), 1277 (m), 1261 (m), 1245

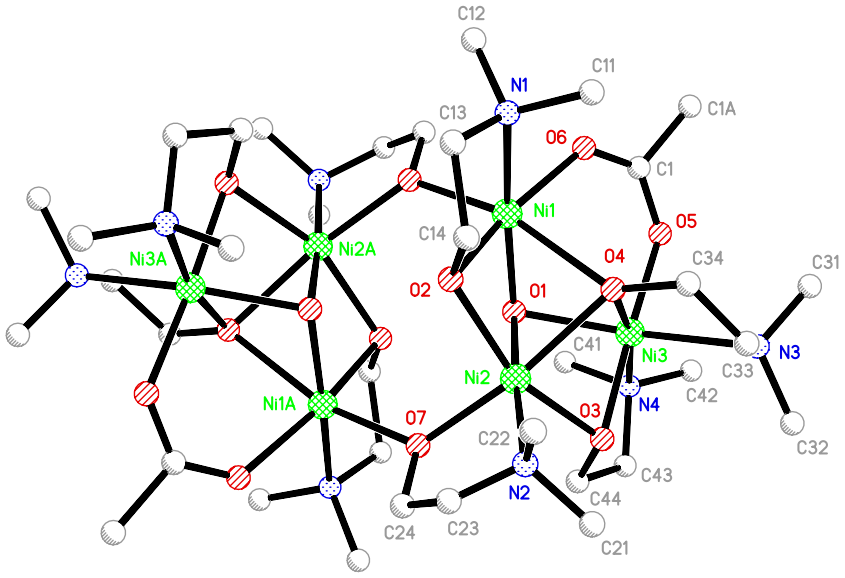

Fig. 2. Molecular structure of $Ni_6(OH)_2(OR^N)_8(CH_3COO)_2$ ($R = CH_2CH_2N\text{-}(CH_3)_2$) (**3**).

(m), 1029 (m), 951 (s), 890 (m), 780 (m), 664 (w), 588 (w), 486 (m), 450 (m), 421 (m). UV–Vis, λ, nm (ε, $M^{-1}\,cm^{-1}$): 670 (38), 760 (22).

2.4. Crystallography

The data collection for all the single crystals of compounds studied was carried out at 22 °C (for details see Table 1). All the structures were solved by standard direct methods. The coordinates of the metal atoms were obtained from the initial solutions and for all other non-hydrogen atoms found in subsequent difference Fourier syntheses. The structures were refined by least squares first in isotropic and then in anisotropic approximations. The coordinates of the hydrogen atoms were calculated geometrically and were included into the final refinement in isotropic approximation for all the compounds. All calculations were performed using the SHELXTL-NT program package [13] on an IBM PC.

3. Results and discussion

The original aim of this work was to investigate the structure of nickel dimethylamino-ethoxide. This compound has even been included into the product list of the Epichem Company, UK, producer of precursors for MOCVD technologies, but its synthesis and properties were never described in literature. We applied a synthetic procedure analogous to that described earlier by us for the preparation of nickel dimethylamino-isopropoxide and discovered unexpectedly formation of a mixture of products: a liquid with the composition (by microanalysis) corresponding to $Ni(OC_2H_4NMe_2)_2$ as a major product and a small amount of crystalline solid. The X-ray single crystal study of the latter showed it to contain formiate ligands. The latter originated apparently from oxidation of the aminoalcohol by the traces of oxygen dissolved in the solvents in strongly basic media formed on dissolution of sodium metal on reflux. Water is the other product in this kind of oxidation processes and the occurrence of hydroxo-ligands in the structure of the modified species is due to its presence. Modification of the reaction mixture with a stoichiometric amount of formic acid strongly improved the yield of the product. The reaction in total can be then represented by the following equation:

$$6\ Ni(OR)_2 + 2H_2O + 2\ HCOOH \xrightarrow[R\ =\ OC_2H_4NMe_2]{} Ni_6(OH)_2(OR)_8(HCOO)_2\ (\mathbf{1}) + 4\ ROH$$

The structure of compound **1** (see Fig. 1, please compare with Fig. 2) is a centrosymmetric hexanuclear aggregate composed of two triangular $Ni_3(\mu_3\text{-}OH)(\mu_3\text{-}OR)$ fragments, consisting of three octahedra, sharing a common edge, defined by the OH–OR vector. The fragments are connected to each other by alkoxobridges. All bidentate alkoxide ligands are coordinated in a μ,η^2-mode, combining the bridging (double or triple one) and a chelating function. The coordination of the nickel atoms is distorted octahedral with the bond lengths falling into the range commonly observed for the nickel aminoalkoxides complexes [11,12]. This structure is bearing two peculiar features. One of them is that the distances between the nickel atoms are rather short (the shortest being 2.8481(12) Å) with the angles in the Ni_3-triangle rather close to each other, which indicates possibility for strong magnetic interactions in this structure. The other unusual feature is that the motive of this structure is in fact very close to that of one of the known structure types for titanium alkoxide carboxylates present, for example, in $Ti_6O_4(OAc)_4(O^iPr)_{12}$ [14] (see Fig. 3). This fact provides one more confirmation for the fact that the structures of metal alkoxides can be derived from packing motives of negatively charged ligands and metal cations [15,16]. Application of bidentate alkoxide ligands in combination with divalent metal cations has already offered a series of molecular structures analogous to those of titanium alkoxides, for example, $Co_4Cl_2(O\text{-}C_2H_4OEt)_6$ [17]. Modification of such systems with carboxylic acids provides access to bigger aggregates again following the same principles in molecular construction.

We sought to confirm the idea about the pronounced stability of the structural types for the alkoxides involving ligands with the same structural requirements and decided to carry out the synthesis of an acetate analogue of **1**. The synthesis employing the stoichiometric

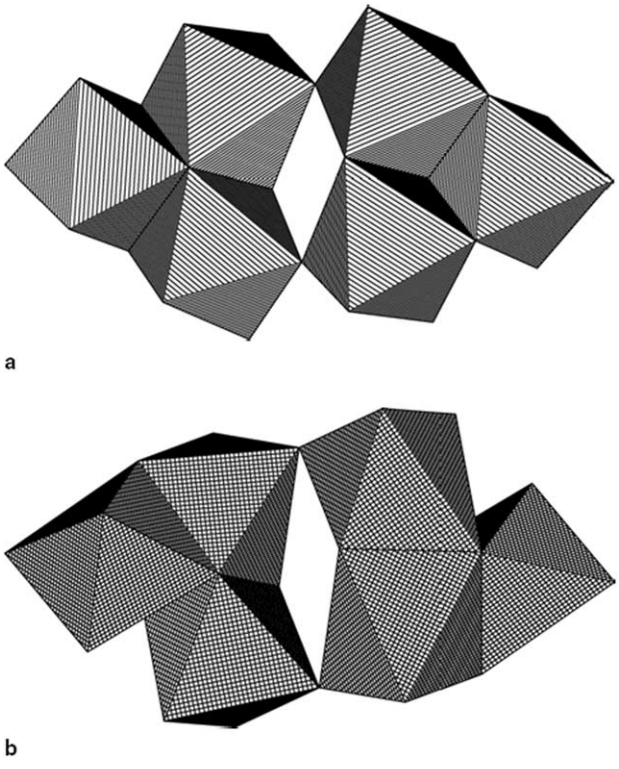

Fig. 3. Comparison of the polyhedral presentations for the structures of (a) $Ti_6O_4(OAc)_4(O^iPr)_{12}$ [14] and (b) compounds **1** and **3**.

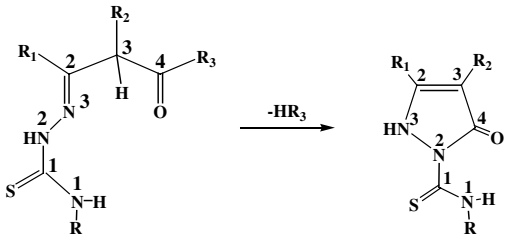
Symmetry transformations used to generate equivalent atoms: #1 $-x+1, -y, -z+2$.

amounts of acetic acid was, however, not successful offering $Ni(OAc)_2(ROH)$ (**2**) instead of the desired complex. This latter compound possesses apparently rather high thermodynamic stability and is easily separated from the reaction medium by crystallization. We achieved formation of the compound **3**, an acetate analogue of **1** applying a significantly lower amount of the modifying acid. The molecular structure of **3** is very closely analogous to that of **1** (see Fig. 2 and Table 2). The structure type of compounds **1** and **3** is unusual for the homometallic alkoxide derivatives of nickel. The most commonly observed structural element for these compounds is a $Ni_4(\mu_3\text{-}OR)_4$ core with chelating ligands attached in a terminal η^2-mode to the nickel atoms [3], a fragment corresponding to cubic packing of the metal and donor atoms. Application of other bi- and oligodentate ligands such as benzotriazol and benzotriazol oxide resulted in the complexes with more open chain structures [18] or even bigger aggregates involving separate octahedrally coordinated Ni(II) centers connected through the longer ligand fragments [19]. Possibility to obtain a series of analogous alkoxide carboxylates opens a possibility to prepare complexes with related molecular structures involving unsaturated carboxylate ligands that can be transformed into hybrid organic–inorganic magnetic materials via organic polymerization reactions in analogy to the processes described recently for the polymerization of carboxylate complexes of manganese [7].

Acknowledgments



The authors express their gratitude to The Swedish Institute for providing Dr. Ilina with a Guest Researcher Grant for the work at SLU in 2002–2003.

Appendix A. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition numbers CCDC 272517 and 272518 for **1** and **3**, respectively. Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2005.06.054.

Scheme 2. Thiosemicarbazone (**I**) and pyrazolone (*II*) ligands.

^{13}C NMR spectra of DMSO solutions were recorded on AMX-300 or AMX-500 spectrometers; chemical shifts are expressed on the δ scale (downfield shifts positive) relative to tetramethylsilane (^{1}H and ^{13}C NMR spectra). All physical measurements were carried out by the RIAIDT services of the University of Santiago de Compostela.

2.2. Materials

Thiosemicarbazide (Merck), N^1-ethylthiosemicarbazide (Merck), methyl propionylacetate (Aldrich), ethyl benzoylacetate (Aldrich), ethyl 2-ethylacetoacetate (Aldrich), methyl acetoacetate (Aldrich) and zinc acetate (Aldrich) were used as received.

2.3. Synthesis of ligands

The synthesis and determination of the physical and analytical properties of HTSC[1], HTSC[2], HL[1] and HL[2] were carried out as described elsewhere (designated in this reference as HTSC[3], HTSC[5], HL[3] and HL[5]) [4].

2.3.1. HTSC[3] (ethyl 2-ethylacetoacetate thiosemicarbazone)

A mixture of ethyl-2-ethylacetoacetate (4.83 mL, 30 mmol) and thiosemicarbazide (2.70 g, 30 mmol) in ethanol (150 mL) was stirred and heated under reflux for 14 h. The solution was allowed to cool down to room temperature and diethyl ether was slowly added until a white solid was obtained. The solid was filtered off and dried under vacuum. M.p. 72 °C. *Anal.* Calc. for $C_9H_{17}N_3O_2S$: C, 46.7; H, 7.4; N, 18.2; S, 13.8. Found: C, 45.6; H, 7.4; N, 18.8; S, 14.8%. MS (electrospray), *m*/*z* (%): 232 (100) $[M+H]^+$. ^{1}H NMR: δ[N(2)H] = 10.07s(1); δ[N(1)H$_2$] = 8.14s(1), 7.47s(1); δ[C(8)H$_2$] = 4.08q(2), δ[C(3)H] = 3.19t(1); δ[C(5)H$_3$] = 1.88s(3); δ[C(6)H$_2$] = 1.68m(2); δ[C(9)H$_3$] = 1.15t(3); δ[C(7)H$_3$] = 0.80t(3). ^{13}C NMR: δ[C(1)] = 179.0; δ[C(4)] = 171.4; δ[C(2)] = 150.0; δ[C(8)] = 60.4; δ[C(3)] = 55.1; δ[C(6)] = 21.9; δ[C(5)] = 14.5; δ[C(9)] = 14.0; δ[C(7)] = 11.7.

2.3.2. HTSC[4] (methyl acetoacetate-^{1}N-ethyl thiosemicarbazone)

A mixture of ^{1}*N*-ethyl-thiosemicarbazide (1.04 g, 9 mmol) and methyl acetoacetate (1 mL, 9 mmol) in ethanol (20 mL) was heated under reflux for 10 min (a longer reaction time afforded the pyrazolone ligand). The resulting solution was concentrated to give an oil, which was stirred with diethyl ether for 24 h to afford a yellow solid. The solid was filtered off and dried under vacuum. M.p. 162 °C. *Anal.* Calc. for $C_8H_{15}N_3O_2S$: C, 44.2; H, 6.9; N, 19.4; S, 14.7. Found: C, 44.3; H, 7.0; N, 19.7; S, 15.1%. MS (electrospray), *m*/*z* (%): 218 (30) $[M+H]^+$. ^{1}H NMR: δ[N(2)H] = 10.02s(1); δ[N(1)H] = 8.22m(1); δ[C(8)H$_3$] = 3.62s(3), δ[C(5)H$_2$] = 3.57m(2); δ[C(3)H$_2$] = 3.46s(2); δ[C(7)H$_3$] = 1.94 s(3); δ[C(6)H$_3$] = 1.09t(3). ^{13}C NMR: δ[C(1)] = 177.7; δ[C(4)] = 170.0; δ[C(2)] = 146.5; δ[C(8)] = 52.2; δ[C(3)] = 44.0; δ[C(5)] = 38.6; δ[C(7)] = 17.0; δ[C(6)] = 14.8.

2.3.3. HL[3] (2,5-dihydro-3-methyl-4-ethyl-5-oxo-1H-pyrazolone-1-carbothioamide)

For the measurement of the ^{1}H and ^{13}C NMR spectra of HL, the 5-pyrazolone ligands were also obtained by cyclization in a basic medium. A 1 M aqueous solution of NaOH was added to a solution of HTSC[3] (0.50 g, 2.26 mmol) in methanol (5 mL) until a pH ca. 8 was reached. The mixture was stirred for 6 h and the resulting white solid was filtered off and dried under vacuum. M.p. 142 °C. *Anal.* Calc. for $C_7H_{11}N_3OS$: C, 45.4; H, 6.0; N, 22.7; S, 17.1. Found: C, 45.3; H, 6.2; N, 22.6; S, 17.1%. MS (electrospray), *m*/*z* (%): 208 (45) $[M+Na]^+$, 186 (95) $[M+H]^+$, 127 (100) $[M+H-(C(S)NH_2)]^+$. ^{1}H NMR: δ[N(3)H] = 11.49s(1); δ[N(1)H$_2$] = 10.38s(1), 9.57s(1); δ[C(5)H$_3$] = 2.15s(3), δ[C(6)H$_2$] = 2.14q(2); δ[C(7)H$_3$] = 0.98t(3). ^{13}C NMR: δ[C(1)] = 175.6; δ[C(4)] = 162.6; δ[C(2)] = 149.5; δ[C(3)] = 104.6; δ[C(6)] = 14.5; δ[C(7)] = 13.7; δ[C(5)] = 10.5.

2.3.4. HL[4] (2,5-dihydro-3-methyl-5-oxo-1H-pyrazolone-^{1}N-ethyl-1-carbothioamide)

This ligand was obtained by treating a solution of HTSC[4] with 1 M NaOH in methanol. The resulting white

solid was filtered off and dried under vacuum. M.p. 187 °C. *Anal*. Calc. for $C_7H_{11}N_3OS$: C, 45.4; H, 5.9; N, 22.7; S, 17.3. Found: C, 45.2; H, 6.0; N, 22.7; S, 17.4%. MS (electrospray), *m*/*z* (%): 208 (40) $[M + Na]^+$, 99 (30) $[M + H - (C(S)NHCH_2CH_3)]^+$. ^{1}H NMR: δ[N(3)H] = 11.39s(1); δ[N(1)H] = 12.05s(1), δ[C(3)H] = 5.18s(1), δ[C(5)H_2] = 3.62m(2); δ[C(7)H_3] = 2.17s(3); δ[C(6)H_3] = 1.17t(3). ^{13}C NMR: δ[C(1)] = 174.8; δ[C(4)] = 163.4; δ[C(2)] = 152.3; δ[C(3)] = 91.4; δ[C(5)] = 39.2; δ[C(6)] = 13.4; δ[C(7)] = 12.0.

2.4. Synthesis of complexes

[ZnL^2] · MeOH was prepared as described previously ([4], in which it was designated as [$ZnL^5{}_2$] · MeOH]) and crystals suitable for X-ray analysis were obtained from the mother liquor.

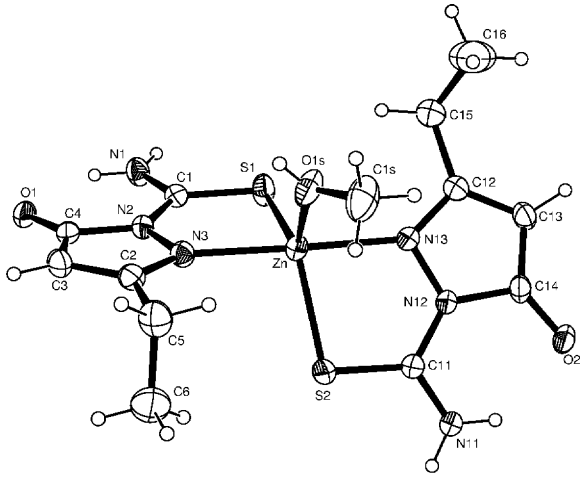
2.4.1. [$ZnL^1{}_2$(MeOH)]

Crystals of this new complex were isolated from the mother liquor when the synthesis of [$ZnL^1{}_2$] ([$ZnL^3{}_2$] in [4]) was repeated. This product was only used in the X-ray study.

2.4.2. [$ZnL^3{}_2$]

A solution of $HTSC^3$ (0.10 g, 0.43 mmol) in methanol (5 mL) was slowly added to a stirred solution of Zn $(OAc)_2 \cdot H_2O$ (0.05 g, 0.23 mmol) in methanol (5 mL). The mixture was stirred for 6 h and the resulting yellowish crystalline solid was filtered off. This solid contained two different types of crystals (white, *Form I*, and amber, *Form II*) and these were easily separated by hand with the aid of a magnifying glass. *Form I*: M.p. 146 °C. *Anal*. Found: C, 39.1; H, 4.6; N, 19.4; S, 14.6%. *Form II*: M.p. 148 °C. *Anal*. Calc. for $C_{14}H_{18}N_6O_2S_2Zn$: C, 39.1; H, 3.7; N, 19.5; S, 14.9. Found: C, 39.1; H, 4.1; N, 18.8; S, 14.3%.

Both types of crystal showed the same spectroscopic properties. MS (electrospray), *m*/*z*(%): 433 (50) $[M]^+$, 374 (100) $[M + H - (C(S)NH_2)]^+$. ^{1}H NMR: δ[N(1)H_2] = 11.45s(1), 10.23s(1); δ[C(6)H_2] = 2.09m(2); δ[C(5)H_3] = 2.04m(3); δ[C(7)H_2] = 0.97t(3). ^{13}C NMR: δ[C(1)] = 173.7; δ[C(4)] = 164.0; δ[C(2)] = 152.5; δ[C(3)] = 99.3; δ[C(6)] = 14.9; δ[C(5)] = 14.4; δ[C(7)] = 12.7, 12.3.



2.4.3. [$ZnL^4{}_2$]

A solution of $HTSC^4$ (0.10 g, 0.46 mmol) in methanol (5 mL) was added dropwise to a solution of $Zn(OAc)_2 \cdot H_2O$ (0.05 g, 0.23 mmol) in methanol (5 mL) and the mixture was heated under reflux and stirred for 6 h. The mixture was allowed to cool down to room temperature. The resulting white crystalline solid was filtered off. M.p. 205 °C. *Anal*. Calc. for $C_{14}H_{20}N_6O_2S_2Zn$: C, 38.8; H, 4.7; N, 19.4; S, 14.8. Found: C, 37.8; H, 4.6;

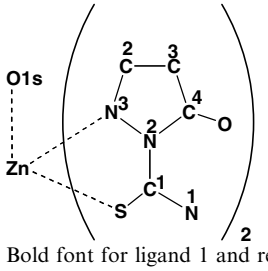
Fig. 1. Molecular structure of Zn(II) pyrazolonate complexes. Displacement ellipsoids are drawn at the 30% probability level.

2.5. X-ray crystallography

X-ray data were collected at the RIAIDT services of the University of Santiago de Compostela using a Bruker SMART CCD-1000 diffractometer. Data were corrected for absorption by SADABS [5]. The structures were solved by the Patterson method and refined using SHELX97 [6]. For $[ZnL^3{}_2]$ (*Form I*), the Flack parameter [7] was refined and converged to 0.55(7), which indicated the crystal was racemically twinned. All the H atoms were introduced in calculated positions except H(1) in $[ZnL^4{}_2]$ and H(1S) in $[ZnL^1{}_2(MeOH)]$, which were located in the Fourier difference map and refined isotropically. Molecular graphics were obtained with ORTEP [8], PLATON [9] and MERCURY [10]. Crystal data, experimental details and refinement results are listed in Table 1.

3. Results and discussion



3.1. X-ray crystal structures

The molecular structures of the Zn(II) pyrazolonate complexes are shown in Fig. 1 along with the numbering scheme used. Selected bond lengths and angles are listed in Tables 2 and 3, respectively.

Two polymorphic forms – *Form I* and *Form II* – were isolated for $[ZnL^3{}_2]$ and both of these are orthorhombic, albeit with different cells and space groups. In the *Form I*, the asymmetric unit contains just one complex molecule with crystallographically different ligands. In the *Form II* crystals the asymmetric unit includes two half molecules of the complex. The same situation occurs in $[ZnL^4{}_2]$ but in $[ZnL^2{}_2]\cdot MeOH$ and $[ZnL^1{}_2(MeOH)]$

the asymmetric unit contains one molecule of complex and one molecule of MeOH. The methanol is not bound to the metal in $[ZnL^2_2]\cdot$ MeOH but in $[ZnL^1_2(MeOH)]$ it occupies one coordination position, thus increasing the coordination number to five.

All five structures contain monodeprotonated N(3), S-coordinated pyrazolones formed by cyclization processes. Deprotonation of the N(3)H group and coordination induce, in all cases, lengthening of the C=S bond {d(C–S) (Å) = 1.6703(15) in HL^3 [11], 1.673(2) in HL^4 [11], 1.663(2) in HL^2 [4] and 1.659(3) in HL^1 [4]} to the thiol form [1.695(2)–1.716(3) Å in the complexes, Table 2], whereas the N(1)–C(1) and N(2)–C(1) bonds become shorter and N(2)–N(3) and N(2)–C(4) either become longer or are not modified.

In $[ZnL^3_2]$ (*Form I*), $[ZnL^3_2]$ (*Form II*), $[ZnL^4_2]$ and $[ZnL^2]\cdot$ MeOH the coordination polyhedron can be described as a very distorted tetrahedron, with the main distortion being the N(3)–Zn–N(6) angle for $[ZnL^3_2]$ (*Form I*), the N(3)–Zn–N(3)^{i} and N(6)–Zn–N(6)^{ii} angles for $[ZnL^3_2]$ (*Form II*), the S–Zn–S^{i} angle for $[ZnL^4_2]$ and the N(3)–Zn–S(2) angle in $[ZnL^2_2]\cdot$ MeOH (see Table 3).

In $[ZnL^1_2(MeOH)]$, the incorporation of the solvent into the coordination sphere increases the coordination number to five and the geometry around the metal is now distorted trigonal bipyramidal ($\tau = 0.85$) [12], with the N(3) and N(13) atoms apical and the main distortions associated with the O(1S)–Zn–S(2) [113.92(8)°] and S(2)–Zn–S(1) [126.75(3)°] bond angles. The additional interaction of the metal with the MeOH induces a lengthening of the Zn–S bonds compared to those in four-coordinate complexes. Similar changes occur when other Zn(II) pyrazolonate complexes incorporate a water molecule into the metal coordination sphere [2]. The Zn–O1s bond distance in $[ZnL^1_2(MeOH)]$ [2.043(2) Å] is similar to the Zn–O(water) bond distance found in these complexes [2.017(4) and 2.092 Å] [4].

Several hydrogen bonding interactions were detected in all of these compounds (see Table 4). These interactions give rise to associations that expand the systems in one ($[ZnL^4_2]$), two {$[ZnL^3_2]$ (*Form II*) and $[ZnL^2_2]\cdot$ MeOH} or three {$[ZnL^3_2]$ (*Form I*) and $[ZnL^1_2(MeOH)]$} directions.

In $[ZnL^4_2]$, the substitution of one hydrogen in the $N(1)H_2$ group by one R group reduces the possibilities for hydrogen bonding with respect to the unsubstituted ligand. Thus, only two bonds are formed; one intramolecular N(1)–H ··· O, which is present in all the compounds, and one intermolecular N(1)–H···O^{i}, which links the molecules in chains (Fig. 2).

In $[ZnL^3_2]$ (*Form II*), in addition to the intramolecular N(1)–H(1A)···O(1) and N(4)–H(4A)···O(2) hydrogen bonds, there are intermolecular hydrogen bonds connecting molecule 1 and molecule 2 (see Table 4 and Figure S3) and this gives rise to a layered lattice that expands along the *ac* plane. Each of these layers is formed by stacking of tubes (or channels) that grow along the *a* axis and are piled up along the *c* axis. Adjacent layers are partially intercalated (although not intertwined) (see Fig. 3).

In $[ZnL^2_2]\cdot$ MeOH (Figure S4), one [N(11)–H(11B) ··· O(2)^{iii}] intermolecular hydrogen bond links molecules in chains parallel to the *c* axis. Each of these chains interacts with two neighbouring chains through MeOH bridges that give rise to – as in the previous complex – a layered network (see Fig. 4).

As mentioned above, the hydrogen bonding in $[ZnL^3_2]$ (*Form I*) and $[ZnL^1_2(MeOH)]$ (Table 4, Figures S5 and S6) results in a 3-D network (Figs. 5 and 6). In $[ZnL^3_2]$ (*Form I*), an N(1)–H(1B)···O(1)^{i} intermolecular hydrogen links molecules to give polymeric chains in the direction of the *a* axis. Furthermore, N(4)–H(4B)···O(1)^{ii} interactions between adjacent chains lead to an infinite three-dimensional network (Fig. 5). In $[ZnL^1_2(MeOH)]$, the O(1S)–H(1S)···O(1)^{iii} interaction associates molecules in dimers. These dimers, which are formed through N(11)–H(11B)···O(1)^{ii} interactions, associate in chains along the *a* axis and these chains, in turn, interact with one another [through N(1)–H(1B)···O(2)^{i} bonds] to give a 3-D network (Fig. 6).

3.2. NMR spectroscopy

The main signals observed in the ^1H and ^{13}C NMR spectra of $[ZnL^1_2(MeOH)]$ and $[ZnL^2]\cdot$ MeOH have

been described elsewhere [4] and those of $[ZnL^3{}_2]$ and $[ZnL^4{}_2]$ are given in Section 2 of this work. All signals show changes with respect to those of the free thiosemicarbazones and this is indicative of cyclization and metallation.

Evidence for cyclization is provided by: (a) the disappearance of signals corresponding to the R_3 groups, (b) the absence of the signal corresponding to the proton on C(3) in the ^{1}H NMR spectra and (c) the shielding (about 50 ppm) of the C(3) signal in the ^{13}C NMR spectra.

On the other hand, the absence of the signal corresponding to the N(3)H group in the ^{1}H NMR spectrum of the complexes is consistent with the deprotonation and metallation of the pyrazolone ligand. Furthermore,

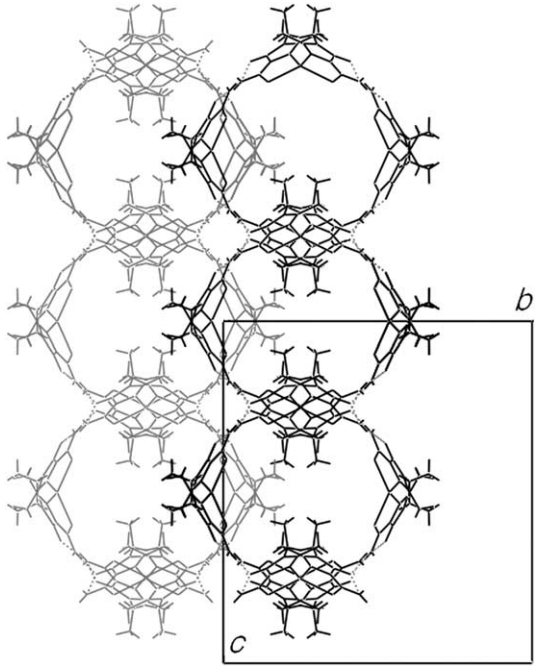

Fig. 3. Layers disposition in $[ZnL^3{}_2]$ (*Form II*) (view parallel to x axis).

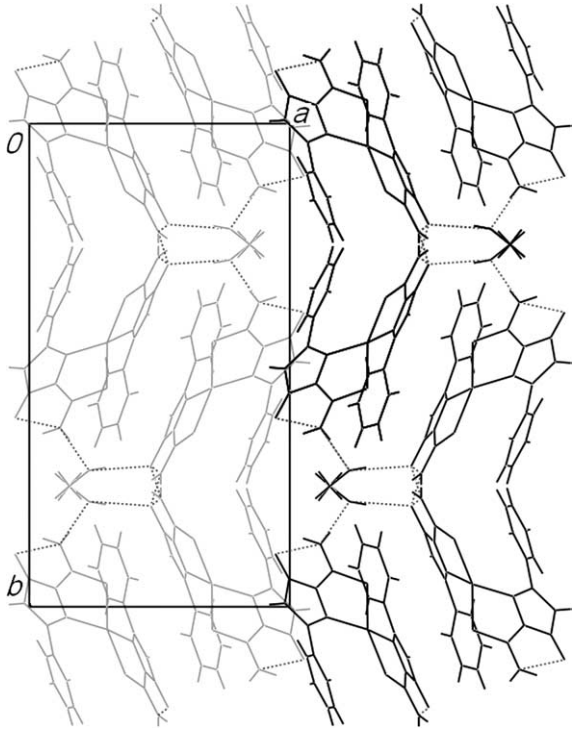

Fig. 4. Layers in $[ZnL^2_2]\cdot$ MeOH (view parallel to z axis).

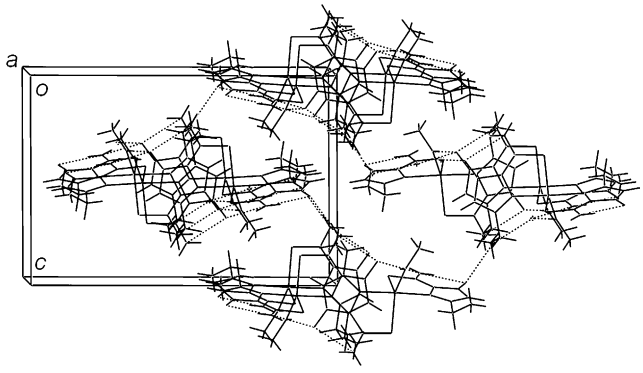

Fig. 6. Three-dimensional network in $[ZnL^1_2(MeOH)]$ (view parallel to the x axis).

the protons of the amine group and the C(2) atom are more deshielded and the C(1) atom slightly more shielded in the complexes than in the free pyrazolones. These changes could be associated with the presence, at least partially, of N(3), S-coordination in DMSO solution.

In summary, zinc(II) acetate is able to induce cyclization under mild conditions of the thiosemicarbazones derived from β-keto esters, possibly with any substituents in the starting molecule. The resulting 5-pyrazolone-1-carbothioamide reacts with the metal to give pyrazolonate complexes with the ligand bound in an N(3), S manner. When the reaction is performed using 1(metal):2(ligand) molar ratio of reactants – as in this work – the 5-pyrazolone loses one proton upon metallation to give molecular complexes that are only associated through hydrogen bonds (for another possibility see [4]).

As the metal retains some residual acidity, it can increase its distorted tetrahedral coordination up to five by interacting with an additional molecule of base, such as a solvent molecule. It is probable that this acidity can be modulated by changing the substituents on the amine group or on the ring, leading to a range of options to obtain five-coordinate complexes. Additional work in this area is currently underway.

limited to $Hf(OSi^tBuMe_2)_4(Et_2NH)$ [12] and to $Hf(acac)_2(OSi^tBuMe_2)_2$ [15f] although SSP might allow better homogeneity and lower temperature of deposition [16,17].

We wish to report herein the synthesis and characterization of precursors containing both hafnium and silicon, namely $Hf(thd)_2[N(SiMe_3)_2]_2$ (**3**), $Hf(thd)_2(OSiMe_3)_2$ (**4**) and $Hf(thd)_2(OSi^tBuMe_2)_2$ (**5**). Preliminary results of their evaluation for the deposition of $HfSi_xO_y$ films are also reported.

2. Experimental

Syntheses were performed under argon using Schlenk tubes and vacuum line techniques. Solvents were purified by standard methods and stored over molecular sieves. $HfCl_4$, lithium trimethylsilyloxide and lithium bis(trimethylsilyl)amide (Aldrich) were used as received. 2,2,6,6-tetramethyl-3,5-heptanedione (thdH) was dried over molecular sieves. $HfCl_2(thd)_2$ was obtained by improving the reported procedure.[18] FT-IR spectra were recorded with a Perkin–Elmer Paragon 500 Spectrometer as Nujol mulls. ^1H NMR spectra were registered on a Bruker 300 MHz NMR spectrometer. Elemental analyses were done at the Centre de microanalyses du CNRS. TGA experiments were performed under N_2 with a Netzsch-Gerätebau STA 409PC system between 20 and 800 °C using a thermal ramp of 10 °C/min. The spectroscopic data (FT-IR, NMR) are collected in Table 1.

2.1. Synthesis of $Hf(thd)_2Cl_2$ (1) and of $Hf(thd)_3Cl$ (2)

2,2,6,6-tetramethyl-3,5-heptanedione (1.99 g, 10.8 m mol) was added to a suspension $HfCl_4$ (1.73 g, 5.4 mmol) in 15 ml of toluene. Dissolution gave a sligthly yellow solution after 15 min. After refluxing for 16 h and evaporation to dryness, the crude product was washed with petroleum ether (10 ml) giving **1** as a precipitate (2.32 g, 84%). Evaporation of the washings gave **2** (0.1 g, 3%). **1** sublimes at 120–130 °C/2×10^{-4} Torr. *Anal.* Calc. for $C_{22}H_{38}Cl_2HfO_4$: C, 42.90; H, 6.22; Cl, 11.52. Found: C, 43.10; H, 6.34; Cl, 11.07%.

The same procedure applied to 0.97 g of $HfCl_4$ (3 mmol) and 2,2,6,6-tetramethyl-3,5-heptanedione (1.68 g, 9.1 mmol) in 30 ml of toluene, gave after 18 h of reflux and cooling, crystals of **2** (0.8 g, 35%) at −20 °C. **2** sublimes at 130–140 °C/2×10^{-4} Torr. *Anal.* Calc. for $C_{33}H_{57}ClHfO_6$: C, 51.90; H, 7.52; Cl, 4.64. Found: C, 52.05; H, 7.65; Cl, 4.35%.

2.2. Synthesis of $Hf(thd)_2[N(SiMe_3)_2]_2$ (3)

0.72 g (4.2 mmol) of lithium bis(trimethylsilyl)amide were added to $Hf(thd)_2Cl_2$ (1.33 g, 2.1 mmol) in 30 ml

Table 1

of toluene. After refluxing for 18 h, filtration and evaporation to dryness, the crude product was recrystallized in pentane (1.5 g, 72%) at −20 °C. **3** sublimes at 130–140 °C/2×10^{-4} Torr. *Anal.* Calc. for $C_{28}H_{56}HfO_6Si_2$: C, 49.21; H, 8.26. Found: C, 49.55; H, 8.32%. **3** is extremely air sensitive giving a soluble product analyzing as $Hf_2(thd)_4O([N(SiMe_3)_2]_2$.

2.3. Synthesis of $Hf(thd)_2(OSiMe_3)_2$ (4)

0.51 g of lithium trimethylsiloxide (5.2 mmol) was added to $Hf(thd)_2Cl_2$ (1.65 g, 2.6 mmol) in 15 ml of toluene. After refluxing for 3 h and filtration, the filtrate was concentrated. Crystals (1.2 g, 69%) were obtained at −20 °C. **4** sublimes at 130–140 °C/2×10^{-4} Torr. *Anal.* Calc. for $C_{28}H_{56}HfO_6Si_2$: C, 46.49; H, 7.80. Found: C, 46.72; H, 7.95%.

