Polyhedron Report No. 71

The coordination chemistry of tripodal tetraamine ligands

Allan G. Blackman *

Department of Chemistry, University of Otago, P.O. Box 56, Dunedin, New Zealand

Received 27 July 2004; accepted 26 October 2004
Available online 8 December 2004

Abstract

The coordination chemistry of tripodal tetrammine ligands is reviewed. These ligands contain a tertiary N atom bonded to three arms, each of which contains an N-donor atom, via at least one methylene group on each arm, and generally bind to a single transition metal or lanthanide ion using all four N-donor atoms. Fifty-four such ligands, not including substituted derivatives, are described. References are given to methods for the synthesis of these, and the coordination chemistry of each ligand with both transition metals and lanthanide ions is detailed, with emphasis being placed on structural features of the resulting metal complexes.

Keywords: Tripodal; Tetraamine; Ligands; Coordination chemistry; Review

1. Introduction

Tetradentate tripodal ligands have the general structure depicted in Fig. 1 and consist of a central donor atom X attached to three arms, each of which also contains at least one methylene group and a donor atom Y.

A large number of such ligands containing identical sets or combinations of the donor atoms N, S, O and P are known, but this paper will discuss only those ligands having four N donor atoms and which normally bind to a single metal ion using all of these. These tetradentate tripodal tetraamine ligands thus contain a single tertiary N atom, which 'caps' the tripod, and one N-donor atom on each arm. The ligands can differ both in the lengths of the arms and in the nature of the N-donor atoms on each arm and there are at least 54 such ligands (not including their alkylated and substituted derivatives) known. The majority of these ligands have been prepared only in the last 20 years and much of their coordination chemistry remains to be explored in detail. This paper presents a review of the chemistry of tripodal tetraamine ligands. It aims not to be comprehensive in terms of a discussion of every known complex containing a tripodal tetraamine ligand (such a task would fill a book for the complexes of tris(2-aminoethyl)amine (tren) alone!); rather, it aims to provide the reader some idea of the range of chemistry that has been carried out (and indeed remains still to do) with these ligands. Each section details the synthesis of the ligand, and discusses some of its more important transition metal and (where applicable) lanthanide complexes, with particular emphasis being placed on structural aspects of these.

2. General remarks

2.1. Nomenclature

As is the case with many organic ligands, most tripodal tetraamine ligands are known by an abbreviation, usually of three or four letters, nominally derived from the full name of the ligand. Thus, the systematically named ligand *N*,*N*-bis(2-aminoethyl)ethane-1,2-diamine is better known as tren (Section 3.1.1), the abbreviation being derived from the non-systematic name

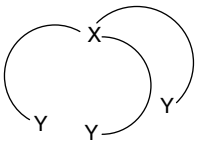

Fig. 1. General structure of a tetradentate tripodal ligand.

tris(2-aminoethyl)amine, and the name tren is in fact part of the 2004 provisional IUPAC recommendations on ligand abbreviations. However, this is the only tripodal tetraamine ligand for which IUPAC has proposed such a recommendation, and the abbreviations of other tripodal tetraamine ligands are somewhat haphazard and confusing. For example, the common ligand tris(2-pyridylmethyl)amine (Section 3.2.9) is variously abbreviated as tpa or tmpa, while the abbreviation bppa has been used for both bis(1-pyrazolylmethyl)(2-pyridylmethyl)-amine (Section 4.2.8) and bis(2-(3,5-dimethylpyrazol-1-yl)ethyl)(pyrazol-1-yl)methyl)amine (Section 4.2.9). Obviously, this is an unsatisfactory situation and ideally a systematic abbreviation system should be developed. However, in what follows, the ligand abbreviations given are those used most commonly in the literature (in some cases, more than one), and, where no abbreviation exists, a suitable one is proposed.

2.2. Synthesis

While the majority of tripodal tetraamine ligands discussed herein have been synthesised in the laboratory, some have been found in natural systems. Trpn (Section 3.1.4) and abbp (Section 3.1.8) have been found in the aquatic plants *Potamogeton distinctus* and *Sagittaria trifolia* L. [1], and also in the thermophilic eubacteria *T. thermophilus* HB8, *T. filoformis* Wai33 A1, *T. flavus* AT-62 and *T. caldophilus* GK24 [2].

Various methods are available for the synthesis of tripodal tetraamine ligands, with the route of choice generally dictated by the nature of the donor atoms on the three arms. All routes have in common the alkylation of the N atom of ammonium ion, or a primary or secondary amine precursor, with this N atom becoming the tertiary N atom of the resulting tripodal ligand. Bromo- and chloroalkylphthalimides are useful for the synthesis of ligands having aliphatic donor atoms as these can alkylate both primary and secondary N atoms at elevated temperatures, and deprotection using acid then gives the amine directly. Aliphatic N-donor atoms can also result from reduction of nitrile precursors with such reagents as $LiAlH_4/H_2SO_4$ or $NaBH_4$/Raney nickel, with the nitrile precursors generally being prepared from the reaction of acrylonitrile with the appropriate protected amine. Ligands having aromatic amine donor atoms are often prepared using haloalkylpyridines, imidazoles or pyrazoles as alkylating agents, while 2-vinylpyridine has proven useful as a reagent for the introduction of 2-(pyridylethyl) arms and 1-hydroxymethylpyrazole has been used in the synthesis of a number of pyrazole-containing tripodal ligands. The Mannich reaction has also been used in the synthesis of a number of tripodal tetraamine ligands.

2.3. Stereochemistry

The so-called "symmetric" tripodal ligands, in which all three arms are identical, usually have nominal C_{3v} symmetry about the central N atom, providing all the arms have the same conformations about the C–C and C–N bonds. Ligands in which the lengths of the arms differ, or which have N-donors of different types on each arm, are usually termed "asymmetric" and are of C_s symmetry or lower. Crystal structures of the free ligands show a variety of geometries, ranging from a "splayed" arrangement of the three arms, to internally H-bonded structures in which the three arms are folded to form a cavity into which an anion can bind. The latter arrangement is often found in protonated salts of the ligands.

Coordination to a metal ion generally results in a complex having a lower symmetry than the free ligand, depending on the coordination number of the metal ion. Four-coordinate complexes of tripodal amine ligands, in which all four N atoms are coordinated to a single metal ion, are relatively rare, as the ligands are often too constrained to be able to accommodate the square planar or tetrahedral geometries preferred by such complexes. Thus, four-coordinate complexes of tripodal tetradentate ligands often display either a very distorted tetrahedral geometry, or a trigonal pyramidal geometry, with the tertiary N atom occupying the apical position. Five-coordinate complexes are much more common, and the geometries of these occupy a continuum between the idealised trigonal bipyramidal and square pyramidal geometries. Such complexes are characterised by their τ value, where $\tau = 1$ for perfect trigonal bipyramidal geometry and $\tau = 0$ for perfect square pyramidal geometry [3]. It has been found that complexes having trigonal bipyramidal geometries are significantly more numerous than those having square pyramidal geometries. Indeed, five-coordinate complexes containing ligands such as tren (Section 3.1.1) and tpa (Section 3.2.9), almost invariably display trigonal bipyramidal geometries with the tertiary N atom at an apical position, reflecting the low-energy conformation of the ligand in such complexes. However, when the ligand arm lengths differ, such that a mixture of five- and six-membered chelate rings are present in the complex, square pyramidal geometries become more common, due presumably to the increased strain resulting from the accommodation of larger chelate rings in a trigonal bipyramidal geometry. Six-coordinate complexes containing tripodal amine ligands usually adopt distorted octahedral geometries, while seven coordinate

and above complexes appear to have no preferred stereochemistries, with a variety of geometries having been found.

2.4. Isomerism

The isomeric possibilities available to complexes of tripodal amine ligands is an oft-overlooked feature of such complexes. Most investigations have centred on six-coordinate complexes of symmetric ligands of the type outlined in Fig. 2. The two coordination sites labelled *p* and *t* are chemically inequivalent, being trans to a primary and tertiary amine N atom, respectively, and thus complexes such as $[M(tren)(X)(Y)]^{n+}$ can exist as geometric isomers.

When the arms of the tripodal ligands are of unequal lengths, then further isomeric possibilities exist, depending on the orientation of the tripodal ligand with respect to the two remaining coordination sites not occupied by this ligand. Thus a six-coordinate complex of baep (Section 3.1.2), a ligand which forms one six-membered and two five-membered chelate rings on coordination to a metal ion, can exist as either a 5-isomer or a 6-isomer, in which a five-membered or six-membered chelate ring lies in the same plane as the remaining two coordination sites, respectively (Fig. 3).

Should these sites be occupied by two monodentate ligands, or an asymmetric bidentate ligand, then *p*- and *t*-isomerism is also possible in addition to this. The 5- and 6-terminology is simple, unambiguous, and can be adapted to any type of asymmetric tetradentate tripodal tetraamine ligand. Note that a somewhat more rigorous nomenclature system which is applicable to all multidentate amine ligands has also been recently proposed [4]. Six-coordinate complexes of symmetric tripodal ligands are potentially chiral, owing to the different possible conformations of the chelate rings, and complexes such as $[Co(tren)(DL\text{-leucinato})]X_2$ ($X = ClO_4^-$, BF_4^-, PF_6^-, N atom of the amino acid *trans* to the tertiary N atom of tren) [5] and $[Co(tren)(N_3)_2]Br$ [6] have been found to undergo conglomerate crystallisation from solutions of the racemates. More remarkable is the behaviour of $[Co(tren)(N_3)_2]I$, which crystallises as a racemate in the space group $P2_1/n$ at room temperature, but which undergoes a phase change to the space group $P2_1$ upon cooling the crystal [6]. Six-coordinate complexes of asymmetric tripodal ligands are also chiral and the complexes $[Co(abap)(NO_2)_2]Cl$ and $[Co(abap)(NO_2)_2]ClO_4 \cdot H_2O$ crystallise as conglomerates [7]. Donor atoms of different types on the arms of the tripodal ligand, even when the arms are the same length, can lead to geometric isomerism, in that a choice of donor atom in the same plane as the two remaining coordination sites can exist (Fig. 4), and such possibilities have been realised in, for example, complexes of the uns-penp ligand (Section 4.1.7).

While isomerism in six-coordinate systems is well recognised, the same cannot be said of five-coordinate complexes. Square pyramidal complexes containing asymmetric tetradentate tripodal ligands can potentially exist as geometric isomers, as outlined in Fig. 5. In cases where the tertiary N atom lies in the square plane, the size of the chelate ring involving the apical N atom can differ (**A** and **B**), while complexes in which the tertiary N atom occupies the apical position can have different sized chelate rings situated *cis* and *trans* to the fifth coordination site (**C** and **D**). These types of isomerism have not been well documented, and a simple nomenclature system has yet to be proposed.

Polymetallic complexes containing more than one tripodal ligand have numerous isomeric possibilities resulting from the relative orientations of the tertiary N atoms with respect to each other and also, in the case of asymmetric tripodal ligands, from the relative positioning of the different sized chelate rings or the different types of N-donor atoms. Such possibilities are rarely remarked on, and it is certain that the solution chemistry of these complexes is more complicated than might be suggested by the crystallisation and structural characterisation of a single isomer from solutions of such complexes.

3.1. Ligands containing three aliphatic N-donor atoms

3.1.1. Tris(2-aminoethyl)amine

Tren was the first tripodal tetraamine ligand to be synthesised, and dates from 1896 when Ristenpart [8] prepared it as the trihydrochloride salt from the reaction of 2-bromoethylphthalimide with dry ammonia, and subsequent deprotection of the formed tris(2-phthalimidoethyl)amine using HCl (Scheme 1). This method was slightly modified by Mann and Pope in 1925 [9] and these workers also studied the coordination chemistry of the ligand with a number of metals.

An alternative method for the synthesis of tris(2-phthalimidoethyl)amine starting from triethanolamine was published by Collman and coworkers in 1970 involving reaction of triethanolamine with $SOCl_2$ to give tris(2-chloroethyl)amine hydrochloride, which is then reacted with potassium phthalimide [10]. [1] Tris(2-phthalimidoethyl)amine can also be deprotected using aqueous hydrazine and this gives the free base ligand directly. There are also numerous reports in the Patent literature of the synthesis of tren by reduction of tris(cyanomethyl)amine. The free base ligand is now commercially available.

Tren may be derivatised at either the terminal N atoms or a methylene carbon to give a variety of ligands having different steric and electronic properties from the parent. Exhaustive methylation at the terminal N atoms using formic acid/formaldehyde gives hexamethyltren [11], while the hexaethyl and hexa(isopropyl) derivatives are obtained from the reaction of tris(2-chloroethyl)amine with *N*,*N*-diethylethylenediamine and diisopropylamine, respectively [11]. *N*,*N*′,*N*″-trimethyltren has been prepared by reaction of tren with ethylchloroformate and subsequent reduction with $LiAlH_4$ [12] while the corresponding triethyl derivative is formed on reaction of tritosyltren with ethyl iodide [11]. Two isomeric monomethylated tren derivatives are known. Reaction of phthalimido-protected diethylenetriamine with phenylsulfonylaziridine, methylation with MeI and deprotection with HCl gives monomethyltren with the methyl group on a primary N atom [13], while monomethylation at the tertiary N atom can be achieved by methylation of tris(2-phthalimidoethyl)amine or triBoc-protected tren and deprotection [14,15]. The resulting cation is a poor ligand towards transition metal ions. The preparation of tren-based ligands having substituents on the carbon atoms of the ethyl chain is less facile, and there are consequently fewer examples of these than their *N*-alkyl congeners. The synthesis of homochiral tris(2-methyl-2-aminoethyl)amine has been reported, involving reaction of commercially available *N*-Boc-

[1] Tris(2-chloroethyl)amine hydrochloride is a powerful vesicant, while the free base form is a Schedule 1 Chemical Weapons Convention chemical. Indeed, the author's own laboratory was subject to a search by a three-person United Nations Chemical Weapons Inspection Team in 1997, owing to the large amounts of the hydrochloride salt stored therein. The synthesis of tren via this method is thus not recommended.

alanal with NH_4OAc and subsequent deprotection [16].

Tren and its derivatives have been used as the basis for the synthesis of a variety of Group 12, 13, 14, and 15 atranes [17], and tren has also been used in the synthesis of a large number of cryptate and cryptand species [18]. Both mono- [19–21] and diprotonated [22] derivatives of tren have been structurally characterised, and there are over 30 reported X-ray structures containing tri- and tetraprotonated tren. The tetraprotonated derivatives tend to adopt a ''splayed'' arrangement of the ligand arms, while the triprotonated congeners often have the three arms wrapping around to form a cleft which can bind an anion. The acid/base chemistry of tren has been extensively studied, and pK_a values obtained in various studies are given in Table 1.

As can be seen from these data, protonation of the tertiary N atom is more difficult than for similar ligands having longer arms, due to the relatively close proximity of the three primary N atoms. Likewise, there are many studies in which formation constants for 1:1 M^{n+}/tren species have been measured and some representative data from these are given in Table 2.

Tren generally binds as a tetradentate ligand to a single metal ion, but it is also found as a monodentate ligand bound through a primary N atom in $[Co(NH_3)_5(trenH_3)]Cl_6 \cdot 3H_2O$ and *p*-$[Co(tren)(NH_3)(trenH_3)]Cl_6 \cdot 2H_2O$ [23], a bidentate ligand (presumably through the tertiary and a primary N atom) in *trans*-$[ReO_2(tren)_2]I$ [24] and the $[Cr(trenH_2)(H_2O)_2(ox)]^{3+}$ cation [25], and a tridentate ligand bound through the tertiary and two primary N atoms in $[Ni(tren)_2]X$ (X = Cl_2, WS_4, [26] $(BF_4)_2$ [27]) and $[Co(tren)_2][Co(CO)_4]_2$ [28]. Tren has also been found as a bridging ligand between both two [29–31] and three [32,33] metal ions. An aesthetically pleasing example of the latter is $[Cd_7(tren)_{12}]$

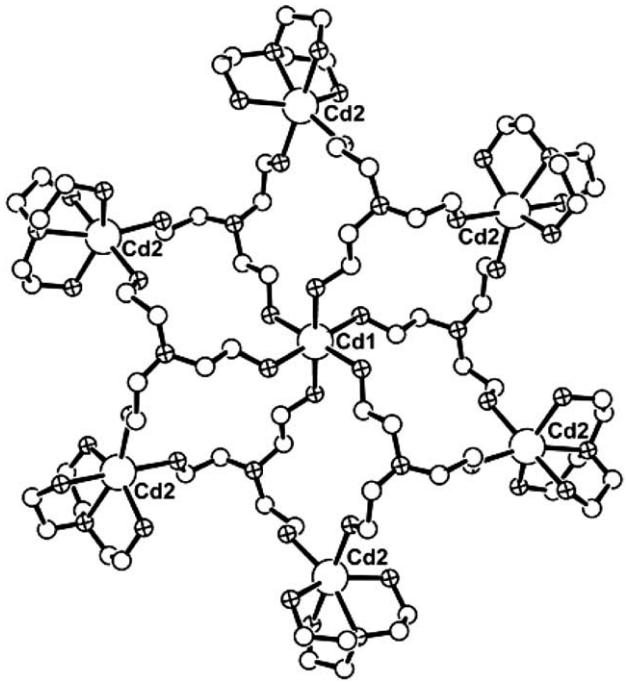

Fig. 6. The X-ray structure of the $[Cd_7(tren)_{12}]^{14+}$ cation. Hydrogen atoms are omitted for clarity.

$(ClO_4)_{14}$, the cation of which is shown in Fig. 6, in which tren acts both as a tetradentate ligand towards six separate Cd^{2+} ions and as a triply bridging monodentate ligand [34].

There are no crystallographically characterised examples of four-coordinate $[M(tren)]^{n+}$ complexes, owing presumably to the inability of the ligand to accommodate a suitable geometry. There are numerous examples of monomeric five-coordinate complexes containing tren, and those for which X-ray structures are available are listed in Table 3.

It can be seen that the majority of such complexes adopt some type of distorted trigonal bipyramidal geometry, with the only two having τ values less than 0.50, namely $[Cu(4,5\text{-diazafluorene-9-hydrazine})](ClO_4)_2$ [35] and $[Cu(4,5\text{-diazafluoren-9-one})](ClO_4)_2$ [36], containing ligands having a potential donor N-atom situated ~3 Å from the metal ion in a possible sixth coordination site. Six-coordinate complexes containing tren are numerous but, in contrast to other tripodal ligands having longer arms, there are surprisingly few crystallographically characterised examples of tren complexes containing a metal ion with a coordination number greater than six, with a seven-coordinate Cd^{2+} coordination polymer [37], and the nine-coordinate lanthanide complexes $[Nd(tren)_2(MeCN)](ClO_4)_3$ [38] and $[Pr(tren)(trien)(OSO_2CF_3)](CF_3SO_3)_2$ [39] apparently being the only examples [40,41].

Of the many metal ions with which tren forms complexes, undoubtedly the best studied is Co(III). Over five hundred complexes of the type $[Co^{III}(tren)(L)_2]^{n+}$ ($(L)_2$ = one bidentate or two monodentate ligands) are known (it is interesting to note that a previous review of tripodal amine ligands in 1977 listed fewer than fifty

[a] More than one independent molecule in the asymmetric unit.

such complexes [42]) and X-ray structures of nearly one hundred of these are available. Much of the interest in these complexes has stemmed from their utilility in assisting the determination of the stereochemical course of ligand substitution reactions at Co(III) centres. The diastereoisomeric *p*- and *t*-isomers possible in bis(monodentate) complexes of the type $[Co(tren)(X)(Y)]^{n+}$ often have quite different physical properties; for example, *p*-$[Co(tren)(NH_3)Cl]^{2+}$ is red, while *t*-$[Co(tren)(NH_3)Cl]^{2+}$ is purple [43]. Such isomers can often be easily separated, and analysis of the products obtained in either hydrolysis or anation reactions of these complexes readily shows the presence of any stereochemical change during such reactions [44–47]. In addition, tren has the ideal geometry to stabilise putative trigonal bipyramidal 5-coordinate intermediates which may be formed in these reactions. Ligands in the *p*- and *t*-positions can also be distinguished by a variety of NMR techniques, and an elegant example of this is the ^{17}O NMR study of a number of Co(III) aquo and hydroxo tren complexes by Buckingham and Clark and coworkers [48]. The two ^{17}O NMR peaks observed for $[Co(tren)(OH_2)_2]^{3+}$ at −95 ppm and −131 ppm (relative to solvent $H_2{}^{17}O$) were assigned to the *p*- and *t*-aquo ligands, respectively, and all other tren complexes studied were found to have the *p*-aquo or hydroxo resonance at a less negative chemical shift than the corresponding *t*-resonance. This study also showed that solvent exchange at the *p*-site was faster than at the *t*-site under all pH conditions, and that solvent exchange in $[Co(tren)(OH_2)(OH)]^{2+}$ was much faster than in either the diaqua or dihydroxo complexes.

Despite the large number of Co(III) complexes of tren, it is interesting to note that there are currently no known Co(III) complexes containing hexamethyltren, with the five-coordinate Co(II) complex $[Co(Me_6tren)(OH_2)]^{2+}$ being unreactive towards air-oxidation [49]. Notable amongst recent Co(III) complexes of tren is $[Co(tren)(L^{ISQ})](ClO_4)_2 \cdot 0.5CH_3OH \cdot 0.5H_2O$, where L^{ISQ} is the chelated *o*-iminobenzosemiquinonate radical anion derived from 2-anilino-4,6-di-*tert*-butylphenol

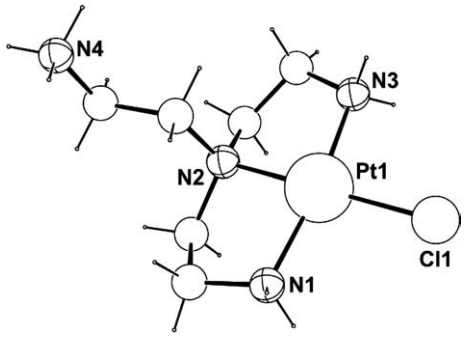

Fig. 7. Hypodentate coordination of tren in the $[Pt(trenH)Cl]^{2+}$ cation.

[50]. This complex is prepared by air oxidation of a methanolic solution of $Co(OAc)_2 \cdot 4H_2O$, tren and 2-anilino-4,6-di-*tert*-butylphenol in the presence of Et_3N, with subsequent addition of $LiClO_4$, and displays a temperature independent magnetic moment of 1.7 μ_B, indicating the presence of an O,N-coordinated radical anion with an $S_{rad} = 1/2$ ground state, and a diamagetic low-spin d^6 Co(III) ion.

Complexes of tren with all first row transition metals except vanadium are known, but complexes of the second and third row transition metals are less numerous. While there are over 20 known tren complexes of Rh(III), surprisingly there are only two examples of tren complexes of ruthenium, and both *fac*-$[RuCl_3(trenH)]Cl \cdot 0.5H_2O$ and *fac*-$[RuCl(ox)(trenH)]Cl \cdot 1.5H_2O$ feature hypodentate tridentate coordination of the tren ligand [51]. Equally surprisingly, there are no known examples of either osmium or iridium complexes. Metal ions such as Pd^{2+} and Pt^{2+} which prefer square planar geometries also, of necessity, form hypodentate complexes with tren. For example, the structurally characterised complex $[Pt(trenH)Cl]Cl_2$ contains monoprotonated tren coordinated as a tridentate ligand, with one arm remaining unbound (Fig. 7) [52].

$[Ag(tren)]PF_6$ is polymeric and again features tridentate coordination of the tren ligand to a single Ag^+ ion, but in this case one arm of the tren ligand bridges to a neighbouring silver ion [53]. The binding geometry of the tren ligand is ideal for the formation of molecular squares from six-coordinate monomers, owing to the *cis* configuration of the remaining two ligand binding sites, and this has been exploited in the heterometallic complex $K_2\{[Co(tren)]_2[W(CN)_8]_2\} \cdot 9H_2O$, the anion of which features a tetranuclear square of alternating Co(III) and W(IV) ions bridged by cyanide ligands [54].

Iron provides a number of examples of polynuclear complexes containing the tren ligand. The tetranuclear complex $[\{Fe_2(tren)_2(\mu\text{-}O)\}_2(\mu_4\text{-}PO_4)](ClO_4)_5 \cdot 2.5H_2O$, in which the four Fe(III) ions are bridged by a single phosphate ligand, is formed from the reaction of $Fe(ClO_4)_3 \cdot 9H_2O$ with 4-nitrophenylphosphate and tren in MeOH (Fig. 8) [55], hexanuclear $[Fe_6(\mu_4\text{-}O)_2(\mu_2\text{-}OMe)_8(OMe)_4(tren)_2](CF_3SO_3)_2 \cdot 2MeOH$ results from the solvolytic aggregation of the $[Fe_3O_2(OH)(tren)_3]^{4+}$ ion in MeOH [56], and the octanuclear iron complex $[Fe_8O_5(OAc)_8(tren)_4](CF_3SO_3)_6 \cdot 5MeCN$, which features a four-coordinate square planar oxo bridge, is obtained from air oxidation of a mixture of $[Fe(tren)(OAc)_2]$ and $Fe(CF_3SO_3)_2 \cdot 2MeCN$ in butyronitrile [57].

In all these complexes, the tren ligand acts as a type of capping ligand which mediates the otherwise uncontrolled polymerisation of Fe-oxo species. Similarly, the dodecanuclear mixed-valence manganese complex $[Mn_{10}O_{14}(tren)_6](CF_3SO_3)_8 \cdot 6MeCN$ forms on air oxidation of a solution of $Mn(CF_3SO_3)_2$ and tren in MeCN

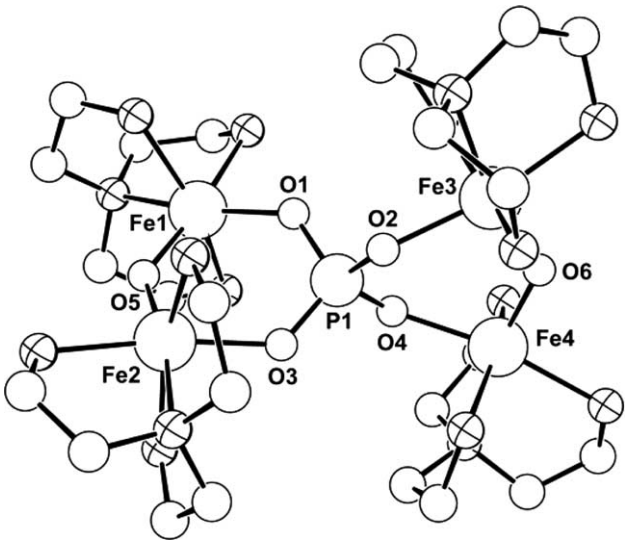

Fig. 8. X-ray structure of the tetranuclear $[\{Fe_2(tren)_2(\mu\text{-}O)\}_2(\mu_4\text{-}PO_4)]^{5+}$ cation. Hydrogen atoms are omitted for clarity.

[58]. Other multinuclear tren complexes, based on hexacyanometallates, include heptanuclear $[\{Cu(tren)CN\}_6Fe](ClO_4)_8 \cdot 10H_2O$ (Fig. 9), which is obtained from a mixture of $Cu(ClO_4)_2 \cdot 6H_2O$, tren and $K_3[Fe(CN)_6]$ [59], while the pentanuclear cation $[\{Cu(tren)CN\}_4Fe(CN)_2]^{4+}$, in which the non-bridging cyanide ligands are mutually *trans*, is present in $[\{Cu(tren)CN\}_6Fe][\{Cu(tren)CN\}_4Fe(CN)_2][Fe(CN)_6]_4 \cdot 6DMSO \cdot 21H_2O$ [59]. The analogous heptanuclear $[\{Cu(tren)CN\}_6Cr]^{9+}$ and $[\{Cu(tren)CN\}_6Co]^{9+}$ complexes have also been structurally characterised [33].

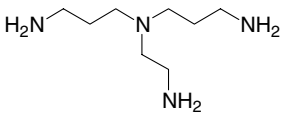
3.1.2. 3-Aminopropylbis(2-aminoethyl)amine (baep)

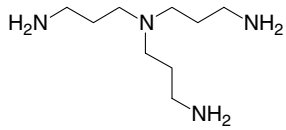


The free base form of baep was first reported in 1966 as the product of a multistep synthesis involving reaction of acrylonitrile with a protected diethylenetriamine derivative and subsequent reduction [60] but its use as a ligand was not investigated at this time. A more convenient synthesis of $baep \cdot 4HCl \cdot 2H_2O$ was detailed by Sargeson and coworkers in 1993 from the reaction of phthaloyl-protected diethylenetriamine with 3-bromopropylphthalimide followed by deprotection with HCl [61], while Hahn and coworkers reported an alternative synthesis in 1996 involving synthesis of the trinitrile and reduction with $LiAlH_4/H_2SO_4$ [62]. Two independent studies under identical conditions (potentiometric titration, 0.1 M KCl, 25.0 °C) have given successive pK_a values of 10.22, 9.51, 8.78 and 1.60 [63] and 10.14, 9.72, 8.40 and 2.1 [64] while formation constants (log *K*) for the 1:1 complexes of baep with Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+} and Cd^{2+} are 12.15, 14.17, 16.55, 13.35 and 9.74, respectively [63].

Only three complexes of baep have been structurally characterised; the cation of the 5-coordinate complex $[Cu(baep)(NH_3)](PF_6)_2$ displays a distorted trigonal bipyramidal geometry ($\tau = 0.58$) [62], while both $[Ni(baep)(ONO_2)_2]$ and dimeric $[(baep)Ni(\mu\text{-}Cl)_2Ni(baep)]Cl_2 \cdot 2CH_3OH$ contain approximately octahedral Ni^{2+} [65]. Geometric isomeric possibilities exist for the Ni^{2+} complexes, although both appear to crystallise as the 5-isomer in which a 5-membered chelate ring lies in the same plane as the nitrate and chloride ligands. This is particularly interesting in the case of the dimeric complex, where a total of at least eight isomers are possible, due to the different relative positionings of both the tertiary N atoms and the six-membered chelate rings. Solution studies of the Cu^{2+}(aq)/baep system have given evidence for the formation of the hypodentate complex $[Cu(baepH)(OH_2)_2]^{3+}$ in which the tripodal ligand binds in a tridentate fashion. This species in fact predominates in aqueous solution over the pH range 4–6 and similar behaviour is observed in both the Cu^{2+}(aq)/abap and Cu^{2+}(aq)/trpn systems. Log *K* values for the formation of the 1:1 complexes of Cu^{2+} with tren, baep, abap and trpn are 18.5, 17.1, 16.0 and 13.21, respectively, with the observed decrease in stability being ascribed to the decreasing number of 5-membered chelate rings in the complexes. Attempts to measure the rate of ligand substitution in Cu^{2+} complexes of baep, abap and trpn using T-jump techniques were unsuccessful, indicating

that ligand exchange in these species occurs orders of magnitude more rapidly than in $[Cu(tren)(OH_2)]^{2+}$ [64]. The Co(III) complexes $[Co(baep)(NO_2)_2]Cl$ and $[Co(baep)(O_2SOCF_3)_2]CF_3SO_3$ have been reported. Dissolution of the latter in aqueous solution and adjustment to neutral pH gave in situ formation of $[Co(baep)(OH_2)(OH)]^{2+}$, which was found to hydrolyse metal-bound pyrophosphate at rates comparable to the corresponding tren complex [61].

3.1.3. 2-Aminoethylbis(3-aminopropyl)amine (abap)



The preparation of abap from the reaction of dipropylenetriamine with aziridine in acidic solution was first described in a 1972 patent. However, this synthesis gave an inseparable mixture of abap and the straight chain product obtained from alkylation at the primary N atom in a 65:35 ratio [66]. Over 20 years elapsed before independent syntheses of the pure ligand were reported in the literature almost simultaneously by two separate groups [62,67]. These syntheses both involve alkylation at the secondary N atom of a dipropylenetriamine derivative. Reaction of phthalimido-protected dipropylenetriamine with 2-bromoethylphthalimide and subsequent deprotection with HCl gives $abap \cdot 4HCl \cdot 2.5H_2O$, while reaction of $HN(CH_2CH_2CN)_2$ with formaldehyde and KCN in the presence of $Na_2S_2O_5$ gives the trinitrile, which is then reduced to the free-base amine using $LiAlH_4/H_2SO_4$. It has been suggested that free base abap may have been prepared as early as 1964 when attempts to prepare the linear ligand 3-2-3-tet following a published procedure [68] involving cyanoethylation of ethylenediamine and subsequent reduction resulted in isolation of a product which was not identical to authentic 3-2-3-tet prepared by an alternative route [69]. The authors thus proposed that the unknown amine was abap, although frustratingly, no ^{13}C NMR data, which would allow an unambiguous distinction between the two amines to be made, were reported.

Potentiometric titration of abap (0.1 M KCl, 25.0 °C) in two independent studies reveals successive pK_a values of 10.38, 9.68, 8.95 and 3.81 [70] and 10.4, 9.87, 8.85 and 3.86 [64], while formation constants (log *K*) for the 1:1 complexes of abap with Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+} and Cd^{2+} are 9.26, 11.95, 15.98, 12.01 and 8.33, respectively [70]. Several complexes of abap have been structurally characterised and these are listed in Table 4.

While it may appear from this table that the 5-isomer is formed exclusively in complexes where the remaining two coordination sites are occupied by monodentate ligands, this is not the case in solution where, for example, the 5- and 6-forms of $[Co(abap)(OH_2)_2]^{3+}$ exist in equilibrium [71]. There appears to be no isomeric preference for the complexes containing bidentate CO_3^{2}, PO_4^{3-} and NO_3^{-}, indicating that the metal ion can accommodate bond angles of significantly less than 90° without requiring expansion of the opposite angle in the same plane. The low symmetry of the abap ligand leads to a large number of isomeric possibilities in binuclear complexes, and ^{31}P NMR spectroscopy has been used to identify 9 of the 12 possible isomers of $[(abap)CoO_2P(O)OCo(abap)(OH/H)]^{2+/3+}$ in which the bridging phosphate ligand is chelated to one Co centre and binds monodentate to the other, and all three possible isomers of the doubly chelated dimer $[(abap)Co(O_2PO_2)Co(abap)]^{3+}$ [71].

3.1.4. Tris(3-aminopropyl)amine (trpn)

The trpn ligand was first prepared as the tetrahydrochloride hemihydrate by Mann and Pope in 1926, from the reaction of molten 3-(bromopropyl)phthalimide with $NH_3(g)$ followed by deprotection with HCl, and this paper also described the first metal complexes of trpn, namely $[Ni(trpn)](SCN)_2$ (which was thought to contain four-coordinate Ni^{2+}, but is most likely six-coordinate $[Ni(trpn)(NCS)_2]$) $[Ni(trpn)]I_2 \cdot 1.5H_2O$ and $[Ni(trpn)]I(OH) \cdot 2H_2O$ [72]. Modifications of this synthesis of trpn have since been published, involving reaction of phthaloyl-protected dipropylenetriamine with *N*-(3-bromopropyl)phthalimide and subsequent deprotection in acid [73,74]. Alternative routes involving formation of tris(2-cyanoethyl)amine or tris(3-acetamidopropyl)amine and reduction of these to the amine have also been reported. Thus, reaction of acrylonitrile with ammonia gives the trinitrile [75] and this can be reduced using Raney nickel/H_2 to the triamide, which can then undergo acid hydrolysis to give trpn [76,77]. Use of Raney nickel/hydrazine as reductant has also been reported to give trpn in good yield [62]. Tris(3-acetamidopropyl)amine can also be prepared directly from acrylamide and ammonia, and reduction of this with either $LiAlH_4$ [78] or B_2H_6 [79] gives trpn. Trpn is also commercially available. Some N-substituted derivatives of trpn have been reported. Thus tris(3-(*N*-methylamino)propyl)amine, in which each pendant-arm N atom is monomethylated can be prepared by either $LiAlH_4$ reduction of tris(3-(ethoxycarbonylamino)propyl)amine or treatment of tris(3-bromopropyl)amine with methylamine [80] while the hexamethylated ligand is obtained on reaction of trpn with HCOOH/HCHO [81]. The trpn ligand generally crystallises as the tetrahydrochloride

[a] Structure determined in solution by ^{13}C NMR.

salt from solutions of HCl, and pK_a values of 5.615, 9.129, 9.824 and 10.511 ($I = 0.1$ M, KCl) [82,83], 5.62, 9.13, 9.97 and 10.52 ($I = 0.1$ M, Me_4NCl) [79] and 5.80, 9.28, 9.92 and 10.58 ($I = 0.1$ M, KCl) [64] have been measured in separate studies.

Despite its long pedigree, there are surprisingly few studies of simple metal complexes of trpn, with the majority of work in this area concentrating on the metal-assisted condensation reactions of trpn with a variety of carbonyl compounds to give aminopropyl-appended Schiff-base macrocycles, or cryptates. Formation constants (log *K*) for the 1:1 complexes of trpn with Co(II), Ni(II), Cu(II) and Zn(II) in aqueous solution are 6.360, 8.702, 13.117 and 10.702, respectively and these values are some 4–6.5 log units smaller than the corresponding values for tren, reflecting the lower stability of six-membered chelate rings when compared to their five-membered congeners [82]. This is further emphasised by potentiometric measurements which show that the predominant Cu(II) complex between pH 6 and 8 is the hypodentate cation $[Cu(Htrpn)(OH_2)_2]^{3+}$ in which one arm of the tripodal ligand is protonated and uncoordinated [64]. Likewise, $[Cu(trpn)(N_3)]ClO_4$, prepared by reaction of $Cu(ClO_4)_2 \cdot 6H_2O$ with trpn and azide in $MeOH/H_2O$, is not, as might be expected, a simple five-coordinate mononuclear complex, but a polymeric species in which one arm of the tripodal ligand bridges two Cu ions, and a similar bridging motif is also observed in the dimeric complex $[(tren)Cu(trpn)Cu(ONO)(OH_2)](ClO_4)_3$ (Fig. 10) [84].

Thermodynamic data suggested that the 1:1 Zn^{2+}/trpn complex was four-coordinate [83] and this was subsequently confirmed by the isolation from aqueous solution and structural characterisation of both $[Zn(trpn)]Cl_2 \cdot 2H_2O$ [85] and $[Zn(trpn)](ClO_4)_2$ [81] in which the Zn ion displays a trigonal pyramidal geometry, although it should be noted that, in the former complex, a water oxygen atom lies in an ideal apical coordination site 2.91 Å from the Zn ion (Fig. 11).

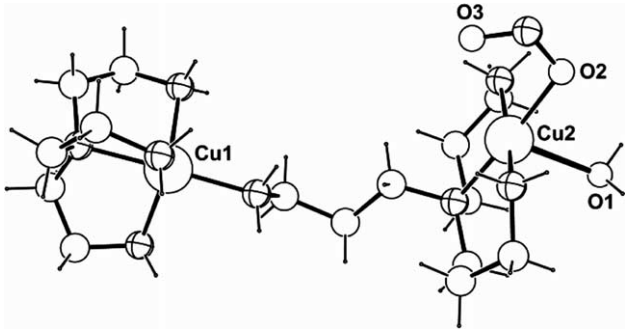

Fig. 10. X-ray structure of the $[(tren)Cu(trpn)Cu(ONO)(OH_2)]^{3+}$ cation.

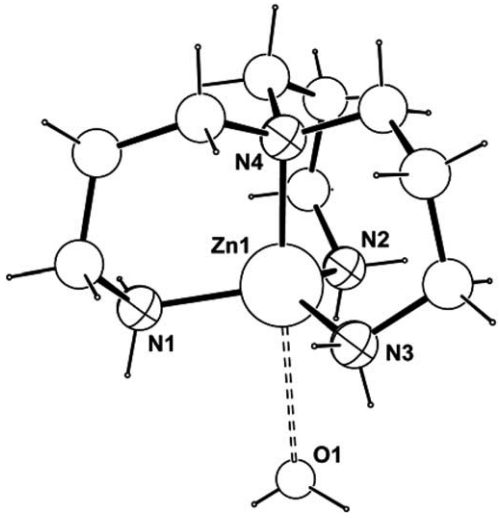

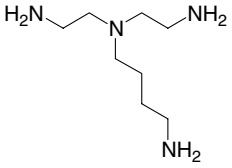

Fig. 11. X-ray structure of the cation of $[Zn(trpn)]Cl_2 \cdot 2H_2O$, showing the long Zn–O interaction.

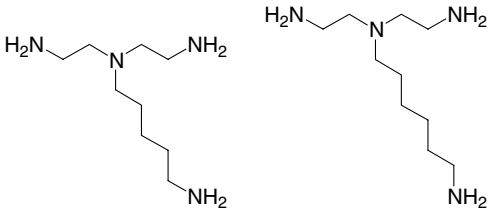
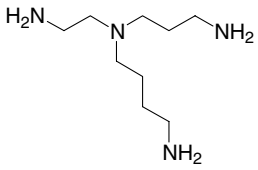
$[Zn(trpn)](ClO_4)_2$ reacts with potassium *O*,*O*-diethylthiophosphate (DETP) to give five-coordinate $[Zn(trpn)(DETP)](ClO_4)$ in which the thiophosphate acts as a monodentate ligand to give a distorted trigonal bipyramidal geometry about the metal ion ($\tau = 0.91$). Other five-coordinate trpn complexes to have been structurally characterised include $[Co(trpn)Br]Br \cdot 0.5\text{-}C_2H_5OH$ [86], $[Cu(trpn)(NH_3)](PF_6)_2$ [62] and $[Cu(trpn)(MeCN)](ClO_4)_2$ [87]; the cation of the latter has $\tau = 0.46$, while $[Co(trpn)Br]^+$ and $[Cu(trpn)(NH_3)]^{2+}$ ($\tau = 0.81$) are distorted trigonal bipyramidal. The axial Co–Br bond distance of 2.658(3) Å in $[Co(trpn)Br]^+$ is very long and invites comparison with the complex $[Zn(trpn)]Cl_2 \cdot 2H_2O$ discussed above.



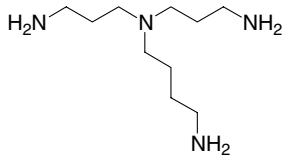
The chemistry of Co(III) complexes of trpn has been extensively studied and a large number of these complexes have been prepared [88,89]. Crystal structures of mononuclear $[Co(trpn)(OH_2)_2][Na(CF_3SO_3)_4(H_2O)]$ [90], $[Co(trpn)(O_2SO_2)]ClO_4 \cdot H_2O$ [91], $[Co(trpn)(O_2CCMe_3)](ClO_4)_2$ [92] and binuclear $[(trpn)CoO_2PO_2Co(trpn)](ClO_4)_3 \cdot 3H_2O$ [93] are available. Interestingly, $[Co(trpn)(O_2SO_2)]ClO_4 \cdot H_2O$ was the first authenticated example of sulfate chelated to Co(III). The $[Co(trpn)(OH_2)(OH)]^{2+}$ ion has been found to be particularly effective as a hydrolytic agent for ADP [94], ATP [95], AMP [96], RNA [97], and a variety of other phosphate esters [93,98,99], as well as organic esters [100] and nitriles [101], and its high reactivity, when compared to the analogous tren complex, has been ascribed to the greater flexibility of the trpn ligand which is thought to facilitate intramolecular nucleophilic attack of coordinated hydroxide ion at the coordinated substrate. However, $[Co(trpn)(OH_2)(OH)]^{2+}$ was shown under acidic conditions to be unstable with respect to oxidative N-dealkylation of the trpn ligand and concomitant reduction of the metal ion to Co(II) [102,103] and this hence limits the use of this complex as a hydrolytic agent. Ni^{2+} forms six-coordinate complexes with trpn, and both $[Ni(trpn)(O_2NO)]NO_3 \cdot CH_3OH$ and $[Ni(trpn)(OH_2)_2]Cl_2 \cdot H_2O$ have been structurally characterised [65]. It is interesting to note that no complexes of trpn with second or third row transition metal ions have yet been isolated, as it may well be that these larger metal ions are better able to accommodate three six-membered chelate rings.

3.1.5. 4-Aminobutylbis(2-aminoethyl)amine (bee, abba)



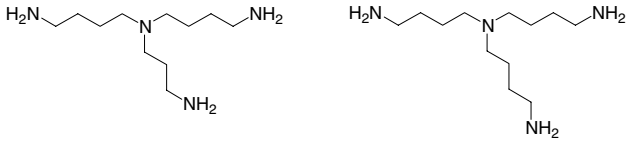
Two syntheses of the tetrahydrochloride salt of this ligand have been reported, both involving reaction of phthalimido-protected diethylenetriamine with *N*-(4-bromobutyl)phthalimide in a melt, followed by deprotection with HCl [104,105]. Reaction of abba · 4HCl with $CuCO_3 \cdot Cu(OH)_2$ gives the 5-coordinate complex $[Cu(abbaH)Cl_2]Cl \cdot 2H_2O \cdot CH_3OH$ in which the abba ligand coordinates as a tridentate ligand, with the protonated aminobutyl arm remaining unbound.

3.1.6. 5-Aminopentylbis(2-aminoethyl)amine (apba) and 6-aminohexylbis(2-aminoethyl)amine (ahba)



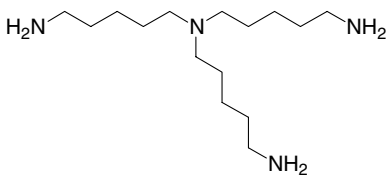
These ligands have been prepared by reaction of phthalimido-protected diethylenetriamine with *N*-(5-bromopentyl)phthalimide and *N*-(6-bromohexyl)phthalimide, respectively [105]. Their coordination chemistry has not been extensively investigated and is limited to the Cu(II) complexes $[Cu(apbaH)Cl(ClO_4)]ClO_4$ and $[Cu(ahbaH)Cl(ClO_4)]ClO_4$ in which the longest arms of the tripodal ligands are presumably protonated and not coordinated to the metal ion.

3.1.7. (4-Aminobutyl)-(3-aminopropyl)-(2-aminoethyl)amine (epb)



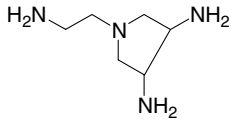
The first example of a tetradentate aliphatic tripodal amine ligand with all arms of different lengths, the tetrahydrochloride salt of epb was prepared by fusing 2,3′-diphthalimidoethylpropylamine and *N*-(4-bromobutyl)phthalimide at 160 °C, with subsequent deprotection using HCl [106]. The coordination chemistry of this ligand has not yet been investigated, but condensation of epb with 2,6-diacetylpyridine in the presence of Cu(II) and Ni(II) salts gives 5-coordinate macrocyclic Schiff-base complexes in which all three arms of the tripodal amine are coordinated to the metal ion.

3.1.8. 4-Aminobutylbis(3-aminopropyl)amine (abbp)



The first reported synthesis of this ligand involved reaction of phthaloyl-protected dipropylenetriamine with *N*-(4-bromopropyl)phthalimide in refluxing MeCN followed by deprotection using hydrazine hydrate and purification on Dowex cation exchange resin with HCl as eluent to give the ligand as the tetrahydrochloride salt [107]. More recently, a synthesis of the tetra(hydrogenperchlorate) salt from melts of either phthaloyl-protected dipropylenetriamine and *N*-(4-bromobutyl)phthalimide or 3,4-diphthalimidopropylbutylamine and *N*-(3-bromopropyl)phthalimide and subsequent deprotection have been reported [108]. Reaction of the perchlorate salt with copper(II) chloride gives the 5-coordinate complex $[Cu(abbpH)Cl_2]ClO_4$ in which the protonated aminobutyl arm is not coordinated to the metal ion.

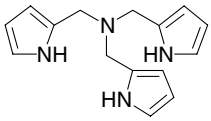
3.1.9. 3-Aminopropylbis(4-aminobutyl)amine (apbb) and tris(4-aminobutyl)amine (trbn)



The tetrahydrochloride salts of these ligands have been prepared by treatment of phthaloyl-protected dibutylenetriamine with either *N*-(3-bromopropyl)phthalimide or *N*-(4-bromobutyl)phthalimide respectively in refluxing MeCN followed by deprotection using hydrazine hydrate and purification on Dowex cation exchange resin with HCl as eluent [107]. No metal complexes of either ligand have been reported.

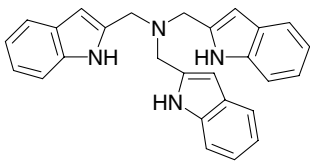
3.1.10. Tris(5-aminopentyl)amine (trpa)

The free base ligand is formed from the reaction of ammonia with 1-cyanobutadiene and subsequent hydrogenation over Raney nickel [109]. Although first prepared in 1978, the coordination chemistry of this ligand remains to be investigated.



3.1.11. N-(2-aminoethyl)pyrrolidine-3,4-diamine (aepd)

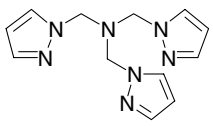
The synthesis of this ligand has not been reported, but the ligand was in fact found as an impurity in commercial 96% tren, during the serendipitous synthesis of $[Ni_2(tren)_2(aepd)][ClO_4]_4 \cdot 2H_2O$ [110]. In this complex, aepd acts as a bridging ligand, binding in a bidentate fashion to the two Ni^{2+} ions.



3.2. Ligands containing three aromatic N-donor atoms

3.2.1. Tris((2-pyrrolyl)methyl)amine (H_3tpa)

This ligand was prepared in 84% yield by a triple Mannich reaction involving 1 equivalent of NH_4Cl, 3 equivalents of formaldehyde and 3 equivalents of pyrrole [111]. The coordination chemistry of this ligand has thus far been restricted to complexes of Ti(IV) and Zr(IV). Treatment of $[Ti(NMe_2)_4]$ with one equivalent of H_3tpa gives trigonal bipyramidal $[Ti(tpa)(NMe_2)]$ which has been structurally characterised, while the analogous reaction with $[Zr(NMe_2)_4]$ and subsequent addition of either pyridine or 4,4′-*t*-Bu_2-2,2′-bipy gives the seven-coordinate complexes $[Zr(tpa)(NMe_2)(py)_2]$ and $[Zr(tpa)(NMe_2)(4,4'\text{-}Bu_2bipy)]$, respectively, the latter of which has also been structurally characterised. The triply deprotonated ligand can be isolated as the lithium salt Li_3tpa by treatment with BuLi, and reaction of this with $[ZrCl_4(THF)_2]$ gives $[Zr(tpa)(THF)_2Cl]$.



3.2.2. Tris((2-indolyl)methyl)amine ($N(CH_2in)_3$)

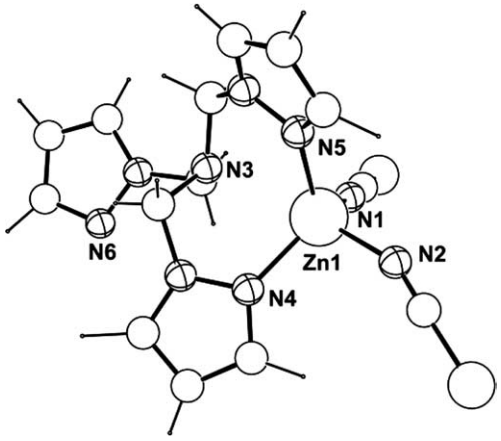
Reaction of 2-bromomethyl-1-indolecarboxylate with NH_3 and subsequent deprotection with NaOMe/NaOH gives $N(CH_2in)_3$ [112]. The syntheses of several tantalum complexes of this ligand have been reported, in all cases starting with dimethylamido tantalum species. Reaction

of $[Ta(Me_2N)_3(NAr)]$ $(Ar = 2,6\text{-}C_6H_3Pr^i_2)$ with $N(CH_2in)_3$ gives the structurally characterised 6-coordinate complex $[Ta(N(CH_2in)_3)(NAr)(NMe_2H)]$, while reaction of $[Ta(NMe_2)_5]$ with $N(CH_2in)_3$ gives the hypodentate complex $[Ta((N(CH_2in)_3)(NMe_2)_3]$ in which the tripodal ligand is tridentate, with one indole N atom remaining protonated and unbound to the metal centre. Reaction of this complex with MeLi leads to deprotonation of the non-coordinated indole and eventual formation of $[Ta((N(CH_2in)_3)(NMe_2)_2]$ in which the tripodal ligand is tetradentate.

3.2.3. Tris(2-(1-pyrazolyl)methyl)amine (amtp)

The 3,5-dimethylpyrazolyl derivative of amtp was first prepared in 1980 from the reaction of potassium 3,5-dimethylpyrazolate with $N(CH_2Cl)_3$ in THF [113] while amtp itself was first reported in 1982 as the product of the reaction of 1-hydroxymethylpyrazole with ammonium acetate [114], and this latter method has also been adapted for the synthesis of the 3,5-dimethylpyrazolyl derivative [115]. Reaction of the amtp ligand with hydrated MX_2 salts (M = Co, Cu, Zn, X = Cl, NCS) in ethanol gives five-coordinate $[M(amtp)X]X \cdot nH_2O$ or six-coordinate $[M(amtp)X_2] \cdot nH_2O$ when excess ligand is used, whereas five-coordinate $[M(amtp)X]_2(MX_4)$ complexes are obtained under conditions of excess metal salt [116]. The amtp ligand, but not its 3,5-dimethylpyrazolyl derivative, is found to hydrolyse in the presence of some metal salts [117,118], with loss of a pyrazolylmethyl arm resulting in formation of a tridentate ligand, and this reactivity has been ascribed to the three small bite angles of the amtp ligand (~80°) which leads to highly strained complexes on coordination of a metal ion to all four N donor atoms. This strain appears to be exemplified in the complex $[Zn(amtp)(NCS)_2]$, where the X-ray structure (Fig. 12) shows the amtp ligand to bind in a hypodentate fashion through only two pyrazole N atoms (the Zn–N_{tert} distance is 2.599 Å), to give a four-coordinate trigonal pyramidal geometry about the Zn ion [119].

Hypodentate coordination of amtp is also proposed in the Rh(I) and Ir(I) complexes $[Ir(coe)(amtp)]BF_4$, $[M(cod)(amtp)]BF_4$ (M = Ir, Rh) and $[Rh(CO)_2(amtp)]BF_4$, although no X-ray structural data are available [120]. In contrast to the analogous trpyn ligand (Section 3.2.5), the 3,5-dimethylpyrazolyl derivative of amtp readily forms five-coordinate complexes. Thus treatment of the ligand with the appropriate metal salt gives five-coordinate $[M(amtpMe_6)X]BPh_4$ complexes (M = Fe, Co; X = Cl, Br, I), and Ni complexes of the formula $[Ni_2(amtpMe_6)_2X_2](BPh_4)_2$ (X = Cl, Br) are thought to be halo-bridged dimers with each Ni ion six-coordinate [113]. The five-coordinate complexes $[Co(amtpMe_6)(OH_2)](ClO_4)_2$ [121], $[Co(amtpMe_6)(OH_2)][Co(amtpMe_6)F](BF_4)_3 \cdot 1.5EtOH$ [115], and $[Cu(amtpMe_6)(ONO_2)](NO_3)$ [122] have been structurally characterised and display approximate trigonal bipyramidal geometries about the metal ion ($\tau > 0.60$) with the aliphatic N atom and the ancillary ligand occupying the apical positions. Six-coordinate $[Ni(amtpMe_6)(O_2NO)]NO_3$ [122], $[Co(amtpMe_6)(OH_2)(OAc)]ClO_4$ [123], $[Fe(amtpMe_6)(NO)(ClO_4)]ClO_4$ [124] and $[Fe(amtpMe_6)(NO)Cl]BPh_4$ [124,125], and seven coordinate $[Cd(amtpMe_6)(ONO_2)(O_2NO)]$ [122] have also been structurally characterised, as has dimeric $[(amtpMe_6)Fe(Cl)_2Fe(amtpMe_6](BPh_4)_2$ in which both Fe ions are six-coordinate [126]. The latter complex displays weak ferromagnetic coupling between the high-spin Fe(II) centres. Both blue $[Co(amtpMe_6)(N_3)](ClO_4)$ and red-purple $[Co(amtpMe_6)(N_3)_2]$ can be prepared, with the latter formed only under conditions of excess azide $(Co^{2+} : N_3^- = 1 : 5)$ [127]. X-ray structures show an approximate trigonal bipyramidal geometry about the five-coordinate Co(II) ion in the blue complex ($\tau = 1.01$), while the red-purple complex displays a distorted octahedral geometry, with an angle of 95.93° between the *cis* azide ligands. Potentiometric titration of $[Co(amtpMe_6)(OH_2)](ClO_4)_2$ reveals two pK_a values (7.4 and 8.9) with the latter ascribed to deprotonation of coordinated water and the former to proton loss from the tertiary N atom [128,129]. Two further derivatives of amtp, the chiral camphor-derived ligand L^1 [130] and the bulky *p*-methoxyphenyl-substituted ligand L^2 (Fig. 13) [131] have recently been reported. Cu(I) and Cu(II) complexes of the latter ligand have been structurally characterised, with five-coordinate $[CuL^2Cl_2]$ displaying hypodentate coordination through three N donor atoms, while both $[CuL^2Cl](SbF_6)$ and



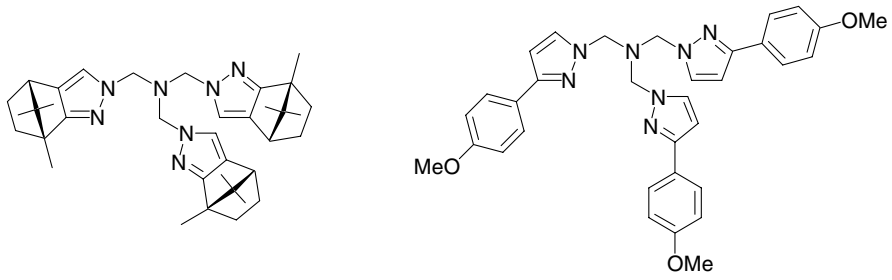


Fig. 12. X-ray structure of $[Zn(amtp)(NCS)_2]$.

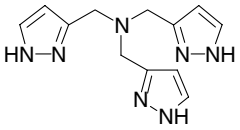
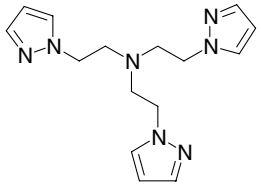


L^1 L^2

Fig. 13. Sterically demanding ligands derived from amtp.

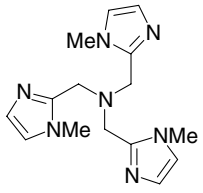


$[CuL^2(OH_2)](SbF_6)_2 \cdot MeOH$ show square pyramidal geometries about the Cu(II) ion ($\tau = 0.16$ and 0.17, respectively). All three complexes are reduced by BPh_4^- to give the $[CuL^2]^+$ ion, and the X-ray structure of $[CuL^2](CuCl_2)$ shows a trigonal pyramidal geometry about the Cu(I) ion in the cation. This complex is unreactive towards both O_2 and CO.

3.2.4. Tris(2-(3-pyrazolyl)methyl)amine (L^3)

The synthesis of this ligand and its 1-methylpyrazolyl and 1-benzylpyrazolyl derivatives from the appropriate 3-pyrazolyl esters was reported in 1985 [132], but there has been no further mention of this ligand in the literature.

3.2.5. Tris(2-(1-pyrazolyl)ethyl)amine (trpyn)



The preparation of the 3,5-dimethylpyrazolyl derivative of trpyn was first reported in 1981 [133,134] while the synthesis of trpyn and its 3,5-di-*t*-butylpyrazolyl derivative was published the following year [135]. The ligands were prepared by the reaction of the appropriate deprotonated pyrazole with tris(2-chloroethyl)amine, and metal complexes of each have been reported. Reaction of all three ligands with $[Cu(MeCN)_4]BF_4$ in MeCN gives the air-stable four-coordinate complexes $[Cu(L)]BF_4$, and the X-ray structure of $[Cu(trpynMe_6)]BF_4$ shows a distorted trigonal pyramidal geometry about the Cu(I) ion with the aliphatic N atom occupying the apical position. In THF solution, the Cu(I) complexes emit in the visible region between 433 and 453 nm on excitation in the UV (255–273 nm), with the excited state lifetimes for these processes being much longer than those found in Cu(I) polypyridyl complexes [136]. Reaction of both trpyn and $trpynMe_6$ with $[Cu(H_2O)_6](BF_4)_2$ in MeOH gives the five-coordinate Cu(II) complexes $[Cu(L)(OH_2)](BF_4)_2$, but the same reaction with $trpynBu_6$ results in isolation of the Cu(I) complex $[Cu(trpynBu_6)](BF_4)_2$ only, and the Cu(II) complex of this ligand cannot be prepared chemically, although cyclic voltammetry experiments show a one-electron oxidation at high potential (+0.94 V vs. SCE) which is chemically reversible only at scan rates of 5 $V\,s^{-1}$ or above [135]. The X-ray structure of $[Cu(trpyn)(OH_2)](BF_4)_2$ shows a distorted square pyramidal geometry about the Cu(II) ion with the aliphatic N atom in the square plane *trans* to the aquo ligand. Reaction of trpyn with hydrated $CuBr_2$ gives the green Cu(II) complex $[Cu(trpyn)Br]_3(CuBr_3)Br \cdot 3H_2O$, which contains three crystallographically non-equivalent $[Cu(trpyn)Br]^+$ moieties. The X-ray structure of this complex shows the three cations adopt distorted square pyramidal structures ($\tau = 0.36$–0.42) with the aliphatic N atom at the apical position [137]. A larger distortion towards trigonal bipyramidal geometry is found in $[Cu(trpyn)(NCS)][Cu(NCS)_2]$ ($\tau = 0.59$), with the tertiary N atom and NCS^- ligand being pseudo axial [138]. Neither $[Cu(trpyn)(OH_2)]^{2+}$ nor $[Cu(trpyn)Cl]^+$ were found to oxidise 3,5-di-*t*-butylcatechol, in contrast to a number of other Cu(II) complexes of tripodal amine ligands containing pyrazole or pyridine donors, and this was ascribed to a combination of both steric and electronic effects [139].

Several Co(II) complexes of trpyn and its 3,5-dimethylpyrazolyl derivative have been prepared. The trpyn complexes [Co(trpyn)X]Y (X = F, Cl, Br, I, NCS, NCO, N_3, ClO_4, acac, bzac, thbz, $(NCS)_2$, Y = BF_4, BPh_4, ClO_4) are five- and six-coordinate [140], but the $trpynMe_6$ ligand gives predominantly the four-coordinate cation $[Co(trpynMe_6)]^{2+}$, with the five coordinate

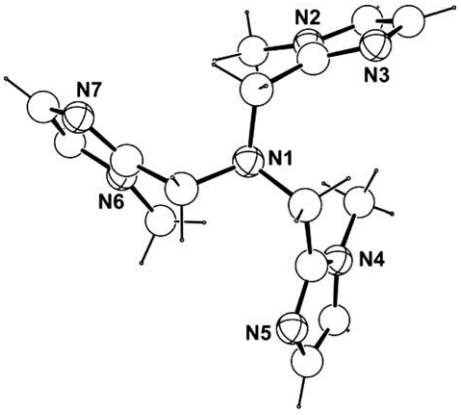
isothiocyanato complex $[Co(trpynMe_6)(NCS)]BPh_4$ being the only apparent exception [141]. The pink to magenta $[Co(trpyn)X]BPh_4$ complexes (X = F, Cl, Br, N_3) change colour to violet on heating, and the X-ray structure of the magenta form of the bromide complex shows this to be dimeric $[(trpyn)Co(Br)_2Co(trpyn)](BPh_4)_2$ with two bromide ligands bridging the six-coordinate metal ions. Six-coordinate $[Co(trpyn)(Me_2CO)_2](BPh_4)_2$ has also been structurally characterised [142]. The crystal structure of $[Co(trpynMe_6)](BPh_4)_2$ shows a tetrahedrally distorted trigonal pyramidal geometry about the metal ion with the aliphatic N atom in the apical position, and the methyl groups effectively shielding the remaining apical coordination site, thus preventing binding of further ligands [133]. This complex displays an unusual UV–Vis spectrum, with four d–d transitions at very high energy (7000–21,500 cm^{-1}) when compared to those of typical tetrahedral complexes, and this has been ascribed to the high ligand-field strength of the pyrazole donors [143]. In contrast to Co(II), the Ni(II) cations $[Ni(trpynMe_6)L]^{+/2+}$ (L = Cl, Br, NCS, OH_2) are five-coordinate, and yellow and emerald forms of the bromo complexes can be isolated. Crystal structures of yellow $[Ni(trpyn)Br]BPh_4 \cdot C_2H_5OH$ and emerald $[Ni(trpyn)Br]BPh_4 \cdot CH_3COCH_3$ show both cations to be five coordinate, with the yellow isomer displaying a significant distortion towards a trigonal bipyramidal geometry about the metal ion ($\tau = 0.44$) whereas the emerald isomer is essentially square pyramidal ($\tau = 0.12$) [141]. The extremely air-sensitive blue Cr(II) complex $[Cr(trpyn)(NCS)]BPh_4$ can be prepared from in situ-generated $[Cr(NCS)_2]$ in ethanol, and air-oxidation of this gives the green oxo-bridged dimer $[(trpyn)(NCS)Cr(O)Cr(NCS)(trpyn)](BPh_4)_2$ containing an essentially linear (176.5°) Cr–O–Cr bridge which is thought to mediate a strong antiferromagnetic coupling between the Cr ions (μ_{eff} (300 K) = 1.63 μ_B per Cr ion) [144]. A Ru(II) complex containing the trpyn ligand has also been reported [145].

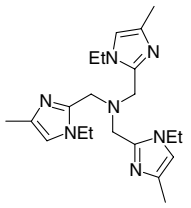
3.2.6. Tris(2-(1-methylimidazolyl)methyl)amine (tmima)

The first reference to tmima in the literature came in 1990 in a study of alkane functionalisation by iron complexes in the presence of H_2O_2 [146] and the synthesis of the ligand was detailed shortly thereafter from the reaction of 1-methyl-2-aminomethylimidazole with two equivalents of 2-chloromethyl-1-methylimidazole [147]. While the free ligand is hygroscopic and cannot be easily crystallised, it can be co-crystallised with boric acid and the crystal structure of this assembly shows the ligand to have approximate three-fold symmetry, with a paddle-wheel-like arrangement of the imidazole rings (Fig. 14) [148].

pK_a values for triprotonated tmima are 4.57, 6.00 and 7.30 [149]. Reaction of tmima with $CuCl_2 \cdot 2H_2O$ in MeOH and addition of $NaPF_6$ gives five-coordinate $[Cu(tmima)Cl]PF_6 \cdot MeCN$ (crystallised from MeOH/MeCN) which adopts a trigonal bipyramidal geometry ($\tau = 0.94$), and reaction of this complex with 1-methylimidazole gives $[Cu(tmima)(1\text{-}Meim)](PF_6)_2$. Electrochemical and UV/vis spectral data for these complexes suggest that the tmima ligand exerts a weaker ligand field than tpa (Section 3.2.9) [147]. Reaction of tmima with anhydrous $FeCl_3$ in ethanol and addition of $NaClO_4$ gives monomeric six-coordinate $[Fe(tmima)Cl_2]ClO_4 \cdot 0.5MeCN$ [150] while dimeric $[(tmima)(OH_2)Fe\text{-}OFe(OH_2)(tmima)](ClO_4)_4$ is obtained on reaction of tmima with $Fe(ClO_4)_3 \cdot 9H_2O$ [151]. The asymmetric dimer $[(temima)Fe(O)(OAc)Fe(tmima)](ClO_4)_3$ (the structure of temima is depicted in Fig. 15) has also been reported [152].

The Mn(III,III) dimer $[(tmima)Mn(O)(OAc)Mn(tmima)](ClO_4)_3 \cdot 2MeCN$ is obtained on reaction of tmima with $Mn(OAc)_3 \cdot 2H_2O$ in ethanol, addition of $NaClO_4$ and crystallisation from MeCN, and the Mn ions in this complex display weak ferromagnetic coupling ($J = 1.33$ cm^{-1}) [153]. Three Hg(II) complexes of tmima, namely eight-coordinate $[Hg(tmima)_2](ClO_4)_2$, five-coordinate $[Hg(tmima)(NCCH_3)](ClO_4)_2$ and five-coordinate $[Hg(tmima)Cl]_2(HgCl_4)$, have been prepared and structurally characterised [154]. The latter complexes display trigonal bipyramidal geometries ($\tau = 1.15$ and 0.85, respectively) and both show Hg–H coupling at −40 °C in CD_3CN. Tmima binds Zn^{2+} strongly as a 1:1 complex in aqueous solution (log $K = 11.98$) and the pK_a for the so formed $[Zn(tmima)(OH_2)]^{2+}$ cation is 8.72 [149].





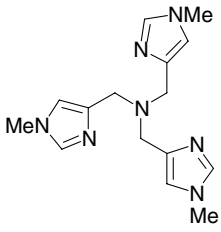


Fig. 14. X-ray structure of the tmima ligand (co-crystallised H_3BO_3 molecule not shown).

38

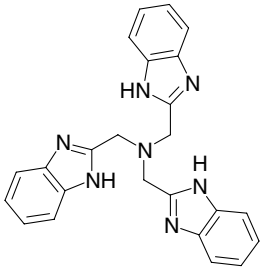

Fig. 15. Structure of the temima ligand.

3.2.7. Tris(4-(1-methylimidazolyl)methyl)amine (T4IA)

This ligand was first reported in 2003, from the reaction of 1-methylimidazole-4-carboxaldehye with ammonium chloride and subsequent hydrogenation (Pd/C) [149]. pK_a values for the triprotonated ligand are 5.26, 5.79 and 8.36. The only complex thus far reported is $[Zn(T4IA)OH_2]^{2+}$ generated in aqueous solution ($\log K = 12.47$), which has a pK_a of 9.11.

3.2.8. Tris(2-benzimidazolylmethyl)amine (ntb)

The benzimidazole derived ligand ntb and its complexes have been studied extensively since the first report of the synthesis of ntb in 1977 [155]. The ligand was originally prepared in over 50% yield by fusion of either nitrilotriacetonitrile or nitrilotriacetic acid with *o*-phenylenediamine at ~200 °C, while a more recent synthesis involves heating a mixture of nitrilotriacetic acid and *o*-phenylenediamine in ethylene glycol at 140–200 °C [156]. Reaction of the appropriately substituted *o*-phenylenediamine with nitrilotriacetic acid also allows synthesis of ntb derivatives having substituents on the benzene ring and both the tris(5,6-dimethyl)-substituted [157] and tris(6-sulfonato)-substituted [158] ntb ligands have been prepared by this route. The free ntb ligand can be crystallised as a monohydrate, and the crystal structure shows the water molecule to sit in the cleft formed by the aliphatic N atom and the three arms of the tripodal ligand, where it is hydrogen-bonded in an approximately tetrahedral fashion to three imidazole N donors of one ligand molecule, and one of a neighbouring molecule [159]. The free ligand also forms a 1:2 inclusion compound with 4-nitrobenzoic acid in which one acid molecule is hydrogen-bonded in the same cleft [160]. The ligand can be deprotonated with potassium, and subsequent reaction with alkylating agents gives the tris-alkylated products. Thus the tris(N-methyl) [161], tris(N-ethyl), tris(benzyl), tris(*o*-methylbenzyl) [162] and tris(N-propyl) [163] derivatives of ntb have been prepared by this method. Ntb can also be selectively alkylated at a benzimidazole N atom and the mono(*N*-carboxymethyl) derivative HAcntb has been reported [164]. Similarly, ntb derivatives having a methyl, isobutyl or isopropyl group in place of a methylene proton on only one of the tripodal arms can be prepared by condensation of *o*-phenylenediamine with an asymmetric nitrilotriacetic acid derivative, which is itself prepared from the reaction of alanine, leucine or valine with two equivalents of chloroacetic acid [165].

The ntb ligand forms predominantly five- and six-coordinate complexes, a significant number of which have been structurally characterised. Table 5 lists the mononuclear five-coordinate complexes of ntb for which X-ray structures are available, and it can be seen that these almost exclusively exhibit trigonal bipyramidal geometries about the metal ion.

The notable exception to this is $[Cu(ntb)Cl]Cl \cdot 3H_2O$ [166] ($\tau = 0.34$) which is distorted square pyramidal with the chloride ligand and three N atoms constituting the square plane (Fig. 16).

τ values slightly greater than unity are obtained for some ntb complexes owing to the fact that the metal ion generally sits slightly below the plane of the three imidazole donor N atoms, and this arrangement results in the bond between the metal ion and the aliphatic N atom usually being significantly longer than those to the imidazole N atoms. In some cases, this results in hypodentate tridentate coordination of the ligand, with binding to the metal ion through the imidazole N atoms only. Examples of this include $[Zn(ntb)(SPh)]BPh_4 \cdot MeCN \cdot 2CH_3OH$ [167] ($Zn–N_{tert} = 2.590$ Å), $[Mn(ntb)Cl]Cl \cdot 2H_2O$ [168] ($Mn–N_{tert} = 2.483$, 2.498 Å), $[Mn(ntb)Cl]Cl \cdot 2CH_3OH \cdot 0.5H_2O$ [169] ($Mn–N_{tert} = 2.502, 2.519$ Å), $[Mn(ntb)(sal)]ClO_4$ [170] ($Mn–N_{tert} = 2.507$ Å), [Mn(ntb)(terephthalate)]$0.5CH_3OH \cdot 0.5H_2O \cdot DMF$ [171] ($Mn–N_{tert} = 2.526$ Å) and $[Mn(ntb)Cl][Mn(ntb)Cl_2]Cl \cdot EtOH \cdot 3H_2O$ [172] ($Mn–N_{tert} = 2.516$ Å). The latter complex contains both four- and five-coordinate cations in which the metal ion is formally not bound to the tertiary N atom. $[Cu(ntb)(PPh_3)]NO_3 \cdot 1.5H_2O$ provides a crystallographically characterised example of a hypodentate ntb com-

plex in which one of the benzimidazole arms is not coordinated to the metal centre, presumably due to the steric bulk of the PPh_3 ligand [166].

Complexes of ntb with the first row transition metals from V–Zn and some second and third row transition metals have been reported. Of particular note are the complexes $[Cd(ntb)X]^+$ (X = Cl^-, Br^-, I^-, CN^-, PhS^-, L-cysteinate) which, unusually, display slow exchange ^{113}Cd NMR spectra in d^6-Me_2SO solution [173]. A number of lanthanide and actinide complexes of ntb have also been synthesised and studied. The eight-coordinate lanthanide complexes have the stoichiometry $[Ln(ntb)_2]^{3+}$ (Ln = Eu, Pr, Tb, La, Nd, Lu) [174–177] when prepared by reaction of the metal perchlorate with the ligand, even in the presence of excess metal ion, and this has been ascribed to strong intramolecular π–π interactions between the two ntb ligands both in the solid state and in solution (Fig. 17) [176].

Reaction of $LuCl_3 \cdot 6H_2O$ with 2 equivalents of ntb also gives the bis ligand cation $[Lu(ntb)_2]^{3+}$, but reaction of a number of lanthanide nitrates with ntb in a 1:1 ratio gives ten-coordinate $[Ln(ntb)(O_2NO)_3] \cdot H_2O$ complexes (Ln = La, Ce, Nd, Sm, Eu, Gd, Tb, Dy, Er) which undergo dissociation of the ntb ligand in DMSO solution [178]. The U(III) bis ligand complex $[U(ntb)_2]I_3$ can also

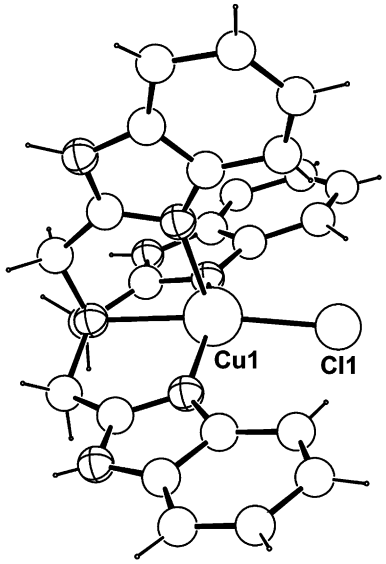

Fig. 16. X-ray structure of the $[Cu(ntb)Cl]^+$ cation.

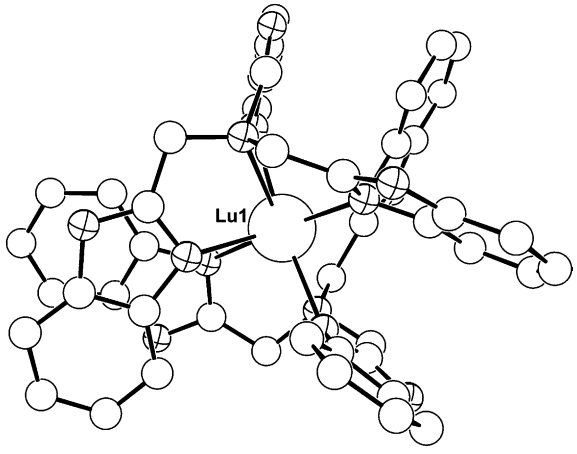

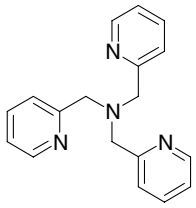

Fig. 17. View of the $[Lu(ntb)_2]^{3+}$ cation emphasising the π–π interactions between the ntb ligands.

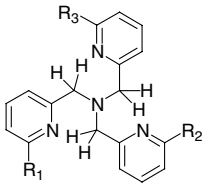
be prepared from reaction of $[UI_3(THF)_4]$ with two equivalents of ntb [174]. The ntb ligand and its N-alkylated derivatives display a rich coordination chemistry with Ag(I), with mono-, di-, tri- and tetranuclear complexes having been reported. Thus reaction of $AgCF_3SO_3$ with ntb in a 3:2 molar ratio gives the trinuclear complex $[Ag_3(ntb)_2](CF_3SO_3)_3$ [179] while reaction of $AgCF_3CO_2$ with ntb in a 2:1 molar ratio gives tetranuclear $[Ag_4(ntb)_2(CF_3CO_2)_2(MeCN)_2](CF_3CO_2)_2 \cdot 2H_2O$ [163]. The sodium salt of the HAcntb ligand (vide supra) reacts with $Cu(ClO_4)_2 \cdot 6H_2O$ to give the hexameric cation $[Cu_6(Acntb)_6]^{6+}$, the perchlorate salt of which crystallises to give a nanoporous network containing large octahedral voids [164].

3.2.9. Tris(2-pyridylmethyl)amine (tpa, tmpa)

Tpa was first prepared by Anderegg and Wenk in 1967 from the reaction of 2-(aminomethyl)pyridine with two equivalents of 2-(chloromethyl)pyridine in aqueous solution [180] and this, or slight modifications thereof, appears to be the method of choice for the synthesis of this ligand to the present day [181]. Derivatives of tpa substituted on either the pyridine rings or at a methylene carbon can be prepared by adaptation of this method and use of the appropriately substituted starting materials. Particular interest has centred on the synthesis of tpa derivatives having substituents at the 6-positions of the pyridyl rings and the ligands of this type that have been prepared are detailed in Table 6.



While the free base of tpa is an oil, the triprotonated ligand has been crystallographically characterised as the $\cdot 3HClO_4$ [182], $\cdot (SO_4)(NO_3)$ [183], $\cdot (CF_3SO_3)_2(PF_6)$, $\cdot (Br)(PF_6)_2$ and $\cdot (Cl)(PF_6)_2$ [184] salts, and in all cases, the ligand adopts a similar conformation to that which obtains when it coordinates to a metal ion, with the three protonated N atoms positioned to form a cleft into which the anion is hydrogen-bonded. The pK_a values for the triprotonated ligand have been measured in a number of studies, with values of 2.55, 4.35 and 6.17 (20 °C, 0.1 M KNO_3) [180,185] and 2.73, 4.49 and 6.28 (25 °C, 0.1 M $NaClO_4$) [186] having been measured by potentiometric titration. Observation of peaks over the range chemical shift range $\delta = 200$–300 ppm in ^{14}N and ^{15}N NMR studies of the protonation of tpa in both MeOH and 1 M HNO_3 confirm the pyridine N atoms as the most basic in the molecule, with the failure to observe a signal for the aliphatic N atom even at high acidity being ascribed to the long relaxation times typical of unprotonated N atoms [187].

Tpa is one of the two most studied tripodal tetradentate amine ligands (tren being the other), with complexes of all first row metals except Ti having been reported, along with most second and third row metals, as well as the majority of lanthanide ions. Formation constants for the formation of 1:1 $[M(tpa)]^{n+}$ complexes with a number of metal ions have been measured, and these are given in Table 7.

Various 1:2 $[M(tpa)_2]^{n+}$ complexes have also been prepared and a study of these has shown that the ionic radius of the metal ion is crucial in determining the stoichiometry of the complexes obtained from the reaction of the metal ion with tpa, with 1:2 complexes being formed for metal ions having ionic radii greater than 0.9 Å, while smaller ions give 1:1 complexes [183]. There are no crystallographically characterised examples of four-coordinate transition metal complexes of the type $[M(tpa)]^{n+}$, although the thallium complex $[Tl(tpa)]_2(H_3O)(NO_3)_3$ has been shown to contain a $[Tl(tpa)]^+$ cation [188]. Monomeric five-coordinate complexes containing tetradentate tpa are relatively common, and those that have been structurally characterised are listed in Table 8.

These complexes display, without exception, trigonal bipyramidal geometries in which the aliphatic N atom occupies an axial site, with the smallest τ value being 0.74. Numerous six-coordinate complexes have been structurally characterised, while $[Cd(tpa)(O_2NO)OH_2](NO_3) \cdot 3H_2O$ (seven-coordinate) [189], $[Fe(tpa)_2](BPh_4)_2$ [190], $[Hg(tpa)_2](ClO_4)_2$ [191], $[Cd(tpa)_2](ClO_4)_2 \cdot C_7H_8$ [192], $[La(tpa)(py)(I)_3]$ [174] and $[Mn(tpa)_2](ClO_4)_2$ [193] (eight coordinate) providing examples of structurally characterised high coordinate tpa complexes. Iron complexes of tpa have received particular attention, most notably due to their reactivity in alkane hydroxylation reactions [194]. Thus, complexes such as $[Fe(tpa)Cl_2]ClO_4$ [195], $[Fe(tpa)Br_2]ClO_4$ [196], $[Fe_2O(OAc)(tpa)_2](ClO_4)_3$ [197] and $[Fe_2O(tpa)_2(H_2O)_2](CF_3SO_3)_4$ [198] have been found to catalyse alkane functionalisation reactions in the presence of *t*-BuOOH, purportedly via a mechanism involving production of a high valent Fe(IV)-oxo species, although an alternative mechanism involving H-atom abstraction by hydroperoxide-derived alkoxyl radicals has also been proposed [199,200]. However, the reaction of $[Fe(tpa)(MeCN)_2]^{2+}$ with one equivalent of peracetic acid in MeCN at −40 °C has recently been shown to give the pale green Fe(IV) complex $[Fe(O)(tpa)]^{2+}$, which is stable for several days at −40 °C, and which was characterised by ES-MS, Mössbauer spectroscopy, XANES and EXAFS spectroscopy [201], thus demonstrating that high valent oxo species can indeed be accessed in Fe/tpa systems. Reaction of $Fe(CF_3SO_3)_2 \cdot 2MeCN$ with tpa in a variety of solvents affords a

range of products having different stoichiometries, coordination numbers and spin states. Reaction with one equivalent of tpa in MeCN gives low-spin [Fe(tpa)-$(MeCN)_2$]$(CF_3SO_3)_2$ but dissolution of this complex in $CHCl_3$ and addition of pentane gives high-spin [Fe(tpa)-$(OSO_2CF_3)_2$]. Reaction of $Fe(CF_3SO_3)_2 \cdot 2MeCN$ with two equivalents of tpa in MeOH gives eight-coordinate $[Fe(tpa)_2](BPh_4)_2$ (Fig. 18) on addition of $NaBPh_4$,

[a] More than one independent molecule in the aysmmetric unit.

while the same reaction in acetone in the absence of $NaBPh_4$ gives $[Fe(tpa)_2](CF_3SO_3)_2$ which contains six-coordinate Fe(II), with one arm of each ligand remaining uncoordinated to the metal centre (Fig. 19) [190].

Reaction of $CuCl_2$ with tpa in MeOH and subsequent addition of $NaPF_6$ gives $[Cu(tpa)Cl]PF_6$ [202] while addition of the ligand to $[Cu(MeCN)_4]X$ (X = ClO_4, PF_6) in MeCN under argon gives [Cu(tpa)(MeCN)]X [203]. $[Cu(tpa)(MeCN)]PF_6$ is extremely reactive towards O_2 at −85 °C, initially giving a transient monomeric superoxo complex which then reacts further to give the peroxo-bridged dimer $[(tpa)Cu(O_2)Cu(tpa)](PF_6)_2 \cdot 5Et_2O$ which has been structurally characterised. The same reaction at room temperature gives a mixture of the fluoride-bridged dimer $[Cu(tpa)F]_2(PF_6)_2$ and monomeric $[Cu(tpa)F](PF_6)_2 \cdot CH_2Cl_2$, with the coordi-

nated fluoride ligands being derived from the PF_6^- counterion [204]. $[Cu(tpa)(MeCN)]PF_6$ also reacts with PPh_3 to give the four coordinate complex $[Cu(tpa)(PPh_3)]PF_6$, which contains hypodentate tridentate tpa, presumably due to the steric bulk of the PPh_3 ligand. A number of polynuclear complexes containing multiple $[Cu(tpa)]^{n+}$ units have been prepared. In addition to the peroxo- and bis(fluoro)-bridged dimers mentioned above, dimeric $[(tpa)CuCNCu(tpa)](ClO_4)_3$ [205,206], $[(tpa)Cu(S_2)Cu(tpa)](ClO_4)_2 \cdot 3Et_2O$ [207], $[(tpa)Cu(\mu_2\text{-}CO_3)Cu(tpa)](ClO_4)_2 \cdot 2EtCN$ [208] and $[(tpa)CuCNCu(tpa)]ClO_4$ [209] have been reported; the latter features two tridentate tpa ligands, in keeping with the preference of Cu(I) for four-coordination. The tricopper complexes $[(tpaCu)_3(\mu_3\text{-}CO_3)](ClO_4)_4$ [210], containing a triply-bridging carbonate ligand, and $[(tpaCu)_3(\mu_3\text{-}1,3,5\text{-benzenetricarboxylate})](ClO_4)_3 \cdot 4H_2O$ are also known [211]. The trinuclear complex $[((tpa)Cu(NC))_2Fe(CN)_4]ClO_4 \cdot 6H_2O$ [212], in which the two Cu(tpa) units are situated *trans* with respect to the octahedral Fe centre, and the related complex $[(tpa)Cu(\mu\text{-}NC)(F_8\text{-}TPPFe)(\mu\text{-}CN)Cu(tpa)](PF_6)_3 \cdot 4CH_2Cl_2$ [213], which contains two $[Cu(tpa)NC]^+$ units coordinated in the *trans* axial positions of an iron porphyrin, have also been structurally characterised. The heptanuclear complex $[Fe((CN)Cu(tpa))_6](ClO_4)_8 \cdot 3H_2O$ is prepared by reaction of $K_3[Fe(CN)_6]$ with six equivalents of $[Cu(tpa)(OH_2)](ClO_4)_2$ in water, while reaction of $[Cu_6((PhSiO_2)_6)_2(n\text{BuOH})_{6-x}(H_2O)_x]$ with $[Cu(tpa)(CN)]PF_6$ gives the decacopper complex $[Cu_6((PhSiO_2)_6)_2(NCCu(tpa))_4](PF_6)_4$ [214].

The chemistry of tpa with chromium is dominated by dimeric species, and monomeric complexes are relatively rare. Reaction of $CrCl_2$ with one equivalent of tpa in THF gives $[Cr(tpa)Cl_2]$, while treatment of $[Cr(THF)_3Cl_3]$ with one equivalent each of tpa and $NaBPh_4$ in THF gives $[Cr(tpa)Cl_2]BPh_4$ [215]. The Cr(II) complex is tetragonally distorted, with the axial Cr–N and Cr–Cl bond distances significantly longer than their equatorial counterparts, and magnetic measurements confirm the high-spin nature of the metal ion which gives rise to this Jahn–Teller distortion. Reaction of the Cr(III) complex with the appropriate Grignard reagent gives the cationic Cr(III) alkyl species $[Cr(tpa)(Me)_2]BPh_4$ and $[Cr(tpa)(Ph)_2]BPh_4$, and all the complexes studied were found to be active catalysts for the polymerisation of ethene in the presence of MAO. Routes to other monomeric Cr/tpa complexes often utilise cleavage of dimeric Cr(III) species, which are themselves generally obtained from treatment of a Cr(II) salt with tpa and subsequent air oxidation, or reaction of the ligand with a Cr(III) salt. Thus the dihydroxy-bridged dimer $[(tpa)Cr(OH)_2Cr(tpa)](ClO_4)_4 \cdot 4H_2O$ results from treatment of aqueous $Cr(ClO_4)_2$ with tpa in EtOH and subsequent air oxidation, and can also be prepared by reaction of $tpa \cdot 3HClO_4$ with $Cr(NO_3)_3 \cdot 9H_2O$ [216]. Treatment of this with a twenty-fold excess of NaSCN gives the linear μ-oxo dimer $[(tpa)(NCS)CrOCr(NCS)(tpa)](ClO_4)_2 \cdot 0.5H_2O$ [217,218]. Other dimeric species to have been structurally characterised are $[(tpa)Cr(\mu\text{-}O)(\mu\text{-}CO_3)Cr(tpa)](ClO_4)_2 \cdot 2H_2O$ [219], $[(tpa)Cr(\mu\text{-}Cl)_2Cr(tpa)]X_2$ ($X = BPh_4$, $BAr^F{}_4$) [215] and $[(tpa)Cr(\mu\text{-}O)(\mu\text{-}CH_3CO_2)Cr(tpa)](ClO_4)_3 \cdot 0.7H_2O$ [220], while the tetranuclear malonate ($n = 1$) and succinate ($n = 2$) complexes $[(\mu\text{-}O_2C(CH_2)_nCO_2)(tpa)Cr(\mu\text{-}O)Cr(tpa)_2](ClO_4)_6 \cdot 4H_2O$ have also been isolated [221]. Monomeric Ru(II) and Ru(III) complexes of tpa have been investigated as catalysts for the *m*-CPBA-mediated functionalisation of various alkanes [222,223], and it is of note that the two geometric isomers of $[Ru(tpa)(Me_2SO)Cl]^+$ show different catalytic activities in the reaction with adamantane. Mono-oxo ruthenium species have been suggested to be the active agents in such reactions. The crystal structure of $[Ru(tpa)(bipy)](PF_6)_2$ indicates steric congestion manifested by elongated Ru–N bond distances, and NMR studies in CD_3CN show this complex relieves the steric strain by undergoing thermal dissociation of one arm of the tpa ligand to give the hypodentate complex $[Ru(tpa)(bipy)(NCCD_3)]^{2+}$. This reaction can also be initiated by photoirradiation and was found to be reversible under these conditions [224].

Rhodium alkene complexes of tpa have been found to react with oxidants such as H_2O_2 and O_2 to give unusual metallacyclic products. For example, while the Rh(I) complex $[Rh(tpa)(CH_2CH_2)]BPh_4$ is oxidised by air in solution to give unidentified products, reaction of the solid complex with air leads to the formation of only one of two possible isomeric 3-rhoda-1,2-dioxolanes (Fig. 20), whereas the PF_6^- salt gives a 1:1 mixture of both isomers [225]. The analogous Ir complex reacts similarly. $[Rh(tpa)(CH_2CH_2)]^+$ is also oxidised by H_2O_2 to give the rhodaoxetane [226,227].

Given the extensive chemistry of Co(III) with tren, it is remarkable that there have been so few Co(III)

complexes of tpa reported. Of these very few, the most interesting are the complexes $[Co(tpa)(CH_2NH_2)](ClO_4)_2$ and $[Co(tpa)(CH_2NHMe)](ClO_4)_2 \cdot H_2O$ containing three-membered metallacycles, which are prepared by photolysis of the amino acid chelates $[Co(tpa)(AA)]^{2+}$ (AA = gly, sar), respectively [228]. Mono- [189,229, 230], di- [229,231–233] and trinuclear (Fig. 21) [210, 231] Zn complexes of tpa have been structurally characterised, and nickel tpa complexes also exhibit a variety of nuclearities.

A variety of bridging ligands have been found in structurally characterised complexes containing the dimeric cations $[(tpa)Ni(\mu\text{-}X)_2Ni(tpa)]^{2+}$ (X = OH [234–236], Cl [237,238], Br [239], $O_2P(OPh)_2$ [240]) and the X-ray structures of analogous dimers containing the bidentate bridging ligands CO_3^{2} [234] and $C_2O_4^{2}$ [241] have also been reported. The tpa ligand can stabilise Re in both low and high oxidation states, with the Re(I) and Re(II) dinitrogen complexes $[Re(tpa)(PPh_3)(N_2)](CF_3SO_3)$ and $[Re(tpa)(PPh_3)(N_2)](CF_3SO_3)_2$ [242], and the Re(VII) oxo complex $[Re(O)_3(tpa)]PF_6$ [243] having been structurally characterised. X-ray structures of the Re(V)-oxo complexes $[Re(tpa)(O)L]PF_6$ (L = chelated 2-amidophenolate, catecholate, 1,2-ethanediolate) show hypodentate tridentate coordination of the tpa ligand, while it is tetradentate in the analogous complex $[Re(tpa)(O)(OMe)](PF_6)_2$, which contains a monodentate methanoate ligand [243,244]. Oxo-complexes are also found in vanadium complexes of tpa, with the (IV/V) mixed-valence oxo-bridged dimer $[(tpa)(O)VOV(O)(tpa)](ClO_4)_3 \cdot MeCN$ being notable amongst these [245], while the mixed valence manganese (III,IV) dimer $[(tpa)Mn(\mu\text{-}O)_2Mn(tpa)](S_2O_6)_{1.5} \cdot 7H_2O$ has also been structurally characterised [246]. Reaction of $LnCl_3 \cdot 6H_2O$ with one equivalent of tpa in MeOH gives seven- or eight-coordinate $[Ln(tpa)(MeOH)_nCl_3]$ species (n = 0 for Eu, Tb, Lu, n = 1 for La, Nd), and X-ray structures of the Eu, Tb and Lu complexes are available [247].

3.2.10. Tris(2-(2-pyridyl)ethyl)amine (tepa)

Tepa was first reported by Karlin and coworkers in 1982, from the reaction of 2-vinylpyridine with ammonium acetate in methanol [248], and although another partial synthesis was subsequently reported [249], a detailed synthesis of the ligand was not published until 1994 [250]. Two further syntheses have since been reported [139,251], and the ligand can also be isolated as the mono(hydrogenperchlorate) [251] and tetrahydrochloride [250] salts. The crystal structure of the former (Fig. 22) shows the proton to reside on the aliphatic N atom, which is presumably the most basic centre in the free base ligand [251]. This is in contrast to the aliphatic tripodal tetraamine ligands, where this N atom is the least basic centre, and indeed cannot be protonated in some instances. Measured pK_a values for tepa in aqueous solution (25.0 °C, I = 0.10) are 8.21, 3.94, 3.51 and <2 [252].

The majority of investigations into the coordination chemistry of the tepa ligand have involved complexes of Cu(I) and Cu(II), owing to the importance of such complexes as possible models for the active sites of various copper-containing metalloproteins. Reaction of tepa with cupric nitrate in MeOH and subsequent addition of $NaBPh_4$ gives the four-coordinate Cu(I) complex $[Cu(tepa)]BPh_4$ in which the metal ion adopts a distorted tetrahedral geometry, while Cu(II) complexes of tepa are almost exclusively five-coordinate. The crystallographically characterised five-coordinate complexes $[Cu(tepa)(ONO_2)]NO_3$ [253], $[Cu(tepa)Cl]PF_6 \cdot CH_2Cl_2$

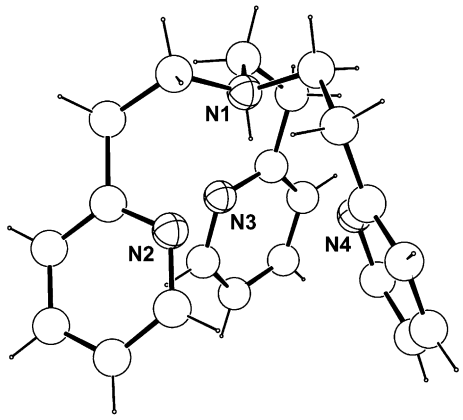

Fig. 22. X-ray structure of the monoprotonated tepa cation in tepa · $HClO_4$.

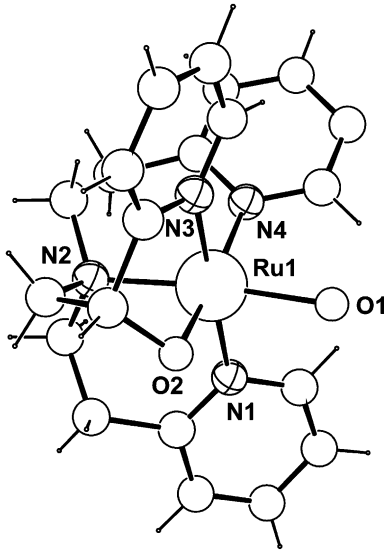
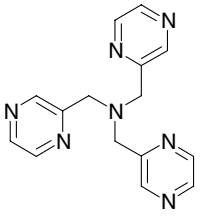
[202], [Cu(tepa)(OH_2)](CF_3SO_3)$_2$ · H_2O [254] and [Cu(tepa)($OC(O)CH_3$)]PF_6 [254] all display approximate square pyramidal geometries about the metal ion (τ values of 0.07, 0.19, 0.12 and 0.04, respectively), with a pyridyl N atom occupying the apical site, while the 1-methylimidazole complex [Cu(tepa)(1-Meim)](PF_6)$_2$ lies exactly halfway between square pyramidal and trigonal bipyramidal geometry ($\tau = 0.50$) [248]. The six-coordinate complex [Cu(tepa)(ONO)]PF_6 contains an asymmetrically chelated nitrite ligand with one short (2.012 Å) and one long (2.633 Å) Cu–N bond and a resulting distorted octahedral geometry about the Cu ion [255]. Rate data for the reaction of both free base and monoprotonated tepa with $[Cu(H_2O)_6]^{2+}$ in aqueous solution suggest that initial Cu–N bond formation with a pyridyl nitrogen atom is probably rate-determining in the case of the free base ligand, whereas the monoprotonated ligand reacts such that proton loss from the tertiary N atom following initial coordination of a pyridine nitrogen atom becomes rate determining [256]. Despite the aforementioned rationale for the synthesis of Cu/tepa complexes, the oxygen chemistry of such species is virtually non-existent. $[Cu(tepa)]^+$ is unreactive towards dioxygen in both acetone and propionitrile solution [251] which is surprising given the measured reduction potentials for the $[Cu(tepa)]^{2+/+}$ couple of 0.51 V [252] and 0.315 V [257] obtained in two separate studies, although these values do refer to aqueous solution. Stopped flow studies of the reaction of [Cu(tepa)(ClO_4)]ClO_4 with H_2O_2 in MeOH at −90 °C have given evidence for the formation of a Cu^{II}-hydroperoxo intermediate which rapidly decays to give $[Cu(tepa)]^+$ [258].

Few other transition metal complexes containing tepa have been reported. Four-coordinate [Zn(tepa)](ClO_4)$_2$ displays a distorted tetrahedral geometry about the metal ion [259] and a very similar overall structure to [Cu(tepa)]BPh_4. The Co(III) complex [Co(tepa)(O_2CO)]ClO_4 can be protonated in aqueous solution to give the structurally characterised complex [Co(tepa)O_2COH](ClO_4)$_2$ · $3H_2O$ which contains a rare example of chelated bicarbonate [260]. Interestingly, [Co(tepa)(O_2CO)]ClO_4 cannot be prepared by air oxidation of a Co(II) precursor in the presence of the ligand, and PbO_2 must be used as the oxidant in this reaction. ^1H and ^{13}C NMR data show that tepa forms an adduct with Li^+ but not with Na^+ in D_2O and deuterioacetone [250], while qualitative ESI-MS experiments suggest that tepa binds Li^+ with high selectivity in MeOH/H_2O mixtures containing equimolar Li^+, Na^+, K^+, Rb^+ and Cs^+. No peaks corresponding to K^+, Rb^+ or Cs^+ binding were observed, and the Li/Na selectivity was 10:1, compared to 8:1 found for tpa [261]. [Ru(tepa)Cl_2]Cl has been prepared by reaction of K_2[Ru(H_2O)Cl_5] with tepa in refluxing ethanol. Treatment of this with silver *p*-toluenesulfonate and subsequent addition of H_2O_2 and NaClO_4 results in the formation of [Ru(N_4O)(OH_2)](ClO_4)$_2$ (Fig. 23), in which C–H bond activation at the methylene carbon adjacent to the pyridyl ring of one arm of the tripodal ligand has occurred to give the formally pentadentate N_4O ligand [249,262]. Remarkably, the same reaction occurs in the absence of H_2O_2, indicating the possible involvement of the Ru(III) centre in the oxidation process. Treatment of [Ru(N_4O)(H_2O)](ClO_4)$_2$ with $(NH_4)_2$[Ce(NO_3)$_6$] in cold water gives the Ru(V)-oxo complex [Ru(N_4O)O](ClO_4)$_2$ which exhibits a strong Ru=O stretch at 872 cm^{-1} in its IR spectrum. This complex is stable for several days in the solid state at 0 °C and is found to oxidise a wide variety of organic substrates in good yield. Its oxidising strength is attested to by the fact that it can oxidise chloride ion to molecular chlorine.





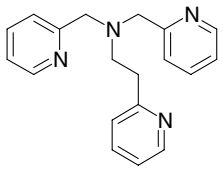


Fig. 23. X-ray structure of the $[Ru(N_4O)OH_2]^{2+}$ cation.

3.2.11. Tris((2-pyrazinyl)methyl)amine (tpza)

Tpza was first reported in 1998, from the reaction of two equivalents of 2-(chloromethyl)pyrazine with 2-(methylamino)pyrazine in THF [247]. Only a single pK_a value for this ligand can be measured over the pH range 0.9–6.5, and this presumably corresponds to deprotonation of the aliphatic N atom. Thus far, the coordination chemistry of this ligand is restricted to a number of lanthanide and actinide complexes. The ten-coordinate complex $[Nd(tpza)(MeCN)_3(OH_2)_3](ClO_4)_3 \cdot 3H_2O$ is obtained on reaction of the ligand with $Nd(ClO_4)_3 \cdot 6H_2O$ in MeCN and other less well-characterised high coordinate complexes are obtained for La^{3+} and Eu^{3+}. The isostructural eight-coordinate complexes $[La(tpza)I_3(MeCN)] \cdot MeCN$ and $[U(tpza)I_3(MeCN)] \cdot MeCN$ are obtained on treatment of the appropriate $MI_3(THF)_4$ complex with one equivalent of ligand in THF/MeCN, while the same reaction in solely THF as solvent gives the isostructural complexes $[La(tpza)I_3(THF)] \cdot THF$ and $[U(tpza)I_3(THF)] \cdot THF$. All four complexes have been structurally characterised [263].

3.2.12. Bis((2-pyridyl)methyl)-2-((2-pyridyl)-ethyl)amine (pmea)

Pmea was first prepared in 1983 from the reaction of (2-(2-pyridyl)ethyl)amine with 2-(chloromethyl)pyridine [264]. Although this procedure gave only a 10% yield of ligand, subsequent improvements have now allowed yields approaching 50% to be obtained [251,265].

Both Fe(II) and Fe(III) complexes of pmea have been reported. In contrast to the analogous tpa complex, $[Fe(pmea)(NCS)_2]$ does not show spin-crossover behaviour, with effective magnetic moments of 4.33 BM at 80 K and 4.59 BM at 300 K indicative of an equal mixture of $^5T_2$ and $^3T_1$ phases. The 5- and 6-isomeric possibilities in this complex were recognised, but the presence of only one isomer was assumed [264]. $[Fe(pmea)Cl_2]Cl$ and a number of similar Fe(III) complexes containing tripodal tetradentate amine ligands have been studied as functional models for the enzyme catechol 1,2-dioxygenase. $[Fe(pmea)Cl_2]Cl$ is high-spin at room temperature and catalyses the oxidative cleavage of 3,5-di-*t*-butylcatechol by molecular oxygen, but no attempt was made at the characterisation of possible 5- and 6-isomers of this complex [266]. The diferric complex $[(pmea)Fe(O)(OAc)Fe(pmea)](ClO_4)_3$ catalyses the ^{t}BuOOH-promoted oxidation of cyclohexane to a variety of products, but is not as effective as the analogous tpa complex [197]. The Cu(I) and Cu(II) complexes $[Cu(pmea)]PF_6$ and $[Cu(pmea)Cl]ClO_4 \cdot H_2O$ have been prepared from the reaction of $[Cu(MeCN)_4]PF_6$ and $Cu(ClO_4)_2 \cdot 6H_2O$/$CuCl_2 \cdot 2H_2O$, respectively with pmea. X-ray crystallographic analysis shows that $[Cu(pmea)]PF_6$ adopts an unusual 4-coordinate pyramidal geometry about the metal ion (Fig. 24), with the Cu ion essentially coplanar with the three pyridyl donor atoms. The complex is very reactive towards dioxygen, giving formation of a transient purple species at −90 °C thought to be a peroxo-bridged dimer, while the same reaction at room temperature gives formation of the Cu(II) complex $[Cu(pmea)F]PF_6$.

Five-coordinate $[Cu(pmea)Cl]ClO_4 \cdot H_2O$ ($\tau = 0.12$ and 0.14 for the two independent molecules in the asymmetric unit) and $[Cu(pmea)F]PF_6$ ($\tau = 0.14$) both adopt an essentially square pyramidal geometry with a pyridyl N atom of the unique pyridylethyl arm occupying the axial position. Five-coordinate complexes of tepa and pmap are also square pyramidal, in contrast to analogous $[Co(tpa)X]^{+/2+}$ complexes ($X = Cl^-$, MeCN, F^-, H_2O, CN^-) which are uniformly trigonal bipyramidal with the aliphatic N atom and the X ligand occupying the apical positions, and the introduction of additional methylene units into the ligand arms obviously disfavours this geometry. The bis(μ-oxo) dimer $[(pmea)Mn(O)_2Mn(pmea)](ClO_4)_3 \cdot MeCN$ has been prepared by H_2O_2 oxidation of an equimolar aqueous mixture of

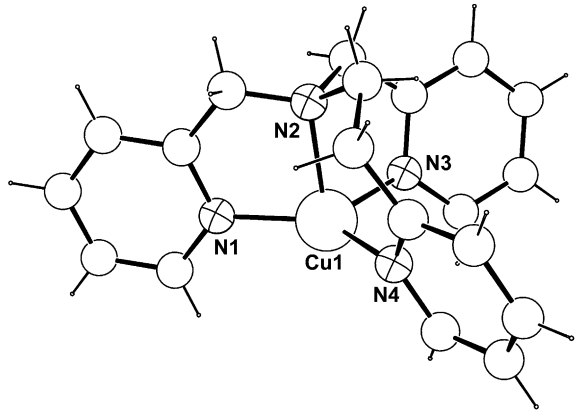

Fig. 24. X-ray structure of the $[Cu(pmea)]^+$ cation.

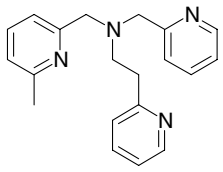

Fig. 25. Structure of the pmea derivative L^4.

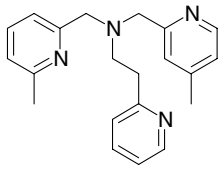

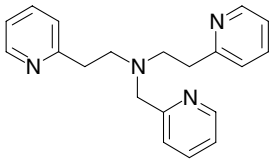

Fig. 26. Structure of the pmea derivative L^5.

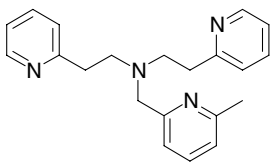
$Mn(ClO_4)_2 \cdot 6H_2O$ and pmea [265]. The complex was proposed to contain discrete localised Mn(III) and Mn(IV) ions, although these could not be distinguished by X-ray crystallography at room temperature due to disorder in the crystal which led to the observation of an apparent centre of inversion. The six-membered chelate rings lie in the same plane as the bridging oxo ligands and the tertiary N atoms lie mutually trans to each other, as required by the apparent centre of inversion. A similar synthetic strategy was used to prepare the Mn(III,IV) dimer of the related ligand L^4 (Fig. 25), and this complex was able to be oxidised to the Mn(IV,IV) dimer by treatment with NaOCl.

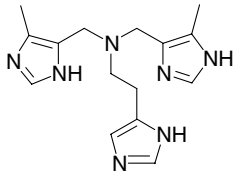
X-ray structural analysis of this (IV,IV) complex again showed the six membered chelate rings to lie in the same plane as the bridging oxo ligands. The Mn(III,III) dimer of the dimethyl analogue L^5 (Fig. 26) has also been prepared by H_2O_2 oxidation of a methanolic solution of $Mn(ClO_4)_2 \cdot 6H_2O$ and ligand, and the complex shows similar structural features to those discussed above [267].

3.2.13. Bis(2-(2-pyridyl)ethyl)-((2-pyridyl)-methyl)amine (pmap)

Pmap was first prepared in 1999 from the reaction of 2-vinylpyridine with 2-(aminomethyl)pyridine in MeOH/HOAc [268], and a subsequent preparation using a similar method has also been reported [251]. The coordination chemistry of pmap has been little studied, and only complexes of Zn, Cu and Mn have been reported. Reaction of pmap with $Zn(ClO_4)_2 \cdot 6H_2O$ in the presence of Et_3N and CO_2 gives the dimeric complex $[(pmap)Zn(CO_3)Zn(pmap)](ClO_4)_2 \cdot 7H_2O$ in which the bridging carbonate ligand chelates to both Zn ions. The unique five-membered chelate rings are situated perpendicular to the plane containing the Zn ions and the carbonate ligand, and the tertiary N atoms lie mutually *cis* [268]. The Mn(III,IV) dimer $[(pmap)Mn(O)_2Mn(pmap)](ClO_4)_3 \cdot MeCN$ is prepared in a similar fashion to the analogous pmea complex (Section 3.2.12) and the X-ray structure again shows the cation to contain an apparent centre of inversion for the same reasons as discussed for the pmea complex. The Mn···Mn separation of 2.7379(13) Å is longer than that found in the tpa (2.643(1) Å) and pmea (2.693(1) Å) complexes, and the unsuccessful attempts to prepare the analogous tepa complex were attributed to the Mn···Mn separation in such a complex being too long to accommodate a bis (μ-oxo) bridge [269]. The methyl-substituted pmap ligand L^6 (Fig. 27) forms the distorted octahedral monomeric Mn(II) complex $[Mn(L^6)(MeCN)(OH_2)](ClO_4)_2$ on reaction with $Mn(ClO_4)_2 \cdot 6H_2O$ under aerobic conditions, with X-ray analysis confirming production of the 6-isomer [267]. Addition of H_2O_2 to a MeOH solution of this complex did not produce the expected bis(μ-oxo) dimer.

$[Cu(pmap)]PF_6$ adopts a similar structure to $[Cu(pmea)]PF_6$, with a pseudo trigonal pyramidal geometry about the Cu(I) ion and the aliphatic N atom occupying the apical position [251]. The complex reacts rapidly with O_2 at −90 °C in propionitrile and no superoxo or peroxo intermediate can be observed, while at room temperature the same reaction in MeCN gives $[Cu(pmap)F]PF_6$ as also found for the analgous pmea complex. $[Cu(pmap)Cl]ClO_4$ can be obtained either anhydrous or as the monohydrate, and both show similar structures. The five-coordinate Cu(II) ion adopts a square pyramidal geometry ($\tau = 0.08$) with both the chloride ligand and the five-membered chelate ring in the basal plane.





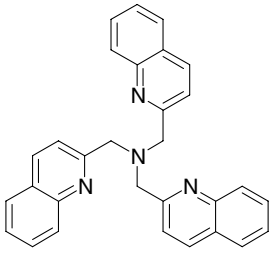


Fig. 27. Structure of the pmap derivative L^6.

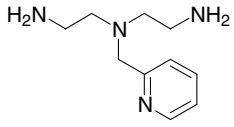
3.2.14. N,N′-bis(imidazole-4-ylmethyl-5-methyl)histamine (bimhm)

Bimhm · 4HCl was first prepared in 2002 from the reaction of histamine with 4-methyl-5-imidazolecarboxaldehyde and subsequent reduction with sodium borohydride [270]. pK_a values of 5.86, 6.59 and 8.61 (I = 0.1 M, T = 25 °C) were obtained by potentiometric titration, while the pK_a corresponding to deprotonation of the tertiary N atom could not be measured by this method. Reaction of the ligand with Cu(II) and Zn(II) up to pH ~ 9 was studied potentiometrically, and log K values for the $[M(bimhm)]^{2+}$ complexes were 16.06 and 12.73 for Cu and Zn, respectively. Evidence for hypodentate coordination of the ligand was found for both metals, with log K values for $[Cu(bimhmH)]^{3+}$ (20.15) and $[Cu(bimhmH_2)]^{4+}$ (22.10) complexes being significantly greater than those for $[Cu(bimhm)]^{2+}$. The formation of dinuclear complexes was also observed for Cu^{2+} but not for Zn^{2+}.

3.2.15. Tris(2-quinolylmethyl)amine (tmqa)



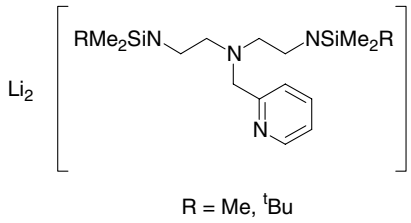
The synthesis of tmqa from the reaction of 2-(bromomethyl)quinoline and ammonium hydroxide in THF was reported in 1994 [271], and the coordination chemistry of this ligand has thus far been limited to some copper complexes. [Cu(tmqa)]X (X = PF_6, ClO_4) results from reaction of $[Cu(MeCN)_4]X$ with the ligand in CH_2Cl_2 under argon. The complex adopts a trigonal pyramidal geometry with the tertiary N atom occupying the apical position, and the three quinolyl moieties provide a binding pocket for another axial ligand. Both the PF_6^- and ClO_4^- salts are unreactive towards O_2 in the solid state, and the PF_6^- salt decomposes only very slowly under oxygen in MeCN solution. [Cu(tmqa)Cl]P-F_6 · MeCN · 0.5Et_2O, formed from the reaction of Cu-Cl_2 · 2H_2O with tmqa in MeOH, addition of $NaPF_6$ and crystallisation from MeCN/Et_2O, is nearly perfectly square pyramidal, with τ = 0.06, and this geometry has been rationalised on the basis that adoption of a trigonal bipyramidal structure would lead to unfavourable steric interactions between the Cl^- ligand and the protons at the 8-position of the three quinolyl rings [272].

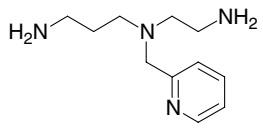
4. Ligands containing non-identical N-donor atoms on each arm

4.1. Ligands containing mixed aliphatic and aromatic N-donor atoms

4.1.1. N,N-bis(aminoethyl)-2-(aminomethyl)pyridine (pdt)

The pdt ligand was first mentioned in the literature in 1985 in a paper describing the template synthesis of a macrocycle derived from this, although the synthesis of pdt was not detailed [273]. The first reported synthesis dates from 1990 and involves the reaction of phthalimido-protected diethylenetriamine with 2-(chloromethyl)pyridine (although it should be noted that the experimental section of this paper refers to reaction with a "bromoalkane" to effect substitution at the central N atom) in refluxing ethanol followed by deprotection with HCl [274]. This, and some subsequent [275–277], papers dealt solely with the formation of macrocycles derived from tripodal ligands and thus the coordination chemistry of free pdt was not investigated. Similarly, pdt was reported as an intermediate in the construction of a tetraaminetetracarboxylic acid ligand, but no metal complex of the pdt ligand itself was reported [278]. A recent alternative synthesis of pdt involves reaction of 2-(aminomethyl)pyridine with two equivalents of tosylaziridine in ethanol, followed by detosylation with H_2SO_4 [279], and the X-ray structure of the tosylated intermediate has been reported [280]. Surprisingly, there is only one reference to a metal complex of pdt in the literature, namely $[Zn(pdt)(OH_2)]^{2+}$, which was generated in aqueous solution by reaction of a Zn(II) salt with pdt · 3HCl [149]. This study also reported the pK_a values of pdt · 3HCl as 4.00, 9.27 and 10.04, while the pK_a of $[Zn(pdt)(OH_2)]^{2+}$ was given as 9.63. Reaction of pdt with Me_3SiCl or t-BuMe_2SiCl and subsequent reaction with BuLi gives the trialkylsilyl-substituted pdt derivatives shown in Fig. 28 and some Ti, Ta, Zr, Hf and Y amido complexes of these ligands have been reported [279,280].





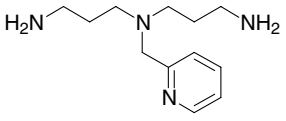


Fig. 28. Silylated derivatives of pdt.

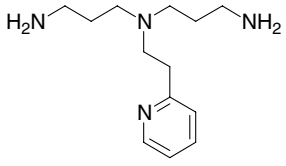
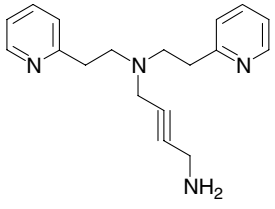
4.1.2. N-(3-aminopropyl)-N-(2-aminoethyl)-2(aminomethyl)pyridine (TO-PY)



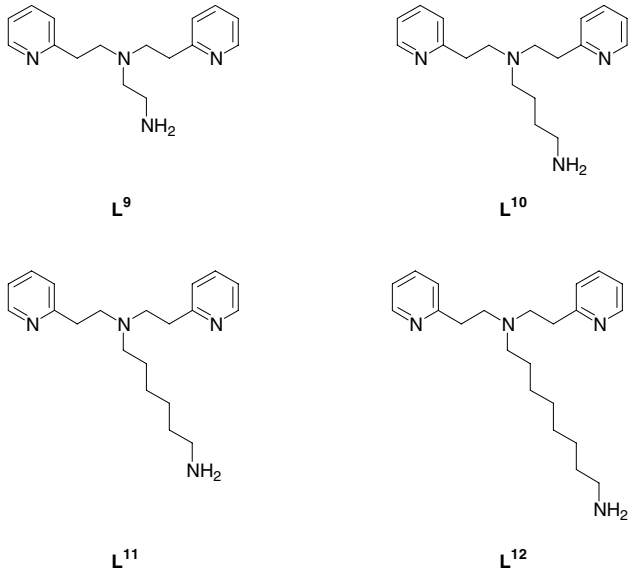
The synthesis of this ligand was described in 2001 from the reaction of phthalimido protected *N*-(2-aminoethyl)-1,3-propanediamine with 2-(chloromethyl)pyridine [281], but its coordination chemistry appears not to have been investigated to date.

4.1.3. N,N-bis(aminopropyl)-2-(aminomethyl) pyridine (dapp)



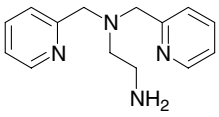
Three methods for the synthesis of dapp have been reported. The first, dating from 1990, is very similar to that used for the synthesis of pdt (Section 4.1.1), involving reaction of phthalimido-protected dipropylenetriamine with 2-(chloromethyl)pyridine followed by deprotection with HCl [274]. The other syntheses both use 2-(aminomethyl)pyridine as the starting material, in one case reacting it with two equivalents of 3-(bromopropyl)phthalimide and deprotecting with HCl [282], or reacting it with two equivalents of acrylonitrile and subsequent reduction with $NaBH_4$/Raney nickel [283]. Dapp has been mostly used to synthesise pyridyl-appended macrocyclic ligands [274,277,283,284] and there are few reports of discrete metal complexes of dapp. $[Zn(dapp)](ClO_4)_2$, $[Co(dapp)Br_2]Br$, $[Cr(dapp)Cl_2]Cl$, $[Ni(dapp)(MeCN)_2](ClO_4)_2$ and $[Cu(dapp)Cl]ClO_4$ have all been reported [285], and the two latter complexes have been structurally characterised. $[Ni(dapp)(MeCN)_2](ClO_4)_2$ adopts a distorted octahedral geometry about the metal ion, and crystallises as the 5-isomer, while $[Cu(dapp)Cl]ClO_4$ is distorted square pyramidal ($\tau = 0.24$) with an aliphatic N atom in the apical position. This paper is in fact one of the first to specifically detail the isomeric possibilities available in five-coordinate complexes containing asymmetric tripodal ligands. The Fe(II) spin-crossover complex [Fe(dapp)(abpt)] (abpt = 4-amino-3,5-bis(pyridin-2-yl)-1,2,4-triazole) has also been structurally characterised at 293, 183 K (both high spin) and 123 K (low spin) [282]. The complex crystallises in the same space group at all temperatures to give the 6-isomer in which a pyridyl N atom of the triazole ligand lies *trans* to the tertiary N atom of the tripodal ligand. The low spin form of the complex shows the expected diminution of the Fe–N bond distances by amounts between 0.127 and 0.224 Å. The obtained hysteresis loop is unusually wide (10 K) for a mononuclear complex.

4.1.4. N,N-bis(aminopropyl)-2-(aminoethyl)pyridine (L^7)



This ligand was prepared in an analogous fashion to dapp (Section 4.1.3) by reaction of 2-(2-aminoethyl)pyridine with acrylonitrile and reduction of the resulting nitrile with $NaBH_4$/Raney nickel [284]. The coordination chemistry of this ligand has yet to be studied.

4.1.5. N,N-bis(2-(2-pyridyl)ethyl)-1,4-diamino-2-butyne (L^8)



This ligand provides a rare example of a tripodal tetraamine ligand containing unsaturation in one of the arms. The tetrahydrochloride salt of this ligand was first reported in 2003 from the reaction of 1-chloro-4-phthalimido-2-butyne with bis(2-(2-pyridyl)ethyl)amine) in MeCN, followed by deprotection with aqueous hydrazine [286]. No metal complexes of this ligand have yet been reported.

4.1.6. N,N-bis(2-(2-pyridyl)ethyl)-1,2-diaminoethane (L^9), N,N-bis(2-(2-pyridyl)ethyl)-1,4-diaminobutane (L^{10}), N,N-bis(2-(2-pyridyl)ethyl)-1,6-diaminohexane (L^{11}) and N,N-bis(2-(2-pyridyl)ethyl)-1,8-diaminooctane (L^{12})

These ligands were first reported in 1962 from the reaction of the reaction of the appropriate α,ω-diamine with 2-vinylpyridine [287]. Their coordination chemistry remains to be studied.

4.1.7. N,N-bis(2-pyridylmethyl)ethylenediamine (uns-penp, dpea, N,N-bispicen, bpen)

The synthesis of this ligand as the hydrochloride salt was first reported in 1988 from the reaction of *N*-acetylethylenediamine with 2-(chloromethyl)pyridine followed by deprotection with HCl [288]. The free base ligand can also be prepared by reaction of bis(2-pyridylmethyl)amine with *N*-(2-bromoethyl)phthalimide, deprotection with HCl and ether extraction of the basified solution [289], reaction of mono Boc-protected ethylenediamine with 2-(chloromethyl)pyridine, deprotection with TFA and CH_2Cl_2 extraction of the basified solution [290], or reductive amination of *N*-acetylethylenediamine with 2-pyridinecarbaldehyde using $NaBH(OAc)_3$, deprotection with HCl, basification and extraction with CH_2Cl_2 [291]. The triprotonated ligand displays pK_a values of 3.17, 5.22 and 9.93, and a formation constant (log *K* of 12.48 for the 1:1 Zn^{2+} complex, which exhibits a pK_a of 9.14 [149]. The coordination chemistry of uns-penp has not been extensively studied, and the ligand has more often been used as an intermediate in the synthesis of various multidentate ligands [290,292–295]. Reaction of the hydrochloride salt of the ligand with copper chloride in water and addition of $NaClO_4$ results in crystallisation of the hypodentate complex $[Cu(uns\text{-}Hpenp)Cl_2](ClO_4)$ in which the aminoethyl arm is protonated and not coordinated to the metal ion [288,296], while reaction of the monoprotonated ligand with $Cu(ClO_4)_2 \cdot 6H_2O$ and $CuCl_2 \cdot 2H_2O$ in water gives the hypodentate chloride-bridged dimer $[(Cu(uns\text{-}Hpenp)Cl)_2Cl](ClO_4)_3$ in which both copper ions are square pyramidal ($\tau = 0.05$) and which contains two uncoordinated protonated aminoethyl arms [291]. However, use of the free base ligand ensures coordination of all four N atoms, and thus reaction of this with $Cu(ClO_4)_2 \cdot 6H_2O$ and $CuCl_2 \cdot 2H_2O$ in water/MeOH gives $[Cu(uns\text{-}penp)Cl]ClO_4$, which exhibits trigonal bipyramidal geometry ($\tau = 0.84$). Reaction of free base uns-penp with $[Cu(MeCN)_4]ClO_4$ in MeCN gives the dimeric Cu(I) species $[Cu_2(uns\text{-}penp)_2](ClO_4)_2 \cdot MeCN$, in which the two extremely distorted four-coordinate metal centres are bridged by the aminoethyl arms from the two tripodal ligands (Fig. 29). This complex reacts with O_2 at −89.9 °C to give formation of both superoxo and peroxo complexes, although the exact nature of these was unable to be determined.

Interestingly, the dimethyl-substituted derivative of uns-penp, in which the amine protons are replaced by methyl groups, reacts quite differently to uns-penp with both Cu(I) and Cu(II) starting materials. Reaction with $[Cu(MeCN)_4]ClO_4$ gives the monomeric five-coordinate Cu(I) product $[Cu(Me_2\text{-}uns\text{-}penp)(MeCN)]ClO_4$ ($\tau = 0.81$) while reaction with $Cu(ClO_4)_2 \cdot 6H_2O$ and $CuCl_2 \cdot 2H_2O$ in water/MeOH gives five-coordinate $[Cu(Me_2\text{-}uns\text{-}penp)Cl]ClO_4$ which is square pyramidal

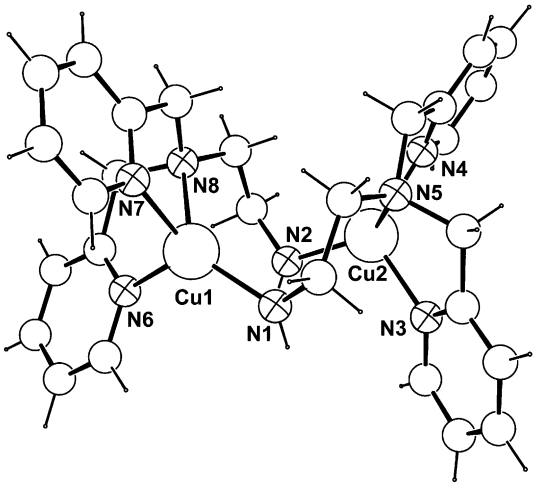


Fig. 29. X-ray structure of the $[Cu_2(uns\text{-}penp)_2]^{2+}$ cation.

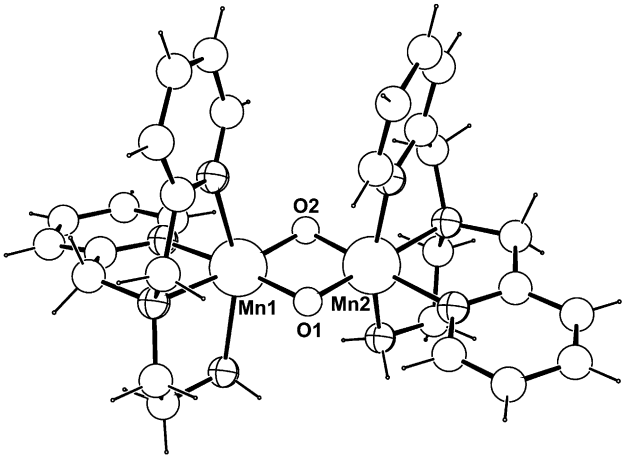
($\tau = 0.26$) with the aliphatic N atom in the apical position [297].

Two spin-crossover Fe(II) complexes containing uns-penp have been reported. [Fe(uns-penp)$(NCS)_2$] crystallises with the thiocyanate ligands in the same plane as the chelate ring formed by the two aliphatic N atoms, and undergoes an abrupt HS–LS transition centred at 138 K [289]. [Fe(uns-penp)(bim)]$(ClO_4)_2 \cdot 0.5H_2O$ (bim = 2,2′-bisimidazole) undergoes a two-step HS–LS transition, with centres at 218 and 171 K. Structural characterisation of the complex at 293 and 123 K showed the expected shortening of the Fe–N bond lengths in the LS form, and in both cases, the bim ligand was found to lie in the same plane as the two aliphatic N atoms [298]. The Mn(III,IV) dimer [Mn_2O_2(uns-penp)$_2$]$(ClO_4)_3 \cdot$ MeCN was prepared from reaction of the free base ligand with $Mn(OAc)_3 \cdot 2H_2O$ in EtOH, addition of $NaClO_4$ and crystallisation from MeCN [299]. A number of isomeric possibilities exist for this dimer, but it crystallises as the single isomer depicted in Fig. 30. The X-ray structure shows localised Mn(III) and Mn(IV) centres which are strongly antiferromagnetically coupled ($J = -316$ cm^{-1}), and a Mn–Mn distance of 2.646(2) Å which is typical of bis-μ-oxo bridged manganese dimers.

The Co(III) complex [Co(uns-penp)(OH_2)Cl]-$(ClO_4)_2 \cdot H_2O$ was prepared from the reaction of $Na_3[Co(NO_2)_6]$ with the ligand hydrochloride in water followed by anation in concentrated HCl and purification on Sephadex cation exchange resin [288]. The stereochemistry of the complex was determined by NMR, with the Cl and OH_2 ligands lying in the same plane as the aliphatic N atoms of the uns-penp ligand.



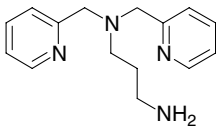


Fig. 30. X-ray structure of the mixed-valence [Mn_2O_2(uns-penp)$_2$]$^{3+}$ cation.

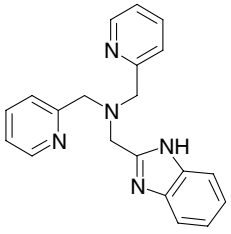
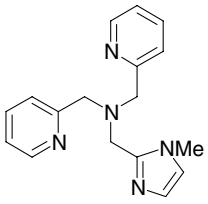


4.1.8. 3-Aminopropylbis(2-pyridylmethyl)amine (dppa, bptn)

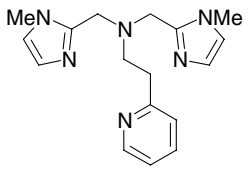
Dppa was first reported in 1997 as the product of the reaction between bis(2-pyridylmethyl)amine and *N*-(3-bromopropyl)phthalimide in refluxing toluene [300]. An alternative synthesis involves reaction of bis(2-pyridylmethyl)amine with acrylonitrile and subsequent reduction of the dinitrile with $NaBH_4$/Raney nickel [301]. Few complexes of dppa have been prepared, with only [Fe(dppa)$(NCS)_2$], [Co(dppa)$(NO_2)_2$]-$NO_3 \cdot 0.5H_2O$ and [Co(dppa)Cl_2]ClO_4 having been reported. Three polymorphs of [Fe(dppa)$(NCS)_2$] have been structurally characterised, and each shows a distinctive variable temperature magnetic behaviour. Polymorph A undergoes a gradual HS–LS transition at 176 K without hysteresis, polymorph B is paramagnetic over the temperature range 4.5–295 K, and polymorph C undergoes an abrupt HS–LS transition around 116 K, with a 8 K wide hysteresis loop [300]. The three polymorphs crystallise in different space groups, but in all cases the 5-isomer is obtained. The differing magnetic behaviour is explained on the basis of different crystal packing within the three-dimensional assemblies. [Co(dppa)$(NO_2)_2$]$NO_3 \cdot 0.5H_2O$ was prepared by air oxidation of a solution of $Co(NO_3)_2 \cdot 6H_2O$ and dppa in the presence of $NaNO_2$, and reaction of this complex with HCl followed by addition of $NaClO_4$ gave the dichloro complex [Co(dppa)Cl_2]ClO_4. The observation of five methylene signals in the ^{13}C NMR of these complexes shows that both were obtained as the 5-isomer, and this was confirmed for the dichloro complex by X-ray structural characterisation [228].



4.2. Ligands containing three aromatic N-donor atoms

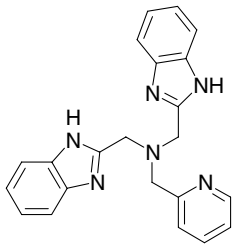
4.2.1. ((Benzimidazol-2-yl)methyl)bis((2-pyridyl)-methyl)amine (bpba)

The asymmetric tripodal ligand bpba was first prepared in 2001 from the reaction of excess 2-(chloromethyl)pyridine with ((benzimidazol-2-yl)methyl)amine in CH_2Cl_2 [302]. Bpba reacts with $Fe(ClO_4)_3 \cdot 9H_2O$ and deprotonated tetrachlorocatechol (tcc) in acetone to give the catecholate chelate complex [Fe(bpba)(tcc)]-$ClO_4 \cdot (CH_3)_2CO$ in which the benzimidazole and catecholate rings are essentially coplanar. This, and a number of other Fe(III) catecholate complexes of bpba react with oxygen to give cleavage of the catecholate ligand [302]. The ten-coordinate lanthanide complexes $[Ln(bpba)(O_2NO)_2]$ (Ln = La, Eu, Gd, Tb) have been prepared and the Eu, Gd and Tb complexes have been structurally characterised [303], as has the silver dimer $[Ag_2(bpba)(dppm)](BF_4)_2 \cdot MeOH$ [304].



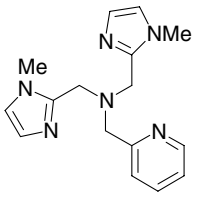
4.2.2. Bis(2-(pyridyl)methyl)(2-(1-methylimidazolyl)-methyl)amine (bpia)

The mixed donor tripodal ligand bpia was first reported in 1990 [147]. The original synthesis involved reaction of 1-methyl-2-aminomethylimidazole with two equivalents of 2-(chloromethyl)pyridine in acetonitrile, although bpia has also been prepared by an alternative method from the reaction of 2-(chloromethyl)-1-methylimidazole with bis(2-pyridylmethyl)amine in CH_2Cl_2 [305]. Reaction of bpia with $CuCl_2 \cdot 2H_2O$ and addition of $NaPF_6$ gives five-coordinate trigonal bipyramidal $[Cu(bpia)Cl]PF_6$ ($\tau = 0.79$) [306], which reacts further with 1-methylimidazole to give [Cu(bpia)(1-Meim)]$(PF_6)_2$ [147]. The dimeric Cu(I) complex $[(bpia)_2Cu_2](CF_3SO_3)_2$ can be prepared from reaction of the ligand with $[Cu(MeCN)_4]CF_3SO_3$ in MeCN [305]. The crystal structure shows two four-coordinate Cu centres (Cu···Cu = 3.329 Å) bridged by the two imidazole-appended arms of the two tripodal ligands. This complex reacts rapidly with dioxygen at −80 °C in a Cu:O_2 ratio of ~2:1 to give a peroxo-bridged dimer which is EPR-silent.



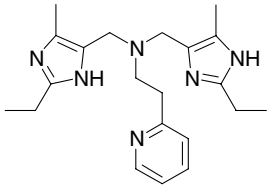
Several mono- and binuclear manganese complexes of bpia have been described in studies aimed at preparing catalase mimics [307] and oxidation catalysts [308]. The mononuclear Mn(III) complexes $[Mn(bpia)(OAc)(OCH_3)]PF_6$ and $[Mn(bpia)Cl_2]ClO_4$ both crystallise as a single isomer having the imidazole ring essentially coplanar with the monodentate ligands. The structurally characterised binuclear complexes $[(bpia)Mn(\mu\text{-}OAc)_2Mn(bpia)](ClO_4)_2$, $[(bpia)Mn(\mu\text{-}O)(\mu\text{-}OAc)Mn(bpia)](ClO_4)_3 \cdot MeCN$, $[(bpia)Mn(\mu\text{-}O)_2Mn(bpia)](ClO_4)_2(PF_6) \cdot 2MeCN$ and $[(bpia)ClMn(\mu\text{-}O)MnCl(bpia)](ClO_4)_2 \cdot 2MeCN$ form an interesting set of complexes having differing oxidation states ((II,II), (III,III), (III,IV) and (III,III), respectively) and differing bridging ligands. All except the (II,II) complex have the imidazole ring coplanar with the bridging ligand(s), although the relative orientations of the two bpia ligands vary. Fe(III) complexes of bpia have been studied as models for catechol dioxygenases, and a number of in situ-generated Fe(III)/bpia complexes are found to cleave catechols in the presence of O_2. $[Fe(bpia)Cl_2][FeCl_4]$, $[(bpia)ClFe(\mu\text{-}O)FeCl(bpia)]Cl_2 \cdot 4MeOH$ [309] and $[Fe(bpia)(tcc)]ClO_4$ [302] have been structurally characterised and all three complexes have the imidazole ring in the same plane as the two coordination sites not occupied by the bpia ligand. The Fe(III) dithiolato complex $[Fe(bpia)(dtc)](ClO_4)$ has also been structurally characterised, and exhibits a similar ligand geometry to the three complexes discussed above [310].

4.2.3. Bis(1-methylimidazol-2-yl)methyl)(2-(pyridyl-2-yl)ethyl)amine (L^{13})



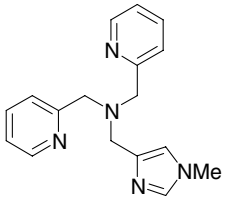
This ligand was first reported in 2004, as the product of the reaction of 1-methyl-2-imidazolecarboxaldehyde with 2-(2-aminoethyl)pyridine in CH_3OH [311]. Reaction of the ligand with $K_2[Ru(OH_2)Cl_5]$ in EtOH and addition of $NaClO_4$ gives the structurally characterised 5-isomer of $[Ru(L^{13})Cl_2]ClO_4$, which can be chemically reduced (Zn(Hg) or Eu^{2+}) to the diaqua species $[Ru\text{-}(L^{13})(OH_2)_2]^{2+}$ in aqueous solution. The five-coordinate complex $[Cu(L^{13})Cl]ClO_4$ is formed on reaction of the ligand with $CuCl_2 \cdot 2H_2O$ in EtOH, and this reacts with one equivalent of $NaNO_2$ to give the distorted square-pyramidal complex $[Cu(L^{13})(ONO)]ClO_4$ ($\tau = 0.27$) which has an imidazole in the apical position [312].

4.2.4. Bis(2-benzimidazolylmethyl)(2-pyridylmethyl)-amine (pb2)



This ligand was first mentioned in the literature in 1991, although no preparative details were given [313]. A subsequent paper by different authors detailed two methods for the synthesis of pb2, both starting from iminodiacetic acid and differing only in the order of addition of reactants [314]. Reaction of iminodiacetic acid with *o*-phenylenediamine gives bis(2-benzimidazolylmethyl)amine which is then reacted with 2-(chloromethyl)pyridine in MeOH to give the ligand in low yield. Conversely, reaction of iminodiacetic acid with 2-(chloromethyl)pyridine under alkaline conditions gives dipotassium *N*-(2-pyridylmethyl)iminodiacetate, and condensation of this with *o*-phenylenediamine in acidic aqueous solution gives the ligand in moderate (42%) yield. The nitrate salt of the diprotonated (at the imidazole N atoms) ligand has been structurally characterised [303], and thus far, only lanthanide complexes of this ligand have been prepared. Thus, reaction of either $Ln(NO_3)_3$ (Ln = La, Sm, Eu, Gd, Tb, Tm) or $LnCl_3$ (Ln = La, Sm, Eu, Tb, Ho) with one equivalent of ligand in ethanol gives $[Ln(pb2)(NO_3)_3]\cdot C_2H_5OH$ and $[Ln(pb2)Cl_3(H_2O)]\cdot C_2H_5OH$, respectively [314]. Structural characterisation of $[Sm(pb2)(NO_3)_3]\cdot C_2H_5OH$ and $[Gd(pb2)(NO_3)_3]\cdot C_2H_5OH$ show the metal ions in these complexes to be ten-coordinate, while the samarium ion in $[Sm(pb2)Cl_3(H_2O)]\cdot C_2H_5OH$ is eight-coordinate. The antipyrine complexes $[Ln(pb2)(antipyrine)_3](ClO_4)_3$ (Ln = La, Pr, Eu, Gd, Tb, Y) and $[Ln(L)(antipyrine)Cl(H_2O)_2]Cl_2\cdot 2H_2O$ (Ln = Eu, Gd, Tb) have also been prepared; structural characterisation (Pr, Y) shows the former to be seven-coordinate, while the latter (Eu) are eight-coordinate [303].

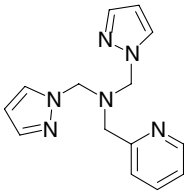
4.2.5. Bis(2-(1-methylimidazolyl)methyl)(2-(pyridyl)-methyl)amine (bipa)



The synthesis of bipa was first reported in 1990, from the reaction of bis(2-(1-methylimidazolyl)methyl)amine with 2-(chloromethyl)pyridine in dry acetonitrile [147], while a subsequent alternative synthesis involves reaction of 2-(chloromethyl)imidazole with 2-(methylamino)pyridine in CH_2Cl_2 [305]. The trigonal bipyramidal Cu(II) complex $[Cu(bipa)Cl]PF_6\cdot MeCN$ ($\tau = 0.85$) is prepared by reaction of the ligand with $CuCl_2\cdot 2H_2O$ and this reacts further with 1-methylimidazole to give $[Cu(bipa)(1\text{-}Meim)](PF_6)_2$ [147]. The dimeric Cu(I) complex $[(bipa)_2Cu_2](ClO_4)_2\cdot 1/2Et_2O$ results from the reaction of the ligand with $[Cu(MeCN)_4]ClO_4$, and this reacts rapidly with O_2 at −80 °C to give an unidentified red product which decomposes rapidly [305]. Reaction of $Fe(ClO_4)_3\cdot 9H_2O$ and $FeCl_3$ with bipa in MeOH/EtOH gives the red complex $[Fe(bipa)Cl_2](ClO_4)$ and this crystallises as a single isomer with an imidazole in the same plane as the chloride ligands [309]. The analogous Mn(III) complex $[Mn(bipa)Cl_2](ClO_4)$ is essentially isostructural while the mononuclear complex $[Mn(bipa)(OAc)(OCH_3)](PF_6)$ also adopts the same ligand configuration [308].

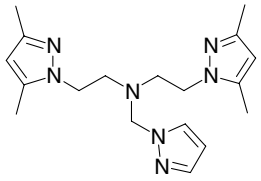
4.2.6. N,N-bis(2-ethyl-5-methyl-imidazolyl 4-methyl)amino-2-ethylpyridine (biapy)

The ligand biapy was first reported in 2003 [315], and was prepared from the Mannich reaction of 2-ethyl-4-methylimidazole, 2-(aminoethyl)pyridine and formaldehyde in aqueous solution. The coordination chemistry of this ligand remains to be studied.



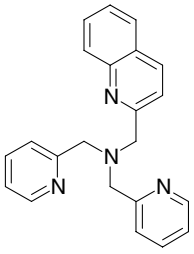
4.2.7. ((1-Methyl-4-imidazolyl)methyl)bis(2-pyridylmethyl)amine (MeIm(Py)$_2$)

This ligand was first prepared in 2000 from the reaction of bis(2-pyridylmethyl)amine with 1-methylimidazole-4-aldehyde and subsequent reduction of the generated imine with $NaBH_3CN$ [316]. Reaction of the ligand with $Cu(ClO_4)_2\cdot 6H_2O$ in MeOH and subsequent crystallisation of the obtained crystals from MeCN gives five-coordinate $[Cu(MeIm(Py)_2)MeCN](ClO_4)_2\cdot MeCN$, which is trigonal bipyramidal ($\tau = 0.96$). Methylation of the pyridine rings at the carbon adjacent to the N-donor atom affects the geometry of the obtained Cu(II) complexes markedly; the complex $[Cu(MeIm(Me)_1)(MeCN)](ClO_4)_2$, in which one pyridyl ligand is methylated is square pyramidal ($\tau = 0.15$) while the analogous complex of the dimethylated ligand,



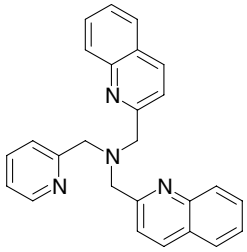
$[Cu(MeIm(Me)_2)(MeCN)](ClO_4)_2$ has $\tau = 0.65$ [317]. The three complexes react with H_2O_2 at −80 °C to give Cu(II)-hydroperoxo complexes. Five-coordinate $[Zn(MeIm(Py)_2)(MeCN)](ClO_4)_2$ may be prepared from $Zn(ClO_4)_2 \cdot 6H_2O$ in an analogous fashion to the Cu(II) complexes described above [318], and this reacts with superoxide ion in EtCN to give $[Zn(MeIm(Py)_2)(O_2)]^+$ which can be detected by ESR.

4.2.8. Bis(1-pyrazolylmethyl)(2-pyridylmethyl)amine (bppa)



The synthesis of the bppa ligand was first reported in 1996, and used a modification of the method used to prepare the amtp ligand (Section 3.2.3) [319]. Reaction of the ligand with CuI in MeCN gives the polymeric species $[Cu_2(\mu\text{-BPPA})(\mu\text{-I})_2]_n$ in which each bppa ligand binds bidentate to two Cu ions.

4.2.9. Bis(2-(3,5-dimethylpyrazol-1-yl)ethyl)(pyrazol-1-yl)methyl)amine (bppa)



The synthesis of the asymmetric ligand bppa from reaction of bis(2-(3,5-dimethylpyrazol-1-yl)ethyl)amine with (1-hydroxymethyl)pyrazole was reported in 2001 [320]. The crystal structure of the five-coordinate complex $[Co(bppa)Cl]BPh_4 \cdot C_2H_5OH$ shows a distorted trigonal bipyramidal geometry ($\tau = 0.80$) about the Co(II) ion, with the tertiary N atom and Cl ligand occupying the apical positions.

4.2.10. Bis(2-pyridylmethyl)(2-quinolylmethyl)amine (bpqa)

The synthesis of this ligand was first reported in 1994, from the reaction of 2-(bromomethyl)quinoline with one equivalent of dipicolylamine [271]. Reaction of $[Cu(MeCN)_4]PF_6$ with bpqa in MeCN under argon gives $[Cu(bpqa)]PF_6$, which reacts rapidly with dioxygen at −80 °C to give an intensely purple complex formulated as a *trans*-(μ-1,2-peroxo)-bridged dimer. The Cu(II) complex $[Cu(bpqa)Cl]PF_6 \cdot 0.5CH_2Cl_2$ is obtained on reaction of $CuCl_2 \cdot 2H_2O$ with bpqa in MeOH, addition of $NaPF_6$ and crystallisation from MeCN/Et_2O [272]. The cation displays a distorted square-pyramidal geometry ($\tau = 0.16$). Reaction of $Fe(CF_3SO_3)_2 \cdot 2MeCN$ with bpqa in THF under argon gives six-coordinate $[Fe(bpqa)(OSO_2CF_3)_2]$, in which the triflate ligands lie in the same plane as a pyridyl ring [321]. This complex is active as a catalyst in H_2O_2-promoted alkane hydroxylation reactions. The Fe(III) complex $[Fe(bpqa)(tcc)]ClO_4 \cdot EtOH$ is formed from reaction of $Fe(ClO_4)_3 \cdot 9H_2O$ with bpqa and $H_2tcc \cdot H_2O$ in EtOH, and in situ-generated Fe(III) complexes of bpqa are reactive with respect to air-oxidation of various catechol substrates [302].

4.2.11. Bis(2-quinolylmethyl)(2-pyridylmethyl)amine (bqpa)

Bqpa was first reported in 1994, resulting from the reaction between 2-(bromomethyl)quinoline and 2-(methylamino)pyridine in THF [271], while a more recent synthesis utilises 2-(chloromethyl)quinoline and MeCN as solvent [322]. The Cu(I) complex $[Cu(bqpa)]PF_6$ is obtained from reaction of $[Cu(MeCN)_4]PF_6$ with a slight excess of ligand in propionitrile under argon, and reacts with dioxygen at −80 °C to give a brown EPR-silent species with a $Cu:O_2$ ratio of 1:1, formulated as a superoxo complex. $[Cu(bqpa)]ClO_4$ reacts with PPh_3 in MeCN to give $[Cu(bqpa)PPh_3]ClO_4$, and the crystal structure of this shows that the bqpa ligand coordinates in a tridentate fashion with a dangling quinolyl group. Reaction of $CuCl_2 \cdot 2H_2O$ with bqpa in MeOH, addition of $NaPF_6$ and crystallisation from CH_2Cl_2 gives the Cu(II) complex $[Cu(bqpa)Cl]PF_6$ [272]. The dimeric Fe(III) complex $[Fe_2O(OH)(bqpa)_2](ClO_4)_3 \cdot MeCN$ is obtained from the reaction of $Fe(ClO_4)_3 \cdot 10H_2O$ with bqpa in MeOH and subsequent crystallisation from MeCN/THF. This complex crystallises as a single isomer having both pyridine rings in the same plane as

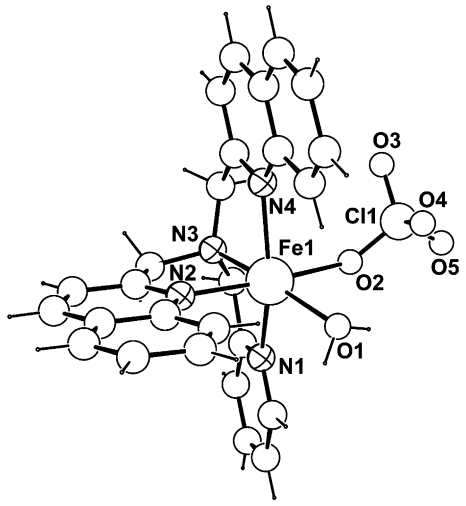


Fig. 31. X-ray structure of the $[Fe(bqpa)(H_2O)(ClO_4)]^+$ cation.

the oxo and hydroxo bridging ligands [323]. The Fe(III) catecholate complex $[Fe(bqpa)(dbc)]BPh_4$ (dbc = the dianion of 3,5-di-*tert*-butylcatechol) has been prepared by reaction of anhydrous $FeCl_3$ with bqpa and $dbcH_2$ in EtOH, and addition of $NaBPh_4$. Bubbling O_2 through a DMF solution of this complex for 24 h results in complete degradation of the catechol ligand to mostly 3,5-di-*tert*-butyl-5-(carboxymethyl)-2-furanone [322]. Reaction of equimolar amounts of $Fe(ClO_4)_2 \cdot 6H_2O$ with bqpa in MeCN gives the Fe(II) complex $[Fe(bqpa)(H_2O)(ClO_4)]$-ClO_4, with the presence of the coordinated perchlorate ligand confirmed by X-ray crystallography (Fig. 31) [321]. This complex crystallises such that a quinoline moiety lies in the same plane as the H_2O and ClO_4^- ligands. The bis (μ-oxo) mixed valence manganese dimer $[(bqpa)Mn(\mu\text{-}O)_2Mn(bqpa)]^{3+}$ has also been reported [399].

5. Conclusions

It is obvious from the preceding pages that, just over a century since the first synthesis of a tripodal tetraamine ligand, the coordination chemistry of such ligands is an expanding field of great current interest. This area of research will undoubtedly continue to expand, given the relatively recent nature of the majority of references in this paper, and the numerous synthetic methods now documented for the synthesis of tripodal tetraamines. Obvious areas for further investigation include the chemistry of second and third row transition metals with such ligands, the use of hypodentate tripodal amine complexes in supramolecular systems, and further studies of the chemistry of tripodal amine ligands with the generally oxophilic lanthanide ions. The results of such future investigations will, in all probability, be collated by another chronicler.

Abstract

The synthesis and characterization of two new bis(μ-alkoxo)-bridged dinuclear iron(III) complexes with the ligands 1-(2-hydroxyethyl)-pyrazole (Hnhep) and 1-(2-hydroxyethyl)-3,5-dimethylpyrazole (Hnhed), $[Fe(nhep)Cl_2(EtOH)]_2$ (**1**) and $[Fe(nhed)Cl_2]_2$ (**2**) are reported. The crystal structures of both complexes reveal the presence of centrosymmetric dinuclear units. In compound **1**, the iron(III) center has a coordination number of six, with a slightly distorted octahedral geometry. In compound **2**, the bulkier nhed ligand, with methyl groups at the 3- and 5-positions of the pyrazole ring, leads to a coordination number of five at the iron(III) center in a distorted square pyramidal geometry. The magnetic properties of both complexes have been investigated in the range 2–300 K and indicate the presence of fairly weak antiferromagnetic exchange interactions between iron(III) ions ($J_1 = -10.04$ cm^{-1} for **1** and $J_2 = -12.5$ cm^{-1} for **2**). The inactivity of both complexes in the cyclohexane hydroxylation appears to be partly due to the presence of the strong iron(III)–chloride bond that does not allow exchange with the reactant molecules.

Keywords: Iron; Pyrazole; Alkoxo-bridged; Model compounds

1. Introduction

Over the past few decades, considerable progress has been made in the development of oxo-bridged dinuclear iron(III) complexes that can reproduce both the structural and the functional properties of the metallic cores of the non-heme proteins including hemerytin (Hr) [1], ribonucleotide reductase (RR) [2], methane monooxygenase (MMO) and purple acid phosphatase (PAPs) [3]. In particular, the ability of the MMO enzyme to activate inert C–H bonds under ambient conditions has received special attention over the past 20 years. The enzyme is known to catalyze the conversion of methane into methanol (Eq. (1)). Substrate oxidation occurs at the diiron centre of the hydroxylase component of the enzyme, which receives two electrons from NADH via reductase to activate the dioxygen molecule [4].

$$2NADH + CH_4 + O_2 \rightarrow 2NAD^+ + CH_3OH + H_2O + 2e^- \quad (1)$$

In the oxidized state of methane monooxygenase (MMO_{ox}), the positive charge of the two high-spin iron(III) ions is balanced by four glutamate and two bridging hydroxide ligands; two additional histidine ligands complete the octahedral coordination spheres of the iron ions [5]. Because of the rather elaborate synthesis

of imidazole-based ligands, aliphatic amines, imine or pyridines are commonly used to synthesize model compounds [3,6–11]. Pyrazole-based ligands have been less well investigated for the purpose of synthesizing model complexes that can mimic the active site of those metalloenzymes and metalloproteins which are known to contain imidazole groups from histidine bound to the iron center in the active site [12,13]. This type of ligands might be preferred in the field of biomimetic chemistry, both because they are good structural analogues for the size and electronic properties of histidine and because of their relative ease of preparation as compared to imidazole ligands.

Although a large number of oxygen-bridged dinuclear iron(III) complexes have been synthesized and characterized as structural and functional models for the MMO enzyme, the most efficient models for alkane hydroxylation remain μ-oxo dinuclear iron(III) complexes with didentate (bipyridine, bpy) [10,14], or tetradentate (tris(2-pyridylmethyl)amine, tpa) pyridine-like ligands [7,15–17] and exchangeable μ-acetato or terminal aquo ligands. In these cases, both *tert*-butylhydroperoxide and H_2O_2 have proven to be the most widely studied oxidants in association with these catalysts. In a programme to search for more adequate synthetic models for the active site of MMO, we report herein the synthesis, characterization, magnetic properties and the reactivity studies of two new bis(μ-alkoxo)-bridged dinuclear iron(III) complexes, $[Fe(nhep)Cl_2(EtOH)]_2$ (**1**) (Hnhep = 1-(2-hydroxyethyl)-pyrazole) and $[Fe(nhed)Cl_2]_2$ (**2**) (Hnhed = 1-(2-hydroxyethyl)-3,5-dimethylpyrazole).

2. Experimental

2.1. Synthesis

Chemicals were purchased from Aldrich and were used as received. The ligands 1-(2-hydroxyethyl)-pyrazole (Hnhep) [18] and 1-(2-hydroxyethyl)-3,5-dimethylpyrazole (Hnhed) [19] were synthesized as previously reported.

2.1.1. $Fe(nhep)Cl_2(EtOH)]$ (**1**)

The complex was obtained by slow diffusion, in an H-shaped tube, of two ethanolic solutions, one containing 1 mmol (0.2 g) $FeCl_2 \cdot 4H_2O$ and the other one containing 1 mmol (0.15 g) of 1-(2-hydroxyethyl)-pyrazole. Dark orange crystals were obtained in one week. The crystals were collected by filtration, washed with diethyl ether and dried in vacuum. Yield: 0.32 g (60%) *Anal.* Calc. for $C_{14}H_{26}Cl_4Fe_2N_4O_4$: C, 29.57; H, 4.57; N, 9.85. Found: C, 29.89; H, 4.62; N, 9.48%. IR (ν_{max}/cm^{-1}): 3288m, 2938m, 2873w, 1624w, 1546m, 1421s, 1280m, 1188s, 1060s, 1028s, 1004m, 893s, 765s, 611m, 562s, 467s, 386m. UV–Vis (λ_{max}/nm): 411, 639, 1050.

2.1.2. $Fe(nhed)Cl_2]$ (**2**)

The complex was prepared by adding 2 mmol (0.3 g) of the ligand 1-(2-hydroxyethyl)-3,5-dimethylpyrazole (Hnhed) dissolved in 10 ml of tetrahydrofuran to a solution of 2 mmol (0.4 g) $FeCl_2 \cdot 4H_2O$ in 20 ml tetrahydrofuran. Slow diffusion of hexane into the resulting orange solution over 3 days yielded orange crystals that were collected by filtration, washed with hexane and dried in air. Yield: 0.45 g (78%) *Anal.* Calc. for $C_{14}H_{22}Cl_4Fe_2N_4O_2$: C, 30.45; H, 3.98; N, 10.15. Found: C, 31.07; H, 3.74; N, 10.48%. IR (ν_{max}/cm^{-1}): 2925m, 2865w, 1636w, 1558m, 1473s, 1364m, 1227m, 1133s, 1084m, 1049s, 895s, 798s, 627m, 570s, 513m, 450s, 356m. UV–Vis (λ_{max}/nm): 407, 589, 1018.

2.2. Physical measurements

Elemental analyses of C, H, and N were performed on a Perkin Elmer 2400 Series II analyzer. Infrared spectra (4000–300 cm^{-1}) were recorded using the reflectance technique on a Perkin–Elmer Paragon 1000 FTIR spectrometer equipped with a Golden Gate ATR device. Ligand field spectra were obtained on a Perkin-Elmer Lambda 900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference. Magnetic susceptibility measurements (2–300 K) were carried out at 1 T using a Quantum Design MPMS-5 5T SQUID magnetometer. Data were corrected for the magnetization of the sample holder and for diamagnetic contributions, the latter of which were calculated from the Pascal constants [20]. The GC–MS measurements were carried out on a Hewlett–Packard 5890 Series II gas chromatograph, equipped with WCOT fused silica column (stationary phase: CP-Was 58 (FFAP) CB) and coupled to a Hewlett–Packard 5971 series mass spectrometer with a mass-selective detector. Standard oxidation reactions were carried out under ambient conditions. The Mössbauer spectra were measured on a constant-acceleration spectrometer which utilized a room temperature rhodium matrix cobalt-57 source and was calibrated at room temperature with α-iron foil.

2.3. X-ray crystallography and data collection

Intensity data for a single crystals of **1** and **2** were collected using Mo Kα radiation (λ = 0.71073 Å) on a Nonius KappaCCD diffractometer. A correction for absorption was considered unnecessary in the case of compound **1**. In the case of compound **2**, an empirical absorption correction was made using PLATON/DELABS (0.600–0.800 transmission) [21]. The structures were solved by automated Patterson methods using DIRDIF99 (**1**) or direct methods using SHELX-97 (**2**) and were refined on F^2 by least-squares procedures using SHELXL-97 [22–24]. All non-hydrogen atoms were refined with anisotropic displacement parameters. In the

case of compound **1**, all hydrogen atoms were independently refined. For compound **2**, all hydrogen atoms were constrained to idealized geometries and allowed to ride on their carrier atoms with an isotropic displacement parameter related to the equivalent displacement parameter of their carrier atoms. Structure validation and molecular graphics preparation were performed with the PLATON package [21].

2.4. Oxidation reactions

2.4.1. Procedure I

In a typical run, 10 equiv. of H_2O_2 (30%) were added to a methanol solution (10 ml) containing 1 mM catalyst (stock solution) and 1 M cyclohexane at room temperature with a final catalyst:substrate:H_2O_2 ratio of 1:1000:10.

2.4.2. Procedure II

The complexes (0.05 mmol) were dissolved in methanol (10 ml) containing 2.5 mmol of substrate. The reaction was started by adding 5 mmol of 30% H_2O_2. The final catalyst:substrate:H_2O_2 ratio was 1:50:100. In both procedures, after 3 h of reaction at 25 °C, aliquots were taken from the reaction mixtures and analyzed twice by GC–MS: both with and without the addition of an excess of triphenylphosphane for the quantification of the amount of hydroperoxide [25]. Chlorobenzene was used as internal standard.

3. Results and discussions

3.1. Synthesis and spectroscopic studies

The reaction of Hnhep or Hnhed with either $FeCl_2$ or $FeCl_3$ affords two new bis(μ-alkoxo)-bridged dinuclear iron(III) complexes (**1** and **2**), as confirmed by their X-ray structure determinations (vide infra).

The infrared spectra of the complexes **1** and **2** exhibit the bands expected for the deprotonated ligands 1-(2-oxyethyl)-pyrazole and 1-(2-oxyethyl)-3,5-dimethylpyrazole. The most significant effect of the coordination of the pyrazole-based ligands to the iron(III) center is observed in the range 1500–1650 cm^{-1}. In this spectral range, both free ligands exhibit two characteristic bands, ν(C=N) (at 1636 cm^{-1} for Hnhep and 1642 cm^{-1} for Hnhed) and ν(C–O) (at 1508 cm^{-1} for Hnhep and 1512 cm^{-1} for Hnhed). Upon coordination of these ligands to iron(III), the energy of the ν(C=N) band decreases (to 1624 cm^{-1} for **1** and 1632 cm^{-1} for **2**) and that of ν(C–O) increases (to 1546 cm^{-1} for **1** and 1558 cm^{-1} for **2**), suggesting the presence of an alkoxo bridge. Both the symmetric and the asymmetric Fe–O–Fe vibrations have associated bands in the infrared spectra of complexes **1** and **2** [26]. The asymmetric stretching vibrations at 611 cm^{-1} for **1** and 627 cm^{-1} for **2** and the symmetric stretching vibrations at 562 cm^{-1} for **1** and 570 cm^{-1} for **2** are in the range of those observed for similar $Fe_2(OR)_2$ dimers [3,6–11]. A sharp peak at 3288 cm^{-1} observed in the infrared spectrum of **1** indicates the presence of moderately strong hydrogen bonds.

The ligand field spectra of both **1** and **2** display the features typical of bis(μ-alkoxo)-bridged iron(III) compounds: an intense absorption band (at 411 nm for **1** and 407 nm for **2**) with a lower energy shoulder (at 639 nm for **1** and 589 nm for **2**), assigned to the ligand-to-iron(III) charge-transfer transitions [27]. In the ligand field spectrum of complex **2**, a medium intensity absorption band that occurs at 1018 nm is attributed to the d–d transitions involving forbidden states of high-spin iron(III). The unusually high intensity of this band may be due either to the exchange coupling between the iron(III) centers that engenders a relaxation of the spin selection rules or to the low symmetry of the iron(III) coordination [28]. For complex **1**, a weak poorly-resolved absorption band at 1050 nm is observed.

3.2. Description of crystal structures

The structures of complexes **1** and **2** were determined by X-ray crystallography. Crystallographic data and selected bond lengths and angles are listed in Tables 1 and 2.

A Pluton projection of the centrosymmetric dinuclear unit of **1** is depicted in Fig. 1. Each iron center, coordinated to two bridging alkoxo-groups, two terminal chloride ions, one nitrogen atom of the Hnhep pyrazole ring and one oxygen atom of an ethanol molecule, has a Cl_2NO_3 donor set in a pseudo-octahedral geometry. The two metal-centred octahedra share an edge in the dinuclear complex. The anionic Hnhep ligand is found in a didentate coordination mode forming the alkoxo-bridges of a planar $Fe_2(OR)_2$ core. The O6–Fe1–N1 bite angle (87.78(5)°) is smaller than that found in a related copper compound [29]. The Fe1–O_{alkoxo} bond distances of 1.9707(10) and 2.0026(10) Å are nearly equivalent to those observed in other bis(μ-alkoxo)-iron complexes [30–33]. The Fe–O–Fe angle (105.69(5)°) and the Fe···Fe separation (3.1670(5) Å) are within the range of values found in bis(μ-alkoxo)-bridged iron(III) complexes [26,30,31,33]. The positions of *trans* coordinating ligands deviate slightly from linearity (161.75(5)°–175.67(4)°), and the iron(III) ion is lifted from the basal plane by 0.17 Å in the direction of the ethanol molecule. The two chloride ions are *cis* to each other (Cl1–Fe1–Cl2 = 93.936(19)°) with Fe–Cl bond distances of 2.2667(5) and 2.3400(5) Å that are close to the values generally observed for iron(III) complexes [34–38]. An interesting feature of the crystal structure of **1** is the presence of two intramolecular hydrogen bonds (Fig. 1) that are established between the chloride ions

and the ethanol molecules of the adjacent iron(III) centers (O9–H9···Cl1a = 3.163(2) Å). The observed O-H stretching vibration of the ethanol molecule (3288 cm^{-1}) and the O–H···Cl distance fit fairly well the relationship developed by Bellamy et al. (O9–H9···Cl1a = 3.158 Å) [39]. No evidence was found for strong intermolecular contacts between dinuclear units.

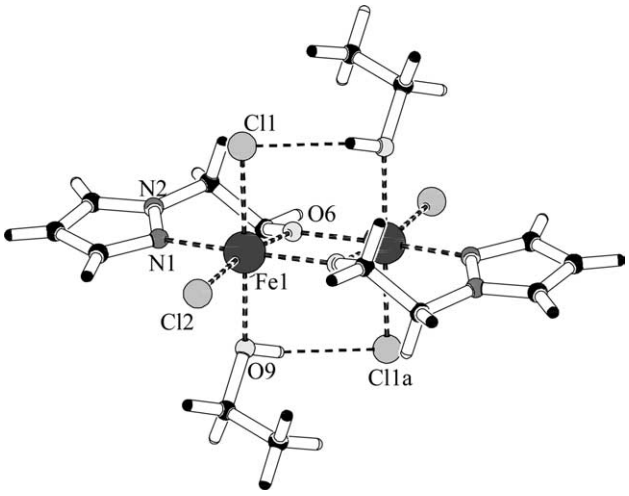

Fig. 1. Pluton projection and numbering scheme of the dinuclear structure of **1**.

The crystal structure of compound **2** (Fig. 2) reveals a centrosymmetric dinuclear unit, similar to that observed for compound **1**. The presence of the methyl groups at the 3- and 5-positions of the pyrazole ring of the Hnhed ligand in **2** results in a change of the coordination geometry around the iron(III) ions. Each iron(III) center is now five-coordinate and has a distorted square pyramidal geometry (as ascertained by the factor $\tau = 0.4$; $\tau = 0$ for a square pyramid and $\tau = 1$ for trigonal bipyramid) [40]. One chloride ion, the two bridging O_{alkoxo} ligands and the nitrogen donor of the pyrazole ring constitute the basal plane of the square pyramid, and the other chloride ion occupies the apical position of the square pyramid. As a result, the dinuclear complex consists of two square pyramids sharing a basal edge (Fig. 2). The largest distortion from the square pyramidal geometry is evidenced by the angles N12–Fe1–O10a = 157.64(6)° and O10–Fe1–Cl1 = 72.75(6)°. The O10–Fe1–N12 = 87.23(6)° bite angle of the didentate ligand is similar to that observed for Hnhep in compound **1**.

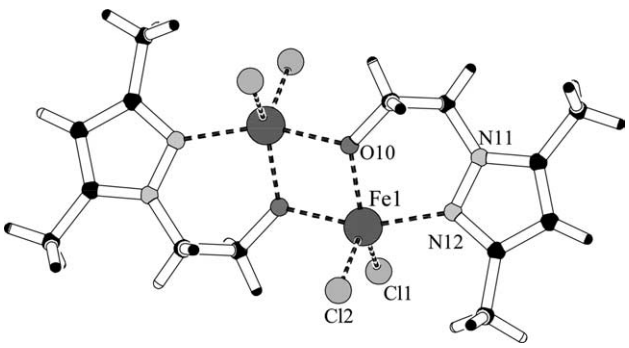

Fig. 2. Pluton projection and numbering scheme of the dinuclear structure of **2**.

The Fe–O–Fe angle (107.25(6)°), Fe–O distances (1.9384(14) and 2.0157(16) Å) and Fe···Fe separation (3.184 Å) are within the range of values found for related bis(μ-alkoxo) bridged iron(III) complexes [30–32,41]. The angle between the two chloride ions is Cl1–Fe1–Cl2 = 112.05(2)°; the average Fe–Cl bond distance of 2.2336(5) Å, is significantly shorter than in compound **1**, but still within the range of the values observed for other iron(III) complexes [34–38]. No stacking interactions or classical hydrogen bonds are observed in the crystal structure of compound **2**.

3.3. Magnetic properties

The variable temperature solid-state magnetic susceptibilities of **1** and **2** have been investigated in the range 2–300 K in an applied magnetic field of 1 T. The values of the $\chi_m T$ product at room temperature are 8.761 $cm^3\,K\,mol^{-1}$ for **1** and 8.749 $cm^3\,K\,mol^{-1}$ for **2**, in agreement with the expected value for two independent spins $S = 5/2$ (8.754 $cm^3\,K\,mol^{-1}$). The $\chi_m T$ versus T curves of both compounds are similar and show a continuous decrease, as the temperature is lowered from 300 to 2 K indicating that the two iron(III) ions are antiferromagnetically coupled. Fig. 3 shows the $\chi_m T$ versus T plot for compound **1**; a very similar behaviour was observed for **2** (not shown).

The six possible states for a dinuclear Fe(III)–Fe(III) complex have total spins of $S = 0, 1, 2, 3, 4, 5$. These spin states are split in energy and produce a spin ladder that can be modeled by the Heisenberg–Dirac–van Vleck phenomenological Hamiltonian: $H = -2JS_1S_2$ [20]. The value of the exchange interaction J can be obtained from the fit of the $\chi_m T$ versus T curve, where the measured magnetic susceptibility is a sum of three terms without zero field splitting (Eq. (2)):

$$\chi_{exp} = \chi_{para} + \chi_{dia} + \chi_{TIP} \tag{2}$$

in which χ_{para} is the paramagnetic (temperature-dependent) contribution, χ_{dia} is the diamagnetic contribution and χ_{TIP} is the temperature-independent paramagnetism, arising from mixing of the excited states into the ground state by the magnetic field. Typically J is determined from a fit of the magnetic susceptibility data using the Van Vleck equation evaluated for an exchange-coupled high-spin dinuclear Fe(III)Fe(III) complex (Eq. (3)) [20]:

$$\chi = \frac{2Ng^2\beta^2}{kT} \times \frac{e^x + 5e^{3x} + 14e^{6x} + 30e^{10x} + 55e^{15x}}{1 + 3e^x + 5e^{3x} + 7e^{6x} + 9e^{10x} + 11e^{15x}}, \tag{3}$$

with $x = J/kT$. The temperature-independent paramagnetism (TIP = 400×10^{-6} $cm^3\,K\,mol^{-1}$ for each iron ion) was taken into account. Using this approach, the best fit parameters were $J_1 = -10.04$ cm^{-1}, $g_1 = 2.02$, for compound **1** and $J_2 = -12.5$ cm^{-1}, $g_2 = 2.03$, for compound **2**. The values obtained are in the range of those observed for other weak antiferromagnetically coupled alkoxo-iron complexes. A correlation between the experimental and calculated magnetic data together with structural parameters is shown in Table 3 [42].

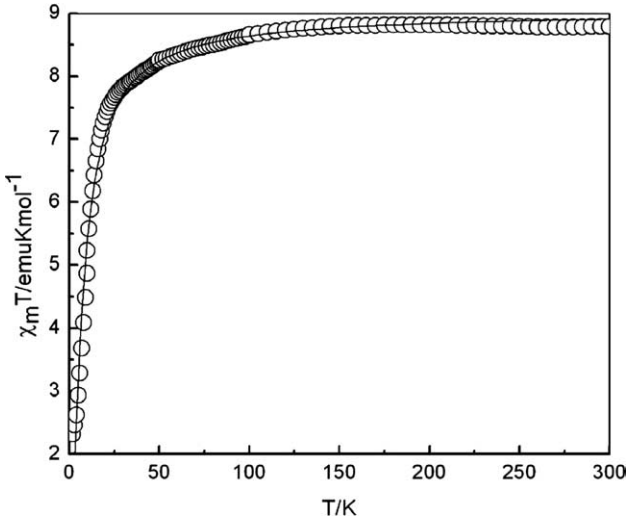

Fig. 3. Plot of the χ_mT vs. T for compound **1**: circles experimental values; (—) calculated values.

3.4. Mössbauer spectral studies

The Mössbauer spectra of **1** and **2** have been measured at 295 and 78 K and show the expected single quadrupole doublet. The hyperfine parameters resulting from quadrupole doublet fits are given in Table 4 and the 78 K spectra are shown in Fig. 4. The 295 K spectra are essentially identical to the 78 K spectra. The hyperfine parameters are typical of iron(III) [43–45] in a somewhat distorted five- or six-coordinate environment and, as expected, the isomer shifts increase slightly upon cooling as a result of the second-order Doppler shift. Rather surprisingly there is little difference in the isomer shift between the six-coordinate iron(III) in **1** and the

Table 3
Magnetic and structural parameters

Complex	P (Å)[a]	d(Fe···Fe) (Å)	α (°)[b]	J_{calc} (cm^{-1})[c]	J_{exp} (cm^{-1})
1	1.9708	3.167	105.69	−12.7	−10
2	1.9384	3.184	107.25	−19.5	−12.5

five-coordinate iron(III) in **2**, but the five-coordinate **2** does exhibit a slightly larger quadrupole splitting.

3.5. Reactivity studies

The monooxygenase-like activity of complexes **1** and **2** has been tested in the oxidation of cyclohexane using H_2O_2 as oxidant, in methanol as solvent, and under ambient conditions. However, by using either one of the procedures described in the experimental part, no cyclohexane conversion was observed. Several additives (*N*-methylimidazole, acetic acid, benzoic acid, pyridine 2-carboxylic acid, pyridine 2,6-dicarboxylic acid, 3,5-pyrazoledicarboxylic acid, 4,5-imidazoledicarboxylic acid, 2-pyrazinecarboxylic acid) have been screened for possible improvement of the catalytic efficiency, however, no improvement was observed. The inactivity of the complexes **1** and **2** in cyclohexane oxidation is most probably due to the presence of iron(III)–chloride bonds that are too strong to allow exchange with solvent molecules or reactants.

Fontecave et al. [46] have reported that the activation of the C-H bond by hydroperoxides requires the presence of exchangeable coordination sites, in order to allow the binding of the oxidant to the metal centre. Therefore, it was decided to evaluate the corresponding in situ $CF_3SO_3^-$ salts of compounds **1** and **2** (obtained by addition of $AgCF_3SO_3$ to the methanol solution of **1** or **2**, followed by stirring and filtration through Celite to remove the silver salt) for the oxidation of cyclohexane. Using the procedure II, the maximum catalytic activity is reached after 3 h and it results in the formation of 3.2 equiv. cyclohexanol and 1.4 equiv. cyclohexanone in the reaction catalyzed by **1** and 1.8 equiv. cyclohexanol and 1.2 equiv. cyclohexanone in the reaction catalyzed by **2**. The use of the procedure I does not lead to any catalytic activity. Also, H_2O_2 dismutation has not been observed in both complexes.

By using a large excess of H_2O_2 (100 to 1000 equiv. in procedure II) neither cyclohexane conversion nor H_2O_2 dismutation activity was observed. In order to gain insight into the total lack of activity of complexes **1** and **2** under these conditions, the oxidation attempts were also followed by UV–Vis and ES-MS spectroscopy. The UV–Vis spectra of both compounds in methanol solution show similar features and no significant changes are observed when the solutions are kept at room temperature for several days. In both cases, the UV–Vis spectrum is dominated by a broad band at about 360 nm which is assigned to the iron-to-oxygen charge transfer transition. When H_2O_2 is added, the alkoxo-to-iron(III) LMCT band at 360 nm of **1** (356 nm for **2**) starts to decrease in intensity and to shift to higher energy; however in the presence of 10–20 equiv. H_2O_2, only insignificant changes are observed. When the amount of H_2O_2 added is increased, the intensity of the band decreases progressively and the band disappears completely after addition of 1000 equiv. of H_2O_2. The observed spectroscopic changes observed for compound **1** are presented in Fig. 5. This behaviour suggests a change in, or loss of, the coordination of the pyrazole ligand. Indeed, after addition of 1000 equiv. of H_2O_2, the ES-MS mass spectrum of complex **1** shows a peak at $m/z = 113$ with an abundance of 100% corresponding to the free Hnhep ligand and some other peaks of low intensity (abundance <10%) that could not be clearly assigned. A similar ES-MS mass spectrum was observed for complex **2** after addition of H_2O_2 (m/z = 141 $[Hnhed + H]^+$, 176 $[(H_2nhed)Cl + H]^+$).

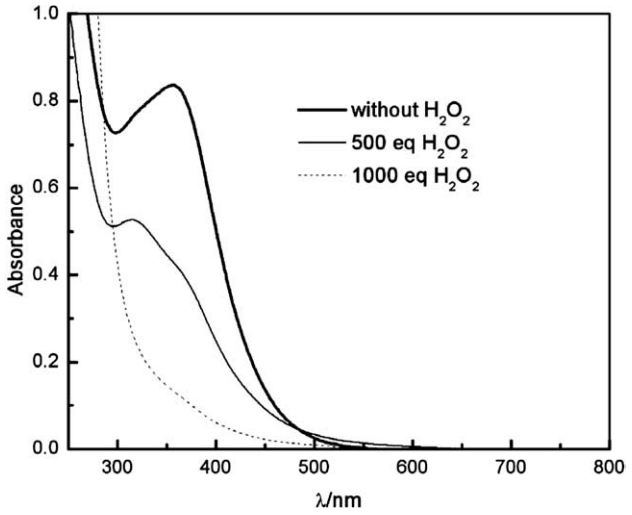

Fig. 5. Spectroscopic changes observed for a methanol solution of compound **1** upon the addition of H_2O_2.

4. Conclusions

We have synthesized and characterized two new bis(μ-alkoxo)diiron(III) complexes, $[Fe(nhep)Cl_2(EtOH)]_2$ (**1**) and $[Fe(nhed)Cl_2]_2$ (**2**) which have been inspired by the methane monooxygenase enzyme. The structural analysis of both complexes demonstrates the ability of the 1-(2-hydroxyethyl)pyrazole ligands to form dinuclear iron(III) compounds with a coordination number of five or six at the metal centre. A detailed characterization of complexes **1** and **2** including structural, spectroscopic and magnetic studies has been carried out. Replacing chloride ions with non-coordinating anions ($CF_3SO_3^-$) in compounds **1** and **2**, results in apparent catalytic activity in the oxidation of cyclohexane. This observation suggests that the inactivity of these complexes appears to be partly due to the presence of iron(III)-chloride bonds that are too strong to allow exchange with solvent molecules or reactants. Further optimization of the reaction conditions and the investigation of other substrates are in progress.

5. Supplementary material

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 216734 (for **1**) and CCDC 223689 (for **2**). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Abstract

The reaction of $[VO(dipic)(H_2O)_2]\cdot H_2O$ with creatinine in a H_2O–CH_3OH mixture yields yellow crystals of a bis(oxo-bridged) binuclear vanadium(V) compound of stoichiometry $[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$, ($dipic^{2-}$ = pyridine 2,6 dicarboxylate; $CH_3NHC(NH_2)_2^{+}$) = methylguanidinum). The molecular structure of the compound was determined by X-ray diffraction methods. The binuclear complex crystallizes in the monoclinic space group $P2_1/c$ with $a = 9.557(1)$, $b = 12.363(1)$, $c = 10.466(1)$ Å, $\beta = 101.56(2)°$ and $Z = 2$. It sits at a crystallographic inversion center with the pair of V(V) atoms in an edge-sharing distorted octahedral environment. In the $[VO_2(dipic)]^-$ halves of the dimer, the VO_2^+ cation is coordinated to a dipicolinate group acting as a tridentate planar ligand through one oxygen of each carboxylic group and the hetereocyclic nitrogen atom. The oxo ligand lying near the coordination plane bridges through a weak axial V–O bond to the other half of the dimer. This gives rise to a V=O2 bond length slightly longer than the other terminal V=O1 bond. The infrared and Raman spectra of the compound were recorded and discussed on the basis of its structural data and compared with those of the free acid. The results are also compared with the corresponding results of related structures.

1. Introduction

Vanadium coordination chemistry constitutes a field of increasing interest and has been the subject of extensive studies during recent decades by many different authors. A great number of ligands have been employed in the study of biologically relevant vanadium systems with the aim of finding a possible correlation between activity and coordination geometry. Diverse aspects related to its biological and pharmacological activity have been reviewed [1–4].

Vanadium(III, IV and V) has a high affinity for N, O and/or S donor groups. It reacts with many naturally occurring species, including pyridine carboxylic acids, forming stable complexes of diverse stoichiometries. Metal complexes of pyridine carboxylic acids and some of their derivatives have recently received considerable attention as model systems for the design of new metallopharmaceutical compounds. Furthermore, several vanadium complexes were investigated as antidiabetic agents,

doi:10.1016/j.poly.2004.09.032

most of them involving vanadium(IV) as the metal center [5–9]. Among others, oxovanadium(IV) associated with picolinate and other related ligands appear as very promising insulin-mimetic oral active drugs [7–9].

Dipicolinic acid (H_2dipic – Fig. 1) is a versatile N–O chelating agent that can act as a bidentate, tridentate, meridian or bridging ligand with different metal ions as well as with oxometal cations [10–14]. It is present in many natural compounds as an oxidative degradation product of vitamins, coenzymes and alkaloids and is also a component of fulvic acids. It shows various biological functions including activation-inactivation of some metalloenzymes and inhibition of electron transport and of LDL oxidation [15]. Lately, it has become one of the more suitable ligands for modeling potential pharmacological active compounds because of its low toxicity and amphophilic nature. It was also determined that vanadium complexes of this bio-ligand are more effective than the ligand alone in the treatment of diabetes [16]. The insulin-like properties of the V(V) dipicolinate compound, $[VO_2dipic]^-$, originally prepared by Wieghard [17,18], and its 4-hydroxydipicolinate derivative, $[VO_2dipic\text{-}OH]^-$, have been recently determined [16,19,20].

The structural chemistry of vanadium(V), like that of other transition metals in high oxidation states, is mainly related to the oxo complexes. Although a great number of oxo-bridged vanadium(IV and V) and mixed valence complexes are described in the literature, these compounds are less abundant than those of Ti(IV) or Mo(V,VI). Moreover, only few examples of bis-oxo-bridged compounds have been reported [21–24]. In the present paper, we report the synthesis, crystal structure and spectroscopic characterization of $[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$, a new vanadium(V) bis-oxo-bridged dimer complex. The dimeric complex anion has two methyl-guanidinium counterions.

Methylguanidine (MG) is a metabolic product of creatinine oxidation in living organisms. However, it is uncertain which enzymes are involved in its biosynthesis [25]. Clinical studies led to the conclusion that MG is adsorbed in the gastrointestinal tract and is not converted into other products. It has been also determined that MG is formed by incubation of creatinine, at 38 °C in the presence of oxygen, indicating that the conversion can take place non-enzymatically [26].

2. Experimental

2.1. Reagents and instrumentation

All chemicals were of analytical grade. $VOSO_4 \cdot 5H_2O$ (Merck), Dipicolinic acid (Sigma) and Creatinine (Merck) were used without further purification.

IR spectra were recorded on a Bruker 113 v FTIR instrument, using the KBr pellet technique. Raman spectra were obtained with a Brucker IFS 66 FTIR spectrophotometer, using the FRA 106 Raman accessory and the 1064 nm line of a Nd:YAG solid state laser for excitation. The electronic absorption spectra were recorded on a Hewlett–Packard 8453 diode – array spectrophotometer using 1 cm quartz cells. Elemental analysis (C, H, N) was performed using a Carlo Erba EA 1108 analyzer.

2.2. Synthesis of complexes

*$[VO(dipic)(H_2O)_2]H_2O$ (**1**).* The complex was prepared according to the reported procedure [12]. 0.5 g of $VOSO_4.5H_2O$ (1.75 mmol) and 0.4 g of dipicolinic acid (2.45 mmol) were dissolved in 20 ml of hot water. The bright green solution obtained was then cooled to 5 °C and the precipitated ligand excess was filtered off. The filtrate was kept overnight in a refrigerator. The blue crystalline product obtained was filtered, washed with absolute ethanol and dried in air. (yield: 66%). *Anal.* Calc. for $C_7H_9NO_8V$: C, 29.3; H, 3.2; N, 4.7. Found: C, 28.9; H, 3.1; N, 4.5%.

*$[CH_3NHC(NH_2)_2]_2[V_2O_4(dipic)_2]$ (**2**).* 0.207 g (0.72 mmol) of complex **1** was dissolved in 12 ml of hot water and added dropwise to 25 ml of a methanolic solution of creatinine (0.168 g, 1.49 mmol), kept under continuous stirring. After 30 min stirring of the resulting solution, its color changed from bright deep green to pale light green. The solution was then kept at room temperature for 24 h before storing it in a refrigerator. After several months, yellow crystals of the complex, suitable for X–ray structural analysis, were obtained. During this period the color of the solution changed to yellow. The crystalline product obtained was filtered out, washed with small portions of 1:1 methanol:water mixture and dried in air. The low yield of the reaction (28%) can be improved by further precipitation from the filtrate at 5 °C. *Anal.* Calc. for $C_{18}H_{22}N_8O_{12}V_2$: C, 33.5; H, 3.4; N, 17.4. Found: C, 32.9; H, 3.3; N, 17.1%.

2.3. Crystal structure determination

The measurements were performed at 120 K on an Enraf-Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The temperature was controlled employing an Oxford

Cryosystems low-temperature device. Diffraction data were collected (φ and ω scans with κ offsets) with COLLECT [27]; integration and scaling of the reflections were performed with the HKL DENZO-SCALEPACK [28] suite of programs. The unit cell parameters were obtained by least-squares refinement based on the angular settings for all collected reflections using HKL SCALEPACK [28]. Absorption correction was not applied as μ times the largest crystal size was less than 0.103. The structure was solved by Patterson (SHELXS-97 [29]) and Fourier (SHELXL-97 [30]) methods and the molecular model refined by full-matrix least-squares procedure on F^2 with SHELXL-97. The H-atoms were positioned stereochemically and refined with the riding model. The data for publication were prepared with SHELXL-97. Crystal data, data collection procedure, structure determination methods and refinement results are summarized in Table 1.

Largest peak and hole (e Å^{-3})	0.275 and −0.363

3. Results and discussion

3.1. Structure of the complex

Fractional coordinates and equivalent isotropic displacement parameters are presented in Table 2. Bond distances and angles around the metal ion are given in Table 3. An ORTEP [31] drawing of the binuclear vanadium(V) complex with the atom numbering scheme is shown in Fig. 2.

The $[(VO_2)(dipic)]^-$ ions are arranged in the lattice as centrosymmetric oxo-bridged binuclear complexes. The pair of vanadium(V) atoms in a dimer are in an edge-sharing octahedral environment, with the dioxo vanadium(V) cation coordinated to a dipicolinate molecule acting as a tridentate ligand through one oxygen of each carboxylic group [V–O distances of 1.984(1) and 1.995(1) Å] and the heterocyclic nitrogen atom [d(V–N) = 2.097(2) Å]. The dipicolinate group defines an equatorial ligand plane [with a rms deviation of atoms from the least-squares plane of 0.025 Å] with the metal lying close to this plane [at 0.144(1) Å]. The bridging oxo ligand [d(V–O2) = 1.684(1) Å] is much closer to this plane [at 0.486(2) Å] than the terminal oxo atom [at 1.739(2) Å] which shows a slightly shorter V=O bond distance [d(V–O1) = 1.606(1) Å] and occupies an axial position. The O1–V–O2 angle is 105.36(7)°. The octahedral bonding structure around the metal is completed at the other axial position by the weak interaction with the bridging oxo ligand of the inversion related VO_2^+ group in the dimer [d(V–O2′) = 2.370(1) Å]. The bonding structure around vanadium(V) agrees well with other

[a] Primed atoms are related to unprimed ones through the inversion symmetry operation: $-x+1,-y,-z$.

binuclear dioxovanadium(V) complexes of tridentate ligands reported in the literature [22,23].

To rationalize the changes in the bonding structure of $[(VO_2)(dipic)]^-$ upon dimerization we can compared the above structural data with that reported for the monomeric complex, $Cs[(VO_2)(dipic)]\cdot H_2O$ [18]. Here the V=O double bond distances are equal to within experimental accuracy [1.610(6) and 1.615(6) Å], while in our dimeric complex the V–O2 bond involving the bridging oxygen atom is 0.078(2) Å longer than the terminal V–O1 distance. This slight bond asymmetry within the dioxovanadium(V) ion is due to the formation of the weak intermolecular V···O bond bridging the halves of the binuclear complex.

As expected, significant bond localization is also observed in the carboxylic groups of the dipicolinate ligand. In fact, the terminal C–O bond lengths are about 0.1 Å shorter than the C–O distances involving the coordinated-to-vanadium oxygen atoms.

The C–N geometrical parameters of the methylguanidinium cation (MG) are in good accord with those found in related structures [32]. It has a singular planar CN_3 skeleton with a strong electronic delocalization that makes it able to participate in nets of H-bonding.

The $[(VO_2)(dipic)]^-$ monomeric units and the $CH_3NHC(NH_2)_2^+$ ions are arranged in the lattice along layers parallel to (101) crystallographic planes. Adjacent layers in the crystal are linked by the dimer-bridging bond. These layers are stabilized by a net of medium to strong N–H...O bonds involving the methylguanidinium NH and NH_2 groups and the oxo-bridge and the carboxylic oxygen atoms of the dipicolinate ligand [N···O distances are in the range 2.858–2.964 Å and N–H···O angles from 156.0° to 176.6°]. Each methylguanidinium has two N–H groups, from different N atoms, linked to one monomeric $[(VO_2)(dipic)]^-$ unit through an oxo-bridge atom and the carboxylate oxygen coordinated to the metal. The structural feature of this pattern is similar to that described for the interaction of phosphate, sulfonate and nitrate with the guanidinium cation [32]. The other N–H groups of the same MG ion bond to adjacent monomer units through N–H···O hydrogen bonds, forming a layer structure. Fig. 3 is a PLUTON [33] view of the crystal packing showing the layered and H-bonding structures.

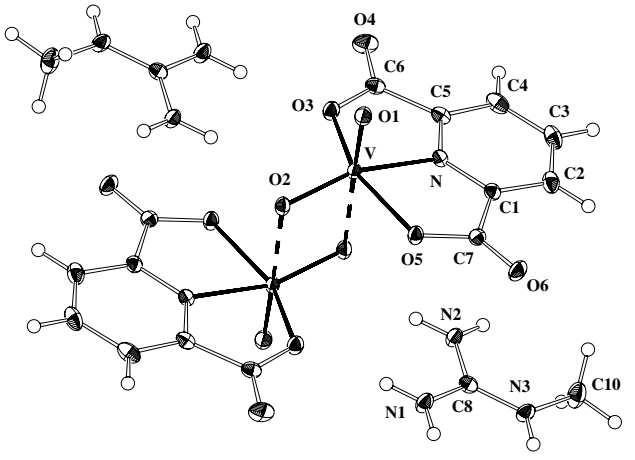

Fig. 2. Molecular plot of the centrosymmetric binuclear $[CH_3NHC(NH_2)_2]_2[(VO_2)(dipic)]_2$ vanadium(V) complex showing the labelling of the non-H atoms and their displacement ellipsoids at the 50% probability level. Full lines indicate vanadium-ligand bonds within the monomeric units and dashed lines indicate bridging bonds.

3.2. Vibrational spectra

The solid-state properties of the compound were examined by infrared and Raman spectroscopy. The spectra were compared with those of the free ligand and of methyl guanidine hydrochloride. Assignments of the spectroscopic bands are given in Table 4.

The dipicolinic acid spectra were coincident with those previously reported [34]. The IR spectrum of the free ligand shows a strong absorption in the 3100–2500 cm^{-1} region due to the O–H stretching mode of the COOH group, overlapped with the C–H stretching bands. The broad and irregular shape of this signal is indicative of the hydrogen bonded dimer structure of the acid. The corresponding C–OH in-plane bending and out-of-plane OH···O deformation modes are observed at 1417 cm^{-1} and 927 cm^{-1}, respectively. These modes are not present in the $[VO_2(dipic)]^-$ units, hence revealing the deprotonation of the carboxylic group

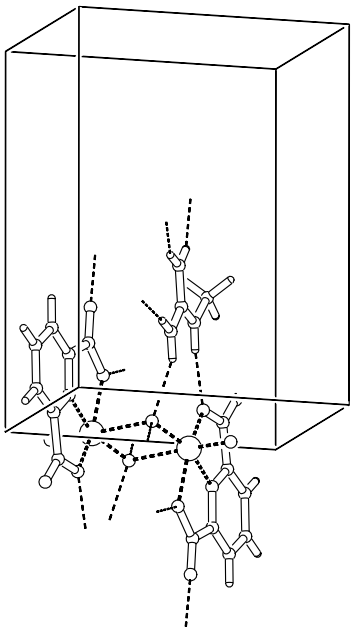

Fig. 3. Partial view showing the crystal packing in the $[CH_3NHC(NH_2)_2]_2[(VO_2)(dipic)]_2$ solid. Thick dashed lines indicate vanadium(V)–ligand bonds and thin dashed lines H-bonds. The crystal unique *b*-axis is along the vertical and the *a*-axis is horizontal.

upon complex formation. The typical ν(C=O) stretch is observed as a broad and very strong IR band centered at 1705 cm^{-1} due to the out-of-phase vibrations of the monomeric units in the dipicolinic acid dimer. The respective in-phase mode appears at 1644 cm^{-1} in the Raman spectra [35]. Two strong IR bands are observed at 1332 and 1301 cm^{-1} (Ra: 1325, 1296) that corresponds to the ν(C–O) vibration. Ring modes were also observed in the expected range [34].

The IR spectrum of the complex shows additional rather broad bands in the 3400–3200 cm^{-1} region that can be attributed to N–H stretching modes of the methylguanidinum, which is involved in hydrogen bonds. Characteristic bands of this cation related to C–NH_2 stretching and N–CH_3 deformation are also present in the compound's spectra [35,36]. After complex formation the carboxylate ν(C=O) and ν(C–O) bands are transformed into the symmetric and antisymmetric stretching vibrations of the carboxylate anion. The antisymmetric mode should be located at the same spectral zone as expected for the ν(C=N) and $\delta(NH_2)$ modes of guanidinium. The three strong IR bands present in the 1700–1620 cm^{-1} region can be assigned to these modes. The symmetric stretch vibration leads to a characteristic strong Raman line at 1329 cm^{-1}, with the corresponding IR band at 1327 cm^{-1}. The frequency difference between these two vibrations in the IR spectrum $[\Delta\nu = \nu_{as}(COO^-) - \nu_s(COO^-)]$ is higher than that reported for the calcium dipicolinate compound [34]. This value ($\Delta\nu > 300$ cm^{-1}) is in accordance with monodentate coordination of the carboxylate group [37]. Coordination of the heterocyclic nitrogen of dipicolinate to vanadium is indicated by an upward shift of some ring modes: skeletal vibration and in plane deformation [11,37]. These observations were confirmed by the X-ray crystallographic study.

Upon chelation, changes in intensity and position of some of the ligand bands were also observed in the 1000–200 cm^{-1} region. The strong IR absorption at 957 cm^{-1} and the intense Raman dispersion at 965 cm^{-1} are assigned to a Davydov split asymmetric VO_2 stretching mode. The first one is due to the IR-active crystal anti-symmetric optic mode and the second, to the Raman-active centrosymmetric optic vibration. The ordering of the IR and Raman wavenumbers agrees with that expected for transition dipole-dipole coupling between the $\nu_{asym}(VO_2)$ mode of the close VO_2 groups in the dimer (V–V distance of 3.2 Å), where the interacting dipoles are nearly parallel to the vanadium-vanadium direction. The other VO_2 stretching vibration, namely the $\nu_{sym}(VO_2)$ mode, appears as a strong doublet, both in the IR (at 862 and 849 cm^{-1}) and the Raman (at 837 and 817 cm^{-1}) spectra. The doublet can be interpreted as a Fermi resonance between the IR- and Raman-active VO_2 symmetric stretching vibration and the first overtone of the also active and symmetric $\delta(VO_2)$ bending mode. It is to be noted that the ordering of the IR and Raman doublets is inverse to that observed for the asymmetric VO_2 stretching mode. Again, this can be rationalized in terms of the correlation (Davydov) interaction between the transition dipole moments localized on the neighboring VO_2 groups of the dimer. Now, however, the coupling constant is of opposite sign to the one of the optical VO_2 asymmetric mode because the transition dipole moments are nearly perpendicular, rather than parallel, to the coupling V–V direction.

Furthermore, new bands were found at 457 and 366 cm^{-1} which are assigned to the stretching modes of the metal-to-ligand bonds, ν(V–O) and ν(V–N), respectively, as they lie in similar ranges to other V(V) compounds with N–O donor ligands (reviewed in [38]).

3.3. Electronic spectra

The electronic spectrum of the pale yellow aqueous solution of the complex shows two bands. The very strong absorption with a maximum at 194 nm can be assigned to intramolecular transitions as both the dipicolinic acid and the N-methylguanidinium salt spectra show strong bands in this region.

The second absorption, centered at 276 nm, denotes the presence of three components (approximate maxima at 268, 276 and 284 nm). It can be interpreted as an intraligand band (located at 274 nm in the free ligand spectrum) overlapped with ligand-to-metal charge transfer transitions. The higher energy component could

essentially involve the oxygen of the carboxylate moiety, whereas the lower energy one can be related to the nitrogen of the heterocycle. This pattern has been described for vanadium(V) complexes with other N, O-donor ligands [38]. According to MO calculations on related compounds the $O \rightarrow V$ charge transfer involving the double bonded oxo group is expected to appear at shorter wavelength than the ligand-to-metal bands [39]. In our compound this absorption is probably superimposed with the band at 194 nm.

Abstract

The reactions of $[Ru(PPh_3)_3Cl_2]$ and *N*-(aroyl)-*N*′-(picolinylidene)hydrazines (HL), derived from 2-pyridinecarbaldehyde and 4-substituted aroylhydrazines in boiling methanol provide mixed-ligand complexes having the general formula *trans*-$[RuL(PPh_3)_2Cl]$. The complexes were characterized by analytical, spectroscopic and electrochemical measurements. The +2 oxidation state of the metal ions in these complexes is confirmed by their diamagnetic nature in the solid state and electrically non-conducting behavior in solution. The X-ray structure of a representative complex has been determined. The metal ion is in a distorted octahedral N_2OP_2Cl coordination sphere. The monoanionic pyridine-N, imine-N and deprotonated amide-O donor ligand and the chlorine atom form an N_2OCl square-plane around the metal centre and the P-atoms of the PPh_3 molecules occupy the remaining two axial sites. The ^{31}P NMR spectra of all the complexes in $CDCl_3$ solutions are consistent with the *trans* orientation of the PPh_3 molecules. Electronic spectra of the complexes in dichloromethane solution display several bands in the range 590–261 nm due to metal-to-ligand charge transfer and intraligand transitions. Cyclic voltammograms of the complexes in dimethylformamide solution display the reversible Ru(III)/Ru(II) couple in the potential range 0.40–0.52 V (versus saturated calomel electrode). The trend in these potential values reflects the polar effect of the substituents on the aroyl moiety of the ligand (L^-).

1. Introduction

The interest in coordination complexes of ruthenium stems from their versatile electron-transfer and energy-transfer properties [1–20]. As a result these complexes exhibit a wide range of reactivities. Due to these characteristics a large variety of ruthenium complexes have found applications in diverse types of research areas. These include artificial photosynthesis, photomolecular devices, elucidation of structural and electron transfer properties of proteins and DNA, catalytic oxidation of water and organic substrates, and stoichiometric as well as catalytic reactions for organic synthesis [12–20]. Due to such a wide range of applications, new ruthenium complexes with different types of ligands are of particular interest. The purpose is to alter the metal ion coordination environment, which is primarily responsible for the properties exhibited by the complex. The Schiff bases derived from aroyl- or acylhydrazines can provide an amide oxygen for metal coordination. Such ligands also give the scope to scrutinize the effect of the amide protonation state on the structural and physical properties of the complex.

Hpabh(R = H) Hpadh (R = NMe_2)
Hpath (R = Me) Hpach (R= Cl)
Hpamh (R= OMe) Hpanh (R = NO_2)

(I)

Prior to our reports on ruthenium(II) bis complexes with *N*-(aroyl)-*N*′-(picolinylidene)hydrazines (HL, **I**) [21] and ruthenium(III) bis complexes with *N*-(acetyl)-*N*′-(salicylidene)hydrazine (H_2L') [22], there were no examples of ruthenium complexes with aroyl- or acylhydrazones. In the former, the ligand (L^-) coordinates the metal ion via pyridine-N, imine-N and deprotonated amide-O atoms and in the latter the monoanionic (HL'^-) or dianionic ligand (L'^{2-}) coordinates the metal ion via phenolate-O, imine-N and amide-O atoms of the protonated or deprotonated amide functionality. For the ruthenium(II) complexes, spectroscopic and electrochemical studies suggest that the energy gap between the metal-dπ and the ligand-π* levels remains constant despite the variation in the polar effect of the substituent on the aroyl fragment of the ligand [21]. On the other hand, electrochemical measurements with the ruthenium(III) complexes of L'^{2-} indicate that the +4 oxidation state of the metal ion can be accessed and the potential of the Ru(IV)/Ru(III) couple is dependent on the protonation state of the coordinated amide functionalities [22]. In the present work, we have described the synthesis and characterization of a new series of mixed-ligand ruthenium(II) complexes having the general formula *trans*-$[RuL(PPh_3)_2Cl]$ obtained from *N*-(aroyl)-*N*′-(picolinylidene)hydrazines (HL) and $[Ru(PPh_3)_3Cl_2]$. In solution, electron transfer and spectroscopic properties have been investigated. An X-ray structure of a representative complex has been determined.

2. Experimental

2.1. Materials

The Schiff bases were prepared in 80–90% yield by condensation of one mole equivalent of 2-pyridinecarbaldehyde and one mole equivalent of the corresponding aroylhydrazine by following a reported procedure [21,23]. All other chemicals and solvents were of analytical grade, available commercially and were used as received.

2.2. Physical measurements

Microanalytical (C, H, N) data were obtained with a Thermo Finnigon Flash EA1112 series elemental analyzer. Infrared spectra were collected using KBr pellets on a Jasco-5300 FT-IR spectrophotometer. A Shimadzu 3101-PC UV/vis/NIR spectrophotometer was used to record the electronic spectra. ^1H and ^{31}P NMR spectra were recorded on a Bruker 200 MHz spectrometer. A Sherwood Scientific balance was used for magnetic susceptibility measurements. Solution electrical conductivities were measured with a Digisun DI-909 conductivity meter. A CH-Instruments model 620A electrochemical analyzer was used for cyclic voltammetric experiments with dimethylformamide solutions of the complexes containing tetrabutylammonium perchlorate (TBAP) as supporting electrolyte. The three electrode measurements were carried out at 298 K under a dinitrogen atmosphere with a platinum working electrode, a platinum wire auxiliary electrode and a saturated calomel reference electrode (SCE). The potentials reported in this work are uncorrected for junction contributions.

2.3. Synthesis of $[Ru(pabh)(PPh_3)_2Cl]$

To a yellow methanol solution (30 ml) of Hpabh (50 mg, 0.22 mmol) and KOH (12 mg, 0.22 mmol), solid $[Ru(PPh_3)_3Cl_2]$ (213 mg, 0.22 mmol) was added and the mixture was refluxed to boiling for 24 h and then cooled to room temperature. The complex, precipitated as a brown solid, was collected by filtration, washed with ether and dried in vacuum. Recrystallization was performed by dissolving the complex in a 1:1 dichloromethane–hexane mixure. Yield, 80 mg (41%).

The other five complexes reported in this work were synthesized from a methanolic medium using one mole equivalent each of $[Ru(PPh_3)_3Cl_2]$, the corresponding Schiff base and KOH in 40–70% yields by following similar procedures as described above.

2.4. X-ray crystallography

Single crystals of *trans*-$[Ru(pamh)(PPh_3)_2Cl]$ were grown by slow evaporation of its dichloromethane–hexane (1:1) solution. A crystal of dimensions $0.50 \times 0.15 \times 0.03$ mm was used for the structure determination. Unit cell parameters and the intensity data were obtained on a Bruker-Nonius SMART APEX CCD single crystal diffractometer, equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å) operated at 2.0 kW. The detector was placed at a distance of 6.0 cm from the crystal. Data were collected at 100 K with a scan width of 0.3° in ω and an exposure time of 15 s/frame. The SMART software was used for data acquisition and the SAINT-Plus software was used for data extraction [24]. The absorp-

tion correction was performed with the help of the SADABS program [25]. The structure was solved by direct methods in the C_2/c space group and refined on F^2 by full-matrix least-squares procedures. The asymmetric unit contains a molecule of *trans*-[Ru(pamh)(PPh_3)$_2$Cl] and a water molecule. All non-hydrogen atoms were refined using anisotropic thermal parameters. The hydrogen atoms of the water molecule located in a difference map and the rest of the hydrogen atoms obtained by using a riding model were included in the structure factor calculation at idealized positions, but not refined. The SHELX-97 programs [26] were used for structure solution and refinement. The ORTEX6a package [27] was used for molecular graphics. Selected crystallographic data are listed in Table 1.

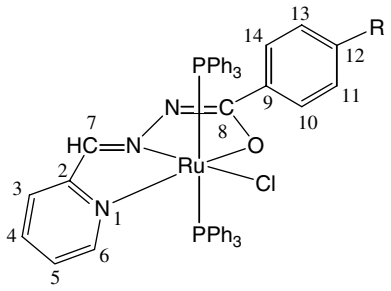
3. Results and discussion

3.1. Synthesis and some properties

The Schiff bases (HL) were obtained by the condensation of 2-pyridinecarbaldehyde and 4-substituted aroylhydrazines (1:1 mole ratio) in methanol. Reactions of one mole equivalent each of [Ru(PPh_3)$_3$Cl$_2$], HL and KOH in boiling methanol afforded the complexes in moderate to good yields. The elemental analysis data of the complexes are consistent with the general formula [RuL(PPh_3)$_2$Cl] (Table 2). The complexes are more soluble in less polar solvents such as dichloromethane and chloroform than polar solvents such as methanol and acetonitrile. In dimethylformamide solutions, the complexes are electrically non-conducting. Thus the chloride ion is coordinated to the metal ion in each complex. All the complexes are diamagnetic and NMR active. Thus the oxidation state of the metal ion is +2 and it is in a low-spin state in each complex.

3.2. Spectroscopic characteristics

Infrared spectra of the complexes do not display the characteristic bands associated with the N–H and C=O bonds of the amide functionality present in the free Schiff bases [28,29]. Thus in each complex the amide functionality is deprotonated and exists in the enolate form (**II**). A medium to strong band observed in the range 1585–1606 cm^{-1} is most likely associated with the conjugated —C=N—N=C— fragment of the ligands [21–23,30]. The presence of the {Ru(PPh_3)$_2$} unit in all the complexes has been indicated by three strong bands at ~743, ~694 and ~515 cm^{-1}. Similar bands are displayed by [Ru(PPh_3)$_3$Cl$_2$] and complexes containing the {Ru(PPh_3)$_2$} unit [31].



Dichloromethane solutions of the complexes are brown in colour. These solutions have been used to record the electronic spectra. All the complexes display several absorptions in the visible and ultraviolet region. The spectroscopic data are listed in Table 2. The intense absorptions in the higher energy region are most likely due to transitions involving the ligand orbitals only [21]. The absorptions in the visible region are attributed to metal-to-ligand charge-transfer transitions. Multiple absorptions in this region for these types of mixed-ligand ruthenium(II) complexes are not unusual considering the possibilities of several closely spaced acceptor levels, lower symmetry splitting of the metal orbitals

and singlet–triplet transitions made allowed by spin–orbit coupling [21,31–33].