2.4. Synthesis of $Hf(thd)_2[OSi^tBuMe_2]_2$ (5)

0.79 ml of tertbutyldimethylsilanol (5 mmol) were added to $Hf(thd)_2[N(SiMe_3)_2]_2$ (2.12 g, 2.5 mmol) in 20 ml of toluene. After refluxing for 15 h, the solution was evaporated to dryness. The crude product was recrystallized in pentane, giving crystals (1.48 g, 75%) at −20 °C. **5** sublimes at 130–140 °C/2×10^{-4} Torr. The same product was obtained quantitatively by reacting **1** (1 g, 1.6 mmol) with $OHSi^tBuMe_2$ (0.43 g, 3.2 mmol) in 30 ml of toluene. After refluxing for 3 h, the solution was evaporated to dryness. *Anal.* Calc. for $C_{34}H_{68}HfO_6Si_2$: C, 50.57; H, 8.49. Found: C, 50.75; H, 8.65%.

All compounds were soluble in usual organic solvents including aliphatic and aromatic hydrocarbons.

2.5. X-ray structure determination

Suitable crystals of $HfCl(thd)_3$ **2** were obtained as colorless plates from the last crop of crystals of a synthesis of **1** after recrystallization in petroleum ether. Crystals of **5** were obtained in pentane at 0 °C. The crystals were mounted on a Nonius KappaCCD diffractometer equipped with Mo Kα radiation. Accurate cell dimensions were obtained from 262 (**2**) and 72 (**5**) reflections collected at 150 K in the range $2° < \theta < 25°$. Crystallographic data, main collection parameters and refinement features are listed in Table 2. The data were corrected for Lorentz and polarization effects. Computations were performed by using the PC version of CRYSTALS [19]. Scattering factors and corrections for anomalous dispersion were taken from [20]. The structures were solved by direct methods (SIR92) [21] for **2** and SHELX [22] for **5** and refined on F^2 by full-matrix least-squares with anisotropic displacement parameters for all non hydrogen atoms. Hydrogen atoms (except for compound **2**, those on disordered ^{t}Bu groups in a crystallographic mirror) were introduced in calculated positions in the last refinements with an overall isotropic displacement parameter.

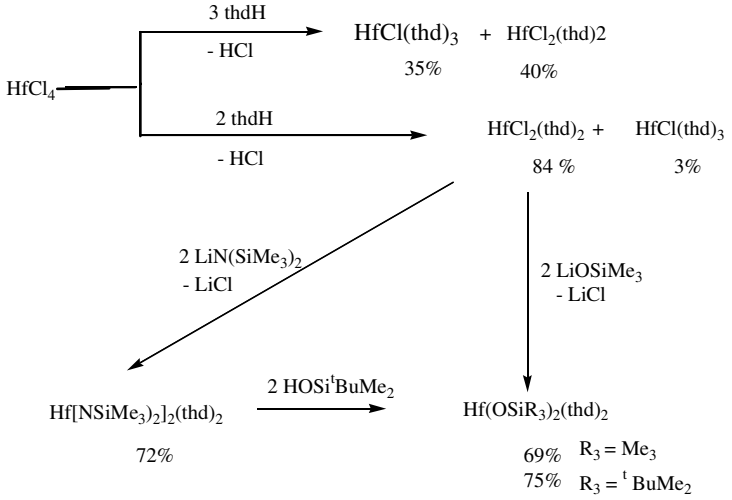
2.6. CVD experiments

Pulsed liquid-injection MOCVD (PI-MOCVD) was used for preliminary tests of the new compounds for deposition of hafnium silicate films. This technique is based on repetitive injections of microdoses of solutions of a volatile metal-organic precursor, flash evaporation, vapor transport by a carrier gas and decomposition on a hot substrate [23]. Depositions were carried out on Si(1 0 0) substrates at 600–800 °C, using an Ar + O_2 mixture as carrier gas. Solutions of **3**–**5** in toluene (0.05 M) were used as precursor sources. They were injected by microdoses of several micro-litres into an evaporator heated at 250 °C. The crystallization of the films was studied by X-ray diffraction (XRD) with a Bruker D8 diffractometer (Cu Kα radiation). X-ray photoelectron spectroscopy (XPS; RIBER LAS-3000, Mg Kα radiation) was used for composition analysis.



3. Results and discussion

3.1. Synthesis and characterization

The reaction between $HfCl_4$ and thdH (1:2 stoichiometry) afforded after refluxing and work-up a crystalline material **1** analysing as $HfCl_2(thd)_2$. The last crop of crystals corresponded to a more substituted compound $HfCl(thd)_3$ **2**. **2** was obtained in better yields by reacting $HfCl_4$ and thdH in the appropriate stoichiometry, 1:3. Various substitution reactions (Scheme 1) applied to **1** afforded single-source precursors for MOCVD of hafnium silicate namely $Hf[N(SiMe_3)_2](thd)_2$ (**3**), $Hf(OSiMe_3)_2(thd)_2$ (**4**) and $Hf(OSi^tBuMe_2)(thd)_2$ (**5**) in high yields. Surprisingly, the chlorine atoms of $HfCl_2(thd)_2$ were quite labile toward the $OHSi^tBuMe_2$ silanol and **5** could be obtained either by silanolysis of **3** or by reaction between **1** and the silanol, in the absence of any base. The compounds were isolated by crystallization. They were volatile and sublimed in similar conditions [130–140 °C/2×10^{-4} Torr]. The *tert*-butyldimethylsiloxide OSi^tBuMe_2 was selected as siloxide because of the well known ability of the *tert* butyl group to be thermally eliminated as isobutylene [24].

The various compounds were characterized by elemental analyses, FT-IR and ^1H NMR. The spectroscopic data are collected in Table 1. The FT-IR spectra display the characteristics *ν*CO absorption of the β-diketonate ligands. These, as well as the Hf–O vibration in the 650–480 cm^{-1} area were diagnostic for the identification of either the bis or tris-substituted β-diketonates **1** and **2**. The siloxides are also characterized by a strong absorption band at 950 cm^{-1}. The FT-IR spectra confirmed the absence of *ν*OH of NH absorption bands and thus the absence of coordination either by silanol or by an amine as observed for instance for the reaction between $Hf(NMe_2)_4$ and $OHSi^tBuMe_2$ giving $Hf(OSi^tBuMe_2)_4(Me_2NH)$ [15d]. The ^1H NMR spectra confirm the formula of the various compounds. The chemical shifts of the CH groups of the β-diketonate ring are, as well as the FT-IR data, diagnostic for their identification.

The thermal properties of precursors **3**–**5** were studied by TGA under 1 atm of N_2 (Fig. 1) in the 20–800 °C range. **3** leaves 11.5% of residue, the theoretical value for decomposition into HfO_2 being 24.3%. The main process is thus sublimation (∼53%), with part of **3** being decomposed into oxide. In contrast, **4** and **5** sublime to at least ∼90% as shown by the small residues (∼3%). **4** appears as the most volatile under the TGA conditions used. Thus, the thermal stability of the complexes under the TGA conditions used increases along the ranking **3** < **4** < **5.**

Scheme 1. Syntheses of the various derivatives (all reaction in at r.t.).

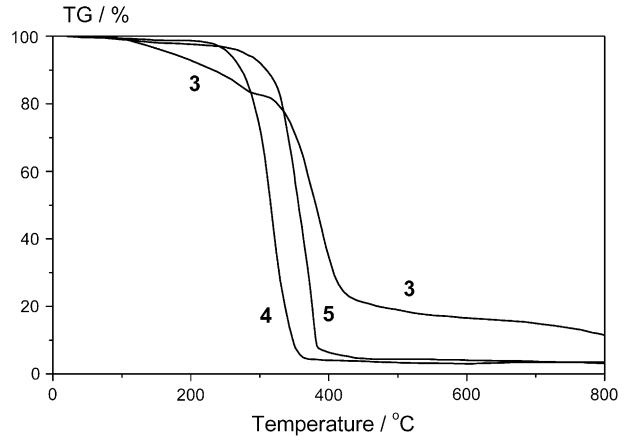


Fig. 1. Thermogravimetric data (N_2, 1 atm) of compounds **3**–**5**.

3.2. Molecular structures of $Hf(thd)_2(OSi^tBuMe_2)_2$ and of $HfCl(thd)_3$

The identity of compound **5** was established by X-ray diffraction studies. $Hf(thd)_2(OSi^tBuMe_2)_2$ corresponds to a monomer as depicted in Fig. 2, the metal being 6-coordinate. The Hf–O bond lengths range from 1.937(7) to 2.170(7) Å, the Hf–O(Si) are as expected shorter (1.951 Å av.) than the Hf–O(thd) ones. The Hf–O–Si angles (169.5° av.) are large. This can be attributed to π-donation of the oxygen lone pairs either into the empty 3d Si orbitals. [25] or into the empty 5d orbitals of hafnium. Indeed, large Hf–O–C bonds are also associated to terminal alkoxide ligands [26]. Hf–O–C angles as large as 175.5° av. have for instance been observed for $HfAl_2(\mu\text{-}OiPr)_2(\mu,\eta^2\text{-}OC_2H_4NMe_2)_2(OiPr)_6$ [27]. The siloxide ligands exert a trans effect and the Hf–O(thd) distances *trans* to the siloxides are noticeably longer (2.168 Å av.) than those *trans* to a β-diketonate (av. 2.078 Å) (Table 3). The coordination polyhedron is distorted as a result of the bulky siloxide in *cis* position (∠O5–Hf–O6 99.6(3)°] and of the small bite angle (78.45° av.) of the β-diketonate ligands.

Hafnium is 7-coordinate in $HfCl(thd)_3$ (Fig. 3, Table 4). The stereochemistry is that of a distorted capped trigonal prism, the molecule having a plane of symmetry through Hf–Cl–O3–C4–C5–C6 and O4–C41–C43–C61–C62. The Hf–Cl bond distance is quite long 2.482(2) Å. The Hf–O(thd) bond lengths are shorter, they display similar values (2.105(5)–2.122(4) Å], their average value being similar to that observed in **5** for hexacoordinated hafnium.

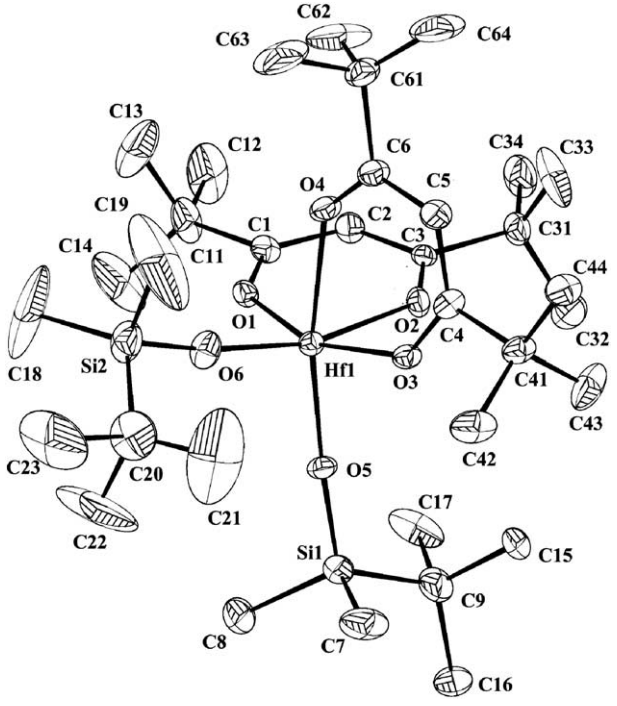

Fig. 2. Molecular structure of $Hf(thd)_2(OSi^tBuMe_2)_2$ showing the atom labeling scheme (ellipsoids at 20% probability).

3.3. $HfSi_xO_y$ films

$HfSi_xO_y$ films were deposited at 600–800 °C. X-ray diffraction $\theta/2\theta$ scans for some $HfSi_xO_y$ films are presented in Fig. 4. Films grown with **3** and **5** were amorphous in all the temperature range, while those deposited with **4** at 800 °C showed some signs of crystallization. XPS was used for the study of composition of the deposited $HfSi_xO_y$ films and of their contamination level. XPS spectra revealed that both Hf and Si were present in all films (Fig. 5). The bulk of the films (studied

after removal of several nanometers thick surface layer by etching with Ar^+ ions) contained high amounts of hafnium with respect to silicon ($Hf/(Hf + Si) = 0.70$–

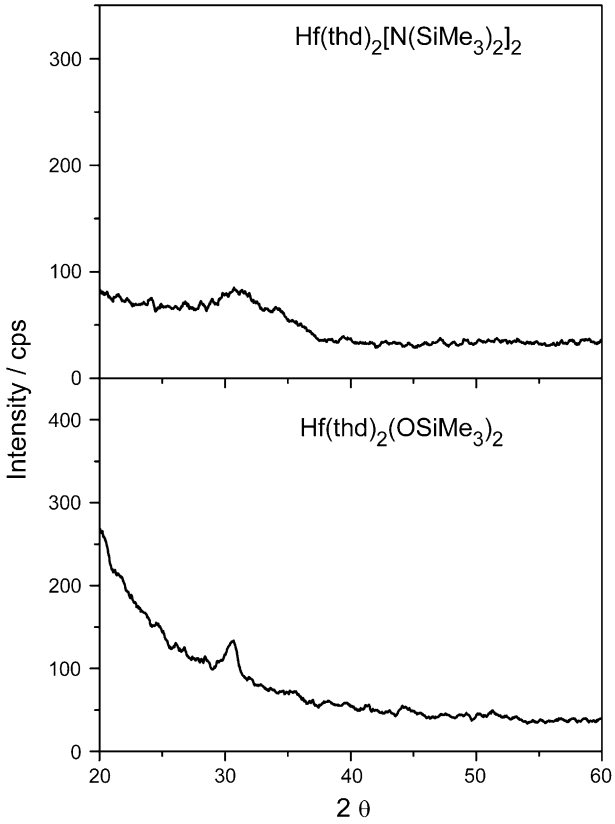

Fig. 4. XRD θ–2θ patterns of some $HfSi_xO_y$ films deposited on silicon and R plane sapphire at 700 °C.

0.85). The bulk of the film was quite pure, the contamination by carbon decreased for higher deposition temperatures and was ~0% after etching for the films issued from 5 for instance). In general, the Si/Hf ratio in the $HfSi_xO_y$ films was significantly lower than in the initial precursor without clear dependence on the temperature of deposition or on the precursor used. Similar observations were reported with $Hf(NEt_2)_4$/^{t} Bu-

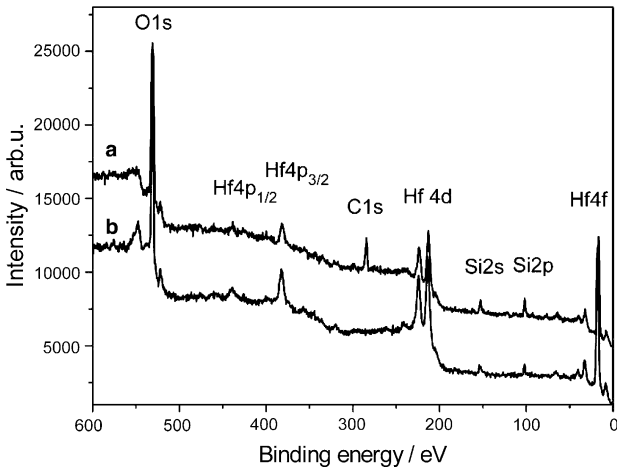

Fig. 5. XPS spectra of a $HfSi_xO_y$ film grown at 700 °C from $Hf(thd)_2(OSi^tBuMe_2)_2$: (a) surface, (b) after 30 min surface cleaning by sputtering with Ar^+ at 1.5 keV.

Me_2SiOH as source [15d]. These results suggest that desorption of Si-containing fragments from the substrate might occur, partial precursor decomposition in the gas phase near the substrate can also play a role. However, our first data allow us to conclude that compounds **3**–**5** are suitable for the incorporation of SiO_2 into HfO_2 films in an amount sufficient for the stabilization of amorphous films. More detailed study of the growth and properties of the $HfSi_xO_y$ films are in progress in order to define the best precursor among compounds **3**–**5** [28].

4. Conclusions

$Hf[N(SiMe_3)_2]_2(thd)_2$ (**3**), $Hf(OSiMe_3)_2(thd)_2$ (**4**), $Hf(OSi^tBuMe_2)_2(thd)_2$ (**5**) were synthesized and characterized by elemental analyses, FT-IR, ^1H NMR and TGA. The molecular structure of **5** is a distorted octahedron with siloxide ligands in *cis* positions despite their steric bulk. The complexes are volatile and were tested as single-source MOCVD precursors for the deposition of hafnium silicate films $HfSi_xO_y$. Amorphous films were grown at 600–800 °C on Si(100). The Si/Si + Hf ratio in the bulk of films varied from 0.15 to 0.30 without clear dependence on the deposition temperature and/or on the precursor. These ratio although far from those in the initial precursors were sufficient for the stabilization of amorphous films.

5. Supplementary material

Crystallographic data (tables of coordinates, of thermal parameters, of bond lengths and angles) have been deposited at the Cambridge Crystallographic Data Base Centre. CCDC Reference Nos. 220717 for $HfCl(thd)_3$ and 220718 for the Si derivative. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: + 44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

only simple substitution products $[M_3(CO)_{10}(C_4H_4N_2)]$. The Ru and Os analogues have different structures. The Os-derivative has only terminal carbonyl ligands but the Ru analog has three bridging carbonyls [8,9]. However, in both the structures, the two nitrogen atoms of the 1,2-diazine occupy axial positions of two metal atoms. The diimine bridged bis-triosmium pyrazine compound, $[(\mu\text{-H})Os_3(CO)_{10}]_2(pyz)$, and its 1:1 ligand to cluster complex, $[(\mu\text{-H})Os_3(CO)_{10}(pyz)]$ were prepared by reacting $[Os_3(CO)_{10}(MeCN)_2]$ with pyrazine [10]. Very recently Machhado et al. [11] reported that treatment of $[Os_3(CO)_{10}(MeCN)_2]$ with 2,3-bis(2-pyridyl)pyrazine at room temperature gave the cluster $[Os_3(CO)_{10}(C_{14}H_{10}N_4)]$ which contains the chelating ligand coordinated axially through one of the pyridine rings and equatorially through a pyrazine-nitrogen atom. The reaction of the trirhenium cluster $[(\mu\text{-H})_4Re_3(CO)_{10}]^-$ with 1,2-diazine has been reported to give $[(\mu\text{-H})_3Re_3(CO)_{10}(\mu\text{-}\eta^2\text{-}N_2C_4H_3)]^-$ and $[(\mu\text{-H})_2Re_3(CO)_{10}(\mu\text{-}\eta^2\text{-}N_2C_4H_4)]^-$ where the former contains the orthometallated diazine, and the latter shows the ligand bridging through the two nitrogen atoms [12].

We previously reported the synthesis of triosmium clusters of the type $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})L]$ $\{L = SC(NMe_2)_2, PPh_3, P(OMe)_3\}$ from the reactions of $[Os_3(CO)_{11}L]$ with water in the presence of Me_3NO [13]. With the aim of synthesizing 2:1 cluster to ligand complexes of the type $[\{Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})\}_2(pyz)]$ we have investigated the reactions of $[Os_3(CO)_{12}]$ with pyrazine, 2-methylpyrazine, 2,3-dimethylpyrazine, and 2,3,5-trimethylpyrazine and water in the presence of a methanolic solution of Me_3NO. However, our initial objective of linking two triosmium clusters analogous to observation with reactions of pyrazine with $[Os_3(CO)_{10}(MeCN)_2]$ [11] remains unfulfilled. In contrast, the reactions exclusively resulted in 1:1 complexes of the type $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})L]$ (L = pyrazine, 2-methylpyrazine, 2,3-dimethylpyrazine, and 2,3,5-trimethylpyrazine). The synthetic and characterization details of these clusters as well as the crystal structures of four compounds are described herein.

2. Experimental

All the reactions were performed under a nitrogen atmosphere using standard Schlenk techniques. Solvents were dried and distilled prior to use by standard methods. $[Os_3(CO)_{12}]$ was purchased from Strem. Pyrazine, 2-methylpyrazine, 2,3-dimethyl pyrazine, 2,3,5-trimethylpyrazine, PPh_3, $P(OMe)_3$, ^tBuNC and C_5H_5N were purchased from Aldrich and used as received. Infrared spectra were recorded on a Shimadzu FT-IR 8101 spectrophotometer. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded on a Varian Unity Plus 400 and a Bruker DPX 400 spectrometers.

2.1. Reaction of $[Os_3(CO)_{12}]$ with pyrazine and water in the presence of Me_3NO/CH_3OH

To a suspension of $[Os_3(CO)_{12}]$ (0.200 g, 0.221 mmol), pyrazine (0.089 g, 1.1 mmol) and water (two drops) in benzene (60 mL), a methanolic solution (5 mL) of Me_3NO (0.043 g, 0.573 mmol) was added dropwise from a dropping funnel for 45 min. The reaction mixture was heated to reflux for 5 h during which time the color changed from yellow to orange. The solvent was removed under reduced pressure and the residue dissolved in a minimum volume of acetone and chromatographed on silica gel TLC plates. Elution with hexane/CH_2Cl_2 (3:2, v/v) gave two bands. The faster moving band was too small for complete characterization. The slower moving band gave $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})(\eta^1\text{-NCHCHNCHCH-})]$ (**1**) (0.098 g, 45%) as red crystals from benzene (*Anal.* Calc. for $C_{15}H_8N_2O_{12}Os_3$: C, 18.40; H, 0.82; N, 2.86. Found: C, 18.65; H, 0.98; N, 2.92%). IR (ν (CO), CH_2Cl_2): 2091s, 2074w, 2054vs, 1999vs, 1984s, 1921m cm^{-1}, KBr: ν (OH) 3404m, methoxycarbonyl, 1495m cm^{-1}; ^1H NMR (CD_2Cl_2): δ 9.00 (d, 2H, $J = 2.8$ Hz), 8.85 (d, 1H, $J = 2.8$ Hz), 8.78 (d, 1H, $J = 2.8$ Hz), 3.97 (s, 3H), −1.05 (s, 1H); mass spectrum: (m/z) 978 $[M]^+$.

2.2. Reaction of $[Os_3(CO)_{12}]$ with 2-methylpyrazine and water in the presence of Me_3NO/CH_3OH

A similar reaction to that above of $[Os_3(CO)_{12}]$ (0.200 g, 0.221 mmol), 2-methylpyrazine (0.104 g, 1.10 mmol), water (2 drops) and a methanolic solution (5 mL) of Me_3NO (0.043 g, 0.57 mmol) for 7 h followed by similar chromatographic separation afforded $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})(\eta^1\text{-N=C(CH}_3\text{)CH=NCH=CH—})]$ (**2**) (0.083 g, 38%) as orange crystals recrystallization from benzene at room temperature (*Anal.* Calc. for $C_{16}H_{10}N_2O_{12}Os_3$: C, 19.37; H, 1.02; N, 2.82. Found: C, 19.58; H, 1.25, N, 2.91%). IR (ν (CO), CH_2Cl_2): 2091s, 2053s, 1997vs, 1983s , 1921s cm^{-1}, KBr: ν (OH) 3405m, methoxycarbonyl, 1500m cm^{-1}; ^1H NMR (CD_2Cl_2): δ 8.59 (s, 1H), 8.45 (s, 1H), 8.35 (s, 1H), 3.95 (s, 3H), 2.64 (s, 3H), −1.31 (s, 1H); mass spectrum: (m/z) 992 $[M]^+$.

2.3. Reaction of $[Os_3(CO)_{12}]$ with 2,3-dimethyl pyrazine and water in the presence of Me_3NO/CH_3OH

A similar treatment of $[Os_3(CO)_{12}]$ (0.200 g, 0.221 mmol), 2,3-dimethylpyrazine (0.119 g, 1.10 mmol), water (2 drops) and a methanolic solution (5 mL) of Me_3NO (0.047 g, 0.63 mmol) followed by removal of solvent gave an orange residue which was dissolved in a minimum volume of CH_2Cl_2 and chromatographed by TLC

on silica gel. Elution with hexane/CH_2Cl_2 (2:3, v/v) gave one major and three minor bands. The major band afforded $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C(CH_3){=}NCH{=}CH{-}\}]$ (**3**) (0.078 g, 35%) as orange crystals recrystallization from benzene at room temperature (*Anal*. Calc. for $C_{17}H_{12}N_2O_{12}Os_3$: C, 20.28; H, 1.20; N, 2.78. Found: C, 20.42; H, 1.35; N, 2.93%). IR (ν (CO), CH_2Cl_2): 2093s, 2074w, 2054s, 1997vs, 1965s, 1919w, KBr: ν (OH) 3400m, methoxycarbonyl, 1500m cm^{-1}; ^1H NMR (CD_2Cl_2): δ 8.42 (1H), 8.35 (1H), 3.94 (3H), 2.76 (3H), 2.58 (3H), −1.13 (s, 1H); mass spectrum: (*m*/*z*) 1006 $[M]^+$.

2.4. Reaction of $[Os_3(CO)_{12}]$ with 2,3,5-trimethylpyrazine and water in the presence of Me_3NO/MeOH

$[Os_3(CO)_{12}]$ (0.200 g, 0.221 mmol), 2,3,5-trimethylpyrazine (0.135 g, 1.10 mmol), water (2 drops), Me_3NO (0.043 g, 0.57 mmol) in MeOH (5 mL) were reacted as above for 8 h. The solvent was removed under reduced pressure. The residue was dissolved in a minimum volume of acetone and chromatographed on silica gel TLC plates. Elution with hexane/CH_2Cl_2 (3:7, v/v) gave two bands. The first band was was too small for complete characterization. The second band gave $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C(CH_3){=}NC(CH_3){=}CH{-}\}]$ (**4**) (0.124 g, 55%) as yellow crystals after recrystallization from benzene at room temperature (*Anal*. Calc. for $C_{18}H_{14}N_2O_{12}Os_3$: C, 21.17; H, 1.38. Found: C, 21.32; H, 1.48%). IR (ν (CO), CH_2Cl_2): 2092s, 2074w, 2054vs, 1997vs, 1983w, 1918m cm^{-1}, KBr: ν (OH) 3420m, methoxycarbonyl, 1488m cm^{-1}; ^1H NMR (CD_2Cl_2): δ 8.23 (s, 1H), 3.94 (s, 3H), 2.88 (s, 3H), 2.62 (s, 3H), 2.51 (s, 3H), −1.19 (s, 1H); mass spectrum: (*m*/*z*) 1020 $[M]^+$.

2.5. Reaction of **1** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine

The reactions of **1** with PPh_3, $P(OMe)_3$, and ^{t}BuNC were carried out with 2 equiv. of the respective ligand. A typical reaction of **1** with PPh_3 was carried as follows: To a dichloromethane solution (20 ml) of **1** (0.051 g, 0.052 mmol) was added PPh_3 (0.027 g, 0.10 mmol) and the reaction mixture was stirred at room temperature for 30 min. Analytical TLC indicated complete consumption of **1**. The solvent was removed under reduced pressure and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (2:1, v/v) gave a single band which afforded $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)(PPh_3)]$ (**5**) (0.045 g, 74%) as yellow crystals after recrystallization from hexane/CH_2Cl_2 at −4 °C. IR (ν (CO), CH_2Cl_2): 2087s. 2050vs, 2004vs, 1992s, 1980m, 1932w cm^{-1}; ^1H NMR (CD_2Cl_2): δ 7.41 (m, 15H), 3.58 (s, 3H), 1.93 (d, 1H, $J = 4.8$ Hz); $^{31}P\{^1H\}$ MNR (CD_2Cl_2): δ 21.1 (s). A similar treatment of **1** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine afforded $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{P(OMe)_3\}]$ (**6**) (85%), IR (ν (CO), CH_2Cl_2): 2088m, 2049vs, 2007s, 1978s, 1960w cm^{-1}; ^1H NMR (CD_2Cl_2): δ 3.90 (s, 3H), 3.75 (d, 9H, $J = 11.8$ Hz), 0.56 (d, 1H, $J = 5.9$ Hz); $^{31}P\{^1H\}$ NMR (CD_2Cl_2) 104.5 (s)), $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)(^t\text{BuNC})]$ (**7**) (89%), IR (ν (CO), CH_2Cl_2): 2177m, 2087s, 2049vs, 2007s, 1978m, 1945w cm^{-1}; ^1H NMR (CD_2Cl_2): δ 3.95 (s, 3H), 1.58 (s, 9H). 0.87 (s, 1H)), and $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)(\eta^1\text{-}NC_5H_5)]$ (**8**) (73%). IR (ν (CO), CH_2Cl_2): 2089m, 2050vs, 2005s, 1994s, 1979m, 1963w cm^{-1}; ^1H NMR (CD_2Cl_2): δ 8.57 (m, 2H), 7.92 (m, 1H), 7.42 (m, 2H), 3.92 (s, 3H), −1.54 (s, 1H).

2.6. Reaction of **2** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine

A similar reaction to that above of **2** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine followed by a similar chromatographic separation gave **5**, **6**, **7** and **8** in 81%, 88%, 75% and 71% yields, respectively.

2.7. Reaction of **3** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine

A similar treatment of **3** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine followed by similar chromatographic separation gave **5**, **6**, **7** and **8** in 79%, 81%, 77% and 79% yields, respectively.

2.8. Reaction of **4** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine

A similar reaction of **4** with PPh_3, $P(OMe)_3$, ^{t}BuNC and pyridine followed by similar chromatographic separation gave **5**, **6**, **7** and **8** in 78%, 73%, 84% and 88% yields, respectively.

2.9. X-ray structure determination of **2**, **3**, **4**, and **8**

Single crystals of **2**–**4** suitable for X-ray diffraction were grown by slow evaporation of benzene solution at room temperature and those of **8** by slow diffusion of hexane into a dichloromethane solution at −4 °C. Crystallographic data were collected at 150 K, on a CAD4 diffractometer using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were determined from all observed reflections in a θ-range of 3–10° and refined using the entire data set. The structures were solved by direct methods (SHELXS-97) [14] and refined on F^2 by full matrix least-squares (SHELXL-97) [15] using all unique data. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included in calculated positions (riding model) with U_{iso} set at 1.2 times the U_{eq} of the parent atom. Final difference maps did not show any residual electron den-

Table 1

3. Results and discussion

The reactions of $[Os_3(CO)_{12}]$ with pyrazine, 2-methylpyrazine, 2,3-dimethylpyrazine, and 2,3,5-trimethylpyrazine and water in the presence of a methanolic solution of Me_3NO at 80 °C followed by usual workup and chromatographic separation gave the new compounds $[Os_3(CO)_9[(\mu\text{-OH})(\mu\text{-OMeCO})(\eta^1\text{-NCHCHN-CHCH-})]$ (**1**), $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})\{\eta^1\text{-N=C-(CH}_3)\text{CH=NCH=CH—}\}]$ (**2**), $[Os_3(CO)_9[(\mu\text{-OH})(\mu\text{-CH}_3\text{OCO})\{\eta^1\text{-N=C(CH}_3)\text{C(CH}_3)\text{=NCH=CH—}\}]$ (**3**), and $[Os_3(CO)_9[(\mu\text{-OH})(\mu\text{-CH}_3\text{OCO})\{\eta^1\text{-N=C(CH}_3)\text{C-(CH}_3)\text{=NC(CH}_3)\text{=CH—}\}]$ (**4**) in 45%, 38%, 35% and 55% yields, respectively. The synthetic details for all the compounds are shown in Scheme 1. The compounds have been characterized by spectroscopic data together with single crystal X-ray diffraction studies for **2**–**4**. Single crystals of **2** were found to exist as discrete molecules in the unit cell with no unusually short inter- or intramolecular contacts.

The solid-state structure of **2**, **3**, and **4** are shown in Figs. 1–3, respectively, crystallographic data are presented in Table 1 and selected bond distances and angles are listed in Table 2. The basic triangular metal skeleton core of **2**–**4** are the same. Each of them contains two Os–Os bonds and a non-bonded separation defined by two osmium atoms Os(1) ⋯ Os(3), nine terminal CO groups, a bridging hydroxy and a bridging methoxycarbonyl (MeOCO) ligand and one substituted pyrazine unit bonded to Os(1) atom though the N(1) atom. Atoms Os (1), Os (2) and Os (3) are ligated by two, four and three CO ligands, respectively. The open edge defined by the atoms Os(1) and Os(3) is mutually bridged by a hydroxy and a methoxycarbonyl ligand. A set of distinctly different metal–metal bonds, {Os(1)–Os(2) = 2.8286 (4) and Os(2)–Os(3) = 2.8744(4) Å for **2**; Os(1)–Os(2) = 2.8259(15) and Os(2)–Os(3) = 2.8805(14) Å for **3**; Os(1)–Os(2) = 2.8166(8) and Os(2)–Os(3) = 2.8631(9) Å for **4**} and non-bonded separation {Os(1) ⋯ Os(3) = 3.359 Å for **2**; Os(1) ⋯ Os(3) = 3.357 Å for **3**; and Os(1) ⋯ Os(3) = 3.375(1) Å for **4**} is comparable with the corresponding distances in $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})\{\eta^1\text{-SC(N-Me}_2)_2\}]$ {bonding distance = 2.836(1), 2.875 (1), and non-bonded separation = 3.379(1) Å} [13c]. The osmium–oxygen distances involving the asymmetrical

Scheme 1. Reagents and conditions: (i) pyrazine, $Me_3NO/MeOH + H_2O$, C_6H_6, 80 °C, 5 h; (ii) 2-methylpyrazine, $Me_3NO/MeOH + H_2O$, C_6H_6, 80 °C, 7 h; (iii) 2,3-dimethylpyrazine, $Me_3NO/MeOH + H_2O$, C_6H_6, 80 °C, 8 h; (iv) 2,3,5-trimethylpyrazine, $Me_3NO/MeOH + H_2O$, C_6H_6, 80 °C, 8 h; (v) $L' = PPh_3$, $P(OMe)_3$, ^tBuNC, C_5H_5N, CH_2Cl_2, 25 °C.

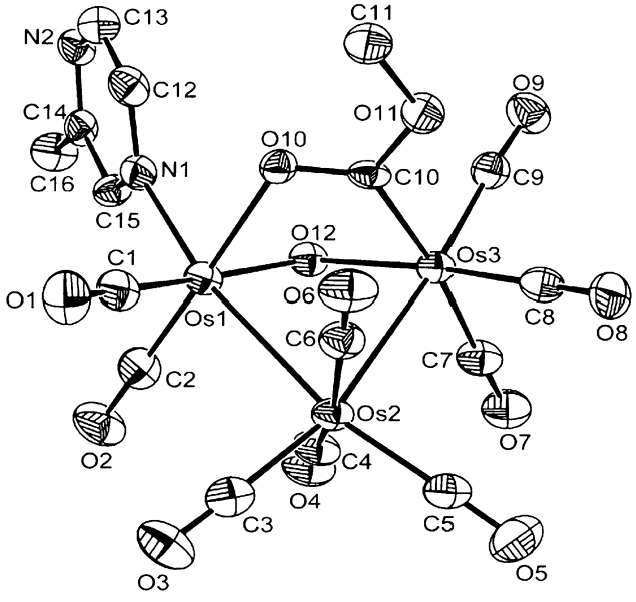

Fig. 1. Molecular structure of $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)\{\eta^1\text{-}N{=}C(CH_3)CH{=}NCH{=}CH{-}\}]$ (**2**) showing the atom-labeling scheme. Thermal ellipsoids are drawn at the 50% probability level.

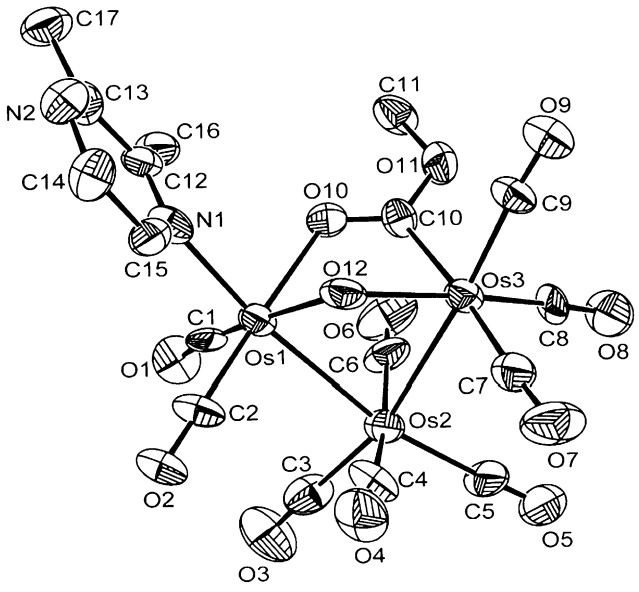

Fig. 2. Molecular structure of $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C{-}(CH_3){=}NCH{=}CH{-}\}]$ (**3**) showing the atom-labeling scheme. Thermal ellipsoids are drawn at the 35% probability level.

hydroxy bridge in **2** {Os(1)–O(12) = 2.113(5) and Os(3)–O(12) = 2.142(5) Å} are similar to those of the corresponding distances in **3** {2.17(2) and 2.128(18) Å} and comparable to those found in $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeOCO)\{\eta^1\text{-}SC(NMe_2)_2\}]$ {2.148(8) and 2.084(9) Å} [13c] and $[(\mu\text{-}H)Os_3(CO)_9(\mu\text{-}OH)(PMe_2Ph)]$ {2.135(5) and 2.118(5) Å} [16]. In contrast, the μ-hydroxy ligand symmetrically spans the Os(1)–Os(3) edge in **4** and the Os–O distances {2.134(10) and 2.130(10) Å} are very similar to those found in $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}OH)]$ {2.136(7) and 2.146(7) Å} [17]. The Os(1)–C(10) bond distance {2.146(5)Å} to methoxycarbonyl bridge in **2** is also similar

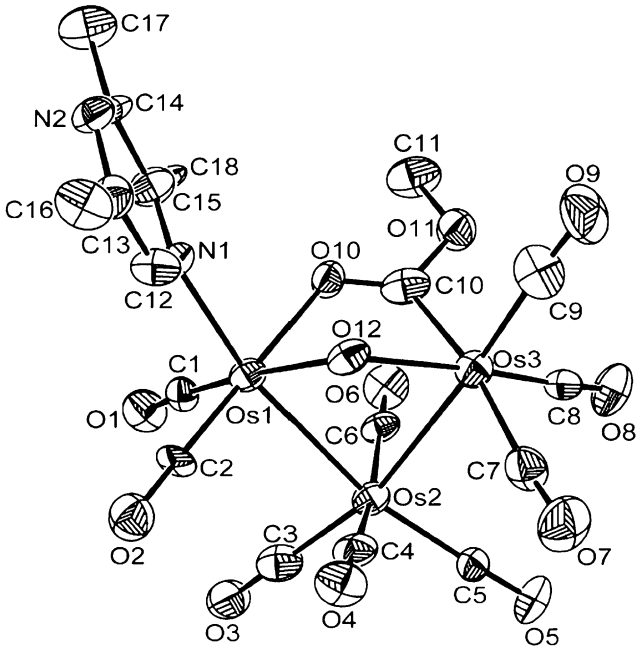

Fig. 3. Molecular structure of $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C(CH_3){=}NC(CH_3){=}CH{-}\}]$ (**4**) showing the atom-labeling scheme. Thermal ellipsoids are drawn at the 50% probability level.

to that in **4** {2.137(10) Å} but slightly shorter than that in **3** {2.195(18) Å}. The Os(3)–C(10) bond distance of 2.074(7) Å in **2** is almost equal in magnitude to that of 2.093(16) Å in **4** but substantially shorter than that of 2.13(3) Å in **3**. The 2-methylpyrazine ligand in **2** is coordinated through the *meta* imino nitrogen atom and occupies an equatorial coordination site on Os(1). Similarly, 2,3-dimethylpyrazine and 2,3,5-trimethylpyrazine are also equatorially bound to the Os(1) atom in **3** and **4**, respectively. The η^1-coordinated Os(1)–N(1) bond distance of 2.171(6) Å in **2** is identical to that of 2.217(11) Å in **4**, but somewhat longer than the corresponding distance in **3** {2.23(2) Å} and comparable to that of 2.19(3) in $[(\mu\text{-}H)_4Os_4(CO)_{11}(\eta^1\text{-pyp})]$ (pyp = pyrido[2,3-b]pyrazine) in which the pyp ligand is coordinated through the nitrogen atom of the pyrazole ring [18]. The three acute angles defined by Os(1)–Os(2)–Os(3) in **2**, **3** and **4** are almost equal in magnitude {Os(1)–Os(2)–Os(3) = 72.179(10) for **2**; 72.07(4) for **3** and 72.91(2) for **4**}. Thus, the mode of attachment and disposition of all the ligands in **2** are akin to that of **3** and **4**. The MeOCO ligand is a normal 3 electron donating acyl type bridge that is most probably formed by deprotonation of methanolic OH bond (by NMe_3) followed by attack of CH_3O^- at a coordinated CO ligand. As usual, in each compound, both the bridging MeOCO and OH ligands act as three-electron donor, and the pyrazine derivatives donate two electrons to the cluster which results in a total of 50 valence electrons and the observation of two formal Os–Os bonds in the trinuclear framework is consistent with the electron count.

The spectroscopic data of **2**, **3**, and **5** are consistent with the solid-state structure and are very similar to the spectroscopic data for **1**. The infrared spectra of **1**–**4** in the carbonyl stretching region are very similar to those reported for $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)(PPh_3)]$ [13b], indicating that they have very similar structures.

O(10)–C(10)–Os(3)	123.4(5)	123.2(19)	125.8(12)	123.7(7)

In addition to the adsorption bands due to terminally coordinated carbonyl ligands, the solid-state infrared spectra of **1**–**4** exhibit absorptions due to the methoxy carbonyl bridge (1500–1488 cm^{-1}) and bridging hydroxyl group (3420–3400 cm^{-1}). The mass spectra of compounds **1**–**4** exhibit a parent peak at *m*/*z* 979, 993, 1007 and 1027, respectively, and fragmentation peaks due to the successive loss of nine carbonyl ligands. In addition to the aromatic proton resonances for the pyrazine ring, the ^1H NMR spectra of **1**–**4** exhibit characteristic resonances for the methyl protons of the methoxy carbonyl ligand (δ 3.97 for **1**; 3.95 for **2**; 3.94 for **3**; 3.94 for **4**) and the hydroxyl proton (δ −1.05 for **1**; −1.31 for **2**; −1.13 for **3**; −1.19 for **4**). It is notable that the resonances of the bridging hydroxyl proton of these complexes are strongly shielded. The strongly shielded resonances for the protons of bridging hydroxy ligands have been observed previously [13,19,20].

We have previously reported that the η^1-tetramethylthiourea ligand in $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)\{\eta^1\text{-}SC(NMe_3)_2\}]$ is labile and could be easily displaced by various two electron donor ligands [13b]. Keeping this in mind, we have investigated the reactions of **1**–**4** with a series of two electron donor ligands. As expected each of the compounds **1**–**4** reacts with L′ at room temperature to give the previously reported compounds $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)(L')]$ {**5**, L′ = PPh_3; **6**, L′ = $P(OMe)_3$; **7**, L′ = ^{t}BuNC; **8**, L′ = C_5H_5N} in high yields (70–90%) as shown in Scheme 1. We have characterized compounds **5**–**8** by a comparison of their spectroscopic data (see Section 2) with those reported [13b] along with a single crystal X-ray diffraction studies for **8**. As described for **2**–**4**, crystals of **8** were found to exist as discrete molecules in the unit cell with no unusually short inter- or intramolecular contacts. The solid-state structure of **8** is depicted in Fig. 4, crystallographic data are presented in Table 1 and selected bond distances and angles are listed in Table 2. The molecule consists of an open cluster of three osmium atoms with two different metal–metal bonds {Os(1)–Os(2) = 2.8394(5) and Os(2)–Os(3) = 2.8861(6) Å} which are comparable with the corresponding distances of 2.875(1) and 2.836(1) Å in $[(\mu\text{-}H)Os_3(CO)_8(\mu_3\text{-}S)(\mu\text{-}OMeCO)\{\eta^1\text{-}SC(NMe_3)_2\}]$ [13c], 2.8286(4) and 2.8744(4) Å in **2**, 2.8259(15) and 2.8805(14) Å in **3** and 2.8166(8) and 2.8631(9) Å in **4**. The open Os(1)–Os(3) edge is simultaneously bridged by the methoxycarbonyl and the hydroxy ligands and the non-bonded distance of 3.373 Å is virtually identical to that of 3.379(1) Å in $[(\mu\text{-}H)Os_3(CO)_8(\mu_3\text{-}S)(\mu\text{-}OMeCO)\{\eta^1\text{-}SC(NMe_3)_2\}]$ [13c], and 3.375 in **4** and slightly longer than that of 3.359 in **2**, and 3.357 in **3**. The μ-hydroxy ligand symmetrically bridges the Os(1)–Os(3) edge and the Os–O distances {2.108(6) and 2.118(6) Å} are comparable to those found in **2**. The disposition of pyridine, two bridging ligands (MeOCO– and –OH) and the nine terminal CO groups are quite similar to that of **2**, **3** and **4**. The Os(3)–O(10) bond distance in the methoxycarbonyl bridge {2.110(10) Å} is slightly shorter than that of 2.13(3) Å in **3** but slightly larger than 2.074(7) Å in **2** and 2.093(16) Å in **4**. The pyridine ligand is coordinated to Os(1) through nitrogen atom N(1) and occupies an equatorial coordination site of Os(1). The Os(1)–N(1) bond distance of 2.185(8) Å is slightly longer than that of 2.14(3) Å in the η^1-coordinated pyridinecarboxyaldehyde ligand in $[(\mu\text{-}H)_4Os_4(CO)_{11}(\eta^1\text{-pya})]$ [18] and comparable to that of 2.171(6) Å in **2** but somewhat shorter than those of 2.23(2) Å in **3** and 2.217(11) Å in **4**. The overall structure of **8** is very similar to those of **2**–**4**, with exception of the pyridine ligand coordinated to Os(1) instead of the pyrazine ligands in **2**–**4**.

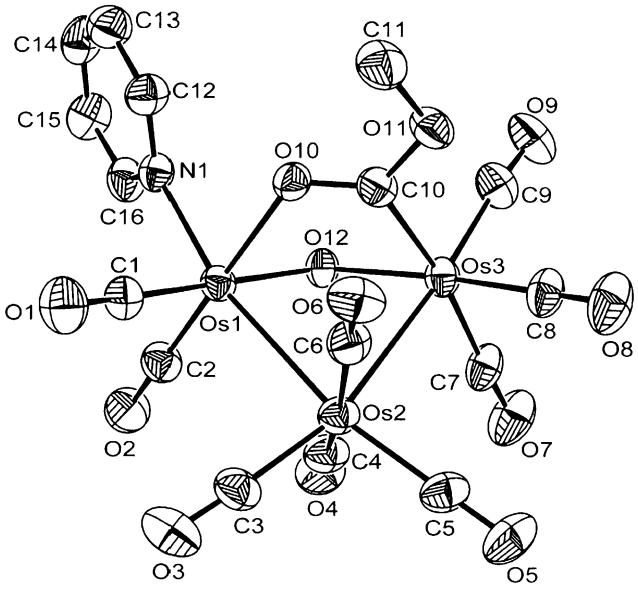

Fig. 4. Molecular structure of $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)(\eta^1\text{-}NC_5H_5)]$ (**8**) showing the atom labeling scheme. Thermal ellipsoids are drawn at the 35% probability level.

4. Conclusions

The present work has provided a facile one-step synthetic route to 50 electron triosmium compounds $[(\mu\text{-}OH)Os_3(CO)_9(\mu\text{-}OMeCO)\{\eta^1\text{-}NCHCHN\text{-}CHCH\text{-}\}]$ (**1**), $[(\mu\text{-}OH)Os_3(CO)_9(\mu\text{-}OMeCO)\{\eta^1\text{-}N{=}C(CH_3)CH{=}NCH{=}CH{-}\}]$ (**2**), $[Os_3(CO)_9[(\mu\text{-}OH)(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C(CH_3){=}NCH{=}CH{-}\}]$ (**3**), and $[(\mu\text{-}OH)Os_3(CO)_9(\mu\text{-}CH_3OCO)\{\eta^1\text{-}N{=}C(CH_3)C(CH_3){=}NC(CH_3){=}CH{-}\}]$ (**4**), containing terminal pyrazines, bridging hydroxy and methoxycarbonyl ligands. It is well documented that Me_3NO promotes decarbonylation of metal carbonyls by conversion of a CO ligand into a CO_2 molecule [21]. Thus treatment of $[Os_3(CO)_{12}]$

with pyrazines and water in the presence of a methanolic solution of Me_3NO facilitates the removal of CO as well as the addition of water and the pyrazine ligand to the resulting transient species. The reactions of **1**–**4** with various two electron donor ligands L′ afford the substituted products $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)L']$ (**5**, L′ = PPh_3; **6**, L′ = $P(OMe)_3$; **7**, L′ = ^{t}BuNC; **8**, L′ = C_5H_5N) in high yields, demonstrating that the pyrazine ligands in these complexes are relatively labile. The formation of compound **8** from the reactions of **1**–**4** with pyridine is consistent with the fact that pyridine is a stronger base than diazines (pK_a 0.65 for pyrazine and 5.23 for pyridine). An interesting outcome of these reactions is that compound **8** is inaccessible from the thermal reaction of $[Os_3(CO)_{12}]$ with pyridine, due to the lability of pyridine to orthometallation compared to diazines. The dispositions of the bridging OH and MeOCO ligands and the η^1-coordinated nitrogen heterocyclic ligands in all the compounds are similar.

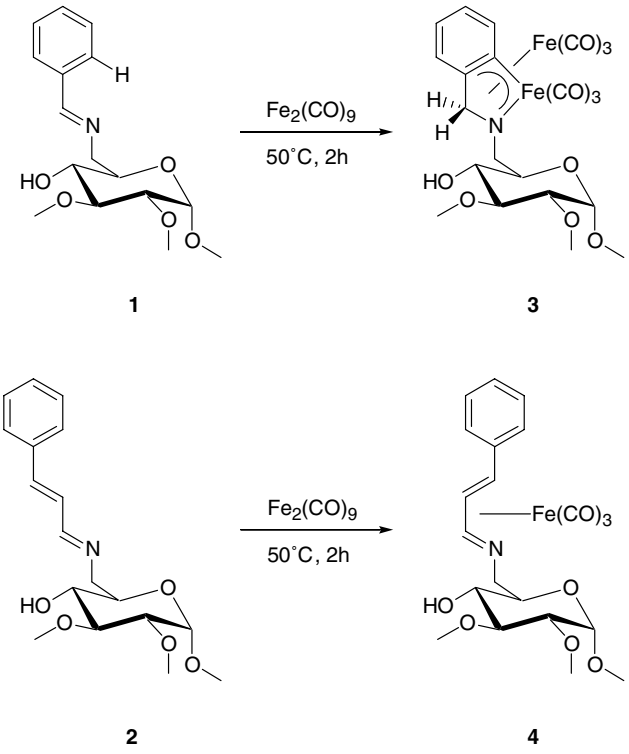
$Fe_2(CO)_9$ also a mononuclear $Fe(CO)_3$ complex may be isolated in very small yields, in which one of the aromatic carbon carbon bonds shows a side-on coordination to the iron atom [4f]. In addition, treatment of the imine from cinnamaldehyde and *p*-anisidine ends up in the formation of a dinuclear cluster compound with a C–H activated ligand [5].



Both kinds of imines may be catalytically activated using $Ru_3(CO)_{12}$ as the precatalyst. Aromatic imines normally react via the formal insertion of an olefin to give alkylated species [6] or via the insertion of CO and ethylene building up a propionyl group [6d,7]. The reaction of β-naphthylimines produces chiral dihydroisoindolone derivatives [7d]. The latter reaction pathway is the typical reaction of acyclic unsaturated imines with CO and ethylene giving chiral dihydropyrrolone derivatives in a selective three component reaction [8]. Recently, we were able to show that the use of chiral 1-azadienes may result in a diastereoselective formation of the new stereogenic center in the dihydropyrrolones in the case of steroidal imines as the substrates [8c].

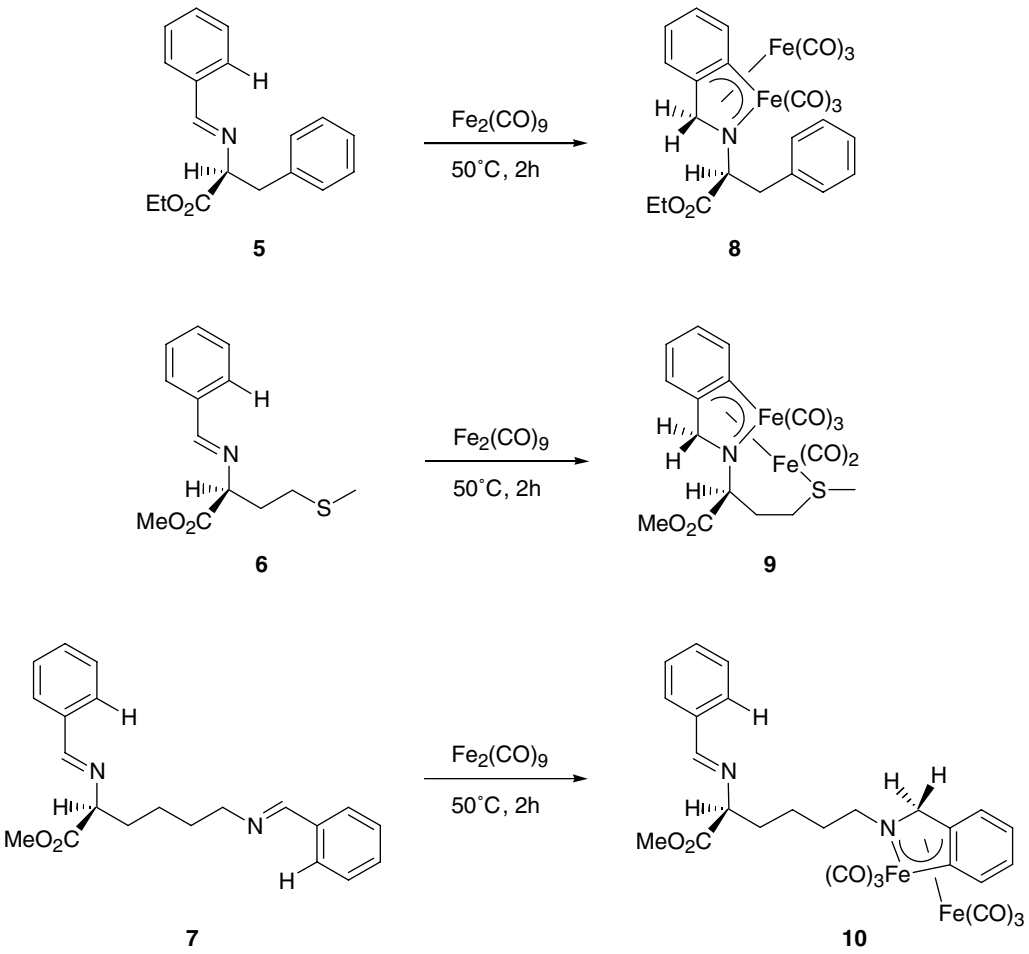
In this paper, we wish to report the use of carbohydrates and amino acid derivatives as chiral substituents at the nitrogen atoms of α,β-unsaturated imines. The reaction of the corresponding imines with $Fe_2(CO)_9$ will be described.

2. Results and discussion

Scheme 1 shows the formation of mono- and dinuclear iron carbonyl complexes from the reaction of $Fe_2(CO)_9$ with imines derived from 6-amino-6-desoxy-1,2,3-*O*-trimethyl-α-D-glucopyranose. Related imines have recently been used to synthesize chiral copper complexes showing catechol oxidase reactivity [9]. The reaction of 6-amino-6-desoxy-1,2,3-*O*-trimethyl-α-D-glucopyranose with benzaldehyde producing **1** only works if trimethoxymethane is used as the solvent because this acetal readily reacts with water from the condensation reaction, thus shifting the equilibrium towards imine formation. If the reaction time is prolonged the yield of **1** decreases dramatically. In contrast the synthesis of **2** proceeds almost quantitatively at room temperature in ethanol as the solvent.

The reaction of **1** and **2** with $Fe_2(CO)_9$ follows the expected reaction pathways. The benzaldimine **1** reacts via a sequence of C–H activation in *ortho*-position with respect to the exocyclic imine moiety followed by an intramolecular hydrogen transfer reaction towards the former imine carbon atom producing a dinuclear diiron hexacarbonyl compound **3**. Most indicative for this reaction sequence is the observation of a singlet in the proton NMR spectrum at $\delta = 4.13$ ppm representing the methylene group which is produced during the reaction in the place of the former imine carbon atom. The corresponding carbon resonance is found at $\delta = 72.3$ ppm. Both

Scheme 1.



NMR shifts are in the typical range for this kind of iron carbonyl compounds [4]. Although the protons of the methylene group built up during the reaction of **1** with $Fe_2(CO)_9$ as well as the protons of the methylene group of C_6 of the carbohydrate moiety are diastereotopic due to the chiral coordination sphere of the dinuclear $Fe_2(CO)_6$ moiety, only one set of resonances is observed in the NMR spectra of **3** due to the high fluxionality of the iron hexacarbonyl moiety.

The reaction of **2** with $Fe_2(CO)_9$ yields the mononuclear iron carbonyl complex **4**. So in this case, no C–H activation reaction is observed. The NMR spectra are typical for this class of compounds, since the resonances for the hydrogen and carbon atoms of the α,β-unsaturated chain are shifted upfield due to the coordination of the $Fe(CO)_3$ group. In addition, the formation of two diastereomers in a ratio of ≈70:30 is obvious from the splitting of most of the carbon resonances into two seperate signals with very similar chemical shift. Since the 1-azadiene ligand is prochiral, the addition of the iron carbonyl moiety from above or below the plane of the ligand produces an additional element of chirality. Similar observations have been made for quite a number of chiral [(1-azadiene)$Fe(CO)_3$] complexes based on chiral amines, steroidal amines or campher, respectively [5,10]. Up to now only the azadiene complexes derived from imines based on steroidal amines have shown no tendency of epimerization even at elevated temperatures [10j]. In addition, these steroidal imines turned out to react with perfect diastereoselectivities in catalytic

reactions with carbon monoxide and ethylene producing dihydropyrrolones with a new stereogenic center [8c]. So **2** will be a promising candidate to explore the influence of the carbohydrate auxiliary on the diastereoselectivity of catalytic reactions.

Scheme 2 shows the reaction of $Fe_2(CO)_9$ with three different benzylidene amino acid derivatives. All compounds **5**–**7** are easily prepared from the corresponding amino acid ester hydrochlorides and benzaldehyde under basic reaction conditions [11]. Phe–OEt · HCl was prepared from L-Phe and ethanol in the presence of stoichiometric amounts of HCl. It became evident during our investigations of the iron carbonyl complexes of **5** that this esterification led to a complete reacemization of the stereogenic center of the amino acid. So in the synthesis of **6** and **7** enantiomerically pure commercially available amino acid ester hydrochlorides were used. The reaction of L-Lys with benzaldehyde always leads to the diimine **7** no matter which stoichiometry of the reactants is chosen. The L-Met and L-Lys derivatives **6** and **7** were synthesized because of the potential additional donor sites in the side chain of the amino acid. We wanted to explore whether these sulfur and nitrogen donor atoms take part in the coordination of the transition metals in the iron carbonyl complexes used as model compounds for intermediates in the catalytic reactions starting from the same substrates. During catalytic reactions, the additional coordination sites might be helpful to differentiate between diastereomeric intermediates in the catalytic cycle, thus enhancing the overall diastereoselectivity of the reaction.

The dinuclear iron carbonyl compounds **8**–**10** are produced via the same reaction sequence of C–H activation and hydrogen transfer already described for the synthesis of **3**. The NMR spectra of **8** show two sets of signals for the protons of the benzyl group of L-Phe as well as for the protons of the methylene moiety at the former imine carbon atom due to the chiral coordination sphere of the iron atoms. In addition, two resonances representing the carbon monoxide ligands show that in contrast to analogous diiron hexacarbonyl complexes [4] the $Fe(CO)_3$ moieties are not interconverting at room temperature on the NMR time scale. Recrystallization of **8** from a mixture of light petroleum and CH_2Cl_2 at −20 °C produced single crystals suitable for X-ray diffraction. Fig. 1 shows the molecular structure

Scheme 2.

Selected bond lengths [pm] and angles [°]: Fe1–Fe2 245.83(3), Fe1–N1 196.7(1), Fe1–C2 232.9(2), Fe1–C3 217.7(2), Fe2–N1 198.1(2), Fe2–C3 198.7(2), C1–N1 148.2(2), C1–C2 150.7(3), C2–C3 141.5(3), N1–C8 148.4(2), Fe2–Fe1–N1 51.75(4), Fe2–Fe1–C3 50.32(5), Fe2–Fe1–C2 73.44(5), N1–Fe1–C3 74.65(6), N1–Fe1–C2 64.34(6), C2–Fe1–C3 36.40(7), C1–N1–Fe1 99.0(1), N1–Fe2–C3 113.6(1), Fe2–C3–C2 77.66(1), C3–C2–C1 114.7(2), C2–C1–N1 101.4(1), C1–N1–C8 115.1(1), Fe2–N1–C8 120.7(1).

of **8**, crystal data are summarized in Table 1. The crystal structure analysis of **8** clearly indicates the racemization of the amino acid since the compound crystallizes in the non-chiral space group $P\bar{1}$. In Fig. 1, the diastereomer with L-configuration at C8 is shown, but due to the crystallographic center of inversion the corresponding diastereomer with *R*-configuration is also present in the crystal structure. Despite this fact, the molecular structure corresponds very well to those reported for similar iron carbonyl complexes [4]. The C–H activation reaction took place in *ortho*-position with respect to the imine substituent and a new iron carbon bond (Fe2–C3) is established instead. The hydrogen atom is transferred towards the former imine carbon atom (C1) producing a methylene group instead. So a formally six electron donating enylamido ligand is formed coordinating a $Fe_2(CO)_6$ moiety which adopts a slightly distorted saw-horse configuration.

The reaction of $Fe_2(CO)_9$ with **6** also proceeds via the reaction sequence of C–H activation and hydrogen transfer. The most important difference in the molecular structure of **9** (Fig. 2, Table 1) is the coordination of the sulfur atom of the L-Met side-chain towards the apical iron atom of the cluster core. This additional donor site of **6** leads to the formation of another six-membered chelate ring system. The coordination of the enylamido ligand towards the iron carbonyl moieties in **9** is essentially identical to the one described for **8** within experimental errors. **9** crystallizes in the chiral space group $P2_12_12_1$ and thus only the diastereomer exhibiting a L-configuration at C8 is present in the crystal structure

(Fig. 2). Nevertheless, the flexibility of the dinuclear iron carbonyl complex is diminished due to additional sulfur coordination. This again leads to the observation of two signals for the carbonyl ligands in the carbon NMR spectrum. In addition, the diastereotopic protons at *C*1 give two dubletts in the proton NMR and the proton at *C*8 gives rise to a dublett of dubletts upon coupling with the diastereotopic protons at *C*9.

The reaction of the diimine **7** with $Fe_2(CO)_9$ also ends up in the formation of a dinuclear iron carbonyl complex **10** as the only product that is obtainable from column chromatography no matter which stoichiometry was chosen. In **10**, only the imine function of the alkylamino side chain of **7** reacted, whereas the imine group attached to the chiral carbon atom of the amino acid remains unreacted. The assignment of the structure is due to the NMR data of **10**. In **7**, the carbon atoms of the imine moieties show resonances at 161.0 and 163.4 ppm, the latter representing the imine function next to the carboxyl group. In the ^{13}C NMR spectrum of **10** only one imine resonance at 163.6 ppm is left indicating that the imine function in α-position with respect to the carboxymethyl moiety did not react. Another hint that the C–H activation reaction took place at the alkylimino group is the downfield shift of the carbon resonance representing the methylene group next to the imine function of the butylimino side-chain. This reactivity may be rationalized by the fact that the nitrogen atom of the imine group of the side-chain is more basic compared to the imine moiety next to the carboxymethyl functional of the former amino acid. This enhanced basicity results in a more efficient coordination of iron carbonyl fragments thus inducing the C–H activation at the observed position. **10** is a highly flexible structure in solution at room temperature as revealed by only one signal representing the terminal carbon monoxide ligands. Corresponding to this finding, there is no diastereotopicity observed for the different methylene groups present in **10**.

In conclusion, we have shown that carbohydrates and amino acid derivatives may be used as chiral auxiliaries in unsaturated imine ligands. The reaction with $Fe_2(CO)_9$ yield the same types of iron carbonyl compounds that we introduced as model systems for catalytic C–H activation reactions before. Catalytic reactions using the same unsaturated imines as substrates exploring the influence of these chiral auxiliaries on the diastereoselectivity of catalytic carbon carbon bond formation reactions are going to be reported in the near future.

3. Experimental

3.1. General

All procedures were carried out under an argon atmosphere in anhydrous, freshly distilled solvents.

Infrared spectra were recorded on a Perkin–Elmer FT-IR System 2000 using 0.2-mm KBr cuvettes. NMR spectra were recorded on a Bruker AC 200 spectrometer (^{1}H: 200 MHz, ^{13}C: 50.32 MHz, $CDCl_3$ as internal standard). Mass spectra were recorded on a Finnigan MAT SSQ 710 instrument. High resolution mass spectra (HRMS) were carried out using a Finnigan MAT 95 XL spectrometer using FAB techniques.

3.2. X-ray crystallographic studies

The structure determinations of **8** and **9** were carried out on an Enraf Nonius Kappa CCD diffractometer, crystal detector distance 29 mm, using graphite monochromated Mo Kα radiation [12]. The crystal was mounted in a stream of cold nitrogen. Data were corrected for Lorentz and polarization effects but not for absorption. The structure was solved by direct methods and refined by full-matrix least squares techniques against F^2 using the programs SHELXS86 and SHELXL97 [13], the molecular illustrations were drawn using the program XP [14]. The crystal and intensity data are given in Table 1.

3.3. Synthesis of *1*

0.750 g (3.390 mmol) 6-amino-6-desoxy-1,2,3-*O*-trimethyl-α-D-glucopyranose and 1.079 g (10.170 mmol) benzaldehyde are refluxed in 5 mL trimethoxymethane for 5 h. Evaporation of all volatile material yields **1** in 98% yield as a pale brown waxlike compound.

MS (CI, H_2O) [*m*/*z* (fragment, rel. intensity in %)]: 310 (MH^+, 54), 292 ($C_{16}H_{22}NO_4^+$, 30), 278 ($C_{15}H_{20}NO_4^+$, 12), 260 ($C_{15}H_{18}NO_3^+$, 2), 229 ($C_{14}H_{15}NO_2^+$, 4), 190 ($C_8H_{16}NO_4^+$, 9), 150 ($C_9H_{12}NO^+$, 13), 123 ($C_8H_{11}O^+$, 95), 107 ($C_7H_7O^+$/$C_4H_{11}O_3^+$, 100), 84 ($C_5H_{10}N^+$, 30), 75 ($C_3H_7O_2^+$, 45); HRMS (ESI in $CHCl_3$/methanol): 310.16464, $C_{16}H_{24}NO_5$ (MH^+), $\Delta = 0.81$ mmu; IR (nujol, 298 K) [cm^{-1}]: 1727–1614 (w, CH=N); ^{1}H NMR ($CDCl_3$, 298 K) [ppm]: 3.04–3.80 (m, 4H, C_2H, C_3H, C_4H, C_5H), 3.37 (s, 3H, OCH_3), 3.48 (s, 3H, OCH_3), 3.61 (s, 3H, OCH_3), 3.80–3.98 (m, 1H, C_6H_2), 4.08 (d, $^3J_{HH} = 12.3$ Hz, 1H, C_6H_2), 4.78 (d, $^3J_{HH} = 3.5$ Hz, 1H, C_1H), 7.09–7.48 (m, 3H, CH_{ar}), 7.62–7.77 (m, 2H, CH_{ar}), 8.29 (s, 1H, CH=N); ^{13}C NMR ($CDCl_3$, 298 K) [ppm]: 54.8 (OCH_3), 58.6 (OCH_3), 60.7 (OCH_3), 61.0 (C_6), 69.3 (C_5), 74.4 (C_3), 82.3 (C_4), 83.0 (C_2), 96.8 (C_1), 128.0 (CH_{ar}), 128.3 (CH_{ar}), 130.4 (CH_{ar}), 136.2 (C_{ar}), 162.8 (CH=N).

3.4. Synthesis of *2*

A 0.750 g (3.390 mmol) sample of 6-amino-6-desoxy-1,2,3-*O*-trimethyl-α-D-glucopyranose is dissolved in 15 mL anhydrous ethanol and 0.448 g (3.390 mmol) cinnamaldehyde are added. After stirring the reaction mixture at room temperature for 20 h, all volatile material is evaporated at slightly elevated temperature. **2** is quantitatively produced as a colourless to pale brown waxlike compound.

MS (CI, H_2O) [*m*/*z* (fragment, rel. intensity in %)]: 336 (MH^+, 100), 304 ($C_{17}H_{22}NO_4^+$, 6), 272 ($C_{16}H_{18}NO_3^+$, 2), 131 ($C_9H_9N^+$, 14), 104 ($C_8H_8^+$, 10); HRMS (ESI in $CHCl_3$/methanol): 336.18132, $C_{18}H_{26}NO_5$ (MH^+), $\Delta = -0{,}22$ mmu; IR (nujol, 298 K) [cm^{-1}]: 1634 (w, CH=N); ^{1}H NMR ($CDCl_3$, 298 K) [ppm]: 3.06–3.96 (m, 6H, C_2H, C_3H, C_4H, C_5H, C_6H_2), 3.38 (s, 3H, OCH_3), 3.46 (s, 3H, OCH_3), 3.63 (s, 3H, OCH_3), 4.79 (d, $^3J_{HH} = 3.4$ Hz, 1H, C_1H), 6.91 (s, 1H, CH), 6.93 (s, 1H, CH), 7.15–7.59 (m, 5H, CH_{ar}), 7.99 (dd, $^3J_{HH} = 4.0$ Hz, $^4J_{HH} = 4{,}0$ Hz, 1H, CH=N); ^{13}C NMR ($CDCl_3$, 298 K) [ppm]: 54.8 (OCH_3), 58.3 (OCH_3), 60.9 (OCH_3), 61.5 (C_6), 70.1 (C_5), 71.8 (C_3), 81.6 (C_4), 83.0 (C_2), 97.3 (C_1), 127.1 (CH_{ar}), 127.6 (CH_{ar}), 128.6 (CH_{ar}), 129.0 (CH), 135.4 (C_{ar}), 142.2 (CH), 164.8 (CH=N).

3.5. Synthesis of *3*

A 0.425 g (1.374 mmol) portion of **1** is stirred together with 0.500 g (1.374 mmol) $Fe_2(CO)_9$ in 35 mL *n*-heptane in a Schlenk tube at 50–60 °C for 2 h. The colour of the suspension turns to dark brown as $Fe_2(CO)_9$ slowly dissolves. All volatile material is evaporated in vacuo. Then, the oily residue is dissolved in 12 ml dichloromethane and chromatographed on silica. Using a mixture of light petroleum (b.p. 40–60 °C) and dichloromethane 20:5 $Fe_3(CO)_{12}$ is eluted as a green band. With a mixture of light petroleum and THF as the eluent **3** is obtained as a deep red band. Yield: 0.322 g (39.8%).

MS (FAB in nba) [*m*/*z* (fragment)]: 590 (MH^+), 561 ($M^+ - CO$), 533 ($M^+ - 2CO$), 505 ($M^+ - 3CO$), 477 ($M^+ - 4CO$), 449 ($M^+ - 5CO$), 421 ($M^+ - 6CO$), 366 ($MH^+ - 6CO - Fe$), 310 ($C_{16}H_{24}NO_5^+$); HRMS (FAB in nba): 590.11628, $C_{22}H_{24}NO_{11}Fe_2$ (MH^+), $\Delta = 0.22$ mmu; IR (nujol, 298 K) [cm^{-1}]: 2063 (s, C=O), 2024 (s, C=O), 1987 (s, br, C=O), 1979 (s, br, C=O), 1959 (sh, s, C=O); ^{1}H NMR ($CDCl_3$, 298 K) [ppm]: 2.43 (d, $^3J_{HH} = 2.6$ Hz, 1H, C_2H), 2.84–3.87 (m, 5H, C_3H, C_4H, C_5H, C_6H_2), 3.36 (s, 3H, OCH_3), 3.46 (s, 3H, OCH_3), 3.60 (s, 3H, OCH_3), 4.13 (s, 2H, CH_2–N), 4.76 (d, $^3J_{HH} = 3{,}4$ Hz, 1H, C_1H), 7,01 (dd, $^3J_{HH} = 7.0$ Hz, $^3J_{HH} = 7.0$ Hz, 1H, CH_{ar}), 7.26 (dd, $^3J_{HH} = 7.0$ Hz, $^3J_{HH} = 7.0$ Hz, 1H, CH_{ar}), 7.51 (d, $^3J_{HH} = 8.0$ Hz, 1H, CH_{ar}), 8.01 (d, $^3J_{HH} = 8.2$ Hz, 1H, CH_{ar}); ^{13}C NMR ($CDCl_3$, 298 K) [ppm]: 56.8 (OCH_3), 58.4 (OCH_3),

61.2 (O*C*H$_3$), 70.4 (*C*$_5$), 72.3 (*C*$_6$, *C*H$_2$–N), 73.7 (*C*$_3$), 81.8 (*C*$_4$), 82.1 (*C*$_2$), 97.8 (*C*$_1$), 121.2 (*C*$_{ar}$), 125.6 (*CH*$_{ar}$), 128.6 (*CH*$_{ar}$), 130.0 (*CH*$_{ar}$), 147.4 (*CH*$_{ar}$), 150.3 (*C*–Fe), 210.8 (*C*O), 210.8 (*C*O).