(II)

The proton NMR spectra of the complexes (**II**) in $CDCl_3$ are consistent with the presence of one tridentate ligand and two PPh_3 molecules. Significant NMR data are listed in Table 3. In all the spectra, a broad peak corresponding to a single proton is observed in the range δ 7.95–8.10 ppm. This signal is assigned to the azomethine hydrogen (H7) of the ligand. For the complexes of $padh^-$, $pamh^-$ and $path^-$ the methyl protons of the substituent on the aroyl fragment of the ligands are observed as singlets at δ 2.96, 3.77 and 2.30 ppm, respectively. The *ortho* proton (H6) of the pyridyl ring appears as a doublet in the range δ 6.77–6.84 ppm. A multiplet observed within δ 6.56–6.62 ppm is assigned to the *para* proton (H4) of the pyridyl unit. A doublet corresponding to two protons is observed in all the spectra except in that of the complex of $pach^-$. This doublet shows a down-field shift with the progressive increase in the electron withdrawing ability of the R group on the aroyl moiety (Table 3). For the complex of $padh^-$ (R = NMe_2) this signal appears at δ 6.41 ppm and for the complex of $panh^-$ (R = NO_2) it appears at δ 7.99 ppm. This doublet is attributed to the two protons (H11 and H13) that are *ortho* to the R group. In each spectra, broad signals observed in the range δ 7.1–7.8 ppm correspond to the phenyl ring protons of the two PPh_3 ligands. The signal due to the H11 and H13 protons for the complex of $pach^-$ and the signals due to the H3, H5, H10 and H14 protons for all the complexes are buried under these broad signals.

Two geometrical isomers are possible for each of these complexes with respect to the arrangement of the two PPh_3 molecules in the coordination sphere. To probe whether the two PPh_3 molecules are a *cis* or *trans* pair we have recorded the ^{31}P NMR spectrum of each of the six complexes. All the complexes display a singlet in the range δ 26.34–27.62 ppm. Thus the $\{Ru(PPh_3)_2\}$ unit in these complexes exists in the *trans* configuration.

3.3. X-ray structure of *trans*-$[Ru(pamh)(PPh_3)_2Cl]\cdot H_2O$

The structure of the complex molecule is illustrated in Fig. 1. Selected bond lengths and angles are listed in Table 4. The ruthenium(II) centre is in a distorted octahedral N_2OP_2Cl coordination sphere constituted by pyridine-N, imine-N and amide-O donor $pamh^-$, two PPh_3 molecules and the chloride ion. The *trans* and *cis* angles are in the ranges 156.77(10)°–179.38(9)° and 77.29(10)°–102.21(6)°, respectively. As observed in solution the PPh_3 molecules are *trans* to each other. The P1–Ru–P2 angle is 169.05(3)°. The tridentate ligand forms two five-membered chelate rings. The bite angles are 79.61(11)° and 77.29(10)°. The N–N, N–C and C–O bond lengths in the =N–N=C(O^-)– fragment of $pamh^-$ are consistent with the enolate form of the amide functionality [21–23]. The Ru(II)–N(pyridine) and Ru(II)–N(imine) bond lengths are within the range reported for ruthenium(II) complexes containing the same coordinating atoms [21,34–36]. The two Ru(II)–P bond lengths are very similar and comparable to that reported for other PPh_3 coordinated ruthenium(II) complexes [31,35]. The Ru(II)–Cl bond length is unexceptional [34,35].

The tridentate ligand is not planar due to the twisting of the anisoyl ring plane (C8–C14, O2; mean deviation 0.019 Å) and the plane containing the rest of the atoms (N1–N3, C1–C7, O1; mean deviation 0.073 Å) along the C7–C8 bond. The angle between these two planes is

P(2)–Ru–Cl	83.79(3)		

30.34(10)°. As a consequence one of the aromatic C–H bonds of the anisoyl ring (C9) is directed toward a phenyl ring plane (C33–C38) of one PPh_3 ligand (Fig. 1). The C9···cg (centroid of the phenyl ring) and H9···cg distances are 3.914 and 3.475 Å, respectively. The C9–H9···cg angle is 110.77°. These parameters indicate the possibility of a C–H···π interaction [37]. Perhaps this intramolecular C–H···π interaction is responsible for the twisting of the anisoyl ring of pamh$^-$ along the C7–C8 vector. However, the existence of any such interaction in solution could not be verified due to non-appearance of the NMR signal corresponding to this proton of the anisoyl ring (vide supra).

The water molecule is hydrogen bonded to the uncoordinated amide nitrogen atom (N3) of pamh$^-$. The O3···N3 distance and the O3–H3A···N3 angle are 3.034(5) Å and 168.69°, respectively. It also participates in another weak hydrogen bonding interaction with the methoxy O-atom of a symmetry related complex molecule. The O3···O2 distance and the O3–H3B···O2 angle are 3.233(6) Å and 140.68°, respectively. Thus the *trans*–[Ru(pamh)(PPh_3)$_2$Cl] · H_2O units form discrete dimers in the crystal lattice. Two complex molecules are bridged by two water molecules via the above mentioned two hydrogen bonds. The second hydrogen bonding interaction may also contribute to the twisting of the anisoyl ring of pamh$^-$ along the C7–C8 vector.

3.4. Redox properties

Dimethylformamide solutions of the complexes have been used to study the redox properties with the help of cyclic voltammetry. A representative voltammogram has been depicted in Fig. 2 and the potential data are listed in Table 5. The complexes display the Ru(III)/Ru(II) couple in the potential range 0.40–0.52 V (versus

[b] $E_{1/2} = (E_{pa} + E_{pc})/2$, where E_{pa} and E_{pc} are anodic and cathodic peak potentials, respectively; $\Delta E_p = E_{pa} - E_{pc}$.

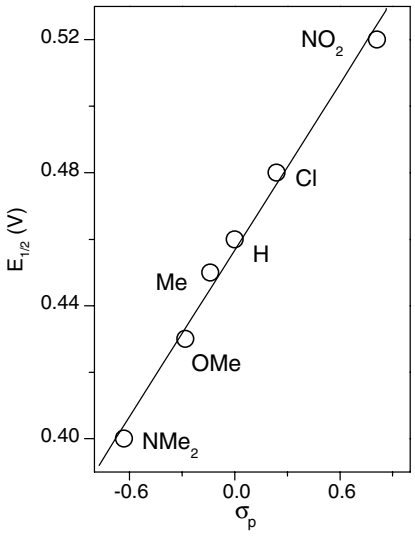

Fig. 3. Correlation between the $E_{1/2}$ values for the Ru(III)/Ru(II) couple and the Hammett substituent constants. The straight line represents a linear least-squares fit.

SCE). The peak-to-peak separations are in the range 70–80 mV. The cathodic and anodic peak currents are essentially identical for all the complexes. The one-electron stoichiometry of this response is confirmed by comparing the current heights with known one-electron redox processes under identical experimental conditions [21,22,30,31,34]. The trend in the $E_{1/2}$ values reflects the influence of the electronic nature of the substituents (R) at the *para* position of the O-coordinating deprotonated amide functionality present in the ligands. For the most electron releasing substituent (R = NMe_2) the oxidation of the metal ion occurs at the lowest potential and for the most electron withdrawing substituent (R = NO_2) it occurs at the highest potential. When these $E_{1/2}$ values are plotted against the Hammett substituent constants (σ_p) [38] a linear correlation is observed (Fig. 3). Thus, as the σ-bonding ability of the O-atom of the deprotonated amide functionality decreases with the increasing electron withdrawing ability of the substituent, the Ru(II) to Ru(III) oxidation becomes more difficult.

4. Conclusion

The synthesis and physical properties of a new series of ruthenium(II) complexes with the general formula *trans*-[RuL(PPh_3)$_2$Cl] have been described. The ligands used are pyridine-N, imine-N and amide-O donor deprotonated Schiff bases *N*-(aroyl)-*N*′-(picolinylidene)hydrazines (HL). These Schiff bases differ by the substituent present in the aroyl fragment. The *trans* configuration of the {Ru(PPh_3)$_2$} unit in each complex molecule has been confirmed by NMR spectroscopic measurements. The solid state structure of a representative complex has been determined by X-ray crystallography. The molecular structure indicates the possibility of an intramolecular C–H···π interaction involving an aroyl ring C–H and a PPh_3 phenyl ring. All the complexes exhibit low-energy metal-to-ligand charge transfer bands. The complexes are redox active and display a reversible one electron metal centred oxidation. The potential of this Ru(II) to Ru(III) oxidation is sensitive to the electronic nature of the substituent on the aroyl moiety of the ligand.

5. Supplementary material

Crystallographic data for *trans*-[Ru(pamh)(PPh_3)$_2$Cl]·H_2O have been deposited with the Cambridge Crystallographic Data Centre (deposition number CCDC-240872). Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1233 336033; email: deposit@ ccdc.cam.ac.uk; or the web: http://www.ccdc.cam.ac. uk).

Abstract

Complexes containing polypyridyl Ru(II) and the organic chromophore acridine (as the acridinium ion) separated by an amide, proline and diproline groups attached to one of the pyridyl ligands were prepared, and their photophysical properties, including electronic absorption and emission spectra, luminescence quantum yields and lifetimes, were determined in different solvents. Generally, the inductive effect of the carbonyl group from the amide or from the proline as well as the solvent interactions cause a decrease of the energy level of the metal-to-ligand charge transfer excited state, with energy stabilization of about 5 kJ/mol in polar solvents when compared with the properties of $[Ru(bpy)_3]^{2+}$. The excited state dynamics of the dyads is more favorable for triplet–triplet energy transfer between the Ru(II) donor and the acridine acceptor than for electron transfer and photoreduction of the dye, but the efficiency of the energy transfer is low in all compounds. However, the luminescence decay of the dyad with a diproline bridge is biexponential, displaying a fast component of low weight percent. This result has been ascribed to a presence of a *cis* conformer in which the diproline peptide is folded allowing a more close contact of the donor and acceptor species, and therefore a fast triplet–triplet energy transfer process. This assumption is supported by the ^{13}C NMR spectrum analysis which indicates the presence of about 11% of the *cis* conformation in solution.

1. Introduction

The study of photoinduced electron or energy transfer between donor and acceptor molecules that are spatially separated by a molecular bridge is an interesting subject for learning about the factors controlling primarily photochemical events in chemistry and biology [1–4], and for designing of new artificial systems for photonic applications [5–7]. Among several types of molecular bridges, the separation of donor and acceptor species by a peptide spacer has been used in many experimental systems [8–13]. In this sense, we have designed and characterized molecular systems composed of a single amide, one and two prolines as spacers for the separation of donor and acceptor chromophores, which under favorable conditions may undergo a photoinduced energy transfer reaction.

The system described herein utilizes polypyridyl Ru(II) as the donor and an acridinium ion as the acceptor. The tris-bipyridine Ru(II) complex was chosen because of its lowest electronic excited state, which is based on a metal-to-ligand charge transfer (MLCT) transition that is able to transfer energy to aromatics

doi:10.1016/j.poly.2004.09.030

or dyes by a Dexter type mechanism [14–26]. The ^{3}MLCT electronic excited state is a long lived and luminescent species, allowing easy measurement of excited state kinetics by using the conventional time resolved emission techniques. Compounds derived from the tris-bipyridine Ru(II) complex with amide, $[Ru(bpy)_2mbpy–acrd]^{3+}$, one proline, $[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$, and two prolines, $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$, as spacers, all of them molecular bridged to acridine (in the acridinium ion form), were carefully prepared (Scheme 1). The solvent effect and the role of the molecular structure of the spacer on the donor–acceptor energy transfer process are discussed.

2. Experimental

2.1. Equipments

Absorption spectra were measured with a Hitachi U-2000 spectrophotometer and the corrected steady state emission and excitation spectra were recorded using a CD-900 Edinburgh spectrofluorimeter. Emission quantum yields (Φ_{em}) were calculated relatively to $[Ru(bpy)_3]^{2+}$ in CH_3CN, assuming a standard value of $\Phi_{em} = 0.062$. Luminescence decays were measured by a time-correlated single photon counting technique using a CD-900 Edinburgh spectrometer operating with a hydrogen-filled nanosecond flash lamp at 40 kHz pulse frequency and a cooled PMT Hamamatsu R955 as photon detector. The decays were analyzed by monoexponential or biexponential fittings using reconvolution of the δ-function with the instrument response function (pulse width of 1.5 ns FWHM). Absorption transients with excitation at 532 nm from the second harmonic of the Surelite I-10 Nd:YAG laser were determined using an Edinburgh LP 900 laser flash photolysis system. Oxygen was removed from the samples by repeated freeze–pump–thaw cycles. ^{1}H and ^{13}C NMR spectra were obtained in the designated solvents on a Bruker (400 MHz) spectrometer. Syntheses were accompanied by the HPLC (column: μ-Bondapak C18 Waters Associates −10μ, 3.9 mm × 30 cm) technique using a Shimadzu LC-10AD chromatograph with a SPD-10A UV–VIS detector. Electrochemical data were obtained by cyclic voltammetry with a BAS 100W. The experiments were performed in CH_3CN solutions degassed with an argon flow, with Pt-bead work, Au-wire auxiliary and Ag/AgCl reference electrodes in a single compartment cell. The tetra-*n*-butylammonium perchlorate, TBAP (0.1 M) was used as a supporting electrolyte throughout the experiment. All the potentials reported in this study are quoted versus the Ag/AgCl electrode, which under the experimental conditions gave a value of 0.37 V for the ferrocene/ferrocenium couple.

Scheme 1. Bichromophoric compounds.

2.2. Reagents

Acetonitrile (AN), 9-aminoacridine, tetrafluorborate acid, 1,3-diisopropilcarbodiimide (DIC), 1-hydroxybenzotriazole hydrate (HOBT) and *N*-methylmorpholine (NMM) were obtained from Aldrich Co. HCl, dichloromethane, ethanol, ammonium hydroxide, sodium hydroxide and methanol were obtained from Mallinckrodt. Trifluoracetic acid (HTFA) and silver nitrate were obtained from Merck. These reagents, as well as Boc-proline (Peptides International), ammonium carbonate (Reagen), ruthenium trisbipyridine chloride (G. Frederick Smith Chemical Co.) and cobalt nitrate (Carlo Erba), were all used as received. Acetone (Mallinckrodt) was treated with sodium sulfate and then distilled and stored with 4 Å molecular sieves. Dimethylformamide (DMF, Merck) was distilled under reduced pressure at 75 °C and dried with 4 Å molecular sieves. Diethyl ether (Synth) was treated with sodium and then distilled twice before use.

2.3. Synthesis $[Ru(bpy)_2mbpy–acrd](BF_4)_2$

This compound was prepared according to the method described in the literature [21].

2.4. $[(NH_3)_5CoCO_3]NO_3$ and $[(NH_3)_5CoOH_2](ClO_4)_3$

These precursor compounds were prepared by following the procedures previously published in the literature [27].

2.5. $[ProCo(NH_3)_5](BF_4)_3$ and $[Pro_2Co(NH_3)_5](BF_4)_3$

These compounds were prepared following the procedures described by Isied and Kuehn [28].

2.6. $[Ru(bpy)_2mbpy–(Pro)Co](BF_4)_5$

The active ester was prepared by the reaction of 0.23 g (0.29 mmol) $[Ru(bpy)_2mbpy–OH](BF_4)_2$, 70 μL (0.44 mmol) DIC and 0.051 g (0.38 mmol) HOBT in 400 μL DMF. After 15 min, 0.30 g (0.60 mmol) of the compound $[ProCo(NH_3)_5](BF_4)_3$ and 20 μL (0.18 mmol) NMM were mixed with the active ester, and the system was stirred at room temperature for 1 h. The reaction mixture was filtered, the solvent was removed by rotary evaporation and the residue was dissolved in a minimum amount of water and loaded on a BIO-GEL P2 column. The column was washed with the same solvent and the fractions were collected and analyzed by HPLC. The first and major orange fraction was dried by rotary evaporation and the solid obtained was dissolved in a minimum amount of ethanol. The compound was precipitated by addition of a few drops of concentrated HBF_4 and diethyl ether. The precipitate was filtered off, washed with an excess of anhydrous diethyl ether and dried under vacuum. (0.31 g, 82% yield). *Anal*. Calc. for $C_{37}H_{47}N_{12}O_3CoRuB_5F_{20}$: C, 34.14; H, 3.64; N, 12.91. Found: C, 34.16; H, 3.67; N, 12.92%.

2.7. $[Ru(bpy)_2mbpy–(Pro)_2Co](BF_4)_5$

The procedure followed was the same as that described before, but substituting $[Pro_2Co(NH_3)_5](BF_4)_3$ for $[ProCo(NH_3)_5](BF_4)_3$ (0.32 g, 79% yield). *Anal*. Calc. for $C_{42}H_{54}N_{13}O_4CoRuB_5F_{20}$: C, 36.06; H, 3.89; N, 13.02. Found: C, 36.01; H, 3.85; N, 13.00%.

2.8. $[Ru(bpy)_2\ mbpy–(Pro)](BF_4)_2$

0.28 g (0.22 mmol) $[Ru(bpy)_2mbpy–(Pro)Co](BF_4)_5$ was dissolved in a degassed aqueous 0.2 M solution of HTFA. A pellet of Zn/Hg was added and an argon flow was maintained through the solution for 4 h. The reaction mixture was concentrated by rotary evaporation, dissolved in a minimum amount of ethanol–water (20:80) mixture and purified by using reversed-phase liquid chromatography in a low pressure column loaded with a reversed phase C_{18} resin (Yamamura Chemical Lab Co.). The column was slowly washed with the same solvent mixture. The first orange fraction was collected and concentrated by rotary evaporation and dissolved in a minimum amount of ethanol. A few drops of a concentrated solution of HBF_4 were added followed by a minimal amount of diethyl ether to precipitate the final product (0.15 g, 75% yield). *Anal*. Calc. for $C_{37}H_{33}N_7O_3RuB_2F_8$: C, 49.47; H, 3.70; N, 10.91. Found: C, 49.41; H, 3.68; N, 10.88%.

2.9. $[Ru(bpy)_2mbpy–(Pro)_2\ ](BF_4)_2$

The complex was prepared by following the same procedure used to synthesize the $[Ru(bpy)_2mbpy–(Pro)](BF_4)_2$ complex, but using $[Ru(bpy)_2mbpy–(Pro)_2-Co](BF_4)_5$ instead of $[Ru(bpy)_2mbpy–(Pro)Co](BF_4)_5$. (0.15 g, 73% yield). *Anal*. Calc. for $C_{42}H_{40}N_8O_4RuB_2F_8$: C, 50.67; H, 4.05; N, 11.26. Found: C, 50.64; H, 4.02; N, 11.23%.

2.10. $[Ru(bpy)_2mbpy–(Pro)acrd](BF_4)_2$

A solution of 0.100 g (0.11 mmol) $[Ru(bpy)_2mbpy–(Pro)](BF_4)_2$ dissolved in 250 μL DMF was mixed with 22 μL (0.14 mmol) DIC and 0.013 g (0.11 mmol) HOBT to prepare the active ester. After 15 min, 0.069 g (0.28 mmol) 9-aminoacridrine and 15 μL (0.14 mmol) NMM were added, and the coupling reaction mixture was allowed to proceed for 3 h, under stirring at room temperature. At the end of the reaction, a small amount of water was added and the reaction mixture was filtered to remove an excess of organic starting materials. The

solvent was removed by rotary evaporation. The resulting slurry was dissolved in a minimum amount of water and loaded on a Bio-Gel P2 (45–90 μm, from Bio-Rad laboratories) column. The elution was performed by washing the column with water. The collected fractions were concentrated and their purity level was evaluated by HPLC (μ-Bondapak C18 Waters Associates – 10μ, 3.9 mm × 30 cm). The first and major orange fraction, containing the desired complex, was dried by rotary evaporation, dissolved in a minimum amount of ethanol and precipitated by adding a few drops of an aqueous solution of HBF_4 followed by anhydrous diethyl ether. The precipitate was filtered off, washed with an excess of ethanol and diethyl ether, and dried under vacuum (0.095 g, 80% yield). Spectral data: ^{1}H NMR ($(CD_3)_2SO$): δ 1.29–1.37 (m, 4H, β–γ Pro), 2.50 (3H, m4′-CH_3), 3.31–3.32 (2H, δ Pro), 4.70 (1H, α Pro), 7.40–7.41 (2H, a2 and a7), 7.44–7.46 (2H, a4 and a5), 7.52–7.58 (7H, a1, a8, m5′ and b5), 7.68–7.76 (7H, m5, m6′, b6 and m6), 7.78–7.80 (2H, a3 and a6), 8.12–8.18 (4H, b4), 8.70–8.74 (1H, m3′) and 8.82 (5H, b3 and m3). ^{13}C NMR: δ 13.93 (γ Pro), 20.56 (4′-CH_3), 36.52 (β Pro), 46.39 (δ Pro), 63.71 (α Pro), 121.03 (a1′ and a8′), 121.54 (a2 and a7), 121.89 (a4 and a5), 122.64 (m5′), 124.38 (b5), 125.30 (m5), 125.89 (m6′), 126.08 (a1 and a8), 127.78 (b6), 128.79 (a3 and a6), 129.01 (m6), 137.89 (b4), 140.6 (a4′ and a5′), 144.70 (m4′), 150.04 (m3′), 150.95 (b3), 151.59 (m3), 152.35 (a9), 155.17 (m2′), 156.26 (m2), 156.39 (b2), 156.70 (m4), 160.0 (CO-Pro) and 164.54 (m4-CO_2H). *Anal.* Calc. for $C_{50}H_{42}N_9O_2RuB_2F_8$: C 55.83; H 3.94; N 11.72. Found: C 55.91; H 3.99; N 11.81%.

2.11. *[Ru(bpy)$_2$ mbpy–(Pro)$_2$acrd](BF$_4$)$_2$*

The procedure used here was the same as that described in the preparation of [Ru(bpy)$_2$mbpy–(Pro)-acrd](BF$_4$)$_2$, except the complex [Ru(bpy)$_2$mbpy–(Pro)$_2$]-(BF$_4$)$_2$ was the coupling reagent for 9-aminoacridine (0.086 g, 72% yield). Spectral data: ^{1}H NMR (D_2O): δ 1.25–1.28 (3H, m4′-CH_3), 1.87–1.92 (2H, γ-p2), 1.99–2.01 (2H, γ-p1), 2,13–2.23 (4H, β-p2 and p1), 3.51–3.60 (2H, δ-p2), 3.68–3.71 (2H, -p1) 4.38–4.39 (1H, α-p2), 4.54–4.55 (1H, α-p1), 7.18–7.21 (2H, a2 and a7), 7.28–7.29 (4H, a4, a5, a1 and a8), 7.30–7.33 (5H, m5′ and b5), 7.55–7.56 (2H, m5 and m6′), 7.67–7.73 (5H, b6 and m6), 7.88–7.89 (2H, a3 and a6) 7.95–7.98 (4H, b4), 8.35 (1H, m3′) 8.43–8.47 (4H, b3) and 8.85 (1H, m3). ^{13}C NMR: δ 23.52 (4′-CH_3), 29.01(γ-p2), 29.58 (γ-p1), 33.04 (β-p2), 33.75 (β-p1), 46.12 (δ-p2), 47.22 (δ-p1), 56.05 (α-p2), 58.83 (α-p1), 120.02 (a1′ and a8′), 121.84 (a2 and a7), 123.05 (a4 and a5), 125.55 (m5′), 126.91 (b5), 127.89 (m5), 125.89 (m6′), 129.08 (a1 and a8), 129.93 (b6), 130.03 (a3 and a6), 130.98 (m6), 138.23 (b4), 140.17 (a4′ and a5′), 141.90 (m4′), 152.92 (m3′), 154.78 (b3), 155.56 (m3), 157.60 (a9), 159.01 (m2′), 159.96 (m2), 156.39 (b2), 161.35 (m4), 164.96 (CO-Pro) and 171.02 (m4-CO_2H). *Anal.* Calc. for $C_{55}H_{49}N_{10}O_3RuB_2F_8$: C 56.33; H 4.21; N 11.94. Found: C 56.40; H 4.27; N 11.98%.

3. Results and discussion

The electronic absorption spectra for all of the studied complexes were similar to the $[Ru(bpy)_3]^{2+}$ spectrum, especially in the visible region (see Fig. 1). The relatively intense and broad absorption band in the visible region (around 450 nm) is due to the spin-allowed metal-to-ligand charge transfer (MLCT) transition. The MLCT band displays a small red shift in the dyads compared to the precursor complex.

When the complexes are excited at the maximum wavelength of the MLCT absorption spectrum, broad emission bands, similar in shape to the luminescence band of the $[Ru(bpy)_3]^{2+}$ complex, are obtained (see Fig. 2). However, the luminescence spectra of the model compounds show a bathochromic shift when compared to that of the precursor complex. The change in electronic energy of the ^{3}MLCT excited state of the new complexes and that of the $[Ru(bpy)_3]^{2+}$ complex are

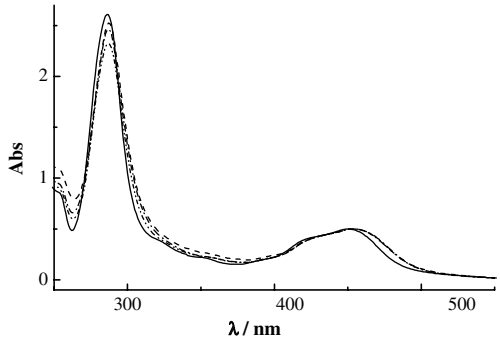

Fig. 1. Electronic spectra of the complexes: (—) $[Ru(bpy)_3]^{2+}$, (– –) $[Ru(bpy)_2mbpy\text{-}acrd]^{3+}$, (–·–) $[Ru(bpy)_2mbpy\text{-}(Pro)acrd]^{3+}$, and (–··–) $[Ru(bpy)_2mbpy\text{-}(Pro)acrd]^{3+}$, in methanol ($10^{-5}$ M) at 293 K.

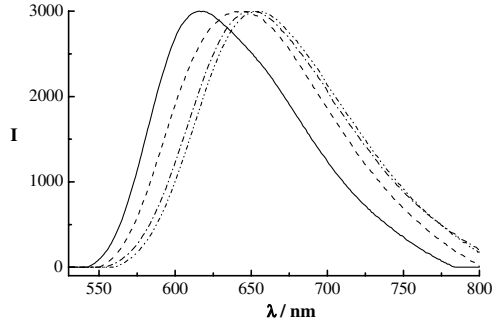

Fig. 2. Luminescence spectra of the compounds in methanol at 293 K. (—) $[Ru(bpy)_3]^{2+}$, (– –) $[Ru(bpy)_2mbpy–acrd]^{3+}$, (–·–) $[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$ and (–··–) $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$.

Table 1
Difference in triplet energy level (ΔE_{0-0}, kJ/mol) of the MLCT transition of the complexes at 293 K in different solvents compared to $[Ru(bpy)_3]^{2+}$

Compound	Acetonitrile	methanol	Dichloromethane
$[Ru(bpy)_2mbpy–acrd]^{3+}$	−4.6	−2.5	−0.4
$[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$	−4.6	−4.6	0.4
$[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$	−6.3	−6.3	0.0

summarized in Table 1. The spectral shift indicates a more stable ^{3}MLCT state, which could be the result of the enhanced solvation at the mbpy ligand due to the presence of the polar groups, in addition to an inductive effect of the amide or proline groups of the molecular bridge. Proline has a permanent dipole moment and its orientation and solvation would affect the charge distribution, and therefore the energy of the ^{3}MLCT state.

The inclusion of the spacers causes a symmetry breakdown among the bipyridyl ligands. The energy stabilization in acetonitrile and methanol, calculated from the spectral shift, is in the range of 4.6–6.3 kJ/mol, when compared to the energy of the ^{3}MLCT of the $[Ru(bpy)_3]^{2+}$ complex of 205 kJ/mol [29].

The ^{3}MLCT state of the Ru complexes may be deactivated by energy or electron transfer to the acridinium acceptor. The possibility of deactivation of the ^{3}MLCT excited state by electron transfer to the acridinium derivative (dye photoreduction) was evaluated from $\Delta G^0 \approx E_{1/2}(Ru^{2+}/Ru^{3+}) - E_{1/2}(dye/dye^-) - E_{0,0}(^3MLCT)$. According to the data of $E_{1/2}$ reported in Table 2, and assuming the excitation energy of the ^{3}MLCT corresponds to 2.12 eV, photoinduced electron transfer will be an endothermic process. On the other hand, the free-energy change for triplet–triplet energy transfer ($\Delta G^0 \approx E_{0,0}{}^3MLCT + E_{0,0}{}^3Dye$) is negative (exothermic process), and therefore is a more favorable process than electron transfer.

The numerical values for the driving force in T–T energy transfer or electron transfer in acetonitrile are reported in Table 3. These results are consistent with those reported in the early studies in which acridine dyes were more capable to have T–T energy transfer with $*[Ru(bpy)3]^{2+}$ than oxidative quenching [23–26].

Table 2
Redox Potentials for the one-electron processes on the complexes in 0.1 M TBAP/AN solution at 298 K

Complex	$E_{1/2}$[b] (V)	
	Oxidation	Reduction[a]
$[Ru(bpy)_2mbpy–acrd]^{3+}$	1.31	−0.87; −1.15
$[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$	1.31	−0.88; −1.22
$[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$	1.28	−0.88; −1.22

[a] The first reduction potential refers to the reduction of the acrd group while the second value listed is the reduction of the first bpy ligand. The non-complexing dye 9-aminoacridine has a reduction potential of −0.92 V [30].

[b] All the potentials are quoted against the Ag/AgCl electrode with $E_{1/2}$ = 0.37 V for the F_c/F_c^+ couple.

Table 3
Free-energy change ΔG^0 (acetonitrile solution at 298 K) considering T–T Energy transfer and electron-transfer processes

Complex	ΔG^0 (kJ/mol)	
	Energy transfer*	Electron transfer
$[Ru(bpy)_2mbpy–acrd]^{3+}$	−6.4	5.8
$[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$	−6.4	6.7
$[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$	−4.7	5.8

(*) Values calculated assuming the energy values of the ^{3}MLCT of $[Ru(bpy)_3]^{2+}$ = 205 kJ/mol [29], ^{3}acrd = 194 kJ/mol [31,32], and the differences observed in the energy of the compounds given in Table 1.

The lifetimes and luminescence quantum yields of the systems prepared are reported in Table 4. The data for the $[Ru(bpy)_3]^{2+}$ complex and for its derivative with 2-aminonaphthalene ($[Ru(bpy)_2mbpy–naph]^{2+}$) were enclosed for a comparative purpose with those containing the spacers and acridine. An ideal reference is a compound which carriers the isolated properties (lifetime and quantum yield) of the donor part of the supramolecule. Thus, the difference in lifetime and quantum yield of the reference compound (τ_0,ϕ_0) and of the donor–acceptor system (τ,ϕ) would be ascribed to the presence of an energy transfer process in an ideal situation. $[Ru(bpy)_2mbpy–naph]^{2+}$ approaches to a reference compound [21], the triplet energy of the naphthalene is much higher than the triplet energy of the Ru complex, which precludes an energy transfer process from the metal complex to the peripheral naphthalene. The value of the rate constant for energy transfer (k_{et}) in the case of irreversible energy transfer can be estimated by the difference of lifetimes of the dyad and the reference compound

$$k_{et} = \tau^{-1} - \tau_0^{-1}. \quad (1)$$

Assuming the experimental values of τ_0 and τ reported in Table 3, the k_{et} values of $[Ru(bpy)_2mbpy–acrd]^{3+}$ are 4.0×10^4, 3.6×10^4 and 1.5×10^5 s^{-1} in acetonitrile, methanol and dichloromethane, respectively [21].

In the case of the $[Ru(bpy)_2mbpy–(Pro)acrd]^{3+}$ complex, the rate constants are 1.6×10^4 and 1.5×10^5 s^{-1} in methanol and dichloromethane, respectively. For the system with two prolines, the difference in the luminescence quantum yield between the reference and dyad indicates a very low efficiency of energy transfer. In general, the results indicate the tendency of an increase of

Table 4
Lifetime (τ), and quantum yield (Φ_{em}) of the complexes in different solvents at 293 K

Compound	τ (ns), Φ_{em}					
	Acetonitrile		Methanol		Dichloromethane	
$[Ru(bpy)_3]^{2+}$	836	0.061	813	0.045	485	0.091
$[Ru(bpy)_2$ mbpy–naph$]^{2+}$	1321	0.078	941	0.034	792	0.124
$[Ru(bpy)_2$mbpy–acrd$]^{3+}$	1255	0.064	910	0.029	707	0.101
$[Ru(bpy)_2$mbpy–(Pro)acrd$]^{3+}$	1343	0.068	927	0.037	708	0.105
$[Ru(bpy)_2$mbpy–$(Pro)_2$acrd$]^{3+}$	1350; 90 (0.89; 0.11)	0.076	977; 306 (0.95; 0.05)	0.038	678; 63 (0.85; 0.15)	0.114

Excitation of the samples was performed at 450 nm. The normalized pre-exponential factors of the biexponential decay of the compound $[Ru(bpy)_2$mbpy–$(Pro)_2$acrd$]^{3+}$ are show in parentheses. The $[Ru(bpy)_2$ mbpy–naph$]^{2+}$ complex was used as a reference (see text for details and [21]).

the energy transfer efficiency with the decrease of the solvent polarity, reflecting the effect of the solvent reorganization in the process [26]. Moreover, the lifetime of the dyad compounds get larger as the spacer increases in size, which is qualitatively in agreement with the effect of distance in the energy transfer by an exchange mechanism. Laser excitation at 532 nm for the $[Ru(bpy)_2$mbpy–acrd$]^{3+}$ complex in methanol resulted in an absorption transient in the region of 700–800 nm (see Fig. 3). The decay was exponential with a lifetime of 904 ns, which agrees quite well with the parameters determined by luminescence decay (910 ns) given in Table 4.

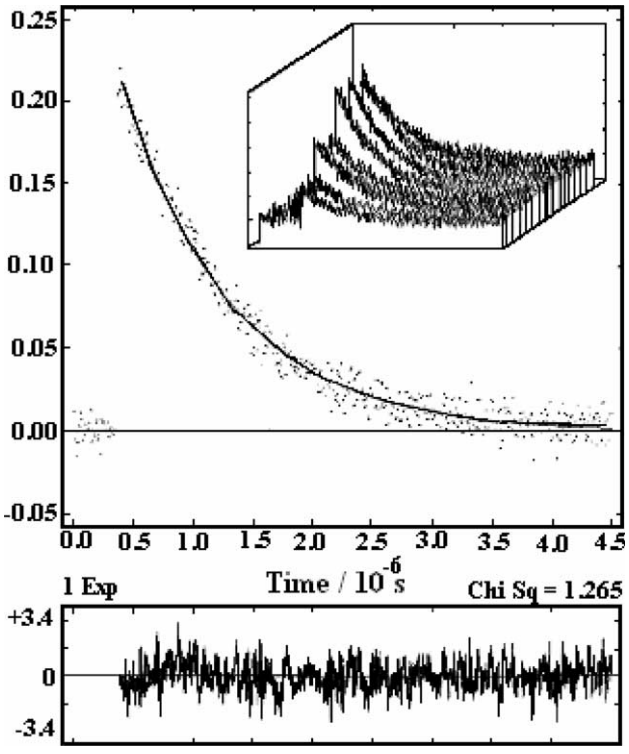

Fig. 3. Absorption transient (760 nm) of the $[Ru(bpy)_2$mbpy–acrd$]^{3+}$ complex in methanol from laser excitation at 532 nm. Inset: Decay traces in the region 700 800 nm.

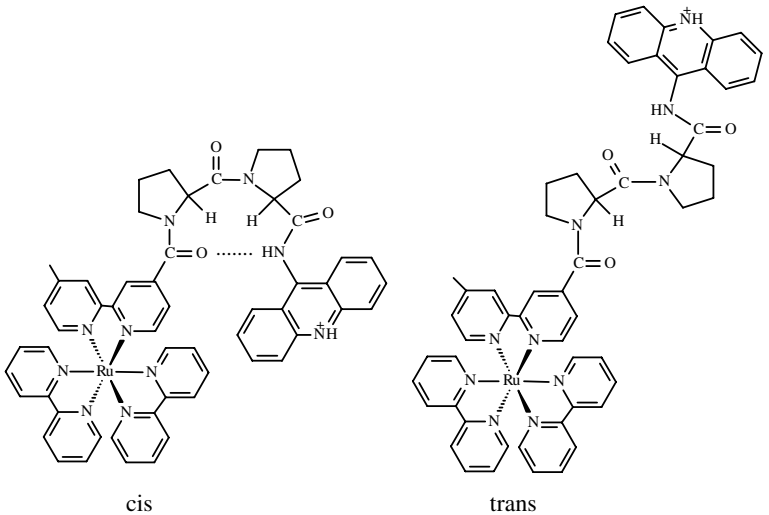
The rate constants of energy transfer in these compounds are considerably low, deserving a discussion about the factors that control the process. In polar solvents, the energy difference between the triplet levels of the Ru complex and the acceptor is 6 kJ/mol. In acetonitrile and methanol, the intrinsic dipolar nature of the ^{3}MLCT excited state accounts for the solvent reorganization energy, 23 kJ/mol, and the inner contribution concerning bond rearrangement of the reactant is about 20 kJ/mol [26]. Thus, the total reorganization energy is seven times higher than the driving force, decreasing the rate of the energy transfer.

The energy transfer rate in an exchange or super-exchange (via bridge) mechanism in weakly coupled systems is given by [2],

$$k_{et} = \frac{2\pi}{\hbar} \mid V\mid^2 \mathrm{FC}, \tag{2}$$

where V is the electronic coupling matrix element and FC is the Franck–Condon weighted density of states. The extent of the electronic coupling in the model compounds investigated should be dictated by the geometry attained by the ligand–amide–acridine. The electronic coupling matrix element, V, is enhanced when the π systems of donor and acceptor are coplanar. An affect that reduces the energy transfer rate is the unfavorable Franck–Condon factors related to the low frequency conformational change of the amide bridge (torsional motion) necessary for the donor and acceptor π systems to approach a coplanar alignment. When the bridge is extended with one and two prolines, not only the center-to-center distance between donor and acceptor is increased, but also more degrees of freedom and conformations are introduced, and both factors are expected to decrease the rate of energy transfer.



An unexpected result in the present study, however, was the biexponential character of the decay of the system with two prolines, contrasting with the monoexponential decay of the other systems (within the time resolution of the performed experiments). Solutions of proline oligomers are known to exist in either *cis*- or *trans*-helical structures, depending on solvent polarity and ionic strength of the solution [33–35]. Proline-con-

taining dipeptides may have several types of rotamers and conformers in solution that are stabilized by specific intramolecular hydrogen bonding between carbonyl oxygen and amide hydrogen atoms of the molecule [36–41]. Therefore, the fast decay component of the biexponential fitting could be ascribed to the presence of a molecular conformer allowing a more efficient energy transfer pathway. An analysis of the molecular geometry of the donor–acceptor system with two prolines in *trans* and *cis* conformations (related to the carbonyl position) is draw in Scheme 2.

The *cis* conformer would allow a close contact between the bpy ligand with the acridine acceptor, while the distance between the donor and acceptor moieties are bigger in the *trans* conformer, and therefore hinder the T–T energy transfer. In the *cis* geometry the energy transfer would be mediated by a solvent shell between donor and acceptor centers, while in the *trans* geometry the process would occur through the diproline bridge. The decay time and weight of the short-lived component depends on the solvent used. In methanol, there is a very weak contribution of 5% of the decay time of 306 ns. In acetonitrile, a short-lived component (90 ns and 11% weight) was observed, while in dichloromethane the decay time is 63 ns with 15%. These results could be ascribed to the presence of a *cis* conformer. In oligoprolines, the *cis* conformer increases its fraction with the decrease of the solvent polarity [13].

The decay time decreases due to the solvent effect in the energy transfer process as discussed before. Considering these short-lived components, the rate constant of T–T energy transfer of the *cis* conformer is estimated to be in the range $(0.2–1.4) \times 10^7\ s^{-1}$, being larger (a factor of 10–100) than that of the previous values found for the donor–acceptor system with amide or one proline as spacers. This difference should not be ascribed only to a distance effect in the T–T energy transfer process. The diproline bridge in the *cis* conformer is a folded structure that may allow a closest contact and more efficient electronic coupling between donor and acceptor orbitals, maximizing the electronic coupling matrix element V of the donor–acceptor interaction. A second factor that could account for the enhancement of the energy transfer rate is a contribution of a predicted hydrogen bonding involving the C=O of the mbpy and the NH of 9-amido-acridine (see the *cis* conformer structured in Scheme 2). Note that this kind of geometry of the diproline bridge resembles the intramolecular hydrogen bond structure of the classical 10-member β-turn present in model peptides [35–40]. In the dynamics of the excited state, this interaction will promote a high frequency mode that may contribute favorably in the Franck–Condon factors, thus increasing the rate constant of energy transfer.

In order to extend the investigation of the intramolecular T–T energy transfer process, the compound $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$ was studied in dioxane–water mixtures, and the results obtained are summarized in Table 5. These results in solvents with different polarities evidence the importance of the molecular structure and the presence of conformers in the process of energy transfer as well as the effect of the solvent in the whole process of T–T energy transfer. If the isomerization of the oligoprolines is considered a slow process [42], then the decay observed may be related to each type of conformer and its fraction in solution. The formation of a fraction of the *cis* conformer in water may result from the hydrophobic character of the complex that drives it to a more packed structure. In aqueous solution, the normalized amplitude of the fast decay component is 0.18, which would indicate 18% of the *cis* conformer in solution (see Table 5).

Scheme 2. *cis* and *trans* conformers of the proline bridge in $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$.

(*) Dielectric constant is from [43]. Emission lifetimes (±5%) at the emission maximum following excitation at 450 nm. $b_1 + b_2 = 1$. χ^2 is the chi-square of biexponential fitting.

The fraction of conformers of proline peptides has been determined from the analysis of NNMR data [13]. Our analysis of the ^{13}C NMR spectrum of the dyad with respect to the signals of β and γ carbons of the proline rings indicated that the percent of the *cis* conformer is near to 11%. The ^{13}C NMR spectrum of the dyad with two prolines is shown in Fig. 4. Proceeding similar analysis with the compound $[Pro_2Co(NH_3)_5](BF_4)_3$ in D_2O, the fraction of the *cis* conformer was calculated as 10%. These values are not far from the results of 14–16% of the *cis* conformer found for $[Pro_2Co(NH_3)_5]^{3+}$ by ^{13}C and ^1H NMR spectra analysis in a 0.01 M DCl solution [13].

The difference in the inverse of the decay time of the two components is a measure of the rate constant k_{et}, considering that the ET process is irreversible and the *trans* conformer is almost inactive for energy transfer. Under these conditions, the values of k_{et} of the *cis* conformer in different solvent compositions are calculated within the range of $(0.16–2.20) \times 10^7$ s^{-1} (see Table 5). Thus, the folded structure, here defined as the *cis* conformer of the proline bridge in $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$, presents a faster rate of T–T energy transfer when compared to similar reported systems [21].

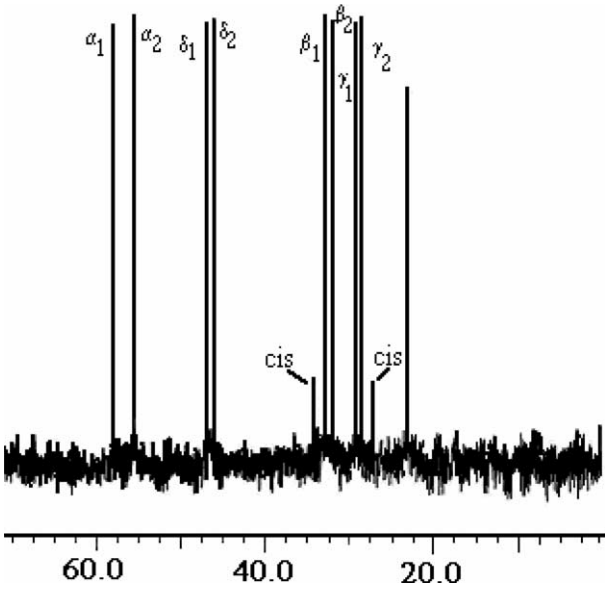

Fig. 4. ^{13}C NMR spectrum of the dyad $[Ru(bpy)_2mbpy–(Pro)_2acrd]^{3+}$ in D_2 O, illustrating the signal of the α, β, γ and δ carbons of the proline rings and the indication of the signal from the *cis* conformer.

Abstract

The systematic coordination chemistry of the wide-angle diphosphine *o*-$C_6H_4(CH_2PPh_2)_2$ (L^1) has been investigated with metal ions from Groups 9–11 in order to explore the consequences of the steric demands of the phosphine and its flexibility towards different oxidation states and coordination geometries. The products isolated include the tetrahedral $[CoX_2(L^1)]$ (X = Cl, Br or I), the very distorted square planar $[Rh(L^1)_2]^+$, $[M(cod)(L^1)]^+$ (M = Rh or Ir), square planar $[NiX_2(L^1)]$ (X = Cl or Br), $[M'Cl_2(L^1)]$ (M′ = Pd or Pt), the chloro-bridged $[Pd_2Cl_2(L^1)_2]^{2+}$, $[Pd(L^1)_2]^{2+}$, the tetrahedral $[M''(L^1)_2]^+$ (M″ = Cu, Ag or Au) and the dinuclear $[(AuCl)_2(L^1)]$. Chemical oxidation of some of the complexes are described, giving examples of Co(III), Ni(III) and Pt(IV) species. Where possible the products have been characterised by IR, UV–vis, NMR (^1H, ^{31}P, ^{63}Cu and ^{195}Pt as appropriate) spectroscopies, mass spectrometry and microanalysis. Crystal structures of six representative examples confirm the coordination environments in particular species and illustrate the steric demands of L^1. L^1 is a versatile ligand which can readily alter its chelate bite angle to accommodate a range of coordination geometries (the P···P distances within the chelate rings varies by >0.5 Å), and the presence of the rigid aromatic ring in the C_4 backbone leads to some preorganisation favouring *cis* chelation. It also shows a preference for low coordination numbers and this results in some unexpected products.

Keywords: Diphosphine; Metal complexes; X-ray structures

1. Introduction

The reaction chemistry of sterically demanding wide-angle diphosphines is attracting great interest at present owing to the remarkably high catalytic activities exhibited by some transition metal complexes involving these ligands. Major reactions of interest are Rh-catalysed hydroformylation of alkenes, Ni-catalysed hydrocyanation and Pd-catalysed copolymerisation of CO and alkenes. In particular, the P–M–P bite angle plays an important role in determining the selectivity and rates in these catalytic reactions [1,2]. In previous studies platinum metal complexes incorporating the xylyl diphosphine *o*-$C_6H_4(CH_2PPh_2)_2$ have been shown to be active catalysts for several different transformations, e.g., platinum-tin catalysed hydroformylation [3], rhodium-catalysed hydrogenation of CO_2 [4] and iridium-catalysed hydrogenation of aldehydes [5]. Given the level of interest in these systems, it is surprising that the systematic coordination chemistry of L^1 with transition metal ions has been rather neglected. Initial studies on the complexation of L^1 with medium and low valent late transition metal centres were conducted by Venanzi and co-workers [6,7] who reported the preparations of some mononuclear derivatives and dinuclear halide- and hydride-bridged complexes. Example, include the structurally characterised $[Ag_2X_2(L^1)_2]$ (X = Cl or I) which involve distorted tetrahedral coordination at Ag(I) via two halides and a chelating L^1, and the Pt(0) complex, $[Pt(H_2C{=}CH_2)(L^1)]$ [8]. have reported a number of other platinum metal complexes of L^1 with various organic co-ligands, while sulfido- and selenido-Ru and Fe carbonyl clusters, which result from chalcogen transfer from the phosphine sulfide or selenide derivatives of L^1 to the metal centre, have also been reported [12,13].

In this paper we describe a systematic study of the coordination of L^1 with metal ions from Groups 9–11, including their syntheses and spectroscopic properties. The transition metal ions studied adopt square planar, tetrahedral, linear and octahedral coordination geometries and thus allow the ligating properties of the *o*-xylyl diphosphine to be probed. Comparisons are drawn with the ligating properties of the related flexible C_4-diphosphine, $Ph_2P(CH_2)_4PPh_2$ (dppb), and the more rigid *o*-phenylene derivative *o*-$C_6H_4(PPh_2)_2$.

2. Results and discussion

The diphosphine L^1 was prepared in high yield as a white solid by a slight modification of the literature method [8] involving reaction of Ph_2PLi with *o*-$C_6H_4(CH_2Br)_2$ in thf solution. In solution L^1 is quite air-sensitive, hence all measurements and subsequent reactions used deoxygenated solutions and Schlenk techniques.

2.1. Co, Rh and Ir complexes

Treatment of an isopropanol solution of CoX_2 (X = Cl, Br or I) with one mol equiv. of L^1 under N_2 affords the distorted tetrahedral $[CoX_2(L^1)]$ as brightly coloured blue, green or brown-green solids, respectively, in good yield. The formulation follows from the microanalytical data, [1] while magnetic measurements are consistent with high spin Co(II) species. The UV–vis spectra show absorptions consistent with tetrahedral Co(II) [14,15], and the spectra are the same in the solid state and in CH_2Cl_2 solution. The far IR spectrum of $[CoCl_2(L^1)]$ shows a broad peak at 318 cm^{-1}, consistent with ν(Co–Cl). The distorted tetrahedral coordination with one chelating L^1 is confirmed in the solid state by a structure determination on a very small crystal of $[CoCl_2(L^1)]$ (Fig. 1, Table 1). The Co–P bond distances are 2.3795(16) and 2.4034(16) Å, while *d*(Co–Cl) = 2.2045(15) and 2.2165(15) Å.

[1] We note that microanalytical data for several of the complexes are consistent with there being some CH_2Cl_2 solvent associated with the compounds even after drying in vacuo. For the diamagnetic complexes, there is evidence for CH_2Cl_2 in the ^1H NMR spectra, and indeed four of the crystal structures show two molecules of CH_2Cl_2 (or $CHCl_3$) solvent per metal ion. Thus, we conclude that the steric bulk of the coordinated L^1 probably leaves considerable voids in the lattice which can accommodate solvent molecules.

The related, but more rigid *o*-phenylene diphosphine, *o*-$C_6H_4(PPh_2)_2$, gives planar cations $[Co\{o\text{-}C_6H_4(PPh_2)_2\}_2][CoX_4]$ and 5-coordinate $[Co\{o\text{-}C_6H_4(PPh_2)_2\}_2X]^+$ on reaction with Co(II) halides, reflecting

both the stronger ligand field imposed and the 5-membered chelate rings present [15], whereas larger chelate rings give tetrahedral Co(II) (as in $[CoX_2(L^1)]$ above) [16]. We note that an early assignment [16] of the product from reaction of $CoCl_2$ with dppe (Ph_2PCH_2-CH_2PPh_2) as $[CoCl_2(dppe)]$ was in error and the compound was subsequently shown to be the phosphine oxide complex [17].

Low temperature oxidation of a CH_2Cl_2 solution of $[CoCl_2(L^1)]$ with NOCl gives the Co(III) species $[CoCl_3(L^1)]$ as a deep blue-green solid. The electronic spectrum of this product is characteristic of the rare 5-coordinate geometry and the Cl_3P_2 donor set [18]. The far IR spectrum shows the three Co–Cl bands expected. The Co(III) compound decomposes slowly in CH_2Cl_2 solution at room temperature.

In an attempt to explore the coordination chemistry of rhodium with L^1 we reacted $RhCl_3 \cdot 3H_2O$ with two molar equivalents of L^1 in EtOH solution in the presence of a few drops of 40% aqueous HBF_4. Stirring at room temperature for approximately 30 min gave an orange solution and concentration of this solution in vacuo afforded an orange solid. The IR spectrum shows peaks associated with coordinated L^1 and BF_4^- anion. Inspection of the far IR region did not reveal any significant peaks due to Rh–Cl bonds. The electrospray mass spectrum (MeCN) shows peaks with the correct isotope distribution for $[Rh(L^1)_2]^+$ and $[Rh(L^1)]^+$, however again there is no evidence for any Cl containing species or significant higher mass peaks.

The ^1H NMR spectrum shows the ligand resonances shifted to high frequency upon coordination, while the $^{31}P\{^1H\}$ NMR spectrum of this product is a sharp doublet at +11.6 ppm, indicative of one P environment, with $^1J_{RhP} = 140$ Hz. This large coupling constant, together with the mass spectrometry data were unexpected for a Rh(III) species, but more in line with the values expected for a planar Rh(I) derivative with more s-orbital character in the Rh(I)–P bond (sp^2d hybridisation). This result prompted us to seek X-ray structural data to authenticate our assignment of the product as $[Rh(L^1)_2]BF_4$.

Orange single crystals were obtained by layering a $CHCl_3$ solution of the complex with hexane. The structure shows (Fig. 2, Table 2) two chelating L^1 units bound to the Rh centre in a distorted square planar arrangement, with no evidence for other co-ligands. One BF_4^- anion and two $CHCl_3$ solvent molecules also occupy general positions in the asymmetric unit, consistent with a Rh(I) complex. The Rh–P bond distances are in the range 2.31–2.34 Å. These are in accord with *d*(Rh–P) in other Rh(I) phosphine complexes, e.g., $[RhCl(PPh_3)_3]$ *d*(Rh–P_{trans}P) = 2.304–2.338 Å [19,20]. The sum of the P–Rh–P angles is 370°, indicating a significant tetrahedral distortion, which probably results from the significant steric requirements of the two bulky L^1 ligands. The P1···P2 and P3···P4 distances within the chelates are 3.28 and 3.37 Å, and the P1–Rh–P2 and P3–Rh–P4 angles are 90.05(3) and 92.31(3) Å, respectively.

The formation of the bis-diphosphine Rh(I) cation under these reaction conditions is unexpected as this is the method used to obtain the Rh(III) species $[RhCl_2(L\text{-}L)_2]^+$ (L-L = $Ph_2PCH_2CH_2PPh_2$, *o*-C_6H_4-$(PPh_2)_2$) [21,22]. The different reaction course may also be a consequence of the steric bulk imposed by the wide angle diphosphine L^1, which disfavours formation of the 6-coordinate Rh(III) dichloro derivative. The preparation of the very well known Wilkinson's compound, $[RhCl(PPh_3)_3]$, is however readily achieved by reaction of $RhCl_3 \cdot 3H_2O$ with excess PPh_3 in ethanol [23].

We note also that a CCl_4 suspension of the $[Rh(L^1)_2]BF_4$ is not oxidised when treated with Cl_2 saturated CCl_4 at room temperature (monitored by ^{31}P NMR spectroscopy).

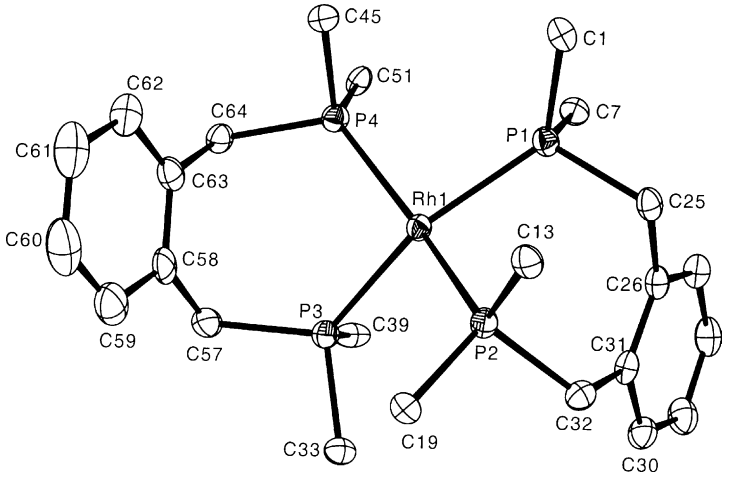

Fig. 2. View of the structure of the $[Rh(L^1)_2]^+$ cation with numbering scheme adopted. H atoms and phenyl rings (except the *ipso* C atoms) are omitted for clarity. Ellipsoids are shown at the 50% probability level.

The reaction of L^1 with 0.5 mol equiv. of the Rh(I) dimer $[Rh_2Cl_2(cod)_2]$ in CH_2Cl_2 solution in the presence of NH_4PF_6 yields, after work-up, the Rh(I) species $[Rh(cod)(L^1)]PF_6$ as an orange solid in good yield. The IR spectrum confirms the presence of the anionic PF_6^- as well as coordinated L^1. Phosphorus-31 NMR spectroscopy of this species shows a sharp doublet at +10.3 ppm ($^1J_{RhP}$ = 146 Hz) and a septet at −145 ppm from the PF_6^- anion. Evidence for the cod ligation comes from the ^{1}H NMR spectrum which also confirms a 1:1 L^1:cod ratio. The Rh–P coupling constant is comparable to that for $[Rh(L^1)_2]^+$ described above, and the ^{31}P NMR shift is also similar, further supporting the earlier assignments.

The analogous reaction using $[Ir_2Cl_2(cod)_2]$ with 0.5 mol equiv. of L^1 in CH_2Cl_2 and NH_4PF_6 gives the corresponding Ir(I) complex $[Ir(cod)(L^1)]PF_6$ as an orange-red solid in good yield ($\delta^{31}P = -1.8$ (L^1); electrospray MS *m/z* 775 $[Ir(cod)(L^1)]^+$.

2.2. Ni, Pd and Pt complexes

The hydrated Ni(II) halides $NiX_2 \cdot xH_2O$ (X = Cl or Br) react with one mol equiv. of L^1 in isopropanol to give deep red solids with formation $[NiX_2(L^1)]$ in good yield. These are similar to the species described previously by Venanzi and co-workers, who assigned them as tetrahedral apparently on the basis that they did not give NMR spectra [7,8]. However, from the diffuse reflectance electronic spectra which show one d–d transition, we assign them as square planar compounds. The far IR spectra show two peaks which are assigned as Ni–X stretching vibrations, indicative of a *cis*-NiX_2 unit. These data, together with ^{1}H NMR and microanalyses, confirm the assignment of these compounds as square planar Ni(II) species with a chelating L^1 and mutually *cis* halides.

The square planar geometry identified for $[NiX_2(L^1)]$ is somewhat unexpected given that the corresponding Ni(II) complexes with the flexible dppb ligand, $[NiX_2(dppb)]$ (also incorporating a 7-membered chelate ring) [24] adopt tetrahedral geometries. Therefore, it appears that the increased rigidity of L^1 over dppb results in a preference for square planar coordination. The *o*-phenylene diphosphine in $[NiX_2\{o\text{-}C_6H_4(PPh_2)_2\}]$ (5-membered chelate ring) which exerts a strong ligand field, leads to square planar coordination at Ni(II) [25].

An attempt to generate the 5-coordinate Ni(II) species $[NiI(L^1)_2](ClO_4)$ through reaction of NiI_2 and $Ni(ClO_4)_2 \cdot 6H_2O$ with four mol equiv. of L^1, using the method described by Meek and co-workers [26] for other diphosphines was unsuccessful. Similarly, we were unable to isolate the square planar bis-L^1 species $[Ni(L^1)_2](ClO_4)_2$.

The deep orange-brown, unstable Ni(III) species $[NiCl_3(L^1)]$ was obtained by NOCl oxidation of $[NiCl_2(L^1)]$. The formulation follows from the electronic spectrum, which is characteristic of the 5-coordinate molecule, and the IR spectrum which shows *v*(Ni–Cl) in the same region as previously reported Ni(III) species [27].

Dissolution of $Na_2[PdCl_4]$ in EtOH followed by addition of one mol equiv. of L^1 results in formation of a cream coloured precipitate with formulation $[PdCl_2(L^1)]$. The far IR spectrum of this compound shows two peaks in the region expected for *v*(Pd–Cl), indicative of a *cis*-$PdCl_2$ unit. The ^{1}H NMR spectrum is unexceptional, showing small high frequency shifts

upon coordination of L^1, while the $^{31}P\{^1H\}$ NMR spectrum shows a singlet at 16.4 ppm, in accord with the data obtained by Venanzi and co-workers [8] and assigned as $[PdCl_2(L^1)]$. The crystal structure of this compound (Fig. 3, Table 3) confirms a distorted square planar coordination environment at Pd(II) through one chelating L^1 ligand and mutually *cis* Cls. The molecule has crystallographic *m* symmetry, with *d*(Pd–P) = 2.2572(11) and *d*(Pd–Cl) = 2.3536 Å. The P1–Pd–P1′ angle in the chelate of 100.04(6)° is much more obtuse than those seen in the Rh(I) species described above, reflecting the considerable reduction in steric demand when the metal centre only needs to accommodate one L^1 rather than two. The P1···P1′ distance of 3.46 Å is larger than in $[Rh(L^1)_2]^+$ above.

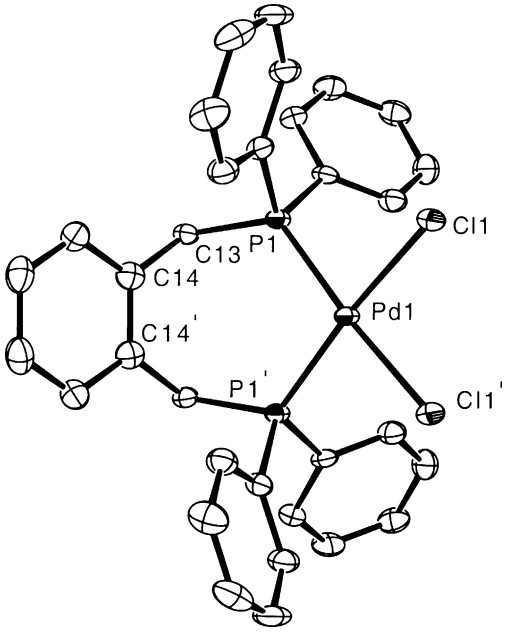

Fig. 3. View of the structure of $[PdCl_2(L^1)]$ with numbering scheme adopted. Ellipsoids are drawn at 50% probability and H atoms are omitted for clarity (symmetry operation: ′, *x*, 1/2 − *y*, *z*).

Symmetry operation: ′, *x*, 1/2 − *y*, *z*.

Attempts to abstract both the Cl's from $[PdCl_2(L^1)]$ in MeCN solution using 2.1 mol equiv. of $TlPF_6$ were not successful – the only identifiable Pd-containing species after work-up being the dinuclear $[Pd_2Cl_2(L^1)_2](PF_6)_2$. This complex was prepared in good yield by reaction of $[PdCl_2(NCMe)_2]$ with one mol equiv. of L^1 and one mol equiv. of $TlPF_6$ in $MeCN/CH_2Cl_2$. Removal of the TlCl precipitate left a light yellow solution from which the complex was obtained as a yellow solid following work-up. The IR, ^1H NMR spectroscopic and microanalytical data are consistent with the formulation $[Pd_2Cl_2(L^1)_2](PF_6)_2$. The $^{31}P\{^1H\}$ NMR spectrum of this compound shows a singlet at 27.3 ppm, significantly to high frequency of the mononuclear $[PdCl_2(L^1)]$ above.

The structure of $[Pd_2Cl_2(L^1)_2](PF_6)_2 \cdot 2CH_2Cl_2$ shows (Fig. 4, Table 4) a dinuclear $(\mu^2\text{-}Cl)_2$ palladium dication with a chelating L^1 bound to each Pd centre to give a distorted square planar geometry. The dication is centrosymmetric, the centre of inversion in the middle of the Pd_2Cl_2 core. The Pd–P bond distances are 2.2481(10) and 2.2657(10) Å, very similar to *d*(Pd–P) in the mononuclear complex above. The P1–Pd–P2 angle in this species is 98.00(4)° and *d*(P1···P2) is 3.41 Å.

The homoleptic bis-ligand ion $[Pd(L^1)_2]^{2+}$ was subsequently prepared by addition of an aqueous solution of $Pd(NO_3)_2$ to two mol equiv. of L^1 in $EtOH/CH_2Cl_2$ solution, followed by addition of aqueous HBF_4. The IR spectrum of the yellow solid isolated shows peaks consistent with coordinated L^1 and ionic BF_4^-, with no evidence for any remaining nitrate or H_2O/OH^- in the product. The ^1H NMR spectrum only shows resonances due to L^1. These are shifted to high frequency of the 'free' ligand. The $^{31}P\{^1H\}$ NMR spectrum of this

Symmetry operation: ′, $2-x$, $2-y$, $1-z$.

P_4-coordinated species shows a singlet at 7.1 ppm. These data, together with microanalyses, are consistent with the formulation $[Pd(L^1)_2](BF_4)_2$. The Pd(II) centre is likely to be rather crowded, however this formulation is not unreasonable given the structural evidence for distorted planar $[Rh(L^1)_2]^+$ cation described above.

The Pt(II) species $[PtCl_2(L^1)]$ is formed in high yield by addition of a solution of $K_2[PtCl_4]$ to one mol equiv. of L^1 in CH_2Cl_2/EtOH. Acetone was then added to give a homogeneous solution which was stirred for 72 h before filtering and concentrating the filtrate in vacuo to give a white solid. The ^1H NMR spectrum is unexceptional and the far IR spectrum shows two peaks, indicating a *cis*-$PtCl_2$ unit. The $^{31}P\{^1H\}$ NMR spectrum shows a singlet at −1.8 ppm with ^{195}Pt satellites (J = 3584 Hz), consistent with the literature data [8]. Confirmation that the product is indeed the neutral $[PtCl_2(L^1)]$ and not the dinuclear $[Pt_2Cl_2(L^1)_2]Cl_2$ (cf. the Pd analogue above) comes from conductivity measurements which show that in $MeNO_2$ solution the complex is a non-electrolyte. The ^{195}Pt NMR spectrum shows a triplet at −4503 ppm, in accord with a P_2Cl_2 donor set at Pt(II) [28].

Treatment of a CCl_4 suspension of $[PtCl_2(L^1)]$ with excess Cl_2 saturated CCl_4 gives the Pt(IV) species $[PtCl_4(L^1)]$ as a yellow solid. This formulation follows from the far IR spectrum and the microanalysis. The Pt(IV) complex readily reverts to $[PtCl_2(L^1)]$ in solution (as observed by ^{31}P NMR spectroscopy), and the $^{31}P\{^1H\}$ NMR spectrum measured in CH_2Cl_2 solution in the presence of Cl_2 shows δ −4.8, $^1J_{PtP}$ = 2170 Hz, consistent with a $PtCl_4(L^1)$ composition [28,29]. Similar treatment of $[PdCl_2(L^1)]$ did not result in a colour change, and the $^{31}P\{^1H\}$ NMR spectrum is unchanged.

2.3. Cu, Ag and Au complexes

Reaction of $[Cu(NCMe)_4]BF_4$ or $AgBF_4$ with two molar equivalents of L^1 in CH_2Cl_2 solution in the dark affords colourless solutions from which the homoleptic phosphine complexes $[Cu(L^1)_2](BF_4)$ and $[Ag(L^1)_2](BF_4)$ were obtained in high yield. The 2:1 L^1:M composition follows from microanalyses and from the magnitude of the $^{107/109}Ag$–^{31}P coupling constants in the $^{31}P\{^1H\}$ NMR spectra – below. Electrospray mass spectrometry (MeCN) shows the only significant species in each case is $[M(L^1)_2]^+$, with much weaker fragment peaks corresponding to $[M(L^1)]^+$. The ^1H NMR spectra for these compounds each show small high frequency shifts in the CH_2 resonance compared to L^1 itself, and the aromatic protons appear as a broad overlapping multiplet. The $^{31}P\{^1H\}$ NMR spectrum of the Cu(I) complex shows a single broad resonance at −8.7 ppm, giving a small high frequency coordination shift. A *pseudo*-tetrahedral bis-L^1 coordination environment at Cu(I) is confirmed by the observation of a broad ^{63}Cu NMR resonance at +193 ppm which does not change significantly upon cooling. Phosphorus–copper coupling is not observed in either the $^{31}P\{^1H\}$ or ^{63}Cu NMR spectra. This chemical shift is typical of a P_4-donor set at Cu(I) and compares with +150 ppm for $[Cu(Ph_2PCH_2CH_2PPh_2)_2]^+$ and +231 ppm for $[Cu(dppp)_2]^+$, although no ^{63}Cu NMR resonance has been observed for $[Cu(dppb)_2]^+$ between 300 and 175 K, probably due to reversible chelate ring-opening [30]. The $^{31}P\{^1H\}$ NMR spectrum of the Ag(I) complex reveals two overlapping doublets at room temperature at −1.5 ppm, giving $^1J(^{107}Ag$–$^{31}P) = 226$ Hz and $^1J(^{109}Ag$–$^{31}P) = 257$ Hz, indicating that ligand exchange and/or dissociation are slow on the NMR time-scale. Furthermore, the magnitude of the coupling constants provides a good indication of the coordination environment at Ag. In this species the coupling constants are consistent with tetrahedral P_4-coordination in solution (compare for example the tetrahedral $[Ag(dppe)_2]^+$ $J(^{107}Ag$–$^{31}P) = 231$ and $J(^{109}Ag$–$^{31}P) = 266$ Hz) [31]. The dihalo-bridged complexes $[Ag_2Cl_2(L^1)_2]$ (distorted tetrahedral P_2Cl_2 coordination) give $J(^{107}Ag$–$^{31}P) = 359$ and $J(^{109}Ag$–$^{31}P) = 413$ Hz, small reductions in the J values occur as the Cl is replaced by Br or I [6].

The coordination environment at Ag(I) was subsequently confirmed by a crystal structure determination on $[Ag(L^1)_2](BF_4)\cdot CH_2Cl_2$. The structure of the cation shows (Fig. 5, Table 5) two L^1 ligands coordinated in a bidentate manner to Ag(I), giving a distorted tetrahedral coordination environment, consistent with the solution spectroscopic studies. The Ag–P bond distances are in the range 2.47–2.54 Å, while the P1–Ag–P2 and P3–Ag–P4 chelate angles are 102.88(3)° and 104.21(3)°, only slightly larger than those observed in the 1:1 Pd:L^1 complexes above, but some 10°–12° larger than in the bis-L^1 complex $[Rh(L^1)_2]BF_4$. The obtuse angles within the chelate rings in $[Ag(L^1)_2]^+$ are also confirmed by the P1···P2 and P3···P4 distances of 3.90 and 3.96 Å, respectively. These are over 0.5 Å larger than in $[Rh(L^1)_2]^+$, reflecting the structural flexibility of the 7-membered chelate ring incorporating the somewhat rigid *o*-xylyl unit.

The structures of the Ag(I) complexes $[Ag_2X_2(L^1)_2]$ (X = Cl or I) have been described previously. These both show distorted tetrahedral coordination at Ag(I) via two bridging X ligands and a chelating L^1, with *d*(Ag–P) very similar to those seen here for $[Ag(L^1)_2]^+$ (X = Cl: *d*(Ag–P) = 2.446(1), 2.450(2) Å; X = I: *d*(Ag–P) = 2.487(1), 2.493(2) Å), although the P–Ag–P angles within the chelate rings are closer to the ideal tetrahedral value in the halo-bridged complexes. Again, this probably reflects the reduction in steric bulk when only one L^1 is present on the Ag centre [6].

The analogous Au(I) complex $[Au(L^1)_2]PF_6$ was obtained in good yield as a white solid by reaction of [AuCl(tht)] with two mol equiv. of L^1 and one mol equiv. of $TlPF_6$ in CH_2Cl_2 solution. The electrospray mass spectrum reveals a cluster of peaks with the correct isotope distribution at ca. 1145, consistent with $[Au(L^1)_2]^+$, with a lower intensity cluster corresponding to a fragment ion derived from loss of one L^1, while the IR spectrum shows the presence of ionic PF_6^-, but no

Au–Cl unit. The $^{31}P\{^1H\}$ NMR spectrum shows a singlet at +0.8 ppm due to coordinated L^1 and a septet (PF_6^-) at −143.9 ppm with a 4:1 integral ratio. The coordination environment is confirmed from a crystal structure of the complex. The structure of $[Au(L^1)_2]PF_6\cdot 2CH_2Cl_2$ shows a distorted tetrahedral cation (Fig. 6, Table 6) derived from two chelating L^1 ligands and giving Au–P bond lengths in the range 2.40–2.43 Å. These bond distances compare very well with the range 2.39–2.42 Å reported for $[Au(Ph_2PCH_2CH_2PPh_2)_2]^+$ (flattened tetrahedron) [32].

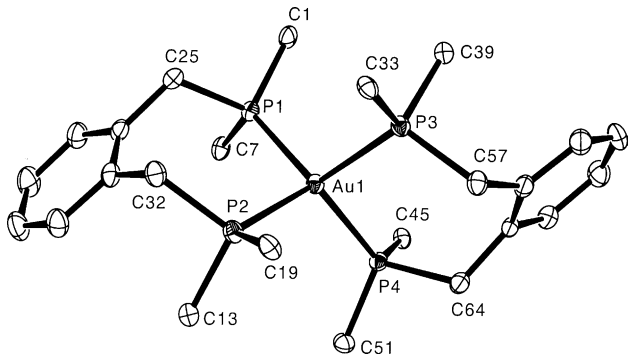

Fig. 6. View of the structure of the $[Au(L^1)_2]^+$ cation with numbering scheme adopted. Ellipsoids are drawn at 50% probability and H atoms and phenyl rings (except the *ipso* C atoms) are omitted for clarity.

The chelate angles subtended at Au are 103.62(2)° and 103.65(2)°, with d(P1···P2) and d(P3···P4) = 3.78 Å. Comparison of this structure with the Ag(I) analogue above reveals a small but significant shortening of the metal–phosphorus bond distances in the 5d Au(I) complex. Similar observations have been made on other related systems [33].

A similar reaction between [AuCl(tht)] and L^1 in a 2:1 ratio and in the absence of $TlPF_6$ also gives a white, light sensitive solid. The IR spectrum of this compound clearly indicates the presence of terminal Au–Cl units (319 cm^{-1}), and its $^{31}P\{^1H\}$ NMR spectrum is a singlet at 30.5 ppm, very significantly to high frequency of the PF_6^- salt above. The $^{31}P\{^1H\}$ NMR spectrum of the related $[Au_2Cl_2(Ph_2PCH_2CH_2PPh_2)]$ displays a similar coordination shift, giving $\delta(^{31}P)$ = +31.5 [32]. These data together with ^1H NMR data confirm the formulation as $[(AuCl)_2(L^1)]$, probably involving linear Au–Cl coordination at each P atom of a bridging diphosphine.

3. Conclusions

These results show that L^1 is an effective ligand for a range of late transition metal ions, functioning routinely as a chelating bidentate. The steric demands of L^1 favour the formation of lower coordination numbers, and indeed the only bis-L^1 complexes we have isolated involve either distorted square planar or tetrahedral coordination environments and are sterically quite hindered. This factor may also be responsible for formation of the unusual Cl-bridged dimer $[Pd_2Cl_2(L^1)_2]^{2+}$, as the Pd(II) centre can more readily accommodate one L^1 and two relatively small Cl ligands rather than two chelating L^1's. The presence of the aromatic unit in the ligand backbone leads to increased rigidity relative to the aliphatic dppb, a greater tendency to chelate, and promotes coordination chemistry more akin to the rigid *o*-phenylene analogue *o*-$C_6H_4(PPh_2)_2$. The flexibility of L^1 is also evident from the wide range of P···P distances measured within the chelate rings from the six crystal structures.

4. Experimental

Infrared spectra were recorded as either Nujol mulls between CsI plates or as CsI disks using a Perkin–Elmer

983G spectrometer over the range 4000–200 cm^{-1}. UV/vis spectra were recorded either as solids by diffuse reflectance or in CH_2Cl_2 solution using 1 cm path length quartz cells using a Perkin–Elmer Lambda19 spectrometer. Mass spectra were run by electron impact on a VG-70-SE Normal geometry double focusing spectrometer or by positive ion electrospray (MeCN solution) using a VG Biotech platform. ^1H NMR spectra were recorded using a Bruker AC300 spectrometer. $^{13}C\{^1H\}$, $^{31}P\{^1H\}$, ^{63}Cu and $^{195}Pt\{^1H\}$ NMR spectra were recorded using a Bruker DPX400 spectrometer operating at 100.6, 162.0, 106.11 or 85.62 MHz, respectively, and are referenced to TMS, external 85% H_3PO_4, $[Cu(NCMe)_4]BF_4$ and 1 mol dm^{-3} $Na_2[PtCl_6]$, respectively. Microanalyses were undertaken by the University of Strathclyde microanalytical service.

Solvents were dried prior to use and all preparations were undertaken using standard Schlenk techniques under a N_2 atmosphere. The ligand L^1 was prepared as described previously [8].

4.1. $[CoCl_2(L^1)]$

$CoCl_2 \cdot 6H_2O$ (0.075 g, 0.316 mmol) was dissolved in isopropanol (20 cm^3). One molar equivalent of L^1 (0.150 g, 0.316 mmol) dissolved in CH_2Cl_2 (10 cm^3) was added and the reaction mixture was stirred for ca. 30 min. to give a turquoise solid. The solvent was concentrated to ca. 5 cm^3 in vacuo and the solid was collected by filtration, washed with isopropanol and dried in vacuo (yield 67%). Required for $[C_{32}H_{28}Cl_2CoP_2] \cdot 1/4CH_2Cl_2$: C, 61.9; H, 4.6. Found: C, 62.4; H, 4.3%. UV/vis (diffuse reflectance): ν 6120, 7750, 13460, 15080, 16155, 25700 sh cm^{-1}; (CH_2Cl_2 solution): ν 13590 (ε_{mol} 1000 cm^{-1} mol^{-1} dm^3), 15625 (900), 16920 (1060) cm^{-1}. IR (Nujol mull): ν 318 br cm^{-1}. Magnetic moment = 4.68 μ_B.

4.2. $[CoCl_3(L^1)]$

Treatment of a CH_2Cl_2 solution of $[CoCl_2(L^1)]$ with a stream of NOCl at ca. −15 °C leads to immediate formation of a deep green-blue solution which, upon pumping to dryness in vacuo affords a green-blue solid. IR (Nujol mull): ν 349, 321, 311 cm^{-1}. UV/vis (CH_2Cl_2 solution): ν 6580, 16130, 16530 sh, 28570 cm^{-1}.

4.3. $[CoBr_2(L^1)]$

Method as above, but using $CoBr_2 \cdot 6H_2O$. Green solid (yield 62%). Required for $[C_{32}H_{28}Br_2CoP_2]$: C, 55.4; H, 4.1. Found: C, 55.4; H, 3.7%. UV/vis (diffuse reflectance): ν 6540, 7605, 13265, 15130, 15875 cm^{-1}; (CH_2Cl_2 solution): 13280 (ε_{mol} 1580 cm^{-1} mol^{-1} dm^3), 15040 (1560), 16050 (1460) cm^{-1}. IR (Nujol mull): ν 243 br cm^{-1}. Magnetic moment = 4.41 μ_B.

4.4. $[CoI_2(L^1)]$

Method as above, but using CoI_2. Brown-green solid (yield 55%). Required for $[C_{32}H_{28}CoI_2P_2] \cdot 1.5CH_2Cl_2$: C, 44.0; H, 3.4. Found: C, 43.7; H, 3.1%. UV/vis (diffuse reflectance): ν 6610, 7350, 12770, 14045, 14730, 20830 sh, 2500 sh cm^{-1}; (CH_2Cl_2 solution): 12805 (ε_{mol} 920 cm^{-1} mol^{-1} dm^3), 13965 (885), 14840 (770) cm^{-1}. Magnetic moment = 4.84 μ_B.

4.5. $[Rh(L^1)_2]BF_4$

$RhCl_3 \cdot 3H_2O$ (0.0416 g, 0.158 mmol) was dissolved in EtOH (20 cm^3). Two equivalents of L^1 (0.15 g, 0.316 mmol) dissolved in CH_2Cl_2 (10 cm^3) was then added, together with 40% aqueous HBF_4 (1 cm^3). The resulting mixture was stirred at room temperature for 30 min. Concentrating the mixture in vacuo gave an orange precipitate, which was filtered, washed with diethyl ether and dried in vacuo (yield 52%). Required for $[C_{64}H_{56}BF_4P_4Rh] \cdot 2CHCl_3$: C, 57.5; H, 4.2. Found: C, C, 58.3; H, 4.6%. ^1H NMR ($CDCl_3$): 7.00–7.40 (m) [40H] (Ph), 6.90 (m) [4H] (*o*-C_6H_4), 6.35 (m) [4H] (*o*-C_6H_4), 3.65 (br s) [8H] (CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): 11.6 ppm (d, $^1J_{RhP} = 140$ Hz). IR spectrum (Nujol mull): ν 1060 s, 506 s cm^{-1}. Electrospray MS (MeCN): *m/z* 1051 $[Rh(L^1)_2]^+$, 557 $[Rh(L^1)]^+$, 475 $[L^1 + H]^+$.

4.6. $[Rh(cod)(L^1)]PF_6$

$[RhCl(cod)]_2$ (0.077 g, 0.158 mmol) was dissolved in a degassed solution of CH_2Cl_2 (20 cm^3). NH_4PF_6 (0.057 g, 0.35 mmol) and L^1 (0.15 g, 0.316 mmol) were added to the mixture and the reaction was stirred under nitrogen for 30 min. The reaction mixture changed from yellow to red and the white precipitate (NH_4Cl) was filtered off. The solution was reduced in volume to ~5 cm^3 in vacuo. Upon addition of diethyl ether (10 cm^3) an orange precipitate formed which was filtered and washed with diethyl ether (2×10 cm^3). The orange solid (0.145 g, 55%) was dried in vacuo. Required for $[C_{40}H_{40}F_6P_3Rh] \cdot 1/2CH_2Cl_2$: C, 55.7; H, 4.7. Found: C, 56.1; H, 3.9%. ^1H NMR ($CDCl_3$): δ 7.70–7.50 (m) [20H] (Ph), 6.85 (m) [2H] (*o*-C_6H_4), 6.40 (m) [2H] (*o*-C_6H_4), 4.40 (br m) [4H] (cod CH), 3.90 (br m) [4H] (L^1CH_2), 2.0–2.2 (m) [8H] (cod CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): 10.3 ppm (d, $^1J_{RhP} = 146$ Hz) [2P], −143.8 (septet, PF_6^-) [1P]. IR (Nujol mull): 840 s, 557 s cm^{-1}.

4.7. $[Ir(cod)(L^1)]PF_6$

Method as above, using $[Ir_2Cl_2(cod)_2]$, giving an orange-red solid (yield 55%).

Required for $[C_{40}H_{40}F_6IrP_3]\cdot CH_2Cl_2$: C, 49.0; H, 4.2. Found: C, 48.3; H, 3.7%. ^{1}H NMR ($CDCl_3$): δ 7.70–7.30 (m) [20H] (Ph), 6.85 (m) [2H] (*o*-C_6H_4), 6.40 (m) [2H] (*o*-C_6H_4), 4.18 (br m) [4H] (cod CH), 3.92 (br m) [4H] (L^1CH_2), 1.7–2.0 (m) [8H] (cod CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): −1.8 ppm (s) [2P], −143.8 (septet, PF_6^-) [1P]. IR (Nujol mull): 841 s, 557 s cm^{-1}. Electrospray MS (MeCN): *m*/*z* 775 $[Ir(cod)(L^1)]^+$.

4.8. $[NiCl_2(L^1)]$

$NiCl_2\cdot 6H_2O$ (0.075 g, 0.316 mmol) was dissolved in isopropanol (20 cm^3) and one mol equiv. of L^1 (0.15 g, 0.316 mmol) was added. Stirring the reaction mixture for 1 h afforded a deep pink solid which was filtered and dried in vacuo. Recrystallisation from CH_2Cl_2 gave a deep pink solid (yield 76%). Required for $[C_{32}H_{28}Cl_2NiP_2]\cdot 1.5CH_2Cl_2$: C, 55.0; H, 4.3. Found: C, 55.5; H, 5.0%. ^{1}H NMR ($CDCl_3$): δ 6.90–7.40 (br m) [20H] (Ph), 6.70 (br m) [2H] (*o*-C_6H_4), 6.30 (br m) [2H] (*o*-C_6H_4), 3.40 (br m) [4H] (CH_2) ppm. UV/vis (diffuse reflectance): 20325, 29415, 37310 cm^{-1}; (CH_2Cl_2 solution): 20410 (ε_{mol} 510 cm^{-1} mol^{-1} dm^3). IR (Nujol mull): *v* 337 m, 322 m cm^{-1}.

4.9. $[NiCl_3(L^1)]$

Treatment of a CH_2Cl_2 solution of $[NiCl_2(L^1)]$ with a stream of NOCl at ca. −50 °C gave a deep orange-brown solution, from which an orange brown solid was obtained upon pumping to dryness in vacuo. IR (Nujol mull): *v* 340, 312, 300 sh cm^{-1}. UV/vis (CH_2Cl_2 solution): 12900 v br, 21050, 28570 cm^{-1}.

4.10. $[NiBr_2(L^1)]$

Prepared as above with $NiBr_2\cdot 3H_2O$ (0.086 g, 0.316 mmol) and L^1 (0.15 g, 0.316 mmol) to afford a brick red solid (yield 87%). Required for $[C_{32}H_{28}Br_2NiP_2]\cdot 1.5CH_2Cl_2$: C, 49.0; H, 3.8. Found: C, 48.3; H, 4.9%. ^{1}H NMR ($CDCl_3$): δ 6.70–7.50 (br m) [24H] (Ar–CH), 3.80 (br m) [4H] (CH_2) ppm. UV/vis (diffuse reflectance): 19600, 24040, 29240 cm^{-1}; (CH_2Cl_2 solution): 19920 (ε_{mol} 450 cm^{-1} mol^{-1} dm^3), 25000 (1485), 30675 (3140) cm^{-1}. IR (Nujol mull): 282 w, 262 cm^{-1}.

4.11. $[PdCl_2(L^1)]$

Na_2PdCl_4 (0.093 g, 0.316 mmol) was dissolved in EtOH (20 cm^3). One equivalent of L^1 (0.15 g, 0.316 mmol) was added in EtOH (~5 cm^3). The reaction mixture was stirred overnight, and a pale cream precipitate formed. After filtering and drying in vacuo a cream solid (yield 58%) was recovered. Required for $[C_{32}H_{28}Cl_2P_2Pd]\cdot CH_2Cl_2$: C, 53.8; H, 4.1. Found: C, 54.2; H, 4.2%. ^{1}H NMR ($CDCl_3$): δ 7.85–7.98 (m), 7.44–7.60 (m) [20H] (Ph), 6.88 (m) [2H] (*o*-C_6H_4), 6.15 (m) [2H] (*o*-C_6H_4), 3.75 (br d, J = 10 Hz) [4H] (CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ 16.4 ppm. IR (CsI disk): *v* 3064 w, 2971 w, 2933 w, 1586 w, 1481 m, 1433 s, 1360 m, 1188 w, 1103 s, 1073 w, 1027 w, 1000 m, 867 w, 837 m, 746 s, 700 s, 504 s, 452 w, 316 m, 304 m cm^{-1}.

4.12. $[Pd_2Cl_2(L^1)_2](PF_6)_2$

$PdCl_2$ (0.056 g, 0.316 mmol) was dissolved in MeCN (20 cm^3), by refluxing for 1 h. One equivalent of L^1 (0.15 g, 0.316 mmol) was added to the reaction mixture, followed by, one equivalent of $TlPF_6$ (0.11 g, 0.316 mmol). The resulting reaction mixture was stirred overnight and then filtered. The yellow filtrate was reduced to ~5 cm^3. Cold diethyl ether (~10 cm^3) was added dropwise to precipitate a yellow solid, which was filtered and dried in vacuo (yield 44%). Required for $[C_{64}H_{56}Cl_2F_{12}P_6Pd_2]$: C, 50.5; H, 3.7. Found: C, 50.9; H, 3.8%. ^{1}H NMR ($CDCl_3$): δ 7.40–7.90 (m) [40H], (Ph), 6.80 (m) [4H] (*o*-C_6H_4), 6.20 (m) [4H] (*o*-C_6H_4), 3.90 (br d, J = 12 Hz) [8H], (CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ 27.3 (s) [4P] (–P–Ph), −143.7 (septet) [2P] (PF_6^-) ppm. IR (CsI disk): *v* 3082 w, 3067 w, 3031 w, 2932 w, 1587 w, 1485 w, 1437 s, 1356 m, 1185 w, 1167 w, 1106 m, 1068 w, 1002 m, 843 br s, 777 m, 746 m, 696 m, 561 s, 501 m, 457 m, 374 w, 315 m cm^{-1}. Electrospray MS (MeCN): *m*/*z* 617 $[PdCl(L^1)]^+$, 658 $[PdCl(L^1)(MeCN)]^+$.

4.13. $[Pd(L^1)_2](BF_4)_2$

L^1 (0.15 g, 0.316 mmol) was dissolved in a mixture of EtOH (20 cm^3) and CH_2Cl_2 (10 cm^3). $Pd(NO_3)_2$ (0.036 g, 0.158 mmol) was dissolved in deionised H_2O (~10 cm^3) and added forming an orange solution. An excess of 40% aqueous HBF_4 (2 cm^3) was then added, and the reaction was stirred for 1 h. The solution was reduced in volume until a yellow precipitate formed which was filtered and dried in vacuo (yield 69%). Required for $[C_{64}H_{56}B_2F_8P_4Pd]$: C, 62.5; H, 4.6. Found: C, 63.0; H, 4.9%. ^{1}H NMR ($CDCl_3$): δ 7.30–7.80 (m) [40H] (Ph), 6.20–6.80 (m) [8H] (*o*-C_6H_4), 3.70 (br m) ppm [8H] (CH_2). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ 7.1 ppm. IR (Nujol mull): *v* 1067 s, 505 s cm^{-1}.

4.14. $[PtCl_2(L^1)]$

K_2PtCl_4 (0.13 g, 0.316 mmol) was dissolved in deionised H_2O (10 cm^3) and added to EtOH (20 cm^3) whilst stirring. One equivalent of L^1 (0.15 g, 0.316 mmol) dissolved in CH_2Cl_2 (10 cm^3) was added. The reaction mixture was stirred for 3 h, and the subsequent two layers were combined with the addition of acetone (10 cm^3). After stirring for 72 h, the mixture was filtered and then reduced in volume until a cream precipitate formed

which was filtered and dried in vacuo (yield 98%). Required for $[C_{32}H_{28}Cl_2P_2Pt]$: C, 51.9; H, 3.8. Found: C, 51.1; H, 3.9%. ^{1}H NMR ($CDCl_3$): δ 7.90–8.00 (m), 7.45–7.60 (m) [20H] (Ph), 6.90 (m) [2H] (*o*-C_6H_4), 6.20 (m) [2H] (*o*-C_6H_4), 3.95 (br d, $J = 11$ Hz) [4H] (CH_2) ppm. $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ −1.8 ppm, $^1J_{Pt-P} = 3584$ Hz. ^{195}Pt NMR: −4503 (t, $^1J_{PtP} = 3584$ Hz). IR (Nujol mull): *v* 326 w, 304 w cm^{-1}. Conductivity Λ_M/Ω^{-1} cm^2 mol^{-1} (10^{-3} mol dm^{-3} $MeNO_2$): 11.0. Electrospray MS (MeCN): *m*/*z* 745 $[PtCl(L^1)(MeCN)]^+$.

4.15. $[PtCl_4(L^1)]$

Treatment of a CH_2Cl_2 solution of $[PtCl_2(L^1)]$ with Cl_2 in CCl_4 gave a bright yellow solution, which upon concentrating in vacuo gave a bright yellow solid. Required for $[C_{32}H_{28}Cl_4P_2Pt]\cdot CH_2Cl_2$: C, 44.2; H, 3.4. Found: C, 44.8; H, 3.4%. $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ −4.8 ppm, $^1J_{Pt-P} = 2160$ Hz. IR (Nujol mull): *v* 344, 299, 288 cm^{-1}.

4.16. $[Cu(L^1)_2](BF_4)$

$[Cu(NCMe)_4](BF_4)$ (0.044 g, 0.158 mmol) was dissolved in CH_2Cl_2 (20 cm^3) and stirred. Two equivalents of L^1 (0.15 g, 0.316 mmol) were added, and the reaction was stirred for 2 h. The solution was reduced in volume to ~5 cm^3 and hexane (15 cm^3) was added to precipitate a solid. This was filtered and the white solid (yield 92%) was dried in vacuo. Required for $[C_{64}H_{56}BCuF_4P_4]\cdot 2CH_2Cl_2$: C, 62.5; H, 4.8. Found: C, 62.5; H, 4.9%. ^{1}H NMR ($CDCl_3$): δ 7.70–6.80 (br m) [44H] (Ar–CH), 6.30 (br m) [4H] (*o*-C_6H_4) 3.65 (br m) [8H] (CH_2). $^{31}P\{^1H\}$ NMR: δ −8.7 (s) ppm. ^{63}Cu NMR: δ +193 ppm. Electrospray MS (MeCN): *m*/*z* 1011 $[Cu(L^1)_2]^+$, 578 $[Cu(L^1)](MeCN)]^+$, 537 $[Cu(L^1)]^+$. IR (CsI disk): *v* 3059 w, 2964 w, 2927 w, 1590 w, 1482 m, 1437 s, 1359 w, 1272 w, 1186 m, 1159 w, 1096 s, 1062 br s, 1003 w, 865 m, 842 m, 766 m, 735 s, 700 s, 504 s, 486 s, 445 w, 342 w cm^{-1}.

4.17. $[Ag(L^1)_2](BF_4)$

$AgBF_4$ (0.031 g, 0.158 mmol) was dissolved in CH_2Cl_2 (20 cm^3) in a foil wrapped reaction vessel to exclude light, at 0 °C. Two equivalents of L^1 (0.15 g, 0.316 mmol) were dissolved in CH_2Cl_2 (10 cm^3) and added dropwise whilst stirring to the reaction mixture, keeping the temperature at 0 °C. After stirring for 2 h, the white precipitate was recovered by filtration, and dried in vacuo to afford a white solid (yield 82%). The solid was stored in a foil wrapped container to exclude light. Required for $[C_{64}H_{56}AgBF_4P_4]\cdot 1.5CH_2Cl_2$: C, 61.9; H, 4.7. Found: C, 62.4; H, 5.1%. ^{1}H NMR ($CDCl_3$): δ 6.95–7.30 (m) [40H] (Ph), 6.65 (br m) [4H] (*o*-C_6H_4), 6.20 (br m) [4H] (*o*-C_6H_4), 3.65 (br s) [8H] (CH_2) ppm. $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ −1.5 (2 × d, $^1J_{^{107}Ag-^{31}P} = 226$ Hz, $^1J_{^{109}Ag-^{31}P} = 257$ Hz). Electrospray MS (MeCN): *m*/*z* 1055 $[^{107}Ag(L^1)_2]^+$, 1057 $[^{109}Ag(L^1)_2]^+$. IR (Nujol mull): *v* 1059 m, 504 m cm^{-1}.

4.18. $[Au(L^1)_2]PF_6$

L^1 (0.15 g, 0.316 mmol) was dissolved in CH_2Cl_2 (20 cm^3). AuCl(tht) (0.051 g, 0.158 mmol) was added to the reaction vessel, followed by $TlPF_6$ (0.055 g, 0.158 mmol). The vessel was wrapped in foil to exclude light. This was stirred for 1 h, and filtered to remove TlCl. The volume was reduced to ~5 cm^3 and a white precipitate formed, which was filtered and dried in vacuo. The resulting fine white powder (yield 66%) was stored in a sample bottle excluding light. Required for $[C_{64}H_{56}AuF_6P_5]\cdot CH_2Cl_2$: C, 56.7; H, 4.2. Found: C, 57.3; H, 3.9%. ^{1}H NMR ($CDCl_3$): δ 7.10–7.35 (m) [40H] (Ph), 6.40 (m) [4H] (*o*-C_6H_4), 5.83 (m) [4H] (*o*-C_6H_4), 3.75 (br s) [8H], (CH_2) ppm. $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ 0.8 (s) [4P] (P–Ph), −143.9 (sep) [1P] (PF_6) ppm. Electrospray MS (MeCN): *m*/*z* 1145 $[Au(L^1)_2]^+$, 671 $[Au(L^1)]^+$. IR (Nujol mull): *v* 850 br s, 560 s cm^{-1}.

4.19. $[(AuCl)_2(L^1)]$

L^1 (0.072 g, 0.152 mmol) was dissolved in CH_2Cl_2 (20 cm^3). AuCl(tht) (0.098 g, 0.304 mmol) was added and the vessel was wrapped in foil to exclude light. The reaction mixture was stirred for 30 min at room temperature, and then reduced in volume to ~5 cm^3. The resulting white precipitate was filtered and dried in vacuo to afford a fine white powder (yield 23%), which was placed in a foil wrapped container. ^{1}H NMR ($CDCl_3$): δ 7.30–7.60 (m) [20H] (Ph), 6.86 (m) [2H] (*o*-C_6H_4), 6.35 (m) [2H] (*o*-C_6H_4), 3.92 (br) [4H] (CH_2) ppm. $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): δ 30.5 (s) ppm. IR (Nujol mull): *v* 319 m cm^{-1}.

5. X-ray crystallography

Details of the crystallographic data collection and refinement parameters are given in Table 7. Small blue crystals of $[CoCl_2(L^1)]$ were obtained by vapour diffusion of diethyl ether into a CH_2Cl_2 solution of the complex. Orange crystals of $[Rh(L^1)_2]BF_4\cdot 2CHCl_3$ were obtained by liquid diffusion of hexane into a solution of the complex in $CHCl_3$, while yellow crystals of $[PdCl_2(L^1)]\cdot 2CH_2Cl_2$ and $[Pd_2Cl_2(L^1)_2](PF_6)_2$ and colourless crystals of $[Ag(L^1)_2]BF_4\cdot 2CH_2Cl_2$ and $[Au(L^1)_2]PF_6\cdot 2CH_2Cl_2$ were grown by liquid diffusion of hexane into a CH_2Cl_2 solution of the appropriate complex. Data collection used a Nonius Kappa CCD diffractometer ($T = 120$ K) and with graphite-monochromated

Table 7

Abstract

We report here on dialkyldithiocarbamates complexes of the type $[C_6H_3(CH_3)S_2MS_2CNR_2]$ (M = As and Bi; R = CH_3, C_2H_5 and CH_2–CH_2), prepared by the reaction of toluene-3,4-dithiolatoarsenic(III) and -bismuth(III) chlorides $[C_6H_3(CH_3)S_2MCl]$ (M = As and Bi) with sodium/ammonium salts of dialkyldithiocarbamates $[XS_2CNR_2]$ (X = Na and NH_4; R = CH_3, C_2H_5 and CH_2–CH_2). The new derivatives were characterized by melting point, elemental analysis (C, H, N, S and As/Bi) and spectroscopic studies (IR, ^1H and ^{13}C NMR). Single crystal X-ray diffraction analyses of toluene-3,4-dithiolatoarsenic(III) dimethyldithiocarbamate and toluene-3,4-dithiolatoarsenic(III) pyrrolidine-dithiocarbamate revealed a monodentate chelating mode of the dimethyl as well as the pyrrolidine-dithiocarbamate moieties in these complexes.

Keywords: Arsenic(III); Bismuth(III); Toluene-3,4-dithiol; Dialkyldithiocarbamate derivatives

1. Introduction

Dialkyldithiocarbamate [1–5] groups are versatile ligands that exhibit different types of coordination patterns towards metals [1–10]. A number of arsenic(III) [8,11–15] and bismuth(III) [15–20] complexes with these ligands have been described and some of them have also been characterized by X-ray crystal structure determination [11–13,15–17,21–27]. However, the heteroleptic complexes of toluene-3,4-dithiolatoarsenic(III) and -bismuth(III) complexes with dialkyl-dithiocarbamate ligands have not been investigated so far. Recently we have reported on toluene-3,4-dithiolatoantimony(III) complexes based on these ligands [6]. Our continuing interest in the group 15 metal derivatives of dithiolato ligands [6–10,15,28,29] has prompted us to investigate the mixed toluene-3,4-dithiolatodialkyldithiocarbamates of arsenic(III) and bismuth(III) of the type $[C_6H_3(CH_3)S_2MS_2CNR_2]$ (M = As and Bi; R = CH_3, C_2H_5 and CH_2–CH_2).

2. Experimental

2.1. Reagents and general procedures

All the preparative reactions were performed under strictly moisture-free conditions due to hydrolysable nature of the reactants and the products. Solvents were

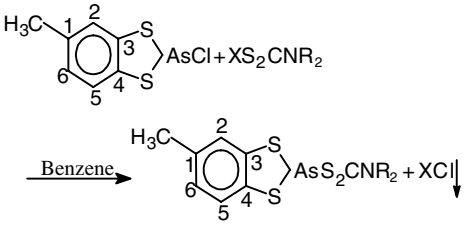
dried by standard methods [30]. Bismuth trichloride (Fluka), toluene-3,4-dithiol (Merck), the sodium salt of dimethyldithiocarbamate (Fluka), the sodium salt of diethyldithiocarbamate (BDH) and the ammonium salt of pyrrolidinedithiocarbamate (Merck) were used as received. Toluene-3,4-dithiolato arsenic(III) and bismuth(III) chlorides were prepared by reacting equimolar ratios of toluene-3,4-dithiol with arsenic trichloride and bismuth trichloride, respectively in anhydrous benzene. Sulfur was determined gravimetrically as barium sulfate [31], while arsenic was determined iodometrically [32]. Bismuth was titrated complexometrically against a standard EDTA solution using xylenol orange as an indicator [33]. Carbon, hydrogen and nitrogen were analysed at the Sophisticated Analytical Instrument Facility (SAIF) of the Central Drug Research Institute (CDRI), Lucknow. The IR spectra of these complexes were recorded as Nujol mulls on a Perkin–Elmer 557 spectrophotometer in the range 4000–200 cm^{-1}. The ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Bruker DRX-300 spectrophotometer using TMS as an internal standard. The single crystal X-ray diffraction analysis was performed on a STOE IPDS (imaging plate system) diffractometer at 25 °C, using graphite-monochromated Mo Kα X-ray radiation ($\lambda = 0.71073$ Å). A suitable crystal, grown from a toluene–isopropyl alcohol solution, was sealed in a glass capillary under dry nitrogen atmosphere and mounted on the goniometer head. The data collection was performed at room temperature using the ω–θ scan technique. The crystal structure was solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXS software package for crystal structure solution and refinement. All non-hydrogen atoms were refined with anisotropic thermal parameters in the later cycles of refinement. The hydrogen atoms were placed in idealized positions and refined using the riding model with general isotropic temperature factors. One of the crystals ($[C_6H_3(CH_3)S_2AsS_2CN(CH_2–CH_2)_2]$) showed gradual decay during measurements as inferred from the intensity of the diffraction data. The data collection was therefore performed only up to 22.50°.

2.2. Syntheses of complexes

2.2.1. Synthesis of toluene-3,4-dithiolatoarsenic(III) dimethyldithiocarbamate

A mixture of toluene-3,4-dithiolatoarsenic(III) chloride (0.59 g, 2.23 mmol) and sodium dimethyldithiocarbamate (0.40 g, 2.23 mmol) was refluxed in ~30 mL benzene for ~4 h. The precipitated sodium chloride (0.13 g) was filtered off. The solvent was removed from the filtrate under reduced pressure. The yellow solid compound thus obtained was crystallized in dichloromethane (Yield: 0.74 g, 95%).

2.2.2. Synthesis of toluene-3,4-dithiolatobismuth(III) diethyldithiocarbamate

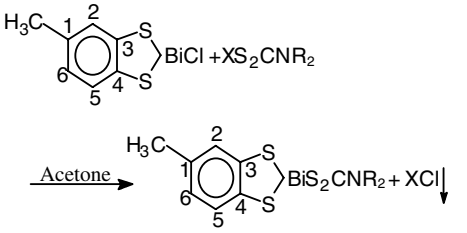


Toluene-3,4-dithiolatobismuth(III) chloride (0.34 g, 0.86 mmol) and sodium diethyldithiocarbamate (0.19 g, 0.86 mmol) in ~30 mL acetone were refluxed for ~4 h. The precipitated sodium chloride (0.05 g) was filtered off. The solvent was removed under reduced pressure from the filtrate, and the orange–red solid compound thus obtained was crystallized in acetone (Yield: 0.34 g, 77%).

The other derivatives were prepared by adopting the above methods. Pertinent analytical and physico-chemical data for these complexes are listed in Table 1.

3. Results and discussion

3.1. Synthesis of arsenic(III) complexes



Toluene-3,4-dithiolatodialkyldithiocarbamate derivatives of arsenic(III) have been prepared by the reaction of toluene-3,4-dithiolatoarsenic(III) chloride with sodium/ammonium dialkyldithiocarbamates in 1:1 molar ratios in anhydrous benzene.

(where, R= CH_3,$C_2H_5$and CH_2-CH_2;X= Na and NH_4)

3.2. Synthesis of bismuth(III) complexes

The mixed-ligand toluene-3,4-dithiolatobismuth(III) dialkyldithiocarbamate derivatives were obtained by refluxing the mixture of toluene-3,4-dithiolatobismuth(III) chloride and sodium/ammonium dialkyldithiocarbamates in equimolar ratios in anhydrous acetone.

(where, R= CH_3,$C_2H_5$and CH_2-CH_2;X= Na and NH_4)

Derivatives of arsenic(III) (compounds **1**, **2** and **3** (Table 1)) are yellow crystalline solids and those of bismuth(III) (compounds **4**, **5** and **6** (Table 1)) are orange–red crystalline solids. These compounds are soluble in common organic solvents such as benzene, acetone, chloroform and dichloromethane. They tend to decompose in carbon tetrachloride.

3.3. ^1H NMR spectra

The ^1H NMR spectra of these compounds have been recorded in $CDCl_3$ solutions using TMS as internal standard. These compounds exhibit characteristic signals without any appreciable shifts from reported values [6,8,13,28].

In these compounds the protons on the ring C(2) appear as a single proton singlet in the region 6.90–7.21 ppm and those on the rings C(6) and C(5) appear as single proton doublets in the region 6.44–6.87 and 6.98–7.26 ppm, respectively. A sharp singlet corresponding to three protons appears in the region 2.21–2.28 ppm due to methyl protons on the ring. In addition, these compounds also show expected proton resonances due to alkyl protons of dithiocarbamate moieties [34,35] (Table 2). The dimethyldithiocarbamate derivatives (**1** and **4**) show a sharp singlet around 3.28–3.35 ppm due to the methyl protons thus suggesting the magnetic equivalence of these protons. The ethyl protons in the diethyldithocarbamate derivatives (**2** and **5**) appear as a triplet at 1.24–1.34 ppm and a quartet at 3.66–3.75 ppm due to methyl and *N*-methylene protons, respectively. The pyrrolidine dithiocarbamate derivatives (**3** and **6**) appear as multiplets in the region 1.97–2.08 and 3.66–3.86 ppm due to CH_2 and NCH_2 protons of the heterocyclic pyrrolidine ring, respectively.

3.4. ^{13}C NMR spectra

The proton decoupled ^{13}C NMR spectra of these compounds ($CDCl_3$) exhibit signals in the region 135.1–137.1, 137.5–139.2 and 141.1–142.8 ppm assignable to the resonances of ring carbon no. C (2,5,6); C (1) and C (3,4), respectively. A sharp signal is observed in the region 20.1–20.8 ppm due to ring the methyl carbon. A weak signal in the region 190.3–201.2 ppm is observed due to NCS_2 carbon atoms of the dithiocarbamate moieties. In addition, these derivatives also exhibit the expected signals due to *N*-alkyl carbons of the dithiocarbamate moieties [6,8] (Table 2). The dimethyldithiocarbamate derivatives (**1** and **4**) show a signal at 43.1–44.5 δ ppm for the methyl carbon. The ethyl carbon in diethyldithiocarbamate derivatives (**2** and **5**) appear as two signals one at 23.6–25.9 ppm due to the methyl group carbons and the other at 48.5–58.6 ppm due to the *N*-methylene carbons. The pyrrolidine dithiocarbamate derivatives (**3** and **6**) exhibit two signals

s = singlet, d = doublet, q = quartet, sep = septet, m = multiplet.

around 25.6–25.8 and 52.8–54.2 ppm due to the CH_2 group and NCH_2 group carbons, respectively.

3.5. Crystal structure

The solid-state structures of two compounds, $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$ and $[C_6H_3(CH_3)S_2AsS_2CN(CH_2–CH_2)_2]$ have been established by single crystal X-ray analysis, which revealed monomeric units in both cases.

3.6. Crystal structure of $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$

The molecular structure of $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$ is shown in Fig. 1 and selected interatomic parameters are collected in Table 3. The arsenic atom forms three close contacts, two to the toluene-3,4-dithiolato sulfur atoms at As(1)–S(5) (2.266 Å) and As(1)–S(2) (2.235 Å) and one to the dithiocarbamato sulfur atom

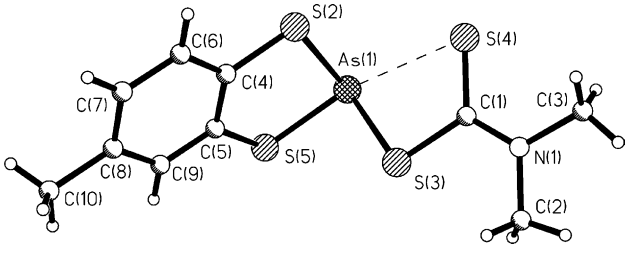

Fig. 1. Molecular structure of $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$.

As(1)–S(3) (2.298 Å). If these close contacts were considered to define the coordination geometry, the dithiocarbamate ligand behaves in a monodentate fashion. Considering the observed As–S interactions, the environment about the arsenic atom would be best described as pyramidal with the lone pair of electrons being stereochemically active, but with non-equivalent S–As–S bond angles (91.36(5)°, 93.79(5)° and 103.23(4)°) (Table 4)

[26]. The remaining sulfur atom (S(4)) is in proximity to the arsenic atom with an As ··· S(4) distance of 2.984 Å. This interaction is possibly responsible for the observed distortion from the ideal pyramidal geometry. This distance is significantly shorter than the sum of the van der Waal's radii of arsenic and sulfur (3.74 Å). Based on the relationship between bond order and bond distances suggested by Pauling [36], the As ··· S distances correspond to a bond order of 0.0532 for As–S(4) suggesting the interactions to be rather weak.

It is noticeable that in dithiocarbamate ligands the C–S bond associated with the strong As–S bonds is significantly longer (1.767(4) Å) than that associated with the weaker As ··· S bond (1.689(4) Å), showing clearly the localization of the double bond. The disparity in the associated C–S distances indicate that the As ··· S interaction present would be weak [22]. A remarkable feature concerns the N–C–S angles of the two sets of N–C–S angles (viz. 124.0(3)° and 116.8(3)°), the larger value is as expected owing to the mutual repulsion between the double bond and the adjacent electronegative "N" atom [22]. Similar coordination behaviour of dithiocarbamate ligands towards arsenic was also found in (i) [$RAsS_2CNEt_2$], R = Me and Ph [21], As–S = 2.344–2.323 Å and As ··· S = 2.943–2.840 Å, (ii) [$As\{S_2CNEt_2\}_3$], As–S = 2.34(9) Å and As ··· S = 2.84(9) Å [23], (iii) [$As\{S_2CN(Me)CH_2–CH_2OH\}_3$], As–S = 2.320(3) Å and As ··· S = 2.927(2) Å [24], (iv) [$As\{S_2CN(CH_2–CH_2OH)_2\}_3$], As–S = 2.34(2) Å and As ··· S = 2.84(2) Å [22].

3.7. Crystal structure of $[C_6H_3(CH_3)S_2AsS_2CN(CH_2–CH_2)_2]$

The coordination environment of the arsenic atom (Fig. 2) in $[C_6H_3(CH_3)S_2AsS_2CN(CH_2–CH_2)_2]$ is similar to that described for $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$. The selected interatomic parameters are listed in Table 3. The arsenic atom is coordinated by the two sulfur atoms of the toluene-3,4-dithiol group and one sulfur atom derived from the dithiocarbamate ligand. The As–S(3) and As–S(4) separations of 2.233(3) and 2.279(3) Å, respectively, are equivalent to As(1)–S(2) and As(1)–S(5) distances observed in $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$ (Table 4). Similarly, the As–S(1) and As–S(2) separations of 2.276(2) and 2.931 Å, respectively, are comparable to the As(1)–S(3) and As(1)–S(4) contacts found in the $[C_6H_3(CH_3)S_2AsS_2CN(CH_3)_2]$. The bonding situation suggests that substitution of the nitrogen-bound CH_2 groups of the pyrrolidine moiety, does not have any profound influence on the coordination geometry about the arsenic atom. The non-equivalent S–As–S angles (90.98(10)°, 103.62(9)° and 92.03(10)°) indicate a distorted pyramidal geometry about the central arsenic atom.

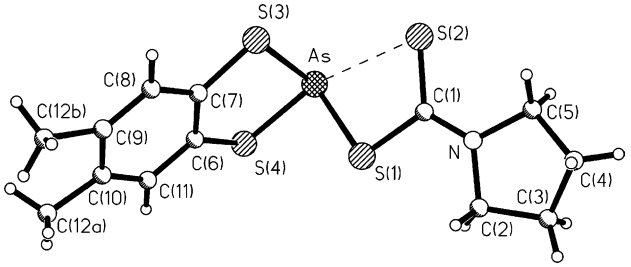

Fig. 2. Molecular structure of $[C_6H_3(CH_3)S_2AsS_2CN(CH_2–CH_2)_2]$.

3.8. Infrared spectra

These newly synthesized compounds show medium to strong intensity bands in the regions 920–1030 and 1442–1480 cm^{-1} due to C---S and C---N stretching vibrations, respectively. The bands of weak intensities at 310–320 and 340–360 cm^{-1} are due to As–S and Bi–S stretching vibrations, respectively. The characteristic bands observed in the region 680–695 cm^{-1} may be attributed to an asymmetric tri-substituted benzene ring [6,28].

4. Supplementary materials

Crystallographic data, tables of atomic coordinates, thermal parameters, bond lengths and bond angles of the structures have been deposited with the Cambridge Crystallographic Data Center, with the deposition numbers: CCDC 245175 and 245176. Copies of this information are available free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Reactions of a mixed dioxa-diaza macrocycle 5,6,14,15-dibenzo-1,4-dioxa-8,12-diazacyclopentadeca-5,14-diene (**L**) and various sodium salts NaX (X = picrate, ClO_4, BF_4, PF_6, SCN and BPh_4) in methanol afford the ion-pair compounds containing the protonated macrocyclic ligand as the cation, with the anion from the sodium salt as a counterion. The new compounds were identified and characterized on the basis of elemental analysis, spectroscopic studies (IR, ^{1}H NMR and MS), conductivity data and X-ray structure analysis. The mode of ligand protonation, as well as the hydrogen bond network which stabilizes the binding site of the proton in the protonated macrocyclic species, depend on the sodium salt used. It was found that the proton-to-ligand ratio is 1:1 in the picrate salt (**1**), 1:2 in the perchlorate (**2**), tetrafluoroborate (**3**), hexafluorophosphate (**4**) and thiocyanate (**5**) salts, and 2:3 in the tetraphenylborate salt (**6**), which was converted by recrystallization in acetonitrile into the 1:1 salt (**7**). In the 1:1 proton:ligand compounds, [H(**L**)]X, the intraligand monoprotonation occurs in two modes: the proton is either bound to one of the nitrogen atoms (**1**) or is disordered between two nitrogen atoms (**7**). In the compounds with 1:2, $[H(\mathbf{L})_2]X$, and 2:3, $[H_2(\mathbf{L})_3](X)_2$, proton-to-ligand ratios, there is interligand protonation where one proton is located between nitrogen atoms from two macrocyclic molecules (**2**–**5**) or two protons are shared between nitrogens from three ligand moieties (**6**). Crystallographic and infrared spectroscopic data indicate some differences in location of the proton between the nitrogen atoms in the monoprotonated ligand salts **2**–**5**.

1. Introduction

The chemistry of oxygen–nitrogen mixed-donor macrocycles has attracted continuous attention due to their ability to bind selectively different chemical species. With an appropriate combination of the macrocyclic cavity size, shape and topology, substituent effects as well as the number, type and arrangement of donor atoms, these polydentate ligands are able to bind a wider variety of both cations and anions than single heteroatom ligands such as oxygen-containing or nitrogen-containing macrocycles [1,2]. Although these ligands favour transition and post-transition metal ions [3–7], the selected derivatives also form complexes with alkali [8], alkaline earth [9] and lanthanide cations [10], as well as with ammonium [2,11] and oxonium [12]

doi:10.1016/j.poly.2004.10.013

ions. In the case of the interaction with some anionic and neutral organic and biological substrates, supramolecular compounds of specific properties and applications were prepared [12,13]. The presence of basic amino sites in the macrocyclic molecule also enables diffusion of a proton inside the molecular cavity, followed by ligand protonation and formation of the protonated derivatives [14–16]. In general, the proton transfer reaction is of great importance in chemistry and biology. It plays a fundamental role in numerous processes including acid–base neutralization and electrophilic addition, and it is involved in transport phenomena, photosynthesis, enzyme reactions, etc. [17]. In general, the problem of proton transfer is important but very complex and far from resolution although there is significant progress due to the application of new theoretical methods using powerful computers [18] and experimental findings on ultrafast reactions involving proton transfers that are induced by lasers [19]. The proton transfer properties of macrocyclic compounds are connected with the number of amino groups in the molecular skeleton, their type (secondary and tertiary) and nature (aliphatic and aromatic), the length of the linkers, the presence of different donor groups in the ligand frame as well as the flexibility/rigidity and the overall structure of the macrocyclic molecule [15]. In addition, the protonated macrocycles can interact with simple as well as with more complex inorganic and organic anions, and their complexation properties are based on the solvation and hydrogen bonding capabilities of both the protonated moiety and the accompanying anion.

In the present work, we investigate the protonation behaviour of 5,6,14,15-dibenzo-1,4-dioxa-8,12-diazacyclopentadeca-5,14-diene (**L**) in the interaction with various sodium salts in methanol solution, since it was shown that this dioxa-diaza macrocycle forms the protonated species and does not bind the sodium ion in these reactions. In general, protonation of aza macrocycles would be expected in acidic medium. Thus, the dihydronitrate salt $[H_2(\mathbf{L})](NO_3)_2$ was obtained by the hydrogenation with sodium tetrahydroborate of the structurally related macrocyclic diimine, which was used as a precursor for the synthesis of **L**, and the successive reaction with HNO_3 in a methanol–water solution [16]. In previous studies, it was demonstrated that this mixed-donor ligand binds some transition metal ions in reactions with the corresponding metal salts in methanol solution. Complexes of the type $M(\mathbf{L})X_2$, where M = Ni, Co, Zn or Cd; X = Cl, Br, I or NCS, were synthesized and examined [4,5,20,21]. Interactions between **L** and alkali metal ions have not been studied yet. We report here the preparation and structural characterization of the protonated ligand salts obtained by reactions of this 15-membered macrocycle with a series of sodium salts.

2. Experimental

2.1. Materials and instrumentation

5,6,14,15-Dibenzo-1,4-dioxa-8,12-diazacyclopentadeca-5,14-diene (**L**) was used directly as supplied (Aldrich). Sodium perchlorate, tetrafluoroborate, hexafluorophosphate, tetraphenylborate and thiocyanate salts were commercial chemicals of the highest purity available and used without further purification except for vacuum drying over P_4O_{10} and storing in a dry-box prior to use. Sodium picrate was prepared and purified as described. Solvents used (AR grade) were purified and dried by standard procedures.

Melting points were determined on a hot stage microscope and are uncorrected. FTIR spectra were recorded on an ABB Bomen MB102 spectrometer using KBr pellets. ESI mass measurements were performed on a Finnigan LCQ DECA instrument (ThermoFinnigan, Palo Alto, CA) operating in the positive ion mode. Compounds were dissolved in methanol or acetonitrile (10^{-6} M solutions) and directly injected by a syringe pump at a flow of 5 μL min^{-1}. LDI mass spectra were performed on a Voyager-DE PRO instrument (Applied Biosystems, Foster City, CA), operating in the linear positive ion mode. External mass calibration was done using the Calibration Mixture 1 of Sequazyme Peptide Mass Standards Kit, based on the monoisotopic values of $[M + H]^+$ of des-arg-bradykinin, angiotensin, glu-fibrinopeptide B and neurotensin at *m/z* 905, 1297, 1571 and 1673, respectively. The ^1H NMR spectra were recorded with Varian 300 Gemini and Bruker XWIN-600 Fourier-transform spectrometers in DMSO-d_6 at 300 K. Chemical shifts were referred to the residual solvent signal at 2.51 ppm. The two-dimensional experiments were performed by standard pulse sequences, using Gemini Data System software Version 6.3 Revision A and Bruker XWIN-NMR software Version 3.5. Conductance measurements were carried out at room temperature using a CD 7A Tacussel conductance bridge for 10^{-3} mol^{-1} solutions in DMF. Elemental analyses (CHNS) were performed on a Perkin–Elmer Analyser PE 2400 Series 2 and thermogravimetric analyses with a Cahn RG electromicrobalance in air atmosphere.

2.2. Preparations of the compounds

2.2.1. *[H(**L**)](picrate) (**1**)*

A mixture of 5,6,14,15-dibenzo-1,4-dioxa-8,12-diazacyclopentadeca-5,14-diene (**L**) (0.110 g, 0.35 mmol) and sodium picrate (0.108 g, 0.40 mmol) in dry MeOH (10 cm^3) was refluxed for 1–2 h with continuous stirring. The yellow-orange microcrystalline product, which precipitated immediately after cooling to room temperature was collected by filtration, washed with cold MeOH,

and dried overnight in vacuo under P_4O_{10}. Yield: 0.172 g, 91%; m.p. 205–207 °C. *Anal.* Calc. for $C_{25}H_{27}N_5O_9$: C, 55.65; H, 5.03; N, 12.93. Found: C, 55.55; H, 5.02; N, 12.68%. Molar conductance Λ_M (DMF, 22 °C) 56.3 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3297 s [ν(NH)], 2812 m–s br [$\nu(NH_2^+)$], 1634 s, 1621 m, 1590 s, 1562 s and 1552 s [ν(C═C), $\nu_{as}(NO_2)$, δ(NH), $\delta(NH_2^+)$], 1309 vs [$\nu_s(NO_2)$], 1264 s br and 1249 vs [ν_s(ArCOC), ν(CNC)], 949 m–s, 924 m–s and 913 w [$\omega,\tau,\rho(CH_2)$, ν(aliphCC)], 762 s, 753 m–s, 734 w and 712 m [δ(NH) and δ(ArCH) out-of-plane, $\gamma(NO_2)$]. ^{1}H NMR (300 MHz, DMSO-d$_6$, δ ppm) 1.73 (2H, m, CH_2-CH_2-CH_2), 2.82 (4H, t, J = 5.1 Hz, NH-CH_2-CH_2), 3.41 (3H, br s, NH, NH_2^+), 3.84 (4H, s, Ar–CH_2–NH), 4.41 (4H, s, O-CH_2), 6.95 (2H, t, J = 7.4 Hz, ArH-c), 7.08 (2H, d, J = 8.1 Hz, ArH-a), 7.29 (2H, d, J = 6.0 Hz, ArH-d), 7.36 (2H, t, J = 8.0 Hz, ArH-b), 8.59 (2H, s, ArH-picrate). MS (+ ESI, MeCN) m/z 313 ([LH]$^+$, 100%). MS (+LDI) m/z 542 ([MH]$^+$, 3%), 313 ([LH]$^+$, 100%). Crystals for X-ray analysis were obtained by very slow overnight cooling of the methanolic reaction solution to room temperature. Single crystals of **1** were also grown from acetonitrile solution.

2.2.2. *[H(**L**)$_2$]ClO$_4$ (**2**)*

A mixture of **L** (0.105 g, 0.34 mmol) and $NaClO_4$ (0.022 g, 0.18 mmol) in dry MeOH (5 cm^3) was stirred at ca. 50 °C for 6 h. The solution was allowed to stand for 6 days at 4 °C and the crystalline solid was isolated by filtration, washed with cold MeOH, and dried in vacuo over P_4O_{10}. A certain amount of single crystals were grown from the mother liquor. Although no problems were encountered in the preparation of this compound, a precaution should be taken when handling such potentially hazardous compounds. Yield: 0.088 g, 71%; m.p. 198–201 °C. *Anal.* Calc. for $C_{38}H_{49}ClN_4O_8$: C, 62.93; H, 6.81; N, 7.73. Found: C, 62.71; H, 6.82; N, 7.69%. Molar conductance Λ_M (DMF, 22 °C) 71.7 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3337 w–m, 3328 w–m and 3183 m–s [ν(NH)], 2600–1900 w–m br [ν(HN···H$^+$)], 1634 w [δ(NH)], 1601s and 1592 s [ν(C═C)], 1248 s br [ν_{as}(ArCOC), ν(CNC)], 1087 s br [$\nu_{as}(ClO_4^-)$], 982 m, 942 m and 914 m [$\omega,\tau,\rho(CH_2)$, ν(aliphCC)], 762 s and 732 m [δ(NH) and δ(ArCH) out of plane], 622s [$\nu_s(ClO_4^-)$]. ^{1}H NMR (300 MHz, DMSO-d$_6$, δ ppm) 1.64 (4H, m, CH_2-CH_2-CH_2), 2.67 (8H, t, J = 5.4 Hz, NH-CH_2-CH_2), 3.72 (8H, s, Ar-CH_2-NH), 4.38 (8H, s, O-CH_2), 5.13 (5H, br s, NH, NH_2^+), 6.92 (4H, t, J = 7.4 Hz, ArH-c), 7.05 (4H, d, J = 8.3 Hz, ArH-a), 7.23 (4H, d, J = 6.6 Hz, ArH-d), 7.31 (4H, t, J = 7.7 Hz, ArH-b). MS (+ ESI, MeOH) m/z 313 ([LH]$^+$, 100%); MS (+ LDI) m/z 625 ([L$_2$H]$^+$, 10%), 313 ([LH]$^+$, 100%).

2.2.3. *[H(**L**)$_2$]BF$_4$ (**3**)*

A mixture of **L** (0.115 g, 0.37 mmol) and $NaBF_4$ (0.022 g, 0.20 mmol) was refluxed for 3 h in dry MeOH (10 cm^3). The rod-like single crystals, gradually grown on cooling over a few days at 4 °C, were collected after removing the solvent with a syringe, washed with cold MeOH, and dried under reduced pressure. Yield: 0.101 g, 77%; m.p. 196–197 °C. *Anal.* Calc. for $C_{38}H_{49}BF_4N_4O_4$: C, 64.04; H, 6.93; N, 7.86%. Found: C, 64.15; H, 6.79; N, 7.68%. Molar conductance Λ_M (DMF, 22 °C) 74.4 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3339 m, 3331 sh and 3185 m [ν(NH)], 2600–1900 w–m br [ν(HN···H$^+$)], 1636 w [δ(NH)], 1601 s and 1592 s [ν(C═C)], 1233 s br [ν_{as}(ArCOC), ν(CNC)], 1073 s vbr [$\nu_{as}(BF_4^-)$], 985 m, 941 s and 916 m [$\omega,\tau,\rho(CH_2)$, ν(aliph(CC))], 760 vs and 731 s [$\nu_s(BF_4^-)$, δ (NH) and δ(ArCH) out of plane]. ^{1}H NMR (300 MHz, DMSO-d$_6$, δ ppm) 1.61 (4H, m, CH_2-CH_2-CH_2), 2.63 (8H, br s, NH-CH_2-CH_2), 3.69 (8H, s, Ar-CH_2-NH), 4.20 (5H, br s, NH, NH_2^+), 4.35 (8H, s, O-CH_2), 6.90 (4H, t, J = 7.1 Hz, ArH-c), 7.03 (4H, d, J = 8.1 Hz, ArH-a), 7.21 (4H, d, J = 7.0 Hz, ArH-d), 7.29 (4H, t, J = 7.6 Hz, ArH-b). MS (+ ESI, MeOH) m/z 313 ([LH]$^+$, 100%). MS (+ LDI) m/z 625 ([L$_2$H]$^+$, 5%), 313 ([LH]$^+$, 100%).

2.2.4. *[H(**L**)$_2$]PF$_6$ (**4**)*

A mixture of **L** (0.121 g, 0.39 mmol) and $NaPF_6\cdot H_2O$ (0.040 g, 0.22 mmol) in dry MeOH (5 cm^3) was refluxed for 8 h with vigorous stirring. The filtered solution was subjected to slow evaporation, first overnight at room temperature then at 4 °C for two days. The solvent was removed with a syringe and the remaining white single crystals were washed with cold MeOH, and dried under reduced pressure over P_4O_{10} at room temperature. Yield: 0.122 g, 82%; m.p. 208–210 °C. *Anal.* Calc. for: $C_{38}H_{49}F_6N_4O_4P$: C, 59.21; H, 6.41; N, 7.27. Found: C, 59.33; H, 6.48; N, 7.31%. Molar conductance Λ_M (DMF, 22 °C) 66.2 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3338 w–m and 3184 w–m [ν(NH)], 2600–2000 w–m br [ν(HN···H$^+$)], 1654 w [δ(NH)], 1601 s and 1591 s [ν(C═C)], 1249 m–s br [ν_{as}(ArCOC), ν(CNC)], 986 w, 937 s and 918 m [$\omega,\tau,\rho(CH_2)$, ν(aliphCC)], 830 s br [$\nu_{as}(PF_6^-)$], 759 s and 735 s [δ(NH) and δ(ArCH) out of plane], 557 s [$\nu_s(PF_6^-)$]. ^{1}H NMR (300 MHz, DMSO-d$_6$, δ ppm) 1.63 (4H, m, CH_2-CH_2-CH_2), 2.67 (8H, t, J = 5.2 Hz, NH-CH_2-CH_2), 3.72 (8H, s, Ar-CH_2-NH), 4.03 (5H, br s, NH, NH_2^+), 4.31 (8H, s, O-CH_2), 6.92 (4H, t, J = 7.3 Hz, ArH-c), 7.05 (4H, d, J = 8.0 Hz, ArH-a), 7.23 (4H, d, J = 7.3 Hz, ArH-d), 7.31 (4H, t, J = 7.8 Hz, ArH-b). MS (+ ESI, MeCN) m/z 625 ([L$_2$H]$^+$, 4%), 313 ([LH]$^+$, 100%); MS (+ LDI) m/z 313 ([LH]$^+$, 100%).

*2.2.5. [H(**L**)$_2$]SCN (**5**)*

A mixture of **L** (0.118 g, 0.38 mmol) and NaSCN (0.018 g, 0.22 mmol) in dry MeOH (5 cm^3) was refluxed for 5 h with continuous stirring under a stream of nitrogen. The clear solution was filtered hot and allowed to stand first overnight at 4 °C and then at −10 °C for two weeks. The crystalline precipitate that gradually formed during that time was filtered off, washed with a minimum of ice-cold MeOH, and dried in a desicator under reduced pressure over P_4O_{10}. Yield: 0.085 g, 66%; m.p. 180–181 °C. *Anal.* Calc. for $C_{39}H_{49}N_5O_4S$: C, 68.49; H, 7.22; N, 10.24; S, 4.69. Found: C, 68.72; H, 7.32; N, 10.34; S, 4.80%. Molar conductance Λ_M (DMF, 22 °C) 72.7 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3339 w, 3330 vw and 3183 w–m [ν(NH)], 2600–2100 w br [ν(HN···H$^+$)], 2057 s [ν(SCN$^-$)], 1649 w [δ(NH)], 1599 s and 1587 m [ν(C=C)], 1245 s and 1239 sh [ν_{as}(ArCOC), ν(CNC)], 978 w–m, 937 s and 920 sh [ω,τ,ρ(CH$_2$), ν(aliphCC)], 761 vs and 732 m–s [δ(NH) and δ(ArCH) out of plane]. ^{1}H NMR (300 MHz, DMSO-d$_6$, δ ppm) 1.63 (4H, m, CH$_2$-C*H*$_2$-CH$_2$), 2.65 (8H, s br, NH-C*H*$_2$-CH$_2$), 3.45 (5H, br s, NH, NH$_2^+$), 3.71 (8H, s, Ar-C*H*$_2$-NH), 4.37 (8H, s, O-C*H*$_2$), 6.91 (4H, t, J = 7.3 Hz, Ar*H*-c), 7.05 (4H, d, J = 7.8 Hz, Ar*H*-a), 7.22 (4H, d, J = 7.5 Hz, Ar*H*-d), 7.30 (4H, t, J = 7.7 Hz, Ar*H*-b). MS (+ESI, MeCN) *m/z* 625 ([L$_2$H]$^+$, 1%), 313 ([LH]$^+$, 100%); MS (+ LDI) *m/z* 313 ([HL]$^+$, 100%). Good quality crystals were grown by very slow evaporation from MeCN solution in a desicator over silica gel.

*2.2.6. [H$_2$(**L**)$_3$](BPh$_4$)$_2$ (**6**)*

An equimolar amount of **L** (0.101 g, 0.32 mmol) and NaBPh$_4$ (0.111 g, 0.32 mmol) was dissolved in dry MeOH (10 cm^3) and refluxed for 6 h with continuous stirring. Solvent was partly removed from the filtered solution to give, on gradual cooling at 4 °C, a pale-ochre precipitate. The crystalline compound was filtered off, washed with cold MeOH and dried in vacuo over P_4O_{10}. Yield: 0.145 g, 85%; m.p. 150–151 °C. *Anal.* Calc. for $C_{105}H_{114}B_2N_6O_6$: C, 79.93; H, 7.28; N, 5.33. Found: C, 80.05; H, 7.20; N, 5.27%. Molar conductance Λ_M (DMF, 22 °C) 96.5 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3292 vw, 3160 w br and 3121 w [ν(NH)], 2600–2150 w br [ν(HN···H$^+$)], 1643 w [δ(NH)], 1602 m–s, 1591 m, 1580 m and 1561 w [ν(C=C)], 1247 vs br and 1228 m [ν_{as}(ArCOC), ν(CNC)], 983 w, 943 m and 934 m [ω,τ,ρ(CH$_2$), ν(aliphCC)], 752 vs, 734 vs and 705 vs [δ(NH) and δ(ArCH) out of plane]. ^{1}H NMR (600 MHz, DMSO-d$_6$, δ ppm) 1.67 (6H, m, CH$_2$-C*H*$_2$-CH$_2$), 2.73 (12H, t, J = 5.2 Hz, NH-C*H*$_2$-CH$_2$), 3.77 (12H, s, Ar-C*H*$_2$-NH), 4.38 (12H, s, O-C*H*$_2$), 5.10 (8H, br s, NH, NH$^+$), 6.94 (6H, t, J = 7.2 Hz, Ar*H*-c), 7.08 (6H, d, J = 8.2 Hz, Ar*H*-a), 7.27 (6H, d, J = 7.3 Hz, Ar*H*-d), 7.34 (6H, t, J = 7.8 Hz, Ar*H*-b); tetraphenylborate: 6.80 (16H, t, J = 7.1 Hz, Ar*H*-c′), 6.93 (16H, t, J = 7.3 Hz, Ar*H*-b′), 7.19 (8H, br s, Ar*H*-a′). MS (+ESI, MeOH) *m/z* 945 ([(LH)$_2$BPh$_4$]$^+$, 2%), 313 ([LH]$^+$, 100%); MS (+ LDI) *m/z* 945 ([(LH)$_2$BPh$_4$]$^+$, 5%), 937 ([L$_3$H]$^+$, 5%), 867 ([(L$_2$H)BPh$_3$]$^+$, 5%), 789 ([(L$_2$)BPh$_2$]$^+$, 14%), 625 ([L$_2$H]$^+$, 50%), 555 ([(LH)-BPh$_3$]$^+$, 20%), 477 ([(L)BPh$_2$]$^+$, 12%), 313 ([LH]$^+$, 100%). It is worth noting that regardless of the proportion of macrocycle and sodium salt used, only compound with a 2:3 proton to ligand ratio was observed.

*2.2.7. [H(**L**)]BPh$_4$ (**7**)*

Recrystallization of **6** from MeCN yielded the compound **7**. It was also obtained by reaction of **L** and NaBPh$_4$ in MeCN.

A mixture of **L** (0.095 g, 0.30 mmol) and NaBPh$_4$ (0.104 g, 0.30 mmol) was dissolved in MeCN (10 cm^3) and refluxed for 3 h with continuous stirring. The reaction solution was filtered hot to remove some impurities and allowed to stand first at room temperature for 2 days and then it was left at 4 °C. The crystalline precipitate gradually formed was filtered off, washed with cold MeCN and dried under vacuum overnight over P_4O_{10}. Yield: 0.114 g, 60%; m.p. 160–162 °C. *Anal.* Calc. for $C_{43}H_{45}BN_2O_2$: C, 81.63; H, 7.17; N, 4.43. Found: C, 81.45; H, 7.22; N, 4.26%. Molar conductance Λ_M (DMF, 22 °C) 56.5 S cm^2 mol^{-1}. Selected IR data (KBr, cm^{-1}) 3344 vw br, 3280 vw br, 3145 w-m and 3120 sh [ν(NH)], 1653 w–m [δ(NH)], 1602 m–s, 1592 m–s and 1579 m [ν(C=C)], 1247 s br [ν_{as}(ArCOC), ν(CNC)], 984 w and 934 w–m [ω,τ,ρ(CH$_2$), ν(aliphCC)], 753 vs, 734 vs and 706 vs [δ(NH) and δ(ArCH) out of plane]. ^{1}H NMR (600 MHz, DMSO-d$_6$, δ ppm) 1.73 (2H, m, CH$_2$-C*H*$_2$-CH$_2$), 2.82 (4H, t, J = 5.2 Hz, NH-CH$_2$-C*H*$_2$), 3.85 (4H, s, Ar-C*H*$_2$-NH), 4.41 (4H, s, O-C*H*$_2$), 6.10 (3H, s br, NH, NH$^+$), 6.97 (2H, t, J = 7.2 Hz, Ar*H*-c), 7.10 (2H, d, J = 8.2 Hz, Ar*H*-a), 7.30 (2H, d, J = 7.3 Hz, Ar*H*-d), 7.37 (2H, t, J = 7.8 Hz, Ar*H*-b); tetraphenylborate: 6.80 (8H, t, J = 7.1 Hz, Ar*H*-c′), 6.94 (8H, t, J = 7.4 Hz, Ar*H*-b′), 7.19 (4H, s br, Ar-a′). MS (+ESI, MeCN) *m/z* 633 ([MH]$^+$, 1%), 313 ([LH]$^+$, 100%); MS (+ LDI) *m/z* 633 ([MH]$^+$, 2%), 555 ([(LH)BPh$_3$]$^+$, 3%), 313 ([LH]$^+$, 100%). Single crystals of poor quality were grown by slow evaporation from a mixture of MeOH, MeCN and CHCl$_3$ (1:2:1) in a desicator over silica gel after a few weeks.

2.3. X-ray diffraction

X-ray data were collected on an Enraf Nonius CAD4 diffractometer using Cu Kα radiation (λ = 1.54178 Å) at room temperature, except for compound **4** (measured at 100 K). The WINGX [22] data reduction procedure was applied. The structures were solved by direct methods with SIR97 [23], and refined by full-matrix least square refinement on F^2 using all reflections, with SHELXL [24]. All non-hydrogen atoms were refined anisotropi-

cally. The hydrogen atoms were located according to the relevant established geometry, and refined as a riding model, except those included in hydrogen bonding (attached to N8 and/or N12) that were located in the Fourier map and refined freely. Poor crystal quality and sensitivity to air of **4** affected the accuracy of data (Table 1) and consequently N–H bond distances (Table 2). Details of the crystal data and refinement are listed in Table 1.

3. Results and discussion

3.1. Preparation of the compounds

Reactions of a series of sodium salts with a mixed dioxa-diaza macrocycle 5,6,14,15-dibenzo-1,4-dioxa-8,12-diazacyclopentadeca-5,14-diene (**L**) in methanol yielded the ion-pair compounds shown in Scheme 1. The microanalytical, conductance, spectroscopic and X-ray structure analysis confirmed formation of the protonated ligand salts with different modes of inside and outside protonation, and hydrogen bonding systems. The proton-to-ligand ratio depends on the sodium salt and in the case of sodium tetraphenylborate also on the solvent used: 1:1 for the picrate salt (**1**), 1:2 for the perchlorate (**2**), tetrafluoroborate (**3**), hexafluorophosphate (**4**) and thiocyanate (**5**) salts, and 2:3 or 1:1 for the tetraphenylborate salt obtained from methanol (**6**) or acetonitrile (**7**) solution, respectively. A transformation of compound **6** to **7** in acetonitrile solution was confirmed by the ^{1}H NMR measurements. There are many effects influencing the formation of the protonated species, although the hole size of **L**, defined by the N_2O_2-donor set, of 2.06–2.26 Å would be suitable for complexation of Na^+ [25]. The main effects are related to the structural properties of the ligand. Since **L** as a diamine is a moderately strong base ($\log K_1 = 9.81$ and $\log K_2 = 6.84$, determined potentiometrically in 95% methanol) [20], it gives rise to competition between the protonation and metal complexation reactions. The presence of nitrogen donors having a low affinity for alkali metal cations and the presence of oxygen donor atoms next to the benzene rings having a reduced basicity and flexibility, are in favour of proton binding. In addition, the solvation power of Na^+ is strong due to its high charge density, and the formation of a protonated macrocycle is preferred. On the other hand, the dioxa-diaza macrocycle **L**, which contains both a hydrogen bond donor atom (the hydrogen on the nitrogen atom) and hydrogen bond acceptors (oxygen atom and the lone pair on the nitrogen atom) must also be strongly solvated in methanol, disrupting the hydrogen bonds which were shown to exist between the amine hydrogens and the ether oxygens [26]. This fact presumably gives rise to favourable outside ligand protonation in methanol solution, which is supported by the X-ray structure of **L** determined on crystals obtained from a mixture of methanol and water [25]. It was found that the water of hydration is placed between two ligand molecules and forms with each of them N–H···O(s) and N···H(s)–O hydrogen bonds. A similar interligand position of the proton is in compounds **2**–**6**. The exception is the picrate salt **1** with inside protonation, which is stabilized by a hydrogen bonding network with the picrate anion.

In the case of compounds **6** and **7**, with the bulky tetraphenylborate anion, the solvent media effects are shown to be important for the type of ligand protonation, which may arise from a difference in the ion and ligand solvation in methanol and acetonitrile solution. In general, methanol causes extensive solvation of both cations and anions, while acetonitrile shows moderate cation solvating ability and a rather weak anion solvating ability, which decreases with the anion size [13,27]. The ligand solvation in acetonitrile is also expected to be small.

The prepared protonated ligand salts **1**–**7** are crystalline compounds, insoluble in water, slightly soluble in alcohols and other common organic solvents, and very soluble in dimethylformamide and dimethylsulfoxide. The molar conductance measurements are consistent with the proposed structure of the ion-pair compounds and their stoichiometry. Thus, all compounds except **6**, which behaves as an 1:2 electrolyte ($\Lambda_M = 96.5$ S cm^2 mol^{-1} in DMF), exhibit conductivity comparable to that of 1:1 electrolytes ($\Lambda_M = 56$ to 75). The anhydrous character of the compounds was checked by thermogravimetric analyses. Crystals suitable for X-ray structural determination were obtained for all compounds, apart of **6**, under conditions outlined in Section 2.

3.2. IR spectra

The infrared spectra of the compounds support a different mode of ligand protonation and different hydrogen bond networks in the various types of protonated ligand salts, which is in agreement with the X-ray crystal structure data. The protonation of the macrocyclic moiety is evident by the characteristic changes in the ligand bands arising from various stretching and deformation modes of the NH vibrations present in the 3400–1500 (see Fig. 1) and 790–730 cm^{-1} regions. In the free macrocycle, the absorption of the antisymmetric and symmetric ν(NH) vibrations occurs as two strong bands at 3295 and 3185 cm^{-1} as well as a weak absorption at 3259 cm^{-1} [28], indicating different hydrogen bonding behaviour of the two amine protons. This is in accordance with the X-ray data, which show that the NH groups are involved in intra- and intermolecular hydrogen bonding with the ether oxygens [26]. The δ(NH) vibrations are displayed along with the aromatic

ν(C=C) vibrations within 1600 and 1500 cm^{-1}. The most prominent feature in the spectrum of **L** is the appearance of a series of sharp bands of strong to medium intensity within 2800–2600 cm^{-1}, assigned to the perturbed ν_s(CH) vibrations as a result of α-CH_2 hydrogens being *trans*-anti-parallel to N lone-pairs (Bohlmann bands) [14]. In all the protonated ligand salts, great changes may be noticed in this region due to electronic redistribution in the macrocycle molecule caused by various types of intra- or inter-ligand protonation and hydrogen-bonding interactions. In the 1:1 proton-to-ligand compounds, the proton is located inside the macrocyclic cavity either on one of the nitrogen atoms as in **1** or is disordered between two nitrogen atoms as in **7**. For this reason, their spectra are significantly different. In the picrate salt, in the ν(NH) region one strong sharp band at 3297 cm^{-1} is present which is associated with the unprotonated amino group, while a medium band at 2182 cm^{-1}, partly superimposed upon the alkane ν(CH) absorptions on the higher frequency side and with shoulders on its lower side, could be ascribed to the $\nu(NH_2^+)$ absorption [29]. The broadness and position of the later absorption can be rationalized with the additional hydrogen bonding not only to the second nitrogen atom but also to oxygens of the macrocyclic and picrate moieties. On the other hand, in the tetraphenylborate salt **7**, the presence of two very small absorptions at 3344 and 3280 cm^{-1} and a broader band of medium intensity at 3140 cm^{-1}, associated with the NH stretching vibrations, indicates a proton disordering inside the macrocyclic cavity and no association with the counterion. Hence, a completely different hydrogen bond network could be proposed to that observed in **1**. A weak band at 1653 cm^{-1} could be assigned to the NH bending mode. It is known that these absorptions are shifted towards higher frequencies under associated conditions [29]. In **1**, δ(NH) is overlapped with the strong absorptions of the picrate anion in the 1635–1550 cm^{-1} region.

In the compounds with 1:2 and 2:3 proton-to-ligand ratios, there is interligand protonation in which a proton is dislocated between nitrogen atoms from two macrocyclic

Scheme 1. The protonated ligand salts formed by the reactions of **L** with sodium salts.

molecules (**2**–**5**) or two protons are shared among nitrogens from three ligand molecules (**6**). In general, the spectral features of the monoprotonated ligand salts **2**–**5** are similar, but the presence of extra bands attributed to the anion moiety [30], gives a different profile of their spectra (Fig. 2, see c and d and data in Section 2). Some variations observed in the position and intensity of the NH stretching vibrations may arise from some differences in location of the proton in the $N\cdots H^{+}\cdots N$ bonds between two ligand molecules. Two ν(NH) bands appear at about 3338 (mostly split) and 3185 cm^{-1}, while a very broad complex progression of absorptions displayed in the 2600–1900 cm^{-1} region could be assigned to the $HN\cdots H^{+}$ bonding system. It was found that the absorption region arisen from this type of hydrogen bonding shifts towards smaller wave numbers and gains more in intensity with increasing symmetry in the $N\cdots H^{+}\cdots N$ bond [14,31,32]. In the perchlorate and tetrafluoroborate salts, which were shown to be isostructural compounds, this absorption is the most intense and is centred around 2250 cm^{-1}, suggesting the symmetrical position of the proton between two nitrogen atoms. In the hexafluorophosphate and thiocyanate salts, this absorption is less intense and is centred at higher frequencies at about 2280 and 2300 cm^{-1}, respectively, indicating that the proton is placed asymmetrically between the two nitrogen atoms. In addition, it could be concluded that it is closer to one of the nitrogen atoms in the thiocyanate than in the hexafluorophosphate salt. A series of bands of less intensity between 2000 and 1800 cm^{-1} arises from overtones and a number of combination bands enhanced by Fermi resonance and is visible both in the spectrum of the **L** and in all its protonated derivatives [32]. The δ(NH) vibration in **2**–**5** appears as a weak band between 1654 and 1634 cm^{-1}. In general, the spectral pattern associated with the NH vibrations is also similar in the tetraphenylborate salt **6**, although some variation in position and intensity of these absorptions could be observed. Both bands over 3100 cm^{-1} are split and display at lower frequencies (around 3292 and 3140 cm^{-1}), while a broad complex band occurs at a narrow frequency region within 2600–2150 cm^{-1}. All these absorptions are less intense than those in the 1:2 (proton to ligand) compounds.

Compared to the free macrocycle, in the spectra of the protonated species considerable changes can be noticed also in the NH deformation region between 800 and 700 cm^{-1}. Overlap of the out of plane bending of

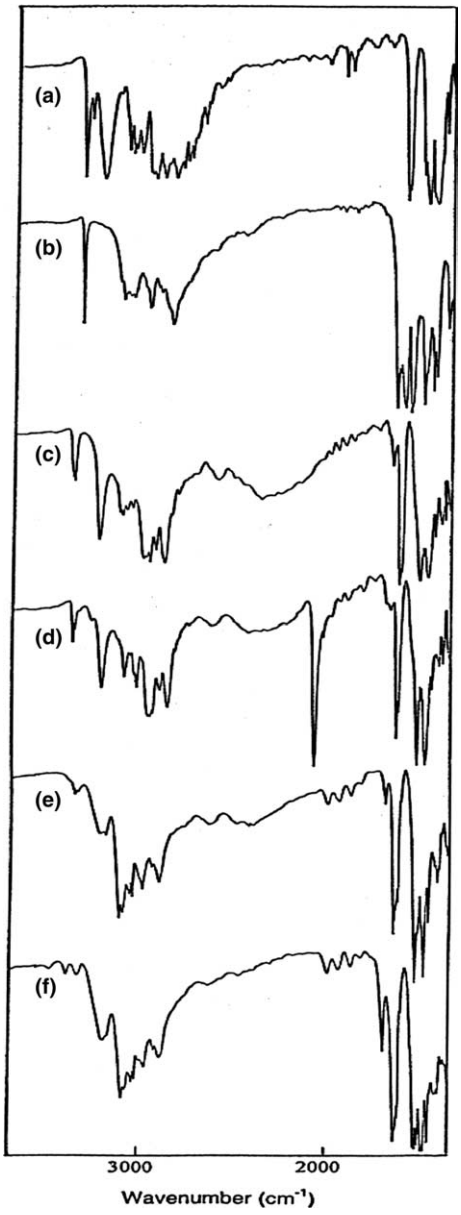

Fig. 1. Part of the infrared spectra of **L** and its salts: (a) **L**, (b) **1**, (c) **2**, (d) **5**, (e) **6** and (f) **7**.

the NH and ArCH vibrations gives a very complex spectral pattern of **L** with two strong split bands at 768 and 730 cm^{-1} and a very strong band at 753 cm^{-1}. Compounds **2**–**5** in this region show a strong to very strong band at 760 and a medium to strong band at 732 cm^{-1}. The situation is more complicated in compounds **1**, **6** and **7** due to overlapping with absorptions of the picrate or tetraphenylborate anions. In addition, some changes could be observed in the ligand vibration region around 1250 cm^{-1} ascribed to the stretching Ar-COC and CNC vibrations as well as between 1000 and 900 cm^{-1} where wagging, twisting and rocking modes of vibration of the methylene groups occur [33].

3.3. Mass spectra

The mass spectra (ESI and LDI) of all the compounds show the base peak at *m*/*z* 313, corresponding to the protonated ligand ion $[LH]^+$. The weak peak corresponding to $[MH]^+$ (1–2%) is only visible in the 1:1 proton-to-ligand compounds (**1** and **7**), while $[L_2H]^+$ (4–10%) is visible in the 1:2 compounds (**2**–**5**). In **6**, besides $[LH]^+$, $[L_2H]^+$ and $[L_3H]^+$ peaks, there is a series of ions which also contains tetraphenylborate fragments.

3.4. ^1H NMR spectra

The ^1H NMR spectra of the protonated macrocyclic species show a set of four resonant signals for the methylene protons and a set of four resonances for the ligand aromatic protons. In free **L**, an unresolved quintet at 1.54 and a triplet at 2.49 ppm are found for the methylene protons of the $NHCH_2CH_2CH_2NH$ group, whereas two singlets at 3.58 and 4.34 ppm are assigned to methylene protons of the Ar-CH_2NH and OCH_2 groups, respectively [28]. Two partly split doublets and two triplets appear in the aromatic region. In compounds **6** and **7**, these absorptions are overlapped with those arising from the tetraphenylborate anion and their relationship confirms the 2:3:2 proton–ligand–anion ratio in **6** as well as 1:1:1 in **7** (Fig. 2). Signal assignments were ascertained by 2D NMR spectra. It could be presumed that protonation of the macrocycle in solution is kinetically labile in all compounds, as evidenced by the averaging of the free and the protonated NH signal. The NH proton in **L** appears as a single absorption at 1.94 ppm. Upon ligand protonation, it broadens and moves to lower fields by 1.5–4.5 ppm due to a dynamic process involving fast intra- or inter-ligand proton exchange between the amino groups. Furthermore, the protonation of the basic site in the macrocycle leads to a deshielding of the adjacent methylene groups. A downfield shift of 0.11–0.26 ppm is observed in the salts for the Ar-CH_2-NH protons as well as that of 0.14–0.33 ppm for the NH-CH_2-CH_2 protons. The resonances for OCH_2 protons and of the aromatic protons undergo quite small shifts of 0.01–0.07 and 0.03–0.14 ppm, respectively. All these changes are more pronounced in compounds with the intraligand protonation.

3.5. X-ray structure analysis

The crystal structures solved (**1**–**5** and **7**, Table 1) revealed intra- (compounds **1** and **7**) and inter-macrocycle protonated compounds (compounds **2**–**5**) (Scheme 1). For the interligand protonated compounds (**2**–**5**), the proton is statistically distributed between two nitrogen atom pairs of two macrocyclic ligands as defined by crystallographic symmetry: each ligand molecule involves two N···N pairs but only one shares the proton.

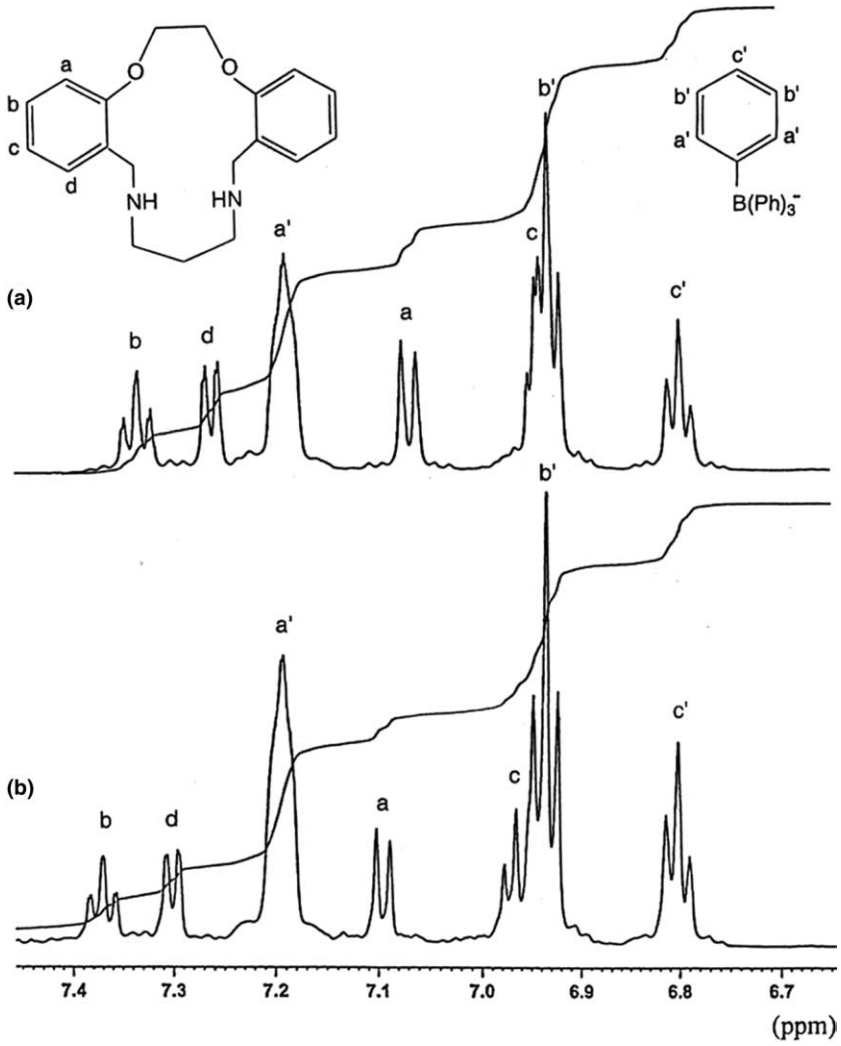

Fig. 2. The aromatic part of the ^{1}H NMR spectra of tetraphenylborate salts: (a) **6** and (b) **7**.

The proton locations in the electron density maps can be recognized using good quality intensity data. However, the crystal quality does not always permit the required experimental standards to be met, as for compounds **4** and **7** (Table 1). Sometimes, it is not possible to produce crystals at all (as for **6**). But for the structures of **1**–**5**, the proton locations were identified and the assignment of the correct structural formula was possible. Thus, in the [H(**L**)]picrate salt (**1**, Fig. 3) the proton attached to the nitrogen atom forms a $N12^+H_2$-cation (Fig. 4). The crystal structure of **7** (Fig. 5) also reveals an intraligand protonation. In the structure of **7**, the non-covalent intraligand distances N···N, N···O and O···O can be interpreted as possible hydrogen bonds upon distance criteria defined by Jeffrey (1997) but without the exact proton location, a particular hydrogen bond cannot be assigned [34]. The compounds **2**–**5**, with the ligand-to-proton ratio of 2:1, revealed intermacrocycle protonation as well as for compound **6** with a 3:2 ratio (deduced from ^{1}H NMR measurements, see Section 2 and Scheme 1). The crystal structure of **2** clearly reveals that the proton H12B (with a population parameter value of 0.5) participates in hydrogen bonding N···H^+···N (Table 2) involving N12 and N8 of two ligands, forming a centrosymmetric ring dimer of two macrocycles (Fig. 6). The distances from nitrogen to hydrogen are somewhat longer and can be related to the quality of the crystals: 1.46(4) and 1.51(4) Å. In addition to N···H^+···N hydrogen bonds, N8H and N12H also realise intraligand hydrogen bonds to O1 and O4 (Table 2), generating bifurcated hydrogen bonds. The isostructural relationship between **2** and **3** [perchlorate and tetrafluoroborate tetrahedral analogues (Fig. 7), respectively] is obvious from crystallographic evidence (both crystallise in the monoclinic space group *C*2/*c*, Table 1) and the protonation type is identical. The interligand N···N separation as donor to acceptor distances of hydrogen bonds are similar to intraligand ones involving nitrogen atoms: 2.963 and 2.984 Å, respectively (in **2**). The analogous protonation model is

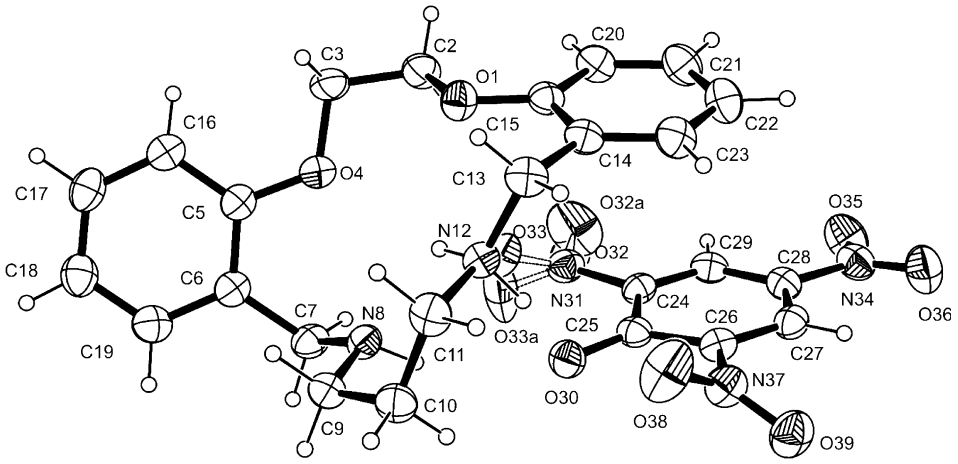

Fig. 3. ORTEP [38] drawing of **1**. The thermal parameters are scaled at the 30% probability level. The bonds to the disordered atoms are dashed.

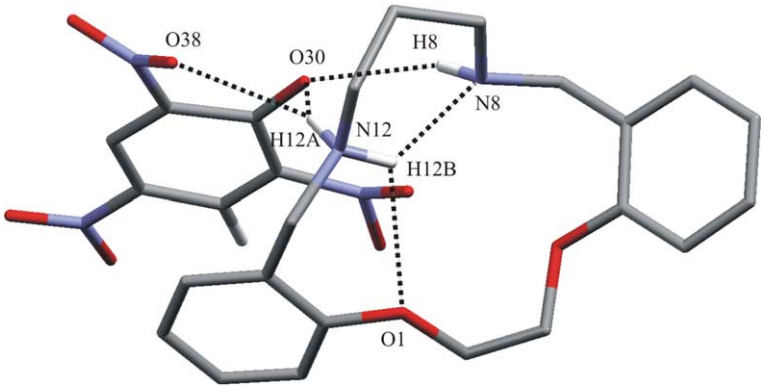

Fig. 4. Hydrogen bonding in **1**. Hydrogen atoms are omitted for clarity, except those included in hydrogen bonding. Donor, acceptor and hydrogen atoms involved in hydrogen bonds are labelled. The protonated $N^{+}12H_2$ of the macrocycle is involved in two bifurcated hydrogen bonds: to picrate via N12–HA···O30 and N12–HA···O38, and with the same ligand through N12–HB···N8, and N12–H12B···O1. The additional hydrogen bond between the ligand and the anion is through N8–H···O30.

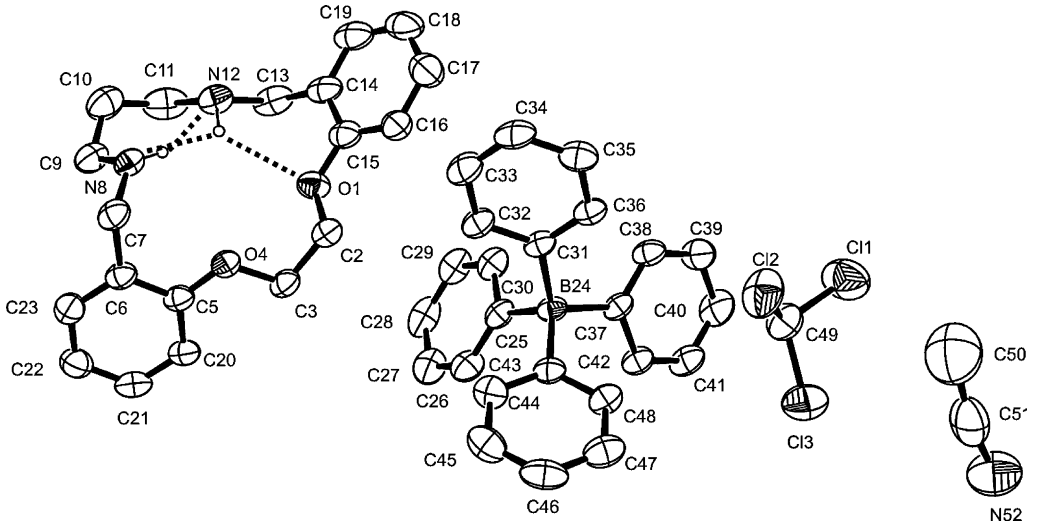

Fig. 5. ORTEP drawing of **7** with the hydrogen bonds marked by dashed lines. The thermal parameters are scaled to the 30% probability level. The hydrogen atoms are omitted for clarity except those included in hydrogen bonding.

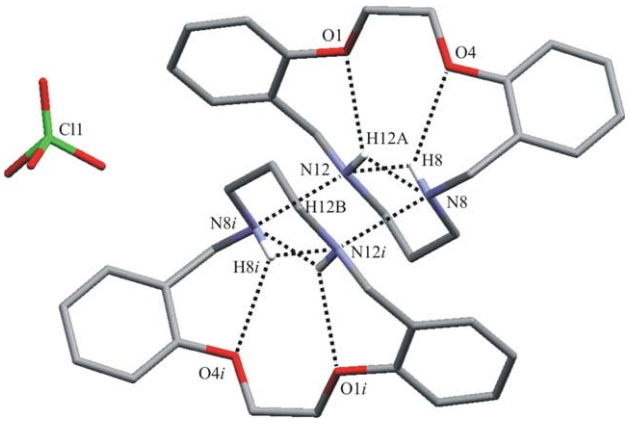

Fig. 6. Hydrogen bonding scheme in **2**. Hydrogen atoms are omitted for clarity, except those included in hydrogen bonding. Only non-hydrogen atoms included in hydrogen bonding are labelled.

present in the crystal structure of $[H(\mathbf{L})_2]PF_6$ salt (**4**, Fig. 8, Scheme 1). From the values of nitrogen to proton distances involved in hydrogen bonding, 1.33 (4) and 1.81(5) Å, the asymmetrical position of the proton is obvious but less pronounced than in the structure of **5** which exhibits the proton located on N12. Crystals of **4** include methanol as a solvent and they are sensitive to air. The low temperature data were collected but they were not of high quality. Disorder of a methanol molecule with two orientations and a partly occupied position (pp ~ 0.5) affects the data. In spite of these problems, protons were located in a difference Fourier map and interligand protonation, as observed in **2** and **3**, was confirmed with hydrogen bonding in **4** (Table 2). In the crystal of $[H(\mathbf{L})_2]SCN$, compound **5** (Fig. 9), the interligand protonation mode is analogous to that

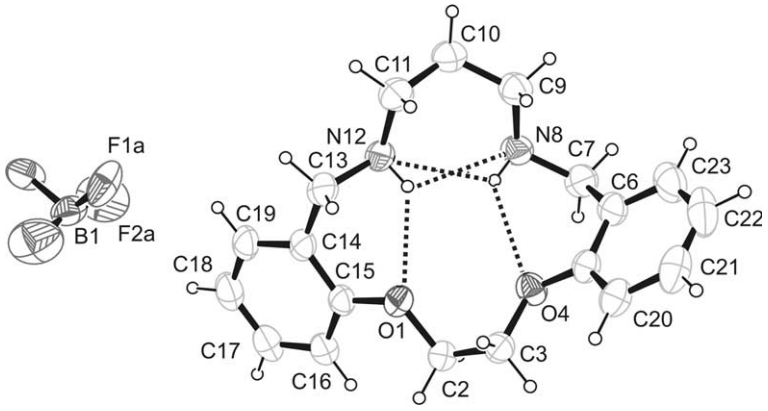

Fig. 7. ORTEP drawing of **3** with the hydrogen bonds. The thermal parameters are scaled at the 30% probability level.

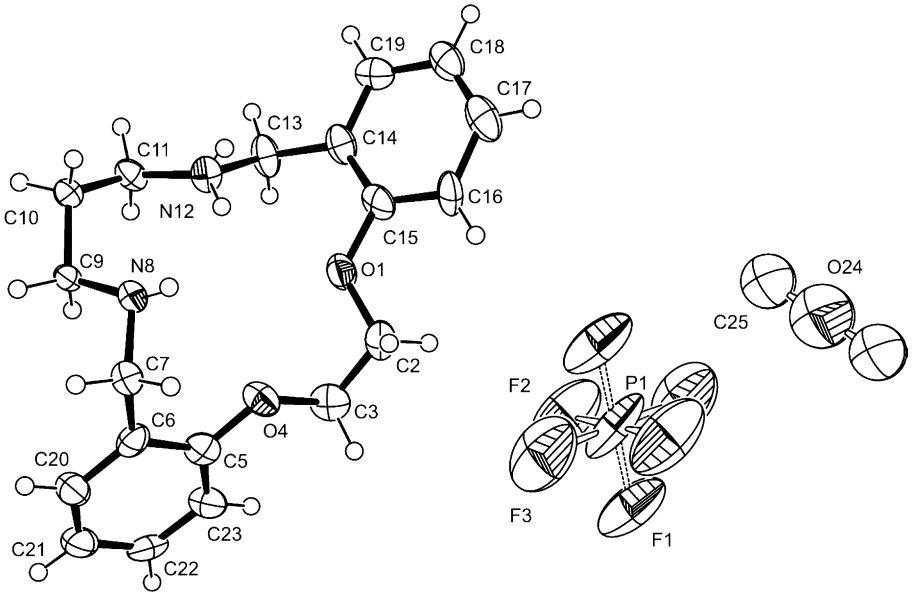

Fig. 8. ORTEP drawing of **4**. The thermal parameters are scaled to the 50% probability level.

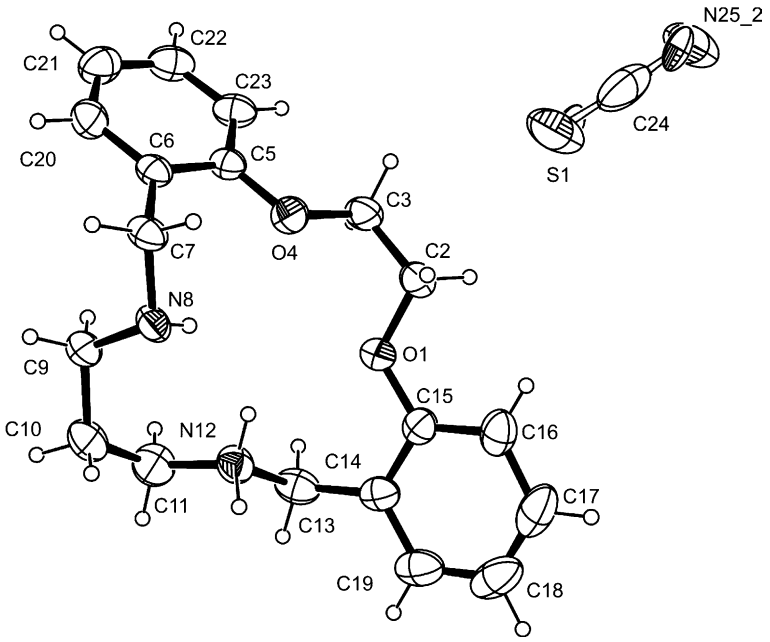

Fig. 9. ORTEP drawing of **5**. Thermal ellipsoids are scaled to the 30% probability level.

already described for **2**, also including the formation of the centrosymmetric hydrogen bonded macrocycle dimer (Scheme 1). However, the geometrical parameters of the hydrogen bonds are slightly different; the proton is located at N12 as can be seen from asymmetrical nitrogen to proton distances: N12–H12A, 1.23 (2) Å and N8···H12A, 1.74 (6) Å. The acceptor to donor distance $N^{+}12\cdots N8$ of 2.961 Å (Table 2) of two centrosymmetrically related ligands is shorter than the intraligand $N^{+}12\cdots N8$ distance of 3.025 Å.

The conformation of the macrocyclic rings defined as *anti–gauche–anti* for the sequence O–C–C–O and *anti–gauche–gauche–anti* for the N–C–C–C–N fragment is preserved in all the compounds studied. Different modes of protonation observed in the compounds and the presence of tetrahedral or octahedral anions of different polarity and the completely different thiocyanate anion do not affect the overall conformations of the O_2N_2-macrocycle (Fig. 10). The comparison with two transition metal complexes (Ni and Cu) coordinated by this type of ligand reveals significant differences in two torsion angles for the sequence C–N–C–C_{ar} due to the coordination of nitrogen to the metal [3,4]. The intraligand N···N, N···O and O···O distances are close to the sum of van der Waals radii in all the structures analysed. The optimization of the macrocycle ring conformation explains its stability under various steric and electronic influences. The same type of ring puckering is related to the narrow range of values of the dihedral angles between the two aromatic rings (from 59.7° to 69.7°).

The intraligand protonation in structures **1** and **7** results in intraligand hydrogen bonding (Table 2); however there are no common features in the crystal packing of **1** and **7**. The crystal structure of the picrate salt reveals interactions between the cation and anion via N–H···O hydrogen bonds (Table 2, Fig. 4). On the contrary, the crystal packing of **7** is dominated by van der Waals interactions, whereas hydrogen bonds only occur within the ligand (Fig. 5).

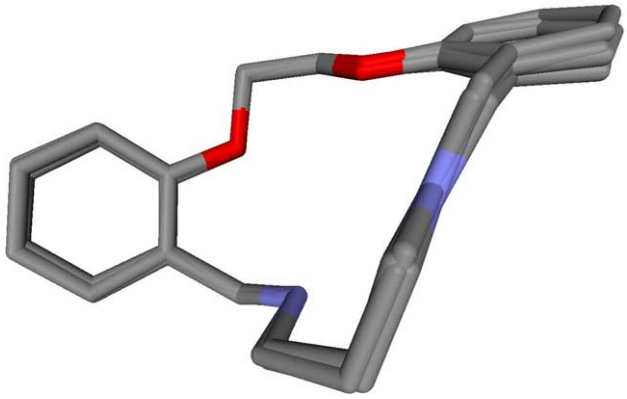

Fig. 10. Overlap of the O_2N_2-15-membered ring observed in the structures **1**–**5** and **7**.

The interligand protonation is characterized by formation of dimers via hydrogen bonds between two macrocycles (**2**–**5**). Channels occupied by anions separate these dimers. In the crystal structure of **2**, the perchlorate anion is involved in C2–H2B···O1A interactions [H···O1A, 2.54 Å, C2···O1A, 3.501(8) Å, C–H···O, 169°] using the methylene group (carbon attached to the macrocycle oxygen atom) creating an interaction between the cation and anion. According to the geometry

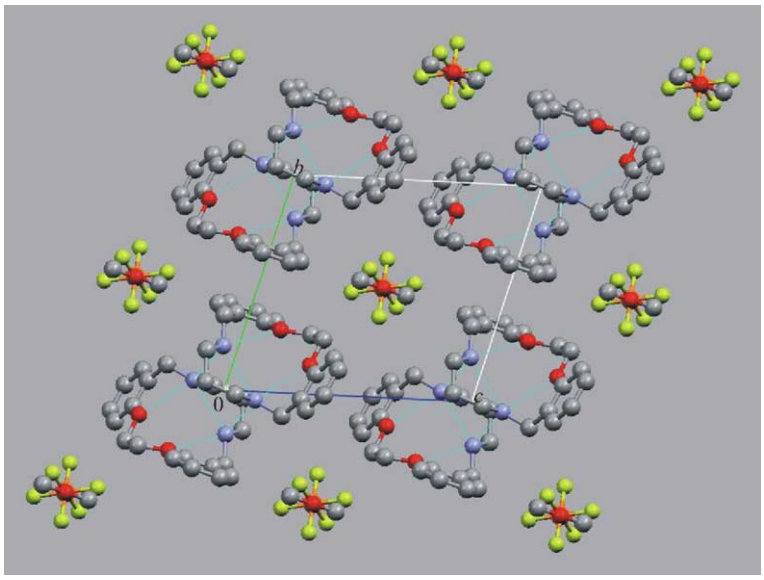

Fig. 11. The crystal packing of **4** with cation dimers arranged around the inversion centres of the corners of the triclinic unit cell and the channels between them occupied by PF_6 anions. Methanol molecules are in disorder.

observed this is the classical example of a C–H···O hydrogen bond [38]. The structures of **2** and **3** are isostructural, where the tetrahedral anions realize either C–H···O (**2**) or C–H···F (**3**) interactions connecting the macrocycle and the anion. In (**3**), the interaction with the cation is via C2–H2B···F1A [H2B···F1A ($1 + x$, y, $1 + z$), 2.39 Å, C2···F1A, 3.351(10) Å, C2–H2B···F1A 169°; H19···F1A, 2.53 Å, C19···F1A, 3.244(1) Å, C19–H19···F1A, 134°]. Anionic fluorine acts as the acceptor of the C–H donor group. There are controversial comments on the acceptor function of the covalently bound fluorine in organic compounds [35–37], whereas the fluoride acceptor function is well documented. The geometry of the observed contacts in the structure containing BF_4 (**3**) and PF_6 (**4**) anions can be characterized as the C–H···F interaction. However, the crystal packing of **4** reveals no contacts between cations and anions but involves the PF_6 anion and a solvent. The ligands arranged around the inversion centres at the corners of the triclinic unit cell leave the channel that is occupied by PF_6 anions (Fig. 11). A disordered methanol solvent molecule is located between two anions, realizing C–H···F contacts [C24–H24B···F3 ($1 - x$, y, z) with H···F3, 2.45 Å, C24···F3, 3.31(2) Å, C24–H···F3, 149° and C24–H24B···F2 ($1 - x$, $1 - y$, $1 - z$) with H···F2 2.39 Å, C24···F2, 3.29(2) Å, C24–H···F2, 154°]. Because of the disorder of the methanol, it was not possible to locate the hydrogen atom of the hydroxy group. Thus the hydrogen bond involving the OH group cannot be specified, but from the O25···F1 distance of 3.34 Å, a hydrogen bond can be expected. In the crystal structure of **5**, two dimeric cations are connected by a weak interaction of C–H···SCN^- generating a large ring. As usual, the thiocyanate anion is in disorder and unambiguous specification of S or N in the interaction with the cations is not possible.

4. General conclusions

The results of an investigation on the interaction of a 15-membered macrocycle containing an O_2N_2-donor set with a number of sodium salts in methanol show that affinity of this macrocycle for protons is much larger than for the sodium ion. This is primarily connected with the stereochemistry of this ligand. The type, number and arrangement of the donor atoms in the macrocyclic cavity are shown to have a great influence on the cation binding selectivity. The choice of anion in a salt-ligand system, along with the choice of solvent (methanol or acetonitrile) in the case of the tetraphenylborate compound, is important on the resulting inter- or intraligand protonation. The position of the proton depends on the size, shape and polarizability of the anion, which ranged from planar SCN^-, tetrahedral ClO_4^- and BF_4^-, octahedral PF_6^-, inorganic anions to bulky Pic^- and BPh_4^- organic anions. Transfer of proton either inside or outside the molecular cavity imposes different hydrogen bond networks in the various types of protonated macrocyclic salts.

5. Supplementary material

CCDC-243426, CCDC-243427, CCDC-243428, CCDC-243429, CCDC-243430 and CCDC-243431 contain the supplementary crystallographic data for this pa-

per. This data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retreiving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, Fax: +44 1223 336033; or deposit@ccdc.cam.ac.uk).

Acknowledgements

The financial support granted by the Croatian Ministry of Science, Education and Sports (Grants No. 0098035 and 0098036) is gratefully acknowledged. The authors thank Mr. Ž. Marinić (Ruđer Bošković Institute) for recording the NMR spectra and Prof. P. Traldi for valuable discussions.

Coordination properties of a dicompartmental ligand with tetra- and hexadentate coordination sites towards copper (II) and nickel (II) ions

K.R. Krishnapriya, M. Kandaswamy *

Department of Inorganic Chemistry, University of Madras, Guindy Campus, Chennai 600 025, India

Received 25 August 2004; accepted 18 October 2004

Abstract

A new dicompartmental ligand, *N*,*N*′-bis[2-iminomethyl-4-methyl-6-(4-methylpiperazin-1-ylmethyl)1-hydroxybenzene]1,8,naphthalene (H_2L) possessing contiguous tetra- and hexadentate coordination sites has been synthesized in simple route by the Schiff's base condensation of the precursor compound (PC) 2-formyl-4-methyl-6[4-methyl-6-(4-methylpiperazin-1-yl)methyl]phenol with 1,8-diaminonaphthalene.The mononuclear and binuclear Cu(II) and Ni(II) complexes of this ligand have been prepared and characterized by elemental analysis, IR, NMR and UV–Vis spectra.The electronic spectra of the mono- and binuclear Cu(II) complexes and mononuclear Ni(II) complex revealed one d–d transition in the region 570–600 nm, whereas the binuclear Ni(II) complex showed three d–d transitions at 800 nm ($\varepsilon \sim 95\ M^{-1}\ cm^{-1}$), 620 nm ($\varepsilon \sim 140\ M^{-1}\ cm^{-1}$) and 560 nm ($\varepsilon \sim 250\ M^{-1}\ cm^{-1}$), which were assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(P)$, and these spin allowed electronic transitions are characteristic of an octahedral Ni^{2+} centre.The electrochemical studies evidenced for the mononuclear Cu(II) complex shows a single quasireversible one electron wave at −0.83 V (E_{pc}).The binuclear Cu(II) complex shows two quasireversible one electron reduction waves at −0.68 V (E^1_{pc}) and − 1.35 V (E^2_{pc}) in the cathodic region.The mononuclear Ni(II) complex shows one quasireversible reduction potential at −0.80 V (E_{pc}) and the binuclear Ni(II) complex shows two irreversible reduction potentials at −1.10 V (E^1_{pc}) and − 1.40 V (E^2_{pc}) in the cathodic region.The room-temperature magnetic moment value for the mononuclear Cu(II) complex is $1.72\mu_B(\mu_{eff})$ and for the binuclear Cu(II), $2.05\mu_B(\mu_{eff})$. The mononuclear Ni(II) complex is square planar and diamagnetic whereas the binuclear Ni(II) complex has a magnetic moment value of 3.05 μ_B (μ_{eff}). Kinetic studies on the oxidation of pyrocatechol to *o*-quinone using the copper (II) complexes and hydrolysis of 4-nitrophenyl phosphate using the nickel (II) complexes as catalysts showed that the binuclear complexes have higher rate constant values than that of the corresponding mononuclear complexes.

Keywords: Compartmental ligands; Copper (II) and Nickel (II) complexes

1. Introduction

The term ''dinucleating ligands'' was first introduced in 1970 by Robson [1] to describe the class of polydentate chelating ligands, able to bind simultaneously two metal ions. Since then, a very large number of such ligands have been designed, and their coordination compounds have been thoroughly investigated.

Among the many different types of dinucleating ligands, the phenol-based compartmental ligands attracted particularly wide attention of scientists. The term ''compartmental'' was introduced to indicate a

doi:10.1016/j.poly.2004.10.010

ligand containing two adjacent, but dissimilar coordination sites [2]. Particular interest in this type of ligand resulted from the recent recognition of the asymmetric nature of a number of dimetallic biosites [3,4]. Understanding of the ability of individual metal ions to play possibly different functions in dinuclear sites in metalloenzymes led to the design of a great number of asymmetric ligands where two compartments would provide a different coordination surrounding for the two metal ions.

Complexes of dicompartmental ligands with hexa- and tetradentate coordination sites were sparse; only three types of ligands have been reported in the literature (**I**–**III**, Fig. 1) [5–8]. Thus, in the present work, we have synthesized a new dicompartmental ligand (H_2L) by the Mannich base reaction followed by the Schiff's base condensation in a simple route, which contains a hexa-(N_4O_2) and tetradentate (N_2O_2) coordination site. Using this dicompartmental ligand (H_2L), mono- and homobinuclear Cu(II) and Ni(II) complexes were synthesized and their spectral, magnetic, electrochemical and catalytic properties were studied.

2. Experimental

2.1. Physical measurements

Elemental analysis was carried out on a Carlo Erba model 1106 elemental analyzer. ^{1}H NMR and ^{13}C NMR spectra were recorded using a model FX-80-Q Fourier transition NMR spectrometer. IR spectra were recorded on a Hitachi model 270-50 spectrophotometer on KBr discs in the wavenumber range of 4000–250 cm^{-1}. Electronic spectral studies were conducted on a Hitachi model 320, spectrophotometer in the wavelength range of 200–800 nm. Molar conductivity was measured with an Elico model SX 80 conductivity bridge, using a freshly prepared solution of the complex in DMF. Cyclic voltammograms were obtained on CHI600A electrochemical analyzer. The measurements were carried out under oxygen free conditions using a three-electrode cell, in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and a platinum wire was used as the auxiliary electrode. A ferrocene/ferrocenium(1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple, under the experimental conditions, is 470 mV in dimethylformamide (DMF) and the ΔE_p value for Fc/Fc^+ is 70 mV. Tetra(*n*-butyl) ammonium perchlorate was used as the supporting electrolyte. The catalytic studies of the copper (II) and nickel (II) complexes were studied by taking 10^{-3} M solutions of the complexes in DMF and treating them with 10^{-1} M solutions of pyrocatechol and 4-nitrophenyl phosphate respectively in the presence of air. The reaction was followed spectrophotometrically by choosing the strongest absorbance of the *o*-quinone for the Cu(II) complexes at 390 nm and the 4-nitrophenolate anion for the Ni(II) complexes at 420 nm, and monitoring the increase in the absorbance at these wavelengths as a function of time. A plot of $\log(A_\infty/A_\infty - A_t)$ versus time was made for mono- and binuclear Cu(II) and Ni(II) complexes and the initial rate constant values were calculated.

2.2. Materials

5-Methylsalicylaldehyde was prepared by the literature method [9]. Tetra(*n*-butyl) ammonium perchlorate (TBAP), used as the supporting electrolyte in the electrochemical measurements, was purchased from Fluka and recrystallized from hot methanol. (*Caution!* TBAP is potentially explosive; hence, care should be taken in the handling of the compound). All other chemicals and solvents were of analytical grade and used as received.

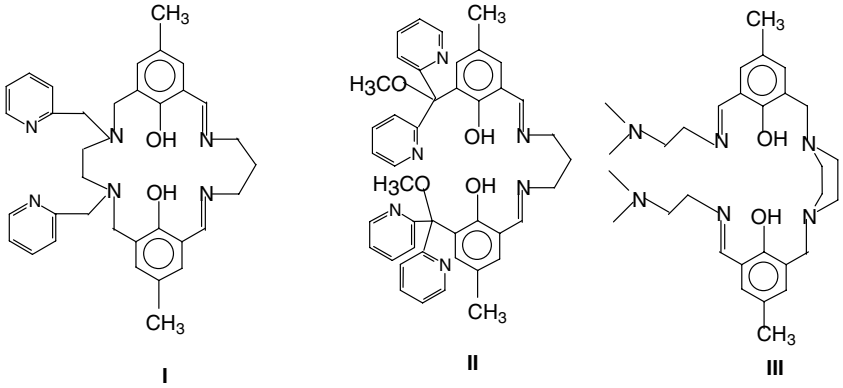

Fig. 1. (**I**)–(**III**) Examples of dicompartmental ligands reported in the literature.

2.3. Synthesis of 2-formyl-4-methyl-6[4-methyl-6-(4-methylpiperazin-1-yl)methyl] phenol (precursor compound PC)

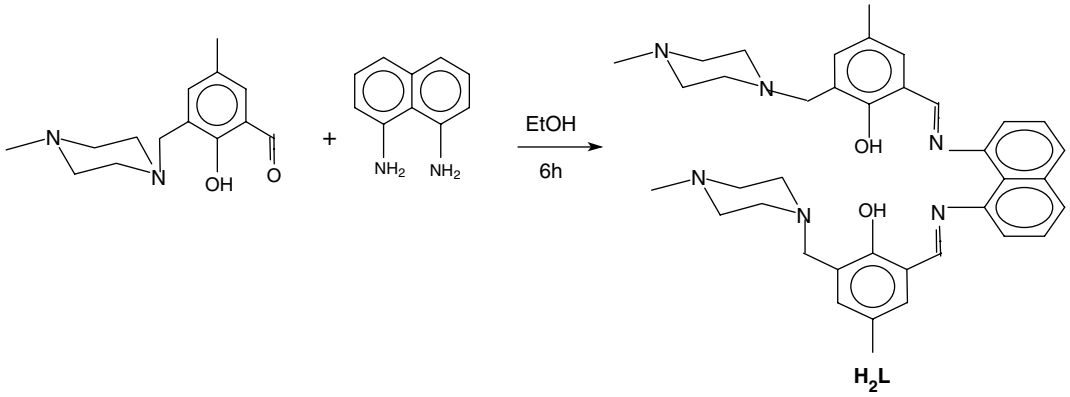
Precursor compound PC was prepared by following the procedure in the literature [10].

2.4. Synthesis of N,N′-bis[2-iminomethyl-4-methyl-6-(4-methylpiperazin-1-yl methyl)1-hydroxybenzene]1,8, naphthalene (the dicompartmental ligand, H_2L)

The dicompartmental ligand (H_2L) was prepared by the dropwise addition of a solution of the precursor compound, PC (2.48 g, 0.01 mol) in ethanol (30 ml) to a stirred solution of 1,8-diaminonaphthalene (0.79 g, 0.005 mol) in ethanol (30 ml). After the addition was completed, the stirring was continued for a further hour. The solution was then refluxed on a water bath for 6 h and was allowed to cool by standing at room temperature. A brown coloured compound was recovered after removing the solvent by distillation under reduced pressure, which was then recrystallised from chloroform. (Scheme 1). Yield: 4.2 g (68%). M.p. 170 °C. *Anal*. Calc. for $C_{38}H_{46}N_6O_2$: C, 73.78; H, 7.44; N, 13.59. Found: C, 73.75; H, 7.46; N, 13.58%. ^{1}H NMR ($CDCl_3$, δ ppm): 2.56–2.74 (m, 16H, methylene protons), 2.59 (s, 4H, benzylic protons), 2.3 (s, 6H, Ar–CH_3), 2.06(s, 6H, –N–CH_3) 7.01–7.12 (m, 10H, Ar–H), 8.12 (s, 2H, CH=N), 10.1 (s, 2H, Ar–OH). Selected IR data (KBr, ν cm^{-1}): 3378, 1615, 1582. UV–Vis (λ_{max}, nm) (ε, M^{-1} cm^1) (CH_3CN): 345(45 000), 310(31 500), 275(23 500).

2.5. Synthesis of complexes

2.5.1. Synthesis of the [CuL](ClO$_4$) complex



To ligand H_2L (0.618 g, 1 mmol) dissolved in MeOH (30 ml) was added $Cu(ClO_4)_2\cdot 6H_2O$ (0.37 g, 1 mmol) dissolved in MeOH (20 ml), and the mixture was refluxed for 6 h. The resulting solution was evaporated to half the volume and then allowed to cool by standing at room temperature (25 °C). After the slow evaporation of the solvent at 25 °C, the brown coloured compound obtained was recrystallised from ethanol. Yield: 0.60 g (77%). *Anal*. Calc. for $C_{38}H_{45}N_6O_2Cu(ClO_4$: C, 58.46; H, 5.77; N, 10.77; Cu, 8.16. Found: C, 58.45; H, 5.79; N, 10.76; Cu, 8.17%. Selected IR data (KBr, ν cm^{-1}): 1625, 1561, 1096, 626. Conductance in CH_3CN was given as $\Lambda_m = 82\ \Omega^{-1}\,mol^{-1}\,cm^2$. UV–Vis ($\lambda_{max,}$ nm) (ε, M^{-1} cm^1) (DMF): 600(141), 345(19 000), 275(10 400). $\mu_{eff} = 1.72\mu_B$.

2.5.2. Synthesis of the [NiL](ClO$_4$) complex

This Ni(II) complex was prepared by following the above procedure using the ligand H_2L (0.618 g, 1 mmol) and $Ni(ClO_4)_2\cdot 6H_2O$ (0.365 g, 1 mmol). An orange red compound was obtained on recrystallisation from ethanol. Yield: 0.56 g (72%). *Anal*. Calc. for $C_{38}H_{45}N_6O_2$-$Ni(ClO_4)$: C, 58.83; H, 5.80; N, 10.84; Ni, 7.57. Found: C, 58.82; H, 5.81; N, 10.83; Ni, 7.58%. ^{1}H NMR (DMSO-d_6, δ ppm): 2.06 (s, 6H, N–CH_3), 2.35 (s, 6H, Ar–CH_3), 3.40 (s, 2H, benzylic protons attached to $^+$NH), 2.59 (s, 2H, benzylic protons attached to N), 2.23–2.46 (m, 16H, methylene protons) 7.20–7.32 (m, 10H, Ar–H), 8.24 (s, 2H, CH=N). ^{13}C NMR (DMSO-d_6, δ ppm): 160 (s, 2C, CH=N), 110–140 (m, 22C, aromatic carbons), 46 (s, 1C, benzylic carbon attached to $^+$NH), 52 (s, 1C, benzylic carbon attached to N), 30 (s, 2C, methylene carbons attached to $^+$NH), 28 (s, 6C, methylene carbons attached to N–CH_3 and N–CH_2). Selected IR data (KBr, ν cm^{-1}): 1632, 1556, 1092, 628. Conductance in CH_3CN was given as $\Lambda_m = 87\ \Omega^{-1}\,mol^{-1}\,cm^2$. UV–Vis: ($\lambda_{max}$, nm) ($\varepsilon$, M^{-1} cm^{-1}) (DMF): 570(110), 345(12 100), 270(18 200).

2.5.3. Synthesis of the [Cu$_2$L](ClO$_4$)$_2$ complex

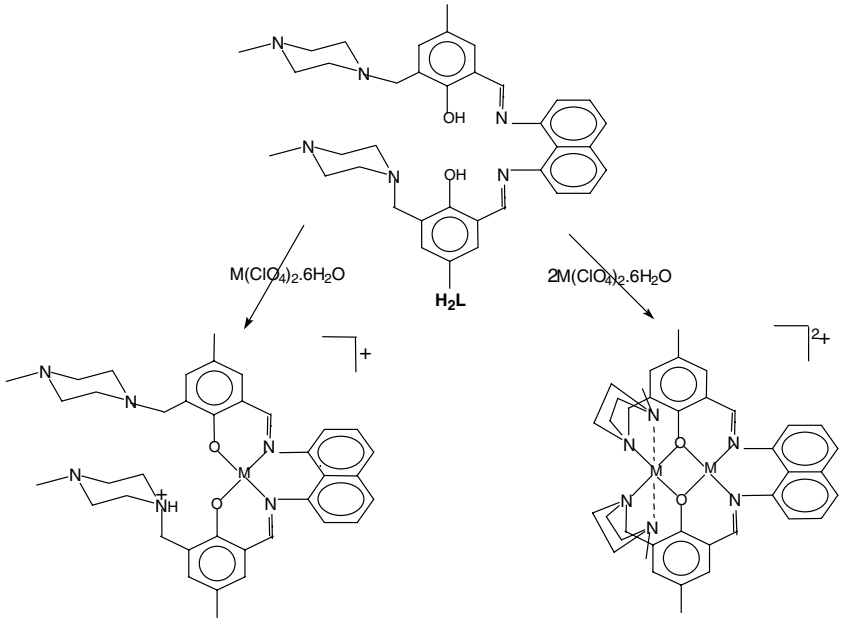
The binuclear Cu(II) complex was prepared by taking the ligand H_2L (0.618 g, 1 mmol) dissolved in MeOH (30

Scheme 1.

ml) and adding $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 2 mmol) dissolved in MeOH (20 ml) and refluxing for 6 h. A brown precipitate was collected on evaporation of the resulting solution to half the volume and then allowing cooling by standing at room temperature (25 °C). A brown coloured compound was obtained on recrystallisation from ethanol. Yield: 0.60 g (64%). *Anal.* Calc. for $C_{38}H_{44}N_6O_2Cu_2(ClO_4)_2$: C, 48.42; H, 4.67; N, 8.92; Cu, 13.47. Found: C, 48.40; H, 4.69; N, 8.91; Cu, 13.48%. Selected IR data (KBr, ν cm^{-1}): 1630, 1580, 1100, 625. Conductance in CH_3CN was given as $\Lambda_m = 128\ \Omega^{-1}mol^{-1}\,cm^2$. UV–Vis: ($\lambda_{max}$, nm) ($\varepsilon$, $M^{-1}\,cm^{-1}$) (DMF): 575(257), 350(28 200), 275(21 000). $\mu_{eff} = 2.05\mu_B$.

2.5.4. Synthesis of the $[Ni_2L](ClO_4)_2$ complex

The $[Ni_2L](ClO_4)_2$ complex was prepared by following the above procedure using $Ni(ClO_4)_2 \cdot 6H_2O$ (0.73 g, 2 mmol). An orange red coloured compound was obtained on recrystallisation from ethanol. Yield: 0.70 g (75%). *Anal.* Calc. for $C_{38}H_{44}N_6O_2Ni_2(ClO_4)_2$: C, 48.91; H, 4.72; N, 9.01; Ni, 12.59. Found: C, 48.90; H, 4.74; N, 9.00; Ni, 12.58%. Selected IR data (KBr, ν cm^{-1}): 1630, 1554, 1100, 622. Conductance in CH_3CN was given as $\Lambda_m = 140\ \Omega^{-1}\,mol^{-1}\,cm^2$. UV–Vis: ($\lambda_{max}$, nm) ($\varepsilon$, $M^{-1}\,cm^{-1}$) (DMF): 800(95), 620(140), 560(250), 350(19 000), 280(25 200). $\mu_{eff} = 3.05\mu_B$.



3. Results and discussion

A novel dicompartmental ligand (H_2L) with tetra- and hexadentate coordination sites has been synthesized (Scheme 1) and characterized. Using this dicompartmental ligand (H_2L) mono- and binuclear Cu(II) and Ni(II) complexes were prepared as shown in Scheme 2. The complexes were characterized by spectral studies. Their magnetic, electrochemical and catalytic behaviors are discussed.

3.1. Spectral studies

The IR spectrum of the dicompartmental ligand (H_2L) shows a ν(C=N) peak at 1625 cm^{-1}, and the absence of a ν(C=O) peak around 1700 cm^{-1} is indicative of Schiff's base condensation. The IR spectra of all the complexes show ν(C=N) bands at 1620–1640 cm^{-1} [11] and it is found that the ν(C=N) bands in the complexes are shifted by about 15–20 cm^{-1} to the lower energy regions compared to the free ligand (H_2L). This phenomenon appears to be due to the coordination of the azomethine nitrogens to the metal ion [12–14]. Also, a broad ν(OH) band of free ligand at 3378 cm^{-1} disappears on complexation. The peaks around 1100 and 620 cm^{-1} indicates the presence of perchlorate ions in the complexes. Furthermore, there is no splitting of the 1100 cm^{-1} peak. This indicates that the perchlorate ions are not coordinated to the metal ions.

^1H NMR and ^{13}C NMR of the mononuclear Ni(II) complex in DMSO-d_6 solution shows that it is NMR active. The ^1H NMR spectrum of the free ligand shows a multiplet in the range 7.01–7.12 ppm due to aromatic protons, and O–H protons of the two phenolic groups are at 10.1 ppm. The azomethine protons in the free ligand appear at 8.12 ppm. The mononu-

Scheme 2.

clear Ni(II) complex shows the aromatic protons as a multiplet in the range 7.20–7.32 ppm and the azomethine protons are shifted downfield at about 8.24 ppm, and the phenolic O–H disappears. These observations suggest that the dicompartmental ligand coordinates to the Ni(II) atom through the charged phenolic oxygen and the nitrogen atoms of azomethine groups of the N_2O_2 compartment in its mononuclear complex.

3.2. Electronic absorption spectroscopy

The electronic spectrum of the dicompartmental ligand (H_2L) in CH_3CN shows absorption bands at 345, 310 and 275 nm. These bands are indicative of naphthalene and other chromophore moieties present in the ligand. The electronic spectra of the mono- and binuclear Cu(II) complexes and the mononuclear Ni(II) complex showed three main transitions. The electronic spectra of the Cu(II) complexes show a d–d transition in the region 570–600 nm and the mononuclear Ni(II) complex shows one d–d transition at 570 nm. A moderately intensive band observed in the range of 340–350 nm is due to a ligand-to-metal charge transfer transition, and the strong band observed in the range of 270–280 nm is due to an intraligand charge transfer transition [15] for these complexes. The binuclear Ni(II) complex shows three d–d transitions at 800 nm ($\varepsilon \sim 95$ $M^{-1}\,cm^{-1}$), 620 nm ($\varepsilon \sim 140$ $M^{-1}\,cm^{-1}$) and 560 nm ($\varepsilon \sim 250$ $M^{-1}\,cm^{-1}$), assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ spin allowed electronic transitions, which are characteristic of Ni^{2+} in an octahedral site [16,17].

3.3. Magnetic studies

The room-temperature magnetic studies of the mononuclear Cu(II) complex resulted in a magnetic moment value of $1.72\mu_B$, which is very close to the spin-only value ($1.73\mu_B$) for complexes that have one Cu(II) ion [18] with a single unpaired electron sited in an essentially $d_{x^2-y^2}$ orbital. The observed room-temperature magnetic moment value for the binuclear Cu(II) complex is found to be $2.05\mu_B$ for the binuclear entity, suggesting the presence of antiferromagnetic coupling between the two Cu(II) ions [7]. The mononuclear Ni(II) complex has a square planar geometry and is diamagnetic [18]. The binuclear Ni(II) complex has a magnetic moment value of $3.05\mu_B$ (μ_{eff}), characteristic of Ni^{2+} in an octahedral site [16,19].

3.4. Electrochemistry

Conductivity measurements [20] of the mononuclear Cu(II) and Ni(II) complexes in DMF resulted in Λ_m values in the range of 80–90 $\Omega^{-1}\,mol^{-1}\,cm^2$, which indicates that they are of the 1:1 electrolyte type, and the binuclear complexes show Λ_m values in the range of 125–140 $\Omega^{-1}\,mol^{-1}\,cm^2$ indicating that they are of 2:1 electrolyte type. The electrochemical properties of all the complexes reported in the present work were studied by cyclic voltammetry in DMF containing 10^{-1} M TBAP as a supporting electrolyte and the reduction potentials are summarized in Table 1. The cyclic voltammograms of the complexes are shown in Figs. 2 and 3.

3.4.1. Reduction process at negative potential

Reduction at negative potential is the usual trend observed for phenoxo copper and nickel complexes because of the electronegativity and hard nature of the phenoxide atoms in the ligand [21–23]. The cyclic voltammograms of mononuclear complexes at negative potential show a single electron transfer. The redox process

Table 1
Electrochemical data for the complexes (reduction at the cathodic potential region)

Complexes	E^1_{pc} (V)	E^1_{pa} (V)	$E^1_{1/2}$ (V)	ΔE (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E^2_{1/2}$ (V)	ΔE (mV)
$[CuL](ClO_4)$	−0.83	−0.60	−0.72	170				
$[Cu_2L](ClO_4)_2$	−0.68	−0.50	−0.59	180	−1.35	−1.15	−1.25	200
$[NiL](ClO_4)$	−0.80	−0.64	−0.72	160				
$[Ni_2L](ClO_4)_2$	−1.10				−1.40			

Measured by CV at 100 mV s^{-1}. E vs. Ag/AgCl conditions: GC working and Ag/AgCl reference electrodes; supporting electrolyte, TBAP; concentration of complex, 1×10^{-3} M, concentration of TBAP, 1×10^{-1} M.

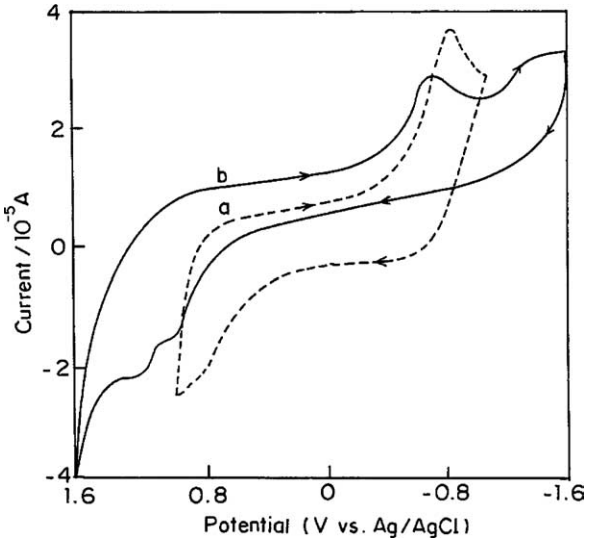

Fig. 3. Cyclic voltammograms of the nickel (II) complexes: (a) $[NiL](ClO_4)$ and (b) $[Ni_2L](ClO_4)_2$.

is quasireversible in nature as is evident from the criteria: the $E_{1/2}$ values are independent of scan rate; E_P increases with increasing scan rate (25, 50, 75 and 100 mV s^{-1}) and is always greater than 60 mV; i_{pc}/i_{pa} are not the same at different scan rates.

The reduction potential of mononuclear Cu(II) is −0.83 V (E_{pc}) and the reduction process is found to be quasireversible. The binuclear Cu(II) complex is associated with two quasireversible reduction waves. The reduction potentials are found to be −0.68 V (E^1_{pc}) and − 1.35 V (E^2_{pc}). Controlled potential electrolysis also carried out for the complexes at 100 mV s^{-1} more negative consumed one electron per molecule ($n = 0.95$), which reports that each couple corresponds to a one electron transfer process. So, the two redox processes are assigned as follows:

$$Cu^{II}Cu^{II} \rightleftharpoons Cu^{II}Cu^{I} \rightleftharpoons Cu^{I}Cu^{I}$$

The mononuclear Ni(II) complex of the same ligand undergoes a quasireversible reduction at −0.80 V and the binuclear Ni(II) complex shows irreversible reduction potentials at −1.10 V (E^1_{pc}) and − 1.40 V (E^2_{pc}).

The reduction potentials of the mononuclear complexes are comparable to those observed for the $[M(salen)]^{2+}$ complexes and may suggest that the couple observed for the mononuclear complexes refers to the reduction of the metal (II) ion in the naphthalene (N_2O_2) compartment.

The electrochemical studies of similar types of complexes with hexa- and tetradentate coordination sites reported in the literature [24] suggest that the formal reduction potentials of the binuclear complexes may be assigned to the metal ion in the first binding site, that is the naphthalene compartment. The second reduction potentials are comparable to that of the metal in the 6-coordination (N_4O_2) site.

3.4.2. Oxidation process at anodic potential

The mononuclear Ni(II) complex shows an irreversible oxidation wave in positive potentials at +0.85 V (E_{pa}). The binuclear Ni(II) complex shows two step single electron transfer processes in the potential range +1.0 V (E^1_{pa}) and + 1.2 V (E^2_{pa}) and both are found to be irreversible in nature.

3.5. Kinetic studies

3.5.1. Oxidation of pyrocatechol

A great interest has developed in the investigation of the catechol oxidase activity of copper complexes using suitable model substrates, which can serve as functional mimics for catechol oxidases or as new biomimetic catalysts for oxidation reactions [25–32]. The catecholase activity of mono- and binuclear copper (II) complexes synthesized in the present work were carried out using pyrocatechol as the model substrate. The course of the reaction was followed spectrophotometrically for nearly 45 min at regular time intervals of 5 min. The slope was determined by the method of initial rates by monitoring the growth of the 390 nm band of the product *o*-quinone. A linear relationship for initial rate and the complex concentration obtained for the copper complexes shows a first order dependence on the complex concentration for the systems. The rate constants for the mono- and binuclear copper complexes were found to be 4.6×10^{-3} and 1.52×10^{-2} min^{-1}, respectively. The kinetic plot of $\log(A_\infty/A_\infty - A_t)$ versus time of catecholase activity is shown in Fig. 4. It is found that the binuclear

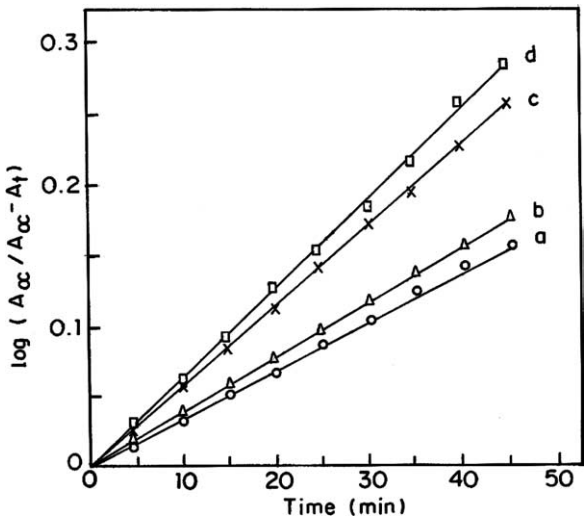

Fig. 4. The kinetic plot for the oxidation of pyrocatechol and hydrolysis of 4-nitrophenyl phosphate: (a) $[NiL](ClO_4)$, (b) $[CuL](ClO_4)$, (c) $[Ni_2L](ClO_4)_2$ and (d) $[Cu_2L](ClO_4)_2$.

Cu(II) complex show higher reactivity than its mononuclear complex. This is due to the fact that the oxidation of pyrocatechol to *o*-quinone requires the presence of two metal ions in close proximity [26]; hence the rate constant for the binuclear copper complex is high.

3.5.2. Hydrolysis of 4-nitrophenyl phosphate

The catalytic activity of the mono- and binuclear Ni(II) complexes on the hydrolysis of 4-nitrophenyl phosphate was determined spectrophotometrically by monitoring the increase of the 4-nitrophenolate anion characteristic absorption at 420 nm over time in DMF at 25 °C. The nickel (II) complexes were able to hydrolyze *p*-nitrophenyl phosphate to the 4-nitrophenolate anion. The rate constants were calculated by the initial rate method. The rate constants for the catalytic hydrolysis of 4-nitrophenyl phosphate catalyzed by the mono- and binuclear nickel (II) complexes were found to be 8.8×10^{-3} and 1.3×10^{-2} min^{-1}, respectively. The kinetic plot of $\log(A_\infty/A_\infty - A_t)$ versus time for the nickel (II) complexes is shown in Fig. 4.

Upon comparing the kinetics of the mononuclear and binuclear nickel (II) complexes, the rate constants were found to be higher for the binuclear analogue. This is due to the fact that the mononuclear complex proceeds via a SN_1 type of reaction followed by deprotonation of the OH group and formation of an intermediate with the phosphate group and then cleavage of the bond to form the phenolate anion, along with hydroxylation of the phosphate group.

The binuclear nickel (II) complex followed a concerted SN_2 type of mechanism where the nucleophile OH adds to one of the nickel ions and the phosphate group simultaneously gets bounded to another nickel ion. Here, bond formation and bond breakage occurs at the same time. This kind of mechanism requires two metal ions in close proximity. Convincingly, the rate constants are also higher than the corresponding mononuclear complexes. The mechanism of action has already been explained with the help of model complexes [33,34].