3.6. Synthesis of **4**

A 0.461 g (1.374 mmol) portion of **2** is stirred together with 0.500 g (1.374 mmol) $Fe_2(CO)_9$ in 35 mL *n*-heptane in a Schlenk tube at 50–60 °C for 2 h. The colour of the suspension turns to an orange to light brown colour as $Fe_2(CO)_9$ slowly dissolves. All volatile material is evaporated in vacuo. Then, the oily residue is dissolved in 12 ml dichloromethane and chromatographed on silica. Using a mixture of light petroleum (b.p. 40–60 °C) and dichloromethane 20:5 $Fe_3(CO)_{12}$ is eluted as a green band. With a mixture of light petroleum and THF as the eluent **4** is obtained as a orange band. Yield: 0.229 g (35.1%).

MS (FAB in nba) [*m*/*z* (fragment)]: 476 (MH^+), 419 ($M^+ - 2CO$), 391 ($M^+ - 3CO$), 336 ($C_{18}H_{26}NO_5^+$); HRMS (FAB in nba): 476.10040, $C_{21}H_{26}NO_8Fe$ (MH^+), $\Delta = 0.38$ mmu; IR (Nujol, 298 K) [cm^{-1}]: 2053 (s, C=O), 1991 (s, C=O), 1974 (s, br, C=O); ^{1}H NMR ($CDCl_3$, 298 K, mixture of two diastereomers) [ppm]: 2.39–3.89 (m, 14H, C*H*, C$_2$*H*, C$_3$*H*, C$_4$*H*, C$_5$*H*, C$_6$*H*$_2$), 3.33 (s, 3H, OC*H*$_3$), 3.39 (s, 3H, OC*H*$_3$), 3.46 (s, 6H, OC*H*$_3$), 3.61 (s, 3H, OC*H*$_3$), 3.63 (s, 3H, OC*H*$_3$), 4.78 (d, $^3J_{HH} = 3.5$ Hz, 1H, C$_1$*H*), 4.81 (d, $^3J_{HH} = 3.4$ Hz, 1H, C$_1$*H*), 5.35–5.58 (m, 2H, C*H*), 6.50 (s, 2H, C*H*=N), 7.01–7.62 (m, 10H, C*H*$_{ar}$); ^{13}C NMR ($CDCl_3$, 298 K, mixture of two diastereomers) [ppm]: 54.8 (OCH_3), 54.9 (OCH_3), 58.3 (OCH_3), 58.4 (OCH_3), 60.5 (*C*$_6$), 60.8 (CH), 61.0 (OCH_3), 61.1 (OCH_3), 61.2 (CH), 70.3 (*C*$_5$), 70.7 (*C*$_5$), 72.0 (*C*$_3$), 72.9 (*C*$_3$), 73.0 (CH), 73.1 (CH), 81.4 (*C*$_4$), 81.7 (*C*$_4$), 82.6 (*C*$_2$), 82.8 (*C*$_2$), 97.0 (*C*$_1$), 97.3 (*C*$_1$), 111.1 (CH=N), 111.6 (CH=N), 126.3 (CH_{ar}), 126.5 (CH_{ar}), 126.6 (CH_{ar}), 128.5 (CH_{ar}), 138.6 (C_{ar}), 138.9 (C_{ar}), 209.1 (br, CO), 210.2 (CO), 215.7 (CO).

3.7. Synthesis of **5**–**7**

A 2-g portion of the corresponding amino acid ester hydrochloride (8.7 mmol L-Phe–OEt · HCl, 9.1 mmol L-Met–OMe · HCl, 8.5 mmol L-Lys-OMe · HCl) is dissolved in 30 mL water and stirred together with an equimolar amount of benzaldehyde and Na_2CO_3 per amino group. This reaction mixture is kept at 40 °C for 1 h and then stirred at room temperature for another 16 h. The solution is then extracted with chloroform (3 × 12 mL) and the collected chloroform layers are dried over $MgSO_4$. Evaporation of chloroform leads to the analytically pure compounds **5**–**7** (Yield: **5**, 1.91 g, 77.9%, white solid; **6**, 1.04 g, 41.4%, pale yellow oil; **7**, 1.87 g, 65.1%, orange oil).

3.8. Synthesis of **8**–**10**

A 500-mg portion of $Fe_2(CO)_9$ (1.374 mmol) is stirred together with an equimolar amount of the corresponding imine of the amino acid esters (387 mg **5**, 345 mg **6**, 463 mg **7**) at 50 °C for 2 h. The colour of the reaction mixture turns to deep red (**8**, **10**) or to dark green (**9**), respectively, as the iron carbonyl slowly dissolves. After the reaction is finished, all volatile material is removed in vacuo, the oily residue is dissolved in dichloromethane and the reaction mixture is chromatographed on silica. The dinuclear iron carbonyl complex **8** is eluted using mixtures of light petroleum (b.p. 40–60 °C) and CH_2Cl_2 1:2 as the eluent, **9** and **10** are obtained using mixtures of light petroleum (b.p. 40–60 °C) and THF 4:1. Yields: **8**, 92 mg (11.9%); **9**, 146 mg (19.4%); **10**, 42 mg (6.0%).

Scheme 1.

their preparative accessibilities, structural varieties and varied denticities. Self-assembly [3] of a metal ion, blocking ligand and bridging unit is the most important way to make different sets of complexes. With the neutral tetradentate N-donor Schiff bases L [L = *N*,*N*′-(bis(pyridin-2-yl)benzylidene)propane-1,3-diamine-(pbpd) or *N*,*N*′-(bis(pyridin-2-yl)formylidene)butane-1,4-diamine (pfbd)] and using different mole ratios of metal ion:Schiff base:azide, mono-, di- and polynuclear complexes may be produced. A 1:1:2 molar ratio should result in a mononuclear neutral compound $[Cu(L)(N_3)_2]$ and a 1:1:1 ratio should yield dicationic dinuclear $[Cu(L)(N_3)]_2^{2+}$ or polycationic polymer $[Cu(L)(N_3)]_n^{n+}$ compounds. However, with both ratios a pentacoordinated mononuclear cationic complex of the type $[Cu(L)(N_3)]^+$ is afforded. In this work, we report the synthetic details and luminescence, magnetic and some physicochemical properties of these mononuclear complexes of the type [Cu(L)(N$_3$)]X (**1**–**4**) [L = pbpd; X = ClO_4 (**1**); L = pbpd; X = PF_6 (**2**); L = pfbd; X = ClO_4 (**3**); L = pfbd; X = PF_6 (**4**)]. An X-ray crystallographic study has been made for **2** and **3** to define the coordination sphere (Scheme 1).

2. Experimental

2.1. Materials

High purity pyridine-2-carboxaldehyde (Lancester, UK), 2-benzoylpyridine (Lancester, UK), propane-1,3-diamine (Lancester, UK), butane-1,4-diamine (Lancester, UK), copper nitrate tetrahydrate (E. Merck, India), sodium azide (Aldrich, USA) and potassium hexafluorophosphate (Fluka, Germany) were purchased from the respective concerns and were used as received. Copper perchlorate hexahydrate was prepared by treatment of copper carbonate (E. Merck, India) with perchloric acid (E. Merck, India) followed by slow evaporation on a steam-bath, filtration through a fine glass-frit, and preservation in a desiccator containing concentrated sulfuric acid (E. Merck, India) for subsequent use. Purification of solvent (MeOH) and preparation of supporting electrolyte ($[Et_4N][ClO_4]$) for electrochemical work were executed following a published procedure [16]. All other chemicals and solvents were AR grade and were used as received. The synthetic reactions and work-up were done in the open air.

Caution! Perchlorate and azido compounds of metal ions are potentially explosive especially in the presence of organic ligands. Only a small amount of the material should be prepared and it should be handled with care.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a JASCO FTIR model 420 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry MeOH was used as the solvent. Ground-state absorption and steady-state fluorescence measurements were made with a JASCO model V-530 UV–Vis spectrophotometer and Hitachi model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer, Edinburgh Instruments, model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photomultiplier tube were, respectively, used as the excitation source and the fluorescence detector. Magnetic susceptibilities were measured with a PAR 155 vibrating sample magnetometer. Electrochemical measurements were carried out with the use of a computer controlled EG&G PARC VersaStat model 270 electrochemical instrument using a platinum disk working electrode as described elsewhere [17]. The solutions were IR compensated and the results were collected at 25 °C. The following parameters and relations were used: scan rate (v), 50 mV s^{-1}; formal potential $E^\circ = 0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are anodic and cathodic peak potentials, respectively; ΔE_p is the peak-to-peak separation. The potentials are referenced to a saturated calomel electrode (SCE) and are uncorrected for junction contributions.

2.3. Preparation of ligands

The Schiff base blockers were prepared following a reported [15] procedure. 2-Benzoyl-pyridine/pyridine-2-carboxaldehyde was condensed with the respective amine in a 2:1 molar ratio. Details are described below.

2.3.1. *N*,*N*′-(bis(pyridin-2-yl)benzylidene)propane-1,3-diamine (pbpd)

Propane-1,3-diamine (0.074 g, 1 mmol) was refluxed with 2-benzoyl pyridine (0.366 g, 2 mmol) in dehydrated alcohol (25 cm^3) for 12 h. The tetradentate ligand was isolated after evaporating the solvent and purified from alcohol. The product is isolated as a brown semi-solid

mass after being dried in vacuo over P_4O_{10} for subsequent use. Yield, 0.425 g (78%). *Anal*. Calc. $C_{27}H_{24}N_4$: C, 80.16; H, 5.98; N, 13.85. Found: C, 80.09; H, 5.92; N, 13.92%. IR: ν(C=N) 1590 cm^{-1}; UV–Vis, λ_{max}: 375 nm.

2.3.2. N,N′-(bis(pyridin-2-yl)formylidene)butane-1,4-diamine (pfbd)

Pyridine-2-carboxaldehyde (0.214 g, 2 mmol) was refluxed with butane-1,4-diamine (0.088 g, 1 mmol) in dehydrated alcohol. After 10 h, the reaction solution was evaporated under reduced pressure to give a gummy mass, which was dried and stored in vacuo over $CaCl_2$ for subsequent use. Yield, 0.242 g (80%). *Anal.* Calc. $C_{16}H_{18}N_4$: C, 72.2; H, 3.0; N, 21.0. Found: C, 72.4; H, 3.1; N, 21.3%. IR: ν(C=N) 1590 cm^{-1}; UV–Vis, λ_{max}: 375 nm.

2.4. Preparation of the complexes

Mononuclear complexes **1**and **3** were prepared from the perchlorate salt of copper(II) using the same mole ratio (1:1:1) of metal, pbpd/pfbd and azide. Complexes **2** and **4** were prepared using a 1:1:1:1 ratio of copper (II) nitrate, pbpd/pfbd, sodium azide and potassium hexafluorophosphate; these were also isolated by metathesis of **1** and **3**, respectively, with potassium hexafluorophosphate. The quality of compound **2** was poor compared to the other complexes. The typical syntheses are described below.

2.4.1. [Cu(pbpd)(N_3)]ClO_4 (**1**)

A methanolic solution (5 ml) of pbpd (0.40 g, 1 mmol) was added dropwise to a solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol) in the same solvent (10 cm^3). NaN_3 (0.065 g, 1 mmol) in warm MeOH (5 cm^3) was added slowly to it. The green solution was filtered and the supernatant liquid was kept in air for slow evaporation. After a few days the desired complex that separated was washed with toluene and dried in vacuo over silica gel indicator. Yield, 0.12 g (70%). *Anal.* Calc. for $C_{27}H_{24}N_7O_4ClCu$ (**1**): C, 53.20; H, 3.97; N, 16.08. Found: C, 53.21; H, 3.95; N, 16.05%. IR (KBr, cm^{-1}): ν(C=N) 1637, 1592; $\nu(ClO_4)$ 1080, 622; $\nu(N_3)$ 2072. Λ_M (MeOH, $\Omega^{-1}\,cm^2\,mol^{-1}$): 130; UV–Vis (MeOH; λ nm): 717, 406. E°_{298}, V (ΔE_p, mV): 0.11 (100).

2.4.2. [Cu(pbpd)(N_3)]PF_6 (**2**)

$Cu(NO_3)_2 \cdot 4H_2O$ (0.24 g, 1 mmol) was dissolved in MeOH (10 cm^3). To this pbpd (0.40 g, 1 mmol) dissolved in same solvent (5 cm^3) was added slowly, followed by NaN_3 (0.065 g, 1 mmol). KPF_6 (0.18 g, 1 mmol) was added at a time. The final solution was filtered, kept for slow evaporation and processed as in **1** to yield pure **2**. Yield, 0.20 g (72%). This was also prepared by metathesis of **1** (0.60 g, 1 mmol) with KPF_6 (0.18 g, 1 mmol) in MeOH–H_2O (2:1) mixture in a better yield 0.34 g (75%). *Anal.* Calc. for $C_{27}H_{24}N_7F_6PCu$ (**2**): C, 49.51; H, 3.69; N, 14.96. Found: C, 49.51; H, 3.66; N, 14.98%. IR (KBr, cm^{-1}): ν(C=N) 1635, 1593; (PF_6) 820, 540; $\nu(N_3)$ 2073. Λ_M (MeOH, $\Omega^{-1}\,cm^2\,mol^{-1}$): 120; UV–Vis (MeOH; λ nm): 718, 404. E°_{298}, V (ΔE_p, mV): 0.11 (100).

2.4.3. [Cu(pfbd)(N_3)]ClO_4 (**3**)

Solid pfbd (0.418 g, 1 mmol) was added pinch by pinch to a solution (10 cm^3) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g; 1 mmol) in MeOH. To this resulting solution, a methanolic solution of sodium azide (0.065 g, 1 mmol) was added. The mixture was filtered and the supernatant liquid was kept in air for slow evaporation. After 7 days **3** was separated, washed with toluene and dried in vacuo over silica gel indicator. Yield, 0.09 g (70%). *Anal.* Calc. for $C_{16}H_{18}N_7O_4ClCu$ (**3**): C, 40.77; H, 3.85; N, 20.80.Found: C, 40.75; H, 3.86; N, 20.85%. IR (KBr, cm^{-1}): ν(C=N) 1639, 1590; $\nu(ClO_4)$ 1082, 620; $\nu(N_3)$ 2072. Λ_M (MeOH, $\Omega^{-1}\,cm^2\,mol^{-1}$): 120; UV–Vis (MeOH; λ nm): 720, 406. E°_{298}, V (ΔE_p, mV): 0.14 (110).

2.4.4. [Cu(pfbd)(N_3)]PF_6 (**4**)

Complex **4** was prepared using the same procedure and reaction stoichiometry as in **2** except that pfbd instead of pbpd was used as the organic ligand. Yield, 0.16 g (73%).This was also prepared by metathesis of **3** (0.51 g, 1 mmol) with KPF_6 (0.18 g, 1 mmol) in a MeOH–H_2O (2:1) mixture in a higher yield 0.87 g, (80%). *Anal.* Calc. for $C_{16}H_{18}N_7F_6PCu$ (**4**): C, 37.18; H, 3.51; N, 18.97. Found: C, 37.19; H, 3.53; N, 18.95%. IR (KBr, cm^{-1}): ν(C=N) 1637, 1595; $\nu(PF_6)$ 820, 542; $\nu(N_3)$ 2073. Λ_M (MeOH, $\Omega^{-1}\,cm^2\,mol^{-1}$): 130; UV–Vis (MeOH; λ nm): 717, 405. E°_{298}, V (ΔE_p, mV): 0.13 (110).

2.5. X-ray diffraction study

Single crystals of the title complexes were obtained by slow evaporation of a methanolic solution of the reaction mixtures at room temperature (298 K). Suitable colourless crystals were mounted on a Siemens SMART CCD diffractometer equipped with a graphite-monochromator and Mo Kα ($\lambda = 0.71073$ Å) radiation. Diffraction data were measured using the ϕ and ω-scan method. Crystal data, data collection parameters and the results of analyses can be found in Table 1. The intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was employed using the SAINT [18] and SADABS [19] program for crystals **2**and **3**, respectively. The structures were solved and refined used SHELXTL [20] and the refinement is based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters, whereas hydrogen atoms were placed in calculated positions

where possible and given isotropic *U* values 1.2 times that of the atom to which they are bonded. All crystallographic calculations were conducted with SHELXL-97 [21], ORTEP-3 [22] and PLATON programs [23].

3. Results and discussion

3.1. Synthesis and formulation

The pentacoordinated mononuclear complex $[Cu(pbpd)(N_3)]ClO_4$ (**1**) is initially formed in an MeOH solution containing a 1:1:2 mixture of $Cu(ClO_4)_2 \cdot 6H_2O$, pbpd and NaN_3, a reactant ratio expected to yield a mononuclear species of the composition $[Cu(pbpd)(N_3)_2]_n$. However, microanalyses showed a 1:1:1 ratio of metal, blocking ligand and the pseudohalide, and in the IR spectrum the presence of perchlorate bands was noticed. A reactant ratio corresponding to the product stoichiometry afforded better yields of **1**. In an effort to prepare $[Cu(pbpd)(N_3)_2]$, the starting material was changed to $Cu(NO_3)_2 \cdot 4H_2O$, and a 1:1:2 molar ratio of nitrate salt, ligand and the pseudohalide produced a gummy mass of indefinite composition; however, addition of KPF_6 to the green reaction solution yielded shining microcrystalline powder of **2**. The latter was also obtainable from metathesis of **1** with KPF_6. A change of the ligand from pbpd to pfbd showed similar behaviour and compounds **3** and **4** were isolated. All the four complexes were characterized by elemental analysis, solution electrical conductivity, magnetic susceptibility, IR, UV–Vis, reflectance spectra and electrochemistry. The results are consistent with the proposed mononuclear formulation. The air-stable moisture-insensitive complexes are powders, soluble in a range of common organic solvents such as methanol, ethanol, dichloromethane, acetonitrile, but are insoluble in water. In methanol solutions they behave [24] as 1:1 electrolytes as reflected in their Λ_M values. Room-temperature solid-phase magnetic susceptibility measurements show that the copper (II) complexes have a moment close to the spin-only value ($S = 1/2$), 1.73 BM, expected from discrete and a magnetically non-coupled mononuclear $3d^9$ ion.

In the IR spectra, the point of interest is the band due to azide at ~2070 cm^{-1}. The presence of ionic perchlorate bands at ~1090 and ~620 cm^{-1} and ionic hexafluorophosphate at ~840 and ~540 cm^{-1} is routinely noticed. The ν(C=N) stretching vibrations of the metal bound Schiff bases are seen at ~1635 and ~1590 cm^{-1} [25]. All other characteristic ligand vibrations are seen in the 1600–600 cm^{-1} range. The solutions of **1**–**4** in MeOH are dark green and exhibit absorption in the 400–720 range [**1**: λ, 717, 406 nm; **2**: λ, 718, 404 nm; **3**: λ, 720, 406 nm; **4**: λ, 717, 405 nm]. The transition 700 nm corresponds to a d-d transition of the copper(II) moiety and the band around 400 nm for an intramolecular ($n \rightarrow \pi^*/\pi \rightarrow \pi^*$) charge transfer transition [26].

Reflectance [**1**: λ, 715, 400 nm; **2**: λ, 715, 408 nm; **3**: λ, 716, 404 nm; **4**: λ, 716, 402 nm] in nujol and electronic spectra for each complex in MeOH solutions are akin reflecting similar gross structure and electronic structure in the solid state and in solution of each compound.

3.2. Electrochemistry

The electroactivity of the complexes was studied in MeOH solutions using cyclic voltammetry and coulometry at platinum working electrodes. A one-electron reductive response is observed, presumably due to the electrode reaction shown as follows:

$$[Cu^{II}(L)(N_3)]^{1+} + e \rightarrow [Cu^{I}(L)(N_3)] \quad (1)$$

The electrode process in the CV is reproducible in the potential range 0.08 to −0.08 V with no trace of decomposition as reflected in a smooth cyclic voltammogram. The one-electron stoichiometry of couple 1 was confirmed from the comparison of current height with that of a standard [27] copper(II)–copper (I) couple, since attempted coulometry at potentials more cathodic than E_{pc} gave a continuous coulomb count due to some unidentified side reactions [28]. The similar pattern in electron transfer behaviour of all the complexes at about same potential once again corroborates the closely similar structure of the cationic units.

3.3. X-ray structure

In order to define the coordination sphere conclusively, a single-crystal X-ray diffraction study was made. An ORTEP diagram with the atom numbering scheme of the mononuclear units in **2** and **3** are shown in Figs. 1 and 2. Selected interatomic bond lengths and bond angles are listed in Table 2. The crystal lattice consists of $[Cu(pbpd)(N_3)]^+$ cations and PF_6^- anions for **2** and $[Cu(pfbd)(N_3)]^+$ cations and ClO_4^- anions for **3**. The coordination polyhedron around the metal centre is best described as distorted trigonal bipyramid (tbp) with a CuN_5 chromophore. The coordination includes a tetradentate Schiff base ligated by two pyridine nitrogens (N1, N4) and two imine nitrogens (N2, N3), and one terminal azide nitrogen (N5). The equatorial positions are occupied by one imine nitrogen (N3), one pyridine nitrogen (N1) and the azide nitrogen (N5) while the axial positions are occupied by the remaining imine (N2) and pyridine (N4) nitrogen atoms. The distortion from ideal tbp geometry is due to the asymmetric nature of the Schiff base and the deviations of the defining angles (90degr/120°) formed at the metal centre. The propylinic/butylenic part of the Schiff base N2–C13–C14–C15–N3/N3–C10–C9–C8–C7–N2 is to some extent puckered (Figs. 1 and 2). The equatorial Cu–N distances [2.003(7)–2.121(8) Å] (**2**) and [1.992(2)–2.198(2) Å] (**3**) as well as the bond angles [95.1(3)–134.4(3)°] (**2**) and [101.57(10)–144.53(10) °] (**3**) show significant variations. The axial Cu–N distances [Cu1–N1 1.986(8) Å, Cu1–N3 1.977(8) Å] in **2** and [Cu1–N1 1.997(2) Å, Cu1–N3 1.991(2) Å] in **3** are however close. The three bite angles N4–Cu1–N3, N3–Cu1–N2 and N2–Cu1–N1 are 78.8(3)°, 91.4(3)° and 81.30(3)° in **2** and 79.16(9)°, 96.17(9)° and 81.33(9)° in **3**. The larger bite in N3–Cu1–N2 arises from the six- and seven-membered puckered loop formed from the propylenic and butylenic arm for **2** and **3**, respectively, and it is of a similar value to the non-bite angle [N1–Cu1–N4] 97.35(9)° for complex **3**, but there is significant variation [101.00(3)°] for complex **2**. The axial bond angle N1–

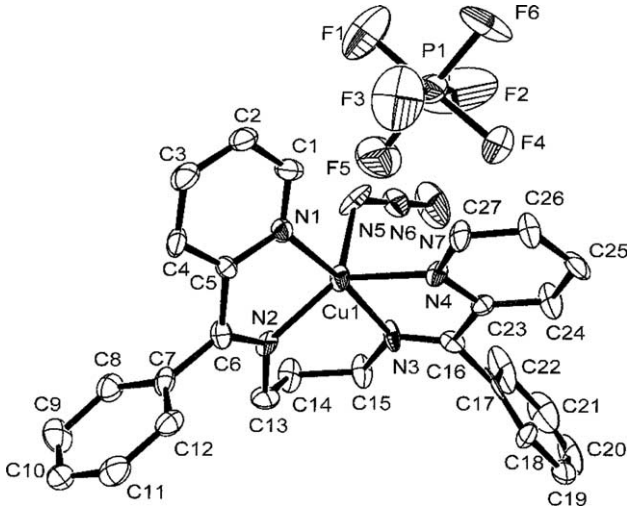

Fig. 1. ORTEP representation of $[Cu(pbpd)(N_3)]PF_6$ (**2**) with the atom labelling scheme and 50% probability ellipsoids for all non-hydrogen atoms.

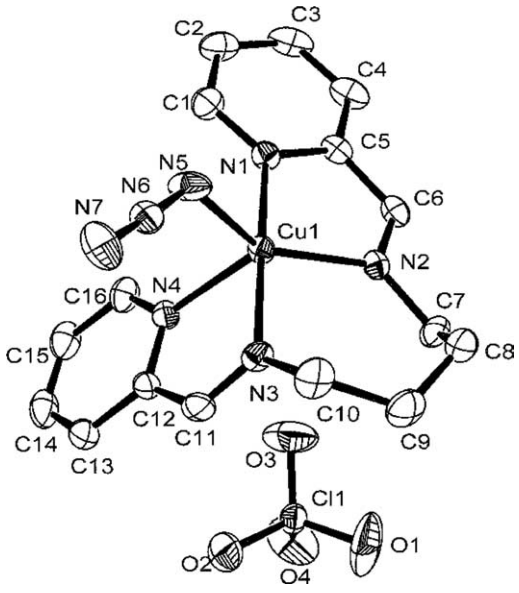

Fig. 2. ORTEP diagram of $[Cu(pfbd)(N_3)]ClO_4$ (**3**) with the atom labelling scheme and 50% probability ellipsoids for all non-hydrogen atoms.

Table 2
Selected bond distances (Å) and angles (°) for **2** and **3**

	2	**3**
Bond distances (Å)		
Cu(1)–N(1)	1.986(8)	1.997(2)
Cu(1)–N(2)	2.003(7)	2.015(2)
Cu(1)–N(3)	1.977(8)	1.991(2)
Cu(1)–N(4)	2.121(8)	2.198(2)
Cu(1)–N(5)	2.074(9)	1.992(2)
N(5)–N(6)	1.198(13)	1.191(3)
N(6)–N(7)	1.124(14)	1.160(3)
Bond angles (°)		
N(5)–Cu(1)–N(4)	95.10(3)	101.57(10)
N(5)–Cu(1)–N(2)	134.40(3)	144.53(10)
N(4)–Cu(1)–N(2)	130.40(3)	113.73(8)
N(2)–Cu(1)–N(l)	81.30(3)	81.33(9)
N(4)–Cu(1)–N(1)	101.00(3)	97.35(9)
N(5)–Cu(1)–N(3)	95.50(3)	93.64(9)
N(4)–Cu(1)–N(3)	78.80(3)	79.16(9)
N(2)–Cu(1)–N(3)	91.40(3)	96.17(9)
N(5)–Cu(1)–N(1)	94.20(3)	91.17(10)
N(3)–Cu(1)–N(1)	170.30(3)	174.54(9)
N(5)–N(6)–N(7)	179.00(13)	177.1(3)

Cu1–N3 [170.3(3)°] (**2**) and [174.54(9)°] (**3**) deviates slightly from the ideal value (180°). The sum (359.9°/359.83°) (**2**/**3**) of the equatorial angles are very close to 360.00°; so the atoms N2, N4, N5 and Cu1 are almost in a same plane. In the terminal azide ligand, the N5–N6 distance 1.198(13) and 1.191(3) Å is longer than the N6–N7 length [1.124(14) and 1.160(3) Å for **2** and **3**, respectively, and the values are very similar to the ones previously reported [29]. The azide is coordinated in a linear fashion as seen from its N5–N6–N7 angle 179.0(13)° and 177.1(3)° for **2** and **3**, respectively.

3.4. Luminescence studies

The spectroscopic data are listed in Table 3. The complexes with pbpd and pfbd feature two intense absorptions at ca. 405 nm which are assigned to intraligand π–π^* transitions. The emission energy of the complexes in MeOH solutions at 298 K is almost same ($\lambda_{max} \approx 475$ nm) and is assignable to intraligand fluorescence [30,31]. The lifetimes of the fluorescence of **1**, **2**, **3** and **4** are 2.63, 2.59, 2.59 and 2.62 ns, respectively. In glassy solutions (MeOH at 77 K) both fluorescence and $^3(\pi$–$\pi^*)$ phosphorescence is observed at 525 nm. In solid state, they show a distinct emission band at 492 nm, differing from their fluorescence spectra in MeOH (Fig. 3).

4. Supplementary data

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Centre No 238521 for **2** and 238522 for **3**. Copies of this information can be obtained free of charge from

Table 3
Photophysical data for **1**–**4**

Sample	Absorption, λ (nm)	Emission, λ (nm)			Lifetime (ns)
		Fluor-escence[a]	Phosph-orescence[b]	Solid state[c]	
Pbpd/pfbd	375	470	525	486	2.58
1	406	475	525	492	2.63
2	404	476	525	492	2.59
3	406	475	525	492	2.59
4	404	475	525	492	2.62

[a] In MeOH at room temperature (298 K).
[b] In MeOH at 77 K.
[c] At room temperature.

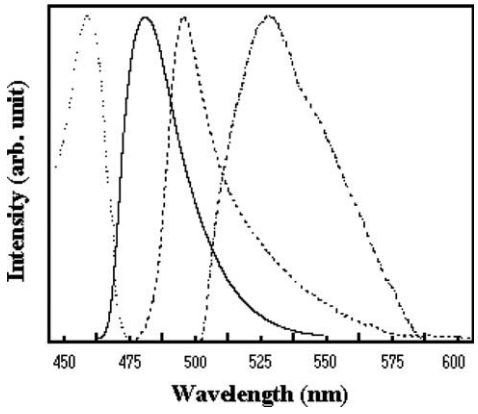

Fig. 3. Emission spectra of **2**: UV in MeOH solution at 298 K (·····), fluorescence (——), phosphorescence in MeOH glassy solution (-·-·-·), solid state at 298 K (– – –).

The Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2005, volume 24 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2005, volume 24 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Instructions to Authors

The instructions can also be found on the World Wide Web: http://www.elsevier.com/locate/poly

General

Polyhedron publishes full length papers, commissioned reports and symposia-in-print. All contributions should conform to the Aims and Scope of the journal. All contributions shall be rigorously refereed.
Papers – should be substantial, completed pieces of original research in inorganic and organometallic chemistry which have special significance, general interest and which, in addition are presented clearly and concisely.
Reports – are specially commissioned critical reports reviewing research results of topical importance. Reports will be commissioned by the Editorial Board from recognized authorities in the appropriate fields.
Symposia-in-Print – are collections of original research papers brought together to cover timely areas of inorganic and organometallic chemistry. For each, a Symposium Editor will invite authors active in the field to submit papers.

Submission of contributions

Authors should select the name of the appropriate Regional Editorial Office from the dropdown menu:
Papers from the Americas: G. Christou
Papers from China: T.C.W. Mak
Papers from the Rest of the world: C.E. Housecroft
Papers from Australia: any of the Editors
Polyhedron Reports: G. Christou
Symposia-in-Print: G. Parkin
Alternatively, contributions may be submitted in hardcopy, in triplicate.

Crystallographic data

Crystallographic data need to be validated and deposited (usually by sending a CIF file to deposit@ccdc.cam.ac.uk prior to submission).

Electronic submission

We accept most word processing formats, but Word, WordPerfect or LaTeX is preferred.
Submission of both regular and special issue articles to this journal proceeds totally on-line via the journal's submission website http://ees.elsevier.com/poly. At the submission website you will be guided stepwise through the creation and uploading of the various files. Once the uploading is done, our system automatically generates an electronic (PDF) proof, which is then used for reviewing. All correspondence, including notification of the Editor's decision and requests for revisions, will be by e-mail. Every paper must be accompanied by a letter from the senior author, stating that he/she is submitting the paper for publication in Polyhedron. In the letter, possible reviewers may be suggested.

Manuscript preparation

Language. Articles must be written in good English. For information about language editing services, please contact authorsupport@elsevier.com who will be happy to deal with any questions.
Manuscripts should be prepared with numbered lines, wide margins and double spacing throughout, i.e. also for abstracts, footnotes and references.
Corresponding author. Clearly indicate who is willing to handle correspondence at all stages of refereeing and publication, also post publication. Ensure that telephone and fax numbers (with country and area code) are provided in addition to the e-mail address and the complete postal address. This corresponding author should be clearly indicated by an asterisk.
Please note that the Contents contain Pictograms and Synopses. The authors are therefore asked to provide a drawing or reaction scheme of restricted size illustrating their work and a short synopsis of maximum 50 words.
Every contribution should include a concise, informative *Abstract* and a maximum of six *Keywords*. Equations, tables and legends should be numbered consecutively and separately throughout the paper. The presentation of tables, graphs and formulae should be kept to an absolute minimum, and where possible the results from a series of investigations should be in table form or as a graph. The same data should not be presented in both tables and figures or given in the Discussion as well as the Experimental section.
Illustrations. Graphics and photographs should not be embedded in the text of the manuscript. They should be uploaded separately in a form suitable for reproduction. A detailed guide on electronic artwork is available on our website: http://authors.elsevier.com/artwork. Authors may now submit colour pictures and other supplementary material along with their paper. If, together with the accepted article, usable colour figures are submitted then Elsevier will ensure, at no additional charge, that these figures will appear in colour on the web (e.g., ScienceDirect and other sites) regardless of whether or not these illustrations are reproduced in colour in the printed version. Figure captions should always be listed on a separate page.
References should be numbered consecutively throughout the text, and should be collected together in a reference list, at the end of the paper. Journal abbreviations should normally conform to the ''Chemical Abstracts Service Source Index''.

Nomenclature

All nomenclature should be consistent, clear and unambiguous, and should conform to the rules established by IUPAC. The following IUPAC publications should be consulted: Nomenclature of Inorganic Chemistry and Nomenclature of Organic Chemistry.

Copyright

Upon acceptance of an article, authors will be asked to transfer copyright (for more information on copyright see http://authors.elsevier.com). This transfer will ensure the widest possible dissemination of information. A letter will be sent to the corresponding Author confirming receipt of the manuscript. A form facilitating transfer of copyright will be provided. If excerpts from other copyrighted works are included, the Author(s) must obtain written permission from the copyright owners and credit the source(s) in the article. Elsevier has preprinted forms for use by authors in these cases: contact Elsevier's Rights Department, Oxford, UK, phone: (+44) 1865 843830, fax: (+44) 1865 853333, e-mail: permissions@elsevier.com. Requests may also be completed on-line via the Elsevier homepage (http://www.elsevier.com/locate/permissions).

Proofs

One set of page proofs in PDF format will be sent by e-mail to the corresponding Author, to be checked for typesetting/editing. No changes in, or additions to, the accepted (and subsequently edited) manuscript will be allowed at this stage. Proofreading is solely your responsibility. Elsevier will do everything possible to get your article corrected and published as quickly and accurately as possible. In order to do this we need your help. When you receive the (PDF) proof of your article for correction, it is important to ensure that all of your corrections are sent back to us in one communication. Subsequent corrections will not be possible, so please ensure your first sending is complete. Note that this does not mean you have any less time to make your corrections, just that only one set of corrections will be accepted.

Reprints

Authors are provided with twenty-five reprints free of charge. Additional reprints can be ordered. The order form containing price quotations will be sent to the authors together with a copyright transfer form upon acceptance of the manuscript.

There are no page charges

Author enquiries

For enquiries relating to the submission of articles (including electronic submission where available) please visit Elsevier's Author Gateway at http://authors.elsevier.com. The Author Gateway also provides the faculty to track accepted articles and set up e-mail alerts to inform you of when an article's status has changed as well as detailed artwork guidelines, copyright information, frequently asked questions and more. Contact details for questions arising after acceptance of an article, especially those relating to proofs, are provided after registration of an article for publication.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2005, volume 24 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2005, volume 24 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

VALIDATION AND DEPOSITION OF CRYSTALLOGRAPHIC DATA

Information and Instructions to Authors of Papers Containing or Comprising Crystal Structures Determinations

1. ***Policy*** Polyhedron will accept for publication papers containing or comprising the results of crystal structure determinations which will be of interest to inorganic chemists. Papers reporting only crystallographic results must relate to work of novelty or special significance to inorganic chemistry, which must be emphasized.