From the above studies we conclude that, in the mononuclear complexes, the metal ions prefer the tetradentate compartmental site rather than the hexadentate site. This may be due to the stronger coordination behaviour of azomethine nitrogens in the tetradentate site than the tertiary nitrogens in the hexadentate compartmental site.

Abstract

The distorted tetrahedral $[M(OPPh_3)_4](SbCl_6)_2$ (M = Mg, Ca, Sr) are obtained from MCl_2, $OPPh_3$ and $SbCl_5$ in suitable solvent conditions, while Ba^{2+} gives $[Ba(OPPh_3)_5](SbCl_6)_2$. The chelating o-$C_6H_4(P(O)Ph_2)_2$ gives the tris complexes $[M\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$, while under similar conditions the stoichiometries of the products obtained using $Ph_2P(O)CH_2P(O)Ph_2$ vary with M; and products include the five-coordinate $[Mg\{Ph_2P(O)CH_2P(O)Ph_2\}_2(H_2O)](SbCl_6)_2$, the distorted octahedral $[M\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$ (M = Ca or Sr) and the seven-coordinate $[Sr\{Ph_2P(O)CH_2P(O)Ph_2\}_3(EtOH)](SbCl_6)_2$. Strontium is unusual in that both six- and seven-coordinate species are evident and may be isolated depending upon the reaction conditions. These are the first reported Group 2 complexes with bidentate phosphine oxides and there are no other phosphine oxide complexes with Sr or Ba. Crystal structures are reported for $[Mg(OPPh_3)_4](SbCl_6)_2\cdot CH_2Cl_2$, $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2\cdot 2CH_2Cl_2$ and $[Sr\{Ph_2P(O)CH_2P(O)Ph_2\}_3(EtOH)](SbCl_6)_2\cdot 0.45CH_2Cl_2$ The compounds isolated show significant dependence upon the charge:radius ratio of the metal and the steric bulk and rigidity of the ligand.

Keywords: Homoleptic phosphine oxide complexes; Alkaline earth dications

1. Introduction

The coordination chemistry of especially the heavier alkaline earth cations is among the least studied of the metal ions in the periodic table. Examples of complexes involving these closed shell dications with neutral ligands are dominated by those with crown ethers and their derivatives while complexes with anionic diamine tetracarboxylate ligands are also well known [1,2], although these are hugely outnumbered by crown ether complexes of the Group 1 metal ions. The role of the lighter Mg^{2+} ion in chlorophyll has been the stimulus for the majority of studies of Mg-containing complexes, many of which have been prepared as model compounds [1,2].

In recent work, we have shown that homoleptic phosphine oxide complexes involving the Group 3 metal ions Sc^{3+}, Y^{3+} and La^{3+}, also closed shell ions, exhibit a surprisingly wide speciation, with considerable dependence upon both the steric bulk of the ligand and the charge: radius ratio of the metal [3–6]. There are some early reports of phosphine oxide complexes with Mg^{2+} and Ca^{2+}, including $[M(OPPh_3)_4]^{2+}$, although these are mainly part of wider compilations and characterisation

data are very limited [7,8], while Rodley and co-workers [9,10] have reported crystal structure analyses for the magnesium cations $[Mg(OPMe_3)_5]^{2+}$ and $[Mg(OPMe_3)_5(OH_2)]^{2+}$.

In order to probe further the effect of the charge:radius ratio upon the M-phosphine oxide coordination we have synthesised and spectroscopically characterised a systematic series of Group 2 metal (Mg, Ca, Sr and Ba) complexes with the phosphine oxide ligands $OPPh_3$, $Ph_2P(O)CH_2P(O)Ph_2$ and o-$C_6H_4(P(O)Ph_2)_2$. The results are reported here together with crystal structures of representative examples, including the first structure of a strontium phosphine oxide complex and the first structure of a homoleptic phosphine oxide complex of calcium. The structures confirm the conclusions from the spectroscopic assignments.

2. Results and discussion

The tetrakis complexes $[M(OPPh_3)_4](SbCl_6)_2$ were obtained in good yield by treatment of dehydrated MCl_2 (M = Mg or Ca) with four molar equivalents of $OPPh_3$ in anhydrous CH_2Cl_2 solution, with addition of two molar equivalents of $SbCl_5$ to abstract chlorine. There is no indication that these compounds take up solvent molecules or water into the coordination sphere, suggesting that despite the unusually low coordination number for Ca^{2+}, they are coordinatively saturated. This contrasts with the previously studied $Mg^{2+}/OPMe_3$ system where both the five-coordinate $[Mg(OPMe_3)_5]^{2+}$ and the six-coordinate $[Mg(OPMe_3)_5(OH_2)]^{2+}$ have been structurally characterised (see below) even with the small Mg(II) ion [9,10]. While the ionic radii of Ca^{2+} and Y^{3+} are the same (approximately 106 pm), [1] we have shown previously that with Y^{3+} we can obtain the six-coordinate $[YCl(OPPh_3)_5]^{2+}$, hence it is possible to accommodate more ligands on size grounds [4]. It is therefore likely that the lower charge:radius ratio of Ca^{2+} disfavours higher coordination numbers. The corresponding strontium and barium complexes cannot be obtained by direct addition of $SrCl_2$, $OPPh_3$ and $SbCl_5$ in CH_2Cl_2. Under these conditions the major product is $[SbCl_5(OPPh_3)]$ on the basis of IR and ^{31}P NMR spectroscopic measurements [11]. This difficulty was alleviated by forming $Sr(SbCl_6)_2$ in MeCN solution initially (from anhydrous $SrCl_2$ and $SbCl_5$) [12] with subsequent addition of $OPPh_3$ giving $[Sr(OPPh_3)_4](SbCl_6)_2$. Using $Ba(SbCl_6)_2$ gave the 5:1 species $[Ba(OPPh_3)_5](SbCl_6)_2$, probably as a consequence of the much larger radius of Ba(II). Unlike the lighter Group 2 analogues, this barium compound is poorly soluble in CH_2Cl_2, but dissolves readily in MeCN in the presence of added $OPPh_3$ (without incorporation of solvent into the coordination sphere). These formulations follow from microanalysis and from the IR spectra which show a small low frequency shift in the P=O stretching vibration (ca. 10 cm^{-1}) and a single strong absorption at ca. 345 cm^{-1}, attributed to the octahedral $SbCl_6^-$ anion. The ^{31}P NMR spectra show a single resonance in each with a small high frequency coordination shift ($\delta^{31}P$ for $OPPh_3$ = +28).

Crystals of $[Mg(OPPh_3)_4](SbCl_6)_2 \cdot CH_2Cl_2$ were obtained by diffusion of diethyl ether into a solution of the complex in CH_2Cl_2. The structure shows (Fig. 1, Table 1) four O-bonded $OPPh_3$ ligands coordinated in an almost regular tetrahedral arrangement to the central Mg^{2+} cation. The Mg–O distances are in the range 1.890(2)–1.919(2) Å, while the P–O distances are 1.507(2)–1.513(2) Å. The only other crystallographically characterized Mg(II) phosphine oxide complexes are the five-coordinate $[Mg(OPMe_3)_5](ClO_4)_2$ (d(Mg–O) = 1.94(2)–2.06(2) Å) and the six-coordinate, distorted octahedral $[Mg(OPMe_3)_5(OH_2)](ClO_4)_2$ (d(Mg–O(P)) = 2.06(3)–2.11(3) Å, d(Mg–O(H_2)) = 2.19(2) Å) [9,10]. The significantly shorter Mg–O bond distances in the $[Mg(OPPh_3)_4]^{2+}$ cation almost certainly reflect the lower coordination number in this species. The Mg–O–P angles show surprising variation, taking values in the range 139.41(15)°–163.08(16)°, probably mainly due to the steric influence and packing of the phenyl rings.

We have also examined the coordination chemistry of the diphosphine dioxides $Ph_2P(O)CH_2P(O)Ph_2$ and o-$C_6H_4(P(O)Ph_2)_2$ with the alkaline earth chlorides. Using $MgCl_2$, three molar equivalents of $Ph_2P(O)CH_2$-

$P(O)Ph_2$ and two molar equivalents of $SbCl_5$ in CH_2Cl_2 solution, followed by precipitation with Et_2O gives the five-coordinate $[Mg\{Ph_2P(O)CH_2P(O)Ph_2\}_2(OH_2)](SbCl_6)_2\cdot Et_2O$ with a coordinated water molecule (presumably arising from traces of adventitious water in the solvent during recrystallisation). The IR spectrum shows ν(P=O) at 1179 cm^{-1} and ionic $SbCl_6^-$ at 346 cm^{-1}, as well as confirming the presence of the coordinated water, while the ^1H NMR spectrum shows 1 mol of Et_2O solvent per two diphosphine dioxide ligands. The $^{31}P\{^1H\}$ NMR spectrum is a singlet at 34.0 ppm, consistent with a small high frequency coordination shift ($\delta^{31}P$ for $Ph_2P(O)CH_2P(O)Ph_2$ itself is +25). The six-coordinate, tris-chelated calcium complex $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$ is obtained similarly, with precipitation achieved using ethanol. The ^1H NMR and IR spectra, as well as microanalysis indicate that there is no incorporation of EtOH in this product, and $\delta(^{31}P)$ is 32.6 ppm. For strontium both the six-coordinate $[Sr\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$ and the seven-coordinate $[Sr\{Ph_2P(O)CH_2P(O)Ph_2\}_3(EtOH)](SbCl_6)_2$ (see crystal structure below) can be obtained, the former by concentrating the CH_2Cl_2 solution until precipitation occurs, the latter by adding EtOH to initiate precipitation. The $^{31}P\{^1H\}$ NMR spectra are very slightly different, however the presence of EtOH is clearly evident in the ^1H NMR and IR spectra of the latter. No product could be isolated from reaction of $Ba(SbCl_6)_2$ with $Ph_2P(O)CH_2P(O)Ph_2$ in either MeCN or CH_2Cl_2 solution, consistent with a much reduced affinity of Ba^{2+} for the phosphine oxide compared to the lighter metals. This series of compounds reveals a clear variation in coordination number as Group 2 is descended, with Sr^{2+} representing a cross-over point were both six- and seven-coordinate species are accessible with this ligand.

The coordination environment at Ca^{2+} was confirmed from a crystal structure determination on $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2\cdot 2CH_2Cl_2$, the first structural study on a homoleptic phosphine oxide complex of Ca^{2+}. The crystals obtained were very small and hence the diffraction data weak. However, the structure shows (Fig. 2, Table 2) the Ca atom coordinated to all six O atoms of three chelating diphosphine dioxide ligands to give a distorted octahedral geometry. The Ca–O bond distances of 2.283(6)–2.332(6) Å are markedly longer (by ca. 0.4 Å) than d(Mg–O) in the $[Mg(OPPh_3)_4]^{2+}$ described earlier, reflecting both the increase in radius on going down Group 2 and the increase in coordination number. The O–Ca–O angles within the chelate rings are ca. 85°, while the Ca–O–P angles are all in the range 130°–136°. The distorted octahedral tris chelate observed here contrasts with that observed for $[Na\{Ph_2P(O)CH_2P(O)Ph_2\}_3]X$ which is precisely trigonal prismatic (X = Cl: d(Na–O) = 2.4566(14), d(P–O) = 1.4883(13) Å) [13–15]. The only other reported structure of a Ca^{2+} phosphine oxide species is the organometallic cation $[Ca(\eta^5\text{-}C_5Me_5)(OPPh_3)_3]^+$ which shows similar Ca–O bond lengths, d(Ca–O) = 2.254(2), 2.282(1), 2.300(2) Å [16].

Crystals of $[Sr(EtOH)\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2\cdot 0.45CH_2Cl_2$ were obtained by layering a CH_2Cl_2 solution of the complex with EtOH and cooling to ca. −18 °C in the freezer. The structure shows (Fig. 3, Table 3) the Sr atom coordinated to three chelating diphosphine dioxide ligands, with the EtOH ligand completing the coordination sphere. The Sr–O distances

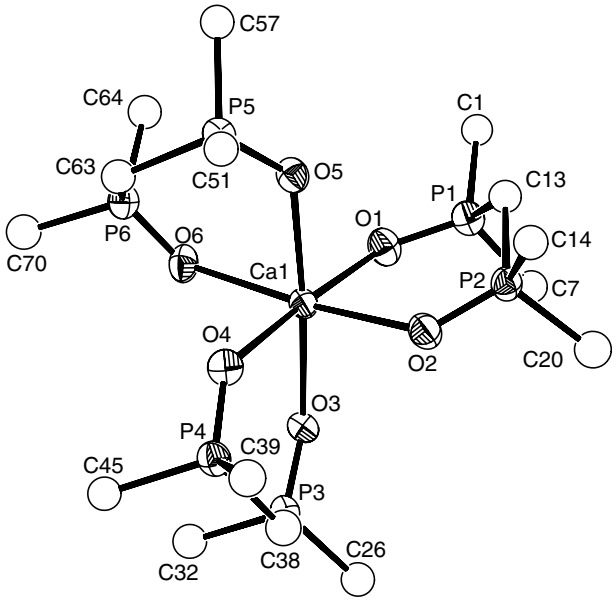

Fig. 2. View of the structure of the $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3]^{2+}$ cation with numbering scheme adopted. Ellipsoids are drawn at 50% probability. H atoms and phenyl rings (except the *ipso* C atoms) are omitted for clarity.

within the phosphine oxide coordination lie in the range 2.502(6)–2.597(6) Å, with the Sr–O(EtOH) distance being 2.573(6) Å . These are ca. 0.2 Å longer than *d*(Ca–O) in the six-coordinate $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3]^{2+}$ above. As expected on the basis of the seven-coordination, the O–Sr–O angles reveal much greater variation compared to the corresponding Ca species, those within the chelate rings are 72.2(2)°, 76.0(2)° and 76.5(2)°. The coordination environment approximates to a capped octahedron. This represents the first structural study of a Sr^{2+} phosphine oxide complex.

Similar reactions using the more rigid *o*-phenylene diphosphine dioxide, $o\text{-}C_6H_4(P(O)Ph_2)_2$, gives the compounds $[M\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$ (M = Mg, Ca

or Sr), all of which are six-coordinate, with no coordinated solvent. The spectroscopic properties parallel those for the compounds described earlier, with a small (ca. 10 cm^{-1}) low frequency shift in ν(P=O) and a small high frequency shift in $\delta(^{31}P)$ upon coordination ($\delta^{31}P$ for o-$C_6H_4(P(O)Ph_2)_2$ is +33). The compounds were also characterised by ^1H NMR spectroscopy and microanalysis. The occurrence of only the six-coordinated tris-chelates with this ligand may be a consequence of the increased rigidity of the o-phenylene-based ligand (we have shown that this plays a significant role in dictating the coordinating properties of other related 7-membered chelate ligands e.g. involving o-xylylene linkages which also show a greater tendency for chelation than their analogues with saturated aliphatic (C4) linkages) [17–19]. Using o-$C_6H_4(P(O)Ph_2)_2$ we were also able to obtain the Ba^{2+} complex, $[Ba\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$, although the poor affinity of Ba^{2+} for the phosphine oxide ligands is reflected in the tendency of this species to dissociate with loss of ligand in CH_2Cl_2 solution, readily precipitating Ba species with lower barium:phosphine oxide ratios. Hence recrystallisation was carried out in the presence of a small amount of added ligand. While the spectroscopic properties are in line with those of the lighter Group 2 analogues, the need for added ligand during recrystallisation meant that the microanalytical data were slightly higher in C, H than predicted.

3. Experimental

Infrared spectra were recorded as Nujol mulls between CsI plates using a Perkin–Elmer 983G spectrometer over the range 4000–200 cm^{-1}. ^1H NMR spectra were recorded at 300 K using a Bruker AM300 spectrometer. $^{31}P\{^1H\}$ NMR spectra were recorded using a Bruker DPX400 spectrometer operating at 162.0 MHz and are referenced to external 85% H_3PO_4. Microanalyses were undertaken by the University of Strathclyde microanalytical service.

Solvents were dried prior to use and all preparations were undertaken using standard Schlenk techniques under a N_2 atmosphere. The alkaline earth dichlorides were obtained from Aldrich and were dehydrated by strong heating in vacuo prior to use. The diphosphine dioxide ligands were obtained by oxidation of the parent diphosphines by either I_2/OH^- or SnI_4/O_2 according to the literature methods [20,21]. The CH_2Cl_2 was dried by distilling from CaH_2 prior to use.

3.1. $[Mg(OPPh_3)_4](SbCl_6)_2$

$MgCl_2$ (0.025 g, 0.26 mmol) was added to CH_2Cl_2 (10 cm^3). Four molar equivalents of $OPPh_3$ (0.297 g, 1.10 mmol) dissolved in CH_2Cl_2 (2 cm^3) was added, together with two molar equivalents of $SbCl_5$ (0.168 g, 0.56 mmol) in CH_2Cl_2 (5 cm^3). The reaction mixture was stirred for 72 h. The solvent was concentrated to ca. 3 cm^3 in vacuo to give a white solid which was collected by filtration and washed with diethyl ether. The product was then recrystallised from CH_2Cl_2/diethyl ether (yield 0.34 g, 70%). *Anal.* Calc. for $[C_{72}H_{60}Cl_{12}MgO_4P_4Sb_2]$: C, 47.9; H, 3.5. Found: C, 47.8; H, 3.2%. IR (Nujol mull): 1156 (P=O), 339 ($SbCl_6^-$) cm^{-1}. ^1H NMR ($CDCl_3$): 7.30–7.75 ppm (m, aromatic H). $^{31}P\{^1H\}$ NMR ($CH_2Cl_2/CDCl_3$): 41.6 ppm.

3.2. $[Ca(OPPh_3)_4](SbCl_6)_2$

Method as above, but using $CaCl_2$. A white solid was obtained upon addition of EtOH to a concentrated solution of the product in CH_2Cl_2 (yield 70%). *Anal.* Calc. for $[C_{72}H_{60}CaCl_{12}O_4P_4Sb_2]$: C, 47.5; H, 3.3. Found: C, 48.6; H, 3.0%. ^1H NMR ($CDCl_3$): 7.00–8.00 ppm (m, aromatic H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): 36.2 ppm. IR (Nujol mull): 1169 (P=O), 342 ($SbCl_6^-$) cm^{-1}.

3.3. $[Sr(OPPh_3)_4](SbCl_6)_2$

$SrCl_2$ (0.027 g, 0.17 mmol) was suspended in stirred MeCN (3 cm^3) and $SbCl_5$ (0.11 g, 0.37 mmol) was added, when the suspended strontium salt dissolved to give a clear solution. After 1 h, a solution of $OPPh_3$ (0.19 g, 0.68 mmol) in CH_2Cl_2 (5 cm^3) was added and the mixture stirred overnight. The solvent was removed in vacuo, and the white product recrystallised from CH_2Cl_2/diethyl ether. White solid (yield 0.28 g, 86%). *Anal.* Calc. for $[C_{72}H_{60}Cl_{12}O_4P_4Sb_2Sr]$: C, 46.2; H, 3.2. Found: C, 45.4; H, 3.3%. ^1H NMR ($CDCl_3$): 7.2–7.7 ppm (m, aromatic H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): 37.9 ppm. IR (Nujol mull): 1162 (P=O), 344 ($SbCl_6^-$) cm^{-1}.

3.4. $[Ba(OPPh_3)_5](SbCl_6)_2$

$BaCl_2$ (0.052 g, 0.25 mmol) was suspended in dry MeCN (15 cm^3), $SbCl_5$ (0.15 g, 0.5 mmol) added and the solution boiled gently until all the $BaCl_2$ had dissolved to give a clear solution. A solution of $OPPh_3$ (0.39 g, 1.5 mmol) in MeCN (10 cm^3) was added and the mixture stirred overnight. The solution was concentrated to ca. 5 cm^3, and the white solid filtered off, rinsed with MeCN (2 cm^3) and dried in vacuo. White solid (yield 0.35 g, 65%). *Anal.* Calc. for $[C_{90}H_{75}BaCl_{12}O_5P_5Sb_2]$: C, 49.2; H, 3.5. Found: C, 50.0; H, 3.5%. ^1H NMR ($CDCl_3$): 7.2–7.8 ppm (m, aromatic H). $^{31}P\{^1H\}$ NMR (MeCN): 31.0 (br) ppm. IR (Nujol mull): 1162sh, 1156 (P=O), 341 ($SbCl_6^-$) cm^{-1}.

3.5. $[Mg\{Ph_2P(O)CH_2P(O)Ph_2\}_2(H_2O)](SbCl_6)_2 \cdot Et_2O$

Anhydrous $MgCl_2$ (0.015 g, 0.15 mmol) was suspended in CH_2Cl_2 (10 cm^3), $SbCl_5$ (0.09 g, 0.3 mmol)

added and the mixture stirred for 30 min. A solution of the diphosphine dioxide (0.19 g, 0.45 mmol) in CH_2Cl_2 (5 cm^3) was added, and the mixture stirred overnight. The solution was concentrated to about 5 cm^3 in vacuo, diethyl ether (5 cm^3) added dropwise, and the mixture refrigerated. The white precipitate was filtered off, rinsed with diethyl ether and dried in vacuo (yield 0.15 g, 65%). *Anal*. Calc. for $[C_{54}H_{56}Cl_{12}O_6MgP_4Sb_2]$: C, 40.5; H, 3.5. Found: C, 41.1; H, 3.4%. ^1H NMR ($CDCl_3$): 7.2–7.7 (m, Ph, 20H), 3.58 (t, 2H, PCH_2), 3.41 (q, 2H, CH_2), 1.23 (t, 3H, CH_3) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 34.0 ppm. IR (Nujol mull): ca. 3400 (OH), 1630 (HOH), 1179 (P=O), 346 ($SbCl_6^-$) cm^{-1}.

3.6. $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$

Anhydrous calcium chloride (0.013 g, 0.12 mmol) was suspended in CH_2Cl_2 (10 cm^3) and a solution of $SbCl_5$ (0.075 g, 0.25 mmol) in CH_2Cl_2 (1 cm^3) added, followed immediately by powdered $Ph_2P(O)CH_2P(O)Ph_2$ (0.15 g, 0.36 mmol). The mixture was stirred for 3d. then concentrated in vacuo to ca. 5 cm^3. Ethanol (10 cm^3) was added and the white precipitate allowed to settle and the ethanol decanted off. The white solid was washed with a further quantity of ethanol (5 cm^3), separated, and dried in vacuo. White solid (yield 0.13 g, 79%). *Anal*. Calc. for $[C_{75}H_{66}CaCl_{12}O_6P_6Sb_2]$: C, 46.0; H, 3.4. Found: C, 45.9; H, 2.6%. ^1H NMR ($CDCl_3$): 7.05–7.65 (m, Ph, 10H), 3.55 (t, CH_2, 1H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 32.6 ppm. IR (Nujol mull): 1175 (P=O), 345 ($SbCl_6^-$) cm^{-1}.

3.7. $[Sr(EtOH)\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$

Method as for the calcium salt above, but using $SrCl_2$. Pale cream solid (yield 17%). *Anal*. Calc. for $[C_{77}H_{72}Cl_{12}O_7P_6Sb_2Sr]$: C, 45.1; H, 3.5. Found: C, 45.6; H, 3.6%. ^1H NMR ($CDCl_3$): 7.10–7.60 (m, Ph, 60H), 3.55 (t, CH_2P, 6H), 3.65 (q, CH_2O, 2H), 1.22 (t, CH_3, 3H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 31.3 ppm. IR (Nujol mull): 1174 (P=O), 341 ($SbCl_6^-$) cm^{-1}.

3.8. $[Sr\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$

Made in the same way except that the addition of ethanol in the work up was omitted. White solid (yield 38%). *Anal*. Calc. for $[C_{75}H_{66}Cl_{12}O_6P_6Sb_2Sr]$: C, 44.9; H, 3.3. Found: C, 44.5; H, 3.2%. ^1H NMR ($CDCl_3$): 7.10–7.60 (m, Ph, 60H), 3.56 (t, CH_2, 6H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 31.5 ppm. IR (Nujol mull): 1177 (P=O), 346 ($SbCl_6^-$) cm^{-1}.

3.9. $[Mg\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$

Method as described above for $[Mg(OPPh_3)_4](SbCl_6)_2$ using $MgCl_2$: o-$C_6H_4(P(O)Ph_2)_2$ mol. ratio of 1:2. The reaction mixture was taken to dryness in vacuo, the white solid stirred with ethanol (5 cm^3) for 20 min., filtered off and dried in vacuo (yield 37%). *Anal*. Calc. for $[C_{90}H_{72}Cl_{12}MgO_6P_6Sb_2]$: C, 50.7; H, 3.4. Found: C, 49.9; H, 3.5%. ^1H NMR ($CDCl_3$): 7.2–7.7 (m, aromatic H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 40.1 ppm. IR (Nujol mull): 1170 (P=O), 341 ($SbCl_6^-$) cm^{-1}.

3.10. $[Ca\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$

Method as described above for $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2$, White solid (yield 47%). *Anal*. Calc. for $[C_{90}H_{72}CaCl_{12}O_6P_6Sb_2]$: C, 50.4; H, 3.4. Found: C, 49.6; H, 3.0%. ^1H NMR ($CDCl_3$): 6.90–7.80 (m, aromatic H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 36.7 ppm. IR (Nujol mull): 1185, 1169(sh) (P=O), 343 ($SbCl_6^-$) cm^{-1}.

3.11. $[Sr\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$

Method as described for $[Sr(OPPh_3)_4](SbCl_6)_2$ using a $SrCl_2$: ligand mol. ratio of 1:3. The solution was concentrated to ca. 5 cm^3, and refrigerated for 48 h. The white solid was filtered off, rinsed with diethyl ether, dried in vacuo (yield 55%). *Anal*. Calc. for $[C_{90}H_{72}Cl_{12}O_6P_6Sb_2Sr]$: C, 49.3; H, 3.3. Found: C, 48.2; H, 3.2%. ^1H NMR ($CDCl_3$): 7.2–7.7 (m, aromatic H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 36.5 ppm. IR (Nujol mull): 1169, 1156(sh) (P=O), 347 ($SbCl_6^-$) cm^{-1}.

3.12. $[Ba\{o\text{-}C_6H_4(P(O)Ph_2)_2\}_3](SbCl_6)_2$

Was made similarly to the calcium salt. The white solid was obtained by concentrating the CH_2Cl_2 solution in vacuo to a small volume. The solid was only partially soluble in CH_2Cl_2 but dissolved on warming after addition of more diphosphine dioxide, and was recrystallised twice from CH_2Cl_2/diethylether in the presence of added ligand. White powder (yield 45%). *Anal*. Calc. for $[C_{90}H_{72}BaCl_{12}O_6P_6Sb_2]$: C, 48.2; H, 3.2. Found: C, 49.9; H, 3.5%. ^1H NMR ($CDCl_3$): 7.2–7.7 (m, aromatic H) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 36.4 ppm. IR (Nujol mull): 1186, 1172(sh) (P=O), 343 ($SbCl_6^-$) cm^{-1}.

3.13. X-ray crystallography

Details of the crystallographic data collection and refinement parameters are given in Table 4. Colourless crystals of $[Mg(OPPh_3)_4](SbCl_6)_2 \cdot CH_2Cl_2$ were obtained by liquid diffusion of diethyl ether into a solution of the complex in CH_2Cl_2, while small crystals of $[Ca\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2 \cdot 2CH_2Cl_2$ and $[Sr(EtOH)\{Ph_2P(O)CH_2P(O)Ph_2\}_3](SbCl_6)_2 \cdot 0.45CH_2Cl_2$ were obtained by liquid diffusion of EtOH into a solution of the appropriate complex in CH_2Cl_2. Data collection used a Nonius Kappa CCD diffractometer ($T = 120$ K) and with graphite-monochromated Mo Kα X-radiation

Table 4

($\lambda = 0.71073$ Å). Structure solution and refinement were routine [22–24]. Selected bond lengths and angles are given in Tables 1–3.

4. Conclusions

We have successfully prepared and isolated an unusual series of homoleptic phosphine oxide complexes involving Group 2 metal dications, including the first examples with bidentate phosphine oxides and the first examples with Sr^{2+} and Ba^{2+}. The M–L interactions in these complexes are weaker than those involving the Group 3 metal ions, a consequence of the reduction in charge:radius ratio in the alkaline earth systems. The affinity of Ba^{2+} for phosphine oxide coordination is very low. There is also a clear dependence upon the metal ion radius and the spectroscopic and structural results from the $Sr^{2+}/Ph_2P(O)CH_2P(O)Ph_2$ system show that this represents a crossover point where both the six- and seven-coordinate species may be isolated. As expected the coordination number at the metal centre is dependent upon the steric requirements, denticity and the rigidity of the phosphine oxide as well as the metal ion radius. However, the coordination numbers identified in this work (4–6) are much lower than those seen typically for Ca^{2+} and Mg^{2+} complexes with neutral O-donor ligands [25,26] Comparisons with the literature show that for Ca^{2+} coordination numbers below six are extremely rare, while for Mg^{2+} six-coordination is dominant, although a small number of lower coordination species are known.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 250370 (Mg), 250371 (Ca), 250372 (Sr). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CD2 1EZ, UK (Fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The cobalt(II) complexes dichloro[2-(3,4-dichlorophenyl)imino-κN-N-(2-thiazolin-κN-2-yl)thiazolidine]cobalt(II) (**1**) and dichloro[2-(3,4-dichlorophenyl)imino-κN-N-(2-thiazin-κN-2-yl)thiazolidine]cobalt(II) (**2**) have been isolated and characterized in the solid state by X-ray diffraction, elemental analysis, IR spectra, magnetic measurements and UV–Vis–NIR diffuse reflectance spectroscopy. In both complexes, the environment around the cobalt(II) ion may be described as a distorted tetrahedral geometry, with the metallic atom coordinated to two chlorine atoms [Co–Cl(1) = 2.213(1) Å; Co–Cl(2) = 2.226(1) Å], one imino nitrogen [Co–N(3) = 1.992(2) Å] and one thiazoline nitrogen [Co–N(1) = 1.974(2) Å] in complex **1** and to two chlorine atoms [Co–Cl(1) = 2.244(2) Å; Co–Cl(2) = 2.226(1) Å], one imino nitrogen [Co–N(3) = 1.970(4) Å] and one thiazine nitrogen [Co–N(1) = 1.946(4) Å] in complex **2**.

1. Introduction

Multidentate ligands containing N,N donors are extensively used in coordination chemistry with the aim of obtaining new frameworks having potential bioactivity [1]. Among these ligands, thiazoline and thiazine derivative ligands have attracted our attention due to their biological and pharmaceutical activity. The use of compounds containing thiazine, thiazoline or/and thiazolidine rings as antitumoral, analgesic, antibiotic, antiviral, antihistamine, anti-HIV, antiinflammatory and sedative agents, is well known [2–9]. In some cases, the structural and biological properties of the corresponding coordination compounds are more noteworthy than those of the ligands [10].

The synthesis of new siderophore analogues constitutes another pharmacological application example. Microbial siderophores are relatively low molecular weight compounds synthesized in order to solubilize and transport iron (III) into the procariotes cells in the necessary concentrations. New siderophore analogues are prototypes for the synthesis of chelating agents employed for clinical use [11]. Thus, there have been characterized siderophores containing thiazoline and thiazine rings that have been used in the treatment of acute iron poisoning and in chronic iron overload resulting from transfusion therapy of β-thalasemia [12].

Because of the aforementioned, recently we have been investigating the coordination chemistry of compounds containing these heterocycles [13–17]. As a continuation of this research, we report here the synthesis and characterization by elemental analysis, infrared spectra (IR), ultraviolet and visible spectra (UV–Vis), proton nuclear

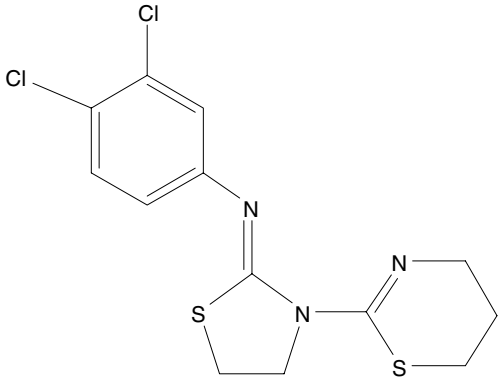
magnetic resonance (^{1}H NMR) and carbon nuclear magnetic resonance (^{13}C NMR) of the ligand TdTz [TdTz = 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)-thiazolidine]. Likewise, the cobalt(II) complexes [$CoCl_2$(TdTn)] [TdTn = 2-(3,4-dichlorophenyl)imino-N-(2-thiazolin-2-yl)thiazolidine] and [$CoCl_2$(TdTz)] have been isolated and their characterization has been carried out by means of single crystal X-ray diffraction, elemental analysis, spectroscopic and magnetic measurements.

2. Experimental

2.1. Preparation of 2-(3,4-dichlorophenyl)imino-N-(2-thiazolin-2-yl)thiazolidine (TdTn)

The preparation of TdTn has been carried out as described by Outcalt et al. [18]. ^{1}H NMR (deuteriochloroform): δ 7.37 (d, J = 8.49 Hz, 1H), 7.10 (d, J = 2.45 Hz, 1H), 6.85 (dd, J = 2.45, 2.49 Hz, 1H), 4.33 (t, J = 7.05 Hz, 2H), 4.01 (t, J = 8.28 Hz, 2H), 3.28 (t, J = 7.05 Hz, 2H), 3.23 (t, J = 8.16 Hz, 2H); ^{13}C NMR (deuteriochloroform): δ 157.58, 155.68, 148.73, 132.47, 130.53, 127.29, 123.30, 120.89, 57.27, 51.30, 33.87, 26.74. *Anal.* Calc. for $C_{12}H_{11}Cl_2N_3S_2$: C, 43.38; H, 3.34; N, 12.64; S, 19.30. Found: C, 43.44; H, 3.36; N, 12.71; S, 18.95%. UV–Vis (EtOH): λ_{max}, nm; (ε, l mol^{-1} cm^{-1}) 205 (35 087), 239 (17 542), 289 (12 351).



TdTn

2.2. Preparation of 2-(3,4-dichlorophenyl)imino-N-(2-thiazin-2-yl)thiazolidine (TdTz)

A solution of 2.01 g (8.1 mmoles) of 2-(3,4-dichlorobenzylamino)-2-thiazoline (that was obtained by the method of Fanta and Deutsch [19] and by the method of Outcalt et al. [18]) and 1.38 g (10.2 mmoles) of 3-chloropropylisothiocyanate [20] in 30 ml of toluene was stirred and heated to reflux for 4 h. At this point, a white precipitate had separated out and the reaction mixture was allowed to cool to room temperature. A solution of 1.62 g (15.3 mmoles) of sodium carbonate in 20 ml of water was added and the mixture was stirred until dissolution of the solid was complete. The phases were separated and the aqueous layer was extracted with dichloromethane. The combined organic layers were dried over anhydrous magnesium sulfate and concentrated under reduced pressure to give a solid that was recrystallized from ethanol 96% (1.5 g; 53%).

^{1}H NMR (deuteriochloroform): δ 7.32 (d, J = 8.76 Hz, 1H), 7.07 (d, J = 2.24 Hz, 1H), 6.80 (dd, J = 2.24, 8.76 Hz, 1H), 4.19 (t, J = 7.04 Hz, 2H), 3.72 (t, J = 5.62 Hz, 2H), 3.15 (t, J = 7.01 Hz, 2H), 2.95 (t, J = 6.01 Hz, 2H), 1.90 (m, J = 5.88 Hz, 2H); ^{13}C NMR (deuteriochloroform): δ 156.48, 149.61, 148.31, 132.32, 130.42, 126.86, 123.37, 121.03, 51.42, 46.46, 27.07, 26.46, 20.64. *Anal.* Calc. for $C_{13}H_{13}Cl_2N_3S_2$: C, 45.09; H, 3.78; N, 12.13; S, 18.52. Found: C, 45.26; H, 3.78; N, 11.82; S, 18.07%. UV–Vis (EtOH): λ_{max}, nm; (ε, l mol^{-1} cm^{-1}) 205 (35 140), 247 (19 059), 292 (10 833).

TdTz

2.3. Preparation of [$CoCl_2$(TdTn)]

This complex was isolated from a freshly prepared ethanol solution (1 ml) of $CoCl_2 \cdot 6H_2O$ (71.6 mg, 0.3 mmol) that was added to an ethanol solution (15 ml) of TdTn (100 mg, 0.3 mmol). The resulting solution was allowed to evaporate slowly at room temperature. After a few days, blue crystals were isolated from the solution (124 mg, 89.2%). The crystals were separated by filtration, washed with cold ether and air-dried. *Anal.* Calc. for $C_{12}H_{11}Cl_4CoN_3S_2$: C, 31.19; H, 2.40; N, 9.09; S, 13.88. Found: C, 31.33; H, 2.42; N, 8.97; S, 14.37%.

2.4. Preparation of [$CoCl_2$(TdTz)]

This complex was prepared by reacting an ethanol solution (1 ml) of $CoCl_2 \cdot 6H_2O$ (68.7 mg, 0.3 mmol)

with an ethanol solution (15 ml) of TdTz (100 mg, 0.3 mmol), blue crystals being obtained after a slow evaporation of the solution at room temperature (96.5 mg, 67.5%). The crystals were filtered, washed with cold ether and air-dried. *Anal.* Calc. for $C_{13}H_{13}Cl_4CoN_3S_2$: C, 32.79; H, 2.75; N, 8.82; S, 13.47. Found: C, 32.76; H, 2.74; N, 8.58; S, 12.93%.

2.5. Instrumental procedures

Chemical analyses of carbon, hydrogen, nitrogen and sulfur were performed by microanalytical methods using a Leco CHNS-932 microanalyser. IR spectra were recorded on a Perkin–Elmer FT-IR 1720 spectrophotometer, from KBr pellets in the 4000–370 cm^{-1} range and on a Perkin–Elmer FT-IR 1700X spectrophotometer, from polyethylene pellets in the 500–150 cm^{-1} range. Electronic spectra of the ligands in solution were measured on a Shimadzu UV-3101 PC using a 10 mm quartz cell. UV–Vis–NIR reflectance spectra for complexes in the 200–2000 nm range were obtained from a pellet of the samples, using a Shimadzu UV-3101 PC spectrophotometer and $BaSO_4$ as a reference. Magnetic measurements were made at room temperature on a magnetometer with a pendulum MANICS DSM8, equipped with a helium continuous-flow cryostat and an electromagnetometer DRUSCH EAF 16 UE. Data were corrected for temperature-independent paramagnetism and diamagnetic contributions, which were estimated from Pascal constants. ^1H and ^{13}C NMR spectra were obtained with a Bruker AM 400 instrument at 400 and 100 MHz, respectively, in $CDCl_3$ using Me_4Si as internal standard.

2.6. Crystal structure determinations

Experimental details of the crystal structure determinations including crystal data, data collection, structure determination and refinement for complexes **1** and **2** are listed in Table 1. X-ray diffraction measurements were

performed using a Bruker SMART CCD diffractometer. The first fifty frames were recollected at the end of the data collection to monitor for decay. Absorption corrections were applied using the program SADABS. The structures were solved by direct methods and subsequent Fourier differences using the WINGX package [21] and refined by full-matrix least-squares. The H atoms were placed from a differential Fourier synthesis and included in the final refinement cycles in calculated positions.

3. Results and discussion

3.1. Description of the crystal structures

3.1.1. [$CoCl_2$(TdTn)] (1)

The structure of **1** consists of discrete neutral monomeric units in which the environment around the cobalt(II) atom may be described as a distorted tetrahedral geometry. The metallic atom is coordinated by two chlorine atoms [Co–Cl(1) = 2.213(1) Å; Co–Cl(2) = 2.226(1) Å], one thiazoline nitrogen [Co–N(1) = 1.974(2) Å] and one imino nitrogen [Co–N(3) = 1.992(2) Å]. A diagram of the molecular structure and the atom numbering system used is shown in Fig. 1. The most relevant bond lengths and angles are given in Table 2.

The Co–Cl bond lengths are similar and comparable to the calculated average value [2.240(26) Å] for 100 tetrahedral cobalt(II) complexes with a chromophore group $CoCl_2N_2$, obtained from CONQUEST software [22] from the Cambridge Structural Database (CSD) [23]. Likewise, the Co–N_{imino} bond distance is slightly shorter than the mean value [2.027(24) Å] calculated for 16 cobalt(II) complexes with an Cl_2N_2 environment collected in the CSD. The Co–$N_{thiazoline}$ bond distance is closer to that found in [$CoCl_2$(PyTT)] (1.982 Å) [13], but shorter than those observed in [Co(2,2′-bithiazoline)-$(N_3)_2]_n$ (average 2.155 Å) [24]. The ligand–metal–ligand bite angles differ from the ideal value of 109.5°, varying between 116.6(1)° [Cl(1)–Co–N(3)] and 90.8(1)° [N(3)–Co–N(1)].

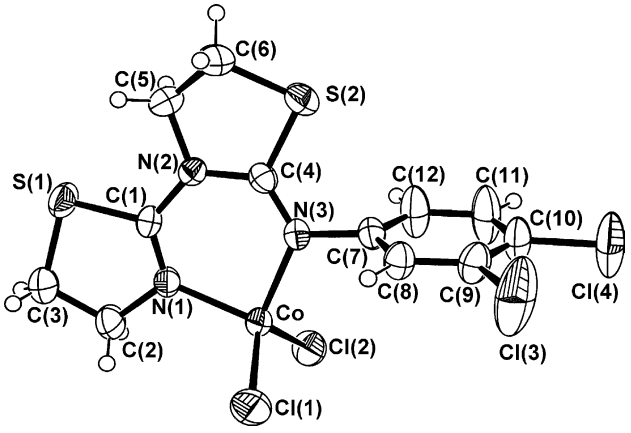

Fig. 1. Molecular structure of [$CoCl_2$(TdTn)] (**1**), showing the atom numbering scheme. The thermal ellipsoids are drawn at the 50% level.

Table 2
Selected bond lengths (Å) and bond angles (°) for [$CoCl_2$(TdTn)] (**1**)

Bond lengths			
Co–Cl(1)	2.213(1)	Co–Cl(2)	2.226(1)
Co–N(1)	1.974(2)	Co–N(3)	1.992(2)
C(1)–N(1)	1.280(3)	N(2)–C(4)	1.381(3)
N(2)–C(1)	1.382(3)	C(7)–N(3)	1.445(3)
C(4)–N(3)	1.292(3)		
Bond angles			
Cl(1)–Co–Cl(2)	114.4(4)	Cl(1)–Co–N(3)	116.6(1)
Cl(2)–Co–N(3)	109.4(1)	Cl(1)–Co–N(1)	108.7(1)
Cl(2)–Co–N(1)	114.8(1)	N(3)–Co–N(1)	90.8(1)
C(4)–N(2)–C(1)	126.4(2)	N(2)–C(4)–N(3)	124.5(2)
Co–N(3)–C(4)	126.3(2)	Co–N(3)–C(7)	115.5(2)
C(4)–N(3)–C(7)	118.1(2)	Co–N(1)–C(1)	126.9(2)
C(1)–N(1)–C(2)	112.6(2)	N(2)–C(1)–N(1)	125.0(2)
N(3)–C(4)–N(2)	124.5(2)		

The six-membered chelate ring Co–N(1)–C(1)–N(2)–C(4)–N(3) is essentially planar with maximum mean-plane deviation for C(4) (0.020 Å). In the organic ligand, the values of the puckering parameters for the 2-thiazoline ring, calculated according to Cremer and Pople [25], are q = 0.143 Å and ϕ = 251.2°, whereas for the thiazolidine ring these are q = 0.330 Å and ϕ = 289.3°. These values indicate that both five-membered rings show a conformation near to envelope, with the apex at C(3) [deviating 0.230 Å from the plane formed by S(1)–C(1)–N(1)–C(2), maximum mean plane deviation for N(1) = 0.001 Å] for the 2-thiazoline ring, and at C(6) [deviating 0.514 Å from the plane formed by S(2)–C(4)–N(2)–C(5), maximum mean plane deviation for N(2) = 0.004 Å] for the thiazolidine ring.

3.1.2. [$CoCl_2$(TdTz)] (2)

The X-ray study revealed that the crystals of **2** are made up of monoclinic unit cells, each containing four complex molecules. A diagram of the molecular structure and the atom numbering system used is shown in Fig. 2. Selected bond lengths and angles are given in Table 3.

The cobalt(II) is bound to two chlorine atoms [Co–Cl(1) = 2.244(2) Å; Co–Cl(2) = 2.226(1) Å], one thiazine nitrogen [Co–N(1) = 1.946(4) Å] and one imino nitrogen [Co–N(3) = 1.970(4) Å] in a distorted tetrahedral geometry. The distortion of the tetrahedral environment of the cobalt(II) ion is smaller than in complex **1**, being indicated by the ligand–metal–ligand bite angles that vary between 115.1(2)° [Cl(1)–Co–N(1)] and 92.5(2)° [N(3)–Co–N(1)]. This compound is the first structurally characterized compound having a 1,3-thiazine link to cobalt(II). The Co-ligand bond lengths were compared with the same values collected from the CSD used during discussion of complex **1**. Thus, the Co–Cl bond

Co–Cl(1)	2.244(2)	Co–Cl(2)	2.226(1)
Co–N(1)	1.946(4)	Co–N(3)	1.970(4)
C(1)–N(1)	1.284(6)	N(2)–C(5)	1.384(6)
N(2)–C(1)	1.403(6)	C(8)–N(3)	1.433(6)
C(5)–N(3)	1.288(6)		
Bond angles			
Cl(1)–Co–Cl(2)	112.8(1)	Cl(1)–Co–N(3)	108.2(1)
Cl(2)–Co–N(3)	115.0(1)	Cl(1)–Co–N(1)	115.1(2)
Cl(2)–Co–N(1)	111.7(1)	N(3)–Co–N(1)	92.5(2)
C(5)–N(2)–C(1)	127.0(4)	N(2)–C(5)–N(3)	125.6(4)
Co–N(3)–C(5)	124.4(3)	Co–N(3)–C(8)	117.1(3)
C(5)–N(3)–C(8)	118.5(4)	Co–N(1)–C(1)	127.8(3)
C(1)–N(1)–C(2)	119.2(4)	N(2)–C(1)–N(1)	122.1(4)
N(3)–C(5)–N(2)	125.6(4)		

lengths are similar to those collected, whereas the Co–N_{imino} bond length is shorter to those collected.

The six membered chelate ring Co–N(1)–C(1)–N(2)–C(5)–N(3), similarly to complex **1**, is essentially planar with maximum mean-plane deviation for C(1) (0.047 Å). The 1,3-thiazine ring shows a conformation near to boat with S(1) and C(2) deviating 0.350 and 0.215 Å, respectively, above the plane formed by C(1), N(1), C(3), C(4) [maximum mean-plane deviation for N(1) = 0.051 Å]. This geometry is proved by the puckering parameters $q = 0.336$ Å, $\phi = 303.4°$ and $\theta = 82.9°$ [25]. For the thiazolidine ring, the puckering parameters $q = 0.356$ Å and $\phi = 303.4°$ [25] indicate a conformation near to envelope with the apex at C(7), deviating 0.546 Å from the plane formed by C(5), N(2), C(6), S(2) [maximum mean-plane deviation for N(2) = 0.038 Å].

Finally, it should be pointed out that the organic moiety in both complexes presents a different degree of rotation of the 3,4-dichlorophenyl ring around the N(3)–C(7) [or N(3)–C(8)] bond, which could be due to the molecular packing of the crystal structures [torsion angle C(4)–N(3)–C(7)–C(12) = −78.5° in complex **1**; torsion angle C(5)–N(3)–C(8)–C(13) = −119.2° in complex **2**].

3.2. Physical measurements

A pseudotetrahedral stereochemistry may be assigned to the two complexes reported in this paper on the basis of their diffuse reflectance spectra, which closely resemble those of other Co(II) tetrahedral complexes.

Complex **1** exhibits one intense band at 34 720 cm^{-1} (288 nm), which is assigned to the $\pi \rightarrow \pi^*$ transition of the organic ligand. Moreover, the spectrum shows two multicomponent absorptions in the near infrared and visible regions with intensities consistent with spin-allowed d–d transitions. These bands may be assigned to ν_2 [$^4A_2(F) \rightarrow {}^4T_1(F)$] (10 800, 8300, 6930 cm^{-1}) and ν_3 [$^4A_2(F) \rightarrow {}^4T_1(P)$] (18 870 and 16 290 cm^{-1}) transitions, respectively, in an idealized T_d symmetry.

The very large splitting for these bands suggests a marked effect of a low symmetry component of the crystal field, C_1, prevailing on the spin-orbit coupling effects, although such a mechanism may contribute [26].

The ligand field parameters, 10 Dq and B, were calculated from the average values of the ν_2 and ν_3 bands taking the centre of gravity of the total intensity, using the following known relationships [27] for tetrahedral d^7 complexes:

$$\nu_2[^4A_2(F) \rightarrow {}^4T_1(F)] = 15Dq + (15/2)B - 1/2[(-6Dq + 15B)^2 + 64(Dq)^2]^{1/2} \quad (1)$$

$$\nu_3[^4A_2(F) \rightarrow {}^4T_1(P)] = 15Dq + (15/2)B + 1/2[(-6Dq + 15B)^2 + 64(Dq)^2]^{1/2} \quad (2)$$

The calculated values of the ligand field parameters 10 Dq = 4870 cm^{-1} and B = 746 cm^{-1} are in fair agreement with the predicted values for tetrahedral complexes and are consistent with the presence of a chromophore group $[CoCl_2N_2]$ [13,28–30].

The electronic spectra of **1** and **2** resemble each other closely. Thus, complex **2** shows one intense band at 34 480 cm^{-1} (290 nm) which can be assigned to the $\pi \rightarrow \pi^*$ transition of the organic ligand.

Likewise, in a similar form to **1**, the electronic spectrum exhibits a splitting of the ν_2 and ν_3 transitions. Thus, the bands at 18 670 and 16 500 cm^{-1} are assigned to the ν_3 [$^4A_2(F) \rightarrow {}^4T_1(P)$] transition, whereas the bands at 11 130 cm^{-1}, 8200 cm^{-1} and 7130(sh) cm^{-1} are assigned to the ν_2 [$^4A_2(F) \rightarrow {}^4T_1(F)$] transition.

Attention is now given to the splitting of the ν_2 transition of **2** (two bands and a shoulder) that is smaller than that of **1** (three bands). This fact may possibly be explained in terms of geometrical effects, since in accordance with the X-ray crystallographic results, the distortion of the coordination polyhedron around the cobalt(II) atom in **1** is greater than that in **2** [31].

The ligand field parameters, 10 Dq and B, were collected in the same way as for **1** using the Eqs. (1) and (2). Likewise, the calculated values of the ligand field

parameters, 10 Dq = 4861 cm^{-1} and B = 754 cm^{-1}, are consistent with the presence of the chromophore group $[CoCl_2N_2]$ [13,28–30].

The observed molar magnetic susceptibilities for **1** and **2** were corrected for diamagnetism and temperature-independent paramagnetism to provide the fully corrected magnetic moments at room temperature of 4.37 and 4.44 MB, respectively. These values are consistent with an ion with an $e^4t_2^3$ electronic configuration in a tetrahedral field [32,33].

It should be pointed out that the magnetic moment of **2** is a little higher than that of **1**, this fact can be explained by considering, according to Cotton [34,35], that the orbital contribution to the spin only value of the magnetic moment varies inversely with the strength of the ligand field, and that is lower for **2** than for **1**.

The IR spectra of TdTn and TdTz in the 4000–370 cm^{-1} region show the presence of bands due to thiazolidine ring vibrations at 1027 (νn_1), 906 (νn_2), 828 (νn_3), 704 (νn_4), 673 (νn_5) and 477 cm^{-1} (δn_2) for TdTn, and at 1024 (νn_1), 923 (νn_2), 891 (νn_3), 701 (νn_4), 675 (νn_5) and 475 cm^{-1}(δn_2) for TdTz [36,37].

Likewise, the spectrum of TdTn exhibits bands assignable to the thiazoline ring vibrations at 1602 (W_1), 985 (W_2), 937 (W_3), 799 (W_4), 733 (W_5), 644 (W_6), 593 (W_8), 526 (W_7) and 445 cm^{-1} (Γ_1) [38], whereas the spectrum of TdTz shows bands assignable to the thiazine ring vibrations at 1604 (Ψ_1), 1010 (Ψ_2), 947 (Ψ_3), 823 (Ψ_4), 765 (Ψ_5), 710 (Ψ_6), 628 (Ψ_7), 592 (Ψ_8) and 528 cm^{-1} (ϕ_1) [14,39,40].

Moreover, the bands of 3,4-dichlorophenyl ring vibrations are detected at 1586 (8b), 1550 (8a), 1470 (19b), 1384 (19a), 1253 (14), 1131 (1) and 433 cm^{-1} (16b) for TdTn, and at 1585 (8b), 1548 (8a), 1466 (19b), 1372 (19a), 1244 (14), 1136 (1) and 428 cm^{-1} (16b) for TdTz [41].

Other relevant bands are registered at 1635 [$\nu(C{=}N)_{imine}$] and 1035 cm^{-1} [$\nu(C–Cl)_{orto}$] for TdTn, and at 1631 [$\nu(C{=}N)_{imine}$], 1358 [$\nu(C–N)$] and 1048 cm^{-1} [$\nu(C–Cl)_{orto}$] for TdTz [42,43].

Table 4

The IR spectra of **1** and **2** in the 4000–370 cm^{-1} region show the presence of bands due to the organic moiety ring vibrations as is shown in Table 4.

The two complexes showed a strong $\nu(C{=}N)_{imine}$ absorption, at 1606 cm^{-1} in **1** and at 1598 cm^{-1} in **2**, suffering a shift to a lower wavenumber when compared with that for the uncoordinated imine function of the respective ligands. Likewise, the in-plane stretching vibrations corresponding to $\nu(C{=}N)$ skeletal vibrations of the heterocyclic rings (W_1 of **1** and ψ_1 of **2**), were also shifted to lower wavenumbers compared with that for the respective free ligands (Table 4). From this a coordination via the imino nitrogens of the ligands can be deduced [44–47].

In the low-frequency region, the C_1 symmetry of both complex cations predicts the appearance of four bands assignable to metal–ligand stretching vibrations. The IR spectrum of **1** shows three such bands at 345, 322 and 226 cm^{-1}. The band at 345 cm^{-1} could include the $\nu(Co–N_{imino})$ vibration [13,44–46,48] and one $\nu(Co–Cl)$ vibration [13,49–52], whereas the band at 322 cm^{-1} is assigned to the other $\nu(Co–Cl)$ vibration [13,49–52]. Finally, the band at 226 cm^{-1} is assignable to $\nu(Co–N_{thiazoline})$ [13,29,30]. In a similar form, only three such bands are observed for **2**. Of these, the band at 337 cm^{-1} can include the $\nu(Co–N_{imino})$ vibration [13,44–46,48] and one $\nu(Co–Cl)$ vibration [13,49–52], whereas the band at 320 cm^{-1} is assigned to the other $\nu(Co–Cl)$ vibration [13,49–52]. The last band at 230 cm^{-1} is tentatively assigned to $\nu(Co–N_{thiazine})$, in good accord with literature data for several complexes containing thiazoline or thiazine derivative ligands [13,29,30].

4. Supplementary material

CCDC 247453, corresponding to $[CoCl_2(TdTn)]$, and CCDC 247454, to $[CoCl_2(TdTz)]$ contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

New saturated dimeric Er(III)-chelated model complexes based on benzoate and bipyridine ligands were synthesized through a ligand-exchange reaction in the presence of the Er(III) ion and potassium benzoate salts. The crystal structure of the novel 8-coordinated dimeric complex, $[Er_2(benzoate)_6(bipyridine)_2]$, involving four bridging and two chelating benzoate ligands and two bipyridine ligands, was determined by X-ray crystal structure analysis. The dimeric Er(III)-chelated complex has an asymmetric unit with a Er(1)–Er(2) distance of 4.33 Å and its crystal exhibited a very strong intensity near-IR emission, taking place from the first excited state ($^4I_{13/2}$) to the ground state ($^4I_{15/2}$) in the region of 1.53 μm.

1. Introduction

Very recently, the development of integrated planar waveguide optical amplifiers has been extremely essential to achieve photonic devices in super high speed communication systems [1]. In particular, wavelength division multiplexing (WDM)-integrated planar waveguide amplifiers are recognized to be essential for successfully realizing photonic devices in WDM technology. Despite such needs, the problem still remains to be the materials for the use in the real optical amplifiers. At present, erbium-doped silica amplifiers are widely used, but the poor solubility of the erbium ion (Er^{3+}) in conventional inorganic/organic media leads to low amplification properties. When the higher doping concentration of the erbium ion was introduced, clustered Er^{3+} species can be formed, which in turn have a limited amplification property. It is ascribed to the cooperative energy-transfer processes between the clustered Er^{3+} species. For critical problems of erbium-doped silica, the optical amplification gain is currently not enough for amplifying the optical signals in small sized photonic devices. In order to enhance the amplified luminescence intensity, the development of luminescent lanthanide complexes based on energy transfer mechanisms by using supramolecular complexes as organic ligands has been extensively studied [1–7]. Luminescent lanthanide complexes consist of lanthanide ions and chelating luminescent ligands as a sensitizer. They efficiently absorb and transfer lights to the central lanthanide ion through energy transfer. Their supramolecular

complexes contain well-known antenna chromophores to photoexcite the lanthanide ions via the energy transfer process, but crystal structural studies of their complexes are rare [7b]. Crystal structures of dimeric Eu(III)-chelated complexes based on *p*-methoxybenzoate [8a], *o*- or *p*-aminobenzoate [8b,c], and *p*-methylbenzoate [8d] with bipyridine are well known. Recently, dimeric and polymeric Ln(III) complexes (Ln = Eu, Gd, Tb) based on benzoic acid and its derivatives have been studied [10]. Even more recently, dimeric Eu, Nd and Sm(III) lanthanide complexes based on bis-diketonate ligands have been reported [9]. However, structural studies and photophysical properties of these dimeric Er(III)-chelated complexes are not known. Also, even though the structure of the Er(III)-chelated complexes are similar to Eu(III)-chelated complexs, the Er(III)-chelated complexes have quite different features with regards to their optophysical properties and applications, in comparison with the Eu(III) complexes [1,11].

Recently, we studied the synthesis and photophysical properties of luminescent lanthanide complexes based on coumarin [12a], benzoate and pentafluorobenzoate [12b], porphyrin [13,14b] and naphthalene [14] derivatives for advanced photonic applications such as planar waveguide amplifiers and light-emitting diodes, in order to get highly efficient lanthanide emission via energy transfer between the luminescent ligands and the lanthanide ions. In this paper, a novel dimeric Er(III)-chelated complex, through a ligand exchange reaction using $ErCl_3$ in the presence of bipyridine and potassium benzoate salt, has been synthesized and its molecular structure and photophysical properties have been investigated.

2. Experimental

2.1. Synthesis of $[Er_2(benzoate)_6(bipyridine)_2]$

A mixture of benzoic acid (0.500 g, 4.094 mmol), bipyridine (0.469 g, 3.002 mmol) and KH (0.167 g, 4.163 mmol) was dissolved in 150 mL of dried THF. This suspension was stirred at room temperature overnight. A suspension was formed with gas evolution during the reaction. After the complete formation of the salt, a methanol solution of anhydrous $ErCl_3$ (0.373 g, 1.365 mmol) in 10 mL of methanol was added dropwise to the reaction solution. After stirring at room temperature for one day, the resulting solution was filtered and solvents were removed to give a pinkish solid. The solid was washed with diethylether and *n*-hexane, and dried under vacuum. This pinkish solid was dissolved in hot methanol, filtered, and then the filtrate was left at room temperature. $[Er_2(benzoate)_6(bipyridine)_2]$ (0.629 g, 0.458 mmol, 67%) was obtained over a period of several weeks. *Anal.* Calc. (%) for $C_{31}H_{23}ErN_2O_6$: C, 54.21; H, 3.38; N, 4.08; Er, 24.35. Found: C, 54.15; H, 3.37; N, 4.05; Er, 24.34%. UV–Vis. (λ nm (%), reflectance) 306 (37.8), 380 (91.5), 490 (94.5), 523 (90.7). FT-IR (KBr pellet, cm^{-1}) 3115, 3089, 3059, 3024, 2928, 1641, 1597, 1537, 1406, 1311, 1179, 1155, 1065, 1014, 854, 764, 720, 687, 669, 642, 570, 429.

2.2. X-ray structure determination

A pinkish crystal of the erbium complex, suitable for X-ray structure analysis, was obtained by slow evaporation of methanol over a period of several weeks. All data were collected on a Bruker SMART diffractometer equipped with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation source and a CCD detector; 45 frames of two-dimensional diffraction images were collected and processed to obtain the cell parameters and orientation matrix [15a]. The two-dimensional diffraction images were collected, each of which was measured for 30 s. The frame data were processed to give structure factors using the program SAINT [15a]. The molecular structure was solved by a direct method and refined by full-matrix least-squares against F^2, for all data using SHELXTL software [15b]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The final cycle of the refinement gave $R = 0.0244$ with 12774 reflections in the θ range of 1.85°–28.27° ($-18 \leqslant h \leqslant 14$, $-20 \leqslant k \leqslant 19$, $-22 \leqslant l \leqslant 34$) at −100 °C. A summary of the crystallographic data is given in Table 1.

2.3. Measurements and apparatus

FT-IR spectra, in the region of 4000–400 cm^{-1}, were recorded on a Perkin–Elmer 1000 FT-IR spectrometer using the conventional KBr pellet method. UV–Vis spectra were measured with a Shimazu UV–Vis spectrophotometer using UV-2401PC. A TGA curve was carried out with a Dupont 9900 Model 951 thermogravimetric analyzer with a heat rate of 10 °C/min under N_2 atmosphere. Photoluminescence spectra were measured on a steady-state fluorimeter (Edinburgh Instruments. FS920) with a 450W Xe lamp. A He–Cd laser (325 nm) and an Ar-ion laser (488 nm) were used as an excitation light source when the emission was measured. The emission from the sample was collected and refocused to the emission monochrometer with 300 nm focal length. The emission spectra in the visible region were taken with a PMT system (Hamamatsu R955) and in the near infrared region with a liquid nitrogen cooled Ge-detector (Edinburgh Instruments. EI-L). All spectra were taken at room temperature. The excitation laser powers were adjusted to the same power (about 16 mW) at the sample.

Table 1
Crystal data and structure refinement for $[Er_2(benzoate)_6(bipyridine)_2]$

Empirical formula	$C_{62}H_{46}Er_2N_4O_{12}$
Formula weight	1373.55
T (K)	173(2)
Crystal system	monoclinic
Space group	$P2_1/n$

β (°)	103.5340(10)
V (Å^3)	5391.0(3)
Z	4
$F(000)$	2712
D_{calc} (Mg/m^3)	1.692
Absorption coefficient (mm^{-1})	3.162
Crystal size (mm)	$0.40 \times 0.30 \times 0.30$
Range hkl collected	$-18 \leqslant h \leqslant 14$, $-20 \leqslant k \leqslant 19$, $-22 \leqslant l \leqslant 34$
Reflections collected	34239
Independent reflections	12774 [$R_{int} = 0.0296$]
Completeness to θ (=28.27 °C)	95.5%
Absorption correction	SADABS [11c]
Maximum and minimum transmission	0.509488 and 0.414415
Data/restraints/parameters	12774/0/721
Goodness-of-fit on F^2	1.068
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0244$, $wR_2 = 0.0539$
R indices (all data)	$R_1 = 0.0334$, $wR_2 = 0.0572$
Largest difference peak and hole (e Å^{-3})	1.066 and −0.725

3. Results and discussion

3.1. Synthesis

The synthesis of the dimeric Er(III)-chelated complex was verified by elementary analysis, TGA, FT-IR, absorption and emission spectroscopies, and X-ray crystal analysis. The paramagnetic nature of the Er complex does not permit NMR characterization. The FT-IR spectrum of the Er(III)-chelated complex exhibited the vibration modes of the carbonyl moieties of two bidentate-like carboxylate bands in the region of 1640 and 1410 cm^{-1}. According to previous studies for acetate complexes [16], the difference between asymmetric and symmetric vibration modes shows that the values of unidentate complexes have a significant difference in comparison with those of bridging bidentate and/or chelating complexes. But, the two different modes of benzoate ligand coordination, by X-ray structure analysis, are almost not distinguished in the IR spectrum of the dimeric Er-chelated complex. As seen from Fig. 1, the 8-coordinated dimeric Er(III)-chelated complex shows two obvious weight loss processes in the TGA curve. The first one, with a weight loss of 23%, is assigned to the releasing of bipyridine from 180 to 237 °C, and the second one is assigned to the loss of six benzoate ligands up to ca. 550 °C. There is no obvious weight loss process before 180 °C in the TGA trace, indicating that the 8-coordinated dimeric Er(III)-chelated complex has no coordinated H_2O molecules.

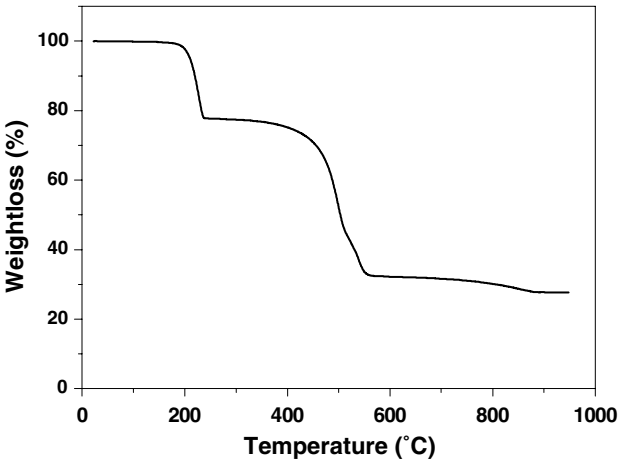

Fig. 1. TGA trace of $[Er_2(benzoate)_6(bipyridine)_2]$.

3.2. Crystal structure

In order to clarify the exact structure of the novel dimeric Er(III)-chelated complex, we have carried out an X-ray structure analysis for the pinkish white crystals of the dimeric Er(III)-chelated complex.

The molecular structure, as shown in Fig. 2, shows that the crystal structure consists of two Er(III) ions, having 8-coordinated asymmetric units, remarkably bridged by four benzoate groups, and chelated by two benzoate and two bipyridine groups to give the dimeric $[Er_2(benzoate)_6(bipyridine)_2]$. It is similar to {[Eu(*o*-aminobenzoate)$_3$(bipyridine)]bipyridine}$_2$ [8b], but the former complex, having a more distorted coordination mode due to a higher trans influence and asymmetry, has a greater steric effect than the latter complex.

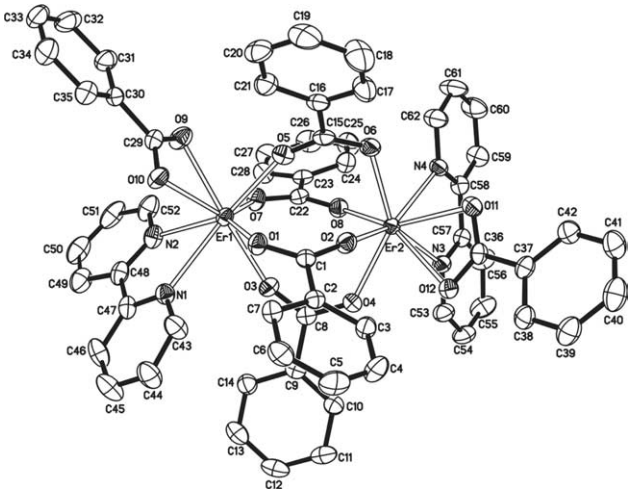

Fig. 2. ORTEP drawing of the molecular structure for $[Er_2(benzoate)_6(bipyridine)_2]$. Hydrogen atoms are omitted for clarity.

The coordination geometries of the Er(1) and Er(2) centers are distorted square antiprisms consisting of O(1), O(3), O(5), O(7), O(9), O(10), N(1) and N(2), and of O(2), O(4), O(6), O(8), O(11), O(12), N(3) and N(4), respectively. Selected bond distances and bond angles are given in Tables 2 and 3. The bond distances of Er(1)–O are in the range 2.258(2)–2.4370(19) Å and those of Er(1)–N are in the range 2.437(2)–2.533(2) Å, while the bond distances of Er(2)–O are 2.2742(19)–2.4289(19) Å and those of Er(2)–N are in the range 2.516(2)–2.573(2) Å. The average distances of Er–O [2.404 Å] for the bridged benzoate groups are shorter than those of Er–O [2.2899 Å] for chelated benzoate groups and the average distance Er–N [2.552 Å] for bipyridine groups are longer than those of Er–O for benzoate groups. The average distances of Er–O and Er–N in this work are somewhat longer than those of $Er(C_{23}H_{20}N_5O_2)](H_2O)(NO_3)]$ ($C_{23}H_{20}N_5O_2$ = bis(2,6-diacetylpyridine-bis-(phenylhydrazone) [17], while the average distances of Er–O are similar to $[Er_2(Acc^6)_4(H_2O)_8](ClO_4)_6(H_2O)_{11}$ (Acc = 1-amino cyclohexane-1-carboxylic acid) [18]. The distance of Er(1)–Er(2) (4.33 Å) is relatively long. Therefore, there are no significant intermolecular interactions in the crystal.

Table 2
Selected bond lengths (Å) for $[Er_2(benzoate)_6(bipyridine)_2]$

3.3. UV–Vis absorption and emission spectra

The absorption spectrum of the dimeric Er(III)-chelated complex shows a very intense absorption band at 306 nm, indicating a π–π* electronic transition. Also, some absorption bands at 380, 490 and 523 nm were observed with relatively narrow bandwidths, as shown Fig. 3. These bands are in good agreement with the absorption spectrum of the trivalent Er ion itself. Upon photoexcitation with a wavelength of 325 nm, the emission spectrum of the dimeric Er(III)-chelated complex was observed, the emission band in the UV–Vis region around 335 nm corresponding to the organic ligand emission. Interestingly, three spectral hollow points at 357, 365 and 378 nm were explicitly observed in the crystal state. These hollow points are consistent with the absorption bands ($^2G_{7/2}$, $^4G_{9/2}$ and $^4G_{11/2}$) of the Er ion itself. It should be noted to spectrally visualize that the energy transfer between the exited organic ligands and trivalent Er ion takes place at the three corresponding bands. It reduces the PL intensity of the organic ligand, thus yielding stronger near IR emission bands.

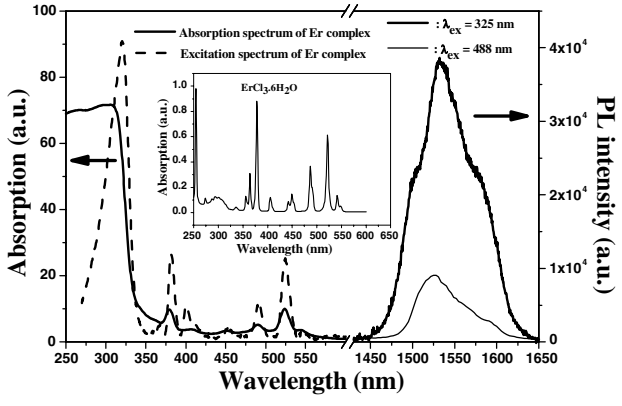

Fig. 3. Absorption (reflectance) and excitation (at λ_{em} = 1.53 μm) spectra of $[Er_2(benzoate)_6$ (bipyridine)$_2]$; and emission spectra of $[Er_2(benzoate)_6(bipyridine)_2]$ in the crystal state at λ_{ex} = 325 (He–Cd laser) and 488 (Ar ion laser) nm with a power of about 16 mW. The inset shows the UV–Vis spectrum of the Er(III) salt (H_2O, 0.1 M). Here, λ_{ex} means the excitation wavelength, while λ_{em} means the the emission wavelength.

Fig. 3 shows a strong near IR emission band, corresponding to the characteristic $^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition of trivalent erbium ions at 1.53 μm, of the dimeric Er(III)-chelated complex using a photoexcitation wavelength of 325 and 488 nm. The near IR emission band, obtained with a photoexcitation wavelength of 325 nm, which excited through the organic ligands, exhibited a much stronger emission intensity in the crystal state than the direct excitation of Er ions at 488 nm. The maximum emission band of the dimeric Er-chelated complex was observed at 1.53 μm, at which the excitation spectrum exhibits the maximum excitation band at 335 nm. Several additional excitation bands, corresponding to the Er ion itself, were exhibited in the region of 350–550 nm. These results are very similar to the absorption spectrum of the dimeric Er-chelated complex. Thus, we think that the major factor for the effect of the emission bands is the ligands coordinated to the central metal ion. With these results, it should be considered that an energy transfer process from the excited organic ligands to the erbium ions takes place. Fig. 3 shows the near IR emission spectra of the Er-chelated complex at a photoexcitation wavelength of 325 and 488 nm. Here, using a photoexcitation wavelength of 325 nm, the energy transfer process between the excited ligand and the Er ion takes place possibly to generate the emission of the central lanthanide ion (Er ion), while using a photoexcitation wavelength of 488 nm, the emission of the inherent lanthanide ion (Er ion) was obtained through the direct excitation of the Er ion without an energy transfer process between the excited ligand and the Er ion. The PL intensity of the Er complex by photoexcitation at 325 nm shows a much stronger PL intensity than that at 488 nm, as shown in Fig. 3 in which the stronger emission band of the Er(III) complex was obtained by the indirect photoexcitation of the ligands rather than by the direct photoexcitation of the Er(III) ions. This could be explained by an energy transfer between the PL emission band of the ligands and the absorption band of the erbium ion. Thus, these results could be attributed to the efficient energy transfer process between the organic ligands and the Er ion, since spectral overlap between the PL band of the organic ligands and the absorption bands of the Er ion at 357, 365 and 379 nm occurs.

4. Supplementary material

Abstract

The nickel(II) complexes of *N*,*N*′-xylylenebis(tetraazamacrocycles) have been isolated. The description of these dinuclear bismacrocyclic complexes have been carried out by means of magnetic measurements and spectrophotometric experiments (UV–Vis). The metal environment and the ligand shape have been specified by XANES and EXAFS experiments, since attempts to obtain suitable crystals failed.

1. Introduction

Over the last 10 years, numerous polyamine ligands that are able to bind increasing number of metallic ions have been described in the literature. For this purpose, macrocyclic polyamines are often involved because of their strong ligating properties towards metallic ions, and then for the thermodynamic and kinetic stability of the corresponding complexes [1,2]. According to the design of the macrocyclic framework, these ligands may particularly be able to hold two or more metal centres in relatively close proximity [3].

There have been few reports on the X-ray structures of bistetrazamacrocyclic complexes [4,5] because they often failed to crystallize. In this study, besides magnetic measurements and UV–visible spectroscopy of Ni(II) dinuclear bistetraazamacrocyclic complexes formed with various ligands (Scheme 1), X-ray absorption spectroscopy is used as alternative technique to crystallography. X-ray absorption near edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) are well known to provide reliable information about the geometry, the oxidation state of metal ions and the structure of the metallic complexes including tetraazamacrocyclic complexes [4,6]. Moreover, in dinuclear complexes with symmetrical ligands $\mathbf{L}^{1-4}$, the XAS spectroscopy is expected to give an average of the two metal environments, since the few known X-ray structures of bistetraazamacrocyclic complexes [4,5] indicated that the two metallic sites are almost identical.

2. Results and discussion

2.1. Magnetic measurements and UV–Vis spectroscopy

Magnetic and spectroscopic data for complexes $[Ni_2\mathbf{L}^{1-5}]^{4+}$ are listed in Table 1. The molar magnetic susceptibilities of cyclen complexes $[Ni_2\mathbf{L}^{1,2}(ClO_4)_4]$ (respectively, 7793 and 7160×10^{-6} cgs unit at 293 K) indicate that the two d^8 nickel ions are held in an octahedral geometry (this value is calculated if one assume that there is no strong interaction between the two metal centers). On the contrary, the diamagnetism of cyclam complexes $[Ni_2\mathbf{L}^{3,4}(ClO_4)_4]$ indicate that the metal ions included in the macrocyclic cavity are held in a square planar geometry. Nevertheless, when the counter anion is chloride, the biscyclam complex $[Ni_2\mathbf{L}^{3}Cl_4]$ becomes again paramagnetic (7670×10^{-6} cgs unit) indicating that two chloride anions are coordinated to each nickel(II) center whose geometry becomes octahedral. Finally, the low-magnetic susceptibility of $[Ni_2\mathbf{L}^{5}(ClO_4)_2](ClO_4)_2$ is, as expected for a complex based on a dissymmetrical cyclen–cyclam ligand, an average of the magnetic susceptibility of a square planar Ni(II) ion (in the cyclam cavity, Ni(II) is diamagnetic) and an octahedral Ni(II) ion (in the cyclen moiety, Ni(II) is then paramagnetic).

The UV–visible absorbance spectra are also indicative of coordination of the nickel ions (Table 1). Solid spectra of the dinuclear cyclen complexes $[Ni_2\mathbf{L}^{1}(ClO_4)_4]$ and $[Ni_2\mathbf{L}^{2}(ClO_4)_4]$ present several similar bands (respectively, 390–392, 571–588, 950–980 nm) typical of Ni(II) d^8 ions in an octahedral geometry. Electronic spectra of the biscyclam complexes $[Ni_2\mathbf{L}^{3}](ClO_4)_4$ and $[Ni_2\mathbf{L}^{4}](ClO_4)_4$ are simplest since they exhibit a single band at 460 nm characteristic of Ni(II) ions in a square planar geometry. On the other hand, the solid spectrum of the dinuclear complex $[Ni_2\mathbf{L}^{3}Cl_4]$ exhibits several bands at 364, 448(sh), 558, 741(sh) and 1240 nm. These values can be attributed to the transitions of nickel(II) ions d^8 in a weak D_{4h} field, i.e., an octahedral environment, in accordance with magnetic measurements. At last, the electronic spectrum of $[Ni_2\mathbf{L}^{5}(ClO_4)_2](ClO_4)_2$ exhibits either the bands of the octahedral Ni ion in the cyclen moiety (392, 588, 799(sh), 950(br) nm) and the band of a square planar nickel(II) ion in a cyclam moiety (460 nm).

2.2. XANES and EXAFS studies

As Ni(II) complexes of $\mathbf{L^1}$ to $\mathbf{L^5}$ bismacrocycles failed to crystallize, XANES and EXAFS spectra were recorded. The Ni K-edge XANES spectra of nickel(II)

Table 1
Magnetic susceptibilities and electronic spectra of nickel(II) complexes, in solid state

Complexes	Magnetic susceptibilities $\chi_{Mcorr.}$ (10^{-6} cgs unit) at 293 K	λ_{max} (nm)
$[Ni_2\mathbf{L}^{1}(ClO_4)_4]$	7793	390–571–792(sh)–950(br)
$[Ni_2\mathbf{L}^{2}(ClO_4)_4]$	7160	392–588–799(sh)–980(br)
$[Ni_2\mathbf{L}^{3}Cl_4]$	7670	364–448(sh)–558–741(sh)–1240
$[Ni_2\mathbf{L}^{3}](ClO_4)_4$	diamagnetic	460
$[Ni_2\mathbf{L}^{4}](ClO_4)_4$	diamagnetic	460
$[Ni_2\mathbf{L}^{5}(ClO_4)_2](ClO_4)_2$	4600	392–460–588–799(sh)–950(br)

complexes, gathered in Fig. 1, display a very small peak around 8330 eV (α) assigned to 1s → 3d transition, a main edge resonance around 8350 eV (β) and a multiple scattering feature above 8353 eV (γ). This last feature is related to the geometry of the medium range structure around the investigated element. The absence of a shift for this feature in all the spectra indicates a similar organization around Ni(II) ions. In Fig. 1(a), the XANES spectra of cyclam complexes $[Ni_2\mathbf{L}^3Cl_4]$, $[Ni_2\mathbf{L}^3](ClO_4)_4$, $[Ni_2\mathbf{L}^4](ClO_4)_4$ are reported. For the $[Ni_2\mathbf{L}^3Cl_4]$ spectrum, the low intensity of the pre-edge peak (α) near 8330 eV and the high intensity of the shape resonance (β) indicate that Ni(II) ions may be closed to an octahedral environment, since the intensity of this latter peak decreases with the cation coordination number [7]. The Ni(II) geometry is confirmed by the absence of splitting for the main edge resonance (β). On the contrary, $[Ni_2\mathbf{L}^3](ClO_4)_4$ and $[Ni_2\mathbf{L}^4](ClO_4)_4$ spectra exhibit a splitting of the main edge peak (β) associated with $1s \rightarrow 4p_z$ and $1s \rightarrow 4p_{x,y}$ transitions, which means that nickel ions may be closed to a square planar geometry. One should notice that the comparison of $[Ni_2\mathbf{L}^3Cl_4]$ and $[Ni_2\mathbf{L}^3](ClO_4)_4$ spectra illustrates the influence of the anion on the signal for these cyclam complexes, depending on whether the anion is coordinated (Cl^-) or not (ClO_4^-).

The XANES spectra of the cyclen complexes $[Ni_2\mathbf{L}^1(ClO_4)_4]$, $[Ni_2\mathbf{L}^2(ClO_4)_4]$ (Fig. 1(b)) are similar to the $[Ni_2\mathbf{L}^3Cl_4]$ one, i.e., without splitting of the main-edge resonance. Consequently, nickel ions display an octahedral mode of coordination, which means that in these cyclen complexes, the perchlorate ions are coordinated.

Finally, in Fig. 1(c), the XANES spectrum of the $[Ni_2\mathbf{L}^5(ClO_4)_2](ClO_4)_2$ complex and those of $[Ni_2\mathbf{L}^2(ClO_4)_4]$ and $[Ni_2\mathbf{L}^4](ClO_4)_4$ complexes are reported. The dissymmetrical ligand $\mathbf{L}^5$ involves both a cyclen and a cyclam cavity. The intensity of the $1s \rightarrow 4p_z$ transition around 8335 eV, intermediate between a D_{4h} and an O_h symmetry, may significate that the nickel ion is held in two different geometries according to the macrocyclic cavity.

The k^3-weighted experimental and least-squares fitted EXAFS spectra of nickel(II) compounds are shown in Fig. 2 and the results of least-squares fitting reported in Table 2. Two kinds of EXAFS spectra are obtained depending on the shape of the sinusoidal signal. For the perchlorate complexes based on the cyclam cavity, no beating is noticed between 6 and 8 $Å^{-1}$ (spectra 2 and 3, Fig. 2) whereas for the complexes based on the cyclen moiety (spectra 4 and 5, Fig. 2) a splitting of the second sinusoid is observed. This discrepancy is due to the metal environment and, for the first two complexes, the nickel is held in a square-planar environment whereas, for the latter, the metal is held in an octahedral system. One-coordination shell is therefore found for square planar compounds, whereas, for the octahedral ones, two-coordination shells are determined. In all cases, the first coordination sphere around the Ni(II) is

Scheme 2.

than in the case of $[Ni_2\mathbf{L^3}](ClO_4)_4$, is in accordance with the octahedral geometry proposed from the XANES spectrum. Finally, for the dissymmetrical complex $[Ni_2\mathbf{L^5}(ClO_4)_2](ClO_4)_2$, the best fit is in accordance with an average bond around 2.03 Å, since the shells between the Ni–N_{cyclen} and Ni–N_{cyclam} bonds cannot be distinguished.

In tetraazamacrocyclic complexes, the metal–N bond lengths can generally be correlated to the conformation of the macrocyclic cavity. The comparison between these distances determined either by X-ray or by EXAFS can give an estimation of the shape of the ligand in the $[Ni_2\mathbf{L^{1-5}}]^{4+}$ complexes. For instance, the X-ray characterisation of mononuclear perchlorate Ni cyclam complexes [8] demonstrates that the Ni–N length is 1.96–1.98 Å in average. The Ni(II) ion is then in a square planar geometry and the ligand adopts the *trans*-III conformation [8] (Scheme 2). The comparison between these distances and the ones determined by EXAFS for bis-cyclam complexes $[Ni_2\mathbf{L^3}](ClO_4)_4$ and $[Ni_2\mathbf{L^4}](ClO_4)_4$ (Ni–N lengths of 1.96 and 1.98 Å, respectively) seems to indicate that in these dinuclear complexes, the macrocyclic cavities can be considered as similar and exhibit a *trans-III* conformation with a Ni(II) ion in a square planar environment.

Furthermore, in Ni cyclam complexes with halide [9,10] as counter-ions, the X-ray structures of complexes show that Ni–N length are 2.05 Å in average, with the Ni(II) ion in a distorted octahedral geometry and the ligand in a *trans-III* conformation. The Ni–N distances determined by EXAFS for $[Ni_2\mathbf{L^3}Cl_4]$ (2.08 Å) leads to propose, by comparison, a distorted octahedral environment for the nickel ion with a *trans-III* conformation for each cyclam subunit. The determination by EXAFS of a second coordination shell around the nickel ion on the radial distribution function, corroborates this analysis since it indicates that the nickel coordination sphere is probably completed with two chloride ions at a distance of approximately 2.84–2.90 Å. This long distance between Ni(II) and chloride ions is in agreement with a tetragonal distortion along the *z*-axis in $[Ni_2\mathbf{L^3}Cl_4]$. Since it is well known that N (or O) atom presents quite out of phase signals (for the same inter-atomic distance) with Cl, we can not rule out by EXAFS that oxygen atoms from solvent molecules complete the Ni coordination sphere. But, the chemical analysis of the $[Ni_2\mathbf{L^3}Cl_4]$ complex clearly indicates the presence of four chloride atoms (see Section 4).

In the case of the mononuclear Ni cyclen complexes, the known crystal structures [11,12] show that the nickel(II) ion is six coordinated. The macrocyclic cavity is in a *cis-V* conformation (Scheme 2) which leads to the extrusion of the metal ion from the macrocyclic nitrogen plane and to Ni–N lengths of 2.10 Å in average [12]. The distances determined by EXAFS for the complexes $[Ni_2\mathbf{L^1}(ClO_4)_4]$ and $[Ni_2\mathbf{L^2}(ClO_4)_4]$ are, respectively, of 2.10 and 2.12 Å. They seem then to indicate that in these complexes, each cyclen cavity is in a *cis-V* conformation and the Ni(II) ion held in an octahedral geometry. This is strengthened by the determination in the radial distribution function, of a second coordination shell with two oxygen atoms (Ni–O distance of 2.88–2.89 Å coming probably from the perchlorate counter-ion, as already observed for Ni(II) Schiff base macrocycle [13]).

Finally, for $[Ni\mathbf{L^5}(ClO_4)_2](ClO_4)_2$ complex, according to the counter-ions and the Ni–N distances one can assume that the cyclam cavity is in a *trans-III* conformation with a Ni(II) in a square planar environment (N_4 chromophore), while the cyclen cavity is in a *cis-V* conformation with a six-coordinated nickel(II) (N_4O_2 chromophore).

These structural data implicate that the metal is situated over the cyclen cavity in each biscyclen complex whereas for the biscyclam ones, the nickel is held inside the cyclam cavity.

3. Conclusion

X-ray absorption spectroscopy represents an alternative technique for the characterisation of the metallic environment in bismacrocyclic complexes. The nature of the surrounding chromophore can be specified by XANES, confirmed by UV–Vis spectrospcopy and magnetic measurements, especially for Ni (II) complexes. The determination of bond lengths between the nickel

atom and its closest neighbours was achieved by EXAFS. The good agreement between Ni–N EXAFS distances in dinuclear macrocycles and the distances obtained by crystallography for the mononuclear complexes, allowed the description of the complex stereochemistry. Consequently, these methods may be useful for the knowledge of the metal coordination polyhedron in bistetraazamacrocyclic complexes, especially when these compounds failed to crystallize.

4. Experimental

4.1. Materials

The metal salts and the ion exchanger resin "Amberlite IRA-900" were purchased from Aldrich.

4.2. Synthesis of the ligands and their complexes

The ligands were synthesised following a new three-step method [14] that used a macrocyclic bisaminal as an intermediate. The bismacrocycles are obtained in good yields as hydrochloride salts for the cyclam derivatives and neutral powders for the cyclen ones. When necessary, the products were eluted with water on an anionic exchange resin.

4.2.1. Synthesis of complexes $[Ni_2\mathbf{L}](ClO_4)_4$, $\mathbf{L} = \mathbf{L^1}$ to $\mathbf{L^5}$

The neutral ligand (10^{-4} mol) was dissolved in methanol (20 mL) and the nickel(II) perchlorate in methanolic solution (2.1×10^{-4} mol) was added dropwise. The yellow solution was refluxed for 2 h, and evaporated under vacuum. The solid obtained was filtered and washed twice with absolute ethanol. The presence of ethyl alcohol in complexes was revealed by NMR spectroscopy, the perchlorate by IR. *Caution*: The perchlorate compounds must be handled with care due to their tendency to explode.

$[Ni_2\mathbf{L^1}(ClO_4)_4] \cdot EtOH$: *Anal*. Calc. for $C_{26}H_{52}N_8O_{17}Cl_4Ni_2$ (1007,93 g. mol^{-1}): C, 30.97; H, 5.16; N, 11.12. Found: C, 30.95; H, 5.15. N, 11.11%. IR (KBr pellet, ν/cm^{-1}): 1088. Yield: 70%.

$[Ni_2\mathbf{L^5}](ClO_4)_4 \cdot EtOH$: *Anal*. Calc. for $C_{28}H_{56}N_8O_{17}Cl_4Ni_2$ (1035.99 g. mol^{-1}): C, 32.45; H, 5.41; N, 10.81. Found: C, 32.60; H, 5.55; N, 11.05%. IR (KBr pellet, ν/cm^{-1}): 1095. Yield: 40%.

4.2.2. Synthesis of $[Ni_2\mathbf{L^3}Cl_4] \cdot H_2O$

A methanolic nickel(II) chloride solution (2.1×10^{-4} mol) was added dropwise to the neutral $\mathbf{L^3}$ ligand (10^{-4} mol, 20 mL MeOH). The yellow solution was refluxed for 2 h, and evaporated under vacuum. The purple solid obtained was filtered and washed twice with absolute ethanol.

Anal. Calc. for $C_{28}H_{56}N_8OCl_4Ni_2$ (779.99 g. mol^{-1}): C, 43.11; H, 7.19; N, 14.37. Found: C, 43.43; H, 7.38; N, 14.54%. Yield: 30%.

4.3. UV–Vis spectroscopy

Electronic spectra were measured in the 300–1100 nm range on a Shimadzu UV 160A spectrophotometer. Solid spectra were obtained by depositing the product on a "Schleicher and Schul" paper. IR spectra were obtained in KBr pellets with a Nicolet Avatar 320 spectrometer.

4.4. Magnetic susceptibility measurements

Magnetic susceptibilities were determined at room temperature (293 K) using $HgCo(SCN)_4$ as a calibrant. Diamagnetic susceptibility corrections were calculated from Pascal's constants.

4.5. X-ray absorption data collection and processing

Experiments were made at room temperature on the beam line D44 of the LURE-DCI storage ring (Orsay, France), with a double crystal Si(1 1 1) for EXAFS and Si(3 1 1) for XANES mono-chromator. The DCI storage ring was operating at 1.85 GeV, with a 300 mA positron current. Nickel K-edge spectra were obtained in transmission mode with two low-pressure (≈0.2 atm) air-filled ionisation chambers. The compounds were dispersed in cellulose pellets. The weight of the samples was calculated in order to have an absorption edge equal to 1. XANES spectra were recorded with an energy step of 0.3 eV and 2 s per step, from the beginning of the spectrum to 100 eV after the edge (E_K = 8333 eV). EXAFS spectra were recorded with a 2 eV energy step and an accumulation time of 2 s per step. For each compound, three spectra were averaged to improve the signal-to-noise ratio for both XANES and EXAFS regions. A nickel metallic foil was used for energy calibration. All XANES spectra were normalised using the Galaad software from the "EXAFS pour le Mac" package [15].

The EXAFS data analysis was performed by means of the "EXAFS pour le Mac" package. The $\chi(k)$ functions were extracted from the data [16–18] with a linear

pre-edge background, a combination of polynomials and spline atomic-absorption background, and normalised by using the Lengeler–Eisenberg method [19]. The energy threshold, E_0, was taken at the middle of the absorption edge. E_0 was corrected for each spectrum in the fitting procedure. The experimental XAFS signal $\chi(k)$ was multiplied by a factor k^3 to compensate for the decrease in its amplitude with the increase in the wave-vector value. The k^3 weighted $\chi(k)$ function was Fourier transformed by means of a Kaiser-Bessel window with a smoothness parameter τ equal to 2.5 (k is the photoelectron wave number). In this work, all Fourier transforms were calculated and presented without phase correction; therefore, the position of the peaks differs about 0.4 Å from the true crystallographic values. In all the FTs of the experimental spectra, there is one main peak located at 1.6 Å, a second peak at 2.4 Å, and a third one at 2.7 Å. The lower peaks located above 3.0 Å were attributed to multiple-scattering contributions [6a]. Only the two first peaks, which correspond to the atoms directly bound to the metal (first coordination shell), were analysed using a single scattering approach which is suitable for the first shell, since multiple scattering is negligible under 2.8 Å [6a]. The latest, corresponding to carbon atoms, is not analysed because of the low interest of this coordination shell for our purpose.

The peaks corresponding to the first-coordination shell were then isolated and back-Fourier transformed into k space to determine the mean coordination number, N, the bond length, R, and the Debye-Waller factor, σ, by a fitting procedure realised in the framework of single scattering using the standard EXAFS formula

$$\chi(k) = -S_0^2 \sum_i \left[\frac{N_i}{R_i^2} A_i(k)\, \mathrm{e}^{-2\sigma_i^2 k^2}\, \mathrm{e}^{-2R_i/\lambda(k)} \sin(2kR_i + \Phi_i(k)) \right].$$

The number of fitting parameters did not exceed the number of independent points (N_{IDP}) throughout the fitting process, where $N_{IDP} = 2\Delta k(\Delta R/\pi)$, where Δk is the range fit and ΔR is the width of the R-space Fourier window [18]. Optimization of the parameters was performed with the E_0 shift constrained, and the amplitude reduction factor, S_0^2, fixed at 0.90.

The experimental XAFS signals of the first coordination shell of Cu were singled out by the back FT procedure in the range 0.7–2.6 Å. The back-scattering phase, $\Phi_i(k, R_i)$, and amplitude, $A_i(k, R_i)$, functions were extracted from the EXAFS data of the model compounds of known crystallographic structure: [Ni(cyclam)$(ClO_4)_2$] [8], and $Ni(NO_3)_2 \cdot 6H_2O$ [20]. The XAFS signal was Fourier transformed in the k range from 2.0 to 15.0 $Å^{-1}$ and filtered in the 0.8–2.1 Å range (see ESI1). Theoretical approach, using the ab-initio code FEFF 7.02 [21], was used to check the back-scattering amplitude and phase-shift functions, and if multiple scattering was effectively negligible under 2.8 Å. These functions were calculated assuming the following local structure around the metallic cation in [Ni(cyclam)$(ClO_4)_2$] [8]: NiN_4C_{10} ($R_{Ni-N} = 1.98$ Å, $R_{Ni-C} = 2.77$, 2.95, and 3.29 Å). The phase and amplitude functions for the Ni–Cl pair were extracted from the Ni(cyclam)Cl_2 compound [9] using the FEFF 7.02 code. Coordination numbers, N, were kept constant during each optimization although different coordination numbers were tested to find the best fit. During the final fitting procedure, coordination numbers, N, were fixed, while distance R, Debye-Waller factor σ^2, and energy shift ΔE_0 were varied. Interatomic distances and coordination numbers derived from fitting of model compounds are in close agreement with those obtained by X-ray diffraction (XRD) in limit of ±0.02 Å and ±20% atoms for the first atomic shell (Table 2).

Abstract

Reaction of $TiCl_4$ with the reagents $RN(SiMe_3)_2$ in dichloromethane precipitates red to black powders (R = 1-adamantyl, phenyl, pentafluorophenyl, 3,5-bis(trifluoromethyl)phenyl), which on treatment with tetrahydrofuran gives the new THF adducts $[Ti(NR)Cl(\mu\text{-}Cl)(THF)_2]_2$. The complexes are dimeric in the solid state with bridging chloride and terminal imido ligands. Activation with MAO (methylaluminoxane) gives ethene polymerisation catalysts with productivities of up to 31 kg PE [(mol complex) h bar]$^{-1}$.

1. Introduction

Metal imido complexes are known to adopt a number of structural motifs [1]. For example, titanium forms complexes in which imido ligands adopt either bridging (for example **I**, Chart 1) [2] or terminal (**II**) [3] bonding modes [4]. We recently reported the synthesis and structure of $[Ti(\mu\text{-}NAr^P)Me_2(THF)]_2$ (**III**) (Ar^P = *m*-$C_6H_4P(3,5\text{-}(CF_3)_2C_6H_3)_2$) in which the imido ligand is bridging [5]. This result contrasts with Nielson's 2-*tert*-butyl- (**IV**) and 2-phenyl-phenylimido complexes which form chloride-bridged dimers [6] and Carmalt's exclusively chloride-bridged tetramer (**V**) [7]. In the absence of basic co-ligands structures with even higher nuclearity have been observed [8–10]. We continue to be interested in the factors dictating whether the imido ligand adopts a bridging or terminal bonding mode and the implications for alkene polymerisation catalysis using titanium imido precatalysts [6,11]. We report here the synthesis, structure and polymerisation activity of compounds of the type $[Ti(NR)Cl_2(THF)_2]$.

2. Results and discussion

Most commonly imidotitanium complexes are prepared through an imido exchange reaction between $[Ti(NBu^t)Cl_2(L)_x]$ and the corresponding primary amine [6]. We chose to employ an alternative dehalosilylation methodology in order to access the base-free compounds [12]. The ligand precursors $RN(SiMe_3)_2$ (**1a**–**g**) were readily prepared by the step-wise deprotonation of the parent amine and reaction with trimethylsilylchloride (Scheme 1). Treating $TiCl_4$ with **1a**–**d** in dichloromethane solution led to the precipitation of sparingly soluble red to black solids (Scheme 2). Unfortunately the poor solubility of these crude materials in non-basic

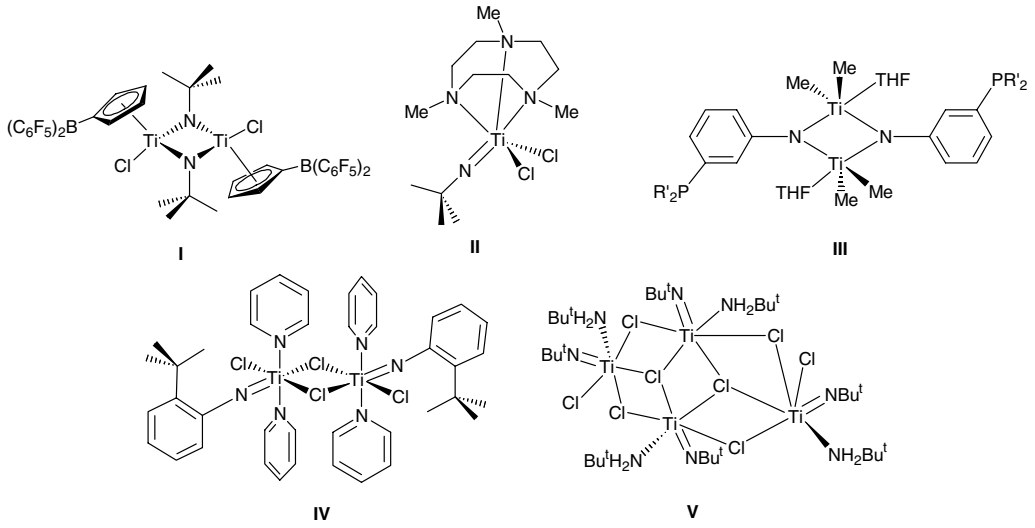

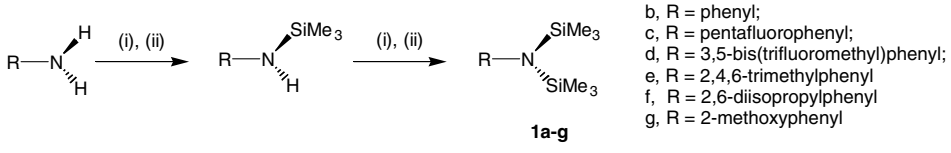

Chart 1.

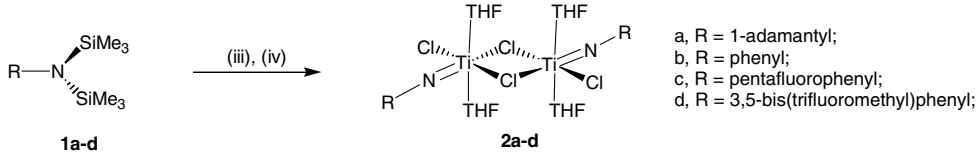

solvents, which presumably reflects high nuclearity, precluded spectroscopic characterisation or attempts to obtain X-ray quality crystals. However, the solids reacted exothermically on dissolution in tetrahydrofuran and could be isolated as THF adducts **2a**–**d** on crystallisation from THF/light petroleum mixtures. ^{1}H NMR spectroscopy of **2a**–**d** confirmed that quantitative dehalosilylation had taken place and indicated a ligand RN:THF ratio of 1:2, which was supported by the elemental analysis. This composition differs from that observed for $[Ti(\mu\text{-}NAr^P)Cl_2(THF)]_2$ where the ligand RN:THF ratio is 1:1 [5], but is consistent with a formulation analogous to complex **IV**, which has a chloride-bridged structure with terminal imido ligands. While the dehalosilylation route is effective for the introduction of *meta*-substituted aryl imido ligands, the *ortho* disubstituted reagents **1e** and **1f** failed to react with $TiCl_4$, even after refluxing in toluene, presumably as a consequence of steric encumbrance. However, the mononuclear complex $[Ti(NAr'')Cl_2(py)_3]$ (Ar″ = 2,6-diisopropylphenyl, py = pyridine) is accessible through an imido exchange reaction [3c]. The *o*-OMe compound **1g** reacted with $TiCl_4$ but the resulting product was intractable and could not be isolated even after treatment with THF.

The structure of **2b** (Fig. 1) was determined by X-ray crystallography and confirmed as a chloride-bridged dimer with two edge-sharing octahedral metal coordination spheres. Each distorted octahedron is completed by terminal chloride and imido ligands opposite the bridging chlorides and two mutually *trans* THF ligands. The geometry resembles the 2-*tert*-butylphenyl imido complex **IV**, which has *trans* pyridine ligands.

Selected bond lengths and angles for complex **2b** are shown in Table 1. While the terminal imido bond length is insensitive to the differences between **2b**, **IV** and the mononuclear complex $[Ti(NC_6H_5)Cl_2(py)_3]$ at 1.710(2), 1.702(2) and 1.714(2) Å, respectively, the C1–N1–Ti1 angle decreases from the almost linear, 177.5(2)°, in $[Ti(NC_6H_5)Cl_2(py)_3]$ to 167.5(2)° in **2b** and 165.9(2)° in **IV**, which reflects the increase in steric crowding.

Since complexes **2b**, **IV** and $[Ti(NCMe_3)Cl(\mu\text{-}Cl)(NH_2CMe_3)_2]_2$ [6] all adopt similar dimeric structures with bridging chlorides, its seems likely that the remaining examples **2a,c,d,** which all have two THF ligands per metal centre, have a similar structure. Our complexes are consistent with the pattern illustrated by **II** and **IV**, whereas bridging imido ligands are preferred to bridging chloride ligands only in relatively electron rich complexes, with low steric hindrance.

We reasoned that exchanging the chloride for methyl ligands in complexes **2a**–**2d** might result in structural analogues to **III**. Unfortunately, attempts to isolate the products of treating **2a**–**d** with the alkylating agents LiMe, MgClMe and $ZnMe_2$ were unsuccessful, yielding only black tars. [1] This is in sharp contrast to the reaction of $[Ti(\mu\text{-}NAr^{P})Cl_2(THF)]_2$ with LiMe which proceeds smoothly in diethyl ether at 0 °C to give **III**. Nevertheless, it remains possible that dinuclear imido-bridged complexes are formed during the reaction of **2a**–**d** with the catalyst activator methylaluminoxane (MAO).

[1] Similar difficulties were reported in [6].

3. Polymerisation studies

Complexes **2a**–**d** were screened as ethene polymerisation pre-catalysts in combination with MAO (methylaluminoxane) and the results are presented in Table 2. The productivities are in the region of 10 kg [(mol complex) h bar]$^{-1}$, and there is no suggestion of mass transport limitation. The gel permeation chromatography (GPC) traces indicated bi- or polymodal distributions preventing the assignment of meaningful polydispersities and implying the formation of more than one active species. In each of the systems studied increasing the polymerisation temperature from 20 to 60 °C resulted in significantly lower molecular weight polymer. The effect of raising the polymerisation temperature on the productivity appears to be highly dependent on the nature of the imido substituent, such that **2a** and **2d** showed a modest increase in productivity, while in contrast **2b** and **2c** showed a decrease, possibly as a result of catalyst decomposition. Mountford has recently reported a dramatic productivity dependence on polymerisation temperature for imido titanium catalysts of the type illustrated by **II** [11b]. Our results are broadly comparable with those observed for $[Ti(NC_6H_4\text{–}Ph\text{-}2)Cl(\mu\text{-}Cl)(tmeda)]_2$ (12.7 kg PE [(mol complex) h bar]$^{-1}$ at 20 °C) [6] but they do not approach the 1.1×10^6 g PE [(mol complex) h bar]$^{-1}$ we obtained with **III**/MAO [5].

4. Conclusion

Titanium tetrachloride undergoes a facile dehalosilylation reaction with the relatively unhindered bis(silyl)amines **1a**–**1d** but fails to react with 2,6-substituted silyl anilines (**1f, 1g**). The resulting products react with tetrahydrofuran to give the adducts $[Ti(NR)Cl(\mu\text{-}Cl)(THF)_2]_2$ (**2a**–**2d**). **2a**–**d** are chloride-bridged dimers with terminal imido ligands. Activation of **2a**–**2d** with MAO (methylaluminoxane) gives ethene polymerisation catalysts with moderate productivity.

5. Experimental

5.1. General

Syntheses were performed under nitrogen using standard Schlenk techniques. Solvents were distilled over sodium–benzophenone (diethyl ether, tetrahydrofuran), sodium (toluene), sodium–potassium alloy

(light petroleum, b.p. 40–60 °C), or CaH_2 (dichloromethane). NMR solvent ($CDCl_3$) was dried over activated 4 Å molecular sieves and degassed by several freeze thaw cycles. NMR spectra were recorded using a Bruker DPX300 spectrometer. Data are reported in ppm and referenced to residual solvent resonances (^1H, ^{13}C); ^{19}F is relative to $CFCl_3$. IR spectra were measured as nujol mulls on a Perkin–Elmer Spectrum 1000 FT IR spectrometer in the range of 600–4000 cm^{-1}. Nitrogen and ethene (BOC, 99.5%) were purified by passing through columns of supported P_2O_5 with moisture indicator, and activated 4 Å molecular sieves. MAO was purchased from Witco as a 10% solution in toluene and used as received. GPC analyses were performed on a Polymer Labs PL-GPC-220 chromatograph. Elemental analyses were performed by the School Microanalysis Service.

5.2. Ligand synthesis

5.2.1. *(1-Adamantyl)N(SiMe$_3$)$_2$ (**1a**)*

To a stirred solution of 1-adamantylamine (4.6 cm^3, 50 mmol) in tetrahydrofuran (100 cm^3), held at −78 °C, was slowly added *n*-butyllithium (31.3 cm^3 of a 1.6 M hexane solution, 50 mmol). The reaction was stirred for 2 h at room temperature before slow addition of trimethylsilylchloride (6.4 cm^3, 50 mmol). The resulting mixture was stirred for 2 h at room temperature before cooling to −78 °C and treatment with a second portion of *n*-butyllithium (31.3 cm^3 of a 1.6 M hexane solution, 50 mmol). This suspension was stirred for 2 h at room temperature before adding further trimethylsilylchloride (6.4 cm^3, 50 mmol) and stirring for 2 h to ensure complete reaction. The volatiles were removed under reduced pressure and the product extracted with light petroleum (2×50 cm^3). The product was purified by vacuum distillation, 65 °C at 0.1 mbar to give a colourless oil in 80% yield. ^1H NMR (300 MHz, 293 K, $CDCl_3$): δ 0.51 (br m, 3H, $(CH)_3$), 0.18 (br m, 6H $(CH_2)_3$), 0.1 (br m, 6H $(CH_2)_3$), 0.08 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 36.7 (CH), 30.4 (CH_2), 30.1 (CH_2), 3.3 ($Si(CH_3)_3$).

5.2.2. *C$_6$H$_5$N(SiMe$_3$)$_2$ (**1b**)*

1b was prepared from aniline following the procedure outlined for **1a**. The product was purified by vacuum distillation, 81 °C at 15 mbar giving the product as a colourless oil in 80% yield. ^1H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.26 (t, 2H, $J = 7.0$ Hz, Ar), 7.11 (t, 1H, $J = 7.3$ Hz, Ar), 6.96 (d, 2H, $J = 6.9$ Hz, Ar), 0.14 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 148.4, 130.6, 128.7, 123.9 (Ar), 2.5 ($Si(CH_3)_3$).

5.2.3. *C$_6$F$_5$N(SiMe$_3$)$_2$ (**1c**)*

1c was prepared from pentafluoroaniline following the procedure outlined for **1a**. The product was purified by vacuum distillation, 75 °C at 15 mbar to give a colourless oil in 90% yield. ^1H NMR (300 MHz, 293 K, $CDCl_3$): δ 0.13 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 146.4 (d, $J_{C-F} = 242$ Hz, *o*-C), 138.0 (d, $J_{C-F} = 249$ Hz, *m*-C), 127.9 (*i*-C), 1.6 ($Si(CH_3)_3$). ^{19}F NMR (283.4 MHz, 293 K, $CDCl_3$): δ −147.5 (d, 2F, $J_{F-F} = 20$ Hz, *o*-F), −162.5 (tr, 1F, $J_{F-F} = 20$ Hz, *p*-F), −165.0 (tr, 2F, $J_{F-F} = 20$ Hz, *m*-F).

5.2.4. *C$_6$H$_3$(CF$_3$)$_2$N(SiMe$_3$)$_2$ (**1d**)*

1d was prepared from 3,5-bis(trifluoromethyl)aniline following the procedure outlined for **1a**. The product was purified by vacuum distillation, 70 °C at 20 mbar to give a colourless oil in 80% yield. ^1H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.60 (s, 1H, *p*-H), 7.34 (s, 2H, *o*-H), 0.12 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 150.9 (*p*-C), 132.2 (q, $J_{C-F} = 33$ Hz, *m*-C(CF_3)), 130.2 (*o*-C), 123.7 (q, $J_{C-F} = 273$ Hz, CF_3), 117.5 (*i*-C), 2.2 ($Si(CH_3)_3$). ^{19}F NMR (283.4 MHz, 300 K, $CDCl_3$): δ −63.5 (s, 6F, CF_3).

5.2.5. *C$_6$H$_2$Me$_3$N(SiMe$_3$)$_2$ (**1e**)*

1e was prepared from 2,4,6-trimethylaniline following the procedure outlined for **1a**. The product was purified by vacuum distillation, 95 °C at 15 mbar to give a colourless oil in 80% yield. ^1H NMR (300 MHz, 293 K, $CDCl_3$): δ 6.89 (s, 2H, *m*-H), 2.31 (s, 6H, *o*-CH_3), 2.31 (s, 3H, *p*-CH_3), 0.18 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 143.5 (*p*-C), 136.8

(*m*-C), 132.7 (*i*-C), 129.5 (*o*-C), 21.2 (*p*-CH_3), 20.8 (*o*-CH_3), 2.9 ($Si(CH_3)_3$).

5.2.6. $C_6H_3{}^iPr_2N(SiMe_3)_2$ (**1f**)

1f was prepared from 2,6-di(isopropyl)aniline following the procedure outlined for **1a**. The product was purified by crystallisation from light petroleum at −30 °C to give white crystals in 90% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.07 (m, 3H, Ar), 3.49 (sep, 2H, $J = 6.9$, $CH(CH_3)_2$), 1.21 (d, 12H, $J = 6.9$ Hz, $CH(CH_3)_2$), 0.11 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 147.4 (*m*-C), 143.6 (*p*-C), 124.5 (*i*-C), 123.9 (*o*-C), 27.9 ($CH(CH_3)_2$), 25.5 ($CH(C_3)_2$), 2.9 ($Si(CH_3)_3$).

5.2.7. $C_6H_4OMeN(SiMe_3)_2$ (**1g**)

1g was prepared from 2-methoxyaniline following the procedure outlined for **1a**. The product was purified by vacuum distillation, 85 °C at 15 mbar to give a colourless oil in 80% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.09 (t, 1H, $J = 6.0$ Hz, Ar), 6.98 (d, 1H, $J = 6.3$ Hz, Ar), 6.88 (m, 2H, $J = 6.2$ Hz, Ar), 3.80 (s, 1H, OCH_3), 0.12 (s, 18H, $Si(CH_3)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 157.5, 137.4, 131.5, 124.8, 120.6, 110.9 (Ar), 55.2 (OCH_3), 2.3 ($Si(CH_3)_3$).

5.3. Complex synthesis

5.3.1. $[Ti(N\text{-}1\text{-}adamantyl)Cl(\mu\text{-}Cl)(THF)_2]_2$ (**2a**)

To a stirred solution of $TiCl_4$ (0.54 cm^3, 5 mmol) in dichloromethane (40 cm^3), **1a** (1.4 g, 5 mmol) was added drop wise and stirred for 2 h. The volatiles were removed under reduced pressure and the resulting red solid was washed with light petroleum (2×20 cm^3). The product was crystallised from a tetrahydrofuran (20 cm^3)/light petroleum (5 cm^3) solvent mixture at −30 °C to give yellow needle-shaped crystals in 65% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 4.57 (m, 4H, THF), 2.10 (m, 4H, THF), 1.88 (br m, 3H, $(CH)_3$), 1.66 (br m, 6H, $(CH_2)_3$), 1.44 (br m, 6H, $(CH_2)_3$). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 75.6 (THF), 45.2 ($(CH)_3$), 41.4 ($(CH_2)_3$), 29.9 ($(CH_2)_3$), 26.0 (THF). IR (cm^{-1}): 1278s, 1170m, 1039m, 1024s, 926w, 864m, 698w, 682w. *Anal.* Calc. for $C_{34}H_{62}N_2Cl_4O_4Ti_2$: C, 51.02; H, 7.81; N, 3.50; Cl, 17.72. Found: C, 50.81; H, 7.30; N, 3.42; Cl, 17.56%.

5.3.2. $[Ti(NPh)Cl(\mu\text{-}Cl)(THF)_2]_2$ (**2b**)

2b was prepared following a similar procedure to **2a** from $TiCl_4$ (1.1 cm^3, 10 mmol) and **1b** (2.4 g, 10 mmol) giving a black powder. Tetrahydrofuran (20 cm^3) was added and stirred for 5 min. An exothermic reaction took place to give a red solution. The product was crystallised from a tetrahydrofuran (20 cm^3)/light petroleum (5 cm^3) mixture at −30 °C to give red block crystals suitable for X-ray crystallography in 95% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.05 (t, 2H, $J = 7.7$ Hz, Ar), 6.80–6.88 (m, 3H, Ar), 4.47 (m, 8H, THF), 2.11 (m, 8H, THF). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 128.0 (Ar), 123.5 (Ar), 123.1 (Ar), 75.3 (THF), 25.5 (THF). IR (cm^{-1}): 1576m, 1342m, 1315s, 1246m, 1172w, 1066m, 1042m, 1017s, 970m, 825m, 860s, 772s, 684m, 649w, 619w. *Anal.* Calc. for $C_{28}H_{42}N_2Cl_4O_4Ti_2$: C, 47.48; H, 5.98; N, 3.96; Cl, 20.02. Found: C, 46.20; H, 6.02; N, 3.40; Cl, 19.31%.

5.3.3. $[Ti(NC_6F_5)Cl(\mu\text{-}Cl)(THF)_2]_2$ (**2c**)

2c was prepared following a similar procedure to **2a** from $TiCl_4$ (0.54 cm^3, 5 mmol) and **1c** (1.6 g, 5 mmol) giving a red solid. The product was crystallised from a tetrahydrofuran (20 cm^3)/petroleum (5 cm^3) mix at −30 °C to give dark red block crystals in 70% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 4.50 (m, 4H, THF), 2.15 (m, 4H, THF). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 76.4 (THF), 26.0 (THF). ^{19}F NMR (283.4 MHz, 293 K, $CDCl_3$): δ −152.8 (d, 2F, *o*-F), −164.7 (t, 1F, *p*-F), −165.5 (d, 2F, *m*-F). IR (cm^{-1}): 1525m, 1505s, 1334m, 1216w, 1171w, 1377w, 1350s, 1014m, 988m, 949w, 920w, 852m. *Anal.* Calc. for $C_{28}H_{32}F_{10}N_2Cl_4O_4Ti_2$: C, 37.87; H, 3.63; N, 3.15; Cl, 15.97. Found: C, 37.26; H, 3.66; N, 3.10; Cl, 15.53%.

5.3.4. $[Ti(NC_6H_3(CF_3)_2\text{-}3,5)Cl(\mu\text{-}Cl)(THF)_2]_2$ (**2d**)

2d was prepared following a similar procedure to **2a** from $TiCl_4$ (1.1 cm^3, 10 mmol) and **1d** (3.7 g, 10 mmol) giving a red solid. The product was crystallised from a tetrahydrofuran (20 cm^3)/petroleum (5 cm^3) mix at −30 °C to give bright red/orange needle-shaped crystals in 75% yield. ^{1}H NMR (300 MHz, 293 K, $CDCl_3$): δ 7.29 (s, 1H, *o*-H), 7.25 (s, 2H, *p*-H), 4.44 (m, 4H, THF), 2.09 (m, 4H, THF). ^{13}C NMR (75.5 MHz, 293 K, $CDCl_3$): δ 158.7 (Ar), 132.0 (q, $J_{C-F} = 33$ Hz, *m*-$C(CF_3)$), 129.0 (Ar), 123.8 (Ar), 123.5 (q, $J_{C-F} = 271$ Hz, CF_3), 116.2 (Ar), 76.0 (THF), 26.0 (THF). ^{19}F NMR (283.4 MHz, 300 K, $CDCl_3$): δ −63.5 (s, 6F, CF_3). IR (cm^{-1}): 1229m, 1089m, 1021s, 920w, 864m, 672w. *Anal.* Calc. for $C_{32}H_{38}F_{12}N_2Cl_4O_4Ti_2$: C, 39.21; H, 3.91; N, 2.86; Cl, 14.47. Found: C, 39.31; H, 3.97; N, 3.60; Cl, 14.72%.

5.4. Polymerisation procedure

A solution of MAO in toluene (50 cm^3) was saturated with ethene (1 bar) at the given temperature. Polymerisation was initiated by addition of a toluene solution of pre-catalyst into the reactor under vigorous stirring (1000 rpm). Methanol (1 cm^3) was added to terminate the polymerisation. The polymeric product was precipitated and separated from aluminium residues by addition of methanol (~300 cm^3) and 2 M HCl (~5 cm^3). The polymer was collected by filtration, washed with methanol, 2 M HCl, distilled water and

again with methanol before drying until constant mass at 80 °C. Each run is the average of at least two polymerisations.

6. Crystal structure analysis

Intensity data were recorded at the EPSRC National Crystallography Service at the University of Southampton on a Nonius Kappa CCD diffractometer (with Mo Kα radiation and graphite monochromator).

From a sample of orange block crystals of **2b** under oil, one, $0.44 \times 0.38 \times 0.22$ mm was mounted on a glass fibre and fixed in the cold nitrogen stream.

The cell was determined using DirAx [13]. Data were collected using Collect [14] and processed using the DENZO program [15]. The absorption was correction using SORTAV [16]. The structure was determined by the direct methods routines in the SHELXS [17] program and refined by full-matrix least-squares methods, on F^2's, in SHELXL [18]. The non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were included in idealised positions and their U_{iso} values were set to ride on the U_{eq} values of the parent carbon atoms.

Crystal data for **2b**: $C_{32}H_{50}Cl_4N_2O_5Ti_2$, Mr = 780.34, $T = 120(2)$ K, monoclinic, space group $C2/c$, $a = 19.5782(8)$ Å, $b = 9.0622(4)$ Å, $c = 31.5335(9)$ Å, $\beta = 107.507(2)°$, $V = 3643.5(3)$ Å^3, $\rho_{(calc)} = 1.423$ Mg/m^3, $\mu = 0.772$ mm^{-1}, $Z = 4$, reflections collected: 19 476, independent reflections: 4079 ($R_{int} = 0.0554$), completeness (to $\theta = 27.48°$) = 97.8%, final R indices [$I > 2\sigma(I)$]: $R_1 = 0.0461$, $wR_2 = 0.1148$, R indices (all data): $R_1 = 0.0638$, $wR_2 = 0.1248$.

7. Supplementary material

Crystallographic data (excluding structure factors) for structure **2b** have been deposited with the Cambridge Crystallographic Data Centre as Supplementary Publication No. CCDC-251697. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) +44 1223 336 033, e-mail: deposit@ccdc.cam.ac.uk, or www at http://www.ccdc.cam.ac.uk].

Abstract

Reaction of picolinic acid (Hpic) with rhodium trichloride or iridium trichloride affords tris-picolinate complexes of the type $[M(pic)_3]$ (M = Rh, Ir). The crystal structures of both complexes have been determined by X-ray diffraction. In both complexes, the picolinate ligands are coordinated to the metal center as bidentate N,O-donors forming five-membered chelate rings. There is one molecule of water of crystallization per molecule of each $[M(pic)_3]$ complex. The water molecule is hydrogen bonded to the carboxylate fragments of two adjacent $[M(pic)_3]$ molecules and thus acts as a bridge between the individual complex molecules. The complexes are diamagnetic (low-spin d^6, $S = 0$) and show intense MLCT transitions in the visible region. Cyclic voltammetry on the $[M(pic)_3]$ complexes shows a M(III)–M(IV) oxidation near 1.0 V versus SCE and a ligand-centered reductive response near −1.0 V versus SCE.

Keywords: Rhodium and iridium tris-picolinate complexes; Crystal structures; Electronic spectra; Electrochemical properties

1. Introduction

The chemistry of rhodium and iridium has been receiving considerable current attention [1], largely because of the interesting properties exhibited by the complexes of these two metals. As the properties of the complexes are dictated primarily by the coordination environment around the metal center, complexation of these metals by ligands of selected types has been of significant importance, and the present work has originated from our interest in this area [2]. For the complexation of rhodium and iridium, picolinic acid (**1**) has been chosen as the ligand in the present study. Picolinic acid (abbreviated as Hpic, where H stands for the dissociable carboxylic proton) is known to bind to metal ions as a bidentate N,O-donor forming a stable five-membered chelate ring (**2**) [3]. It is interesting to note that the two donor sites of the picolinate ligand are of significantly different nature.

1 **2**

The pyridine nitrogen is a soft donor and a recognized stabilizer of the lower oxidation states of transition metals, whereas the carboxylate oxygen is a hard donor and is known to stabilize transition metals in their higher oxidation states. Hence, coordination of rhodium and iridium by the picolinate ligand may be expected to have an interesting effect on the redox properties of the complexes. The main objective of the present work has been to synthesize the tris-picolinate complexes of rhodium

doi:10.1016/j.poly.2004.10.015

and iridium, and to study their physicochemical properties. It may be mentioned here that though tris-picolinate complexes of many transition metals have been studied well [4], those of rhodium and iridium appear to have remained unexplored. It may also be mentioned here that the tris-picolinate complexes of several transition metals have important applications in the biological field [4c,4e–4g]. Reaction of picolinic acid with the trichlorides of rhodium and iridium has afforded the targeted $[M(pic)_3]$ (M = Rh, Ir) complexes and the chemistry of these two complexes is reported in this paper with special reference to their synthesis, structure and, spectroscopic and electrochemical properties.

2. Experimental

2.1. Materials and measurements

Rhodium trichloride and iridium trichloride were obtained from Arora Matthey, Kolkata, India. Picolinic acid was purchased from Merck, India. All other chemicals and solvents were reagent grade commercial materials and were used as received. Purification of acetonitrile and preparation of tetrabutylammonium perchlorate (TBAP) for electrochemical work were performed as reported in the literature [5]. Microanalyses (C, H, N) were performed using a Heraeus Carlo Erba 1108 elemental analyzer. Magnetic susceptibilities were measured using a PAR 155 vibrating sample magnetometer fitted with a Walker Scientific L75FBAL magnet. ^{1}H NMR spectra were obtained on a Bruker AV300 NMR spectrometer using TMS as the internal standard. Thermogravimetric analyses were carried out on a Shimadzu DT-30 thermal analyzer. IR spectra were obtained on a Perkin–Elmer spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on a JASCO V-570 spectrophotometer. Electrochemical measurements were made using a CH Instruments Model 600A electrochemical analyzer. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in the cyclic voltammetry experiments. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials.

2.2. Synthesis

2.2.1. $[Rh(pic)_3] \cdot H_2O$

Picolinic acid (0.4 g, 3.25 mmol) was dissolved in ethanol (40 ml) and to it was added triethylamine (0.1 g, 0.99 mmol) followed by $RhCl_3.3H_2O$ (0.1 g, 0.38 mmol). The solution was heated at reflux for 4 h to produce a bright yellow solution. Upon cooling the solution to room temperature, a white precipitate separated, which was removed by filtration. Upon partial evaporation of the filtrate, yellow crystals of $[Rh(pic)_3] \cdot H_2O$ separated,

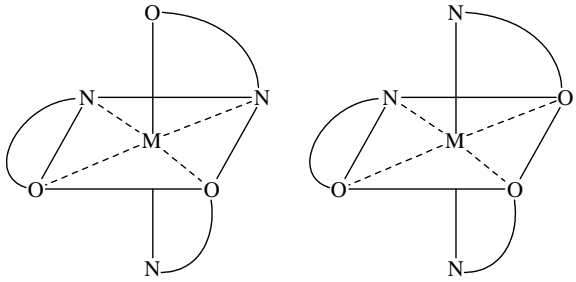
which were collected by filtration, washed with water and dried in vacuo over P_4O_{10}. (~70% yield). *Anal.* Calc. for $C_{18}H_{14}N_3O_7Rh$: C, 44.35; H, 2.87; N, 8.62. Found: C, 45.01; H, 2.83; N, 8.64%. FT-IR (KBr phase), cm^{-1}: 3522m, 1676s, 1604s, 1472m, 1329s, 1285m, 1149m, 1098w, 1057m, 862m, 766m, 716m, 689m, 475m (s, strong; m, medium; w, weak).

2.2.2. $[Ir(pic)_3] \cdot H_2O$

Sodium acetate (1 g, 12.2 mmol) and $IrCl_3.3H_2O$ (0.1 g, 0.28 mmol) were taken in glacial acetic acid (40 ml). The solution was warmed and picolinic acid (0.4 g, 3.25 mmol) was added to it. The solution was heated at reflux for 4 h to produce a bright yellow solution. Upon partial evaporation of this solution, yellow crystals of $[Ir(pic)_3] \cdot H_2O$ separated, which were collected by filtration, washed with water and dried in vacuo over P_4O_{10} (~75% yield). *Anal.* Calc. for $C_{18}H_{14}N_3O_7Ir$: C, 37.50; H, 2.43; N, 7.29; Found: C, 37.83; H, 2.37; N, 7.28%. FT-IR (KBr phase), cm^{-1}: 3529m, 1684s, 1608s, 1472m, 1326s, 1282m, 1148m, 1099w, 1059m, 864m, 770m, 718m, 688m, 471m (s, strong; m, medium; w, weak).



2.3. X-ray crystallography

Single crystals of both $[Rh(pic)_3] \cdot H_2O$ and $[Ir(pic)_3] \cdot H_2O$ were obtained directly from the synthetic reactions. Selected crystal data and data collection parameters are given in Table 1. Data were collected on a Bruker SMART CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by ω scans. X-ray data reduction and, structure solution and refinement were done using SHELXS-97 and SHELXL-97 programs [6,7]. The structures were solved by direct methods.

3. Results and discussion

3.1. Syntheses and crystal structures

Reaction of picolinic acid with rhodium trichloride proceeds smoothly in refluxing ethanol in the presence of triethylamine to afford the targeted tris-picolinate rhodium(III) complex, $[Rh(pic)_3]$, in a decent yield. The analogous iridium complex, $[Ir(pic)_3]$, has been obtained in a similar yield from the reaction of picolinic acid with iridium trichloride using slightly different experimental conditions. Such differences in experimental procedure is often required for the synthesis of analogous complexes of rhodium and iridium [8]. An excess of picolinic acid has been used in both synthetic reactions to optimize the yield of the $[M(pic)_3]$ (M = Rh, Ir) complexes. The observed elemental (C, H, N) analytical data of the two complexes agree well with their compositions. As the picolinate anion is an unsymmetrical bidentate ligand, the tris-picolinate complexes of rhodium and iridium may exist, in principle, in two different isomeric forms, viz. facial (**3**) and meridional (**4**). Chromatographic experiments have shown that these $[M(pic)_3]$ complexes are isomerically pure.

To find out the stereochemistry of these complexes, structure of both the complexes has been determined by X-ray crystallography. Both the structures have been found to be very similar. The structure of the $[Rh(pic)_3]$ complex is shown in Fig. 1 and structure of the $[Ir(pic)_3]$ complex is deposited as Fig. S1. Some selected bond parameters are listed in Table 2. In each complex the picolinate ligands are coordinated to the metal center in the usual fashion (**2**), with a bite angle of ~81°. In both complexes, the central metal ion is thus sitting in an N_3O_3 coordination sphere, which is distorted from an ideal octahedral geometry as reflected in all the bond parameters around the metal centers. The relative

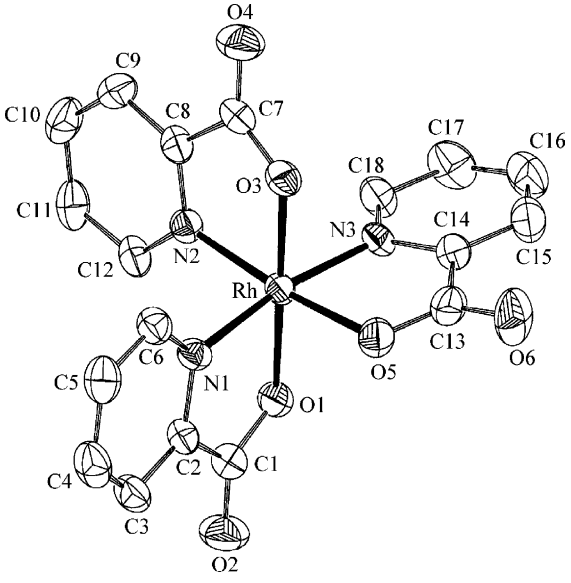


Fig. 1. View of the $[Rh(pic)_3]$ complex. The $[Ir(pic)_3]$ complex is visually identical to the $[Rh(pic)_3]$ complex and the same atom numbering scheme has been used for both structures.

disposition of the nitrogen and oxygen atoms shows that both $[M(pic)_3]$ (M = Rh, Ir) complexes have the meridional stereochemistry (**4**), which is quite common in trischelates of rhodium and iridium [1]. The M–N and M–O distances are all quite normal and so are the C–O distances in the carboxylate fragments [2,3]. There is one molecule of water of crystallization per molecule of both $[M(pic)_3]$ complexes. A closer look at the packing pattern of the crystals reveals that the water molecule is hydrogen bonded to the carboxylate fragments of two adjacent $[M(pic)_3]$ molecules, which is illustrated in Fig. 2. One hydrogen of the water molecule is hydrogen-bonded to a carboxylate oxygen, which is coordinated to the metal center. The other hydrogen of the same water molecule is hydrogen-bonded to another carboxylate oxygen of an adjacent $[M(pic)_3]$ molecule, which is not coordinated to the metal center. The water molecule thus acts as a bridge between individual complex molecules. The $[M(pic)_3]\cdot H_2O$ complex molecules, when viewed along the *b*-axis, exhibit an extended spiral of M(pic)···H–O–H···(pic)M chains, which run along the *c*-axis and thus the $[M(pic)_3]$ complexes have acquired a chain supramolecular structure (Fig. 2). This extended intermolecular hydrogen-bonding has resulted in poor solubility of these $[M(pic)_3]$ complexes (vide infra). To assess the strength of the observed hydrogen-bonding, both the $[M(pic)_3]\cdot H_2O$ complexes have been subjected to thermogravimetric analysis. Within 120–150 °C each complex shows a mass loss, which corresponds well with the loss of one molecule of water per molecule of the $[M(pic)_3]\cdot H_2O$ complexes. This shows that the water molecule is held fairly tightly in the crystal lattice of both the complexes through hydrogen bonding.

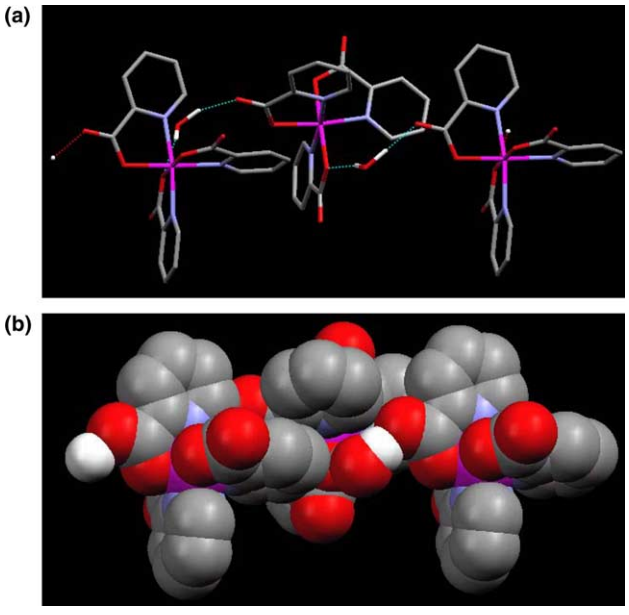

Fig. 2. Chain structure of $[Rh(pic)_3]\cdot H_2O$ through intermolecular hydrogen-bonding in (a) the stick style and (b) the space-filling model.

3.2. Spectral and electrochemical properties

Magnetic susceptibility measurements show that the $[M(pic)_3]$ complexes are diamagnetic, which corresponds to the +3 state of rhodium and iridium (low-spin d^6, $S = 0$) in these complexes. ^1H NMR spectra of both the complexes have been recorded in DMSO-d_6 solution. Each complex shows several overlapping signals within 7.7–8.6 ppm. The spectra clearly show the absence of any C_3 symmetry in the complex molecules and thus indicate that the meridional stereochemistry (**4**) also prevails in solution for both the complexes. The infrared spectra of both the $[M(pic)_3]$ complexes are very similar. Each complex shows a broad band around 3520 cm^{-1} due to the water of crystallization and several bands of different intensities in the 1700–400 cm^{-1} region. Assignment of each individual band to a specific vibration has not been attempted. However, a broad and strong band observed at 1676 cm^{-1} in $[Rh(pic)_3]$ and at 1684 cm^{-1} in $[Ir(pic)_3]$ is attributable to the coordinated carboxylate fragment [9].

The $[M(pic)_3]$ complexes are poorly soluble in methanol, ethanol and acetonitrile, and moderately soluble in dimethylformamide and dimethylsulfoxide, producing light yellow solutions. Electronic spectra of these complexes have been recorded in acetonitrile solution. Each complex shows several intense absorptions below 400 nm (Table 3). The lowest energy absorption, displayed near 370 nm by both the complexes, is probably due to a metal-to-ligand charge-transfer transition. The other absorptions at higher energies are believed to be due to transitions within the ligand orbitals. To have a better in-

Table 3

sight into the nature of the absorption near 370 nm, qualitative EHMO calculations have been performed [10] on computer generated models of both $[M(pic)_3]$ complexes. Results of these calculations have been found to be similar for both the complexes. A partial MO diagram of the $[Rh(pic)_3]$ complex is shown in Fig. 3, and that of the $[Ir(pic)_3]$ complex is deposited as supporting information (Fig. S2). Compositions of some selected molecular orbitals are given in Table 4. The highest occupied molecular orbital (HOMO) and the next two filled orbitals (HOMO − 1 and HOMO − 2) are relatively close and have major (⩾74%) contributions from the metal d_{xy}, d_{yz} and d_{zx} orbitals, and hence they may be regarded as the metal t_2 orbitals. The lowest unoccupied molecular orbital (LUMO) and next two vacant orbitals (LUMO + 1 and LUMO + 2) are also close in energy and they are delocalized almost entirely (⩾95%) on the picolinate ligands. The intense absorption near 370 nm may therefore be assigned to the charge-transfer transition taking place from the filled metal t_2-orbital (HOMO) to the vacant π*-orbital (LUMO) of the picolinate ligand.

Electrochemical properties of both the complexes have been studied by cyclic voltammetry in acetonitrile solution (0.1 M TBAP). Each complex shows an oxidative response on the positive side and one reductive response on the negative side. Voltammetric data are given in Table 3. Keeping the results of the EHMO calculations in view, the oxidation is assigned to the M(III)–M(IV) oxidation and the reduction is attributable to reduction of the coordinated picolinate ligands.

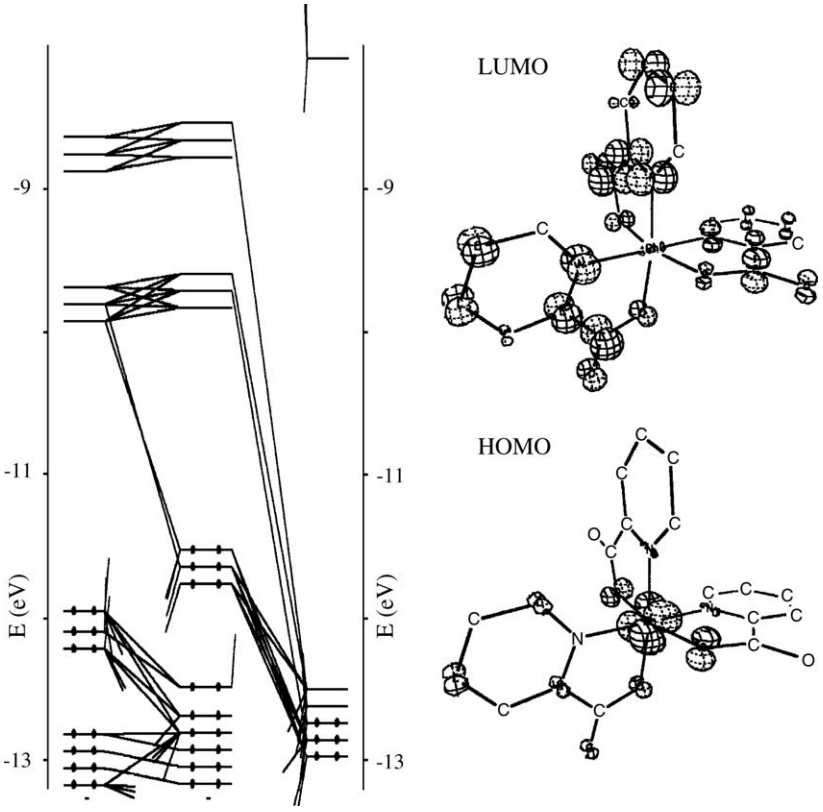

Fig. 3. Partial molecular orbital diagram of $[Rh(pic)_3]$.

Table 4
Composition of molecular orbitals

Compound	Contributing fragment	Percentage contribution of fragments to					
		HOMO	HOMO − 1	HOMO − 2	LUMO	LUMO + 1	LUMO + 2
$[Rh(pic)_3]$	Rh	76	74	76	1	3	5
	pic	24	26	24	99	97	95
$[Ir(pic)_3]$	Ir	77	84	88	1	2	4
	pic	23	16	12	99	98	96

Both the redox responses are irreversible in nature, which indicates that the oxidized $[M(pic)_3]^+$ and reduced $[M(pic)_3]^-$ species are unstable in nature and undergo rapid decomposition.

4. Conclusion

The present study shows that coordination by picolinic acid (**1**), in the usual bidentate fashion (**2**) via dissociation of the carboxylic proton, can stabilize the higher oxidation states of a transition metal. This is manifested in the stabilization of the trivalent state of rhodium and iridium in the $[M(pic)_3]$ (M = Rh, Ir) complexes. This study also shows that simple water of crystallization may give rise to an interesting supramolecular chain structure through intermolecular hydrogen-bonding.

Abstract

A novel alcohol and phenol containing polyamine ligand H_2L (H_2L = *N*,*N*′-bis(2-hydroxybenzyl)-1,3-bis[(2-aminoethyl) amino]-2-propanol) and its $Co^{(III)}$ and $Cu^{(II)}$ complexes, $[CoL]ClO_4$ (**1**) and $[Cu(H_2L)Cl]ClO_4 \cdot CH_3OH \cdot H_2O$ (**2**) have been synthesized and characterized. Single crystal X-ray diffraction analyses indicate that both of the complexes are mononuclear. The $Co^{(III)}$ center in complex **1** has a distorted octahedral geometry, with four N atoms of L^{2-} situated in the equatorial plane, and two deprotonated phenoxo O atoms strongly coordinated at the axial positions. Along the *c*-axis, the $[CoL]^+$ cations are connected alternatively by double ClO_4^- and double alkoxyl hydrogen-bonding bridges, affording a 1D supramolecular structure. In **2**, the $Cu^{(II)}$ center has a similar coordination geometry, whereas the axial positions are weakly coordinated by Cl^- and a protonated phenolic O atom. Approximately along the *ab*-plane, a 2D structure is assembled via multiple hydrogen bonds involving the alkoxyl, phenoxyl, amino, Cl^- and the lattice water molecules. In this work, the structures of the supramolecular coordination assemblies are shown to be tuned by various factors, such as the donor sets of the ligands, the central metal atoms and the counteranions.

1. Introduction

In the past decades, great efforts have been devoted to the self-assembly of supramolecular coordination structures, due to its appealing potential applications in various fields, such as catalysis and molecular electronics [1,2]. Hydrogen bonds, as specific and strong non-covalent forces, have shown their great versatility in constructing these assemblies [3–8]. The structures of supramolecular coordination assemblies can be tailored by varying the functional groups of the organic ligands with various hydrogen bonding donor sets [9–11]. In this respect, we have demonstrated that various supramolecular structures can be obtained starting from tridentate and tetradentate ligands containing amino, alcoholic and phenolic groups (Scheme 1) [12–15]. In the complexes of the tridentate ligands, the phenolic and alcoholic groups are readily deprotonated and act as bridges, yielding binuclear, tetranuclear and hexanuclear complexes [15–17]. While in the complexes of the tetradentate ligands, the deprotonated phenolates can act as either terminal or bridging groups, yielding binuclear or mononuclear complexes.

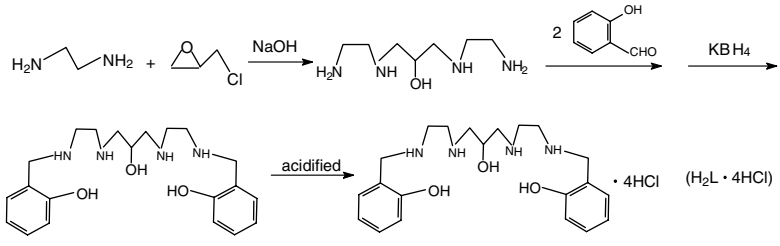
Scheme 1. Polydentate ligand H_2L and related tridentate and tetradentate ligands.

Herein, we report the design and synthesis of a novel polydentate alcohol and phenol containing polyamine ligand, *N*,*N*′-bis(2-hydroxybenzyl)-1,3-bis[(2-aminoethyl)amino]-2-propanol (H_2L) (Scheme 1), and the crystal structures of its mononuclear $Co^{(III)}$ and $Cu^{(II)}$ complexes, $[CoL]ClO_4$ (**1**) and $[Cu(H_2L)Cl]ClO_4 \cdot CH_3OH \cdot H_2O$ (**2**). In these complexes, the deprotonation and coordination of the phenol groups are modified by the metal ions, affording 1D and 2D supramolecular structures, respectively. H_2L has up to seven donor atoms. It tends to form mononuclear complexes, as compared with the previously reported tridentate and tetradentate ligands (Scheme 1). The tuning of the supramolecular structures by the ligand, the central metal atoms, and the counteranions are discussed. The results herein provide further insight into the design and synthesis of hydrogen-bonded supramolecular coordination assemblies.

2. Experimental



2.1. Safety note and materials

Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of the materials should be used and handed with extreme care. All of the chemicals were analytical grade and used as received without further purification.

2.2. Preparation of $H_2L \cdot 4HCl$ (H_2L = *N*,*N*′-bis(2-hydroxybenzyl)-1,3-bis[(2-aminoethyl) amino]-2-propanol)

The synthetic procedure of ligand $H_2L \cdot 4HCl$ is shown in Scheme 2. With continuous stirring, epichlorohydrin (23.2 ml, 0.296 mol) was added slowly to ethylenediamine (200 ml, 2.96 mol) cooled in an ice-bath. Several hours later, water (60 ml) was added. After stirring for 24 h at room temperature, the solution was refluxed for 10 h. The colorless solution gradually changed to light orange. Then, solid NaOH (14.2 g, 0.35 mol) was added in portions. One hour later, the solution was concentrated by rotary evaporation to give an orange-red oil. Upon adding a small amount of ethanol, solid NaCl was precipitated. After filtration, the resulting orange solution was distilled in vacuo, yielding a light yellow oil of 1,3-bis[(2-aminoethyl) amino]-2-propanol. b.p. 172–176 °C/30 mmHg.

To the methanol solution of the oil (29.1 g, 0.17mol) was added salicylaldehyde (42.5 g, 0.34 mol). After stirring for 2 h, KBH_4 (21 g) was added in small portions to the yellow-orange solution. The solution gradually faded to nearly colorless. Six hours later, the pH of the solution was adjusted to about 5 with hydrochloric acid, and then to about 9 with NaOH. The solvent was removed in vacuo, and the residue was dissolved in water and extracted with CH_2Cl_2. The CH_2Cl_2 layers were combined, dried overnight with Na_2SO_4, and concentrated in vacuo. The oily residue was dissolved in ethanol. Upon introduction of hydrochloric acid, a white precipitate formed, which was collected, washed with cooled ethanol and dried. Yield: 24 g, 15.2% (based on epichlorohydrin). *Anal.* Calc. for: $C_{21}H_{36}Cl_4N_4O_3$: C, 47.29; H, 6.79; N, 10.51. Found: C, 47.07; H, 6.83; N, 10.38%. IR (KBr disc, cm^{-1}): 2942(s), 2769(br, vs), 2694(br, vs), 2420(m), 1615(w), 1584(m), 1492(s), 1458(s), 1321(w), 1213(s), 1165(m), 1149(m), 1037(m), 897(w), 811(w), 755(s), 478(w). ^1H NMR (D_2O): δ 6.98–7.41 (8H, m, Ar–H), 4.33 (4H, s, Ar–CH_2), 4.33 (1H, s, CHOH), 3.52 (8H, s, $N(CH_2)_2N$), 3.14–3.34 (4H, m, NCH_2C).

Scheme 2. Synthesis of ligand $H_2L \cdot 4HCl$.

2.3. Preparation of [CoL]ClO_4 (1)

To a methanol solution of $H_2L \cdot 4HCl$ (0.1602 g, 0.3 mmol) was added $Co(OAc)_2 \cdot 4H_2O$ (0.1494 g, 0.6 mmol), followed by addition of aqueous NaOH (4.0 N, 0.40 ml). After refluxing for an hour, $NaClO_4 \cdot H_2O$ (0.1734 g, 1.2 mmol) was added. Three hours later, the residue was filtered off. The resulting solution was concentrated in vacuo to 6 ml and left undisturbed at room temperature for three weeks, yielding plate-like dark red single crystals of **1** suitable for X-ray diffraction analysis. Yield: 0.0510 g, 31.2%. *Anal*. Calc. for $C_{21}H_{30}Cl$- CoN_4O_7: C, 46.29; H, 5.55; N, 10.28. Found: C, 46.50; H, 5.32; N, 10.03%. IR (KBr, cm^{-1}): 3223.1(s), 2923.0(w), 1593.3(s), 1565.5(w), 1479.0(vs), 1446.1(s), 1290.1(s), 1270.6(s), 1204.3(w), 1108.5(br, vs), 1071.6(vs), 1030.1(s), 972.5(w), 877.3(m), 760.1(m), 624.0(s), 487.8(w).

2.4. Preparation of [Cu(H_2L)Cl]$ClO_4 \cdot CH_3OH \cdot H_2O$ (2)

To a methanol solution of $H_2L \cdot 4HCl$ (0.1067 g, 0.20 mmol) was added $Cu(ClO_4)_2 \cdot 6H_2O$ (0.1482 g, 0.40 mmol), followed by addition of aqueous NaOH (4.0 N, 0.35 ml). After refluxing for two hours, the resulting dark blue solution was concentrated in vacuo and left undisturbed at room temperature for over two months, yielding X-ray quality of needle-like violet-red single crystals of **2**. Yield: 0.014 g, 11%. *Anal*. Calc. for $C_{21}H_{32}Cl_2CuN_4O_7$: C, 42.97; H, 5.50; N 9.54. Found: C, 42.65; H, 5.32; N, 9.78%. IR (KBr, cm^{-1}): 3279.9(w), 3233.9(w), 1612.0(w), 1594.9(w), 1461.4(s), 1356.6(w), 1273.0(w), 1250.9(m), 1194.5(w), 1120.2(vs), 1042.7(s), 1016.6(s), 964.2(w), 888.6(w), 773.0(s), 759.3(s), 727.0(w), 624.0(m).

2.5. X-ray data collection and structural determination

All measurements on single crystals of **1** and **2** were made at 18 °C on a Rigaku RAXIS-IV image plate area detector with graphite monochromated Mo Kα radiation. The structure was solved by direct methods and the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. The final cycle of full-matrix least-squares refinement was based on observed reflections ($I > 2.00\sigma(I)$) and variable parameters. All calculations were performed using the SHELX-97 software package [18]. Crystallographic data as well as details of data collection and refinement for complexes **1** and **2** are listed in Table 1.

2.6. Other physical measurements

The FT-IR spectra were recorded on a Bruker Vector-22 Spectrometer (KBr disc). The ^{1}H NMR measurements were carried out on a Bruker 300 Ultrashield NMR Spectrometer in D_2O (99.85%). Elemental analyses (C, H and N) were performed on an Elementar Vario EL-III Elemental analyzer. Electronic spectra were obtained on an UV-2401PC spectrophotometer in DMSO.

3. Results and discussion

3.1. Synthesis and spectroscopic characterization of *1* and *2*

In the IR spectrum of **1**, the strong band at 3223 cm^{-1} can be assigned to ν(N–H), while the medium band at 877 cm^{-1} and the weak band at 972 cm^{-1} correspond to staggering vibrations of CH_2 groups of the ligand with four amine N atoms coordinating in a coplanar fashion [19]. The strong bands at 1108–1030 cm^{-1} and one sharp band at 624 $cm^{-1}$are characteristic of ClO_4^- [20,21]. For **2**, free ClO_4^- exhibits similar absorption bands. The strong band at 1461 cm^{-1} is ascribed to δ (CH_2), with two absorption bands at 3280 and 3234 cm^{-1} of ν(NH). It is noted that the band at 1038 cm^{-1} for ν(C–O) of the isopropanol moiety [22] in $H_2L \cdot 4HCl$ shifts to 1043 cm^{-1} in **2**, but to 1030 cm^{-1} in **1**.

The electronic spectra of **1** show two weak transition bands at 816 nm ($\varepsilon = 6.86\ l\,cm^{-1}\,mol^{-1}$) and 560 nm ($\varepsilon = 128\ l\,cm^{-1}\,mol^{-1}$), which can be assigned to $^1A_{1g} \rightarrow {}^1T_{1g}$, and $^1A_{1g} \rightarrow {}^1T_{2g}$ ligand field transitions, respectively. The appearance of two d–d transitions is consistent with the pseudo-octahedral geometry of low spin $Co^{(III)}$ complexes [23]. For **2**, the d–d transition appears at 637 nm ($\varepsilon = 168\ l\,cm^{-1}\,mol^{-1}$).

3.2. Description of the structures

Selected bond angles and lengths for **1** and **2** are collected in Table 2.

In complex **1**, $Co^{(III)}$ has a distorted octahedral coordination geometry (Fig. 1). The *cis* angles around $Co^{(III)}$ vary in the range of 86.5(1)°–95.8(1)°, indicating the distortion of the octahedron. Despite the relatively short Co(1)–N(4) bond (1.943(3) Å), the other three Co–N bond lengths are very similar (1.968(3)–1.973(3) Å), and lie in the normal range [24,25]. The short Co–O bond lengths of 1.904(3) and 1.909(3) Å indicate the strong coordination of the deprotonated phenoxo groups. In complex **2** (Fig. 2), the $Cu^{(II)}$ center is coordinated by four N atoms and a protonated phenolic oxygen atom, O3, from a neutral H_2L ligand. The other protonated phenol group is left uncoordinated. The positive charge of $Cu^{(II)}$ is balanced by Cl^- and ClO_4^-.

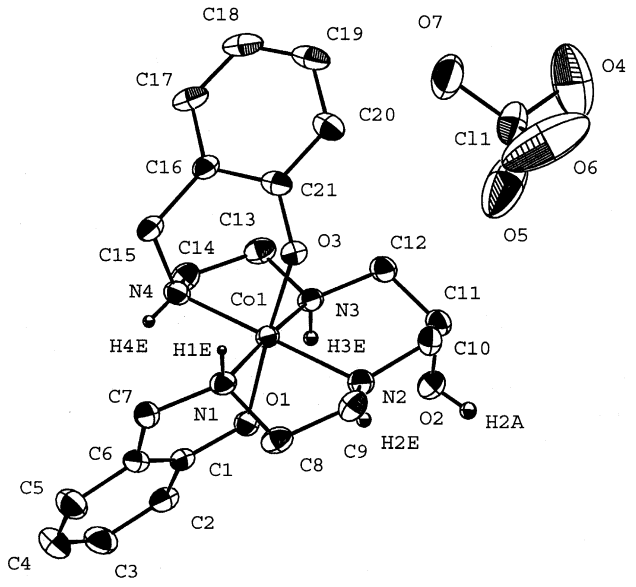

Fig. 1. View of complex **1** showing the numbering scheme.

For complex **1**, Along the *c*-axis, the $[Co^{(III)}L]^+$ cations are connected alternatively by double ClO_4^- and double alcoholic hydrogen bonding bridges in the complementary mode, forming a 1D supramolecular structure (Fig. 3 and Table 3). The 2D supramolecular structure of **2**, approximately along the *ab*-plane, is shown in Fig. 4. In detail, along the *a*-axis, a rather weak Cu–Cl coordination bond with the a bond length of 2.892 Å occurs between $Cu^{(II)}$ and the Cl^- from a neighboring molecule. Thus, the coordination geometry of $Cu^{(II)}$ can be viewed as an axially elongated octahe-

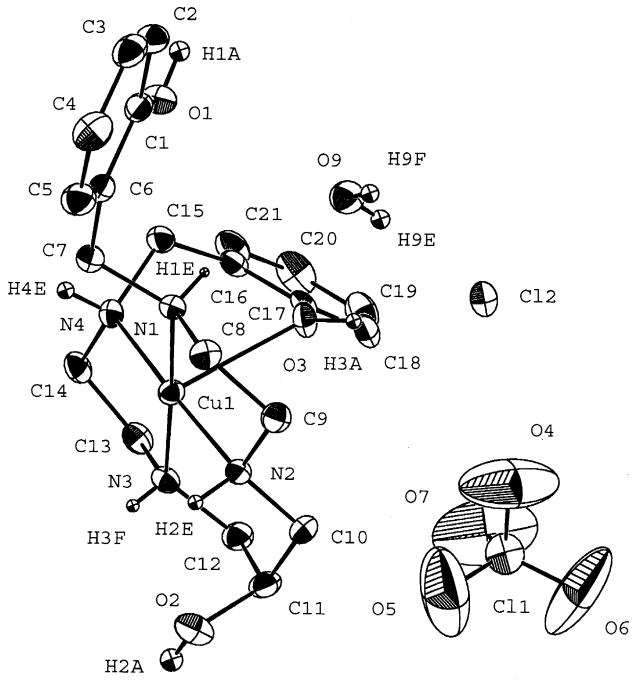

Fig. 2. View of complex **2** showing the numbering scheme (the methanol molecule is omitted for clarity).

dron. Along the *a*-axis, the adjacent $[Cu(H_2L)]^{2+}$ cations are connect by hydrogen bonds involving Cl^- (Table 3). Approximately along the *b*-axis, the $[Cu(H_2L)]^{2+}$ cations are connected by hydrogen bonds containing double water bridges and two sets of N1–H1E and O1–H1A groups. Furthermore, the alcoholic group O2–H2A is involved in intermolecular hydrogen bonds with N2–H2E, also in the complementary mode. Thus, approximately along the *ab*-plane, each molecule is connected to adjacent ones through multiple hydrogen bonds involving the alcoholic, phenolic and amino groups, as well as the Cl^- and the lattice water molecules, affording the 2D structure.

In both complexes of **1** and **2**, four amino groups are coordinated in the equatorial plane. The deprotonation and coordination of the phenol groups are related to the central metal atoms. In complex **1**, the cobalt atom has a high oxidation state of +3. It promotes the deprotonation and the subsequent coordination of the phenol groups, thus, both of the phenol groups are deprotonated and coordinated. In contrast, in complex **2**, $Cu^{(II)}$ coordinates to H_2L without deprotonating its phenolic groups. This may be ascribed to the weak axial coordination due to the Jahn–Teller effect and the lower oxidation

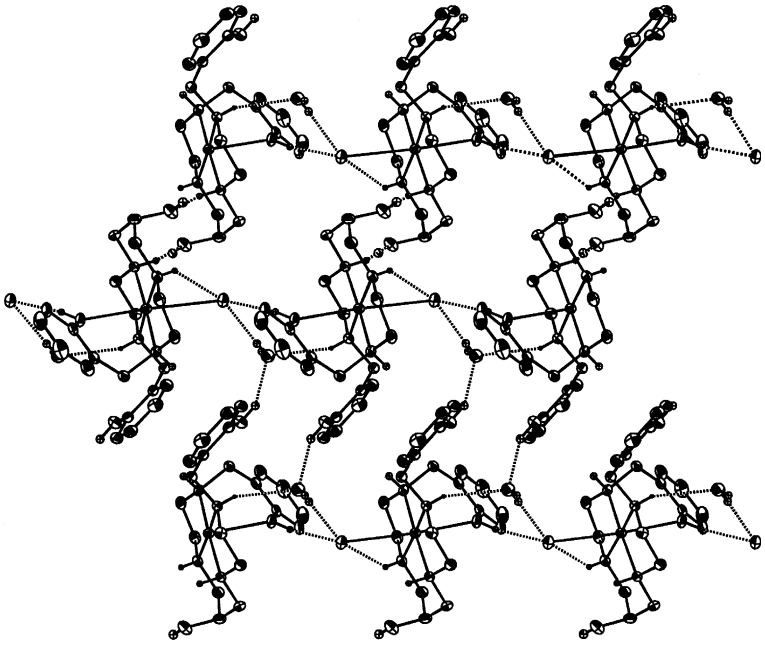

Fig. 4. 2D supramolecular structure of complex **2** (along the *ab*-plane).

state of $Cu^{(II)}$, as compared with $Co^{(III)}$. Thus, the $Cu^{(II)}$ atom has an axial elongated octahedral geometry, with a weak coordination of one of the protonated phenolic groups. The alcoholic group remains non-coordinated in the protonated form, directed outwards for intermolecular hydrogen bonding interactions. The coordination behavior of the phenolic and alcoholic groups are different from the corresponding groups in the previously reported complexes of the tridentate and tetradentate ligands (Scheme 1). In the latter complexes [15–17], these groups tend to deprotonate and act as bridges to form binuclear and polynuclear complexes, which may be related to the unsaturated coordination sphere in the supposed mononuclear 1:1 (M:L) complexes, due to the relatively fewer donor atoms. Whereas in **1** and **2** the ligand H_2L has more coordination atoms, so in the 1:1 mononuclear complexes the coordination spheres of the metal atoms are relatively more saturated. Therefore, the alkoxyl groups remain non-coordinated in the protonated form. The deprotonation and coordination of the phenolic groups are more difficult, and they can be tuned by varying the metal centers.

As for the roles of the anions ClO_4^- and Cl^- in **1** and **2**, apart from acting as the counteranions to balance the positive charge, they also form various multiple hydrogen bonds to assist in the formation of the supramolecular structures.

4. Conclusion

A polydentate ligand H_2L and its $Co^{(III)}$ and $Cu^{(II)}$ complexes are reported. The coordination environment of $Co^{(III)}$ in **1** can be described as a distorted octahedron, with four N atoms of the ligand H_2L defining the equatorial plane and two deprotonated phenoxo O atoms strongly coordinating at the axial positions. Along the *c*-axis, a 1D supramolecular structure is constructed by multiple hydrogen bonds. The $Cu^{(II)}$ center in **2** also has a distorted octahedral geometry, with the axial positions occupied by weakly coordinating Cl^- and a protonated phenolic O atom. Approximately along the *ab*-plane, the molecules are assembled to form a 2D structure by multiple hydrogen bonds.

In both **1** and **2**, the four amino N atoms of the ligand H_2L coordinate in the equatorial positions. The deprotonation and coordination of the phenolic groups are dependent on the metal centers. The high oxidation state of $Co^{(III)}$ facilitates the deprotonation and coordination of the phenolic groups in **1**, while the phenolic groups in **2** are not deprotonated.

The results in this work indicate that the new polydentate ligand H_2L is promising for the construction of novel hydrogen-bonded supramolecular coordination assemblies, which can be tailored by controlling the deprotonation and the coordination of the phenol groups with various metal ions, and also by varying the counteranions.

5. Supplementary material

The crystal structure data of complexes **1** and **2** have been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition numbers 237180 (**1**) and 237181 (**2**). Copies of this information can be ob-

tained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Abstract

Michael addition of substituted pyrazoles **2** to 1-alkynyl Fischer carbene complexes $(CO)_5M{=}C(OEt)(C{\equiv}CPh)$ (**1**) (**a**, M = Cr and **b** M = W) afforded (pyrazolyl)alkenyl Fischer carbene complexes $(CO)_5M{=}C(OEt)(CH{=}C(R^1R^2R^3pz)Ph)$ ($R^1R^2R^3pz$ = pyrazolyl) **3** (M = Cr) and **4** (M = W), respectively, with an exclusive (*E*)-configuration in mild to excellent yields. The reaction of **1a** and 3,5-dimethylpyrazole (**2b**) was monitored to demonstrate the formation and decomposition of complex **3b** by ^1H NMR measurements in $CDCl_3$ at 23 °C. Complexes **3** and **4** were characterized with ^1H, $^{13}C\{^1H\}$ NMR, IR spectroscopies and elemental analysis. When the substituted pyrazoles were 3-methylpyrazole (**2a**) and 3,5-di-*tert*-butylpyrazole (**2d**), molecular structures of the corresponding (pyrazolyl)alkenyl Fischer carbene complexes **3a** and **4d** were characterized by X-ray crystallographic study.

Keywords: Fischer carbene; Pyrazole; Michael addition; Chromium; Tungsten

1. Introduction

Fischer carbene complexes were first synthesized by Fischer and Maasböl in 1964 [1,2] and have been paid much attention in the last two decades because they can be rather readily prepared and manipulated to demonstrate diverse reactivity in organic synthesis [3]. Transformations from alkynyl carbene to alkenyl carbene complexes have been extensively investigated. Michael addition of dimethylamine to Fischer alkynylcarbene complexes was reported by Fischer and Kreissl [4] as early as 1972, followed by several other groups [5]. Michael-type addition of amines or N–H bond-containing compounds to α,β-unsaturated Fischer carbene complexes to form β-aminovinyl-substituted products has been considered a useful methodology for certain preparative organic synthesis because the resultant Michael-type adducts are usually reactive intermediates [6–18]. A rich chemistry of pyrazoles [19] and pyrazolato ligands [20–22] has been evolved since pyrazoles were first prepared in 1968 [23], due to the presence of pyrazolyl-containing compounds in nature and potential bioactivity of pyrazole derivatives as well as their good coordination ability as ligands. Pyrazole contains a reactive N–H bond which can be easily deprotonated to proceed a lot of reactions. However, up to date no β-pyrazolyl subsitituted alkenyl Fischer carbene complexes have been synthesized, although 1-methoxy-1-(5-pyrazole) Fischer carbene complexes were reportedly generated in the reactions of 1-alkynyl Fischer carbene

complexes with Me_3SiCHN_2 [24a] and $(CO)_5W$-C(OEt)(CH=C($C_3H_3N_2$)Ph) was detected by UV spectroscopy [24b]. Herein, we report the synthesis of (pyrazolyl)alkenyl Fischer carbene complexes **3** and **4** by the reactions of substituted pyrazoles **2** with 1-alkynyl Fischer carbene complexes **1a**,**b** (**a**, M = Cr; **b**, M = W) under mild conditions, as well as their structural characterization.

2. Results and discussion

2.1. Synthesis of (pyrazolyl)alkenyl carbene complexes 3 and 4

Treatment of the 1-alkynyl Fischer carbene complexes **1a** and **1b** with an equivalent amount of substituted pyrazole in dichloromethane at ambient temperature afforded (pyrazolyl)alkenyl Fischer carbene complexes **3** and **4** in mild to excellent yields (Eq. (1)). The reaction temperature was elevated to 38 °C due to the poor solubility of 3,5-di-*tert*-butylpyrazole and 3,5-di-phenylpyrazole in CH_2Cl_2. 3-Methylpyrazole exhibited very low reactivity to both complexes **1a** and **1b** and only 32.2% and 17.6% yields of the desired products were achieved over a period of 77–85 h for **1a** and **1b**, respectively.

[a] Containing small amounts of decomposition products.

In the other cases, the tungsten carbene complex **1b** demonstrated higher reactivity (shorter reaction time) to the investigated substituted pyrazoles than its chromium analogue, leading to higher yields for the tungsten products (80.5–99.6%) and lower isolated yields for their chromium analogues (60.5–88.5%). It was observed that the chromium products were subject to decomposition on silica gel when the crude products were purified by column chromatography.

It is noteworthy that complex **4b** was obtained in 99.6% isolated yield while its chromium analogue, i.e., complex **3b** underwent decomposition under mild conditions to form some unidentified products when 3,5-dimethyl pyrazole was used. In order to understand the behavior of complex **3b**, Fischer carbene complex **1a** was treated with an equivalent amount of 3,5-dimethyl pyrazole (**2b**) in $CDCl_3$ in a 5-mL NMR tube at ambient temperature and the reaction was monitored by ^1H NMR measurements over a period of ten days (Scheme 1). The ^1H NMR measurements revealed that the reaction exclusively proceeded to form **3b** and the reaction was completed in 24 h at ambient temperature. It was noticed that the product, i.e., **3b**, gradually decomposed when the reaction solution was kept at ambient temperature for a longer time (e.g., 10 days). It was also observed that the reaction of **1a** with an excess of the pyrazole (2.0 equiv.) in $CDCl_3$ at ambient temperature did not lead to any formation of the de-ethoxy product, i.e., the 2,4-dipyrazolyl alkenylcarbene complex. Due to its decomposition at ambient temperature, the full characterization data for complex **3b** could not be collected, but its NMR data was tentatively assigned.

2.2. Spectroscopy of (pyrazolyl)alkenyl carbene complexes 3 and 4

The strong bands in the region 2069–1902 cm^{-1} of the IR spectra are characteristic of the typical patterns expected for a $M(CO)_5$ moiety in Fischer carbene complexes. The proton resonances of HC=C($R^1R^2R^3$pz)Ph in complexes **3** and **4** in $CDCl_3$ are shown in the region 8.20–7.31 ppm as singlets and those of the alkenyl complexes of chromium, **3**, are slightly shifted downfield as compared with their tungsten analogues. The ^{13}C resonances of the carbene carbons, i.e., Cr=C in complexes **3** are at 331.4–338.4 ppm and those of W=C in complexes **4** are at 310.5–304.6 ppm, while the ^{13}C NMR signals of typical β-aminoalkenyl Fischer carbene complexes exhibiting some conjugation between the metal carbene M=C and the alkenyl moiety are in the region ~270–290 ppm [7,10], and those of metal carbene M=C in $(OC)_5M$=

Scheme 1. Formation and decomposition of **3b** from the reaction of **1a** and 3,5-dimethylpyrazole (**2b**) monitored by ^1H NMR measurements in $CDCl_3$ at 23 °C.

C(OMe)Me showing no conjugation between the M=C and methyl moieties are at ~320 ppm (M = Cr) to 361 ppm (M = W) [25]. These results indicate that only little (or even no) π-conjugation is expected to operate within the (pyrazolyl)alkenyl unit and the metal carbene bond M=C. The ^{13}C resonance signals of the $M(CO)_5$ moieties are always shown at about 224 ppm/216 ppm for the chromium complexes **3** and at about 204 ppm/197 ppm for the tungsten complexes **4** with a 1:4 intensity ratio. The proton signals of the 4′-H in the pyrazolyl ring appear at 7.00–5.96 ppm as singlets, and the ^{13}C resonance signals of the C4′ and C3′ (i.e., C=N) carbons are shown in the region 102.8–119.5 and 150.5–161.5 ppm, respectively, corresponding to those of an NH deprotonated pyrazolyl ring [22].

2.3. Crystal structure analyses of complexes *3a* and *4d*

Fig. 1 is a perspective SCHAKAL-97 drawing of complex **3a** showing the labelling scheme. The molecular structure is in line with the assignment by IR and NMR spectra of the complex. The pyrazolyl ring is situated at an (*E*)-configuration with respect to the $(CO)_5Cr$=C moiety. The distances Cr–C6, C6–C7 and C7–C8 are 2.057(3), 1.456(4) and 1.344(4) Å, respectively, corresponding to a typical Cr=C bond in alkenyl Fischer carbene complexes, single and double carbon–carbon bonds, indicating little or even no π-conjugation in the metal butadienyl system. The pyrazolyl ring is bound to C8 atom via the N1 atom of the pyrazolyl moiety and the methyl substituent on the pyrazolyl ring is arranged in a position separated far away from the phenyl group to reduce the steric hindrance. The lengths N2–C19 (1.321(3) Å) and C17–C18 (1.336(4) Å) are in

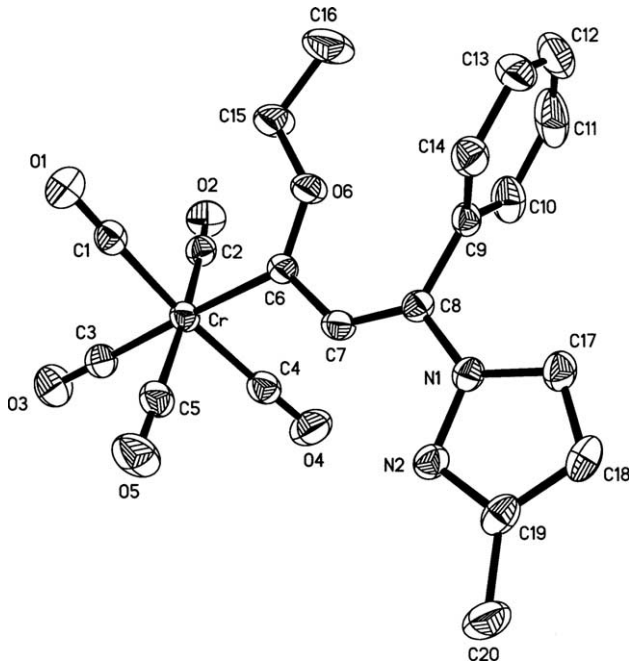

Fig. 1. Molecular structure of complex **3a**.

accordance with C=N and C=C bonds, respectively, revealing no structural change for the pyrazolyl ring. All the structural data confirms a Michael addition product from the 1-alkynylcarbene complex **1a**. No obvious difference is observed between the molecular structures of **3a** and **4d** (Fig. 2). The W–C6 bond length is 2.150(5) Å and C7–C8 bond length in **4d** is 1.342(7) Å. The N1–C8 bond (1.405(6) Å) is longer than its analogue in **3a** (1.395(3) Å), presumably due to bigger steric hindrance from the *tert*-butyl groups. The angle C17–N1–C8 (133.9(4)°) in **4d** is bigger than that in **3a**

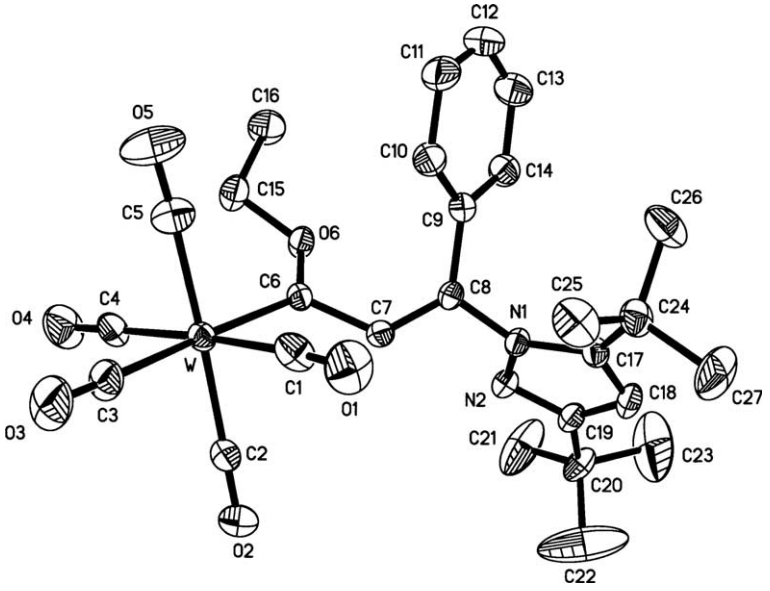

Fig. 2. Molecular structure of complex **4d**.

(127.7(3)°) and N1–C8 (1.405(6) Å) in **4d** is longer than that in **3a** (1.395(3) Å), demonstrating that the 3,5-di-*tert*-butylpyrazolyl ring is separated farther away from the backbone of the alkenyl carbene complex than the less steric ring, i.e., 3-methylpyyrazolyl.

3. Experimental

Dried solvents were used in all experiments. Melting points are not corrected. Instrumentation: ^{1}H and ^{13}C NMR spectra were obtained with Bruker DRX-400 spectrometer (chemical shifts refer to $\delta_{TMS} = 0.00$ ppm); IR spectra were obtained on a Bruker Tensor 27 spectrophotometer. Elemental analysis was achieved by the Analysis Center, Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences. Substituted pyrazoles were prepared as reported [23]. 3,4,5-Trimethylpyrazole [26] and 3,5-dimethyl-4-benzyl-pyrazole [27] were synthesized by reported procedures, respectively.

*General procedure for the synthesis of the (pyrazolyl)alkenyl carbene complexes **3** and **4***. A mixture of 1-alkynylcarbene complex **1** (1.0 mmol) and substituted pyrazole (1.0 mmol) in 3 mL of dichloromethane was stirred in a 5-mL screwtop vessel at ambient temperature (23 °C) or elevated temperature as stated. The reaction was monitored by TLC analysis on silica gel. After the reaction was completed, the resultant mixture was subject to column chromatography on silica gel to collect the product **3** or **4**. Recrystallization at −20 °C afforded single crystals suitable for X-ray crystallographic study. The crystal color of complexes **3** and **4** are red and dark red, respectively.

*2-Ethoxy-4-phenyl-4-(3′-methylpyrazol-1′-yl)-1,1,1,1,1-pentacarbonyl-1-chroma-1,3-butadiene (**3a**):* 23 °C, 85 h, 139 mg (32.2%). M.p. 89–91 °C. *Crystallographic study of complexes **3a** and **4d**.* Single crystals were mounted on a glass fiber and sealed with epoxy glue. Diffraction measurements were made on a Bruker Smart diffractometer (graphite monochromated Mo Kα radiation, λ = 0.71073 Å) at 293 K. The crystal structures were solved by means of the program SHELXS-86 and refined by a full-matrix least-squares procedure on F^2 with the program SHELXL-97. Table 1 lists the crystal data and refinement details for complexes **3a** and **4d**. The selected bond lengths and angles are summarized in Tables 2 and 3. The molecular structures of **3a** and **4d** are given in Figs. 1 and 2.

4. Conclusion

(Pyrazolyl)alkenyl Fischer carbene complexes were synthesized from the reactions of 1-alkynyl Fischer carbene complexes $(CO)_5M{=}C(OEt)(C{\equiv}CPh)$ (M = Cr, W) with substituted pyrazoles under mild conditions. Transformation of these complexes into organic heterocyclic compounds are under way.

5. Supplementary material

The X-ray crystallographic files, in CIF format, are available from the Cambridge Crystallographic Data Centre on quoting the deposition numbers: CCDC 243529 for **3a** and CCDC 243528 for **4d**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 IEZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

New silver(I) derivatives containing bidentate phosphine and anionic bis(triazol-1-yl)borate ligands have been prepared from the reaction of $AgNO_3$ and dppm (bis(diphenylphosphino)methane), dppe (1,2-bis(diphenylphosphino)ethane), or dppf (1,1′-bis(diphenylphosphino)ferrocene) and potassium dihydrobis(1,2,4-triazolyl)borate, $K[H_2B(tz)_2]$; their solid state and solution properties have been investigated through analytical and spectroscopic measurements (IR, ^1H and ^{31}P NMR). All the compounds are soluble in chlorinated solvents and are non-electrolytes in CH_2Cl_2 and acetone solutions. $[\{H_2B(tz)_2\}Ag(dppf)]$ is simple mononuclear array, the silver atom lying in four-coordinate N_2AgP_2 environment. In $[\{H_2B(tz)_2\}_2Ag_3(dppm)_2(NO_3)]$, the silver environment is still four-coordinate but $PAgN_3$, utilizing the coordinating capability of one of the additional ('exo'-) ring nitrogens not only to complete the four-coordinate array about the silver but, necessarily, to link successive asymmetric units into a single-stranded polymer. $[\{H_2B(tz)_2\}_2Ag_3(dppm)_2(NO_3)]$ may be regarded as a hemi-adduct of $[\{H_2B(tz)_2\}Ag(dppm)]$ with silver(I) nitrate, thus $[\{H_2B(tz)_2\}Ag(dppm)]$: $AgNO_3$ (2:1).

1. Introduction

Since the pioneering work by Trofimenko [1], a very large number of papers has appeared describing the synthesis and the application of poly(pyrazolyl)borate, in an extraordinarily wide range of chemistry, from modelling the active site of metallo-enzymes, through analytical chemistry and organic synthesis, to catalysis and materials science [2]. By contrast, only a few poly(azolyl)borate complexes with azolyl groups other than pyrazole have been investigated, although it has been shown that the chemistry of poly(azolyl)borate complexes may be critically dependent on the pattern of ring substitution [3]. This aspect has induced several researchers to study the behaviour of metal complexes of analogous ligand systems with modified steric and/or electronic properties, such as poly(tetrazolyl)borate [4], poly(1,2,3-benzotriazolyl)borate [5], poly(2-sulfanyl-1-methylimidazolyl)borate [6] and poly(imidazolyl)borate ligands [7]. These modifications have led to new scorpionates capable of bridging different metal centers, yielding dimers or coordination polymers characterized by peculiar spectroscopic and structural features. Two features of triazole-based ligands make them attractive candidates for further examination: (i) they should be electron-withdrawing relative to their pyrazole-based counterparts so that the properties of metal complexes should differ accordingly [8]; (ii) the *exo* ring-nitrogen

atoms of triazole-based ligands may bridge between metal centers, thereby creating coordination polymers with interesting solid-state structures and optical properties, as recently shown by Janiak et al. [9]. Moreover, the exocyclic nitrogen atoms might take part in hydrogen-bond interactions assisting the formation of two-dimensional water-intercalate or water-layer clathrates [10], thus leading to water soluble species [11].

As part of this study, we have been interested in complexes incorporating poly(azolyl)borate and phosphine ligands with different steric and electronic profiles. The different coordination characteristics of poly(triazolyl)borate species offer the prospect of new and interesting chemistry, paralleling that of pyrazolyl and imidazolyl arrays [12]. In our research concerning modifications of the poly(pyrazolyl)borate ligands in which the pyrazolyl rings are replaced by 1,2,4-triazolyl or imidazolyl rings, some interesting single strand silver(I) coordination polymers containing bridging poly(1-imidazolyl) borates have been reported [13].

We have also previously reported that the substitution of triazole for pyrazole in poly(pyrazolyl)alkanes to form poly(triazolyl)alkanes as bis(1,2,4-triazolyl)alkane ligand, extends the capability to coordinate silver(I) salts through the additional nitrogen atoms yielding two- and three-dimensional coordination polymers [14].

We have now decided to extend this work by reporting the synthesis, characterization and reactivity of some new metal complexes obtained from the interaction of dihydrobis(1,2,4-triazolyl)borate, $[H_2B(tz)_2]^-$ (Fig. 1), with $AgNO_3$ and diphosphines, together with the crystal and molecular structures of some representative arrays as determined by X-ray diffraction studies.

2. Experimental

2.1. Materials and methods

All syntheses and handling were carried out under an atmosphere of dry oxygen-free dinitrogen, using standard Schlenk techniques or a glove box. All solvents were dried, degassed and distilled prior to use. All chemicals were purchased from Aldrich and used without further purification. The potassium salt of the donor dihydrobis(1,2,4-triazolyl)borate, $[H_2B(tz)_2]^-$ was prepared in accordance with the procedure first reported by Trofimenko [1]. KBH_4, $AgNO_3$, dppm, dppe, dppf and 1,2,4-triazole were purchased from Aldrich and used without further purification. Elemental analyses (C, H and N) were performed in-house with a Fisons Instruments 1108 CHNS-O Elemental Analyser. IR spectra were recorded from 4000 to 100 cm^{-1} with a Perkin–Elmer System 2000 FT-IR instrument. ^1H and ^{13}P NMR spectra were recorded on a VXR-300 Varian spectrometer (300 MHz for ^1H and 121.4 MHz for ^{31}P). The electrical resistances of acetone, DMSO and CH_2Cl_2 solutions were measured with a Crison CDTM 522 conductimeter at room temperature.

2.1.1. Syntheses of complexes

*2.1.1.1. [{$H_2B(tz)_2$}Ag(dppm) (**1**).* $K[H_2B(tz)_2]$ (0.188 g, 1.0 mmol) was added at room temperature to a methanol solution (50 ml) of $AgNO_3$ (0.170 g, 1.0 mmol) and $(PPh_2)_2CH_2$ (0.384 g, 1.0 mmol). After the addition, the solution was stirred for 2 h and subsequently the solvent was removed with a rotary evaporator. Chloroform (50 ml) was added. The suspension was filtered and the organic layer was dried over Na_2SO_4, filtered and concentrated under reduced pressure. A colourless precipitate was formed, which was filtered off and washed with diethylether. Re-crystallization from diethylether (1:2) gave complex **1** as a micro-crystalline solid in 60% yield. m.p. 161–163 °C. ^1H NMR ($CDCl_3$, 293 K): δ 3.0 (s br, 2H, C*H*$_2$), 6.97–7.20 (m, 20H, C*H*), 7.44 (s, 2H, 3- or 5-C*H*), 8.07 (s, 2H, 3- or 5-C*H*). $^{31}P\{^1H\}$ NMR ($CDCl_3$, 293 K): δ 3.90 (m, $^1J(^{13}P, Ag) = 330$ Hz; $^{31}P\{^1H\}$ NMR ($CDCl_3$, 218 K): δ 3.56 (m, $^1J(^{13}P, Ag) = 435$ Hz. IR (nujol, cm^{-1}): 3045w (CH), 2430w, 2405m (BH), 1498s (C=C + C=N), 515m, 504m, 473br, 438br, 412br (Ar_3P), 348w. *Anal.* Calc. for $C_{29}H_{28}AgBN_6P_2$: C, 54.32; H, 4.40; N, 13.11. Found: C, 54.64; H, 4.60; N, 13.07%.

*2.1.1.2. [{$H_2B(tz)_2$}$_2$$Ag_3$(dppm)$_2$($NO_3$)]($H_2O$)$_{0.5}$ (**2**).* Compound **2** was prepared similarly to compound **1**, by using $AgNO_3$ (0.255 g, 1.5 mmol), $(PPh_2)_2CH_2$ (0.384 g, 1.0 mmol) and $K[H_2B(tz)_2]$ (0.188 g, 1.0 mmol) in methanol solution (50 ml). Re-crystallisation from dichloromethane gave complex **2** as a micro-crystalline solid in 50% yield. m.p. 160 °C dec. ^1H NMR ($CDCl_3$, 293 K): δ 3.0 (s br, 2H, C*H*$_2$), 6.97–7.20 (m, 20H, C*H*), 7.44 (s, 2H, 3- or 5-C*H*), 8.07 (s, 2H, 3- or 5-C*H*). $^{31}P\{^1H\}$ NMR ($CDCl_3$, 293 K): δ −2.4 (d br $^1J(^{31}P, Ag) = 433$ Hz), 3.90 (m, $^1J(^{13}P, Ag) = 330$ Hz; $^{31}P\{^1H\}$ NMR ($CDCl_3$, 218 K): δ 3.56 (m, $^1J(^{31}P, Ag) = 435$ Hz. IR (nujol, cm^{-1}): 3370 (OH), 3045w (CH), 2430w, 2405m (BH), 1964br, 1895br, 1824wbr, 1732w br (NO_3), 1498s (C=C + C=N), 515m, 504m, 473br, 438br, 412br, 399m, 375m, 351w, 325w, 302w, 278w (Ar_3P), 348w. *Anal.* Calc. for $C_{58}H_{57}Ag_3B_2N_{13}O_{0.5}P_4$:

*2.1.1.3. [{$H_2B(tz)_2$}$_2Ag_2(dppe)$] (**3**).* K[$H_2B(tz)_2$] (0.188 g, 1.0 mmol) was added at room temperature to a methanol solution (50 ml) of $AgNO_3$ (0.170 g, 1.0 mmol) and $(PPh_2)_2C_2H_4$ (0.398 g, 1.0 mmol). After the addition, the solution was stirred for 2 h. The colourless precipitate obtained was filtered off and washed with methanol. Re-crystallisation from methanol gave complex **3** as a micro-crystalline solid in 56% yield. mp 130–133 °C. ^{1}H NMR ($CDCl_3$, 293K): δ 2.48 (s, 4H, CH_2), 7.37-7.78 (m, 20H, C*H*), 7.69 (s, 4H, 3- or 5-C*H*), 8.14 (s, 4H, 3- or 5-C*H*). ^{31}P{^{1}H} NMR ($CDCl_3$, 293K): δ 11.05 (d, $^1J(^{13}P, Ag) = 604$ Hz). ^{31}P{^{1}H} NMR ($CDCl_3$, 218K): δ 10.2 (d, $^1J(^{31}P, Ag) = 600$ Hz). IR (nujol, cm^{-1}): 3098w (CH), 2411m (BH), 1514m, 1501m (C═C + C═N), 512s, 474m, 421w (Ar_3P), 343w. *Anal.* Calc. for $C_{34}H_{36}Ag_2B_2N_{12}P_2$: C, 44.78; H; 3.98; N, 18.43. Found: C, 45.23; H, 3.67; N, 17.96%.

*2.1.1.4. [{$H_2B(tz)_2$}$Ag(dppf)$] (**4**).* Compound **4** was prepared similarly to compound **3**, by using $AgNO_3$ (0.170 g, 1.0 mmol), $(PPh_2)_2(C_5H_4)_2Fe$ (0.544 g, 1.0 mmol) and K[$H_2B(tz)_2$] (0.188 g, 1.0 mmol) in methanol solution (50 ml). Re-crystallisation from methanol gave complex **4** as a micro-crystalline solid in 77% yield. m.p. 209–211 °C. ^{1}H NMR ($CDCl_3$, 293.K): δ 4.24 (s, 4H, C*H*), 4.36 (s, 4H, C*H*), 7.29–7.50 (m, 22H, C*H* and 3- or 5-C*H*), 8.17 (s, 2H, 3- or 5-C*H*). ^{31}P{^{1}H} NMR ($CDCl_3$, 293K): δ −5.18 (dd, $^1J(^{31}P,^{107}Ag) = 361$ Hz, $^1J(^{31}P,^{109}Ag) = 415$ Hz). IR (nujol, cm^{-1}): 3039w (CH), 2399m (BH), 1492s (C═C + C═N), 533m, 516m, 487s, 460s, 442m, 425m (Ar_3P), 350w. *Anal.* Calc. for $C_{38}H_{34}AgBFeN_6P_2$: C, 56.26; H, 4.22; N, 10.36. Found: C, 55.88; H, 4.46; N, 10.33%.

2.2. Structure determinations

Full spheres of 'low'-temperature CCD area-detector diffractometer data were measured (Bruker AXS instrument, ω-scans; monochromatic Mo Kα radiation, $\lambda = 0.71073$ Å, T ca. 153 K) yielding $N_{(total)}$ reflections, these merging to N unique (R_{int} cited) after 'empirical'/multiscan absorption correction (proprietary software), N_o with $F > 4\sigma(F)$ considered 'observed' and used in the full-matrix least squares refinements, refining anisotropic displacement parameter forms for the non-hydrogen atoms, (x, y, z, $U_{iso})_H$ being constrained at estimates. Conventional residuals R, R_w (weights: $(\sigma^2(F) + 0.000n_wF^2)^{-1}$) are quoted at convergence; neutral atom complex scattering factors were employed within the context of the XTAL 3.7 program system [15]. Pertinent results are given below and in the tables and figures, the latter showing 50% probability amplitude displacement envelopes for the non-hydrogen atoms, hydrogen atoms where shown having arbitrary radii of 0.1 Å.

3. Results and discussion

3.1. Syntheses

The interaction between $AgNO_3$, K[$H_2B(tz)_2$] and equimolar quantity of diphosphine ligand L in methanol at room temperature readily gave the complexes **1**, **3** and **4** in good yields, in accordance with the following general equation:

$$2K[H_2B(tz)_2] + 2AgNO_3 + xL \rightarrow x[\{H_2B(tz)_2Ag\}_y(L)] + 2KNO_3 \quad (1)$$

1: L = dppm, $x = 2$, $y = 1$;

3: L = dppe, $x = 1$, $y = 2$;

4: L = dppf, $x = 2$, $y = 1$.

It is noteworthy that when the reaction between $AgNO_3$, dppm and K[$H_2B(tz)_2$] was carried out in the presence of an excess of $AgNO_3$, the derivative [{$H_2B(tz)_2$}$_2Ag_3$-(dppm)$_2$(NO_3)](H_2O)$_{0.5}$ (**2**) is obtained, which could be considered as a hemi-adduct of [{$H_2B(tz)_2$}Ag(dppm)] (**1**) with silver(I) nitrate.

All of the colourless compounds **1**–**4** are soluble in $CHCl_3$, acetone and DMSO, in which, with exception of **2**, are non-electrolytes.

3.2. Spectroscopy

The IR spectra (see Section 2) show all the bands expected by the presence of the organic nitrogen donor and the phosphine ligand. For the derivatives of $H_2B(tz)_2$ **1**–**4** the BH stretches generally appear as a series of broad peaks in the expected regions (2399–2430 cm^{-1}). Upon coordination these bands are slightly shifted to higher frequency with respect to the same absorptions observed for free dihydrobis(1,2,4-triazolyl)borate ligands [10]. In the far IR spectra of all the derivatives, we have assigned, on the basis of a previous report on phosphino silver(I) complexes, the broad absorptions near 500 cm^{-1} and those at ca. 450 cm^{-1} to Whiffen's y and t vibrations [16]. In some cases, weak to medium bands at ca. 300 cm^{-1} appeared, similar to those described for silver-azolato complexes [17], which are tentatively assigned to ν(Ag–N) stretching vibrations.

The room temperature proton spectra of **1**–**4** in $CDCl_3$ (see Section 2) are very similar to each other and also to the potassium salt of bis-(1,2,4-triazolyl)borate in respect of their chemical shifts [18].

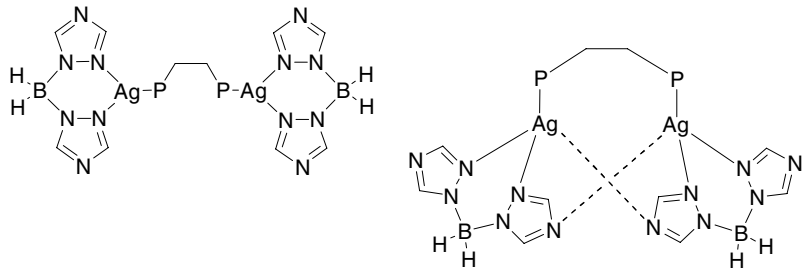

Fig. 2. Hypothetical structures for the dppe adduct **3**.

The BH signal was not observed in any case, presumably due to broadening of the resonance in consequence of quadrupolar coupling and relaxation effects from the boron atom [19].

Compound **1** may have a dinuclear $[Ag(dppm)]_2$ core analogous to that found in other dppm compounds, not only in the solid state but also in solution [20]. The ^{31}P NMR spectra of **1** support this finding. A double triplet has been observed at room temperature whereas the low temperature ^{13}P spectrum consists of an AA′XX′A″A* pattern [21], presumably due to the non-equivalence of the phosphorus atoms in perturbed $[AgX(dppm)]_2$ systems [20].

The δ and the coupling constant values found for the derivative **3** are typical of silver(I) species in AgN_2P or AgN_3P environments [22] suggesting a bridging coordination mode for the dppe ligand (Fig. 2), as expected on the basis of the stoichiometry, but not excluding a bridging coordination also of the $H_2B(tz)_2$ ligand.

3.3. Structure determinations

The results of the 'low'-temperature single crystal X-ray structure determinations are consistent with the above stoichiometries. The $H_2B(tz)_2$ ligand although exhibiting diverse hapticities, in all cases exhibits a chelate interaction with a silver atom through N(11,21), forming a six-membered ring with a 'boat' conformation, B and Ag at the prows, the latter the 'flatter' of the two (Table 1), although there are considerable diversities in detail among the various torsion components for the different complexes. Complex **4** is a simple mononuclear array, the silver atoms lying in four-coordinate N_2AgP_2 environments (Fig. 3). As usual in such species, the Ag–P distances are remarkably constant across a diversity of angular parameters, in particular, that imposed by ligand 'bite' in **4** (Tables 2 and 3), and in all cases P–Ag–N angles span a range of over 20°, with similar diversity in Ag–N, despite a constant N^N 'bite' angle. In each of these cases, one formula unit (devoid of

crystallographic symmetry) comprises the asymmetric unit of the structure.

The last statement is also true of **2**, where the stoichiometry is different, and where difference map residues have been modelled in terms of included solvent. This complex contains three independent silver atoms and may be regarded as a hemi-adduct of [{$H_2B(tz)_2$}Ag (dppm)] (1:1) with silver(I) nitrate, thus {$H_2B(tz)_2$}Ag:- dppm:$AgNO_3$ (2:2:1), one such formula unit, devoid of crystallographic symmetry, comprising the asymmetric unit of the structure (Fig. 4). The complex may be viewed even more appropriately as {$H_2B(tz)_2$}Ag: dppm (2:1)/$AgNO_3$:dppm (1:1). Ag(3) lies close to a crystallographic inversion centre and is linked to its inversion image by a pair of symmetry related bridging dppm ligands, an *O*-nitrato group pendent from each silver atom, thus [(O_2NO)Ag(*P*-dppm-*P*)$_2$Ag(ONO_2)], an array familiar in numerous 1:1 dppm adducts of silver(I) oxyanion salts. In the nitrate adduct of this type, in particular, the form taken is [(ONO_2)Ag(*P*-dppm-*P*)$_2$Ag(O_2NO)]; in the present complex the remainder of the structure impacts by supplanting of one of the chelating nitrato oxygen donors (N(24)) by an exo-nitrogen of a triazine ring, the association of the oxygen in the four-coordinate array about the silver becoming tenuous (Table 4). The second $H_2B(tz)_2$ ligand is associated solely with Ag(2) as a chelate, without further exocyclic interactions. The other diphosphine ligand bridges Ag(1) and Ag(2) which are then bridged further afield by the first $H_2B(tz)_2$ ligand, forming a centrosymmetric 16-membered metallacycle (Fig. 5).

Thus, whereas one $H_2B(tz)_2$ ligand is associated exclusively with Ag(2) as a chelate, the other $H_2B(tz)_2$ ligand not only chelates Ag(1), but its additional 'exo'-nitrogen atoms function as donors, the N(14) enabling the formation of the macro-metallacycle, and the N(24) linking these to the binuclear centrosymmetric eight-membered rings, formed by the second diphosphine ligand and the Ag(3), the totality of the array being a one-dimensional polymer. It should be noted that the Ag(1) are three-coordinate (PAgNP′), the array being essentially planar (angle sum 359.7°) (see Fig. 4).

4. Conclusions

We have here reported the synthesis, spectroscopic and structural characterization of new silver(I) derivatives containing bidentate phosphines and anionic bis(triazol-1-yl)borate ligand and demonstrated the formation of different types of complexes depending on the reaction conditions and nature (basicity and steric hindrance) of the ancillary phosphine ligands. From the interaction of $K[H_2B(tz)_2]$ with diphosphine ligands we have obtained simple mononuclear arrays (L = dppf), (likely) dimeric structures (L = dppe or dppm) or

hemi-adducts of [{$H_2B(tz)_2$}AgL] with silver(I) nitrate (L = dppm).

5. Supporting information available

X-ray crystallographic files, in CIF format, for the structure determinations of **2** and **4** have been deposited with the Cambridge Crystallographic Data Centre, CCDC: 236838 and 236841. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.uk or at www: http://www.ccdc.cam.ac.uk).

Abstract

The cyclometallated ligand 2-(4′,6-difluorophenyl)-4-methoxypyridine (F_2MeOppyH), whose complexes with iridium(III) emit bright blue to green light, was synthesized in five separate steps. Ir(F_2MeOppy)$_2$(acac), (acacH = 2,4-pentanedione), Ir(F_2MeOppy)$_2$(pic) (picH = 2-picolinic acid), *fac*-Ir(F_2MeOppy)$_3$ and *mer*-Ir(F_2MeOppy)$_3$ complexes were synthesized from solution and fully characterized. The structures of Ir(F_2MeOppy)$_2$(acac) and *fac*-Ir(F_2MeOppy)$_3$ were authenticated by X-ray single crystal structure analysis. *fac*-Ir(F_2MeOppy)$_3$ showed a much higher solution photoluminescence (PL) quantum efficiency and blue-shifted emission compared to its counter *mer*-isomer. All of the complexes showed reversible oxidations between 0.3 and 0.7 V versus the ferrocene/ferrocenium ion. The relative thermodynamic stability of the *mer* versus *fac* isomer was investigated and correlated to their corresponding redox and PL properties. Two electroluminescent (EL) devices (D-1 and D-2) were fabricated using the same blue Ir(F_2MeOppy)$_2$(acac) complex as a a dopant but with two different hole blockers, BCP and BAlq, and consequently BCP proved itself a good hole blocker for this type of system. The fabrication of another EL device (D-3) was carried out by using the same dopant, only replacing the host CBP by a wider band gap host, *m*CP which showed improved luminance, luminance yield and power efficiency (D-2: 133 cd m^{-2}, 0.66 cd A^{-1}, 0.22 lm W^{-1}; D-3: 326 cd m^{-2}; 1.63 cd A^{-1}; 0.26 lm W^{-1}).

1. Introduction

Syntheses of materials based on heavy metal (Ir(III), Pt(II), Os(II), Re(I)) complexes, used as phosphorescent dopants, have attracted a great deal of attention due to their potential applications in organic light emitting devices (OLEDs) [1–4]. Of the above heavy metal-containing phosphor emitters that have been reported in OLEDs, cyclometallated complexes of iridium(III) materials have shown the most promising applications due to their higher stability, higher photoluminescence (PL) efficiency and relatively shorter excited state lifetime. Purely green- and red-emitting phosphorescent complexes of iridium(III) [5] are common, whereas the purely blue-emitting complex dopants [6] are scarcely found. Hence, the current effort of scientists has been focused on the syntheses of blue-emitting iridium(III)-based materials.

Amongst the complexes, the syntheses of Ir(F_2ppy)$_2$(acac) and Ir(F_2ppy)$_2$(pic) (F_2ppy = 2-(2′, 4′-difluorophenyl)pyridine; acacH = 2,4-pentanedione; picH = 2-picolinic acid) [7] are notable examples for blue-emitting materials. Recently, Coppo et al. [8] reported the blue-emitting phenylpyridine iridium(III) complexes using triazolyl pyridine types as ancillary ligands. In this work, we have introduced strong electron donating substituents at the 4-position of the LUMO containing pyridyl moiety in 2-(2′,4′-difluorophenyl)pyridine, which is

doi:10.1016/j.poly.2004.10.016

supposed to further raise the LUMO energy state of the corresponding iridium(III) complex. Hence, the energy gap will be enhanced and consequently result in a more hypsochromic shift when compared to the parent complex. Our first choice was to incorporate a methoxy substituent at the 4-position of the pyridyl moiety in 2-(2,4′-difluorophenyl)pyridine. We have also synthesized both the *fac*-/*mer*-isomers of the same ligand, investigated and differentiated their photoluminescence and redox behaviors as well as their thermal stability. We report on the syntheses of four blue-emitting iridium(III) complex dopants using the same cyclometallated ligand, 2-(2′,4′-difluorophenyl)-4-methoxypyridine, and characterization and detailed studies of their photophysical as well as redox properties, X-ray single-crystal structure analyses of $Ir(F_2MeOppy)_2(acac)$ and *fac*-$Ir(F_2MeOppy)_3$ and the application of $Ir(F_2MeOppy)_2(acac)$ as a dopant in electroluminescent (EL) devices.

2. Experimental

2.1. Materials

$IrCl_3 \cdot 3H_2O$ was purchased from Alfa Aesar, USA, 2,4-difluoroboronic acid, picolinic acid and glycerol from Aldrich Chemicals, USA and the remaining compounds from Tokyo Kasei Kogyo Co. Ltd., Japan, and all were used as received.

2.2. Syntheses

2-Chloropyridine-N-oxide (yield 95%): 2-Chloropyridine was allowed to react with excess *m*-chloroperoxybenzoic acid in dichloromethane at ~0 °C, for 16 h. Then, the volume of the solvent was reduced to half and it was passed through a basic alumina bed using dichloromethane as an eluent, which resulted in pure 2-chloropyridine-N-oxide. ^1H NMR (300 MHz, $CDCl_3$): δ 8.39 (t, 1H, *J* 3.9 Hz), 7.54 (t, 1H, *J* 5.1 Hz), 7.27 (m, 2H). EIMS: *m*/*z* 130, Calc. 130.5.

2-Chloro-4-nitropyridine-N-oxide (yield 70%) [9]: 2-chloropyridine-N-oxide (10 g) was added to conc. sulfuric acid (15 ml) at 0–5 °C. Then, a mixture of conc. sulfuric acid (15 ml) and fuming nitric acid (30 ml) (sp. gr. 1.5) was added dropwise with stirring at 1–2 °C over a 45-min period. The mixture was heated slowly to 90 °C over 1 h and then maintained at 90 °C with stirring for an additional hour after which the mixture was cooled to 10 °C, poured into a stirred ice–water mixture, and neutralized with sodium carbonate. The yellow precipitate was collected, air-dried, and then recrystallized from an ethanol–chloroform mixture. ^1H NMR (300 MHz, $CDCl_3$): δ 8.45 (m, 2H), 8.04 (m, 1H). EIMS: *m*/*z* 176, Calc. 175.5.

2-Chloro-4-nitropyridine (yield 90%) [9]: 2 g of 2-chloro-4-nitropyridine-N-oxide was taken in 30 ml of ethyl acetate and ~3 ml of phosphorous tribromide was added slowly. Then, the mixture was heated with stirring at 70 °C for 10 min. The mixture was cooled, poured into an ice–water mixture, made alkaline to litmus with 10% aqueous sodium hydroxide and extracted with chloroform. The solvent was evaporated and purified by column chromatography. ^1H NMR (300 MHz, $CDCl_3$): δ 8.67 (dd, 1H, *J* 0.5, 5.4 Hz), 8.20 (d, 1H, *J* 1.8 Hz), 7.99 (dd, 1H *J* 1.8, 5.4 Hz). EIMS: *m*/*z* 158, Calc. 158.5.

2-Chloro-4-methoxypyridine (yield 55%): 2-Chloro-4-nitropyridine (1 eq.) was reacted with sodium methoxide (1.3 eq.) in dioxane at 100 °C for 12 h. The reaction mixture was cooled to room temperature and poured into water. Then, the organic layer was separated out and the aqueous layer was washed by ethyl acetate. The combined organic extracts were dried and evaporated to dryness. The compound was purified by column chromatography. ^1H NMR (300 MHz, $CDCl_3$): δ 8.43 (d, 1H, *J* 6 Hz), 7.26 (d, 1H, *J* 2.1 Hz), 7.06 (m, 1H). EIMS: *m*/*z* 143, Calc. 143.5.

2-(2′,4′-Difluorophenyl)-4-methoxypyridine (yield 80%) [10]. 5 g of 2-chloro-4-methoxy pyridine (1 eq.), 8.8 g of 2,4-difluorophenylboronic acid (1.6 eq.) and 1.15 g of triphenylphosphine (0.1 eq.) were dissolved in 1,2-dimethoxyethane (50 ml). 60 ml of 2 M K_2CO_3 (2.7 eq.) aqueous solution was added and the mixture was purged with argon gas. 0.25 g of palladium acetate (0.025 eq.) was added and the mixture was refluxed for 18 h. The two phases were then separated and the aqueous phase was extracted with ethyl acetate. The combined organic phases were washed with water and brine, successively, and then dried over $MgSO_4$. After evaporation of the solvent, the pure product was obtained by column chromatography. ^1H NMR (300 MHz, $CDCl_3$): δ 8.51 (d, 1H, *J* 5.7 Hz), 7.98 (m, 1H), 7.26 (t, 1H, *J* 2.1 Hz), 6.94 (m, 2H), 6.78 (dd, 1H, *J* 2.4, 5.7 Hz), 3.87 (s, 3H). EIMS: *m*/*z* 221, Calc. 221.

$(F_2MeOppy)_2Ir(\mu\text{-}Cl)Ir(F_2MeOppy)_2$ (yield 75%) [5e–5f]. Calc. for $C_{48}H_{32}N_4O_4F_8Cl_2Ir_2$: C, 43.1; H, 2.4; N, 4.2. Found: C, 43.0; H 2.3; N 4.0%. A solution of $IrCl_3 \cdot 3H_2O$ (1 mmol) and 2-(2′,4′-difluorophenyl)-4-methoxypyridine (3 mmol) in 2-ethoxyethanol (30 ml) was refluxed for 24 h. The pale green mixture was cooled to room temperature and 20 ml of 1 M HCl was added to precipitate the product. The mixture was filtered and washed with 100 ml of 1 M HCl followed by 50 ml of methanol, and then dried. The product was obtained as a light green powder. ^1H NMR (300 MHz, $CDCl_3$): δ 8.91 (d, 4H, *J* 6.6 Hz), 7.80 (s, 4H), 6.43 (m, 4H), 6.31 (t, 4H, *J* 9.9 Hz), 5.37 (d, 4H, *J* 9.0 Hz), 4.01 (s, 12H). FABMS: *m*/*z* 1335, Calc. 1335.

$Ir(F_2MeOppy)_2(acac)$ (yield 85%) [5e–5f]. Calc. for $C_{29}H_{23}N_2O_4F_4Ir$: C, 47.6; H, 3.1; N, 3.8. Found: C, 47.3; H 3.1; N 3.6%. $(F_2MeOppy)_2Ir(\mu\text{-}Cl)Ir(F_2MeOp-$

$py)_2$ (1 mmol), acetylacetone (3 mmol) and sodium carbonate (10 mmol) were mixed in 10 ml of 2-ethoxyethanol. The mixture was refluxed under nitrogen for 12 h. The reaction mixture was then cooled and the pale green precipitate was filtered off. The product was washed by methanol several times, followed by hexane. Then it was recrystallised from the mixture of dichloromethane and methanol (1:1). ^{1}H NMR (300 MHz, $CDCl_3$): δ 8.19 (d, 2H, *J* 6.6 Hz), 7.75 (s, 2H), 6.76 (dd, 2H, *J* 2.5, 6.3 Hz), 6.30 (t, 2H, *J* 10.5 Hz), 5.70 (d, 2H, *J* 7.2 Hz), 5.22 (s, 1H), 4.20 (s, 6H), 1.85 (s, 6H). FABMS: *m*/*z* 731, Calc. 731.