2. ***Submission of papers***. The following procedures should be followed:

   a) **Prior** to the submission of the manuscript, the author(s) should **validate and deposit files in Crystallographic Information File (CIF) format.**
   Validation should occur before deposition via the "checkCIF" service developed by the International Union of Crystallography (IUCr) available at http://checkcif.iucr.org. Authors are strongly recommended to take advantage of this service and submit manuscripts accompanied by an IUCr validation report to help the referees reviewing the manuscript.
   Authors deposit with the relevant Data Centre the data corresponding to each structure to be reported in the intended publication.
   Data for **metal organic** structures, i.e. those which contain organic carbon in **any** of the species present in the structure (including metal carbonyls) should be sent to the Cambridge Crystallographic Data Centre (CCDC) by e-mail (address: deposit@ccdc.cam.ac.uk) preferably in CIF format. A checklist of data items to be included in the deposition can be obtained from the CCDC Home Page on the Worldwide Web (http://www.ccdc.cam.ac.uk/) or by e-mail (to fileserv@ccdc.cam.ac.uk) with the one line message **sendme checklist**.
   Data for **inorganic** compounds should be sent to Fachinformationszentrum Karlsruhe (FIZ) by e-mail (address: crysdata@FIZ-Karlsruhe.de) by FTP (please contact FIZ if you choose this option) or on disk. No hard copy submissions will be accepted.
   The Data Centres will provide, within a day or two of submission, deposition codes for each data set, which should be quoted in suitable form in the manuscript submitted to the Journal. The deposited data will be accessed by the Journal and checked as part of the refereeing process.

   b) When the paper is submitted to the Journal, the following guidelines should be adhered to:

   - The **Title** should contain reference to the presence in the paper of X-ray crystallographic results.
   - The **Abstract** should **not** contain crystal data, but should include a concise statement of the main features of the structural results.
   - The **Experimental** results must be presented in a concise format. In general, authors should not include a detailed text description of data collection, crystal structure solution and refinement, especially if these followed standard procedures and no difficulties were met. Reference to a previous paper containing a more detailed experimental description can be given if relevant. However, if any parts of the structure analysis were unusual, and affected the presentation and/or accuracy of the results, then these should be discussed. The following crystallographic data should be given, all contained in a paragraph (if one structure reported) or Table (two or more structures).

   i) Color, habit and size of crystals used, and behavior of compound under ambient conditions if not mentioned elsewhere in the paper.
   ii) Chemical formula. This should correspond to the complete chemical unit encompassing crystallographic symmetry (e.g. a centrosymmetric dimer should be included in full form). The use of fractional coefficients (e.g. $0.5H_2O$) should be used only if the unit has partial occupancy of its site. Formulae should be presented in a way that molecules, ionic fragments, solvate molecules etc. are separately identified.

iii) Unit cell parameters with esd's, and X-ray wavelength used.
iv) Crystal system, space group and number of complete chemical unit (see ii) per cell.
v) Type of diffractometer used and method of data collection; total number of data collected, excluding any intensity controls, number unique, R_{int} value, number observed (with cut-off parameter) and completeness of data to suitable 2θ or sin θ/γ limit; use or otherwise of absorption correction.
vi) Final results. Give values of R, R_w (and their definitions) and number of parameters. Indicate form of refinement (F or F^2) and treatment of hydrogens.

Note that easily derived parameters (F_{wt}, $F(000)$, μ, D_x) should not be given unless required in discussion of other data (e.g. number of solvent molecules, etc.).

- **Discussion of the structure.** This must include a clear, labelled diagram of the structure (molecule, complex ion or unit cell contents if the structure is polymeric) and a list of relevant geometry parameters – interatomic distances, interbond angles, torsion angles etc. Data for geometrically less important parts of the structure, such as ligand sub groups (phenyl rings, alkyl groups etc.) should not be given. Packing diagrams of crystal structures of "molecular" compounds should not be given unless there are chemically important intermolecular interactions.

3. ***Supplementary data.*** It is not necessary to submit copies of the Supplementary Data with the manuscript. However, authors are recommended to submit with the manuscript, as supplementary sheets, not for publication, any further information which they feel may aid the refereeing process, particularly if any of the usual quality-of-structure indicators point to problems in the analysis.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.
Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.
In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2005, volume 24 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

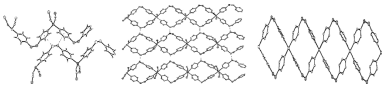
Contents



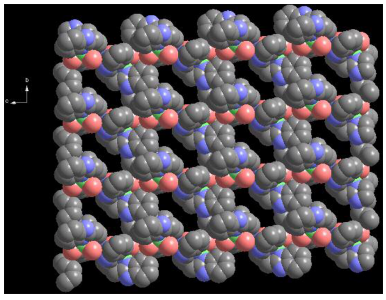
Papers

Maw-Cherng Suen, Yuen-Hua Wang, Yi-Fen Hsu, Chun-Wei Yeh, Jhy-Der Chen, Ju-Chun Wang

Polyhedron 24 (2005) 2913

Syntheses and structural characterization of transition metal(II) coordination polymers containing 4,4′-dipyridyldisulfide

The synthesis and structures of three new coordination polymers, $Zn(NCS)_2(4\text{-PDS})]_n$-(4-PDS = 4,4′-dipyridyldisulfide) (**1**), $[Fe(NCS)_2$-$(4\text{-PDS})_2 \cdot 4H_2O]_n$ (**2**), and $\{[Co(4\text{-PDS})_2]$-$[Cl]_2 \cdot 2CH_3OH\}_n$ (**3**), are reported. Complex **1** exibits 1-D zigzag-chains, while complexes **2** and **3** shows 1-D channel chains structures.

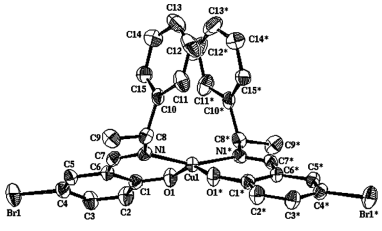


Anangamohan Panja, Sanchita Goswami, Nizamuddin Shaikh, Partha Roy, Mario Manassero, Ray J. Butcher, Pradyot Banerjee

Polyhedron 24 (2005) 2921

Synthesis and X-ray crystallographic characterization of copper and iron complexes with tetradentate-N_4 ligands: Reactivity towards catechol oxidation

The synthesis and structural characterization of new copper and iron complexes $[Cu(ntb)Cl]_2$-$[CuCl_4] \cdot 2H_2O$ (**1**), $[Fe(ntb)Cl_2]Cl \cdot 3H_2O$ (**2**) and $[Fe(bispicpn)Cl_2]Cl$ (**3**) with tetradentate N-ligands, ntb (ntb = tris(2-benzimidazolylmethyl)amine) and bispicpn (bispicpn = *N*,*N*′-bis(2-pyridylmethyl)-1,2-propanediamine) are reported. Detailed structural analysis revealed 3D, 2D and 1D networks. The packing diagram of **2** shows interesting hexagonal pores. Oxidation reactions of 3,5-di-*tert*-butylcatechol by oxygen were performed with these complexes; the copper complex exhibits catechol oxidase like activity while the two iron complexes show catechol dioxygenase like activity.

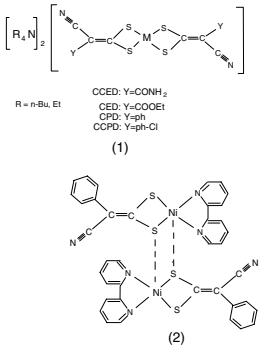


Takashiro Akitsu, Yasuaki Einaga

Polyhedron 24 (2005) 2933

Syntheses, crystal structures and electronic properties of a series of copper(II) complexes with 3,5-halogen-substituted Schiff base ligands and their solutions

We have systematically compared structures, electronic properties, structural phase transitions and absorption spectra depending on solvents for ten Cu(II) complexes incorporating 3,5-halogen-substituted Schiff base ligands. We could observe spectral changes in the π–$\pi*$ region of a complex in chloroform solution of the complex and 4-hydroxyazobenzene caused by its *cis*–*trans* photoisomerization.

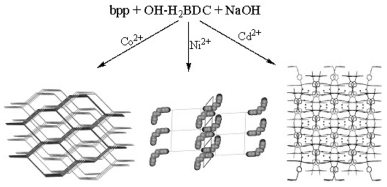


Hussein H. Alkam, Khalid M. Kanan, Christos C. Hadjikostas

Polyhedron 24 (2005) 2944

Syntheses and characterization of some homoleptic (1,1-dithiolato)copper(II) and nickel(II) complexes, and mixed-ligand (1,1-dithiolato)-nickel(II) chelates containing nitrogenous bases. Crystal structures of tetrabutylammonium(1-cyano-1-chlorophenyl-2,2-ethylenedithiolato)copper(II), [(2,2′-bipyridine)(1-cyano-1-phenyl-2,2-ethylenedithiolato)nickel(II)], and 5-amino-4-(4-chlorophenyl)-[1,2]dithiole-3-thione

A series of divalent nickel and copper complexes $[R_4N]_2[M(S_2C{=}C(CN)Y)_2]$ (**1**), and a series of mixed-ligand nickel(II) chelates $[Ni(enR)S_2C{=}C(CN)Y]$ have been prepared and characterized. The crystal structures of three compounds have been determined. The molecules of the complex [Ni(bipy)CPD] are arranged in pairs, each pair forms two weak intermolecular Ni···S bond interactions (**2**).

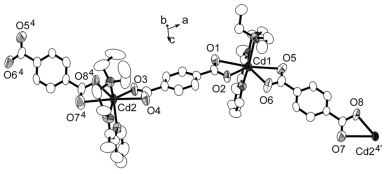


Xiao-Ju Li, Rong Cao, Wen-Hua Bi, Yan-Qin Wang, Yu-Ling Wang, Xing Li

Polyhedron 24 (2005) 2955

Three interpenetrated frameworks constructed by long flexible *N*,*N*′-bipyridyl and dicarboxylate ligands

The hydrothermal reactions of 1,3-bis(4-pyridyl)propane (bpp), 5-hydroxyisophthalic acid ($OH\text{-}H_2BDC$) and different metal ions gave rise to three coordination polymers, $\{[Co(bpp)(OH\text{-}BDC)]\cdot H_2O\}_n$ (**1**) $[Ni(bpp)_{1.5}(H_2O)(OH\text{-}BDC)]_n$ (**2**) and $\{[Cd(bpp)(H_2O)(OH\text{-}BDC)]\cdot 2H_2O\}_n$ (**3**). The long flexible bpp ligands adopt different conformations to take part in coordination in the three compounds.

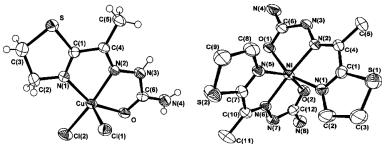


Suparna Banerjee, Paul-G. Lassahn, Christoph Janiak, Ashutosh Ghosh

Polyhedron 24 (2005) 2963

Supramolecular architecture of cadmium(II)–terephthalate complexes having a tridentate or tetradentate Schiff base as blocking coligand

Two new cadmium(II)–terephthalate complexes, one with the tridentate ligand N^1,N^1-diethyl-N^2-(1-(pyridin-2-yl)ethylidene)ethane-1,2-diamine and other with the tetradentate ligand *N*,*N*′-bis-(1-pyridin-2-yl-ethylidene)-ethane-1,2-diamine, have been synthesized. The compound having the tridentate ligand is a 1D polymeric chain whereas the compound with the tetradentate ligand is a very rare type of dinuclear complex.

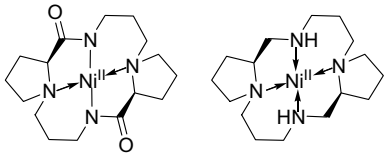


F.J. Barros-García, F. Luna-Giles, M.A. Maldonado-Rogado, E. Viñuelas-Zahínos

Polyhedron 24 (2005) 2972

Ligation properties of 2-acetyl-2-thiazoline semicarbazone (ATsc): Isolation, spectroscopic and X-ray study of ATsc and its Cu(II) and Ni(II) complexes

A new Schiff base ligand 2-acetyl-2-thiazoline semicarbazone (ATsc) and its copper(II) and nickel(II) complexes were synthesized and characterized by physical measurements. The X-ray crystal structures of ATsc, its copper complex and its nickel complex have also been determined. The geometry around the metallic atoms can be described as a distorted square-pyramid for the copper complex and as a distorted octahedron for the nickel complex.

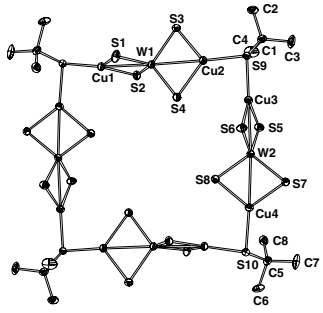


Agnieszka Szumna, Michał Achmatowicz, Tomasz Zieliński, Janusz Jurczak

Polyhedron 24 (2005) 2981

Structural studies of new chiral nickel (II) complexes of cyclams: The influence of a systematically varied number of amide groups

The nickel (II) complexes of the chiral cyclam and its mono- and dioxo derivatives show different complexation modes as proved by the X-ray analysis.

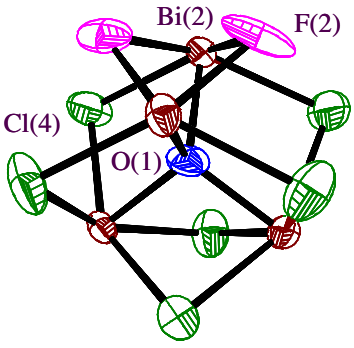


Zhi-Hua Li, Shao-Wu Du, Xin-Tao Wu

Polyhedron 24 (2005) 2988

Assembly of molecular squares and helical chain polymers of Mo(W)/Cu/S clusters using thiolato ligands as linkers

By using linear CuS_2WS_2Cu fragments as building blocks and monodentate or bidentate thiolato ligands as linkers, two novel molecular squares of Mo(W)/Cu/S clusters $[Et_4N]_4[\{MS_4Cu_2(\mu\text{-}SBu^t)\}_4]$ (**1**, M = Mo; **2**, M = W) and two helical chain polymers $\{[Et_4N]_2[MS_4Cu_2(SSS)]\}_n$ (**3**, M = Mo; **4**, M = W) have been isolated. The structural types of these clusters have not been previously reported in the Mo(W)/Cu/S system.



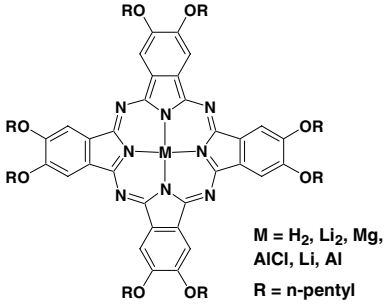
$[Et_4N]_4[\{WS_4Cu_2(\mu\text{-}SBu^t)\}_4]$ **2**

Andreas Decken, Grigori B. Nikiforov, Jack Passmore

Polyhedron 24 (2005) 2994

Evidence for SO_2, $C_2H_4Cl_2$ and CH_2Cl_2 soluble salts of bismuth homopolyatomic cations and $[Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2 \cdot C_6Me_6$, containing the novel $[Bi_4OF_2Cl_6]^{2+}$ cation

Compound $[Bi_4OF_2Cl_6(C_6Me_6)_4][Al(OC(CF_3)_3)_4]_2 \cdot C_6Me_6$ contains the novel $[Bi_4OF_2Cl_6]^{2+}$ cation.

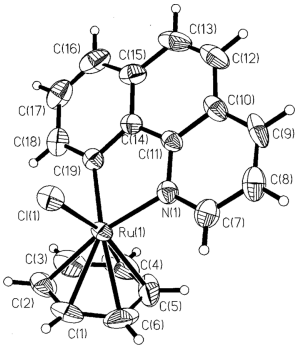


Xiaobin Deng, William W. Porter III, Thomas P. Vaid

Polyhedron 24 (2005) 3004

Aluminum and lithium octa(pentoxy)phthalocyanine radicals

The synthesis and characterization of the aluminum and lithium octa(pentoxy)phthalocyanine radicals, AlPc* and LiPc*, are described. In the solid state LiPc* and AlPc* are electrical conductors with pressed-pellet conductivities of $8 \times 10^{-11\ -1}$ cm^{-1} and $5 \times 10^{-7\ -1}$ cm^{-1}, respectively.

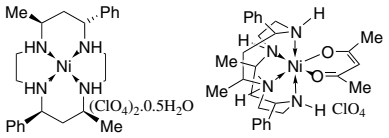


J.G. Małecki, M. Jaworska, R. Kruszynski, J. Kłak

Polyhedron 24 (2005) 3012

Reaction of $[(C_6H_6)RuCl_2]_2$ with 7,8-benzoquinoline and 8-hydroxyquinoline

The reaction of $[(C_6H_6)RuCl_2]_2$ with 7,8-benzoquinoline and 8-hydroxyquinoline in methanol were performed. The obtained complexes have been studied by IR, UV–VIS, ^1H and ^{13}C NMR spectroscopy and X-ray crystallography. The electronic spectra of the obtained compounds have been calculated using the TDDFT method. Magnetic properties of $[Ru(C_9H_6NO)_3] \cdot CH_3OH$ complex suggest the antiferromagnetic coupling of the ruthenium centers in the crystal lattice. EPR spectrum of $[Ru(C_9H_6NO)_3] \cdot CH_3OH$ compound indicates single isotropic line only characteristic for Ru^{3+} with spin equal to 1/2.

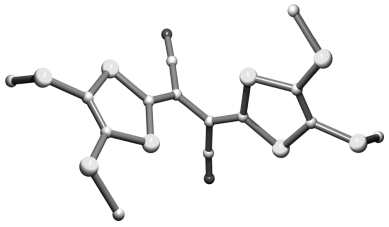


Donald F. Cook, Neil F. Curtis, Clifton E.F. Rickard, Joyce M. Waters

Polyhedron 24 (2005) 3022

Compounds of nickel(II) with 5*SR*,7*RS*,12*SR*,14*SR*-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane, rmL^2: The structures of $[Ni(rmL^2)](ClO_4)_2 \cdot 0.5H_2O$ and *cis*-$[Ni(rmL^2)(acac)]ClO_4$

The cyclic tetraamine 5*SR*,7*RS*,12*SR*,14*SR*-5,12-dimethyl-7,14-diphenyl-1,4,8,11-tetraazacyclotetradecane (rmL^2) with nickel(II) mainly forms compounds with the amine planar for $[Ni(rmL^2)]^{2+}$ salts and *trans*-diligand compounds *trans*-$[Ni(rmL^2)L_2]$. Compounds with the amine in folded coordination with *cis* ligands, *cis*-$[Ni(rmL^2)L_2]$, usually metastable with respect to the *trans* form, or with a chelate, as for *cis*-$[Ni(rmL^2)(acac)]ClO_4$ are also formed. Structures of *trans*-$[Ni(rmL^2)](ClO_4)_2 \cdot 1/2H_2O$ with the methyl substituents disordered over axial and equatorial orientations, and *cis*-$[Ni(rmL^2)(acac)]ClO_4$ are reported.

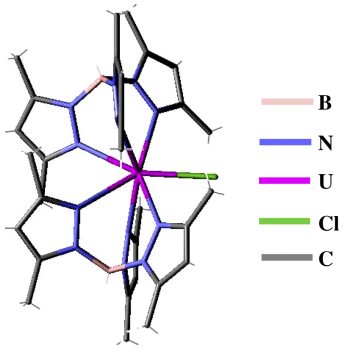


Chunyang Jia, Shi-Xia Liu, Antonia Neels, Gal Labat, Silvio Decurtins

Polyhedron 24 (2005) 3032

Coordination networks of 2,3-bis(4,5-dimethylthio-1,3-dithiole-2-ylidene)succinonitrile with silver salts: A study of network connectivity and topology as a function of counterion

Two new Ag(I) complexes **1** and **2** with a multitopic ligand **L** have been prepared. Their structures illustrate how the metal coordination assembly in the solid state may be influenced significantly not only by the nature of the counterion, but also by the topicity of the ligand.



Maria Augusta Antunes, Ângela Domingos, Isabel Cordeiro dos Santos, Noémia Marques, Josef Takats

Polyhedron 24 (2005) 3038

Synthesis and characterization of uranium(III) compounds supported by the hydrotris(3,5-dimethyl-pyrazolyl)borate ligand: Crystal structures of $[U(Tp^{Me2})_2(X)]$ complexes (X = OC_6H_2-2,4,6-Me_3, dmpz, Cl)

A series of $[U(Tp^{Me2})_2(X)]$ complexes has been prepared by reaction of $[U(Tp^{Me2})_2(NR_2)]$ with protic substrates and halide sources and/or metathesis of $[U(Tp^{Me2})_2I]$. The compounds are structurally similar to the analogous samarium complexes, but the availability of higher oxidation states for uranium leads to a different outcome for the thermolysis of $[U(Tp^{Me2})_2Cp]$.

Sparkle/AM1 modeling of holmium (III) complexes

The sparkle/AM1 model, recently defined for Eu(III), Gd(III) and Tb(III), is now extended to Ho(III). Sparkle/AM1 constitutes the only semiempirical model for the quantum chemical calculation of Ho(III) coordination compounds available, and with geometry prediction accuracies comparable to present day lanthanide complex ab-initio/ECP calculations, while being hundreds of times faster.

Polyhedron 24 (2005) 3052

Unexpected structural analogy between early and late 3d transition metal alkoxide carboxylates: Synthesis and single crystal X-ray study of $Ni_6(OH)_2(OR^N)_6(OCOR)_2$, $R^N = C_2H_4NMe_2$, R = H, CH_3

Modification of the liquid $Ni(OR^N)_2$, $R^N = C_2H_4NMe_2$, with carboxylic acids, results in formation of crystalline heteroleptic complexes $Ni_6(OH)_2(OR^N)_6(OCOR)_2$, R = H (**1**), CH_3 (**3**) with the core structure closely analogous to that of hexanuclear titanium (IV) alkoxide carboxylates.

Polyhedron 24 (2005) 3057

Zn(II) pyrazolonate complexes obtained by metal-induced cyclization of thiosemicarbazones: Crystal structures and spectroscopic properties

The reaction of zinc(II) with thiosemicarbazones derived from β-keto esters induces the cyclization of the thiosemicarbazone to afford $[ZnL_2]$ and $[ZnL_2(MeOH)]$ complexes, where HL is a pyrazolone ligand. The complexes were studied by X-ray diffraction, which showed that the pyrazolonate ligand binds with the metal through the S and N(3) atoms. The ^1H and ^{13}C NMR spectra of these complexes are also discussed.

Polyhedron 24 (2005) 3066

Synthesis and characterisation of $Hf(thd)_2X_2$ derivatives [X = $N(SiMe_3)_2$, $OSiMe_3$ and OSi^tBuMe_2] as precursors for MOCVD of hafnium silicate films

Volatile hafnium β-diketonato derivatives namely $Hf(thd)_2[N(SiMe_3)_2]_2$ (**3**), $Hf(thd)_2(OSiMe_3)_2$ (**4**) and $Hf(thd)_2(OSi^tBuMe_2)_2$ (**5**) (thd = 2,2,6,6-tetramethyl-3,5-heptanedionate) were synthesized and characterized by FT-IR, ^1H NMR, TGA. and by single-crystal X-ray diffraction for $Hf(thd)_3Cl$ and **5**. These compounds were tested as single-source precursors for the deposition of $HfSi_xO_y$ films by pulsed liquid injection MOCVD on Si(100) and R plane sapphire. The films were characterized by XRD and XPS. The as-deposited at 600–800 °C films were essentially amorphous, Hf-rich, smooth and quite pure with respect to carbon contamination

Polyhedron 24 (2005) 3074

Synthesis, structures and reactivity of triosmium clusters containing terminal pyrazines, bridging hydroxy and methoxycarbonyl ligands

Four triosmium carbonyl clusters bearing terminal pyrazines, bridging hydroxy and methoxycarbonyl ligands of general formula $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})L]$ (**1**, L = pyrazine; **2**, L = 2-methylpyrazine; **3**, L = 2, 3-dimethylpyrazine; **4**, L = 2, 3, 5-trimethylpyrazine) were synthesized by the reactions of $[Os_3(CO)_{12}]$ with the corresponding pyrazine derivatives and water in the presence of a methanolic solution of Me_3NO in moderate yields. The reactions of $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})L]$ with a series of two electron donor ligands L′ afforded $[Os_3(CO)_9(\mu\text{-OH})(\mu\text{-OMeCO})L']$ (**5**, L′ = PPh_3; **6**, L′ = $P(OMe)_3$; **7**, L′ = ^{t}BuNC; **8**, L′ = C_5H_5N) in high yields.

Polyhedron 24 (2005) 3082

Synthesis and characterization of chiral iron carbonyl complexes from imine ligands with carbohydrates and amino acids as substituents

Imines derived from 6-amino-6-desoxy-1,2,3-*O*-trimethyl-α-d-glucopyranose or from various amino acid esters react with $Fe_2(CO)_9$ to produce chiral iron carbonyl complexes. The molecular structure of the diiron hexacarbonyl complex of benzylideneamino-l-methionine methyl ester shows that in addition to the α,β-unsaturated imine moiety the sulphur atom of the amino acid side-chain is engaged in binding the metal centres.

Polyhedron 24 (2005) 3091

A study on copper(II)-Schiff base-azide coordination complexes: Synthesis, X-ray structure and luminescence properties of $[Cu(L)(N_3)]X$ (L = Schiff bases; X = ClO_4, PF_6)

Two Schiff bases *N*,*N*′-(bis(pyridin-2-yl)benzylidene)propane-1,3-diamine (pbpd) and *N*,*N*′-(bis(pyridin-2-yl)formylidene)butane-1,4-diamine (pfbd) have been used to synthesize four complexes of the type $[Cu(L)(N_3)]X$ (**1**–**4**) [L = pbpd; X = ClO_4 (**1**); L = pbpd; X = PF_6 (**2**); L = pfbd; X = ClO_4 (**3**); L = pfbd; X = PF_6 (**4**)]. Two representative members of the series, **2** and **3**, have been characterized by single crystal X-ray diffraction measurements. They display intraligand $^1(\pi\text{–}\pi)$ fluorescence at room temperature and intraligand $^3(\pi\text{–}\pi)$ phosphorescence in glassy solutions (MeOH at 77 K). Electrochemical electron transfer study reveals Cu^{II}–Cu^{I} reduction in methanolic solutions.

Syntheses, photoluminescence and electroluminescence of some new blue-emitting phosphorescent iridium(III)-based materials

Some blue-emitting iridium(III) based phosphorescent materials were synthesized and their photoluminescence and electroluminescence behaviors were studied. The relative thermodynamic stability of the *mer* versus *fac* isomer was investigated and correlated to their corresponding redox and photoluminescence properties. The fabrication of a device using *m*CP as the host exhibited improved electroluminescence performance.

Polyhedron 24 (2005) 201

Synthesis, spectroscopic and electrochemical properties of some heteroleptic tris-chelates of ruthenium (II) involving 2,2′-bipyridine (bpy) and *N*-(aryl) pyridine-2-aldimine(L): X-ray crystal structures of $[Ru(bpy)(L_2)_2](ClO_4)_2{\cdot}H_2O$ and 3-*N*(4-tolyl) imidazo [1,5a] pyridinium perchlorate

Reactions of $Ru(bpy)Cl_3$' with *N*-(aryl) pyridine-2-aldimine(L) afford the heteroleptic tris chelate metal complex of the formula $[Ru(bpy)(L)_2](ClO_4)_2{\cdot}H_2O$ (**A**) along with an unusual organic compound, 3-*N*(4-aryl) imidazo [1,5a] pyridinium perchlorate (**B**). One representative member of each has been characterized by X-ray crystallography. All the complexes undergo a quasi-reversible oxidation at ~1.3 to 1.4 V, which may be assigned to a Ru(II) to Ru(III) oxidation. The visible region of the electronic spectra of the complexes consists of a weak transition at ~630 nm and a broad envelope from 600 to 375 nm. 3-*N*(4-Tolyl) imidazo [1,5a] pyridinium perchlorate exhibits luminescence, with a strong emission at ~380 nm.

Polyhedron 24 (2005) 215

Synthesis, characterization and crystal structures of 2,4-di(2-aminopyridine)-6-methypyrimidine (dapmp), $[Cu(dapmp)Cl_2]$ and $[Cu(dapmp)(CH_3COO)_2] \cdot H_2O$

The new ligand dapmp (**1**) and two crystalline polymorphic forms: $[Cu(dapmp)Cl_2]$ (**2**) and $[Cu(dapmp)(CH_3COO)_2] \cdot H_2O$ (**3**), have been synthesized. Single crystal X-ray diffraction showed that (**1**) and (**2**) are each connected by hydrogen bonding to form a one-dimensional supermolecular compound, and (**3**) is connected by hydrogen bonding to form a three-dimensional supermolecular compound.

Polyhedron 24 (2005) 221

One-dimensional coordination polymer $[Co(H_2O)_4(pyz)](NO_3)_2 \cdot 2H_2O$ (pyz=pyrazine) with intra- and inter-chain H-bonds: structure, electronic spectral studies and magnetic properties

Complex (**1**) $[Co(H_2O)_4(pyrazine)](NO_3)_2 \cdot 2H_2O$ forms a one-dimensional coordination polymer along the crystallographic *b*-axis. Hydrogen-bonding between chains forms a two-dimensional network in the *ac*-plane. The solvent effect on the electronic spectra of pyrazine and pyrazine cobalt complex **1** has been investigated. The magnetic susceptibility of **1** versus temperature data showed a strong antiferromagnetic coupling between Co ions.

Polyhedron 24 (2005) 229

Uranyl complexes with the pyridine-2,6-dicarboxylato ligand: new dinuclear species with μ-η^2,η^2-peroxide, μ_2-hydroxide or μ_2-methoxide bridges

New dinuclear uranyl complexes are formed with pyridine-2,6-dicarboxylic acid in the presence of tertiary amines. The two uranyl ions, each of them bound to the nitrogen and two carboxylate groups of the ligand, are bridged by μ-$\eta\eta^2$-peroxide, μ_2-hydroxide or μ_2-methoxide ions. The latter case is the first example of uranyl-bridging methoxide ions to be crystallographically characterized.

Polyhedron 24 (2005) 249

Azido-bridged Cu(II) compounds with asymmetric end-to-end and end-on binding modes: magnetic assignments using a spin dimer model

Dinuclear $[Cu(aepi)(N_3)_2]_2$ (**1**) [aepi=1-(2-aminoethyl)piperidine] and 1D chain $[Cu(aepy)(N_3)_2]_n$ (**2**) [aepy=1-(2-aminoethyl)pyrrolidine] have been prepared and characterized by means of X-ray analysis and magnetic measurements. For **1**, the Cu(II) centers are doubly bridged by end-on (EO) azido units in a basal–apical fashion. The molecular structure of **2** features magnetic centers that are linked by μ-1,1,3 azido groups, forming a 1D chain with alternating EO and end-to-end (EE) azido bridging patterns. Magnetic data for **1** and **2** reveal that ferromagnetic and antiferromagnetic interactions are mediated through EE and EO azido bridges, respectively. These assignments are also confirmed by MO calculations using spin dimer model.

Polyhedron 24 (2005) 257

Dioxomolybdenum(VI) complexes with tri- and tetradentate aminobis(phenolate)s

The reactions of tridentate aminobis(phenol)s with $[MoO_2(acac)_2]$ in methanol lead to the precipitation of monomeric dioxomolybdenum(VI) complexes $[MoO_2(ONO)(MeOH)] \cdot MeOH$. Identical reactions in acetonitrile provide dimeric complexes $[Mo_2O_2(\mu\text{-}O)_2(ONO^R)_2]$. $[MoO_2(acac)_2]$ reacts with tetradentate diaminobis(phenol)s to yield monomeric complexes of type $[MoO_2(ONNO^R)]$. All studied complexes catalyse oxotransfer reactions between DMSO and benzoin or PPh_3.

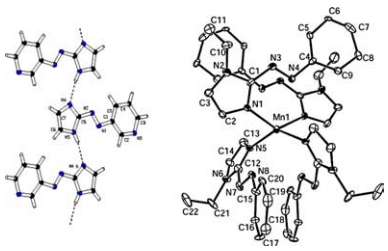
Synthesis, properties and gas phase collision-induced dissociation of the heptanuclear doubly bridged complex $[Ru(bpy)_2(BPE)_2\{Ru_3O(CH_3COO)_6(py)_2\}_2](PF_6)_4$

The electronic coupling in the heptanuclear complex containing two triangular $[Ru_3O]$ clusters attached to a ruthenium polypyridine center, is strong enough to quench its luminescence and the *cis–trans* photoisomerization of the bridging *trans*-1,2-*bis*(4-pyridyl)ethylene (BPE) ligand.

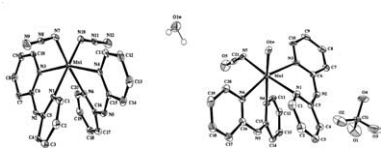


T. Mathur, U.S. Ray, J.-C. Liou, J.S. Wu, T.-H. Lu, C. Sinha

Polyhedron 24 (2005) 739

Manganese(II) complexes of pyridyl-azoimidazoles. Single crystal X-ray structures of 3′-PyaiH and $[Mn(3'\text{-PyaiEt})_4](ClO_4)_2$ (3′-PyaiH = 2-(3′-pyridylazo)imidazole; 3′-PyaiEt = 1-ethyl-2-(3′-pyridylazo)imidazole)

The X-ray structure of 2-[(3′-Pyridyl)azo]imidazole (3′-PyaiH) shows a hydrogen bonded 1D chain. 1-Alkyl-2-[(3′-pyridyl)azo]imidazole (3′-PyaiR′) gives tetrahedral $[Mn(3'\text{-PyaiR}')_4](ClO_4)_2$. The structure has been confirmed by an X-ray study in one case. Azido and thiocyanato complexes, $[Mn(3'\text{-PyaiR}')_2(X)_2]$ (X = N_3, NCS) are also described.



Doyel Bose, Golam Mostafa, Hoong-Kun Fun, Barindra K. Ghosh

Polyhedron 24 (2005) 747

The Mn(II)-2,2′-dipyridylamine-pseudohalide system: Synthesis, crystal structure and luminescence behaviour of $[Mn(dpa)_2(X)_2]\cdot H_2O$ and $[Mn(dpa)_2(X)(OH_2)]ClO_4$ (dpa = 2,2′-dipyridylamine; $X = N_3^-$, NCO^-)

Four mononuclear complexes of the type $[Mn(dpa)_2(X)_2]\cdot H_2O$ (dpa=2,2′-dipyridylamine; $X = N_3^-$, **1**; X = NCO, **2**) and $[Mn(dpa)_2(X)(OH_2)]ClO_4$ ($X = N_3^-$, **3**; $X = NCO^-$, **4**) were synthesized using single-pot reactions of manganese(II) salt, dpa and X in 1:2:2 and 1:2:1 molar ratios, respectively. The compounds have been characterized by X-ray crystallography, microanalytical, physicochemical, spectroscopic and magnetic results. Supramolecular 2D sheet structures are obtained, arising from N–H···N, O–H···N, N–H···O and O–H···O weak intermolecular forces. All thecomplexes display high-energyintraligand $^1(\pi-\pi*)$ fluroscence and intraligand $^3(\pi-\pi*)$ phosphorescence in glassy solutions (DMF at 77 K).

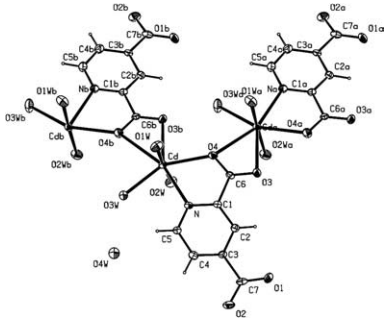
Self-assembly of $[M(Hida)_2]$ ($Hida^-$=iminodiacetate; M=Pd and Pt) in a 2D supramolecular network via extensive hydrogen bonded interactions: Synthesis, X-ray crystal structure, spectroscopic and thermal studies

Reaction of the typically tridentate iminodiacetate ligand (N,O,O′) with M=Pd(II) and Pt(II) results in the self-assembly of $[M(Hida)_2]$ showing 2D supramolecular network via extensive intermolecular hydrogen bonding.



Guillermo Mendoza-Díaz, Graciela Rigotti, Oscar E. Piro, Elsa E. Sileo

Polyhedron 24 (2005) 777

Solid-state ^{111}Cd NMR studies on cadmium(II)-2,*x*-pyridinedicarboxylates. Crystal structure of 2,4-pyridinedicarboxylato triaqua cadmium(II) hemihydrate: $[Cd(II)(2,4\text{-}pydc)(H_2O)_3]\cdot 1/2H_2O$

This paper reports the synthesis and characterisation by solid-stateCd NMR of cadmium 2,*x*-pyridine-dicarboxylates. ^{111}Cd NMR chemical shift is sensitive to the relative position of both carboxylates. The crystal and molecular structure of the seven-coordinated cadmium complex, $[Cd(2,4\text{-}pyridinedicarboxylato)(H_2O)_3]\cdot 1/2H_2O$ is reported. This structure helps in the understanding of how to correlatate coordination and geometry with ^{111}Cd chemical shifts. Anisotropy data is reported.

Polyhedron 24 (2005) 791

Synthesis, electrochemical, and spectroelectrochemical properties of tetrakis(13, 17-dioxa nonacosane-15-sulphanyl)phthalocyaninato zinc(II)

Tetrakis(13,17-dioxa nonacosane-15-sulphanyl) phthalocyaninato zinc(II), ZnPc(SCH(CH_2-$OR)_2)_4$, where R=$C_{12}H_{25}$, was synthesised and investigated electrochemically and spectroelectrochemically in dichloromethane. The well-defined UV–Vis spectra of the electro-reduced and electro-oxidised species of the complex obtained by applied potentials in a thin-layer cell provide a good evaluation of spectral changes. The former shows dimeric formation of the mono-cationic species, while the latter gives characteristic spectral changes corresponding to mono- and di-anionic species of zinc phthalocyanines.

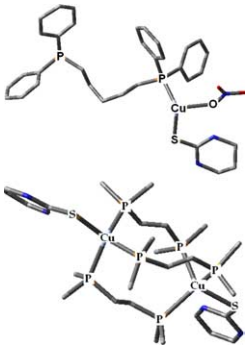
Polyhedron 24 (2005) 847

Structure and solution properties of the cadmium(II)-substituted tungstoarsenate $[Cd_4Cl_2(B\text{-}\alpha\text{-}AsW_9O_{34})_2]^{12-}$

We report on the synthesis and structure of the cadmium(II)-substituted tungstoarsenate $[Cd_4Cl_2(B\text{-}\alpha\text{-}AsW_9O_{34})_2]^{12-}$ (**1**). Polyanion **1** consists of two lacunary $[B\text{-}\alpha\text{-}AsW_9O_{34}]^{9-}$ Keggin moieties linked via a rhomblike $(Cd_4O_{14}Cl_2)$ group leading to a sandwich-type structure. Interestingly, the two external Cd atoms have a terminal Cl ligand, but the derivative with terminal water ligands, $[Cd_4(H_2O)_2(B\text{-}\alpha\text{-}AsW_9O_{34})_2]$(**2**), can also be prepared as shown by ^{183}W and ^{111}Cd solution NMR.



P. Aslanidis, S. Divanidis, P.J. Cox, P. Karagiannidis

Polyhedron 24 (2005) 853

Polymer and cage-type structures in silver(I) complexes with heterocyclic thiones and bridging diphosphine ligands. Crystal structures of $[Ag(\mu\text{-dpppent})(tHpymtH)(ONO_2)]_n$ and $[Ag_2(\mu\text{-}trans\text{-dppen})_3(pymtH)_2](NO_3)_2 \cdot CH_3CN$

The behaviour of the diphos ligands 1,5-bis-(diphenylphosphino)pentane (dppent) and *trans*-1,2-bis(diphenylphosphino)ethene (*trans*-dppen) towards coordination of Ag(I) nitrate in the presence of several heterocyclic thione ligands has been investigated. Both diphosphines adobt the doubly-bridging coordination mode, however, dependent on the nature of the diphos ligand, two types of products have been obtained for the tetrahedraly coordinated metal, namely polymer in the case of the longer chained dppent and triply bridged dimer for the short bite *trans*-dppen. The crystal structure of one representative for each of these two types have been characterized by X-ray crystallography.

Polyhedron 24 (2005) 469

The synthesis and lanthanide coordination chemistry of 2,6-bis[(dicyclohexyl)phosphino-methyl]pyridine *N*,*P*,*P*′-trioxide

The title pyridine *N*-oxide ligand and its pyridine precursor were prepared and characterized by spectroscopic methods. The coordination chemistry was examined with $Er(NO_3)_3$, and the 1:1 complex of the pyridine *N*-oxide ligand, $Er(L)(NO_3)_3 \cdot Me_2CO$, was isolated and structurally characterized by X-ray diffraction methods. The complex contains a nine coordinate Er(III) ion bonded to a tridentate ligand and three bidentate nitrate ions.

Nucleic acid cleavage by a Cu(II) polyaza macrocyclic complex

In this paper, we describe the activity of the $[Cu_2BMXD]$ complex as a nucleic acid cleav-age agent. The rate constant for the DNA backbone cleavage reaction was estimated to be $4.67 \times 10^{-2}\ h^{-1}$ at 50 °C, pH 7.0. We demonstrate that the DNA cleavage reaction promoted by this complex may occur via an oxidative pathway. This study establishes $[Cu_2BMXD]$ as a novel artificial nuclease.

Polyhedron 24 (2005) 549

Lanthanide complexes with a chelating methylenediphosphonate

Reaction of lanthanide (Ln) triflates with tetrakis(*O-iso*propyl)methylenediphosphonate (L) in a 2:1 ratio afforded $[Ln(L)_2(OTf)_2(O\text{-}H_2)_2](OTf)$. In the crystal structure (Ln = Nd), the 8-coordinated metal atom is chelated by the phosphoryl groups of the two phosphonate ligands, and only bonded to two monodentate triflates. This is in contrast with $[Ln(L)_2(NO_3)_2](CH_3CN)_2$ (Ln = Ce, Pr, Nd) where all nitrates are bonded and bidentate. When the L:Ln ratio was increased to 4:1, $[Ln(L)_4](OTf)_3(CH_3CN)_3$ was obtained (Ln = La), in which the triflates are no longer bonded to the metal.

Polyhedron 24 (2005) 383

Diphenyltin(IV) complexes of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate (Hqaldsme and Hqaldsbz): X-ray crystal structures of Hqaldsme and two conformers of its diphenyltin(IV) complex

The complexes, $Sn(NNS)Ph_2Cl$ (NNS= anionic forms of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate) have been prepared and characterized. The structures of the free ligand, Hqaldsme and its diphenyltin(IV) complex, $[Sn(qaldsme)Ph_2Cl]$ have been determined by X-ray diffraction. The complex, $Sn(qaldsme)Ph_2Cl$ crystallizes in two distinctly different conformationally isomeric forms each having the same space group but different lattice parameters. In each polymorph, the tin atom adopts a distorted octahedral geometry.

Polyhedron 24 (2005) 397

New α,ω-dicarboxylate coordination polymers with 4,4′-bipyridine: $Cu(bpy)(C_5H_6O_4)$, $Zn(bpy)(C_5H_6O_4)$, $Zn(bpy)(C_6H_8O_4)$ and $Mn(bpy)(C_8H_{12}O_4) \cdot H_2O$

Metal dimers are co-bridged by 4,4-bipyridine (bpy) and dicarboxylate anions such as glutarate, adipate and suberate anions into (4,4) open layers in $Cu(bpy)(C_5H_6O_4)$ **1**, $Zn(bpy)(C_5H_6O_4)$ **2** and $Mn(bpy)(C_8H_{12}O_4) \cdot H_2O$ **4** as well as into 3D frameworks in $Zn(bpy)(C_6H_8O_4)$ **3**. Twofold interpenetration of 3D frameworks completes the crystal structure of **3**.

Polyhedron 24 (2005) 407

Synthesis and properties of iron (II) quinoline-2-carboxylates, crystal structure of *trans*-diaquabis(quinoline-2-carboxylato)iron (II) bis(dichloromethane) solvate

Reaction between metallic iron and quinoline-2-carboxylic acid (Hquin-2-c) in dichloromethane yielded the amorphous $Fe(quin\text{-}2\text{-}c)_2$ (**1**). In the presence of a small amount of water, X-ray suitable crystals of $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2] \cdot 2CH_2Cl_2$ (**2**) were obtained. The structure of **2** is compared with the literature reported $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2] \cdot 2EtOH\ 2H_2O$ (**3**), a system of strong hydrogen bonds in **2** and **3** create the 2D framework. The spectral and magnetic properties of all compounds are reported.

Polyhedron 24 (2005) 413

New silver(I) coordination architectures of pyridyl dithioether ligands with Ag···Ag, Ag···O, Ag···S and C–H···F weak interactions

The syntheses and crystal structures of three new silver(I) complexes with three structurally related flexible pyridyl dithioether bridging ligands are reported. The differences of the ligand spacers remarkably influence the coordination modes of the ligands and result in different structural complexes. Weak interactions play a crucial role in the self-organization of such supramolecular complexes, and stabilize the complex structures in the solid state.

Polyhedron 24 (2005) 419

Reactions of $[ReX_5(NO)]^{2-}$ with triphenylstibine. Spectroscopic investigations of $[ReX_2(NO)(SbPh_3)_3]$, X-ray structures of $[ReCl_2(NO)(SbPh_3)_3]$ and $[ReBr_2Cl(SbPh_3)_3]$ and DFT calculations for $[ReCl_2(NO)(SbPh_3)_3]$

New rhenium nitrosyls – $[ReCl_2(NO)(SbPh_3)_3]$ (**1**), $[ReBr_2(NO)(SbPh_3)_3]$ (**2**) – have been obtained in the reactions of $[NBu_4]_2[ReX_5(NO)]$ (X=Cl, Br) with triphenylstibine. The complex $[ReBr_2Cl(SbPh_3)_3]$ (**3**) has been isolated in low yield during slow recrystallization of complex **2** from a mixture of chloroform and ethanol. The stibine rhenium nitrosyls have been characterized by IR and UV–vis spectroscopy. The X-ray structures have been determined for **1** and **3**, and the geometric parameters of **1** have been examined using the density functional theory (DFT) method.

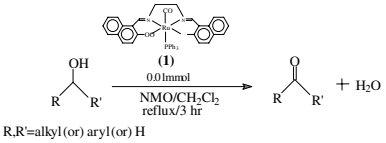
Phosphorus-31 nuclear magnetic resonance study of aluminium(III) *ortho*-phosphate complexes in aqueous solution

^{31}P NMR spectra have been obtained from a set of aqueous solutions containing $Al(ClO_4)_3$–H_3PO_4–NaH_2PO_4 mixtures. It was assumed that there is slow exchange on the NMR time scale at the aluminium centre. Peaks corresponding to phosphate containing species have been assigned by correlating observed fractional peak areas with fractional complex concentrations calculated using a model previously proposed on the basis of potentiometric titration data. The results provide strong support for the model.



peak	species	obsd	calcd
A	H_3PO_4 and $H_2PO_4^-$	0.37	0.40
C+D+H	$Al(H_2PO_4)_2^+$ and $Al(H_2PO_4)_3^0$	0.41	0.47
K	$Al_3H_4(H_3PO_4)_4^{3+}$	0.10	0.08

Novel [3]ferrocenophanes: Syntheses, redox properties and molecular structures of $[Fe\{(\eta^5\text{-}C_5H_4)CMe_2\}_2PR]$ (R=Ph, Cy)

The [3]ferrocenophanes $[Fe\{(\eta^5\text{-}C_5H_4)CMe_2\}_2PR]$ [R=Ph, Cy] were obtained from $Li[\{(C_5H_4)CMe_2\}PR]$ and $FeCl_2$ and characterised spectroscopically (^1H, ^{13}C, ^{31}P, IR, MS), and by crystal structure determination. Electrochemical investigation on $[Fe\{(\eta^5\text{-}C_5H_4)CMe_2\}_2PPh]$ shows a reversible one-electron oxidation in CH_2Cl_2 solution.

Copolymerizations of ethylene and α-olefins with supported piano-stool catalysts

Piano-stool catalysts ($CpTiCl_3$, and related analogues) were covalently bound to a poly(styrene-*r*-4-hydroxystyrene) copolymer, affording macroligated catalysts. Through copolymerization of α-olefins and ethylene, the effects that the macroligand and substituents on the cyclopentadienyl ring have on various polymer properties were investigated.

Polyhedron 24 (2005) 1356

Ansa-titanocene pyrrolyl complexes: The synthesis and structural characterization of $[Me_2Si(C_5Me_4)_2]Ti(NC_4H_4)X$ (X=H, Me, Cl and NC_4H_4) and $[Me_2Si(C_5Me_4)(C_5Me_3\text{-}CH_2)]Ti(NC_4H_4)$

A series of titanium–pyrrolyl compounds, namely $[Me_2Si(C_5Me_4)_2]Ti(NC_4H_4)X$ (X=H, Me, Cl, NC_4H_4) and $[Me_2Si(C_5Me_4)(C_5Me_3\text{-}CH_2)]Ti(NC_4H_4)$ has been synthesized and structurally characterized by X-ray diffraction. Analysis of the $TiNC_4H_4$ bond lengths in these complexes indicates that pyrrolyl does not, by comparison to dialkylamido, act as an efficient π-donor ligand.

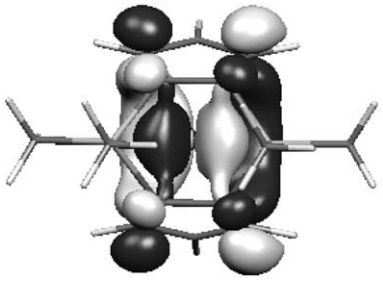
Polyhedron 24 (2005) 1366

The first example of an *ansa*-bis(cyclopentadienyl)aluminum compound. X-ray crystallographic characterization of $[Me_4C_2\text{-}(C_5H_4)_2Al\text{-}\mu\text{-}Cl]_2$ and its monomeric THF and *t*-BuNC adducts. NMR spectroscopic characterization of the structures and fluxional behavior of these compounds in solution

The *ansa*-aluminocene compound $[Me_4C_2\text{-}(C_5H_4)_2Al\text{-}\mu\text{-}Cl]_2$ and its Lewis base adducts $[Me_4C_2(\eta^5\text{-}C_5H_4)_2Al(L)]$ (L=THF, *t*-BuNC) were prepared and their X-ray crystal structures were determined. The solution structures and fluxional rearrangement of these compounds were characterized using a combination of 1-D and 2-D NMR spectroscopic methods.

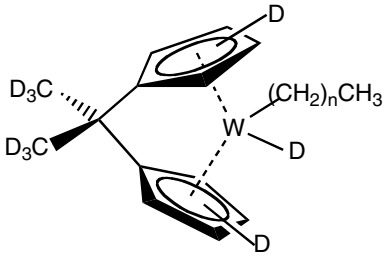


Jennifer C. Green

Polyhedron 24 (2005) 1382

Tuning the gap: Doubly Si-bridged *ansa*-tungstenocene, a proposed intermediate for C–H activation

The doubly Si-bridged *ansa*-tungstenocene, $[W(\eta^5\text{-}C_5H_3)_2(SiMe_2)_2]$ is calculated to have singlet and triplet states of comparable energy, therefore, on an SCF energy surface there is no barrier to formation of a sigma complex with methane, and formation of a methyl hydride is exo-energetic by −125 kJ mol^{-1}.



Malcolm L.H. Green, Stephen L.J. Conway, Linda H. Doerrer

Polyhedron 24 (2005) 1388

Hydrogen/deuterium exchange in alkyl-hydride derivatives of *ansa*-tungstenocene compounds

The higher deuterated *n*-alkyl hydrides $[W\{(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}(R)H](R=\{(CH_2)_n\text{-}CH_3\}$, n=1–4) and $[W\{(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}\{CD_2CD_3\}H]$ undergo hydrogen/deuterium exchange processes under thermal conditions and in every case of all the possible alkyl hydrogens of the alkyl groups R only H/D exchange with the α-CH_2 methylene hydrogens was observed.

Polyhedron 24 (2005) 1133

Novel binuclear copper(II) complexes of di-2-pyridyl ketone *N*(4)-methyl, *N*(4)-phenylthiosemicarbazone: Structural and spectral investigations

Four binuclear complexes $[Cu(dptsc)Cl]_2 \cdot 3H_2O$, $[Cu(dptsc)Br]_2$, $[Cu(dptsc)(\mu\text{-}N_3)]_2$ and $[Cu(dptsc)(NO_3)]_2 \cdot H_2O$ (where Hdptsc = di-2-pyridyl ketone *N*(4)-methyl, *N*(4)-phenylthiosemicarbazone) have been synthesized and physicochemically characterized. Each Cu(II) atom in the monomeric unit exists in a penta-coordinate environment. The single crystals of $[Cu(dptsc)Br]_2$ and $[Cu(dptsc)(\mu\text{-}N_3)]_2$ are centrosymmetric dimers. A distorted square pyramidal geometry is observed around Cu(II) for both the complexes.

Polyhedron 24 (2005) 1153

Electrospray ionization and tandem mass spectrometry characterization of novel heterotrimetallic $Ru(\eta^5\text{-}C_5H_5)(dppf)SnX_3$ complexes and their heterobimetallic $Ru(\eta^5\text{-}C_5H_5)(dppf)X$ precursors

Electrospray ionization and tandem mass spectrometry were used to characterize some novel heterotrimetallic complexes $Ru(\eta^5\text{-}C_5H_5)(dppf)\text{-}SnX_3$ (**1**) (dppf = diphenylpho-sphine ferrocene; X = Cl, Br) and their heterobimetallic precursors $Ru(\eta^5\text{-}C_5H_5)(dppf)X$ (**2**) (X = Cl, Br, I, N_3). The positive-ion ESI mass spectra of **1** and **2** in acetonitrile solution showed the predominant presence of the $[Ru(^5\text{-}C_5H_5)(dppf)]^+$ cation (**3**) of *m*/*z* 721. In the positive-ion ESI mass spectrum of the complex $Ru(\eta^5\text{-}C_5H_5)(dppf)N_3$ (**2d**), another prominent cation of *m*/*z* 735, $[Ru(\eta^5\text{-}C_5H_5)(dppf)N]^+$ (**4**), was also observed. Its formation was proposed to occur via the oxidation of the ruthenium atom followed by the loss of N_2. Cation **3** was proposed to be the catalytic active species in the single-step conversion of methanol to acetic acid.

Polyhedron 24 (2005) 1212

Heterobimetallic cuboidal $[Mo_3NiS_4]$ and $[W_3NiS_4]$ cluster diphosphane complexes as molecular models in hydrodesulfurization catalysis

$[M_3NiS_4X_3(diphos)_3(CH_3CN)]^+$ (M = Mo, W; X = Cl, Br; diphos = dmpe, dppe) clusters have been prepared by addition of $[Ni(cod)_2]$ to incomplete cubane-type sulfido clusters-$[M_3S_4X_3(diphos)_3]^+$. The acetonitrile ligand could be substituted by pyridine, tetrahydrothiophene and carbon monoxide in CH_2Cl_2 at room temperature modelling the catalytic sites of heterogeneous Ni–MoS_2 hydrodesulfurization catalysts. All heterobimetallic $[M_3NiS_4]$ clusters reported show two quasireversible oxidation processes, the molybdenum complexes being ca. 0.2 V more difficult to oxidize than the tungsten analogues.

Polyhedron 24 (2005) 1002

Sucrose bis(1,10-phenanthroline) cobalt(III). Comparison of semi-empirical and ab initio geometrical optimizations

The title compound (sucrose $Co(phen)_2$) is a dication with the Δ-configuration at Co(III) and ligation through O-2(g) and OH-1(f). Earlier geometrical optimization with semi-empirical PM3(tm) parameters had fitted most of the structural evidence from absorption, CD and NMR spectroscopy, although the site of deprotonation was predicted to be OH-1(f) rather than OH-2(g) as shown by NMR spectroscopy. Both HF and DFT treatments have now been used and they correctly predict deprotonation of OH-2(g), in agreement with experimental data. The earlier PM3(tm) optimization indicated extensive bowing of both phenanthrolines due to steric repulsions, but the ab initio treatments indicate limited bowing which fits the NMR chemical shifts of the phenanthroline hydrogens.

Polyhedron 24 (2005) 1015

Synthesis and spectroscopic characterisation of new nickel (II) complexes with 5-methyl-3-formylpyrazole-3-piperidinylthiosemicarbazone (HMP_z3Pi): X-ray structures of HMP_z3Pi and $[Ni(HMP_z3Pi)_2]Cl_2 \cdot 2H_2O$ with indication for unusual rotation about the azomethine double bond of the free ligand on complexation

The synthesis and spectroscopic characterization of 5-methyl-3-formylpyrazole-3-piperidinylthiosemicarbazone, (HMP_z3Pi) and its nickel (II) complexes, $[Ni(HMP_z3Pi)_2]X_2 \cdot 2H_2O$ (X = Cl, Br, ClO_4, BF_4 and NO_3) have been reported. X-ray crystallography of $[Ni(HMP_z3Pi)_2]Cl_2 \cdot 2H_2O$, as a representative species, has authenticated a NiN_4S_2 octahedral coordination with neutral NNS tridentate function of the primary ligand system with two azomethine nitrogen atoms in *trans*-positions and the pyrazolyl nitrogen atoms and thio-keto sulfurs in *cis*-positions. On comparing the crystal structure of the free ligand, HMP_z3Pi, with that of its Ni(II) complex, $[Ni(HMP_z3Pi)_2]Cl_2 \cdot 2H_2O$, it is observed that an unusual rotation about the azomethine double bond occurs during complex formation. A possible mechanism for this phenomenon has been proposed.

Polyhedron 24 (2005) 1047

Ligand behavior of 2,6-pyridinediylbis(2-pyridinyl)methanone in solvent-controlled formation of iron(III) complexes: A novel asymmetric quasi-linear trinuclear core containing an eight-coordinate iron center

The crystal structures of two polymorphic forms of 2,6-pyridinediylbis(2-pyridinyl)-methanone (**1**) crystallized from different solvents have been determined by X-ray crystallography. Solvent-controlled reaction between $FeCl_3$ and **1** yielded four crystalline iron(III) complexes exhibiting two structural types: an asymmetric quasi-linear triiron core with a rarely observed eight-coordinate iron(III) center and three mononuclear moieties. Ligand **1** is solvolyzed at both carbonyl groups in the trinuclear complex but hydrolysis/solvolysis occurs at only one carbonyl site in its mononuclear complexes. The variable-temperature magnetic susceptibilities of **2** were also measured.

Cobalt(II)–azoimidazole complexes: Structures of $[Co(MeaaiMe)_4](ClO_4)_2 \cdot H_2O$ and $[Co(HaaiMe)_2(NCS)_2]$ (MeaaiMe = 1-methyl-2-(*p*-tolylazo)imidazole; HaaiMe = 1-methyl-2-(phenylazo)imidazole)

1-Alkyl-2-(arylazo)imidazole (RaaiR′) coordinates through imidazole-N to Co(II) in a tetrahedral orientation to synthesise $[Co(RaaiR')_4](ClO_4)_2 \cdot H_2O$. The reaction of N_3^- or SCN^- with $[Co(RaaiR')_4](ClO_4)_2 \cdot H_2O$ has synthesized $Co(RaaiR')_2(X)_2$ $(X = N_3^-, SCN^-)$. Representative complexes are characterized by single-crystal X-ray diffraction studies.

The EPR pattern of Cr^V complexes of D-ribose derivatives

1-Substituted D-ribose derivatives form stable Cr^V bischelates where the ligand is bound to Cr^V through the 2,3-diolato moiety of the furanose ring. Cr^V complexes formed with the α- and β-D-ribose derivatives can be easily identified by EPR spectroscopy.

Polyhedron 24 (2005) 1093

Syntheses and X-ray crystal structures of monomeric zinc and mercury bis(silylamides)

Lithium amides $Li[N(SiMe_3)(R)]$ (R = $-SiPh_2{}^tBu$ and adamantyl) have been treated with anhydrous $ZnCl_2$ and $HgBr_2$ to yield the corresponding homoleptic metal silylamides. All complexes are fully characterized and are monomeric as determined by single crystal X-ray crystallography. The adamantyl-containing compounds differ significantly in their solid-state structures. Reactivities of these new compounds with CO_2 are also presented.

Polyhedron 24 (2005) 865

Synthesis and X-ray crystal structures of dinuclear hydrogen-bonded cadmium and lead 2-aminoethanethiolates

An in-depth study of dinuclear Cd and Pbcysteamine complexes has been carried out using NMR, IR, mass spectrometry and X-ray crystallography. The intermolecular hydrogen-bonding involving nitrogen, sulfur and counter anion has not been reported for similar dinuclear complexes, except for $[Hg(aet)_2]Cl_2$, previously reported by us. The structures described here should contribute to the understanding of fundamental Cd and Pb-thiolate chemistry of simple as well as complex molecules such as metallothioneins.

Polyhedron 24 (2005) 872

Triruthenium clusters bearing bridging dppm and capping sulfido ligands: X-ray structures of $[Ru_3(CO)_6(\mu_3\text{-}CO)(\mu_3\text{-}S)(PPh_3)(\mu\text{-}dppm)]$ and $[Ru_3(CO)_6(\mu_3\text{-}S)_2(PPh_3)(\mu\text{-}dppm)]$

Treatment of $[Ru_3(CO)_{10}(\mu\text{-}dppm)]$ (**1**) with PPh_3S at ambient temperature gave $[Ru_3(CO)_7(\mu_3\text{-}CO)(\mu_3\text{-}S)(\mu\text{-}dppm)]$ (**2**) and $[Ru_3(CO)_6(\mu_3\text{-}CO)(\mu_3\text{-}S)(PPh_3)(\mu\text{-}dppm)]$ (**3**). The reaction of $[Ru_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-}dppm)]$ (**4**) with PPh_3 in the presence of Me_3NO afforded **3**, $[Ru_3(CO)_6(\mu_3\text{-}S)_2(PPh_3)(\mu\text{-}dppm)]$ (**5**) and $[(\mu\text{-}H)_2Ru_3(CO)_7(\mu_3\text{-}S)(\mu\text{-}dppm)]$ (**6**). A similar reaction of $[Ru_3(CO)_7(\mu_3\text{-}S)(\mu_3\text{-}Se)(\mu\text{-}dppm)]$ (**7**) with PPh_3 afforded $[Ru_3(CO)_6(\mu_3\text{-}S)(\mu_3\text{-}Se)(PPh_3)(\mu\text{-}dppm)]$ (**8**). Protonation of **4** and **7** with CF_3COOH gave $[(\mu\text{-}H)Ru_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-}dppm)]$ (**10**) and $[(\mu\text{-}H)Ru_3(CO)_7(\mu_3\text{-}Se)(\mu_3\text{-}S)(\mu\text{-}dppm)]^+$ (**11**), respectively, isolated as their PF_6 salts.

Polyhedron 24 (2005) 889

Transition metal quinone–thiosemicarbazone complexes 1: Evaluation of EPR covalency parameters and redox properties of pseudo-square-planar copper(II)–naphthoquinone thiosemicarbazones

EPR studies on pseudo-square-planar copper(II) complexes of naphthoquinone–thiosemicarbazones of the formula [CuLCl] reveal appreciable covalency in the metal–ligand bonding as a consequence of extensive delocalization, while cyclic voltammetric response of these complexes suggests metal-centered redox behavior. There exists a linear relationship between the degree of tetrahedral distortion $f(\alpha)$ with EPR and redox parameters.

Polyhedron 24 (2005) 1907

Synthesis, crystal structures and magnetic properties of two new coordination polymers based on the tricyanoethenolate ligand: $\{Fe(C_5N_3O)_2(CH_3CN)_2\}_\infty$ and $\{Co(C_5N_3O)_2(C_4H_4O)_2\}_\infty$

This paper reports two new Fe(II) and Co(II) compounds in which the 1,2,2-tricyanoethanolate ligand coordinates via two of its three nitrile N atoms which leads to the formation of two-dimensional sheets. The metal atoms are in slightly distorted octahedral environments with axially bonded solvent molecules.

Polyhedron 24 (2005) 1968

Identification of different Co(III) apda complexes: Crystallisation of $[Co(H_2O)_6] \cdot [Co(Hapda)_2]_2 \cdot H_2O$

Two cobalt(III) complexes with a potentially tridentate ligand, apda was investigated. Crystals of $[Co(H_2O)_6] \cdot [Co(Hapda)_2]_2 \cdot H_2O$ were isolated and studied with X-ray diffraction. The Hapda ligand acts as a tridendate ligand with the longer, pronated β-alaninato arms not bonded. The effective use of ^1H NMR to determine the positioning of the chelate rings of apda is illustrated with a comparative study of the title complex with $[Co(apda)(H_2O)_2]$ where apda acts as a tetradentate ligand.

Polyhedron 24 (2005) 1975

Synthesis, molecular characterization by infrared spectroscopy, and crystal structure determination by X-ray powder diffractometry of $[ZnCl_2(TdTz)]$ [TdTz = 2-(3,4-dichlorophenyl) imino-N-(2-thiazin-2-yl)thiazolidine]

The title zinc(II) complex was synthesized through the reaction of 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)thiazolidine (TdTz) with $ZnCl_2$. The crystal structure of the TdTz organic-ligand was resolved by X-ray single-crystal diffractometry. The zinc(II) complex was first characterized by elemental analysis and infrared spectroscopy, and its crystal structure then resolved by X-ray powder diffractometry using direct-space methods. It was found that the complex adopts a pseudotetrahedral geometry around the zinc(II) ion.

Polyhedron 24 (2005) 2027

Synthesis and structural characterization of 2-(−)-menthoxycarbonylethyltin compounds

The title compounds, (−)-MenOCO-$CH_2CH_2SnCl_nPh_{3-n}$ (n = 0, **1**; 1, **2**; 2, **3**; 3, **4**) and [(−)-MenOCOCH$_2$CH$_2$Sn(OH)Cl$_2$]$_2$ · 2(C_2H_5)$_2$O (**5** · 2(C_2H_5)$_2$O) were synthesized and characterized by means of elemental analysis, IR, NMR (^{1}H, ^{13}C and ^{119}Sn) and X-ray crystallography. Compounds **2**–**5** · 2(C_2H_5)$_2$O contain intramolecular carbonyl-to-tin coordination, and the strengths of the interaction between the CO and Sn generally increase in order **1** < **2** < **3** < **4** < **5** · 2(C_2H_5)$_2$O.

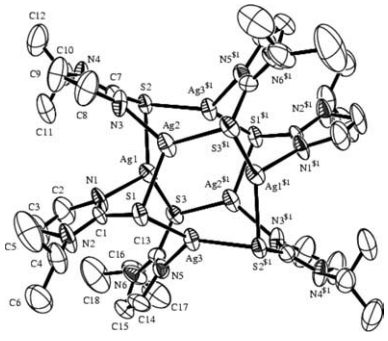
Polyhedron 24 (2005) 2035

Synthesis and characterization of copper complexes with the 2,3-dicyano-5,6-dimercaptopyrazine ligand: Magnetic properties of a ferrocenium salt

Cu(dcdmp)$_2$ was obtained in both dianionic and monoanionic states. The [Fe(Cp*)$_2$]$_2$-[Cu(dcdmp)$_2$] salt presents paramagnetic contributions from both cations and dianions with a large anisotropy and no magnetic ordering down to 1.7 K.



Cu(dcdmp)$_2$

Polyhedron 24 (2005) 2043

Electrochemical synthesis and structural characterization of copper and silver complexes of imidazolidine-2-thione ligands

New multinuclear copper (I) and silver (I) 1-R-imidazolidine-2-thionates of the general formula [Cu(1-RImS)] and [Ag(1-RImS)] (where R = Me, Et, Pr, ^{i}Pr) have been synthesized and characterized. The crystal structures of [Cu(1-EtImS)] (**1**), [Cu(1-PrImS)] (**2**), [Ag(1-PrImS)] (**3**) and [Ag(1-^{i}PrImS)] (**4**) were determined by X-ray diffraction. Compounds (**1**) and (**2**) are tetranuclear and the complexes (**3**) and (**4**) are hexanuclear. In all these compounds each metal atom has a distorted trigonal [MS_2N] environment with each ligand acting as a μ^2-N,S(η^2-S; η^1-N) bidentate S-bridging ligand.

Polyhedron 24 (2005) 2055

Synthesis and characterization of new Ru-CoM (M = Co, Mo) mixed-metal linked tetrahedral clusters containing (−)-DIOP and reaction of $[(\mu_3\text{-Se})RuCo_2(CO)_8]_2$((−)-DIOP) with $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4COCH_3)]$

Four mixed-metal Ru–Co linked tetrahedral clusters have been synthesized from reactions of diphosphine compound (−)-DIOP with $[(\mu_3\text{-E})RuCo_2(CO)_9]$ and $[(\mu_3\text{-E})RuCoMo(CO)_8(CpC(O)CH_3)]$ in *n*-hexane or THF at r.t., respectively. The metallic exchange reaction of $[(\mu_3\text{-Se})RuCo_2(CO)_8]_2$((−)-DIOP) with $Na[Mo(CO)_3(\eta^5\text{-}C_5H_4COCH_3)]$ has also been investigated.

Polyhedron 24 (2005) 1617

Crystal structures and polyphenol oxidase activities of dinuclear copper(II) and cobalt(II) complexes with *N*,*N*,*N*′,*N*′-tetrakis (2′-benzimidazolylmethyl)-1,4-diethylene amino glycol ether (EGTB)

Dinuclear copper and cobalt complexes as model compounds for polyphenol oxidase have been synthesized and characterized. Their activities toward pyrogallol and catechol have been studied, and the kinetics obey the Michaelis–Menten equation.

Polyhedron 24 (2005) 1624

Molecular spectral analysis and crystal structure of the 4-aminopyridinium tetrachloropalladate(II) complex salt

The distortion of aromatic character and stabilization of imino-form as a result of N_{py} protonation of 4-aminopyridine was proved by conventional and linear-dichroic IR-spectroscopy, UV- and ^{1}H-NMR-data. The structure of the model system 4-aminopyridinium tetrachloropalladate(II) complex salt is determined by single crystal X-ray study. The crystallographic results are compared with the spectroscopic ones.

Polyhedron 24 (2005) 1656

Homo- and hetero-metallic manganese citrate complexes: Syntheses, crystal structures and magnetic properties

Mn citrate coordination polymers including Mn/Na and Mn/Ca hetero-bimetal components were synthesized and characterized. The citrate exhibits new coordination modes to connect up to eight or nine metal ions. Weak antiferromagnetic interactions between the Mn(II) sites were correlated to the coordination modes of the carboxylate groups.

Polyhedron 24 (2005) 1689

Transition metal quinone–thiosemicarbazone complexes 2: Magnetism, ESR and redox behavior of iron (II), iron (III), cobalt (II) and copper (II) complexes of 2-thiosemicarbazido-1,4-naphthoquinone

Reactions of naphthoquinone-thiosemicarbazone with Fe(II), Fe(III), Co(II) and Cu(II) yields thionato and thiolato complexes under two different conditions. Magnetic, Mössbauer and EPR measurements reveal unusual magnetic properties for the ferrous and ferric complexes with stabilization of intermediate spin-states, while there exists a significant amount of covalent character in the copper–ligand bonding. These complexes possess metal-centered redox behavior with the iron (III) complexes exhibiting a reversible Fe(III)/Fe(II) redox couple at a fairly positive potential.

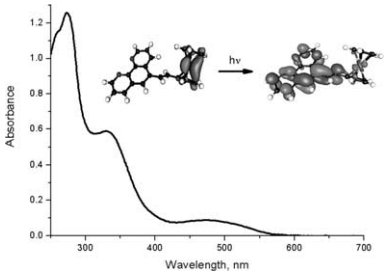
Polyhedron 24 (2005) 1739

Synthesis and structure of lithium amides and solvated derivatives containing bulky bis(silylamide) ligands

Eight new lithium amides, containing various sterically demanding –N[$(SiMe_3)(SiR_3)$] ligands, have been synthesized and structurally characterized in solvated and solvent-free forms. These amides can and have been used in the synthesis of congested metal and main group complexes. Additionally, an unusual trilithium amide with a μ_3-I atom was formed in the reaction between Li[N(adamantyl)$(SiMe_3)$] and CaI_2.

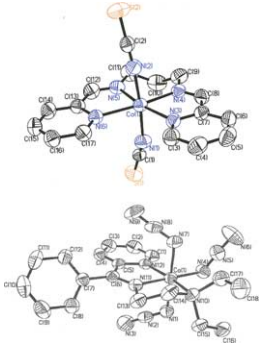


Alvaro Delgadillo, Ana Maria Leiva, Bárbara Loeb

Polyhedron 24 (2005) 1749

Intramolecular excited state quenching: 5-[(*E*)-2-ferrocenylvinyl]-1,10-phenanthroline, a new donor ligand

The 5-[(*E*)-2-ferrocenylvinyl]-1,10-phenanthroline ligand, fcvp, and its corresponding ruthenium complex were synthesized. Ferrocenyl to phenanthroline charge transfer absorption bands were observed in the UV–Vis spectrum. In the ruthenium complex no interaction between the Ru and Fe metal centers was observed in the ground state. In the excited state, the absence of photoluminescence from the Ru center evidences a quenching process, probably of electron transfer nature.