$Ir(F_2MeOppy)_2$(pic) (yield 92%) [6d]. Calc. for $C_{30}H_{20}N_3O_4F_4Ir_2$: C, 47.7; H, 2.7; N, 4.8. Found: C, 47.6; H 2.6; N 4.8%. 2.2 mmol of picolinic acid was added to a room temperature solution of 0.8 mmol of $(F_2MeOppy)_2Ir(\mu\text{-}Cl)Ir(F_2MeOppy)_2$ in 60 ml of dichloromethane. The mixture was heated to reflux under nitrogen in an oil bath for 16 h. The reaction mixture was cooled to room temperature and the pale yellow precipitate was filtered off. The pure product was obtained by flash chromatography. ^{1}H NMR (300 MHz, $CDCl_3$): δ 8.48 (d, 1H, *J* 6.9 Hz), 8.32 (d, 1H, *J* 7.2 Hz), 7.92 (t, 1H, *J* 6.6 Hz), 7.76 (m, 3H), 7.40 (td, 1H, *J* 1.5, 5.7 Hz), 7.17 (d, 1H, *J* 6.6 Hz), 6.73 (dd, 1H, *J* 2.7, 6.9 Hz), 6.53 (dd, 1H, *J* 2.7, 6.6 Hz), 6.42 (m, 2H), 5.88 (dd, 1H, *J* 2.3, 8.7 Hz), 5.64 (dd, 1H, *J* 2.6, 8.7 Hz), 4.06 (s, 6H). FABMS: *m*/*z* 754, Calc. 754.

mer-$Ir(F_2MeOppy)_3$ (yield 60%) [6a]. Calc. for $C_{36}H_{24}N_3O_3F_6Ir$: C, 50.7; H, 2.8; N, 4.2. Found: C, 50.5; H 2.7; N 4.0%. 1 equivalent of $(F_2MeOppy)_2Ir(\mu\text{-}Cl)$ $Ir(F_2MeOppy)_2$, 2 equivalents of the cyclometallated ligand ($F_2MeOppyH$) and 10 equivalents of sodium carbonate were mixed and refluxed in 2-ethoxyethanol for 20 h. The reaction was then allowed to cool to room temperature and distilled water was poured down on it. Immediately, the impure product was precipitated out and it was purified by flash chromatography by using dichloromethane as an eluant. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.77 (m, 3H), 7.64 (m, 2H), 7.31 (t, 1H, *J* 7.5 Hz), 6.64 (td, 1H, *J* 2.1, 7.9 Hz), 6.52 (td, 2H, *J* 3.0, 6.6 Hz), 6.39 (m, 4H), 6.06 (dd, 1H, *J* 2.4, 7.5 Hz), 5.88 (dd, 1H, *J* 2.4, 9.3 Hz), 4.14 (s, 9H). FABMS: *m*/*z* 852, Calc. 852.

fac-$Ir(F_2MeOppy)_3$ (yield 50%) [6a]. Calc. for $C_{36}H_{24}N_3O_3F_6Ir$: C, 50.7; H, 2.8; N, 4.2. Found: C, 50.4; H 2.7; N 4.1%. 1 equivalent of $Ir(F_2MeOppy)_2$(acac) and 1.5 equivalents of the cyclometallated ligand ($F_2MeOppyH$) were refluxed in glycerol for 24 h. Then the reaction mixture was cooled to room temperature and distilled water was added to it. The impure product was separated out and purified by flash chromatography. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.39 (s, 3H), 7.28 (d, 3H, *J* 6.6 Hz), 6.50 (t, 3H, *J* 4.2 Hz), 6.31 (m, 2H), 4.11 (s, 9H). FABMS: *m*/*z* 852, Calc. 852.

2.3. Crystallography

Single crystal diffraction data for $Ir(F_2MeOppy)_2$(acac) and *fac*-$Ir(F_2MeOppy)_3$ were collected on a Bruker Smart CCD diffractometer equipped with a normal focus, 3kW sealed-tube X-ray source (λ = 0.71073 Å). The intensity data were collected in the ω scan mode (width of 0.3/° frame) and corrected for *Lp* and absorption effects by using the SAINT [11] program. Cell refinement and data reduction were carried out by using the program Bruker SHELXTL [12] and the crystal structure was solved by direct methods using the SHELXTL [12] version 5.1 software packages. The structure was further refined by full-matrix least-squares methods based on F^2 using SHELXTL version 5.1 [12]. Positions of non-hydrogen atoms were refined anisotropically, whereas the hydrogen positions were not refined.

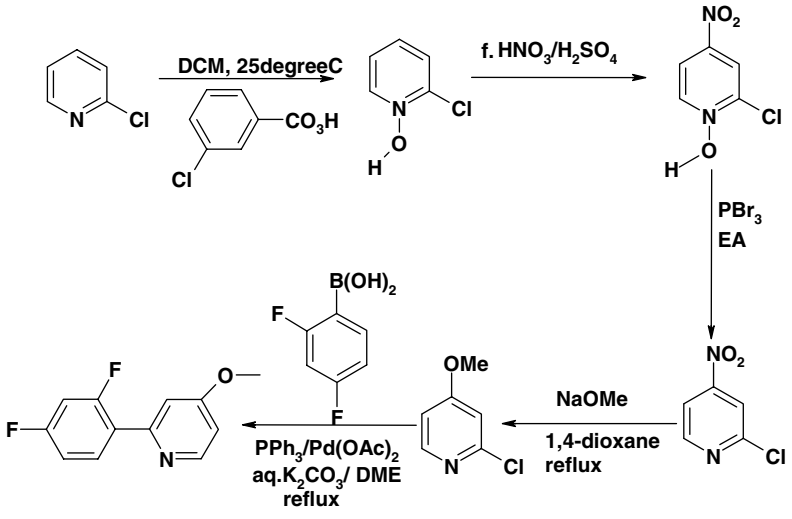
2.4. Optical measurements and compositions analysis

The ultraviolet-visible (UV–Vis) spectra of the phosphorescent Ir(III) complexes were measured on an UV–Vis spectrophotometer (Agilent model 8453) and corrected for background due to solvent absorption. Photoluminescence (PL) spectra were carried out with a spectrophotometer (Jobin-Yvon Spex, model Fluorolog-3). Emission quantum yields were measured by the method of Demas and Crosby [13] using *fac*-$Ir(ppy)_3$ as a reference [14]. NMR spectra were recorded on Varian 300 MHz. MS spectra (EI and FAB) were taken by micromass TRIO-2000. Cyclic voltammetry (CV) analyses were performed by using CHI 2.05; dichloromethane was used as a solvent in an inert atmosphere and 0.1 M tetra(*n*-butyl)ammonium tetrafluoroborate was used as the supporting electrolyte. A glassy carbon rod was used as the working electrode, platinum was used as the counter electrode and a silver wire was used as a pseudo-reference electrode. The TG-DTA analysis was carried out by using a thermal analyzer (SEIKO 1TG/DTA model 200). Emission lifetimes were obtained by exponentially fitting the emission decay curves recorded on Continuum model NY61 spectrofluorometer.

2.5. OLED fabrication and testing

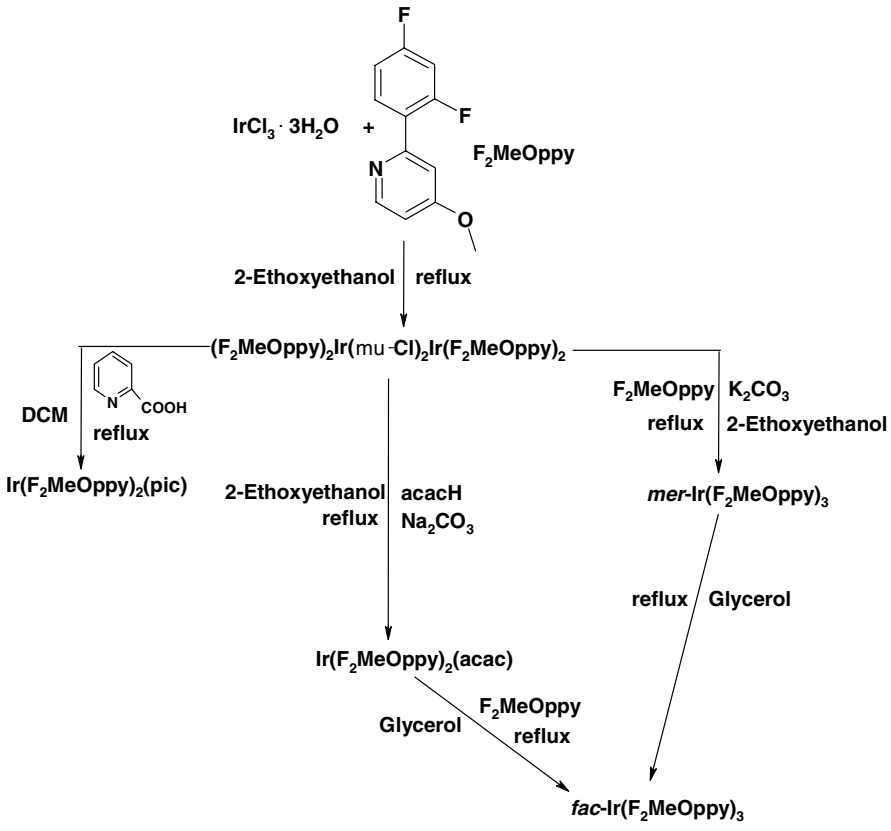
In the fabrication of OLEDs organic layers were thermally evaporated onto a glass substrate precoated with an indium–tin–oxide (ITO) layer with a sheet resistance of 20 Ω under high-vacuum. Prior to use, the ITO surface was ultrasonicated in a detergent solution followed by rinsing with deionized (DI) water, dipped into acetone, trichloroethylene and 2-propanol, and then degreased with a vapor of 2-propanol. After degreasing, the substrate was oxidized and cleaned in a UV-ozone chamber before it was loaded into an evaporator. In a vacuum chamber at a pressure of 10^{-6} Torr, 500 Å of

NPB as the hole transporting layer; 200 Å of the complex doped (7%) CBP as the emitting layer; 100 Å of 2,9-dimethyl-4,7-diphenyl-1,10-phenanthroline (BCP) as a hole and exciton blocking layer (HBL); 650 Å of Alq_3 as the electron transport layer; and a cathode composed of 10 Å lithium fluoride and 2000 Å aluminum were sequentially deposited onto the substrate to give the device structure. The current–voltage (*I–V*) profiles and light intensity characteristics for the above-fabricated devices were measured in a vacuum chamber of 10^{-6} Torr at ambient temperature using a Keithley 2400 Source Meter/2000 Multimeter coupled to a PR 650 Optical Meter.



3. Results and discussion

3.1. Synthesis



The ligand, 2-(2′,4′-difluorophenyl)-4-methoxypyridine (F_2MeOppyH) has been synthesized in five separate steps smoothly (Scheme 1; see experimental part). The yield of 4-methoxy-2-chloro-pyridine (4th step) is relatively poor (~55%) as compared to the other intermediates and the final compound (F_2MeOppyH). $IrCl_3 \cdot 3H_2O$ was allowed to react with an excess of F_2MeOppyH to give chloride-bridged dinuclear complex [5e,5f]. The mononuclear complexes, Ir(F_2MeOppy)$_2$(acac) and Ir(F_2MeOppy)$_2$(pic) have been synthesized [5e,5f] by replacing the bridging chlorides from the dinuclear species (Scheme 2), with bidentate, monoanionic acetylacetonate and picolinate, respectively. The proton NMR spectra of these complexes are consistent with the heterocyclic rings of the cyclometallated ligand being in a *trans*-disposition. The tris-isomeric complexes (*facial/meridional*) have also been synthesized by varying the temperature and using the cyclometallated ligand, F_2MeOppyH. Thompson et al. [6a] reported the syntheses of the *mer*-isomer at 140 °C and the *fac*-isomer of iridium(III) complexes at 200 °C along with little amount of *mer*-isomer as a by-product. In our case, the *meridional* form has been synthesized at a relatively lower temperature (~120 °C), whereas the synthesis at higher temperature (~200 °C) generates absolutely the *facial* form (Scheme 2). We have always isolated a mixture of *fac* and *mer* isomers at 140 °C. Furthermore, pure *mer*-isomer was taken in glycerol and refluxed for 24 h. It was observed that the *mer*-isomer converted to the *fac*-isomer almost completely, inferring that the *mer*-isomer was a kinetically controlled product, whereas the *fac*-isomer was favored thermodynamically. These isomers could also been differentiated clearly on the TLC plate due to their large polarity differences. ^{1}H NMR and ^{19}F NMR spectra (Fig. 1) clearly distinguished the *fac*-isomer from the *mer*-form. In ^{19}F spectra, we observed two peaks for the inherent-C_3 symmetric *facial* isomer and the six peaks for the asymmetric *mer*-isomer. Furthermore, TGA-DTA studies showed that the complexes are stable up to 340–360 °C and they can be sublimed easily under a pressure of 10^{-3} mm Hg.

3.2. X-ray crystallography

Single crystals of Ir(F_2MeOppy)$_2$(acac) and *fac*-Ir(F_2MeOppy)$_3$ were grown from methanol/dichloromethane (1:1) and chloroform, respectively, and characterized using X-ray crystallography. The ORTEP drawings of Ir(F_2MeOppy)$_2$(acac) and *fac*-Ir(F_2MeOppy)$_3$ are represented in Figs. 2(a) and (b), respectively. The crystal data and the selected bond lengths of both complexes are displayed in Tables 1 and 2, respectively. The dispo-

$(C^N)_2Ir(\mu\text{-}Cl)Ir(C^N)_2$ [16] complexes. The *mer*-Ir$(F_2MeOppy)_3$ complex should have the same disposition of F_2MeOppy ligand as found in Ir$(F_2MeOppy)_2$(acac). The mutually *trans*-disposed Ir–N bonds in Ir$(F_2MeOppy)_2$(acac) have shorter bond lengths (Table 2) in comparison with those in *fac*-Ir$(F_2MeOppy)_3$ where the bond lies in a *trans* position (Fig. 2(b)) to the strong *trans* influencing phenyl group. Another point to be noted is that the weak *trans* influence of the acetylacetonate ligand leads to shorter Ir–C bonds for the Ir$(F_2MeOppy)_2$(acac) complex than those observed in *fac*-Ir$(F_2MeOppy)_3$, as indicated in Table 2.

3.3. Photophysical properties

The solution UV–Vis absorption and PL spectra of all these complexes have been measured. The UV–Vis absorption spectra of these complexes show intense bands appearing in the ultraviolet part of the spectrum between 240 and 340 nm. The measured energies and the extinction coefficients are comparable to those of the free ligand, which helped us to assign the bands as spin allowed $^1(\pi\text{–}\pi^*)$ transitions of the ligand. These ligand-centered bands are accompanied by weaker transitions with lower energy extending into the visible region from 350 to 400 nm (Fig. 3). With reference to the previous photophysical studies of cyclometallated complexes of the iridium(III) system [17], these absorption features are assigned to intra-ligand (IL) $\pi\text{–}\pi^*$ ($F_2MeOppy^-$) and also spin-allowed metal-to-ligand charge transfer ^{1}MLCT [$d\pi$ (Ir) $\rightarrow \pi$ $F_2MeOppy^-$)] transitions. In addition, spectra of all the complexes exhibit weaker absorption tails toward the further lower energy region (400–470 nm) (Fig. 3), which may be recognized as the spin-forbidden ^{3}MLCT [$d\pi$ (Ir) $\rightarrow \pi^*$ ($F_2MeOppy^-$)] transitions. The high intensity of these MLCT bands (shown by the extinction coefficients in the Table 3) has been attributed to an effective mixing of these charge transfer transitions with higher lying spin-allowed transitions on the cyclometallated ligand, which is facilitated by the strong spin–orbit coupling of the iridium(III) center. The energy of the MLCT transitions for the *fac*-isomer is comparatively higher than those of the rest of the complexes. These MLCT bands in the *fac*-isomer are more prominent and easily distinguishable as compared to its *mer*-counterpart, which is indicated in Fig. 3. The lowest energy transitions show blue-shifted absorption with increasing polarity of the solvents (i.e., toluene → chloroform → acetone → methanol). As shown in Fig. 4, the solution PL emission spectra of all the complexes exhibit structured features. These facts support that the lowest excited states of the complexes have a mixed ligand centered (LC) as well as MLCT character. As shown in Fig. 4, the PL intensity of the *fac*-isomer is much higher and exhibits ~6 nm hypsochromic shift with respect to its *mer*-counterpart. Similarly, the PL intensity of the Ir$(F_2MeOppy)_2$(acac) complex is found to be much higher and its emission spectrum much sharper relative to that of Ir$(F_2MeOppy)_2$(pic), whose spectrum is red-shifted, broad and

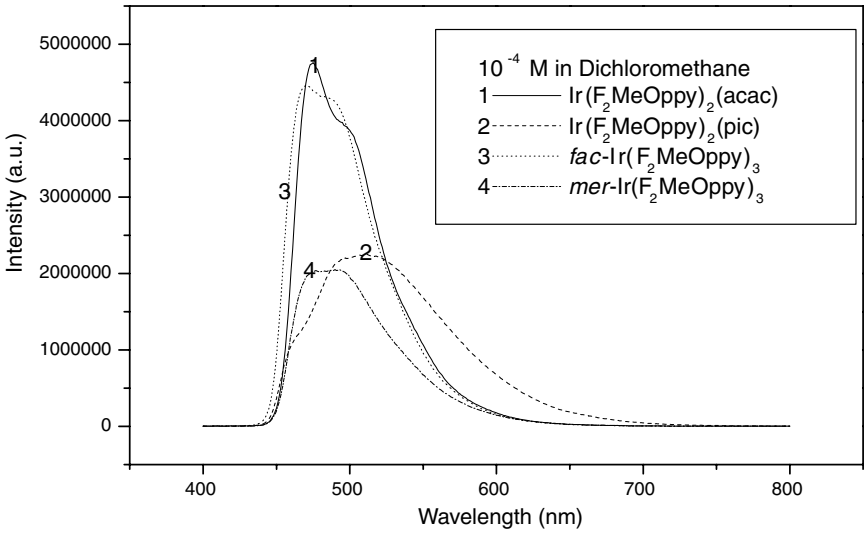

Fig. 4. Room temperature solution PL spectra for all the complexes in CH_2Cl_2.

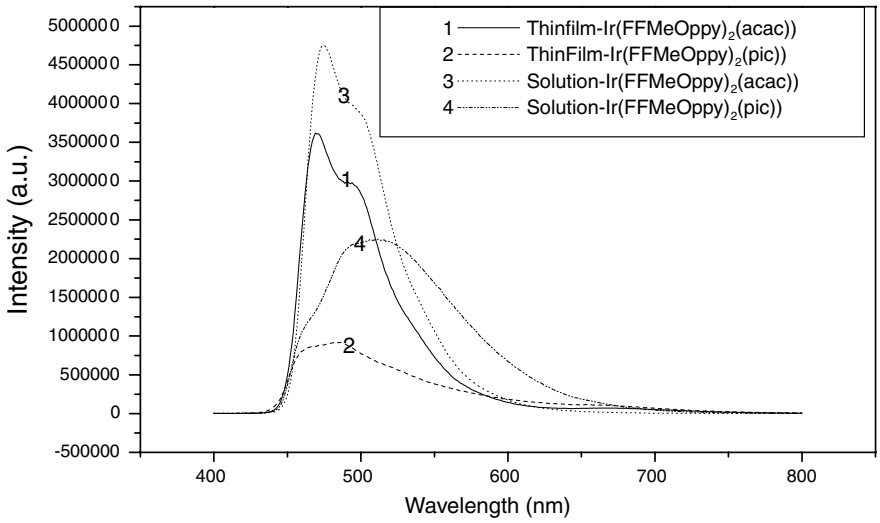
featureless. The solution spectrum of Ir(F_2MeOppy)$_2$-(pic) also markedly differs from its thin-film emission spectrum (Fig. 5), which shows blue-shifted emission to a larger extent (~30 nm). It has also been observed that the nature of the emission spectra of Ir(F_2MeOppy)$_2$-(pic) is red-shifted in order of increasing polarity of the solvents, which suggest that the energy of the lowest emitting state of Ir(F_2MeOppy)$_2$(pic) is highly solvent dependent. The thin-film spectra for the other complexes, as shown in Fig. 5, exhibit blue-shifted emission to a smaller extent (~5–8 nm) as compared to their respective solution spectra.

The complexes, Ir(F_2ppy)$_2$(acac) and Ir(F_2ppy)$_2$(pic) [F_2ppy = 2-(2,4-difluorophenyl)pyridyine], have been reported [6d,7] and well characterized. The strong electron-donating methoxy substituent was incorporated onto the LUMO containing pyridyl ring of F_2ppy, and, therefore, it raised the LUMO energy and thereby increased the HOMO–LUMO energy gap. Hence, the complex Ir(F_2MeOppy)$_2$(acac) (λ_{max} = 471 nm) shows the expected blue-shifted emission as compared to the reported complex, Ir(F_2ppy)$_2$(acac) (λ_{max} = 476 nm). It is also known that Ir(F_2ppy)$_2$(pic) (λ_{max} = 456 nm) exhibits blue shifted emission compared to its acetylacetonate analogue, Ir(F_2ppy)$_2$(acac) (λ_{max} = 476 nm). But in our case, Ir(F_2MeOppy)$_2$(pic) (λ_{max} = 509 nm) shows a wide red shifted emission compared to its acetylacetonate analogue (λ_{max} = 471 nm). We have measured the solution quantum efficiency of the complexes and the results are shown in Table 3. The *fac*-isomer shows a much higher quantum efficiency as compared to its counter *mer*-isomer. Furthermore, as shown in Table 3, the measured lifetime for thin film samples falls into the microsecond regime, which evidence the lowest excited states are the triplet-emitting states for these complexes. The short life-time also indicates that there is strong spin–orbit coupling in the presence of heavy metal iridium(III).

3.4. Electrochemistry

The electrochemical properties of the bis- and tris-cyclometallated complexes were examined by cyclic voltammetry. Redox potentials, given in Table 3, were measured relative to an internal ferrocene reference (Cp_2Fe/Cp_2Fe^+ = 0.62 versus SCE in dichloromethane solvent). All of these complexes showed reversible oxidation, in



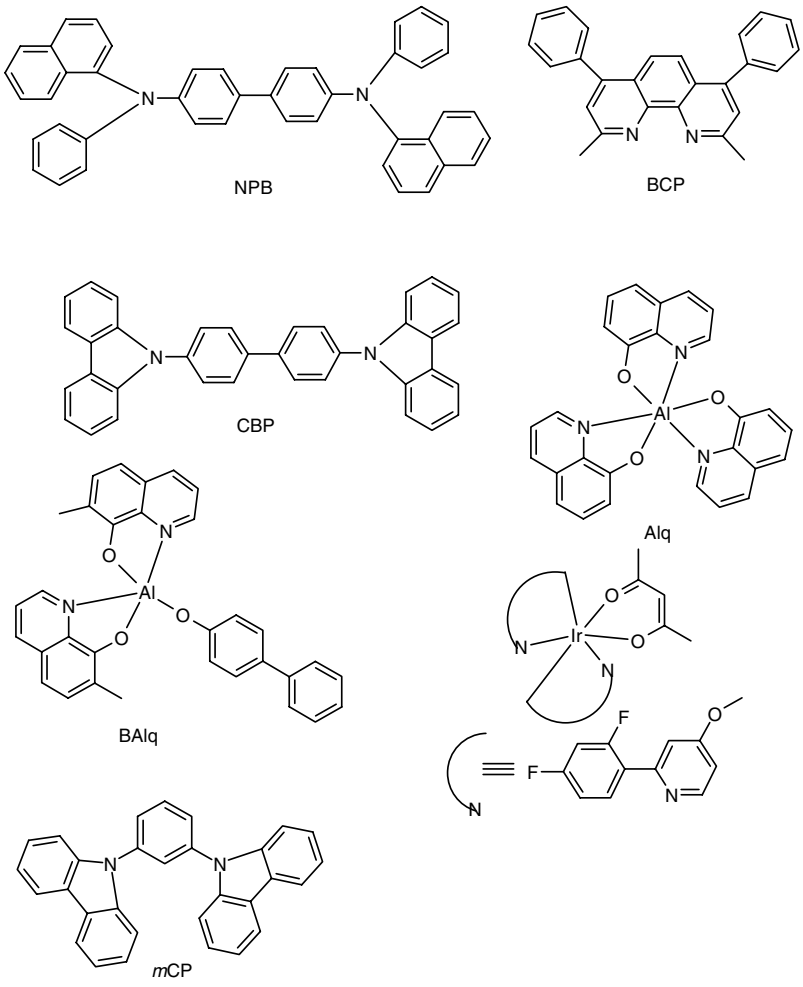


Fig. 5. Comparison of thin-film and solution PL spectra for $Ir(F_2MeOppy)_2X$ (X = acac and pic).

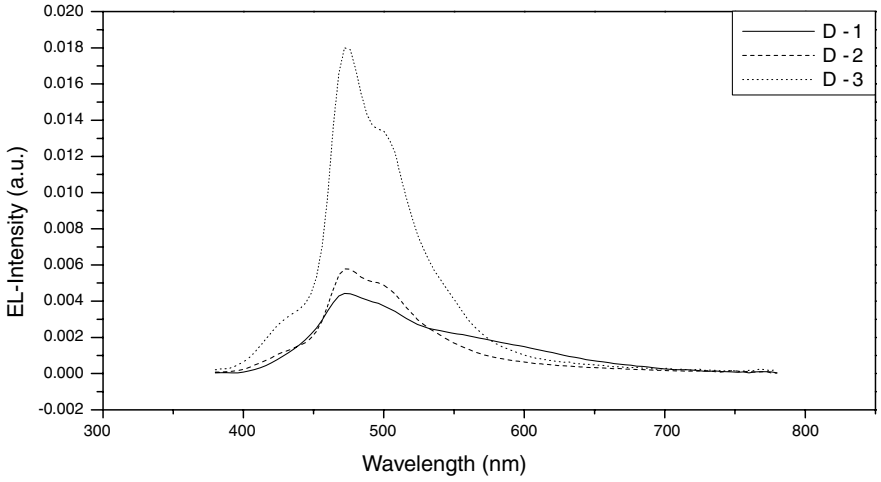
the range from 0.34 to 0.67 V. The *fac*-isomer has oxidation potentials ca. ~200 mV more positive than the corresponding *mer*-form (i.e., fac_{ox}: 0.55 V; mer_{ox}: 0.34 V), whereas the reduction potential for the *fac*-form is slightly more negative than that of the *mer*-isomer (i.e., fac_{red}: −2.67 V; mer_{red}: −2.62 V). It was known that for phenyl-pyridyl based complexes, the oxidation processes involve the Ir–phenyl center (major HOMO contribution), while reduction processes occur primarily on the heterocyclic portion (major LUMO contribution) of the ligand [6]. The difference in electrochemical properties between *facial* and *meridional* isomers can be rationalized by the presence of mutually *trans* phenyl rings of the ligands in the *mer*-isomer, whereas in the *facial* form all the phenyls are *cis* (Fig. 2(b)) with respect to one another. Electron-rich sigma phenyl ligands normally exhibit a very strong *trans* influence and *trans* effect, which results in a lengthening of the *transoid* Ir–C bonds and hence destabilization of the HOMO to a significant extent, which is supported by the HOMO–LUMO energy calculations using redox data and absorption wavelength, summarized in Table 3. Therefore, it is concluded that the *mer*-isomer is easier to oxidize than the *fac*-isomer.

3.5. Description and performance of OLED devices

Initially, we fabricated an electroluminescent device D-1 with structure ITO/CF_x/NPB (300 Å)/CBP + 7% dopant (200 Å)/BAlq (300 Å)/Alq_3 (150 Å)/LiF (10 Å)/Al (2000 Å) (the molecular structures of each compound used in the EL device are shown in Scheme 3) using the complex $Ir(F_2MeOppy)_2(acac)$ as a dopant in the emitting layer. Fig. 6 shows the EL emission spectra of the device where a broad and long tail extending up to 735 nm was observed. Clearly, the emission appearing in the green and red regions is attributed to the leakage of holes into the BAlq and Alq_3 layers and the consequent recombination in those layers infers that BAlq is not an effective hole blocker (HB) for deep-blue electroluminescent material (Scheme 4a). Consequently, we replaced BAlq with BCP, which has a comparatively higher HOMO level (6.5 eV) as compared to BAlq (6.0 eV). Accordingly, we fabricated another device by incorporating the same dopant, $Ir(F_2MeOppy)_2(acac)$ (D-2) into the emitting layer, with BAlq replaced by BCP as a hole blocker. No observation of a broad emission was found in this device, but another extra emission was observed at ca. 425 nm, which was attributed to the NPB hole transport material as shown in Fig. 6. The external luminance efficiency and the power efficiency is found to be 0.66 cd A^{-1} and 0.22 lm W^{-1}, respectively, at a current density of 20 mA cm^{-2}, as indicated in Fig. 7. The lowest triplet energy levels for the dopant, $Ir(F_2MeOppy)_2(acac)$ and the host, CBP are 2.64 [1] and 2.56 eV [12], respectively, which suggests that the endothermic energy transfer [7] is being operated between the host and the dopant. This type of energy transfer in an EL device is not completely favorable for blue-emitting dopants (Scheme 4b) [c]. The fabrication of another EL device was carried out with the host *m*CP, having a wider band gap, i.e., 2.90 eV [18]. The layer sequences and the thicknesses of each layer were kept constant as before. The comparisons of device performance of D-2 and D-3 have been shown in Table 4. As indicated in Fig. 7, in this case the external quantum efficiency and the power efficiency are improved and found to be 1.63 cd A^{-1} and 0.47 lm W^{-1} at 20 mA cm^{-2} current density, respectively, as compared

[1] The triplet emitting state of $Ir(F_2MeOppy)_2(acac)$ has been calculated from the maximum emission wavelength at 298 K.

Scheme 3.



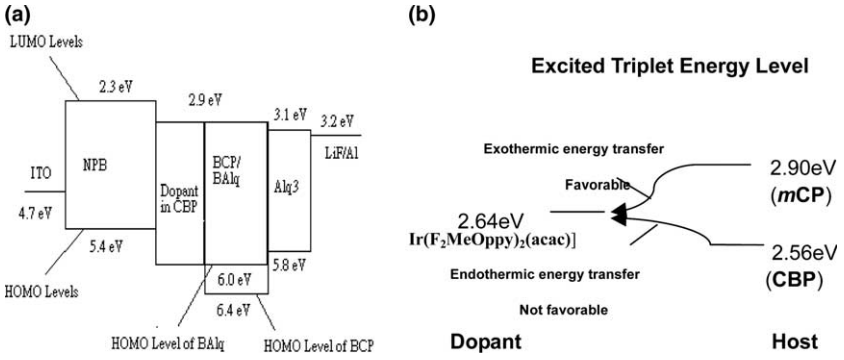


Fig. 6. Comparative electroluminescent emission spectra of devices D-1, D-2 and D-3.

to the previous devices. This device shows a luminance value of 326 cd m^{-2} at 20 mA cm^{-2} current density, that is also higher than that of the former device (133 cd m^{-2} at 20 mA cm^{-2}) (Figs. 8(a) and (b)). Hence the exothermic triplet energy transfer to the blue dopant Ir(F_2-MeOppy)$_2$(acac) is more efficient when using the wider band gap host *m* CP. The comparisons of *I–V* curves have also been shown in Fig. 8(a) and (b).

Scheme 4.

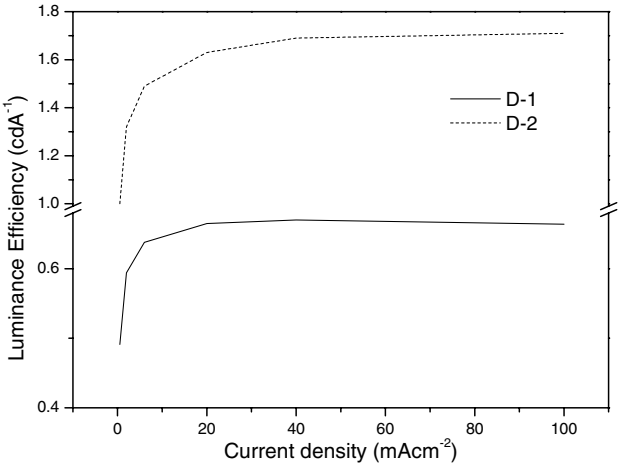

Fig. 7. Comparative plot of luminescent efficiency vs. current density of D-2 and D-3 devices.

Table 4
Comparisons of the EL performances of the devices with structure: ITO/CHF_3/NPB (300 Å)/Host + 7% dopant (200 Å)/BAlq (300 Å)/Alq_3(150 Å)/LiF (10 Å)/Al (2000 Å), Host − CBP for D-2; *m*CP for D-3

	D-2	D-3
EL color	blue	blue
Peak wavelength (nm)	472	472
CIE-x at 20 mA cm^{-2}	0.19	0.17
CIE-y	0.31	0.30
Luminance (cd m^{-2} at 20 mA cm^{-2})	133	327
External quantum efficiency (cd A^{-1} at 20 mA cm^{-2})	0.66	1.63
Power efficiency (lm W^{-1} at 20 mA cm^{-2})	0.22	0.88

All these parameters have been recorded at 20 mA cm^{-2}.

4. Conclusion

We have synthesized four iridium(III)-based phosphorescent dopants that emit in the blue range, using the same cyclometallated ligand, 2-(2′,4′-difluorophenyl)-4-methoxypyridine. These complexes show different maximum emission wavelengths and quantum efficiencies with respect to the ancillary ligands (actylacetonate and picolinate) and the types of isomerism. The strong

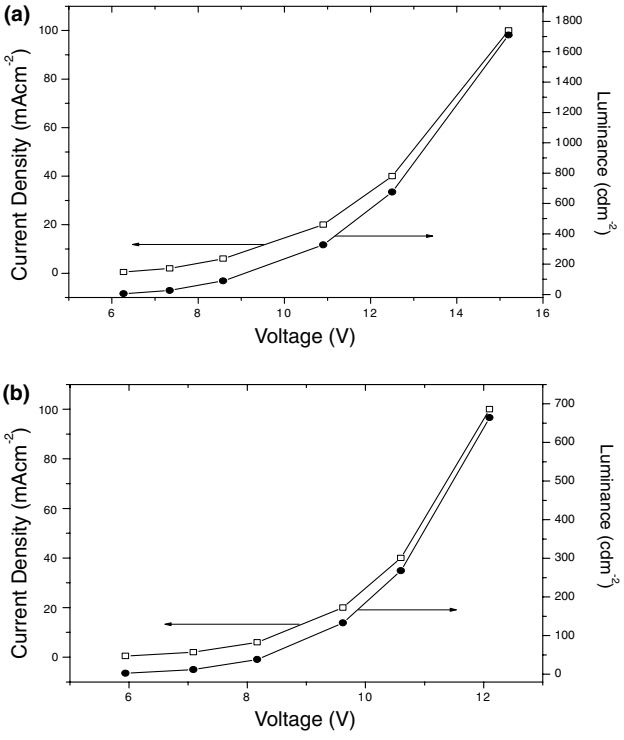

Fig. 8. Comparative plot of current density, voltage and luminance characteristics for the devices 2 (presented in **b**) and 3 (presented in **a**).

trans-influence in the *meridional* isomer leads to less stable, broader, red-shifted and lower quantum efficiencies than the *facial* counterpart. Three EL devices were fabricated. It can be stated that BAlq is not a good hole blocker in the EL device for a blue-emitting phosphorescent dopant. It has also been shown that the wider band gap host *m*CP shows good EL performances with respect to the host CBP having a relatively lower band gap, for the same blue-emitting iridium(III) dopant.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic

Data Centre, CCDC Nos. 228968 and 228969 for compounds $Ir(F_2MeOppy)_2(acac)$ and *fac*-$Ir(F_2MeOppy)_3$, respectively. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; email: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Received 28 September 2004; accepted 1 November 2004

Abstract

Four ruthenium (II) complexes of the formulae $[Ru(bpy)(L_1)_2](ClO_4)_2 \cdot H_2O$ (**A1**), $[Ru(bpy)(L_2)_2](ClO_4)_2 \cdot H_2O$ (**A2**), $[Ru(bpy)(L_3)_2](ClO_4)_2 \cdot H_2O$ (**A3**), $[Ru(bpy)(L_4)_2](ClO_4)_2 \cdot H_2O$ (**A4**) (where L_1 = *N*-(2-pyridylmethylene) phenyl amine, L_2 = *N*-(2-pyridylmethylene) 4-(methyl) phenyl amine, L_3 = *N*-(2-pyridylmethylene) 4-(chloro) phenyl amine, L_4 = *N*-(2-pyridylmethylene) 4-(fluoro) phenyl amine and bpy = 2,2′-bipyridyl) have been synthesized. In addition to these ruthenium complexes, we have also been able to isolate four imidazopyridinium perchlorate compounds **B1**–**B4** from the same reactions. The X-ray crystal structures of one representative ruthenium complex (**A2**) and the imidazopyridinium perchlorate compound (**B2**) have been determined. The Ru(II) center in the complex is coordinated by six N donors with a distorted octahedral geometry. The imine ligands (L) act as bidentate N,N donors.

1. Introduction

Chemistry of ruthenium with α–α′ diimine ligands is an area of unabated interest during the past two decades [1–16] because of the interesting photophysical and photochemical characteristics of these compounds and their possible applications in energy research [7,17], in electroluminescent devices [18,19], as well as sensors and switches [20,21]. A number of these compounds are also reported to exhibit an interesting non-linear optical response [22,23]. The α–α′ diimine ligands, most commonly investigated in these studies, are those where both the donor nitrogen atoms are part of heterocyclic rings like pyridine, pyrimidine and pyrazine. Comparatively less attention has been devoted [15,16,30] to systems where at least one nitrogen atom is not part of a heterocyclic ring. In this paper, we report on the synthesis and spectroscopic properties of four heteroleptic ruthenium (II) complexes (**A1**–**A4**), where Ru(II) is coordinated by one bipyridyl and two *N*-(aryl) pyridine-2-aldimine ligands (L). We also report here the

synthesis and spectroscopic properties of four 3-*N*(aryl) imidazo [1,5a] pyridinium compounds (**B1**–**B4**), which were obtained as side products during the synthesis of the ruthenium complexes.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride ($RuCl_3 \cdot xH_2O$) purchased from Arora Matthey (Kolkata, India) was processed by repeated evaporation to dryness with conc. HCl. '$Ru(bpy)Cl_3$' was prepared by the published procedure [24]. Acetonitrile used for spectroscopic and electrochemical studies was purified according to a reported method [25]. Tetraethyl ammonium perchlorate (TEAP), used for the electrochemical work, was prepared as reported in the literature [25]. All other chemicals were of analytical grade and used without further purification. The ligands (L) were prepared by reacting pyridine-2-aldehyde with the appropriate aryl amine using the published procedure [8].

2.2. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 240 C, H, N analyzer. UV–Vis spectra were recorded using a JASCO7850 spectrophotometer. Luminescence spectra were obtained using a Perkin–Elmer LS55 fluorescence spectrophotometer. Magnetic susceptibilities were measured with a PAR model 155 vibrating sample magnetometer with $Hg[Co(SCN)_4]$ as the calibrant. Cyclic voltammetry and differential pulse voltammetry experiments were carried out using a PAR Versastat-II instrument driven by E-chem software. A three-electrode configuration with a Pt working and auxiliary electrodes, Ag/AgCl reference electrode and TEAP as the supporting electrolyte were used. The potentials were calibrated against the ferrocene/ferrocenium couple (0.44 V versus Ag/AgCl reference).

2.3. Synthesis of the complexes

CAUTION! Perchlorate salts of organic and metallo-organic species are potentially explosive, and though we have not encountered any problems in our work, nevertheless they should be handled with care.

The complexes **A1**–**A4** and the organic products **B1**–**B4** reported in this work were synthesized by a general procedure in almost similar yields; therefore, details are given for **A2** and **B2** as a representative example.

To a 30 ml methanolic solution of L_2 (1 mmol, 182 mg) solid '$Ru(bpy)Cl_3$' (0.5 mmol, 181.75 mg) was added and the reaction mixture was heated to reflux for 4 h. The solution was allowed to come to room temperature; a saturated methanolic solution (2 ml) of $NaClO_4$ was added and filtered. The filtrate was evaporated to dryness and the crude product was washed with water and dried over fused $CaCl_2$. The crude mass was then dissolved in chloroform and purified by column chromatography using a silica gel (60–120 mesh) column. A pink band was eluted with $CHCl_3$–CH_3CN (4:1), followed by a brown band eluted with $CHCl_3$–CH_3CN (3:2). Evaporation of the pink fraction led to isolation of **B2**, whereas **A2** was obtained from the brown fraction. The pink product **B2** was recrystallized from ethanol–isopropanol (1:1) (yield 70–75 mg, 34–36%). The brown product was recrystallized from dichloromethane to acetonitrile (1:2) solution (yield 175–180 mg, 31%). The elemental analyses data of all the compounds are in good agreement with the calculated values (Calc. values are in parentheses). $RuC_{34}H_{30}N_6O_9Cl_2$ (**A1**): C, 48.87 (48.92); H, 3.52 (3.59); N, 9.98 (10.07)%. $RuC_{36}H_{34}N_6O_9Cl_2$ (**A2**): C, 49.67 (49.88); H, 3.77 (3.92); N, 9.69 (9.70)%; $RuC_{34}H_{28}N_6O_9Cl_4$ (**A3**): C, 44.88 (44.98); H, 2.98 (3.08); N, 9.19 (9.26)%; $RuC_{34}H_{28}N_6O_9F_2Cl_2$ (**A4**): C, 46.53 (46.68); H, 3.13 (3.20); N, 9.54 (9.61)%; $C_{13}H_{11}N_2O_4Cl$ (**B1**): C, 52.89 (52.97); H, 3.66 (3.73); N, 9.43 (9.50)%; $C_{14}H_{13}N_2O_4Cl$ (**B2**): C, 54.41 (54.43); H, 4.17 (4.21); N, 8.97 (9.07)%; $C_{13}H_{10}N_2O_4Cl_2$ (**B3**): C, 47.37 (47.41); H, 2.99 (3.03); N, 8.46 (8.51)%; $C_{13}H_{10}N_2O_4FCl$ (**B4**): C, 49.86 (49.92); H, 3.18 (3.20); N, 8.89 (8.96)%.

2.4. X-ray crystallography

For both **A2** and **B2**, data were collected on a Bruker smart CCD area detector diffractometer at 93(2) K, using graphite monochromated Mo Kα radiation. The data were solved by direct methods [26] and refined by a least square program [27] using SHELX 97. The non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were placed at calculated positions and refined as riding atoms using isotropic displacement parameters. The refinement converged with residuals summarized in Table 1. Corrections for Lorentz polarization effects and semiempirical absorption were applied.

2.4.1. Description of the structures

A2: The molecular structure of **A2** is given in Fig. 1. In this complex, Ru(II) is in an octahedral N_6 donor environment with the average *trans* angles being. ~175°, where as *cis* angles lie between 78° and 101°. The average Ru–N distance is 2.0602 Å (Table 2), which is quite comparable to that observed [28] for $[Ru(bpy)_3]^{2+}$. The average Ru–N distance (2.0585Å) observed for the Ru(II)-bpy fragment is also similar to that of the Ru(II)–$(L_2)_2$ fragment, where it has a value of 2.061 Å. The Ru–N_{imine} distances (2.057 Å) within the Ru(II)–$(L_2)_2$ fragment are shorter than the Ru–N_{py}

distances (the average is 2.065 Å). The fact that the Ru–N_{imine} distances are shorter than the Ru–N_{py} distances of Ru-bpy as well as the Ru(II)–$(L_2)_2$ fragment is probably due the greater back bonding acceptor capability of the imine moiety compare to the pyridine moiety. The bite angle of the imine ligand (78.02(9)° (Table 2)) is also very similar to that of bpy (78.61(9)°) and agrees well with the values reported earlier [29,30]. One of the perchlorate ions is disordered in the lattice.

B2: The ORTEP diagram along with the atom numbering scheme for the compound **B2** is shown in Fig. 2. The bond distances within the imidazo pyridine fragment clearly indicate that there is extensive delocalization within the imidazole ring and the C5–C4 and N1–C1 part of the pyridine ring. However the C4–C3 and C1–C2 bonds are more like double bonds. The aryl ring attached to the N2 atom is twisted by about 46° from the plane of the imidazopyridine fragment (Table 3).

3. Results and discussion

Reaction of 'Ru(bpy)Cl_3' with L in refluxing methanol produces a mixture of the Ru(II) complex **A** and the imidazopyridine derivative **B**, both of which can be separated by column chromatography and on recrystallization, crystalline compounds can be isolated for both species. Crystal structure determinations were made for **A2** and **B2** as representative members of **A** and **B**, respectively.

The imidazopyridinium derivatives **B1** to **B4**: The formation of the imidazopyridinium derivatives in the reaction described in Scheme 1 is very interesting. Though imidazopyridine compounds and some of their simple salts are well known [31,32], the 3-*N*(aryl) imidazopyridinium derivatives are rare. Thus a simple single step synthesis of these compounds starting from readily available laboratory chemicals, as described above, is attractive. It has been reported [31] that imidazopyridine is formed in the reaction of 2-picolylamine with formic acid in presence of $POCl_3$. Probably, a similar mechanism is operative here. The 'Ru(bpy)Cl_3' (where the oxidation state of ruthenium is closer to +4 than +3) first

Scheme 1.

oxidizes the solvent methanol to formaldehyde, which then reacts with the schiff base in the presence of 'Ru(bpy)Cl_3' to produce **B**, as described in Scheme 2.

The 3-*N*(aryl) imidazo [1,5a] pyridinium compounds (**B1**–**B4**) are deep pink in colour due to a strong absorption at 520–535 nm. The solvatochromism (Fig. 3) exhibited by this band clearly suggests it is a charge transfer transition. It was also observed that for a given solvent the energy of the longest wavelength band followed the order **B3** < **B1** = **B2** < **B4**. The same trend was followed in the E^0 value of the first oxidation peak for the compounds (Table 7). In fact, a plot of energy of the transition (cm^{-1}) versus E^0 value yields a good linear relationship ($R = 0.99$; supplementary Figure. 1). However, this trend is different from that observed for the HOMO–LUMO gap for these compounds (in the gaseous phase) as calculated by the PM3 method [33a,b], which follows the order **B3** < **B4** ≈ **B1** < **B2**. This indicates that solvation plays a very important role in determining the energy of the frontier orbitals of these compounds, which is quite expected because of their charged structures and appreciable ground state dipole moment (Table 5). Interestingly, the transition energy follows a roughly linear relationship (Table 6, supplementary Figure. 2) with the change in dipole moment ($\Delta\mu_{ge} = \mu_e - \mu_g$) between the ground state (μ_g) and the first excited singlet state (μ_e), assuming the excited state has the same geometry as the ground state i.e., a Franck–Condon excited state. It was also observed that the intensity of the first charge transfer transition follows a linear correlation (Table 6, supplementary Figure 3) with $\Delta\mu_{ge}^2$. All the four compounds **B1**–**B4** exhibit luminescence, with a strong emission at ~380 nm (excited at 280 nm or 240 nm) at room temperature (Table 4). These compounds with a strong charge transfer transition near the visible region, appreciable dipole moment in the ground state, moderate value of $\Delta\mu$, as

Scheme 2.

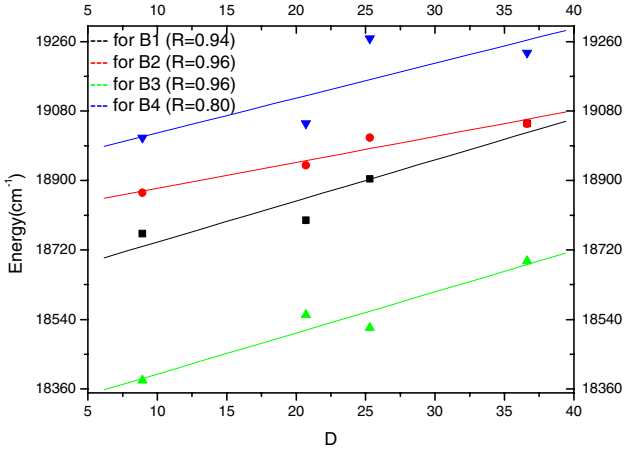

Fig. 3. Plot of energy of CT transition vs. Dielectric constant (*D*) for compounds **B**.

well as stable excited state, are good candidates for screening of their possible non linear optical properties [23]. Besides, the imidazopyridinium cephalosporins are known to exhibit good Gram positive activity, as well as excellent activity against K1 β-lactamase producing *Klebsiella aerogenes* 1082 E strain [34].

Table 5
HOMO and LUMO energies and calculated dipole moments of the imidazopyridinium derivatives

Compounds	B1	B2	B3	B4
E_{HOMO} (eV)	−13.09	−13.23	−12.77	−13.17
E_{LUMO} (eV)	−4.99	−5.05	−5.16	−5.11

μ_g (debye)	2.70	3.70	7.15	6.53
μ_e (debye)	4.29	1.42	2.06	8.36
$\Delta\mu_{ge}$ (i.e., $\mu_e - \mu_g$) (debye)	1.59	−2.28	−5.09	1.83
$(\Delta\mu_{ge})^2$	2.53	5.20	25.91	3.349

The redox behaviors of the pink compounds (**B**) have been investigated using cyclic voltammetry (CV), as well as differential pulse voltammetry (DPV) (Table 7). Both **B1** and **B2** exhibit one quasi reversible oxidative response at around 1.02 V; in the DPV one sharp peak is obtained at the same potential demonstrating that only one redox couple is involved. However for **B3** and **B4** no resolvable peak was observed in the CV,

B4	1.26, 1.06 (DPV)

but in the DPV two well-defined oxidation peaks are observed at 0.91 and 1.07 V for **B3** and at 1.06 and 1.26 V for **B4**.

The ruthenium complexes **A1** to **A4**: The heteroleptic tris chelate complexes are brown in colour with a strong absorption around 480nm. For *tris*-chelate complexes such as these three isomers are possible [16]. However determination of the X-ray crystal structure of one representative complex **A2**, shows that in the isolated complex only one isomer is present in the solid state where the two N_{py} of the two ligands (L) are *cis* to each other, whereas the two N_{imine} are *trans* to each other, which may be called a *cis–trans* isomer. The similarity of spectroscopic, electrochemical and chromatographic behaviors of **A1**, **A3** and **A4** with that of **A2** led us to believe that in these complexes the same isomer also predominates.

The redox behavior of the complexes was studied by cyclic voltammetry (CV) and differential pulse voltammetry (DPV). All the complexes undergo a quasi-reversible oxidation at ~1.3 to 1.4 V which may be assigned to Ru(II) to Ru(III) oxidation. In the reductive side all the complexes show a two-electron quasi-reversible reduction at −0.8 V and two one electron quasi-reversible reductions near −1.4 to −1.7 V. The last two peaks are not resolved in the CV, but they can be well identified in the DPV (supplementary Figure 4). As our PM3 calculations show that the LUMO of the ligand L is about 0.2 eV lower in energy than that of bpy, the first reduction is assigned to electron addition to the π* orbital of coordinated L. In fact the EHMO calculation shows that LUMO and LUMO + 1 have large contributions from $L_{\pi*}$ orbitals and are separated from each other by only 0.03 eV, so that the first two electron reduction is probably due to simultaneous electron addition to LUMO and LUMO + 1. The second and third reductions are probably due to addition of electrons to LUMO + 2 and LUMO + 3, where the former is mainly based on bpy, and the later have contributions from all the three ligands (see supplementary Figure 5 for pictures of the HOMOs and LUMOs).

The visible region of the electronic spectra of the complexes consists of a weak transition at ~630 nm and a broad envelope from 600 to 375 nm consisting of two peaks at ~480 and ~440 nm and a poorly resolved shoulder around 380 nm. The weak intensity of the first transition suggests that it is probably a charge transfer transition to a ^{3}MLCT state [4,35,36]. The bands near 480nm and 440nm are charge transfer transitions to ^{1}MLCT states. Under the C_2 symmetry of the complex, the metal dπ orbitals will transform as $a + 2b$. The lowest energy π* orbital of bpy will transform as b while the lowest energy π* orbitals of the two imine ligands will transform as $a + b$. Thus nine MLCT transitions are possible in principle, six of them are charge transfer from metal to imine ligand Lπ* orbitals, while three of them are charge transfer from metal to bpy π* orbital. Overlapping of these bands is expected to give rise to a broad envelope. As mentioned earlier, the ligand Lπ* orbitals are of lower energy than the bpy π* orbital, so the MLCT transition to the later orbital is expected to be of higher energy than those involving the Lπ* orbital. Earlier workers [15] have assigned the peak around 480 nm to that involving the Lπ* orbital, while the peak near 440 nm to that involving the bpy π* orbital. However the comparable intensity of both the bands precludes such an assignment, as only one bpy ligand is present, compared to two L ligands. Moreover it was pointed out by Lever [37,38] that for a MLCT transition involving the bpy π* orbital, a molar extinction coefficient of ~4000 $M^{-1}\,cm^{-1}$ per bpy ligand is expected. As the molar extinction coefficients of the transition near 440nm for the present complexes are much larger than that predicted by Lever, so the band ~440 nm as well as that ~480 nm are assigned to MLCT transitions involving the Lπ* orbital, while the shoulder around 380nm is probably due to that involving the bpy π* orbital. This is also supported by the large difference of the observed reduction potential in the complexes between the L based reduction and bpy based reduction. The other higher energy transitions are probably intraligand in nature. An EHMO calculation on the compound **A2** supports this conclusion. Since the actual symmetry of the molecule in this case is less than C_2 (it is C_1), all

the orbitals are of 'a' symmetry. The three d orbitals are 106A (−12.25 eV), 105A (−12.31 eV) and 104A (−12.38 eV), where 106A and 105A have appreciable contribution from schiff base ligands and 104A has similarly appreciable contribution from bpy. The LUMO, LUMO + 1 and LUMO + 2 are 107A (−10.01 eV), 108A (−9.97 eV) and 109A (−9.68 eV), respectively; again the first two are schiff base ligand based where as the last one is bpy based. Thus the first two bands are probably due to the transitions between 106A → 107A, 108A and 105A → 107A, 108A, where as the charge transfer to bpy 104A → 109A is expected to lie at higher energy. A preliminary luminescence study shows that all the complexes are luminescent at room temperature. Excitation at 480 nm leads to a broad emission at 700–730 nm.

4. Computations

The PM3 and EHMO calculations were carried out with the HYPERCHEM 7.01 program [39] using the default parameters of the program. Single point PM3 calculations (which includes configuration interaction involving single, excited states arising from the 10 highest occupied and 10 lowest unoccupied orbitals) on the ligands were made on the geometries obtained directly from the crystal structure or when the structure was not available, the geometry was optimized by the MM+ method. An extended Hückel calculation was done on **A2** using the geometry taken directly from the crystal structure after removing the perchlorate counter ions.

Available online 19 December 2004

Abstract

3,5-Dimethyl-4-(4′-pyridyl)pyrazole, prepared by the reaction of 3-(4-pyridyl)pentane-2,4-dione with hydrazine hydrate, reacts with R_2SnCl_2 (R = Ph, Et and *n*-Bu) in a 1:1 ratio to yield 2:1 (ligand:tin) adducts. In the crystal structure of the Ph_2SnCl_2 adduct, two 3,5-dimethyl-4-(4′-pyridyl)pyrazole ligands coordinate to the tin atom through the pyridyl nitrogen atom instead of the pyrazolyl nitrogen atom, and the molecules are connected into a linear chain through intermolecular N–H···N hydrogen bonds. The reaction of 3,5-dimethyl-4-(4′-pyridyl)pyrazole with dibromomethane under phase transfer catalytic conditions affords bis[3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl]methane. Treatment of this potential polydentate ligand with R_2SnCl_2 yields 1:1 adducts, in which bis[3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl]methane coordinates to the tin atom through the pyridyl nitrogen atom to form six-coordinate diorganotin linkage coordination polymers, leading to a bridging instead of a general chelating metal coordination. In all new complexes, the pyridyl nitrogen atom exhibits stronger donating ability than the pyrazolyl nitrogen to the tin atom.

Keywords: Bis(pyrazol-1-yl)methane; Organotin(IV); Pyridine; X-ray structure

1. Introduction

For a long time diorganotin complexes containing nitrogen donor ligands have attracted considerable attention due to their potential biological applications [1,2]. Many complexes of the type R_2SnX_2(N–N) have been synthesized and tested for their antitumor activities [3–5]. Poly(pyrazol-1-yl)alkanes, especially bis(pyrazol-1-yl)methanes, have also been found to act as good donors to organotin compounds [6–11]. The interactions between poly(pyrazol-1-yl)alkanes and tin(IV) or organotin(IV) acceptors indicate that the donating ability of the ligands can be easily controlled by varying the substituents of the pyrazolyl ring, leading to a variable coordination geometry of the tin atom. Recently, we have also successfully prepared a variety of five and six-coordinate organotin(IV) complexes with symmetric or asymmetric bis(pyrazol-1-yl)methane [12,13], and bidentate organotin Lewis acid derivatives of bis(pyrazol-1-yl)methane [14,15], as well as novel five and six-coordinate diorganotin(IV) linkage coordination polymers with bis(1,2,4-triazol-1-yl)methane [16]. Poly(pyrazol-1-yl)alkanes containing heteroatoms such as phosphine or sulfur in the pyrazolyl rings display variable coordination modes toward different metals [17,18], which encourages us to investigate the effects of more extensive donor sets on the coordination modes of poly(pyrazol-1-yl)alkanes. Herein, we report the synthesis and structural characterization of diorganotin(IV) derivatives containing 3,5-dimethyl-4-(4′-pyridyl)pyrazole. Treatment of diorganotin(IV) chloride with this ligand yields 1:2 adducts, while employment of its

derivative, bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl) methane, gives a 1D linkage coordination polymer.

2. Experimental

Solvents were dried by standard methods and distilled prior to use. NMR spectra (^{1}H, ^{13}C and ^{119}Sn) were recorded on a Bruker AV300 spectrometer, and the chemical shifts were reported in ppm with respect to reference standards (internal $SiMe_4$ for ^{1}H NMR and ^{13}C NMR spectra, external $SnMe_4$ for ^{119}Sn NMR). IR spectral data were obtained from a Bruker Equinox55 spectrometer in KBr pellets. Elemental analyses were carried out on a Perkin–Elmer 240C analyser. Melting points were reported with a PHMK melting-point apparatus and were uncorrected.

2.1. Preparation of 3,5-dimethyl-4-(4′-pyridyl)pyrazole (*1*)

Hydrazine hydrate (4 ml, 85%, 68 mmol) was added to a toluene solution of raw 3-(4-pyridyl)pentane-2,4-dione, obtained by the reaction of 4-methylpyridine (18.2 ml, 186 mmol) with acetyl chloride (10.6 ml, 149 mmol) according to the literature method [19], and then the mixture was stirred at room temperature overnight. After removal of the solvent under reduced pressure, the residue was recrystallized from water to yield 1.6 g of **1** as white plate crystals, m.p. 105–107 °C. ^{1}H NMR ($CDCl_3$): δ 8.63 (d, 2H, α-Py*H*), 7.24 (d, 2H, β-Py*H*), 4.30 (s, br, 1H, N*H*), 2.37 (s, 6H, CH_3). ^{13}C NMR ($CDCl_3$): δ 11.83 (*C*H_3), 100.00, 115.72, 123.71, 142.39, 149.55 (carbons of pyrazolyl and pyridyl rings). IR: ν_{NH} = 3407.0 (m); $\nu_{pyridyl\ ring}$ = 1605.7 (s) cm^{-1}. *Anal.* Calc. for $C_{10}H_{11}N_3$: C, 69.34; H, 6.40; N, 24.26. Found: C, 69.12; H, 6.17; N, 24.43%.

2.2. Reaction of *1* with R_2SnCl_2 (R = Ph, Et or n-Bu)

All reactions were carried out in a similar manner, so a general procedure is described. To a stirred solution of R_2SnCl_2 (1 mmol) in 15 ml ether at room temperature, a solution of **1** (1 mmol) in 15 ml ether was added. The reaction mixture was stirred continuously for 6 h at room temperature, during which time a precipitate gradually formed. The precipitate was filtered off, washed with ether and dried in vacuo. Yields, melting points and analytical data are given below.

2.2.1. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazole)] diphenyltin dichloride (*2*)

This compound was obtained by the reaction of **1** with Ph_2SnCl_2. White solid; yield: 82%; m.p. 155–158 °C. ^{1}H NMR (CD_3COCD_3): δ 8.61 (d, 4H, α-Py*H*), 7.50 (d, 4H, β-Py*H*), 8.06, 7.41 (m, m, 4H, 6H, C_6H_5), 2.36 (s, 12H, CH_3). IR: ν_{NH} = 3294.0 (m); $\nu_{pyridyl\ ring}$ = 1612.4 (s) cm^{-1}. *Anal.* Calc. for $C_{32}H_{32}Cl_2N_6Sn$: C, 55.68; H, 4.67; N, 12.18. Found: C, 55.75; H, 4.84; N, 12.49%.

2.2.2. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazole)] diethyltin dichloride (*3*)

This compound was obtained by the reaction of **1** with Et_2SnCl_2. Pale-yellow solid; yield: 85%; m.p. 162–165 °C. ^{1}H NMR (CD_3SOCD_3): δ 8.57 (d, 4H, α-Py*H*), 7.36 (d, 4H, β-Py*H*), 2.28 (s, 12H, CH_3), 1.56 (q, 4H, SnCH_2), 1.26 (t, 6H, CH_2 CH_3). IR: ν_{NH} = 3262.3 (m); $\nu_{pyridyl\ ring}$ = 1611.7 (s) cm^{-1}. *Anal.* Calc. for $C_{24}H_{32}Cl_2N_6Sn$: C, 48.52; H, 5.43; N, 14.14. Found: C, 48.34; H, 5.28; N, 14.29%.

2.2.3. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazole)] di(n-butyl)tin dichloride (*4*)

This compound was obtained by the reaction of **1** with *n*-Bu_2SnCl_2. Pale-yellow solid; yield: 78%; m.p. 152–154 °C. ^{1}H NMR (CD_3SOCD_3): δ 8.56 (d, 4H, α-Py*H*), 7.35 (d, 4H, β-Py*H*), 2.27 (s, 12H, CH_3), 1.65–1.56 (m, 8H, SnCH_2CH_2), 1.36–1.24 (m, 4H, CH_2CH$_3$), 0.87 (t, 6H, CH_2CH_3). ^{13}C NMR (CD_3SOCD_3): δ 11.37, 13.62, 25.56, 27.76, 37.72 (carbons of butyl and methyl groups), 114.13, 122.41, 142.13, 149.24 (carbons of pyrazolyl and pyridyl rings). ^{119}Sn NMR (CD_3SOCD_3): δ −214 (s, br). IR: ν_{NH} = 3250.0 (m); $\nu_{pyridyl\ ring}$ = 1612.9 (s) cm^{-1}. *Anal.* Calc. for $C_{28}H_{40}Cl_2N_6Sn$: C, 51.72; H, 6.20; N, 12.92. Found: C, 51.96; H, 6.08; N, 12.69%.

2.3. Preparation of bis[3,5-dimethyl-4-(4′-pyridyl) pyrazol-1-yl]methane (*5*)

3,5-Dimethyl-4-(4′-pyridyl)pyrazole (3.25 g, 18.8 mmol), dibromomethane (1.38 ml, 9.4 mmol), tetrabutylammonium bromide (0.5 g, 1.6 mmol) and sodium hydroxide (5.7 g, 142.5 mmol) were added into a mixed solvent of water (10 ml) and benzene (50 ml). The mixture was stirred and refluxed for 48 h. After cooling to room temperature, the benzene layer was separated and the water phase was extracted with benzene (3 × 40 ml). The organic layers were combined and dried by $MgSO_4$. After evaporating the solvent, the residue was recrystallized (charcoal treatment) from benzene to yield 1.35 g of **5** (40%) as white crystals, m.p. 139–140 °C. ^{1}H NMR ($CDCl_3$): δ 8.63 (d, 4H, α-Py*H*), 7.18 (d, 4H, β-Py*H*), 6.21 (s, 2H, CH_2), 2.58, 2.27 (s, s, 6H, 6H, CH_3). ^{13}C NMR ($CDCl_3$): δ 10.55, 12.75 (*C*H_3), 60.58 (*C*H_2), 117.99, 123.95, 138.29, 141.73, 146.72, 149.97 (carbons of pyrazolyl and pyridyl rings). IR: $\nu_{pyridyl\ ring}$ = 1599.7 (s) cm^{-1}. *Anal.* Calc. for $C_{21}H_{22}N_6$: C, 70.37; H, 6.19; N, 23.45. Found: C, 70.12; H, 6.11; N, 23.06%.

2.4. Reaction of **5** with R_2SnCl_2 (R = Ph, Et or n-Bu)

A general procedure was used for all preparations. The solution of **5** (0.5 mmol) in 10 ml CH_2Cl_2 was added to the stirred solution of R_2SnCl_2 (0.5 mmol) in 10 ml CH_2Cl_2 at room temperature. The reaction mixture was stirred continuously for 4 h, during which time a precipitate gradually formed. The precipitate was filtered off, washed and dried in vacuo. Yields, melting points and analytical data are given below.

2.4.1. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl) methane]diphenyltin dichloride (**6**)

This compound was obtained by the reaction of **5** with Ph_2SnCl_2. White solid; yield: 90%; m.p. 131–133 °C. ^{1}H NMR (CD_3COCD_3): δ 8.63 (d, 4H, α-Py*H*), 7.39 (d, 4H, β-Py*H*), 7.96, 7.47 (m, m, 4H, 6H, C_6H_5), 6.34 (s, 2H, CH_2), 2.65, 2.23 (s, s, 6H, 6H, CH_3). IR: $\nu_{\text{pyridyl ring}}$ = 1614.7 (s) cm^{-1}. *Anal.* Calc. for $C_{33}H_{32}Cl_2N_6Sn$: C, 56.44; H, 4.59; N, 11.97. Found: C, 56.63; H, 4.73; N, 12.06%.

2.4.2. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl) methane]diethyltin dichloride (**7**)

This compound was obtained by the reaction of **5** with Et_2SnCl_2. White solid; yield: 89%; m.p. 138–140 °C. ^{1}H NMR (CD_3SOCD_3): δ 8.59 (d, 4H, α-Py*H*), 7.31 (d, 4H, β-Py*H*), 6.31 (s, 2H, CH_2), 2.56, 2.18 (s, s, 6H, 6H, CH_3), 1.55 (q, 4H, $SnCH_2$), 1.26 (t, 6H, CH_2CH_3). ^{13}C NMR (CD_3SOCD_3): δ 10.14, 10.55, 12.61, 31.79 (carbons of ethyl and methyl groups), 59.30 (CH_2), 116.66, 123.52, 137.96, 141.05, 145.82, 149.61 (carbons of pyrazolyl and pyridyl rings). ^{119}Sn NMR (CD_3SOCD_3): δ −227.06 (s, br). IR: $\nu_{\text{pyridyl ring}}$ = 1612.6 (s) cm^{-1}. *Anal.* Calc. for $C_{25}H_{32}Cl_2N_6Sn$: C, 49.54; H, 5.32; N, 13.86. Found: C, 49.88; H, 5.44; N, 13.87%.

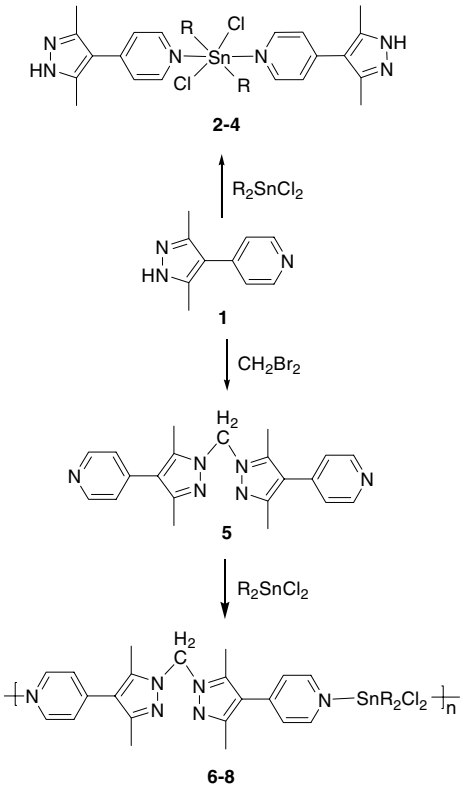
2.4.3. [Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl) methane]di(n-butyl)tin dichloride (**8**)

This compound was obtained by the reaction of **5** with *n*-Bu_2SnCl_2. After the reaction was completed, the solvent was concentrated to ca. 5 ml, then the same volume hexane was slowly added to yield a white solid; yield: 80%; m.p. 105–106 °C. ^{1}H NMR ($CDCl_3$): δ 8.73 (d, 4H, α-Py*H*), 7.29 (d, 4H, β-Py*H*), 6.23 (s, 2H, CH_2), 2.62, 2.29 (s, s, 6H, 6H, CH_3), 1.84–1.66 (m, 8H, $SnCH_2CH_2$), 1.43–1.34 (m, 4H, CH_2CH_3), 0.92 (t, 6H, CH_2CH_3). ^{13}C NMR ($CDCl_3$): δ 10.67, 12.99, 13.53, 26.09, 27.84, 35.93 (carbons of butyl and methyl groups), 117.27, 124.41, 138.92, 144.27, 147.01, 148.16 (carbons of pyrazolyl and pyridyl rings). ^{119}Sn NMR ($CDCl_3$): δ −98.46, −145.68. IR: $\nu_{\text{pyridyl ring}}$ = 1621.1 (s) cm^{-1}. *Anal.* Calc. for $C_{29}H_{40}Cl_2N_6Sn$: C, 52.59; H, 6.09; N, 12.69. Found: C, 52.37; H, 5.89; N, 12.63%.

2.5. Crystal structure determinations

Crystals of complexes **2** and **6** suitable for X-ray analysis were obtained by slowly cooling hot acetone solutions of **2** and **6**. Crystals of complex **2** contain one-half of a co-crystallized acetone molecule. The methyl carbon and oxygen atoms of the acetone molecule as well as the hydrogen atom on the pyrazolyl nitrogen exhibit disorder. Satisfactory results were obtained when they were given occupancy factors of 0.5. Crystals of complex **6** have the stoichiometry **6** · H_2O · $\frac{1}{4}$ acetone, in which the phenyl group of C7–C12, pyrazolyl group of N4–N5–C28 and pyridyl group of N6–C33 are disordered, and their occupancy factors were refined to 0.594 for C7–C12 and 0.406 for C7′–C12′, 0.906 for N4–N5–C28 and 0.094 for N4′–N5′–C28′, and 0.788 for N6–C33 and 0.212 for N6′–C33′, respectively. The N4′ atom was refined to the same position with N4 by EXYZ and EADP. When acetone (occupancy factor of 0.25) appears, the disordered phenyl group locates in the position of C7–C12 (occupancy factor of 0.594). All intensity data were collected with a Bruker SMART CCD diffractometer, using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). The structures were resolved by the direct method and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically. A summary of the fundamental crystal data for complexes **2** and **6** is listed in Table 1.

Table 1
Crystal data for compounds **2** and **6**



Compound	**2** · $0.5CH_3COCH_3$	**6** · H_2O · $0.25CH_3COCH_3$
Formula	$C_{33.5}H_{35}Cl_2N_6O_{0.5}Sn$	$C_{33.75}H_{35.5}Cl_2N_6O_{1.25}Sn$

3. Results and discussion

3.1. Synthesis and characterization of complexes

Since 3-(4-pyridyl)pentane-2,4-dione is unstable [19], the raw pyridylpentadione was directly reacted with an excess of hydrazine hydrate to give 3,5-dimethyl-4-(4′-pyridyl)pyrazole (**1**) in a reasonable yield. Treatment of this pyrazolyl ligand with R_2SnCl_2 (R = Ph, Et or *n*-Bu) in a 1:1 ratio affords 2:1 (ligand:tin) adducts **2**–**4** (Scheme 1), according to the results of ^1H NMR data and elemental analyses. The ^1H NMR spectra of the complexes are consistent with the formulae of 2:1 adducts, which exhibit the expected proton signals for two equivalent pyridylpyrazole ligands. The chemical shifts of the protons for the ligand in the complexes are similar to those of the free ligand. Complexes **2**–**4** are insoluble in ether, chlorinated solvents, slightly soluble in acetone at room temperature, and moderately soluble in stronger polar organic solvents such as DMF and DMSO.

Reaction of **1** with CH_2Br_2 under phase-transfer conditions gives the new bridging ligand bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl)methane (**5**). Treatment of **5** with an equimolar amount of R_2SnCl_2 in CH_2Cl_2 affords 1:1 adducts **6**–**8**. Like complexes **2**–**4**, **6** and **7** are insoluble in ether, chlorinated solvents, and slightly soluble in acetone at room temperature, but complex **8** is soluble in chlorinate solvents possibly because the longer alkyl groups increase its solubility in organic solvents.

Scheme 1. R = Ph (**2**) and (**6**); R = Et (**3**) and (**7**); R = *n*-Bu (**4**) and (**8**).

It is well known that the δ (^{119}Sn) values in the ^{119}Sn NMR spectra are markedly dependent on the coordination environments around the tin atom. Owing to low solubility, only ^{119}Sn NMR spectra of complexes **4**, **7** and **8** can be clearly observed. The ^{119}Sn NMR signals of **4** and **7** in CD_3SOCD_3 occur at −214.0 and −227.1 ppm, respectively, as broad peaks, while complex **8** exhibits two ^{119}Sn NMR signals in $CDCl_3$ at −98.5 and −145.7 ppm. These data indicate that these adducts may partially dissociate in polar solutions. This kind of dissociation equilibrium can often be observed in other diorganotin derivatives containing N-donor ligands [8,12,16,20].

3.2. Crystal structures of complexes 2 and 6

The molecular structure of **2** has been confirmed by X-ray diffraction analysis as shown in Fig. 1, which clearly shows that two 3,5-dimethyl-4-(4′-pyridyl)pyrazole ligands coordinate to the tin atom through the pyridyl nitrogen atom instead of the pyrazolyl nitrogen atom. The pyridylpyrazole acts as a monodentate ligand toward the tin atom, which is six-coordinate with a slightly distorted octahedral geometry, containing two nitrogen atoms of pyridyl groups, two phenyl carbons as well as two chlorine atoms in an all-*trans* configuration. The Sn–Cl and Sn–C bond distances are similar to those in other diorganotin derivatives with monodentate or bidentate N-donor ligands [8,20,21]. The average Sn–N bond distance (2.365(3) Å) in **2** is also close to those in other diorganotin derivatives with monodentate N-donor ligands [8], such as in $Ph_2SnCl_2(Tz)_2$ (2.369(8) Å, Tz = thiazole) [20]. The dihedral angle between the two phenyl planes is 46.2°, larger than that between the two pyridyl planes (40.9°). The pyridyl group is not coplanar with the pyrazolyl ring. The dihedral angle formed by the N(1)–C(1A) pyridyl plane and the N(2)–C(5) pyrazolyl plane is 33.0°, slightly larger than the dihedral angle formed by the N(3)–C(7A) pyridyl plane and the N(4)–C(11) pyrazolyl plane (30.5°).

It is also noteworthy that molecules of complex **2** are linked into a linear chain in the solid state through intermolecular N–H···N hydrogen bond interactions (Fig. 2), while bis(pyrazole) or bis(imidazole) complexes of diorganotin dihalides tend to self-organize into chain polymers by intermolecular N–H···X hydrogen bonding (X = Cl or Br) [22–28].

Bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl)methane is a potential multidentate ligand which can act as a chelating multidentate ligand, like original bis(pyrazol-1-yl)methane using the pyrazolyl nitrogens coordinated to metals, as well as a bridging ligand by the exodentate pyridyl nitrogens. In order to confirm the coordination mode of this ligand with diorganotin halides, the

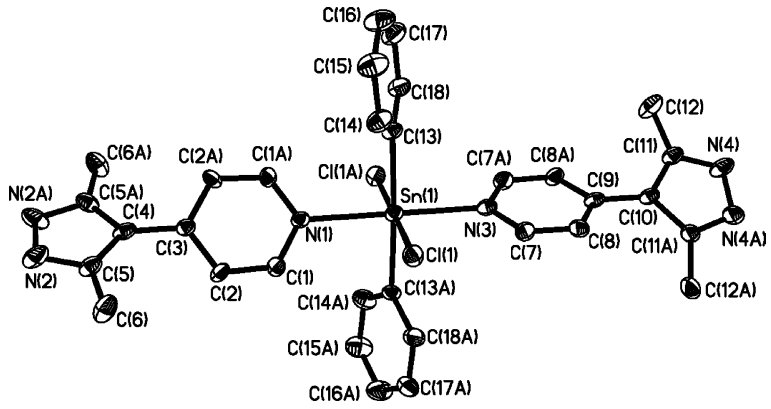

Fig. 1. The molecular structure of complex **2**. The thermal ellipsoids are drawn at the 30% probability. Selected bond distances (Å) and angles (°): Sn(1)–N(1) = 2.352(3), Sn(1)–N(3) = 2.377(3), Sn(1)–C(13) = 2.177(3), Sn(1)–Cl(1A) = 2.534(1), C(3)–C(4) = 1.478(6); C(13)–Sn(1)–C(13A) = 177.0(1), N(1)–Sn(1)–N(3) = 180.0, Cl(1)–Sn(1)–Cl(1A) = 179.11(4), C(13)–Sn(1)–N(3) = 91.50(9), C(13A)–Sn(1)–Cl(1) = 89.5(1), N(1)–Sn(1)–Cl(1A) = 89.55(2); torsion angles: C(2)–C(3)–C(4)–C(5) = 32.7(3); C(2)–C(3)–C(4)–C(5A) = −147.3(3)° (symmetry code: A = x, $-y + 1/2$, $-z + 1/4$).

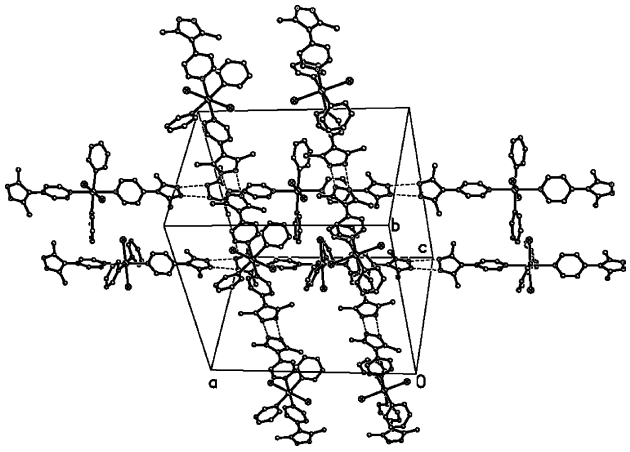

Fig. 2. The crystal packing diagram of complex **2** emphasizing the intermolecular hydrogen bonding interactions (N(2)–H···N(4)^{i} = 2.984 Å, N(4)–H···N(2)^{ii} = 2.984 Å; symmetry code: i = $x - 1$, $-y + 1/2$, $-z + 1/4$, ii = $x + 1$, $-y + 1/2$, $-z + 1/4$) and the one-dimensional chain. The solvent molecule is omitted for clarity.

X-ray diffraction analysis of complex **6** was undertaken. Fig. 3 shows that **6** is a 1D coordination polymer and bis(3,5-dimethyl-4-(4′-pyridyl)pyrazol-1-yl)methane acts as a bridged bidentate ligand by two exodentate pyridyl nitrogen atoms. The coordination environment around the tin atom is similar to that in complex **2**, i.e., a slightly distorted octahedral geometry, as well as an all-*trans* configuration of pyridyl nitrogen atoms, phenyl carbons and chlorine atoms. The Sn–Cl, Sn–C and Sn–N bond distances are also similar to those in complex **2**. The coordination mode of ligand **5** in complex **6** with the tin atom is analogous to those of bis(triazol-1-yl)methane [16] and pyrazine [28]. However, in the diorganotin derivatives of bis(triazol-1-yl)methane and pyrazine, the halide atoms as well as the coordinated nitrogen atoms are in *cis*-positions.

In conclusion, the coordination modes of 4-pyridylpyrazole and bis(4-pyridylpyrazol-1-yl)methane with diorganotin are quite different from those of the original azole and 2-pyridylpyrazole as well as bis(pyrazol-1-yl)methane. In diorganotin derivatives of pyridylpyrazole, the exodentate pyridyl nitrogen atoms have priority in coordinating to the tin atom possibly owing to their stronger donor ability over the pyrazolyl nitrogen. The coordination mode of ligand **5** to the tin atom is similar to those of 4,4-bipyridine and bis(1,2,4-triazol-1-yl)methane.

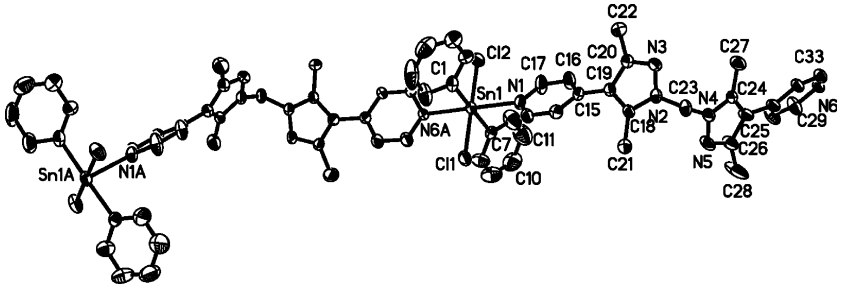

Fig. 3. The molecular structure of complex **6**. The thermal ellipsoids are drawn at 30% probability. The solvent molecules are omitted for clarity. Selected bond distances (Å) and angles (°): Sn1–Cl1 = 2.551(2), Sn1–Cl2 = 2.526(2), Sn1–N1 = 2.371(6), Sn1–N1A = 2.361(6), Sn1–C1 = 2.132(10), C15–C19 = 1.470(10), N2–C23 = 1.452(9), C23–N4 = 1.446(9); C1–Sn1–C7 = 177.0(4), N6A–Sn1–N1 = 178.3(3), Cl1–Sn1–Cl2 = 179.37(8), N6A–Sn1–Cl1 = 89.1(1), C1–Sn1–Cl1 = 90.2(3), C1–Sn1–Cl2 = 89.5(3), C7–Sn1–N1 = 89.0(3), C1–Sn1–N1 = 88.7(3), N4–C23–N2 = 110.9(5); torsion angles: C16–C15–C19–C20 = 40.1(13), C16–C15–C23–C18 = −142.0(10), N3–N2–C23–N4 = −81.5(8)° (symmetry code: A = $x + 1, -y + 1/2, z - 1/2$).

4. Supplementary material

Crystallographic data (CIF files) for the structures of complexes **2** and **6** have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 248284 for complex **2** and CCDC No. 248283 for complex **6**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The new ligand dapmp (**1**) has been synthesized and the reactions of $CuCl_2 \cdot 2H_2O$ and $Cu(CH_3COO)_2 \cdot H_2O$ with the new ligand in methanol afforded two crystalline polymorphic forms: [Cu(dapmp)Cl_2] (**2**) and [Cu(dapmp)$(CH_3COO)_2$] · H_2O (**3**), where dapmp = 2,4-di(2-aminopyridine)-6-methylpyrimidine. Single crystal X-ray diffraction showed that (**1**) and (**2**) are each connected by hydrogen bonding to form a one-dimensional supermolecular compound and (**3**) is connected by hydrogen bonding to form a three-dimensional supermolecular compound.

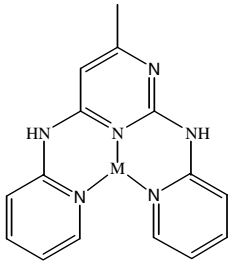
1. Introduction

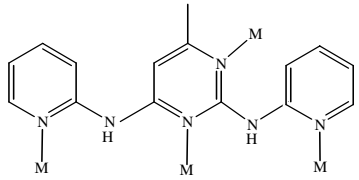
In recent years, the synthesis of multidentate N-donor ligands has attracted considerable interest [1,2], mainly because they can be used to design multinuclear metal compounds, coordination polymers and supermolecular compounds, which play a very important role in biological systems, magnetic materials, electronic materials, optical materials and other fields [3–7]. In the present paper, we describe a new multidentate N-donor ligand 2,4-di(2-aminopyridine)-6-methylpyrimidine (dapmp), which can exhibit several coordination modes: anti–anti–anti–anti, syn–syn–syn–syn, anti–syn–syn–anti, anti–syn–syn–syn and syn–syn–syn–anti (see Scheme 1).

Herein we report the anti–anti–anti–anti configuration of dapmp, in which the chain is formed by hydrogen bonding. The crystal structures of its copper(II) complexes with the all-*anti* conformation of the chelating ligand are presented.



2. Experimental

2.1. Materials and physical measurements



All reagents were commercial grade and were used as received. Infrared spectra on KBr pellets were recorded on a Nicolet 170SX FT-IR spectrophotometer in the range 4000–400 cm^{-1}. NMR spectra were recorded using a VARIAN INOVA400MHZ spectrometer. Electronic spectra were recorded on a Cary 300 Bio UV–visible spectrophotometer. Elemental analyses were determined with a Perkin–Elmer model 240C instrument. FAB-MS

mass spectra were obtained with a JEOL HX-110 HF double focusing spectrometer operating in the positive ion detection mode. TGA analyses were recorded with a NETZSCH STA 449C rnicroanalyzer in an atmosphere of nitrogen at a heating rate of 5 °C min^{-1}.

2.2. Synthesis of 2,4-di(2-aminopyridine)-6-methylpyrimidine (dapmp, 1)

2,4-Dichloro-6-methylpyrimidine (5.0 g, 31.1 mmol) and 2-aminopyridine (6.0 g, 72.9 mmol) were added to 100 ml dry benzene in a 200 ml flask. Then BuOK (14.3 g, 127.7 mmol) and tris(dibenzylideneacetone)dipalladium ($Pd_2(dba)_3$) (2.0 g, 2.2 mmol) were added to the solution under nitrogen. The resulting solution was stirred for 148 h under reflux. The product was filtered and washed three times each with methanol and water. Compound **1** was obtained as a white powder in 64% yield (8.7 g). *Anal.* Calc. for $C_{15}H_{14}N_6$: C, 64.47; H, 5.070; N, 30.18.

2.3. Synthesis of [Cu(dapmp)Cl_2] (2)

A solution of the ligand dapmp (61.2 mg, 0.22 mmol) and $CuCl_2 \cdot 2H_2O$ (34.1 mg, 0.2 mmol) in methanol (15 ml) were mixed together and stirred for 3 h. The green solution was filtered. Suitable X-ray quality crystals were obtained by slow evaporation of this green solution. Yield: 42%. *Anal.* Calc. for $[Cu(C_{15}H_{14}N_6)Cl_2]$: C, 43.65; H, 3.419; N, 20.36. Found: C, 43.46; H, 3.485; N, 20.12%.

2.4. Synthesis of [Cu(dapmp)$(CH_3COO)_2$] · H_2O (3)

A solution of the ligand dapmp (61.2 mg, 0.22 mmol) and $Cu(CH_3COO)_2 \cdot H_2O$ (39.9 mg, 0.2 mmol) in methanol (15 ml) were mixed together and stirred for 3 h. The blue-green solution obtained was filtered, from which X-ray quality crystals were obtained by slow evapora-

2.5. Crystal structure determination

X-ray diffraction data were collected with graphite-monochromated Mo Kα radiation $\lambda = 0.71073$ Å) on a BRUKER SMART APEXCCD diffractometer for compound **1**, on a NONIUS KaCCD diffractometer for complex **2** and on a BRUKER SMART APEXCCD diffractometer for complex **3**. The structures were solved by direct methods with the SHELXL-93 [8] program and refined by full-matrix least-squares methods on F^2 with SHELXTL-PC V 5.03 [9]. Crystal data and structure refinement details are summarized in Table 1. Selected bond lengths and bond angles are given in Table 2.

3. Results and discussion

3.1. Description of structures

Fig. 1 shows the molecular packing of compound **1**. It can be seen that the ligand dapmp forms *zigzag* chains in the solid state, and the molecules are held together by a series of donor–acceptor (DA) double hydrogen bonds. Each molecule with the *all-anti* conformation is linked via two hydrogen bonds (N(1)···N(10) 3.104 Å, N(2)···N(11) 3.107 Å) with a centrosymmetrically related counterpart to form a dimer as depicted in Fig. 1. The structural characterization of such hydrogen-bonded dimeric compounds linked by self complementary donor–acceptor groups is well documented in organic chemistry [10–13]. The adjacent dapmp dimer units are interlanced and are connected by two hydrogen bonds (N(7)···N(4) 3.147 Å, N(8)···N(5) 3.189 Å), forming a one-dimensional supermolecular compound along the *c* axis (Fig. 1).

The bond length of N(6)–C(7) 1.350(4) Å is shorter than that of N(12C)–C(22B) (1.358(4) Å) while the angle of C(5)–N(2)–C(6) (129.9(2)°) is similar to that of C(9)–N(4)–C(10) (128.3(2)°). The three rings of the dapmp ligand are each planar and the dihedral angle between each pair of neighboring rings is 144.7° and 163.1°.

The crystal structure of complex **2** (Fig. 2) reveals that the coordination geometry around copper(II) is distorted trigonal bipyramidal with the monohelical dapmp ligand existing in an all-*anti* configuration. The equatorial sites consists of N(3), which comes from the pyrimidyl ring of the tridentate dapmp, and two Cl-donors, and the apical sites are occupied by N(1) and N(5) atoms of the pyridal rings. The bond angles Cl(1)–Cu–Cl(2) (136.88(4)°), N(3)–Cu–Cl(1) (115.64(8)°) and N(3)–Cu–Cl(2) (107.48(8)°) sum up to 360° and the Cu(II) atom lies in the equatorial plane. The average Cu–N bond length is observed to be 2.004 Å while the Cu–Cl bond length is 2.393 Å. The dihedral angle between the plane 1 (Cu, Cl(1), Cl(2), N(3)) and the plane 2 (N(3), N(6), C(6), C(7), C(8), C(9)) is 88.9°. The mononuclear unit is connected via two N–H···Cl hydrogen bonds (N(4B)···Cl(2A) 3.225 Å, Cl(2B)···N(4A) 3.225 Å) with a centrosymmetrically related counterpart to form a dimer as depicted in Fig. 3. The structural characterization of such hydrogen-bonded dimeric compounds linked by self complementary donor/acceptor groups is scarce for inorganic compounds. We are aware of only a few transition metal carboxylates of, e.g. zinc [14] and platinum [15] displaying pairs of symmetric C=O···H–N bridges, while here copper displays pairs of symmetric Cl···H–N bridges. The dimer is linked via another two Cl···H–N bridges to form a one-dimensional supermolecular chain along the *c* axis (Fig. 3).

Complex **3** has the same coordination configuration as **2**. The copper(II) atom is 5-coordinated with three N atoms from the ligand dapmp and two monodentate CH_3COO^{-1} ligands in an approximately trigonal bipyramidal environment (Fig. 4). The basal plane is formed by two O atoms from CH_3COO^{-1} and one N atom of the

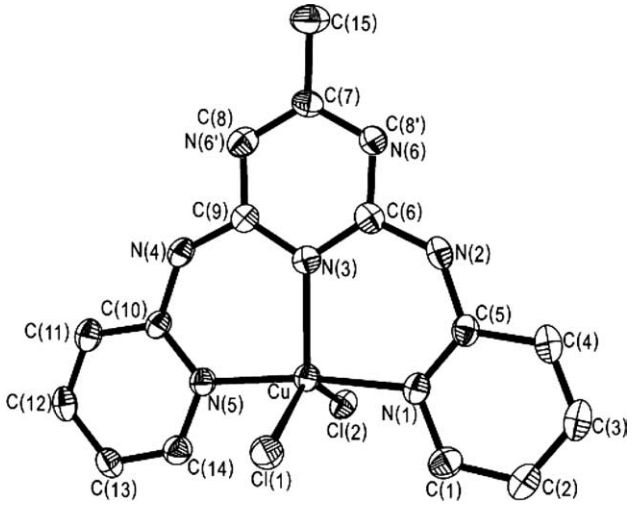

Fig. 2. The ORTEP drawing of $Cu(dapmp)Cl_2$ (**2**). Thermal ellipsoids are drawn at the 50% probability level.

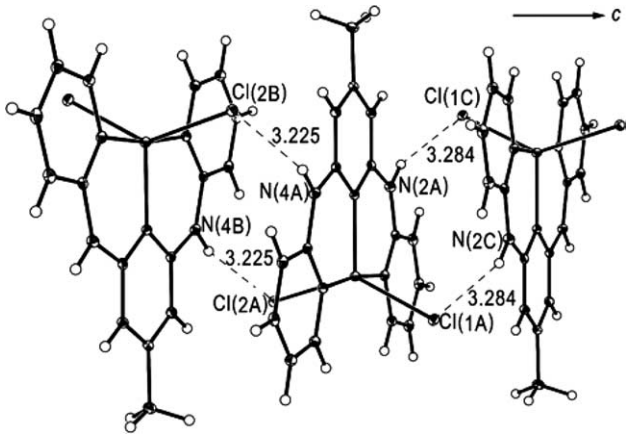

Fig. 3. The one-dimensional chains structure of Cu(dapmp)Cl_2 (**2** formed by hydrogen-bonding interactions (dashed lines).

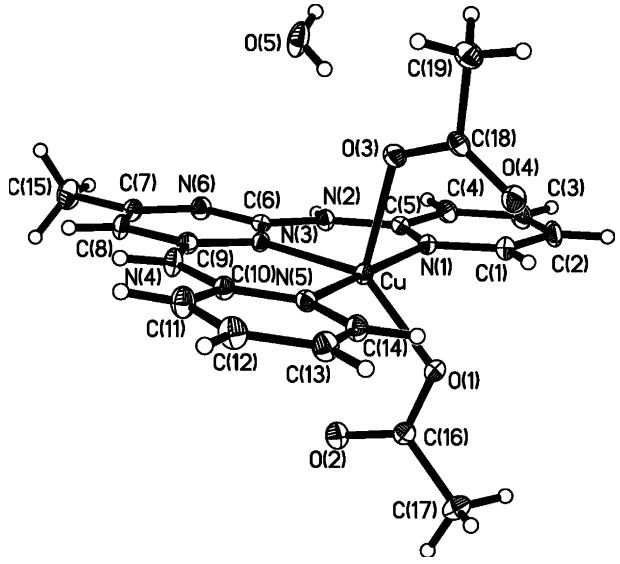

Fig. 4. The ORTEP drawing of [Cu(dapmp)$(CH_3]\cdot H_2O$ (**3**). Thermal ellipsoids are drawn at the 50% probability level.

central pyrimidine, which is indicated by bond angle summation (360°) of O(1)–Cu–O(3) (121.54(8)°), N(3)–Cu–O(1) (139.58(8)°) and N(3)–Cu–O(3) (98.88(8)°). The apical positions are occupied by two N atoms of terminal pyridine groups (N(1)–Cu–N(5) 172.84(9)°). The corresponding Cu–$N_{(dapmp)}$ and Cu–$O_{(CH3COO^-)}$ distances have the same magnitude, ranging from 1.975(2) to 2.067(2) Å. Within the acetate groups the C–O distances are greater for the strongly coordinated O atoms C(18)–O(3) and C(16)–O(1) (average 1.270 Å) than for the non-coordinated O atoms (average 1.243 Å). Intermolecular bonding of O(2) results in an intermediate C(16)–O(2) distance (1.244 Å). Both Cu–N bond lengths are typical of those found for the 5-coordinate Cu(II)-μ-pmea analogues [16]. Buckling of the tridentate dapmp ligand produces a dihedral angle between the two pyridyl rings of 10.5°. The Cu–O(3) bond has the longest distance (2.162(2) Å) in the 5-coordinated unit. The average Cu–N bond length is observed to be 2.006 Å, which is similar to the average Cu–N bond length of **2**. The dihedral angle (84.6°) between the plane (Cu, O(1), O(3), N(3)) and the pyrimidine ring plane is smaller than that of **2** between the plane (Cu, Cl(1), Cl(2), N(3)) and the plane of the pyrimidine ring (88.9°).

The mononuclear units are bridged by two H_2O molecules via four hydrogen bonds to form a dimeric unit (Fig. 5). On the other hand, via two hydrogen bondings ($O_{uncoord}\cdots N(H)$,2.806 Å), adjacent dimers are interconnected, giving rise to a one-dimensional supermolecular chain along the crystallographic *a* axis. It is worthy of note that the H_2O molecule binds the other uncoordinated O atom of CH_3COO^{-1} by hydrogen bonds (O(5)···O(4), 2.744 Å) in the *b*–*c* plane, and the neighboring chains are extended into a three-dimensional supermolecular structure.

3.2. Spectroscopic properties

The IR spectra of the complexes exhibit several characteristic strong bonds. In complex **2**, the bands around 1598 and 1569 cm^{-1} in ligand dapmp (**1**), attributed to the C=N grouping, are shifted to 1651 and 1588cm^{-1}, respectively, confirming the involvement of the ligand dapmp (**1**) in the copper complexation. In complex **3**, the corresponding bands are shifted to 1684 and 1642 cm^{-1}. The bands corresponding to v_{as}(COO) and v_{sym}(-COO) are at 1590 and 1397 cm^{-1} [17,18]. The Δv of the complex are 193 cm^{-1} more than the corresponding values for CH_3COONa (164 cm^{-1}), indicating that the CH_3COO^- group behaves as a monodentate ligand [18]. Other obsorption peaks can also be assigned to the ligand dapmp (**1**). These are in good agreement with the crystallographic results. The electronic spectra of the two complexes in methanol at ambient temperature were measured. On the basis of high extinction coefficient, the bands at 49 505, 46 296 and 47 393 cm^{-1} can be ascribed to a π–π transition of the ligand in **1**, **2** and **3**, respectively. There are two bands 39 370 cm^{-1} (complex **2**)

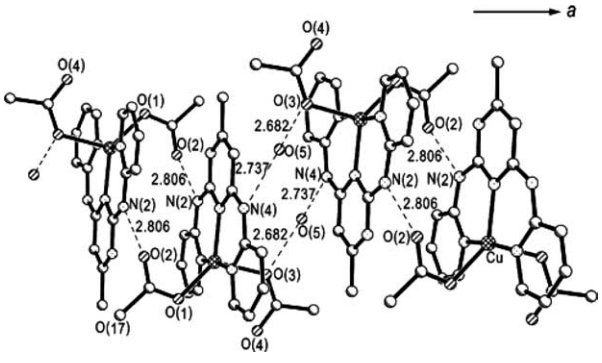

Fig. 5. The molecule packing of [Cu(dapmp)$(CH_3]\cdot H_2O$ (**3**) formed by hydrogen-bonding interactions (dashed lines). For the interest of clarity, the hydrogen atoms are omitted.

and 39063 cm^{-1} (complex **3**) corresponding to a metal–ligand charge transfer transition. The shoulder band 32573 cm^{-1} is due to the d–d transition in **2** and the band 32468 cm^{-1} due to the d–d transition in **3**. In addition, there is a weak unresolved shoulder at 30581 cm^{-1} in **1**.

3.3. Thermogravimetric analysis

Thermogravimetric analysis of complex **3** was carried out to examine its thermal stability. The TGA curve shows that the first weight loss of 3.68%, which occurs between 80 and 105 °C, corresponds to the loss of an uncoordinated water molecule (calc.: 3.77%). Further decomposition begins at 175 °C and ends at 560 °C with residue CuO in 17.5% yield (calc.: 16.6%). Thermogravimetric analysis of complex **2** shows that the decomposition begins at 291 °C and ends at 690.2 °C with residue CuO in 20.2 yield (calc.: 19.4%).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 236246 for compound **1**, 236245 for compound **2** and 236244 for compound **3**. Copies of this information may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The synthesis, structure and magnetic properties of the cobalt(II) complex (**1**) $[Co(H_2O)_4(pyz)](NO_3)_2 \cdot 2H_2O$ is reported. The compound crystallizes in the triclinic system, space group $P\bar{1}$, with cell constants: $a = 7.0328(15)$ Å, $b = 7.1255(16)$ Å, $c = 8.4198(19)$ Å, $\alpha = 107.226(4)°$, $\beta = 114.242(4)°$, $\gamma = 90.487(4)°$, $Z = 1$ and $V = 363.35(14)$ Å^3. The structure of **1** consists of elongated octahedral CoO_4N_2 chromophores with bridging pyrazine ligands forming a one-dimensional coordination polymer along the crystallographic *b*-axis. The nitrate ions hydrogen-bond to the water ligands (L) and guest water (G), and form $H_2O(L)\cdots H_2O(G)\cdots NO_3^-\cdots H_2O(G)\cdots H_2O(L)$ chains which flank either side of the coordination polymer chains. Hydrogen-bonding is extended to neighboring chains forming a two-dimensional network. The solvent effect on the electronic spectra of pyrazine and pyrazine cobalt complex **1** has been investigated. The magnetic susceptibility of complex **1** versus temperature data showed a strong antiferromagnetic coupling between Co ions. The best fitting parameters were obtained for $J_1/k_B = -26.4$ K, $J_2/k_B = -2.2$ K and $g = 2.3$.

1. Introduction

During the last decade, there has been great interest in the design of various supramolecular self assemblies from basic building blocks. Self assembly concerns the reversible spontaneous association of a limited number of tectons under the intermolecular control of relatively labile coordination, hydrogen-bonds and dipolar interactions. The reversibility is key to the resulting systems ability to sift through the available components to form the thermodynamically most favorable structure. The tectons come together spontaneously in a well defined way to give assemblies in one, two or three dimensions [1,2]. Molecular recognition occurring between host and guest may be an intrinsic part of the operation of the supramolecular device, which might be designed to bind and then signal the presence of a guest [3]. Supramolecular assemblies of the polymer type are of interest in the area of tunable zeolite mimics [4]. Other interests are applications in catalysis and advanced materials such as magnetic, optic and electronic materials [5–8]. In the crystal engineering 'toolbox' [9], hydrogen-bonding moieties are perhaps the most used implements in

doi:10.1016/j.poly.2004.11.017

the design of such supramolecular systems [10], and have been particularly strongly applied towards the synthesis of molecular magnetic materials [11–16].

Because of its rod like rigidity and length, pyrazine is a good candidate for molecular building blocks. Several factors influence the specific framework structure that is formed: One factor is the role of the solvent, for example a large difference has been obtained between the double-layer structure of the solvent inclusion compound $[Ag(pyz)_2][Ag_2(pyz)_5](PF_6)_3 \cdot 2S$ ($S = CH_2Cl_2$, $CHCl_3$, CCl_4) [17] and the layer structure of the solvent-free compound $[Ag(pyz)_2](PF_6)$ [18]. The counterion can also influence the final structure, replacing the counterion PF_6^- by SbF_6^-, or BF_4^- changes the structure from the two-dimensional undulated sheet structure of $[Ag(pyz)_2](PF_6)$ [18], to the three-dimensional non-interpenetrating cubic framework of $[Ag(pyz)_3](SbF_6)$ [17], or to the interpenetrated three-dimensional structure of $[Ag_2(pyz)_3](BF_4)_2$ [19]. The specific oxidation of the metal cation can also determine the final polymer structure: Cu^{2+} is in a distorted octahedral coordination and forms a square two-dimensional network with pyrazine or substituted pyrazine [20], while Cu^+ adopts a tetrahedral coordination forming three-dimensional networks with substituted pyrazine or 4,4′-bipyridine [21], Cu^+ may also be trigonally coordinated by pyrazine or 4,4′-bipyridine forming three-dimensional networks or two-dimensional layers containing six-membered rings [21–26], where only $[Cu_2(pyz)_3](SiF_6)$ [22] has an interpenetrated structure. In addition the type of metal cation affects the coordination preference and thus the final polymer structure; when bonded to pyrazine, Cu^+ is tetrahedral, or trigonal as just described, whereas Ag^+ is found in a wide range of coordination environments: linear [19,27], trigonal [19], tetrahedral [18,19,28], square-planar, square-pyramidal and octahedral [17].

It is noted from the above discussion that the formation of coordination polymers of group IB and IIB metal ions with pyrazine has been well studied, and that more work needs to be devoted to the study of complexation with other transition metals. In the present work, we report the reaction of $Co(NO_3)_2 \cdot 6H_2O$ with pyrazine. A new polymer compound (**1**) $[Co(pyz)(H_2O)_4](NO_3)_2 \cdot 2H_2O$ is formed, which has a linear chain structure (Fig. 1). There are straight chain polymers, such as (**2**) $[Co(H_2O)_4(pyz)](SO_4) \cdot 2H_2O$ [29] and $[Co(acac)_2(pyz)]$ (**3**) [30], two-dimensional sheets examples are $[CoCl_2(pyz)_2]$ [31] and $[M(pyz)_2(NCS)]$ (M = Co, Fe) [32,33], and a three-dimensional network example is $[M(pyz)(Au(CN)_2)_2]$ (M = Cu, Ni, Co) [34]. Measurement of variable temperature magnetic susceptibilities of various cobalt pyrazine complexes indicated anti-ferromagnetic behaviors [30,32–35]. The conducting properties of pyrazine metal complexes were investigated, with Fe(II) complexes showing higher conductance values compared to other metal complexes [36,37].

One important feature about the structure of compound **1** is that guest water molecules occupy void spaces in the structure and that both intra- and intermolecular hydrogen-bonding interactions are observed involving coordinated water molecules, guest water molecules and the nitrate counterions. The compound also shows weak antiferromagnetic behavior.

2. Experimental

All reagents were obtained from Aldrich and were used as received.

2.1. Synthesis of $[Co(H_2O)_4(pyrazine)](NO_3)_2 \cdot 2H_2O$

An acetonitrile solution (30.0 ml) of pyrazine (0.310 g, 3.87 mmol) was added to an ethanolic solution (20.0 ml) of $Co(NO_3)_2 \cdot 6H_2O$ (0.75 g, 2.58 mmol). The mixture was refluxed for 2 h then left to stand at room temperature. Red block crystals of **1** were formed in one week. The typical yield was 92% based on $Co(NO_3)_2 \cdot 6H_2O$. Calc. for $C_4H_{16}CoN_4O_{12}$: C, 12.94; H, 4.35, N 15.10; Co, 15.88. *Anal.* Found: C, 12.40; H, 4.30; N, 15.30; Co, 15.80.

2.2. Physical measurements

Elemental analyses of Co, C, H, N were performed by Kanti Labs Ltd., Mississauga, Canada. Infrared data

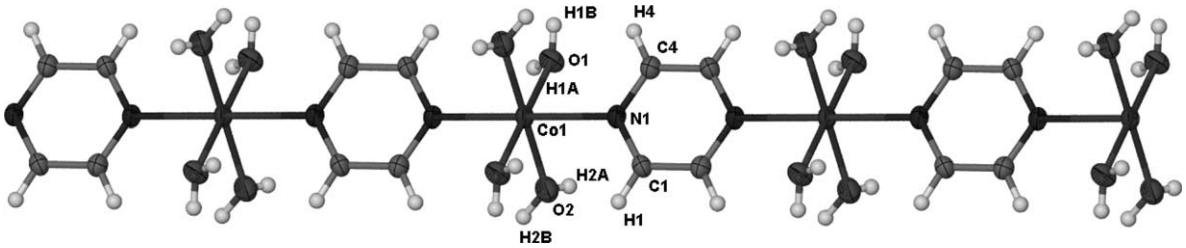

Fig. 1. Thermal ellipsoid plot of the one-dimensional polymer chain of **1**.

were collected on a Schimadzu 8300 FTIR spectrophotometer using the KBr pellet method. The electronic absorption spectra were obtained using a Ciba Corning 2800 spectrophotometer. The magnetic susceptibility of crystalline samples was measured on a Quantum Design Model 6000 Physical Property Measurement System. Diamagnetic corrections were applied using Pascal's constants.

2.3. Crystallography

Experimental parameters pertaining to single crystal X-ray analysis of **1** are given in Table 1. Data were collected on a single prismatic crystal measuring $0.35 \times 0.30 \times 0.20$ mm mounted and centered on a Siemens SMART 1000 CCD platform diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 173(2) K. The final unit cell was determined from 1222 reflections in the range of $2.8° < \theta < 28.0°$. The data were integrated using the SAINT suite of software. Lorentz and polarisation effects were accounted for using SADABS. The structure was solved by direct methods and refined iteratively via full-matrix least-squares and difference Fourier analysis using the SHELX-97 suite of software [38] and with the assistance of X-SEED [39].

The cell symmetry triclinic $P\bar{1}$ has been preferred over monoclinic $C2/m$ symmetry: The internal R-factor, $R_{(int)}$ for the triclinic setting is 0.036 whereas in the monoclinic setting $R_{(int)}$ it was 0.28. Structure solution and refinement in the monoclinic setting led to very high R-factors as well as unreasonable thermal parameters (and imposed disorder) for both pyrazine ligand and nitrate anions.

All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms of the pyrazine ligand were placed in idealized positions and refined with a riding model whereas those on the coordinated and lattice water molecules were located and fully refined with isotropic displacement parameters. The nitrate anions are disordered and the two orientations are very well resolved, hinting at statistical disorder.

3. Results and discussion

3.1. Reaction chemistry

The title compound was obtained by the reflux reaction of hydrated cobaltous nitrate in ethanol with pyrazine in acetonitrile. Single crystals suitable for X-ray diffraction were obtained by slow evaporation of the reaction mixture after several days.

3.2. Description of the structure

3.2.1. One-dimensional linear chain structure

The compound has a one-dimensional linear chain structure along the crystallographic b-axis, which is formed by bridging pyrazine ligands connecting the $Co(H_2O)_4$ units. A thermal ellipsoid plot of the one-dimensional polymer chain of **1** is depicted in Fig. 1. The Co atom lies at a center of symmetry and is coordinated by the oxygen atoms of four water molecules and the nitrogen atoms from two pyrazine molecules, forming an elongated octahedral cobalt coordination sphere. The oxygen atoms occupy the equatorial positions forming four short bonds with cobalt (Co(1)–O(1) = 2.073(2) Å, Co(1)–O(2) = 2.064(2) Å). The oxygens form an essentially square planar array around the central cobalt ion; the angles O(1)–Co(1)–O(1) and O(2)–Co(1)–O(2) are ideal 180.08(7)°, and the angles O(2)–Co(1)–O(1) are 89.12(10)° and 90.88(10)° (Fig. 1). The nitrogen atoms are located in axial positions with a perfect angle of 180.00(7)°. They form two long bonds with cobalt (Co(1)–N(1) = 2.173(2) Å) (Fig. 1), with values that are consistent with those found in related linear chain polymers (e.g. Co–N = 2.198 Å in $[Co(H_2O)_4(pyz)]$ $(SO_4) \cdot 2H_2O$ (**2**) [29] and 2.227(2) Å in $[Co(acac)_2(pyz)]$ (**3**) [30]). The cobalt atoms in **1** are bridged by pyrazine ligands with the nearest Co···Co separation of 7.125 Å within the chain (Fig. 1), compared to 7.189 Å in **2** [29]. Each chain is surrounded by six identical chains. The separations of the metal ions between two neighboring chains are 7.033, 8.420 and 8.469 Å (see Fig. 2). This compares separations of 6.308, 7.189 and 8.724 Å in **2** [29], and 6.290 and 6.27 Å in **3** [30]. Other one-dimensional

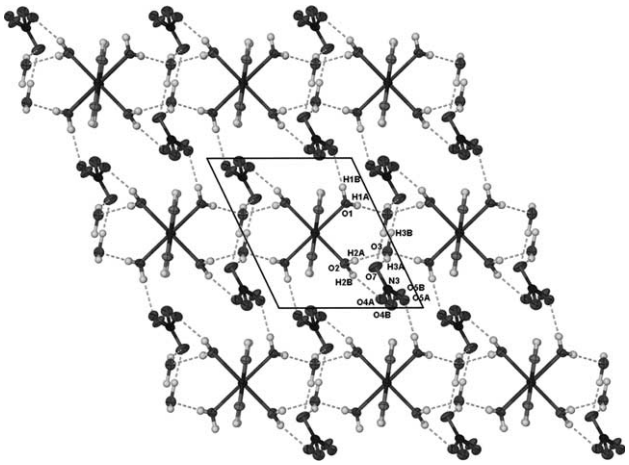

Fig. 2. Cross-sectional view in the *ac*-plane. Two-dimensional network caused by H-bonds between cobalt units in **1**.

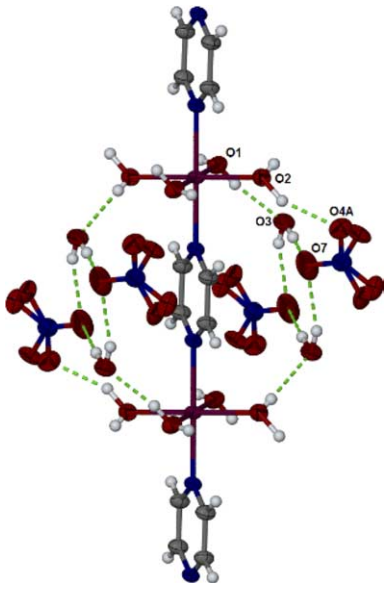

Fig. 3. Intra-chain H-bond interactions in **1**.

straight chain compounds are $[Co(DBSQ)_2(pyz)]$ (DBSQ = 3,6-dibutylbenzocatecholato-*O*,*O*′) [40] and $[Co(WO)_2(pyz)]$ (WO = dimethylglyoximato) [41]. Further bridging of pyrazine ligands can lead to two-dimensional extended structures such as in $[CoCl_2(pyz)_2]$ [31] and $[Co(NCS)_2(pyz)_2]$ [32]. Thus the type of anion greatly affects the final structure of the cobalt pyrazine complex: reaction of cobalt nitrate with pyrazine produces one-dimensional polymer (**1**) $[Co(pyz)(H_2O)_4](NO_3)_2 \cdot 2H_2O$ with two included water molecules and no participation of nitrate in the inner coordination sphere. Notably, the reaction of cobalt nitrate with 4,4′-bipyridine, a linear *N*,*N*′-bidentate spacer similar to pyrazine, produces in the presence of *p*-nitroaniline (PNA) an interpenetrated square grid two-dimensional network $[Co(bipy)_2(NO_3)_2] \cdot 2PNA$ that results from a higher ligand:metal stoichiometry. In this compound, two nitrate ions occupy the axial positions within the inner coordination sphere of Co. The interpenetrated PNA forms planar networks sustained by edge-to-face interactions between the edges formed by NO_2 moieties and the faces formed by the NH_2 moieties [42].

3.2.2. H-Bond

The nitrate ions of **1** hydrogen-bond to the coordinated water ligand (L) and the lattice-included guest water (G) such that each $[Co(pyz)_2(H_2O)_4]$ chain is flanked on either side by two hydrogen-bonded $H_2O(G)$ molecules and two NO_3^- ions. Thus two adjacent cobalt units within the same chain interact on each side by six extended intra-chain H-bond paths: two through $H_2O(L) - NO_3^- - H_2O(G) - H_2O(L)$, and four through $H_2O(L) - H_2O(G) - NO_3^- - H_2O(G) - H_2O(L)$, (Fig. 3). The bonds distances and bond angles involved in the H-bonds labelled in Fig. 3 follow. For $H_2O(L)$ with NO_3^- ions: O(2)···O(4A) = 2.866(6) Å, H(2B)···O(4A) = 2.0 Å, O(2)–H(2B)···O(4A) = 156°; for $H_2O(G)$ molecules with NO_3^- ions: O(3)··· O(5B) = 2.87(1) Å, H(3A)···O(5B) = 2.2 Å, O(3)–H(3A)··· O(5B) = 149°, O(3)···O(7) = 2.907(4) Å, H(3A)··· O(7) = 2.2 Å, O(3)–H(3A)···O(7) = 159° and O(3) ···O(7) = 2.788(4) Å, H(3B)···O(7) = 1.8 Å, O(3)–H(3B) ···O(7) = 177°; for $H_2O(L)$ with $H_2O(G)$ molecules: O(1)···O(3) = 2.740(3) Å, H1(A)···O(3) = 2.1 Å, O(1)–H(1A)···O(3) = 178° and O(2)···O(3) = 2.704(4) Å, H(2A)···O(3) = 1.9 Å, O(2)–H(2A)···O(3) = 170°.

Fig. 2 shows that each linear chain is surrounded by six neighboring chains in a cross-sectional view along the *b*-axis in the *ac*-plane. Each cobalt unit interacts directly by extended inter-chain H-bonds with six neighboring units making a two-dimensional network. Complex **1** thus forms a three-dimensional supramolecular structure due to both coordination bonds (bridging by pyrazine) and H-bonds. Four types of inter-chain H-bonds paths are involved: (1) $H_2O(L) - NO_3^- - H_2O(L)$, (2) $H_2O(L) - H_2O(G) - NO_3^- - H_2O(L)$, (3) $H_2O(L) - H_2O(G) - H_2O(L)$, and (4) $H_2O(L) - H_2O(G) - NO_3^- - H_2O(G) - H_2O(L)$. The extension of intra-chain H-bonds described previously serve also in inter-chain H-bonds. The difference is in the coordinated water molecules whether they belong to the same chains or to two different chains. Thus the bonds distances and bond angles involved in inter-chain H-bonds are the same as before. Only for inter-chain H-bondings between $H_2O(L) - NO_3^- - H_2O(L)$ two additional bondings values should be listed: O(1)···O(4B) = 2.83(1) Å, H(1B)···O(4B) = 2.1 Å, O(1)–H(1B)··· O(4B) = 149° and O(1)···O(5A) = 2.742(8) Å, H(1B)··· O(5A) = 2.0 Å, O(1)–H(1B)···O(5A) = 150°.

Solvent or guest molecules are generally included in the void between chains and hydrogen-bonding interac-

tions have been also observed in related one-dimensional structures such as compound (**2**), $[Co(H_2O)_4(pyz)](SO_4)\cdot 2H_2O$ [29], $[Co(pyz)(H_2O)_4](C_8H_4O_4)$ [43] but not in $[Co(acac)_2(pyz)]$ [30].

3.3. Discussion on IR

The absorbances between 1055.0, 1116.7 and 1163.0 cm^{-1} are assignable to pyrazine bands; the peak at 474.5 cm^{-1}, shifted from 417.0 cm^{-1} in free pyrazine, is particularly diagnostic of bridging bidentate ligands [44–47]. Nitrate group absorbances are observed at 1615.0 cm^{-1} due to an assymmetric stretch, and very strong at 1433.3 and 1384.8 cm^{-1} (symmetric stretch). Broadened O–H stretches are observed for H_2O(G) and H_2O(L) at 3319.1 cm^{-1}.

3.4. Discussion on electronic absorption spectra

Complex **1** shows a d–d transition at 521 nm in DMF, 536 nm in DMSO and 502 nm in pyridine.

The solvent effect on the electronic absorption spectra of pyrazine in the free state and in the complexed state in cobalt pyrazine complex **1** has been investigated, see Table 2. The absorption peak location Y (λ_{max} nm) of the species in a given solvent has been expressed by the following multi-parameter [48,49]:

$$Y = a_0 + a_1X_1 + a_2X_2 + a_3X_3 + a_4X_4.$$

This is amenable to solution for the intercept a_0 and the coefficient a_i by multiple regression techniques. The independent variables X_i are the solvent interaction mechanisms E, K, M and N. The empirical solvent polarity E is sensitive to both solvent–solute hydrogen-bonding and to dipolar interactions. It is related to v, which is the wave number of the absorption maximum in the given solvent, $E = 2.859 \times 10^{-3}v$.

K is a measure of the polarity of the solvent that depends on the solvent dielectric constant D. $K = (D - 1)/(2D + 1)$.

M is a measure of solute permanent dipole–solvent induced dipole interactions that depend on the solvent refractive index n. $M = (n^2 - 1)/(2n^2 + 1)$.

N is a measure of permanent dipole–permanent dipole interactions

$$N = (D - 1)/(D + 2) - (n^2 - 1)/(n^2 + 2).$$

A multiple regression analysis has been performed. In each case fits are obtained as a function of one parameter alone, two parameters or three parameters. The results are summarized in Tables 3 and 4. The λ_{max} studied λ_1 and λ_2 are for B and R bands, respectively, for pyrazine and complex **1**. The values obtained are very close for both species. B bands (λ_1) which originate from π–π* transitions shift to longer wavelengths in the polar solvents DMF and DMSO, while the R bands (λ_2), which are due to n–π* transitions, shift to shorter

wavelengths in hydrogen-bonding solvents. The data for λ_1 shows good dependence of the shift in λ_{max} on *M*, the data indicates improvement in the fit in going from one parameter to two, three and four parameter correlations. The data for λ_2 shows very good dependence of the shift in λ_{max} on *E*, *K*, *M* and *N* parameters. The multiple correlation coefficients MCC in the complex are higher than in the free pyrazine.

3.5. Magnetic study

The temperature dependence of the inverse magnetic susceptibility for compound **1** as a function of the temperature in the range 2–300 K is shown in Fig. 4 (χ_M^{-1} versus *T*). This figure shows that χ_M^{-1} follows the Curie–Weiss law, and decreases linearly as the temperature decreases down to 25 K. The best fitting to a straight line yields a negative Curie–Weiss temperature of −16.8 K, indicative of a strong antiferromagnetic coupling between Co ions. At 300 K $\chi_M T$ versus *T* is equal to 2.985 cm^3 K mol^{-1} which is quite different from the value of 2.1 cm^3 K mol^{-1} reported by Ma et al. [30].

The $\chi_M T$ versus *T* curve exhibits a continuous decrease from 300 to 2 K as the temperature is lowered. Such behavior is characteristic for Co(II) complexes,

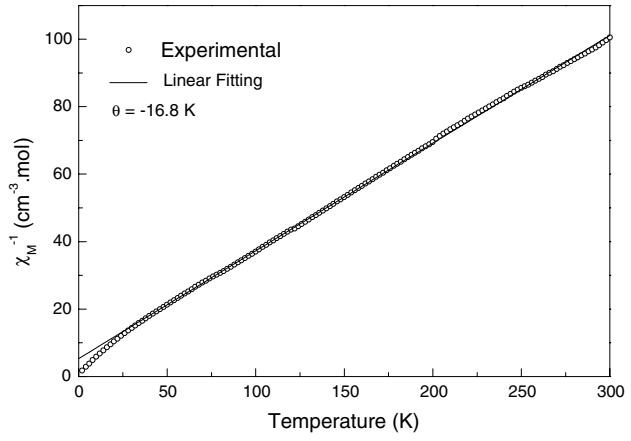

Fig. 4. Inverse of the molar magnetic susceptibility of **1** vs. temperature, the straight line represents the best fit to a Curie–Weiss law obtained for $\theta = -16.8$ K.

due to single ion anisotropy with some contribution of antiferromagnetic exchange between the Co(II) centers. The magnetic coupling can be mediated through extensive intra-chain as well as inter-chain H-bondings interactions between the cobalt atoms. The experimental susceptibility data has been tentatively fitted for $S = 3/2$ using the classical spin model for the magnetic susceptibility of an infinite chain derived by Fisher [50]. Thus, the best fitting gave the following values for the parameters: $J = -1.1$ cm^{-1}, $g = 2.55$. However, the experimental data did not match the calculated ones especially at low temperature, and the Landé factor obtained does not reflect the ground of Co as seen in many systems [51–55]. A three-dimensional magnetic behavior with two exchange couplings rather than one should be considered. Also the analysis of magnetic data for cobalt complexes is complicated by single ions effects such as spin–orbit coupling, distortion from regular stereochemistry, electron delocalization, crystal field mixing of excited states into the ground state and by magnetic exchange interactions [56]. To improve the correlation between the experimental and theoretical data we attempted to include a second exchange coupling constant, thus our model consists of two linear chains corresponding to the shortest Co distances deduced from the X-rays data that are 7.125, 7.033, 8.420 and 8.469 Å. We calculated the spin Hamiltonian and the magnetic susceptibility of the linear chains taking into account two isotropic exchange-coupling constants, J_1 and J_2 [57]. For simplicity reasons each linear chain is considered to be a closed triplet that contains three Co ions interacting among themselves [58]. Thus, the spin Hamiltonian of a closed triplet is given by

$$H = -2J_i(S_1S_2 + S_1S_3 + S_2S_3) \quad i = 1, 2. \tag{1}$$

The magnetic susceptibility was calculated using the expression given by Spasojevic et al. [59]

$$\chi = \left(\frac{g\mu_B}{k_BT}\right)^2 \left(\frac{\sum_{S,m} m^2 \mathrm{Exp}(E(\alpha,S,m)/k_BT)}{\sum_{S,m} \mathrm{Exp}(E(\alpha,S,m)/k_BT)} - \left(\frac{\sum_{S,m} m \mathrm{Exp}(E(\alpha,S,m)/k_BT)}{\sum_{S,m} \mathrm{Exp}(E(\alpha,S,m)/k_BT)}\right)^2\right), \tag{2}$$

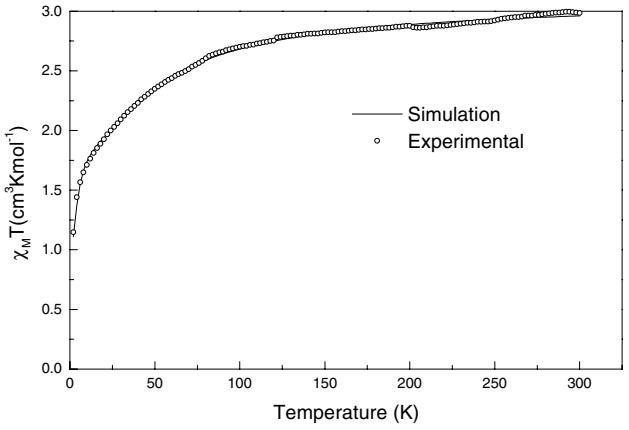

Fig. 5. $\chi_M T$ vs. temperature for **1**, the continuous line represents the best fitting using Eq. (2).

where μ_B is the Bohr magneton k_B is the Boltzman constant, g is the Landé factor and α is a notation for all quantum numbers besides S and m. Using this model the fit has been improved tremendously, as shown in Fig. 5. The best fitting parameters were obtained for $J_1/k_B = -26.4$ K, $J_2/k_B = -2.2$ K and $g = 2.3$.

Appendix A. Supplementary data

CCDC No. 211146 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre (CCDC), 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2004.11.017.

Abstract

Pyridine-2,6-dicarboxylic acid (LH_2) reacts with uranyl nitrate in the presence of triethylamine to form either mononuclear or new dinuclear complexes, the latter being different from the species obtained up to now with this ligand under different experimental conditions. In all cases, the uranium atom is bound to the pyridine nitrogen atom and to one oxygen atom from each carboxylate group. Its coordination sphere is completed either by a second ligand L^{2-}, giving the 1:2 mononuclear complex **1**, by a water molecule and a bridging μ-η^2,η^2-peroxide ion in the dinuclear complex **2**, by two bridging μ_2-hydroxide ions in **3** and **4** or by two bridging μ_2-methoxide ions in **5**. Complex **5** provides the first example of uranyl-bridging by methoxide ions to be crystallographically characterized. Extended hydrogen bonded networks involving the carboxylate groups, the bridging species and the counter-ions and solvent molecules are formed in all cases, resulting in chain, ribbon or sheet assemblages.

1. Introduction

We have recently been interested in exploiting the peculiar geometric requirements of the linear uranyl ion in its coordination complexes for the design of new polynuclear cyclic architectures, and polycarboxylate appeared suitable candidate ligands [1]. The tetra-, penta- or hexa-coordinated equatorial planar environment suitable for this ion is well suited, in association with bent ligands, for the design of macrocyclic species. While tri- or tetra-nuclear metallamacrocycles could be obtained with the tetraacid of tetrahydrofuran [1], we turn here our attention to diacids. Among the latter, the planar pyridine-2,6-dicarboxylic acid (dipicolinic acid, denoted LH_2 hereafter) has previously been used as a ligand for UO_2^{2+} [2–5] or U^{IV} [6] ions. In the most usual case, two tridentate ligands encompass one uranyl ion bound to the nitrogen atoms and one oxygen atom from each acid group [2,4], which is also the case with the related ligand pyridine-2,6-bis(monothiocarboxylic)-acid [7]. Polymeric arrangements occur when one acid group is bridging two metal centres through its two oxygen atoms [3,5]. Of particular interest in the prospect of using this ligand to get supramolecular systems is the helical polymeric neutral arrangement found by Immirzi et al. [3] which shows that, although LH_2 is a planar and not a bent molecule, three-dimensional architectures

doi:10.1016/j.poly.2004.11.002

incorporating uranyl ions can be generated. So, we decided to investigate the uranyl complexes formed with LH_2 under experimental conditions different from those used up to now, namely in the presence of triethylamine as a deprotonating agent. On changing the reactant ratio, both a 1:2 mononuclear complex and a 2:2 binuclear dimer including triethylammonium ions could be obtained. Moreover, with the aim of preparing mixed uranyl complexes, a different potential bidentate ligand, namely *N*,*N*,*N*′,*N*′-tetramethylethylenediamine, bis(2-hydroxyphenyl)methane or (1*R*,3*S*)-(+)-camphoric acid, was added together with LH_2. In no such experiment the additional species was included as a ligand, but each mixture allowed a structurally different 2:2 dimeric complex with L^{2-} to be isolated, with a geometry unprecedented in this family of uranyl complexes. The role of the additional species in the formation of the different dimeric complexes has not been rationalized.

2. Experimental

2.1. Synthesis

^{1}H NMR spectra (300 MHz) were taken on a Bruker AC 300 spectrometer in either $CDCl_3$ stored on activated molecular sieves (4 Å) or in $(CD_3)_2SO$.

2.1.1. $[HNEt_3]_2[UO_2L_2]\cdot 2H_2O$ (**1**)

Uranyl nitrate hexahydrate (50 mg, 0.10 mmol) in MeOH (1 ml) was added dropwise to a boiling stirred mixture of LH_2 (33 mg, 0.20 mmol) and triethylamine (200 mg, 2.0 mmol) in MeOH (9 ml). Stirring and heating of the resulting yellow solution were continued for additional 5 min. Greenish yellow single crystals of compound **1**, suitable for X-ray crystallography, deposited on solvent evaporation. The complex (40 mg, 48% yield) was readily soluble in chloroform. ^{1}H NMR ($CDCl_3$) $\delta = 1.47$ (t,18H, $J = 7.1$ Hz), 3.88 (q,12H, $J = 7.1$ Hz), 8.29 (t, 7.6 Hz, 2H), 8.54 (d, 7.6 Hz, 4H), 11.13 (s, 2H). *Anal*. Calc. for $C_{26}H_{42}N_4O_{12}U$: C, 37.15; H, 5.04; N, 6.66. Found: C, 36.96; H, 5.39; N, 6.38%.

2.1.2. $[HNEt_3]_2[(UO_2)_2L_2O_2(H_2O)_2]\cdot 2H_2O$ (**2**)

Uranyl nitrate hexahydrate (50 mg, 0.10 mmol) in MeOH (1 ml) was added dropwise to a boiling stirred mixture of LH_2 (17 mg, 0.10 mmol), (1*R*,3*S*)-(+)-camphoric acid (20 mg, 0.10 mmol) and triethylamine (270 mg, 2.7 mmol) in MeOH (9 ml). Stirring and heating of the resulting yellow solution were continued for additional 5 min. A few yellow single crystals of compound **2**, suitable for X-ray crystallography, deposited on standing.

2.1.3. $[HNEt_3]_2[(UO_2)_2L_2(OH)_2]\cdot 2H_2O$ (**3**)

Uranyl nitrate hexahydrate (110 mg, 0.22 mmol) in MeOH (2 ml) was added dropwise to a boiling stirred mixture of LH_2 (36 mg, 0.22 mmol), bis(2-hydroxyphenyl)methane (46 mg, 0.23 mmol) and triethylamine (350 mg, 3.5 mmol) in MeOH (20 ml). Stirring and heating of the resulting reddish orange solution were continued for additional 5 min. The reddish oil obtained on solvent evaporation was dissolved in acetonitrile and yellow crystals of compound **3**, suitable for X-ray crystallography, deposited on standing. The complex (13 mg, 10% yield) appeared to be insoluble in chloroform, acetone and acetonitrile. ^{1}H NMR [$(CD_3)_2SO$], $\delta = 0.92$ (t, 18H, $J = 7.0$ Hz), 2.42 (q,12H, $J = 7.0$ Hz), 8.50–8.60 (superimposed signals, 8H). *Anal*. Calc. for $C_{26}H_{44}N_4O_{16}U_2$: C, 27.28; H, 3.87; N, 4.89. Found: C, 27.42; H, 3.98; N, 4.42%.

2.1.4. $[HNEt_3][HNMe_2(CH_2)_2NMe_2][(UO_2)_2L_2(OH)_2]\cdot 2H_2O$ (**4**)

Uranyl nitrate hexahydrate (110 mg, 0.22 mmol) in MeOH (2 ml) was added dropwise to a boiling stirred mixture of LH_2 (36 mg, 0.22 mmol), *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (14 mg, 0.12 mmol) and triethylamine (350 mg, 3.5 mmol) in MeOH (9 ml). Stirring and heating of the resulting solution were continued for an additional 5 min. A few yellow crystals of compound **4**, suitable for X-ray crystallography, deposited on standing.

2.1.5. $[HNEt_3]_2[(UO_2)_2L_2(MeO)_2]\cdot MeOH\cdot H_2O$ (**5**)

Uranyl nitrate hexahydrate (50 mg, 0.10 mmol) in MeOH (1 ml) was added dropwise to a boiling stirred mixture of LH_2 (17 mg, 0.10 mmol), and triethylamine (200 mg, 2.0 mmol) in MeOH (7 ml). Stirring and heating of the resulting yellow solution were continued for additional 5 min. Yellow crystals of compound **5**, suitable for X-ray crystallography, deposited on standing. The complex (16 mg, 26% yield) appeared to be slightly soluble in chloroform. ^{1}H NMR ($CDCl_3$) $\delta = 1.41$ (unresolved t, 18H), 3.50 (s, 9H) 3.67 (unresolved q, 12H), 8.37 (t, 7.5 Hz, 2H), 8.62 (d, 7.5 Hz, 4H). *Anal*. Calc. for $C_{29}H_{50}N_4O_{16}U_2$: C, 29.35; H, 4.25; N, 4.72. Found: C, 29.12; H, 4.39; N, 4.50%.

2.2. Crystallography

Data were collected at 100(2) K with a Nonius KappaCCD area detector diffractometer [8] using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The crystals were placed inside glass capillaries with a protecting 'Paratone-N' oil (Hampton Research) coating. The unit cell parameters were determined from ten frames, then refined on all data. A 180° φ-range was scanned with 2° steps during data collection, with a crystal-to-detector distance fixed at 28 mm. The data were processed with DENZO-SMN [9]. The structures were solved by Patterson map interpretation (**1**) or direct methods (**2**–**5**) with SHELXS-97 and subsequent Fou-

rier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [10]. Absorption effects were corrected empirically with the program DELABS from PLATON [11]. In compound **5**, one ethyl group of a triethylammonium ion was found to be disordered over two positions which were refined with occupancy parameters constrained to sum to unity. All non-hydrogen atoms were refined with anisotropic displacement parameters, with a few additional restraints for some badly behaving parts (triethylammonium ion containing N3 in compound **2**, two carbon atoms of a triethylammonium ion and methanol atom O15 in compound **5**). The hydrogen atoms bound to oxygen and nitrogen atoms were found on Fourier-difference maps (those bound to oxygen only in compound **2**) and all the other hydrogen atoms were introduced at calculated positions. All hydrogen atoms were treated as riding atoms with a displacement parameter equal to 1.2 (OH, NH, CH, CH_2) or 1.5 (CH_3) times that of the parent atom. Crystal data and structure refinement details are given in Table 1 and selected bond lengths and angles in Table 2. The molecular plots were drawn with SHELXTL [12].

3. Results and discussion

The compound $[HNEt_3]_2[UO_2L_2] \cdot 2H_2O$ (**1**) contains a 1:2 dianionic complex analogous to those previously obtained under different conditions [2,4] (Fig. 1). The asymmetric unit contains only half a molecule, the other half being generated by the binary axis containing the uranyl ion. The latter is bound, in its equatorial plane, to the two nitrogen atoms and to one oxygen atom from each carboxylate group, resulting in a hexagonal bipyramidal environment for the uranium atom, as usual for small bite polydentate ligands. The U–N bond length [2.626(2) Å] is larger than the mean U–O(carboxylate) bond length [2.459(14) Å] and both values agree with those in the previous mononuclear, hexa-coordinated uranyl complexes with the same ligand [2,4]. The mean value of the N–U–O(carboxylate) and O(carboxylate)–U–O(carboxylate) angles is 60.7(5)°, the O–U–O angle, involving the two ligands, being only about 1° larger than the N–U–O angles. The six equatorial donor atoms define a strongly distorted plane with a rms deviation of 0.26 Å. The atoms O1 and O1′ are little displaced from this plane, by 0.042(2) Å, whereas atoms O3 and N1, and their symmetry equivalents, are located on either side, with deviations of 0.339(2) and −0.298(2) Å, respectively. The environment of the uranyl ion, with two nitrogen atoms in *trans* position and four oxygen atoms, is reminiscent of that found in the complex with diaza-18-crown-6 [13], but the differing charges and ligand rigidity result in much larger U–N and U–O bond lengths in the latter (2.68–2.74 Å). The acid groups in **1** are slightly tilted with respect to the aromatic ring best plane, with deviations of −0.232(4) and 0.122(4) Å for the donor atoms O1 and O3, respectively. The two aromatic rings define a dihedral angle of 37.44(6)°. The triethylammonium counter-ions are located so as to form

bifurcated hydrogen bonds with the coordinated oxygen atoms O1, O3 and their symmetry equivalents (Table 3), thus resulting in the formation of a 16-membered ring around the uranium atom. The water molecules are hydrogen bonded to the non-coordinated carboxylate oxygen atoms O2 and O4 from different molecules related by a symmetry centre. This results in the formation

of zig-zag chains of doubly hydrogen bonded molecules along the *c*-axis.

Compounds **2**–**5** all contain dianionic complexes comprising two metal ions, two dicarboxylate ligands and one dianionic or two monoanionic bridging species. Complex **2**, $[HNEt_3]_2[(UO_2)_2L_2O_2(H_2O)_2]\cdot 2H_2O$, is an example of a μ-η^2,η^2-peroxide bridged uranyl dinuclear complex (Fig. 2). The occurrence of such $[O_2]^{2-}$ bridges has been discussed previously in the role that they play in the formation of uranyl-containing molecular boxes or cages [14]. Due to the presence of an extra coordinated water molecule, each uranyl ion in **2** retains the hexagonal bipyramidal coordination found in compound **1**, but, since the O–U–O angles defined by the μ-η^2,η^2-peroxide ion [36.3(2)° and 35.5(2)°] are much smaller than the other equatorial bond angles [61.7(3)°–70.6(2)°], this case can be considered as borderline between hexa- and pentagonal coordinations, the μ-η^2,η^2-peroxide ion being considered as a single atom in the latter. The mean plane defined by the six equatorial donor atoms around each uranyl ion is less distorted than in compound **1**, with rms deviations lower than 0.10 Å. The U–N and U–O(carboxylate) bond lengths are also shorter than in **1**, with mean values of 2.57(2) and 2.423(11) Å, respectively, and, as a consequence, the N–U–O(carboxylate) angles are slightly larger [mean value 62.2(4)°]. These differences likely result from the less crowded uranium environment in **2**. The

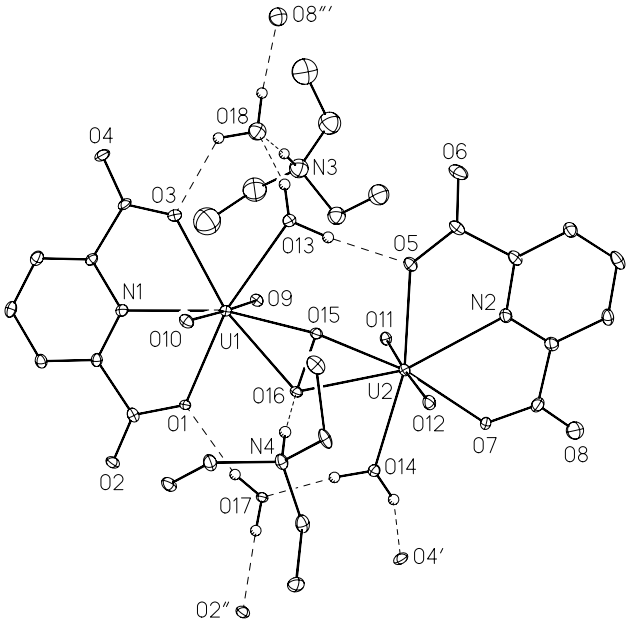

Fig. 2. View of the complex $[HNEt_3]_2[(UO_2)_2L_2O_2(H_2O)_2] \cdot 2H_2O$ (**2**). The hydrogen atoms not involved in hydrogen bonding have been omitted. Hydrogen bonds are shown as dashed lines. Displacement ellipsoids are drawn at the 10% probability level. Symmetry codes: ′ = *x*, 1+*y*, *z*; ″ = 1 − *x*, 1 − *y*, 1 − *z*; ‴ = *x*, *y* − 1, *z*.

O–O and the mean U–O(peroxo) bond lengths, 1.464(9) and 2.37(8) Å, are in fair agreement with the values found in the molecular cages, 1.48(5) and 2.33(3) Å [14a] or 1.541(13) and 2.38(6) Å [14b] as well as with the mean values for the $(UO_2)_2(\mu\text{-}\eta^2,\eta^2\text{-peroxo})$ molecular systems previously reported, 1.478(12) and 2.324(13) Å [15]. However, the bonding of the $\mu\text{-}\eta^2$, η^2-peroxide ion in **2** is slightly asymmetric, with mean values of 2.304(17) and 2.43(3) Å for the U–O15 and U–O16 bond lengths, and 128.9(3)° and 117.4(3)° for the angles U1–O15–U2 and U1–O16–U2, respectively. This may be partly due to the involvement of O16 in a strong hydrogen bond with a triethylammonium counter-ion (see below). The dihedral angle characterizing the folding about the O–O bond in the U_2O_2 central group amounts to 44.2(3)° and the dihedral angle between the mean planes defined by the six donor atoms around each uranyl ion is 39.52(11)°. The mean U–O(water) bond length, 2.49(2) Å, agrees with the mean value of 2.45(3) Å for the similar groups present in the Cambridge Structural Database (CSD, Version 5.25) [16]. The U1···U2 distance of 4.1570(6) Å indicates the absence of any metal–metal bond. The carboxylate donor atoms are closer to the best aromatic mean planes than in compound **1**, with deviations lower than 0.14(2) Å. The two triethylammonium ions are differently bound to the complex unit: one of them, containing N4, forms a hydrogen bond with the peroxide atom O16, as stated above, whereas the other one, containing N3, acts as a hydrogen bond donor towards the water molecule containing O18, which is also an acceptor from the coordinated water molecule containing O13. The latter forms a second bond with the coordinated carboxylate atom O5. The second coordinated water molecule (O14) is a donor towards another water molecule (O17) and the non-coordinated carboxylate atom O4 of a neighbouring complex unit related to the first by a translation along the *b*-axis. The two non-coordinated water molecules are further hydrogen bond donors towards the coordinated carboxylate atoms O1 and O3 in the same unit, and also towards the non-coordinated ones O2 and O8 from different neighbouring complexes related to the first unit by a symmetry centre or a translation along the *b*-axis, respectively. Each asymmetric unit is thus connected to three of its neighbours through six water-carboxylate hydrogen bonds (two per neighbour), which gives rise to the formation of double-stranded ribbons roughly parallel to the *ab*-plane and running along the *b*-axis.

Compounds **3**, **4** and **5** present many common features: all are doubly bridged dianionic dimers in which the uranium atom is in a pentagonal bipyramidal environment. In compounds **3**, $[HNEt_3]_2[(UO_2)_2L_2(OH)_2] \cdot 2H_2O$ (Fig. 3), and **4**, $[HNEt_3][HNMe_2(CH_2)_2\text{-}NMe_2][(UO_2)_2L_2(OH)_2] \cdot 2H_2O$ (Fig. 4), the bridging involves two μ_2-hydroxide groups, whereas it is effected through two μ_2-methoxide groups in compound **5**, $[HNEt_3]_2[(UO_2)_2L_2(MeO)_2] \cdot MeOH \cdot H_2O$ (Fig. 5). The anionic complex in **3** contains an inversion centre, whereas those in **4** and **5** have no crystallographic symmetry.

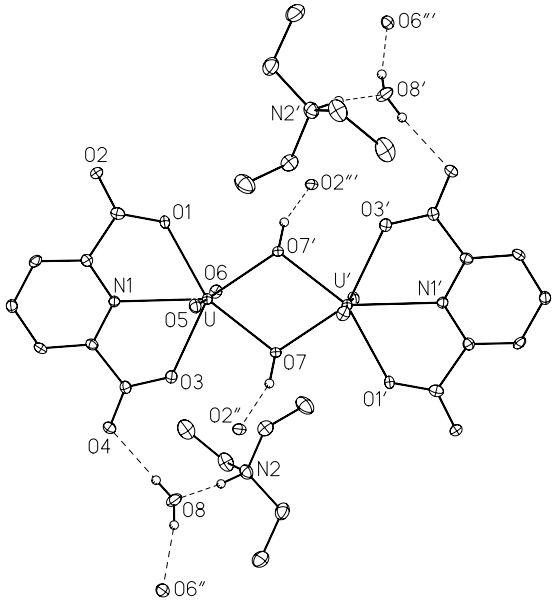

Fig. 3. View of the complex $[HNEt_3]_2[(UO_2)_2L_2(OH)_2] \cdot 2H_2O$ (**3**). The hydrogen atoms not involved in hydrogen bonding have been omitted. Hydrogen bonds are shown as dashed lines. Displacement ellipsoids are drawn at the 30% probability level. Symmetry codes: ′ = −*x*, −*y*, 1 − *z*; ″ = *x*, 0.5 − *y*, *z* − 0.5; ‴ = −*x*, *y* − 0.5, 1.5 − *z*.

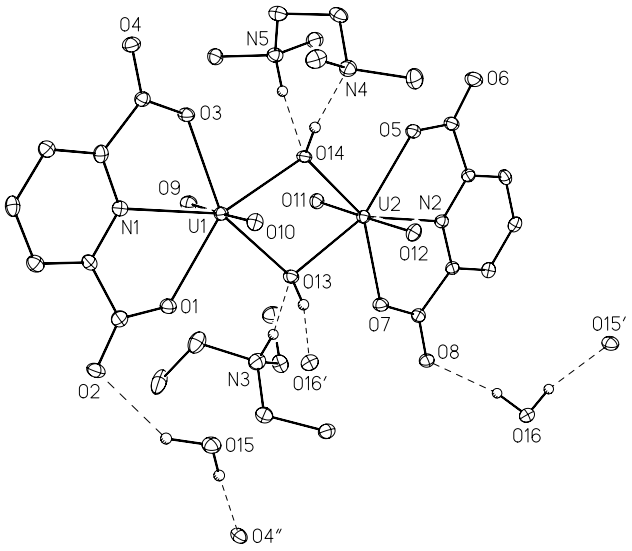

Fig. 4. View of the complex $[HNEt_3][HNMe_2(CH_2)_2NMe_2][(UO_2)_2L_2(OH)_2]\cdot 2H_2O$ (**4**). The hydrogen atoms not involved in hydrogen bonding have been omitted. Hydrogen bonds are shown as dashed lines. Displacement ellipsoids are drawn at the 20% probability level. Symmetry codes: $' = 1-x, -y, -z$; $'' = 2-x, y-0.5, 0.5-z$.

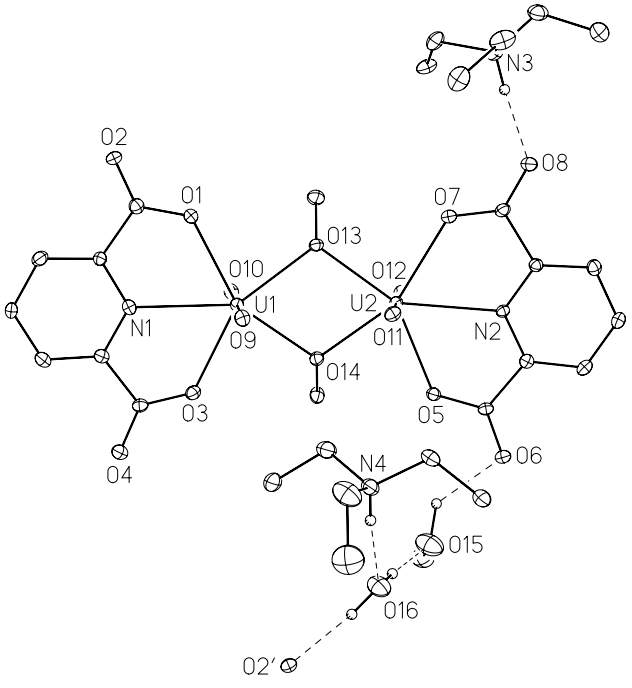

Fig. 5. View of the complex $[HNEt_3]_2[(UO_2)_2L_2(MeO)_2]\cdot MeOH\cdot H_2O$ (**5**). The hydrogen atoms not involved in hydrogen bonding have been omitted. Hydrogen bonds are shown as dashed lines. Only one position of the disordered ethyl group is represented. Displacement ellipsoids are drawn at the 20% probability level. Symmetry code: $' = x, 1+y, z$.

The U–N and U–O(carboxylate) bond lengths, with mean values of 2.542(5) and 2.377(11) Å, respectively, are shorter than in **1** (by about 0.08 Å) and even than in **2** (by about 0.035 Å), as expected from the difference in coordination number and geometry, as previously noticed [7]. The mean U–O(methoxo) bond length in **5**, 2.346(8) Å, is not different from the mean U–O(hydroxo) bond length in **3** and **4**, 2.349(16) Å and both are in good agreement with the mean U–O bond length for dihydroxide bridges in the CSD, 2.345(5) Å. To the best of our knowledge, compound **5** is the first example of a uranyl complex with methoxide bridges to be crystallographically characterized; however, comparable mean U(uranyl)–O(alkoxo) bond lengths have been reported [17–21] and several examples of bridging phenoxide ligands are also found in the CSD, with a mean U–O bond length of 2.44(9) Å. One example only of a terminal methanol/methoxide ligand has been reported for the uranyl ion, in which the hydroxylic proton is distributed over the methanol and methoxide ligands of adjacent units [22]; as expected, the mean U–O bond length in this case, 2.31(5) Å, is shorter than for the bridging species. The central U_2O_2 group in **5** defines a plane with a rms deviation of 0.112 Å, with respect to which the two methoxide carbon atoms are displaced (on the same side) by 1.119(10) and 1.045(10) Å. The N–U–O(carboxylate) angles in all three compounds [mean value 63.3(2)°] are about 3° larger than the corresponding angles in **1**, in keeping with the shorter bond lengths, whereas the O(carboxylate)–U–O(bridge) angles span a wide range [71.21(13)°–85.32(16)°]. The five equatorial donor atoms around each uranium atom define mean planes with rms deviations lower than 0.10 Å. The dihedral angle between the pentagonal mean planes in each dimer is 0°, 8.57(8)° and 12.68(10)° in **3**, **4** and **5**, respectively; all complexes are thus nearly planar. The mean value of the U–O–U angles around the bridging atoms is 107.6(7)° in **3**–**5** and the U···U distances are 3.8015(4), 3.7907(3) and 3.7791(4) Å in **3**, **4** and **5**, respectively. The displacements of the donor carboxylate oxygen atoms with respect to the best mean aromatic planes are in the range 0.008(11)–0.196(8) Å. It may be noted that dinuclear Fe^{III} and Cr^{III} complexes with the ligand L and μ_2-hydroxide double bridges have been reported previously, but the metal ion environment is distorted octahedral in these cases [23].

Compounds **3**–**5** further differ by their counter-ions and/or the features of the hydrogen bonding network. In compound **3**, the two crystallographically equivalent triethylammonium ions are hydrogen bonded to a water molecule, the latter also bridging between the non-coordinated carboxylate atom O4 in the same unit and the uranyl oxo atom O6 in the adjacent unit related by the glide plane perpendicular to the *b*-axis. The hydroxide ion is in its turn bound to the non-coordinated atom O2 of the same neighbouring unit. Each complex is thus linked to four of its neighbours by eight hydrogen bonds, which gives rise to sheets parallel to the *bc*-plane containing molecules tilted with respect to one another. Only in the case of **4** the potential additional bidentate

species was found in the isolated crystalline complex, actually as a counter-ion along with triethylammonium ion, rather than as a ligand. In this case, the triethylammonium ion is simply hydrogen bonded to the hydroxide atom O13, but the behaviour of the mono-protonated *N*,*N*,*N*′,*N*′-tetramethylethylenediammonium counter-ion is more interesting since it is both a donor (through N5) and an acceptor (through N4) with respect to the hydroxide group HO14. This leads to the formation of a seven-membered ring stabilized by cooperative (homodromic) hydrogen bonds [24]. The water molecule H_2O15 links two neighbouring molecules, related by a binary screw axis, through the carboxylate atoms O2 and O4, while H_2O16 is both an acceptor from O13 in an adjacent unit related by a symmetry centre and a donor towards O8 and O15, the latter in the same neighbouring unit. Hence, six hydrogen bonds insure the linking of each unit to three of its neighbours and result in the formation of sheets perpendicular to the $(1\,0\,-2)$ direction. In compound **5**, one of the triethylammonium ions, N3, is bound to the uncoordinated carboxylate oxygen O8 and the other, N4, to a water molecule, O16. The latter acts as a donor towards the solvent methanol molecule, O15, itself bound to the carboxylate oxygen O6, and towards the carboxylate atom O2 of a neighbouring molecule related to the first by a translation along the *b*-axis. This results in a linking of each complex moiety to two of its neighbours by two hydrogen bonds only and the subsequent formation of chains of parallel molecules directed along the *b*-axis.

4. Conclusion

The use of tertiary amines in the synthesis of complexes of uranyl ions with pyridine-2,6-dicarboxylic acid has enabled us to obtain new dinuclear compounds, different from the complexes obtained up to now with this system. These 2:2 dimers present many common features, the differences being apparently due to the presence in the experimental conditions employed, basic and non-water free, of several bridging species currently observed in uranyl chemistry, such as peroxide or hydroxide anions, and also, more surprisingly, methoxide anions, which had never been found before to bridge two uranyl ions. Such roughly planar dinuclear complexes are so readily formed that little can be expected of this system, under the present conditions, as a way to get supramolecular architectures based on coordination bonds. However, extended hydrogen bonding due to the counter-ions and solvent molecules result in the formation of infinite chains, ribbons or sheets. The role of the additional ligand used during the synthesis of the complexes is far from being understood. Although the synthesis of most 2:2 dimeric complexes was not a rational one and a control of the reaction outcome seems very difficult, the variations observed in the crystal structures upon slight changes in the reaction environment points out the versatility of LH_2 as a ligand, at least for the uranyl ion.

Abstract

The synthesis and characterization of $Q[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ [Q = NEt_4 (**1**), PPh_4 (**2**)], $Q[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ [Q = NEt_4 (**3**), PPh_4 (**4**), K (**5**)] and $Q[Ru_2I_2(\mu\text{-}O_2CMe)_4]$ [Q = NEt_4 (**6**), PPh_4 (**7**)] are described. All compounds have been characterized by elemental analysis, spectroscopic, mass and magnetic data. The structures of **1–3**, **5** and **7** are determined by the single crystal X-ray diffraction method. The Ru–Ru bond distances vary from 2.2956(5) to 2.312(3) Å, slightly longer than those observed in the corresponding discrete dinuclear complexes $Ru_2X(\mu\text{-}O_2CR)_4(S)$ (S = solvent molecule) with Ru–X terminal and in the polymeric arrangement $[Ru_2X(\mu\text{-}O_2CR)_4]_n$ with Ru–X–Ru bonds. The anionic complexes have two axially coordinated halide ligands. The Ru–X bond distance is in accordance with the size of the axial ligand. Thus, the Ru–Cl bond lengths are 2.5396(15) and 2.5627(10) Å, respectively for **1** and **2**; the Ru–Br distances are 2.6763(14) (**3**) and 2.6779(4) Å (**5**), and the Ru–I length are 2.897(2) and 2.893(2) Å in **7**. The crystal structure determination of complexes **3** and **5** constitutes the first examples of dibromotetracarboxylatodiruthenium(II,III) compounds. The electronic properties of all the compounds are also explored. Their solvatochromism is less accentuated than the corresponding monohalo derivatives.

1. Introduction

Numerous halotetracarboxylatodiruthenium(II,III) complexes, and especially chloro derivatives, of the formula $Ru_2X(\mu\text{-}O_2CR)_4$ (X = halide; R = alkyl, aryl) have been described [1,2]. In these compounds the diruthenium atoms are bridged by four carboxylate ligands, having one axial position occupied by one halogen atom. In the solid state, most of them show a polymeric structure where the dinuclear units are linked by the halide ligands giving zigzag or linear chains [3–16]. Discrete dinuclear molecules of the type $Ru_2X(\mu\text{-}O_2CR)_4(S)$ (S = solvent molecule) have also been reported [4,5,17–19]. Several methods to remove the chloride ligand have been used and many cationic compounds with the general formula $[Ru_2(\mu\text{-}O_2CR)_4(L)_2]^+A^-$ (L = neutral ligand; A = BF_4, PF_6, BPh_4) have been isolated [1,2]. In contrast, anionic tetracarboxylatodiruthenium(II,III) complexes have been scarcely reported. Miskowski and Gray studied the species $[Ru_2X_2(\mu\text{-}O_2CPr)_4]^-$ (X = Cl, Br, I) in solution but the corresponding compounds were not isolated [20]. Only the crystal structures of $K[Ru_2Cl_2(\mu\text{-}O_2CH)_4]$, $Cs[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ and $[RuCl(MeCN)_4(PPh_3)][Ru_2Cl_2(\mu\text{-}O_2CC_6H_4\text{-}p\text{-}OMe)_4]$ have been described [13,21]. However, anionic units $[Ru_2X_2(\mu\text{-}O_2CR)_4]^-$

doi:10.1016/j.poly.2004.11.018

have been found in some compounds with the formula $Ru_2X(\mu\text{-}O_2CR)_4(H_2O)$ [4,10]. Thus, the crystal of $Ru_2Cl(\mu\text{-}O_2CCH_2OEt)_4(H_2O)$ contains not only $Ru_2Cl(\mu\text{-}O_2CCH_2OEt)_4$ zigzag chains but also $[Ru_2(\mu\text{-}O_2CCH_2OEt)_4(H_2O)_2]^+$ cations and $[Ru_2Cl_2(\mu\text{-}O_2CCH_2OEt)_4]^-$ anions [10]. Recently, we have also published [4] the first crystal structure of a iododiruthenium complex, $[Ru_2(\mu\text{-}O_2CCH_2CH_2OPh)_4(H_2O)_2]$-$[Ru_2I_2(\mu\text{-}O_2CCH_2CH_2OPh)_4]$, which shows a cation–anion arrangement in the solid state.

A few anionic tetracarboxylatodiruthenium(II,III) complexes such as $[Ru_2(\mu\text{-}O_2CC_6H_5)_4(EtOH)_2][Ru_2(\mu\text{-}O_2CC_6H_5)_4(HSO_4)_2]$ [22] and $M_3[Ru_2(\mu\text{-}O_2CR)_4(H_2O)_2]\cdot 4H_2O$ (M = Na, R = *m*-$C_6H_4SO_3$; M = K, R = *p*-$C_6H_4SO_3$) [23] have also been described.

The sole example of a dihalotetracarboxylatodiruthenium(II) complex is $[RuCl(MeCN)_4(PPh_3)]_2[Ru_2Cl_2(\mu\text{-}O_2CC_6H_4\text{-}p\text{-}OMe)_4]$ [21], whereas no example of dihalotetracarboxylatodiruthenium(III) is yet known. Even for diruthenium(III) with other equatorial bridging ligands, very few crystal structures of dihalo complexes have been reported [24].

In a previous paper [5] we have described the influence of the halide axial ligand on the properties of the monohalo complexes $Ru_2X(\mu\text{-}O_2CR)_4(S)$ and we have found a strong solvatochromism in the iododerivatives. In this work we report the synthesis of a series of tetraacetatodiruthenium(II,III) compounds where both axial positions are occupied by halide ligands, and analyse their properties. The comparison with the monohalo complexes is also illustrated.

2. Results and discussion

2.1. Synthesis and characterization of the complexes

In the aim to obtain heterometallic species we carried out the reaction of $[Ru_2(\mu\text{-}O_2CMe)_4]BF_4$ with $(NEt_4)_2[CoX_4]$ (X = Cl, Br) in MeOH. However, instead of the formation of heterometallic compounds, the rupture of the Co–X bonds occurs and the formation of the dihalo complexes $NEt_4[Ru_2X_2(\mu\text{-}O_2CMe)_4]$ is produced. The compounds $Q[Ru_2X_2(\mu\text{-}O_2CMe)_4]$ (Q = NEt_4, PPh_4; X = Cl, Br, I) and $K[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ were synthesized using QX and KBr, respectively. $NEt_4[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ can be also obtained directly by the reaction of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ with an excess of NEt_4Cl.

All compounds are thermally stable and can be manipulated in air without appreciable decomposition for a long period of time. The complexes are soluble in dichloromethane or acetone, but insoluble in diethyl ether, toluene or petroleum ether. The tetraphenylphosphonium compounds are always more soluble than the corresponding triethylammonium derivatives. The conductivity measurements in acetone and acetonitrile (101–138 and 126–160 $\Omega^{-1}cm^2mol^{-1}$, respectively) indicate that these complexes are 1:1 electrolytes [25]. However, the conductivity is higher in methanol solution (232–280 $\Omega^{-1}cm^2mol^{-1}$) because of the dissociation of the axial halide ligands.

The IR spectra show in the COO stretching region the typical pattern of a bridging carboxylate ligand. Complexes **1**–**4** and **6**–**7** exhibit characteristic bands of the corresponding cation, $[NEt_4]^+$ or $[PPh_4]^+$.

The room temperature magnetic moment of complexes **1**–**7** corresponds to the presence of three unpaired electrons for the diruthenium unit, in accordance with the $\sigma^2\pi^4\delta^2(\pi^*\delta^*)^3$ ground-state configuration proposed by Norman et al. [26]. The molar susceptibility χ_M increases continuously with decreasing temperature (300–2 K) and a decrease of the magnetic moment with the temperature is observed for all complexes. A similar behaviour has been noticed in other molecular and zigzag polymeric compounds of diruthenium(II,III) [4,5,11,12,15,27] and has been ascribed to a large zero-field splitting (ZFS) and some degree of antiferromagnetic coupling between the diruthenium units. The model of Cukiernik et al. [11] was successfully used to fit the magnetic data of complexes **1**–**7**, obtaining in all cases similar parameters to those described for other diruthenium(II,III) species [4,5,11,12,15]. The zJ values (from -0.02 to -0.11 cm^{-1}) are almost negligible, in accordance with the presence of isolated anionic dimetallic units in the compounds.

The base peak in all mass spectra corresponds to the cation $[NEt_4]^+$ (**1**, **3**, and **6**) or $[PPh_4]^+$ (**2**, **4**, and **7**) and one peak due to the ion $[Ru_2(\mu\text{-}O_2CMe)_4]^+$ is also detected.

2.2. Electronic properties

The electronic spectral data for complexes **1**–**7** in several solvents are collected in Table 1. These compounds show in methanol solution the same electronic spectra corresponding to the species $[Ru_2(\mu\text{-}O_2CMe)_4(MeOH)_2]^+$. A similar behaviour has been observed for the monohalo complexes $Ru_2X(\mu\text{-}O_2CR)_4$ [5], due to the breaking of the Ru–X bonds and the formation of bis(adducts) units $[Ru_2(\mu\text{-}O_2CR)_4(MeOH)_2]^+$, and for cationic species [28]. However, their electronic spectra in dichloromethane, acetonitrile and acetone are different. The presence of the dihalo species was confirmed by the equality of the spectra registered in neat solvents and solutions saturated with QX ($Q = PPh_4^+, NEt_4^+$). The electronic spectra of these species is consistent with those described by Miskowski and Gray [20] for $Ru_2X(\mu\text{-}O_2CPr)_4$ in an excess of halide ions. As expected, the counterion has no influence in the electronic spectra of the complexes.

However, some important differences have been observed varying the nature of the axial ligands. The main visible band for the chloro derivatives (**1** and **2**) appears

at 464–468 nm in dichloromethane, acetonitrile and acetone. This absorption has been assigned to a π(RuO,Ru_2) → π*(Ru_2) transition according to Norman et al. [26] and Miskowski et al. [20,29]. In the dibromo derivatives this absorption is very slightly red shifted (474–480 nm) and remains essentially unaltered changing the nature of the solvents. The greatest shift is observed for the iodo complexes, which show this band in the range 545–566 nm. Moreover, this absorption is sensitive to the nature of the solvents: 545–546 nm in acetonitrile, 554 nm in dichloromethane and 566 nm in acetone.

The complexes $Q[Ru_2X_2(\mu\text{-}O_2CMe)_4]$ (Q = PPh_4, NEt_4) also display a shoulder ranging from 619–649 nm for the dichloro derivatives, which is shifted to 631–672 nm in the dibromo complexes, and to 701–788 nm in the diiodo derivatives. This absorption is attributed to a (Ru-axial ligand) → π*(Ru_2) transition, analogous to the monohalo compounds [5]. Two additional absorption bands appear in the ranges 339–427 and 986–1174 nm, which are assigned to LMCT π(axial ligand) → π*(Ru_2) and δ → δ* transitions, respectively. Similarly to the monoiodo derivatives [5] the absorption detected for the $Q[Ru_2I_2(\mu\text{-}O_2CMe)_4]$ compounds in the range 336–343 nm could be assigned to a σ(Ru-axial ligand) → σ*(Ru_2) transition.

As indicated above, the presence of two iodide ligands at the axial positions of the $[Ru_2(\mu\text{-}O_2CMe)_4]^+$ unit shifts the π(RuO,Ru_2) → π*(Ru_2) transition to the visible range, alike to the $Ru_2I(\mu\text{-}O_2CR)_4(S)$ compounds [5]. A strong solvatochromism has been observed for these monoiodo complexes due mainly to the coordination of a solvent molecule at the free axial position of the dimetallic unit. This coordination is not possible for the $[Ru_2I_2(\mu\text{-}O_2CR)_4]^-$ species, however, a significant solvatochromism is still perceived.

2.3. Crystal structures

The structure of complexes **1**–**3**, **5** and **7** have been determined by X-ray crystallography. PLUTO views of complexes **1**, **5** and **7** are depicted in Figs. 1–3. The corresponding figures for complexes **2** and **3** are deposited as supplementary material. Table 2 gives selected bond distances and angles. The anionic unit of these com-

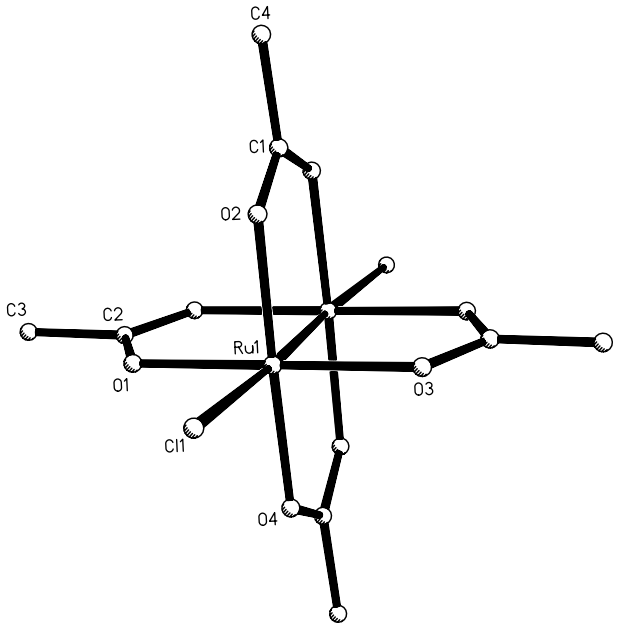

Fig. 1. PLUTO view of the anion $[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]^-$ corresponding to complex **1**. Hydrogen atoms are omitted for clarity.

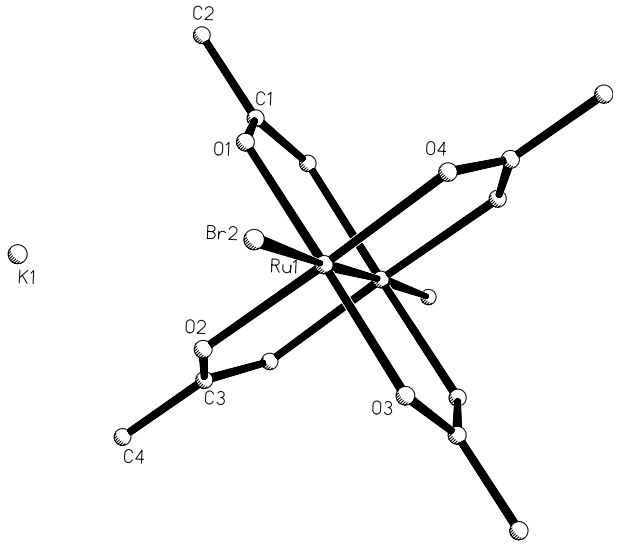

Fig. 2. PLUTO view of $K[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ (**5**). Hydrogen atoms are omitted for clarity.

pounds have two Ru atoms linked by four acetate bridging ligands and the axial positions are occupied by two halide ligands. The cations in these complexes are NEt_4^+ for **1** and **3**, PPh_4^+ for **2** and **7**, and K^+ in **5**.

The Ru–Ru bond lengths for **1**–**3** and **5** are 2.3069(8), 2.3088(6), 2.2999(16), and 2.2956(5) Å, respectively. The Ru–Ru distances for **7** are 2.312(3) and 2.311(3) Å. The metal–metal distance in these dihalocomplexes are slightly longer than those observed in discrete dinuclear molecules $Ru_2X(\mu\text{-}O_2CR)_4(S)$ [3–5] with Ru–X terminal or in polymeric arrangement $[Ru_2X(\mu\text{-}O_2CR)_4]_n$ [3,5], with the only exception of $Cs[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ [13] (Table 3). This tendency is in agreement with the metal-metal distances found in $Ru_2Cl(\mu\text{-}O_2CCH_2OEt)_4(H_2O)$ [10], which contains both anionic (2.294(2) Å) and polymeric (2.277(1) Å) arrangements in the same crystal.

On the other hand, the distance Ru–X varies with the size of the halide ligand. Thus, the Ru–X bond lengths are 2.5396(15) (**1**) and 2.5627(10) (**2**) Å (X = Cl), 2.6763(14) (**3**) and 2.6779(4) (**5**) Å (X = Br), and 2.897(2) and 2.893(2) (**7**) Å (X = I). Only Ru–Cl lengths between $[Ru_2Cl_2(\mu\text{-}O_2CR)_4]^-$ and $[Ru_2Cl(\mu\text{-}O_2CR)_4]_n$ may be compared (Table 3), because there are no other couples of mono- and dihalodiruthenium(II,III) species with the same carboxylate ligand. In contrast to the Ru–Ru bond distance, the metal–chloride length in these complexes are slightly longer in the polymeric arrangements than in the anionic units with two chloride ions at the axial positions. This tendency is illustrated with the Ru–Cl distances in $[Ru_2Cl(\mu\text{-}O_2CCH_2OEt)_4]_n$

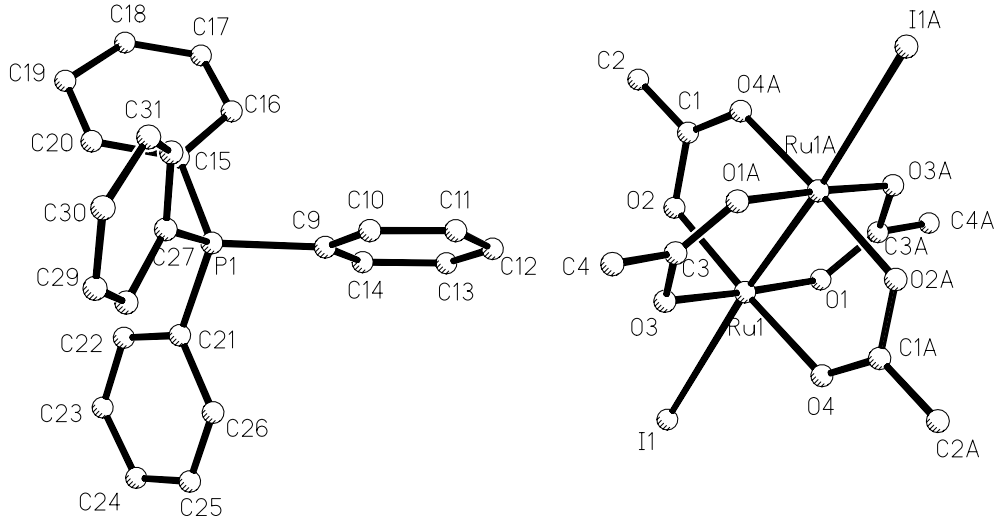

Fig. 3. PLUTO view of $PPh_4[Ru_2I_2(\mu\text{-}O_2CMe)_4]$ (**7**). The complete anionic unit A has been generated by symmetry. Hydrogen atoms and half anionic unit B are omitted for clarity.

3. Conclusions

In this work, we have reported two routes to the preparation of anionic diruthenium(II,III) complexes with two halide ligands at the axial positions. In spite of the tendency of the halotetraacetatodiruthenium(II,III) compounds to give a polymeric structure, in the presence of an excess of halide ligand the formation of $[Ru_2X_2(\mu\text{-}O_2CMe)_4]^-$ is preferred. The other route demonstrates that the tetraacetatodiruthenium(II,III) unit is even capable of abstracting the halide from another complex, namely $[CoX_4]^{2-}$, in order to form these anionic species. Although the diruthenium(II,III) core remains essentially the same in neutral and anionic species, the ruthenium–ruthenium bond lengths in dihalotetracarboxylatodiruthenum(II,III) are slightly longer than those observed in $Ru_2X(\mu\text{-}O_2CR)_4(S)$ or $[Ru_2X(\mu\text{-}O_2CR)_4]_n$. On the contrary, the Ru–X bond distances are shorter for $[Ru_2X_2(\mu\text{-}O_2CR)_4]^-$ species.

The solvatochromism of the diruthenium(II,III) complexes is associated to the presence of halide ligands at the axial positions and increases with their polarizability. However, this property is more accentuated when an axial position is occupied by a solvent molecule.

Finally, these anionic complexes, which contain three unpaired electrons, could be very useful to be combined with admixed or low spin diruthenium(II,III) cationic species [30] in order to obtain materials with singular magnetic properties. The preparation of this type of complexes is currently being investigated.

4. Experimental

All reactions were carried out in an inert atmosphere, using standard Schlenk techniques. The complexes $Ru_2Cl(\mu\text{-}O_2CMe)_4$, $[Ru_2(\mu\text{-}O_2CMe)_4]BF_4$ and $(NEt_4)_2[CoX_4]$ (X = Cl, Br) were prepared by the literature procedures [31–33]. Unless otherwise stated, other chemical and solvents were obtained from commercial sources and used without further purification.

Elemental analyses were done by the Microanalytical Service of the Complutense University of Madrid. IR spectra were recorded on a Midac prospect FT-IR or on a Shimadzu FT-IR Prestige-21 spectrophotometer using KBr discs. Electronic spectra in the range 250–1300 nm were recorded on a Cary 5G spectrophotometer in solutions 10^{-4} M of methanol, acetone, dichloromethane and acetonitrile. The variable-temperature magnetic susceptibility data were measured on a Quatum Design MPMS*XL* SQUID (Superconducting Quantum Interference Device) susceptometer over a temperature range of 2–300 K. All data were corrected for the diamagnetic contribution of both the sample holder and the compound to the susceptibility. The molar diamagnetic corrections for the complexes were calculated on the basis of Pascal's constants. Mass spectra were obtained on a Bruker Esquire-LC with Electrospray Ionization (ESI) using methanol. Nominal molecular masses and distribution isotopic of all peaks were calculated with the MASAS [34] computer program, using a polynomial expansion based on natural abundances of the isotopes.

4.1. Synthesis of $NEt_4[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ (1)

This complex was obtained by two ways: (a) To a solution of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ (0.15 g, 0.32 mmol) in 40 mL of MeOH was added an excess of NEt_4Cl (0.53 g, 3.20 mmol) in 5 mL of MeOH. The reaction mixture was stirred for 30 min. The solution was filtered and the red–brown solid was washed with methanol and diethyl ether, and dried under vacuum to give **1**. Yield: 0.13 g (65%). (b) A suspension of $[Ru_2(\mu\text{-}O_2CMe)_4]BF_4$ (0.15 g, 0.29 mmol) and $(NEt_4)_2[CoCl_4]$ (0.13 g, 0.29 mmol) in 40 mL of dry methanol was stirred for 2 h giving a red–brown solution. This solution was layered with diethyl ether to form red–brown microcrystals of **1** suitable for X-ray study. Yield: 0.09 g (45%). *Anal*. Calc. for $Ru_2O_8NCl_2C_{16}H_{32}$: C, 30.05; H, 5.04; N, 2.19. Found: C, 30.19; H, 5.05; N, 2.28%. IR (KBr, cm^{-1}) = 2984 (m), 2949 (m), 2920 (w), 1642 (w), 1473 (vs), 1450(vs), 1423 (vs), 1409 (vs), 1394 (vs), 1352 (s), 1176 (m), 1056 (s), 1022 (w), 1003 (m), 788 (m), 689 (vs), 631 (m), 604 (w). $\mu_{eff.}$ = 4.06 B.M. at r.t. MS in MeOH (ESI^+): m/z = 440 $[Ru_2(\mu\text{-}O_2CMe)_4 + H]$, 130 $[NEt_4]$.

4.2. Synthesis of $PPh_4[Ru_2Cl_2(\mu\text{-}O_2CMe)_4]$ (2)

To a solution of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ (0.15 g, 0.32 mmol) in 40 mL of MeOH was added an excess of PPh_4Cl (1.20 g, 3.20 mmol) in 15 mL of MeOH. The solution was stirred for 30 min and the volatile components were removed under vacuum. The red–brown solid was washed several times with acetone, dried, and redissolved in 30 mL of MeOH. By slow evaporation of this solution, red crystals of the title compound were obtained. Yield: 0.11 g (40%). *Anal*. Calc. for $Ru_2O_8PCl_2C_{32}H_{32}$: C, 45.29; H, 3.80. Found: C, 45.73; H, 3.84%. IR (KBr, cm^{-1}) = 3060 (w), 2923 (w), 1710 (w), 1637 (w), 1586w (w), 1477 (m), 1439 (vs), 1407 (s), 1351 (w), 1318 (w), 1108 (m), 996 (w), 764 (w), 757 (w), 722 (m), 690 (s), 530 (m). $\mu_{eff.}$ = 4.16 B.M. at r.t. MS in MeOH (ESI^+): m/z = 440 $[Ru_2(\mu\text{-}O_2CMe)_4 + H]$, 474 $[Ru_2Cl(\mu\text{-}O_2CMe)_4]$, 339 $[PPh_4]$.

4.3. Synthesis of $NEt_4[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ (3)

Two methods were used to obtain this compound: (a) An aqueous solution of $AgNO_3$ (0.05 g, 0.32 mmol) was

added to a suspension of $Ru_2Cl(\mu\text{-}O_2CMe)_4$ (0.15 g, 0.32 mmol) in 10 mL of MeOH. The solution was filtered and treated with an excess of NEt_4Br (0.67 g, 3.20 mmol) in 20 mL of MeOH. The reaction mixture was stirred for 30 min and filtered. The red–brown solid was washed with methanol, and dried under vacuum to give **3**. Yield: 0.14 g (61%). (b) The reaction was carried out following the same procedure described for **1** (method b), using $(NEt_4)_2[CoBr_4]$ (0.19 g, 0.29 mmol) and refluxing the reaction mixture for 4 h. Yield: 0.11 g (48%). Crystals of **3** were obtained similarly to **1**. *Anal*. Calc. for $Ru_2O_8NBr_2C_{16}H_{32}$: C, 26.38; H, 4.43; N, 1.92. Found: C, 26.52; H, 4.42; 1.95 N%. IR (KBr, cm^{-1}) = 2982 (m), 2948 (w), 2919 (w), 1640 (w), 1498 (s), 1442 (vs), 1407 (vs), 1392 (s), 1351 (m), 1174 (m), 1054 (m), 1020 (w), 1002 (m), 786 (m), 688 (vs), 629 (m), 604 (w). $\mu_{eff.}$ = 4.10 B.M. at r.t. MS in MeOH (ESI^+): *m/z* = 440 [$Ru_2(\mu\text{-}O_2CMe)_4$+H], 518 [$Ru_2Br(\mu\text{-}O_2CMe)_4$], 130 [$NEt_4$].

4.4. Synthesis of $PPh_4[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ (**4**)

Compound **4** was prepared similarly to **3** (method a), using PPh_4Br (1.34 g, 3.20 mmol) and water instead of MeOH, and isolated as red–brown powder. Yield: 0.20 g (67%). *Anal*. Calc. for $Ru_2O_8PBr_2C_{32}H_{32}$: C, 41.00; H, 3.44. Found: C, 40.76; H, 3.37%. IR (KBr, cm^{-1}) = 3010 (w), 2925 (w), 2360 (w), 2342 (w), 1627 (m), 1482 (m), 1471 (m), 1441(vs), 1399 (s), 1350 (m), 1184 (w), 1163 (w), 1108 (s), 1046 (w), 1029 (w), 996 (w), 758 (m), 723 (s), 691 (vs), 605 (w), 527 (s). $\mu_{eff.}$ = 3.94 B.M. at r.t. MS in MeOH (ESI^+): *m/z* = 440 [$Ru_2(\mu\text{-}O_2CMe)_4$+H], 339 [$PPh_4$].

4.5. Synthesis of $K[Ru_2Br_2(\mu\text{-}O_2CMe)_4]$ (**5**)

A solution of KBr (0.35 g, 2.90 mmol) in 10 mL of water was layered with a solution of $[Ru_2(\mu\text{-}O_2CMe)_4]BF_4$ (0.15 g, 0.29 mmol) in 15 mL of ethanol. After two days, a precipitate of $Ru_2Br(\mu\text{-}O_2CMe)_4$ had accumulated at the bottom of the Schlenk tube and crystals of **5**, suitable for X-ray study, were formed at the interface. The crystals were carefully collected and dried. Yield: 0.014 g (7%). *Anal*. Calc. for $Ru_2O_8KBr_2C_8H_{12}$: C, 15.08; H, 1.90. Found: C, 15.02; H, 1.85%. IR (KBr, cm^{-1}) = 2933 (w), 1644 (w), 1440 (vs), 1405 (s), 1346 (s), 1262 (w), 1053 (m), 804 (w), 693 (vs), 629 (m), 609 (w). MS in MeOH (ESI^+): *m/z* = 439 [$Ru_2(\mu\text{-}O_2CMe)_4$].

4.6. Synthesis of $NEt_4[Ru_2I_2(\mu\text{-}O_2CMe)_4]$ (**6**)

Compound **6** was obtained similarly to **3** (method a), using NEt_4I (0.82 g, 3.20 mmol), and isolated as red–brown powder. Yield: 0.16 g (62%). *Anal*. Calc. for $Ru_2O_8NI_2C_{16}H_{32}$: C, 23.37; H, 3.92; N, 1.70. Found: C, 23.42; H, 3.95; N, 1.73%. IR (KBr, cm^{-1}) = 2980 (m), 2914 (m), 1653 (w), 1473 (s), 1460 (vs), 1421 (vs), 1405 (vs), 1356 (s), 1349 (s), 1291 (w), 1173 (m), 1047 (m), 1026 (w), 998 (m), 785 (m), 690 (vs), 630 (m), 604 (w). $\mu_{eff.}$ = 3.79 B.M. at r.t. MS in MeOH (ESI^+): *m/z* = 440 [$Ru_2(\mu\text{-}O_2CMe)_4$ + H], 130 [NEt_4].

4.7. Synthesis of $PPh_4[Ru_2I_2(\mu\text{-}O_2CMe)_4]$ (**7**)

Complex **7** was synthesized similarly to **3** (method a), using PPh_4I (1.49 g, 3.20 mmol). The red–brown solution was allowed to stand at room temperature for 48 h, yielding red–brown crystals of **7**. Yield: 0.18 g (55%). *Anal*. Calc. for $Ru_2O_8PI_2C_{32}H_{32}$: C, 37.26; H, 3.13. Found: C, 37.30; H, 3.13%. IR (KBr, cm^{-1}) = 3052 (w), 3005 (w), 2966 (w), 2923 (w), 2852 (w), 2837(w), 1647 (w), 1583 (w), 1482 (m), 1441 (vs), 1435 (vs), 1395 (s), 1346 (s), 1315 (m), 1184 (w), 1162 (w), 1107 (vs), 1045 (w), 1027 (m), 995 (m), 756 (s), 722 (s), 690 (vs), 627 (w), 526 (vs). $\mu_{eff.}$ = 3.94 B.M. at r.t. MS in MeOH (ESI^+): *m/z* = 439 [$Ru_2(\mu\text{-}O_2CMe)_4$], 339 [$PPh_4$].

4.8. X-ray crystallography

Single crystals of compounds **1**–**3**, **5** and **7** were obtained as described above. Details for data collection and crystal structure refinement for these compounds are summarised in Table 4. Representative crystals were mounted on a Bruker Smart-CCD diffractometer with graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. In each case data were collected at 293(2) K over a hemisphere of the reciprocal space by a combination of three exposures sets. The cell parameters were determined and refined by a least-squares fit of all reflections collected. The structures were solved by direct methods and refined by the full-matrix least-squares method against F^2 of all data. Calculations were performed with the aid of the SHELXS and SHELXL programs [35,36]. In complexes **1** and **3** a severe disorder of the tetraethylammonium groups was found and the ethyl groups were refined only isotropically; in complex **3** they were refined also with geometrical restraints and a variable common carbon–carbon distance. In addition, in complex **1** the nitrogen atom of the tetraethylammonium ion is located on a centre of symmetry and a conventional draw of the NEt_4 has not been obtained. A similar NEt_4 group has been found, for example, in the cluster complex $(NEt_4)_2[NiRu_2(CO)_{12}]$ [37]. In complexes **3** and **7** the largest residual peaks and holes in the final Fourier difference maps were associated with the nitrogen atom of the tetraethylammonium cation for complex **3** and near to the ruthenium atom for complex **7**. Final mixed refinement for complexes **2**, **5** and **7** was undertaken with anisotropic thermal parameters

for the non-hydrogen atoms. Complex **7** gave only fibrous and polysynthetically twinned crystals, which lead to high R factors.

Received 10 September 2004; accepted 8 November 2004

Abstract

Dinuclear $[Cu(aepi)(N_3)_2]_2$ (**1**) [aepi = 1-(2-aminoethyl)piperidine] and 1D chain $[Cu(aepy)(N_3)_2]_n$ (**2**) [aepy = 1-(2-aminoethyl)pyrrolidine] have been prepared and characterized by means of X-ray analysis and magnetic measurements. For **1**, the Cu(II) centers are doubly bridged by end-on (EO) azido units in a basal–apical fashion. The molecular structure of **2** features magnetic centers that are linked by μ-1,1,3 azido groups, forming a 1D chain with alternating EO and end-to-end (EE) azido bridging patterns. The magnetic data for the dinuclear complex **1** were fitted with the Bleaney–Bowers equation derived from the Hamiltonian $\boldsymbol{H} = -JS_1 \cdot S_2$, affording parameters of $g = 2.093(1)$, $J = -3.06(1)$ cm^{-1} and $zJ' = -1.32(3)$ cm^{-1}. This indicates that the EO azido group mediates an antiferromagnetic interaction. Complex **2** has two possible magnetic pathways: one is through the EO azido bridge (J_{eo}) and the other via the EE bridge (J_{ee}). The alternating chain model with ferromagnetic and antiferromagnetic interactions based on the exchange Hamiltonian $\boldsymbol{H} = -\sum_i [J_1 S_{2i} \cdot S_{2i+1} + J_2 S_{2i} \cdot S_{2i-1}]$ was employed, leading to $g = 2.076(2)$, $J_1 = -3.22(5)$ cm^{-1}, $J_2 = 17.0(5)$ cm^{-1} and $zJ' = -1.34(6)$ cm^{-1}. By taking into account structural parameters of **1** and **2**, it is rationally suggested that J_1 and J_2 are ascribed to J_{eo} and J_{ee}, respectively. These assignments are also ascertained by MO calculations using a spin dimer model.

Keywords: Copper(II) compounds; Crystal structures; Azide ligand; Magnetic properties

1. Introduction

Coordination materials have received much attention because they have intimate relevance to supramolecular chemistry and molecular magnets [1]. Magnetic coordination materials are devised employing bridging ligands, linking at least two metal ions concurrently, through which spins on paramagnetic centers are coupled to each other. Their magnetic natures are definitely governed by the features of bridging ligands. In this vein, it is essential to choose appropriate bridges to rationally design magnetic systems with desirable properties. Among them, azide is one of the good candidates to construct tailor-made magnetic materials in that the magnetic characters of the complexes bridged by azide are readily predicted in view of its binding pattern. The two main coordination modes for the azido ligand are EE and EO. Generally, the EE mode communicates antiferromagnetic couplings and the EO mode transmits ferromagnetic interactions [2]. In recent years, some exceptional compounds were reported such that even the EE mode enables the mediation of ferromagnetic interactions given large M–N_3–M torsion angles that cause accidental orthogonality between magnetic centers [3–5].

DFT calculations on EO azido-bridged Cu(II) systems revealed that critical regions where the magnetic

doi:10.1016/j.poly.2004.11.022

nature is subject to change are at around 104° for Cu–N(azido)–Cu and about 2.05 Å for Cu–N(azido) [6]. However, the magnetic character for the EO azido bridge can be predestined only in the basal–basal bridging mode. When azido groups bridge Cu(II) centers in a basal–apical fashion, the structural parameters described above did not explain the observed magnetic phenomena. For example, dinuclear EO azido-bridged Cu(II) complexes in basal–apical coordination accompanied magnetic properties ranging from ferromagnetic to antiferromagnetic, regardless of the Cu–N(azido)–Cu angle [7–10]. Likewise, in the basal–apical mode, EE azido bridges in the Cu(II) systems propagate magnetic characters spanning from ferromagnetic to antiferromagnetic interactions [11–14]. Therefore, one should be cautious when attempting to understand magnetic behaviors based on the angles especially in the basal–apical systems.

Several coordination polymers having alternating EO and EE azido bridges were characterized structurally and magnetically, showing that the EO and EE bridges are responsible for ferro- and antiferromagnetic interactions, respectively [15–18]. For Cu(II) systems linked by EO and EE azido groups simultaneously, due to the Jahn–Teller effect of the Cu(II) ion giving rise to a tetragonal elongation, they tend to be coordinated to the metal centers in a basal–apical manner [19]. In this case, it would be a challenge to properly assign the magnetic properties to individual EO and EE pathways owing to the aforementioned reasons.

Herein we report the synthesis, crystal structures and magnetic properties of dinuclear $[Cu(aepi)(N_3)_2]_2$ (**1**) [aepi = 1-(2-aminoethyl)piperidine] and the 1D chain $[Cu(aepy)(N_3)_2]_n$ (**2**) [aepy = 1-(2-aminoethyl)pyrrolidine]. During the course of our studies, compound **2** was reported by others, but their magnetic consequences are different from what we observed in the present work [20]. The magnetic behavior for **1**, with doubly bridged by EO azido ligands in the basal–apical mode, exhibits antiferromagnetic couplings. On the other hand complex **2**, with EO and EE azido bridges in the basal–apical mode, shows dominant ferromagnetic interactions in the high temperature region. Based on structural considerations, the EO azido bridge is responsible for an antiferromagnetic route, while the EE azido bridge provides a ferromagnetic pathway. These assignments are confirmed by MO calculations on spin dimers using the extended Hückel tight binding (EHTB) method.

2. Experimental

2.1. Preparation of $[Cu(aepi)(N_3)_2]_2$ (*1*)

To a methanolic solution (10 ml) of copper(II) perchlorate hexahydrate (0.5 mmol) was slowly added aepi (0.5 mmol) by syringe with stirring. The resulting solution was treated with an aqueous solution (10 ml) of sodium azide (1.0 mmol). After filtration of the solution the filtrate was left undisturbed, giving deep green crystals of **1** suitable for X-ray diffraction. The total yield corresponds to 24% based on Cu. *Anal*. Calc. for $C_7H_{16}CuN_8$ (**1**): C, 30.5; H, 5.85; N, 40.6. Found: C, 30.6; H, 6.15; N, 40.5% Selected IR data (cm^{-1}, KBr pellet): 2051, 2041, 2031 [vs, $\nu_a(N_3^-)$].

2.2. Preparation of $[Cu(aepy)(N_3)_2]_n$ (*2*)

To a methanolic solution (10 ml) of copper(II) perchlorate hexahydrate (0.5 mmol) was slowly added aepy (0.5 mmol) by syringe with stirring. A 10 ml aqueous solution of sodium azide (1.0 mmol) was mixed with the resulting solution. The filtrate of the solution was left to stand for several days, providing deep green crystals of **2**. The product was recrystallized from DMF–ether solvent. The total yield amounts to 25% based on Cu. *Anal*. Calc. for $C_6H_{14}CuN_8$: C, 27.5; H, 5.39; N, 42.8. Found: C, 27.9; H, 5.00; N, 42.3%. Selected IR data (cm^{-1}, KBr pellet): 2057, 2035sh, 2028 [vs, $\nu_a(N_3^-)$].

2.3. Physical measurements

Elemental analyses for C, H and N were performed at the Elemental Analysis Service Center of Sogang University. Infrared spectra were obtained from KBr pellets with a Bomen MB-104 spectrometer. Magnetic susceptibilities for **1** and **2** were carried out using a Quantum Design MPMS-7 SQUID susceptometer. Diamagnetic corrections of **1** and **2** were estimated from Pascal's tables.

2.4. X-ray structural analyses

Data were collected at 293 K using an Enraf-Nonius CAD4TSB diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were calculated by least-squares refinement of 25 well-centered reflections. All data were corrected for Lorentz polarization effects. A total of 2172 (**1**) and 2952 (**2**) reflections with a maximum 2θ of 50.30° (**1**) and 50.40° (**2**) were measured and 1660 (**1**) and 2754 (**2**) reflections were assumed to be observed applying the condition $F_o > 4\sigma(F_o)$. Crystallographic data and details of data collection are listed in Table 1.

The structures were solved and refined by least-squares analysis using anisotropic thermal parameters for non-hydrogen atoms with the WINGX program for **1** and **2** [21]. H atoms were calculated at idealized positions ($d_{CH} = 0.970$ for methylene) and refined riding on the corresponding carbon atoms with isotropic thermal parameters [$U = 1.2U(C_{methylene})$].

3. Results and discussion

3.1. Syntheses and characterization

Compound **1** was prepared by the stoichiometric reaction of Cu(II) ion as a magnetic center, aepi as a capping ligand and azide as a bridge in a methanol–water mixed solution. Three strong $\nu_a(N_3^-)$ peaks were observed in the IR spectrum of **1**, suggesting that there exist different types of azide ligands. The X-ray structure of **1** reveals the presence of terminal and EO azido bridges in a dinuclear Cu(II) compound (see below). To probe the structural variation by altering the capping ligand, we selected aepy with a five-membered ring, instead of aepi with a six-membered ring, using the same reaction conditions. As expected, the less bulky aepy ligand forms 1D chain (**2**) and the copper center is surrounded by six atoms, which is compared with **1** that has a coordination number of five around the central copper ion.

3.2. Description of the structures

The structure of **1**, with the asymmetric unit and symmetry related fragments, is shown in Fig. 1. Selected bond distances and angles are tabulated in Table 2. The Cu1 atom possesses a distorted square pyramidal geometry, based on a geometric parameter τ of 0.15 [22], consisting of two nitrogen atoms from aepi [Cu1–N7 = 2.007(4), Cu1–N8 = 2.090(3) Å], one nitrogen atom from terminal azide [Cu1–N1 = 1.971(4) Å], one nitrogen atom from one azido bridge [Cu1–N4 = 1.971(4) Å], which constitute the basal plane [mean Cu—N distance = 2.02(4) Å], and one apical nitrogen atom [Cu1–N4i = 2.381(4) Å; i = 2 − x, −y, 1 − z]. The longer Cu–N bond length is clearly associated with the Jahn–Teller effect on the Cu(II) ion [23]. The Cu1–N4–Cu1i angle is 98.84(15)° and an inversion center is placed midway between Cu1 and Cu1i. The largest deviation from the basal least-squares plane including N1–N4–N7–N8 atoms is 0.110(2) Å at N7 and the Cu1 atom lies −0.155(2) Å out of the plane toward the apical position (N4i). The six-membered ring of the aepi ligand sits in a chair form, exhibiting that the largest deviation from the C3–C4–C6–C7 least-squares plane is present at C7 with 0.003(4) Å and the C5 and N8 atoms are displaced −0.612(9) and 0.657(8) Å from the plane, respectively. The intradimeric Cu1–Cu1i distance separated by double EO azido bridges in the basal–apical mode is 3.348(1) Å.

[a] Symmetry code: i = 2 − x, −y, 1 − z.

The structure of **2** was reported in the literature [20], so we just delineate some structural characteristics related to magnetic behaviors. Fig. 2(a) illustrates an ORTEP diagram showing the asymmetric unit and atom numbering scheme. The Cu atoms (Cu1 and Cu2) adopt distorted octahedral geometries with axial elongations arising from the Jahn–Teller distortion. The torsion angles for Cu1–N11···N9–Cu2 and Cu1–N1···N3–Cu2 are different, 60.1(5)° and 6.2(7)°, respectively. The Cu—N–N angles concerning the EE azido bridges correspond to 123.0(4)° for Cu1–N1–N2, 134.3(4)° for

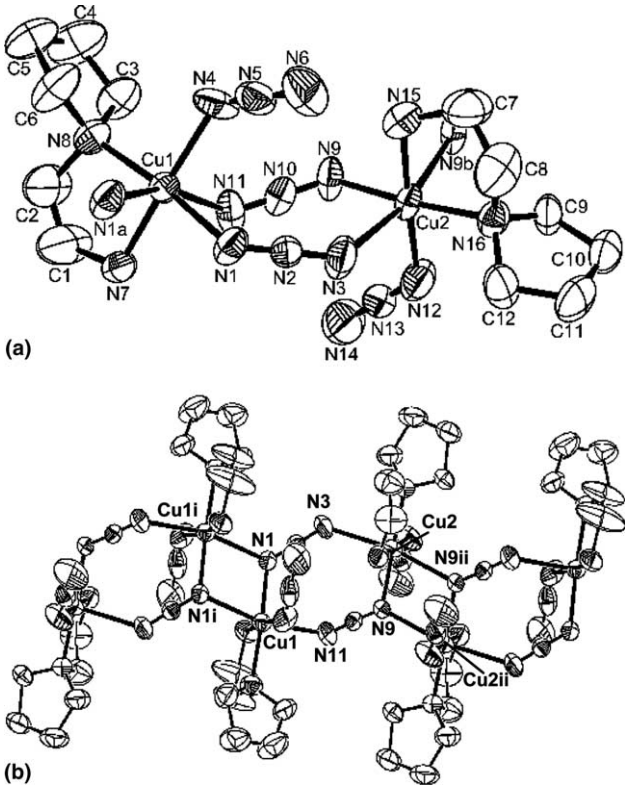

Fig. 2. Perspective molecular representation of **2** showing (a) the asymmetric unit and (b) extended 1D structure. Symmetry code used to generate equivalent atoms: i = 1−*x*, 1−*y*, −*z*; ii = 2−*x*, 1−*y*, −*z*.

Cu2–N3–N2, 122.1(5)° for Cu1–N11–N10 and 123.9(5)° for Cu2–N9–N10. The 1D extended structure is depicted in Fig. 2(b), featuring an alternating EO and EE azido-bridged chain in a basal–apical bridging fashion. The magnetically important Cu–N(azido)–Cu angles with respect to the EO azido bridges are 102.5(2)° for Cu1–N1–Cu1i and 100.0(2)° for Cu2–N9–Cu2ii (i = 1 − *x*, 1 − *y*, −*z* and ii = 2 − *x*, 1 − *y*, −*z*). The intrachain Cu–Cu separations are 3.547(1) Å for Cu1–Cu1i via the EO bridge, 5.342(2) Å for Cu1–Cu2 through the EE bridge and 3.588(1) Å for Cu2–Cu2ii bridged by the EO azide.

3.3. Magnetic results

The magnetic susceptibility data measured in the temperature range 1.8–300 K are shown in Fig. 3. At 300 K, the $\chi_m T$ value is 0.82 cm^3 K mol^{-1}, which falls into the range of two isolated Cu(II) ions ($S = 1/2$). As the temperature is lowered, $\chi_m T$ decreases very slowly and then abruptly at low temperatures, reaching a value of 0.20 cm^3 K mol^{-1} at 1.8 K. This behavior is typical of the existence of antiferromagnetic interactions between Cu(II) centers. The magnetic data for the dinuclear complex **1** were fitted with the Bleaney–Bowers equation derived from the Hamiltonian $\boldsymbol{H} = -JS_1 \cdot S_2$ [24], which is given by

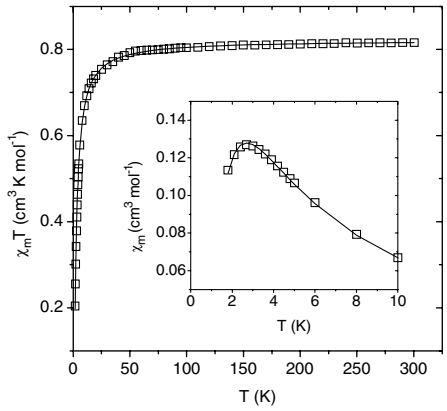

Fig. 3. Plot of $\chi_m T$ vs. T for **1**. The inset shows the temperature dependence of χ_m at low temperatures. The solid lines denote the best theoretical fits.

$$\chi = (2Ng^2\beta^2/kT)/[3 + \exp(-J/kT)]. \quad (1)$$

To take into account interdimer interactions we combined the molecular field correction with Eq. (1). Accordingly, the modified magnetic susceptibility formula can be expressed as [25]

$$\chi_m = \chi/[1 - zJ'\chi/Ng^2\beta^2]. \quad (2)$$

A best fit with this corrected equation provides parameters of $g = 2.093(1)$, $J = -3.06(1)$ cm^{-1} and $zJ' = -1.32(3)$ cm^{-1}. The measure of the goodness of fit R, defined as $R = \Phi/(n-k)$ where n is the number of data points and k the number of parameters, and $\Phi = \sum_i[(\chi_m T)_i^{obs} - (\chi_m T)_i^{calc}]^2$, is equal to 4.0×10^{-6}. The curve calculated with these parameters affords a satisfactory agreement with the experimental points as illustrated in Fig. 3. The inset of Fig. 3 displays the occurrence of a maximum at 2.7 K in χ_m, which is a conspicuous signature of antiferromagnetic coupling. The temperature (T_{max}) of χ_{max} is relevant to the exchange coupling constant (J), i.e., $|J|/kT_{max} = 1.599$ [26]. Using this relation for **1**, J is calculated to be -3.0 cm^{-1}, in good agreement with the above fitting result.

Magnetic properties for complexes with basal–basal EO azido bridges can be predicted depending on the Cu–N(azido)–Cu angle (α) and DFT studies demonstrated that a critical α value for them resides at 104° [6]. From this criterion, **1** should be ferromagnetic because of $\alpha = 98.8°$. However, a number of EO azido-bridged complexes exhibiting antiferromagnetic interactions even at α less than 104° were reported, as given in Table 3. It deserves to be noted that the listed Cu(II) compounds have azide ligands positioned in the basal–apical mode. This suggests that in the case of basal–apical bridging fashion, α is not the determining factor of magnetic nature [7]. It is found that the obtained J value in **1** is consistent with those of Cu(II) compounds in Table 3. On the other hand, the negative zJ' value implies that antiferromagnetic interactions between dimers are

operating. The field dependence of magnetization at 1.9 K is displayed in Fig. 4 in the field range 0–7 T, showing a dominant antiferromagnetic interaction, compared with the calculated value from the Brillouin function for two independent Cu(II) ions.

For **2**, we repeated magnetic measurements to ensure the observed magnetic data and obtained the same results. The collected magnetic susceptibility data are plotted in Fig. 5, which is quite different from the reported magnetic data [20]. The $\chi_m T$ value of 0.41 cm^3 K mol^{-1} (1.81 BM) at 300 K is slightly larger than the spin-only value (0.38 cm^3 K mol^{-1}; 1.73 BM) derived from an isolated Cu(II) ion. This observed value is more reasonable compared to the reported one (1.98 BM) that is abnormally high, even higher than their fitting result (when $g = 2.15$, $\mu_{eff} = 1.86$ BM), for the overall antiferromagnetic system [20]. On cooling, $\chi_m T$ increases gradually and then reaches a maximum of 0.44 cm^3 K mol^{-1} at 20 K, indicative of a typical dominant ferromagnetic behavior. A sharp drop is encountered on further cooling, which originates from intra- and interchain antiferromagnetic interactions.

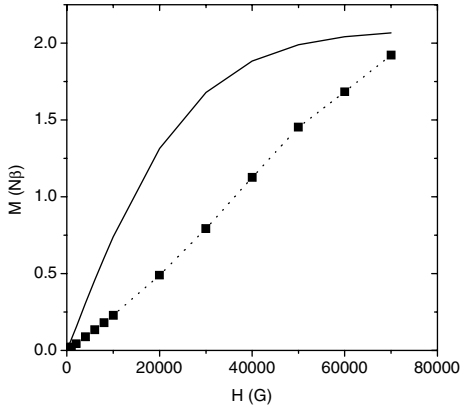

Fig. 4. Field dependence of the magnetization of **1**. The solid line stands for the Brillouin curve for two isolated Cu(II) ions.

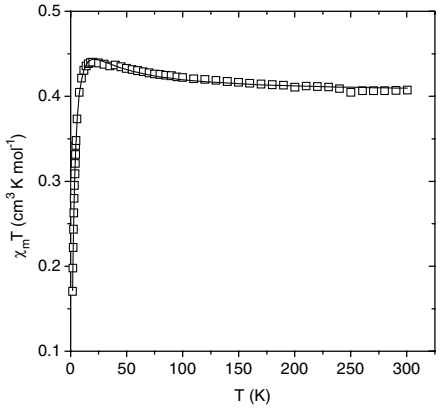

Fig. 5. Plot of $\chi_m T$ vs. T for **2**. The solid line shows the best theoretical fit.

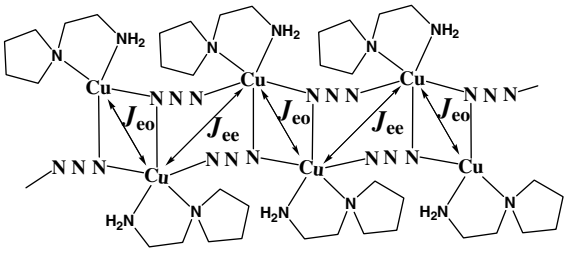

Fig. 6. Schematic view of possible magnetic coupling pathways of **2**.

There are two possible magnetic pathways: one is through the EO azido bridge and the other via the EE bridge. The exchange coupling constants are assigned to J_{eo} for the former route and J_{ee} for the latter, as schematized in Fig. 6. Assuming that one of the couplings is negligible, a best fit with the dimer model using Eqs. (1) and (2) results in $g = 2.07(1)$, $J = 21(2)$ cm^{-1}, $zJ' = -1.57(3)$ cm^{-1} with $R = 2.5 \times 10^{-4}$. If two J are activated in the fitting process, the alternating chain

model with ferromagnetic and antiferromagnetic interactions is applicable on the basis of the exchange Hamiltonian $\boldsymbol{H} = -\sum_i [J_1 S_{2i} \cdot S_{2i+1} + J_2 S_{2i} \cdot S_{2i-1}]$ [27]. The molar magnetic susceptibility is defined as $\chi_m = \chi_r(Ng^2\beta^2/4)/|J_1|$ where χ_r is expressed as Eq. (3).

$$\chi_r = \left[AT_r^3 + BT_r^2 + CT_r + D\right] / \left[T_r^4 + ET_r^3 + FT_r^2 + GT_r + H\right], \quad (3)$$

$$T_r = kT/|J_1|.$$

The parameters A–H are polynominal expressions: $X_i = x_0 + x_1\gamma + x_2\gamma^2 + x_3\gamma^3$ where $\gamma = J_2/|J_1|$. The magnetic data were fitted employing the modified molar magnetic susceptibility formula formed by Eq. (3) incorporated into Eq. (2) to account for interchain interactions. The obtained magnetic parameters are $g = 2.076(2)$, $J_1 = -3.22(5)$ cm^{-1}, $J_2 = 17.0(5)$ cm^{-1} and $zJ' = -1.34(6)$ cm^{-1}, with a significantly improved reliability factor R of 4.9×10^{-6}.

Based on the structural analogy of **2** in the EO mode to **1** and other complexes with asymmetric double EO bridges, as seen in Table 3, it is rationally suggested that J_1 is ascribed to J_{eo}. As exemplified in Table 4, ferromagnetic interactions may take place through EE azido bridges at high torsion angles. In **2**, two EE azido bridges have different values of δ, 6.2° and 60.1°. The larger δ appears to play a role in a ferromagnetic coupling through the EE bridges in **2** [14,28]. The extracted exchange coupling of J_2 is thus assigned to J_{ee}, whose magnitude agrees well with that of a double EE azido-bridged Cu(II) complex [14]. The interchain antiferromagnetic behavior is explained by the negative zJ' in the fitting output. Fig. 7 shows the field dependence of magnetization at 1.9 K and magnetic fields up to 7 T. As seen in the $\chi_m T$ plot of Fig. 5, the global antiferromagnetic coupling occurs at 1.9 K, which is reflected by the $M(H)$ data lower than the Brillouin result for an isolated Cu(II) ion. The magnetization reaches a saturation value at 7 T.