Sk Hafijur Rahaman, Habibar Chowdhury, Doyel Bose, Rajarshi Ghosh, Chen-Hsing Hung, Barindra Kumar Ghosh

Polyhedron 24 (2005) 1755

Synthesis, structure and properties of mononuclear cobalt(II) and cobalt(III) pseudohalide complexes containing N-donor Schiff bases: Synthetic control of metal oxidation levels

Two different sets of hexacoordinated cobalt(II) and cobalt(III) pseudohalide complexes have been prepared in combination with tetra- and tridentate N-donor Schiff bases, respectively. X-ray diffraction measurements of one representative member from each group, viz., *trans*-[Co(pfpd)-$(NCS)_2$] (**1c**) and *mer*-[Co(pbed)$(N_3)_3$] (**2b**) are done to define coordination sphere. All the complexes display intraligand $^1(\pi–\pi^*)$ fluorescence and intraligand $^3(\pi–\pi^*)$ phosphorescence in glassy solutions (MeOH at 77 K).

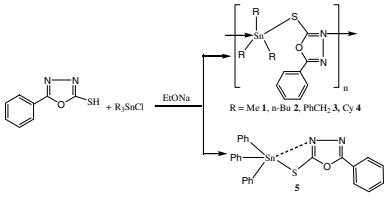
Polyhedron 24 (2005) 1764

Cobalt(II) and cadmium(II) metal complexes of a 2-aminobenzimidazole-thiazine derivative ligand. Synthesis, characterization and X-ray structure determinations

Thiazine/2-aminobenzimidazole derivative ligand *N*-(5,6-dihydro-4H-1,3-thiazin-2-yl)-2-aminobenzimidazole (BzTz) and its cobalt(II) and cadmium(II) complexes were synthesized and characterized by physical measurements. The X-ray crystal structures of BzTz, cobalt and cadmium complexes have also been determined. The geometry around the metallic atoms can be described as a distorted tetrahedron.



Chun-Lin Ma, Guang-Ru Tian, Ru-Fen Zhang

Polyhedron 24 (2005) 1773

Investigation on steric effect in the coordination of S, N and O donor heterocycle to organotin(IV): Syntheses and crystal structures of triorganotin(IV) derivatives with 5-phenyl-1,3,4-oxadiazole-2-thiol

A series of organotin(IV) complexes with 5-phenyl-1,3,4-oxadiazole-2-thiol of the type $R_3Sn[S(C_8H_5N_2O)]$ (R = Me **1**, *n*-Bu **2**, $PhCH_2$ **3**, Cy **4**, Ph **5**) have been synthesized. Among them, the central tin atoms of complexes **1**–**5** are all five-coordinated with the distorted trigonal bipyramidal geometry. Interestingly, the complexes **1**–**4** exhibit 1D polymeric chains through Sn and N intermolecular interactions.

Polyhedron 24 (2005) 1781

Lateral macrobicyclic compartmental mono and binuclear nickel(II) complexes derived from phenolate ligands: Synthesis, spectral, electrochemical and kinetic studies

Lateral macrobicyclic compartmental mono and binuclear nickel(II) complexes were synthesized. Spectral, electrochemical and kinetic studies were carried out. Cyclic voltammetric studies show quasireversible one electron reduction waves both in cathodic and anodic region. The catalytic activities of the complexes towards hydrolysis of 4-nitrophenyl phosphate increase with macrocyclic ring size. Macrocyclic ring size influences the electrochemical (reduction) and catalytic properties of the complexes.

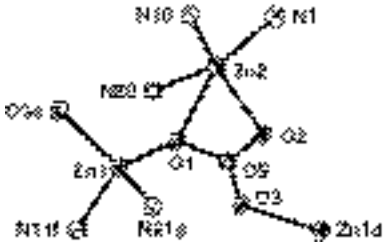
Polyhedron 24 (2005) 571

Synthesis and structural characterization of three new manganese(II) diphosphonates with layered and double-chain architectures

Hydrothermal reactions of two substituted aminodiphosphonic acids, $C_6H_5CH_2N(CH_2PO_3H_2)_2(H_4L^1)$ and 4-CH_3–$C_6H_4CH_2N(CH_2PO_3H_2)_2(H_4L^2)$, with manganese(II) acetate resulted in three manganese(II) diphosphonates with a layered and double chain structure, namely, $Mn(H_2L^1)$ (**1**), $Mn(H_3L^1)_2$ (**2**) and $Mn_2(H_2L^2)_2(H_2O)$ (**3**). Compounds **1** and **3** are layered with interlayer distances of 12.65 and 16.28 Å, respectively. Compound **2** features 1D double chains along the *c*-axis that are interlinked by strong hydrogen bonds between non-coordinated phosphonate oxygens.

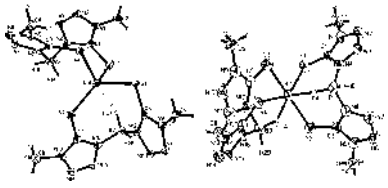


Juraj Černák, Bibiana Ferencová, Zdirad Žák

Polyhedron 24 (2005) 579

First example of atmospheric carbon dioxide uptake by a cyanocomplex: Preparation and structural characterization of $Zn_2(tn)_2(CO_3)Ni(CN)_4{\cdot}H_2O$ (*tn*=1,3-diaminopropane)

Aqueous system Zn(II)-*tn*-$[Ni(CN)_4]^{2-}$ (*tn*=1.3-diaminopropane) in contact with air captured carbon dioxide yielding coordination polymer $Zn_2(tn)_2(CO_3)Ni(CN)_4{\cdot}H_2O$. The carbonato ligand coordinates three zinc atoms by an unusual mode, two by an unidentate and one by a bidentate fashion with one oxygen donor atom forming two ZnO coordination bonds.



Yu-Ling Wang, Rong Cao, Wen-Hua Bi

Polyhedron 24 (2005) 585

Syntheses and characterizations of Co(II) and Ni(II) complexes of dihydrobis(thioxotetrazolyl)borato with $Co[S_4]$ and $Ni[S_4H_2]$ cores

Two novel complexes $Co(Btt^{Me})_2$ (**1**) and $Ni(Btt^{Me})_2$ (**2**) were synthesized by reaction of the dihydrobis(1-methyl-5-thiotetrazolyl)-borato ligand (Btt^{Me}) with anhydrous $CoCl_2$ and $NiCl_2{\cdot}6H_2O$, respectively. **1** features a central $[CoS_4]$ core with a very weak apical Co···H–B interaction, whereas **2** features a central $[NiS_4H_2]$ core and exhibits relatively strong Ni···H–B interactions.

Polyhedron 24 (2005) 601

Chelating behavior of 2-hydroxyacetophenone *N*(4)-disubstituted thiosemicarbazones: Facile formation of Mn(IV) complexes – X-ray structure, EPR and cyclic voltammetric studies

Facile formation of three manganese(IV) complexes (MnL_2) occur when 2-hydroxyacetophenone *N*(4)-disubstituted thiosemicarbazones (H_2L) were treated with manganese(II) acetate tetrahydrate in ethanol–methanol medium under aerobic condition. The crystal structure of $Mn(L^2)_2{\cdot}0.25H_2O$ reveals an octahedral geometry with a skewed arrangement of the ligand about the metal ion. EPR spectra at 77 K shows a weak $g \approx 4$ signal and a strong sextet at $g \approx 2$ consistent with manganese(IV) with marginally distorted octahedral environment. Cyclic voltammetry in DMSO/dichloromethane show reversible and quasi-reversible peaks corresponding to Mn(IV)/Mn(III) redox couple.

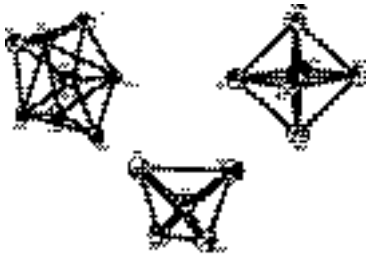
Polyhedron 24 (2005) 619

Raman spectra and structure of $PbCl_2$–ACl (A=K,Cs) melts

Isotropic and anisotropic Raman spectra of molten mixtures of $PbCl_2$–ACl (A=K,Cs) have been measured up to 680 °C. The relative intensities at different temperatures and compositions indicate the formation of polynuclear Pb coordination polyhedra of the type $Pb_nCl_{3n}^{n-}$ ($n \leqslant 4$). Dipole–induced-dipole interactions appear to be important for these melts.



Barbara Barszcz, Stanisław A. Hodorowicz, Katarzyna Stadnicka, Agnieszka Jabłońska-Wawrzycka

Polyhedron 24 (2005) 627

A comparison of the coordination geometries of some 4-methylimidazole-5-carbaldehyde complexes with Zn(II), Cd(II) and Co(II) ions in the solid state and aqueous solution

Reactions of Zn(II), Cd(II) and Co(II) ions with 4-methylimidazole-5-carbaldehyde afforded four novel complexes. The compounds were characterized by X-ray diffraction, establishing tetrahedral, distorted dodecahedral and octahedral coordinating geometries of the Zn(II), Cd(II) and Co(II) metal ions, respectively. In solution, NMR and potentiometric methods have confirmed the preference of the central ions not only to adopt a specific coordination number and geometry of the coordination polyhedra, but also the function of the ligands which can be either monodentate or bidentate.

Polyhedron 24 (2005) 671

Synthesis, structure and properties of mercury complexes with a new extended tetrathiafulvalene 4,5-dithiolate ligand

A new extended tetrathiafulvalene dithiolate ligand, benzotetrathiafulvalenedithiolate ($btdt^{2-}$), and mercury complexes based on it have been synthesized and characterized. The crystal structure of $(Me_4N)_2[Hg(btdt)_2]$ is determined. The extending planar conjugation system with phenyl on the ligand framework increases intermolecular reaction and leads to the enhancement of conductivity.

Polyhedron 24 (2005) 679

Studies on cobalt(II), nickel(II) and copper(II) derivatives of some new *meso*-aryl substituted octabromoporphyrins

A series of Co(II), Ni(II) and Cu(II) derivatives of a variety of porphyrins with tolyl (MTxTP) and naphthyl moieties (MNxTP) as *meso*-substituents and their octabromoderivatives (MTxOBP and MNxOBP) by Br-substitution at the eight β-pyrrole positions were synthesised and characterised. The changes observed in their electronic spectra are explained in terms of the energy level re-ordering of the HOMO and LUMO levels due to electron withdrawing Br substituents and the concerted action of eight bulky Br atoms bringing about distortional change on the π-framework, and also due to the mesomeric effect due to *meso*-aryl moieties. The EPR spectra of the Cu(II) derivatives of bromoporphyrins have their spin-Hamiltonian parameters altered when compared to their nonbrominated analogues indicating pronounced electron spin delocalisation on the porphyrinato moiety.

In situ infrared and EXAFS studies of an Ag cluster in zeolite X

The local structures are investigated by EXAFS for the Ag^+–X zeolite up to 300 °C. By evacuation, the coordination number of N_{Ag-O} decreases by removal of water molecules. At 300 °C, N_{Ag-Ag} becomes 2.9, which indicates the stabilization of Ag clusters in the zeolite framework, as shown by IR results.

Polyhedron 24 (2005) 693

Di- and tetranuclear silver (I)-saccharinate complexes with 2-pyridineethanol and 2-pyridinepropanol: Syntheses, crystal structures, spectroscopic and thermal analyses of $[Ag_2(sac)_2(pyet)_2]$ and $[Ag_4(sac)_4(pypr)_2]$

Two silver (I) complexes of saccharin with 2-pyridineethanol (pyet) and 2-pyridinepropanol (pypr) are reported. In $[Ag_2(sac)_2(pyet)_2]$, two monomeric $[Ag(sac)_2(pyet)]$ units are doubly bridged by the sulfonyl oxygen atoms of the sac ligands, forming an $[Ag_2(sac)_2(pyet)_2]$ dimer, in which each silver (I) centre is three coordinate with a T-shaped coordination. The tetranuclear complex, $[Ag_4(sac)_4(pypr)_2]$, is achieved by bridging of $[Ag_2(sac)_2]$ with two [Ag(sac)(pypr)] units through the sulfonyl oxygen atoms of the sac ligands. The two silver (I) ions in the centre with a short Ag–Ag bond distance of 2.8480(13)Å exhibit a T-shaped geometry with three sac ligands, while the two terminal silver (I) ions are coordinated by a sac ligand and a pypr ligand in a near linear geometry.

Polyhedron 24 (2005) 701

Crystal, molecular and electronic structure of the $[ReCl_3(bipy)(PPh_3)]$ complex

X-ray structure of the $[ReCl_3(bipy)(PPh_3)]$ complex has been determined and its geometric parameters have been examined using the density-functional theory method. The UV–Vis spectrum of the complex has been discussed on the basis of the electronic transitions of $[ReCl_3(bipy)(PPh_3)]$ calculated with the time-dependent DFT method.

Salicylaldoxime (H_2salox) in iron(III) carboxylate chemistry: Synthesis, X-ray crystal structure, spectroscopic characterization and magnetic behavior of trinuclear oxo-centered complexes

Two neutral trinuclear oxo-centered complexes, $[Fe_3(\mu_3\text{-}O)(O_2CPh)_5(salox)L_1L_2]$ (salox = the dianion of salicylaldehyde oxime, $L_1 = L_2 =$ MeOH (**1**), $L_1 =$ EtOH, $L_2 = H_2O$ (**2**)) have been studied by X-ray crystallography, EPR (solid state and frozen solutions) and ^{57}Fe Mössbauer spectroscopies, and their magnetic properties have been explored.

Macrocyclic dioxadiaza from the reaction of the (1,8-diamino-3,6-dioxaoctane)copper(II) cation with formaldehyde and the carbon acids nitroethane or diethylmalonate

New square-planar copper(II) complexes of 13-membered diazadioxa macrocyclic ligands have been prepared by the one-pot template reactions of formaldehyde, 1,8-diamino-3,6-dioxaoctane with the carbon acids nitroalkane or diethylmalonate in the presence of the copper(II) ion. The spectra of the complexes show that the two nitrogen and two oxygen atoms are coordinated to the copper(II) ion.

Laser ablation generation of arsenic and arsenic sulfide clusters

Laser ablation synthesis and simultaneous identification of arsenic clusters As_n^+ (n = 2–7) and arsenic sulfides generated from As_2S_3, As_2S_5 and/or arsenic-sulfur mixtures was studied using MALDI-TOF mass spectrometry. The following arsenic sulfide ions and/or clusters were generated and identified: AsS, AsS_2, AsS_3, AsS_4, AsS_5, AsS_6, AsS_7, AsS_8, As_2S, As_2S_2, As_2S_3, As_2S_4, As_2S_5, As_2S_6, As_2S_7, As_3S, As_3S_2, As_3S_3, As_3S_4, As_3S_5, As_3S_6, As_3S_7, As_4S_3, As_4S_4. Several of them are described for the first time.

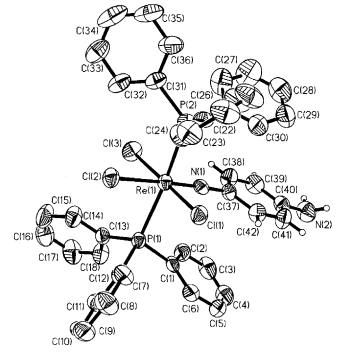
Polyhedron 24 (2005) 1445

Synthesis and characterization of $[RuCl_2(picoline)_4]$ complexes: Crystal structure of $[RuCl_2(\beta\text{-pic})_4]$

The reaction of the $[RuCl_2(PPh_3)_3]$ complex with picolines has been examined. New ruthenium(II) complexes – $[RuCl_2(C_6H_7N)_4]$ have been obtained. The crystal structure of the $[RuCl_2(\beta\text{-pic})_4]$ complex has been determined. The electronic spectra of the complexes have been calculated by the TDDFT method.



B. Machura, R. Kruszynski, M. Jaworska

Polyhedron 24 (2005) 1454

Reactivity of $[ReOX_3(PPh_3)_2]$ complexes towards 1,4-diaminobenzene: X-ray structure and DFT calculations of the $[Re(4\text{-}NC_6H_4NH_2)Cl_3(PPh_3)_2] \cdot PPh_3$ complex

The reaction of $[ReOX_3(PPh_3)_2]$ (X = Cl and Br) complexes with 1,4-diamnobenzene has been examined and novel imido rhenium complexes – $[Re(4\text{-}NC_6H_4NH_2)X_3(PPh_3)_2]$ – have been obtained. The crystal and molecular structure of $[Re(4\text{-}NC_6H_4NH_2)Cl_3(PPh_3)_2]$ has been determined, and its molecular diagram has been calculated with the density functional theory (DFT) with the use of the B3LYP functional. Additional information about binding in the $[Re(4\text{-}NC_6H_4NH_2)Cl_3(PPh_3)_2]$ complex has been obtained by NBO analysis. The time-dependent DFT method (TDDFT) has been used for calculations of spin-allowed singlet–singlet electronic transitions of $[Re(4\text{-}NC_6H_4NH_2)Cl_3(PPh_3)_2]$, and on this basis the UV–Vis spectrum has been interpreted.

Polyhedron 24 (2005) 1461

Syntheses, characterization and glass-forming properties of new bis[5-((4-^{n}dodecyloxyphenyl)azo)-*N*-(4-^{n}alkoxyphenyl)-salicylaldiminato]nickel (II) complex homologues

A homologue series of bis[5-((4-dodecyloxyphenyl)azo)-*N*-(4-alkoxyphenyl)-salicylaldiminato)]nickel (II) complexes has been synthesized and characterized by NMR, elemental analyses and IR spectroscopy. DSC, X-ray powder diffraction and optical polarizing microscopy studies indicated that the Ni complexes have a resistance to crystallization and give an amorphous glassy state, but after annealing at room temperature for several days transform to an anisotropic glass.

Polyhedron 24 (2005) 1478

Synthesis of gadolinium(III) and samarium(III) complexes of new potentially heptadentate (N_4O_3) tripodal Schiff base ligands, and a theoretical study

The synthesis and characterization of two new potentially heptadentate N_4O_3 tripodal Schiff base ligands H_3L^1 and H_3L^2 are reported. The neutral gadolinium(III) and samarium(III) complexes, [Ln(L)], of these bulky ligands and also a gadolinium(III) complex of a previously known ligand, H_3L^3, were also synthesized and characterized by various spectroscopic methods. The relative capability of these ligands as well as their unsubstituted analogs to encapsulate a lanthanide ion, herein La(III), has been theoretically studied.

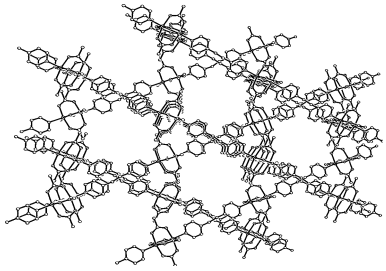
Polyhedron 24 (2005) 1487

1-Dimensional and 2-dimensional coordination network structures in the Ba–Ce–dipicH_2 system (dipicH_2 = dipicolinic acid)

Coordination polymers with similar stoichiometries, but very different network structures form in the Ce–Ba–dipicH_2 system depending on the crystallization conditions. $Ba(OH_2)_6Ce(dipic)_3$ (A) is a structural analog of $SrCl_2 \cdot 6H_2O$. At the vertices of the triangles are $Ce(dipic)_3^{2-}$ ions, while a $Ba(H_2O)_9^{2+}$ chain is threaded through the triangles. Its polymorph (B) has a structure analogous to that of PbO. The dark junctions in the net are $Ce(dipic)_3^{2-}$ ions while the lighter junctions represent carboxylate linked $Ba(H_2O)_4^{2+}$ ions.



Hui-Ling Hu, Maw-Cherng Suen, Chun-Wei Yeh, Jhy-Der Chen

Polyhedron 24 (2005) 1497

Synthesis and structures of two new copper(II) coordination polymers with pyridyl ligands

The reaction of $Cu(OAc)_2 \cdot H_2O$ with bpa (bpa = 1,2-bis(4-pyridyl)ethane) in CH_3OH afforded the complex $[Cu_2(OAc)_4(bpa) \cdot 2H_2O]_n$ (**1**) while the reaction of $CuSO_4 \cdot 5H_2O$ with bpen (bpen = *trans*-bis(4-pyridyl)ethene) in CH_3OH afforded the complex $[Cu(bpen)(H_2O)_3(SO_4) \cdot 4H_2O]_n$ (**2**). Complexes **1** and **2** form molecular chains which, linking by C–H···π, π–π interactions and hydrogen bondings, line up in layers with each layer crossing the layer beneath to form rhombic channels. Thermal gravimetric analyses and differential scanning calorimetry were carried out to investigate their thermal properties.

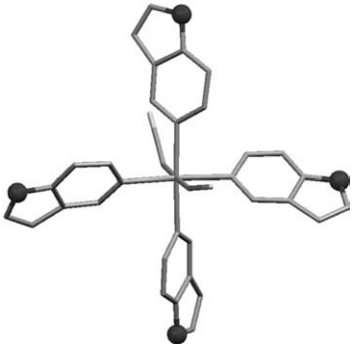
Polyhedron 24 (2005) 1503

mer-Tris(β-alaninato)cobalt(III): Crystal structure, solution properties and its DNA cleavage in the presence of ascorbic acid

The complex *mer*-[Co(β-ala)$_3$] has been characterized by X-ray crystallography, UV–Vis spectroscopy, electrospray ionization-mass spectroscopy and cyclic voltammetry. The complex alone cannot cleave DNA but can do so in the presence of ascorbic acid.



Peter Baran, Miroslav Boča, Roman Boča, Alžbeta Krutošíková, Jozef Miklovič, Juraj Pelikán, Ján Titiš

Polyhedron 24 (2005) 1510

Structural characterization, spectral and magnetic properties of isothiocyanate nickel(II) complexes with furopyridine derivatives

The nickel(II) complexes $[Ni(L^n)_4(NCS)_2]$, where L^1 = furo[3,2-*c*]pyridine, L^2 = 2-methylfuro[3,2-*c*]pyridine, L^3 = 2,3-dimethylfuro [3,2-*c*]pyridine, L^4 = benzo[4,5]furo[3,2-*c*]pyridine and L^5 = isoquinoline, have been prepared and characterized by structural, spectroscopic and magnetic methods. The structures of the all complexes are formed by isolated molecules. The Ni(II) ions are six-coordinate, the equatorial planes are formed by four N-donor heterocycles whereas the isothiocyanate groups coordinate in the axial positions. The magnetism of the complexes exhibits a zero-field splitting, the magnitude of which correlates with the distortion degree of the coordination polyhedra.

Susheela Dholia, Raj N. Mehrotra

Polyhedron 24 (2005) 1517

Estimate of the electron exchange rate constant for the 6-molybdocobaltate(III)/(II) couple from studies on the oxidation with iodide using Marcus theory

Estimate of the electron exchange rate constant for the 6-molybdocobaltate(III)/(II) couple from studies on the oxidation with iodide using Marcus theory. The oxidation of iodide ion by hexahydrogenhexamolybdocobaltate(III) ion in perchloric acid is described by the reactions.

$$[H_6Co^{III}Mo_6O_{24}]^{3-} + H^+ \overset{K}{\rightleftharpoons} [HH_6Co^{III}Mo_6O_{24}]^{2-}$$

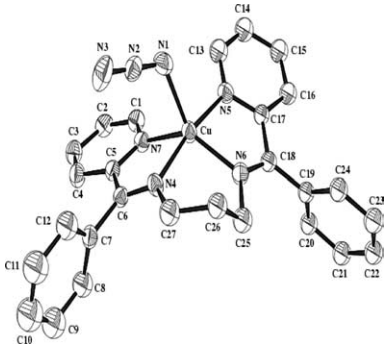
$$[H_6Co^{III}Mo_6O_{24}]^{3-} + I^- \xrightarrow{k_4} [H_6Co^{II}Mo_6O_{24}]^{4-} + I^{\bullet}$$

$$[HH_6Co^{III}Mo_6O_{24}]^{2-} + I^- \xrightarrow{k_5} [HH_6Co^{II}Mo_6O_{24}]^{3-} + I^{\bullet}$$

$$I^{\bullet} + I^- \underset{k_{-6}}{\overset{k_6}{\rightleftharpoons}} I_2^{-\bullet}$$

$$[HH_6Co^{III}Mo_6O_{24}]^{2-} + I_2^{-\bullet} \xrightarrow{k_8} I_2 + [HH_6Co^{II}Mo_6O_{24}]^{3-}$$

$$I_2 + I^- \underset{k_{-9}}{\overset{k_9}{\rightleftharpoons}} I_3^-$$



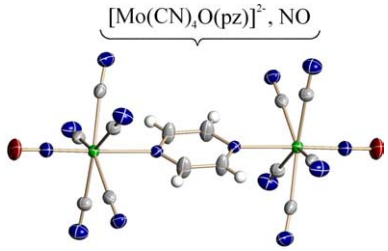
The self-exchange rate constant for the $HCo^{III}Mo_6^{2-}/HCo^{II}Mo_6^{3-}$ couple is estimated from the application of the Marcus theory.

Sk Hafijur Rahaman, Rajarshi Ghosh, Tian-Huey Lu, Barindra K. Ghosh

Polyhedron 24 (2005) 1525

Chelating *N*,*N*′-(bis(pyridin-2-yl)alkylidene)-propane-1,3-diamine pseudohalide copper (II) and cadmium(II) coordination compounds: Synthesis, structure and luminescence properties of $[M(bpap)(X)]ClO_4$ and $[M(bpap)(X)_2]$ [M = Cu, Cd; X = N_3^-, NCS^-]

The chelating ligand, *N*,*N*′-(bis(pyridin-2-yl)-alkylidene)propane-1,3-diamine (bpap) is used to synthesise complexes of type $[Cu(bpap)(N_3/NCS)]ClO_4$ (**1a**–**3b**) and $[Cd(bpap)(N_3/NCS)_2]$ (**4a**–**6b**). Elemental, spectral, electrochemical and other physicochemical results characterize the complexes. The structures of $[Cu(bpbp)(N_3)]ClO_4$ (**3a**) and $[Cd(bpbp)(NCS)_2]$ (**6b**) have been solved using X-ray diffraction. All the complexes display intraligand $^1(\pi-\pi^*)$ fluorescence and intraligand $^3(\pi-\pi^*)$ phosphorescence in glassy solutions (MeOH at 77 K).



Dariusz Matoga, Janusz Szklarzewicz, John Fawcett

Polyhedron 24 (2005) 1533

Unexpected direct incorporation of NO in the Mo(IV) coordination sphere. X-ray crystal structure of $(PPh_4)_4[\{Mo(CN)_5(NO)\}_2(\mu\text{-pz})] \cdot 2C_2H_5OC_2H_5$

The preparation and characterization of the stable molybdenum cyanonitrosyl dimer, $[\{Mo(CN)_5(NO)\}_2(\mu\text{-pz})]^{4-}$ with bridging pyrazine (pz), is described. The product is formed in anaerobic conditions by direct synthesis from NO and $[Mo(CN)_4O(pz)]^{2-}$ ions as starting materials. The reaction involves unexpected oxo ligand release and NO incorporation. The dimer composition is confirmed by elemental analysis, X-ray crystal structure, ESI-MS spectra as well as UV–Vis, EPR and IR spectroscopy.

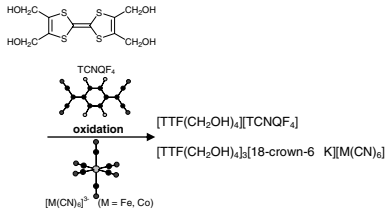
Polyhedron 24 (2005) 1549

An unprecedented $\mu_4\text{-}SiF_6^{2-}$-bridged supramolecular polymer consisting of bis-μ-F^- bridged dinuclear Cu(II) dications

Using thermal conditions a unique supramolecular Cu(II) polymer built up of $[Cu_2(dipyridylamine)_2(\mu\text{-}F)_2]$ motifs repeated infinitely along the (0 1 0) direction via SiF_6^{2-} bridges was synthesised.

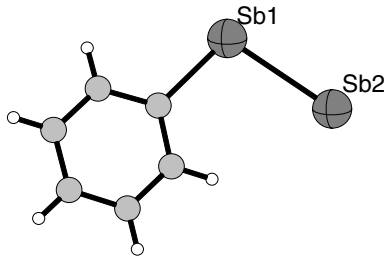


Sandrine Perruchas, Kamal Boubekeur, Philippe Molinié

Polyhedron 24 (2005) 1555

Radical cation salts of $TTF(CH_2OH)_4$ with cyanide anions: Synthesis, crystal structure and magnetic properties of $[TTF(CH_2OH)_4][TCNQF_4]$ and $[TTF(CH_2OH)_4]_3[18\text{-crown-}6 \subset K][M(CN)_6] \cdot DMF$ (M = Fe, Co)

The synthesis, crystal structures and magnetic properties of radical cation salts formulated $[TTF(CH_2OH)_4][TCNQF_4]$ and $[TTF(CH_2OH)_4]_3[18\text{-crown-}6 \subset K][M(CN)_6] \cdot DMF$ (M = Fe, Co) are described. In these salts, associating the tetrakis(hydroxymethyl)tetrathiafulvalene with cyanide anions, the organic molecules are combined in oligomers and strong hydrogen bonds occur between them and the anions.



Katharina Wiesler, Nikolaus Korber

Polyhedron 24 (2005) 1565

Synthesis and crystal structure of the phenyl-substituted diantimonide $PhSb_2^{3-}$ in the ammoniate $[Cs_6(PhSb_2)_2] \cdot 11NH_3$

The highly charged diatomic anions Pn_2^{4-} (Pn = P to Bi) of the group 15 elements are known only in solids like Cs_4Sb_2. However, if the overall charge is reduced by introducing a phenyl residue, an anion like $PhSb_2^{3-}$ may be crystallised as a thermally unstable ammoniate. In analogy to the original Zintl chemistry, the compound $[Cs_6(PhSb_2)_2] \cdot 11NH_3$ forms by reducing triphenylantimony with a solution of caesium in liquid ammonia.

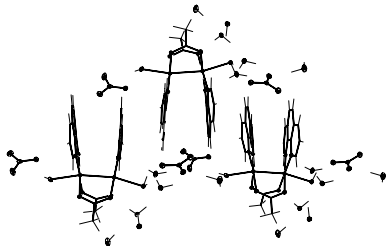
Polyhedron 24 (2005) 1569

Coordination chemistry of Co(III) complexes of an azetidine-derived quadridentate amine and a related macrocycle

The azetidine ring of a quadridentate ligand is protected from nucleophilic ring-opening by coordination and imparts a rigidity to the ligand which limits the stereoisomerism of its Co(III) complexes, crystal structures of which show evidence for extensive hydrogen-bonding and lipophilic interactions.

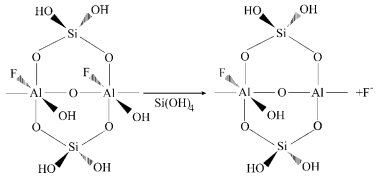


Katarzyna Wajda-Hermanowicz, Florian P. Pruchnik, Marek Zuber, Zbigniew Ciunik

Polyhedron 24 (2005) 1577

Studies of the interaction between adenosine 5′-triphosphate and $[Rh_2(OAc)_2(phen)_2(H_2O)_2](OAc)_2$

ATP interacts with binuclear rhodium (II) complex $[Rh_2(OAc)_2(phen)_2(H_2O)_2](OAc)_2$ by stacking with the phenanthroline ligand. The interaction of Rh(II) complex have been investigated using ^1H, ^{13}C, ^{31}P NMR, ^1H–^{15}N NMR HMBC experiments and UV–VIS difference spectroscopy. NMR and UV–VIS measurements suggest that phosphate residue of ATP does not interact with the positively charged $[Rh_2]^{2+}$ in axial position. In the presence of $[Rh_2(OAc)_2(phen)_2(H_2O)_2](OAc)_2$ in acidic solutions (pD 3.35) deprotonation of N1 nitrogen atom of ATP molecule occurs.

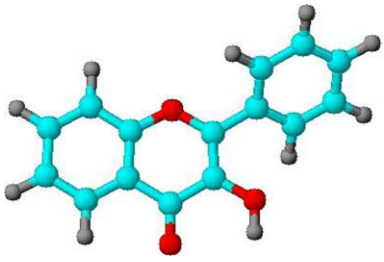


Stanislav Strekopytov, Christopher Exley

Polyhedron 24 (2005) 1585

The formation, precipitation and structural characterisation of hydroxyaluminosilicates formed in the presence of fluoride and phosphate

Hydroxyaluminosilicates (HAS) are important secondary mineral phases formed by the reaction of silicic acid with aluminium. There are two discrete forms of HAS (HAS_A and HAS_B) and we now show the accomodation of fluorine into both forms through its replacement of hydroxyl groups coordinated to octahedral aluminium.



Latitia Dangleterre, Jean-Paul Cornard

Polyhedron 24 (2005) 1593

Interaction of lead (II) chloride with hydroxyflavones in methanol: A spectroscopic study

The interactions between lead (II) ions and 3-hydroxyflavone, 5-hydroxyflavone and 3′,4′-dihydroxyflavone were investigated. The complexes were characterized by electronic absorption spectroscopy combined with chemometrics methods. The stoichiometry composition and stability of complexes have allowed to classify the different sites of chelation of Pb(II) according to their complexing capacity in the following way: catechol > α-hydroxy-carbonyl > β-hydroxy-carbonyl.

The coordination chemistry of tripodal tetraamine ligands

This paper reviews the coordination chemistry of tripodal tetraamine ligands. The different possible arm lengths and N-donor atom types mean that these ligands display a remarkable diversity in their coordination chemistry with both transition metal ions and lanthanide ions, and they are found in chemical species ranging from simple mononuclear metal complexes to heterometallic polynuclear complexes and polymeric metallosupramolecular arrays. Aspects of such chemistry are detailed in this paper.

Polyhedron 24 (2005) 41

Bis(μ-alkoxo)-bridged dinuclear iron(III) complexes of pyrazole-based ligands as models for iron-oxo proteins

The synthesis, characterization, magnetic properties and the reactivity studies of two new bis(μ-alkoxo)-bridged dinuclear iron(III) complexes, $[Fe(nhep)Cl_2(EtOH)]_2$ and $[Fe(nhed)Cl_2]_2$ are reported. In compound **1**, the iron(III) center has a coordination number of six, with a slightly distorted octahedral geometry. In compound **2**, the bulkier nhed ligand, with methyl groups at the 3- and 5-positions of the pyrazole ring, leads to a coordination number of five at the iron(III) center in a distorted square pyramidal geometry. The magnetic properties of both complexes indicate the presence of fairly weak antiferromagnetic exchange interactions between iron(III) ions.

Polyhedron 24 (2005) 49

Synthesis, crystal structure and spectroscopic characterization of a novel bis (oxo-bridged) dinuclear vanadium(V)–dipicolinic acid complex

A new bis(oxo-bridged) binuclear compound of formula $[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$ has been synthesized and characterized by single-crystal X-ray diffraction and spectroscopic techniques. The compound sits at a crystallographic inversion center with the pair of V(V) atoms in an edge-sharing distorted octahedral environment. Two methylguanidinium acts as counterions for charge balance.

Some *trans*-chlorobis(triphenylphosphine)-ruthenium(II) complexes with N,N,O-donor *N*-(aroyl)-*N*′-(picolinylidene)hydrazines

Syntheses, characterization and physical properties of complexes having the formula *trans*-[RuL(PPh$_3$)$_2$Cl] where L$^-$ represents deprotonated tridentate Schiff bases derived from one mole equivalent each of 2-pyridinecarbaldehyde and aroylhydrazines have been described. The complexes are redox active and display several absorptions in the electronic spectra.

Polyhedron 24 (2005) 65

Luminescence study of Ru(II) bipyridine–acridine spaced by amide and proline bridges

The photophysical properties of the polypyridyl ruthenium(II) complexes bridged to the acridine chromophore by an amide, one and two prolines were investigated. The inductive effect of the carbonyl group from the bridges cause a decrease in the energy level of the MLCT excited state. The folded structure of the *cis*-[Ru(bpy)$_2$mbpy–(Pro)$_2$acrd] complex confer the fastest rate of T–T energy transfer.

Polyhedron 24 (2005) 89

Dialkyldithiocarbamate derivatives of toluene-3,4-dithiolato arsenic(III) and -bismuth(III): synthetic, spectral and single crystal X-ray structural studies

Dialkyldithiocarbamate complexes of the type [C$_6$H$_3$(CH$_3$)S$_2$MS$_2$CNR$_2$] [M=As or Bi] have been synthesized and characterized using physico-chemical and spectral methods. Single crystal X-ray diffraction analyses of toluene-3,4-dithiolatoarsenic(III) dimethyldithiocarbamate and pyrrolidinedithiocarbamate revealed a monodentate chelating mode of the ligand moieties.

Polyhedron 24 (2005) 129

Pseudotetrahedral cobalt(II) complexes with thiazoline and thiazine derivative ligands: synthesis and characterization

Two cobalt complexes were obtained through the reaction of 2-(3,4-dichlorophenyl)imino-N-(2-thiazolin-2-yl)thiazolidine (TdTn) with $CoCl_2{\cdot}6H_2O$ and 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)thiazolidine (TdTz) with the same metallic salt. Both compounds were characterized by single crystal X-ray diffraction, elemental analysis, spectroscopic and magnetic measurements. Both complexes present a pseudotetrahedral geometry around the cobalt (II) ion.