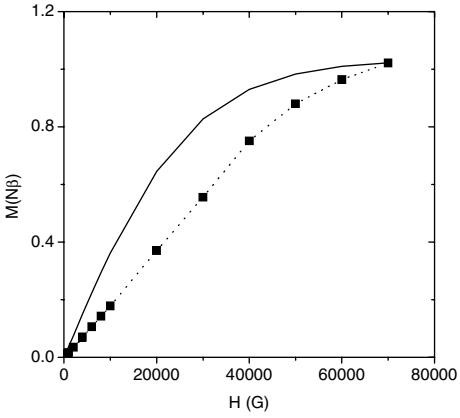

Fig. 7. Field dependence of the magnetization of **2**. The solid line displays the curve calculated from the Brillouin function for an isolated Cu(II) ion.

3.4. MO calculations

To clarify the magnetic nature observed in the alternating ferro- and antiferromagnetic chain system (**2**) we performed MO calculations using the CAESAR program package in which the extended Hückel tight binding (EHTB) method is employed [29–31]. The exchange coupling constant J, contributed from ferromagnetic (J_F) and antiferromagnetic (J_{AF}) components, is mainly dominated by J_{AF}, which is equal to $-(\Delta E)^2/U$. Here $\Delta E = E_2 - E_1$, E_1 and E_2 being the energies of the two singly occupied molecular orbitals (SOMOs) in the triplet state and U the effective on-site repulsion. To assess what magnetic character EE and EO azido bridges belong to, it

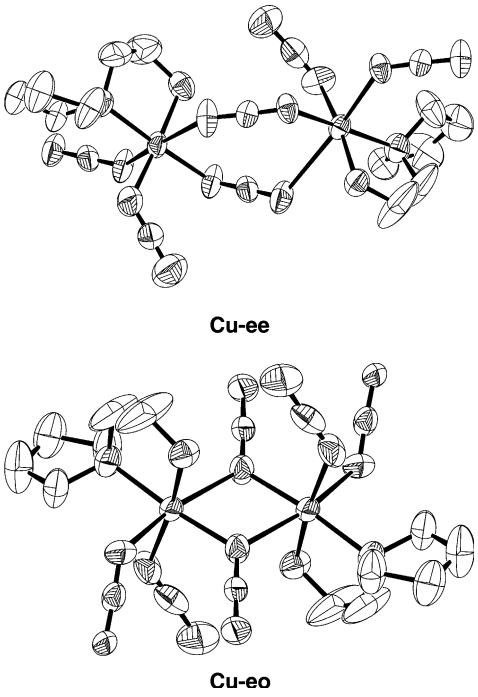

Fig. 8. Molecular representation of the two types of bridging modes between Cu(II) ions in **2**. Cu-ee is the spin dimer $[Cu_2(aepy)_2(N_3)_6]^{2-}$ bridged by double EE azido units and Cu-eo the spin dimer $[Cu_2(aepy)_2(N_3)_6]^{2-}$ linked by double EO azido groups.

is required to estimate the magnitude of ΔE for EE and EO azido bridged spin systems in **2**. To this end, EE azido-bridged Cu(II) dimer, $[Cu_2(aepy)_2(N_3)_6]^{2-}$ (Cu-ee), and EO azido-bridged Cu(II) dimer (Cu-eo) are taken as shown in Fig. 8 [31,32]. MO calculations for each spin dimer were conducted to generate SOMOs at $E_1 = -11.4941$ eV, $E_2 = -11.4863$ eV for Cu-ee, and $E_1 = -11.4938$ eV, $E_2 = -11.4819$ eV for Cu-eo. The ΔE of 0.0119 eV for Cu-eo is larger than that of 0.0078 eV for Cu-ee. Consequently, now that the sign of the J term is basically determined by the magnitude of the J_{AF} term proportional to $(\Delta E)^2$, Cu-eo would undergo an antiferromagnetic interaction when compared with Cu-ee. This result supports that the spins within the Cu-eo dimer are coupled antiferromagnetically in a more significant manner than those in Cu-ee that in contrast experience a ferromagnetic interaction as described above.

4. Conclusion

We have prepared two azido-bridged Cu(II) compounds showing dinuclear and 1D chain structures. The magnetic properties of **1** doubly bridged by the EO azido ligands in a basal–apical pattern demonstrate antiferromagnetic interaction with $J = -3.06$ despite a relatively small α value compared to the critical value of 104° below which ferromagnetic coupling is expected. This suggests that in the basal–apical bridging mode several structural parameters may be taken into consideration to understand the magnetic nature. For **2**, two magnetic pathways, i.e., through EO or EE azido bridges, are possible. To properly assign ferromagnetic/antiferromagnetic couplings to them we examined the structural parameters related to magnetic behavior. From the parameters it is reasonably concluded that magnetic interactions through the EO bridge (J_{eo}) and the EE linkage (J_{ee}) are antiferromagnetic and ferromagnetic, respectively. This result is supported by MO calculations where the ΔE value for the former is rather larger than that for the latter, implicating that J_{eo} should be negative.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 249816 for complex **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; email: deposit@ccdc.cam.ac.uk orwww: http://www.ccdc.cam.ac.uk).

Abstract

The reactions of tridentate ligands, bis(2-hydroxy-3,5-dimethylbenzyl)methylamine (H_2ONO^{Me}) and bis(2-hydroxy-3-*tert*-butyl-5-methylbenzyl)methylamine (H_2ONO^{tBu}) with $[MoO_2(acac)_2]$ (**1**) in methanol lead to the precipitation of monomeric dioxomolybdenum(VI) complexes $[MoO_2(ONO^{Me})(MeOH)] \cdot MeOH$ (**2a**) and $[MoO_2(ONO^{tBu})(MeOH)] \cdot MeOH$ (**2b**), respectively. Identical reactions in acetonitrile provide dimeric complexes $[Mo_2O_2(\mu\text{-}O)_2(ONO^{Me})_2]$ (**3a**) and $[Mo_2O_2(\mu\text{-}O)_2(ONO^{tBu})_2]$ (**3b**). The reactions of **1** with tetradentate ligands, *N*,*N*′-bis(2-hydroxy-3,5-dimethylbenzyl)-*N*,*N*′-dimethylethane-1,2-diamine (H_2ONNO^{Me}) and *N*,*N*′-bis(2-hydroxy-3,5-di-*tert*-butylbenzyl)-*N*,*N*′-dimethylethane-1,2-diamine (H_2ONNO^{tBu}) yield monomeric complexes $[MoO_2(ONNO^{Me})]$ (**4a**) and $[MoO_2(ONNO^{tBu})]$ (**4b**), respectively. All studied complexes catalyse oxotransfer reactions between DMSO and benzoin or triphenyl phosphine. Complexes can also be activated by Et_2AlCl to polymerise norbornene.

1. Introduction

Coordination compounds of molybdenum can catalyse a variety of industrially important chemical reactions such as olefin epoxidation [1], isomerization of allyl alcohols [2] and olefin metathesis [3]. The useful role of molybdenum is not restricted to artificial catalysis alone, since it is an essential element in diverse biological systems, as nature has made use of molybdenum centre in various redox enzymes [4–6]. Oxidized forms of these molybdoenzymes, e.g., aldehyde and sulfite oxidases, are supposed to contain *cis*-MoX_2 units (X = O, S) coordinated to sulfur, nitrogen and oxygen donor atoms of the protein structure. A large number of dioxomolybdenum(VI) complexes are known, some of which have been investigated as molecular models for these molybdoenzymes. For example, Ghosh and co-workers [7] have demonstrated that certain MoO_2^{2+} complexes of diacidic tridentate Schiff base ligands can oxidise PPh_3, thus they mimic the active sites of oxotransfer enzymes. Barbaro et al. [8] have reported similar results about MoO_2^{2+} complexes with enantiomerically pure tridentate aminodiolato ligands.

Aminobis(phenol)s (potential O, N, O donors) and diaminobis(phenol)s (O, N, N, O donors) are versatile ligands, which have used to make complexes with various transition metal ions [9–13]. For instance, Spence and co-workers [12] and Ng and co-workers [13] have reported several six-coordinate dioxomolybdenum(VI) and -tungsten(VI) complexes of tetradentate N_2O_2 donor ligands with different coordination modes and studied their activity toward oxygen atom transfer reactions. However, to the best of our knowledge, there is no reports on dioxomolybdenum(VI) complexes with tridentate

aminobis(phenol)s. In principle, tridentate ligands could form five-coordinate complexes when reacting with dioxomolybdenum(VI) moiety, but molybdenum ion usually completes its coordination sphere by abstracting a solvent molecule or though dimerization. As a part of our studies on W(VI) and Mo(VI) complexes with multidentate ligands [14–16], we discuss here the syntheses of new dioxomolybdenum(VI) complexes with linear tri- and tetradentate aminobisphenolate ligands.

2. Results and discussion

2.1. Monomeric $MoO_2(ONO^R)$ and dimeric $Mo_2O_2(\mu\text{-}O)_2(ONO^R)_2$ complexes

The products formed in reactions between $[MoO_2(acac)_2]$ (**1**) and ligand precursors H_2ONO^R were found to depend on the reaction medium (Scheme 1). When methanol solution of **1** was treated with one equivalent of a ligand precursor H_2ONO^{Me}, the reaction initiated and the reaction mixture subsequently turned yellow in colour (Scheme 1a). Solution was stirred overnight at room temperature and then kept at 277 K for 24 h to obtain yellow prismatic crystals, which were characterised as $[MoO_2(ONO^{Me})(MeOH)]\cdot MeOH$ (**2a**) (see below). Intense yellow crystals of analogous complex $[MoO_2(ONO^{tBu})(MeOH)]\cdot MeOH$ (**2b**) precipitated in an equal reaction during few hours at room temperature. When identical reactions between ligand precursors H_2ONO^R and **1** were carried out in acetonitrile solutions, the reaction mixtures turned orange-red and orange crystals started to precipitate (Scheme 1b). Further analyses (see below) verified, that crystals were formed of dimeric complexes $[Mo_2O_2(\mu\text{-}O)_2(ONO^{Me})_2]$ (**3a**) and $[Mo_2O_2(\mu\text{-}O)_2(ONO^R)_2]$ (**3b**), respectively. Air-sensitive crystals of **2a** and **2b** are soluble in DMSO, DMF and hot MeOH, but they decompose slowly in acetonitrile suspensions to form dimeric complexes of type **3** as red powders. Similar decomposition occurs also in open air and particularly in vacuum due to the loss of methanol. Air-stable crystals of **3** dissolve in DMSO to yield yellow solutions, but they are practically insoluble in other common solvents at room temperature. They dissolve also in methanol upon heating, although recrystallization from hot methanol produces complexes **2** in high yields instead of complexes **3**. In conclusion, it is demonstrated that formation of complexes **2** and **3** can be easily adjusted. Particularly, the monomeric complexes **2** are transformed to their dimeric counterparts **3** as a consequence of leaving of methanol in the solid state, whereas complexes **3** can be turned to complexes **2** by recrystallization from MeOH. This solvent-dependent reactivity of above-mentioned ligands resembles reactions of *N*-salicylidene-2-aminoethanol with **1** [17].

Scheme 1. Formation of monomeric and dimeric Mo(VI) complexes with tridentate aminobis(phenolate)s.

The IR spectra of compounds **2** presented two strong bands within 891–932 cm^{-1}, which are distinctive absorption maxims for MoO_2^{2+} moiety [7,15,16]. Broad bands at ~3340 cm^{-1} are due to the presence of coordinated or hydrogen bonded methanol molecules. Complexes **3** have generally similar IR spectra, although they present a strong IR absorption at around 820 cm^{-1}, which is absent in their monomeric counterparts. Furthermore, complexes **3** show only a single stretch at ca. 930 cm^{-1} instead of a characteristic doublet for *cis*-MoO_2 moieties in complexes **2**. ^1H NMR spectra of **2** in DMSO show typical resonances for C_s-symmetric aminobis(phenolate) complexes together with resonances for free methanol, which indicates that DMSO can replace MeOH molecules from the first coordination sphere around Mo(VI) ion. Compounds **3** give similar ^1H NMR resonances for aromatic ligand as their monomeric counterparts.

X-ray analysis of **2a** and **2b** revealed that both complexes are formed of similar mononuclear units, in which the aminobis(phenolate) is coordinated to the dioxomolybdenum(VI) ion as a tridentate ligand. A methanol molecule *trans* to the oxo group completes the distorted octahedral coordination sphere (see Figs. 1 and 2). Another methanol molecule is attached to the complex unit by hydrogen bonds. The O=Mo=O angles and the Mo=O bonds are typical for *cis*-dioxomolybdenum(VI) complexes [7,16–21]. Uncoordinated MeOH molecules

form H-bonds with terminal oxygen atoms O1, therefore the Mo–O1 bonds are slightly longer than the Mo–O2 bonds. The Mo–$O_{aryloxide}$, Mo–N and Mo–O_{MeOH} distances are as well comparable with previous results [16,18,19]. On the whole these structures resembles to those of dioxomolybdenum(VI) complexes with tridentate Schiff base ligands [16,18]. The bonding parameters around Mo(VI) cations are nearly identical in these compounds (Table 2), though MeOH molecule seems to coordinate more tightly to the Mo(VI) ion in **2a** than in **2b**, as the Mo–O_{MeOH} distance is 2.289(2) Å in **2a** and 2.333(2) Å in **2b**. Furthermore, the alkyl substituents at the *ortho*-positions of the ligand phenyl rings appear to modify the ligand conformation around the metal centre in the solid state. For example, the dihedral angle between the planes C1, C2, ..., C6 and C10, C11, ..., C15 is 54.26(8)° in **2a** and 48.2(1)° in **2b**.

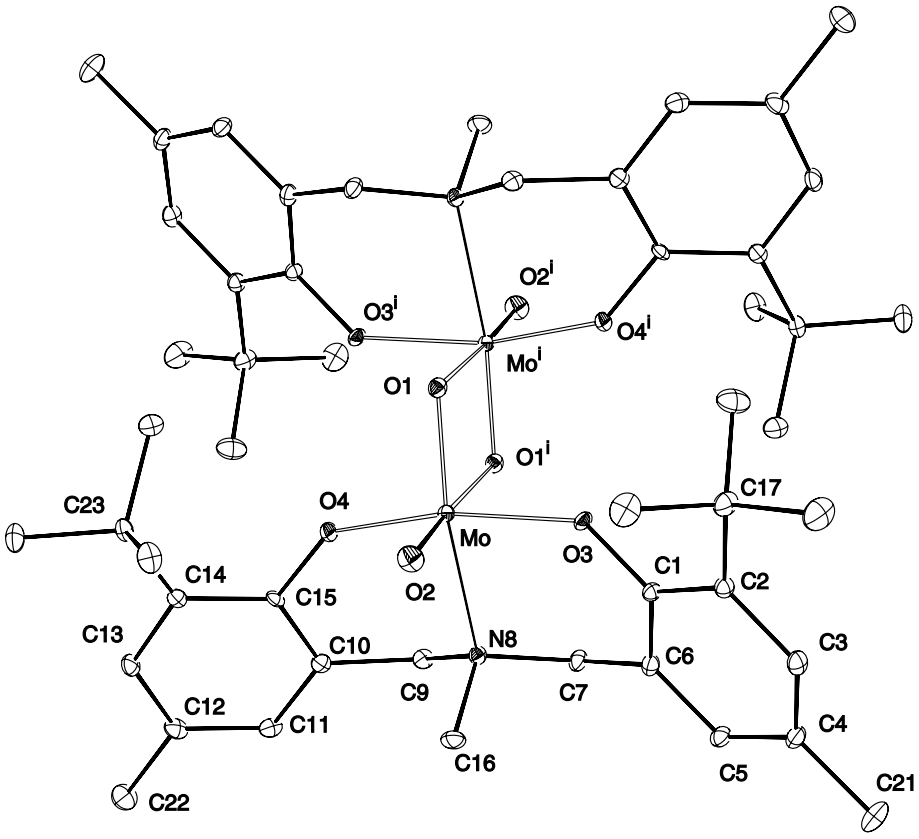
X-ray crystal structure analyses verified that **3b** consist of dinuclear, doubly bridged units of $Mo_2O_2(\mu\text{-}O)_2(ONO^R)_2$. As seen from Fig. 3, each molybdenum ion is bonded to three donor atoms of ONO^R ligand and two bridging and one terminal oxo ligands having a distorted octahedral coordination sphere. Mo(VI) ions and asymmetric oxo bridges form four-membered Mo–O–Mo–O rings, the Mo–O distances being 1.6899(17) and 1.7519(16) Å. Generally, Mo–L (ligand donor atom) distances are shorter in **3b** compared to the relevant bond distances in complexes **2** (Table 2.). Overall structure of **3b** is rather similar to that of dinuclear molybdenum(VI) complex with tridentate *N*-salicylidene-2-amino-4-*tert*-butylphenolate [20].

2.2. Monomeric $MoO_2(ONNO^R)$ complexes

Tetradentate ligand precursors H_2ONNO^R react with **1** in acetonitrile–methanol mixtures at room temperature to produce complexes **4** as intense red crystals (Scheme 2). Air-stable crystals are soluble in $CHCl_3$ and moderately soluble in DMSO. ^{1}H NMR spectra in $CDCl_3$ show expected resonances for octahedral complexes with C_2 rotation axis [13]. The IR absorptions for asymmetric and symmetric Mo=O stretches are seen at 807–903 and 914–916 cm^{-1}, respectively.



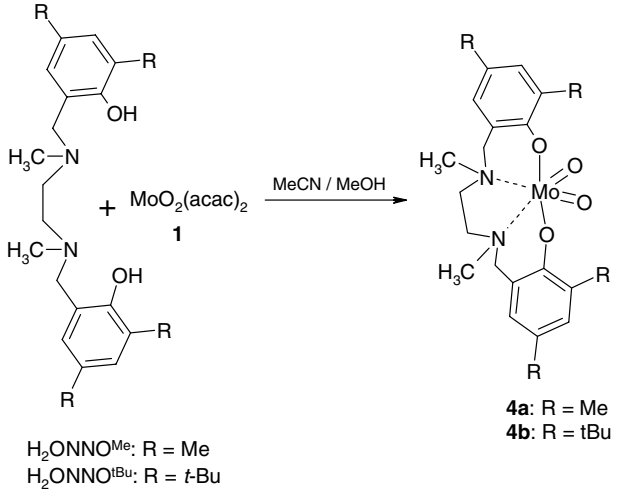


Fig. 3. Molecular structure of $[Mo_2O_4(ONO^{tBu})_2]$ (**3b**). Thermal ellipsoids have been drawn at 30% probability level. Symmetry operation: i = $-x$, $-y + 1$, $-z + 1$.

Scheme 2. Formation of Mo(VI) complexes with diaminobis-(phenolate)s.

X-ray diffraction studies of **4a** (Fig. 4) and **4b** (Fig. 5) revealed the nearly C_2 symmetric distorted octahedral structure of complexes. The bond lengths and angles of both complexes are closely similar and resemble those found in other six-coordinate dioxomolybdenum(VI) complexes [12,13,21]. However, **4b** crystallizes with two independent molecules in the asymmetric unit. A comparison of **4a** and two molecules of **4b** (see Table 3) with other known dioxomolybdenum(VI) complexes reveals, for example, that the O1═Mo═O2 angles are quite flexible. The related Mo complex $[MoO_2(ONNO)]$ (ONNO = *N*,*N*′-bis(2-hydroxybenzyl)-*N*,*N*′-dimethylethane-1,2-diamine) without *ortho*-substituents in the phenyl rings has the C_2 symmetry with the O═Mo═O angle of 108.25(7)° and the Mo═O, Mo–O and Mo–N lengths of 1.702(1), 1.934(1) and 2.390(1) Å, respectively [b]. In solid state, the Mo–O bonds in **4a** are slightly asymmetric (1.923(2) and 1.959(2) Å) and also ligand conformation contradicts C_2 symmetry. In **4b**, the Mo–O bond deviations from the C_2 symmetry are smaller, so it seems that the methyl substituted diaminobis(phenolato) ligand cause more distortions in the coordination sphere of Mo(VI) than the *tert*-butyl substituted analogue.

2.3. Catalytic studies

Oxidation reactions of benzoin and triphenyl phosphine by DMSO were studied as models for oxo-transfer reactions:

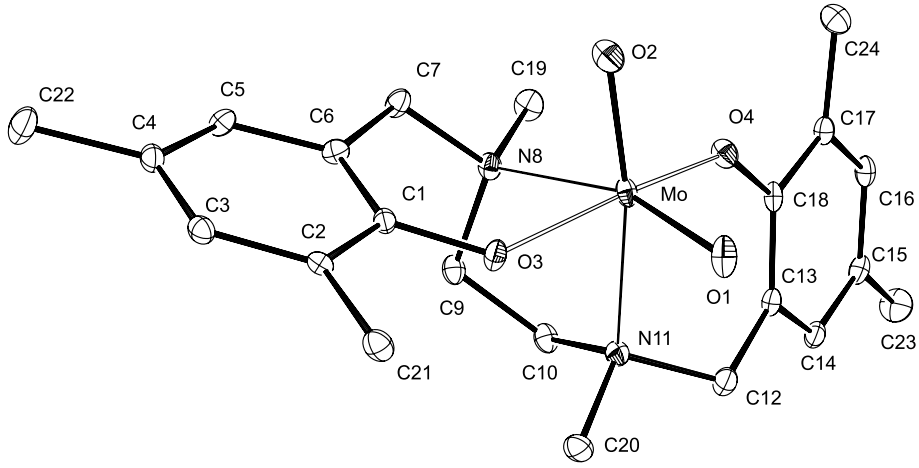

Fig. 4. Molecular structure of $[MoO_2(ONNO^{Me})]$ **(4a)**. Thermal ellipsoids have been drawn at 30% probability level.

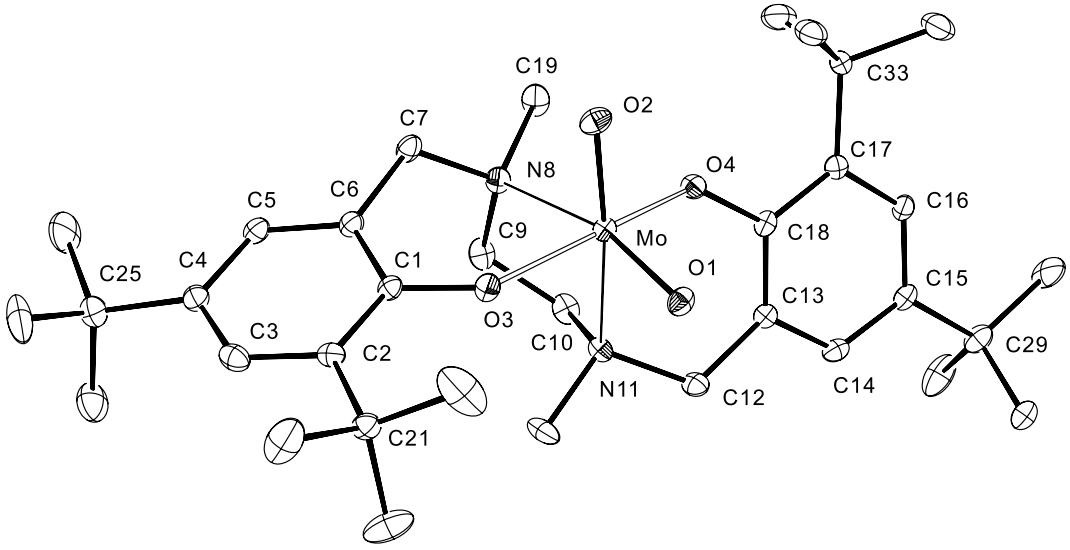

Fig. 5. Molecular structure of $[MoO_2(ONNO^{Bu})]$ (**4b**). Thermal ellipsoids have been drawn at 30% probability level. Only one of the two similar molecules in the asymmetric unit is shown.

$$C_6H_5CH(OH)C(O)C_6H_5 + Me_2SO \rightarrow C_6H_5C(O)C(O)C_6H_5 + Me_2S + H_2O \quad (1)$$

$$Ph_3P + Me_2SO \rightarrow Ph_3PO + Me_2S \quad (2)$$

Benzoin was dissolved in DMSO and subsequently treated with molybdenum catalyst using a 1:25 catalyst:substrate ratio. The yellow reaction mixture was kept at 120 °C under nitrogen atmosphere, cooled to the room temperature and finally treated with water to precipitate benzil as a white solid. Oxidation of triphenyl phosphine was investigated identically. All complexes **2**–**4** catalysed these oxidation reactions, since in all experiments the isolated yields of oxidized products were within 10% of quantitative, whereas in control experiments without catalysts no reactions between substrates and DMSO were observed. Regrettably, all attempts to

recover catalyst complexes failed. On the grounds of analogous catalyst systems, it is supposed, that the dioxomolybdenum(VI) complexes react with benzoin or Ph_3P to yield oxomolybdenum(IV) complexes and oxidized organic substrates. The Mo(IV) complexes are then rapidly oxidized back to the initial dioxocompounds with DMSO to complete the catalytic cycle [7,8,13].

Catalytic activities of complexes **2** and **4** in ring-opening metathesis polymerization of norbornene [22] were studied in CH_2Cl_2 solutions using a Et_2AlCl cocatalyst, while the overall conversion of monomer to insoluble polymers was used as a measure of activity. Studied molybdenum complexes were dissolved in a CH_2Cl_2/norbornene mixture to form orange solutions, which were subsequently treated with toluene solution of Et_2AlCl. As a result, the solutions changed rapidly dark brown in colour and exothermic polymerization started, which was observed as instantaneous increase in the mixture viscosity. The reactions were carried out at room temperature for 30 min and then quenched by MeOH. Brown colour of the reaction mixtures vanished when exposed to the air. The monomer conversions to solid, rubber-like materials were nearly quantitative. The activation mechanism is not known, but it was found Et_2AlCl activator was required for these polymerizations, as other alkylating main-group organometallics (MeMgI, Me_2Zn or Bu_4Sn) did not activate studied precatalysts in these experimental conditions. The orange to brown colour change of catalyst precursors upon addition of Et_2AlCl is probably related to the reduction of Mo(VI) centres to Mo(V). Similar activation by reducing aluminium compound has earlier used in heterogeneous polymerization of norbornene, which was catalysed by single crystals of $(Bu_4N)_2[W_6O_{19}]$ [23].

3. Conclusion

In conclusion, new series of dioxomolybdenum(VI) complexes with aminobis(phenolate)s have been synthesized. Tridentate aminobis(phenol) ligands can form monomeric dioxomolybdenum(VI) complexes in which the sixth coordination site is occupied by solvent methanol. In the absence of methanol, the coordination sphere around oxophilic Mo(VI) ion is completed by dimerization through oxygen bridges. Tetradentate diaminobis(phenols) form monomeric dioxomolybdenum(VI) complexes, in which the central metal have adopted distorted octahedral coordination. Sterical alteration of the substituents on the *ortho*-position on the bis(phenolato) ligands causes only minor variations on the coordination sphere around central Mo(VI) ion. Synthesised new complexes can catalyse oxotransfer reaction between DMSO and benzoin or triphenyl phosphine. They can also be activated by Et_2AlCl to catalyse ROMP of norbornene.

4. Experimental

Starting compound $[MoO_2(acac)_2]$ (**1**) and ligand precursors H_2ONO^R and H_2ONNO^R were prepared according to the literature [24–26]. Other chemicals were of reagent grade and were used as purchased. ^1H NMR spectra were recorded using a Bruker AM 200 spectrometer in $(CD_3)_2SO$ (**2**, **3**) or $CDCl_3$ (**4**) solutions and were referenced internally to $SiMe_4$. IR spectra were recorded as Nujol mulls using a Mattson Galaxy FTIR spectrometer. Adequate elemental analyses for complexes **3** and **4** were obtained using a Perkin–Elmer CHNS-Analyzer 2400, but analyses for complexes **2** gave insufficient results due to the partial loss of methanol during the process.

4.1. Syntheses

4.1.1. $[MoO_2(ONO^{Me})(MeOH)]\cdot MeOH$ (**2a**)

0.50 mmol of **1** (163 mg) and 0.50 mmol of H_2ONO^{Me} (150 mg) were dissolved in 5 ml of methanol. The orange-yellow reaction mixture was stirred overnight and subsequently stored at 277 °C for 24 h to obtain **2a** as yellow prisms (160 mg, 65%). IR: 3347(m), 3135(m), 1319(m), 1242(vs), 1223(vs), 1157(s), 1096(m), 1034(w), 972(m), 932(m), 892(vs), 868(vs), 833(vs), 735(w), 598(m), 576(w). NMR: δ_H 6.90 (s, 2H, ArH), 6.78 (s, 2H, ArH), 4.40 (d, $J = 14$ Hz, 2H, NCH_2), 4.10 (q, $J = 5$ Hz, CH_3OH), 3.17 (d, $J = 5$ Hz, CH_3OH), 3.07 (d, $J = 14$, 2H, NCH_2), 2.19 (s, 6H, $ArCH_3$), 2.10 (s, 6H, $ArCH_3$), 1.97 (s, 3H, NCH_3).

4.1.2. $[MoO_2(ONO^{tBu})(MeOH)]\cdot MeOH$ (**2b**)

0.50 mmol of **1** (163 mg) and 0.50 mmol of H_2ONO^{tBu} (192 mg) were dissolved in 5 ml of methanol by gentle heating. The yellow reaction mixture was allowed to stand at room temperature for 4 hours to obtain **2b** as yellow blocks 210 mg (73%). IR: 3333(m), 3173 (m), 1314(m), 1289(m), 1240(vs), 1211(s), 1148(s), 1096(m), 1018(vs), 988(m), 941(s), 918(m), 891(vs), 862(vs), 833(vs), 762(m), 573(m), 576(w). NMR: δ_H 6.98 (s, 2H, ArH), 6.82 (s, 2H, ArH), 4.37 (d, $J = 12$ Hz, 2H, NCH_2), 4.10 (q, $J = 5$ Hz, CH_3OH), 3.17 (d, $J = 5$ Hz, CH_3OH), 2.92 (d, $J = 14$, 2H, NCH_2), 2.21 (s, 6H, $ArCH_3$), 2.08 (s, 3H, NCH_3), 1.35 (s, 18H, $C(CH_3)_3$).

4.1.3. $[Mo_2O_2(\mu\text{-}O)_2(ONO^{Me})_2]$ (**3a**)

0.50 mmol of **1** (163 mg) was dissolved in 10 ml of anhydrous acetonitrile. To the solution was added 0.50 mmol of H_2ONO^{Me} (150 mg) in 5 ml of same solvent. The orange-red reaction mixture was allowed to

stand at room temperature for 24 h to obtain **3a** (175 mg, 82%) as orange prisms. IR: 1319(m), 1242(vs), 1221(s), 1155(s), 1094(m), 1034(w), 970(m), 933(s), 874(vs, br), 818(vs, br), 760(m), 733(m), 598(m), 565(m), 511(w). NMR: δ_H 6.92 (s, 2H, ArH), 6.78 (s, 2H, ArH), 4.41 (d, $J = 14$ Hz, 2H, NCH_2), 3.09 (d, $J = 14$, 2H, NCH_2), 2.18 (s, 6H, ArCH_3), 2.10 (s, 6H, ArCH_3), 1.98 (s, 3H, NCH_3). *Anal.* Calc. for $C_{38}H_{46}Mo_2N_2O_8$: C, 53.7; H, 5.55; N, 3.3. Found: C, 53.4; H, 5.6; N, 3.3%.

4.1.4. $[Mo_2O_2(\mu\text{-}O)_2(ONO^{tBu})_2]$ (**3b**)

0.50 mmol of **1** (163 mg) was dissolved in 10 ml of anhydrous acetonitrile. To the solution was added 0.50 mmol of H_2ONO^{tBu} (192 mg) in 5 ml of same solvent. The orange reaction mixture was allowed to stand at room temperature for 24 h to obtain **3b** (220 mg, 86%) as orange prisms. IR: 1418(s), 1294(m), 1240(vs), 1217(s), 1152(s), 1088(m), 984(m), 933(s), 914(m), 851(vs), 822(vs), 800(m), 766(m), 673(m), 571(s). NMR: δ_H 6.98 (s, 2H, ArH), 6.84 (s, 2H, ArH), 4.36 (d, $J = 12$ Hz, 2H, NCH_2), 2.93 (d, $J = 14$, 2H, NCH_2), 2.21 (s, 6H, ArCH_3), 2.10 (s, 3H, NCH_3), 1.35 (s, 18H, C(CH_3)$_3$). *Anal.* Calc. for $C_{50}H_{70}Mo_2N_2O_8$: C, 58.9; H, 6.9; N, 2.8. Found: C, 59.0; H, 6.9; N, 2.9%.

4.1.5. $MoO_2(ONNO^{Me})]$ (**4a**)

0.50 mmol of **1** (163 mg) was dissolved in 10 ml of anhydrous acetonitrile. To the solution was added 0.50 mmol (171 mg) of H_2ONNO^{Me} in 5 ml of methanol. The orange-yellow reaction mixture was allowed to stand at room temperature for 24 h to obtain 200 mg (83%) of **4a** as orange-red crystalline solid. IR: 1317(s), 1271(s), 1252(vs), 1229(vs), 1157(vs), 1146(m), 1065(s), 997(s), 972(s), 949(m), 914(s), 903(vs), 868(m), 841(vs), 808(m), 775(m), 741(w), 687(m), 621(w), 592(w), 559(m). NMR: δ_H 6.93 (2H, ArH), 6.76 (2H, ArH), 4.69 (d, $J = 14$ Hz, 2H, NCH_2), 3.66(d, $J = 14$ Hz, 2H, NCH_2), 3.22 (d, $J = 10$ Hz, 2H, NCH_2), 2.82 (s, 6H, NCH_3), 2.28 (d, $J = 10$ Hz, 2H, NCH_2), 2.20 (s, 6H, ArCH_3), 2.09 (s, 6H, ArCH_3). *Anal.* Calc. for $C_{22}H_{30}MoN_2O_4$: C, 54.8; H, 6.3; N, 5.8. Found: C, 54.5; H, 6.5; N, 5.9%.

4.1.6. $[MoO_2(ONNO^{tBu})]$ (**4b**)

0.50 mmol of **1** (163 mg) was dissolved in 10 ml of anhydrous acetonitrile. To the solution was added 0.50 mmol (255 mg) of H_2ONNO^{tBu} in 10 ml of methanol. The orange-yellow reaction mixture was allowed to stand at room temperature for 24 h to obtain 225 mg (79%) of **4b** as large orange blocks. IR: 1304(vs, br), 1244(vs, br), 1206(s), 1175(s), 1125(s), 1065(m), 1015(m), 984(m), 916(s), 897(vs), 874(s), 845(s), 812(m), 779(m), 756(s), 646(w), 617(w), 557(s), 480(m), 469(m). NMR: δ_H 7.30 (d, $J = 4$ Hz, 2H, ArH), 6.86 (d, $J = 4$ Hz, 2H, ArH), 4.88 (d, $J = 14$ Hz, 2H, NCH_2), 3.61 (d, $J = 14$ Hz, 2H, NCH_2), 3.20 (d, $J = 10$ Hz, 2H, NCH_2), 2.74 (s, 6H, NCH_3), 2.27 (d, $J = 10$ Hz, 2H, NCH_2), 1.42 (s, 18H, C(CH_3)$_3$), 1.29 (s, 18H, C(CH_3)$_3$). *Anal.* Calc. for $C_{34}H_{54}MoN_2O_4$: C, 62.8; H, 8.4; N, 4.3. Found: C, 62.2; H, 8.7; N, 4.3%.

4.2. Catalytic studies

4.2.1. Oxidation of benzoin

106 mg of benzoin (0.50 mmol) and 10 mg (ca. 0.02 mmol) of catalyst were dissolved in 5 ml of DMSO. The yellow mixture was heated at 120 °C under nitrogen atmosphere for 18 h. Solution was cooled to the room temperature and subsequently treated with 5 ml of water to obtain benzil as a white precipitate. Precipitate was filtrated, dried and identified by IR spectroscopy.

4.2.2. Oxidation of PPh_3

131 mg of PPh_3 (0.50 mmol) and 10 mg (ca. 0.02 mmol) of catalyst were dissolved in 5 ml of DMSO. The yellow mixture was heated at 120 °C under nitrogen atmosphere for 4 h. Solution was cooled to the room temperature and subsequently treated with 5 ml of water to obtain a white precipitate. Precipitate was filtrated, dried and analysed by IR spectroscopy.

4.2.3. Polymerization of norbornene

Polymerizations were performed at ambient temperature under a nitrogen atmosphere employing a 1:5:100 precatalyst:activator:monomer ratio. The precatalyst (2×10^{-5} mol) was dissolved in 4 ml of 0.5 M norbornene monomer (2.0 mmol) solution in CH_2Cl_2. The reaction mixture was stirred for 5 min and subsequently treated with 0.05 ml of Et_2AlCl solution (1.8 M in toluene, 9×10^{-5} mol). After 30 min stirring, the solution was exposed to the air and subsequently treated with 10 ml of methanol to precipitate polymer as a white solid. Polymers were swelled in CH_2Cl_2, re-precipitated by methanol and dried in vacuo at 40 °C for 8 h. In all experiments, methanol-insoluble polymers were obtained in 85–95% yield.

4.3. X-ray crystallography

Crystals suitable for X-ray measurements were grown from methanol (**2a**, **2b**), acetonitrile (**3b**) or acetonitrile–methanol mixture (**4a**, **4b**). Crystallographic data for **2a**, **2b**, **3b**, **4a** and **4b** along with other experimental details are summarised in Table 1. The crystal data were collected at 173 K on a Nonius Kappa CCD area-detector diffractometer using graphite monochromatised Mo Kα radiation ($\lambda = 0.71073$ Å). The data collection was performed using φ and ω scans. The data were processed using DENZO-SMN V0.93.0. [27] SHELXA [28] absorption correction was applied for the data of all compounds.

The structures were solved by direct methods using the SHELXS-97 program and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [29]. For all compounds, the heavy atoms were refined anisotropically. The CH hydrogen atoms were included at the fixed distances with fixed displacement parameters from their host atoms. Figures were drawn with *ORTEP-3 for Windows* [30].

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as deposition numbers CCDC 247703–247707 for **2a**, **2b**, **3b**, **4a** and **4b**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk, or on the web: http://www.ccdc.cam.ac.uk].

Abstract

A new rhenium nitrosyl – $[ReCl_3(NO)(OPPh_3)(pyz)]$ – has been obtained by two different routes: (i) in the substitution reaction of $[ReCl_3(NO)(OPPh_3)(PPh_3)]$ with pyrazine, and (ii) in the nitrosylation reaction of $[ReOCl_3(PPh_3)_2]$ by gaseous nitric oxide in the presence of an excess of pyrazine. The crystal, molecular and electronic structure of the $[ReCl_3(NO)(OPPh_3)(pyz)]$ complex has been determined. The geometric parameters of $[ReCl_3(NO)(OPPh_3)(pyz)]$ have been examined using the density functional theory (DFT) method. The UV–Vis spectrum of the pyrazine complex has been interpreted on the basis of the electronic transitions of $[ReCl_3(NO)(OPPh_3)(pyz)]$ calculated with the time-dependent DFT method (TDDFT). The paper also includes the results of the DFT and TDDFT calculations for $[ReCl_3(NO)(OPPh_3)(PPh_3)]$.

Keywords: Rhenium nitrosyl complexes; Pyrazine; X-ray structure; DFT and TDDFT calculations

1. Introduction

For many years nitrosyl compounds of transition metals have been the centre of interest of scientists both engaged in basic research and trying to employ these complexes as catalysts of polymerisation, oligomerisation, metathesis, epoxidation, oxidation and reduction [1–11].

One of the most important aspects of the research on nitrosyl complexes is determination of the bonding nature of NO to the metal center. Terminal NO ligands may adopt either linear or bent geometries. Although the bonding in the M–NO moiety is largely of covalent nature and the electron distribution is more or less evenly distributed in this group, the bonding of the M–NO unit is often described by assigning formal oxidation states to the metal centre and the nitrosyl ligand. In such an assignment nitric oxide can be coordinated as NO^+, NO or NO^-. The M–NO core can be also described using the $\{M(NO)_x\}^n$ formalism proposed by Enemark and Feltham, in which n is taken as the total number of electrons associated with the metal d and π*(NO) orbitals [1,3,9,11].

Due to the favourable nuclear properties of ^{186}Re and ^{188}Re nuclides in diagnostic nuclear medicine and applications in radioimmunotheraphy [12,13], the chemistry of nitrosyl rhenium complexes arouses particular interest.

The papers [14–22] present the preparation, structural and spectroscopic characterisation of rhenium mononitrosyls with phosphine and arsine ligands in the coordination sphere.

Here we present the synthesis, crystal, molecular and electronic structure of a new rhenium nitrosyl with pyrazine (pyz) in the coordination sphere – $[ReCl_3(NO)(OPPh_3)(pyz)]$ (**1**). The electronic structure of **1** has been determined on the basis of density functional theory (DFT) calculations. The spin-allowed doublet–doublet electronic transitions of $[ReCl_3(NO)(OPPh_3)(pyz)]$ have been calculated with the time-dependent DFT (TDDFT) method, and the UV–Vis spectrum of the title complex has been discussed on this basis. For comparison, the paper includes also the results of the DFT and TDDFT calculations for $[ReCl_3(NO)(OPPh_3)(PPh_3)]$ (**2**). The crystal, molecular structure and spectroscopic properties of **2** were presented in paper [17].

Recent calculations with the TDDFT method for open- and closed-shell 5d-metal complexes have supported the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [23–29]. Some theoretical investigations have also been carried out on rhenium compounds. The electronic structures of nitrido, oxo, carbonyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [30–37]. Gancheff et al. [32] have performed extended tests of the ability of the B3LYP method in the LANL2DZ basis set for rhenium compounds in a geometry optimisation and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has been shown to be sufficient for geometry optimisation and calculation of spectral properties. It gives good agreement with the experimental data and its use is especially justified in the case of large molecules.

2. Experimental

2.1. General procedure

The reactions were carried out under an argon atmosphere. All the reagents used for the syntheses of the complexes are commercially available and were used without further purification. $[Re(NO)Cl_3(PPh_3)(OPPh_3)]$ and $[ReOCl_3(PPh_3)_2]$ complexes were prepared according to the literature methods [17,38]. Gaseous NO, obtained in reaction (1)

$$2NaNO_2 + 3H_2SO_4 + FeSO_4 \rightarrow 2NO + 2NaHSO_4 + Fe_2(SO_4)_3 + 2H_2O \quad (1)$$

was purified by passing through washers with concentrated KOH solution and over solid NaOH.

The IR spectrum of **1** was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of a KBr pellet. The electronic spectrum of **1** was measured on a Lab Alliance UV–Vis 8500 spectrophotometer in the range 800–220 nm in deoxygenated dichloromethane solution. Magnetic susceptibility was measured at 296 K by the Faraday method. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReCl_3(NO)(OPPh_3)(pyz)]$ (1)

2.2.1. Method A

$[Re(NO)Cl_3(OPPh_3)(PPh_3)]$ (1 g, 1.15 mmol) and pyz (0.5 g, 0.62 mmol) in chloroform (100 cm^3) were refluxed for 12 h. The volume was condensed to 20 cm^3 and a dark green microcrystalline solid was formed by addition of 100 cm^3 of diethyl ether. The product was washed with EtOH and cold ether, and dried in vacuo (Yield: 40%).

2.2.2. Method B

NO was passed through a vigorously stirred and refluxing solution of $[ReOCl_3(PPh_3)_2]$ (1.05 g, 1 mmol) and pyz (0.25 g, 3.1 mmol) in acetone (100 cm^3). The reaction was carried out for 4 h. The colour changed gradually from bright green to dark green. Then the resulting solution was evaporated to a volume of 10 cm^3. A green precipitate was formed by an addition of 40 cm^3 of EtOH and after 15 min it was filtered off. The product was washed with cold ether and dried in vacuo. Crystals suitable for X-ray investigation were obtained by recrystallisation from $CHCl_3$–EtOH (Yield: 70%).

IR (KBr, cm^{-1}) 3059 (w), 1762 (s), 1589 (m), 1484 (s), 1440 (s), 1416 (3), 1354 (w), 1316 (w), 1270 (w), 1163(m), 1122 (s), 1060 (s), 1027 (m), 1001 (m), 807 (m), 753 (s), 727 (s), 691 (s), 616 (w), 552 (s), 536 (s), 466(s). Calc. for $C_{21}H_{19}N_3Br_3OAsRe$: C, 38.80; H, 2.81; N, 6.1. Found: C, 38.92; H, 2.75; N, 6.15%.

2.3. Crystal structure determination and refinement

The X-ray intensity data of complex **1** were collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector with 50 s exposure time and all reflections of the Ewald sphere were collected up to $\theta = 25°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 9937 strongest reflections. Details concerning

crystal data and refinement are given in Table 1. Lorentz, polarisation and numerical absorption corrections [39] were applied. The structure was solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as "riding" on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent carbon atom. SHELXS97 [40], SHELXL97 [41] and SHELXTL [42] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.4. Computational details

The GAUSSIAN03 program [43] was used in the calculations. The geometry optimisation was carried out with the DFT method with the use of the B3LYP functional [44,45]. The electronic spectra were calculated with the TDDFT method [46].

In the calculations, the LANL2DZ basis set [47] was used on the rhenium atom, 6-31G(d) on the chlorine, nitrogen, phosphorous, oxygen and carbon atoms and 6-31G basis on the hydrogen atoms.

Natural bond orbital (NBO) calculations were performed with the NBO code [48] included in GAUSSIAN03.

3. Results and discussion

3.1. Preparation

Two different routes have been employed for the preparation of **1**. The refluxing of $[ReCl_3(NO)(OPPh_3)(PPh_3)]$ with pyrazine (pyz) (Eq. (2)) in chloroform gives complex **1** in a moderate yield

$$[ReCl_3(NO)(OPPh_3)(PPh_3)] + pyz \rightarrow [ReCl_3(NO)(OPPh_3)(pyz)] + PPh_3 \quad (2)$$

A much higher yield of **1** has been reported for the nitrosylation reaction of $[ReOCl_3(PPh_3)_2]$ by gaseous nitric oxide in the presence of an excess of pyrazine.

3.2. Crystal structure

A thermal ellipsoid plot of **1** is shown in Fig. 1. The rhenium atom of **1** is in a distorted octahedral

environment with the chloride ligands in *meridional* geometry and the linear N–O group *trans* to the pyrazine molecule and *cis* to the $OPPh_3$ ligand.

The molecules of **1** are linked via one C(12)–H(12)···O2(x, $-y$, $z + 1/2$) intermolecular interaction, which according to Desiraju and Steiner [50] can be considered as a weak hydrogen bond with a D···A distance equal to 3.317(6) Å and a D–H···A angle of 143.9°. The weak intramolecular interaction C(19)–H(19)···Cl(1) with a D···A distance equal to 3.264(4) Å and a D–H···A angle of 112.0° can also be treated as a weak hydrogen bond [49,50]. It provides additional conformational stabilisation of the $[ReCl_3(NO)(OPPh_3)(pyz)]$ molecule.

Table 1 presents the crystal data and structural refinement for complex **1**. The most important experimental bond lengths and angles of **1** are reported in Table 2. The Re–NO (1.740(4) Å) and N–O (1.184(4) Å) bond distances and the Re–N–O angle (176.0(6)°) indicate the nitrosonium character of the NO group. They are well compared with values previously found for other rhenium nitrosyls [14–22]. In comparison with the $[ReCl_3(NO)(OPPh_3)(PPh_3)]$ compound [1.747(5) and 1.165(8) Å] [25], an insignificant shortening of the Re–N distance and elongation of the N–O bond length can be noticed for complex **1**. The Re–$N_{pyrazine}$ distance is affected by the *trans* influence of the nitrosyl group and thus is longer than the Re–$N_{pyrazine}$ distances detected in $[ReO(OEt)Cl_2(pyz)_2]$ (2.152(16) and 2.103(16) Å) with a *trans* arrangement of the N-heterocyclic molecules [51]. The $OPPh_3$ ligand affects the Re–Cl(2) bond length and causes its shortening. A similar trend is observed for the $[ReCl_3(NO)(OPPh_3)_2]$ and $[ReBr_3(NO)(OPPh_3)_2]$ complexes with the halogen ligand in a *trans* position to the $OPPh_3$ molecule. The Re–$OPPh_3$ [2.058(2) Å] and P–O [1.521(3)] bond lengths in **1** are in good agreement with values found for $[ReCl_3(NO)(OPPh_3)_2]$ (Re–O = 2.055(6) Å, P–O = 1.493(6) Å) and $[ReBr_3(NO)(OPPh_3)_2]$ (Re–O = 2.048(4) Å, P–O = 1.505(4) Å) [18,21]. In complex **2**, the Re–$OPPh_3$ distance (2.103(5) Å) is affected by the nitrosyl group and thus is longer than the Re–$OPPh_3$ bond length in **1**.

3.3. Infrared data and magnetochemical measurements of complex *1*

The IR spectrum of **1** exhibits a strong band at 1762 cm^{-1}, assignable to ν(NO). The value of ν(NO) corresponds to the linear NO range of Haymore and Ibers [52]. In the IR spectrum of complex **2**, the strong band corresponding to the stretching vibration of the nitrosyl group appears at 1745 cm^{-1}.

The sharp absorption band at 1598 cm^{-1} in the spectrum of **1** is typical of mono-coordinated diaza ligands [53]. The strong bands at 1163 and 1122 cm^{-1} confirm the presence of the coordinated $OPPh_3$ molecule.

The complex **1** is a paramagnetic compound with a room temperature magnetic moment of 1.8 BM, corresponding to one unpaired electron.

3.4. Optimised geometries of *1* and *2*

The geometries of **1** and **2** were optimised in a doublet state by the DFT method with the B3LYP functional. The doublet state agrees well with the experimental values of the effective magnetic moment for complexes **1** and **2**. The geometric parameters of **1** and **2** optimised by the DFT method are gathered in Tables 2 and 3, respectively. For comparison, the experimental bonds and bond angles of **2** are also included in Table 3. The structure and atomic numbering scheme of the complex **2** are shown in Fig. 2. The optimised geometries of **1** and **2** are in good agreement with the experimental ones, and the general trends observed in the experimental data are well reproduced in the calculations.

3.5. Charge distribution and spin densities of *1* and *2*

Table 4 presents the atomic charges from the natural population analysis (NPA) and spin densities for **1** and **2**. For both complexes the calculated charges on the rhenium atoms are considerably lower than the formal

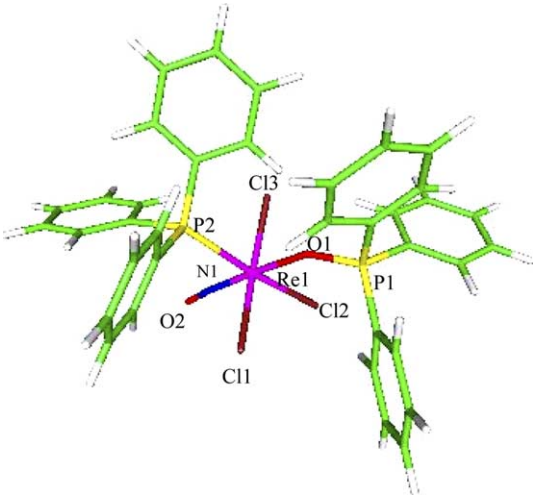

Fig. 2. Atomic numbering scheme of $[ReCl_3(NO)(OPPh_3)(PPh_3)]$.

charge of +2. This is the result of charge donation from Cl^- ions, the charges on the chloride ligands are significantly smaller than −1. The rhenium atom of **2** is less positive than the Re atom of **1**. It results from the presence of triphenylphosphine in the coordination sphere of **2**. The PPh_3 molecule acts as a strong σ-donor; there is a large positive charge on the phosphorus atom of the coordinated triphenylphosphine in complex **2**. The oxygen atoms of the $OPPh_3$ ligands in **1** and **2** are negatively charged. The calculated charges on the nitrogen atoms of the nitrosyl groups are positive, whereas the oxygen atoms are negatively charged. The total charges on the NO groups are positive, being 0.029 and 0.020 for **1** and **2**, respectively.

Table 4
Atomic charges from the natural population analysis (NPA) and spin densities of **1** and **2**

Atom	**1**		**2**	
	Atomic charge	Spin density	Atomic charge	Spin density
Re(1)	0.830	1.079	0.593	1.034
Cl(1)	−0.453	0.036	−0.402	0.080
Cl(2)	−0.380	0.066	−0.441	0.054
Cl(3)	−0.466	0.033	−0.430	0.061
N(1)	0.254	−0.125	0.255	−0.112
O(2)	−0.225	−0.105	−0.235	−0.092
O(1)	−1.097	0.0144	−1.123	−0.001
P(1)	2.339	0.002	2.338	−0.000
N(2)	−0.479	−0.009		
N(3)	−0.400	0.001		
P(2)			1.385	−0.031

For both complexes, there are positive spin densities of about 1 on the rhenium atoms and small negative spin densities of about −0.1 on the nitrogen and oxygen atoms of the nitrosyl ligands. The spin densities on the donor atoms of the other ligands are below 0.1 for complexes **1** and **2**.

3.6. Electronic structure

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of **1** and **2** are presented in Tables 5 and 6, respectively. Most of the MOs of **1** and **2** have complicated characters. The percent participation of atomic orbitals in the selected HOMO and LUMO orbitals for **1** and **2** are shown in Tables 5 and 6, respectively.

3.7. $[ReCl_3(NO)(OPPh_3)(pyz)]$ (1)

In the molecular orbital approach, the bonding of NO to a metal is considered to be made up of two components. The first involves donation of electron density from a σ-type orbital on NO to the metal, and the second – backdonation from the filled d_{xz} and d_{yz} metal orbitals to the π* orbitals of the NO ligand. Among the MOs of **1** there are no orbitals of pure π_{Re-NO} character. The π_{Re-NO} bonding interaction makes the largest contribution into HOMO − 2 and HOMO − 1 with α-spin and HOMO − 1, HOMO orbitals with β-spin. A substantial contribution of π_{Re-NO} orbitals are also visible in HOMO − 16 and HOMO − 15 with α-spin and HOMO − 15 and HOMO − 12 with β-spin. In

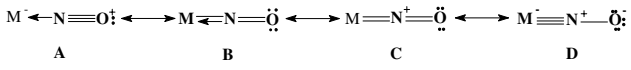
HOMO − 16, HOMO − 2 and HOMO − 1 with α-spin and HOMO − 15, HOMO − 1 and HOMO orbitals with β-spin, the π_{Re-NO} orbitals are mixed with π_{Cl} orbitals. HOMO − 15 with α-spin and HOMO − 12 with β-spin have also a significant contribution of π_{pyz} orbitals. The bonding π_{Re-NO} orbitals with α- and β-spin are localised mainly on the rhenium d orbitals. The anti-bonding π^*_{Re-NO} interaction makes the largest contribution into LUMO, LUMO + 3, LUMO + 4 and LUMO + 5 with α-spin and LUMO, LUMO + 4, LUMO + 5 and LUMO + 6 with β-spin. The π^*_{Re-NO} orbitals have prevalent NO character and they are mixed with π^*_{pyz} or π^*_{Ph} orbitals. Considering the molecular orbital composition and positive total charge on the NO group, the character of the nitrosyl ligand in **1** may be described as NO^+.

The d_{xy} rhenium orbital and π orbitals of the chloride ligands in an anti-bonding arrangement make the main contribution into the HOMO with α-spin and LUMO with β-spin. The LUMO with β-spin is mainly localised on the pyrazine ligand with the admixture of π^*_{Re-NO} anti-bonding orbitals. LUMO + 6 with α-spin and LUMO + 9 with β-spin are mainly of $d_{x^2-y^2} - \sigma_{Cl} - \sigma_O$ character with a substantial contribution from π^*_{pyz} and π^*_{Ph} orbitals. The participation of the dz^2 rhenium orbital is visible in LUMO + 11 with α-spin and LUMO + 12 with β-spin.



3.8. $ReCl_3(NO)(OPPh_3)(PPh_3)]$ (2)

For complex **2**, the π^*_{NO} orbitals are also distributed among several occupied MOs, and the largest contribution of π_{Re-NO} bonding orbitals is noticed for HOMO − 2 and HOMO − 1 with α-spin and HOMO − 1, HOMO orbitals with β-spin. The percent participations of π^*_{NO} orbitals in HOMO − 20 and HOMO − 18 with α-spin and HOMO − 19 and HOMO − 17 with β-spin do not reach 10%. LUMO + 2 and LUMO + 3 with α-spin and LUMO + 2 and LUMO + 4 are mainly composed of π^*_{Re-NO} orbitals (about 60%). Based on the molecular orbital composition and small spin densities on the nitrogen and oxygen atoms of the nitrosyl ligand, the character of the NO group in **2** may be described as NO^+.

Similar to complex **1**, HOMO with α-spin and LUMO with β-spin are d_{xy} rhenium orbitals with the admixture of chlorine π orbitals. The LUMO with α-spin is mainly of $d_{x^2-y^2} - \sigma_{Cl} - \sigma_P$ character with a substantial contribution from π^*_{Ph} orbitals. The dz^2 rhenium orbital makes a contribution into LUMO + 9 with α-spin and LUMO + 11 with β-spin. HOMO − 3 with α and HOMO − 3 with β-spin are localised on the chloride and phenyl ligands with a substantial contribution from the free electron pair on the phosphorous atom of the PPh_3 molecule.

3.9. NBO analysis

Additional information about the binding in complexes **1** and **2** was obtained by NBO analysis. In open-shell systems, the density operator separates into distinct components for α- and β-spin, leading to the possibility of different NBOs for different spins [54]. Table 7 presents the occupancies and NAO compositions of the selected α- and β-spin NBOs for complexes **1** and **2**. For compound **1**, six natural bond orbitals (three with α-spin and three with β-spin) were detected for the Re–N bond, and two orbitals (one with α-spin and one with β-spin) for the N–O bond. The Re–N bond orbitals of σ-character with α- and β-spins are polarised towards the nitrogen atom (ca. 77% at N) and the s and d orbitals of Re take part in the bonding. The Re–N bond orbitals of π-character are mainly polarised toward the metal atom and only d-orbitals of Re are included in the bonding. The N–O bond orbitals with α- and β-spins are slightly polarised towards the oxygen end. In the valence-bond treatment a linear bonding mode of the nitrosyl group may be represented by the following resonance forms [1]:

The results of the NBO analysis indicate that the resonance structure of D makes a significant contribution to the structure of complex **1**.

For complex **2**, significantly different NBOs for different spins are observed. One natural bond orbital for the Re–N bond and three orbitals for the N–O bond were detected in the case of orbitals with α-spin, whereas three NBOs for the Re–N bond and one orbital for the N–O bond were detected for orbitals with β-spin. For complex **2**, the α and β natural Lewis structure can be represented by the resonance structure of A and D, respectively. The total occupancy number of the natural bond orbitals for the Re–N bond is larger for complex **1**, whereas the total occupancy number of the NBOs for the N–O bond is larger for **2**. It indicates that the π-backdonation is stronger for complex **1**. The changes of Re–N and N–O bond distances, listed in Tables 1 and 2, also confirm the above-discussed results. An insignificant shortening of the Re–N distance and elongation of the N–O bond length can be noticed for complex **1**.

3.10. Electronic spectra

The experimental and calculated electronic spectra of **1** are presented in Fig. 3. Each calculated transition in Fig. 3(b) was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.06.

Tables 8 and 9 show the energy and molar absorption coefficients of the experimental absorption bands and the spin-allowed doublet–doublet electronic transitions calculated with the TDDFT method for **1** and **2**, respectively. The positions and molar absorption coefficients of the electronic bands for complex **2** have been taken from paper [17].

The investigated complexes are of large size and the number of basis functions are equal to 510 and 718 for **1** and **2**, respectively. Eighty electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectra of **1** and **2** were calculated to ~260 nm, so the shortest wavelength experimental bands cannot be assigned to the calculated transitions. However, considering that the solution spectra of PPh_3, $OPPh_3$ and pyrazine exhibit intense absorption bands in the 260–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations.

The calculations result in many transitions with very small oscillator strengths. Except for the electronic transitions of $d \rightarrow \pi^*_{NO}$ character and the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.0040 are listed in Tables 7 and 8.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions, the main components of the molecular orbital are used. The bonding $\pi_{Re–NO}$ orbitals are assigned as d orbitals, and the antibonding $\pi^*_{Re–NO}$ orbitals as π^*_{NO}.

3.11. *$ReCl_3(NO)(OPPh_3)(pyz)]$ (**1**)*

In the description of the electronic transitions of **1** the main components of the molecular orbital are used: the LUMO with β-spin is assumed as an orbital of d

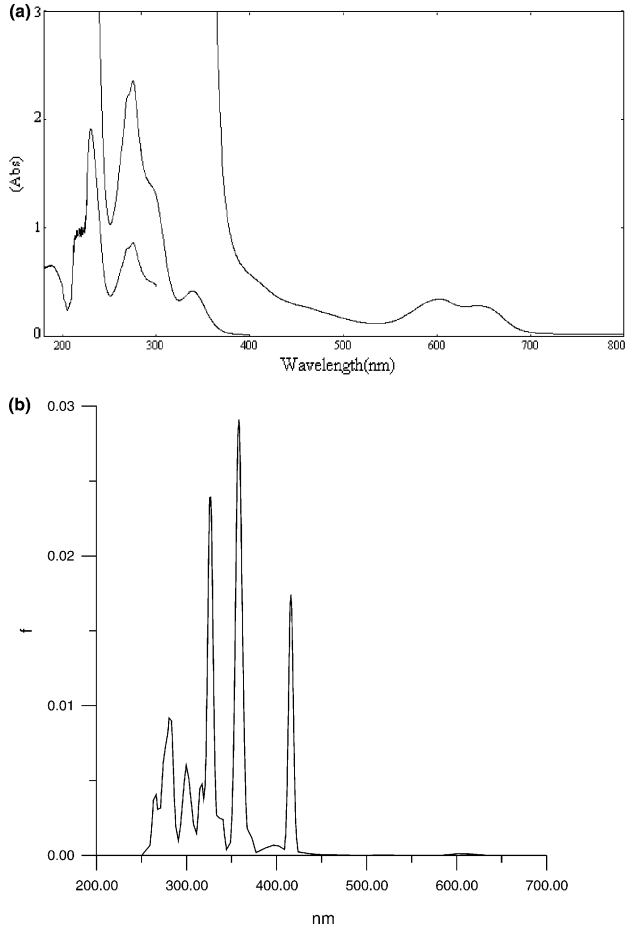

Fig. 3. The experimental (a) and calculated (b) electronic absorption spectrum of **1**.

character, LUMO with α-spin and LUMO + 1 with β-spin are described as π^*_{Ph} orbitals, LUMO + 4 with α-spin and LUMO + 5 with β-spin are treated as π^*_{Ph} orbitals.

The longest wavelength experimental bands at 646.2 and 603.6 nm may be attributed to the transitions of $d_{Re}/\pi_{Cl} \rightarrow d$ character with small oscillator strengths, calculated at 621.3 and 600.9 nm, respectively.

The weak absorption band at 458.9 nm is assigned to the calculated transitions with small oscillator strengths at 526.4 and 463.2 nm. The first one corresponds mainly to the electronic transition from the rhenium d orbitals onto π* orbitals of the nitrosyl group. Considering that the bonding π_{Re-NO} and anti-bonding π^*_{Re-NO} orbitals are mixed with the π chloride and π^*_{Ph} orbitals respectively, the character of the transition at 526.4 nm is determined as $d_{Re}/\pi_{Cl} \rightarrow \pi^*_{NO}/\pi^*_{Ph}$. The transition at 463.2 nm is of $d_{Re}/\pi_{Cl} \rightarrow \pi^*_{pyz}$ origin.

The experimental band at 408.5 nm is also attributed to transitions of $d/\pi_{Cl} \rightarrow \pi^*_{Ph}$ and $d/\pi_{Cl} \rightarrow d/\pi^*_{Ph}/\pi^*_{pyz}$ character with small oscillator strengths, calculated at 449.0 and 437.3 nm, respectively.

The experimental absorption band at 359.4 nm is assigned to the transition calculated between 420 and 335 nm. These transitions are mainly of LMCT ($\pi_{Cl} \rightarrow d$) character. The electronic transitions from the rhenium d orbitals onto π* orbitals of the nitrosyl group calculated in the range 420–335 nm have small oscillator strengths and they do not contribute significantly to the overall shape of the spectrum.

The experimental band at 309.0 nm is attributed to the calculated transition of $\pi_{Cl} \rightarrow \pi^*_{pyz}$ character at 326.7 nm and some LMCT ($\pi_{Cl}/\pi_{Ph}/\pi_O \rightarrow d$) transitions. LUMO + 1 with β-spin has a substantial admixture of the rhenium d orbitals, so the transition from chloride ligand to π^*_{pyz} orbitals are mediated by the metal.

3.12. $ReCl_3(NO)(OPPh_3)(PPh_3)]$ (**2**)

In the description of the electronic transitions of **2** the main components of the molecular orbital are used: the LUMO with β-spin is assumed as an orbital of d character. LUMO + 1 and LUMO + 2 with α-spin and LUMO + 2 and LUMO + 4 with β-spin are described as π^*_{NO} orbitals.

The longest wavelength experimental bands at 719.9 and 656.2 nm may be attributed to transitions of $d/\pi(Cl) \rightarrow d$ character with small oscillator strengths, calculated at 756.8 and 671.3 nm, respectively.

The experimental absorption bands at 421.0 and 356.0 nm are assigned to the LMCT ($\pi_{Cl} \rightarrow d$, $\pi_{Ph} \rightarrow d$ and $n(P) \rightarrow d$) transitions with large oscillator strengths. In comparison with complex **1**, the LMCT ($\pi_{Cl} \rightarrow d$, $\pi_{Ph} \rightarrow d$ and $n(P) \rightarrow d$) electronic transitions are bathochromically shifted. The electronic transitions from the rhenium d orbitals onto π* orbitals of the nitrosyl group have small oscillator strengths and they do not contribute significantly to the overall shape of the bands at 421.0 and 356.0 nm. Similar to complex **1**, they are hidden under the more intense transitions of LMCT character. However, such small values of the oscillator strengths seem to be typical of $d \rightarrow \pi^*_{NO}$ transitions, and they have been supported by the calculations for other metal nitrosyls [55,56].

The experimental band at 279.0 is mainly attributed to the calculated transition of $\pi_{Cl} \rightarrow d$ character at 298.5 nm.

The intense absorption band at 266.0 is assigned to the interligand charge transfer transitions, but this assignment is probably not complete. Similar to complex **1**, some additional intraligand and interligand transitions can be expected at higher energies in the calculated spectrum.

4. Conclusions

The $[ReCl_3(NO)(OPPh_3)(pyz)]$ (**1**) complex has been obtained by two different routes, and characterised by IR, UV–Vis and magnetic measurements. Its crystal and molecular structure has been determined. Theoretical studies of $[ReCl_3(NO)(OPPh_3)(pyz)]$ and the related complex $[ReCl_3(NO)(OPPh_3)(PPh_3)]$ (**2**) have been performed by the DFT method with the aim to investigate their molecular and electronic structures, spectral properties and bonding. Most of the MOs of **1** and **2** have complicated character. The electronic configuration of the metal center in the investigated complexes is as follows: $(d_{xz})^2(d_{yz})^2(d_{xy})^1$. The d_{xy} rhenium orbital makes the main contributions into the HOMO with α-spin and LUMO with β-spin. The occupied d_{yz} and d_{xz} rhenium orbitals participate in back-donation from the central ion to the NO ligand. However, the d_{yz}/d_{xz} and π^*_{NO} orbitals are distributed among several occupied MOs to give a considerable contribution into several HOMO and LUMO orbitals. For both complexes, the bonding π_{Re-NO} orbitals are localised mainly on the rhenium d orbitals, whereas the π^*_{Re-NO} orbitals have prevalent NO character. The results of the NBO analyses indicate a stronger π-backdonation in complex **1**. A shortening of the Re–N distance and elongation of the N–O bond length observed for complex **1** confirms it. The TDDFT calculations for complexes **1** and **2** reveal that the electronic transitions from the rhenium d orbitals onto the π* orbitals of the nitrosyl group have small oscillator strengths and they do not contribute significantly to the overall shape of the spectrum. They are hidden under the more intense transitions of LMCT character.

5. Supplementary data

Supplementary data for $C_{22}H_{19}Cl_3N_3O_2PRe$ are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number: 243040.

Compounds of some alkylamido-substituted cyclic tetraamines with nickel(II); the structure of *trans*-[Ni(L)(OCO_2H)(OH_2)]·*trans*-[Ni(L)(OH_2)$_2$] ClO_4·(HCO_3)$_2$, L = *trans*-6,13-dimethyl-6,13-bis(ethylamido)-1,4,8,11-tetraazacyclotetradecane

Abstract

The amino substituents of (*trans*-6,13-diamino-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) are readily acylated by reaction with acetic or propionic anhydrides to form the 6,13-bismethylamido-(acetylamido) or 6,13-bis(propionylamido)-(ethylamido) substituted cations, $[Ni(diamme)]^{2+}$ or $[Ni(diamet)]^{2+}$. The amide substituents, which are resistant towards hydrolysis, show little tendency to coordinate. Square planar salts and octahedral compounds *trans*-[Ni(diamme/et)X_2], X^- = Cl^-, NCS^-, N_3^-, NO_2^-, were prepared. The structure is reported for *trans*-(aquo-κ^1O)-(hydrogen carbonato-κ^1O)-($S^1S^4R^8R^{11}$-*trans*-6,13-bisethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane-$\kappa^4N^1N^4N^8N^{11}$)nickel(II) *trans*-di(aquo-κ^1O)-($R^1R^4S^8S^{11}$-*trans*-6,13-bisethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane-$\kappa^4N^1N^4N^8N^{11}$)nickel(II) perchlorate bis(hydrogen carbonate), $C_{18}H_{42}N_6NiO_4$·$C_{19}H_{41}N_6NiO_6$·2(CHO_3)·ClO_4. The asymmetric unit has two cations with the macrocycle in square-planar coordination by the endocyclic nitrogen atoms of diamet, one with *trans*-diaqua- and the other with *trans*-aqua-(hydrogen carbonato)-unidentate additional ligands. The two un-coordinated hydrogen carbonate ions are present as a hydrogen-bonded planar dimer.

1. Introduction

There have been many studies of the coordinating properties of amides and peptides [1,2] and of azamacrocycles with N-amido [3] or C-amino substituents, but few of azamacrocycles with C-amido substituents.

Compounds of the di-amino-substituted cyclic tetraamine *trans*-6,13-diamino-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane, diam, have been prepared by reduction of the nitro functions of (*trans*-6,13-diamino-6,13-dinitro-1,4,8,11-tetraazacyclotetradecane)-metal cations, formed by reactions of bis(ethane-1,2-diamine)-metal compounds with methanal plus nitroethane [4–7]. The preparations, properties and structures of compounds of diam with Ni(II) have been described [7].

The amine substituents of $[Cu(diam)]^{2+}$ have been alkylated [8,9] and converted into exo-olefine functions by nitrosation [10]. Reaction of $[Pt(Hdiam)](ClO_4)_3$ with chlorine forms a Pt(IV) compound with dichloroamine substituents [11]. The amine substituents of diam have been converted to the (ferrocenyl-methylamino)-function and Cu(II) and Zn(II) compounds of this ligand

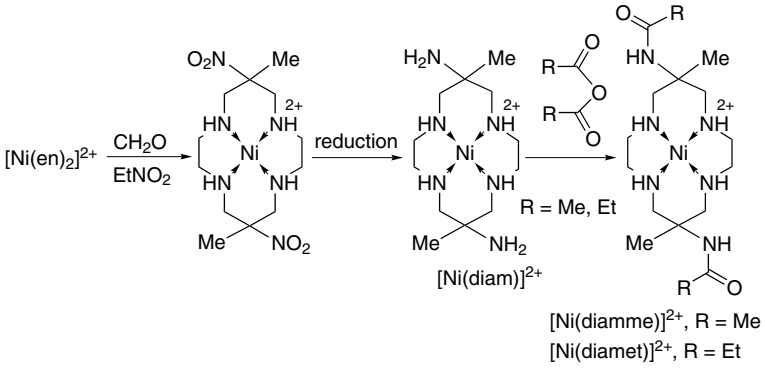
prepared [12]. In this communication the facile acylation of the amine substituents of $[Ni(diam)]^{2+}$ to form methyl- and ethyl-amido substituents is described and the structure of one ethylamido compound reported.

2. Results

Reactions of $[Ni(diam)](ClO_4)_2$ with acetic anhydride or propionic anhydride in DMF or DMSO form the 6,13-bis(methylamido) or 6,13-bis(ethylamido) substituted compounds $[Ni(diamme)](ClO_4)_2$ or $Ni(diamet)](ClO_4)_2$, see the Scheme 1. Analogous reactions occur for $[Ni(diam)]Cl_2$ to form the dichloro compounds $[Ni(diamme)Cl_2]$ and $[Ni(diamet)Cl_2]$. The infrared spectra of the compounds all show bands at c. 1650 and 1550 cm^{-1} assignable as the secondary amide bands I and II. The amido formulations are supported by the X-ray crystal structure determination reported below.

The cations $[Ni(diamme)]^{2+}$ and $[Ni(diamet)]^{2+}$ form orange singlet ground state ($S = 1$) square planar perchlorate salts which form orange $S = 1$ solutions in weakly coordinating solvents such as water, alcohols or acetone. They crystallise as triplet ground state ($S = 3$) solvates from DMSO, DMF (blue-violet) and acetonitrile (green), while broad NMR signals from solutions in these solvents indicate the presence of $S = 3$ species. An ammine adduct crystallizes from aqueous ammonia. In strongly basic aqueous solution (e.g. in 1 mol dm^{-3} NaOH) the compounds form lilac coloured solutions, the spectra showing bands attributable to both $S = 1$ and $S = 3$ species. The latter could have coordinated amidato groups, or coordinated hydroxide. The basic solutions on exposure to the atmosphere slowly deposit blue-violet crystals, also formed by addition of sodium hydrogen carbonate to an aqueous solution of the perchlorate salt. Analysis and IR spectra confirm the diamme compound as $\{Ni(diamme)\}\cdot 2(HCO_3)\cdot 4H_2O$ but the crystals obtained from $[Ni(diamet)](ClO_4)_2$ have the composition $2\{Ni(diamet)\}\cdot 3(HCO_3)\cdot ClO_4\cdot 3H_2O$. This has the structure, below, *trans*-$[Ni(diamet)(OH_2)(OCO_2H)]\cdot$ *trans*-$[Ni(diamet)(OH_2)_2]\cdot (HCO_3)_2\cdot ClO_4$, with two distinct cations, one with two *trans*-coordinated water ligands and the other with *trans*-coordinated water and hydrogen carbonato ligands. Other similarly prepared samples did not contain perchlorate, and are presumably analogous to the diamme compound, which could have coordinated water molecules, and/or hydrogen carbonate ions.

Other octahedral $S = 3$ compounds with *trans*-coordinated chloride, thiocyanate, nitrite and azide were prepared.



The amide functions of the compounds are resistant to hydrolysis, showing no significant hydrolysis when heated in 2 mol dm^{-3} HCl at 100 °C for 1 h and only slight hydrolysis after 1 h at 100 °C in 2 mol dm^{-3} aqueous NaOH.

3. Structural study

The structure of *trans*-di(aquo-$\kappa^1 O$)-($R^1R^4S^8S^{11}$-*trans*-6,13-bisethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane-$\kappa^4N^1N^4N^8N^{11}$)nickel(II) *trans*-(aquo-$\kappa^1 O$)-(hydrogencarbonato-$\kappa^1 O$)-($S^1S^4R^8R^{11}$)-*trans*-6,13-bisethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane-$\kappa^4N^1N^4N^8N^{11}$)nickel(II) perchlorate bis(hydrogen carbonate), $C_{18}H_{42}N_6NiO_4\cdot C_{19}H_{41}N_6NiO_6\cdot ClO_4\cdot 2(CHO_3)$, was determined by X-ray diffractometry, see Section 5.2 for details.

The asymmetric unit contains two cations, each with (*trans*-6,13-bisethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) cations with the Ni(II) in square-planar coordination by the four endocyclic secondary amine nitrogen atoms. The cation including Ni1 has O1 of a water molecule and O42 of the hydrogen carbonate ion including C40 coordinated *trans*, see Figs. 1 and 2. The cation including Ni2 has O2 and O3 of water molecules coordinated *trans*. The charges are balanced by two hydrogen carbonate ions (including C50 and C60), which are linked by hydrogen bonding, and a rotationally disordered perchlorate ion.

The macrocyclic ligand cations have nitrogen configurations $\{R^1R^4S^8S^{11}$ for Ni1 and $S^1S^4R^8R^{11}$ for Ni2$\}$

Scheme 1.

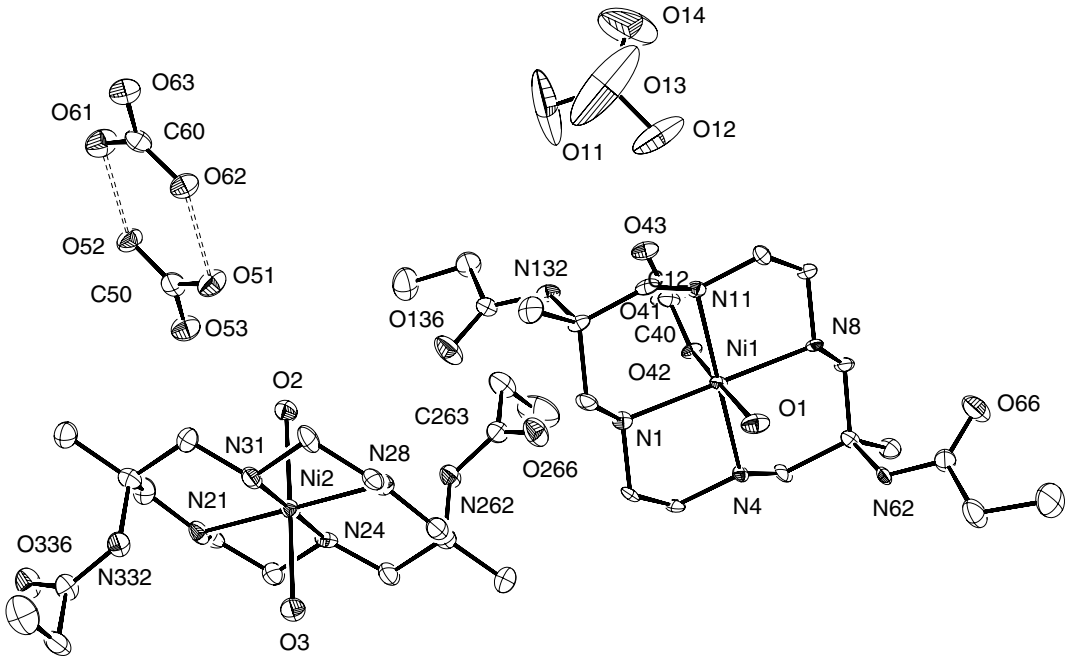


Fig. 1. The asymmetric unit for *trans*-[Ni(diamet)(CO_2OH)(H_2O)]·*trans*-[Ni(diamet)(H_2O)$_2$]·ClO_4·2(CO_2OH), drawn [13] with displacement ellipsoids at the 50% confidence level, with H-atoms omitted for clarity.

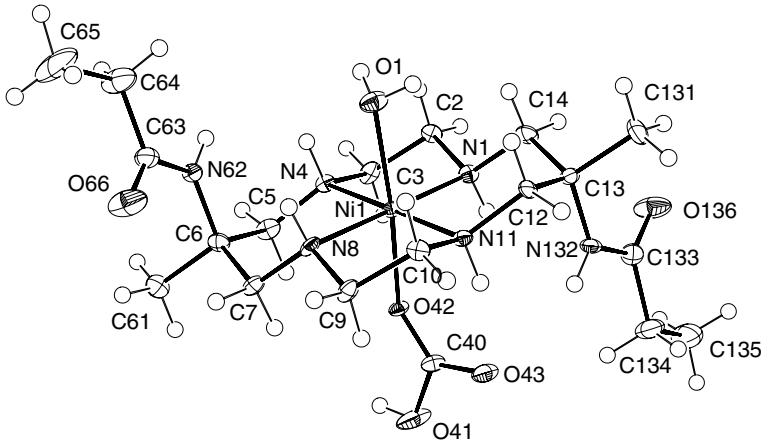

Fig. 2. The cation *trans*-[Ni1(diamet)(CO_2OH)(H_2O)]$^{2+}$, drawn [13] as for Fig. 1, but with H(N) and H(O) atoms shown as circles of arbitrary radius. The cation *trans*-[Ni2(diamet)(H_2O)$_2$]$^{2+}$ is similar.

and conformations with near symmetrical chair and gauche conformations of the chelate rings, similar to compounds with planar coordinated diam [7] or cyclam. The *trans*-diaqua cation including Ni2 is close to centrosymmetrical and the *trans*-aqua-(hydrogen carbonato) cation including Ni1 has near C_2 symmetry and considering only the coordinated oxygen atoms of the *trans* ligands is also close to centrosymmetrical. The ring substituents are arranged *trans*, with the amido substituents axially and the methyl substituents equatorially oriented (cf. *trans*-[Ni(diam)($NCS)_2$] where the un-coordinated amino groups are also axially oriented [9]). The conformations of the two macrocycle cations, as indicated by atomic displacements from the mean N_4 planes are similar (see Table 1), the greatest difference being in the displacement of the terminal methyl groups (C65, C135 and C265, C335).

The mean Ni–N distance is 2.05(1) Å, typical of triplet ground state cyclam-like macrocycles [7]. The Ni–O distances for the diaqua cation are similar, more divergent about the same mean for the aqua (hydrogen carbonato) cation, all slightly longer than usual, see Tables 2 and 3 for significant dimensions. The amide substituents have no interactions with the nickel ions, with Ni–N c. 3.89 Å and Ni–O even longer.

The hydrogen carbonate ion including C40, coordinated to Ni1 by O42, is oriented approximately normal to the NiN_4 plane; aligned 'above' Ni1–N11 (dihedral

angle N11–Ni–O42···O43 = −8.3°) with an N11–H11···O43 hydrogen bond, see Table 4 for hydrogen bond parameters.

The macrocylic cations including Ni1 and Ni2 are arranged in stacks of like cations, linked by hydrogen bond N1–H1···O266, normal to the 100 plane, with the Ni1N_4 and Ni2N_4 planes inclined at 46.1(1)°, see Fig. 1. The Ni1(macrocycle) stacks are linked by hydrogen bond O1–H1D···O43 ($x + 1$, y, z) between the coordinated hydrogen carbonate ion of one cation and the coordinated water of the adjacent cation. The rotationally disordered perchlorate anions form a stack between the Ni1(macrocycle) stacks, with Cl1 aligned approximately midway between the Ni1(macrocycle) layers, linked by hydrogen bonds to the coordinated water [O1–H1···O43 ($x + 1$, y, z)] and the coordinated hydrogen carbonate ion [O41–H41···O13 (x, $y + 1$, z)].

The two un-coordinated hydrogen carbonate ions are close to coplanar (mean displacement of C and O atoms from the C_2O_6 mean plane = 0.006(5) Å) and linked by symmetrical hydrogen bonds O51–H51···O62 and O61–H61···O52. These hydrogen carbonate ions form stacks between the Ni2(macrocycle) stacks, with the N_4 and C_2O_6 planes inclined at 47.4(1)°. The atoms O53 and O63 are interlaced between the stacked Ni2(macrocycle)s, with O53 intruding above bond N31–C32 and O63 intruding above bond N24–C25. Hydrogen bonds [O2–H2C···O53, O2–H2D···O63, O3–H3D···O53 and O3–H3C···O63] link the coordinated water molecules and these hydrogen carbonato ions, to form a chain linking the Ni2(macrocycle) macrocycle stacks normal to the 100 plane.

Table 4

4. Discussion

The ring secondary amine groups of $[Ni(diam)]^{2+}$ are non-labile, while the substituent primary amine groups are either un-coordinated, or coordinated but labile [7], and therefore accessible for acylation, which occurs readily with acyl anhydrides in DMF or DMSO. The resulting amido compounds are resistant to hydrolysis. Developments of this reaction should provide a convenient synthetic pathway for the incorporation of (azamacrocycle)metal cations into more complex systems.

Coordination of the amino substituents of $[Ni(diam)]^{2+}$ requires the associated six-membered chelate ring to adopt a strained boat conformation, which reduces the coordinating ability. However, the amine substituents for $[Ni(diam)]^{2+}$generally coordinate, unless a more competitive ligand, such as thiocyanate is present, or they are protonated [7].

Simple amides are moderately strong ligands, usually coordinating through the nitrogen [1–3], but the amido groups of $[Ni(diamme)]^{2+}$ and $[Ni(diamet)]^{2+}$show no indication of coordination. Deprotonated (amidato) groups are generally stronger ligands and spectra suggest that in base the amidato groups of diamme and diamet *may* coordinate to Ni(II). However, the displacement of the possible amidate ligands by the hydrogen carbonate ion indicates that these amidate functions can have only weak coordinating abilities (see Section 5.1.5). Molecular mechanics calculations indicate that for coordination of the amidate function the strain energy would be less for *O*-coordination than for *N*-coordination.

5. Experimental

The compounds $[Ni(diam)](ClO_4)_2$ and $[Ni(diam)]Cl_2$ [7] were prepared as hydrates, as previously described, and dehydrated by heating at 100 °C. DMSO can be substituted for DMF in the preparations; commercial anhydrous DMF and DMSO were used; these solvents need not be rigorously dried.

The perchlorate salts described were not observed to be shock sensitive and decomposed non-violently if strongly heated. They should still be treated with the caution due to any perchlorate compound.

5.1. Synthesis of compounds

5.1.1. (trans-6,13-bis-Ethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetra-decane)nickel(II) perchlorate, [Ni(diamet)](ClO4)2

$[Ni(diam)](ClO_4)_2$ (1 g) was dissolved in DMF (1 g) by warming. Propionic anhydride (1 g) was added and the solution heated at c. 100 °C for 30 min. The colour slowly darkened, and orange crystals deposited. Propan-2-ol (20 cm^3) was added and after 1 h the orange crystals were filtered off, yield 90+%. The product crystallised from hot DMF (in which it is very soluble)/propan-2-ol, or rapidly from hot water (in which it is sparingly soluble) as orange crystals (a), while yellow crystals (b) formed on slow crystallization from water; mixtures were often observed. The interconversion was inhibited by acid, more rapid in base, suggesting the forms are isomers with different nitrogen configurations. *Anal.* Calc. for $C_{18}H_{38}Cl_2N_6NiO_{10}$: C, 34.4; H, 6.1; N, 13.4. Found for (a): C, 34.4; H, 6.3; N, 13.5%. Spectra: infrared {ν_{max} (cm^{-1})} (a): *v*(NH) 3341sp, 3197sp, 3087w; amide bands 1672, 1542; (b): (NH) 3281, (3194, 3177), 3087w; amide bands 1649, 1553; visible spectra (same for both forms) {λ_{max} (nm) (ε) (mol dm^{-3} cm^{-1})} in water; 446 (48); in 1 mol dm^{-3} NaOH; 450 (14), 524 (22), 696 (8).

5.1.2. trans-Dichloro-(trans-6,13-bis-ethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II), trans-[Ni(diamet)Cl2]

$[Ni(diam)]Cl_2$ (1 g), DMF (1 g) and propionic anhydride (1 g) were heated at c. 100 °C for 1 h. Ethanol (10 cm^3) was added and the insoluble blue-violet product filtered off and washed with ethanol. Alternatively, a few drops of conc. hydrochloric acid were added to a solution of the perchlorate salt in DMF or water, when the product precipitated and was treated as before. The compound is slow to dissolve in hot water, but ultimately quite soluble. It can be recovered as blue crystals by evaporation of this solution. *Anal.* Calc. for $C_{18}H_{38}Cl_2N_6NiO_2$: C, 43.2; H, 7.7; N, 16.8. Found: C, 42.8; H, 7.7; N, 16.8%. Infrared spectrum {ν_{max} (cm^{-1})} *v*(NH) 3307, 3279, 3245, 3064w; amide bands 1676, 1545.

5.1.3. trans-Diazido-(trans-6,13-bis-ethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) Hydrate, trans-[Ni(diamet)(N3)2]·H2O

Sodium azide was added to a hot aqueous solution of $[Ni(diamet)](ClO_4)_2$ when the lilac coloured product slowly crystallized. This was filtered off and washed with a small volume of water and then ethanol. *Anal.* Calc. for $C_{18}H_{40}N_{12}NiO_3$: C, 42.1; H, 7.5; N, 32.7. Found: C, 42.0; H, 7.5; N, 32.8%. Infrared spectrum {ν_{max} (cm^{-1})} *v*(NH) 3333, (3271, 3257), 3069w; *v*(N_3^-) 2045vs; amide bands 1685, 1546.

5.1.4. trans-(trans-6,13-bis-Ethylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)dithiocyanatonickel(II), trans-[Ni(diamet)(NCS-N)2]

This sparingly soluble blue-violet compound was prepared as for the azide, by using sodium thiocyanate. *Anal.* Calc. for $C_{20}H_{38}N_8NiO_2S_2$: C, 44.0; H, 7.0; N, 20.5. Found: C, 44.2; H, 6.9; N, 20.9%. Infrared spectrum {ν_{max} (cm^{-1})} *v*(NH) 3307, 3272; *v*(C≡N) 2086vs; amide bands 1675, 1530.

5.1.5. trans-diaqua-{trans-(6,13-Dimethyl-6,13-bisethylamido-1,4,8,11-tetraazacyclotetradecane)}nickel(II) trans-aqua-(hydrogen carbonato)-{trans-(6,13-dimethyl-6,13-bisethylamido-1,4,8,11-tetraazacyclotetradecane)}-nickel(II) bis(hydrogen carbonate) perchlorate, trans-[Ni(diamet)(HCO$_3$)(H$_2$O)]·trans-[Ni(diamet)(H$_2$O)$_2$]·ClO$_4$·2(HCO$_3$)

The pale blue-violet compound crystallized when $NaHCO_3$ was added to an aqueous solution of [Ni(diamet)](ClO$_4$)$_2$. It was filtered off and washed with cold water. *Anal.* Calc. for $C_{39}H_{85}ClN_{12}Ni_2O_{20}$: C, 39.2; H, 7.2; N, 14.1. Found: C, 39.2; H, 7.2; N, 14.1%. Infrared spectrum {ν_{max} (cm^{-1})}: ν(OH), ν(NH), 3384w, 3246, 3205, 3159, 3065, 2967, 2937, 2875w, (HCO$_3$) 2630br, 1670vs, 1634sh, amide band 1551. The crystals used for the structural determination grew slowly when a solution of [Ni(diamet)](ClO$_4$)$_2$ in 0.1 mol dm^{-3} NaOH solution was exposed to the atmosphere. The yellow perchlorate salt crystallized when a sample was heated in methanol.

5.1.6. (trans-6,13-bis-Methylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) perchlorate, [Ni(diamme)](ClO$_4$)$_2$

The orange compound was prepared as for the propionyl homologue by using acetic anhydride. *Anal.* Calc. for $C_{16}H_{34}Cl_2N_6NiO_{10}$: C, 32.0; H, 5.7; N, 14.0. Found: C, 32.3; H, 5.8; N, 14.2%. When crystallized slowly from water an orange trihydrate formed (weight loss at 100 °C: 8.22%. Calc. for loss of 3H$_2$O: 8.26%). Infrared spectrum {ν_{max} (cm^{-1})}: ν(NH) 3344, 3200, 3070w; amide bands 1675, 1547; hydrate: ν(OH) 3400br, ν(NH) 3246, 3202, 3159, 3068w; amide bands 1676, 1555. The IR spectrum of the hydrate after heating was the same as that of the unhydrated compound.

5.1.7. trans-Diazido-(trans-6,13-bis-methylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) Dihydrate, [Ni(diamme)(N$_3$)$_2$]·2H$_2$O

This lilac coloured compound was prepared as for the propionyl homologue. *Anal.* Calc. for $C_{16}H_{38}N_{12}NiO_4$: C, 36.9; H, 7.3; N, 32.2. Found: C, 37.0; H, 7.4; N, 32.6%. Infrared spectrum {ν_{max} (cm^{-1})} ν(OH) 3514, 3471; δ(HOH) 1627; ν(NH) 3351, 3226; ν(N$_3$) (2061, 2055, 2039sh)vs; amide bands 1676, 1556.

5.1.8. trans-(trans-6,13-bis-Methylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)dithiocyanatonickel(II), [Ni(diamme)(NCS-N)$_2$]

This blue-violet compound was prepared as for the propionyl homologue. *Anal.* Calc. for $C_{18}H_{34}N_8NiO_1S_2$: C, 41.8; H, 6.6; N, 21.7. Found: C, 41.8; H, 6.7; N, 21.8%. Infrared spectrum {ν_{max} (cm^{-1})} ν(NH) 3302, 3296, 3252; ν(NCS) (2086sh, 2079, 2073)vs; amide bands 1679, 1536.

5.1.9. trans-(6,13-Dimethyl-6,13-bisethylamido-1,4,8,11-tetraazacyclotetradecane)}bis(hydrogen carbonato)nickel(II) Tetrahydrate, trans-[Ni(diamme)(HCO$_3$)$_2$]·4H$_2$O

The blue-violet compound was prepared as for the related diamet homologue. The IR spectrum showed no bands assignable to perchlorate. *Anal.* Calc. for $C_{18}H_{44}N_6NiO_{18}$: C, 36.3; H, 7.5; N, 14.1. Found: C, 36.4; H, 7.6; N, 14.2%.

5.1.10. trans-(trans-6,13-bis-Methylamido-6,13-dimethyl-1,4,8,11-tetraazacyclotetradecane)dinitronickel(II), trans-[Ni(diamme)(NO$_2$)$_2$]

This pale brown compound crystallised when sodium nitrite was added to an aqueous solution of [Ni(diamme)](ClO$_4$)$_2$. it was filtered off and washed with a little cold water, then ethanol. *Anal.* Calc. for $C_{18}H_{34}N_8NiO_2S_2$: C, 39.0; H, 6.9; N, 22.7. Found: C, 38.8; H, 7.0; N, 22.7%. Infrared spectrum {ν_{max} (cm^{-1})} ν(NH) (3290, 3253), 3082; amide bands 1681, 1557, ν(NO$_2^-$) (1455, 1285).

5.2. Structural study

The structure of *trans*-[Ni(L)(CO$_2$OH)(H$_2$O)]·*trans*-[Ni(L)(H$_2$O)$_2$]·ClO$_4$·(CO$_2$OH)$_2$ (L = *trans*-(6,13-dimethyl-6,13-bisethylamido-1,4,8,11-tetraazacyclotetradecane)); *trans*-[Ni(diamet)(CO$_2$OH)(H$_2$O)]·*trans*-[Ni(diamet)(H$_2$O)$_2$]·ClO$_4$·2(CO$_2$OH)) was determined by X-ray diffractometry.

5.2.1. Crystal data [14]

$C_{18}H_{42}N_6NiO_4\cdot C_{19}H_{41}N_6NiO_6\cdot 2(CHO_3)\cdot ClO_4$, M_r = 1195.02, blue-violet needle grown from water (see 5.15), 0.8 × 0.02 × 0.02 mm. Triclinic, space group *P*1, a = 7.8940(4), b = 9.6549(4), c = 18.0054(8) Å, α = 86.917(2)°, β = 84.154(2)°, γ = 83.695(2)°, V = 1355.6(1) Å^3, Z = 1. Cell parameters from 5012 reflections.

5.2.2. Data collection [14]

Bruker SMART 1K CCD area detector diffractomer, ω scans, Mo Kα radiation, multi-scan absorption correction (based on symmetry-related measurements [15]), T_{min} = 0.495, T_{max} = 0.992, twinned crystal, 22241 measured reflections, 14372 independent reflections, 9857 reflections with $I > 2\sigma(I)$, R_{int} = 0.034, θ_{max} = 29.1°, h = −15 → 15, k = −19 → 19, l = −24 → 23.

5.2.3. Refinement [16]

Refinement on F^2, $R[F^2 > 2\sigma(F^2)]$ = 0.056 (8437 reflections), $wR(F^2)$ = 0.147 ($w = 1/[\sigma^2(F_o^2) + (0.092P^2)]$) where $P = (F_o^2 + 2F_c^2)/3$, 683 parameters. Flack parameter = 0.02(2) [17].

H(C) and H(N) atoms are in calculated positions, H(O) atoms for the water molecules and hydrogen

carbonate ions were located from difference syntheses and the positions refined with the OH distances and HOH angles constrained (O–H = 0.82(2), H···H = 1.40(2) Å). All H-atoms are riding. Modeling of the rotationally disordered perchlorate ion with two sets of O atoms, with occupancies of 0.6 and 0.4, led to a solution with a small reduction in *R*-values.

A solution of the structure in space group $P\bar{1}$ was investigated. This has essentially the same structure, but with the H_2O and HCO_3 ligands on Ni2 disordered about an inversion centre at Ni2, and the perchlorate ion oxygen atoms disordered about an inversion centre. This solution is less satisfactory, with larger *R*-values, thermal ellipsoids and positional s.u. values than that in space group $P\bar{1}$.

Appendix A. Supplementary data

Crystallographic data has been deposited with the Cambridge Crystallographic Data Centre; CCDC 253370. Abstract

Previously we have proved that barium perchlorate is a highly effective template agent in the formation of the Schiff-base lateral macrobicycles $\mathbf{L^1}$ and $\mathbf{L^2}$ (receptors derived from the condensation of *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 with 2,6-diformylpyridine and 2,6-diformyl-4-methylphenol, respectively). Aiming to understand the effect that the nature of the counteranion present in the reaction medium has on the barium template potential, we have carried out the corresponding template synthesis in the presence of barium thiocyanate. We have found that considerably longer reaction times are required to obtain both receptors when barium thiocyanate is employed. The barium template remains trapped into the formed macrobicyclic cavity and compounds of formula $Ba(L^1)(SCN)_2 \cdot H_2O$ (**1**) and $Ba(L^2)(SCN)_2 \cdot 2H_2O$ (**2**) were isolated. The X-ray crystal structure of **1** shows the metal ion coordinated to the eight donor atoms of the receptor and to the nitrogen atom of a isothiocyanate group, the coordination polyhedron being best described as a monocapped distorted dodecahedron. In **1**, the metal ion is nearly centred inside the macrobicyclic cavity of $\mathbf{L^1}$, whereas NMR studies in solution indicate that in **2** the barium ion is asymmetrically situated in the macrobicyclic cavity of $\mathbf{L^2}$. This asymmetric coordination is attributed to the proton transfer from the phenol group to the nitrogen atom of one of the imine groups.

1. Introduction

The coordination chemistry of macrocyclic ligands [1,2] is a fascinating area of intense study for inorganic chemists. One aspect of the interest that macrocyclic ligands have promoted steams from the fact that depending on features such as the nature, number and arrangement of the ligand donors, as well as ligand conjugation, substitution and flexibility, it is possible to tailor-make different types of macrocyclic molecules for specific uses. In particular, the cyclic framework of crown ethers and cryptands affords an interesting platform for the complexation of metal ions [3]. Likewise, according to the number of connecting bridges used for their construction as well as to the nature of the subunits used as building blocks, a variety of macropolycyclic structures may be envisaged. Lateral macrobicycles (described as dissymmetrical molecules structurally based on the combination of two different binding units, a chelating one and a macrocyclic one) are one of them [4]. Taking into account the peculiar structural features that the lateral macrobicycles show, it is easy to understand that this type of macropolycyclic architectures exhibit a range of interesting and potentially useful molecular recognition properties [5]. However, to date the coordinative properties of lateral macrobicycles remain considerably unexplored.

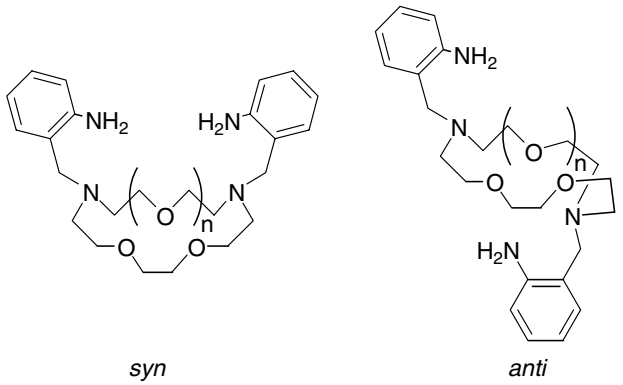
In the recent past a great attention has been devoted to the design and synthesis of Schiff bases with enhanced ability to selectively encapsulate given metal ions [6]. In particular, macrocyclic Schiff bases and Schiff-base derived cryptands and cryptates have successfully been proposed as excellent systems in the complexation of metal ions. However, no example of a Schiff-base lateral macrobicycle was reported until 1999 when we described, at the first time, examples of Schiff-base lateral macrobicycles [7]. These macrobicycles, shown in Scheme 1, structurally derive from bibracchial lariat ethers incorporating pendant aniline moieties. Subsequent studies demonstrated that these systems posses promising coordinating properties [8–10]. We have found that these Schiff-base lateral macrobicycles cannot be prepared by direct reaction between the organic precursors; but barium perchlorate can act as a template, thereby facilitating the formation of the desired macrobicycles in high yields. In fact, it is known that the direct synthesis of a free macrocycle from its organic precursors often results in a low yield of the desired cyclic product, with side reactions such as polymerisation predominating. Consequently, some synthetic strategies such as the use of high dilution conditions, the incorporation of a rigid group in the open chain precursors, and the use of template agents have been developed. Particularly, template Schiff base condensations between dicarbonyl compounds and diamines are among the simplest and most popular methods for macrocycle synthesis [11].

Previously, we have demonstrated that the effectiveness of barium(II) perchlorate to template the macrobicycles $\mathbf{L^1}$ to $\mathbf{L^4}$ comes from its ability to arrange the pendant arms of the diamine precursor [*N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 (for $\mathbf{L^1}$ and $\mathbf{L^2}$) or *N*,*N*′-bis(2-aminobenzyl)-4,13-diaza-18-crown-6 (for $\mathbf{L^3}$ and $\mathbf{L^4}$)] in a *syn* conformation (Fig. 1) [12]. Aiming to understand the effect that the nature of the counteranion present in the medium reaction had on the barium template potential, we also carried out the corresponding template synthesis in the presence of barium thiocyanate under the same experimental conditions used with barium perchlorate, finding that whereas barium thiocyante can also template the formation of the largest macrobicycles $\mathbf{L^3}$ and $\mathbf{L^4}$, it was not able to do it with the smallest $\mathbf{L^1}$ and $\mathbf{L^2}$ [7]. We have now slightly modified the synthetic conditions, and in this paper we discuss the formation of macrobicycles $\mathbf{L^1}$ and $\mathbf{L^2}$ in the presence of barium thiocyanate. We also describe the structures of the corresponding barium complexes both in solution and in the solid state, and we compare them to those previously described for their perchlorate analogues [7,13].



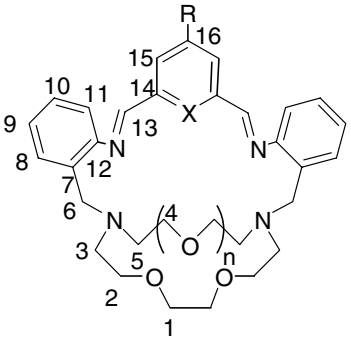


Fig. 1. The *syn* and *anti* conformations of the diamine precursors used for the preparation of macrobicycles $\mathbf{L^1}$ and $\mathbf{L^2}$ ($n = 1$) or $\mathbf{L^3}$ and $\mathbf{L^4}$ ($n = 2$).

$\mathbf{L^1}$: n = 1, R = H, X = N
$\mathbf{L^2}$: n = 1, R = CH_3, X = C-OH
$\mathbf{L^3}$: n = 2, R = H, X = N
$\mathbf{L^4}$: n = 2, R = CH_3, X = C-OH

Scheme 1.

2. Experimental

2.1. Reagents

2,6-Diformylpyridine and 2,6-diformyl-4-methyl-phenol were synthesised according to literature methods [14–16]. The diamine *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 was prepared as previously described by us [8]. All other chemicals were purchased from commercial sources and used without further purification. Solvents were of reagent grade purified by the usual methods.

2.2. Template synthesis

2.2.1. $Ba(L^1)(SCN)_2 \cdot H_2O$ (1)

A solution of $Ba(SCN)_2 \cdot H_2O$ (0.072 g; 0.266 mmol) in absolute ethanol (50 mL) was added with stirring to a solution of the diamine *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 (0.114 g; 0.266 mmol) also in absolute ethanol (120 mL). The mixture was vigorously stirred

and heated while a solution of 2,6-diformylpyridine (0.036 g; 0.266 mmol) in absolute ethanol (60 mL) was added dropwise over one day. After the addition was complete, the resulting pale yellow solution was stirred and refluxed for 26 h. The solution was filtered while hot and the filtrate rotary-evaporated to 30 mL. Upon cooling the filtrate to room temperature, a pale yellow microcrystalline precipitate formed, which was collected by filtration. Yield: 0.085 g (41%). *Anal.* Calc. for $C_{33}H_{37}N_7O_3BaS_2 \cdot H_2O$: C, 49.6; H, 4.9; N, 12.2. Found: C, 49.9; H, 4.9; N, 12.0%. FAB-MS: $m/z = 723$ $[Ba(L^1)(SCN)]^+$, 665 $[Ba(L^1)]^+$. IR (KBr discs): 1631 $\nu(C{=}N)_{imine}$; 1579 $\nu(C{=}N)_{pyridine}$; 2048, 2038 (SCN) cm^{-1}. ^1H NMR (acetonitrile-d_3), δ: 2.3–4.2 (m, 24H); 7.37(m, 4 H); 7.52(t, 2H); 7.18(d, 2H); 8.63(s, 2H); 8.08(d, 2H); 8.32(t, 1H). ^{13}C NMR (acetonitrile-d_3), δ: 165.6; 153.7; 152.7; 141.0; 133.6; 131.6; 131.1; 130.6; 128.1; 121.5; 69.9; 69.6; 69.4; 60.2; 51.9. X-ray quality crystals of formula $[Ba(L^1)(NCS)](SCN) \cdot CH_3CN$ were grown by slow diffusion of diethyl ether into a solution of **1** in acetonitrile.

2.2.2. $Ba(L^2)(SCN)_2 \cdot 2H_2O$ (2)

The orange complex was prepared as described for **1** by using 2,6-diformyl-4-methylphenol (0.043 g; 0.266 mmol). After the addition was complete, the resulting orange solution was stirred and refluxed for 48 h. Yield: 0.094 g (57%). *Anal.* Calc. for $C_{35}H_{40}N_6O_4BaS_2 \cdot 2H_2O$: C, 49.7; H, 5.2; N, 9.9. Found: C, 49.6; H, 5.1; N, 9.5%. FAB-MS: $m/z = 693$ $[Ba(L^1)]^+$. IR (KBr discs): 3430 $\nu(O{-}H)_{phenol}$ 1620 ($\nu(C{=}N)_{imine}$); 2057 (SCN) cm^{-1}. ^1H NMR (acetonitrile-d_3), δ: 2.40 (s, 3H), 4.24 (d, 2H); 3.73–2.96 (m, 22H); 7.60–7.37 (m, 10H); 7.67 (s, 1H); 8.57(s, 1H), 17.15 (b, 1H). ^{13}C NMR (acetonitrile-d_3), δ: 134.10; 131.01; 130.58; 129.08; 121.99; 69.77; 69.09; 68.52; 55.46; 19.80.

2.3. Measurements

Elemental analyses were carried out on a Carlo Erba 1180 elemental analyser. FAB mass spectra were recorded on a Fisons Quatro mass spectrometer with a Cs ion gun using 3-nitrobenzyl alcohol as matrix. ^1H and ^{13}C NMR spectra were run on a Bruker AC 200F using acetonitrile-d_3 as solvent. IR spectra were recorded, as KBr discs, using a Bruker Vector 22 spectrophotometer. Conductivity measurements were carried out with a Crison Micro CM 2201 conductivimeter using ca. 10^{-3} M solutions of the complexes in acetonitrile.

2.4. X-ray crystallography

Three dimensional X-ray data for compound **1** were collected on a Bruker Smart 1000 CCD operating at 25 °C. Data were corrected for Lorentz and polarisation effects and for absorption by semi-empirical methods. Complex scattering factors were taken from the program package SHELXTL [17]. The structure was solved by direct methods and refined by full-matrix least-squares on F^2. Refinement converged with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were included in calculated positions and refined in riding mode. The crystal presents a disorder of both the sulfur atom of one isothiocyanate group and the nitrogen atom of the acetonitrile molecule, and 45 restrains were impossed. The site occupancy factors were 0.55(5) for S(2SA) and 0.4(2) for N(1WA). Crystal data and details on data collection and refinement are summarised in Table 1.

3. Results and discussion

Under similar experimental conditions used to prepare the barium perchlorate derivative (2–3 h of reaction after complete addition of the precursors), the expected Schiff-base lateral macrobicycles $\mathbf{L^1}$ and $\mathbf{L^2}$ are not formed when barium thiocyanate is used as template agent [7]. As previously stated, in this case the template effectiveness of barium (II) or any other metal ion comes from its ability to orient the pendant arms of the diamine precursor [*N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5] to a *syn* conformation [12]. Experimental evidences for this conformation were found both in solid state and in solution for the corresponding barium

intermediate in the presence of both perchlorate [7] and thiocyanate anions [18], what suggests that the presence of thiocyanate in the reaction medium instead perchlorate should not be an obstacle to the template effectiveness of the barium ion. So, we decided to modify the initial conditions and the experiments here described show that longer reaction times are necessary to get the expected macrobicycles ($\mathbf{L^1}$ and $\mathbf{L^2}$) when barium thiocyanate is used as template. There so, the reaction of the diamine precursor *N*,*N*′-bis(2-aminobenzyl)-1, 10-diaza-15-crown-5 and the corresponding dialdehyde (2,6-diformylpyridine or 2,6-diformyl-4-methylphenol) in the presence of barium(II) thiocyanate requires a minimum of one day of refluxing and stirring after complete addition of the dialdehyde to get the formation of $\mathbf{L^1}$ and 2 days to get $\mathbf{L^2}$.

Also in the presence of thiocyanate the barium(II) ion remains trapped in the formed macrobicyclic cavity (so acting as a permanent template), and the corresponding macrobicycles $\mathbf{L^1}$ and $\mathbf{L^2}$ were isolated as the corresponding barium complexes of formulas $Ba(L^1)(SCN)_2 \cdot H_2O$ (**1**) and $Ba(L^2)(SCN)_2 \cdot 2H_2O$ (**2**). In any case, the use of barium thiocyanate leads to lower yields (41% and 57%) than the use of the perchlorate salt (88% and 65%; see [7]). The presence of an absorption, attributable to the ν(C=N) stretching frequency, at 1631 cm^{-1} for **1** and 1620 cm^{-1} for **2** in their IR spectra (KBr discs), as well as the absence of carbonyl and amine bands confirms that condensation and cyclization has occurred. Further evidence for the formation of the Schiff-base lateral macrobicycles comes from the FAB mass spectra, which show peaks at *m*/*z* 723 and 665 (**1**) due to $[Ba(L^1)(SCN)]^+$ and $[Ba(L^1)]^+$ and at *m*/*z* 693 (**2**) due to $[Ba(L^2)]^+$.

Recrystallisation of **1** from acetonitrile gave colourless crystals suitable for single crystal X-ray diffraction. Crystals contain the cation $[Ba(L^1)(NCS)]^+$, a thiocyanate group and an acetonitrile molecule. Fig. 2 illustrates the structure of the complex cation, while selected bond lengths and angles of the coordination sphere are compiled in Table 2. The barium ion is nine-coordinate, bound to the eight heteroatoms of the macrobicycle $\mathbf{L^1}$ and to the nitrogen atom of a thiocyanate group. This is in agreement with the IR spectrum (KBr disc) that displays two bands corresponding to the (CN) stretching mode of the thiocyanate groups at 2048 and 2038 cm^{-1}, suggesting the presence of thiocyanate groups with different binding modes. Like in the analogous previously described perchlorate complex, $[Ba(L^1)(ClO_4)_2]$ [7], the metal ion is almost symmetrically placed with respect to the cavity of the macrobicyclic receptor. The barium–donor atom distances fall within the range found in the literature and they are slightly shorter (about 0.1 Å) than those found for the analogous perchlorate complex [7]. The donors O(1), O(3), N(3) and N(4) of the crown moiety are essentially coplanar, with a deviation from planarity of 0.069 Å, and the barium ion lies 1.3353 Å above it.

In the light of the dihedral angles N(5)–C(1)–C(31)–N(1) (7.7(5)°) and N(5)–C(5)–C(6)–N(2) (3.8(5)°), it follows that both imine groups are not coplanar with the pyridine ring. Probably, the presence of the barium

ion into the macrobicyclic cavity interacting with all the heteroatoms of the macrobicycle host forces it to fold, so diminishing the π conjugation degree. The pyridine ring forms a dihedral angle of 48.9° with the plane containing the benzyl ring attached to N3 and of 49.1° with the plane containing the other aromatic ring. These angles are about 20° smaller than those found in $[Ba(L^1)(ClO_4)_2]$. Both benzyl rings intersects at 87°, a value substantially different than the one found in the perchlorate complex (49°). Therefore, the presence of a thiocyanate group in the coordination sphere of the barium ion instead semi-coordinated perchlorate groups [7] causes a different fold on the organic receptor. This comes because the angle between both benzyl rings opens in order to enable the entrance of the thiocyanate group, which also causes shorter bond distances. The coordination polyhedron, shown in Fig. 3, may be best described as a monocapped distorted dodecahedron. Distance between both pivotal nitrogen atoms, N(3) and N(4), is 4.941(4) Å, 0.38 Å shorter than that found in the barium intermediate [(*N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5)di(isothiocyanate)barium(II)] prevously described,[18] whereas distance between both imine nitrogen atoms, N(1) and N(2) amounts 4.945(4) Å, around 1 Å longer than the distance between the two precursor amine nitrogen atoms in the intermediate.

Conductivity measurements for 10^{-3} M solution in acetonitrile at 20 °C ($\Lambda_M = 259$ cm^2 Ω^{-1} mol^{-1} for **1** and 107 cm^2 Ω^{-1} mol^{-1} for **2**) reveal that both compounds behave as 1:1 electrolyte in this solvent [19], which confirms the presence of one thiocyanate group

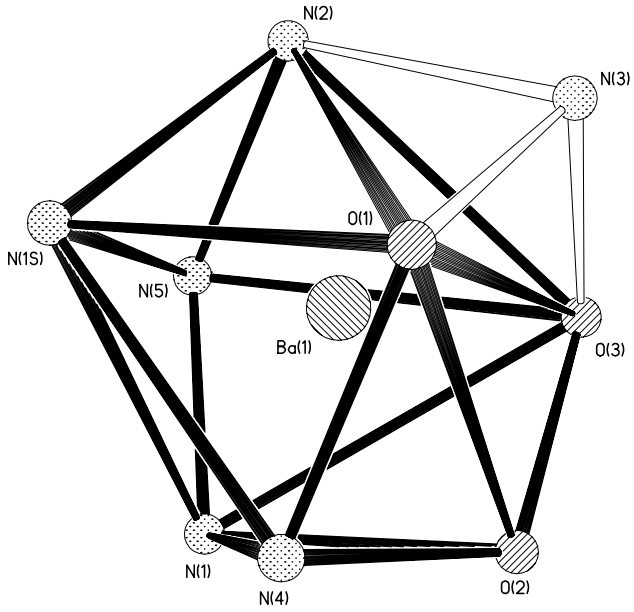

Fig. 3. The coordination polyhedron around the metal ion in the $[Ba(L^1)(NCS)]^+$ complex.

in the coordination sphere of barium(II) in acetonitrile solution as it does in the solid state (vide supra).

The ^{1}H and NMR spectrum of **1** recorded in CD_3CN solution (Table 3, Scheme 1) is also quite similar to that of the analogous perchlorate complex. The spectrum confirms the integrity of the ligand in this solvent; resonances attributable to amino or aldehyde functions are absent. The imine resonances appear as a singlet at 8.63 ppm, which indicates that both imine groups of the macrobicycle are magnetically equivalent. The spectrum shows a group of complicated signals in the region 2.4–4.2 ppm due to the ethylenic and methylenic protons, while the aromatic protons appear between 7.1 and 8.4 ppm. The corresponding ^{13}C NMR spectrum

		C16	141.0

[a] See Scheme 1 for labeling.
[b] Conditions: $T = 293$ K, 200 MHz. $^3J_{16,15} = {}^3J_{15,16} = 7.57$ Hz; $^3J_{11,10} = 7.32$ Hz; $^3J_{10,9}$ 7.81 Hz; $^4J_{11,9} = 2.44$ Hz.
[c] Assignment supported by DEPT experiments.

shows 16 signals for the 33 carbon nuclei of the ligand backbone (Table 3). This points to an effective C_s symmetry of the complexes in acetonitrile solution. The ^1H NMR spectrum of **2** recorded in acetonitrile solution is more complicated. It shows two peaks due to the imine protons at 8.57 and 7.67 ppm, which suggests an unsymmetrical coordination of the metal ion in the macrobicyclic cavity. In particular, this agrees with the barium(II) cation asymmetrically situated in the macrobicyclic cavity of $\mathbf{L^2}$ due to the proton transfer that happens from the phenol group to the nitrogen atom of one of the imine groups as observed in the crystal structure of the perchlorate analogue, $[BaL^2(ClO_4)(CH_3CN)](ClO_4)\cdot 0.5CH_3CH$, previously reported [13]. The spectrum of **2** also shows the signals of the methyl and –OH protons at 2.40 and 17.15 ppm, the latter appearing as a broad resonance as expected.

4. Supplementary material

Crystallographic data for crystal structure of **1** have been deposited at the Cambridge Crystallographic Data Centre as CCDC 246436. Copies of the data can be obtained free of charge upon application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Three new polyoxometalates with *N*-(phosphonomethyl)-*N*-methyl glycine ($MeN(CH_2CO_2H)(CH_2PO_3H_2)$, H_3L), namely, $Cd_9L_6(H_2O)_{12}\cdot 19H_2O$ (**1**), $\{Zn_7L_6\}\{Ni(bipy)(H_2O)_4\}_2\cdot 16H_2O$ (**2**) (bipy = 4,4-bipyridine) and $[H_3O]\{Zn_7L_6\}$ $\{Ni(H_2O)_2(bipy)_2\}_{1.5}\cdot 12H_2O$ (**3**), have been synthesized and structurally determined.The structures of all three compounds are built from oxo-bridged $M_6(M)L_6$(M = Zn or Cd) centered octahedral cages.In compound **1**, the $[Cd_6(Cd)L_6]$ cages are interconnected by Cd_2O_2 dimeric units into a novel $\langle 2\,0\,0\rangle$ layer.Packing of such 2D layers results in cavities that are occupied by lattice water molecules.The structure of compound **2** is composed of $\{Zn_6(Zn)L_6\}^{4-}$ cluster anions and 1D cationic chains of $\{Ni(bipy)(H_2O)_4\}^{2+}$.The lattice water molecules are located in the tunnels created by the above two types of building blocks which are interlinked via hydrogen bonds.In compound **3**, the $\{Zn_6(Zn)L_6\}^{4-}$ cluster anion cages are located at the tunnels formed by the 3D cationic network of$\{Ni(bipy)_2(H_2O)_2\}^{2+}$.

1. Introduction

The chemistry of metal phosphonates has been an area of interest to both inorganic and materials chemists in recent years due to their potential applications in the areas of catalysis, ion exchange, proton conductivity, intercalation chemistry, photochemistry, and materials chemistry [1]. In addition to the layered species, metal phosphonates also exhibit a variety of open framework and microporous structures [1–3]. Materials with open-framework and microporous structures are expected to find their use as hybrid composite materials in electro-optical and sensing application in the future [4–8]. However, reports on metal phosphonates with a molecular cluster unit are relatively rare [9–14]. Synthesis of multi-zinc clusters is of considerable contemporary interest, as exemplified by the potential application of the trinuclear clusters in biological systems such as phospholipase C and P1 nuclease [15]. Phosphonic acid attached with a carboxylate group can function as multidentate chelating and bridging ligand, hence we deem it can also form cluster cage compounds in addition to compounds with layered or 3D structures. Two zinc(II) cage compounds have been obtained by reactions of zinc(II) acetate with *N*-(phosphonomethyl)proline or *N*-(phosphonomethyl)-*N*-methyl glycine [16]. The structures of both zinc(II) amino-carboxylate-phosphonates are composed of a $Zn_6(Zn)(ligand)_6$ cluster anion and two hexahydrated zinc(II) cations [16]. We deem that these hexahydrated zinc(II) cations should be exchangeable by other

doi:10.1016/j.poly.2004.11.007

transition metal ions, such as Co(II) and Ni(II) ions for whom an octahedral geometry is more favored. Furthermore, it is possible for these isolated hexahydrated divalent metal ions to be interconnected into a 1D array, a 2D layer or 3D network if a suitable metal linker such as 4,4′-bipyridine (bipy) is added. Another possibility is that these isolated cluster cages may be interconnected into a 2D layer by a suitable linker. Our such research initiatives afforded three new inorganic–organic hybrids based on $M_6(M)(L)_6(H_3L = CH_3N(CH_2CO_2H)(CH_2PO_3H_2))$ cluster cages, namely, $Cd_9L_6(H_2O)_{12} \cdot 19H_2O$ (**1**), $\{Zn_7L_6\}$ $\{Ni(bipy)(H_2O)_4\}_2 \cdot 16H_2O$ (**2**) (bipy = 4,4′-bipyridine) and $[H_3O]\{Zn_7L_6\}$ $\{Ni(H_2O)_2(bipy)_2\}_{1.5} \cdot 12H_2O$ (**3**). All three compounds belong to a new type of polyoxometalates. Herein we reported their syntheses, characterizations and crystal structures.

2. Experimental

2.1. Materials and methods

N-(phosphonomethyl)-*N*-methyl glycine (H_3L) was prepared by a Mannich type reaction according to procedures previous described [16b]. All other chemicals of reagent grade were obtained from commercial sources and used without further purification. Elemental analyses for C, H, N were performed on a Vario EL III elemental analyzer. Ni and Zn elemental analyses for compounds **2** and **3** were carried out with an ICPQ-100 spectrometer. The FT-IR spectra were recorded on a Nicolet Magna 750 FT-IR spectrometer using KBr pellets in the range of 4000–400 cm^{-1}. Thermogravimetric analysis was carried out with a TGA/SBTA851 unit at a heating rate of 15 °C/min under a nitrogen atmosphere. The XRD powder patterns were collected on a Philips X'Pert-MPD diffractometer using graphite-monochromated Cu Kα radiation in the angular range $2\theta = 5-70°$ with a step size of 0.02° and a counting time of 3 seconds per step. Magnetic susceptibility measurements were performed with a Quantum Design SQUID magnetometer at a field of 1 T over the range of 6–300 K. The diamagnetic contributions of the samples were corrected using Pascal's constants.

2.2. Synthesis of $Cd_9L_6(H_2O)_{12} \cdot 19H_2O$ (*1*)

Compound **1** was synthesized by reacting 1.0 mmol of $CdCl_2$ with 0.5 mmol of H_3L in 10 ml of deionized water. Then the pH value of the resultant solution was adjusted to approximately 5 by adding 20 wt% tetrabutylammonium hydroxide solution. The reaction mixture was stirred at room temperature for 24 h and then filtered. Slow diffusion of ethanol into the filtrate afforded colorless crystals of **1** in a ca. 33% yield based on Cd. The final pH value is close to 5.0. Elemental analysis for **1**, $Cd_9C_{24}H_{106}N_6O_{61}P_6$: *Anal.* Calc.: C, 10.85; H, 4.03; N, 3.17. Found: C, 10.45; H, 3.87; N, 3.43%. IR data (KBr, cm^{-1}): 3383 (br), 2924(w), 2814(w), 2175(w), 1579(s), 1452(m), 1431(m), 1406(s), 1346(m), 1317(s), 1317(m), 1288(m), 1244(w), 1186(m), 1128(s), 1061(s), 972(s), 937(m), 895(m), 854(m), 787(m), 719(m), 590(m), 546(m), 526(w), 496(m).

2.3. Synthesis of $\{Zn_7L_6\}$ $\{Ni(bipy)(H_2O)_4\}_2 \cdot 16H_2O$ (*2*)

Compound **2** was prepared by hydrothermal reactions. A mixture of 1.0 mmol of zinc(II) acetate, 0.5 mmol of nickel(II) acetate, 1.0 mmol of H_3L and 1.0 mmol of 4,4′-bipy in 10 ml of deionized water was heated at 130 °C for 4 days. Green crystals of **2** were obtained in a 42.5% yield based on zinc. The initial and final pH values are 4.0 and 5.5, respectively. Elemental analysis for **2**, $C_{44}H_{106}N_{10}O_{54}P_6$ Zn_7Ni_2: *Anal.* Calc.: C, 22.02; H, 4.45; N, 5.84; Zn, 19.06; Ni, 4.89. Found: C, 21.81; H, 4.23; N, 5.67; Zn, 18.3; Ni, 4.5%. IR data (KBr, cm^{-1}): 3660(m), 3438(br), 2918(w), 2818(w), 1606(s), 1535(m), 1493(w), 1466(w), 1406(s), 1331(s), 1279(m), 1223(w), 1173(s), 1119(s), 1082(s), 999(s), 985(s), 933(m), 891(s), 852(s), 818(s), 791(s), 733(m), 634(m), 588(m), 553(m), 503(w), 469(w).

2.4. Synthesis of $[H_3O]\{Zn_7L_6\}\{Ni(H_2O)_2(bipy)_2\}_{1.5} \cdot 12H_2O$ (*3*)

The method for the preparation of compound **3** is similar to that of compound **2** except that the molar ratio of bipy/Ni was increased to 4:1. Green crystals of **3** were isolated in a 47.0% yield based on zinc. The initial and final pH values are 4.5 and 5.0, respectively. Elemental analysis for **3**, $C_{54}H_{99}N_{12}O_{46}P_6Zn_7Ni_{1.5}$: *Anal.* Calc.: C, 27.18; H, 4.19; N, 7.05; Zn, 19.2; Ni, 3.69. Found: C, 26.43; H, 4.33; N, 6.87; Zn, 18.6; Ni, 3.4%. IR data (KBr, cm^{-1}): 3419(br), 1601(s), 1537(m), 1491(w), 1450(w), 1408(s), 1335(m), 1286(w), 1225(w), 1182(m), 1120(s), 1090(s), 1072(s), 997(s), 982(s), 935(w), 895(m), 854(m), 823(s), 793(m), 733(w), 634(s), 555(s), 515(m), 467(w).

2.5. X-ray crystallography

Intensity data of compounds **1**, **2** and **3** were collected on a Siemens Smart CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. The data sets were corrected for absorption by the SADABS program [17]. All structures were solved by the direct methods and refined by full-matrix least-squares fitting on F^2 by SHELX-97 [17]. For compound **3**, O(wh) located at a position of three-fold position is assumed to be a H_3O^+ cation, and its occupancy factor

is reduced to 1/6 for the sake of charge balance. O2w and O3w of compound **3** are disordered and each has two orientations (O2w, O2w′, O3w, O3w′). The O2w...O2w′ and O3w...O3w′ separations are 1.94(3) and 1.96(3) Å, respectively, and the occupancy factors for these four atoms were assigned to be 50% each. All non-hydrogen atoms, except for O(14w), O(15w) and O(16w) for compound **1**, and O(2w), O(2w′), O(3w) and O(3w′) atoms for compound **3**, were refined with anisotropical thermal parameters. Hydrogen atoms except those for the water molecules were located at the geometrically calculated positions. Crystallographic data and refinement residuals are summarized in Table 1. Important bond distances are listed in Table 2. Further details on the crystallographic studies as well as atomic parameters are given in Section 4.

3. Results and discussion

The structure of compound **1** features a unusual 2D layer built from $[Cd_6(Cd)L_6]$ centered octahedral cluster units interconnected by Cd(2) dimeric units. As shown in Fig. 1, the asymmetric unit of compound **1** contains five independent Cd(II) ions. Cd(1) lies on a position of −1 symmetry, and it is octahedrally coordinated by six phosphonate oxygen atoms from six phosphonate groups. The Cd–O distances are 2.243(7) and 2.296(7) Å, respectively. Cd(2), Cd(3) and Cd(4) have similar coordination geometry, and each is 6-coordinated by a tridentate chelating carboxylate-phosphonate ligand (1 N, 1 carboxylate O and 1 phosphonate O), an aqua ligand and two phosphonate oxygen atoms from two neighboring [CdL] units. The Cd–O and Cd–N distances are in the range of 2.163(8) to 2.43(1) Å, and 2.326(9) to 2.356(9) Å, respectively. Cd(5) forms five normal bonds with two carboxylate oxygen atoms from two ligands and three aqua ligands. The Cd–O distances range from 2.584(9) to 2.631(9) Å, which are much larger than the Cd–O distances for Cd(1), Cd(2), Cd(3) and Cd(4) atoms. Cd(5) also forms two slightly longer Cd–O bonds with two carboxylate oxygen atoms (O3a, O4a, symmetry operator: $1-x$, $2-y$, $-z$) from a neighboring [Cd(2)L] unit. Cd(5)–O(3a) and Cd(5)–O(4a) contacts are 2.662(9) and 2.674(9) Å, respectively. These Cd–O distances are comparable to those reported in other Cd(II) phosphonates [18]. One Cd(1), two Cd(2)L, two Cd(3)L and two Cd(4)L units form an unusual centered $Cd_6(Cd)L_6$ octahedral cluster unit with Cd(1) at its center, and six of its eight Cd_3 triangle phases are each capped by a phosphonate group. This type of cluster cage is similar to that reported in the Zn(II) carboxylate-phosphonates [16]. However, due to a higher coordination number for the Cd(II) ion than that for the Zn(II) ion, all Cd(II) ions in the cage are octahedrally coordinated, whereas in the zinc cages, only the central atom is six-coordinated and the other six are in trigonal bipyramidal geometry [16]. The coordination of the Cd(II) ions in a M_6 octahedron is saturated by an additional aqua ligand. The distances from the central Cd(II) ion to the octahedral ones are in the range of 3.765(5) to 3.790(5) Å. Similar to those in $Zn_6(Zn)L_6$ [16], each phosphonate group bridges with four Cd(II) ions, with one phosphonate oxygen atom acting as a μ_2 metal linker. In addition to the unidentate coordination mode for the carboxylate group (O(5), O(6)) as that in its zinc(II) cluster compounds, two other types of coordination modes are also found in the cadmium(II) compound: the one containing O(1) and O(2) atoms adopts a bidentate bridging coordination mode, whereas the other one containing O(3) and O(4) atoms adopts a tetradentate chelating and bridging mode, connecting with three Cd(II) ions. Two Cd(5)

For **1**: #1 $-x+1, -y+1, -z$; #2 $-x+1, y+1/2, -z+1/2$; #3 $1/2+x, -1/2+y, -z$; #4 $1-x, 2-y, -z$; #5 $x, 3/2-y, 1/2+z$; #6 $3/2-x, 1/2-y, z$; #7 $x, 3/2-y, -1/2+z$; #8 $3/2-x, y, 1/2+z$; #9 $3/2-x, y, -1/2+z$.
For **2**: #1 $-x+2, -y+1, -z+2$; #2 $x+1, y, z$; #3 $-x+1, -y+1, -z+1$.
For **3**: #1 $-z, x+1/2, y-1/2$; #2 $-y+1/2, -z+1/2, x$; #3 $-z+1/2, -x+1/2, y$.

atoms are bridged by a pair of carboxylate groups to form a dimeric unit (Fig. 1).

Unlike the isolated $Zn_6(Zn)L_6$ unit in the zinc(II) phosphonates [16b], the $Cd_6(Cd)L_6$ cluster anions of compound **1** are further interconnected by Cd(5) dimers, resulting in a novel $\langle 2\,0\,0\rangle$ metal carboxylate-phosphonate layer (Fig. 2). Each $Cd_6(Cd)L_6$ unit connects with four dimeric units of Cd(5) by using its four bridging car-

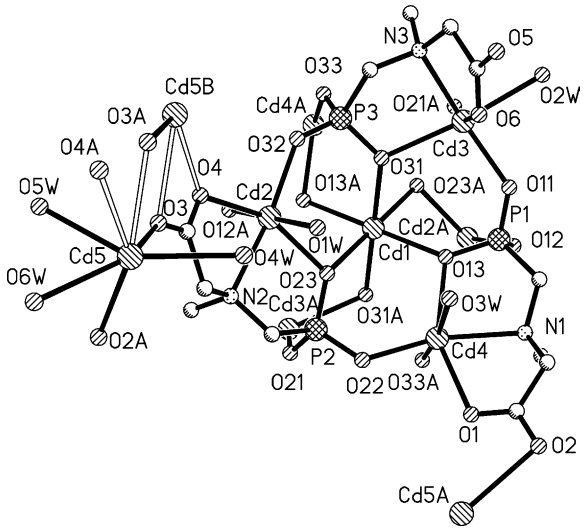

Fig. 1. The asymmetric unit of compound **1**. The open lines represent the weak Cd–O bonds. The lattice water molecules have been omitted for clarity.

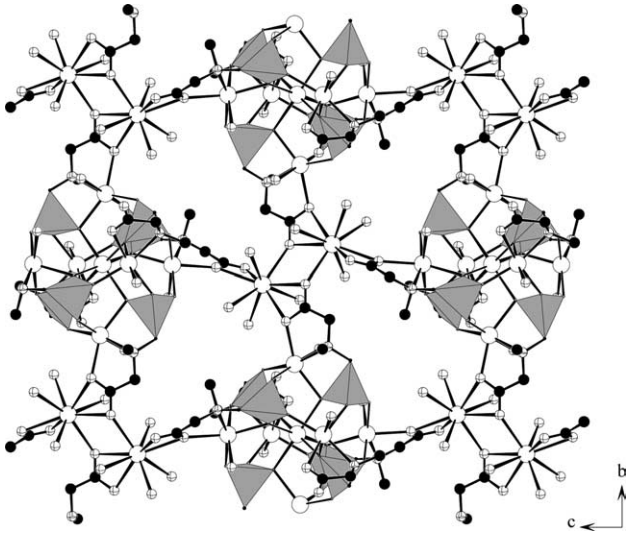

Fig. 2. A ⟨2 0 0⟩ layer of compound **1**. C–PO_3 tetrahedra are shaded in light gray. Cd, N, C and O atoms are represented as open, octand, black and crossed circles, respectively.

boxylate groups, and each dimer is also bridged to four octahedral cluster units. This type of connection creates big voids within the layer. Packing of such layers along the *a*-axis produces micropores that are occupied by the lattice water molecules (Fig. 3), which form a complicated hydrogen bond network with the aqua ligands as well as the non-coordinated carboxylate oxygen atoms (Table 2). In the zinc(II) cluster complex, the four negative charges on a cluster unit are balanced by two hexahydrated Zn(II) cations, which are located in the micropores formed by packing of the cluster cages [16].

Compounds **2** and **3** were obtained in our attempt to replace the two hexahydrated zinc(II) cations by Ni(II)-

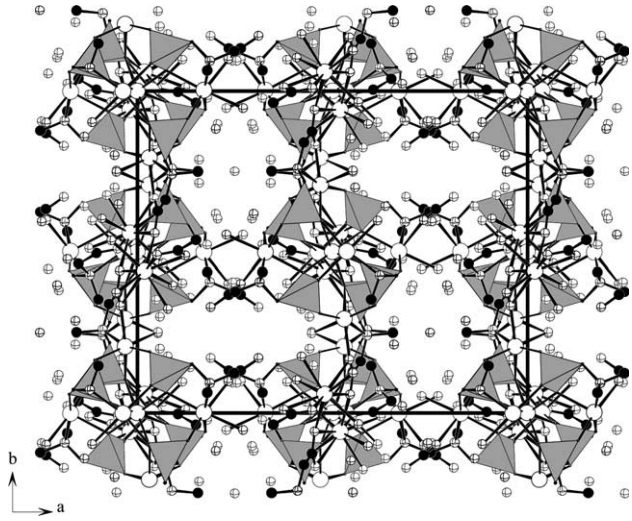

Fig. 3. View of the structure of compound **1** down the *c*-axis. C–PO_3 tetrahedra are shaded in light gray. Cd, N, C and O atoms are represented as open, octand, black and crossed circles, respectively.

bipy complex moieties. Both compounds contain two types of building blocks, a cluster cage and a Ni-bipy complex moiety. This type of compounds is, to some extent, similar to the inorganic-organic hybrids built from polyoxomolybdates with diphosphonates, in which the transition metal complex moieties play a structure directing role [19,20].

The structure of compound **2** is built from anionic $\{Zn_6(Zn)L_6\}^{4-}$ cluster cages and the cationic 1D chains of $\{Ni(H_2O)_4(bipy)\}^{2+}$ (Fig. 4). The $\{Zn_6(Zn)L_6\}$ cluster cage is essentially same as those we reported previously [16]. However, its symmetry is much lowered, and thus a cluster cage contains four independent zinc atoms instead of two as in other $\{Zn_6(Zn)L_6\}$ cluster cages previously reported [16]. Each zinc(II) ion of the Zn_6 cluster unit (Zn1, Zn3 and Zn4) is five-coordinated by a carboxylate phosphonate ligand in a tridentate chelating fashion together with two phosphonate oxygens from two neighboring ZnL chelating units. The zinc(II) ion (Zn2) located at the center of the Zn_6 cluster is octahedrally coordinated by six phosphonate oxygens from six neighboring ZnL chelating units. The coordination mode of the carboxylate-phosphonate ligand is the same as those in other $\{Zn_6(Zn)L_6\}$ cluster cages reported by us [16], but here the four negative charges of the cluster cage are compensated by two $\{Ni(H_2O)_4(bipy)\}^{2+}$ cations. Each nickel(II) ion is octahedrally coordinated by two N atoms from two bipy ligands and four aqua ligands. These nickel octahedra are crosslinked via bridging bipy ligands to form a 1D chain (Fig. 4(b)). The Ni–O, Zn–O, Ni–N and Zn–N distances are comparable to those reported in zinc phosphonates and nickel(II) complexes [6,16,19,20].

The cluster cage anions and 1D chains of $\{Ni(H_2O)_4(bipy)\}^{2+}$ cations are interconnected via electrostatic forces as well as hydrogen bonds. The hydrogen

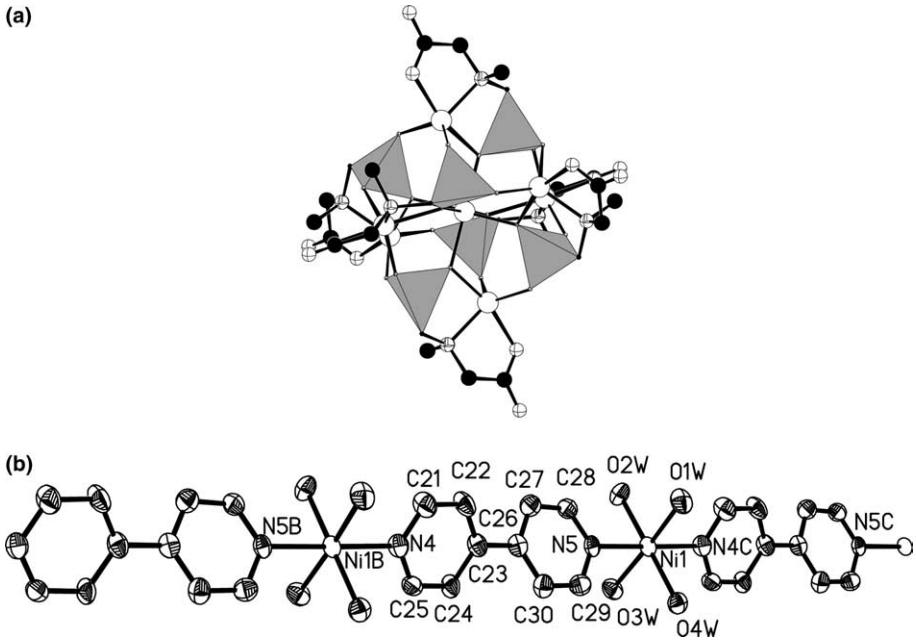

Fig. 4. Building blocks in compound **2**: (a) a $\{Zn_6(Zn)L_6\}^{4-}$ anionic cluster cage; (b) a 1D cationic chain of $\{Ni(bipy)(H_2O)_4\}^{2+}$.

bonds are formed between non-coordinated carboxylate oxygen atoms of the cluster cage and the aqua ligands of the nickel complex chain (Table 2). Interconnection of the above two types of building blocks result in hydrophilic tunnels that accommodate the lattice water molecules (Fig. 5), which are also involved in hydrogen bonding with aqua ligands as well as non-coordinated carboxylate oxygen atoms of the phosphonate ligands (Table 2).

The structure of compound **3** is significantly different from that of compound **2**. It contains two types of building blocks, $\{Zn_6(Zn)L_6\}^{4-}$ cage anion and the $\{Ni(H_2O)_2(bipy)_2\}^{2+}$ cation. Its $\{Zn_6(Zn)L_6\}^{4-}$ cage is similar to those in zinc carboxylate-phosphonates reported previously and that in compound **2**. Unlike that in compound **2**, there are only two unique zinc atoms (central atom, Zn(1) with 222 site symmetry, Zn(2) in a general position). The coordination mode of the carboxylate-phosphonate ligand is same as that in compound **2**. The Ni(II) atom located at a position of a -3 symmetry is octahedrally coordinated by four N atoms from four different bipy ligands and two aqua ligands. The Ni–O and Ni–N bond distances are comparable to those in compound **2**. The NiO_2N_4 octahedra are interconnected by bridging bipy ligands into a novel 3D network with large channels (Fig. 6). It is interesting to note that the square plane defined by NiN_4 is perpendicular to its four neighboring ones generated through symmetry operations and bridged by bipy ligands (Fig. 6). This type of interconnection is unusual and different from the normal two dimensional $\{Ni(H_2O)_2(bipy)_2\}^{2+}$ cation in which the neighboring NiN_4 square planes which are parallel to each other. The size of such a cavity is estimated to be 11.1×11.9 Å^2 after deduction of the van der Waals radius for carbon atoms. The tunnels are occupied by the $\{Zn_6(Zn)L_6\}^{4-}$ cage anions as well as lattice water molecules (Fig. 7). Similar to those in compound **2**, the above two types of building blocks are held together via electrostatic forces as well as hydrogen bonds between non-coordinated carboxylate oxygen of the cluster cage (O2) and the aqua ligand of the $\{Ni(H_2O)_2(bipy)_2\}^{2+}$ cation (O1w) (Table 2).

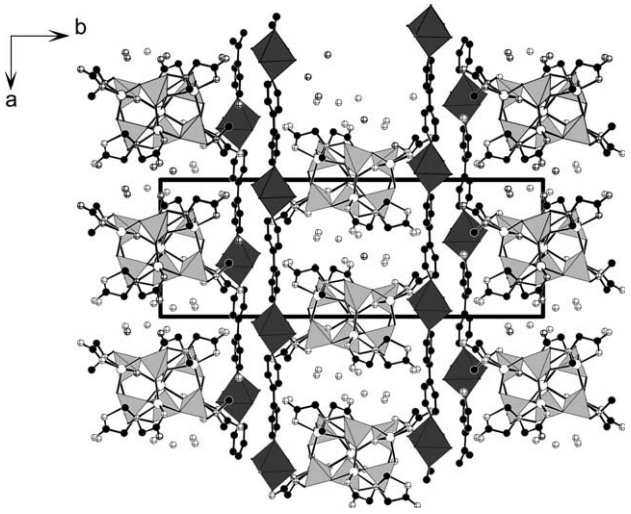

Fig. 5. View of structure of compound **2** down the *c*-axis. Nickel octahedra and C–PO_3 tetrahedra are shaded in dark and light gray, respectively. N, C and O atoms are represented as octand, black and crossed circles, respectively.

It is interesting to note that the ratio of cage anion to nickel complex moiety in compound **2** is 1:2, whereas

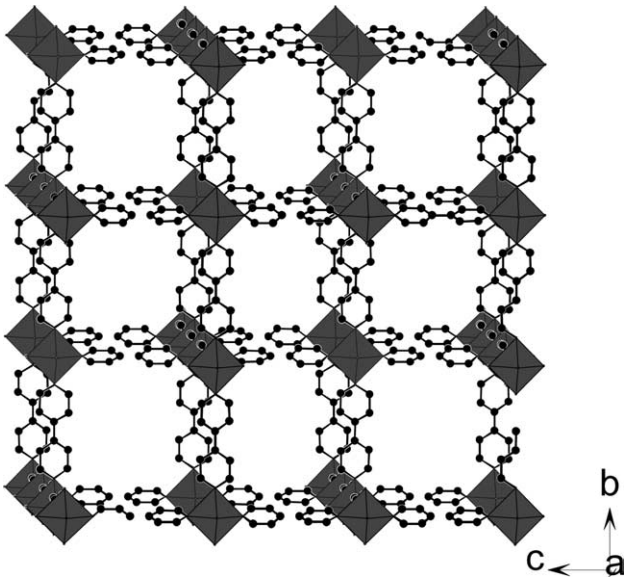

Fig. 6. A 3D cationic network of $\{Ni(bipy)_2(H_2O)_2\}^{2+}$ in compound **3**. The nickel octahedra are shaded in dark grey and the C atoms are drawn as black circles.

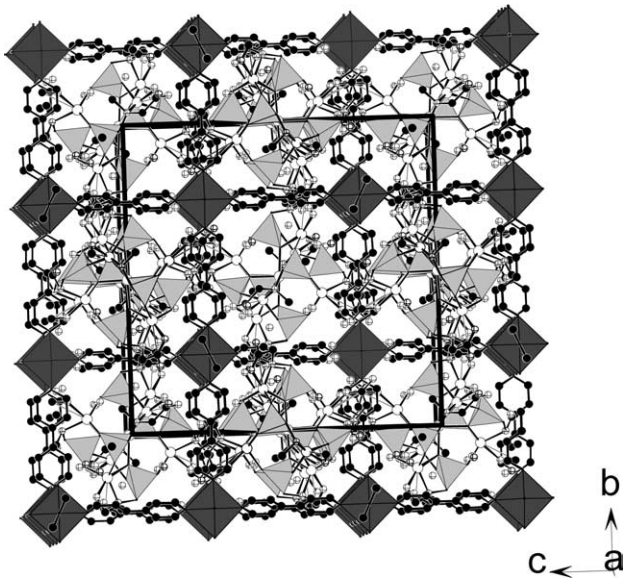

Fig. 7. View of the structure of compound **3** down the *a*-axis. The nickel octahedral and C–PO_3 tetrahedra are shaded in dark and light gray, respectively. The Zn, N, C and O atoms are drawn as open, octand, black and crossed circles, respectively.

that in compound **3** is only 1:1.5, thus an additional positive charge per cluster unit is needed for the sake of charge balance. Therefore, we assign O(wh) to be a $(H_3O)^+$ cation.

The IR spectra of both compounds **1**, **2** and **3**were measured. The broad bands at 3383 (for **1**), 3438 (for **2**) and 3419 cm^{-1} (for **3**) are due to the water molecules. The strong bands at 1579 cm^{-1} (for **1**), 1606 and 1535 cm^{-1} (for **2**) or 1601 and 1537 cm^{-1} (for **3**) correspond to the antisymmetric stretching bands of the carboxylate groups. The symmetric stretching bands of the carboxylate group appeared around 1452, 1466, and 1450 cm^{-1}, respectively for compounds **1**, **2** and **3**. The bands from 900 to 1100 cm^{-1} are due to the stretching vibrations of the tetrahedral CPO_3 group.

The different structures of compounds **2** and **3** are also indicated by their experimental XRD powder patterns. The diffraction peaks from their XRD powder patterns are in good agreement with the ones simulated from single crystal structure data, and thus both compounds **2** and **3** exist as a single phase.

The plots of effective magnetic moments (μ_{eff}) as a function of temperature for compounds **2** and **3** are shown in Fig. 8. At 300 K, μ_{eff} values for compounds **2** and **3** are 4.1 and 3.6 μ_B, respectively, corresponding to 2 and 1.5 isolated nickel(II) ions with S = 1 per formula unit, which is in good agreements with the results from X-ray structure analysis. Upon cooling, the μ_{eff} values for both compounds increase slightly and reach a maximum at about 14 K (4.21 and 4.05 μ_B for compounds **2** and **3**, respectively), which indicates the ferromagnetic behavior for both compounds. Then it decreases slightly upon further cooling, and the μ_{eff} values at 6 K are 4.15 and 3.9 μ_B, respectively for compounds **2** and **3**, indicating that both paramagnetic compounds order antiferromagnetically below 14 K. Non-linear fitting of the data in the range of 50–300 K according to Curie–Weiss law: $\chi_M = C/(T-\theta) + \chi_0$ gave C of 1.96(2) $cm^3\,mol^{-1}\,K$, θ of 5.2(5) K and χ_0 of $-7.4(1)\times10^{-4}$ emu/mol, respectively for compound **2**, and C of 1.72(4) $cm^3\,mol^{-1}\,K$, θ of 7.9(9) K and χ_0 of $-2.3(2)\times10^{-4}$ emu/mol, respectively for compound **3**, indicating mainly a weak ferromagnetic interaction between nickel(II) ions for both compounds. The distances between two nickel(II) ions bridged by a bipy ligand are 11.559(1) and 11.296(1) Å for compounds **2** and **3**, respectively. Thus it is expected that the magnetic interaction in compound **3** will be slightly stronger than that

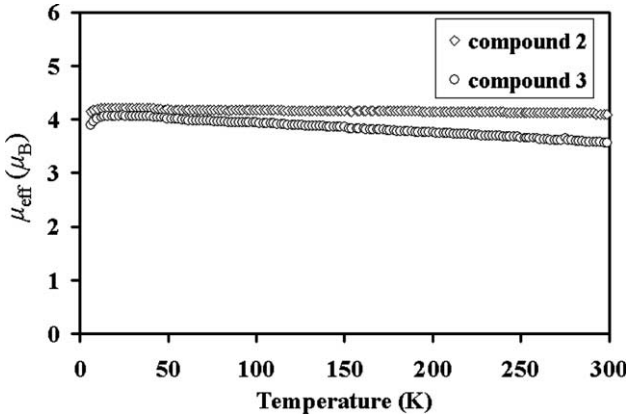

Fig. 8. Plot of effective magnetic moments (μ_{eff}) for compounds **2** and **3** as a function of temperature.

in compound **2**. This may also result from the different structures for the Ni-bipy complex moieties in both compounds. As discussed earlier, the Ni-bipy complex moiety in compound **2** has a 1D chain structure, whereas that in compound **3** features a 3D network structure.

The TGA diagram of compound **1** shows two main steps of weight loss. The first step corresponds to the loss of twenty lattice water molecules and twelve aqua ligands, which started at 61 °C and completed at 255 °C, and the weight loss of 12.2% is in good agreement with the calculated value (13.5%). The second step covering a temperature range of 280–760 °C corresponds to the combustion of the organic group. The final residual is a mixture of $Cd_2P_2O_7$ and CdO in a molar ratio of 1:1 based on XRD powder patterns. The total weight loss of 42.0% is close to the theoretical value (40.7%). The TGA diagram for compound **2** also shows two steps of weight losses. The first weight loss from 40 to 240 °C is the release of the lattice water molecules and aqua ligands, and the observed weight loss of 17.0% is close to the calculated one (18.0%). The second step covers a temperature range from 360 to 650 °C, which corresponding to the burning of organic groups. The third weight loss started from 700 °C and continued up to 1000 °C, corresponding to further decomposing of the compound. The final residual is a mixture of $Zn_2P_2O_7$, ZnO and NiO based on X-ray powder diffraction. The total weight loss of 53.1% is close to the calculated value (52.3%) if we assume the molar ratio of $Zn_2P_2O_7$:ZnO:NiO is 3:1:2. TGA curves of compound **3** also indicate three steps of weight losses. The first step and the second one overlaps and the weight losses cover a temperature range from 37 to 680 °C, during which two processes were undertaking: first, the release of all kinds of water molecules; and second, the burning of organic groups. The combined weight loss is 53.7%, which is good agreement with the calculated value (53.5%) if we assume the residual contains a mixture of $Zn_2P_2O_7$:ZnO:NiO in a molar ratio of 3:1:1.5. The third step started at 720 °C and continued up to 1000 °C, corresponding to partial decomposing of $Zn_2P_2O_7$ to ZnO. The final product is also a mixture of $Zn_2P_2O_7$, ZnO and NiO based on X-ray powder diffraction.

In summary, the reaction of *N*-(phosphonomethyl)-*N*-methyl glycine with divalent metal salts afforded four new divalent metal carboxylate-phosphonate hybrid compounds. The zinc compound contains an isolated heptanuclear $Zn_6(Zn)(ligand)_6$ cluster anion, the packing of which forms micropores which are occupied by hexahydrated zinc(II) cations and lattice water molecules. In the cadmium(II) complex, $Cd_9L_6(H_2O)_{12}\cdot 20H_2O$ (**1**), such heptanuclear $[Cd_6(Cd)(ligand)_6]^{4-}$ cluster anions are no longer isolated, but are interconnected by Cd_2O_2 dimeric units into a hybrid 2D layer. In compounds **2** and **3**, the nickel-bipy complex moieties replace the two hexahydrated zinc(II) cations in the parent Zn compound, and the structure of the nickel(II)-bipy complex depends on the Ni/bipy ratio. These three metal phosphonates resemble a new type of polyoxometalates: the layered compound **1** is homonuclear whereas compounds **2** and **3** are heteronuclear. *N*-(phosphonomethyl)-*N*-methyl glycine contains an aminocarboxylate group and a phosphonate group, so that it can function as a chelating and a bridging ligand simultaneously, and hence cage compounds can be formed. We believe that additional types of polyoxometalates based on metal phosphonates can be obtained by using the present synthetic strategy.

4. Supplementary materials

Crystallographic data for complexes **1**, **2**, and **3** have been deposited with the Cambridge Crystallographic Center, CCDC No. 207759, 231328 and 231329. Abstract

Mg(II) and Ca(II) complexes of a (dichloromethylene)bisphosphosphonic acid *P*,*P*′-diisopropyl ester: $[Na_2Mg\{Cl_2C(PO_3iPr)_2\}_2(H_2O)_4]_n$ (**1**) and $[\{Ca_2[Cl_2C(PO_3iPr)_2]_2(EtOH)_2(H_2O)_2\}\cdot H_2O]_2$ (**2**) were prepared and characterised by X-ray crystallography. Compound **1** contains two independent octahedral Mg atoms at the centres of symmetry and two five-coordinated Na atoms between them, connected to polymeric chains along the *c*-direction by chelating and bridging bisphosphonato ligands. Compound **2** is a tetramer possessing a centre of symmetry; the Ca atoms are connected to each other by chelating and bridging bisphosphonato ligands. Compounds **1** and **2** form layers through hydrogen bonds.

Keywords: Bisphosphonate; Clodronate; Magnesium (II); Calcium (II); Crystal structures

1. Introduction

Due to the chemical applications of metal bisphosphonates in, for example, ion exchange, sorption and catalysis, the recent expansion in research on the chemistry of metal bisphosphonates is focused on the properties of solid materials. The effectiveness of the materials is related to the degree of porosity; and the structures consist of chains, layers, pillared layers or three-dimensional networks. The dimensionality is dependent on the number of donor atoms of the ligand, but also on the length of the organic chain between the phosphonate groups and on the degree of protonation of the phosphonate group [1–4].

In order to study the properties of the solid materials, several metal complexes of medronate, $H_2C(PO_3H)_2^{2-}$ [5–15] and etidronate $(CH_3)(OH)C(PO_3H)_2^{2-}$ [16–27], have already been reported. Clodronate, $Cl_2C(PO_3H)_2^{2-}$, which is one of the best-documented bisphosphonates used effectively in medical applications [28], is similar to these compounds; and recently, some metal complexes of clodronate have also been prepared to study the properties of the solid materials: monomeric Ca and Sr complexes [29,30] and three new, polymeric and porous calcium complexes of clodronate [31]. On the other hand, we have also reported alkaline earth metal complexes of the symmetrical diethyl ester derivative of clodronate in which one O atom of both phosphonate groups of clodronate is masked by an ethyl group; these compounds were either dimers or polymeric chains [32].

Now we have prepared metal complexes of another alkyl ester derivative of clodronate, *P*,*P*′-diisopropyl-(dichloromethylene)bisphosphonate, in order to study the effect of the larger alkyl groups on the complexing properties of the ligand and on the dimensionalities of its metal complexes. Two metal complexes of Cl_2C

$(PO_3iPr)_2^{2-}$, $[Na_2Mg\{Cl_2C(PO_3iPr)_2\}_2(H_2O)_4]_n$ (**1**) and $[\{Ca_2Cl_2C(PO_3iPr)_2\}_2(EtOH)_2(H_2O)_2\}\cdot H_2O]_2$ (**2**) were crystallized by the gel method; and the structures of the complex crystals were determined by single crystal X-ray diffraction methods.

2. Experimental

2.1. General

Reagents used for the synthesis and characterisation of compounds **1** and **2** were analytical reagent grade. Infrared spectra were recorded on a Nicolet Magna-IR™ Spectrometer 750 by the KBr pellet technique. Synthesis of the disodium-*P*,*P*′-diisopropyl(dichloromethylene)-bisphosphonate $Na_2Cl_2C(PO_3iPr)_2$ is described elsewhere [33]. Metal complexes **1** and **2** were crystallized by a gel method. Carefully weighed amounts of bisphosphonate and the metal salt were dissolved separately in water. The solutions were then mixed together, tetramethoxy silane (TMOS) was added, and the two-phase system was shaken until homogenous. The emulsion was left to form a gel, after which a precipitant was added above the gel to induce crystallisation. The crystals for X-ray diffraction analyses were collected from the gel, purified with pure precipitant and dried in air.

2.2. Preparation of $[Na_2Mg\{Cl_2C(PO_3iPr)_2\}_2(H_2O)_4]_n$ (*1*)

In the preparation of **1**, $Na_2Cl_2C(PO_3iPr)_2$ (0.12 mmol) and $MgCl_2$ (0.24 mmol) were dissolved in water (0.9 ml); and TMOS (0.1 ml) was added. After gel formation, acetone (1.0 ml) was placed above the gel as precipitant. Compound **1** crystallised above the gel as small, colourless cubic crystals. *Anal.* Calc. for $C_{14}H_{36}Cl_4MgNa_2O_{16}P_4$: C, 21.1; H, 4.56; Mg, 3.05; Na, 5.77. Found: C, 21.1; H, 4.60; Mg, 2.97; Na, 6.06%. IR/cm^{-1}: 2990 (w), 2982 (m), 2941 (w), 2877 (vw), 1385 (s), 1230 (b, vs), 1177 (m), 1143 (s), 1129 (vs), 1115 (s), 1093 (vs), 1006 (vs), 995 (vs), 895 (s), 859 (s), 770 (m), 756 (m), 742 (m).

2.3. Preparation of $[\{Ca_2[Cl_2C(PO_3iPr)_2]_2(EtOH)_2(H_2O)_2\}\cdot H_2O]_2$ (*2*)

In the preparation of **2**, $Na_2Cl_2C(PO_3iPr)_2$ (0.15 mmol) and $CaCl_2\cdot 2H_2O$ (0.15 mmol) were dissolved in water (0.9 ml); and ethanol (3 drops) and TMOS (0.1 ml) were added. After gelation, an acetone-ethanol solution (1:1, 1.0 ml) was added above the gel as precipitant. Large, colourless cubic crystals of **2** formed in and above the gel. *Anal.* Calc. for $C_{36}H_{92}Ca_4Cl_8O_{34}P_8$: C, 24.6; H, 5.27; Ca, 9.11. Found: C, 24.2; H, 5.52; Ca, 9.25%. IR/cm^{-1}: 2976 (s), 2939 (m), 2875 (w), 1380 (s), 1372 (s), 1235 (b, vs), 1175 (s), 1140 (s), 1125 (vs, b), 1089 (s), 1065 (s), 1000 (vs, b), 995 (s), 895 (s), 859 (s), 770 (m), 755 (m), 741 (m).

2.4. X-ray diffraction measurements

Experimental data were collected on a Nonius Kappa CCD diffractometer using Mo Kα-radiation (λ = 0.71073 Å) at 120 K. Denzo and Scalepack [34] programs were used for cell refinements and data reduction. Crystal data, details of data collection and refinement of the crystal structures of **1** and **2** are given in Table 1. The structures were solved using direct methods with SHELXS-97 and structural refinements were carried out with SHELXL-97 [35]. The hydrogen atoms of the water molecules in **1**, and of the water molecules and hydroxyl groups in **2** were placed from the difference maps with $U_{iso}(H) = 1.5U_{eq}(O)$; and the hydrogen atoms of the isopropyl groups were on calculated positions with $U_{iso}(H) = 1.2U_{eq}(CH)$ and $U_{iso}(H) = 1.5U_{eq}(CH_3)$.

3. Results and discussion

3.1. Crystal structures

The structures of the Mg and Ca complex of some methylenebisphosphonates [5,16,17,29,31] and the symmetrical diethyl ester derivative of clodronate [32] contain both monomeric [16,29] and dimeric structures [32] as well as one-dimensional chains [5,17,31,32] and two-dimensional layers [31]. In the monomers, the bisphosphonato ligands are chelated to the metal atom, forming one six-membered chelate ring [16,29]. In the dimer, the ligand forms six-membered chelate rings with both metal atoms and triatomic bridges between them, providing four O atoms for the metal atoms [32]. The chain and layered structures also contain chelating and bridging bisphosphonato ligands, and the ligands donate four O atoms to the metals in chains [5,17,31,32] and six O atoms in layers [31]. In the one-dimensional structure of **1**, both independent bisphosphonato ligands, $Cl_2C(PO_3iPr)_2^{2-}$, are chelated to metal atoms forming four- or six-membered chelate rings; and they also form monoatomic bridges between the metal atoms. Four of the six O atoms of both $Cl_2C(PO_3iPr)_2^{2-}$ ligands are coordinated to Mg and Na atoms, and one O atom, O33 with the isopropyl substituent is also coordinated to a metal, Na1. Similar but unexpected coordination was observed in the case of the Ba complex of the symmetrical diethyl ester derivative of clodronate [32]. In the tetrameric structure of **2**, the $Cl_2C(PO_3iPr)_2^{2-}$ ligands form six-membered chelate rings and bridge the metals by mono- and triatomic bridges. One $Cl_2C(PO_3iPr)_2^{2-}$ ligand provides three and the other provides four O atoms to Ca atoms.

The overall structure of compound **1** $[Na_2Mg\{Cl_2C(PO_3iPr)_2\}_2(H_2O)_4]_n$ is polymeric, consisting of chains in the direction of the *c*-axis. The chains contain two independent, octahedral Mg atoms in the centres of symmetry [Mg–O_{av} 2.07(1) Å] and two independent, five-coordinated Na atoms [Na–O_{av} 2.39(13) Å] between the Mg atoms, connected to chains by four bridging aqua- and two bridging $Cl_2C(PO_3iPr)_2^{2-}$ ligands (Fig. 1(a)). There are two chelating $Cl_2C(PO_3iPr)_2^{2-}$ ligands in *trans*-positions around both Mg atoms, and the coordination spheres are filled with two aqua ligands. One of the aqua ligands of Mg1 bridges it to the Na2 atom, and the remaining coordination sites around Na2 are occupied by three $Cl_2C(PO_3iPr)_2^{2-}$ ligands and one aqua ligand. Na1, on the other hand, carries one aqua ligand and two chelating $Cl_2C(PO_3iPr)_2^{2-}$ ligands, forming one 4- and one 6-membered chelate ring. The chains of **1** are connected to a layered structure parallel to the (0 1 0) plane through hydrogen bonds [O...O 2.720(2)–2.861(2) Å, 145°–173°]. Isopropyl groups and chlorine atoms point to the interlayer section in the direction of the *b*-axis (Fig. 1(b)).

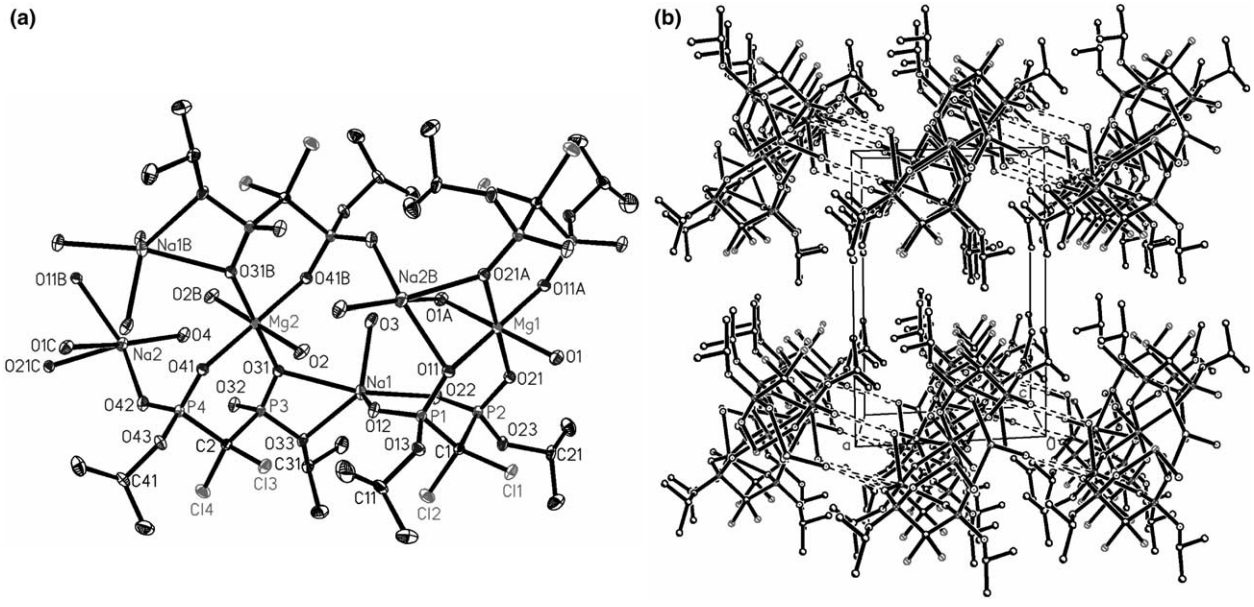

Fig. 1. (a) Part of the chain structure of 1 with numbering scheme and thermal ellipsoids (50%) and (b) packing of the chains. For clarity, hydrogen atoms are omitted. Selected bond distances (Å): Mg1–O11a 2.0558(11), Mg1–O11 2.0558(11), Mg1–O21a 2.0748(11), Mg1–O21 2.0748(11), Mg1–O1 2.0964(12), Mg1–O1a 2.0964(11), Mg2–O31b 2.0640(11), Mg2–O31 2.0640(11), Mg2–O2b 2.0732(12), Mg2–O2 2.0732(12), Mg2–O41b 2.0789(11), Mg2–O41 2.0789(11), Na1–O12 2.2574(13), Na1–O22 2.3021(13), Na1–O3 2.3065(14), Na1–O33 2.4205(13), Na1–O31 2.5420(13), Na2–O4 2.2855(14), Na2–O42 2.3179(14), Na2–O21 2.3577(13), Na2–O11b 2.4102(13), Na2–O1c 2.7112(14). In the figure, A refers to atoms at $(1 - x, -y, 1 - z)$, B at $(1 - x, -y, -z)$, C at $(x, y, z - 1)$.

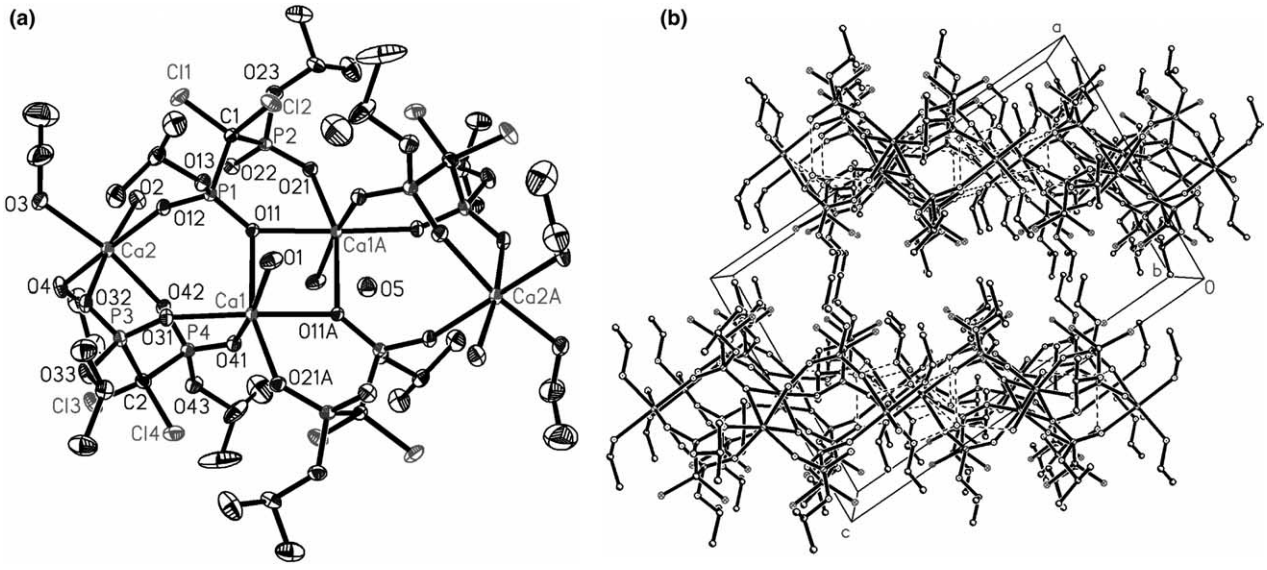

Fig. 2. (a) Structure of the asymmetric unit with numbering scheme and thermal ellipsoids (50%) and (b) packing of compound **2**. For clarity, hydrogen atoms are omitted. Selected bond distances (Å): Ca1–O31 2.2678(14), Ca1–O21a 2.2716(14), Ca1–O41 2.3092(14), Ca1–O1 2.3785(15), Ca1–O11a 2.3830(14), Ca1–O11 2.4574(14), Ca2–O12 2.2862(15), Ca2–O42 2.3092(15), Ca2–O4 2.3458(15), Ca2–O32 2.3479(15), Ca2 O3 2.3528(16), Ca2–O2 2.3603(15). In the figure, A refers to atoms at $(1-x, 1-y, -z)$.

The overall structure of **2** $[\{Ca_2[Cl_2C(PO_3iPr)_2]_2(EtOH)_2(H_2O)_2\}\cdot H_2O]_2$ consists of tetramers connected to layers by hydrogen bonds. There are two crystallographically independent, octahedral Ca atoms [Ca–O_{av} 2.34(5) Å] in the asymmetric unit of **2**, connected to each other by three triatomic bridges formed by $Cl_2C(PO_3iPr)_2^{2-}$ ligands. There are two chelating $Cl_2C(PO_3iPr)_2^{2-}$ ligands around Ca1, forming six-membered chelate rings in *cis*-positions. The fifth coordination site is occupied by a μ-phosphonate O atom that connects Ca1 to the adjacent Ca1 atom, and the sixth site is occupied by an aqua ligand (Fig. 2(a)). The Ca1 atoms form a square plane around a centre of symmetry with two bridging phosphonate O atoms, and the Ca2 atoms lie above and below this plane. The coordination sphere of Ca2 contains one chelating $Cl_2C(PO_3iPr)_2^{2-}$ ligand, forming a six-membered chelate ring, and one $Cl_2C(PO_3iPr)_2^{2-}$ ligand, which provides only one O atom to Ca2. One aqua ligand and two ethanol molecules occupy the rest of the coordination sites. Hydrogen bonds [O...O 2.739(2)–2.972(2) Å, 137°–176°] hold the tetramers together, forming a layered structure parallel to the (−1 0 1) plane. Isopropyl groups and chlorine atoms of the $Cl_2C(PO_3iPr)_2^{2-}$ ligands and ethanol ligands point to the interlayer section (Fig. 2(b)).

3.2. Spectroscopic properties

The characteristic absorption region and characteristic absorption bands of compounds **1** and **2** were determined by IR-spectroscopy. A very strong, broad band attributed to ν(P=O) appeared at ca. 1235–1230 cm^{-1}. The symmetric stretching vibration of the monoanionic, fully ionised PO_2^- group appeared at ca. 1090 cm^{-1}. Bands at 1177–1115 cm^{-1} were assigned to C–O–(P) vibrations and bands at 1065–995 cm^{-1} to P–O–(C) vibrations. Additional features of all the spectra were the bands at ca. 860 and 770 cm^{-1}, which were assigned to the asymmetric and symmetric P–C–P vibrations, respectively. In addition, the metal complexes exhibited bands demonstrating the presence of water molecules: $\nu(H_2O)$ ca. 3400 cm^{-1}, δ(H–O–H) ca. 1640–1630 cm^{-1}; and in both spectra there were bands demonstrating the isopropyl groups (bands in the 2990–2875 cm^{-1} and 1385–1372 cm^{-1} regions). Asymmetric and symmetric stretching vibrations of CCl_2 groups were presented at ca. 755–740 cm^{-1}. The spectra were similar to the spectra of the metal complexes of the diethyl ester derivative of clodronate [32].

4. Conclusion

Magnesium and calcium complexes of the symmetrical diisopropyl ester derivative of clodronic acid are good examples of the ability of bisphosphonates to form different compounds: Mg forms a polymeric chain with the bisphosphonato ligand, while Ca forms a tetramer. In the case of the diethyl ester derivative of clodronate, the Mg complex $[MgCl_2C(PO_3Et)_2(H_2O)_3]_n$ is also a polymeric chain, while the Ca complex $[Ca\{Cl_2C(PO_3Et)_2\}(H_2O)_3]_2$ is a dimer [32]. The esterified bisphosphonato ligands are capable of acting similarly to clodronate in all metal complexes; they are both chelating and bridging ligands, despite the fact that they have two O atoms masked with alkyl groups, which also

cause steric effect. In addition, the esterified compounds are capable of forming polymeric structures and porous materials that can be utilized in chemical applications.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 244607 (**1**) and 244608 (**2**). Copies of this information may be obtained from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk). Structure factors for **1** and **2** are available from the authors on request.

Synthesis, characterization and extraction behaviour of calix[4]arene with four propylene phosphonic acid groups on the lower rim

Irena Matulková *, Jan Rohovec

Department of Inorganic Chemistry, Faculty of Science, Charles University, Hlavova 2030, Albertov 2030, 128 42 Prague 2, Czech Republic

Received 30 July 2004; accepted 22 November 2004

Abstract

A new calix[4]arene based ligand bearing four phosphonic acid groups was prepared by modification of *p-tert*-butylcalix[4]arene on the lower rim by bonding with four $(CH_2)_3PO(OH)_2$ groups. The compound was characterized by NMR spectroscopy. The compound obtained was used as an extractant for certain lanthanide ions (La^{3+}, Eu^{3+}, Yb^{3+}). The extraction experiments were carried out at 25 ± 2 °C and pH 5.5 for 2 h. The formation of the complexes with lanthanide ions was revealed by NMR experiments and luminescence spectroscopy. The extraction efficiencies of the prepared ligand decrease with decreasing radius of the lanthanide ions.

1. Introduction

Nuclear waste is treated by a process based on the separation of its main components. The elements present vary in abundance, toxicity, type and energy of the emitted radiation, life-times and especially in reprocessing and storage.

In industry, the plutonium uranium extraction (PUREX) [1] industrial process is used to separate plutonium/uranium or the transuranium extraction (TRUEX) [2] process is used to extract minor actinides and lanthanides from nuclear waste solutions. The extracting agent is a mixture of (*N*,*N*-diisobutylcarbamoylmethyl)octyl phenyl phosphine oxide (CMPO) [3] (Fig. 1) and tri-*n*-butyl phosphate (TBP) in paraffin diluents. These compounds display high complexing ability for these metal ions and transfer them to the organic phase. The complexing ability of CMPO can be improved by grafting it on the calixarene platform. Actinide and lanthanide ions complex three CMPO molecules, which are not preorganized to form a coordination site. Preorganization of the coordination site could improve the complexing abilities of the ligand. For this reason, a variety of compounds and technologies are now being explored in an attempt to achieve better selectivity and efficiency of the extracting processes.

The highly lipophilic nature of metal–ion complexes of many calixarenes suggests their potential use in solvent extraction. Calixarenes may improve the extraction selectivity because of their hydrophilic properties. Furthermore, ligands based on calixarenes are capable of saturating the relatively high coordination number of f-block elements (8, 9 or higher). The cone conformation of calix[4]arene has the advantage of forming an organized coordination environment. Consequently, the lipophilic calixarene moiety can transfer a metal ion into the organic phase as a complex.

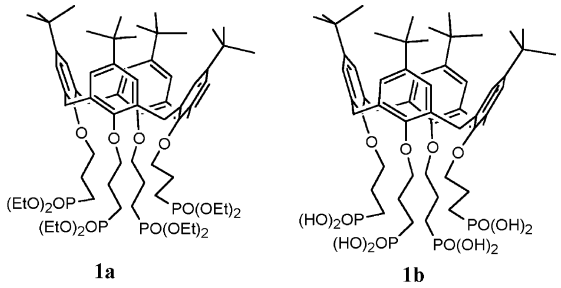

Fig. 3. Compounds studied.

Calixarenes are suitable for chemical modification at the upper or lower rim. The phenolic hydroxy groups on the lower rim can be modified more easily. Thus, a wide range of synthetic receptors for metal cations based on calixarene have been prepared [4]. Earlier work in this area described calixarenes with lower rim carbonyl-containing groups, such as esters, ketones, amides [5], thioamides, carboxylic acids [6] or phosphorus atom-containing groups, such as phosphine oxide [7], phosphate esters (double-bridge alkoxyphosphoryl substituents) [8], phosphine [9] and hydroxamates [10]. Phosphorus-containing extracting agents [11], such as the commonly used tri-*n*-butyl phosphate, have broad utilization in lanthanide (rare earth) and actinide extraction from acidic media, where the phosphoryl oxygen provides a donor atom capable of protonation. Calixarenes bearing phosphoryl groups are more efficient extraction agents for lanthanides and actinides than CMPO itself and also exhibit better actinide/lanthanide selectivity.

Recently, three bis(phosphonic)acid-containing calixarenes (distal disubstitution of calixarene) were described in the literature [12] (Fig. 2). The phosphonic acid groups are connected to the calixarene by a methylene, ethylene or propylene bridge. The phosphonic acid groups are relatively strong and hard acids according to the Hard-Soft-Acid-Base theory, with an affinity for lanthanides and actinides and, therefore, they can form relatively stable complexes with rare-earth elements even in highly acidic media. Unexpected selectivity in the extraction experiments on heavy lanthanides was found for distal disubstitution in the case of the (3-dihydroxyphosphoryl)propoxy ligand. This result corresponds to the presence of a group that can be deprotonated. The extraction power of these three ligands decreases as the acidity of the groups increases, but this dependence is not as obvious as that for carboxylate. High selectivity was observed for Yb^{3+}. The diethoxy esters of this compound exhibit comparable extraction efficiency to CMPO.

In this work, we describe the synthesis and extraction properties of compound **1b**, bearing four PO_3H_2 moieties. These groups are expected to form a preorganized site for the lanthanide ion. They can display a high extraction efficiency and even extra selectivity for lanthanide ions, Fig. 3.

2. Experimental

The starting compounds *p*-*tert*-butylcalix[4]arene and phosphonate ester, $Br(CH_2)_3PO(OEt)_2$, were prepared and purified by the procedures described in the literature [13,14]. All the solvents used in the syntheses were dried and purified by standard methods [15]. The syntheses were performed under an argon atmosphere.

Column chromatography was performed using Merck silica gel 60 (230-400 mesh) and thin layer chromatography (TLC) of the octa-esters using Merck silica 60 F_{254} plates. A chromogenic spray reagent was used for detection of phosphonate groups (a solution

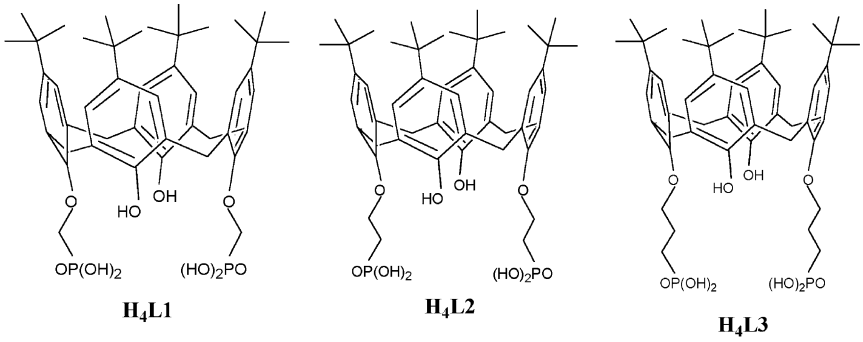

Fig. 2.

of 10 g $Ce(SO_4)_2$, 12 g $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ in 250 ml of 10% H_2SO_4), usually applied after detecting the plate under ultraviolet light, and exposing it to iodine vapour. The nitrates of Ln^{3+} (La^{3+}, Eu^{3+}, Yb^{3+}) were used in the extraction experiments. The metal concentrations in the aqueous phases were determined by complexometric titrations with DTPA (DTPA = diethylene triamine pentaacetic acid, xylenol orange, pH 5.5 acetate buffer) [16]. All the compounds were characterized by the ^1H, ^{13}C and ^{13}P NMR spectra (recorded on a 400 MHz Unity Varian spectrometer, solvent = $CDCl_3$, reference TMS, ^1H frequency = 399.951 MHz) and MS spectra (recorded on an ESQUIRE 3000 Bruker Mass Spectrometer, ESI electrospray ionization, ionic trap detection). The calix[4]-arene compounds were dried for several hours in vacuo before characterization, as they show a tendency to form inclusion complexes of organic solvents and water. The luminescence spectrum of the complex of **1b** with Eu^{3+} was recorded on LS 50B Perkin–Elmer spectrometer in a 1 cm cuvette with an excitation wavelength of 256 nm in a methanol solution. Elemental analyses were not performed.

3. Syntheses

*3.1. Synthesis of compound **1a**: 5,11,17,23-tetra-tert-butyl-25,26,27,28-tetrakis[(3-diethoxyphosphoryl)-propoxy]calix[4]arene*

A suspension of 5 g of *p-tert*-butylcalix[4]arene (1:1 complex with toluene, 6.7 mmol) and 1.3 g of sodium hydride (53.9 mmol) in 120 ml of dry toluene was stirred and heated to 90 °C (in an oil bath) for 21 h. Then a solution of 14 g of diethyl (3-brompropyl)phosphonate (54 mmol) in 20 ml of dry toluene was added to the reaction mixture. The reaction mixture was stirred and heated to 90 °C for 9 days. An argon atmosphere was maintained during the reaction. The reaction was followed by TLC (mobile phase chloroform/ethyl acetate in a 1:1 ratio) and mass spectrometry in common solvents (methanol).

The reaction mixture was extracted twice with 50 ml of water, and dried over anhydrous $MgSO_4$. After removal of most of the solvent, the resulting yellow oil was purified by column chromatography. A mixture of $CHCl_3/CH_3COOC_2H_5$ in a ratio of 1:1 was used as the first mobile phase. This mixture removed the phosphonate ester, *p-tert*-butylcalix[4]arene and products of mono- or di-substitution of *p-tert*-butylcalix[4]arene. Compound **1a** was eluted from the column by a $CH_3COOC_2H_5/CH_3OH$ mixture in 2:1 ratio. The purity of compound **1a** was 70–75% (from ^{13}P NMR) and the reaction yield was 6.7 g of yellow oil (73%).

The negative mode spectrum did not exhibit any peaks. The positive mode spectrum contained a peak at m/z = 1383.9 (compound **1a**).

*3.2. Synthesis of compound **1b**: 5,11,17,23-tetra-tert-butyl-25,26,27,28-tetrakis[(3-dihydroxyphosphoryl)-propoxy]calix[4]arene*

Compound **1b** was prepared from **1a** following a procedure similar to the one described in the literature [17].

A solution of 4.7 g of **1a** (3.4 mmol) and 10.6 ml of trimethyl silyl bromide (82 mmol) in 40 ml of dry acetonitrile was stirred and refluxed for 6 h. Methanol (20 ml) was added very slowly (after cooling the reaction mixture below the boiling point of methanol). The reaction mixture was then stirred and refluxed for 2 h.

The solvents were removed and the residue was evaporated twice with 20 ml of dry toluene and filtered. The yield of the reaction was 1.8 g of compound **1b** (47%) in the form of an orange oil.

The negative mode spectrum revealed a peak at m/z = 1138 (compound **1b**). The positive mode spectrum included peaks at m/z = 1137.8 (compound **1b**); 1016.6.

3.3. General procedure for the extraction experiments

The following conditions were used for the extraction experiments with compounds **1a** and **1b**: the experiments were performed at pH 2 and 5.5, the temperature was maintained at 25 ± 2 °C (water bath), the extraction time was 2 h (this time is sufficient to achieve extraction equilibrium). Aqueous solutions of the metal nitrates ($c_M = 5 \times 10^{-3}$ M, pH 2) and solution of the ligand ($c_L = 5 \times 10^{-3}$ M) in chloroform were prepared for the extraction experiments. Two milliliters of each solution were mixed and shaken for 2 h in ratios of 1:1, 1:2 and 2:1. After separation of the phases (after 6 h), 1 ml of the water phase and 1 ml of the organic phase were analyzed for the metal content. The organic phase had to be evaporated and dissolved in an aqueous solution of concentrated HNO_3 and evaporated three times with water and then dissolved in an aqueous solution of acetate buffer (pH 5.5). The amounts of metal ion were analyzed by complexometric micro-titration. 0.04 M DTPA was used as the complexing agent with xylenol orange as indicator in acetate buffer solution (pH 5.5, acetic acid and sodium acetate).

4. Discussion

4.1. Syntheses

The general method for synthesizing lower-rim calix[4]arene derivatives is based on the alkylation of the phenolic groups with a strong alkylation agent. This

strategy was used to prepare compound **1a**, which was converted into phosphonic acid (Scheme 1). Careful choice of the reaction conditions is necessary – the temperature, type of base, solvent and type of the alkylation agent are important. It was very difficult to choose an alkylation agent with a good leaving group for preparation of compound **1a** directly in one-step synthesis. Acceptable results were obtained for $Br(CH_2)_3PO_3Et_2$.

A variety of conditions were examined for the synthesis of compound **1a**, for example reaction in refluxing acetonitrile and sodium hydride as the base or performance of the reaction under the conditions of phase-transfer catalysis (PTC), utilizing tetrabutyl ammonium bromide and K_2CO_3 as a base in dry acetonitrile. These reactions yielded a mixture of partially substituted compounds containing one to four phosphonic groups. The best solvent for this reaction appeared to be toluene. The reagent with bromide as a suitable leaving group can be used as an alkylation agent, because the phosphonic group is bound to the calix[4]arene molecule by a relatively long propylene spacer.

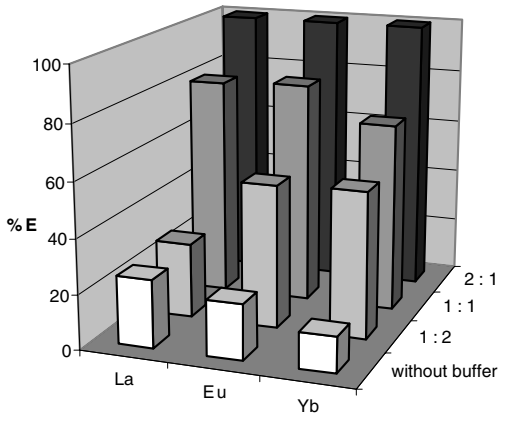
Ligand **1b** was obtained by a well-known method using transesterification with trimethyl silyl bromide in refluxing acetonitrile and subsequent hydrolysis of the trimethyl silyl ester in methanol. The yield of compound **1b** was 47%.

The identity and purity of all the compounds were checked by NMR spectroscopy and mass spectrometry. Elemental analyses were not performed due to the large relative molecular weights of the prepared compounds in comparison with common impurities (traces of solvents, etc.). Elemental analyses are unsuitable for the types of compounds prepared, because the compounds were prepared in the form of an oil or glass. It is not possible to evaporate all of the solvents during long drying under the vacuum of an oil pump.

4.2. Extraction experiments

Extraction experiments were designed to compare the results obtained from the measurements for compounds **1a** and **1b** to the data published in the literature and to investigate the potential industrial applicability of the prepared ligands (low concentration of Ln^{3+}, cheap organic solvent, high acidic nitrate solutions, appropriate concentration of the ligands used). The activities and extraction properties of compounds **1b** in the extraction of the lanthanide ion from its nitrate solution (pH 2 or 5.5) into the chloroform solution at concentration ($c_L = 5 \times 10^{-3}$ M) are depicted in Fig. 4. The concentration of the nitrate solution of lanthanide ions used in the extraction experiments is acceptable for the complexometric titration measurements.

Compound **1a** did not transport Ln^{3+} into the chloroform phase. The extraction conditions were changed in the various extraction experiments, for example, the concentration, the duration of the extraction experiment, the pH (2; 5.5), the temperature (25; 30 °C) and the molar ratios. This result is very interesting, because the literature describes a similar ligand, *p-tert*-butylcalix[4]arene, distally disubstituted with the same group on the lower rim as compound **1a**. The extraction efficiency was published %E = 42 for the extraction experiment of Eu^{3+} from aqueous medium (pH 5.8) into a



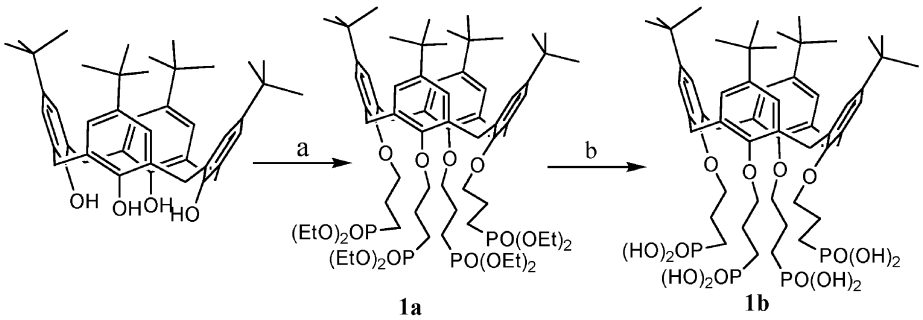


Fig. 4. Extraction efficiencies (%E) for the extraction of chosen lanthanide ions, using molar ratio (ligand **1b**/lanthanide ions), different pH (2 or 5.5) with compound **1b**. The signature without buffer means that the experiment was done with pH 2 in the aqueous phase.

Scheme 1. Synthesis of compounds **1a** and **1b**. (a) NaH, $Br(CH_2)_3PO(OEt)_2$, toluene, 100 °C. (b) (1) $(CH_3)_3SiBr$, CH_3CN, reflux, (2) MeOH.

chloroform phase. The concentrations of Eu^{3+} and of the ligand were the same.

The oxygen atoms in **1a** probably do not form a suitable cavity for the lanthanide ions. The steric requirements for the bulky propylene phosphonic groups entail orienting the non-bonding electron pairs of the oxygen atoms toward the lanthanide ions.

In the series of extraction experiments on compound **1b**, the dependence on the type of lanthanide ion, the pH of the water phase and the molar ratio for compound **1b** and lanthanide ions were observed, Fig. 4.

The extraction efficiencies (%E) for compound **1b** under these conditions are satisfactory and comparable to those for the ligand based on calix[4]arene with (*N*,*N*-diisobutylcarbamoyl)octyl phenyl phosphine oxide (CMPO) groups and better than CMPO itself. The extraction properties for the experiment at pH ≅ 2 increase for charged molecules and the extraction properties were better if an aqueous phase with pH 5.5 (acetate buffer) was used. The differences for the individual lanthanide ions may be caused by an additional protonisation of the molecule in the presence of various large lanthanide ions. We can confirm a higher extraction efficiency for the large lanthanum(III) ion than for the smaller ytterbium(III) ion. The dependence of the extraction properties for the large lanthanum(III) ion and the smaller ytterbium(III) ion is inverse with respect to the dependence which was published in the literature for distally dialkylated compounds bearing the same group $(CH_2)_3PO(OEt)_2$, Fig. 5. This difference is very similar for the calix[4]arene-based diphenyl phosphinoxides with two or four groups on the lower rim, described in the literature [3,18].

The cavity formed from four phosphonic groups on the lower rim is larger than the one formed from two groups, and therefore prefers the larger lanthanum(III) ion to the smaller ytterbium(III) ion.

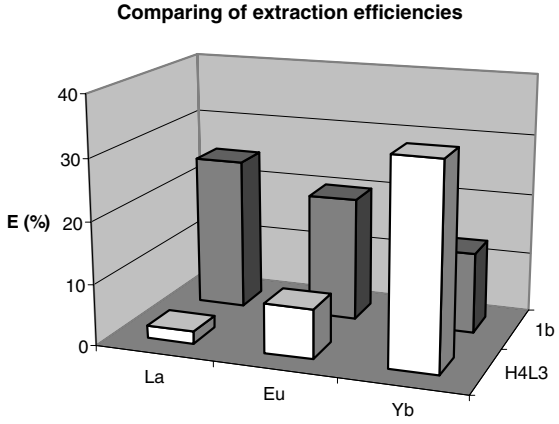

Fig. 5. Comparison of extraction efficiencies compound **1b** presented in this paper and the compound **H_4L3** in the literature [12].

Table 1
Comparison of extraction efficiencies with in the literature described compounds

	Organic phase	Aqueous phase	Th (IV)	Eu (III)	La (III)	Yb (III)

[a] Extraction experiment with molar ratio lanthanide/ligand 1:1 with pH 2 in aqueous phase.
[b] The molar ratio 2:1.
[c] The molar ratio 1:2.
[d] Experiment with $c_L = 10^{-2}$ M and $c_{Ln} = 10^{-4}$ M.

For the ratio 1:2 (compound:lanthanide ions), 100% extraction efficiency can be seen in Fig. 4 for all of the studied lanthanide ions.

The extraction of Ln^{3+} for the studied ligand depended on the ionic radii of the lanthanide cations. The value of %E increases significantly with increasing ionic radius. Ligands with two groups on the lower rim are harder in the Pearson classification than calixarenes with carboxylic groups. Other known selective lanthanide extraction agents are also based on the calixarene moiety. In contrast to most CMPO-based calixarenes [18], the extraction efficiency for compound **1b** is highest for low concentrations of nitric acid and decreases sharply as the acidity increases. This trend is close to the behaviour of CMPO itself. The lower acidity constants of alkyl phosphonic acids indicate that the decrease is not as rapid as for carboxylates or hydroxamates. These results are illustrated in Table 1 and Fig. 6.

We attempted to elucidate the chemical form in which Ln^{3+} is transported from the aqueous phase to the organic chloroform phase. We followed the formation of complexes of the diamagnetic La^{3+} and Y^{3+} ions by ^{13}P NMR (molar ratio 1:1 (Ln^{3+}/**1b**), solvent = methanol, room temperature to −10 °C). For the La^{3+} system in the temperature range given, we observed three wide signals in the range 26.8–29.0 ppm, probably caused by quadrupolar interaction or by the dynamic nature of the ^{139}La and ^{13}P NMR spectra (shift to lower chemical shift values; from 32.7 ppm for **1b** to 26.8 ppm). Then we studied the smaller diamagnetic lanthanide Y^{3+} ion in order to check whether the dynamic nature is retained. In the most favourable case, when no diamagnetic effects occur, $^2J_{YP}$ interaction could be observed (about 5 Hz [19]). For the Y^{3+} experiments (molar ratio 1:1, 1:2, 1:4), we observed three wide signals for a molar ratio of 1:1, but these signals arose from very fast changes between the complex of compound **1b** with Y^{3+} and the free compound **1b**, in contrast to La^{3+}. The experiment for the 1:2 molar ratio resulted in two wide signals at 25.0 and 26.5 ppm and we found only one signal at 27.1 ppm for the 1:4 molar ratio. None of them was split into a doublet. Thus, both experiments (for La^{3+} and Y^{3+}) for a molar ratio of 1:1 yielded the same results. NMR measurements revealed that the complexes possessed dynamic behaviour within the NMR time scale.

The other experiment for description of the complex of compound **1b** and lanthanide ions consisted in estimation of the stability constant. This experiment was performed to compare the formation and stability of the complex of Ln^{3+} with DTPA to the complex of Ln^{3+} with compound **1b**. Two samples were prepared for this experiment. One consisted of Eu^{3+} and compound **1b** and the second one consisted of Eu^{3+}, DTPA and compound **1b** (both in methanol). The samples were measured by luminescence spectroscopy [20]. The excitation line at 256 nm was used, exciting the aromatic system in compound **1b**, and the energy was then transferred to the Eu^{3+} ion, probably via intersystem crossing. A characteristic luminescence spectrum was observed for sample 1 (Fig. 7 and Table 2) while

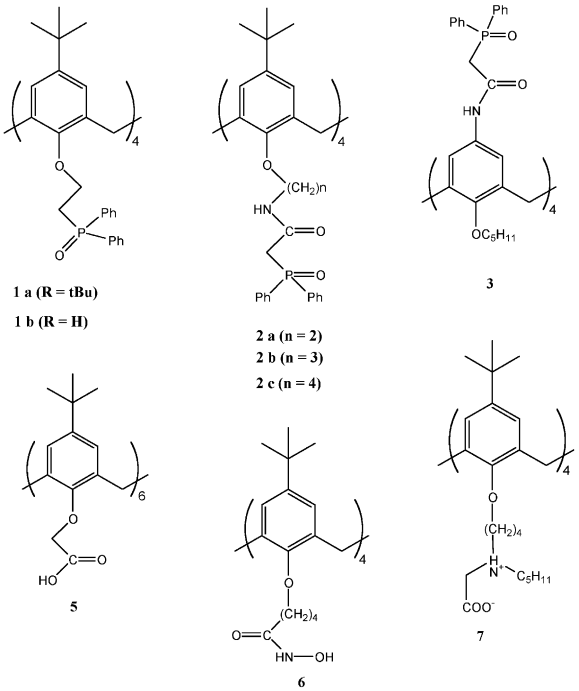

Fig. 6. Formulae of compounds (from the literature) using in Table 1.

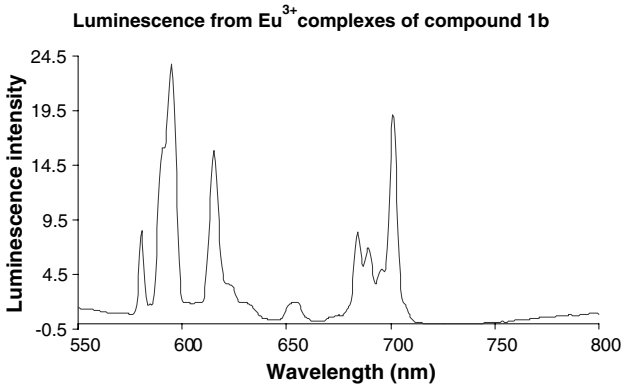

Fig. 7. Europium luminescence emission spectrum (293 K, MeOH, λ_{exc} = 256 nm).

Table 2
Characteristics of the luminescence spectrum of europium(III) complexes

Wavelength (nm)	Characteristics of the $^5D_0$–^7F_j transitions for Eu^{3+} complexes in methanolic solution	
580.5	$^5D_0$–$^7F_0$ $\Delta J = 0$	
594.5	$^5D_0$–$^7F_1$ $\Delta J = 1$	
615.0	$^5D_0$–$^7F_2$ $\Delta J = 2$	hypersensitive
654.5	$^5D_0$–$^7F_3$ $\Delta J = 3$	forbidden
701.0	$^5D_0$–$^7F_4$ $\Delta J = 4$	

sample 2 did not yield a spectrum for this excitation line. It can thus be concluded that there is close contact between Eu^{3+} and the aromatic calixarene system. According to the luminescence spectra, the stability constant of complexes **1b** with the lanthanide ions is lower than that of the DTPA complexes with the lanthanide ions ($pK = 23$) [16,23]. However, the stability constant for compound **1b** and Ln^{3+} is higher than the stability constant for Ln^{3+} and xylenol orange ($pK = 14$) [24]. The solution of Ln^{3+} in methanol can be titrated by a solution of the ligand in methanol (the changes in the colour of the titrimetric solution can be observed). The Job plot experiment revealed simultaneous formation of complexes with Ln^{3+} in various stoichiometries in the solution.

5. Conclusion

A new calix[4]arene with four pendant arms $(CH_2)_3PO(OEt)_2$, used as an extraction agent for lanthanides, was prepared by Williamson alkylation of *p-tert*-butyl calix[4]arene. The extraction studies showed that the ligand is an efficient extraction agent for larger lanthanides, and much more efficient than CMPO and the extraction agent based on calixarene with carboxylic or diphenyl phosphinoxide groups. Because of the presence of groups that can be deprotonated, the extraction behaviour of ligand **1b** decreases with increasing acidity, but not as significantly as in the case of carboxylates, which enables the efficient extraction of lanthanides from 1 M nitric acid. Compound **1a** did not extract Ln^{3+} ions into chloroform solutions from the aqueous phases (pH 2–5.5). NMR measurements revealed that the complexes possessed dynamic behaviour within the NMR time scale. The Job plot result indicated simultaneous formation of complexes **1b** and Ln^{3+} in various stochiometries in the solution. The affinity for Ln^{3+} was reflected in the luminescence spectrum, which revealed energy transfer from the aromatic ring to the lanthanide ion.

Abstract

The synthesis and characterisation of Ni(II), Cu(II) and Cd(II) complexes of 3-furaldehyde thiosemicarbazone (3FTSC) are reported. Elemental analysis, molar conductance and spectral (IR, UV and ^{1}H NMR) measurements have been used to characterise the complexes. In addition, the structure of the complex $[Cu(3FTSC)_2]$ has been determined by X-ray diffraction methods. In Cu(II) and Ni(II) complexes, the metal ion is coordinated through the sulfur atom and the azomethine nitrogen atom while in the Cd(II) complexes the coordinating atoms are sulfur and furanic oxygen ones.

Keywords: Furan thiosemicarbazone; 3d metals complexes; Spectroscopic studies; Crystal structures

1. Introduction

Thiosemicarbazones, their derivatives, as well as their transition metal complexes have aroused considerable interest in the areas of chemistry and biology. These compounds present a wide variety of biological activity such as antitumoral [1–5], fungicidal [6,7], bactericidal [8] or antiviral [3]. They have been used for metals analyses [9], for device applications relative to telecommunications, optical computing, storage and information processing [10].

As part of our continuous research work about synthesis and biological activity, mainly with thiosemicarbazones and semicarbazones deriving from furaldehyde and their metal complexes [11–16], we describe in this work a new series of transition metal complexes obtained from 3-furaldehyde thiosemicarbazone 3FTSC (Fig. 1) as ligand and the chlorides and bromides of Ni(II), Cu(II) and Cd(II). All structures are determined on the basis of elemental analyses and spectroscopic techniques. In addition, the crystal structure of the copper complex $[Cu(3FTSC)_2]$ is described.

2. Experimental

2.1. Reactants

All reactants and solvents were analytical grade. Thiosemicarbazide and 3-furaldehyde were purchased from Merck and Aldrich, respectively. Nickel, copper and cadmium hydrated salts were used as received (Prolabo).

2.2. Preparation of ligand

The 3-furaldehyde thiosemicarbazone was synthesised as previously described [11] by refluxing 3-furaldehyde and thiosemicarbazone (1:1 molar ratio) in absolute ethanol in the presence of pure acetic acid.

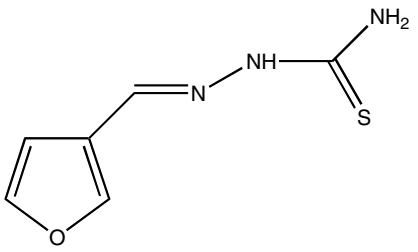

Fig. 1. Chemical structure of 3-furaldehyde thiosemicarbazone (3FTSC).

The mixture was refluxed for 1 h and then cooled, filtered and recrystallised from a mixture of ethanol (75% V/V) and water. Yellow microcrystalline products are obtained. (Elemental *Anal.* Calc. for $C_6H_7N_3OS$: C, 42.59; H, 4.17; N, 24.83. Found: C, 42.90; H, 4.19; N, 24.70%). M.P. = 154 to 155 °C.

2.3. Preparation of complexes

2.3.1. Bis(3-furaldehydethiosemicarbazone)nickel (II) [Ni(3FTSC)$_2$]

The hexahydrated nickel chloride, $NiCl_2 \cdot 6H_2O$ (2.5×10^{-3} mol, 0.59 g), was dissolved in distilled water. An ethanolic solution of FTSC (5×10^{-3} mol; 0.85 g, 10 mL) was added slowly while stirring. The mixture was refluxed for 3 h. After cooling at room temperature, a green precipitate appeared. It was filtered, washed with small amounts of absolute ethanol and finally dried in vacuum over silicagel. All the compounds were washed and dried in the same way.

2.3.2. Dichloro bis(3-furaldehydethiosemicarbazone) copper (II) [CuCl$_2$(3FTSC)$_2$]

This complex was prepared from a mixture of ethanolic solution (10 mL) of 3FTSC (0.42 g, 2.5×10^{-3} mol) and $CuCl_2 \cdot 2H_2O$ (1.25×10^{-3} mol) after 1 h reflux.

2.3.3. Bis(3-furaldehydethiosemicarbazone)copper (II) [Cu(3FTSC)$_2$]

When 2×10^{-3} g of complex [$CuCl_2$(3FTSC)$_2$] was dissolved in ethanol (20 mL), a dark-green crystalline product of formula [Cu(3FTSC)$_2$] was isolated after several days at room temperature. As the crystal structure of this compound was fully solved by X-ray diffraction, its analytical and infrared data are not given in Tables 2 and 4.

2.3.4. Bis(chloro(3-furaldehydethiosemicarbazone) copper (II)) [CuCl(3FTSC)]$_2$

$CuCl_2 \cdot 2H_2O$ (0.24 g, 1.25×10^{-3} mol, 5 mL) was added to 3FTSC (0.21 g, 1.25×10^{-3} mol, 10 mL) in EtOH. The complex is obtained after refluxing EtOH for 1 h.

2.3.5. Bis(bromo(3-furaldehyde thiosemicarbazone) copper (II)) [CuBr(3FTSC)]$_2$

The bromo complex was obtained as the chloro complex starting from 3FTSC (0.21 g, 1.25×10^{-3} mol, 10 mL) and $CuBr_2$ (0.28 g, 1.25×10^{-3} mol, 5 mL).

2.3.6. Dichloro(3-furaldehyde thiosemicarbazone) cadmium (II) [CdCl$_2$(3FTSC)]

This complex was prepared from a mixture of ethanolic solution of 3FTSC (0.21 g, 1.25×10^{-3} mol, 5 mL) and $CdCl_2$ (0.23 g, 1×25.10^{-3} mol, 5 mL) after a 1 h reflux.

2.3.7. Dibromo(3-furaldehyde thiosemicarbazone) cadmium (II) [CdBr$_2$(3FTSC)]

$CdBr_2 \cdot 4H_2O$ (0.34 g, 1.25×10^{-3} mol, 5 mL EtOH) was added to 3FTSC (0.21 g, 1.25×10^{-3} mol, 10 mL) in EtOH. The mixture was refluxed for 1 h.

2.4. Measurements

Elemental analysis were carried out by the Service Central d'Analyses (C.N.R.S. Vernaison, France). Melting points were determined with a digital melting point apparatus using a capillary technique. Conductance values were obtained with a Tacussel CD6NG conductometer at 298 K from 10^{-3} mol L^{-1} solutions of complexes in absolute EtOH. The solvent had a conductance of 10^{-8} S cm^2 mol^{-2}.

The IR spectra were recorded with a Shimadzu FTIR-8010M spectrometer between 4600 and 400 cm^{-1} (KBr disks) and with a Nicolet FTIR 20F in the range 400–50 cm^{-1} using polyethylene disks (Institut des Matériaux Jean Rouxel, UMR 6502, Nantes, France). Electronic spectra were recorded with a Perkin–Elmer Lambda 19 spectrometer from ethanolic solutions (10^{-3} mol L^{-1}). The ^{1}H NMR spectra were recorded on a Bruker Advance DRX 500 spectrometer in DMSO-D6 operating at 500 MHz. The chemical shifts, δ, are given in parts per million (relative to TMS) and coupling constants in hertz.

2.5. Crystal data collection and processing

Crystals of [Cu(3FTSC)$_2$] are monoclinic with space group $P2_{1/c}$. The crystal and instrumental parameters used in the unit-cell determination and data collection are summarised in Table 1. X-ray diffraction data were collected at 293 K on an Enraf Nonius MACH3 four-circles diffractometer ($\lambda_{Mo\ K\alpha} = 0.71073$ Å) equipped with a graphite monochromator (IMMO, UMR, C.N.R.S, 6501 Angers). The structure was solved by direct methods (SIR) using MOLEN package programs [17] and the structure was refined on F by full-matrix least-squares techniques.

The small size of the crystal did not allow us to obtain enough data and carbon atoms were refined isotropically. Oxygen and nitrogen atoms were refined anisotropically. Hydrogen atoms attached to nitrogen atom (N) were located from Fourier difference synthesis [17]. The remaining hydrogen atoms were located using HYDRO program [17].