Polyhedron 24 (2005) 181

Silver(I) bis(1,2,4-triazolyl)borate complexes containing bidentate phosphine ligands

New silver(I) derivatives containing bidentate phosphine and anionic bis(triazol-1-yl)borate ligands have been prepared from the reaction of $AgNO_3$, $K[H_2B(tz)_2]$ and dppm, dppe or dppf. In $[\{H_2B(tz)_2\}_2Ag_3(dppm)_2(NO_3)_3]$, the silver atom has a $PAgN_3$ environment, utilizing the coordinating capability of one of the additional (exo'-) ring nitrogens not only to complete the four-coordinate array about the silver but, necessarily, to link successive asymmetric units into a single-stranded polymer.

Polyhedron 24 (2005) 2065

Single-molecule magnets: a molecular approach to nanoscale magnetic materials

A brief survey is provided of single-molecule magnets (SMMs), or molecular nanomagnets. The $[Mn_{12}O_{12}(O_2CR)_{16}(H_2O)_4]$ (Mn_{12}; R = various) family of SMMs continues to be the one with the highest blocking temperatures, and the one on which the most detailed studies are being performed within the chemistry and physics communities. For this reason, methods have been developed for their controlled modification in various ways, and these are summarized. In addition, new SMMs continue to be sought to improve knowledge of this phenomenon, and several representative examples of new synthetic procedures and the resulting products are described.

Polyhedron 24 (2005) 2076

Synthesis and characterization of germanium (IV) and silicon (IV) complexes derived from 9-hydroxyphenalenone: X-ray crystal and molecular structure of tris-(9-oxophenalenone)-germanium (IV) and silicon (IV) salts

Two new hexacoordinated germanium and silicon cations containing three phenalenyl units were prepared by reacting 9-hydroxyphenalenone with germanium tetrachloride ($GeCl_4$) and silicon tetrachloride ($SiCl_4$) and characterized by single crystal X-ray diffraction. The cyclic voltammograms show three reversible one-electron reduction steps due to the formation of the radical, anion and dianion as each phenalenyl moiety accepts an electron.

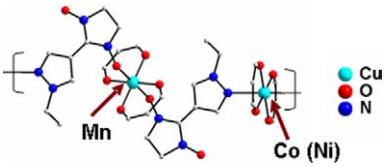
Polyhedron 24 (2005) 2084

Heterospin compounds based on the $[Mn_6(O)_2Piv_{10}]$ cluster unit and nitroxides

Synthetic procedures have been developed to prepare heterospin compounds based on the $[Mn_6(O)_2Piv_{10}]$ polymetallic nucleus. The structure of these compounds has been studied. To obtain highly dimensional structures demands structural complementarity of the $[Mn_6(O)_2Piv_{10}]$ and NIT-R nuclei, which is only possible when R = CH_3.

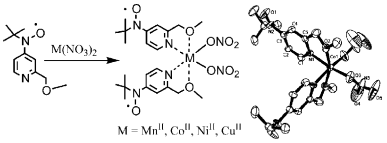


Ksenia Maryunina, Sergey Fokin, Victor Ovcharenko, Galina Romanenko, Vladimir Ikorskii

Polyhedron 24 (2005) 2094

Solid solutions: An efficient way to control the temperature of spin transition in heterospin crystals $M_xCu_{1-x}(hfac)_2L$ (M = Mn, Ni, Co; L = nitronyl nitroxide)

A series of mixed-metal solid solutions $M_xCu_{1-x}(hfac)_2L$ (M = Mn, Ni, and Co) liable to undergo thermally induced spin transitions have been synthesized. The structure and magnetic properties of the compounds have been investigated.

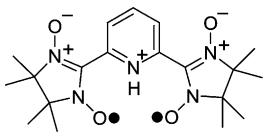


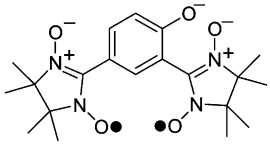
Zhicheng Zhu, Satoru Karasawa, Noboru Koga

Polyhedron 24 (2005) 2102

Crystal structures and magnetic properties of complexes of $M(NO_3)_2$; M = Mn^{II}, Co^{II}, Ni^{II}, and Cu^{II}, with pyridine ligands carrying an aminoxyl radical

Four complexes of $M(NO_3)_2$(**4NOPy-OMe**)$_2$, (**4NOPy-OMe** = 4-(*N-tert*-butyloxylamino)-2-(methoxymethylenyl)pyridine, and M=Mn^{II}, **1**; Co^{II}, **2**; Ni^{II}, **3**; Cu^{II}, **4**), were prepared and fully characterized. The magnetic properties of all complexes were investigated by SQUID magneto/susceptometry.





Tadashi Sugano, Stephen J. Blundell, William Hayes, Peter Day

Polyhedron 24 (2005) 2108

Magnetism in organic diradical ion salts based on nitronyl nitroxide

Magnetism in organic diradical ion salts based on (2,4-POBNN)$^{\bullet-}$ and (2,6-PYBNN)$^{\bullet+}$ were investigated by using SQUID magnetometers. The diradical cation salt (2,6-PYBNN)$^{\bullet+}Cl^-$ shows intramolecular ferromagnetic interaction with the exchange coupling constant J/k = +9.0 K and intermolecular antiferromagnetic interaction with the Weiss constant θ = −0.75 K. The intermolecular interaction in the diradical cation salt is about one hundred times as low as that observed in the neutral diradical (2,6-PYBNN)$^{\bullet}$, while the intramolecular interaction is close to that obtained for the neutral radical.

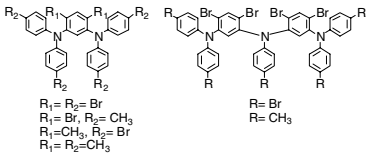
Polyhedron 24 (2005) 2112

Synthesis and properties of a triarylamine derivative with a coordination site and its copper (II) complex

A novel ligand with a redox active triarylsamine unit and its copper complex were designed and synthesized. Electrochemical and spectroscopic properties of the complex were examined.

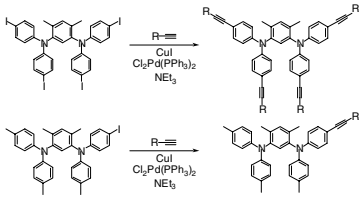


Masafumi Yano, Yasuyuki Nakanishi, Kosuke Matsushita, Masakazu Tatsumi, Munetaka Oyama, Kazunobu Sato, Takeji Takui

Polyhedron 24 (2005) 2116

Organic high-spin systems of oligoarylamines: Properties of tetraaryl-*m*-phenylendiamine oligocations as examined by electron transfer stopped-flow method

Triarylamine-based diamines and triamines were synthesized as precursors of positvely charged high-spin systems. Their electrochemical and spectroscopic prooerties were examined.

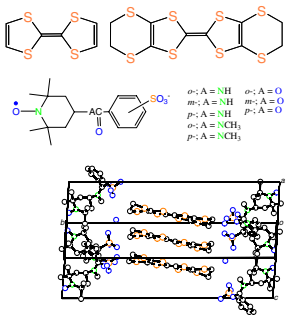


Masafumi Yano, Teruyuki Furuya, Masanori Yonezawa, Masakazu Tatsumi, Munetaka Oyama, Kazunobu Sato, Takeji Takui

Polyhedron 24 (2005) 2121

Synthesis, electrochemical and spectroscopic studies of highly extended tetraaryl-*m*-phenylenediamines as precursors of ground-state triplet dications

Various highly π-extended tetraaryl-1,3-phenylenediamines were synthesized. Their electrochemical and spectroscopic properties were also examined.

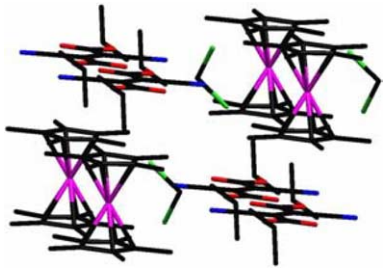


Hiroki Akutsu, Kazuyoshi Masaki, Kenji Mori, Jun-ichi Yamada, Shin'ichi Nakatsuji

Polyhedron 24 (2005) 2126

New organic free radical anions TEMPO–A–CO–(*o*-, *m*-, *p*-)$C_6H_4SO_3^-$(A = NH, NCH_3, O) and their TTF and/or BEDT-TTF salts

We have prepared eight TEMPO-containing anions TEMPO–A–CO–(*n*-)$C_6H_4SO_3^-$ (*n* = *o*, *m*, *p* for A = NH (**N1**, **N2**, **N3**), *n* = *o*, *p* for A = NCH_3 (**M1**, **M3**), and *n* = *o*, *m*, *p* for A = O (**O1**, **O2**, **O3**)) as PPh_4 salts. Metathesis of their salts with $(TTF)_3(BF_4)_2$ gave their TTF salts. Electrocrystallization of BEDT-TTF with $PPh_4 \cdot$ **M1** yielded the α-(BEDT-TTF)$_3$(**M1**)$_2 \cdot 8H_2O$ salt. We report their crystal structures, electrical resistivities, and magnetic properties. The relation between crystal structures and physical properties are discussed.



α-(BEDT-TTF)$_3$(TEMPO-N(CH$_3$)CO-*o*-$C_6H_4SO_3$)$_2 \cdot 8H_2O$

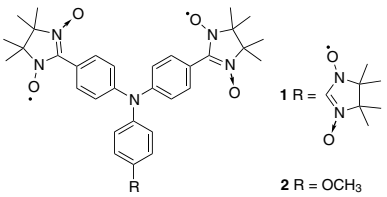
Polyhedron 24 (2005) 2133

Structure–property correlations in a family of decamethylmetallocenium charge-transfer salt magnets using dialkyl dicyanofumarates as the one-electron acceptors: Ferromagnetism versus metamagnetism

Charge-transfer salts from the reactions of decamethylmanganocene or decamethylchromocene and di-*n*-propyl dicyanofumarate or di-isopropyl dicyanofumarate have been prepared and characterized. Taken together with previously published compounds, a homologous series has thus been assembled that exhibits a change from ferromagnetism to metamagnetism correlated to a change in crystal structure.



Yoshiaki Nakano, Takuya Yagyu, Takamasa Hirayama, Akihiro Ito, Kazuyoshi Tanaka

Polyhedron 24 (2005) 2141

Synthesis and intramolecular magnetic interaction of triphenylamine derivatives with nitronyl nitroxide radicals

Two triphenylamine derivatives bearing nitronyl nitroxide radicals, **1** and **2**, were synthesized. The weak antiferromagnetic interactions exist between the nitronyl nitroxide moieties in **1** and **2**, and furthermore, those radical groups are oxidized much easier than the central triphenylamine moiety.

Polyhedron 24 (2005) 2148

Water-induced ferromagnetism in cobalt acetylide CoC_2 nanoparticles

New molecule-based magnet CoC_2 shows water-induced ferromagnetism caused by the orientation ordering of C_2^{2-} molecules. In the anhydrous phase, the orientation of C_2^{2-} is disordered, resulting in the small ferromagnetic domain and superparamagnetism. Once the material absorb the water, the orientation of C_2^{2-} is ordered and the ferromagnetic domains expand, resulting in the ferromagnetic behavior.

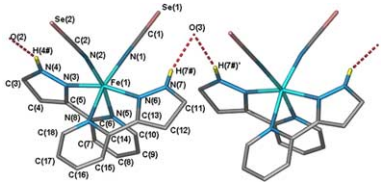
Polyhedron 24 (2005) 2160

Two-dimensional molecular magnets based on $[Pt(mnt)_2]^-$ ions: Structures and magnetic properties

A compound consists of [1-(4′-fluorobenzyl)-pyridinium][$Pt(mnt)_2$], and two polymorphisms of its were caused from the solvent molecule, MeCN, incorporating into lattice. The anions of $[Pt(mnt)_2]^-$ in two polymorphs array into different manner of 2D layer, and the neighboring anions in a 2D layer possess AFM interactions.



Ben A. Leita, Boujemaa Moubaraki, Keith S. Murray, Jonathan P. Smith

Polyhedron 24 (2005) 2165

Spin-crossover in dimeric hydrogen-bonded iron(II) 2-(pyrazolyl)-pyridine and 2-(imidazolyl)-pyridine complexes

A family of iron(II) *cis*-$[FeL_2(NCX)_2]_2(\mu$-solvate) complexes has been made and structurally characterised, where L is a bidentate pyrazolyl- or imidazolyl-pyridine and X = S, Se. Solvate (water and methanol) molecules hydrogen-bond to NH groups on neighbouring L groups thus forming discrete pseudo-dimeric species, one of which, with X = Se, displays a 'half' spin-crossover. This spin transition is absent upon desolvation.

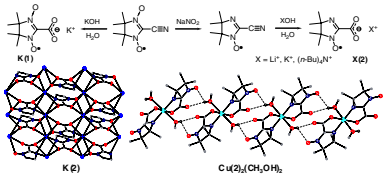
Polyhedron 24 (2005) 2173

Uniaxial strain study in purely organic ferromagnet α-TDAE-C_{60} – Mechanism and structure

ESR has been carried out in ferromagnetic α-TDAE-C_{60} under uniaxial strain to study the mechanism and structure of ferromagnetism. Pressure is applied to a single crystal embedded in epoxy resin with a clamp type pressure cell. A preliminary study demonstrates that the uniaxial strain induces a change of the Curie temperature T_C, which depends on the crystal axis where the uniaxial strain applied.

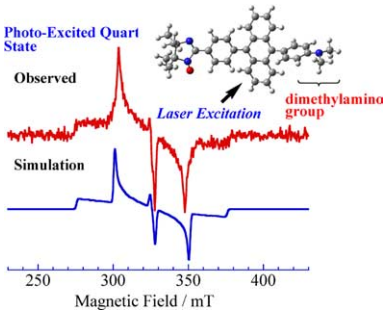


Eugene Tretyakov, Sergey Fokin, Victor Ovcharenko, Galina Romanenko, Yury Shvedenkov

Polyhedron 24 (2005) 2176

A new approach to synthesis of α-nitronyl nitroxide carboxylates. First metal complexes with α-imino nitroxide carboxylate

α-Nitronyl- (**1**) and α-imino nitroxide carboxylates (**2**) were prepared by hydrolysis of the corresponding nitriles. A series of heterospin complexes with **2** were synthesized. For K(**2**), $Cu(\mathbf{2})_2(CH_3OH)_2$, and $Ni(\mathbf{2})_2(py)_2$, crystal and molecular structure has been determined. For $Cu(\mathbf{2})_2$ and $Ni(\mathbf{2})_2$(bipy), cooperative magnetic ordering has been recorded at 16.6 and 4.6 K, respectively.

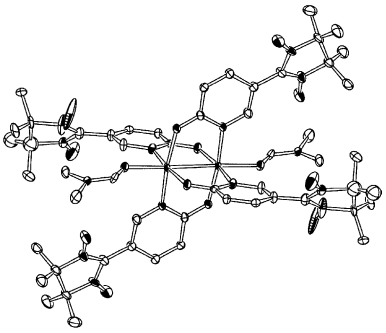


Yoshio Teki, Satoru Nakajima

Polyhedron 24 (2005) 2185

Design, synthesis and electronic states of an iminonitroxide radical with excited quartet high-spin state and photo-induced electron transfer in its CT complex

We report the design, synthesis and electronic state of a π-conjugated stable iminonitroxide radical, **1**, the electron donor property of which is improved by an attachment of dimethylamino group. The photo-excited quartet high-spin state was observed by a time-resolved ESR experiment.

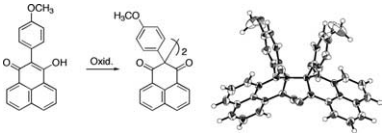


Mikio Ueda, Mamoru Itou, Kazuya Okazawa, Tomoyuki Mochida, Hatsumi Mori

Polyhedron 24 (2005) 2189

Metal complexes with pyridone-based radicals: Preparation and properties of a dinuclear paddle-wheel copper(II) complex and a mononuclear palladium(II) complex

By reaction of a pyridine-based open-shell ligand (**HL**) involving a nitronyl nitroxide moiety with copper(II) and palladium(II) ions, a dinuclear paddle-wheel type complex $[Cu_2(\mathbf{L})_4(DMF)_2]$ (**1**, figure) and a mononuclear complex *trans*-$[PdCl_2(\mathbf{HL})_2]$ (**2**) were prepared. These complexes were characterized structurally and magnetically; the small intramolecular antiferromagnetic interaction in the latter complex may originate from superexchange through the diamagnetic metal center.

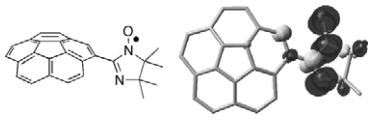


Yasushi Morita, Shinsuke Nishida, Kozo Fukui, Kunio Hatanaka, Tomohiro Ohba, Kazunobu Sato, Daisuke Shiomi, Takeji Takui, Gaku Yamamoto, Kazuhiro Nakasuji

Polyhedron 24 (2005) 2194

2-Aryl substituted 3-oxophenalenoxyl radicals: π-Spin structures and properties evaluated by dimer structure

X-ray crystal structure analysis and variable temperature ^1H NMR study have revealed the dimeric structure of 2-(*p*-methoxyphenyl)-3-oxophenalenoxyl neutral radical. Density functional theory calculations have shown that the kinetic instability of this radical is attributed to the relatively localized nature of the π-spin density distribution, which supports our previous ESR study.



Shinsuke Nishida, Yasushi Morita, Tadahiro Kobayashi, Kozo Fukui, Akira Ueda, Kazunobu Sato, Daisuke Shiomi, Takeji Takui, Kazuhiro Nakasuji

Polyhedron 24 (2005) 2200

Spin delocalization on curved surface π-system: Corannulene with iminonitroxide

Corannulene with iminonitroxide radical has been designed and synthesized as a novel stable bowl-shaped neutral radical. ESR/ENDOR/TRIPLE spectroscopies and density functional theory calculation have shown that appreciable amount of π-spin is delocalized onto the corannulene moiety, although most of the π-spin density is localized on the iminonitroxide moiety.

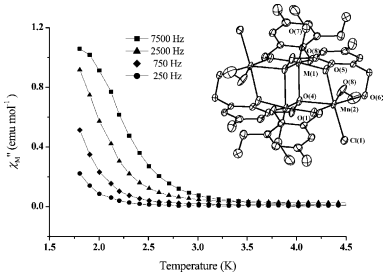
Polyhedron 24 (2005) 2205

Single-molecule magnets: $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]^{0/-}$

The syntheses, X-ray crystal structures and magnetic properties of $[Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]$ (**1**) and $[PPh_4][Mn_{12}O_{12}(O_2CCF_2Cl)_{16}(H_2O)_4]$ (**2**) are reported. The results of DC and AC magnetic susceptibility studies are described. Complexes **1** and **2** exhibit two out-of-phase component of the AC magnetic susceptibility with frequency dependent maxima. The anisotropic energies U/k_B are 82.7, 64.8, 56.4 and 32.4 K for complexes **1**(HT), **2**(HT), **1**(LT) and **2**(LT), respectively. Step-like features are seen on hysteresis loops of complex **1**. DC decay relaxation of complex **1** shows quantum tunneling behavior below 2.1 K.



Chen-I Yang, Gene-Hsiang Lee, Ching-Shuei Wur, Jauyn G. Lin, Hui-Lien Tsai

Polyhedron 24 (2005) 2215

Syntheses, structures and single-molecule magnetic behaviors of two dicubane Mn_4 complexes

Two tetranuclear manganese complexes, $[Mn_4(HL)_4(MeOH)_4X_2]$ (X = Cl, Br; H_3L = 2,6-bis(hydroxymethyl)-4-methylphenol), consist of a mixed-valence dicubane structure, which comprises two Mn^{II} and two Mn^{III} ions. Magnetic susceptibilities and magnetization of both complexes indicate that two clusters have an $S = 9$ ground state. The AC frequency-dependent out-of-phase signals susceptibilities were observed in the low temperature range indicating a slow magnetic relaxation.

Two halide exchange in copper(II) halide dimers: $(Morpholinium)_2Cu_2Cl_xBr_{6-x}$

Hydrogen bonding forces short halide···halide contacts of ~4 Å between otherwise structurally isolated copper(II) dimers in the $(morpholinium)_2Cu_2Cl_xBr_{6-x}$ salts. This contacts provide an efficient magnetic exchange pathway between dimers, so that the systems behave as alternating antiferromagnetic chains. The strength of this halide···halide coupling is approximately seven times as large in the bromide salt as in the chloride salt.

$(NBu_4)Ni(mnt)_2$: A novel bistable high temperature spin-Peierls-like system

The title compound contains novel stacks of antiferromagnetically coupled $[Ni(mnt)_2]^-$ anions. A structural phase transition takes place at 170 K that leads to an increase in the antiferromagnetic interactions, leading to rapid drop in the magnetic susceptibility in the low temperature phase. The phase transition is driven by thermally induced disorder in one arm of the tetrabutylammonium cations. A 7° hysteresis in the phase transition is observed.

Polyhedron 24 (2005) 2274

A theoretical study of electronic structures and intermolecular magnetic interactions for spiro-biphenalenyls

In order to inquire into the mechanism of the change in the magnetism of spiro-biphenalnyls, intermolecular magnetic interaction is investigated in terms of the effective exchange integral of the Heisenberg model for dimeric pairs of diethyl-substituted spiro-biphenalenyl. Variation of the magnetic interaction with respect to temperature is evaluated for X-ray crystallographic structures at several temperature points by Kohn–Sham hybrid-DFT. The intermolecular magnetic interactions were calculated for the π-dimers to be antiferromagnetic at each temperature.

Polyhedron 24 (2005) 2280

Origin of the fast magnetization tunneling in tetranuclear nickel single-molecule magnets

The single-molecule magnet behavior of Ni_4 complexes is characterized by magnetization hysteresis loops. The origin of the fast magnetization tunneling is the result of transverse quartic zero-field interactions (the B_4^4 term in the spin Hamiltonian) as indicated by high-field EPR experiments. The presence of ligand dynamics that become static at low temperatures and are the origin of the splitting of EPR signals observed at low temperature is confirmed by heat capacity and low temperature X-ray crystallography experiments.

Theoretical direct evaluation of inter-dimer *J* values in BETS salts

Inter-dimer magnetic interactions ($J_{ab(D)}$) between BETS donors in the κ-$BETS_2FeCl_4$ crystal were studied theoretically by using of ab initio MO and DFT methods. These interaction parameters can describe spin properties. In cluster of four BETS molecules with two holes, more accurate $J_{ab(D)}$ values were evaluated directly, though such $J_{ab(D)}$ values were already evaluated from inter-molecular magnetic interaction ($J_{ab(M)}$) with the approximate equation $J_{ab(D)} = J_{ab(M)}/2$. In cluster of six molecules with three holes, competition of three antiferromagnetic interaction was discussed. Necessity of calculation under periodic condition and for surrounding cluster was introduced.

Two isomeric $[Mn_{12}O_{12}(OMe)_2(O_2CPh)_{16}(H_2O)_2]^{2-}$ single-molecule magnets and a Mn^{III} polymer prepared by a reductive aggregation synthetic route

Two isomeric $[Mn_{12}O_{12}(OMe)_2(O_2CPh)_{16}(H_2O)_2]^{2-}$ complexes (see core structure; blue Mn, red O, gray C) and the polymer $[Mn(OMe)(O_2CPh)_2]_n$ were the first products isolated by a new synthetic procedure in Mn cluster chemistry involving reductive aggregation of permanganate (MnO_4^-) ions in MeOH/benzoic acid. The new Mn_{12} anions are structural variants of the well known $[Mn_{12}]$ family of SMMs and exhibit SMM properties, whereas the polymer is antiferromagnetically coupled with a diamagnetic ground state.

AF molecular rings for quantum computation

In this work we show that heterometallic molecular rings with dominant antiferromagnetic exchange coupling between nearest neighbors are suitable electronic spin systems for the implementation of quantum algorithms. One of the main advantage in using molecular clusters is the size of the qubit that will help in the addressing single quantum object. We also underline a further resource of molecular clusters made by their excited states that in a proper computational scheme may constitute an important feature to consider.

Molecular nanoclusters as magnetic refrigerants: The case of Fe$_{14}$ with very large spin ground-state

We report on the magnetic and thermal properties of the Fe$_{14}$ molecular nanocluster. We find a huge magnetocaloric response in the temperature range below 10 K. This is to large extent caused by its very large spin ground-state combined with an excess of entropy arising from the admixture of low-lying excited S states. We also show that the high degree of symmetry of the Fe$_{14}$ cluster core, resulting in a very small cluster magnetic anisotropy, enables the occurrence of long-range antiferromagnetic order below T_N = 1.87 K.

Spin dynamics and level crossing in nanoscale molecular magnet V15 cluster studied by ^{1}H-NMR

We have carried out ^{1}H-NMR to investigate the spin dynamics in a molecular magnet $K_6[V_{15}As_6O_{42}(H_2O)]8H_2O$ (in short, V15). The temperature (T) and magnetic field (H) dependences of ^{1}H-NMR spectrum, $1/T_1$ and $1/T_2$ provide evidence for a gradual slowing of fluctuations of the V^{4+} spins with increasing the magnetic field. The T and H dependence of $1/T_1$ is well explained by the model in terms of spin phonon interaction for $H > 2.7$ T where the ground state of the V15 is $S = 3/2$. On the other hand, the T_1 data can not be reproduced by the model for $H \sim 2.7$ T where the ground state is nearly degenerated $S = 1/2$ states, suggesting the importance of additional contribution to $1/T_1$ due to the peculiarities of the $S = 1/2$ triangle configuration in the V15.

Crystal structure and physical properties of $(DODHT)_2FeCl_4$

New organic conductor based on DODHT [(1,4-dioxane-2,3-diyldithio)dihydrotetrathiafulvalene] with an inorganic magnetic anion, $FeCl_4^-$, has been synthesized. A clear transition to an insulator was observed at 130 K in the temperature dependence of resistance, but no anomaly was seen in the magnetic susceptibility measured with SQUID in the same temperature range. Crystal structure analysis of $(DODHT)_2FeCl_4$ revealed that the donor arrangement is β″-type similarly to the superconducting DODHT salts, and there is no strong interaction between donor molecules and inorganic anions.

Polyhedron 24 (2005) 2796

New organic magnetic anions TEMPO-$CONA(CH_2)_nSO_3^-$ (n = 0–3 for A = H, n = 2 for A = CH_3) and their TTF, TMTSF, and/or BEDT-TTF salts

Five TEMPO-containing anions TEMPO-$CONA(CH_2)_nSO_3^-$ (**H0**$^-$, A = H, n = 0; **H1**$^-$, A = H, n = 1; **H2**$^-$, A = H, n = 2; **H3**$^-$, A = H, n = 3; **M2**$^-$, A = CH_3, n = 2) have been prepared as PPh_4 salts. So far three TTF salts ((TTF)(**H1**) · $2H_2O$, (TTF)(**H2**) · H_2O, and (TTF)(**M2**) · $0.50H_2O$), one TMTSF salt ((TMTSF)(**H1**) · $2H_2O$ · PhCl), and one BEDT-TTF salt (α-$(BEDT\text{-}TTF)_5$(**H1**)$_2$ · $6H_2O$) have been obtained. Their crystal structures, electrical resistivities, and magnetic properties are reported.

Polyhedron 24 (2005) 2813

The size-dependent magnetic properties of Co_3O_4 nanoparticles

Co_3O_4 nanoparticles were prepared by mixing cobalt chloride($CoCl_2 \cdot 6H_2O$) aqueous solutions with sodium metasilicate nonahydrate ($Na_2SiO_3 \cdot 9H_2O$) aqueous solutions. The diameters of these particles were estimated from the X-ray diffraction patterns as ranging from 3 to 30 nm. The particle sizes were controlled through the annealing conditions and by the Si concentration of the solutions. Magnetization measurements were performed on the various sizes of Co_3O_4 nanoparticles. The blocking temperatures Tb were observed to be between 4 K and 28 K, while the Néel temperature of Co_3O_4 bulk crystal is known to be $T_N = 33$ K. At the blocking temperature, the superparamagnetic spins in the particle are supposed to be blocked against the thermal fluctuation energy. The saturation magnetization M_s increased dramatically for particle sizes below about 10 nm. The calculated effective magnetic moment μ_{eff} for a Co_3O_4 particle of 3 nm was twice as large as that of bulk crystal. These magnetic anomalies, which are dependent on particle size, could be due to the surface spins of the extremely small Co_3O_4 particles.

Spin-1/2 Heisenberg antiferromagnets on anisotropic triangular lattice, $[Pd(dmit)_2]$ salts – How do they release frustration?

The $[Pd(dmit)_2]$ salts are frustrated antiferromagnets, in which the dimers $[Pd(dmit)_2]_2^-$ form a triangular lattice. Various phenomena related to the release of the frustration can be observed in this system. They are overviewed on the basis of magneto-structural correlation.

Polyhedron 24 (2005) 2835

Magnetic properties of [VO(μ_3-MoO_4)(2,2′-bpy)]: New model compound for $S = 1/2$ zigzag frustrated one-dimensional magnet

The magnetic susceptibility and high field magnetization up to 35 T were measured on $S = 1/2$ zigzag antiferromagnet [VO(μ_3-MoO_4)(2,2′-bpy)]. The magnetization curve was compared with theoretical one to estimate the nearest-neighbor exchange interaction J_1 to be 56 K. The intrinsic magnetic susceptibility had maximum at around $T_{max} = 11$ K. A ratio T_{max}/J_1 was much less than that expected for one-dimensional antiferromagnet without next-nearest-neighbor interaction.

Polyhedron 24 (2005) 2852

Relaxation dynamics of two-step spin-crossover

We study static and dynamical properties of the two-step spin-crossover solids. A Monte Carlo method with the Arrhenius transition probability is applied to a two-sublattice model with an intrasublattice interaction and an intersublattice interaction. There, an intermediate-temperature 'antiferro' phase, where the sublattices have different states, appears between low-temperature phase (LS phase) and high-temperature phase (HS phase), as observed in the experiments. In particular, we focus on the relaxation from the saturated HS state which is realized by photo excitation. There, two-step relaxation is found: a fast relaxation with sigmoidal shape and following slow relaxation. The former is due to the Arrhenius transition rate and the latter is a result of stochastic relaxation from the metastable antiferro state, which reproduces well the relaxation observed in the experiments.

Polyhedron 24 (2005) 2857

Light-induced thermal hysteresis and intensity thresholds in molecular switcheable solids, by mean-field macroscopic master equation approach: Discussion of the experimental data obtained for Co–Fe Prussian Blue Analogues

Typical application of the mean-field macroscopic master equation of interacting photoswitchable systems: the time dependence of the high-spin fraction, $n(t)$, at equilibrium temperature, for a system initially in the low-spin state, irradiated with intensities above the threshold value. Intersections with the horizontal line provide "escape times" from the initial state.

Polyhedron 24 (2005) 2864

What makes a single molecule magnet?

Recent work in designing and synthesising molecules displaying the phenomenon of "Single Molecule Magnet" (SMM) behaviour has shown how a propeller motif with four paramagnetic metal centres can both stabilise non-zero ground spin states and display slow relaxation of the hysteresis: the signature of an SMM. Having thus identified the structural elements required it should be straightforward to produce new examples and learn how to enhance the SMM characteristics. Here we report on an attempt to do this with the surprising result that a molecule specifically designed to display SMM behaviour proves not to, posing the question as to why this should be.

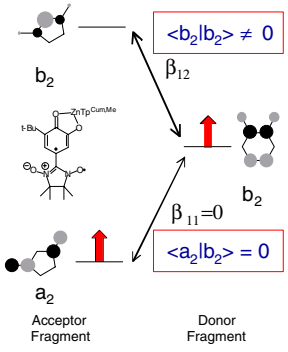
Valence tautomerization and exchange coupling in a cobalt–nitronylnitroxide–semiquinone complex

Synthesis and characterization of a novel cobalt valence tautomer comprised of semiquinone-nitronylnitroxide donor–acceptor ligands is presented. Due to the ferromagnetic coupling inherent to the semiquinone-nitronylnitroxide biradical, the Co^{III} form of the valence tautomer may display an additional stabilization of the high-spin ground state resulting from valence delocalization. As such, this would represent a unique example of double exchange in an organic system.



Martin L. Kirk, David A. Shultz, Ezra C. Depperman

Polyhedron 24 (2005) 2880

Beyond the active-electron approximation: Origin of ferromagnetic exchange in donor–acceptor heterospin biradicals

A valence bond configuration interaction (VBCI) model has been employed to describe the origin of strong ferromagnetic exchange coupling in donor–acceptor organic biradicals. This model is useful for using electronic structure theory to study exchange coupling in organic systems, and correlating magnetic exchange parameters with elements of electron transfer theory.

The influence of catalyst structure on the dehydro-polymerization of phenylsilane
1994 **13**(15/16) 2231–2243 by Toru Immure and T. Don Tilley

No. 51
Structural systematic in nickel carbonyl cluster anions
1995 **14**(3) 339–365 by Anthony F. Masters and Josephine T. Meyer

No. 52
Multidentate ligands bound via alkyne and group 15 or 16 donor sites
1995 **14**(4) 465–481 by Michael J. Went

No. 53
Chemical vapour deposition of copper from (hfac)CuL compounds
1995 **14**(6) 699–732 by Mark J. Hampden-Smith and Toivo T. Kodas

No. 54
Nickel carbonyl cluster complexes
1995 **14**(7) 829–868 by James K. Beattie, Antinony F. Masters and Josephine T. Meyer

Continued from previous page

Reports published

No. 55
Transition metal butadienyl complexes
1995 **14**(10) 1259–1276 by Brian J. Brisdon and Richard A. Walton

No. 56
Bis(diphenylphosphino)amine and related chemistry
1995 **14**(23/24) 3367–3388 by Pravat Bhattacharyya and J. Derek Woollins

No. 57
Stereochemical aspects of phosphor-1,1-dithiolato metal complexes (dithiophosphates, dithiophosphinates): coordination patterns, molecular structures and supramolecular associations – I
1994 **14**(23/24) 3389–3472 by Ionel Haiduc, D. Bryan Sowerby and Shao-Fang Lu

No. 58
Organotellurium precursors for metal organic chemical vapour deposition (MOCVD) of mercury cadmium telluride (MCT)
1996 **15**(5/6) 745–763 by Harkesh B. Singh and Narasimhan Sudha

No. 59
The chemistry of inorganic and organometallic compounds with adamantane-like structures
1996 **15**(10) 1585–1642 by Jagadese J. Vittal

No. 60
Stereochemical aspects of phosphor-1,1-dithiolato metal complexes: coordination patterns, molecular structures and supramolecular associations in dithio- phosphinates and related compounds
1996 **15**(15) 2469–2521 by Ionel Haiduc and D. Bryan Sowerby

No. 61
Toxic and mutagenic effects of chromium(VI). A review
1996 **15**(21) 3667–3689 by Maria Cieślak-Golonka

No. 62
Ring-opened polymerization (ROP) of strained, ring-titled silicon-bridged [l]ferrocenophanes: synthetic methods and mechanisms
1996 **15**(24) 4311–4329 by Ian Manners

No. 63
Metal–metal bond formation in the oxidative addition to dinuclear gold(I) species. Implications from dinuclear and trinuclear gold chemistry for the oxidative additional process generally
1997 **16**(1) 1–17 by John P. Fackler Jr

No. 64
Applications of electrospray mass spectrometry in organometallic chemistry
1998 **17**(25–26) 4291–4313 by William Henderson, Brian K. Nicholson and Louise J. McCaffrey

No. 65
Recent advances in the chemistry of scandium
1999 **18**(12) 1691–1715 by S.A. Cotton

No. 66
Metal-containing dendritic polymers
1999 **18**(27) 3575–3591 by Fiona J. Stoddart and Thomas Welton

No. 67
Primary alanes and alanates: useful synthetic reagents in aluminium chemistry
2000 **19**(14) 1649–1661 by Rudolph J. Wehmschulte and Philip P. Power

No. 68
The Bioinorganic chemistry of chromium (III)
2001 **20**(1–2) 1–26 by John B. Vincent

No. 69
Recent advances in homogenous catalysis using platinum complexes
2001 **20**(3–4) 151–164 by Matthew L. Clarke

No. 70
Structures of alkali and alkaline earth metal clusters with oxygen donor ligands
2004 **23**(9) 1479–1504 by Katharina M. Fromm and Estelle D. Gueneau

No. 71
The coordination chemistry of tripodal tetraamine ligands
2005 **24**(1) 1–39 by Allan G. Blackman