3. Results and discussion

The analytical and physical data for the ligand and the metal complexes are listed in Table 2. All the analytical data are in good agreement with the empirical formulae as given in Table 2. The complexes are stable in air. However, the cadmium complexes showed an hygroscopic character. Their molar conductivities are in a range corresponding to a non-electrolytic nature. These results agreed with measurements of the conductivity carried out with their homologous thiosemicarbazones and semicarbazones [13,18–20]. On heating, all the complexes decomposed and did not present a clear melting point.

3.1. Crystal structure of [Cu(3FTSC)$_2$]

The main crystal parameters are reported in Table 1. The bond distances and their angles for this crystal are shown in Table 3. Fig. 2 shows a view of the molecule of [Cu(3FTSC)$_2$] with numbering scheme.

The centrosymmetric structure consists in the neutral molecules Cu(3FTSC)$_2$, with copper at the centre of symmetry. The coordination results in a square planar configuration, which involves the thiolato sulfur atoms and the imine nitrogen atom N3 of the two ligands in *cis*-configuration.

In the complex, the monodeprotonated bidentate ligand shows a *cis*-configuration for the nitrogen N3 and sulfur S atoms. In the free ligand, however, these

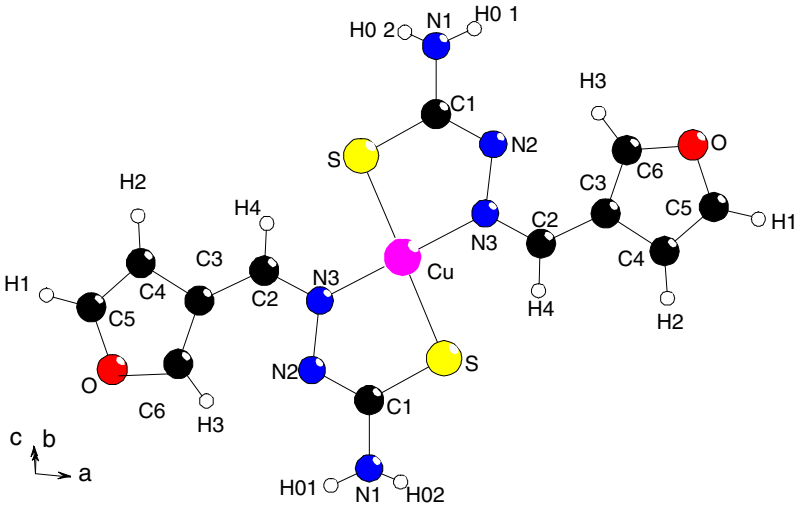

Fig. 2. Perspective view of complex and atom numbering of [Cu(3FTSC)$_2$].

centres present a *trans*-configuration [11], indicating that the complexation occurs after a 180° rotation around the C1–N2 bond.

As the ligand is deprotonated on N2 atom, a negative charge appears and is delocalized along the thiosemicarbazone moiety. This fact is confirmed by the difference between the bond distances in the deprotonated ligand of copper complex: S1–C1 = 1.726(8) Å (thiolato form); C1–N2 = 1.30(1) Å and C2–N3 = 1.30(1) Å, and the same bond distances in the free ligand: S1–C1 = 1.690(2) Å (thione form); C1–N2 = 1.338(2) Å and C2–N3 = 1.271(2) Å [11–13].

The configuration of the complex [Cu(3FTSC)$_2$] is planar, while the carbon atom, C1, is slightly out of this plane, with 0.12 Å deviation.

It is not very easy to compare the S–Cu and N3–Cu bonds lengths with the distances reported in the literature for the same bonds in thiosemicarbazones copper (II) complexes. Generally, these complexes are formulated as [CuLX$_2$] or [CuLX] (X = halogen, L = ligand) with tridentate ligands, whereas the complex [Cu(3FTSC)$_2$] should be written [CuL$_2$] with L being a bidentate ligand.

The molecular arrangement in the unit-cell shows that the neutral molecules Cu(3FTSC)$_2$ in the complex [Cu(3FTSC)$_2$] are stacked, one above the other, so that their main planes are parallel and the copper atoms occupy the apexes and the mid-point of the *c* edges. This is shown by the projection of the structure on the plane (0 1 0) presented in Fig. 3.

The packing is governed by hydrogen bonds between the hydrogen H1 of the amino group N1 and the oxygen atom in furanic ring. This hydrogen bond shows a bond distance of 2.45 Å and a bond angle of 147°. The coordinates of N1 and O are, respectively, $(2 - x, 0.5 + y, 1.5 - z)$ and $(1 - x, 1 - y, 1 - z)$.

3.2. Infrared spectra

Selected vibration bands of 3FTSC and of its metal complexes are given in Table 4.

The vibration ν(C=S) in the spectrum of the ligand shows a band around 837 cm^{-1} [11]. This band is shifted to lower wavenumbers in all the complexes [21,22]. On the other hand, the bands in the region 3421–3290 cm^{-1} attributed to symmetrical and asymmetrical stretching modes $\nu(NH_2)$ in the spectra of the ligand, undergo a change in the spectra of the complexes. This is explained by the coordination of sulfur from the C=S (NH_2) group as reported earlier [23]. In addition, this

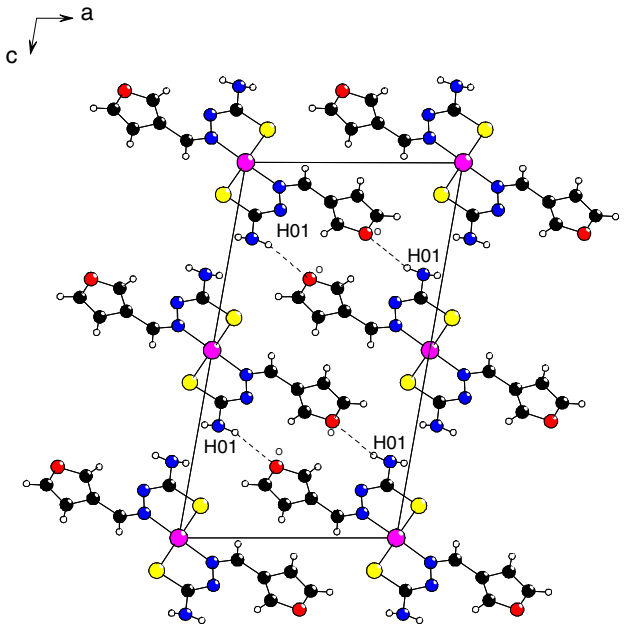

Fig. 3. Packing arrangement and hydrogen bonding in [Cu(3FTSC)2] X-ray structure.

coordination is confirmed by the presence in all complexes of a new band at 380–390 cm^{-1} [5,24], relative to ν(M–S) vibration.

In the ligand spectra, the strong band observed at 1587 cm^{-1} is assigned to (C=N) stretching vibration [11]. This band shifts to higher wavenumbers in the spectra of all metal complexes, indicating the coordination of nitrogen of the azomethine group to the central metal atoms [21,23]. In the case of the cadmium complex, this shift is very feeble. The presence of a new band in the region 430–440 cm^{-1} due to ν(M–N) is an other indication of the involvement of nitrogen of the azomethine group in the coordination [5,24]. However, we did not observe any shifts of frequency of the ν(Cd–N) vibration for the complexes of Cd(II). On the opposite side, we noted a significant displacement of the frequency of the ring breathing and ν(C–O–C) vibrations, and this shows that the coordination occurs through the furanic oxygen atom (instead of the azomethine nitrogen) [25]. This coordination is also supported by the appearance of the ν(Cd–O) vibration for [$CdCl_2$(3FTSC)] and [$CdBr_2$(3FTSC)] at 490 and 485 cm^{-1}, respectively [18,19,25,26].

In the literature, the bands appearing between 160 and 300 cm^{-1} are allotted to the vibration of the M–X bonds, where M = metal and X = Cl or Br [18,26–29]. In our case, the ν(M–X) frequencies appearing between 240 and 260 cm^{-1} (Table 4) are in good agreement with the reported values in the literature.

Generally, the infrared spectra of copper complexes such as [$CuCl_2(L)_2$] or [$CuCl_2$(L)] present two bands between 240 and 280 cm^{-1}, due to ν(Cu–Cl) vibration [27,28]. Billing et al. [30] showed that, when copper(II) complexes present only one vibration band in this range, their structures show halogenide bridges in these compounds. This is observed in the case of the binuclear complexes [CuCl(3FTSC)]$_2$ and [CuBr(3FTSC)]$_2$.

3.3. Electronic spectra

The study of the electronic spectra in ethanol allowed us to determine the geometry of the polyhedrons of coordination for copper complexes. The binuclear complexes [CuCl(3FTSC)]$_2$ and [CuBr(3FTSC)]$_2$ showed only one band around 13 700 cm^{-1}. This band was also observed in the spectrum of the binuclear complex [Cu(TTSC)Cl]$_2$ described by Nair et al. [31], where TTSC is 2-thiophene carboxaldehyde thiosemicarbazone. It is typical of a d–d transition in a square planar environment.

The electronic spectrum of the complex [$CuCl_2$-(3FTSC)$_2$] presents an asymmetrical band with a maximum around 15 410 cm^{-1}. According to Raising [32], the asymmetry of this band is a characteristic of octahedral copper (II) compounds, where a lengthening of the bonds located along the $z'Oz$-axis is often observed. At the outset, this lengthening can lead to an ionic complex with square planar geometry. This fact is confirmed by the high value of the conductivity of [$CuCl_2$(3FTSC)$_2$] (Table 2) and the loss of the two chlorine atoms during the formation of the monocrystals of [Cu(3FTSC)$_2$]. We conclude that the geometry of this complex is closer to square planar rather than regular octahedral geometry.

3.4. NMR spectra

Theoretically, the complexation by azomethine nitrogen should affect the chemical shift of the C=N protons [5]. The recording of spectra ^{1}H NMR for the cadmium complexes did not show any shift of this signal. This confirms our earlier hypothesis, formulated from infrared data, that the second coordinating atom is the oxygen of the furanic ring for the Cd(II) complexes. In addition, no signals appeared around 11.4 ppm (field of appearance of the signal of a NH group next to C=S) and this confirms that the coordination occurs through the thiolato form.

4. Supplementary data

Crystallographic data have been deposited with the CCDC (12 Union Road. Cambridge, CB2 IEZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk)), and are available on request quoting the deposition numbers CCDC 252861.

Abstract

Mononuclear ruthenium complexes of tetrazine derived L, $Ru^{II}(acac)_2(L)$ (**1**), $[Ru^{II}(bpy)_2(L)](ClO_4)_2$ (**2**) and $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**) (L = 3-amino-6-(3,5-dimethylpyrazol-1-yl)-1,2,4,5-tetrazine, acac = acetylacetonate and bpy = 2,2′-bipyridine) were prepared. The free L exists as a dimeric entity in the solid state via hydrogen bonding interactions involving L and water molecules present in the crystal lattice. **1** exhibits unusually strong bonds from Ru^{II} to coordinating pyrazolyl-N (2.040(2) Å) and especially to tetrazine-N (1.913(2) Å). The Ru^{III}/Ru^{II} couples of **1**–**3** appeared at 0.28, 1.34 and 1.50 V versus SCE, respectively. The tetrazine and bpy-based reductions were observed at −1.33 (**1**); −0.55 and −1.55/−1.75/−1.98 (**2**); −0.47/−0.78 and −1.80/−2.02 V (**3**), respectively. **1**, **2** and **3** displayed two MLCT bands each, corresponding to $d\pi(Ru^{II}) \rightarrow \pi^*$ (L, tetrazine) and $d\pi(Ru^{II}) \rightarrow \pi^*$ (acac or bpy or L) transitions. $\mathbf{1}^+$ and $\mathbf{2}^+$ showed rhombic EPR spectra at 110 and 4 K, respectively and $\mathbf{1}^-$, $\mathbf{2}^-$ and $\mathbf{3}^-$ exhibited multiple line EPR spectra at 300 K. **1**–**3** exhibited moderately strong emission spectra in EtOH–MeOH glass at 77 K.

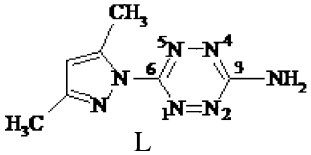
1. Introduction

Among the well established polynucleating ligands in coordination chemistry are the 3,6-disubstituted 1,2,4,5-tetrazines [1]. During the last decade these ligands have become more and more popular because of their special electronic and structural properties. The electronic properties are related to the strong π-accepting nature of the tetrazine moiety due to the low-lying π* MO, while the structural features are essentially based on the efficient metal–metal bridging capacity.



The ability of tetrazine ligand systems to function as efficient electronic spacers between individual metal centers is reflected in a series of diruthenium complexes

doi:10.1016/j.poly.2004.11.019

encompassing a variety of 3,6-disubstituted tetrazine derivatives [2]. Their structural, spectroelectrochemical, EPR, magnetic and luminescence aspects have been thoroughly investigated. However, only a limited number of *mononuclear* ruthenium–tetrazine derivatives are known so far, e.g., $[(trpy)Ru(bphtz)](PF_6)_2$ [3a], $[(CO)(PPh_3)_2(H)Ru(bptz)]PF_6$ [3b], $[(NH_3)_4Ru(bptz)](PF_6)_2$ [3c,d], $[(bpy)_2Ru(bptz)](PF_6)_2$ [3d], $[\{(CH_3)_2SO\}_2(Cl)_2Ru(bptz)]\cdot mH_2O$ [3e] and $[(bpz)_2Ru(bptz)](PF_6)_2$ [3d,f] [bptz = 3,6-bis(2-pyridyl)-1,2,4,5-tetrazine; bphtz = 3,6-bis(1,10-phenanthroline)-1,2,4,5-tetrazine; trpy = 2,2′:6′,2″-terpyridine; bpz = 2,2′-bipyrazine].

This situation has prompted the present program of exploring the metallation aspects of 3-amino-6-(3,5-dimethylpyrazol-1-yl)-1,2,4,5-tetrazine (L), comprising of a five-membered pyrazolyl ring on one side of the tetrazine and an $-NH_2$ group on the other side. Although L has been synthesized previously [4], its structural and metallation aspects have not been investigated so far. As part of our systematic approach, we report in this paper the synthesis of three ruthenium complexes, viz., $[Ru^{II}(acac)_2(L)]$ (**1**), $[Ru^{II}(bpy)_2(L)](ClO_4)_2$ (**2**) and $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**), incorporating ancillary ligands such as σ-donating acetylacetonato ($acac^-$) or π-acidic 2,2′-bipyridine (bpy). The crystal structures of L, **1** and **2**, their spectro-electrochemical and luminescence behavior, and the EPR characteristics of the in situ generated Ru^{III} derivatives ($\mathbf{1}^+$, $\mathbf{2}^+$, $\mathbf{3}^+$) and the reduced radical species ($\mathbf{1}^-$, $\mathbf{2}^-$, $\mathbf{3}^-$) are being reported here.

L

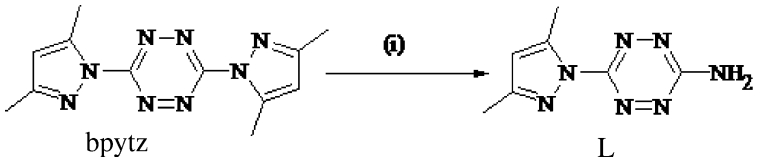
2. Experimental

2.1. Materials

The starting complexes $Ru(acac)_2(CH_3CN)_2$ [5], $Ru(bpy)_2Cl_2\cdot 2H_2O$ [6] and $Ru(bpy)Cl_3$ [7] were prepared according to the reported procedures. The ligand 3-amino-6-(3,5-dimethylpyrazol-1-yl)-1,2,4,5-tetrazine was prepared via a modification of the procedure developed by Glidewell et al. [4]. Other chemicals and solvents were reagent grade and were used as received. For spectroscopic and electrochemical studies HPLC grade solvents were used. Commercial tetraethylammonium bromide was converted into pure tetraethylammonium perchlorate following a published procedure [8].

2.2. Physical measurements

UV–Vis spectra were recorded with a JASCO V-570 spectrophotometer. FT-IR spectra were taken on a Nicolet spectrophotometer with samples prepared as KBr pellets. Solution electrical conductivity was checked using a Systronic 305 conductivity bridge. Magnetic susceptibility was checked with a CAHN electrobalance 7550 model sample magnetometer. ^1H NMR spectra were obtained with a 300 MHz Varian FT spectrometer. The elemental analyses were carried out with a Perkin–Elmer 240C elemental analyzer. The EPR measurements were made in a two-electrode capillary tube [9] with an X-band Bruker system ESP300, equipped with a Bruker ER035M gaussmeter and a HP 5350B microwave detector. Cyclic voltammetric, differential pulse voltammetric and coulometric measurements were carried out using a PAR model 273A electrochemistry system. Platinum wire working and auxiliary electrodes and an aqueous saturated calomel reference electrode (SCE) were used in a three-electrode configuration. The supporting electrolyte was $[NEt_4]ClO_4$ and the solute concentration was $\sim 10^{-3}$ M. The half-wave potential E^0_{298} was set equal to $0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are anodic and cathodic cyclic voltammetric peak potentials, respectively. A platinum wire-gauze working electrode was used in coulometric experiments. All experiments were carried out under a dinitrogen atmosphere and were uncorrected for junction potentials. Electrospray mass spectra were recorded on a Micromass Q-ToF mass spectrometer. Steady state emission experiments were made using a Perkin–Elmer LS 55 luminescence spectrometer fitted with a cryostat. The quantum yields of the complexes were with reference to the reported quantum yield of $[Ru(bpy)_3](PF_6)_2$ in EtOH–MeOH (4:1) solution ($\Phi_{em,77\ K} = 0.35$) [10].



2.3. Preparation of L and complexes *1*, *2* and *3*

2.3.1. Preparation of L, [3-amino-6-(3,5-dimethyl pyrazol-1-yl)-1,2,4,5-tetrazine]

The ligand L was synthesized via a modification (Scheme 1) of the method reported by Glidewell et al. [4]. The ligand bpytz (300 mg, 1.11 mmol) in 20 ml toluene was treated dropwise with 0.3 ml of ammonia at 298 K. The stirring was continued for 2.5 h. The orange solid thus obtained was filtered and washed with toluene and then dried in vacuum. Yield: 170 mg (80%). ^1H NMR in $(CD_3)_2SO$ δ (ppm), 2.20 (s, CH_3), 2.37 (s, CH_3), 6.17 (s, CH), 8.2 (s, NH_2).

2.3.2. $[Ru^{II}(acac)_2(L)]$ (*1*)

The starting complex $Ru(acac)_2(CH_3CN)_2$ (100 mg, 0.26 mmol) and the ligand L (50 mg, 0.26 mmol) were dissolved in 20 ml of ethanol, and the mixture was heated under reflux for 8 h in air. The initially orange

Scheme 1. NH_3, toluene.

solution gradually changed to blue. The solvent was evaporated to dryness under reduced pressure and the solid mass thus obtained was purified by using a silica gel column. Initially, a red compound corresponding to $Ru(acac)_3$ was eluted by CH_2Cl_2–CH_3CN (5:1). With CH_2Cl_2–CH_3CN (1:1), a blue compound corresponding to **1** was separated later. Evaporation of solvent under reduced pressure yielded complex **1**. Yield: **1** (52 mg, 40%). *Anal.* Calc. for complex **1**: C, 41.54; H, 4.69; N, 19.96. Found: C, 41.14; H, 4.33; N, 19.81%. IR, ν/cm^{-1}: 3432 and 3293 ($-NH_2$).

2.3.3. $[Ru^{II}(bpy)_2(L)](ClO_4)_2$ (2)

A mixture of $[Ru(bpy)_2Cl_2]\cdot 2H_2O$ (100 mg, 0.19 mmol) and $AgClO_4$ (100 mg, 0.5 mmol) in 20 ml ethanol was heated with constant stirring for 2 h. The removal of the AgCl precipitate using a sintered-glass funnel resulted in a clear solution containing $[Ru(bpy)_2(EtOH)_2](ClO_4)_2$. To this solution the ligand (L) (39 mg, 0.21 mmol) was added and the mixture was heated under reflux for 5 h in air. The initially red solution gradually changed to purple. The volume of the solution was reduced to about 5 ml under reduced pressure and kept overnight at 268 K. A dark precipitate thus obtained was filtered and washed with cold water followed by cold ethanol. The dried product was then purified by using an alumina column. The purple compound **2** was eluted by CH_3CN. Evaporation of solvent under reduced pressure yielded complex **2**. Yield: **2** (100 mg, 60%). *Anal.* Calc. for complex **2**: C, 40.35; H, 3.14; N, 19.18. Found: C, 40.68; H, 2.87; N, 19.55%. Λ_M/Ω^{-1} ($cm^2\,mol^{-1}$) in MeCN at 298 K: 210. IR, ν/cm^{-1}: 3436/3322 ($-NH_2$) and 1088/618 ClO_4^-.

2.3.4. $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (3)

A mixture of $Ru(bpy)Cl_3$ (100 mg, 0.27 mmol) and the ligand (L) (130 mg, 0.68 mmol) in ethanol was heated to reflux in air for 12 h. The initially brownish solution gradually changed to purple. The solvent of the reaction mixture was then evaporated to dryness under reduced pressure and the solid mass thus obtained was purified by using a silica gel column. A purple compound containing $[Ru(bpy)(L)_2](ClO_4)_2$ was eluted with 4:1 acetonitrile–methanol mixture. The solvent was evaporated to dryness under reduced pressure, the solid mass was dissolved in the minimum volume of acetonitrile, and an aqueous solution of excess $NaClO_4$ was added to the solution. The dark complex **3** was filtered and washed thoroughly with ice-cold water. Yield: (80 mg, 43%). *Anal.* Calc. for complex **3**: C, 34.38; H, 3.13; N, 26.73. Found: C, 34.53; H, 3.59; N, 22.27%. (Repeated measurements showed the lower 'N' value, typical of compounds containing tetrazine). Λ_M/Ω^{-1} ($cm^2\,mol^{-1}$) in MeOH at 298 K: 220. IR, ν/cm^{-1}: 3429/3318 ($-NH_2$) and 1097/629 (ClO_4^-).

2.4. X-ray structure determination

Single crystals for L and **1** were grown by slow diffusion of a dichloromethane solution into *n*-hexane, followed by slow evaporation. For **2**, an acetonitrile solution was allowed to diffuse slowly into benzene, followed by slow evaporation. X-ray data of L and **1/2** were collected on a PC-controlled Enraf–Nonius CAD-4 (MACH-3) and on a Bruker SMART APEX CCD single crystal X-ray diffractometer, respectively. The structures were solved and refined by full-matrix least-squares techniques on F^2 using the SHELX-97 (SHELXTL program package) [11]. SADABS correction was applied for **1** and **2**. All the data were corrected for Lorentz, polarization and absorption effects.

3. Results and discussion

3.1. Synthesis and characterization of L, 1, 2 and 3

The formation of L was authenticated by its single crystal X-ray structure (Fig. 1). The asymmetric unit contains two molecules of L and two water molecules, all crystallographically independent. The crystal structure of L reveals that it crystallizes as a dimer which is held together via hydrogen bonding interactions involving L and H_2O molecules present in the lattice. Important crystallographic data are summarized in Table 1. Selected bond distances and bond angles for one molecule (molecule A) are listed in Table 2, as bond distances and angles of molecule B are close to those for molecule A. The bond parameters are comparable with standard values [2b,12].

In order to synthesize ruthenium complexes of L incorporating ancillary ligands of a differing electronic nature we chose metal precursors encompassing σ-donating acetylacetonate $\{Ru(acac)_2\}$ and π-acidic bipyridine $\{Ru(bpy)_2^{2+}\}$ and $\{Ru(bpy)^{3+}\}$ cores. The reaction of L and $Ru^{II}(acac)_2(CH_3CN)_2$ in ethanol, followed by chromatographic purification using a silica gel

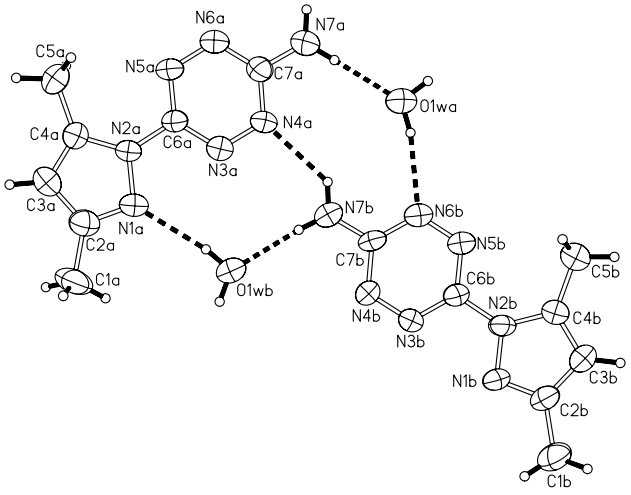


Fig. 1. Asymmetric unit of L.

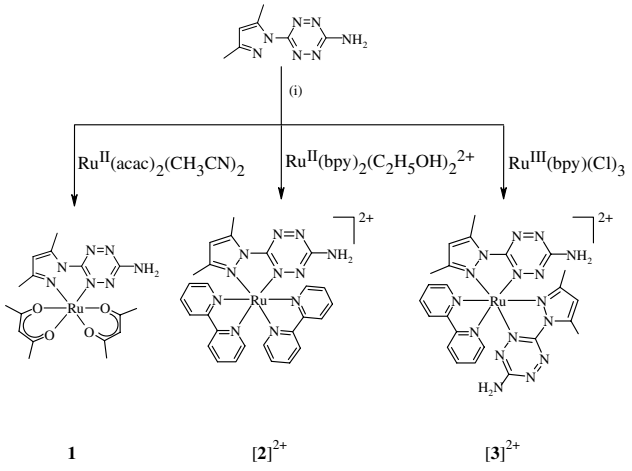
column, yielded the blue diamagnetic complex $[Ru^{II}(acac)_2L]$ (**1**) (Scheme 2).

Similarly, the reactions of L with $[Ru^{II}(bpy)_2(EtOH)_2]^{2+}$ and $Ru^{III}(bpy)Cl_3$ in ethanol under atmospheric conditions, followed by chromatographic purification, afforded the 1:2 conducting diamagnetic complexes $[Ru^{II}(bpy)_2L](ClO_4)_2$ (**2**) and $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**), respectively (Scheme 2). During the course of the reaction the +3 oxidation state of the metal ion in the precursor complex $Ru^{III}(bpy)Cl_3$ was reduced to the Ru^{II} state in **3**, even under atmospheric conditions. The replacement of electron rich Cl^- ligands by the strongly π-acidic L stabilizes the metal ion in the +2 state, reflected also by the high redox potential of **3** (see later).

All our attempts to bind a second metal complex fragment via the other tetrazine nitrogen donor center (N4) and the pendant NH_2 group or its anionic form failed altogether. On all occasions the monomeric species **1**–**3** were obtained.

The neutral compound **1** is soluble in non-polar solvents such as CH_2Cl_2 or $CHCl_3$ whereas **2** and **3** are soluble in polar solvents such as CH_3CN and CH_3OH. The NH_2 vibrations of coordinated L and the ClO_4^- vibrations appear near 3300 and 1100/630 cm^{-1}, respectively (see Section 2). The electrospray mass spectra of **1** in CH_2Cl_2 and of **2** and **3** in CH_3CN show maximum molecular ion peaks (*m*/*z*) at 492.23, 704.24 and 739.12, respectively (Fig. S1), corresponding to $[\mathbf{1}]^+$ (calculated molecular mass: 491.08), $\{[\mathbf{2}]\text{-}ClO_4\}^+$ (calculated molecular mass: 704.09) and $\{[\mathbf{3}]\text{-}ClO_4\}^+$ (calculated molecular mass: 739.10).

3.2. Crystal structures of the complexes



The formation of **1** and **2** was confirmed by single crystal X-ray structures (Figs. 2 and 3). Important crystallographic parameters are given in Table 1, selected bond distances and bond angles are listed in Table 2. The single crystal of **1** contains 0.5 equivalents of H_2O of crystallization. The RuO_4N_2 coordination sphere is slightly distorted octahedral as can be seen from the angles at the metal (Table 2). Although the bite angles involving the acac ligands in **1** are close to the ideal value at 90.95(8)° and 93.19(8)°, the bite angle involving L is only 80.11(9)°, reflecting the smaller chelate ring size. The average *trans* angle is 177.41(11)°. The Ru^{II}–O distances vary between 2.0312(19) and 2.048(2) Å. These are comparable to reported Ru^{II}–O(acac) distances [2d]. The Ru^{II}–N(1)(pyrazolyl) and Ru^{II}–N(4)(tetrazine) distances in **1** are 2.040(2) and 1.913(2) Å, respectively, showing the expected stronger bonding to the better π-accepting tetrazine ring. The Ru^{II}–N(pyrazolyl) distance in **1** is distinctly shorter than that found in

Scheme 2. (i) EtOH, Δ.

$[(bpy)_2Ru^{II}(\mu\text{-bpytz})Ru^{II}(bpy)_2]^{4+}$ at 2.114(16) Å [2b]. The Ru^{II}–N(tetrazine) distances found in dinuclear complexes such as $[(bpy)_2Ru^{II}(\mu\text{-bpytz})Ru^{II}(bpy)_2]^{4+}$ [2b] and $[(acac)_2Ru^{II}(\mu\text{-bptz})Ru^{II}(acac)_2]$ [2d] are 1.976(14)/1.993(11) and 1.946(6)/1.943(6) Å, respectively, which is appreciably longer than the 1.912(3) Å observed for **1**.

The RuN_6 center in **2** is more distorted octahedral. The distortion of the coordination sphere is primarily caused by the small bite angles, viz., 79.3(2)° (bpy), 78.2(2)° (bpy) and 78.5(2)° (L). The average *trans* angle is 172.23(2)°. The Ru^{II}–N(bpy) distances lie between 2.048(6) and 2.074(5) Å which is comparable with reported data of similar species [13]. The Ru^{II}–N(1)(pyrazolyl) and Ru^{II}–N(4)(tetrazine) distances are at 2.077(6) and 1.996(5) Å, respectively. Thus, the back bonding

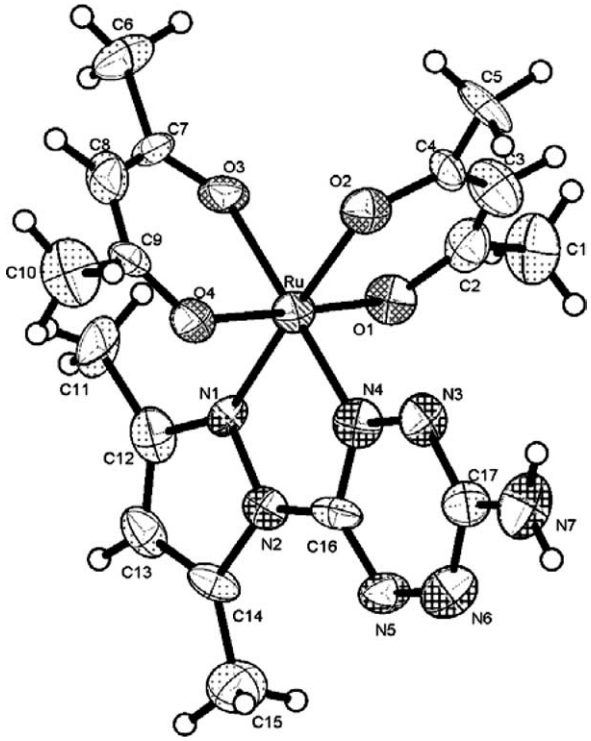

Fig. 2. ORTEP diagram of the complex $[Ru^{II}(acac)_2L]\cdot 0.5H_2O$ (**1**). Ellipsoids are drawn at 50% probability. Water of crystallization has been removed for clarity.

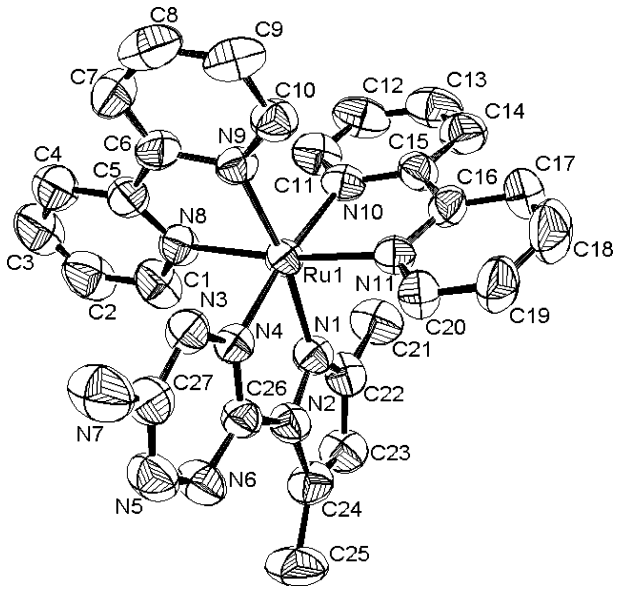

Fig. 3. ORTEP diagram of the complex cation $[Ru^{II}(bpy)_2L]^{2+}$ of (**2**). Ellipsoids are drawn at 50% probability.

effect $d\pi(Ru^{II}) \rightarrow \pi^*$(tetrazine) is also reflected in the structure of **2**. The presence of π-acidic bpy ancillary ligands competing with L in **2** is held responsible for the observed Ru–N bond lengthening, leading to appreciable decreasing $Ru^{II} \rightarrow \pi^*$ back donation on moving from **1** to **2**.

The strong $Ru^{II} \rightarrow \pi^*$(tetrazine) back bonding in **1** is also reflected in the appreciable lengthening of the tetrazine bond lengths involving the coordinated nitrogen donor center [N(4)], C(16)–N(4) 1.377(7) and N(3)–N(4) 1.345(3) Å, as compared to those of the free ligand (L), C(6)–N(3), 1.336(5) and N(3)–N(4), 1.311(5) Å. However, in the case of the corresponding bipyridine complex (**2**) only a slight increase in bond distances has been observed [C(26)–N(4), 1.340(8) and N(3)–N(4), 1.334(7) Å], which is certainly due to the existence of much weaker $Ru^{II} \rightarrow \pi^*$(tetrazine) back bonding in **2** compared to **1** as stated above.

3.3. ^1H NMR spectra

^1H NMR spectra of the complexes **1**, **2** and **3** were recorded in $CDCl_3$ (**1**) and $(CD_3)_2SO$. The spectra are shown in Fig. 4. The unsymmetrical nature of L makes the protons associated with the chelate rings magnetically different. Therefore, the ^1H NMR spectrum of **1** displays three distinct singlets corresponding to two acac CH protons (δ, 5.57 and 5.20 ppm) and one CH proton associated with L (δ, 5.92 ppm) (Fig. 4(a)). The NH_2 protons of L appear as a slightly broad singlet at 4.92 ppm. In addition, six singlets are observable in the upfield region at 2.85, 2.24, 2.18, 2.16, 2.11 and 1.92 ppm, corresponding to four and two CH_3 groups associated with acac and L, respectively.

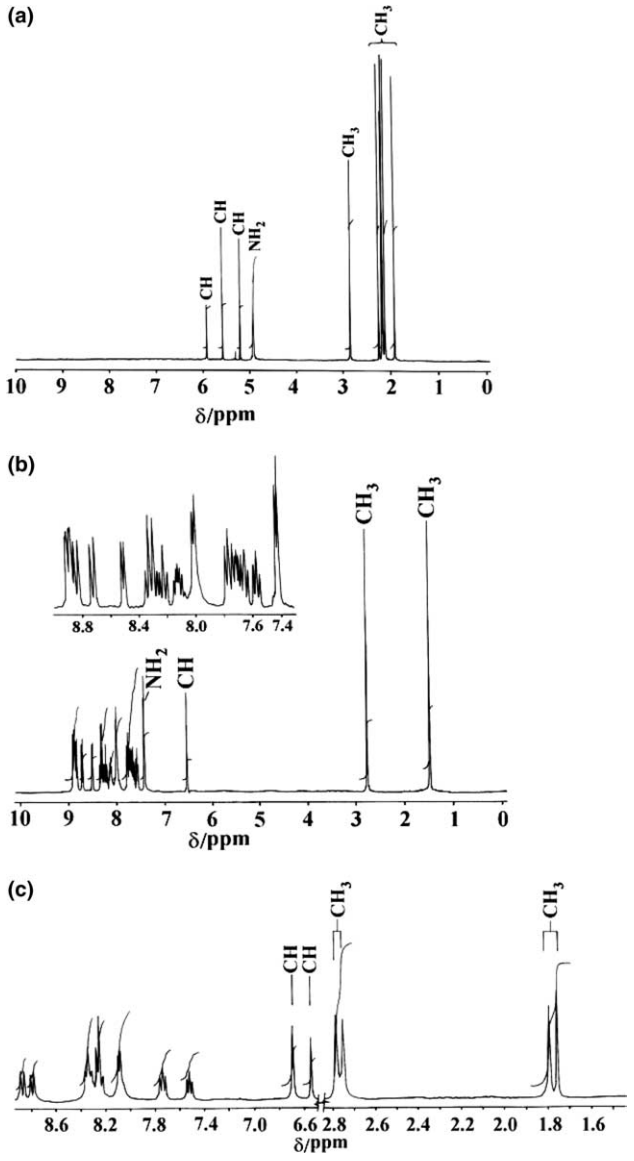

Fig. 4. ^1H NMR spectra of (a) $[Ru^{II}(acac)_2L]$ (**1**) in $CDCl_3$, (b) $[Ru^{II}(bpy)_2L](ClO_4)_2$ (**2**) in $(CD_3)_2SO$, inset shows the expanded aromatic region (δ, 7.4–9.0 ppm), (c) $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**) in $(CD_3)_2SO$ (solvent peaks are substracted for clarity).

Similarly, the four pyridine rings of two bpy ligands in **2** are inequivalent. Complex **2** should thus exhibit 16 non-equivalent ''aromatic'' proton signals. Since the electronic environment of many such hydrogen atoms is similar, their signals may appear in a narrow chemical shift range. In fact, the ''aromatic region'' of the spectrum of **2** is complicated due to the overlapping of several signals, which has essentially precluded the identification of individual resonances (Fig. 4(b)). However, a direct comparison of the intensity of these signals with that of the clearly observable CH (6.53 ppm) and CH_3 (2.76 and 1.47 ppm) protons of coordinated L in the upfield region revealed the presence of the expected 16 aromatic protons. The NH_2 protons of L appear at 7.4 ppm.

In **3** two distinct CH signals at 6.69 and 6.54 ppm and four CH_3 signals at 2.77, 2.74, 1.79 and 1.47 ppm, corresponding to two L, were observed (Fig. 4(c)). The eight protons of bpy and the NH_2 protons of L appear between 7.4 and 9.0 ppm as partially overlapping signals.

3.4. Metal oxidation

Compounds **1**–**3** exhibit one quasi-reversible Ru^{III}/Ru^{II} couple each at $E_{1/2}$ = 0.28, 1.34 and 1.50 V versus SCE, respectively (Table 3, Fig. 5). The data reveal that a redox potential shift of >1.0 V has taken place on switching from the acac ancillary ligands in $[Ru(acac)_2(L)]$ (**1**) to the bpy co-ligands in $[Ru(bpy)_2(\mathbf{L})](ClO_4)_2$ (**2**). The presence of electron-rich acac ligands in **1** clearly stabilizes the Ru^{III} state [14].

The combination of two bpy ligands and one L ligand around the Ru^{II} center in **2** shifted the Ru^{III}/Ru^{II} couple to 1.34 V which is even higher than that of $[Ru^{II}(bpy)_3]^{2+}$ ($E_{1/2}$ = 1.29 V versus SCE) [15]. This implies that the donor strength of L is lower than that of bpy. It may be noted that the first Ru^{III}/Ru^{II} couple of the related diruthenium complex $[(bpy)_2Ru(\mu\text{-bpytz})Ru(bpy)_2]^{4+}$ appears at 1.25 V [2b].

On the other hand, the replacement of two bpy ligands from $[Ru^{II}(bpy)_3]^{2+}$ by two ligands L in **3** increases the $Ru^{II} \rightarrow Ru^{III}$ oxidation potential further to 1.50 V. Thus, successive exchange of bpy by L from $Ru(bpy)_3^{2+}$ via $Ru(bpy)_2(L)^{2+}$ to $Ru(bpy)(L)_2^{2+}$ enhances the stability of the Ru^{II} state.

3.5. Ligand reduction

Complex **1** shows one reversible reduction at −1.33 V versus SCE. Since tetrazines are known to undergo facile reduction at relatively low potentials due to the low lying π* orbital [1–3], the observed reduction is therefore considered to involve the tetrazine function of coordinated L.

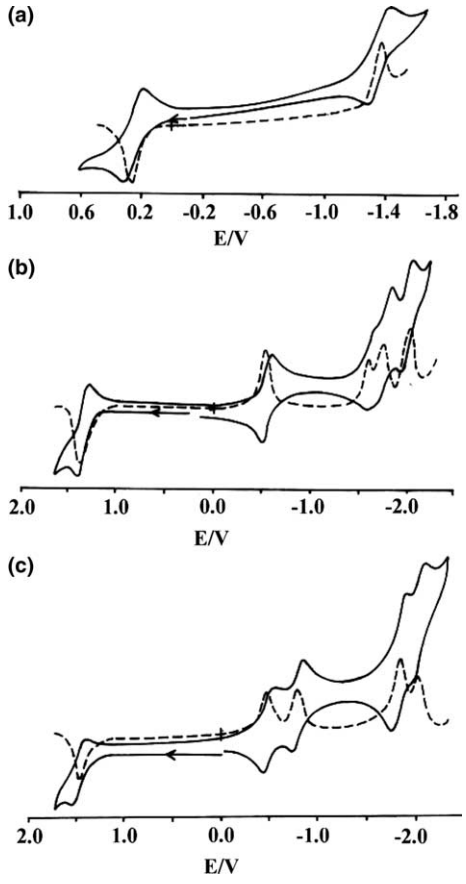

Fig. 5. Cyclic (—) and differential pulse (------) voltammograms of (a) $[Ru^{II}(acac)_2L]$ (**1**) in CH_2Cl_2, (b) $[Ru^{II}(bpy)_2L](ClO_4)_2$ (**2**) and (c) $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**) in CH_3CN at 298 K.

			−1.80(60)				
			−2.02(60)				

[a] **1** in CH_2Cl_2 and **2**/**3** in CH_3CN.
[b] As stated in the text.
[c] Calculated by Eq. (2) in the text.
[d] Calculated by Eq. (1) in the text.

Similarly, the reduction of the tetrazine in **2** appears at −0.55 V. This substantial increase in the reduction potential by 0.78 V on moving from strongly σ-donating acac as a co-ligand in **1** to π-acidic bpy in **2** parallels to some extent the stabilization of the Ru^{II} state in **2** as compared to **1**.

In addition to the tetrazine-based reduction of L, **2** also shows three more bpy-based quasi-reversible one-electron reduction processes in the range from −1.55 to −1.98 V. Each bpy can accommodate two electrons, therefore, a total of four such reduction waves is expected. Three such waves are detected within the experimental potential limit (−2.0 V versus SCE). The potentials at which the bpy reductions of **2** are observed is consistent with the reduction range of $Ru(bpy)_3^{2+}$ (−1.3 to −1.8 V versus SCE) [16].

Compound **3** contains two tetrazine units from two L ligands, therefore the expected two tetrazine-based one-electron reduction waves were observed at −0.47 and −0.78 V. Two bpy-based reductions appear at −1.80 and −2.02 V. The first tetrazine reduction potential in **3** is slightly less negative relative to **2**, which correlates with the enhanced stabilization of the Ru^{II} state in **3**.

3.6. Spectral properties

Electronic absorption spectra of **1**, **2** and **3** were recorded in CH_2Cl_2 (**1**) and CH_3CN. The spectral data are given in Table 3 and the spectra are shown in Fig. 6. The complexes exhibit strong ligand-based π − π* transitions in the UV region. In the visible region, **1** and **2** display two well separated broad bands at 600/366 and 538/400 nm, respectively, whereas **3** exhibits one main transition at 540 nm with a high-energy shoulder at 480 nm. The lowest energy bands for all the three complexes are attributed to MLCT transitions $d\pi(Ru^{II}) \rightarrow \pi_1^*L$ (where π_1^*L is essentially dominated by the tetrazine moiety) [2]. The higher energy transitions are assigned as $d\pi(Ru^{II}) \rightarrow \pi^*$ (acac), $d\pi(Ru^{II}) \rightarrow \pi^*$(bpy) and $d\pi(Ru^{II}) \rightarrow \pi^*$ L for **1**, **2** and **3**, respectively. This is based on the observation that the reduction of L takes place at a much lower potential than that of bpy. The above assignments find justification through the spectro-electrochemical correlations stated below.

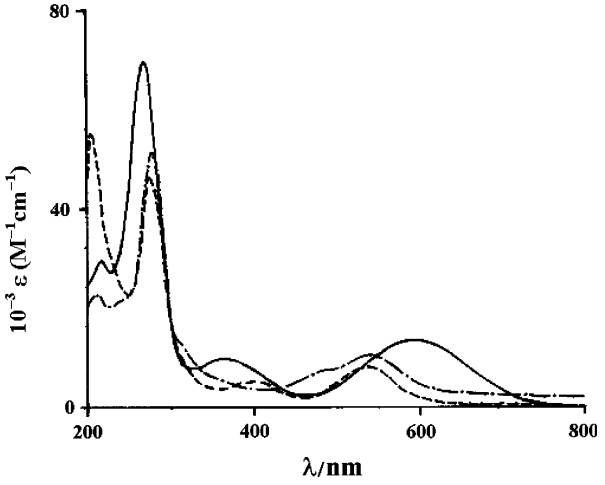

Fig. 6. Electronic spectra of (a) $[Ru^{II}(acac)_2L]$ (**1**) (——), (b) $[Ru^{II}(bpy)_2L](ClO_4)_2$ (**2**) (------) and (c) $[Ru^{II}(bpy)(L)_2](ClO_4)_2$ (**3**) (-·-·-·-) in CH_3CN.

3.7. Spectro-electrochemical correlation

The energies of the MLCT transitions at the band maximum can be reproduced with the help of empirical Eqs. (1) and (2) [17]:

$$\nu(\text{MLCT}) = 8065(\Delta E_{1/2}) + 3000\ \text{cm}^{-1}, \quad (1)$$

$$\Delta E_{1/2} = E_{1/2}(Ru^{III}/Ru^{II}) - E_{1/2}(L). \quad (2)$$

Here $E_{1/2}(Ru^{III}/Ru^{II})$ is the potential of the reversible Ru^{III}/Ru^{II} couple, $E_{1/2}(L)$ is that of the first ligand-based reduction and ν(MLCT) is the wave number of the charge transfer band in cm^{-1}. The factor 8065 is used to convert the potential difference ΔE from V into cm^{-1} and the term 3000 cm^{-1} is of empirical origin (reorganization energy of polypyridine ruthenium MLCT transitions). The calculated and experimentally observed MLCT energies are given in Table 3. Using Eqs. (1) and (2) and $\Delta E_{1/2}$ values of 1.61, 1.89/2.89 and 1.97/2.28, for **1**, **2** and **3**, respectively, the calculated ν(MLCT) values agree rather well with the experimental values (Table 3).

3.8. EPR spectra

The in situ generated species $\mathbf{1}^+$ in CH_2Cl_2 at 110 K exhibits a rhombic EPR signal ($g_1 = 2.260$, $g_2 = 2.170$, $g_3 = 1.880$, Fig. 7(a)), typical of low-spin Ru^{III}. The g anisotropy $g_1 - g_3 = 0.380$ and the average g factor of $\langle g \rangle = 2.11$), derived from $\langle g \rangle = [1/3(g_1^2 + g_2^2 + g_3^2)]^{1/2}$ indicate a slightly distorted octahedral arrangement around the ruthenium center [18] as consistent with the molecular structure of **1**. The electrochemically generated $\mathbf{2}^+$ in CH_3CN failed to show any EPR signals at 110 K, however, at 4 K it displays a poorly resolved rhombic type EPR signal with $g_1 = 2.50$, $g_2 = 2.360$ and an undetectable g_3 component (probably < 1.8). On the other hand, the in situ generated $\mathbf{3}^+$ did not show any EPR response even at 4 K, which signifies rapid relaxation due to excited paramagnetic states lying close to the doublet ground state.

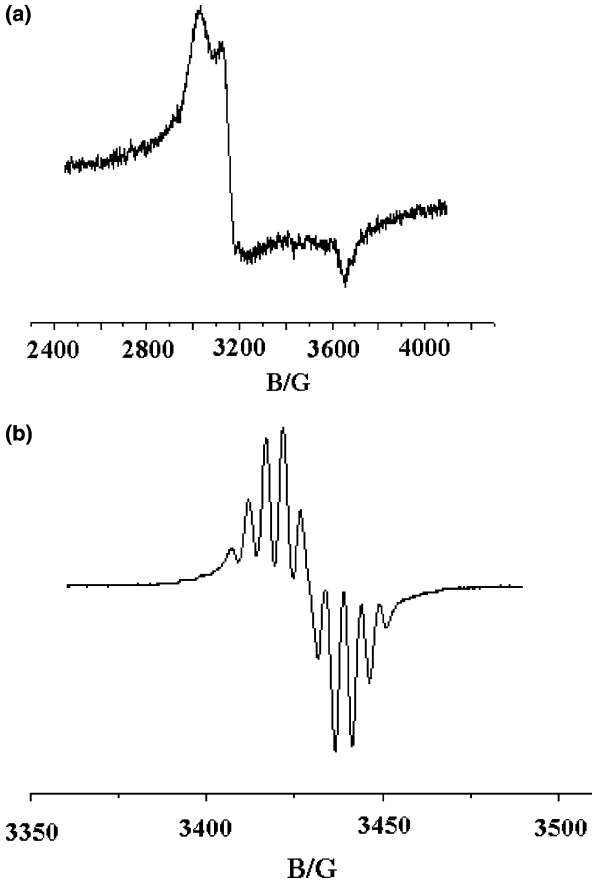

Fig. 7. EPR spectra of (a) $\mathbf{1}^+$ in CH_2Cl_2 at 100 K and (b) $\mathbf{1}^-$ in CH_2Cl_2 at 300 K.

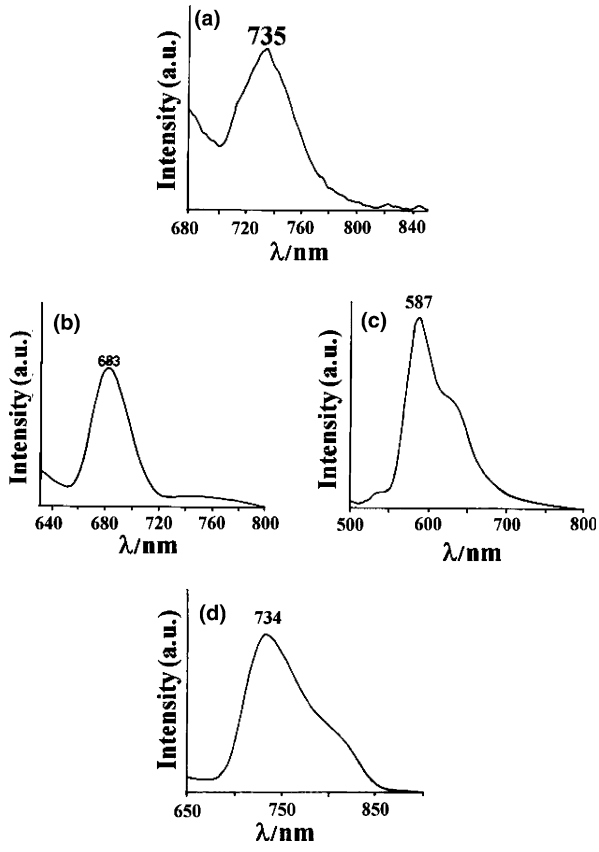

Fig. 8. Emission spectra of (a) **1** ($\lambda_{excitation}$, 592 nm), (b) **2** ($\lambda_{excitation}$, 530 nm), (c) **2** ($\lambda_{excitation}$, 413 nm) and (d) **3** ($\lambda_{excitation}$, 524 nm) in ethanol–methanol (4:1) glass at 77 K.

In situ generated reduced species $\mathbf{1}^-$ (in CH_2Cl_2), $\mathbf{2}^-$ and $\mathbf{3}^-$ (in CH_3CN) exhibit multiple line EPR spectra at 300 K due to hyperfine coupling from four different ^{14}N atoms of the tetrazine ring of L, the signals are centered at $g = 1.9962$, 1.9991 and 1.9984, respectively (Fig. 7(b)) [2,19].

3.9. Emission spectra

Emission properties of the complexes were studied in EtOH–MeOH (4:1) at 77 K. The spectra are shown in Fig. 8. Excitations of the complexes **1**, **2** and **3** at 592, 530/413 and 534 nm, respectively, result in emissions with maxima at 735 nm (quantum yield, $\Phi = 0.65 \times 10^{-2}$), 682/586 nm (quantum yield, $\Phi = 1.8 \times 10^{-1}$, 1.1×10^{-1}) and 734 nm (quantum yield, $\Phi = 1.15 \times 10^{-2}$), respectively, with vibrational structures characteristic of emissions from a ^{3}MLCT excited state [20]. The origin of the emissions was further confirmed by the excitation spectra of the same solutions in each case. The observed moderately strong emissions for **1** and **3** presumably involve primarily L. On the other hand, **2** appears to exhibit strong emissions from both the bpy and L-based MLCT transitions.

4. Conclusion

Although tetrazine based ligands are quite popular in developing polynuclear complexes for varying perspectives, rather rare mononuclear complexes **1**, **2** and **3** have been synthesized using hitherto unexplored tetrazine derived ligand, 3-amino-6-(3,5-dimethylpyrazol-1-yl)-1,2,4,5-tetrazine (L) in combination with σ-donating acetylacetonate and π-accepting bipyridine co-ligands. Structural studies reveal that the presence of electron-rich acetylacetonate co-ligands attributes to a strong $Ru^{II} \rightarrow \pi^*$ (tetrazine) back bonding in **1** which is much stronger than that in the corresponding mononuclear bipyridine derivative (**2**) as well as that in the analogous dinuclear complexes $[(bpy)_2Ru^{II}(\mu\text{-bpytz})Ru^{II}(bpy)_2]^{4+}$ and $[(acac)_2Ru^{II}(\mu\text{-bptz})Ru^{II}(acac)_2]$.

Abstract

A binuclear manganese(III) complex $[Mn_2(L^1)(N_3)_6]$ (**2**) and an unprecedented 1D chain of manganese(II) binuclear units bridged by two end-to-end thiocyanato anions $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ (**3** · $2CH_3CN$) have been prepared from *N*-(1-pyridin-2-ylbenzylidene)-*N*′-[2-({2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}amino)ethyl]ethane-1,2-diamine (L), manganese(II) salts and azide/thiocyanate anions in air. L^1, *N*-(1-pyridin-2-ylbenzylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}piperazin-1-yl)ethyl]amine, results from an alkylating cyclization of the flexible hexadentate Schiff base L occurring along the course of the complexation reactions. Both complexes have been characterized by single crystal X-ray diffraction studies. The Mn centres of complexes **2** and **3** are in distorted octahedral (**2**: $Mn^{III}N_6$, **3**: $Mn^{II}N_5S$) coordination environments with intramolecular Mn···Mn distance (**2**: 6.473(2) Å, **3**: 6.437(1) Å) consistent with the absence of intramolecular magnetic interactions. Compound **3**, exhibits weak intermolecular antiferromagnetic interactions ($J = -1.5$ cm^{-1}) between pairs of Mn^{II} ions bridged via two $\mu_{1,3}$-NCS.

1. Introduction

Coordination chemistry of manganese compounds is an area of considerable interest [1]. These complexes are significant not only for their redox active role in several biochemical processes, but also for the diversity of their magnetic properties [2–4]. Bridging ligands play an important role in the magnetic exchange pathways between paramagnetic centres: pseudo-halides (N_3^-, NCS^-, NCO^-) have been well documented for their numerous bonding abilities leading to various species [5]. End-on ($\mu_{1,1}$-N_3/NCS/NCO) [6] and end-to-end ($\mu_{1,3}$-N_3/NCS/NCO) [7] bridged complexes are known to mediate ferromagnetic [8] and antiferromagnetic [9] exchange interactions, respectively. The use of polydentate ligands, especially polynucleating ones, is an efficient way for assembling metal centres in close proximity, thus ensuring electronic communication. Coordination compounds including both polydentate ligands and suitable bridging anions such as

pseudo-halide ions capable of propagating magnetic interactions between paramagnetic centres play an important role in the area of molecular magnetism [3–10].

We report here on the unusual behaviour of a flexible hexadentate ligand, *N*-(1-pyridin-2-ylbenzylidene)-*N*′-[2-({2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}amino)ethyl] ethane-1,2-diamine, (L, Scheme 1) resulting from the bis-condensation reaction of 2-benzoylpyridine and triethylenetetramine. While $[Mn^{II}L](ClO_4)_2$ (**1**) resulted from the reaction of L with manganese(II) perchlorate, the binuclear complex $[Mn_2^{III}(L^1)(N_3)_6]$ (**2**) and the 1D polymer $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ (**3** · $2CH_3CN$) resulted from the reaction of L and manganese(II) salts, in the presence of sodium azide (**2**) or ammonium thiocyanate (**3**), respectively. L^1, *N*-(1-pyridin-2-ylbenzylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]-ethyl}piperazin-1-yl)ethyl]amine, results from an alkylating cyclization of L. The synthesis, characterization including X-ray structure, and magnetic properties of the novel compounds **2** and **3** are described in this report.

2. Experimental

2.1. Materials

Triethylenetetramine, 2-benzoylpyridine, sodium azide and ammonium thiocyanate were purchased from Lancaster and used as received. All other solvents and chemicals were of analytical grade. The hexadentate ligand (L) was prepared as reported previously and gave satisfactory elemental analysis [11].

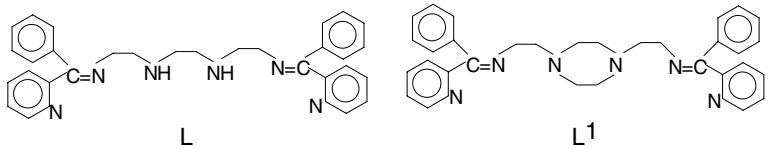
2.2. Synthesis of complexes

2.2.1. $[Mn^{II}L](ClO_4)_2$ (*1*)

A methanolic solution (4 cm^3) of the L ligand (0.239 g, 0.5 mmol) was added dropwise to a methanolic solution (4 cm^3) of $Mn(ClO_4)_2\cdot 6H_2O$ (0.181 g, 0.5 mmol) with constant stirring for 1 h at room temperature. The orange-red compound of composition $[MnL](ClO_4)_2$ (**1**) was filtered off, washed with methanol and dried under vacuum. Yield: 0.220 g, ~60%. *Anal.* Calc. for $C_{30}H_{32}N_6O_8Cl_2Mn$: C, 49.33; H, 4.42; N, 11.51, Mn, 7.52. Found : C, 49.28; H, 4.53; N, 11.39; Mn, 7.37%.

2.2.2. $[Mn_2^{III}(L^1)(N_3)_6]$ (*2*)

To a methanolic solution (5 cm^3) of $MnCl_2\cdot 4H_2O$ (0.396 g, 2.0 mmol) was added 0.477 g (1.0 mmol) of the L ligand in methanol (15 cm^3) over a period of 15 min. To the resulting deep orange solution, an aqueous solution of sodium azide (0.260 g, 6.0 mmol, 8 cm^3 H_2O) was added slowly. The solution was then filtered and the filtrate was left to stand. Within 2–3 days of slow evaporation a black compound was obtained. This resulting compound was dissolved in dichloromethane (~12 cm^3) and layered with hexane (~36 cm^3). After about 5 days black prismatic crystals suitable for X-ray analysis were obtained. Yield: 0.225 g, ~27%. *Anal.* Calc. for $C_{32}H_{34}N_{24}Mn_2$: C, 44.41; H, 3.96; N, 38.88, Mn, 12.70. Found: C, 44.48; H, 3.82; N, 38.76; Mn, 12.62%.



2.2.3. $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ ($3\cdot 2CH_3CN$)

Compound **3** was synthesized by slow addition of an acetonitrile solution (12 cm^3) containing the L ligand (0.239 g, 0.5 mmol) to an acetonitrile solution (16 cm^3) of $Mn(ClO_4)_2\cdot 6H_2O$ (0.362 g, 1.0 mmol) with constant stirring for 30 min. To the resulting solution, an aqueous solution of ammonium thiocyanate (0.152 g, 2.0 mmol, 12 cm^3 H_2O) was added slowly with constant stirring for 15 min. The resulting solution was left to stand at room temperature and after several days, orange, prismatic, X-ray quality single-crystal were obtained. Due to solvent loss when the crystals are taken out of the mother solution, the fully desolvated (under vacuum) sample subjected to elemental analyses had the formulation $[Mn_2^{II}(L^1)(NCS)_4]_n$ (**3**). Yield: 0.138 g, ~17%. *Anal.* Calc. for $C_{36}H_{34}N_{10}S_4Mn_2$: C, 51.18; H, 4.06; N, 16.58, Mn, 13.0. Found: C, 51.06; H, 3.92; N, 16.39; Mn, 12.74%.

CAUTION: *Perchlorate salts and azido compounds are potentially explosive especially in the presence of organic compounds. They must be prepared and handled in small amounts, and with special care.*

2.3. Physical measurements

Elemental analyses for C, H and N were performed using a Perkin Elmer 2400II elemental analyzer. Manganese contents were determined by titrimetric methods. IR spectra (4000–400 cm^{-1}) were recorded on KBr pellets at 298 K using a JASCO FT/IR-420 spectrometer. Magnetic data were obtained with a Quantum Design MPMS SQUID susceptometer. Magnetic susceptibility

Scheme 1. The hexadentate Schiff base ligands L and L^1.

measurements were performed in the 2–300 K temperature range in a 1 T applied magnetic field, and diamagnetic corrections were applied by using Pascal's constants [12]. The magnetic susceptibility has been computed by exact calculation of the energy levels associated to the spin Hamiltonian through diagonalization of the full matrix with a general program for axial symmetry [13]. Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [14].

2.4. Crystal structures determination and refinement

Single-crystals suitable for X-ray crystallographic analysis were selected following examination under a microscope. X-ray data of **2** were collected at 293 K with a Siemens SMART CCD diffractometer. Crystals of $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ ($\mathbf{3}\cdot 2CH_3CN$) were quickly coated with an inert oil to prevent solvent loss and the X-ray data were collected at 200 K on a Bruker-AXS SMART APEX/CCD diffractometer. Both data collections were carried out using Mo Kα radiation ($\lambda = 0.71073$ Å) in an $\omega - 2\theta$ scan mode. 11 942 reflections were collected for **2**, of which 4434 were independent ($R_{int} = 0.056$) and 14195 reflections for **3**, of which 5227 were independent ($R_{int} = 0.039$). In both cases, intensity data were corrected for Lorentz and polarization effects. Empirical absorption corrections were made based on ψ-scans for **2** [15] and using the SADABS program [16] for **3**. The structures were solved by direct methods and the structure solution and refinement was based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters except those of the disordered acetonitrile which were refined isotropically. Even when located in the Fourier map, hydrogen atoms were placed in calculated positions and given isotropic U values 1.2 times that of the atom to which they are bonded. Acetonitrile hydrogen atoms were neither located nor placed in calculated positions. The atomic scattering factors and anomalous dispersion terms were taken from the standard compilation [17]. All crystallographic calculations were carried out using SHELX-97 [18] and ORTEP-3 [19] program packages. The crystal data and data collection details are gathered in Table 1.

3. Results and discussion

3.1. Synthesis

The reaction of L with manganese(II) perchlorate hexahydrate using a 1:1 molar ratio in methanol/water or acetonitrile/water mixtures yielded an orange-red compound (**1**) formulated $[Mn^{II}L](ClO_4)_2$ on the basis of elemental analyses and IR data. The crystal structure of the nickel analogue $[NiL](ClO_4)_2$, prepared by a similar synthetic route evidenced a monomeric Ni^{II} compound where the hexadentate N_6 ligand is L (no L to L^1 rearrangement) [20].

On the other hand, a manganese(III) binuclear crystalline complex, $[Mn_2^{III}(L^1)(N_3)_6]$ (**2**) has been prepared in methanol/water from manganese(II) salts, L, and sodium azide (2:1:6 (or 2:1:4) molar ratio) in air. The same reactions carried out in acetonitrile/water instead of methanol/water yielded compound **1**, i.e., no L to L^1 rearrangement. Reaction of manganese(II) salts, L, and ammonium thiocyanate (2:1:4 (or 2:1:6) molar ratio) in acetonitrile/water yielded orange crystals of an unprecedented 1D chain of manganese(II) binuclear units bridged by $\mu_{1,3}$-NCS anions, $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ ($\mathbf{3}\cdot 2CH_3CN$). The same reactions carried out in methanol/water instead of acetonitrile/water yielded compound **1**, i.e., no L to L^1 rearrangement.

The rearrangement from L to L^1 (Scheme 2), consisting in an alkylating cyclization centred on the two secondary amine functions of L, occurred exclusively along the course of complexation reactions where a pseudo-halide was involved in addition to L and a metal salt in the required solvent (methanol/water for **2**, and acetonitrile/water for **3**). L^1 could not be identified from reaction media devoid either of pseudo-halide or of metal salt, or carried out in different solvent mixtures. Similar rearrangement reactions also occurred with nickel(II) salts and pseudo-halides [11]. However, replacement of pseudo-halides by halides did not yield rearrangement of L to L^1. In addition, the poor yields of **2** and **3** suggest that the extra $-CH_2-CH_2-$ fragment present in L^1 compared to L most probably originates from the L ligand itself. A plausible mechanism for this

Scheme 2. A plausible mechanism for the alkylating cyclization of L to L^1 (case of complex **2**).

alkylating cyclization of L to L^1 may involve the following steps: (a) pseudo-halides in the presence of manganese ions may undergo a nucleophilic attack on the $–CH_2–CH_2–$ bridge located between the two secondary amine functions of L (A), producing a di-azido (-thiocyanato) (B) intermediate which on subsequent hydrolysis would generate an oxamido-like derivative (C) [21]; (b) this oxamido-like derivative would break down, producing glyoxal and C fragments; (c) glyoxal would then react, most possibly through a metal assisted concerted route, with the two secondary amine functions of another L ligand molecule, producing a di-imminium-like intermediate (D) [22], that would be subsequently reduced to L^1.

The role of the solvent with regard to the formation of compounds **2** or **3** is also remarkable. Indeed, while formation of **3** only requires the L to L^1 rearrangement, formation of **2** requires manganese oxidation from the +2 to the +3 state, in addition to the L to L^1 rearrangement. A possible explanation is that the stronger σ donor ability of the azido anion favours oxidation of the manganese centres in the presence of methanol, allowing formation of the $[Mn_2^{III}(L^1)(N_3)_6]$ (**2**) species. This oxidation may be further assisted by coordination of two extra azido ligands per binuclear unit, yielding the neutral hexacoordinated complex **2**. On the other hand, while the weaker σ donor ability of NCS does not favour oxidation of manganese centres, the presence of the very weakly coordinating acetonitrile solvent allows bridging of manganese(II) binuclear units into the 1D chain of **3** through $\mu_{1,3}$-NCS anions. Finally, formation of **1** in the reaction conditions of **2** or **3**, but in the absence of the required solvent (MeOH for **2** and CH_3CN for **3**), i.e. absence of L to L^1 rearrangement, indicates that at least one intermediate in this ligand rearrangement results from an equilibrium reaction: precipitation of the resulting complex (**2** or **3**) is most probably the driving force allowing the L to L^1 rearrangement.

3.2. IR spectroscopy

The IR spectrum of **2** exhibits a very strong absorption at 2040 cm^{-1} corresponding to the azido asymmetric stretching vibrations [6b,6c]. The IR spectrum of **3** exhibits strong absorptions at 2098 and 2053 cm^{-1} corresponding to the N,S-bonded thiocyanate ions [10a,10f]. The absorptions corresponding to the ν(C=N) stretches of L^1 are located at 1639 and 1590 cm^{-1} and 1633 and 1588 cm^{-1} for compounds **2** and **3**, respectively [10a,10f].

4. X-ray structures

4.1. $[Mn_2^{III}(L^1)(N_3)_6]$ (2)

The molecular structure of **2** consists of isolated binuclear molecules. The ORTEP drawing of the centrosymmetric binuclear unit with atom labeling scheme is shown in Fig. 1 and selected bond distances and angles are listed in Table 2.

Each manganese atom is located in a distorted octahedral N_6 coordination environment, with three nitrogen atoms from L^1 (N1, N2 and N3) and three nitrogen donors from terminal azido groups (N4, N7 and N10). The Mn–N(L^1) distances are in the

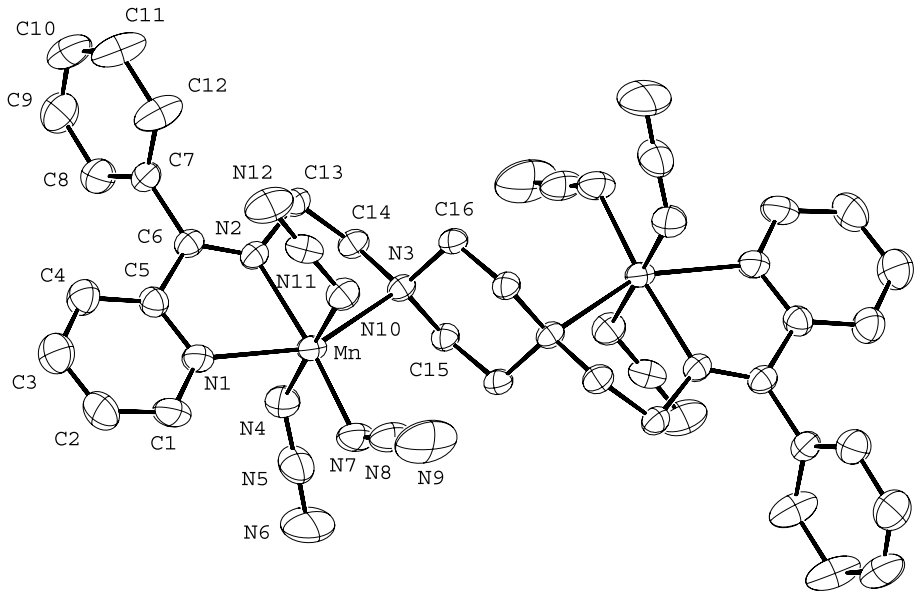

Fig. 1. ORTEP plot with atom labeling scheme for $[Mn_2(L^1)(N_3)_6]$ (**2**). For clarity the hydrogen atoms are omitted.

Table 2
Selected bond lengths (Å) and angles (°) for $[Mn_2(L^1)(N_3)_6]$ (**2**)

Bond lengths			
Mn–N1	2.249(3)	Mn–N2	2.094(3)
Mn–N3	2.395(3)	Mn–N4	1.949(3)
Mn–N7	1.955(4)	Mn–N10	1.962(3)
Bond angles			
N1–Mn–N2	73.76(10)	N1–Mn–N3	152.01(10)
N1–Mn–N4	90.74(12)	N1–Mn–N7	99.93(12)
N1–Mn–N10	90.41(13)	N2–Mn–N3	78.35(10)
N2–Mn–N4	91.24(12)	N2–Mn–N7	173.59(12)
N2–Mn–N10	89.01(12)	N3–Mn–N4	87.46(11)
N3–Mn–N7	108.00(11)	N3–Mn–N10	91.48(10)
N4–Mn–N7	89.94(13)	N4–Mn–N10	178.84(12)
N7–Mn–N10	89.94(13)	N4–N5–N6	177.8(5)
N7–N8–N9	174.8(5)	N10–N11–N12	177.9(4)

2.094(3)–2.395(3) Å range, while the Mn–N(azido) distances are almost equal (1.949(3)–1.962(3) Å range). It is worth noting that none of the azido anions behaves as a bridging ligand: this unusual azido coordination mode [6,7] may originate from the L to L^1 rearrangement. Due to the presence of the central –N(–CH_2–CH_2–)$_2$N– cycle in L^1, the intramolecular Mn···Mn distance in complex **2** is quite large (6.473(2) Å).

4.2. $\{[Mn_2^{II}(L^1)(NCS)_4]\cdot 2CH_3CN\}_n$ (**3**)

The structure of $\mathbf{3}\cdot 2CH_3CN$ (Fig. 2) consists of centrosymmetric binuclear $[Mn_2^{II}(L^1)(NCS)_4]$ repeat units doubly $\mu_{1,3}$-NCS bridged into 1D chains extending along a. Selected bond distances and angles are listed in Table 3.

The octahedral coordination sphere around each manganese(II) consists of three nitrogen donors from L^1 (N3, N4 and N5, 2.183(2)–2.390(2) Å), two nitrogen donors from thiocyanate anions (N1 (2.090(2) Å) from an end-to-end NCS bridge and N2 (2.097(2) Å) from a terminal NCS), and one sulfur donor (S2) (3.084(1) Å) from another end-to-end NCS. This end-to-end thiocyanato bridging mode has already been observed, with corresponding M–S distances either in the 2.6–2.9 Å range [23], or in the longer 3.11–3.18 Å range [10f], the latter suggesting weak M···S interactions rather than the covalent bonding suggested by the former. The intermediate 3.084 Å value observed for 3 is close to the lower limit for weak M···S interactions preventing us to qualify this Mn···S interaction as a covalent bonding. The N_5S coordination sphere is severely distorted from octahedral symmetry, with quite large deviations from the regular *cis* and *trans* angles and large axial distortion evidenced by the quite long Mn–S distance. The intradimer $Mn^{II}\cdots Mn^{II}$ separation (6.437(1) Å), originating from the presence of the central –N(–CH_2–CH_2–)$_2$N– cycle in L^1, is understandably quite similar to that in complex **2**, and slightly longer than the interdimer $Mn^{II}\cdots Mn^{II}$ distance (6.203(1) Å).

4.3. Magnetic properties

As expected from the large intramolecular $Mn^{III}\cdots Mn^{III}$ separation and nature of the polyatomic bridge, and absence of intermolecular contacts in compound **2**, there are no pathways for intra- and/or intermolecular magnetic interactions, as indicated by the paramagnetic behaviour of this binuclear compound. Its $\chi_M T$ product of 5.97 $cm^3\,K\,mol^{-1}$, close to the spin-only value for two non-interacting $S = 2$ ions, is constant over the whole 300–25 K temperature range and decreases from 5.78 (25 K) to 2.44 $cm^3\,K\,mol^{-1}$ (1.95 K) due to single-ion zero fields splitting (ZFS) of

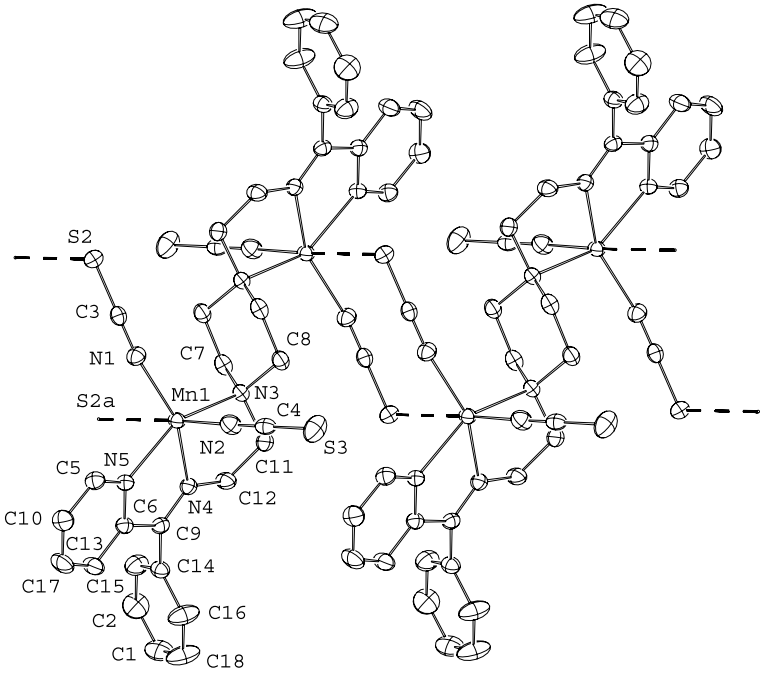

Fig. 2. ORTEP plot with atom labelling scheme of the $[Mn_2^{II}(L^1)(NCS)_4]_n$ 1D polymeric chain of ($\mathbf{3} \cdot 2CH_3CN$). For clarity the hydrogen atoms and solvent molecules are omitted.

Table 3

Symmetry operation *a*: $1 - x$, $1 - y$, $-z$.

high-spin Mn^{III}. This result being perfectly consistent with the severe distortion of the MnN_6 octahedron evidenced by the crystal structure, we did not attempt to fit these data.

The experimental $\chi_M T$ product of **3** (desolvated crystals) smoothly decreases from 8.48 cm^3 K mol^{-1} at 300 K (slightly below the spin-only value for two non-interacting $S = 5/2$ ions) to 7.61 cm^3 K mol^{-1} at 80 K, and then sharply, down to 0.67 cm^3 K mol^{-1} at 1.96 K, clearly indicating operation of antiferromagnetic interactions in **3**. While no intramolecular magnetic interaction is expected between the Mn^{II} centres of **3** (same rationale as for **2**), weak intermolecular interactions are expected to be mediated by the double end-to-end thiocyanate bridges between binuclear $[Mn_2^{II}(L^1)\ (NCS)_4]$ repeat units along the 1D chains [9]. Taking into account the absence of intramolecular magnetic interaction between the Mn^{II} ions of binuclear constituting units, the overall magnetic behaviour of **3** can not result from extended magnetic interactions along 1D chains, but from pairwise interactions between Mn^{II} bridged by two NCS anions; in other words, the structural constituting units of complex **3** do not correspond to the magnetically interacting pairs.

The experimental magnetic susceptibility data (χ_M, lozenges in Fig. 3) were thus fitted by using the theoretical magnetic susceptibility calculated by exact diagonalization of the effective spin Hamiltonian for a pair of interacting $S_1 = S_2 = 5/2$ ions, taking into account single-ion ZFS: $\hat{H} = -2J\hat{S}_1\hat{S}_2 + D\hat{S}_Z^2$. The best fit (solid lines in

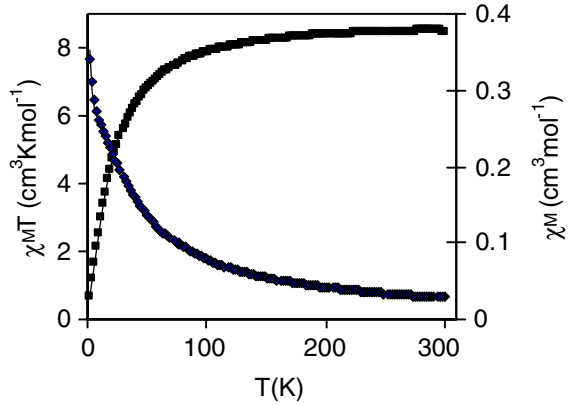

Fig. 3. χ_M and $\chi_M T$ vs. T data for complex **3**. Solid lines represent the best fit of the data with the model described in the text.

Fig. 3) was obtained for the following set of parameters: $J = -1.5\,cm^{-1}$, $D = -2 \times 10^{-4}\,cm^{-1}$, $g = 1.996$, and 1.4% of paramagnetic impurity. This result is in good agreement with the presence of a weak antiferromagnetic interaction between the binuclear $[Mn_2^{II}(L^1)(NCS)_4]$ repeat units along the 1D chains of **3**. The negligible single Mn^{II} ion ZFS value, D, is in agreement with the expectation for a d^5 shell. The fit evidenced as well a low contribution from temperature independent paramagnetism (TIP = 1.2×10^{-4}). Finally, attempts made to take into account additional inter-pair interactions (molecular field approximation according to Ginsberg and Lines' approach [24]) also yielded a negligible value of the intermolecular interaction parameter zj', thus confirming that the magnetic behaviour of **3** does not result from extended magnetic interactions along 1D chains, but from pairwise interactions between Mn^{II} ions.

5. Concluding remarks

Upon reaction with metal salts the Schiff base L, resulting from the bis-condensation of triethylenetetramine and 2-benzoylpyridine, behaves as a straightforward hexadentate ligand, yielding mononuclear complexes where the metal centre is coordinated to the six nitrogen donors of L. On the other hand, when such reactions are conducted in suitable solvents and in the presence of pseudo-halides (N_3^-, NCS^-) a rearrangement from L to L^1, consisting in an alkylating cyclization centred on the two secondary amine functions of L, systematically occurs. In the case of manganese(II), the reaction between the product L^1 and the metal assisting this rearrangement depends on the pseudo-halide and solvents used: while a binuclear manganese(III) complex, $[Mn_2(L^1)(N_3)_6]$ (**2**) is obtained in the case of azido anions in methanol/water mixtures, a polymeric manganese(II) compound, $\{[Mn_2^{II}(L^1)(NCS)_4] \cdot 2CH_3CN\}_n$ ($3.2CH_3CN$), is obtained with thiocyanato anions in acetonitrile/water mixtures.

The Mn centres of complexes **2** and **3** are in distorted octahedral coordination environments (**2**: $Mn^{III}N_6$, **3**: $Mn^{II}N_5S$) with intramolecular Mn···Mn distance (**2**: 6.473(2) Å, **3**: 6.437(1) Å) consistent with the absence of intramolecular magnetic interactions. Compound **3**, the first example of manganese(II) 1D chain where binuclear units are bridged via two $\mu_{1,3}$-NCS anions, exhibits weak intermolecular antiferromagnetic interactions ($J = -1.5\ cm^{-1}$) between pairs of Mn^{II} ions.

Abstract

Several mixed-ligand complexes of the composition [CuX(*trans*-dppen)(L)] (X = Br, I) have been prepared by treatment of copper(I) halide with equimolar amounts of *trans*-1,2-bis(diphenylphosphino)ethene (*trans*-dppen) in acetonitrile followed by the addition of a methanolic solution of one equivalent of a heterocyclic thione (L). The novel complex compounds have been characterized by ^{1}H NMR and IR spectroscopy as well as by elemental analyses and melting points. The X-ray structures of two representative examples, namely the pyrimidine-2-thione complexes of copper(I) bromide and iodide confirm that the compounds are dimers of type $[CuX(\mu_2\text{-}trans\text{-dppen})(L)]_2$ containing two tetrahedral coordination units joined by two diphosphine bridges.

1. Introduction

Due to their relevance in biological systems, the use of heterocyclic thiones as ligands in transition metal complexes has drawn much attention in the recent past [1]. Among others, an impressive amount of thione-ligated copper(I) halide complexes have been obtained over the years, that display a rich diversity of stoichiometries and structural prototypes. For some time the focus of our research in this field was directed towards incorporation of tertiary arylphosphines as bulky soft donors. This produced a large amount of mixed-ligand Cu(I) complexes with a variety of structures ranging from mononuclear three- or four-coordinate species with trigonal planar and tetrahedral Cu(I), respectively, to double bridged dimers. In all these complexes the thione molecules were always found to bind the metal exclusively through the exocyclic sulfur atom in either a μ_2-S bridging [2–4] or in a terminal [2,5] fashion, with the preference for each of these two modes of coordination strongly dependent on the nature of the halide ligand. As for the coordination number of the complexes being formed, only the influence of the bulkiness of the phosphine, but not of that of the thione ligands used, could be definitively stated so far [6].

Sometime ago, we started comparative studies into the substitution of unidentate arylphosphines with oligomethylene-backboned symmetric diphosphines of the type $Ph_2P(CH_2)_nPPh_2$ (n = 1–6), whereby we demonstrated that, dependent on the nature of the phosphorus

doi:10.1016/j.poly.2004.11.015

donors, it is possible to prepare and isolate diphosphine complexes of copper(I) of different nuclearity and stoichiometry. Thus, 1,3-bis(diphenylphosphino)propane (dppp), but also *cis*-1,2-bis(diphenylphosphino)ethylene (*cis*-1,2-dppen), were found to chelate at a single metal centre yielding mononuclear pseudo-tetrahedral copper (I) species [7,8] or halide bridged dimers [8], whereby cyclic dimeric compounds in which the two copper(I) centres are linked together by two bidentate phosphine ligands have been obtained when a longer methylene chain connects the two P atoms, but surprisingly also in the case of 1,2-bis(diphenylphosphino)ethane (dppe) [9]. The most recent step within the aforementioned studies deals with the coordination capability of the rigid diphosphine *trans*-1,2-bis(diphenylphosphino)ethene (*trans*-dppen) toward Cu(I) chloride, in the presence of heterocyclic thione donor groups [10]. There, we described the preparation and crystallographic characterization of some examples of complexes of the formula $[CuCl(\mu_2\text{-}trans\text{-dppen})L]_2$ (L = heterocyclic thione), in which the metal centres are spanned by two diphosphine molecules to afford a 10-membered dimetallacyclic ring. In continuation of our efforts in this area, we now extend the use of this diphos ligand to obtain mixed ligand complexes of copper(I) bromide and iodide. This seems necessary, since the Cu(I) halide complexes, depending on the halide present, often show very different structural properties. Thus, to fully define the prepared compounds and to gain additional information concerning trends in the copper–thione and copper–phosphine interactions, the structures of two examples, representative for each type of halide, have been determined by single-crystal X-ray analysis.

2. Experimental

2.1. Materials and instruments

Commercially available copper(I) halides and *trans*-1,2-bis(diphenylphosphino)ethene were used as received while the thiones (Fig. 1) were recrystallized from hot ethanol prior to their use. All the solvents were purified by respective suitable methods and allowed to stand over molecular sieves. Infra-red and electronic absorption spectra, melting points, molar conductivities, magnetic susceptibility measurements and elemental analyses for carbon, nitrogen and hydrogen were performed as described previously [11]. ^{1}H NMR spectra were recorded on a Bruker AM 300 spectrometer at 25 °C; chemical shifts in ppm are quoted relative to internal TMS.

2.2. X-ray crystallographic study

Single crystals suitable for crystal structure analysis were obtained by slow evaporation of acetonitrile/methanol solutions of the complexes at room temperature. X-ray diffraction data were collected on an Enraf-Nonius Kappa CCD area-detector diffractometer. The programs DENZO [12] and COLLECT [13] were used in data collection and cell refinement. Details of crystal and structure refinement are shown in Table 1. The structures were solved using program SIR 97 [14] and refined with program SHELX-97 [15]. Molecular plots were obtained with program ORTEP-3 [16].

2.3. Synthesis of complexes *1–16*

The complexes were prepared according to the following general procedure. To a suspension of copper(I) bromide or iodide (0.5 mmol) in 30 cm^3 of dry acetonitrile, *trans*-1,2-bis(diphenylphosphino)ethene (198.2 mg, 0.5 mmol) was added and the mixture was stirred for 2 h at ambient temperature during which time a white precipitate was formed. A solution of the appropriate thione (0.5 mmol) in 30 cm^3 methanol was added dropwise into the reaction mixture whereupon the white precipitate gradually disappeared. After heating at 50 °C for 2 h followed by stirring at ambient temperature overnight, the resulting clear solution was filtered off and left to evaporate. The microcrystalline solid, which was

3. Results and discussion

3.1. General considerations

The reaction of equimolar quantities of copper(I) bromide or iodide and *trans*-1,2-bis(diphenylphosphino)ethene (*trans*-dppen) followed by the addition of one equivalent of the apropriate thione (L) [L = pyridine-2-thione (py2SH), pyrimidine-2-thione (pymtH), tetrahydropyrimidine-2-thione (tHpymtH), 4-methyl-5-trifluoromethyl-4H-1,2,4-triazoline-3(2H)-thione (mftztH), 5-methyl-1,3,4-thiadiazole-2-thione (mtdztH), benz-1,3-oxazoline-2-thione (bzoxtH), 5-methyl-benz-1,3-imidazole-2-thione (mbzimtH_2), and 6-mercaptopurine (pur6SH) (Fig. 1) in dry acetonitrile/methanol solution at 30 °C afforded microcrystalline air stable solids which, on analysis were found to be of composition [CuX(*trans*-dppen)L].

Our initial use of *trans*-1.2-bis(diphenylphosphino)ethene as ligand in low valent coinage metal chemistry had been in the reaction with copper(I) chloride, which had led to formation of homobridged dinuclear derivatives of the type [CuCl(μ_2-dppen)(L)]$_2$ [10]. This was not surprising in view of the geometrical rigidity of the unsaturated carbon backbone which holds the two phosphorus atoms too far apart to chelate at a single metal centre. In respect of this finding we anticipated that dppen would adopt the same bridging mode upon coordination to copper(I) bromide or iodide. Moreover, the Cu···Cu separation of about 6 Å found in these diphosphine bridged dimers prevents the halide or thione-S donors from participating in additional bridges within the dimeric unit. However, one should additionally take the formation of other frequently observed structure types like thione-free dimers or even coordination polymers into consideration, as the structures of copper(I) halides are often determined by the choice of the halide. In fact, only on the grounds of the aforementioned composition were we able to definitively exclude these latter two possibilities, thus, all the new compounds turned out to be once more diphosphine-bridged dimers. Note that we have performed several additional experiments treating the metal salts with various phosphine/thione ratios or even applying more forcing reaction conditions to definitively conclude that the outcome of this reaction is independent of reaction conditions and ligand-to-metal ratio employed.

All prepared complexes are air-stable, coloured, diamagnetic, microcrystalline materials, slightly soluble in polar solvents such as acetonitrile and dimethylsulfoxide, and only marginally soluble in chloroform,

dichloromethane and acetone. Their solutions in acetonitrile and chloroform are non-conducting.

3.2. Spectroscopic investigations

The infrared spectra of compounds **1**–**16**, recorded over the range 4000–250 cm^{-1} are consistent with the formulations proposed, showing all of the bands required by the presence of the thione ligands. The shifts observed for these bands due to coordination in combination with the lack of ν(SH) bands at ca. 2500–2600 cm^{-1} as well as the characteristic NH stretching vibrations observed in the ~3150 cm^{-1} region, signify the exclusive S-coordination mode of the thione ligands. Moreover, the spectra of compounds under investigation contain distinct strong vibrational bands which are only slightly shifted with respect to those of the free donors.

The electronic absorption spectra of the complexes in chloroform solutions are dominated by two intense sharp main bands in the regions 245–265 and 280–308 nm, accompanied by a third one in the 312–410 region. The two former bands correspond to intraligand π* ← π transitions on the phenyl group of the phosphine ligand, since the uncoordinated *trans*-1,2-bis(diphenylphosphino)ethene reveals two strong absorptions at 258.5 and 296.9 nm which are known not to undergo significant shifts upon coordination to Cu(I), whereby the latter are attributed to thione-originating intraligand excitations.

Unfortunately, the prepared complexes are sparingly soluble in common organic solvents and in strongly polar ones such as DMSO and DMF. In addition, they decompose slowly in DMF even under nitrogen. Therefore, ^1H NMR spectra could be only be recorded in $CDCl_3$ or a mixture of $[D_6]DMSO/CDCl_3$. In most of these spectra the phenyl region is dominated by rather uninformative multiplets. Upon coordination, the signals due to bridging ethene protons of the phosphine ligand show a more complicated pattern with respect to those found for the free donor. In addition, they undergo low-field shifts towards the region of the signals attributable to the aromatic protons of the thione groups as well as to the aromatic phosphine protons. In some cases, the extent of overlapping does not allow to resolution of all these signals, making interpretation of the splitting pattern of the individual thione resonances very difficult. Nevertheless, these spectra confirm at least the existence of the complexes in solution. Moreover, the observation of a broad singlet in the 12–15 ppm region due to NH group, considerably highfield shifted with respect to that of the corresponding free donor, clearly indicates that the ligands bond to the metal in their thionato form.

3.3. Description of the structures

Single crystals of complexes **2** and **10** suitable for X-ray crystallographic study were grown by slow concentration of acetonitrile/methanol solutions of the compounds over several days at ambient temperature. Details regarding the crystal data collection and refinement are reported in Table 1. Bond lengths and angles around the Cu(I) are listed in Tables 2 and 3, and respective drawings of the complexes with the labelling of the atoms are given in Figs. 2 and 3. Complex **2** crystallizes in the monoclinic space group $P2_1/n$ with the unit cell containing two dinuclear species, whereas compound **10** crystallizes in the triclinic space group P. Its structure contains one discrete molecule per unit cell, as well as two lattice CH_3CN molecules; the latter solvate molecules do not interact specifically with the dimer and will not be further discussed. Both structures contain a centre of symmetry and each show some degree of molecular disorder. In **2**, atoms of the bromine and pymtH ligands are each disordered over two separate sites. Similarly three atoms of a phenyl ring are also disordered over two sites. In **10**, the dppen carbon atoms each occupy two sites and there are high displacement parameters associated with some of the phenyl ring carbon atoms.

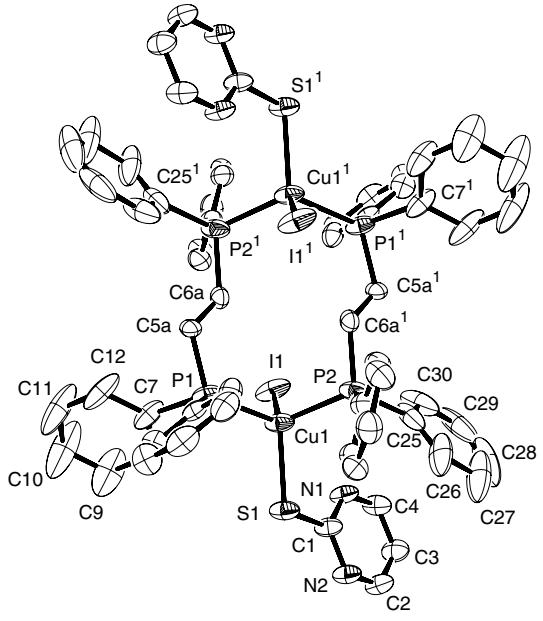

Fig. 3. An ORTEP view of **10** with disorder removed. Displacement ellipsoids are shown in the 50% probability level.

In general, the main structural characteristics of compounds **2** and **10** are very similar. A comparison of the structural parameters of the two compounds with the three previously described copper(I) chloride counterparts $[CuCl(\mu_2\text{-}trans\text{-dppen})(pymtH)]_2$, $[CuCl(\mu_2\text{-}trans\text{-dppen})(tHpymtH)]_2$ and $[CuCl(\mu_2\text{-}trans\text{-dppen})(mftzdtH)]_2$ [10] also reveals strong similarities of their cores. The subsequent comparative discussion will therefore mainly focus on details which underline some of the most interesting fine differences between the two structures under investigation.

In the two dimeric complexes the geometry of each copper(I) involved is a highly distorted tetrahedron, with the metal atom being surrounded by one halogen atom, the S-atom of the pyrimidine-2-thione ligand and two bridging P-atoms belonging to two different diphosphine units. Interestingly, the most regular angle arises even between these two terminally bonded ligands, being in the two complexes almost equal to the ideal tetrahedral value of 109.4°, although this arrangement is accompanied by the formation of the expected strong intramolecular hydrogen bond between the halogen and the hydrogen atom attached to N(1) only within the structure of **10**. Contrary to that, the P–Cu–P angles are markedly larger than the tetrahedral one, with the irregularities being counterbalanced by appropriate smaller P–Cu–Br angles. Particular attention deserve the two S–Cu–P angles around each copper atom, which are in **10** close to the ideal value, against the situation in **2**, where two essential different values are present, one of them being significantly narrowed.

While angular distortions from the ideal tetrahedral geometry around each Cu(I) are considerable, bond distances involving the central metal atom appear normal, generally retaining their values within the range normally observed for tetrahedrally coordinated copper(I) bonded to two phosphorous, one halogen and one sulfur atoms. In detail, the Cu–S bond distances of 2.286(6) and 2.3169(17) Å in **2** and **10**, respectively, remain typical of the usual range of 2.27–2.35 Å observed in other mixed ligand copper(I) complexes bearing terminal bonded pyrimidine-2-thione [17,7]. The Cu(1)–Br(1) bond length of 2.586(3) Å in **2** is quite large for a bromine terminally bonded to a copper(I) centre in a tetrahedral coordination environment, clearly larger than the value of 2.4455 (11) Å found in $[CuBr(py2SH)(PPh_3)]_2$ [18] or that of 2.5369(4) Å found in [CuBr(pymtH)-(dppp)] (dppp = 1,3-bis(diphenylphosphino)propane) [7]. As in the three copper(I) chloride counterparts, each copper atom participates in two inequal Cu–P bonds, with the inequality being particularly marked in **2**. Nevertheless, the values of the individual Cu–P distances remain all within the limits expected for tetrahedrally coordinated Cu(I).

Upon coordination, some significant alterations within the *trans*-dppen geometries appear, which merit special mention. In detail, the P(1)–C(6)–C(5) angle in **2** is very close to the P–C–C angle of 126.9(3)° found in the free *trans*-dppen [19], but the value for the P(2)–C(5)–C(6) angle is suppressed by 5°. At the same time the olefinic C=C double-bond may be considered a little shorter (1.327(8) in **2**, against the value of 1.340(15) found in the non-coordinated *trans*-dppen). Although statistically this difference is not significant, such moderate conformational distortions from the ideal geometry

within the diphosphine units are observed in the three previously described copper(I) chloride counterparts, and are obviously inevitable in order to allow the 10-membered $Cu_2P_4C_4$-ring to be formed. This is strongly supported by the fact that the conformational features of the dppen unit in the dimeric [ClAu(μ-*trans*-dppen)AuCl], where the two metal centres are linked only by one bridging diphosphine unit, which is therefore not forced to lose its favourable conformation, remain practically unaffected [20]. Each of the dppen carbon atoms (C5 and C6) in **10** are disordered over two sites such that the errors associated with the geometries here are high. Finally, another feature of the two molecules under investigation that deserves some interest occurs in respect of the coordination plane of the diphosphine bridges. As indicated by the P(1)–C(6)–C(5)–P(2) torsion angles (169.8 (3)° in **2** and −177.9(10)° in **10**), upon coordination the two P atoms twist about the ethene bridge altering the dihedral angle through the four atoms by about 6.8° and 5.5° respectively with respect to the corresponding value (176.6°) in the free *trans*-dppen, thus significantly modifying the bite size of the diphosphine. Nevertheless, these conformational rearrangements do not affect noticeably the Cu···Cu separation, which remains actually close to the values found in the three already reported copper(I) chloride derivatives.

4. Conclusion

In this paper, we demonstrate the coordination behaviour of copper(I) bromide and iodide in the presence of *trans*-1,2-bis(diphenylphosphino)ethene and a series of heterocyclic thiones. In all the complexes Cu(I) adopts the common distorted pseudo-tetrahedral coordination environment with the neutral thione ligands coordinating to the metal center through the exocyclic sulfur atom. The *trans*-1,2-bis(diphenylphosphino)ethene ligand coordinates in a bidentate manner the two metals exclusively favouring dimeric complexes of the formula $[CuX(\mu_2\text{-}trans\text{-dppet})L]_2$ independent of the reaction stoichiometries and conditions chosen. On the grounds of our hitherto results, this doubly bridging mode of coordination seems to be practically the only possibility for the diphos ligand under investigation to bind Cu(I) centres. Thus, this behaviour supports once more our supposition that for diphosphines inefficient to chelate at a single metal center, but having the appropriate geometrical features to act as bridging ligands, dimerization is on principle favoured over polymerization.

5. Supplementary material

CCDC Nos. 238432 (**2**) and 238433 (**10**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; e-mail: deposit@ccdc.cam.ac.uk].

Abstract

The reaction of $[RuCl_3(NO)(PPh_3)_2]$ complex with pyrazole has been examined. The new ruthenium complex – $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ has been obtained and characterised by IR and UV–Vis measurements. Crystal, molecular and electronic structures of the complexes have been determined. The electronic spectrum of the complex was calculated by the TDDFT method.

Keywords: Ruthenium nitrosyl complexes; Pyrazole; X-ray structure; TDDFT method

1. Introduction

The chemistry of ruthenium nitrosyls is a recent renewed interest in particular in the field of medicinal inorganic chemistry [1–10]. The complexes are investigated as controlled NO-releasing agents for medicinal applications, in particular for the control of high blood pressure (vasodilatation), and as antitumor agents which might perform the release of cytotoxic NO within tumor cells, thus leading to cell death. In other hand the nitrosyl ruthenium complexes have been studied due to their importance as potential catalysts in homogeneous processes [11–16].

In this paper we report the synthesis of the new ruthenium nitrosyl complex with pyrazole ligand. The molecular and crystal structures of the obtained complex are presented. The electronic structure was calculated with the DFT method by using the GAUSSIAN03 program package.

2. Experimental

All reagents used to the synthesis of the complex are commercially available and were used without further purification. The $[RuCl_3(NO)(PPh_3)_2]$ complex was synthesized by publishing procedure [17] from $RuCl_3NO$, which was prepared by passing NO through a solution of $RuCl_3$ in dichloromethane until the solution become red followed by evaporation to dryness. The dried solid obtained was kept in a vacuum desiccator for at least three days before used. Gaseous NO, obtained in the reaction: $2NaNO_2 + 3H_2SO_4 + FeSO_4 \rightarrow 2NO + 2NaHSO_4 + Fe_2(SO_4)_3 + 2H_2O$, was purified by passing through the washers with concentrated KOH solution and over solid NaOH.

2.1. Synthesis of $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$

A mixture of $[RuCl_3(NO)(PPh_3)_2]$ (0.76 g; 1×10^{-3} mol) and pyrazole (0.42 g; 6×10^{-3} mol) in acetone (100 cm^{-3}) was refluxed for 4 h, cooled and filtered. The yellow-orange crystals suitable for X-ray crystal analysis grew after the reaction mixture was left overnight.

Yield 92%. IR (KBr): 3137 ν_{NH}; 3058 $\nu_{CH-pyrazole}$; 3021, $\nu_{CH-phenyl}$; 1879 ν_{NO}; 1572 ν_{CN}, $\nu_{C=C}$; 1487 $\delta_{(C-CH\ in\ the\ plane)}$; 1436 $\nu_{Ph(P-Ph)}$; 1320 $\delta_{(NH;\ CH)}$; 1095 $\delta_{(C-CH\ in\ the\ plane)}$; 994 $\delta_{(C-C\ out\ of\ the\ plane)}$; 749 $\delta_{(C-C\ out\ of\ the\ plane)}$; 687 $\delta_{(C-C\ in\ the\ plane)}$; 598 ν_{P-Ph}. *Anal*. Calc. for $C_{21}H_{19}Cl_3N_3OPRu$: C, 44.42%; H, 3.37%; Cl, 18.73%; N, 7.40%; O, 2.28%; P, 5.46%; Ru, 17.80%. Found: C, 44.12%; H, 3.35%; N, 7.29%.

2.2. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of KBr pellet. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 800–200 nm in dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN–2400 analyzer.

2.3. DFT calculations

GAUSSIAN03 program [18] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [19,20]. The electronic spectrum was calculated with the TDDFT method [21].

Two basis set were used in the calculation. LANL2DZ basis set [22] was used on the ruthenium atom, 6–31G(d) on the chlorine, nitrogen, oxygen and carbon atoms and 6–31G basis on the hydrogen atoms in the first calculations the second one was performed using the SSD basis set on ruthenium atom. The obtained results of calculation were compared.

Natural bond orbital (NBO) analyses was performed using the NBO program as implemented in the GAUSSIAN03 program.

2.4. Crystal structures determination and refinement

A orange crystal of $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ was mounted on a KM–4–CCD automatic diffractometer equipped with CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at temperature 293.0(2) K, with ω scan mode. The 21-s exposure time was used and a full Ewald sphere was collected up to $2\theta = 50.28°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 16,950 strongest reflections. Details concerning crystal data and refinement are given in Table 1. During the data reduction above decay correction coefficient was taken into account. Lorentz, polarization, and numerical absorption [23] corrections were applied. The structure was solved by direct methods. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique on F^2. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent atom with individual isotropic temperature factor equal 1.2 times the value of equivalent temperature factor of the parent atom. SHELXS97 [24], SHELXL97 [25] and SHELXTL [26] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

Refluxing of the $[RuCl_3(NO)(PPh_3)_2]$ complex with an excess of pyrazole in acetone leads to the new ruthenium nitrosyl $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ complex in high yield. The elemental analysis of the complex is in

good agreement with its formulation. The characteristic bands of the pyrazole ligand ν(NH) at 3137 cm^{-1} and ν(CN), ν(C=C) at 1572 cm^{-1} are present in the IR spectrum of the obtained complex. The spectrum of the complex shows ν (NO) at 1879 cm^{-1}, what is consistent with the linear NO range of Haymore and Ibers (ν(NO) above 1620–1610 cm^{-1} were assigned to linear M–N–O systems, while ν(NO) below 1610 cm^{-1} were assigned to bent M–N–O systems) [27].

3.1. Crystal structure

The $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ complex crystallises in the orthorhombic space group *Pca*2/1 The relative orientation of molecules is depicted in Fig. 1 which also shows the displacement vibration ellipsoids (structural drawing of the complex is presented in Fig. 2.). The selected bond lengths and angles are listed in Table 2. The two crystallographically independent molecules are structurally nearly identical (I and II hereafter for molecules containing Ru(1) and Ru(51), respectively). The most different distances are Ru(1)–Cl(1) 2.396(7) Å and Ru(51)–Cl(51) 2.372(7) Å. The most different angles are N(1)–Ru(1)–N(2) 94.68(10)° and N(51)–Ru(51)–N(52) 91.16(10)°. The ruthenium atom is in a distorted octahedral environment with linear N–O group *trans* to one of Cl ligands, two mutually *cis* Cl ligands and the PPh_3 and pyrazole molecules in *trans*. The short bond distances Ru–N (1.735(3) Å), N–O (1.134(3) Å) and particularly the Ru–N–O (176.4(3)°) angle (average values) strongly indicate the nitrosonium character of the NO group, in accordance with the similar data observed for the other ruthenium nitrosyl complexes [28]. The Ru–Cl bond distances (2.372(7)–2.396(7) Å) fall in the range reported in the literature for Ru^{II} complexes, with the exception of the

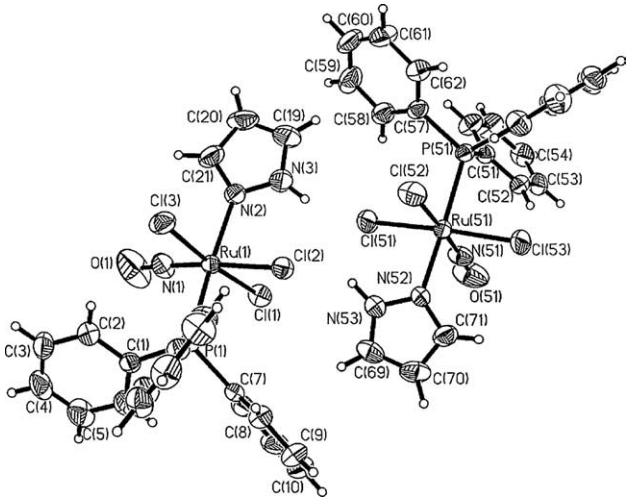

Fig. 1. Relative orientation of the two molecules of the $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ complex in the asymmetric unit. Thermal vibration ellipsoids scaled to include 50% probability.

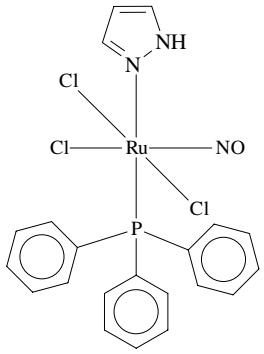

Fig. 2. Structural drawing of $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$.

chlorine *trans* to the nitrosyl group (2.342 Å average value). The NO bond length (1.135(3), 1.133(3) Å) is a little longer than the distance 1.06 Å of the free NO^+ group [29]. The pyrazole and triphenylphosphine ligands display Ru–N and Ru–P distances which are in the range of these reported in the literature.

The bond valences were computed as $v_{ij} = \exp[(R_{ij} - d_{ij})/0.37]$ [30–33], where R_{ij} is the bond-valence parameter (in the formal sense R_{ij} is the single-bond length between *i* and *j* atoms) [22]. The R_{Ru-N}, R_{Ru-P}, R_{Ru-Cl} were taken as 1.656 [34], 1.985 [35] and 1.932 [34], respectively. The computed bond valences of the ruthenium are $v_{Ru-N(nitrosyl)} = 0.817$, $v_{Ru-N(pyrazole)} = 0.262$, $v_{Ru-P} = 0.334$; $v_{Ru-Cl} = 0.285, 0.335, 0.300$ v.u. (valence units) for molecule I and $v_{Ru-N(nitrosyl)} = 0.801$, $v_{Ru-N(pyrazole)} = 0.265$, $v_{Ru-P} = 0.325$; $v_{Ru-Cl} = 0.304$, 0.327, 0.300 v.u. which means that Ru–N(nitrosyl) bonds are almost three times stronger than other bonds, and the Ru–N(pyrazole) bonds are the weakest ones. The valence sum rule states that the sum of the valences of the bonds formed by an atom is equal to the valence of the atom. Computed total valence of the Ru atom is 2.332 and 2.323 v.u. for molecules I and II, respectively. Which means that differences in coordination sphere arrangement are local in character and do not influence the molecule.

The three intermolecular hydrogen bond [36–38] linking the Cl ligand and pyrazole ring N(53)–H(53N)···Cl(1) (D···A distance 3.368(2) Å, D–H···A angle 128.0°), C(53)–H(53)···Cl(2) (#1 $x + 1/2, -y - 3, z$) (D···A distance 3.316(3) Å, D–H···A angle 116.7°) and NO with pyrazole C(71)–H(71)···O(1) (#2 $x, y - 1, z$) (D···A distance 3.208(4) Å, D–H···A angle 126.0°) atoms are observed (Table 3). Other intramolecular hydrogen bonds are presented in the structure of the complex: between pyrazole N(3)–H(3A) and Cl(2) (D···A distance 3.092(3) Å, D–H···A angle 115.4°), N(53)–H(53N) and Cl(51) (D···A distance 3.160(2) Å, D–H···A angle 122.6°), between phenyl C(14)–H(14) and Cl(2) (D···A distance 3.372(3) Å, D–H···A angle 140.3°), C(58)–H(58) and Cl(51) (D···A distance 3.268(3) Å, D–H···A angle 112.8°), C(64)–H(64) and

Cl(52) (D···A distance 3.501(3) Å, D–H···A angle 147.1°) and between phenyl C(52)–H(52) and N_{NO}(51) (D···A distance 3.035(4) Å, D–H···A angle 109.0°). In this way infinite three-dimensional hydrogen-bonded net has been created.

3.2. Geometry and electronic structure

The optimized geometry parameters for the complex are given in Table 4. In Table 5 the energies of several HOMO and LUMO orbitals are gathered. The calculated bond lengths agree well with the experiment. The largest difference were found for the ruthenium–chlorine bonds (0.152 Å, 0.056 Å, 0.084 Å – LANL2DZ basis and 0.114 Å, 0.028 Å, 0.045 Å – SSD for Ru–Cl(1), Ru–Cl(2) and Ru–Cl(3), respectively), but the relative differences in these bond lengths are reproduced in the calculations. The N–O distance calculated by using both basis sets are comparable (the difference is 0.005 Å). The SSD basis set has given better $Ru–N_{(NO)}$ and Ru–P distances.

In Table 6 the atomic charges from natural population analysis (NPA) are shown. The formal charge of ruthenium is +2 in this complex. The calculated charge, obtained from NPA, on the ruthenium is close 0.342. This is a result from a charge donation from chloride ions and triphenylphosphine group. There are large positive charges on the phosphorus atom (1.268, total charge on PPh_3 is 1.18), and the charges on the chloride ions are significantly smaller than −1 (Cl1 −0.491, Cl2 −0.409 and Cl3 −0.462). The charge on the pyrazole nitrogen atom bonded with ruthenium is negative (−0.318) – the pyrazole ligands act as electron acceptors (total charge on pyrazole ligand is −0.14). The total charge on the NO group is 0.217 (the charge of $N_{(NO)}$ is 0.370). The π-acceptor nature of NO^+ enhances π-donation by *trans* chlorine ligand, and according to the structural *trans* effect the Ru–Cl(2) distance is shorter than the other ruthenium chlorine ones. The *trans* effect of NO ligand in the complex is presented in Fig. 3.

The linear unit M–NO is usually deemed to coordinate as NO^+ to the metal. In the valence-bond treatment the resulting NO^+ group is considered to involve sp hybridization at the N and O atoms. The following resonance forms may present the linear bonding mode:

A B C D

Taking into consideration the electron population in the Ru–N and N–O bonds, from NBO analysis, (Ru–N/(BD + BD*) = 5.099, N–O/BD = 1.991 and N–O/BD* = 0.018) the resonance structure D becomes more important for the investigated complex.

The structure of the M–NO bond is composed of a σ-bond, using the nitrogen lone pair and two π-interactions involving the filled d_{xz} and d_{yz} orbitals on ruthenium atom and the π* orbitals of the NO (in this complex LUMO and LUMO + 1) [39]. The LUMO and LUMO + 1 orbitals are composed mainly of π^*_{NO} orbitals (about 63%). In the occupied orbitals the π^*_{NO} are distributed among several MOs, but their participation do not excess 15%. On the basis of the molecular orbital composition and the small charge on the NO group (Table 6) the NO^+ character of nitrosyl in this complex can be confirmed.

The HOMO orbital is d_{xy} metal orbital with the admixture of chlorine π orbitals. HOMO − 1, HOMO − 2 and HOMO − 3 are π orbitals of phenyl groups with a contribution from the π Cl atoms. LUMO + 2 and LUMO + 3 are d_z^2 and $d_{x^2-y^2}$ orbitals with an antibonding admixture of the chlorine, phosphorus and pyrazole nitrogen lone pairs orbitals The HOMO − 4, HOMO − 5 and HOMO − 6 orbitals are π type (phenyl and Cl) with a substantial contribution from the appropriate d ruthenium orbitals. The participation of d_{xy}, d_{xz} and d_{yz} orbitals is visible in the lowest HOMO orbitals (H − 15, H − 16, H − 18, H − 19, H − 20, H − 21, H − 22) which are mainly π orbitals of phenyl with contribution of π Cl. The pyrazole ligand participates in lower HOMO orbitals (H − 8, H − 12 and H − 13) with contribution from π phenyl and Cl orbitals. The character of the HOMO and LUMO orbitals calculated by using the SSD basis set on ruthenium are close to these obtained from calculation with LANL2DZ basis. The energy of appropriate HOMO and LUMO orbitals calculated with SSD basis set is

lower than obtained from calculation with LANL2DZ basis on Ru atom (maximum difference is about 0.4 eV). The HOMO–LUMO gap in both calculations are similar (the difference is 0.15 eV).

3.3. Electronic spectrum

The experimental spectrum of $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ shows bands at 534.6, 468.4, 438.6, 330.8 300.0, 228.8 and 216.8 nm. There is also a shoulder at about 270 nm. The measured electronic spectrum is shown in Fig. 4.

With the use of the TDDFT method 80 electronic transitions were calculated for $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$ using the LANL2DZ basis set and 90 transitions with SSD basis set. The calculated electronic transitions are gathered in Tables 7 and 8. Both LANL2DZ and SSD calculation predict the experimental spectra of the complex with similar accuracy. Except for the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.01 are listed. The calculated spectra obtained by both calculations are depicted in Fig. 5. Each calculated transition in Fig. 5 was represented by a gaussian function with the height equal to the oscillator strength and width equal to 0.05.

We ascribe the first experimental bans at 534 nm to the calculated transitions at 517 and 513 nm with small oscillator strengths. These are $d \rightarrow \pi^*_{NO}$ transitions. The transition calculated with SSD basis set is at 502.1 nm. The experimental band at 468 nm is assigned to the transitions calculated between 461 and 429 nm in the case of

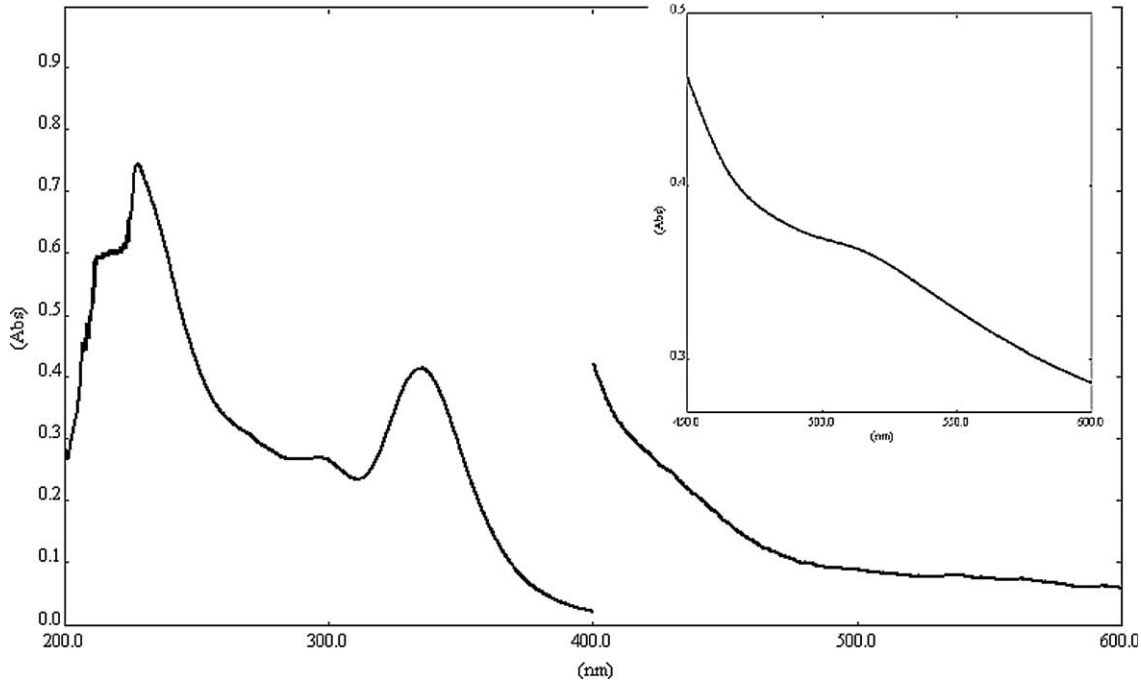

Fig. 4. UV–Vis spectrum of $[RuCl_3(NO)(PPh_3)(C_3H_4N_2)]$.

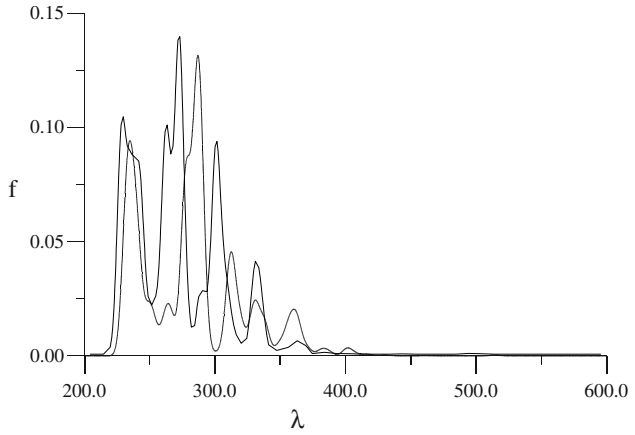

Fig. 5. Calculated electronic spectrum of $[RuCl_3(NO)(PPh_3)(HPz)]$ (solid line – LANL2DZ, dashed line – SSD).

calculation with LANL2DZ basis and with SSD basis set the band we ascribe to the calculated transition at 498.3 nm. These transitions are of d→d and $\pi_{Cl} \rightarrow \pi^*_{NO}$ type (LLCT). In these range of energy transitions the prediction of experimental values with LANL2DZ basis set is better than with using the ECP basis (SSD). The transitions calculated between 418 and 400 nm (442–407 nm SSD) are ascribed to the band at 438 nm. These transitions are again of LCT type and occur from the chlorine, phenyl and pyrazole orbitals to the π^*_{NO} orbitals.

The experimental band at 330 nm is ascribed to the transitions calculated between 356 and 312 nm with medium oscillator strengths and to transitions between 366.3 and 311.0 nm while the SSD basis set was using. These are mainly transitions from the pyrazole, phenyl and chlorine ligands orbitals to the metal d orbitals (LMCT). The transitions 289 and 263 nm (304.4 to 269.9 – SSD) are assigned to the band at 300 nm and shoulder at about 270 nm. These are again transitions of LMCT character.

The transitions between 240 and 231 nm and 259.8 to 222.2 nm in calculation with SSD, respectively, are assigned to the band at 228 nm. They are of LLCT type (interligand transitions) and intraligand ($\pi_{Ph} \rightarrow \pi^*_{Ph}$) (transitions). The experimental band at 216 nm could not be assigned on the basis of the calculated transitions. This band probably corresponds also to $\pi_{Ph} \rightarrow \pi^*_{Ph}$ transitions in the PPh_3 ligand.

As it can be seen from Tables 7 and 8 the UV–Vis spectrum calculated with the SSD basis set on the ruthenium atom gave better results in the higher energy and the LANL2DZ basis set in the lower energy range of the spectrum.

4. Supplementary material

Crystallographic data for the structure of the complex have been deposited at Cambridge Crystallographic Data Center (CCDC 239378). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk).

Acknowledgements

Crystallographic part was financed by funds allocated by the State Committee for Scientific Research to the Institute of General and Ecological Chemistry, Technical University of Łódź. The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland under calculational Grant No. 51/96.

Abstract

Mononuclear molybdenum(VI) complexes of the type $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(D)]$ [D = pyridine (**1d**), γ-picoline (**1c**)] and $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot CH_3OH \cdot 1/2bpy$ (**1e**) have been prepared by the reaction of $[MoO_2(C_5H_7O_2)_2]$ ($C_5H_7O_2$ = acetylacetonate ion) with salicylaldehyde thiosemicarbazone $[C_6H_4(OH)CH{:}NNC(SH)NH_2]$ and Lewis base in dry methanol. The dinuclear complex $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_2$ (**1b**) has been prepared by the reaction of $[MoO_2(C_5H_7O_2)_2]$ with salicylaldehyde thiosemicarbazone $[C_6H_4(OH)CH{:}NNC(SH)NH_2]$ in dry dichloromethane. In all complexes, except in the case of complex **1e**, molybdenum is coordinated by two terminal oxo-oxygen atoms, (O_t), by ONS atoms from the salicylaldehyde thiosemicarbazone ligand and by an oxygen atom from the methanol molecule in **1a**, and either by a nitrogen atom from γ-picoline in **1c** or pyridine in **1d**. In $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot CH_3OH \cdot 1/2bipy$ (**1e**), salicylaldehyde thiosemicarbazone is coordinated to molybdenum through ONN atoms, while the sixth coordination site around the molybdenum atom is completed by the methanol molecule.

All complexes have been characterized by means of chemical and thermogravimetric analyses and IR spectroscopy. The molecular structures of complexes **1b**, **1c** and **1e** have been determined by a single crystal X-ray diffraction method.

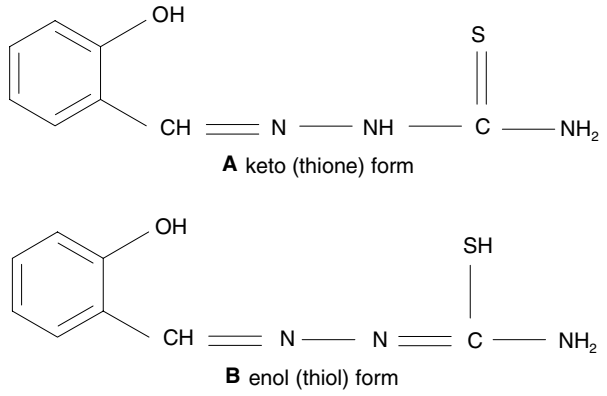
1. Introduction



The chemistry of thiosemicarbazones, mixed hard–soft nitrogen–sulfur chelating ligands, has attracted considerable interest primarily due to their biological activities. Those activities have been correlated with their metal-chelating abilities and reductive capacity. Also, such complexes are considered important because of their potential antibacterial, antiviral and antitumor activities [1,2].

Salicylaldehyde thiosemicarbazone [3] can exist in two tautomeric forms A and B (Scheme 1). In form A it can act as a tridentate ligand by coordinating either through hydroxyl–O, after losing its proton, and by imino N and thiocarbonyl S or as a doubly negatively charged tridentate ligand by losing another proton from the mercapto group of tautomeric form B.

Chemistry of nitrogen–sulfur chelating ligands bound to Mo at higher oxidation states is a field of current interest. These studies have been considered even more important after the revelation that several enzymes like DMSO reductase, xanthine oxidase and other oxotransferases in their prosthetic groups contain Mo(IV), Mo(V) or Mo(VI) ions coordinated by nitrogen, oxygen

Scheme 1.

or sulfur donor atoms of a macromolecular ligand system [4–6].

For some time our laboratory has been active in this field and has already reported syntheses and characterizations of several new Mo(VI) and Mo(V) complexes with ONS, ONO or ONN chelating ligand systems [7–9].

This paper presents a study of the $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(D)]$ and $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(D)]$ complexes in which the Mo atom is coordinated by a tridentate ONS salicylaldehyde thiosemicarbazone ligand and one donor molecule D (CH_3OH, γ-picoline, pyridine). To our knowledge the syntheses and structures of $[MoO_2(L)(H_2O)]Cl \cdot H_2O$ [10], $[MoO_2(L)(MeOH)]$ [11] and $[MoO_2(HL')(X)]$-(H_2L' = tridentate ONN salicylaldehyde *S*-methylisothiosemicarbazone and X = MeOH, EtOH and py), and only the synthesis of $[MoO_2(L)(X)]$, where L = salicylaldehyde thiosemicarbazone and X = γ-picoline, imidazole have been reported so far [12].

2. Experimental

The starting complex $[MoO_2(C_5H_7O_2)_2]$ and salicylaldehyde thiosemicarbazone were prepared as described in the literature [13]. 4,4′-Bipyridine, pyridine and γ-picoline were of reagent grade and used as purchased. Methanol was dried over magnesium ethoxide, acetonitrile and dichloromethane over P_2O_5.

C, H and N analyses were provided by the Analytical Services Laboratory of Rudjer Bošković Institute, Zagreb. Molybdenum was determined according to the already known method [14]. Infrared spectra were recorded in KBr with an FTIR 1600 Fourier transform spectrophotometer in the 4500–450 cm^{-1} region. Thermogravimetric analyses were measured on a Mettler TG 50 thermobalance using aluminum crucibles under oxygen atmosphere with a heating rate of 5 °C min^{-1}. For all experiments the temperature ranged from 25 to 600 °C. The results were developed by applying the Mettler STAR^e 6.1 programme.

2.1. Syntheses of molybdenum(VI) complexes

2.1.1. Synthesis of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_n$ (1) and $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(CH_3OH)]$ (1a)

A mixture of $[MoO_2(C_5H_7O_2)_2]$ (0.15 g, 0.46 mmol) and salicylaldehyde thiosemicarbazone (0.09 g, 0.46 mmol) in dry acetonitrile (20 cm^3) (**1**) (or dry methanol, 25 cm^3 for **1a**) was warmed up for 4 h for **1** and 2 h for **1a**.

Whereas the yellowish-brown product **1** deposited during warming of the acetonitrile solution, the methanolic solution should be evaporated to one-third of its volume and upon standing at room temperature for few days the orange crystals of **1a** were obtained and filtered off.

(**1**) Yield: 0.09 g, 61%. *Anal.* Calc. for $C_8H_7MoN_3O_3S$: C, 29.9; H, 2.2; Mo, 29.9; N, 13.1; S, 10.0. Found: C, 29.9; H, 2.1; Mo, 29.4; N, 13.1; S, 10.1%.

2.1.2. Synthesis of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_2$ (1b)

A mixture of $[MoO_2(C_5H_7O_2)_2]$ (0.15 g, 0.46 mmol) and salicylaldehyde thiosemicarbazone (0.09 g, 0.46 mmol) in dry CH_2Cl_2 (150 cm^3) was warmed up for 14 h. The dark red crystals **1b** were deposited during the warming of the reaction mixture. The same product can be obtained by warming of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(CH_3OH)]$ in dry CH_2Cl_2.

Yield: 0.09 g, 61%. *Anal.* Calc. for $C_{18}H_{22}Mo_2N_6O_8S_2$: C, 29.9; H, 2.2; Mo, 29.9; N, 13.1; S, 10.0. Found: C, 29.9; H, 2.1; Mo, 30.5; N, 13.1; S, 10.1%.

2.2. X-ray crystallography

Single crystals of complexes **1b**, **1c** and **1e** were grown by slow evaporation of solutions obtained from the above described preparations. Intensity data were collected on an Oxford Diffraction Xcalibur CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.7107$ Å), using 1° ω-scans at a crystal to detector distance of 50 mm and 100, 40 and 10 s exposure times per frame for **1b**, **1c** and **1e**, respectively. Data were reduced using the CrysAlis RED program [15].

Crystal data, experimental conditions, details of structure determination and final refinement parameters are summarized in Table 1.

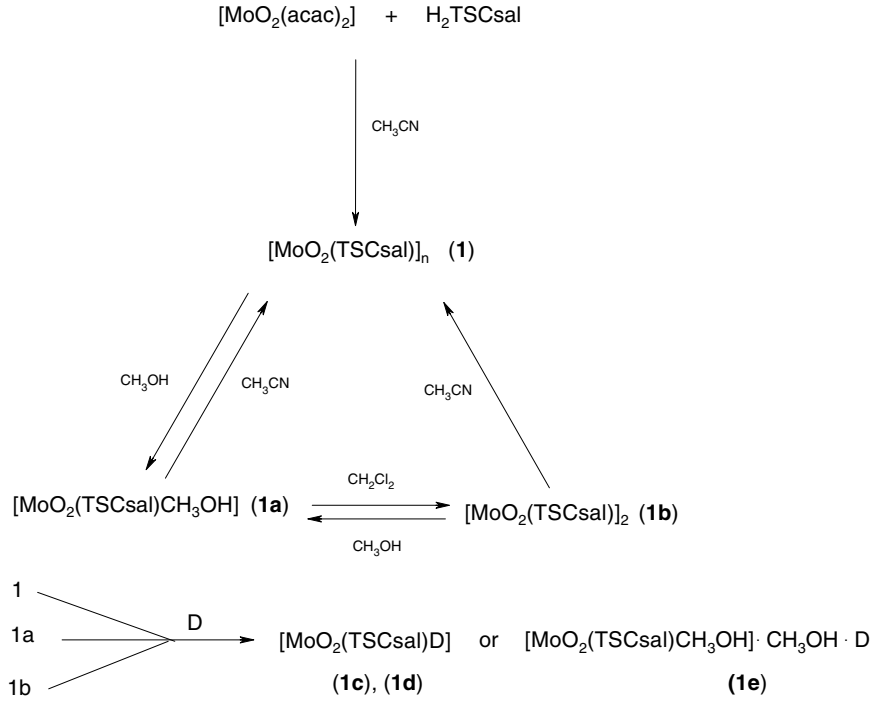
In all structures the molybdenum atoms were located by the Patterson method while the remaining non-hydrogen atoms were found in subsequent difference Fourier maps. In the structure of **1c** two crystallographically independent complex molecules, denoted **A** and **B**, were located in the asymmetric unit. Refinements in which all non-hydrogen atoms were treated anisotropically were performed by the full-matrix least-squares method based on the F^2 values against all reflections. The final Fourier maps revealed positions of all H atoms but some with poor geometry. Therefore, all hydrogen atoms attached to carbon atoms were generated on geometrical grounds. The hydrogen atoms bound to the nitrogen and oxygen atoms were refined isotropically, except H14 attached to oxygen atom O5 of the solvent methanol molecule in **1e**, which was kept fixed during the refinement.

All calculations were performed on an IBM ThinkPad microcomputer (Pentium II processor, 300 MHz) using SHELXS97 [16] and SHELXL97 [17] programs. The molecular structure drawings were prepared using ORTEP [18] and PLATON [19].

[1] The compound was dried before analysis since it loses methanol at room temperature.

3. Results and discussion

3.1. Syntheses of the complexes



In this paper, we describe syntheses (Scheme 2) and structures of several dioxomolybdenum(VI) complexes coordinated by the tridentate ONS (or ONN) salicylaldehyde thiosemicarbazone ligand.

The yellowish-brown polymeric complex $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_n$ (**1**) was obtained by the reaction of $[MoO_2(C_5H_7O_2)_2]$ with a stoichiometric amount of salicylaldehyde thiosemicarbazone, L, in dry acetonitrile. Its IR spectrum showed a characteristic strong vibration at 812 cm^{-1} which was absent in the case of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(D)]$ (D = CH_3OH in **1a**; γ-pic in **1c**; py in **1d**) and in $[MoO_2\text{-}\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)]\cdot CH_3OH\cdot$ 1/2bpy (bpy = 4,4′-bipyridine in **1e**). Also, $[MoO_2\text{-}\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_n$ showed a single stretching frequency at 915 cm^{-1} instead of a doublet characteristic of the presence of *cis*-MoO_2 group, as found in $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(D)]$ (at 937 and 896 cm^{-1} in **1a**, at 918 and 890 cm^{-1} in **1c**, at 926 and 898 cm^{-1} in **1d** and at 932 and 890 cm^{-1} in **1e**) so that the stretching frequency at 915 cm^{-1} in (**1**) was assigned to ν(Mo=O) while that at 812 cm^{-1} to the weakened ν(Mo=O) present in the bridging Mo–O → Mo moiety. These observations strongly suggests that the polymerization of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]$ is realized via oxo bridging as found in $[MoOL(LH)]_n$ (L = diacetyldihydrazone) [20]. If the same reaction was carried out in methanol or in dry dichloromethane we were able to isolate monomeric orange crystals of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}\ (CH_3OH)]$ (**1a**) and the dark red crystalline product of $[MoO_2\text{-}\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_2$ (**1b**), respectively. The dimeric structure of **1b** was confirmed by X-ray analysis. The strong stretching frequency at 840 cm^{-1}, found in its IR spectrum, is characteristic of the presence of a Mo_2O_{2b} group [21]. The behavior of the complex $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(CH_3OH)]$ (**1a**) is different, it undergoes a substitution reaction of the type

$$[MoO_2\{C_6H_4(O)CH\cdot NNC(S)NH_2\}(CH_3OH)] + D \rightarrow [MoO_2\{C_6H_4(O)CH\cdot NNC(S)NH_2\}(D)] + CH_3OH$$

where D is a Lewis base such as pyridine or γ-picoline.

In all complexes (except **1e**) molybdenum is coordinated by two terminal (O_t), by ONS atoms of salicylaldehyde thiosemicarbazone, while the sixth coordination site is occupied by methanol in **1a**, γ-picoline in **1c** and a pyridine molecule in **1d**. Only in $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)]\cdot CH_3OH\cdot$ 1/2bpy (**1e**), is the salicylaldehyde thiosemicarbazone coordinated to molybdenum through ONN atoms, and the sixth coordination site around molybdenum is likewise completed by the methanol molecule. As the deprotonation of the ligand-NH_2 group occurs in alkaline media [22], in our case the presence of acetylacetone,

Scheme 2. TSCsal = salicylaldehyde thiosemicarbazone; D: py = pyridine (**1c**) γ-pic = γ-picoline (**1d**); bpy = 4,4′-bipyridine (**1e**); acac = acetylacetonate ion.

an evidently good proton acceptor and 4,4′-bipyridine as a strong Lewis base, gives favourable conditions for such deprotonation. Most probably this is one of the reasons for obtaining the above mentioned adduct $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot CH_3OH \cdot 1/2bpy$.

The thermal analysis data for $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(D)]$ (D = pyridine in **1d** or methanol in **1a**) revealed two main processes: (1) loss of coordinated D molecules [148–182 °C **1d**; 69–100 °C **1a**], and (2) complex decomposition [258–488 °C **1d**; 249–472 °C **1a**]. In the case of complexes $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(\gamma\text{-pic})]$ (**1c**) and $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot CH_3OH \cdot 1/2bpy$ (**1e**) loss of γ-picoline or 4,4′-bipyridine was accompanied by the decomposition of the salicylaldehyde thiosemicarbazone ligand without any stable intermediate product (174–492 °C in **1c**; 203–543 °C in **1e**). The compound **1e** was already losing methanol at room temperature.

The thermal analysis of complexes $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(CH_3OH)]_2$ (**1a**) and $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_n$ (**1**) showed that their ligands were decomposing within the ranges 247–476 and 249–480 °C, respectively.

3.2. Structural studies

Complex molecules found in the crystal structures of $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_2$ (**1b**), $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(\gamma\text{-pic})]$ (**1c**) and $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot (CH_3OH) \cdot 1/2bpy$ (**1e**) are shown in Fig. 1, relevant bond lengths involving non-hydrogen atoms are listed in Table 2, and hydrogen bonding parameters in Table 3.

The crystal structure of complex **1b** is built up of dinuclear centrosymmetric complex molecules $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}]_2$, with two dioxomolybdenum–salicylaldehyde thiosemicarbazone units bridged through oxo-oxygen atoms. In such a way a planar asymmetric bridge between Mo atoms is formed. Each bridging oxygen atom is more closely associated with a single molybdenum, with the bond lengths Mo–O1 = 1.741(4) [which is significantly longer than the bond to the terminal oxygen, Mo–O2 = 1.698(5) Å] and Mo–O1^i = 2.516(5) Å, ($i = 1 - x$, $1 - y$, $2 - z$). The Mo–Mo distance of 3.424(1) Å shows that in such a d^0 system there is not any possible metal-to-metal interaction. Octahedral coordination of molybdenum is completed by the tridentate salicylaldehyde thiosemicarbazone ligand bonded to the Mo_2O_4 through the oxygen atom from the deprotonated –OH group [Mo–O3 = 1.895(4) Å], imine nitrogen atom [Mo–N3 = 2.224(5) Å] and sulfur atom from the deprotonated mercapto group [Mo–S1 = 2.410(2) Å]. By chelating the Mo atom, the tridentate ligand forms one six- and one five-membered ring. The bond length values within the Schiff base are as expected and similar to those found in the free ligand [3,10].

oxygen O2 and hydrazinic nitrogen N2 atoms of neighbouring molecules, thus forming sheets of molecules parallel to the crystallographic *bc* plane (Fig. 2).

The complexes $[MoO_2\{C_6H_4(O)CH{:}NNC(S)NH_2\}(\gamma\text{-pic})]$ (**1c**) and $[MoO_2\{C_6H_4(O)CH{:}NNHC(S)NH\}(CH_3OH)] \cdot CH_3OH \cdot 1/2bpy$ (**1e**) are mononuclear molecules with a *cis*-MoO_2 core surrounded by the tridentate salicylaldehyde thiosemicarbazone ligands. However, the molybdenum atoms are differently coordinated. In **1c** the molybdenum atom is octahedrally surrounded by two terminal oxo-oxygen atoms, O1 and O2, and by oxygen O3, imine nitrogen N3 and sulfur atom S1 belonging to the ligand molecule, and finally by nitrogen atom N4 from the coordinated γ-picoline molecule. In **1e** molybdenum is coordinated by the deprotonated amide nitrogen N1 instead of the thiocarbonyl atom S1. Octahedral coordination is completed by oxygen O4 from the methanol molecule. In both structures the values of the Mo = O_t bonds, ranging from 1.697(2) to 1.717(2) Å, are usual for *cis*-MoO_2 complexes. Similarly to **1b** in both independent molecules of **1c** as well as in **1e** the tridentate ligands, occupying meridional positions, form one six- and one five-membered chelate ring, with Mo–O3 bond lengths varying from 1.932(3) to 1.953(3) Å, and Mo–N3 bond lengths, with the imine nitrogen *trans* to the terminal oxo-oxygen ligand, ranging from 2.284(4) to 2.289(4) Å. In **1e** the Mo–N1 bond, *cis* to the oxo ligands, is significantly shorter, amounting to 2.057(2) Å. The longest bonds in the molybdenum coordination sphere in **1c** are those

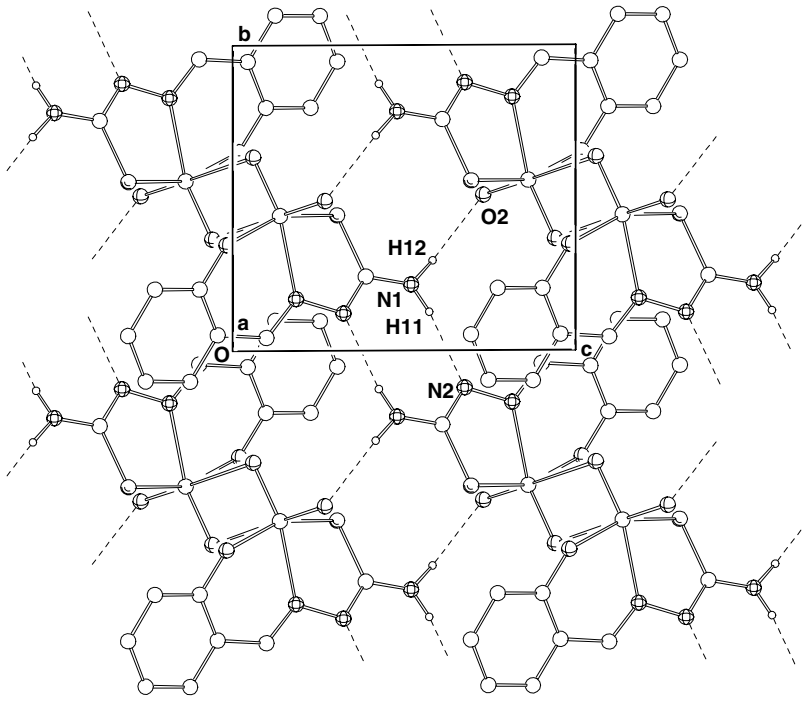

Fig. 2. Hydrogen bonding scheme in **1b** projected along the *a* axis. Sheets of molecules are formed parallel to the *bc* plane.

with sulfur atoms S1, [2.433(1) and 2.435(1) Å], and to the γ-picoline nitrogen atoms [2.412(4) and 2.431(4) Å], while in **1e** the longest bond around Mo is that to the methanol [2.325(2) Å].

Comparing the bond lengths within the thiosemicarbazone ligands it is obvious that the ligand exists in two tautomeric forms. Bond lengths C1–N2, observed in **1b** and **1c**, varying from 1.300(7) to 1.318(6) Å, are significantly shorter than the analogous bond of 1.360(3) Å in **1e**, while the bonds C1–S1, varying from 1.752(5) to 1.763(7) Å (**1b** and **1c**) are longer than that of 1.707(2) Å, observed in **1e**.

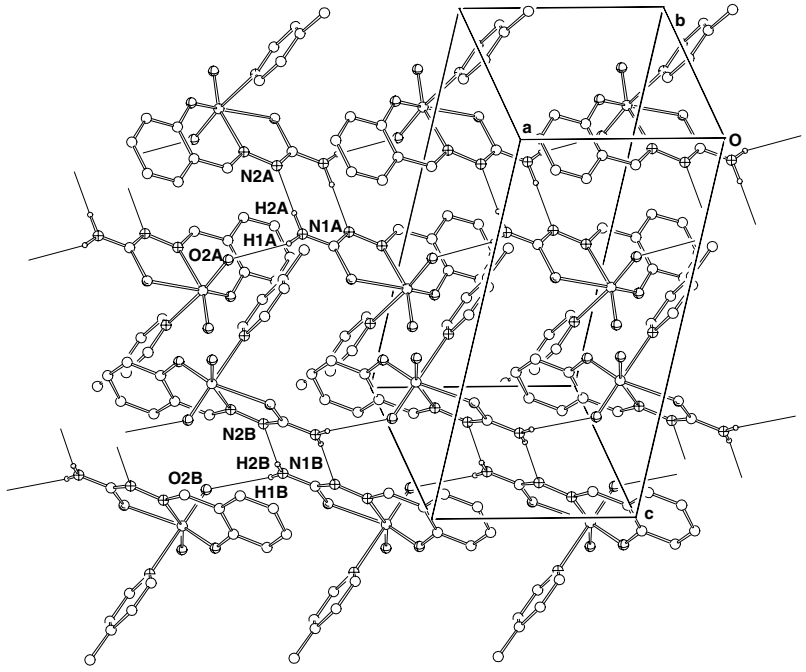

Fig. 3. Hydrogen bonding in **1c**. Symmetry independent double chains of molecules are formed in the *a* axis direction.

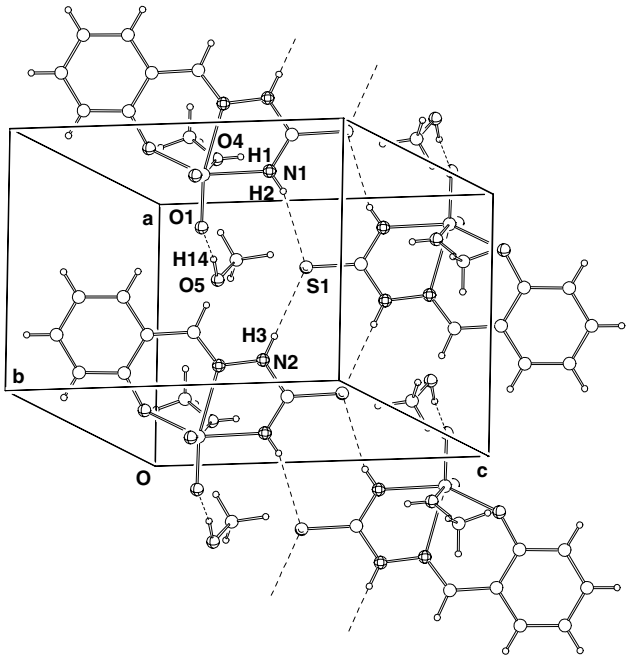

Fig. 4. Hydrogen bonding in **1e**. Chains of molecules are formed along the *a* axis direction, parallel to the (0 1 1) plane, with a solvent methanol hydrogen bonded to a terminal oxo-oxygen atom. The 4,4′-bipyridine solvent molecule is omitted for clarity.

The molecules in **1c** are mutually hydrogen bonded in a similar way as in **1b**, thus forming double chains of molecules in the *a* axis direction (Fig. 3). In **1e** chains of molecules along the *a* axis direction, parallel to the (0 1 1) plane, are formed through intermolecular hydrogen bonds N1–H2 ⋯ S1 and N2–H3 ⋯ S1 between –NH groups and thiocarbonyl sulfur atoms, (Fig. 4). The solvent methanol molecule is hydrogen bonded to a terminal oxo-oxygen atom, O5–H14 ⋯ O1. Additionally, these chains are interconnected through H-bonds O4–H1 ⋯ N4 between the hydroxy group of a coordinated methanol molecule and a 4,4′-bipyridine molecule.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 251692 for compound **1b**, CCDC 251693 for compound **1c** and CCDC 251694 for compound **1e**. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (internat.) 144 1223/336 033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk].

Abstract

Dimeric complexes, bis[dihalo(2-dimethylaminomethyl-3-hydroxypyridine)-copper(II)], $[Cu(dmamhp)X_2]_2$, were prepared from the reaction of copper(II) halide (Cl, Br) with 2-dimethylaminomethyl-3-hydroxypyridine (dmamhp) in methanol, and their single crystal structures were determined. The chloro compound was crystallized as green needles in space group $P\bar{1}$ of the triclinic system with $Z = 1$ and unit cell dimensions $a = 7.3420(12)$, $b = 9.196(3)$, $c = 9.817(2)$ Å, $\alpha = 115.16(3)°$, $\beta = 92.433(16)°$ and $\gamma = 111.59(2)°$. The corresponding values for the bromo complex are $a = 7.5652(15)$, $b = 9.191(3)$, $c = 9.7926(13)$ Å, $\alpha = 113.912(14)°$, $\beta = 92.396(14)°$ and $\gamma = 111.24(2)°$. The chloro compound consists of a dimeric molecule $[Cu(dmamhp)Cl_2]_2$, in which copper(II) ions are bridged by chloride ligands. The geometry at the copper is distorted trigonal bipyramidal with the pyridine nitrogen [N9], terminal chloride [Cl1] and the bridging chloride [$Cl2^i$] in the equatorial site; and with the amine nitrogen [N9] and the remaining bridging chloride [Cl2] in the axial site. The dimer units are held through the hydrogen bonding between the hydroxy group in a pyridine ring and the terminal chloride ion. The bromo compound shows a similar structure. The magnetic susceptibility data of both compounds were followed by the Bleaney–Bowers dimer equation with $J = -11.17$ and -21.11 cm^{-1} for the chloro and bromo complexes respectively, indicating that there are antiferromagnetic interactions between the copper(II) ions in the solid state.

Keywords: Binuclear 5-coordinated copper(II) complex; Antiferromagnetic interaction; Halide bridging copper(II) complex

1. Introduction

Binuclear five-coordinated copper(II) complexes with monoatomic bridges have been extensively studied, especially those containing halo (chloro and bromo) bridging ligands to develop a correlation between molecular structure and magnetic behavior [1]. The magneto-structural correlations in these kinds of complexes are worthy of constructing molecular-based functional materials [2] and proposing model compounds that mimic the biological active site in copper proteins [3]. This family of compounds show structures ranging from square pyramid to trigonal bipyramid with a variety of bond distances (Cu–X) and bond angles (Cu–X–Cu) in the resulted copper(II) dimer units. However, the structures of these compounds strongly depend on coordinated environments, such as the nature of the coordinated ligand and the crystal packing forces resulting from the existence of the inter- or intra-molecular hydrogen bond in the unit cell. The small changes in structure can have important effects on the magnetic properties of this system [4]. The magnetic behaviors are influenced by the Cu···Cu separation, Cu–X bond distances and Cu–X–Cu angles formed by the bridging CuX moiety in a Cu_2X_2 dimer unit.

doi:10.1016/j.poly.2004.12.004

We selected 2-dimethylaminomethyl-3-hydroxypyridine (dmamhp) and reacted it with copper(II) halides since the dmamhp ligand is interesting in that two methyl groups on the amine nitrogen influence the $Cu–N_{amine}$ bond strength and that the hydroxy group on the pyridine ring can form a hydrogen bond with the halide ions in the unit cell. Herein, binuclear copper(II) complexes, $[Cu(dmamhp)X_2]_2$ where X = Cl and Br, were prepared, and the structures were determined. The magnetic properties (EPR and magnetic susceptibility) were examined to investigate the magneto-structural correlation of the prepared compounds.

2. Experimental

2.1. Materials and synthesis

All reagents and solvents were obtained commercially from either Aldrich or Sigma Chemicals. $[Cu(dmamhp)Cl_2]_2$ was prepared from the direct reaction of 2-dimethylaminomethyl-3-hydroxypyridine (dmamhp) with $CuCl_2$. A solution of $CuCl_2$ (0.1 mmol) in 20 ml of absolute methanol was added dropwise to 20 ml of dmamhp (0.1 mmol) absolute methanol solution. The solution changed to a dark blue color immediately. The resulting mixture was stirred for approximately 2 h and then allowed to stand at room temperature. The crystals suitable for X-ray analysis were obtained by slow evaporation from this solution. $[Cu(dmamhp)Br_2]_2$ was obtained by an analogous method using $CuBr_2$.

2.2. Physical measurements

The EPR spectral measurements were carried out both for powered samples and for frozen glass samples (DMF/CH_2Cl_2) at 77 K using an ESP-300S EPR spectrometer at the X-band frequency. The field modulation frequency was 100 kHz, and DPPH was used as a reference. Magnetic susceptibility data was collected from 4 to 300 K by the SQUID method using the Magnetic Property Measurement System (MPMS7) Quantum Design. The data was corrected for the diamagnetism of the constituent atoms using Pascal's constants and for the temperature-independent paramagnetism of the copper estimated to be 60×10^{-6} cgsu/Cu atom.

2.3. X-ray single crystal structure determination

Crystals of $[Cu(dmamhp)Cl_2]_2$ and $[Cu(dmamhp)Br_2]_2$ for X-ray analysis were obtained by slow evaporation from the methanol solution. The crystals were mounted and aligned on a CAD-4 diffractometer [5]. The accurate cell parameters were refined from the setting angles of 21 reflections with $10.0° < \theta < 13.59°$ for $[Cu(dmamhp)Cl_2]_2$ and from the setting angles of 20 reflections with $10.16° < \theta < 14.09°$ for $[Cu(dmamhp)Br_2]_2$.

All non-H atoms were found by the direct method, and their parameters were refined successfully by full matrix least-squares. The weights used for least-squares refinement were $w^{-1} = [\sigma^2(F_o)^2 + (0.0938P)^2]$ for $[Cu(dmamhp)Cl_2]_2$ and $w^{-1} = [\sigma^2(F_o)^2 + (0.0804P)^2]$ for $[Cu(dmamhp)Br_2]_2$, where P is a function of intensity. H atoms were geometrically positioned and fixed. Empirical absorption corrections were applied to the intensity data for the prepared crystals by using ψ-scans. Data collection and cell refinement: CAD4 EXPRESS [6]. Data reduction: XCAD4 [7]. Program used to solve structure and to refine structure: SHELXS97 and SHELXL97 [8]. Molecular graphics: ORTEP-3 for WINDOWS [9].

3. Results and discussion

3.1. Description of the structures

The crystallographic data and structure refinement parameters of the titled compounds are summarized in Table 1. Both compounds consist of dimeric $[Cu(dmamhp)X_2]_2$ where X = Cl and Br, and each dimer unit is connected through the hydrogen bond in the cell. The selected bond distances and bond angles in these two compounds are summarized in Table 2. A typical ORTEP view of $[Cu(dmamhp)Cl_2]_2$ including the atomic numbering scheme is shown in Fig. 1. The Cu–Cl–Cu bridge is formed by atoms Cu, Cl2, $Cl2^i$ and Cu^i (symmetry code: (i) $-x + 1, -y + 1, -z$); and the bridging Cu_2Cl_2 unit is planar with a crystallographic inversion center, which is located in the center of the two copper(II) atoms. The Cu–Cl distances in the bridging unit are 2.298(2) and 2.639(2) Å, and the Cu–Cl–Cu angle is 94.75°. These values are normal as observed in other dimeric copper chloride compounds [1g,10].

The Cu, N1, Cl1 and $Cl2^i$ atoms are quite coplanar, there being a deviation of the Cu atom from the N1–Cl1–$Cl2^i$ plane of only 0.04 Å. This out-of plane deviation value was obtained from the best least-square method. The N9–Cu–Cl2 angle was obtained to be 174.02(19)°. These results indicate that the geometry around the Cu center is the distorted trigonal bipyramid with N1, Cl1 and $Cl2^i$ forming the equatorial site, and N9 and Cl2 occupying the axial one. The crystal structure of $[Cu(dmamhp)Br_2]_2$ complex is similar to that of $[Cu(dmamhp)Cl_2]_2$ with the deviation out of the equatorial plane of the Cu atom being 0.07 Å.

In the $[Cu(dmamhp)Cl_2]_2$ compound, the Cu–N9 bond length of 2.065(6) Å is larger than the Cu–N1 value of 2.035(6) Å. This is not consistent with the expectation that the basicity of the amine nitrogen [N9] is greater than that of the pyridine nitrogen [N1]. Moreover, the electron donating ability of the methyl groups

on N9 presumably leads to the enhancement of electron density at N9 relative to that at N1. This observed longer distance of Cu–N9 than that of Cu–N1 can be explained by the fact that the steric hinderances of the methyl groups at N9 cause a lengthening of the Cu–N9 bond and lead to a smaller angle of C8–N9–Cu [104.4(4)°] than that of C6–N1–Cu [113.1(5)°]. Similar results are found in $[Cu(dmamhp)Br_2]_2$.

A molecular packing diagram for the dimeric $[Cu(dmamhp)Cl_2]_2$ compound is shown in Fig. 2. The distance between the hydrogen atom [HO7] in the hydroxyl group in the dmamhp ligand and the adjacent terminal chloride [Cl1] is 2.32 Å, and the O7···Cl1^{ii} (symmetry code: (ii) $x-1, y-1, z$) separation is 3.061(6) Å, which is smaller than the sum of the van der Waals radii of oxygen [~1.5 Å] and the chlorine [1.7–1.9 Å] atom. Furthermore, the O7–HO7···Cl1^{ii} angle is 151.1°. These results imply that there is a hydrogen bond formation between the hydroxyl group in the dmamhp ligand and the terminal chloride. The dimer units are held together in an one dimensional network through these hydrogen bondings. The hydrogen bond distances and bond angles are summarized in Table 3. The $[Cu(dmamhp)Br_2]_2$ complex shows a similar hydrogen bonded network in the crystal.

3.2. EPR and magnetic properties

EPR spectra were obtained both for solid and for frozen glass samples (DMF/CH_2Cl_2) at 77 K. The powdered EPR spectrum of $[Cu(dmamhp)Cl_2]_2$ shows a sharp and symmetric singlet at $\langle g \rangle = 2.007$, whereas the anisotropic g values were well resolved in $[Cu(dmamhp)Br_2]_2$ showing a typical axial symmetry. EPR spectra of frozen solution for both compounds exhibited well-defined hyperfine structure with parallel ($g_\parallel$) and perpendicular ($g_\perp$) components, indicating that no significant inter-dimer interactions are present. The resulted EPR parameters are summarized in Table 4.

The magnetic susceptibilities were collected as a function of temperatures (4–300 K). The magnetic susceptibility data of $[Cu(dmamhp)Br_2]_2$ increases to a maximum at around 18 K and decreases as the temperatures decreases, as shown in Fig. 3. The magnetic susceptibility data of $[Cu(dmamhp)Cl_2]_2$ exhibited a different behavior. The magnetic susceptibility data in the temperature region of 4–300 K increases as the temperatures decreases, but it does not follow the

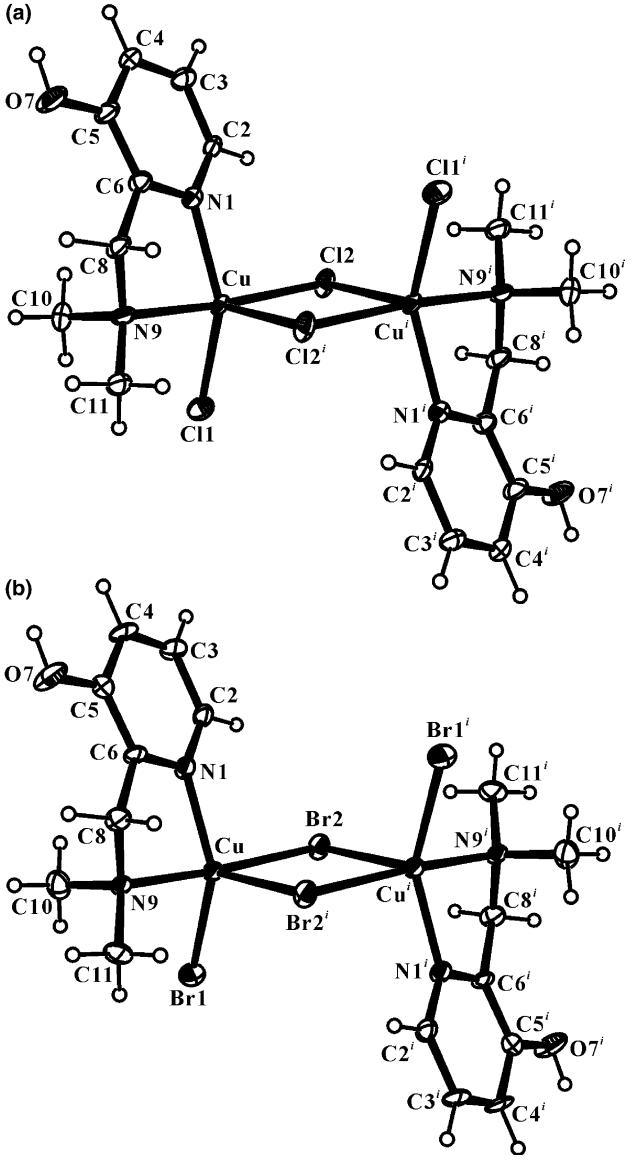

Fig. 1. ORTEP diagrams of $[Cu(dmamhp)Cl_2]_2$ (a) and $[Cu(dmamhp)Br_2]_2$ (b), showing the atom-numbering scheme (Symmetry code: (i) $-x+1, -y+1, -z$).

Curie–Weiss law. However, the data of both compounds can be fit to the Bleaney–Bowers dimer equation [11]

$$\chi_M^{exptl} = \left(\frac{2N\beta^2g^2}{kT}\right)\left\{3+\exp\left(-\frac{J}{kT}\right)\right\}^{-1}(1-\rho) + \left(\frac{N\beta^2g^2}{2kT}\right)\rho + 2N\alpha, \quad (1)$$

where ρ is the mass proportion of uncoupled impurity assumed to follow a Curie law, and the temperature independent paramagnetism $N\alpha$ was taken as 60×10^{-6} cm^3/mol per copper(II) ion. The other symbols have their usual meanings.

The best fit calculated values are $2J = -42.22$ cm^{-1} and $g = 2.134$ for the $[Cu(dmamhp)Br_2]_2$ compound, and $2J = -22.34$ cm^{-1} and $g = 2.130$ for the $[Cu(dmamhp)Cl_2]_2$ compound. The calculated g values are in good agreement with those experimental values obtained by EPR experiments. The calculated singlet–triplet exchange coupling constants ($2J$) clearly show that there are antiferromagnetic interactions between the copper metal ions in both of the compounds in solid state. Fig. 3 shows the excellent agreement between the theoretical Bleaney–Bowers dimer equation and the experimental data in $[Cu(dmamhp)Br_2]_2$.

Hatfield [12] reported the effect of bridge geometry on the singlet–triplet exchange coupling in ligand bridged copper(II) dimers, in which the exchange coupling depended on the angle at the bridging ligand and on the length of the superexchange pathway. In the case of chloro bridged copper(II) dimers, singlet–triplet exchange coupling constant ($2J$) smoothly correlated with the quotient of structure parameters φ/r, where φ is the angle at the bridging chloride atom and r is the long out-of-plane bond distance [12]. Alves et al. [1g] showed this smooth correlation in a variety of the chloro bridged copper(II) dimers. As the quotient φ/r increases from 28 to 40° Å^{-1}, $2J$ values rise from -17 cm^{-1} to a maximum of $+6.3$ cm^{-1} at 32.62° Å^{-1} and fall down to -82.6 cm^{-1} at 40° Å^{-1} of the quotient value. On the ba-

Table 4
EPR and magnetic susceptibility parameters for the complexes, $[Cu(dmamhp)Cl_2]_2$ and $[Cu(dmamhp)Br_2]_2$

Compound	Solution[a]		Powder[a]	Magnetic property[b]	
	g Value	A Value ($\times 10^4$ cm^{-1})	g Value	J (cm^{-1})	g Value
$[Cu(dmamhp)Cl_2]_2$	$g_{\parallel} = 2.275$	$A_{\parallel} = 146$	$g_{zz} = 2.254$ $g_{yy} = 2.083$	−11.17	2.130
	$g_{\perp} = 2.053$	$A_{\perp} = 27$	$g_{xx} = 2.029$		
$[Cu(dmamhp)Br_2]_2$	$g_{\parallel} = 2.288$ $g_{\perp} = 2.057$	$A_{\parallel} = 156$ $A_{\perp} = 31$	$\langle g \rangle = 2.007$	−21.11	2.134

[a] EPR parameters were obtained at 77 K.
[b] These values were calculated by the Bleaney–Bowers equation.

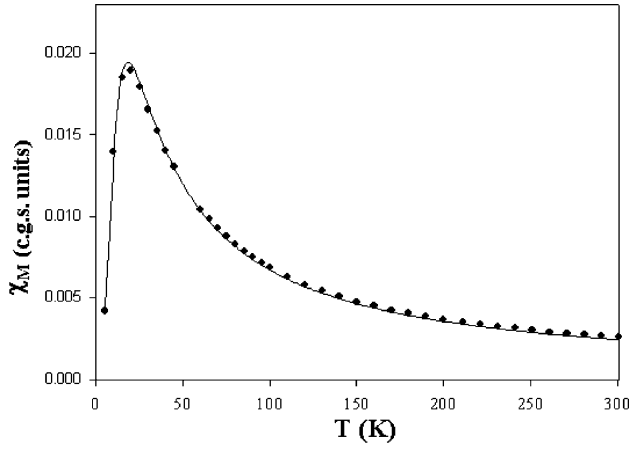

Fig. 3. A plot of magnetic susceptibilities vs. temperature in the temperature region of 4–300 K for $[Cu(dmamhp)Br_2]_2$. Calculated (—) and experimental (•) magnetic data are shown. Calculated curve with $J = -21.11$ cm^{-1}, $g = 2.134$ and $\rho = 0.0205$ was obtained by the Bleaney–Bowers equation, $\chi_M = (2N\beta^2g^2/kT)[3 + \exp(-J/kT)]^{-1}(1-\rho) + (N\beta^2g^2/2kT)\rho + 2N\alpha$.

sis of this correlation, the antiferromagnetic coupling is characterized for the values of the quotient lower than 32.6 and higher than 35.0° Å^{-1}, whereas the ferromagnetic coupling appears when this quotient is between these two values. The calculated antiferromagnetic coupling constants of $[Cu(dmamhp)Cl_2]_2$ ($2J = -22.34$ cm^{-1} and $\varphi/r = 35.90°$ Å^{-1}) fit well in this correlation.

In the bromo bridged copper(II) complexes, $2J$ values do not correlate either with the bridging angle or with the bridged Cu–Br distances. However, in spite of the smaller quotient of $[Cu(dmamhp)Br_2]_2$ ($\varphi/r = 34.02°$ Å^{-1}) than that of the chloro compound and the longer Cu···Cu contact distance of bromo compound in the bridging unit [3.887 Å] than that of chloro compound [3.640 Å], it was found that the exchange coupling constant of $[Cu(dmamhp)Br_2]_2$ ($2J = -42.22$ cm^{-1}) is larger than that of the analogous chloro compound. This relatively larger antiferromagnetic interaction in $[Cu(dmamhp)Br_2]_2$ is explained on the basis of the fact that the magnetic orbital of bromine atom contacts more easily with the copper atom than that of chlorine to provide a superexchange Cu–Br–Cu pathway. Contact of bromine atoms has been discussed in some copper(II) complexes. We have recently reported the magnetic properties of sparteinium tetrahalocuprate(II) compounds and suggested that the antiferromagnetic superexchange in $CuBr_4$ was occurred through a Cu–Br···Br–Cu contact, whereas the magnetic superexchange via a Cu–Cl···Cl–Cu contact was not likely to be observed [13]. A similar Cu–Br···Br–Cu two bromide exchange pathway through Br···Br contact was reported in a bis(cyclophenylammonium) tetrabromocuprate(II) compound [14].

4. Conclusions

2-Dimethylaminomethyl-3-hydroxypyridine (dmamhp) reacts with CuX_2 (X = Cl and Br) to yield the halo-bridged dimeric $[Cu(dmamhp)X_2]_2$ compounds. The geometry around the copper(II) center in the dimeric unit is a distorted trigonal bipyramid, and the Cu–X–Cu bridge provides the magnetic superexchange pathway. There are no magnetic interactions between the dimer units even though the dimers are held together through the hydrogen bondings in the unit cell.

5. Supplementary material

Crystallographic data for the structures reported here have been deposited with the Cambridge Crystallo-

graphic Data Centre (Deposition Nos. CCDC-2244689 and CCDC-244690). The data can be obtained free of charge via www.ccdc.cam.ac.uk/perl/catreq/catreq.cgi (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Diphenyltin(IV) complexes of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate (Hqaldsme and Hqaldsbz): X-ray crystal structures of Hqaldsme and two conformers of its diphenyltin(IV) complex

Abstract

New organometallic tin(IV) complexes of the empirical formula $Sn(NNS)Ph_2Cl$ (NNS = anionic forms of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate) have been prepared and characterized by IR, electronic, ^1H NMR and ES mass spectroscopic techniques. The molecular structures of the 2-quinolinecarboxaldehyde Schiff base of *S*-methyldithiocarbazate (Hqaldsme) and its diphenyltin(IV) complex, $Sn(qaldsme)Ph_2Cl$, have been determined by X-ray diffraction. In the solid state, the ligand remains as the thione tautomer in which the dithiocarbazate chain adopts an *E*,*E* configuration and is almost coplanar with the quinoline ring. The $Sn(qaldsme)Ph_2Cl$ complex crystallizes in two distinctly different conformationally isomeric forms, each having the same space group but different lattice parameters. X-ray analysis shows that in each polymorph, the tin atom adopts a distorted octahedral geometry with the Schiff base coordinated to it as a uninegatively charged tridentate chelating agent via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. The two phenyl groups occupy axial positions and the chloride ligand occupies the sixth coordination position of the tin atom. The deprotonated ligand adopts an *E*,*E*,*Z* configuration in the complex.

1. Introduction

There have been a large number of studies on metal complexes of sulfur–nitrogen chelating agents such as Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid [1–6] and thiosemicarbazones [6–11]. Interest in these compounds has been stimulated by their interesting physical and chemical properties [12–14] and potentially useful biological activities [15–19]. However, the majority of work that has been reported so far involves complexes of these ligands with transition metal ions. Complexes of non-transition metal ions such as tin have received less attention. In recent years, organotin(IV) compounds have received much attention both in academic and applied research because of the ability of tin to afford stable bonds with carbon as well as with other hetero atoms. Since organotin complexes of Schiff base ligands have potential applications in organic synthesis, catalysis, medicinal chemistry and biotechnology [20–23] and as very little work has been done on

organotin(IV) compounds of Schiff bases derived from *S*-alkyl and *S*-aryldithiocarbazates, we report here the synthesis and characterization of two new diphenyltin(IV) complexes of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyl esters of dithiocarbazic acid together with the X-ray crystal structures of the free ligand, Hqaldsme, and two forms of its diphenyltin(IV) complex, Sn (qaldsme)$(Ph)_2Cl$.

2. Experimental

2.1. Reagents

Chemicals and solvents used were of analytical reagent grade and used without any further purification. 2-Quinolinecarboxaldehyde and diphenyltin(IV)dichloride were purchased from the Aldrich Chemical Company and *S*-methyl- and *S*-benzyldithiocarbazates were prepared according to published procedures [24,25].

2.2. Physical measurements

Microanalyses for C, H and N were performed by the Elemental Analysis Laboratory, National University of Singapore, Singapore. Molar conductances of ca. 10^{-3} M solutions of the complexes in DMSO were measured by means of a Jenway 4310 conductivity meter. The IR spectra in KBr discs and the electronic spectra either as Nujol mulls or in solution were recorded on a Perkin–Elmer 2000 FT-IR spectrometer and a Shimadzu MPC-3100 spectrophotometer, respectively. The ^1H NMR spectra of the tin(IV) complexes were run in $CDCl_3$ on a Bruker DPX 300 MHz spectrometer using TMS as an internal standard. The electrospray mass spectra were recorded on a Finnigan Model LCQ mass spectrometer.

2.3. Preparation of the ligands

The Schiff bases were prepared by following procedures similar to those reported previously [26].

2.4. Preparation of the complexes.

2.4.1. Preparation of syn- and anti-[Sn(qaldsme)Ph_2Cl]

Diphenyltin(IV) dichloride (0.51 g; 1.5 mmol) dissolved in boiling absolute ethanol (10 ml) was mixed with a hot solution of Hqaldsme (0.39 g; 1.5 mmol) in a mixture of absolute ethanol (100 ml) and dichloromethane (30 ml). The resulting yellow solution on being heated under reflux for 3 h yielded some yellow crystals (0.26 g) which were filtered off, washed with cold absolute ethanol and dried in a desiccator. X-ray analysis (vide Section 3) showed that this was the *syn*-form of the complex. The filtrate was refluxed for a further period of ca. 72 h during which time the colour of the solution became reddish-brown. On standing overnight, some brown crystals (0.11 g) were obtained. X-ray analysis showed that these were the *anti*-form of the [Sn(qaldsme)Ph_2Cl] complex. Both polymorphs of the complex gave very similar analytical data. *Anal.* Calc.

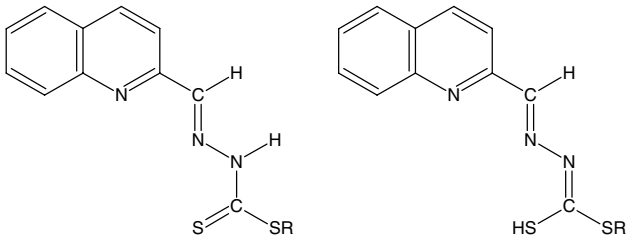
for [Sn(qaldsme)Ph_2Cl] ($C_{24}H_{20}N_3S_2SnCl$): C, 50.69; H, 3.54; N, 7.39. Found: C, 50.73; H, 3.58; N, 7.16%.

2.4.2. Preparation of [Sn(qaldsbz)Ph_2Cl]

The Schiff base (0.20 g; 0.6 mmol) dissolved in a mixture of absolute ethanol (25 ml) and dichloromethane (15 ml) was mixed with a hot solution of $SnPh_2Cl_2$ (0.20 g; 0.6 mmol) in absolute ethanol (10 ml). The yellow coloured solution on being heated for 30 min yielded a small amount of yellow crystals (0.05 g) which were filtered off. The filtrate was then heated under reflux for ca. 72 h during which time the colour of the solution changed from yellow to brown. Reduction of the volume of the reaction mixture to ca. 30 ml resulted in the deposition of some brown crystals which were filtered off and recrystallized from an acetonitrile–methanol mixture (90:10). Yield, 0.15 g. *Anal.* Calc. for [Sn(Hqaldsbz)Ph_2Cl] ($C_{30}H_{24}N_3S_2SnCl$): C, 55.88; H, 3.75; N, 6.51. Found: C, 55.76; H, 3.49; N, 6.62%.



2.5. Crystallography

Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf-Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the $\omega - 2\theta$ mode within the range $2° < 2\theta < 50°$. Empirical absorption correction (ψ scans) and data reduction were performed with the WINGX [27] suite of programmes. The structures were solved by direct methods with SHELX86 and refined by full-matrix least-squares analysis with SHELXL97 [28]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions. Drawings of each molecule were produced with ORTEP3 [29] or PLUTON [30]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1 and selected bond lengths appear in Tables 4 and 5.

3. Results and discussion

Compounds containing the thioamide —N—NH—C(=S) moiety are capable of exhibiting thione-thiol tautomerism and therefore the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazate (Fig. 1(a); R = —SCH_3, —$SCH_2C_6H_5$) can exist either as the thione form (**1a**) or the thiol form (**1b**) or as an equilibrium mixture of both forms. However, our previous studies [26] have shown that these ligands remain solely as the thione tautomer both in the solid state as well as in solution.

An X-ray crystal structure determination (see later) of Hqaldsme shows that it remains as an *E* isomer in the solid state but its ^{1}H NMR spectrum in DMSO-d_6 exhibits the sec. –NH– proton resonance at 13.65 ppm indicating that in a DMSO solution it rearranges to the *Z* isomer with the hydrogen atom on N(1) being intra-molecularly hydrogen bonded with the quinoline nitrogen atom, similar to that observed in the closely related 1-quinolinecarboxaldehydethiosemicarbazone [31].

(1a ; R = -CH_3, -$CH_2C_6H_5$) Thione form

(1b ; R=-CH_3, -$CH_2C_6H_5$) Thiol form

Fig. 1. The thione and thiol forms of the Schiff bases; Hqaldsme = the 2-quinolinecarboxaldehyde Schiff base of *S*-methyldithiocarbazate (R = CH_3) and Hqaldsbz = the 2-quinolinecarboxaldehyde Schiff base of *S*-benzyldithiocarbazate (R = $CH_2C_6H_5$).

Although, both in the solid state and in solution, the Schiff bases remain in their thione tautomeric forms, in an ethanolic solution and in the presence of diphenyltin(IV) dichloride, they quickly tautomerize to the thiol forms, deprotonate and coordinate with the tin atom forming stable diphenyltin(IV) complexes of the empirical formula, Sn(NNS)Ph_2Cl (NNS = deprotonated form of the Schiff base). The ready conversion of the Schiff bases from the thione tautomeric forms to the thiol forms in the presence of a metal ion followed by deprotonation and coordination to the metal may be attributed to the extra stability gained by them through π-electron delocalization along the –C–N–N–C–S– chains of the dithiocarbazate moieties. The thione-to-thiol evolution in the presence of metal ions has been found to be common to all Schiff bases derived from *S*-alkyl/aryl dithiocarbazates [1–6,32–34]. The closely related thiosemicarbazone ligand, 1-formylisoquinolinethiosemicarbazone, however, has been shown to react with metal ions in neutral media yielding complexes of both protonated and deprotonated [35] forms. On the other hand, Schiff bases derived from *S*-alkyl esters of dithiocarbazic acid, although they are structurally very similar to thiosemicarbazones, invariably coordinate to metal ions in their deprotonated forms even in the presence of mineral acids.

Reaction of diphenyltin(IV) dichloride with the Schiff bases in boiling absolute ethanol afforded crystalline diphenyltin(IV) complexes of empirical formula, Sn(NNS)Ph_2Cl (NNS = anionic form of the Schiff bases) which are quite stable in the atmosphere and could be stored in a desiccator over silica gel over a long period of time without any sign of decomposition. They are sparingly soluble in acetonitrile, chloroform,

dichloromethane and DMSO, but insoluble in methanol, ethanol and acetone. The complexes Sn(qaldsme)Ph_2Cl and Sn(qaldsbz)Ph_2Cl exhibit molar conductances of 2.5 and 8.6 $ohm^{-1}\,cm^2\,mol^{-1}$, respectively, in DMSO, indicating that they behave essentially as non-electrolytes in this solvent. The low conductance data also support the fact that the Schiff bases are coordinated to the tin atom in their deprotonated anionic forms and that the two phenyl and chloride ligands are also coordinated to the tin atom.

A comparison of the IR spectra of the ligands with those of the two tin complexes indicate that the νNH bands of the free ligands (Table 2) are not present in the spectra of the complexes, supporting deprotonation of the ligands during coordination. The shift of the νC=N bands of the free ligands to lower wavenumbers (Table 2) and the shift of the νN–N bands to higher wavenumbers in the IR spectra of the complexes support coordination of the ligands to the tin atom via the azomethine nitrogen atom. The splitting of the ν_aCSS band of the ligand in the spectra of the complexes indicates coordination of the ligands to tin via one of the sulfur atoms [36,37].

The electronic spectral data of the Schiff bases and their tin(IV) complexes are given in Table 2. The spectra of the ligands exhibit several bands in the 390–247 nm range attributable to the intra-ligand $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions. These bands do not shift much in the spectra of the diphenyltin(IV) complexes but the band ca. 345 nm in the spectra of the ligands disappears in the spectra of the complexes. In addition to the intra-ligand bands, the electronic spectrum of Sn(qaldsme)Ph_2Cl exhibits a strong $S \rightarrow Sn^{IV}$ charge-transfer band at 426 nm. The presence of a $S \rightarrow Sn^{IV}$ LMCT band lends further support to the IR evidence that bonding of the ligands to the tin atom occurs via one of the sulfur atoms. Such LMCT bands are quite common in the electronic spectra of metal complexes of thiosemicarbazones [38] and dithiocarbazates [39–41].

The ESI (positive electrospray ionization) spectra of Sn(qaldsbz)Ph_2Cl and Sn(qalsme)$(Ph)_2Cl$, display base peaks at m/z 610 and 534, which are assigned to the $[Sn(qaldbz)Ph_2]^+$ and $[Sn(qaldsme)Ph_2]^+$ fragment ions, respectively. The simulated isotope patterns of these ions match completely the experimental spectra, supporting assignment of these base peaks to the $[M - Cl]^+$ ions.

The ^1H NMR spectra of the complexes were recorded in $CDCl_3$. Unfortunately, because of inadequate solubilities of these complexes in most non-polar and polar organic solvents, their ^{13}C NMR spectra could not be recorded. The ^1H NMR data of the ligands and their diphenyltin(IV) complexes are shown in Table 3. A comparison of the data for the ligands with those of the complexes shows that the signals due to the sec. –NH protons of the free ligands are absent in the spectra of the complexes, lending further support to the IR and conductance results discussed earlier that the ligands are coordinated to the tin atom in their deprotonated thiolate forms. Also, the signals due to the azomethine protons of the free ligands move downfield in the spectra of the complexes consistent with coordination of the li-

gands to the tin via the azomethine nitrogen atoms. As has been observed in the ^{1}H NMR spectra of metal complexes of Schiff bases derived from *S*-alkyl- and *S*-aryl esters of dithiocarbazic acid, signals due to the SCH_3/SCH_2 protons of the free ligands do not shift significantly when the ligands coordinate with tin [26].

3.1. The crystal structure of Hqaldsme

The crystal structure of the free ligand Hqaldsme, together with the numbering scheme, is shown in Fig. 2.

The structure shows that the molecule is essentially planar with all non-H atoms lying within 0.009 Å of the least squares plane. The *E*,*E* conformation of the C3–N2 and N1–N2 bonds is apparent, which results in an *anti*-arrangement of both donor atoms pairs S1/N2 and N2/N3. Thus, the ligand must undergo a 180° rotation of the C3–C4 and C1–N1 bonds in order to bind as a tridentate chelate. The bond distances in the dithiocarbazate chain [$NNCSSCH_3$] of Hqaldsme (Table 4) are close to those observed in the *S*-benzyl analogue [26] and in other Schiff bases derived from *S*-alkyl/aryldithiocarbazates [4,42]. The C1-S1 distance [1.645(7) Å] in this compound is by far the shortest value observed in this class of compounds, but the value is still intermediate between a C–S single bond [1.82 Å] and a C═S double bond [1.56 Å] [43,44]. The C1–N1 and C3–N2 bond distances are 1.346(8) and 1.285(9) Å, respectively indicating that the bond order of the former is greater than one but that of the latter is less than two. A comparison of the N–N distance [1.375(8) Å] with that in *S*-methyldithiocarbazate [45] shows that the bond is shorter than a single bond, indicating significant π-charge delocalization along the C(S)NNC moiety. The attachment of the extensively delocalized quinoline group to the imino nitrogen atom is probably responsible for shortening of the N–N distance.

The intermolecular hydrogen bonds, which link the molecules together in the solid state, are shown in Fig. 3. There is only one significant intermolecular H-bonding contact involving the NH group as donor and the quinoline N-atom as acceptor: N1–H1...N3* 2.13 Å, 168°, symmetry operation*: $-x$, $y + 1/2$, $-z + 3/2$, which results in a one-dimensional H-bonded polymer oriented in the direction of the *c* axis.

3.2. Crystal structures of Sn(qaldsme)Ph_2Cl

Interestingly, the complex Sn(qaldsme)Ph_2Cl crystallizes in two distinctly different forms; each having the same space group but with different lattice parameters. In both crystalline forms, the tin atom adopts a distorted octahedral geometry with the Schiff base coordinated to it as a uninegatively charged tridentate chelating agent via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom.

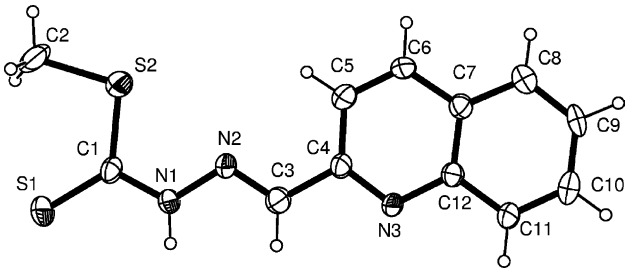

Fig. 2. ORTEP view of Hqaldsme (30% probability ellipsoids).

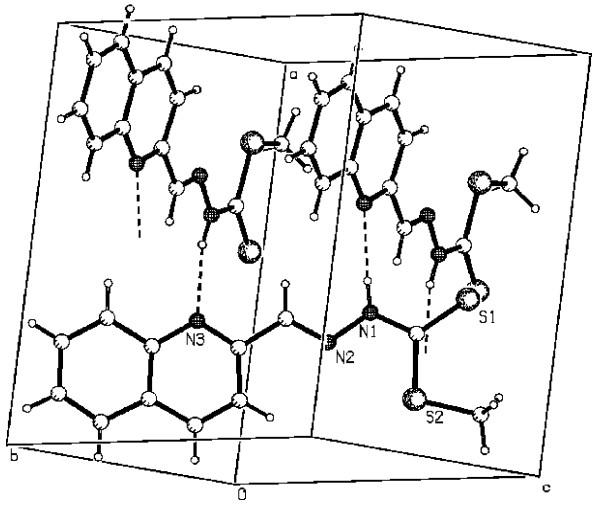

Fig. 3. PLUTON drawing showing the polymeric H-bonded chain in Hqaldsme.

The intrinsic differences in the structures of the two polymorphs lie in the orientation of the *S*-methyl group (C2) with respect to the coordinated S-atom (S1); defined here as *syn* or *anti*.

The structure of the *syn*-conformer (Fig. 4) defines a six coordinate complex with large distortions from an ideal octahedron. The proton attached to N1 in the metal free ligand dissociates upon meridional tridentate coordination of the qaldsme anion. The chloro ligand is formally *trans* to N2, as are the pair of phenyl ligands although there are large deviations from linearity in each pairing (N2–Sn1–Cl1 164.57(6)° and C13–Sn1–C19 153.9(1)°). The shortest coordinate bonds are to the phenyl ligands (~2.15 Å) reflecting the preference of the metal for C-donors over N-donors cf. Sn1–N2 2.321(2) Å. The bond lengths to the Cl- and S-donors are similar. The bond lengths including C1 are greatly affected by deprotonation of N1 and coordination of S1. By a comparison with the bond orders suggested in the structure of Hqaldsme, in the coordinated anion the C1–S1 and C1–S2 bond lengths are similar (1.720(3) and 1.757(2) Å, respectively) and approach that expected for a single bond cf. C2–S2 1.782(4) Å.

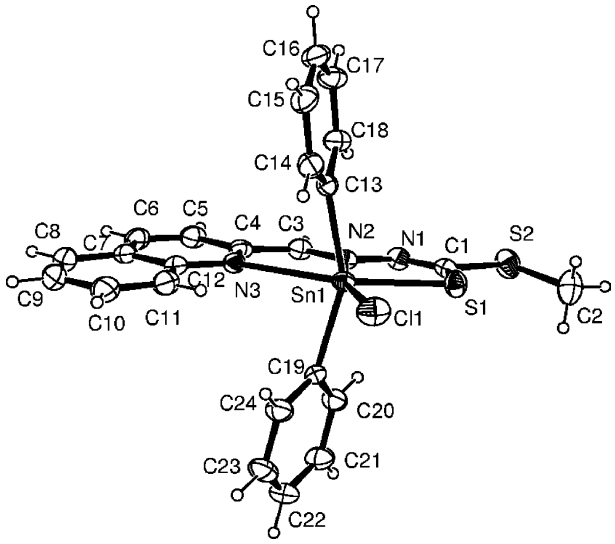

Fig. 4. ORTEP drawing of *syn*-Sn(qaldsme)Ph_2Cl (30% probability ellipsoids).

The C1–N1 bond length (1.298(4) Å) approaches that expected of a true double bond cf. C2–N2 (1.279(4) Å). These observations indicate that upon deprotonation of the ligand, the negative charge, formally on the terminal sulfur atom in the thiolate tautomer, is actually delocalized significantly over the entire —C=N—N=C—S— chain.

The crystal structure of the *anti*-conformational isomer (Fig. 5) reveals a similar coordination environment. The coordinate bond lengths and the internal ligand bond lengths equal the corresponding dimensions found in the *syn*-conformer within experimental error, but

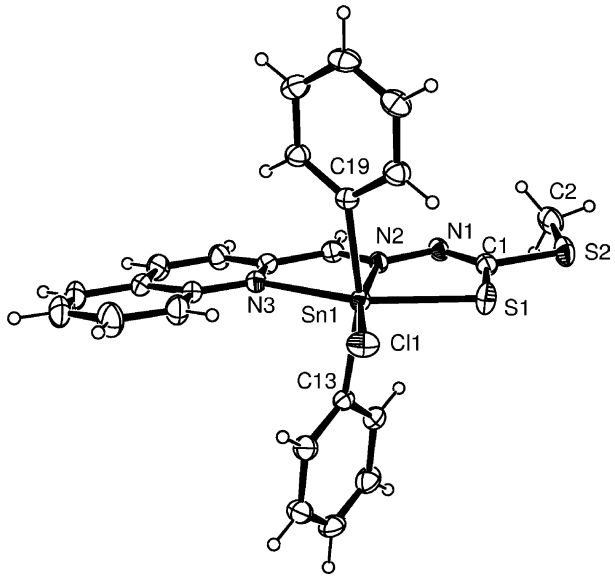

Fig. 5. ORTEP drawing of *anti*-Sn(qaldsme)Ph_2Cl (30% probability ellipsoids).

there is significant variance in the coordination angles. Essentially the *anti*-conformer is less distorted from octahedral geometry.

In both conformers distortions from octahedral geometry are reflected in the 12 bond angles subtended at the tin atom, which show substantial deviations here from 90° or 180°. The largest deviations appear in the ideally 180° angles S1–Sn1–N3 [149.1(5)°/143.09(6)°], and the ideally 90° angles N2–Sn1–S1 [77.1/75.48(6)°], N2–Sn1–N3 [65.95(8)°/67.71(8)°] and Cl1–Sn1–N3 [129.42(6)°/123.03(6)°]. The deviation from octahedral geometry can be attributed to the restricted bite size of the ligand and crystal packing in respect of angles formed by the monodentate ligands.

We recently published the structure of the tri-iodo Sn(IV) complex Sn(qaldsbz)I_3, where a similar tridentate binding mode of the Schiff base was identified [26]. The only other structurally characterized six-coordinated tin complexes of N-heterocyclic thiosemicarbazones and dithiocarbazates are Sn(Hapt)Ph_2Cl (apt = monodeprotonated form of the 2-acetylpyridine thiocarbodiazone) [46] and the carbonato-bridged dimer {Sn(pyaldsme)(*n*-Bu)$_2$}(O-CO-O){Sn(pyaldsme)(*n*-Bu)$_2$} [47]. In the former, similar to that in Sn(qaldsme)Ph_2Cl, the tin atom is also coordinated to a N_2S tridentate ligand, two phenyl groups and a chloride ligand in an approximately octahedral environment, and the latter may be considered as an analogue of the present structures if the *n*-butyl ligands are replaced by phenyls and the carbonato O-donor on each monomeric unit is substituted by a terminal chloro ligand. A comparison of bond lengths of Sn(qaldsme)Ph_2Cl with those in Sn(Hapts)Ph_2Cl indicates while the Sn–S and Sn–$N_{azomethine}$ bond distances have comparable values, the Sn–C, Sn–Cl and Sn–N_{ring} bond lengths differ significantly. The Sn-Cl bond in the present complex is shorter than that found in the Hapt complex but the Sn-C bonds are weaker in both Sn(qaldsme)Ph_2Cl conformers relative to the Sn(Hapt)Ph_2Cl complex. The structural changes that are observed in the structure of the free ligand (Fig. 2) upon coordination with the diphenyltin(IV) cation are similar to those that usually accompany the formation of metal complexes by thiosemicarbazones.

4. Conclusions

In the solid state as well as in solution, the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzydithiocarbazates, like most Schiff bases derived from *S*-alkyl esters of dithiocarbazic acid, remain as thione tautomers. However, in the presence of diphenyltin(IV) dichloride they switch to the iminothiol form, deprotonate and coordinate with the tin atom as uninegatively charged NNS tridentate chelating agents. The ensuing 1:1 diphenyltin(IV) Schiff base complexes adopt a distorted octahedral geometry with the two phenyl groups occupying the apical positions of the coordination sphere.

5. Supplementary material

Crystallographic data in CIF format (CCDC Deposition Nos. 247969-71) have been deposited at the Cambridge Crystallographic Data Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033 ; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Received 8 November 2004; accepted 22 November 2004

Abstract

The reaction of $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)_2Cl]$ (**1**) with acetonitrile in the presence of excess NH_4PF_6 leads to the formation of the cationic ruthenium(II) complex $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)_2(CH_3CN)]PF_6$ (**2**). The complex (**2**) reacts with a series of *N*,*N*′ donor Schiff base ligands viz. *para*-substituted *N*-(pyrid-2-ylmethylene)-phenylamines (ppa) in methanol to yield pentamethylcylopentadienyl ruthenium(II) Schiff base complexes of the formulation $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)(C_5H_4N\text{-}2\text{-}CH{=}N\text{-}C_6H_4\text{-}p\text{-}X)]PF_6$ **[3a]PF$_6$**–**[3f]PF$_6$**, where C_5Me_5 = pentamethylcylopentadienyl, X = H, **[3a]PF$_6$**, Me, **[3b]PF$_6$**, OMe, **[3c]PF$_6$**, NO_2, **[3d]PF$_6$**, Cl, **[3e]PF$_6$**, COOH, **[3f]PF$_6$**. The complexes were isolated as their hexafluorophosphate salts. The complexes were fully characterized on the basis of elemental analyses and NMR spectroscopy. The molecular structure of a representative complex, $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)(C_5H_4N\text{-}2\text{-}CH{=}N\text{-}C_6H_4\text{-}p\text{-}Cl)]PF_6$ **[3e]PF$_6$**, has been established by X-ray crystallography.

Keywords: Ruthenium; Pentamethylcyclopentadienyl; *N*-(pyrid-2-ylmethylene)-phenyl-amines; Pyridine-2-carboxaldehyde

1. Introduction

Half sandwich ruthenium(II) complexes have received great attention in the past few decades owing to their high reactivity ([1] and reference cited in) and catalytic activity [2]. The syntheses, structures and reactivity of half sandwich ruthenium(II) complexes viz., cyclopentadienyl, indenyl and arene have been studied in our laboratory. Our current interest has involved substitution of one triphenylphosphine and a chloride ligand of the complex $[Cp'Ru(PPh_3)_2Cl]$, where Cp′ = ind., Cp*, Cp with N-donor ligands [3,4], which is one of the key routes to explore their chemistry. There exist an extensive study on the chemistry of cyclopentadienyl ruthenium(II) with a variety of ligands [5]. In contrast, the analogous pentamethylcyclopentadienyl ruthenium(II) complexes have not been much studied. The chemistry of the pentamethylcylopentadienyl ruthenium fragment is largely based on the tetramer $[Cp^*RuCl]_4$ [6] and on the tris-acetonitrile $[Cp^*Ru(CH_3CN)_3]PF_6$ adduct [7], which upon addition of monodentate ligands yield octahedral complexes $[Cp^*RuX(L)_2]$ [8,9] and $[Cp^*Ru(L)_2(CH_3CN)]PF_6$ [7], respectively. However, to the best of our knowledge, pentamethylcylopentadienyl ruthenium(II) phosphine complexes chelated with *N*,*N*′ donor Schiff base ligands are not known, although there is an extensive chemistry available on arene and cyclopentadienyl ruthenium(II) [3b,10–12] systems.

This present work arises from our interest to synthesize various half sandwich ruthenium(II) complexes containing N,N' donor Schiff base ligands. Having this in mind, we have previously described the syntheses of indenyl, cyclopentadienyl and arene [3,10] ruthenium(II) Schiff base complexes. In a continuation of our study, herein we report the syntheses of a series of pentamethylcyclopentadienyl ruthenium(II) Schiff base complexes **[3a]**PF_6–**[3f]**PF_6. The elemental analyses, spectral and structural characterization of the complexes is presented.

2. Experimental

2.1. General remarks

Reactions were carried out in distilled and dried solvents under nitrogen atmosphere. The solvents were purified according to the standard procedures. $RuCl_3\cdot 3H_2O$ was purchased from Arora Matthey (P) Ltd. and used as such. Pyridine-2-carboxaldehyde (Fluka) was used as received. All liquid aromatic amines were reagent grade and were distilled prior to use while solid aromatic amines were used as such. Microanalyses (C, H, N) were done by Regional Sophisticated Instrumentation Centre (RSIC), NEHU using a Perkin–Elmer-2400 CHNS/O analyzer. FT-IR spectra were recorded on a Perkin–Elmer-model 983 spectrophotometer with samples prepared as KBr pellets. Electronic spectra were recorded on a Hitachi-U-2300 spectrophotometer and conductivity measurements were done by Wayne Kerr Automatic Precession Bridge B905 using ca. 10^{-4} M solutions in dry acetonitrile at room temperature (Λ_m value in $S\,cm^2\,mol^{-1}$). The NMR spectra were obtained in $CDCl_3$ solution and recorded on a Bruker ACF-300 MHz spectrometer. Chemical shifts are relative to TMS (^1H, $^{13}C\{^1H\}$) and to 85% H_3PO_4 ($^{31}P\{^1H\}$); coupling constants are given in hertz. The ligands (C_5H_4N-2-CH=N-C_6H_4-*p*-X), (where X = H, Me, OMe, Cl, NO_2, COOH) [13] were prepared by the condensation of pyridine-2-carboxaldehyde with the appropriate amines. The precursor complex [(η^5-C_5Me_5)Ru(PPh_3)$_2$Cl] [14] was prepared by following the literature method.

2.2. Preparation of [(C_5Me_5)Ru(PPh_3)$_2$($NCCH_3$)]PF_6 [2]PF_6

The complex was prepared by following the literature method [15] as delineated here. The complex [Cp*Ru(PPh_3)$_2$Cl] (0.1 g, 0.125 mmol) and NH_4PF_6 (0.041 g, 0.250 mmol) were refluxed in CH_3CN (30 ml) for 2 h. During this time the orange red suspension turned yellow and a white solid appeared. The white solid was filtered off and the filtrate was rotary evaporated. The yellow residue was dissolved in dichloromethane (5 ml) and filtered to remove excess NH_4PF_6. The filtrate on concentration and addition of excess hexane gave a yellow crystalline solid. The yellow solid was collected and washed with hexane to afford 83% yield of complex (**2**).

^1H NMR ($CDCl_3$, δ): 1.32 (s, 15H, Cp), 2.17 (s, 3H, CH_3CN), 6.78–7.83 (m, 30H).

$^{31}P\{^1H\}$ NMR ($CDCl_3$, δ): 45.28 (s. 2P, PPh_3), −143 (septet, PF_6^-).

2.3. Preparation of [(η^5-C_5Me_5)Ru(PPh_3)(C_5H_4N-2-CH=N-C_6H_4-p-X)]PF_6 [X = H [3a]PF_6, Me [3b]PF_6, OMe [3c]PF_6, NO_2 [3d]PF_6, Cl [3e]PF_6, COOH [3f]PF_6

These complexes were prepared by using a general method.

The complex (**2**), (0.1 g, 0.105 mmol) and the appropriate ligand (0.210 mmol) were mixed in 20 ml of methanol. After a few minutes the yellow solution turned into a dark brown suspension. The mixture was refluxed for 1 h under nitrogen atmosphere. The solution was cooled to room temperature and solvent was removed in a rotary-evaporator to dryness. The brown residue was dissolved in dichloromethane (5 ml) and filtered through a short silica gel column. The filtrate on subsequent concentration and addition of excess diethyl ether gave complexes **[3a]**PF_6–**[3f]**PF_6 as dark brown solids in 81–87% yield.

2.4. Analytical and spectroscopic data

2.4.1. [(η^5- C_5Me_5)Ru(PPh_3)(C_5H_4N-2-CH=N-C_6H_5)]-PF_6 [3a]PF_6

Yield: 83% (72 mg). *Anal.* Calc. for $C_{40}H_{40}N_2P_2F_6Ru$: C, 58.13; H, 4.81; N, 3.39. Found: C, 57.6; H, 5.01; N, 3.45%. IR (KBr, cm^{-1}): $\nu_{(C=N)}$ 1600, $\nu_{(PF_6^-)}$ 844.

^1H NMR ($CDCl_3$, *J* Hz): δ 1.31 (s, 15H, C_5Me_5); 7.14 (d, 2H, J_{H-H} = 2.89); 7.18–7.64 (m, 21H); 8.25 (d, 1H, 2.64); 8.92 (d, 1H, 3.38).

$^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 9.31 (s, $C_5Me_5(CH_3)$); 88.73 (s, C_5Me_5 (ring)); 122.46–151.26 (phenyl and pyridyl carbons); 157.83 (N=CH).

$^{31}P\{^1H\}$ NMR: δ 45.26 (s, PPh_3); −141 (septet, PF_6^-).

2.4.2. [(η^5-C_5Me_5)Ru(PPh_3)(C_5H_4N-2-CH=N-C_6H_4-p-Me)]PF_6 [3b]PF_6

Yield: 86% (76 mg). *Anal.* Calc. for $C_{41}H_{42}N_2P_2F_6Ru$: C, 58.59; H, 5.00; N, 3.33. Found: C, 59.35; H, 4.99; N, 3.67%.

IR (KBr, cm^{-1}): $\nu_{(C=N)}$ 1598, $\nu_{(PF_6^-)}$ 844.

^{1}H NMR ($CDCl_3$, J Hz): δ 1.31 (s, 15H, C_5Me_5); 2.38 (s, 3H); 7.07 (d, 2H, J_{H-H} = 5.73); 7.18 (d, 2H, J_{H-H} = 4.82); 7.29–7.62 (m, 18H); 8.22 (d, 1H, J_{H-H} = 3.48); 8.92 (d, 1H, J_{H-H} = 3.38).

$^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 9.23 (s, $C_5Me_5(CH_3)$); 15.29 (s, Me); 88.47 (s, C_5Me_5 (ring)); 123.48–152.01 (phenyl and pyridyl carbons); 160.46 (N=CH).

$^{31}P\{^1H\}$ NMR: δ 46.55 (s, PPh_3); −142 (septet, PF_6^-).

2.4.3. *[(η^5-C_5Me_5)Ru(PPh_3)(C_5H_4N-2-CH=N-C_6H_4-p-OMe)]PF_6 [3c]PF_6*

Yield: 87% (78 mg). *Anal.* Calc. for $C_{41}H_{42}N_2OP_2F_6Ru$: C, 57.49; H, 4.91; N, 3.27. Found: C, 56.29; H, 4.97; N, 3.54%.

IR (KBr, cm^{-1}): $\nu_{(C=N)}$ 1602, $\nu_{(PF_6^-)}$ 844.

^{1}H NMR ($CDCl_3$, J Hz): δ 1.32 (s, 15H, C_5Me_5); 3.84 (s, 3H); 6.77 (d, 2H, J_{H-H} = 5.73); 7.13–7.65 (m, 20H); 8.24 (d, 1H, J_{H-H} = 2.97); 8.87 (d, 1H, J_{H-H} = 5.10).

$^{31}P\{^1H\}$ NMR: δ 47.28 (s, PPh_3); −145 (septet, PF_6^-).

2.5. Structure analysis and refinement

X-ray quality crystals of complex **[3e]PF_6** were grown by slow diffusion of hexane into a dichloromethane solution of complex **[3e]PF_6**. The X-ray intensity data were collected on a Rigaku Mercury CCD area detector employing graphite-monochromated Mo Kα radiation (λ = 0.71069 Å) at 143 K. Intensity data were corrected for Lorentz and polarization effects and for absorption correction using REQAB [16]. The structure was solved by direct methods (SIR 97) [17] and refinement was by full matrix least squares based on F^2 using (SHELXL-97) [18]. The weighting scheme used was $W = 1/[\sigma^2(F_0^2) + 0.0822P^2 + 3.3880P]$, where $P = (F_0^2 + 2F_c^2)/3$. The X-ray data were corrected for the presence of disordered solvent using "SQUEEZE" [19]. Non-hydrogen atoms were refined anisotropically and hydrogen atoms were refined using a "riding" model.

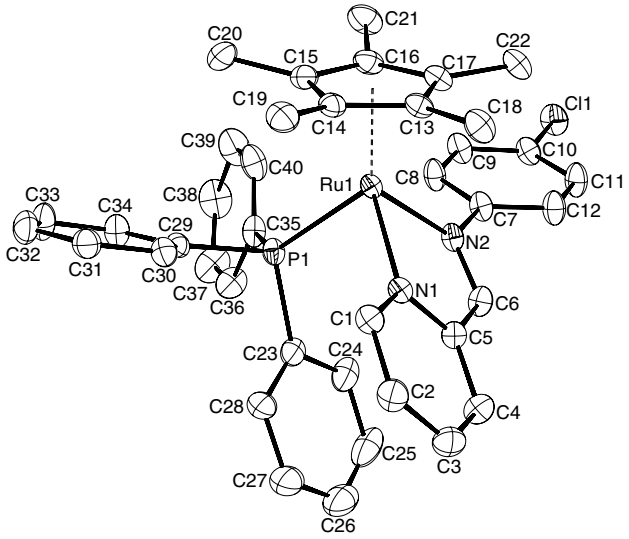

Fig. 1. Molecular structure of complex **[3e]PF_6** with 30% thermal ellipsoids. Hydrogen atoms and the PF_6 ion have been omitted for clarity.

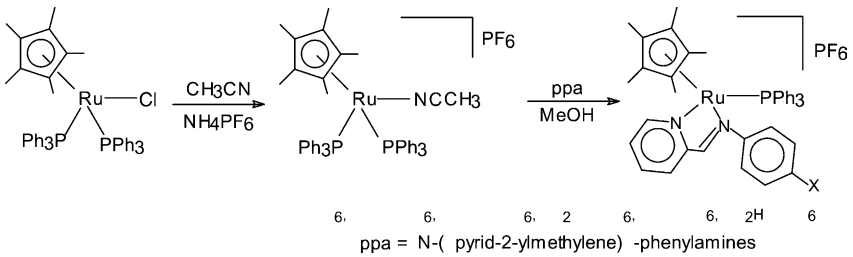

Refinement converged to $R_1 = 0.0444$ and $wR_2 = 0.1267$. Fig. 1 is an ORTEP [20] representation of the molecule with 30% thermal ellipsoids displayed.

3. Results and discussion

While N-chelating cyclopentadienyl ruthenium(II) complexes are well known [3b,5,10], only a few reports about the analogous pentamethylcyclopentadienyl are available in the literature [4]. Here we described the preparation of six new monocationic pentamethylcyclopentadienyl ruthenium(II) phosphine complexes **[3a]PF$_6$**–**[3f]PF$_6$** containing *N*,*N*′ donor Schiff base ligands, and their characterization with the help of elemental analyses, IR and NMR (^{1}H, ^{31}P{^{1}H}, ^{13}C{^{1}H}) spectroscopy. The molecular structure of a representative complex **[3e]PF$_6$** was determined by a single X-ray study. To the best of our knowledge this complex is the first structurally characterized pentamethyl-cyclopentadienyl ruthenium(II) Schiff base complex containing a phosphine ligand. The complexes were obtained in good yield, by reacting complex **[2]PF$_6$** with the appropriate ligands in methanol as depicted in Scheme 1.

We have recently synthesized cyclopentadienyl ruthenium(II) complexes of Schiff base ligands such as $[CpRu(PPh_3)(ppa)]^+$ [3b] by reacting the ligand (ppa) with the complex $[CpRu(PPh_3)_2Cl]$. However, in this present case the complexes are readily obtained in high yields by the reaction of the acetonitrile complex **[2]PF$_6$** with the appropriate ligand. These complexes can also be prepared in lower yield by the reaction of complex (**1**) with the ligand over a longer period of time. This suggests the acetonitrile complex **[2]PF$_6$** is a better precursor than their chloro analog (**1**) for the preparation of these complexes **[3a]PF$_6$**–**[3f]PF$_6$**. This is due to the cationic nature of the complex **[2]PF$_6$** which makes ready coordination of the ligand to the metal atom compared to the neutral chloro complex (**1**). It has been reported that the pentamethylcyclopentadienyl complexes, $[Cp^*Ru(PPh_3)_2Cl]$ are much more reactive than the analogous cyclopentadienyl complexes, which is attributed to the electron rich nature of the Cp* ligand and the presence of five sterically hindered methyl groups associated with these complexes which facilitates ready dissociation of one of the triphenylphosphine ligands. In fact, one triphenylphosphine can be readily substituted by diazonium salts from $[Cp^*Ru(PPh_3)_2Cl]$ irrespective of the solvent used (acetone or toluene), in contrast the same substitution is only possible in the analogous $[CpRu(PPh_3)_2Cl]$ complex using toluene under drastic conditions [21]. It is notable that the Cp* ligand is less stable as compared to the analogous Cp ligand and that prolonged reaction under drastic conditions results in removal of the Cp* ligand from the complex. Very recently we have studied the reaction of $[Cp'Ru(PPh_3)_2Cl]$, [where Cp′ = ind., Cp*, Cp] with sterically demanding the multidentate tetra-2-pyridyl-1,4-pyrazine (tppz) ligand, where attempts to synthesis Cp* and indenyl complexes chelated with the tppz ligand were unsuccessful, instead we isolated complexes of the type $[(tppz)Ru(PPh_3)_2X]$ [22]. However, when the reaction was carried out with $[CpRu(PPh_3)_2Cl]$, the η^5-bonded cyclopentadienyl group remained intact to the metal thus forming a complex of the type $[CpRu(L_2)(PPh_3)]^+$ [5b]. This indicates the more labile nature of the indenyl and Cp* ligands as compared to the cyclopentadienyl ligand.

The complexes **[3a]PF$_6$**–**[3f]PF$_6$** are highly soluble in polar solvents but insoluble in non-polar solvents. The conductivity measurement (10^{-4} in CH_3CN) of the complexes showed the complexes are ionically dissociated into a 1:1 electrolytic system [23]. The microanalyses data of the complexes are in good agreement with that of their formulations. The IR spectra of the complexes exhibit bands corresponding to $\nu_{C=N}$ of the coordinated ligands at 1598–1612 cm^{-1}, while ν_{P-F} of the PF_6^- counter ion appears at 844 cm^{-1}. The IR spectra showed a shift of the C=N stretching frequency towards lower wavenumbers as compared with the free base ligands (1598–1612 versus 1619–1638 cm^{-1}) indicating N-coordination of the C=N group [24]. The complex (**[3d]PF$_6$**) showed a characteristic IR band for symmetric ν_{NO_2} and asymmetric ν_{NO_2} at 1348 and 1458 cm^{-1}, respectively, similar to those observed for other reported compounds. The proton NMR spectra of these complexes displayed a sharp singlet (except **[3d]PF$_6$**) at δ 1.3 for the methyl protons of the pentamethylcyclopentadienyl while for the complex **[3d]PF$_6$** the resonance is observed as a doublet.

Scheme 1. X = H, **[3a]PF$_6$**; Me, **[3b]PF$_6$**; OMe, **[3c]PF$_6$**; NO_2, **[3d]PF$_6$**; Cl, **[3e]PF$_6$**; COOH, **[3f]PF$_6$**.

The doublet observed could be due to the coupling of methyl protons of the Cp* moiety with the phosphorus of the triphenylphosphine. The resonance of ortho proton of the pyridine ring of the ligand appeared as a doublet in the range of δ 8.87–8.95. The doublet observed was probably due to coupling of the methine proton with the proton of the aromatic ring of the coordinated ligands. However, this proton appears as singlet at δ 8.6 in the case of the complex **[3f]PF$_6$**. We did not observe the resonance for the acidic proton CO_2H in the proton NMR spectrum of the complex **[3f]PF$_6$**. The spectra of all these complexes also contained multiple resonances for the aromatic protons in the range of δ 6.94–8.05. The $^{13}C\{^1H\}$ NMR spectra of the complexes contained resonances for C_5Me_5 carbons at around δ 9.49 for the methyl group of Cp* and δ 89.26 for the ring carbons. The resonance observed at around δ 161 could be due to the imine carbon (CH=N) of the Schiff base ligand. The $^{13}C\{^1H\}$ NMR spectrum of complex **[3f]PF$_6$** showed a singlet at δ 178, which is assignable to the carbon of COOH. The spectra also showed resonances in the range of δ 123.48–155.96 for the aromatic carbons and carbons of the pyridyl ring. The $^{31}P\{^1H\}$ NMR spectra of the complexes displayed a singlet in the range of δ 45.26–46.7 due to the triphenylphosphine moiety as compared to δ 38.5, observed in the neutral precursor complex $[Cp^*Ru(PPh_3)_2Cl]$. The spectra also contained a septet in the range of δ −141 to −145 for the PF_6^- counter ion. The electronic spectra of the complexes in dichloromethane exhibited absorption bands in the range of 475–493 nm (Table 1). These low energy absorption bands present in all of these complexes are characteristics of Ru(dπ)–L(π^*), metal to ligand charge transfer transitions (MLCT).

3.1. Crystal structure

The crystal structure determination was carried out for the representative complex **[3e]PF$_6$**. There is a disordered area in the crystal, which was a combination of PF_6's and dichloromethane, the solvent of crystallization. The space group has four symmetry-related positions in the unit cell, of which the PF_6's ions occupy two and the other two by the CH_2Cl_2 molecules. The effect of this disorder was removed from the data using the "SQUEEZE" program, which was written to correct data for the presence of disordered solvents [19]. The perspective view of the cationic part of the complex with the numbering scheme of the atoms is shown in Fig. 1. Details of the crystallographic data collection are given in Table 2. Selected bond lengths and angles are presented in Table 3.

The complex crystallized in the $P2_1/c$ space group and consists of complex cation and PF_6 anions joined by columbic forces. The ruthenium atom presents a pseudo-octahedral environment with the Cp* ligand occupying three facile coordination sites, π-bonded to the metal in η^5-fashion, while the remaining coordination positions are occupied by the P atom of the triphenylphosphine

Table 3
Molecular structure of complex [**3e**]PF_6 with 30% thermal ellipsoids

Bond lengths (Å)			
Ru–N(1)	2.106(2)	Ru–P(1)	2.3593(7)
Ru–N(2)	2.097(2)	N(2)–C(6)	1.297(4)
C*–Ru	1.8536(2)		
C* = centroid of C(13), C(14), C(15), C(16), C(17)			
Bond angles (°)			
N(1)–Ru–N(2)	75.67(9)	N(1)–Ru–P(1)	88.79(6)
N(2)–Ru–P(1)	92.84(6)		

Hydrogen atoms and the PF_6 ion have been omitted for clarity.

and N atoms of the Schiff base ligand. The average bond distance of ruthenium to ring carbon is 2.2198 Å, whereas the distance between the ruthenium and the centroid of the ring is 1.8536(2) Å. The Ru–P(1) bond length, 2.3593(7) Å, is within the usual range of Ru–P bond distances (2.20–2.43 Å) [25]. The ruthenium and nitrogen bond distances, 2.106(2) and 2.097(2) Å, are within the range of reported compounds. There is no significant difference in the C–C bond lengths in the cyclopentadienyl ring. The bond lengths falls within the range of 1.418(4)–1.452(4) Å, suggesting the delocalization of π-electrons in the ring. Further, the five-membered ring is planar as evident by the nearly equal bond distances between the ruthenium and ring carbons. The angle between N(1)–Ru(1)–N(2), 75.67(9)°, is very close to those reported for the similar ligand in indenyl ruthenium(II) complexes [3a]. The complex adopts the familiar ''piano stool'' structure as evident by the nearly 90° bond angles for N(1)–Ru–P(1) (88.79(6)°) and N(2)–Ru–P(1) (92.84(6)°).

4. Conclusions

The present study describes the simple synthetic methodology for the preparation of six new monocationic pentamethylcyclopentadienyl ruthenium(II) Schiff base complexes. Complex [**3e**]PF_6 provides a first insight into the structural data of pentamethylcyclopentadienyl ruthenium(II) Schiff base complexes containing a phosphine ligand.

Appendix A. Supplementary data

Crystallographic data for the structural analysis have been deposited at the Cambridge Crystallographic Data Centre (CCDC), CCDC No. 252029 for complex **3e**. Abstract

Four 4,4′-bipyridine α,ω-dicarboxylate coordination polymers $Cu(bpy)(C_5H_6O_4)$ (**1**), $Zn(bpy)(C_5H_6O_4)$ (**2**), $Zn(bpy)(C_6H_8O_4)$ (**3**) and $Mn(bpy)(C_8H_{12}O_4)\cdot H_2O$ (**4**) have been synthesized and structurally characterized by single crystal X-ray diffraction methods (bpy = 4,4-bipyridine, $(C_5H_6O_4)^{2-}$ = glutarate anion, $(C_6H_8O_4)^{2-}$ = adipate anion, $(C_8H_{12}O_4)^{2-}$ = suberate anion). Their crystal structures are featured by dimeric metal units, which are co-bridged by 4,4′-bipyridine ligands and dicarboxylate anions such as glutarate, adipate and suberate anions to generate 2D layers with a (4,4) topology in **1**, **2** and **4** as well as to form 3D frameworks in **3**. Two 3D frameworks in 3 interpenetrate with each other to form a topology identical to the well-known Nb_6F_{15} cluster compound. Over 5–300 K, the paramagnetic behavior of **4** follows the Curie–Weiss law $\chi_m(T-\Theta) = 4.265(5)\ cm^3\ mol^{-1}$ with the Weiss constant $\Theta = -6.3(2)$ K. Furthermore, the thermal behavior of **3** and **4** is also discussed.

1. Introduction

Currently there is considerable interest in metal-organic coordination polymers with fascinating network topologies and specific properties for potential applications in the field of molecular magnetism, electrical conductivity and photoluminescence, as well as in inclusion chemistry, molecular recognition and catalysis [1–4]. One commonly used strategy for designing such materials relies on the utilization of multidentate N- or O-donor ligands which have the capacity to bridge between metal centers to form polymeric structures. For example, benzene polycarboxylic acid ligands are good candidates for this purpose [5–7]. In contrast to the rigid aromatic polycarboxylate anions, the aliphatic α,ω-dicarboxylate ligands as important flexible spacer ligands, due to their conformational and coordination versatility, tend to bridge transition metal ions to form coordination polymers with low dimensionality [8–10]. On the other hand, even the high dimensional α,ω-dicarboxylate coordination polymers normally exhibit little porosity [11]. To avoid such drawbacks, our recent research has been intensively focused on construction of porous α,ω-dicarboxylate coordination polymers by introduction of rigid 4,4′-bipyridine as ancillary ligands [12,13]. Hitherto, however, reports about co-bridging of rigid 4,4′-bipyridine and flexible α,ω-dicarboxylate ligands to construct coordination polymers seem very scarce [14–21].

As part of our ongoing work [12,13], we report here the syntheses and crystal structures of four 4,4′-bipyridine α,ω-dicarboxylate coordination polymers

$Cu(bpy)(C_5H_6O_4)$ (**1**), $Zn(bpy)(C_5H_6O_4)$ (**2**), $Zn(bpy)(C_6H_8O_4)$ (**3**) and $Mn(bpy)(C_8H_{12}O_4)\cdot H_2O$ (**4**) along with the magnetic behavior of **4**, in addition to the thermal characterization of **3** and **4**. The title compounds (Table 1) are featured by dimeric metal units, which are co-bridged by 4,4′-bipyridine ligands and dicarboxylate anions into 2D layers with (4,4) topologies in **1**, **2** and **4**, as well as into 3D frameworks in **3**.

2. Results and discussion

2.1. Syntheses and thermal analyses

Systematic investigation showed that hydrothermal reactions of $Cu(NO_3)_2\cdot 3H_2O$, 4,4′-bipyridine and glutaric acid in a methanolic aqueous solution afforded a mixture of $Cu_2(bpy)(C_5H_6O_4)_2\cdot 3H_2O$ [14] and **1** as a minor product. It is very difficult to separate **1** from the mixture in a sufficient quantity for characterization. Much work has been done to suppress the formation of $Cu_2(bpy)(C_5H_6O_4)_2\cdot 3H_2O$ [14]. Unfortunately, all attempts have failed. Complexes **2**–**4** were prepared by reaction of a fresh hydroxo carbonate precipitate of the relevant transition metal and corresponding dicarboxylic acids with 4,4′-bipyridine in methanolic aqueous solutions under ambient conditions. The low synthetic yields of **2** and **3** suggest low reactivity of zinc hydroxo carbonate and dicarboxylic acids with 4,4′-bipyridine at ambient temperature.

When heated up to 600 °C, **3** decomposes in two steps and the DTA curve displays two endothermic peaks centered at 303 and 358 °C. The observed weight loss of 43.3% over 25–320 °C corresponds well to the calculated value of 42.7% for liberation of one mole of bpy per formula unit. Upon further heating up to 395 °C, the sample loses additional weight (35.5%) in good agreement with a value of 35.1% calculated for sublimation of one mole of adipic anhydride ($C_6H_8O_3$). The residue collected at 600 °C was identified to be ZnO according to powder X-ray diffraction patterns.

The DTA curve of **4** exhibits four endothermic peaks centered at 122, 234, 289 and 323 °C. The observed weight loss of 4.6% at 140 °C agrees well with the calculated value of 4.5% for release of one mole of H_2O per formula unit, suggesting complete dehydration. Over

140–465 °C, the observed weight loss of 76.6% is very close to the value of 77.8% calculated for one mole 4,4′-bipyridine and one mole suberic anhydride (“$C_8H_{12}O_3$”). Powder X-ray diffraction patterns confirm the residue of 18.3% at 600 °C to be MnO (Calc. 17.7%).

2.2. Structure of Cu(bpy)($C_5H_6O_4$) (**1**) and Zn(bpy)($C_5H_6O_4$) (**2**)

2.2.1. Cu(bpy)($C_5H_6O_4$) (**1**) and Zn(bpy)($C_5H_6O_4$) (**2**)

Compounds **1** and **2** crystallize isostructurally with Mn(bpy)($C_5H_6O_4$) [12]. As depicted in Fig. 1, the metal atoms (Cu and Zn) are each surrounded by two pyridyl nitrogen atoms (N(1) and N(2)$^{\#4}$) at a mean distance of 2.035 and 2.172 Å for **1** and **2**, respectively, and three carboxylate oxygen atoms (O(1)$^{\#3}$, O(2) and O(3)$^{\#5}$) at distances in the range 1.965–2.223 and 2.020–2.028 Å for **1** and **2**, respectively (Table 2). The next carboxylate oxygen atom (O(4)$^{\#5}$) is at a more remote distance of 2.672 and 2.683 Å for **1** and **2**, respectively, suggesting a negligibly weak interaction between the central metal atom and the O(4)$^{\#5}$ atom. In this sense, the coordination sphere of the metal atoms in **1** and **2** could be regarded as a distorted trigonal bipyramid with the oxygen atoms at the equatorial sites, rather than a severely distorted octahedron as observed in Mn(bpy)($C_5H_6O_4$) [12]. The glutarate anions have normal bond lengths and angles [14], adopting a gauche-gauche conformation with one end carboxylate group bidentately bonded to two metal atoms in a *syn–syn* fashion and the other end monoatomically coordinating one metal atom. Two symmetry-related metal atoms are bridged by two carboxylate groups to form 8-membered rings. Along [1 0 0], the resulting dimeric metal units are linked by the glutarate anions to generate ribbon-like chains with alternative 8- and 16-membered rings. The M···M distances within the former ring are 3.898 and 4.105 Å for **1** and **2**, respectively, and the closest M···M separation within the latter is 6.284 and 6.568 Å for **1** and **2**, respectively. The chains are interconnected by 4,4′-bipyridine ligands to form grid-like layers with a (4,4) topology, showing apertures of dimensions 8.0×11.4 and 8.1×11.2 Å in **1** and **2**, respectively. As illustrated in Fig. 2, the layers are ar-

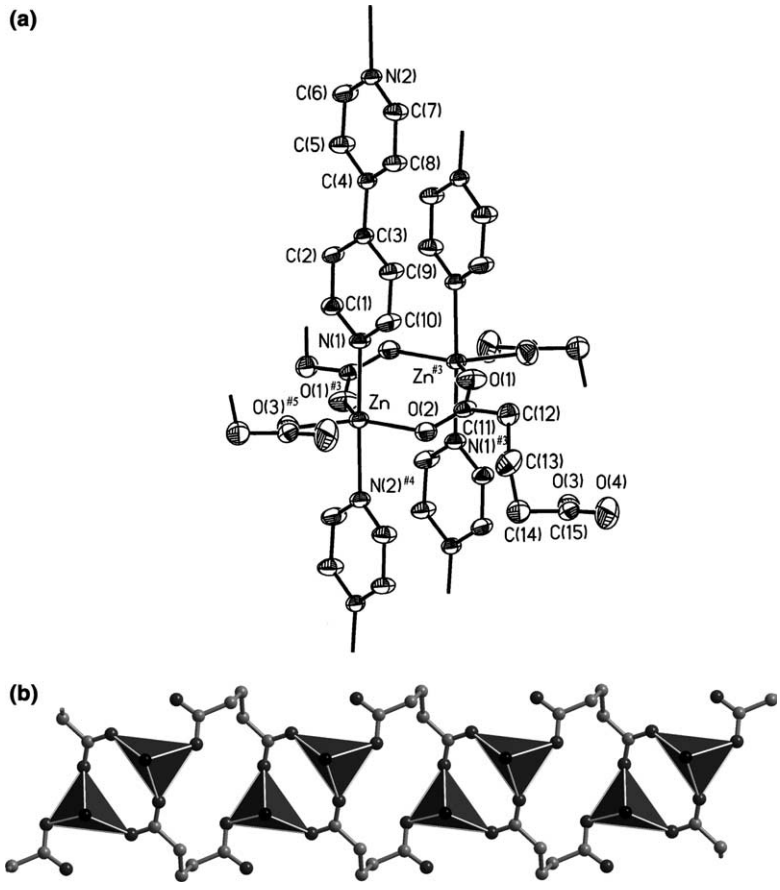

Fig. 1. (a) Coordination environment of the Zn atom along with the atomic labelling for **2**. The displacement ellipsoids are drawn at the 60% probability level (Symmetry transformations used to generate equivalent atoms: #1 = x, $y-1$, $z-1$; #2 = x, y, $z-1$; #3 = $-x+1$, $-y+1$, $-z+1$; #4 = x, $y+1$, $z+1$; #5 = x, y, $z+1$). (b) 1D ribbon-like chains of Zn atoms bridged by glutarato ligands.

[a] Symmetry codes: #1 = x, $y-1$, $z-1$; #2 = x, y, $z-1$; #3 = $-x+1$, $-y+1$, $-z+1$; #4 = x, $y+1$, $z+1$; #5 = x, y, $z+1$.
[b] Symmetry codes: #1 = x, $y-1$, $z-1$; #2 = $-x+1$, $-y+2$, $-z+1$; #3 = x, $y+1$, $z+1$; #4 = $-x+2$, $-y+3$, $-z+1$; #5 = $-x+2$, $-y+2$, $-z+2$.

ranged parallel to $(0\,1\,\bar{1})$ and close packed with the bent glutarate anions approaching the apertures of the neighboring layers. Two CH groups from C(8) and C(9) of one 4,4′-bipyridine donate two hydrogen atoms to one uncoordinating carboxylate O(4) atom to form interlayer $R_2^1(7)$ C–H···O hydrogen bonds according to graph set notation [22]. These hydrogen bonding interactions seem essential for supramolecular assembly of the layers.

2.3. Structure of Zn(bpy)($C_6H_8O_4$) (**3**)

This compound is found to be isostructural with Mn(bpy)($C_6H_8O_4$) [12] and Mn(bpe)($C_6H_8O_4$) with bpe = 1,2-bis(4-pyridyl)ethane [19]. Substitution of Zn for Mn brings about no significant variation in the structural features. As shown in Fig. 3, the asymmetric unit cell of **3** contains one Zn atom, one 4,4′-bipyridine molecule and two halves of adipate anions, out of which the twisted one is disordered with the middle two carbon atoms each equally populated over two sites (C(16A) and C(16B)) and the linear one possesses an inversion center at the middle C–C bond. The coordination sphere of the Zn atoms is a considerably distorted octahedron with a ZnN_2O_4 chromophore, where the equatorial oxygen atoms belong to three adipate anions and two nitrogen atoms to different 4,4′-bipyridine ligands. The Zn–O and Zn–N bond distances fall in the ranges 2.017–2.227 and 2.171–2.201 Å, respectively (Table 2), which are comparable

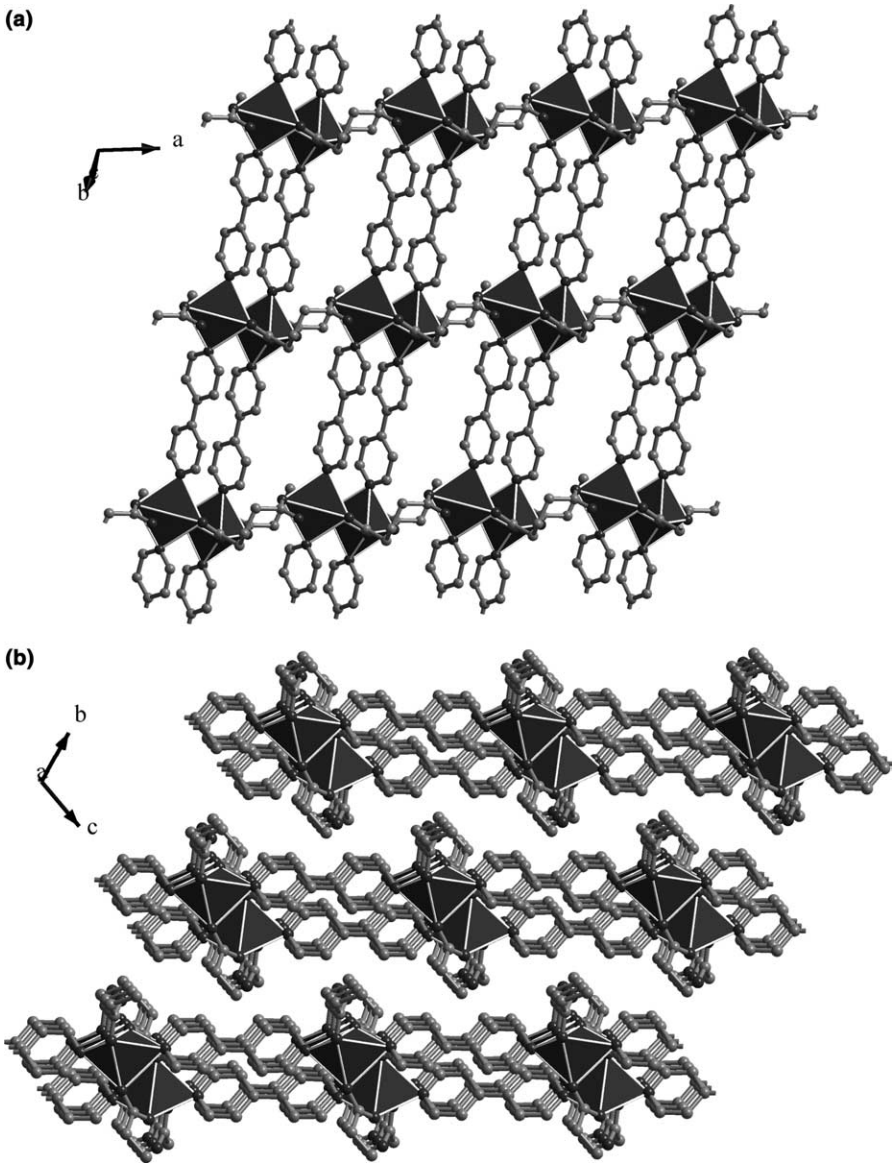

Fig. 2. (a) The ribbon-like chains are pillared by rigid bpy ligands into a 2D layer in **2**. (b) Crystal structure of **2**.

with those reported for Zn(bpy)($C_4H_4O_4$) [21]. The disordered and linear adipate anions function as bischelating and bisbidentate ligands, respectively, to bridge two and four Zn atoms. The dimeric Zn_2 units are interconnected into (4,4) grid-like nets containing 8-membered rings and 36-membered rings of dimension 10.9×13.1 Å (Fig. 3). The 8-membered ring is enclosed by two Zn ions and two carboxylate groups with the Zn···Zn separation being 3.954 Å, substantially less than that in **2**. The resulting nets are pillared by 4,4′-bipyridine ligands to generate 3D frameworks (Fig. 4), which form twofold interpenetration with a topology identical with the well-known Nb_6F_{15} cluster compound containing Nb_6F_{12} clusters [4, 23]. The adipate anions exhibit usual bond distances and angles [24].

2.4. Structure of $Mn(bpy)(C_8H_{12}O_4) \cdot H_2O$ (**4**)

This coordination polymer consists of 2D open layers and hydrogen bonded water molecules. The distorted octahedral coordination sphere of the Mn atoms in **4** is practically identical to those in Mn(bpy)($C_6H_8O_4$) [12] and Mn(bpe)($C_6H_8O_4$), with bpe = 1,2-bis(4-pyridyl)ethane [19]. As shown in Fig. 5, the MnN_2O_4 chromophore is defined by four oxygen atoms from one chelating and two bidentately bridging carboxylate groups of different suberate anions and two nitrogen atoms at the opposite positions from different 4,4′-bipyridine ligands. The Mn–O and Mn–N bond distances fall in the regions 2.110–2.302 and 2.279–2.290 Å, respectively (Table 3). The suberate anions exhibit normal bond distances and angles [24–29] and are

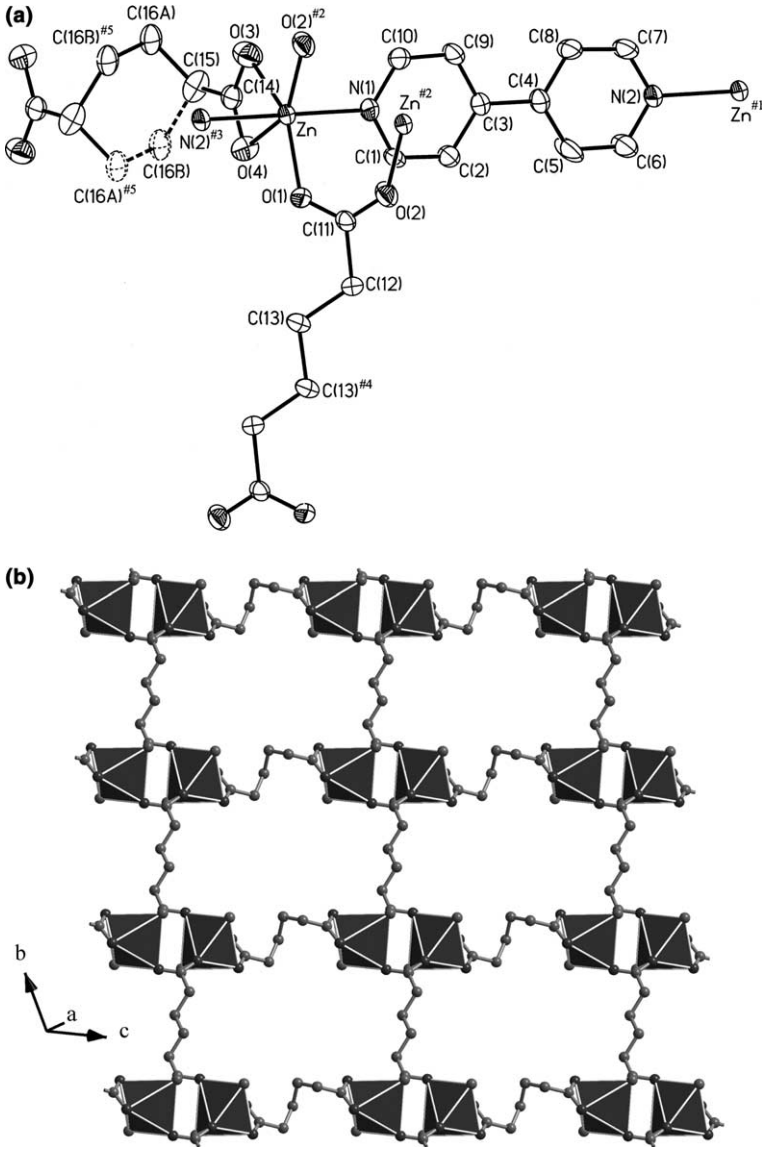

Fig. 3. (a) Coordination environment of the Zn atoms along with the atomic labelling for **3**. The displacement ellipsoids are drawn at the 60% probability level (Symmetry transformations used to generate equivalent atoms: #1 = x, $y-1$, $z-1$; #2 = $-x+1$, $-y+2$, $-z+1$; #3 = x, $y+1$, $z+1$; #4 = $-x+2$, $-y+3$, $-z+1$; #5 = $-x+2$, $-y+2$, $-z+2$). (b) 2D square grid-like network generated from six-coordinate Mn atoms by bis-bidentate and bis-chelating adipato ligands.

each coordinated to three Mn atoms with one end carboxylate group chelating one metal atom and the other bidentately bridging two metal atoms in a syn-anti fashion. This coordination mode of the suberate anion is very similar to the glutarate anions in Mn(bpy)($C_5H_6O_4$) [12], but significantly different from that in $Mn_2(H_2O)(C_8H_{12}O_4)_2$ [10]. The dimeric Mn_2 units are interconnected by suberate anions to generate a 1D ribbon-like chain with alternative 8- and 22-membered rings (Fig. 5). The Mn···Mn distance within the 8-membered ring is 3.914 Å, much less than those in Mn(bpy)($C_5H_6O_4$) (3.973 Å) and Mn(bpy)($C_6H_8O_4$) (4.035 Å) [12]. The resulting chains are interlinked through the 4,4′-bipyridine ligands into grid-like layers with a (4,4) topology (Fig. 6). The formed 2D layers are arranged parallel to (1 0 0) and between them are sandwiched the lattice H_2O molecules, which are hydrogen bonded to both chelating carboxylate oxygen atoms from different layers (Table 3). The 4,4′-bipyridine ligands in **4** are significantly twisted by 23.4(2)° around the middle C–C bonds in comparison with **1**–**3**, where the bpy ligands show nearly perfect coplanarity, with the dihedral angles between both pyridine rings being in the region 4.9(2)°–6.3(3)°. Within the four title coordination polymers, no π-stacking interactions are found between the bpy bridges [30].

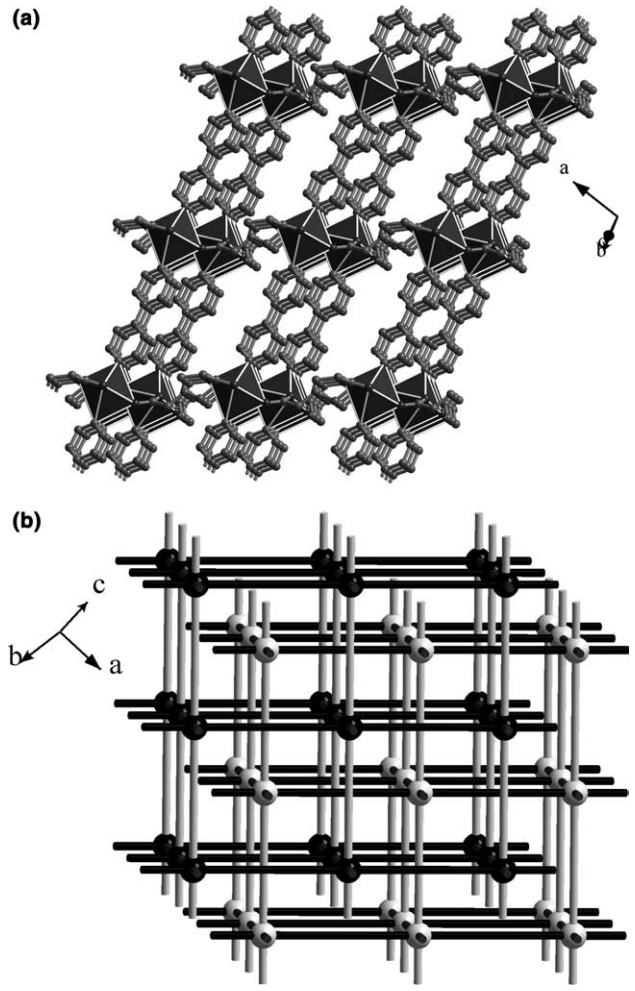

Fig. 4. (a) 3D framework in **3**. (b) The topology of the structure of **3** display twofold interpenetration viewed along the 4,4′-bipyridine ligands (darker and grey rods representing the bis-chelating and bis-bidentate adipato groups, respectively).

2.5. Magnetic properties of $Mn(bpy)(C_8H_{12}O_4)\cdot H_2O$ (**4**)

Fig. 7 demonstrates the temperature dependence of the inverse magnetic susceptibilities (χ_m^{-1}) and effective magnetic moments (μ_{eff}) of **4**, where χ_m is the magnetic susceptibility per molar Mn^{2+} ions and the effective magnetic moments were calculated by the equation $\mu_{eff} = 2.828(\chi_m T)^{1/2}$. The effective magnetic moment at room temperature is $5.77\mu_B$, slightly less than the spin-only value of $5.92\mu_B$ expected for high-spin Mn(II) in an octahedral crystal field [31]. Upon cooling from room temperature to 80 K, the value of μ_{eff} remains essentially constant, then gradually decreases to $3.53\mu_B$ at 5 K, indicative of an overall antiferromagnetic coupling between the Mn^{2+} centers. Over the temperature range 5–300 K, the title complex obeys the Curie–Weiss law $\chi_m(T-\Theta) = 4.265(5)\ cm^3\ mol^{-1}$ with the Weiss constant $\Theta = -6.3(2)$ K.

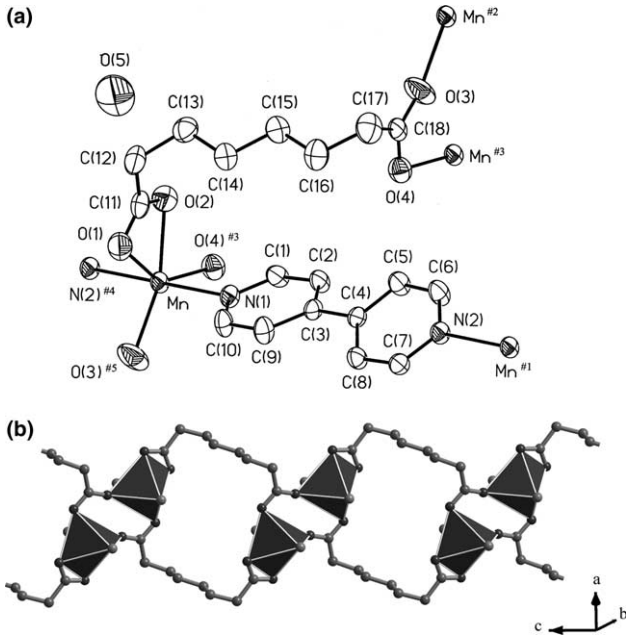

Fig. 5. Coordination environment of the Zn atom along with the atomic labelling for **4**. The displacement ellipsoids are drawn at the 60% probability level (Symmetry transformations used to generate equivalent atoms: #1 = x, $y-1$, $z-1$; #2 = x, y, $z-1$; #3 = $-x+1$, $-y+1$, $-z+1$; #4 = x, $y+1$, $z+1$; #5 = x, y, $z+1$; #6 = $-x+2$, $-y+2$, $-z+2$). (b) 1D ribbon-like chains of Zn atoms bridged by suberato ligands.

3. Experimental

All chemicals of p.a. grade were commercially available and used without further purification. The C, H and N microanalyses were performed with a PE 2400 CHNO/S elemental analyzer. The FT-IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Shimadzu FTIR-8900 spectrometer. The combined measurements on thermogravimetric and differential thermal analyses (TG/DTA) were carried out between 25 and 600 °C on powdered samples in a nitrogen stream using Seiko Exstar6000 TG/DTA6300 equipment with a heating rate of 10 °C/min. The magnetic susceptibility of the title complex was measured on a powdered sample (68.86 mg, **4**) using a SQUID magnetometer (Quantum Design Model MPMS-7) in the temperature range $5 \leqslant T\ (K) \leqslant 300$ with an applied field of 10 000 G. Diamagnetic corrections were estimated from Pascal's constants [31].

3.1. Preparation of $Cu(bpy)(C_5H_6O_4)$ (**1**)

The hydrothermal reaction of 0.242 g (1 mmol) $Cu(NO_3)_2\cdot 3H_2O$, 0.132 g (1 mmol) glutaric acid, 0.156 g (1 mmol) 4,4′-bipyridine, 8 ml CH_3OH and 8 ml H_2O in a 23 ml Teflon-lined stainless-steel reactor at 160 °C for 24 h yielded a mixture of green plate-like crystalline

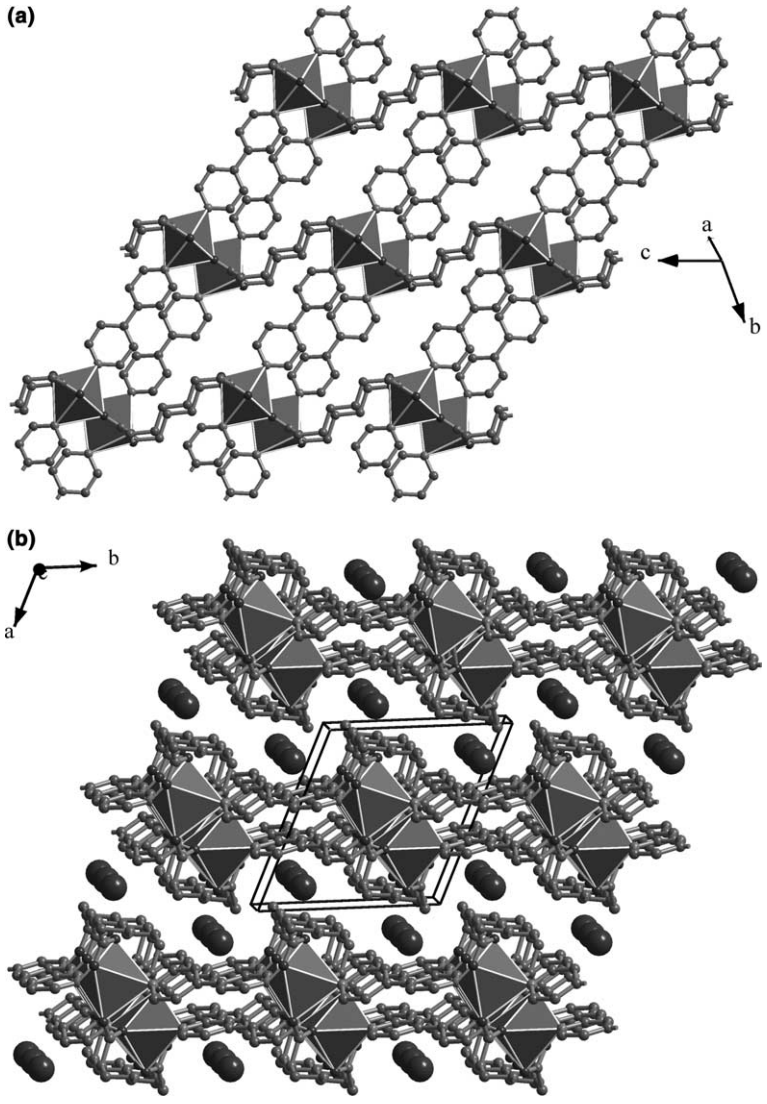

Fig. 6. (a) The ribbon-like chains are pillared by rigid bpy ligands into a 2D layer in **4**. (b) Crystal structure of **4**.

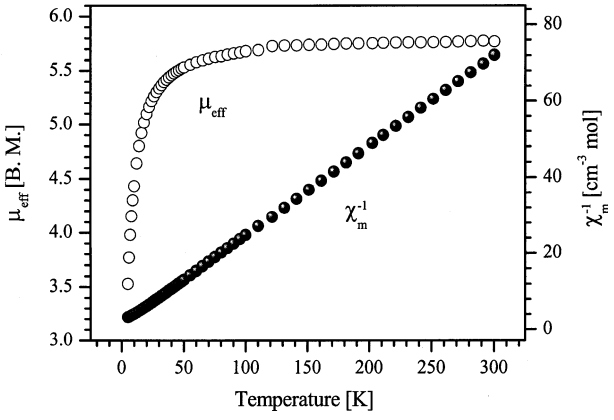

Fig. 7. Temperature dependence of the magnetic susceptibilities of **4** (χ_m being the magnetic susceptibility per Mn(II) ion).

$Cu(bpy)(C_5H_6O_4)$ (**1**) as a minor product and green prismatic crystalline $Cu_2(bpy)(C_5H_6O_4)_2 \cdot 3H_2O$ [14] as the major product.

3.2. Preparation of $Zn(bpy)(C_5H_6O_4)$ (**2**)

Dropwise addition of 1.0 ml Na_2CO_3 (1 M) to a stirred aqueous solution of $ZnSO_4 \cdot 7H_2O$ (0.081 g, 0.50 mmol) in 5.0 ml H_2O produced the white precipitate $Zn(OH)_{2-2x}(CO_3)_x \cdot yH_2O$, which was then centrifuged and washed with double-distilled water until no SO_4^{2-} anions were detectable in the supernatant. The precipitate was subsequently moved to a stirred suspension of glutaric acid (0.066 g, 0.50 mmol) in 20.0 ml CH_3OH–H_2O (v/v = 1:1), and then a methanolic solution of 4,4′-bipyridine (0.078 g, 0.50 mmol) in 5.0 ml CH_3OH was added. The mixture was further stirred for 30 min and the insoluble solid was filtered off. The colorless filtrate (pH 5.33) was allowed to stand at room temperature. Slow evaporation for several days afforded a small amount of colorless prismatic crystals (yield: less than 5% based on the initial $ZnSO_4 \cdot 7H_2O$ input). *Anal.* Calc. for $C_{15}H_{14}N_2O_4Zn$: C, 51.23; N, 7.97; H, 4.01.

3.4. Preparation of $Mn(bpy)(C_8H_{12}O_4) \cdot H_2O$ (**4**)

Dropwise addition of 1.0 ml (1 M) Na_2CO_3 to a stirred aqueous solution of $MnSO_4 \cdot H_2O$ (0.085 g, 0.50 mmol) in 5.0 ml H_2O produced a pale yellow precipitate of $Mn(OH)_{2-2x}(CO_3)_x \cdot yH_2O$, which was then centrifuged and washed with double-distilled water until no SO_4^{2-} anions were detectable in the supernatant. The precipitate was moved to a stirred suspension of suberic acid (0.087 g, 0.50 mmol) in 20.0 ml H_2O, and then a methanolic solution of 4,4′-bipyridine (0.078 g, 0.50 mmol) in 5.0 ml CH_3OH was added. The mixture was further stirred for 30 min and the insoluble solid was filtered off. The nearly colorless filtrate (pH 6.00) was allowed to stand at room temperature. Slow evaporation over several weeks afforded yellow crystals (Yield: ca. 50% based on the initial $MnSO_4 \cdot H_2O$ input). *Anal*. Calc. for $C_{18}H_{22}MnN_2O_5$: C, 53.82; N, 6.98; H, 5.48. 3.5. Crystal structure determination

The reflection intensities of **1**, **2**, **3** and **4** were collected at 293 K on a Bruker P4 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) using the ϑ–2ϑ scan technique. SHELXS-97 [32] and SHELXL-97 [33] programs were used for structure determination and refinements. The structures were solved with direct methods and refined with full-matrix least-squares techniques. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms associated with carbon atoms were generated geometrically, while the water hydrogen atoms were located from the difference Fourier syntheses. Details of crystal data, collection and refinement of the complexes are

summarized in Table 1 and selected interatomic distances and bond angles are listed in Tables 2 and 3.

4. Supplementary data

Supplementary data for the four structures are available from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk, or www: http://www.ccdc.cam.ac.uk), on request quoting the deposition Nos. CCDC 251786, CCDC 251787, CCDC 251788 and CCDC 251789.

Received 1 October 2004; accepted 24 November 2004

Abstract

Two mononuclear iron complexes with the quinoline-2-carboxylate ion (quin-2-c ion) have been obtained by the reaction of iron powder with quinoline-2-carboxylic acid in dichloromethane. The compounds $[Fe(quin\text{-}2\text{-}c)_2]$ (**1**), $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2] \cdot 2CH_2Cl_2$ (**2**) and $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2] \cdot 2EtOH \cdot 2H_2O$ (**3**) have been investigated by IR and UV–Vis spectroscopy, magnetic susceptibility and field-dependent magnetization measurements. The structure of **2** has been characterised by X-ray diffraction. The 2D bilayered frameworks of **2** and **3** are constructed by extensive hydrogen bonding interactions between water and the organic ligand coordinated to iron (II). The magnetic properties of **2** and **3** were interpreted on the basis of a spin Hamiltonian that included axial and rhombic crystal field components. The weak antiferromagnetic (**2**) and ferromagnetic (**3**) interactions are evident in the low temperature data and possibly occur via strong hydrogen bonds.

1. Introduction

The carboxylate group is very common in biological ligands and is often used as the functional group in preparing hybrid materials, ceramic precursors and in systems of catalytic activity. The carboxylate group offers a variety of coordination modes and many types of complexes are known [1]. Examples of catalytic applications of iron carboxylates are Gif [2] and Fenton [3] chemistry. In these experiments, several iron (II/III) picolinate species have been employed as oxidation agents. Some of them have been obtained in the synthetic route starting from the products of the reaction between metallic iron and picolinic acid in dichloromethane [4].

We decided to study the iron/quinoline-2-carboxylic acid/dichloromethane system. Quinoline-2-carboxylic acid, the biological ligand, is the close analogue of picolinic acid (pyridine-2-carboxylic acid) and provides the coordination set characteristic of the PQQ cofactor [5] found in quinoproteins. In our previous study, we have obtained and characterised the complexes of Fe(II) and Co(II) with quinoline-2-carboxylate ion [6]. The structures of quin-2-c complexes with Cu(II) [7], Rh(III) [8], Ga(III) [9], Mn(II) [10–13], Nd(III) [14], Au(III) [15], Fe(II) [16] have also been reported. Here, we describe the amorphous compound $Fe(quin\text{-}2\text{-}c)_2$ and the 2D supramolecular network created by extensive hydrogen

bonding interactions in the crystal of Fe(quin-2-c)$_2$(H$_2$O)$_2$] · 2CH$_2$Cl$_2$. The influence of the system of strong intermolecular hydrogen bonds on the magnetic and spectral properties in **2** and **3** have been studied.

2. Experimental

2.1. Bis(quinoline-2-carboxylato)iron(II) (1)

This compound was obtained by the method described for iron (II) picolinate [4]. A mixture of quinoline-2-carboxylic acid (1 mmol) and Fe powder (0.55 mmol) in dichloromethane was left for three days. The dark-red solution thus obtained was filtered from any remaining Fe and the solvent was removed in a vacuum evaporator to obtain a red-black powder. Yield: 98%. *Anal*. Calc. for C$_{20}$H$_{12}$FeN$_2$O$_4$: C, 60.0; H, 3.0; N, 7.0. Found: C, 60.7; H, 3.3; N, 7.5%.

2.2. trans-Diaquabis(quinoline-2-carboxylato)iron(II) bis dichloromethane solvate (2)

This compound was obtained by the analogous method as for **1**, but with the addition of one drop of water to the reaction mixture. The deep red crystals of **2** which deposited on the wall of the flask were suitable for X-ray analysis. Yield: 95%. *Anal*. Calc. for C$_{22}$H$_{20}$Cl$_4$FeN$_2$O$_6$: C, 43.6; H, 3.3; N, 4.6. Found: C, 43.2; H, 3.1; N, 4.4%

2.3. trans-Diaquabis(quinoline-2-carboxylato)iron(II) bis ethanol bis water (3)

This compound was obtained by the method described by Okabe and Makino [16]. Yield: 94%.

2.4. Physical measurements

The solid-state electronic spectra of the powdered samples were measured in the diffuse reflectance mode on a Carry 500 Scan (Varian) UV–Vis–NIR spectrophotometer. IR spectra were recorded as KBr pellets or nujol mulls using Perkin–Elmer 1600 and Perkin–Elmer 180 spectrophotometers.

Magnetic susceptibility down to 1.9 K and magnetization up to 5 T were measured with a Quantum Design SQUID magnetometer. Diamagnetic corrections were calculated using Pascal's constants [17] and were found to be -215×10^{-6}, -335×10^{-6} and -335×10^{-6} for **1**, **2** and **3**, respectively.

2.5. X-ray diffraction data collection and refinement

Preliminary examinations were carried out on oscillation and Weissenberg photographs. Data collection were performed on a KUMA KM4 κ-axis diffractometer with graphite-monochromated Mo Kα radiation and with a CCD camera. The data were corrected for Lorentz, polarization and absorptions effects (analytical method) [18]. The structures were solved by direct methods and refined by the full-matrix least-squares method on all F^2 data using the SHELXTL (version 5.10) program [19]. Carbon bonded hydrogen atoms were included in calculated positions and refined in the riding mode. Other hydrogen atoms were located in a difference map and refined without any restraints. The crystal data and structure refinement details for **2** are given in Table 1.

3. Results and discussion

3.1. Crystal structure

The studied compounds, Fe(quin-2c)$_2$ (**1**), [Fe(quin-2c)$_2$(H$_2$O)$_2$] · 2CH$_2$Cl$_2$ (**2**) and [Fe(quin-2-c)$_2$(H$_2$O)$_2$] · 2EtOH · 2H$_2$O (**3**), have been obtained under aerobic conditions. The solid complexes are very stable in air, whereas **1**, dissolved in dichloromethane, undergoes oxidation in a few days and yields yellow crystals of the iron (III) complex, which are now under study.

The structure of the Fe(quin-2-c)$_2$(H$_2$O)$_2$ molecule is shown in Fig. 1, the packing in the crystals of **2** and **3** (along with the hydrogen bond system) is shown in Fig. 2. The 2D networks of hydrogen bonds connecting the iron centers in **2** and **3** are presented in Fig. 3. Selected bond lengths and angles are listed in Table 2. The hydrogen bonding parameters for **2** are collected in Table 3.

The crystal of **2** consists of neutral molecules of the iron (II) complex, $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2]$, and of molecules of dichloromethane. The iron (II) ion is six coordinated with a N_2O_4 donor set. The quin-2-c ions bind to iron in a chelate mode by two *trans* carboxylate O atoms and two *trans* quinoline N atoms, in the equatorial plane. Two water molecules complete the axial positions of the distorted octahedron around the ferrous ion. The Fe(II) ion lies on an inversion centre. Okabe and Makino [16] obtained $[Fe(quin\text{-}2\text{-}c)_2(H_2O)_2] \cdot 2EtOH \cdot 2H_2O$ (**3**) from the ethanolic solution of Hquin-2-c and iron(II) sulfate. Compound **3** comprises a complex molecule almost identical to that found in **2**. The coordination mode and the geometry of the $Fe(quin\text{-}2\text{-}c)_2(H_2O)_2$ moiety is the same in **2** and **3**. Small differences are observed for the coordination bonds length, for example, the Fe–N distance in **2** is equal to 2.254(3) Å, whereas the length of the respective bond found in **3** is 2.270(1) Å. Both values are characteristic for high spin ferrous complexes [20]. The iron-carboxylate oxygen distances in **2** and **3** are very close to the medium value of this bond

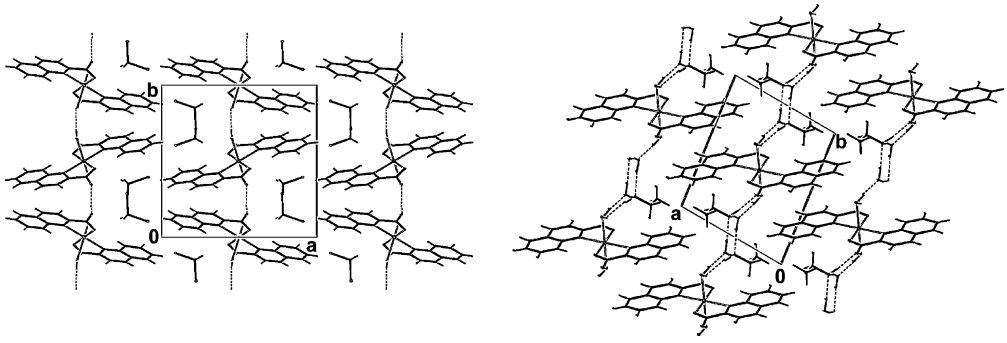

Fig. 2. Projections of the structures **2** (left) and **3** (right) down the *c*-axis, showing the layers comprising of iron ions.

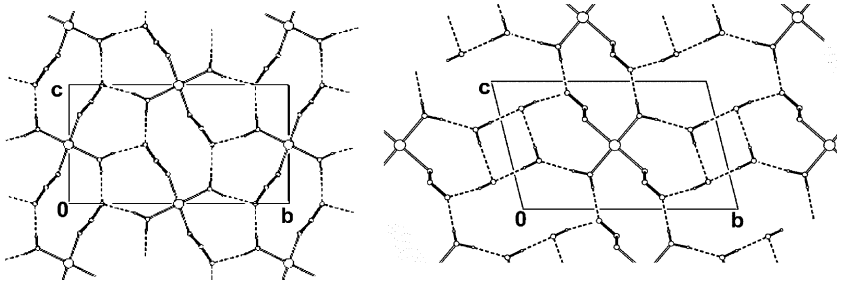

Fig. 3. 2D layers in **2** (left) and **3** (right) constructed by hydrogen bonding interactions between coordination centers (quinoline rings, dichloromethane and C_2H_5 groups of ethanol are omitted for clarity).

(2.10 Å) estimated by Hocking for 68 monodentately coordinated high spin iron (II) carboxylate complexes [21]. However, the structural characteristics of the carboxylate groups in **2** and **3** are very different from the medium parameters estimated for terminal ferrous carboxylates [21,22]. The distances C(10)–O(11) and C(10)–O(12) are surprisingly almost equal (1.257(5) and 1.258(5) Å, respectively) which is mostly observed for the carboxylate group acting in a bridging mode [22].

The organisation of the crystals of **2** and **3** is also very similar, as shown in Fig. 2. The molecules of the complex in **2** and **3** are connected by extensive hydrogen bonding interactions (Table 3). In **2**, each water coordinated to iron makes two strong hydrogen bridges with carbonyl oxygen atoms from the carboxylate group of neighbouring molecules of the complex. In **3**, five strong hydrogen bonds involving the coordinated and lattice water molecules as well as ethanol molecules have been found. The hydrogen bonding networks in **2** and **3** create the 2D, inorganic layers, Fig. 3. The quinoline parts of the quin-2-c ligand form the organic layers in both compounds, in **2** the dichloromethane molecules are also packed in this layer, in **3** the C_2H_5 group of ethanol is located in the organic layer. The organic layers and layers of iron complexes are packed alternately. The shortest Fe–Fe distance within a layer in **2** is equal to 7.212 Å, in the crystal of **3** the closest iron ions are separated by 7.299 Å. In the crystal of **2**, the dichloromethane molecules are involved in hydrogen bonds of C–H···Cl type (Table 3). The weak intramolecular C–H···O interaction (C(8)–H(8)···O(12)^{iii}) stabilize the equatorial plane of the complex in **2** and **3**.

3.2. Spectral and magnetic data

The selected frequencies observed in the IR spectra of **1**, **2**, **3**, Fe(quin-2-c)$_2$(EtOH)$_2$ and of Naquin-2-c are collected in Table 4, together with their assignments. The values of $\Delta\nu$ [$\Delta\nu = \nu_{as}(COO) - \nu_s(COO)$] found for **2** and **3** are equal to 220 and 235 cm^{-1}, respectively. They are smaller than expected for the monodentately coordinated carboxylate group [23]. Such low $\Delta\nu$ values result from the strong hydrogen bonds between the hydroxyl group or water molecules and the carboxylate oxygens. A similar effect was reported earlier for other complexes [24]. The coordination mode in those compounds can be regarded as a "pseudo bridging" arrangement. It is interesting to note that in the case of **1**, $\Delta\nu$ equals 275 cm^{-1} and is in the normal range for terminal carboxylates. On this basis the carboxylates in **1** can be assumed to be monodentately bonded and not involved in any hydrogen bonding. The comparison of the infrared spectra of **1**, **2** and **3** as well as that of [Fe(quin-2-c)$_2$(EtOH)$_2$] [5] and literature data [25] allowed the assignment of the stretching vibrations of coordination bonds in the discussed compounds as shown in Table 4.

The electronic spectra of **1**, **2** and **3** are very similar and feature two bands, representing the transitions to the ^5E_g state, typical of a Fe(II) high-spin chromophore (Table 5). The intense bands with maxima located near 18 000 cm^{-1} are assigned as $t_{2g} \rightarrow \pi^*$ [26].

The magnetic susceptibility of **2** obeys the Curie–Weiss (CW) law above ca. 20 K with the moment $\mu = 5.66\mu_B$ and the Weiss constant $\theta = -1.8$ K, $\mu = 2.828\sqrt{\chi(T-\theta)}$. The effective magnetic moment $\mu_{eff} = 2.828\sqrt{\chi T}$ is almost constant in this temperature range and decreases quickly below it (Fig. 4). The susceptibility of **3** fulfills the CW equation above ca. 100 K with $\mu = 5.30\mu_B$ and $\theta = 8.6$ K. The effective moment increases with temperature in the low temperature range, reaches the rounded maximum around 22 K and then the shallow minimum around 130 K.

While the compounds **2** and **3** may be considered as high-spin Fe(II) complexes, the magnetic properties of **1** cannot be unambiguously categorized. The susceptibility of **1** is low – only 7.7×10^{-3} cm^3 mol^{-1} at 300 K compared to 13.5×10^{-3} and 12.9×10^{-3} for **2** and **3**, respectively. The magnetization of the three compounds also shows similar differences. A more detailed analysis of the magnetic properties of **1** must be postponed until the crystal structure of the compound will be solved.

The shortest Fe–Fe distances in **2** and **3** are greater than 7 Å (7.212 Å for **2** and 7.229 Å for **3**). Thus, their magnetic properties may be calculated using the Hamil-

tonian of Ginsberg et al. [27], containing the Zeeman effect, crystal field and weak exchange interactions in the molecular field approximation. Details of the calculations are included in the supplementary material and the results are presented in Fig. 4.

The coordination of the Fe(II) ion in **3** is almost identical to that in **2**, but their magnetic properties are quite different. The maximum of the effective moment of **3**, around 22 K, cannot be explained on the ground of pure crystal field theory. Similar effects usually result from ferromagnetic exchange interactions [28]. The theoretical calculations of the magnetic susceptibilities of **2** and **3** seems to justify such an assumption: when the CF interactions in both compounds are comparable ($D = 2.8$ and 3.2 cm^{-1} and $E = -0.3$ and -0.8 cm^{-1} for **2** and **3**, respectively), the exchange parameters zJ' are different (-0.1 and $+0.88$ cm^{-1}, respectively).

The contribution of H-bonds to weak indirect exchange is well documented [29,30]. It has been also suggested that hydrogen bonds can transmit strong exchange interactions, which may result in long-range magnetic ordering [29,31,32]. The former type of interactions were found in compounds **2** and **3**. The monomeric units in **2** and **3** are connected by hydrogen bonds forming extended 2D structures. The bond net is particularly compact in **3**, whereas the interactions involving dichloromethane molecules in **2** are weak. This may explain the differences between the exchange parameters zJ' for both compounds.

4. Conclusions

Two new iron (II) complexes, **1** and **2**, with quinoline-2-carboxylate ion have been obtained in the direct reaction between metallic iron and quinoline-2carboxylic acid in dichloromethane. A spectral and magnetic study has been performed for **1**, **2** and **3**, and the crystal structure of **2** has been found. The high spin state of the ferrous ions in **1**, **2** and **3** has been confirmed by UV–Vis and magnetic data. The strong intermolecular hydrogen bridges found in **2** and **3** create 2D inorganic networks and strongly affect the vibrational characteristic of the carboxylate groups. They are also responsible for the weak, indirect magnetic exchange interactions observed in **2** and **3** at low temperatures.

Appendix A. Supplementary data

Crystallographic data for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC 234055. Copies of the data can be obtained free of charge from The CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (44) 1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2004.11.026.

Received 12 October 2004; accepted 30 November 2004

Abstract

In our continuous efforts to investigate the coordination architectures of silver(I) complexes with thioethers, we report herein the syntheses and crystal structures of three new silver(I) complexes, a trinuclear complex $[Ag_3L^2_2(NO_3)_2](NO_3)(CH_3CN)$ **2** and two one-dimensional chain complexes $[Ag_2L^1(BF_4)_2(CH_3CN)_2]_\infty$ **1** and $[Ag_2L^3(NO_3)_2]_\infty$ **3**, where L^1, L^2 and L^3 are three structurally related pyridyl dithioether ligands: 1,4-bis(2-pyridylthio)butane (L^1), 1,5-bis(2-pyridylthio)pentane (L^2) and 1,6-bis(2-pyridylthio)hexane (L^3). The structural differences of **1**, **2** and **3** show the influences of the ligand spacers on the coordination modes of the terminal pyridylsulfanyl groups and the coordination geometries of the Ag^I ion. There exist Ag···Ag contacts in the three complexes, C–H···F weak hydrogen bonds in **1**, Ag···S weak coordination bonds in **2** and Ag···O weak interactions in **2** and **3**, and these weak interactions link the low-dimensional complexes into high-dimensional supramolecular structures and further stabilize the crystal structures in the solid states.

1. Introduction

The self-assembly of supramolecular coordination polymers is the result of combinations of various forces including strong and directional interactions (for example metal–ligand coordination) [1–4] and weak interactions such as π–π stacking [5,6], halogen–halogen [7,8] and C–H···X (X = O, N, Cl or I, etc.) contacts [9,10]. The self-assembly process of metal complexes is quite complicated and the understanding of the factors that affect the process between labile metal ions and flexible multidentate ligands is an interesting and challenging topic in supramolecular and coordination chemistry. Due to the conformational freedom, flexible multidentate bridging ligands show interesting coordination chemistry with transition metal ions and have great possibilities for generating novel coordination frameworks [11,12]. In addition, the flexible bridging ligands are very sensitive to changes of conditions, so they are suitable candidates for investigating the roles of various factors such as solvents, counter anions and weak supramolecular interactions in the aggregation of molecular architectures.

In our previous works, dithioethers as flexible multidentate ligands have been successfully used to construct various structures of complexes including discrete molecules, 1-D, or 2-D network architectures [13–20]. We report herein the synthesis and characterization of three

Chart 1.

Ag^{I} complexes with three flexible multidentate pyridyl dithioether ligands that are closely related in structure: 1,4-bis(2-pyridylthio)butane ($\mathbf{L^1}$), 1,5-bis(2-pyridylthio) pentane ($\mathbf{L^2}$) and 1,6-bis(2-pyridylthio)hexane ($\mathbf{L^3}$) (see Chart 1), and the roles of weak interactions in the formation of coordination architectures have also been discussed.

2. Experimental

2.1. Materials and general methods

All the reagents for syntheses were commercially available and employed without further purification or purified by standard methods prior to use. Elemental analyses were performed on a Perkin–Elemer 240C analyzer and IR spectra were measured on a 170SX (Nicolet) FT-IR spectrometer with KBr pellets. The three ligands, $\mathbf{L^1} \sim \mathbf{L^3}$, were prepared according to the reported procedures [17].

2.2. Preparation of complexes

2.2.1. $[Ag_2\mathbf{L^1}(BF_4)_2(CH_3CN)_2]_\infty$ (1)

A solution of $AgBF_4 \cdot H_2O$ (21 mg, 0.1 mmol) in CH_3CN (10 mL) was carefully layered on top of a solution of $\mathbf{L^1}$ (28 mg, 0.1 mmol) in $CHCl_3$ (10 mL) in a test-tube. After three days at room temperature, colorless single crystals appeared at the boundary between CH_3CN and $CHCl_3$ (Yield: 25%). IR (KBr pellets, cm^{-1}): 2154w, 1629w, 1581s, 1554s, 1456s, 1416s, 1401m, 1311m, 1127vs, 1043vs, 985s, 766s, 733m, 710m. *Anal*. Calc. for $C_9H_{11}AgBF_4N_2S$: C, 28.91; H, 2.97; N, 7.49. Found: C, 28.31; H, 3.02; N, 7.56%.

2.2.2. $[Ag_3\mathbf{L^2_2}(NO_3)_2](NO_3)(CH_3CN)$ (2)

A solution of $AgNO_3$ (17 mg, 0.1 mmol) in CH_3CN (3 mL) was slowly added to a solution of $\mathbf{L^2}$ (30 mg, 0.1 mmol) in $CHCl_3$ (3 mL). Slow diffusion of ether into the resulting solution yielded colorless single crystals **2** suitable for X-ray analysis (Yield: 34%). IR (KBr pellets, cm^{-1}): 2131w, 1629w, 1578s, 1556m, 1454s, 1414vs, 1384vs, 1124s, 1088m, 1043w, 825w, 757s, 724m. *Anal*. Calc. for $C_{32}H_{39}Ag_3N_8O_9S_4$: C, 33.97; H, 3.47; N, 9.90. Found: C, 33.49; H, 3.23; N, 9.68%.

2.2.3. $[Ag_2\mathbf{L^3}(NO_3)_2]_\infty$ (3)

Colorless crystals of **3** suitable for X-ray analysis (Yield: 31%) were obtained by a similar method as described for **2**. IR (KBr pellets, cm^{-1}): 1578m, 1556w, 1454m, 1414s, 1383vs, 1124m, 757m. *Anal*. Calc. for $C_{16}H_{20}Ag_2N_4O_6S_2$: C, 29.83; H, 3.13; N, 8.70. Found: C, 30.01; H, 3.26; N, 8.51%.

2.3. X-ray crystallographic studies of complexes 1–3

Single-crystal X-ray diffraction measurements were carried out on a Bruker Smart 1000 CCD diffractometer equipped with a graphite crystal monochromator situated in the incident beam for data collection at room temperature. The determination of unit cell parameters and data collections were performed with Mo-Kα radiation ($\lambda = 0.71073$ Å). Unit cell dimensions were obtained with least-squares refinements and all structures were solved by direct methods. Silver atoms in each complex were located from *E*-maps. The other non-hydrogen atoms were located by successive difference Fourier syntheses. The final refinement was performed by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The hydrogen atoms were added theoretically and riding on the concerned atoms. In **1**, the BF_4^- ion is disordered and was refined in the occupation ratio of 7:3 in two different positions based on fixing one B–F bond. One C atom of the coordinated CH_3CN molecule is also disordered and refined in two positions with a 1:1 occupation ratio. Crystallographic data and experimental details for structural analyses are summarized in Table 1.

3. Results and discussion

The crystal structure of $[Ag_2\mathbf{L^1}(BF_4)_2(CH_3CN)_2]_\infty$ (**1**) features a one-dimensional (1-D) chain. Fig. 1(a) shows the structure with the atom labelling, and selected bond lengths and angles are listed in Table 2. Each Ag^{I} center is four-coordinated by an N and an S atom from distinct $\mathbf{L^1}$ ligands, an N atom of CH_3CN and an F atom from BF_4^-, showing a distorted tetrahedral coordination geometry. The Ag–N bonds fall in the expected ranges for such coordination bonds [21], while the Ag–S bond is slightly longer than those in the Ag^{I} complexes with thioether ligands [13,15]. The ligands adopt an *N*,*N*,*S*,*S*-tetradentate *anti*-bridging mode to coordinate to the Ag^{I} centers, resulting in an infinite chain. This kind of coordination mode of the ligand is also found in our reported complexes $\{[Ag_2(\mathbf{L^1})_2](ClO_4)_2(CHCl_3)\}_\infty$, $\{[Ag\mathbf{L^1}](ClO_4)(C_3H_6O)\}_\infty$, $\{[Ag_2\mathbf{L^1}](NO_3)_2\}_\infty$ and $[Ag_2\mathbf{L^1}(CF_3SO_3)_2]_\infty$ [17], but is different to that in $\{[Ag\mathbf{L^1}](ClO_4)\}_\infty$ and $\{[Ag\mathbf{L^1}(CH_3CN)](PF_6)\}_\infty$ [19]. Two pyridylsulfanyl groups from two $\mathbf{L^1}$ ligands bridge two Ag^{I} atoms to

Ag···Ag interaction [23–25], and such metal–metal contacts are also found in other d^{10} metal complexes [26].

An interesting point is the stacking pattern of **1** in the solid state. The hydrogen atoms from the pyridine rings of the 8-membered metallomacrocycle have been activated by the positive charge due to the coordination of the nitrogen atoms to the Ag^{I} centers, and two F atoms of the coordinated BF_4^- (here only the larger occupation part of disordered BF_4^- was considered) form the acceptors of two kinds of C–H···F intermolecular hydrogen bonds (Fig. 1(b)), which link the complex to form a 2-D supramolecular framework structure. The C···F separations are 3.352 Å with H···F distances of 2.526 Å, falling into the range of weak C–H···F hydrogen bond interactions [27]. In addition, the H atoms of disordered CH_3CN molecules also form C–H···F weak interactions, which link these 2-D layers into a 3-D framework.

Complex **2** consists of a trinuclear $[Ag_3\mathbf{L}^2_2(NO_3)_2]^+$ cation, an uncoordinated NO_3^- and a CH_3CN solvent molecule. The crystal structure of **2** shows three different Ag^{I} centers lying on a crystallographic plane of symmetry (Fig. 2(a)). Ag(1) is coordinated by two pyridine nitrogens from different $\mathbf{L}^2$ligands showing linear coordination geometry with an N–Ag–N bond angle of 169.9(3)° (Table 2). In addition, NO_3^- shows weak coordination to Ag(1) in the chelated mode with the Ag···O distances of ~2.685 Å. The CH_3CN molecule also weakly coordinates to Ag(1) with an Ag···O distance of 2.716 Å. Ag(2) is coordinated by two pyridine nitrogens from distinct ligands with an N–Ag–N bond angle of 175.2(3)°, but Ag(2) has a different chemical environment from Ag(1). Ag(3) is coordinated to two sulfur atoms of different ligands and four oxygens from two

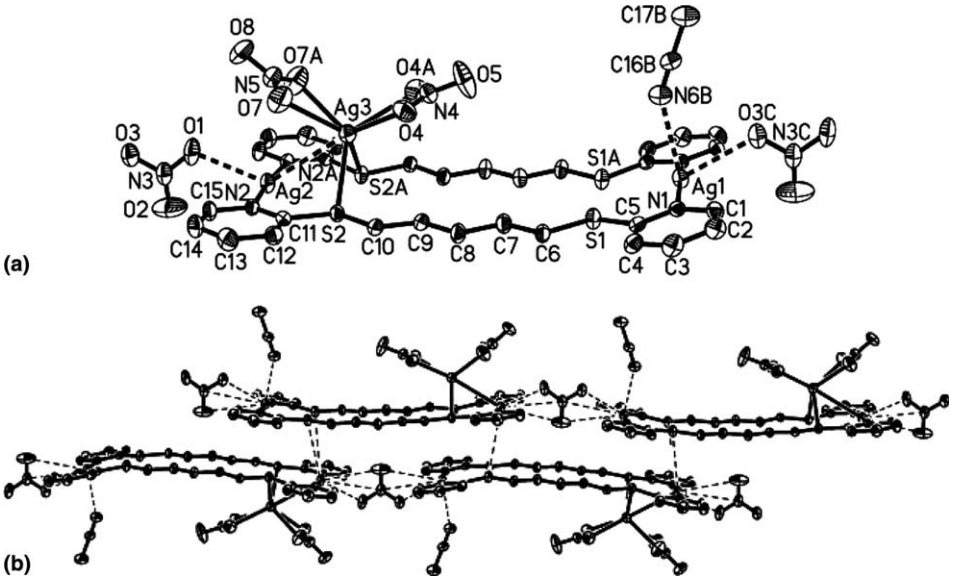

Fig. 2. (a) Perspective view of the trinuclear complex **2** (symmetry codes A: x, $-y+1/2$, z; B: $x-1/2$, y, $-1/2-z$; C: $x-1$, y, z), and (b) the double chain structure formed by weak Ag···S and Ag···O coordination bonds.

chelating nitrate anions to form a rare six-coordination geometry. The Ag–N (average 2.187 Å) and Ag–O [ranging from 2.516(8) to 2.560(8) Å] bond lengths in **2** are in the expected range for such complexes [22], and the Ag–S [2.681(2) Å] distances are close to the values of **1**.

Differing from the reported complexes in which the ligand adopts a bidentate coordination mode [17,19], $\mathbf{L}^2$ in **2** adopts a tridentate coordination mode using its two pyridine nitrogens and a sulfur atom. In the trinuclear structure, the two terminal pyridine rings of each ligand are inclined to each other at an angle of 17.9°, while the two pyridine ring planes around the Ag(1) and Ag(2) centers are basically parallel to each other. A feature of the trinuclear unit is the formation of an Ag···Ag interaction with a distance of 3.176(2) Å which is shorter than that in **1**. Another feature is the stacking pattern of **2** in the solid state. There exist Ag···O weak interactions between Ag(1), Ag(2) and nitrate counter ions with an average distance of 2.650 Å, and the trinuclear units are bridged by nitrate anions using Ag···O weak interactions to form a quasi 1-D chain. In addition, the interchain Ag···S weak interactions link two quasi 1-D chains into a double-chain structure as depicted in Fig. 2(b).

The crystal structure of **3** consists of a 1-D chain in which each Ag^I center is four-coordinated by an N and an S atom from two distinct $\mathbf{L}^3$ ligands as well as two O atoms from chelated nitrate anions (Fig. 3(a)). The coordination geometry of the Ag^I center can be best described as a distorted tetrahedron with bond angles around the Ag^I center ranging from 49.92(9)° to 139.9(1)°. The 8-membered ring formed by two pyridylsulfanyl groups from two $\mathbf{L}^3$ ligands bridging two Ag^I also has an inversion center and adopts a chair configuration with the two pyridine rings parallel to each other. The Ag–N, Ag–S and Ag–O bond lengths are comparable to those in **1**, while the Ag···Ag distance of 3.123(1) Å is significantly shorter than that in **1**, indicating the presence of Ag···Ag interactions. One of the coordinated O atoms from the nitrate ion shows weak coordination to the Ag^I center from another 1-D chain, and these weak interactions link these 1-D chains into a quasi 2-D network (Fig. 3(b)).

In **3**, the ligand adopts an *N*,*N*,*S*,*S*-tetradentate *anti*-bridging mode to coordinate to the Ag^I centers, resulting in an infinite chain, and this kind of coordination mode of $\mathbf{L}^3$ is different from that of the previously reported complexes in which $\mathbf{L}^3$ usually adopts an *N*,*N*-bidentate *anti*-bridging mode [17].

The present study of **1**–**3** further indicates that the coordination modes of the spacer ligands result in different structures [17,19,20]. The ligands $\mathbf{L}^1$, $\mathbf{L}^2$ and $\mathbf{L}^3$ all possess a long flexible segment. Owing to the flexible nature of their spacers, these ligands may be able to adopt various conformations in solution. Depending on their conformation in the self-assembly with metal ions, one may expect the formation of either discrete complexes of the metallomacrocycle type for the *syn* disposition of the coordination sites ($\mathbf{L}^2$) or infinite polymeric structures for the *anti* orientation of the coordination sites ($\mathbf{L}^1$ and $\mathbf{L}^3$). In addition to the strong coordination bonds, there exist other interactions including Ag···Ag contacts, weak coordination bonds

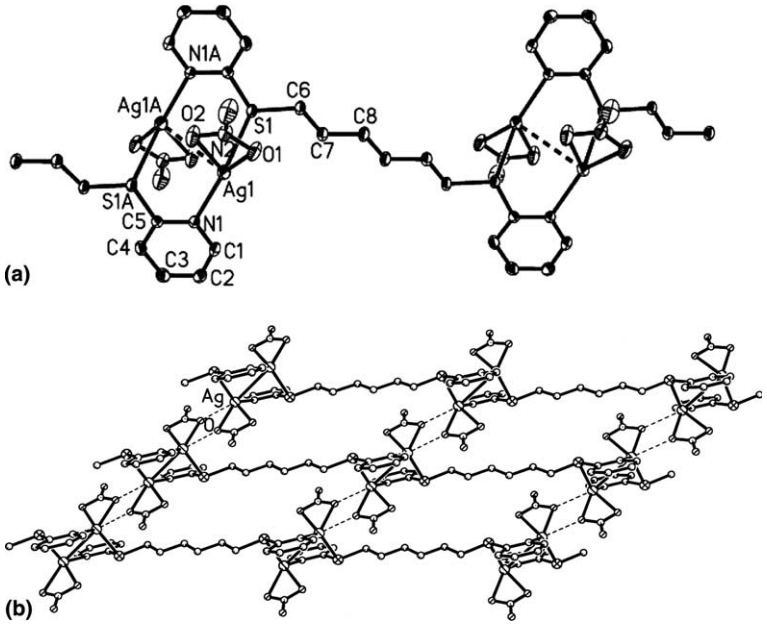

Fig. 3. (a) Perspective view of the 1-D chain of **3** (symmetry code A: $-x+1, -y+2$), and (b) the quasi 2-D network formed by the weak Ag···O coordination bonds.

and weak hydrogen bonds. These weak interactions play a crucial role in the self-organization of supramolecular polymers as well as the stabilization of the complex structures in the solid state.

4. Supplementary materials

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center (CCDC Nos. 228101, 228102 and 228103). These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

The reactions of $[NBu_4]_2[ReX_5(NO)]$ (X = Cl, Br) with triphenylstibine have been examined and three new rhenium complexes – $[ReCl_2(NO)(SbPh_3)_3]$ (**1**), $[ReBr_2(NO)(SbPh_3)_3]$ (**2**) and $[ReBr_2Cl(SbPh_3)_3]$ (**3**) – have been obtained. The last one has been isolated in a low yield during slow recrystallization of the complex **2** from a mixture of chloroform and ethanol. The stibine rhenium nitrosyls have been characterized by IR and UV–vis spectroscopy. The X-ray structures of **1** and **3** have been determined. The geometric parameters of **1** have been examined using the density functional theory (DFT) method.

Keywords: Rrhenium; Stibine; Nitrosyl complexes; X-ray structure; DFT calculations

1. Introduction

The introduction of β^- emitting isotopes ^{188}Re and ^{186}Re in radiotherapy, the similarity with technetium [1–5], and the key role of nitric oxide in human cardiovascular and nervous systems and in immune response to pathogen invasion [6–9] are the main reasons of the still growing interest in rhenium nitrosyl complexes.

Previously, we reported the preparation, spectroscopic and structural characterization of rhenium nitrosyls with triphenylphosphine and triphenylarsine ligands [10–18]. The $[ReOX_3L_2]$ complexes react with NO to give various products, depending on the reaction conditions: $[ReX_3(NO)(OPPh_3)_2]$, $[ReX_3(NO)(PPh_3)_2]$, $[ReX_2(NO)_2(PPh_3)_2]$, $[ReBr_3(NO)(MeCN)(PPh_3)]$, $[ReCl_3(NO)(PPh_3)(OPPh_3)]$, $[ReCl_4(PPh_3)_2]$, $[ReBr_3(NO)(dppe)][ReBr_4(dppe)]$, $[ReX_3(NO)(OAsPh_3)_2]$, $[ReCl_4(OAsPh_3)_2]$ and $[ReCl_3(NO)(AsPh_3)_2]$ $[ReCl_4(AsPh_3)_2]$. The reactions of $[NBu_4]_2[ReX_5(NO)]$ with PPh_3 and $AsPh_3$ lead to $[ReX_3(NO)(PPh_3)_2]$, $[ReBr_3(NO)(AsPh_3)_2]$ and $[ReCl_3(NO)(AsPh_3)_2][ReCl_4(AsPh_3)_2]$.

Now we are extending our studies to the examination of the reactivity of $[NBu_4]_2[ReX_5(NO)]$ (X = Cl, Br) compounds towards triphenylstibine, and here we report the syntheses of the $[ReX_2(NO)(SbPh_3)_3]$ complexes and X-ray structures of $[ReCl_2(NO)(SbPh_3)_3]$ (**1**) and $[ReBr_2Cl(SbPh_3)_3]$ (**3**). The latter has been

isolated in a low yield during slow recrystallization of the $[ReBr_2(NO)(SbPh_3)_3]$ (**2**) complex from a mixture of chloroform and ethanol. The formation of **3** is particularly interesting since substitution reactions of the nitrosyl ligand are rarely observed [19–21]. This paper also includes the results of the DFT calculations for $[ReCl_2(NO)(SbPh_3)_3]$ based on the B3LYP functional, carried out by using the GAUSSIAN 03 program package.

Gancheff et al. [22] have performed extended tests of the ability of the B3LYP method in the LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown it to be sufficient for geometry optimization and calculation of spectral properties. It gives good agreement with the experimental data and its use is especially justified in the case of large molecules.

2. Experimental

2.1. General procedure

All the reagents used for the syntheses were commercially available and were used without further purification. The $[t\text{-}Bu_4N]_2[ReX_5(NO)]$ (X = Cl, Br) complexes were synthesized according to the literature methods [23]. Gaseous NO was generated in the reaction: $2NaNO_2 + 3H_2SO_4 + FeSO_4 \rightarrow 2NO + 2NaHSO_4 + Fe_2(SO_4)_3 + 2H_2O$, and was purified by passing through washers with concentrated KOH solution and a column containing solid NaOH. The reactions were performed under argon atmosphere.

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a Lab Alliance UV–VIS 8500 spectrophotometer in the range 800–200 nm in deoxygenated dichloromethane solution. Magnetic susceptibilities were measured at 296 K by the Faraday method. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Synthesis of $[ReCl_2(NO)(SbPh_3)_3]$ (**1**)

A mixture of $[t\text{-}Bu_4N]_2[ReCl_5(NO)]$ (1 g, 1.15 mmol) and $SbPh_3$ (5.3 g, 15 mmol) in ethanol (50 cm^3) was refluxed for 12 h. The yellow–green precipitate thus formed was filtered and washed with ether. X-ray quality crystals were obtained by recrystallization from a mixture of chloroform and ethanol. Yield 35%.

IR (KBr, cm^{-1}) 3049 (m), 2924 (w), 1683 (vs), 1477 (m), 1430 (s), 1333 (w), 1300 (w), 1261 (w), 1183 (w), 1157 (w), 1066 (m), 1020 (w), 995 (w), 728 (vs), 691 (vs), 449 (m).

Anal. Calc. for $C_{54}H_{45}Sb_3Cl_2NORe$: C, 48.18; H, 3.37; N, 1.04. Found: C, 48.3; H, 3.5; N, 1.1%.

2.3. Synthesis of $[ReBr_2(NO)(SbPh_3)_3]$ (**2**) and $[ReBr_2Cl(SbPh_3)_3]$ (**3**)

A procedure similar to that for **1** was used with $[t\text{-}Bu_4N]_2[ReBr_5(NO)]$ (1.27 g, 1.15 mmol) and $SbPh_3$ (5.3 g, 15 mmol). A yellow–green precipitate of **2** was collected in 38% yield.

IR (KBr, cm^{-1}) 3049 (m), 1681 (vs), 1576 (w), 1479 (m), 1431 (s), 1332 (w), 1302 (w), 1265 (w), 1186 (m), 1157 (w), 1066 (m), 1020 (w), 997 (w), 727 (vs), 692 (vs), 450 (m).

Anal. Calc. for $C_{54}H_{45}Sb_3Br_2NORe$: C, 45.19; H, 3.16; N, 0.98. Found: C, 45.3; H, 3.2; N, 1.1%.

Slow recrystallization of **2** from a mixture of chloroform and ethanol leads to the formation of the $[ReBr_2Cl(SbPh_3)_3]$ complex (**3**) in low yield (~3%).

2.4. Crystal structure determinations and refinement

The X-ray intensity data of **1** and **3** were collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector. 32- and 29-s exposure times were used, respectively, and all the Ewald sphere was collected up to $\theta = 25.11°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 16321 and 7104 strongest reflections, respectively, for **1** and **3**. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption corrections [24] were applied. The structures were solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares techniques. The hydrogen atoms of the phenyl rings were treated as ''riding'' on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent carbon atom. SHELXS 97 [25], SHELXL 97 [26] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.5. Computational details

The GAUSSIAN 03 program [28] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of the B3LYP functional [29,30].

The LANL2DZ basis set [31] was used on the rhenium and antimony atoms, 6-31G(d) on the nitrogen, chlorine, oxygen and carbon atoms, and 6-31G basis on the hydrogen atoms in the calculations.

Natural bond orbital (NBO) calculations were performed with the NBO code [32] included in GAUSSIAN 03.

3. Results and discussion

The [t-Bu_4N]$_2$[$ReX_5(NO)$] complexes (X = Cl, Br) react with PPh_3 and $AsPh_3$ to give [$ReX_3(NO)(PPh_3)_2$], [$ReBr_3(NO)(AsPh_3)_2$] and [$ReCl_3(NO)(AsPh_3)_2$][$ReCl_4(AsPh_3)_2$] [18]. The reactions of [t-Bu_4N]$_2$[$ReX_5(NO)$] with triphenylstibine in ethanol lead to the [$ReX_2(NO)(SbPh_3)_3$] complexes. The smaller steric demand of $SbPh_3$ in comparison with PPh_3 and $AsPh_3$ explains the formation of [$ReX_2(NO)(SbPh_3)_3$]. The increase of M–E and E–C (E = P, As or Sb) bond lengths in the order P > As > Sb leads to the decrease of the EPh_3 cone angles [33].

The yield of the [$ReX_2(NO)(SbPh_3)_3$] complexes depends on: (i) the mole ratio of [NBu_4]$_2$[$ReX_5(NO)$] to triphenylstibine (it is the highest when it is ~1:13) and (ii) the reaction time (it drops considerably when the reaction is carried out in less than 12 h). Compounds **1** and **2** were recrystallized from a mixture of $CHCl_3$/EtOH. The crystals of **1** were of good quality, whereas the crystals of **2** were small and badly shaped. Moreover, in the case of the bromine nitrosyl, the formation of a small amount of well-shaped yellow crystals of **3** was observed during the slow recrystallization. The oxidation reactions of rhenium complexes by halogen-containing solvents have been known for years [34]. Substitution reactions of nitrosyl ligands by halogen ligands, however, are very sparse [19–21].

The structure of **1** has been modelled with the Cl and NO ligands disordered over two sites using fractional occupancies equal to 0.45 for Cl(1), N(2), O(2) atoms and 0.55 for Cl(3), N(1) and O(1) atoms. A similar disorder of NO ligands has also been reported for iridium, rhodium and ruthenium complexes [35]. The $SbPh_3$ ligands are arranged in a *meridional* fashion, and the Cl(3) ligand is involved in weak intramolecular hydrogen bonds with the H(36) and H(54) atoms of the phenyl rings [36–38]. Fig. 1 shows a displacement ellipsoid plot of **1** and selected bond lengths and angles of this compound are summarized in Table 2.

Two groups of ligands of **3** (halide ions and stibine molecules) are arranged in a *meridional* fashion, the bromine ligands occupy a *cis* position to each other. Fig. 2 shows the molecular structure of this compound, and selected bond lengths and angles for **3** are summarized in

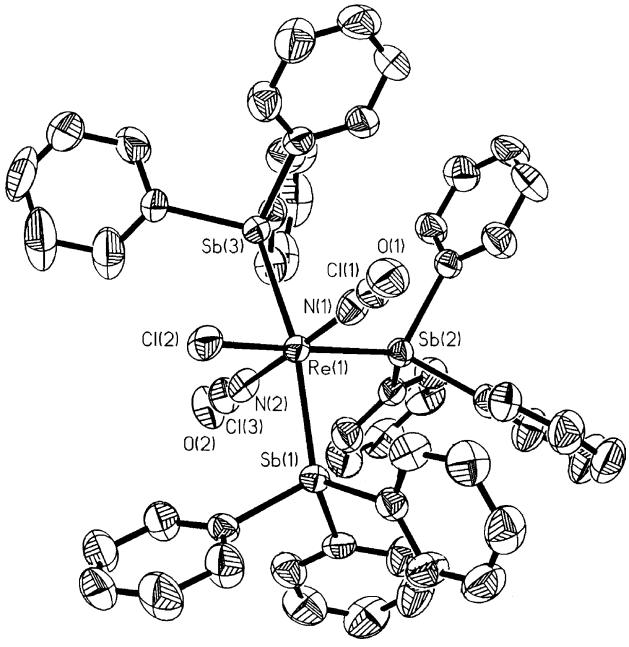

Fig. 1. The molecular structure of **1**.

		Br(2)–Re(1)–Sb(3)	85.01(3)
		Sb(2)–Re(1)–Sb(3)	96.02(2)
		Sb(1)–Re(1)–Sb(3)	169.30(2)

Table 3. The conformations of $[ReBr_2Cl(SbPh_3)_3]$ molecules are stabilized by two weak intramolecular hydrogen bonds [35–37]. The Cl(1) ligand is involved in a weak hydrogen bond with the H(20) atom of the phenyl ring, while the Br(1) ion interacts with the H(36) atom.

Due to steric repulsion of the three bulky $SbPh_3$ molecules, the octahedral Re geometries of **1** and **3** show the expected angular distortions. The angles between *cis*-ligands vary between 83.60(19)° and 97.95(17)° for **1**, and 85.01(3)° and 96.02(2)° for **3**; the *trans*-angles are between 169.64(1)° and 178.2(9)° for **1**, and 169.30(2)° and 177.56(9)° for **3**.

There are only a few Re–Sb distances reported in the Cambridge Structural Database, with $[ReCl_2(NO)_2(SbPh_3)_2]$ [39] [Re–Sb: 2.711(8) and 2.710(8) Å] and $[ReCl(CO)_3(SbPh_3)_2]$ [40] [Re–Sb: 2.726(1) and 2.729(2) Å] being the closest chemical examples and showing little longer Re–Sb bond lengths compared to the presented compounds (Tables 2 and 3).

Relative small C–Sb–C tetrahedral angles were found: 94.78(17)°–102.48(17)°, 100.2° (av) for **1** and 95.2(4)°–102.1(4)°, 99.1° (av) for **3**. This is most likely due to the large Sb–C bond lengths making it possible for the phenyl rings to be compressed a little more than that which is encountered for the analogous phosphine and arsine ligands. Table 4 presents the Re–E and E–C bond lengths and C–E–C angles (E = P, As or Sb) for the selected rhenium complexes.

The average Re–NO (1.793 Å) and N–O (1.225 Å) bond lengths and the average value of the Re–N–O angle (176.5°) for **1** confirm a linear coordination of the nitrosyl group, and they are comparable with values found for phosphine and arsine rhenium nitrosyls [13–18].

A notable *trans* influence of the triphenylstibine ligand is observed in both **1** and **3**; the Re–X(2) bond lengths are longer by about 0.08 Å in comparison with the corresponding Re–X distances in *cis* positions to the $SbPh_3$ ligand. A difference between Re–Cl(1) and Re–Cl(3) in **1** is a consequence of the nitrosyl disorder.

The nitrosyl stretching frequency in $[ReX_2(NO)(SbPh_3)_3]$ compounds is independent of the halogen ligand, the strong band corresponding to ν_{NO} appears at ~1680 cm^{-1} in the IR spectrum of the chloro (**1**) and bromo (**2**) nitrosyl. The considerable lowering of the ν_{NO} for $[Re^{I}X_2(NO)(SbPh_3)_3]$ complexes in comparison with the $[Re^{II}X_3(NO)(PPh_3)_2]$ and $[Re^{II}X_3(NO)(AsPh_3)_2]$ nitrosyls [15,17,18] is consistent with the lower oxidation state of the rhenium ion. It results in an increased backdonation of electron density from the filled rhenium d-orbitals into the π* antibonding orbital of the NO group.

The complexes **1** and **2** are diamagnetic, which confirms the low-spin d^6 configuration of the rhenium ion in the O_h field.

Table 5 presents the positions and molar absorption coefficients of the electronic bands for **1** and **2**. The electronic absorption spectra of both rhenium (I) complexes are very similar. They are dominated by three intense bands below 300 nm due to interligand electronic transitions of $SbPh_3$. In addition, two less intense absorption bands appear at ~420 and ~380 nm, and they can be assigned to d–d transitions and metal-to-ligand charge transfer (MLCT) transitions from Re(I) to π* ligand orbitals.

Table 5
Band positions and molar absorption coefficients for **1** and **2**

Band position (nm)	ε
Compound ***1***	
420.0	560
378.5	740
282.5	8440
230.0	14900
215.0	9760
Compound ***2***	
415.0	530
381.0	490
290.5	8200
232.0	12580
223.5	7580

ε is the molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$).

Considering the magnetic measurements, the geometry of **1** was optimized in the singlet state by the DFT method with the B3LYP functional. The optimized geometry is in quite good agreement with the experimental one, the largest differences are found for the Re–Cl and Re–Sb bond distances. A similar elongation of the rhenium–halogen bond lengths in the B3LYP with different basis sets has been found in other rhenium complexes [41].

Table 6 presents the atomic charges from the natural population analysis (NPA) for **1**. The calculated charge on the nitrogen atom of the nitrosyl group is positive, whereas the oxygen atom is negatively charged. The total charge on the NO group of the title complex is negative: −0.176. The calculated charge on the rhenium atom of **1** is far from the formal charge +1. It results from charge donation from the chloride ions and triphenylstibine ligand, which act as σ-donors. There are large positive charges on the Sb atoms, and the charges on the chloride ions are significantly smaller than −1.

Table 4
The Re–E and E–C bond lengths and C–E–C angles (E = P, As or Sb) for the selected rhenium complexes

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of **1** are presented in Table 7. The selected HOMO and LUMO orbitals of **1** are depicted in Fig. 3. The investigated complex is of a large size, the number of basis functions is equal 956. Among the occupied MOs of **1** the largest numbers constitute orbitals of the phenyl rings which are not relevant for the discussion of the bonding. The others have complicated character. The percent participations of the ligand atomic orbitals in the selected HOMO and LUMO orbitals are shown in Table 7.

The bonding of NO to the rhenium center involves a synergic interaction between the nitrosyl ligand orbitals and the metal orbitals. The Re–NO bond consists of two components: (i) a donation of electron density from a σ-type orbital on NO onto the metal orbital and (ii) a donation of electron density from the occupied metal d-orbitals into the π* antibonding orbitals of the NO ligand. The occupied d_{yz} and d_{xz} rhenium orbitals participate in the back-donation from the central ion to the nitrosyl ligand in complex **1**. In the occupied orbitals, the π^*_{NO} are distributed among several highest MOs. A substantial contribution of π_{Re-NO} orbitals are shown in HOMO − 4, HOMO − 2 and HOMO − 1. Percent participations of the d rhenium and π^*_{NO} orbitals in these MOs are very similar. The LUMO + 1, LUMO + 2 and LUMO + 3 orbitals are of π^*_{Re-NO} antibonding character. The LUMO + 1 orbital has prevalent NO character, whereas the LUMO + 2 and LUMO + 3 orbitals are localised almost evenly on the d rhenium and π^*_{NO} orbitals.

Additional information about the binding in complex **1** was obtained by NBO analysis. Table 8 presents the occupancies and natural atomic orbital compositions (NAO) of the selected NBOs for complex **1**. The occupancies of the bonding and antibonding Re–N bond orbitals (BD_{Re-N} and BD^*_{Re-N} orbitals) confirms a great donation of electron density from the occupied rhenium d-orbitals into the π* antibonding orbitals of the NO ligand. For compound **1**, three natural bond orbitals were detected for the Re–N bond, and one orbital – for the N–O bond. The Re–N bond orbital of σ-character is polarized towards the nitrogen atom (ca. 73% at N) and the s- and d-orbitals of Re take part in the bonding. In the case of the Re–N bond orbitals of π-character, only d-orbitals of Re are included in the bonding. The N–O bond orbital is slightly polarized towards the oxygen end. In the valence-bond treatment a linear bonding mode of the nitrosyl group may be represented by the following resonance forms [42]:

The results of the NBO analysis indicate that the resonance structure D makes a significant contribution to the structure of complex **1**.

It is consistent with the charges on the nitrogen and oxygen atoms of the nitrosyl group and the relatively low nitrosyl stretching frequency.

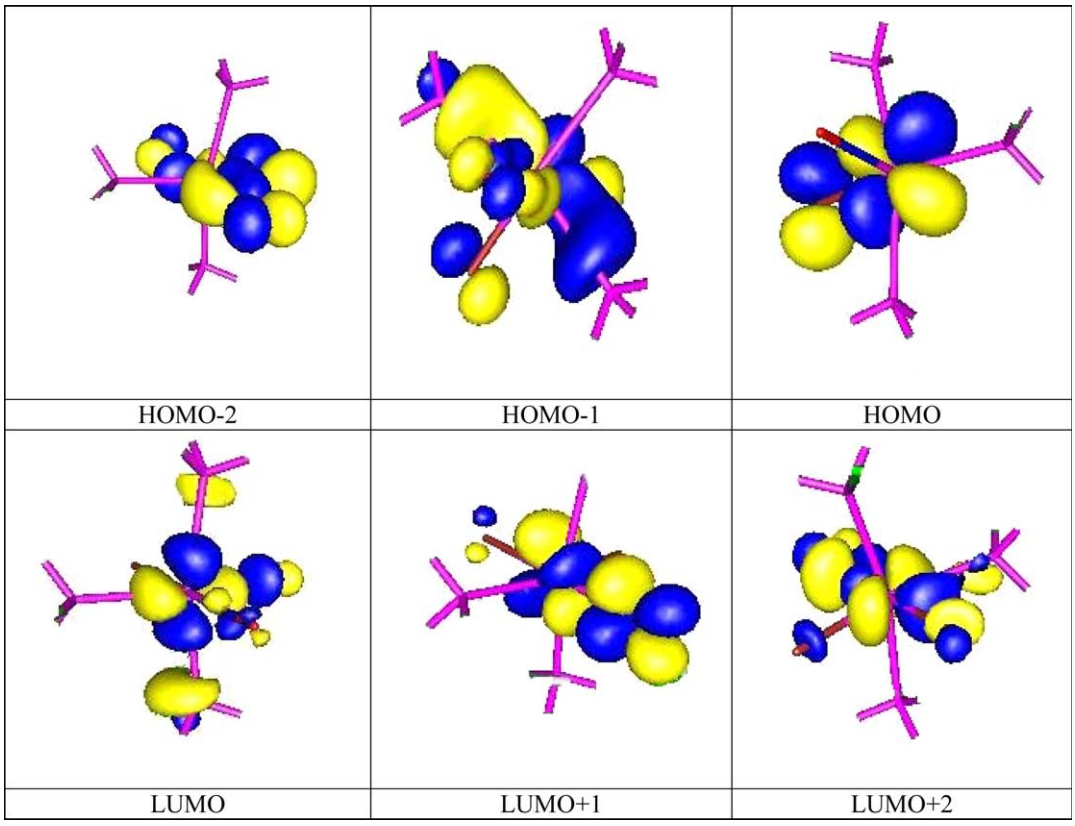

Fig. 3. Selected HOMO and LUMO orbitals for **1**. The phenyl rings are omitted for clarity, they make no contribution to the presented orbitals. Positive values of the orbital contour are represented in blue (0.04 a.u.) and negative values – in yellow (−0.04 a.u.).

Preparation and structures of polymeric lanthanide nitrate complexes of $CH_3C[CH_2P(O)Ph_2]_3$

Anthony M.J. Lees, Andrew W.G. Platt *

School of Sciences, Staffordshire University, College Road, Stoke-on-Trent ST4 2DE, UK

Received 30 June 2004; accepted 13 December 2004
Available online 12 January 2005

Abstract

The synthesis of complexes between lanthanide nitrates and $MeC(CH_2P(O)Ph_2)_3$ (=L) in ethanol or methanol leads to the formation of polymeric complexes $Ln(NO_3)_3L$ as alcohol solvates. The ligand adopts a chelating–bridging mode. The structures of the complexes $La(NO_3)_3L \cdot EtOH$ and $Pr(NO_3)_3L \cdot MeOH$ are reported and the coordination of L is discussed in terms of that of the related free ligand $EtC(CH_2P(O)Ph_2)_3$. Infrared spectroscopy implies structural differences between the early and later lanthanide complexes.

Keywords: Lanthanide nitrate; Complex; Phosphine oxide; Tripdal; Structure

1. Introduction

Phosphine oxide complexes with lanthanides and actinides have been well known for some time [1] and continue to attract interest [2,3]. Polyphosphine oxide complexes have also been much investigated with studies of their structural chemistry and application to the solvent extraction processes in nuclear fuel reprocessing [4–7]. Considerable recent interest in lanthanide complexes has centred on their clinical applications [8]. Complexes with tripodal ligands have been examined as potential relaxivity enhancement agents for magnetic resonance imaging [9,10] and as luminescent probes of biochemical interest [11–13]. The structures adopted by these mainly N, O donor ligands vary from monomeric [11,12,14], oligomeric [9,15] and polymeric [13,16]. Tripodal ligands could effectively block one side of the metal and leave the other face free for the coordination of other substrates. This has been exploited in relaxivity studies where the exposed face of the metal provides sites for water exchange [9].

The structural diversity shown by the complexes prompted us to study the coordination chemistry of relatively simple tripodal ligands, and we have previously investigated the coordination chemistry of the tris-phosphonates $1,3,5[(RO)_2P(O)]_32,4,6Me_3C_6$ (Fig. 1(a)) which formed dimeric structures with bridging ligands $(NO_3)_3LnL_2Ln(NO_3)_3$ [17].

The ligand $MeC(CH_2P(O)Ph_2)_3$ (=L) has potential coordination modes as illustrated in Fig. 1 and from the structural chemistry aspect it is interesting to see which bonding mode is adopted and the reasons for this. Previous studies with transition and p-block metals with similar ligands have identified the tris-chelate by ^{113}Cd NMR measurements with $PhP(O)(C_2H_4P(O)Ph_2)_2$ [18] whilst the complex with $FeCl_3$ with the tetradentate $[Ph_2P(O)C_2H_4]_4C$ give either binuclear or polymeric ionic complexes in which the ligand chelates to two metal centres [19].

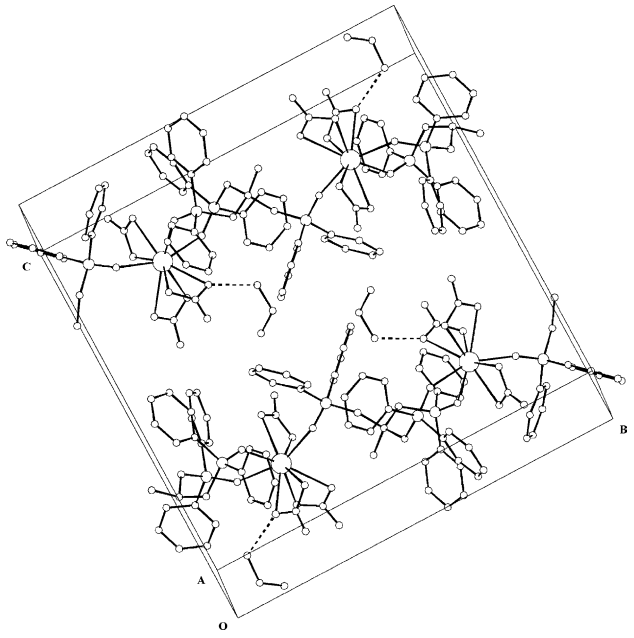

Fig. 3. The unit cell of $LaL(NO_3)_3 \cdot EtOH$ showing polymeric chains running along the crystallographic *b* axis. Hydrogen bonds are indicated by dotted lines.

2. Results and discussion

The complexes were formed by reaction of $MeC(CH_2P(O)Ph_2)_3$ with lanthanide nitrates in hot ethanol, methanol or acetonitrile. The compounds precipitated spontaneously on cooling the alcohol solutions giving $Ln(NO_3)_3L \cdot ROH$ (R = Me, Et) in good yield. The complexes are insoluble in common organic solvents and NMR spectra could not be obtained. Electrospray mass spectra were obtainable for the Yb complex only. Crystals suitable for X-ray diffraction were formed for the lighter lanthanides. Attempts to obtain crystals of the complexes of the heavier lanthanides were not successful. The solid state structures of $La(NO_3)_3L \cdot EtOH$ and $Pr(NO_3)_3L \cdot MeOH$ were determined by single crystal X-ray diffraction and are essentially identical in their coordination geometry around the metal and the ligand structure. The structure of the Pr complex is

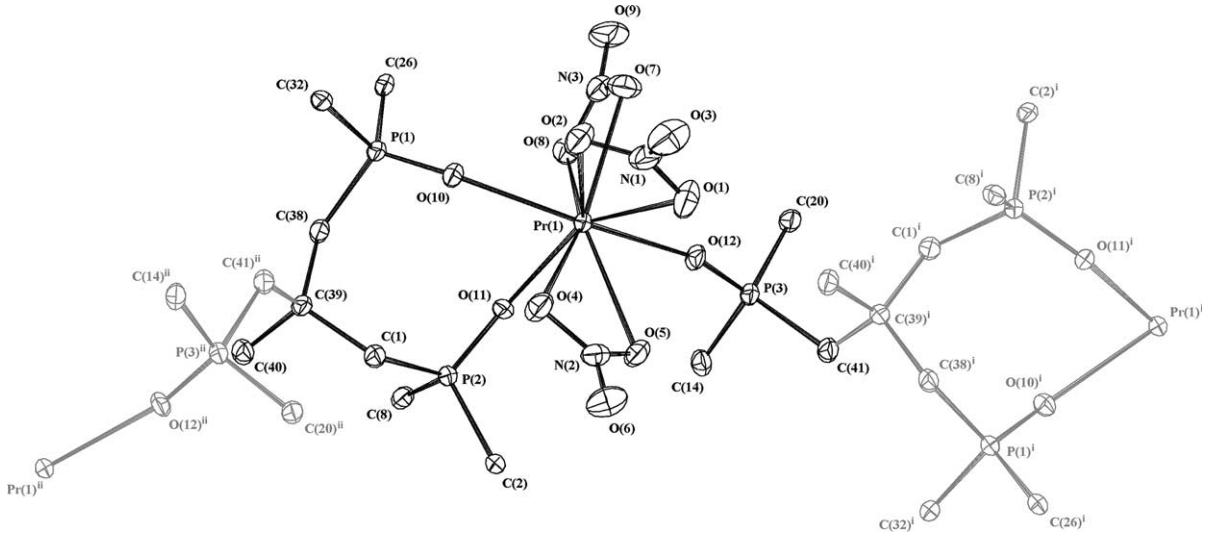

Fig. 2. The coordination of praseodymium in $[PrL(NO_3)_3]_n$. Thermal ellipsoids are drawn at the 50% probability level. Phenyl groups and hydrogen atoms are omitted for clarity. [Symmetry codes: i = $-x + 1.5$, $y - 0.5$, $-z + 1.5$, ii = $-x + 1.5$, $y + 0.5$, $-z + 1.5$].

shown in Fig. 2. The unit cell showing the two polymeric chains of the La complex and the hydrogen bond to ethanol is given in Fig. 3, details of the data collection and refinement for both complexes in Table 1 and selected bond lengths and angles in Table 2. The ligand adopts a bridging–chelating role, Fig. 1(b), B, with two PO groups chelating to give a puckered eight membered ring whilst the third bridges to another lanthanide ion, thus giving a polymeric chain. The P–CH_2–C ring angle ranging between 121.7(3)° and 123.9(3)° is considerably wider than expected for sp^3 hydridised carbon. There is, however, precedent for this in the structure of the

Symmetry code: i = $-x + 1.5$, $y - 0.5$, $-z + 1.5$.

related free ligand, $EtC(CH_2P(O)Ph_2)_3$ [20] where these angles range from 118.9° to 120.3°. The nitrate groups are bidentate in all cases with one hydrogen bonded to the lattice ethanol. The overall coordination geometry can be considered as a distorted *mer*-LnO_3N_3 octahedron, if the nitrates are taken as pseudo-monodentate ligands. The angles at the lanthanide subtended by the pseudo *trans*-atoms range from 172.04(10)° to 153.16(9)° whilst the *cis*-atoms give angles in the range 104.54(9)–71.28(10)°.

Whilst the atoms of the N(3) nitrate are essentially coplanar with almost linear Ln···N–O vectors, the terminal oxygens of the other two nitrates lie significantly out of the mean NO_2Ln plane. This tilting of the nitrate seems to be linked to the extent of hydrogen bonding or other secondary interactions with the nitrate oxygen atoms. Thus with no short contacts or hydrogen bonds to the oxygens the Ln···N(3)–O(9) angles at 177.9(3)° (La) and 177.4(3)° (Pr) are almost linear. With short contacts between the oxygens and hydrogens of the aromatic rings from adjacent polymer chains the Ln···N(1)–O(3) angle decreases to 172.8(3)° (La) and 173.9(3)° (Pr). Stronger hydrogen bonding interaction with the alcohol leads to a further tilting of the nitrates with Ln···N(2)–O(6) angles of 168.4(3)° (La) and 169.9(3)° (Pr). We have previously observed a this effect [21] when hydrogen bonding between two nitrates and the OH group of $[(MeO)_2P(O)]_2CMe(OH)$ causes tilting of nitrates by a similar amount whilst the third NO_3 ligand which is not involved in any secondary interaction has a linear Ln···N–O arrangement.

The phosphoryl groups fall into two categories; two form the chelate ring and one bridges between two metals. When the coordination of the PO group is unrestricted, as in monodentate phosphine oxides, the angle at the oxygen tends towards 180° [3,21,22]. The adoption of a chelate ring imposes restrictions on this angle, which falls within the range of 140°–150° here, compared with 163°–166° for the less constrained bridging group. This in turn is reflected in the strength of the bonding to the metal ions. The Ln–OP(bridging) distance being around 0.03 Å shorter than Ln–OP(chelating). Comparing the bond lengths observed here with $EtC(CH_2P(O)Ph_2)_3$ [20], it is found that the PO bond lengthens, as expected, on coordination by about 0.15 Å, while the P–C distance shortens by about 0.03 Å.

It is interesting to speculate on the preferred mode of binding of the ligand in these complexes. Examination of the overall geometry of $EtC(CH_2P(O)Ph_2)_3$ shows that two PO groups are relatively close together with an O···O separation of 3.24 Å, with the third PO situated much further away from these with distances of O···O 6.71 and 6.81 Å. This situation is mirrored by the structure of $MeC(CH_2P(O)Ph_2)_3$ in the complexes where the chelating oxygen atoms move slightly closer together (O···O 2.922(3) Å (La), 2.952(3) Å (Pr)) and the bridging oxygen is still considerably removed from these at between 6.509(4) and 6.795(3) Å. Thus on adopting the chelating–bridging bonding mode the ligand has to undergo relatively little reorganisation of its structure. The recently reported complex of Nd with $[CpCo(P(O)(OMe)_2]^-$ shows the ligand bonding

in a tridentate fashion to the metal [23]. Here the secondary structure of the ligands constrains the coordinating PO groups thus favouring coordination mode A. The adoption of the tris-chelating mode of bonding in Cd^{2+} complexes [18] is probably favoured by the lack of competition in the primary coordination sphere (the relatively non coordinating AsF_6^- or SbF_6^- anions were used) and, possibly, by significant covalent metal–ligand interactions. The conformation in the free ligand will mainly reflect the minimised steric repulsions and electrostatic repulsions of the P–O groups, and whilst it obviously has the structural flexibility to adopt other geometries it will only be expected to do so if the overall energy of the complex is minimised as a result. In lanthanide complexes, where electrostatic interactions are expected to dominate, the ligand will adopt a conformation which balances the repulsions between P–O groups with the attraction between oxygen atoms and the lanthanide ion. In our complexes the basic ligand structure appears largely unchanged by the interactions with positively charged lanthanide centres.

3. Infrared spectroscopy

The infrared spectra show the features expected for phosphoryl complexes with bidentate nitrates. The ν_{PO} decreases by about 20 cm^{-1} on coordination and two intense broad envelopes at ~1150 and 1300 cm^{-1} are assigned to the N–O stretches of the coordinated nitrate ligands. A distinction between the spectra of the lighter and heavier lanthanides is apparent in that there is a considerable amount of fine structure evident on the N–O absorptions for $Ln(NO_3)_3L$ (Ln = La–Gd) whilst these bands have a much simplified appearance for the complexes of the heavier metals. This may indicate some changes in the structures but we have been unable to produce crystals suitable for X-ray analysis for these complexes.

4. Electrospray mass spectrometry

Three complexes (La, Nd, Gd and Yb) were investigated in methanol solution. Poor ionisation was apparent for the La, Nd and Gd complexes with $[L + Na]^+$ and $[L + H]^+$ being the main features in the resulting spectra. Better quality spectra were obtained for the Yb complex which showed peaks consistent with dissociation and ligand redistribution. A cluster of peaks of low intensity centred at $m/z = 970.2$ is assigned to $[Yb(NO_3)_2L]^+$ which can be considered as being derived from the solid state structure. The most intense Yb containing ions, however, are multiply charged species such as $[Yb(NO_3)L]^{2+}$, $[YbL_n]^{3+}$ (n = 2–6). Here the compression of the characteristic isotope pattern makes assignment less certain.

5. Experimental

5.1. X-ray data collection, structure determination and refinement

Data were collected by the EPSRC National Crystallography Service at the University of Southampton using previously described procedures [24–27].

The La structure was solved by estimating the position of the metal atom using Patterson methods (SHELXS-97) [28,29], and all remaining non-H atom positions were obtained through consecutive fourier syntheses (SHELXL-97) [30]. Refinement to convergence was by full-matrix least-squares on F^2 data using SHELXL-97 [30] from within the WINGX [31,32] suite of software. The Pr structure was refined by isomorphous replacement into the La structure.

In each of the structures, alcohol molecules were modelled in the interstices between the parallel chains of the lanthanide-triphosphine oxide polymer. In the La structure, peaks in the difference Fourier map indicated ethanol disordered over two positions. A disordered model with complementary site occupation factors was adopted. The site occupation factor refined to a value of 0.524(21). The Pr data were weaker making conclusive assignment of the solvent more difficult. Fewer peaks were evident in the difference Fourier map of the Pr structure in this region, and a plausible solution consisting of a single methanol molecule was adopted.

In both structures, with the exception of the carbon atoms of the alcohol molecules, non-H atoms were refined with anisotropic displacement parameters. All H atoms were refined at idealised geometric positions (phenyl C–H = 0.95 Å, methylene C–H = 0.99 Å, methyl C–H = 0.98 Å, Hydroxyl O–H = 0.84 Å). The H atoms of each functional group of the triphosphine oxide ligand were assigned common, refined isotropic displacement parameters. On convergence, these displacement parameters were: phenyl 0.035(2) $Å^2$ (La), 0.031(2) $Å^2$ (Pr); methylene 0.015(4) $Å^2$ (La), 0.027(5) $Å^2$ (Pr); methyl 0.024(6) $Å^2$ (La), 0.015(5) $Å^2$ (Pr). The H atoms of solvent molecules were given thermal parameters equivalent to 1.2 (non-methyl) or 1.5 (methyl) times those of the carrier atom.

Molecular graphics were generated using SNOOPI [33].

5.2. Electrospray mass spectrometry

Spectra were obtained from the EPSRC National Mass Spectrometry Service at Swansea University as described previously [17].

5.3. Infrared spectroscopy

Infrared spectra were obtained on a Thermo Nicolet Avatar 370 FTIR. The spectra were run without any sample preparation.

5.4. Synthetic work

The ligand was prepared by H_2O_2 oxidation of the phosphine in acetone. The phosphine (5 g) was suspended in 50 ml acetone and hydrogen peroxide (4 g 30% solution) in 20 ml acetone was added over 1 h. The mixture was refluxed for 5 min to give a clear solution, evaporated to 20 ml, cooled in ice and filtered to give 4.40 g white solid. A further crop (1.19 g) was obtained on slow evaporation of the filtrate. Principle infrared bands/cm^{-1}: ν_{PO} 1167 (s) Lit 1185 [34] NMR (MeOD) ^1H 400 MHz, δ 6.4, 6.2 (30H) (m), δ 1.81 d (6H) d $^2J_{PH}$ 11.2 Hz δ 0.84s 3H. ^{31}P 162 MHz, δ 32.1 (s). Mass spectrometry ESMS (MeOH) $[L + H]^+$ $C_{41}H_{40}P_3O_3$ 673.2 (40%), $[L + Na]^+$ $C_{41}H_{39}NaP_3O_3$ 695.5 (100%).

The complexes were prepared by the same general method. Methanol solutions of the lanthanide nitrates and ligand were mixed and warmed to 50 °C for 3 h during which time crystals formed. These were filtered and dried at the pump to give $Ln(NO_3)_3L \cdot EtOH$ in yields of 75–90%.

$La(NO_3)_36H_2O$ (0.63 g, 1.47 mmol) in 50 ml EtOH was added to the ligand (0.49 g, 0.72 mmol) in 20 ml EtOH. On warming colourless crystals formed which were filtered and dried at the pump to give 0.58 g, 81% based on L. *Anal.* expected for $LaC_{43}H_{45}N_3O_{13}P_3$: C, 48.48; H, 3.94; N, 4.21. Found: C, 48.99; H, 4.04; N, 4.28%. Principle infrared bands/cm^{-1}: ν_{PO} 1157(w) 1141(s), ν_{NO} 1482(s), 1458(s), 1308(s), 1271(s).

$Nd(NO_3)_36H_2O$ (0.58 g, 1.25 mmol) in 50 ml EtOH was added to the ligand (0.41 g, 0.61 mmol) in 20 ml EtOH. On warming lilac crystals formed which were filtered and dried at the pump to give 0.50 g, 82% based on L. *Anal*. expected for $NdC_{43}H_{45}N_3O_{13}P_3$: C, 49.22; H, 4.32; N, 4.01. Found: C, 48.89; H, 4.13; N, 3.70%. Principle infrared bands/cm^{-1}: ν_{PO} 1141(s), ν_{NO} 1481(s), 1458(s), 1311(s), 1273(s).

$Gd(NO_3)_36H_2O$ (0.51 g, 1.12 mmol) in 50 ml EtOH was added to the ligand (0.52 g, 0.77 mmol) in 20 ml EtOH. On warming colourless crystals formed which were filtered and dried at the pump to give 0.67 g, 85% based on L. *Anal*. expected for $GdC_{43}H_{45}N_3O_{13}P_3$: C, 48.64; H, 4.27; N, 3.96. Found: C, 47.85; H, 4.15; N, 4.02%. Principle infrared bands/cm^{-1}: ν_{PO} 1141(s), ν_{NO} 1483(s), 1459(s), 1316(s), 1279(s).

$Er(NO_3)_36H_2O$ (0.36 g, 0.80 mmol) in 50 ml EtOH was added to the ligand (0.47 g, 0.69 mmol) in 20 ml EtOH. On warming a pink powder formed which was filtered and dried at the pump to give 0.50 g, 61% based on L. *Anal*. expected for $ErC_{43}H_{45}N_3O_{13}P_3$: C, 48.17; H, 4.23; N, 3.92. Found: C, 47.84; H, 3.98; N, 4.12%. Principle infrared bands/cm^{-1}: ν_{PO} 1145(s), ν_{NO} 1483(s), 1290(s).

6. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC 220339 and 220340 for the La and Pr complexes respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax +44 1223 336033; e-mail deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The title compounds were synthesized by the reactions of $[NH_4]_2[MS_4]$ (M = Mo, W), AgI and Hmimt in acetone and characterized by IR, ^{1}H NMR and UV–Vis spectroscopy. The polymeric structure of $[WS_4Ag_2(Hmimt)_2]_n$ was determined by X-ray crystallography. In this compound, there are two distinctly different coordination modes for the silver atoms. One Ag atom has a pseudo-tetrahedral geometry with one terminal monodentate-S Hmimt, two μ_2-S bridging Hmimt and one S atom of a monodentate WS_4 unit. The other is surrounded by four sulfur atoms belonging in pairs to two WS_4 fragments; the coordination geometry is distorted tetrahedral. The $[WS_4Ag_2(Hmimt)_2]_n$ polymer represents the first example of tetrathiometalate anions $[MS_4]^{2-}$ (M = Mo, W, or V) coordinated to another metal atom in a monodentate fashion. In both crystal structures determined the Hmimt ligands are present in the thione form, with coordination taking place via the sulfur atom only.

1. Introduction

Imidazole-type heterocycles represent an important class of ligands in coordination chemistry. The imidazole ring of the amino acid histidine is an essential component of many biological systems, such as proteins, nucleic acids and the vitamin B_{12} coenzyme [1]. Complexes of heterocyclic thiones such as imidazolidine-2-thione (Imt) and diazinane-2-thione (Diaz), and their complexes with transition metals, are of interest in bioinorganic chemistry, because of the search for simple model compounds for metalloproteins. In view of this, Cu(I), Ag(I), Au(I), Hg(II) and Cd(II) complexes with thiones have been widely studied in recent years [2]. The tetrathiometalate anions $[MS_4]^{2-}$ (M = Mo, W) have been shown to be useful and versatile reagents, which play a key role in some biological processes [3,4]. One of their important functions is coordination to other metal ions [5]. They bond to a wide variety of metal centres M′ via the sulfur atoms, thus acting as bi- or tridentate ligands. An important stabilizing factor is the ability of the ligands to delocalize electron density from M′ into low-lying empty d-based orbitals. The present paper details the synthesis and structural

characterization of a trinuclear complex of the bio-active molecule 1-methyl-imidazoline-2(3H)-thione (Hmimt), commercially known as methimazole, with $[WS_4]^{2-}$ and Ag^+ ions.

2. Experimental

2.1. Materials and physical measurements

Starting materials were purchased from commercial sources and used without further purification. $[NH_4]_2[MoS_4]$, $[NH_4]_2[WS_4]$ and $[NH_4]_2[WOS_3]$ were prepared from them by published methods [6]. The infrared spectra (4000–400 cm^{-1}) were recorded from KBr disks with an FT-IR model BOMEN MB102 spectrometer. UV–Vis spectra of the ligands and complexes were recorded on a JASCO model 7850 spectrophotometer. ^1H NMR spectra were obtained using a Bruker DRX 500 AVANCE spectrometer. Melting points could not be determined, as the complexes decomposed on heating.

2.2. Preparation of $[WS_4Ag_2(Hmimt)_2]_n$ (1)

AgI (0.0585 g, 0.249 mmol) was added to a suspension of $[NH_4]_2[WS_4]$ (0.029 g, 0.0833 mmol) in 30 ml of acetone and the mixture was stirred for ca. 30 min at room temperature. Hmimt (0.045 g, 0.0394 mmol) was added to this solution and the mixture was stirred for another 30 min. The precipitate was centrifuged and filtered off and the filtrate was evaporated to dryness in vacuo. The residue was washed with distilled water (2×2 ml), ethanol (2×2 ml) and diethyl ether (2×5 ml) and dried in vacuo to give a red powder (yield 0.033 g, 75%). Red crystals of this compound were obtained from the freshly made sample in acetone, by slow evaporation of the solvent. The air-stable crystals are insoluble in all usual organic solvents except dimethylformamide (DMF) and dimethylsulfoxide (DMSO).

2.3. Preparation of $[MoS_4Ag_2(Hmimt)_2]_n$ (2)

This compound was prepared in the same way as $[WS_4Ag_2(Hmimt)_2]_n$, using $[NH_4]_2[MoS_4]$ (0.260 g, 1 mmol) instead of $[NH_4]_2[WS_4]$, and an equivalent amount of AgI, and was isolated as a violet powder (yield 0.468 g, 70%).

2.4. Attempted preparation of $[WOS_3Ag_3I(Hmimt)_n]$

The preparative procedure was the same as that used for $[WS_4Ag_2(Hmimt)_2]_n$, with $[NH_4]_2[WOS_3]$ (0.316 g, 1 mmol), AgI (0.704 g, 3 mmol) and Hmimt (0.365 g, 3.2 mmol) in acetone (30 ml). Both IR [ν(W–S) = 448 cm^{-1} and ν(W–O) = 872 cm^{-1}] and UV–Vis (267 nm) spectra confirm the presence of WOS group in the complex, but the complex decomposed when the orange solution was allowed to evaporate slowly, resulting in the formation of micro-crystals of compound **3** with a chemical formula of $C_4H_6Ag_2I_2N_2S$, as confirmed by X-ray analysis. The yield was not determined.

2.5. X-ray crystallography

Crystal data together with other relevant information on the structure determinations for compounds **1** and **3** are listed in Table 1. All measurements were made on a Bruker SMART CCD diffractometer with narrow frames (0.3° in ω). Mo Kα radiation ($\lambda = 0.71073$ Å) was employed for data collection at 150 K. Absorption corrections were based on the high redundancy of symmetry-equivalent and repeated reflections. The structures were solved by direct methods and refined by full-matrix least-squares on all F^2 values. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions and refined with isotropic displacement parameters, riding on their parent atoms. The structure of **1** was found to be twinned. Large residual electron density peaks were found for **3**, as a result of relatively poor diffraction data and the presence of several heavy atoms in the structure, but these have no chemical significance. Programs were standard Bruker AXS control and integration software, SADABS [7] and SHELXTL [8],

together with ROTAX [9] and ROTWIN [10] to handle the twinning.

3. Results and discussion

3.1. Infrared spectra

The IR spectra of the complexes (Table 2) exhibit characteristic strong bands at 435 and 455 cm^{-1} for $[WS_4Ag_2(Hmimt)_2]_n$ (**1**) and 441 and 459 cm^{-1} for $[MoS_4Ag_2(Hmimt)_2]_n$ (**2**), assigned to the μ_3-S and μ_2-S stretching vibrations of the WS_4 and MoS_4 groups, respectively. The band at 478 cm^{-1} for $[WS_4Ag_2(Hmimt)_2]_n$ and at 482 cm^{-1} for $[MoS_4Ag_2(Hmimt)_2]_n$ is assigned to ν[W(1)–S(3)] (see Fig. 1 for atom numbering) and the corresponding $\nu(Mo–S_b)$ band. Comparing these values with the corresponding ones for $[NH_4]_2[WS_4]$ (458 cm^{-1}) and $[NH_4]_2[MoS_4]$ (476 cm^{-1}) [11], an increase of π-character of the W(1)–S(3) and $Mo–S_b$ bonds is indicated.

Infrared spectroscopy may also be used to probe the mode of Hmimt ligand coordination. In the IR spectrum of a compound such as Hmimt, where the carbon atom is directly linked to nitrogen, ν(C=S) is strongly coupled and, as a result, there are a number of different bands in the 1570–700 cm^{-1} region, each of which contains some contribution from the C=S stretching mode. This accounts for the difficulty in identification of this band and for the diversity of assignments that have been made [12]. Thus, the thioamide group in Hmimt normally shows four bands in the regions 1570–1395, 1420–1260, 1140–940 and 800–700 cm^{-1} and these bands are known as the thioamide I, II, III and IV bands, respectively. Bands I and II have little C=S content and originate mainly in C=N and NH deformation modes, but III and IV have a significant C=S content [12]. The monodentate sulfur-donating character of ligands of this kind is evident by comparison of the positions of the four thioamide bands in the infrared spectra of the complexes and of the free Hmimt ligand (Table 2). In these complexes, the absence of a ν(SH) band at

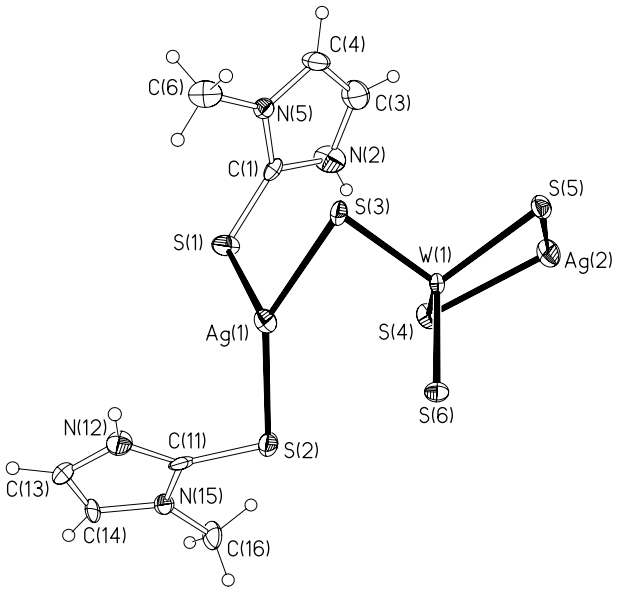

Fig. 1. The asymmetric unit of $[WS_4Ag_2(Hmimt)_2]_n$ (**1**), showing the atom numbering scheme. The two Ag atoms make connections with sulfur atoms in adjacent symmetry-related units to generate the two-dimensional polymeric structure.

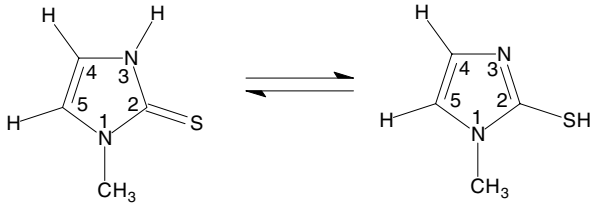

~2500 cm^{-1}, the presence of the ν(NH) band in the range 3193–3227 cm^{-1}, and a low-frequency shift in the ν(C=S) band clearly indicate that the Hmimt ligands are coordinated only via the thione sulfur in the complexes. The NH bands of $[WS_4Ag_2(Hmimt)_2]_n$ are shifted to higher frequency (3227 cm^{-1}) relative to the free ligand (3120 cm^{-1}). These shifts probably result from changes in the electronic state when the ligand coordinates via the thione sulfur and the C=S bond loses some of its double-bond character. This clearly indicates that nitrogen is not involved in coordination. The most significant changes are seen for the thioamide (III) band and especially for the thioamide (IV) band. This has the largest proportion of ν(C=S) activity and the shift to lower frequency of the band [2,13,14] is consistent with ligand thione donation for these complexes. The thioamide (IV) band is particularly affected, with the bands in the free ligand (767 and 740 cm^{-1}) [15]

b, broad, m, medium, s, strong, vs, very strong, w, weak.

replaced by a sharp but split band at 718 and 710 cm^{-1} in $[WS_4Ag_2(Hmimt)_2]_n$, 735 and 717 cm^{-1} for $[MoS_4Ag_2(Hmimt)_2]_n$. These spectroscopic results are consistent with the structure of $[WS_4Ag_2(Hmimt)_2]_n$ as determined by X-ray crystallography. In the IR spectrum of the complex $[Ag_2I_2(Hmimt)]_n$, the absence of the ν(SH) band and the presence of the ν(NH) band at 3230 cm^{-1}, as well as shifts to lower frequency in the ν(C=S) absorption [ν(C=S) = 515 cm^{-1}], clearly indicate that the Hmimt ligand is coordinated via the thione sulfur.

3.2. Solution spectra

3.2.1. Electronic spectra

The UV–Vis spectra of the compounds **1** and **2** in DMF have effective absorption bands at 261.5 and 492.5 nm for the Mo cluster **2**, and 261.5 and 410 nm for the W cluster **1**. The first strong bands lie in the region for absorption by the free thione and may thus be attributed to thione-based intraligand transitions [16] and the other two absorptions can be assigned as charge-transfer bands of the type (π)S–(d)M (M = Mo, W) arising from the MS_4 moiety; these are red-shifted compared to the free $[MS_4]^{2-}$ anion (397 nm for W and 472 nm for Mo).

3.2.2. ^1H NMR spectra

The ^{1}H NMR spectra of Hmimt and of the complexes in DMSO-d_6 are summarized in Table 3. In the proton spectra of the complexes, the ligand signals are shifted down-field from their positions in the spectrum of the free ligand, suggesting that in DMSO-d_6 the ligand remains coordinated to the metal.

The absence of a weak SH signal of the thiol form of the ligand in the ^{1}H NMR spectra of the complexes confirms that coordination of Hmimt in DMSO-d_6 solution, as in the solid state, takes place only through the sulfur atom. Thus the Hmimt ligands in the complexes are neutral and they are in the thione form.

3.3. Description of the structures

3.3.1. Crystal structure of $[WS_4Ag_2(Hmimt)_2]_n$ (1)

Views of a single repeat unit and the neutral polymeric sheet arrangement of this complex are presented in Figs. 1 and 2, respectively. Important bond lengths and angles are listed in Table 4.

In the complex, there are two distinctly different coordination modes for the silver atoms. Ag(1) has a pseudo-tetrahedral geometry with large compression of the S(3)–Ag(1)–S(1) angle [95.10(13)]° and enlargement of the S(2)–Ag(1)–S(3) angle [147.77(13)]° with respect to ideal tetrahedral. The deviation from ideal tetrahedral geometry is probably due to the large steric hindrance of the Hmimt ligands. Coordination of Ag(1) involves two bridging μ_2-S(thione)-donating Hmimt ligands with average Ag(1)–S(thione) distances of 2.640(4) Å, as well as one terminal monodentate S(thione)-donating Hmimt with Ag(1)–S(2) of 2.488(4) Å and one asymmetrically bridging μ_2-S $[WS_4]^{2-}$ moiety with Ag(1)–S(3) of 2.536(4) Å. The Ag(1)–(μ_2-S)–W bridges between two neighbouring chains join them together to generate the

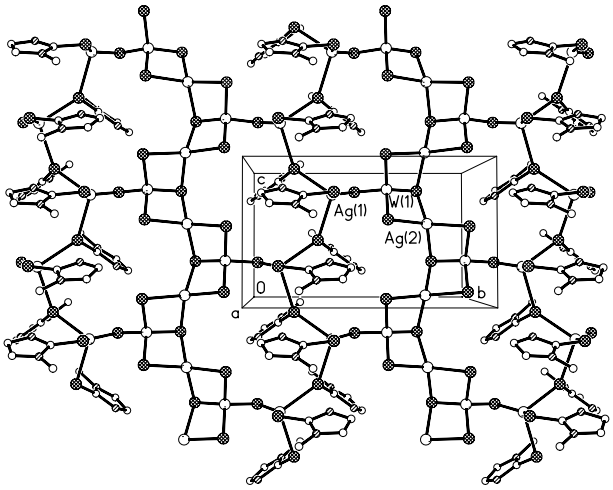

Fig. 2. Polymeric sheet structure of $[WS_4Ag_2(Hmimt)_2]_n$, seen along the unit cell *a* axis. The W and Ag atoms of the 'home' asymmetric unit are labelled. H atoms have been omitted.

two-dimensional polymeric structure. Narrowing of the Ag(1)–(μ_2-S)–W bridging angle [84.40(12)]° is inevitably accompanied by a reduction in the Ag(1)···W distance (3.178 Å). The $[MXS_3]^{2-}$(X = O, S; M = V, Mo, W) moiety as a bidentate ligand always coordinates to another metal M′ as $M(\mu_2\text{-}S)_2M'$, but here we have the first example of monodentate coordination of this unit to any metal. The observation can be rationalized as $[WS_4]^{2-}$ acting as a strong π-acceptor, while the lone pairs on the sulfur donors of the Hmimt ligands overlap efficiently with the silver orbitals, giving strong π-donation [17]. This situation is reflected in the observed short W–S(3) bond [2.180(4) Å]. This is one of the shortest W–S bridging bonds that have been reported so far, in keeping with the increased π-character of the W–S(3) bond by charge delocalization through the μ_2-S(3) bridging atom. The W–S(3) bond length can be compared with the mean W–S bond lengths in the isolated $[WS_4]^{2-}$ anion [2.165(11) Å] in the ammonium salt [18]. This is consistent with the infrared spectrum of the complex, which exhibits a high-frequency band at 478 cm^{-1} due to the stretching vibration of the W–S(3) bond. In the complex, the independent Hmimt ligands have very similar structure, with localized C=C double bonds. The main difference from the free ligand concerns the C=S (thione) bond length, which shows a partial reduction of π–character and thus a slight lengthening of the C=S(thione) distances [1.715(15) and 1.714(16) Å] relative to the mean free ligand distance (1.685 Å); otherwise, the ligand dimensions are essentially unchanged upon coordination. However, the C=S bond distances in the complex indicate that the C=S bonds are double bonds, as in the free ligand.

Ag(2) is surrounded by four sulfur atoms belonging in pairs to two WS_4 fragments. The $Ag(2)S_4$ tetrahedron shares edges with two WS_4 tetrahedra, generating chains. The tetrahedral environment of Ag(2) is strongly distorted, with S(5)–Ag(2)–S(4) angles of 94.75(12)° within the strained four-membered $Ag(S_b)_2W$ chelate rings. The $Ag(S_b)_2W$ rings are planar and the four Ag(2)–S bonds are chemically equivalent; their distances [av. 2.534(4) Å] can be compared with 2.536(4) Å found for Ag(1)–S(3). The variation in bond angles within the $Ag(S_b)_2W$ plane is striking, in particular, the sharply acute $Ag(2)(S_b)_2W(1)$ angles 75.25°–76.42°, partly due to the requirements of the two lone pairs on S_b, which are accompanied by the expanded S_b–W–S_b [112.84(14)]° and S_b–Ag–S_b [94.75(12)]° angles as shown in Table 4. Owing to the two kinds of bridging modes of the S atoms, the two W–S_b bonds of the $Ag(2)(S_b)_2W$ rings are obviously different in length. The [W–μ_3-S(5)] distance [2.269(4) Å] is longer than the [W–μ_2-S(4)] distance [2.207(4) Å], as is indicated by the vibrational spectrum. More significantly, the observed distortion of the $Ag(S_b)_2W$ plane may imply a direct transnuclear Ag(2)–W bonding interaction. Such an interpretation has been applied in thiometalate systems such as $[Ag(WS_4)_2]^{3-}$ [5]. The Ag(2)···W distances of 2.937 and 2.942 Å of the title compound are 0.297–0.302 Å greater than the sum of the covalent radii, 2.64 Å [19], and can be compared with the 2.971 Å found in the $[Ag(WS_4)_2]^{3-}$ anion.

The overall sheet structure can be regarded as polymeric $Ag(WS_4)^-$ chains (running vertically in Fig. 2) joined together by AgL_2^+ chains (also vertical), in which each Ag^+ ion has one terminal ligand L and shares in two bridging ligands.

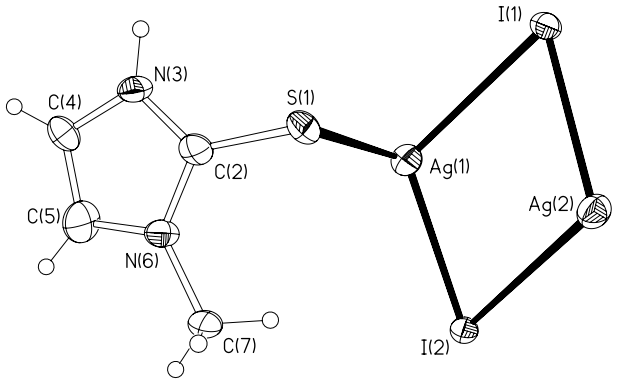

Fig. 3. The asymmetric unit of $[Ag_2I_2(Hmimt)]_n$ (**3**), showing the atom numbering scheme.

3.3.2. Crystal structure of $[Ag_2I_2(Hmimt)]_n$ (3)

The structure of this complex is shown in Figs. 3 (the asymmetric unit) and 4 (the polymeric sheet structure), and selected bond lengths and angles are in Table 5. Each silver atom has an SI_3 donor set and pseduo-tetrahedral geometry, with angles at the metal ranging from 95.85(12)° to 116.48(6)°, and is coordinated by three μ_3-I and one thione μ_2-S. Because of the crystallographic inversion centre, the silver atoms and the bridging μ_3-I atoms from a planar four-membered $Ag_2(\mu_3\text{-}I)_2$ ring. In the $Ag_2(\mu_3\text{-}I)_2$ ring, there are two distinctly different angles Ag–(μ_3-I)–Ag (62.33°) and I–Ag–I (116.15°) and only one type of Ag–(μ_3-I) bond with an average Ag–I distance of 2.871 Å. The Ag–S distance [av. 2.581(5) Å] in this complex is only slightly shorter than the Ag–(μ_2-S) [2.649(4) Å] distance found in $[WS_4Ag_2(Hmimt)_2]_n$. The C–S bond length is 1.706(19) Å in the complex, compared with 1.685 Å in the free ligand [20]. Comparison of these values supports the idea that the C–S distances lengthen upon coordination of the sulfur to the metal. However, the bond distance in the complex indicates that the C=S bond is a double bond, as in the free Hmimt ligand.

The very acute angles about the bridging iodine atoms (ranging from 62.14° to 62.33°), together with short Ag···Ag distances (average length 2.975 Å, slightly longer than 2.89 Å in Ag metal) [21,22] are suggestive of direct Ag–Ag bonding, which is associated with π-stacking interactions between ligands attached to two adjacent metal ions.

The polymeric sheet structure (Fig. 4) is made up of undulating ladders of AgI linked by bridging Hmimt ligands through Ag–S bonds. The ladders extend in the $[1\bar{1}0]$ direction and the sheets are in the (001) plane.

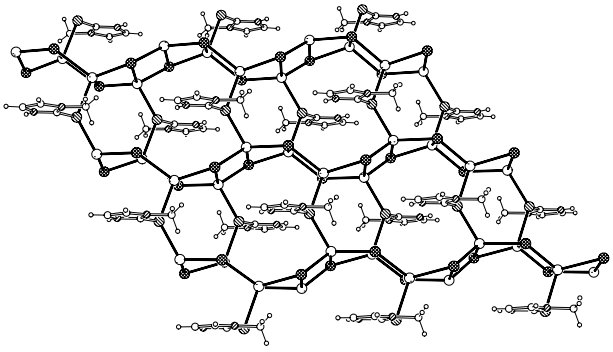

Fig. 4. The polymeric sheet structure of compound (**3**). Ladders of Ag and I atoms run from left to right and are bridged by Hmimt ligands.

Abstract

The proctolin (Arg–Tyr–Leu–Pro–Thr, RYLPT) analogues modified in fifth position of the peptide chain (RYLPP, RYLPI, RYLP–Dab, where Dab – 2,4-diamminobutyric acid) have been synthesised and their complexes with H^+ and Cu^{2+} studied by potentiometry and spectroscopy (UV–Vis, CD and EPR) at 25 °C and I = 0.10 mol dm^{-3} (KNO_3). The results obtained support the earlier suggestion on the specific role of a proline residue as a ''break-point'' in copper complex formation with peptides. The presence of a proline residue into the fourth position of the proctolin analogues (RYLPP, RYLPI) leads in wide pH range of the existence the CuL and $CuH_{-1}L$ complexes with expected stabilities. Spectroscopic studies confirm that these are 2N {NH_2, N^-, CO} and 3N {NH_2, $2N^-$, CO} species, respectively. The amine group of the Dab residue of the RYLP–Dab proctolin analogue, in whole pH range (2.5–10.5) is coordinated to the copper(II) ions, and the deprotonation and coordination of the second amide nitrogen atom to the metal ion is prevented. In solution in wide pH range (5–10.5) the 3N {NH_2, N^-, CO, NH_{2Dab}} complex is present. Proctolin and its analogues modified in fifth position contain in the second position of the peptide sequence the Tyr residue and the CD results show that $TyrO^-$–Cu^{2+} bonding is present at pH above 8.

1. Introduction

Proctolin, the first structurally characterized myotropic insect neuromodulator, is a pentapeptide, L-arginyl–L-tyrosyl–L-leucyl–L-prolyl–L-threonine (Arg–Tyr–Leu–Pro–Thr), which was isolated in 1975 by Brown and Starratt [1] from whole-body extracts of the American cockroach *Periplaneta americana.* The peptide has been shown to occur in species of six insect orders and in other invertebrates [2–5]. Proctolin is a neuroactive substance which is found in various neuronal cell types, including motoneurons inervating visceral and skeletal muscles [6,7], neurosecretory [8,9] and sensory neurons [10]. On the basis of myotropic properties manifested in stimulation of contractions of visceral and skeletal muscles [8,9,11,12] of insects and other invertebrates [13], proctolin was classified as an neurotransmitter. Structural modifications by replacement residues in positions 1–5, as well as syntheses of truncated or elongated analogues were made to studies structure–myotropic function relationship [14–16]. Functional significance of the amino acid residues in the peptide chain of the proctolin is described and discussed [17]. Among the proctolin analogues modified in position 5 of the peptide skeleton only C-terminally modified analogues with Ala [14], Val, Ile, Asn, Gln or Ser replacements showed agonistic or weak-agonistic effects [18]. The data suggest that the C-terminal Thr residue plays an important role for myotropic activity in insects.

Copper is an essential element widely distributed throughout the body but concentrating particularly in the liver–gall bladder area and the brain. The peptides have been identified as neurotransmitters, many with opiate activity [19]. Many of these peptides contain one or more Pro residues, e.g. substance P (L-Pro in positions 2 and 4 while the antagonist contains D-Pro in position 2), thyrotropin releasing hormone (L-Pro-NH_2 in position 3), and β-casomorphin (L-Pro in positions 2, 4, and 6). In general biologically active forms of such molecules are in the β-conformation, hence a possible role for copper is the biological activation of many neuropeptides [20]. L-Proline does not contain an $–NH_2$ group but the secondary =NH group. Hence when inserted in a peptide chain there is no ionizable hydrogen so that the nitrogen atom is unable to bond to copper [21,22]. As a result proline in the second, third or fourth positions of a short peptide chain acts as a "break-point" to copper coordination allowing the two ends of the chain to behave independently, hence any labile Cu^{2+} present would tend to coordinate neuropeptide molecules and, likely, influence their conformations and so their biological activity [20].

Tyrosine is another interesting component of many neuropeptides, e.g. all enkephalins [23]. The phenolic oxygen of tyrosine can coordinate to Cu(II) but, for steric reasons, cannot bond to a metal ion which is already coordinated to the amide nitrogen of the tyrosine residue. When tyrosine is in an amino acid sequence, however, the phenolic oxygen of the side chain can coordinate to Cu(II) by at least two ways; it can participate in the formation of dimmers or of large ring chelated complexes [24].

The present paper reports the results of combined spectroscopic and potentiometric studies on the copper(II) complexes of proctolin analogues modified in fifth position of the peptide chain. The peptides involved in the study are: Arg–Tyr–Leu–Pro–Pro (RYLPP), Arg–Tyr–Leu–Pro–Ile (RYLPI) and Arg–Tyr–Leu–Pro–Dab (RYLP–Dab, where Dab – 2,4-diamminobutyric acid). This study was performed in order to examine the difference of the binding ability of proctolin analogues modified in position 5, especially the effect of Dab containing the amine group, on the formation of complexes with Cu^{2+}ions.

2. Experimental

2.1. Materials

The proctoline analogues modified in fifth position of the peptide chain were synthesized according to a procedure reported below. As a metal ion source $Cu(NO_3)_2 \cdot 3H_2O$ (Merck) was used. KNO_3, KOH and HNO_3 were Merck products.

2.2. Peptide syntheses, purification and characterization

Peptides were synthesized by the solid-phase method according to the Boc-procedure [25,26]. Dicyclohexylcarbodiimide (DCC, Merck) in the presence of 1-hydroxybenztriazole (OHBt, Aldrich) was used as a coupling reagent. The C-terminal amino acids were bound to the Merrifield resin by a cesium salt procedure to give substitution level of 0.7 mmol/g of Boc–Y–OH, where Y = Ile, Pro, Dab(Z). The protected amino acids were coupled using DCC as a coupling reagent or by the linear anhydride methods. The following amino acid derivatives were used: Boc–Arg(Tos)–OH, Boc–Tyr(OBzl)–OH, Boc–Leu–OH, Boc–Pro–OH (Bachem). The amino acids and DCC were used in 3-fold excess. The N^{α}–Boc-group was subsequently removed with 30% trifluoroacetic acid (TFA) in dichloromethane (DCM) according to standard methods. The neutralization was made with 10% triethylamine (TEA) in DCM. Finally, RYLPP, RYLPI and RYLP–Dab peptides were obtained by deprotection and cleavage from the support resin with trifluoromethanesulfonic acid (CF_3SO_3H) in anisole. All peptides were purified on Sephadex G-25 column by elution with 5% acetic acid and then by preparative HPLC. The peptides after preparative HPLC were dissolved with 5% acetic acid and lyophilizated.

The amino acid composition was confirmed using a Mikrotechna T 339 M analyzer (Czechoslovakia). The optical activity of the chiral compounds was determined with a Polamat polarimeter (Carl Zeiss, Jena, Germany). The molecular wieghts of the peptides were determined using the Finigan Mat TSQ 700 (USA). TLC was performed in three solvent systems on silica gel and visualized using ninhydrin.

The purity of all peptides has been also checked by pH-metric titrations.

2.3. Potentiometric measurements

Stability constants for proton and Cu^{2+} complexes were calculated from pH-metric titrations carried out in argon atmosphere at 298 K using a total volume of 2 cm^3. Alkali was added from a 0.250-cm^3 micrometer syringe which was calibrated by both weight titration and the titration of standard materials.

Experimental details: ligand concentration 2×10^{-3} mol dm^{-3}; metal-to-ligand ratio 1:1.1; ionic strength 0.10 mol dm^{-3} (KNO_3); pH-metric titration on a MOLSPIN pH-meter system using a Russel CMAW 711 semi-mikro combined electrode, calibrated in concentration using HNO_3 [27], number of titrations 2; method of calculation SUPERQUAD [28]. The samples were titrated in the pH region 2.5–10.5. Standard deviations (σ values) quoted were computed by SUPERQUAD and refer to random errors only. They are, however, a good indi-

cation of the importance of the particular species involved in the equilibria.

2.4. Spectroscopic measurements

Solutions were of similar concentrations to those used in potentiometric studies. The solutions for EPR measurements with ethylene glycol (water:glycol, 2:1, v/v) were prepared to ensure good glass formation in frozen solutions. EPR spectra were recorded on a Bruker ESP 300E spectrometer at X-band frequency (9.3 GHz) at 120 K. The EPR parameters were calculated for the spectra obtained at the maximum concentration of the particular species for which well-resolved components were observed. Absorption spectra were recorded on a Beckman DU 650 spectrophotometer in the 850–300 nm range. Circular dichroism (CD) spectra were recorded on a Jasco J-715 spectropolarimeter in the 750–250 nm range. The values of $\Delta\varepsilon$ (i.e. $\varepsilon_l - \varepsilon_r$) and ε were calculated at the maximum concentration of the particular species obtained from potentiometric data.

3. Results and discussion

3.1. Protonation constants

Calculated protonation constants and Cu^{2+} complex formation constants are given in Tables 1 and 2, respectively, together with literature values for related complexes. Calculated species distribution curves for 1:1 Cu^{2+}:L mixtures (0.002 mol dm^{-3}) are shown in

Figs. 1 and 2. Spectroscopic data for the major complexes are given in Table 3.

While values for log K_{HL}, log K_{H2L} for the peptides RYLPP, RYLPI and also log K_{H3L} for the analogue of proctolin RYLP–Dab are precise and reliable, values for the carboxyl protonation are less certain as a result of residual acetate in the peptides that is very difficult to remove. The proctolin analogues were, otherwise, analytically pure. Acetate ions form only very weak complexes with Cu^{2+}; hence, the presence of traces of acetate in the background would not give spurious metal complex formation constants. However the protonation constant of the acetate ion (log $K_a = 4.64$) prevents a precise determination of the protonation constant of the peptide carboxyl group unless the exact acetate concentration is known. In peptides this carboxyl group is normally ionized above pH 3.5; hence the protonation constant would not have any significant influence on the calculation of formation for the Cu^{2+} complexes that form above pH 4. SUPERQUAD gave the same concentration ratios for peptide to acetate over a range of total concentrations of ligand and the calculated formation constants were entirely consistent. Molar ratios found for the peptides studied to acetate were 1:0.785 for RYLPP, 1:0.564 for RYLPI and 1:0.383 for RYLP–Dab.

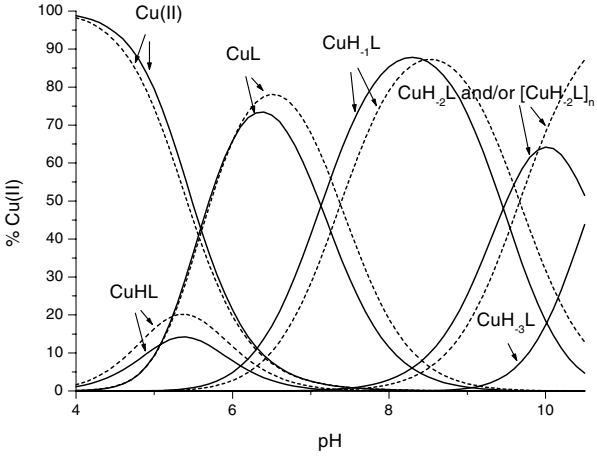

Fig. 1. Species distribution curves for Cu(II) complexes of the RYLPP (solid lines) and RYLPI (dashed lines). Cu(II) to peptide molar ratio 1:1, $[Cu(II)] = 2 \times 10^{-3}$ M.

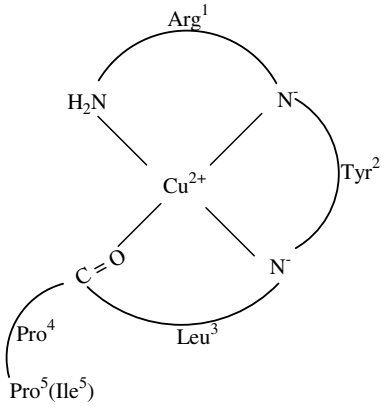

Fig. 2. Proposed structure for the $CuH_{-1}L$ complex of RYLPP and RYLPI peptides.

All peptides studied contain at first position of the peptide chain the arginine. The arginine residue contains a very basic terminal nitrogen atom as a result of resonance stabilization of the protonated guanidine group (log $K \approx 12$) [29]. Under the experimental conditions used, the pH never exceeded 10.5 and, at this value, the degree of deprotonation of the guanidine group is insignificant. Hence the proton was considered as unionisable under the conditions used and its protonation constant ignored.

The neutral forms of the peptides studied can be regarded as H_2L. Both, RYLPP and RYLPI, have three possible protonation centres: the terminal amino nitrogen, the C-terminal carboxylate, and the phenolic oxygen of the Tyr residue. The peptide analogue of proctolin, RYLP–Dab has a additional protonation constant since it has Dab with amine group in side chain of the peptide.

The first protonation constant, log $\beta_{HL} = 9.66$ or 9.54 for the peptides RYLPP or RYLPI (Table 1), respectively, refers to protonation of the phenolate group of the Tyr side chain and this value compares well with literature values [30–32]. The peptide RYLP–Dab has two dissociable protons: the amine group of Dab residue and the phenolic group of the Tyr residue with the values comparable to each other (log $K = 10.11$ and 9.32, Table 1) [30–33]. From a consideration of these log K values, it can be suggested that two sets of deprotonation processes overlap each other. Deprotonation of the amine and tyrosyl groups takes place at around pH 9–10, which means that the log K values cannot be separated and the constants measured are macro-constants. The protonation constant (log $K = 7.09$–7.19) of the N-terminal amine group of the peptides studied is close to those of RKDVG [34] and PACAP 3 [35] peptides containing the same residue in first position (Arg^1).

3.2. Cu(II) complexes with RYLPP and RYLPI

Four and five metal complex species can be fitted to the experimental titration curves obtained for the Cu^{2+}–RYLPI and RYLPP systems: CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and also $CuH_{-3}L$ (for RYLPP, charges omitted for simplicity, Table 2, Fig. 1). RYLPP and RYLPI contain in amino acid sequence the same donor sets and the potentiometric and spectroscopic results suggest the formation of the complexes with similar coordination modes (Tables 2 and 3, Fig. 1). The coordination of metal ion starts at pH around 4 (Fig. 1). The minor species CuHL with 1N coordination {NH_2, CO}

[a] d–d transition.
[b] $N^-_{amide} \rightarrow Cu^{2+}$ charge transfer transition.
[c] $O^-_{Tyr} \rightarrow Cu^{2+}$ charge transfer transition.
[d] $NH_2 \rightarrow Cu^{2+}$ charge transfer transition.

is usually found by potentiometric data calculations in metal–peptide systems [36]. This species cannot be supported by spectroscopic data because of its very low concentration, however, for RYLPP, the EPR spectrum for the CuHL species was observed with parameters: A_{II} = 160 G, g_{II} = 2.312 suggesting the $\{NH_2, CO\}$ coordination mode (Table 3) [37]. The CuHL species of both peptides corresponds to the CuL species of penta-alanine amide with the tyrosyl oxygen protonated.

The log K^* values for 1N $\{NH_2, CO\}$ complexes of the peptides studied and the complexes of AAAAA–NH_2, GGGP and GGG–Sar peptides are similar to each other supporting the same coordination mode (Table 2). With increasing pH, the CuHL complex loses the proton to give a species of stoichiometry CuL. The deprotonation constants of the CuHL complexes for RYLPP and RYLPI peptides, $CuHL \leftrightarrow CuL + H^+$ (pK values, 5.08; 5.27; respectively, Table 2) correspond very well to the deprotonation and coordination of the first amide nitrogen to copper(II) ion [38]. The d–d transition energy at 656–647 nm, the presence in CD spectra $N^-_{am} \rightarrow Cu^{2+}$ charge transfer transition at 336–332 nm and the EPR parameters: A_{II} = 172–170 G, g_{II} = 2.249–2.248 support the 2N $\{NH_2, N^-, CO\}$ coordination mode (Table 3) [38–40]. Above pH 6, the CuL complex of both peptides loses the next amide proton to give a $CuH_{-1}L$ species which has three nitrogen donor centres arranged in equatorial plane of the tetragonal geometry around copper(II) ion (Fig. 2). The shift of absorption maximum to 570–563 nm, and the EPR parameters: A_{II} = 174–172 G, g_{II} = 2.216–2.215 suggest coordination of the additional nitrogen donor atom to the copper(II) ion (Table 3) [37,40]. The low value of A_{II} parameter (172–174 G) of the 3N $\{NH_2, 2N^-_{amide}, CO\}$ complex in comparison to those of GGGP (194 G) and GGG–Sar (195 G) [37] may suggest a distortion from the tetragonal geometry around the copper(II) ion.

Increasing the pH above 8 results in the formation of a species of formula $CuH_{-2}L$. The protonations constants of the $CuH_{-2}L$ complex (9.46 and 9.67 for RYLPP and RYLPI, respectively, Table 2) are in good agreement with those for protonations of the

Tyr residues in the free ligands (9.66 and 9.54, respectively, Table 1). It means that in the $CuH_{-2}L$ complex the Tyr residue is deprotonated. The parameters of UV–Vis, CD (d–d transition region) and EPR spectra for the $CuH_{-2}L$ complex are similar to those obtained for $CuH_{-1}L$ complex suggesting similar numbers of N–Cu^{2+} bonds (NH_2 and $2N^-_{amide}$, Table 3). In the CD spectrum for the $CuH_{-2}L$ complex of both peptides the characteristic charge transfer bands the phenolate–$O^- \rightarrow Cu^{2+}$ are observed (Table 3) supporting the coordination of the phenolate oxygen of the Tyr residue to copper(II) ion [24,39,41,42]. At pH about 10 the phenolate oxygen–Cu^{2+} charge transfer transitions were also observed for the Cu^{2+}–Tyr–Tyr and Tyr–Phe systems suggesting the phenolate oxygen coordination in these complexes [43]. For the $CuH_{-2}L$ complex, three coordination positions in equatorial plane are occupied by the nitrogen atoms {NH_2, $2N^-_{amide}$}, and the fourth position may be occupied by the oxygen atoms of the carbonyl group of Leu residue, water molecule or deprotonated phenolate group of the Tyr residue. The Tyr residue in second position of the peptide chain of proctolin analogues cannot be coordinated to Cu^{2+}ions by the phenolate oxygen and the amide nitrogen atoms simultaneously. Therefore, bonding to both atom donors can only occur in polynuclear $(CuH_{-2}L)_n$ complexes (Table 3). For RYLPP pentapeptide by potentiometry at pH above 9 (Fig. 1) the $CuH_{-3}L$ complex was also detected. The presence of the $CuH_{-3}L$ complex may suggest the coordination of the water molecule in the fourth coordination position of the copper(II) ion. The protonation constant of the $CuH_{-3}L$ species equals 10.57 corresponds very well to the deprotonation of the coordinated water molecule [44]. The log K* values for the 1N, 2N and 3N complexes of the both peptides studied are comparable to those of the peptides containing in fourth coordination position the Pro or Sar as ''break-point'' residues in the peptide chain (Table 2).

3.3. Cu(II) complexes with RYLP–Dab peptide analogue

According to potentiometric and spectroscopic results, RYLP–Dab peptide analogue forms with Cu^{2+} ions the CuHL, CuL and $CuH_{-1}L$ species (Table 2, Fig. 3). The coordination of the metal ion starts at pH around 4 with the formation of the 2N {NH_2, CO, NH_2} complex.

The absorption band of the d–d transition at 639 nm and the parameters of CD spectra: the presence of the $NH_2 \rightarrow Cu^{2+}$ charge transfer transition at 278 nm, and d–d transition band at 659 nm clearly indicate to involve 2N coordination with {NH_2, CO, NH_2} bonding mode. The chelate ring forming by the carbonyl oxygen of Arg^1 and amine group of Dab residue is unexpectedly large but the Pro(4) residue is acting as a β-turn in the peptide chain and so forcing the bend required to bring the Dab(5) amine group close to the terminal –NH_2 group [45]. In the CuHL complex the phenolate oxygen of the Tyr residue is protonated. The log K* value for the CuHL complex of RYLP–Dab is about four orders of magnitude higher in comparison to those of RYLPP and RYLPI (Table 2). This increase may be explained by the coordination of the second amine nitrogen atom of the peptide analogue (Dab residue). With increasing pH above 5 the CuL complex is formed with pK value for deprotonation of the CuHL species ($CuHL \leftrightarrow CuL + H^+$) equals 5.80. The formation of the CuL is accompanied by a significant blue shift of the absorption band to 608 nm suggesting coordination of the additional nitrogen atom donor (Table 3, Fig. 4).

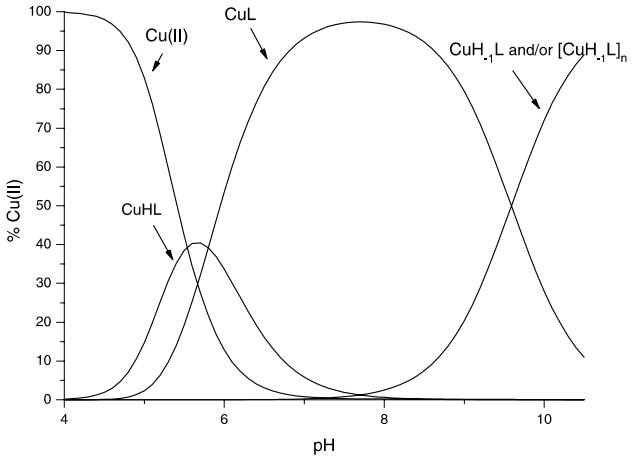

Fig. 3. Species distribution curves for Cu(II) complexes of the RYLP–Dab. Cu(II) to peptide molar ratio 1:1, $[Cu(II)] = 2 \times 10^{-3}$ M.

The EPR parameters for CuL complex: A_{II} = 161 G, and especially g_{II} = 2.219, and the presence in CD spectra the charge transfer transition $N^-_{amide} \rightarrow Cu^{2+}$ at 290 nm, clearly support the 3N {NH_2, N^-_{amide}, CO, NH_2}

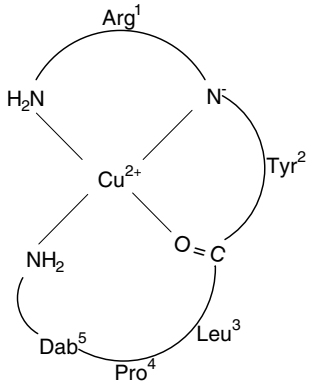

Fig. 4. Proposed structure for the CuL complex of RYLP–Dab peptide.

coordination mode (Table 3). The value for A_{II} is distinctly lower than for the other 3N species which form typical, small, chelate rings [37,46]. Such changes in A_{II} may reflect deformation of the complex plane expected when a macrochelate ring is formed [47]. Moreover, the value of 608 nm for the d–d band energy of the CuL species is a little above that typical of the 3N complexes of simple peptides (ca. 570 nm) but can easily be explained when ligand effects are taken into account since these are in the order $NH_2 < N^-_{amide}$ [48]. As a result a 3N species involving $2NH_2$, N^-_{amide} coordination would be expected to have a higher value for λ_{max} than 3N species involving Cu^{2+}–NH_2 and two $Cu^{2+} - N^-_{amide}$ bonds. The log K^* value for the CuL complex is about 4.6–4.8 orders of magnitude higher in comparison to that of RYLPP and RYLPI (Table 2). This increase of stability may be explained by the coordination of the amine nitrogen atom of Dab residue to the copper(II) ion. In pH range 8–10.5 the $CuH_{-1}L$ species was detected (Fig. 2, Table 2). The deprotonation constant of the CuL complex (pK value, $CuL \leftrightarrow CuH_{-1}L + H^+$) equals 9.59 corresponds very well to that of the phenolate oxygen of the Tyr residue for free ligand (9.32, Tables 1 and 2). The EPR parameters (A_{II}, g_{II}) and the d–d transition energy for the $CuH_{-1}L$ complex are similar to those of the CuL complex suggesting the same 3N bonding mode (Table 3). Moreover, in CD spectrum for the $CuH_{-1}L$ complex the charge transfer transition $O^-_{Tyr} \rightarrow Cu^{2+}$ at 369 nm is observed suggesting the formation of the $(CuH_{-1}L)_n$ polynuclear complexes with 3N $\{NH_2, N^-_{amide}, O^-_{Tyr}, NH_2\}$ coordination mode. RYLP–Dab analogue at high pH may also form the polynuclear complexes as the peptides RYLPP and RYLPI from the same reasons (see above). The presence of the Dab containing the amine nitrogen donor atom in fifth position of the proctolin analogue changes its coordination ability compared to those of RYLPP and RYLPI peptides. The amine nitrogen atom of Dab residue in whole pH range is coordinated to copper(II) ion and its coordination prevents the deprotonation and coordination of the second amide nitrogen atom to the copper(II) ion.

4. Conclusions

L-Proline (Pro, P) residue inserted in a peptide sequence may act as a "break-point" in the coordination of donor centres of the peptide chain to metal ions which are able to deprotonate peptide nitrogens (e.g. Cu^{2+}). Proctolin and its analogues modified in fifth position of the peptide chain contain the proline residue in fourth position, and therefore with Cu^{2+} ions the 1N, 2N and 3N complexes of RYLPP and RYLPI are formed. The presence of L-proline in fourth position of the peptide sequence prevents the deprotonation and coordination of the third amide nitrogen atom and the 4N $\{NH_2, 3N^-\}$ complex is not formed. The insertion of the Dab in fifth position of proctolin peptide sequence changes the coordination ability of the peptide analogue to the copper(II) ions. The amine group of the Dab residue is coordinated to copper(II) in whole (2.5–10.5) pH range and it prevents the deprotonation and coordination of the second amide nitrogen atom. In wide (5–10.5) pH range the CuL complex dominates with the 3N $\{NH_2, N^-, CO, NH_{2Dab}\}$ bonding mode. All proctolin analogues studied in pH above 8 give in CD spectra the charge transfer transition band $O^-_{Tyr} \rightarrow Cu^{2+}$ at 360–370 nm suggesting the formation of phenolate oxygen of Tyr residue–Cu^{2+} bond. The tyrosine residue in second position of the peptide chain is already bonded to the metal ion by the amide nitrogen atom and cannot be coordinated to the same copper(II) ion by the phenolate oxygen for steric reasons. Therefore, the formation of the polynuclear complexes may be suggested.

Abstract

Reaction of 2,9-dioxo-1,4,7,10-tetraazabicyclo[1.10.1]hexadeca-1(11),13,15-triene-4,7-diacetic acid (**H_2L1**) with $CuCl_2 \cdot 2H_2O$ in ethanol at pH 6 led to the monomeric benzodioxochlorocomplex [Cu(**L′1**)Cl] (**1**) (**HL′1** = monoethylesther of **H_2L1**). X-ray structural analysis has shown that in complex **1** the Cu is five-coordinated by two nitrogen and two oxygen atoms of the macrocycle and by a chloride, displaying a square pyramidal coordination geometry. One of the acetate arms does not coordinate to the Cu and has suffered an in situ ethanolic esterification reaction. The protonation constants of **H_2L1** and the stability constants of its complexes with Cu^{2+}, Ni^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+} were determined by potentiometric methods and in some cases by ^{1}H NMR spectroscopy. The stability constants of the complexes follow the trend $[Ni(\mathbf{H_{-1}L1})]^- > [Cu(\mathbf{H_{-1}L1})]^- \gg [Pb(\mathbf{H_{-1}L1})]^- > [Zn(\mathbf{H_{-1}L1})]^- > [Cd(\mathbf{H_{-1}L1})]^-$, probably due to steric requirements. Spectroscopic measurements (absorption and EPR) at different pH values have shown the effect of the pH on the coordination sphere of the Cu complexes.

1. Introduction

Due to their participation in a great number of important biological processes, all organisms accumulate certain levels of copper, zinc, nickel and iron, in order to survive. However, an excess of these metals is very toxic and macrocyclic polyamine ligands have been explored as possible sequestering chelators. The stability and kinetic inertness of d-transition complexes with macrocyclic polyamines, when compared with those formed with the corresponding linear ligands, make the macrocyclic polyamine complexes interesting for application in a wide variety of areas, such as catalysis, biomimicry, metallotherapy and diagnostic or therapeutic applications in Nuclear Medicine. In this specific field, copper is a very interesting d-transition element due to the large number of radionuclides with physical properties suitable for imaging (^{60}Cu, ^{61}Cu, ^{62}Cu and ^{64}Cu) or therapy (^{64}Cu and ^{67}Cu) [1].

As a part of our ongoing research work on the synthesis and characterisation of complexes with d- and f-transition metals, potentially interesting for radio diagnostic and/or radiotherapy [2–5], we have been exploring the chemistry of the previously described benzodioxotetraazamacrocyclic 2,9-dioxo-1,4,7,10-tetraazabicyclo [1.10.1] hexadeca-1(11),13,15-triene-4,7-diacetic acid (**H_2L1**) (Fig. 1) [6,7].

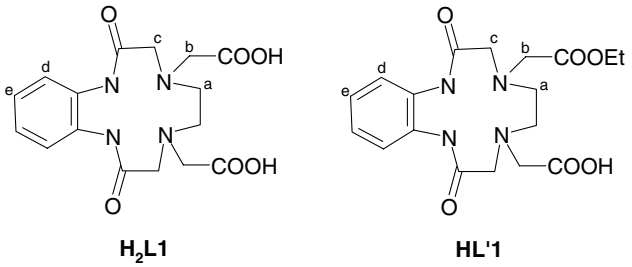

Fig. 1. 2,9-Dioxo-1,4,7,10-tetraazabicyclo[1.10.1]hexadeca-1(11),13, 15-triene-4,7-diacetic acid (**H_2L1**) and its monoethylesther (**HL′1**).

In this work, we describe the new monomeric and neutral chlorocomplex [Cu(**L′1**)Cl] (**1**) (**HL′1** = monoethylesther of **H_2L1**: 4-methylethylesther-2,9-dioxo-1,4,7, 10-tetraazabicyclo[1.10.1]hexadeca-1(11),13,15-triene-7-acetic acid ($C_{18}H_{23}N_4O_6$)). The structural differences between **1** and the dimeric Cu complex, previously described [7], led us to study more deeply the acid–base equilibrium of compound **H_2L1** as well as the stability constants of its complexes with Cu^{2+}, Ni^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+}, which will be also reported therein.

2. Experimental

2.1. Materials

Reactions were run under nitrogen atmosphere with magnetic stirring. Bulk solvent removal was done by rotary evaporation under reduced pressure and trace solvent removal from solids was done by vacuum pump. Solvents were either used as purchased or dried according to the standard literature procedures. Ethylenediaminetetraacetic dianhydride and *o*-phenylenediamine were obtained from the Aldrich Chemical Co. Copper salts were obtained from Baker's Analyzed. All reagents for synthesis and analyses were of analysis grade.

The benzodioxotetraazamacrocycle-*N*,*N*′-diacetic acid (**H_2L1**) was synthesised as previously described [6]. The purity of the compound was checked by the usual characterisation techniques.

2.1.1. Synthesis of [Cu^{II}(**L′1**)Cl] (**1**)

A solution of $CuCl_2 \cdot 2H_2O$ (0.11 g, 0.651 mmol in 2 cm^3 of ethanol) was added to a solution of **H_2L1** (0.237 g, 0.651 mmol in 8 cm^3 of ethanol). The resulting brown mixture was refluxed for 2 h. After cooling to room temperature, the solution was filtered through diatomaceous earth and washed with methanol. X-ray-quality green single crystals were obtained by slow diffusion of methanol. *Anal.* Calc. for $C_{18}H_{23}ClCuN_4O_6.H_2O$: C, 42.44; H, 5.14; N, 11.00. Found: C, 42.45; H, 4.63; N, 11.02%. UV: 704 nm (54 mol^{-1} dm^3 cm^{-1}), 382 nm (133 mol^{-1} dm^3 cm^{-1}).

2.2. X-ray crystal analyses

Suitable green crystals ($0.25 \times 0.20 \times 0.06$ mm) were mounted in air on a goniometer head. Data were collected at room temperature with the crystal mounted in a glass capillary. An Enraf-Nonius CAD4 diffractometer equipped with graphite monochromatised Mo Kα radiation ($\lambda = 0.71069$ Å) in the ω–2θ scan was used for measurements. Lorentz, polarisation effects and empirical absorption correction based on psi-scans [8] were applied to the collected intensities.

The structure was solved by direct methods using SIR97 [9] and refined by full-matrix least-squares on F^2 methods using the program SHELXL97 [10] and the WINGX software package [11]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions. Molecular graphics were prepared with Ortep3 [12].

The crystal data and structure refinement details for **1**: Empirical formula, $C_{18}H_{23}N_4O_6ClCu$; $M = 490.39$ g mol^{-1}; Orthorhombic, $P2_12_12_1$, $a = 10.6410(13)$, $b = 13.0690(16)$, $c = 14.505(2)$ Å, $V = 2017.2(4)$ $Å^3$, $Z = 4$, $D_{calc} = 1.615$ g cm^{-3}, $\mu = 1.260$ mm^{-1}, $F(0\,0\,0) = 1012$; 271 parameters, no restraints, 2372 unique reflections measured, of which 2216 observed [$I > 2\sigma(I)$], $R_1 = 0.0624$, $wR_{all} = 0.1130$, Highest peak and deepest hole 0.574 and −0.282 e A^{-3}, θ range: 2.37–25.97°, Limiting indices, $-13 \leqslant h \leqslant 13$, $0 \leqslant k \leqslant 16$, $-17 \leqslant l \leqslant 0$, Goodness-of-fit = 1.061.

2.3. Spectroscopic studies

^1H and ^{13}C NMR spectra were recorded with a Bruker AMX-300 spectrometer at probe temperature in D_2O, using 3-(trimethylsilyl)-propanoic acid-*d*4-sodium salt as internal reference in the ^1H and dioxane in the ^{13}C spectra.

Electronic spectra were measured with a Cary 500 Version 8.01 spectrophotometer using aqueous solutions $\approx 1 \times 10^{-3}$ mol dm^{-3} of the copper complexes and $\approx 2 \times 10^{-3}$ mol dm^{-3} of the nickel complexes, at different pH values: ≈3, ≈6 and 10 for copper and ≈4, ≈8 and ≈11 for nickel complexes. The choice of the pH values was based on the species distribution diagram for each metal, selecting the maximum pH of formation of the species: [ML], $[M(H_{-1}L)]_-$ and $[M(H_{-2}L)]_{2-}$.

EPR spectroscopic measurements of the copper complex were recorded with a Bruker ESP 380 spectrometer equipped with continuous-flow cryostats for liquid nitrogen, operating at X-band. The complexes ($\approx 2 \times 10^{-3}$ mol dm^{-3} in 1:1 DMSO:H_2O solution) were prepared at pH 3.51, 6.37 and 10.26 and were recorded at 96 K. The EPR spectrum of a 1:1 DMSO/H_2O solution of **1** (at pH 3.23) was also recorded.

2.4. Potentiometric measurements

2.4.1. Reagents and solutions

Metal ion solutions were prepared at about 2.5×10^{-3} mol dm^{-3} from the nitrate salts of the metals and were titrated using standard methods [13]. Deionised (Millipore/Milli-Q System) distilled water was used. Carbonate-free solutions of the KOH titrant were obtained, maintained and discarded when the percentage of carbonate was about 0.5% of the total amount of base [14].

2.4.2. Equipment and work conditions

The equipment was used as described before [2–4,15]. The temperature was kept at 25.0 ± 0.1 °C, atmospheric CO_2 was excluded from the cell during the titrations by passing purified nitrogen across the top of the experimental solution in the reaction cell. The ionic strength of the solutions was kept at 0.10 mol dm^{-3} with KNO_3.

2.4.3. Measurements

The $[H^+]$ of the solutions was determined by the measurement of the electromotive force (emf) of the cell, $E = E^{\circ\prime} + Q\log[H^+] + E_j$. $E^{\circ\prime}$, Q, E_j and $K_w = ([H^+][OH^-])$ were obtained as described previously [2–4,15]. The term pH is defined as $-\log[H^+]$. The value of K_w was found equal to $10^{-13.80}$ $(\text{mol dm}^{-3})^2$. The potentiometric equilibrium measurements were made on 20.00 cm^3 of $\approx 2.00 \times 10^{-3}$ mol dm^{-3} ligand solutions diluted to a final volume of 25.00 cm^3, in the absence of metal ions and in the presence of each metal ion for which the C_M:C_L ratio was 1:1. A minimum of two replicate measurements was taken.

The emf data were taken after additions of 0.050 cm^3 increments of standard KOH solution, and after stabilisation in this direction, equilibrium was then approached from the other direction adding standard nitric acid.

In the cases of copper (II) and nickel (II), the degree of complex formation of the metal complexes was too high to prevent the use of the direct potentiometric method. Metal–metal competition titration methods were used. Lead (II) and cadmium (II) were the second metals used, respectively.

2.4.4. Calculation of equilibrium constants

Protonation constants $K_i^H = [H_iL]/[H_{i-1}L][H]$ were calculated by fitting the potentiometric data for the free ligand to the HYPERQUAD program [16]. Stability constants of the various species formed in solution were obtained from the experimental data corresponding to the titration of solutions of different ratios of the ligand and metal ions, also with the aid of the HYPERQUAD program. The initial computations were obtained in the form of overall stability constants or $\beta_{M_mH_hL_l}$ values:

$$\beta_{M_mH_hL_l} = \frac{[M_mH_hL_l]}{[M]^m[L]^l[H]^h}.$$

The hydrolysis constants of the metal ions were taken from the literature and kept constant for the calculations [17].

For ligand **H$_2$L1**, the first protonation constant was determined by ^{1}H NMR titration, due to its high value. For this determination, a solution of **H$_2$L1** (≈0.01 mol dm^{-3}) was prepared in D_2O and the pD was adjusted by addition of DCl or CO_2-free KOD with an Orion 420A instrument fitted with a combined Ingold 405M3 microelectrode. The $-\log[D^+]$ was measured directly in the NMR tube, after the calibration of the microelectrode with buffered aqueous solutions. The final pD was calculated from pD = pH* + (0.40 ± 0.02), where pH* corresponds to the reading of the pH meter [18,19].

3. Results and discussion

The benzodioxotetraazamacrocycle **H$_2$L1** has been synthesised and characterised as previously described [6]. Reaction of **H$_2$L1** with $CuCl_2 \cdot 2H_2O$ in ethanol, at pH 6 in 1:1 (Cu: **H$_2$L1**) molar ratio, resulted in a brown solution, upon refluxing for 2 h. This solution was filtered at room temperature and a small portion of methanol added. Slow diffusion of MeOH led to green monocrystals suitable for X-ray crystallographic analysis. By X-ray diffraction analysis, the complex formed was formulated as [Cu(**L′1**)Cl] (**1**). This is a monomeric Cu^{2+} complex anchored by a modified benzodioxotetraazamacrocycle. In complex **1**, the Cu is five-coordinated by two nitrogen atoms of the macrocyclic backbone, two oxygen atoms, one from one amide group and the other from an acetate arm, and a chloride atom occupies the fifth position. The second acetate arm of the macrocycle does not coordinate to the Cu and it has experienced an in situ ethanolic esterification reaction. The ORTEP drawing of **1** is shown in Fig. 2, and selected bond lengths and angles are listed in Table 1.

The Cu(II) centre displays a five-coordination environment, which can be described as a square pyramidal polyhedron (SP). The basal plane is defined by the N(3), O(2), O(5) and the chloride atoms, while the apical position is occupied by the N(4) atom.

Most of the Cu(II) five-coordinate complexes known display either distorted square pyramidal (SP) or distorted trigonal bipyramidal (TBP) coordination geometries. To evaluate the degree of distortion from the ideal polyhedron mainly two methods have been developed. The simplest method, which can be applied when there is an apical bond distance longer then the others, is based on the ratio of the two basal angles of the square plane, which is given by the expression $\tau = [(\theta - \phi)/$

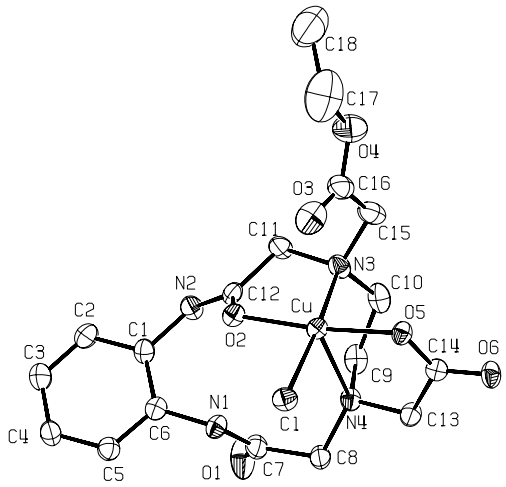

Fig. 2. ORTEP view of the complex **1**; thermal ellipsoids are drawn at 40% probability level.

Table 1
Selected bond lengths (Å) and angles (°) for **1**

Bond lengths			
Cu–O(5)	1.942(4)	O(2)–C(12)	1.265(7)
Cu–O(2)	1.964(4)	O(5)–C(14)	1.264(8)
Cu–N(3)	2.100(6)	O(6)–C(14)	1.225(8)
Cu–N(4)	2.420(5)	O(3)–C(16)	1.246(9)
Cu–Cl	2.2540(19)	O(1)–C(7)	1.220(8)
O(2)–C(12)	1.258(6)	O(4)–C(16)	1.319(10)
Bond angles			
O(5)–Cu–O(2)	172.66(18)	Cl–Cu–N(4)	96.17(14)
O(5)–Cu–N(3)	89.30(17)	C(13)–N(4)–C(9)	111.1(5)
O(2)–Cu–N(3)	83.60(17)	C(13)–N(4)–C(8)	107.4(5)
O(5)–Cu–Cl	96.10(14)	C(9)–N(4)–C(8)	111.9(5)
O(2)–Cu–Cl	91.12(13)	C(13)–N(4)–Cu	99.3(3)
N(3)–Cu–Cl	173.54(17)	C(9)–N(4)–Cu	100.7(4)

O(2)–Cu–N(4)	99.27(17)	C(12)–O(2)–Cu	112.2(4)
N(4)–Cu–N(3)	81.10(18)	C(14)–O(5)–Cu	119.7(4)

60] × 100 (%), being $\tau = 0$ for an ideal SP and $\tau = 100$ for an ideal TBP coordination geometries [20]. For complex **1**, the angles considered were Cl–Cu–N(3) and O(2)–Cu–O(5), and the value calculated for τ was 1.46%. The square plane is folded along the axis defined by Cl, Cu and N(3), yielding a dihedral angle between the planes [Cl, N(3), O(5)] and [O(2), Cl, N(3)] of 5.65(23)°. The angle between basal plane and the apical line Cu–N(4) is 78.91(15)°. The copper is 0.0217(24) Å above the basal plane and the apical N(4) atom is 2.348(6) Å below this plane, yielding a Cu–N(4) apical bond distance of 2.420(4) Å, which is longer than the copper nitrogen bond distance in the basal plane (Cu–N(3), 2.100(6) Å). The dihedral angle between the aromatic ring and the plane defined by the nitrogen atoms of the macrocyclic backbone is 14.45(30)°, being the copper atom 1.6750(31) Å above this plane. The Cu–N(3) bond distance is in the expected range of 1.99–2.08 Å, normally found for five-coordinated Cu(II) complexes stabilised by amines [20a, 21].

In complex **1**, the Cu–O(2) and Cu–O(5) bond lengths are 1.964(4) and 1.942(4) Å, respectively. As in other five-coordinated Cu(II) complexes, the bond Cu–O_{amide} is slightly longer than Cu–$O_{carboxylate}$. The Cu–Cl bond length of 2.254(2) Å in **1** is in the expected range [22].

The formation of the monomeric complex **1**, described herein, is certainly related with the reaction conditions used for the synthesis and recrystallisation of this complex (1:1 **H_2L1**:$CuCl_2 \cdot 2H_2O$, pH 6, ethanol, 2 h reflux, slow diffusion of MeOH), which certainly were also responsible for the in situ sterification of one carboxylic acid arm. In fact, a dimer copper complex, isolated by Fernando and co-workers [7], has been obtained by reacting **H_2L1** with $CuCl_2 \cdot 2H_2O$ in basic aqueous conditions and monocrystals were formed by the slow concentration of this solution. In the dimer, the Cu atom is six-coordinated by two oxygen atoms of the carboxylate arms, an oxygen from an amide group and two nitrogen atoms from the macrocyclic backbone; the sixth coordination position being occupied by an oxygen atom of a carboxylate arm from an adjacent molecule.

Taking into account that different complexes can be formed using different reaction conditions and also the potential interest of copper for biological applications, we decided to study the coordination chemistry of this ligand, including the determination of the stability constants of **H_2L1** with Cu and also with other metals, such as Ni, Zn, Cd and Pb, which also have biological interest, due to their high toxicity. Spectroscopic measurements were also performed in order to understand the structure of some of the complexes in aqueous solution.

3.1. Acid–base behaviour

The acid–base behaviour of compound **H_2L1** has been studied by potentiometry and by ^{1}H NMR spectroscopy. Only four protonation constants were determined. From the remaining two constants, one is very high (corresponding to the amide centre) and the other very low to be determined. Indeed, in our work conditions only one amide centre can be deprotonated, and even this one at very high pH values, then the corresponding constant was determined by ^{1}H NMR spectroscopy. The protonation constants of **H_2L1** are shown in Table 2 as well the values published in literature for other related tetraazamacrocyclic ligands shown in Fig. 3.

Taking into account the structure of **H_2L1**, results published in the literature and our ^{1}H NMR data (see below), the values in Table 2 indicate that the first protonation occurs at one amide nitrogen atom, as already mentioned. The second constant corresponds to the protonation of an amine nitrogen, which in spite of being a low value it is the usual number found for

Table 2
Protonation constants (log units) for **H_2L1** and other similar ligands

Overall protonation constants [stepwise constants]	**H_2L1**[a]	**H_2L1**[b]	**H_2L2**[c,d]	**H_2L3**[c,d]
$\beta_1^H[k_1^H]$	12.81(20) [12.81]			
$\beta_2^H[k_2^H]$	18.84(1) [6.03]	6.07 [6.07]	6.50 [6.50]	6.41 [6.41]
$\beta_3^H[k_3^H]$	22.24(1) [3.40]	9.34 [3.27]	10.04 [3.54]	9.81 [3.40]
$\beta_4^H[k_4^H]$	24.35(3) [2.11]			

[a] This work, 25.0 °C, $I = 0.10$ mol dm^{-3} KNO_3, values in parentheses are standard deviations in the last significant figures.
[b] 25 °C, $I = 0.1$ mol dm^{-3} KCl, [7].
[c] 25 °C, $I = 0.1$ mol dm^{-3} KCl, [23,24].
[d] The β values shown were calculated based on the stepwise stability constants given by the authors.

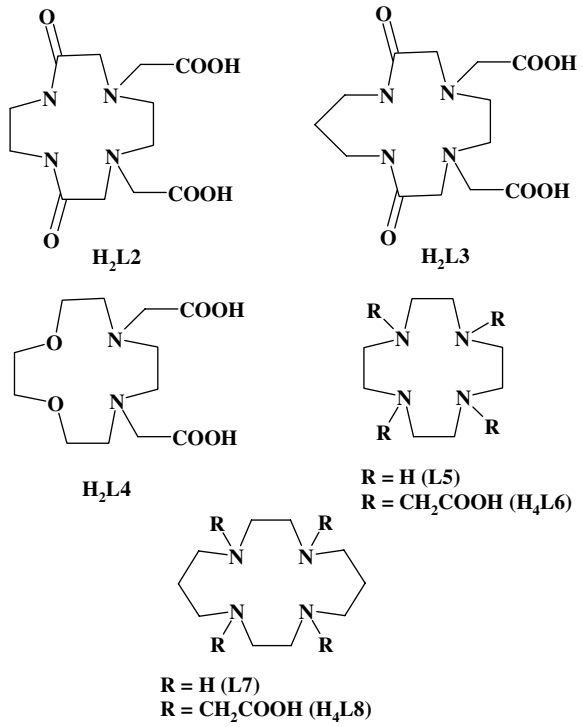

Fig. 3. Tetraazamacrocyclic ligands related with **H_2L1**: **H_2L2** (2,9-dioxo-1,4,7,10-tetraazacyclododecane-4,7-diacetic acid), **H_2L3** (2,9-dioxo-1,4,7,10-tetraaza-cyclotridecane-4,7-diacetic acid), **H_2L4** (1,4-dioxa-7,10-diazacyclododecane-7,10-diacetic acid), **L5** (1,4,7,10-tetraazacyclododecane; cyclen), **H_4L6** (1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid; dota), **L7** (1,4,8,11-tetraazacyclotetradecane; cyclam), **H_4L8** (1,4,8,11-tetraazacyclotetradecane-1,4,8,11-tetraacetic acid; teta).

the protonation of amine centres in close proximity of one electron-withdrawing amide group [25,26]. The third constant corresponds to the protonation of the acetate arm bound to the non-protonated amine nitrogen [25] and finally, the fourth constant can be attributed to the protonation of the remaining amine nitrogen or the remaining acetate or both simultaneously.

The first determined protonation constant is so high that only could be determined by ^{1}H NMR titration in the pD range 8–15, Fig. 4.

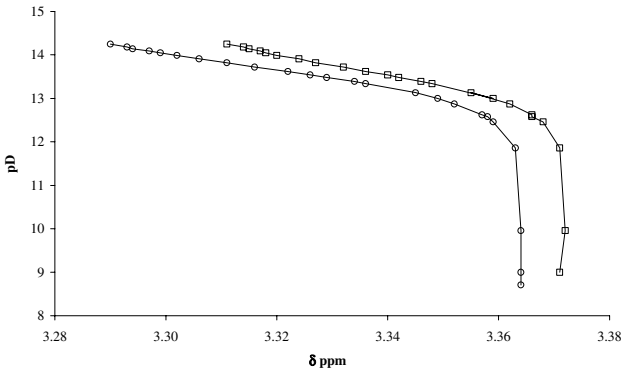

Fig. 4. ^{1}H NMR titration curves of **H_2L1**: proton H_b (○) and proton H_c (□).

The ^{1}H NMR spectra of compound **H_2L1** exhibit four resonances for the entire pD range. At high pD values, the spectra show two multiplets assigned to the aromatic protons (H_d and H_e) and two singlets, integrating for four and two protons, assigned to the H_b, H_c and H_a, respectively. At low pD values, the spectra show only one multiplet resonance for the four aromatic protons (H_d/H_e) and three singlets of equal intensity (2H) for the H_a, H_b and H_c protons.

The variation of chemical shifts (δ) of the H_b and H_c protons in function of pD values were used to determine the first protonation constant. As can be seen in Fig. 4, the δ are downfield shifted when the pD value increases. The shifts are small, because the centre to be protonated is far from H_b or H_c, but significant enough to be used for calculations. Based on these data, two pK_D values were determined independently, converted in pK_H, and the final pK_H given by the average of these. The conversion of the pK_D values in pK_H was made using the correlation pK_D = 0.11 + 1.10pK_H determined for polyaza and polyoxa-polyaza macrocyclic compounds by Delgado et al. [18]. The average pK_H value found was 12.81(4). However if all the experimental errors for the determination of this value were taken into account a standard deviation of about 0.2 should be indicated as more realistic.

The values determined in this work (see Table 2) for the second and the third stepwise protonation constants are comparable to the values previously reported by Cathala et al. [6] and Fernando and co-workers [7]. It was possible to determine the protonation constant of one amide centre for **H_2L1**, and not in the case of **H_2L2** and **H_2L3** and many other similar cyclic amide complexones studied by Fernando and co-workers [23,24,26], due to the presence of the benzene ring in **H_2L1** that turn the adjacent amide more acidic. However, the inclusion of this constant, and also the fourth one, led to an overall basicity for **H_2L1**, which is about 15 log units higher than the previously described value with the consequent repercussions on the stability constant values of its metal complexes.

Potentiometric studies of **H_2L1** with Cu^{2+}, Ni^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+} were performed also at 25.0 °C and 0.10 M ionic strength in KNO_3, in order to determine the corresponding stability constant. The values found are shown in Table 3, together with those taken from literature for the related **H_2L2** and **H_2L3** macrocycles.

Only mononuclear species were formed with the studied metal ions, namely $[M(\mathbf{H_{-1}L1})]^-$, $[M\mathbf{L1}]$ and $[M(\mathbf{H_{-2}L1})]^{2-}$. The $[M(\mathbf{HL1})]^+$ species only appears with Ni^{2+}, while $[M(\mathbf{H_{-3}L1})]^{3-}$ is formed with Cu^{2+} and Cd^{2+}.

At physiological pH, the $[M(\mathbf{H_{-1}L1})]^-$ complex is formed at about 100% for Cu^{2+} and Ni^{2+}, while for Pb^{2+} and Zn^{2+} this species is the main complex only at pH $\geqslant$ 9, and for Cd^{2+} the amount of $[Cd(\mathbf{H_{-1}L1})]^-$ formed is low at physiological pH, being $[M\mathbf{L1}]$ always present. This information suggests that Ni^{2+} and Cu^{2+} easily deprotonate the first amide centre, while the other studied metal ions only manage to do it at higher pH values. Even though the thermodynamic stability constants do not give structural information, being impossible to ascribe the acid–base reactions that occur at high pH values to amide deprotonation or to the hydrolysis of water molecules directly coordinated to the metal centre. Based in these experiments is also impossible to realize if a structural arrangement occurs upon deprotonation of the amide centre for the nickel and copper complexes. However a slow reaction occurs after the deprotonation of the first amide centre for the case of nickel, because it was found completely different potentiometric curves when the solution containing the metal and ligand in a 1:1 ratio is titrated with base (formation of complexes) or with acid upon the complete formation of complexes which clearly suggests a structural rearrangement (supplementary material).

The Ni(II) complex $[M(\mathbf{H_{-1}L1})]^-$ exhibits the highest thermodynamic stability constant followed by Cu(II) being the corresponding values significantly lower for

Table 3
Stability constants (log units) for complexes of **H_2L1** and other related ligands with several divalent metal ions (charges were ignored)

Ion	Equilibrium quotient	**H_2L1**[a]	**H_2L1**[b]	**H_2L2**[c,d]	**H_2L3**[c,d]

[d] The β values shown were calculated based on the stepwise stability constants given by the authors.

the other three metal ions, Pb, Zn and Cd. The trend $[Ni(\mathbf{H_{-1}L1})]^- > [Cu(\mathbf{H_{-1}L1})]^- \gg [Pb(\mathbf{H_{-1}L1})]^- > [Zn(\mathbf{H_{-1}L1})]^- > [Cd(\mathbf{H_{-1}L1})]^-$ does not follow the usual Irving–Williams order of stability [27]. However, analogous trends have already been reported. In general, steric requirements of the ligands on complex formation (macrocyclic type or other) or coordination geometry preferences are on the basis of the inversion of stability for the nickel and copper complexes [28].

The stability constant values of **H_2L1** with all the metals studied are higher than the previously reported [7], which is expected on the basis of the different protonation values presented. The direct comparison of values of this work and the previously reported ones can be made by the calculation of pM ($-\log[M^{2+}]$) values. In Table 4 are shown the pM values for the different complexes together with those calculated from the potentiometric data for other related ligands (see Fig. 3), at physiological pH [29]. The pCu and pZn values for **H_2L1** calculated using our stability constants are identical, but the pNi is higher, than the reported ones.

The discrepancy found for Ni probably results from the very high value of its stability constant added to its slow kinetic formation. Indeed this constant, as well as that for the copper complex, was determined by a competition reaction (see Section 2) because the complex is completely formed at the beginning of the titration, this means at very low pH values, see Fig. 5. The ligand **H_2L3** presents lower pM values when compared with those of **H_2L1**, except for zinc. The lower values for **H_2L3** are expected due to the larger cavity size of this macrocycle, although the high value presented for Zn is not expected. The pM values for **H_2L1** and **H_2L2** are very similar suggesting that the introduction of the benzene ring into the framework of **H_2L1** has a minor influence on complex formation, or that the donor atoms involved in the coordination to the metal are not specially affected by the presence of the benzene ring.

Table 4
pM ($-\log[M^{2+}]$)[d] values determined for metal complexes of **H_2L1** at physiological pH

Ion	**H_2L1**[a]	**H_2L1**[b]	**H_2L2**[c]	**H_2L3**[c]
Ni^{2+}	12.32	9.99	11.67	10.04
Cu^{2+}	11.73	11.91	11.64	11.83
Zn^{2+}	8.00	7.99	8.93	9.09

[d] The values were calculated for 100% excess of free ligand, using the program HYSS [29], $C_L = 2C_M = 1 \times 10^{-5}$ mol dm^{-3}, and the stability constants given in Table 2.

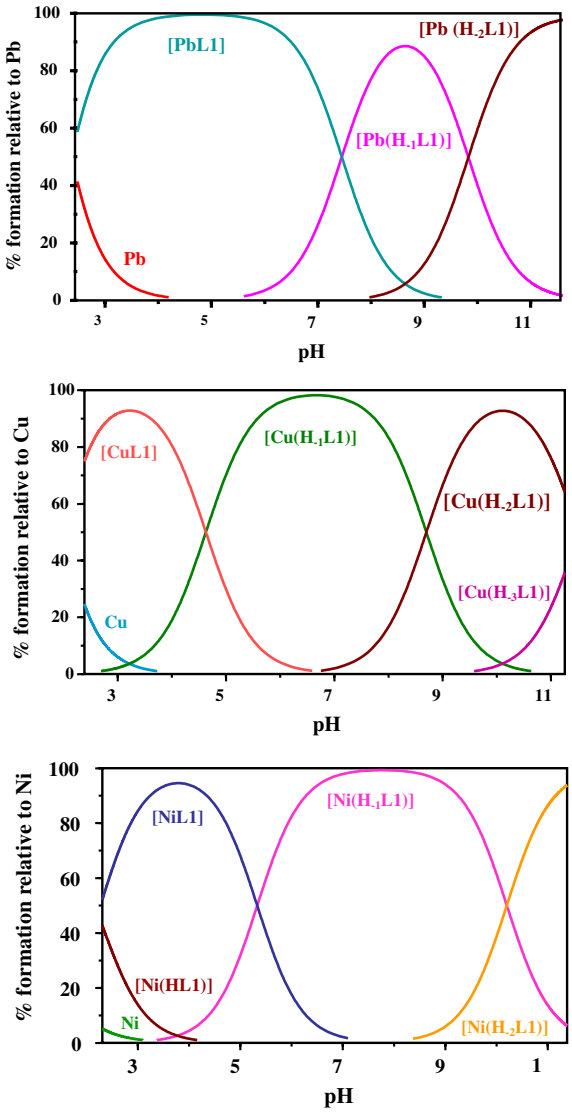

Fig. 5. Species-distribution diagrams for the Pb^{2+}, Cu^{2+} and Ni^{2+} complexes with **H_2L1** in water, $C_L = C_M = 4.201 \times 10^{-5}$ mol dm^{-3}.

3.2. Spectroscopic studies in solution

The UV–Vis-near IR spectra of the Ni(II) and the Cu(II) complexes, and the X-band EPR spectra of the Cu(II) ones were recorded at pH values of about 3, 6.5 and 10 for the copper complexes and about 4, 8 and 11 for the nickel ones. The selected pH values correspond to the maximum percentage of [M**L**], $[M(\mathbf{H_{-1}L})]^-$ and $[M(\mathbf{H_{-2}L})]^{2-}$ species, respectively, with minimum percentage of the other species present, as shown on the species distribution diagrams, see Fig. 5.

3.3. UV–Vis-near IR spectra

The electronic spectra of the Ni/**H_2L1** complexes exhibit at all pH values three main bands typical of distorted octahedral or square pyramidal geometries: one

in the range 1008–952 nm (broadband), the second in the range 597–562 nm and the third at about 380 nm, (Table 5). The spectra were recorded upon full stabilisation (about 18 h) of solutions at each pH. Indeed the slow kinetics, already verified in the potentiometric measurements, was confirmed, the final spectra displaying important differences in number of bands and absorption maxima from those recorded immediately upon preparation.

The visible and especially the near-IR bands shift to higher energies (of about 50 nm for the first and 35 nm for the second one), when the pH increases from 3.76 to 11.39. The observed blue shift indicates an increase of the ligand field, suggesting the coordination of an additional donor atom to the metal centre. The increase of the molar absorptivity accounts to a more distorted geometry of the complex.

The electronic spectra of the copper complexes are not especially informative about the adopted geometry in solution, however the band in the near-IR region points to a distorted geometry, and the blue shifts of the visible band with the increase of the pH were also observed, see Table 5. However, a faster kinetics of formation of the copper complex in comparison with that of nickel was noted, as already mentioned above.

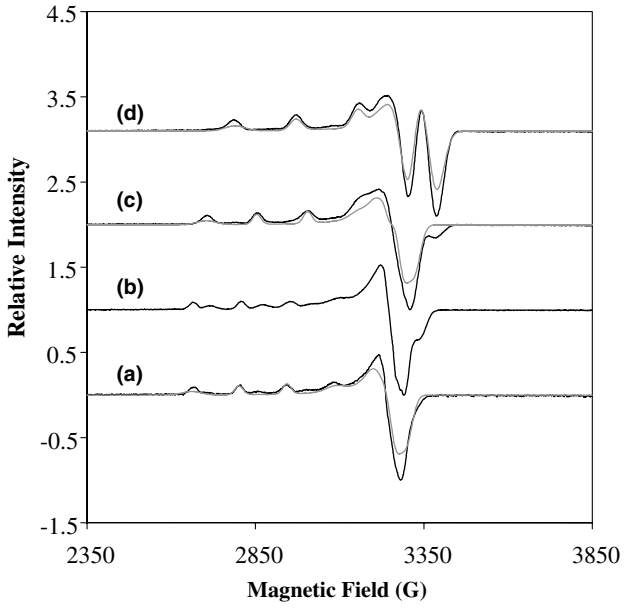

Fig. 6. X-band EPR spectra of copper complexes of **H_2L1** in $\approx 2 \times 10^{-3}$ mol dm^{-3} and 1:1 H_2O/DMSO solutions (black lines) and its simulated spectra (grey lines) at different pH values: (a) pH 3.51; (b) pH 6.37 and (c) pH 10.26. The spectrum of a solution of **1** in 1:1 H_2O/DMSO (pH 3.23) is also shown (d). All the spectra were recorded at 96 K, microwave power of 2.0 mW and modulation amplitude of 1 mT. The frequency was 9.405, 9.407, 9.408 and 9.407 GHz, respectively.

3.4. EPR spectroscopy of copper complexes

The EPR spectra of copper complexes in solution at different pH indicated the presence of only one species, while the EPR spectrum of the solution obtained by dissolving the crystals of **1** in DMSO/H_2O indicated the presence of two species, see Fig. 6. All spectra showed the expected four well-resolved lines at low field, due to the interaction of the unpaired electron spin with the copper nucleus. The hyperfine coupling constants (A) and g values obtained by the simulation of the spectra [30] are shown in Table 6, together with those of other copper (II) complexes taken from literature for comparison. The simulation of the spectra indicates three different g values with $g_z > (g_x + g_y)/2$ and the lowest $g \geqslant 2.04$, which is characteristic of mononuclear copper (II) complexes having rhombic-octahedral with elongation of the axial bonds or distorted square-based pyramidal symmetries, and $d_{x^2-y^2}$ ground state.

At the three pH studied, the complexes have g_z and A_z parameters consistent with different type of donor atoms close lying the metal. At pH 3.51, these parameters are consistent with N_2O_2 equatorial coordination sphere [31]. The differences between them can be visualised in the diagram g_z versus A_z presented in Fig. 7, and rationalised in terms of different axial field for each complex. Indeed, the g_i and A_i values are related to the electronic transitions by the factors derived from the ligand-field theory [32,33]: the g_i values increase

Table 5
Spectroscopic UV–Vis-near IR data for the Ni^{2+} and Cu^{2+} complexes of **H_2L1** at several pH values in aqueous solution and 25 °C

and the A_i values decrease as the equatorial ligand field becomes weaker or stronger the axial ligand field and this occurs with the simultaneous red-shift of the d–d absorption bands in the electronic spectra (see Tables 5 and 6) [33–35]. Herein, when the pH increases a blue-shift is observed, and simultaneously the g_z decrease and the A_z values increase, which is consistent with the increase of the equatorial field. These features are also consistent with the potentiometric results, which have shown that the deprotonation of one amide nitrogen atom occurs at pH ~ 6.

The EPR spectrum of crystals of **1** showed that two species are present in different proportions. The g_z and A_z parameters suggest that the crystals of **1** in solution have a different structure than in the solid state, as the chloride atom is probably replaced by an oxygen of a water molecule. The resulting parameters are consistent with a mixture of the spectrum of **H_2L1** at pH 3.51 (specie A) and of **H_2L1** at pH 6.37 (specie B), being the first in a higher proportion (about 75%). This suggests that an equilibrium between the two corresponding structures is responsible by the observed EPR spectrum.

The A_z versus g_z diagram shown in Fig. 7, together with the known geometries of some of the complexes taken from the literature [36], allow the following considerations: (1) the right region of the diagram, having higher g_z and lower A_z values, is occupied by complexes with oxygen atoms in the equatorial plane, such as Cu(H_2O)$_6$ (⁎); (2) in the middle region of the diagram complexes with octahedral geometry are found, having the four nitrogen atoms of the macrocycle forming the equatorial plane and oxygen atoms in the axial positions (● **H_4L8**); (3) the complexes having four nitrogen atoms of the macrocyclic ring at the equatorial plane are located in the left part of the diagram and exhibit square-planar (○ **L7**) or square pyramidal (△ **L5**) geometries. The parameters of the copper complexes of **H_2L1** change considerably with the increase of the pH, with the decrease of g_z, the increase of A_z and a corresponding blue shift, accounting a stronger equatorial ligand field. Indeed, at pH 3.5 these parameters are consistent with a N_2O_2 coordination sphere, while those for the complexes at pH ≈ 6 and ≈10 point to arrangements with stronger equatorial ligand fields, in agreement to the presence of an increased number of nitrogen as donor atoms.

4. Concluding remarks

Although **H_2L1** was reported before, the present study allowed to extend the knowledge of its behaviour and of its metal complexes in solution and in the solid state. Our potentiometric and ^1H NMR studies revealed that the deprotonation of one of the amides occurs at a pH lower than usual due to the presence of the benzene ring into the macrocyclic backbone, allowing its determination. It was also verified that the nickel complex has a thermodynamic stability higher than the copper one, and therefore the usual Irving–Williams trend of stability is not found, probably due to steric strain imposed by the ligand.

By reacting **H_2L1** with $[CuCl_2] \cdot 2H_2O$, in EtOH at pH 6 and using the 1:1 M/L molar ratio, the monomeric complex **1** was obtained. This complex is quite different from the dimeric Cu^{2+} complex isolated previously by Fernando and co-workers [7].

Based on the electronic data, it was possible to predict that at low pH values (pH 3.51) two amine nitrogen atoms and two oxygen atoms from the acetate arms or from the amides of the framework are involved in the coordination sphere of the Cu, as the EPR parameters are consistent with a N_2O_2 donor atoms close lying the metal [31] and the X-ray structure of **1** also suggests. At higher pH values (about 6), the EPR parameters are consistent with a N_3O equatorial coordination sphere for the copper, in agreement also with the blue shift of the band in the visible region. This means that the deprotonation of the amide of the macrocyclic backbone, which occurs in this pH range, leads to a rearrangement of the complex with the repositioning of the Cu atom towards the centre of the macrocycle for the coordination to this amide nitrogen. This probably also happens with the nickel complex, and in this case the rearrangement is kinetically slow, as observed by our potentiometric and UV–Vis results. At high pH values is impossible to predict, based only on our potentiometric experiments, if the deprotonation of the second amide of the macrocycle occurs or if the proton that is titrated in this region derive from the hydrolysis of a water molecule directly coordinated to the metal ion. However, the EPR spectra showed unambiguously that, at least for the copper complex, the increase of the strength of the equatorial ligand field at high pH can only be ascribed to the contribution of the fourth nitrogen of the macrocycle on the metal coordination.

Abstract

Treatment of $NbCl_5$ with excess $HN(SiMe_2Ph)_2$ in toluene resulted in the formation of crystalline $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$. In the presence of excess 3,5-lutidine (3,5-$Me_2C_5H_3N$), the reaction of $TaCl_5$ with 2 equivalents of $HN(SiMe_3)_2$ resulted in the isolation of the monomeric complex $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$. The X-ray crystal structure of $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ has been determined. Low pressure chemical vapour deposition of $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ and $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ forms thin films of niobium and tantalum nitride, respectively, at 600 °C.

Keywords: Tantalum nitride; Niobium nitride; CVD

1. Introduction

Transition metal nitrides constitute a diverse class of materials with many interesting technological applications [1]. For example, the metallic conductivity and refractory stability of transition metal nitrides makes them the materials of choice for diffusion barriers in various metallization structures of advanced microelectronic devices [1]. Of the many nitrides known, titanium nitride (TiN) is the most commonly used of these materials because of its low resistivity, good stability, high resistance to chemical etching and good conformality. However, recent studies involving the interdiffusion of Cu into TiN thin films found that TiN remained stable up to 450 °C for 30 min, after which time Cu started to diffuse into the TiN layer [2]. Therefore, developing an alternative CVD route to a metal nitride capable of withstanding the diffusion of Cu at a high sintering temperature would be advantageous to the microelectronics industry. It has been shown that TaN and Ta_2N act as excellent metallurgical diffusion barriers between Cu and Si and between Al and Si [3]. Tantalum(V) nitride (Ta_3N_5) and tantalum(III) nitride (TaN) are the most common forms of tantalum nitride, however, only TaN thin films are suitable for use as diffusion barriers in integrated circuits. Niobium nitride (NbN) is a hard silver-colored refractory material and has been studied due to its superconducting properties (T_c = 17.3 K) [4].

Attempts to grow niobium and tantalum metal nitride thin films via chemical vapour deposition (CVD) of $[M(NR_2)_n]$ and NH_3 resulted in the formation of nitrides with stoichiometries Nb_3N_4 and Ta_3N_5 [5]. Other CVD processes available for the preparation of metal nitride films include the reaction of $NbCl_5$ or $TaCl_5$ with NH_3, resulting in the formation of NbN or Ta_3N_5, respectively [6]. Preparation of TaN films has also been reported from the CVD reaction of $TaCl_5$, N_2 and H_2 [7]. These reactions release corrosive HCl vapour, which along with the high deposition temperature, makes the

process largely unsuitable for microelectronic applications [4].

An alternative approach to transition metal nitride coatings is the use of single-source precursors, which are required to be highly volatile and have a metal–nitrogen bonded fragment at the core of the molecule. There has been heightened interest in metal imido complexes either as single-source metal nitride precursors, or as proposed intermediates in the conversion of metal–nitrogen derivatives to metal nitride [8]. The single-source precursor approach to NbN and TaN is underdeveloped, with only the complexes $[Ta(NR)(NEt_2)_3]$ (R = *t*-Bu, Et) [3,9], $[(t\text{-}BuCH_2)_2TaN]_5$ [10], $[MCl_2(NR)(NHR)(NH_2R)_2]_2$ (M = Nb or Ta, R = NMe_2; M = Nb, R = *t*-Bu) [11] and $[Ta(NEt_2)_5]$ [12] having been investigated to date in any detail.

We have been studying the reactivity of metal halides with silylamines in an attempt to isolate volatile single-source precursors to metal nitrides [13–16]. We have previously found that the trimethylsilyl group is very labile and can lead to materials with no silicon contamination [16]. Herein, we describe the reactivity of MCl_5 with $HN(SiR_2R')_2$ (M = Nb, R = Me, R′ = Ph; M = Ta, R = R′ = Me) under various conditions. The crystal structure of a new complex $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ is described. Low pressure chemical vapour deposition of the precursors is also discussed.

2. Experimental

2.1. General procedures

All manipulations were performed under a dry, oxygen-free dinitrogen atmosphere using standard Schlenk techniques or in an Mbraun Unilab glove box. All solvents were distilled from appropriate drying agents prior to use (sodium/benzophenone–toluene and hexanes; CaH_2 for CH_2Cl_2). All other reagents were procured commercially from Aldrich and used without further purification. Microanalytical data were obtained at University College London (UCL). BDH microscope slides were used for the CVD experiments.

2.2. Physical measurements

^1H and ^{13}C NMR spectra were recorded on Bruker AMX400 spectrometer at UCL. The NMR spectra are referenced to $CDCl_3$ or C_6D_6, which was degassed and dried over molecular sieves prior to use; ^1H chemical shifts are reported relative to $SiMe_4$ (0.00 ppm). FTIR spectra on a Nicolet 205 instrument. TGA of the compounds were obtained from the Thermal Methods Laboratory at Birkbeck College (ULIRS). X-ray powder diffraction patterns were measured on a Siemens D5000 diffractometer using monochromated Cu $K\alpha_1$ radiation ($\lambda_1 = 1.5406$ Å). The diffractometer used glancing incident radiation (1.5°). Samples were indexed using unit cell and compared to database standards. EDAX was obtained using a JEOL 35-CF instrument and SEM was obtained on a Hitachi S570 instrument using the KEVEX system. X-ray photoelectron spectra were recorded using a VG ESCALAB 220i XL instrument using focused (300 mm spot) monochromatic Al Kα radiation at a pass energy of 20 eV. Scans were acquired with steps of 50 meV. A flood gun was used to control charging and the binding energies were referenced to an adventitious C 1s peak at 284.8 eV. Depth profile measurements were obtained by using argon beam sputtering. UV–Vis spectra were recorded in the range 190–1100 nm using a Helios double beam instrument.

2.3. Preparation of $[NbCl_3(NSiMe_2Ph)\{NH_2(SiMe_2Ph)\}]_2$ (**1**)

$HN(SiMe_2Ph)_2$ (0.8 cm^3, 3.8 mmol) was added to a suspension of $NbCl_5$ (0.4 g, 1.48 mmol) in toluene (20 cm^3) at room temperature. After stirring at room temperature for 3 h, a red solution resulted. The mixture was allowed to stir for a further 12 h resulting in a white crystalline solid and olive-green solution. After filtering using a filter stick a white crystalline solid was obtained, which was washed with hexanes (2×5 cm^3) and dried in vacuo (0.69 g, 93% yield). *Anal.* Calc. for $C_{16}H_{24}Cl_3N_2Si_2Nb$: C, 38.45; H, 4.84; N, 5.61. Found: C, 38.35; H, 4.46; N, 5.48%. ^1H NMR ($CDCl_3$): δ 0.21 (s, 6H, $NSiMe_2Ph$), 0.61 (s, 6H, $NH_2(SiMe_2Ph)$), 3.23 (br, 2H, NH_2), 7.11–7.74 (m, 10H, $NSiMe_2Ph$ and $NH_2(SiMe_2Ph)$). $^{13}C\{^1H\}$NMR ($CDCl_3$): δ 1.7 ($NSiMe_2Ph$), 2.7 ($NH_2(SiMe_2Ph)$), 128.2, 128.8 (*m*-SiC_6H_5), 130.9, 130.2 (*p*-SiC_6H_5), 133.7, 133.9 (*o*-SiC_6H_5), *ipso*-SiC_6H_5 not detected. 2.4. Preparation of $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ (**2**)

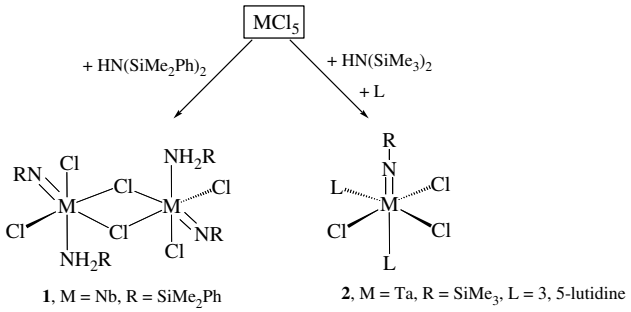
$HN(SiMe_3)_2$ (0.95 cm^3, 4.5 mmol) and 3,5-$Me_2C_5H_3N$ (2.30 cm^3, 20.2 mmol) was added to a suspension of $TaCl_5$ (1.50 g, 4.2 mmol) in toluene (20 cm^3) at room temperature. After stirring at room temperature for 20 h, a yellow solution and off-white precipitate resulted. The yellow solution was decanted from the off-white precipitate and filtered through Celite. The solvent was removed in vacuo to give a yellow oil. Triturating this yellow oil with pentane (3×5 cm^3) produced a beige solid, which was washed with pentane (3×5 cm^3) and dried in vacuo (1.33 g, 54% yield). X-ray quality crystals of **2** were obtained at −20 °C over a few

days by dissolving a small amount of the beige solid (~0.3 g) in CH_2Cl_2 (5 cm^3) and overlaying with hexanes (10 cm^3). *Anal*. Calc. for $C_{17}H_{27}Cl_3N_3SiTa$: C, 34.68; H, 4.62; N, 7.14. Found: C, 34.31; H, 4.25; N, 7.12%. ^1H NMR (C_6D_6): δ 0.43 (s, 9H, $Si(CH_3)_3$), 1.53 (s, 6H, $NC_6H_3(CH_3)_2$), 1.70 (s, 6H, $NC_6H_3(CH_3)_2$), 6.40 (s, 1H, *p*-C_6H_3N), 6.59 (s, 1H, *p*-C_6H_3N), 8.60 (s, 2H, *o*-C_6H_3N), 8.94 (s, 2H, *o*-C_6H_3N). $^{13}C\{^1H\}$ NMR(C_6D_6): δ 1.3 ($Si(C H_3)_3$), 17.6 ($NC_6H_3(C H_3)_2$), 17.8 ($NC_6H_3(C H_3)_2$), 133.4 (s, *p*-$NC_6H_3(CH_3)_2$), 133.9 (s, *p*-$NC_6H_3(CH_3)_2$), 139.4 (s, *m*-$NC_6H_3(CH_3)_2$), 140.6 (s, *m*-$NC_6H_3(CH_3)_2$), 150.8 (s, *o*-$NC_6H_3(CH_3)_2$), 151.6 (s, *o*-$NC_6H_3(CH_3)_2$). FT-IR 2348 m, 1632 s, 1604 s, 1534 m, 1482 m, 1403 s, 1254 w, 815 w, 747 m, 677 m, 436 w, 467 w cm^{-1}.

2.5. Low pressure CVD experiments

The same procedure was carried out for all compounds (**1** and **2**) shown here for **2**. A sample of compound **2** (0.3 g) was loaded into the end of a glass ampoule (40 cm length × 16 mm diameter) in the glovebox. Glass substrates (10 cm × 7 mm) were placed carefully inside the ampoule. The ampoule was then placed in a furnace such that 30 cm was inside the furnace and the end containing the sample protruded by 4 cm. The ampoule was heated to a temperature of 600 °C under dynamic vacuum, except for the section of the tube containing the sample. The ampoule was slowly drawn into the furnace over a period of a few minutes until **2** started to melt. Once the compound had decomposed the furnace was allowed to cool to room temperature. A shiny, golden-brown film was deposited on the glass substrates. The film was analyzed by EDAX/SEM, electron probe and reflectance/transmission measurements.

2.6. X-ray crystallography



Crystals of **2** were grown from CH_2Cl_2/hexanes layers at −20 °C. Table 2 provides a summary of the crystallographic data for compound **2**, CCDC 249229.

3. Results and discussion

Treatment of $NbCl_5$ with two equivalents of $HN(SiMe_2Ph)_2$, resulted in the formation of white crystalline $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ (**1**). Analytical data (CHN) for **1** was consistent with the formation of $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ but unfortunately X-ray quality crystals could not be isolated. The ^1H and ^{13}C NMR of **1** in $CDCl_3$ shows two singlets of equal intensity for two different $SiMe_2Ph$ groups. A broad singlet at 3.23 ppm was observed in the ^1H NMR of **1** corresponding to two equivalent NH_2 protons. The FT-IR of **1** supports the formulation $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ since two sharp bands above 3100 cm^{-1} corresponding to symmetric and asymmetric N–H stretches of the monosilylated amine, NH_2SiMe_2Ph, were observed [17]. Compound **1** is similar to some related niobium imido complexes, of the type $[NbCl_3(NR)(NH_2R)]_2$ (R = *t*-Bu, *i*-Pr, $SiMe_3$, 2,6-$(CH(CH_3)_2)_2C_6H_3$) [17–21]. The structure of **1** is expected to be similar to the *tert*-butylimido/*tert*-butylamine analogue and related complexes published previously, which are dimeric via chloride bridges [19,21].

The silyamido group in **1** is formed by cleavage of an N–Si bond in $HN(SiMe_2Ph)_2$, to give $Me_2PhSiCl$, and transfer of its proton to a second equivalent of $HN(SiMe_2Ph)_2$. The latter results in the formation of the amine $H_2N(SiMe_2Ph)$, which coordinates to the niobium centre (Scheme 1). Based on related reactions, [17] it is likely that the reaction of $NbCl_5$ with two equivalents of $HN(SiMe_2Ph)_2$ to afford **1**, precedes via the intermediate complex $[Nb(NHSiMe_2Ph)_2Cl_3]$, which then undergoes interligand proton transfer to yield $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$.

The reaction of $TaCl_5$ and $HN(SiMe_3)_2$ in the presence of 3,5-lutidine (3,5-dimethylpyridine, 3,5-$Me_2C_5H_3N$) resulted in the formation of colorless crystalline **2**. Analytical and spectroscopic data for **2** were consistent with the formulation $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$. The monomeric nature of **2** was confirmed by an X-ray crystallographic study (Fig. 1). The geometry at the tantalum centre is distorted octahedral, the metal lying ca. 0.32 Å out of the "equatorial" $\{NCl_3\}$ plane (which is coplanar to within ca. 0.01 Å) in the direction of the imido nitrogen N(1); the *cis* angles involving N(1) [94.6(2)–100.9(2)°] are all noticeably increased from 90°, whilst those involving N(6) are all reduced [81.0(2)°–83.57(13)°] (Table 1). The bond length to the imido nitrogen [1.772(5) Å] is similar to that seen in the related complexes $[TaCl_3(N\text{-}t\text{-}Bu)(py)_2]$ [22] [1.745(5) Å] and $[TaCl_2(NSiMe_3)\{HB(pz)_3\}]$ [23,24] [1.767(6) Å] (where pz = 3,5-dimethylpyrazolyl). The $NSiMe_3$ unit in this latter complex is noticeably more bent than seen here in **2**, the Ta–N–Si angles being 164.8(4)° and 172.2(4)° respectively; the corresponding Si–N distances are 1.742(6) and

Scheme 1.

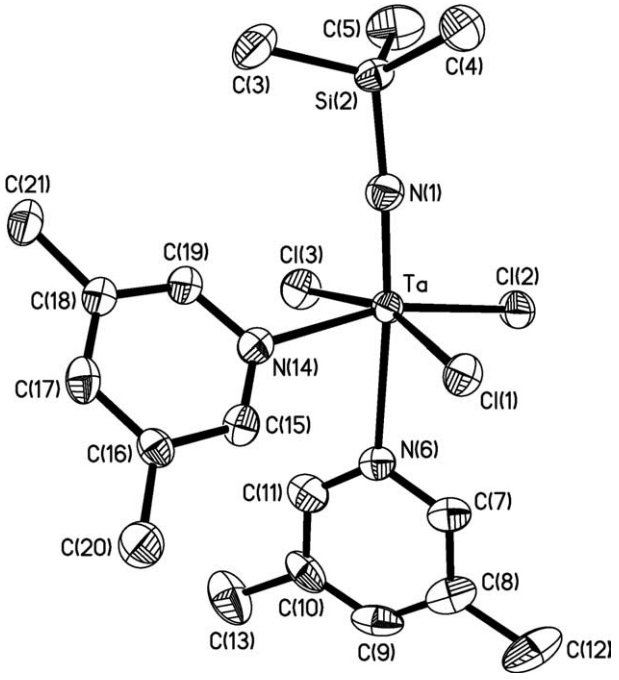


Fig. 1. The molecular structure of **2** (50% probability ellipsoids).

Table 1
Selected bond lengths (Å) and angles (°) for **2**

Bond lengths			
Ta–Cl(1)	2.387(2)	Ta–Cl(2)	2.3588(15)
Ta–Cl(3)	2.389(2)	Ta–N(1)	1.772(5)
Ta–N(6)	2.508(5)	Ta–N(14)	2.271(6)
Bond angles			
Cl(2)–Ta–Cl(1)	91.72(6)	Cl(1)–Ta–Cl(3)	162.12(6)
Cl(1)–Ta–N(1)	99.1(2)	Cl(1)–Ta–N(6)	82.67(13)
Cl(1)–Ta–N(14)	84.22(15)	Cl(2)–Ta–Cl(3)	94.16(6)
Cl(2)–Ta–N(1)	100.9(2)	Cl(2)–Ta–N(6)	83.57(13)
Cl(2)–Ta–N(14)	164.41(14)	Cl(3)–Ta–N(1)	96.4(2)
Cl(3)–Ta–N(6)	81.23(13)	Cl(3)–Ta–N(14)	85.6(2)
N(1)–Ta–N(6)	175.1(2)	N(1)–Ta–N(14)	94.6(2)
N(6)–Ta–N(14)	81.0(2)	Ta–N(1)–Si(2)	172.2(4)

1.736(5) Å respectively. The Ta–N distances to the two 3,5-lutidine ligands are noticeably different, with that to the axial group *trans* to the imido [Ta–N(6) 2.508(5) Å] being more than 0.2 Å longer than that to its equatorial counterpart [Ta–N(14) 2.271(6) Å] (*trans* to chloride), reflecting the strong *trans* influence of the imido ligand. One of these lutidine ligands is involved in an intermolecular π–π stacking interaction with its centrosymmetrically related counterpart, the centroid···centroid and mean interplanar separations being ca. 3.76 and 3.53 Å, respectively. The ^{1}H NMR of **2** indicates that in solution the same structure is adopted with two sets of non-equivalent 3,5-$Me_2C_5H_3N$ signals present. Reaction of $TaCl_5$ and amines has been studied previously [22,25]. A series of related complexes of formula $[TaCl_3(NR)(py)_2]$ have been reported and were prepared via the reaction of $TaCl_5$ and two equivalents of an amine in the presence of sodium silicate and pyridine [26]. No structures of these complexes have been reported.

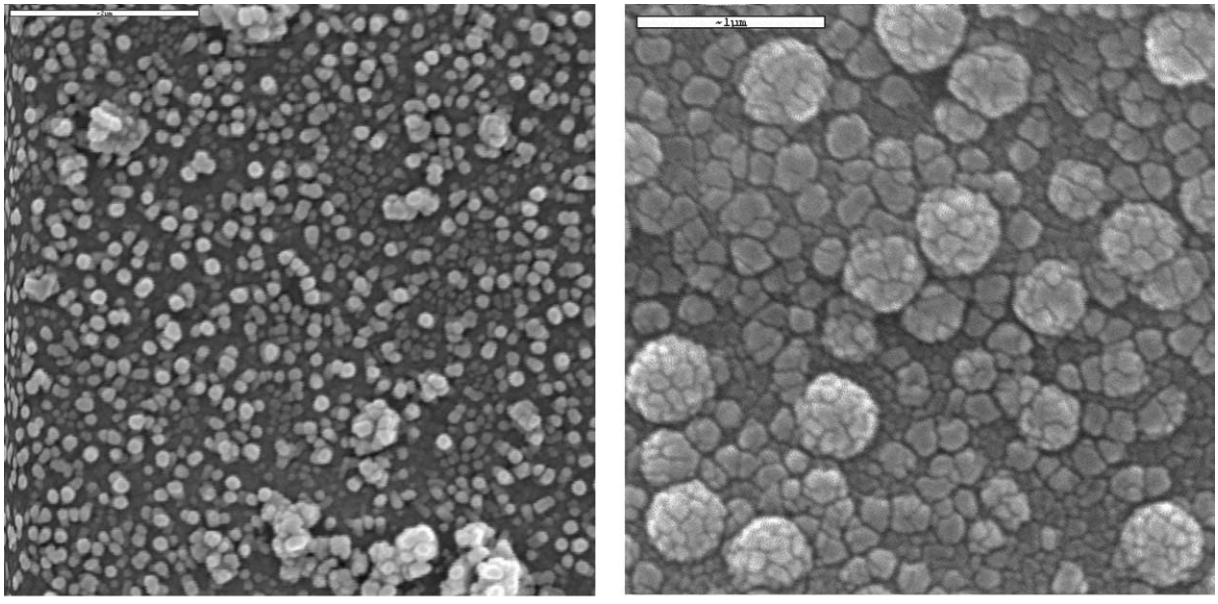
In order to study the decomposition pathway of compounds **1** and **2** thermal analyses were carried out. The TGA (thermal gravimetric analysis) of **1** (10 °C/min from 20 to 500 °C) shows a weight loss of 69.2% (calculated weight loss 78.6% for NbN formation from **1**). This behavior indicates an incomplete decomposition to NbN up to 500 °C, although it is possible that the required weight loss could be attained at higher temperatures (the TGA set-up allows analysis only to 500 °C). The TGA of **2** indicates that this compound may be a suitable single-source precursor for the deposition of TaN thin-films. Thus, the TGA of **2** is clean and shows a total weight loss of 72.9% (calculated weight loss 67% from **2** for the formation of TaN). It is worth noting that TGA at atmospheric pressure only gives an indication of the potential of the precursors to form bulk metal nitrides. Any sublimation of the precursor, a desirable characteristic for low pressure CVD studies, would register as a further mass loss, as observed in the TGA of **2**.

Low pressure CVD of **1** and **2** were investigated, the details of which are described in the Experimental section [16]. Shiny, golden-brown films were deposited on glass substrates from **1** and **2** at 600 °C. The films produced were analyzed by EDAX/SEM, XPS, powder XRD and reflectance/transmission measurements. Both the niobium and tantalum nitride films deposited from **1** and **2**, respectively, were resistant to attack by common solvents (water, acetone, toluene, petroleum ether), concentrated nitric acid and concentrated hydrochloric acid for over 72 h. All the films passed the Scotch tape



test and could not be abraded with a brass stylus. These results indicate that the films are hard and chemically robust, which are typical properties expected for refractory cubic early transition metal nitrides.

The contact angle of the niobium nitride film was found to be 63° and the tantalum nitride film 70°. Contact angle measurements are valuable in the glass industry in assessing whether films have self cleaning properties. Low contact angles arising from hydrophilic films give rise to the water spreading across the surface and hence washing away any loose dirt. Therefore, the observed contact angles suggest that the nitride films are hydrophobic and not porous, which would significantly decrease the contact angle. The contact angles for both the niobium and tantalum nitride films did not change upon photo-irradiation. This suggests that the surface of the films has minimal oxidation as the corresponding niobium oxides show marked hydrophilicity and photo-induced superhydrophilicity [27]. The tantalum nitride film produced showed a maximum transmission in the visible region (450–700 nm), which is characteristic of tantalum nitride films [28]. The niobium and tantalum nitride films were electrically conducting with typical resistivities of 500 μΩ cm.

X-ray powder diffraction of the film obtained from **1** showed a broad diffraction pattern for NbN consistent with a cubic NaCl structure. Determination of the lattice constant gave a value of $a = 4.34(3)$ Å which compares with a literature value of $a = 4.395$ Å for $NbN_{1.00}$ [29]. Crystallite size determination from line broadening studies of the (200) peak, ignoring strain effects, gave a value of ca. 250 Å. The tantalum nitride films grown from **2** were amorphous to X-rays.

Energy dispersive X-ray analysis showed the presence of niobium and nitrogen in the film grown from **1**; tantalum and nitrogen in the film deposited from **2**. Quantitative analysis by EDAX was not possible as the oxygen signal from the glass substrate (breakthrough to the underlying glass) partially obscured that of the nitrogen from the film. However, EDAX data showed that chlorine contamination was below 0.1%. Wavelength dispersive analysis using an electron probe indicated that the niobium and tantalum to nitrogen ratios were 1:1. By scanning electron microscopy (SEM) the niobium and tantalum nitride films showed the formation of agglomerates of approximately 0.1 μm (Fig. 2). SEM showed that each film grew by a Volmer–Webber type growth mechanism.

The XPS depth profile analysis of the films formed from **1** showed the presence of Nb, N, C and O, those from **2** showed Ta, N, C and O. The carbon concentration dropped dramatically on the first etch, indicating that this was surface bound. Furthermore, no evidence of metal carbide formation was observed. The oxide surface layer was also removed by sputtering to leave the bulk of the film consisting of niobium and nitrogen, or tantalum and nitrogen. No evidence of chloride or silicon contamination (1–2 at.% detection limit) was observed. XPS of films grown from **1** gave Nb 3d and N 1s binding energy shifts of 206.8 and 396.8 eV, respectively. These are in good agreement with previous literature measurements for $NbN_{1.00}$ thin films [5]. The binding energy value for Ta 4f was measured at 18.60 eV and for N 1s was measured at 396.8 eV. The N 1s binding energy is in agreement with published XPS data for $TaN_{1.00}$ [28]. It has been demonstrated that the Ta $4f_{7/2}$ binding

(a) (b)

Fig. 2. SEM of a film grown from: (a) **1**; (b) **2** at by LPCVD at 600 °C.

energy shift in cubic nitrides shifts to lower values with nitrogen content [27].

Thin films of tantalum nitride were also deposited from **2** on aluminum and copper substrates. However, there appeared to be no difference in film composition or morphology with substrate. The advantages of compounds **1** and **2** compared to other single-source precursors to NbN and TaN are: (i) the compounds can be prepared in good yield; (ii) no significant carbon or chlorine contamination is observed in the resulting film; (iii) cubic MN_x films are deposited rather than other stoichiometries, e.g., Nb_3N_4 and Ta_3N_5.

4. Conclusions

The group Vb silylimido complexes, $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ and $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ have been synthesized and characterized. X-ray crystallography showed that $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ is monomeric. Low pressure CVD indicates that $[NbCl_3(NSiMe_2Ph)(NH_2SiMe_2Ph)]_2$ and $[TaCl_3(NSiMe_3)(NC_5H_3Me_2\text{-}3,5)_2]$ are effective niobium nitride and tantalum nitride precursors, respectively. Analysis of these films shows that they are conductive and consist of uniform particles of niobium nitride–NbN or tantalum nitride TaN. Interestingly, despite the presence of silicon and carbon in the silyl subtituent of the imido ligand, these elements were not observed in the film. This indicates that the elimination of R_3SiCl is facile during the LPCVD process.

Abstract

The title ligand is obtained in two steps with high overall yield, and is soluble in aromatic solvents, making its liquid–liquid extraction performance of potential interest. The ligand forms a stable 1:1 coordination complex with $Er(NO_3)_3$ and the molecular structure was determined by single crystal X-ray diffraction methods. The Er(III) ion is chelated by one tridentate ligand and three bidentate nitrate groups. The structural results are discussed in the context of complexes formed by related ligands.

1. Introduction

A number of options are under consideration for the treatment of high level radioactive waste present in spent nuclear fuels. Nuclear incineration is one option that could potentially reduce the hazardous storage period for the transuranic elements and some of their fission products [1]. This process requires that the so-called minor actinides be separated from other elements; therefore, there has been renewed interest in the development of new separations agents that would selectively partition Np, Am and Cm [2,3]. Several families of chelating ligands are under study worldwide with the greatest attention garnered by bifunctional CMP carbamoylmethylphosphonate, $(RO)_2P(O)CH_2C(O)NR'_2$ [4], CMPO carbamoylmethyl phosphine oxide, $RR'P(O)CH_2C(O)NR''_2$ [5–8] and malonamide, $[RR'NC(O)]_2CR''H$ ligands [9–15]. Our group has studied several variants on the CMP/CMPO theme and Hay has reported interesting new variants in the malonamide system [16]. Recently, we have also described the synthesis and coordination chemistry of a series of phosphino pyridine *N*-oxide ligands (**NOPOPO**) [17–23], some of which display favorable extraction performance for trivalent actinide ions in strongly acidic aqueous solutions [24–27]. In order to improve the **NOPOPO** extractant process performance for specific applications, it is necessary to derive additional derivatives that might show modified organic phase solubility, improved aqueous acid stability, improved radiation stability and enhanced metal coordination properties. In this paper, we report the synthesis of

an arene soluble **NOPOPO** ligand derivative and its coordination chemistry with $Er(NO_3)_3$. The physical properties and coordination chemistry are compared with data from other recently prepared ligands.

NOPOPO

2. Experimental

2.1. General Information

The organic reagents were purchased from Aldrich Chemical Co. and organic solvents were purchased from VWR. Solvents were dried and distilled using standard procedures. The $Er(NO_3)_3$ was purchased from Ventron. Infrared spectra were recorded on a Mattson 2020 FTIR spectrometer and NMR spectra were recorded on JEOL GSX-400 and Bruker FX-250 spectrometers. Standards employed were Me_4Si (^1H and ^{13}C) and H_3PO_4 (^{31}P) and downfield shifts were assigned as $+\delta$. Mass spectra were obtained from the Midwest Center for Mass Spectrometry, University of Nebraska. Elemental analyses were obtained from Galbraith Laboratories.

2.2. Synthesis of the ligand

Diethyl phosphite (6.08 g, 0.044 mol) in dry diethyl ether (10 ml) and benzene (30 ml) was added dropwise with stirring at 23 °C to cyclohexylmagnesium chloride (66 ml, 2 M solution in Et_2O, 0.13 mol). The temperature of the mixture increased during addition and tetrahydrofuran (THF) (60 ml) was added following completion of the reagent addition. The mixture was then refluxed (oil bath 67 °C, for 2 h) and then 2,6-bis(chloromethyl)pyridine (3.52 g, 0.02 mol) in dry benzene (30 ml) was added with stirring. The resulting mixture was refluxed (5 h) and the solvent removed by vacuum evaporation (23 °C). A saturated aqueous NH_4Cl solution (100 ml) was added to the residue and the mixture extracted with Et_2O/CH_2Cl_2 (5:1) (2×100 ml). The combined organic phases were dried (Na_2SO_4 anhyd.) and vacuum evaporated. The residue was washed with Et_2O (3×40 ml) giving 2,6-bis[(dicyclohexyl)phosphinomethyl]pyridine *P*,*P*′-dioxide (**1**) as a white solid. Yield: 8.7 g, 82%; m.p. 183–184 °C. ^{31}P NMR ($CDCl_3$): δ 50.1. ^1H NMR ($CDCl_3$): δ 1.21–1.37 (m), 1.72–1.97 (m), 3.27 (d, $J = 13.6$ Hz), 7.29 (d, $J = 7.7$ Hz), 7.56 (t, $J = 7.7$ Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 25.27, 25.50, 25.81, 26.34, 26.39, 26.54, 26.59, 34.80 (d, $J = 52.6$ Hz), 36.09 (d, $J = 63.9$ Hz), 122.52, 136.84, 153.40, 153.50. IR (KBr, cm^{-1}): 2930, 2850, 1587, 1450, 1275, 1222, 1174, 1118, 893, 835, 745, 594, 563, 493.

To a solution of **1** (7.4 g, 0.014 mol) in $CHCl_3$ (70 ml) was added 3-chloroperoxybenzoic acid (3.8 g, 57–86%, Aldrich). The mixture was stirred (23 °C, 2 h) and then extracted with aqueous saturated $NaHCO_3$–Na_2CO_3 (5:1) solution (80 ml). The aqueous phase (pH 8–9) was washed with CH_2Cl_2 (2×60 ml) and the combined organic phases ($CHCl_3$, CH_2Cl_2) were dried (Na_2SO_4 anhyd.) and then evaporated to dryness at 23 °C leaving 10 g of white solid. This was further purified by column chromatography (silica gel) using $CHCl_3$/MeOH (100:3) as the eluant. White, solid 2,6-bis[(dicyclohexyl)phosphinomethyl]pyridine *N*,*P*,*P*′-trioxide (**2**) was recovered. Yield: 6.5 g, 85.3%; m.p. 197–198 °C. ^{31}P NMR ($CDCl_3$): δ 51.2. ^1H NMR ($CDCl_3$): δ 1.23–1.41 (m), 1.72–1.98 (m), 3.59 (d, $J = 11.8$ Hz), 7.14 (t, $J = 7.8$ Hz), 7.72 (d, $J = 7.8$ Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 25.20 (d, $J = 53$ Hz), 25.23, 25.27, 25.53, 25.57, 25.73, 26.30, 26.50, 36.85 (d, $J = 64.6$ Hz), 124.31, 125.86, 144.65, 144.73. IR (KBr, cm^{-1}): 2924, 2850, 1564, 1489, 1444, 1388, 1276, 1242, 1165, 1008, 891, 856, 796, 573, 486. FAB-HRMS: 547.3331 M^+; $C_{31}H_{51}NO_3P_2$ requires M^+ 547.3344. *Anal.* Calc. for $C_{31}H_{51}NO_3P_2$: C, 67.98; H, 9.39; N, 2.56. Found: C, 66.16; H, 9.87; N, 2.50.

2.3. Synthesis of the complex

The complex was prepared by combination of $Er(NO_3)_3 \cdot 5H_2O$ (133 mg, 0.3 mmol) in acetone (6 ml) and **2** (164 mg, 0.3 mmol) in acetone (6 ml). The mixture was stirred (23 °C, 10 min) and filtered. The filtrate was slowly evaporated leaving pink crystals of the complex $Er(\mathbf{2})(NO_3)_3 \cdot (CH_3)_2CO$. IR (KBr, cm^{-1}): 2930, 2858, 1705, 1574, 1481, 1361, 1315, 1222, 1124, 1031, 893, 860, 817, 752, 638, 526, 495. *Anal.* Calc. for $C_{34}H_{57}ErN_4O_{13}P_2$: C, 42.48; H, 5.98; N, 5.83. Found: C, 42.36; H, 5.87; N, 5.87.

2.4. Crystallographic analysis

A pink platelet, $0.46 \times 0.36 \times 0.26$ mm was sealed in a glass capillary and data collected at 20 °C on a Siemens R3m/V diffractometer equipped with a graphite monochromator and using Mo Kα radiation ($\lambda = 0.71073$ Å). Data were collected in the omega scan mode with $\theta = 1.60$–25.00 [28]. A small semi-empirical adsorption correction based on psi scans was applied [29]. The structure was solved by direct methods using SHELX-97 [30]. The refinement was well behaved except that disorder appeared in one cyclohexyl group [C(28), C(31)

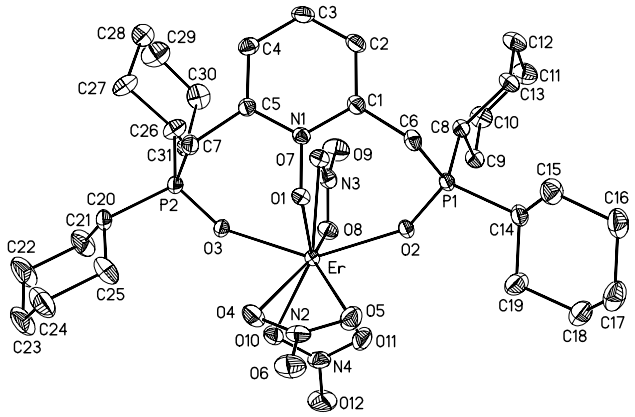

Fig. 1. Molecular structure and atom labelling scheme for Er(**2**)$(NO_3)_3 \cdot (CH_3)_2CO$ (acetone molecule of crystallization and hydrogen atoms omitted for clarity).

76.9%; C(28′), C(31′) 23.1%] on P(2) and in a methyl group in an acetone molecule of crystallization [C(33) 50%, C(33′) 50%]. These atoms were refined with the indicated occupancies and all ordered non-hydrogen atoms were refined anisotropically with H-atoms fixed in idealized positions (riding model) and $U_{iso} = 1.2$–$1.5U_{equiv.}$ of the parent atom. Atom labelling is shown in Fig. 1.

Crystallographic data: empirical formula $C_{34}H_{57}ErN_4O_{13}P_2$, monoclinic space group P_1/c, $a = 13.144(1)$ Å, $b = 17.125(1)$ Å, $c = 19.202(3)$ Å, $\beta = 99.96(1)°$, $V = 4257.1(8)$ Å^3, $Z = 4$, $D_{calc} = 1.496$ g cm^{-3}, $\mu = 2.109$ mm^{-1}, $F(000)$ 1964, 15390 reflections collected, 7509 independent reflections ($R_{int} = 0.0277$), 484 parameters; $R_1(F)[I > 2\sigma(I)] = 0.0278$, $wR_2(F^2) = 0.0642$, where $w^{-1} = [\sigma(F)^2 + gF^2]$, $\Delta\rho_{max} = 0.473$ e Å^{-3}, $\Delta\rho_{min} = -0.777$ e Å^{-3}.

2.5. Molecular modeling

Molecular mechanics calculations were carried out using the MM3 program [31–33], modified to support POS metal atom types [34,35]. Conformational searches of the free ligands, and the complexes $[M(L)(NO_3)_3]$ and $[M(L)_2(NO_3)]^{2+}$ were performed using the Saunders' stochastic search algorithm [36] as implemented in MM3. In all calculations, the dielectric constant was set to 4.0 to approximate the influence of a non-polar organic environment. The input files required to repeat these calculations, including the initial coordinates for all structures and the metal-dependent parameter set, are available as supplementary material.

3. Results and discussion

Our prior ligand design and synthesis work revealed that phosphinomethylpyridine *N*,*P*-oxides act as excellent ligands toward strongly polarizing Ln(III) and Pu(IV) ions [17–23]. In particular, it was found that the specific derivative bis[(diphenylphosphino)methyl] pyridine *N*,*P*,*P*′-trioxide, **NOPOPO** (R = Ph) forms 1:1 and 2:1 L/metal complexes and X-ray crystallographic studies indicate that the ligand binds in a tridentate fashion in both complex classes in the solid state [17–23]. The **NOPOPO** ligand with R = Ph is soluble in $CHCl_3$ and initial solvent extraction analyses showed that these solutions extract Ln(III) and An(III) ions from strongly acidic HNO_3 [24] and HCl [25] solutions. The resulting organic phases undergo facile back-extraction when exposed to weakly acidic aqueous solutions. However, this promising performance for trivalent f-element ion partitioning was negated by the limited solubility of the specific ligand in aromatic or aliphatic organic solvents. As a result, considerable effort has been given to the development of reliable and convenient syntheses of **NOPOPO** derivatives having improved solution properties. Recently, we reported syntheses for several aliphatic derivatives, **NOPOPO** R = *n*-alkyl, and mixed aromatic-aliphatic derivatives, **NOPOPO** R = Ph, *n*-alkyl [22]. These ligands have greatly improved solvation properties in hydrocarbon solvents. Furthermore, the derivative with R = 2-ethylhexyl has good solubility in alkanes. A thorough study of the extraction performance in *n*-dodecane has been completed with $Eu(NO_3)_3$ and $Am(NO_3)_3$ [27]. The results from these studies have stimulated new questions regarding the nature of the chelate interaction with Ln(III) and An(III) ions and in particular the participation of the *N*-oxide group in ligand binding. As a result, it became of interest to obtain a set of ligands with R = Ph, *n*-octyl, 2-EtHx, *n*-hexyl and *c*-hexyl for comparative structural and spectroscopic studies. The *c*-hexyl derivative is particularly interesting since the linear and branched chain aliphatic substituted ligands are oils or waxy solids and none form crystalline complexes that can be structurally compared against the complexes containing aromatic substituents.

The intermediate bis[(dicyclohexyl)phosphinomethyl]pyridine *P*,*P*′-dioxide (**1**) was prepared in good yield by combination of bis(chloromethyl)pyridine and the phosphino Grignard reagent (*c*-hexyl)$_2$P(O)MgCl. The compound shows a single ^{31}P NMR resonance at δ 50.1 which is slightly downfield of the resonances for $[(n\text{-hexyl})_2P(O)CH_2]_2C_5H_3N$ and $[(n\text{-octyl})_2P(O)CH_2]_2C_5H_3N$, δ 47.8 and 47.3, respectively [22]. The compound also shows a doublet in the $^{13}C\{^1H\}$ NMR spectrum, δ 34.80, $J_{PC} = 52.6$ Hz, that is diagnostic of the methylene carbon atoms between the phosphorous atoms and the 2,6-carbon atoms of the pyridine ring. The cyclohexyl ring carbon atoms bonded to the phosphorous atoms display a doublet resonance, δ 36.09, $J_{PC} = 63.9$ Hz, slightly downfield of the exo methylene groups. Compound **1** displays a characteristic strong

absorption in the IR spectrum at 1174 cm^{-1} that is tentatively assigned to the ν_{PO} stretching frequency. Similar IR frequencies are observed for $[(n\text{-hexyl})_2P(O)CH_2]_2C_5H_3N$ and $[(n\text{-octyl})_2P(O)CH_2]_2C_5H_3N$ at 1157 and 1165 cm^{-1}, respectively [22]. No absorption is seen in the region 1260–1240 cm^{-1} typically associated with the ν_{NO} stretching frequency.

Subsequent oxidation of **1** with 3-chloroperoxybenzoic acid gave **2** with greater than 95% yield. Column chromatography was required to remove residual impurities that include **1**. Some loss during separation resulted in isolation of **2** as a white solid in 85% yield. Compound **2** is analytically pure and it displays a parent ion in the FAB-MS. It shows a single resonance in the ^{31}P NMR spectrum, δ 51.2, shifted slightly downfield from the pyridine compound **1**. This downfield shift upon *N*-oxidation is typical [17,18,22]. The $^{13}C\{^1H\}$ NMR spectrum displays a doublet, δ 36.85, $J_{PC} = 64.6$ Hz, that is assigned to the cyclohexyl ring carbon atom bonded to the phosphorous atom. Based on our prior observations, it is expected that upon *N*-oxidation of the pyridine ring, the exo methylene carbon atom resonance would be shifted upfield by 7–10 ppm. For compound **2** only the upfield member of the doublet is clearly resolved with the downfield member being obscured by cyclohexyl ring CH_2 group resonances. The resonance for the exo-CH_2 group is estimated to fall at 25.2 ppm. The IR spectrum of **2** displays a strong absorption at 1165 cm^{-1} which is assigned to ν_{PO} and a second strong absorption at 1242 cm^{-1} that is tentatively assigned to ν_{NO} based upon the assignments made in our earlier reports [17,18,22]. Compound **2** has good solubility in $CHCl_3$ (>0.5 M), useful solubility in benzene (3.3×10^{-2} M), toluene (1.5×10^{-2} M), xylenes (2.2×10^{-2} M) and low solubility in hexane (3.6×10^{-4} M).

From our prior work it is known that $[Ph_2P(O)CH_2]_2C_5H_3NO$ readily forms 1:1 and 2:1 L/M complexes with Ln(III) nitrates [17,18] and chlorides [19] and in each case this **NOPOPO** derivative is bonded to the central Ln(III) ion in a tridentate fashion in the solid state. Tridentate chelate structures were also found for the 1:1 complex $\{[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO\}Er(NO_3)_3$ and the 2:1 complex $\{[Tol_2P(O)CH_2]_2C_5H_3NO\}_2Er(NO_3)_3$ [22]. An interesting variation appeared in the latter case where all three nitrate ions are displaced to the outer coordination sphere and the oxygen atoms of two water molecules appear in the eight coordinate inner sphere. In the case of ligand **2**, it was considered that the large steric volume of the cyclohexyl substituents might inhibit the reorganization of the ligand and therefore lead to bidentate and/or perhaps bridging ligand/metal coordination.

The examination of 1:1 and 2:1 L/M combinations of **2** with $Er(NO_3)_3$ resulted in the isolation of only the 1:1 complex as a crystalline solid. The 2:1 complex may form, but it was not isolated. The 1:1 complex gives strong IR adsorptions at 1222 and 1124 cm^{-1} that are tentatively assigned to coordinated ν_{NO} and ν_{PO} frequencies based upon earlier assignments. The determination of the molecular structure of the complex confirms the 1:1 L/M stoichiometry and the tridentate chelation mode for **2**. A view of the molecule is shown in Fig. 1. The Er(III) is nine coordinate with inner sphere coordination positions occupied by the oxygen atoms from three bidentate nitrate anions and three oxygen donor atoms from ligand **2**. In this regard, the structure is very similar to the structure of $\{[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO\}Er(NO_3)_3$ [22]. However, there are interesting differences. The Er(**2**) complex has two Er–O(P) bond lengths, Er–O(2) 2.249(2) Å and Er–O(3) 2.253(2) Å, that are shorter than the related bond lengths in $\{[(Ph)(Bz)P(O)CH_2C_5H_3NO\}Er(NO_3)_3$ (2.280(7) and 2.281(6) Å), while the Er–O(N) bond length, Er–O(1) 2.318(2) Å, is longer than that in $\{[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO\}Er(NO_3)_3$ (2.278(7) Å). The Er–O bond shortening involving the P=O donor groups in the Er(**2**) fragment may be rationalized by the expected stronger donor strength of the phosphoryl groups, $R_2P(O)$–, containing two alkyl substituents. The resulting stronger, shorter Er–O(P) interactions may result in weakening and concomitant lengthening of the Er–O(N) donor interaction, either through electronic effects or chelate ring strain influences (see Table 1).

In our previous reports on **NOPOPO** ligand/metal complexes, it has proven interesting to evaluate variations in the triangular ligand "footprint" defined by the non-bonded O(P)···O(N)···O(P) distances of the tridentate coordinated **NOPOPO** ligands. Typically, in 1:1 complexes, the footprint approximates an isosceles triangle with nearly equivalent O(P)···O(N) edge distances (~2.86–3.04 Å) and a longer O(P)···O(P) edge distance (~3.1–3.4 Å) with the O(P)···O(P) edge contracting or expanding the most to meet the ionic radius demands of the metal cation. For example, the dimensions of the footprint triangles in $[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO$ $Nd(NO_3)_3$ are O(P)···O(N) 2.991(4) Å, O(P)···O(N) 3.040(4) Å, O(P)···O(P) 3.389(4) Å and those in

Table 1
Selected bond lengths (Å)

Er–O(P)		Er–O(N)	
Er–O(2)	2.249(2)	Er–O(1)	2.318(2)
Er–O(3)	2.253(2)		
$Er–O(N)_{nitrate}$			
Er–O(4)	2.435(3)	Er–O(10)	2.428(2)
Er–O(5)	2.477(3)	Er–O(11)	2.418(3)
Er–O(7)	2.531(2)		
Er–O(8)	2.410(3)		
P=O		N–O	
P(1)–O(2)	1.506(2)	N(1)–O(1)	1.330(3)
P(2)–O(3)	1.503(2)		

$\{[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO\}Er(NO_3)_3$, containing the smaller Er(III) cation, are O(P)···O(N) 2.900(7) Å, O(P)···O(N) 2.961(7) Å, O(P)···O(P) 3.239(8) Å [22]. However, in the complex Er(**2**)$(NO_3)_3$ the footprint triangle is enlarged as indicated by the non-bonded distances O(1)···O(2) 2.993(3) Å, O(1)···O(3) 3.035(3) Å and O(2)···O(3) 4.287(3) Å. The internal bond angle at O(1) is also much more open (90.7°) than has been observed in previous examples (67°–69°). These footprint modifications probably result from the shorter, tighter Er–O(P) coordinate bond interactions in the Er(**2**) fragment, although increased steric demands of the two cyclohexyl groups relative to phenyl and benzyl groups may also contribute. The P=O and N–O bond lengths in Er(**2**)$(NO_3)_3$, P(1)–O(2) 1.506(2) Å, P(2)–O(3) 1.503 Å, N(1)–O(1) 1.330(3) Å are closely comparable with the related distances in $\{[(Ph)(Bz)P(O)CH_2]_2C_5H_3NO\}Er(NO_3)_3$ 1.500(7), 1.498(6) and 1.352(10) Å; therefore, they do not provide additional information about the relative binding strengths of the ligands.

The three inner sphere nitrate anions are each bonded to the Er(III) ion in a bidentate fashion. Those associated with N(1) and N(3) are held in a relatively symmetric fashion with average Er–O (N) distances, 2.456(3) and 2.423(3) Å, while the third nitrate is bonded in a more asymmetric manner, Er–O(7) 2.531(2) Å and Er–O(8) 2.410(3) Å. Such bonding variations for nitrate ions have been observed in related complexes [22]. Lastly, the unit cell contains one slightly disordered acetone molecule per molecular unit and that molecule is not depicted in Fig. 1. It is present as a solvent of crystallization as indicated by the closest approach distances between the carbonyl oxygen atom and near neighbor Er(III) ions, Er···O(13): 6.99, 7.42 and 7.57 Å.

Previous extraction analyses of Ln(III) and An(III) ions from aqueous HNO_3 and HCl solutions by NOPOPO (R = Ph) in $CHCl_3$ solutions and by NOPOPO (R = 2-ethylhexyl) in *n*-dodecane solution indicated that 2:1 ligand/metal complexes form in solution [27]. In studies of the coordination chemistry of NOPOPO ligands with Ln(III) ions it has been possible with some ligands to isolate 2:1 complexes, but in many cases, as observed here with ligand **2**, only the 1:1 complexes are isolated. Whether this is a result of steric, electronic or solvation effects or a combination of factors is not clear.

In the present case, molecular mechanics calculations have been performed to examine the steric differences between the two ligands L = NOPOPO with R = Ph and cyclohexyl (**2**). To quantify the intrinsic steric differences the change in steric energy, ΔU, was calculated for the following reaction:

$$[M(L)(NO_3)_3] + L \rightarrow [M(L)_2(NO_3)]^{2+} + 2NO_3^-$$

where $\Delta U = U(1{:}1)\text{complex} + U(\text{ligand}) - U(2{:}1\ \text{complex}) - 2U(\text{nitrate})$. The computed strain energy differences, $\Delta U = 14.0$ kcal/mol for R = Ph and $\Delta U = 19.4$ kcal/mol for R = cyclohexyl reveal that while significant strain develops with both ligands, the cyclohexyl case is 5.4 kcal/mol less favorable. These ΔU values reflect both conformational reorganization of the ligand and the additional steric crowding present in the 2:1 complexes. The lowest energy resting states of the free ligands have the P = O bond vectors rotated away from the region occupied by the N–O bond vector and reorganization to achieve the observed tridentate metal binding orientations is endoergic and accounts for the bulk of the ΔU values: R = Ph, 8.3 kcal/mol; R = cyclohexyl, 10.1 kcal/mol.

From the foregoing analysis, steric differences alone predict that the 2:1 complex with the cyclohexyl substituents will be 10^4 times less stable than the 2:1 complex with the phenyl substituents at room temperature. However, as mentioned earlier, the unfavorable steric effects may be offset by electronic effects that would tend to favor formation of stronger ligand/metal interactions

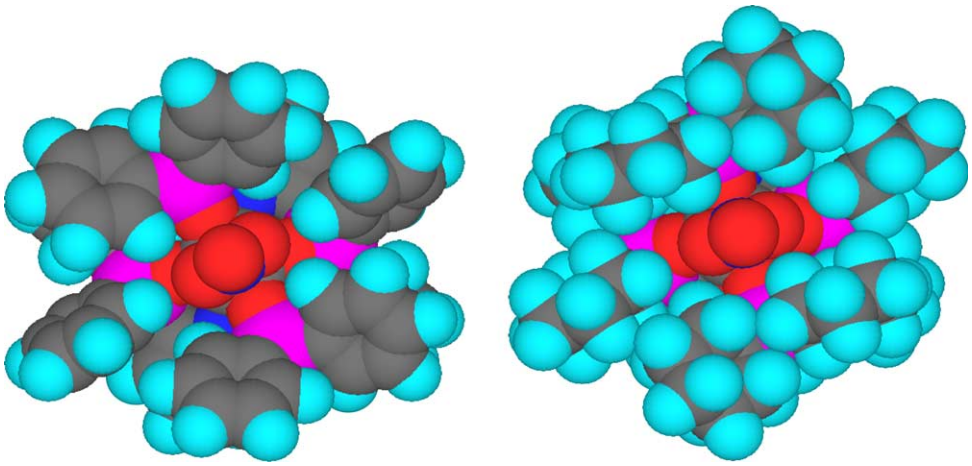

Fig. 2. Computed, energy minimized structures for $Er(NOPOPO)_2(NO_3)^{2+}$ complexes: R = Ph (left); R = cyclohexyl (right).

when cyclohexane substituents are present. In addition, as shown in Fig. 2, in the 2:1 complexes the cyclohexyl substituents more completely engulf the Er(III) cation in a lipophilic environment, which could lead to enhanced solubility in organic phases. Thus, it is possible that NOPOPO with R = cyclohexyl will produce a favorable extraction thermodynamic performance. We plan to explore this point in future solvent extraction studies.

4. Supplementary material

Crystallographic data for the complex have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 221899. Copies of this material may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www.http://www.ccdc.cam.ac.uk). Structure input files and parameter file used for the MM3 calculations are available on request (ben.hay@pnl.gov).

Abstract

The reaction of cyclohexane-1,4-diol with chlorodiphenylphosphine affords bis(phosphinite), $Ph_2PO(C_6H_{10})OPPh_2$ (**1**) in good yield. The bis(phosphinite) (**1**) reacts with H_2O_2, elemental sulfur or selenium to give the corresponding dichalcogenide; the structures of the disulfide (**3**) and diselenide (**4**) derivatives are confirmed by X-ray crystal structure analysis. The reaction of **1** with phosphoryl azide, $N_3P(O)(OPh)_2$ gives the phosphinimine derivative, $(PhO)_2(O)PN{=}PPh_2O(C_6H_{10})OPh_2P{=}NP(O)(OPh)_2$ (**5**) in quantitative yield. Treatment of the ligand **1** with $CpRu(PPh_3)_2Cl$ results in a bis(phosphinite) bridged dinuclear complex, $[CpRuCl(PPh_3)]_2(\mu\text{-}PPh_2O(C_6H_{10})OPPh_2)$ (**7**) whereas the reaction of **1** with Pd(II) and Pt(II) derivatives afford *cis*-chelate complexes, $[MCl_2\{Ph_2PO(C_6H_{10})OPPh_2\}]$ (M = Pd, **8**; Pt, **9**). The reaction of **1** with $Mo(CO)_6$ in the presence of $TMNO \cdot 2H_2O$ does not give the expected *cis*-$[Mo(CO)_4\{Ph_2PO(C_6H_{10})OPPh_2\}]$; instead a cubane-shaped tetranuclear molybdenum(V) complex, $[Mo_4O_4(\mu^3\text{-}O)_4(\mu\text{-}O_2PPh_2)_4]$ (**6**) was obtained due to water assisted cleavage of P–O bonds.

Keywords: Bis(phosphinite); Cyclohexane-1,4-diol; Disulfide and diselenide; Crystal structure

1. Introduction

Synthesis of new chelating bis(phosphines) to stabilize transition metals in low valent states is considered to be a most challenging task in view of their potential utility in a variety of metal-mediated organic transformations [1]. To date, a number of such systems with a variety of backbone frameworks have been synthesized and their transition metal chemistry has been explored [2], whereas similar studies on analogous bis(phosphinites) are less extensive, although some of them have proved to be efficient catalysts [3]. Also, the number of bis(phosphinites) having cyclic systems as bridging units are also limited [4]. As a part of our interest [5] in designing new ligand systems with different spacers to control the electronic attributes at the phosphorus centers and to explore their coordination chemistry, we report here the synthesis of a new bis(phosphinite), $Ph_2PO(C_6H_{10})OPPh_2$ (**1**) derived from 1,4-cyclohexanediol, and its chalcogen and imine derivatives and transition metal complexes. The disulfide and diselenide derivatives are structurally characterized.

2. Experimental

All manipulations were performed under an atmosphere of dry nitrogen or argon using standard Schlenk

and vacuum line techniques. Solvents were dried and distilled by standard methods prior to use. The ^{1}H and ^{31}P NMR spectra were recorded on a VXR 300 S spectrometer operating at the appropriate frequencies using tetramethylsilane and 85% H_3PO_4 as internal and external references, respectively. Positive shifts lie downfield of the standard in all cases. Microanalyses were performed on a Carlo Erba Model 1112 elemental analyzer.

2.1. Preparation of $Ph_2PO(C_6H_{10})OPPh_2$ (1)

A solution of PPh_2Cl (1.23 g, 5.57 mmol) in dry toluene (20 ml) was added, with stirring, to a mixture of 1,4-cyclohexanediol (0.32 g, 2.73 mmol) and triethylamine (0.56 g, 5.57 mmol) in toluene (80 ml) at 0 °C. After completion of the addition, the reaction mixture was refluxed under nitrogen with stirring for 24 h. The solution was cooled to 25 °C and Et_3NHCl was filtered off. The filtrate was passed through activated silica gel and then passed through celite and the solvent was evaporated under reduced pressure to give a white residue. An analytically pure sample of **1** was obtained by recrystallizing in a 4:1 mixture of CH_2Cl_2–hexane. Yield: 78% (1.02 g), m.p. 120–122 °C. *Anal*. Calc. for $C_{30}H_{30}O_2P_2$: C, 74.37; H, 6.24. Found: C, 74.21; H, 6.18%. ^{1}H NMR ($CDCl_3$): δ 7.27–8.15 (20H, m, phenyl), 1.62–2.24 (10H, m, cyclohexyl). ^{31}P NMR (300 MHz, $CDCl_3$): δ 106.4 (s).

2.2. Preparation of $Ph_2(O)PO(C_6H_{10})OP(O)Ph_2$ (2)

To a solution of **1** (0.5 g, 1.03 mmol) in acetonitrile was added 1 ml of 10% H_2O_2 and the mixture was stirred for 20 min at 25 °C. On cooling the solution to 0 °C, analytically pure crystalline **2** was obtained in quantitative yield.

A dichloromethane solution **1** on exposure to air also results in the formation of the white crystalline product **2** in quantitative yield. M.p.: 160–162 °C (dec.). *Anal*. Calc. for $C_{30}H_{30}O_4P_2$: C, 69.76; H, 5.85. Found: C, 70.01; H, 5.87%. ^{1}H NMR ($CDCl_3$): δ 7.36–8.16 (20H, m, phenyl), 1.58–2.15 (10H, m, cyclohexyl). ^{31}P NMR (300 MHz, $CDCl_3$): δ 20.9 (s).

2.3. Preparation of $Ph_2(S)PO(C_6H_{10})OP(S)Ph_2$ (3)

A mixture of compound **1** (0.5 g, 1.03 mmol) and sulfur (0.066 g, 2.06 mmol) in toluene (50 ml) was refluxed under nitrogen with stirring for 6 h. The solution was cooled to 25 °C, concentrated to 5 ml under vacuum and 3 ml of hexane was added. Keeping this solution at 0 °C gave the analytically pure sample of **3** in 92% (0.52 g) yield. M.p.: 178–180 °C (dec.). *Anal*. Calc. for $C_{30}H_{30}O_2S_2P_2$: C, 65.67; H, 5.51; S, 11.69. Found: C, 65.47; H, 5.50; S, 11.32%. ^{1}H NMR ($CDCl_3$): δ 7.34–8.16 (20H, m, phenyl), 1.62–2.28 (10H, m, cyclohexyl). ^{31}P NMR (300 MHz, $CDCl_3$): δ 79.4 (s).

2.4. Preparation of $Ph_2(Se)PO(C_6H_{10})OP(Se)Ph_2$ (4)

A mixture of compound **1** (0.5 g, 1.03 mmol) and selenium powder (0.162 g, 2.06 mmol) in toluene (20 ml) was refluxed under nitrogen for 6 h. The solution was then cooled to 25 °C and passed through celite and the solvent was removed under reduced pressure to give a white residue. The analytically pure product of **4** was obtained by recrystallizing in a mixture of CH_2Cl_2–hexane (4:1) at 0 °C. Yield: 80% (0.53 g). M.p.: 254–256 °C. *Anal*. Calc. for $C_{30}H_{30}O_2Se_2P_2$: C, 56.08; H, 4.71. Found: C, 56.07; H, 4.56%. ^{1}H NMR ($CDCl_3$): δ 7.27–8.15 (20H, m, phenyl), 1.62–2.24 (10H, m, cyclohexyl). ^{31}P NMR (300 MHz, $CDCl_3$): δ 82.4 (s); $^{1}J_{PSe}$ = 794.6 Hz.

2.5. Preparation of $(PhO)_2(O)PN{=}PPh_2O(C_6H_{10})OPh_2P{=}NP(O)(OPh)_2$ (5)

A solution of $(PhO)_2(O)PN_3$ (0.18 g, 0.65 mmol) in CH_2Cl_2 (6 ml) was added dropwise to a solution of **1** (0.15 g, 0.31 mmol), also dissolved in CH_2Cl_2 (10 ml) at −78 °C. After the addition was complete the reaction mixture was slowly warmed to room temperature and stirred for 3 h. The solution was then concentrated to 8 ml, 2–3 ml of *n*-hexane was added, and the solution was cooled to 0 °C whereupon **5** precipitated as a analytically pure white crystalline solid. Yield: 93% (0.23 g). M.p.: 148–150 °C (dec.). *Anal*. Calc. for $C_{54}H_{50}N_2O_8P_4 \cdot 0.5CH_2Cl_2$: C, 64.09; H, 5.03; N, 2.74. Found: C, 63.93; H, 4.97; N, 2.63%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 6.78–7.72 (m, 40H, Ph), 1.82 (d, 8H, C_2H_4), 1.51 (m, 2H, CH); $^{31}P\{^{31}H\}$ NMR (300 MHz, $CDCl_3$): δ 20.8 (2P, d, $^{2}J_{PP}$ = 36 Hz), −12.6 (2P, d). MS (FAB): 979 ($M^+ + 1$).

2.6. Preparation of $[Mo_4O_4(\mu^3\text{-}O)_4(\mu\text{-}Ph_2PO_2)_4]$ (6)

To a solution of **1** (0.16 g, 0.34 mmol) and $Mo(CO)_6$ (0.10 g, 0.33 mmol) in CH_2Cl_2 (10 ml) was added a solution of $Me_3NO \cdot 2H_2O$ (0.04 g, 0.36 mmol) in methanol, and the reaction mixture was stirred at room temperature for 18 h, filtered through celite and the solvent was evaporated under reduced pressure. The solid residue obtained was dissolved in a 1:1 diethylether/CH_2Cl_2 mixture. Cooling this solution to 0 °C gave **6** as red crystals. Yield: 85% (0.1 g). M.p.: 168–170 °C. *Anal*. Calc. for $C_{48}H_{40}O_{16}P_4Mo_4 \cdot CH_2Cl_2$: C, 40.16; H, 2.88. Found: C, 40.27; H, 2.79%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.26–7.87 (m, 40H, Ph), 5.30 (s, 2H, CH_2Cl_2); $^{31}P\{^{1}H\}$ NMR (300 MHz, $CDCl_3$): δ 44.2 (s).

2.7. Preparation of $[C_5H_5RuCl(PPh_3)]_2(PPh_2O(C_6H_{10})OPPh_2)$ (7)

To a solution of **1** (0.03 g, 0.07 mmol) in CH_2Cl_2 (10 ml) was added, dropwise, a solution of $CpRuCl(PPh_3)_2$ (0.05 g, 0.07 mmol) also in CH_2Cl_2 (10 ml) at room temperature. The mixture was stirred for 8 h before it was concentrated to 5 ml, and 3 ml of petroleum ether was added. Cooling this solution to 0 °C gave **7** as yellow crystals. Yield: 82% (0.08 g). M.p.: 178–182 °C. *Anal.* Calc. for $C_{76}H_{70}O_2P_4Ru_2Cl_2 \cdot CH_2Cl_2$: C, 61.76; H, 4.84. Found: C, 61.51; H, 4.77%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.13–8.15 (m, 20H, Ph), 1.91 (d, 8H, C_2H_4), 1.31 (t, 2H, CH); $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 138.1 (2P, d, $^2J_{PP}$ = 58.6 Hz), 43.3 (2P, d).

2.8. Preparation of $[PdCl_2(Ph_2(O)PO(C_6H_{10})OP(O)Ph_2)]$ (8)

To a solution of $[Pd(NCCH_3)_2Cl_2]$ (0.04 g, 0.23 mmol) (generated in situ by refluxing $PdCl_2$ in CH_3CN for 4 h) in CH_3CN (8 ml) was added, dropwise, a solution of **1** (0.12 g, 0.25 mmol) also in CH_3CN (4 ml), and the reaction mixture was stirred at room temperature for 3 h. The solution was concentrated to 3 ml, and 1 ml of petroleum ether was added. Cooling this solution to 0 °C gave **8** as yellow crystals. Yield: 90.5% (0.25 g). M.p.: 174–176 °C. *Anal.* Calc. for $C_{30}H_{30}Cl_2O_2P_2Pd$: C, 54.4; H, 4.5. Found: C, 54.6; H, 4.5%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.24–7.58 (m, 20H, Ph), 1.73 (d, 8H, C_2H_4), 1.33 (m, 2H, CH). $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 79.4 (s).

2.9. Preparation of $[PtCl_2(Ph_2(O)PO(C_6H_{10})OP(O)Ph_2)]$ (9)

To a solution of [Pt(COD)Cl_2] (0.03 g, 0.08 mmol) in CH_2Cl_2 (5 ml), a solution of **1** (0.02 g, 0.08 mmol) also in CH_2Cl_2 (8 ml) was added dropwise and the reaction mixture was stirred at room temperature for 4 h. The solution was concentrated to 5 ml, and 2 ml of petroleum ether was added. Cooling this solution to 0 °C gave **9** as a white crystalline material. Yield: 98% (0.04 g). M.p.: 158–160 °C. *Anal.* Calc. for $C_{30}H_{30}Cl_2O_2P_2Pt$: C, 48.06; H, 4.03. Found: C, 47.92; H, 3.9%. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.26–7.64 (m, 20H, Ph), 1.75 (d, 8H, C_2H_4), 1.35 (m, 2H, CH); $^{31}P\{^1H\}$ NMR (300 MHz, $CDCl_3$): δ 76.04 (s), $^1J_{PPt}$ = 4132 Hz.

2.10. Structure determination

Colorless crystals of **3** and **4**, crystallized from CH_2Cl_2 at 0 °C, were mounted on Pyrex filaments with epoxy resin. Unit cell dimensions were determined from 25 well-centered reflections. Intensity data were collected with a Nonium MACH3 diffractometer using graphite-monochromated Mo Kα (0.71073 Å) radiation. Periodic monitoring of check reflections showed stability of the intensity data. The structures were solved by direct methods [6] and refined using SHELXS-97 software [7]. The non-hydrogen atoms were geometrically fixed and allowed to refine using a riding model. Details of the data collections and refinements are summarized in Table 1.

3. Results and discussion

The reaction of cyclohexane-1,4-diol with two equivalents of chlorodiphenylphosphine in the presence of triethylamine in toluene affords bis(phosphinite), $Ph_2PO(C_6H_{10})OPPh_2$ (**1**) in good yield. The $^{31}P\{^1H\}$ NMR spectrum of **1** shows a single resonance at 106.4 ppm indicating the symmetric nature of the molecule. Treatment of **1** with 10% H_2O_2 solution in CH_3CN affords the dioxide derivative **2** in quantitative yield. The diethyl ether or acetonitrile solution of **1** on exposure to air also gives the same dioxide after 2–3 days in quantitative yield. The ^{31}P NMR spectrum of **2** shows a singlet at 20.9 ppm, which is considerably deshielded when compared to the parent ligand **1** with a shift of 85.5 ppm. The reaction of **1** with two equivalents of sulfur or selenium in toluene under refluxing conditions affords the corresponding disulfide (**3**) and diselenide (**4**) in 70–80% yield. The disulfide can also be prepared by reacting the chlorodiphenylphosphinesulfide with cyclohexane-1,4-diol. Attempts to synthesize the monochalcogenides have been unsuccessful. The reaction of **1** with one mole

of elemental sulfur or selenium did not give the expected monochalcogenide derivatives, instead dichalcogenides were obtained in low yields and half the original amount of bis(phosphinite) was left unreacted. The physical and analytical data for the compounds are summarized in Section 2 (see Scheme 1).

The ^{31}P NMR spectrum of **3** and **4** show single resonances at 79.4 and 82.4 ppm, respectively. The selenide derivative **4** shows a $^{1}J_{PSe}$ coupling of 795 Hz, characteristic of tetracoordinated pentavalent phosphine selenides [4a,5e,8]. ^{1}H NMR spectra of all the compounds are consistent with the structural compositions. Further, the structures of $Ph_2P(S)OC_6H_{10}OP(S)PPh_2$ (**3**) and $Ph_2P(Se)OC_6H_{10}OP(Se)PPh_2$ (**4**) were confirmed by single crystal X-ray analysis.

The solid-state structures of disulfide, $Ph_2P(S)O(C_6H_{10})OP(S)PPh_2$ (**3**) and diselenide $Ph_2P(Se)O(C_6H_{10})OP(Se)PPh_2$ (**4**) were determined by single-crystal X-ray diffraction studies. The perspective views of the molecular structures of compounds **3** and **4** are shown in Figs. 1 and 2, respectively. Crystal data and details of the structure determinations are given in Table 1 while selected bond lengths and inter-bond angles appear in Table 2.

The phosphorus centers are in typical tetrahedral environments. The P=S bond length of 1.928(1) Å is shorter than those observed in amine derivatives, $Ph_2P(S)N(Ph)C_2H_4N(Ph)P(S)PPh_2$ (1.951(1) Å) [8b] and $Ph_2P(S)N(C_4H_8)NP(S)PPh_2$ [8c] (1.943(1) Å). Interestingly, the P=Se distance in **4** is 2.089(3) Å which is longer than those observed in aminophosphonite, $PhN\{P(Se)(OC_6H_4OMe\text{-}o)_2\}_2$ (2.058(6) Å) or bisphosphinite, $Ph_2P(Se)\{(-OC_{10}H_6)(\mu\text{-}CH_2)(C_{10}H_6O-)\}P(Se)Ph_2$ (2.072(1) Å). However, the P=Se distance in **4** is quite comparable with those found in $Ph_2P(Se)NHP(Se)Ph_2$ (2.085(1) Å). The chalcogen

Scheme 2.

atoms in both **3** and **4** are in an approximately *syn*-disposition. The P–O bond distances in **3** and **4** are 1.591(2) and 1.596(3) Å whereas the average P–C bond distances are 1.806(2) Å.

The reaction of **1** with $Mo(CO)_6$ in the presence of $Me_3NO \cdot 2H_2O$ in THF resulted in the formation of a cubane shaped tetramolybdenum(V)oxo complex (**6**), containing four bridging $Ph_2PO_2^-$ units instead of the expected tetracarbonylmolybdenum(0) complex, [$Mo(CO)_4(Ph_2POC_6H_{10}OPPh_2)$] as shown in Scheme 2. It is presumed that during the reaction, the P–O bonds of the ligand **1** undergo hydrolytic cleavage to give Ph_2POH moieties which are readily oxidized to give $Ph_2P(O)OH$. Thus, $Ph_2PO_2^-$ generated in situ readily oxidize Mo to its higher oxidation state and lead to the formation of the unexpected complex **6**. A similar reaction of $Mo(CO)_6$ with *N*,*N*′-bis(diphenylphosphino)-2,6-diaminopyridine, $Ph_2PNH(NC_5H_5)NHPPh_2$ led to the isolation of [$Mo(CO)_3\{Ph_2PNH(NC_5H_5)NHPPh_2$-κP,κP,κN}] which on further aerial oxidation in tetramethylbenzene at 180 °C resulted in P–N bond rupture and formation of $[Mo_4\{(\mu^3\text{-}O)_4(\mu\text{-}Ph_2PO_2)_4\}_4]$. The $^{31}P\{^1H\}$ NMR of **6** shows a single resonance at 42 ppm. The structure of **6** was further confirmed by a single X-ray structure determination. The reaction of ligand **1** with $CpRuCl(PPh_3)_2$ in a 1:1 ratio in dichloromethane at room temperature for 48 h afforded diruthenium complex, $[CpRuCl(PPh_3)]_2(\mu\text{-}PPh_2O(C_6H_{10})OPPh_2)$ (**7**) with the ligand **1** acting as a bridging bidentate ligand as shown in Scheme 2. The $^{31}P\{^1H\}$ NMR spectrum of **7** shows two doublets at 44 and 138.1 ppm which are assigned, respectively, to PPh_3 and phosphinite centers. The $^2J_{PP}$ is 58.6 Hz. Treatment of $M(COD)Cl_2$ (M = Pd, Pt) with 1:1 molar proportions of the ligand **1** in dichloromethane afford the chelate complexes **8** and **9** in good yield. The $^{31}P\{^1H\}$ NMR spectra of **8** and **9** exhibit single resonances at 79.0 and 76.0 ppm ($^1J_{Pt-P} = 4137$ Hz), respectively. The chemical compositions of complexes **6**–**9** are established by element analyses and the proposed structures are consistent with their spectroscopic data.

4. Conclusions

Although, to date, several bisphosphinites are known, the number of bis(phosphinites) having cyclic systems as bridging units are limited. The cyclohexyl group in ligand **1** offers more flexibility for its coordination behavior as demonstrated in the case of Pd(II), Pt(II) and Ru(II) complexes. Interestingly, the reaction of **1** with $Mo(CO)_6$ in the presence of $TMNO \cdot 2H_2O$ gave a cubane-shaped tetramolybdenum(IV) complex containing four bridging $Ph_2PO_2^-$ units, through P–O bond cleavage. This method can be conveniently explored with various other metals to get unexpected but interesting metal oxide clusters which might find application in materials, heterogeneous catalysis and also in heterogenised homogeneous catalysis. The disulfide and diselenide derivatives may also find application in making silver and gold monolayers. Work in this direction is in progress in our laboratory.

Abstract

Three new M/Ag/S heterobimetallic compounds $[Et_4N]_2[(MS_4)Ag_8(SBu^t)_8]$ (**1a**, M = W; **1b**, M = Mo) and $\{[Et_4N][WOS_3Ag_2(S_2COEt)]\}_n$ (**2**) have been prepared from the reactions of $[MO_nS_{4-n}]^{2-}$ (M = W, Mo; n = 0–1) with $AgSBu^t$ or AgS_2COEt. Single crystal structural studies show that the compound **1a** contains a $[WS_4]^{2-}$ dianion encapsulated in a neutral octanuclear $(AgSBu^t)_8$ cage via weak Ag···S(WS_4) interactions. In compound **2**, butterfly WOS_3Ag_2 fragments are connected via bidentate bridging $[S_2COEt]^-$ ligands to give a chain polymeric anion. These compounds are fully characterized by IR, UV–vis and microanalyses. Compound **2** is the first W/Ag/S polymer with bidentate thiolato linkages.

1. Introduction

The syntheses and characterization of compounds containing thioanions of molybdenum (VI) or tungsten (VI), such as $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–2), have been widely studied due to their relevance to biological systems, interesting physicochemical properties and versatile structural types [1–8]. In particular, the study of compounds containing these multidentate chelating ligands with Ag(I) has continued to attract attention because of their high tendency to form Ag–S bonds [9–16]. A common synthetic strategy for the preparation of W(Mo)/Ag/S compounds is to employ neutral species AgX ($X = NO_3^-, Cl^-, Br^-, I^-, CN^-, SCN^-$) to react with $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–2), often using transition metal complexes, rare earth metal complexes or alkali metal complexes as cations. These reactions resulted in the formation of a large number of W(Mo)/Ag/S compounds, such as a zigzag chain with unequal steps: $[W_4Ag_4S_{16}\cdot 2Ca(DMSO)_6]_n$ [12], a loose helical chain: $[W_3Ag_3S_{12}\cdot Nd(DMSO)_8]_n$ [13], a single-stranded helical chain: $[W_3Ag_3S_{12}\cdot La(DMAC)(H_2O)_3\cdot(DMAC)_4]_n$ [14], a hanging ladder-like polymer chain: $[W_4Ag_6S_{16}\cdot Ca(DEAC)_6]_n$ [15] and an one-dimensional linear chain: $[WS_4Ag\cdot Li(DMF)_4]_n$ [16]. However, reactions employing AgSR or AgS_2COEt as a silver source to react with thiomolybdates or thiotungstates have not been reported.

Recently we have reported several W(Mo)/Cu/S heterobimetallic clusters prepared from the reactions between $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–1) and $CuSBu^t$ or

Cudtp (dtp = diethyldithiophosphate), such as $[Et_4N]_2[\{MOS_3\}_2Cu_4(\mu\text{-S-Bu}^t)_2]$ (double butterfly), $[Et_4N][\{MOS_3\}_2Cu_6(\mu\text{-S-Bu}^t)_3]$ (double incomplete cubane), $[Bu_4N][\{MOS_3\}_3Cu_9(\mu\text{-S-Bu}^t)_3(\mu_3\text{-S-Bu}^t)]$ (triple incomplete cubane) [17], $[Bu_4N]_2[\{MoOS_3\}_4Cu_{12}(dtp)_6]$ (closed double cubane) and $[Et_4N][\{WS_4Cu_4\}(dtp)_3]$ (1-D polymer) [18]. To expand our studies to the W(Mo)/Ag/S system, we have investigated the reactions of $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–1) with $AgSBu^t$ and AgS_2COEt. Herein we report three new compounds prepared from these reactions, namely, $[Et_4N]_2[(MS_4)Ag_8(SBu^t)_8]$ (**1a**, M = W; **1b**, M = Mo) and $[Et_4N][WOS_3Ag_2(S_2COEt)]_n$ (**2**).

2. Experimental

2.1. General procedures

All experiments were carried out in air. Starting materials $[Et_4N]_2[WS_4]$, $[Et_4N]_2[MoS_4]$ and $[Et_4N]_2[WOS_3]$ were prepared by published procedures [19]. Complex $AgSBu^t$ was synthesized by adding $AgNO_3$ to $HSBu^t$ in ethanol. Complex AgS_2COEt was synthesized by the reaction of $AgNO_3$ with potassium ethylxanthate in aqueous solution. Other chemicals were obtained from commercial sources and used without further purification.

2.2. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 750 FT-IR spectrophotometer as KBr pellets in the range 4000–400 cm^{-1}. Electronic spectra were recorded on a Lambda 35 spectrophotometer in MeCN solution between 600 and 200 nm. Elemental analyses were performed in the Elemental Analysis Laboratories at our institute.

2.3. Synthesis of $[Et_4N]_2[(WS_4)Ag_8(SBu^t)_8]$ (**1a**)

Complex $AgSBu^t$ (0.20 g, 1.0 mmol) was added to a DMF solution (5 mL) of $[Et_4N]_2[WS_4]$ (0.29 g, 0.5 mmol). After stirring at room temperature for 30 min, the resulting orange–red solution was filtered. The filtrate was allowed to slowly evaporate in an *i*-PrOH atmosphere to afford **1a** as red crystals. Yield: 54% (based on $AgSBu^t$). IR (KBr pellet, cm^{-1}): ν(W–S) 445 (s). UV–vis (MeCN) λ_{max}/nm (10^{-3} ε_{max}/M^{-1} cm^{-1}): 291(37.3), 407(16.2). *Anal.* Calc. for **1a**: C, 26.83; H, 5.25; N, 1.30. Found: C, 26.70; H, 5.02; N, 1.39%.

2.4. Synthesis of $[Et_4N]_2[(MoS_4)Ag_8(SBu^t)_8]$ (**1b**)

Dark crystals of **1b** were obtained in a 50% yield (based on $AgSBu^t$) by a similar way as for **1a** except $[Et_4N]_2[MoS_4]$ (0.24 g, 0.5 mmol) was used instead of $[Et_4N]_2[WS_4]$. IR (KBr pellet, cm^{-1}): ν(Mo–S) 458 (s). UV–vis (MeCN) λ_{max}/nm ($10^{-3}\varepsilon_{max}/M^{-1}$ cm^{-1}): 243(23.6), 324(22.4), 486(12.4). *Anal.* Calc. for **1b**: C, 27.97; H, 5.48; N, 1.36. Found: C, 27.70; H, 5.28; N, 1.51%.

2.5. Synthesis of $\{[Et_4N][WOS_3Ag_2(S_2COEt)]\}_n$ (**2**)

A solution of $[Et_4N]_2[WOS_3]$ (0.28 g, 0.5 mmol) and AgS_2COEt (0.23 g, 1.0 mmol) in 6 mL of DMF was stirred for 1 h. A small amount of black precipitate was removed by filtration and the filtrate was slowly evaporated in an *i*-PrOH atmosphere to give yellow crystals of **2** (yield 23%). IR (KBr pellet, cm^{-1}): ν(W–S_{br}) 455 (m), 435 (s), 417 (m), ν(W–O) 921 (vs). UV–vis (MeCN) λ_{max}/nm ($10^{-3}\varepsilon_{max}/M^{-1}$ cm^{-1}): 309(8.1), 353(sh)(4.1), 408(sh)(2.6). *Anal.* Calc. for compound **2**: C, 17.30; H, 3.28; N, 1.83. Found: C, 17.32; H, 3.09; N, 1.96%.

2.6. X-ray crystallography

Intensity data for the two compounds were collected at 293(2) K on a Rigaku Mercury CCD area-detector diffractometer with a graphite monochromator utilizing Mo Kα radiation (λ = 0.71073 Å). The structures were solved by direct methods using SHELXS-97 [20]. Anisotropic displacement parameters were refined for all non-hydrogen atoms. The organic hydrogen atoms were generated geometrically (C–H, 0.96 Å). The crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

The polymeric complex $AgSBu^t$ was not soluble in DMF but it dissolved rapidly in the presence of the tetrathiotungstate anion to form a cyclic octanuclear Ag compound **1a**. The ratio of $AgSBu^t$ to $[Et_4N]_2[WS_4]$ did not change the nature of the product. However, the reaction with 2 equiv. of $AgSBu^t$ gave a better yield of **1a**. The reaction between $[Et_4N]_2[MoS_4]$ and $AgSBu^t$ by the same method afforded $[Et_4N]_2[(MoS_4)Ag_8(SBu^t)_8]$ (**1b**), a Mo analogue of **1a**. The structure of **1b** was confirmed by IR, microanalyses and the X-ray diffraction study. The X-ray crystal data was not good enough and only a raw structure could be obtained. The reactions between $[W(Mo)S_4]^{2-}$ or $[W(Mo)OS_3]^{2-}$ and AgS_2COEt often gave rise to a large amount of Ag_2S precipitation or insoluble solids. However, a polymeric W/Ag/S cluster **2** was successfully isolated from the reaction between $[Et_4N]_2[WOS_3]^{2-}$ and AgS_2COEt in moderate yield under appropriate conditions.

3.2. Infrared and UV–vis spectra

The 400–520 cm^{-1} region of the IR spectra of heterothiometallic cluster compounds containing $[W(Mo)S_4]^{2-}$ moieties has proven to be valuable in studying their structural characteristics [1,21–23]. It has been observed that the ν(M–S) frequency decreases on increasing the number of coordinated hetero-metal atoms (M = W, Mo) [22–24]. The spectra of compounds **1a** and **1b** exhibit a single strong band at 445 and 458 cm^{-1}, which may be contributed to the ν(W = S) and ν(Mo = S) stretching vibrations, respectively. Comparing these values with the corresponding values for $[Et_4N]_2[WS_4]$ (458 cm^{-1}) and $[Et_4N]_2[MoS_4]$ (470 cm^{-1}) reveals some red shift to low frequencies, indicating weakening of the M = S bonds as a result of interactions with Ag atoms. The spectra of compound **2** exhibits a very strong band at 921 cm^{-1}, which is ascribed to the ν(W = O) vibrations, and the bands at 455, 435 and 417 cm^{-1} were due to the vibrations of ν(W-μ_2-S) and ν(W-μ_3-S), respectively [25].

It is apparent that the UV–vis spectra of the clusters are characterized by the three strong absorptions (ν_1, ν_2, ν_3) which are attributable to the S–W(Mo) charge transfer transitions. By comparison with the electronic spectra of $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–1), one can see that the addition of Ag(I) to $[W(Mo)O_nS_{4-n}]^{2-}$ (n = 0–1) shifts the spectra of **1a**, **1b** and **2** to lower energies. For example, the ν_1 absorptions for **1a** is at 407 nm, which shifts to lower energies compared to that of $[WS_4]^{2-}$ (398 nm). This low energy shift was different from that observed for another related compound, $[W_2Ag_4S_8(AsPh_3)_4]$, which exhibited a ν_1 absorption at 356 nm [26,27].

3.3. Description of the crystal structure of $[Et_4N]_2[(WS_4)Ag_8(SBu^t)_8]$ (1a)

The complex of compound **1a** consists of an octanuclear monocyclic $[Ag(SBu^t)]_8$ ring, a $[WS_4]^{2-}$ anion and two $[Et_4N]^+$ cations. A view of the anion of compound **1a** is shown in Fig. 1 and selected bond lengths and angles are summarized in Table 2. In the structure of the anion, eight Ag atoms construct a distorted cage with several Ag_4 planes, e.g. atoms Ag2, Ag5, Ag6, Ag9 almost lie in a plane (mean deviation: 0.1668 Å) while the rest are also coplanar (mean deviation: 0.1191 Å). It is noted that this distorted cage structure is different from those reported for the octanuclear monocyclic AgSR ring compounds. For example, the octanuclear cluster $[Ag_8(mba)_{10}]^{12-}$ (H_2mba = 2-mercaptobenzoic acid) is composed of two butterfly type Ag_4S_4 cones [28] and the complexes $(Ag_8SCMeEt_2)_8(PPh_3)_2$ [29,30], $[AgSCH(SiMe)_2]_8$ [31] and $\{[Ag(SC_6H_4\text{-}o\text{-}SiMe_3)]_4\}_2$ [32] all show bis-cyclic structures. In the Ag_8 ring, adjacent Ag atoms are connected through one bridging –SBu^t ligand. The distance between an Ag atom and the bridging –SBu^t ranges from 2.380(5) to 2.453(5) Å, which is similar to the corresponding values in $[Ag_8(mba)_{10}]^{12-}$ [28], $(Ag_8SCMeEt_2)_8(PPh_3)_2$ [29,30], $[AgSCH(SiMe)_2]_8$ [31] and $\{[Ag(SC_6H_4\text{-}o\text{-}SiMe_3)]_4\}_2$ [32]. There are weak secondary metal–metal interactions between the adjacent Ag atoms (Ag3···Ag4: 3.022(6); Ag5···Ag6: 3.184(4) Å), which are intermediate between the Ag–Ag separation found in metallic silver (2.88 Å) [33] and twice the van der Waals radii for silver (3.44 Å) [34,35], and also are comparable to those found in other related compounds [28–32]. A $[WS_4]^{2-}$ fragment

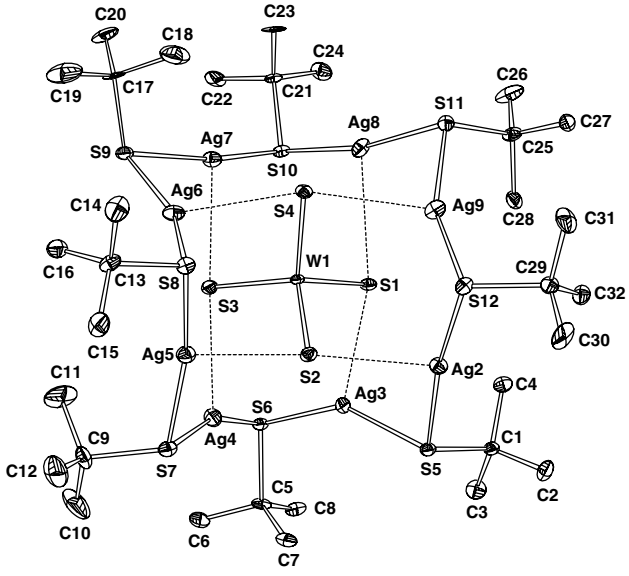

Fig. 1. Structure of the $[(WS_4)Ag_8(SBu^t)_8]^{2-}$ anion of **1a** (20% probability displacement ellipsoids). The hydrogen atoms are omitted for clarity and the weak secondary interactions are drawn as broken lines.

is encapsulated in the Ag_8 cage. The coordination geometry about the W atom is tetrahedral with a slight distortion (angles of S–W–S range from 108.3(2)° to 111.4(2)°). The average bond length of W–S is 2.200 Å, which is similar with those reported in the compounds $[H_3NCH_2CH_2NH_3][WS_4]$ [36], $[H_3NCH_2CH_2CH_2NH_3][WS_4]$ [37] and $[PPh_4][WS_3(SH)]$ [38]. The distance between S atoms of the $[WS_4]^{2-}$ fragment and the Ag atoms ranges from 2.796(5) to 3.101(5) Å, revealing weak interactions [29–31], which are also demonstrated by the IR spectrum.

Up until now, there have been only a few crystal structures reported for monocyclic silver alkanethiolates or areneticthiolates AgSR, largely due to difficulties with insolubility and poor crystal habit [30]. One important method around this problem is to react them with small proportions of ligands that are bulky and structure terminating, in order to get the resulting compounds representing monocylic structures. For example, the structures of $Ag_6(SAr)_6(PPh_3)_5$ [39], $(Ag_8SCMeEt_2)_8(PPh_3)_2$, $(Ag_8SBu^t)_{14}(PPh_3)_4$ [30] and $(AgSPh)_7(dppm)_3$ [40] have been determined by employing PPh_3 or dppm as structure-terminating ligands. It is interesting and rare that a $[WS_4]^{2-}$ fragment is encapsulated in a monocyclic $Ag_8(SBu^t)_8$ cage via weak Ag···S interactions, as in compound **1a**, and it is the first example with this kind of structure in the W(Mo)/Ag/S system.

3.4. Description of the crystal structure of $\{[Et_4N][WOS_3Ag_2(S_2COEt)]\}_n$ (2)

The structure of the polymeric anion of **2** is depicted in Fig. 2 and the important bond lengths and angles are listed in Table 3. The cluster skeleton of the repeating unit consists of a butterfly OWS_3Ag_2 cluster, in which the W atom has basically retained the tetrahedral geometry of the free $[WOS_3]^{2-}$ anion. Two such butterfly fragments connected by a pair of ethylxanthato bridges form a double-butterfly dimer. Atom Ag2 is in an approximately trigonal planar environment, coordinated with two S atoms of the oxothiotungstate and one S atom from the bridging ethylxanthato ligand. The coordination environment of Ag1 is almost the same as that of Ag2 except that there is an additional weak Ag···S interaction [2.7917(9) Å] between Ag2 and S of the adjacent OWS_3Ag_2 butterfly unit. These weak Ag–S bonds link the double-butterfly dimers together to form a polymeric chain structure running

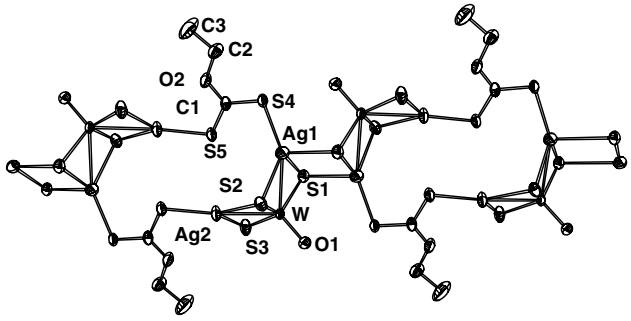

Fig. 2. Structure of the polymeric anion of **2**. The hydrogen atoms are omitted for clarity.

along crystallographic *b* axis. The W–Ag1 distance [2.9726(6) Å] is a little longer than that of W–Ag2 [2.9116(7) Å], but both of them are in the normal range for W/Ag/S clusters [41,42]. As observed in the Cu(I) clusters, the W–S bonds involving triply bonded S (average value 2.257 Å) are slightly longer than that of doubly bonded S [W–S3: 2.210 Å]. W/Ag/S clusters containing butterfly structures are not common, the only example is $WOS_3Ag_2(PPh_3)_3$ [43].

4. Supplementary material

Crystallographic data, excluding structure factors, have been deposited at the Cambridge Crystallographic Data center, CCDC reference numbers 253418 for **1a** and 248288 for **2**. Abstract

The syntheses, structures and magnetic properties of three 1-D complexes with the formulae $[Co_2(tppz)(dca)_4]$ (**1**), $[Ni_2(tppz)(dca)_4]C_2H_5OH$ (**2**) and $[Cu_2(tppz)(dca)(Cl)_2](dca)\cdot H_2O$ (**3**), where tppz = tetra-2-pyridylpyrazine and dca = dicyanamide, are described. Complexes **1**–**3** are one-dimensional metal-complexes. In **1** the dinuclear tppz-chelated Co(II) centers are linked by two double $\mu_{1,5}$-dca ligands. Compound **2** forms a ladder-like structure in which the rungs are formed by bis-chelating tppz bridged dinuclear Ni(II) ions and the uprights by $\mu_{1,5}$-dca units. Compound **3** forms a helical chain structure which consists of alternately single $\mu_{1,5}$-dca linked dinuclear tppz-chelated Cu-centers. The temperature dependence of magnetic measurements show antiferromagnetic couplings between two metal ions with a pathway through tppz and $\mu_{1,5}$-dca in all cases, with $J = -1.10\ cm^{-1}$, $J' = -0.05\ cm^{-1}$ for **1**, $J = -1.28\ cm^{-1}$, $J' = -0.11\ cm^{-1}$ and $D = 9.50\ cm^{-1}$ for **2**, and $J = -10.26\ cm^{-1}$, $J' = -0.06\ cm^{-1}$ for **3**.

1. Introduction

The dicyanamide (dca) ligand, $N(CN)_2^-$, possessing three potential donor sites, has been shown to coordinate to metal ions in various modes [1–13]. When it functions as a terminal ligand, usually one of the two nitrile nitrogens coordinates to the metal ion [2,12]. However, in a recent example, preferential coordination of the amide nitrogen has been observed [3]. As a bridging ligand, five types of bridging modes have been structurally characterized so far [1–11,13]; two connecting [2–8], three connecting [1,9,10], four connecting [13] and even five connecting [11]. Furthermore, the introduction of auxiliary ligands with multidentate sites into the metal–dca moiety has led to the design of a series of metal complexes with a wide variety of magneto-structural topologies, e.g., one-dimensional chain [3,4], two-dimensional sheet [5] and several types of three-dimensional networks [4d,6]. Taking into account the above-mentioned aspects, in the present work, three metal complexes with dca and the auxiliary ligand tetra-2-pyridylpyrazine (tppz), $[Co_2(tppz)(dca)_4]$ (**1**), $[Ni_2(tppz)(dca)_4](C_2H_5OH)$ (**2**) and $[Cu_2(tppz)(dca)(Cl)_2](dca)(H_2O)$ (**3**) have been synthesized and magnetostructurally characterized. The ligand tppz (Scheme 1) was first reported by Goodwin and Lyons [14] and there have been reports on the synthesis and characterization of

Tppz

Scheme 1.

some mono-, dinuclear and oligomeric transition metal complexes [15–19], most of which deal with their redox, luminescence and mixed-valence properties. Recently, one-, two- and three-dimensional composite materials constructed from molybdophosphonate and polyoxomolybdate subunits linked through binuclear copper tppz ligands have been reported [20]. To our knowledge there is as yet no investigation on complexes containing both dca and tppz ligands.

2. Experimental

2.1. Synthesis

Nickel(II) perchlorate hexahydrate, cobalt(II) chloride hexahydrate, cupric chloride dihydrate, sodium dicyanamide and tetra-2-pyridylpyrazine were purchased from commercial sources (Aldrich) and used as received.

2.1.1. Synthesis of the complex $[Co_2(tppz)(dca)_4]$ (1)

This compound is obtained as dark red crystalline solid by slow addition of a methanol solution (20 cm^3) containing sodium dicyanamide (190 mg, 2 mmol) to a methanolic solution of $CoCl_2 \cdot 6H_2O$ (0.366 g, 1 mmol) and tetra-2-pyridylpyrazine (tppz) (200 mg, 0.5 mmol). After refluxing for 24 h, the solution was left standing at room temperature. Dark red prismatic crystals suitable for single crystal X-ray analysis appeared after 2 weeks from the resulting solution. Yield: 75%. *Anal.* Calc. for $C_{32}H_{16}Co_2N_{18}$: C, 49.8; H, 2.09; N, 32.7. Found: C, 48.9; H, 2.08; N 31.8%. IR (KBr/cm^{-1}) ν(CN): 2188, 2246, 2343.

2.1.2. Synthesis of the complex $[Ni_2(tppz)(dca)_4]C_2H_5OH$ (2)

To a methanol solution (20 cm^3) of $NiClO_4 \cdot 6H_2O$ (0.366 g, 1 mmol) and tppz (400 mg, 1 mmol) in 20 cm^3 methanol, a solution of $NaN(CN)_2$ (380 mg, 4 mmol) in 20 cm^3 water was added. The solution was stirred at 25 °C for 24 h and then left standing at room temperature for several days. The resulting solution was filtered to remove a green precipitate, which was dissolved in *N,N*-dimethylformamide (dmf)/CH_3OH for crystal growth. After several days dark green crystals of **2** were deposited. Yield: 70%. *Anal.* Calc. for $C_{34}H_{22}Ni_2N_{18}O$: C, 50.04; H, 2.71; N, 30.9. Found: C, 49.68; H, 2.88; N 31.03%. IR (KBr/cm^{-1}) ν(CN): 2190, 2247, 2346.

2.1.3. Synthesis of the complex $[Cu_2(tppz)(dca)(Cl)_2](dca) \cdot H_2O$ (3)

To a methanol solution (10 cm^3) of $CuCl_2 \cdot 2H_2O$ (140 mg, 1 mmol) and tppz (200 mg, 0.5 mmol) in 30 cm^3 methanol, $NaN(CN)_2$ (190 mg, 2 mmol) in 20 cm^3 water was added. The mixture was stirred at 25 °C for 24 h and then left standing at room temperature. After several days dark green block like crystals of **3** were obtained. Yield: 76%. *Anal.* Calc. for $C_{28}H_{20}Cl_2Cu_2N_{12}O_2$: C, 44.6; H, 2.67; N, 22.3. Found: C, 44.8; H, 2.64; N 21.8%. IR (KBr/cm^{-1}) ν(CN): 2182, 2252, 2320.

2.2. Physical measurements

IR spectra were recorded on a Bio-Rad FTS-40 FTIR spectrophotometer with samples as KBr disks in the 400–4000 cm^{-1} region. Variable-temperature (2–300 K) magnetic susceptibility measurements under fixed field strength of 1 T were carried out with a Quantum Design MPMS SQUID magnetometer. Diamagnetic corrections were estimated from Pascal's constants [21].

2.3. X-ray crystal structure analysis

Intensity data were collected on a Bruker SMART CCD diffractometer for **1** and **2**, and a Siemens P4 diffractometer for **3** in the ω–2ϑ scan mode at 295 K using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 using the programs SHELXS-97 and SHELXL-97 [22]. All non-hydrogen atoms were readily located and refined using anisotropic thermal parameters. Crystallographic details for the structures of **1**–**3** are summarized in Table 1.

3. Results and discussion

3.1. Description of the crystal structures

The selected bonds lengths and angles of complexes **1**, **2** and **3** are listed in Tables 2–4, respectively. The structure of **1** consists of 1-D alternating chains $[Co_2(tppz)(dca)_4]_n$ along the *c*-axis (Figs. 1 and 2), in which the dinuclear tppz-chelated Co(II) units are linked by two double $\mu_{1,5}$-dca groups. As illustrated in Fig. 1, each Co atom is coordinated with a distorted octahedral geometry by six N atoms (three from a tppz bridged ligand, two from $\mu_{1,5}$-dca groups and one from a terminal dca). The $[Co_2(tppz)(dca)_4]$ subunit of **1** is located at a crystallographic center of symmetry. The Co(1)···Co(1b) distance through the tppz ligand is 6.879 Å, whereas the Co(1)···Co(1a) distance through the $\mu_{1,5}$-dca bridge is 7.377 Å. The central pyrazine ring is twisted by 13.2° (defined by the dihedral angle between the planes made up of atoms C(6) N(2) C(7) and C(6B) N(2B) C(7B)), and the planes of coordinated pyridyl rings (N(1)–C(1)–C(2)–C(3)–C(4)–C(5) and N(3)–C(8)–C(9)–C(10)–C(11)–C(12)) are inclined to one another by 7.3°.

The compound $[Ni_2(tppz)(dca)_4]C_2H_5OH$ (**2**) forms a ladder-like 1-D alternating polymer structure along the *b*-axis (Figs. 3 and 4), in which the rungs are formed by centrosymmetric, tridentate bis-chelating tppz bridges and the uprights by two end-to-end bridging $\mu_{1,5}$-dca units (Fig. 3). In addition, the C_2H_5OH molecules are inserted inside the rungs in the ladder-like complex **2** (Fig. 4). The nickel atom is best described as distorted octahedral, the equatorial positions being occupied by four nitrogen atoms: three from tppz

(Ni(1)–N(1) 2.102(2), Ni(1)–N(2) 2.067(2) and Ni(1)–N(3) 2.0358(18) Å), and one from monodentate dca (Ni(1)–N(4) 2.018(2) Å). The apical positions are occupied by two bridging $\mu_{1,5}$-dca (Ni(1)–N(7) 2.079(2) and Ni(1)–N(9) 2.084(2) Å). The Ni(1)···Ni(1a) distance through the tppz ligand is 6.709 Å, whereas the Ni(1)···Ni(1)′ distance through the $\mu_{1,5}$-dca bridge is 8.660 Å. The central pyrazine ring is twisted by 9.9° and the coordinated pyridyl rings are inclined to one another by 12.7°.

The crystal structure of **3** consists of uniform cationic $[Cu_2(tppz)(dca)(Cl)_2]_n^{n+}$ helical chains (Figs. 5 and 6) extending along the *a*-axis, the dca units serving as an asymmetric $\mu_{1,5}$-dca bridging ligand to link the dinuclear Ni–tppz units, such that the convex tppz bow of one chain extends into the concave section of the neighbouring chain (Fig. 6). As seen in Fig. 6, the copper atom has

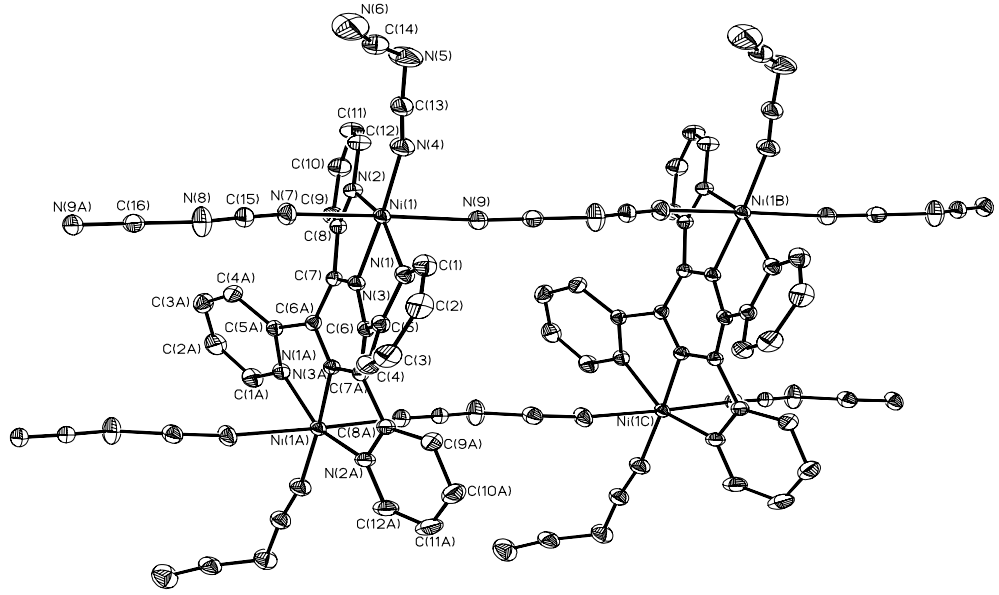

Fig. 3. Perspective drawing of complex **2** with the atom numbering scheme. Thermal ellipsoids are drawn at the 30% probability level. The solvent ethanol molecule was omitted for clarity.

one $\mu_{1,5}$-dca nitrogen atom [Cu(1)–N(4) 1.996(2) Å] in the equatorial positions and a chloride [Cu(1)–Cl(1) 2.3878(11) Å] in the apical position. The equatorial plane has significant tetrahedral distortion with the copper atom displaced by 0.457 Å from this plane in the direction towards the apical ligand. The Cu(1)···Cu(1a) distance through the tppz ligand is 6.560 Å, whereas the Cu(1)···Cu(1b) distance through the $\mu_{1,5}$-dca bridge is 7.604 Å. The central pyrazine ring is twisted by 10.7° and the coordinated pyridyl rings are inclined to one another by 11.3°.

3.2. Magnetic properties

The magnetic properties of the complexes **1**–**3** in the form of $\chi_m T$ versus T plots (χ_m is the magnetic susceptibility per metal ion) are shown in Fig. 7. For **1**, the value

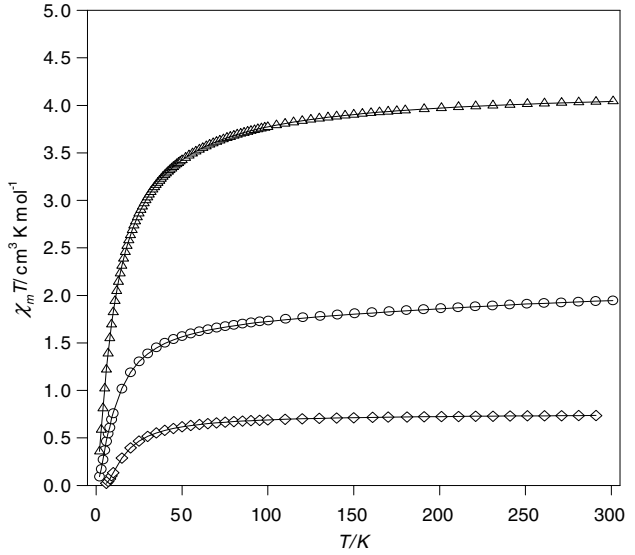

Fig. 7. Temperature dependence of $\chi_m T$ for complexes **1** (-△-), **2** (-○-), and **3** (-◇-) The solid lines are calculated with the fitted parameters reported in the text.

of $\chi_m T$ at 300 K is 4.12 cm^3 mol^{-1} K, as expected for two magnetically isolated spin systems of $S = 3/2$. When the sample is cooled, the $\chi_m T$ values decrease slowly from 300 K, more quickly below 50 K, and drop to 0.20 cm^3 mol^{-1} K down to 2 K. This is in agreement with antiferromagnetic interactions in compound **1**. To fit quantitatively the magnetic data for **1**, we first considered the exchange interaction as the leading term corresponding to the alternating chain with the nearest neighbor exchange interactions described by the spin Hamiltonian:

$$H = -J_1 \sum S_{2i} S_{2i+1} - J_2 \sum S_{2i+1} S_{2i+2} \quad [23]. \tag{1}$$

However, fitting the data with this model gave poor results. Thus, we used the simple model of two spins $S_1 = S_2 = 3/2$ of a Hamiltonian $H = -2JS_1S_2$ with an assumed interdimer exchange interaction (J') pathway through the dca bridges. The final expressions of the temperature dependence of magnetic susceptibility are given as Eqs. (1) and (2):

$$\chi_{\text{dimer}} = \frac{2N\mu_B^2 g^2}{kT}\left[\frac{e^{-10x} + 5e^{-6x} + 14}{e^{-12x} + 3e^{-10x} + 5e^{-6x} + 7}\right], \tag{2}$$

where z is the number of nearest neighbors of the dimers of **1** (2 in this case). An excellent simulation of the experimental magnetic data using Eq. (1) is obtained with $J = -1.10$ cm^{-1}, $J' = -0.05$ cm^{-1}, $g = 2.05$ and the agreement factor $R = 2.0 \times 10^{-5}$ which is defined as

$$\left[\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2 / \sum (\chi_M T)_{obs}^2\right].$$

The results show that the low magnetic coupling constants of J and J' by a pathway through tppz and $\mu_{1,5}$-dca, respectively, are weak antiferromagnetic interactions between cobalt ions.

The $\chi_m T$ versus T plots for **2** are also shown in Fig. 7. The $\chi_m T$ value decreases gradually with decreasing temperature from 1.2 cm^3 mol^{-1} K at 300 K to 0.05 cm^3 mol^{-1} K at 2 K, indicating the presence of antiferromagnetic exchange interactions between the nickel ions in **2**. Considering the structural results, the fitting of the magnetic data of this alternating ladder-like chain of **2** was also attempted using the magnetic susceptibility equation obtained from the alternating form of $H = -J_1\sum S_{2i}S_{2i+1} - J_2\sum S_{2i+1}S_{2i+2}$ [23]. The least-squares fitting of the experimental data to the equation for an alternating chain did not afford reasonable results, especially in the low temperature range. Finally, the experimental magnetic susceptibility data were least-squares fitted to the theoretical expression with zero-field splitting for a magnetic interaction between two $S_1 = S_2 = 1$ ions given by Ginsberg et al. [24], from the Hamiltonian

$$H = -2JS_1S_2 - D(S_{1z}^2 + S_{2z}^2) - g\mu_B H(S_1 + S_2) - zJ'S\langle S\rangle. \tag{3}$$

In which J is the intradimer (Ni–tppz–Ni) exchange parameter, D is the single ion zero-field splitting, zJ' is the effective interdimer exchange pathway through dca bridges (Ni–dca–Ni), z is the number of nearest neighbors of the dimers of **2** (2 in this case) The resulting χ_m expression is

$$\chi_m = (2Ng^2\mu_B^2/3k)[F_1/(T - 4zJ'F_1) + 2F'/(1 - 4zJ')], \tag{4}$$

where F_1 and F' are functions of temperature, zero-field splitting and the intradimer exchange parameter J. The best fitting parameters obtained from minimizing R were $J = -1.28$ cm^{-1}, $J' = -0.11$ cm^{-1} $D = 9.50$ cm^{-1} $g = 2.21$ and $R = 2.0 \times 10^{-4}$. Here, J and J' are the representative magnetic coupling constants for pathways through tppz and $\mu_{1,5}$-dca, respectively.

For complex **3** the $\chi_m T$ versus T plot is shown in Fig. 7, the value of $\chi_m T$ per copper(II) ion decreases gradually on cooling. The $\chi_m T$ values decrease slowly from 0.72 cm^3 mol^{-1} K at 300 K, more quickly below 100 K and tend to 0.08 cm^3 mol^{-1} K down to 2 K. These features are characteristic of a weak antiferromagnetic interaction between a pair of copper(II) ions. We have accordingly analyzed the magnetic data through a numerical expression in a zero field appropriate for an alternating polymeric chain coupling system of $S = 1/2$ given by Hatfield [21a,25]. However, fitting the data with this model gave poor results, consequently, the magnetic data of **3** were analyzed by the use of the Bleaney–Bowers expression (Eqs. (5) and (6)) with interdimer exchange interactions (1) [26] for the exchange coupling in a two spin $S = 1/2$ system.

$$\chi_m = \frac{\chi_{dimer}}{[1 - (2zJ'/N\mu_B^2 g^2)]\chi_{dimer}}, \quad (5)$$

$$\chi_{dimer} = (Ng^2\mu_B^2/kT)[3 + \exp(-2J/kT)]^{-1}. \quad (6)$$

The best-fit parameters obtained through this procedure are $J = -10.26\ cm^{-1}$, $J' = -0.06\ cm^{-1}$, $g = 2.01$ and $R = 2.0 \times 10^{-5}$. Where J and J' also represent magnetic coupling constants of pathways through tppz and $\mu_{1,5}$-dca, respectively.

The results of the present system show that the J values ($J = -1.10\ cm^{-1}$ for **1**, $-1.28\ cm^{-1}$ for **2** and $-10.26\ cm^{-1}$ for **3**) are higher than those of J' ($-0.05\ cm^{-1}$ for **1**, $-0.11\ cm^{-1}$ for **2** and $-0.06\ cm^{-1}$), indicating the tppz bridge should be a better superexchange mediator than the $\mu_{1,5}$-dca bridge. The $\mu_{1,5}$-dca bridge behaves as a poor magnetic mediator, and the magnitude of exchange integrals (J) has been observed in the range -0.05 to $-0.11\ cm^{-1}$, which are in agreement with those in the range -0.06 to $-0.17\ cm^{-1}$ [1–13]. Although no magnetic parameters for polymeric metal complexes with tppz bridging ligands have been reported, we examined the values of J for complexes **1**–**3** in relation to the magnitude of exchange couplings reported for the dinuclear tppz bridged system. According to the literature the J values of magnetic exchange interaction pathways through (i) the pyrazine-bridged metal complexes show negligible or very low values ($J = -3.5$ to $0\ cm^{-1}$) [27], or (ii) the tppz-bridged dinuclear metal complexes show low values ($J \sim 4.0\ cm^{-1}$, $D \sim 10\ cm^{-1}$) for Ni(II) or medium values ($J \sim 15$–$30\ cm^{-1}$) for Cu(II) [19]. In addition, based on the magnetic orbital overlap π- or σ-model, the magnitude of magnetic coupling between two metal ions via a pathway through tppz is dependent on the planarity of the pyrazine ring, dihedral angles between the pyridine ring, or the planarity of the basal coordination plane of the metal ion [19]. The antiferromagnitic exchange parameter J value obtained for the present complexes in the order **1** < **2** < **3** is correlated to their magnetic orbital properties and twisted angles of the central pyrazine ring of the tppz ligand.

4. Conclusions

The combined use of dca and tppz as ligands in generating new transition metal complexes has led to (i) alternating 1-D chains with dca-linked dinuclear tppz-chelated Co(II), Ni(II) and Cu(II) building blocks, and (ii) weak antiferromagnetic exchange interactions between two metal ions via a pathway through dca and tppz bridging ligands.

5. Supplementary material

Abstract

The search for efficient artificial nucleases is a consequence of the huge efforts towards DNA sequencing by genome projects around the world. In the present study, we describe the activity of the Cu(II)–BMXD complex (BMXD = 3,6,9,17,20,23-hexaazatricyclo[23.3.1.1^{11,15}]triaconta-1(29),11(30),12,14,25,27-hexaene) as a DNA cleavage agent. The rate constant for the DNA backbone cleavage reaction at room temperature (25 °C) and pH 7.0 was estimated to be 1.1×10^{-6} s^{-1}, which corresponds, approximately, to a half-life ($t_{1/2}$) of one week. We demonstrated that the DNA cleavage reaction promoted by the Cu_2BMXD complex may occur via an oxidative pathway through performing reactions in the presence of free-radical acceptors and comparing the activity under aerobic and anaerobic conditions. The Cu_2BMXD complex reported here is established as a novel artificial nuclease.

1. Introduction

Drugs or molecules that interact with nucleic acids have been the subject of great interest because they serve as tools in molecular biology and biochemistry, as well as therapeutics [1], especially those capable of nucleic acid cleavage [2]. Chemical nucleases are compounds that mimic the action of enzymatic nucleases [3] and can be alternatively used in biochemical and biotechnological processes. They are smaller than enzymes, which allows them to attack macromolecular regions that are inaccessible to enzymes [4] and also their specificity and efficiency may be modulated [5]. These properties have turned chemical nucleases into useful tools as adjuvants in PCR diagnostics [6], nucleic acid attacking agents [7], nucleic acid structural probes [4], DNA cleaving and marking agents for microarrays [8], controlling agents for fungal diseases [9] and antitumor drugs [10–13]. Chemical nucleases have also been used in studies on the interactions between nucleic acids and proteins [14,15] and on the mode of action of some metalloproteins [16,17]. The polyaza macrocyclic ligand 3,6,9,17,20,23-hexaazatricyclo[23.3.1.1^{11,15}] triaconta-1(29),11(30),12,14,25,27-hexaene (BMXD) (Fig. 1) was first synthesized in 1990 [18].

This ligand consists of a macrocycle formed by two diethylenetriamine moieties separated by two *m*-xylyl bridges, and is capable of coordinating one or two Cu(II) centers via its diethylenetriamine moieties [18]. In aqueous medium, depending on the pH, the metal centers of the dinuclear copper(II) complex (Cu_2BMXD) can, in turn, coordinate hydroxide anions (Fig. 1) as suggested by Martell el al. [18,19], as well as other anions, some of them of biological relevance

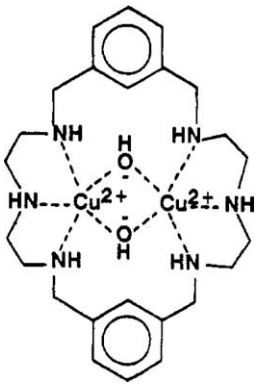

Fig. 1. Chemical structure of the [Cu_2BMXD] complex.

[19–21]. More recently, it has been shown that [Cu_2BMXD] can also form a complex with the dipeptide glycylglycine [22]. It has previously been demonstrated that the BMXD complex shows affinity for ATP and is able to convert it into ADP and orthophosphate through an oxidative process [23]. When coordinating a zinc(II) ion in one or two centers, the BMXD ligand has been shown to bind maleate, pyrophosphate and norleucine [24] and to promote the hydrolytic cleavage of bis(4-nitrophenyl)phosphate (BNP) [25]. In this paper we describe, for the first time, the oxidative cleavage of DNA promoted by the [Cu_2BMXD] complex.

2. Experimental

Abbreviations: BMXD (3,6,9,17,20,23-hexaazatricyclo [23.3.1.1^{11,15}] triaconta-1(29),11(30),12,14,25,27-hexaene), BNP (bis(4-nitrophenyl)phosphate).

The hexabasic macrocycle BMXD ligand has been synthesized according to the literature procedure [18a]. A 10^{-3} M stock solution of [Cu_2BMXD] was prepared by adding $CuCl_2$ to a BMXD solution and neutralizing to pH 7 and the species distribution in aqueous solution has been previously reported [18b]. Plasmid DNA pBSKII (Stratagene) was produced in *Escherichia coli* and extracted following protocols described in the literature [26]. Quality and concentration of the plasmid DNA was assessed by spectrophotometry and the relative amount of supercoiled DNA was evaluated by agarose gel electrophoresis analysis, as previously described [27]. Cleavage experiments were carried out incubating in a 20 μl final volume: 400ng plasmid DNA, corresponding to a final concentration of 30 μM bp (nucleotide base pairs), and 1, 5 or 10 μM [Cu_2BMXD], for 16 h at 50 °C, pH 7.0, in 50 mM PIPES buffer (other conditions are depicted in the figure titles). Reactions were stopped by chilling tubes on ice and adding 4 μl of ice-cold loading-buffer (50% glycerol, 2 M EDTA, 0.05% bromophenol blue). All tests were performed in triplicate. Reaction products observed by agarose gel electrophoresis were digitally recorded and analyzed with the software Scion Image for Windows. Quantified results were subjected to analysis of variance (ANOVA), followed by the Tukey test for honest significant difference (HSD). Electrochemical experiments were performed on a Princeton Applied Research 273 potentiostat/galvanostat. The supporting electrolyte was 0.1 M NaCl in water. Cyclic voltammograms (CV) were obtained with a vitreous carbon working electrode, a platinum wire as an auxiliary electrode, and a Ag/Ag^+ (3 mol l^{-1} NaCl) reference electrode. The scan rate was 100 mV s^{-1}. Potassium hexacyanoferrate(III) was used as an internal standard [28].

3. Results and discussion

In this paper, the activity of the binuclear copper(II) complex [Cu_2BMXD] towards plasmid DNA is described. DNA cleavage activity is achieved at micromolar concentrations of the complex under mild conditions of pH and temperature (Fig. 2).

As shown in Fig. 2, supercoiled plasmid DNA (FI) is converted into nicked circular DNA (FII) when it is incubated with [Cu_2BMXD] for 16 h at 50 °C and at pH 7.0. This conversion is complex-concentration dependent. Plasmid form FI decreased from 79.7% (control) to 56.1%, 29.8% and 21.2%, when the complex concentration is increased from 0 μM (control) to 1, 5 and 10 μM, respectively. DNA cleavage assays were also performed at 20, 30 and 60 °C (Fig. 3) in order to compare our results with the DNA cleavage promoted by metal complexes under conditions similar to those described in previous studies [2,27,29–33].

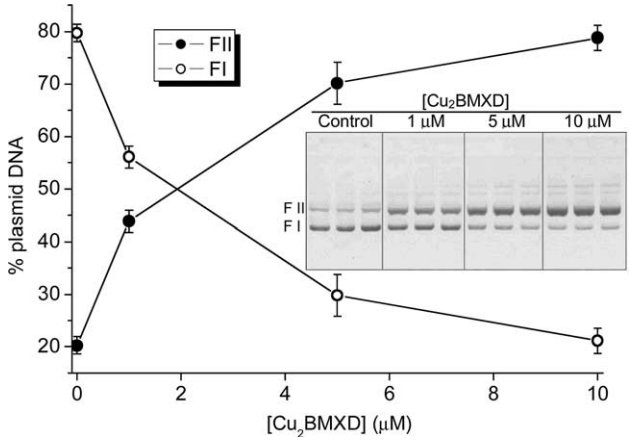

Fig. 2. Plot of % plasmid DNA forms (FI – supercoiled; FII – nicked) after incubation with different concentrations of [Cu_2BMXD] for 16 h at pH 7.0 and 50 °C. Data were obtained from the agarose gel electrophoresis shown in the inset.

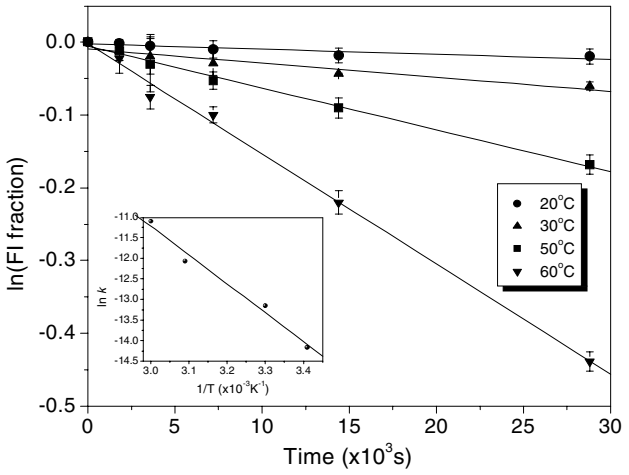

Fig. 3. Effect of temperature on supercoiled plasmid DNA cleavage by [Cu_2BMXD]. All reactions were performed with 20 μM Cu_2BMXD at pH 7.0 (50 mM PIPES buffer). Inset – Arrhenius plot of ln k versus 1/T, obtained from kinetic data.

The rate constant for the DNA cleavage activity promoted by 20 μM [Cu_2BMXD] at 20–60 °C and pH 7.0 was determined by incubating the complex with 10 nM of plasmid DNA for different time periods (Fig. 3, Table 1).

Although there are compounds that are capable of performing remarkable hydrolytic cleavage of DNA [29,32,34], oxidative agents that cleave DNA have been described to be even more efficient. Among these oxidative cleaving DNA agents is bleomycin, capable of promoting double-strand DNA cleavage. This drug complexed with Fe(II) is able to nick plasmid DNA, causing it to pass from the supercoiled to the open circular form with a rate constant of 8.6×10^{-1} h^{-1} in concentrations as little as 0.62 μM [35]. Another iron-complexing agent was reported by Roefles and coworkers to have DNA nicking effects detectable after 20 s of incubation with a catalyst concentration of 1 μM [36]. The [Cu_2BMXD] complex is capable of promoting DNA cleavage with reasonably high efficiency. Most of the chemical compounds described so far to cleave DNA demand a molar concentration many orders of magnitude greater than the concentration of the substrate to perform an activity detectable in a reasonable period of time and under close to physiological conditions [2].

Table 1
Thermodynamic and kinetic parameters of [Cu_2BMXD] DNA cleavage activity

Temperature (°C)	k ($\times 10^{-7}$ s^{-1})
20	7.0 ± 1.6
30	19.3 ± 2.9
50	57.4 ± 2.1
60	151.4 ± 4.8

From data obtained in Fig. 3, and summarized in Table 1, the activation energy for the DNA cleavage reaction was estimated to be 58.6 kJ K^{-1} mol^{-1}, a value that is greater than the diffusion barrier for small molecules. One reason for this barrier could be the DNA structural changes requirement for the complex accommodation, in the slow step of the cleavage mechanism. Another cause for this barrier may be related to the activation of the metal center to produce hydroxyl radicals, given that known hydroxyl radical scavengers (DMSO and glycerol) inhibit plasmid DNA cleavage by [Cu_2BMXD] (Fig. 4). At concentrations of 5 and 10 μM [Cu_2BMXD] a partial inhibition of the cleavage activity in the presence of DMSO was observed. Glycerol was able to partially inhibit the DNA cleavage activity promoted by [Cu_2BMXD] only at the highest complex concentration tested (10 μM).

Complementarily, an aerobic versus anaerobic (argon atmosphere) experiment was performed to investigate the influence of molecular oxygen (O_2) on this DNA cleavage process (Fig. 5). In this experiment, the activity of [Cu_2BMXD] was tested comparatively with that of an Fe-EDTA/DTT system, a known hydroxyl radical producer when in the presence of O_2. It was observed that DNA cleavage promoted by

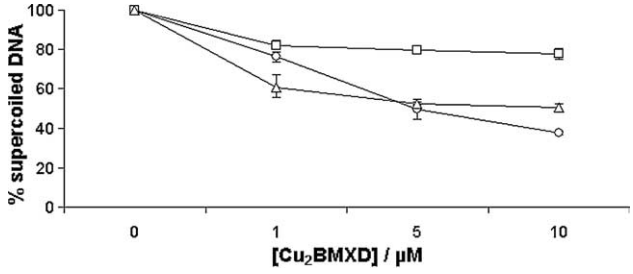

Fig. 4. Percentage of supercoiled DNA in relation to the control after 16 h of incubation at 50 °C. Control (no complex – 0); in the presence of [Cu_2BMXD] 1 μM (1); 5 μM (5) and 10 μM(10), pH 7.0. ○, without free-radical acceptor, △, with glycerol 10%, □, with DMSO 10%. Error bars are indicated.

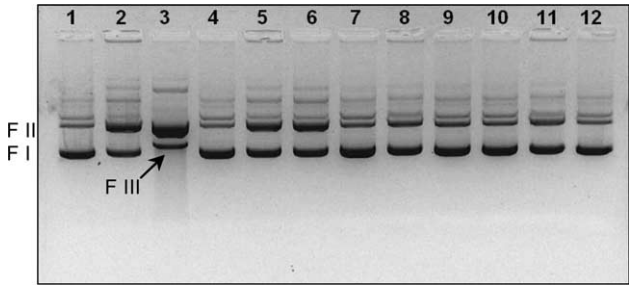

Fig. 5. Incubation of 10 μM (bp) plasmid DNA for 4 h at 50 °C. Lanes 1–6: aerobic atmosphere, lanes 7–12: argon atmosphere. Lanes 1 and 7: Control reactions, lanes 2 and 8: 20 μM Cu_2BMXD, lanes 3 and 9: 100 μM Fe-EDTA + 10 mM DTT, lanes 4 and 10: 400 μM DMSO, lanes 5 and 11: 20 μM [Cu_2BMXD] + 400 μM DMSO, lanes 6 and 12: 100 μM Fe-EDTA + 400 μM DMSO. Plasmid DNA forms: FI – supercoiled; FII – nicked circular; FIII – linear.

Fe-EDTA/DTT, as well as by [Cu_2BMXD] suffered partial inhibition in the presence of the tested free-radical acceptor, DMSO, though this inhibition was less evident for [Cu_2BMXD]. It was also observed that Fe-EDTA/DTT was not able to cleave DNA under an oxygen-free atmosphere while for [Cu_2BMXD] a small residual activity was noted.

These results indicated that the presence of oxygen plays a fundamental role in the process of DNA cleavage by the [Cu_2BMXD] complex. This gives strong evidence of an oxidative process intervening in the DNA cleavage reaction. The initial reduction of the copper centers often requires the participation of a reducing agent [2], some times in great excess, up to 100-fold the concentration of the catalyst [37]. Yet, it has been shown that there are some compounds that do not need external reducing agents to activate the metal centres [35,36,38–41] as has been demonstrated here for [Cu_2BMXD]. However, buffer species such as HEPES, PIPES or MES may fulfil the role of agents to reduce Cu(II) [42].

As shown in Fig. 6 the reaction of [Cu_2BMXD] with DNA is only partially inhibited by changing PIPES for phosphate buffer, thus excluding the amino buffer as a reducing agent in this reaction. It is important to stress that the inhibition caused by phosphate buffer may be due to a competition between the buffer and the DNA for the complex, since it has been previously shown that [Cu_2BMXD] has an affinity for inorganic phosphate [43]. Another important observation is that when 1 ml of experimental solution was prepared with 500 μM of [Cu_2BMXD] under argon atmosphere, a white precipitate formed almost immediately when 250 μM (bp) of DNA was added to the solution. This precipitate was re-dissolved when air was passed

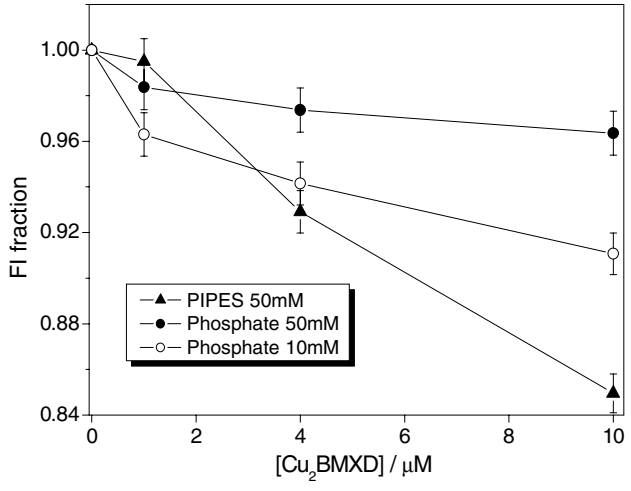

Fig. 6. Effect of buffer on supercoiled plasmid DNA cleavage by [Cu_2BMXD]. All reactions were carried out at pH 7.0 and 50 °C for 8 h.

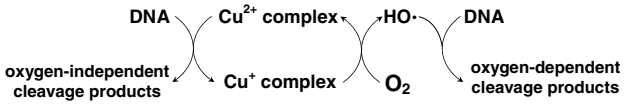

Fig. 7. Scheme of the pathways for oxygen-dependent (and independent) DNA cleavage by Cu_2BMXD.

through the solution, and acquired a blue color. We attribute the production of this precipitate to the reduction of Cu^{2+} to Cu^{+} (less soluble) by DNA, and the dissolution of the white precipitate to a blue solution to the re-oxidation of Cu^{+} to Cu^{2+} in the presence of O_2 (air).

All these results led us to propose, not the mechanisms, but the pathways, or the sequential events, by which the DNA cleavage by [Cu_2BMXD] takes place (Fig. 7).

The electrochemical behaviour of [Cu_2BMXD] was studied using cyclic voltammetry. The cyclic voltammogram of the [Cu_2BMXD] complex measured in H_2O/0.1 M NaCl is shown in Fig. S1 in the potential range −1.0 to 1.0 V versus Ag/Ag^+. The complex shows two irreversible redox processes at −0.46 and −0.59 V versus Ag/Ag^+, regarded as cathodic peak potentials. These irreversible processes are tentatively attributed to the successive one-electron $2Cu^{II} + 1e^- \rightarrow Cu^{II}Cu^{I}$ and $Cu^{II}Cu^{I} + 1e^- \rightarrow 2Cu^{I}$ redox couples. For comparison, two reduction processes at −0.35 and −1.09 V versus Ag/Ag^+ have been reported for a dinuclear copper(II) complex containing dissimilar N_2O_2 coordination environments [44a]. The wave at −0.13 V versus Ag/Ag^+ in the CV (Fig. S1) is attributed to adsorption of the complex onto the electrode surface [44b] while the oxidation wave at +0.22 V is most probably related to the oxidation of the BMXD ligand.

4. Conclusions

We have described a novel chemical nuclease, in the form of a previously identified macrocyclic complex, Cu_2BMXD. The kinetic parameters of the reaction, as well as the temperature and the complex concentration necessary to achieve nucleic acid cleavage, indicate its potential as a gentle footprinting agent and chemical nuclease. Our efforts are now concentrated on the determination of the reaction specificity towards particular DNA sequences or structures and also on the biological activity of the complex.

Abstract

The reaction between sulfathiazole and cobalt(II) leads to a pink solid, $[Co^{II}(ST)_2(H_2O)_4]$ (**1**), which, after 7–10 days in the mother solution, transforms into red crystals of $[Co^{II}(ST)_2(H_2O)_3]_n$ (**2**) (ST = sulfathiazolate). The Co(II) ion exhibits an octahedral environment in both compounds. Differences between them were noted in the IR spectra in the region corresponding to signals of the amine group. Antifungal properties of (**1**) were evaluated, showing activity against both *Aspergillus fumigatus* (the same as the ligand) and *Aspergillus flavus* (better than the ligand).

1. Introduction

Among the many and so different families of organic–inorganic chemicals being currently investigated because of their applications, sulfonamides and their N-derivatives are one of the outstanding groups [1].

Sulfonamides were the first effective chemotherapeutic agents employed systematically for the prevention and cure of bacterial infections in humans [2,3]. After the introduction of penicillin and other antibiotics, the popularity of sulfonamides decreased. However, they are still considered useful in certain therapeutic fields, especially in the case of ophthalmic infections as well as infections in the urinary and gastrointestinal tract [4]. Besides, sulfadrugs are still today among the drugs of first election (together with ampicillin and gentamycin) as chemotherapeutic agents in bacterial infections by *Escherichia coli* in humans [5]. The sulfanilamides exert their antibacterial action by the competitive inhibition of the enzyme dihydropterase synthetase towards the substrate *p*-aminobenzoate [6]. Sulfathiazole, (4-amino-*N*-2-thiazolylbencenosulfonamide), HST (Fig. 1), is clinically one of the most used [7].

Neutral sulfonamides are expected to be poor ligands because of the withdrawal of the electron density from

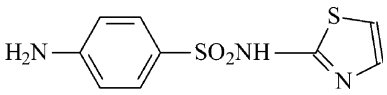

Fig. 1. Sulfathiazole (HST).

the nitrogen atom onto the electronegative oxygen atoms. However, if the sulfonamide N atom bears a dissociable hydrogen atom, this same electron-withdrawing effect increases its acidity and, in the deprotonated form, sulfonamide anions are effective σ-donor ligands [8]. On the other hand, complex formation between metal ions and sulfadrugs, pointing to the combined antibacterial activity of sulfonamides and the antimicrobial activity of heavy metals in some cases, and the activity of the metal complexes themselves, constitute an important field of research [1,2]. Furthermore, sulfadrugs and their metal complexes possess many applications, in addition to antibacterial activity such as diuretic, antiglaucoma or antiepileptic drugs, among others [9–14], like antifungal activity [15,16], and, in many cases, the activity of the metal complex is much better than the ligand alone [1].

Although the synthesis of metal complexes of sulfathiazole has been reported, the structural determination is often incomplete and conflicting [17,18]. Relating to sulfathiazole metal complexes, different compounds were reported in which the sulfathiazole moiety acts with a high versatility in its coordination ability. For example, with Zn(II) the drug acts as a bridging ligand through both the N_{amino} and $N_{thiazole}$ atoms [18]. As a neutral ligand, HST acts as a monodentate ligand, binding the metal ion through the N_{amino} atom [19]. As a deprotonated ligand, ST^- has a variety of coordination behaviors, e.g., besides the Zn(II)–ST complex [18], in Cu(II) complexes coordination through the N-thiazole atom could be seen, and in another case the sulfathiazolato exhibits bidentate behavior linking the metal ion through the $N_{thiazolic}$ and the $N_{sulfonamido}$ atoms [20]. More recently, we have analyzed the interaction of mercury(II) with sulfathiazole: IR and NMR spectral studies suggested a coordination of Hg(II) with the $N_{thiazolic}$ atom, unlike the related Hg-sulfadrugs compounds [21].

Despite its low availability in the earth's crust [22], cobalt plays important roles in biological systems. The most common examples are vitamin B_{12} and coenzyme B_{12}, a cofactor required for a group of enzymatic systems of central importance in biochemistry [23]. Cobalt is vitamin B_{12}'s only apparent biological site. Vitamin B_{12}-deficiency causes the severe disease of pernicious anemia in humans, which indicates the critical role of cobalt. The cobalt in vitamin B_{12} is coordinated to five N atoms, four attributed to a tetrapyrrole (corrin); the sixth ligand is C, provided either by C5 of deoxyadenosine in enzymes such as methylmalonyl-CoA (fatty acid metabolism) or by a methyl group in the enzyme that synthesizes the amino acid methionine in bacteria [24]. Besides, cobalt in organometallic complexes, has been shown to display a wide-ranging reactivity which includes alkyl transfer reactions and insertion reactions of small molecules such as O_2 and SO_2 into metal–alkyl bonds [25]. Because of its high sensitivity to the coordination site geometry and the many experimental techniques that can be used in its characterization, cobalt has been used to replace other metal ions to gather information about changes in metal sites in proteins during protein function [26–29]. Spectroscopic characterization of these systems has revealed that cobalt can be present as Co(II) and Co(III) ions in several types of coordination, which lead to different electronic and magnetic properties. In this context, the use of simple Co-containing systems with low molecular weight ligands is useful for understanding the correlation between spectroscopic and structural properties.

As part of a research program dedicated to the investigation of the structural, physicochemical and biological properties of metal complexes of sulfadrugs, the present paper reports the synthesis, spectral, structure and antifungal studies of compounds of sulfathiazole with Co(II), Co(II)–ST.

2. Experimental

2.1. Materials and methods

Sulfathiazole, as a sodium salt (Sigma, >99%), cobalt (II) chloride hexahydrate (Merck, GR), and all other chemicals of commercially available reagent grade were used as received.

The content of Co was determined by both complexometric back-titration with EDTA (ethylenediaminetetraacetic acid) [30,31] and atomic absorption spectroscopy with a double beam Perkin–Elmer spectrometer, model 3110, at UNL.

Elemental chemical analyses (C, H, N, S) were performed in a microanalyser Carlo Erba EA1108.

IR spectra of powdered samples were measured with a Bruker IFS 66 FTIR-spectrophotometer from 4000 to 400 cm^{-1}, using the KBr pellet technique. The Raman spectrum was measured with a Spex-Ramalog double monochromator spectrometer, using the 514.5 nm line of an Ar ion laser for excitation, over the region 200–2000 cm^{-1}.

Thermogravimetric (TG) and differential thermal analysis (DTA) were performed on a Shimadzu system (models TG-50 and DTA-50, respectively), working in an oxygen flow (50 mL/min) and a heating rate of 10 °C/min. Sample quantities ranged between 10 and 20 mg. Al_2O_3 was used as a DTA standard.

Room temperature magnetic susceptibility was determined with a Cahn-2000 balance, calibrated with $Hg[Co(SCN)_4]$ and at a magnetic field strength of 6 kG.

Electronic spectra were recorded between 200 and 800 nm in a Jasco model 530 double beam spectrophotometer using quartz cells of 1 cm path length at room temperature and in the following solvents: water, methanol (both in order to observe ligand transitions) and DMSO (for d–d transitions). Diffuse reflectance spectra were recorded with a Shimadzu UV-300 instrument, using MgO as an internal standard.

EPR spectroscopy: X-band EPR spectra were recorded as the first derivative of absorption on a Bruker EMX spectrometer operating at 77 K. The microwave frequency was generated with a Bruker 04 ER (9–10 GHz) and measured with a Bruker EMX 048T frequency meter. The magnetic field was measured with a Bruker EMX 035M NMR-probe gaussmeter. Spectral parameters were: 100 kHz field modulation, 10.0 G modulation amplitude, ca. 9.31 GHz microwave frequency, 5.6×10^3 receiver gain, CF = 2000 G, sweep width: 3950 G. Measurements were done on ca. 0.1 mL volume samples of DMSO frozen solution of Co(II)–ST, both pink powder and red crystals, drawn into a plane cell. Typically 1024 points were accumulated per spectrum. Number of scans: 3

Despite Co^{2+} being an excellent paramagnetic shift ion in protein NMR studies [32], it was not possible to take NMR spectra of the complexes because of the paramagnetism observed.

2.2. X-ray crystal structure determination

Highly redundant diffractometer data sets were collected at room temperature ($T = 295$ K) for compound (**2**), up to a 2θ max. of ca. 58°, with a Bruker AXS SMART APEX CCD diffractometer using monochromatic Mo Kα radiation, $\lambda = 0.71069$ Å, and a 0.3° separation between frames. Data integration was performed using SAINT and a semi-empirical absorption correction was applied using SADABS, both programs being included in the diffractometer package. The structure resolution was achieved by Patterson methods and difference Fourier. The structure was refined by least squares on F^2, with anisotropic displacement parameters for non-H atoms. Hydrogen atoms attached to carbon (C–H's) were placed at their calculated positions and allowed to ride onto their host carbons both in coordinates as well as in thermal parameters. Terminal methyl groups were allowed to rotate as well. Hydrogen atoms deemed as potentially active in H-bonding interactions (O–H's and N–H's) were searched in the late Fouriers, and treated in accordance to the data set qualities. In the structure, the amino H atoms [N(6)] were found in the final difference Fourier map and were refined to ensure a reasonable geometry.

All calculations to solve the structures, refine the proposed models and obtain derived results were carried out with the computer programs SHELXS97, SHELXL97 [33a] and SHELXTL/PC [33b]. Relevant parameters of the crystal structure determination are listed in Table 1.

2.3. Biological evaluation

Microorganisms and media: The microorganisms used for the fungistatic evaluation were purchased from the American Type Culture Collection (identified with the initials ATCC) Rockville, MD, USA, or were clinical isolates from CEREMIC, (identified with the capital letter C), Centro de Referencia Micológica, Facultad de Ciencias Bioquímicas y Farmacéuticas, Suipacha 531-(2000)-Rosario, Argentina. *Candida albicans* ATCC 10231, *Saccharomyces cerevisiae* ATCC 9763, *Cryptococcus neoformans* ATCC 32264, *Aspergillus flavus* ATCC 9170, *Aspergillus fumigatus* ATCC 26934, *Aspergillus niger* ATCC 9029, *Trichophyton mentagrophytes* ATCC 9972, *Trichophyton rubrum* C113, *Microsporum gypseum* C115 and *Candida tropicalis* C131 were grown on Sabouraud-chloramphenicol agar slants for 48 h at

30 °C. Cell suspensions in sterile distilled water were adjusted to give a final concentration of 10^6 viable yeast cells/mL [34].

The strains were maintained on slopes of Sabouraud-dextrose agar (SDA, Oxoid) and subcultured every 15 days to prevent pleomorphic transformations. Spore suspensions were obtained according to reported procedures [34] and adjusted to 10^6 spores with colony forming ability/mL.

2.4. Antifungal assays

The antifungal activity was evaluated with the agar dilution method by using Sabouraud-chloramphenicol agar for both yeast and dermatophyte species as previously described [35,36]. Stock solutions of compounds (10 mg/mL in DMSO) were diluted to give serial twofold dilutions that were added to each medium resulting in concentrations ranging from 0.10 to 250 mg/mL. MIC for each compound was defined as the lowest concentration that produces no visible fungal growth after the incubation time. Amphotericin B (Janssen Pharmaceutica, Belgium), Ketoconazole (Sigma Chemical Co., St. Louis, MO, USA) and Terbinafine (Novartis, Bs. As., Argentina) were used as positive controls.

2.5. Preparation of the complexes

2.5.1. $[Co(II)(ST)_2(H_2O)_4]$ (1)

10 mL of an aqueous solution of cobalt chloride containing 0.2377 g (1 mmol) of $CoCl_2 \cdot 6H_2O$, was added dropwise to 20 mL aqueous solution of sulfathiazole as the sodium salt, NaST, containing 0.6101 g NaST (2.2 mmol), with stirring at room temperature [2,21]. Immediately, the resulting mixture became blue, because a blue precipitate was formed. Then, the reaction mixture was left to stand at room temperature, away from light. After 4 days the precipitate, which turned into a pink solid, was centrifuged, washed with water several times, filtered off and dried under vacuum, away from light. Yield: 0.567 g, 88.6%.

2.5.2. $[Co(II)(ST)_2(H_2O)_3]_n$ (2)

After several attempts, when the concentrations of both reactive solutions for the obtainment of (**1**) were twice that reported above, the pink precipitate, left in the mother solution between 7 and 10 days, changed into little single red crystals (**2**), suitable for X-ray structural analysis. After 10–12 days, the red crystals were centrifuged, washed with water several times, filtered off and dried under vacuum, away from light. Yield: 0.547 g, 88.0%. Elemental analyses of the red crystals gave satisfactory results for $Co(II)(ST)_2(H_2O)_3$. Found (calc. for $CoC_{18}H_{22}N_6S_4O_7$): C, 34.1 (34.8); H, 3.0 (3.6); N, 13.3 (13.5); S, 21.2 (20.6); Co: 10.2 (9.5). It was not possible to obtain (**2**) from suspensions of (**1**) in water, in the presence and absence of: NaST and NaST plus Co(II), in several concentrations, left about 20 days at room temperature.

3. Results and discussion

3.1. General physicochemical characteristics of (1)

Elemental analyses of the pink powder gave satisfactory results for $Co(II)(ST)_2(H_2O)_4$. Found (calc. for $CoC_{18}H_{24}N_6S_4O_8$): C, 34.2 (33.8); H, 3.2 (3.8); N, 13.0 (13.1); S, 19.8 (20.1); Co: 9.9 (9.2). Compound (**1**) is only slightly soluble in water at room temperature (38 mg/100 mL), but it is soluble in DMSO. In a HCl 1 M solution it suffers hydrolysis, and turns brownish in NaOH 1 M solution, maybe due to oxidation by means of the atmospheric oxygen.

3.2. Crystal description of (2)

The structure of the complex (**2**), $[Co^{II}(ST)_2(H_2O)_3]_n$ as determined by means of X-ray diffraction, resulted in a polymeric chain along the 101 direction. The repeating unit of this chain is a monomeric entity built up of one cobalt atom bonded to three nitrogen atoms from three different ST ligands, N1 of a hanging ST monodentate ligand, N(4) of a bridging ST group and N(6) coming from a neighboring monomeric unit. Completing the coordination sphere three oxygen atoms from water molecules were found (Fig. 2). The cobalt atom exhibits a distorted octahedral coordination sphere. The basal plane of this octahedral sphere is formed by Co(1) N(1) N(4) O(6) N(6A) (with a minimum plane deviation of 0.0174 Å); O(5) and O(7) occupy the apical positions. The Co–O bond distances vary between 2.109 and 2.195 Å and the Co–N distances vary

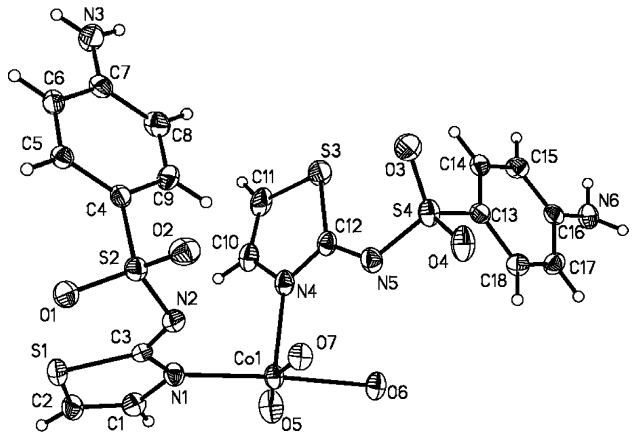

Fig. 2. Structure and atom numbering scheme for (**2**). XP view (Sheldrick, 1994), thermal ellipsoids at 50% probability level.

from 2.114 to 2.220 Å. A selected list of interatomic bond distances and angles are given in Table 2. The bond distances Co–O_{water} and Co–N found are similar to that in other cobalt(II) complexes, e.g., the Co–O_{water} bond distance is 2.090 Å in the complex [Co(L-threonine)$_2$(H_2O)$_2$] [37]. Co–N bond distances vary from 2.039 Å (Co–N_{NCS}) to 2.1951 Å (Co–N_{amino}) in the complex [Co(sulfacetamide)$_2$(NCS)$_2$] [1]. For the complex of cobalt(II) with sulfamethizolate, smtz, and pyridine, py, [Co(smtz)$_2$(py)$_2$(H_2O)], the Co–O_{water} bond distance is shorter (2.0457 Å) than in (**2**) and shorter than the Co–N distances (both $N_{thiadiazole}$ and N_{py}) in the same complex, because its geometry is a distorted octahedral one, with two sulfamethiazolate ligands in the equatorial sites and two water O atoms in the apical positions [38]. In the polymer {[Zn(smtz)$_2$(py)·H_2O]}$_\infty$, the Zn–$N_{thiadiazole}$ bond distances (1.962 and 1.989 Å) are slightly shorter than the Zn–N_{amino} ones (2.070 Å) [39], which is similar to that found in the complex Co(II)–ST (**2**). This fact seems to suggest that the thiazole N atom is able to bind the Co(II) ions much closer compared to the amino N atom, which can be due to the increase of the negative charge on the thiazole ring N atom as a consequence of the charge delocalization through the thiazole ring upon the deprotonation of the sulfonamido group [39].

The chains interact with each other by means of hydrogen bonding, involving the hydrogen atoms of the amino group of the hanging ST monodentate ligand and oxygen atoms of the sulfonamide group belonging to bridging ST group from a nearby chain [H3A···O3 = 2.512 Å, H3A···O4 = 2.680 Å] and also with an oxygen atom from a hanging ST monodentate ligand of the same nearby chain [H3B···O2 = 2.151 Å]. This hydrogen bonding scheme repeats throughout the complete crystal structure (Fig. 3).

3.3. Infrared spectra

IR selected spectral data of the Co(II)–ST complexes (pink powder and red crystals) and the ligand (as sulfathiazole and its sodium salt) are presented in Table 3.

In the 3600–3000 cm^{-1} region, broad bands appear for NaST and Co(II)–ST (both pink powder and red crystals) due to the presence of hydration water [40,41]. The strong band at 1536 cm^{-1}, attributed in the sulfadrug to the thiazole ring vibration, was shifted to lower frequencies. This fact is in agreement with the interaction through the $N_{thiazole}$ atom [42]. In the two cobalt compounds the bands attributed to the SO_2 vibrations remain unaltered, suggesting no interaction of the –SO_2-group with the metal ion. This was confirmed for (**1**) by Raman spectroscopy: the symmetric stretching located at 1123 cm^{-1} increased its intensity as expected. According to the observed changes in the IR spectra of (**1**) and (**2**) it is possible to infer that the thiazole nitrogen atoms might be sites of coordination of the cobalt atom with the sulfathiazolato anions in

Table 3
Assignment of the vibrational spectra (frequency: υ, cm^{-1}) of sulfathiazole (HST), its sodium salt (NaST) and its Co(II) complex (Co(II)–ST), as pink powder (**1**) and red crystals (**2**)

both complexes. This conclusion is consistent with related systems containing sulfathiazole and different metal ions [21,43–46]. The differences that are noted in the region between 4000 and 3000 cm^{-1} of the IR spectra of (**1**) and (**2**) are probably due to differences in the coordination of the amino group in both complexes.

3.4. Thermogravimetric behavior

The thermal behavior of compounds HST and Co(II)–ST (**1**), pink powder, are shown in Fig. 4. The thermal degradation of sulfathiazole proceeds in four different stages. The first decomposition process takes place between 10 and 296 °C with about 18.4% weight loss (DTA signals: 175 °C (endo, w) and 207 °C (endo, w)). Upon further heating, the sample loses mass in two steps ($\Delta\omega$ = 8.6% and 6.1%) up to 425 °C, then the decomposition speeds up suddenly with a strong DTA signal at 514 °C (exo, s), giving volatile products.

In the case of Co(II)–ST (**1**), the sample first loses weight corresponding to four water molecules (observed 11.2%, calculated 11.3%) between 15 and 210 °C, DTA: 125 °C (endo, vw). On further heating the decomposition occurs in the range 210–1000 °C, showing that there are at least four chemical processes in progress, associated with three exothermic signals at 287 °C (exo, vw), 466 °C (exo, vw) and 576 °C (exo, vs). The final product, Co_2O_3, could be identified based on its IR spectrum. The final formation of Co_2O_3 entails $\Delta\omega$ = 87% in agreement with the experimental determination. Therefore, the following general decomposition scheme can be formulated:

$$[Co(ST)_2(H_2O)_4] \xrightarrow{\phi,O_2} Co_2O_3 + \text{other volatile products}$$

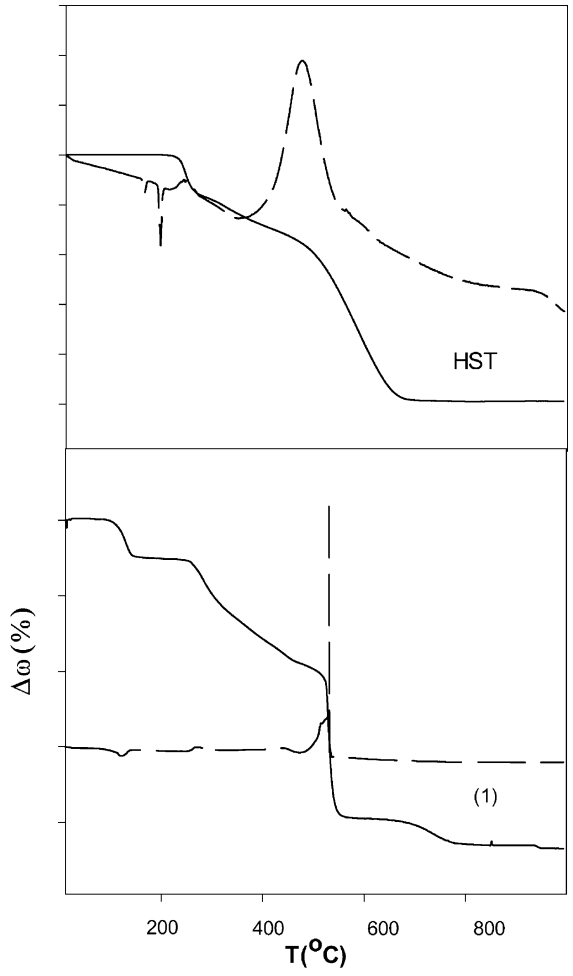

Fig. 4. TG (—) and DTA (- - -) traces for the thermal decomposition of HST and (**1**) system (O_2 flow = 60 cm^3/min, heating rate: 10 °C/min).

3.5. Magnetic behavior

The measured μ_{eff} for Co(II)–ST (1), 4.63 BM, is in the range of 4.1–5.2 BM according to the values expected for a d^7 (s = 3/2) system with spin–orbit coupling [47].

3.6. Electronic spectra

Electronic spectra of complexes can provide valuable information related to bond and structure, since the colors are intimately related to the magnitude of the spacing between d-orbitals (e_g and t_{2g} or e and t_2 orbitals in octahedral and tetrahedral complexes, respectively), which depends on factors such as the geometry of the complex, the nature of the ligands present and the oxidation state of the central metal atom [47].

The diffuse reflectance spectrum was measured in the 400–900 nm range. The spectrum of Co(II)–ST (**1**) suggests an octahedral geometry around the metal ion [48]. There can be observed two of the three possible electronic transitions: $\nu_2[^4T_{1g} \rightarrow {}^4A_{2g}]$ = 610 nm and $\nu_3[^4T_{1g} \rightarrow {}^4T_{1g}(P)]$, multiple structured at 532, 480 (sh) and 435 (sh) nm. The $\nu_1[^4T_{1g} \rightarrow {}^4T_{2g}]$ transition is expected at 1300 nm, outside the measured range.

3.6.1. Electronic spectra in solution

The wavelength of the absorption maxima, in nm, and their respective molar absortivity (ε, in $M^{-1}\,cm^{-1}$) are summarized for both (**1**) and $CoCl_2\cdot 6H_2O$ in methanol and DMSO solutions in Table 4.

The electronic spectrum produced by $CoCl_2\cdot 6H_2O$ in methanol seems very similar to that arising from the octahedral $[Co(H_2O)_6]^{2+}$ complex in water [49]. The major differences between the spectra of (**1**) and $CoCl_2\cdot 6H_2O$ are observed in an aprotic solvent, DMSO, where the two bands observed ($\lambda 1$ and $\lambda 2$) are shifted to lower wavelength for (**1**). The absortion maxima for cobalt chloride in DMSO occur at 615 and 679 nm. The absortion maxima of (**1**) are shifted to lower wavelength respect to the maxima corresponding to $CoCl_2\cdot 6H_2O$,

Table 4
Electronic spectra in solution

Compound	Solvent							
	Methanol				DMSO			
	$\lambda 1$	$\varepsilon 1$	$\lambda 2$	$\varepsilon 2$	$\lambda 1$	$\varepsilon 1$	$\lambda 2$	$\varepsilon 2$
$[Co(II)(ST)_2(H_2O)_4]$ (**1**)	531	33	620 (sh)		539	158	584	213
$CoCl_2 \cdot 6H_2O$	528	8	668	3	615	127	679	185

suggesting an increase in the ligand field strength [50]. Because their ε value in a protic solvent, the two spectra suggest an octahedral environment around the Co(II) ion, while for (**1**) in DMSO there is a tetrahedral arrangement around the Co(II) ion. Comparing both the color of the DMSO solution of (**1**) and the precipitate obtained in the first moment (which turn in a spontaneous way into the pink solid (**1**)), it is possible to suggest that the blue unstable solid obtained as the initial precipitate, could have a tetrahedral geometry around the Co(II) ion.

3.7. EPR measurements

X-band EPR spectra of a frozen DMSO solution of (**1**) and (**2**) were recorded at 77 K. Both spectra were very similar. The isotropic g value is close to 2.9. The hyperfine structure expected for the 100% abundant ^{59}Co isotope ($^{59}I = 7/2$) is not observed in the spectra of both samples (pink solid (**1**) and red crystals (**2**)). This suggests that the magnitude of the exchange interaction between Co(II) ions is larger than the magnitude of the hyperfine coupling parameter A, so the hyperfine structure collapses and gives a single collapsed peak [37]. The collapse of the hyperfine structure produces the observed Lorentzian line shape. A similar line shape EPR spectrum was observed for a complex of Co(II) and citric acid, at pH $\cong$ 5, in the form of its K^+ salt, at 4 K, which would produce mononuclear octahedral Co(II)–citrate species [51]. In the EPR spectrum of Co(II)–ST it is possible to observe a shoulder of the main resonance at a g value of ca. 3.4, which is absent in the Co(II)–citrate one. It might be probably due to the presence of N-atoms coordinated to cobalt in Co(II)–ST, in addition to O-atoms, while in Co(II)–citrate, there are only O-atoms coordinated to Co(II). Another difference with respect to the citrate system is that the resonance of Co(II)–ST is observable at 77 K, which suggests minor intensity of relaxation effects in the sulfathiazole system.

3.8. Antifungal activity

Some metal complexes of sulfadrugs promote rapid healing of skin disorders (e.g., the Ag(I)- and the Zn(II)-sulfadiazine) in preventing bacterial infection in burnt animals [52]. In addition to its well-known antibacterial activity, silver sulfadiazine was recently reported to possess strong antifungal properties [53], which makes it a clinically widely used topical agent for the treatment of wound and burnt infections [54].

Although several classes of antifungal compounds are presently available, resistance to these drugs constantly emerges [55] and it is of crucial importance to investigate new types of antifungal agents in order to prevent this serious medical problem. Metal ions (such as Zn(II)) or metal complexes with putative clinical applications were extensively studied in recent years [56]. Complexes of silver and zinc sulfonamides (and some cerium derivatives) have successfully been used for the last 20 years for the prophylaxis and treatment of microbial and fungal burnt wound infections and they seem to constitute a valuable alternative for resolving the resistance problem [57,58]. Results of the antifungal assay with (**1**) (and NaST in order to compare with the ligand) are showed in Table 5. Only the two species of the *Aspergillus* genus tested were susceptible to both compounds.

When tested against *A. fumigatus*, both compounds, Co(II)–ST (**1**) and NaST, showed the same MIC values suggesting that the activity could be due to the sulfathiazole moiety. In contrast, it is interesting to note that compound (**1**) inhibits *A. flavus* while the ligand NaST does not. This difference in activity could be due to the presence of the metal in the complex which, according with previous reports, might exert its antifungal action by inhibition of enzymes that are involved in the biosynthesis of cell walls of fungi [59].

Table 5
MIC values (μg/mL)[a] of sodium sulfathiazole (NaST) and the Co(II)–sulfathiazolate complex $[Co^{II}(ST)_2(H_2O)_4]$ (**1**) acting against human opportunistic pathogenic fungi

	NaST	(**1**)	Amp	Ket	Terb
C. albicans	>250	>250	0.75	0.50	
C. tropicalis	>250	>250	0.50	0.125

4. Conclusion

The reaction between sulfathiazole and cobalt(II) leads to two stable compounds, obtained in sequencial steps, whose molecular formulas differ from each other by one water molecule. The IR spectra of both compounds differ in the region of the signals of the amino group. The 6th position around Co(II), which in (**2**) is filled with the amino group of a sulfathiazolate moiety – acting as a bidentated ligand – would be filled with a water molecule in (**1**).

The metal complex Co(II)–ST (**1**) displayed a moderate antifungal activity against both species of *Aspergillus* tested. This activity was showed to be the same as that of the corresponding ligand NaST against *A. fumigatus* but interestingly, it marked an important difference with the antifungal behavior of NaST against *A. flavus*, which was not inhibited by the ligand up to 250 μg/mL.

Received 15 June 2004; accepted 8 December 2004

Abstract

The formation of transition metal complexes between dichlorocopper(II) and a poly(4-vinylpyridine)/divinylbenzene(2%) polymeric matrix is described in this contribution. The nitrogen atom of the pyridine groups of the organic polymer is coordinatively bonded to the Cu center as suggested by X-ray photoelectron spectroscopy (XPS), UV–vis/diffuse reflectance (UV–vis/DR), electron paramagnetic resonance (EPR), differential scanning calorimetry (DSC) and Fourier transform infrared (FT-IR) techniques. The immobilized catalyst was also characterized by DTA-TGA analysis and the morphology and elemental analysis of this copper/poly(4-vinylpyridine) complex were studied by the scanning electron microscopy/energy dispersive X-ray (SEM/EDX) technique. This material catalyzes the water gas shift reaction as well as the reduction of nitrobenzene to aniline and azobenzene.

1. Introduction

The characterization of ion-containing polymers has been the subject of numerous investigations. It has been demonstrated that the themophysical properties of polymeric ligands can be modified by coordination to transition metal complexes [1,2].

The $CuCl_2 \cdot 2H_2O$ salt is an attractive candidate to form coordination complexes with the pyridine moieties of poly(4-vinylpyridine). For example, a soluble Cu–pyridine complex of the type $CuCl_2(py)_2$ complex is known [3].

Studies in our laboratories have long been concerned with the use of the rhodium (I) complexes $[Rh(COD)(amine)_2](PF_6)$ (amine = pyridine, 2-picoline, 3-picoline, 4-picoline, 3,5-lutidine or 2,6-lutidine) immobilized on poly(4-vinylpyridine)/divinylbenzene(2%) as catalyst precursors for various chemical reactions (namely, water gas shift reaction (WGSR) [4,5], reduction of nitrobenzene [6,7] and hydroformylation of 1-hexene [8,9]) due to their easy preparation, good stability and high or moderate catalytic activities. The granular nature of this polymer and its insolubility in all organic solvents allows for it isolation by simple filtration [10].

doi:10.1016/j.poly.2004.12.014

We previously reported the homogenous catalysis of the WGSR by copper dichloride dissolved in aqueous substituted pyridine (methyl and dimethyl pyridines) solutions [11]. For example, TF(H_2) of about 6 mol/day for [Cu] = 20 mM (2.0×10^{-4} mol), P(CO) = 1.9 atm at 120 °C was observed for the more active 4-picoline (4-methylpyridine) system. In the course of continuing to explore similar systems in our laboratories it became a matter of interest to study the Cu/P(4-VP) system because it is known that the most commercial active heterogeneous system catalyst for the WGSR contains a mixture of copper and zinc oxide [12].

In the present study, we extend the use of the poly-(4-vinylpyridine)/divinylbenzene(2%) polymeric matrix instead of pyridine as a ligand coordinated to $CuCl_2$ salt. Here, we report the preparation, the characterization by XPS, UV–vis/DR, EPR, DSC, FT-IR, DTA-TGA and SEM/EDX techniques and the catalytic activity of P(4-VP)-immobilized $CuCl_2$ on the water gas shift reaction and the reduction of nitrobenzene.

2. Experimental

2.1. Materials

2-Ethoxyethanol (Aldrich) was distilled from anhydrous stannous chloride. Water was doubly distilled. Poly(4-vinylpyridine)/divinylbenzene(2%) (P(4-VP)), was used as provided by Reilly Industries. Nitrobenzene (Aldrich) was distilled in H_2SO_4 (1 M) and redistilled from $CaCl_2$ prior to use. All gas mixtures He/H_2 (91.4%/8.6%, v/v), CO/CH_4 (95.8%/4.2%, v/v) and CO/CH_4/CO_2/H_2 (84.8%/5.1%/5.3%/4.8%, v/v) were purchased from BOC Gases and were used as received. Dichlorocopper(II) salt (Merck) was used as received.

2.2. Instrumentation

The UV–vis spectra of the solutions (1 cm quartz cell) and of the solids (Labsphere RSA-PE-20 diffuse reflectance cell) were recorded on a Perkin–Elmer Lambda 10 spectrophotometer. Infrared spectra were recorded on a Perkin–Elmer 1760X-FT spectrophotometer using KBr pellets for solid samples. Electron paramagnetic spectroscopy experiments were carried out in a conventional Varian E-line X-band spectrometer, using a rectangular cavity operating in the TE 102 mode. The scanning electron micrographs were recorded on a Hitachi S-500 microscope with an energy dispersive X-ray detector. The thermal behavior studies were carried out using a TA Instruments SDT 2960 Simultaneous DTA-TGA analyzer. Glass transition temperatures were measured on a Perkin–Elmer DSC 7 at a rate of 20 °C/min under a nitrogen purge.

Photoelectron spectra of the solid were recorded with a VG-220i-XL ESCALAB spectrometer using monochromatized X-ray Mg Kα radiation (1235.6 eV). The solid was mounted on a standard sample stud. Nominal resolution was measured as full-width at half-maximum of 1.0 (core-level spectrum) to 1.5 eV (survey spectrum). The analyzed core-level lines were calibrated against the C 1s binding energy set at 285 eV of CH_x neutral carbon. The signals were deconvoluted using mixed Gaussian–Lorentzian curves where the Gaussian character was set at 80%. Since the Cu_{2p} line is rather insensitive to the oxidation state of copper (the Cu $2p_{3/2}$ component is at: 932.6, 932.5, 933.7 and 935.1 eV for Cu, Cu_2O, CuO and $Cu(OH)_2$, respectively), it is important to follow the energy position of the LMM Auger line of Cu.

Gas samples analyses from catalytic runs were performed as described in detail previously [4] on a Hewlett–Packard 5890 Series II programmable (ChemStation) gas chromatograph fitted with a thermal conductivity detector. The column used was Carbosieve-B (80–100) mesh obtained from Hewlett–Packard using a He/H_2 mixture as the carrier gas.

2.3. Complex preparation

A mixture of 0.5 g of P(4-VP) and 0.0341 g (2.0×10^{-4} mol) of $CuCl_2 \cdot 2H_2O$ dissolved in 10 mL of 80% aqueous 2-ethoxyethanol was stirred for 72 h in air until about 99% of the copper was extracted by the polymer from the solution as determined by UV–vis spectrophotometry. The amount of the absorbed copper on P(4-VP) was determined by subtracting the initial amount of copper salt from the unabsorbed one. The resulting blue polymer was filtered, washed with 5 mL of 2-ethoxyethanol/H_2O 8/2, v/v, and dried in vacuum at room temperature. This material will be referred herein as Cu/P(4-VP).

2.4. Catalyst testing

WGSR catalytic runs were conducted in all-glass reactor vessels consisting of a 100 mL round bottomed flask connected to an "O" ring sealed joint to a two-way Rotoflow Teflon stopcock attached to the vacuum line [4]. In a typical run, the loaded polymer beads and 10 mL of 80% aqueous 2-ethoxyethanol were added to the glass reactor vessel, then the solution was degassed by three freeze–pump–thaw cycles. The reaction vessel was charged with a CO/CH_4 mixture at the desired CO partial pressure (1.4 atm at 25 °C, but 1.9 atm at 110 °C), and then suspended in a circulating thermostated glycerol oil bath set at 110 °C for 8–48 h. The specified temperature was maintained at ±0.5 °C by continuously stirring the oil bath as well as the reaction mixture which was provided with a Teflon-coated magnetic stirring bar. Gas samples (1.0 mL) were ana-

lyzed by GC at the end of the reaction time. Methane was used as internal standard to allow calculation of absolute quantities of CO consumed and H_2 and CO_2 produced during a time interval, with calibration curves being prepared periodically for CO, CH_4, H_2, and CO_2, and analyzing known mixtures checked their validities.

Nitrobenzene reduction catalytic runs were conducted in a 150 mL mechanically stirred stainless steel Parr reactor. In a typical run, 0.5 g of the Cu/P(4-VP) solid, 10 mL of 80% aqueous 2-ethoxyethanol and 1.2 mL (8.1×10^{-3} mol) sample of nitrobenzene were added to the reaction vessel. Subsequent to the addition of nitrobenzene, the Parr reactor was charged with the CO/CH_4 mixture (27.2 atm partial CO pressure at 150 °C) and placed in the oil bath at 150 °C for 4–72 h. After a given time, the reaction was stopped, the reactor cooled to room temperature and excess pressure was vented and products analyzed by GC and GC–MS. A response factor method for the GC analyses of the aniline was employed [13]. The GC–MS of the aniline (molecular ion peak at $m/e = 93$ and base peak at $m/e = 65$) and azobenzene (molecular ion peak at $m/e = 182$ and base peak at $m/e = 77$) products is similar to a pure sample of aniline and azobenzene, respectively. Also the organic products were separated by column chromatography and analyzed by ^{13}C and ^{1}H NMR in a Jeol Eclipse 270 NMR spectrometer.

3. Results and discussion

3.1. General aspects

Dissolution of a solid sample of $CuCl_2 \cdot 2H_2O$ (0.0341 g, 2.0×10^{-4} mol) in 10 mL of 80% aq. 2-ethoxyethanol at room temperature leads to the gradual formation of a green–blue solution. This solution in contact with 0.5 g of P(4-VP) under continuous stirring for 72 h in air at room temperature gradually leads to formation of a blue solid material and a colorless solution.

After charging the mixture formed by the Cu/P(4-VP) ([Cu] = 2.5 wt%) blue solid and 10 mL of 80% of aqueous 2-ethoxyethanol with CO (1.9 atm) and heating the reaction vessel and its content at 110 °C in a glycerol bath, the blue solid first changed to a light-blue color, then (over 1–5 min) to a yellow color and to a final light brown–green color, characteristic of the mature catalyst system. The solution above the light brown–green solid remains uncolored.

3.2. Characterization studies

Kirsh et al. [14] reported the characterization by EPR and UV–vis spectroscopies of the water-soluble $CuCl_2$/P(4-VP) system. The P(4-VP) employed in their study was not cross-linked with any copolymer, allowing its solubility in water. They observed the formation of tetrapyridine–Cu(II) complexes, $[CuL_4]^{2+}$ (L = a nitrogen atom of the P(4-VP)). Coordination of the nitrogen atom of the pyridine moiety to the Cu(II) center was proposed. Also, G. Jeschke, provided for this soluble copper (II) complex of poly(4-vinylpyridine) a model for the geometry of the first coordination sphere supported by a combination of EPR, electron-nuclear double resonance methods (ENDOR) and molecular modelling techniques, and found that the structure of this copper complex derives from the propeller structure of $Cu(pyridine)_4$ mainly by rotation of the ligand pyridine rings with a modest tetrahedral distortion [15]. On the other hand, the addition of 2% of divinylbenzene to the poly(4-vinlypyridine) polymer makes the latter insoluble in water and in all organic solvents.

In this section, the results of SEM/EDX, UV–vis/DR, EPR, FT-IR, XPS, DTA-TGA and DSC techniques, which were used to determine the nature of the water insoluble $CuCl_2$/P(4-VP)/divinylbenzene(2%) immobilized species, are discussed.

The SEM with energy dispersive X-ray (EDX) technique was used for studying the morphology of the solid samples. We previously reported a SEM micrograph of a P(4-VP) sample, from which it can be observed that the P(4-VP) is formed by agglomerates of grains with a smooth surface [6]. Fig. 1 corresponds to the micrograph of the solid product of the reaction of P(4-VP) with the $CuCl_2 \cdot 2H_2O$ salt in contact with 80% aqueous

Fig. 1. Scanning electron micrograph of the Cu/P(4-VP) fresh catalyst sample. Magnification 5000×.

2-ethoxyethanol after 72 h of stirring in air. The elemental analysis revealed Cu and Cl in the etched areas. The same type of analysis of the smooth regions, whose morphology had not been modified, did not show the presence of Cu and/or Cl. The observed modifications in some areas on the surface of the polymeric insoluble ligand can be attributed to the anchoring of the Cu(II) center to the P(4-VP).

The UV–vis spectrum of $CuCl_2 \cdot 2H_2O$ dissolved in 80% aqueous 2-ethoxyethanol and the UV–vis/DR spectrum of the Cu/P(4-VP) blue solid sample show the displacement of the d–d transition band from 246 to 384 nm after the immobilization process. The significant difference in the d–d transition bands between the solution and the solid would be a consequence of a different coordination environment around copper (II). Efforts to obtain the UV–vis/DR spectrum of the Cu/P(4-VP) light brown–green solid were unsuccessful inasmuch that this solid undergoes oxidation to produce the blue cupric polymer-complex during the handling procedures. However, the fact that the used catalyst has a light brown–green color suggested that Cu(II) is the predominant oxidation state. It has been stated that Cu(I) complexes would be colorless since d–d electronic transitions are not feasible to take place in a d^{10} system, and metal-to-ligand charge transfer possible for d^{10} complex with aromatic structure also does not occur in the visible region of the spectrum [16].

EPR experiments show signals (Fig. 2(a)) for the Cu/P(4-VP) ([Cu] = 2.5 wt%) fresh catalyst (blue-colored solid) and these indicate the presence of copper(II) d^9 paramagnetic species in this system as expected. Similar EPR behavior was observed on reaction of $CuCl_2 \cdot 2H_2O$ with 4-picoline and 2-picoline [11]. Fig. 2 also shows the EPR spectrum of the used catalyst (light brown–green colored solid) of the same system (b) in the presence of CO. The EPR result is similar to the one observed for the Cu/P(4-VP) (blue-colored solid) system mentioned above. The samples of both did not have the same amounts of Cu/P(4-VP) as a result of handling procedures. In spite of that, the amplitude of both spectra are the same, the amount of the fresh catalyst sample (blue solid) is roughly half that the used catalyst (light brown–green solid). For that reason the intensity of spectrum (a) is smaller than the other spectrum. However, the widening of the spectrum (a) is larger than spectrum (b). The observed strong EPR signal in the used catalyst indicates the presence of copper(II) d^9 species, even though this solid was formed under CO/H_2O mixture at the working temperature. Under these reaction conditions the expected reduction of Cu(II) d^9 paramagnetic species to Cu(I) d^{10} non-paramagnetic species by the CO/H_2O mixture (as reported in the homogeneous $CuCl_2$/aqueous 4-picoline or 2-picoline systems under CO [11]) was not observed. In spite of the presence of the Cu(II) d^9 species at high concentration in the light brown–green solid, both spectra are dissimilar due to different molecular environments that surround the Cu(II) center in both solids. Based on these EPR results it is reasonable to propose the existence of at least two kinds of Cu(II) species in the blue-colored fresh catalyst. Under the CO/H_2O mixture at the working temperature, one of the Cu(II) species is relatively easily reduced to Cu(I) and the other Cu(II) species remains unreduced.

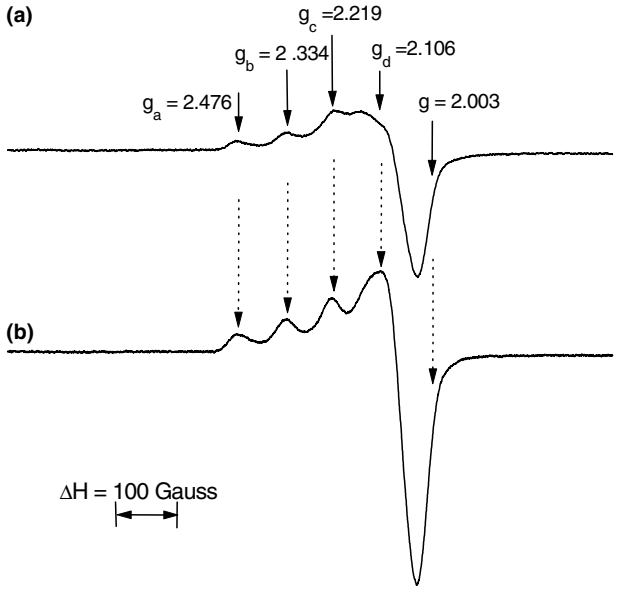

Fig. 2. EPR spectra in the 2500–3500 G region of: (a) Cu/P(4-VP) fresh catalyst; (b) Cu/P(4-VP) used catalyst.

Pomogailo and Golubeva [17] carried out magnetic susceptibility measurements and EPR spectroscopy to study the distribution of cupric ion attached to a polyethylene-grafted poly(acrylic acid) support (PE-gr-PAA). Their EPR studies revealed changes in the form of the EPR spectrum upon increasing the copper concentration in the PE-gr-PAA matrix. For example, a broad asymmetric singlet is observed which increases steadily in intensity as well as in width with increasing copper(II) content. These data indicate the proximity of the structure of Cu(II) polymer-complexes and also suggests the existence of an increase in dipole–dipole interactions between them. The temperature dependence of the magnetic susceptibility as a function of copper content also supports the conclusion of the existence of three types of copper(II) complexes: (1) isolated complexes (type-I) (2) complexes bonded by dipole–dipole interactions (type-II) and (3) clusters with strong exchange interactions (type-III).

The observed narrowing in the width of the hyperfine bands with decreasing Cu(II) content (due to its reduction to Cu(I) by the CO/H_2O couple) seen in the EPR spectrum (b) of our Cu(P-4VP) system is probably due to the existence of the same type of dipole-dipole inter-

action between copper centers described by Pomogailo and Golubeva (type-II complexes). Also our EPR results include the existence of isolated Cu/P(4-VP) complexes (type-I complexes). However, the copper concentration (2.5 wt%) used in our studies is not high enough to form clusters with strong exchange interactions (type-III complexes). The study of the magnetic susceptibility of this Cu/P(4-VP) system, which constitutes an appropriate method for determining the copper valence will be explored in future investigations.

The FT-IR spectrum (KBr pellet) of a P(4-VP) sample shows one C–N ring stretching band (n_{C-N}) at 1596(m, broad) and side group absorption bands (C–C ring stretching vibrations) at 1554(m), 1493(m), 1449(m) and 1415(m, broad) cm^{-1}. On the other hand, the FT-IR spectrum of fresh prepared KBr pellets of $CuCl_2$/P(4-VP) ([Cu] = 2.5 wt%) also shows the same bands, but three of them (1596, 1493 and 1449 cm^{-1}) shifted by ca. +3 cm^{-1}. The slight blue shift observed in the n_{C-N} of Cu/P(4-VP) could indicate N-coordination of the P(4-VP) polymer to the metal [2,16,18]. Unfortunately, a comprehensive molecular explanation is not available.

After charging the Cu/(P4-VP) blue solid with CO atmosphere (1.9 atm) in contact with 10 mL of 80% aqueous solution of 2-ethoxyethanol and heating the reaction vessel in a 110 °C glycerol bath for 6 h, the blue solid changed to a light brown–green color characteristic of the mature catalyst system. The FT-IR spectrum (KBr pellets) of the light brown–green color mature Cu/P(4-VP) catalyst sample shows one band in the v_{CO} region at 2068 cm^{-1} (carbonyl-linear Cu species) suggesting the presence of a single carbonyl copper species [11] anchored to the nitrogen-functionalized polymer. Also, the infrared spectrum of the light brown–green solid shows the v_{C-N} band at 1598 cm^{-1} and the side group absorption bands (C–C ring stretching vibrations) at 1556(m), 1495(m), 1451(m) and 1415(m, broad) cm^{-1}. A slight blue shift of ca. +2 cm^{-1} in the v_{C-N} and the side group absorption bands is observed. However, the presence of the coordinated-CO decreased the blue shift due to the back-bonding donation of dπ atomic orbital of the Cu to the π*-antibonding molecular orbital of the CO, which leads to a competition for electronic density with the π-bonding molecular orbitals of the pyridine ring. Further, a band at 3385 cm^{-1}, characteristic of the coordinated OH group, is observed in both blue and light brown–green solid samples.

Table 1 shows the XPS data for the fresh (blue solid) and used (light brown–green solid) catalysts. The N_{1s} spectrum for free P(4-VP) features a symmetric peak at 399.0 eV. However, the N_{1s} peaks of the fresh and used catalysts are broader and more asymmetric than the one for free P(4-VP), and each peak can be deconvoluted into two peaks, with one at 399.0 eV and the other at 400.3 eV. The peak at 400.3 eV indicates that a fraction of the pyridine nitrogen of the P(4-VP) interacts with the copper cations.

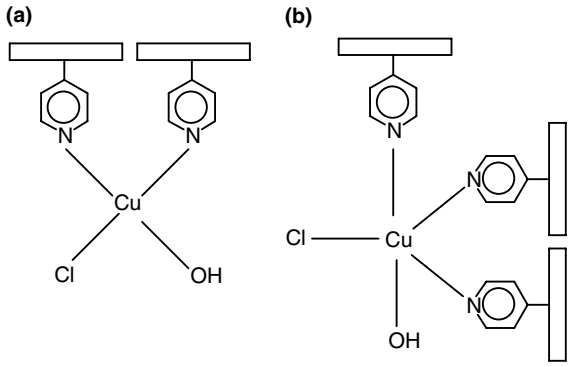
Table 1
XPS data for fresh (blue-colored solid) and used (light brown–green colored solid) catalysts

XPS peak	Binding energy (eV)	
	Fresh catalyst	Used catalyst
N_{1s}	399.0, 400.3	399.0, 400.3
O_{1s}	529.4, 530.4, 531.1	529.4, 530.4, 531.1, 532.0, 533.1
Cl_{2p}	198.0	
C_{1s}	285.0, 285.9	285.0, 284.9
$Cu_{2p3/2}$	933.8	932.5
Cu_{LMM}	569.6	567.8

Two C_{1s} intense peaks are present in the fresh and used catalyst. The first (the main peak) at 285.0 eV, is attributed to the aliphatic carbons of adsorbed contaminants, and the second peak at 285.9 (fresh catalyst) and 284.9 eV (used catalyst) is attributed to carbon linked to the nitrogen atom of the pyridine heterocyclic [19].

The XPS spectrum of the fresh Cu/P(4-VP) catalyst shows $Cu_{2p3/2}$ and Cu_{LMM} peaks at 933.8 and 569.6 eV, respectively, in conjunction with intense shake-up features around 938–945 eV, which are assigned to Cu(II)–OH species [20].

On the other hand, the $Cu_{2p3/2}$ component for the used Cu/P(4-VP) catalyst shows a sharp peak at 932.5 eV and there is no sign of the shake-up features around 938–945 eV, within the detection limits of the XPS technique, and these results suggest the presence of Cu(I) as expected (vide supra). Also, a peak at 567.8 eV was observed, which is typical of metallic copper. It is well known that Cu(I) complexes disproportionate rapidly at ambient temperature to Cu(II) and Cu(0) [21].



Further, the XPS analysis showed O_{1s} lines, for both fresh and used catalyst. The fresh solid presents peaks at 529.4, 530.4 and 531.1 eV, which could be assigned to Cu(II)–O species (e.g., Cu–OH). The O_{1s} peak of the used catalyst is less intense than in the case of the fresh solid. Two additional signals are observed, at 532.0 and 533.1 eV, which could be due to CO (coordinated to Cu) and to water, respectively. Finally, a XPS peak at 198.0 eV (Cl_{2p}) reveals the presence of chloride that is coordinated to the copper in the fresh catalyst.

The atomic ratios $I_N/I_{Cu} = 2.5$, $I_O/I_{Cu} = 1$ and $I_{Cl}/I_{Cu} = 1$ for the fresh catalyst were calculated from the XPS-peaks intensity ratios using the Scofield cross-section relative to each core level [22]. In such calculations it is assumed that the transmission factor T of the spectrometer and the mean free electron path λ are both functions of the kinetic energy, K.E., of the considered photoelectron [23]. The value of 2.5 for the N/Cu ratio indicates that there are at least two different Cu/P-(4-VP) species; one with two and another with three N atoms bonded to the Cu.

Further, the DTA-TGA data (Fig. 3) show that the Cu/P(4-VP) complex is stable at 250 °C, however a weight loss was observed around 100 °C due to the moisture content coming from the preparative method. The differential scanning calorimetry (DSC) technique was used to determine the glass transition temperatures. The poly(4-vinylpiridine)/2% cross-linked polymer, which exhibits a glass transition temperature (T_g) at 127.1 °C, T_g increases by 23.6 °C after the immobilization of 2.5 wt% of Cu(II) as the $CuCl_2 \cdot 2H_2O$ salt. The produced polymeric coordination complex exhibits a synergistic thermal property and it is related to the coordination of the pyridine moieties of P(4-VP) on the coordination sphere of the Cu(II) center. The pyridine, which is classified as a strong base, can displace one or two water molecules from $CuCl_2 \cdot 2H_2O$ and occupy the vacant coordination site on the Cu. Hence is it possible that the Cu bridges two different polymer chains via coordination to the pyridine lone pair, forming coordination crosslinks as suggested by the XPS results. Therefore, hindered mobility of this nature provides a way for the enhancement in the T_g. It is noteworthy that the enhancing of the glass transition temperature of poly(4-vinylpyridine) after coordination to ruthenium [2] and osmium [24] complexes has been reported.

3.3. Proposed structures for Cu/P(4-VP) complexes

The UV–vis, EPR, FT-IR, XPS and DSC results constitute experimental evidences for the formation of a coordination complex between the nitrogen electron lone pair on the P(4-VP) and the copper center in the $CuCl_2$ salt. Based on these spectroscopic results, we therefore, propose the following structures (Scheme 1). The blue-colored solid contains Cu(II) species. On the other hand, the light brown–green colored solid contains Cu(II) and Cu(I) species. The Cu(I) species present in the used catalyst comes from the reduction of the Cu(II)

Scheme 1. Proposed Cu(II) structures in the fresh catalyst.

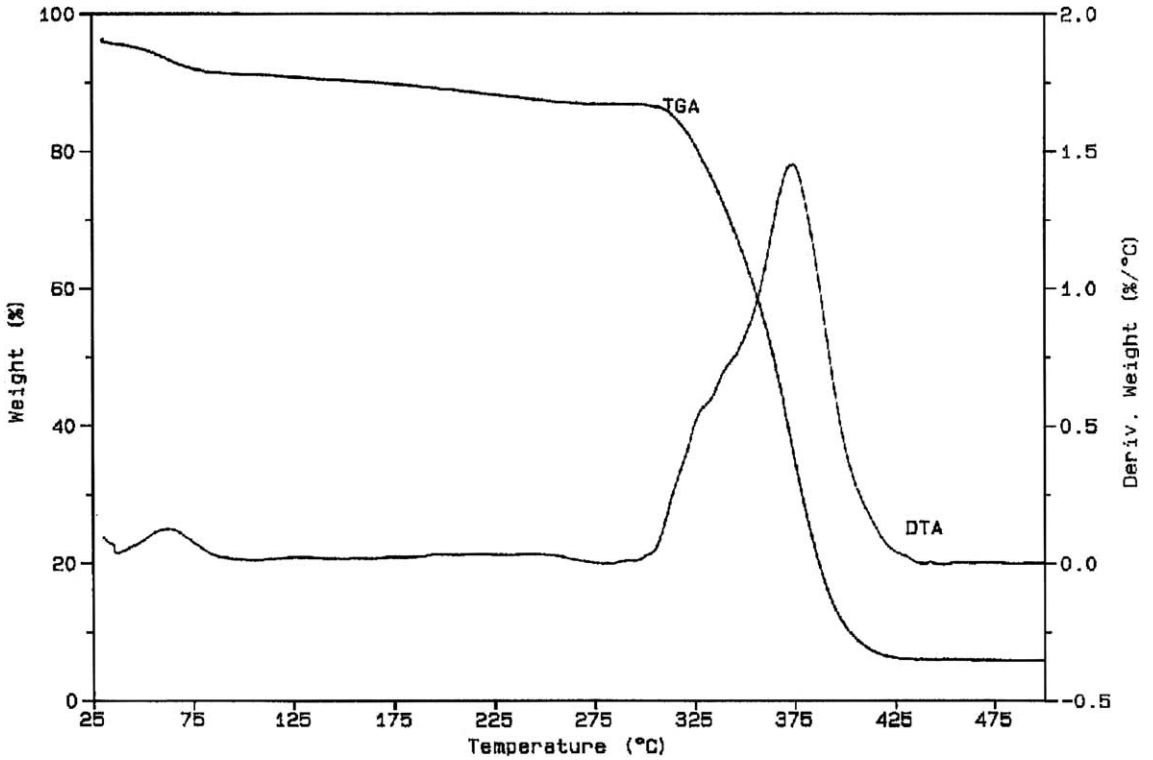


Fig. 3. DTA-TGA curves for the Cu/P(4-VP) fresh catalyst sample.

by the CO/H_2O couple under the catalytic conditions. The ligands coordinated to the Cu(II) d^9 center of the blue-colored solid are Cl^-, vinylpyridine and $(OH)^-$, the last one coming from the hydrolysis of the pyridine residues of P(4-VP). The structures (**a**) and (**b**) correspond to the blue solid. The structure (**a**) has two vinylpyridine groups and the structure (**b**) has three vinylpyridine groups coordinated to the Cu and this assignment is supported by the EPR and XPS results. Also, two and three-coordination of a metal transition ion by coordinating P(4-VP) is well known [2,25]. McCurdie and Belfiore proposed the concept of coordination crosslinks for a metal acting as a bridge between pyridine ligands of two different polymer chains [2]. Based of the DSC results it is likely probable that the Cu(II) species (**a**) and (**b**) are coordinated in a crosslink fashion through the polymeric matrix.

The number of vinylpyridine groups coordinated to Cu(II) and Cu(I) species in the light brown–green colored solid is not known although the Cu(II) and Cu(I) species present in this solid must contain OH^- and CO, and OH^- ligands, respectively. The last assignment is supported by the FT-IR and XPS results.

Although, there is no direct evidence to point which of the two (**a**) and (**b**) copper(II) species of the blue solid is reduced to Cu(I), which further by ligand exchange reaction coordinates a CO molecule. However, Gagné et al. [26] reported the reaction of carbon monoxide with blue $Cu(LBF_2)$ solution at 25 °C (LBF_2 = [difluoro-3,3′-trimethylenedinitrilo-bis(2-butanone oximato)borate]), yielding a yellow solid. The IR and the X ray structure of this yellow solid show a ν_{CO} band at 2068 cm^{-1} and a single monocarbonyl copper(I) with a 20-electron count for the metal atom coordinated to five two-electron donors, $Cu(LBF_2)(CO)$. Accordingly, the similarity in the value of the ν_{CO} band (2068 cm^{-1}) for both Cu(I)–CO/P(4-VP) and $Cu(LBF_2)(CO)$ solids and the absence of an XPS chlorine signal on the Cu(I)–CO/P(4-VP) points to propose that the copper(II) species (**b**) is reduced to Cu(I) by the CO/H_2O couple followed by a substitution of the Cl^- ligand by a CO molecule yielding a five coordinated $[P(4\text{-}VP)_x\text{–}Cu(OH)(CO)]$ ($x = 3$) immobilized species with three vinylpyridine groups (x) bonded to the Cu(I). The structures (**a**) and (**b**) that we proposed for this water insoluble Cu(II)/P(4-VP) system are different from the one proposed for the water soluble copper(II) complex of poly(4-vinypyridine) described at the beginning of Section 3.2. Applications of molecular modelling techniques for our water insoluble system are in progress and their results will be published in a forthcoming paper.

3.4. WGSR catalysis

The copper immobilized complex ([Cu] = 2.5 wt%) in contact with 10 mL of 80% aqueous 2-ethoxyethanol generates a system that shows low catalytic activity for the (WGSR equation (1)) at 110 °C under P(CO) = 1.9 atm. Quantitative analysis of gas samples taken after the reaction solution reached working temperature, indicated that production of H_2 and CO_2 and consumption of CO follow the stoichiometry shown in Eq. (1). The effect of the reaction time on the WGSR catalytic activity was studied. Blank experiments revealed that no WGS reaction occurred in the absence of the catalyst. The activities defined as turnover frequency (turnover frequency (gas) = [(mol of gas)/(mol of Cu) × (rt)] × 24 h, where (rt) is the reaction time in hours) are summarized in Table 2. It is seen that the reaction time variation has no influence on the $TF(H_2)$ and $TF(CO_2)$ values. Also the WGS catalytic activity displayed by this Cu/P(4-VP) system is similar to that showed by the homogeneous $CuCl_2$/amine system described above, under comparable reaction conditions. The catalysis of WGSR by this Cu/P(4-VP) system probably goes through a mechanism similar to that proposed for the $Rh(4\text{-picoline})_2$/P(4-VP)/aqueous 2-ethoxyethanol system [27]. The immobilized carbonyl copper(I), Cu(I)–CO/P(4-VP), species formed under the catalytic conditions plays an important role as a reaction intermediate in the catalytic cycle (namely, it must be subject to nucleophilic attack by water to generate a hydroxycarbonyl copper species, which eventually through successive transformations leads to CO_2 and H_2 WGSR-products).

$$CO + H_2O \rightleftharpoons CO_2 + H_2 \quad (1)$$

3.5. Nitrobenzene reduction catalysis

Immobilized transition metal complexes into polymers combine the good activity, selectivity and reproducibility typical of homogeneous catalysts with the easy product separation and catalyst recovery characteristic of heterogeneous catalysts [28–30].

Table 2
WGSR by $CuCl_2 \cdot 2H_2O$ immobilized on P(4-VP) in contact with 80% aqueous 2-ethoxyethanol[a]

Reaction time (h)	H_2[b] (mol × 10^{-4})	CO_2[b] (mol × 10^{-4})	$TF(H_2)$[c]	$TF(CO_2)$[c]
8	4.5	4.7	6.8	7.1
12	6.6	7.1	6.6	7.0
18	10.2	10.5	6.9	7.0
24	14.6	14.0	7.2	7.1
48	29.2	28.2	7.3	7.0

[a] 0.5 g of P(4-VP), 8 mL of 2-ethoxyethanol, 2 mL of H_2O, [Cu] = 2.0×10^{-4} mol, (2.5 wt%), P(CO) = 1.9 atm at 110 °C.
[b] Based on the gas formed after a given time.
[c] Turnover frequency (gas) = [(mol of gas)/(mol of Cu) × (rt)] × 24 h, where (rt) is the reaction time in hours. Experimental uncertainty ca. 15%.

$CuCl_2 \cdot 2H_2O$ immobilized on P(4-VP) in contact with 80% aqueous 2-ethoxyethanol mainly catalyzes the reduction of nitrobenzene to aniline (98%) (Eq. (2)) and additionally produces a minor amount of azobenzene (2%), under water gas shift reaction conditions. In addition, hydrogen gas from the WGSR was not detected at the end of the reduction process. The turnover frequencies for aniline production were calculated as mol of aniline per mol of $CuCl_2 \cdot 2H_2O$ in 24 h (TF(aniline) = [(mol of aniline)/(mol of Cu) × (rt)] × 24 h). The calculated catalytic activity defined as TF(aniline) was reproducible to ca. 15% for a series of experimental runs. Furthermore, control experiments show that no reaction was detected in the absence of the polymer-immobilized Cu complex. The data obtained from these studies are reported in Table 3. It is seen that the reaction time variation has a slight influence on the TF(aniline) values and that change can be associated with the slight shift to the basic zone on the pH final value of the catalytic mixture due to the increase of the amount of the aniline product (Brønsted base) with time. Reduction of nitrobenzene (1.2 mL) to aniline or other organic products [31] by this Cu/P(4-VP) ([Cu] = 2.5 wt%) system in contact with 10 mL of 80% aqueous 2-ethoxyethanol were not observed under the mild reaction conditions (P(CO) = 1.9 atm at 110 °C) previously employed in the catalysis of the WGSR above described, but under the severe reaction conditions (P(CO) = 27.2 atm at 150 °C) summarized in Table 3.

The nitrobenzene catalytic activities displayed by this Cu/P(4-VP) system are lower than those shown by the immobilized $Rh(amine)_2$/P(4-VP) system [6]. A TF(aniline)/24 h value = 53 (0.65 mmol of aniline formed after 3 h (25% conversion)) was observed under the following reaction conditions: 0.5 g of polymer, 0.26 mL of nitrobenzene, 8 mL of 2-ethoxyethanol, 2 mL of H_2O, [Rh] = 2.0 wt%, P(CO) = 0.9 atm at 100 °C and [nitrobenzene]/[Rh] = 25 for the most active amine (2-picoline) system.

Further, the reduction of nitrobenzene to aniline by this Cu/P(4-VP) catalyst system probably occurs through a mechanism similar to that proposed for the $Rh(2\text{-picoline})_2$/P(4-VP)/aqueous 2-ethoxyethanol system [7]. The immobilized carbonyl copper(I), Cu(I)–CO/P(4-VP), species formed under the catalytic conditions plays an important role as reaction intermediate in the catalytic cycle (namely, a cycloaddition of the nitro group to the Cu–CO bond followed by elimination of CO_2 should lead to the formation of the copper nitrosobenzene $[Cu(\eta^2\text{–ONR})]^+$ species, which eventually through successive transformations leads to aniline and azobenzene production).

Unfortunately, the concentration of Cu(I)–CO/P(4-VP) species formed under the catalytic conditions is small as seen from the EPR studies described above. Perhaps this is the reason for the low catalytic activity observed for both WGSR and nitrobenzene reduction. Finally, analyses of the effects of varying the CO pressure, Cu content and temperature on the activity of this Cu/P(4-VP) catalytic system, which are important parameters for the nitrobenzene reduction, are in progress and they will be reported elsewhere.

$$C_6H_5\text{–}NO_2 + 3CO + H_2O \rightarrow C_6H_5\text{–}NH_2 + 3CO_2 \qquad (2)$$

3.6. Recycling of the anchored catalyst

The recycling efficiency of the $CuCl_2$/P(4-VP) catalyst was studied in the reduction of nitrobenzene. The results are in Table 4. A change of the catalytic activity was observed after a second use. The above results show that the polymer-anchored catalyst does not have high stability. It is recognized that most Cu(I) complexes are air sensitive. Perhaps, during the recycling process the system was contaminated with air even though care was taken to avoid that.

Table 3
Nitrobenzene reduction by $CuCl_2 \cdot 2H_2O$ immobilized on P(4-VP) in aqueous 2-ethoxyethanol[a]

Reaction time (h)	Aniline[b] ($mol \times 10^{-4}$)	pH final	Nitrobenzene conversion (%)	TF (aniline)[c]
4	1.9	7.23	2.3	5.6
8	4.2	7.27	5.1	6.3
12	7.5	7.30	9.3	7.5

[a] 0.5 g of P(4-VP), 8 mL of 2-ethoxyethanol, 2 mL of H_2O, [Cu] = 2.0×10^{-4} mol, (2.5 wt%), 1.2 mL of nitrobenzene (8.1×10^{-3} mol), nitrobenzene/Cu = 44, P(CO) = 27.2 atm at 150 °C.

[b] Based on aniline formed after a given time. Selectivity 98%.

[c] Turnover frequency (aniline) = ([(mol of aniline)/(mol of Cu) × (rt)]) × 24 h, where (rt) is the reaction time in hours. Experimental uncertainty ca. 15%.

Table 4
Recycling efficiency of nitrobenzene reduction catalysis by $CuCl_2 \cdot 2H_2O$ immobilized on P(4-VP) in contact with 80% aqueous 2-ethoxyethanol[a]

Cycle no.	Yield of CO_2[b] (mmol)	Yield of aniline[b] (mmol)	TF (aniline)[c]
1	181.6	58.9	9.8
2	103.1	33.2	5.5
3	19.0	6.1	1.0

[a] 0.5 g of P(4-VP), 8 mL of 2-ethoxyethanol, 2 mL of H_2O, [Cu] = 2.0×10^{-4} mol, (2.5 wt%), 1.2 mL of nitrobenzene (8.1×10^{-3} mol), nitrobenzene/Cu = 44, P(CO) = 27.2 atm at 150 °C.

[b] Based on aniline formed after 72 h. Selectivity 98%.

[c] Turnover frequency (aniline) = ([(mol of aniline)/(mol of Cu) × (rt)]) × 24 h, where (rt) is the reaction time in hours. Experimental uncertainty ca. 15%.

4. Conclusions

The following conclusions can be drawn from the characterization and catalytic studies of the WGSR and nitrobenzene reduction by $CuCl_2 \cdot 2H_2O$ immobilized on the aminated polymer P(4-VP) in contact with aqueous 2-ethoxyethanol under CO.

The characterization study of the immobilized Cu solid by SEM, UV–vis, EPR, FT-IR and XPS techniques shows the variation of the copper environment during the immobilization process. This study suggests that the nitrogen lone pair of the vinylpyridine of the P(4-VP) coordinates to the copper metal center. Coordination crosslinks are also proposed which is consistent with the DSC data. The EPR studies of fresh and used catalyst show that there are two types of immobilized cupric polymer-complex: isolated complex and complexes bonded by dipole–dipole interactions. The presence of terminal carbonyl in the used catalyst, indicated by the IR spectrum under WGSR conditions as well as the EPR and XPS studies, provides strong experimental evidence for the formation of Cu(I)–CO/P(4-VP) complexes as reaction intermediates.

It was found that $CuCl_2 \cdot 2H_2O$ immobilized on P(4-VP) in contact with aqueous 2-ethoxyethanol under CO formed a low active catalyst system for both the WGSR and the reduction of nitrobenzene to aniline and azobenzene.

Abstract

The synthesis and characterization of the gold(III) complexes $[(HSDT)AuX_2]$ and $[(HSDT)_2Au]X$ (X = Cl, Br; HSDT = sarcosinedithiocarbamate (*N*-methylglycinedithiocarbamate)) are reported. In the discussed compounds coordination takes place through the sulfur atoms in a square-planar geometry around the gold(III) metal center. The characterization of the complexes has been carried out by means of elemental analysis, conductance measurements, FT-IR, ^1H and ^{13}C NMR spectroscopy, and thermogravimetric analysis. In addition, the molecular structure of the 1:1 metal-to-ligand complexes has been further investigated by means of density functional calculations, confirming the conclusions reached upon application of the other chemical characterization techniques. The complex $[(HSDT)_3Au]$ has been also synthesized and characterized by mass spectrometry, FT-IR, NMR and X-ray photoelectron spectroscopy, even if a definitive determination of its structure has not been undoubtedly accomplished.

Keywords: Gold; S ligands; Chelates; Density functional calculations; X-ray photoelectron spectroscopy; Mass spectrometry

1. Introduction

In the widespread scenario of gold organometallic chemistry [1–3], different aspects are receiving increasing attention, such as the study of gold compounds in unusual oxidation states and stereochemistry [4–7], the bioinorganic chemistry of certain gold complexes for the treatment of rheumatoid arthritis (chrysotherapy) and their antitumor and antimicrobial properties [8]. Other research work has been devoted to the synthesis and properties of gold clusters and other complexes with gold–metal bonds [9,10].

In recent years, much interest has been focused on the synthesis of gold(I) derivatives containing sulfur and/or phosphorous donor ligands [11–13]. Among the former, dithiocarbamate complexes have been extensively studied in view of their applications as vulcanization accelerators, flotation agents and pesticides [14,15]; their antimicrobial activity has been reported [16,17] and they have been used to fight against metal poisoning [18].

In the literature, a large number of gold(I) [19,20], gold(III) [20–22] and gold(II) [4,23] dithiocarbamate syntheses are present. In particular, binuclear gold(I) dithiocarbamate derivatives have drawn considerable recent attention due to their significant medical applications or useful optical properties [19c].

The dithiocarbamate moiety has received much attention in recent years due to its ability to act as a bidentate ligand. Dithiocarbamates may easily undergo many

different reactions, thus being useful when studying substitution reactions in cation-bound ligands or between the ligands themselves. The introduction of the dithiocarbamate group in α-amino acids gives rise to molecules with up to three potential bonding residuals: amino (–NH_2, –NHR, –NHRR′), dithiocarbamate (–CSS^-) and carboxylate (–COO^-). Many proteins have cysteine and methionine residuals, which are both characterized by the presence of a sulfur atom in their structure. Consequently, dithiocarbamate derivatives of α-amino acids may be considered as valid models to study the coordination of proteins to metallic cations. Unfortunately, only few literature contributions on the synthesis of such complexes are available up to date [21,24–27].

In this work, compounds formed through reaction of dithiocarbamate derived from *N*-methylglycine (sarcosine) in 1:1, 1:2 and 1:3 metal-to-ligand ratios have been synthesized and characterized by different analytical techniques, in order to gain as much information as possible on their chemico-physical properties. Remarkably, particular attention has been paid to the characterization of 1:3 metal-to-ligand complex, for which a definitive determination of the chemical structure has not been accomplished yet. In the present paper the most relevant experimental and theoretical results are presented and discussed.

2. Experimental

2.1. Apparatus

N-Methylglycine (Aldrich), $KAuCl_4$ and $KAuBr_4$ (Alfa Aesar) were used as received. All other reagents and solvents were used as purchased without any further purification.

Conductivity measurements were carried out with an Amel 134-type conductivity bridge for freshly prepared 1.0×10^{-3} mol L^{-1} solutions in DMSO at (25.0 ± 0.1) °C.

FT-IR spectra were recorded in nujol between two polyethylene tablets on a Nicolet Vacuum Far FT-IR 20F spectrophotometer for the range 50–600 cm^{-1}, and in solid KBr on a Nicolet FT-IR 55XC spectrophotometer for the range 400–4000 cm^{-1}.

^1H NMR spectra were recorded in DMSO-d_6 on a Bruker Avance DRX400 spectrophotometer, equipped with a Silicon Graphics O2 workstation operating in Fourier transform, using tetramethylsilane (TMS) as internal standard. ^{13}C NMR spectra were recorded on the same instrument using TMS as internal standard; proton noise decoupling was normally used to obtain an increase of the observed resonance peaks intensity.

Elemental analyses were performed with a Perkin–Elmer 2400 CHN microanalyser; S, Cl and Br were determined with Schöninger method.

Thermogravimetric and differential scanning calorimetry curves were recorded with a TA Instruments thermobalance equipped with a DSC 2929 calorimeter. Measurements were carried out in the range 25–1400 °C in alumina crucibles under air (flow rate 30 cm^3 min^{-1}) at a heating rate of 10 °C min^{-1}, using alumina as reference.

ESI-MS (electrospray mass spectra) were performed on a Finnegan LCQ ion trap instrument operating in positive ion mode (sheath gas flow N_2: 50 a.u.; source voltage: 4 kV; capillary voltage: 3 V; capillary temperature: 200 °C). 50 μL of the sample (2.9×10^{-3} mol L^{-1} in TFA/H_2O/CH_3CN 1:45:45) were directly injected into the source by a syringe pump with a flow rate of 8.0 μL min^{-1}.

X-ray photoelectron spectra (XPS) were recorded on a ground sample of [$(HSDT)_3Au$] (**6**) by a Perkin–Elmer Φ 5600ci spectrometer at a working pressure of lower than 2.0×10^{-9} mbar with a monochromatized AlKα source (1486.6 eV). The spectrometer was calibrated by assuming the binding energy of the Au($4f_{7/2}$) line at 84.0 eV with respect to the Fermi level. The standard deviation for the binding energy values was ±0.2 eV. Binding energies were corrected for charging effects by assigning to the C(1s) line of adventitious carbon the value of 284.8 eV [28]. After a Shirley-type background subtraction, the spectra were fitted using a non-linear least-square fitting program, adopting Gaussian–Lorentzian peak shapes. The atomic compositions were evaluated using sensitivity factors as provided by Φ V5.4 A software.

All the computational calculations were performed by running ADF 2002.02 code [29], a program package based on density functional theory (DFT). Calculations were run within the generalized gradient approximation (GGA), with the inclusion of Becke–Perdew exchange-correlation formulas [30,31]. A Triple-ξ Slater-type basis set was used for all the atoms in the system and the relativistic effect was also taken into account by employing the ZORA Hamiltonian which included the scalar relativistic coupling. The inner cores of gold (1s–4d), sulfur (1s–2p), oxygen (1s), carbon (1s) and bromine (1s–3d) were treated by the frozen-core approximation. Furthermore, the harmonic frequencies of the system were calculated by the ADF package employing a numerical differentiation of energy gradients in slightly displaced geometries.

2.2. General procedures and methods

N-Methylglycine (Aldrich), $KAuCl_4$ and $KAuBr_4$ (Alfa Aesar) were used as received. All other reagents and solvents were used as purchased without any further purification.

2.2.1. Preparation of the ligand $Ba(SDT) \cdot 3H_2O$ (*1*)

The dithiocarbamate derivative of the α-amino acid *N*-methylglycine (sarcosine) was prepared as the trihy-

drated barium salt, following a method similar to that described by Musil and Irgolic [35]. *N*-methylglycine (22.95 mmol) was reacted with an aqueous solution (70 ml) of $Ba(OH)_2$ (22.96 mmol) and the suspension was magnetically stirred until total dissolution was achieved. In order to prevent the precipitation of barium carbonate, the presence of air was avoided, performing the reaction under a nitrogen atmosphere. Acetone was then added until its content was ~40% of the total volume (25 ml), and subsequently CS_2 (22.95 mmol) was dropwise added. Once CS_2 was dissolved, the solution was kept under stirring at 0 °C under a nitrogen flow for 24 h; formation of the barium salt occurred according to the reaction shown in Fig. 1.

Addition of acetone yielded a white precipitate that was filtered off and washed with acetone. The white solid was finally dried in a desiccator with P_4O_{10}, the final yield being 85%. According to the elemental and thermogravimetric analyses, the compound contains three molecules of water of crystallization.

2.2.2. Synthesis of the complexes [(HSDT)AuX_2] (X = Br (**2**), Cl (**4**))

An aqueous solution (6 ml) of Ba(SDT) · $3H_2O$ (0.98 mmol) was treated with a stoichiometric amount of Na_2CO_3 (0.99 mmol), resulting in the formation of a white precipitate ($BaCO_3$) that was filtered off, and the solution thus obtained was dropwise added to an aqueous solution (2 ml) of $KAuX_4$ (X = Cl, Br; 0.98 mmol) at 0 °C. The solution was subsequently treated with a stoichiometric amount of a 0.2 mol L^{-1} solution of HX (X = Cl, Br; 4.92 ml ≅ 0.98 mmol), yielding a reddish-brown precipitate that was filtered off and washed with water and diethyl ether (Fig. 2).

The reddish-brown solid was finally dried in a desiccator wit P_4O_{10}, the final yield being 80–90%.

2.2.3. Synthesis of the complexes [(HSDT)$_2$Au]X (X = Br (**3**), Cl (**5**))

1:2 metal-to-ligand gold(III) HSDT derivatives were prepared with a method similar to that of the corresponding 1:1 derivatives. These complexes were obtained by reaction of $KAuX_4$ (X = Cl, Br) with Ba(SDT) · $3H_2O$ in a 1:2 molar ratio ($KAuX_4$/Ba(SDT) · $3H_2O$ = 0.52/1.15 mmol), yielding a reddish-brown powder (final yield: 80–85%).

2.2.4. Synthesis of the complex [(HSDT)$_3$Au] (**6**)
